Reference manual

SPC574Kx - 32-bit Power Architecture® based MCU for automotive powertrain applications

Introduction

Overview

This document defines the functionality of the SPC574Kx microcontroller for use by software and hardware developers. The SPC574Kx is built on Power Architecture® technology and integrates technologies that are important for today's and tomorrow's automotive applications, including automotive powertrain controller applications for four-cylinder gasoline and diesel engines, chassis control applications, transmission control applications, steering and braking applications, as well as low-end hybrid applications and safety applications that require a high safety integrity level.

The information in this book is subject to change without notice, as described in the disclaimers on the title page. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the ST Web site at *http://www.st.com.*

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC574Kx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or provide device-specific information.
- Part II includes chapters that describe the functionality of the individual modules on the device.

Contents

1 Preface 146

1.1 Overview 146
1.2 Audience 146
1.3 Document organization 146
1.4 Register conventions 146
1.5 Acronyms and abbreviations 147
1.6 Reference documents 147

2 Introduction 148

2.1 SPC574Kx microcontroller 148
2.1.1 Target applications 148
2.1.2 Overall architecture 148
2.1.3 Core features 149
2.1.4 I/O processor 149
2.1.5 Memory hierarchy 150
2.2 Features summary 151
2.3 Feature list 152
2.4 Packaging 154
2.5 Software debug and calibration 154
2.6 Block diagrams 155

3 Embedded memories 158

3.1 Overview 158
3.2 SRAM 158
3.2.1 System SRAM 158
3.2.2 Overlay SRAM 158
3.2.3 Processor core local SRAM 159
3.3 Embedded flash memory 159
3.3.1 Flash memory controller 160
3.3.2 Flash memory array 160
3.4 End-to-end Error Correction Code (e2eECC) 163
3.5 Security features 165

4 Signal description 166
4.1 Production packages 166
4.2 Emulation packages 166
4.2.1 TQFP144 Exposed Pad 166
4.2.2 LQFP176 Exposed Pad 166
4.3 Package pinouts 166
4.4 Pin descriptions 166
4.4.1 Pin startup and reset states 167
4.4.2 Power supply and reference voltage pins 167
4.4.3 System pins 167
4.4.4 LVDS pins 168
4.4.5 Generic pins 171

5 Memory map 173

6 Functional Safety 187
6.1 Introduction 187
6.2 Safety overview 187
6.3 Module categorization 187
6.4 System implementation 189
6.4.1 General concept 189
6.4.2 Dual-core lockstep 200
6.4.3 Common Cause Failure measures 203
6.4.4 ECC 203

7 Device Configuration 207
7.1 Introduction 207
7.2 Core modules 207
7.2.1 Core reset settings 207
7.2.2 Special purpose register (SPR) summary 210
7.3 System modules 212
7.3.1 SIUL2 configuration 212
7.3.2 Semaphores2 (SEMA42) 212
7.3.3 Crossbar switch configuration 213
7.3.4 System Memory Protection Unit (SMPU) configuration 217
7.3.5 Peripheral bridge configuration 221

7.3.6 Platform Configuration Module (PCM) . . . 222
7.3.7 Interrupt Controller (INTC) configuration . . . 229
7.3.8 DMA controller configuration . . . 258
7.3.9 DMAMUX configuration . . . 259
7.3.10 Clocking . . . 263
7.4 Memories and memory interfaces . . . 263
7.4.1 Flash memory controller (PFLASH) configuration . . . 264
7.4.2 Decorated Storage Memory Controller (DSMC) . . . 266
7.5 Analog modules . . . 267
7.5.1 Temperature sensor configuration . . . 267
7.5.2 Analog-to-Digital Converters (ADC) configuration . . . 268
7.5.3 SDADC configuration . . . 268
7.5.4 SARADC configuration . . . 268
7.6 Timers . . . 268
7.6.1 System Timer Module (STM) configuration . . . 269
7.6.2 Software Watchdog Timer (SWT) configuration . . . 269
7.6.3 PIT configuration . . . 271
7.6.4 GTM subsystem configuration . . . 274
7.7 Communication interfaces . . . 276
7.7.1 FEC interface . . . 276
7.7.2 CAN subsystem configuration . . . 276
7.7.3 LFAST and SIPI . . . 277
7.7.4 DSPI configuration . . . 278
7.7.5 FlexRay Configuration . . . 281
7.7.6 PSI5 controller configuration . . . 282
7.7.7 SENT Receiver (SRX) configuration . . . 282
7.7.8 LINFlexD configuration . . . 284
7.8 Reset and Boot modules . . . 287
7.8.1 Flash initialization during reset . . . 287
7.8.2 BAF configuration . . . 287
7.8.3 System Status and Configuration Module (SSCM) configuration . . . 289
7.9 Safety modules . . . 290
7.9.1 CRC – Number of contexts . . . 290
7.9.2 MEMU configuration . . . 291
7.9.3 Indirect Memory Access (IMA) . . . 302
7.9.4 Register protection (REG_PROT) configuration . . . 323

7.10 Security modules 329
7.10.1 Password and Device Security Module (PASS) configuration 329
7.10.2 Tamper Detection Module (TDM) configuration 334
7.11 Power Management modules 339
7.11.1 PMC ADC test mode 339
7.11.2 LVD / HVD self test 342
7.12 Production device vs. emulation and debug device 344

8 Reset and Boot 347
8.1 Introduction 347
8.1.1 Boot Assist Flash 347
8.1.2 TEST flash memory block 347
8.1.3 UTEST flash memory block 348
8.1.4 Boot header 348
8.2 Modules used in reset sequence 348
8.2.1 Power Management Controller 348
8.2.2 Reset Generation Module 348
8.2.3 Mode Entry module 349
8.2.4 System Status and Configuration Module 349
8.2.5 Self-Test Control Unit 350
8.3 Reset sequence 350
8.3.1 Power-on and the Reset Generation Module 350
8.3.2 Power-up phase: power stabilization 353
8.3.3 PHASE0 Phase: analog supply initial configuration 354
8.3.4 PHASE1[DEST] Phase: temporization and monitoring setup 354
8.3.5 PHASE2[DEST] Phase: flash initial configuration 354
8.3.6 PHASE3[DEST] Phase: device configuration 355
8.3.7 IDLE[DEST] Phase: self-test execution 356
8.3.8 PHASE1[FUNC] Phase: temporization and monitoring setup 357
8.3.9 PHASE2[FUNC] Phase: flash initial configuration 357
8.3.10 PHASE3[FUNC] Phase: device configuration monitoring 358
8.3.11 IDLE[FUNC] Phase 358
8.4 MC_RGM passes boot sequence control to the System Status and Control Module 358
8.4.1 Reset sequence flow based on initial device condition 358
8.4.2 Possible boot-up sequences 359
8.4.3 Sequence from MC_RGM IDLE to IOP and Boot CPU running code 359

8.4.4 Path from MC_RGM IDLE to serial boot mode 362
8.4.5 Path from MC_RGM IDLE with IOP enabled to watchdog timer timeout 365

9 Device Configuration Format (DCF) Records 375
9.1 Introduction 375
9.2 DCF clients 375
9.3 DCF records 376
9.3.1 UTEST DCF records 379
9.4 DCF client table 379
9.4.1 DCF client list 380
9.4.2 Miscellaneous DCF registers 395

10 Security 397
10.1 Basic security 397
10.2 Advanced security 397
10.3 Detailed security information 397

11 Power management 398
11.1 Overview 398
11.1.1 Power management framework 398
11.1.2 Power management supply description 399
11.1.3 SPC574Kx power management controller overview 400
11.2 Low power mode support 403
11.2.1 Low power support and STOP mode implementation 404
11.3 Flash power requirements 405
11.4 Device trimming 406
11.5 Supply monitoring (POR and LVDs) 406
11.5.1 Power-on reset (POR) 406
11.5.2 Behavior of device LVDs/HVDs 406
11.5.3 Low Voltage Detection (LVD) and High Voltage Detection (HVD) 407
11.6 Power sequence 414
11.6.1 Power-up sequence 414
11.6.2 Power-down sequence 419
11.6.3 Brown-out management 419
11.6.4 Low voltage requirement during crank 420

12 Calibration and Debug 421
12.1 Core debug support 421
12.2 Run control and memory access 421
12.2.1 Debug and Calibration Interface (DCI) 422
12.2.2 JTAG Data Communication (JDC) 425
12.2.3 Sequence Processing Unit (SPU) 425
12.3 Calibration interface 437
12.3.1 JTAG Master (JTAGM) 438
12.3.2 Debug LFAST 438
12.3.3 Development Trigger Semaphore (DTS) 438
12.4 Debug over CAN 439
12.5 Nexus Aurora interface 439
12.5.1 Nexus Aurora overview 440
12.5.2 Nexus Aurora Router (NAR) 442
12.5.3 Nexus Aurora Link (NAL) 444
12.5.4 Nexus Aurora Phy (NAP) 444
12.6 Nexus clients 445
12.6.1 e200z4 and e200z2 Nexus 3 445
12.6.2 GTM Development Interface (GTMDI) 445
12.6.3 Nexus Crossbar Multi-master Client (NXMC) 446

13 Core Complex Overview 449
13.1 Introduction 449
13.2 Overview of the e200z410Dn3, e200z409D, and e200z225Bn3 cores . 449
13.3 Features 451
13.4 Microarchitecture summary 452
13.4.1 Instruction unit features 454
13.4.2 Integer unit features 454
13.4.3 Load/Store unit features 454
13.4.4 EFPU2 Floating-Point Unit features 455
13.4.5 Saturation Instructions Extension features 455
13.4.6 MPU features 456
13.4.7 Cache features 456
13.4.8 Local memory features 456
13.4.9 Performance Monitor Unit Features 457
13.4.10 e200z410Dn3 and e200z225Bn3 system bus features 457

13.4.11 e200z409D system features 457

14 Core e200z410Dn3 description 459

14.1 Overview of the e200z410Dn3 core 459
14.2 Register model 459
14.3 Single-issue operation 463
14.4 Reservation instructions and cache interactions 463
14.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR) 463
14.5.1 Cache overview 466
14.5.2 L1 Cache Control and Status Register 0 (L1CSR0) 466
14.5.3 L1 Cache Control and Status Register 1 (L1CSR1) 469
14.5.4 L1 Cache Configuration Register 0 (L1CFG0) 471
14.5.5 L1 Cache Configuration Register 1 (L1CFG1) 472
14.5.6 Data Cache Software Coherency 473
14.5.7 Data Cache Hardware Coherency 473
14.5.8 Cache Invalidate by Set and Way 473
14.5.9 Cache EDC/ECC Parity Protection 475
14.5.10 Cache Error Injection 477
14.6 Exceptions 477
14.6.1 Exception Syndrome Register (ESR) 478
14.6.2 Machine State Register (MSR) 479
14.6.3 Machine Check Syndrome Register (MCSR) 480
14.6.4 Interrupt Vector Prefix Registers (IVPR) 483
14.6.5 Interrupt Definitions 484
14.7 Memory Protection Unit (MPU) 493
14.7.1 MPU Overview 493
14.7.2 Software Interface and MPU Instructions 493
14.7.3 MPU Read Entry Instruction (mpure) 493
14.7.4 MPU Write Entry Instruction (mpuwe) 494
14.7.5 MPU Synchronize Instruction (mpusync) 494
14.7.6 MMU/MPU Configuration Register (MMUCFG) 494
14.7.7 MPU0 Configuration Register (MPU0CFG) 495
14.7.8 MPU0 Control and Status Register 0 (MPU0CSR0) 496
14.7.9 MPU Assist Registers (MAS) 498
14.7.10 MAS Registers Summary 503

14.8 Local memories . . . 503
14.8.1 Local Instruction and Data memory overview . . . 503
14.8.2 Local memory control and configuration . . . 503
14.9 End-to-End ECC support . . . 516
14.9.1 End-to-End ECC control and configuration . . . 516

15 Core e200z225Bn3 description . . . 520
15.1 Overview of the e200z225Bn3 core . . . 520
15.2 EFPU2 Floating-Point Unit features . . . 520
15.3 Register model . . . 521
15.4 Single-issue operation . . . 525
15.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR) . . . 525
15.6 Exceptions . . . 527
15.6.1 Exception Syndrome Register (ESR) . . . 528
15.6.2 Machine State Register (MSR) . . . 530
15.6.3 Machine Check Syndrome Register (MCSR) . . . 531
15.6.4 Interrupt Vector Prefix Registers (IVPR) . . . 534
15.6.5 Interrupt Definitions . . . 534
15.7 Memory Protection Unit (MPU) . . . 543
15.7.1 MPU Overview . . . 543
15.7.2 Software Interface and MPU Instructions . . . 543
15.7.3 MPU Read Entry Instruction (mpure) . . . 543
15.7.4 MPU Write Entry Instruction (mpuwe) . . . 544
15.7.5 MPU Synchronize Instruction (mpusync) . . . 544
15.7.6 MMU/MPU Configuration Register (MMUCFG) . . . 544
15.7.7 MPU0 Configuration Register (MPU0CFG) . . . 545
15.7.8 MPU0 Control and Status Register 0 (MPU0CSR0) . . . 546
15.7.9 MPU Assist Registers (MAS) . . . 549
15.7.10 MAS Registers Summary . . . 554
15.8 Local memories . . . 554
15.8.1 Local Instruction and Data memory overview . . . 554
15.8.2 Local memory control and configuration . . . 554
15.9 End-to-End ECC support . . . 567
15.9.1 End-to-End ECC control and configuration . . . 567

16 System Integration Unit Lite2 (SIUL2) 571
16.1 Introduction 571
16.1.1 Overview 571
16.1.2 Features 573
16.1.3 Register protection 573
16.2 Memory map and register description 574
16.2.1 Memory map 574
16.2.2 Register descriptions 575
16.3 Functional description 593
16.3.1 General 593
16.3.2 Pad control 593
16.3.3 General purpose input or output pads (GPIO) 593
16.3.4 External interrupts/DMA requests (EIRQ pins) 594

17 Crossbar Switch (XBAR) 598
17.1 Introduction 598
17.1.1 Features 598
17.1.2 Memory map and register definition 598
17.2 Functional description 603
17.2.1 General operation 604
17.2.2 Register coherency 604
17.2.3 Arbitration 604
17.3 Initialization/application information 606

18 Crossbar Integrity Checker (XBIC) 607
18.1 Overview 607
18.2 Features 607
18.3 Block diagram 608
18.4 External signal description 609
18.5 Memory map and register definition 609
18.5.1 Memory map 609
18.5.2 Register descriptions 610
18.6 Functional description 613

19 Peripheral Bridge 616
19.1 Introduction 616

19.1.1 Features . . . 616
19.1.2 General operation . . . 616
19.2 Memory map and register definition . . . 616
19.2.1 Master Privilege Registers (AIPS_MPRA & AIPS_MPRB) . . . 618
19.2.2 Peripheral Access Control Registers (AIPS_PACR*x*) . . . 619
19.2.3 Off-Platform Peripheral Access Control Registers (AIPS_OPACR*x*) . . . 620
19.3 Functional description . . . 623
19.3.1 Access support . . . 623

20 System Memory Protection Unit (SMPU) . . . 624
20.1 Overview . . . 624
20.2 Block diagram . . . 624
20.3 Features . . . 625
20.4 Memory map and register definition . . . 626
20.4.1 Memory map . . . 626
20.4.2 Register descriptions . . . 631
20.5 Functional description . . . 640
20.5.1 Access evaluation macro . . . 640
20.5.2 Putting it all together and error terminations . . . 641
20.6 Initialization information . . . 642
20.7 Application information . . . 642

21 Intelligent AHB Gasket (IAHBG) . . . 644
21.1 Introduction . . . 644
21.2 Timing diagrams . . . 644
21.2.1 1:1 . . . 644
21.2.2 2:1 . . . 646
21.2.3 1:2 . . . 650
21.2.4 64->32 Interface . . . 654
21.2.5 32->64 Interface . . . 654

22 Semaphores2 (SEMA42) . . . 656
22.1 Introduction . . . 656
22.1.1 Multi-core programming 101: software gates . . . 656
22.1.2 Features . . . 657
22.2 Memory map/register definition . . . 659

22.2.1 Semaphores Gate n Register (SEMA4_GATE) 660
22.2.2 Semaphores (Secure) Reset Gate (SEMA4_RSTGT) 661
22.3 Functional description 662

23 Interrupt Controller (INTC) 665
23.1 Introduction 665
23.2 Block diagram 665
23.3 Features 667
23.4 Modes of operation 667
23.4.1 Software vector mode 667
23.4.2 Hardware vector mode 668
23.5 Memory map and register definition 668
23.5.1 Memory map 668
23.5.2 Register descriptions 669
23.6 Functional description 677
23.6.1 Interrupt request sources 677
23.6.2 Priority management 678
23.6.3 Handshaking with processor 680
23.7 Initialization/application information 682
23.7.1 Initialization flow 682
23.7.2 Interrupt exception handler 683
23.7.3 ISR, RTOS, and task hierarchy 685
23.7.4 Order of execution 685
23.7.5 Priority ceiling protocol 687
23.7.6 Selecting priorities according to request rates and deadlines 689
23.7.7 Software-settable interrupt requests 690
23.7.8 Lowering priority within an ISR 690
23.7.9 Negating an interrupt request outside of its ISR 691
23.7.10 Examining LIFO contents 691
23.8 Interrupt sources 692

24 Enhanced Direct Memory Access (eDMA) 693
24.1 Introduction 693
24.1.1 Features 693
24.2 Modes of operation 694
24.2.1 Normal mode 694

24.2.2 Debug mode 694
24.2.3 Wait mode 695
24.3 Memory map/register definition 695
24.3.1 Control Register (DMA_CR) 718
24.3.2 Error Status Register (DMA_ES) 720
24.3.3 Enable Request Register Low (DMA_ERQL) 722
24.3.4 Enable Error Interrupt Register Low (DMA_EEIL) 725
24.3.5 Set Enable Request Register (DMA_SERQ) 728
24.3.6 Clear Enable Request Register (DMA_CERQ) 729
24.3.7 Set Enable Error Interrupt Register (DMA_SEEI) 729
24.3.8 Clear Enable Error Interrupt Register (DMA_CEEI) 730
24.3.9 Clear Interrupt Request Register (DMA_CINT) 731
24.3.10 Clear Error Register (DMA_CERR) 731
24.3.11 Set START Bit Register (DMA_SSRT) 732
24.3.12 Clear DONE Status Bit Register (DMA_CDNE) 732
24.3.13 Interrupt Request Register Low (DMA_INTL) 733
24.3.14 Error Register Low (DMA_ERRL) 736
24.3.15 Hardware Request Status Register Low (DMA_HRSL) 739
24.3.16 Channel *n* Priority Register (DMA_DCHPRI*n*) 742
24.3.17 Channel *n* Master ID Register (DMA_DCHMID*n*) 743
24.3.18 TCD Source Address (DMA_TCD*n*_SADDR) 744
24.3.19 TCD Transfer Attributes (DMA_TCD*n*_ATTR) 745
24.3.20 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF) 745
24.3.21 TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCD*n*_NBYTES_MLNO) 746
24.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO) 747
24.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES) 747
24.3.24 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST) 749
24.3.25 TCD Destination Address (DMA_TCD*n*_DADDR) 749
24.3.26 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_CITER_ELINKYES) 750
24.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO) 751
24.3.28 TCD Signed Destination Address Offset (DMA_TCD*n*_DOFF) 751
24.3.29 TCD Last Destination Address Adjustment/Scatter Gather Address (DMA_TCD*n*_DLASTSGA) 752

24.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES) . . . 753
24.3.31 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_BITER_ELINKNO) . . . 754
24.3.32 TCD Control and Status (DMA_TCD*n*_CSR) . . . 754
24.4 Functional description . . . 756
24.4.1 eDMA microarchitecture . . . 757
24.4.2 eDMA basic data flow . . . 758
24.4.3 Error reporting and handling . . . 761
24.4.4 Channel preemption . . . 763
24.4.5 eDMA performance . . . 763
24.5 Initialization/application information . . . 766
24.5.1 eDMA initialization . . . 766
24.5.2 DMA programming errors . . . 768
24.5.3 DMA Arbitration mode considerations . . . 769
24.5.4 DMA transfer . . . 770
24.5.5 eDMA TCD*n* status monitoring . . . 773
24.5.6 Channel linking . . . 775
24.5.7 Dynamic programming . . . 776

25 Direct Memory Access Multiplexer (DMAMUX) . . . 779
25.1 Introduction . . . 779
25.1.1 Overview . . . 779
25.1.2 Features . . . 780
25.1.3 Modes of operation . . . 780
25.2 External signal description . . . 780
25.3 Memory map/register definition . . . 780
25.3.1 Channel Configuration register (DMAMUX_CHCFGn) . . . 781
25.4 Functional description . . . 782
25.4.1 DMA channels with periodic triggering capability . . . 782
25.4.2 DMA channels with no triggering capability . . . 784
25.4.3 Always-enabled DMA sources . . . 784
25.5 Initialization/application information . . . 785
25.5.1 Reset . . . 785
25.5.2 Enabling and configuring sources . . . 785

26 Clocking . . . 790

26.1 Introduction . . . 790
26.2 Clock generation . . . 790
26.2.1 MC_CGM registers . . . 793
26.3 System clock frequency limitations . . . 794
26.3.1 JTAG frequencies . . . 795
26.4 Default clock configuration . . . 795
26.5 Clock sources . . . 796
26.5.1 PLL . . . 796
26.5.2 External oscillator (XOSC) . . . 799
26.5.3 16 MHz internal RC oscillator (IRCOSC) . . . 801
26.6 Peripheral clocks . . . 801
26.6.1 PSI5 clock dividers . . . 803
26.6.2 LFAST clocking . . . 803
26.6.3 Ethernet clocking . . . 804
26.6.4 FlexRay clocking . . . 805
26.6.5 M_TTCAN/M_CAN clocking . . . 806
26.6.6 Sigma-Delta ADC clocking . . . 806
26.6.7 Successive Approximation Register ADC clocking . . . 807
26.6.8 System Clock/GTM output clock/Ethernet clock pin muxing . . . 807
26.7 Clock monitoring . . . 808
26.7.1 CMU configuration . . . 808
26.7.2 PLL0 monitor . . . 811
26.7.3 External oscillator (XOSC) monitor . . . 811
26.7.4 Internal RC oscillator (IRCOSC) monitor . . . 811
26.7.5 System clock monitors . . . 811
26.8 Loss of system clock behavior . . . 811
26.8.1 Loss of PLL/XOSC clock . . . 811
26.8.2 Loss of IRCOSC clock . . . 812
26.9 Progressive clock switching . . . 812

27 Dual PLL Digital Interface (PLLDIG) . . . 813

27.1 Introduction . . . 813
27.2 Block Diagram . . . 813
27.3 Features . . . 813
27.4 Modes of operation . . . 813
27.4.1 Normal mode with reference, PLL0 or both PLLs enabled . . . 813

27.5 Memory map and register definition . . . 814
27.5.1 Memory map . . . 814
27.5.2 Register descriptions . . . 814
27.5.3 Register classification for safety requirements . . . 824
27.6 Functional description . . . 824
27.6.1 Input clock frequency . . . 824
27.6.2 Clock configuration . . . 824
27.6.3 Loss of lock . . . 826
27.6.4 Frequency modulation . . . 826
27.7 Initialization information . . . 827

28 Clock Monitor Unit (CMU) . . . 828
28.1 Introduction . . . 828
28.1.1 Main features . . . 828
28.2 Block diagram . . . 828
28.3 Signals . . . 829
28.4 Memory map and register definition . . . 830
28.4.1 Register descriptions . . . 830
28.5 Functional description . . . 835
28.5.1 Frequency meter . . . 835
28.5.2 CLKMN0_RMT supervisor . . . 835
28.5.3 CLKMN1 supervisor . . . 835

29 Clock Generation Module (MC_CGM) . . . 837
29.1 Introduction . . . 837
29.1.1 Overview . . . 837
29.1.2 Features . . . 838
29.2 External signal description . . . 839
29.3 Memory map and register definition . . . 839
29.3.1 Register descriptions . . . 841
29.4 Functional Description . . . 877
29.4.1 System Clock Generation . . . 877
29.4.2 Auxiliary Clock Generation . . . 883
29.4.3 Dividers Functional Description . . . 888

30 OSC Digital Interface (XOSC) . . . 891

30.1 Introduction . . . 891
30.2 Functional description . . . 891
30.2.1 Oscillator power-down control and status . . . 891
30.2.2 Oscillator startup delay . . . 891
30.2.3 Oscillator clock available interrupt . . . 892
30.2.4 Oscillator bypass mode . . . 892
30.3 Memory map and register definition . . . 892
30.3.1 Register descriptions . . . 893

31 IRCOSC digital interface . . . 895
31.1 Introduction . . . 895
31.2 Functional description . . . 895
31.3 Memory map and register definition . . . 895
31.3.1 Register descriptions . . . 896

32 RAM controller (PRAMC) . . . 899
32.1 Introduction . . . 899
32.2 SRAM controller memory map and register definition . . . 900
32.2.1 Platform RAM Configuration Register 1 (PRAMC_PRCR1) . . . 900
32.3 Functional description . . . 901
32.3.1 Read / Write introduction . . . 901
32.3.2 Writes . . . 902
32.4 Initialization/application information . . . 903
32.5 Safety considerations . . . 904
32.5.1 Hsiao ECC algorithm . . . 904
32.5.2 Transaction monitor . . . 907

33 Flash memory controller (PFLASH Controller) . . . 909
33.1 Introduction . . . 909
33.2 Features . . . 909
33.3 Block diagrams . . . 909
33.4 Flash memory controller memory map . . . 913
33.4.1 Overview . . . 913
33.5 Functional description . . . 940
33.5.1 Basic interface protocol . . . 940
33.5.2 Access protections . . . 940

33.5.3 Read cycles - buffer miss . . . 941
33.5.4 Read cycles – buffer hit . . . 941
33.5.5 Error termination . . . 941
33.5.6 Flash error response operation . . . 941
33.5.7 Censorship . . . 942
33.5.8 Line read buffers and prefetch operation . . . 942
33.5.9 Instruction/Data prefetch triggering . . . 943
33.5.10 Per-Master prefetch triggering . . . 943
33.5.11 Buffer allocation . . . 943
33.5.12 PFlash calibration remap support . . . 943
33.5.13 Safety considerations . . . 948
33.5.14 Array integrity considerations . . . 952

34 Embedded Flash Memory (MP55) . . . 953
34.1 Introduction . . . 953
34.1.1 Overview . . . 953
34.1.2 Features . . . 955
34.1.3 Modes of operation . . . 955
34.2 Flash memory map and description . . . 956
34.2.1 Flash array memory map . . . 957
34.3 Register memory maps and descriptions . . . 960
34.3.1 Register memory maps . . . 960
34.3.2 User register descriptions . . . 962
34.4 Functional description . . . 995
34.4.1 Reset . . . 995
34.4.2 Power-down mode (Disable mode) . . . 995
34.4.3 Low-power mode (Sleep mode) . . . 996
34.4.4 Read mode . . . 997
34.4.5 Modify mode . . . 999
34.4.6 Protection strategy . . . 1010

35 Decorated Storage Memory Controller (DSMC) . . . 1012
35.1 Introduction . . . 1012
35.2 DSMC Block Diagram . . . 1013
35.3 Decorated Stores: st[b,h,w]d{cb}x rS,rB,rA . . . 1015
35.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container . . 1015

35.4 DSMC Timing Diagram 1020
35.5 DSMC Instantiations 1021

36 Flash Memory Programming and Configuration 1023
36.1 Selection of flash memory blocks for erase 1024
36.2 Non-secure write protection 1026
36.3 Secure write protection 1027
36.3.1 Implementing secure write protection 1029
36.3.2 Overriding secure write protection 1032
36.4 Secure read protection 1034
36.4.1 Implementing secure read protection 1035
36.4.2 Overriding secure read protection 1037
36.5 Debug port enable/disable 1038
36.6 Implementing OTP 1038
36.7 Implementing test mode disable 1038
36.7.1 Unconditional test mode disable seal 1039
36.7.2 Passcode-protected test mode disable seal 1039
36.7.3 Selecting flash memory blocks for test mode disable seal 1040
36.8 Security configuration planning 1040
36.8.1 Creating password groups 1040
36.8.2 Planning secure write protection 1041
36.8.3 Planning secure read protection 1041
36.8.4 Planning debug port enable/disable 1041
36.8.5 Planning OTP flash memory block assignment 1041
36.8.6 Planning factory test mode disable 1041

37 Analog-to-digital converter (ADC) configuration 1042
37.1 ADC overview 1042
37.1.1 ADC subsystem block diagram 1042
37.1.2 Analog input pin multiplexing 1044
37.2 Configuration of ADC modules 1044
37.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC) 1045
37.2.2 Successive Approximation Register Analog-to-Digital Converter (SARADC) 1054

38 Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface 1098

38.1 Introduction 1098
38.2 Overview 1098
38.3 Features 1100
38.4 Modes of operation 1100
38.4.1 Differential input mode 1100
38.4.2 Single-ended input mode 1100
38.4.3 External modulator mode 1100
38.5 External signal description 1101
38.5.1 Detailed signal descriptions 1101
38.6 Memory map and register descriptions 1102
38.6.1 Memory map 1102
38.6.2 Register descriptions 1102
38.7 Functional description 1116
38.7.1 Differential input mode 1116
38.7.2 Single-ended input mode 1117
38.7.3 External modulator mode 1117
38.7.4 Low consumption mode 1117
38.7.5 Analog input multiplexing and bias support 1117
38.7.6 Programmable gain and decimation rate 1117
38.7.7 High-pass filter support 1117
38.7.8 Data conversion 1118
38.7.9 Hardware triggering 1119
38.7.10 Interrupt/DMA request support 1119
38.7.11 Gain calibration support 1120
38.7.12 Offset calibration support 1121
38.8 Initialization information 1121
38.8.1 Data conversion step 1122

39 Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface 1123

39.1 Introduction 1123
39.2 Overview 1123
39.3 Feature description 1125
39.3.1 Main features 1125

39.4 Functional description 1125
39.4.1 Normal channel conversion 1125
39.4.2 Injected channel conversion 1127
39.4.3 Abort conversion 1128
39.4.4 Analog conversion timings and reference selection 1129
39.4.5 Test channel connection with internal analog channel 1130
39.4.6 Programmable analog watchdog 1131
39.4.7 DMA functionality 1132
39.4.8 Interrupts 1132
39.4.9 Power down mode 1133
39.4.10 Stop Mode 1133
39.5 Memory map and registers 1133
39.5.1 Register descriptions 1136
39.6 Start of conversion pulse delay 1166
39.7 Initialization Information 1168

40 Temperature Sensor 1170
40.1 Introduction 1170
40.1.1 Signal Descriptions 1170
40.2 Functional Description 1170
40.2.1 Temperature threshold detection (digital output generation) 1170
40.2.2 Linear temperature sensor (analog output generation) 1171
40.3 Temperature formula 1172
40.4 Calculating device temperature 1173

41 Timers overview 1174

42 System Timer Module (STM) 1175
42.1 Introduction 1175
42.1.1 Overview 1175
42.1.2 Features 1175
42.1.3 Modes of operation 1175
42.2 External signal description 1175
42.3 Memory map and register definition 1175
42.3.1 Memory map 1175
42.3.2 Register descriptions 1176

42.4 Functional description 1179

43 Software Watchdog Timer (SWT) 1180

43.1 Introduction 1180
43.1.1 Overview 1180
43.1.2 Features 1180
43.1.3 Modes of operation 1180
43.2 External signal description 1180
43.3 Memory map and register definition 1180
43.3.1 Register descriptions 1181
43.4 Functional description 1185

44 Periodic Interrupt Timer (PIT) 1188

44.1 Introduction 1188
44.1.1 Block diagram 1188
44.1.2 Features 1189
44.2 Signal description 1189
44.2.1 Memory map/register description 1189
44.3 Functional description 1198
44.3.1 General 1198
44.3.2 Interrupts 1200
44.3.3 Chained timers 1200
44.4 Initialization and application information 1200
44.5 Example configuration for chained timers 1201
44.6 Example Configuration for the Lifetime Timer 1202

45 GTM Integration (GTMINT) Module 1203

45.1 About this module 1203
45.1.1 Definition 1203
45.1.2 Features 1203
45.1.3 Modes of operation 1203
45.2 GTMINT 1204
45.2.1 GTMINT Block diagram 1204
45.3 GTMINT components 1205
45.4 Clock controller 1206
45.4.1 Clock controller block diagram 1206

45.4.2 Clock controller components 1206
45.4.3 Clock controller signals 1206
45.4.4 Important guidelines for selecting clocks 1207
45.5 Event controller 1207
45.5.1 Event controller block diagram 1207
45.5.2 Event controller components 1208
45.5.3 Event controller signals 1208
45.6 CPU interface 1209
45.6.1 CPU interface block diagram 1209
45.6.2 CPU interface signals 1210
45.6.3 Important guidelines for configuring the CPU interface 1210
45.7 AEI reset 1211
45.7.1 Reset controller block diagram 1211
45.7.2 Reset controller components 1211
45.7.3 Reset controller signals 1212
45.8 ECC controller 1212
45.8.1 ECC controller block diagram 1212
45.8.2 ECC controller components 1212
45.8.3 Automatic GTM RAM initialization 1213
45.8.4 ECC syndromes 1213
45.8.5 Error report 1214
45.9 Using GTMINT 1215
45.9.1 Clearing interrupts 1215
45.9.2 Resetting the GTM Subsystem 1217
45.10 Memory map and registers 1218
45.10.1 Memory map 1218

46 Generic Timer Module (GTM122) 1222
46.1 About this module 1222
46.2 For more information 1222

47 GTM Development Interface (GTMDI) 1223
47.1 About this module 1223
47.2 Introduction 1223
47.3 Overview 1224
47.3.1 Features 1228

47.3.2 Modes of operation . . . 1229
47.3.3 DATA port . . . 1229
47.4 External signal description . . . 1229
47.4.1 Event in (EVTI) . . . 1230
47.4.2 Event out EVTO[1:0] . . . 1230
47.4.3 Test clock input (TCK) . . . 1230
47.4.4 Test data input (TDI) . . . 1230
47.4.5 Test data output (TDO) . . . 1230
47.4.6 Test Mode Select (TMS) . . . 1231
47.5 Register definition . . . 1231
47.5.1 Register descriptions . . . 1233
47.5.2 Unimplemented registers . . . 1295
47.6 Functional description . . . 1295
47.6.1 Debug enable logic . . . 1296
47.6.2 TIM-TOM-ATOM selection and control logic . . . 1296
47.6.3 GTMDI reset configuration . . . 1297
47.6.4 Message Data Bus —interface with NAR module . . . 1298
47.6.5 IEEE 1149.1 (JTAG) input port . . . 1302
47.6.6 Nexus Class 1 development support . . . 1307
47.6.7 Debug status . . . 1307
47.6.8 Data trace . . . 1307
47.6.9 Fetch trace . . . 1310
47.6.10 Watchpoint trace . . . 1312
47.7 Initialization/application information . . . 1312
47.7.1 Accessing GTMDI tool-mapped registers . . . 1312

48 CAN Subsystem . . . 1314
48.1 Introduction . . . 1314
48.2 Features . . . 1316
48.3 Modular CAN (M_CAN) cores . . . 1316
48.3.1 Features . . . 1317
48.3.2 Block diagram . . . 1318
48.3.3 Dual clock sources . . . 1319
48.3.4 Dual interrupt lines . . . 1319
48.3.5 Memory map and register descriptions . . . 1319
48.3.6 Message RAM . . . 1369

48.3.7 M_CAN functional description . . . 1378
48.3.8 Timestamp generation . . . 1387
48.3.9 Timeout counter . . . 1388
48.3.10 Rx handling . . . 1388
48.3.11 Dedicated Rx Buffers . . . 1395
48.3.12 Debug on CAN Support . . . 1396
48.3.13 Tx handling . . . 1398
48.3.14 FIFO acknowledge handling . . . 1402
48.3.15 Clock Calibration on M_CAN . . . 1403
48.4 Time Triggered Modular CAN (M_TTCAN) core . . . 1414
48.4.1 Features . . . 1415
48.4.2 Block Diagram . . . 1416
48.4.3 Dual clock sources . . . 1417
48.4.4 Dual interrupt lines . . . 1417
48.4.5 Memory map and registers description . . . 1418
48.4.6 Message RAM . . . 1484
48.4.7 M_TTCAN functional description . . . 1493
48.4.8 FIFO acknowledge handling . . . 1509
48.4.9 M_TTCAN operations . . . 1510
48.4.10 M_TTCAN configuration . . . 1511
48.4.11 Message scheduling . . . 1513
48.4.12 M_TTCAN gap control . . . 1520
48.4.13 Stop watch . . . 1521
48.4.14 Local time, cycle time, global time, and external clock synchronization . . . 1521
48.4.15 M_TTCAN error level . . . 1524
48.4.16 M_TTCAN message handling . . . 1525
48.4.17 M_TTCAN interrupt and error handling . . . 1528
48.4.18 Level 0 . . . 1528
48.4.19 Synchronization to external time schedule . . . 1531
48.5 CAN RAM arbiter . . . 1532
48.5.1 Features . . . 1532
48.5.2 Functional overview using examples . . . 1533
48.6 SRAM interface and memory organization . . . 1533
48.6.1 Shared memory . . . 1533
48.6.2 ECC controller . . . 1534
48.7 Time Triggered CAN matrix and basic cycles management . . . 1535

48.8 CAN nodes 1 and 2 I/Os sharing 1536
48.9 External signal description 1537
48.10 Memory map and register description 1537
48.10.1 Shared memory map 1537

49 Serial Interprocessor Interface (SIPI) 1540
49.1 Introduction 1540
49.1.1 Scalability 1540
49.2 Overview 1540
49.3 SIPI block diagram 1542
49.4 Feature description 1542
49.4.1 Main features 1542
49.4.2 Standard features 1543
49.5 SIPI operation from reset 1543
49.6 Functional description 1543
49.6.1 External signals 1543
49.6.2 Frame format 1543
49.7 Transfer types 1548
49.7.1 Read transfer 1549
49.7.2 Register read answer transfer 1549
49.7.3 Register Write transfer 1551
49.7.4 Write Acknowledge transfer 1553
49.7.5 ID request response 1554
49.8 Transfer API and flow charts 1555
49.9 DMA programming sequence 1562
49.10 Modes of operation 1562
49.10.1 Initialization mode (INIT) 1562
49.10.2 Normal mode (NM) 1562
49.10.3 Module disable (MD) 1563
49.11 Errors 1563
49.11.1 Timeout error 1563
49.11.2 CRC error 1563
49.11.3 Maximum count reached error 1563
49.11.4 Transaction ID error 1563
49.11.5 Acknowledge error 1564

49.12 CRC calculation 1564
49.13 Interrupt logic 1564
49.14 SIPI control and status overview 1565
49.15 Memory map and register description 1566
49.15.1 Register descriptions 1569

50 Deserial Serial Peripheral Interface (DSPI) 1583
50.1 Introduction 1583
50.1.1 Block diagram 1583
50.1.2 Features 1584
50.1.3 DSPI configurations 1585
50.1.4 Modes of operation 1587
50.2 DSPI signal description 1588
50.2.1 PCS0/SS — Peripheral Chip Select/Slave Select 1588
50.2.2 PCS1 – PCS3 — Peripheral Chip Selects 1 – 3 1588
50.2.3 PCS4 — Peripheral Chip Select 4 1588
50.2.4 PCS5/PCSS — Peripheral Chip Select 5/Peripheral Chip Select Strobe 1588
50.2.5 PCS[6] – PCS[7] — Peripheral Chip Selects 6 – 7 1589
50.2.6 SIN — Serial Input 1589
50.2.7 SOUT — Serial Output 1589
50.2.8 SCK — Serial Clock 1589
50.3 Memory map/register definition 1589
50.3.1 DSPI Module Configuration Register (DSPI_MCR) 1592
50.3.2 DSPI Transfer Count Register (DSPI_TCR) 1595
50.3.3 DSPI Clock and Transfer Attributes Register (In Master Mode) (DSPI_CTAR*n*) 1596
50.3.4 DSPI Clock and Transfer Attributes Register (In Slave Mode) (DSPI_CTAR*n*_SLAVE) 1601
50.3.5 DSPI Status Register (DSPI_SR) 1602
50.3.6 DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER) 1605
50.3.7 DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR) 1608
50.3.8 DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE) 1610
50.3.9 DSPI POP FIFO Register (DSPI_POPR) 1611
50.3.10 DSPI Transmit FIFO Registers (DSPI_TXFRn) 1612
50.3.11 DSPI Receive FIFO Registers (DSPI_RXFRn) 1612
50.3.12 DSPI DSI Configuration Register 0 (DSPI_DSICR0) 1613

50.3.13 DSPI DSI Serialization Data Register 0 (DSPI_SDR0) 1615
50.3.14 DSPI DSI Alternate Serialization Data Register 0 (DSPI_ASDR0) . . 1616
50.3.15 DSPI DSI Transmit Comparison Register 0 (DSPI_COMPR0) 1617
50.3.16 DSPI DSI Deserialization Data Register 0 (DSPI_DDR0) 1617
50.3.17 DSPI DSI Configuration Register 1 (DSPI_DSICR1) 1618
50.3.18 DSPI DSI Serialization Source Select Register 0 (DSPI_SSR0) 1619
50.3.19 DSPI DSI Deserialized Data Interrupt Mask Register 0 (DSPI_DIMR0) 1620
50.3.20 DSPI DSI Deserialized Data Polarity Interrupt Register 0 (DSPI_DPIR0) 1621
50.3.21 DSPI DSI Serialization Data Register 1 (DSPI_SDR1) 1621
50.3.22 DSPI DSI Alternate Serialization Data Register 1 (DSPI_ASDR1) . . 1622
50.3.23 DSPI DSI Transmit Comparison Register 1 (DSPI_COMPR1) 1623
50.3.24 DSPI DSI Deserialization Data Register 1 (DSPI_DDR1) 1623
50.3.25 DSPI DSI Serialization Source Select Register 1 (DSPI_SSR1) 1624
50.3.26 DSPI DSI Deserialized Data Interrupt Mask Register 1 (DSPI_DIMR1) 1624
50.3.27 DSPI DSI Deserialized Data Polarity Interrupt Register 1 (DSPI_DPIR1) 1625
50.3.28 DSPI Clock and Transfer Attributes Register Extended (DSPI_CTARE*n*) 1626
50.3.29 DSPI Status Register Extended (DSPI_SREX) 1626
50.4 Register classification for safety 1627
50.5 Functional description 1628
50.5.1 Start and Stop of DSPI transfers 1629
50.5.2 Serial Peripheral Interface (SPI) configuration 1630
50.5.3 Deserial Serial Interface (DSI) configuration 1634
50.5.4 Combined Serial Interface (CSI) configuration 1637
50.5.5 DSPI baud rate and clock delay generation 1639
50.5.6 Transfer formats 1642
50.5.7 Continuous Serial Communications Clock 1651
50.5.8 Slave mode operation constraints 1653
50.5.9 Timed Serial Bus (TSB) 1653
50.5.10 Interleaved TSB (ITSB) Mode 1656
50.5.11 Parity generation and check 1659
50.5.12 Interrupts/DMA requests 1660
50.5.13 Power saving features 1663
50.6 Initialization/application information 1664

50.6.1 Managing DSPI queues . . . 1664
50.6.2 Switching master and slave mode . . . 1664
50.6.3 Initializing DSPI in Master/Slave Modes . . . 1665
50.6.4 Baud rate settings . . . 1665
50.6.5 Delay settings . . . 1666
50.6.6 Calculation of FIFO pointer addresses . . . 1667

51 LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications . . . 1670

51.1 Introduction . . . 1670
51.2 Block diagram . . . 1670
51.3 External signals . . . 1670
51.3.1 LFAST operating data rates . . . 1671
51.4 LFAST frame structure . . . 1671
51.5 Features . . . 1674
51.6 Memory map and register definition . . . 1674
51.6.1 Memory map . . . 1674
51.6.2 Register descriptions . . . 1677
51.6.3 Register safety classification requirements . . . 1705
51.7 Functional description . . . 1705
51.7.1 Startup procedure . . . 1705
51.7.2 Line Receiver (LR) . . . 1708
51.7.3 Transmit Controller . . . 1718
51.7.4 CTS mode support . . . 1722
51.7.5 Frames supported . . . 1723
51.7.6 Frame flow . . . 1723
51.7.7 Test and Debug Support . . . 1729
51.7.8 Interrupts . . . 1736
51.8 Packet memory . . . 1738
51.9 Resets . . . 1739
51.10 Clocks . . . 1739
51.10.1 Clocking strategy . . . 1739
51.10.2 Slow speed clock . . . 1740
51.10.3 Rx controller clocks . . . 1743
51.10.4 Tx controller clocks . . . 1744

52 Fast Ethernet Controller (FEC) 1746
52.1 Introduction 1746
52.1.1 Block diagram 1746
52.1.2 Features 1749
52.2 Modes of operation 1749
52.2.1 Full and half duplex operation 1749
52.2.2 Interface options 1750
52.2.3 Address recognition options 1750
52.2.4 Internal loopback 1750
52.3 External signal description 1751
52.4 Memory map and register definition 1752
52.4.1 Interrupt Event Register (EIR) 1755
52.4.2 Interrupt Mask Register (EIMR) 1757
52.4.3 Receive Descriptor Active Register (RDAR) 1758
52.4.4 Transmit Descriptor Active Register (TDAR) 1759
52.4.5 Ethernet Control Register (ECR) 1760
52.4.6 MII Management Frame Register (MMFR) 1760
52.4.7 MII Speed Control Register (MSCR) 1762
52.4.8 MIB Control Register (MIBC) 1763
52.4.9 Receive Control Register (RCR) 1763
52.4.10 Transmit Control Register (TCR) 1765
52.4.11 Physical Address Lower Register (PALR) 1766
52.4.12 Physical Address Upper Register (PAUR) 1767
52.4.13 Opcode/Pause Duration Register (OPD) 1767
52.4.14 Descriptor Individual Upper Address Register (IAUR) 1768
52.4.15 Descriptor Individual Lower Address Register (IALR) 1768
52.4.16 Descriptor Group Upper Address Register (GAUR) 1768
52.4.17 Descriptor Group Lower Address Register (GALR) 1769
52.4.18 Transmit FIFO Watermark Register (TFWR) 1769
52.4.19 FIFO Receive Bound Register (FRBR) 1770
52.4.20 FIFO Receive Start Register (FRSR) 1770
52.4.21 Receive Descriptor Ring Start Register (ERDSR) 1771
52.4.22 Transmit Buffer Descriptor Ring Start Register (ETSDR) 1771
52.4.23 Receive Buffer Size Register (EMRBR) 1772
52.4.24 Count of frames not counted correctly (RMON_T_DROP) 1773
52.4.25 RMON Tx packet count (RMON_T_PACKETS) 1773

52.4.26 RMON Tx broadcast packets (RMON_T_BC_PKT) 1773
52.4.27 RMON Tx multicast packets (RMON_T_MC_PKT) 1774
52.4.28 RMON Tx packets with CRC/align error (RMON_T_CRC_ALIGN) . . 1774
52.4.29 RMON Tx packets < 64 bytes, good CRC (RMON_T_UNDERSIZE) 1774
52.4.30 RMON Tx packets > MAX_FL bytes, good CRC (RMON_T_OVERSIZE) 1775
52.4.31 RMON Tx packets < 64 bytes, bad CRC (RMON_T_FRAG) 1775
52.4.32 RMON Tx packets > MAX_FL bytes, bad CRC (RMON_T_JAB) . . . 1775
52.4.33 RMON Tx collision count (RMON_T_COL) 1776
52.4.34 RMON Tx 64 byte packets (RMON_T_P64) 1776
52.4.35 RMON Tx 65 to 127 byte packets (RMON_T_P65TO127) 1776
52.4.36 RMON Tx 128 to 255 byte packets (RMON_T_P128TO255) 1777
52.4.37 RMON Tx 256 to 511 byte packets (RMON_T_P256TO511) 1777
52.4.38 RMON Tx 512 to 1023 byte packets (RMON_T_P512TO1023) 1777
52.4.39 RMON Tx 1024 to 2047 byte packets (RMON_T_P1024TO2047) . . 1778
52.4.40 RMON Tx packets with > 2048 bytes (RMON_T_P_GTE2048) 1778
52.4.41 RMON Tx Octets (RMON_T_OCTETS) 1778
52.4.42 Count of transmitted frames not counted correctly (IEEE_T_DROP) 1779
52.4.43 Frames transmitted OK (IEEE_T_FRAME_OK) 1779
52.4.44 Frames transmitted with single collision (IEEE_T_1COL) 1779
52.4.45 Frames transmitted with multiple collisions (IEEE_T_MCOL) 1780
52.4.46 Frames transmitted after deferral delay (IEEE_T_DEF) 1780
52.4.47 Frames transmitted with late collision (IEEE_T_LCOL) 1780
52.4.48 Frames transmitted with excessive collisions (IEEE_T_EXCOL) . . . 1781
52.4.49 Frames transmitted with Tx FIFO underrun (IEEE_T_MACERR) . . . 1781
52.4.50 Frames transmitted with carrier sense error (IEEE_T_CSERR) 1781
52.4.51 Frames transmitted with SQE error (IEEE_T_SQE) 1782
52.4.52 Flow control pause frames transmitted (IEEE_T_FDXFC) 1782
52.4.53 Octet count for frames transmitted without error (IEEE_T_OCTETS_OK) 1782
52.4.54 Count of received frames not counted correctly (RMON_R_DROP) . 1783
52.4.55 RMON Rx packet count (RMON_R_PACKETS) 1783
52.4.56 RMON Rx broadcast packets (RMON_R_BC_PKT) 1783
52.4.57 RMON Rx multicast packets (RMON_R_MC_PKT) 1784
52.4.58 RMON Rx packets with CRC/Align error (RMON_R_CRC_ALIGN) . 1784
52.4.59 RMON Rx packets < 64 bytes, good CRC (RMON_R_UNDERSIZE) 1784
52.4.60 RMON Rx packets > MAX_FL bytes, good CRC (RMON_R_OVERSIZE) 1785

52.4.61 RMON Rx packets < 64 bytes, bad CRC (RMON_R_FRAG) 1785
52.4.62 RMON Rx packets > MAX_FL bytes, bad CRC (RMON_R_JAB) . . . 1785
52.4.63 Reserved (RMON_R_RESVD_0) 1786
52.4.64 RMON Rx 64 byte packets (RMON_R_P64) 1786
52.4.65 RMON Rx 65 to 127 byte packets (RMON_R_P65TO127) 1786
52.4.66 RMON Rx 128 to 255 byte packets (RMON_R_P128TO255) 1787
52.4.67 RMON Rx 256 to 511 byte packets (RMON_R_P256TO511) 1787
52.4.68 RMON Rx 512 to 1023 byte packets (RMON_R_P512TO1023) 1787
52.4.69 RMON Rx 1024 to 2047 byte packets (RMON_R_P1024TO2047) . . 1788
52.4.70 RMON Rx packets with > 2048 bytes (RMON_R_P_GTE2048) 1788
52.4.71 RMON Rx octets (RMON_R_OCTETS) 1788
52.4.72 Count of received frames not counted correctly (IEEE_R_DROP) . . 1789
52.4.73 Frames received OK (IEEE_R_FRAME_OK) 1789
52.4.74 Frames received with CRC error (IEEE_R_CRC) 1789
52.4.75 Frames received with alignment error (IEEE_R_ALIGN) 1790
52.4.76 Receive FIFO overflow count (IEEE_R_MACERR) 1790
52.4.77 Flow control pause frames received (IEEE_R_FDXFC) 1790
52.4.78 Octet count for frames received without error (IEEE_R_OCTETS_OK) . . .1791
52.5 Functional description 1791
52.5.1 MII data frame 1791
52.5.2 MII management frame structure 1792
52.5.3 Buffer descriptors 1793
52.5.4 Initialization sequence 1798
52.5.5 User initialization (Prior to Setting ECR[ETHER_EN]) 1798
52.5.6 Microcontroller initialization 1799
52.5.7 User initialization (after setting ECR[ETHER_EN]) 1799
52.5.8 Network interface options 1799
52.5.9 FEC frame transmission 1801
52.5.10 FEC frame reception 1802
52.5.11 Ethernet address recognition 1803
52.5.12 Hash algorithm 1805
52.5.13 Full duplex flow control 1808
52.5.14 Inter-Packet Gap (IPG) time 1809
52.5.15 Collision managing 1809
52.5.16 MII internal and external loopback 1809
52.5.17 RMII loopback 1809

52.5.18 RMII echo . . . 1810
52.5.19 Ethernet error-managing procedure . . . 1810

53 FlexRay Communication Controller (FlexRay) . . . 1812

53.1 Introduction . . . 1812
53.1.1 Reference . . . 1812
53.1.2 Glossary . . . 1812
53.1.3 Color coding . . . 1813
53.1.4 Overview . . . 1813
53.1.5 Features . . . 1816
53.1.6 Modes of operation . . . 1817
53.2 External Signal Description . . . 1818
53.2.1 Detailed signal description . . . 1818
53.3 Controller Host Interface clocking . . . 1819
53.4 Protocol engine clocking . . . 1819
53.4.1 Oscillator clocking . . . 1819
53.4.2 PLL clocking . . . 1819
53.5 Memory map and register description . . . 1820
53.5.1 Memory map . . . 1820
53.5.2 Register descriptions . . . 1827
53.6 Functional description . . . 1910
53.6.1 Message buffer concept . . . 1910
53.6.2 Physical message buffer . . . 1910
53.6.3 Message Buffer Types . . . 1911
53.6.4 FlexRay memory area layout . . . 1917
53.6.5 Physical message buffer description . . . 1920
53.6.6 Individual message buffer functional description . . . 1929
53.6.7 Individual message buffer search . . . 1947
53.6.8 Individual message buffer reconfiguration . . . 1950
53.6.9 Receive FIFOs . . . 1950
53.6.10 Channel device modes . . . 1958
53.6.11 External clock synchronization . . . 1959
53.6.12 Sync frame ID and sync frame deviation tables . . . 1960
53.6.13 MTS generation . . . 1963
53.6.14 Key slot transmission . . . 1964
53.6.15 Sync frame filtering . . . 1964

53.6.16 Strobe signal support . . . 1965
53.6.17 Timer support . . . 1966
53.6.18 Slot status monitoring . . . 1967
53.6.19 System bus access . . . 1971
53.6.20 Interrupt support . . . 1972
53.6.21 Lower bit rate support . . . 1977
53.6.22 PE data memory (PE DRAM) . . . 1978
53.6.23 CHI lookup-table memory (CHI LRAM) . . . 1979
53.6.24 Memory content error detection . . . 1980
53.6.25 Memory error injection . . . 1984
53.6.26 StopWatch function . . . 1986
53.7 Application information . . . 1988
53.7.1 Module configuration . . . 1988
53.7.2 Initialization sequence . . . 1989
53.7.3 Memory error injection out of POC:default config . . . 1991
53.7.4 Shutdown sequence . . . 1991
53.7.5 Number of usable message buffers . . . 1991
53.7.6 Protocol Control Command Execution . . . 1992
53.7.7 Message buffer search on simple message buffer configuration . . . 1993

54 Inter-Integrated Circuit (I^2C) . . . 1996
54.1 Overview . . . 1996
54.2 Introduction to I^2C . . . 1996
54.2.1 Definition: I^2C module . . . 1996
54.2.2 Advantages of the I^2C bus . . . 1996
54.2.3 Module block diagram . . . 1996
54.2.4 Features . . . 1998
54.2.5 Modes of operation . . . 1998
54.2.6 Definition: I^2C conditions . . . 1999
54.3 External signal descriptions . . . 1999
54.3.1 Signal overview . . . 2000
54.3.2 Detailed external signal descriptions . . . 2000
54.4 Memory map and register definition . . . 2000
54.4.1 I^2C memory map . . . 2000
54.4.2 Register accessibility . . . 2001
54.4.3 Register figure conventions . . . 2001
54.4.4 I^2C Bus Address Register (IBAD) . . . 2001

54.4.5 I2C Bus Frequency Divider Register (IBFD) . . . 2002
54.4.6 I2C Bus Control Register (IBCR) . . . 2003
54.4.7 I2C Bus Status Register (IBSR) . . . 2004
54.4.8 I2C Bus Data I/O Register (IBDR) . . . 2006
54.4.9 I2C Bus Interrupt Config Register (IBIC) . . . 2007
54.4.10 I2C Bus Debug Register (IBDBG) . . . 2008
54.5 Functional description . . . 2009
54.5.1 Notes about module operation . . . 2009
54.5.2 Transactions . . . 2009
54.5.3 Arbitration procedure . . . 2012
54.5.4 Clock behavior . . . 2012
54.5.5 Interrupts . . . 2021
54.5.6 IPG STOP mode . . . 2022
54.5.7 IPG DEBUG mode . . . 2022
54.5.8 DMA interface . . . 2024
54.6 Initialization/application information . . . 2025
54.6.1 Recommended interrupt service flow . . . 2025
54.6.2 General programming guidelines (for both master and slave mode) . 2027
54.6.3 Programming guidelines specific to master mode . . . 2028
54.6.4 Programming guidelines specific to slave mode . . . 2031
54.6.5 DMA application information . . . 2031

55 Peripheral Sensor Interface (PSI5) . . . 2037
55.1 Introduction . . . 2037
55.1.1 Overview . . . 2037
55.1.2 Features . . . 2039
55.1.3 Modes of operation . . . 2040
55.2 External signal description . . . 2045
55.3 Memory map and register description . . . 2045
55.3.1 Memory map . . . 2045
55.3.2 Register description . . . 2053
55.4 Functional description . . . 2104
55.4.1 Sensor-to-ECU communication . . . 2105
55.4.2 Data Link Layer . . . 2106
55.4.3 ECU-to-sensor communication . . . 2127
55.4.4 Tx/Rx scenario . . . 2137

55.4.5 Interrupt handling . . . 2138
55.4.6 DMA support . . . 2139
55.4.7 Message read through interrupt generation . . . 2141
55.5 Clock and Reset . . . 2142
55.5.1 Latency and Jitter related requirements . . . 2144
55.5.2 Reset . . . 2144
55.6 Initialization information . . . 2144
55.6.1 Initialization . . . 2144
55.7 Design Assumptions and Limitations . . . 2145
55.7.1 Assumptions . . . 2145
55.7.2 Limitations . . . 2145
55.8 Miscellaneous descriptions . . . 2146
55.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels . . . 2146
55.8.2 Valid states for integrated sync pulse generator . . . 2150
55.8.3 Implementation of EI Diagnostic Register . . . 2152

56 SENT Receiver (SRX) . . . 2153
56.1 Introduction . . . 2153
56.1.1 Features . . . 2154
56.1.2 Modes of operation . . . 2155
56.1.3 Block diagram . . . 2156
56.1.4 Design overview . . . 2157
56.2 External signal description . . . 2158
56.2.1 SENT_RX [(CH-1):0] . . . 2158
56.3 Memory map and register definition . . . 2158
56.3.1 Memory map . . . 2158
56.3.2 Register descriptions . . . 2160
56.3.3 Register Classification for Safety . . . 2190
56.4 Functional description . . . 2191
56.4.1 Initialization sequence . . . 2191
56.4.2 DMA read logic . . . 2192
56.4.3 Message reading via interrupts . . . 2196
56.4.4 Overflow behavior . . . 2197
56.4.5 Adjustment for variation in sensor (Tx) clock . . . 2198
56.4.6 Input programmable filter . . . 2198

56.4.7 Receiver diagnostics . . . 2199
56.4.8 Time stamp logic . . . 2201
56.4.9 Bus Idle Diagnostic . . . 2202
56.5 Clocks and resets . . . 2202
56.5.1 Clocking strategy . . . 2202
56.5.2 System bus clock requirements . . . 2203
56.5.3 High frequency receiver clock (protocol clock) requirements . . . 2204

57 LINFlexD . . . 2205
57.1 Introduction . . . 2205
57.2 Main features . . . 2207
57.2.1 LIN mode features . . . 2207
57.2.2 UART mode features . . . 2208
57.2.3 Standard features . . . 2208
57.3 Functional description . . . 2208
57.3.1 LIN protocol . . . 2208
57.3.2 LINFlexD features . . . 2210
57.3.3 Timer . . . 2226
57.3.4 UART mode . . . 2227
57.3.5 DMA interface . . . 2232
57.4 Memory map and register description . . . 2250
57.4.1 Memory map . . . 2250
57.4.2 Register description . . . 2252
57.4.3 Register map . . . 2288
57.5 Programming considerations . . . 2291
57.5.1 Master node . . . 2291
57.5.2 Slave node . . . 2292
57.5.3 Extended frames . . . 2297
57.5.4 Timeout . . . 2297
57.5.5 UART mode . . . 2298
57.5.6 Interrupts . . . 2298

58 Reset Generation Module (MC_RGM) . . . 2301
58.1 Introduction . . . 2301
58.1.1 Overview . . . 2301
58.1.2 Features . . . 2302

58.1.3 Reset sources . . . 2302
58.2 External signal description . . . 2303
58.3 Memory map and register definition . . . 2303
58.3.1 Register descriptions . . . 2305
58.4 Functional description . . . 2340
58.4.1 Reset state machine . . . 2340
58.4.2 Destructive resets . . . 2343
58.4.3 External reset . . . 2343
58.4.4 Functional resets . . . 2344
58.4.5 Alternate event generation . . . 2345
58.4.6 Functional reset escalation . . . 2345
58.4.7 Destructive reset escalation . . . 2345
58.4.8 Individual peripheral resets . . . 2346

59 Boot Assist Flash (BAF) . . . 2347
59.1 Introduction . . . 2347
59.1.1 BAF image header . . . 2347
59.2 Functional description . . . 2348
59.2.1 Boot modes . . . 2348
59.2.2 Device initialization . . . 2348
59.2.3 Flow of control . . . 2349
59.2.4 Optionally remap calibration RAM . . . 2350
59.2.5 Initialization of BAF DCF clients . . . 2351
59.2.6 Production disable activation protocol and implementation . . . 2357
59.2.7 Optionally perform a serial boot . . . 2361
59.2.8 Serial boot configuration . . . 2365
59.3 Resources . . . 2368

60 System Status and Configuration Module (SSCM) . . . 2369
60.1 Introduction . . . 2369
60.1.1 Overview . . . 2369
60.1.2 Glossary . . . 2369
60.1.3 Features . . . 2370
60.1.4 Modes of operation . . . 2370
60.2 External signal description . . . 2370
60.3 Memory map and register definition . . . 2370

60.3.1 Register descriptions . . . 2371
60.4 Functional description . . . 2374
60.4.1 DCF mechanism . . . 2374
60.4.2 ECC error monitoring . . . 2376
60.4.3 Boot mode functionality . . . 2376
60.4.4 BAF configuration . . . 2377
60.4.5 Life Cycle . . . 2377
60.5 Initialization and application information . . . 2378
60.5.1 Reset . . . 2378
60.6 Additional safety measures . . . 2378
60.6.1 Spurious reset protection . . . 2378

61 Power Management Controller digital interface (PMC_dig) . . . 2380
61.1 Introduction . . . 2380
61.2 Block diagram . . . 2380
61.3 Memory map and register definition . . . 2382
61.3.1 Register descriptions . . . 2384
61.4 Analog PMC interface . . . 2427
61.5 Temperature Sensor Interface Logic . . . 2428
61.6 Power On Reset (MC_RGM Phase Gates) . . . 2428
61.7 Flash interface (DCF client usage) . . . 2429
61.8 Other module interfaces . . . 2429

62 Power Control Unit (MC_PCU) . . . 2431
62.1 Introduction . . . 2431
62.1.1 Overview . . . 2431
62.1.2 Features . . . 2432
62.2 External signal description . . . 2432
62.3 Memory map and register definition . . . 2432
62.3.1 Memory map . . . 2432
62.3.2 Register descriptions . . . 2432

63 Mode Entry Module (MC_ME) . . . 2434
63.1 Introduction . . . 2434
63.1.1 Overview . . . 2434
63.1.2 Features . . . 2435

63.1.3 Modes of operation . . . 2435
63.2 External signal description . . . 2436
63.3 Memory map and register definition . . . 2437
63.3.1 Memory map . . . 2437
63.3.2 Register description . . . 2441
63.4 Functional description . . . 2472
63.4.1 Mode transition request . . . 2472
63.4.2 Modes details . . . 2473
63.4.3 Mode transition process . . . 2476
63.4.4 Protection of mode configuration registers . . . 2484
63.4.5 Mode transition interrupts . . . 2484
63.4.6 Peripheral clock gating . . . 2486
63.4.7 Application example . . . 2486

64 e200z410Dn3 Core Debug Support . . . 2488
64.1 Overview . . . 2488
64.1.1 Software debug facilities . . . 2488
64.1.2 Additional debug facilities . . . 2489
64.1.3 Hardware debug facilities . . . 2489
64.1.4 Sharing debug resources by software/hardware . . . 2490
64.2 Software debug events and exceptions . . . 2491
64.2.1 Instruction Address Compare event . . . 2492
64.2.2 Data Address Compare event . . . 2493
64.2.3 Linked Instruction Address Compare and Data Address Compare events . . . 2496
64.2.4 Trap debug event . . . 2496
64.2.5 Branch Taken debug event . . . 2497
64.2.6 Instruction Complete debug event . . . 2497
64.2.7 Interrupt Taken debug event . . . 2497
64.2.8 Critical Interrupt Taken debug event . . . 2498
64.2.9 Return debug event . . . 2498
64.2.10 Critical Return Debug Event . . . 2498
64.2.11 External debug event . . . 2498
64.2.12 Unconditional debug event . . . 2498
64.2.13 Performance Monitor Interrupt debug event . . . 2499
64.3 Debug registers . . . 2499
64.3.1 Debug Address and Value registers . . . 2499

64.3.2 Debug Control and Status registers 2500
64.3.3 External Debug Resource Allocation Control (EDBRAC0) register . . 2520
64.3.4 Debug Event Select register (DEVENT) register 2528
64.3.5 Debug Data Acquisition Message (DDAM) register 2528
64.4 Using debug resources for stack limit checking 2529
64.5 External debug support 2531
64.5.1 External debug registers 2532
64.5.2 OnCE introduction 2537
64.5.3 JTAG/OnCE pins 2540
64.5.4 OnCE internal interface signals 2540
64.5.5 OnCE interface signals 2541
64.5.6 OnCE controller and serial interface 2543
64.5.7 Access to debug resources 2550
64.5.8 Methods of entering Debug mode 2552
64.5.9 CPU Status and Control Scan Chain Register (CPUSCR) 2553
64.5.10 Reserved registers (Reserved) 2559
64.6 Watchpoint support 2559
64.7 MPU operation during debug 2562
64.8 Cache array access during debug 2563
64.9 Basic steps for enabling, using, and exiting External Debug mode . . . 2563

65 e200z225Bn3 Core Debug Support 2565
65.1 Overview 2565
65.1.1 Software debug facilities 2565
65.1.2 Additional debug facilities 2566
65.1.3 Hardware debug facilities 2566
65.1.4 Sharing debug resources by software/hardware 2567
65.2 Software debug events and exceptions 2568
65.2.1 Instruction Address Compare event 2569
65.2.2 Data Address Compare event 2570
65.2.3 Linked Instruction Address Compare and Data Address Compare events 2573
65.2.4 Trap debug event 2573
65.2.5 Branch Taken debug event 2574
65.2.6 Instruction Complete debug event 2574
65.2.7 Interrupt Taken debug event 2574

65.2.8 Critical Interrupt Taken debug event . . . 2575
65.2.9 Return debug event . . . 2575
65.2.10 Critical Return Debug Event . . . 2575
65.2.11 External debug event . . . 2575
65.2.12 Unconditional debug event . . . 2575
65.2.13 Performance Monitor Interrupt debug event . . . 2576
65.3 Debug registers . . . 2576
65.3.1 Debug Address and Value registers . . . 2576
65.3.2 Debug Control and Status registers . . . 2577
65.3.3 External Debug Resource Allocation Control (EDBRAC0) register . . 2597
65.3.4 Debug Event Select register (DEVENT) register . . . 2604
65.3.5 Debug Data Acquisition Message (DDAM) register . . . 2605
65.4 Using debug resources for stack limit checking . . . 2606
65.5 External debug support . . . 2608
65.5.1 External debug registers . . . 2609
65.5.2 OnCE introduction . . . 2614
65.5.3 JTAG/OnCE pins . . . 2617
65.5.4 OnCE internal interface signals . . . 2617
65.5.5 OnCE interface signals . . . 2618
65.5.6 OnCE controller and serial interface . . . 2620
65.5.7 Access to debug resources . . . 2627
65.5.8 Methods of entering Debug mode . . . 2629
65.5.9 CPU Status and Control Scan Chain Register (CPUSCR) . . . 2630
65.5.10 Reserved registers (Reserved) . . . 2636
65.6 Watchpoint support . . . 2636
65.7 MPU operation during debug . . . 2639
65.8 Basic steps for enabling, using, and exiting External Debug mode . . . 2640

66 Debug and Calibration Interface (DCI) . . . 2642
66.1 Introduction . . . 2642
66.1.1 Features . . . 2642
66.1.2 Overview . . . 2642
66.1.3 Operating modes . . . 2644
66.2 External signal description . . . 2656
66.3 Register description . . . 2656
66.3.1 DCI control register (DCI_CR) . . . 2656

66.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR) 2658
66.4 Functional description 2658
66.4.1 DCI mode transition 2658
66.4.2 LFAST LVDS pad fault 2660

67 JTAG Controller (JTAGC) 2661
67.1 Introduction 2661
67.1.1 Block Diagram 2661
67.1.2 Features 2662
67.1.3 Modes of operation 2662
67.2 External signal description 2663
67.2.1 TCK—Test clock input 2663
67.2.2 TDI—Test data input 2663
67.2.3 TDO—Test data output 2663
67.2.4 TMS—Test mode select 2663
67.2.5 JCOMP—JTAG compliancy 2663
67.3 Register description 2664
67.3.1 Instruction register 2664
67.3.2 Bypass register 2664
67.3.3 Device identification register 2664
67.3.4 JTAG_PASSWORD register 2665
67.3.5 Boundary scan register 2666
67.4 Functional description 2666
67.4.1 JTAGC reset configuration 2666
67.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port 2666
67.4.3 TAP controller state machine 2666
67.4.4 JTAGC block instructions 2668
67.4.5 Boundary scan 2671
67.5 Initialization/Application information 2671

68 IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) 2673
68.1 References 2673
68.2 Abbreviations 2673
68.3 Introduction 2674
68.3.1 Types of operation 2675
68.3.2 Deployment by class 2675

68.3.3 1149.7 TAP signals . . . 2675
68.3.4 TAP.7 architecture . . . 2676
68.3.5 Protocols . . . 2677
68.3.6 Operating models . . . 2679
68.4 CJTAG implementation summary . . . 2679
68.4.1 T0 Functions . . . 2679
68.4.2 T1 functions . . . 2679
68.4.3 T2 functions . . . 2679
68.4.4 T3 functions . . . 2679
68.4.5 T4 functions . . . 2680
68.5 Ancillary services . . . 2680
68.5.1 Overview . . . 2680
68.5.2 Resets . . . 2680
68.5.3 Start-up Options . . . 2684
68.5.4 RSU operation . . . 2684
68.5.5 TAPC State Machine . . . 2686
68.6 EPU (Extended Protocol Unit) Operation . . . 2687
68.6.1 EPU Operation . . . 2687
68.6.2 EPU Registers . . . 2689
68.6.3 EPU Commands . . . 2699
68.6.4 EPU operating states . . . 2707
68.6.5 System and EPU Paths . . . 2708
68.7 APU (Advanced Protocol Unit) Operation . . . 2708
68.7.1 Overview . . . 2708
68.7.2 Operation . . . 2711
68.7.3 Escape sequences . . . 2712
68.7.4 Signal behaviors . . . 2712
68.7.5 APU Functions . . . 2712
68.7.6 Configuration Change Packets (CP) . . . 2719
68.7.7 Scan Packet . . . 2719
68.7.8 SP Format . . . 2719
68.8 Functional Description . . . 2725
68.8.1 Switching from Standard Protocol to Advanced Protocol . . . 2725

69 JTAG Data Communication (JDC) . . . 2726
69.1 Introduction . . . 2726

69.2 Overview . . . 2726
69.3 Register definition . . . 2727
69.3.1 Register descriptions . . . 2727
69.3.2 Non-Memory mapped register definition . . . 2729
69.4 Functional description . . . 2731
69.4.1 IPS register access . . . 2731
69.4.2 JTAG register access . . . 2731

70 JTAG Master (JTAGM) . . . 2732
70.1 Introduction . . . 2732
70.1.1 Overview . . . 2732
70.1.2 Feature description . . . 2733
70.2 Functional description . . . 2733
70.2.1 Module architecture . . . 2733
70.2.2 JTAGM JCOMP usage in LFAST . . . 2734
70.2.3 JTAGM data error detection . . . 2735
70.2.4 JTAGM message tagging . . . 2735
70.2.5 JTAGM Ready signal . . . 2735
70.2.6 EVTO and EVTI signals . . . 2736
70.2.7 JTAGM configuration and status monitoring . . . 2736
70.2.8 JTAGM to DCI serial interface . . . 2737
70.2.9 JTAGM data handling and CRC calculation in LFAST mode . . . 2737
70.2.10 Software interface . . . 2738
70.3 Modes of operation . . . 2738
70.4 Memory map and register definition . . . 2738
70.4.1 Register descriptions . . . 2739

71 Sequence Processing Unit (SPU) . . . 2747
71.1 Introduction . . . 2747
71.1.1 SPU block diagram . . . 2747
71.1.2 Overview . . . 2748
71.1.3 Features . . . 2750
71.2 SPU actions . . . 2751
71.3 Operation mode . . . 2752
71.3.1 SPU enable/disable . . . 2752
71.4 SPU module interface . . . 2753

71.5 Register definition . . . 2753
71.5.1 Register descriptions . . . 2758
71.6 Functional description . . . 2789
71.6.1 Input Mux unit . . . 2789
71.6.2 Processor exception vector encoding . . . 2791
71.6.3 State logic unit (SLU) . . . 2792
71.6.4 Sequence formation . . . 2793
71.6.5 Performance counters/timers unit . . . 2796
71.6.6 Action unit . . . 2798
71.6.7 Optional trace group . . . 2798
71.6.8 Format for CKSRC & CKDATA Values . . . 2798

72 Development Trigger Semaphore (DTS) . . . 2800
72.1 Introduction . . . 2800
72.2 Overview . . . 2800
72.3 DTS device connections . . . 2802
72.3.1 DTS register access . . . 2803
72.4 Memory map and register definition . . . 2803
72.4.1 Register descriptions . . . 2804
72.5 Example application . . . 2806

73 Nexus Aurora Router (NAR) . . . 2809
73.1 Introduction . . . 2809
73.2 Overview . . . 2810
73.3 Features . . . 2810
73.4 Register definition . . . 2810
73.4.1 Register descriptions . . . 2811
73.4.2 Message filtering registers . . . 2814
73.4.3 Trace memory bus configuration registers . . . 2817
73.4.4 Suppress mode triggers register (NAR_STCR) . . . 2819
73.4.5 Receive queue client disable register (NAR_CDR) . . . 2821
73.4.6 Trace Memory fill level and partition configuration register (NAR_AHFPAR) . . . 2823
73.5 Functional description . . . 2823
73.5.1 Reset/Startup . . . 2823
73.5.2 Operation modes . . . 2824

73.5.3 Data reception and arbitration . . . 2826
73.5.4 Suppress mode . . . 2827
73.5.5 Stall detection . . . 2828
73.5.6 Output arbitration . . . 2829
73.5.7 Message translation and formatting . . . 2830
73.5.8 Aurora interface . . . 2831
73.5.9 Trace memory bus output port usage . . . 2831
73.5.10 Internal message generation . . . 2832
73.5.11 Timestamp function . . . 2836
73.5.12 Overlay and internal trace memory full status generation . . . 2837
73.5.13 Configuration/debug interface JTAG (1149.1) . . . 2838
73.5.14 Trace memory bus controller . . . 2841
73.5.15 Legacy client interface controller . . . 2843
73.6 Initialization information . . . 2843
73.7 Application information . . . 2844

74 e200z410Dn3 Nexus 3 Module . . . 2845
74.1 Introduction . . . 2845
74.1.1 General Description . . . 2845
74.1.2 Terms and Definitions . . . 2845
74.1.3 Feature List . . . 2846
74.1.4 Functional Block Diagram . . . 2848
74.2 Enabling Nexus 3 Operation . . . 2848
74.2.1 Interaction with Low Power Modes . . . 2849
74.3 TCODEs supported . . . 2849
74.4 Nexus 3 Programmer's Model . . . 2855
74.4.1 Client Select Control (CSC) register . . . 2857
74.4.2 Port Configuration Register (PCR) — reference only . . . 2857
74.4.3 Nexus Development Control Register 1 (DC1) . . . 2858
74.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3) . . . 2859
74.4.5 Nexus Development Control Register 4 (DC4) . . . 2864
74.4.6 Development Status Register (DS) . . . 2865
74.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers . . . 2866
74.4.8 Nexus Watchpoint Mask (WMSK) register . . . 2872
74.4.9 Nexus Overrun Control (OVCR) register . . . 2873
74.4.10 Data Trace Control (DTC) register . . . 2874

74.4.11 Data Trace Start Address Registers (DTSA1–4) 2876
74.4.12 Data Trace End Address 1–4 (DTEA1–4) registers 2877
74.4.13 Read/Write Access Control/Status (RWCS) register 2878
74.4.14 Read/Write Access Data (RWD) register 2879
74.4.15 Read/Write Access Address (RWA) 2881
74.5 Nexus 3 Register Access via JTAG/OnCE 2881
74.6 Nexus 3 Register Access via Software 2882
74.7 Nexus Message Fields 2882
74.7.1 TCODE Field 2882
74.7.2 Source ID Field (SRC) 2882
74.7.3 Relative Address Field (U-ADDR) 2882
74.7.4 Full Address Field (F-ADDR) 2883
74.7.5 Timestamp Field (TSTAMP) 2883
74.8 Nexus Message Queues 2884
74.8.1 Message Queue Overrun 2884
74.8.2 CPU Stall 2884
74.8.3 Message Suppression 2884
74.8.4 Nexus Message Priority 2885
74.8.5 Data Acquisition Message Priority Loss Response 2886
74.8.6 Ownership Trace Message Priority Loss Response 2886
74.8.7 Program Trace Message Priority Loss Response 2886
74.8.8 Program Trace Sync Message Priority Loss Response 2887
74.8.9 Data Trace Message Priority Loss Response 2887
74.9 Debug Status messages 2887
74.10 Error messages 2887
74.11 Ownership trace 2888
74.11.1 Overview 2888
74.11.2 Ownership Trace Messaging (OTM) 2888
74.12 Program Trace 2889
74.12.1 Branch Trace Messaging types 2889
74.12.2 BTM Message For mats 2891
74.12.3 Program Trace Message Fields 2891
74.12.4 Resource Full Messages 2893
74.12.5 Program Correlation Messages 2894
74.12.6 Program Trace Overflow Error messages 2895
74.12.7 Program Trace Synchronization messages 2895

74.12.8 Program Trace Direct/Indirect Branch with Sync messages 2896
74.12.9 Enabling Program Trace 2897
74.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration) . 2898
74.13 Data Trace 2899
74.13.1 Data Trace Messaging (DTM) 2899
74.13.2 DTM Message formats 2899
74.13.3 DTM operation 2901

74.17.1 Single write access 2908
74.17.2 Block write access 2908
74.17.3 Single read access 2909
74.17.4 Block read access 2909
74.17.5 Error handling 2910
74.17.6 Read/Write access error message 2911
74.18 Nexus 3 pin interface 2911
74.18.1 Pins implemented 2911
74.18.2 Pin protocol 2913
74.19 Rules for output messages 2916
74.20 Auxiliary port arbitration 2916
74.21 Examples 2916
74.22 Electrical characteristics 2919
74.23 IEEE 1149.1 (JTAG) RD/WR sequences 2919
74.23.1 JTAG sequence for accessing internal Nexus registers 2919
74.23.2 JTAG sequence for read access of memory-mapped resources 2920
74.23.3 JTAG sequence for write access of memory-mapped resources . . . 2920

75 e200z225Bn3 Nexus 3 Module 2921

75.1 Introduction 2921

75.1.1 General Description . . . 2921
75.1.2 Terms and Definitions . . . 2921
75.1.3 Feature List . . . 2922
75.1.4 Functional Block Diagram . . . 2924
75.2 Enabling Nexus 3 Operation . . . 2924
75.2.1 Interaction with Low Power Modes . . . 2925
75.3 TCODEs supported . . . 2925
75.4 Nexus 3 Programmer's Model . . . 2933
75.4.1 Client Select Control (CSC) register . . . 2934
75.4.2 Port Configuration Register (PCR) — reference only . . . 2935
75.4.3 Nexus Development Control Register 1 (DC1) . . . 2936
75.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3) . . . 2937
75.4.5 Nexus Development Control Register 4 (DC4) . . . 2941
75.4.6 Development Status Register (DS) . . . 2942
75.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers . . . 2943
75.4.8 Nexus Watchpoint Mask (WMSK) register . . . 2949
75.4.9 Nexus Overrun Control (OVCR) register . . . 2950
75.4.10 Data Trace Control (DTC) register . . . 2951
75.4.11 Data Trace Start Address Registers (DTSA1–4) . . . 2953
75.4.12 Data Trace End Address 1–4 (DTEA1–4) registers . . . 2954
75.4.13 Read/Write Access Control/Status (RWCS) register . . . 2955
75.4.14 Read/Write Access Data (RWD) register . . . 2956
75.4.15 Read/Write Access Address (RWA) . . . 2958
75.5 Nexus 3 Register Access via JTAG/OnCE . . . 2958
75.6 Nexus 3 Register Access via Software . . . 2959
75.7 Nexus Message Fields . . . 2959
75.7.1 TCODE Field . . . 2959
75.7.2 Source ID Field (SRC) . . . 2959
75.7.3 Relative Address Field (U-ADDR) . . . 2959
75.7.4 Full Address Field (F-ADDR) . . . 2960
75.7.5 Timestamp Field (TSTAMP) . . . 2960
75.8 Nexus Message Queues . . . 2961
75.8.1 Message Queue Overrun . . . 2961
75.8.2 CPU Stall . . . 2961
75.8.3 Message Suppression . . . 2962

75.8.4 Nexus Message Priority 2962
75.8.5 Data Acquisition Message Priority Loss Response 2963
75.8.6 Ownership Trace Message Priority Loss Response 2963
75.8.7 Program Trace Message Priority Loss Response 2963
75.8.8 Program Trace Sync Message Priority Loss Response 2964
75.8.9 Data Trace Message Priority Loss Response 2964
75.9 Debug Status messages 2964
75.10 Error messages 2964
75.11 Ownership trace 2965
75.11.1 Overview 2965
75.11.2 Ownership Trace Messaging (OTM) 2965
75.12 Program Trace 2966
75.12.1 Branch Trace Messaging types 2966
75.12.2 BTM Message For mats 2968
75.12.3 Program Trace Message Fields 2969
75.12.4 Resource Full Messages 2970
75.12.5 Program Correlation Messages 2971
75.12.6 Program Trace Overflow Error messages 2972
75.12.7 Program Trace Synchronization messages 2973
75.12.8 Program Trace Direct/Indirect Branch with Sync messages 2974
75.12.9 Enabling Program Trace 2975
75.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration) . 2976
75.13 Data Trace 2977
75.13.1 Data Trace Messaging (DTM) 2977
75.13.2 DTM Message formats 2977
75.13.3 DTM operation 2980
75.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration) 2982
75.14 Data Acquisition messaging 2982
75.14.1 Data Acquisition ID Tag field 2982
75.14.2 Data Acquisition Data field 2982
75.14.3 Data Acquisition Trace event 2983
75.15 Watchpoint Trace messaging 2983
75.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration) 2985
75.16 External Hardware Trigger Controls 2985
75.17 Nexus 3 Read/Write access to memory-mapped resources 2986
75.17.1 Single write access 2987

75.17.2 Block write access . . . 2987
75.17.3 Single read access . . . 2988
75.17.4 Block read access . . . 2988
75.17.5 Error handling . . . 2989
75.17.6 Read/Write access error message . . . 2990
75.18 Nexus 3 pin interface . . . 2990
75.18.1 Pins implemented . . . 2990
75.18.2 Pin protocol . . . 2992
75.19 Rules for output messages . . . 2995
75.20 Auxiliary port arbitration . . . 2995
75.21 Examples . . . 2995
75.22 Electrical characteristics . . . 2998
75.23 IEEE 1149.1 (JTAG) RD/WR sequences . . . 2998
75.23.1 JTAG sequence for accessing internal Nexus registers . . . 2998
75.23.2 JTAG sequence for read access of memory-mapped resources . . . 2999
75.23.3 JTAG sequence for write access of memory-mapped resources . . . 2999

76 Nexus Crossbar Multi-Master Client (NXMC) . . . 3000
76.1 Introduction . . . 3000
76.1.1 Features . . . 3000
76.2 External signal description . . . 3000
76.3 Supported messages and TCODEs . . . 3001
76.4 Register description . . . 3004
76.4.1 Register descriptions . . . 3005
76.5 Programming considerations (RESET) . . . 3012
76.5.1 IEEE 1149.1 (JTAG) Test Access Port . . . 3012
76.5.2 Enabling NXMC operation . . . 3012
76.5.3 Enabling NXMC TAP controller . . . 3012
76.5.4 NXMC register access via JTAG . . . 3012
76.6 Functional description . . . 3013
76.6.1 Data trace . . . 3013
76.6.2 Watchpoint support . . . 3018
76.6.3 Peripheral interface . . . 3019
76.6.4 Timestamping feature . . . 3020

77 Cyclic Redundancy Check (CRC) Unit . . . 3021

77.1 Introduction . . . 3021
77.2 Main features . . . 3021
77.2.1 Standard features . . . 3021
77.3 Block diagram . . . 3021
77.4 Signal description . . . 3022
77.4.1 Peripheral bus interface . . . 3022
77.5 Memory map and registers . . . 3022
77.5.1 Register description . . . 3022
77.6 Functional description . . . 3026
77.7 Use cases . . . 3028
77.7.1 Programming example . . . 3028
77.7.2 Register programming . . . 3030

78 Memory Error Management Unit (MEMU) . . . 3031
78.1 Introduction . . . 3031
78.2 Features . . . 3032
78.3 Block diagram . . . 3032
78.4 Design overview . . . 3033
78.5 External signal description . . . 3037
78.6 Memory map and register definition . . . 3037
78.6.1 Memory map . . . 3037
78.6.2 Register descriptions . . . 3039
78.7 Functional description . . . 3053
78.7.1 Initializing MEMU . . . 3053
78.7.2 Reading the reporting table . . . 3054
78.7.3 Handling overflows (Multiple error reporting) . . . 3056

79 Indirect Memory Access (IMA) . . . 3057
79.1 Introduction . . . 3057
79.2 Accessing memory via CPU End2End ECC test . . . 3057
79.2.1 Accessing I-cache and D-cache memory via processor core . . . 3057
79.2.2 Accessing non I-cache or D-cache memory via processor core . . . 3059
79.3 Accessing memory via the IMA module . . . 3061
79.3.1 Features . . . 3061
79.3.2 Block diagram . . . 3061

79.3.3 IMA Module Memory Map and Registers . . . 3062
79.3.4 IMA module functional description . . . 3069
79.3.5 Application information . . . 3071

80 Fault Collection and Control Unit (FCCU) . . . 3072
80.1 Introduction . . . 3072
80.1.1 Acronyms and abbreviations . . . 3073
80.2 Main features . . . 3073
80.2.1 Standard features . . . 3074
80.3 Block diagram . . . 3074
80.4 Signal description . . . 3075
80.4.1 Pinout . . . 3075
80.4.2 IPS bus interface . . . 3075
80.5 Functional description . . . 3075
80.5.1 Definitions . . . 3075
80.5.2 FSM description . . . 3076
80.5.3 Reset interface . . . 3078
80.5.4 Fault priority scheme and nesting . . . 3079
80.5.5 Fault recovery . . . 3080
80.5.6 NMI interface . . . 3081
80.5.7 FAULT interface . . . 3082
80.5.8 STCU interface . . . 3083
80.5.9 EOUT interface . . . 3084
80.5.10 Error signal flow for RF case . . . 3090
80.6 Register description . . . 3091
80.6.1 FCCU Control Register (FCCU_CTRL) . . . 3094
80.6.2 FCCU CTRL Key Register (FCCU_CTRLK) . . . 3096
80.6.3 FCCU Configuration Register (FCCU_CFG) . . . 3097
80.6.4 FCCU RF Configuration Registers (FCCU_RF_CFG[0:3]) . . . 3099
80.6.5 FCCU RFS Configuration Registers (FCCU_RFS_CFG[0:7]) . . . 3100
80.6.6 FCCU RF Status Register (FCCU_RF_S[0:3]) . . . 3101
80.6.7 FCCU RF Key Register (FCCU_RFK) . . . 3103
80.6.8 FCCU RF Enable Registers (FCCU_RF_E[0:3]) . . . 3104
80.6.9 FCCU RF Timeout Enable Registers (FCCU_RF_TOE[0:3]) . . . 3105
80.6.10 FCCU RF Time-out Register (FCCU_RF_TO) . . . 3106
80.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO) . . . 3107

80.6.12 FCCU IO Control Register (FCCU_EINOUT) . . . 3108
80.6.13 FCCU Status Register (FCCU_STAT) . . . 3109
80.6.14 FCCU NA Freeze Status Register (N2AF_STATUS) . . . 3110
80.6.15 FCCU AF Freeze Status Register (A2FF_STATUS) . . . 3111
80.6.16 FCCU NF Freeze Status Register (N2FF_STATUS) . . . 3112
80.6.17 FCCU FA Freeze Status Register (F2A_STATUS) . . . 3113
80.6.18 FCCU RF Fake Register (FCCU_RFF) . . . 3114
80.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT) . . . 3115
80.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN) . . . 3116
80.6.21 FCCU XTMR Register (FCCU_XTMR) . . . 3117
80.6.22 FCCU MCS Register (FCCU_MCS) . . . 3117
80.6.23 FCCU Transient Register (FCCU_TRANS_LOCK) . . . 3118
80.6.24 FCCU Permanent Lock Register (FCCU_PERMNT_LOCK) . . . 3119
80.6.25 FCCU Delta T Register (FCCU_DELTA_T) . . . 3120
80.6.26 FCCU IRQ Alarm Enable Registers (FCCU_IRQ_ALARM_EN[0:3]) 3120
80.6.27 FCCU NMI Enable Registers (FCCU_NMI_EN[0:3]) . . . 3121
80.6.28 FCCU EOUT Signaling Enable Registers (FCCU_EOUT_SIG_EN[0:3]) . . . 3122
80.7 Register map . . . 3123
80.8 FCCU Output Supervision Unit . . . 3126
80.9 Use cases and limitations . . . 3127
80.9.1 Misconfigurations . . . 3127
80.9.2 Recommendations to configure FCCU . . . 3128

81 Self-Test Control Unit (STCU2) . . . 3129
81.1 Introduction . . . 3129
81.2 Main features . . . 3130
81.3 Block diagram . . . 3131
81.3.1 IPS bus interface . . . 3132
81.4 Functional description . . . 3133
81.4.1 FSM description . . . 3133
81.4.2 Reset management . . . 3133
81.4.3 LBIST and MBIST scheduling . . . 3134
81.4.4 ABORT management . . . 3134
81.4.5 PLL interface . . . 3135
81.4.6 Interrupt interface . . . 3135
81.4.7 FCCU interface . . . 3136

81.4.8 Watchdogs . . . 3136
81.4.9 CRC . . . 3137
81.4.10 SSCM interface . . . 3137
81.4.11 LBIST/MBIST execution restriction . . . 3137
81.5 Register description . . . 3137
81.5.1 STCU2 Run Register (STCU_RUN) . . . 3139
81.5.2 STCU2 Run Software Register (STCU_RUNSW) . . . 3140
81.5.3 STCU2 SK Code Register (STCU_SKC) . . . 3141
81.5.4 STCU2 Configuration Register (STCU_CFG) . . . 3142
81.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG) . . . 3145
81.5.6 STCU2 Watchdog Register Granularity (STCU_WDG) . . . 3146
81.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG) . . . 3147
81.5.8 STCU2 CRC Expected Status Register (STCU_CRCE) . . . 3148
81.5.9 STCU2 CRC Read Status Register (STCU_CRCR) . . . 3148
81.5.10 STCU2 Error Register (STCU_ERR_STAT) . . . 3149
81.5.11 STCU2 Error FM Register (STCU_ERR_FM) . . . 3152
81.5.12 STCU2 Off-line LBIST Status Register (STCU_LBS) . . . 3153
81.5.13 STCU2 Off-line LBIST End Flag Register (STCU_LBE) . . . 3154
81.5.14 STCU2 On-line LBIST Status Register (STCU_LBSSW) . . . 3155
81.5.15 STCU2 On-line LBIST End Flag Register (STCU_LBESW) . . . 3155
81.5.16 STCU2 On-line LBIST Reset Management (STCU_LBRMSW) . . . 3156
81.5.17 STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM) . . . 3157
81.5.18 STCU2 Off-line MBIST Status Low Register (STCU_MBSL) . . . 3158
81.5.19 STCU2 Off-line MBIST Status Medium Register (STCU_MBSM) . . . 3159
81.5.20 STCU2 Off-line MBIST Status High Register (STCU_MBSH) . . . 3159
81.5.21 STCU2 Off-line MBIST End Flag Low Register (STCU_MBEL) . . . 3160
81.5.22 STCU2 Off-line MBIST End Flag Medium Register (STCU_MBEM) . 3161
81.5.23 STCU2 Off-line MBIST End Flag High Register (STCU_MBEH) . . . 3161
81.5.24 STCU2 On-line MBIST Status Low Register (STCU_MBSLSW) . . . 3162
81.5.25 STCU2 On-line MBIST Status Medium Register (STCU_MBSMSW) 3163
81.5.26 STCU2 On-line MBIST Status High Register (STCU_MBSHSW) . . . 3163
81.5.27 STCU2 On-line MBIST End Flag Low Register (STCU_MBELSW) . 3164
81.5.28 STCU2 On-line MBIST End Flag Medium Register (STCU_MBEMSW) . . . 3165
81.5.29 STCU2 On-line MBIST End Flag High Register (STCU_MBEHSW) . 3165
81.5.30 STCU2 MBIST Unrecoverable FM Low Register (STCU_MBUFML) 3166

81.5.31 STCU2 MBIST Unrecoverable FM Medium Register (STCU_MBUFMM) 3167
81.5.32 STCU2 MBIST Unrecoverable FM High Register (STCU_MBUFMH) 3168
81.5.33 STCU2 LBIST Control Register (STCU_LB_CTRLn) 3169
81.5.34 STCU2 LBIST PC Stop Register (STCU_LB_PCSn) 3171
81.5.35 STCU2 LBIST PRPG Low Register (STCU_LB_PRPGLn) 3172
81.5.36 STCU2 LBIST PRPG High Register (STCU_LB_PRPGHn) 3173
81.5.37 STCU2 Off-line LBIST MISR Expected Low Register (STCU_LB_MISRELn) 3173
81.5.38 STCU2 Off-line LBIST MISR Expected High Register (STCU_LB_MISREHn) 3174
81.5.39 STCU2 Off-line LBIST MISR Read Low Register (STCU_LB_MISRRLn) 3175
81.5.40 STCU2 Off-line LBIST MISR Read High Register (STCU_LB_MISRRHn) 3175
81.5.41 STCU2 On-line LBIST MISR Expected Low Register (STCU_LB_MISRELSWn) 3176
81.5.42 STCU2 On-line LBIST MISR Expected High Register (STCU_LB_MISREHSWn) 3177
81.5.43 STCU2 On-line LBIST MISR Read Low Register (STCU_LB_MISRRLSWn) 3178
81.5.44 STCU2 On-line LBIST MISR Read High Register (STCU_LB_MISRRHSWn) 3179
81.5.45 STCU2 MBIST Control Register (STCU_MB_CTRL) 3180
81.6 Register map 3181
81.7 Use cases and limitations 3186
81.7.1 Off-line Self-Test sequence 3186
81.7.2 On-line Self-Test Sequence 3188
81.7.3 Bypass USER Mode 3190
81.7.4 Design implementation information 3190

82 Register Protection (REG_PROT) 3191
82.1 Introduction 3191
82.1.1 Overview 3191
82.1.2 Features 3191
82.1.3 Modes of operation 3192
82.2 External signal description 3192
82.3 Memory map and register definition 3192
82.3.1 Memory map 3193

82.3.2 Register descriptions . . . 3194
82.4 Functional description . . . 3197
82.4.1 General . . . 3197
82.4.2 Change lock settings . . . 3197
82.4.3 Access errors . . . 3200
82.5 Initialization/application information . . . 3201
82.5.1 Reset . . . 3201

83 Password and Device Security Module (PASS) . . . 3202
83.1 Introduction . . . 3202
83.1.1 Overview . . . 3202
83.1.2 Features . . . 3202
83.1.3 Modes of operation . . . 3202
83.2 External signal description . . . 3203
83.3 Memory map and register definition . . . 3203
83.3.1 Register descriptions . . . 3204
83.4 DCF clients . . . 3215
83.4.1 Censorship . . . 3215
83.4.2 Production Disable . . . 3216
83.4.3 Fuse Bypass DCF Client . . . 3218
83.5 Functional description . . . 3218
83.5.1 Censorship . . . 3218
83.5.2 Debug Interface Access . . . 3219
83.5.3 Flash Memory Read Protection . . . 3220
83.5.4 Production Disable . . . 3220
83.5.5 Fuse Bypass . . . 3222
83.6 Initialization/application information . . . 3224
83.6.1 Reset . . . 3224
83.6.2 Modifying Life Cycle (maturing the device) . . . 3224
83.6.3 Setting lock bits in a password group . . . 3224
83.6.4 Censoring and uncensoring the device . . . 3225

84 Tamper Detection Module (TDM) . . . 3226
84.1 Overview . . . 3226
84.2 Features . . . 3227
84.3 External signal description . . . 3227

84.4 DCF client . . . 3227
84.4.1 Diary Base Address (DBA) DCF client . . . 3229
84.4.2 Tamper Region Override (TO) DCF client . . . 3229
84.4.3 One Time Programmable Enable (OTPEN0) DCF client . . . 3230
84.4.4 One Time Programmable Enable (OTPEN1) DCF client . . . 3231
84.4.5 One Time Programmable Enable (OTPEN2) DCF client . . . 3232
84.4.6 One Time Programmable Enable (OTPEN3) DCF client . . . 3233
84.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0) . . . 3234
84.4.8 Tamper Region Assignment DCF client (TDR*n* _LOCK1) . . . 3234
84.4.9 Tamper Region Assignment DCF client (TDR*n*_LOCK2) . . . 3235
84.4.10 Tamper Region Assignment DCF client (TDR*n*_LOCK3) . . . 3236
84.5 Memory Map and Registers . . . 3237
84.5.1 TDR Status Register (TDM_TDRSR) . . . 3237
84.5.2 Last Flash Programmed Address Register (TDM_LFPAR) . . . 3239
84.5.3 Diary Base Address (TDM_DBA) . . . 3240
84.6 Functional description . . . 3240
84.6.1 Flash erase counter and tamper detection . . . 3240
84.6.2 Assigning blocks to Tamper Detect Regions (TDR) . . . 3242
84.6.3 Diary . . . 3242
84.6.4 Specifying the diary base address . . . 3243
84.6.5 Diary Base Address Verification . . . 3244
84.6.6 One Time Programmable (OTP) . . . 3244

85 Wakeup Unit (WKPU) . . . 3245
85.1 Introduction . . . 3245
85.1.1 Overview . . . 3245
85.1.2 Features . . . 3246
85.2 External signal description . . . 3246
85.3 Memory map and register description . . . 3246

1 Preface

1.1 Overview

This document defines the functionality of the SPC574Kx microcontroller for use by software and hardware developers. The SPC574Kx is built on Power Architecture® technology and integrates technologies that are important for today's and tomorrow's automotive applications. SPC574Kx applications include automotive powertrain controller applications for four-cylinder gasoline and diesel engines, chassis control applications, transmission control applications, steering and braking applications, as well as low-end hybrid applications and safety applications that require a high safety integrity level.

The information in this book is subject to change without notice, as described in the disclaimer. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the ST Web site at http://www.st.com.

1.2 Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC574Kx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

1.3 Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or device-specific information.
- Part II includes chapters that describe the functionality of the individual modules on the device.
- Part III includes chapters that describe the functionality of the emulation device.

1.4 Register conventions

Figure 1 and *Table 1* provide the register conventions used throughout this manual.

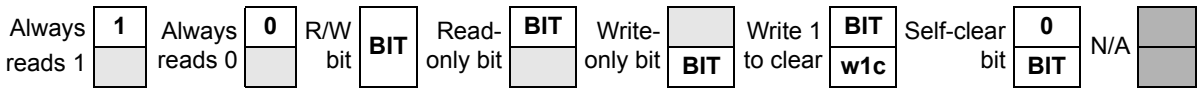

Figure 1. Key to register fields

Table 1. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset values	
0	Resets to zero
1	Resets to one
—	Undefined at reset
u	Unaffected by reset
[*signal_name*]	Reset value is determined by polarity of indicated signal.

1.5 Acronyms and abbreviations

Section Appendix A: Acronyms and abbreviations lists acronyms and abbreviations used in this document.

1.6 Reference documents

In addition to this reference manual, the following documents provide additional information on the operation of the SPC574Kx:

- IEEE-ISTO 5001-2003 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture

2 Introduction

2.1 SPC574Kx microcontroller

The SPC574Kx microcontroller is a new member in a family of devices superseding the SPC56 family. SPC574Kx builds on the legacy of the SPC56 family, while introducing new features coupled with higher throughput to provide substantial reduction of cost per feature and significant power and performance improvement (MIPS per mW). The SPC574Kx device has three processor cores.

Table 2. Processor cores

Computational shell		
Core0	Main Core_0	e200z410Dn3
Checker Core0	Checker Core_0s	e200z409D
I/O processor		
Core2	Peripheral Core_2	e200z225Bn3

2.1.1 Target applications

This device is targeted at automotive powertrain controller applications for four-cylinder gasoline and diesel engines, chassis control applications, transmission control applications, steering and braking applications, as well as low-end hybrid applications.

Many of these applications are considered to be functionally safe and are designed to achieve ISO26262 ASIL-D compliance. For this reason, safety measures have been added which are furthur described in *Chapter 6: Functional Safety*, as well as the *SPC574Kx safety manual/AN4446.*

2.1.2 Overall architecture

The architecture is split into two distinct regions, the computational shell and the I/O subsystem as shown in *Figure 2*. The computational shell consists of two CPUs (in lock-step for safety), fast local memories inside the CPUs, and fast system memory. All components of the computational shell are connected through a fast crossbar switch (XBAR_0).

The I/O subsystem consists of an I/O processor (IOP), DMA, and all the other peripherals connected through a slow crossbar switch (XBAR_1).

The computational shell is optimized for performance and the I/O subsystem is optimized for low power.

The two crossbars (XBAR_0 and XBAR_1) are connected by a pair of cross-connected master-slave ports so that all crossbar masters on both crossbars can directly access all crossbar slaves on both crossbars. From a software perspective, every bus master (all CPUs, DMA, SIPI, ethernet, FlexRay) sees every memory and peripheral (all RAM modules, Flash, and peripherals) in a consistent, flat memory map.

2.1.3 Core features

The computational shell consists of an e200z4 CPU operating up to 160 MHz with a second identical CPU running as a checker core in delayed lockstep mode.The I/O subsystem includes a CPU targeted at managing the peripherals.The I/O subsystem core is a e200z2 CPU running up to 80 MHz and includes enhancements to implement Digital Signal Processing (DSP) algorithms.All CPUs are compatible with the Power Architecture® VLE instruction set, that supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.1.4 I/O processor

The I/O processor (IOP), or Peripheral Core_2, is one of three processor cores on the SPC574Kx device shown in *Figure 2*. The IOP is intended to configure the machine and control various device peripheral elements. However, the IOP is not limited to any particular duty.

The data bus structure (32-bit address and 32-bit data) of the IOP is connected to the 80 MHz Slow Crossbar Switch and the instruction bus structure (32-bit address and 64-bit data) of the IOP is connected to the 160 MHz Fast Crossbar Switch, so data fetches run at only one-half the speed of instruction fetches. The address bus structure and the data bus structure of Main Core_0 are also connected to the Fast Crossbar Switch.

Fetching data from memory elements connected to the Fast Crossbar Switch or fetching instructions from memory elements connected to the Slow Crossbar Switch is possible, but requires passage through both the Slow and Fast Crossbar Switches and is relatively slow.

When the IOP starts, it executes from memory elements on the Fast Crossbar Switch.

The IOP is automatically started during the boot-up sequence after the release of RESET. This process is fully described in *Chapter 8: Reset and Boot*. During the boot sequence, the System Status and Configuration Module (SSCM) reads device configuration (DCF) records for the IOP start address in the Boot Assist Flash (BAF) code. This information is stored in the Mode Entry Module (ME) until the internal reset signal is released and the IOP can begin code execution at the designated location.

SPC574Kx devices are pre-configured to begin IOP code execution at a start address located in the BAF with default start-up code. In the absence of user application code, the BAF initiates download of user code via the LINFlexD port and program execution begins at the start address embedded in the downloaded code.

The IOP data bus connection to the Slow Crossbar Switch provides access to many of the peripheral devices. The IOP instruction bus connection to the Fast Crossbar Switch gives access to the BAF and the other memory elements. When the IOP begins code execution, a considerable amount of traffic through the Fast Crossbar Switch is required. Accesses to the peripheral elements on the Slow Crossbar Switch is transparent to activity occurring on the Fast Crossbar Switch.

The IOP is placed in the SPC574Kx architecture so that it accesses many of the peripheral elements without affecting the processing speed of Main Core_0. On the SPC574Kx device there are several A/D channels taking data that must be analyzed for various spectral components.

The IOP has an integrated DSP processor with hardware to execute multiply and accumulate (MAC) operations. The DSP unit functions as a co-processor integrated into the e200z225Bn3 core, so data fetched by the z225 core is evaluated with much greater speed than data residing in a memory element outside the core.

One function of the IOP is to manage a system of analog-to-digital converters and fetch the digital data that is generated. The integrated DSP unit uses a signal processing algorithm to digest the incoming data. The results of this signal processing algorithm are used in other engine control algorithms. Using the IOP to manage the A/D converters and do the initial signal processing of the data allows the main core to focus on other compute intensive applications instead of managing relatively slow peripheral elements.

Once the IOP has performed initialization via preloaded instruction code in the BAF and downloaded any eventual application code, the IOP can be programmed to perform any duty or access any memory element.

2.1.5 Memory hierarchy

The SPC574Kx computational shell has three levels of memory hierarchy:

1. CPU-specific Instruction Cache, Data Cache, Local Instruction RAM and Local Data RAM. The local RAM arrays are embedded into the CPU's pipeline for the fastest possible access time.
2. System RAM and Flash connected via a 160 MHz, 64-bit crossbar.
3. The I/O subsystem. All the I/O peripherals are connected via an 80 MHz 32-bit crossbar switch at 80 MHz or 40 MHz. The reduced speed helps to reduce power consumption.

2.2 Features summary

On-chip modules within /SPC574Kx include the following features:

- One main processor core and one checker core, single-issue, 32-bit CPU core complexes (e200z4), running in lockstep
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - 16 KB local instruction SRAM and 64 KB local data SRAM
  - 4 KB I-Cache and 2 KB D-Cache
- I/O processor, single issue, 32-bit CPU core complexes (e200z2), with
  - Power Architecture embedded specification compliance
  - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
  - Single-precision floating point operations
  - Lightweight Signal Processing Auxiliary Processing Unit (LSP APU) instruction support for digital signal processing (DSP)
  - 16 KB local instruction SRAM and 48 KB local data SRAM
- 2624 KB (2560 KB code + 64 KB EEPROM) on-chip flash memory: supports read during program and erase operations, and multiple blocks allowing EEPROM emulation
- 64 KB on-chip general-purpose SRAM (+ 112 KB data RAM included in the CPUs)
- Multi-channel direct memory access controller (eDMA) with 32 channels
- Dual interrupt controller (INTC)
- Dual phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual crossbar switch architecture for concurrent access to peripherals, flash memory, or SRAM from multiple bus masters with end-to-end ECC
- System integration unit lite (SIUL2)
- Boot Assist Flash (BAF) supports factory programming using serial bootload through ‘Serial Boot Mode Protocol’. Physical Interface (PHY) can be
  - UART
  - CAN
- Generic timer module (GTM122)
  - Intelligent complex timer module
  - 88 channels (24 input and 64 output)
  - 3 programmable fine grain multi-threaded cores
  - 26 KB of dedicated SRAM
  - 24-bit wide channels
  - Hardware support for engine control, motor control and safety related applications
- Enhanced analog-to-digital converter system with:
  - 5 separate 12-bit SAR analog converters
  - 2 separate 16-bit Sigma-Delta analog converters

- 5 Deserial Serial Peripheral Interface (DSPI) modules
- 5 LIN and UART communication interface (LINFlexD) modules
  - LINFlexD_0 is a Master/Slave
  - LINFlexD_1, LINFlexD_2, LINFlexD_14, and LINFlexD_15 are Masters
- 2 modular Controller Area Network (M_CAN) modules, and one time-triggered Controller Area Network (M_TTCAN)
- Dual-channel FlexRay controller
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with partial support for 2010 standard
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- On-chip voltage regulator controller manages the supply voltage down to 1.2 V for core logic

Note: The source clock for this device can be: external oscillator, external crystal or 16 MHz internal RC oscillator (IRCOSC)

2.3 Feature list

Table 3 lists a summary of major features for the SPC574Kx device. The feature column represents a combination of module names and capabilities of certain modules. Detailed descriptions of each on-chip module is given later in this document.

Table 3. SPC574Kx device feature summary

Feature		Description
Process		55 nm
Main processor	Core	e200z4
	Number of main cores	1
	Number of checker cores	1
	Local RAM (per main core)	16 KB Instruction 64 KB Data
	Single precision floating point	Yes
	VLE	Yes
	Cache	4 KB Instruction 2 KB Data
I/O processor	Core	e200z2
	Local RAM	16 KB Instruction 48 KB Data
	Single precision floating point	Yes
	LSP	Yes
	VLE	Yes
	Cache	No
Main processor frequency		140 MHz and 160 MHz

Table 3. SPC574Kx device feature summary(Continued)

Feature	Description
I/O processor frequency	70 MHz and 80 MHz
MPU	Yes
Semaphores	Yes
CRC channels	2
Software watchdog timer (task SWT/safety SWT)	3 (2/1)
Core Nexus class	3+
Sequence processing unit (SPU)	Yes
Debug and calibration interface (DCI) / run control module	Yes
System SRAM	64 KB
Flash memory	2560 KB
Flash memory fetch accelerator	2 × 2 × 256-bit
Data flash memory (EEPROM)	4 × 16 KB
Flash memory overlay RAM	16 KB
UTEST flash memory	16 KB
Boot assist flash (BAF)	16 KB
Calibration interface	64-bit IPS slave
DMA channels	32
DMA Nexus Class	3
LINFlexD (UART/MSC)	5 (3/2)
CAN (M_CAN/M_TTCAN)	3 (2/1)
DSPI (SPI/MSC/sync SCI)	5 (3/2/1)(1)
Microsecond bus downlink	Yes
SENT bus	6
I^2C	1
PSI5	2
FlexRay	1 × dual channel
Ethernet (RMII)	Yes
Zipwire (SIPI/LFAST) interprocessor bus	High speed
System timers	6 PIT channels 2 AUTOSAR® (STM) 64-bit PIT
GTM timer	24 input channels, 64 output channels
GTM RAM	26 KB
Interrupt controller	360 sources
ADC (SAR)	5

Table 3. SPC574Kx device feature summary(Continued)

Feature	Description
ADC (SD)	2
Temperature sensor	Yes
Self-test control unit (STCU2)	Yes
PLL	Dual PLL with FM
Internal linear voltage regulator	1.2 V
External power supplies	5 V 3.3 V(2)
Low-power modes	Stop mode Slow mode
Packages	KGD(3) /eTQFP144 /eLQFP176 172-pin FusionQuad®(4) 216-pin FusionQuad®4

1. One of the two MSC DSPIs is remapped to be used as sync SCI.
2. Optional: can be used for special I/O segments.
3. Known good die.
4. Also available in a 172-pin FusionQuad® package, which allows an /eTQFP144 pin-compatible package for development, and in a 216-pin FusionQuad® package, which allows an /eLQFP176 pin-compatible package for development.

2.4 Packaging

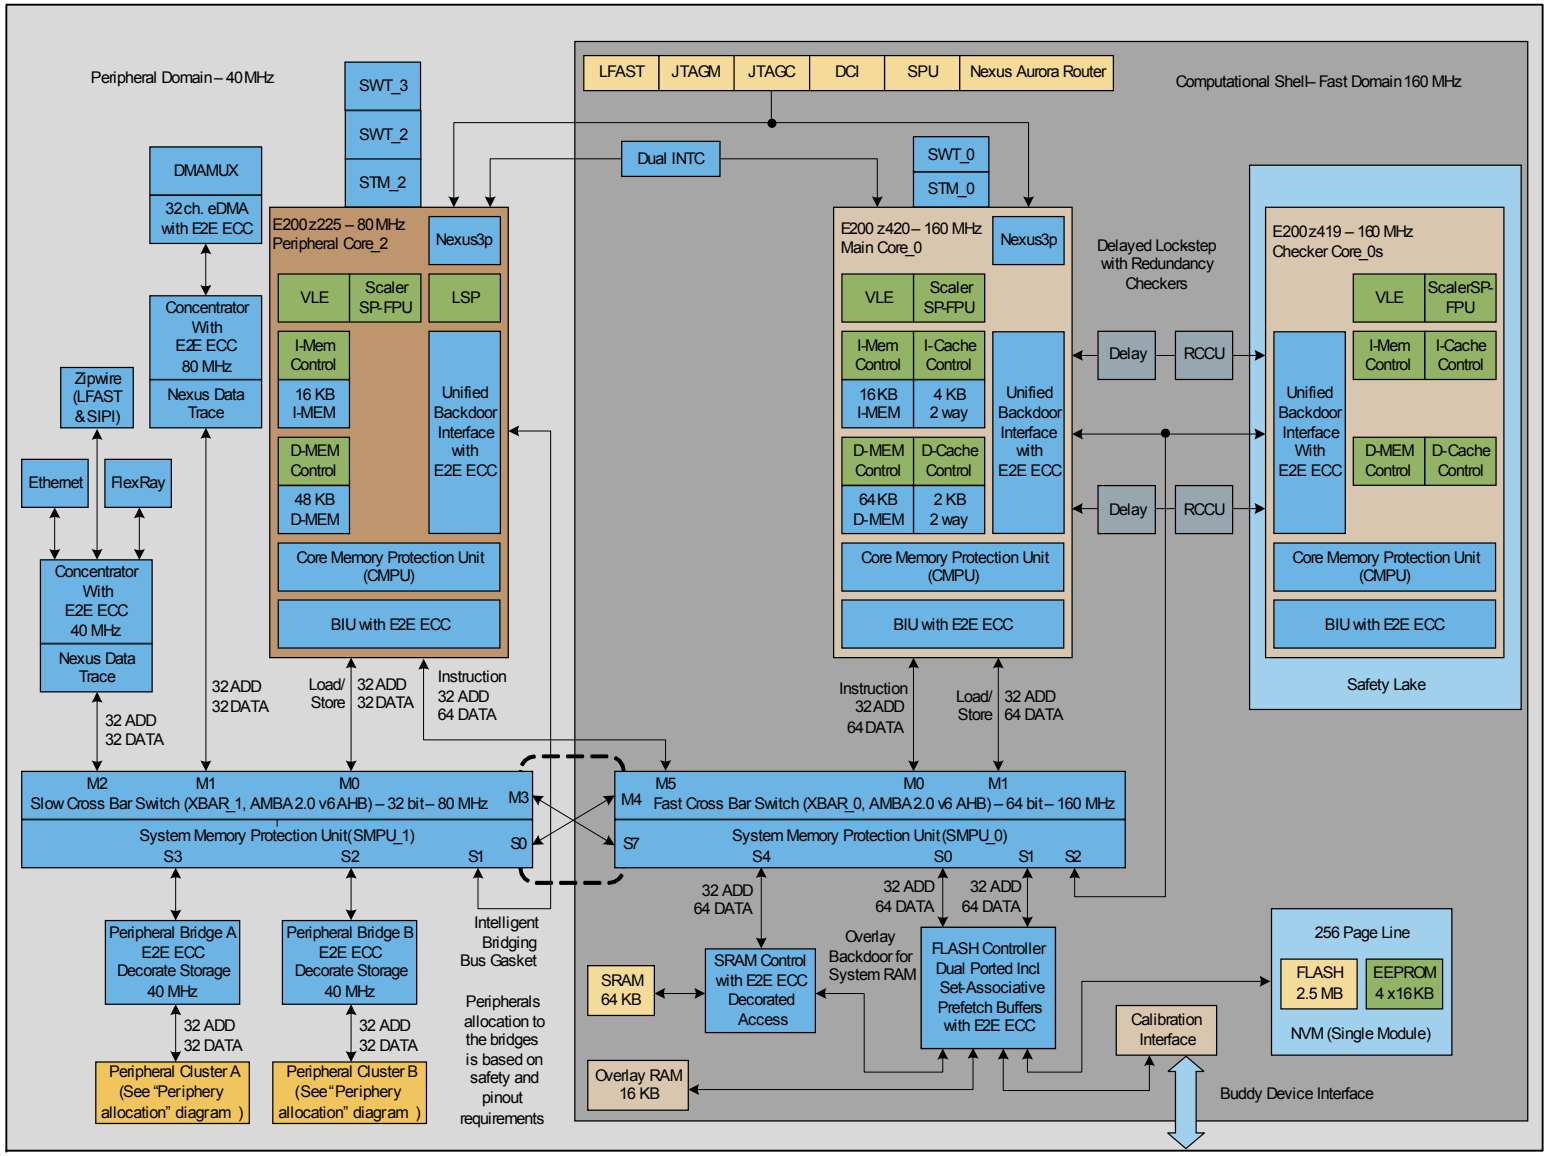
The SPC574Kx is available in these production packages:

- eTQFP144—a 172-pin FusionQuad® emulation and debug package is available in limited quantities for manufacturer development purposes.
- eLQFP176—a 216-pin FusionQuad® emulation and debug package is available in limited quantities for manufacturer development purposes.

2.5 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development and calibration of constant data:

- Nexus code execution trace on all CPUs.
- Nexus data trace on all bus masters (DMA, interprocessor bus, CPUs, etc.).
- Performance monitors for each CPU.
- Sequence Processing Unit for complex trace triggering.
- 16 KB of overlay RAM.



An Emulation Device (ED) is available for more complex development. It includes:

- A Buddy Device (BD) packaged with the SPC574Kx Production Device as a multi-die emulation.
- Additional overlay RAM.
- A high speed Nexus trace output port consisting of two lanes of Aurora (LVDS) operating up to 1.25 Gbit/s.

2.6 Block diagrams

Figure 2 and *Figure 3* show the top-level block diagrams.

Figure 2. Block diagram

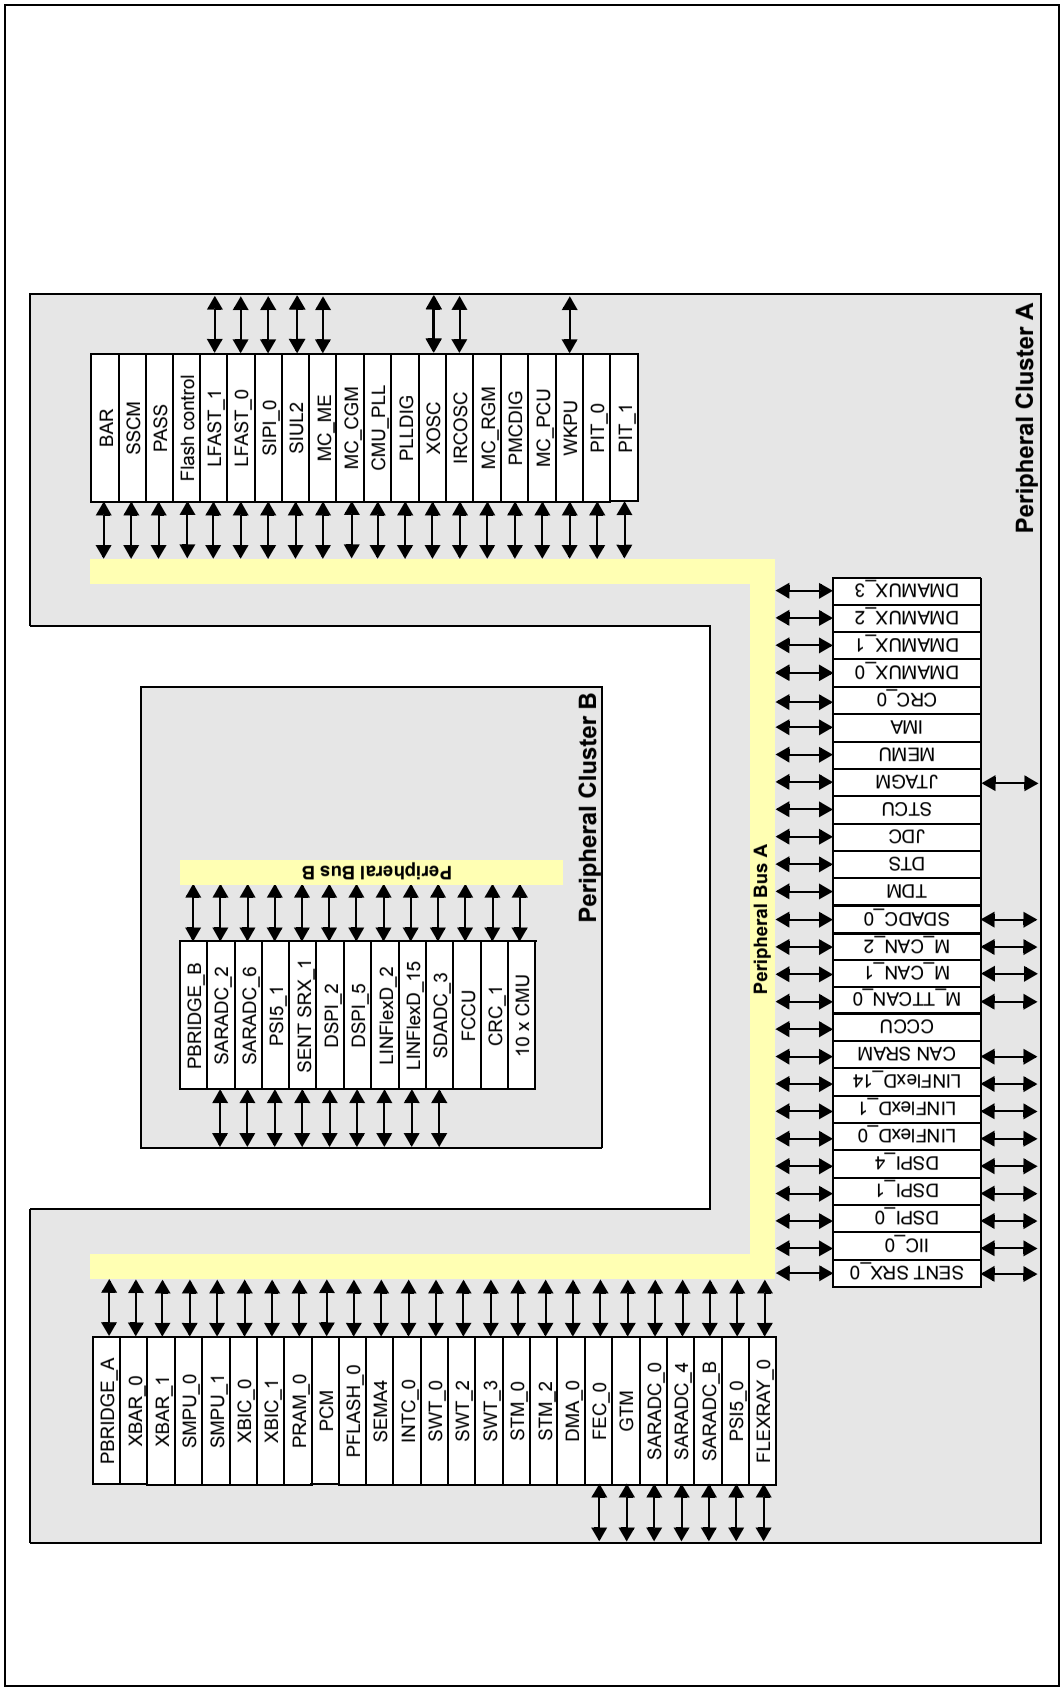


Figure 3. Periphery allocation

3 Embedded memories

3.1 Overview

The embedded memory architecture for SPC574Kx devices is a significant departure from previous-generation devices. Features include:

- Onboard SRAM, including system SRAM, local instruction and data memory for each processor core, and overlay SRAM
- Onboard system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Embedded memories in the peripherals[(a)]:
  - CAN
  - eDMA
  - FEC
  - FlexRay
  - GTM

3.2 SRAM

3.2.1 System SRAM

SPC574Kx devices include 64 KB of general-purpose on-chip ECC SRAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PFCR1 register in the SRAM controller.

- See *Chapter 32: RAM controller (PRAMC)* for details on configuring the SRAM controller.
- See *Table 13: RAM memory map* in *Chapter 5: Memory map* for the SPC574Kx SRAM map.

3.2.2 Overlay SRAM

Overlay SRAM is included in the SPC574Kx family of devices as part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces.The SPC574Kx has two 8 KB banks of ECC-protected RAM, for a total of 16 KB.

Note: Overlay SRAM is normally used for system development purposes only. Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) regardless of the PFCRCR[IRMEM] setting.

a. Refer to the respective module chapter for details.

Overlay memory can also be used to hold the device debug trace stream without requiring complex debug tool hardware and access to a high-speed trace port. Timing for calibration accesses to a particular overlay SRAM is the same as access to the underlying flash memory if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The calibration remap function supports three different types of overlay SRAM:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is available only on special emulation and debug devices.
- A portion of the system RAM can be used as the overlay RAM.

The overlay function is implemented using registers in the flash memory controller.

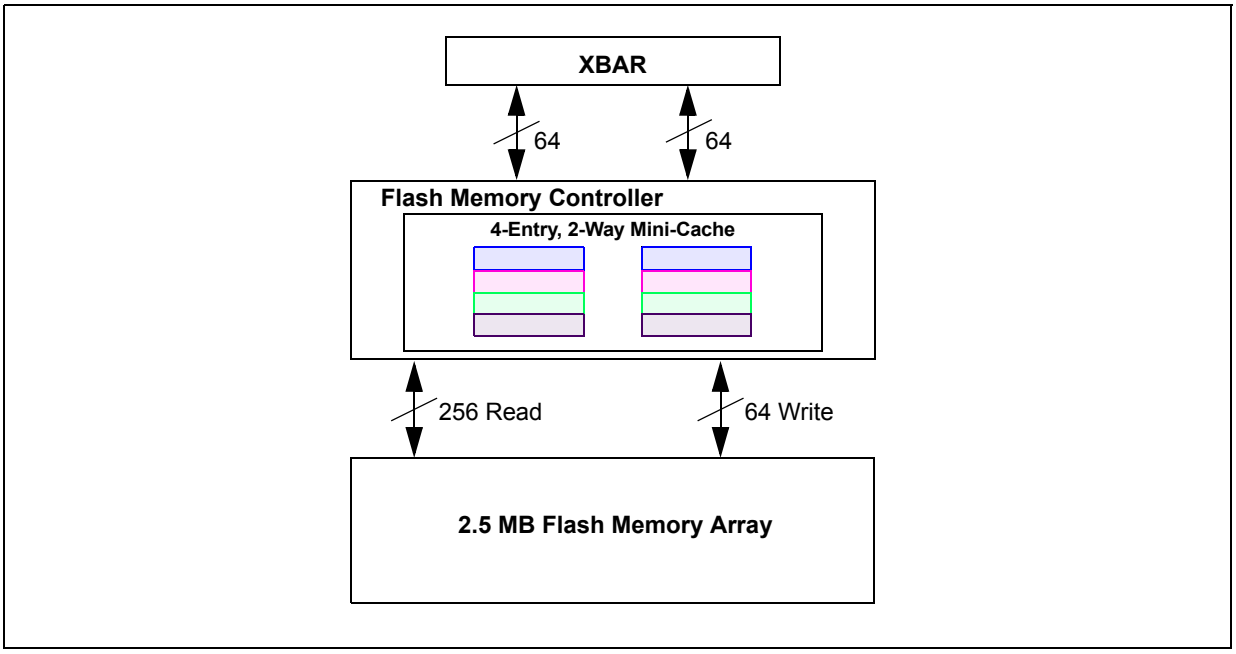
1. Using PFlash Calibration Region Descriptors (PFCRD*n*) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFDCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

See *Section 33.5.12: PFlash calibration remap support*, for details on memory overlay (remapping).

3.2.3 Processor core local SRAM

SPC574Kx devices include local instruction and data SRAM (I-MEM and D-MEM) for each processor core to provide enhanced performance.

- Each main processor core has 16 KB of instruction SRAM and 64 KB of data SRAM.
- The peripheral processor core has 16 KB of instruction SRAM and 48 KB data SRAM.



The core SRAM supports zero wait-state, single-cycle latency on processor local accesses.

Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices. See *Table 13: RAM memory map* in *Chapter 5: Memory map* for details.

3.3 Embedded flash memory

Flash memory on SPC574Kx devices consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. *Figure 4* shows the memory architecture.

Figure 4. SPC574Kx flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

3.3.1 Flash memory controller

The SPC574Kx flash memory controller acts as an interface between the system bus and the flash memory array and serves as the interface to the on-chip overlay RAM and off-chip Buddy Device.(b)

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash memory.

See *Chapter 33: Flash memory controller (PFLASH Controller)*, for details.

3.3.2 Flash memory array

SPC574Kx devices include a single 2.5 MBflash memory array, referred to as “main space,” plus an independent 16 KB block of one-time-programmable (OTP) flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as “UTEST space.”

b. The Buddy Device is an optional companion chip with additional memory and debug features. A Buddy Device is combined with a Production Device to form an Emulation and Debug Device (ED) for use during system development. It is not used in production systems.

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

3.3.2.1 Features

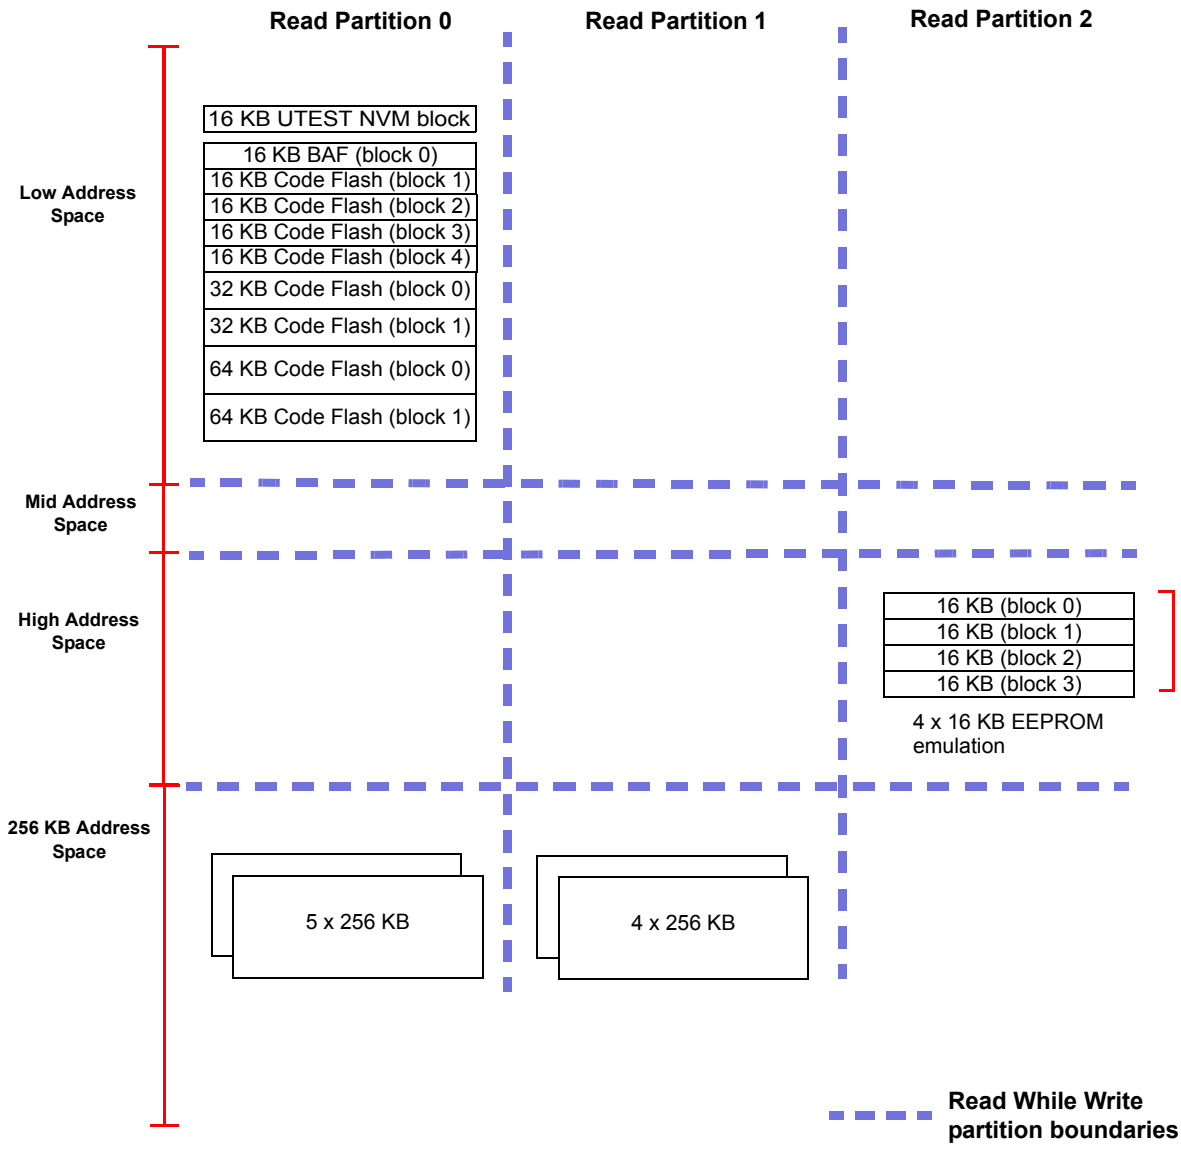
- Flash segmentation
  - 16 KB, 32 KB, 64 KB, and 256 KB blocks provided for code or data
  - Four 16 KB blocks provided for EEPROM emulation
  - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with double bit detection, single bit correction

Erase suspend, program suspend, and erase-suspended program all supported

3.3.2.2 Flash organization

The embedded flash memory consists of six address spaces in four groupings:

- 16 KB low address space, 32 KB low address space, and 64 KB low address space
- 16 KB mid address space
- 64 KB high address space
- 256 KB address space



Address space group (low-, mid-,or high-address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The flash module is further divided into three partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

Figure 5 shows the flash block segmentation and read-while-write partitioning for SPC574Kx devices.

Figure 5. Flash memory segmentation and read-while-write partitioning

Note: See Table 11: Flash memory and overlay RAM map in Chapter 5: Memory map for the SPC574Kx flash memory map.

3.3.2.3 UTEST memory space

Devices in the SPC574Kx family contain a **16** KB area of One-Time Programmable (OTP) flash memory for storing test information and device configuration data. See *Table 14: UTEST flash memory map* in *Chapter 5: Memory map* for the SPC574Kx UTEST flash memory map..

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional “ECC at memory” functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in *Table 4*.

Table 4. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields for the computational shell or 32-bit data field for the peripheral shell
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to

the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.5 Security features

The SPC574Kx architecture uses a combination of device life cycle monitoring and password protection to limit the conditions under which debugging interfaces can access certain areas of flash memory.

Note: Detailed information on the SPC574Kx security architecture is published in a separate document and is available on a limited basis to customers who have a non-disclosure agreement (NDA) with STMicroelectronics.

4 Signal description

4.1 Production packages

The following production packages are for the SPC574Kx device:

- TQFP144 Exposed Pad
- LQFP176 Exposed Pad

Case number and outline drawings for each package are provided in the SPC574Kx datasheet.

4.2 Emulation packages

4.2.1 TQFP144 Exposed Pad

For application debug and calibration support for the 144-pin QFP package, a 172-pin FusionQuad QFP package will be used for the SPC574Kx. This package has an inner row of pins on each side (14 pins on south and north side), that allow the ED signals to be placed there, without affecting the outer row pinout. These ED signals will be connected from the inner row pins of the FusionQuad package to bond sites in the padring of the production device. Those bond sites will be connected to the emulation device I/O pads with routing on the die.

Case number and outline drawings for each package are provided in the SPC574Kx datasheet.

4.2.2 LQFP176 Exposed Pad

For application debug and calibration support for the 176-pin QFP package, a 216-pin FusionQuad QFP package will be used for the SPC574Kx. This package has an inner row of pins on each side (20 pins on south and north side), that allow the ED signals to be placed there, without affecting the outer row pinout. These ED signals will be connected from the inner row pins of the FusionQuad package to bond sites in the padring of the production device. Those bond sites will be connected to the emulation device I/O pads with routing on the die.

Case number and outline drawings for each package are provided in the SPC574Kx datasheet.

4.3 Package pinouts

For package pinouts refer to the SPC574Kx datasheet.

4.4 Pin descriptions

The following sections provide signal descriptions and related information about the functionality and configuration of the SPC574Kx devices.

4.4.1 Pin startup and reset states

Table 5 provides startup state and reset state information for device pins.

Table 5. Pin startup and reset states

Pin	Startup state(1)	State during reset	State after reset
I/O pins(2)	Weak pull-up	Input, weak pull-up	Input, weak pull-up
Analog Inputs(3)	High-impedance	High-impedance	High-impedance
F0 (ERROR0)	High-impedance	Input, high-impedance	Input, high-impedance
ESR0	Output	Output, open-drain	Input, weak pull-up
ESR1	Weak pull-up	Input, weak pull-up	Input, weak pull-up
PORST	Output pull-down	Input, weak pull-down	Input, weak pull-down
TESTMODE(4)	Weak pull-down	Input, weak pull-down	Input, weak pull-down
JCOMP (TRST)	High-impedance	Input, weak pulldown	Input, weak pull-down
TDI	Weak pull-up	Input, weak pull-up	Input, weak pull-up
TDO	High-impedance	High-impedance	High-impedance
TMS	Weak pull-up	Input, weak pull-up	Input, weak pull-up
TCK	High-impedance	Input, weak pulldown	Input, weak pull-down
XTAL/EXTAL(5)	High-impedance	High-impedance	High-impedance

1. Startup state is exited when the core and high-voltage supplies reach minimum levels as defined in the Power Management chapter.
2. Pins on the device that are not supply or reference are not explicitly defined in this table.
3. Pure analog inputs, on digital output function.
4. Device does not implement system configuration pin. TESTMODE is the only pin affecting device configuration. It is latched on PORST rising edge and internally pull-down.
5. Function of XTAL/EXTAL pins defined by the enable bit in the flash user test row. If enabled, the pins are analog inputs to the oscillator. If disabled, the XTAL/EXTAL pins remain in High impedance after reset.

4.4.2 Power supply and reference voltage pins

Power supply and reference pins for the device are listed in this section.

The Supply Pins Table contains information on power supply and reference pins. See the Signal Table (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it and select the Supply Pins Table tab.

4.4.3 System pins

Table 6 contains information on system pin functions for the devices.

Table 6. System pins

Symbol	Description	Direction	QFP pin			
			144	FQ172	176	FQ216
PORST	Power on reset with Schmitt trigger characteristics and noise filter. PORST is active low	Bidirectional	97		121	
ESR0	External functional reset with Schmitt trigger characteristics and noise filter. ESR0 is active low	Bidirectional	98		122	
TESTMODE	Pin for testing purpose only. An internal pull-down is implemented on the TESTMODE pin to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to $V_{SS_HV_IO}$ on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. The device will not exit reset with the TESTMODE pin asserted during power-up.	Input only	94		118	
XTAL	Analog output of the oscillator amplifier circuit needs to be grounded if oscillator is used in bypass mode.	Output	82		103	
EXTAL	Analog input of the oscillator amplifier circuit when oscillator is not in bypass mode Analog input for the clock generator when oscillator is in bypass mode	Input	81		102	

4.4.4 LVDS pins

Table 7 contains information on LVDS pin functions for the devices.

Table 7. LVDS production pin descriptions

Functional block	Port pin	Signal	Signal description	Direction	Package pin number	
					eTQFP144, FQ172	eLQFP176, FQ216
SIPI LFAST(1)	PF[13]	SIPI_RXN	Interprocessor Bus LFAST, LVDS Receive Negative Terminal	I	84	107
	PD[7]	SIPI_RXP	Interprocessor Bus LFAST, LVDS Receive Positive Terminal	I	85	108
	PD[6]	SIPI_TXN	Interprocessor Bus LFAST, LVDS Transmit Negative Terminal	O	86	109
	PA[14]	SIPI_TXP	Interprocessor Bus LFAST, LVDS Transmit Positive Terminal	O	87	110

Table 7. LVDS production pin descriptions(Continued)

Functional block	Port pin	Signal	Signal description	Direction	Package pin number	
					eTQFP144, FQ172	eLQFP176, FQ216
Debug LFAST(1),(2)	PA[8]	DEBUG_TXN	Debug LFAST, LVDS Transmit Positive Terminal	O	88	111
	PA[7]	DEBUG_TXP	Debug LFAST, LVDS Transmit Negative Terminal	O	89	112
	PA[9]	DEBUG_RXP	Debug LFAST, LVDS Receive Negative Terminal	I	90	113
	PA[5]	DEBUG_RXN	Debug LFAST, LVDS Receive Positive Terminal	I	91	114
DSPI 4 Microsecond Bus	PD[3]	SCK_N	DSPI 4 Microsecond Bus Serial Clock, LVDS Negative Terminal	O	128	156
	PD[2]	SCK_P	DSPI 4 Microsecond Bus Serial Clock, LVDS Positive Terminal	O	129	157
	PD[1]	SOUT_N	DSPI 4 Microsecond Bus Serial Data, LVDS Negative Terminal	O	130	158
	PD[0]	SOUT_P	DSPI 4 Microsecond Bus Serial Data, LVDS Positive Terminal	O	131	159
DSPI 5 Microsecond Bus	PF[9]	SCK_N	DSPI 5 Microsecond Bus Serial Clock, LVDS Negative Terminal	O	74	95
	PF[10]	SCK_P	DSPI 5 Microsecond Bus Serial Clock, LVDS Positive Terminal	O	75	96
	PF[11]	SOUT_N	DSPI 5 Microsecond Bus Serial Data, LVDS Negative Terminal	O	76	97
	PF[12]	SOUT_P	DSPI 5 Microsecond Bus Serial Data, LVDS Positive Terminal	O	77	98
Differential DSPI 2	PD[3]	SCK_N	Differential DSPI 2 Clock, LVDS Negative Terminal	O	128	156
	PD[2]	SCK_P	Differential DSPI 2 Clock, LVDS Positive Terminal	O	129	157
	PD[1]	SOUT_N	Differential DSPI 2 Serial Output, LVDS Negative Terminal	O	130	158
	PD[0]	SOUT_P	Differential DSPI 2 Serial Output, LVDS Positive Terminal	O	131	159
	PF[13]	SIN_N	Differential DSPI 2 Serial Input, LVDS Negative Terminal	I	84	107
	PD[7]	SIN_P	Differential DSPI 2 Serial Input, LVDS Positive Terminal	I	85	108

Table 7. LVDS production pin descriptions(Continued)

Functional block	Port pin	Signal	Signal description	Direction	Package pin number	
					eTQFP144, FQ172	eLQFP176, FQ216
Differential DSPI 5	PF[9]	SCK_N	Differential DSPI 5 Clock, LVDS Negative Terminal	O	74	95
	PF[10]	SCK_P	Differential DSPI 5 Clock, LVDS Positive Terminal	O	75	96
	PF[11]	SOUT_N	Differential DSPI 5 Serial Output, LVDS Negative Terminal	O	76	97
	PF[12]	SOUT_P	Differential DSPI 5 Serial Output, LVDS Positive Terminal	O	77	98
	PF[13]	SIN_N	Differential DSPI 5 Serial Input, LVDS Negative Terminal	I	84	107
	PD[7]	SIN_P	Differential DSPI 5 Serial Input, LVDS Positive Terminal	I	85	108

1. DRCLK and TCK/DRCLK usage for SIPI LFAST and Debug LFAST are described in the SPC574Kx reference manual, refer to SIPI LFAST and Debug LFAST chapters.
2. Pads use special enable signal from DCI block: DCI driven enable for Debug LFAST pads is transparent to user.

Table 8. LVDS emulation pin descriptions

Functional block	Pad	Signal	Signal description	Direction	Package pin number			
					eTQFP144	FQ172	eLQFP176	FQ216
Nexus Aurora High Speed Trace	—	TXAP	Not available	O	—	—	—	—
	—	TXAN	Not available	O	—	—	—	—
	—	TXBP (TX0P)	Nexus Aurora High Speed Trace Lane 0, LVDS Positive Terminal	O	—	A7	—	A10
	—	TXBN (TX0N)	Nexus Aurora High Speed Trace Lane 0, LVDS Negative Terminal	O	—	A6	—	A9
	—	TXCP (TX1P)	Nexus Aurora High Speed Trace Lane 1, LVDS Positive Terminal	O	—	A3	—	A6
	—	TXCN (TX1N)	Nexus Aurora High Speed Trace Lane 1, LVDS Negative Terminal	O	—	A2	—	A5
	—	TXDP	Not available	O	—	—	—	—
	—	TXDN	Not available	O	—	—	—	—
	—	CLKP (BD-AGBTCLKP)	Nexus Aurora High Speed Trace Clock, LVDS Positive Terminal	O	—	A13	—	A19
	—	CLKN (BD-AGBTCLKN)	Nexus Aurora High Speed Trace Clock, LVDS Negative Terminal	O	—	A12	—	A18
	—	LPBK_P	Aurora High Speed Trace Loopback, LVDS Positive Terminal (LVDS Test In +)	I	—	A18	—	A27
	—	LPBK_N	Aurora High Speed Trace Loopback, LVDS Negative Terminal (LVDS Test In –)	I	—	A19	—	A28

4.4.5 Generic pins

The I/O Signal Description Table contains the port definition, multiplexing, direction, pad type, and package pin numbers for each I/O pin on the device.

Note: The SPC574Kx I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® workbook file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

Note: Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination.

Note: For additional information, refer to Chapter 16: System Integration Unit Lite2 (SIUL2).

5 Memory map

Table 9 shows the device memory map for the SPC574Kx.

All addresses on the SPC574Kx, including those that are reserved, are identified in the table. The addresses represent the physical addresses assigned to each region or module name. All memory not listed in this table is reserved, and access to those locations may produce undesirable results.

Table 9. Overview memory map

Start address	End address	Allocated size	Used size	Description
Flash memory (XBAR port 0 – 0)				
0x00000000	0x003FFFFF	—	Reserved	
0x00400000	0x005FFFFF	2 MB	32 KB	UTEST NVM and BAF Block – no overlay
0x00600000	0x007FFFFF	2 MB	Reserved	
0x00800000	0x009FFFFF	22048 KB	64 KB(1)	Data Flash Blocks – no overlay
0x00A00000	0x00FFFFFF	6 MB	256 KB	Small & Medium Flash Blocks – no overlay
0x01000000	0x01FFFFFF	16 MB	2304 KB	Large Flash Blocks – no overlay
0x02000000	0x089FFFFF	8 MB	Reserved	
0x08A00000	0x08FFFFFF	6 MB	256 KB	Small & Medium Flash Blocks – overlay enabled mapping
0x09000000	0x09FFFFFF	16 MB	2304 KB	Large Flash Blocks – overlay enabled mapping
0x0A000000	0x0BFFFFFF	32 MB	Reserved	
0x0C000000	0x0C1FFFFF	2 MB	1 MB	Extended Overlay RAM(2)
0x0C200000	0x0C7FFFFF	6 MB	Reserved	
0x0C800000	0x0CFFFFFF	8 MB	1 MB	Buddy Device Registers
0x0D000000	0x0D003FFF	16 KB	16 KB	Internal Overlay RAM
0x0D004000	0x0FFFFFFF	—	Reserved	
XBAR Slave Port 0 – 1				
0x10000000	0x1FFFFFFF	256 MB	Reserved	
XBAR Slave Port 0 – 2				
0x20000000	0x2FFFFFFF	256 MB	Reserved	
Spare Port (XBAR Slave Port 0 – 3)				
0x30000000	0x3FFFFFFF	256 MB	Reserved	
System RAM (XBAR Slave Port 0 – 4)				
0x40000000	0x401FFFFF	2048 KB	64 KB	System RAM
0x40200000	0x4FFFFFFF	—	Reserved System RAM	

Table 9. Overview memory map(Continued)

Start address	End address	Allocated size	Used size	Description
Local Memory (XBAR Slave Port 0 – 5)				
0x50000000	0x5FFFFFFF	256 MB	144 KB	Processor Core local SRAM
Reserved Port A (XBAR Slave Port 0 – 6)				
0x60000000	0x6FFFFFFF	256 MB	Reserved	
Reserved Port B (XBAR Slave Port 0 – 7)				
0x70000000	0x7FFFFFFF	256 MB	Reserved	
Spare Port (XBAR Slave Port 1 – 8)				
0x80000000	0x8FFFFFFF	256 MB	Reserved	
Spare Port (XBAR Slave Port 1 – 9)				
0x90000000	0x9FFFFFFF	256 MB	Reserved	
Reserved Port (XBAR Slave Port 1 – A)				
0xA0000000	0xA000FFFF	64 KB	Reserved	
0xA0010000	0xAFFFFFFF	262080 KB	Reserved	
Spare Port (XBAR Slave Port 1 – B)				
0xB0000000	0xBFFFFFFF	262144 KB	Reserved	
Reserved Port C (XBAR Slave Port 1 – C)				
0xC0000000	0xCFFFFFFF	262144 KB	Reserved	
Reserved Port D (XBAR Slave Port 1 – D)				
0xD0000000	0xDFFFFFFF	262144 KB	Reserved	
Spare Port (XBAR Slave Port 1 – E)				
0xE0000000	0xEFFFFFFF	262144 KB	Reserved	
Peripherals PBRIDGE_A, PBRIDGE_B (XBAR Slave Port 1 – F)				
0xF0000000	0xFFFFFFFF	256 MB	—	Peripheral address space(3)

1. 64 KB are confirmed for final silicon, but first silicon will contain 8 × 16 KB = 128 KB in total.
2. Address range is for extended overlay RAM for buddy device.
3. See *Table 10* for details.

Table 10. Peripheral (PBRIDGE_A, PBRIDGE_B) memory map

Start address	End address	Allocated size	Used size	PBRIDGE	PBRIDGE Access Control Register	Description
0xF0000000	0xF7FFFFFF	131072 KB	Reserved

0x00400300	0x00400307	8	DCF Start Record	DCF start Record. Programmed by JDP during Test. Contiguous list of DCF records start at this address
0x00400308	0x00400FFF	3584	DCF Records	Contiguous list of DCF Records starting at 0x00400200. Initial records programmed by factory. Subsequent records added to the end of the list by the customer
0x00401000	0x00403FFF	12288	Reserved for cust. OTP data	Programmed by the customer
BAF Block				
0x00404000	0x00407FFF	16384	BAF code	Reserved for Boot Assist Flash (BAF). This is factory code that executes every reset to implement boot features. It is programmed at the factory and is OTP.

6 Functional Safety

6.1 Introduction

The SPC574Kx offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL D of ISO 26262. This chapter gives an overview of the safety implementation for the SPC574Kx, and discusses the operation of the safety mechanisms.

6.2 Safety overview

The SPC574Kx has been designed for automotive applications executing safety-relevant tasks that require a fail-silent or fail-indicate MCU. The SPC574Kx supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms as documented in the Safety Manual (SM), but the SPC574Kx generally supports an FTTI of 10 ms.

6.3 Module categorization

The definition of the SPC574Kx safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in *Table 15*.

Table 15. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules that belong in one of the above categories but that do not require hardware-level safety measures. Examples include the DMA, the performance core, and the I/O core. Only their non-interference with modules from the other categories is ensured by hardware. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation.
Other support modules	SuMo	These are modules that, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

Table 16 shows module classifications for the SPC574Kx.

Table 16. Module classification

Classification	Modules
ViMos	Master Safety Core, Master Safety Core D-Cache controller, Master Safety Core I-Cache controller, Local Memory Controllers Master Core, Safety Core D-Cache array, Safety Core I-Cache array, Safety Core Local D-Mem array, Safety Core Local I-Mem array, INTC, XBAR_0 (Computational), SRAM controller, system RAM array, flash memory controller, flash memory array, overlay RAM, system timer, MC_RGM, Dual PLL Digital, XOSC, MC_CGM, MC_ME, voltage regulator, MC_PMC, STCU2, SSCM, PIT
PeMos	SAR ADC, PSI5, SENT, LINFlexD, DSPI, M_CAN/M_TTCAN, FlexRay, FEC, SIUL2, XBAR_1 (Peripheral), Concentrator FEC, FlexRay, and LFAST, SD ADC PBRIDGEs

Table 16. Module classification(Continued)

Classification	Modules
SuMos	RCCU, Checker Safety Core, System RAM/local memory controllers of Checker Safety Core (overall 4), Checker Safety Core D-Cache controller, Checker Safety Core I-Cache controller, CRC units, Temperature Sensors, IRCOSC, CMUs, HVDs, LVDs, Bandgap reference, LBIST controllers, IMA, REG_PROT, SWT, FCCU, MEMU
NoSaMos	Peripheral Core (Core_2), local memories of Peripheral Core (Core_2), EBI (LFAST, SIPI), eDMA, DMAMUX, GTM, Nexus, JTAG, Concentrator DMA, I2C, SEMA4, WKPU SPU

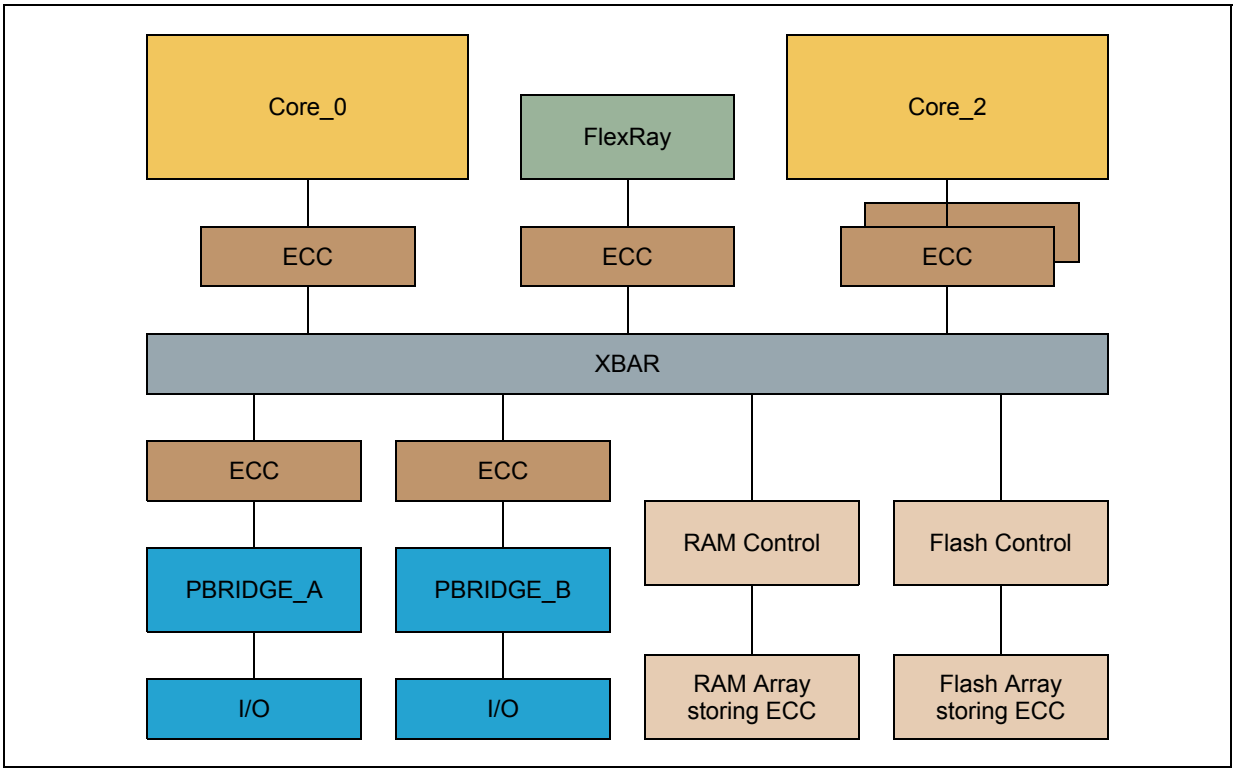
The SPC574Kx implements no specific protection of NoSaMos against Common Cause Failures between them.

6.4 System implementation

6.4.1 General concept

In general, safety integrity is achieved in the following ways:

- For the Safety Core and its closely related periphery, safety is ensured by a delayed lockstep approach (see *Section 6.4.2: Dual-core lockstep*).
- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for



individual modules. For the periphery, end-to-end ends at the I/O bridges (see *Section 6.4.1.1: End-to-End protection on data path*).

- Clock-and-power generation and distribution are supervised by dedicated monitors (see *Section 6.4.1.2: Clock and power monitoring*).
- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (see *Section 6.4.1.3: I/O peripherals*, and *Section 6.4.1.4: Communication controllers*).
- MBIST and LBIST are provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms (see *Section 6.4.1.5: Built-In Self-Tests (BIST)*). Dedicated mechanisms are provided to check the availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection). <Cross Refs>Table 17 (LBIST partitions) and *Table 18: Not in LBIST partitions* detail the available LBIST partitions.
- The Fault Collection and Control Unit (see “Fault Collection and Control Unit (FCCU)” chapter for FCCU details) is responsible for collecting and reacting to failure notifications (see *Section 6.4.1.7: FCCU and failure monitoring*). MEMU (see *Section 6.4.4.4: Memory Error Management Unit (MEMU)*) is responsible for the collection and reporting (to the FCCU) of error events in system memories, and flash memory, as well as E2E ECC errors caused by the XBAR, or RAM or flash memory controllers. Error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (see *Section 6.4.3: Common Cause Failure measures*).

6.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected with at least 99% coverage via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a single-error correction, double-error detection (SECDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. *Figure 6* shows a general view of ECC schema.

Figure 6. General view of E2E ECC

Note: Specific implementation for the SPC574Kx vary depending on the special requirements of RAM and flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters (including, but not limited to the Safety Core) and checked on reads. The ECC correction bits are stored alongside the data in flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, apart from memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGEs and peripherals can be used redundantly (see *Section 6.4.1.3: I/O peripherals*), or other mechanisms may be used to validate peripheral operation.

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) does allow the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address;
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash controllers; the target is respectively an XBAR slave port, the RAM array, or the Flash module (see “Crossbar Switch (XBAR)”, “Flash memory controller”, and “RAM controller (PRAMC)” chapters).

6.4.1.2 Clock and power monitoring

6.4.1.2.1 Clock

Clocks in the SPC574Kx are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of clock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

The clock tree for Core_0 and Core_0 – Checker (the two lockstep cores comprising the Safety Core) consists of separate clock branches that are not shared with any other module. One CMU (CMU_1) is connected to the Main Core clock path, downstream from the common part of the clock tree for the Main and Checker Cores. In this way any frequency failure affecting the Main Core clock or the common clock (SYS_CLK) is detected by the CMU, and any frequency failure affecting the Checker Core clock is detected by the Redundancy Control and Checker Units (RCCUs) (see *Chapter 26: Clocking*, for MCU clocking details).

6.4.1.2.2 Power

There are two types of voltage supervisors on the SPC574Kx, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads, and so on) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion) (see “Power management” and “Power Control Unit (MC_PCU)” chapters for details on power monitoring).

6.4.1.3 I/O peripherals

To allow a safety application to make redundant use of all I/O peripherals, each peripheral has at least two instances (except for the GTM), and each instance is connected to a different PBRIDGE. This means, for example, that if DSPI is provided by the MCU, two DSPI modules (DSPI*n*, DSPI*m*) are included and connected externally through different pins. Internally, DSPI*n* would then be connected to PBRIDGE_A and DSPI*m* to PBRIDGE_B and be accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGEs, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism. The allocation of peripherals along the two PBRIDGEs are depicted in block diagrams found in the “Introduction” chapter of this reference manual.

6.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and are therefore subject to the same safety criteria as I/O peripherals. Yet we assume that for high bandwidth communication controllers, additional software measures are employed that do not require redundant communication peripherals.

The following communication controllers do not contain special safety mechanisms beyond their protocol specifications, nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, see *Section 6.4.1.3: I/O peripherals*):

- FlexRay
- FEC
- M_CAN
- M_TTCAN

Software measures for the communication controllers (also called fault-tolerant communication layer) may contain E2E CRC data protection, sender identification, sequence numbering, and an acknowledgement mechanism.

PSI5 represents an exception to the replication of low bandwidth communications controllers. The module itself is replicated, but the two PSI5 modules share a single synchronization bit needed for staggered sync mode. This single bit is a single source of failures for both PSI5 modules if it triggers spurious synchronizations. The failure mode must be addressed by application level measures, which are in any case needed to cover the single transceiver used in such a configuration.

6.4.1.4.1 Disabling of communication controllers

In the event of a dangerous failure, the MCU offers the capability of disabling transmission of individual channels of communication controllers (such as CAN modules and FlexRay). This prevents the transmission of erroneous messages while preserving the capability of communicating over the diagnostic bus. Disabling outputs is controlled by resetting the SIUL2_MSCR*n*[SMC] for the pins that are associated with communication controllers where this feature is needed. See the “System Integration Unit Lite2 (SIUL2)” chapter for details on disabling communication signals.

The FCCU can drive a fault state on FI[0] via:

- Error pin reaction to a fault.
- Software writing FCCU_CFG[FCCU_SET_CLEAR] = 01b.

When the FCCU drives FI[0] to a fault state, the SIUL2 disables the output drivers of all pins whose SIUL2_MSCR*n*[SMC] = 0. This disables the possible transmission of erroneous messages. As long as the FCCU drives FI[0] to faulty state, the communication controllers’ Tx pins are disabled and internal pull-up are enabled. As soon as FI[0] is driven to non-faulty state, the communication controllers’ Tx pins are automatically enabled and state of internal pull-up/down restored.

The application should configure SIUL2_MSCR*n*[SMC] for pins that have active mapping of CAN modules (M_CAN and M_TTCAN) or FlexRay functionality and ensure that pin does not stay in undriven state.

Note: The FCCU uses an internal signal to disable the communication controller transmission, so transmission is disabled even when the FCCU cannot drive the FI[0] pin because the pin is configured as GPIO. If FI[0] is used as error input, externally pulling it down will disable the communication controller transmission if this event drives FCCU to a fault state.

Note: Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, M_TTCAN, M_CAN, FlexRay) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events.

6.4.1.5 Built-In Self-Tests (BIST)

The term BIST refers to the set of built-in hardware mechanisms that permits a device to test itself (typically at startup) in order to avoid the accumulation of latent faults, a requirement defined by the ISO 26262 standard.

Different types of BIST are implemented in the SPC574Kx:

- LBIST for digital logic—managed by the Self-Test Control Unit.
- MBIST for memories—managed by the Self-Test Control Unit.
- MCU built-in mechanisms for testing analog peripherals—requires software intervention.

See the “Self-Test Control Unit (STCU2)” chapter for further details.

6.4.1.5.1 BIST during boot (off-line)

A device BIST is performed every time the device boots, and is application transparent while the device is still under reset. BIST failure holds the device in reset, but the BIST continues running where possible and informs the system of the failure. Since LBIST and MBIST are destructive, a reset is performed for the tested module (memory or partition) before going into operation again. Application software starts when the BIST finishes without detecting a fault.

The boot time BIST comprises:

- Memory BIST for all RAMs and ROM
- Scan-based Logic BIST for digital logic, which is divided into multiple partitions that can be configured to be tested in parallel or sequentially to find the best time versus power consumption trade off.

6.4.1.5.2 Online Logical BIST (LBIST)

Though LBIST and MBIST are primarily intended to be run at startup under STCU2 control, the MCU allows software to trigger a memory self-test or LBIST of one partition during runtime. Since LBIST and MBIST are destructive, a reset is performed for the tested module (memory or partition) before going into operation again. This leads to a reset of the MCU or of those LBIST partitions. If a runtime LBIST requires a reset of the whole device, the LBIST result is accessible to software after the reset. If a reset occurs during LBIST, the LBIST is aborted. Output signals from each LBIST partition are set to a defined state when starting LBIST of that partition until the entire LBIST sequence completes. This has influence on the state of I/O signals. *Table 17* and *Table 18* below show the module groupings for each LBIST partition.

Note: When Scan mode is entered through LBIST, the flash memory must be in IDLE state, therefore Program or Erase operations must not be either active or suspended.

Note: Since LBIST/MBIST is running on top of functional modules present in partition or memory module, execution of LBIST/MBIST is preventing to use contemporaneously the associated resources of the partition/memories. For example, it is not possible to run memory BIST on the RAM of the core while the core is executing code.

Table 17. LBIST partitions

6.4.1.6 Redundancy Control and Checker Units (RCCUs)

The RCCU compares a set of equivalent input signals provided by different sources and issues an alarm in case of a mismatch. For example, an RCCU compares the output of the checker core against the output of the main core and issues an alarm if they do not match. Signals are arranged in comparison groups, i.e. all signals in one group are compared in one RCCU.In case of a compare mismatch the fault stays stable until clearing the FCCU channel status.

6.4.1.7 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

6.4.1.7.1 External error indication

Failure of the MCU is signaled to one or two pins, FI[0] (ERROR0) and FI[1] (ERROR1). FI[0] can also serve as an error input mechanism (see “Fault Collection and Control Unit (FCCU)” chapter, and “FCCU configuration” section of the “Device configuration” chapter, for details on the fault output signals). Both pins can be multiplexed with other functions with different defaults.

The error indication on pins FI[0] and FI[1] is controlled by SIUL2 and FCCU. The mapping of the FCCU output signals on the relevant pins and the associated electrical characteristics are enabled by the SIUL2_MSCR[*n*] register (see table “SIUL2_MSCR0 - SIUL2_MSCR511 field description” in the “System Integration Unit Lite2 (SIUL2)” chapter for signal mapping details). Once the FCCU is mapped onto the pin, the logic level is driven by the FCCU.

FI[0] is controlled by the FCCU at startup by default, but the state of FI[1] is like other I/O signals (see table “Pin startup and reset states” in chapter “Signal Description” for default states of FI[0] and FI[1]).

Since it is possible to reset FCCU and SIUL2 independently, the behavior of FI[0] and FI[1] is the result of the combined state of SIUL2_MSCR[*n*] and the FCCU. (see section “Reset interface” in chapter “Fault Collection and Control Unit (FCCU)” for FCCU reset details, and chapter “Reset and Boot” for the state of the FCCU relative to the system during different reset phases).

FCCU_STAT[ESTAT] flags whether the FCCU is in an error state. This flag can be set by software to a ‘1’ (fault) or ‘0’ (operational) when the FCCU is in operational state. FCCU_STAT[PSTAT] mirrors the physical state of the *Fn* external pin's value, though this may differ from the logical state if a toggling protocol is used.

6.4.1.7.2 Failure handling

The FCCU is an autonomous module that manages the different reactions configured for each failure source. Overall failure reaction time includes error detection, processing, and indication. In this interval, the SPC574Kx may provide wrong results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU.
- Control logic and signals monitored by the FCCU itself (see chapter “Fault Collection and Control Unit (FCCU)”).
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Note that software can also directly influence the state of the F*n* pins.
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERROR*n*
- Disabling the transmission capabilities of communication controllers (FlexRay, CAN, FEC) (Note: only possible in conjunction with changing the state of the failure indication pins)
- No reaction

Software can read the failure source that caused a fault, either before or after a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication remains for a configurable minimum time. If necessary, software can also reset the MCU (see *Table 97: FCCU failure inputs1* for details).

6.4.1.8 Operational interference protection

Being a multi-master system, SPC574Kx provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom mechanisms are arranged in a hierarchical memory protection schema including:

- MPUs
- PBRIDGEs
- Register protection.

There are two Memory Protection Unit levels included in the SPC574Kx. The Core Memory Protection Unit (CMPU) is a mechanism included in each core to protect address ranges against access by software developed according to lower ASIL. The CMPU is typically used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. The MPUs prevent access of different bus masters to address ranges and are typically used by the safety application to prevent NoSaMos (such as the DMA or the Performance Core) to access the application's safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual registers to be locked against any manipulation without unlocking.

These safety mechanisms are further described in the "System Memory Protection Unit (SMPU)" chapter.

6.4.1.9 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU observes the outputs of the FCCU (IRQ, RESET, F*n*). If the FCCU does not react within a predefined interval as specified in the "FCCU configuration" section of the "Device configuration" chapter, the FOSU assumes the FCCU has failed and causes a destructive reset.

The FOSU does not require any configuration by software.

6.4.2 Dual-core lockstep

The SPC574Kx duplicates its safety-relevant processing elements and compares their operation in Lockstep mode (LSM). This Safety core consists of two cores, Checker Core_0 and Main Core_0, and as far as software is concerned they behave as one core.
Main Core_0 is the main execution core of the pair, where Checker Core_0 follows the execution of the Main Core in lockstep.

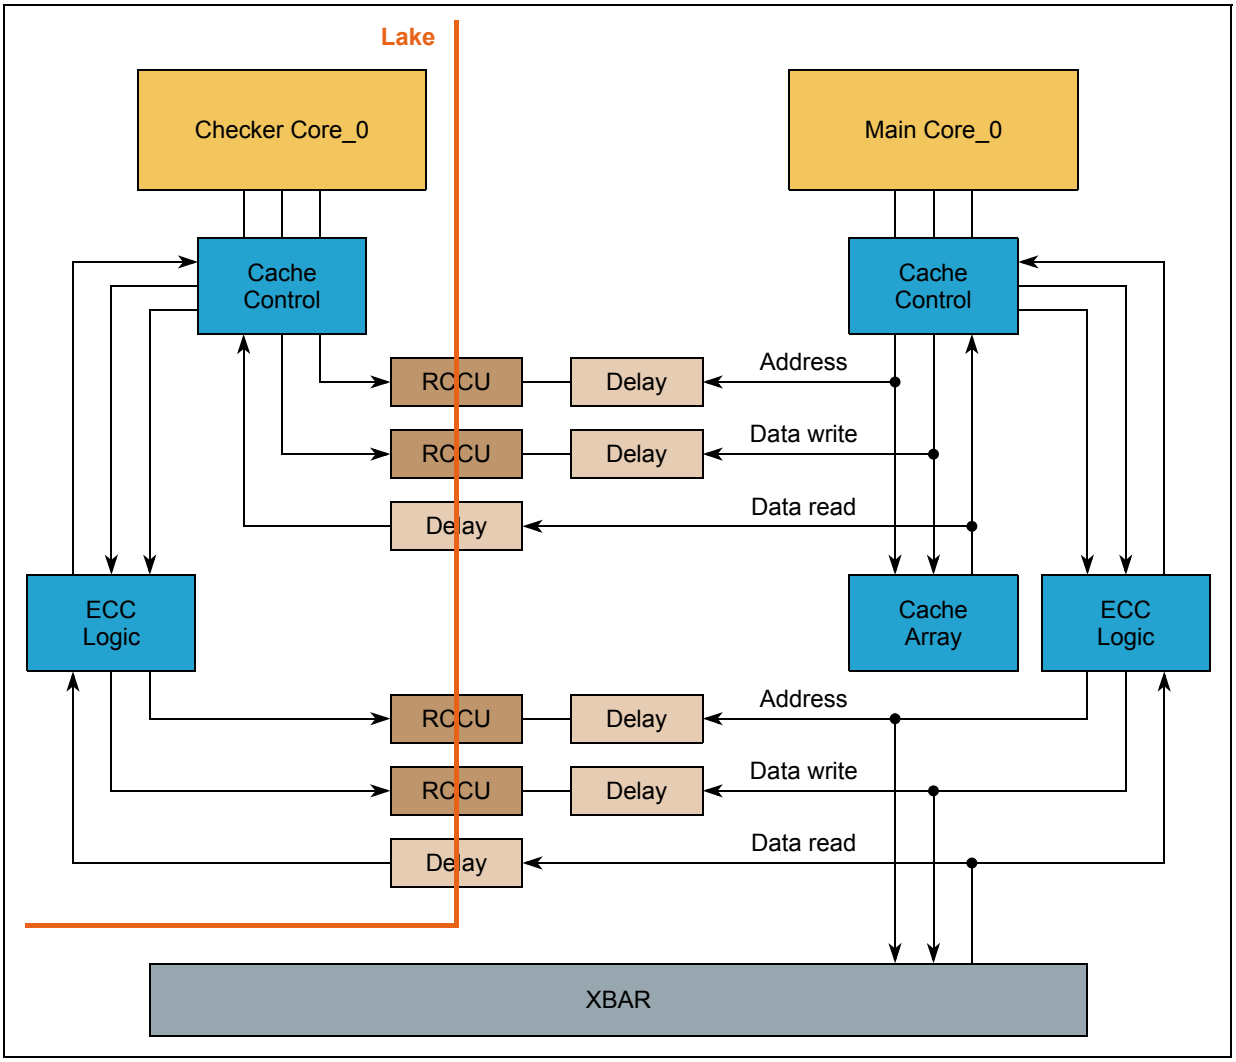
The replicated processing elements contain:

- Core
- Cache control
- Local memory control
- Core MPU
- Core System Bus Interface, including e2eECC logic

Together each set of replicated elements forms a channel (for example, the Main channel and the Checker channel).

Elements that are not replicated are:

- Performance or I/O cores
- Cache and local memory arrays
- INTC
- Interconnect (XBAR)
- RAM controller
- Flash memory controller
- eDMA controller



Note: This is not a complete list of all non-replicated elements. The elements listed are sometimes replicated in similar lockstep architectures.

Equivalent operation of replicated resources is supervised by comparators on all functional signals leaving the channels for the rest of the MCU. Any operational deviations between the supervised signals causes the FCCU to be notified of the discrepancy.

The Checker Core does not have a direct connection to the XBAR. All of the outputs of Checker Core_0 that target the XBAR (as well as any other non-duplicated resource, like local memories) end in an RCCU for verification, and all the inputs to Checker Core_0 from the XBAR are split off from the Main Core_0 XBAR inputs.

An abstract view of the implementation including delays and RCCUs is shown in *Figure 7*, but does not show local memory.

Figure 7. Dual core concept

A delay of two clock cycles exists between the Main and Checker channel to reduce their susceptibility to CCFs caused by power and clock disturbances. Outputs of the Main Core (such as XBAR addresses) are registered and delayed before being forwarded to the RCCUs, while inputs signals (such as XBAR read data) are registered and delayed before being fed to the Checker channel.

LSM can be disabled during boot by reprogramming the Flash memory (UTEST Miscellaneous DCF Client) or on-line by disabling the checker core but not the main Core_0[(c)]. LSM is also automatically disabled when Core_0 enters debug mode and automatically reenabled when it leaves it. If LSM is disabled, the RCCUs are disabled and a signal is sent to the FCCU. If SW enables the checker core by writing in MC_ME_CCTL register while LSM is disabled (not recommended), this does not enable LSM and the RCCUs do not generate any errors in case of mismatch. Thus no user-initiated dynamic enabling of LSM is possible; a reset is needed to reestablish LSM. Furthermore, it is not a valid operation to stop main core_0 only or to reset one of the cores only. If the cores are out

c. Disabling both cores in a single mode transition will not disable LSM.

of lock, a destructive or functional reset is needed to reestablish LSM.When safety core enters debug mode, the signaling of potential mismatches by RCCUs (FCCU channels #10 and #11) is disabled. RCCU signaling is automatically re-enabled when safety core leaves debug mode. If LSM or the RCCU signaling is disabled a signal is sent to the FCCU (FCCU channels #51). A reset is needed to reestablish LSM.Also, in contrast to the SPC560ELx, no Decoupled Parallel Mode (DPM) is available (Main Core_0 and Checker Core_0 cannot operate as two independent cores running different software). Main Core_0 is able to operate as an independent core if Checker Core_0 is disabled. The status of LSM for the Safety core can be verified by checking the appropriate FCCU register.

6.4.3 Common Cause Failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the replication of the Safety Core or of the peripherals. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

There are also configuration registers that can affect the execution of the MCU's safety function when changed and simultaneously disable the respective safety mechanism. These are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing the register protection described above.

6.4.4 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

6.4.4.1 ECC for storage

All storage (system RAM, local memory, Flash memory, peripheral RAM) used in normal operation is protected by ECC with SECDED (Single Error Correct and Double Error Detect), with the following exceptions:

- The caches in the cores are protected by EDC (Error Detection Code), which only detects errors.
- FlexRay’s schedule information RAM is protected by EDC only.

A list showing the implementation of RAMs with ECC (including address protection) and for the SPC574Kx is shown in *Table 19*.

Table 19. ECC RAM implementations

Location	Memory	Memory classification	ECC	Address in ECC	Muxing factor	Reacts to uncorrectable error
Core_0 (Safety Core) (Master and Checker cores)	I-Mem	System RAM	SEC/DED	Y	8	Y
	D-Mem	System RAM	SEC/DED	Y	8	Y
	I-Cache	System RAM	EDC	Y	4	Y
	D-Cache	System RAM	EDC	Y	4	Y
	ITAG	System RAM	SEC/DED	Y	4	Y
	DTAG	System RAM	SEC/DED	Y	4	Y
Core_2 (IOP core)	I-Mem	System RAM	SEC/DED	Y	8	Y
	D-Mem	System RAM	SEC/DED	Y	16	Y

	(MCSi)-RAM1, i=0~2	Peripheral	SEC/DED	Y	8	N
	DPLL-1A	Peripheral	SEC/DED	Y	8	N
	DPLL-1B	Peripheral	SEC/DED	Y	8	N
	DPLL-2	Peripheral	SEC/DED	Y	8	N
M_TTCAN	M_TTCAN	Peripheral	SEC/DED	N	16	Y
NAR	NAR	Other	No	—	4	N
Platform/DMA	DMA	Peripheral	SEC/DED	Y	4	Y
Platform	Overlay	System RAM	SEC/DED	Y	4	Y
Platform	SRAM	System RAM	E2E-ECC	Y	16	Y
Platform	FEC/FIFO	Peripheral	SEC/DED	Y	4	N
Platform	FEC/MIB	Peripheral	SEC/DED	Y	4	N

Table 19 shows that some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback).This is different for storage related to PeMos. PeMos generally use an ECC without address error protections and do not include additional measures to detect them. All ECC calculations for RAMs in PeMos are accomplished by logic outside of the RAM, not in the RAM block.

An exception to this is the GTM's RAMs. They include addressing failure detection measures in the ECC. In addition, the individual RAM ports of the GTM do not share common parts and connect to individual (non-interfering) RAM arrays.

6.4.4.2 All-x words and ECC

There is a special case for legal ECC values in the SPC574Kx. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not legal for memory that is checked by ECC. The flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses, All-0 or All-1 may be legal.

All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be uncorrectable errors.For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, an All-x content may result in a correctable error.

Note: For flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (see "Embedded Flash Memory" chapter, for more details on flash memory safety mechanisms).

6.4.4.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU . The MEMU (see *Section 6.4.4.4: Memory Error Management Unit (MEMU)*) may filter ECC error notification for known ECC error addresses (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU, which filters and then forwards unfiltered notifications in an aggregated manner to the FCCU.

6.4.4.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events associated with ECC logic used on SRAM (system RAMs in this context are those RAMs with "System RAM" memory classification as in *Table 19*), peripheral RAM, and flash memory. When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU .

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses in the table is ensured. For example, if an address is already stored in the MEMU's table, correctable errors at that address will no longer be reported to the FCCU.
- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory.
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU.

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (see "Memory Error Management Unit (MEMU)" chapter for more information).

6.4.4.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- the (optional) ECC-syndrome or MBIST bad-bit information
- A configuration specifying whether the ECC unit is attached to a vital memory (SRAM, local memory, and system RAM of Safety Core), to flash memory, or to a peripheral RAM

Not all ECC units provide a syndrome. If an ECC unit does not provide the syndrome, FFh is stored in the MEMU error table instead of the syndrome. If an error is signaled, it is compared against all errors known for that storage:

Note: If a previously known error has been marked invalid by software, no comparison against the address will occur.

- If no entry of that address is already in the buffer, it is to be added into the appropriate table depending on the SBE versus UCE indicator
- If there is no free entry left in that buffer, the overflow flag is set.

If a valid entry of that address is in the buffer and If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. In case the same error is reported by ECC which reports the syndrome and additionally by ECC which does not, the reporting order becomes important.

- If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer. If ECC which provides the syndrome reports first, the second reporting without syndrome is discarded.
- If ECC which does not provide the syndrome reports first, a second entry with the syndrome is stored in the table.

7 Device Configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device,
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters, and
- Links for more information.

7.2 Core modules

SPC574Kx has three separate cores that perform various computational and control functions.

Table 20. SPC574Kx core modules

Instance	Description
Main Core_0	The main computational shell includes the Main Core_0, which uses an e200z410Dn3 core. This core is used for general computational functions.
Checker Core_0s	A second core, referred to as Checker Core_0s, uses an e200z409D core which is a true subset of the e200z410Dn3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly.
Peripheral Core_2	The third processor, Peripheral Core_2, employs an e200z225Bn3 core and is generally used to control various I/O modules.

For more information, please see *Chapter 13: Core Complex Overview*, *Chapter 14: Core e200z410Dn3 description* and *Chapter 15: Core e200z225Bn3 description*.

7.2.1 Core reset settings

Table 21 shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately following a system reset.

4. Read-only registers

7.2.2 Special purpose register (SPR) summary

PowerISA 2.06 and implementation-specific SPRs for the e200z420Dn3, e200z419D, and e200z225Bn3 cores are listed in *Table 22*. All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR may be read or written with the **mfspr** and **mtspr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in *Table 22*.

Table 22. Special purpose registers

Mnemonic	Name	SPR No.	Access	Privileged	e200z specific

1. The Debug Status Register can be read using *mfspr RT,DBSR*. The Debug Status Register cannot be directly written to. Instead, bits in the Debug Status Register corresponding to '1' bits in GPR(RS) can be cleared using *mtspr DBSR,RS*.
2. Undefined on **POR** assertion, unchanged on **external PORESET** assertion
3. The Machine Check Syndrome Register can be read using *mfspr RT,MCSR*. The Machine Check Syndrome Register cannot be directly written to. Instead, bits in the Machine Check Syndrome Register corresponding to '1' bits in GPR(RS) can be cleared using *mtspr MCSR,RS*.
4. The 64-bit DVC registers are accessed by using the DVC1,2 spr #s for the lower 32 bits, and the DVC1,2U spr #s for the upper 32 bits.

7.3 System modules

7.3.1 SIUL2 configuration

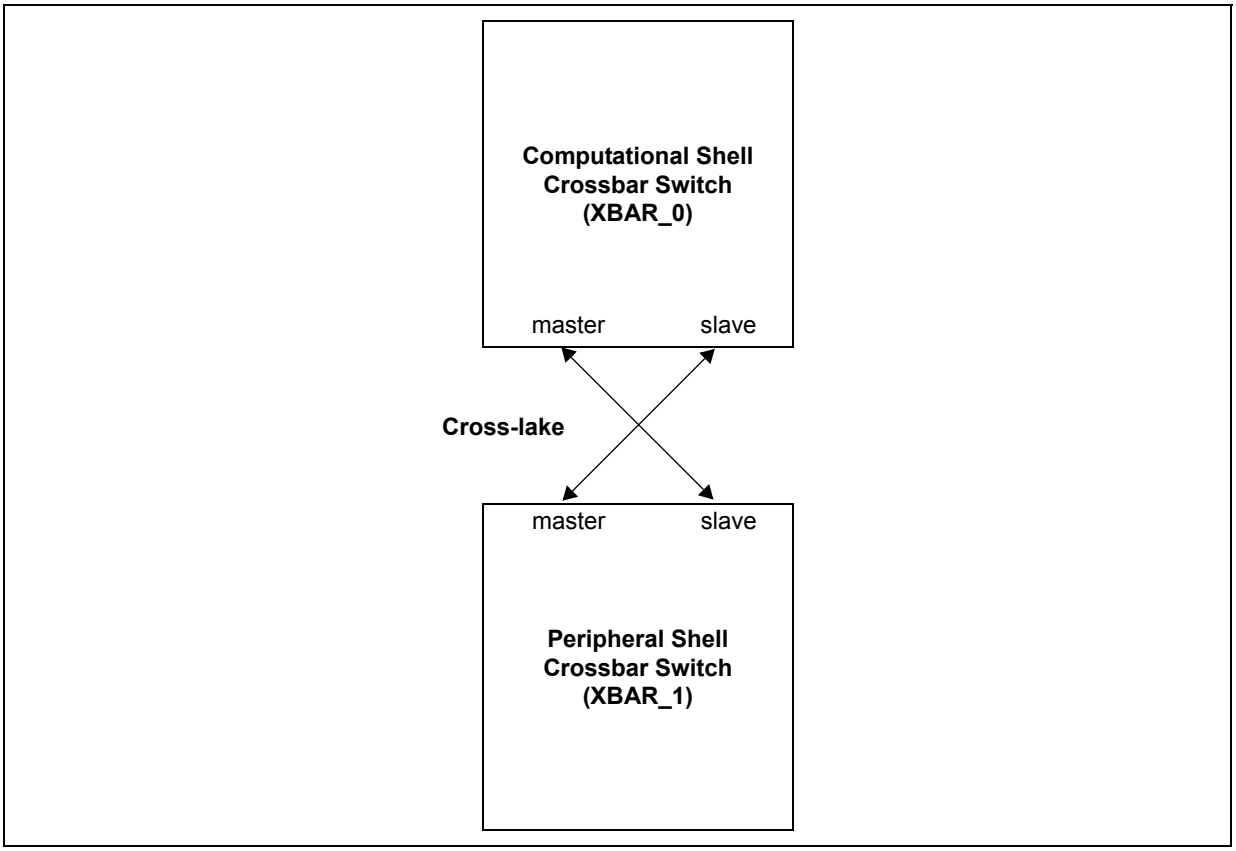
The System Integration Unit Lite 2 (SIUL2) controls the MCU pad configuration, ports, general-purpose input and output (GPIO) signals and external interrupts with trigger event configuration.

For details please refer *Chapter 16: System Integration Unit Lite2 (SIUL2)*.

7.3.2 Semaphores2 (SEMA42)

The peripheral platform shell includes a memory-mapped module (SEMA42) that provides

- robust hardware support needed in multi-core systems for implementing semaphores
- a simple mechanism to achieve "lock/unlock" operations via a single write access.



The hardware semaphore module is an architecture-neutral solution that provides 16 hardware-enforced gates for SPC574Kx as well as other useful system functions related to the gating mechanisms. The capabilities provided by the hardware semaphore module are currently utilized in dual core AUTOSAR® implementations and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

For details refer to *Chapter 22: Semaphores2 (SEMA42)*.

7.3.3 Crossbar switch configuration

This device contains two crossbar switch modules. *Figure 8* illustrates that they are connected via a cross-lake, which is comprised of intelligent bridging bus gaskets. These bus gaskets handle the traffic which crosses between the shells and do not require any interaction with the user. This dual-crossbar architecture allows all masters to access all slaves across the computational shell and peripheral shell..

Figure 8. Crossbar switches diagram

The following sections explain how each crossbar switch is configured on this device.

7.3.3.1 Computational shell crossbar switch (XBAR_0) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see *Chapter 17: Crossbar Switch (XBAR)*.

Figure 9. Computational shell's crossbar switch integration

7.3.3.1.1 Computational shell crossbar switch master assignments

This device contains four masters connected to the computational shell's crossbar switch.

Table 24 contains the master assignments.

Table 24. Computational shell crossbar switch master assignments

Master module	Physical master port number
Core 0 instruction bus	0
Core 0 data bus	1
Peripheral shell crossbar switch	4
Core 2 instruction bus	5

7.3.3.1.2 Computational shell crossbar switch slave assignments

This device contains five slaves connected to the computational shell's crossbar switch.

Table 25 contains the slave assignments.

Table 25. Computational shell crossbar switch slave assignments

Slave module	Physical slave port number
Flash memory controller port 0	0
Flash memory controller port 1	1
Backdoor port to Core 0's xMEM	2
System RAM	4
Peripheral shell crossbar switch	7

Access to the flash memory via slave ports 0 and 1 is routed based on the master. The master-to-flash memory port routing have been assigned in a way to balance data traffic, with attention paid to facilitate core instruction fetches. *Table 26* shows the flash memory port assignments.

Table 26. Flash memory port assignments

Flash Memory Slave Port 0	Flash Memory Slave Port 1
Core0 Instruction fetch (M0)	Core0 Data fetch (M1)
Peripheral shell crossbar switch (M4)	Core2 Instruction fetch (M5)

7.3.3.1.3 PRS register reset values

The computational shell's XBAR_0 PRS*n* registers reset to 0030_1425h. Note that these registers are read-only.

7.3.3.2 Peripheral shell crossbar switch (XBAR_1) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see *Chapter 17: Crossbar Switch (XBAR)*.

7.3.3.2.1 Peripheral shell crossbar switch master assignments

This device contains four masters connected to the peripheral shell's crossbar switch.

Table 28 contains the master assignments.

Table 28. Peripheral shell crossbar switch master assignments

Master module	Physical master port number
Core 2 data bus	0
DMA	1
FEC, LFAST, and FlexRay	2
Cross-lake (computational shell crossbar switch)	3

7.3.3.2.2 Peripheral shell crossbar switch slave assignments

This device contains four slaves connected to the peripheral shell's crossbar switch.

Table 29 contains the slave assignments.

Table 29. Peripheral shell crossbar switch slave assignments

Slave module	Physical slave port number
Computational shell crossbar switch	0
Backdoor port to Core 2's xMEM	1
Peripheral bridge B	2
Peripheral bridge A	3

7.3.3.2.3 PRS register reset values

The peripheral shell's XBAR_1 PRS*n* registers reset to 0000_3102h.

7.3.4 System Memory Protection Unit (SMPU) configuration

This chip contains two instances of the System Memory Protection Unit (SMPU):

- SMPU_0 for the Computational Shell
- SMPU_1 for the Peripheral Shell

The following sections explain how SMPU_0 and SMPU_1 are configured on this chip.

7.3.4.1 SMPU_0 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the SMPU module itself, see the module's dedicated chapter.

Figure 11. SMPU_0 configuration

7.3.4.1.2 Number of region descriptors supported by SMPU_0

This instance of the SMPU module supports up to 12 region descriptors.

7.3.4.1.3 RGD_WORD2 formats supported by SMPU_0

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.1.4 Master Access permissions for SMPU0

The only masters allowed to access the SMPU0 registers are Core 2 and Core 0. It is also required that the core be in supervisor mode.

7.3.4.2 SMPU_1 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the module’s dedicated chapter.

7.3.4.2.2 Number of region descriptors supported by SMPU_1

This instance of the SMPU module supports up to eight region descriptors.

7.3.4.2.3 RGD_WORD2 formats supported by SMPU_1

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.2.4 Master Access permissions for SMPU1

The only masters allowed to access the SMPU1 registers are Core 2 and Core 0. It is also required that the core be in supervisor mode.

7.3.5 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 13. Peripheral bridge configuration

Crossbar switch	Crossbar switch	*Section 7.3.3: Crossbar switch configuration*

7.3.5.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

7.3.5.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See *Chapter 5: Memory map* for the memory slot assignment for each module.

7.3.5.3 MPR registers

Each of the two peripheral bridges supports up to 16 crossbar switch masters, each assigned to a MPROT*n* field in the MPRA-B registers. However, fewer are supported on this device. See *Section 7.3.3: Crossbar switch configuration* for details of the master port assignments for this device.

7.3.5.4 PACR/OPACR registers

Each of the two peripheral bridges support up to 320 peripherals, each assigned to a PACR*n* or OPACR*n* field within the PACRA-H/OPACRA-AF registers. However, fewer peripherals are supported on this device. See *Chapter 5: Memory map* for details of the peripheral slot assignments for this device. Unused PACR*n* fields are reserved.

7.3.6 Platform Configuration Module (PCM)

The Platform Configuration Module contains four miscellaneous configuration registers for the device:

- FEC Burst Optimization Master Control Register (FBOMCR)
- IAHB Burst Enable 1 (IAHB_BE1) Register
- IAHB Burst Enable 2 (IAHB_BE2) Register
- IPS Clock Gating Module Enable 0 (IPS_CGM_EN0) Register

Currently, the configuration registers are related to the operation of the intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

7.3.6.1 FEC Burst Optimization Master Control Register (FBOMCR)

The FEC burst optimization master control register (FBOMCR) controls FEC burst optimization behavior on the system bus.

Offset: 00h Access: Supervisor read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 14. FEC Burst Optimization Master Control Register (FBOMCR)

Table 35. FBOMCR field descriptions

Field	Description
0–20	Reserved
21 ACCERR	Accumulate error This bit determines whether an error response for the first half of the write burst is accumulated to the second half of the write burst or discarded. In order to complete the burst, the FEC interface to the system bus responds by indicating that the first half of the burst completed without error before it actually writes the data so that it can fetch the second half of the write data from the FIFO. When actually written onto the system bus, the first half of the write burst can have an error. Because this half initially responded without an error to the FIFO, the error is discarded or accumulated with the error response for the second half of the burst. 0 Any error to the first half of the write burst is discarded. 1 Any actual error response to the first half of the write burst is accumulated in the second half's response. In other words, an error response to the first half will be seen in the response to the second half, even if the second half does not error.
22 WBEN	Global write burst enable to XBAR slave port designated by FXSBE*n* 0 Write bursting to all XBAR slave ports is disabled. 1 Write bursting is enabled to any XBAR slave port whose FXSBE*n* bit is asserted.

Table 35. FBOMCR field descriptions(Continued)

Field	Description
23 RBEN	Global read burst enable from XBAR slave port designated by FXSBE*n* 0 Read bursting from all XBAR slave ports is disabled. 1 Read bursting is enabled from any XBAR slave port whose FXSBE*n* bit is asserted.
24–31 FXSBE[7:0]	FXSBE – FEC XBAR slave burst enable FXSBE*n* enables bursting by the FEC interface to the XBAR slave port controlled by that respective FXSBE*n* bit. If FXSBE*n* is asserted, then that XBAR slave port enabled by the bit can accept the bursts allowed by RBEN and WBEN. Otherwise, the FEC interface will not burst to the XBAR slave port controlled by that respective FXSBE*n* bit. Read bursts from that XBAR slave port are enabled by RBEN. Write bursts to that XBAR slave port are enabled by WBEN. FXSBE*n* assignments to XBAR slave ports: FXSBE0 = Flash FXSBE1 = Reserved FXSBE2 = RAM, TCMA, TCMB, and TCMC FXSBE3 = Reserved FXSBE4 = Reserved FXSBE5 = Reserved FXSBE6 = Reserved FXSBE7 = PBRIDGE_A and PBRIDGE_B

Field	Description
0–4	Reserved
5–7 RSV	Reserved, undefined
8–12	Reserved

Table 36. IAHB_BE1 Register field descriptions(Continued)

Field	Description
13 PRE_DMA	Pending read enable (PRE) DMA. This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_DMA	Burst read enable (BRE) DMA. This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_DMA	Burst write enable (BWE) DMA. This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20	Reserved
21 PRE_S0	Pending read enable (PRE) S0. This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
22 BRE_S0	Burst read enable (BRE) S0. This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_S0	Burst write enable (BWE) S0. This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24–28	Reserved
29 PRE_M3	Pending read enable (PRE) M3. This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_M3	Burst read enable (BRE) M3. This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_M3	Burst write enable (BWE) M3. This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

Table 37. IAHB_BE2 field descriptions

Field	Description
0–4	Reserved
5–7 RSV	Reserved, undefined
8–12	Reserved
13 PRE_SIPI	Pending read enable (PRE) SIPI This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_SIPI	Burst read enable (BRE) SIPI This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_SIPI	Burst write enable (BWE) SIPI This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20	Reserved
21 PRE_Flexray	Pending read enable (PRE) Flexray This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.

Table 37. IAHB_BE2 field descriptions(Continued)

Field	Description
22 BRE_Flexray	Burst read enable (BRE) Flexray This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_Flexray	Burst write enable (BWE) Flexray This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24–28	Reserved
29 PRE_FEC	Pending read enable (PRE) FEC This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_FEC	Burst read enable (BRE) FEC This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_FEC	Burst write enable (BWE) FEC This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

Figure 17. IPS Clock Gating Module Enable 0 (IPS_CGM_EN0) Register

Table 38. IPS_CGM_EN0 field descriptions

Field	Description
0–2	Reserved
3 IPS_CGM_DMA0	IPS clock gating enable for DMA0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
4–6	Reserved
7 IPS_CGM_MPU1	IPS clock gating enable for MPU1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
8–10	Reserved
11 IPS_CGM_AXBS1	IPS clock gating enable for AXBS1 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
12–14	Reserved
15 IPS_CGM_INTC	IPS clock gating enable for INTC 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
16–18	Reserved
19 IPS_CGM_MPU0	IPS clock gating enable for MPU0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.

Table 38. IPS_CGM_EN0 field descriptions(Continued)

Field	Description
20–22	Reserved
23 IPS_CGM_AXBS0	IPS clock gating enable for AXBS0 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
24–26	Reserved
27 IPS_CGM_PRAM	IPS clock gating enable for PRAM 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.
28–30	Reserved
31 IPS_CGM_PFLASH	IPS clock gating enable for PFLASH Controller 0 Disable clock gating. 1 Enable clock gating, one IPS clock delay is introduced between master and slave.

7.3.7 Interrupt Controller (INTC) configuration

7.3.7.1 INTC configurable parameters

The INTC on this chip supports 2 processors.

7.3.7.2 INTC implemented registers

Table 39 shows the registers implemented on the INTC on this chip.

Table 39. INTC implemented registers

Address offset	Register
000h	INTC Block Configuration Register (INTC_BCR)
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)
018h	INTC Current Priority Register for Processor 2 (INTC_CPR2)
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)
028h	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)
030h	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)
038h	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)
040h–05Fh	INTC Software Set/Clear Interrupt Register 0 (INTC_SSCIR0)– INTC Software Set/Clear Interrupt Register 31 (INTC_SSCIR31)
060h–85Eh	INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023)(1)

1. Not all INTC_PSRs are implemented and the access to them generates an error. The INTC_PSRs implemented are relative to the sources described in *Table 40*

7.3.7.3 Interrupt sources

Table 40 defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 40. Interrupt sources

IRQ #	Offset	Source description	Source name
0	1000h	Software settable flag 0	SSCIR0_3[CLR0]
1	1004h	Software settable flag 1	SSCIR0_3[CLR1]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
376	15E0h	LINFlexD_0 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wakeup – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_0_LINIER[HRIE] | LINFlexD_0_LINIER[DRIE] | LINFlexD_0_LINIER[DBFIE] | LINFlexD_0_LINIER[WUIE] | LINFlexD_0_LINIER[LSIE]
377	15E4h	LINFlexD_0 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_0_LINIER[HRIE] | LINFlexD_0_LINIER[DTIE] | LINFlexD_0_LINIER[DBEIE]
378	15E8h	LINFlexD_0 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_0_LINIER[SZIE] | LINFlexD_0_LINIER[OCIE] | LINFlexD_0_LINIER[BEIE] | LINFlexD_0_LINIER[CEIE] | LINFlexD_0_LINIER[HEIE] | LINFlexD_0_LINIER[FEIE] | LINFlexD_0_LINIER[BOIE] | LINFlexD_0_LINIER[TOIE]
380	15F0h	LINFlexD_1 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wakeup – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_1_LINIER[HRIE] | LINFlexD_1_LINIER[DRIE] | LINFlexD_1_LINIER[DBFIE] | LINFlexD_1_LINIER[WUIE] | LINFlexD_1_LINIER[LSIE]
381	15F4h	LINFlexD_1 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_1_LINIER[HRIE] | LINFlexD_1_LINIER[DTIE] | LINFlexD_1_LINIER[DBEIE]
382	15F8h	LINFlexD_1 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_1_LINIER[SZIE] | LINFlexD_1_LINIER[OCIE] | LINFlexD_1_LINIER[BEIE] | LINFlexD_1_LINIER[CEIE] | LINFlexD_1_LINIER[HEIE] | LINFlexD_1_LINIER[FEIE] | LINFlexD_1_LINIER[BOIE] | LINFlexD_1_LINIER[TOIE]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
384	1600h	LINFlexD_2 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wakeup – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_2_LINIER[HRIE] | LINFlexD_2_LINIER[DRIE] | LINFlexD_2_LINIER[DBFIE] | LINFlexD_2_LINIER[WUIE] | LINFlexD_2_LINIER[LSIE]
385	1604h	LINFlexD_2 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_2_LINIER[HRIE] | LINFlexD_2_LINIER[DTIE] | LINFlexD_2_LINIER[DBEIE]
386	1608h	LINFlexD_2 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_2_LINIER[SZIE] | LINFlexD_2_LINIER[OCIE] | LINFlexD_2_LINIER[BEIE] | LINFlexD_2_LINIER[CEIE] | LINFlexD_2_LINIER[HEIE] | LINFlexD_2_LINIER[FEIE] | LINFlexD_2_LINIER[BOIE] | LINFlexD_2_LINIER[TOIE]
432	16C0h	LINFlexD_14 Reception combined interrupt – Header Received – Data Reception complete – Data Buffer Full – Wakeup – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_14_LINIER[HRIE] | LINFlexD_14_LINIER[DRIE] | LINFlexD_14_LINIER[DBFIE] | LINFlexD_14_LINIER[WUIE] | LINFlexD_14_LINIER[LSIE]
433	16C4h	LINFlexD_14 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_14_LINIER[HRIE] | LINFlexD_14_LINIER[DTIE] | LINFlexD_14_LINIER[DBEIE]
434	16C8h	LINFlexD_14 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_14_LINIER[SZIE] | LINFlexD_14_LINIER[OCIE] | LINFlexD_14_LINIER[BEIE] | LINFlexD_14_LINIER[CEIE] | LINFlexD_14_LINIER[HEIE] | LINFlexD_14_LINIER[FEIE] | LINFlexD_14_LINIER[BOIE] | LINFlexD_14_LINIER[TOIE]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
436	16D0h	LINFlexD_15 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wakeup – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_15_LINIER[HRIE] | LINFlexD_15_LINIER[DRIE] | LINFlexD_15_LINIER[DBFIE] | LINFlexD_15_LINIER[WUIE] | LINFlexD_15_LINIER[LSIE]
437	16D4h	LINFlexD_15 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_15_LINIER[HRIE] | LINFlexD_15_LINIER[DTIE] | LINFlexD_15_LINIER[DBEIE]
438	16D8h	LINFlexD_15 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_15_LINIER[SZIE] | LINFlexD_15_LINIER[OCIE] | LINFlexD_15_LINIER[BEIE] | LINFlexD_15_LINIER[CEIE] | LINFlexD_15_LINIER[HEIE] | LINFlexD_15_LINIER[FEIE] | LINFlexD_15_LINIER[BOIE] | LINFlexD_15_LINIER[TOIE]
440	16E0h	I2C Combined interrupt: – Byte transfer complete – Addressed as slave – Arbitration Lost – No Acknowledge from Slave – I2C Bus going idle	I2C_0_IBSR[IBIF] | I2C_0_IBSR[IAAS] | I2C_0_IBSR[IBAL]
453	1714h	FlexRay LRAM Non-Corrected errors combined interrupt: – LRAM Non-Corrected Error Overflow – LRAM Non-Corrected Error	FR_0_EEIFER[LRNE_OF] | FR_0_EEIFER[LRNE_IF]
454	1718h	FlexRay LRAM Corrected errors combined interrupt: – LRAM Corrected Error Overflow – LRAM Corrected Error	FR_0_EEIFER[LRCE_OF] | FR_0_EEIFER[LRCE_IF]
455	171Ch	FlexRay Receive FIFO Channel A Almost Full Interrupt	FR_0_GIFER[FAFAIF]
456	1720h	FlexRay Receive FIFO Channel B Almost Full Interrupt	FR_0_GIFER[FAFBIF]
457	1724h	FlexRay Wakeup Interrupt	FR_0_GIFER[WUPIF]
458	1728h	FlexRay Protocol global interrupt	FR_0_GIFER[PRIF]
459	172Ch	FlexRay Controller Host Interface global interrupt	FR_0_GIFER[CHIF]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
460	1730h	FlexRay Transmit Message Buffer global Interrupt	FR_0_GIFER[TBIF]
461	1734h	FlexRay Receive Message Buffer global Interrupt	FR_0_GIFER[RBIF]
462	1738h	FlexRay Module global Interrupt	FR_0_GIFER[MIF]
477	1774h	Power Management Controller Supply Gauge Low Voltage Detect and High Voltage Detect Interrupts	GR_S[VD15] | GR_S[VD14] | GR_S[VD13] | GR_S[VD12] | GR_S[VD10] | GR_S[VD9] | GR_S[VD7] | GR_S[VD4] | GR_S[VD3]
478	1778h	Power Management Controller Temperature Sensor interrupts	EPR_TD[TEMP_3] | EPR_TD[TEMP_2] | EPR_TD[TEMP_0]
488	17A0h	FCCU Alarm interrupt	FCCU_IRQ_STAT[ALRM_STAT]
489	17A4h	Configuration Time-out Status interrupt request	FCCU_IRQ_STAT[CFG_TO_STAT]
494	17B8h	STCU2 LBIST Interrupt Enable	STCU_RUNSW[LBIE]
495	17BCh	STCU2 MBIST Interrupt Enable	STCU_RUNSW[MBIE]
528	1840h	SAR ADC 0 combined interrupt: – NEOC (end of normal conversion of each channel) – NECH (end of normal chain) – JEOC (end of injected conversion of each channel) – JECH (end of injected chain) – WTISR – WTIMR	SARADC_0_ICIPR0[EOC_CH[7]] | SARADC_0_ICIPR0[EOC_CH[6]] | SARADC_0_ICIPR0[EOC_CH[5]] | SARADC_0_ICIPR0[EOC_CH[4]] | SARADC_0_WTISR[WDG0L] | SARADC_0_WTISR[WDG0H] | SARADC_0_WTISR[WDG1L] | ... | SARADC_0_WTISR[WDG3L] | SARADC_0_WTISR[WDG3H] | SARADC_0_WTIMR[WDG0L] | SARADC_0_WTIMR[WDG0H] | SARADC_0_WTIMR[WDG1L] | ... | SARADC_0_WTIMR[WDG3L] | SARADC_0_WTIMR[WDG3H]
530	1848h	SAR ADC 2 combined interrupt: – NEOC (end of normal conversion of each channel) – NECH (end of normal chain) – JEOC (end of injected conversion of each channel) – JECH (end of injected chain) – WTISR – WTIMR	SARADC_2_ICIPR0[EOC_CH[23]] | SARADC_2_ICIPR0[EOC_CH[22] | SARADC_2_ICIPR0[EOC_CH[19]] | SARADC_2_ICIPR0[EOC_CH[18]] | SARADC_2_ICIPR0[EOC_CH[17]] | SARADC_2_ICIPR0[EOC_CH[16]] | SARADC_2_WTISR[WDG0L] | SARADC_2_WTISR[WDG0H] | SARADC_2_WTISR[WDG1L] | ... | SARADC_2_WTISR[WDG3L] | SARADC_2_WTISR[WDG3H] | SARADC_2_WTIMR[WDG0L] | SARADC_2_WTIMR[WDG0H] | SARADC_2_WTIMR[WDG1L] | ... | SARADC_2_WTIMR[WDG3L] | SARADC_2_WTIMR[WDG3H]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
532	1850h	SAR ADC 4 combined interrupt: – NEOC (end of normal conversion of each channel) – NECH (end of normal chain) – JEOC (end of injected conversion of each channel) – JECH (end of injected chain) – WTISR – WTIMR	SARADC_4_ICIPR0[EOC_CH[35] | SARADC_4_ICIPR0[EOC_CH[34] | SARADC_4_ICIPR0[EOC_CH[33] | SARADC_4_ICIPR0[EOC_CH[32]] | SARADC_4_WTISR[WDG0L] | SARADC_4_WTISR[WDG0H] | SARADC_4_WTISR[WDG1L] | ... | SARADC_4_WTISR[WDG3L] | SARADC_4_WTISR[WDG3H] | SARADC_4_WTIMR[WDG0L] | SARADC_4_WTIMR[WDG0H] | SARADC_4_WTIMR[WDG1L] | ... | SARADC_4_WTIMR[WDG3L] | SARADC_4_WTIMR[WDG3H]
534	1858h	SAR ADC 6 combined interrupt: – NEOC (end of normal conversion of each channel) – NECH (end of normal chain) – JEOC (end of injected conversion of each channel) – JECH (end of injected chain) – WTISR – WTIMR	SARADC_6_ICIPR0[EOC_CH[51]] | SARADC_6_ICIPR0[EOC_CH[50]] | SARADC_6_ICIPR0[EOC_CH[49]] | SARADC_6_ICIPR0[EOC_CH[48]] | SARADC_6_ICIPR0[EOC_CH[43]] | SARADC_6_ICIPR0[EOC_CH[42]] | SARADC_6_ICIPR0[EOC_CH[41]] | SARADC_6_ICIPR0[EOC_CH[40]] | SARADC_6_WTISR[WDG0L] | SARADC_6_WTISR[WDG0H] | SARADC_6_WTISR[WDG1L] | ... | SARADC_6_WTISR[WDG3L] | SARADC_6_WTISR[WDG3H] | SARADC_6_WTIMR[WDG0L] | SARADC_6_WTIMR[WDG0H] | SARADC_6_WTIMR[WDG1L] | ... | SARADC_6_WTIMR[WDG3L] | SARADC_6_WTIMR[WDG3H]
543	187Ch	SAR ADC B combined interrupt: – NEOC (end of normal conversion of each channel) – NECH (end of normal chain) – JEOC (end of injected conversion of each channel) – JECH (end of injected chain) – WTISR – WTIMR	SARADC_B_ICIPR0[EOC_CH[31] | SARADC_B_ICIPR0[EOC_CH[30] | ... | SARADC_B_ICIPR0[EOC_CH[1] | SARADC_B_ICIPR0[EOC_CH[0]] | SARADC_B_ICIPR1[EOC_CH[61]] | ... | SARADC_B_ICIPR1[EOC_CH[56]] | SARADC_B_ICIPR1[EOC_CH[53]] | ... | SARADC_B_ICIPR1[EOC_CH[0]] | SARADC_B_WTISR[WDG0L] | SARADC_B_WTISR[WDG0H] | SARADC_B_WTISR[WDG1L] | ... | SARADC_B_WTISR[WDG7L] | SARADC_B_WTISR[WDG7H] | SARADC_B_WTIMR[WDG0L] | SARADC_B_WTIMR[WDG0H] | SARADC_B_WTIMR[WDG1L] | ... | SARADC_B_WTIMR[WDG7L] | SARADC_B_WTIMR[WDG7H]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
544	1880h	SD ADC 0 combined interrupt: – Data FIFO empty – Data FIFO full – Data FIFO overrun	SDADC_0_SFR[DFEF] | SDADC_0_SFR[DFORF] | SDADC_0_SFR[DFFF]
547	188Ch	SD ADC 3 combined interrupt: – Data FIFO empty – Data FIFO full – Data FIFO overrun	SDADC_3_SFR[DFEF] | SDADC_3_SFR[DFORF] | SDADC_3_SFR[DFFF]
558	18B8h	SENT_0 Fast messages combined interrupt: OR of all enabled Fast message Ready flags	SENT_0_FMSG_RDY[0] | SENT_0_FMSG_RDY[1] | SENT_0_FMSG_RDY[2] | SENT_0_FMSG_RDY[3]
559	18BCh	SENT_0 Slow messages combined interrupt: OR of all enabled Slow message Ready flags	SENT_0_SMSG_RDY[0] | SENT_0_SMSG_RDY[1] | SENT_0_SMSG_RDY[2] | SENT_0_SMSG_RDY[3]
560	18C0h	SENT_0 Error combined interrupt: OR of following events: – Fast message DMA underflow – Slow message DMA underflow – Channels 0 to 3: - Successive calibration check resynchronized error - Calibration variation 20 – 25% - Slow message overflow - Fast message overflow - Number of negative edges error - Checksum error in fast message - Checksum error in slow message - Nibble data value error - Calibration pulse length error - Calibration pulse length ratio to message length error	SENT_0_GBL_STATUS[FMDU] | SENT_0_GBL_STATUS[SMDU] | SENT_0_CHn_STATUS[4:7] | SENT_0_CHn_STATUS[9:15]
561	18C4h	SENT_1 Fast messages combined interrupt: OR of all enabled Fast message Ready flags	SENT_1_FMSG_RDY[0] | SENT_1_FMSG_RDY[1]
562	18C8h	SENT_1 Slow messages combined interrupt: OR of all enabled Slow message Ready flags	SENT_1_SMSG_RDY[0] | SENT_1_SMSG_RDY[1]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
563	18CCh	SENT_1 Error combined interrupt: OR of following events: – Fast message DMA underflow – Slow message DMA underflow – Channels 0 to 1: - Successive calibration check resynchronized error - Calibration variation 20 – 25% - Slow message overflow - Fast message overflow - Number of negative edges error - Checksum error in fast message - Checksum error in slow message - Nibble data value error - Calibration pulse length error - Calibration pulse length ratio to message length error	SENT_1_GBL_STATUS[FMDU] | SENT_1_GBL_STATUS[SMDU] | SENT_1_CHn_STATUS[4:7] | SENT_1_CHn_STATUS[9:15]
564	18D0h	SENT_0 Channel 0 Fast message interrupt	SENT_0_FMSG_RDY[0]
565	18D4h	SENT_0 Channel 0 Slow message interrupt	SENT_0_SMSG_RDY[0]
566	18D8h	SENT_0 Channel 0 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_0_CH0_STATUS[4:7] | SENT_0_CH0_STATUS[9:15]
567	18DCh	SENT_0 Channel 1 Fast message interrupt	SENT_0_FMSG_RDY[1]
568	18E0h	SENT_0 Channel 1 Slow message interrupt	SENT_0_SMSG_RDY[1]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
569	18E4h	SENT_0 Channel 1 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_0_CH1_STATUS[4:7] | SENT_0_CH1_STATUS[9:15]
570	18E8h	SENT_0 Channel 2 Fast message interrupt	SENT_0_FMSG_RDY[2]
571	18ECh	SENT_0 Channel 2 Slow message interrupt	SENT_0_SMSG_RDY[2]
572	18F0h	SENT_0 Channel 2 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_2_CH2_STATUS[4:7] | SENT_2_CH2_STATUS[9:15]
573	18F4h	SENT_0 Channel 3 Fast message interrupt	SENT_0_FMSG_RDY[3]
574	18F8h	SENT_0 Channel 3 Slow message interrupt	SENT_0_SMSG_RDY[3]
575	18FCh	SENT_0 Channel 3 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_0_CH3_STATUS[4:7] | SENT_0_CH3_STATUS[9:15]
579	190Ch	SENT_1 Channel 0 Fast message interrupt	SENT_1_FMSG_RDY[0]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
580	1910h	SENT_1 Channel 0 Slow message interrupt	SENT_1_SMSG_RDY[0]
581	1914h	SENT_1 Channel 0 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_1_CH0_STATUS[4:7] | SENT_1_CH0_STATUS[9:15]
582	1918h	SENT_1 Channel 1 Fast message interrupt	SENT_1_FMSG_RDY[1]
583	191Ch	SENT_1 Channel 1 Slow message interrupt	SENT_1_SMSG_RDY[1]
584	1920h	SENT_1 Channel 1 combined Error interrupt: – Successive calibration check resynchronized error – Calibration variation 20 – 25% – Slow message overflow – Fast message overflow – Number of negative edges error – Checksum error in fast message – Checksum error in slow message – Nibble data value error – Calibration pulse length error – Calibration pulse length ratio to message length error	SENT_1_CH1_STATUS[4:7] | SENT_1_CH1_STATUS[9:15]
612	1990h	PSI5_0 Channel 0 DMA Combined interrupt: – DMA transfer complete – DMA SENT frame transfer complete – Fifo full or underflow of the RAM register – underflow in the PSI5 SENT message area	PSI5_0_CH_0_DSR[IS_DMA_TF_PM_DS] | PSI5_0_CH_0_DSR[IS_DMA_TF_SF] | PSI5_0_CH_0_DSR[IS_DMA_PM_DS_FIFO_FULL] | PSI5_0_CH_0_DSR[IS_DMA_SFUF] | PSI5_0_CH_0_DSR[IS_DMA_PM_DS_UF]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
613	1994h	PSI5_0 Channel 0 combined General interrupt: – New SENT message reception – CRC error – Overwrite of unread message in corresponding SENT location (in PSI5_SFR) – DPR is ready for receiving a new data – DBR is ready for receiving a new data – DSR is ready for receiving a new data – Write to DPR while it is NOT ready – Write to DBR while it is NOT ready – Write to DSR while it is NOT ready – New value in data time stamp register – New value in sync time stamp read register	PSI5_0_CH_0_GISR[IS_CESM[6:1]] | PSI5_0_CH_0_GISR[IS_STS] | PSI5_0_CH_0_GISR[IS_DTS] | PSI5_0_CH_0_GISR[[IS_DSROW] | PSI5_0_CH_0_GISR[IS_BROW] | PSI5_0_CH_0_GISR[[DSR_RDY] | PSI5_0_CH_0_GISR[DBR_RDY] | PSI5_0_CH_0_GISR[DPR_RDY] | PSI5_0_CH_0_GISR[IS_OWSM[6:1]] | PSI5_0_CH_0_GISR[IS_NVSM[6:1]]
614	1998h	PSI5_0 Channel 0 New message combined interrupt: New data received in any enabled PSI5_0 Channel 0 message buffer	PSI5_0_CH_0_NDSR[NDS31] | PSI5_0_CH_0_NDSR[NDS30] | … | PSI5_0_CH_0_NDSR[NDS1] | PSI5_0_CH_0_NDSR[NDS0]
615	199Ch	PSI5_0 Channel 0 Message Overwrite combined interrupt: Overwrite of any PSI5_0 Channel 0 message buffer	PSI5_0_CH_0_OWSR[NDS31] | PSI5_0_CH_0_OWSR[NDS30] | … | PSI5_0_CH_0_OWSR[NDS1] | PSI5_0_CH_0_OWSR[NDS0]
616	19A0h	PSI5_0 Channel 0 Error combined interrupt: Error in any enabled PSI5_0 Channel 0 message buffer	PSI5_0_CH_0_EISR[NDS31] | PSI5_0_CH_0_EISR[NDS30] | … | PSI5_0_CH_0_EISR[NDS1] | PSI5_0_CH_0_EISR[NDS0]
617	19A4h	PSI5_0 Channel 0 Global interrupt: Global OR of all the previous PSI5_0 Channel 0 sources	PSI5_0_CH_0_DSR[*] | PSI5_0_CH_0_GISR[*] | PSI5_0_CH_0_NDSR[31:0] | PSI5_0_CH_0_OWSR[31:0] | PSI5_0_CH_0_EISR[31:0]
624	19C0h	PSI5_1 Channel 0 DMA Combined interrupt: – DMA transfer complete – DMA SENT frame transfer complete – Fifo full or underflow of the RAM register – Underflow in the PSI5 SENT message area	PSI5_1_CH_0_DSR[IS_DMA_TF_PM_DS] | PSI5_1_CH_0_DSR[IS_DMA_TF_SF] | PSI5_1_CH_0_DSR[IS_DMA_PM_DS_FIFO_FULL] | PSI5_1_CH_0_DSR[IS_DMA_SFUF] | PSI5_1_CH_0_DSR[IS_DMA_PM_DS_UF]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
625	19C4h	PSI5_1 Channel 0 combined General interrupt: – New SENT message reception – CRC error – Overwrite of unread message in corresponding SENT location (in PSI5_SFR) – DPR is ready for receiving a new data – DBR is ready for receiving a new data – DSR is ready for receiving a new data – Write to DPR while it is NOT ready – Write to DBR while it is NOT ready – Write to DSR while it is NOT ready – New value in data time stamp register – New value in sync time stamp read register	PSI5_1_CH_0_GISR[IS_CESM[6:1]] | PSI5_1_CH_0_GISR[IS_STS] | PSI5_1_CH_0_GISR[IS_DTS] | PSI5_1_CH_0_GISR[[IS_DSROW] | PSI5_1_CH_0_GISR[IS_BROW] | PSI5_1_CH_0_GISR[[DSR_RDY] | PSI5_1_CH_0_GISR[DBR_RDY] | PSI5_1_CH_0_GISR[DPR_RDY] | PSI5_1_CH_0_GISR[IS_OWSM[6:1]] | PSI5_1_CH_0_GISR[IS_NVSM[6:1]]
626	19C8h	PSI5_1 Channel 0 New message combined interrupt: New data received in any enabled PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_NDSR[NDS31] | PSI5_1_CH_0_NDSR[NDS30] | … | PSI5_1_CH_0_NDSR[NDS1] | PSI5_1_CH_0_NDSR[NDS0]
627	19CCh	PSI5_1 Channel 0 Message Overwrite combined interrupt: Overwrite of any PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_OWSR[NDS31] | PSI5_1_CH_0_OWSR[NDS30] | … | PSI5_1_CH_0_OWSR[NDS1] | PSI5_1_CH_0_OWSR[NDS0]
628	19D0h	PSI5_1 Channel 0 Error combined interrupt: Error in any enabled PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_EISR[NDS31] | PSI5_1_CH_0_EISR[NDS30] | … | PSI5_1_CH_0_EISR[NDS1] | PSI5_1_CH_0_EISR[NDS0]
629	19D4h	PSI5_1 Channel 0 Global interrupt: Global OR of all the previous PSI5_1 Channel 0 sources	PSI5_1_CH_0_DSR[*] | PSI5_1_CH_0_GISR[*] | PSI5_1_CH_0_NDSR[31:0] | PSI5_1_CH_0_OWSR[31:0] | PSI5_1_CH_0_EISR[31:0]
654	1A38h	SIPI combined Error Interrupt: – Channels 0 to 3 Timeout error – Channels 0 to 3 transaction ID error – Channels 0 to 3 acknowledge error	SIPI_ERR[TOEn] | SIPI_ERR[TIDEn] | SIPI_ERR[ACKEn] n = [0..3]
655	1A3Ch	SIPI CRC Error interrupt	SIPI_SR[GCRCE)
656	1A40h	SIPI Channel 0 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR0[RAR] | SIPI_CSR0[ACKR]
657	1A44h	SIPI Channel 1 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR1[RAR] | SIPI_CSR1[ACKR]
658	1A48h	SIPI Channel 2 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR2[RAR] | SIPI_CSR2[ACKR]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
659	1A4Ch	SIPI Channel 3 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR3[RAR] | SIPI_CSR3[ACKR]
660	1A50h	SIPI combined Event Interrupt: – Channel 0 to 3 trigger events – Maximum count reached (streaming mode) event	SIPI_SR[TE0] | SIPI_SR[TE1] |SIPI_SR[TE2] |SIPI_SR[TE3] |SIPI_SR[MCR]
661	1A54h	LFAST_0 Transmit Complete combined interrupt: – Ping response frame transmitted – Unsolicited Frame transmitted – ICLC Frame transmitted – Data frame transmitted	LFAST_0_TISR[TXPNGF] | LFAST_0_TISR[TXUNSF] | LFAST_0_TISR[TXICLCF] | LFAST_0_TISR[TXDTF]
662	1A58h	LFAST_0 Transmit Error combined interrupt: – Transmit interface not enabled error – Transmit data FIFO overflow error	LFAST_0_TISR[TXIEF] | LFAST_0_TISR[TXOVF]
663	1A5Ch	LFAST_0 Receive combined interrupt: – Frame with CTS bit low received – Data frame received – Unsolicited Frame received	LFAST_0_RISR[RXCTSF] | LFAST_0_RISR[RXDF] | LFAST_0_RISR[RXUNSF]
664	1A60h	LFAST_0 Receive Error combined interrupt: – Unsolicited frame register overflow – Rx Data FIFO Minimum Threshold reached – Rx Data FIFO Max Threshold reached – Rx Data FIFO Underflow – Rx Data FIFO Overflow – Frame with unsupported frame size received – Invalid ICLC code Received – Invalid Logical Channel Type	LFAST_0_RISR[RXUOF] | LFAST_0_RISR[RXMNF] | LFAST_0_RISR[RXMXF] | LFAST_0_RISR[RXUFF] | LFAST_0_RISR[RXOFF] | LFAST_0_RISR[RXSZF] | LFAST_0_RISR[RXICF] | LFAST_0_RISR[RXLCEF]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
665	1A64h	LFAST_0 ICLC receive combined interrupt: – Ping Frame Response failed – Ping Frame Response successful – ICLC Ping Frame Request received – ICLC frame for Test mode off received – ICLC frame for Loopback On received – ICLC frame for Clk Test mode received – ICLC frame for LFAST Slaves Tx Interface – Disable received – ICLC frame for LFAST Slaves Tx Interface Enable received – ICLC frame for LFAST Slaves Rx Interface fast mode switch received – ICLC frame for LFAST Slaves Rx Interface slow mode switch received – ICLC frame for LFAST Slaves Tx Interface fast mode switch received – ICLC frame for LFAST Slaves Tx Interface slow mode switch received – ICLC frame for PLL OFF received – ICLC frame for PLL ON received	LFAST_0_RIISR[ICPFF] | LFAST_0_RIISR[ICPSF] | LFAST_0_RIISR[ICPRF] | LFAST_0_RIISR[ICTOF] | LFAST_0_RIISR[ICLPF] | LFAST_0_RIISR[ICCTF] | LFAST_0_RIISR[ICTDF] | LFAST_0_RIISR[ICTEF] | LFAST_0_RIISR[ICRFF] | LFAST_0_RIISR[ICRSF] | LFAST_0_RIISR[ICTFF] | LFAST_0_RIISR[ICTSF] | LFAST_0_RIISR[ICPOFF] | LFAST_0_RIISR[ICPONF]
674	1A88h	JTAG Master combined interrupt: – Idle interrupt – Sequence Processing Unit interrupt	JTAGM_SR[SPU_INT] | JTAGM_SR[Idle]
675	1A8Ch	JTAG Data Communication combined interrupt: – JDC Input data received – JDC output data sent	JDC_MSR[JIN_INT] | JDC_MSR[JOUT_INT]
677	1A94h	M_TTCAN_0 Line0 combined interrupt Rx FIFO 0 New Message	(M_TTCAN_0_IR[0] & ~M_TTCAN_0_ILS[0])| ... | (M_TTCAN_0_IR[11] & ~M_TTCAN_0_ILS[11]) | (M_TTCAN_0_IR[13] & ~M_TTCAN_0_ILS[13]) | … | (M_TTCAN_0_IR[31] & ~M_TTCAN_0_ILS[31])
678	1A98h	M_TTCAN_0 Line1 combined interrupt	(M_TTCAN_0_IR[0] & M_TTCAN_0_ILS[0])| ... | (M_TTCAN_0_IR[11] & M_TTCAN_0_ILS[11]) | (M_TTCAN_0_IR[13] & M_TTCAN_0_ILS[13]) | … | (M_TTCAN_0_IR[31] & M_TTCAN_0_ILS[31])
679	1A9Ch	M_TTCAN_0 Register Time Mark	M_TTCAN_0_TTIR[RTMI]
688	1AC0h	M_CAN_1 Line0 combined interrupt	(M_CAN_1_IR[0] & ~M_CAN_1_ILS[0])| ... | (M_CAN_1_IR[11] & ~M_CAN_1_ILS[11]) | (M_CAN_1_IR[13] & ~M_CAN_1_ILS[13]) | … | (M_CAN_1_IR[31] & ~M_CAN_1_ILS[31])
689	1AC4h	M_CAN_1 Line1 combined interrupt	(M_CAN_1_IR[0] & M_CAN_1_ILS[0])| ... | (M_CAN_1_IR[11] & M_CAN_1_ILS[11]) | (M_CAN_1_IR[13] & M_CAN_1_ILS[13]) | … | (M_CAN_1_IR[31] & M_CAN_1_ILS[31])

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
690	1AC8h	M_CAN_2 Line0 combined interrupt	(M_CAN_2_IR[0] & ~M_CAN_2_ILS[0])| ... | (M_CAN_2_IR[11] & ~M_CAN_2_ILS[11]) | (M_CAN_2_IR[13] & ~M_CAN_2_ILS[13]) | … | (M_CAN_2_IR[31] & ~M_CAN_2_ILS[31])

741	1B94h	GTM DPLL TRIGGER event 1 interrupt	GTM_ICM_IRQG_1[DPLL_TE1I_IRQ]
742	1B98h	GTM DPLL TRIGGER event 2 interrupt	GTM_ICM_IRQG_1[DPLL_TE2I_IRQ]
743	1B9Ch	GTM DPLL TRIGGER event 3 interrupt	GTM_ICM_IRQG_1[DPLL_TE3I_IRQ]
744	1BA0h	GTM DPLL TRIGGER event 4 interrupt	GTM_ICM_IRQG_1[DPLL_TE4I_IRQ]
745	1BA4h	GTM DPLL TRIGGER calculated duration interrupt	GTM_ICM_IRQG_1[DPLL_CDTI_IRQ]
746	1BA8h	GTM DPLL STATE calculated duration interrupt	GTM_ICM_IRQG_1[DPLL_CDSI_IRQ]
747	1BACh	GTM DPLL TRIGGER out of range interrupt	GTM_ICM_IRQG_1[DPLL_TORI_IRQ]
748	1BB0h	GTM DPLL STATUS out of range interrupt	GTM_ICM_IRQG_1[DPLL_SORI_IRQ]
749	1BB4h	GTM TIM0 Channel 0 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH0_IRQ]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
750	1BB8h	GTM TIM0 Channel 1 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH1_IRQ]
751	1BBCh	GTM TIM0 Channel 2 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH2_IRQ]
752	1BC0h	GTM TIM0 Channel 3 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH3_IRQ]
753	1BC4h	GTM TIM0 Channel 4 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH4_IRQ]
754	1BC8h	GTM TIM0 Channel 5 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH5_IRQ]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
755	1BCCh	GTM TIM0 Channel 6 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH6_IRQ]
756	1BD0h	GTM TIM0 Channel 7 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM0_CH7_IRQ]
757	1BD4h	GTM TIM1 Channel 0 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH0_IRQ]
758	1BD8h	GTM TIM1 Channel 1 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH1_IRQ]
759	1BDCh	GTM TIM1 Channel 2 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH2_IRQ]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
760	1BE0h	GTM TIM1 Channel 3 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) ECNT – Counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH3_IRQ]
761	1BE4h	GTM TIM1 Channel 4 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH4_IRQ]
762	1BE8h	GTM TIM1 Channel 5 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH5_IRQ]
763	1BECh	GTM TIM1 Channel 6 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH6_IRQ]
764	1BF0h	GTM TIM1 Channel 7 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM1_CH7_IRQ]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
765	1BF4h	GTM TIM2 Channel 0 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH0_IRQ]
766	1BF8h	GTM TIM2 Channel 1 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH1_IRQ]
767	1BFCh	GTM TIM2 Channel 2 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH2_IRQ]
768	1C00h	GTM TIM2 Channel 3 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH3_IRQ]
769	1C04h	GTM TIM2 Channel 4 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH4_IRQ]

Table 40. Interrupt sources(Continued)

IRQ #	Offset	Source description	Source name
770	1C08h	GTM TIM2 Channel 5 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH5_IRQ]
771	1C0Ch	GTM TIM2 Channel 6 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH6_IRQ]
772	1C10h	GTM TIM2 Channel 7 shared interrupt: – New measurement value detected by SMU for channel (NEWVALx_IRQ) – ECNT counter overflow of channel (ECNTOFLx_IRQ) – SMU counter overflow (CNTOFLx_IRQ) – GPRz data overflow (GPRzOFLx_IRQ) – Timeout of input signal (TOx_IRQ) – Glitch detected on input (GLITCHDETx_IRQ)	GTM_ICM_IRQG_2[TIM2_CH7_IRQ]

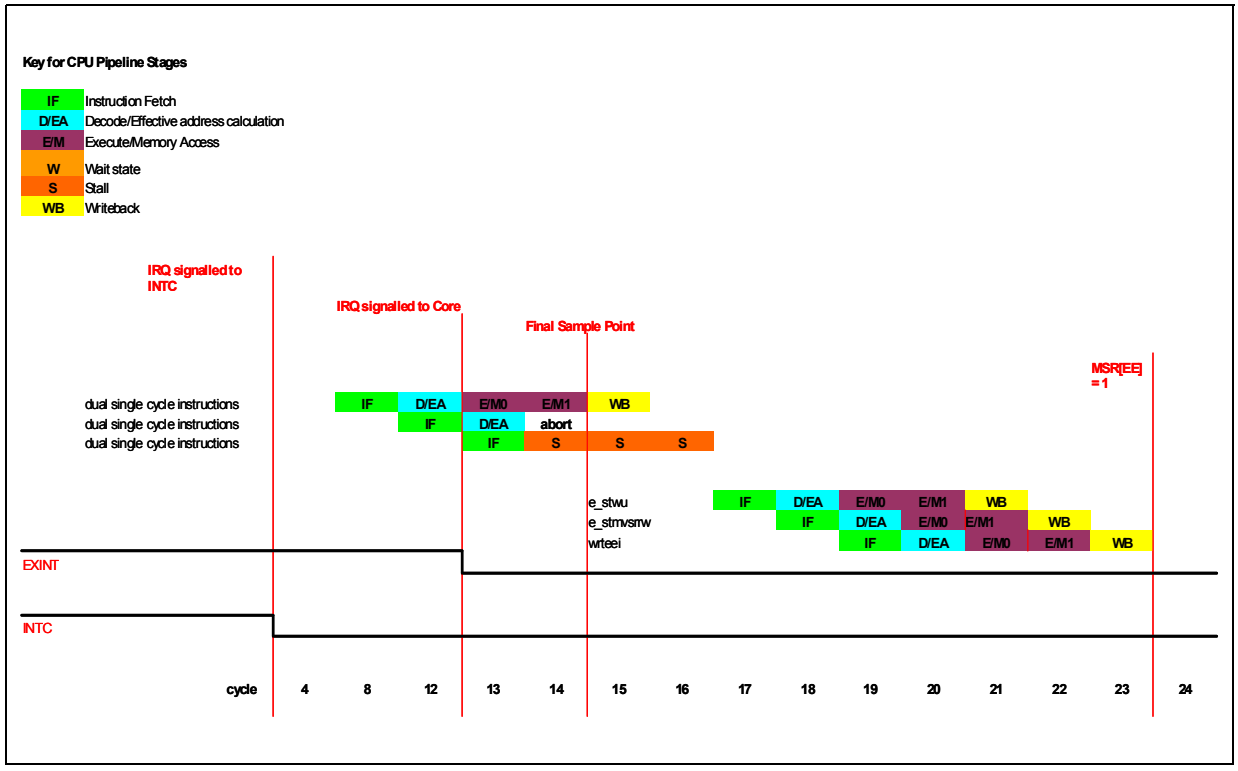
7.3.7.4 Interrupt Latency

The Interrupt systems is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

The latency time is difficult to define exactly because it depends what interrupts the INTC is processing and what the CPU is doing.



But in general, the latency time is divided into 3 sub-sections:

- INTC Latency
  - 3 clock cycles (INTC clock domain) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency
  - 4 clock cycles (CPU clock domain) from the assertion of the interrupt request from the INTC to the execution of the first instruction
- Software Latency
  - 7 clock cycles (CPU clock domain) to execute the 3 instructions needed to save essential registers and enable interrupts

For the SPC574Kx, the INTC operates at 40 MHz and the CPU operates at 160 MHz. So interrupt latency is:-

INTC Latency = 75 ns
CPU Latency = 25 ns
Software Latency = 43.75 ns
Interrupt Latency Total = 143.75 ns

Figure 18. Interrupt timing

7.3.8 DMA controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter in the device reference manual.

Figure 19. DMA controller configuration

7.3.9 DMAMUX configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.3.9.1 DMA channel assignment

SPC574Kx has four multiplexers. *Table 42* lists which channels apply to each multiplexer.

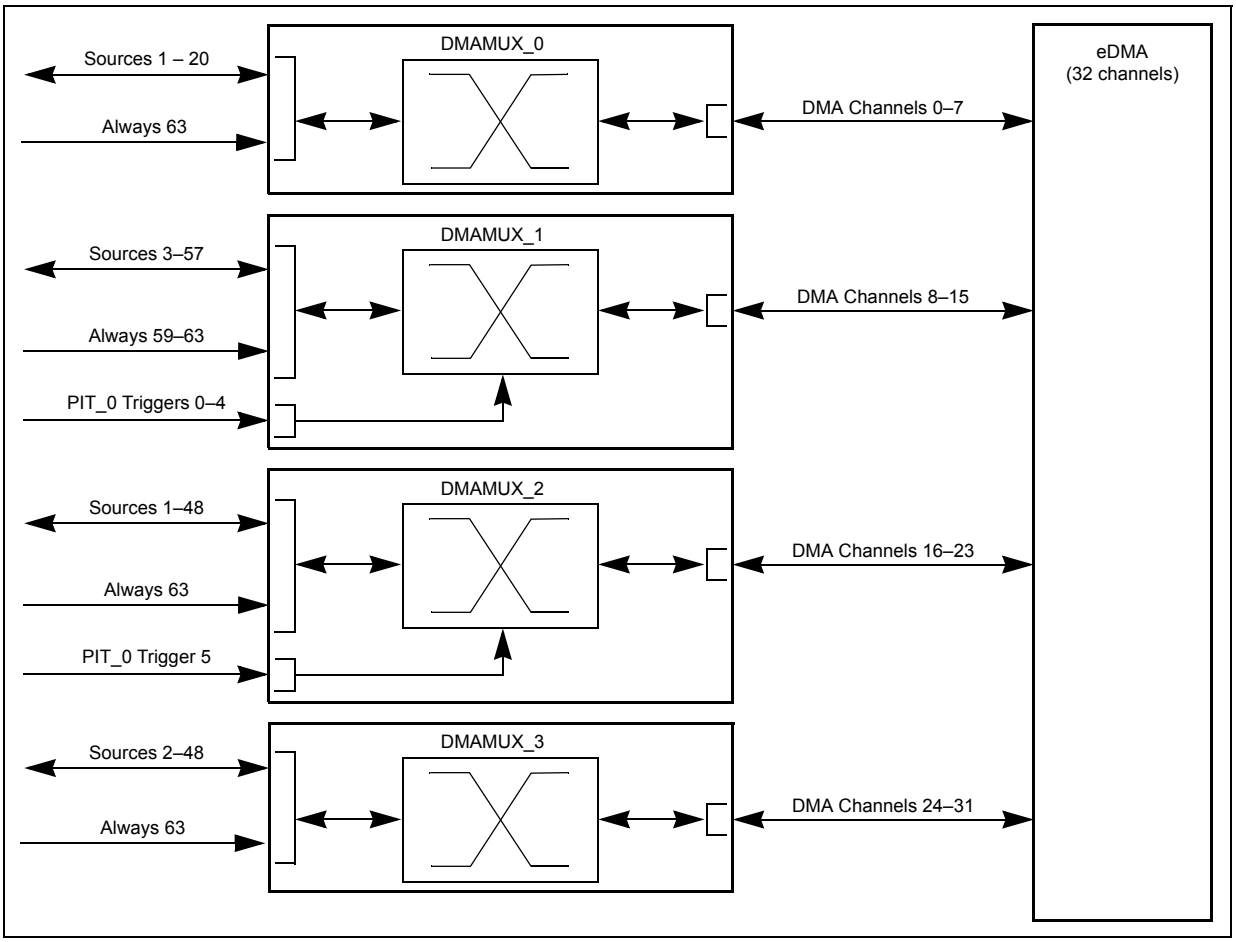

Table 42. SPC574Kx multiplexer and channel list

DMAMUX instance	DMA channel
0	0–7
1	8–15
2	16–23
3	24–31

7.3.9.2 DMA channel multiplexing block diagram

The connections of the DMA channel multiplexers to the eDMA are shown in *Figure 20*. One DMAMUX is instantiated for every eight DMA channels.

Figure 20. DMA channel multiplexing

7.3.9.3 DMA request mapping

The mapping of the peripheral DMA requests to the DMAMUX input sources is shown in *Table 43*.

5	16

7.3.9.4 DMAMUX memory map

The 4 instances of DMAMUX (0–3) share one PBRIDGE slot. Each instance is allocated 512 bytes of memory space. The DMAMUX address offsets are shown in *Table 45*.

Table 45. DMAMUX memory map

Offset[1]	Register[2]	Access
0x0000	DMAMUX_0_CHCFG0–DMAMUX_0_CHCFG7 — Channel configuration registers	R/W
0x0200	DMAMUX_1_CHCFG0–DMAMUX_1_CHCFG7 — Channel configuration registers	R/W
0x0400	DMAMUX_2_CHCFG0–DMAMUX_2_CHCFG7 — Channel configuration registers	R/W
0x0600	DMAMUX_3_CHCFG0–DMAMUX_3_CHCFG7 — Channel configuration registers	R/W

1. Offsets are from DMAMUX_0 base address , shown in *Chapter 5: Memory map*.
2. Each channel must be configured separately via settings in a dedicated configuration channel. There is one configuration register per channel for each DMAMUX. See the DMAMUX chapter for details.

7.4.1 Flash memory controller (PFLASH) configuration

The Flash controller provides Flash configuration and control functions and manages the interface between the Flash memory array and the Crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three registers PFCR1, PFCR2 and PFAPR control the interaction of master modules with the Flash array by enabling or disabling prefetch, or by controlling access to the Flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See *Table 26* in the crossbar switch configuration section for details. See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

The master assignments are shown in *Table 48*. Note that these are the same master assignments used elsewhere in the chip, for example, the SMPU.

Table 48. Flash controller bus master assignments

System memory map	—	*Chapter 5: Memory map*

7.4.1.1 Calibration remapping support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM or on-chip system RAM that can be used as overlay RAM. The relationship between flash access latency and remapped overlay RAM latency is contingent upon operating frequency and intrinsic memory access times. *Table 48* describes the intrinsic cycle latency on a random, initial access for each supported overlay RAM target.

See *Section 33.5.12: PFlash calibration remap support* for more details on the relationship between flash access latency and overlay RAM access latency.

Note: Cycle times measured based on the PFLASH clock.

See Chapter 26: Clocking for more details on clocking.

Table 50. Calibration memory access times

Calibration memory	Burst access time (cycles)
On-chip overlay RAM	5
Buddy device overlay RAM	8
System RAM	9

7.4.1.2 Wait state settings for overlay flash latency matching

A remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to

a value which sufficiently covers the intrinsic access time for a flash access as well as the required access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. *Table 51* describes the minimum supported flash wait state setting to guarantee a remapped access matches the response latency of a flash access.

Table 51. Minimum wait state settings for overlay flash latency match

Overlay Target	PFCR1[RWSC] Minimum Value
On-chip overlay RAM	3
Buddy device overlay RAM	6
System RAM	6

If PFCR1[RWSC] is set sufficiently high such that the remapped burst access completes before flash read data is expected to be returned, the flash controller stalls the return of overlay data the appropriate number of additional cycles to ensure the access time matches the response latency of a flash access. Once the overlay access is stored in the flash controller mini-cache, subsequent requests that hit in the mini-cache are returned with zero wait state latency.

7.4.2 Decorated Storage Memory Controller (DSMC)

The DSMC supports five store and three load operations, including:

- Bit field inserts
- Compare-and-store
- Bitwise AND, OR and XOR operators
- Simple memory load
- Swap
- Load-and-set-1(bit)

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.

The module includes error checking logic that validates whether the decoration field is properly defined (all illegal commands are rejected and the transfer error-terminated). Additionally, the DSMC operates on aligned, single data transfers only (misalignment and bursts are not supported and error-terminated if attempted).

The DSMC is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

For the SPC574Kx device, the DSMC is instantiated five times:

- 2 instantiations in the computational platform shell:
  - System RAM
  - Main Core 0 xMEM (Backdoor Port to the core local Instruction and Data Memories)
- 3 instantiations in the peripheral platform shell:
  - IOP xMEM (Backdoor Port to the core local Instruction and Data Memories)
  - AIPS-Lite A (Peripheral Bridge A)
  - AIPS-Lite B (Peripheral Bridge B)

Caution: Do NOT perform decorated accesses to any address spaces other than those explicitly listed above.

7.5 Analog modules

The following analog modules are implemented on SPC574Kx:

Table 52. Analog modules

Module or Subsystem	Device-specific information	Block details
Temperature sensor	*Section 7.5.1: Temperature sensor configuration*	*Chapter 40: Temperature Sensor*
ADC subsystem	*Section 37.1: ADC overview*	See individual modules.
Sigma-Delta Analog-to-Digital Converters (SDADCs)	*Section 38: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface*	*Chapter 38: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface*
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	*Section 37.2.1: Sigma-Delta Analog-to-Digital Converter (SDADC)*	*Chapter 39: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface*

7.5.1 Temperature sensor configuration

The temperature sensor is used to measure the temperature of the SPC574Kx device. In general, the temperature sensor generates an analog voltage that is linearly proportional to temperature.

During production testing of the device, the output of the temperature sensor is sampled by SARB input channel 120 of the onboard ADC module at a predefined high and a predefined low temperature. These two temperature sensor readings are used to calculate constants, TSCA and TSCB, according to the formulas in *Chapter 40: Temperature Sensor*.

Once calculated, the values for TSCA and TSCB are programmed during production test into the UTEST flash memory at locations 0x0040_0000 and 0x0040_0002, respectively.

The ADC bandgap voltage used in the temperature calculation is sampled by SARB input channel 121 of the onboard ADC module.

Software must perform the following steps in order to calculate device temperature:

1. Measure the bandgap voltage, $V_{BG}(T)$, using SARB input channel 121 of the onboard ADC module.
2. Calculate $V_{BG_CODE}(T)$ according to the formula in *Chapter 40: Temperature Sensor*.
3. Measure the temperature sensor output voltage, $V_{TSENS}(T)$, using SARB input channel 120 of the onboard ADC module.
4. Calculate $T_{TSENS_CODE}(T)$ according to the formula in *Chapter 40: Temperature Sensor*.
5. Retrieve parameters TSCA and TSCB from flash memory.
6. Calculate T according to the formula in *Chapter 40: Temperature Sensor*.

7.5.2 Analog-to-Digital Converters (ADC) configuration

See *Chapter 37: Analog-to-digital converter (ADC) configuration* for an overview of the ADC subsystem including a block diagram and summary of analog input pin multiplexing. The chapter also provides configuration details for the SARADCs and SDADCs.

7.5.3 SDADC configuration

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides the accurate conversion data for a wide range of applications.

SPC574Kx includes two independent 16-bit SDADCs.

For details, see *Chapter 37: Analog-to-digital converter (ADC) configuration*.

7.5.4 SARADC configuration

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

SPC574Kx includes five independent 12-bit SARADCs. SARADC_B has access to all external analog input pins, access to the external multiplexed inputs, and has special safety features.

For details, see *Chapter 37: Analog-to-digital converter (ADC) configuration*.

7.6 Timers

Three types of timers and a complex timer subsystem are implemented on SPC574Kx.

Table 53. Timers

Timer	Device-specific information	Block details
System Timer Module (STM)	*Section 7.6.1: System Timer Module (STM) configuration*	*Chapter 42: System Timer Module (STM)*
Software Watchdog Timer (SWT)	*Section 7.6.2: Software Watchdog Timer (SWT) configuration*	*Chapter 43: Software Watchdog Timer (SWT)*

Table 53. Timers(Continued)

Timer	Device-specific information	Block details
Periodic Interrupt Timer (PIT)	*Section 7.6.3: PIT configuration*	*Chapter 44: Periodic Interrupt Timer (PIT)*
GTM122 Generic Timer Module	*Section 7.6.4: GTM subsystem configuration*	*Chapter 46: Generic Timer Module (GTM122)*

Each core will have a dedicated System Timer Module (STM) and a dedicated Software Watchdog Timer (SWT). The checker core does not have a dedicated STM.

Two Periodic Interrupt Timer (PIT) module instances are implemented. One PIT module is for 64-bit timer implementation by way of two 32-bit timer channels (0 and 1) with chaining mode. The timer value of this 64-bit timer is unchanged by a non-destructive reset. The other PIT module is for general use and has eight 32-bit timer channels with no chaining mode.

The GTM122 is an implementation of the Robert Bosch GmbH GTM timer subsystem. It is not a single module; it is a complex timer subsystem that consists of many modules. It can be used to implement highly complex timer functions.

7.6.1 System Timer Module (STM) configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the appropriate system clock divided by an 8-bit prescale value (1 to 256).

SPC574Kx includes two STMs, one for each core, both with four 32-bit compare channels and clocked with the peripheral bridge frequency (PBRIDGEx_CLK).

Table 54. System Timer Module (STM) instances

Instance	Description	Number of channels	Number of registers (32-bit)
STM_0	Intended for Main Core_0	4	14
STM_2	Intended for Peripheral Core_2	4	14

7.6.2 Software Watchdog Timer (SWT) configuration

SPC574Kx includes three SWTs.

Table 55. Software Watchdog Timer (SWT) instances

Instance	Description
SWT0	Intended for Main Core_0 in the high-speed computational clock domain.
SWT2	Intended for Peripheral Core_2 in the peripheral clock domain. Elapsed times recorded in timeout register are different from SWT0.
SWT3	Intended as security watchdog timer in the peripheral clock domain. Elapsed times recorded in timeout register are different from SWT0.

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Programmable selection of system or internal oscillator clock for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.6.2.1 Security watchdog

SWT3 (SWT3 Security) is identical to the other SWT modules except the Instruction Address Compare feature is **not** instantiated.It is anticipated that each CPU would use an SWT to ensure software tasks continue to execute correctly.

If a CPU malfunctions (either software or hardware) the SWT is no longer serviced and a reset occurs. This is referred to as a Task Watchdog. The Security Watchdog is slightly different from the Task Watchdog.

The Security watchdog is intended to be serviced when the CPU executes an instruction at a specific address location. This address location would be an address within some fundamental section of security code. If this address location is not executed regularly, it implies that a malicious security attack has occurred and the device should be reset.

Additionally, the Security watchdog is deactivated by a device Power-On-Reset.

This security code could be executed on any of the CPUs. The SWT for that CPU would perform the Security Watchdog (SWT0 or SWT2) because it includes the IAC feature. The Task Watchdog for that CPU would need to use SWT3 (Security), which does **not** include the IAC feature.

As a result the SWT3 (Security) is never used to perform the Security Watchdog; but is used for Task Watchdog to replace the SWT that **is** actually being used for Security Watchdog.

7.6.2.2 Reset assertion

The SWT can assert a reset when the watchdog timer expires. This reset causes a system reset equivalent to assertion of the RESET pin.

7.6.2.3 Default configuration

On SPC574Kx, the SWTs come out of reset with the default reset values summarized in *Table 56*. Minimum timeout value is 256 cycles for SWT0, SWT2 and SWT3.

Table 56. Register reset values

SWT instance	Register	Reset value
SWT0	SWT Control Register (SWT_CR)	0xFF00_010A
SWT0	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT2	SWT Control Register (SWT_CR)(1)	0xFF00_011B
SWT2	SWT Time-out (SWT_TO)	0x0003_FDE0

Table 56. Register reset values(Continued)

SWT instance	Register	Reset value
SWT3	SWT Control Register (SWT_CR)	0xFF00_010A
SWT3	SWT Time-out (SWT_TO)	0x0005_FCD0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is '1', but the DCI can override that default value by setting it to '0'. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT; it cannot enable it.) See the DCI chapter for details on the system watchdog control.

The Security Watchdog (SWT3) is enabled using DCF Records in conjunction with the BAF. Please see *Section 59.2.5.2: Security watchdog configuration* for details.

7.6.2.4 Service mode watchpoint input

Each SWT comes out of reset in 'Fixed Service Sequence' mode (SWT_CR[SMD] = 2'b00), but the Instruction Address Compare 8 (IAC8) register (SPR 568) can be used for servicing by using the SWT jd_watchpt input.

To use SWT address execution modes for this purpose, the e200z2 and e200z4 core IAC8 register signal jd_watchpt[15] is connected to the SWT jd_watchpt input. (See *Section 65.6: Watchpoint support* for details.) The jd_watchpt[15] signal tells the SWT that an IAC8 compare occurred.

Set SWT_CR[SMD] to one of the following so the SWT is serviced by executing code at the address loaded into the IAC8 register:

- 2'b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this 'freezes' changes to the IAC8 register when the SWT is enabled.
- 2'b11 for Incremental Address Execution; the IAC8 register can be updated.

7.6.3 PIT configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 21. PIT configuration

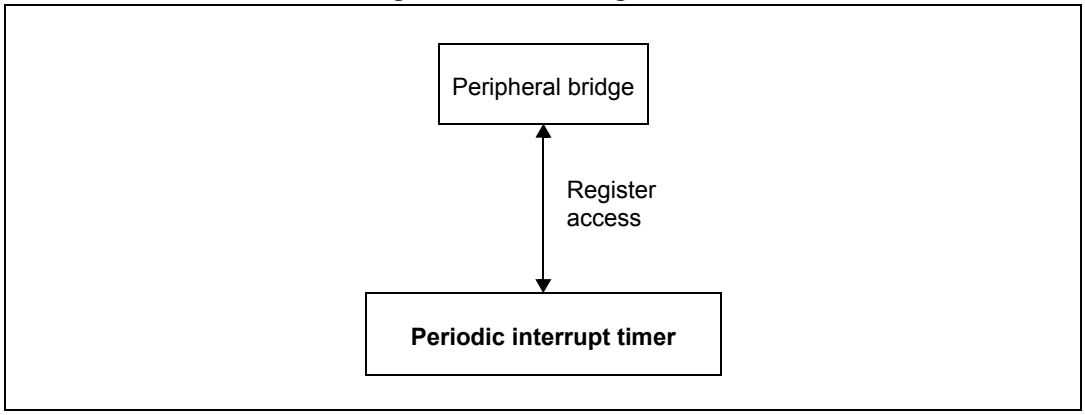

Table 57. Reference links to related information

Topic	Related module	Reference
Full description	PIT	*Chapter 44: Periodic Interrupt Timer (PIT)*
System memory map	—	*Chapter 5: Memory map*
Clocking	—	*Chapter 26: Clocking*
Power management	—	*Chapter 11: Power management*
DMA channel assignments	Direct memory access multiplexer	*Chapter 25: Direct Memory Access Multiplexer (DMAMUX)*

7.6.3.1 PIT instantiation

Table 58. PIT information

PIT module	Number of channels	Description
PIT0	6 + RTI	PIT0 has 6 standard channels and 1 RTI channel. In PIT0, all registers are cleared by any reset.
PIT1	2	PIT1 has chaining mode to implement a 64-bit timer and the timer value is unchanged by a functional reset.

7.6.3.2 PIT/DMA periodic trigger assignments

In PIT1, DMA is not supported. PIT0 generates periodic trigger events to the DMAMUX as shown in *Table 59*.

Table 59. PIT0 channel assignments for periodic DMA triggering

DMA channel	PIT0 channel
DMA Channel 8	PIT0 Channel 0
DMA Channel 9	PIT0 Channel 1
DMA Channel 10	PIT0 Channel 2
DMA Channel 11	PIT0 Channel 3
DMA Channel 12	PIT0 Channel 4
DMA Channel 16	PIT0 Channel 5

To check the mapping of the PIT0 channel number with the corresponding DMA channel number, refer to the *Table 43*.

On top of DMA periodic triggering, it is possible to use PIT0 - Channel0 timer to regularly generate the tick event to the FlexRay module (*Chapter 53: FlexRay Communication Controller (FlexRay)*) and the time trigger CAN (*Section 48.4: Time Triggered Modular CAN (M_TTCAN) core*).

7.6.3.3 PIT registers

Table 60 and *Table 61* show the implementation of PIT registers in this MCU.

Table 60. PIT0 memory map

Absolute address (hex)	Register name
FFF8_0000	PIT Module Control Register (PIT0_MCR)(1)
FFF8_00E0 – FFF8_00E4	Reserved
FFF8_00F0 – FFF8_00FC	RTI Timer Channel Registers (PIT0_RTI_LDVAL, PIT0_RTI_CVAL, PIT0_RTI_TCTRL, PIT0_RTI_TFLG)
FFF8_0100 – FFF8_017C	Timer Channel [0:5] Registers (PIT0_LDVALn, PIT0_CVALn, PIT0_TCTRLn, PIT0_TFLGn)
FFF8_0180 – FFF8_3FFF	Reserved

1. The reset value of PIT0_MCR is 0x06.

Table 61. PIT1 memory map

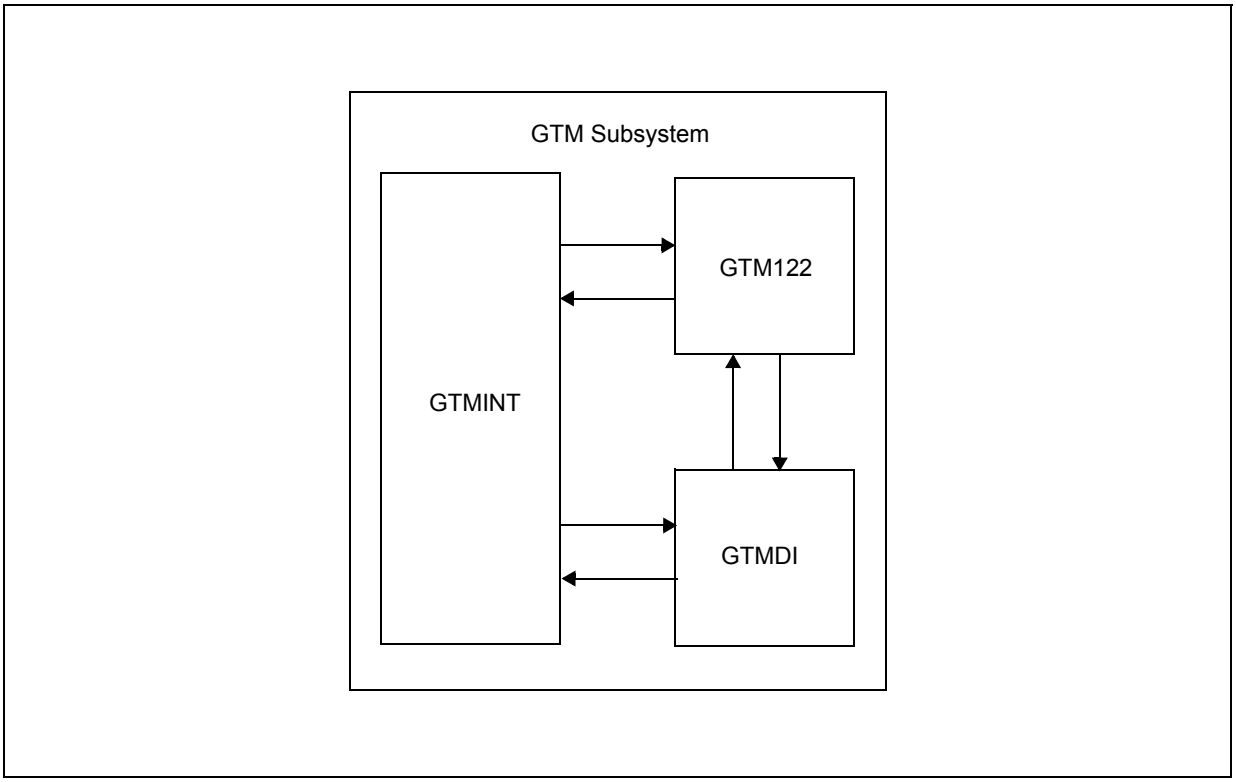
Absolute address (hex)	Register name
FFF8_4000	PIT Module Control Register (PIT1_MCR)(1)
FFF8_40E0	PIT Upper Lifetime Timer Register (PIT1_LTMR64H)
FFF8_40E4	PIT Lower Lifetime Timer Register (PIT1_LTMR64L)
FFF8_40F0 – FFF8_40F8	Reserved
FFF8_4100 – FFF8_411C	Timer Channel [0:1] Registers (PIT1_LDVALn, PIT1_CVALn, PIT1_TCTRLn, PIT1_TFLGn)
FFF8_4120 – FFF8_7FFF	Reserved

1. The reset value of PIT1_MCR is 0x02.

7.6.3.4 PIT clocking

The PIT0 standard channels are clocked with the peripheral clock (PER_CLK).

The PIT0 RTI channel clock source is selectable between XOSC and RCOSC via the auxiliary clock selector 9.



The PIT1 channels are clocked with the peripheral clock (PER_CLK).

7.6.4 GTM subsystem configuration

7.6.4.1 GTM subsystem

This diagram illustrates the parts of the GTM subsystem.

Figure 22. GTM subsystem

7.6.4.2 Parts of the GTM subsystem

This table describes the parts of the GTM subsystem.

Table 62. Parts of the GTM subsystem

Part	Function
GTMINT	Provides reset control, clock control, error-correcting code (ECC) functionality, interrupt and DMA control, and access to GTM122's memorymapped registers. For debug accesses from GTMDI to GTM122 registers, prevents destructive read accesses into the GTM122 registers.
GTM122	Provides programmable timer functionality.
GTMDI	Provides real-time development capabilities for the GTM subsystem.

7.6.4.3 GTM subsystem clock sources

The system clock and the peripheral clocks to the GTM subsystem are provided by the Clock Generation Module (MC_CGM).

Table 63. GTM subsystem clock sources

GTM subsystem clock	MC_CGM source	Maximum frequency
SYS_CLK	SXBAR_CLK	80 MHz
GTMIP_CLK	PER_CLK	80 MHz

Table 63. GTM subsystem clock sources(Continued)

GTM subsystem clock	MC_CGM source	Maximum frequency
GTMDI_CLK	PER_CLK	80 MHz
GTMINT_CLK	PER_CLK	80 MHz

7.6.4.4 Reset value of GTM Module Configuration Register (GTMMCR)

GTMMCR contains the control bits to configure the general operation of GTMINT and GTM-IP. The reset value of the register is 4000_4000h, which means that after reset the GTM subsystem is in Stop mode.

7.7 Communication interfaces

7.7.1 FEC interface

The Fast Ethernet Controller on the SPC574Kx device only supports the Reduced Media Independant Interface (RMII) mode. The MII_MODE field in the Receive Control Register *Figure 892: Receive Control Register (RCR)* must be set by the user to “1” prior to FEC initialization — see section *Section 52.5.5: User initialization (Prior to Setting ECR[ETHER_EN])*.

Note: The RMII_MODE field is fixed by hardware to ‘1', and is not configurable by the user. SIUL2_SCR0[FEC_MODE] is not implemented on this device.

Refer to *Chapter 52: Fast Ethernet Controller (FEC)* for detailed description.

7.7.2 CAN subsystem configuration

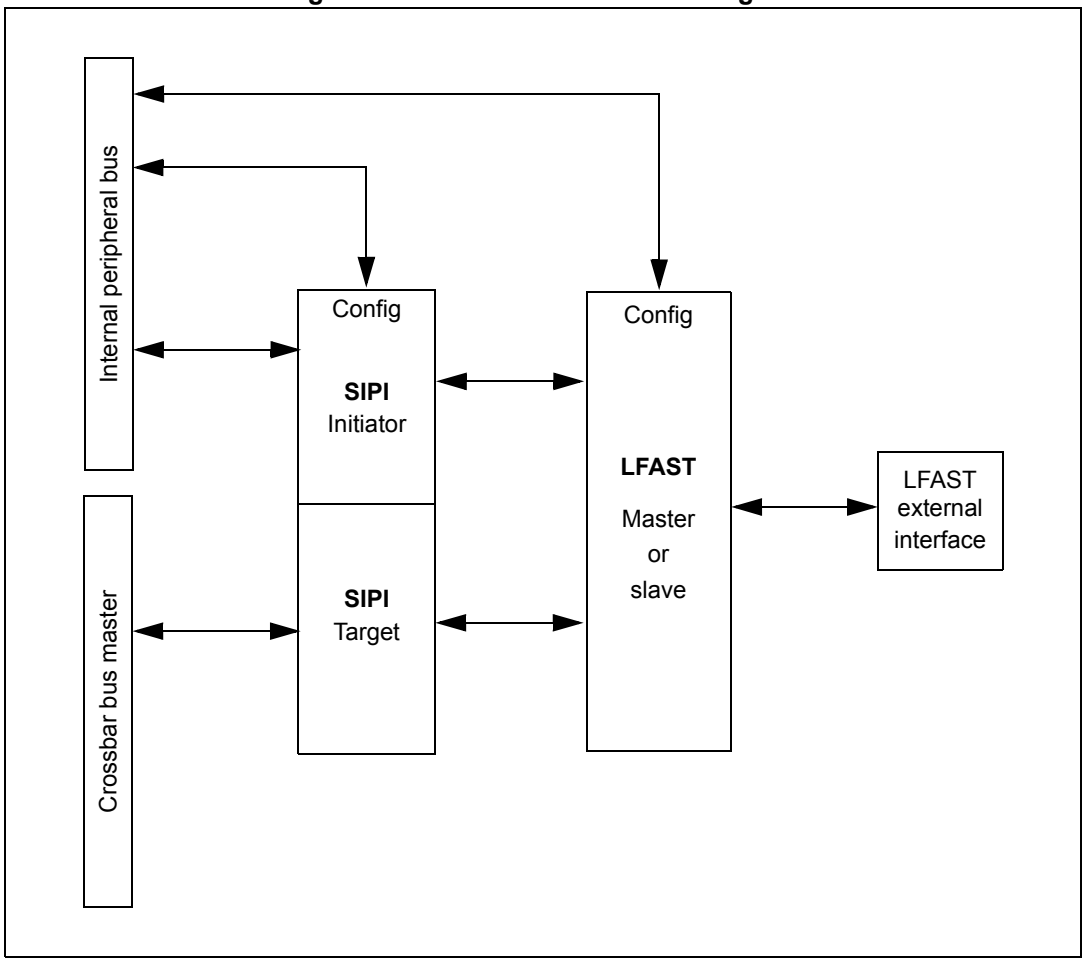
7.7.2.1 CAN nodes

Table 64 lists the different CAN nodes.

Table 64. CAN bus controllers

Type	Instances	CAN FD support up to 64 data byte (M_CAN Rev 3.x)	CAN FD support up to 8 data byte (M_TTCAN Rev 2.x)	Debug on CAN support	Clock calibration(1)
M_CAN	M_CAN_1	Yes	—	Yes	Yes
	M_CAN_2	Yes	—	Yes	Yes
	M_CAN with TTCAN (M_TTCAN)	—	Yes	Yes(2)	Yes

1. *Clock calibration* based on M_CAN_1 messages.
2. *Debug on CAN* support is available on this M_TTCAN instance, but there is no DMA channel assigned.



7.7.3 LFAST and SIPI

This section summarizes the module configuration in the controller. For a comprehensive description of SIPI and LFAST, please reference the specific dedicated chapters for SIPI and LFAST.

7.7.3.1 Instantiation

The SIPI and LFAST are connected together appearing as a single unit. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules (see *Figure 23*).

Figure 23. LFAST and SIPI block diagram

7.7.3.2 Device specific features

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link but SIPI in both master and slave nodes can act as both Initiator and Target for SIPI commands simultaneously. Please see the SIPI and LFAST dedicated chapters for detailed information on module operations. The SIPI CHIP ID = 0AF06041h for the SPC574Kx.

7.7.3.3 Memory map and register description

7.7.4.1 DSPI instantiation

This device contains five DSPI modules. *Table 67* shows the instantiation information for each module.

Table 67. DSPI instantiation

DSPI module	CTARs	TX FIFO depth	RX FIFO depth	PCS signals	LVDS support	Data serialization support
DSPI_0	8	4	4	PCS[7:0]	Not available	—
DSPI_1	8	4	4	PCS[7:0]	Not available	—
DSPI_2	8	4	4	PCS[7], PCS[4:0]	Available	—
DSPI_4	8	4	4	PCS[7:0]	Available(1)	64
DSPI_5	8	4	4	PCS[7:0]	Available(2)	32

1. Supports Microsecond Bus SCK and SOUT LVDS signal pairs.
2. Supports Microsecond Bus SCK and SOUT LVDS signal pairs; supports Differential DSPI with SCK, SIN and SOUT LVDS signal pairs.

7.7.4.2 Serial input for DSI mode

Serial input for the DSI mode is selected using the SIUL register(d):

- DSPI4 DSI0-31 is managed by MSCR656-MSCR687
- DSPI4 DSI32-63 is managed by MSCR936-MSCR967
- DSPI5 DSI0-31 is managed by MSCR688-MSCR719

7.7.4.3 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all ‘1’s.

7.7.4.4 Serialized timed I/O

The timer sources and injection pin inputs to be DSPI serialized downstream outputs are selected through the SIUL2 Multiplexed Single Configuration Registers (MSCRs). Inversion of these signals is also handled in the SIUL2. Refer to the Signal Description chapter for details.

7.7.4.5 High speed and microsecond channel support

The baud rate generator in the DSPI is clocked from the peripheral clock. The DSPI module can operate at a baud rate up to half the peripheral clock. The peripheral clock frequency specification is 16 MHz to 80 MHz. As long as the peripheral clock is ≥ 100 MHz, 50 MHz baud is achievable.

To support microsecond channel functionality, two pairs of LVDS pads are implemented per DSPI. In the SIUL2_MSCR, the user can configure the desired port driving behavior (either

d. The SPC574Kx I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® workbook file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

CMOS or LVDS) for the DSPI SOUT and CLK signals for those instances specified with LVDS pins. Also configurable inside the SIUL2_MSCR are the input signals which should be serialized for TSB mode.

The following four external pins can be inserted into the MSC data stream:

- 0000_0010 IO_PAD PC[2]
- 0000_0011 IO_PAD PD[8]
- 0000_0100 IO_PAD PF[3]
- 0000_0101 IO_PAD PJ[4]

Details of these pin assignments can be found in the SPC574Kx I/O Signal Description and Input Multiplexing Tables(d).

7.7.4.6 DSPI HT External Trigger

Use of external hardware triggers are not supported.

7.7.4.7 DSPI ITSB Mode

For the ITSB trigger, the internal DSPI trigger (TRGPRD in DSICR1) will be used. Use of external trigger is not supported.

7.7.4.8 DSPI registers

Table 68 shows the absolute addresses of DSPI module registers in this MCU.

Table 68. DSPI registers memory map

Absolute address (hex)	Module
FBE7_0000	DSPI2 registers
FBE7_8000	DSPI5 registers
FFE7_0000	DSPI0 registers
FFE7_4000	DSPI1 registers
FFE7_8000	DSPI4 registers

7.7.4.8.1 DSPIx_MCR Implementation

Figure 25 shows the implementation of the DSPIx_MCR in this MCU.

Address: Base + 0x0000 Access: User read/write

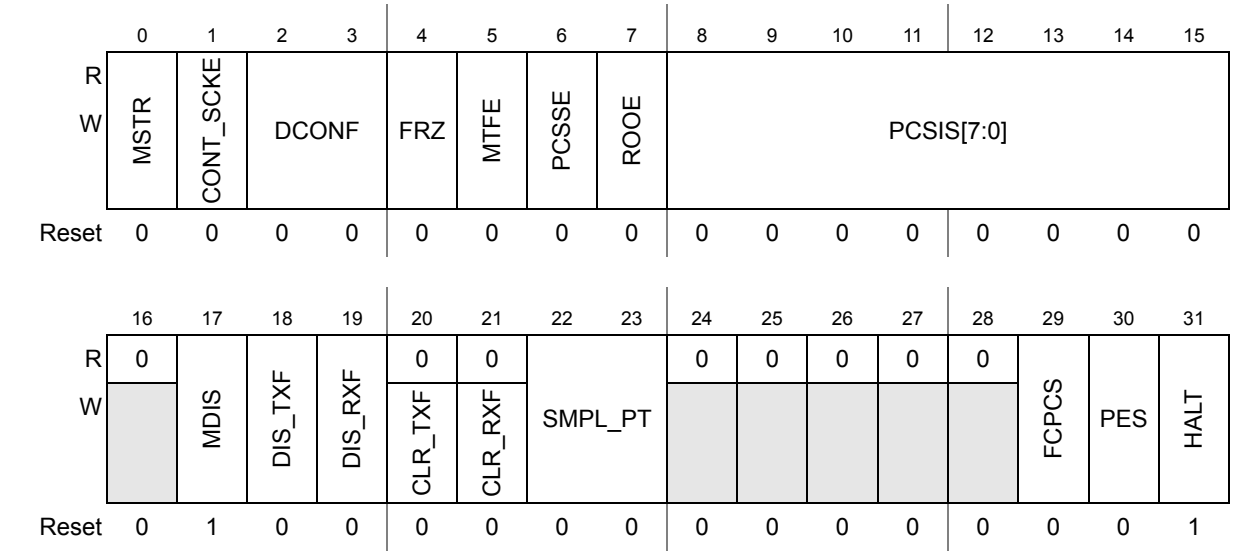

Figure 25. DSPI Module Configuration Register (DSPI*x*_MCR)

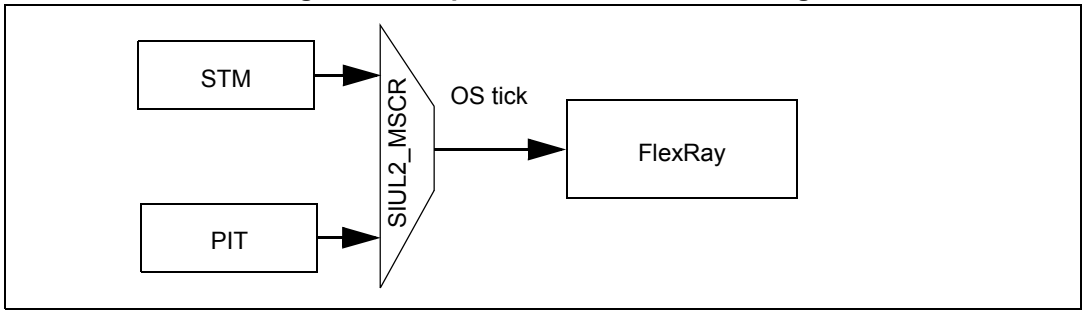
7.7.5 FlexRay Configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of safety system.

7.7.5.1 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 69. FlexRay_0 pin names



Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXD0_A
FR_A_TX (Transmit Data Channel A)	TXD0_A
$\overline{\text{FR_A_TX_EN}}$ (Transmit Enable Channel A)	TXEN0_A
FR_B_RX (Receive Data Channel B)	RXD0_B
FR_B_TX (Transmit Data Channel B)	TXD0_B
$\overline{\text{FR_B_TX_EN}}$ (Transmit Enable Channel B)	TXEN0_B
FR_DBG[0] (Debug Strobe Signal 0)	FR0_DBG0
FR_DBG[1] (Debug Strobe Signal 1)	FR0_DBG1
FR_DBG[2] (Debug Strobe Signal 2)	FR0_DBG2
FR_DBG[3] (Debug Strobe Signal 3)	FR0_DBG3

7.7.5.2 FlexRay Stopwatch timer source muxing

Stopwatch timer input is routed to FlexRay module (selected by SIUL MSCR register) via:

- STM0_CMP0
- STM2_CMP0
- PIT0_CH0

Figure 26. Stopwatch timer source muxing

7.7.6 PSI5 controller configuration

The PSI5 controller has two instances in SPC574Kx. *Table 70* shows the configuration for the two instances.

Table 70. PSI5 controller configuration

Signal name	Description	Value	
		PSI5_0	PSI5_1
PSI5_NUM_CH	Number of channels	1	1
PSI5_PDIS_RST	Default state of the IP after reset	1	1

7.7.7 SENT Receiver (SRX) configuration

7.7.7.1 SRX channels

Table 71 shows the SENT receiver channels for each instance configured on this chip.

Table 71. SENT channel configuration

Instance	Channels (CH)
SENT 0	4
SENT 1	2

7.7.7.2 SRX registers

Table 72 lists the address offset and memory map for both SENT receiver (SRX) instances for this chip.

Table 72. SENT receiver memory map

7.7.8 LINFlexD configuration

7.7.8.1 LINFlexD instance configurations

SPC574Kx has five instances of LINFlexD. *Table 73* lists the configuration for each instance.

Table 73. LINFlexD instance configurations

Description	linflex_0	linflex_1	linflex_2	linflex_14	linflex_15
Number of filters implemented	16	0	0	0	0
Number of Tx DMA channels	1	1	1	1	1
Number of Rx DMA channels	1	1	1	1	1
LIN operation mode	Master/Slave	Master	Master	Master	Master
Value of autosynchronization	1	0	0	0	0

7.7.8.2 LINFlexD implemented registers

Table 74 shows the registers implemented for each LINFlexD instance on the SPC574Kx chip.

Table 74. LINFlexD register comparison map

7.8 Reset and Boot modules

7.8.1 Flash initialization during reset

This section describes the behavior of the Flash Initialization under specific conditions. If a High Voltage Detect (HVD) for the 5 V supply (also named HVD15_C) is set to be a functional reset, then some HVD15_C events will also cause a Flash Initialization error due to the SWT watchdog timer that monitors the Flash during reset. This is because the voltage must be returned to a valid range before exits from reset is allowed, and the SWT watchdog timer is enabled during this time. This does not affect destructive resets, or any other LVDs or HVDs than the HVD15_C.

7.8.2 BAF configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

7.8.2.1 Memory map

The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block. The BAF block base address is 0040_4000h. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in *Table 75*.

Table 75. BAF memory organization

BAF Component	Address
BAF version number	0040_4000h
BAF code entry point	0040_4100h
BAF data area and stack	5280_0000h – 5280_034Fh

7.8.2.2 Search boot header and boot options

The BAF searches the flash memory for the boot header, checking the first word location of the 4 × 16 KB blocks and then the 4 × 256 KB blocks. The blocks are searched in the order shown in the following table and once a Boot Header is found, no further blocks are searched.

Table 76. Locations of boot headers

Search order	Block	Address
1st	16 KB Code flash memory block1	00FC_0000h
2nd	16 KB Code flash memory block2	00FC_4000h
3rd	16 KB Code flash memory block3	00FC_8000h
4th	16 KB Code flash memory block4	00FC_C000h
5th	256 KB Code flash memory block0	0100_0000h
6th	256 KB Code flash memory block1	0104_0000h
7th	256 KB Code flash memory block2	0108_0000h
8th	256 KB Code flash memory block3	010C_0000h

The first header found that contains the value 005Ah in the first half-word is valid for booting. The whole header structure is shown in *Table 77*.

Table 77. Boot header structure

Address offset	Contents
00h	Boot Header Configuration (see *Figure 27*)
04h	CPU2 Reset Vector
08h	Configuration Bits
0Ch	Configuration Bits
10h	CPU0 Reset Vector
14h	Reserved
18h	CPUC Reset Vector

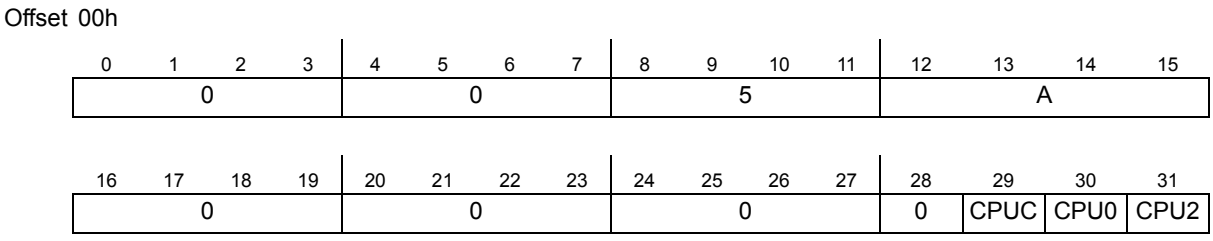

Figure 27. Boot header configuration

Table 78. Boot header configuration field description

Field	Description
CPUC	CPU0-Checker Core is enabled. (starts execution at CPUC Reset Vector. If this is different from CPU0 Reset Vector, then a lockstep error occurs as the CPU comes out of reset)
CPU0	CPU0 is enabled (starts execution at CPU0 Reset Vector)
CPU2 (IOP)	CPU2 (IOP) is enabled (starts execution at CPU2 Reset Vector)

The cores that are enabled in the boot header configuration field are enabled by programming ME_CCTL*n*[DRUN] register to run in all DRUN modes and their reset vector is set in register ME_CADDR*n*. Then, the memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration and make the cores jump to their respective reset vectors. At this point the BAF has finished its operation.

7.8.2.3 LINFlexD_0 and M_CAN_1 pin configuration

Table 79 shows the device pin configurations for LINFlexD_0 and M_CAN_1 modules.

Table 79. M_CAN_1 and LINFlexD_0 pin configuration

Pads	Reset Function	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received	Serial Boot Mode after a valid LINFlexD message received
		Function	Pad Configuration	Function	Function
PA[10]	GPIO Input buffer off Output buffer off	M_CAN_1 Tx	Output:— Push/Pull medium drive no pullup/pulldown	M_CAN_1 Tx	LINFlexD_0 Tx
PA[11]	GPIO Input buffer off Output buffer off	LINFlexD_0 Rx and M_CAN_1 Rx	Input:— pull-up hysteresis TTL voltage level	M_CAN_1 Rx	LINFlexD_0 Rx

7.8.3 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the SPC574Kx. For a comprehensive description of the SSCM, please refer to the SSCM's dedicated chapter.

7.8.3.1 SSCM instantiation

There is one SSCM instance in the SPC574Kx device.

7.8.3.2 Device-specific features

The SSCM will set the reset vector for the IOP to execute from the BAF (*Chapter 59: Boot Assist Flash (BAF)*). The BAF allows boot from Flash and external booting from the LINFlexD port without autobaud.

The device-specific reset values for the SSCM_MEMCONFIG register are shown in *Table 80*.

Table 80. SSCM_MEMCONFIG reset values

Field	Field definition	Value
MREV	Minor Revision	Minor silicon version(1)
JPIN	JTAG Part ID	302h(2)

1. This value will change for each minor revision of the device.
2. This value will change for each major revision of the device.

Table 81 shows the address locations that the SSCM uses to search for startup information.

Table 81. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET).	0040_0000h
Location of the Boot Assist code in Flash (BAF)	0040_4000h

7.8.3.3 Protected registers

The SSCM registers are protected by a register protection module. After software has activated the protection for a register, writes can only be performed in supervisor mode until the protection is either deactivated by software or the device undergoes reset.

See the Register Protection chapter (*Chapter 82: Register Protection (REG_PROT)*) for a detailed description of the register protection mechanism.

7.9 Safety modules

7.9.1 CRC – Number of contexts

Table 82 lists the number of contexts available for the current CRC computation of multiple data streams of CRC.

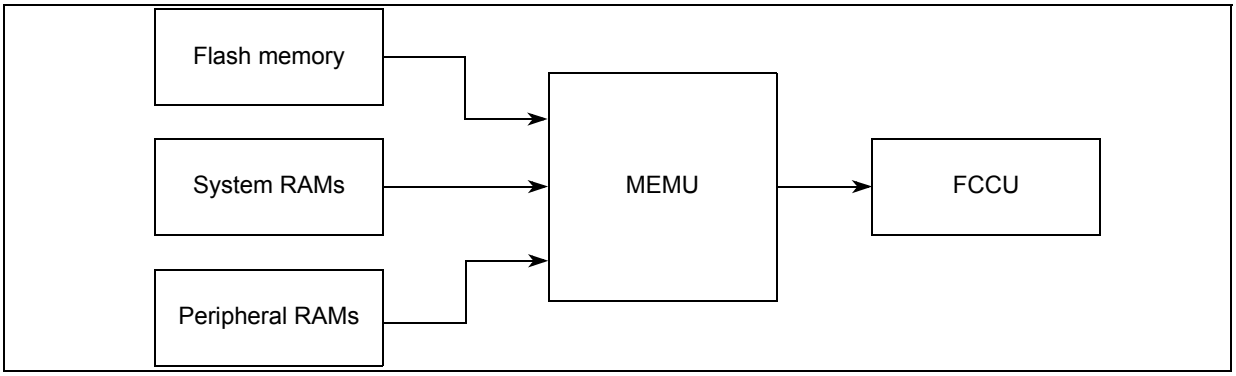

Table 82. CRC contexts

Signal name	Description	CRC_0	CRC_1
CRC_CNTX_NUM (N)	Number of contexts available for the current CRC computation of multiple data streams	1	1

7.9.2 MEMU configuration

7.9.2.1 MEMU system connections

Figure 28. MEMU system connections

7.9.2.2 MEMU error sources

Table 83 shows the MEMU error sources for each instance configured on this chip. MEMU does not support fake fault generation.

Table 83. MEMU error sources

Instance	Value
Number of system RAM unique error sources	56
Number of peripheral RAM unique error sources	20
Number of Flash memory unique error sources	2

7.9.2.3 Reporting tables implementation

There are three categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting—Any RAM that is CPU accessible falls into this category.
- Peripheral RAM error reporting—Any RAM that is not CPU accessible falls into this category.

Each category of error reporting has two tables associated with it; these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

Table 84 describes the number of entries in each reporting table for the different error sources.

Table 84. Number of entries in each reporting table

Error source	Number of entries in correctable error reporting table	Number of entries in uncorrectable error reporting table
Flash memory	20	1
System RAM	10	1
Peripheral RAM	2	1

7.9.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from one of three categories: Flash, System RAMs or Peripheral RAMs. In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Table 85. Corresponding error sources for System RAM OFLW0 register

7.9.3 Indirect Memory Access (IMA)

The IMA refers to the alteration of memory data values during system development and test activities. This section provides details about what memory locations can be accessed—either via processor core access or via the IMA module—and how they are configured.

7.9.3.1 SRAM Arrays accessible by processor cores

The SRAM arrays in the following table are accessible by the Main CPU (CPU0) and the IOP (CPU2).

Table 93. SRAM with processor Core access

Block	Function	SRAM		
		Words	Bits	ECC bits
Safety Core (Main core in lock-step with Checker core)	IMEM	2048	72	—
	DMEM	8192	40	—
		8192	40	—

7.9.3.3 Memory with inaccessible ECC bits

The following table shows memory locations that cannot be accessed.

Table 95. No ECC bit access

IMA ARRAY SELECT	Block	Function	SRAM		
			Words	Bits	ECC bits
No IMA Access Required - Debug function					
—	NAR	NAR	64	128	—
—			64	128	—
—			64	128	—
—			64	128	—

7.9.3.4 FCCU configuration

7.9.3.5 Available FCCU output signals

Table 96 shows the available FCCU output signals implemented on this chip. Clearing fault(s) corresponding to LVD/HVD threshold breach, does not guarantee that the device turns back above the LVD threshold or below HVD threshold. FCCU fault status is latched when LVD/HVD threshold is breached and it is possible to clear the fault in FCCU fault status register, but that doesn't imply that the voltage is still not below LVD threshold or above HVD threshold.

Table 96. FCCU output signals

FCCU output signal name	Chip-top signal name
EOUT[0], FI[0], ERROR0	F0
EOUT[1], FI[1], ERROR1	F1

7.9.3.6 FCCU failure inputs from other modules

Table 97 shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset[e].

e. All of these faults require a long functional reset.

Table 97. FCCU failure inputs *1*

FCCU channel *2*	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism *3*
0	TEMP_ERROR	Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_dig_EPR_TD, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	PMC_dig_EPR_TD *Section 61.3.1.5: Event Pending register (EPR_VD3)*	Correction of violating condition and power reset cycle
1	LVD_ERROR	Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VD*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LVD assertion test by tap point manipulation	No reaction	PMC_dig_EPR_VD 3 PMC_dig_EPR_VD 4 PMC_dig_EPR_VD 9 PMC_dig_EPR_VD 10 PMC_dig_EPR_VD 14 *Section 61.3: Memory map and register definition*	Correction of violating condition and power reset cycle
2	HVD_ERROR	Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VD*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	Self-test by TAP point manipulation	No reaction	PMC_dig_EPR_VD 7 PMC_dig_EPR_VD 8 PMC_dig_EPR_VD 15 *Section 61.3: Memory map and register definition*	Correction of violating condition and power reset cycle

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
3	DPMC_DCF_SAFETY_ERR	Digital PMC initialization error during DCF data load. The fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The status gets cleared if the fault is not persistent.	LBIST	No reaction	*Section 61.8: Other module interfaces*	POR, Destructive Reset
4	MEMORY_DCF_SAFETY_ERR	Indication of fault during timing/repair configuration initialization by SSCM of different memories. The status is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The status gets cleared if the fault is not persistent. Additionally, this error will cause a MBIST failure.	LBIST	No reaction	*Section 60.3.1.1: System Status Register (STATUS)*	POR, Destructive Reset
5	SSCM_XFER_FLASH_ERR	SSCM transfer error (during the SSCM and STCU DCF loading), or flash memory initialization error. The fault is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	Not testable (but wrong configuration can trigger other detection)	No reaction	*Section 60.3.1.1: System Status Register (STATUS)*	POR, Destructive Reset

Table 97. FCCU failure inputs *1* (Continued)

FCCU channel *2*	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism *3*
6	STCU_UF	STCU2 unrecoverable fault indication during self-test. It is simultaneously reported to the MC_RGM which will initiate a destructive reset in case of an offline self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	Destructive reset by MC_RGM directly during offline self-test	*Section 81.5.10: STCU2 Error Register (STCU_ERR_STAT)* *Section 58.1.3: Reset sources* *Section 58.3.1.2: Destructive Event Reset Disable (RGM_DERD) register*	POR, Destructive reset. During offline test, assertion of this fault will automatically cause a destructive reset request by MC_RGM.
7	STCU_RF	STCU2 recoverable fault indication during self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	No reaction	*Section 81.5.10: STCU2 Error Register (STCU_ERR_STAT)*	—
8	STCU_LMBIST_USR_ERR	Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]. The status will clear if the fault is not persistent.	Feedback loop via FCCU Fake bit.	No reaction	—	POR, Destructive Reset

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
9	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG, NPC or Debug functionality moved out of reset or SSCM, or DCF client, activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit	No reaction	—	Long Functional Reset
10	RCCU_019	Safety cores out of sync during lockstep (RCCU0a). Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
11	RCCU_119	Safety cores out of sync during lockstep (RCCU0b ... RCCU0e, RCCU1). Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	*Section 6.4.1.6: Redundancy Control and Checker Units (RCCUs)*	Functional Reset
12	SWT2_ResetReq	Reset request from Software Watchdog of Peripheral Core_2 domain. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared inside SWT2.	LBIST + SW test by not triggering SWT during startup	Long Reset	*Chapter 43: Software Watchdog Timer (SWT)*	Functional Reset (application dependent)

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
14	SWT0_InterrutpReq	First timeout interrupt request from Software Watchdog of Safety Core (Main Core_0). Fault is cleared by clearing SWT0_SWT_IR[TIF], followed by clearing the FCCU channel status FCCU_RF_S*n*[RFS*m*].	LBIST + SW test by not triggering SWT during startup	No reaction	*Chapter 43: Software Watchdog Timer (SWT)*	Functional Reset (application dependent)
15	SWT0_ResetReq	Second timeout (reset) request from Software Watchdog of Safety Core (Main Core_0). The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared inside SWT0.	LBIST + SW test by not triggering SWT during startup	No reaction	*Chapter 43: Software Watchdog Timer (SWT)*	Functional Reset
16	MEMU_RAM_CE	Indication by MEMU of occurrence of correctable errors in system RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[SR_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Injection of RAM ECC error via ECC bit access and later reading	No reaction	*Section 78: Memory Error Management Unit (MEMU)*	—
17	MEMU_RAM_UCE	Indication by MEMU of occurrence of uncorrectable errors in system RAMs. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_UCE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Injection of RAM ECC error via ECC bit access and later reading	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
18	MEMU_RAM_BOV4, 17	Indication of overflow of system RAM ECC buffer or table in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_EBO, SR_CEO or SR_UCO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Functional test12	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
19	MEMU_PER_CE4, 17	Indication by MEMU of the occurrence of correctable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Functional test13	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
20	MEMU_PER_UCE4, 17	Indication by MEMU of the occurrence of uncorrectable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_UCE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Functional test14	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
21	MEMU_PER_BOV4, 17	Indication of overflow of peripheral RAM ECC buffer or table in MEMU. The fault is cleared by clearing MEMU_ERR_FLAG[PR_EBO, PR_CEO or PR_UCO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Functional test15	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—

Table 97. FCCU failure inputs *1* (Continued)

FCCU channel *2*	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism *3*
22	MEMU_FLS_CE *17*	Indication by MEMU of occurrence of correctable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_CE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Reading preprogrammed correctable ECC error from UTEST flash memory	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
23	MEMU_FLS_UCE *17*	Indication by MEMU of occurrence of uncorrectable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_UCE], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Reading pre-programmed uncorrectable ECC error from UTEST flash memory	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
24	MEMU_FLS_BOV *4*, *17*	Indication of overflow of flash memory ECC buffer or table in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[F_EBO, F_CEO or F_UCO], followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Functional test *16*	No reaction	*Section 78.6.2.2: Error flag register (ERR_FLAG)*	—
25	IMA_SOC	MCU IMA active	LBIST + IMA read	No reaction	*Section 79: Indirect Memory Access (IMA)*	—

Table 97. FCCU failure inputs *1* (Continued)

FCCU channel *2*	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism *3*
26	SMPU_MONITOR	Indication of fault in SMPU_0 or SMPU_1 logic fault resulting in an incorrectly refused access, but failure to indicate the error to the requesting bus master. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
27	Platform_Safety_Failure	Indication of failed transaction due to ECC failure detected by e2eECC or address/control failure inside dedicated memories of safety core, namely, I/D-Mem, I/D-Cache, ITAG, DTAG. In case of e2eECC detected error, MCSR[BUS_DRERR] is set for error in data load and MCSR[BUS_WRERR] in data write transaction. MCSR[IF] is set when instruction with e2eECC error is decoded. The fault is cleared by clearing FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU fake bit	—	—	Functional Reset
29	FM_PLL_0	PLL0 loss of lock. In order for this fault source to be asserted in the event of loss of lock, the Loss of Lock flag needs to be enabled by writing (PLLDIG_PLL0CR[LOLIE]) = 1. Fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_RF_S*n*[RFS*m*].	LBIST + Forced loss by PLL reconfiguration	No reaction	*Section 27.5.2.2: PLL0 Status Register (PLL0SR)*	application integrity checks

Table 97. FCCU failure inputs[1](Continued)

FCCU channel[2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
30	FM_PLL_1	PLL1 loss of lock. In order for this fault source to be asserted, the Loss of Lock flag needs to be enabled by writing PLLDIG_PLL1CR[LOLIE] = 1. Fault is cleared by clearing PLLDIG_PLL1SR[LOLF], followed by clearing FCCU_RF_S*n*[RFS*m*].	LBIST + Forced loss by PLL reconfiguration	No reaction	*Section 27.5.2.5: PLL1 Status Register (PLL1SR)*	Application integrity checks
31	CMU_0_OSC[5, 6]	Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	*Section 28.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional reset
32	CMU_0_PLL[5, 7]	SYSCLK frequency out of range. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by mis configuration[7]	No reaction	*Section 28.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional reset
33	CMU_comp_subsys [5, 8]	Exception from monitoring internal clocks of comp_subsys. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by mis-configuration[7]	No reaction	*Section 28.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional reset

Table 97. FCCU failure inputs[1](Continued)

FCCU channel[2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
34	CMU_other[5, 9]	Exception from monitoring internal clocks of other subsystems. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_*n*, followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*]	LBIST + Test by mis-configuration[7]	No reaction	*Section 28.4.1.5: CMU Interrupt Status Register (CMU_ISR)*	Functional reset
35	PERIPH_XBIC_GASKET_MONITOR	Indication of a hardware fault resulting in corrupted transaction through the peripheral XBAR or gaskets handling communication from Safety core to PERIPH_XBAR and back. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	*Chapter 18: Crossbar Integrity Checker (XBIC)*	—
36	EDC_ECC_FLASH	Indication of a hardware fault in the ECC logic of the flash memory resulting in corrupted ECC detection/correction. Fault is cleared by a dummy read of the flash memory followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
37	EDC_ ECC_FLASH_C	Indication of hardware fault in the flash memory controller resulting in corrupted ECC detection / correction. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
38	ENC_ERR_FLASH	Indication of hardware fault resulting in corrupted flash memory access, or Read Reference were out of range for a previous read. Fault is cleared by clearing and MCR[RRE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	*Section 34.3.2.1: Module Configuration Register (MCR)*	—
39	ADDR_FDBK_ERR_FLASH_C	Indication of an addressing error in the flash memory controller resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
40	COMP_XBIC_DSMC_Monitor	Indication of an addressing or control fault resulting in corrupted transaction through the computational XBAR or interference by system RAM DSMC. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	*Chapter 18: Crossbar Integrity Checker (XBIC)*	—
41	ADDR_FDBK_ERR_CAL_RAM	Indication of an addressing error in the on-chip overlay RAM resulting in corrupted access to on-chip overlay RAM. Status should be cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—	—

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
42	SAFE_CAL_ERR	Indication of hardware fault in the flash memory controller resulting in corrupted overlay remap evaluation. Status should be cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
43	ADDR_FDBK_ERR_PRAM + RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
44	SMPU_ERROR	Indication of the prevention of an unauthorized access by SMPU_0 or SMPU_1. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + willfully causing an access to an unauthorized location	No reaction	—	—
45	PRAM_TRANSACTION_MONITOR	Indication of a fault in the controller PRAMC of the system RAM resulting in a potentially corrupted RAM word during RMW access or stale word during read. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	*Section 32.5.2: Transaction monitor*	—
46	DFT1	Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—

Table 97. FCCU failure inputs[1](Continued)

FCCU channel[2]	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism[3]
47	DFT2	Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
48	DFT3	Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
49	DFT4	Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST	No reaction	—	—
50	Safety Core Machine Check Exception[10]	Safety Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Willfully cause an appropriate exception (for example, access a non-existing address)	No reaction	—	—
51	Lockstep mode[19]	Indication of disabled Checker Core or RCCUs.Fault is cleared by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + Feedback loop via FCCU Fake bit	No reaction	*Section 6.4.2: Dual-core lockstep*	—

Table 97. FCCU failure inputs1(Continued)

FCCU channel2	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information	Recommended Recovery Mechanism3
52	Safe_Mode	Indication of safe mode request assertion from MC_RGM. The event is also captured in MC_ME and available as status for crosscheck. Status should be cleared first in the MC_RGM_FES, then followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	LBIST + (in principle requesting an RGM “safe mode” though that is not typical, and should be avoided)	No reaction	*Section 58.3.1.5: Functional Event Status (RGM_FES) register*	—
53	Compensation Disable	Indication of undesired deactivation of pad compensation. Fault may effect a distorted transmissions on I/Os associated with VDD_HV_IO_JTAG, VDD_HV_IO_FLEX and VDD_HV_IO_MAIN. The indication is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	—	No reaction	—	—
54	EIN_ERR11, 18	Error input pin (FI[0], external of the MCU) signalling an error condition. The fault is cleared by clearing the fault driving FI[0] followed by clearing the FCCU channel status, FCCU_RF_S*n*[RFS*m*].	External activation of EIN. External entity has to pull the error input low.	No reaction	—	—
55	SWT3_ResetReq	Reset request from Security Watchdog. The fault is cleared by clearing FCCU_RF_S*n*[RFS*m*] after the status has been cleared in the SWT3.	LBIST+ SW test by not triggering SWT during startup	No Reaction	*Section 7.6.2.1: Security watchdog*	—

1. All of these faults require a long functional reset.
2. See “Fault Collection and Control Unit (FCCU)” chapter for channel mapping details.
3. During execution of the safety function. Application level reactions not limited to FCCU reactions
4. Error reaction path check contents subject to change.
5. See Clock generation figure (*Figure 246: Clock generation*) in the Clocking chapter (*Chapter 26: Clocking*).
6. CMU_0 OLR event.
7. CMU_0 FLL and FHH events.
8. CMU_1, CMU_2, CMU_3, FLL, and FHH events.
9. CMU_4, CMU_5, CMU_6, CMU_7, CMU_8, CMU_9, CMU_10, FLL and FHH events.
10. Alarm #50 is asserted by Main Core_0 when a machine check condition causes an “Async Mchk” or “Error Report” type syndrome bit to be set in the Machine Check Syndrome register (Refer to Section 14.7.4, “Machine Check Syndrome Register (MCSR)”). in the *e200z4 Core Reference Manual*, the “Exceptions and Conditions” table lists all exceptions which can occur in the core and the “Error report machine check exceptions” table lists errors indicated by a machine check exception. Note that the following do not cause a machine check and thus do not signal the FCCU: access blocked by MPU, wrongly aligned access, execution of a privileged or trap instruction, FPU exceptions. Such errors have to be handled by the respective exception handler if they are safety-relevant.
11. EIN_ERR can be used only when bistable protocol is selected for external error indication, and the FI[0] pin is configured as open drain.
12. Assert the fault line by writing '1', followed by '0', to MEMU_DEBUG[FR_SR_EBO]. Deassert by writing '1' to MEMU_ERR_FLAG[SR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].
13. Assert the fault line by writing '1', followed by '0', to MEMU_DEBUG[FR_PR_CE]. Deassert by writing '1' to MEMU_ERR_FLAG[PR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].
14. Assert the fault line by writing '1', followed by '0', to MEMU_DEBUG[FR_PR_UCE]. Deassert by writing '1' to MEMU_ERR_FLAG[PR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].
15. Assert the fault line by writing '1', followed by '0', to MEMU_DEBUG[FR_PR_EBO]. Deassert by writing '1' to MEMU_ERR_FLAG[PR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].
16. Assert the fault line by writing '1', followed by '0', to MEMU_DEBUG[FR_F_EBO]. Deassert by writing '1' to MEMU_ERR_FLAG[F_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]
17. Fake fault cannot be generated for FCCU channel (these faults are injected only through the MEMU).
18. Fake fault can be injected in filter bypass mode.
19. Default fault can be generated only when checker core is enabled.

7.9.3.7 FCCU register availability and reset values

Table 98 shows the availability and reset values of selected FCCU registers.

Table 98. Availability and reset values of selected FCCU registers

Register	Reset value
FCCU_RF_CFG0	0xFFFF_FFFF
FCCU_RF_CFG1	0x00FF_FFFF
FCCU_RF_CFG2	0x0000_0000
FCCU_RF_CFG3	0x0000_0000

7.9.3.8 FOSU parameters

The FOSU_COUNT, or FOSU timeout response time, is 1000 safe clock cycles.

7.9.3.9 Error signal flow diagram

In *Figure 29*, the FCCU_RF registers are labeled as FCCU_NCF registers.

Figure 29. Error signal flow

7.9.4 Register protection (REG_PROT) configuration

Some modules include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the *Chapter 82: Register Protection (REG_PROT)*.

Table 111. Protected JTAGM registers

Register	Register Size (bits)	Offset from Module Base Address	Protected Size (bits)
JTAGM_MCR	32	0x00	32

7.10 Security modules

7.10.1 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks on the SPC574Kx MCU. Up to four levels of password protection can be implemented for each flash block.

Note: The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See the Password and Device Security Module (PASS) chapter for further details.

7.10.1.1 PASS_LOCK*n*_*PGn* register bit mapping

Each password group defined in the DCF records has a set of four LOCKn registers association with it—PASS_LOCK*n*_PG*n*. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note: The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

Bit number	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Note: Refer to Section 36.4: Secure read protection for details of flash read lock protection.

7.10.1.2 PASS Module DCF Records (includes life cycle state and censorship)

The records required to configure the initial values for the PASS module password group registers is shown in *Table 112*. These values provide the following capabilities:

- Set flash memory to censored/uncensored state (censorship also depends on life cycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part.

Most DCF records represent an initial value or reset value for a module register. See the relevant register documentation for details on values that can be assigned.

Table 112. PASS DCF records

DCF CS[14:0]	DCF address (binary)		DCF client description	Number of

000_0000_0000_1000	0000000	01001100–11111111	Reserved		

1. See *Section 83.6.4: Censoring and uncensoring the device* for values.
2. See *Section 7.10.1.1: PASS_LOCKn_PGn register bit mapping* for values.

7.10.2 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

The TDM also provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), i.e., write-once blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

Warning: The TDM configuration registers detailed in this section are DCF clients. In general, DCF clients can only be written once so their intended values must be carefully selected beforehand.

See *Chapter 84: Tamper Detection Module (TDM)* for further details on the TDM, including the DCF clients and two additional memory-mapped registers.

7.10.2.1 Diary Base Address (DBA) DCF client

The DBA DCF client holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations. This DCF client is more fully described in the TDM chapter.

7.10.2.2 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. This DCF client is more fully described in the TDM chapter. The mapping is shown below.

Offset: 0x01 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 34. Tamper Region Override (TO) DCF client

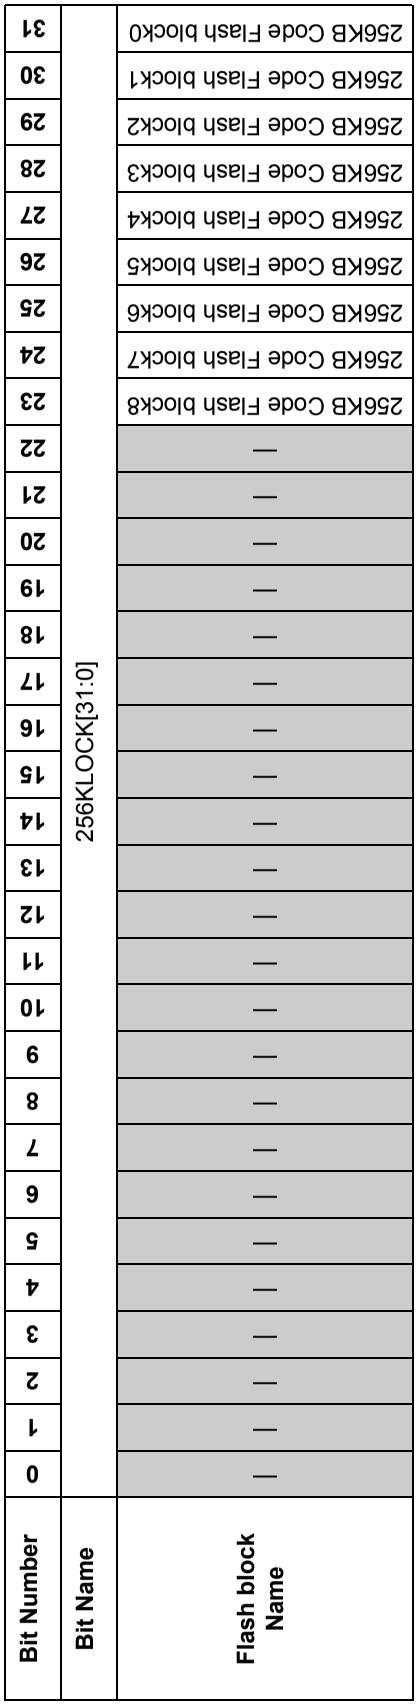
The mapping of the Tamper Region Override Enable (TOE*n*) is as follows:

Table 113. _TDM_TO[TOE*n*] field mapping

Field	TDR
TOE0	0
TOE1	1
TOE2	2
TOE3	3
TOE4	4
TOE5	5

7.10.2.3 OTPEN*n* DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPEN*n* DCF clients. Each mapped bit is associated with a specific flash block. A ‘1’ bit value indicates a block is OTP.



The mapping is shown in *Figure 8*–*Figure 38*.

Bit Number	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Figure 38. TDRx_LOCK3/OTPEN3 DCF client

7.10.2.4 TDR*x*_LOCK*n* DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A '1' in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDRx_LOCKn bits to flash blocks is identical to the OTPEN*n* mapping shown in *Figure 8* - *Figure 38*. Any available flash block can be mapped to any tamper protection region.

7.10.2.5 DCF client details

Table 114 contains the DCF client information.

Table 114. Tamper Detection Module (TDM) DCF clients

DCF CS[14:0]	DCF Address [16:10]	DCF Address [9:2] (Binary)	DCF Client Description	No. of Valid Bits	No. of DCF Records

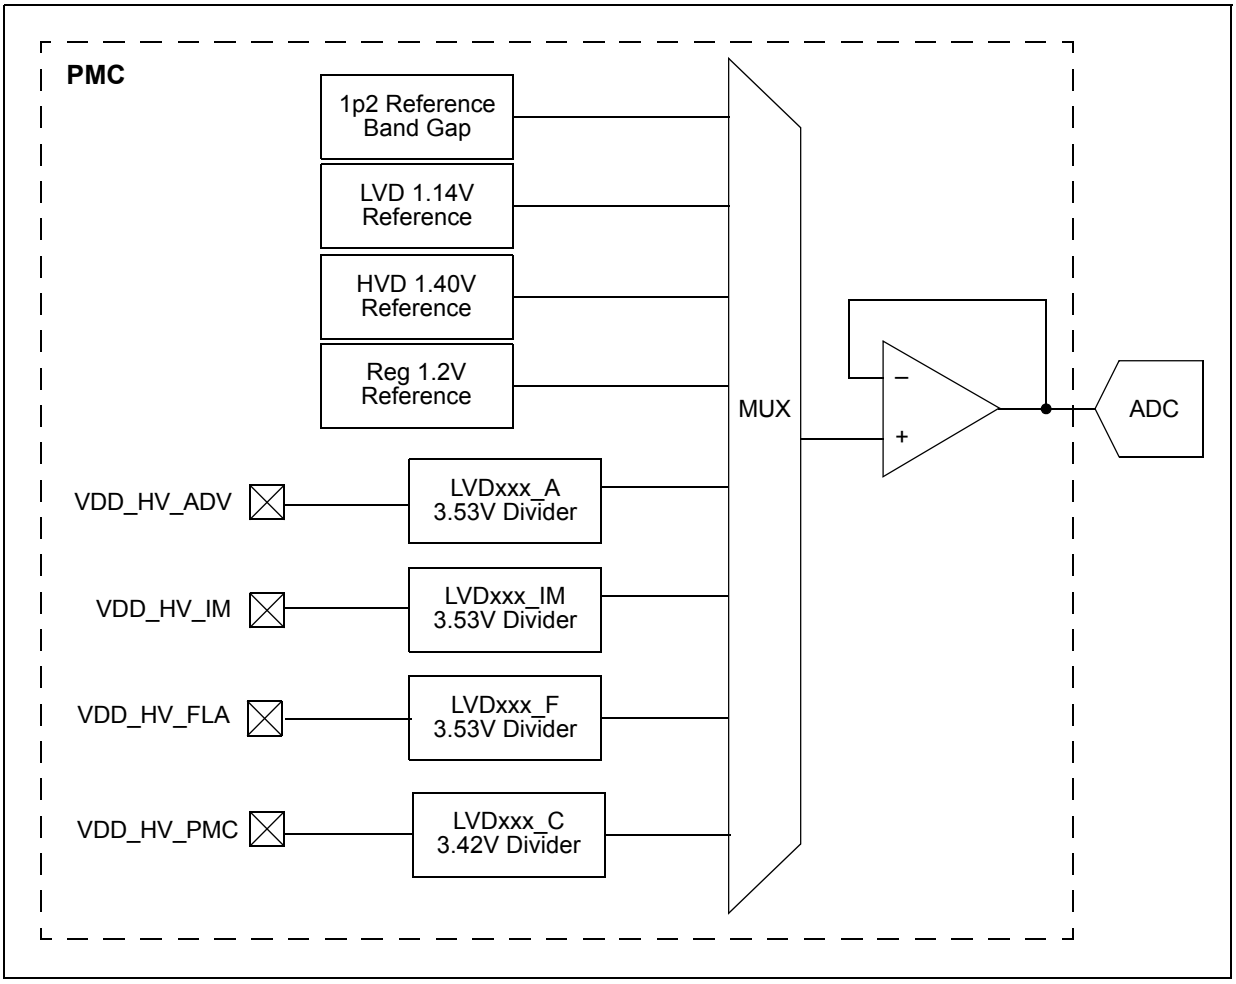
000_0000_0001_0000	0000000	00101010	TDR5_LOCK2	32	1
000_0000_0001_0000	0000000	00101011	TDR5_LOCK3	32	1
000_0000_0001_0000	0000000	00101100 - 1111111	Reserved		



1. OTP DCF clients have the same structure and mapping as the write-protect bits of the flash and PASS module LOCK DCF clients. A value of ‘1’ in an OTP bit indicates a block is programmable only once. Note that a block cannot be reconfigured as non-OTP after it has been configured as OTP.
2. There are no flash memory blocks mapped to the OTPEN3 DCF client.

7.11 Power Management modules

7.11.1 PMC ADC test mode

All of the internal Power Management Controller (PMC) system analogue signals can be monitored by one of the Analog-to-Digital Converters (ADCs). SARADC_B Test channel TCDR 110 is dedicated for these monitoring purposes. The PMC ADC test mode is used for calibration, test diagnostics and active user monitoring of the signal levels. PMC signals are buffered to ensure correct ADC sampling. Supply for PMC to ADC buffer and transmission gates is the main PMC supply.

Figure 39. Simplified PMC ADC test multiplexer block diagram

The table below lists the parameters that can be monitored, the ADC channel select register value, and reference to the expected nominal value. Use maximum ADC sample time for most accurate results.

Table 115. Parameter monitoring via ADC channel

PMC ADC Mode Signal Description	ADC Channel Select Register	ADC Mode Description	Nominal value expected
Internal Voltage	6b011111	Internal Voltage	0.855V
POR for security	6b011110	Power-On-Reset on LV core supply for security	1.0V

For additional information see *Chapter 37: Analog-to-digital converter (ADC) configuration*, for an overview of the ADC subsystem, including a block diagram and a summary of analog input pin multiplexing. The chapter also provides configuration details for the SARADCs.

7.11.2 LVD / HVD self test

A self test functionality exists for each LVD / HVD. Programming LVD / HVD self test register to a specific value designated to a LVD /HVD will start the self test for that LVD / HVD. During the self test, the voltage sense input of the LVD /HVD comparator is connected to an internal voltage which is lower than the LVD reference for LVD test (higher than HVD reference for HVD test), so that an artificial assertion of the LVD /HVD comparator can be triggered. After the comparator is triggered, the voltage sense input will be re-connected to the supply it monitors automatically.

The self test takes less than 5µs from programming a self test register start to LVD / HVD comparator output changing.

While programming the self test register bits, a timer should be started. If the LVD / HVD status has not been updated when the timer runs out, this indicates the LVD / HVD self test failed. The figure below shows a block diagram of the LVD self test. The table below provides LVD / HVD self test decoding.

Figure 40. LVD self test simplified diagram

7.12 Production device vs. emulation and debug device

SPC574Kx microcontrollers have a comprehensive feature set to assist debug and calibration. Specialized variants, referred to as Emulation and Debug Devices (EDs), include additional calibration and debug features. An ED consists of the normal production die plus an additional die, called a Buddy die or Buddy Device (BD), bonded together in the same chip package. A Production Device (PD) includes a production die only and no buddy die.

Note: All features and modules included in the PD are also included in the ED.

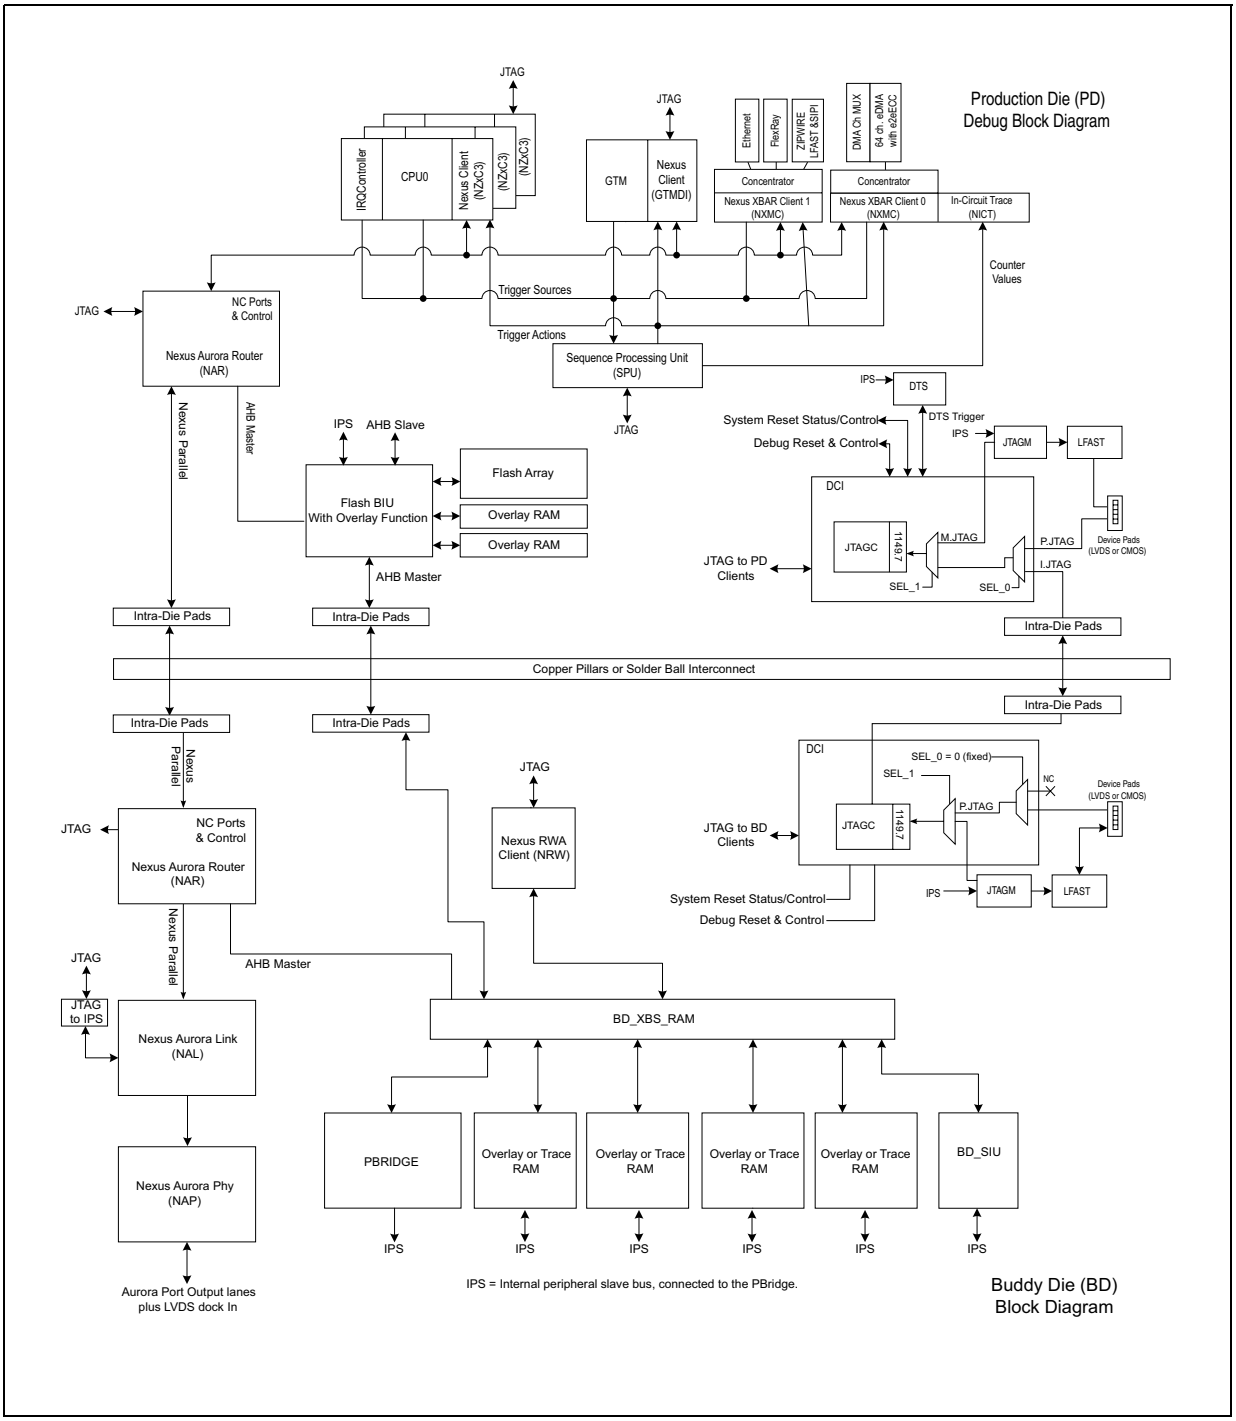
Table 117 lists the key differences between the ED and PD of the SPC574Kx microcontroller.

Table 117. Debug and calibration features per SPC574Kx type

Debug or calibration feature	SPC574Kx PD	SPC574Kx ED
Internal Overlay Memory	16 KB	16 KB
Extended Overlay Memory	—	1 MB
Debug Interface	JTAG / LFAST	JTAG / LFAST
Trace Interface	—	Aurora (1.25 GHz, 2 Lanes)
Trace Sources	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA, and GTM	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA, and GTM
Trace Destination	Internal Overlay	Internal Overlay, Extended Overlay, Aurora Trace Port
Calibration Remap capabilities	32 Region	32 Region
System Level Performance Monitor Counters(1)	16 × 32 bits	16 × 32 bits
CPU Level Performance Monitor Counters	4 × 32 bits (4 × 32 bits in e200z410Dn3, 0 × 32 bits in e200z225Bn3)	4 × 32 bits (4 × 32 bits in e200z410Dn3, 0 × 32 bits in e200z225Bn3)

1. The system level PMCs are included in the Sequence Processing Unit (SPU). All system level PMCs can also be configured for use as debug timers. System level PMCs can also be configured as timers.

Figure 41 shows the top-level block diagram of the SPC574Kx ED, which consists of the production die packaged together with the 1 MB Buddy die (BD1M). The figure shows the general interconnection of functional debug modules including interconnections between the two devices. All functional blocks are shown for the BD, but for clarity only blocks relevant to the debug and calibration system are shown for the PD.



Acronyms used in the block diagram include:

- BD_SIU—BD System Integration logic
- BD_XBS_RAM—Buddy Device RAM Crossbar
- DCI—Debug and Calibration Interface
- DTS—Development Trigger Semaphore
- DCU—Debug Control Unit
- I.JTAG—Inter-die JTAG
- JTAGC—JTAG Controller
- JTAGM—JTAG Master
- M.JTAG—Mastered JTAG
- NAL—Nexus Aurora Link
- NAR—Nexus Aurora Router
- Nexus RWA—Nexus Read/Write Access client
- P.JTAG—Peripheral JTAG
- SPU—Sequence Processing Unit

On ED devices, the device packaging routes the tool interface to the interface logic on the BD. On standard production devices packages, the device packaging routes the tool interface to the interface logic on the PD.

Note: For Global (Development tool client) stall control, dct_evti[0] is selected. For more information, refer Section 92.5.13: Global (Development tool client) stall control.

Figure 41. Debug and calibration architecture for SPC574Kx ED

8 Reset and Boot

8.1 Introduction

Resetting the SPC574Kx starts with the application of power and ends with fetching the first instruction of the user's application code. A review of chip architecture is helpful to appreciate reset.

The processor cores on the SPC574Kx are:

- Core_0 based on e200_z420 architecture, generally execute user application code.
- Checker Core_0 executes the same instruction stream as Core_0. The results of each instruction execution are compared between the two cores and mismatches are flagged.
- Peripheral Core_2 (IOP or I/O Processor) is implemented using an e200_z225 core. It is intended to control the various peripherals on the SPC574Kx, but may be used to execute any user code.

Memory elements involved in the boot-up process include:

- UTEST flash memory.
- TEST flash memory.
- Boot Assist Flash (BAF).

8.1.1 Boot Assist Flash

The Boot Assist Flash (BAF) contains factory code to facilitate the device boot-up procedure.

If the BAF code does not locate a valid boot header, it runs the Serial Boot Loader which receives files from an external serial link controlled by the internal LINFlexD module. The received file is placed in RAM and program execution begins at the start address specified in the received file.

The Serial Boot Loader is only an option in the early stages of the device life cycle. In later stages (for example *FIELD*) the device waits for the watchdog to reset the device if no boot header is found.

8.1.2 TEST flash memory block

The TEST flash memory block contains Device Configuration Format (DCF) records used to hold trim values and other variables, as well as general device configuration information.

The trim values are for:

- Adjusting low-voltage and high-voltage detect circuit trip points.
- Temperature sensor adjustments.
- Power-on reset voltage trip point.
- Analog-to-digital adjustments.
- Internal RC oscillator (IRCOSC) trim values.

Note: The DCF records are written by the device manufacturer and programmed into TEST flash memory during production testing. Further programming of the TEST flash is disabled at the end of the factory test cycle.

8.1.3 UTEST flash memory block

The UTEST flash memory block also contains DCF records. Some UTEST DCF records are written by the factory and programmed during production testing. Others are written by the end user and programmed at the same time application code is programmed into the flash memory. UTEST DCF records are used to set up various control and configuration registers, including the Self-Test Control Unit (STCU2) and default memory configuration.

8.1.4 Boot header

A boot header is used to supply the start address for code execution for Core_0 and Checker Core_0s. It is written by the application programmer and loaded into specific flash memory locations. It contains the reset vectors for the various cores and specifies the BOOT CPU to execute application code.

8.2 Modules used in reset sequence

The modules involved in the SPC574Kx reset sequence are:

- Power Management Controller (PMC).
- Reset Generation Module (MC_RGM).
- Mode Entry Module (MC_ME).
- System Status and Configuration Module (SSCM).
- Self-Test Control Unit (STCU2).

8.2.1 Power Management Controller

The Power Management Controller (PMC) controls and monitors:

- Its own supply voltage.
- The supply voltages to all the high- and low-voltage detect circuits.
- The trip points for all the high- and low-voltage detect circuits.
- The power supplies and reference voltages to the Analog-to-Digital Converter.
- The major power supplies to the SPC574Kx.

8.2.2 Reset Generation Module

The Reset Generation Module (MC_RGM) is a complex state machine that begins sequencing the SPC574Kx through the initial steps of the reset process. The MC_RGM does not execute program code, it is a state machine that centralizes the different reset sources and manages the reset sequence. Reset sources are organized into two categories: destructive and functional.

See *Figure 42* for more information on the MC_RGM reset sequence.

8.2.2.1 Destructive resets

A destructive reset source is related to a critical error or dysfunction, usually caused by a hardware malfunction. When a destructive reset event occurs, software recovery is not possible and the contents of memory are assumed unknown. A full device reset sequence starting from PHASE0 is therefore applied to the device, ensuring a safe startup state for both digital and analog modules.

Examples of destructive resets are:

- Power-on reset
- Low voltage detection
- Reset escalation (when too many functional resets occur simultaneously)

8.2.2.2 Functional resets

A functional reset source is related to a less critical error or dysfunction not usually not associated with hardware malfunction. When a functional reset event occurs, a partial reset sequence is applied to the device starting with PHASE1[FUNC]: most digital modules are reset normally and the state of analog modules, specific digital modules (for example, debug and flash memory modules) and system memory content is preserved.

Examples of functional resets are:

- External reset.
- Machine check.
- Software reset from mode entry.
- Boundary scan instructions.

8.2.3 Mode Entry module

The Mode Entry module (MC_ME) is responsible for delivering initial values to many registers, including the reset vectors to all the SPC574Kx cores.

During the power-up sequence, the System Status and Configuration Module (SSCM) searches for a boot header at defined locations in the flash memory, derives the necessary reset vectors from the boot header and then writes these vectors to their respective locations in the Mode Entry module.

The SSCM also interprets the DCF records which contain further information that is written to the MC_ME. As the boot-up sequence progresses, the SSCM instructs the MC_ME to transfer the reset vectors to the respective processor cores.

Even though the reset vectors are in the boot header located in flash memory, the Mode Entry module always provides them to the CPU cores.

8.2.4 System Status and Configuration Module

During the reset sequence, the Reset Generation Module (MC_RGM) enables the SSCM state machine which reads the DCF records in the TEST and UTEST flash memory areas for device setup information to be written to various registers in the SPC574Kx.

The DCF records are primarily for setting up the memory, configuring the Self-Test Control Unit (STCU2), and providing initial device configuration values.

The SSCM continues with the reset or boot-up sequence by locating boot vectors for the various cores. Once the SSCM locates the boot header, the SSCM writes the start address information for the CPU cores to special locations in the Mode Entry Module (MC_ME). For all cores enabled by the boot header, the MC_ME feeds a reset vector to each enabled core and the respective cores begins program execution at the specified address.

The SSCM starts up the IOP in different ways depending on whether there is valid code in the Boot Assist Flash (BAF).

The boot-up sequence ends when the SSCM starts up the Core_0 boot CPU.

8.2.5 Self-Test Control Unit

The Self-Test Control Unit (STCU2) is a self-contained module that runs a Logic Built-In Self-Test (LBIST) and a Memory Built-In Self-Test (MBIST). The DCF record can be used to select which individual tests are run for LBIST and MBIST and disable tests for modules and memory elements that are not going to be used in user applications, thus shortening device boot-up time.

8.3 Reset sequence

The power-up reset sequence always begins with the application of power and follows different sequences depending on the condition of the SPC574Kx device and whether various modes are enabled from settings in the DCF records. For instance, the SPC574Kx device enters Serial Boot mode (the Serial Boot Loader receives startup code and begins program execution) if a valid boot header file is not found.

If an emulation and debug device is detected during the reset sequence, the device enters the calibration sequence. The calibration sequence is not a user mode and is only used for code development.

Another reset outcome is that the IO Processor, and the boot CPU are properly started and begin executing their respective program code.

8.3.1 Power-on and the Reset Generation Module

When power is applied to the SPC574Kx, the Reset Generation Module (MC_RGM) advances the device through a series of steps shown in *Figure 42*.

The Reset Generation Module (MC_RGM) starts the System Status and Control Module (SSCM), which continues the boot-up process detailed in *Figure 43* through to *Figure 47* after the MC_RGM enters the IDLE state.

The STCU is reset on any power-on, 'destructive,' or long external reset (external reset in this case is ESR0).

Figure 42. Reset Generation Module Reset Sequence

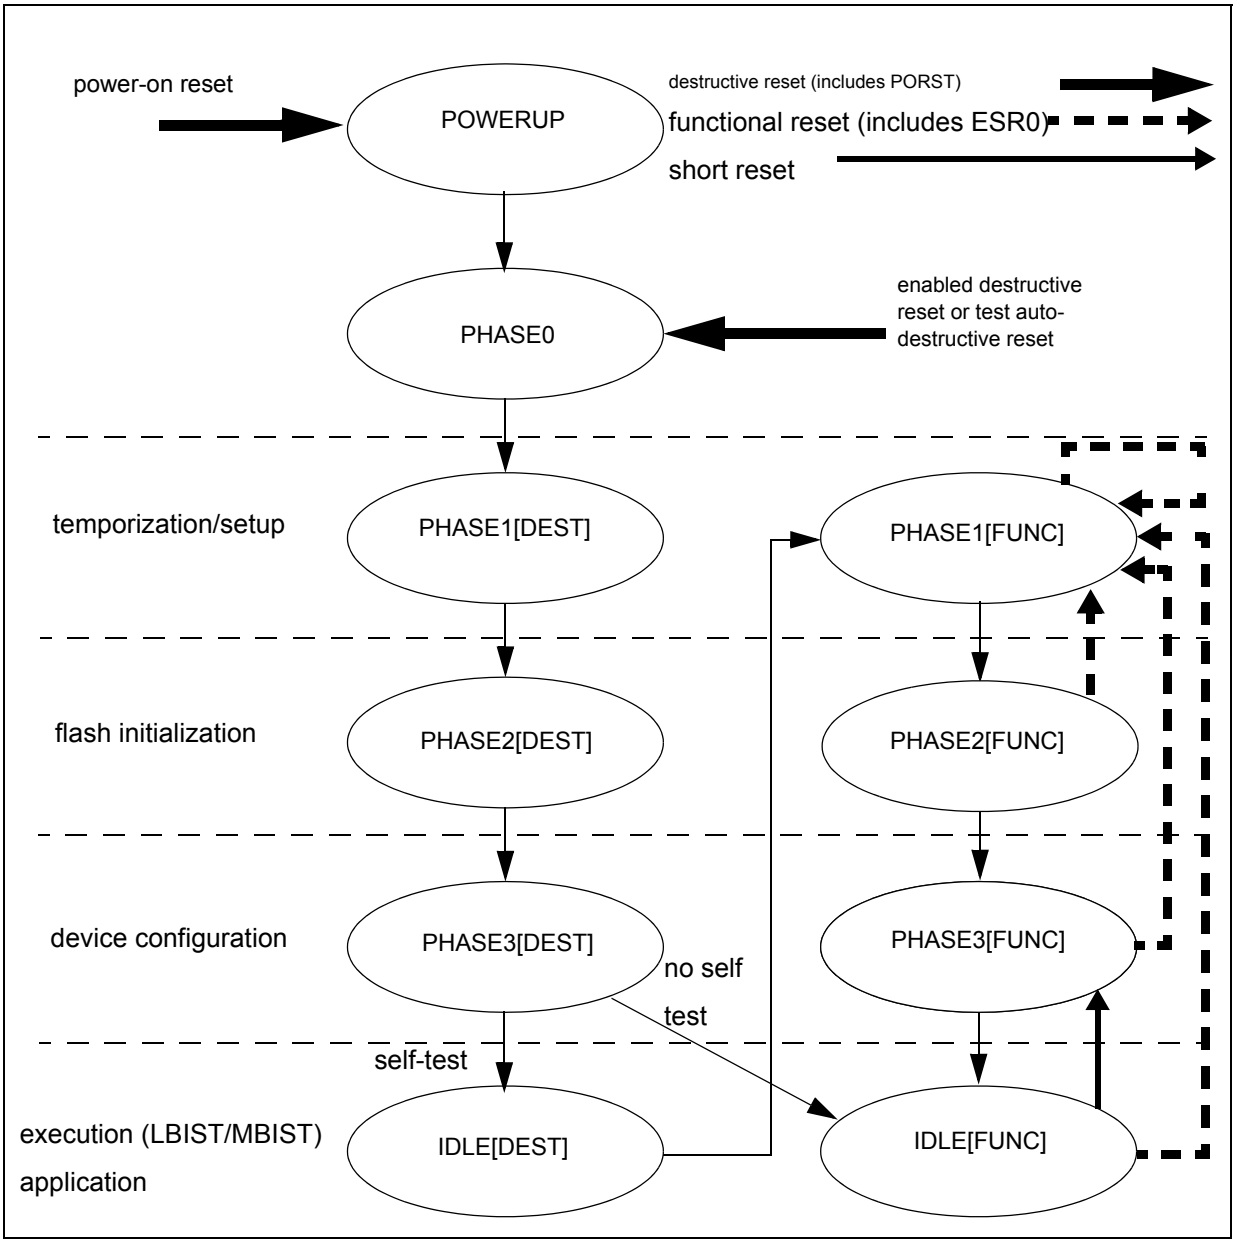


Table 118. Module status during reset phases

Module	PHASE								
	P0	P1 [DEST]	P2 [DEST]	P3 [DEST]	IDLE [DEST]	P1 [FUNC]	P2 [FUNC]	P3 [FUNC]	IDLE [FUNC]

								Short functional reset	
						functional reset			
	destructive reset								

1. RESET only during POR
2. STCU time-out monitoring LBIST/MBIST execution
3. Depending on flash configuration
4. Device configuration is not loaded in case of short functional reset
5. FCCU remains ON during functional reset; it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST]
6. The STCU remains idle during functional reset; it is instead reset on long external reset (external reset here is ESR0).
7. Can be triggered by SW. Please refer to *Chapter 81: Self-Test Control Unit (STCU2)*.
8. MEMU is reset whenever STCU is reset.
9. LBIST is optionally triggered depending on safety execution directives after enabling from IOP. Please refer to *Chapter 59: Boot Assist Flash (BAF)*.

8.3.2 Power-up phase: power stabilization

When a power-on reset event occurs (initial application of power), the reset generation module (MC_RGM) causes the device to enter the power-up phase of the reset sequence (See *Figure 42*). The only method to enter the power-up phase is from a power-on reset event.

The device remains in the power-up phase until the Power Management Controller module (PMC) determines that all power supplies are in their respective operational ranges.

The supplies for initial configuration are:

- VDD_HV_CORE: high voltage supply for core module, including power management unit, internal RC oscillator (IRCOSC), external oscillator (XOSC) driver.
- VDD_LV_CORE: low voltage supply for digital module.
- VDD_HV_FLA: high voltage supply for flash module.
- VDD_LV_FLA: low voltage supply for flash module.
- VDD_HV_IO_IM: high voltage supply associated with system pins (PORST, ESR0, TEST Mode).

Peripheral supplies such as VDD_HV_IO_JTAG, VDD_HV_IO_FLEX or VDD_HV_ADC do not gate the power-up process. The low- and high-voltage detect circuits for these and other power supplies are managed by the PMC, which provides enable and status bits for these voltage detection circuits.

The PMC sends a signal to the Reset Generation Module when power stabilization has been achieved. The Reset Generation Module then advances to the PHASE0 state (see *Figure 42*). During the power-up phase, the PMC does the following:

- Drives to a logic ‘0’ all LVDxx (low-voltage detect) and HVDxx (high-voltage detect) signals monitored by the Power Management Control (PMC) module.
- Monitors its own power supply voltage (VDD_HV_PMC) to determine that the applied voltage is within a specified range.
- Monitors the core power supply voltage (VDD_LV_CORE) to determine that the applied voltage is within a specified range.
- Monitors the low- and high-voltage detect circuit power supply voltage to determine that the applied voltage is within a specified range.
- Holds the outputs of the internal low- and high-voltage detect circuits at a ground state until the PMC determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Enables all low- and high-voltage detect circuits once all power supplies are at their functional levels.
- Begins to monitor the various power supplies using the high- and low-voltage detect circuits.
- Provides status information to the Reset Generation Module (MC_RGM) indicating whether or not power is properly applied.

To exit power-up and enter PHASE0:

- All enabled ‘destructive’ resets must be processed.
- All power supplies must be at their functional voltages.
- The PMC must signal the MC_RGM that all power supplies are at the required levels.

8.3.3 *PHASE0* Phase: analog supply initial configuration

This phase is entered:

- On exit from power-up phase.
- On PORST pin falling edge detection except for the initial power-up sequence.
- Immediately from PHASE2[DEST], PHASE3[DEST], IDLE[DEST], PHASE1[FUNC], PHASE2[FUNC], PHASE3[FUNC] or IDLE[FUNC], on the occurrence of a PORST falling edge event other than power-on reset.

During PHASE0:

- All digital modules are reset, including safety, security, and test modules.
- All trimming bits for analog modules are reset.
- Startup of the internal analog modules (PMC, IRCOSC, and I/Os) begins:
  - PMC determines that proper voltages are applied.
  - I/O pins are ensured correctly configured: outputs are driven to known levels, inputs ignored.

To exit PHASE0 and enter PHASE1[DEST]:

- All enabled destructive resets must be processed.
- Gating PHASE0 must be released. See *Table 124: POR and voltage monitors description*.
- All processes initiated in PHASE0 must be completed. This generally includes startup of the internal analog modules: PMC, IRCOSC, and I/Os.

This phase is typically completed in less than 20 µs. The device is guaranteed to remain in this phase for at least 0.5 µs.

Note: The core voltage must rise above LVD112 upper threshold to exit PHASE0. This ensures significant hysteresis on low voltage supply avoiding spurious low voltage detection during the power-up process.

8.3.4 *PHASE1[DEST]* Phase: temporization and monitoring setup

This phase is entered on exit from PHASE0.

During PHASE1[DEST]:

- Initial configuration of the watchdog to monitor the reset sequence.
- Temporization for reset signal propagation in case of reset.

This phase is completed in less than 1 µs and corresponds to eight IRCOSC clock cycles.

Test modules are available during PHASE1[DEST], but their functionality is limited by the security module (no security waiver granted at this phase).

All PHASE1[DEST] tasks must be completed before entering PHASE2[DEST].

8.3.5 *PHASE2[DEST]* Phase: flash initial configuration

This phase is entered on exit from PHASE1[DEST].

During PHASE2[DEST]:

- Reset is released to the flash memory module by the Reset Generation Module.
- The flash memory module starts its initial configuration process.
- The flash memory initialization is performed by a state machine internal to the flash module.
- The system watchdog starts monitoring flash memory configuration execution so that a reset occurs in the event of configuration failure.

Note: System Watchdog is configured to generate destructive reset in case of flash memory failure during boot process. If, on boot completion, the watchdog event is converted to generate an FCCU fault only, application software should re-configure the MC_RGM watchdog register bit to prevent destructive reset from being triggered.

All PHASE2[DEST] tasks must be completed before entering PHASE3[DEST].

This phase is completed in less than 200 µs.

8.3.6 *PHASE3[DEST]* Phase: device configuration

This phase is entered on exit from PHASE2[DEST].

During PHASE3[DEST], the System Status and Configuration Module (SSCM) starts by retrieving the Device Configuration Format (DCF) record from the TEST and UTEST flash memory areas, and uses the configuration and initialization information therein to:

- Configure the Self-Test Control Unit (STCU2) and the initial memory map of the device.
- Transfer reset vectors for the various cores to the Mode Entry Module (MC_ME). This information enables tests that the STCU runs and also provides the memory map setup information so that the STCU can test memory.
- Write trim values for analog modules including the Analog-to-Digital Converter, low- and high-voltage detect circuits, and the temperature sensor to their respective registers.

The DCF record programmed into the TEST flash memory area is generally written by the manufacturer. The portion of the DCF record programmed into the UTEST flash memory is usually written by the customer, although there is a default DCF record programmed into both the TEST and the UTEST flash memory areas during device production testing. In general, you write your own DCF record for the UTEST area to replace the default DCF.

The DCF record also provides configuration information for the following:

- Trimming of the analog modules (for example, voltage regulator, voltage detectors, I/Os, and oscillator)
  - Trim values are in DCF records in the TEST flash memory area.
  - Trim values are determined during production test and programmed into the TEST flash memory area.
- Device life cycle information:
  - Censorship configuration.
  - Debug security configuration.
  - Functional security configuration.
- Application configuration bits:
  - Watchdog configuration.
  - Safety execution directives (self-test, LBIST/MBIST).
  - Boot Assist Flash options.
  - Oscillator startup during reset sequence configuration.

To exit PHASE3[DEST]: All processes that need to be completed in PHASE3[DEST] must be finished.

This phase depends on actual trim values, especially those used for safety execution directives. This device configuration is maintained until the next internal power-on reset. Each time a destructive reset event occurs, the SSCM takes values from the DCF record and writes them to the applicable registers.

During this phase, the internal STCU watchdog is started and is only cleared after completion of STCU configuration.

If self-test execution is the configuration information from the DCF record requests , the device moves to IDLE[DEST] and the STCU2 begins self-test. At the end of the test, the STCU2 asserts a functional interrupt causing the Reset Generation Module to move to PHASE1[FUNC]. If self-test execution is not requested, the device moves directly to IDLE[FUNC]. The Reset Generation Module determines whether self-test execution is enabled or not by examining an entry in the DCF record stored in the UTEST flash memory.

Note: When self-test execution is not requested, it is possible to maintain the device in PHASE3[DEST] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.

8.3.7 *IDLE[DEST]* Phase: self-test execution

This phase is entered upon exit from PHASE3[DEST] if the execution of self-test is enabled.

During the IDLE[DEST] phase:

- Dedicated watchdog is configured to monitor self-test execution completion within expected time. The length of this phase is variable depending on the self-test requirements.
- The Self-Test Control Unit (STCU2) executes all tests specified by the DCF information retrieved in PHASE3[DEST].
- The self-test engine updates the self-test completion flag and triggers an associated functional reset on completion of self-test.

The length of this phase is variable depending on the self-test requirements.

Note: When the SSCM is decoding the Device Configuration field, it sets and clears various flags in STCU registers and memory that can later be examined by the SSCM to determine which self-test directives must be run.

Exiting IDLE[DEST] and moving to PHASE1[FUNC]:

- The IDLE[DEST] phase is automatically exited when the self-test code generates a functional reset on completion.
- The functional reset causes the reset generation module to move to the PHASE1[FUNC] phase.

Note: In case of unrecoverable fault detection during STCU execution, unrecoverable fault reset is triggered and device re-enters PHASE1[DEST].

8.3.8 *PHASE1[FUNC]* Phase: temporization and monitoring setup

This phase is entered either:

- On exit from IDLE[DEST]
- Immediately from PHASE2[FUNC], PHASE3[FUNC], or on IDLE[FUNC] when a non-masked external or “functional” reset event occurs, providing the source of the reset event has not been configured to trigger a ‘short’ reset sequence

During PHASE1[FUNC]:

- Initial configuration of the watchdog to monitor reset process
- Temporization for reset signal propagation in case of reset

To exit PHASE1[FUNC] and enter PHASE2 [FUNC]:

- All enabled, non-shortened “functional” resets must be processed.
- All processes started in PHASE1[FUNC] must be completed.
  - Initial configuration of the watchdog to monitor reset process
  - Temporization for reset signal propagation in case of reset

This phase is completed in ~1 µs or less. During this phase, test modules are available.

8.3.9 *PHASE2[FUNC]* Phase: flash initial configuration

This phase is entered on exit from PHASE1[FUNC].

During the PHASE2[FUNC] phase:

- The reset signal is released to the flash memory.
- Flash initialization and configuration begins using a state machine that is internal to the flash memory module.
- A watchdog monitors flash initialization to ensure a reset in case of flash memory configuration failure.

The reset state machine exits PHASE2[FUNC] and enters PHASE3[FUNC] on verification that all processes started in PHASE2[FUNC] are completed.

This phase is completed in ~200 µs.

8.3.10 *PHASE3[FUNC]* Phase: device configuration monitoring

PHASE3[FUNC] is entered:

- On exit from PHASE2[FUNC].
- Immediately from IDLE[FUNC] when an enabled, short functional reset event occurs.

During PHASE3[FUNC], configuration information contained within the UTEST flash memory sector is checked against information extracted during PHASE3[DEST] and written to the Self-Test Control Unit (STCU2). In case of mismatches, a dedicated boot fault is triggered within the FCCU which, if enabled, can cause a system reset. The purpose of PHASE3[FUNC] is to verify that the DCF information transferred to the STCU, MC_ME and other modules, in PHASE3[DEST], was performed correctly and has not been corrupted.

The Reset Generation Module exits PHASE3[FUNC] and enters the IDLE[FUNC] on verification of the following:

- All processes started in PHASE3[FUNC] are completed.
- PORST and ESR0 pin are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened “functional” reset event.

After all PHASE3[FUNC] internal actions have been completed, it is possible to maintain the device within PHASE3[FUNC] by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes in order to connect through the JTAG port to the internal debugger. In the case of a secured device, it is possible to submit the debug password to access device debug through the JTAG module.

8.3.11 *IDLE[FUNC]* Phase

This is the Reset Generation Module’s final phase of the reset sequence. It is entered either on exit from PHASE3[DEST] (if self-test was not enabled) or at the completion of ***PHASE3[FUNC]***. When the IDLE[FUNC] phase is reached, the MC_RGM releases control of the system to the System Status and Control Module. The SSCM, which started in PHASE3[FUNC], runs and waits for a signal from the MC_RGM indicating that the MC_RGM is now in the IDLE state. The MC_RGM then waits for new reset events that can trigger a reset sequence. The SSCM continues with the system boot-up sequence.

8.4 MC_RGM passes boot sequence control to the System Status and Control Module

The SSCM continues the boot-up sequence after the Self-Test Control Unit (STCU2) finishes executing the MBIST and LBIST functions that were initiated by the MC_RGM during the IDLE[DEST] state.

A flow chart of the boot-up sequence is shown in *Figure 43*, *Figure 44*, *Figure 45*, *Figure 46*, and *Figure 47*.

8.4.1 Reset sequence flow based on initial device condition

The boot-up sequence takes different paths depending on which modules are enabled and which header files are present. For instance, a device shipped from the factory has pre-

installed programs in the Boot Assist Flash and the Boot Assist ROM. Also DCF records are programmed into the TEST flash memory area and the UTEST flash memory area.

- Boot Assist Flash contains factory code which cannot be modified by user.
- Boot Assist ROM contains factory code which cannot be modified by user.
- TEST DCF record cannot be modified by user.
- UTEST flash memory contains a default DCF record which can be replaced with a user file.

After the SPC574Kx flash memory has been programmed, it contains the CPU boot header file, together with the user application. This boot header is used by the boot-up sequence flow managed by the SSCM module.

8.4.2 Possible boot-up sequences

8.4.2.1 Enter JTAG test mode

- Used for JTAG testing (non-user mode)
- Interface to JTAG port Development Equipment for Code Development

8.4.2.2 Enable IOP and Boot CPU (CPU_0)

- Normal operation for I/O Processor (IOP).
- Normal operation for the selected boot CPU.

8.4.2.3 Enable IOP and enter serial boot mode if no application code is present

- Mode used to download program code and place it in RAM.
- Mode used to start downloaded application program.

The following sections detail the exact flow through the reset sequence to achieve the various outcomes.

8.4.3 Sequence from MC_RGM IDLE to IOP and Boot CPU running code

A Boot CPU is selected and starts executing application code; it also starts all of the processor cores: CPU_0, Checker Core_0s, and IOP.

8.4.3.1 Assumptions

- Boot Assist Flash bypass mode is not enabled (execute BAF code).
- Application code for the IOP is programmed into Boot Assist Flash memory.
- Application code for the Boot CPU is programmed into flash memory.
- A valid boot header for CPU_0 and Checker Core_0s has been programmed into flash memory.
  - Boot Header_ID
  - Boot CPU selection
  - Boot CPU start address (address of first instruction in application code)
  - CPU_0 reset vector
  - Checker Core_0s reset vector
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.3.2 Reset Generation Module has entered idle state (state 1 and 2)

The Reset Generation Module (MC_RGM) enters the IDLE[FUNC] state and completes all tasks. The MC_RGM then signals the System Status and Control Module (SSCM) that it has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.3.3 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining whether a JTAG request is pending. The JTAG test circuitry is for production test and used by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.3.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the Boot Assist Flash bypass mode is enabled. If this mode is enabled, any eventual code in the BAF is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the Boot Assist Flash is always executed during a boot-up sequence.

The factory BAF code also runs the serial boot loader, setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins IOP execution at the start address specified in the file header.

8.4.3.5 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code is transferred to the MC_ME.

The SSCM releases reset to the I/O Processor (IOP) and then turns on the clock to the IOP. The BAF code start address is transferred to the IOP at this time under the control of the SSCM. Execution of the Boot Assist Flash code begins.

8.4.3.6 BAF code execution begins (state 22)

After the reset signal is released to the IOP, BAF code execution begins.

8.4.3.7 The IOP executes code to apply device setting (state 23)

The IOP executes BAF code written by the manufacturer to apply specific device settings to the SPC574Kx.

The BAF code begins by initializing registers and applying device settings. The BAF code, written by the device manufacturer, changes from device to device.

8.4.3.8 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC574Kx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC574Kx reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC574Kx production device.

8.4.3.9 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that a valid Boot Header is present.

This is the header file that specifies which Boot CPU starts executing the user application code. Generally, the Boot CPU is Core_0. The boot header file also contains the reset vector addresses for Core_0 and the Checker Core_0s.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

1. Boot Header_ID/Boot_CPU
2. Start address
3. Configuration bits
4. Configuration bits
5. CPU_0 reset vector
6. Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘2’ selects the Checker Core_0s.
- Bits ‘3–15’ are not implemented.

8.4.3.10 Is a valid boot header present? (decision point N)

In the present example, a valid boot header is assumed to be present in flash memory.

8.4.3.11 Decode boot CPU (state 32)

The I/O Processor decodes the boot header and then writes the reset vectors for CPU_0 and the Checker Core_0s to the Mode Entry Module (MC_ME).

8.4.3.12 Lock BAF access (state 33)

Further access to the Boot Assist Flash is locked.

8.4.3.13 Boot from internal flash (state 34)

The MC_ME transfers the reset vectors to the respective CPUs and code execution for each of the cores begins at their respective reset vector.

8.4.4 Path from MC_RGM IDLE to serial boot mode

Here no application program or valid boot headers for CPU_0 or Checker Core_0s is programmed into flash memory. It is an unusual scenario, but it is shown here for illustrative purposes.

8.4.4.1 Initial conditions

- No valid boot header for CPU_0 and Checker Core_0s has been programmed into flash memory.
- BAF bypass mode is NOT enabled (execute BAF code).
- Application code for the IOP is programmed into the BAF.
- Application code for the Boot CPU is not programmed into flash memory.
- The Life Cycle variable is set to FACTORY, indicating an unprogrammed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.4.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. The MC_RGM then signals the SSCM that it has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.4.3 Is a JTAG request pending? (state A)

The SSCM now controls the boot-up sequence and begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.4.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the BAF bypass mode is enabled. If enabled, any code in the BAF is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the BAF is always executed during a boot-up sequence.

The BAF code written by the device manufacturer also runs the serial boot loader. This involves setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins the IOP execution at the start address specified in the header portion of the program file.

8.4.4.5 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME by the SSCM.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the BAF code.

8.4.4.6 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.4.7 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.4.8 Calibration Sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC574Kx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC574Kx Reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC574Kx production device.

8.4.4.9 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is Core_0.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

1. Boot Header_ID/Boot_CPU
2. Start address
3. Configuration bits
4. Configuration bits
5. CPU_0 reset vector
6. Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘2’ selects the Checker Core_0s.
- Bits ‘3–15’ are not implemented.

8.4.4.10 Valid boot header is not found (decision point N)

The IOP, executing code in the BAF, does not find a valid boot header file in flash memory. Because there is no valid boot header, serial boot mode must be entered to obtain an application program.

Note: This mode uses a defined protocol to receive a program over a serial port via the LINFlexD port. The IOP then jumps to the start address of the program and begins execution.

8.4.4.11 Initialize RAM (state 35)

The IOP, executing code in the Boot Assist Flash, initializes RAM in preparation for entering serial boot mode. Serial boot mode configures the LINFlexD port to receive code from an external source. The LINFlexD port comes in a number of hardware configurations. The SPC574Kx uses LINFlexD, which implements a basic UART. Code in the BAF operates the LINFlexD module and implements the protocol.

8.4.4.12 Enter serial boot mode (state 14)

Figure 47: Boot-up sequence, part E shows the boot loader flow.

8.4.4.13 Life Cycle check indicates FACTORY (decision point G)

There are two possible settings for the Life Cycle parameter:

- FIELD indicates that application code has been programmed into the flash memory of the device. Serial boot mode is exited and IOP enters a ‘wait’ mode until a watchdog reset occurs.
- FACTORY means that there is no application code programmed into the flash memory. For the present example a setting of FACTORY is assumed.

8.4.4.14 Receive and install application code

In general, a serial link is implemented using the LINFlexD port and a particular protocol for data transmission has been defined and implemented in the Boot Assist Flash code. Once the LINFlexD port is configured, the serial boot loader waits to receive the code.

Note: There is a software watchdog timer that is started by the BAF code. If a program is not received before the watchdog timer timeout, a reset occurs.

1. Configure LINFlexD module and external pins (state 37).
2. Wait for START WORD (state 38).
3. Receive START WORD (state 39).
4. Receive START ADDRESS (state 40).
5. Receive DOWNLOAD SIZE (state 41).
6. Receive CODE (state 42).
7. Branch to START ADDRESS (state 43).

Application code, using the IOP, begins at the received START ADDRESS.

8.4.5 Path from MC_RGM IDLE with IOP enabled to watchdog timer timeout

Here the operation of the IOP is desired but there is no valid boot header file and the Life Cycle variable is set to FIELD, indicating that the device was programmed with application code and the appropriate boot header files.

This path is only taken if a catastrophic event has occurred or the device is improperly programmed.

8.4.5.1 Initial conditions

- BAF bypass mode is not enabled (execute BAF code).
- A valid boot header for CPU_0 and Checker Core_0s has not been programmed into flash memory.
  - Boot Header_ID
  - Boot CPU selection
  - Boot CPU start address (address of first instruction in application code)
  - CPU_0 reset vector
  - Checker Core_0s reset vector
- The Life Cycle variable is set to FIELD, indicating a programmed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.5.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. It then signals the SSCM that the MC_RGM has become idle and the SSCM can take control of the boot-up sequence.

At this point:

- LBIST and MBIST have completed their test cycles.
- The data in the DCF record has been written to the appropriate registers.
- All the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.5.3 Is a JTAG request pending? (state A)

The SSCM now controls the boot-up sequence and begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems.

The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.5.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether or not the boot assist flash bypass mode is enabled. If this mode is enabled, any eventual code in the Boot Assist Flash is not executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. This means that the code in the BAF is always executed during a boot-up sequence.

The factory BAF code also runs the serial boot loader, setting up pins on the device to act as a UART: receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM begins IOP execution at the start address specified in the file header.

8.4.5.5 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the Boot Assist Flash code.

8.4.5.6 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.5.7 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.5.8 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC574Kx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC574Kx reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC574Kx production device.

8.4.5.9 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is Core_0.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of the following words:

1. Boot Header_ID/Boot_CPU
2. Start address
3. Configuration bits
4. Configuration bits
5. CPU_0 reset vector
6. Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

- Bit ‘0’ selects the I/O Processor
- Bit ‘1’ selects CPU_0,
- Bit ‘3’ selects the Checker Core_0s.
- Bits ‘4–15’ are not implemented.

8.4.5.10 Valid boot header is not found (decision point N)

The IOP, executing code in the BAF, enters serial boot mode to obtain an application program as it does not find a valid boot header file in flash memory.

Note: This mode uses a defined protocol to receive a program over a serial port via the LINFlexD port. The IOP then jumps to the start address of the program and begins execution.

8.4.5.11 Initialize RAM (state 35)

The IOP, executing code in the BAF, initializes RAM areas in preparation for serial boot mode. This mode configures the LINFlexD port to receive code from an external source using a basic UART protocol.

8.4.5.12 Enter serial boot mode (state 14)

Figure 47: Boot-up sequence, part E shows the boot loader flow.

8.4.5.13 Life Cycle check indicates FIELD (decision point G)

There are two settings for the Life Cycle parameter: FIELD and FACTORY.

FIELD indicates that application code has been programmed into the flash memory. In this case, the IOP enters a ‘wait’ mode until a watchdog reset occurs.

8.4.5.14 Stop—wait for watchdog (state 36)

This state is entered when the SPC574Kx’s program flash memory is incorrectly programmed.

9 Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record consists of a pointer to the location of a register internal to the device and the respective data.

There are two broad categories of DCF records:

- TEST DCF records are developed by the factory. They can be used to write any DCF client, but are used mainly to:
  - Program registers involved in trimming trip points for voltage comparators.
  - Adjusting analog to digital voltage supplies.
  - Trim oscillator frequencies.
  - Enable RAM repair.

Note: The TEST DCF Records are programmed into TEST flash during production and cannot be modified. TEST flash is not visible to the user.

- UTEST DCF records can be either:
  - Factory programmed during production testing (see “UTEST flash memory map” table in *Chapter 5: Memory map*).
  - User programmed when application code is written into the flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the factory UTEST DCF records. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) runs during the boot sequence, assign flash memory blocks to specific tamper detect regions, assign memory blocks as OTP and assign flash blocks to be associated with specific password groups.

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective flash memories.

When power is applied to a properly programmed device:

1. The Power Management Controller (PMC) takes control of the device until the system power supplies have reached predefined levels.
2. The PMC then signals the Reset Generation Module (RGM) to begin the boot sequence.
3. During boot, the RGM enables the System Status and Control Module (SSCM) to read the device configuration records and write information to specific registers.
4. After registers are initialized, the SSCM starts the Self-Test Control Unit (STCU2), which begins running the tasks enabled by the DCF record information.

9.2 DCF clients

DCF clients are 32-bit hardware registers inside a module that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features.

DCF Clients have a default value before any DCF Records are written and may have special writing constraints like ‘Write Once’ or only allowing bits to be written from ‘1’ to ‘0’ or vice versa. DCF clients need not implement all 32 bits. DCF clients may be designated ‘TEST DCF Record Only’ so that only DCF Records stored in TEST flash can write to the DCF Client.

A list of DCF clients is shown in *Table 121*. (TEST DCF Record Only clients are not shown as these are not accessible by the user).

The DCF Records select the target DCF client via a 30-bit field in the DCF Record consisting of:

- A 15-bit Chip-Select field—each module that includes DCF clients is assigned a Chip Select during chip definition.
- A 15-bit Address field—the address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory beginning at 0x0040_000.

The structure of a DCF Record is shown in *Figure 48*.

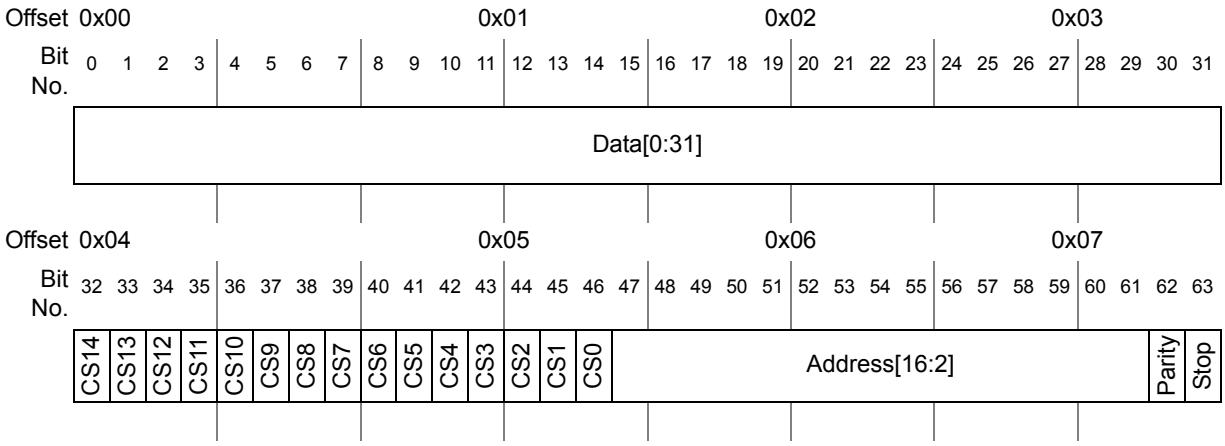

Figure 48. DCF record structure

Table 119. DCF record field description

Field	Description
0–31 Data[0:31]	32 bits of data to be written to the DCF Client.
32–46 CS*n*	Chip Select n. **Note:** Only assert one chip per DCF record to select the target module for the DCF client. All other Chip Selects should be negated. 1 Chip select is asserted 0 Chip Select is negated

Table 119. DCF record field description(Continued)

Field	Description
47–61 Address[16:2]	Address of the DCF client within the selected module. **Note:** Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter.
62 Parity	Parity Bit for the DCF Record. **Note:** This bit is NOT implemented for DCF Clients written from UTEST.
63 Stop	This bit indicates the end of the list of DCF Records. **Note:** The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list. 1 End of the list. 0 NOT the end of the list.

The following structure must be present:

- The first record must be a start record.
- DCF records containing configuration data must immediately follow the start record with no blank records between—an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a stop record.

Each record is 64 bits in length. *Figure 49* shows the DCF start record.

Warning: The start record must be placed at the beginning of the DCF area in UTEST flash memory to indicate that the following data records must be processed.

Figure 49. DCF start record

0x00 0:31	0x04 32:63
0x05AA55AF	0x00000000

During system boot, while the reset signal is asserted, the SSCM reads the device configuration records and writes the data to the appropriate internal module registers. Many operational aspects of the device are therefore already configured when the reset signal is released and normal device operation begins.

Some device configuration records are calculated during production testing and programmed into the TEST flash memory area. Other DCF records are developed by the user and programmed into the UTEST flash area.

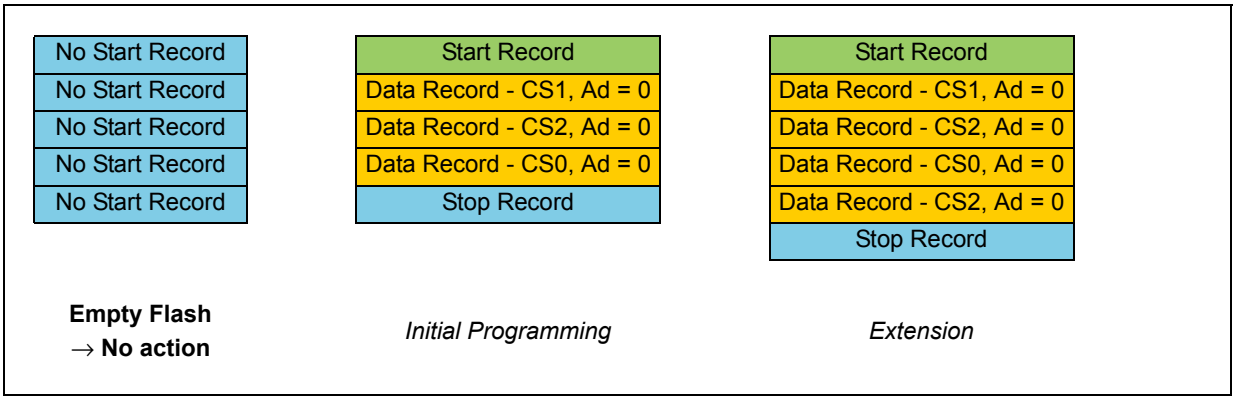
The stop bit designates the last device configuration record in a set of records. It is not normally set in a valid UTEST DCF record programmed during production as this prevents additional UTEST records from being appended to the factory programmed UTEST DCF records. However, the flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location whose contents is

0xFFFF_FFFF_FFFF_FFFF. The stop bit location in this unprogrammed flash memory location is therefore a logic 1, signifying that this is the last DCF record and not to be acted on.

The general format of the stop record is shown in *Figure 50*. Only the stop bit needs to be '1' in order to form a stop record—all other bits are ignored. An unprogrammed location in UTEST flash is interpreted as a stop record.

Figure 50. DCF stop record

0:31	32:62	63
Reserved	Reserved	1



If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 120*.

Table 120. Series of DCF records in UTEST flash memory

ADDR offset	DATA			
0x00	0x05AA55AF			
0x04	0x00000000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
8*n* + 0x0	Reserved			
8*n* + 0x4	Reserved			STOP=1
8(*n*+1) + 0x0	—			
8(*n*+1) + 0x4				

Warning: There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored. Records to be programmed in several sessions, appending new records to the end of the list each time, is shown in *Figure 51*.

Figure 51. Appending DCF records

It is possible for more than one DCF Record to write to the same DCF client. The later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST flash memory area (refer to UTEST flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory and the user may add USER DCF records from the first unprogrammed location following the factory programmed UTEST DCF records. An unprogrammed location in flash memory contains 0xFFFF_FFFF.

When programming UTEST DCF records, the records must start at the first address in the UTEST flash memory area and be continuous: one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module.

9.4 DCF client table

A list of DCF clients is shown in *Table 121*. Various attributes of the DCF clients are listed in these tables:

- DCF Chip Select—the CS field is a 15-bit field with each bit acting as a module select signal for the internal modules. Only one bit in this field should be set in a DCF record.
- DCF address—the 15-bit ADDR field specifies an internal address for a DCF client. These addresses are only used by the SSCM when interpreting DCF records and writing data to specified modules.
- DCF Client Description—the name of the DCF clients.
- Reset value of DCF client—the reset value of DCF client before being written by the SSCM with the associated DCF record.
- Typical value of DCF client—a typical value that users may program into the various DCF clients. It is for information only.
- IPS read—this column specifies whether or not a DCF client can be read by user software after the release of reset.
- DCF client special strategy—registers are designated as DCF clients if they need to be written with a DCF record. Other features that must be designated for DCF clients

include different write strategies listed below. The following list defines the special strategies.:

- None—no special DCF strategy is used.
- Parity—not implemented for UTEST DCF clients. Used for TEST Only DCF clients not accessible to the user.
- Write Once—a DCF client can only be written once. The DCF client ignores subsequent writes.
- Triple Voted—DCF clients have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. Triple voting allows for 'bit-flip' error tollerance without changing the DCF client output data.
- Triple Voted with second write—as per 'Triple Voted' but during the second execution of Phase 3 of the reset sequence, the SSCM attempts to write the DCF client again and the DCF client checks that the register contains the same data.
- Write 0 only—a bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a logic 1 is ignored.
- Write 1 only—a bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a logic 0 is ignored.
- DCF order dependency in flash memory—this column details whether or not there are special conditions on the location of a particular DCF record in flash memory.

9.4.1 DCF client list

Table 121. DCF client list(1)

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description	Reset value of DCF client	Typical value of DCF client	IPS read direct access	DCF client special strategy	DCF order dependency in flash memory	Estimated UTEST flash memory space (bytes)
STCU - Support for 8 LBIST partitions; 41 Memory Cuts; 32-bit PRPG; 64-bit MISR								
000_0000_0000_0100	00000000000 0010	STCU_SKC	0x00000000	0xD3FEA98B 0x2C015674	yes	None	First Record among STCU, Key1/Key2 dcf record sequence; Write Key2 every (1024-8) clock edges	16
000_0000_0000_0100	00000000000 0000	STCU_RUN	0x00000000	0x00000400	yes	None	None	8

Table 121. DCF client list[1](Continued)

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description	Reset value of DCF client	Typical value of DCF client	IPS read direct access	DCF client special strategy	DCF order dependency in flash memory	Estimated UTEST flash memory space (bytes)

9.4.2 Miscellaneous DCF registers

Offset: 000000000000000 Access: DCF Client

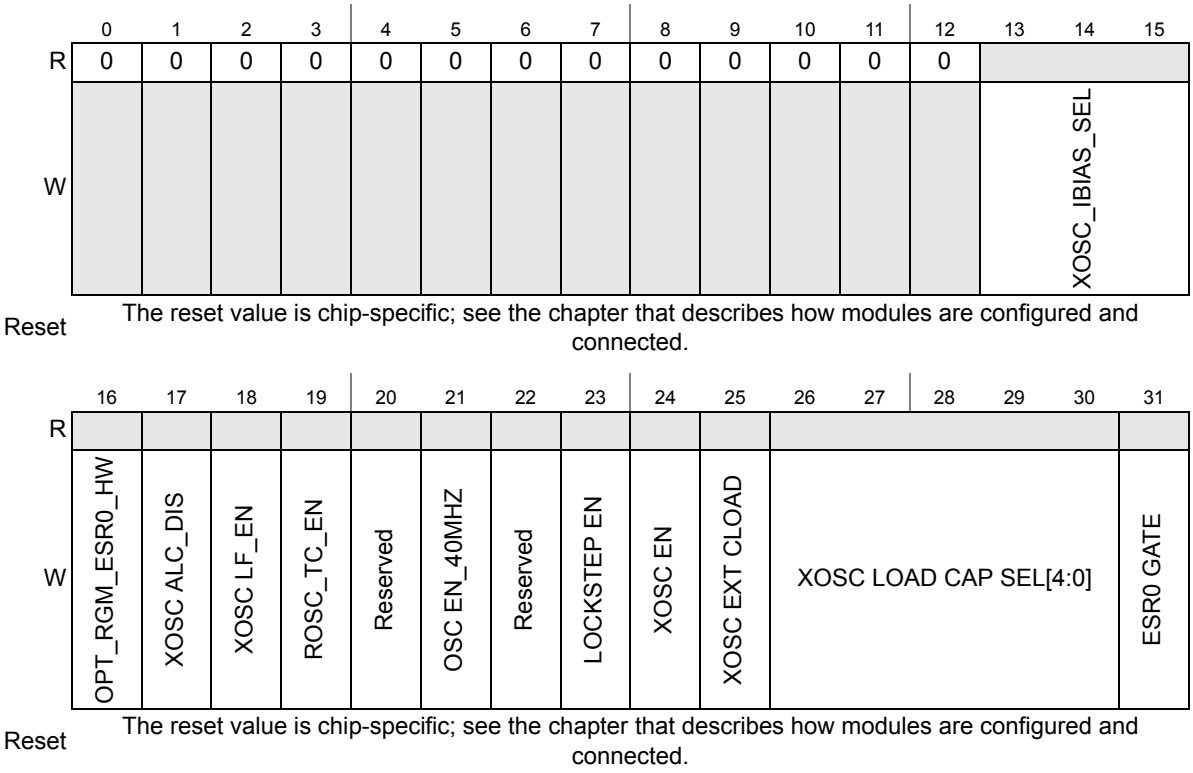

Figure 52. UTEST Miscellaneous DCF Client

Table 122. UTEST Miscellaneous DCF Client field descriptions

Field	Description
0–12	Reserved
13–15 XOSC_IBIAS_SEL	XOSC ibias_sel[2:0]. There are 3 bits to control the XOSC bias current. 1*x* is the default current consumption in the external oscillator (XOSC). 000 0 (no current) 001 0.25*x* 010 0.5*x* 011 Reserved 100 1*x* 101 1.25*x* 110 1.5*x* 111 1.75*x* (maximum current)
16 OPT_RGM_ESR0_HW	OPT_RGM_ESR0_HW 0 Allows MC_RGM to continue to assert ESR0 until RGM_EROEC[EROEC] bit has been cleared by software 1 Does not allow MC_RGM to continue to assert ESR0 until RGM_EROEC[EROEC] bit has been cleared by software

Table 122. UTEST Miscellaneous DCF Client field descriptions(Continued)

Field	Description
17 XOSC ALC_DIS	XOSC ALC_DIS 0 Enable Automatic Level Controller 1 Disable Automatic Level Controller
18 XOSC LF_EN	XOSC LF_EN 0 Oscillator is not used for low frequency (~8 MHz) 1 Oscillator is used for low frequency (~8 MHz) It is possible to use a low-frequency oscillator (< 16 MHz) configuring properly the CMU_PLL instance—specifically, modifying the field CSR[RCDIV] value. To configure properly the field RCDIV, see *Section 28.5.2: CLKMN0_RMT supervisor*.
19 ROSC_TC_EN	ROSC_TC_EN — RC oscillator temperature compensation enable. This field is set by default. 0 The temperature compensation is disabled. It is disabled when the XOSC frequency trimming is guaranteed by dedicated software tracking procedure, eventually including CCCU hardware module output. 1 The temperature compensation is enabled. The XOSC precision is guaranteed across temperature values.
20	Reserved
21 OSC EN_40MHZ	XOSC EN_40MHz 0 20 MHz 1 40 MHz XOSC
22	Reserved
23 LOCKSTEP EN	LOCKSTEP EN — Enable Safety Core to be in lockstep with Checker Core. 0 Lockstep disabled 1 Lockstep enabled
24 XOSC EN	XOSC EN — Enable XOSC 0 XOSC disabled 1 XOSC enabled
25 XOSC EXT CLOAD	XOSC EXT CLOAD 0 Selects XOSC internal cap (ok for 20–40 MHz operation) 1 External (required for 4–16 MHz operation)
26–30 XOSC LOAD CAP SEL[0:4]	XOSC LOAD CAP SEL [0:4] — Five trim bits to program the load capacitance. Load capacitor values are determined by the crystal manufacturer data sheet. **Note:** To know the capacitance values relative to the 5-bit binary combinations, refer to the "Selectable load capacitance" table of the device datasheet.
31 ESR0 GATE	ESR0 Gate — Gate ESR0 Input 0 ESR0 Input Disabled. ESR0 only asserted as an output from the device. 1 ESR0 Input Enabled. Assertion of the $\overline{\text{ESR0}}$ pin causes a hard system reset.

10 Security

All SPC57xx family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations while other more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off; they require significant involvement for implementation. Consequently, they provide an important opportunity to define the security level of the device.

10.1 Basic security

All SPC574Kx devices have the following basic set of security features.

- Device censorship based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
  - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection
  - SRAM and caches initialized to a constant value after reset (power-on reset, when in a test mode, when not booting from internal flash memory); MBIST functionality used in case of power-on and destructive resets to initialize RAMs selected via configuration in UTEST flash; BAF software routines to initialize RAMs when not booting from internal flash memory
- Monitoring of operating conditions
- Unique ID for each device: each SPC574Kx device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device
- Secure watchdog timer
- Basic debugger restrictions (on/off via censorship mode)

10.2 Advanced security

Depending on the device configuration, the following features are available:

- Secure debugger interface
- Boot mode: Trusted/secure boot support

10.3 Detailed security information

Details of most of the SPC574Kx security features are published in a separate *SPC574Kx Microcontroller Security Reference Manual*, which is only available to qualified customers.

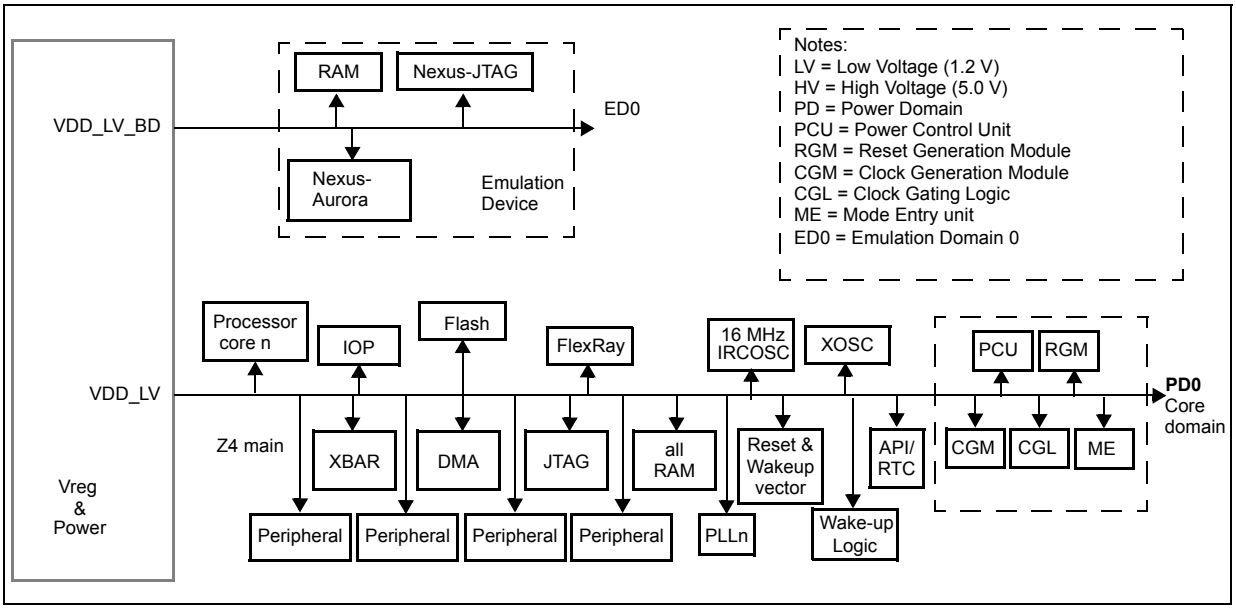
11 Power management

11.1 Overview

SPC574Kx microcontrollers include a robust power management infrastructure for applications to select various Operational and Low-power modes and monitor internal voltages for High- and Low-voltage conditions. This monitoring is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller leaves reset.

This chapter gives an overview of the built-in power management features.

The power management infrastructure encompasses the following modules:



- Power Control Unit (MC_PCU): provides a status register, and the Power Management Control Digital Interface (PMC_dig) submodule, which provides an interface to configure and control internal voltages.
- Clock Generation Module (MC_CGM): generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement Low-power modes.
- Mode Entry Module (MC_ME): controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application.
  - System modes RESET, SAFE, TEST and DRUN are entered automatically on system events or on application request.
  - User modes RUNx, HALT, and STOP control performance and consumption during normal application operation. The modes are organized according to the performance provided. Each mode is entered via a dedicated key-protected register to avoid unwanted transition.

See the respective module chapters for further details.

11.1.1 Power management framework

The power management framework supports a variety of configuration options. See *Figure 53* for more details. SPC574Kx implements a unique core voltage power domain. There are no separate functional power domains.

Figure 53. Device power management framework

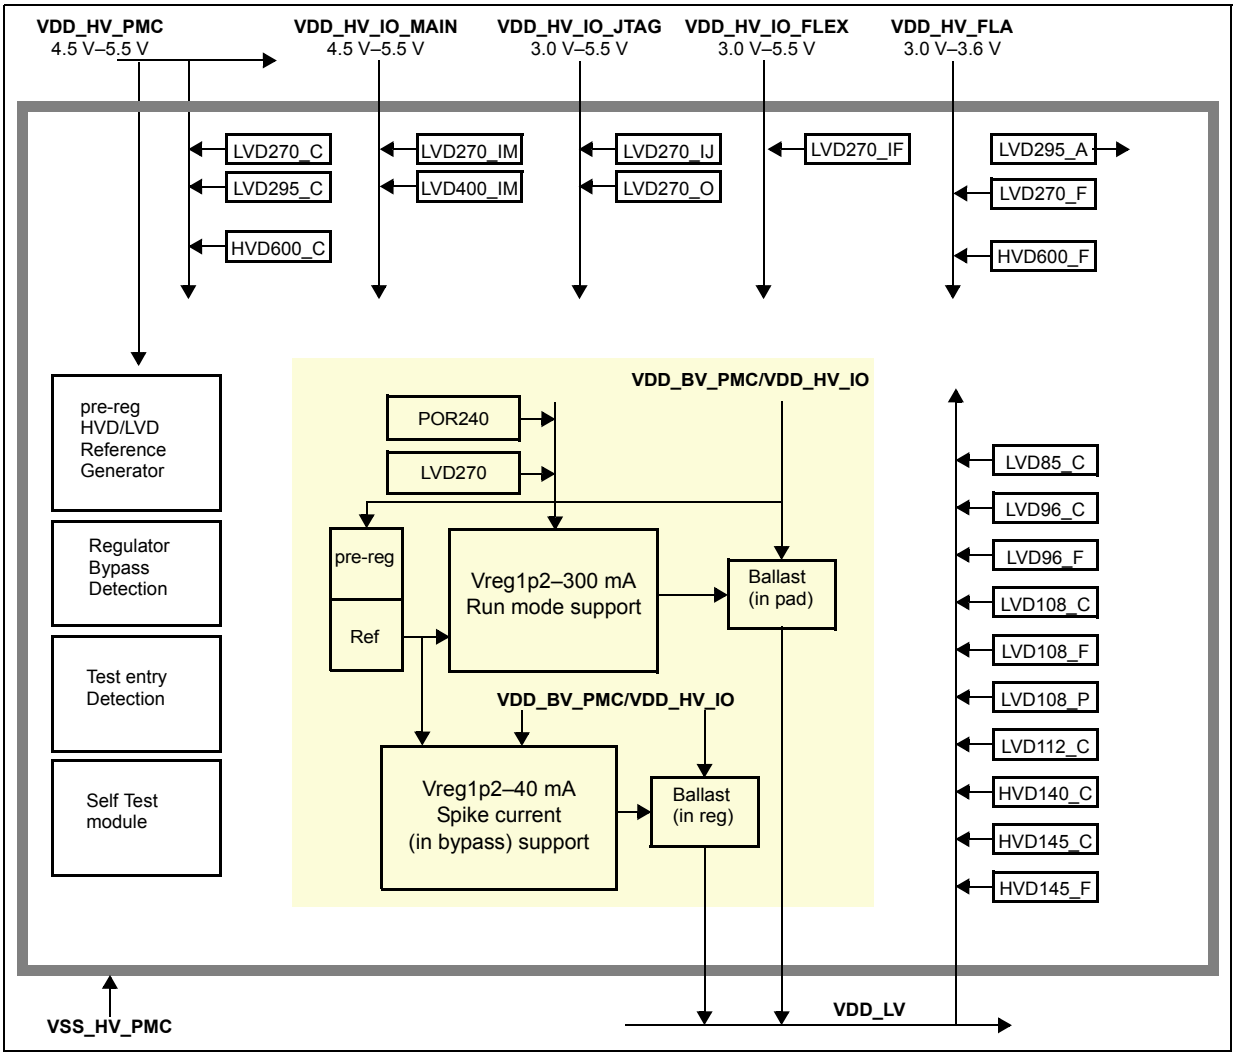
11.1.2 Power management supply description

Table 123 provides an overview of the PMC supply signals.

Table 123. Device power management controller external signals

Name	Type	Description
VDD_HV_ADR_D	Reference	Voltage reference of ADC Σ/Δ module
VDD_HV_ADR_S	Reference	Voltage reference of ADC SAR module
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_IO_MAIN	Supply	High voltage power supply for the I/Os
VDD_HV_IO_FLEX	Supply	FlexRay/Ethernet 3.3 V I/O supply
VDD_HV_IO_JTAG	Supply	Oscillator and JTAG pin supply
VDD_HV_PMC	Supply	High voltage power supply for internal power management unit
VDD_LV	Supply	External low voltage power supply for the core area
		Low voltage power supply for the core area generated by internal regulator
VDD_LV_BD	Supply	Low voltage power supply for the buddy device(1)
VSS	Ground	Ground supply for the device / I/O. This covers both VSS_LV and VSS_HV in case of exposed pad device.
VSS_HV_ADR_D	Reference	Ground reference of ADC Σ/Δ module
VSS_HV_ADR_S	Reference	Ground reference of ADC SAR module
VSS_HV_ADV	Supply	Ground supply for the ADC modules

1. VDD_LV_BD to be supplied before VDD_LV or at the same time.



Warning: There are constraints on some input voltages relative to other input voltages. Please refer to the device data sheet for detailed information.

11.1.3 SPC574Kx power management controller overview

SPC574Kx power management controller (PMC) implements the following modules:

- Main regulator with internal ballast with dedicated reference.
- LVDs/HVDs monitoring low voltage supply with characteristics as defined in *Table 124* working on dedicated reference, different from regulator reference.
  - Low voltage detector: LVD096_C, LVD096_F, LVD108_C, LVD108_F, LVD108_P, and LVD112_C
  - High voltage detector: HVD140_C, HVD145_C, and HVD145_F
- LVDs/HVDs monitoring high and medium voltage supplies with characteristics as defined in *Table 124* working on dedicated reference, different from regulator reference.
  - HV Low voltage detector: LVD270_C, LVD270_O, LVD270_F, LVD270_IM, LVD270_IJ, LVD270_IF, LVD295_A, LVD295_C, and LVD400_IM
  - HV High voltage detector: HVD600_C
- 2 separate voltage references for safety detection in case of single reference failure:
  - Regulators run on VDD_BV_PMC dedicated supply and dedicated reference.
  - Core supply is monitored using VDD_HV_PMC and associated reference

Figure 54. Device PMC block diagram (simplified)

11.1.3.1 Core supply main regulator characteristics

Main regulator ensures supply remains in functional range without triggering HVDs/LVDs.

Main regulator uses dedicated reference supplied by VDD_BV_PMC.

11.1.3.2 SPC574Kx power management controller integration

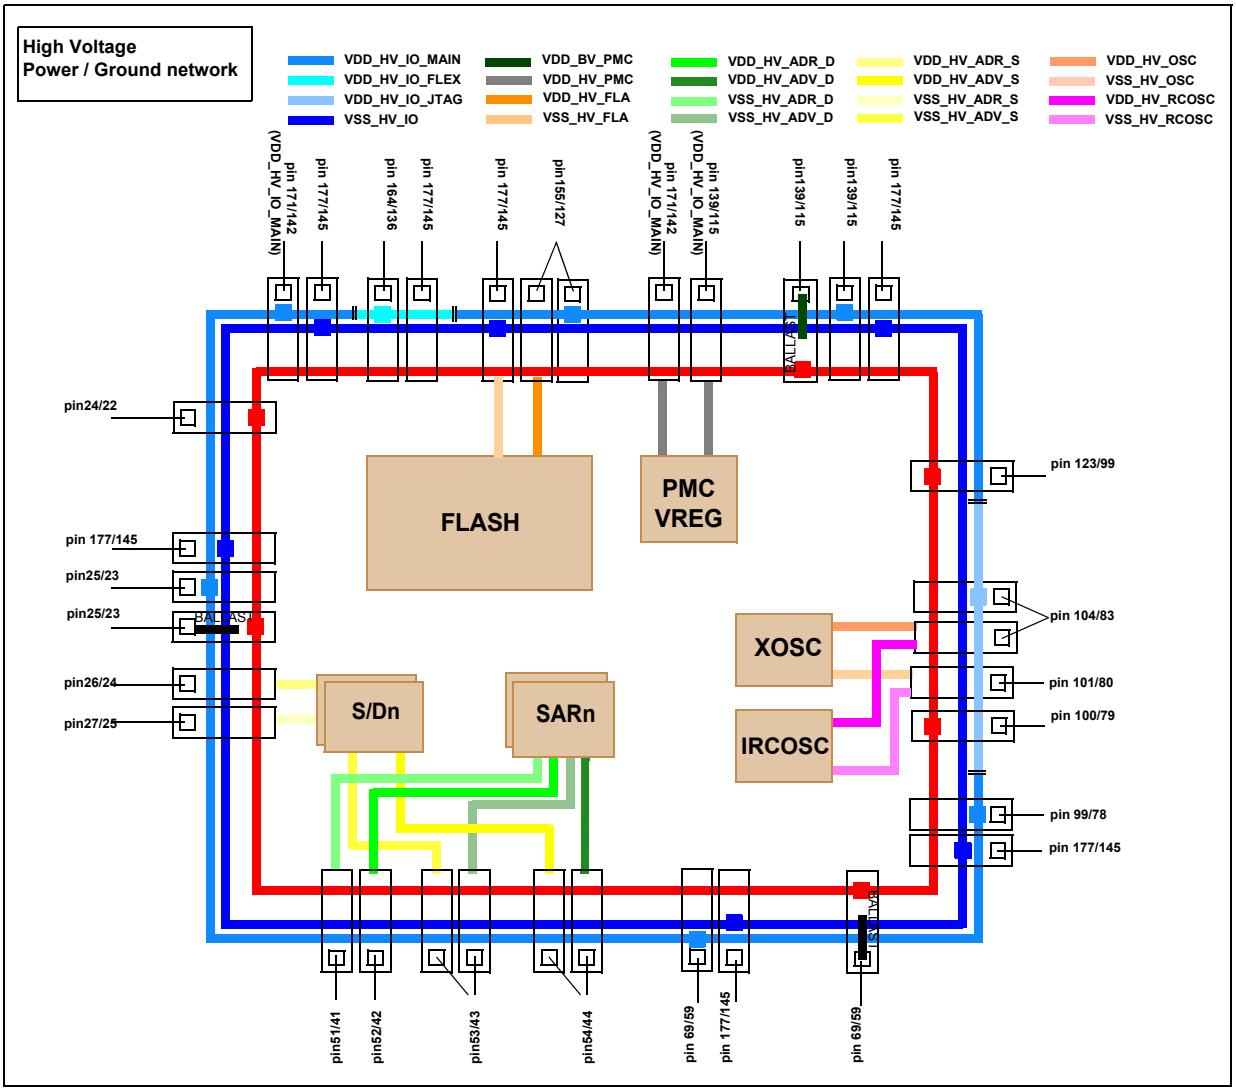
The power management controller has two separate supplies:

- VDD_HV_PMC: provides the main module supply to the power management controller
- VDD_BV_PMC: provides the low voltage ballast supply, the regulator and the reference for low voltage generation.

Note: The internal ballasts are distributed around the device to reduce the temperature gradient on the silicon.

VDD_HV_PMC should always be shorted with VDD_HV_IO_MAIN externally.

Figure 55. Device high voltage power-ground network



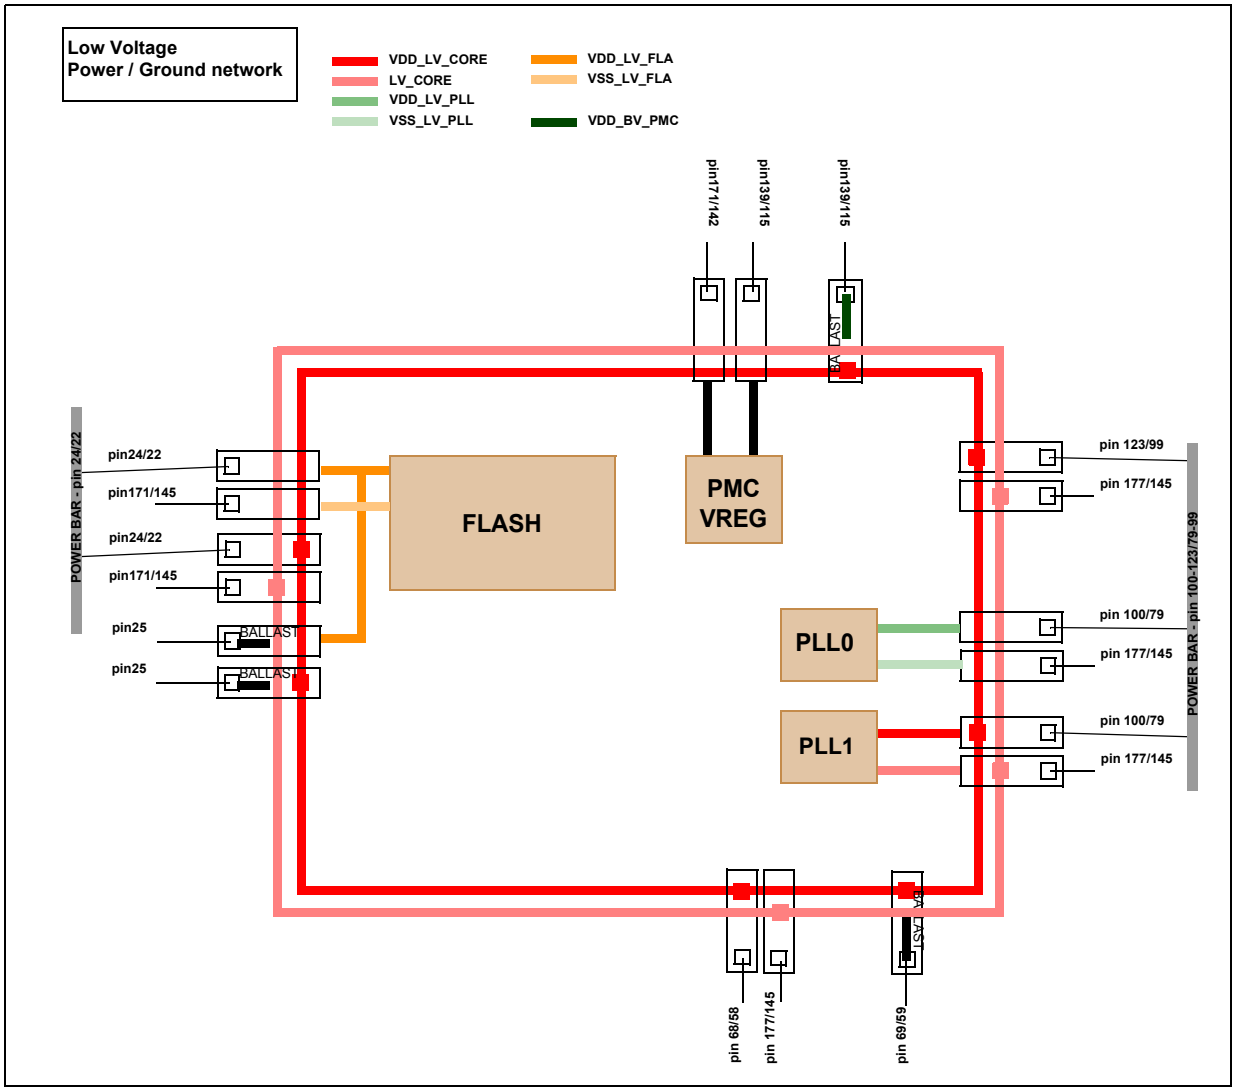


Figure 56. Device low voltage power-ground network

VDD_HV_IO_MAIN redundancy ensures that single pin failure does not prevent device function, although full specification may not be guaranteed.

VDD_HV_PMC redundancy ensures that single pin failure does not prevent device function, although full specification may not be guaranteed.

VDD_LV is redundant, ensuring that single pin failure does not prevent the device from functioning correctly.

The device remains functional when more than four supply pins are available for the same supply, although it may not satisfy all electrical specifications, including EMC performance. This requirement is not applicable to: SAR, S/D, FlexRay, Ethernet, oscillator, JTAG.

11.2 Low power mode support

The SPC574Kx microcontroller supports low power modes.

Dedicated logic prevents uncontrolled activation of low-power mode. This is implemented using protected sequence from the Mode Entry control module MC_ME.

Any register associated with low power entry is triple-voted.

11.2.1 Low power support and STOP mode implementation

Low power mode may be used to control the engine during the power-up phase, as in a Start-Stop system or when the key has been turned off.

After-run is defined as part of RFQ500, the requirement has since been clarified as follows.

The device implements the equivalent of an idle or power-down mode through STOP and HALT mode configuration.

The microcontroller application code can be used to put the device or modules into STOP mode.

A combination of mode control and clock control allows the user to configure the STOP mode.

In After-run mode, peripheral modules can be enabled/disabled in STOP using the control described in the Mode Entry control section. For example, it is possible to make two CAN modules, one ASC module and a few requested pins active. For alternate configurations, other modules can be enabled/disabled in STOP using the control described in the Mode Entry section. External interrupt request channels and external wake-up channels can be actived to wake-up the device as alternatives to peripherals interrupts.

All pins associated with the active modules are functional. Control of the pins is defined by user during run-time. A wake-up line is associated with each selectable module.

One of the available modules can be configured to perform the wake-up task. For example, with *n* CAN modules on the chip, one is configured to receive wake-up signals and the others are set to power-down completely. Any of the modules can be configured to do this.

All CAN modules can be independently configured to receive messages and respond to wake-up messages. Control of the pins is defined by user during run-time.

These modules can also be idle in idle mode, but wake-up and wake the core as soon as activity is detected.

All these modules can be configured to a low power state. Wake-up recovery is programmable: for instance, depending on the state or activity of the associated pin.

All parts of the device can be disabled. The following modules are configurable:

- There is one CAN module, selectable from any of the CAN modules on the device. The others can be disabled.
  - The maximum CAN baud rate is 1 MBaud.
  - One CAN module is able to receive messages from the CAN bus and wake-up the controller if the received message contains the correct message identifier.
- One LIN/UART module is able to recognize special wake-up messages on the receive line and then wake up the controller.
- Some request pins are able to initiate a wake-up. Refer to the pinout chapter for more information.
- The system timer (PIT) is able to initiate a wake-up.

Configurable modules (ASC, three CANs, timer) can all be off in STOP mode.

The CAN module recovers from wake-up instantaneously but its ability to capture the message depends on settings of certain peripherals such as the CAN protocol clock. SInce the recovery time impacts whether the first message can be captured, software must be used as a workaround.

Device implements all three mechanisms to exit from stop mode: pin wakeup, CAN wake-up and timed wake-up.

Some customer implementations may use an external ASIC regulator that does not have low-power mode support. The Asic regulator is either on or off, with no possibility of changing the regulated output in operation.

11.2.1.1 After-run mode implementation

After-run mode is mainly implemented via clock gating, module disabling, reduced frequency and mode switching. This is done based on revised RFQ500 targets.

In this mode:

- The selected CAN is kept enabled (clocked and active) so it can maintain synchronization with the CAN network.
- The supplied Bosch CAN module can buffer the received (first) message and then interrupt the IOP.
- The IOP executes from TCM (i.e., Flash is disabled) and uses the internal RC oscillator (IRCOSC) or the external oscillator (XOSC).
- The PMC, LVD, Temperature Sensor, IRCOSC, XOSC and pads are active.
- The PLL, Flash, and ADC are disabled, with rest of the device static and the clock gated off.

11.2.1.2 Checker core disabling

The checker core is clocked or gated off in the same manner as the main core when they are in lock-step. It is however possible to disable the safety checker core to reduce current consumption.

In STOP (after-run) mode, the checker core can be placed in idle mode so that it no longer mimics the main core, but is clock gated off while continues to be clocked.

The checker core is implemented in such a way that its entire clock tree can be gated off while the core logic remains supplied.

The checker core (part of the Checker Logic) and the corresponding ‘checked’ main core share the same cache SRAM arrays and local SRAM arrays. When the checker logic is disabled (i.e., its clock is gated) the SRAM array of the cache and the local memory of the main core are still usable by the main core.

11.3 Flash power requirements

During start-up, an untrimmed regulator supplies the flash module. The flash can still be read, but at a slower rate (and reduced voltage requirements).

On completion of the start-up phase, the regulator and the flash module reference current are trimmed so the flash can be read at full specification.

The LV portion of flash is powered directly from the internally generated 1.2 V and the supplied high voltage.

11.4 Device trimming

During the initialization phase, the device defaults to a pre-determined state for each of the LVDs, HVDs and the internal regulators. As the flash becomes available, the differential read process allows the trimming data to be available for the internal LVDs, HVDs and regulators. Refer to *Section 11.6: Power sequence* for further details.

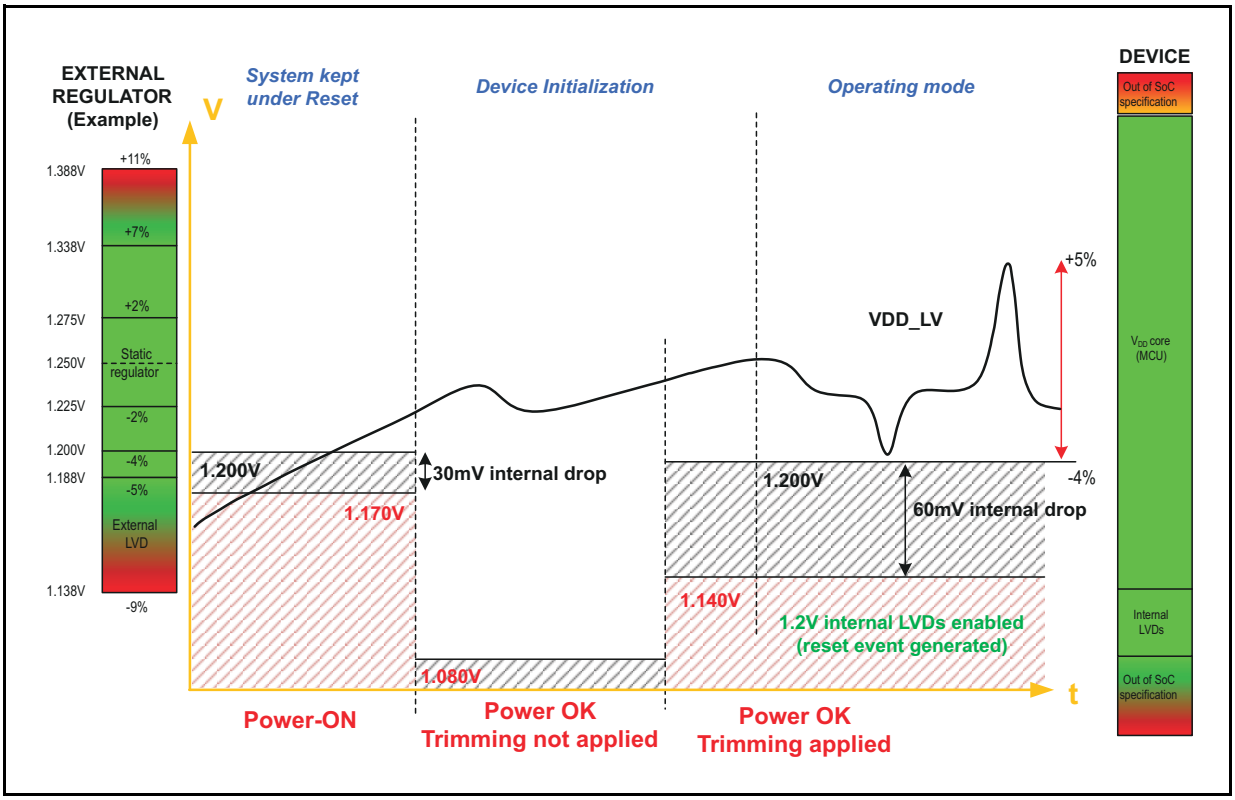
11.5 Supply monitoring (POR and LVDs)

The POR and LVD circuits function correctly even if the input voltage is non monotonic and hold the device in reset until release requisites are met.

11.5.1 Power-on reset (POR)

The PMC implements two internal power-on reset circuits:

- PORUP_LV monitors the voltage on the 1.2 V input VDD_LV_CORE pin and asserts a reset when the input supply is below defined values.
- PORUP_HV monitors the voltage on the 5.0 V input VDD_HV_PMC pin. The POR trip point is set high enough to ensure all the LVD circuits are functional.



See *Chapter 8: Reset and Boot* for PORST/ESR0 pin functionality.

11.5.2 Behavior of device LVDs/HVDs

After reset, some LVDs and HVDs can be disabled (see section *Section 11.5.3: Low Voltage Detection (LVD) and High Voltage Detection (HVD)*) or used in a ‘monitor’ only mode, as well as generating a safe/interrupt event. *Figure 57* illustrates the behavior of internal LVD/HVD circuits from the power-on phase through to device initialization and subsequent ‘normal’ run or operating mode.

After initialization, the LVDs/HVDs can be configured to operate with a higher voltage range by preventing threshold breaches from triggering resets. The application must ensure that the supply remains in the functional range.

Figure 57. Internal LVD and HVD in configuration example during power-up

11.5.3 Low Voltage Detection (LVD) and High Voltage Detection (HVD)

Internal Voltage Detector circuits monitor the voltage on assigned supplies and assert resets or interrupts when limits are breached. The voltage detectors support hysteresis in the falling and rising trip points.

11.5.3.1 LVD and HVD implementation

- All LVDs and HVDs are capable of generating an RGM and/or FCCU event, with the following exceptions:
  - LVD270 monitor high voltage supply input and always generate a reset when triggered (can only be disabled for test purposes).
  - LVD096 monitor the internal core voltage and always generate a reset when triggered (cannot be disabled). LVD096 is integral to POR management.
- All LVDs and HVDs configured for reset generation can cause functional or destructive resets. MC_RGM cannot exit PHASE0 until all destructive reset conditions are cleared.
- The appropriate bits in the PMC registers are set by LVD and HVD events.
- Modification of LVD and HVD control registers is subject to procedures in *Chapter 82: Register Protection (REG_PROT)*.
- REE DCF records configure LVDs/HVDs to a RESET event. This is a write-once mechanism managed by SSCM during device initialization. When a REE DCF record configures a RESET event, it cannot be changed until the next RESET event. When a REE DCF record does not configure a RESET, LVDs/HVDs default to triggering FCCU events.

Note: Details regarding configurable LVDs/HVDs are provided in Table 124

- The external PORST pin is driven low when a destructive-reset-enabled LVD or HVD is triggered.

Note: LVD096 and LVD270 (low range LVDs) cannot be disabled by the user during boot sequence. These modules are used during the power-up phase and ensure that the absolute lowest threshold of operation is not breached. This is not a guarantee that the device will function down to this level, only that the device will recover if this level is crossed.

Warning: LVD270 monitors can be disabled for test purposes via software access of the PMC_REE register. However, the internal monitors of the device may not detect that VDD_HV voltage is outside functional range (below LVD270 threshold) so the user must ensure a reset state by assertion of the external PORST pin.

Note: When supply falls below the internal power-on state detector threshold, the device automatically resets and LVD270 is re-enabled.

Table 124. POR and voltage monitors description

Monitor name	Register bit	Description	Monitor/ sensing	POWERUP-PHASE0	PHASE1-2-3	User configurability

DISABLE	DISABLE	DISABLE	DISABLE	—	DISABLE	DISABLE	– Monitor enabled in PHASE3 on DCF reading. – VD triggers an FCCU event. After reset completion:(5) – FCCU associated event is disabled. – sw configures LVD to generate **no** event.

1. REE: Reset event enable
2. RES: Reset event select
3. FEE: FCCU event enable
4. IE: Interrupt enable
5. Configuration can be changed by software to any of following events: functional reset, destructive reset, FCCU or interrupt event by software

When using an external regulator for the 1.2 V generation, the voltage regulator system shall have an internal LVD to satisfy the safety requirement.

An external 4.5V LVD will always be present in the system and hence there is no requirement for one on the device.

11.6 Power sequence

The following sections describe the power sequence and the relation between the different supplies during power-up and power-down.

An internal power-on signal identifies the POWERUP state when the device is not supplied or partially supplied, and is released high on power-sequence exit. The signal is a combination of LVDs monitoring:

- VDD_LV
- VDD_HV_PMC
- VDD_HV_IO
- VDD_HV_FLA

LVD thresholds are configurable by hardware (flash option bits content) or by software (LVD event configuration via register interface). Once the power-on signal is asserted, device configuration resets to default power-up configuration.

11.6.1 Power-up sequence

In this section it is assumed that all supplies are low when entering the power-up sequence. Brown-out and power-down sequences are discussed separately.

11.6.1.1 POWERUP state

At the beginning of power-up, the internal power-on signal remains low due to internal parasitic diodes. When the minimum threshold is reached on VDD_LV and VDD_HV supply, the internal power-on signal is forced low until power-up LVDs reach upper un-trimmed threshold (refer to datasheet).

The different supplies can rise independently as long as the constraints described in the datasheet are met.

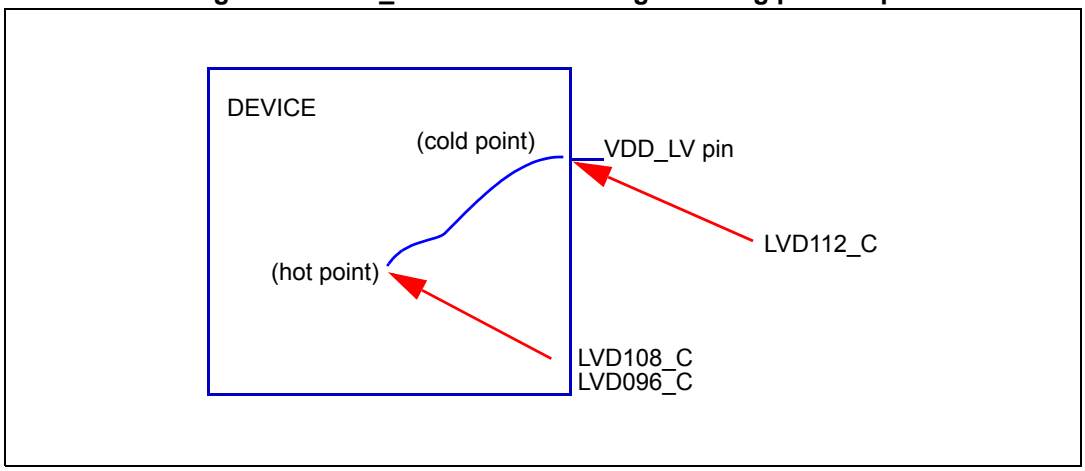
During power-up, all functional terminals are maintained in a known state as described in *Table 5: Pin startup and reset states*.

Digital reset is asserted, ensuring that all module registers are reset to power-on value.

11.6.1.2 POWERUP exit

The device exits POWERUP when VDD_LV and VDD_HV are above the internal LVD thresholds.

11.6.1.2.1 VDD_LV conditions and LVD trimming/enabling sequence



During POWERUP, the enabled LVDs are:

- LVD112_C
- LVD096_C,

VDD_LV exits POWERUP when:

- LVD096_C, upper threshold is crossed
- LVD112_C upper threshold is crossed

Figure 58. VDD_LV monitored voltages during power-up

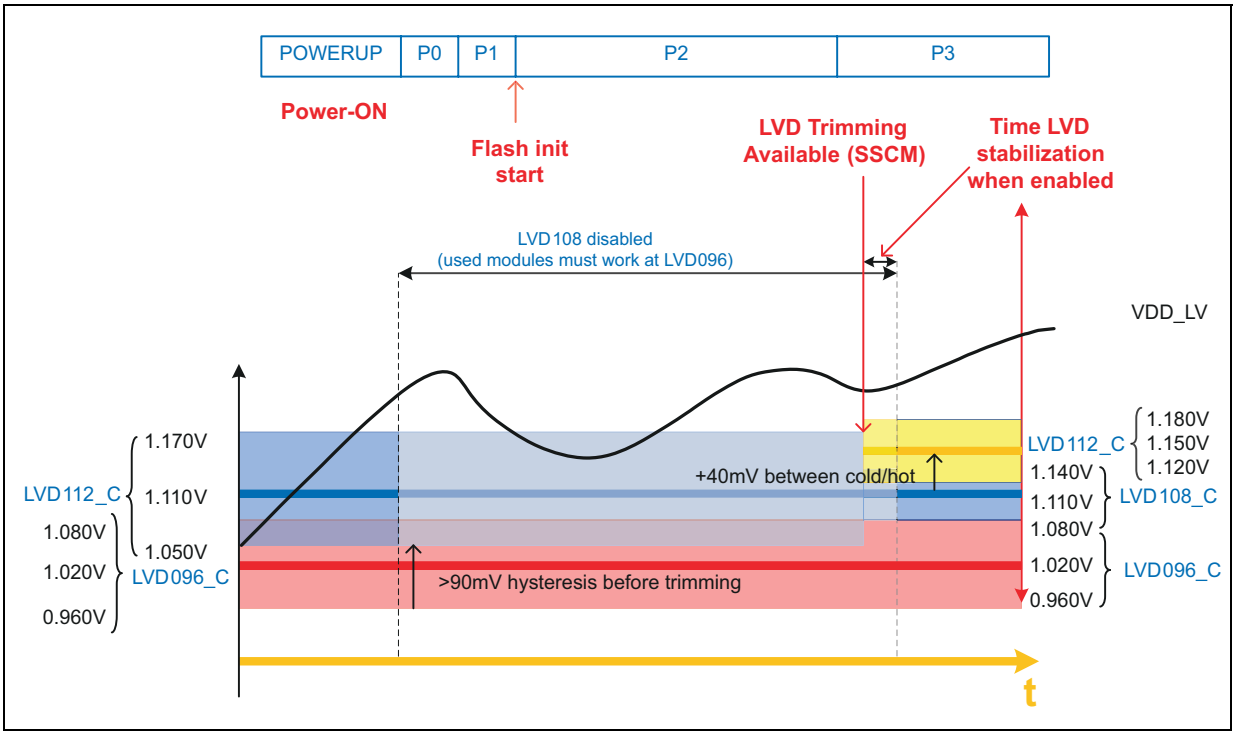
1. Once the POWERUP exit conditions (low and high voltage) have been verified, the internal power-on signal is released to all analog modules.
2. The internal RC oscillator module (IRCOSC) starts initialization and provides clock to the system after $t_{RCSTARTUP}$. The PMC digital interface reset is released after two RC clock cycles and LVD112_C is masked, leaving only LVD096_C active.

   LVD096_C, and LVD112_C share the same reference. LVD112_C – LVD096_C > 90 mV ± 5%. This difference provides margin with respect to maximum internal resistive drop (40 mV at I_{max}) and 50 mV hysteresis addressing external supply drop.
3. The device proceeds through the RGM reset sequence: PHASE0–PHASE1[DEST]–PHASE2[DEST]–PHASE3[DEST].
4. Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST].
   - Trim values for LVDs/HVDs are stored as internal DCF records.
   - The SSCM uses the flash low-voltage (low-speed) read feature to access the DCF records and apply the trim values to each LVD/HVD module.
   - After analog delay ($t_{LVDTRIM}$) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold
   - the SSCM proceeds with the reset sequence, eventually accessesing the flash at full speed to read the option bits required to complete device configuration.
5. The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

When LVD108_C is masked by the application using the flash user option bits, the device should rely on PORST signal to detect a voltage failure during power-up: PORST must be released high before proceeding with the power-up sequence, which may increase reset sequence completion time.

Figure 59 provides an example of VDD_LV power-up sequence from POWERUP to PHASE3[DEST].

Figure 59. Example of VDD_LV power-up sequencing



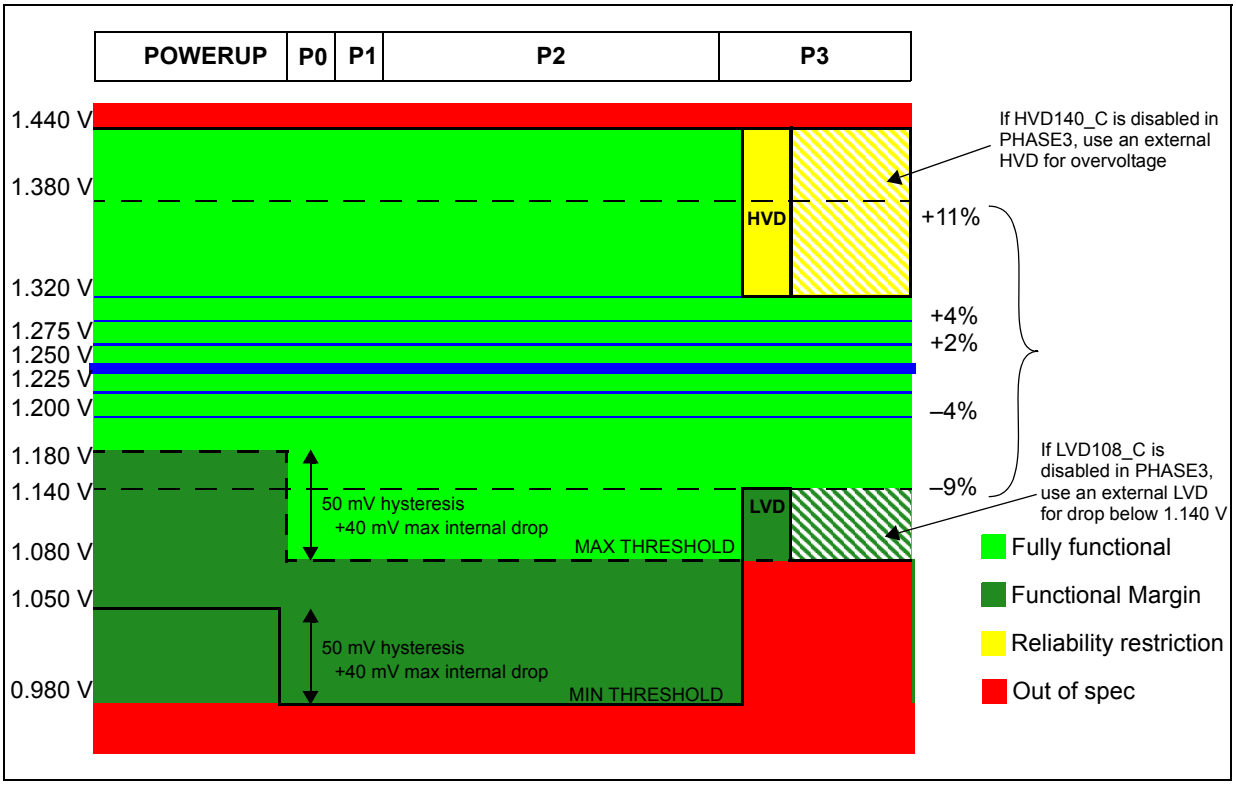


Figure 60 illustrates threshold variation of VDD_LV LVD monitor during power-up sequence from POWERUP to PHASE3[DEST].

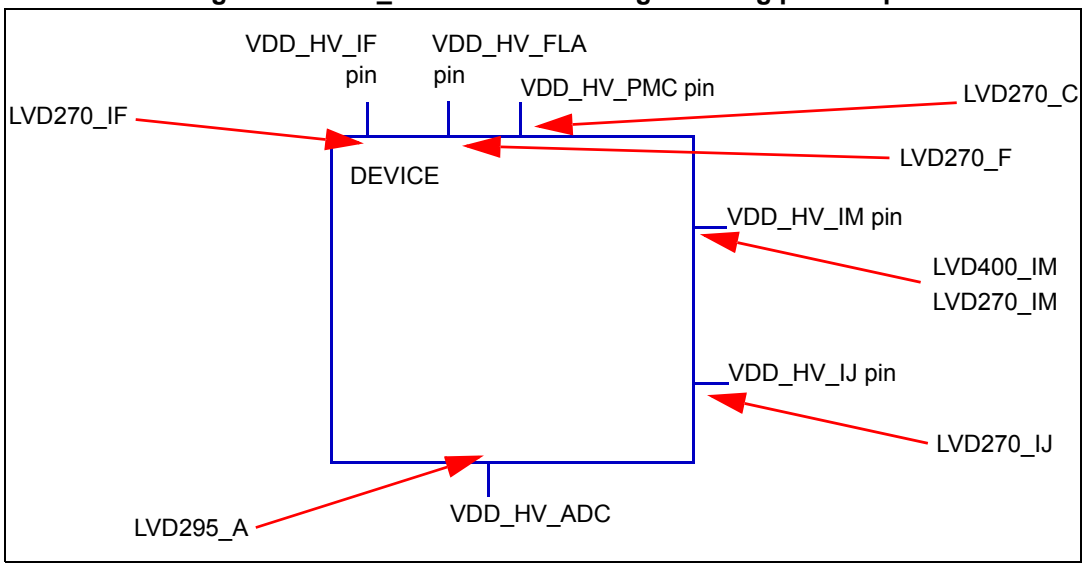
Figure 60. Threshold variation during power-up sequence

11.6.1.2.2 VDD_HV conditions and LVD trimming/enabling sequence



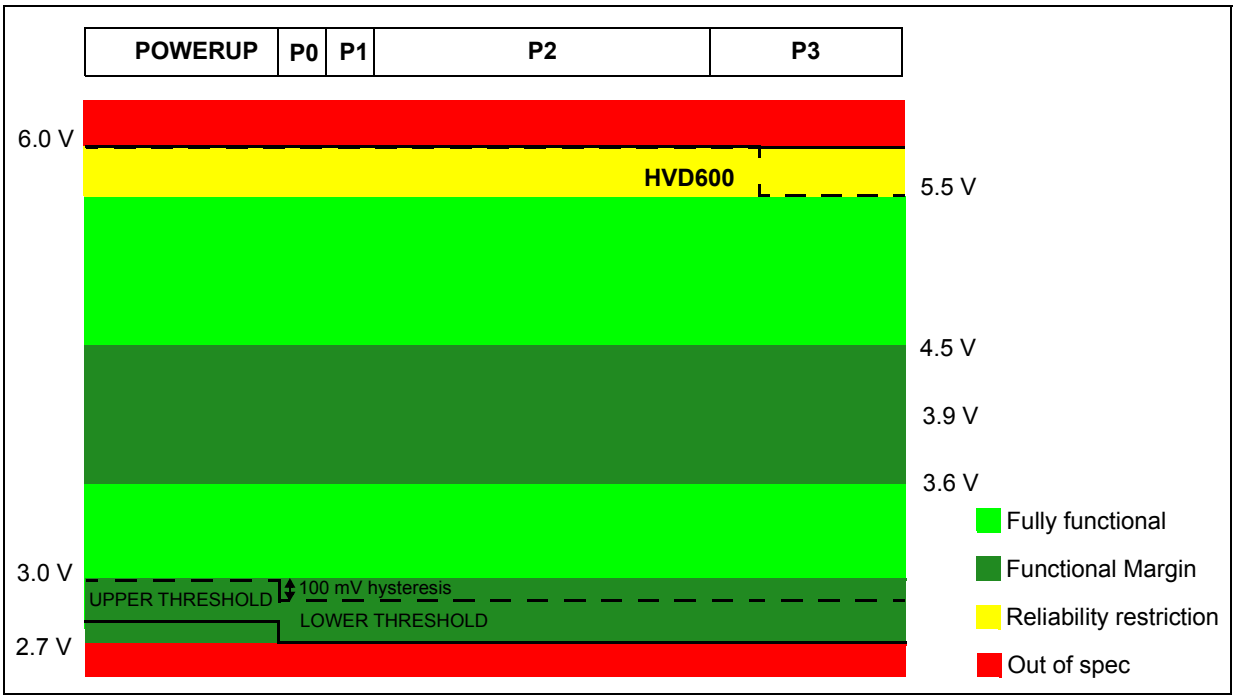
During POWERUP, the following high voltage LVDs are enabled:

- LVD400_IM
- LVD270

The VDD_HV conditions to exit POWERUP are the following:

- LVD400_IM upper threshold is crossed.
- LVD270 upper threshold is crossed.

Figure 61. VDD_HV monitored voltages during power-up



1. After both LV and HV POWERUP exit conditions have been verified, ipp_por_en_b signal is released to all analog modules.
2. The IRCOSC module starts initialization and provides the clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and LVD400_IM is masked. All other HV LVDs remain active.

   LVD270_C and LVD400_IM share the same reference. The LVD400_IM - LVD270_C difference represents the margin with respect to the maximum internal resistive drop and hysteresis addressing external supply drop.
3. The device proceeds through the RGM reset sequence: PHASE0–PHASE1[DEST]–PHASE2[DEST]–PHASE3[DEST].
4. Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST].
   - Trim values for LVDs/HVDs are stored as internal DCF records.
   - The SSCM uses the flash low-voltage (low-speed) read feature to access the DCF records and apply the trim values to each LVD/HVD module.
   - After analog delay ($t_{LVDTRIM}$) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold
   - the SSCM proceeds with the reset sequence, eventually accessesing the flash at full speed to read the option bits required to complete device configuration.
5. The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

Figure 62 provides the threshold variation of VDD_HV LVDs monitor during power-up sequence from POWERUP to PHASE3[DEST].

Internal LVD270_C and HVD600_IM are enabled during PHASE3[DEST].

Figure 62. Threshold variation during power-up sequence—2.7 V–5.5 V hot point LVD disabled, 4.5 V–5.5 V range

The device needs to fulfill all conditions described on *Section 11.6.1: Power-up sequence* to recover.

11.6.2 Power-down sequence

When the threshold of the higher-range LVDs configured to generate a destructive reset is crossed but neither LVD096 nor LVD270 threshold are crossed, the device enters PHASE0.

1. The power-down sequence initiates when the LVD096 or LVD270 threshold is crossed
2. The device enters the POWERUP state and the internal power-on signal ipp_por_en_b is asserted.
3. On ipp_por_en_b assertion, all analog modules reach their safe state.
4. Device supplies may then proceed to drop down to ground either through device leakage or external pull-down. During power-down, all supplies should comply with supply constraints.

11.6.3 Brown-out management

During brown-out, the device re-enters the POWERUP phase as soon as the threshold of either LVD096 or LVD270 is crossed. The internal power-on signal ipp_por_en_b is asserted.

Note: The device will correctly start independently from any residual voltage.
The device remains in the POWERUP state until the voltage rises above the LVD270 threshold. It then passes to a RESET state defined by Voltage monitor or external PORST pin, or ACTIVE state when all have been released.

Warning: **LVD270 monitors can be disabled for test purposes via software access of the PMC_REE register. However, the internal monitors of the device may not detect that VDD_HV voltage is outside functional range (below LVD270 threshold) so the user must ensure a reset state by assertion of the external PORST pin.**

Note: When supply falls below the internal power-on state detector threshold, the device automatically resets and LVD270 is re-enabled.

On internal power-on signal assertion, all analog modules reach their safe state.

11.6.4 Low voltage requirement during crank

The device can continue operation to the minimum input voltage during crank.

In order to proceed with execution during cranking and prevent device reset, it is important to correctly configure the high voltage LVDs.

During device switch-off, external LVD monitoring may not be activated quickly enough (external assertion of the PORST pin) to avoid the –10% level being crossed before POR is asserted. Malfunction is possible in this case, but reliability is not impacted and flash is not corrupted.

Internal LVDs that monitor the supply ensure that the flash content is protected.

12 Calibration and Debug

The chapter discusses the device specific information for the debug and calibration modules. This device implements a high speed serial Nexus trace Auxiliary Port. The Aurora interface allows the Nexus protocol information to be transmitted serially at a high rate of speed over two Aurora lanes. The Aurora protocol handles encoding the data and striping the information across the two Aurora lanes available on the device. In addition, the LFAST module, a high speed calibration interface, is supported for run control and memory access. The LFAST signals are alternate functions on the JTAG pins of the device. The device starts up in JTAG mode and the tool can request that the JTAG interface be converted to the LFAST high speed interface. All standards used have freely available specifications for tool developers.

The debug and calibration features for this device are provided in two separate dies: the Production die and the Buddy die or Buddy Device (BD). The Production die is packaged alone in the Production device (PD) package. The Production device is also assembled into an Emulation device (ED) package that consists of the Production die along with the Buddy die. The Buddy device supports additional debug capability. The Nexus Aurora interface is only available on the ED. The PD only supports trace to the internal trace/calibration memory.

The Event Out ($\overline{\text{EVTO}}$[0,1]) signals are connected to the external TGOUT[0,1] device pins and the Event In ($\overline{\text{EVTI}}$) signals are connected to the external TGIN[0,1] device pins.

12.1 Core debug support

Internal debug support in the e200z410Dn3 and e200z225Bn3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug mode, such that no code runs. This allows debuggers to perform operations such as configuration of calibration remap or edit of overlay memory prior to user code execution.

For details, see *Chapter 64: e200z410Dn3 Core Debug Support* and *Chapter 65: e200z225Bn3 Core Debug Support*.

12.2 Run control and memory access

Run control is any operation required to control the device operation. Run control includes starting and stopping execution of code by the processor, as well as access to memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both boundary scan and debug modes. It is based on the IEEE 1149.1 standard and the IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can be fed either directly from the JTAG pins or from the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross triggering of events from the device. The SPU can access some of the DCU run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the $\overline{\text{EVTI}}$ pins. Further, the SPU can use system triggers to cause many

different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

12.2.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug and calibration features. The DCI module includes the device JTAG controller, the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug and calibration features may operate simultaneously

The DCI sends and receives the $\overline{\text{EVTI}}$[1:0] and $\overline{\text{EVTO}}$[1:0] signals to/from the cores and other modules. *Table 127* and *Table 128* summarize the sources and destinations of $\overline{\text{EVTI}}$, $\overline{\text{EVTO}}$, and related signals for the PD and the BD. For example, for the PD, $\overline{\text{EVTI}}$[0] are outputs of the JTAGM and SPU, and inputs to the Cores, GTM, and NXMC.

Table 127. PD DCI signals

Signal	Cores	GTM	NXMC	NAR	JTAGM	SPU	DTS
$\overline{\text{EVTI}}$[0]	I	I	I	—	O	O	—
$\overline{\text{EVTI}}$[1]	—	—	—	—	O	O	—
$\overline{\text{EVTO}}$[0]	O	O	O	—	I(1)	I	—
$\overline{\text{EVTO}}$[1]	—	—	—	—	I(1)	I	O
Core debug event	I	—	—	—	—	—	—
DCI cross triggering	O	O	—	—	—	—	—

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16 MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32 MHz.

Table 128. BD DCI signals

Signal	RWA	NAR	NAL	JTAGM
$\overline{\text{EVTI}}$[0]	—	I	—	O
$\overline{\text{EVTI}}$[1]	—	—	—	O
$\overline{\text{EVTO}}$[0]	—	—	—	I(1)
$\overline{\text{EVTO}}$[1]	—	—	—	I(1)

1. The EVTO signal provided to the JTAGM is stretched by the DCI on the 16 MHz IRC clock. Therefore, the incoming EVTO cannot be reliably detected by the JTAGM when the JTAGM clock is configured at less than 32 MHz.

The DCI sends the system debug signal, ipg_debug, to the following modules. For details regarding module functionality during system debug, refer to the individual module chapter.

- CAN
- LFAST (Interprocessor Communications instance only)
- DSPI
- eDMA
- FCCU
- GTMINT
- I2C
- NXMC
- PIT
- PSI5
- SARADC
- SDADC
- SRX
- SSCM

12.2.1.1 DCI $\overline{\text{EVTx}}$ pin multiplexing control register (DCI_PINCR)

The DCI $\overline{\text{EVTx}}$ pin multiplexing control register (DCI_PINCR) is described below. The $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ functions share the same set of possible pins. If this register is written to enable both $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ on the same pin, the $\overline{\text{EVTI}}$ function is selected, although this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}$[0] or $\overline{\text{EVTI}}$[1] inputs to come from more than one pin is considered a programming error and no pin is enabled.

3 EVTI0D	Enables $\overline{\text{EVTI}}$[0] function on pin PM[5]
2 EVTI0C	Enables $\overline{\text{EVTI}}$[0] function on pin PM[4]
1	Reserved
0 EVTI0A	Enables $\overline{\text{EVTI}}$[0] function on pin PF[14]

12.2.1.2 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG controller.

12.2.1.3 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

12.2.2 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows access to two registers by JTAG and software running on one of the CPUs in the device. These registers can be used to exchange data between an internal CPU and an external debug tool. For security applications, these registers can be used to exchange passwords or to implement a challenge/response authorization protocol.

12.2.3 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, using internal device signals as trigger sources. Performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in their debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions,

complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

12.2.3.1 SPU Level1 input Mux configurations registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0–7) are described in the following tables.*Table 130* contains the L1SEL0 register field descriptions.

12.3 Calibration interface

This device includes an alternate calibration interface for high speed run control and advanced software control. This calibration interface is based on the LFAST interface. The LFAST based calibration has the capability of performing all of the functions that JTAG supports, only at a faster speed. The MCU implements the slave module and the pins for the LFAST interface are multiplexed onto the same pins as the JTAG pins. Initially, the device powers up with the JTAG module having control of the pins. Under tool commands, the

LFAST interface can be enabled and the pins become LFAST signals. Once the LFAST interface has been activated, all run control and other JTAG operations are converted in the MCU from LFAST messages into JTAG control operations of the JTAG Controller. The interface is supported entirely in hardware for both LFAST and JTAG modes, with no software or system overhead required to support interface traffic.

Table 138. Reference links to related information

JTAG Master (JTAGM)	*Chapter 70: JTAG Master (JTAGM)*
LFAST Module—JTAGM	*Chapter 51: LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications*
Development Tool Semaphore (DTS)	*Chapter 72: Development Trigger Semaphore (DTS)*

12.3.1 JTAG Master (JTAGM)

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The module is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data was coming from an external tool. JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

12.3.2 Debug LFAST

The high speed calibration interface provides up to a 320 Mbps interface between a calibration tool and the device. The calibration interface uses the MIPI LFAST as the physical layer between the tool and the JTAGM for access to debug resources. The calibration debug LFAST module is one of two instantiations of the LFAST module on the device. The calibration LFAST is configured for slave only operation and is meant to be used as a calibration interface to provide higher speed (than JTAG) debug and calibration operations.The calibration LFAST interface supports full duplex operation, where the available bandwidths for upstream and downstream traffic are independent.

12.3.3 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different from the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.

12.4 Debug over CAN

As well as supporting debug via JTAG and LFAST interfaces, the device supports the use of a CAN interface for debug. This allows debug of application hardware where access to the dedicated JTAG/LFAST interface signals is not easily available. The debug over CAN mechanism is intended to provide basic debug functionality with some reduction in bandwidth and features compared to use of the dedicated JTAG or LFAST interfaces.

Use of the CAN interface for debug purposes requires the use of some M_CAN, eDMA and JTAGM resources. Some initialization of these resources via software is required, but once this initialization has completed, debug over CAN is possible without any further software overhead.

As the debug over CAN scheme generates internal JTAG messages based on received CAN data, all JTAG clients and included debug resources are accessible. Basic device trace capability is also possible by configuring the device trace hardware to stream to a device overlay/trace RAM, which can be read later using debug over CAN.

The debug over CAN scheme supports the following features:

- Supports operation through M_CAN0 or M_CAN1 interfaces
  - Makes use of M_CAN debug enhancements
  - Debug message selected by filter configuration EFEC[2:0]=111
- Allows debug of hardware where JTAG access is not available
- Debug traffic carried over application CAN bus
- Debug traffic on CAN coexists with application traffic
- No software overhead after initialization
- flexible selection of CAN identifiers for debug use
- Access to all JTAG debug facilities, includes CPU run control

12.5 Nexus Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at a high rate of speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and striping the information across the lanes. The Aurora interface is only available on the Emulation device. Trace information is transferred to the Buddy device for transmission via the Aurora interface.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the MCU. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client and, generally, can be individually enabled (both the type of messages and which clients). *Table 139* shows a few examples of Nexus messages. All messages can be enabled to have a timestamp included.

Table 139. Types of nexus messages

Message type	Description
Program Trace	Nexus Program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership Trace	Ownership Trace provides information on process identification changes.

Table 139. Types of nexus messages(Continued)

Message type	Description
Watchpoint Trace	Watchpoint messages are generated anytime a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device Identification	The device identification message allows information about the MCU to be transmitted on power up to allow tools to identify the target system MCU type.
Debug Status	Debug status message provides additional information that may be needed to reconstruct software execution, such as whether the device has entered debug mode or low power mode.
Data Acquisition	Data Acquisition messages are an optional feature that allows software control of information to be transmitted.
Error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory or the parallel information can be serialized for transmission over a serial type interface through the Nexus Aurora interface.

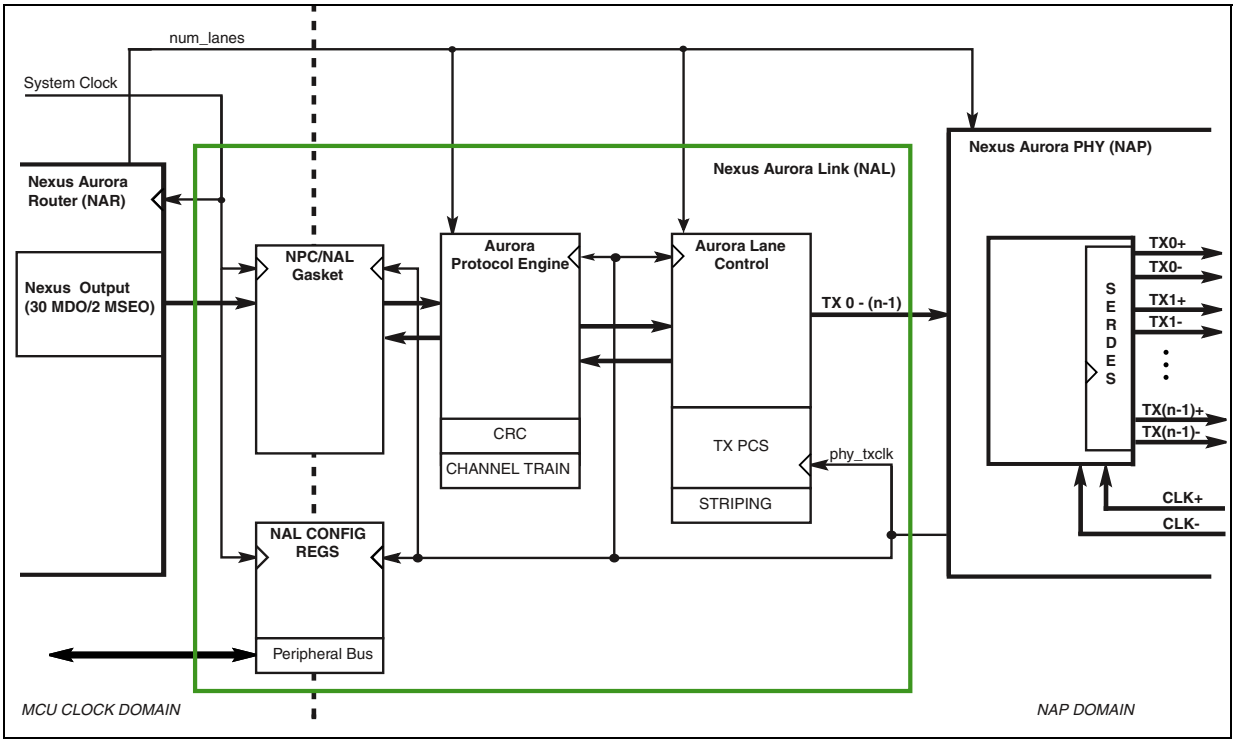
Buddy Device—Nexus Read Write Access (RWA)	*Chapter 95: Buddy Device—Nexus Read Write Access (RWA)*

12.5.1 Nexus Aurora overview



The IEEE-ISTO 5001-2011 standard added a new type of Auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8B/10B encoded LVDS driver. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on XAUI (10 Gb Attachment Unit Interface used in communication protocols) and covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

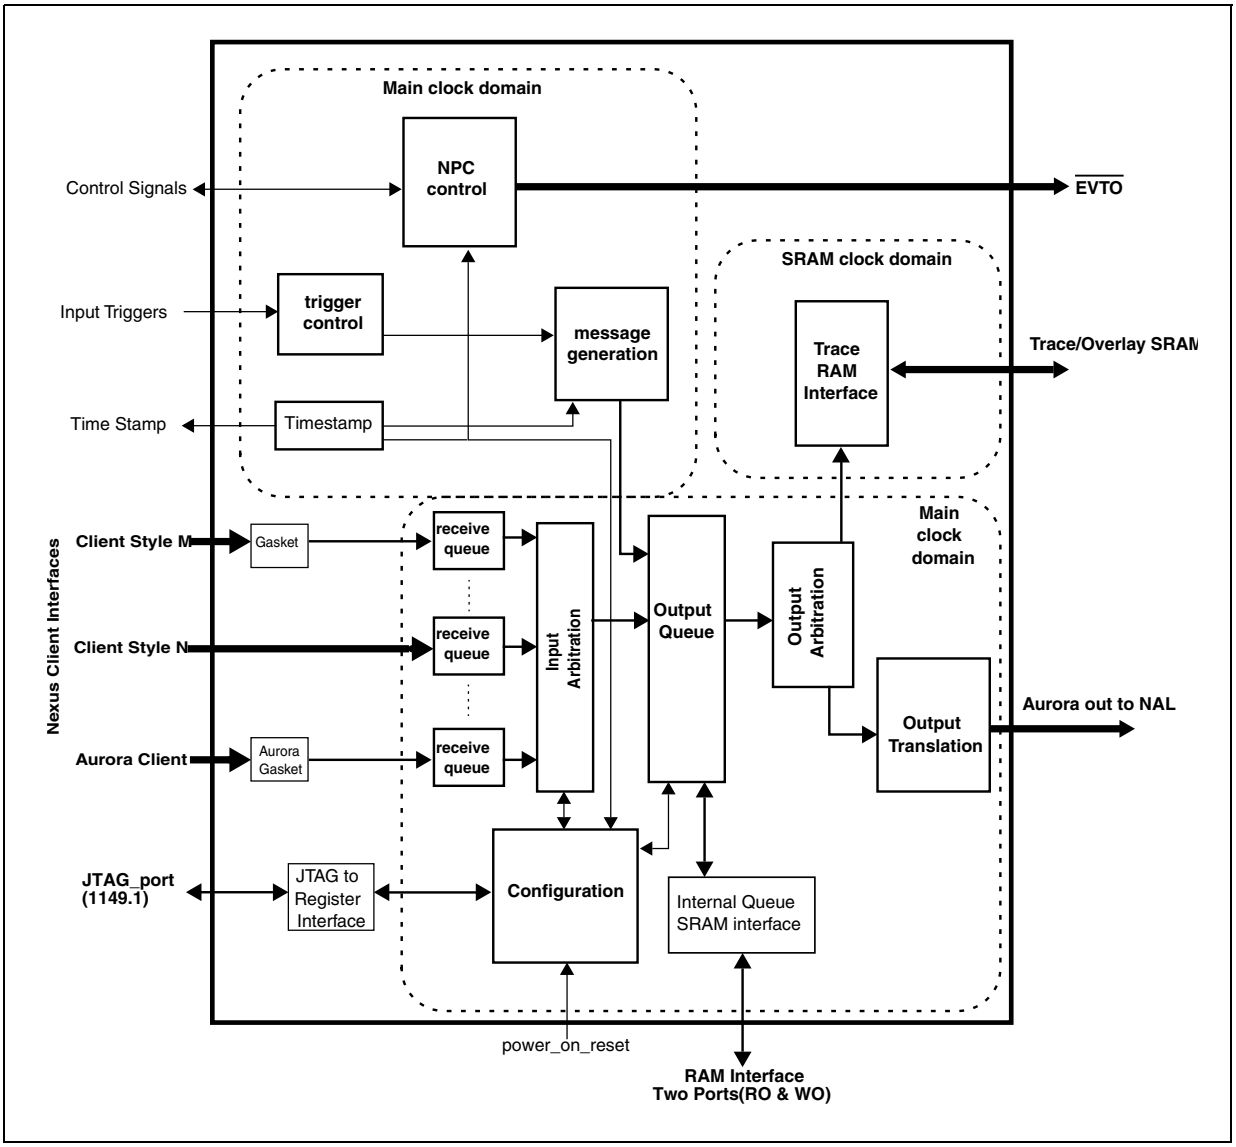
The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation implements a simplex output only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC) and the Nexus Aurora Physical interface (NAP). *Figure 64* shows the Aurora interface block diagram, where the number of lanes, n, is 2.

Figure 64. Aurora interface block diagram

The Nexus blocks do not have memory mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The enable instructions for the different Nexus clients are shown in *Table 141*. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 141. Nexus client JTAG enable instructions



Die type	Module	Enable instruction	Opcode

	GTM		
	NAR		
	SPU		
Buddy	RWA	CORE_ENABLE	0x7C (10 bits)
	NAR	NEXUS_ENABLE	0x0 (4 bits)
	NAL		

12.5.2 Nexus Aurora Router (NAR)

All Nexus trace information from each of the Nexus clients is managed by the Nexus Aurora Router (NAR). The NAR takes the parallel trace information from each of the connected clients, buffers it to avoid overruns, and routes the information either to the internal overlay RAM or transfers trace information to the Buddy device for storage to on-chip SRAM or to the physical Aurora interface to be transmitted out of the device.

16 KB of trace SRAM is available on the PD (located in the flash module), and 1 MB of trace SRAM is available in the Emulation device. (Some of this SRAM may be used for calibration overlay content as well as trace content.) Similarly, a smaller NAR output queue is located on the PD (2 KB), and a much larger NAR output queue is located in the ED (8 KB). The physical Aurora pins are only available on the ED. *Figure 65* shows the NAR block diagram.

Figure 65. NAR block diagram

The PD NAR module has five clients with client index 1, 3, 4, 6, and 7. All other client indexes are not connected. *Table 142* contains the client connections and the

corresponding NAR client index. The NAR client index is used in the NAR_STCR, NAR_CSSR, and NAR_CDR registers. The source trace ID is used in the NAR_SFR.

Table 142. PD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
—	NAR	0b1111 (0xF)	—
1	GTM	0b0111 (0x7)	3
2	—	—	—
3	Core 0	0b0000 (0x0)	1
4	NXMC Client 0 Concentrator	0b1100 (0xC)	1
5	—	—	—
6	NXMC Client 1 Concentrator	0b1101 (0xD)	1
7	Core 2	0b0010 (0x2)	1
8	—	—	—
9	—	—	—
10	—	—	—
11	—	—	—
12	—	—	—
13	—	—	—
14	—	—	—
15	—	—	—
16	—	—	—

The BD NAR module has one client. *Table 143* contains the client connections and the corresponding NAR client index.

Table 143. BD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
1	PD NAR	—	2

The NAR is limited writing trace information to the Overlay RAM. The PD NAR only has access to the 16 KB internal Overlay RAM. Therefore the PD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0D000000–0x0D003FFF. The BD NAR also has access to 1 MB of extended Overlay RAM. Therefore the BD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0C000000–0x0C1FFFFF.

Table 144 contains the NUM_LANES field description of the NAR_NAPCR.

Table 144. NAR_NAPCR field descriptions

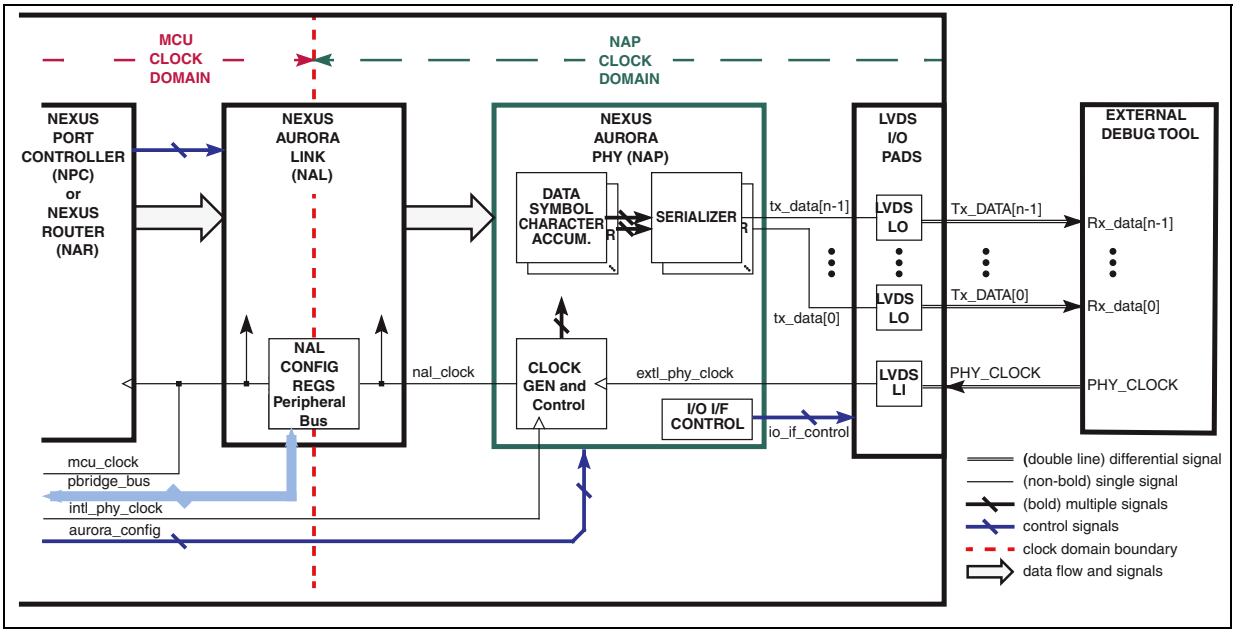
Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. 0000 Disable NAP and NAL 0001 Reserved 0010 Enable 2 lanes (Lane 0–1) 0011 Reserved 0100 Reserved 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001–1111Reserved

12.5.3 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) is only included in the Emulation device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into 32-bit format by the clients and then collected by the NAR. The NAL encodes the message data (8/10), stripes then across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

12.5.4 Nexus Aurora Phy (NAP)



The Nexus Aurora PHY (NAP) is only included in the Emulation device. The NAP, in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY Lane's LVDS pads. The NAL performs lane striping with settings in the NAL and NAR specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator which registers the 10-bit character for that lane from the ALC on the rising edge of the NAL clock. A Serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

Figure 66 shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, n, is 2.

Figure 66. NAP block diagram

12.6 Nexus clients

Nexus supports multiple trace clients within the device to all transmit information through a single Aurora port.

Table 145. Reference links to related information

Related module	Reference
e200z4 Nexus Support	*Chapter 74: e200z410Dn3 Nexus 3 Module*
GTM Development Interface (GTMDI)	*Chapter 47: GTM Development Interface (GTMDI)*
Nexus Crossbar Multi-Master Client (NXMC)	*Chapter 76: Nexus Crossbar Multi-Master Client (NXMC)*

12.6.1 e200z4 and e200z2 Nexus 3

The e200z410Dn3 and e200z225Bn3 Nexus 3 modules provide real-time development capabilities for e200z4d and e200z2 processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

12.6.2 GTM Development Interface (GTMDI)

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-channel Sequencer (MCS) cores, Advanced Routing Unit

(ARU) data trace, Input Channel Filters trace, Output Timer channels, DPLL and Sensor Pattern Evaluation Module (SPE) sub-modules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events. The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability via the JTAG port and the on-chip NAR.

12.6.3 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) is implemented that monitors traffic into the master port of the XBAR. Two NXMCs are implemented, one for the fast masters and one for the slow masters. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message, as well as an identifier of the pre-concentrator source of the message. In addition to the XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used for trace of the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four total—two from each NXMC) for events from the SPU.

Figure 67 shows a block diagram illustrating the NXMC integration.

Figure 67. NXMC integration block diagram

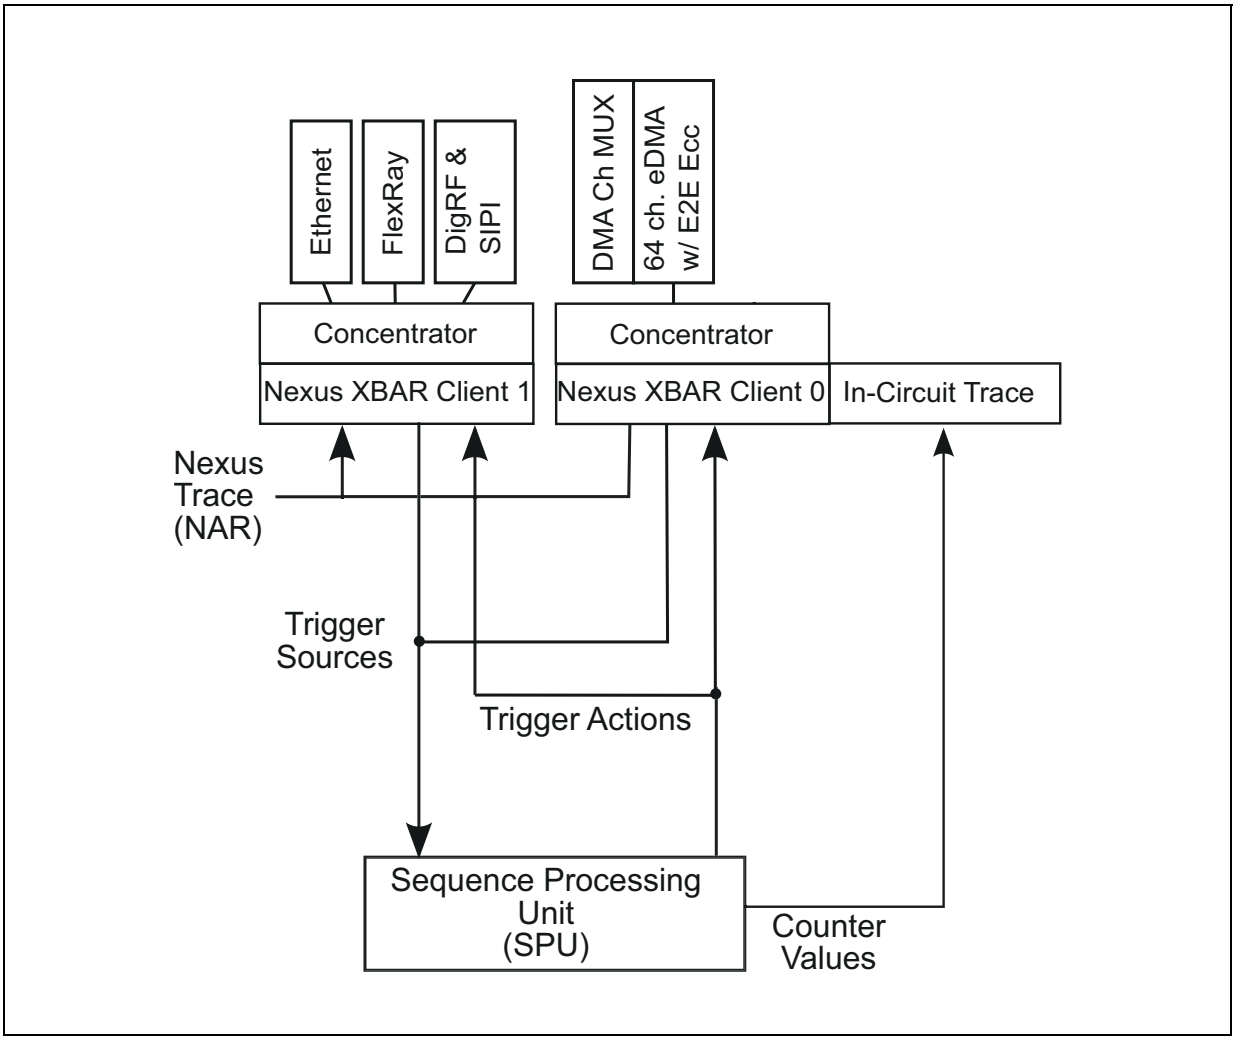


Table 146 contains the values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients.

Table 146. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-circuit Trace	SPU	0b1011	0b0000

13 Core Complex Overview

13.1 Introduction

The SPC574Kx has three separate cores that perform various computational and control functions. The main computational shell includes Main Core_0, which uses an e200z410Dn3 core. This core is used for general computational functions. A second core, referred to as Checker Core_0s, uses an e200z409D core which is a true subset of the e200z410Dn3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to ensure that Main Core_0 is executing correctly. The third processor, Peripheral Core_2, employs an e200z225Bn3 core and is generally used to control various I/O modules.

This chapter provides overviews of the e200z410Dn3 core, the e200z409D core and the e200z225Bn3 core.

The e200z410Dn3, e200z409D, and e200z225Bn3 cores are very similar. The register set for all three of these cores is identical. The e200z225Bn3 core differs in hardware from the e200z410Dn3 core in several ways. The e200z225Bn3 has no Instruction Cache and no Data Cache. Also, the e200z225Bn3 incorporates a Lightweight Signal Processing Extension (LSP) APU to provide support for real time SIMD fixed point embedded numeric operations. The e200z409D core differs in hardware from the e200z410Dn3 in that no Instruction Cache, Data Cache, I-memory or D-memory is implemented.

Note: The processor ID for each CPU core is contained in its Processor ID Register (PIR).

13.2 Overview of the e200z410Dn3, e200z409D, and e200z225Bn3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power architecture.

The e200z410Dn3, e200z409D, and e200z225Bn3 are single-issue, 32-bit Power VLE compliant designs with 32-bit general purpose registers (GPRs).

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

The e200z410Dn3, e200z409D, and e200z225Bn3 cores implement the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document. The base *PowerISA 2.06* fixed-length 32-bit instruction set is not directly supported.

The e200z410Dn3, e200z409D, and e200z225Bn3 processor cores integrate a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock for the e200z410Dn3 and e200z409D cores and three read and two write operations per clock for the e200z225Bn3. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

A Nexus Class 3+ module is integrated in each e200z410Dn3 and e200z225Bn3 processor core.

A Memory Protection Unit is integrated in each e200z410Dn3, e200z409D, and e200z225Bn3 processor core.

13.3 Features

The following is a list of some of the key features of the e200z410Dn3, e200z409D, and e200z225Bn3 processor cores:

- Single-issue, 32-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
  - Dedicated branch address calculation adder
  - Branch target prefetching using BTB
- Load/store unit
  - 2 cycle load latency
  - Fully pipelined
  - Misaligned access support
- 32-bit General Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit System buses
- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z410Dn3 core—16 KB IMEM, 64 KB DMEM
  - e200z225Bn3 core—16 KB IMEM, 48 KB DMEM
  - e200z409D core does not contain either Instruction or Data memories
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
  - e200z410Dn3 core—4 KB I-Cache, 2 KB D-Cache
  - e200z225Bn3 core—no I-Cache, no D-Cache
  - e200z409D core does not contain either Instruction or Data Cache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Saturation Instructions Extension adding scalar saturating arithmetic support to the *PowerISA* Integer Saturation (ISAT).
- Lightweight Signal Processing (LSP) APU (e200z225Bn3 core only) supporting fixed-point multiply/accumulate and integer/fixed point operations using the 32-bit General Purpose Register file
- Performance Monitor APU supporting execution profiling
- Nexus Class 3-plus Real-time Development Unit
- Power management
  - Low power design with extensive clock gating
  - Power saving modes: doze, nap, sleep, wait
  - Dynamic power management of execution units, caches and Local memories
- Testability
  - Synthesizeable, MuxD scan design
  - ABIST/MBIST for arrays

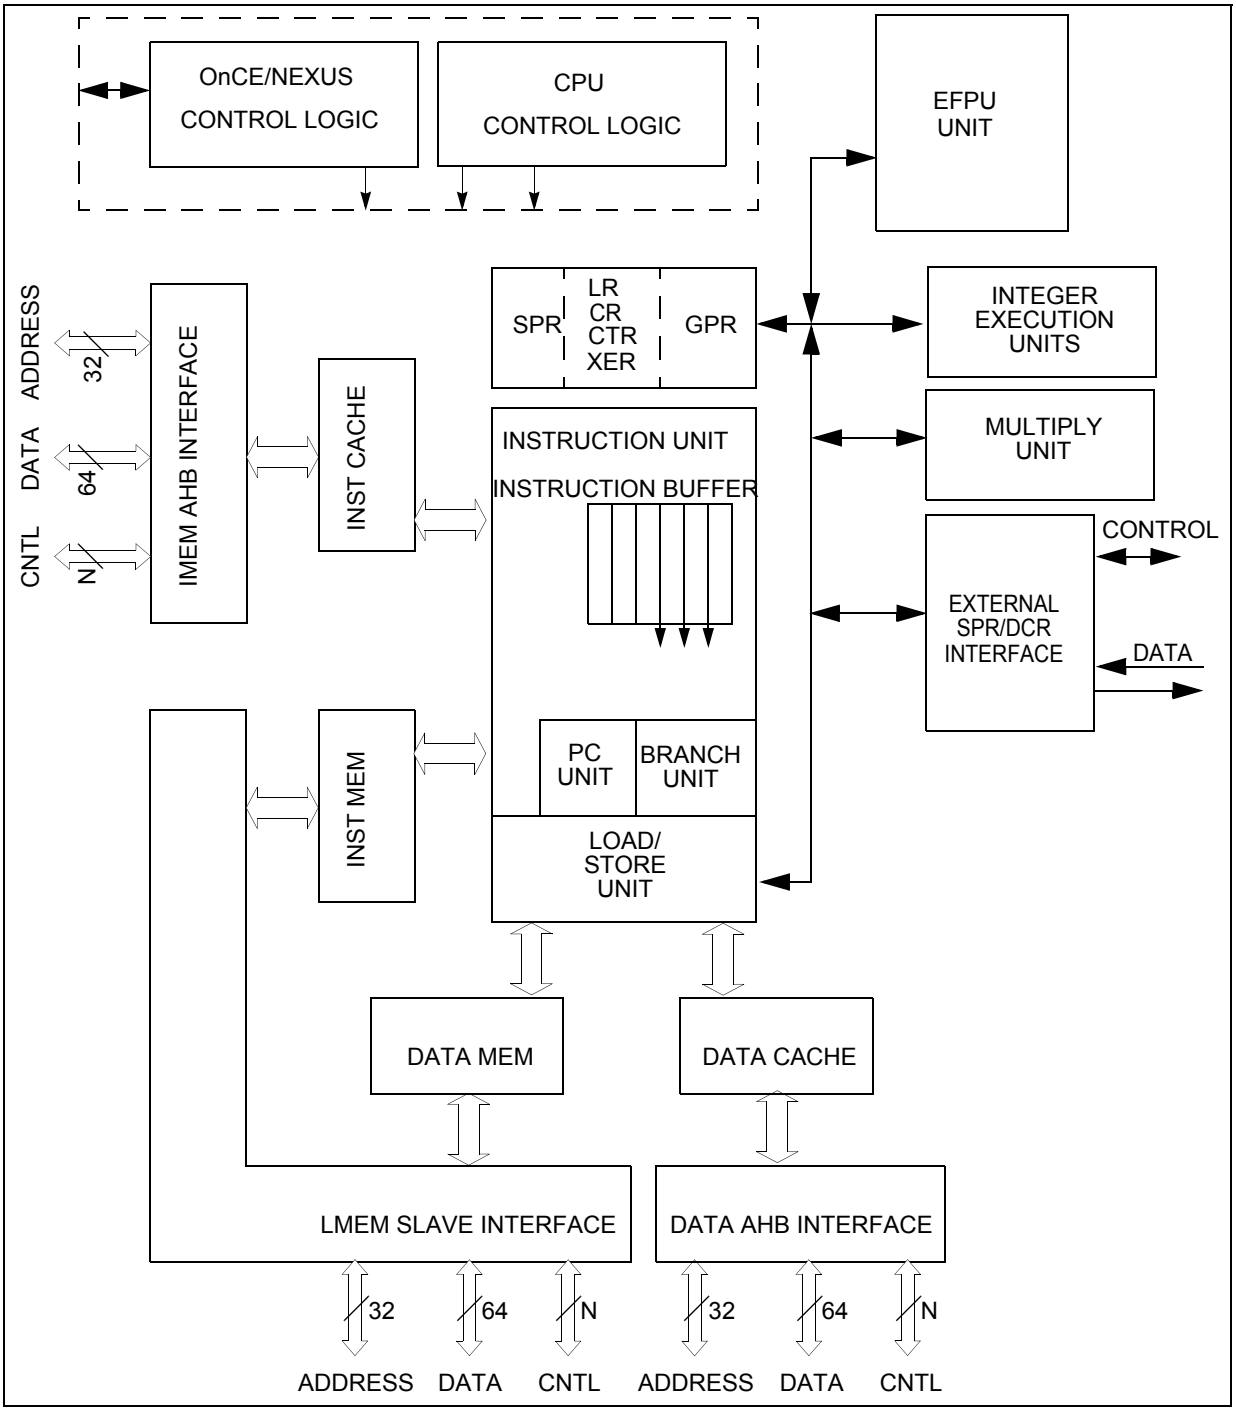
– Built-in LBIST unit

13.4 Microarchitecture summary

The e200z410Dn3, e200z409D, and e200z225Bn3 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/ EA Calc, Execute 0/ Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single clock instruction execution for most instructions. *Figure 68* shows a block diagram of the e200z architecture.

The integer execution units each consist of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register manipulation Unit (CRU), a Count-Leading-Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32×32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single cycle with the exception of multiply, which is implemented with a pipelined hardware array, and the divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.



The Instruction Unit contains a PC incrementer and dedicated Branch Address adders to minimize delays during change of flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clocks for correctly predicted branches. Conditional branches which are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal of data. These instructions can be pipelined to allow effective single cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to allow effective address generation to be optimized.

The Condition Register unit supports the condition register (CR) and condition register operations defined by the Power architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations, such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Figure 68. e200z block diagram

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The LSP APU (included only on the e200z225Bn3 core) supports vector instructions operating on 16-bit and 32-bit fixed-point data types. The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats and operates in a pipelined fashion. The 32-bit

general-purpose register file is used for source and destination operands. There is a unified storage model for scalar single-precision floating-point data types of 32-bits and the normal integer type. Low latency floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided. Most operations can be pipelined.

13.4.1 Instruction unit features

The features of the e200z410Dn3, e200z409D, and e200z225Bn3 Instruction units are:

- 64-bit path to cache supporting fetching of two 32-bit instructions per clock
- Instruction buffer holding up to eight 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single cycle execution of successfully predicted branches

13.4.2 Integer unit features

The e200z410Dn3, e200z409D, and e200z225Bn3 integer units support single cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the count leading zeros function
- 32-bit single cycle barrel shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4-14 clocks with minimized execution timing (EU1 only)
- Pipelined 32×32 hardware multiplier array supports 32×32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

13.4.3 Load/Store unit features

The e200z410Dn3, e200z409D, and e200z225Bn3 load/store units support load, store, and the load multiple/store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

13.4.4 EFPU2 Floating-Point Unit features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion <-> single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 15 (FP sqrt) clock cycles

13.4.5 Saturation Instructions Extension features

The Saturation Instructions Extension APU adds scalar saturating arithmetic support to the *PowerISA* Integer Saturation (ISAT). It also includes instructions to support add and subtract for both signed and unsigned word, halfword, and byte data types. These instructions can be used by compilers to avoid sign extension or zero extension operations when operating on data types which are smaller than the implemented register size. The Saturation Instructions Extension APU supports:

- All of the instructions in the extension which are category 32-bit; category 64-bit instructions (signed and unsigned word add/sub) are not supported.
- Saturating addition and subtraction operations for signed and unsigned byte, halfword, and word data types.
- Unsaturating signed and unsigned forms.
- Saturating multiply for signed and unsigned halfword and word data types.
- Saturating divide for signed and unsigned word types.
- Augmented divide word and divide word extended instruction architecture to saturate results when an overflow occurs.
- Unary saturation instruction which takes an arbitrary value and saturates it to a word, halfword, or byte, in both signed and unsigned forms.
- Saturated absolute values can also be computed.

13.4.6 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit Process Identifier
- Bypass capability for individual access types
- Maskable Address and Process Identifier
- Programmable Memory Attributes
- Entry Invalidation Protection
- Write-Once Option
- Alternate Debug Breakpoint/Watchpoint function

13.4.7 Cache features

The features of the Caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
  - e200z410Dn3—4 KB I-Cache, 2 KB D-Cache
  - e200z225Bn3—no I-Cache, no D-Cache
  - e200z409D—no I-Cache, no D-Cache
- Writethrough support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Supports Way locking
- Supports Write allocation policies
- Supports multi-bit EDC with Correction/Auto-invalidation capability for the I- and D-caches
- Hardware Debug Cache Invalidate Support for the Data Cache
- Software and hardware debug access to cache tag, status, and data storage via dedicated control registers

13.4.8 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
  - e200z410Dn3—16 KB IMEM, 64 KB DMEM
  - e200z225Bn3—16 KB IMEM, 48 KB DMEM
  - e200z409D—no IMEM, no DMEM
- I-MEM provides RAM storage for instructions, allowing the CPU to execute these instructions with zero wait-state delay.
- I-MEM includes a feature to allow the memory to be relocated in the memory map as seen by the local CPU, so that it overlays MCU code flash (the memory map to other

bus masters is unchanged). This relocation of the I-MEM into the flash region, allows it to be accessed directly from any location in flash with a single short branch instruction

- Instruction and data memories (IMEM, DMEM) are not duplicated on e200z409D core.
- Supports zero wait-state access relative to cache hit timings
- Supports multi-bit (SECDED) ECC with correction/scrubbing capability
- 4-entry ECC R-M-W Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

13.4.9 Performance Monitor Unit Features

The features of the e200z42x performance monitor include:

- Four configurable 32-bit performance monitor counters each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including # of clock cycles, CPU stall cycles, # of instructions completed, # of interrupts taken, # of memory accesses (by type), # of instruction or data cache misses, # of cycles with 0, or 1, or 2 instructions issued, # of instructions in a given class completed (such as ldst, branch, integer, FP), cache linefills, and many other event types

13.4.10 e200z410Dn3 and e200z225Bn3 system bus features

The features of the e200z410Dn3 and e200z225Bn3 System Bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

13.4.11 e200z409D system features

Checker Core_0 is implemented using an e200z409D core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z409D core can only be enabled or disabled by the user. For the SPC574Kx device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main-Core-0.

The e200z409D core is identical to the e200z410Dn3 with five exceptions:

- I MEM memory array is not present
- I-Cache memory array is not present
- D MEM memory array is not present
- D-Cache memory array is not present
- The e200z409D has a pair of system bus interfaces, which are driven/sampled by the delayed lockstep logic

14 Core e200z410Dn3 description

14.1 Overview of the e200z410Dn3 core

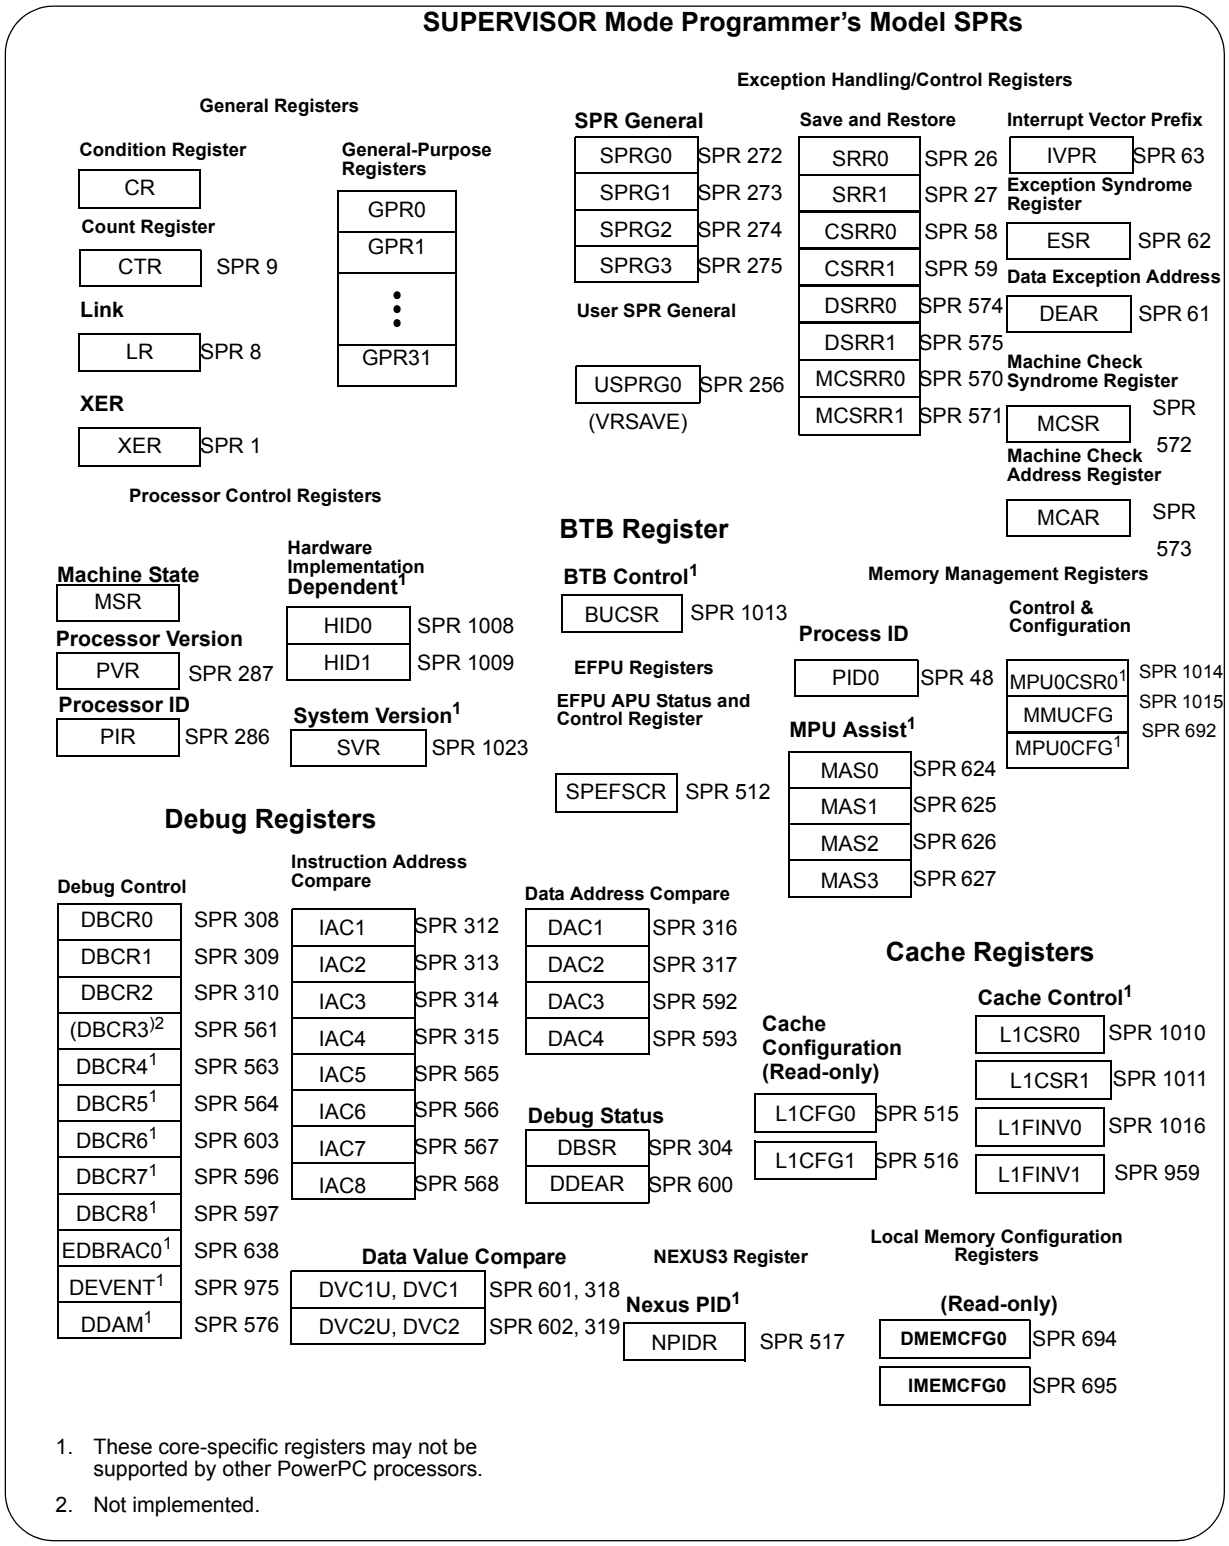
The e200z410Dn3 is a single-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z410Dn3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z410Dn3 processor integrates an integer execution unit, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining three read and two write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z410Dn3 contains a 4 KB Instruction Cache, and a 2 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.



14.2 Register model

This section describes the registers implemented in the e200z410Dn3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z410Dn3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

Figure 69 and *Figure 70* show the complete e200z410Dn3 register set, all of which are accessible in supervisor mode. *Figure 71* and *Figure 72* show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 69. e200z410Dn3 Supervisor Mode Programmer's Model SPRs

1. These core-specific registers may not be supported by other PowerPC processors.
2. Not implemented.

Figure 70. e200z410Dn3 Supervisor Mode Programmer's Model DCRs and PMRs

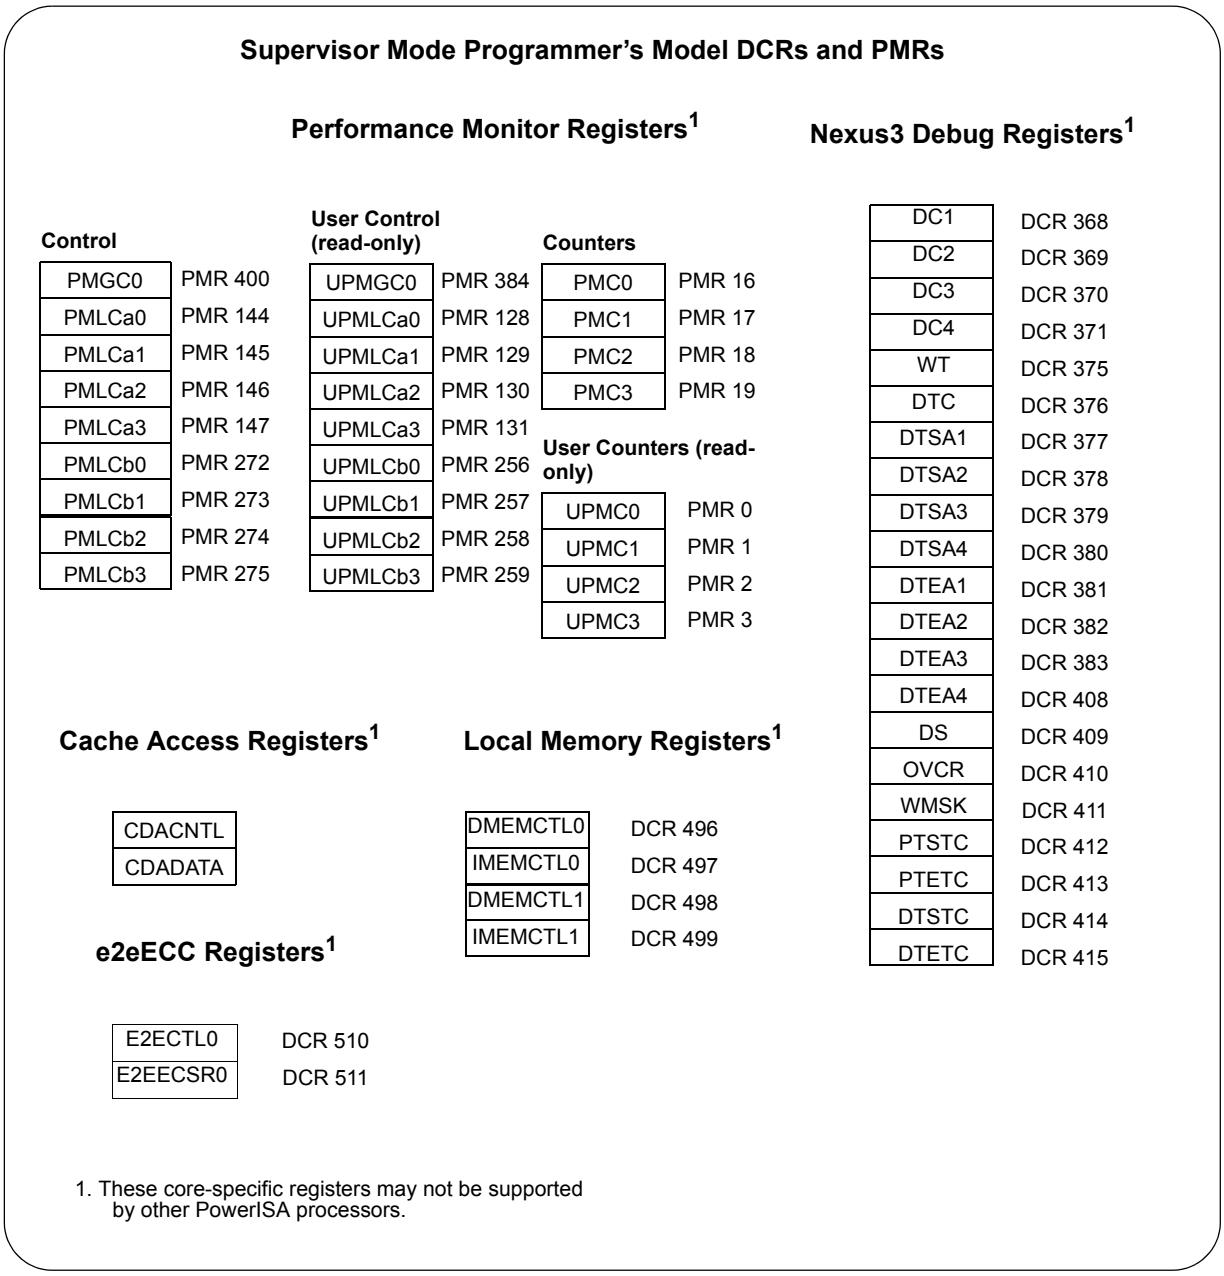


Figure 71. e200z410Dn3 User Mode Programmer's Model SPRs

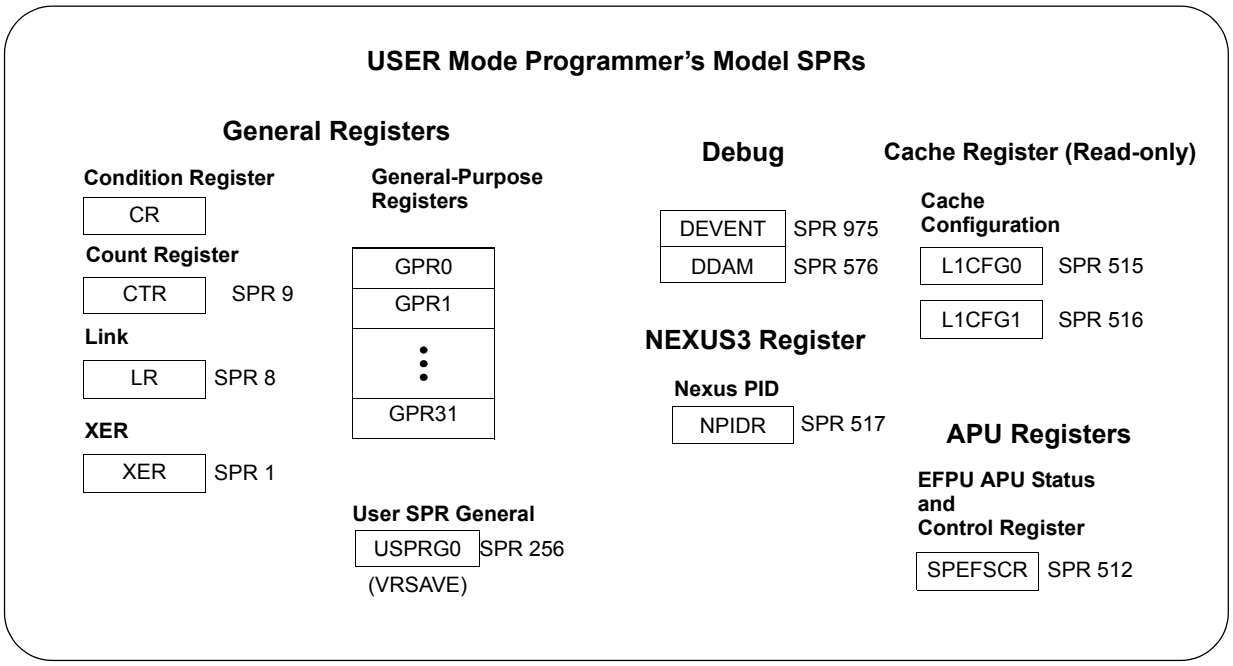

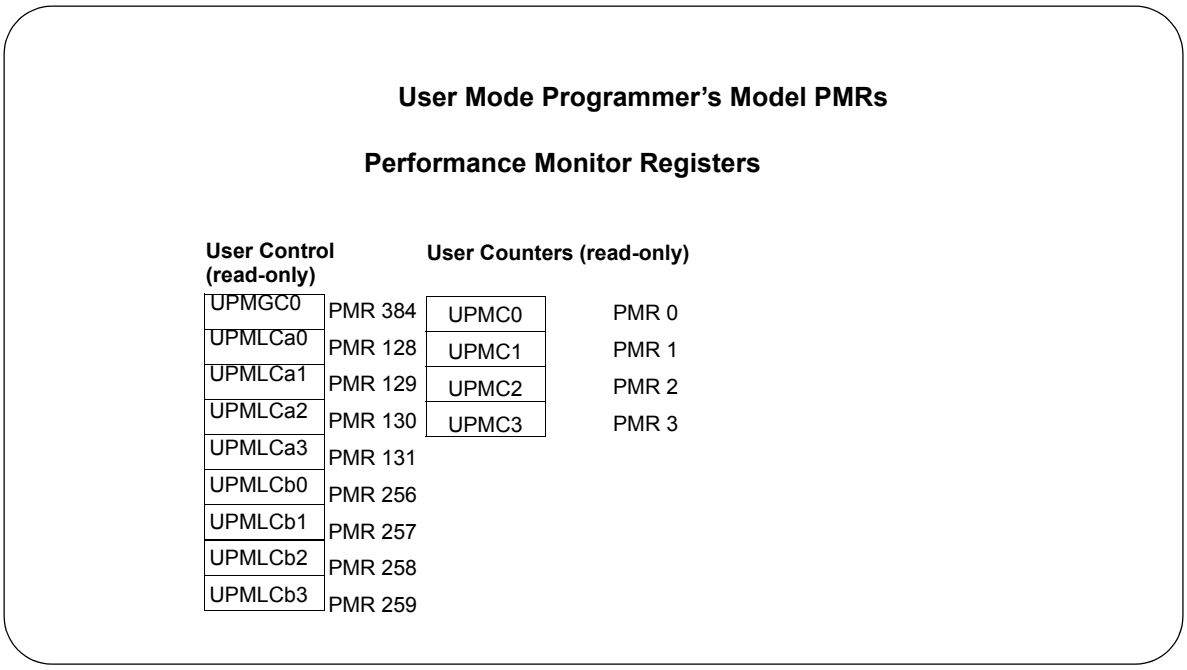

Figure 72. e200z410Dn3 User Mode Programmer's Model PMRs

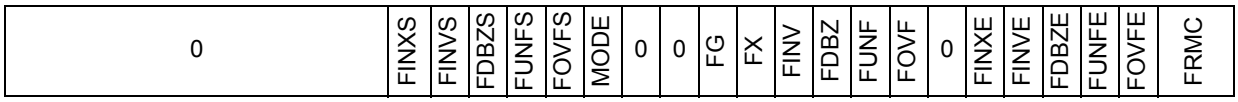
14.3 Single-issue operation

The instruction issue unit attempts to issue an instruction to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to two results can be simultaneously written.



14.4 Reservation instructions and cache interactions

The CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

14.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in Figure 73.

Figure 73. EFPU Status and Control Register (SPEFSCR)

SPR 512; Read/Write; Reset: 0x0

The SPEFSCR bits are defined in *Table 147*.

Table 147. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z410Dn3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)
16 (48)	—	Reserved
17 (49)	—	Reserved

Table 147. EFPU Status and Control Register field descriptions(Continued)

Bits	Name	Description
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite nonzero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

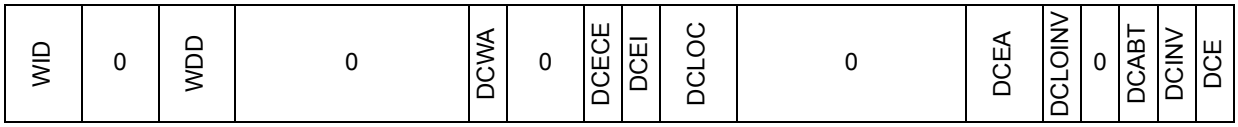
Table 147. EFPU Status and Control Register field descriptions(Continued)

Bits	Name	Description
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
30:31 (62:63)	FRMC	Embedded Floating-point Rounding Mode Control 00 Round to Nearest 01 Round toward Zero 10 Round toward +Infinity 11 Round toward –Infinity

14.5.1 Cache overview

The e200z410Dn3 processor supports a 4 KB 2-way set-associative instruction and 2 KB 2-way set-associative data cache with a 32-byte line size.

The caches improve system performance by providing low-latency data to the e200z410Dn3 instruction and data pipelines, which decouples processor performance from system memory performance.



The e200z410Dn3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

14.5.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in *Figure 74*.

Figure 74. L1 Cache Control and Status Register 0 (L1CSR0)

SPR 1010; Read/Write; Reset: 0x0

The L1CSR0 fields are described in *Table 148*.

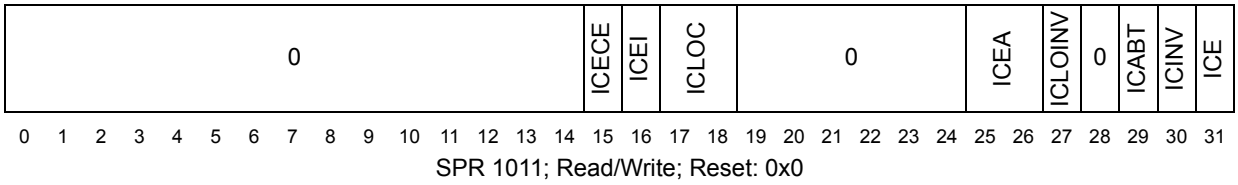
Table 148. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved(1)
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved[1]
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved[1]
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.

Table 148. L1CSR0 field descriptions(Continued)

Bits	Name	Description
17:18	DCLOC	Data Cache Lockout Control **Note:** For the **dcbi** and **dcbf** instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled. **Note:** When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored. 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved[1]
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved[1]
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 148. L1CSR0 field descriptions(Continued)



Bits	Name	Description
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.5.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfspr** or **mtspr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in *Figure 75*.

Figure 75. L1 Cache Control and Status Register 1 (L1CSR1)

SPR 1011; Read/Write; Reset: 0x0

Bits	Name	Description
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.5.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z410Dn3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in *Figure 76*.

Figure 76. L1 Cache Configuration Register 0 (L1CFG0)

Table 150. L1CFG0 field descriptions

Bits	Name	Description
0:1	CARCH	Cache Architecture 00 The cache architecture is Harvard
2	CWPA	Cache Way Partitioning Available 1 The caches support partitioning of way availability for I/D accesses
3	DCFAHA	Data Cache Flush All by Hardware Available 0 The data cache does not support Flush All in Hardware
4	DCFISWA	Data Cache Flush/Invalidate by Set and Way Available 1 The data cache supports invalidation by Set and Way via L1FINV0

Table 150. L1CFG0 field descriptions(Continued)

Bits	Name	Description
5:6	—	Reserved — read as zeros
7:8	DCBSIZE	Data Cache Block Size 00 The data cache implements a block size of 32 bytes
9:10	DCREPL	Data Cache Replacement Policy 11 The data cache implements a FIFO replacement policy
11	DCLA	Data Cache Locking APU Available 0 The data cache does not implement the line locking APU
12	DCECA	Data Cache Error Checking Available 1 The data cache implements error checking
13:20	DCNWAY	Data Cache Number of Ways 0x01 The data cache is 2-way set-associative
21:31	DCSIZE	Data Cache Size 0x002 The size of the data cache is 2 KB

14.5.5 L1 Cache Configuration Register 1 (L1CFG1)

The L1 Cache Configuration Register 1 (L1CFG1) is a 32-bit read-only register. L1CFG1 provides information about the configuration of the e200z410Dn3 L1 instruction cache design. The contents of the L1CFG1 register can be read using a **mfspr** instruction. The SPR number for L1CFG1 is 516 in decimal. The L1CFG1 register is shown in *Figure 77*.

Figure 77. L1 Cache Configuration Register 1 (L1CFG1)

0	ICFISWA	0	ICBSIZE	ICREPL	ICLA	ICECA	ICNWAY	ICSIZE

SPR 516; Read-only

The L1CFG1 fields are described in *Table 151*.

Table 151. L1CFG1 field descriptions

Bits	Name	Description
0:3	—	Reserved — read as zeros
4	ICFISWA	Instruction Cache Flush/Invalidate by Set and Way Available 1 The instruction cache supports invalidation by Set and Way via L1FINV1
5:6	—	Reserved — read as zeros
7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes

Table 151. L1CFG1 field descriptions(Continued)

Bits	Name	Description
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x004 The size of the instruction cache is 4 KB

14.5.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

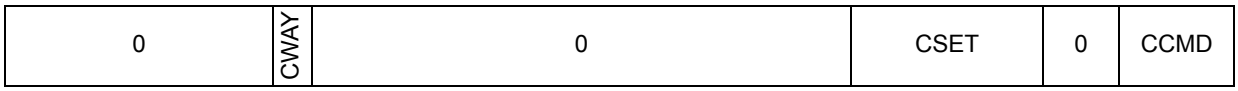
Data cache misses will force the store buffer to empty prior to performing the access.

14.5.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency.

Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle.

14.5.8 Cache Invalidate by Set and Way



e200z410Dn3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

14.5.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in *Figure 78*.

Figure 78. L1 Flush/Invalidate Register 0 (L1FINV0)

SPR 1016; Read/Write; Reset: 0x0

The L1FINV0 bits are described in *Table 152*.

Table 152. L1FINV0 field descriptions

Bits	Name	Description
0:6	—	Reserved(1) for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8:21	—	Reserved[1] for set extension
22:26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01*x* Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11*x* Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.5.8.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in *Figure 79*.

Figure 79. L1 Flush/Invalidate Register 1 (L1FINV1)

SPR 959; Read/Write; Reset: 0x0

The L1FINV1 bits are described in *Table 153*.

Table 153. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved(1) for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:20	—	Reserved[1] for set extension
21:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved[1] for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01*x* Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11*x* Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.5.9 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC — SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC — DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the $L1CSR0_{DCECE}$ and $L1CSR1_{ICECE}$ control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache ($L1CSR\{0,1\}_{[D,I]CECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

14.5.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR\{0,1\}_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

14.5.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If $L1CSR1_{ICEI}$ is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If $L1CSR0_{DCEI}$ is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV{0,1} invalidation operation.

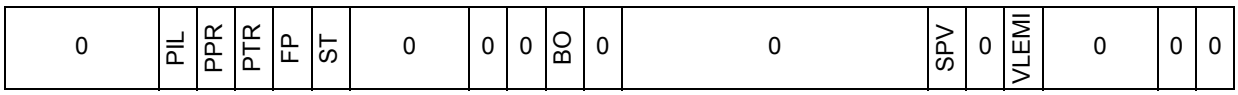
14.6 Exceptions

Interrupts implemented in e200z410Dn3 and the exception conditions that cause them are listed in *Table 154*.

Table 154. Exceptions and conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00(1)	$\overline{\textbf{p_critint_b}}$ is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40(2)	$\overline{\text{Interrupt Controller interrupt}}$ and MSR_{EE} = 1

Table 154. Exceptions and conditions(Continued)



Interrupt type	Interrupt vector offset value	Causing conditions
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	See section “Embedded Floating-point Data Exception” in the Power Architecture core reference manual relative to this core.
EFPU Round Exception	0xB0	See section “Embedded Floating-point Round Exception” in the Power Architecture core reference manual relative to this core.
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

14.6.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

Figure 80. Exception Syndrome Register (ESR)

SPR 62; Read/Write; Reset: 0x0

The ESR bits are defined in *Table 155*.

Table 155. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For core e200z410Dn3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program

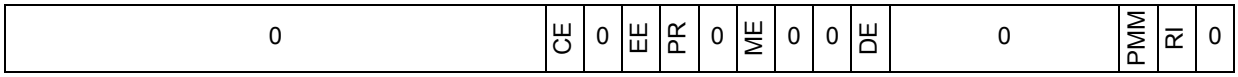


Table 155. ESR field descriptions(Continued)

Bit(s)	Name	Description	Associated interrupt type

31	—	Reserved	—

14.6.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z410Dn3 MSR is shown in *Figure 81*.

Figure 81. Machine State Register (MSR)

Read/ Write; Reset: 0x0

The MSR bits are defined in *Table 156*.

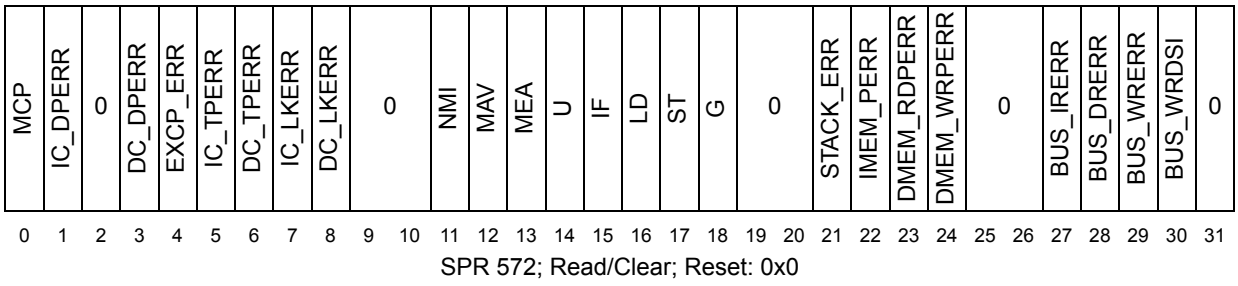

Table 156. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23:28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

14.6.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 82*.

Figure 82. Machine Check Syndrome Register (MCSR)

SPR 572; Read/Clear; Reset: 0x0

Table 157 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write 1 to clear.” Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME} = 1.

Table 157. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type(1)	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—

Table 157. Machine Check Syndrome Register (MCSR) field descriptions(Continued)

Bit	Name	Description	Exception type(1)	Recoverable
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1,MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise

Table 157. Machine Check Syndrome Register (MCSR) field descriptions(Continued)

Bit	Name	Description	Exception type(1)	Recoverable
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.

   — “Error Report” indicates that this bit is only set for error report exceptions that cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   — “Status” indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   — “NMI” indicates that this bit is only set for the non-maskable interrupt type exception, which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a ‘1’ to the bit position.

   — “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if $MSR_{ME} = 1$. If $MSR_{ME} = 0$, the machine check exception will remain pending. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

14.6.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 83*.

Figure 83. Zen Interrupt Vector Prefix Register (IVPR)

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 63; Read/Write

The IVPR fields are defined in *Table 158*.

Table 158. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

14.6.5 Interrupt Definitions

14.6.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 159 lists register settings when a Critical Input interrupt is taken.

Table 159. Critical Input Interrupt—register settings

Register	Setting description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME — FE0 0 DE —/0(1)	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x00 (autovectored) $IVPR_{0:15}$ || ($IVPR_{16:29}$ | **p_voffset[0:13]**) || 2'b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

14.6.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 160*.

Table 160. Machine Check Interrupt—register settings

Register	Setting description		
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.		
MCSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME 0 FE0 0 DE 0/—(1)	FE1 0 IS 0 DS 0 PMM 0 RI 0
ESR	Unchanged		
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.		
Vector	$IVPR_{0:23}$ || 0x10		

1. Clearing of DE is optionally supported by control in HID0.

14.6.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 161 lists register settings when a DSI is taken.

Table 161. Data Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting load/store instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Access:	[ST], [SPV], VLEMI. All other bits cleared.	
MCSR	Unchanged		

Table 161. Data Storage Interrupt—register settings(Continued)

Register	Setting description
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.
Vector	$IVPR_{0:23}$ || 0x20

14.6.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

Table 162 lists register settings when an ISI is taken.

Table 162. Instruction Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged

14.6.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 163 lists register settings when an External Input interrupt is taken.

Table 163. External Input Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.

14.6.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z410Dn3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z410Dn3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR} = 1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5$ = 1 (even if the SPR is undefined)

The e200z410Dn3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

Table 165 lists register settings when a Program interrupt is taken.

14.6.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 168 lists register settings when a System Reset interrupt is taken.

14.6.5.13 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 171 lists register settings when an performance monitor interrupt is taken.

Table 171. Performance Monitor Interrupt—Register Settings

Register	Setting description		
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.

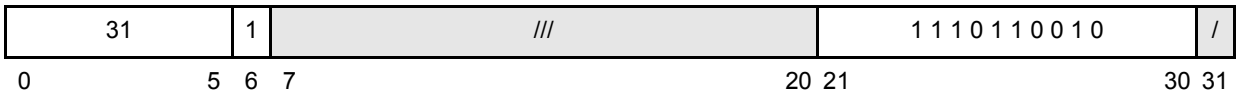
14.7 Memory Protection Unit (MPU)

14.7.1 MPU Overview

The e200z410Dn3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

14.7.2 Software Interface and MPU Instructions



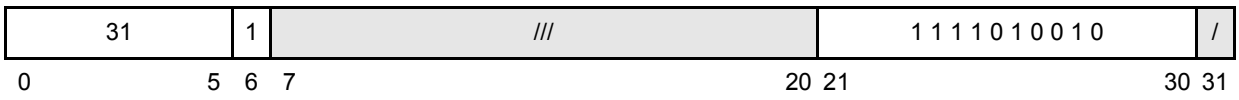
The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

14.7.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure **mpure**
mpu read entry



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
```

```
MAS0, MAS1, MAS2, MAS3 = result
```

14.7.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

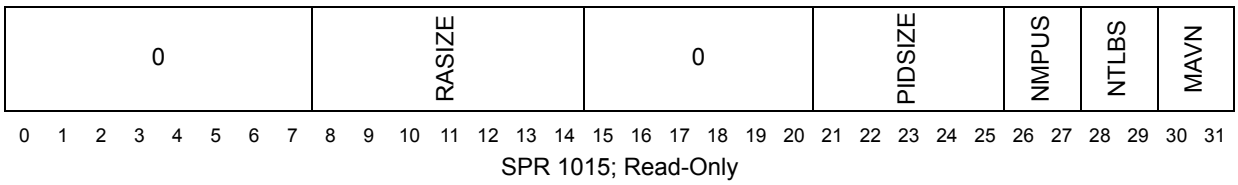
mpuwe **mpuwe**
mpu write entry

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

14.7.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z410Dn3.

mpusync **mpusync**
MPU Synchronize



mpusync

14.7.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z410Dn3 MPU design. The MMUCFG register is shown in *Figure 84*.

Figure 84. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 172*.

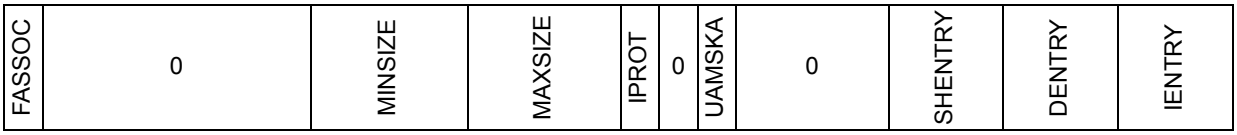


Table 172. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved

SPR 1014; Read/ Write; Reset: 0x0(1)

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in *Table 174*.

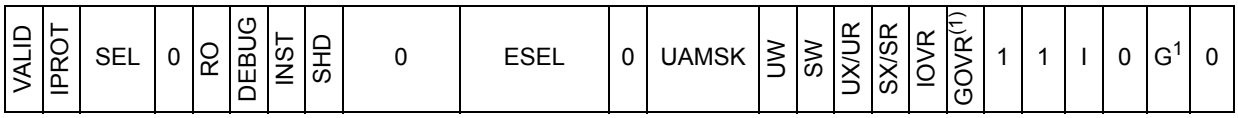
Table 174. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses

Table 174. MPU0CSR0 field descriptions(Continued)

Bits	Name	Description
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses

Table 174. MPU0CSR0 field descriptions(Continued)



Bits	Name	Description
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

14.7.9 MPU Assist Registers (MAS)

The e200z410Dn3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 87*. Fields are defined in *Table 175*.

Figure 87. MPU Assist Register 0 (MAS0)

SPR 624; Read/ Write; Reset: Unaffected

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 175. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 This MPU entry is invalid 1 This MPU entry is valid
1	IPROT	Invalidation Protect 0 Entry is not protected from invalidation 1 Entry is protected from invalidation
2:3	SEL	Selects MPU for access: 00 Reserved, no access 01 Reserved, no access 10 Select MPU 11 Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 This MPU entry is writable 1 This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for **mpure** and **mpuwe** instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 This MPU entry is used for matching data accesses only 1 This MPU entry is used for matching instruction accesses only

Table 175. MAS0—MPU Read/Write and Replacement Control(Continued)

Bit	Name	Comments, or Function when Set
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 No upper address bits are masked, address matching uses all 32 address bits for accesses 001 The most significant access address bit is forced to 0 before matching 010 The two most significant access address bits are forced to 0 before matching 011 The three most significant access address bits are forced to 0 before matching 100 The four most significant access address bits are forced to 0 before matching 101 The upper five access address bits are forced to 0 before matching 11*x* Reserved, do not use
20	UW	User Mode Write Permission Determines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No User mode Write permission 1 User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No Supervisor mode Write permission 1 Supervisor mode has Write permission
22	UX/UR	User Mode Execute / Read Permission Determines User mode Execute (X) permission when INST = 1, or User mode Read (R) permission when INST = 0. 0 No User mode Execute/ Read permission 1 User mode has Execute/ Read permission

Table 175. MAS0—MPU Read/Write and Replacement Control(Continued)

Bit	Name	Comments, or Function when Set

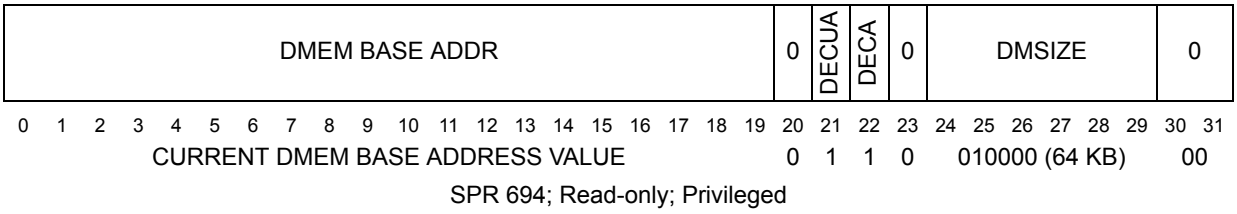
1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1.

14.8 Local memories

14.8.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

14.8.2 Local memory control and configuration



DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that

are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

14.8.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z410Dn3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 92*.

Figure 92. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 179*.

Table 179. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 010000 The size of the DMEM is 64 KB.
30:31	—	Reserved

14.8.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

Figure 93. DMEM Control Register 0 (DMEMCTL0)

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCPECE	DSECE

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 180. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16:18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input.

Table 180. DMEMCTL0 field descriptions(Continued)

Bits	Name	Description
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input.
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).

Table 180. DMEMCTL0 field descriptions(Continued)

Bits	Name	Description
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs.
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input.

14.8.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.

Table 183. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.
18:19	—	Reserved for Base Address extension
20:21	—	Reserved

Table 183. IMEMCTL0 field descriptions(Continued)

Bits	Name	Description
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[0]** input. 0Error Correction Update is disabled 1Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_imem_baseaddr[0:n]**) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_imem_rstcfg[1:2]** inputs.
29	IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[3]** input.

Table 183. IMEMCTL0 field descriptions(Continued)

Bits	Name	Description
30	ICPECE	IMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[4]** input.
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[5]** input.

14.8.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

Figure 97. IMEM Control Register 1 (IMEMCTL1)

14.9 End-to-End ECC support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

14.9.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

14.9.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

Figure 98. e2eECC Control Register 0 (E2ECTL0)

DCR 510; Read/Write; Reset: 0x0 || p_e2e_rstcfg[0:3]; Privileged

Table 185. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

E2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

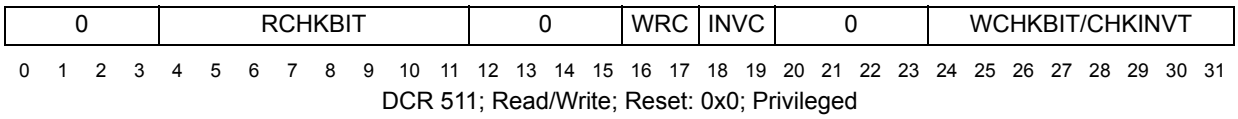
The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

14.9.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit

information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.



Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 99 shows the layout of E2EECSR0.

Figure 99. e2eECC Error Control/Status Register 0 (E2EECSR0)

DCR 511; Read/Write; Reset: 0x0; Privileged

Table 186. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection.

Table 186. E2EECSR0 field descriptions(Continued)

Bits	Name	Description
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection.
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

15 Core e200z225Bn3 description

15.1 Overview of the e200z225Bn3 core

The e200z225Bn3 is a single-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z225Bn3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver vector and scalar results. A wide variety of data manipulation, multiply, multiply/accumulate, and dot product instructions along with specialized memory access instructions allow a sustained throughput of up to one 16 × 16-bit multiply/accumulate operation per cycle.

The e200z225Bn3 processor integrates an integer execution unit, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining three read and two write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z225Bn3 contains a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

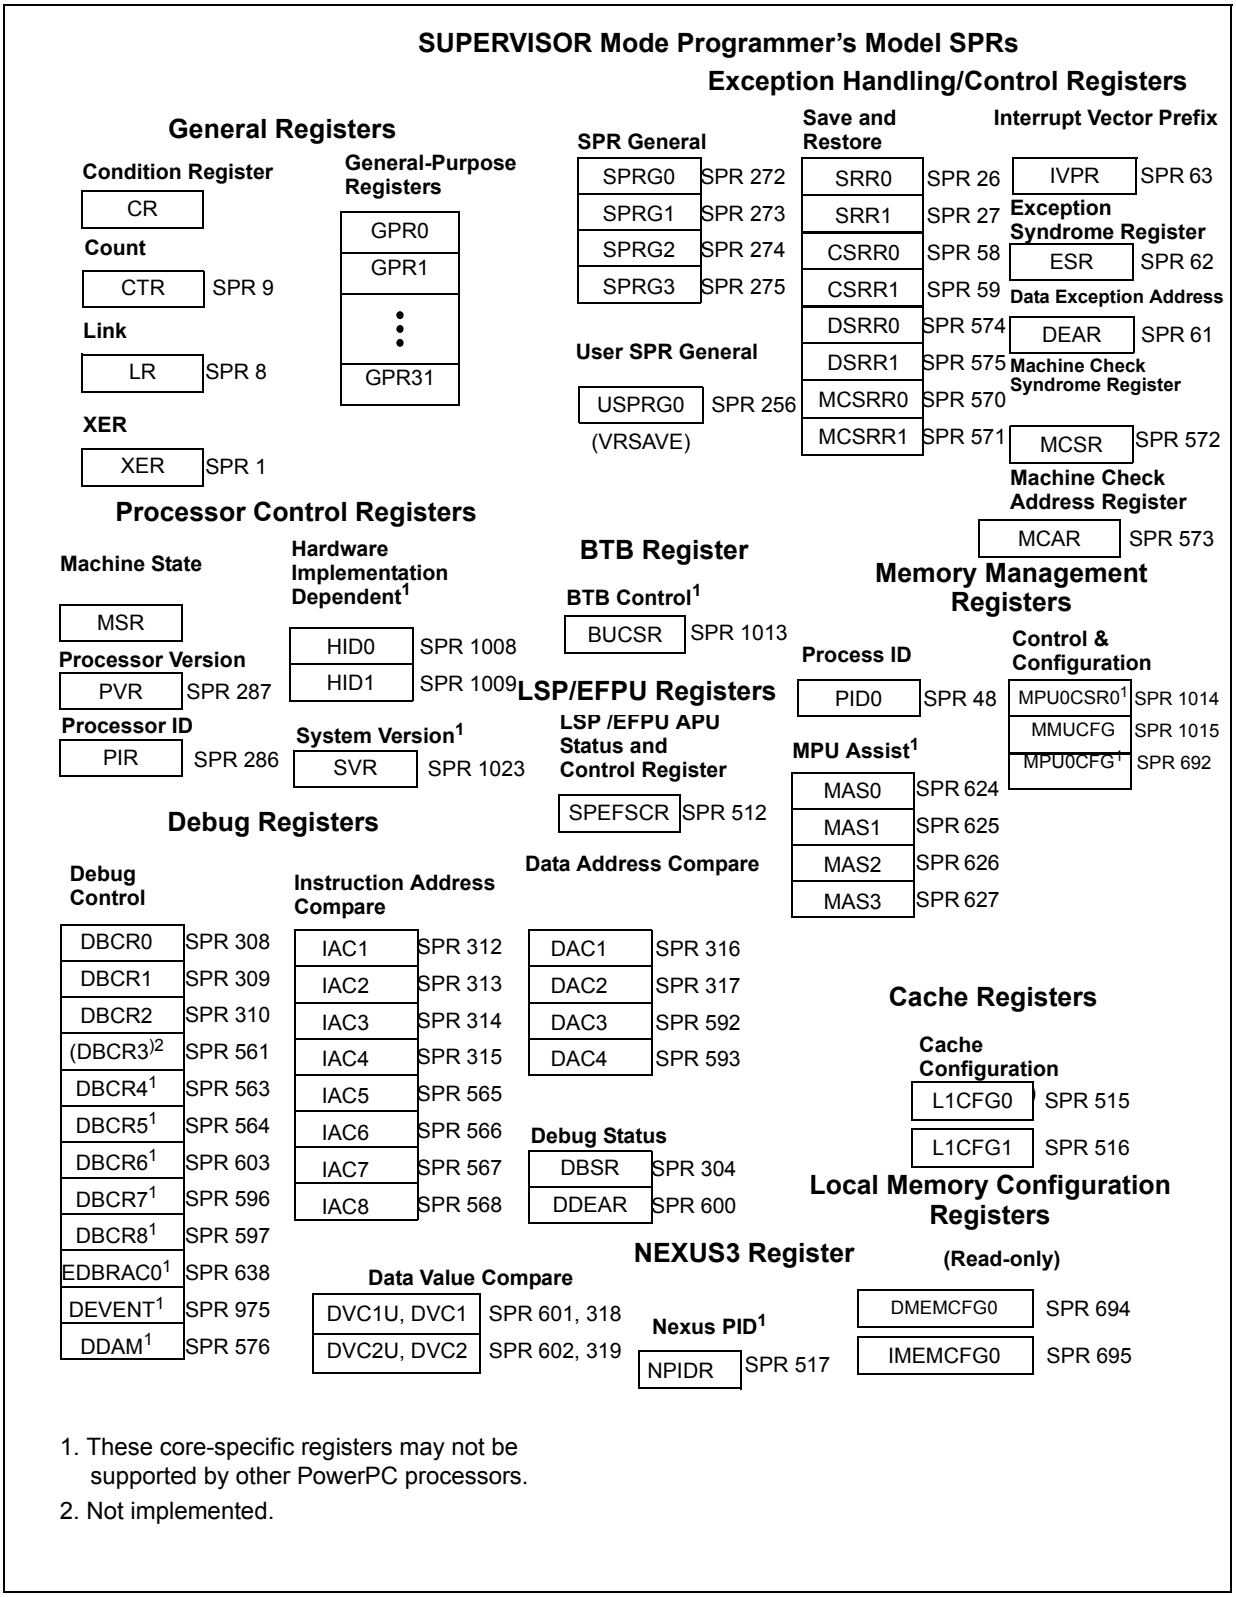
A Memory Protection Unit that protects various instruction and data memory areas is also included.

15.2 EFPU2 Floating-Point Unit features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion <-> single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results

Floating-point Divide and Square root logic operating in 13 (FP div) and 11 (FP sqrt) clock cycles



15.3 Register model

This section describes the registers implemented in the e200z225Bn3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z225Bn3 extends usage of the general purpose registers to support EFPU/LSP APU operations on the 32-bit GPR registers.

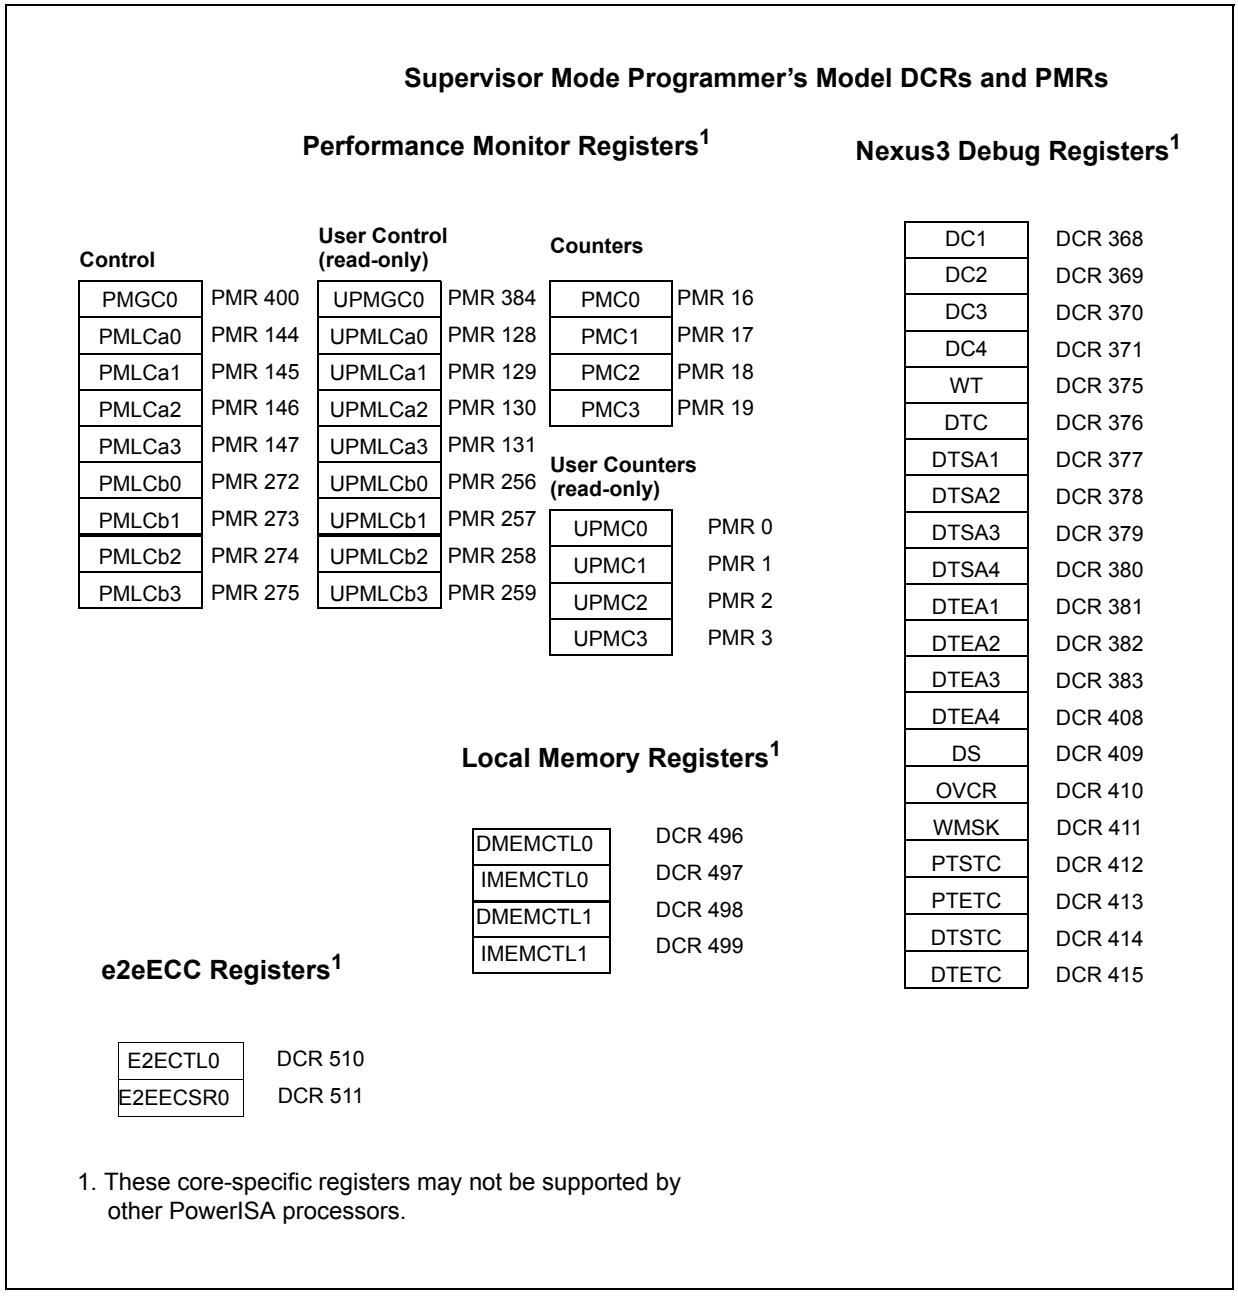


Figure 100 and *Figure 101* show the complete e200z225Bn3 register set, all of which are accessible in supervisor mode. *Figure 102* and *Figure 103* show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

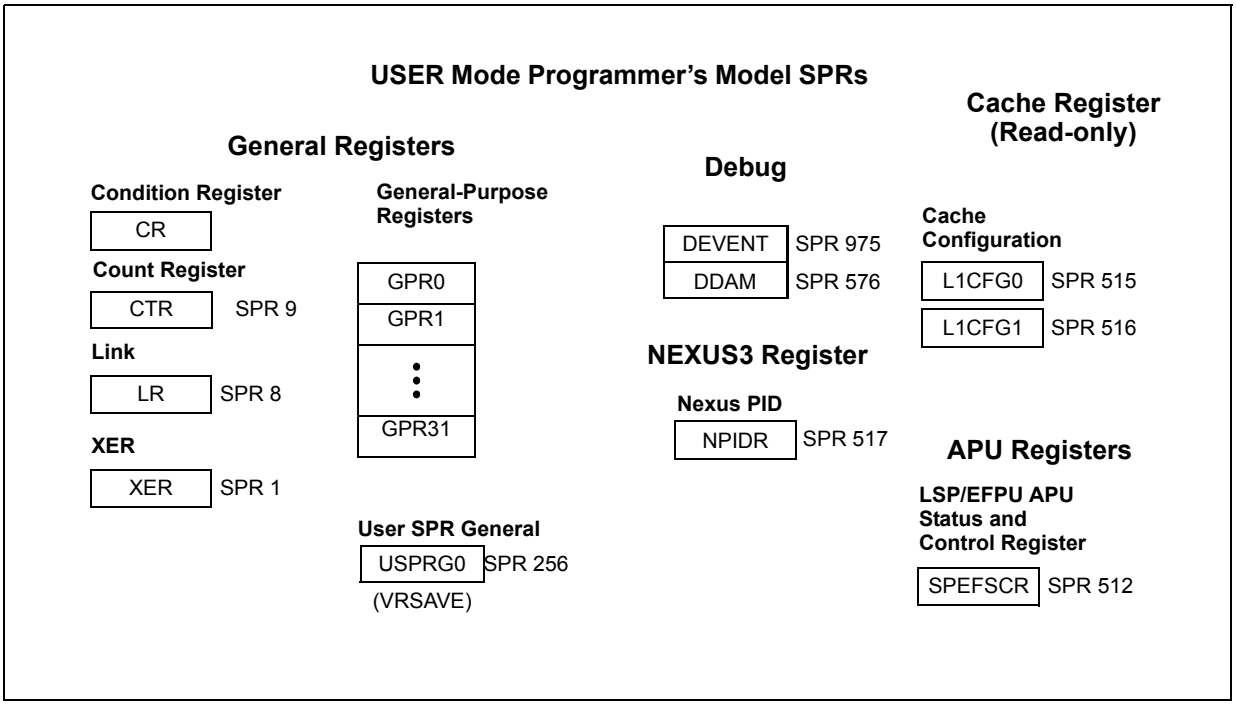
Figure 100. e200z225Bn3 Supervisor Mode Programmer's Model SPRs

1. These core-specific registers may not be supported by other PowerPC processors.
2. Not implemented.

Figure 101. e200z225Bn3 Supervisor Mode Programmer's Model DCRs and PMRs

1. These core-specific registers may not be supported by other PowerISA processors.

Figure 102. e200z225Bn3 User Mode Programmer's Model SPRs



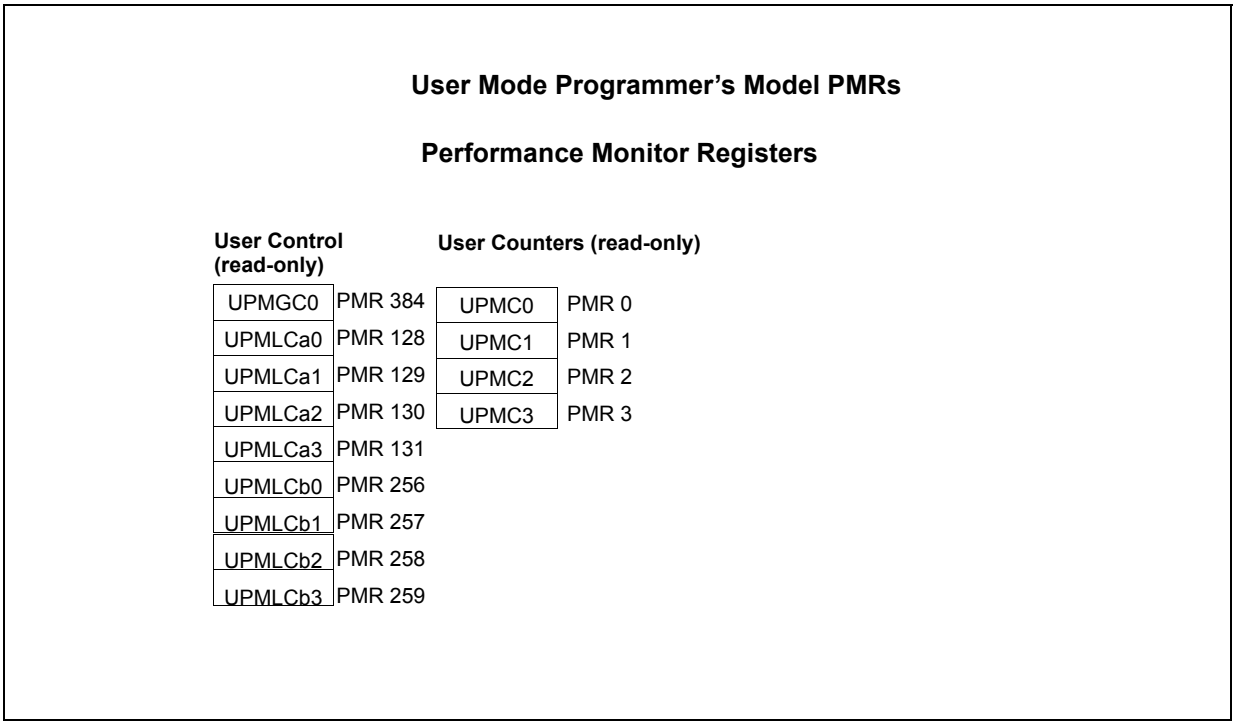


Figure 103. e200z225Bn3 User Mode Programmer's Model PMRs

15.4 Single-issue operation

The instruction issue unit attempts to issue an instruction to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to two results can be simultaneously written.

15.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. This register is also used by the LSP APU. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in Figure 104.

0	FINXS	FINVS	FDBZS	FUNFS	FOVFS	MODE	SOV	OV	FG	FX	FINV	FDBZ	FUNF	FOVF	0	FINXE	FINVE	FDBZE	FUNFE	FOVFE	FRMC

SPR 512; Read/Write; Reset: 0x0

Figure 104. LSP/EFPU Status and Control Register (SPEFSCR)

The SPEFSCR bits are defined in *Table 187*.

Table 187. LSP/EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.

Table 187. LSP/EFPU Status and Control Register field descriptions(Continued)

Bits	Name	Description
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a **mtspr** instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z225Bn3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)
16 (48)	SOV	Summary integer overflow Defined by LSP APU.
17 (49)	OV	Integer overflow Defined by LSP APU.
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler.FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the l dividend is a finite nonzero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved

Table 187. LSP/EFPU Status and Control Register field descriptions(Continued)

Bits	Name	Description
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact (FG | FX = 1), or if the result of a Floating-point instruction does result in overflow (FOVF = 1) but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1 or FUNFH = 1) but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

15.6 Exceptions

Interrupts implemented in e200z225Bn3 and the exception conditions that cause them are listed in *Table 188*.

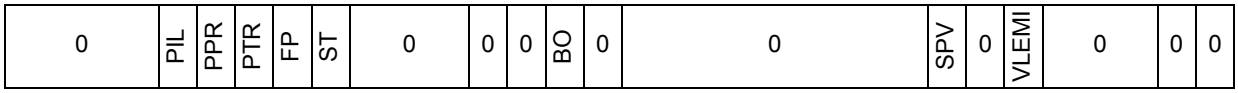

Table 188. Exceptions and conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] || 2'b00	Reset
Critical Input	0x00(1)	**p_critint_b** is asserted and MSR_{CE} = 1.
Machine check	0x10	1. **p_mcp_b** transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Local Memory access 4. External bus error 5. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40(2)	Interrupt Controller interrupt and MSR_{EE} = 1
Alignment	0x50	1. **lmw**, **stmw** not word aligned 2. **lwarx** or **stwcx.** not word aligned, **lharx** or **sthcx.** not halfword aligned 3. LSP ld and st instructions not properly aligned 4. **dcbz**
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 0
System call	0x80	Execution of the System Call (**se_sc**) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/$PMGC0_{UDI}$ = 1
EFPU Data Exception	0xA0	See section "Embedded Floating-point Data Exception" in the Power Architecture core reference manual relative to this core.
EFPU Round Exception	0xB0	See section "Embedded Floating-point Round Exception" in the Power Architecture core reference manual relative to this core.
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

15.6.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

SPR 62; Read/Write; Reset: 0x0

Figure 105. Exception Syndrome Register (ESR)

The ESR bits are defined in *Table 189*.

Table 189. ESR field descriptions

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For core e200z225Bn3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program

Bit(s)	Name	Description	Associated interrupt type
30	—	Reserved	—
31	—	Reserved	—

15.6.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z225Bn3 MSR is shown in *Figure 106*.

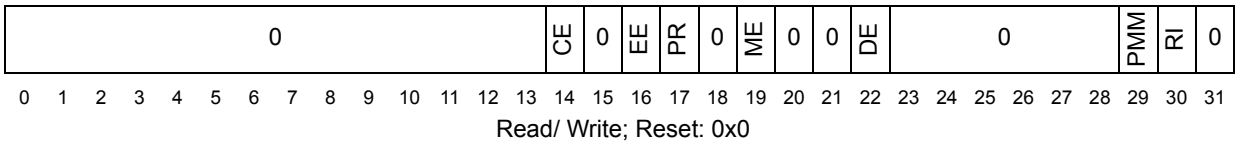

Figure 106. Machine State Register (MSR)

The MSR bits are defined in *Table 190*.

Table 190. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23:28	—	Reserved

Table 190. MSR field descriptions(Continued)

Bit(s)	Name	Description
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR_{PR} and MSR_{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLCa*n* Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

15.6.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in *Figure 107*.

MCP	IC_DPERR	0	DC_DPERR	EXCP_ERR	IC_TPERR	DC_TPERR	IC_LKERR	DC_LKERR	0	NMI	MAV	MEA	U	IF	LD	ST	G	0	STACK_ERR	IMEM_PERR	DMEM_RDPERR	DMEM_WRPERR	0	BUS_IRERR	BUS_DRERR	BUS_WRERR	BUS_WRDSI	0

SPR 572; Read/Clear; Reset: 0x0

Figure 107. Machine Check Syndrome Register (MCSR)

Table 191 describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write 1 to clear.” Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME} = 1.

Table 191. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type(1)	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR(2)	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR(3)	Data Cache data array parity error	Async Mchk	Maybe

Table 191. Machine Check Syndrome Register (MCSR) field descriptions(Continued)

Bit	Name	Description	Exception type(1)	Recoverable
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR[2]	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR[3]	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR[2]	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR[3]	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1,MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise

Table 191. Machine Check Syndrome Register (MCSR) field descriptions(Continued)

Bit	Name	Description	Exception type(1)	Recoverable
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.

   — “Error Report” indicates that this bit is only set for error report exceptions that cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   — “Status” indicates that this bit is provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

   — “NMI” indicates that this bit is only set for the non-maskable interrupt type exception, which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a ‘1’ to the bit position.

   — “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if $MSR_{ME} = 1$. If $MSR_{ME} = 0$, the machine check exception will remain pending. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

2. Will not be set by e200z225Bn3 since no instruction cache is present.

3. Will not be set by e200z225Bn3 since no data cache is present.

15.6.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in *Figure 108*.

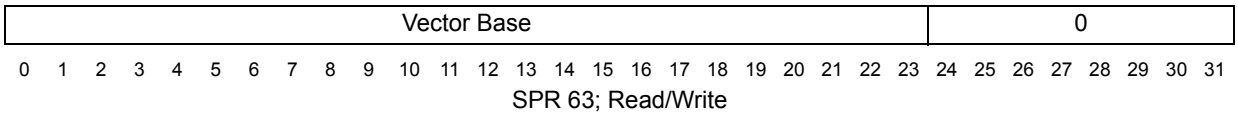

Figure 108. Zen Interrupt Vector Prefix Register (IVPR)

The IVPR fields are defined in *Table 192*.

Table 192. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.6.5 Interrupt Definitions

15.6.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE}, the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

Table 193 lists register settings when a Critical Input interrupt is taken.

Table 193. Critical Input Interrupt—register settings

Register	Setting description
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.
CSRR1	Set to the contents of the MSR at the time of the interrupt

Table 193. Critical Input Interrupt—register settings(Continued)

Register	Setting description		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME — FE0 0 DE —/0(1)	FE1 0 IS 0 DS 0 PMM 0 RI —

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

15.6.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register ($HID0_{MCCLRDE}$).

When a Machine Check interrupt is taken, registers are updated as shown in *Table 194*.

Table 194. Machine Check Interrupt—register settings

Register	Setting description		
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.		
MCSRR1	Set to the contents of the MSR at the time of the interrupt

Vector	$IVPR_{0:23}$ || 0x10		

1. Clearing of DE is optionally supported by control in HID0.

15.6.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

Table 195 lists register settings when a DSI is taken.

Table 195. Data Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting load/store instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt

ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	$IVPR_{0:23}$ || 0x30		

15.6.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the

interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

Table 197 lists register settings when an External Input interrupt is taken.

Table 197. External Input Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
SRR1	Set to the contents of the MSR at the time of the interrupt

15.6.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of an LSP APU load or store instruction that is not properly aligned.

Table 198 lists register settings when an alignment interrupt is taken.

Table 198. Alignment Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.

ESR	[ST], [SPV], VLEMI. All other bits cleared.		
MCSR	Unchanged		

Table 198. Alignment Interrupt—register settings(Continued)

Register	Setting description
DEAR	Set to the effective address of a byte of the load or store access causing the violation.
Vector	$IVPR_{0:23}$ || 0x50

15.6.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z225Bn3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspr** instructions with an undefined SPR specified
- **mtdcr** and **mfdcr** instructions with an undefined DCR specified

The e200z225Bn3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when MSR_{PR} = 1 (user mode):

- A privileged instruction
- **mtspr** and **mfspr** instructions that specify a SPRN value with $SPRN_5$ = 1 (even if the SPR is undefined)

The e200z225Bn3 will invoke an Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfdcrx**, **mtdcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

Table 199 lists register settings when a Program interrupt is taken.

1. Assumes that the Debug interrupt is precise.
2. Conditional based on control bits in HID0.
3. Note that multiple DBSR bits may be set.

15.6.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

Table 202 lists register settings when a System Reset interrupt is taken.

Table 202. System Reset Interrupt—register settings

Vector	$IVPR_{0:23}$ || 0xB0		

15.6.5.13 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMC*x* register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, $PMGC0_{PMIE}$ must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

Table 205 lists register settings when an performance monitor interrupt is taken.

Table 205. Performance Monitor Interrupt—Register Settings

Register	Setting description		
SRR0/ DSRR0(1)	Set to the effective address of the next instruction to be executed.		
SRR1/ DSRR1[1]	Set to the contents of the MSR at the time of the interrupt.		
MSR	SPV 0 WE 0 CE —/0(2) EE 0/—(3) PR 0	FP 0 ME — FE0 0 DE —/0(4)	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Unchanged		
MCSR	Unchanged		

Table 205. Performance Monitor Interrupt—Register Settings(Continued)

Register	Setting description
DEAR	Unchanged
Vector	$IVPR_{0:23}$ || 0x70

1. DSRR0/1 are used if $PMGC0_{UDI}$ = 1.
2. CE is cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLRCE}$ = 1.
3. EE is not cleared if $PMGC0_{UDI}$ = 1 and $HID0_{DCLREE}$ = 0.
4. DE is cleared if $PMGC0_{UDI}$ = 1.

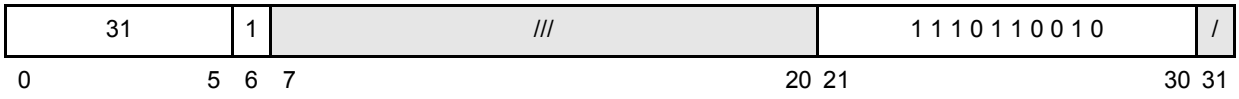
15.7 Memory Protection Unit (MPU)

15.7.1 MPU Overview

The e200z225Bn3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 8-entry region descriptor table with support for arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

15.7.2 Software Interface and MPU Instructions



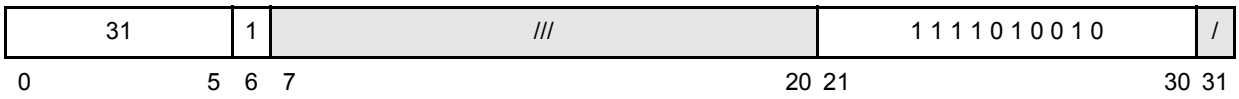
The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mfspr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

15.7.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure **mpure**
mpu read entry

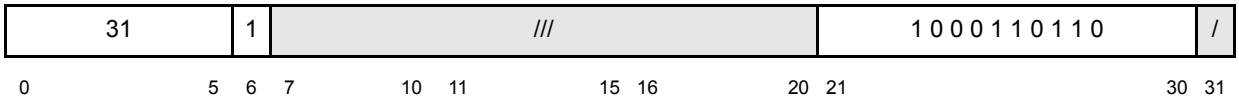


```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

15.7.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe **mpuwe**
mpu write entry



```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

15.7.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z225Bn3.

mpusync **mpusync**
MPU Synchronize

mpusync

15.7.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z225Bn3 MPU design. The MMUCFG register is shown in *Figure 109*.

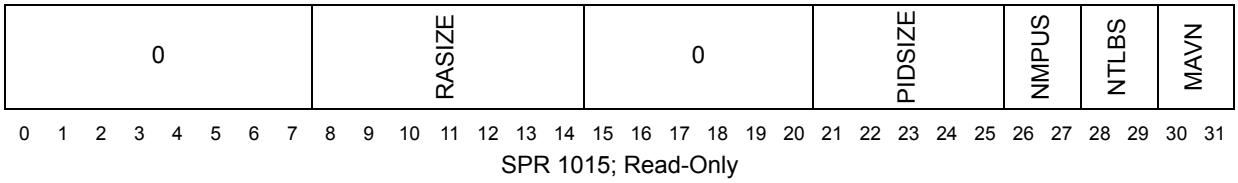


Figure 109. MMU/MPU Configuration Register (MMUCFG)

The MMUCFG bits are described in *Table 206*.

Table 206. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

15.7.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z225Bn3 MPU. The MPU0CFG register is shown in *Figure 110*.

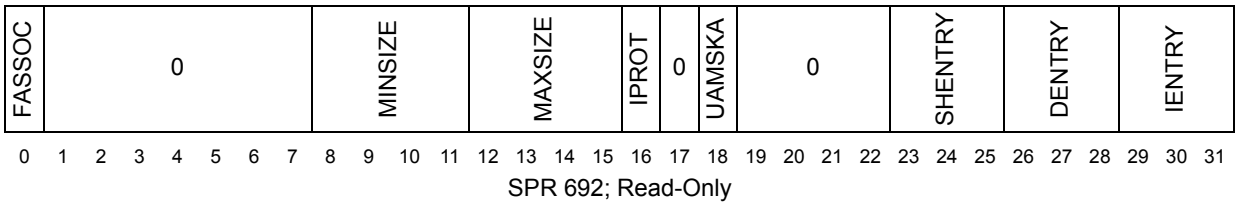

Figure 110. MPU0 Configuration Register (MPU0CFG)

The MPU0CFG bits are described in *Table 207*.

Table 207. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IPROT	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x3 Indicates that MPU0 contains 8 shared entries
26:28	DENTRY	Number of Data Entries 0x0 Indicates that MPU0 contains 0 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x0 Indicates that MPU0 contains 0 dedicated Instruction entries

15.7.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in *Figure 111*.

0	BYPSR	BYPSW	BYPSX	BYPUR	BYPUW	BYPUX	0	DRDEN	DWDEN	IDEN	0	TIDCTL	0	MPUFI	MPUEN

SPR 1014; Read/ Write; Reset: 0x0(1)

Figure 111. MPU0 Control and Status Register 0 (MPU0CSR0)

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$ = 0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$ = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in *Table 208*.

Table 208. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYPUW	Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYPUX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved

Table 208. MPU0CSR0 field descriptions(Continued)

Bits	Name	Description
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved

Table 208. MPU0CSR0 field descriptions(Continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation **Note:** Entries that have the IPROT bit set will not be invalidated.
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

15.7.9 MPU Assist Registers (MAS)

The e200z225Bn3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mfspr** and **mtspr** instructions.

The MAS0 register is shown in *Figure 112*. Fields are defined in *Table 209*.

Figure 112. MPU Assist Register 0 (MAS0)

VALID	IPROT	SEL	0	RO	DEBUG	INST	SHD	0	ESEL	0	UAMSK	UW	SW	UX/UR	SX/SR	IOVR	GOVR(1)	1	1	I	0	G1	0

SPR 624; Read/ Write; Reset: Unaffected

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 209. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 This MPU entry is invalid 1 This MPU entry is valid
1	IPROT	Invalidation Protect 0 Entry is not protected from invalidation 1 Entry is protected from invalidation

Table 209. MAS0—MPU Read/Write and Replacement Control(Continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 Reserved, no access 01 Reserved, no access 10 Select MPU 11 Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 This MPU entry is writable 1 This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 This MPU entry is used for matching data accesses only 1 This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. For core e200z225Bn3, this bit should always be set to ‘1’. 0 The shared portion of the region descriptor table is not accessed on a **mpure** or **mpuwe** operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 The shared portion of the region descriptor table is accessed on a **mpure** or **mpuwe** operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:12	—	Reserved
13:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

Table 209. MAS0—MPU Read/Write and Replacement Control(Continued)

Bit	Name	Comments, or Function when Set
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 No upper address bits are masked, address matching uses all 32 address bits for accesses 001 The most significant access address bit is forced to 0 before matching 010 The two most significant access address bits are forced to 0 before matching 011 The three most significant access address bits are forced to 0 before matching 100 The four most significant access address bits are forced to 0 before matching 101 The upper five access address bits are forced to 0 before matching 11*x* Reserved, do not use
20	UW	User Mode Write Permission Determines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No User mode Write permission 1 User mode has Write permission

15.7.10 MAS Registers Summary

The MAS registers are summarized in *Figure 116*.

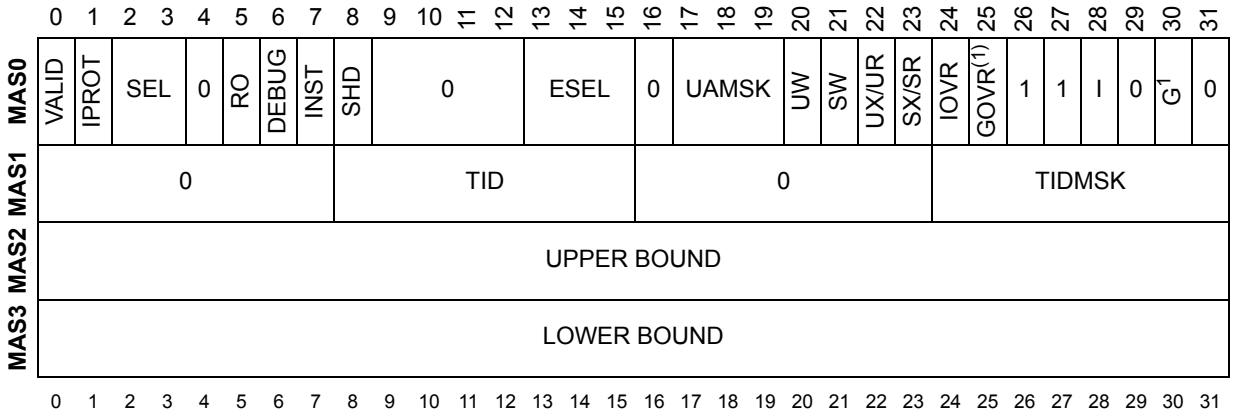

Figure 116. MPU Assist Registers Summary

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1.

15.8 Local memories

15.8.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

15.8.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mfspr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mfdcr** and **mtdcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.8.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z225Bn3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mfspr**

instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in *Figure 117*.

DMEM BASE ADDR	0	DECUA	DECA	0	DMSIZE	0

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
CURRENT DMEM BASE ADDRESS VALUE																				0	1	1	0	001100 (48 KB)						00	

SPR 694; Read-only; Privileged

Figure 117. DMEM Configuration Register 0 (DMEMCFG0)

The DMEMCFG0 fields are described in *Table 213*.

Table 213. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. **Note:** Low order bits of this field are driven to 0s when the DMEM size is > 4 KB
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 001100 The size of the DMEM is 48 KB.
30:31	—	Reserved

15.8.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

Figure 118. DMEM Control Register 0 (DMEMCTL0)

Bits	Name	Description
0:15	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
16:18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (**lbcbx**, **lhcbx**, **lwcbx**, and **stwwtx**, **sthwtx**, **stbwtx**) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[8]** input.
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[6]** input.
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (**lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb**) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[7]** input.

Table 214. DMEMCTL0 field descriptions(Continued)

Bits	Name	Description
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[0]** input.
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_dmem_baseaddr[0:n]**) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (**p_dmem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_dmem_rstcfg[1:2]** inputs.

Table 214. DMEMCTL0 field descriptions(Continued)

Bits	Name	Description
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[3]** input.
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[4]** input.
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_dmem_rstcfg[5]** input.

15.8.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0$_{DBYPCB, DBYPATF, DBYPDEC}$.

A single control field is used for each access based on the upper two address bits used to index into the DMEM. DURAC0 is used when these two bits = 2'b00 00 User-mode CPU read accesses are allowed to quadrant 0 of DMEM 01 User-mode CPU read accesses are not allowed to quadrant 0 of DMEM 10 User-mode CPU read accesses are conditionally allowed to quadrant 0 of DMEM based on memory protection logic 11 Reserved

15.8.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the e200z225Bn3 local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mfspr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in *Figure 120*.

IMEM BASE ADDR	0	IECUA	IECA	0	IMSIZE	0

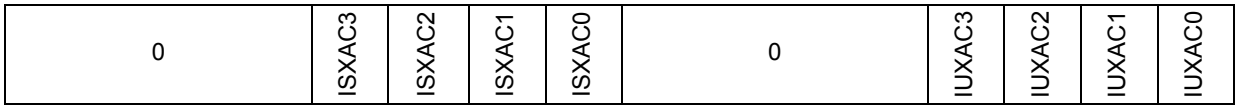
Table 217. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. **Note:** Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated.
18:19	—	Reserved for Base Address extension
20:21	—	Reserved

Table 217. IMEMCTL0 field descriptions(Continued)



Bits	Name	Description
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[0]** input. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port (**p_imem_baseaddr[0:n]**) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port (**p_imem_baseaddr[0:n]**) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the values of the **p_imem_rstcfg[1:2]** inputs.
29	IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[3]** input.

Table 217. IMEMCTL0 field descriptions(Continued)

Bits	Name	Description
30	ICPECE	IMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[4]** input.
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. **Note:** This field is updated on **m_por** and **slv_reset_b** based on the value of the **p_imem_rstcfg[5]** input.

15.8.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

Table 218. IMEMCTL1 field descriptions(Continued)

Bits	Name	Description
28:29	IUXAC1	MEM User Instruction Fetch Access Control for Quadrant 1 00 User-mode CPU instruction fetch accesses are allowed to quadrant 1 of IMEM 01 User-mode CPU instruction fetch accesses are not allowed to quadrant 1 of IMEM 10 User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 1 of IMEM based on memory protection logic 11 Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC1 is used when these two bits = 2'b01.
30:31	IUXAC0	IMEM User Instruction Fetch Access Control for Quadrant 0 00 User-mode CPU instruction fetch accesses are allowed to quadrant 0 of IMEM 01 User-mode CPU instruction fetch accesses are not allowed to quadrant 0 of IMEM 10 User-mode CPU instruction fetch accesses are conditionally allowed to quadrant 0 of IMEM based on memory protection logic 11 Reserved **Note:** Individual control fields are provided for four equal sized sections of IMEM regardless of IMEM size. A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC0 is used when these two bits = 2'b00.

15.9 End-to-End ECC support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

15.9.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

15.9.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

DCR 510; Read/Write; Reset: 0x0 || p_e2e_rstcfg[0:3]; Privileged

Figure 123. e2eECC Control Register 0 (E2ECTL0)

Table 219. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[0]** input.
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[1]** input.
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[2]** input.
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. **Note:** This field is updated on **p_reset_b** based on the value of the **p_e2e_rstcfg[3]** input.

E2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the initialization, software may enable e2eECC operation by writing the appropriate values to the $E2ECTL0_{[I,D]ECCEN}$ control bits.

The $E2ECTL0_{[I,D]DAC}$ control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.9.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit

information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 124 shows the layout of E2EECSR0.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

DCR 511; Read/Write; Reset: 0x0; Privileged

Figure 124. e2eECC Error Control/Status Register 0 (E2EECSR0)

Table 220. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to **p_hrchkbit[7:0]**. for external reads and to **p_dchk[0:7]** for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving **p_hwchkbit[7:0]** with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection.

Table 220. E2EECSR0 field descriptions(Continued)

Bits	Name	Description
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying **p_hwchkbit[7:0]** based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying **p_hwchkbit[7:0]** based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection.
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to **p_hwchkbit[7:0]**. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on **p_hwchkbit[7:0]** when error injection occurs.

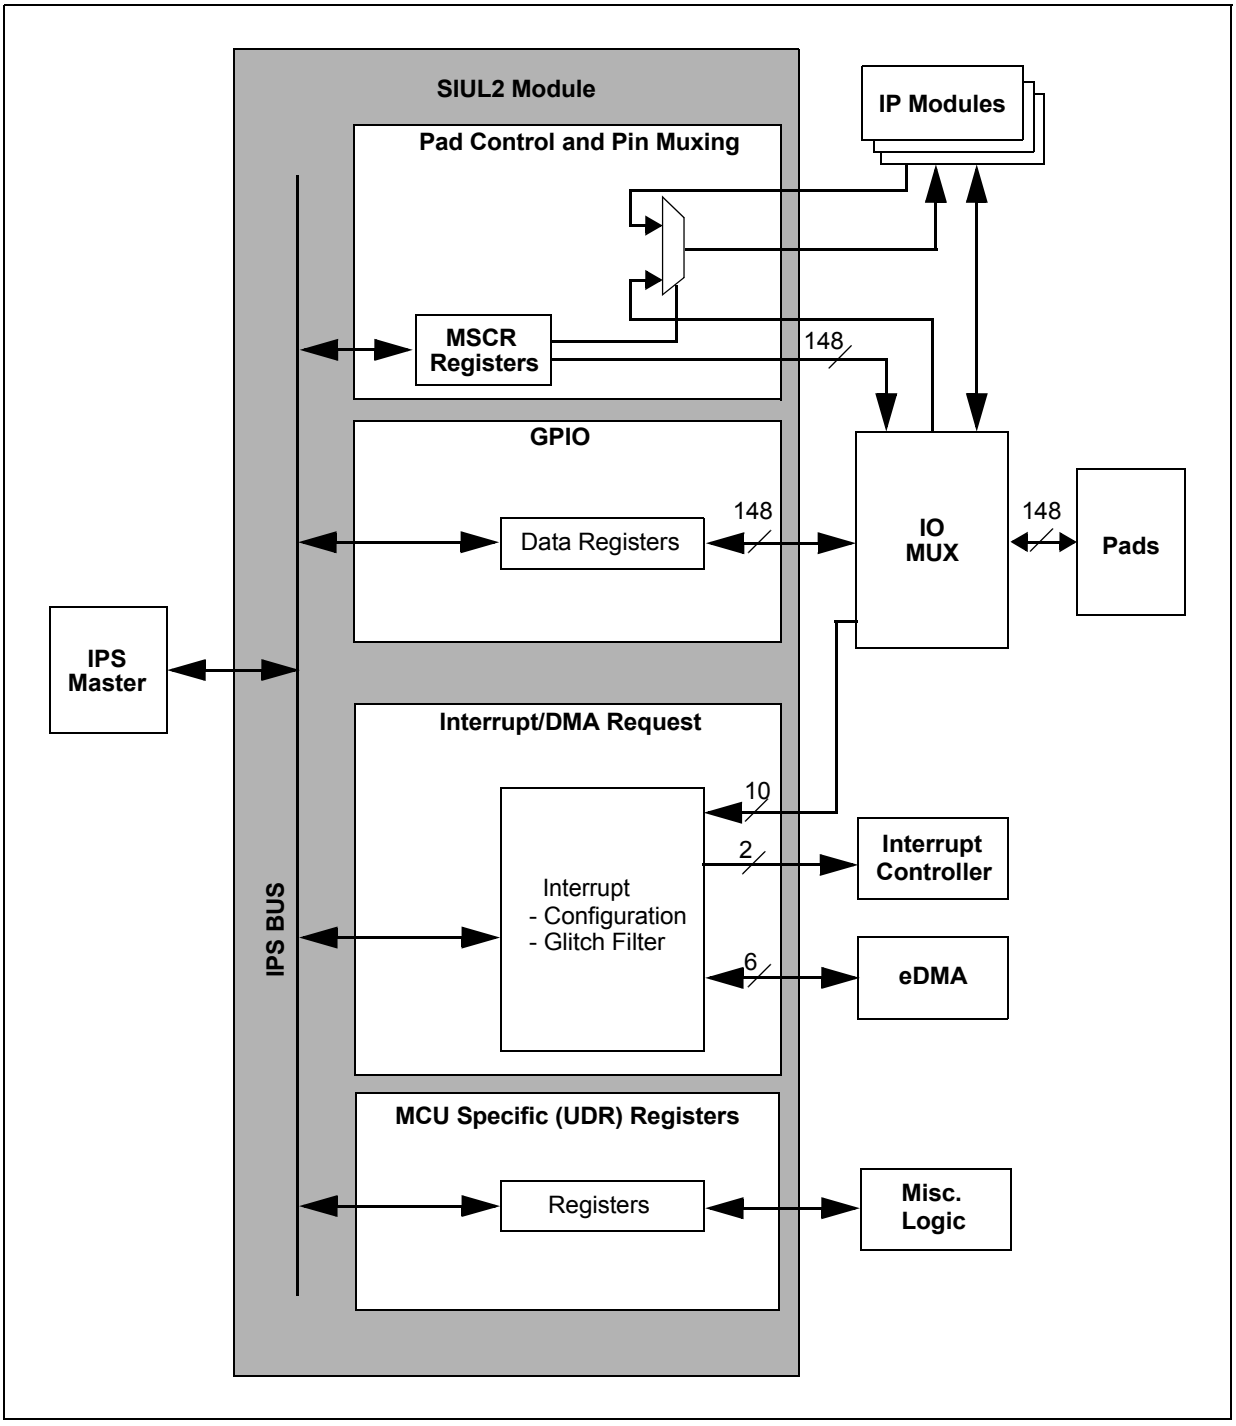
16 System Integration Unit Lite2 (SIUL2)

16.1 Introduction

16.1.1 Overview

The System Integration Unit Lite2 (SIUL2) controls the I/O ports via 16-bit bidirectional, general-purpose input and output signals. *Figure 125* shows SIUL2 and its interfaces to other system components.

The module provides dedicated general-purpose pads that can be configured as:



- Output – to write to an internal register to control the state driven on the associated output pad.
- Input – to read the state of the associated pad from an internal register.
- Input and output – to read back the pad value, which can be used to check if the written value appeared on the pad.

The different access mechanisms to the GPIO data registers aid software development, allowing port access or bit manipulation without read-modify-write operations or Power Architecture reservation access.

- Access to two 16-bit ports in one access.
- Read/Write access to a single bit.
- A 16-bit port write with a bit mask, using single 32-bit access.

The external interrupt sources can be configured at MCU level to be used with any chip pad. The interrupt sources can be configured with a digital filter to reject short glitches on the inputs. The external interrupt/DMA requests map to the EIRQ pins in the device packages.

Figure 125. SIUL2 block diagram

16.1.2 Features

The SIUL2 supports:

- 10 GPIO ports with data control.
  - Drive data to up to 16 independent I/O channels.
  - Sample data from up to 16 independent I/O channels.
- Two 16-bit registers can be read/written with one access to a 32-bit port if needed.
- External interrupt/DMA request support with:
  - 2 system interrupt vectors for 10 interrupt sources connected to EIRQ pins with independent interrupt mask.
  - 10 programmable digital glitch filters (one for each EIRQ pin).
  - 6 DMA channels [0, 1, 2, 4, 5, 8].
  - Edge detection.

The multiplexed signal configuration registers control the electrical parameters and settings of all 148 functional pads to configure the following pad features:

- Drive strength.
- Output impedance control.
- Open drain/source output enable.
- Slew rate control of JTAG pins.
- Internal weak pull control.
- Pin function assignment.
- Control of analog path switches.
- Safe mode behavior configuration.
- TTL or CMOS or Automotive input levels

16.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the following registers from accidental writes:

- SIUL2 DMA/Interrupt Request Enable Register 0 (SIUL2_DIRER0).
- SIUL2 DMA/Interrupt Request Select Register 0 (SIUL2_DIRSR0).
- SIUL2 Interrupt Rising-Edge Event Enable Register 0 (SIUL2_IREER0).
- SIUL2 Interrupt Falling-Edge Event Enable Register 0 (SIUL2_IFEER0).
- SIUL2 Interrupt Filter Enable Register 0 (SIUL2_IFER0).
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31).
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR).
- SIUL2 SoC Configuration Register 0 (SIUL2_SCR0)
- SIUL2 I/O pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_IO_0–SIUL2_MSCR_IO_511).
- SIUL2 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_MUX_512–SIUL2_MSCR_MUX_1023).

Details regarding the protected registers at specific addresses can be found in *Section 7.9.4: Register protection (REG_PROT) configuration* and *Chapter 82: Register Protection (REG_PROT)*.

16.2 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL2 module.

16.2.1 Memory map

Table 221 gives an overview of the SIUL2 registers implemented.

Table 221. SIUL2 memory map

1. 32-bit writes, 8/16/32-bit reads are allowed (only 8-bit and 16-bit writes are not supported and generate a transfer error).

Note: Reserved registers are read as '0' while write has no effect. If supported and enabled in this MCU, a transfer error is issued when trying to access completely reserved register space. Attempts to access unimplemented registers also return a transfer errors.

16.2.2 Register descriptions

This section describes in address order all the SIUL2 registers. Each description includes a standard register diagram with an associated figure number.

16.2.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register contains identification information about the device.The reset values are:

- eTQFP144: 0x5744_341x
- eLQFP176: 0x5744_441x
- 172-pin FusionQuad®: 0x5744_B41x
- 216-pin FusionQuad®: 0x5744_C41x

Note: The "x" value in the reset values above listed depends on the minor device silicon version.

16.2.2.3 SIUL2 DMA/Interrupt Status Flag Register 0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set irrespective of whether the corresponding enable bit (SIUL2_DIRER0[EIRE*x*]) is enabled. The EIF bit remains set until cleared by software or through the servicing of a DMA request. The EIF bits are cleared by writing a '1' to the bits. A write of '0' has no effect.

This register contains the interrupt flags.

24:25	Reserved
26:31 EIF5 EIF4 EIF3 EIF2 EIF1 EIF0	External Interrupt Status Flag x—This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

16.2.2.4 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding

DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

Table 225. SIUL2_DIRER0 field descriptions

Field	Description
0:22	Reserved
23 EIRE8	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR
24:25	Reserved
26:31 EIRE5 EIRE4 EIRE3 EIRE2 EIRE1 EIRE0	External Interrupt or DMA Request Enable x 0 Interrupt or DMA requests from the corresponding EIF[x] bit are disabled 1 Set EIF[x] bit causes either a DMA or an interrupt request depending on SIUL2_DIRSR

16.2.2.5 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

Figure 134. SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0)

Table 230. SIUL2_IFMCR0 field descriptions

Field	Description
28:31 MAXCNTx	Maximum Interrupt Filter Counter setting Filter Period = TCK*MAXCNTx+ n*TCK where (n = –1 to 3) MAXCNTx can be 0 to 15 (for MAXCNT < 3 filter behaves as all PASS filter) TCK Prescaled Filter Clock Period, which is IRC clock prescaled to IFCP value specified in SIUL2_IFCPR T(IRC) Basic Filter Clock Period: 62.5 ns (F = 16 MHz) Also note that Filter delay is 2 system clock cycles more than Filter period. In general, Filter Period and Filter delay are not integer multiple of TCK because input to Filter is asynchronous whereas output is synchronous with respect to the TCK. T(DELAY) = (1 to 5)*TCK + MAXCOUNT * TCK. The SW is to expect the worst filter delay value.

16.2.2.10 SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)

This register is used to configure a clock prescaler which is used to select the clock for all digital filters. Prescaler is applied to the input clock to the SIUL2, which is the system PBRIDGE clock counters in the SIUL2. See *Section 26.6: Peripheral clocks*.

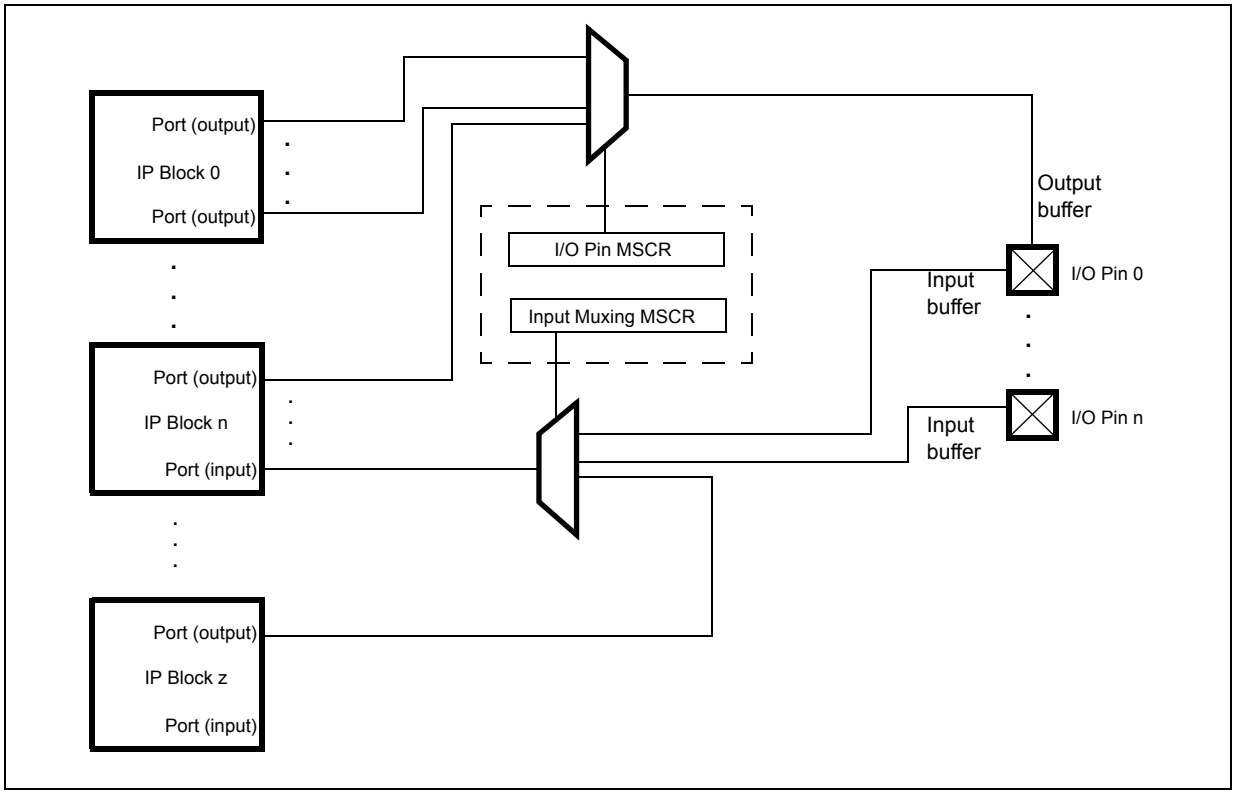
Figure 136. SIUL2 SoC Configuration Register0 (SIUL2_SCR0)

Table 232. SIUL2_SCR0 field descriptions

Field	Description
8 ESR0_ASSERT	ESR0_ASSERT is an active high signal enabling to force ESR0 as a strong pull-down. 0 ESR0 status is controlled by RGM. 1 ESR0 status is forced low if ESR0 is configured as output only (associated DCF record DCF.UTEST_MISCELLANEOUS[ESR0_Gate] is low).

16.2.2.12 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

The MSCRs control the I/O pin function and electrical properties for each pin on the device and are used to select the input signal for IP blocks with multiple input sources. There is a dedicated MSCR for each I/O pin on the device. Each MSCR is independent, except in the



case of an LVDS configuration, where two MSCRs must be configured together in this mode.

The MSCRs are divided into two sets:

- I/O pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_0–SIUL2_MSCR_511)
- Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_512–SIUL2_MSCR_1023)

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in *Figure 137*.

Figure 137. MSCR I/O pin and IP block port connectivity

16.2.2.12.1 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_0–SIUL2_MSCR_511)

The I/O pin MSCRs are defined in *Figure 138*. These registers select the output function on the associated I/O pin. The I/O MSCRs control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, safe-mode operation, and analog input enable of the associated I/O pin.

Note that when an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

Field	Description
0:1	Reserved
2:3 OERC	Output Edge Rate Control—When a pin is used as input, the destination (output of MUX) is a module port. Specifies the output impedance, drive strength, and slew rate of the associated pin. Refer to output Impedance columns in the I/O Signal Description table for the applicable edge rates for each I/O pin on the device. The I/O Signal Description and Input Multiplexing tables are contained in a Microsoft Excel® workbook file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description table tab. See the device data sheet for both the electrical characteristics and impedance figures of the weak, medium, strong, and very strong pad types. **Note:** OERC[2] programming is required for forward compatibility. 00 Weak 01 Medium 10 Strong 11 Very Strong
4	Reserved
5:7 ODC	Output Drive Control—Used only when the associated destination is a chip pin. Specifies the type of output drive control for the associated pin. 000 Output buffer disabled 001 Open-drain 010 Push-pull 011 Open-source 100 Microsecond Channel LVDS 101 LFAST LVDS 110 Reserved 111 Reserved

Table 233. SIUL2_MSCR_0–SIUL2_MSCR_511 field description(1)(Continued)

Field	Description
8 SMC	Safe Mode Control—Used only when the associated destination is a chip pin. Specifies whether the chip disables the pin's output buffer when the FCCU state machine enters the FAULT state. 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control—Enables the pin's analog-input-path switch if the associated pin has an analog input function. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10:11 ILS	Input Level Selection—When a pin is used as input, the destination (output of MUX) is a module port. Specifies the logic family for the associated pin, which determines its logic switching levels. See the device data sheet for the electrical characteristics of the I/O pad input buffer types. 00 Automotive 01 TTL 10 LVDS 11 CMOS **Note:** The input level is unknown during the ILS transition from a configuration to another one. Before modifying ILS, IBE has to be disabled (IBE='0').
12 IBE	Input Buffer Enable—When a pin is used as input, the destination (output of MUX) is a module port. Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis for CMOS configuration — this field is relevant only when ILS field is configured for CMOS (ILS="11"). When a pin is used as input, the destination (output of MUX) is a module port. Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable—When a pin is used as input, the destination (output of MUX) is a module port. Enables the associated pin's weak pulldown resistor. It is OK for both WPDE and WPUE to be enabled. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable—When a pin is used as input, the destination (output of MUX) is a module port. Enables the associated pin's weak pullup resistor. It is OK for both WPDE and WPUE to be enabled. 0 Disabled 1 Enabled
16 INV	Invert—The output selected by the corresponding MSCR SSS field can be inverted before it is driven on the I/O pin with the INV bit. **Note:** Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection. 0 The output selected by the SSS field is not inverted before being driven to the pin 1 The output selected by the SSS field is inverted before being driven to the pin

Table 233. SIUL2_MSCR_0–SIUL2_MSCR_511 field description[1](Continued)

Field	Description
17:23	Reserved
24:31 SSS	Source Signal Select—Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. See *Section 16.2.2.12.3: Chip-pin MSCR assignments and related information* and *Section 16.2.2.12.4: Module-port MSCR assignments and SSS values*.

1. The SPC574Kx I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® workbook file attached to this document.Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

All bits and fields in the I/O MSCRs are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV, and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The MSCR reset state given in *Figure 138* applies to all GPIO pins on the devices, which defaults to input/pull-up enabled. The exceptions to this are documented in *Table 234*. The OERC, ODC, HYS, SSS, WPDE, and WPUE bits have exceptions to the default MSCR reset value.

Table 234. I/O MSCR reset state exceptions

1. When JTAG is enabled (JCOMP asserted) during reset, the TDO pin is pulled up during reset, but hi-z after reset. If JTAG is disabled, the TDO pin defaults to input/pull-up during and after reset.

16.2.2.12.2 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_512–SIUL2_MSCR_1023)

The multiplexed input selection MSCR definition is given in *Figure 139*. These registers select the input source for IP blocks on the device that have inputs from multiple sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

Figure 142. SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO0_1)

Table 238. SIUL2_PGPDO0_1 field description

Field	Description
0:15 PPDO[x][0:15]	Parallel Pad Data Out—Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: PPDO[x][y] = PDO[(x*16)+y]

Note: The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

PPDO[0][0] = PDO[0]

PPDO[2][0] = PDO[32]

PPDO[31][15] = PDO[511]

16.2.2.16 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI0_1–SIUL2_PGPDI30_31)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, depending on the individual pad configuration.

PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read while GPDI registers are used to read the value on a specific pin with a byte read.

Address:0x1740–0x177C Access: User read-only

Table 239. SIUL2_PGPDI0_1 field description

Field	Description
0:15 PPDI[x]	Parallel Pad Data In —Reads the current pad value. Accesses to this register location are coherent with accesses to the bit-wise GPIO Pad Data Input Registers (SIUL2_GPDI). The x and y bit index define which PPDI register bit is equivalent to which PDI register bit according to the following equation: PPDI[x][y] = PDI[(x*16)+y]

16.2.2.17 SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO0–SIUL2_MPGPDO31)

This register can be used to selectively modify the pad values associated to PPDO[x][0:15]. The MPGPDO[x] register may only be accessed with 32-bit writes. 8-bit or 16-bit writes will not modify any bits in the register and cause a transfer error response by the module. Read access will return ‘0’.

0:15 MASK[x] [0:15]	Mask Field—Each bit corresponds to one data bit in the MPPDO[x] register at the same bit location. 0 The associated bit value in the MPPDO[x] field is ignored 1 The associated bit value in the MPPDO[x] field is written
16:31 MPPDO[x] [0:15]	Masked Parallel Pad Data Out—Write the data register that stores the value to be driven on the pad in output mode. Access to this regi ster location are coherent with access to the bit-wise GPIO Pad Data Output Registers (PDO). The x and bit index define which MPPDO register bit is equivalent to which PDO register bit according to the following equation: MPPDO[x][y] = PDO[(x*16)+y]

16.3 Functional description

16.3.1 General

This section provides a complete functional description of the SIUL2.

16.3.2 Pad control

The SIUL2 is capable of controlling the electrical characteristic of 148 pads on this device. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2. Not all of these features are supported on all pads as this depends on the specific application needs and the pads implemented on the device.

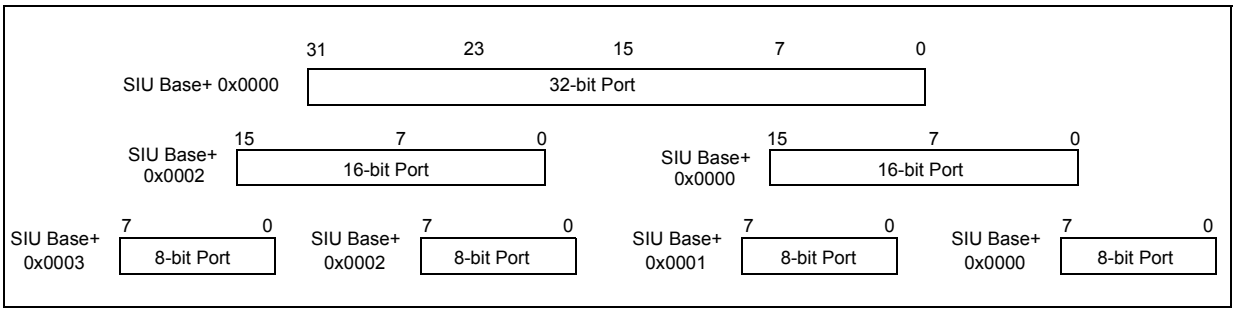
The required controls are:

- Drive strength control to improve EMC performance. Up to 4 different drive strength levels can be supported.
- Internal weak pull capability to offer flexibility in the device configuration and the elimination of external hardware in some cases. The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Control of analog path switches
- Safe Mode behavior configuration
- Open drain/source enable to support different pads muxed (e.g. mux IIC, with non open drain pads)
- Pin Function Assignment to define which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed by the MCU, but can be configured individually. It is possible to select special pull settings or peripheral pad ownership per design.

The user software can configure each pad independently on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and provides the necessary flexibility for the individual operation of the pads. This is achieved by grouping all of the functions listed above into a single register for each pad on the device, allowing each pad to be configured with a single write to one register which in turn simplifies duplication of software for each pad with indexed changes for each pad.

16.3.3 General purpose input or output pads (GPIO)



The SIUL2 can configure each pad as either a General Purpose Input Output pad (GPIO) or as one or more alternate functions (input or output) determined by the peripheral using the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 203 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in *Figure 145*, all port accesses are identical with each read or write being performed only at a different location to access a different port width.

Figure 145. Data Port example arrangement showing configuration for different port width accesses

The registers are arranged to support this range of port widths without having to split reads or writes into multiple accesses.

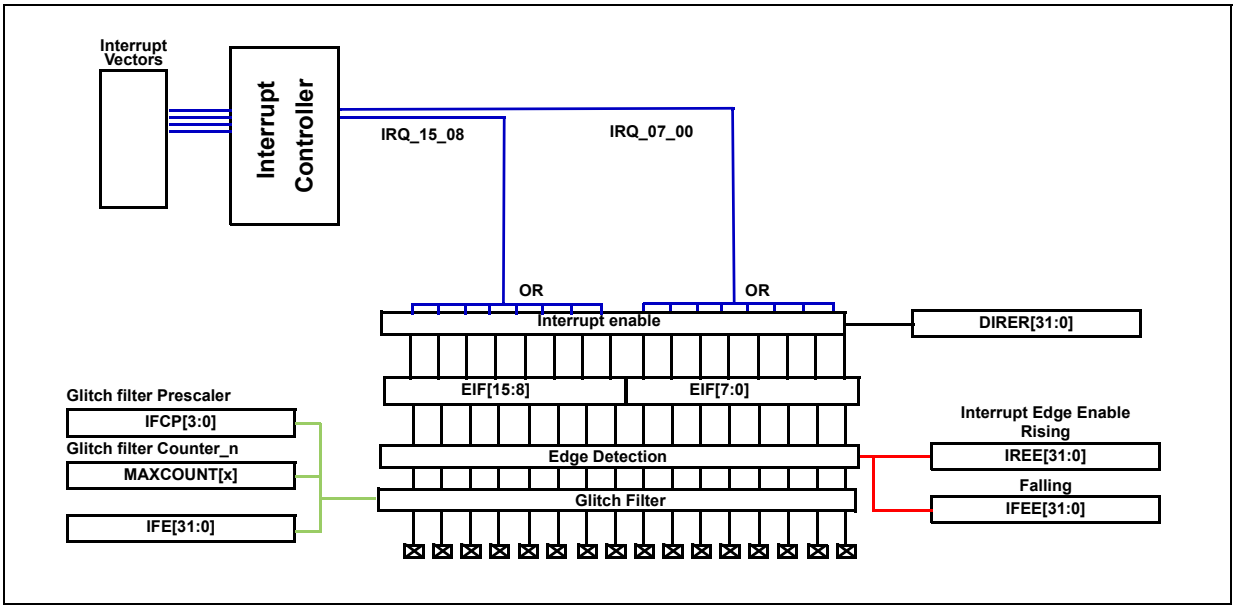
The SIUL2 has separate data input and data output registers for all pads, allowing direct reads of a pad input or output value. This enables validation ofwhat is present on the pad rather than simply confirming the value written to the data register via the data input registers.

Data output registers support both read and write operations to be performed while data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflects the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non GPIO), this write is not reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note: If bi-directional operation impacts performance (e.g. ADC accuracy) or is not required for a specific pad function, limit the functionality of some pads to "Input Only".



16.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports external interrupts which can be allocated to any pad necessary at the MCU level. This allocation is fixed per MCU.

The SIUL2 supports two interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support ten external interrupt sources from the device pads.

Refer to *Figure 146* for an overview of the external interrupt implementation.

Figure 146. External interrupt pad diagram

All the external interrupt pads within a single group (maximum 8 pads) have equal priority. The user software must search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU-specific number of external interrupt lines can have digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work, otherwise external interrupts are effectively disabled when the glitch filter is enabled on an interrupt line.

16.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent this, the user must do the following:

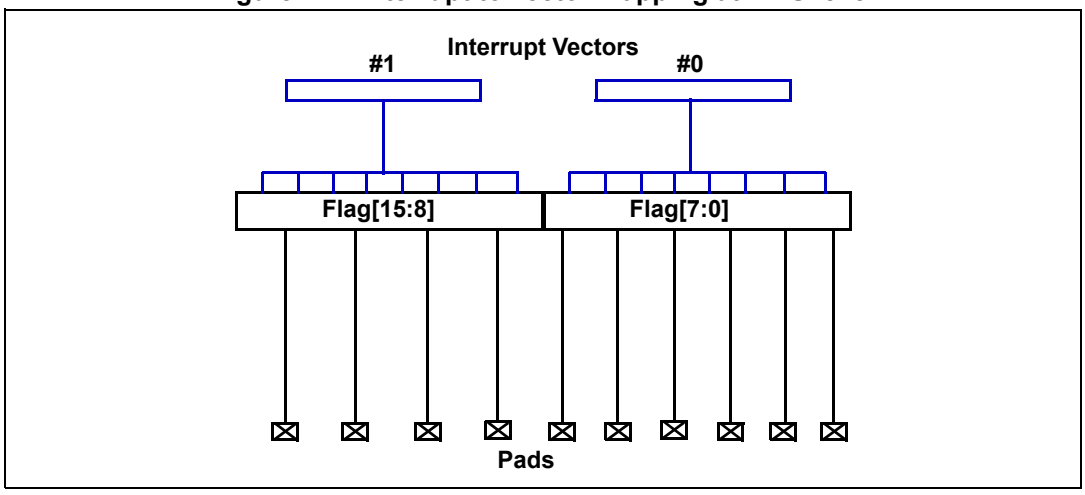
- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEn bits in IREER0 and the appropriate IFEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
  - Clear the ODC bits to do disable output.
  - Set the IBE bit to enable the pin's input buffer.
  - If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note: MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

Note: External interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
  - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
  - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR.
  - Enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.
- Write to EIFn bits in DISR0 to as desired to clear any flags.
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

16.3.4.2 External interrupt management



Each interrupt can be enabled or disabled independently. This can be performed using a single rolled-up register (SIUL2_DIRER0, *Figure 129*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges active. Setting both edge events to disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

The SPC574Kx device supports two SIUL2 interrupt vectors, aggregating the external interrupt sources shown in *Figure 147*.

Figure 147. Interrupt to vector mapping at MCU level

16.3.4.3 External interrupt request

The EIRQ input pin sources for interrupt or DMA requests are mapped to two interrupt requests given in *Table 241*.

Table 241. Interrupt source mapping to SIUL2 interrupt request output

Interrupt requests	EIRQ pins
0	EIRQ0 | EIRQ1 | EIRQ2 | EIRQ3 | EIRQ4 | EIRQ5
1	EIRQ8 | EIRQ9 | EIRQ10 | EIRQ11

16.3.4.4 Interrupt Vector

The EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note: See Section 7.3.7: Interrupt Controller (INTC) configuration for Interrupt Vector table.

16.3.4.5 DMA requests

The EIRQ pins on the device map to DMA request channels in the eDMA controller.

Note: See Section 7.3.9: DMAMUX configuration for DMA request mapping table.

17 Crossbar Switch (XBAR)

17.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

17.1.1 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
  - Concurrent accesses from different masters to different slaves
  - Configurable slave arbitration attributes on a slave-by-slave basis
- 64-bit datapath width
- Support for 8-, 16-, 32-, and 64-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers including a 4-beat, 64-bit burst for cache line accesses
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

17.1.2 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require two bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the Chip Configuration details for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

17.1.2.1 XBAR Priority Registers Slave (XBAR_PRS*n*)

The priority registers (XBAR_PRS*n*) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. The XBAR_PRS*n* register is read-only; attempts to write to it have no effect on it and result in a bus-error response to the master initiating the write.

See *Section 7.3.3: Crossbar switch configuration* for XBAR_PRS*n* priority values.

Offset: 0x0000 + n*0x100 (n = 0 to 7) Access: Supervisor read-only

Figure 149. XBAR Control Register (XBAR_CRS*n*)

Table 244. XBAR_CRS*n* field descriptions

Field	Description
0 RO	Read only Forces both of the slave port's registers to be read-only. After set, only a hardware reset clears it. 0 The slave port's registers are writable. 1 The slave port's registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
1 HRP	Halt Request Priority Determines if a request to halt the crossbar is treated as the highest priority request, or the lowest priority request. 0 The halt request has the highest priority for arbitration on this slave port. 1 The halt request has the lowest initial priority for arbitration on this slave port.
2–7 Reserved	This read-only bitfield is reserved and always has the value zero.

Table 244. XBAR_CRS*n* field descriptions(Continued)

Field	Description
8–15 HPEx	High Priority Enable Determines if Master x is able to temporarily elevate it's request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master x are ignored and are treated the same as regular requests. 1 High Priority requests from Master x can temporarily elevate the priority level of the master's request to the slave.
16–21 Reserved	This read-only bitfield is reserved and always has the value zero.
22–23 ARB	Arbitration mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved
24–25 Reserved	This read-only bitfield is reserved and always has the value zero.
26–27 PCTL	Parking control Determines the slave port's parking control. The low-power park feature results in overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11 Reserved
28 Reserved	This read-only bit is reserved and always has the value zero.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. **Note:** Only select master ports that are actually present on the device. If not, undefined behavior may occur. 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

17.2 Functional description

This section provides the functional details of the crossbar switch.

17.2.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
  - An outstanding request to one slave port that has a long response time and
  - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes. When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being IDLEd by the crossbar, it can park the slave port on the master port indicated by the XBAR_CRS*n*[PARK]. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using XBAR_CRS*n*[PCTL].

17.2.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

17.2.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

17.2.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the XBAR_PRS*n* (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer or a locked transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master's priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

17.2.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

17.2.3.3 Priority assignment

Each master port needs to be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (XBAR_PRS*n*), the crossbar switch responds with a bus error and the registers are not updated.

17.3 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

18 Crossbar Integrity Checker (XBIC)

18.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comapring the consistance of the signals during the AHB dataphase.There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core's decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

18.2 Features

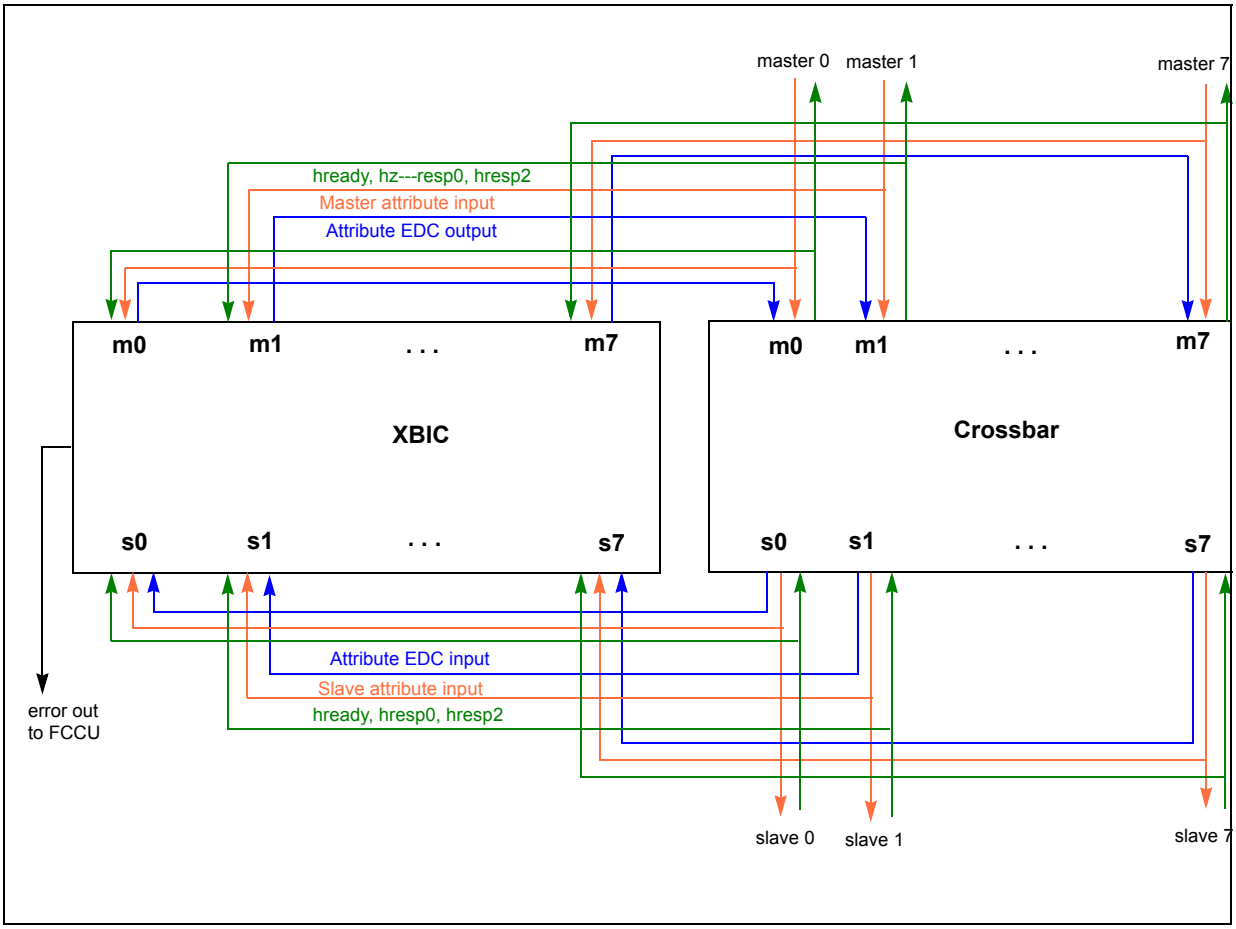
The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
  - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
  - hready, hresp0, and hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
  - Programmable master and slave port specifiers
  - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
  - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable integrity feedback check enable on a per-master-port basis

18.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown in *Figure 150* and *Figure 151*.

Figure 150. XBIC system block diagram



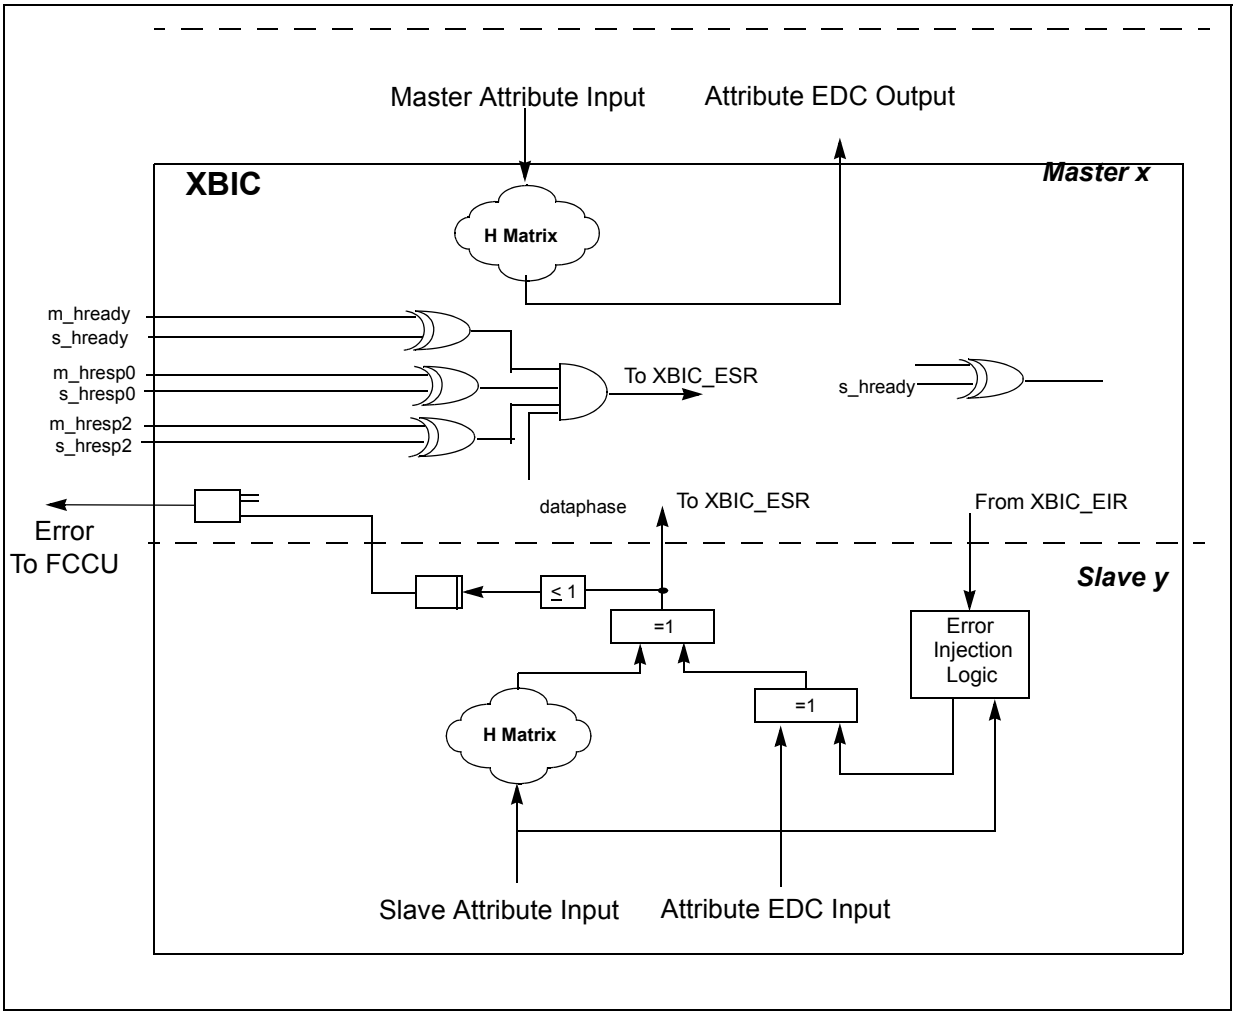


Figure 151. XBIC block diagram

18.4 External signal description

The XBIC has no external interface signals.

18.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references with a different access size, to an undefined (reserved) address, with a non-supported access type (a write to a read-only register), or in user mode generate an error termination.

18.5.1 Memory map

The XBIC memory map is shown in *Table 245*.

Table 245. XBIC memory map

Address offset	Register name	Register description	Size (bits)	Access
0x0000	XBIC_MCR	XBIC Module Control Register	32	R/W
0x0004	XBIC_EIR	XBIC Error Injection Register	32	R/W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 152. XBIC Module Control Register (XBIC_MCR)

Table 246. XBIC_MCR field descriptions

Field	Description
SEn	Slave Port Enable for EDC error detect. 0 Attribute integrity checking disabled for slave port n. 1 Attribute integrity checking enabled for slave port n.
MEn	Master Port Enable for slave driven signal safety check 0 Attribute integrity checking disabled for master port n. 1Attribute integrity checking enabled for master port n.

18.5.2.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing

the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Offset 0x004

Access: Supervisor Read/Write

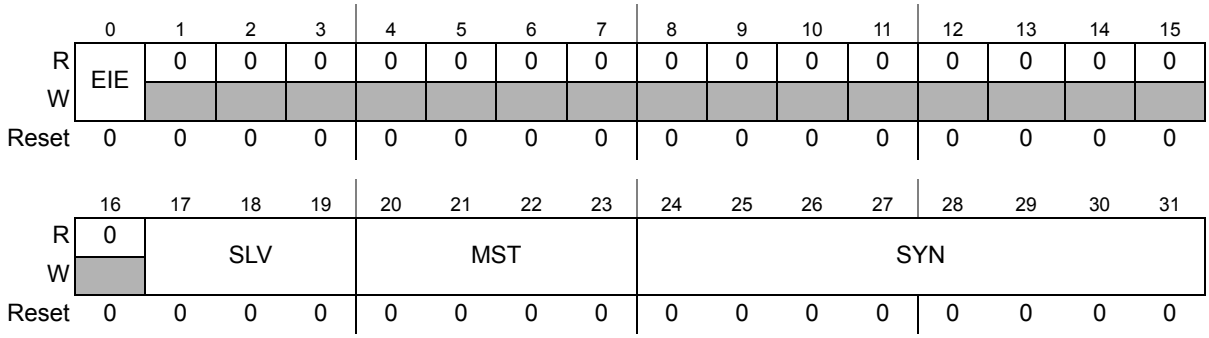

Figure 153. XBIC Error Injection Register (XBIC_EIR)

Table 247. XBIC_EIR field descriptions

Field	Description
EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

18.5.2.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the *last* transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are catured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

Offset 0x008 Access: Supervisor Read

Figure 154. XBIC Error Status Register (XBIC_ESR)

Table 248. XBIC_ESR field descriptions

Field	Description
VLD	Error Status Valid. 0 No error detected, other fields of the ESR and EAR are not valid. 1 Error detected, all fields of the ESR and EAR are valid.
DPSEn	Data phase slave port error 0) No error on slave port n 1) Data phase error on slave port n
DPMEn	Data phase master port error 0) No error on master port n 1) Data phase error on master port n
SLV	Slave Port. The slave port targeted by the last transfer with an error.
MST	Master ID. The master ID value of the last transfer with an error.
SYN	Syndrome. The syndrome calculated for the last transfer with an error. For single bit errors the signal in error can be determined, see *Table 250*.

18.5.2.4 XBIC Error Address Register (XBIC_EAR)

The Error Address Register (XBIC_EAR) contains the address of the *last* transfer in which an attribute integrity check error was detected on an enabled slave port. This register is only cleared on reset.

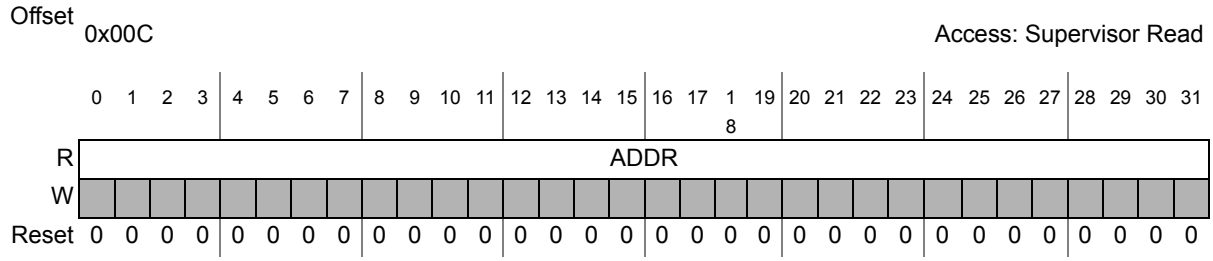

Figure 155. Error Address Register (XBIC_EAR)

Table 249. XBIC_EAR Register field descriptions

Field	Description
ADDR	The address of the last transfer with an error.

18.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified *without* compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

Forwarding errors (master to slave) are detected during the AHB address phase. When a forwarding error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in *Table 250*. Any other syndrome indicates a multi-bit error.

XBIC also detects backward signal (slave to master) errors during AHB data phase. For the three slave driven signals (hready, hresp0, and hresp2), XBIC performs the comparison between the input of the slave port and output of the master port during the AHB data phase. When a mismatch occurs, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE0-7, and the current master port will be registered in XBIC_ESR bit field DSME0-7.

19 Peripheral Bridge

19.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space. (Not all peripheral slots may be used. See *Chapter 7: Device Configuration* or *Chapter 5: Memory map* for details on slot assignment.) The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

19.1.1 Features

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality

19.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

Note: FlexRay access to peripherals via the peripheral bridge is not supported.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map. Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots.
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots.

All other 64-bit accesses result in an error response.

19.2.1 Master Privilege Registers (AIPS_MPRA & AIPS_MPRB)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. See *Chapter 7: Device Configuration* for details about the master assignments to these registers.

1 MTR	Master trusted for read Determines whether the master is trusted for read accesses. 0 This master is not trusted for read accesses. 1 This master is trusted for read accesses.
2 MTW	Master trusted for writes Determines whether the master is trusted for write accesses. 0 This master is not trusted for write accesses. 1 This master is trusted for write accesses.
3 MPL	Master privilege level Determines how the privilege level of the master is determined. 0 Accesses from this master are forced to user mode. 1 Accesses from this master are not forced to user mode.

19.2.2 Peripheral Access Control Registers (AIPS_PACR*x*)

Each of the on-platform peripherals has a four-bit PACR*n* field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACR*x* register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. See *Chapter 5: Memory map* for the assignments for your particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes, and writes are ignored.

Table 254 shows the top-level structure of the PACRs.

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT*n*[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

19.2.3 Off-Platform Peripheral Access Control Registers (AIPS_OPACR*x*)

Each of the off-platform peripherals has a four-bit OPACR*n* field which defines the access levels supported by the given module. Eight OPACRs are grouped together to form a 32-bit OPACR*x* register.

The peripheral assignments to each OPACR field are defined by the memory map slot to which the peripherals are assigned. See *Chapter 5: Memory map* for the assignments for your particular device. If a peripheral is absent, the corresponding OPACR is not implemented. Reads to the location return zeroes and writes are ignored.

Table 256 shows the top-level structure of the OPACR registers.

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT*n*[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

19.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

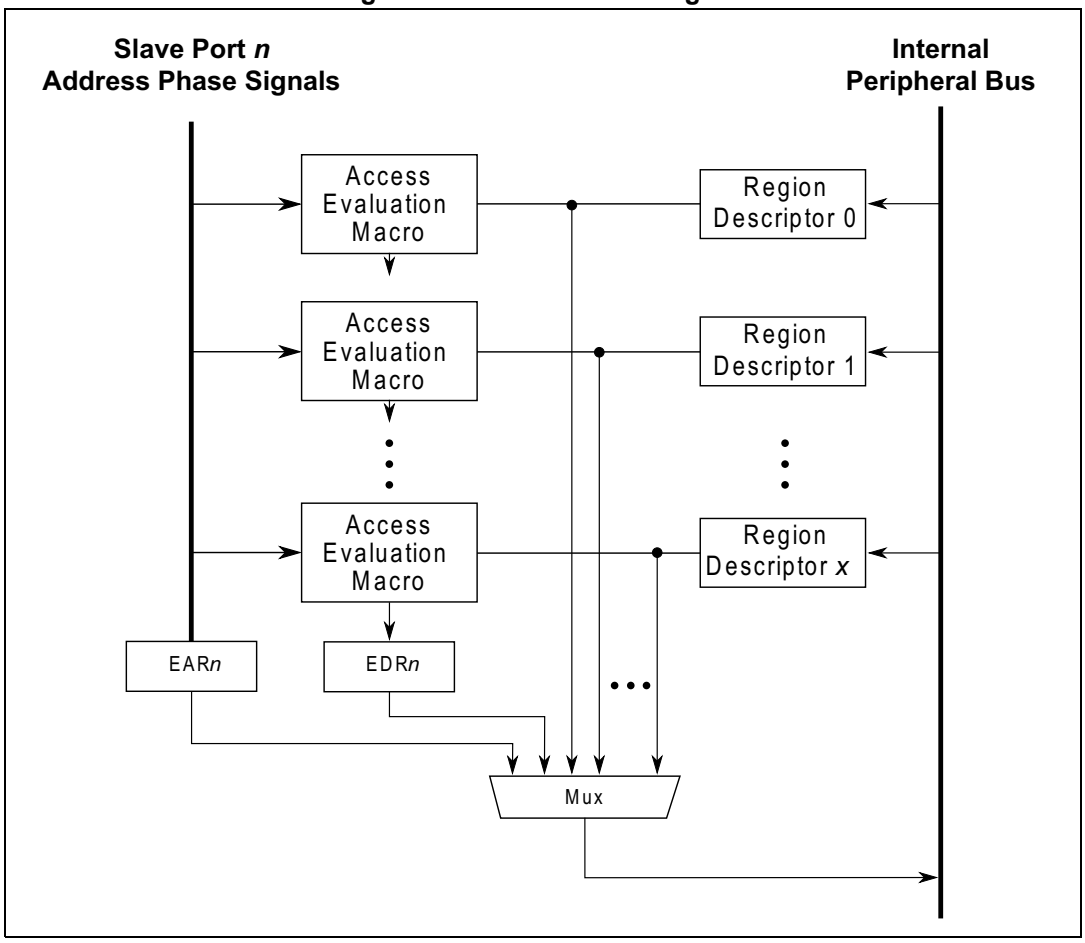
19.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

20 System Memory Protection Unit (SMPU)

20.1 Overview



The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

20.2 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, see *Section 20.5.1: Access evaluation macro*.

Figure 163. SMPU block diagram

20.3 Features

The SMPU feature set includes:

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24).
  - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
    - Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
  - Read/write access control permissions defined in region descriptor
  - Cache-inhibit attribute indicator per region descriptor
  - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
  - Priority given to granting permission over denying access for overlapping region descriptors
- Supports as many as eight crossbar slave ports
- Detects access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the

reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.

- Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (see the documentation related to the core for details).
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information
- Global SMPU enable/disable control bit

20.4 Memory map and register definition

20.4.1 Memory map

The programming model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

The programming model can be accessed only in supervisor mode.

Note: See the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to eight region descriptors.

Table 259. SMPU*x*_CESR0 field descriptions

Field	Description
0–15 MERR	Master *n* error, where the bus master number matches the bit number Indicates a captured error in EAR*n* and EDR*n*. A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing ‘1’ to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master *n*. 1 An error has occurred for bus master *n*.
16 Reserved	This read-only bit is reserved and always has the value ‘1’.
17–27 Reserved	This read-only bitfield is reserved and always has the value ‘0’.
28–30 HRL	Hardware revision level Specifies the SMPU’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled

20.4.2.2 Control/Error Status Register 1 (SMPUx_CESR1)

Address SMPU0_CESR1 – FC01_0000h base + 4h offset = FC01_0004h
SMPU1_CESR1 – FC01_4000h base + 4h offset = FC01_4004h

Figure 165. Control/Error Status Register 1 (SMPU*x*_CESR1)

Table 260. SMPU*x*_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master *n* error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master *n* has occurred before the previous error was processed. The details of the first error are recorded in the EAR*n* and EDR*n* registers, and no information on subsequent errors is recorded until the associated CESR0[MERR] flag is cleared. 0 No error overrun condition has been detected for bus master *n*. 1 An error overrun condition has been detected for bus master *n*.
16 Reserved	This read-only bit is reserved and always has the value ‘1’.
17–27 Reserved	This read-only bitfield is reserved and always has the value ‘0’.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

20.4.2.3 Error Address Register, Bus Master *n* (SMPUx_EAR*n*)

When the SMPU detects an access error on bus master *n*, the 32-bit reference address is captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Additional information about the faulting access is captured in the corresponding EDR*n* at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the original error is processed.

Address SMPU0_EAR*n* – FC01_0100h + (8d × n), where *n* = 0d to 15d
SMPU1_EAR*n* – FC01_4100h + (8d × n), where *n* = 0d to 15d

Table 261. SMPU*x*_EARn field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error

20.4.2.4 Error Detail Register, Bus Master *n* (SMPUx_EDR*n*)

When the SMPU detects an access error associated with bus master *n*, 32 bits of error detail are captured in this read-only register and the corresponding bit in CESR0[MERR] is set. Information on the faulting address is captured in the corresponding EAR*n* register at the same time.

Note: The corresponding EARn and EDRn registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the CESR1[MEOVR] field until the original error is processed.

Address SMPU0_EDR*n* – FC01_0104h + (8d × n), where *n* = 0d to 15d
SMPU1_EDR*n* – FC01_4104h + (8d × n), where *n* = 0d to 15d

Figure 167. Error Detail Register, Bus Master *n* (SMPU*x*_EDR*n*)

Table 262. SMPU*x*_EDR*n* field descriptions

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDR*n* contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This read-only bit is reserved and always has the value ‘1’.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

20.4.2.5 Region Descriptor *n*, Word 0 (SMPUx_RGD*n*_WORD0)

Address : SMPU0_RGD*n*_WORD0 – FC01_0400h + (16 × *n*), where *n* = 0 to 11

Table 264. SMPU*x*_RGD*n*_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. **Note:** The SMPU does not verify that ENDADDR ≥ SRTADDR.

20.4.2.7 Region Descriptor *n*, Word 2 Format 0 (SMPUx_RGD_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3[FMT] field.

Note: RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Address: SMPU0_RGD*n*_WORD2_FMT0 – FC01_0408h + (16 × *n*), where *n* = 0 to 11

20.4.2.8 Region Descriptor *n*, Word 2 Format 1 (SMPU_RGD*n*_WORD2_FMT1)

RGD_WORD2 has two formats as determined by the RGD_WORD3[FMT] field.

Note: RGD_WORD2_FMT1 applies when RGD_WORD3[FMT] = 1.

Note: A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

RGD_WORD2_FMT1 defines pointers for each master to select access control flags contained in Word3. For these fields, the bus master number refers to the *logical* bus master number.

The bit settings are as follows:

- 00: RGD*n* cannot be accessed by this master, that is, SR = SW = SX = UR = UW = UX = 0 (where “S” is for supervisor permissions and “U” is for user permissions).
- 01: RGD*n* access flags are defined in RGD*n*_WORD3[ACCSET1].
- 10: RGD*n* access flags are defined in RGD*n*_WORD3[ACCSET2].
- 11: RGD*n* access flags are defined in RGD*n*_WORD3[ACCSET3].

Writes to this word clear the region descriptor’s valid bit.

Address: SMPU0_RGD*n*_WORD2_FMT1 – FC01_0408h + (16 × *n*), where *n* = 0 to 11

20.4.2.9 Region Descriptor *n*, Word 3 (SMPUx_RGD*n*_WORD3)

The final word of the SMPU region descriptor contains the valid bit, the format select (FMT), three sets of access permissions flags used when FMT = 1, plus other configuration bits.

For access permissions used when FMT = 1, there are three flags {read, write, execute} for each operating mode (supervisor, user). These flags follow the traditional definition:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.
- Execute (x) permission refers to the ability to read the referenced memory address using an instruction fetch.

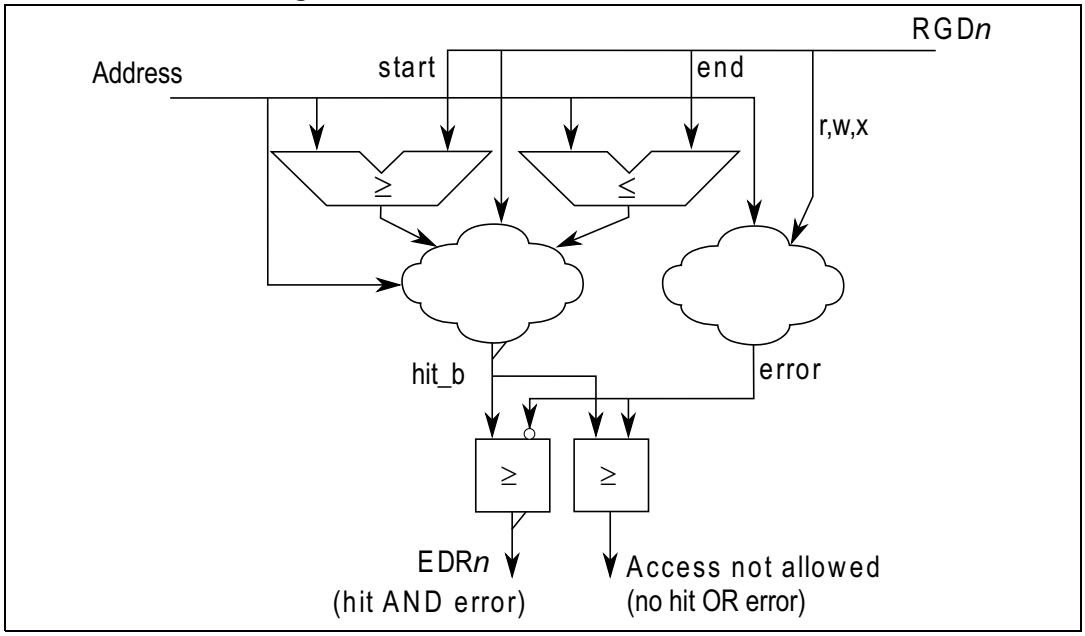
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. **Note:** A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies. 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. **Note:** Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect. 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This read-only bit is reserved and always has the value ‘0’.

Table 267. SMPU*x*_RGD*n*_WORD3 field descriptions(Continued)

Field	Description
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. **Note:** An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size. 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGD*n*_WORD0–2 clears this bit. 0 Region descriptor is invalid 1 Region descriptor is valid



20.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

20.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in *Figure 173*, the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGD*n*), then performs two major functions: region hit determination and detection of an access protection violation. *Figure 173* shows a functional block diagram.

Figure 173. SMPU access evaluation macro

20.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
      (addr[0:31] <= RGDn_Word1[ENDADDR])) &
      RGDn_Word3[VLD]
```

where addr is the current reference address, RGDn_Word0[SRTADDR] and RGDn_Word1[ENDADDR] are the start and end addresses, and RGDn_Word3[VLD] is the valid bit.

Note: The SMPU does not verify that ENDADDR ≥ SRTADDR.

Note: Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

20.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in *Table 268*.

Table 268. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

20.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see *Section 20.7: Application information*.

20.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGD*n*_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD] = 0). Next, load the appropriate region descriptors (RGD*n*), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

20.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGD*n*, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Modifying a region descriptor—Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor—Clearing RGD*n*_Word3[VLD] deletes an existing region descriptor.
- Accessing the SMPU—Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EAR*n* and EDR*n* capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}R*n*. CESR0[MERR] signals. The error registers contain the captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters: the two processors (CP0, CP1) and two DMA engines (DMA1, a traditional data movement engine transferring data between RAM and peripherals, and DMA2, a second engine transferring data to/from the RAM only). Consider the following region descriptor assignments:

Table 269. Overlapping region descriptor example

Region description	RGDn	CP0	CP1	DMA1	DMA2	System memory map space
CP0 code	0	rwx	r--	—	—	Flash
CP1 code	1	r--	rwx	—	—	
CP0 data & stack	2	rw-	—	—	—	RAM
CP0 → CP1 shared data	2 3	r--	r--	—	—	
CP1 → CP0 shared data	4 3					
CP1 data & stack	4	—	rw-	—	—	
Shared DMA data	5	rw-	rw-	rw	rw	
SMPU	6	rw-	rw-	—	—	Peripheral space
Peripherals	7	rw-	rw-	rw	—	

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map (flash, RAM, and peripheral space). Each region indicates the specific permissions for each of the four bus masters, and this definition provides an assigned set of shared, private, and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1, and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the peripheral bus is partitioned into two regions: one containing the SMPU's programming model accessible only to the two processor cores and the remaining peripheral region accessible to both processors and the traditional DMA1 master.

This simple example is intended to show one possible application of the capabilities of the SMPU in a typical system.

21 Intelligent AHB Gasket (IAHBG)

21.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

Table 270 lists the available operation modes.

Table 270. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

21.2 Timing diagrams

The following are a sample of timing diagrams assuming a zero wait state response. The 0:0 flowthru mode is not shown.

21.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. There are different read slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Figure 174. Read, pending read (1:1 timing mode)

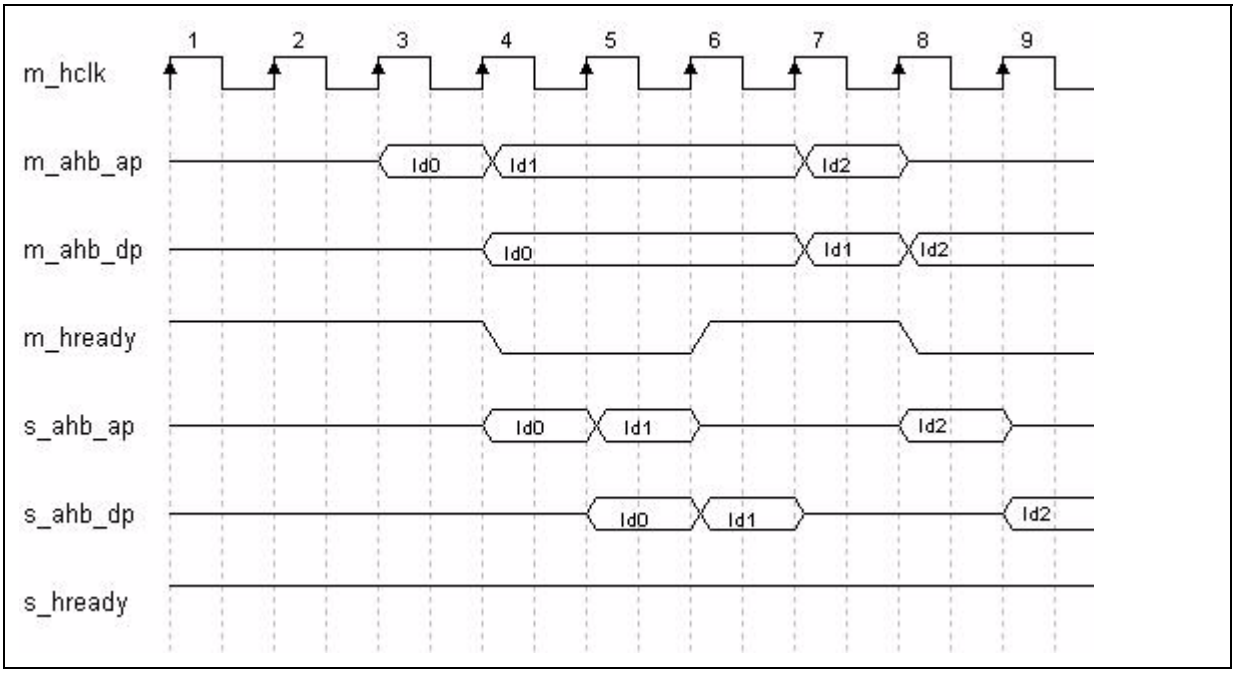


Figure 175. Write, pending read (1:1 timing mode)

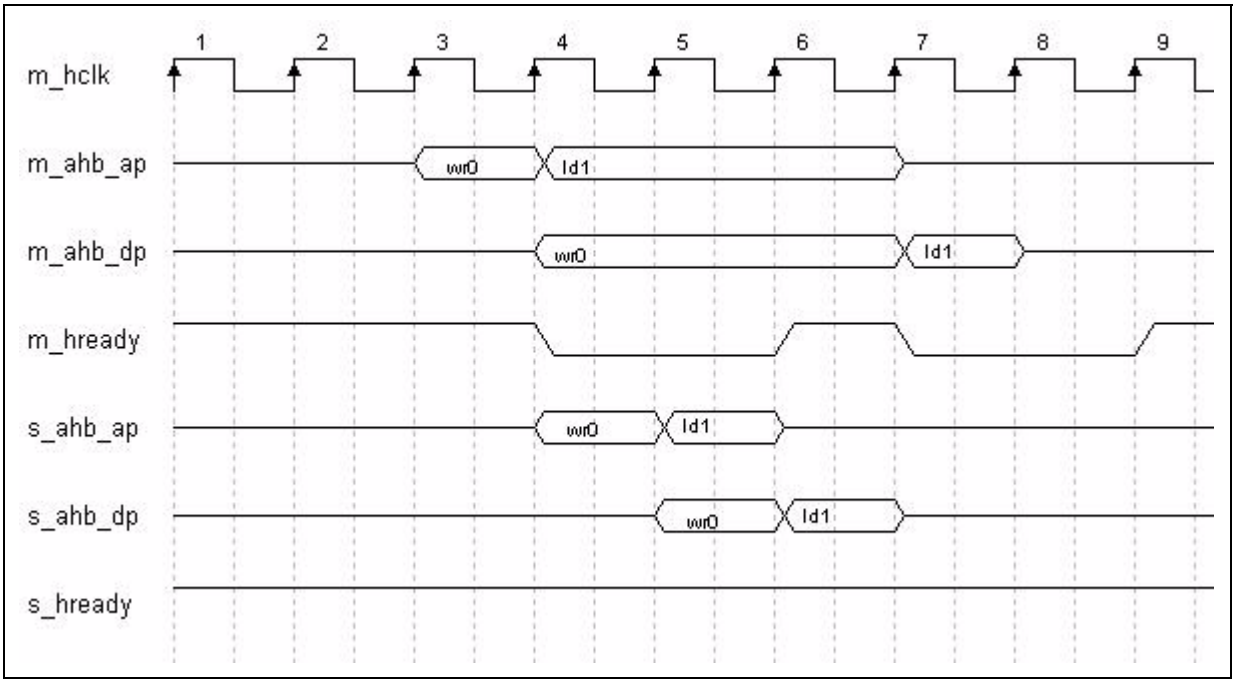

Figure 176. Burst4 read (1:1 timing mode)

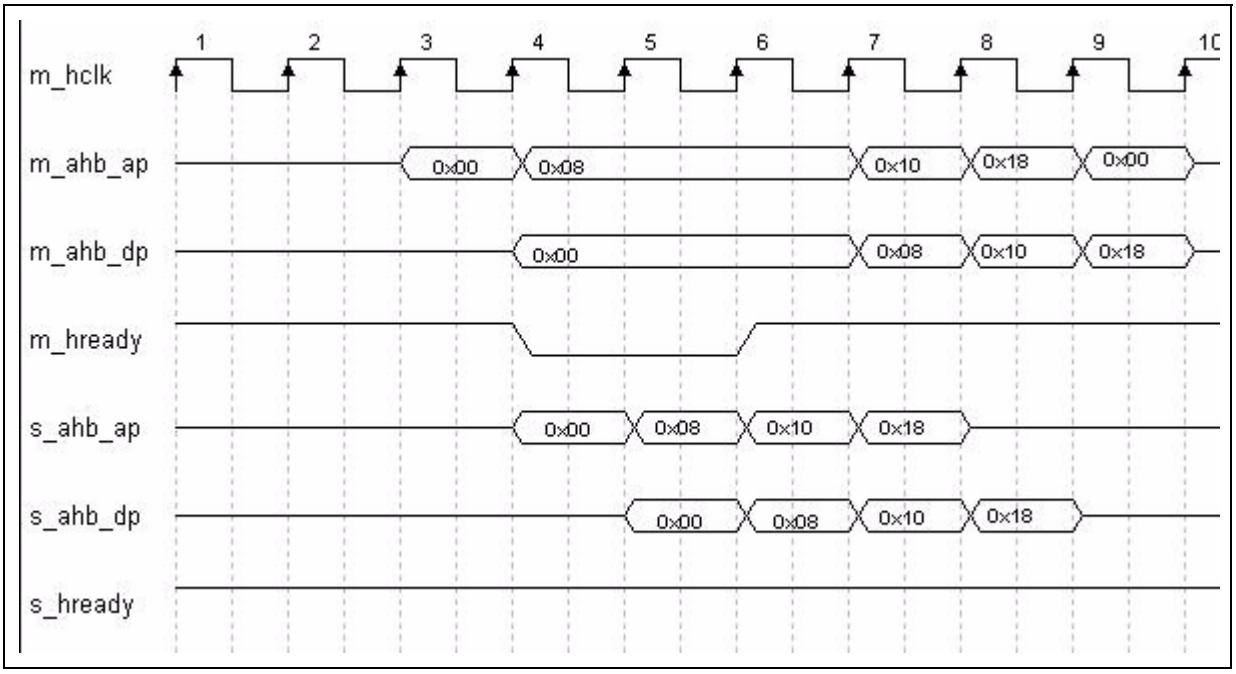

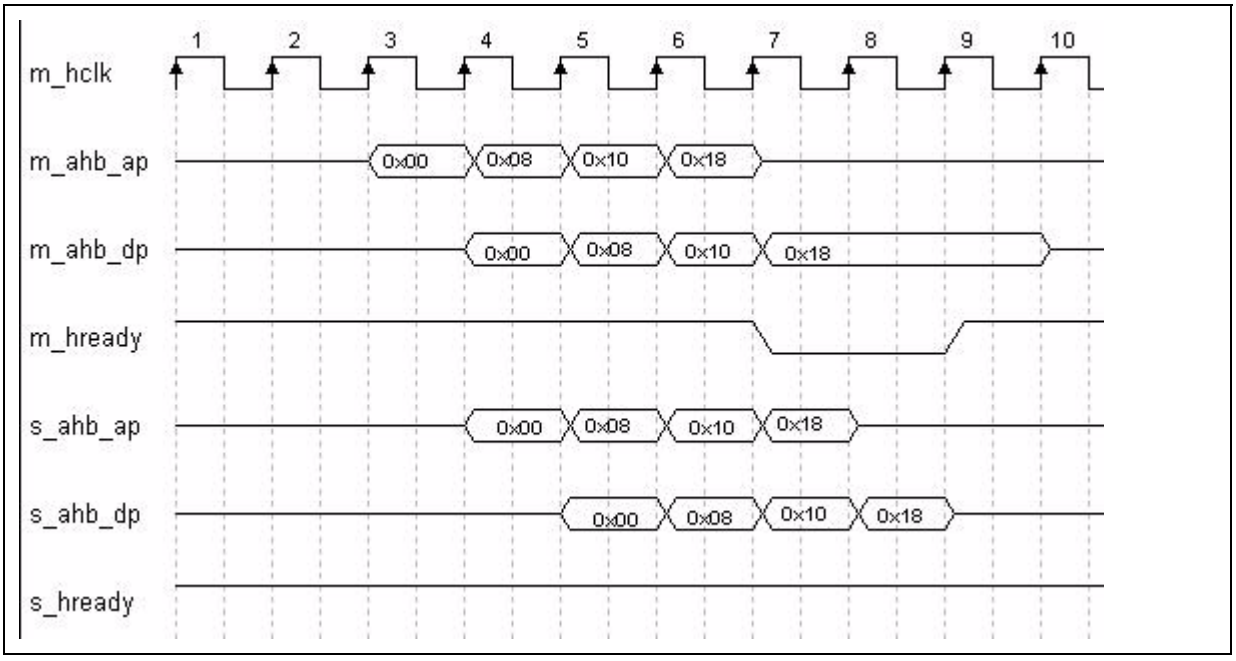

Figure 177. Burst4 write (1:1 timing mode)

21.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is not shown because it is very similar to the 2:1 mode. There are different read slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Figure 178. Read, pending read (2:1 timing mode)

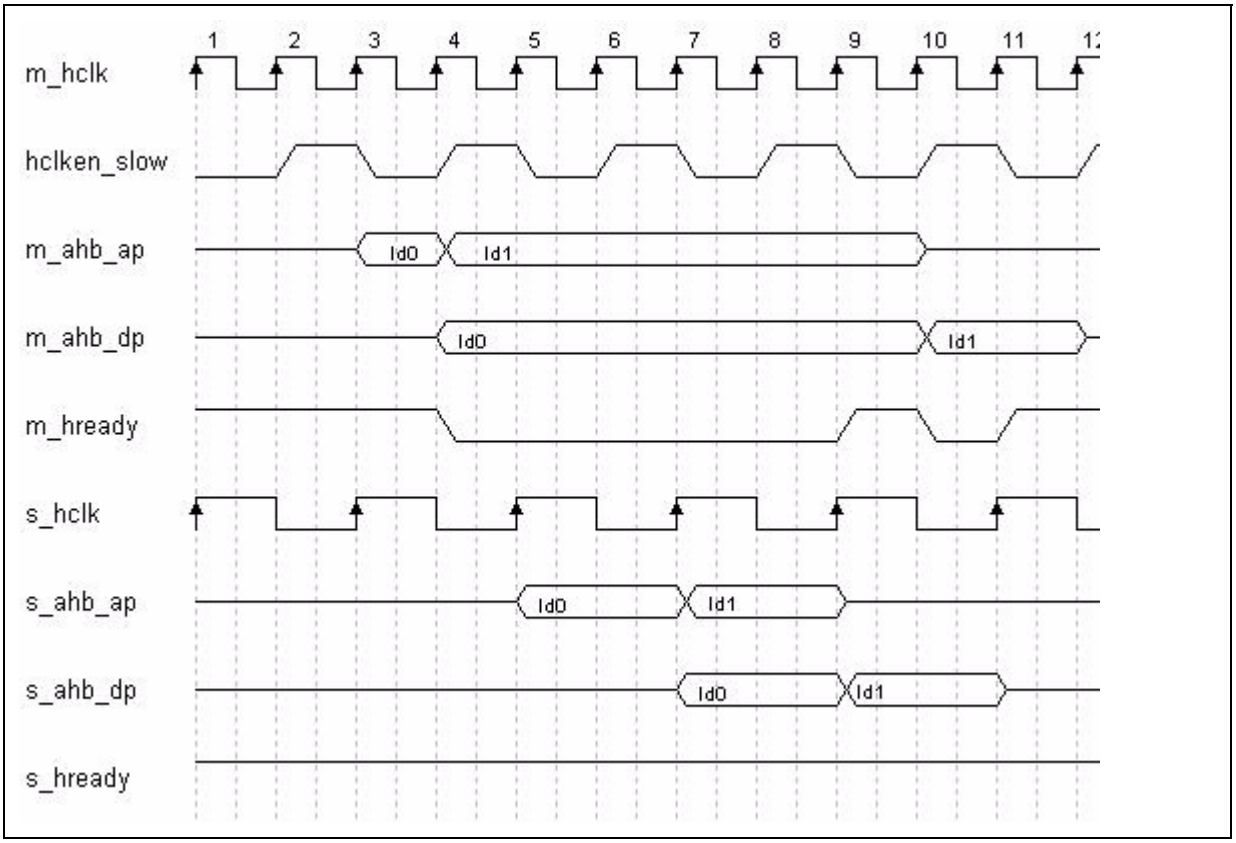

Figure 179. Write, pending read (2:1 timing mode)

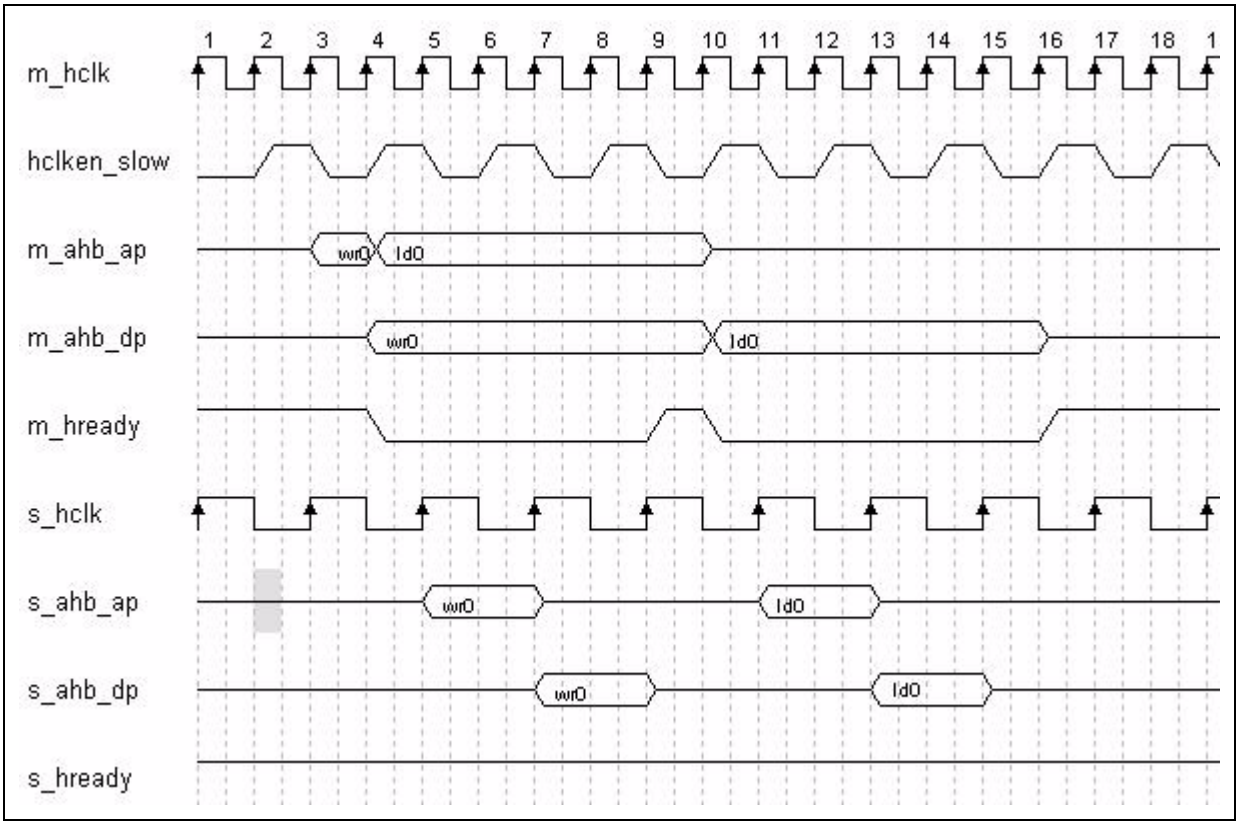

Figure 180. Burst4 read (2:1 timing mode)

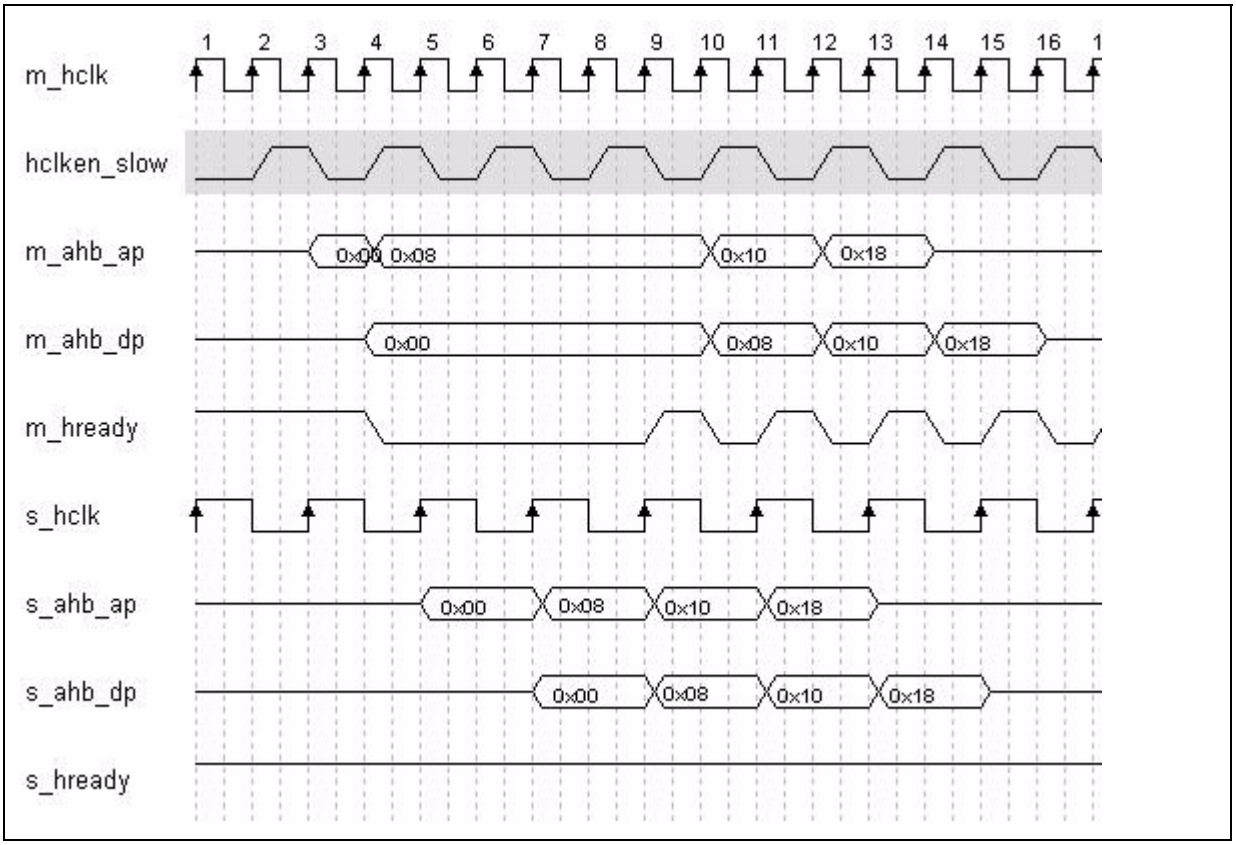

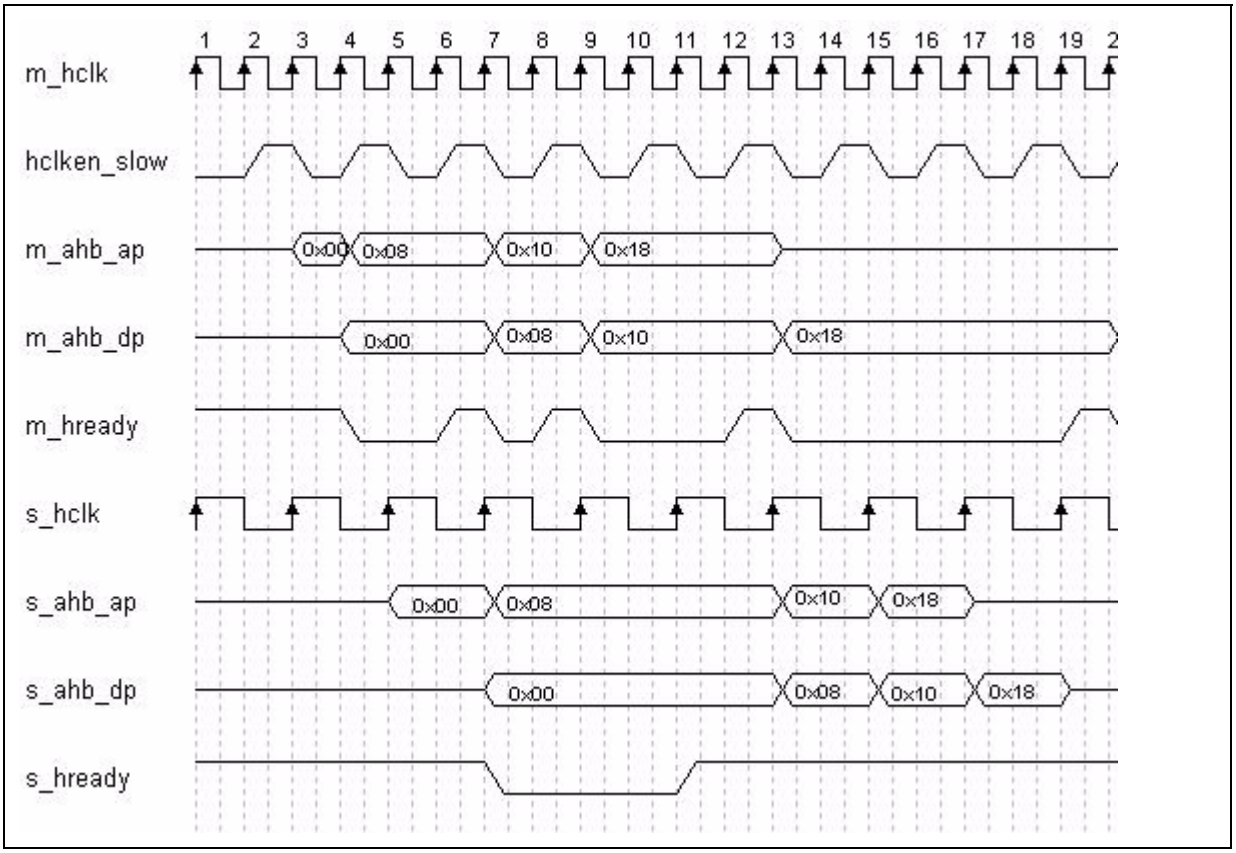

Figure 181. Burst4 write (2:1 timing mode)

21.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master. The 1:4 mode is not shown because it is very similar to the 1:2 mode. There are different read slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write. Burst writes will only work across the IAHBG if an assumption is made where the hresp from the slave is accumulated into the last beat of the burst (implicit burst write mode).

Figure 182. Read, pending read (1:2 timing mode)

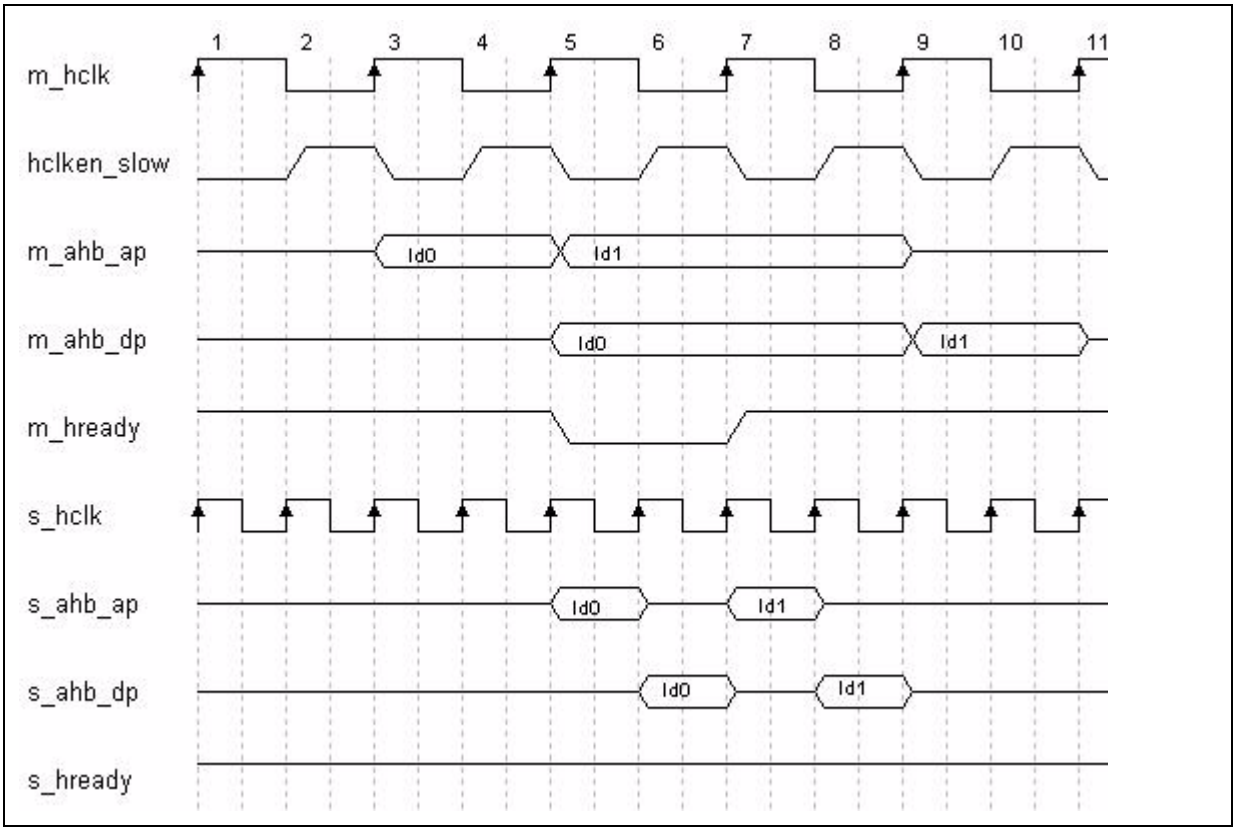

Figure 183. Write, pending read (1:2 timing mode)

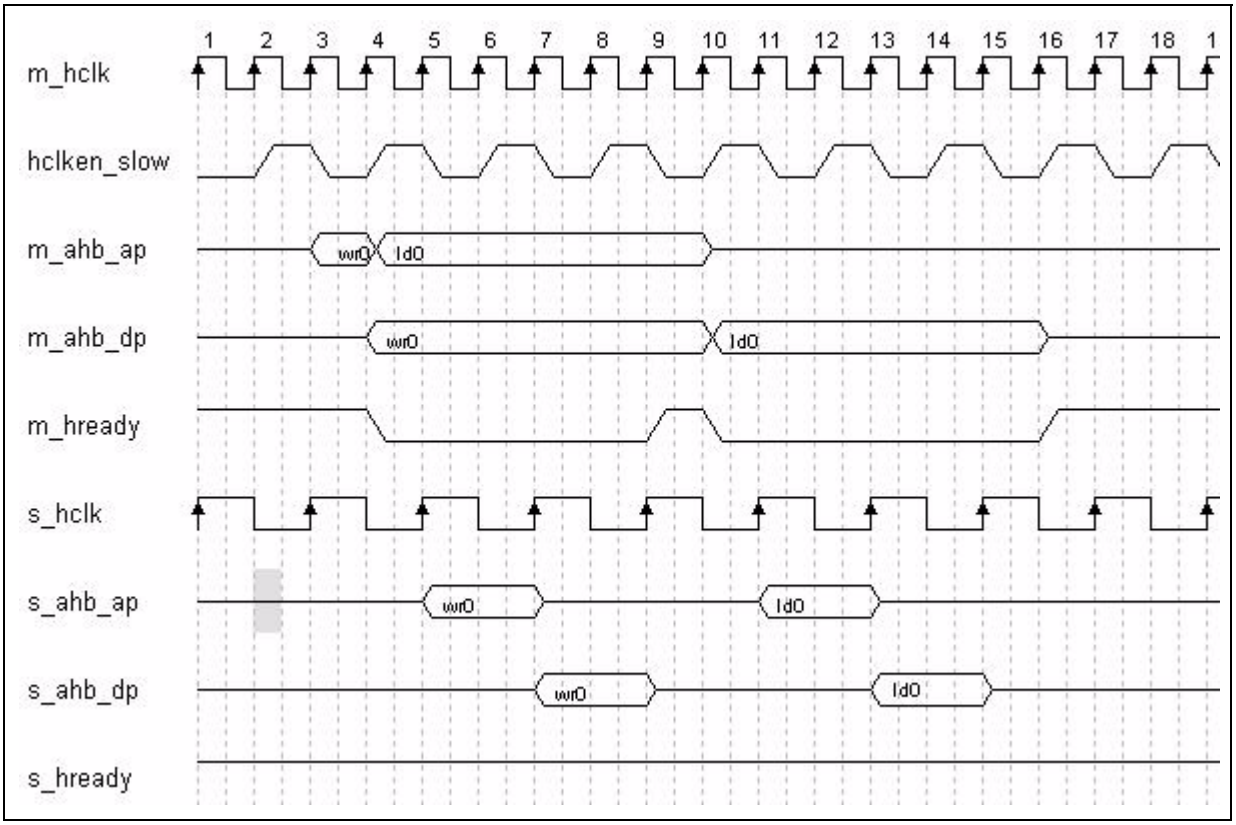

Figure 184. Burst4 read (1:2 timing mode)

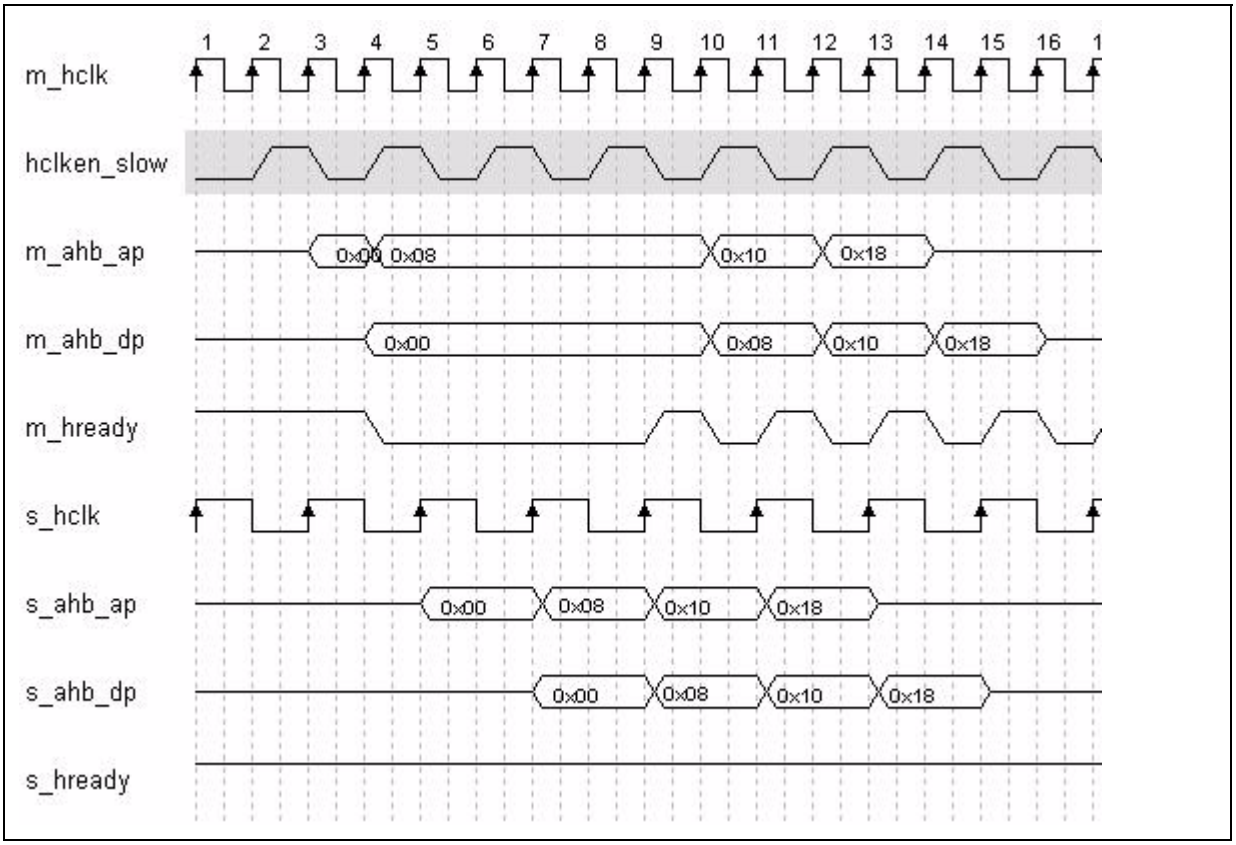

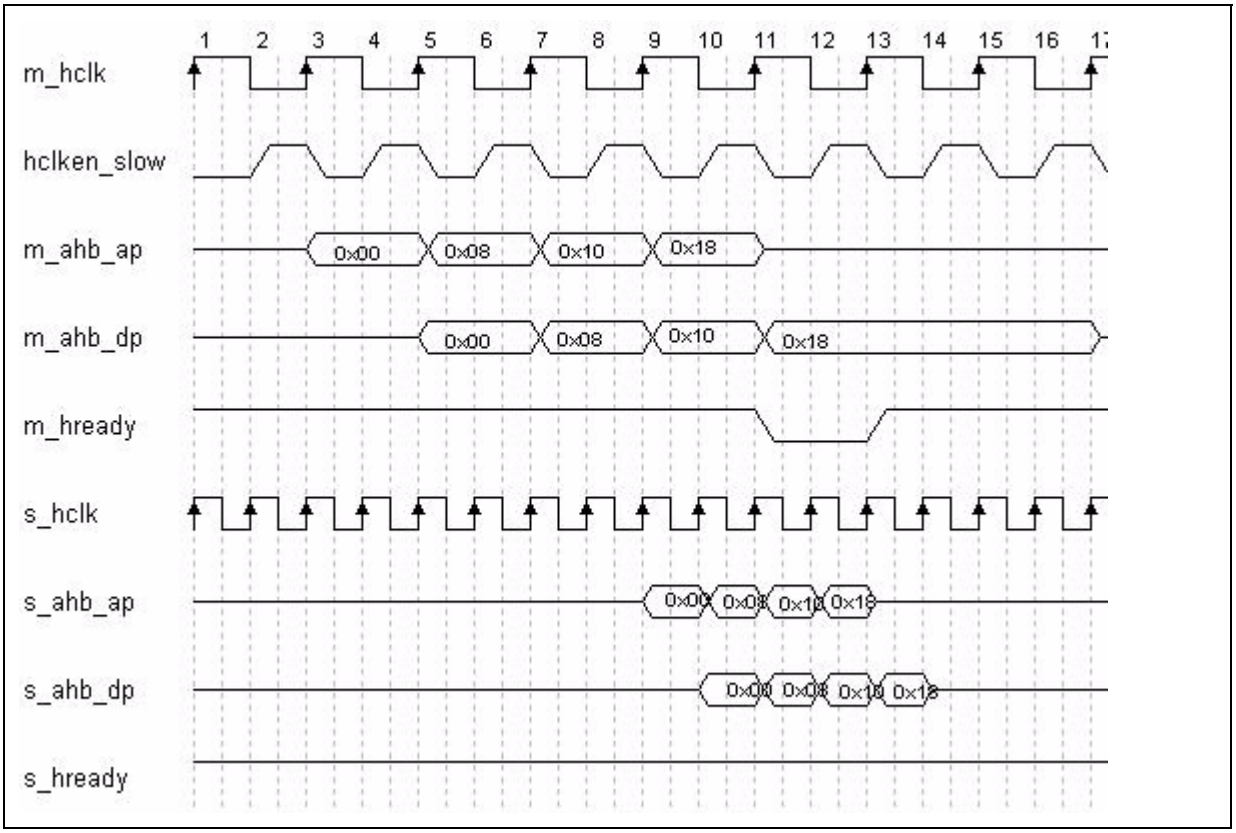

Figure 185. Burst4 write (1:2 timing mode)

21.2.4 64->32 Interface

The 64->32 interface translates a 64-bit access to two 32-bit accesses on the slave side. If there is an hresp on the first 32-bit access to the slave, the iahb_gasket will still do the second 32-bit access. The hresp is aggregated and reported to the master in the data phase of the 64-bit access. One of the 32-bit writes could complete and the other write could return an hresp.

For burst encodings of WRAP4,INCR4 hsize=long, it translates to WRAP8,INCR8 hsize=word.

For burst encodings of WRAP8,INCR8 hsize=long, it translates to WRAP16,INCR16 hsize=word.

Burst encodings WRAP4,8,16 INCR4,8,16 of hsize<long are passed as is through to slave.

All other burst encodings are not optimized and are translated as NSEQ.

Unaligned bursts are not optimized and are translated as NSEQ.

21.2.5 32->64 Interface

The 32->64 interface translates two 32-bit accesses to one 64-bit access on the slave side.

There is no special translation of 32-bit WRAP8,INCR8 to 64-bit WRAP4,INCR4.

Burst encodings WRAP4,8,16 INCR4,8,16 of hsize<long are passed as is through to slave.

All other burst encodings are not optimized and are translated as NSEQ.

Unaligned bursts are translated to NSEQ.

To support initializing ECC in the SRAM where two 32-bit write accesses through the 32->64 gasket needs to get translated to a single 64-bit write access, the master will send aligned (haddr[2]==0) double word transactions with a burst encoding of INCR with length fixed to 2. The iahb_gasket will translate these two 32-bit writes to a single 64-bit NSEQ. It will never report a hresp on the first 32-bit write. A design parameter on the gasket instantiation is used to compare to the master ID and if there is a match, all INCR are treated as an INCR with length fixed to 2.

22 Semaphores2 (SEMA42)

22.1 Introduction

The peripheral platform shell includes a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve “lock and unlock” operations via a single write access. The hardware semaphore module is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

The capabilities provided by the hardware semaphore module are currently utilized in dual-core AUTOSAR® implementations, and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

22.1.1 Multi-core programming 101: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism that is then used by system software to control access to shared data structures, shared hardware resources, and so on. These gating mechanisms are used by the software to serialize (and synchronize) writes to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered to be locking (or closing) a software gate. Once the gate has been locked, a properly architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate; in other words, other processes/processors are locked out. Many software implementations include a spin-wait loop within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a “gate” variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

“One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory.” [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 471-472]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

“Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly “spin waiting” to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but this does not matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets.” [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 472-473]

Next, consider the features, programming model, and functional operation of the hardware semaphore module.

22.1.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

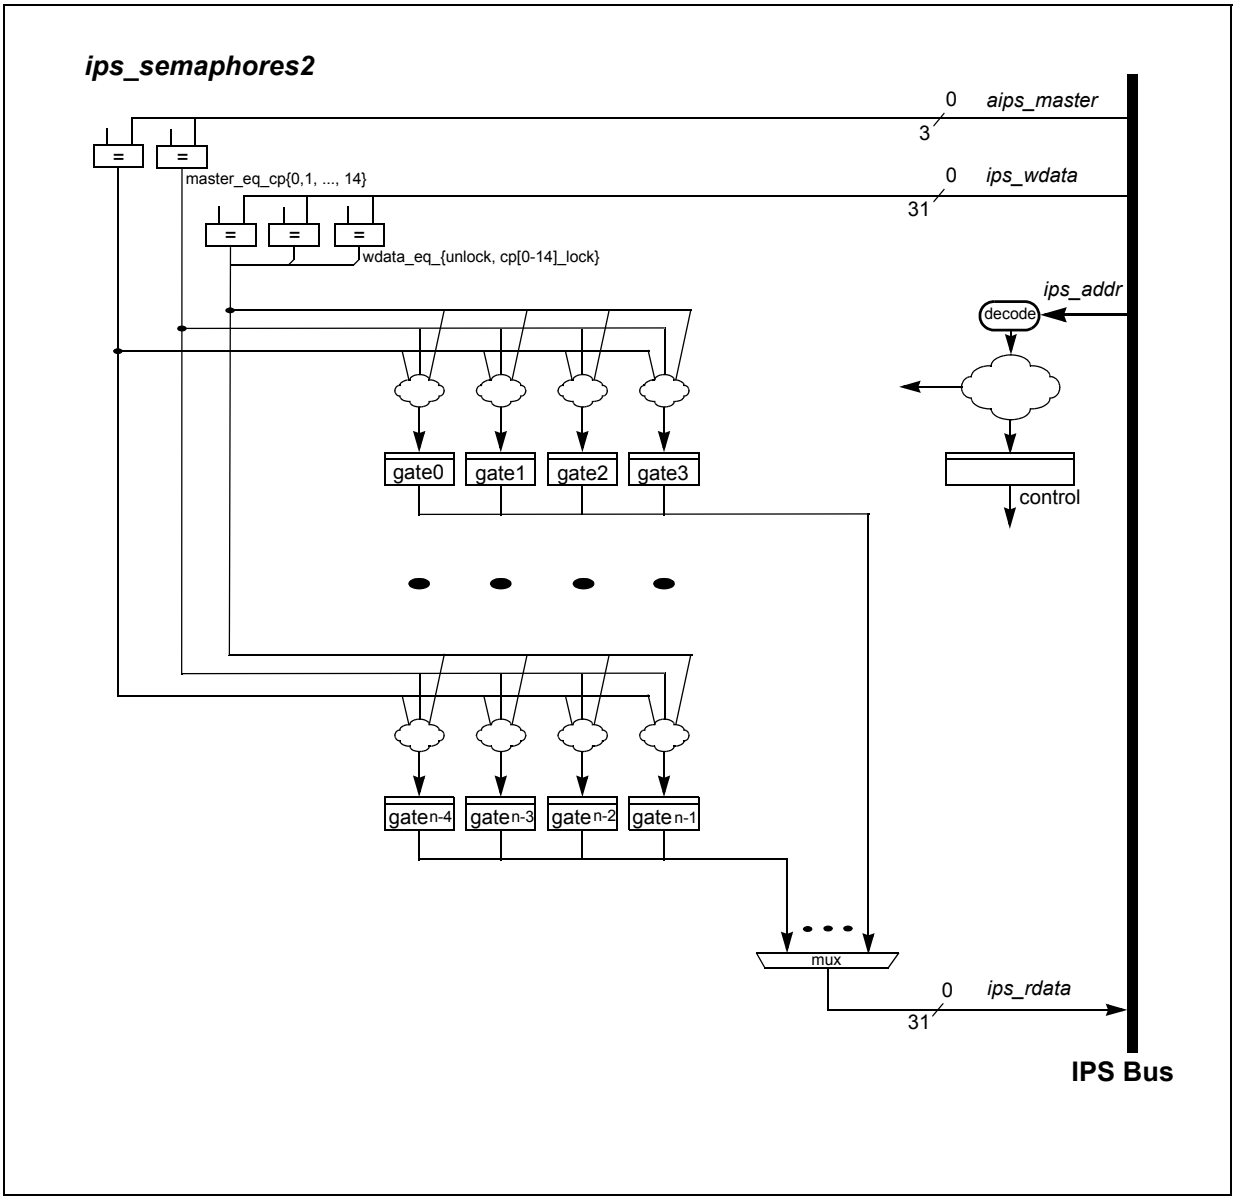
- Module definition supporting 16, 32, or 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cp*X* is meant to represent core processor *X*.
  - Gates appear as an *n*-entry byte-size array with read and write accesses (*n* = 16, 32, 64).
    - Processors lock gates by writing “processor_number+1” to the appropriate gate and must read back the gate value to verify the lock operation was successful.
    - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
    - The number of implemented gates is specified by a hardware configuration define.
  - Each hardware gate appears as a 16-state, 4-bit state machine.
    - 16-state implementation

      if gate = 0x0, then state = unlocked

      if gate = 0x1, then state = locked by processor (master) 0

      if gate = 0x2, then state = locked by processor (master) 1

...
if gate = 0xF, then state = locked by processor (master) 14



- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.

– Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.

- Memory-mapped IPS slave peripheral platform module
  – Interface to the IPS bus for programming-model accesses

A simplified block diagram of the Semaphores module is shown in *Figure 186*. In the diagram, the register blocks named gate0, gate1,..., gate (*n* – 2), gate (*n* – 1) include the finite state machines implementing the semaphore gates.

Figure 186. Semaphores2 block diagram

22.2 Memory map/register definition

Table 271. Memory map/register definition

Offset address	Register name	Access	Reset value	Section/ page
0x0000–0x003F	Semphores2 Gate *n* (GATE*n*)	R/W	0x00	*22.2.1/660*
0x0040	Semphores2 Reset Gate (RSTGT)	R/W	0x0000	*22.2.2/661*
0x0042–0x3FFF	Reserved			

22.2.1 Semaphores Gate *n* Register (SEMA4_GATE)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (processor_number + 1) are simply treated as “no operation” and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

4–7 GTFSM	Gate Finite State Machine. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14. **Note:** The state of the gate reflects the last processor that locked it, which can be useful during system debug. For more details, see *Section 22.2.1, Semaphores Gate n Register (SEMA4_GATE)*.

22.2.2 Semaphores (Secure) Reset Gate (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a “secure” reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a “don’t_care” for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]), and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

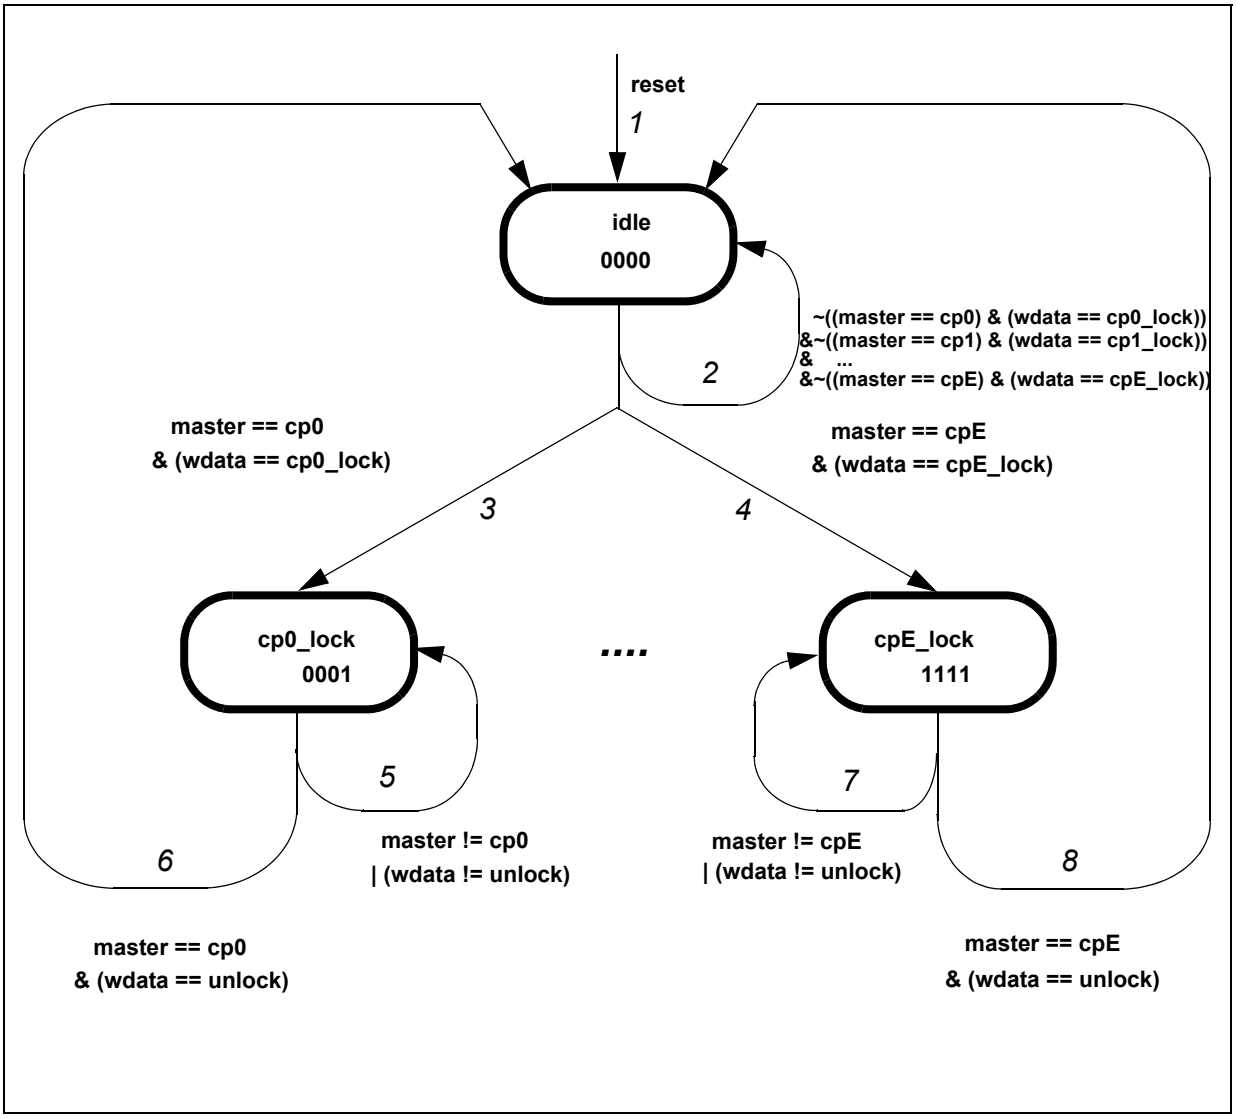
Figure 188. Semaphore2 Reset Gate Register (RSTGT)

Table 273. RSTGT field descriptions



Field	Description
0–1	Reserved
2–3 RSTGSM	Reset Gate Finite State Machine. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The “10” state persists for only one clock cycle. Software will never be able to observe this state. 11 This state encoding is never used and therefore reserved. Reads of the SEMA4_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then *reset the single gate* defined by RSTGTN, else *reset all the gates.*
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.

22.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA4_GATE*n* registers are provided as follows.

As described previously, each of the SEMA4_GATE*n* registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in *Figure 189*.

Figure 189. SEMA4_GATE*n* state machine

The bus master number is used to identify core processor *X* (cp*X*) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the AIPS controller and drives the signal to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATE*n* are defined in *Table 274*.

Table 274. SEMA4_GATE*n* state transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the “cp0_lock” data value is initiated by processor 0, the gate transitions into the cp0_lock state.

Table 274. SEMA4_GATE*n* state transitions(Continued)

Current State	Next State	Transition	Description
idle	cpE_lock	4	When a write of the “cpE_lock” value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

As previously noted, the following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

23 Interrupt Controller (INTC)

23.1 Introduction

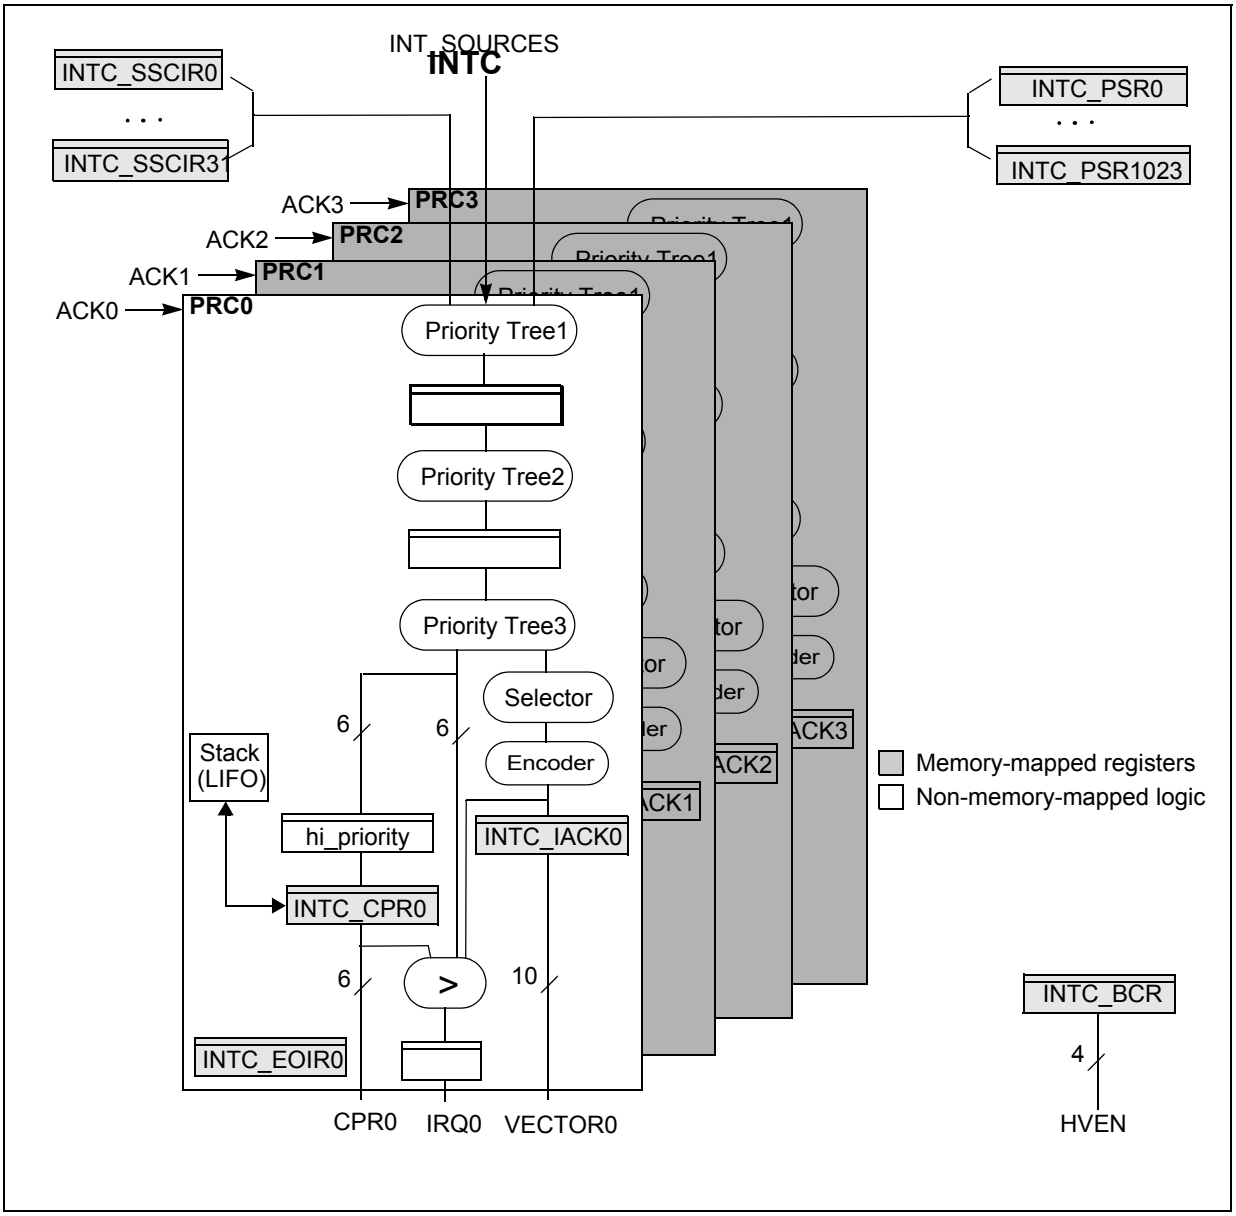
The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and is capable of processing high-demand interrupt sources where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.



When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

23.2 Block diagram

Figure 190 shows the block diagram of an INTC with four processors (PRC0...PRC3). The actual number of processors is described in the chip-specific INTC information. The structure of the INTC remains the same for each implemented processor.

Figure 190. Block diagram for an INTC with four processors

23.3 Features

- Each peripheral interrupt source is software-steerable to processor 0, processor 1, processor 2, processor 3, or any combination of interrupt request outputs
- 32 software-settable interrupt request sources
- 10-bit vector
  - Unique vector for each interrupt request source
  - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
  - Preemptive prioritized interrupt requests to processor
  - ISR with higher priority preempts ISRs or tasks with lower priorities
  - Automatic pushing or popping of preempted priority to or from a LIFO
  - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
  - 3 INTC clock cycles from interrupt request into interrupt request to CPU
- Low latency
  - Two INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; three clock cycles from receipt of software request

23.4 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 bytes of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 bytes for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

23.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRC*n* bit in the INTC_BCR (see *Section 23.5.2.1, INTC Block Configuration Register (INTC_BCR)*) is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRC*n* bit is negated. The vector is read from the INTC_IACKRn registers (see *Section 23.5.2.4, INTC Interrupt Acknowledge Register for Processor n (INTC_IACKRn)*). Reading the INTC_IACKR*n* negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPR*n* (see *Section 23.5.2.3, INTC Current Priority Register for Processor n (INTC_CPRn)*) onto

the associated LIFO, and updates PRI in the associated INTC_CPR_PRC*n* with the new priority.

23.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVEN*n* bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKR*n*, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR*n* register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR*n* register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR*n* does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs (see *Section 23.5.2.6, INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–INTC_SSCIR31)*) is written at a time such that the PRI value in the associated INTC_CPR*n* register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR*n* is updated with the new priority, and the associated LIFO is neither pushed or popped.

23.5 Memory map and register definition

23.5.1 Memory map

Table 275 is the INTC memory map.

The actual availability and number of registers are chip-specific. For this information, see the chapter that describes how modules are configured and connected.

Table 275. INTC memory map

Address offset	Register	Location
000h	INTC Block Configuration Register (INTC_BCR)	*on page 669*
004h	INTC Master Protection Register (INTC_MPROT)	*on page 669*
008h–00Ch	Reserved	
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)	*on page 671*
014h	INTC Current Priority Register for Processor 1 (INTC_CPR1)	*on page 671*
018h	INTC Current Priority Register for Processor 2 (INTC_CPR2)	*on page 671*
01Ch	INTC Current Priority Register for Processor 3 (INTC_CPR3)	*on page 671*

Table 275. INTC memory map(Continued)

Address offset	Register	Location
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)	*on page 672*
024h	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)	*on page 672*
028h	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)	*on page 672*
02Ch	INTC Interrupt Acknowledge Register for Processor 3 (INTC_IACKR3)	*on page 672*

034h	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)	*on page 673*
038h	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)	*on page 673*
03Ch	INTC End Of Interrupt Register for Processor 3 (INTC_EOIR3)	*on page 673*
040h–05Fh	INTC Software Set/Clear Interrupt Register 0 (INTC_SSCIR0)– INTC Software Set/Clear Interrupt Register 31(INTC_SSCIR31)	*on page 674*
060h–85Eh	INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023)	*on page 675*
860h-FFC	Reserved	

Note: A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

23.5.2 Register descriptions

With the exception of the INTC_SSCIR*n* and INTC_PSR*n* registers, all of the registers are 32-bit. Any combination of accessing the four bytes of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two bytes, and aligned 32 bits.

Although INTC_SSCIR*n* are 8 bits wide and INTC_PSR*n* are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR*n*) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR*n*) does not affect the operation of the write.

23.5.2.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Offset: 000h Access: User read/write

Figure 192. INTC Master Protection Register (INTC_MPROT)

Table 277. INTC_MPROT field descriptions

Field	Description
ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. Only the field values related to core bus masters can be selected. Non-core bus masters cannot be selected and would result in a bus access error. 00 - master0 (reset default) 01 - master1 10 - master2 11 - master3
MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

23.5.2.3 INTC Current Priority Register for Processor *n* (INTC_CPR*n*)

The INTC_CPRn masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR*n*[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR*n*) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR*n*) is written, the LIFO is popped into the INTC_CPR*n* PRI field. An exception case in hardware vector mode to this behavior is described in *Section 23.4.2, Hardware vector mode*.

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See *Section 23.7.5, Priority ceiling protocol*.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Note: A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See Section 23.7.5.2, Ensuring coherency, for example code to ensure coherency.

Field	Description
PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

23.5.2.4 INTC Interrupt Acknowledge Register for Processor *n* (INTC_IACKR*n*)

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR*n* has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKR*n* does not have side effects in hardware vector mode.

If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

Offsets: 020h (INTC_IACKR0)
024h (INTC_IACKR1)
028h (INTC_IACKR2)
02Ch (INTC_IACKR3)

Table 279. INTC_IACKRn field descriptions

Field	Description
VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.

23.5.2.5 INTC End of Interrupt Register for Processor *n* (INTC_EOIR*n*)

Writing to the INTC_EOIR*n* signals the end of the servicing of the interrupt request. When the INTC_EOIR*n* is written, the priority last pushed on the LIFO is popped into INTC_CPR*n*. The values and size of data written to the INTC_EOIR*n* are ignored. Those values and sizes written to this register neither update the INTC_EOIR*n* contents nor affect whether the LIFO pops. Typically, when you write to this register, write four all-zero bytes.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Table 280. INTC_EOIR*n* field descriptions

Field	Description
EOI	End of Interrupt. Write four all-zero bytes to this field to signal the end of the servicing of an interrupt request.

23.5.2.6 INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–INTC_SSCIR31)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET will leave SET unchanged at 0 but will set CLR. Writing a 0 to SET will have no effect. CLR is the flag bit. Writing a 1 to CLR will clear it. Writing a 0 to CLR will have no effect. If a 1 is written to a pair of SET and CLR bits at the same time, CLR is asserted, regardless of whether CLR was asserted before the write.

Figure 196 shows the structure of the first INTC_SSCIR. The other registers follow the same structure.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIR*n* register.

If INTC_MPROT[MPROT]=0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit, otherwise, a termination error is asserted.

Note: If INTC_MPROT[MPROT] is enabled, processors with master ID != INTC_MPROT[ID] must only write the INTC_SSCIRn registers using a byte operation. A write of any other size will result in a termination error.

Table 281. INTC_SSCIR*n* field descriptions

Field	Description
SET	Set flag bits. Writing a 1 will set the corresponding CLR bit. Writing a 0 will have no effect. Each SET is read as a 0.
CLR	Clear flag bits. CLR is the flag bit. Writing a 1 to CLR will clear it provided that a 1 is not written simultaneously to its corresponding SET bit. Writing a 0 to CLR will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

23.5.2.7 INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSR*n* is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32–1023, and their priorities are configured in INTC_PSR32–1023, respectively.

Figure 197 and *Figure 198* show the structure and numbering scheme of the first and last PSRs, respectively. The other registers follow the same numbering scheme.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SEL,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID (0-3) = INTC_MPROT[ID] and the processor who's master ID (0-3) matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.

Note: Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.

Note: Interrupts are not detected while the PSRs are being written.

Note: If INTC_MPROT[MPROT] is enabled, the core with master ID (0-3) = INTC_MPROT[ID] will be able to write the INTC_PSRn with either byte, half-word or word operations. All other master IDs are restricted to byte operations to the INTC_PSRn[PRI] bits (i.e. the odd

addresses). Any other sized write operation, or a byte operation to the INTC_PSRn[PRC_SEL] (i.e. the even byte) will result in a termination error.

Table 282. INTC_PSR*n* field descriptions

Field	Description
PRC_SEL*n*	Processor select bits. See *Table 283*. If an interrupt source is enabled, PRC_SEL*n*[3:0] selects whether the interrupt request is to be sent to processor 0, processor 1, processor 2, processor 3, or any combination.
SWT*n*	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWT*n* sets the bit. On the interrupt acknowledge cycle, the SWT*n* bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SEL*n* field of the PSR.
PRI*n*	Priority select. Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

Table 283. Selected Processor for Interrupt Request

PRC_SEL*n*[3:0]	Meaning
0000	No interrupt request sent
0001	Interrupt request sent to processors 3
0010	Interrupt request sent to processors 2
0011	Interrupt request sent to processors 2, 3
0100	Interrupt request sent to processors 1
0101	Interrupt request sent to processors 1, 3
0110	Interrupt request sent to processors 1, 2
0111	Interrupt request sent to processors 1, 2, 3

Table 283. Selected Processor for Interrupt Request(Continued)

PRC_SEL*n*[3:0]	Meaning
1000	Interrupt request sent to processors 0
1001	Interrupt request sent to processors 0, 3
1010	Interrupt request sent to processors 0, 2
1011	Interrupt request sent to processors 0, 2, 3
1100	Interrupt request sent to processors 0, 1
1101	Interrupt request sent to processors 0, 1, 3
1110	Interrupt request sent to processors 0, 1, 2
1111	Interrupt request sent to processors 0, 1, 2, 3

23.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

23.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI*n* value in INTC_PSR*n* is higher than the PRI value in INTC_CPR*n*, negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR*n* is updated with the corresponding PRI*n* value in INTC_PSR*n*.

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

23.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

23.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR*n*) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set

and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET bit in INTC_SSCIR*n*. This write sets the corresponding CLR bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR bit. Specific behavior includes the following:

- Writing a 1 to SET leaves SET unchanged at 0 but sets the flag bit (which is the CLR bit).
- Writing a 0 to SET has no effect.
- Writing a 1 to CLR clears the flag (CLR) bit.
- Writing a 0 to CLR has no effect.
- If a 1 is written to a pair of SET and CLR bits at the same time, the flag (CLR) is set, regardless of whether CLR was asserted before the write.

The time from the write to the SET bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR*n*[PRC_SELn] bits.

23.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

23.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI*n* and PRC_SEL*n* values set in INTC_PSR*n*. The result of that comparison also is compared to PRI in the associated INTC_CPR*n*. The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

23.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in *Figure 190* are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR*n*, and if in hardware vector mode, for the interrupt vector provided to the processor.

23.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

23.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

23.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

23.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR*n*. If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR*n*, or the PRI value in the associated INTC_CPR*n* is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR*n* when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI*n* in INTC_PSR*n* are zero will not cause a preemption because their PRI*n* will not be higher than PRI in the associated INTC_CPR*n*.

Another function of the comparator is to signal an update of the INTC_IACKR*n* with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR*n* occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

23.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR*n*. Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR*n* does not need to be loaded from the associated INTC_CPR*n* and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR*n*.

The PRI value in the associated INTC_CPR*n* is pushed onto the LIFO when the associated INTC_IACKR*n* is read in software vector mode or the interrupt acknowledge signal from the associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR*n* whenever the associated INTC_EOIR*n* is written. An exception case in hardware vector mode to this behavior is described in *Section 23.4.2, Hardware vector mode*.

Although the INTC supports up to 64 priorities, an ISR executing with PRI in the INTC_CPR*n* equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop

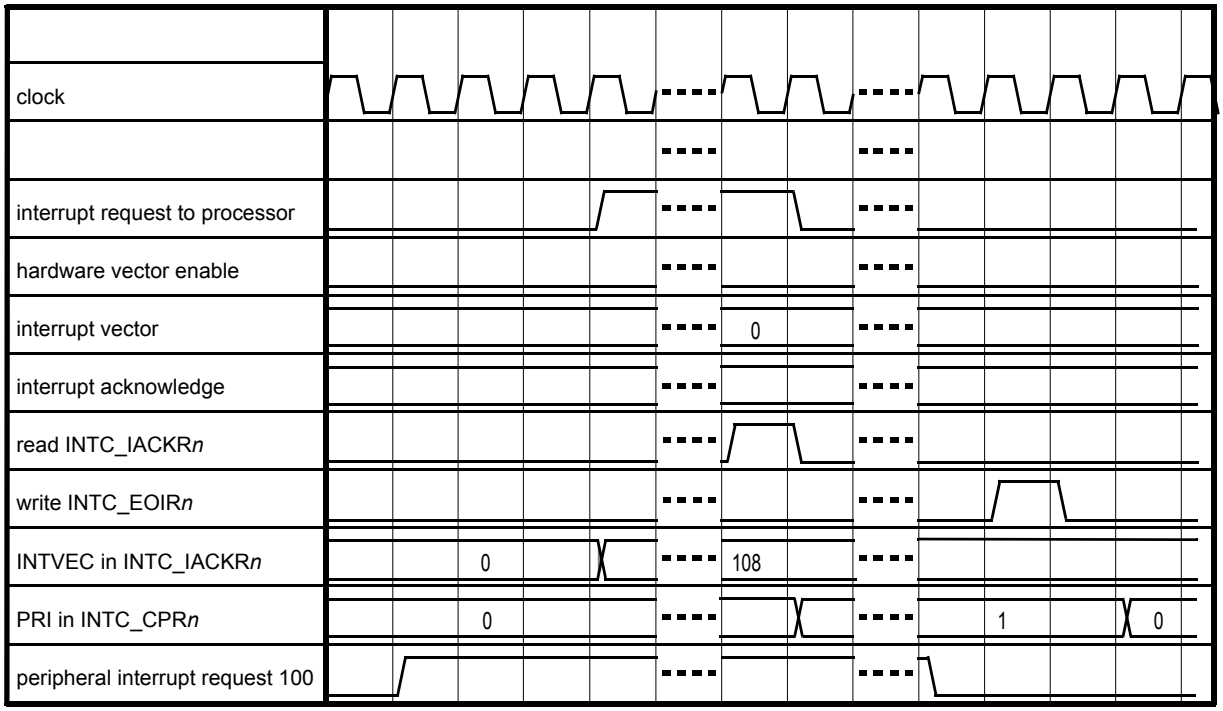
zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

23.6.3 Handshaking with processor

23.6.3.1 Software vector mode handshaking

23.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to *Figure 199*.



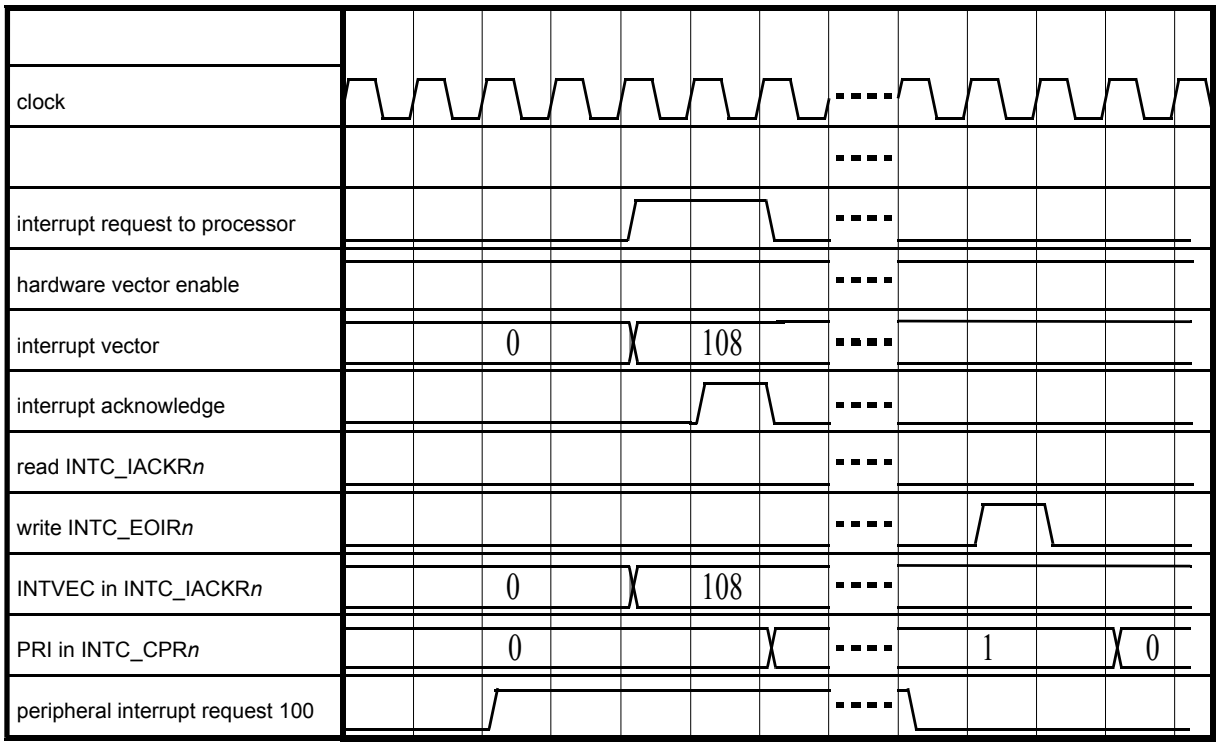
A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 199*. The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in *Section 23.4.1, Software vector mode*.

23.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR*n* must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR*n*. Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR*n* is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 199. Timing diagram of software vector mode handshaking



23.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in *Figure 200*. As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPR*n*, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR*n* is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKR*n*. The rest of the handshaking is described in *Section 23.4.2, Hardware vector mode*.

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIR*n*, is the same as in software vector mode. See *Section 23.6.3.1.2, End of interrupt exception handler*.

Figure 200. Timing diagram for hardware vector mode handshaking

23.7 Initialization/application information

23.7.1 Initialization flow

After exiting reset, all of the PRI*n* and PRC_SEL*n* fields in INTC_PSR*n* are zero, and PRI in the INTC_CPRn registers is 63. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

- Interrupt_request_initialization:
  - Configure HVENn in INTC_BCR.
  - Configure VTBA*n* in INTC_IACKR*n.*
  - Raise the PRI*n* fields and set the PRC_SEL*n* fields to the desired processor in INTC_PSR*n*.
  - Set the enable bits or clear the mask bits for the peripheral interrupt requests.
  - Lower PRI in INTC_CPR*n* to zero.
  - Enable processor(s) recognition of interrupts.

23.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

23.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 bytes of vector space available at the single ISR entry point.

```
interrupt_exception_handler:
b  interrupt_exception_handler_continued# 16 bytes available, branch to
continue

interrupt_exception_handler_continued:
code to create stack frame, save working register, and save SRR0 and SRR1

23.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPR*n* having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPR*n* priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPR*n* priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPR*n* priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPR*n* while the shared resource is being accessed.

An ISR whose PRI*n* in INTC_PSR*n* has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

23.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority

is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in *Table 284* shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 284. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 (1)	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIR*n*.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

23.7.5 Priority ceiling protocol

23.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR*n*) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR*n* to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR*n* to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

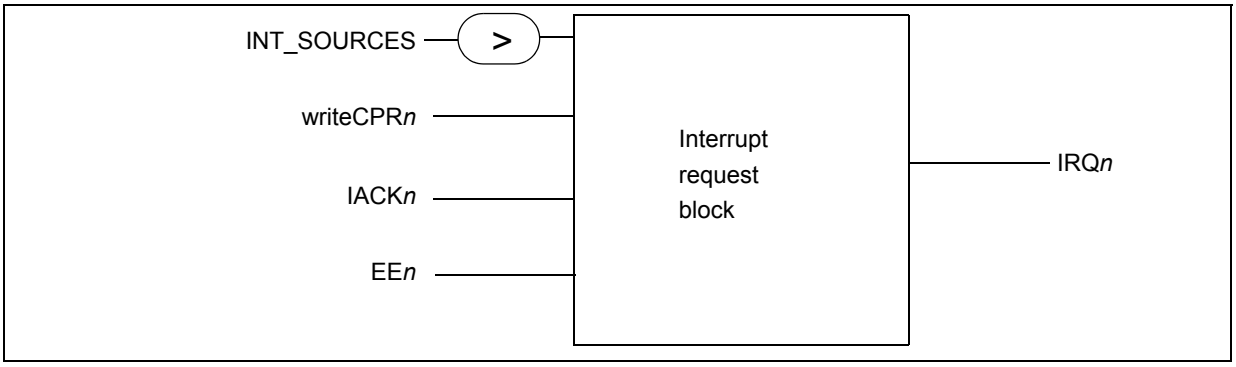
23.7.5.2 Ensuring coherency

23.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR*n*. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR*n* can be made by those system services with the code sequence:

```
GetResource:
   wrteei 0# disable external interrupts to the Processor
   raise PRI# Write to CPR, cache inhibit, guarded
   mbar # flush out writes from store buffer
   wrteei 1# enable external interrupts to the Processor
   isync# re-fetch Processor pipeline



ReleaseResource:
   mbar # flush out writes from store buffer
   wrteei 0# disable external interrupts to the Processor
   lower PRI# Write to CPR, cache inhibit, guarded
```

```
wrteei 1# enable external interrupts to the Processor
```

23.7.5.2.1.1 Interrupt request to processor

Referencing *Figure 190*, the interrupt request logic to the processor is shown in *Figure 201*.

Figure 201. Interrupt request block diagram

Assuming that there are no IRQ*n* deasserted (no pending interrupt requests to processor *n*), if one of the external interrupt sources (INT_SOURCES) has a priority higher than the INTC_CPR*n*, then interrupt request to the processor (IRQ*n*) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge (IACK) is asserted
- If the EE*n* bit has been cleared by the wrteei instruction (see *Figure 201*), IRQ*n* will be re-evaluated when processor *n* writes to the INTC_CPR*n* while processor *n* ignores IRQ*n*

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the INTC_CPR*n*.

23.7.5.2.2 Raised priority preserved

Before the instruction after the GetResource system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. The shared coherent data block now can be accessed coherently. *Figure 202* shows the timing diagram for this scenario, and *Table 285* explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 202. Timing diagram of raised priority preserved

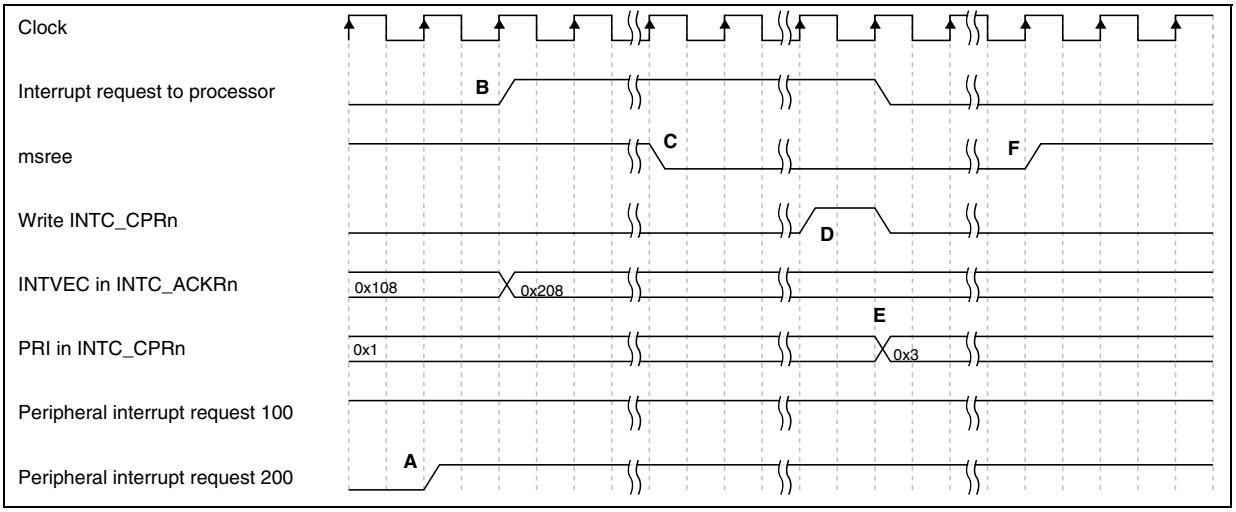


Table 285. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 of priority 2 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	Write to msree bit to disable external interrupts
D	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
E	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
F	Write to msree bit to enable external interrupts

23.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 µs, ISR2 executes every 200 µs, and ISR3 executes every 300 µs. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 µs, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 µs would share a priority, ISRs with request rates around 250 µs would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

23.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

23.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI*n* value in INTC_PSR*n*, which becomes the PRI value in INTC_CPR*n* with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET bit in INTC_SSCIR*n*. Writing a 1 to SET causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI*n* value in the INTC_PSR*n*, therefore will not cause preemptive scheduling inefficiencies.

23.7.7.2 Scheduling an ISR on another processor

Since the SET bits in the INTC_SSCIR*n* are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR bit in INTC_SSCIR*n* is asserted before again writing a 1 to the SET bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR bit and then writes 1 to a SET bit on the first processor, informing it that it now can access the block of data.

23.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR*n*, one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling

inefficiencies with an ISR whose work spans multiple priorities (as described in *Section 23.7.7.1, Scheduling a lower priority portion of an ISR*) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note: Lowering the PRI value in INTC_CPRn within an ISR to below the ISR's corresponding PRI value in INTC_PSRn allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

23.7.9 Negating an interrupt request outside of its ISR

23.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

23.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

23.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI*n* values in INTC_PSR*n* must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to INTC_SSCIR*n* as the clearing of the flag bit that caused the present ISR to be executed. Refer to *Section 23.6.3.1.2, End of interrupt exception handler* for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI*n* value in INTC_PSR*n*.

23.7.10 Examining LIFO contents

There are multiple methods for tracking interrupts in a system, one of which is described here using existing hardware (LIFO) within the INTC. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register (INTC_CPR*n*). To avoid a lower-level interrupt being serviced because the popping of the LIFO updates the INTC_CPR*n*, the processor recognition of interrupts should be disabled when examining LIFO contents. The pseudo-code is as follows:

```
wrteei 0 # disable processor recognition of external interrupts
```

```
   oldCPRn = INTC_CPRn; # save INTC_CPRn
   (branch to the pop_lifo)

pop_lifo:
   store INTC_EIORn # pop INTC_CPR from LIFO, examine PRI, etc...
   examine INTC_CPRn[PRI], and store onto stack
   if PRI is not zero or value when interrupts were enabled, branch to
pop_lifo
   branch to push_lifo
```

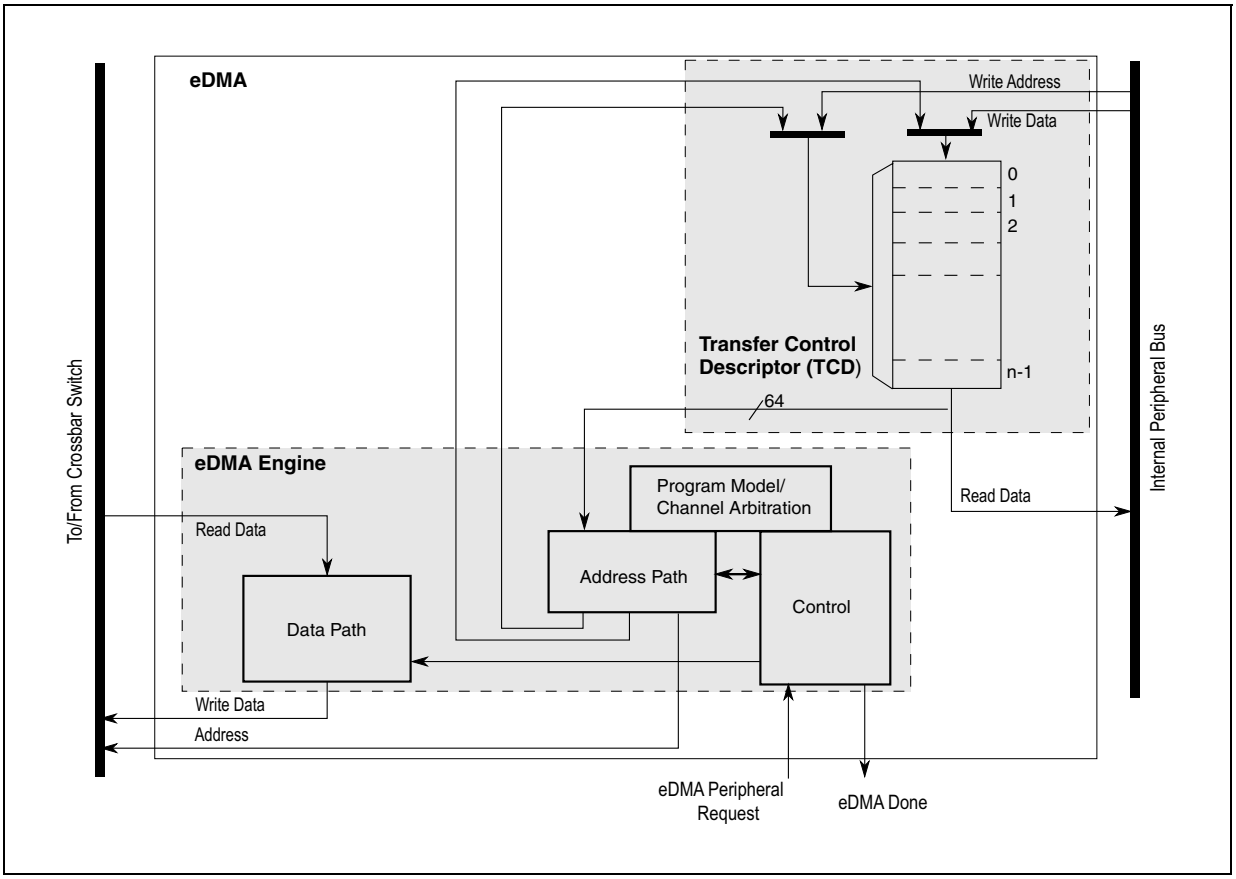
When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
   load stacked PRI value and store to INTC_CPRn
   load INTC_IACKn # IACK; push INTC_CPRn into LIFO
   if stacked PRI values are not depleted, branch to push_lifo
   INTC_CPRn = oldCPRn; # restore original INTC_CPRn and re-evaluate
pending
            external interrupts
   wrteei 1 # enable processor recognition of interrupts
```

Note: Disabling the processor recognition of interrupts during LIFO examination will introduce latency, but none of the interrupt requests will be missed.

23.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chip-specific INTC information.



24 Enhanced Direct Memory Access (eDMA)

24.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 32 channels.

Figure 203 illustrates the eDMA module.

Figure 203. eDMA block diagram

24.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers—read from source, write to destination:

  Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes

- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests (one per channel)
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
  - One interrupt per channel, optionally asserted at completion of major iteration count
  - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing
- Support for complex data structures
- Support to cancel transfers via software

Throughout this chapter, *n* is used to reference the channel number.

24.2 Modes of operation

The eDMA supports the following modes of operation.

24.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

24.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

24.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

24.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. *Table 286* provides a 32-bit view of the eDMA's memory map.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

Table 286. DMA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Location
FC0A_0000	Control Register (DMA_CR)	32	R/W	0000_0000h	*on page 718*

24.3.1 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in two groups (0, 1) of 16 channels each. Group 1 contains channels 31–16; and group 0 contains channels 15–0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (see the DCHPRI*n* registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

Note: Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRP*n*PRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

Figure 204. Control Register (DMA_CR)

Table 287. DMA_CR field descriptions

Field	Description
0–13 Reserved	This read-only field is reserved and always has the value zero.
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt.

Table 287. DMA_CR field descriptions(Continued)

Field	Description
16–19 Reserved	This read-only field is reserved and always has the value zero.
20–21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22–23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCD*n*.word2 is defined as a 32-bit NBYTES field 1 Enabled. TCD*n*.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection. 1 Round-robin arbitration is used for channel selection.
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.
31 Reserved	This bit is reserved and always has the value zero.

24.3.2 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an

illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

See *Section 24.4.3: Error reporting and handling*, for more details.

Figure 205. Error Status Register (DMA_ES)

Table 288. DMA_ES field descriptions

Field	Description
0 VLD	ERRL status bits 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared
1–13 Reserved	This read-only bitfield is reserved and always has the value zero.
14 UCE	Uncorrectable ECC error 0No uncorrectable ECC error 1The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer cancelled 0 No cancelled transfers 1 The last recorded entry was a cancelled transfer by the error cancel transfer input
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18–23 ERRCHN	Error channel number or cancelled channel number GPE and/or last recorded error cancelled transfer
24 SAE	Source address error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCD*n*_SADDR field. TCD*n*_SADDR is inconsistent with TCD*n*_ATTR[SSIZE]

Table 288. DMA_ES field descriptions(Continued)

Field	Description
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_SOFF field. TCD*n*_SOFF is inconsistent with TCD*n*_ATTR[SSIZE].
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DADDR field. TCD*n*_DADDR is inconsistent with TCD*n*_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DOFF field. TCD*n*_DOFF is inconsistent with TCD*n*_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_NBYTES or TCD*n*_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCD*n*_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCD*n*_CSR[ESG] is enabled. TCD*n*_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

24.3.3 Enable Request Register Low (DMA_ERQL)

The ERQL registers provide a bit map for the 32 implemented channels to enable the request signal for each channel. EQRL covers channels 31–00.

The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQL.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

24.3.4 Enable Error Interrupt Register Low (DMA_EEIL)

The Enable Error Interrupt Register Low (DMA_EEIL) provides a bit map for the 32 channels to enable the error interrupt signal for each channel. EEIL covers channels 1531–00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEIL registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

24.3.5 Set Enable Request Register (DMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQL to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQL to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000 + 0x0018 Access: User write-only

1 SAER	Set all enable requests 0Set only those ERQ bits specified in the SERQ field 1Set all bits in ERQL
2–7 SERQ	Set enable request Sets the corresponding bit in ERQL

24.3.6 Clear Enable Request Register (DMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQL to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQL to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQL to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

24.3.7 Set Enable Error Interrupt Register (DMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEIL to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be set. Setting the SAEE bit provides a global set function, forcing the entire EEIL contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 SAEE	Sets all enable error interrupts 0Set only those EEI bits specified in the SEEI field. 1Sets all bits in EEI
2–7 SEEI	Set enable error interrupt Sets the corresponding bit in EEIL

24.3.8 Clear Enable Error Interrupt Register (DMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEIL to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEIL to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEIL contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2–7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEIL

24.3.9 Clear Interrupt Request Register (DMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INTL to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INTL to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INTL to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000 + 0x001C Access: User write-only

1 CAIR	Clear all interrupt requests 0Clear only those INT bits specified in the CINT field 1Clear all bits in INTL
2–7 CINT	Clear interrupt request Clears the corresponding bit in INTL

24.3.10 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR{H,L} to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR{H,L} to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR{H,L} contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 CAEI	Clear all error indicators 0Clear only those ERR bits specified in the CERR field 1Clear all bits in ERR
2–7 CERR	Clear error indicator Clears the corresponding bit in ERRL

24.3.11 Set START Bit Register (DMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000 + 0x001E Access: User write-only

Field	Description
0 NOP	0Normal operation 1No operation, ignore bits 1–7 of this register
1 SAST	Set all START bits (activates all channels) 0Set only those TCD*n*_CSR[START] bits specified in the SSRT field 1Set all bits in TCD*n*_CSR[START]
2–7 SSRT	Set START bit Sets the corresponding bit in TCD*n*_CSR[START]

24.3.12 Clear DONE Status Bit Register (DMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: FC0A_0000 + 0x001F Access: User write-only

1 CADN	Clears all DONE bits 0Clears only those TCD*n*_CSR[DONE] bits specified in the CDNE field 1Clears all bits in TCD*n*_CSR[DONE]
2–7 CDNE	Clear DONE bit Clears the corresponding bit in TCD*n*_CSR[DONE]

24.3.13 Interrupt Request Register Low (DMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the lower half of the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INTL.

24.3.14 Error Register Low (DMA_ERRL)

The ERRL provides a bit map for the 32 channels, signaling the presence of an error for each channel. ERRL covers channels 31–00. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16, and 32 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding

channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ{H,L} bits.

24.3.15 Hardware Request Status Register Low (DMA_HRSL)

The HRSL provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. HRSL covers channels 31–00. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQL fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQL bits.

24.3.16 Channel *n* Priority Register (DMA_DCHPRI*n*)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRI*n* register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRI*n* registers. The group priority is assigned in the DMA control register.

Address: FC0A_0000h base + 100h offset + (1d × *n*), where n = 0d to 63d Access: User read/write

Reset(1)	0	0	x	x	x	x	x	x

Figure 219. Channel *n* Priority Register (DMA_DCHPRI*n*)

1. x = Undefined at reset.

Table 302. DMA_DCHPRI*n* field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel *n* cannot be suspended by a higher priority channel's service request 1 Channel *n* can be temporarily suspended by the service request of a higher priority channel
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel *n* can suspend a lower priority channel 1 Channel *n* cannot suspend any channel, regardless of channel priority
2–3 GRPPRI	Channel *n* current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
4–7 CHPRI	Channel *n* arbitration priority Channel priority when fixed-priority arbitration is enabled **Note:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.

24.3.17 Channel *n* Master ID Register (DMA_DCHMID*n*)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (a core, for example) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID*n* registers.

Address: FC0A_0000h base + 140h offset + (1d × n), where n = 0d to 63d Access: User read/write

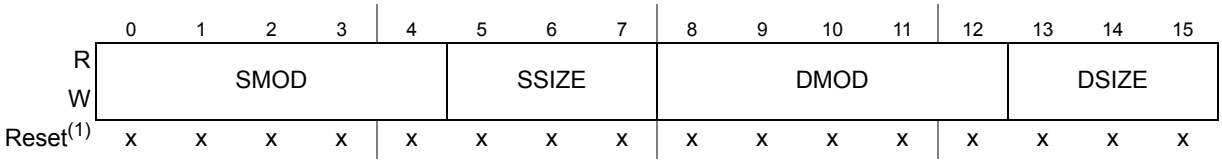

Figure 222. TCD Transfer Attributes (DMA_TCD*n*_ATTR)

1. x = Undefined at reset.

Table 305. DMA_TCD*n*_ATTR field descriptions

Field	Description
16–20 SMOD	Source address modulo. 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
21–23 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 Reserved 100 16-byte 101 Reserved 110 Reserved 111 Reserved
24–28 DMOD	Destination address modulo See the SMOD definition
29–31 DSIZE	Destination data transfer size See the SSIZE definition

24.3.20 TCD Signed Source Address Offset (DMA_TCD*n*_SOFF)

See TCD Signed Source Address Offset register figure and DMA_TCD*n*_SOFF field descriptions table as follows.

Figure 224. TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCD*n*_NBYTES_MLNO)

1. x = Undefined at reset.

Table 307. DMA_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **Note:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

24.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCD*n*_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

Address: FC0A_0000h base + 1008h offset + (32d × n), where n = 0d to 63d Access: User read/write

1. x = Undefined at reset.

24.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset enabled (SMLOE or DMLOE = 1)

Address: FC0A_0000h base + 1008h offset + (32d × n), where n = 0d to 63d Access: User read/write

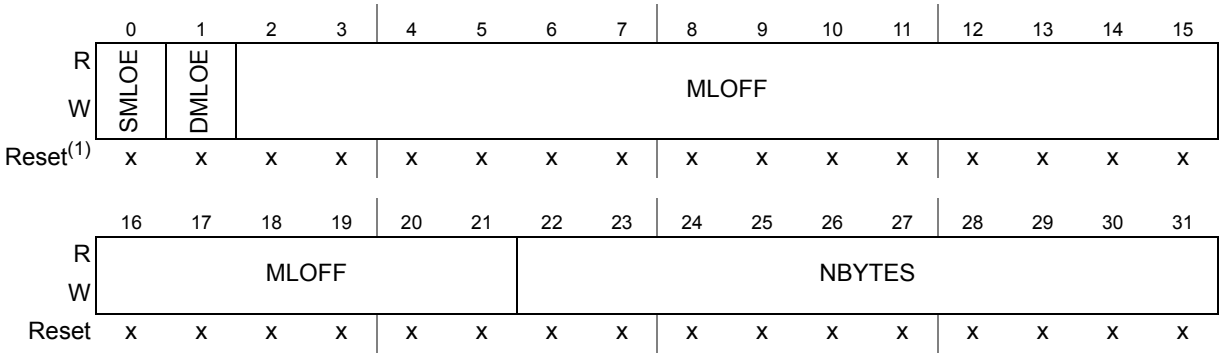

Figure 226. TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCD*n*_NBYTES_MLOFFYES)

1. x = Undefined at reset.

Table 308. DMA_TCD*n*_NBYTES_MLOFFYES field descriptions

Field	Description
0 SMLOE	Source minor loop offset enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
1 DMLOE	Destination minor loop offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
2–21 MLOFF	If SMLOE or DMLOE is set, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
22–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

24.3.24 TCD Last Source Address Adjustment (DMA_TCD*n*_SLAST)

Address: FC0A_0000h base + 100Ch offset + (32d × n), where n = 0d to 63d

1. x = Undefined at reset.

Table 311. DMA_TCD*n*_CITER_ELINKYES field descriptions

Field	Description
16 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
17–22 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.
23–31 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (e.g., final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **Note:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

24.3.27 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCD*n*_CITER_ELINKNO)

See TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) register figure and DMA_TCDn_CITER_ELINKNO field descriptions table as follows.

Address: FC0A_0000h base + 1014h offset + (32d × n), where n = 0d to 63d Access: User read/write

Field	Description
16 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel.If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
17–31 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (for example, final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **Note:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

24.3.28 TCD Signed Destination Address Offset (DMA_TCD*n*_DOFF)

See TCD Signed Destination Address Offset register figure and DMA_TCD*n*_DOFF field descriptions table as follows.

Table 314. DMA_TCD*n*_DLASTSGA field descriptions

Field	Description

0–31
DLASTSGA
	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather).
	If (TCD*n*_CSR[ESG] = 0) then
	– Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure.
	else
	– This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, else a configuration error is reported.

24.3.30 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCD*n*_BITER_ELINKYES)

Address: FC0A_0000h base + 101Ch offset + (32d × n), where n = 0d to 63d Access: User read/write

Field	Description
16 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
17–31 BITER	Starting major iteration count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field. **Note:** When the software loads the TCD, this field must be set equal to the corresponding CITER field. Otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

24.3.32 TCD Control and Status (DMA_TCD*n*_CSR)

See TCD Control and Status register figure and DMA_TCD*n*_CSR field descriptions table as follows.

Address: FC0A_0000h base + 101Eh offset + (32d × n), where n = 0d to 63d Access: User read/write

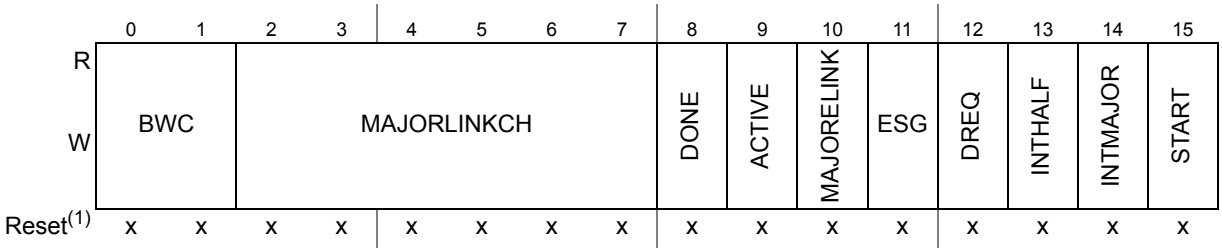

Figure 235. TCD Control and Status (DMA_TCD*n*_CSR)

1. x = Undefined at reset.

Table 317. DMA_TCD*n*_CSR field descriptions

Field	Description
16–17 BWC	Bandwidth control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBAR). **Note:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w

18–23
MAJORLINKCH
	Link channel number
	If (MAJORELINK = 0) then
	– No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted.
	else
	– After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCD*n*_CSR[START] bit.

24 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **Note:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
25 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.

Table 317. DMA_TCD*n*_CSR field descriptions(Continued)

Field	Description
26 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCD*n*_CSR[START] bit of the specified channel. **Note:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
27 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. **Note:** To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCD*n*_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
28 DREQ	Disable request 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
29 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **Note:** If BITER is set, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled 1 The half-point interrupt is enabled
30 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
31 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started 1 The channel is explicitly started via a software initiated service request

24.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

24.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
  - Address path:

    This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

    When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n* _{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the TCD*n* _CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
  - Data path:

    This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

    The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
  - Program model/channel arbitration:

    This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
  - Control:

    This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-

bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

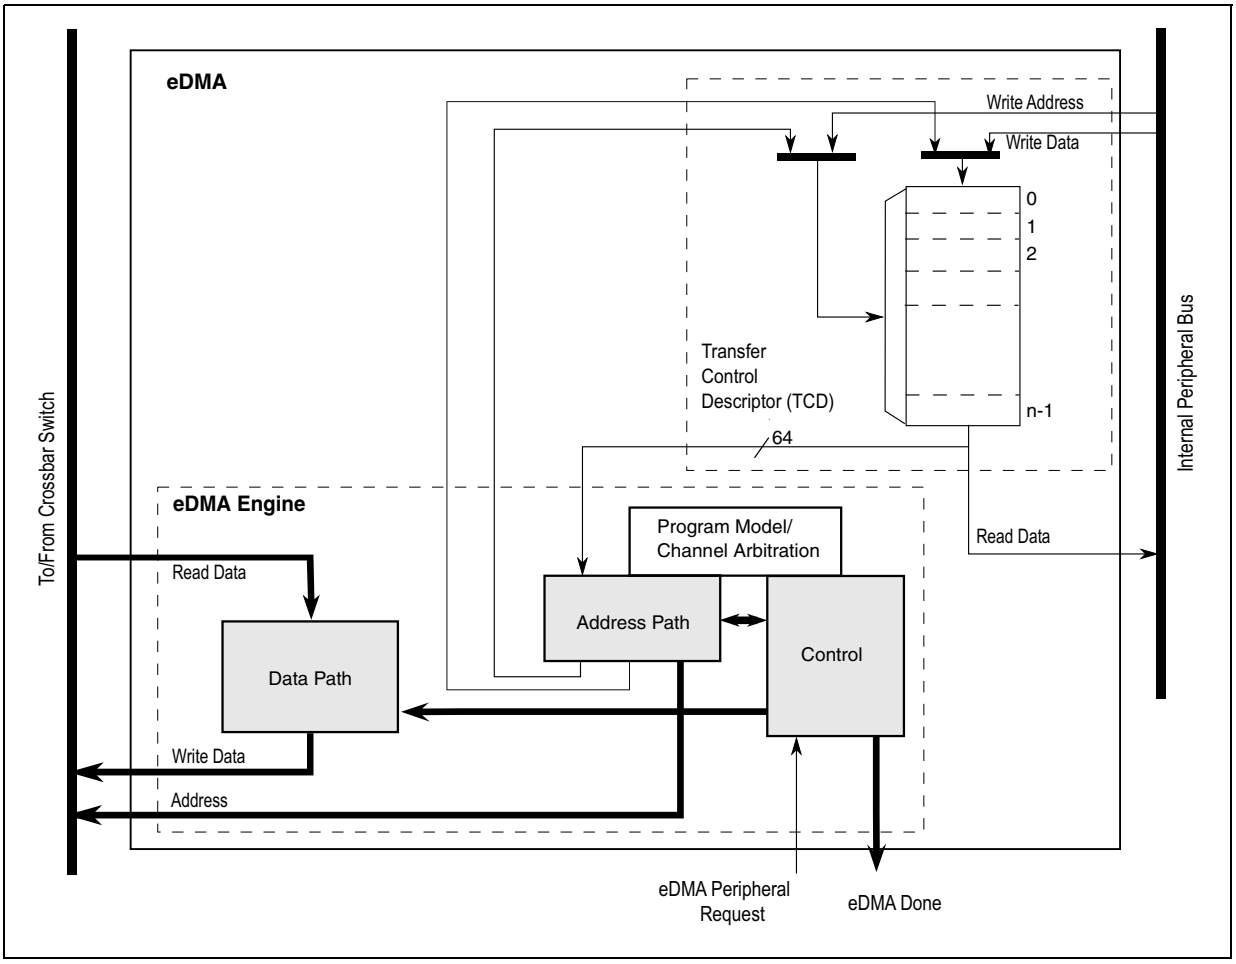
- Transfer control descriptor memory
  - Memory controller:

    This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

    As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
  - Memory array:

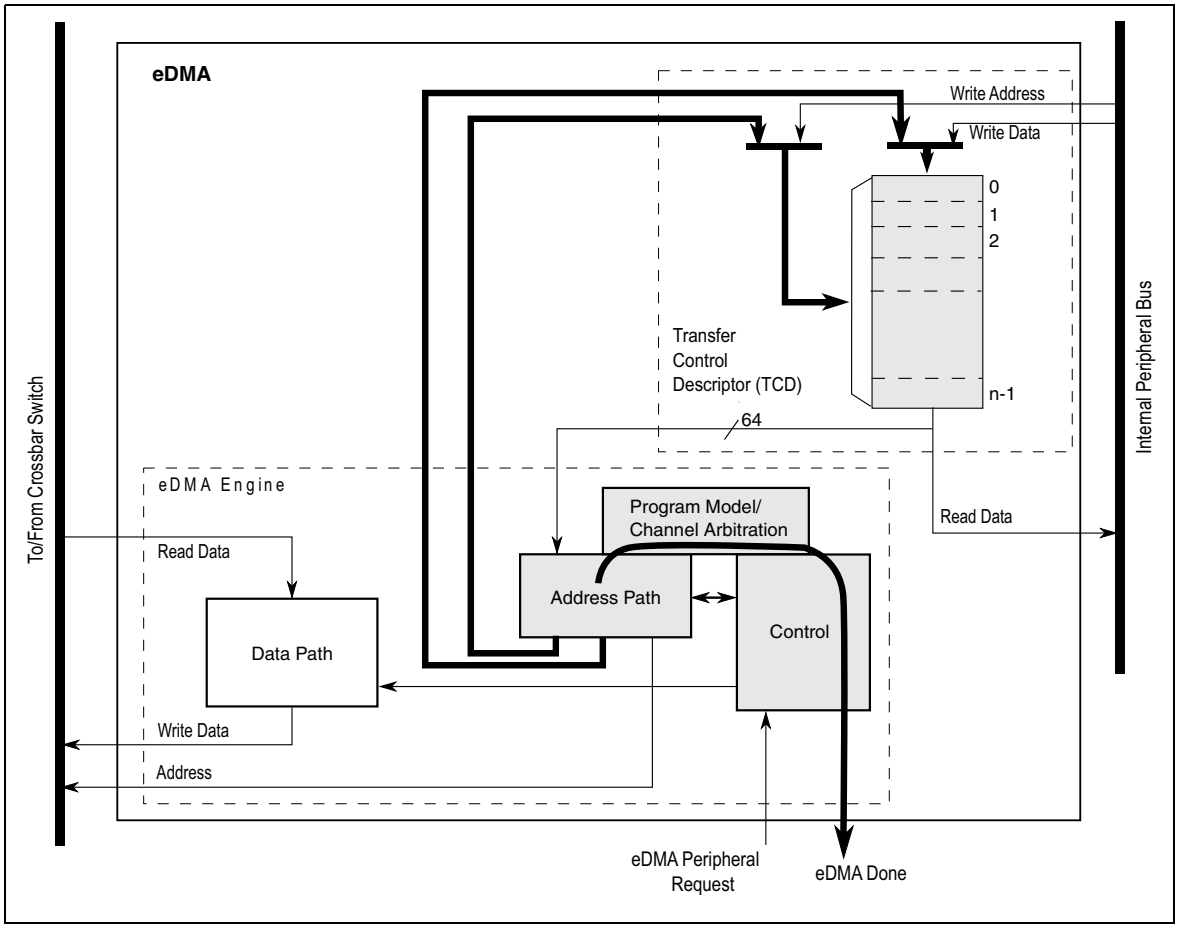
    TCD storage is implemented using a single-port, synchronous RAM array.

24.4.2 eDMA basic data flow



The basic flow of a data transfer can be partitioned into three segments. As shown in *Figure 236*, the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

Figure 236. DMA operation, part 1



In the second part of the basic data flow as shown in *Figure 237* the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

Figure 237. DMA operation, part 2

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in *Figure 238*.

Figure 238. DMA operation, part 3

24.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle.

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively.
- In Fixed Arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups.

All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when Fixed Arbitration mode is enabled.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCD*n*_CITER[E_LINK] bit does not equal the TCD*n*_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

24.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRI*n*[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRI*n*[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

24.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in *Table 318* and *Table 319*. The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- All internal peripheral bus accesses are 32 bits in size.
- All internal SRAM accesses are 64 bits in size.

Table 318 presents a peak transfer rate comparison, measured in megabytes per second.

Table 318. eDMA peak transfer rates (Mbyte/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0

Table 318. eDMA peak transfer rates (Mbyte/s)(Continued)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCD*n* _CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* Word 7).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
- Cycles 8 to *x*[f]: The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

  The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles.

f. "*x*" represents an undefined cycle value dependant on transfer sizes and response times for the channel's read and write accesses.

For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles.

- Cycle x^f + 1: This cycle represents the data phase of the last destination write.
- Cycle x^f + 2: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* Word 7 is read and checked for channel linking or scatter/gather requests.
- Cycle x^f + 3: The appropriate fields in the first part of the TCD*n* are written back into the local memory.
- Cycle x^f + 4: The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle x^f + 5: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles (4 + (3 + 3)/2 + 3). This is the time from Cycle 4 to Cycle *x* + 5. The resulting peak request rate, as a function of the system frequency, is shown in *Table 319*. This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

Table 319. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

Equation 1 PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to internal peripheral bus transfer,

Equation 2 PEAKreq = 150 MHz / [4 + (1 + 0) + (1 + 1) + 3] cycles = 15.0 Mreq/s

For an internal peripheral bus-to-SRAM transfer,

Equation 3 PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 0) + 3] cycles = 15.0 Mreq/s

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCD*n*_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

24.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

24.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by software (setting the TCD*n*_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal).

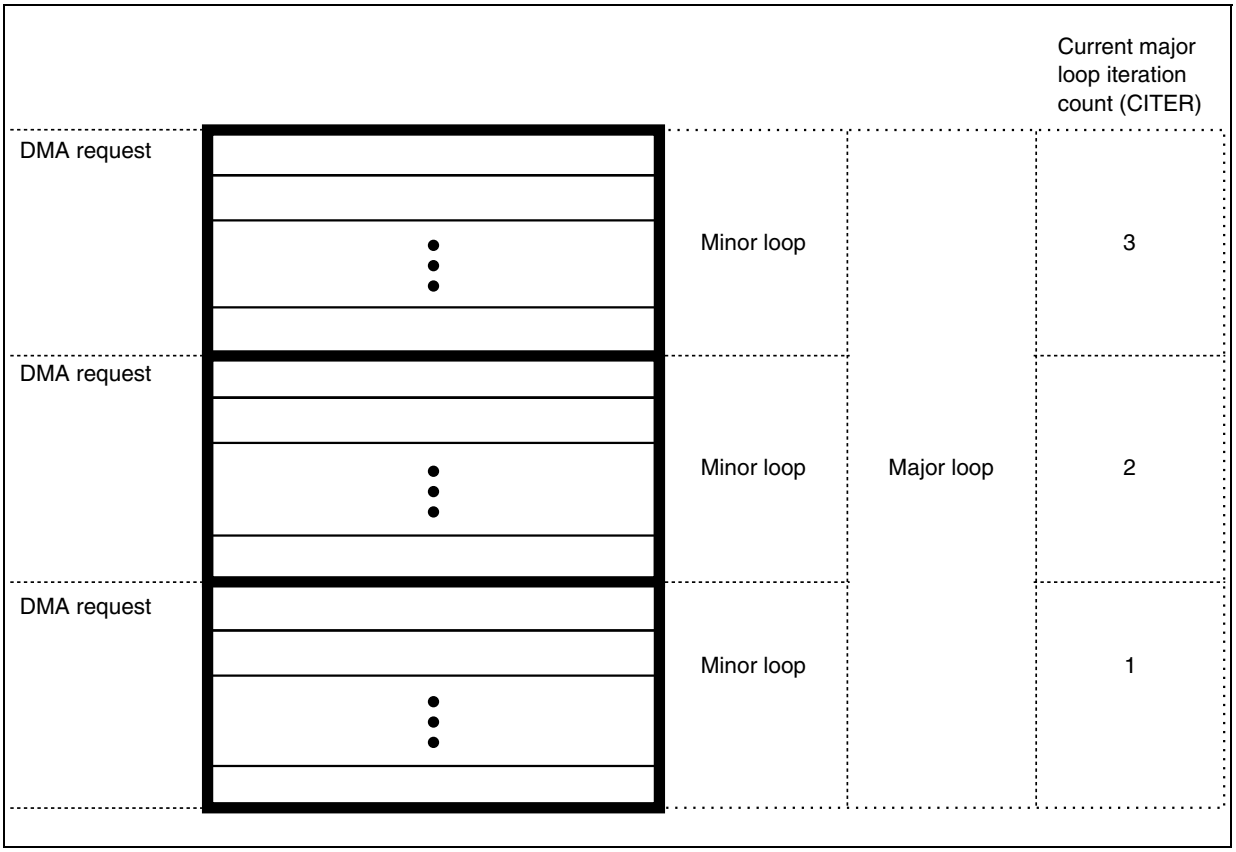
After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in *Table 320*) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCD*n*_SADDR) to the destination (as defined by the destination address, TCD*n*_DADDR) continue until the specified number of bytes (TCD*n*_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

Table 320. TCD control and status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

Figure 239 shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 239. Example of multiple loop iterations



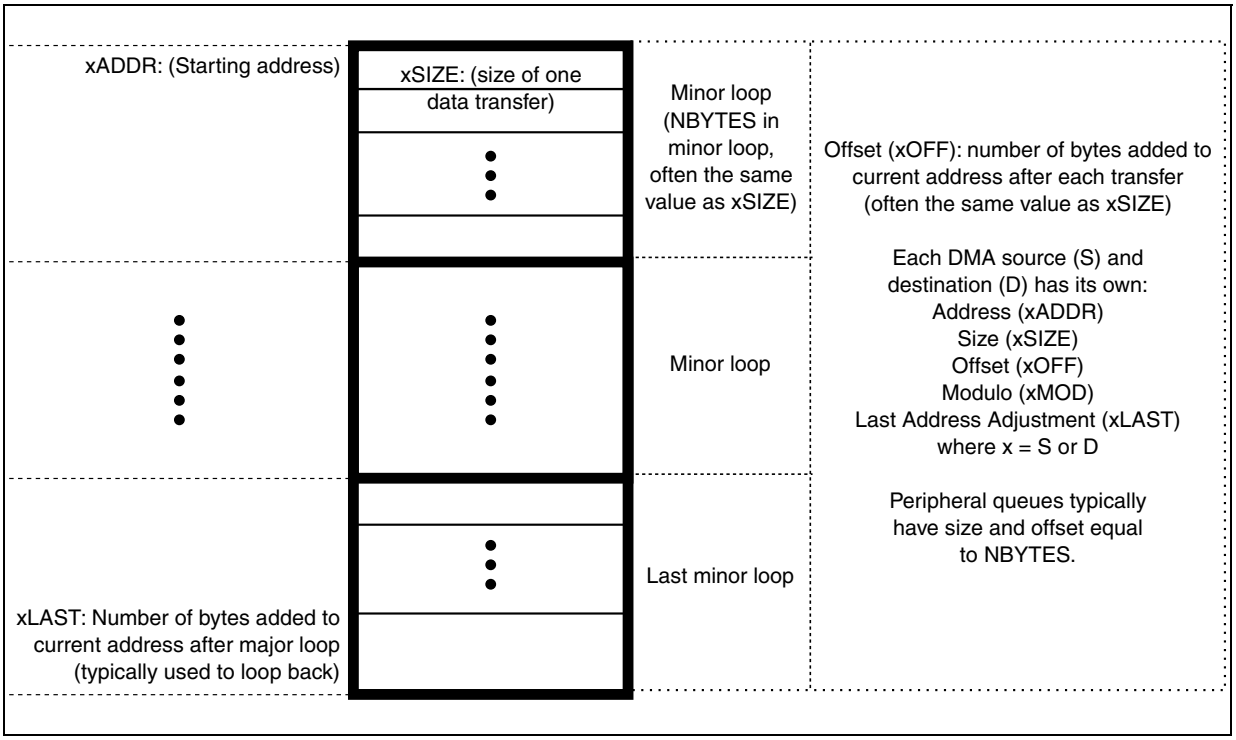


Figure 240 lists the memory array terms and how the TCD settings interrelate.

Figure 240. Memory array terms

24.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: group priority error (ES[GPE]) and channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. Once all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until all of the Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the

ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

24.5.3 DMA Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

24.5.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller—that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

24.5.3.2 Round-robin group arbitration, fixed-channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with an service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

24.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in *Section 24.5.3.2: Round-robin group arbitration, fixed-channel arbitration*, but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

24.5.3.4 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in *Section 24.5.3.1: Fixed-group arbitration, fixed-channel arbitration* but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get very much longer and longer as the group priority decreases.

24.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

24.5.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
```

```
TCDn_CSR[START] = 1 (Should be written last after all other fields have
been
    initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h) Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

24.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as previous. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h) Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
   a) Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
   b) Write 32 bits to location 0x2010 → first iteration of the minor loop.
   c) Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
   d) Write 32 bits to location 0x2014 → second iteration of the minor loop.
   e) Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
   f) Write 32 bits to location 0x2018 → third iteration of the minor loop.
   g) Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
   h) Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2(TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

24.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

Table 321 shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 321. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

24.5.5 eDMA TCD*n* status monitoring

This section discusses how to monitor eDMA status.

24.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute a sequence for a software activated channel as shown in the following table.

Table 322. TCD status sequence – software activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing

Table 322. TCD status sequence – software activated channel(Continued)

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute a sequence for a hardware-activated channel as shown in the following table.

Table 323. TCD status sequence – hardware activated channel

Step	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit. The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

24.5.5.2 Active channel TCD*n* reads

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

24.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in Fixed-Group, Fixed-Channel Arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal (constantly rotating) when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set

simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

24.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note: The TCDn_CITER[E_LINK] bit and the TCDn_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

Table 324 summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 324. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	

Table 324. Channel linking parameters(Continued)

Desired link behavior	TCD control field name	Description
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

24.5.7 Dynamic programming

24.5.7.1 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode.
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

24.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in *Table 325* is recommended when executing a dynamic channel link request.

Table 325. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: – If TCD.major.e_link = 1b, the dynamic link attempt was successful. – If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

24.5.7.3 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note: The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

24.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in *Table 326* may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 326. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
3	Write theTCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.

Table 326. Coherency model for method 1(Continued)

Step	Action
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

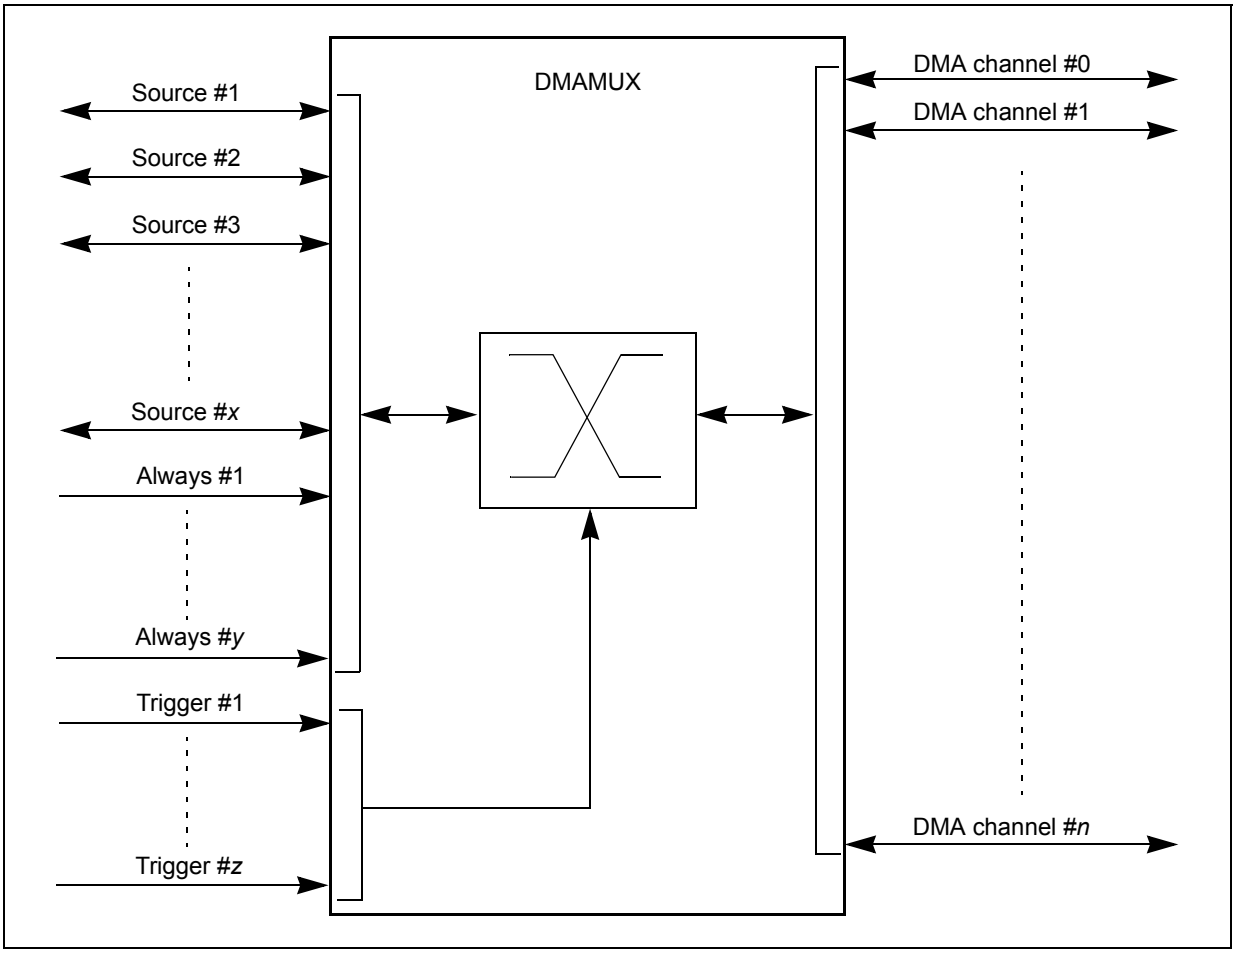
24.5.7.3.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in *Table 327* may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 327. Coherency model for method 2

Step	Action
1	Write 1b to theTCD.d_req bit. **Note:** Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.
2	Write theTCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b, read the 32 bit TCD dlast_sga field. – If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

25 Direct Memory Access Multiplexer (DMAMUX)



25.1 Introduction

Note: For the chip-specific implementation details of this module's instances, see the chip configuration information.

25.1.1 Overview

The Direct Memory Access Multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in *Figure 241*.

Figure 241. DMAMUX block diagram

25.1.2 Features

The DMAMUX module provides these features:

- Up to 64 peripheral slots and up to six always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
  - The first eight channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

25.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

  In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.
- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.
- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically. Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–5.

25.2 External signal description

The DMAMUX has no external pins.

25.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

Table 328. DMAMUX memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Channel Configuration register (DMAMUX_CHCFG0)	8	R/W	00h	*25.3.1/781*
1	Channel Configuration register (DMAMUX_CHCFG1)	8	R/W	00h	*25.3.1/781*
2	Channel Configuration register (DMAMUX_CHCFG2)	8	R/W	00h	*25.3.1/781*

25.3.1 Channel Configuration register (DMAMUX_CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

Note: Setting multiple CHCFG registers with the same source value will result in unpredictable behavior.

Note: Before changing the trigger or source settings, a DMA channel must be disabled via CHCFGn[ENBL].

Address: 0h base + 0h offset + (1d × i), where i=0d to 15d Access: User read/write

	0	1	2	3	4	5	6	7
R W	ENBL	TRIG	SOURCE					
Reset	0	0	0	0	0	0	0	0

Figure 242. Channel Configuration register (DMAMUX_CHCFGn)

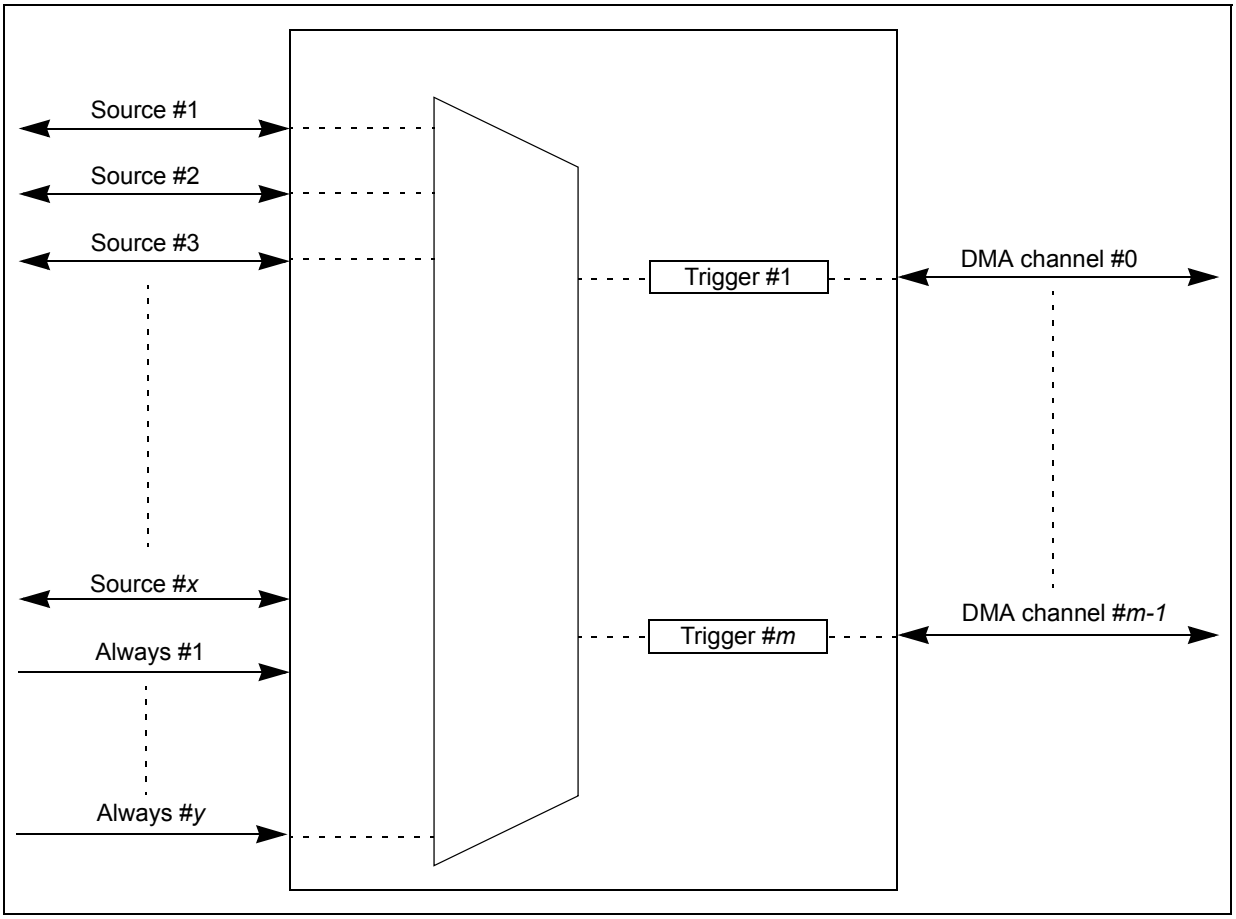
Table 329. DMAMUX_CHCFGn field descriptions

Field	Description
0 ENBL	DMA Channel Enable. Enables the DMA channel 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMUX. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled.
1 TRIG	DMA Channel Trigger Enable . Enables the periodic trigger capability for the triggered DMA Channel. 0 Triggering is disabled. If triggering is disabled and ENBL is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and ENBL is set, the DMAMUX is in Periodic Trigger mode.
2–7 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See your device's chip configuration details for information about the peripherals and their slot numbers.

25.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in *Section 25.5.2, Enabling and configuring sources* is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

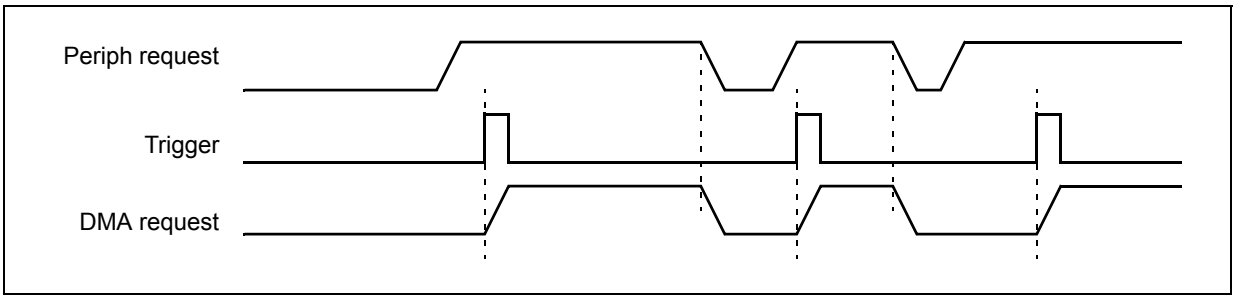
Functionally, the DMAMUX channels may be divided into two classes:



- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

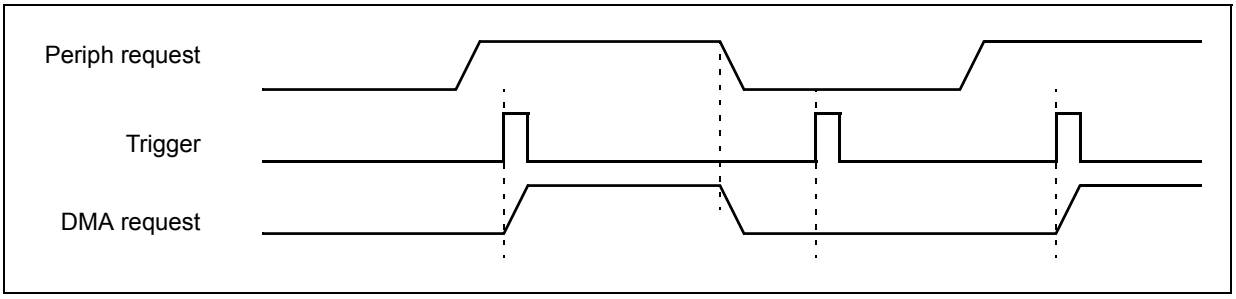
25.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention. The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.



Note: Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 243. DMAMUX triggered channels



The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in *Figure 244*.

Figure 244. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral re-asserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer,then that trigger will be ignored. This situation is illustrated in *Figure 245*.

Figure 245. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 µs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

25.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in *Section 25.1.3, Modes of operation*.

25.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are six additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always

enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.
- Use an always-enabled DMA source.

  In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

25.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

25.5.1 Reset

The reset state of each individual bit is shown in *Section 25.3: Memory map/register definition*. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

25.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

Note: The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"
         :
         :
*CHCFG1 = 0x00;
*CHCFG1 = 0xC5;
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

Note: The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
```

```
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
         :
         :
*CHCFG1 = 0x00;
*CHCFG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8 (base address + 0x08).
3. Write 0x87 to CHCFG8 (base address + 0x08). (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality).

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCFG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCFG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCFG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCFG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCFG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCFG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCFG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
```

```
volatile unsigned char *CHCFG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCFG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCFG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCFG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCFG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCFG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCFG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCFG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCFG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
         :
         :
*CHCFG8 = 0x00;
*CHCFG8 = 0x87;
```

26 Clocking

26.1 Introduction

This chapter describes the architecture of the system level clocks and includes the following information:

- System clock specifics.
- Clock architecture.
- Clock sources.
- Clock monitoring.
- Programmable clock dividers.
- Clock control registers.
- Progressive Clock Switching (PCS).

Note: This chapter only covers clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.

The system clock (CLKOUT) services the computational shell (includes the main CPUs Main Core_0 and Checker Core_0s), modules that run in the high-speed domain, memories and debug logic. Its independence from the peripheral clocks allows CLKOUT to be a frequency modulated (FM) clock with reduced electromagnetic emissions while having a precise clock for the peripheral timer and communication functions. It can be reduced during low computational activity periods to lower power consumption while providing a fixed frequency to the communication interfaces and timers.

The internal 16 MHz RC oscillator (IRCOSC) services device boot up and may be enabled via the Mode Entry Module as a backup clock in the event of PLL or external oscillator failure. See the “Mode Entry Module (MC_ME)” chapter for details.

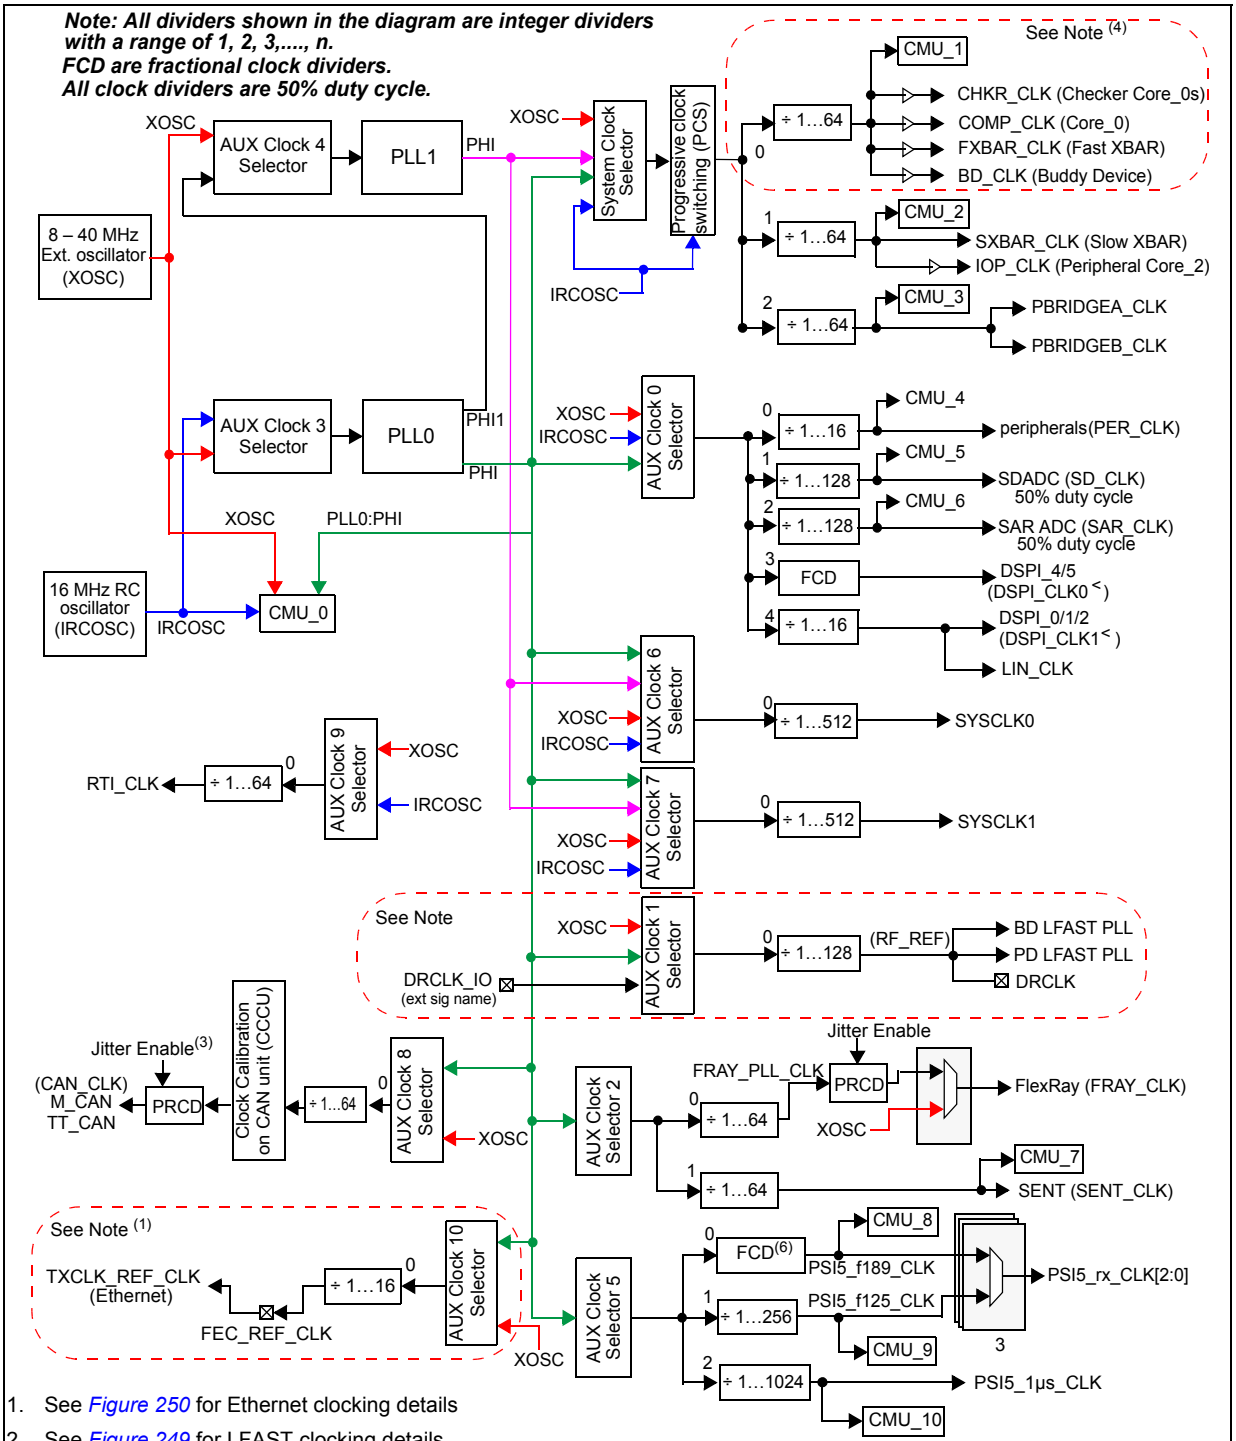
The alternative clock sources are:

- External oscillator/crystal (XOSC).
- Internal 16 MHz RC oscillator (IRCOSC).
- PLL0 (PLL0_PHI).
- PLL1 (PLL1_PHI).

Auxiliary Clock Selectors in the Clock Generation Module (MC_CGM) allow developers to select an independent clock source for each system peripheral. There is an additional System Clock Selector used exclusively for the system clock.

The outputs of the module clock selectors have individual dividers that can divide the clock selector outputs by up to 512 for a given peripheral.

Clock Monitor Units (CMUs) are connected to outputs of clock dividers to verify that clock frequencies stay within operating limits and can be configured to signal an interrupt or initiate a system reset when an issue with a clock is found.



26.2 Clock generation

The top-level clock generation architecture can be seen in *Figure 246*. See the Clock Generation Module (MC_CGM) chapter for details on the Fractional Clock Dividers. All clock selectors and dividers are located and programmed in the MC_CGM. All dividers are integer

dividers (1, 2, 3, …, *n*) with the ranges shown in the divider blocks in *Figure 246*. All dividers connected to the System Clock Selector must have 50% duty cycle outputs.

Note: Clock Monitoring Units CMU1 to CMU10 in Figure 246 use IRCOSC as their reference clock. The user can select either IRCOSC or XOSC as the reference clock for CMU_0.

Figure 246. Clock generation

1. See *Figure 250* for Ethernet clocking details
2. See *Figure 249* for LFAST clocking details
3. See the “Password and Device Security Module (PASS)” chapter for Jitter Enable details.
4. The COMP_CLK and CHKR_CLK clock trees are isolated downstream of System Clock Divider 0. Isolation is maintained in the phyiscal design of the clock trees.
5. DSPI_CLK1 and DSPI_CLK0 are the protocol clocks as described in the “Deserial Serial Peripheral Interface (DSPI)” chapter.
6. See the MC_CGM chapter for details of the Fractional Clock Divider (FCD).

26.2.1 MC_CGM registers

Table 330 shows the relationship between the clocks in *Figure 246* and the MC_CGM registers.

Table 330. MC_CGM relationship to clocks(1)

MC_CGM register(s)	Register description	Output clock	CMU(2)

2. CMU_0 is not shown in table since it does not monitor an output clock from the MC_CGM.

26.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in *Table 331*.

Table 331. Maximum system level clock frequencies[1]

System clock	Max frequency (MHz)	Relation between main clock (System Clock Divider 0, *Figure 246*) and other clocks	
		ratio	max ratio
Safety Core (Main Core_0, Checker Core_0s)	160	1:1	1:1
Computational Shell XBAR	160	1:1	1:1
Peripheral Core_2, Peripheral Shell XBAR	80	1:2	1:2
PBRIDGE_A	40	1:2n (n integer)	1:2
PBRIDGE_A GTM Slot[2]	80	1:2p (p integer)[3]	1:2
PBRIDGE_B	40	1:2n (n integer)	1:2
DMA	80	1:2	1:2
Interrupt Controller	40	1:4	1:4
Peripheral Clock	80	any	1:2
ADCs	16	any	1:2
Ethernet FEC_REF_CLK, TXCLK, RXCLK	50, 25, 25	any	1:2

1. The user is responsible to verify that these values are not exceeded.
2. Each AIPS bridge (PBRIDGE_A, PBRIDGE_B) is capable of clocking the AIPS interface of each peripheral slot individually at the slow XBAR frequency, or at the slow XBAR frequency divided by two. The GTM is clocked at the slow XBAR frequency, and all other peripherals on both AIPS bridges are clocked at the slow XBAR frequency divided by two.
3. Clock ratio is defined through the field MC_CGM.SC_DC[n].DIV0+1. To ensure configuration, an even ratio, DIV0 has to be odd (DIV0 = 2n-1, with n>0).

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

Note: IOP_CLK and PBRIDGEx_CLK are not required to be at the same frequency.
COMP_CLK, CHKR_CLK and FXBAR_CLK must always be at the same frequency.
IOP_CLK and SXBAR_CLK must always be at the same frequency.

26.3.1 JTAG frequencies

Table 332 shows the maximum frequencies of the JTAG interface.

Table 332. JTAG frequencies

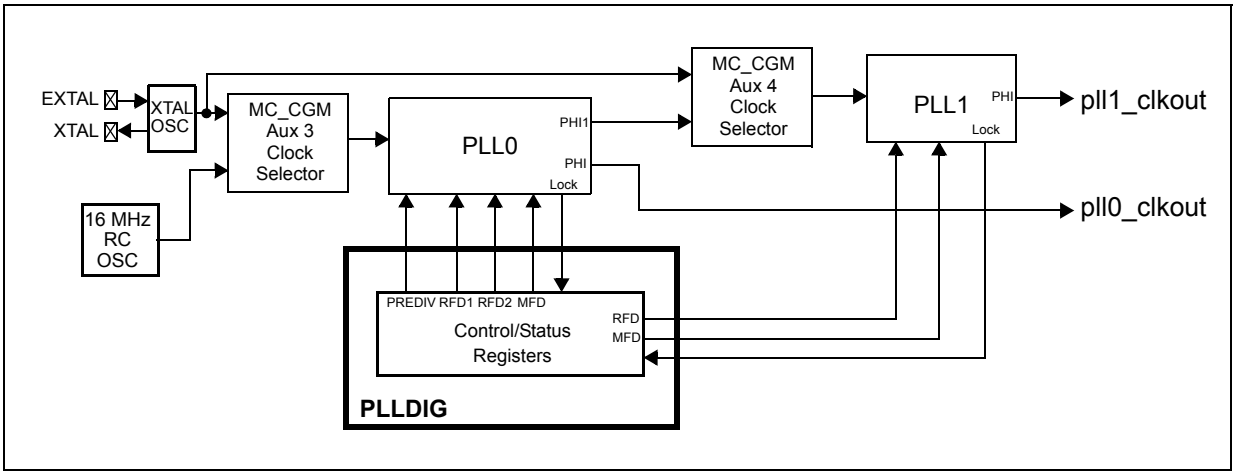
Device	Configuration	e200z4 max. internal JTAG frequency(1)	e200z2 max. internal JTAG frequency<Cross Refs>1	Buddy device max. RWA internal frequency	Max. external JTAG frequency	Notes
PD(2)	Unconfigured clock	—	—	N/A	See electrical characteristics for maximum usable external JTAG frequency	Assumes 16 MHz clock on PD (IRC) with +/– 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 160 MHz	80 MHz	40 MHz			JTAG usable at 1/2 CPU frequency
ED(3)	BD only powered	N/A	N/A	22.4 MHz		BD clocked by internal 64 MHz RC clock (RCOSC64) with +/– 30% tolerance and BD RWA usable at /2 frequency
	PD and BD powered, unconfigured clock	—	—	—		ED clocked by internal 8 MHz RC clock (IRC) with +/– 1.5% tolerance, and BD RWA usable at /2 frequency
	PD and BD powered, PD clock configured clock to 160 MHz	80 MHz	40 MHz	80 MHz		100 MHz JTAG achievable using LFAST mode debug, or s/w mode JTAGM. JTAG messages are generated internally by JTAGM and stay within BD and PD domain. The external tool interface is LFAST only

1. Frequency can further be limited due to device implementation. Refer to datasheet for maximum NEXUS communication frequency
2. PD = Production Die
3. ED = Emulation and Debug Device = Production Die + Buddy Die

26.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to ‘1’ at power on reset.

26.5 Clock sources



The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- External oscillator (XOSC)/External clock (EXTAL bypass)
- 16 MHz internal RC oscillator (IRCOSC)

26.5.1 PLL

The Dual PLL provides separate system and peripheral clocks as shown in *Figure 246*. The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in *Figure 247*.

Figure 247. SPC574Kx Dual PLL digital interface block diagram

26.5.1.1 PLL0 — base PLL (non-FM)

This primary PLL provides a clock that is not Frequency Modulated to the peripheral IPs and the reference clock to PLL1.

The input clock sources for PLL0 are:

- XOSC
- IRCOSC
- The external reference clock (input on the EXTAL pin)

The output clocks from PLL0 are:

- PHI—drives the peripheral clock and the system clock when PLL1 is not locked or active.
- PHI1—provides the input reference clock for PLL1.

26.5.1.2 PLL1 — FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

The input clocks to PLL1 are:

- PHI1 output clock from PLL0
- The external reference clock.

The output clock from PLL1 is:

PHI—drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

26.5.1.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the “Dual PLL Digital Interface” chapter.

26.5.1.4 PLL register write protection

The PLL registers defined in *Table 333* have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the PLL register write protection.

Table 333. PLL register write protection(1)

Offset	Register	Protection
00h	PLL0 Control Register (PLL0CR)	Yes
04h	PLL0 Status Register (PLL0SR)	No
08h	PLL0 Divider Register (PLL0DIVR)	Yes
20h	PLL1 Control Register (PLL1CR)	Yes
24h	PLL1 Status Register (PLL1SR)	No
28h	PLL1 Divider Register (PLL1DIVR)	Yes
2Ch	PLL1 Frequency Modulation Register (PLL1FMR)	Yes
30h	PLL1 Fractional Divider Register (PLL1FDR)	Yes

1. See Register Protection Configuration chapter for bit field details.

26.5.1.5 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in *Table 334*. All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 334. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset value (hex)
0008	PLL0DV — PLL0 Divider Register	0000_0000
0028	PLL1DV — PLL1 Divider Register	0000_0000

Table 334. Dual PLL Digital Interface register reset values(Continued)

Offset (hex)	Register	Reset value (hex)
0034	CLKMUX — Clock Multiplexer Control Register	0000_0000
0038	Reserved	—

26.5.1.6 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition. Software may enable or disable an optional backup clock in the PLL.

26.5.1.7 PLLDIG initialization information

Configure PLL0 and related modules.

1. With PLL0 disabled, program PLL0 clock source in MC_CGM_AC3_SC[SELCTL]. Default source is 16 MHz IRCOSC. Write MC_CGM_AC3_SC[SELCTL] = 1 to select XOSC as source.
2. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].
3. If desired, modify the XOSC_CTL[EOCV] to adjust the external oscillator stabilization count, used when the external oscillator is turned on (by the MC_ME).
4. If necessary, modify the CMU frequency meter values (CMU_MDR and CMU_FDR) used to monitor the XOSC frequency. XOSC frequency is compared to the IRCOSC source when XOSC is turned on.

Turn on XOSC and PLL0.

5. Configure a mode configuration for turning on PLL0 and XOSC. In a mode configuration register (for example, MC_ME_DRUN_MC) set MC_ME_<mode>_MC[XOSCON] = 1 and MC_ME_<mode>_MC[PLL0ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 2 for this new mode configuration to use PLL0(PLL0 PHI output) as the sysclk.
6. Enter that mode by two writes to MC_ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

7. Wait for the mode transition to complete by polling MC_ME_GS[S_MTRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:
   - XOSC counter expires (if the new mode configuration changes MC_ME_<mode>_MC[XOSCON] = 1), and
   - PLL is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL0ON] = 1)
8. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Configure PLL1 and related modules.

9. With PLL1 disabled, program PLL1 clock source in MC_CGM_AC4_SC[SELCTL]. Default is MC_CGM_AC4_SC[SELCTL] = 1 which selects XOSC.
10. Program PLL1DV[MFD] and PLL1DV[RFDPHI].
11. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.

Turn on PLL1.

12. Configure a mode configuration for turning on PLL1, and keeping XOSC and PLL1 on. In a mode configuration register (for example, MC_ME_DRUN_MC), initialize MC_ME_<mode>_MC[XOSCON] = 1, MC_ME_<mode>_MC[PLL1ON] = 1 and MC_ME_<mode>_MC[PLL1ON] = 1. If desired, also set MC_ME_<mode>_MC[SYSCLK] = 4 for this new mode configuration to use PLL1 as the sysclk.
13. Enter that mode by two writes to ME_CTRL register to enter that mode. This is required even if entering the same mode.

Wait for the mode transition to complete.

14. Wait for the mode transition to complete by polling MC_ME_GS[S_TRANS] or enabling an interrupt for flag MC_ME_IS[I_MTC]. A timer, even if it is the watchdog, should be used to make sure the mode transition completes. Mode transition will NOT complete until:
    – XOSC counter expires (if the new mode configuration changes XOSCON to 1), and
    – PLL1 is locked (if the new mode configuration changes MC_ME_<mode>_MC[PLL1ON] = 1).
15. Confirm the desired target mode was entered by checking the status of MC_ME_GS[S_CURRENT_MODE].

Note: See the "Mode Entry Module (MC_ME)" chapter in this Reference Manual more details.

26.5.2 External oscillator (XOSC)

The external oscillator (XOSC):

- Is a reference for the on-chip PLLs.
- Can be used as a clock source for the ADCs, timer, serial interfaces, RTI, LFAST and as a system clock source.
- Is available for observation on either of the CLKOUT pins.
- Is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators.
- Automatic Loop Control (ALC) to remove need for external series resistor.
- Gain selection for <= 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues.
- Reference clock to PLL0.
- Reference clock to CMU0 (IRCOSC trimming).
- Option to drive the CAN and FlexRay protocol clocks directly from the XOSC.

The XOSC provides support for 8 – 44 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor.

26.5.2.1 XOSC Start-up

Enabling of the oscillator at startup is determined by a bit in the UTEST row of flash memory. The default value has the XOSC disabled:

UTEST Miscellaneous[7] = 0 (XOSC EN).

If enabled, the oscillator is started in PHASE 3 of the reset sequence: after negation of the internal POR circuits but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors:

UTEST Miscellaneous[6] = 1 (XOSC EXT LOAD).

Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. See the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During PHASE 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module. Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values:

UTEST Miscellaneous[5:1] = 00000b (XOSC LOAD CAP SEL).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value causing an undetectable error in the system.

The XOSC has the ability to be started with either 8 MHz–20 MHz, or 40 MHz–44 MHz crystal. The default value of this field is for an 8 MHz–20 MHz crystal:

UTEST Miscellaneous[10] = 0 (XOSC EN_40MHz).

See the flash memory chapter for more information on the UTEST row programming.

26.5.2.2 XOSC register write protection

The XOSC registers defined in *Table 335* have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the XOSC register write protection.

Table 335. XOSC register write protection(1)

Offset	Register	Protections?
00h	XOSC_CTL—XOSC Control Register	Yes

1. See “Register Protection Configuration” chapter for bit field details

26.5.2.3 XOSC reset value

Table 336 shows the default reset value for the XOSC registers.

Table 336. XOSC register reset values

Offset	Register	Reset value
00h	XOSC_CTL—XOSC Control Register	8030_8000h

26.5.3 16 MHz internal RC oscillator (IRCOSC)

The 16 MHz internal RC oscillator default clock is always enabled on reset and can be the clock source for the PLLs. The register interface is for user trimming of the oscillator and dividing output from 1 to 32.

26.5.3.1 IRCOSC register interface

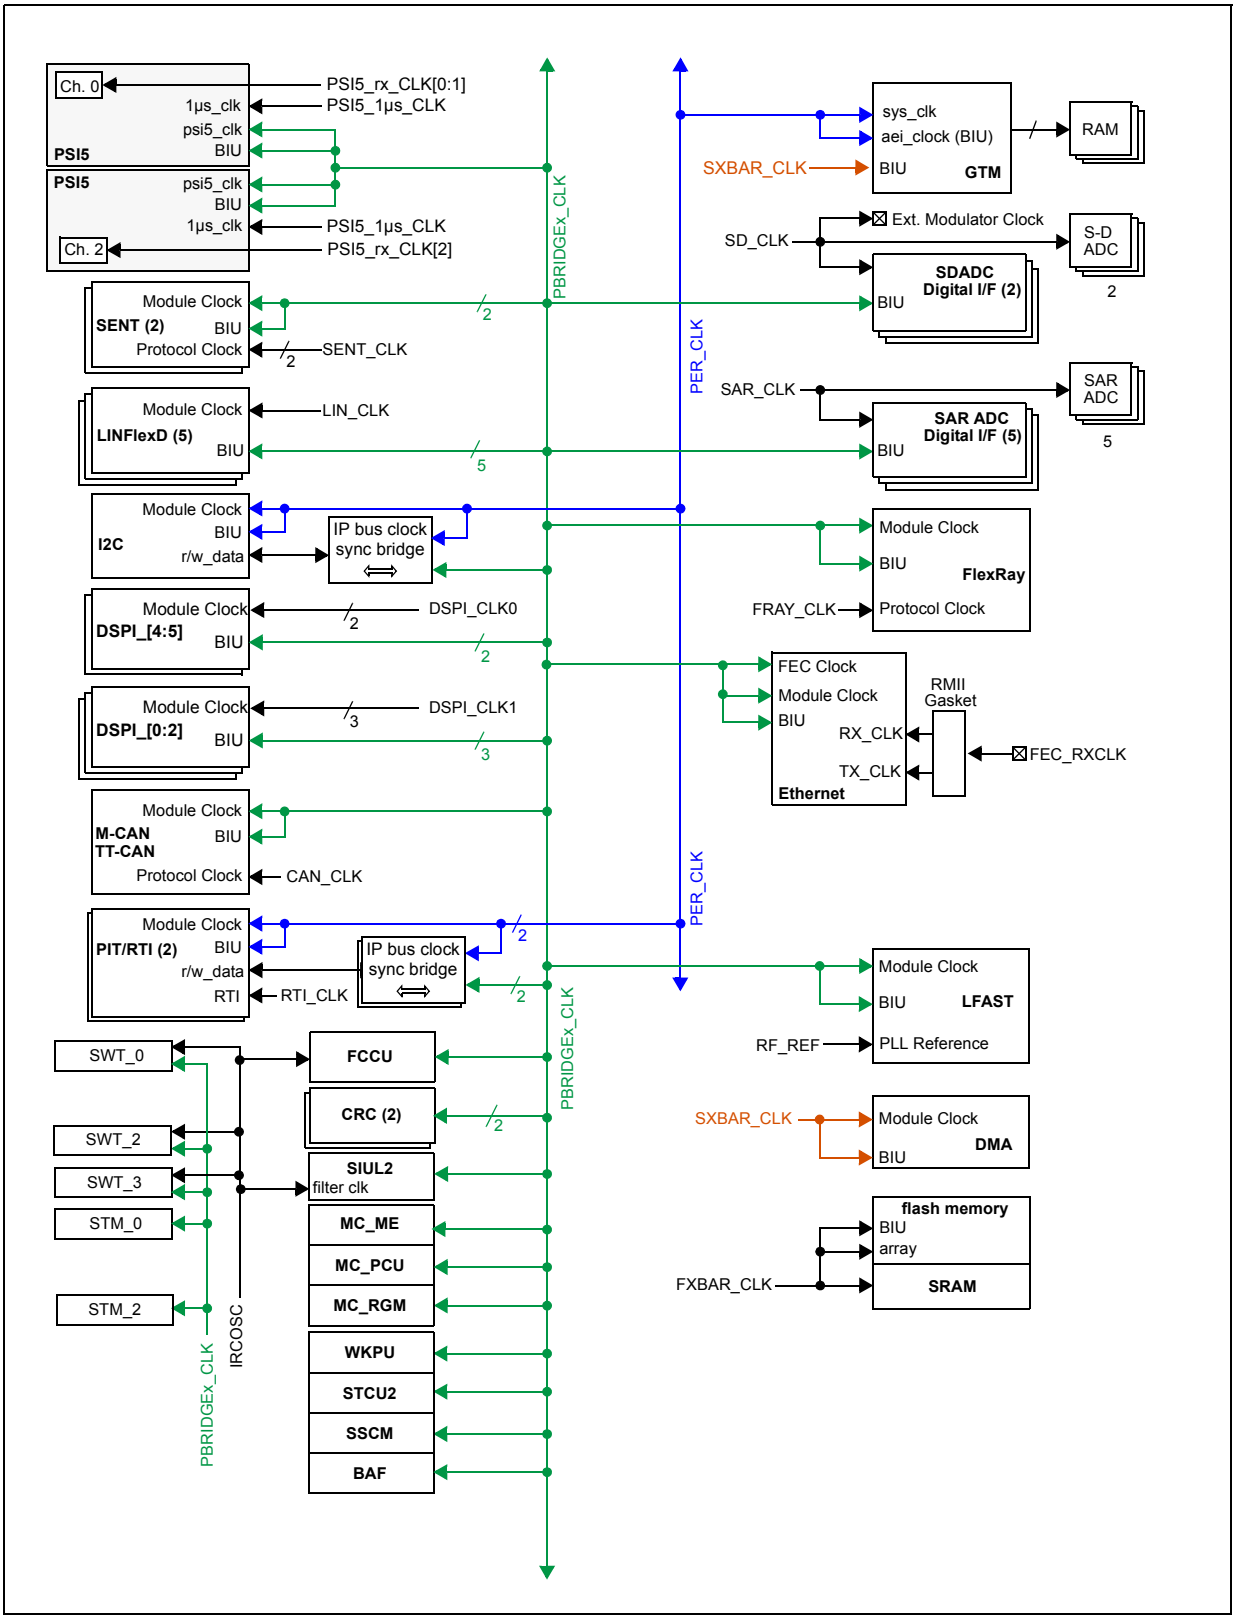
A dedicated digital interface for the IRCOSC has a user register for fine tuning the IRCOSC frequency. Other read-only registers contain settings and values for the IRCOSC temperature sensor, voltage regulator and capacitor trimming.

26.5.3.2 IRCOSC reset value

Table 337 shows the default reset value for the IRCOSC registers.

Table 337. IRCOSC register reset values

Offset	Register	Reset value
04h	NT—IRCOSC Native Trimming Register	0000_0000h
08h	TT—IRCOSC Temperature Trimming Register	0000_0000h



26.5.3.3 IRCOSC register write protection

The IRCOSC registers do not utilize write protection.

26.6 Peripheral clocks

Figure 248 shows the clock distribution to the cores and peripheral modules.

Figure 248. Clock distribution

26.6.1 PSI5 clock dividers

The SPC574Kx microcontroller includes three PSI5 modules, all of which use the three common clocks shown in *Figure 246*. The required frequencies for these clocks are generated from PLL0 as follows:

- $F_{PSI5_f189_CLK} = F_{PLL0_PHI}$ / ((CGM_AC5_DC0[DIV] + 1) / 10CGM_AC5_DC0[FMT]) = 6.048 MHz ±0.1%
- $F_{PSI5_f125_CLK} = F_{PLL0_PHI}$ / (CGM_AC5_DC1[DIV] + 1) = 4 MHz
- $F_{PSI5_1us_CLK} = F_{PLL0_PHI}$ / (CGM_AC5_DC2[DIV] + 1) = 1 MHz

26.6.2 LFAST clocking

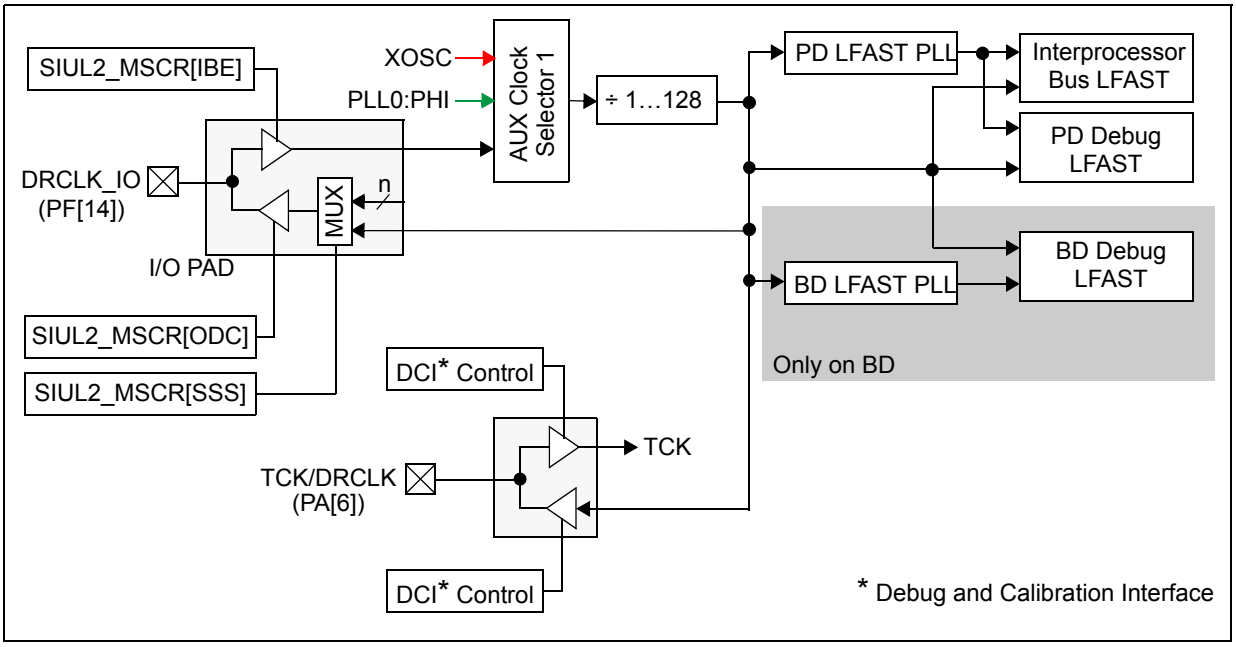
The SPC574Kx includes two LFAST modules:

- In conjunction with the SIPI module for interprocessor communications.
- In conjunction with the JTAGM module for high speed debug.

High-speed operation of both LFAST modules is supported by a single LFAST PLL requiring a 10–20 MHz reference. Low-speed LFAST operation uses the reference clock directly.

The LFAST PLL reference clock source may be:

- PLL0:PHI output.
- External oscillator (XOSC).
- Input from the external LFAST device via the DRCLK_IO package pin.



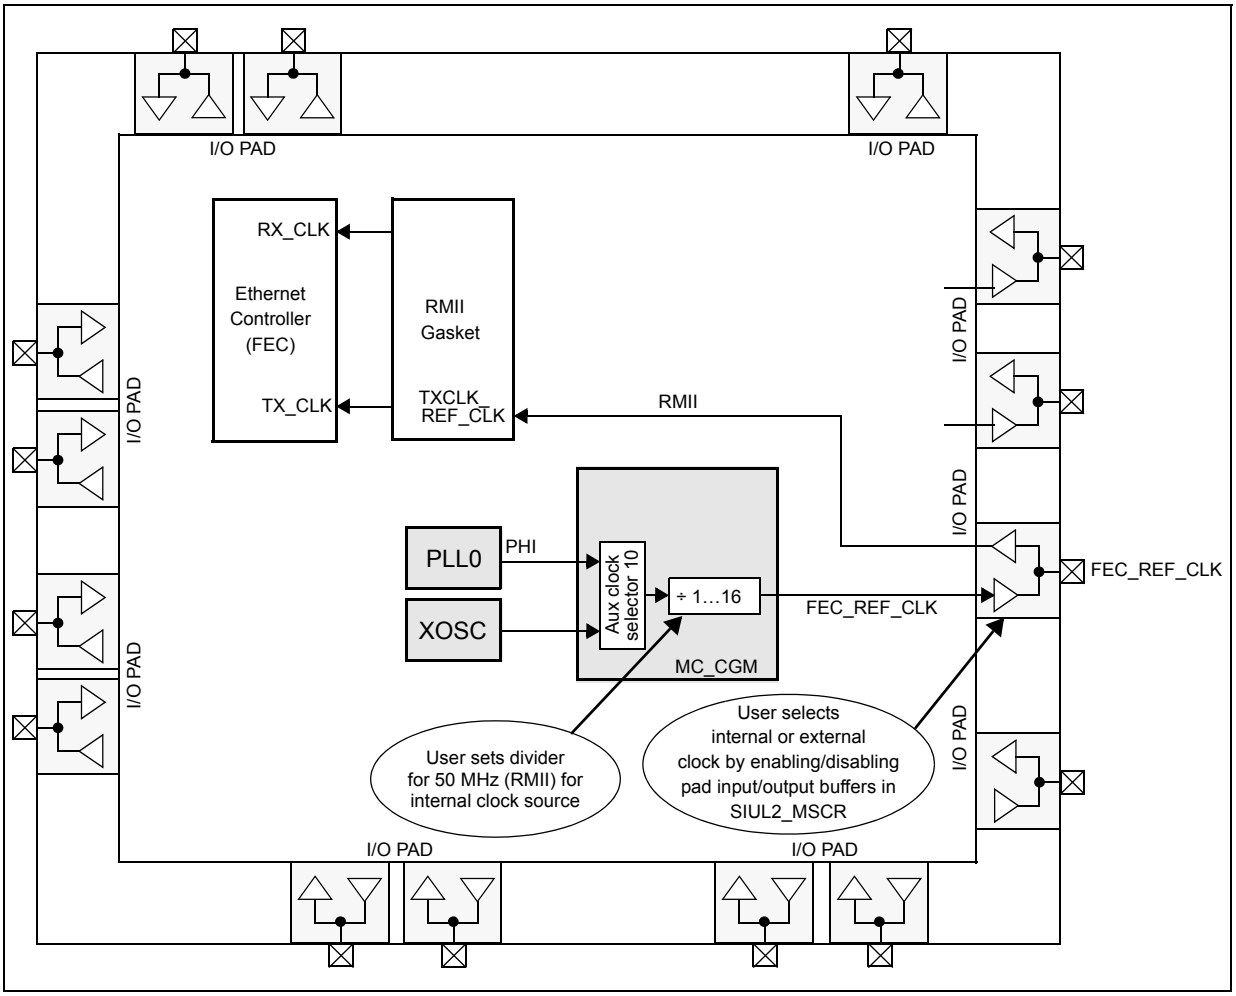
When the reference clock is generated internally, it can be output on the DRCLK_IO pin.

The debug LFAST module only supports the operation mode where it outputs the reference clock to a connected LFAST capable tool as the DRCLK pin only supports output of the DRCLK reference.

On Emulation and Debug Devices (ED), the Buddy Device (BD) LFAST module connects to the package debug pins in place of the Production Device (PD) debug LFAST module. This module has a separate, dedicated LFAST PLL and the DRCLK pin only supports output of the reference clock to a connected LFAST capable tool (as with the Production Device).

Figure 249 shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

Figure 249. Device LFAST clocking



26.6.3 Ethernet clocking

Both internal and external clocks sources for RMII Ethernet interface modes are supported. The RMII clock (FEC_REF_CLK) is 50 MHz. *Figure 250* gives the connections for the Ethernet clocks.

The FEC_REF_CLK can be generated internally or input to the device. FEC_REF_CLK can be generated internally and fed to both the PHY device and to the RMII gasket by enabling the FEC_REF_CLK pad input and output buffers. FEC_REF_CLK can also be provided externally as an input to the device.

Figure 250. Device Ethernet clocking

26.6.4 FlexRay clocking

The FlexRay protocol clock is sourced from the PLL0_PHI clock or the external oscillator (XOSC), but its source selection is different from other modules:

1. PLL0_PHI enters the MC_CGM where it is divided by a value configured in the CGM_AC2_DC0 register and output as FRAY_PLL_CLK.
2. FRAY_PLL_CLK passes through the Pseudo Random Clock Divider (PRCD) which:
   – Divides FRAY_PLL_CLK by 16.
   – Adds approximately 40% of random jitter to both edges of the clock.
3. An internal multiplexer selects the PRCD output or XOSC as the resultant FRAY_CLK.

PLL0_PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

When XOSC is the input clock to the FlexRay controller, a 40 MHz crystal is required for proper operation. Both edges of the clock are used by the module to achieve the required 80 MHz frequency.

Selection of PLL or XOSC as the FlexRay clock is shown in *Figure 330: MC_CGM Auxiliary Clock 2 Generation Overview* in the Clock Generation Module (MC_CGM) chapter.

26.6.5 M_TTCAN/M_CAN clocking

The CAN_CLK is configured in the CGM via the following registers:

- CGM_AC8_SC selects the XOSC or PLL0:PHI as the clock source.
- CGM_AC8_DC0 reduces the CAN_CLK by configuring the dividing factor from 1 to 64.

CAN_CLK passes through the Pseudo Random Clock Divider (PRCD) which:

- Divides CAN_CLK by 16.
- Adds approximately 40% of random jitter to both edges of the clock.

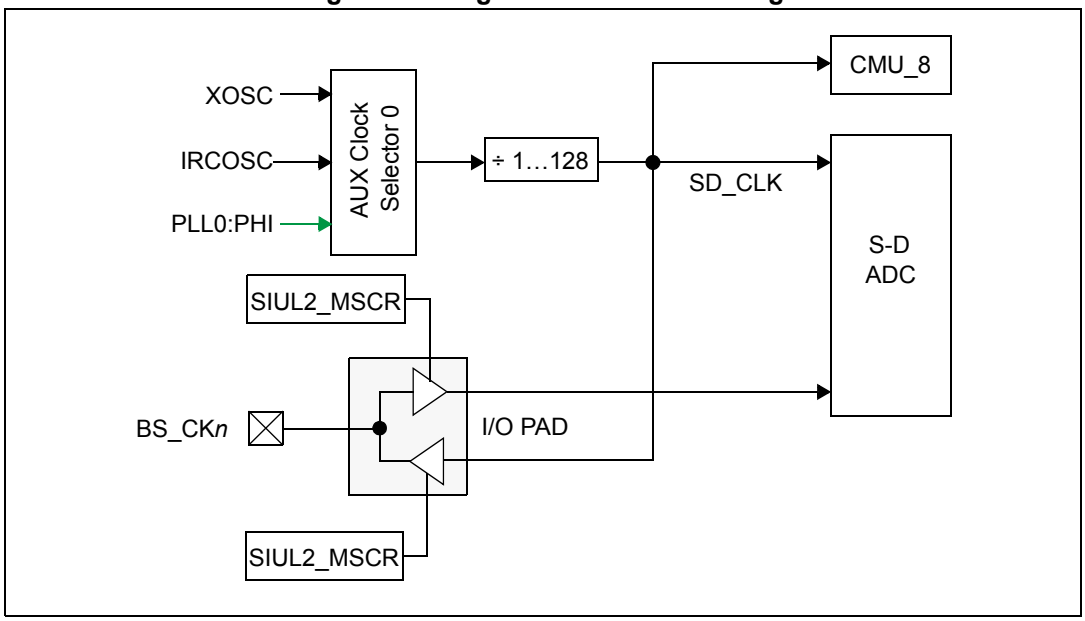
PLL0.PHI is the source whenever the PRCD is enabled. PRCD is passive in normal operation and has no impact on the clock frequency.

26.6.6 Sigma-Delta ADC clocking

The analog portion of the Sigma-Delta ADC (SDADC) works with either an internal or external modulator.

When the internal modulator in the SDADC is enabled the internal clock (SD_CLK) is always used, see *Figure 248*).

When the external modulator is enabled (by disabling the internal modulator), an SDADC internal mux selects either:



- An external input clock (BS_CK).
- An internally generated output clock (SD_CLK) connected to the external modulator clock package pin (BS_CK).

In order to provide an internal clock option when the external modulator is enabled, the SD_CLK output from the MC_CGM must be connected to the BS_CK pin as shown in *Figure 251*.

The MSCR in the SIUL2 control of the input/output direction of the BS_CK pin.

Each SDADC is connected as shown in *Figure 251*, with the SD_CLK being common to all modules, but each SDADC having a dedicated BS_CK pin.

Figure 251. Sigma-Delta ADC clocking

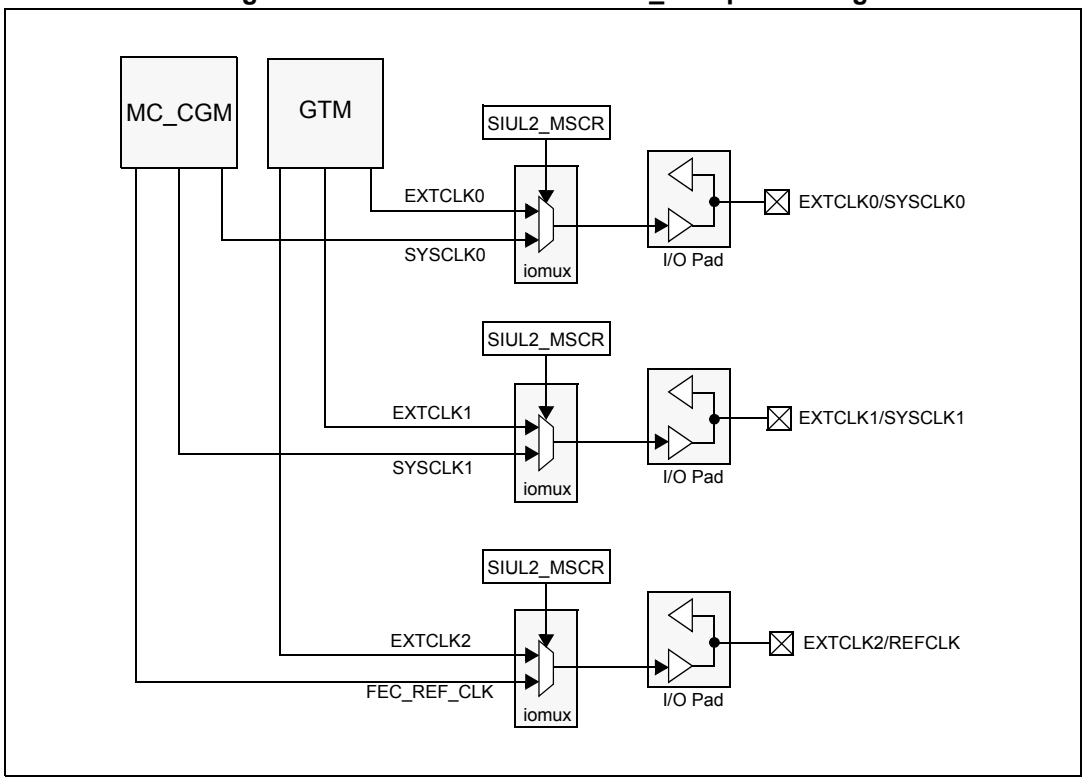
26.6.7 Successive Approximation Register ADC clocking

The analog portion of the Successive Approximation Register ADC (SARADC) requires a dedicated clock SAR_CLK, which should be configured, complying with the frequency constraints defined into the device datasheet. SAR_CLK must be less than PBRIDGEx_CLK.

26.6.8 System Clock/GTM output clock/Ethernet clock pin muxing

The two system clocks (SYSCLK[1:0]) have an independant source clock selected from:

- PLL0_PHI and PLL1_PHI.
- Internal oscillator (IRCOSC)
- External oscillator (XOSC)



The registers CGM_AC6_SC and CGM_AC7_SC configure the clocks for SYSCLK0 and SYSCLK1 respectively. See *Figure 246*.

There are three GTM output clocks available on package pins, EXTCLK[2:0]:

- EXTCLK[1:0] are muxed on the same pins as SYSCLK[1:0].
- EXTCLK[2] is muxed on the same pin as the Ethernet RMII clock (FEC_REF_CLK).

The selection of EXTCLK[*n*], SYSCLK[*n*] or FEC_REF_CLK is handled in the SIUL2_MSCR registers. See *Figure 252*.

Figure 252. SYSCLK/EXTCLK/REF_CLK pin muxing

26.7 Clock monitoring

For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency.

Each CMU is programmed independently (see *Figure 246* for CMU distribution) and uses the IRCOSC or XOSC as the clock monitor reference.

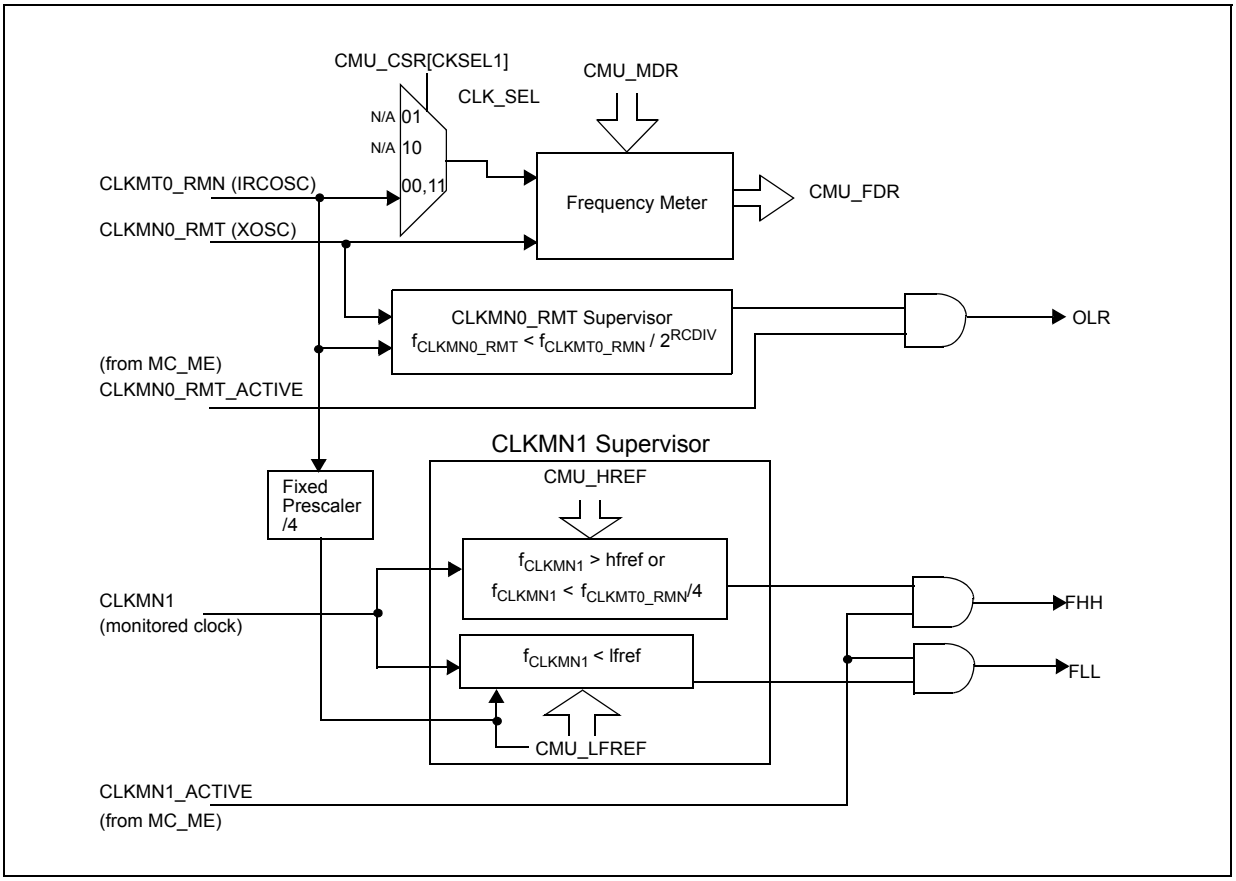
Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

26.7.1 CMU configuration

This section explains the CMU configuration.

Figure 253 shows the block diagram for CMU0 on the SPC574Kx.

Figure 253. CMU0 block diagram



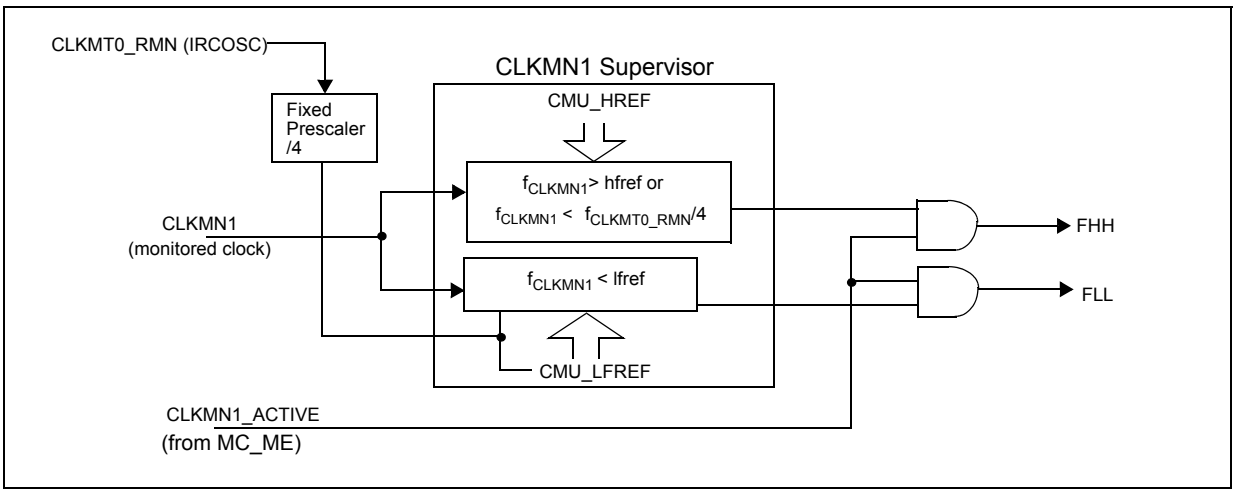


Figure 254 shows the block diagram for CMU[1:10] on the SPC574Kx.

Figure 254. CMU[1:10] block diagram

26.7.1.1 Clock input sources

Table 338 shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC

monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 338. Clock input sources

Clock module	Monitored clock
CMU0	PLL0:PHI, XOSC, IRCOSC
CMU1	Safety Core (Main Core_0, Checker Core_0s), FXBAR_CLK
CMU2	Peripheral Core_2, SXBAR_CLK
CMU3	PBRIDGE_CLK
CMU4	PER_CLK
CMU5	SD_CLK
CMU6	SAR_CLK
CMU7	SENT_CLK
CMU8	PS15_f189_CLK
CMU9	PS15_f125_CLK
CMU10	PS15_1µs_CLK

26.7.1.2 CMU registers and field availability

Table 339 specifies which registers and fields are available for a given CMU.

Table 339. CMU register availability

Address offset	Register	CMU	Note
0000h	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CKSEL1] in CMU0 only.
0004h	CMU_FDR	CMU0	—
0008h	CMU_HFREFR	All	—
000Ch	CMU_LFREFR	All	—
0010h	CMU_ISR	All	CMU_ISR[OLRI] in CMU0 only.
0014h	Reserved	—	—
0018h	CMU_MDR	CMU0	—

26.7.1.3 CMU register write protection

The CMU registers defined in *Table 335* have write protection with:

- Soft locking—can be unlocked by software after being previously locked.
- Hard locking—can only be unlocked by a reset once locked.

The REG_PROT module is used to implement the CMU register write protection.

Table 340. CMU register write protection

Offset	Register[1]	Protection
0000h	*CMU Control Status Register (CMU_CSR)*	Yes
0004h	CMU Frequency Display Register (CMU_FDR)	No
0008h	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	No
000Ch	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	No
0010h	*CMU Interrupt Status Register (CMU_ISR)*	No
0014h	*Reserved*	No
0018h	CMU Measurement Duration Register (CMU_MDR)	No

1. See Register Protection chapter for bit field details.

26.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

26.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

26.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

26.7.5 System clock monitors

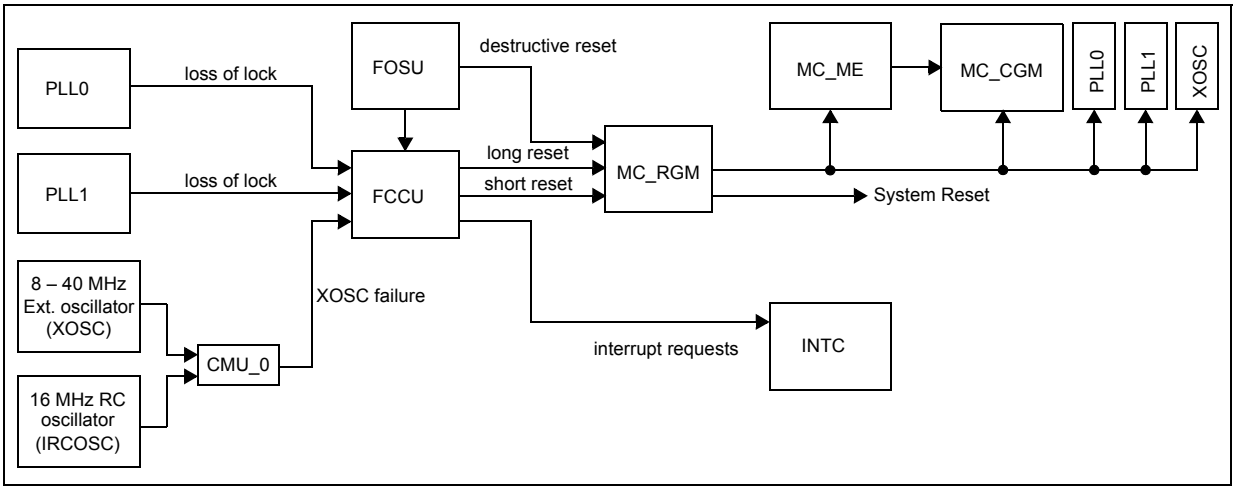
A CMU is assigned to monitor the frequency of the computational core, IOP core, fast and slow XBAR, both peripheral bridges, peripheral, PSI5, SENT and ADC clocks (refer to *Figure 246*).

26.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. *Figure 255* gives a high-level view of the loss of clock logic.

26.8.1 Loss of PLL/XOSC clock

As shown in *Figure 255*, each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU.



When a clock failure occurs, the FCCU can be programmed to generate:

- An interrupt: only the backup clock in the PLL can provide clocks to the system in order to perform a system clock switch. There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).
- A short reset sequence: the clock configuration is maintained but also in this situation the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.
- A long reset sequence: the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states and the system clock is switched to the IRCOSC

26.8.2 Loss of IRCOSC clock

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure is a catastrophic failure.

Figure 255. Loss of clock logic

26.9 Progressive clock switching

The Progressive Clock Switching (PCS) blocks are shown in the system-level clock diagram in *Figure 246*. They are used for ramping the system and peripheral clocks and for obtaining the precise clock frequency input for the PSI5 module. See the clock Generation Module (MC_CGM) chapter for more information on the PCS.

27 Dual PLL Digital Interface (PLLDIG)

27.1 Introduction

The MCU provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 blocks (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1.

The key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by PLL1.

27.2 Block Diagram

The block diagram of the PLLDIG block is found in the “Clocking chapter” of the *SPC574Kx Reference Manual*.

27.3 Features

The Dual PLLDIG has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for reducing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when the PLLs have achieved frequency lock, and continuously monitors lock status to report loss of lock conditions.
  - User-selectable ability to generate an interrupt request upon loss of lock.
  - User-selectable ability to generate a system reset upon loss of lock.
  - The loss of lock indication is sent to the FCCU via the system glue logic.

27.4 Modes of operation

The operating modes of the PLLs is determined by the value of PLL*n*CR[CLKCFG]. The various modes of operation for the PLL are:

- Normal mode with reference, and either PLL0 or both PLLs enabled

Note: Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<mode>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

27.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In the normal mode, PLL0 receives an input clock from the reference and the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a

crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0_PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, output divider (Reduced Frequency Divider) and whether the PLL1 is modulating or not can be programmed by writing to the PLL1FM register, *Section 27.5.2.7: PLL1 Frequency Modulation Register (PLL1FM)*.

Note: While powering down the PLLs, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Only when the PLL0 achieves lock should PLL1 be configured to work in either mode by programming the appropriate MC_ME_<*mode*>_MC register.

27.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs.

27.5.1 Memory map

Table 341 shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

Table 341. Dual PLL Digital Interface memory map

Figure 256. PLL0 Control Register (PLL0CR)

1. This field can be written at any time, but writes are ignored. Reads returns previously written value.
2. CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_<mode>_MC register (see the "Mode Entry Module (MC_ME)" chapter and Clock configuration for details).
3. See the “Clocking” chapter for details on configuring this field.

Table 342. PLL0CR field descriptions

Field	Description
0:21	Reserved
22:23 CLKCFG	Clock Configuration. This field indicates the operational state of PLL. 00 PLL off. 01 Reserved 10 Reserved. 11 Normal mode with PLL running When PLLs are externally powered down the CLKCFG field changes to 00b. When external power down is removed, these bits will read 11b. **Note:** In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1.
24 EXPDIE	External Power Down Cycle Complete indication interrupt enable. This bit enables generation of an interrupt when the external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion
25	Reserved
26	Reserved
27	Reserved
28 LOLIE	Loss of lock interrupt enable. The LOLIE bit enables a loss of lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode. 0 Ignore loss of lock. Interrupt not requested. 1 Enable interrupt request upon loss of lock.

Table 342. PLL0CR field descriptions(Continued)

Field	Description
29 LOLRE	Loss of lock reset enable. The PLL0CR[LOLRE] bit determines whether system reset is asserted or not upon a loss of lock indication from PLL. If both PLL0CR[LOLRE] = 1 and PLL0CR[LOLIE] = 1, PLL0CR[LOLRE] has precedence and the device asserts reset with the interrupt not being taken. 0 Ignore loss of lock. Reset not asserted. 1 Assert reset on loss of lock when operating in normal mode.

24 EXTPDF	External Power Down Cycle Complete indication interrupt flag. This bit indicates that the external power down of the PLL is complete (for example, PLLs are powered down and then powered up). User must write 1 to clear this bit. 0 PLLs not power cycled. Interrupt not requested 1 PLLs power down cycle is complete. Interrupt is requested
25	Reserved
26	Reserved
27	Reserved

Table 343. PLL0SR field descriptions(Continued)

Field	Description
28 LOLF	Loss of lock flag. This bit provides the interrupt flag for the loss of lock condition. Software must write 1 to LOLF to clear it, writing 0 has no effect. The flag is set when the PLL loses lock or when the divider/modulation registers are changed on the fly. This flag bit is sticky in the sense that if lock is reacquired, the bit will remain set until cleared by either writing 1 or asserting reset. 0 No loss of lock detected. Interrupt service not requested. 1 Loss of lock detected. Interrupt service requested.
29 LOCK	Lock status bit. Indicates whether PLL has acquired lock. 0 PLL is unlocked. 1 PLL is locked.
30	Reserved
31	Reserved

27.5.2.3 PLL0 Divider Register (PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. The values of PREDIV and MFD should not be changed when the PLL is on and locked (working in Normal mode). If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled. The reduced frequency divider fields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective after PLL0 is disabled, then reenabled.

27.5.2.7 PLL1 Frequency Modulation Register (PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of PLL1PLL2FM[MODEN] and PLL1PLL2FM[MODSEL] fields once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock, however, the output clock from PLL may have an incorrect frequency for a few cycles after either of these updates (as defined in the Data Sheet).

3:15 MODPRD	Modulation period. MODPRD is the binary equivalent of the modulation period variable derived from the formulas shown in *Section 27.6.4: Frequency modulation*.
16	Reserved
17:31 INCSTP	Increment step. This field is the binary equivalent of the INCSTP variable derived from the formulas shown in *Section 27.6.4: Frequency modulation*

27.5.2.8 PLL1 Fractional Divider Register (PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The dither disable and fractional divider fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates .

20:31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the mean VCO clock frequency is given by the equation in *Section 27.6.2: Clock configuration*.

27.5.3 Register classification for safety requirements

This module is classified as a safety Vital Module (ViMo). Hence, the registers of this module have been classified as shown in the SPC574Kx Reference Manual “Functional Safety” chapter.

27.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

27.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for each PLL are discussed in detail in the *SPC574Kx Data Sheet*.

27.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV, PLL1DV and PLL1FD registers, and calculated according to the following equations:

Equation 4

$$f_{pll0_phi} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI]}$$

Equation 5

$$f_{pll0_phi1} = \left(= f_{pll1_ref} = f_{pll0_ref} \times \frac{PLL0DV[MFD]}{PLL0DV[PREDIV] \times PLL0DV[RFDPHI1]} \right)$$

Equation 6

$$f_{pll1_phi} = f_{pll1_ref} \times \frac{PLL1DV[MFD]}{2 \times PLL1DV[RFDPHI]}$$

The relationship between the VCO frequency f_{VCO} and the output frequency of the PLLs is determined by the PLL0DV, PLL1DV and PLL1FD registers, according to the following equations:

Equation 7

$$f_{pll0_VCO} = f_{pll0_ref} \times \frac{2 \times PLL0DV[MFD]}{PLL0DV[PREDIV]}$$

Equation 8

$$f_{pll1_VCO} = f_{pll1_ref} \times PLL1DV[MFD]$$

NOTE

Note: If the PLL0 PHI1 output is the input to the PLL1, f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1 (see Equation 5).

Note: If the XOSC is the input to the PLL1, the XOSC clock is the reference clock for PLL1 ($f_{pll1_ref} = f_{xosc}$).

Note: The clock source for the PLL1 reference clock depends on the MC_CGM_AC4_SC[SELCTL] field value.

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification for PLL0 or PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLL*n*SR[LOCK] flag are immediately negated if the fields of PLL*n*DV are changed without powering down the analog PLLs. However, changing the PLL*n*DV fields without powering down the PLL is not recommended. If the updated values are able to maintain the PLL frequency within operating parameters, no loss of lock is generated.

When any of these events occur, an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLL*n*SR[LOCK] flag is held negated. After the timer expires, the PLL*n*SR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLL*n*CR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

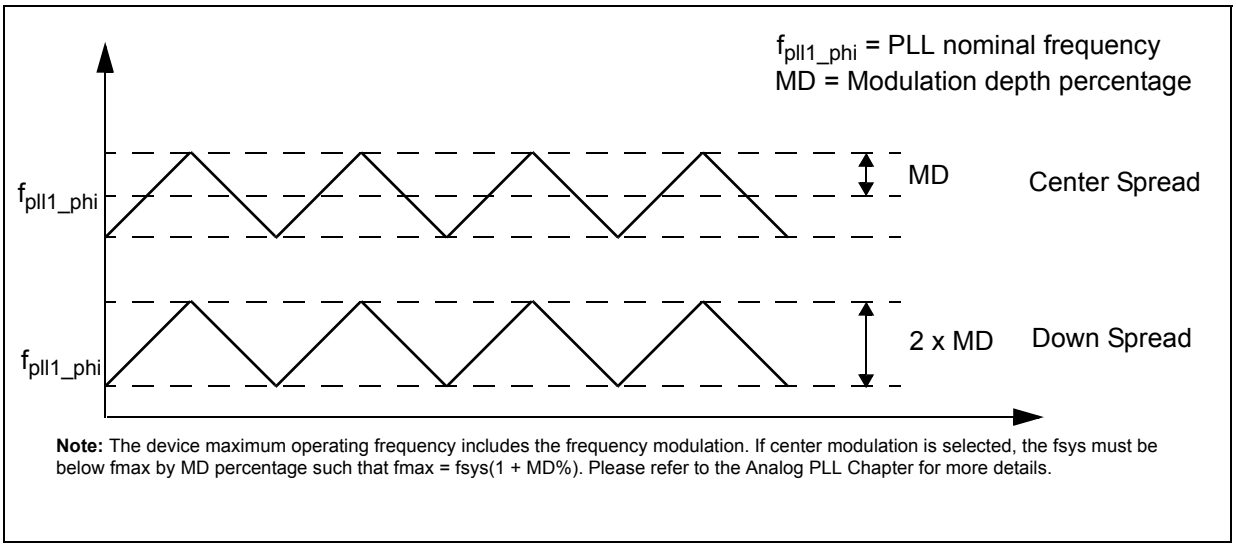
Note: The PLL must be powered down and powered up by configuring, then executing a mode change in the MC_ME_<mode>_MC before PLL0CR[PREDIV], PLL0CR[MFD], PLL1CR[MFD] or the input reference clock values are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in *Section 27.7: Initialization information*.

27.6.3 Loss of lock

The PLL digital interface registers provide the flexibility to select whether to generate an interrupt assert system reset or do nothing in the event that the PLL loses lock according to the available PLL*n*CR options.

Loss of lock reset and interrupt are only generated when the PLL is operating in normal mode.



The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, it will be immediately indicated in the status register (after synchronization time).

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. Once the PLL has locked, the counters continue to monitor the reference and feedback clocks and report whether the PLL has lost lock. The lock status is indicated in the status register.

27.6.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in *Figure 264*. The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Figure 264. Triangular frequency modulation

Note: The device maximum operating frequency includes the frequency modulation. If center modulation is selected, the fsys must be below fmax by MD percentage such that fmax = fsys(1 + MD%). Please refer to the Analog PLL Chapter for more details.

The following equations define how to calculate PLL1FM[MODPRD] (*Equation 9*) and PLL1FM[INCSTP] (*Equation 9*) based on the frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD):

Equation 9

$$\text{PLL1FM[MODPRD]} = \text{round}\left(\frac{f_{pll1_ref}}{4 \times f_{mod}}\right)$$

Equation 10

$$\text{PLL1FM[INCSTP]} = \text{round}\left(\frac{(2^{15} - 1) \times MD \times \text{PLL1DV[MFD]}}{100 \times 5 \times \text{PLL1FM[MODPRD]}}\right)$$

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

Equation 11

$$(\text{PLL1FM[MODPRD]} \times \text{PLL1FM[INCSTP]}) < 2^{15}$$

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is given by the following formula:

Equation 12

$$\text{ModulationDepth} = \left(= \text{round}\left(\frac{\text{PLL1FM[MODPRD]} \times \text{PLL1FM[INCSTP]} \times 100 \times 5}{(2^{15} - 1) \times \text{PLL1DV[MFD]}}\right)\right)$$

FM parameters should only be changed, and FM enabled, after PLL0 has obtained lock. The sequence for reprogramming the FM is:

1. Power down PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 0, followed by a mode change
2. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].
3. Program the PLL1FM while itis powered down.
4. Power up the PLL1 by writing MC_ME_<*mode*>_MC[PLL1ON] = 1, followed by a mode change.
5. Write a mode change to MC_ME_<*mode*>_MC[PLL1ON].

27.7 Initialization information

Coming out of reset the PLLs are disabled per the DRUN mode configuration register, MC_ME_DRUN_MC. The Dual PLLDIG initialization porcedure is described in the “Clocking” chapter.

28 Clock Monitor Unit (CMU)

28.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

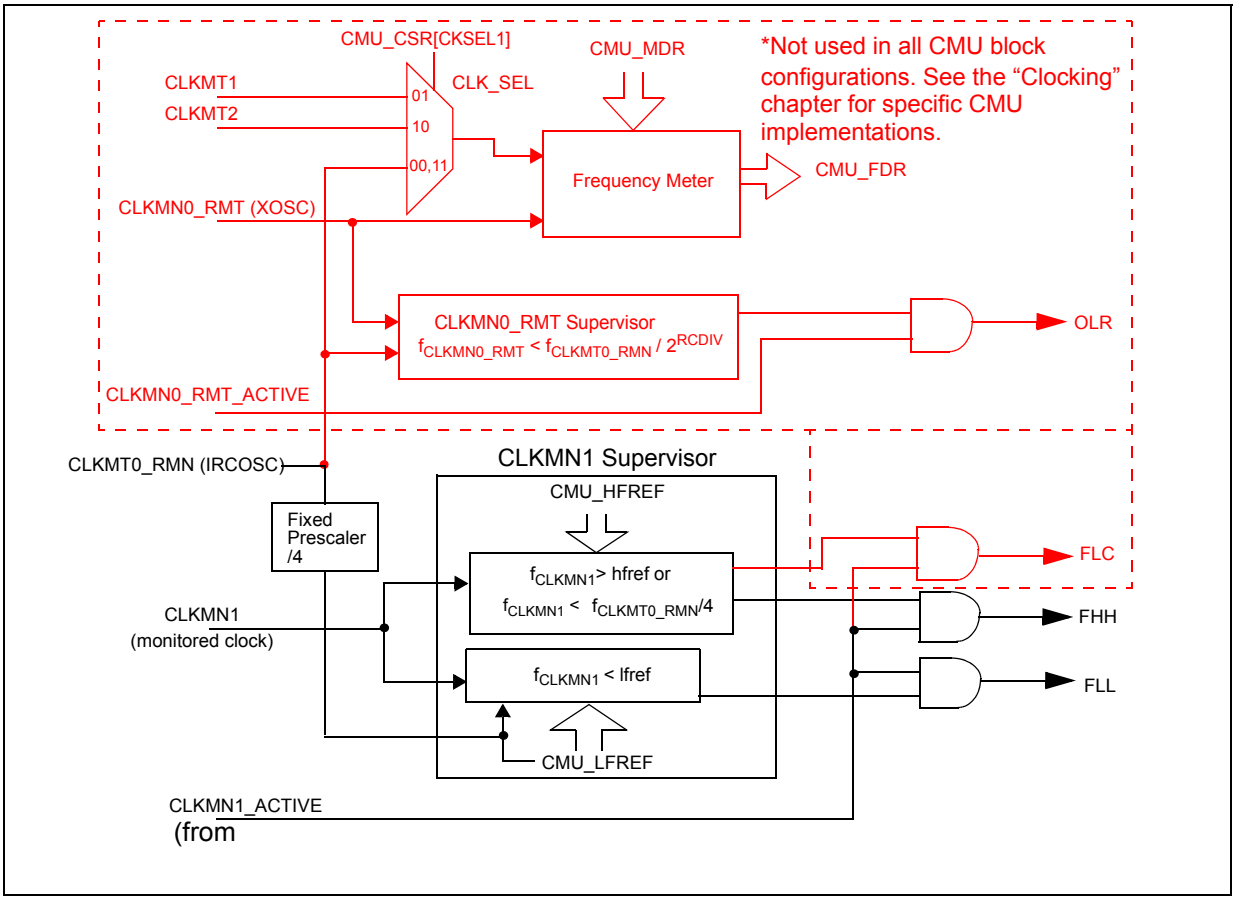
- Measures the frequency of clock sources CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and also detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which in turn can then take whatever corrective action is required as configured in the FCCU.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the division factor given by the RCDIV field of CMU Control Status Register and reports this event. The CMU can also monitor CLKMN1 and generate events when the CLKMN1 frequency is less than the CLKMT0_RMN frequency divided by four or if CLKMN1 leaves an upper or lower frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of one clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note: See the “Clocking” chapter for the number of instances of the CMU in this device.



28.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as the reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN/n clock.
- CLKMN1 frequency monitoring with respect to CLKMT0_RMN / 4 and upper or lower frequency boundary.
- Event generation for various failures detected inside monitoring unit.

28.2 Block diagram

The full block diagram of the CMU is shown in *Figure 265*. Please see the “Clocking” chapter for device specific use of each CMU module.

Figure 265. Clock Monitor Unit diagram

28.3 Signals

Table 350 describes the signals on the boundary of the CMU (in alphabetical order).

Table 350. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

Note: See the "Clocking" chapter for device specific clock sources of each CMU.

28.4 Memory map and register definition

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in *Table 351*.

Table 351. CMU memory map

Offset (hex)	Register	Location
0000	CMU Control Status Register (CMU_CSR)	*on page 830*
0004	CMU Frequency Display Register (CMU_FDR)	*on page 831*
0008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	*on page 832*
000C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	*on page 832*
0010	CMU Interrupt Status Register (CMU_ISR)	*on page 833*
0014	Reserved	—
0018	CMU Measurement Duration Register (CMU_MDR)	*on page 834*

Note: See the "Clocking" chapter for register and field availability details.

2 Field is read only.

Figure 270. CMU Interrupt Status Register (CMU_ISR)

Table 356. CMU_ISR field descriptions

Field	Description
0:28	Reserved
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value and CLKMN1 is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No FLL event 1 FLL event occurred
31 OLRI	Oscillator frequency less than f_{CLKMT0_RMN} /2^{RCDIV} event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than f_{CLKMT0_RMN}/2^{RCDIV} frequency and CLKMN0_RMT is 'ON' as signaled by the MC_ME. It can be cleared by software by writing '1'. 0 No OLR event 1 OLR event occurred **Note:** While entering STOP mode, OLRI may be triggered. To avoid this when the system is running on the PLL, disable XOSC before entering STOP mode.

Note: All the flags in CMU_ISR are set asynchronously. This register must be read only after an interrupt (safe mode entry) is triggered by the CMU as confirmed by MC_RGM. Otherwise, the read access on this register may fetch an incorrect value.

Note: Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

28.4.1.6 CMU Measurement Duration Register (CMU_MDR)

Address: Base + 0018h Access: User read/write

Figure 271. CMU Measurement Duration Register (CMU_MDR)

Table 357. CMU_MDR field descriptions

Field	Description
0:11	Reserved
12:31 MD	Measurement duration bits. This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

28.5 Functional description

This section describes the functionality of the CMU.

28.5.1 Frequency meter

The purpose of frequency meter is to evaluate the deviation from the nominal metered source (such as, CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of metered clocks from a multiplexer that drives a simple Frequency Meter (see *Figure 265*). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

Equation 13 $f_{sel} = (f_{CLKMN0_RMT} \times MDR[MD]) / FDR[FD]$

28.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than frequency of CLKMT0_RMN / $2^{CMU_CSR[RCDIV]}$ and CLKMN0_RMT is ‘ON’ as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note: f_{CLKMN0_RMT} must be greater than $f_{CLKMT0_RMN} / 2^{RCDIV}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

28.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is ‘ON’ as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI]
- The CMU asserts the FHH signal

Note: An example of determining the $HFREF_{Actual}$ value is as follows. Assume a f_{CLKMT0_RMN} = 16 MHz with an accuracy of +/-5%. In order to monitor f_{CLKMN1} = 200 MHz, the ideal $HFREF_{Ideal}$ = 800. The actual HFREF value will be 842 when the accuracy is taken into consideration ($HFREF_{Actual}$ = ($HFREF_{Ideal}$ + 2) × 1.05).

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note: The low reference value must be programmed considering the following factors

- *2 cycles of f_{CLKMN1} which is the built-in tolerance of the monitor implementation*
- *Frequency variation % of f_{CLKMT0_RMN} across PVT*

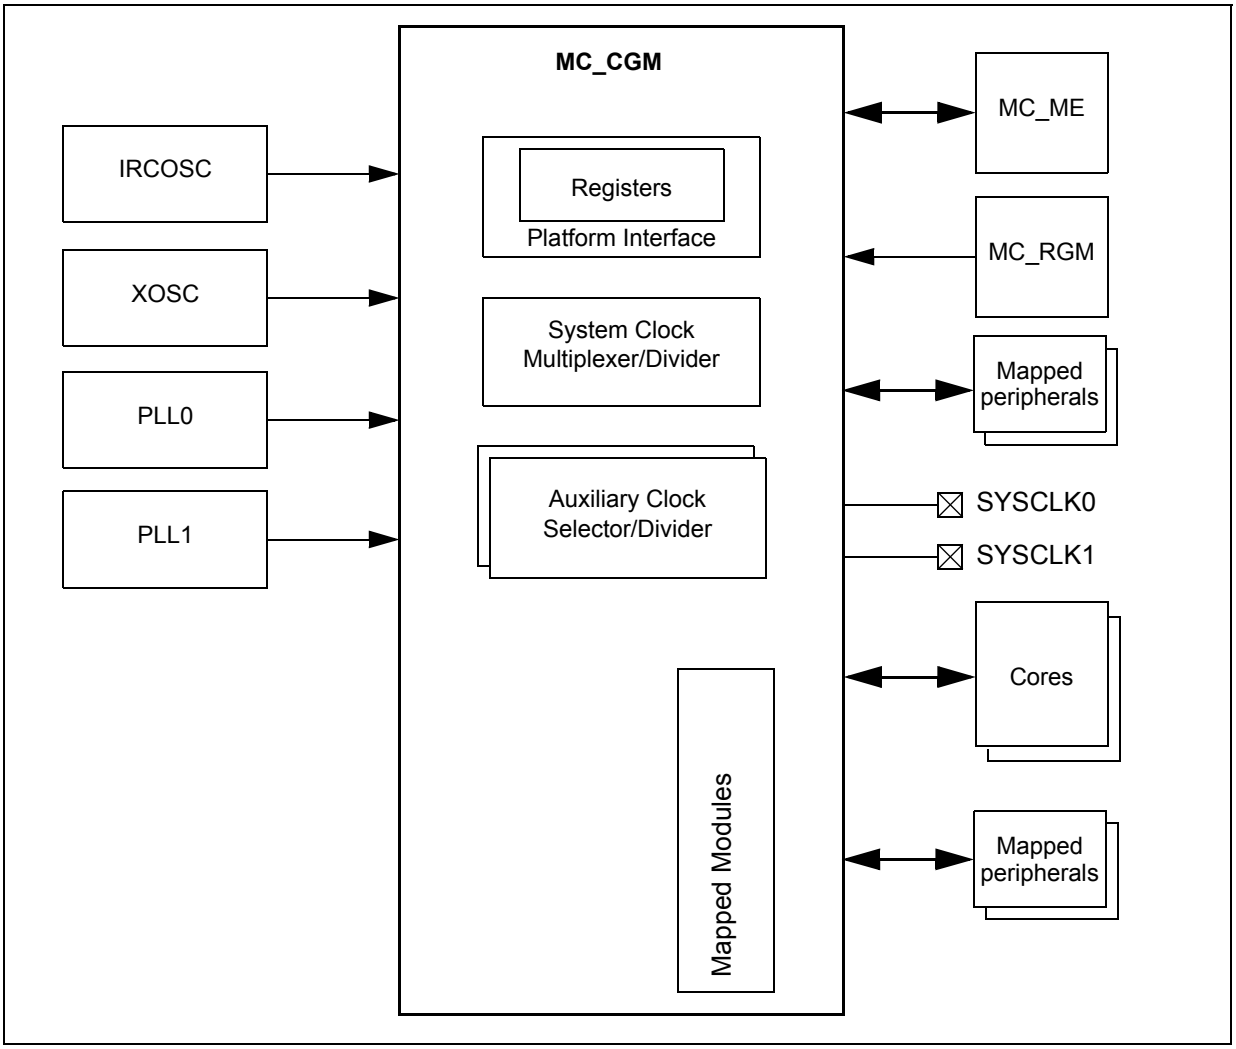
Note: For example, assuming f_{CLKMT0_RMN} is 16MHz with +/-5% variation, in order to monitor the f_{CLKMN1} (200MHz), the ideal $LFREF_{Ideal}$ is 800. The adjusted value considering the tolerances will be 758 ($LFREF_{Actual}$ = ($LFREF_{Ideal}$ -2) x 0.95).

Note: The minimum value that can be programmed in CMU_LFREFR[LFREF] is 3. The minimum frequency that can be monitored using the CLKMN1 supervisor must be >= f_{CLKMT0_RMN}/16.

29 Clock Generation Module (MC_CGM)

29.1 Introduction

This chapter describes the Clock Generation Module (MC_CGM) which includes, but is not limited to, the funtionality, pin descriptions, and registers of the MC_CGM module.



29.1.1 Overview

The Clock Generation Module (MC_CGM) generates reference clocks for all the chip blocks and enables the system clock from one of the available system clock sources. System clock selection is handled in the Mode Entry control module, see the MC_ME chapter for more details.

The addressable memory spaces of system and peripheral clock are accessed through the MC_CGM memory space.

Figure 272 shows the MC_CGM block diagram.

Figure 272. MC_CGM block diagram

29.1.2 Features

The MC_CGM:

- Generates system and peripheral clocks.
- Selects and enables/disables the system clock supply from system clock sources according to MC_ME control.
- Performs progressive system clock frequency change depending on MC_ME mode configuration.
- Contains a set of registers to control clock dividers for divided clock generation.
- Supports multiple clock sources and maps their address spaces to its memory map
- Guarantees glitch-free clock transitions when changing the system clock selection.
- Supports 8, 16, and 32-bit wide read/write accesses.

29.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use and/or observation.

Note: Any access to unused registers as well as write accesses to read-only registers:

- *Does not change register content.*
- *Causes a transfer error*

29.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes.

The bytes are ordered according to big endian. For example, the MC_CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

29.3.1.1 PCS Switch Duration Register (MC_CGM_PCS_SDUR)

This register contains the progressive system clock switching duration for each step. See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set this value.

Address 0x0100 Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7
R W	SDUR							
Reset	0	0	0	0	0	0	0	0

Table 359. MC_CGM_PCS_SDUR field descriptions

Field	Description
0–7 SDUR	Switch Duration. This value defines the duration of one PCS clock switch step in terms of 16 MHz Internal RC oscillator (IRCOSC) cycles.

29.3.1.2 PCS Divider Change 1 Register (MC_CGM_PCS_DIVC1)

This register relates to the external crystal oscillator (XOSC).

When the system clock source switches to this clock or from this clock on ramp-up or ramp-down, the register defines the rate of frequency change and the initial change value for progressive system clock switching.

See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte write accesses are not allowed for the INIT field of this register. Such attempts do not result in an exception, however the new value is not loaded.

Address 0x0104 Access: User read/write, Supervisor read/write, Test read/write

29.3.1.3 PCS Divider End 1 Register (MC_CGM_PCS_DIVE1)

This register relates to the external crystal oscillator (XOSC).

When switching the system clock source away from this clock on ramp-down, the register defines the final division value for progressive system clock switching.

See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set this value.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

29.3.1.4 PCS Divider Start 1 Register (MC_CGM_PCS_DIVS1)

This register relates to the external crystal oscillator (XOSC).

When switching the system clock source to this clock on ramp-up, the register defines the initial division value for progressive system clock switching.

See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

29.3.1.5 PCS Divider Change 2 (MC_CGM_PCS_DIVC2)

This register relates to PLL0_PHI.

When the system clock source switches to this clock or from this clock on ramp-up or ramp-down, the register defines the rate of frequency change and the initial change value for progressive system clock switching.

See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set these values.

Note: Byte write accesses are not allowed for the INIT field of this register. Such attempts do not result in an exception, however the new value is not loaded.

Address 0x0110 Access: User read/write, Supervisor read/write, Test read/write

29.3.1.6 PCS Divider End 2 Register (MC_CGM_PCS_DIVE2)

This register relates to PLL0_PHI.

When switching the system clock source away from this clock on ramp-down, the register defines the final division value for progressive system clock switching.

See *Section 29.4.1.2: Progressive System Clock Switching* for details on how to set this value.

Note: Byte and half-word write accesses are not allowed for this register. Such attempts do not result in an exception, however the new value is not loaded.

29.3.1.11 System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC)

This register selects whether the system clock divider ratios will change from the current configuration to the configuration in the next update. If the value of SYS_DIV_RATIO_CHNG is ‘1’ at the time of a write to the MC_CGM_DIV_UPD_TRIG register and a pre-loaded system clock divider update is pending, the crossbar is halted while the system clock divider update takes place. If the value of SYS_DIV_RATIO_CHNG is ‘0’, the crossbar switch is not halted. This register has no effect if the system clock divider update is configured in the MC_CGM_DIV_UPD_TYPE register to be immediate.

An example of a divider ratio not changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 4. The ratio is 1:2 in both configurations. An example of a divider ratio changing is divider 0 changes from divide by 1 to divide by 2, and divider 1 changes from divide by 2 to divide by 6. The ratio changes from 1:2 to 1:3. The value of SYS_DIV_RATIO_CHNG is returned to ‘1’ automatically on each write to the MC_CGM_DIV_UPD_TRIG register.

Caution: Software must never write a ‘0’ to the SYS_DIV_RATIO_CHNG bit if the system clock divider ratios change from the current configuration to the next configuration. This can potentially cause errors in the crossbar which lead to lost data.

Address 0x01D0 Access: User read/write, Supervisor read/write, Test read

29.3.1.12 Divider Update Type Register (MC_CGM_DIV_UPD_TYPE)

This register selects whether the dividers associated with a clock are updated immediately on writing to the corresponding divider configuration register or only on writing to the divider update trigger register MC_CGM_DIV_UPD_TRIG, after which the pre-loaded configuration in the divider configuration registers will take effect.

Address 0x01D4 Access: User read/write, Supervisor read/write, Test read

0 SYS_UPD _TYPE	System Clock Divider Update Type. 0 The configuration for each system clock divider is updated immediately on writing to the corresponding MC_CGM_SC_DCi register 1 The configuration for each system clock divider is pre-loaded on writing to the corresponding MC_CGM_SC_DCi register, and the pre-loaded configurations of all the system clock dividers are updated on writing to the MC_CGM_DIV_UPD_TRIG register
1–31	Reserved

29.3.1.13 Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG)

Writing any value to this register will cause all dividers that have corresponding bits set to ‘1’ in the MC_CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

Address 0x01D8 Access: User write, Supervisor write, Test read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 285. MC_CGM_DIV_UPD_TRIG

Table 371. MC_CGM_DIV_UPD_TRIG field descriptions

Field	Description
0–31 DIV_UPD_ TRIGGER	Writing any value to this register will cause all dividers that have corresponding bits set to ‘1’ in the MC_CGM_DIV_UPD_TYPE register and have pre-loaded configurations to be updated immediately. Reading this register will always return all zeroes.

29.3.1.14 Divider Update Status Register (MC_CGM_DIV_UPD_STAT)

This register indicates whether a divider for each clock is in the process of being updated. If the MC_CGM_DIV_UPD_TYPE[i] is ‘0’, MC_CGM_DIV_UPD_STAT[i] is set to ‘1’ immediately on writing to one of the corresponding divider configuration registers. Otherwise, MC_CGM_DIV_UPD_STAT[i] is set to ‘1’ immediately on writing to the MC_CGM_DIV_UPD_TRIG register if one of the corresponding divider configurations has been pre-loaded. MC_CGM_DIV_UPD_STAT[i] is cleared to ‘0’ as soon as all the corresponding dividers have been updated and the dividers generate the desired frequency.

29.4 Functional Description

29.4.1 System Clock Generation

Figure 321 shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the IRCOSC as the system clock and ignore the system clock select.

Figure 325. MC_CGM System Clock Generation Overview

29.4.1.1 System Clock Source Selection

During normal operation, the system clock selection is controlled:

- On a SAFE mode or reset event, by the MC_RGM.
- Otherwise, by the MC_ME.

29.4.1.2 Progressive System Clock Switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency up or down based on the power level values of the current and target modes.

During ramp-down, the rate of the frequency change is based on the MC_CGM_PCS_SDUR, MC_CGM_PCS_DIVCn, and MC_CGM_PCS_DIVEn registers, where n corresponds to the current system clock source selection.

During ramp-up, the rate of the frequency change is based on the MC_CGM_PCS_SDUR, MC_CGM_PCS_DIVCn, and MC_CGM_PCS_DIVSn registers, where n corresponds to the target system clock source selection.

29.4.1.2.1 Generic Clock Change Requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in *Equation 14*.

Equation 14

$$a_{max} = \frac{f_{chg}}{f_{src}}$$

29.4.1.2.2 Configuration of MC_CGM_PCS_SDUR

The switch duration field MC_CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of IRCOSC cycles. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

29.4.1.2.3 Configuration of MC_CGM_PCS_DIVC*n*[RATE]

For a given maximum allowed frequency change rate a_{max} the value *d* to be programmed into the PCS_DIVCn[RATE] r$_{egister\ is\ given\ in}$ *Table 411*.

Table 411. MC_CGM_PCS_DIVCn[RATE] values

a_{max}	d = CGM_PCS_DIVCn[RATE]
0.05	0.012
0.10	0.048
0.15	0.112
0.20	0.184
0.25	0.334
0.30	0.429
0.35	0.539
0.40	0.667
0.45	0.819
0.50	1.000

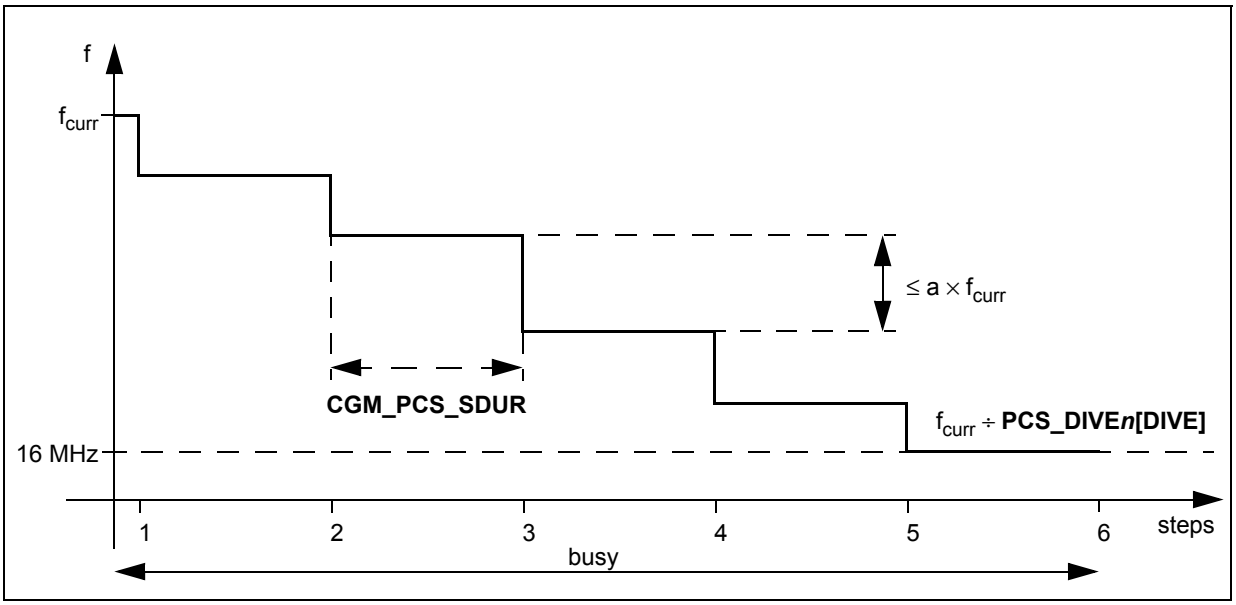
29.4.1.2.4 Generic Clock Change Properties

The number *k* of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in *Equation 15*.

Equation 15

$$k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2\left(1 - \frac{f_{src}}{16MHz}\right)}{d}} \right\rceil$$

29.4.1.2.5 Clock Ramp-Down



The clock ramp-down starts with the divider value 1 and the given divider increment value PCD_DIVCn[RATE], and ends with the given divider value PCS_DIVEn[DIVE].

The divider end value for clock ramp-down is given in *Equation 16*.

Equation 16 $\textbf{PCS_DIVEn[DIVE]} = \frac{f_{src}}{16MHz} \times 1000 - 1$

Where f_{curr} is the frequency of the currently selected system clock source.

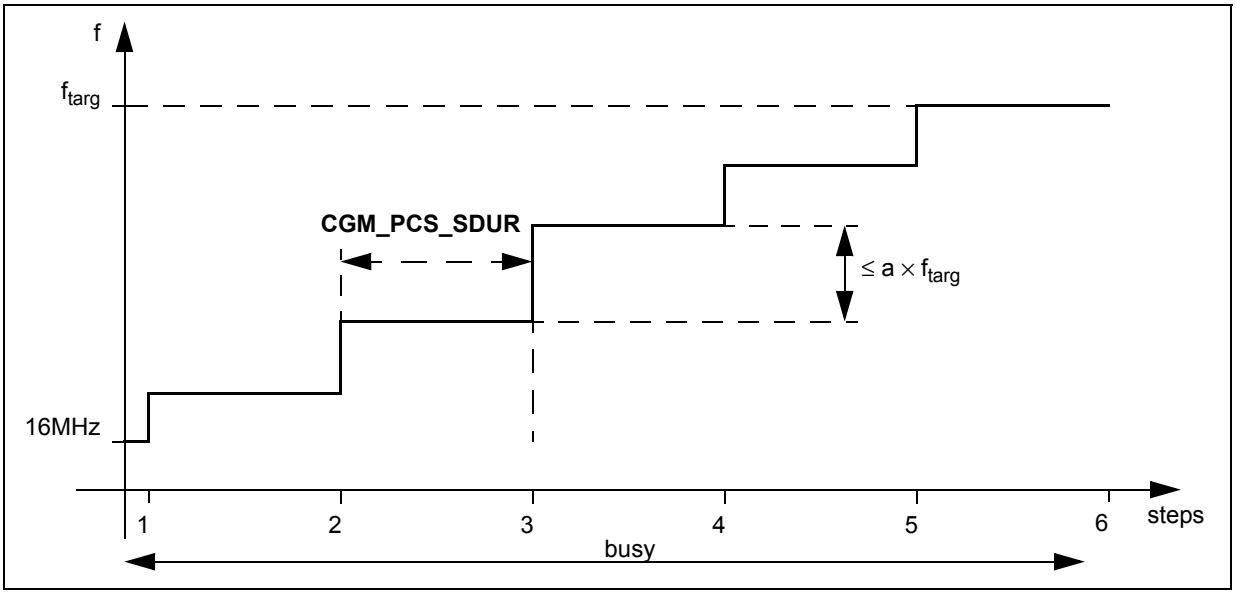
Figure 326. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

29.4.1.2.6 Clock Ramp-Up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in *Equation 17*.

Equation 17



$$\textbf{PCS_DIVCn[INIT]} = d \times k \times 1000 - 1$$

Where *k* is calculated from *Equation 15* using the target system clock source frequency f_{targ}. The divider start value for clock ramp-up is given in *Equation 18*.

Equation 18

$$\text{PCS_DIVSn[DIVS]} = \left(1 + d\frac{k(k+1)}{2}\right) \times 1000 - 1$$

Figure 327. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

29.4.1.3 System Clock Disable

During the TEST mode, the system clock can be disabled by the MC_ME.

29.4.1.4 System Clock Dividers

The MC_CGM generates the following derived clocks from the system clock:

- Fast XBAR clock - controlled by the MC_CGM_SC_DC0 register.
- Slow XBAR clock - controlled by the MC_CGM_SC_DC1 register.
- PBRIDGE clock - controlled by the MC_CGM_SC_DC2 register.

29.4.1.4.1 System Clock Divider Synchronization

The system clock dividers are synchronized such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This imposes limitations on the division factors which can be used:

- Each division factor must be an integer multiple of each division factor that has a lower value.

Example 1. Correct System Clock Divider Configuration

Table 412. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**MC_CGM_SC_DC0[DIV]** = 6b000000
1	2	**MC_CGM_SC_DC1[DIV]** = 6b000001
2	6	**MC_CGM_SC_DC2[DIV]** = 6b000101

The above example is correct because:

- System clock divider 1 has a division factor greater than divider 0; 2 is an integer multiple of 1.
- System clock divider 2 has a division factor greater than dividers 0 and 1; 6 is an integer multiple of 1 and 2.

Example 2. Incorrect System Clock Divider Configuration

Table 413. MC_CGM Example System Clock Division Values Incompatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	**MC_CGM_SC_DC0[DIV]** = 6b000000
1	4	**MC_CGM_SC_DC1[DIV]** = 6b000011
2	6	**MC_CGM_SC_DC2[DIV]** = 6b000101

The above example is incorrect because:

- System clock divider 1 has a division factor greater than divider 0; 4 is an integer multiple of 1.
- System clock divider 2 has a division factor greater than dividers 0 and 1; 6 is not an integer multiple of 4.

Warning: Configuring the system clock dividers incorrectly causes the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the system clock divider division factors without first disabling them or performing a reset.

29.4.1.4.2 System Clock Divider Update Triggering

System clock dividers are updated only with the next software triggered mode change (auxiliary clock dividers update immediately on a configuration change). This ensures that the system clock dividers are updated simultaneously without inconsistent intermediate configurations, and that the divider configurations are aligned with the system clock selection of the target mode.

The system clock divider configuration update sequence is:

1. Configure the target mode in the MC_ME to select the desired system clock source.
2. Configure the MC_CGM_SC_DC0…2 registers as desired but aligned with the target system clock source frequency and compatible with divider synchronization described in *Section 29.4.1.4.1: System Clock Divider Synchronization*.
3. Request a mode change in the MC_ME to the desired target mode.
4. The new system clock divider configuration is effective on mode change completion and successful switching of system clock.

See the MC_ME chapter for details on how to configure modes and make mode change requests.

29.4.2 Auxiliary Clock Generation

Figure 328 through *Figure 338* show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- *Section 29.3.1.19: Auxiliary Clock 0 Select Control Register (MC_CGM_AC0_SC)*
- *Section 29.3.1.26: Auxiliary Clock 1 Select Control Register (MC_CGM_AC1_SC)*
- *Section 29.3.1.31: Auxiliary Clock 3 Select Control Register (MC_CGM_AC3_SC)*

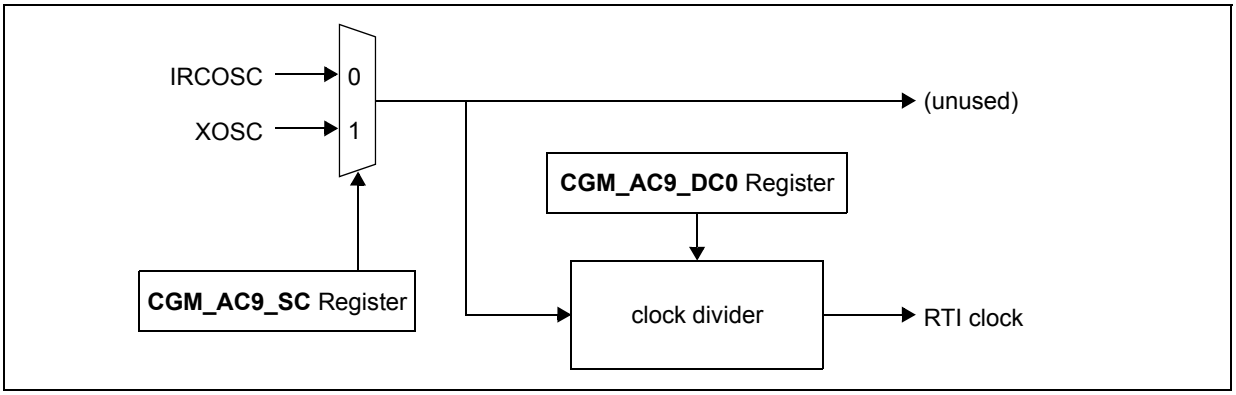

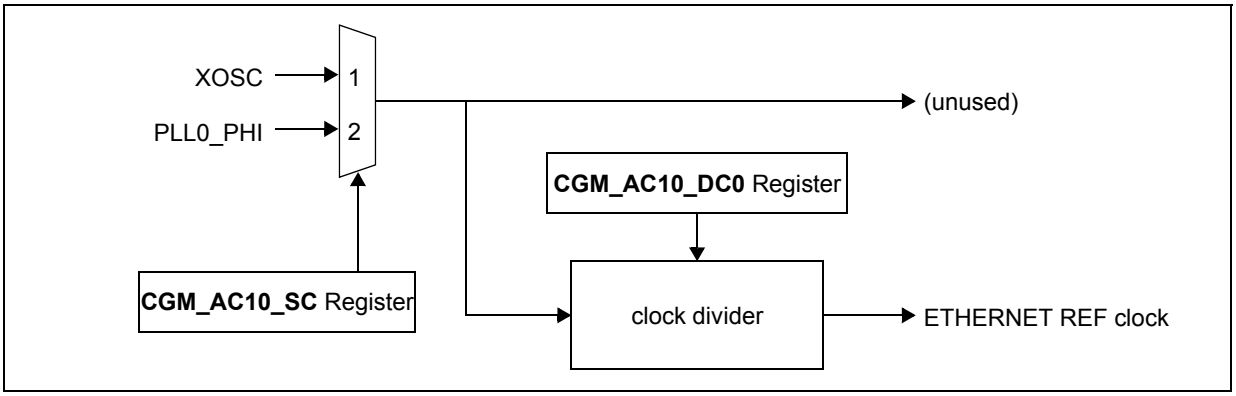

Figure 338. MC_CGM Auxiliary Clock 10 Generation Overview

29.4.2.1 Auxiliary Clock Dividers

The MC_CGM generates clocks the following derived clocks:

- Peripheral clock – controlled by the MC_CGM_AC0_DC0 register.
- Sigma Delta ADC clock – controlled by the MC_CGM_AC0_DC1 register.
- SAR ADC clock – controlled by the MC_CGM_AC0_DC2 register.
- DSPI clock 0 – controlled by the MC_CGM_AC0_DC3 register.
- DSPI clock 1 – controlled by the MC_CGM_AC0_DC4 register.
- LFAST clock – controlled by the MC_CGM_AC1_DC0 register.
- FlexRay clock – controlled by the MC_CGM_AC2_DC0 register.
- SENT clock – controlled by the MC_CGM_AC2_DC1 register.
- PSI5_f189 clock – controlled by the MC_CGM_AC5_DC0 register.
- PSI5_f125 clock – controlled by the MC_CGM_AC5_DC1 register.
- PSI5_1µs clock – controlled by the MC_CGM_AC5_DC2 register.
- SYSCLK0 pin clock – controlled by the MC_CGM_AC6_DC0 register.
- SYSCLK1 pin clock – controlled by the MC_CGM_AC7_DC0 register.
- CAN clock - controlled by the MC_CGM_AC8_DC0 register
- RTI clock - controlled by the MC_CGM_AC9_DC0 register
- Ethernet REF clock - controlled by the MC_CGM_AC10_DC0 register

29.4.3 Dividers Functional Description

Dividers are used for the generation of divided system and peripheral clocks. The control registers for the built-in dividers can be referenced in *Section 29.3.1: Register descriptions*.

The reset value of all counters is ‘1’. If the DE bit of a divider in the respective configuration register is set to ‘0’, the divider is disabled and any value in the DIV field is ignored.

29.4.3.1 Divider Jitter Injection

The clock dividers for the FlexRay clock and the CAN clock inject a jitter so that off-chip communication via the associated peripherals is not possible. For details on enabling this feature, see the ‘Production Disable’ and ‘CAN Jitter Enable’ sections of the PASS chapter.

PLL0 PHI is always the FlexRay clock source when jitter injection is enabled. See *Figure 330*.

29.4.3.2 Fractional Divider Details

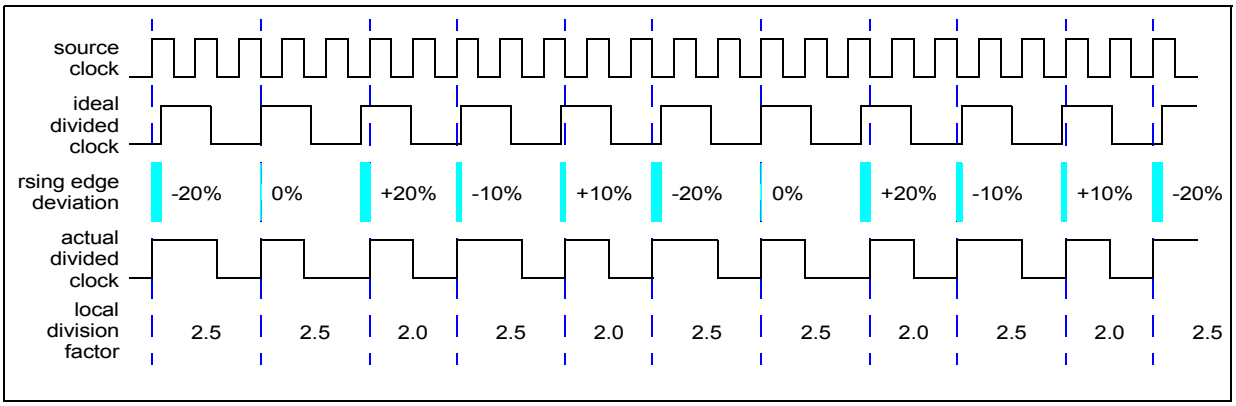
The clock dividers used to generate the PSI5_f189 clock and the DSPI clock 0 divide the selected clock source frequency by a fractional value given by the DIV and DIV_FMT fields in their respective divider configuration registers.

Equation 19

$$f_{\text{divided clock}} = f_{\text{source clock}} \div ((\mathbf{DIV} + 1) \div 10^{\mathbf{DIV_FMT}})$$

The divided clock frequency is an average frequency derived from the available rising and falling edges of the source clock:

The frequency switches between two frequencies closest to the desired frequency (above and below) which can be extracted by a division factor *n*/2, where *n* is an integer greater than 1.



The switching between the two frequencies is such that:

- The resultant clock's rising edge never deviates from the ideal clock's rising edge by more than 25% of the source clock period.
- The resultant average frequency over **DIV** + 1 source clock periods (= $10^{\mathbf{DIV_FMT}}$ divided clock periods) is the desired frequency.

Example 3. Fractional Clock Division

Desired division factor = 2.3. [DIV = 22, DIV_FMT = 1]

Figure 339. MC_CGM Fractional Division Example Waveform (divide by 2.3)

Equation 20

$$f_{\text{divided clock}}\big|_{\text{max}} = f_{\text{source clock}} \div 2.0$$

Equation 21

$$f_{\text{divided clock}}\big|_{\text{min}} = f_{\text{source clock}} \div 2.5$$

Equation 22

Therefore,

$$f_{\text{divided clock}}\big|_{\text{ave}} = f_{\text{source clock}} \div \frac{((2.5 \times 6) + (2.0 \times 4))}{10}$$

Equation 23

$$f_{\text{divided clock}}\big|_{\text{ave}} = f_{\text{source clock}} \div 2.3$$

Figure 333 shows the rising edge of the divided clock 'snapped' to the rising or falling edge of the source clock closest to the rising edge of the ideal divided clock. This results in a theoretical maximum deviation, or jitter, of ±25% of the source clock period. In this particular case, the maximum deviation is ±20% of the source clock period.

30 OSC Digital Interface (XOSC)

30.1 Introduction

The FXOSC digital interface is used to control the on-chip oscillator (FXOSC) and provide the register interface for the programmable features. Selection of the FXOSC as a source clock is controlled by the Clock Generation module (MC_CGM). The FXOSC is enabled and disabled by configuring the Mode Entry module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

30.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to PLLs and can be selected as the reference clock for many of the peripherals on the device.

Table 414 shows the possible configurations of the XOSC.

Table 414. XOSC configurations

OSC EN	XOSC_CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	Crystal, or left opened	Crystal, or left opened	0	Power down, IDDQ
0	1	x	external clock	Undefined	Reserved, OSC Disabled
1	1	x	external clock	XTALOUT	Bypass, OSC Enabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled

30.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<*mode*>_MC[FXOSCON] controls the power-down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the FXOSC is shown in the MC_ME_GS[S_XOSC].

30.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the analog portion of the oscillator is enabled at powerup. If enabled, the analog portion of the oscillator is powered-up during

Phase3 of the device reset sequence (pre-self-test sequence). In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL0).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note: It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

30.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached (OSCCNT = XOSC_CTL[EOCV] × 512). The XOSC_CTL[I_OSC] will be set and an interrupt will be generated if the interrupt mask is set (XOSC_CTL[M_OSC] = 1).

30.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting XOSC_CTL[OSCBYP]. This field can only be set by software, and is only cleared by a system reset. In bypass mode, the oscillator is disabled, and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

Note: The external oscillator must be running before the XOSC is turned off. If XOSC is being turned on, the status will be updated only after the clock starts toggling.

30.2.4.1 Full Swing Pierce mode

Full Swing Pierce mode (FSP) has the following attributes when compared with LCP:

- Provides a wider frequency range
- Less susceptible to noise
- The crystal amplitude is rail-to-rail
  - Distorted oscilation with several harmonics
  - Increased EMI
- Slower settling time
- Feedback resistor and 300 ohms of current limitation are already integrated.

Note: Consult with crystal supplier to determine the need of extra resistance in XTAL to avoid crystal overdrive.

30.3 Memory map and register definition

Table 415 shows the memory map of the XOSC registers.

Table 415. XOSC memory map

1. See the Clocking chapter for reset value
2. These bits can be written with any value, but writes are ignored. A read returns last written value.

Table 416. XOSC_CTL register field descriptions

Field	Description
0 OSCBYP	Crystal Oscillator bypass. This bit specifies whether the oscillator should be bypassed or not. Software can only set this bit. System reset is needed to reset this bit. 0 Oscillator output is used as root clock. 1 EXTAL is used as root clock.
1:7	Reserved
8:15 EOCV	End of Count Value. These bits specify the end of count value to be used for comparison by the oscillator stabilization counter OSCCNT after reset or whenever it is switched on from the off state. This counting period ensures that external oscillator clock signal is stable before it can be selected by the system. When oscillator counter reaches the value EOCV×512, oscillator available interrupt request is generated. The OSCCNT counter is kept under reset if oscillator bypass mode is selected.
16 M_OSC	Crystal oscillator clock interrupt mask. This bit masks the I_OSC interrupt bit. 0 Crystal oscillator clock interrupt is masked. 1 Crystal oscillator clock interrupt is enabled.
17:23	Reserved

Table 416. XOSC_CTL register field descriptions(Continued)

Field	Description
24 I_OSC	Crystal oscillator clock interrupt. This bit can only be set by hardware when OSCCNT counter reaches the count value EOCV × 512. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.
25:31	Reserved

31 IRCOSC digital interface

31.1 Introduction

The Internal RC Oscillator digital interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

31.2 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock with a nominal frequency of 16 MHz. After deassertion of reset, the output clock is available after a short time (see Data Sheet for timing information) which is required for stabilization. The IRCOSC status indication is found in the MC_ME_GS[S_IRC] field (see the “Mode Entry Module MC_ME” chapter).

During a power on reset sequence the following are initialized from TEST flash memory:

- Native trimming bits
- Fine trimming bits
- TSENS code bits

For safety reasons, these bits can be accessed through the IRCOSC Native Trimming register (NT). The main IRCOSC output frequency can be trimmed by configuring IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with dfvar_SW, as defined in the Data Sheet.

31.3 Memory map and register definition

Table 417 shows the memory map of the IRCOSC registers.

Table 417. IRCOSC memory map

Offset (hex)	Register	Access	Reset Value (hex)	Location
00	IRCOSC Control Register (IRCOSC_CTL)	R/W	0000_0000	*31.3.1.1/896*
04	IRCOSC Native Trimming Register (IRCOSC_NT)	R	0000_0yyy*1*	*31.3.1.2/897*
08	IRCOSC Temperature Trimming Register (IRCOSC_TT)	R	yyyy_yyyy*1*	*31.3.1.3/898*

1 See the “Clocking” chapter for specific reset values.

31.3.1 Register descriptions

31.3.1.1 IRCOSC Control register (IRCOSC_CTL)

The IRCOSC_CTL contains user programmable parameters.

Offset 00h Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	—[3]	0	0	0	USER_TRIM[1]

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	—[3]	—[3]	—[3]	—[3]	—[3]	—[3]	0	—[2]	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 IRCOSC_CTL is writable only in supervisor mode.

2 This field may sometimes have the value of 1, and can be cleared by writing a 1 to this bit. However, this field has no effect on the IRCOSC or chip behavior.

3 These bits can be written with any value, but writes are ignored. A read returns last written value.

32 RAM controller (PRAMC)

32.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. *Figure 344* is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture:

Figure 344. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword.

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to present simultaneously the address and associated write data, which is not valid until the

AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

32.2 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses will generate an IPS error termination.

Table 422. RAM controller memory map

26 – 30	Reserved
31 FT_DIS	Flow through disabled This field defines the AHB response of the RAM controller on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

1. The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAMC controller clock frequency.

32.3 Functional description

32.3.1 Read / Write introduction

The RAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The RAM controller captures read data from the RAM array and drives it onto the AHB along with the associated dataphase termination signals. To facilitate operating at higher frequencies, the RAM controller can optionally incur a single wait state on the AHB response.

32.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

32.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the

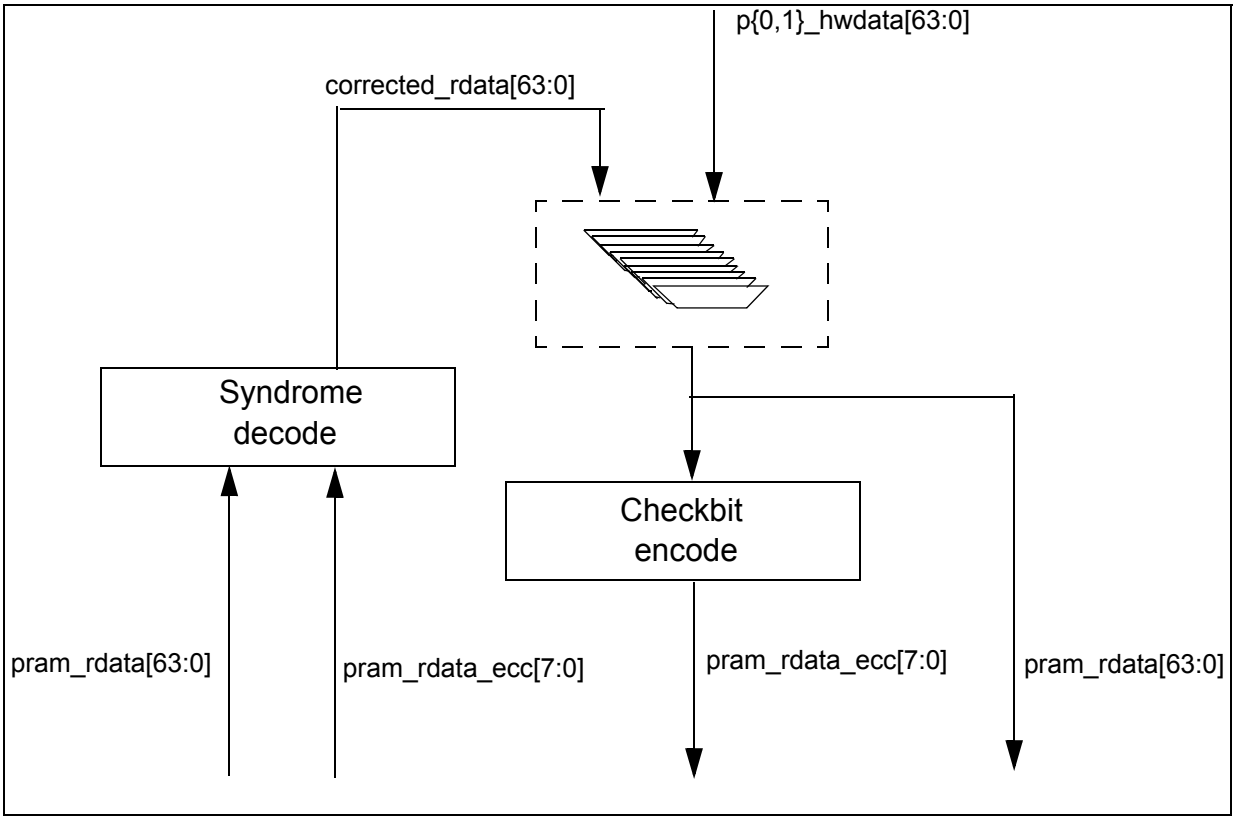
read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCR1[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCR1[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2

Note: The number of cycles taken for a RAM access can vary ±1 clock cycle depending on the RAM speed relative to the PRAMC controller clock frequency. If system RAM is running at the same frequency as the PRAMC controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAMC controller clock frequency.

32.3.2 Writes

32.3.2.1 64-bit writes



Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

32.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially-corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. *Figure 346* provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to *Section 32.5: Safety considerations*."

Figure 346. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

32.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

It should be noted that unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

32.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

A possibility for initializing PRAMC memory space would be to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

32.5 Safety considerations

This section discusses safety considerations of the RAM controller.

32.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is “odd weight”.

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field.

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in *Table 424*. A ‘*’ in *Table 424* indicates the corresponding data or address bit is XOR’ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR’ed) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 424. RAM controller basic H-matrix definition

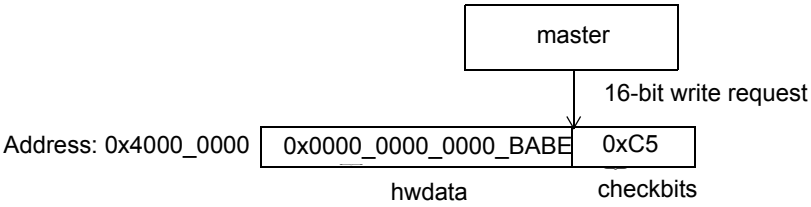
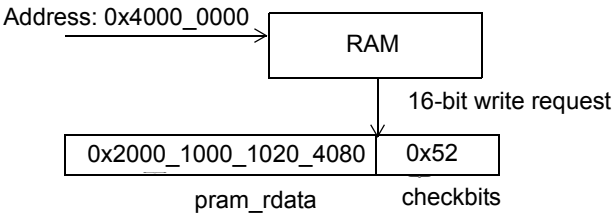
1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.



32.5.1.1 E2EECC considerations on less-than-64-bit write transactions

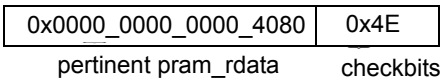
Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following

checkbit manipulation technique to ensure any faults in the PRAMC control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:



- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this “zero-padded” write data.

  Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:



- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

  If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

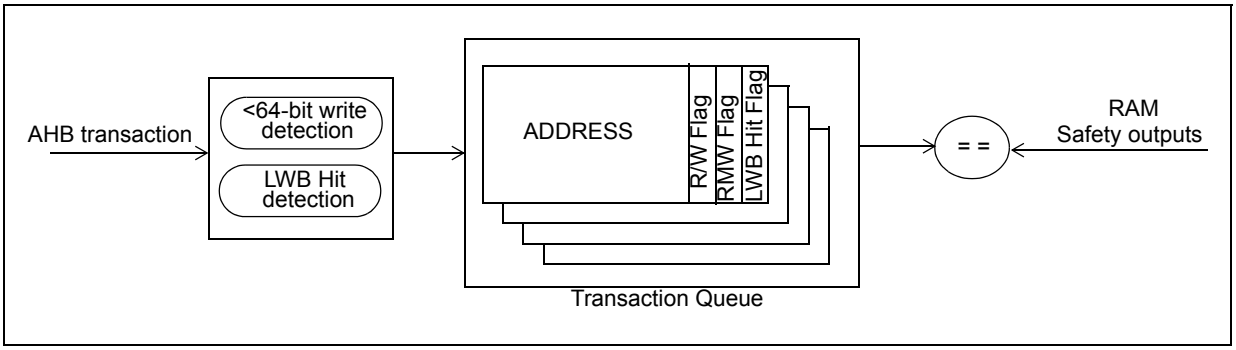
32.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions

- Direct system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated.

Table 425. RAM safety feature outputs



Signal Name	Description
pram_addr_co[17:0]	Safety feature compare outputs for address bus
pram_cs_b_co	Safety feature compare output for chip-select control input
pram_we_co	Safety feature compare output for write-enable control input

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, the safety feature compare outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor must also verify the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

Figure 347. RAM controller transaction monitor block diagram

33 Flash memory controller (PFLASH Controller)

33.1 Introduction

The flash memory controller has two functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash array.
- It serves as the interface to the on-chip overlay RAM and off-chip buddy device.[g]

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface to the flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the code flash array page size and providing 256 bytes of high-speed local storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the PFLASH_MP55 flash memory controller, including the mini-cache, to support end-to-end ECC e2eECC coverage (e2eECC).

33.2 Features

The following list summarizes the key features of the flash memory controller:

- Two 64-bit AHB interface ports (p0, p1).
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle “buffer hit” read response
- Configurable access control based on read/write and AHB master ID attributes
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary
- Configurable overlay remapping of logical flash accesses to on-chip calibration RAM, extended off-chip calibration RAM or on-chip system RAM
- Nexus trace stream interface support for message dumping to the on-chip overlay RAM

33.3 Block diagrams

Figure 348 provides a block diagram showing the flash memory controller and the attached flash array.

g. The term “buddy device” refers to an optional companion chip with additional memory and debug features that is paired with a production chip during system development. It is not used in production devices.

Note: This module is also known as the Platform Flash controller, that is, PFlash or PFLASH_MP55.

33.4 Flash memory controller memory map

33.4.1 Overview

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model is partitioned into two groups: flash access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior.

Field	Description
9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
01 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table 427. PFCR1 field descriptions(Continued)

Field	Description
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. The required settings are documented in the SoC specification. Higher operating frequencies require non-zero settings for this field for proper flash operation. Shown below are the maximum operating frequencies for legal RWSC settings based on specified access times at 150C. The integrator is strongly encourage to verify these settings based on actual silicon results. RWSC=0: 0MHz < fsys < 29.4MHz RWSC=1: 29.4MHz < fsys < 58.8MHz RWSC=2: 58.8MHz < fsys < 88.2MHz RWSC=3: 88.2MHz < fsys < 117.6MHz RWSC=4: 117.6MHz < fsys < 147.0MHz RWSC=5: 147.0MHz < fsys < 176.5MHz RWSC=6: 176.5MHz < fsys < 205.9MHz RWSC=7: 205.9MHz < fsys < 235.5MHz This field is set to 5’b00110 by hardware reset. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access

Table 427. PFCR1 field descriptions(Continued)

Field	Description
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 1x The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit is cleared by hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

33.4.1.2 Platform Flash Configuration Register 2 (PFCR2)

The PFlash Configuration Register 2 (PFCR2) is used to specify operation Port1 of the PFLASH_MP55 flash memory controller.

Table 429. PFCR3 field descriptions

Name	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across all four ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 All four buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 and 1 allocated for instruction fetches and way 2 and 3 for data accesses. 11 Reserved
2–3 P1_WCFG	Port1 Line Buffer Configuration. This field controls the configuration of the line buffers for a given set across all four ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 All four buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffers 0 and 1 allocated for instruction fetches and buffers 2 and 3 for data accesses. 11 Reserved

Table 429. PFCR3 field descriptions(Continued)

Name	Description
11 BDRM	Buddy Device Read Mode - This field controls the PFLASH_MP55 bus response when the master presents a read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address. This field is ignored on production ECUs where the Buddy Device is not present. On production ECUs, this memory map region is provided for the “OLDA” (on-line data acquisition) function. Read requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are terminated with error on the system bus. This field is ignored on write requests targeting the extended overlay RAM using the direct, non-remapped address. Write requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are ignored and terminate cleanly on the system bus. Write requests on engineering ECUs targeting the extended overlay RAM using the direct, non-remapped address are executed. This field is initialized by hardware reset. 0 Read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are aborted, and the request is terminated with error on the system bus. 1 Read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are allowed. The PFLASH_MP55 returns the requested data from the extended overlay RAM, which resides on the BD. Any system bus errors returned by the BD are passed onto the master.
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash, where the access type is detected by evaluating {p0,p1}_hprot[0]. Once this field is set, attempted instruction access attempts targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.

Table 429. PFCR3 field descriptions(Continued)

Name	Description
16–17 ARBM	Arbitration Mode. This 2-bit field controls the arbitration of concurrent flash access requests from the two AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 1- Round-robin arbitration

33.4.1.4 Platform Flash Access Protection Register (PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

Name	Description
0–1 M0AP	Master 0 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
2–3 M1AP	Master 1 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
4–5 M2AP	Master 2 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
6–7 M3AP	Master 3 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
8–9 M4AP	Master 4 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
10–11 M5AP	Master 5 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

Figure 356. PFCRCR register

Table 431. PFCRCR field descriptions

Field	Description
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 32 to 16. This field is initialized by hardware reset. 0 Established calibration overlay regions are not considered safety-critical. 1 Established calibration overlay regions are considered safety-critical.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remapping evaluation on system flash accesses. This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

33.4.1.6 PFlash Calibration Remap Descriptor Enable Register (PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 32 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
30 CRD30EN	Calibration Remap Descriptor 30 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid
31 CRD31EN	Calibration Remap Descriptor 31 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor *n* invalid 1 Calibration Remap Descriptor *n* valid

33.4.1.7 PFlash Calibration Region Descriptor *n* (PFCRD*n*)

Each 96-bit (12 byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16 byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

33.4.1.7.1 PFlash Calibration Region Descriptor *n*, Word0 (PFCRD*n*.Word0)

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-*size* logical start (byte) address of the calibration remap region. It is software's responsibility

to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

Name	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid.

33.4.1.7.2 PFlash Calibration Region Descriptor *n*, Word1 (PFCRD*n*.Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-*size* byte physical start (byte) address of the calibration remap region. The contents of this word define the targeted destination overlay memory. It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

33.5 Functional description

As shown in *Figure 348* the flash memory controller interfaces between the dual AHB system bus ports, Nexus trace, flash memory array, overlay RAM, system RAM, and off-chip Buddy Device.

For accesses targeting the flash array, the flash memory controller generates read and write enables, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

33.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

33.5.2 Access protections

33.5.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in *Section 33.4.1.4: Platform Flash Access Protection Register (PFAPR)*. Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

33.5.2.2 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code, which is loaded in a predetermined OTP flash block. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on either Port0 or Port1 are evaluated. If the flash memory controller detects an attempted instruction fetch access to the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

33.5.3 Read cycles - buffer miss

On an incoming AHB read request, a buffer lookup and access checks are performed during the AHB address phase. In the event of a buffer miss the AHB address and attributes are registered and the flash access is initiated the cycle following the AHB address phase (the first AHB data phase cycle). If globally enabled, the calibration remap evaluation is also performed during the first AHB data phase cycle. If the access is to be remapped, the appropriate access is routed to the destination memory during the second AHB data phase cycle.

If the flash access was the direct result of an AHB transaction, the corresponding page buffer is marked as most-recently-used as it is being loaded. If the flash access was the result of a speculative prefetch to the next sequential line, it is first loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

33.5.4 Read cycles – buffer hit

Single cycle read responses to the AHB are possible with the flash memory controller when the requested read access was previously loaded into one of the page buffers. In these “buffer hit” cases, read data is returned to the AHB data phase with a zero wait-state response.

33.5.5 Error termination

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read Access Control or Write Access Control settings do not allow the access, thus causing a protection violation. See *Section 33.4.1.4, Platform Flash Access Protection Register (PFAPR)* for more detail. In this case the flash memory controller does not initiate a flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See *Section 33.4.1.3, Platform Flash Configuration Register 3 (PFCR3)* for more detail. In this case, the flash memory controller does not initiate a flash array access.
- Attempted access by an AHB master to a flash region, where the corresponding censorship control is asserted.The flash returns an error response on an attempted flash access (See *Section 33.5.6, Flash error response operation*).

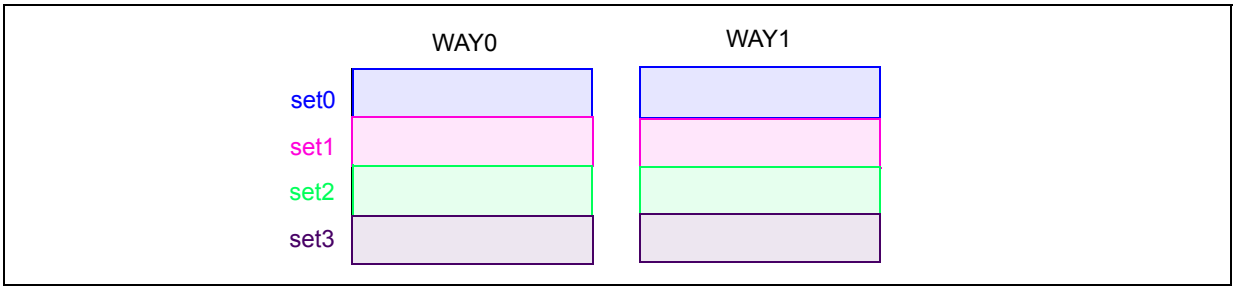
33.5.6 Flash error response operation

The flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations. When an error response is received, the flash memory controller does not update or validate a page read buffer. An error response may be signaled on read operations. For more information on the specifics related to signaling of flash errors, including flash ECC events and read-while-write events, refer to the flash array documentation.

33.5.7 Censorship

The entire flash space is defined by three major regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation)
- TEST flash



Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

33.5.8 Line read buffers and prefetch operation

The two AHB ports of the flash memory controller each containa two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see *Section 33.4.1.1: Platform Flash Configuration Register 1 (PFCR1)*). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 361. Flash memory controller 4-entry, 4-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the just-loaded buffer is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in *Section 33.4.1.1, Platform Flash Configuration Register 1 (PFCR1)*. More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

In order for prefetching to occur, PFCR{1,2}[P{0,1}_BFEN] must be set to '1', PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted. Refer to *Section 33.4.1.1, Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls.

33.5.9 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to *Section 33.4.1.1, Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to *Section 33.4.1.2, Platform Flash Configuration Register 2 (PFCR2)* for a description of these controls. Prefetches are never triggered by write cycles.

33.5.10 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to *Section 33.4.1.1, Platform Flash Configuration Register 1 (PFCR1)* for a description of these controls.

33.5.11 Buffer allocation

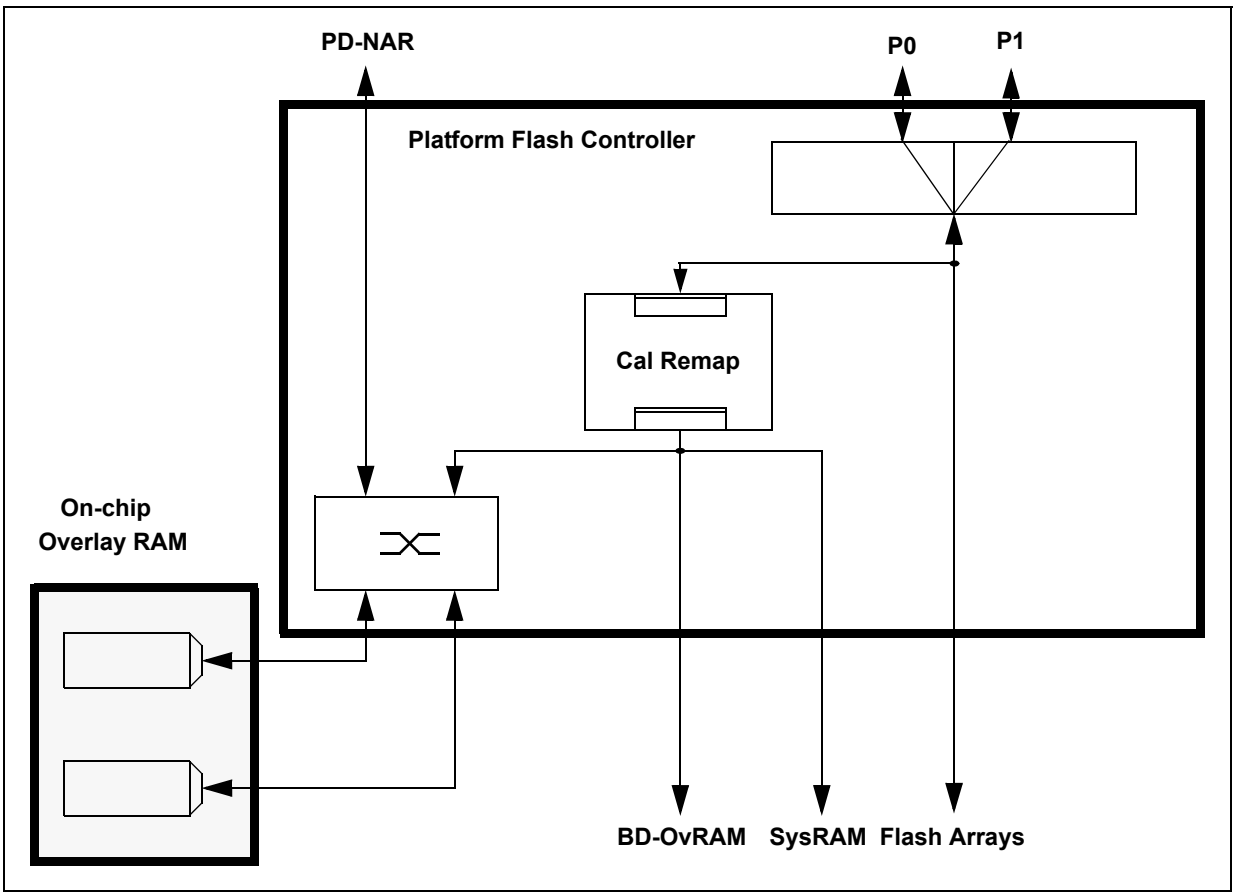
Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to *Section 33.4.1.3, Platform Flash Configuration Register 3 (PFCR3)*. The buffers can be organized as a "pool" of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, ways 0 is allocated for instruction fetches and way1 for data accesses.

33.5.12 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM. Recall this family of devices includes a comprehensive set of features including dedicated overlay RAM arrays to aid calibration and debug. The overlay function supports the following features:

- Can be mapped over internal flash memory
  - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Can be used to hold device debug trace stream
  - Allows limited trace based debug without requirement for complex debug tool hardware and access to high speed trace port
- Protected with error detection and correction mechanism
- Accesses to all overlay RAMs can have the same timing as accesses to internal flash
  - Timing for calibration accesses to a particular overlay RAM is only guaranteed if it is not being used as a destination for trace streaming at the same time
- Support for up to 32 distinct calibration remap regions.

The calibration remap function supports up to three different overlay RAM targets:



1. An internal overlay RAM is included on all standard production devices.
2. An extended overlay RAM is an additional memory that is only available on special ED devices.
3. A portion of the system RAM can be used for overlay.

where the *overlay RAM is selected based on the translated physical address*.

To better understand the functionality of the calibration remap, consider more detailed block diagrams, one showing the overall structure of the calibration remap function and another showing more detail on the actual remap logic. Recall the flash memory controller implements a hardware interconnection matrix connecting the four input ports and four destination memories. See *Figure 362*.

Figure 362 illustrates the calibration remap connection matrix.

Figure 362. PFlash calibration remap connection matrix

Note the 64-bit on-chip overlay RAM is split into 2 equal-sized memories to allow concurrent accesses for calibration data from the P0 or P1 (where these are the crossbar slave input ports) port plus trace data writes from the Production Device Nexus Aurora Router (PD-NAR).

Note that when a reset event asserts while an access to the on-chip overlay RAM is requested, the flash controller aborts the array access.

The translated physical address defines the destination memory. *Table 436* shows the base addresses for the calibration data memories as defined by the system memory map.

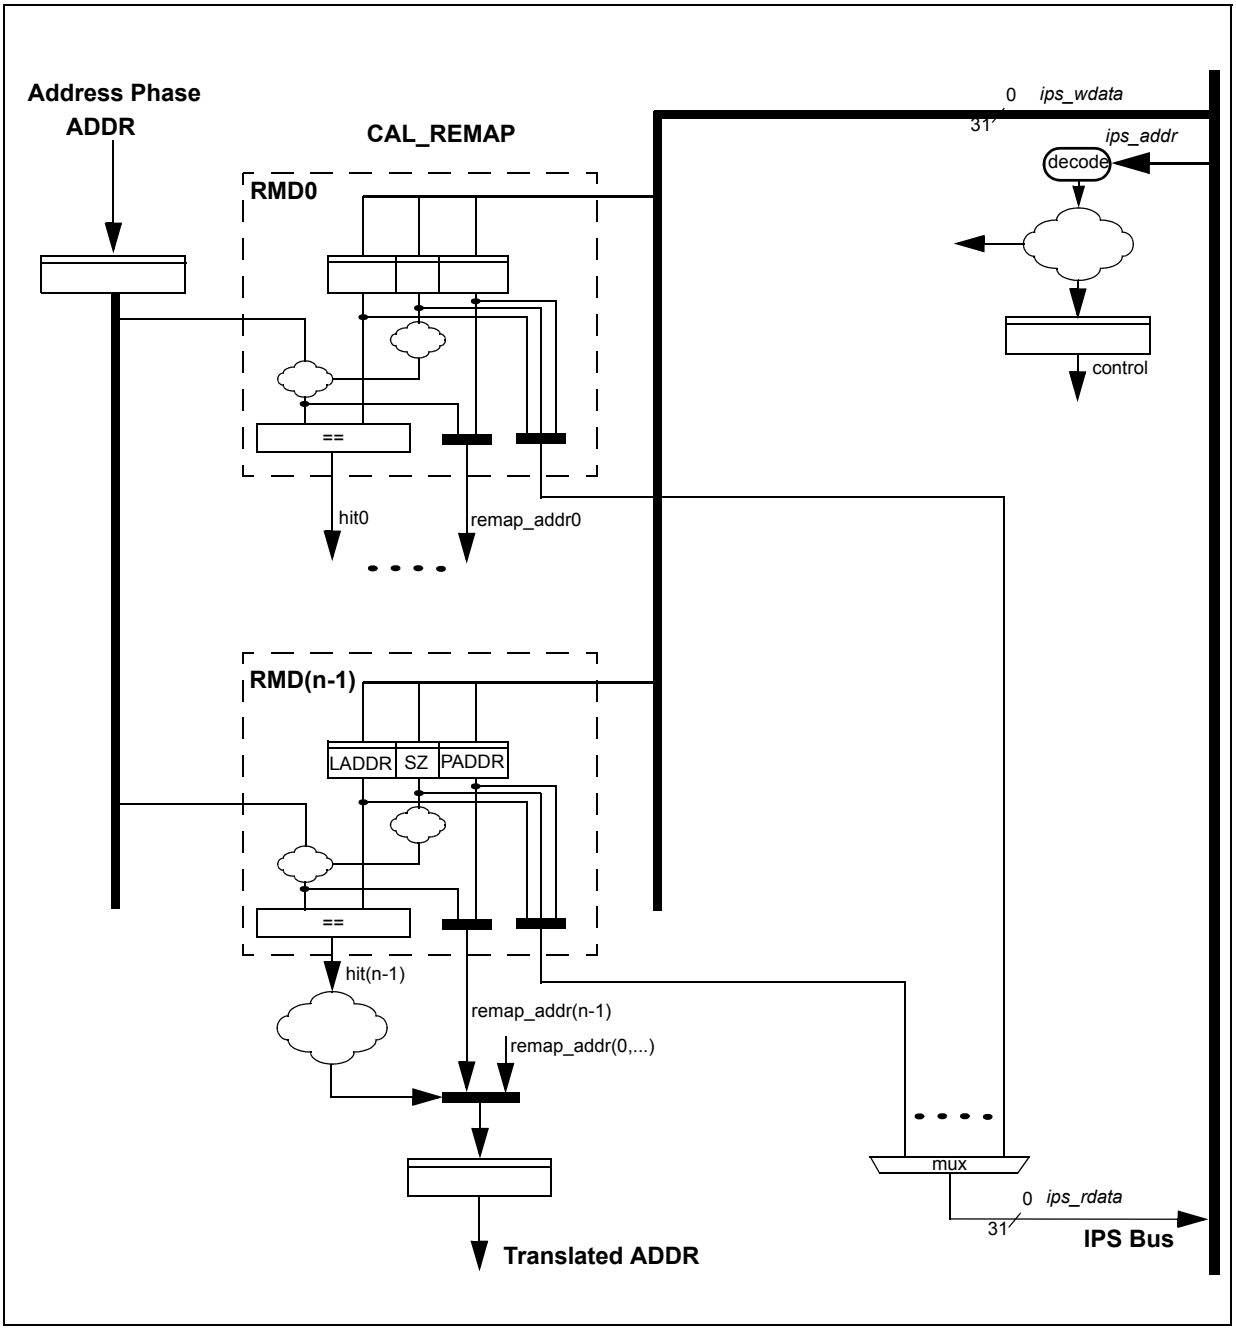
Table 436. Calibration data memory base addresses

Calibration memory	Base address	Possible access sources
Flash Arrays	0x0{8,9,A}--_----	P0, P1
System RAM	0x40{0,1}-_----	P0, P1
On-chip Overlay RAM	0x0D00_----	P0, P1, PD-NAR
Buddy Device (Extended) Overlay RAM	0x0C{0,1}-_----	P0, P1

Note the trace data from the Nexus Aurora Router (PD-NAR) can only be routed to the on-chip overlay RAM; there is a different connection path in the Buddy Device from the BD-NAR into the extended overlay RAM.

The system RAM connection from the calibration remap logic is implemented via *a private 64-bit connection to the platform's RAM controller*. Since the calibration access is defined to have the same access time as a normal flash array access, remapped references to the system RAM are treated as the highest priority request by the platform's RAM controller.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM, on-chip or buddy device (extended) overlay RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a *translated physical address or, if provided by the requesting master, the physical, non-remapped system address.*Doubleword-sized data store references to the on-chip overlay RAM are supported. Byte-, halfword-, word- and doubleword-sized store references to the on-chip calibration RAM or the buddy device (extended) overlay RAM are supported.The read data interface of system RAM, on-chip overlay RAM, and buddy (extended) device are each 64-bits wide, whereas the flash read data interface is 256-bits wide. As a result, a remapped calibration access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration access has a fixed 4-beat latency. The access time of each individual beat depends on the overlay target (system RAM, on-chip overlay RAM, or buddy device). Therefore, PFCR1[RWSC] must be programmed to a value such that the overall flash access latency sufficiently covers the required access time to complete a 4-beat burst sequence from the slowest available overlay target at the specified device operating frequency to guarantee the latency for an initial, random calibration access accurately mimics the flash access time. Expressed mathematically:



$$(\mathrm{RWSC}+1) \geq ((\mathrm{OverlayRAMTranferLatency} \times 4)+1)$$

$$\text{where} \quad \mathrm{RWSC} = \mathrm{ceiling}\left(\frac{\mathrm{IntrinsicFlashAccessTime}}{\mathrm{OperatingFrequencyClockPeriod}}\right)$$

Notice the overall latency as perceived by the requesting master on a random, initial flash access incurs two additional cycles beyond the intrinsic flash access time. The overall latency on a remapped overlay access incurs one additional cycle beyond the burst access time. These cycles accounts for pipleine stalls incured by the flash controller state machine. Calibration data that is available in the flash controller's mini-cache is returned with single-cycle latency

There are memory-mapped calibration remap (region) descriptor (CRD*n*) registers which define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the PFLASH_MP55 flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping. The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries. The translation function is performed during the first AHB data phase cycle. See *Figure 363*.

Figure 363. PFlash calibration remap logic detail

Each instantiation of the basic calibration remap function {RMD0,..., RMD(*n*-1)} in *Figure 363* includes the three descriptor registers containing the logical start address (LADDR in the figure), the physical start address (PADDR) and the region size (SZ). The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to determine the region “hit”. The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the

translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region “hit” data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRDx and CRDy, the translated address from CRDy is used, given y > x. This definition is selected as it minimizes the gate cost and timing impact of the calibration remap descriptor “hit” logic.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

33.5.13 Safety considerations

33.5.13.1 e2eECC (End-to-End ECC)

33.5.13.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all ones codeword, since it reflects the state of an erased flash location, is treated as a valid, error-free encoding. Second, since an erased flash block generates an all ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation; in particular, it is required that the checkbits associated with the all ones data value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller (PFLASH_MP55) before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR’ing the address calculation of the H-matrix from the checkbits.
2. Remove the 3-bit “toggle vector” from the checkbits based on all zeroes (0x70) and all ones (0x07) values of the address ECC calculation. Recall this toggle vector was used to prevent the all zeroes and all ones codewords in the ECC. Since the all ones codeword is required in the flash to support the erased state, these toggle values must be removed.
3. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all ones erased state.

On a flash read operation, a similar but “reversed” set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns fl_rdata = 0xFFFFFFFF_FFFFFFFF, fl_cdata = 0xFF. The flash memory controller calculates the addr_chkbit = 0xC4 using the H-matrix; it inverts the fl_cdata vector to 0x00 and factors in the addr_chkbit = 0xC4 to produce the following valid e2eECC codeword:

addr = 0x00345678, rdata = 0xFFFFFFFF_FFFFFFFF, rchkbit = 0xC4 (0x00 ^ 0xC4)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

addr = 0x00345678, wdata = 0xBABEFACE_DEADBEEF, wchkbit = 0xE3

Before performing the interlock write to the flash array, the PFlashflash memory controller adjusts the chkbit value as fl_wchkbit = 0xE8 (0xE3 ^ 0xff ^ 0xC4) by toggling the original write checkbits and then factoring in the addr_ecc. Accordingly, the codeword stored in the flash array is:

fl_data = 0xBABEFACE_DEADBEEF, fl_checkbit = 0xE8

3. Read address 0x00345678. The flash array returns the stored codeword, fl_rdata = 0xBABEFACE_DEADBEEF, fl_rchkbit = 0xD8. The PFlashflash memory controller inverts the checkbit vector and factors in the address checkbits (0xD8 ^ 0xFF ^ 0xC4) to produce:

addr = 0x00345678, rdata = 0xBABEFACE_DEADBEEF, rchkbit = 0xE3

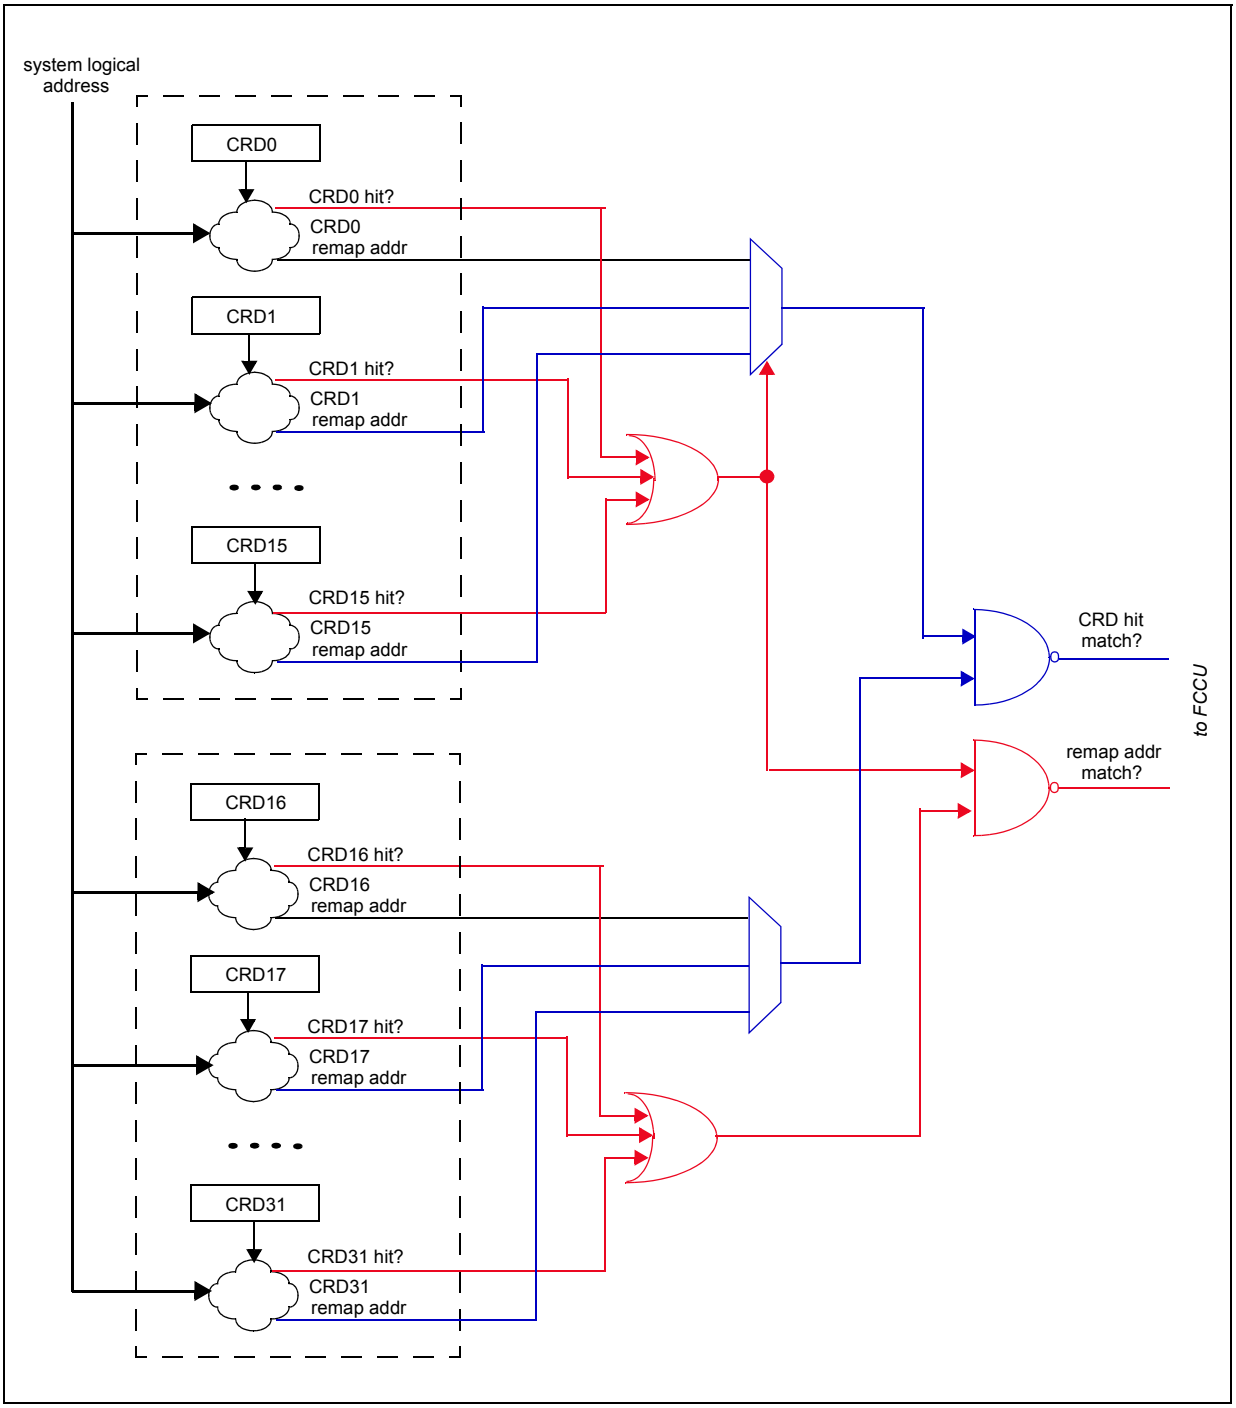
This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The PFLASH_MP55 flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the fault collection module.

33.5.13.1.2 e2eECC and calibration accesses

Recall that calibration write accesses are always presented with the physical, non-remapped system address. As a result, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety- critical component. By programming PFCRCR[SAFE_CAL] = 1, the flash memory



controller treats the 32 available calibration region descriptors (CRD0–CRD31) as a replicated group of 16 region descriptors. More specifically:

- The contents of CRD0 are expected to be redundantly defined in CRD16
- The contents of CRD1 are expected to be redundantly defined in CRD17
- The contents of CRD2 are expected to be redundantly defined in CRD17
- ...and so on
- The contents of CRD15 are expected to be redundantly defined in CRD31

Note: It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0–15 and the calibration regions defined in CRD16–31. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

Figure 364. Safety-critical calibration remap datapath with redundancy

33.5.13.1.3 e2eECC and data flash accesses

ECC events detected on accesses to the data flash blocks are suppressed from being reported to the ECC event collection unit.

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU.

33.5.13.2 Flash address generation check

Functional safety coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Functional safety coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup:

fl_enc_addr[23:2]

fl_enc_error

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the Fault Collection and Control Unit (FCCU) and the corresponding buffer is invalidated. The flash memory controller has a separate MEMU reporting interface associated with each AHB port: p0 and p1.

33.5.13.3 On-Chip Overlay RAM Feedback Check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within theflash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between theflash memory controller and the on-chip overlay RAM arrays.The function of the transaction monitor relies on a feedback path between theflash memory controller and the on-chip overlay RAM arrays, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by theflash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

33.5.14 Array integrity considerations

During an array integrity sequence, the flash array ignores any incoming read requests. The flash provides an output sideband, *fl_aid*, which indicates when an array integrity sequence is in progress. When *fl_aid* is asserted, the flash memory controller aborts any incoming flash access requests and terminates the system bus transfer with an error.

34 Embedded Flash Memory (MP55)

34.1 Introduction

The Flash Memory module serves as electrically programmable and erasable nonvolatile memory, for instructions and data storage.

The Flash Memory module is a nonvolatile, solid-state silicon memory device consisting of blocks of single transistor storage elements, an electrical means for selectively adding (programming) and removing (erasing) charge from these elements, and a means of selectively sensing (reading) the charge stored in these elements.

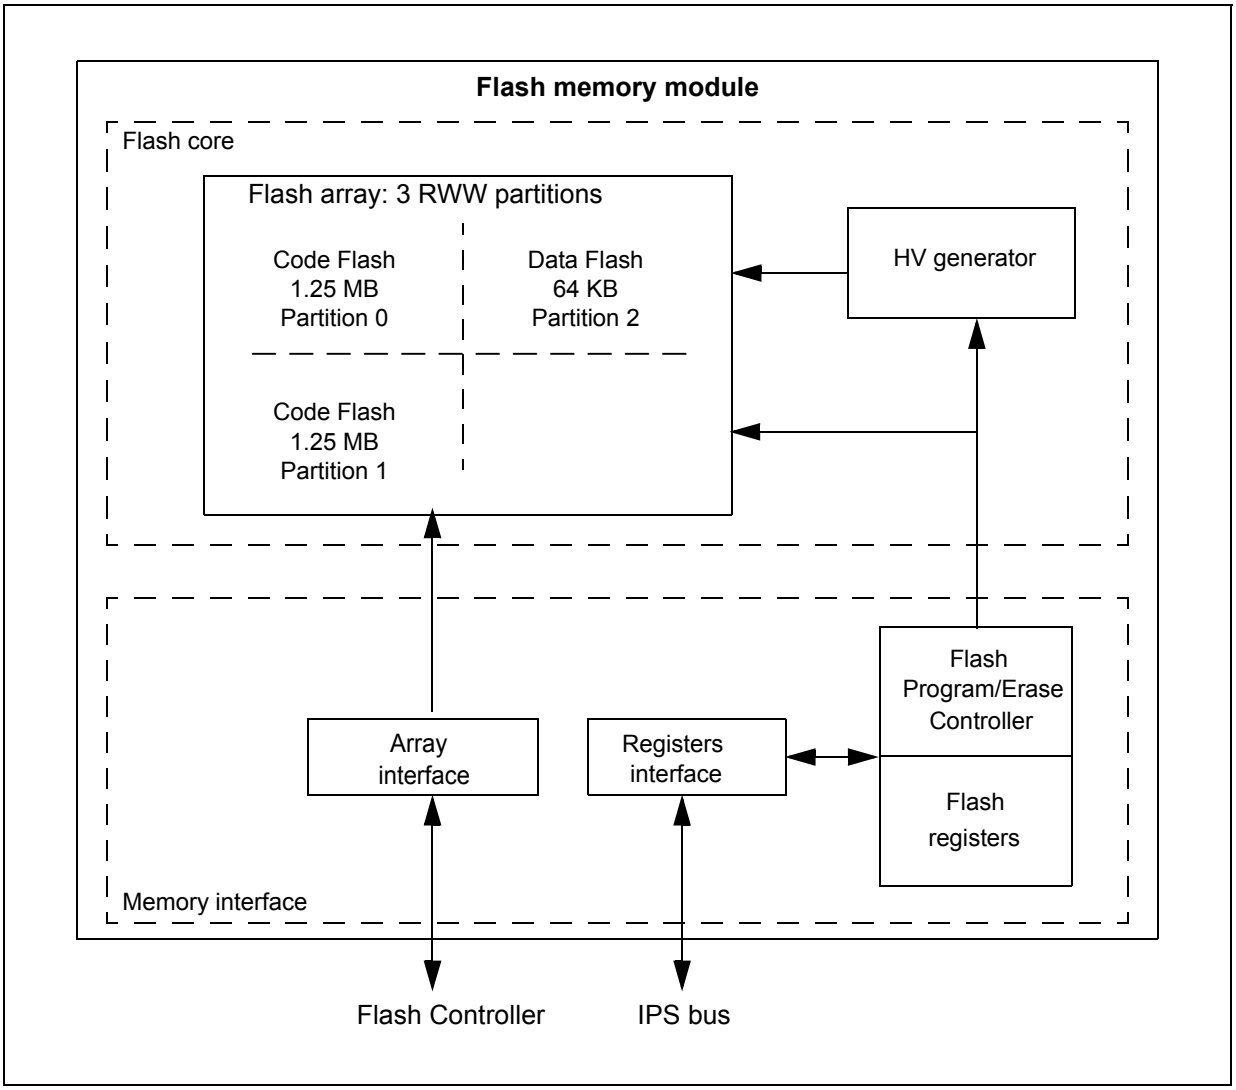
The Flash Memory module has two functional units:

- **The Flash core**. which is composed of a common high voltage HV block and a Flash array which can contain one or more Flash partitions. Each Flash partition is composed of arrayed nonvolatile storage elements, sense amplifiers, row decoders and column decoders. The arrayed storage elements in the Flash partitions are subdivided into physically separate units referred to as blocks.
- **The Memory interface**. Containing the registers and logic which control the operation of the Flash core and contains two main ports: the Array Interface and the Registers Interface. The memory interface is also the interface between the Flash Memory module and a Bus Interface Unit (BIU) and contains the ECC and redundancy logic.

A BIU connects the Flash Memory module to a system bus, and contains all the system level customization required for the SoC application. The Flash Memory module is generic and requires a BIU to configure it for different SoC applications. A BIU is not included.

34.1.1 Overview

The 2720 KB Flash Memory module contains 3 array partitions. Read-While-Write operations are only possible for seperate partitions, meaning fetching/reading from one (or more) partition(s) while a program/erase operation is active on one other partition. Each module counts as an RWW partition.



EEPROM emulation is managed in 1 of the modules, referred to as Data Flash.

The Modify operations are managed by an embedded Flash Program/Erase Controller (FPEC). Commands to the FPEC are delivered through a User Registers interface.

The Read Data bus is 256 bits wide, while the Flash registers are on a separate, 32-bit bus.

The high voltages needed for Program and Erase operations are internally generated and are common for the 3 partitions.

Figure 365. Flash memory module structure

The Flash Memory module is designed for use in embedded MCU/SoC applications which require high density nonvolatile memories with high-speed Read access.

The Flash array is addressable:

- For programs – by word (32 bits) or doubleword (64 bits).
- For reading code partitions – by page (256 bits).
- For reading data partitions – by half-page (128 bits).

Multiple-word or doubleword writes to the Flash memory may be performed to fill the program page buffer (256 bits), enabling page programming (256 bits – requiring 4 doubleword writes) and quad-page programming (1024 bits – requiring 16 doubleword writes). Code flash memory reads always return 256 bits, although Read buffering may be performed by the Bus Interface Unit (BIU). The address for each word retrieved within a page differs from the other addresses in the page by address bits (4:2).

Data Flash memory reads always return 128 bits, or two consecutive doublewords of information. The address for each word retrieved within a doubleword differs from the other addresses by address bits (3:2).

The Flash Memory module supports fault tolerance through Error Correction Code (ECC) and error detection. The ECC implemented within the Flash Memory module corrects single bit failures and detects double bit failures.

The Flash Memory module uses an embedded hardware algorithm implemented in the Flash Program/Erase Controller to program and erase the Flash partitions.

Control logic that works with the software block-enables and software lock mechanisms are included in the embedded hardware algorithm to guard against accidental program/erase. The hardware algorithm performs the necessary steps to ensure that the storage elements are programmed and erased with sufficient margin to guarantee data integrity and reliability.

A programmed bit in the Flash array reads as logic level ‘0’ (or low). An erased bit in the Flash array reads as logic level ‘1’ (or high).

Programming and Erase of the flash array requires multiple system clock cycles to complete.

The Program and Erase sequences may be suspended or aborted.

34.1.2 Features

- 30 ns code/data array access time
- Code Partition High Read parallelism: 256 bits
- Data Partition Read parallelism: 128 bits
- Error Correction Code (SEC-DED) to enhance data integrity
- Doubleword program granularity: 64 bits
- Erase with fast erase time at factory
- Blocks one time programmable (OTP) marking
- Read-While-Modify capability when the accesses are to different partitions
- Erase/Program Suspend
- Programming during Erase-Suspend
- Software programmable program/erase protection to avoid unwanted writings
- Temperature range (–40 °C to 165 °C junction)
- UTEST mode (user-accessible Test modes)
- Critical flops which may affect Flash content are triple-voted for safety application

34.1.3 Modes of operation

The Flash Memory module supports the following modes of operation:

- Reset: the Flash Memory module initializes when the reset is deasserted.
- Power-down (Disable mode): the Flash Memory module removes all static consumption. The embedded Flash memory (array and registers) is not accessible to

Read, Program or Erase once disabled. The wake-up time from Disable mode is longer than the wake-up time from Sleep mode.

- Low-power mode (Sleep mode): the Flash Memory module removes most of the static consumption. It is not accessible to Read, Program or Erase once disabled, however it does maintain a faster exit to Read mode with respect to Power-Down.
- Read mode: the Flash Memory module accepts Read accesses to the array.
- Modify mode: it is possible to read and write registers, Interlock Write the memory array, program the memory array, and erase the memory array. Program and Erase operations are initiated by performing array and register writes, and controlled by an internal state machine. Program/Erase operations or User Test modes (Margin Read or Array Integrity Check) are considered Modify modes.
- Read-While-Write: The Flash Memory module accepts Read accesses to array partitions that are not in Modify mode.

Such modes of operation are described in detail in *Section 34.4: Functional description*.

34.2 Flash memory map and description

The Flash Memory module general architecture supports total memory sizes ranging from 32 KB to 8 MB of user memory, plus up to 48 KB of Test memory (a portion of which is One Time Programmable by the user).

Optionally, an extra memory space ranging from 32 KB to 512 KB can be used as data space for EEPROM emulation, and can be organized in different RWW partitions (in addition to the main User memory Partition).

There are four User Address Spaces: Low, Mid, High and 256K Address Space:

- Low Address Space must always be present and be up to 256 KB in size and may be organized in a maximum of 14 blocks (16 KB[(h)], 32 KB, and 64 KB blocks).
- Mid Address Space can be present and be up to 512 KB in size and may be organized in a maximum of 16 blocks (16 KB, 32 KB, and 64 KB blocks).
- High Address Space can be present and be up to 512 KB may be organized in a maximum of 16 small blocks (8 KB[h], 16 KB, 32 KB, and 64 KB blocks).
- 256K Address Space can be present and be up to 7.5 MB in size and may be organized in a maximum of 30 blocks (256 KB).

Note: There is also a special Test Address space which must always be present and be up to 48 KB in size. Test Address space is part of flash Partition 0.

The Flash Memory module can be divided into a minimum of one to a maximum of eight flash partitions:

The total size of each Code flash Partition cannot be greater than 2 MB and the maximum number of blocks cannot exceed 16, including TestFlash. The total size of each Data flash Partition cannot be greater than 256 KB and the max number of blocks cannot exceed eight.

There are up to six sizes of blocks available for user Flash partitions: 256 KB, 128 KB, 64 KB, 32 KB, 16 KB and 8 KB. The 64 KB, 32 KB and 16 KB blocks can be mapped

h. If the BAF is 8 KB in size, it is integrated with the 8 KB UTEST area to form a single 16 KB block in Low Address Space.

anywhere in the Low, Mid and High address spaces. The 256 KB blocks can be mapped in the 256K address space. 8 KB^{h} blocks may only be mapped in the High address space.

The Flash Memory module block subdivision also facilitates independent Erase and Program protection. A software mechanism is provided to independently lock and unlock each block in Low, Mid, High and Data address spaces against program and erase.

34.2.1 Flash array memory map

34.2.1.1 Code flash

Partition 0 accounts for 1.25 MB of the total Flash Memory and is divided in 12 user blocks for code storage. The first 256 KB blocks are organized as 4 × 16 KB, 2 × 32 KB and 2 × 64 KB. Remaining blocks are 256 KB.

Partition 0 also contains a reserved block named TestFlash in which some One Time Programmable (OTP) user data is stored.

The sectorization of partition 0 of the 2720 KB Flash Memory module is shown in *Table 437*.

Table 437. Flash memory partition 0 memory map

Block	Absolute addresses	Size	Address Space	LOCK	SEL
B0BF	0x0040_4000 to 0x0040_7FFF	16 KB	Low	LOWLOCK[0]	—
B0F1	0x00FC_0000 to 0x00FC_3FFF	16 KB	Low	LOWLOCK[1]	LOWSEL[1]

B0F10	0x0104_0000 to 0x0107_FFFF	256 KB	256 K	A256KLOCK[1]	A256KSEL[1]
B0F11	0x0108_0000 to 0x010B_FFFF	256 KB	256 K	A256KLOCK[2]	A256KSEL[2]
B0F12	0x010C_0000 to 0x010F_FFFF	256 BK	256 K	A256KLOCK[3]	A256KSEL[3]
B0UT	0x0040_0000 to 0x0040_3FFF	16 KB	Low	TSLOCK	—
B0TF	0x0040_8000 to 0x0040_BFFF	16 KB	Reserved	—	—

The sectorization of partition 1 of the 2720 KB Flash Memory module is shown in *Table 438*:

Table 438. Flash Memory Partition 1 memory map

Block	Absolute addresses	Size	Address Space	LOCK	SEL
B1F0	0x0110_0000 to 0x0113_FFFF	256 KB	256K	A256KLOCK[4]	A256KSEL[4]
B1F1	0x0114_0000 to 0x0107_FFFF	256 KB	256K	A256KLOCK[5]	A256KSEL[5]

Table 438. Flash Memory Partition 1 memory map(Continued)

Block	Absolute addresses	Size	Address Space	LOCK	SEL
B1F2	0x0118_0000 to 0x011B_FFFF	256 KB	256K	A256KLOCK[6]	A256KSEL[6]
B1F3	0x011C_0000 to 0x011F_FFFF	256 KB	256K	A256KLOCK[7]	A256KSEL[7]
B1F4	0x0120_0000 to 0x0123_FFFF	256 KB	256K	A256KLOCK[8]	A256KSEL[8]

34.2.1.2 Data flash

Data flash is allocated in partition 2 of the Flash Memory module in 4 × 16 blocks destined for data storage.

The Data Flash sectorization of the Flash Memory module is listed below.

Table 439. Flash Memory Partition 2 memory map

Block	Absolute addresses	Size	Address Space	LOCK	SEL
B2F0	0x0080_0000 to 0x0080_3FFF	16 KB	High	HIGHLOCK[0]	HIGHSEL[0]
B2F1	0x0080_4000 to 0x0080_7FFF	16 KB	High	HIGHLOCK[1]	HIGHSEL[1]
B2F2	0x0080_8000 to 0x0080_BFFF	16 KB	High	HIGHLOCK[2]	HIGHSEL[2]
B2F3	0x0080_C000 to 0x0080_FFFF	16 KB	High	HIGHLOCK[3]	HIGHSEL[3]

34.2.1.3 TestFlash block memory map

The TestFlash block exists outside the normal address space and is programmed, erased and read independently of the other blocks. The independent TestFlash block is also included to support systems which require nonvolatile memory for security and to store system initialization information.

A section of the TestFlash is reserved for storing the nonvolatile information related to Redundancy, Configuration and Protection. The usage of reserved TestFlash block is detailed in *Table 440*.

Table 440. TestFlash block memory map

Address Offset	Description	Size	Access
UTEST (Base Address 0x0040_0000 to 0x0040_3FFF)			
0x0000	OTP area for Device Serial Number	8 byte	R/P
0x0008	Reserved	4 byte	R/P
0x000C	Test Mode Disable Seal	4 byte	R/P
0x0010	Test Mode Disable Block Select 0	16 byte	R/P
0x0020	Factory Erase Diary Location	16 byte	R/P
0x0030	Test Mode Disable Block Select 1	16 byte	R/P
0x0040	Customer Single Bit Correction area	32 byte	R
0x0060	Customer Double Bit Detection area	32 byte	R
0x0080	Customer Programmable Detection area	32 byte	R/P

Table 440. TestFlash block memory map(Continued)

Address Offset	Description	Size	Access
0x00A0	Reserved	96 byte	R/P
0x00B4	Flash Firmware — Minor identifier (f)	1 byte	R
0x00B5	Flash Firmware — Major identifier (F)	1 byte	R
0x00B6	Flash parameters identifiers (P)	1 byte	R
0x00B7	Flash Firmware and parameters — unused	1 byte	R
0x0100	Test Mode Disable Override Passcode0	4 byte	R/P
0x0104	Reserved	252 byte	R/P
0x0200	Reserved	3584 byte	R/P
0x1000	Customer OTP data	12288 byte	R/P
BAF (Base Address 0x0040_4000 to 0x0040_7FFF)			
0x0000	User OTP – BAF Area	16 KB	R/P

The TestFlash block can be enabled by the BIU.When the Test space is enabled, all the operations are mapped to the Test block.The TestFlash supports RWW and is grouped with the Code flash in partition 0.

Erase of the TestFlash block is always locked in User mode.

Programming of any section of the TestFlash block is subject to similar restrictions as the array in terms of how ECC is calculated. Only one program is allowed per 64-bit ECC segment.

The TestFlash block contains two different user sections: UTEST (16 KB) and BAF (16 KB).

The UTEST Nonvolatile Memory section is OTP and erase is not allowed. User mode programming of the UTEST section is enabled only when MCR[PEAS] is high. The UTEST section is divided into a *Flexible* area where content is managed at SoC level, and a *Reserved* area where addresses are pre-allocated for storing certain content. The UTEST section may be locked and unlocked against programming via LOCK0[TSLOCK] in conjunction with the relative sideband (SoC specific). For locking purposes, UTEST is treated as a stand alone block even though it resides in the TestFlash block. UTEST access (both Read and Modify) is disabled in Test mode once the Test Mode Disable Seal password is written. As UTEST is part of the TestFlash physical block, it is also protected.

The UTEST section is also set as OPP once the Test Mode Disable Seal password is written, thus programming is only allowed on virgin 64-bit locations.

The other area of the TestFlash block is BAF and may be used for defined functions (possibly to store boot code, other configuration words or factory process codes). This nonvolatile memory area is OTP and cannot be erased once programmed.

Although the BAF (like UTEST) is part of the TestFlash block, OPP functionality is managed through sideband (SoC specific). Program protection is also managed through sideband (SoC specific), in conjunction with LOCK0[LOWLOCK]. For locking and OPP purposes, BAF is treated as a standalone block.

When the UTEST section (via the entire TestFlash block) is protected via Test Mode Disable Seal, the BAF is also protected from any high voltage operation which may alter the content.

Access to BAF is read only for FPEC in the event that the test interface is open (Failure Analysis scenario).

34.3 Register memory maps and descriptions

In this section some nonvolatile registers are described as well as the usual volatile registers. Note that such entities are not Flip-Flops, but TestFlash block locations with a specific purpose.

During the Flash Initialization phase, the FPEC reads these nonvolatile registers and updates their corresponding volatile registers. When the FPEC detects ECC double errors in these special locations, it behaves in the following way:

- In case of failing system locations (configurations, redundancy, EmbAlgo firmware), the initialization phase is interrupted and a Fatal Error is flagged.
- In case of failing user locations (protections, censorship, BIU, etc.), the volatile registers are filled with ‘1’s and the Flash Initialization ends setting MCR[PEG] to low.

In this section, the following abbreviations are used:

Table 441. Register abbreviations

Case	Abbreviation	Description
Read/Write	R/W	Software can read and write these bits.
Read/Clear	rc	Software can read and clear these bits.
Read/Clear	w1c	Software can read and clear these bits by writing a one.
Read-only	R	Software can only read these bits.
Write-only	W	Software should only write to these bits.

34.3.1 Register memory maps

This section presents the memory mapping of all the flash memory registers.

34.3.1.1 User registers memory map

The Flash User registers represent the communication interface between the host CPU and the FPEC.

Some register bits (command bits) are Read/Write for the CPU and read only for the FPEC. Other register bits (status bits) are Read/Write for the FPEC and read only for the CPU.

The Flash User Registers mapping is shown in *Table 442*.

Table 442. Flash User Registers memory map

Offset address	Description	Access	Reset value(1)	Location
0x0000	Module Configuration Register (MCR)	R/W(2)	0x0000_0600	*on page 962*
0x0004	Reserved	—	—	—

Figure 366. Module Configuration Register (MCR)

Table 443. MCR field descriptions

Field	Description
0	Reserved (read only) Writing to this bit has no effect and Reads always return 0.
1 RRE	Read Reference Error (Read/Clear) RRE provides information on previous reads monitoring the analog Read references. If the current and voltage Read references are out of range, this bit is set to signify that previous reads requested may have been corrupted. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A Read Reference Error occurred during a previous Read.
2 AEE	Address Encode Error (Read/Clear) On every Read request to the Flash, the incoming address is compared to an encoded address (row, column, and block) from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error is recorded. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An Address Encode Error occurred during a previous Read.

Table 443. MCR field descriptions(Continued)

Field	Description
3 EEE	ECC after ECC Error (Read/Clear) EEE provides information on previous reads monitoring the ECC after ECC feature. On every Read request to the flash, ECC parity is recomputed (encoding) just after ECC decoding, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error is reported. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A previous Read may have been corrupted.
4–15	Reserved (read only) Writing to this bit has no effect and Reads always return 0.
16 EER	ECC event Error (Read/Clear) EER provides information on previous reads This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. EER may not be set to ‘1’ by the user. EER is not set for a ECC Single Error detection and correction event. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 An ECC Double Error occurred during a previous Read.
17 RWE	Read-while-Write event Error (Read/Clear) RWE provides information on previous Reads during a Modify operation. Read-While-Write Error means that a Read access to the Flash Array partition has occurred while the FPEC was performing a Program or Erase operation or an Array Integrity Check on the same partition. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. 0 Reads are occurring normally. 1 A RWW Error occurred during a previous Read.
18 SBC	Single Bit Correction (Read/Clear) SBC provides information on previous reads. This bit must then be cleared or a reset must occur before this bit returns to a ‘0’ state. This bit may not be set to ‘1’ by the user. In the event of a ECC Double Error detection, this bit is not set. This status flag is cleared to ‘0’ by writing ‘1’ to the register location. A Write of ‘0’ has no effect. The function of this bit is SoC dependent and it can be disabled (through UT0[SBCE]). 0 Reads are occurring normally. 1 An ECC Single Error occurred and was corrected during a previous Read.
19	Reserved (read only) Writing to this bit has no effect and Reads always return 0.

Table 443. MCR field descriptions(Continued)

Field	Description
20 PEAS	Program/Erase Access Space (read only). PEAS is used to indicate which space is valid for Program and Erase operations: main array space or UTEST section within Test Flash block. – PEAS is captured and held with the first Interlock Write done for Modify operations. – PEAS is retained between sampling events (i.e., subsequent to first interlock writes). – PEAS is changed during erase-suspended program (when program is in UTEST) and reverts back to its original state (related to erase suspended operation) once the erase-suspended program is completed (MCR[PGM] 1–0 transition). 0 UTEST address space is disabled for program and main address space enabled. 1 UTEST address space is enabled for program and main address space disabled.
21 DONE	Modify operation DONE (read only) DONE indicates if the Flash Memory module is performing a high voltage operation. DONE is set to 1: – On termination of the Flash Memory module reset. – At the end of program and Erase High Voltage sequences. – After 1–0 transition of EHV, which aborts a high voltage Program/Erase operation (within t_{PABT} or t_{EABT}, equal to P/E Abort Latency). – After 0–1 transition of ESUS/PSUS which suspends an Erase/Program operation (within t_{ESUS}/t_{PSUS} time equals to Erase/Program Suspend Latency). DONE is cleared to ‘0’: – just after 0–1 transition of EHV, which initiates a high voltage operation, or after resuming a suspended operation. 0 Flash is executing a high voltage operation. 1 Flash is not executing a high voltage operation.

Table 443. MCR field descriptions(Continued)

Field	Description
22 PEG	Program/Erase Good (read only) PEG is automatically updated to show the completion status of the last Flash Program or Erase sequence involving high voltage operations. PEG is evaluated on the completion status of only the interlocked doubleword during page program or quad-page programming where some doubleword addresses are not interlocked (already programmed or intended to remain virgin). PEG is set to ‘0’ after Aborting a Program/Erase high voltage operation, indicating sequence failure. PEG is set to ‘1’ when the Flash Memory module is reset, unless a Flash Initialization error has been detected. **Note:** PEG is valid only when PGM=1 and/or ERS=1 and after DONE 0–1 transitions due to an Abort or the completion of a Program/Erase operation. PEG remains valid until PGM/ERS 1–0 transitions or EHV 0–1 transitions. PEG is not valid after DONE 0–1 transitions when ESUS/PSUS is set to logic ‘1’. If Program or Erase is attempted on blocks that are locked, PEG=1 indicating that the operation was successful and the content of the block was properly protected from the Program or Erase operation. Blocks can be locked through LOCK0/1/2 registers OR with f90_plock0/1/2 sideband signals. If a Program operation tries to write ‘1’ to bits that are ‘0’, the program operation is correctly executed on the new bits to be programmed at ‘0’, but PEG is cleared indicating that the requested operation has failed. If Programming during an Erase-Suspend a location that was under suspended erase, program is not executed and PEG is set to ‘0’. With end2end ECC scheme, during an Interlock Write also ECC parity bit are input. After setting EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, in the page program or in the quad-page program, containS an inconsistency between data and parity, the whole operation is rejected and a PEG=0 is set. PEG behavior with blocks marked as OPP (though f90_otpen0/1/2 sidebands signal) is the following: PEG=0 if the location to be programmed is not virgin, and thus would not be over programmed. In Array Integrity Check or Margin Read PEG is not altered when the operation is completed, regardless the occurrence of any error, abort, break point or suspend. The presence of errors can be detected only comparing checksum value stored in UM0–9 and checking MCR flags. 0 Program, Erase operation failed or Program, Erase aborted. 1 Program or Erase operation successful.
23 PECIE	Program/Erase Complete Interrupt Enable (Read/Write). PECIE provides a mechanism to trigger an interrupt request upon the assertion of the DONE flag. 0 An interrupt request is not generated when the DONE flag is set. 1 An interrupt request is generated when the DONE flag is set.

Table 443. MCR field descriptions(Continued)

Field	Description
24 FERS	Factory Erase (Read/Write). FERS is used for Erase and Program operations to enable faster operation. Factory Erase must adhere to *Initial maximum (All Temperatures)* conditions, with respect to voltage conditions and Write/Erase cycling. The temperature can range from -40 °C to 150 °C. Factory erase does not support Read and RWW operations. – FERS may be set to enable a Factory Erase or Program after setting ERS or PGM but prior to setting EHV. – FERS can be cleared only when EHV is low and DONE is high. – FERS is cleared on reset. **Note:** Factory Erase may also be disabled by writing a location in the UTEST Nonvolatile Memory space. Address 0x800020 in the UTEST Nonvolatile Memory space is checked at reset, and if programmed with data that contains at least one zero, a Factory Erase is not allowed, and FERS is locked. Writes attempted that violate the above cases result in FERS remaining cleared. 0 Factor Erase is disabled. 1 Factory Erase is enabled.
25–26	Reserved (read only) Writing to this bit has no effect and Reads always return 0.
27 PGM	Program (Read/Write) PGM is used to setup the Flash Memory module for a Program operation. – 0–1 transition of PGM initiates a program sequence. – 1–0 transition of PGM ends the program sequence. PGM can be set only under the following conditions: – User Mode Read (ERS is low and UT0[AIE] is low). – Erase Suspend (ERS and ESUS high) with EHV low. PGM can be cleared by the user only when PSUS and EHV are low and DONE is high. PGM is cleared on reset. **Note:** In an erase-suspended program, programming Flash memory locations in blocks which were being operated on in the Erase is forbidden. Command is not accepted and PEG is set to 0 0 Flash is not executing a program sequence. 1 Flash is executing a program sequence.

Table 443. MCR field descriptions(Continued)

Field	Description
28 PSUS	Program Suspend (Read/Write). PSUS is used to indicate that the Flash Memory module is in Program Suspend or in the process of entering a Suspend state. The Flash Memory module is in Program Suspend when PSUS=1 and DONE=1. – PSUS can be set high only when PGM and EHV are high. – 0–1 transition of PSUS starts the sequence which sets DONE and places the flash in Program Suspend. The Flash Memory module enters Suspend within t_{PSUS} of this transition. – PSUS can be cleared only when DONE and EHV are high. – 1–0 transition of PSUS with EHV=1 starts the sequence which clears DONE and returns the module to Program. The Flash Memory module cannot exit Program Suspend and clear DONE while EHV is low. In case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), PSUS has to be cleared first in order to resume currently higher level suspended operation that is program. PSUS is cleared on reset. 0 Program sequence is not suspended. 1 Program sequence is suspended.
29 ERS	Erase (Read/Write) ERS is used to setup the Flash Memory module for an Erase operation. – 0–1 transition of ERS initiates an Erase sequence. – 1–0 transition of ERS ends the Erase sequence. ERS can be set only under User Mode Read (PGM is low and UT0[AIE] is low). ERS can be cleared by the user only when ESUS and EHV are low and DONE is high. ERS is cleared on reset. 0 Flash is not executing an Erase sequence. 1 Flash is executing an Erase sequence.

Table 443. MCR field descriptions(Continued)

Field	Description
30 ESUS	Erase Suspend (Read/Write) ESUS is used to indicate that the Flash Memory module is in Erase Suspend or in the process of entering a Suspend state. The Flash Memory module is in Erase Suspend when ESUS=1 and DONE=1. – ESUS can be set high only when ERS and EHV are high and PGM is low. – 0–1 transition of ESUS starts the sequence which sets DONE and places the flash in Erase Suspend. The Flash Memory module enters Suspend within t_{ESUS} of this transition. – ESUS can be cleared only when DONE and EHV are high and PGM is low. – 1–0 transition of ESUS with EHV=1 starts the sequence which clears DONE and returns the module to Erase. The Flash Memory module cannot exit Erase Suspend and clear DONE while EHV is low. In case of Program Suspend while in Erase Suspend (PSUS=1, ESUS=1), ESUS cannot be cleared first. ESUS is cleared on reset. 0 Erase sequence is not suspended. 1 Erase sequence is suspended.

Table 443. MCR field descriptions(Continued)

Field	Description
31 EHV	Enable High Voltage (Read/Write) The EHV bit enables the Flash Memory module for a high voltage Program/Erase operation. EHV is cleared on reset. EHV must be set after an Interlock Write to start a Program/Erase sequence. EHV may be set under one of the following conditions: – Erase (ERS=1, ESUS=0, UT0[AIE]=0) – Program (ERS=0, ESUS=0, PGM=1, UT0[AIE]=0) – Erase-suspended program (ERS=1, ESUS=1, PGM=1, PSUS=0, UT0[AIE]=0). For a program operation to initiate while an Erase is suspended, EHV must be cleared while in Erase-Suspend (after DONE transitions to 1) before setting PGM. In normal operation, a 1–0 transition of EHV with DONE high, PSUS low and ESUS low terminates the current Program/Erase high voltage operation. In an erase-suspended program operation, a 1–0 transition of EHV with DONE, ESUS, PGM and ERS high and PSUS low terminates the program that is the current high voltage operation. When an operation is aborted, there is a 1–0 transition of EHV with DONE low and the eventual Suspend bit for the current program/erase operation low. An Abort causes the value of PEG to be cleared, indicating failed Program/Erase. Address locations being operated on by the aborted operation contain indeterminate data after an Abort. EHV cannot be set to ‘1’ after an Abort request (EHV being cleared) until the Abort sequence is completed (DONE transitions to 1). Once the Abort sequence is completed (DONE=1) a new operation of the kind aborted can start provided that a new interlock is given and then EHV is set to ‘1’ again. A suspended operation cannot be aborted. Aborting a high voltage operation leaves the Flash Memory module addresses in an indeterminate data state. This may be recovered by executing an Erase on the affected blocks. EHV may be written during Suspend. EHV must be high to exit Suspend, resuming previously suspended command. EHV cannot not be written during transition into Suspend state (after Suspend bit (ESUS or PSUS) is set high) until DONE transitions to ‘1’. EHV may not be written after ESUS is set and before DONE transitions high. EHV may not be cleared after ESUS is cleared and before DONE transitions low. 0 Flash is not enabled to perform a high voltage operation. 1 Flash is enabled to perform a high voltage operation.

A number of MCR bits are protected against Write when another bit, or set of bits, are in a specific state. These Write locks are covered on a bit-by-bit basis in the preceding description, but those locks do not consider the effects of trying to write two or more bits simultaneously.

The Flash Memory module does not allow the user to write bits simultaneously (which puts the device into an illegal state). This is implemented through a priority mechanism among the bits shown in *Table 444*.

Table 444. MCR Bits Set/Clear Priority Levels

Priority level	MCR bits
1	ERS
2	PGM
3	EHV
4	ESUS, PSUS

If the user attempts to write two or more MCR bits simultaneously then only the bit with the lowest priority level is written.

34.3.2.2 Extended Module Configuration Register (MCRE)

The Extended Module Configuration Register value is based on the size, blocks and address space configuration of the Flash Memory module.

Address: 0x0008 Access: User Read

29–31 n16Kl	Number of 16 KB blocks in low space. (read only) 000 Zero 16 KB blocks. 001 Two 16 KB blocks. 010 Four 16 KB blocks. 011 Six 16 KB blocks. 100 Eight 16 KB blocks. 101 Reserved. 110 Reserved. 111 Reserved.

34.3.2.3 Lock 0 register (LOCK0)

The LOCK0 (Low/Mid Address Space Block Locking) register provides a means of protecting blocks from being modified. LOWLOCK and MIDLOCK bits corresponding to non existent blocks are read as ‘1’.

To determine the effective status of the Low/Mid Address Space, combine (Or) LOCK0 with sidebands:

- f90_plock0 – in order to evaluate protection against programming.
- f90_elock0 – in order to evaluate protection against erase.

The effect of programming or erasing a block protected with LOCK0 is that no modification occurs and PEG is set to ‘1’.

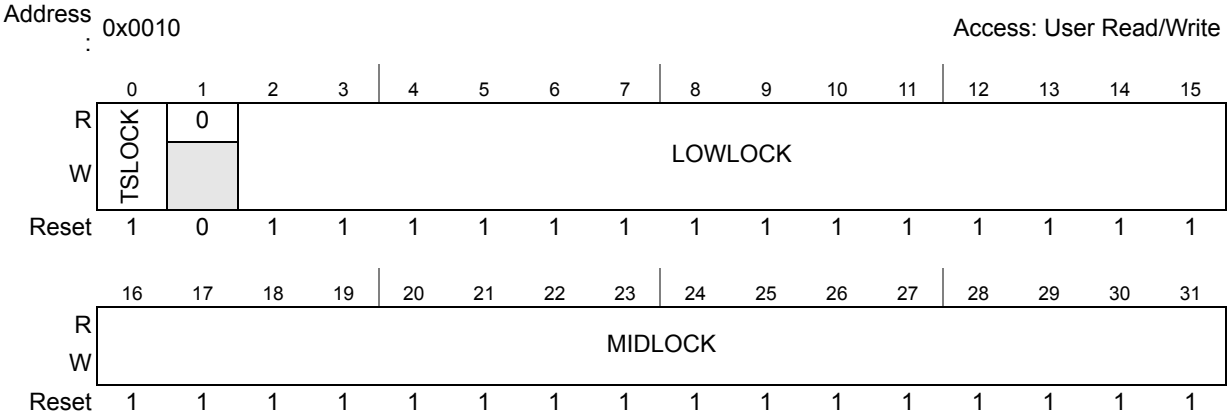

Figure 368. Locking 0 register (LOCK0)

Table 446. LOCK0 field descriptions

Field	Description
0 TSLOCK	UTEST NVM block lock (Read/Write) This bit is used to lock the UTEST NVM from programming (UTEST NVM is not erasable). The LOCK field is not writable: – Once an Interlock Write is completed until MCR[DONE] is set. – If a high voltage operation is suspended. The default value of the TSLOCK bit is locked. The effective status of the UTEST protection is done combining (ORed) LOCK0[TSLOCK] with sidebands *f90_plock0.31* in order to evaluate protection against program. 0 Test Address Space Block is unlocked and can be modified. 1 Test Address Space Block is locked and cannot be modified.
1	Reserved (read only). Writing to this bit has no effect and Reads always return 0.

Table 446. LOCK0 field descriptions(Continued)

Field	Description
2-15 LOWLOCK[13:0]	Low address space block lock 13-0 (Read/Write) These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the Low Blocks starts at LOWLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR[DONE] is set. – If a high voltage operation is suspended. The default value of the LOWLOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the LOWLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Low Address Space Block is unlocked and can be modified. 1 Low Address Space Block is locked and cannot be modified.
16-31 MIDLOCK[15:0]	Mid address space block lock 15-0 (Read/Write) These bits are used to lock the blocks of Mid Address Space from Program and Erase. The block numbering for the Mid Blocks starts at MIDLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR[DONE] is set. – If a high voltage operation is suspended. The default value of the MIDLOCK bits is locked. In the event that blocks are not present (due to configuration or total memory size), the MIDLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Mid Address Space Block is unlocked and can be modified. 1 Mid Address Space Block is locked and cannot be modified.

34.3.2.4 Lock 1 register (LOCK1)

The LOCK1 (High/Data Address Space Block Locking) register provides a means of protecting blocks from being modified. HIGHLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the High Address Space, combine (Or) LOCK1 with sidebands

- f90_plock1 – in order to evaluate protection against program
- f90_elock1 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK1 is that no modification occurs and PEG is set to ‘1’.

Table 447. LOCK1 field descriptions

Field	Description
0–15	Reserved (read only) Writing to this bit has no effect and Reads always return 0.
16–31 HIGHLOCK[15:0]	High address space block lock 15-0 (Read/Write) These bits are used to lock the blocks of High Address Space from Program and Erase. The block numbering for the High Blocks starts at HIGHLOCK[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR[DONE] is set. – If a high voltage operation is suspended. The default value of the HIGHLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the HIGHLOCK bits default to locked, and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 High Address Space Block is unlocked and can be modified. 1 High Address Space Block is locked and cannot be modified.

34.3.2.5 Lock 2 register (LOCK2)

The LOCK2 (256K Address Space Block Locking) register provides a means of protecting blocks from being modified. The A256KLOCK bits corresponding to nonexistent blocks are read as ‘1’.

To determine the effective status of the 256KLOCK Address Space, combine (Or) LOCK2 with sidebands:

- f90_plock2 – in order to evaluate protection against program
- f90_elock2 – in order to evaluate protection against erase.

The effect of programming/erasing a block protected with LOCK2 is that no modification occurs and PEG is set to ‘1’.

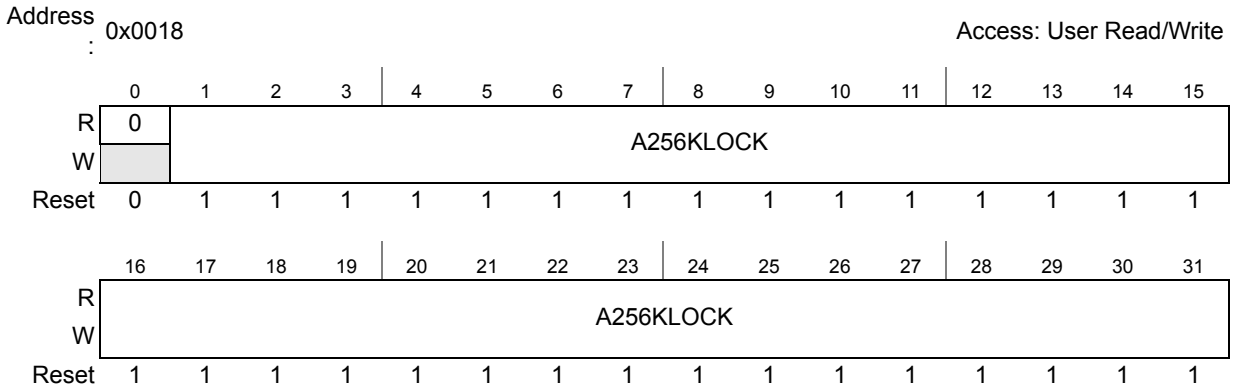

Figure 370. Locking 2 register (LOCK2)

Table 448. LOCK2 field descriptions

Field	Description
0	Reserved (read only). Writing to this bit has no effect and Reads always return 0.
1–31 A256KLOCK[30:0]	256K address space block lock 30-0 (Read/Write) These bits are used to lock the existing blocks of Low Address Space from Program and Erase. The block numbering for the 256 KB blocks starts with A256KLOCK[0] and continues until all blocks are accounted for. The LOCK field is not writable: – Once an Interlock Write is completed until MCR[DONE] is set. – If a high voltage operation is suspended. The default value of the A256KLOCK bits is locked. When blocks are not present (due to configuration or total memory size), the A256KLOCK bits default to locked and are not writable. The reset value is always ‘1’ and register writes have no effect. 0 Low Address Space Block is unlocked and can be modified. 1 Low Address Space Block is locked and cannot be modified.

34.3.2.6 Select 0 register (SEL0)

The SEL0 (Low/Mid Address Space Block Select 0) register provides a means to select blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL0 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR[ERS] (see step 4 in *Section 34.4.5.5: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR[EHV] with MCR[ERS]=1 and with MCR[ESUS]=0). Reading returns latched data (image of the SEL0 at the start of the Erase operation) while writing has no effect.

Figure 371. Select 0 register (SEL0)

Table 449. SEL0 field descriptions

Field	Description
0-1	Reserved (read only). Writing to this bit has no effect and Reads always return 0.
2-15 LOWSEL[13:0]	Low address space block select 13-0 (Read/Write) The block numbering for the Low Blocks starts at LOWSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding LOWSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect 0 Low Address Space Block is unselected for Erase. 1 Low Address Space Block is selected for Erase.
16-31 MIDSEL[15:0]	Mid address space block select 15-0 (Read/Write) The block numbering for the Mid Blocks starts at MIDLSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size), the corresponding MIDSEL bits default to unselected and are not writable.The reset value is always ‘0’, and register writes have no effect. 0 Mid Address Space Block is unselected for Erase. 1 Mid Address Space Block is selected for Erase.

34.3.2.7 Select 1 register (SEL1)

The SEL1 (High Address Space Block Select Register 1) provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL1 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR[ERS] (see step 4 in *Section 34.4.5.5: Erase*) until the completion of the Erase high voltage operation (1–0 transition of MCR[EHV] with MCR[ERS]=1 and with MCR[ESUS]=0). Reading returns latched data (image of the SEL1 at the start of the Erase operation) while writing has no effect.

Address 0x003C Access: User Read/Write

Figure 372. Select 1 register (SEL1)

Table 450. SEL1 field descriptions

Field	Description
0–15	Reserved (read only). Writing to this bit has no effect and Reads always return 0.
16–31 HIGHSEL[15:0]	High/Data address space block select 1 15-0 (Read/Write) The block numbering for the High Blocks starts at HIGHSEL[0] with16 KB block region (if available), then the 32 KB block region (if available), and lastly the 64 KB block region (if available). This continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding HIGHSEL bits default to unselected and are not writable. The reset value is always ‘0’ and register writes have no effect. 0 High Address Space Block is unselected for Erase. 1 High Address Space Block is selected for Erase.

34.3.2.8 Select 2 register (SEL2)

The SEL2 (256K Address Space Block Select 2) register provides a means of selecting blocks to be operated on during Erase or Array Integrity Check – Margin Read.

Starting an Erase operation, SEL2 bits are latched and become non-alterable from the first interlock cycle that follows the rising transition of MCR[ERS] (see step 4 in *Section 34.4.5.5:*

Erase) until the completion of the Erase high voltage operation (1–0 transition of MCR[EHV] with MCR[ERS]=1 and with MCR[ESUS]=0). Reading returns latched data (image of the SEL2 at the start of the Erase operation) while writing has no effect.

Address: 0x0040 Access: User Read/Write

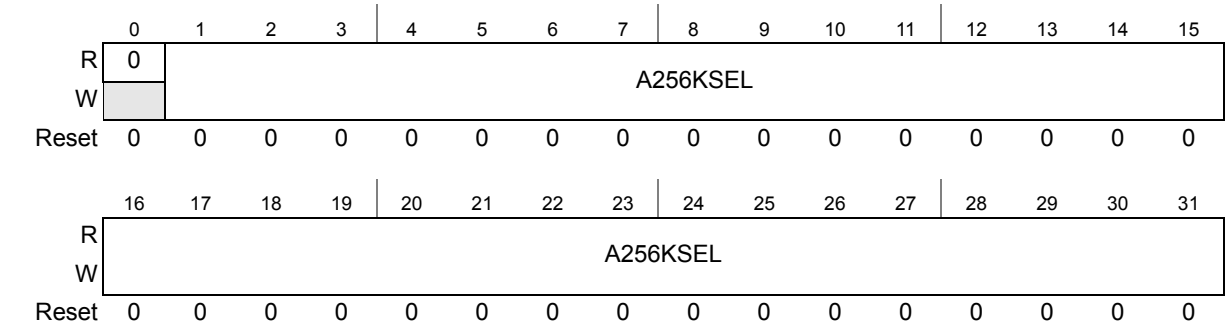

Figure 373. Select 2 register (SEL2)

Table 451. SEL2 field descriptions

Field	Description
0	Reserved (read only). Writing to this bit has no effect and Reads always return 0.
16–31 A256KSEL[30:0]	256K address space block select 30-0 (Read/Write) The block numbering for the 256 KB blocks starts with A256KSEL[0] and continues until all blocks are accounted for. The blocks must be selected (or unselected) before doing an Erase Interlock Write as part of the Erase sequence. The select field is not writable: – once an Interlock Write is completed until DONE is set – a high voltage operation is suspended. The select field must not be written when UT0[AIE] is high. When blocks are not present (due to configuration or total memory size) the corresponding A256KSEL bits default to unselected and are not writable. The reset value is always ‘0’, and register writes have no effect. 0 Low Address Space Block is unselected for Erase. 1 Low Address Space Block is selected for Erase.

34.3.2.9 Address register (ADR)

The Address register provides the first failing address in the event module failures (ECC, RWW or FPEC) or the first address at which ECC single error correction occurs. ADR captures the first failing address for the modes listed in *Table 452* according to the priority rules in *Table 453*.

Table 452. ADR update mode list

Mode	Update on error	Note
Read	ECC Double Error, ECC Single Error (if UT0.SBCE=1)	—
Modify	FPEC error	—

Table 452. ADR update mode list(Continued)

Mode	Update on error	Note
RWW	ECC Double Error, RWW error, FPEC error, ECC Single Error (if UT0.SBCE=1)	—
User Test	ECC Double Error, ECC Single Error (if UT0.SBCE=1)	with Break Point enabled (UT0.AIBPE=1), ADR requires MCR.ERR and MCR.SBC to be cleared

In case of Array Integrity Check or Margin Read with Break Point enabled (UT0[AIBPE]=1), the ADR value matches the address where the Break Point was triggered only when the current run (first start or re-start after a breakpoint (NAIBP cleared)) starts with MCR[ERR] and MCR[SBC] flags cleared, otherwise the ADR priority rule overrides Break Point.

Table 453. ADR content: priority list

Priority level	Error flag	ADR content
1	MCR[EER] = 1	Address of first ECC Double Error
2	MCR[RWE] = 1	Address of first RWW Error
3	MCR[PEG] = 0	Address of first FPEC Error
4	MCR[SBC] = 1	Address of first ECC Single Error Correction

Figure 374. Address register (ADR)

Table 454. ADR field descriptions

Field	Description
0 SAD	Test Address (read only) When this bit is high, the address indicated by ADDR[23-3] belongs to the Test Block.
1–7	Reserved (read only). Writing tothis bit has no effect and a read always returns 0.

Table 454. ADR field descriptions(Continued)

Field	Description
8–28 ADDR[23:3]	Address 23-3 (read only) The Address Register provides the first failing address in the event of ECC error (MCR[EER] set) or the first failing address in the event of RWW error (MCR[RWE] set), or the address of a failure that may have occurred in a FPEC operation (MCR[PEG] cleared). The Address Register also provides the first address at which a ECC single error correction occurs (MCR[EDC] set) if the SoC is configured to show this feature through UT0[SBCE]. The ECC double error detection takes the highest priority, followed by the RWW error, the FPEC error and the ECC single error correction. When accessed, ADR provides the address related to the first event occurred with the highest priority. This address is always a doubleword address that selects 64 bits. In case of a simultaneous ECC Double Error Detection on more than one doubleword of the same page, bits ADDR[4] and ADDR[3] output ‘0’. The same is valid for a simultaneous ECC Single Error Correction on more than one doubleword of the same page. In User mode the Address Register is read only. Address given is in flash format and has to be intended as in the flash memory Map: offset respect to absolute address.
29–31	Reserved (read only). Writing tothis bit has no effect and a read always returns 0.

Table 455. Flash memory partition 0 addresses mapping

Block	Flash format addresses	Absolute addresses
B0BF	0x0080_4000 to 0x0080_7FFF	0x0040_4000 to 0x0040_7FFF

34.3.2.10 User Test 0 register (UT0)

The User Test 0 register feature gives the user of the Flash Memory module the ability to perform test features on the flash.

The User Test 0 register allows control of the way the flash content check is performed. Bits MRE, MRV and AIS of the User Test 0 register are not accessible when MCR[DONE] or UT0[AID] are low. Reading returns indeterminate data while writing has no effect.

Address: 0x0054 Access: User Read/Write

Figure 375. User Test 0 register (UT0)

Table 458. UT0 field descriptions

Field	Description
0 UTE	User Test Enable (Read/Clear) This status bit gives indication when User Test is enabled. All bits in UT0 and UM0–UM9 are locked when this bit is ‘0’. This bit is not writable to a ‘1’, but may be cleared. The reset value is ‘0’. To set UTE, write the password 0xF9F99999 to the UT0 register. The UTE password is only accepted if PGM=0 and ERS=0 (Program and Erase are not being requested). UTE can only be cleared if AID=1, MRE=0 and AIE=0. While clearing UTE, writes to set AIE or MRE are ignored.
1 SBCE	Single Bit Correction Enable (Read/Clear) This bit, when high, enables to flag the information about any eventual ECC Single Bit Correction in the flash array (MCR.SBC and ADR). This is true in read mode and in Array Integrity Check. SBCE also is used as an Enable for interrupt signals created by the embedded flash memory. ECC corrections that occur when SBCE is cleared are not logged.
2-12	Reserved (Read/Write). Writes have no effect. For compatibility purposes, any writes should be ‘0’.
13 CPR	Customer Programmable Read Voltage and Reference Detection (Read/Clear) This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set and the Customer Programmable Detection location in UTEST is read, a Read Voltage and Reference Error detection is set. 0 Customer Programmable Read Voltage and Reference Detection Error is not enabled 1 Customer Programmable Read Voltage and Reference Detection Error is enabled.
14 CPA	Customer Programmable Address Encode Detection (Read/Clear) This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read, an Address Encode Error detection is set. 0 Customer Programmable Address Encode Detection Error is not enabled 1 Customer Programmable Address Encode Detection Error is enabled
15 CPE	Customer Programmable EDC after ECC Detection (Read/Clear) This bit is used to control the error generation for the Customer Programmable Detection area in the UTEST block. If this bit is set, and the Customer Programmable Detection location in UTEST is read, an EDC after ECC Error detection is set. 0 Customer Programmable EDC after ECC Detection Error is not enabled 1 Customer Programmable EDC after ECC Detection Error is enabled
16-21	Reserved (Read/Write). Writes have no effect. For compatibility purposes, any writes should be ‘0’.
22 NAIBP	Next Array Integrity Break Point (Read/Clear) If AIBPE is set, NAIBP is set once a single bit correction (if enabled) or double bit detection is noted during the Array Integrity test. NAIBP is not writable to ‘1’ but may be cleared to ‘0’. Clearing NAIBP to ‘0’ enables the Array Integrity operation to be re-started after a breakpoint is encountered. If the Array Integrity operation completes without encountering another correction or detection, AID is set with NAIBP remaining ‘0’. 0 Array Integrity is not currently at a break point. 1 Array Integrity is at a break point.

Table 458. UT0 field descriptions(Continued)

Field	Description
23 AIBPE	Array Integrity Break Point Enable. (Read/Write) To enable breakpoints during an Array Integrity test, AIBPE may be set. When breakpoints are enabled, if the run has been started with MCR[ERR] (and MCR[SBC] when UT0[SBCE]=1) flag cleared, on the eventual occurrence of a breakpoint condition, MCR flags and ADR value may be updated. See NAIBP description for more information about Array Integrity breakpoints. 0 Array Integrity breakpoints are not enabled. 1 Array Integrity breakpoints are enabled during Array Integrity Checks.
24	Reserved
25 AISUS	Array Integrity Suspend (Read/Write). AISUS toggles Suspend of an Array Integrity - Margin Read Operation. AISUS can be written to ‘1’ only when AID is low AISUS can be written to ‘0’ only when AID is high. Attempting to Write AISUS and AIE on the same clock cycle results in only AIE being written. 0 Array Integrity sequence not suspended. 1 Array Integrity sequence is suspended.
26 MRE	Margin Read Enable (Read/Write) MRE enables margin reads to be done. MRE combined with MRV enables User Margin mode reads to be done. Margin reads run on a block-by-block basis in linear address sequence selected by SEL0, SEL1 and SEL2. This bit is not accessible when MCR[DONE] or UT0[AID] are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Margin Read is not enabled. 1 Margin Read is enabled.
27 MRV	Margin Read Value (Read/Write) If MRE is high, MRV selects the margin level that is being checked. Margin can be checked to an erased level (MRV=1) or to a programmed level (MRV=0). This bit is not accessible whenever MCR[DONE] or UT0[AID] are low or if AISUS or NAIBP are high: reading returns indeterminate data while writing has no effect. 0 Zero’s (programmed) margin reads are requested (if MRE=1). 1 One’s (erased) margin reads are requested (if MRE=1).
28	Reserved (Read/Write). Write this bit has no effect. It’s suggested for compatibility to Write at 0.
29 AIS	Array Integrity Sequence (Read/Write) AIS determines the address sequence to be used during Array Integrity checks. The default AIS=0 checks the read propagation paths along proprietary sequences followed by user code. The sequential run sequence time is significantly shorter than the proprietary sequence. AIS is not writeable if AIE is high. This bit is not accessible whenever MCR[DONE] or UT0[AID] are low: reading returns indeterminate data while writing has no effect. 0 Array Integrity sequence is proprietary sequence. 1 Array Integrity sequence is sequential.

Table 458. UT0 field descriptions(Continued)

Field	Description
30 AIE	Array Integrity Enable (Read/Write) Setting AIE to ‘1’ starts the Array Integrity Check and the Margin Read on all selected blocks. The sequence is selected by AIS and the MISR (UM0–UM9) is checked on completion to determine if a correct signature is obtained. AIE can be set only if MCR[ERS], MCR[PGM] and MCR[EHV] are all low. AIE is not simultaneously writable to ‘1’ while UTE is being cleared to ‘0’. Clearing AIE terminates the check when an Array Integrity operation finishes (AID=1) and aborts the check when and Array Integrity operation is ongoing (AID=0). AIE remains ‘1’ when the Array Integrity Check - Margin read are suspended or are in breakpoint and cannot be cleared. (AIE can be cleared if NAIBP=0 and AISU=0) 0 Array Integrity Check and Margin Read and are not enabled. 1 Array Integrity Check and Margin Read are enabled.
31 AID	Array Integrity Done (read only) AID is set to indicate that the Array Integrity Check - Margin Read is complete and the MISR (UM0–9) can be checked. AID may also assert if breakpoints are enabled (AIBPE is set) and the breakpoint condition is met. AID may also assert if Suspend is set (AISUS 0–1). AID can not be written, and is status only. 0Array Integrity Check is on-going. 1Array Integrity Check is done.

34.3.2.11 User Multiple Input Signature registers

The Multiple Input Signature registers allow evaluation of the Array Integrity or Margin Read run on a block-by-block basis by accumulating signatures from data bit fields.

These registers are not accessible whenever MCR[DONE] or UT0[AID] are low. Reading returns indeterminate data while writing has no effect.

The registers can be written in order to seed signatures before starting an AIC or MR operation.

Note: Do not write to the MISR registers during an Array Integrity operation (including Suspend or Breakpoint)as it may alter the final signature in an unpredictable way.

If reads extend into an invalid address location during address sequencing (i.e., greater than the maximum address for a given array size), reads are still executed to the array but the results are not deterministic: MISR registers are not recalculated and the previous value is retained.

34.3.2.11.1 User Multiple Input Signature 0 register (UM0)

UM0 represents bits 31–0 of the whole 288-bit word (4 doublewords including ECC).

Address: 0x0058 Access: User Read/Write

1–31 A256KOPP[30:0]	256K High address space Over Program Protection 1–31 (Read) The block numbering for the 256 KB Blocks starts at A256KOPP[0] and continues until all blocks are accounted for. The A256KOPP field is not writable, and is status only. The default value of the A256KOPP bits is not over-programming protected. When blocks are not present (due to configuration or total memory size), the A256KOPP bits default to not over-programming protected and will remain 0. 0 High Address Space Block is unprotected from over-programming. 1 High Address Space Block is protected from over-programming.

34.3.2.13 Test Mode Disable Password Check register (TMD)

The Test Mode Disable Password Check (TMD) register provides a means of entering the password to be matched with the one stored in UTEST location in order to allow manufacturer access to protected Test Mode blocks by writing 0x5A4B_3C2D in the Test Mode Disable Seal location.

Address: 0x0090 Access: User Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W	PWD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W	PWD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 389. Test Mode Disable Password Check register (TMD)

Table 472. TMD field descriptions

Field	Description
0–31 PWD	The Test Mode Disable Check register is used as a location to provide a password challenge to unlock blocks selected to be sealed as part of the Test Mode Disable seal mechanism. Please see *Section 34.4.6.2: Test mode disable* for more information. Writes to the register have no effect except for a password challenge. Reads to this register will always return 0. The register's reset value is 0. **Note:** PWD bitfield is byte-reversed compared to UTEST TMD password : for instance, if UTEST TMD password is written 0x01020304, the PWD bitfield must be written 0x04030201

34.4 Functional description

This chapter describes the details of all the modes of operation available to the Flash Memory module.

34.4.1 Reset

A reset is the highest priority operation for the Flash Memory module and terminates all other operations.

The Flash Memory module uses reset to initialize register and status bits to their default reset values. If the Flash Memory module is executing a Program or Erase operation (MCR[PGM]=1 or MCR[ERS]=1) and a reset is issued, the operation is immediately terminated and the module disables the high voltage logic without damage to the high voltage circuits.Reset terminates all operations and forces the Flash Memory module into Read mode ready to receive Read/Write accesses.

Reset and Power-Off must not be used as a systematic way to terminate a Program or Erase operation.

After reset is negated Read register access may be performed, although registers that require updating from shadow information or other inputs may not read updated values until MCR[DONE]transforms. MCR[DONE] may be polled to determine if the Flash Memory module has transitioned out of reset. Note that the registers cannot be written until MCR[DONE] is high.

34.4.2 Power-down mode (Disable mode)

The Power-down (or Disable) modeallows the turning-off of all flash DC current sources. All power dissipation in this mode is due solely to leakage.

In Power-down mode no Read from or Write to the flash array is possible. Every Flash array Read access executed when the Power-down mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the Power-down mode is exited.On the contrary, Write access is locked on all the registers in Power-down mode.

When enabled the Flash Memory module returns to its pre-disable state in all cases unless in the process of executing an Erase or a Program High Voltage operation at the time of disable. If the Flash Memory module is disabled during an Erase operation, the operation is suspended and MCR[ESUS] bits are set to ‘1’. The user may resume the Erase operation at the time the module is enabled by clearing MCR[ESUS]. MCR[EHV] must be high to resume the Erase operation.

If the Flash Memory module is disabled during a program operation, the operation is suspended and MCR[PSUS] is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR[PSUS]. MCR[EHV] must be high to resume the Erase operation.

If the Flash Memory module is disabled during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to a ‘1’. When the module is enabled PSUS must be cleared first to resume the program. Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

If the Flash Memory module is put in Power-down mode and the Vector Table remains mapped in the Flash Address space, the user must be mindful that the Flash Memory module significantly increases the interrupt response time by adding several Wait States.

Note: Do not enter Low-power mode when the Power-down mode is active.

34.4.3 Low-power mode (Sleep mode)

The Low-power (or Sleep) mode turns-off most of the DC current sources within the Flash Memory module. Wake-up time from Low-power mode is faster than wake-up time from Power-down mode.

In Low-power mode no Read from or Write to the Flash array is possible. Every Read access executed when the Low-power mode is active outputs invalid data.

The user may not read some registers (UM0–UM9 and part of UT0) until the Low-power mode is exited. Write access is locked on all the registers in Low-power mode.

When exiting from Low-power mode the Flash Memory module returns to its pre-sleep state in all cases unless in the process of executing an Erase High Voltage operation at the time of entering sleep mode. If the Flash Memory module is put in sleep mode during an Erase operation, MCR[ESUS] is set to ‘1’. The user may resume the Erase operation at the time the module exits from sleep by clearing MCR[ESUS]. MCR[EHV] must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during a program operation, the operation is suspended and MCR[PSUS] is set to ‘1’. The user may resume the program operation at the time the module is enabled by clearing MCR[PSUS]. MCR[EHV] must be high to resume the Erase operation.

If the Flash Memory module is put in Low-power mode during an erase-suspended program operation, the program operation is suspended and both ESUS and PSUS are set to ‘1’. When the module is enabled, PSUS must first be cleared for the program to resume. The Erase may be resumed after the program ends. EHV must be high to resume both operations.

If the Flash Memory module is disabled during AIC or MR, the operation is aborted and the MISR value is not deterministic.

Note: Do not enter Power-down mode when the Low-power mode is active.

34.4.4 Read mode

Read mode is the active mode of operation of the Flash Memory module in which the Flash array can be read or 'written' (the so-called Interlock Write), or the Flash registers can be read or written.

The Flash Memory module enters Read mode when exiting from reset. The default state of the Flash Memory module is Read mode.

The main spaces (Low, Mid, High, and 256K) and Test address space of Flash array can only be read in Read mode.

Flash registers can even be read when the module is in Power-down or Low-power mode (except a few documented registers) as well as in Read mode. However, Flash registers can only be written while in Read mode.

Flash memory module is in Read mode, granting the same access time, under the following conditions:

- The Read state is active when the module is enabled (User Mode Read)
- The Read state is active when MCR[ERS] and MCR[ESUS] are high and MCR[PGM] is low (Erase Suspend)
- The Read state is active when MCR[PGM] and MCR[PSUS] are high (Program Suspend)
- The Read state is active when MCR[PGM] or MCR[ERS] are high and High Voltage operation is ongoing on one partition, thus MCR[EHV] is high (condition referred as Read-While-Write). In this case reads done on the other partitions are allowed, while reads done to the partition being operated on (either Erase or Program) result in an error with MCR[RWE] set and the data read back possibly being random including the possibility of ECC errors.

Code flash partitions reads return 256 bits (1 page = 4 doublewords). Data flash partition reads return 128 bits. Register reads return 32 bits (1 word).

Flash array reads are performed through the Bus Interface Unit. In many cases the BIU applies "Read Page Buffering" to allow sequential reads to be executed with higher performance. This can provide data coherency issues that must be handled by software. Data coherency may be an issue after a program or an Erase operation, as well as Test block operations.

Flash array reads to invalid locations result in indeterminate data. Invalid locations occur when addressing points to blocks that are not included in the flash memory Map of any partition. Interlock writes to invalid locations result in an interlock occurring, but attempts to program these blocks do not eventuate since they are forced into a locked state. Erase occurs to selected and unlocked blocks even if the Interlock Write is to an invalid location.

Register reads to unmapped register address spaces return all 0's. Registers writes to unmapped register address spaces have no effect.

Simultaneous Read cycles on the Flash array and Read/Write cycles on the registers are possible, but not simultaneous register Read/Write accesses with Flash Array Interlock Writes are forbidden.

34.4.4.1 Error correction code

The Flash Memory module implements a strategy for improving the reliability of the data stored in Flash via the use of Error Correction Code. The word size is fixed to 64 bits.

For each doubleword of 64 bits, 8 ECC bits are associated and programmed in such a way as to guarantee Single Error Correction and Double Error Detection (SEC-DED). ECC coding has all 0's (intended as data and parity) as an invalid word and all 1's as a valid word.

In addition to providing the requested Read data, the Flash also provides output sidebands reflecting the status of the single bit corrections and double bit detections performed at the end of each Read.

For functional safety coverage, Flash performs an EDC post ECC operation at every Read to detect mismatches in the ECC logic detection and correction. The result is output as sideband. Also active is a monitor circuit that checks the reference current in the sense amplifiers, including control of the internally regulated Read voltage, to prevent anomalous Read operation.

ECC circuitry provides single-bit fault correction used to achieve automotive reliability targets. Some units experience single-bit corrections throughout the life of the product with no impact on product reliability.

34.4.4.1.1 EEPROM emulation

The chosen ECC algorithm allows some bit manipulation so that a doubleword can be re-written several times without needing an erase of the block. This allows the use of a doubleword to store flags useful for the EEPROM emulation.

As an example, the chosen ECC algorithm allows starting from an all 1's doubleword value and rewriting whichever of its four 16-bit halfwords to all 0's content by keeping the same ECC value.

Table 473 shows a set of doublewords sharing the same ECC value:

Table 473. Bits Manipulation: doublewords with the same ECC value

Doubleword	ECC parity bits
0xFFFF_FFFF_FFFF_FFFF	0xFF
0xFFFF_FFFF_FFFF_0000	0xFF
0xFFFF_FFFF_0000_FFFF	0xFF
0xFFFF_0000_FFFF_FFFF	0xFF
0x0000_FFFF_FFFF_FFFF	0xFF
0xFFFF_FFFF_0000_0000	0xFF
0xFFFF_0000_FFFF_0000	0xFF
0x0000_FFFF_FFFF_0000	0xFF
0xFFFF_0000_0000_FFFF	0xFF
0x0000_FFFF_0000_FFFF	0xFF
0x0000_0000_FFFF_FFFF	0xFF

Table 473. Bits Manipulation: doublewords with the same ECC value(Continued)

Doubleword	ECC parity bits
0xFFFF_0000_0000_0000	0xFF
0x0000_FFFF_0000_0000	0xFF
0x0000_0000_0000_0000	0xFF

Note: When some Flash blocks are used for EEPROM emulation, reserve at least 3 blocks for this purpose.

34.4.4.2 Flash address generation check

For functional safety coverage, flash provides output sidebands reflecting the re-encoded address used to perform the actual Read operation.In the re-encoding process both wordline and column within the selected block are evaluated. For the completion of the re-encoding operation, the addresses related to block selections are also computed. Re-encoding circuitry is able to detect both no-selection as well as multi-selection.Flash provides a self-check of address consistency comparing at each Read the sampling of the current Read address with the re-encoded one, and in case of mismatch an error sideband is set.

34.4.5 Modify mode

All the Modify operations of the Flash Memory module are managed through the Flash User Registers interface.

When a Modify operation is active on some blocks, no Read access is possible on any other block of the same Flash Partition. The Read-While-Modify is supported only among different flash partitions.

During a Flash Modify operation any attempt to read any Flash location in the same Flash partition outputs invalid data and MCR[RWE] is automatically set.

If a reset occurs during a Modify operation, the operation is immediately terminated and the module is reset to Read mode. The data integrity of the Flash section where the Modify operation was terminated is not guaranteed: the interrupted Flash Modify operation must be repeated.

In general each Modify operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in MCR[PGM] or MCR[ERS] or UT0[MRE].
2. The second step is the definition of the operands: the address and the data for Programming, or the blocks for Array Integrity Check or Margin Read.
3. The third instruction is used to start the Modify operation by setting MCR[EHV] or UT0[AIE].

Once selected, but not yet initiated, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Modify operations are shown in *Table 474*.

Table 474. Flash Modify operations

Operation	Select bit	Operands	Start bit
Doubleword Program	MCR[PGM]	Address and Data by Interlock Writes	MCR[EHV]
Block Erase	MCR[ERS]	SEL0, SEL1 and SEL2	MCR[EHV]
Array Integrity Check	None	SEL0, SEL1 and SEL2	UT0[AIE]
Margin Read	UT0[MRE]	UT0[MRV] + SEL0, SEL1 and SEL2	UT0[AIE]

Once MCR[EHV] (or UT0[AIE]) is set, all the operands can no longer be modified until MCR[DONE] (or UT0[AID]) is high.

In general each Modify operation is completed through a sequence of 4 steps:

1. Wait for operation completion: wait for MCR[DONE] (or UT0[AID]) to go high.
2. Check operation result: check MCR[PEG] (or compare UM0–UM9 with expected value).
3. Switch-Off FPEC by resetting MCR[EHV] (or UT0[AIE]).
4. Deselect current operation by clearing MCR[PGM/ERS] (or UT0[MRE]).

Note: Do not initiate a Modify operation on a Flash Memory module while another Modify operation is in progress on a separate module.

In the following sections, all the possible Modify operations are described with accompanying examples of the sequences needed to activate them.

34.4.5.1 Program

A Flash Program sequence operates on any doubleword within the Flash core. Up to two words within the doubleword may be altered in a single doubleword program operation. A single program operation can also alter one page (4 doublewords, 32 bytes), or 4 pages max (128 bytes in total). It is possible to program only certain doublewords in the page or the quad-page, leaving the others with their original content. Whenever the array is programmed, the ECC bits are also programmed.

ECC is handled on a 64-bit boundary. Whenever you program, ECC bits are also programmed. Thus, if only one word in any given 64-bit ECC segment is programmed, the adjoining word (in that segment) should not be programmed, since ECC calculation has already completed for that 64-bit segment. Attempts to program the adjoining word will probably result in an operation failure. All programming operations should be from 64 bits to 1024 bits, and should be 64-bit aligned. The programming operation should completely fill selected ECC segments within the doubleword. Over programming of a 64-bit ECC segment may be done only in case of EEPROM emulation byte zeroing.

Due to the fact that flash is supposed to function in an SoC with an end2end ECC scheme, ECC parity bit are also input during an Interlock Write. After setting MCR.EHV, the FPEC checks the integrity of the data received in terms of ECC. If any doubleword in the doubleword program, the page program or the quad-page program contains an inconsistency between data and parity, the whole operation is rejected and a MCR.PEG=0 is set. The doublewords without data and with parity inconsistency are thus not programmed.

Programming changes the value stored in an array bit from logic ‘1’ to logic ‘0’ only. Programming cannot change a stored logic ‘0’ to a logic ‘1’. If a logic ‘0’ is attempted to be over programmed by a logic ‘1’, the resulting operation fails (MCR[PEG]=0), and the 0s that are interlocked are merged (ORed) with 0s that are already present in the 64-bit ECC segment. Extreme care has to be taken when doing such an operation due to the high risk of producing ECC errors.

Addresses in locked blocks cannot be programmed. Register locked blocks cannot be programmed. Hardware locking is also available which only affects the program operation. Hardware locking is enabled by sideband signals, and if enabled, programs are prevented from accessing hardware locked blocks in the same way as program software locking.

The user may program the values in any or all of eight the words in a page with a single program sequence. Page-bound words have addresses which differ only in address bits [4:2]. Up to four pages can be programmed at once on a quad-page boundary, which differ only in address bits [6:5]. Only certain doublewords may be programmed within the page or the quad-page, without altering the content of the ones un-selected via interlock.

The Program operation consists of the following sequence of events:

1. Change the value of MCR[PGM] from ‘0’ to ‘1’.
2. Ensure the block that contains the address to be programmed is unlocked. Write the first address to be programmed with the program data. The Flash Memory module latches address bits (23:7) at this time, as well as written data. This Write is referred to as a Program Data Interlock Write. An Interlock Write may be as large as 64 bits, and as small as 32 bits (depending on the CPU bus).
3. If more than 1 word is to be programmed, write the additional address in the doubleword with data to be programmed. This is referred to as a Program Data Write. The Flash Memory modules ignore address bits (23:7) for program data writes. The eventual unwritten data word defaults to 0xFFFFFFFF.
4. Write a logic ‘1’ to MCR[EHV] to start the internal program sequence or terminate via step 9.
5. Wait until MCR[DONE] goes high.
6. Confirm MCR[PEG]=1.
7. Write a logic ‘0’ to the MCR[EHV].
8. If more addresses are to be programmed, return to step 2.
9. Write a logic ‘0’ to MCR[PGM] to terminate the program operation.

Programs may be initiated with the 0–1 transition of MCR[PGM] or by clearing MCR[EHV] at the end of a previous program. The first Write after a program is initiated determines the page address to be programmed. This first Write is referred to as an Interlock Write. The Interlock Write determines if the UTEST or normal array space will be programmed via MCR[PEAS].

In the case of an erase-suspended program, the values in MCR[PEAS] may be modified via the Program Interlock Write, enabling erase-suspended programs to UTEST Nonvolatile Memory space and revert back to their original state (related to erase-suspended operation) once the erase-suspended program is completed.

An Interlock Write must be performed before setting MCR[EHV]. An Interlock Write performed after setting MCR[EHV] is forbidden and data and address passed through interlock is lost.The user may terminate a program sequence by clearing MCR[PGM] prior to setting MCR[EHV].

After the Interlock Write, additional writes affect the data to be programmed at the word location determined by address bits [4:2], as well as the page location within a 1024 bit segment (determined by address bits [6:5]). Unwritten locations default to a data value of 0xFFFF_FFFF. If multiple writes are performed on the same location, the data for the last Write is used in programming.

While MCR[DONE] is low and MCR[EHV] is high, the user may clear EHV, resulting in a Program Abort.

A Program Abort forces the module to step 8 of the program sequence.

An aborted program results in MCR[PEG] being set low, indicating a failed operation. MCR[DONE] must be checked to know when the aborting command has completed.

The data space being operated on before the Abort contains indeterminate data. This may be recovered by repeating the same program instruction or executing an Erase of the affected blocks.

The user may not abort a program sequence while in Program Suspend.

Example 4. Doubleword program of data 0x55AA_55AA at address 0x00_AAA8 and data 0xAA55_AA55 at address 0x00_AAAC.

```
MCR  = 0x0000_0010;/* Set PGM in MCR: Select Operation */
(0x00_AAA8) = 0x55AA_55AA;/* Latch Address and 32 LSB data */
(0x00_AAAC) = 0xAA55_AA55;/* Latch 32 MSB data */
MCR = 0x0000_0011;/* Set EHV in MCR: Operation Start */
do            /* Loop to wait for DONE=1 */
{ tmp = MCR; /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status= MCR & 0x0000_0200;/* Check PEG flag */
MCR= 0x0000_0010;/* Reset EHV in MCR: Operation End */
MCR= 0x0000_0000;/* Reset PGM: Deselect Operation */
```

34.4.5.2 Program Suspend/Resume

The program sequence may be suspended to allow Read access to the flash array. It is not possible to program or to erase during a Program Suspend. Read-While-Write operations may also be used to read the array during a program sequence providing the Read is to a different partition.

During Program Suspend, all reads to the doubleword targeted for program return indeterminate data.

A Program Suspend can be initiated by changing the value of MCR[PSUS] from ‘0’ to ‘1’. MCR[PSUS] can be set to ‘1’ at any time when MCR[PGM] and MCR[EHV] are high and MCR[ERS] is low. 0–1 transition of MCR[PSUS] causes the module to start the sequence which places it in Program Suspend.

It is possible to suspend a program performed during an Erase Suspend. The user must wait until MCR[DONE]=1 before the module is suspended and further actions are attempted. MCR[DONE] takes no more time than t_{PSUS} to go high after MCR[PSUS] is set to ‘1’.

Once suspended, the array may be read. Flash memory reads while MCR[PSUS]=1 from the doubleword being programmed return indeterminate data.

Example 5. Doubleword Program Suspend.

```
MCR = 0x0000_0019;/* Set PSUS in MCR: Program Suspend */
do      /* Loop to wait for DONE=1 */
{ tmp = MCR;/* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR.EHV and MCR.PGM in order to perform reads during program suspend.

The Program sequence is resumed by writing a logic ‘0’ to MCR[PSUS].

MCR[EHV] must be set to ‘1’ before MCR[PSUS] can be cleared to resume the operation.

The module continues the program sequence from one of a set of predefined points. This may extend the time required for the program operation.

Example 6. Doubleword Program Resume.

```
MCR = 0x0000_0011;/* Reset PSUS in MCR: Program Resume */
```

Repeated suspends at a high frequency may result in the operation timing out, and the embedded flash memory responds by completing the operation with a fail code (MCR.PEG = 0). The minimum time between Program Suspends to ensure this does not occur is t_{PSRT}.

34.4.5.3 Over-programming protection (OPP) enable

Over Programming Protection can be enabled on a block-by-block basis. In an OPP enabled block, any doubleword which has already been programmed cannot be programmed again. The OPP enable does not affect the Erase operation. It is possible to independently set OPP and (hardware) erase protection in order to avoid any kind of overwrite. Using these protection mechanisms in conjunction with the Test mode disable feature gives even greater overwrite protection. Attempts to over-program result in MCR[PEG] being cleared.

OPP can be enabled for 16 KB, 32 KB, 64 KB and 256 KB blocks. The 256 KB blocks have selects available for the first four 256 KB blocks, and then a single select for the remainder of the 256 KB blocks.

OPP is enabled by sideband signals and, if enabled, the program operation is modified to check for programmed bits prior to undertaking a high voltage program event.

34.4.5.4 Successful program address

To enable the SoC to create logic to authenticate operations with a program (like in a diary operation), the Flash Memory module provides the last successful address programmed as a sideband signal. This value is held until the next successful program. A successful program is defined as a program operation of data that is not all 1s, to an unlocked block and the operation results in MCR[PEG] returning a ‘1’. An all 1’s value is the default (and invalid) address after reset.

In case of page programming, the last successful address returned is the beginning of the page itself regardless of whether that specific address has not been passed through interlock. In case of quad-page programming, the last successful address returned is the beginning of the quad-page itself regardless of whether that specific address has not been passed through interlock.

34.4.5.5 Erase

Erase changes the value stored in all bits of the selected block(s) to logic ‘1’. An Erase sequence operates on any combination of blocks in the low, mid, high or 256K address space. The Test block cannot be erased.

The Erase sequence is fully automated within the Flash. The user only needs to select the blocks to be erased and initiate the Erase sequence.

Register locked blocks cannot be erased. Hardware locking which only affects the Erase operation is also available. Hardware locking is enabled by sideband signals and, if enabled, erases are prohibited on hardware locked blocks in the same way as erase software locking. If multiple blocks are selected for erase during an Erase sequence, no specific operation order can be assumed.

The Erase operation consists of the following sequence of events:

1. Change the value of MCR[ERS] from ‘0’ to ‘1’.
2. Select the block(s) to be erased by writing 1’s to the appropriate register(s) in SEL0, SEL1 and SEL2 registers. Note that Lock and Select are independent. If a block is selected and locked, no erase occurs.
3. Write to any address in flash. This is referred to as an Erase Interlock Write.
4. Write a logic ‘1’ to MCR[EHV] to start the internal Erase sequence or skip to step 9 to terminate.
5. Wait until MCR[DONE] goes high.
6. Confirm MCR[PEG]=1.
7. Write a logic ‘0’ to the MCR[EHV].
8. If more blocks are to be erased, return to step 2.
9. Write a logic ‘0’ to MCR[ERS] to terminate the Erase operation.

After setting MCR[ERS], one Write (referred to as an Interlock Write) must be performed before MCR[EHV] can be set to ‘1’.

Data words written during Erase sequence Interlock Writes are ignored. As flash is supposed to function in an SoC with an end2end ECC scheme, ECC parity bits are also input during an Interlock Write. After setting MCR[EHV], the FPEC checks the integrity of the data received in terms of ECC even if the value of the data is not meaningful for the Erase operation. If an inconsistency between data and parity is found, the whole operation is rejected and MCR.PEG=0 is set.

The user may terminate the Erase sequence by clearing ERS before setting EHV.

An Erase operation may be aborted by clearing MCR[EHV] assuming MCR[DONE] is low, MCR[EHV] is high and MCR[ESUS] is low. An Erase Abort forces the module to step 8 of the Erase sequence. An aborted Erase results in MCR[PEG] being set low, indicating a failed operation. MCR[DONE] must be checked to know when the aborting command has completed.

The block(s) being operated on before the Abort contain indeterminate data. This may be recovered by executing an Erase on the affected blocks. The user may not abort an Erase sequence while in Erase-Suspend.

Example 7. Erase of blocks B0F1 and B0F2.

```
MCR= 0x0000_0004;/* Set ERS in MCR: Select Operation */
SEL0= 0x0006_0000;/* Set LSL2-1 in SEL0: Select Blocks */
(0x00_0000)= 0xFFFF_FFFF;/* Latch a Flash Address */
MCR= 0x0000_0005;/* Set EHV in MCR: Operation Start */
do         /* Loop to wait for DONE=1 */
{ tmp= MCR;/* Read MCR */
} while ( !(tmp & 0x0000_0400) );
status= MCR & 0x0000_0200;/* Check PEG flag */
MCR= 0x0000_0004;/* Reset EHV in MCR: Operation End */
MCR= 0x0000_0000;/* Reset ERS: Deselect Operation */
```

34.4.5.5.1 Erase Suspend/Resume

The Erase sequence may be suspended to allow Read access to the flash array. It is possible to program another block in any Flash Memory module during Erase-Suspend. Programming a location subject to suspended Erase results in the program not being executed and PEG being set to 0.

It is not possible to erase any block during an Erase-Suspend.

During Erase-Suspend, all reads to blocks targeted for Erase return indeterminate data.

An Erase-Suspend can be initiated by changing the value of MCR[ESUS] from ‘0’ to ‘1’. MCR[ESUS] can be set to ‘1’ at any time when MCR[ERS] and MCR[EHV] are high and MCR[PGM] is low. A 0 to1 transition of MCR[ESUS] causes the module to start the sequence which places it in Erase-Suspend. The User must wait until MCR[DONE]=1 before the module is suspended and further actions are attempted.

MCR[DONE] takes no longer than t_{ESUS} to go high after MCR[ESUS] is set to ‘1’.

Once suspended, it is not possible to alter the content of SEL0, SEL1, and SEL2 registers. Once suspended, the array may be read. Flash memory reads while MCR[ESUS]=1 from the block(s) being erased return indeterminate data.

Example 8. Block Erase Suspend.

```
MCR= 0x0000_0007;/* Set ESUS in MCR: Erase Suspend */
do           /* Loop to wait for DONE=1 */
{ tmp= MCR;  /* Read MCR */
} while ( !(tmp & 0x0000_0400) );
```

Note that there is no need to clear MCR[EHV] and MCR[ERS] in order to perform reads during Erase-Suspend.

The Erase sequence is resumed by writing a logic ‘0’ to MCR[ESUS].

MCR[EHV] must be set to ‘1’ before MCR[ESUS] can be cleared to resume the operation. The module continues the Erase sequence from one of a set of predefined points and this may extend the time required for the Erase operation.

Example 9. Block Erase Resume.

```
MCR= 0x0000_0005;/* Reset ESUS in MCR: Erase Resume */
```

Repeated suspends at a high frequency may result in the operation timing out and the embedded flash memory responds by completing the operation with a fail code

(MCR[PEG]=0). The minimum time between Erase suspends to ensure this does not occur is t_{ESRT}.

34.4.5.5.2 Factory Erase

The Factory Erase feature can be used only once through a diary location mechanism. If location UTEST at offset +0x0020 was virgin at the moment of the reset, MCR[FERS] can be set after rising MCR[ERS] and before MCR[EHV]. After setting MCR[EHV] the FPEC recognizes the value of FERS and checks if the diary location has been programmed by the user (having changed from being virgin at reset). Under those conditions a factory Erase can commence and no Read-While-Write is allowed (all the f90_busy sideband signals are set high).

34.4.5.6 User Test mode

Customers can put the Flash Memory module in User Test mode to perform specific tests for the integrity of the flash array.

Two kinds of test can be performed:

- Array Integrity Self Check
- Margin Read

User Test mode is an exclusive operation—it cannot be run in conjunction with any other flash mode (Read, Write, Low-Power and Power-Down), and Read-While-Write functionality is inapplicable. Read accesses attempted by the user during User Test mode generates a Read-While-Write Error (RWE of MCR set).

It is not permitted to perform User Test operations on the Test blocks (including the UTEST section).

34.4.5.6.1 Array Integrity Self Check

Array integrity is checked using a predefined address sequence (proprietary), and this operation is executed on selected (SEL0, SEL1 and SEL2) blocks. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Any random or non-random code is valid. Once the operation is completed, the results of the reads can be checked by reading the MISR value (stored in UM0–9), to determine if an incorrect Read, or ECC detection was noted. Array integrity is controlled by the pfb clock (fclk) and requires that the Read Wait States and Address Pipelined control registers in the BIU be set to match the frequency being used.

The internal MISR calculator is a 64 + 8 + 1-bit register

The 256-bit data, the respective ECC parity data, and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location.

The whole check is done through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction and the double error flag is set after any ECC detection. Single-bit correction is

always active and logging may be enabled (UT0[SBCE]), resulting in the MCR[SBC] flag and related address to be captured in ADR reg, but this doesn't change the final signature in the UM0–9.

Only data from existing locations are captured by the MISR. The MISR can be seeded to any value by writing the UM0–9 registers.

The Array Integrity Self Check consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1 and/or SEL2 registers. Blocks selected for Array Integrity Check do not need to be unlocked. It is not possible to perform Array Integrity operations on the UTEST Nonvolatile Memory block.
3. If desired, UT0[AIS] can be set for sequential addressing only.
4. Seed the MISR UM0–UM9 with desired values.
5. If breakpoints are desired, set UT0[AIBPE] to '1', and ensure that MCR[EER] and MCR[SBC] are cleared. If breaking on single-bit correction is required, ensure that UT0[SBCE] is set.
6. Write a logic '1' to UT0[AIE] to start the Array Integrity Check. Array integrity operations may be aborted prior to UT0[AID] going high. This may be done by clearing UT0[AIE]. It should be noted that in the event of an aborted Array Integrity check, the MISR registers contain a signature for the portion of the operation that was completed prior to the Abort, and is not definitive. Prior to performing further Array Integrity operations, the UM0–UM9 registers may require initialization to the desired seed value by performing register writes. Array Integrity operations may be suspended while UT0[AID] is low. UT0[AISUS] may be set to request an Array Integrity Suspend. Once UT0[AID] has been set high, UT0[AISUS] may be cleared to resume the Array Integrity sequence.
7. Wait until UT0[AID] goes high.
8. Check that UT0[NAIBP] is set to '1' if breakpoints were previously enabled so that the MCR[EER], MCR[SBC] and ADR registers may be checked to determine the cause and address of the break. Prior to resuming the operation, it necessary to clear MCR[SBC] or MCR[EER] in order to preserve coherency of MCR[SBC], MCR[EER] and ADR updates with respect to any subsequent breakpoints. Operation may then be resumed by clearing UT0[NAIBP]. Continue waiting until UT0[AID] goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete.
9. Compare UM0–UM9 content with the expected result.
10. Write a logic '0' to UT0[AIE].

Use sequential addressing for normal integrity checks of the Flash memory. If a more detailed check of the Read path is required (in diagnostic mode), leave UT0[AIS] at '0' and use the proprietary address sequence that checks the Read path more completely, however this sequence takes more time.

Caution: Do not modify the content of Block Select (SEL0, SEL1, and SEL2) and Lock (LOCK0, LOCK1, and LOCK2) registers during execution of the Array Integrity Check operation or the MISR value may vary unpredictably.

User mode array reads requested during the Array Integrity test are ignored to ensure that the Array Integrity operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0[AID] is low and UT0[AIE] is high, the user may clear AIE, resulting in an Array Integrity Check Abort. UT0[AID] must be checked to know when the aborting command has completed.

Array Integrity Check can be suspended by setting UT0[AISUS] while Array Integrity Check is running (UT0[AID]=0). Once suspended (UT0[AID]=1) Array Integrity Check cannot be aborted and clearing UT0[AISUS] starts the Resume.

Example 10. Array Integrity Check of blocks B0F1 and B0F2.

```
UM0/9 = 0x0000_0000;/* Reset UM0/9 content */
UT0   = 0xF9F9_9999;/* Set UTE in UT0: Enable User Test */
SEL0  = 0x0006_0000;/* Set LSL2-1 in SEL0: Select Blocks */
SEL2  = 0x0000_0006;/* Set 256KSL2-1 in SEL2: Select Blocks */
UT0   = 0x8000_0002;/* Set AIE in UT0: Operation Start */
do            /* Loop to wait for AID=1 */
{ tmp= UT0;  /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9= UM0/9;/* Read UM0/9 content*/
UT0   = 0x0000_0000;/* Reset UTE, AIE: Operation End */
```

34.4.5.6.2 Margin Read

User Margin Read may be achieved using the Array Integrity interface and has all the associated features of the Array Integrity interface (MISR calculation, suspend capability and Breakpoints).

Margin Read procedure (either Margin 0 or Margin 1) can be run on selected blocks in order to unbalance the Sense Amplifiers with respect to standard Read conditions, so that all the Read accesses reduce the margin vs ‘0’ (UT0[MRV]=0) or vs ‘1’ (UT0[MRV]=1).

User Margin Read is a self timed event and is independent of system clocks or wait states selected. Margin Read can be run on selected (SEL0, SEL1, and SEL2) blocks, generating checksum calculations on MISR and ECC flagging. Blocks marked by TMDBS are automatically excluded from MISR signature computation. Once the operations are completed, the results of the Margin Reads can be checked, comparing checksum values in UM0–UM9 and reading MCR[EER] and MCR[SBC] to determine if zero, one or two bits are being detected by the Margin Read.

The MISR can be seeded to any value by writing the UM0–UM9 registers.

As with Array Integrity Check, the internal MISR calculator is a 64 + 8 + 1-bit register. The 256-bit data, the corresponding ECC parity data and the double ECC (ERR) errors of the four doublewords are therefore captured by the MISR through 4 different Read accesses at the same location. The whole check is accomplished through 4 complete scans of the memory address space:

1. The first pass scans only bits 63-0 + 8 ecc + ERR of each doubleword.
2. The second pass scans only bits 128-64 + 8 ecc + ERR of each doubleword.
3. The third pass scans only bits 191-129 + 8 ecc + ERR of each doubleword.
4. The fourth pass scans only bits 255-192 + 8 ecc + ERR of each doubleword.

The 256-bit data and the respective ECC parity data are sampled after any single-bit ECC correction, and the double error flags are set after any ECC detection. Single-bit logging is always enabled regardless of the value of UT0[SBCE], resulting in the MCR[SBC] flag and

related address to be captured in ADR reg, but this doesn't alter the final signature in the UM0–9.

In any case, the charge losses detected through the Margin Read cannot be considered device failures and no Failure Analysis is initiated on them.

The Margin Read Setup operation consists of the following sequence of events:

1. Set UTE in UT0 by writing the respective password in UT0.
2. Select the block(s) to be checked by writing 1's to the appropriate register(s) in SEL0, SEL1 and SEL2 registers. Blocks selected for Margin Read do not need to be unlocked. It is not possible to do Margin Read operations on the UTEST Nonvolatile Memory block.
3. Seed the MISR UM0–9 with desired values.
4. Ensure that MCR[EER] and MCR[SBC] are cleared.
5. Set UT0[SBCE] to '1' to detect single bits during Margin Read.
6. Change the value of UT0[MRE] from '0' to '1'.
7. Select the Margin level: UT0[MRV]=0 for 0's margin, UT0[MRV]=1 for 1's margin.
8. Write a logic '1' to UT0[AIE] to start the Margin Read.
9. Wait until the UT0[AID] bit goes high.
10. Check that UT0[NAIBP] is set to '1' if breakpoints were previously enabled so that MCR[EER], MCR[SBC] and ADR[ADDR] may be checked to determine the cause and address of the break. Prior to resuming operation, clear MCR[SBC] or MCR[EER]. Operation may then be resumed by clearing UT0[NAIBP]. Continue to wait until UT0[AID] goes high. If breakpoints were not enabled, or if UT0[NAIBP] is low when UT0[AID] goes high, then the operation is complete.
11. Compare UM0–9 content with the expected results.
12. Check MCR[EER] and MCR[SBC].
13. Write a logic '0' to UT0[AIE], UT0[MRE] and UT0[MRV].
14. If more blocks are to be checked, return to step 2.

The linear address sequence is used regardless of the value of UT0[AIS].

Caution: Do not modify the content of Block Select (SEL0, SEL1, and SEL2) and Lock (LOCK0, LOCK1, and LOCK2) registers during execution of the Margin Read operation, otherwise the MISR value may vary unpredictably.

User mode array reads requested during the Margin Read are ignored to ensure that the Margin Read operation is not corrupted. The memory array does not respond to array Read requests during this time. User mode array reads may be executed if suspended or at a breakpoint.

While UT0[AID] is low and UT0[AIE] is high, the user may abort Margin Read by clearing AIE. UT0[AID] must be checked to know when the aborting command has completed. Margin Read can be suspended by setting UT0[AISUS] while Margin Read is running (UT0[AID]=0). Once suspended (UT0[AID]=1), Margin Read cannot be aborted and clearing UT0[AISUS] starts the Resume.

Example 11. Margin Read Check versus 1's

```
UM0/9= 0x0000_0000;/* Reset UM0/9 content */
UT0  = 0xF9F9_9999;/* Set UTE in UT0: Enable User Test */
SEL0 = 0x0006_0000;/* Set LSL2-1 in SEL0: Select Blocks */
```

```
UT0   = 0x8000_0020;/* Set MRE in UT0: Select Operation */
UT0   = 0x8000_0030;/* Set MRV: Select Margin versus 1's */
UT0   = 0x8000_0032;/* Set AIE in UT0: Operation Start */
do            /* Loop to wait for AID=1 */
{ tmp= UT0;  /* Read UT0 */
} while ( !(tmp & 0x0000_0001) );
data0/9= UM0/9;/* Read UM0/9 content*/
UT0   = 0x8000_0030;/* Reset AIE in UT0: Operation End */
UT0   = 0x0000_0000;/* Reset UTE, MRE, MRV, AIS in UT0:
                Deselect Operation */
```

34.4.6 Protection strategy

Two kinds of protection are available: Modify Protection to avoid unwanted program/erase in flash blocks and Test Mode Disable to avoid piracy.

34.4.6.1 Modify Protection

The Flash Modify Protection information is stored in nonvolatile flash cells located in the UTEST region. This information is read once during the Flash Initialization phase following exit from reset and is stored in volatile registers that act as actuators at SoC level. The information is passed to the Flash Memory module through erase_lock and program_lock sidebands, and allows independent protection of each block of Low, Mid, High and 256K Address Space Block.

There are also Address Space Block Locking registers provided to independently lock/unlock each block of Low, Mid, High and 256K Address Space Block against program and erase. Locking is done through the LOCK0, LOCK1, and LOCK2 registers. These registers do not have a nonvolatile image stored in the UTEST area of TestFlash, so the locking information is kept on reset: volatile content is all 1's, meaning all blocks are locked.

All the volatile registers can be written to '0' or '1' at any time, therefore the user application can lock and unlock blocks when desired. Note, however, that overall protection is achieved by the combination of sidebands with Low, Mid, High and 256K Address Space Block Locking registers in such a way that a block can be programmed/erased only if both (sidebands and Locking registers) indicate an unlocked state. Sidebands independently control program protection, erase protection and over-programming protection (OPP) on a block-by-block basis.

As UTEST and BAF (each one with its own lock bit, LOCK0[TSLOCK] and LOCK0[LOWLOCK] respectively) are two sections of the same physical block (TestFlash), effective locking is achieved via the 'AND' operand of the lock bits. For effective locking, overall protection is obtained in conjunction with sidebands: UTEST and BAF have dedicated program protection sidebands (SoC specific).

34.4.6.2 Test mode disable

In the TestFlash area a mechanism is also available to disable entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected for protection in this way cannot be analyzed for possible failures by manufacture failure analysts.

Protection of this sort prevents all high voltage operations to the flash executed by the internal FPEC as well as reads from FPEC, including Array Integrity Check or Margin Read,

when using Test mode interfaces. Protection through other interfaces is managed through normal User mode protection mechanisms, that are SoC specific.

To disable manufacturer entry into Test mode, first program the Test Mode Disable Seal location to 0x5A4B_3C2D and once the next reset is asserted, Test mode is disabled.

It is possible to create a password to enable manufacturer entry into Test mode. This can be programmed into the Test Mode Disable Override Passcode. It is safest to do this prior to censoring the part to avoid unintended lockout. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and are not accepted for override. If the customer desires that override never be possible, one of the three invalid passcodes should be put into this location. Passcodes may be entered to authenticate entry (if enabled) by performing a register Write to address 0x0x90.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus is it possible for customers to select blocks for this type of protection, and render them ineligible for manufacturer failure analysis. Bits programmed to ‘0’ in the Test Mode Disable Block Select field designate blocks that are controlled by Test Mode Disable feature. The TestFlash block, and thus the UTEST and BAF sections, is always protected once the Test Mode Disable Seal password is written. In order to permit two opportunities to select blocks for Test Mode disable, two regions are available: one at address 0x804010, and the other at address 0x804030; both 128-bit sized (only 80 may be effective, depending on actual sectorization). The bits of these two regions are logically ANDed in order to define which blocks are effectively selected for the Test Mode Disable feature.

The 80-bit Block Select field is organized as follows, and aligned in the way blocks are defined in the LOCK registers:

Table 475. Test Mode Disable block select

Block	Block selection bits
Blocks in Mid space	Data[15:0]
Blocks in Low space	Data[29:16]
Blocks in High space	Data[47:32]
Blocks in 256K space	Data[78:48]

35 Decorated Storage Memory Controller (DSMC)

35.1 Introduction

This section details hardware support for atomic read-modify-write memory operations. In the Power Architecture, these capabilities are called “*decorated storage*”. It is supported by capabilities in the processor cores plus instantiations of a Decorated Storage Memory Controller (DSMC).

The Decorated Storage APU defines instructions for providing load and store operations to memory addresses that require *additional semantics* beyond just the reading and writing of data values to the addressed memory locations. Decorated storage operations are intended to be used for specific devices or memory targets that require these additional semantics. A “decoration” is the additional semantic information to be applied to the decorated storage operation by the DSMC.

Consider the basic mnemonics, syntax and formats for the decorated load instructions.

For loads, the syntax is `l[b,h,w]d{cb}x rT,rB,rA` where the data size specifier is defined as 8-bit (`b` = byte), 16-bit (`h` = halfword) or 32-bit (`w` = word), and the three register specifiers include `rT` as the destination target register, `rB` as the effective address and `rA` as the decoration. The optional `{cb}` specifier defines a version of the instruction which is treated as a cache bypass operation.

The syntax for store instruction is `st[b,h,w]d{cb}x rS,rB,rA` where the same data size specifiers are used, and the three register specifiers are `rS` as the source data register, `rB` as the effective address and `rA` as the decoration. The cache bypass attribute is again specified with the use of the optional `{cb}` in the instruction mnemonic.

For all decorated loads and stores, the memory effective address is simply defined by the rB register (hence the `“x”` mnemonic suffix, signaling an “indexed” addressing mode) and the decoration is specified by the rA register. The core transmits the contents of the rA register as the decoration value along with the access address (register rB) to the DSMC.

The decorated load and store instruction formats are shown in *Figure 390*.

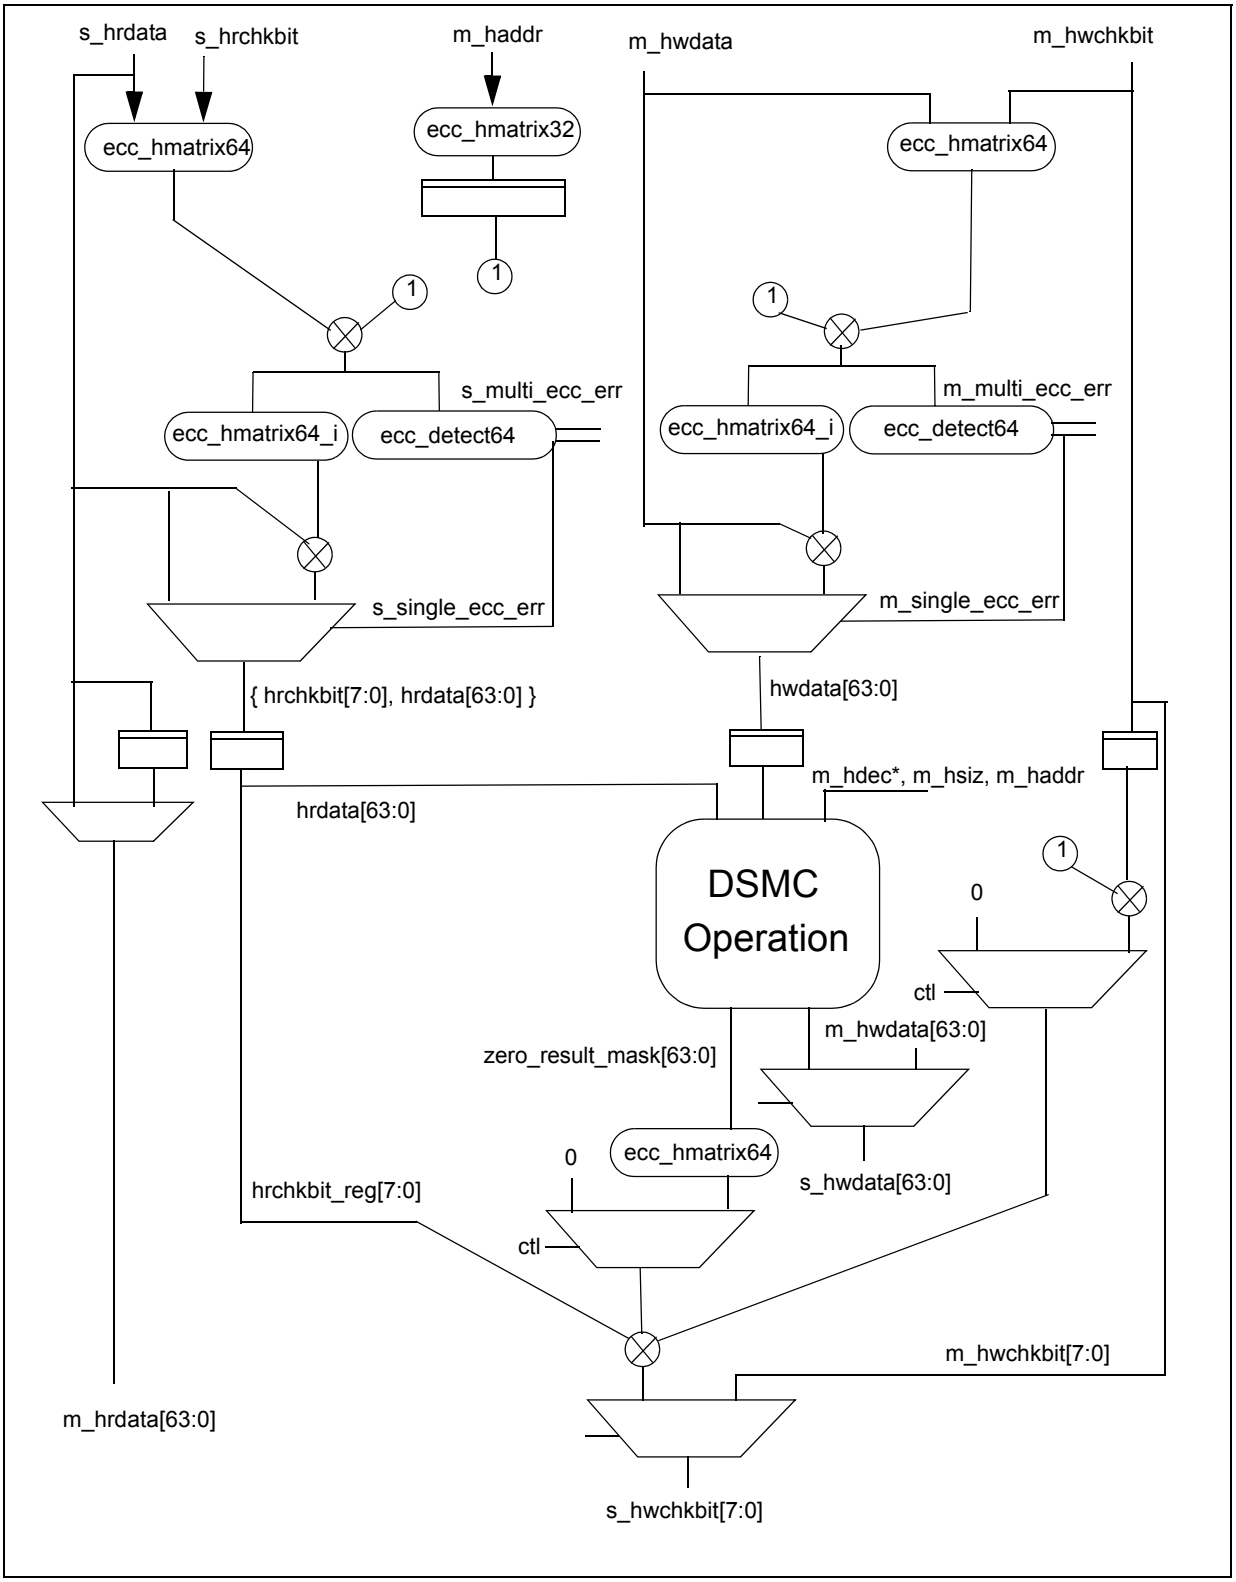
Figure 390. Power Architecture Decorated Load and Store Instruction Formats

The basic decorated load or store memory reference supplements the access address and attribute information with a 32-bit “decoration”. The DSMC decoration defines the special memory operation to be performed and optionally includes bit specifiers and/or operand data for the command.

The default format for the 32-bit decoration field defines a 4-bit command in the most significant bits (decoration[0:3]).

The cache bypass decoration load (`l[b,h,w]dcbx`) and store (`st[b,h,w]dcbx`) instructions do not distinguish between cacheable and cache-inhibited storage attributes, and instead have semantics to effectively emulate a cache-inhibited operation to storage regardless of the actual storage attributes. This is desired in order to allow a small portion of an otherwise cacheable storage area to be treated as non-cacheable using instruction supplied semantics, regardless of storage attributes provided by a memory management, protection or other memory control scheme. This allows decoration or other accesses to be applied to a portion of memory that is normally treated as cacheable according to its storage attributes, as well as to ensure that any stale copies of storage locations present in the cache are not used.



The combination of the decorated load and store instruction support in the e200zX cores plus the decorated storage memory controller in the core platform adds a robust atomic read-modify-write capability to the Power Architecture. The architecture capability defined by these core and platform functions is targeted at manipulation of *n*-bit fields in peripheral registers (and is consistent with I/O hardware addressing in the Embedded C standard) as well as software synchronization data structures needed in multi-core systems (mutexes, semaphores, test-and-set and compare-and-swap structures).

For additional information on the decorated load and store instructions from the core's perspective, refer to the appropriate e200zX core reference manual.

35.2 DSMC Block Diagram

The following block diagram, *Figure 391*, shows the basic datapaths for the ECC logic in the DSMC. On both the read data path (hrdata) and the write data path (hwdata) there is logic to detect an ECC error and correct the data. The circle with X inside represents an XOR operation. The ecc_hmatrix and ecc_detect blocks are coefficient matrixes based on the Hsiao ECC algorithm. Notice in the recalculation of the s_hwchkbit[7:0] that there is a read chkbit from the slave (hrchkbit), a zero padded result contribution, and a contribution from the hwchkbit from the master. The details of the DSMC bit field and other operations are not shown (represented by the DSMC Operation box).

Figure 391. DSMC Block Diagram

35.3 Decorated Stores: `st[b,h,w]d{cb}x rS,rB,rA`

The next sections present descriptions of the specific operations, based on the 4-bit command field defined in decoration[0:3]. These descriptions include the bit pattern definitions for the 32-bit decoration value and include pseudo-code detailing the sequence of operations. The decoration formats are defined using a `<command>.<size>` syntax where the operand size specifier is b (byte, 8-bit), h (halfword, 16-bit) or w (word, 32-bit). The operand size is specified directly in the decorated instruction executed in the core, and this attribute is driven to the system bus as part of the decorated data transfer. Additionally, the write data is taken from the right-justified 8, 16 or 32 bits of the rS register, that is:

```
 8-bit wdata = rS[24:31]
16-bit wdata = rS[16:31]
32-bit wdata = rS[ 0:31]
```

Likewise, read data is loaded into the right-justified 8, 16 or 32 bits of the rT register:

```
 8-bit rdata = rT[24:31]
16-bit rdata = rT[16:31]
32-bit rdata = rT[ 0:31]
```

For the byte and halfword decorated load instructions, the upper bits of the rT register are zero filled.

The starting bit (SRTBIT) position follows the Power Architecture convention where the MSB is bit 0 and the LSB is bit 31. The bit field width (BFW) value defines the width and BFW = 0 specifies the maximum width, that is, the container size.

The basic decorated store includes three data transfer fields sourced from the core: the access address (rB), the decoration (rA) and the write data (wdata) operand (rS). There are five operations defined and most of these transactions convert a single core AHB write bus cycle into an atomic read-modify-write, that is, an indivisible read followed by write sequence. Support for three basic boolean logic functions (AND, OR, XOR) is provided along with a compare-and-store operation plus a bit field insert operation. These operations do not support any type of bit field wrapping.

In the next sections detailing the decorated store operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- wdata = rS

35.3.1 Bit Field Insert (BFINS) into an 8, 16 or 32-bit Memory Container

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
bfins.b	0	0	0	0	0	0	**0**	SRTBIT			0	**0**	0	BFW			**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.h	0	0	0	0	0	0	SRTBIT				0	**0**	BFW				**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
bfins.w	0	0	0	0	0	SRTBIT					0	BFW					**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Figure 392. Decoration Format: BFINS

This command inserts a bit field defined by SRTBIT and BFW into the memory “container” defined by the access size associated with the decorated store instruction using an atomic read-modify-write sequence.

```
tmp = mem[accessAddress, size] // memory read

if bfw == 0
   then bfw = container

if ((srtbit + bfw) <= container)// generate bit mask
    mask = ((1 << bfw) - 1) << (container - (srtbit + bfw))
else
    mask = ((1 << bfw) - 1) >> ((srtbit + bfw) - container)

tmp = tmp   & ~mask// modify
    | wdata &  mask

mem[accessAddress, size] = tmp// memory write
```

The write data operand (wdata) associated with the decorated store instruction contains the bit field to be inserted. *It must be properly aligned within a right-justified container in the source register (rS)*, that is, within the lower 8 bits for a byte operation, the lower 16 bits for a halfword or the entire 32 bits for a word operation.

To illustrate, consider the following example of the insertion of the 3-bit field “xyz” into an 8-bit memory container, initially set to “abcd_efgh”. For all cases, the bit field width (BFW) is 3.

```
if SRTBIT = 0 and the decorated store rS register[24:31] = xyz-_----,
   then destination is "xyzd_efgh"
if SRTBIT = 1 and the decorated store rS register[24:31] = -xyz_----,
   then destination is "axyz_efgh"
if SRTBIT = 2 and the decorated store rS register[24:31] = --xy_z---,
   then destination is "abxy_zfgh"
if SRTBIT = 3 and the decorated store rS register[24:31] = ---x_yz--,
   then destination is "abcx_yzgh"
if SRTBIT = 4 and the decorated store rS register[24:31] = ---_xyz-,
   then destination is "abcd_xyzh"
if SRTBIT = 5 and the decorated store rS register[24:31] = ---_-xyz,
   then destination is "abcd_exyz"
if SRTBIT = 6 and the decorated store rS register[24:31] = ---_--xy,
   then destination is "abcd_efxy"
if SRTBIT = 7 and the decorated store rS register[24:31] = ---_---x,
   then destination is "abcd_efgx"
```

If the bit field insert operation specifies SRTBIT as 0 and BFW as 0 (indicating the width matches the container width), then the operation is logically equivalent to a simple register store operation.

35.3.1.1 Compare-and-Store (CAST)

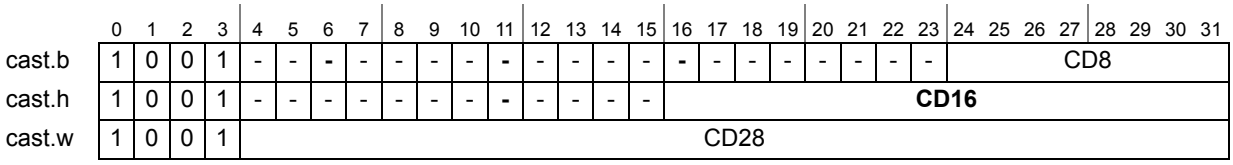


Figure 393. Decoration Format: CAST

This command begins by performing a read of the referenced memory address and comparing that data with the operand included in the decoration word. If the read data is equal to the compare operand, the write data associated with the decorated store instruction is placed into the memory location, else the original read data is rewritten into the memory location. The write operand is selected from the appropriate data byte lanes in the same manner as any memory store operation; this implies the write data operand is right justified in the rS source register.

```
tmp = mem[accessAddress, size] // memory read

if (size == 8)// define compare_operand
    compare_operand = CD8
else if (size == 16)
          compare_operand = CD16
     else compare_operand = {0x0, CD28}// zero-filled data

if (tmp == compare_operand)// compare - "modify"
     mem[accessAddress, size] = wdata// memory write
else mem[accessAddress, size] = tmp
```

Note for the word size operation (cast.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit compare operand.

35.3.1.1.1 Logical AND (AND)

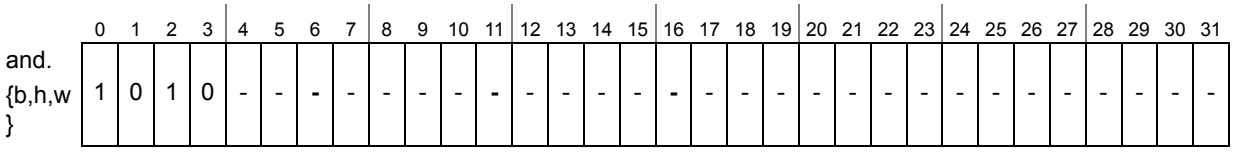

Figure 394. Decoration Format: AND

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical AND operation using the write operand defined by the rS register; finally, the result of the AND operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp & wdata// modify
mem[accessAddress, size] = tmp// memory write
```

35.3.1.1.2 Logical OR (OR)

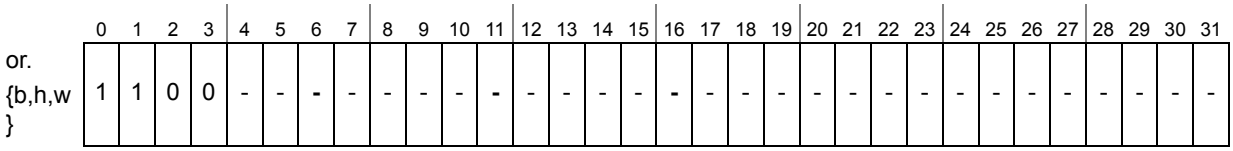

Figure 395. Decoration Format: OR

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical OR operation using the write operand defined by the rS register; finally, the result of the OR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp | wdata// modify
mem[accessAddress, size] = tmp// memory write
```

35.3.1.1.3 Logical Exclusive-OR (XOR)

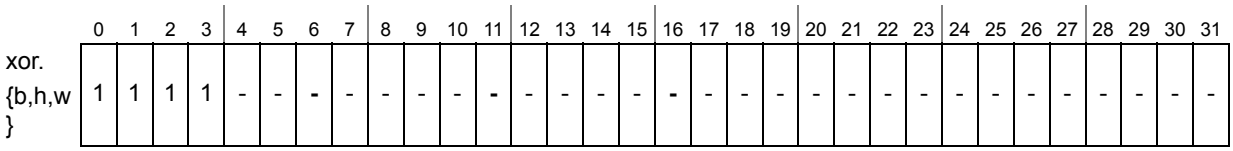

Figure 396. Decoration Format: XOR

This command performs an atomic read-modify-write of the referenced memory location. First, the location is read; it is then modified by performing a logical XOR operation using the write operand defined by the rS register; finally, the result of the XOR operation is written back into the referenced memory location.

```
tmp = mem[accessAddress, size] // memory read
tmp = tmp ^ wdata// modify
mem[accessAddress, size] = tmp// memory write
```

35.3.1.2 Decorated Loads: `l[b,h,w]d{cb}x rT,rB,rA`

The basic decorated load includes two data transfer fields sourced from the core: the access address (rB), the decoration (rA) plus the read data (rdata) operand returned from DSMC to the core and loaded into the destination register (rT). There are 3 operations defined and two of these transactions convert a single core AHB read bus cycle into an atomic read-modify-write. Support for a swap function, a load-and-set-1-bit functions are provided along with a simple load (aka an “extract”) operation.

In the next sections detailing the decorated load operations, the following associations between the pseudocode variables and the core registers apply.

- decoration = rA
- accessAddress = rB
- rdata = rT

35.3.1.2.1 Simple Load (SLD)

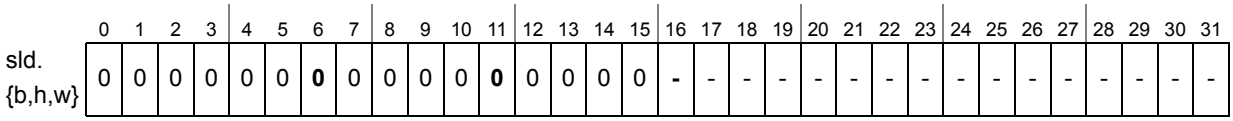

Figure 397. Decoration Format: SLD

This command performs a simple memory load of the reference size from the access address. For this operation, the 12-bit field defined in decoration[4:15] must be zeroes else the transfer is not performed and error terminated.

```
rdata = mem[accessAddress, size] // memory read
```

Support for generic bit field extract operations is best handled using existing core and compiler capabilities involving standard load instructions followed by left and right shift operations to emulate these functions.

35.3.1.2.2 Registers-and-Memory Exchange (SWAP)

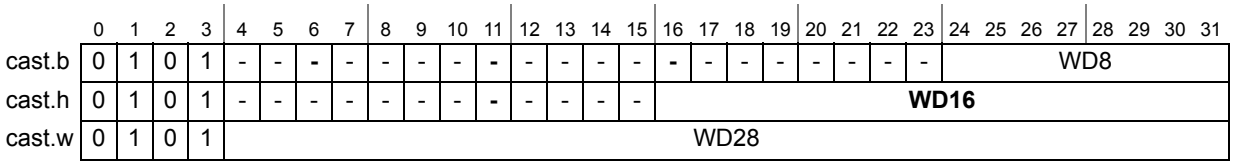

Figure 398. Decoration Format: SWAP

This command loads the contents of the referenced memory location into the core's rT register and stores the source operand from the core's rA register (the decoration) into the memory location.

```
tmp    = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp

if (size == 8)// store_operand - "modify"
    store_operand = WD8
else if (size == 16)
          store_operand = WD16
     else store_operand = {0x0, WD28}// zero-filled write data

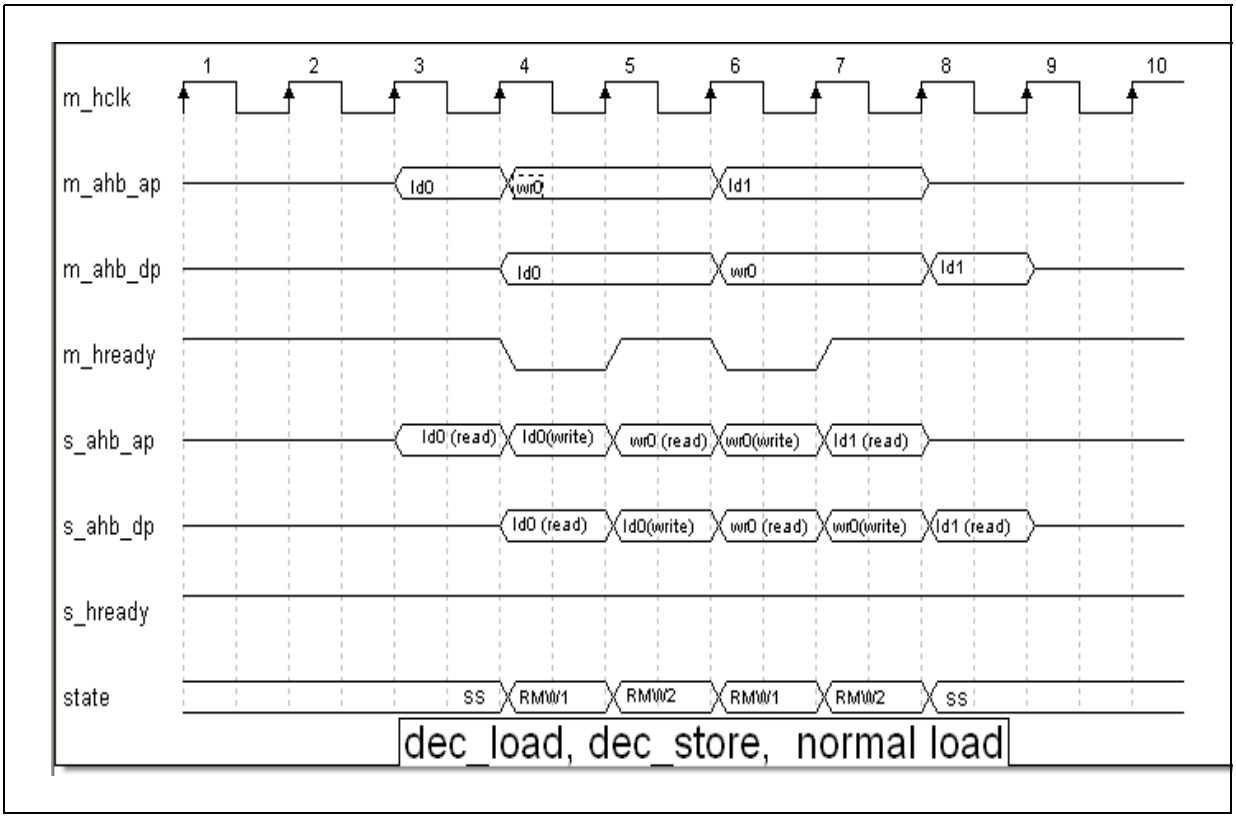
mem[accessAddress, size] = store_operand// memory write
```

Note for the word size operation (swap.w), the data value specified in the low-order 28 bits of the decoration is zero filled in the most significant bits to create the required 32 bit store operand.

35.3.1.2.3 Load-and-Set-1(Bit) (LAS1)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
las1.b	0	1	1	0	0	0	**0**	BIT			-	**-**	-	-	-	-	**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.h	0	1	1	0	0	0	BIT				-	**-**	-	-	-	-	**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
las1.w	0	1	1	0	0	BIT					-	-	-	-	-	-	**-**	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Figure 399. Decoration Format: LAS1



This command first reads the referenced memory location; it then modifies the read operand by setting the single bit position defined in the decoration (BIT); the modified data is then written back to the referenced memory location and the original read data returned to the initiating processor core.

```
tmp   = mem[accessAddress, size] // memory read
rdata = tmp// rT = rdata = tmp
mask  = 1 << (container - bit - 1)// generate bit mask
tmp   = tmp | mask// modify
mem[accessAddress, size] = tmp// memory write
```

35.4 DSMC Timing Diagram

The following timing diagram, *Figure 400*, shows a decorated load followed by a decorated store instruction which is then followed by a normal load instruction. Both decorated instructions are read-modify-write instructions and thus they take at least two cycles to execute. In the first cycle an ECC calculation is performed on the read data as well as the write data. Then in the second cycle of the decorated instruction the decorated operation is performed and if it is a decorated store, the result is merged with the read data and sent to the write data bus along with the recalculated ECC write chkbits.

Figure 400. DSMC Timing Diagram

35.5 DSMC Instantiations

The decorated storage memory controller which performs these operations is instantiated multiple times within the core platform and physically resides between the slave ports of the crossbar and the targeted memory controllers.

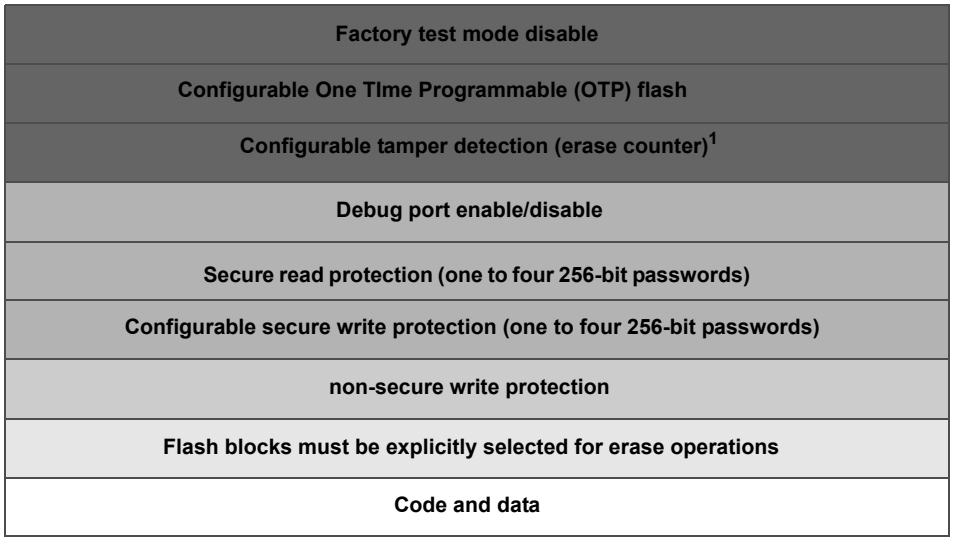
For the SPC574Kx device, the DSMC is instantiated five times, two times in the computational platform shell and three times in the peripheral platform shell.

Table 476. SPC574Kx DSMC Instantiations

DSMC & Memory Controller Association
In the computational shell:
System RAM
Main Core 0 xMEM (Backdoor Port to the Tightly-Coupled Instruction and Data Memories)
In the peripheral shell:
IOP xMEM (Backdoor Port to the Tightly-Coupled Instruction and Data Memories)
AIPS-Lite 0 (Bridge to peripheral subsystem)
AIPS-Lite 1 (Bridge to peripheral subsystem)

The module includes error checking logic that validates the decoration field is properly defined (all illegal commands are rejected and the transfer error terminated). Additionally, the decorated memory controller only operates on aligned, single data transfers (misalignment and/or bursts are not supported and error terminated if attempted).

As the DSMC generates the atomic read-modify-write bus transactions to the attached slave memory controller, the two transactions (read, write) are fully pipelined with no idle cycles introduced. During these transactions, the AHB hlock control signal is asserted to the slave during the entire read-modify-write.



36 Flash Memory Programming and Configuration

This chapter provides basic guidance on activities related to configuring and programming the embedded flash memory in the SPC574Kx microcontroller.

Multiple layers of protection are available to prevent unintended updates to flash contents and unauthorized reads and writes to flash contents. The protection mechanisms range from simple write-protect bits for individual flash blocks to four levels of 256-bit password read and/or write protection and configuration of flash memory blocks as One Time Programmable (OTP).

Additionally, the SPC574Kx microcontroller includes a debug port enable/disable, and the ability to disable the ability for the device to be put into factory test mode.

Figure 401. Flash memory protection layers

Note:

1. Tamper detection module (TDM) is not supported on SPC574Kx.

At the lowest layer of protection, all flash erase operations require the explicit selection of one or more blocks of flash memory before the operation is performed. When executed, the operation is only performed on the selected block(s).

The next layer is the chip's ability to lock individual flash blocks against unintended programming and erase operations. This level of protection does not offer any password protection and is intended to provide protection against *accidental* changes to code and data.

The first layer of *secure* protection is the microcontroller's ability to support up to four levels of 256-bit password-secured *write* protection for individual flash blocks.

Similarly, up to four levels of password-secured *read* protection can be implemented. Unlike the password-secured write protection, which is implemented on a per-block basis, password-secured read protection applies to five pre-defined (at the factory) groups of flash

blocks. The read protection applied to a group applies to each block within the group. In contrast, secure write protection is defined at the individual block level.

Secure password protection can also be implemented for the debug port.

Another protection feature is the ability to configure any flash block as one-time programmable (OTP).

Finally, the microcontroller includes a feature that allows the customer to disable the ability to place the device in factory test mode.

The remainder of the chapter provides details regarding these protection mechanisms and gives a brief overview of security configuration planning.

Note: Most of the topics in this chapter build on information presented in previous topics. To get a clear overview of how the flash protection features work and relate to each other, please read the chapter in sequence from beginning to end.

Access protection configuration is applied on a per-block basis (except read protection applied to groups of flash memory blocks), i.e., a custom level of access protection can be provided for each flash memory block. This is accomplished through the use of registers containing bits that are mapped to individual flash blocks. Understanding the mapping is key to understanding the implementation and use of the SPC574Kx microcontroller's flash protection features.

Depending on the type of protection to be applied, different sets of registers (or even DCF records) are used, but the mapping scheme is consistent. This mapping scheme is first presented in *Section 36.1: Selection of flash memory blocks for erase*. It is important to understand the topic before proceeding to other sections.

36.1 Selection of flash memory blocks for erase

The registers used for selecting flash blocks for erase operations are the flash control registers named LOCK0, LOCK1, and LOCK2. There is also a LOCK3 register, but no flash blocks are mapped to it.

The LOCK0–2 registers are 32-bit registers containing fields associated with specific address spaces: low, mid, high, and 256 KB. Each non-reserved bit in the fields is mapped to a specific flash block.

For example, *Figure 402* shows the Select 0 (SEL0) register for the flash module. This register provides a way of selecting blocks in the low and mid address spaces for erase operations.

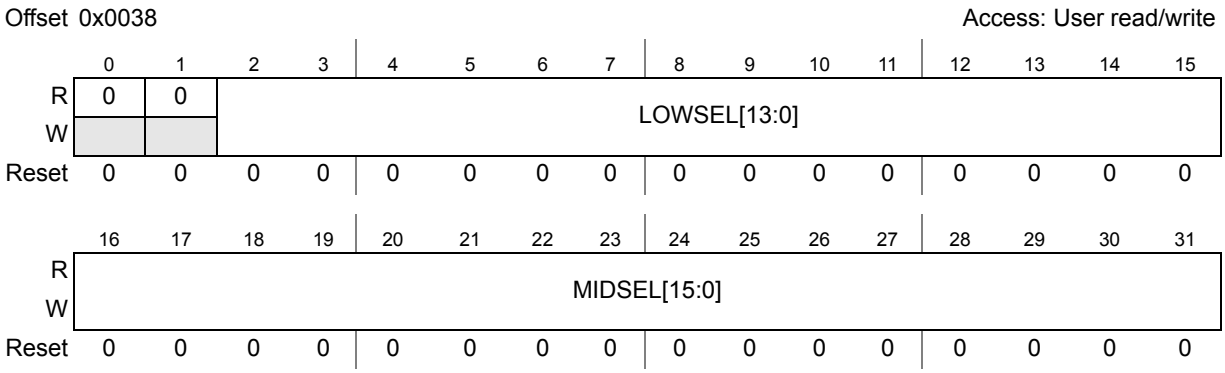


Figure 402. SEL0 flash control register

Table 477 shows an example of a mapping of SEL0 register's LOWSEL and MIDSEL field bits to individual flash blocks[i]. In this case, not all bits of the LOWSEL and MIDSEL fields are mapped—only LOWSEL bits 0–11 (register bits 15–4[j]) and MIDSEL bits 0–2 are mapped. Before any mapped block can be erased, it must be selected by writing a '1' to its corresponding bit in one of the SEL*n* registers. See the device configuration chapter for the complete mapping.

Note: Values written to the SEL registers do not persist through device reset. As indicated by the reset values shown in Figure 402, all bits are reset to '0'. As a result, after a device reset all blocks mapped to the register are, by default, not selected for erase.

Table 477. Sample low and mid address space flash block bit mapping

Start Address	End Address	Size (KB)	Partition	LOCK*n* (1) Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit(2)	Read Lock group (3)	Block No.	Description
0x0040_4000	0x0040_7FFF	16	0	LOCK0	LOWLOCK[0]	16	—	0	BAF(4)
0x00FC_0000	0x00FC_3FFF	16	0	LOCK0	LOWLOCK[1]	17	1	1	Code Flash(5)
0x00FC_4000	0x00FC_7FFF	16	0	LOCK0	LOWLOCK[2]	18	1	2	Code Flash4
0x00FC_8000	0x00FC_BFFF	16	1	LOCK0	LOWLOCK[3]	19	1	3	Code Flash4
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash4
0x00FD_0000	0x00FD_7FFF	32	0	LOCK0	LOWLOCK[6]	22	1	6	Code Flash
0x00FD_8000	0x00FD_FFFF	32	1	LOCK0	LOWLOCK[7]	23	1	7	Code Flash
0x00FE_0000	0x00FE_FFFF	64	0	LOCK0	LOWLOCK[8]	24	1	8	Code Flash
0x00FF_0000	0x00FF_FFFF	64	0	LOCK0	LOWLOCK[9]	25	1	9	Code Flash

i. The table lists the LOWLOCK register field but the structure is identical to the LOWSEL field in *Figure 402*.

j. Register bits in Power Architecture-based microcontrollers are numbered with the most significant bit as 0. This is not necessarily the case with register field bit numbering. The field bit numbering shown in the figure has the least significant bit numbered as 0.

Table 477. Sample low and mid address space flash block bit mapping(Continued)

Start Address	End Address	Size (KB)	Partition	LOCK*n* (1) Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit(2)	Read Lock group (3)	Block No.	Description
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST(6)

1. There are multiple sets of LOCK*n* registers, i.e., the flash module's LOCK0–-3 registers and PASS module's PASS_LOCK0–3_PG0–3, but all use the same mapping of register bits to flash blocks. The same mapping applies the the flash module's SEL0–3 registers.
2. The DCF record DATA bit refers to the DATA[31:0] field contained in DCF records created during OEM configuration activities. The DCF records related to flash blocks are used to implement password-secured write protection, password-secured read protection, tamper detection, and debug port enable/disable as a permanent part of the device configuration.
3. The Read Lock group pertains to protecting code and data blocks from being read by debuggers. This type of protection is implemented using DCF records and the PASS_LOCK3_PG0–3 registers.
4. The Boot Assist Flash (BAF) is one time programmable and the majority of it is programmed in the factory. The BAF handles the initial start up of the device.
5. This block is searched to determine the boot location (if it contains the boot header).
6. One time programmable.

Example 12. Selecting blocks for erase

Referring to *Table 477*, writing the value 0x0030_0000 to the SEL0 register (*Figure 402*) selects the following blocks for erase:

Table 478. Selecting blocks for erase

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash

Note: The mappings of SELn register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC574Kx microcontroller.

36.2 Non-secure write protection

Non-secure write protection refers to the chip's ability to lock individual flash blocks against programming and erase operations. This level of protection is intended to provide protection against *accidental* changes to code and data. Although similar in function, this is *not* associated with the built-in register protection (REG_PROT) feature included with many of the chip's modules. The non-secure write protection feature detailed here applies only to embedded flash memory.

Implementing non-secure write protection is almost identical to selecting specific flash blocks for an erase operation—the only difference is the register used. To provide non-

secure write protection for a block, write a ‘1’ to the corresponding mapped bit found in one of the LOCK0–2 flash control registers.

Note: As indicated by the reset values shown in Figure 403, after reset all blocks mapped to the register are, by default locked against programming and erase. Values written to the LOCK and SEL registers do not persist through device reset.

The same bit mapping that applies to the SEL0–3 registers also applies to the LOCK0–3 registers.

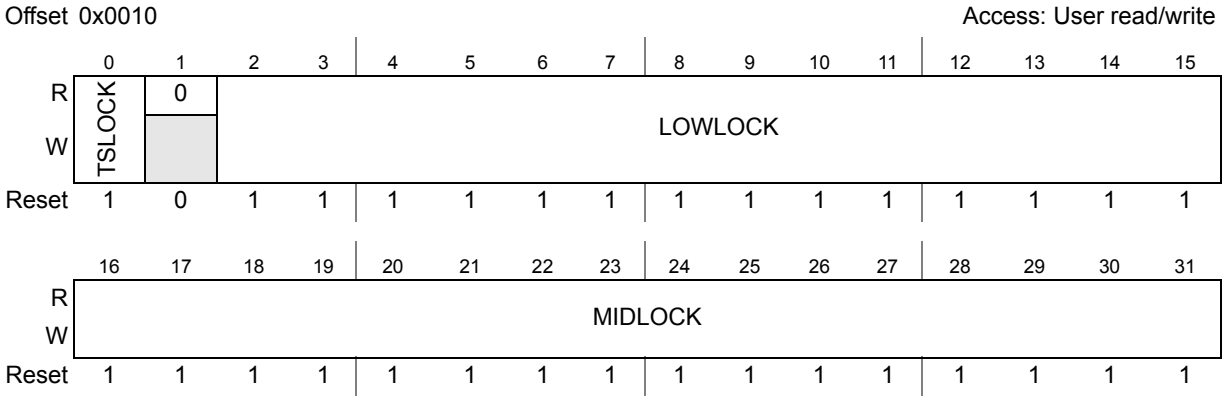

Figure 403. LOCK0 flash control register

Example 13. Selecting

Referring to *Table 477*, writing the value 0x0030_0000 (same value used in *Example 12*) to the LOCK0 register (*Figure 403*) locks the following blocks (same blocks selected in *Example 12*) so they cannot be programmed or erased, even if selected for erase:

Table 479. Selecting

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash

As long as the LOCK0[LOWLOCK] bits are unchanged, the above blocks cannot be modified unless the protection is overridden (discussed in *Section 36.3: Secure write protection*). All other blocks mapped to bits in the LOCK0 *can* be programmed because their corresponding bits have been set to ‘0’.

36.3 Secure write protection

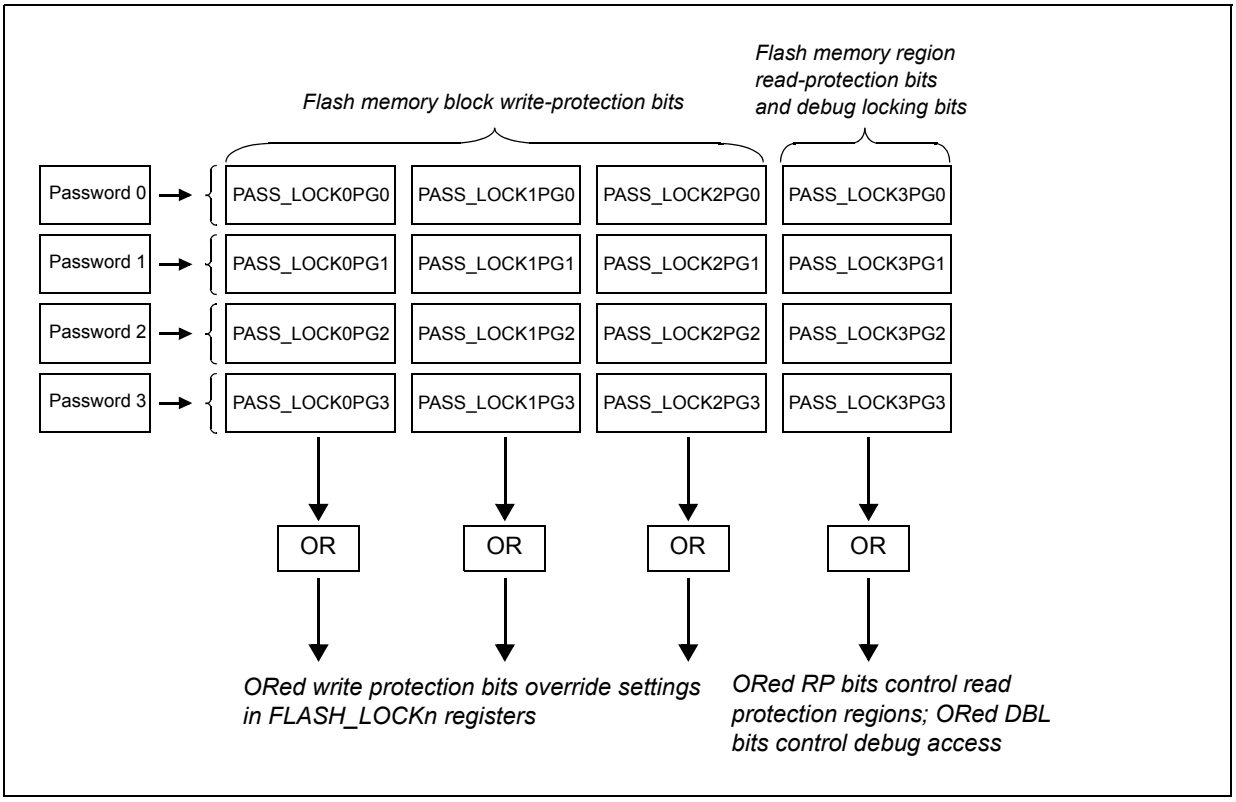
Secure write protection refers to the chip’s ability to implement up to four levels of 256-bit password-secured *write* protection for individual flash blocks. Use of this feature is optional but the default behavior of the SPC574Kx microcontroller is to apply secure write protection. If there is a need to *not* write-protect specific blocks, that needs to be configured by creating the appropriate DCF records.

Note that the *secure* write protection settings override the non-secure write protection detailed in *Section 36.2: Non-secure write protection*.

Implementing a custom secure write protection scheme requires creating DCF records that define the level of write protection to be applied to each flash block. The DCF records use a bit mapping scheme identical to the mapping in the flash module's SEL*n* and LOCK*n* registers. The write protection scheme becomes a permanent part of the device but blocks can be temporarily unlocked. Depending on the specific implementation, temporarily unlocking the write protection requires matching up to four 256-bit passwords.

The easiest way to understand the secure write protection functionality is to examine the role played by the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers are four identical sets of registers contained in the PASS module—they distinguished by the PG*n* suffix. The PG*n* (Password Group *n*) suffix indicates the password required to unlock that set of registers. Password 0 unlocks PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. Similarly, the registers suffixed with PG1 are unlocked by matching password 1, and so on.



The PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* register sets have two functions related to secure write protection:

- Reading the registers provides the secure write lock status for each flash block.
- Changing the value of a mapped bit in a register changes the secure write protect status of the corresponding flash block.

Each set of registers contains the same mapping of bits to flash blocks as the flash module's SEL*n* and LOCK*n* registers. In any of the four PASS_LOCK*x*_PG*n* register sets, if a mapped bit is set to '1', locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access to the register, and setting the bit to '0'. If the same bit is set to '1' in more than one PASS_LOCK*x*_PG*n* register set, each must be unlocked using the corresponding password and the bit must be set to '0' before the flash block is available for programming or erase.

Figure 404 shows how the registers interact. Note that secure write protection is only affected by the settings in PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n*. The PASS_LOCK3_PG*n* registers have additional security functions, discussed in later topics.

Figure 404. Secure write protection

The next sections discuss implementing secure write protection and overriding secure write protection.

36.3.1 Implementing secure write protection

Implementing secure write protection is a one-time task performed either at the factory or by the customer during chip configuration activities. It normally requires creating a DCF record for each of the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers[k]. The DCF records have a structure that includes the same mapping of bits to flash memory blocks as the flash module's SEL*n* and LOCK*n* registers. The values assigned become the permanent register reset values for the PASS_LOCK0_PG*n*–PASS_LOCK2_PG*n* registers.

See *Chapter 9: Device Configuration Format (DCF) Records* for complete details on DCF records. This section summarizes the contents of a DCF record as required to implement secure write protection.

Even though the mapping of bits to flash memory blocks is identical to the mapping used for selecting flash blocks for erase of non-secure write locking, there are two significant differences:

1. Configuring flash blocks for secure write protection is done only during device configuration to customer specifications, either at the factory or by the customer during

k. The default behavior for secure write protection in the case where passwords are created but no secure write protection DCF records are created, is for all blocks to have four levels of password-secured write protection. To vary the protection among all blocks, a DCF record for each password group must be created.

OEM production activities. The selection becomes a permanent part of the device configuration.

2. Configuration of blocks for secure write protection is done by writing *DCF records*, which is why the selection becomes a permanent part of the device.

Caution: Careful planning is required before writing DCF records. They are created in a write-once area of flash. Multiple instances of any DCF record can be created, but in some cases only the record created first is used and with others only the most-recently written record is used. Be sure to understand the characteristics of a DCF record before creating it.

The DCF records required for implementing a secure write protection scheme are detailed in the PASS section of DCF client list table (*Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*). Table entries provide the CS and Address value combinations that correspond to PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers.

The format of a secure write protection record is summarized here for convenience.

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory. The structure of a DCF Record is shown in *Figure 405*.

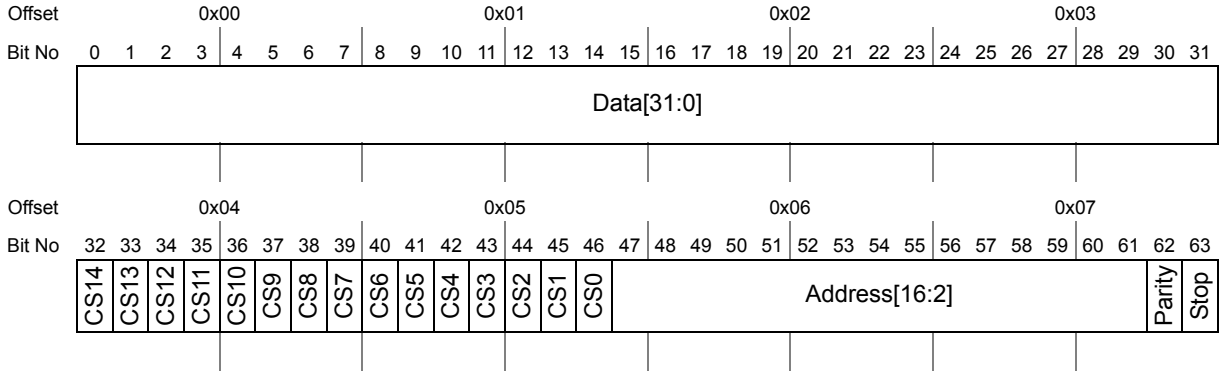


Figure 405. DCF record structure

Note: The values in the PASS_LOCKxPGn registers override the settings in the flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase.

The PASS_LOCKxPGn bits take effect when the life cycle is matured to "OEM Production" or older.

Example 14. Implementing secure write protection

Implementation of secure write protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) must be stored in a protected OTP area of device flash called UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers.
2. DCF records must be created to define which flash memory blocks are to be locked and which blocks are not locked.

The records defined in step 2, determine the reset values of the PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n* registers and therefore the write protection settings that take effect each time the microcontroller is reset.

Assume four passwords have been previously implemented and the following blocks are to be locked in the password 0 group:

Table 480. mplementing secure write protection

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash

From the PASS section of *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*:

Table 481. DCF values

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0000	LOCK0_PG0

Referring to *Figure 405*, the values for the DCF record are:

- Data[31:0] is 0x0030_0000 (bits 0–31) (same value used in previous examples)
- CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
- Address[16:2] is 0b000_0000_0100_0000 (bits 47–61)
- Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
- Preferred Stop value is 0 (see footnotes in *Figure 406*.

The following DCF record provides secure write protection for the blocks in *Table 477* by setting the reset values PASS_LOCK0_PG0 to the appropriate value to lock the blocks.

Bit No	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Bit No	32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63
	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	X (1)	X (2)

Figure 406. Sample DCF record for secure write protection

1. Bit 62 indicates parity strategy, which is not used in the PASS DCF records so it is a “don’t care”.
2. Bit 63 indicates whether the current record is the last DCF. Generally, this should be written as ‘0’ so the first unprogrammed (all 1’s) DCF record acts as the stop record.

The remaining blocks mapped to the PASS_LOCK0_PG*n* registers do *not* have secure write protection provided by the password 0 register set because the DATA field of DCF record has only the bits mapped to flash blocks 4 and 5 set to ‘1’.

Caution: The above example is intended to highlight the need to carefully understand how DCF records work. The protected blocks are secured by password 0 but by default they are also secured by passwords 1, 2, and 3. In contrast the blocks *not* secured by password 0 in this example *are* secured by passwords 1, 2, and 3.

See the PASS section of DCF client list table (*Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*) for details on the DCF records.

36.3.2 Overriding secure write protection

The “PG*n*” (Password Group *n*) suffix on each the register names indicates the password each set of registers is associated with. For example, password 0, is used to unlock PASS_LOCK0_PG0, PASS_LOCK1_PG0, PASS_LOCK2_PG0, and PASS_LOCK3_PG0. The bits in the first three registers (PASS_LOCK0_PG0, PASS_LOCK1_PG0, and PASS_LOCK2_PG0) are mapped exactly the same as the bits in the flash module’s SEL0–2 registers and LOCK0–2 registers.

Like the SEL0 and LOCK0 registers, the PASS_LOCK0_PG*n* registers all contain bits mapped to the low and mid address spaces, and the mapping scheme is the same. A mapped bit set to ‘1’ in any of the registers causes the corresponding block to be locked against program or erase. A mapped bit set to ‘0’ in any of the registers makes the corresponding block available for programming or erase.

If a bit is set to ‘1’, locking a flash block, that value can only be changed by successfully supplying the password value for that set of registers to gain write access, and setting the bit to ‘0’. If the same bit is set to ‘1’ in more than one of the PASS_LOCK*x*PG*n* register sets, each must be unlocked using the corresponding password and the bit must be set to ‘0’ before the flash block is available for programming or erase.

Figure 407 shows the PASS_LOCK0_PG*n* register. As you can see, it has the same structure as the flash module’s LOCK0 register. In addition to the main difference of being among a group of four parallel sets of locking registers, the other difference between the PASS_LOCK*x*_PG*n* registers and the flash LOCK*n* registers is how the reset values are determined.

By default, all mapped bits are set to ‘1’, locking their corresponding flash blocks from programming and erase. The reset value is user-configurable, though, by writing a DCF record. This is discussed in a later section.

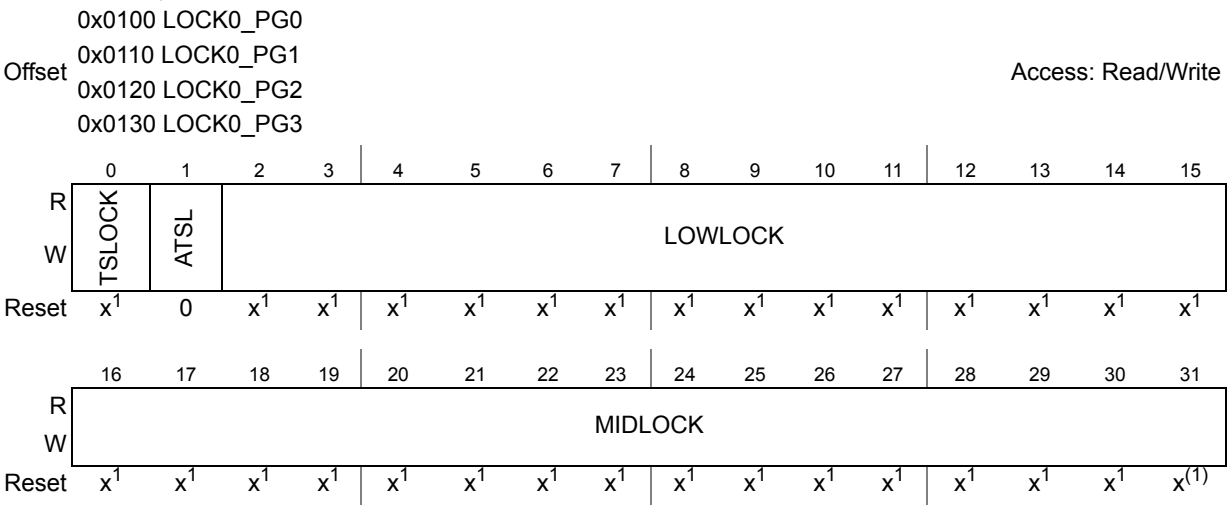

Figure 407. LOCK0_PG*n* register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'

Note: The values in the PASS_LOCKxPGn registers override the settings in the flash module's LOCK0–3 registers.

Values written to the PASS_LOCKxPGn registers do not persist through device reset. The reset value is determined by DCF record or, if no relevant DCF record has been created, each mapped bit has a reset value of '1', which causes the associated flash block to be locked against programming or erase. The purpose of the registers is to indicate secure write protection status and to provide a way to temporarily override secure write protection.

The PASS_LOCKxPGn bits take effect after the life cycle is matured to "OEM Production" or older.

Example 15. Overriding secure write protection

Assume four passwords have been created but no DCF records have been written to set the reset values of the PASS_LOCK*x*_PG*n* registers, so the reset value for each mapped bit defaults to '1', causing all mapped blocks to have four levels of 256-bit password-secured write protection.

Since the settings in the PASS_LOCK*x*_PG*n* registers override the settings in the flash module's LOCK0–3 registers, the settings in those registers are irrelevant. Each of the four sets of the PASS module's LOCK registers must be unlocked by supplying the correct password for each set and then the appropriate bits must be set to '0' to make the desired flash blocks available for program or erase.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write 0xFFCF_FFFF to the PASS_LOCK0_PG0 register and verify a successful write.
4. Repeat the above steps for passwords 1–3.

Just as in previous examples, the result is the following blocks are available for program and erase operations but at a much higher level of security.

Table 482. Overriding secure write protection

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash
0x0060_C000	0x0060_FFFF	16	1	LOCK0	LOWLOCK[5]	21	3	5	Secure Code

36.4 Secure read protection

Read Protection is ability of the flash controller to block read accesses to the flash memory from all bus masters. This includes the blocking of:

- Instruction fetches and load instructions from the CPU
- Debug reads from an outside tool
- DMA reads
- SIPI reads
- All other types of bus master reads

When secure read protection is active, the affected flash blocks are readable by any bus master until a debugger is attached to the JTAG port and debug is enabled. If a debugger is attached and debug is enabled while an application is running, the next access to a flash read protected region terminates with a bus error.

Most instances of flash memory read protection in the SPC574Kx microcontroller are *not* configurable by the customer. An example of this is the 256-bit passwords stored in UTEST flash memory. Password-based read protection *is* customer-configurable[l] and is similar to the password-based write protection mechanism detailed in *Section 36.3: Secure write protection*.

There are two significant differences between password-based read protection and password-based write protection in the SPC574Kx microcontroller.

1. Read protection can only be applied to pre-defined groups of flash memory blocks. These groups, called “Read Lock groups”, cannot be re-defined, meaning the blocks assigned to those groups are permanently assigned and cannot be assigned to other groups and no new groups can be created.
2. Read protection is only active either when a debugger is attached to the JTAG port and debug is enabled; or the lifecycle has been advanced to "Failure Analysis".

l. Secure read protection is user-configurable in that the default lock/unlock state for each mapped block at reset is controlled by user-created DCF records, giving the user the ability to determine the number of levels of password protection implemented. The read protection is applied to groups of blocks instead of individual blocks and the groups are not user-definable.

Another difference is that only the PASS_LOCK3_PG*n* register for each password group is used:

- PASS_LOCK3_PG0
- PASS_LOCK3_PG1
- PASS_LOCK3_PG2
- PASS_LOCK3_PG3

Note: The mappings of PASS_LOCK3_PGn register bits to flash blocks vary with different microcontrollers. See the flash memory section in the Device Configuration chapter of this reference manual for the mappings specific to the SPC574Kx microcontroller.

The next sections discuss implementing secure read protection and overriding secure write protection.

36.4.1 Implementing secure read protection

Implementation of secure read protection is done during initial flash setup as follows:

1. Four 256-bit passwords (passwords 0–3) are stored in a protected OTP area of device flash named UTEST flash. Each password secures a set of registers in the PASS module (PASS_LOCK0_PG*n*–PASS_LOCK3_PG*n*) that have the same mapping of register bits to flash blocks as the flash module's SEL0–3 registers and LOCK0–3 registers. These are the same passwords used by secure write protection and other secure functions. The passwords are only created once.
2. DCF records must be created to define which flash memory blocks are to be locked. Those records determine the reset values of the PASS_LOCK3_PG*n* registers.

   Like the other PASS_LOCK*x*_PG*n* registers, the PASS_LOCK3_PG*n* registers have two functions.
   - Reading the registers provides a lock status for each Read Locking group.
   - Changing the value of a mapped bit in a register changes the read protect status of the corresponding Read Locking group.

The layout of the PASS_LOCK3_PG*n* registers is shown in *Figure 408*. The fields relevant to implementing secure read protection are RL2–RL0.

Offset: 0x010C LOCK3_PG0, 0x011C LOCK3_PG1, 0x012C LOCK3_PG2, 0x013C LOCK3_PG3 — Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 408. PASS_LOCK3_PG*n* Register

1. Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.

2. If no DCF records have been written to change the lock state, the bit will reset to ‘1’.

Example 16. Implementing secure read protection

Assume four passwords have been previously implemented.

Following is an example of a mapping of flash blocks to Read Locking groups.

Table 483. Sample low and mid address space flash block bit mapping

Start Address	End Address	Size (KB)	Partition	LOCK*n* Register	LOCK*n* Register Field Bit	LOCK*n* DCF Record DATA Bit	Read Lock group	Block No.	Description
0x0040_4000	0x0040_7FFF	16	0	LOCK0	LOWLOCK[0]	16	—	0	BAF
0x00FC_0000	0x00FC_3FFF	16	0	LOCK0	LOWLOCK[1]	17	1	1	Code Flash
0x00FC_4000	0x00FC_7FFF	16	0	LOCK0	LOWLOCK[2]	18	1	2	Code Flash
0x00FC_8000	0x00FC_BFFF	16	1	LOCK0	LOWLOCK[3]	19	1	3	Code Flash
0x00FC_C000	0x00FC_FFFF	16	1	LOCK0	LOWLOCK[4]	20	1	4	Code Flash
0x00FD_0000	0x00FD_7FFF	32	0	LOCK0	LOWLOCK[6]	22	1	6	Code Flash
0x00FD_8000	0x00FD_FFFF	32	1	LOCK0	LOWLOCK[7]	23	1	7	Code Flash
0x00FE_0000	0x00FE_FFFF	64	0	LOCK0	LOWLOCK[8]	24	1	8	Code Flash
0x00FF_0000	0x00FF_FFFF	64	0	LOCK0	LOWLOCK[9]	25	1	9	Code Flash
0x0040_0000	0x0040_3FFF	16	0	LOCK0	TSLOCK	31	0	32	UTEST

To provide two level of password protection for only Read Lock group 3 and leave all other groups unlocked, the RL3 bit can be set in any two of the four PASS_LOCK3_PG*n* registers. For this example, we will choose password groups 0 and 1.

We need to create DCF records that define the reset values for all RL*n* bits as 0, with the exception of PASS_LOCK3_PG0 and PASS_LOCK3_PG1. The information required is from the PASS section of *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

Table 484. Implementing secure read protection

DCF CS[14:0]	DCF address [16:2] (binary)	DCF client description
000_0000_0000_1000	000_0000_0100_0011	LOCK3_PG0
000_0000_0000_1000	000_0000_0100_0111	LOCK3_PG1
000_0000_0000_1000	000_0000_0100_1011	LOCK3_PG2
000_0000_0000_1000	000_0000_0100_1111	LOCK3_PG3

Referring to *Figure 405*, the values for the DCF record are:

- For LOCK3_PG0
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG1
  - Data[31:0] is 0x0008_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_0111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG2
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1011 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.
- For LOCK3_PG3
  - Data[31:0] is 0x0000_0000 (bits 0–31)
  - CS[14:0] is 0b000_0000_0000_1000 (bits 32–46)
  - Address[16:2] is 0b000_0000_0100_1111 (bits 47–61)
  - Parity value is irrelevant because it is not used in PASS DCF records (bit 62)
  - Preferred Stop value is 0.

36.4.2 Overriding secure read protection

As noted previously, the PASS_LOCK3_PG*n* registers (see *Figure 408*) contain five read protection fields, RP0–RP4, that correspond to pre-defined Read Lock groups. To temporarily unlock a Read Lock group, the appropriate PASS_LOCK3_PG*n*[RL*n*] bits must be set to 0.

Like the register bits controlling secure write protection, the reset value of bits controlling secure read protection is determined by DCF record or, in the absence of a relevant DCF record, each bit resets to ‘1’, causing the blocks associated with each read group to be read locked.

Example 17. Overriding secure read protection

Building on *Example 16*, where Read Lock group 3 was protected by passwords 0 and 1, temporarily overriding secure read protection for that group is accomplished by first unlocking the PASS_LOCK3_PG0 and PASS_LOCK3_PG1 registers and then setting the RL3 bit to ‘0’ in both.

1. First write 0b00 to the PASS_CHSEL[GRP] register field to indicate registers controlled by password 0 are to be unlocked.
2. Write the 256-bit value for password 0 to the set of eight 32-bit password challenge input registers (PASS_CIN*n*) beginning with PASS_CIN0. The password must be written as a sequence of eight 32-bit writes, with the most significant bits of the password written to PASS CIN0.
3. Write a 0 to PASS_LOCK3_PG0[RL3] bit and verify a successful write.
4. Repeat the above steps for password 1.

The result of a successful sequence is that the blocks associated with the unlocked read lock group can be read by a debugger.

36.5 Debug port enable/disable

The mechanism for temporarily enabling the SPC574Kx debug port after it has been locked by its life cycle state is similar to the flash memory read protection mechanism detailed in *Section 36.4: Secure read protection*. The difference is that the PASS_LOCK3_PG*n*[DBL] field is used instead of the RP0–RP4 fields.

36.6 Implementing OTP

Any flash block within the flash array can be assigned, at any time, to be OTP. OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block becomes OTP after the next reset.

Warning: After a flash block is configured as OTP, it cannot be changed back.

This capability resides within the Tamper Detection Module (TDM). The records are detailed in *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*. See the entries for the OTP_EN0, OTP_EN1, OTP_EN2, and OTP_EN3 DCF records in the Tamper Detect section of the table.

36.7 Implementing test mode disable

The SPC574Kx flash memory module includes a mechanism to disable manufacturer entry into test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method are able to have possible failures analyzed by manufacturer's failure analysts.

Test mode disable prevents all high voltage operations to the flash executed by the internal state-machine, as well as reads through the state machine, and reads through the Array Integrity state machine when using test mode interfaces.

Optionally, the customer can create a password to enable manufacturer entry into test mode.

36.7.1 Unconditional test mode disable seal

Warning: This process is not reversible. After completing these steps the SPC574Kx microcontroller is permanently prevented from entering test mode for factory analysis.

The steps for unconditionally disabling test mode are the same steps required for implementing passcode-protected entry into test mode with one exception—the passcode specified must be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To unconditionally disable test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program one of the three *invalid* passcodes shown above into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently disabled.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.7.2 Passcode-protected test mode disable seal

The steps for implementing passcode-protected entry into test mode are the same required for unconditionally disabling test mode with the exception that —the passcode specified must NOT be one of the following three *invalid* passcodes:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

To implement passcode-protected test mode entry:

1. Select individual flash blocks to be protected by programming the appropriate values into the Test Mode Disable Block Select Group A and Test Mode Disable Block Select Group B areas shown in the UTEST flash memory map.
2. Program a valid passcode into the Test Mode Override Passcode area shown in the UTEST flash memory map.
3. Program the value 0x5A4B_3C2D into the Test Mode Disable Seal location specified in the UTEST flash memory map.

After the next reset is asserted, Test Mode is permanently passcode protected.

Note: Blocks selected for test mode disable can be selected in either or both Test Mode Disable Block Select Groups (A and B) because those fields are logically ORed to determine the blocks to be protected.

The lifecycle state must be programmed to 'Production at OEM' or later for the disable seal to be in effect.

36.7.3 Selecting flash memory blocks for test mode disable seal

Selecting flash memory blocks for test mode disable seal protection involves writing to non-register flash locations. In the case of the test mode disable seal function, there are two areas of UTEST flash memory that have identical mapping to flash memory blocks. When the test mode disable seal takes effect, the mapped bits are logically ORed to determine the blocks to be protected.

The mapping of bits to blocks for this function is identical to the mapping used for other functions. See the table in the device configuration chapter for the map.

Note: Selecting a block for test mode disable requires a ‘0’ in the mapped bit—not a ‘1’ as with other functions.

36.8 Security configuration planning

36.8.1 Creating password groups

Most basic security features in the SPC574Kx microcontroller are password-based. Therefore, one of the early tasks that must be performed is the creation of four 256-bit passwords. They are programmed by the customer into the locations identified in the UTEST memory map (*Table 14*) in *Chapter 5: Memory map*.

The UTEST memory map fields to be written are:

- PASS Password Group 0
- PASS Password Group 1
- PASS Password Group 2
- PASS Password Group 3

Passwords must not be one of the following, which are considered insecure and therefore invalid:

- 0x0000_0000
- 0xFFFF_FFFF
- 0x5555_5555

Warning: **The password fields are in OTP UTEST flash, so they can only be written once.**

36.8.2 Planning secure write protection

Up to four levels of password-secured write protection can be assigned to any block. Note that by default, all blocks of user flash are write protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured write protection. The write protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure write protection, please thoroughly review the implementation steps detailed in *Section 36.3.1: Implementing secure write protection* and *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.8.3 Planning secure read protection

Up to four levels of password-secured write protection can be assigned to flash blocks in pre-defined Read Locking groups. Note that by default, all blocks of user flash are read protected, so this could be more accurately viewed as planning which blocks of user flash will *not* have four levels of password-secured read protection. The read protection desired will depend on the usage of the flash blocks. Before creating DCF records to implement secure read protection, please thoroughly review the implementation steps detailed in *Section 36.4.1: Implementing secure read protection* and *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.8.4 Planning debug port enable/disable

Please see *Section 36.5: Debug port enable/disable* and *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.8.5 Planning OTP flash memory block assignment

Any block of user flash can be configured as OTP. The need to configure blocks as OTP will depend on the data or code to be stored in the block. It is important to note that configuring a flash block as OTP is not reversible.

Before creating DCF records to implemented OTP flash blocks, please thoroughly review the implementation steps detailed in *Section 36.6: Implementing OTP* and *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

36.8.6 Planning factory test mode disable

Please see *Section 36.7: Implementing test mode disable* and *Table 121: DCF client list* in *Chapter 9: Device Configuration Format (DCF) Records*.

37 Analog-to-digital converter (ADC) configuration

37.1 ADC overview

This chapter is organized into the following sections:

- *Section 37.1: ADC overview*
  - *Section 37.1.1: ADC subsystem block diagram*
  - *Section 37.1.2: Analog input pin multiplexing*
- *Section 37.2: Configuration of ADC modules*
  - *Section 37.2.1: Sigma-Delta Analog-to-Digital Converter (SDADC)*
  - *Section 37.2.2: Successive Approximation Register Analog-to-Digital Converter (SARADC)*

SPC574Kx contains the following analog-to-digital converters (ADCs):

- 5 independent 12-bit Successive Approximation Register Analog-to-Digital Converters (SARADCs)
- 2 independent 16-bit Sigma-Delta Analog-to-Digital Converters (Sigma-Delta, or SDADCs)

These ADCs interface to:

- 38 external analog input pins in the 144-pin QFP and in the 172-pin FusionQuad emulation device (ED) package.
- 48 external analog input pins in the 176-pin QFP and in the 216-pin FusionQuad ED package.

Each SAR or Sigma-Delta ADC instance has independent analog input pin multiplexing, register controls, trigger and clock inputs, independent interrupt and DMA capability and a dedicated peripheral bridge (PBRIDGE) interface for CPU access to the registers.

All SAR and Sigma-Delta ADCs share the same supply pins (VDD_HV_ADV/VSS_HV_ADV) and ground, but have separate reference pins. This is true for both packages.

Note that the numbering scheme is aligned along the complete family of devices: the SARADCs on the device are referred to as SARADC_B (48:1 input mux), SARADC_0, SARADC_2, SARADC_4, and SARADC_6 (maximum 12:1 input mux for each).

37.1.1 ADC subsystem block diagram

Figure 409 gives the block diagram for the high-level integration of the SPC574Kx ADC subsystem for, demonstrating how each SAR or Sigma-Delta ADC has independent register interfaces, interrupt/DMA requests, and trigger source selection.

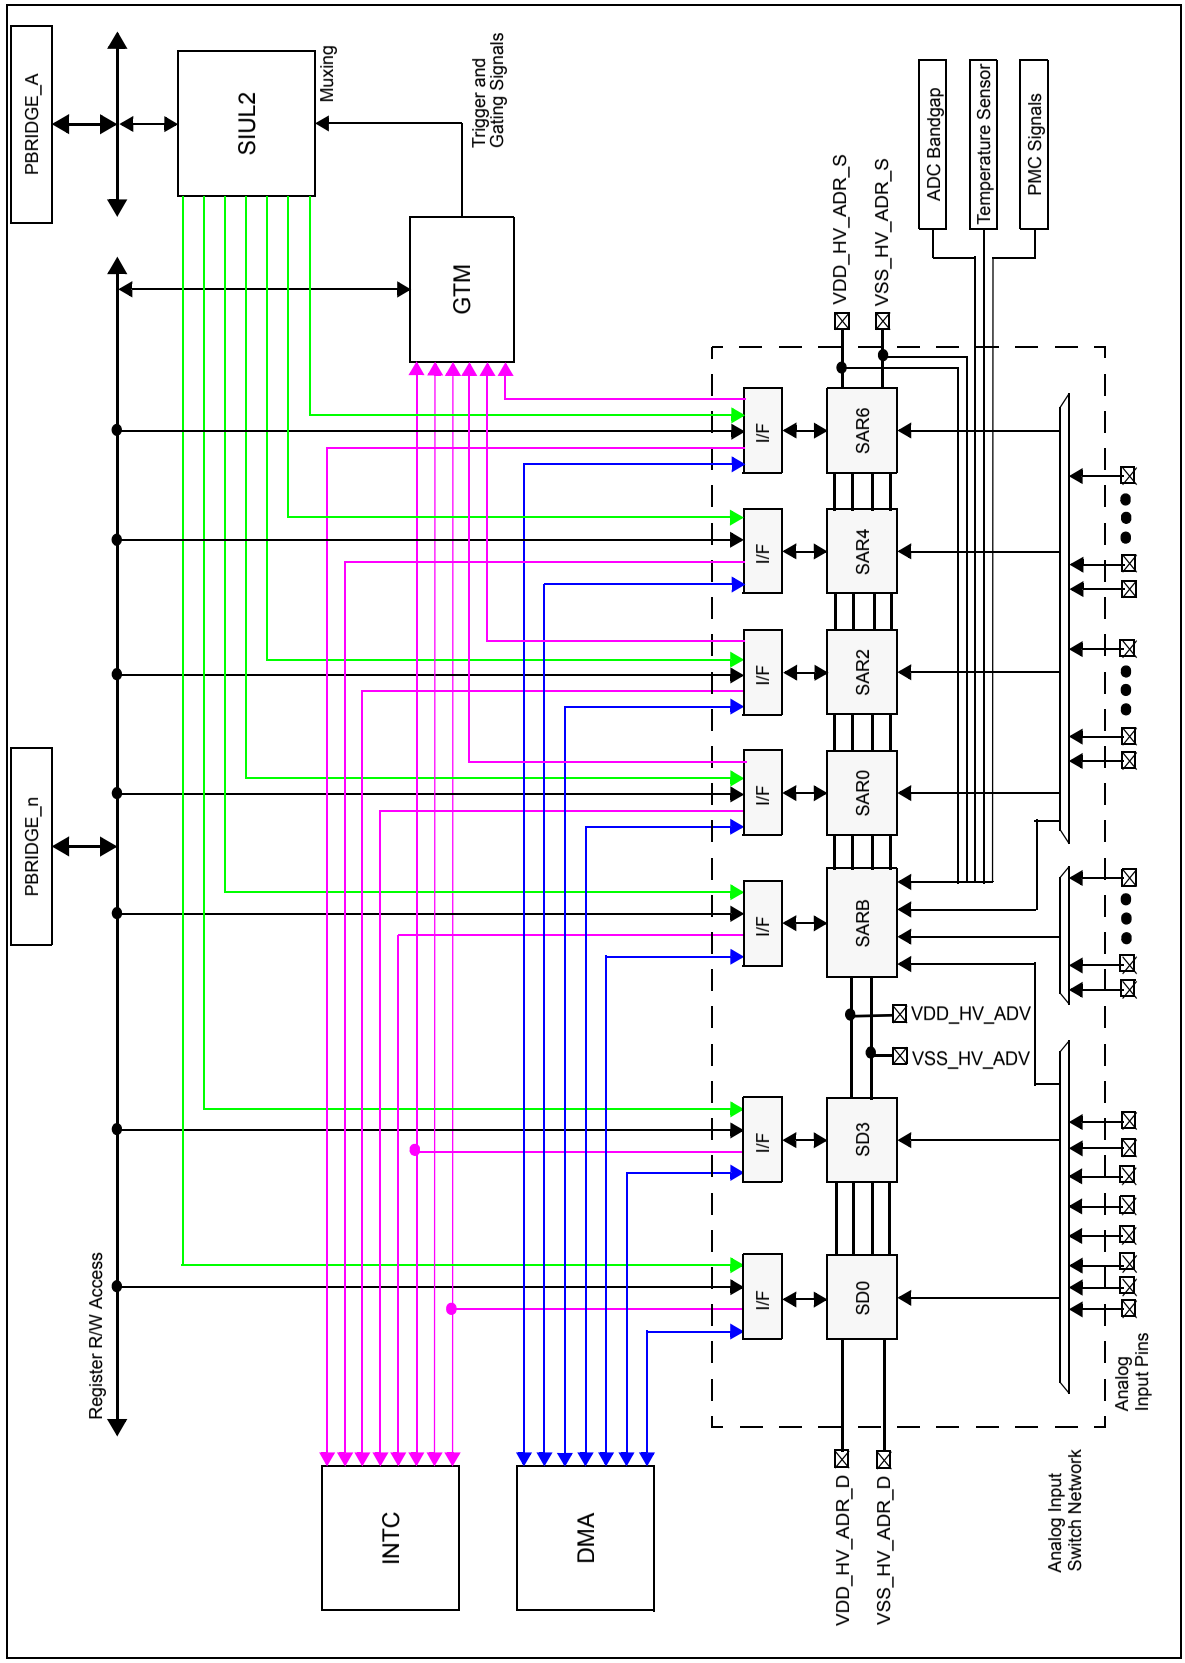

Figure 409. SPC574Kx ADC subsystem

37.1.2 Analog input pin multiplexing

There are 48 external analog input pins in the 176-pin QFP for SPC574Kx, and 38 in the 144-pin QFP. All analog input pins in either package are readable by SARADC_B. In addition to SARADC_B, most analog input pins are routed to either the Sigma-Delta or SAR ADCs, but never both. *Table 485* gives the analog input pin assignment for both SPC574Kx 176-pin and 144-pin packages.

Table 485. SPC574Kx analog input pin multiplexing

ADC instance	144-pin QFP (and 172-pin FusionQuad ED)		176-pin QFP (and 216-pin FusionQuad ED)	
	Analog input pins	Mux input(1)	Analog input pins	Mux input[1]
SARADC_B	AN[0:8] AN[10:13] AN[16:17] AN[20:21] AN[24:25] AN[35:39] AN[44:48] AN[51:53] AN[56:61]	AN[0:8] AN[10:13] AN[16:17] AN[20:21] AN[24:25] AN[35:39] AN[44:48] AN[51:53] AN[56:61]	AN[0:8] AN[10:13] AN[16:21] AN[24:29] AN[32:33] AN[35:39] AN[44:53] AN[56:61]	AN[0:8] AN[10:13] AN[16:21] AN[24:29] AN[32:33] AN[35:39] AN[44:53] AN[56:61]
SARADC_0	AN[4:8] AN[10:13]	AN[4:8] AN[10:13]	AN[4:8] AN[10:13]	AN[4:8] AN[10:13]
SARADC_2	AN[16:17] AN[20:21] AN[24:25]	AN[16:17] AN[20:21] AN[24:25]	AN[16:21] AN[24:29]	AN[16:21] AN[24:29]
SARADC_4	AN[35] AN[44:47]	AN[35] AN[44:47]	AN[32:33] AN[35] AN[44:47]	AN[32:33] AN[35] AN[44:47]
SARADC_6	AN[48] AN[51:53] AN[56:61]	AN[48] AN[51:53] AN[56:61]	AN[48:53] AN[56:61]	AN[48:53] AN[56:61]
SDADC_0	AN[0:3]	AN[0:3]	AN[0:3]	AN[0:3]
SDADC_3	AN[36:39] AN[44:47]	AN[0:7]	AN[36:39] AN[44:47]	AN[0:7]

1. For the Sigma-Delta mux inputs AN[x], the positive and negative input terminals are selected in the Sigma-Delta ADC digital interface.

37.2 Configuration of ADC modules

The following sections describe device-specific details for the following modules:

- *Section 37.2.1: Sigma-Delta Analog-to-Digital Converter (SDADC)*
- *Section 37.2.2: Successive Approximation Register Analog-to-Digital Converter (SARADC)*

37.2.1 Sigma-Delta Analog-to-Digital Converter (SDADC)

There are two independent Sigma-Delta ADCs on SPC574Kx. Refer to *Figure 409* for the ADC subsystem block diagram.

The following sections describe configuration details:

- *Section 37.2.1.1: Sigma-Delta ADC external signal description*
- *Section 37.2.1.2: Sigma-Delta ADC integration diagram*
- *Section 37.2.1.3: Sigma-Delta ADC analog input multiplexing*
- *Section 37.2.1.4: Sigma-Delta ADC clock sources*
- *Section 37.2.1.5: Sigma-Delta ADC starting/triggering*
- *Section 37.2.1.6: Sigma-Delta ADC external modulator*
- *Section 37.2.1.7: Conversion result interrupt/DMA gating signal*
- *Section 37.2.1.10: Sigma-Delta ADC analog input channel selection*

For detailed module information, refer to the Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface chapter.

37.2.1.1 Sigma-Delta ADC external signal description

The Sigma-Delta ADC external package pins for both the SPC574Kx 176-pin and 144-pin LQFPs are defined in *Table 486*.

Table 486. Sigma-Delta ADC external signal description

Signal name	Signal type	Signal voltage	Description
AN[n]	Analog input	0–5 V	Single-Ended or Differential Analog Input
VDD_HV_ADV	Analog supply	5 V	Sigma-Delta ADC Analog Power Supply
VSS_HV_ADV	Analog ground	0 V	Sigma-Delta ADC Analog Ground
VDD_HV_ADR_D	Analog supply	3–5 V	Sigma-Delta ADC Reference
VSS_HV_ADR_D	Analog ground	0 V	Sigma-Delta ADC Ground Reference
BSEXT[3, 0]	Digital input	0–5 V	Sigma-Delta ADC External Modulator Data Input
CLKEXT[3, 0]	Digital input	0–5 V	Sigma-Delta ADC External Modulator Clock Input

37.2.1.2 Sigma-Delta ADC integration diagram

Figure 410 shows the block diagram of the Sigma-Delta ADC integration on SPC574Kx. Note in the diagram that any unused Sigma-Delta ADC input can be read by SARADC_B. This is true for the unused input in single-ended operation.

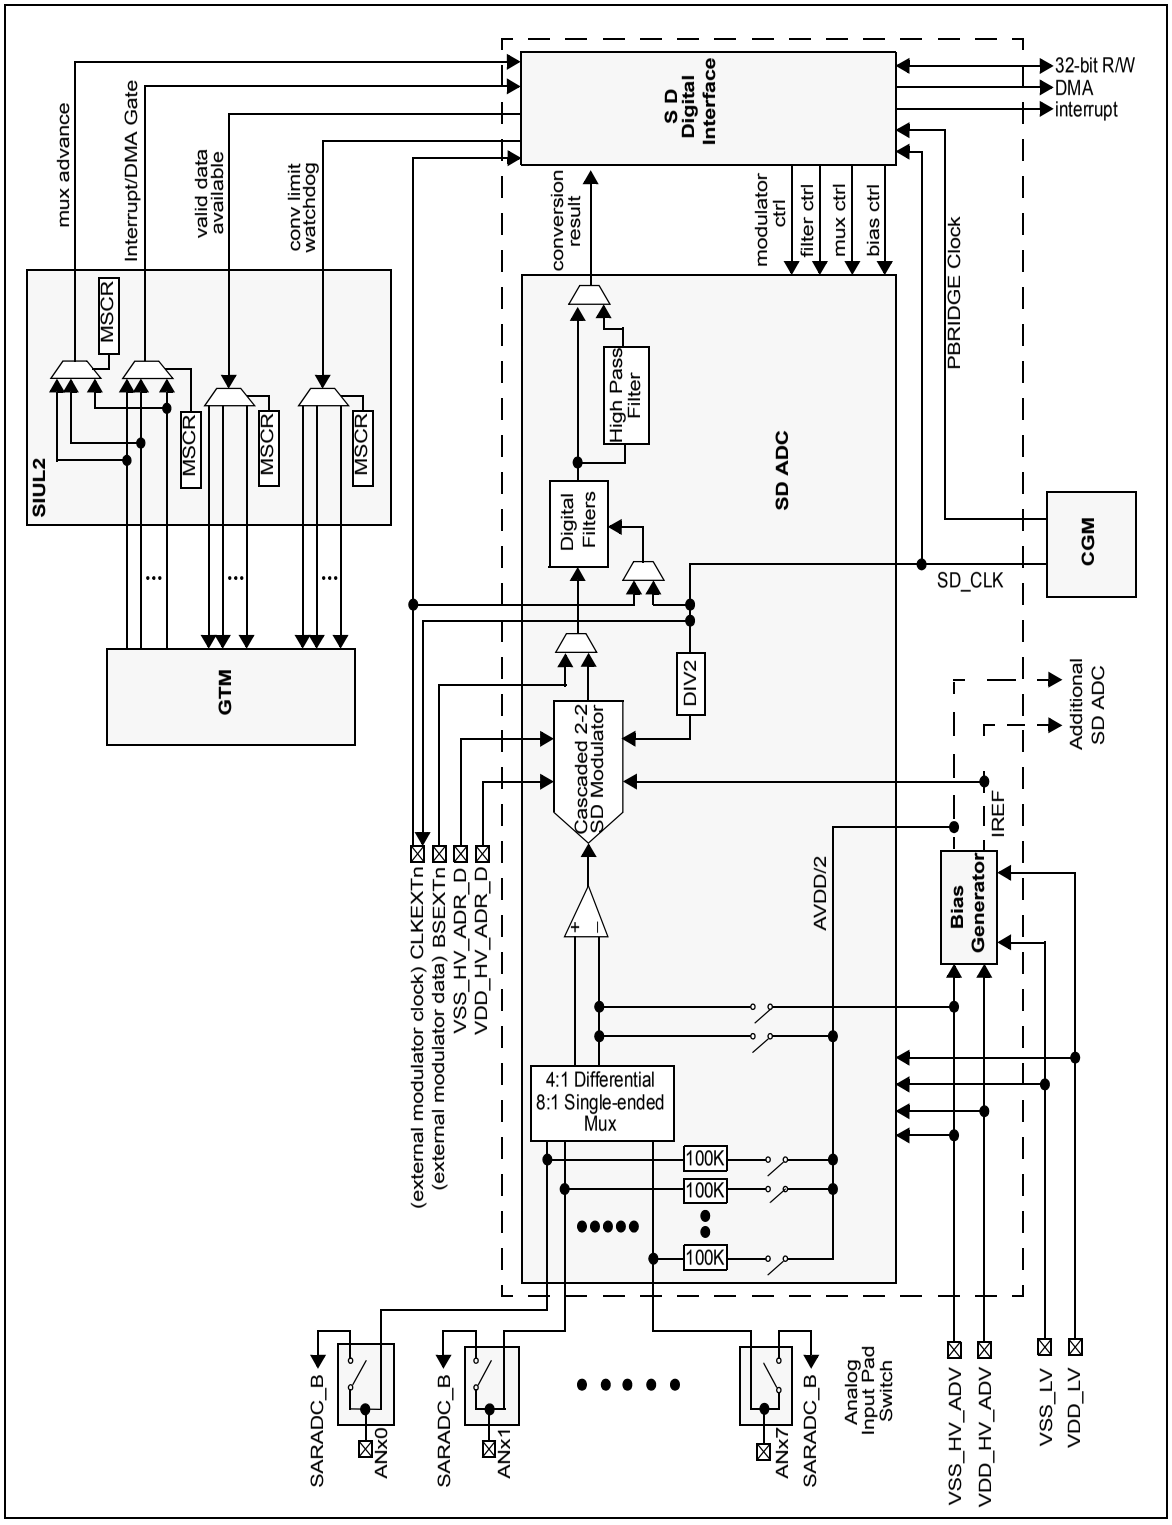

Figure 410. Sigma-Delta ADC integration diagram

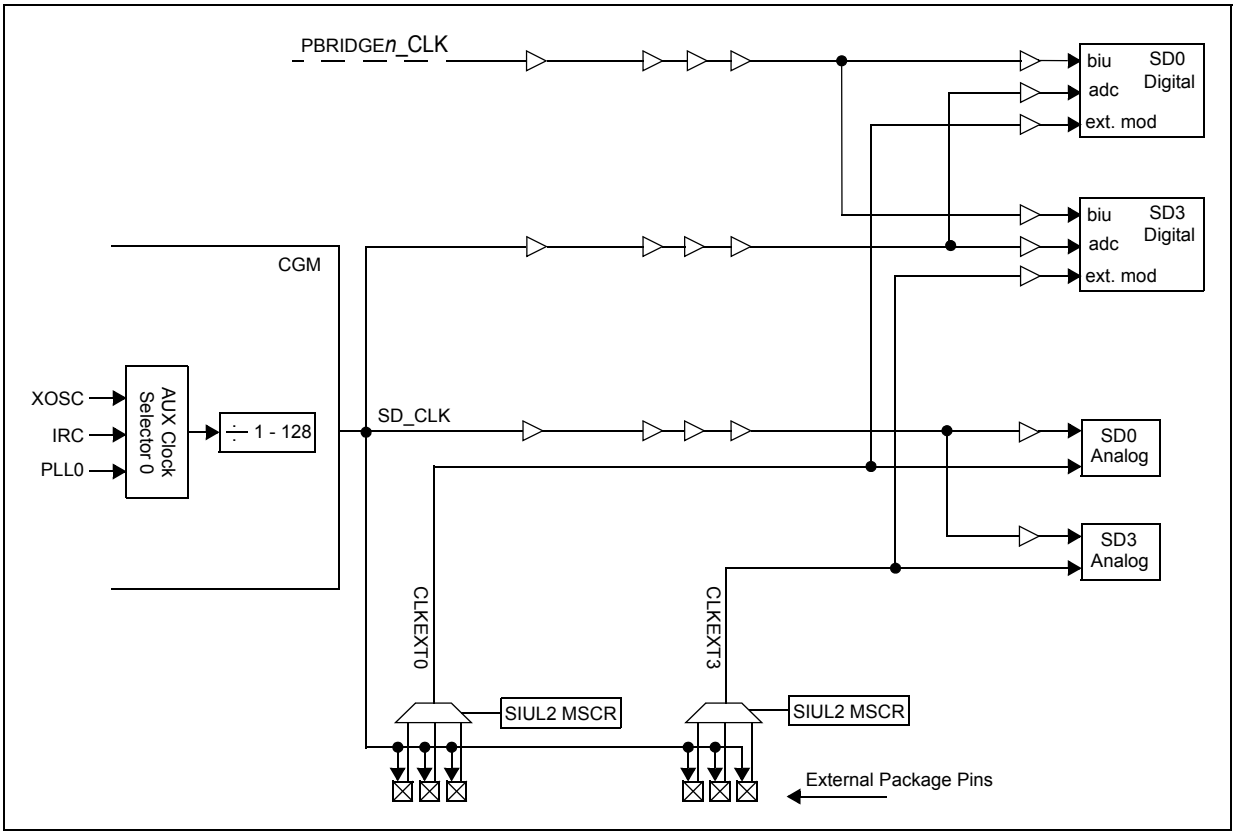
37.2.1.3 Sigma-Delta ADC analog input multiplexing

The analog input multiplexing switches reside in the Sigma-Delta ADCs. A single analog switch pad cell is used for the Sigma-Delta analog input pins in order to share the pin with SARADC_B. The connection to the Sigma-Delta ADC inputs is made to the pad pin through the analog switch pad cell, as shown in *Figure 410*, and is controlled as follows:

- SARADC_B analog inputs are switchable by the SIUL2_MSCRn[APC] bit.
- SDADC analog inputs have no SIUL2_MSCRn[APC] bit control, but are directly connected to the pad.



The mapping of analog input pins to the Sigma-Delta converters is given in *Table 485*.

37.2.1.4 Sigma-Delta ADC clock sources

Each Sigma-Delta ADC digital interface on the SPC574Kx has a register clock input which is separate from the module clock input: the register interface is clocked by the PBRIDGE*n*_CLK while the module clock is sourced by the modulator clock (SD_CLK). See the Clocking chapter for more details regarding clock sources. The input clock for the Sigma-Delta modulator is the SD_CLK. *Figure 411* describes the required Sigma-Delta ADC clock architecture. See *Section 26.6.6: Sigma-Delta ADC clocking*.

The frequency range for the SD_CLK is 4–16 MHz. Both the analog and digital blocks of the ADC contain an internal clock mux for external modulator mode. The external modulator clock (CLKEXT) can be input to the device or generated from SD_CLK from the CGM. The pad input/output settings in the SIUL2 MSCR pad control registers determine the external modulator clock source for the ADC blocks. The CLKEXT pins are multiplexed on multiple external pins on the device. The SIUL2 MSCR input multiplexing registers govern which CLKEXT pin is used for the external modulator clock for each ADC. Each Sigma-Delta ADC has three external pins to select from for an external modulator clock.

Figure 411. Sigma-Delta ADC clock diagram

37.2.1.4.1 Clock Skew

To avoid crosstalk issues, all Sigma-Delta ADCs run at the same clock frequency. Independent programmable decimation rates are provided to support the varying bandwidths of interest on each ADC in the application. Therefore, all Sigma-Delta analog blocks are clocked from the output of a single divider of the peripheral clock at the SoC level. The skew for the clock to each Sigma-Delta is less than 50 ps in order to maintain performance.

All Sigma-Delta ADCs can be triggered simultaneously and synchronize the update of their output registers.

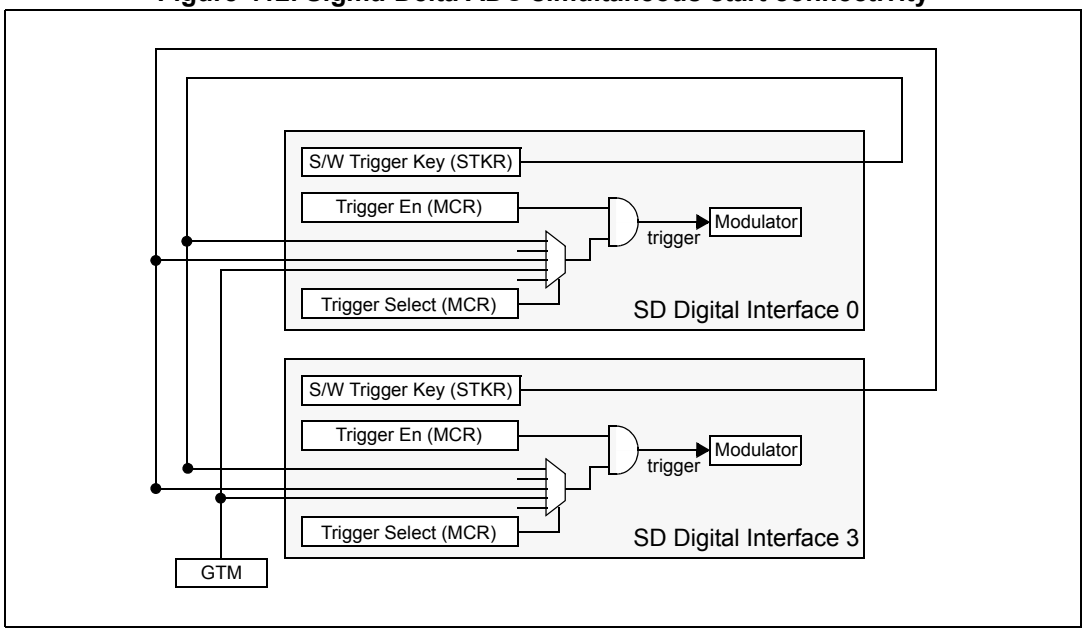
37.2.1.5 Sigma-Delta ADC starting/triggering

Each Sigma-Delta ADC on SPC574Kx supports starting the converter with a software write to an enable bit in a register in the digital interface.

37.2.1.5.1 Simultaneous start of multiple Sigma-Delta converters

A single software write to a control register is available to start multiple Sigma-Delta converters simultaneously, i.e., all selected converters start sampling their inputs on the same SD_CLK clock edge.

The digital interface of the Sigma-Delta ADC contains the control register for simultaneous start of the ADCs. When the register is written to start multiple converters, an output from the digital interface is asserted. The hardware trigger input of each Sigma-Delta ADC is



connected to this simultaneous start output. This way the user controls which ADCs are selected by enabling the hardware trigger of desired ADCs before writing to the starting simultaneous converters.

The connectivity for the simultaneous start of the converters is given in *Figure 412*.

Table 487. SDADC_MCR[TRIGSEL] trigger channel assignments

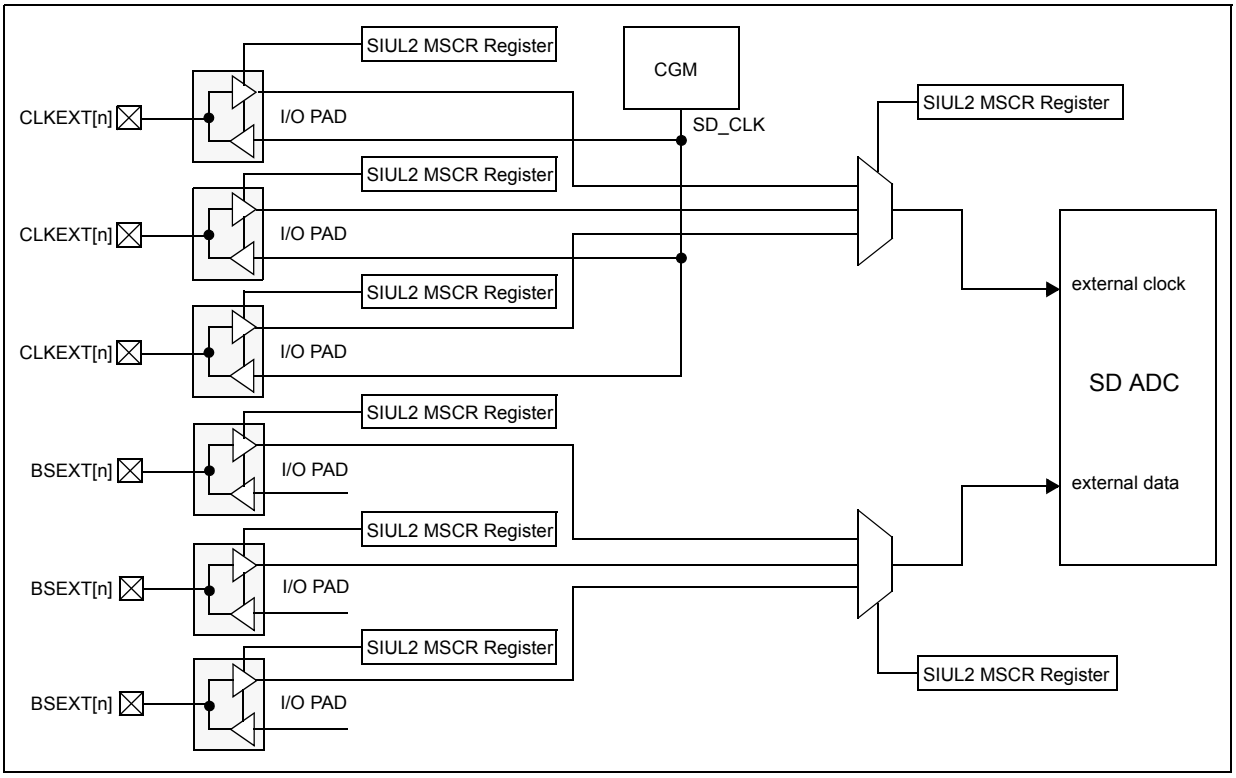
TRIGSEL configuration	Assigned Trigger Channel
0	SDADC_0 software trigger
1	Reserved
2	Reserved
3	SDADC_3 software trigger
4	GTM hardware trigger controlled by MSCR[594] for SDADC_0 and MSCR[597] for SDADC_3
5–15	Reserved

Figure 412. Sigma-Delta ADC simultaneous start connectivity

37.2.1.5.2 Sigma-Delta Mux Input Advance and Wrap Around

The mux wrap around feature is enabled and controlled in the digital interface of the Sigma-Delta ADC, triggered by another Sigma-Delta. The advancing of the mux can be controlled in the interface by software or by external GTM channels. The mapping of GTM output channels to the mux advance input for each Sigma-Delta ADC for each device is given in the SIUL2 MSCR registers.

Note: It is not possible to use both SW and HW triggers for a single Sigma-Delta, because this would results in a double trigger and the multiplexer selection advance by two steps



37.2.1.6 Sigma-Delta ADC external modulator

37.2.1.6.1 External modulators

The Sigma-Delta ADC supports an interface to external Sigma-Delta modulators. In this mode, the Sigma-Delta ADC internal modulator is disabled and a serial bit stream from an external modulator is clocked into the back-end digital filters of the on-chip Sigma-Delta ADC. Currently, the AMC1203 external modulator is supported by the Sigma-Delta ADC. Other external 2nd order modulators with clock rates less than 10 MHz and a compatible electrical interface (see SPC574Kx DataSheet) may be supported.

The external modulator interface for each Sigma-Delta ADC on SPC574Kx is shown in *Figure 413*.

Figure 413. Sigma-Delta ADC external modulator interface

37.2.1.6.2 External modulator clock/data inputs

Two external pins are required for each Sigma-Delta ADC to support an external modulator: an input data pin BSEXT (bitstream data) and an input/output clock pin CLKEXT (bitstream clock). When the external modulator is used, the clock and data inputs to the Sigma-Delta ADC digital filters come from the CLKEXT and BSEXT pins instead of the internal modulator as shown in *Figure 413*. External modulator operation is enabled in the ADC digital interface registers and the internal modulator is disabled. The CLKEXT and BSEXT inputs are multiplexed on port input pins. There are three sets of CLKEXT/BSEXT pins for each Sigma-Delta ADC with pin selection handled in the SIUL2 MSCRs.

37.2.1.6.3 External modulator clock output

SPC574Kx provides an option for an output clock from the device to the external modulator. When providing an output clock, the SD_CLK from the CGM is connected to the CLKEXT output pin. Both the input and output buffer of the CLKEXT pin must be enabled in the corresponding SIUL2 MSCR for both the external modulator and internal filters to be clocked from the SD_CLK. This is shown in *Figure 413*.

37.2.1.7 Conversion result interrupt/DMA gating signal

A DMA or interrupt can be generated for each conversion for each ADC. The Sigma-Delta ADC has an 8-deep result FIFO.

The Sigma-Delta ADC digital interface has an input signal that is used to disable interrupt and DMA requests for conversion results. The input signal is connected to outputs from the GTM timer block. The digital interface has a register bit for enabling and disabling the interrupt/DMA gating feature.

When the signal from the GTM is asserted, no interrupt or DMA request is generated for any conversion results. Interrupt and DMA requests are passed when the gating signal is high and blocked when low.

The gating signal for each ADC is driven by several GTM channels. See *Chapter 16: System Integration Unit Lite2 (SIUL2)* for the specific mapping of GTM channels to Sigma-Delta interrupt/DMA gating signals.

37.2.1.8 Conversion Limit Watchdog Output to GTM

Each Sigma-Delta ADC provides an optional conversion limit check for upper and lower bounds. The enable bit and the two 16-bit limit registers for the feature are included in the SDADC wrapper. If a conversion result exceeds one of the limits, a flag bit is asserted in a status register in the SDADC wrapper. The flag bit is output to the GTM for each SDADC. The mapping of conversion limit watchdog outputs to GTM channels is defined in the SIUL2 MSCR registers.

37.2.1.9 SDADC_MCR[TRIGSEL] definitions

For this chip, the following input triggers apply:

Table 488. Input triggers for this chip

Field	Description
TRIGSEL	Trigger Input Selection This field selects which input will be used for hardware-triggered conversions. 0000 SDADC_0 0001 Reserved 0010 Reserved 0011 SDADC_3 0100 MUX_ADV 0101–1111 Reserved **Note:** Selecting the input trigger source to be from the output trigger of the same SDADC is not prohibited by hardware, but is not supported, and will result in the SDADC never responding to the input trigger.

37.2.1.10 Sigma-Delta ADC analog input channel selection

For the Sigma-Delta mux inputs AN[x], the positive and negative input terminals are selected in the Sigma-Delta ADC digital interface Channel Selection Register (CSR).

This section shows analog channel selections for each combination of Module Configuration Register (MCR) field values MCR_MODE and MCR_VCOMSEL. *Table 489* provides a quick reference key to the MCR fields used in the SD ADC analog input selection tables.

Table 489. Register fields for SDADC analog input channel selection

Field	Description
MCR_VCOMSEL	Common Voltage Bias Selection This bit selects the common voltage bias for the negative input terminal of SDADC during single-ended mode (MODE=1). 0 Negative input terminal is biased with VREFN. 1 Negative input terminal is biased with VREFP/2 (half scale bias).
MCR_MODE	Mode selection 0 Differential input mode is selected. 1 Single-ended input mode is selected.
CSR_ANCHSEL	Analog Channel Selection Based on single-ended or differential mode of operation (MODE bit of MCR), common mode voltage selection (VCOMSEL bit of MCR), this bit-field defines the connectivity of analog inputs to either positive or negative polarity terminals of Sigma-Delta ADC, as shown in the following tables: – *Table 490* for SDADC_0 – *Table 491* for SDADC_3

Table 490. SDADC_0 analog input AN[x] selection

MCR_MODE	MCR_VCOMSEL	CSR_ANCHSEL	INP (positive terminal)	INM (negative terminal)

37.2.2 Successive Approximation Register Analog-to-Digital Converter (SARADC)

There are five independent SAR ADCs on SPC574Kx. Refer to *Figure 409* for the ADC subsystem block diagram.

The following sections describe configuration details:

- *Section 37.2.2.1: SAR ADC external signal description*
- *Section 37.2.2.2: SAR ADC integration diagram*
- *Section 37.2.2.3: SAR ADC analog input pin multiplexing*
- *Section 37.2.2.4: SAR ADC clock sources*
- *Section 37.2.2.5: SAR ADC triggering*
- *Section 37.2.2.6: SAR ADC alternate reference*
- *Section 37.2.2.7: SAR absolute voltage reference*
- *Section 37.2.2.8: SAR ADC diagnostic*
- *Section 37.2.2.9: SAR ADC channel assignment*
- *Section 37.2.2.10: SAR ADC register definitions*

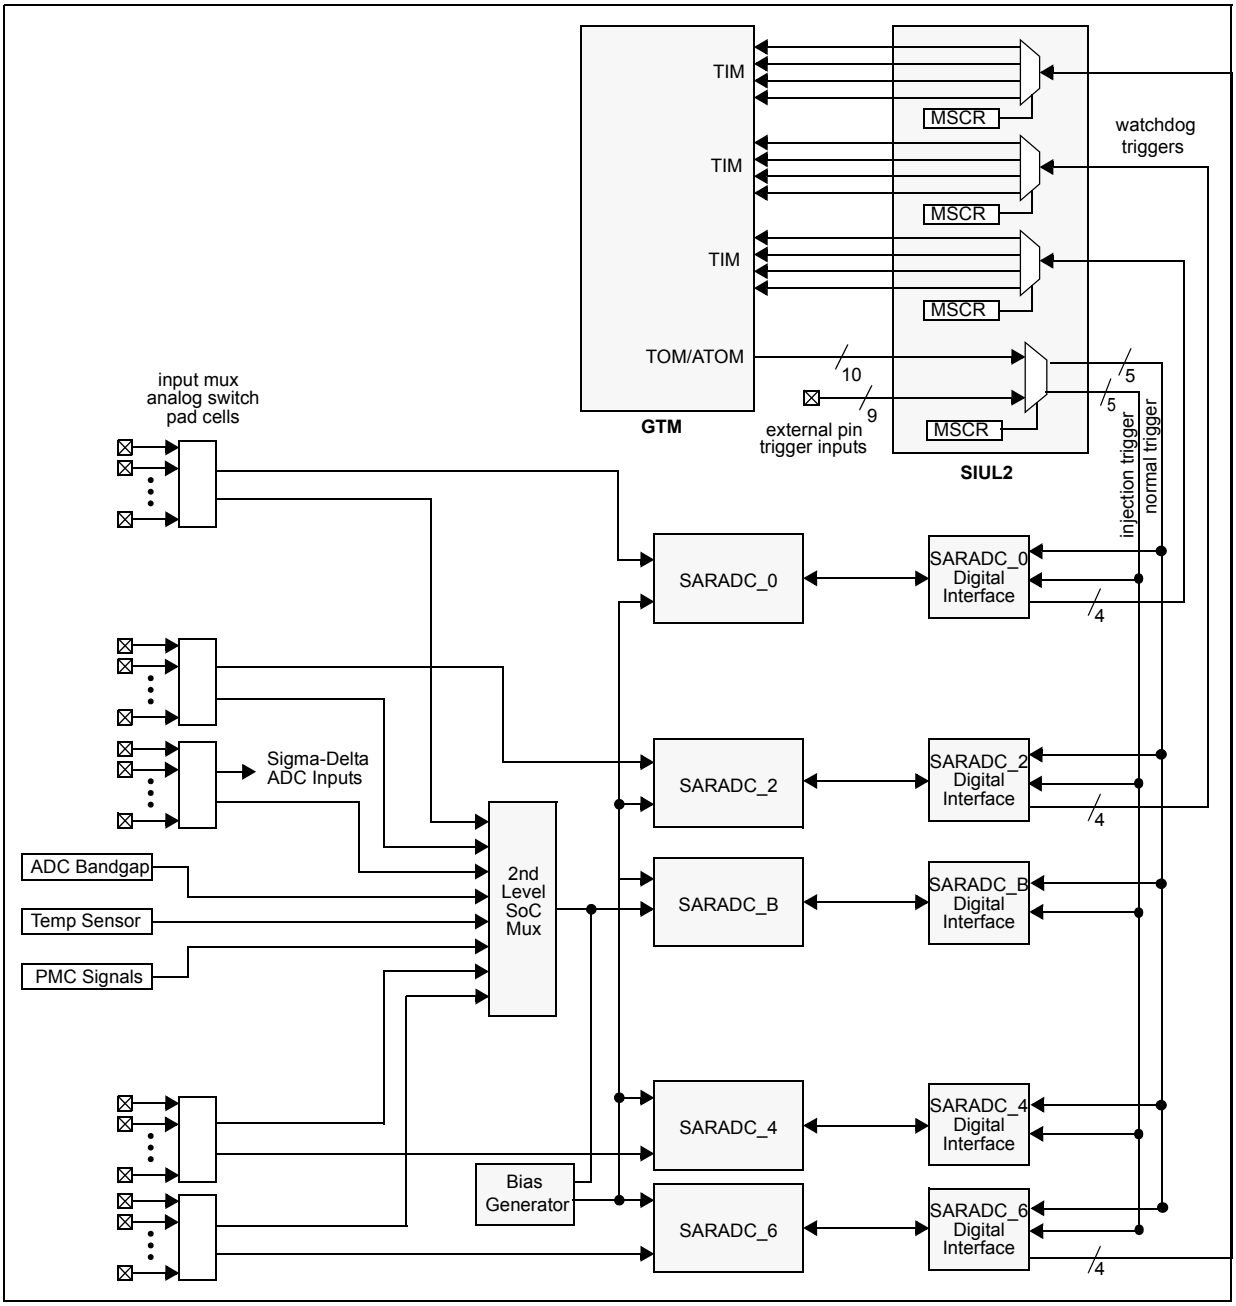
For detailed module information, refer to the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

37.2.2.1 SAR ADC external signal description

The external package pins connecting to the SAR ADC modules on the device are defined in *Table 492*.

Table 492. SAR ADC external signal description

Signal name	Signal type	Signal voltage	Description
AN[0:8], AN[10:13], AN[16:17], AN[20:21], AN[24:25], AN[35:39], AN[44:48], AN[51:53], AN[56:61](1)	Analog input	0–5 V	Single-Ended Analog Input with Pull Up/Down
AN[4:6]	Analog input	0–5 V	Single-Ended Analog Input with no alternate reference selection allowed
AN[7], AN[35]	Analog input	0–5 V	Single-Ended Analog Input with no alternate reference selection allowed, and switch to ground safety feature
VDD_HV_ADV	Analog supply	5 V	SAR ADC Power Supply
VSS_HV_ADV	Analog ground	0 V	SAR ADC Ground Supply
VDD_HV_ADR_S	Analog supply	2–5 V	SAR ADC Reference
VSS_HV_ADR_S	Analog ground	0 V	SAR ADC Ground Reference
DECODE_EXTCH[2:0]	Digital output	0–5 V	SARADC_0 External Mux Address Output



1. Not all signals listed here are implemented on all packages—see also *Table 485*.

37.2.2.2 SAR ADC integration diagram

Figure 414 shows the block diagram of the integration of the five SAR ADCs on SPC574Kx.

SARADC_B implements a Bias Generator converting the 3/3 *($V_{DD_HV_ADR_S}$ – $V_{SS_HV_ADR_S}$), 2/3 *($V_{DD_HV_ADR_S}$ – $V_{SS_HV_ADR_S}$), 1/3 *($V_{DD_HV_ADR_S}$ – $V_{SS_HV_ADR_S}$), and $V_{SS_HV_ADR_S}$ reference points through the internal 20 kΩ source impedance. See the SAR ADC block diagram in the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

Figure 414. SARADC integration diagram

37.2.2.3 SAR ADC analog input pin multiplexing

All analog input pins routed to SARADC_B and another fast SAR ADC are multiplexed with a dual analog input switch pad cell. Analog input pins that only connect to SARADC_B use a single analog switch pad cell.

Note: Simultaneous sampling of two ADCs on same analog input is not allowed.

A second level of multiplexing is required for SARADC_B to reduce the parasitic capacitance on the analog input due to the 48:1 input mux. The second level muxing is done
