- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a “0” to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, please see *Section 55.3.2.34, Counter Target Pulse Register (PSI5_CTPR)*, *Section 55.3.2.35, Counter Initialize Pulse Register (PSI5_CIPR)* and *Section 55.4.3.4.5, Sync Pulse Trigger Generation*.

Figure 1230. CIPR and CTPR

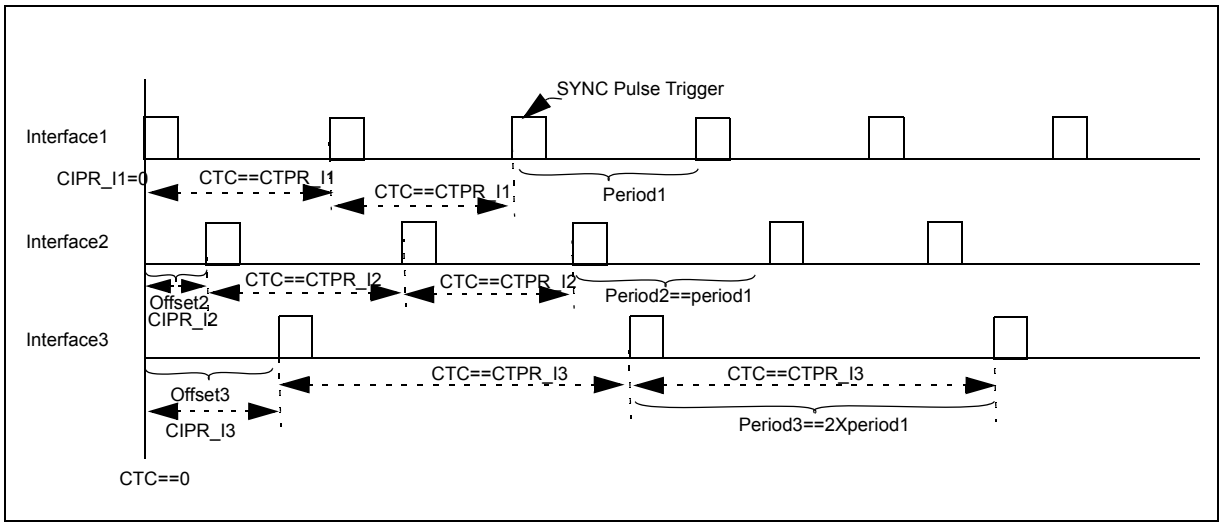

Figure 1230 shows the CIPR and the CTPR definition w.r.t the staggering of the channels. *Figure 1231* is a more detailed representation of these parameters along with the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

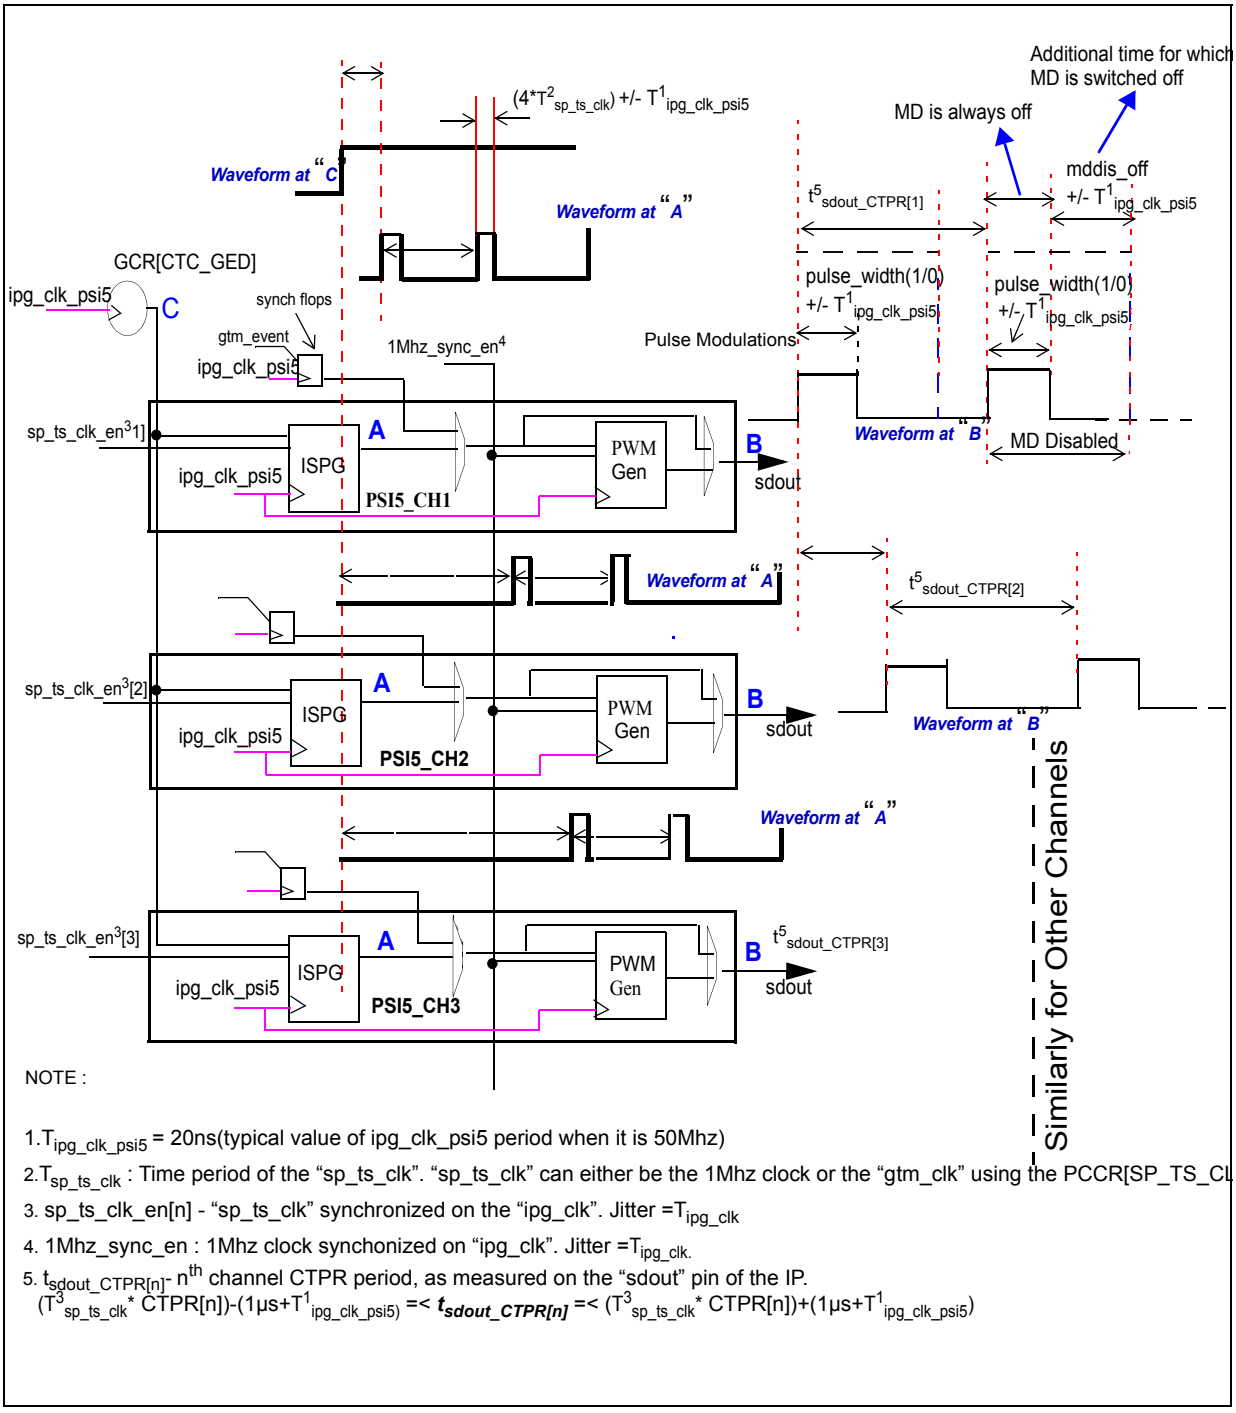
Figure 1231. Sync Pulse Generation Parameters and Jitters



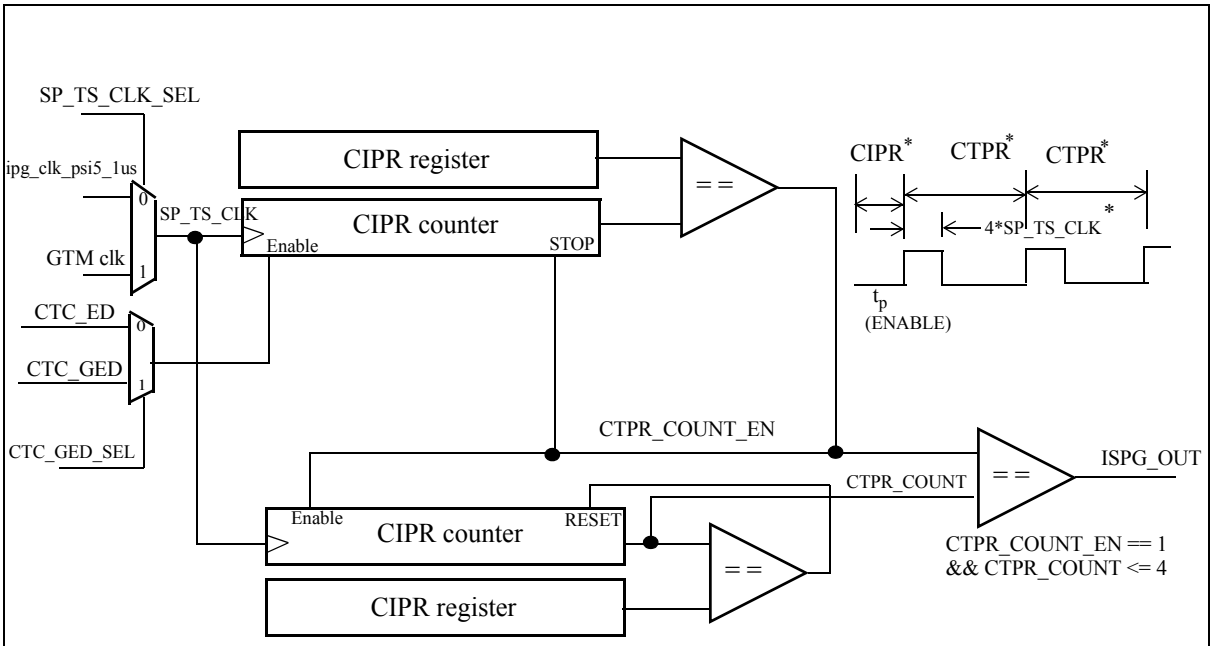


Figure 1231 shows the various jitters.

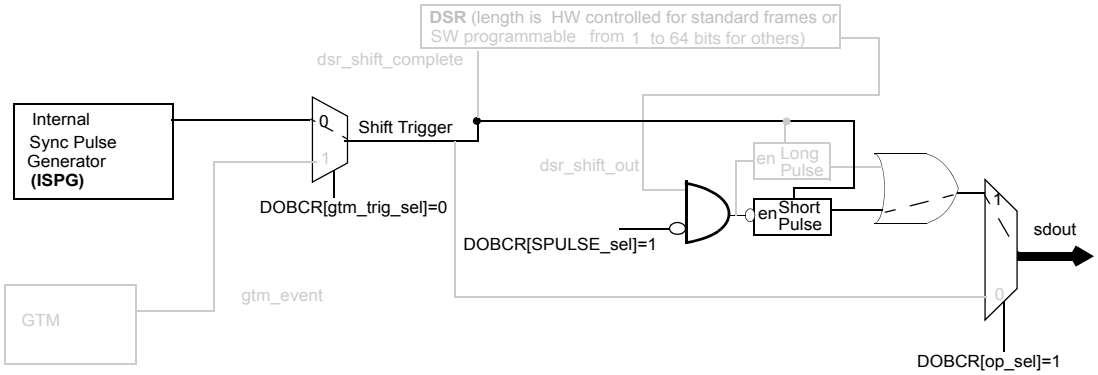
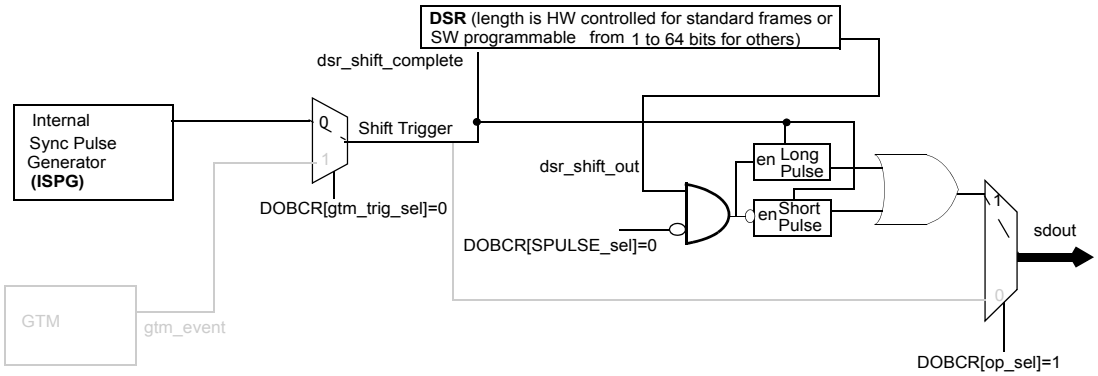
Figure 1232. ISPG(Internal Sync Pulse Generator) Structure



* - For exact values and more details please see *Figure 1231*

Note 1: All channels with CTC_GD selected will be enabled at the same time, enabling staggering of the ispg_out signals.
Note 2: This structure is replicated in each channel, with CTC_GED being a common signal to all channels.



55.8.2 Valid states for integrated sync pulse generator

Figure 1233. ECU to Sensor Communication States (1 of 2)

55.8.3 Implementation of EI Diagnostic Register

Figure 1235. Implementation of EI Diagnostic Register

56 SENT Receiver (SRX)

56.1 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled “SENT - Single Edge Nibble Transmission for Automotive Applications” and released on January 27, 2010, April 2007, and February 2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

56.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See *Section 7.7.7: SENT Receiver (SRX) configuration* for details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
  - Programmable option per channel to support reading of messages via DMA or Interrupt
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
  - Separate buffers for storing Fast and Slow Serial Messages
  - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to ±25% and adjusts its measurement for drift and jitter in the Transmitter and Receiver clocks per channel
  - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 3 µs to 90 µs
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See *Section 56.5: Clocks and resets on page 2202* for more details on the clocks.

56.1.2 Modes of operation

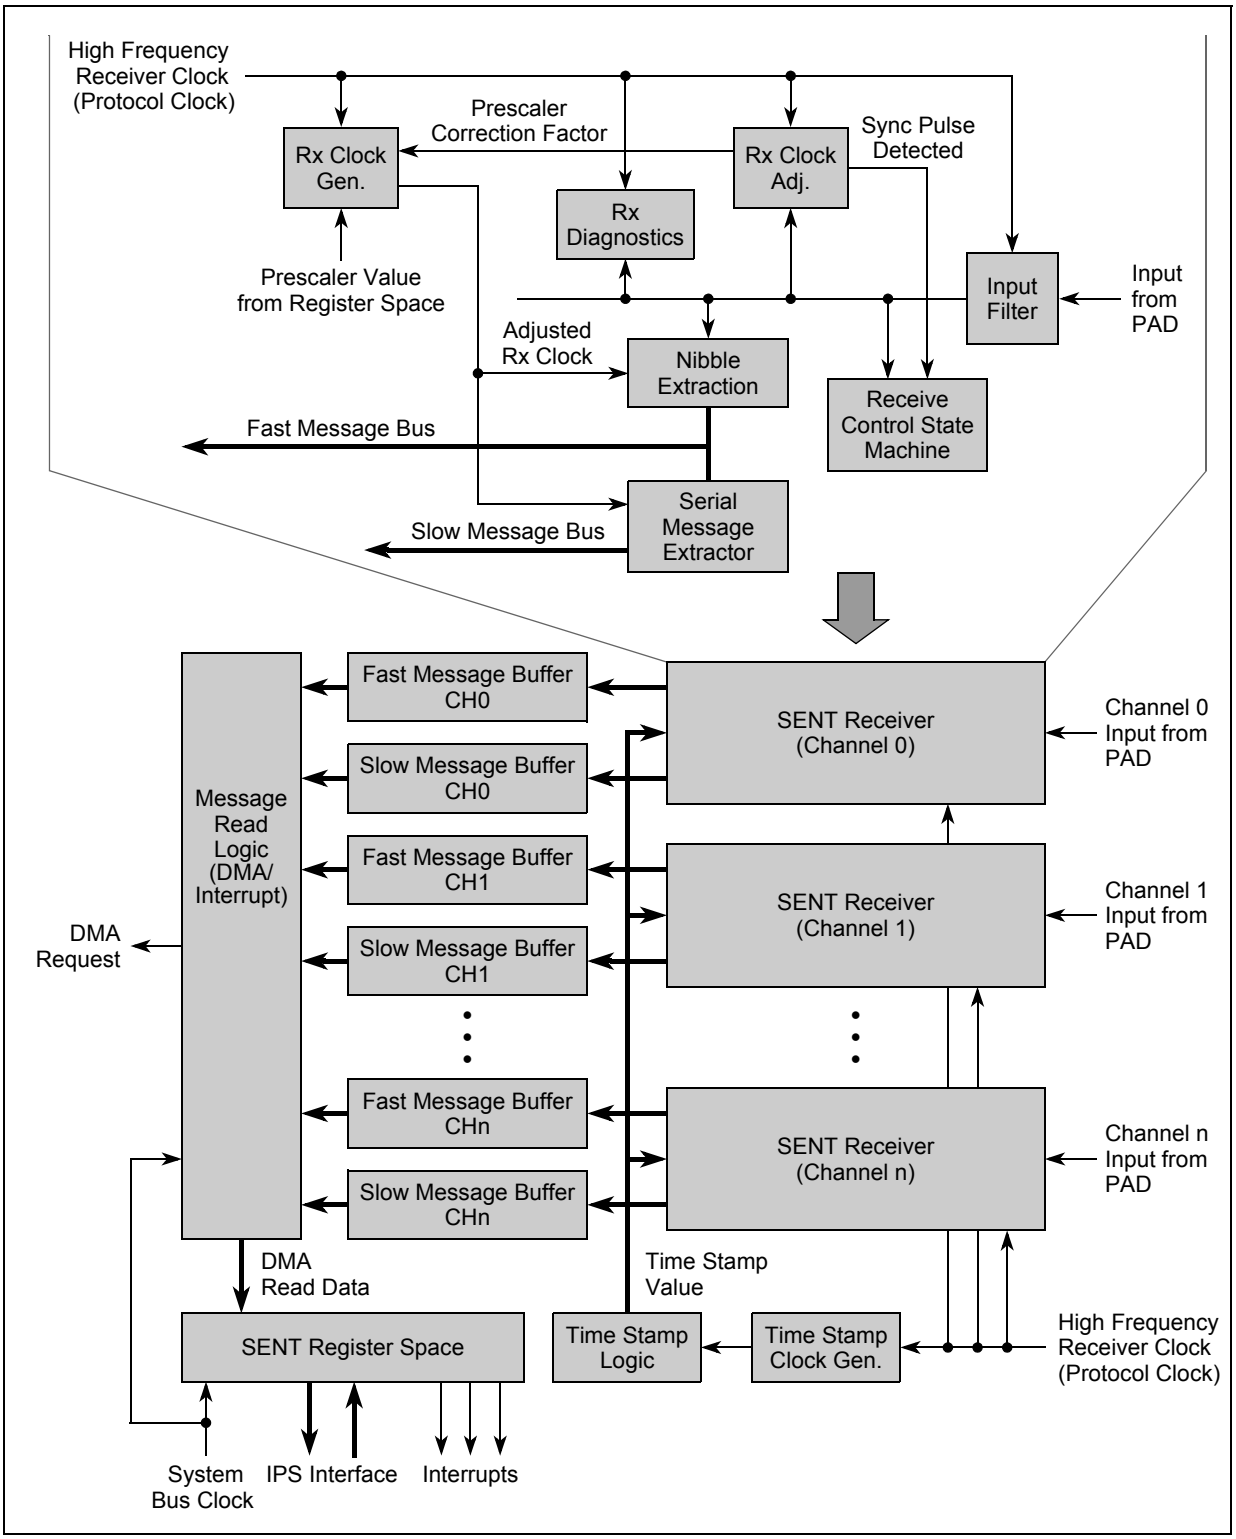
56.1.2.1 Debug mode

In debug mode, message reception will be halted and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

56.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.



Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See *Section 56.5.2: System bus clock requirements on page 2203*) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See *Section 56.5.3: High frequency receiver clock (protocol clock) requirements on page 2204*) for accurate receive operations.

Note: Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

56.1.3 Block diagram

Figure 1236. SENT block diagram

56.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. *Figure 1236* shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages.A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

56.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the message buffer as described in the

subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see *Section 56.4: Functional description on page 2191*.

56.2 External signal description

This section lists all inputs to the SENT block.

56.2.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note: The value of the CH is device-specific. See Section 7.7.7: SENT Receiver (SRX) configuration for details.

56.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT block.

56.3.1 Memory map

Table 1236 gives an overview on all SENT registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

Note: Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the Device Configuration chapter for details.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Section 56.3.2.1: Global Control Register (GBL_CTRL)*

56.3.2 Register descriptions

This section describes in address order all the SENT registers and their individual bits.

56.3.2.1 Global Control Register (GBL_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT_EN bit must be programmed after all other modules settings and control bits have been written to.

Address Offset: 0x0000 Access: RW

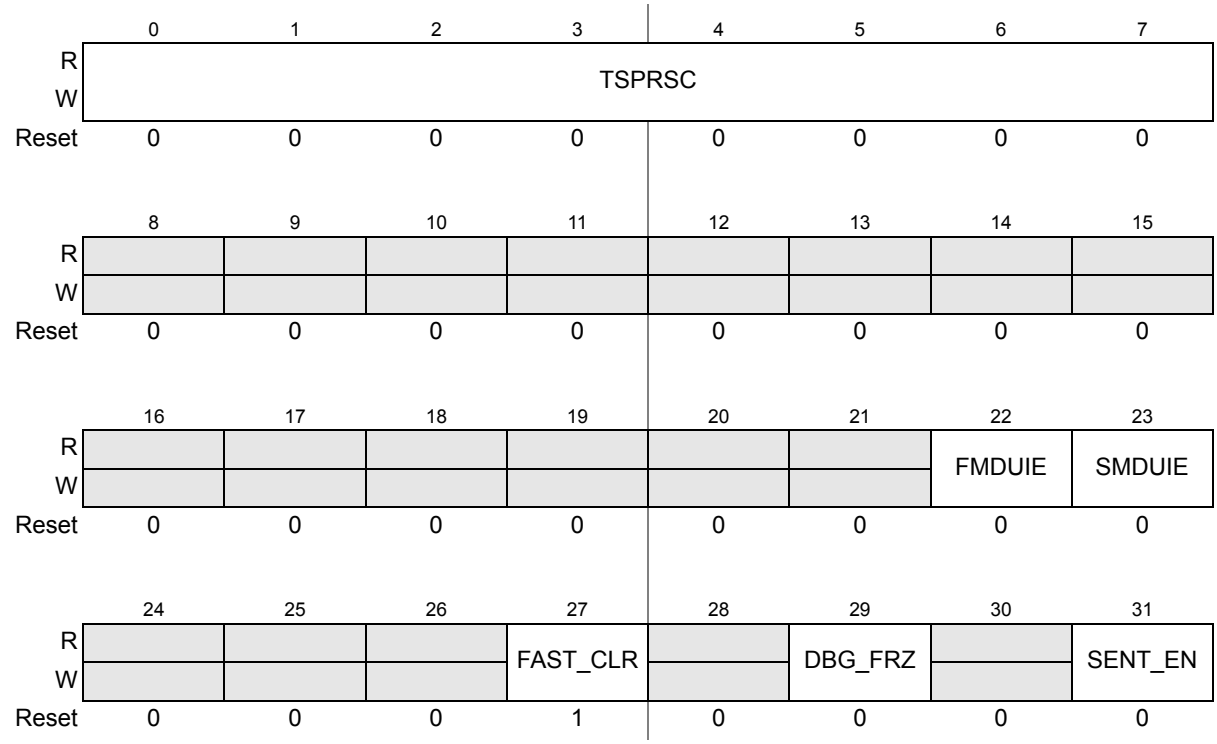

Figure 1237. Global Control Register (GBL_CTRL)

Table 1237. GBL_CTRL field descriptions

Field	Description
0:7 TSPRSC	Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. 0 – Prescaler Bypassed. Time Stamp Clock = High Frequency Receiver Clock 1 to 255 – Value set by user software to obtain a clock period of at least 1*us* for the time stamp counter. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4B (or 75) to obtain a 1µs clock. **Note:** Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
8:15	Reserved. Read returns zero
16:21	Reserved. Read returns zero
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 – Interrupt is disabled 1 – Interrupt is enabled

Table 1237. GBL_CTRL field descriptions(Continued)

Field	Description
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Slow Message DMA registers. Default value is 0. 0 – Interrupt is disabled 1 – Interrupt is enabled
24	Reserved. Read returns zero
25	Reserved. Read returns zero
26	Reserved. Read returns zero
27 FAST_CLR	Fast Clearing Enable bit. Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See *Section 56.3.2.4: Fast Message Ready Status Register (FMSG_RDY)* and *Section 56.3.2.5: Slow Serial Message Ready Status Register (SMSG_RDY)* for details on the ready status bits. 0 – Fast Clearing is disabled. Bits will be cleared by writing 1 1 – Fast Clearing is enabled
28	Reserved. Read returns zero
29 DBG_FRZ	Debug Freeze. This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 – No effect in debug mode 1 – Freeze in debug mode
30	Reserved. Read returns zero
31 SENT_EN	SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 – Entire module is disabled 1 – Module is enabled

56.3.2.2 Channel Enable Register (CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and these bits must be written to 0.

Figure 1239. Global Status Register (GBL_STATUS)

Table 1239. GBL_STATUS field descriptions

Field	Description
0:21	Reserved. Read returns zero
22 FDMU	Fast Message DMA Underflow: Interrupt Status bit that indicates when there is an underflow in Fast Message buffers in any channel which has DMA enabled. This bit is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 – No underflow 1 – Underflow occurred
23 SMDU	Slow Serial Message DMA Underflow: Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 – No underflow 1 – Underflow occurred
24:31	Reserved. Read returns zero

56.3.2.4 Fast Message Ready Status Register (FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA

(via *Fast Message DMA Control Register (FDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Section 56.3.2.10: Fast Message Ready Interrupt Control Register (FRDY_IE)*) and the channel is enabled, the message ready status bit in this register will get asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Section 56.3.2.1: Global Control Register (GBL_CTRL)*.

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see the Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and writes to these bits are unadvisable and may cause unexpected behavior.

Figure 1240. Fast Message Ready Status Register (FMSG_RDY)

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Section 56.3.2.1: Global Control Register (GBL_CTRL)*.

Table 1240. FMSG_RDY field descriptions

Field	Description
0:15	Reserved. Read returns zero
16:31 F_RDYn (n = 15 to 0)	Fast Message Data Ready Status Bit. Indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). 0 – No Fast Message is available to be read out via Interrupt 1 – Fast Message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Section 56.3.2.1: Global Control Register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. **Note:** When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

56.3.2.5 Slow Serial Message Ready Status Register (SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via *Section 56.3.2.8: Fast Message DMA Control Register (FDMA_CTRL)* and *Section 56.3.2.9: Slow Serial Message DMA Control Register (SDMA_CTRL)*), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via *Section 56.3.2.10: Fast Message Ready Interrupt Control Register (FRDY_IE)* and *Section 56.3.2.11: Slow Serial Message Ready Interrupt Enable Register (SRDY_IE)*) and the channel is enabled, the message ready status bit in this register will get asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the *Global Status Register (GBL_STATUS)*.

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and writes to these bits are unadvisable and may cause unexpected behavior.

Figure 1241. Slow Serial Message Ready Status Register (SMSG_RDY)

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the *Section 56.3.2.1: Global Control Register (GBL_CTRL)*.

Table 1241. SMSG_RDY field descriptions

Field	Description
0:15	Reserved. Read returns zero
16:31 S_RDYn (n = 15 to 0)	Slow Serial Message Data Ready Status Bit. Indicates that a Slow Serial Message is ready to be read by CPU from that specific channel. This bit is asserted only when **DMA is NOT** enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Serial Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). 0 – No Slow Serial Message is available to be read out via Interrupt 1 – Slow Serial Message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section *Global Control Register (GBL_CTRL)* for details on FAST_CLR bit. **Note:** When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 Fast Message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported. **Note:** When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.

56.3.2.6 Data Control Register 1 (DATA_CTRL1)

16:31	Reserved. Read returns zeros.

56.3.2.14 DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the *Global Control Register (GBL_CTRL)* register. DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_TS) via DMA.

Address Offset: 0x0048 Access: R

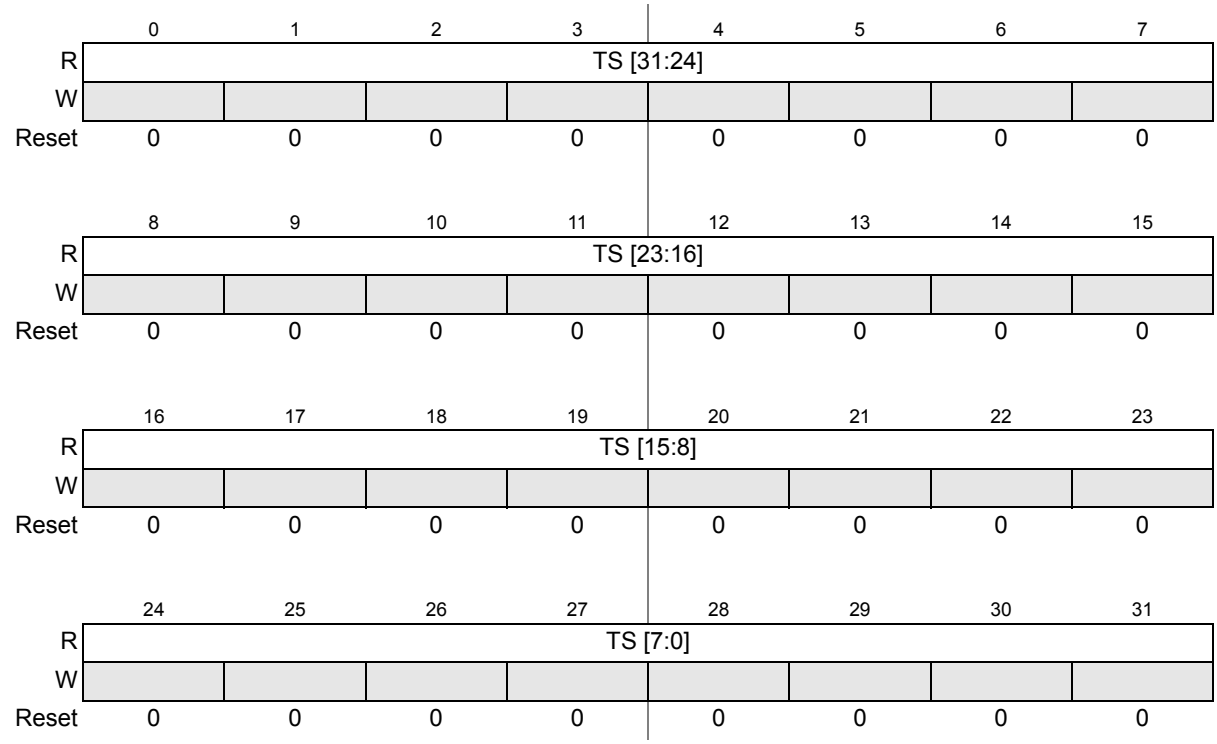

Figure 1250. DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)

Table 1250. DMA_FMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

56.3.2.15 DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

The above register (DMA_SMSG_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in *Figure 1259*, *Figure 1260* and *Figure 1261*. *Figure 1259* and *Figure 1260* shows the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 1261* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Figure 1251. DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

Table 1251. DMA_SMSG_BIT3 Field Descriptions

Field	Description
0:3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to ‘15’
4 TYPE	Serial Message Type. Indicates the type of Serial Message received 0 – Short Serial Message 1 – Enhanced Serial Message
5:19	Reserved. Read returns zeros
20	Placed as 0 by Specification
21 CFG	Configuration bit ‘C’. Indicates the type of Enhanced Serial message 0 – Enhanced Serial Message with 8-bit ID field 1 – Enhanced Serial Message with 4-bit ID field
22:25 ID[7:4]/ID[3:0]	ID Field. Value depends on setting of ‘C’ bit. If ‘C’ bit is 0, this field is ID[7:4] and if the ‘C’ bit is 1, this field is ID[3:0]
26	0 as per SAE Specification

Table 1251. DMA_SMSG_BIT3 Field Descriptions(Continued)

Field	Description
7:30 ID[3:0]/DATA [15:12]	ID or Data Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12]
31	0 as per SAE Specification

Note: If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID & DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID & DATA fields.

56.3.2.16 DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in *Figure 1259*, *Figure 1260* and *Figure 1261*. *Figure 1259* and *Figure 1260* shows the enhanced serial messages format to be used when reading this register for these two types of messages. *Figure 1261* shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Address Offset: 0x0054 Access: R

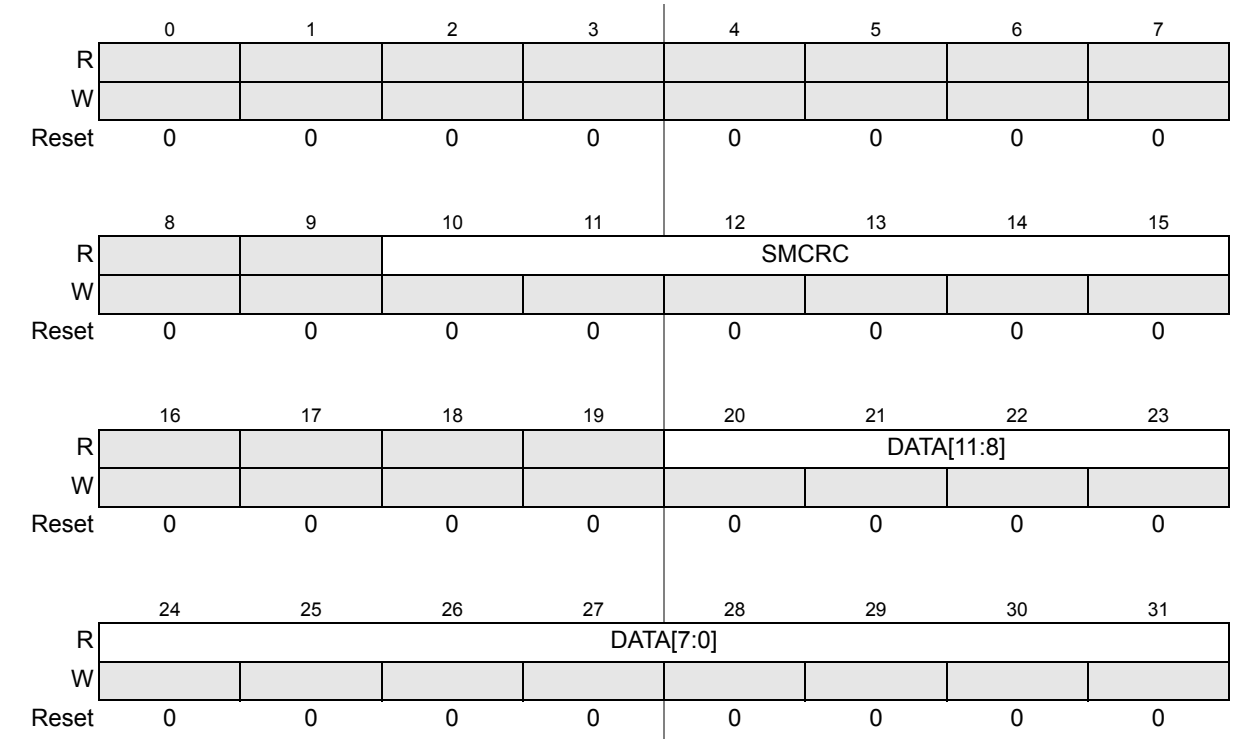

Figure 1252. DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)

Table 1252. DMA_SMSG_BIT2 field descriptions

Field	Description
0:9	Reserved. Read returns zeros.
10:15 SMCRC	6-bit CRC value of the message. When TYPE bit in *Section 56.3.2.15: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)* is set to 0, this CRC is of 4-bits for Short Serial Messages and when TYPE bit is set to 1, this CRC is of 6-bits for Enhanced Serial Messages.
16:19	Reserved. Read returns zeros.
20:31 DATA[11:0]	12-bit Data Value

56.3.2.17 DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the *Section 56.3.2.1: Global Control Register (GBL_CTRL)* register.

DMA Source Size must be set to 32 bits when reading this register (DMA_SMSG_TS) via DMA.

Figure 1253. DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)

Table 1253. DMA_SMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

56.3.2.18 Channel ‘n’ Clock Control Register (n = 0 to (CH-1)) (CHn_CLK_CTRL)

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

The SENT module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock. See *Section 56.4.5: Adjustment for variation in sensor (Tx) clock on page 2198* for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the *Section 56.3.2.2: Channel Enable Register (CHNL_EN)*.

Figure 1254. Channel ‘n’ Clock Control Register (CHn_CLK_CTRL)

Table 1254. CHn_CLK_CTRL field descriptions

Field	Description
0	Reserved. Read returns zero
1:15 CM_PRSC	Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' – No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' – Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' – Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as *Compensated Prescaler Value* $\times$ *High Frequency Receiver Clock Period*
16 COMP_EN	Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 – Compensation is disabled 1 – Compensation is enabled
17	Reserved. Read returns zero
18:31 PRSC	Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (T_{rx_clk}) is not divisible by the high frequency receiver clock (protocol clock) period (T_{hf_clk}), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 – Prescaler is bypassed. Should not be used. Non-Zero Value – Enables Prescaler The required value is computed by software as follows: **Equation 79** $$\text{Prescaler_value} = \text{floor}\left(\frac{T_{rx_clk}}{T_{hf_clk}}\right)$$ (both clock periods taken in µs). Please see *Section 56.5.3: High frequency receiver clock (protocol clock) requirements on page 2204* before setting this value. For example, if the required receiver clock tick period is 43 µs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 µs) then, Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

56.3.2.19 Channel 'n' Status Register (n = 0 to (CH-1)) (CHn_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal

event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the *Section 56.3.2.2: Channel Enable Register (CHNL_EN)* bit for the corresponding channel.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

Figure 1255. Channel 'n' Status Register (CHn_STATUS)

Table 1255. CHn_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value (in *Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). CPU should write 1 to this clear this bit once it is read. 0 – Bus is not idle 1 – Channel has been idle for more than the allowed value
1:3	Reserved. Read returns zero

Table 1255. CHn_STATUS field descriptions(Continued)

Field	Description
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 – No interrupt 1 – Interrupt Status condition has occurred
5 CAL_20_25	Calibration Variation 20 – 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between ±20% to ±25% from 56 ticks. 0 – No Interrupt 1 – Interrupt Status condition has occurred
6 SMSG_OFLW	Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause the older messages (which are not read out) to be overwritten with newly received messages. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 – No Interrupt 1 – Interrupt Status condition has occurred
7 FMSG_OFLW	Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 – No Interrupt 1 – Interrupt Status condition has occurred
8	Reserved. Read returns zero

Table 1255. CHn_STATUS field descriptions(Continued)

Field	Description
9:15	Diagnostic Checks Status bits. These bits indicate which diagnostic has failed or passed on this channel. These bits are cleared by writing 1 to them. NUM_EDGES_ERR: Not the expected number of negative edges between calibration pulse. This bit will not set in case of “Option 2” for successive calibration pulse check is selected. This error will only set when “Option 1” for successive calibration check is selected (SUCC_CAL_CHK). FMSG_CRC_ERR: Checksum error in Fast Message SMSG_CRC_ERR: Checksum error in Slow Serial Message NIB_VAL_ERR: Any nibble data value <0 or >15 CAL_DIAG_ERR: Successive Calibration pulses differ by ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (See *Section 56.5.3: High frequency receiver clock (protocol clock) requirements on page 2204*). CAL_LEN_ERR: This bit indicates that Calibration pulse is more than 56 ticks ±25%. PP_DIAG_ERR: This bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than ±1.5625% between two messages. This check is valid only for messages with pause pulse. 0 – Error Check has passed 1 – Error Check has failed
15:016:31	Reserved. Read returns zero

56.3.2.20 Channel ‘n’ Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in *Section 56.3.2.19: Channel ‘n’ Status Register (n = 0 to (CH-1)) (CHn_STATUS)* and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the *Section 56.3.2.2: Channel Enable Register (CHNL_EN)*.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

Figure 1256. Channel ‘n’ Configuration Register (CHn_CONFIG)

Table 1256. CHn_CONFIG field descriptions

Field	Description
0:3 BUS_IDEL_CNT	Bus Idle Count: This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000: Disabled. 0001: 127*2 Receiver Clock Tick Counts 0010: 127*4 Receiver Clock Tick Counts 0100: 127*8 Receiver Clock Tick Counts 1000: 127*16 Receiver Clock Tick Counts
4 IE_CAL_RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of “Option 2” being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 – Interrupt is disabled 1 – Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 – Interrupt is disabled 1 – Interrupt is enabled

Table 1256. CHn_CONFIG field descriptions(Continued)

Field	Description
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 – Interrupt is disabled 1 – Interrupt is enabled
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 – Interrupt is disabled 1 – Interrupt is enabled
8 FCRC_CHK_OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 – Check is enabled 1 – Check is disabled/off
9:15	Diagnostic Checks Interrupt Enable bits. These bits enables interrupts assertion when respective diagnostic checks fail on corresponding channel. IE_NUM_EDGES_ERR: Not the expected number of negative edges between calibration pulse IE_FMSG_CRC_ERR: Checksum error in Fast Message IE_SMSG_CRC_ERR: Checksum error in Slow Serial Message IE_NIB_VAL_ERR: Any nibble data value <0 or >15 IE_CAL_DIAG_ERR: Successive Calibration pulses differ by more than ±1.56%. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55% IE_CAL_LEN_ERR: Calibration pulse is wider than 56 ticks ±25% IE_PP_DIAG_ERR: Ratio of calibration pulse length to message length varies by more than ±1.5625% between two frames. Valid for messages with pause pulse. Configuration option for each bit as below: 0 – Interrupt is disabled 1 – Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 – All Fast Messages will be received even if data nibbles are same 1 – Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 – 20% variation is acceptable 1 – 25% variation is acceptable

Table 1256. CHn_CONFIG field descriptions(Continued)

Field	Description
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 – Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 – Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 – XOR based implementation (Recommended by SAE Specification) 1 – Legacy LUT based implementation
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 – Status and Communication Nibble not included in CRC calculation 1 – Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 – XOR based implementation (Recommended by SAE Specification) 1 – Legacy LUT based implementation
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse. 0 – Detection of Pause Pulse is disabled 1 – Detection of Pause Pulse enabled
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 – Option 2 i.e. Low Latency Option as per SAE Specification 1 – Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24:31 FIL_CNT	Input Filter Sample Count. This indicates the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0 – No filtering. Input from device's pad is only synchronized Non-Zero – Filtering is enabled

56.3.2.21 Channel 'n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA)

Address offset: 0x0160 + 0x18 × n

This is register CHn_FMSG_DATA. The contents of this register are same as *Section 56.3.2.12: DMA Fast Message Data Read Register (DMA_FMSG_DATA)*.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

56.3.2.22 Channel 'n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC)

Address offset: 0x0164 + 0x18 × n

This is register CHn_FMSG_CRC. The contents of this register are same as *Section 56.3.2.13: DMA Fast Message CRC Read Register (DMA_FMSG_CRC)*.

56.3.2.23 Channel 'n' Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS)

Address offset: 0x0168 + 0x18 × n

This is register CHn_FMSG_TS. The contents of this register are same as *Section 56.3.2.14: DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)*.

56.3.2.24 Channel 'n' Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3)

Address offset: 0x016C + 0x18 × n

This is register CHn_SMSG_BIT3. The contents of this register are same as *Section 56.3.2.15: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)*.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

56.3.2.25 Channel 'n' Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2)

Address offset: 0x0170 + 0x18 × n

This is register CHn_SMSG_BIT2. The contents of this register are same as *Section 56.3.2.16: DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*.

56.3.2.26 Channel 'n' Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS)

Address offset: 0x0174 + 0x18 × n

This is register CHn_SMSG_TS. The contents of this register are same as *Section 56.3.2.17: DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)*.

56.3.3 Register Classification for Safety

The registers of this module are classified as per Safety Requirements as follows:

Safety Critical: There are no safety critical registers in this module.

Safety Relevant: The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU/DMA. The registers containing

these bits must be protected by periodic CRC or equivalent check implemented at SoC Level. The following register bits/fields are classified in this category:

- *Section 56.3.2.1: Global Control Register (GBL_CTRL)*
- *Section 56.3.2.2: Channel Enable Register (CHNL_EN)*
- *Section 56.3.2.4: Fast Message Ready Status Register (FMSG_RDY)*
- *Section 56.3.2.5: Slow Serial Message Ready Status Register (SMSG_RDY)*
- *Section 56.3.2.6: Data Control Register 1 (DATA_CTRL1)* and *Section 56.3.2.7: Data Control Register 2 (DATA_CTRL2)*
- *Section 56.3.2.8: Fast Message DMA Control Register (FDMA_CTRL)*
- *Section 56.3.2.9: Slow Serial Message DMA Control Register (SDMA_CTRL)*
- *Section 56.3.2.10: Fast Message Ready Interrupt Control Register (FRDY_IE)*
- *Section 56.3.2.11: Slow Serial Message Ready Interrupt Enable Register (SRDY_IE)*
- Fast Message DMA Read Register Set and Slow Message DMA Read Register Set

Safety Latent: The register bits/fields in this category should be protected by LBIST at SoC level. The following register bits/fields are classified in this category:

- *Section 56.3.2.3: Global Status Register (GBL_STATUS)*
- *Section 56.3.2.19: Channel 'n' Status Register (n = 0 to (CH-1)) (CHn_STATUS)*
- *Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*

Non-Safety: The following register bits are classified in this category:

- All other registers and bits fall in this category

56.4 Functional description

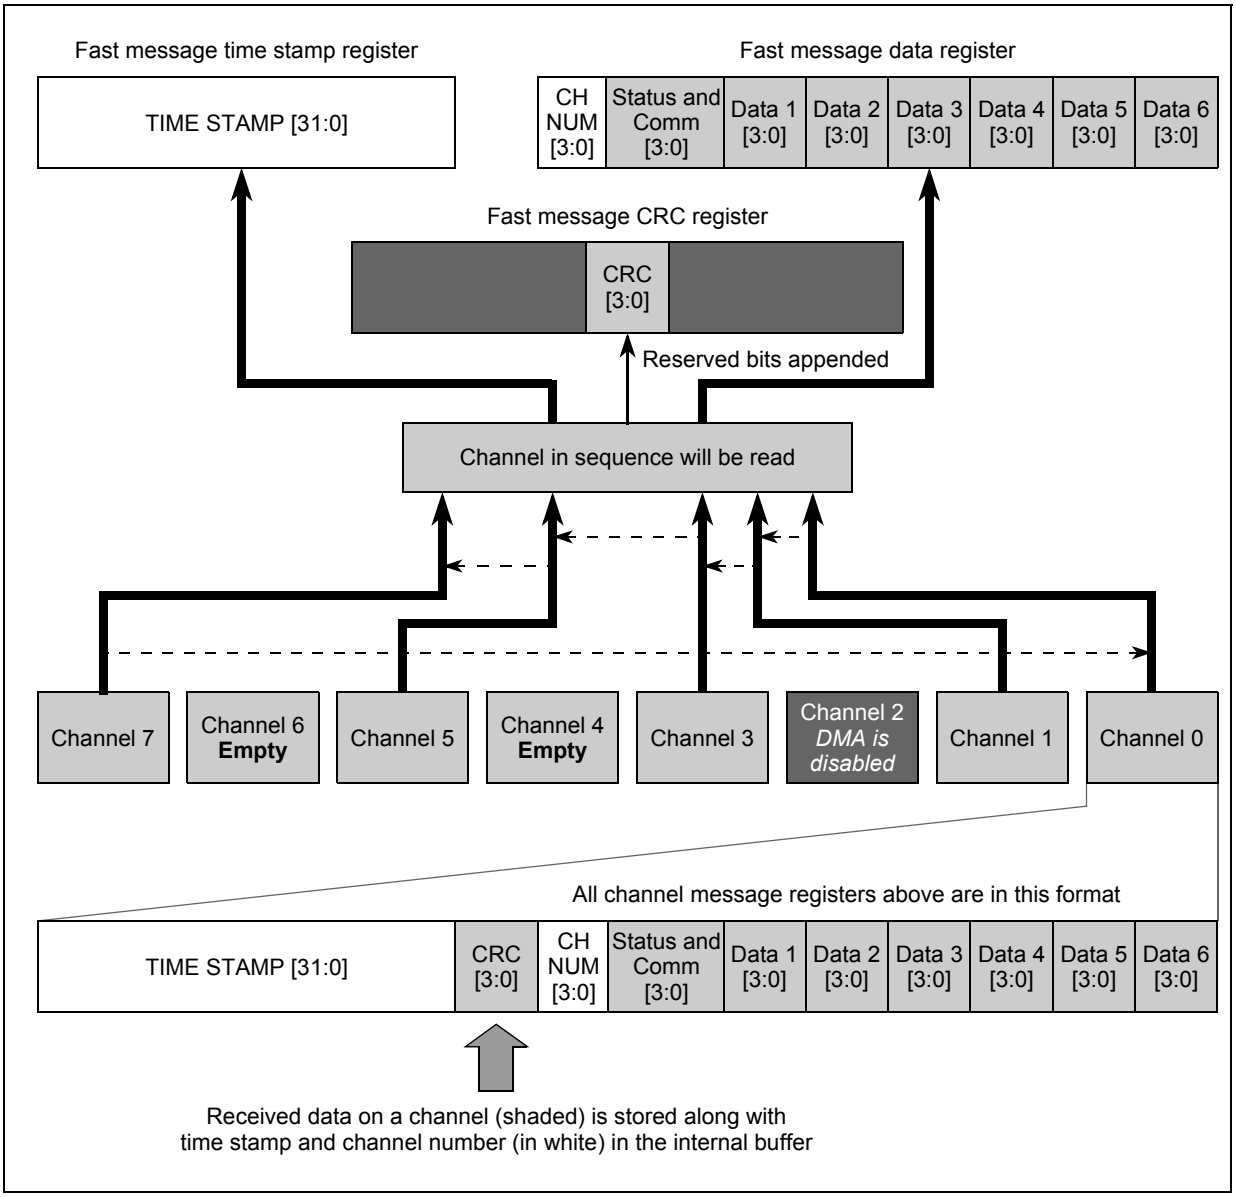
56.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the *Section 56.3.2.2: Channel Enable Register (CHNL_EN)*. There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in *Section 56.3.2.1: Global Control Register (GBL_CTRL)* to generate the time stamping clock
- Rx Prescaler Value in *Section 56.3.2.18: Channel 'n' Clock Control Register (n = 0 to (CH-1)) (CHn_CLK_CTRL)* to generate the channel's receiver clock
- Compensation enable in *Section 56.3.2.18: Channel 'n' Clock Control Register (n = 0 to (CH-1)) (CHn_CLK_CTRL)*
- Channel Configuration settings in the *Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*
- Number of Data Nibbles in Channel in the *Section 56.3.2.6: Data Control Register 1 (DATA_CTRL1)* and *Section 56.3.2.7: Data Control Register 2 (DATA_CTRL2)*
- Control bits that control whether messages received in channel are to read by interrupt or DMA in *Section 56.3.2.8: Fast Message DMA Control Register (FDMA_CTRL)*, *Section 56.3.2.9: Slow Serial Message DMA Control Register (SDMA_CTRL)*,

Section 56.3.2.10: Fast Message Ready Interrupt Control Register (FRDY_IE) and *Section 56.3.2.9: Slow Serial Message DMA Control Register (SDMA_CTRL)*

56.4.2 DMA read logic



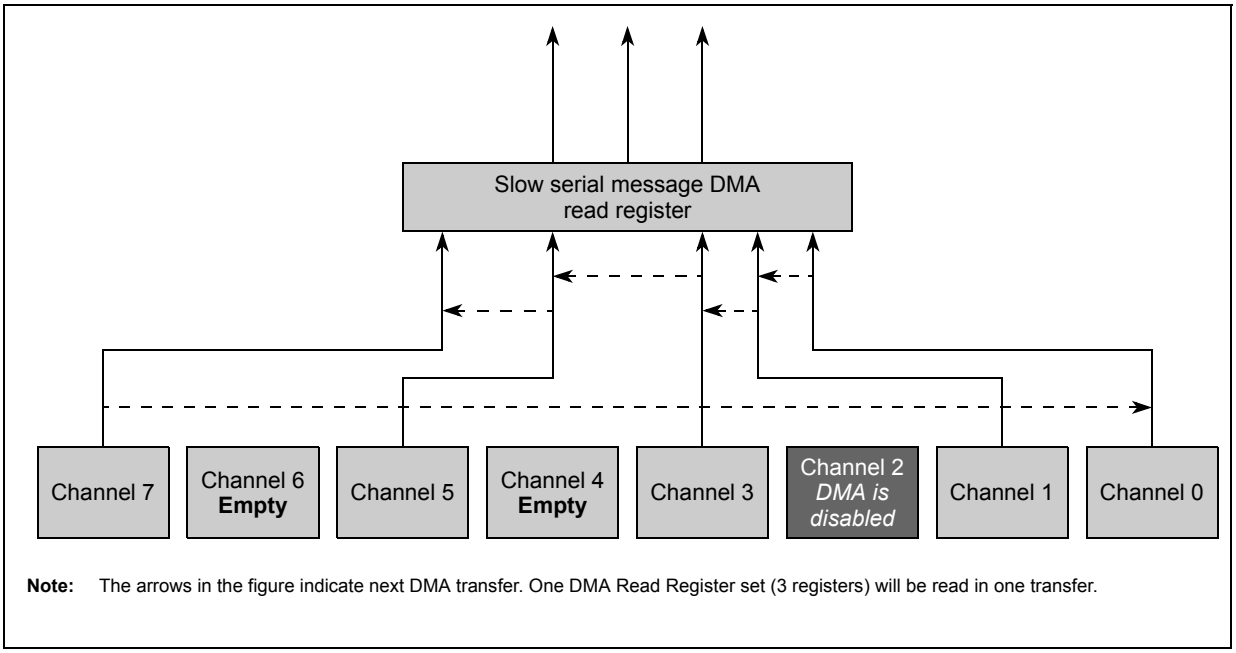
The SENT module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in *Section 56.4.8: Time stamp logic on page 2201*.

56.4.2.1 DMA request for Fast Message reading

Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - *Section 56.3.2.12: DMA Fast Message Data Read Register (DMA_FMSG_DATA)*
  - *Section 56.3.2.13: DMA Fast Message CRC Read Register (DMA_FMSG_CRC)*
  - *Section 56.3.2.14: DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)*
- A fixed round robin sequencing runs, as shown in *Figure 1257*, and this logic checks for messages in sequence 0→1→3 →5→7 and back to channel 0 and so on. Channel 2 is skipped as it's not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

Figure 1257. Fast Message DMA read logic



56.4.2.2 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers
- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - *Section 56.3.2.15: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)*
  - *Section 56.3.2.16: DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)*
  - *Section 56.3.2.17: DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)*
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see *Section 56.4.2.1: DMA request for Fast Message reading*)

Figure 1258 shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

Figure 1258. Slow Serial Message DMA read logic

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in one transfer.

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

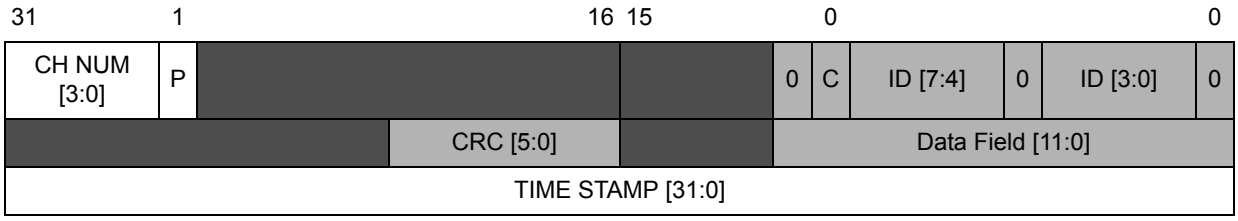


Figure 1259. Enhanced Serial Message with 8-bit ID field

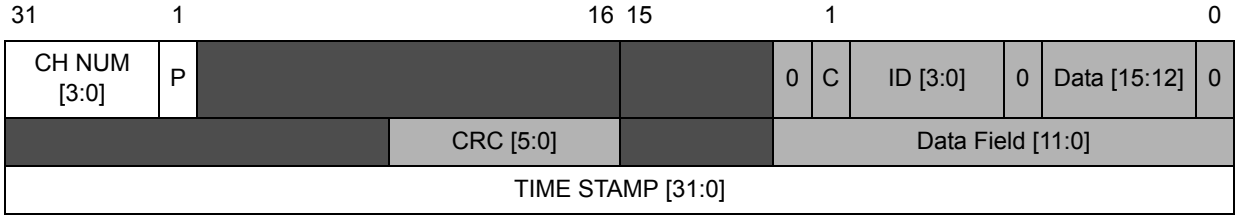

Figure 1260. Enhanced Serial Message with 4-bit ID field

Figure 1259 and *Figure 1260* shows the enhanced serial messages. Bit C (shown in figure) or bit CFG (as shown in *Section 56.3.2.15: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)* description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in *Section 56.3.2.15: DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)* description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Figure 1261 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

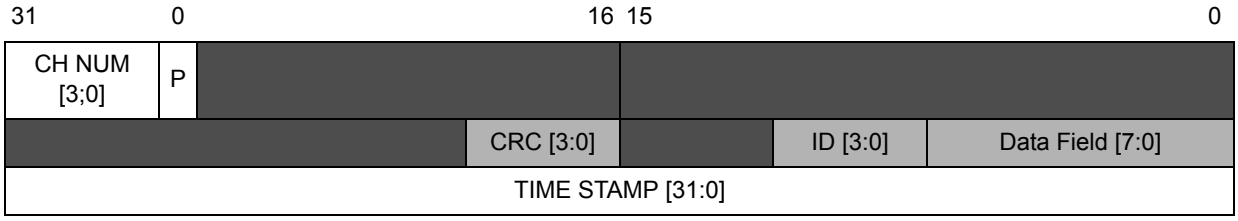

Figure 1261. Short serial message

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

56.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

56.4.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable
- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

56.4.4 Overflow behavior

This section describes the overflow behavior.

56.4.4.1 Fast messages buffers

Overflow in Fast Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

56.4.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

56.4.5 Adjustment for variation in sensor (Tx) clock

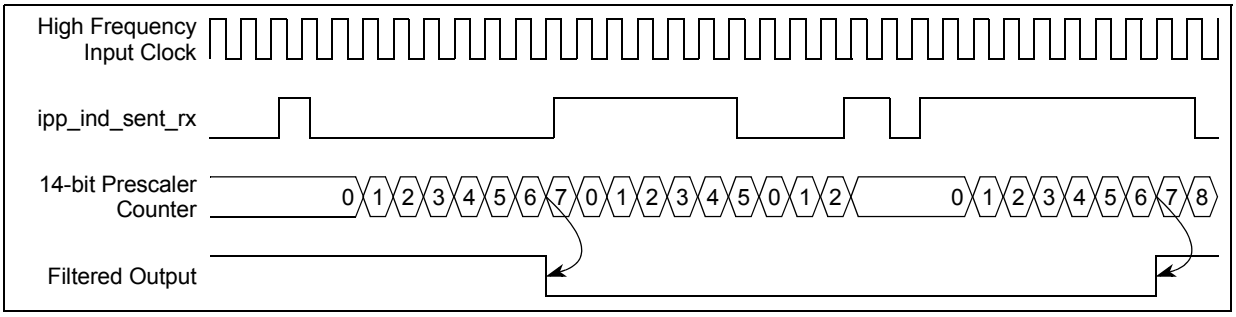
The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register (*Section 56.3.2.18: Channel 'n' Clock Control Register (n = 0 to (CH-1)) (CHn_CLK_CTRL)*). Software can use this value to determine the variation in Tx Clock.

Note: A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

56.4.5.1 Adjustment for nibble length variation



Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

56.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs

in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflows occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register (*Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (*Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). A timing diagram of the input filter is shown in *Figure 1262*.

Figure 1262. Input programmable filter timing diagram

56.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%
- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or XOR-based.
- Any nibble data values measured as < 0 or > 15
- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (*Section 56.3.2.19: Channel 'n' Status Register (n = 0 to (CH-1)) (CHn_STATUS)*). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR) are automatically masked out until a valid calibration pulse is

detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

56.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

56.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is T_{HF_CLK} and channel tick period is T_{TX_CLK} then the check will be of 1.5625% ± {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. So it won't allow variance in clock of a channel by 1.5625% - {100 × (4 × T_{HF_CLK}) / (42 × T_{TX_CLK})}. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

56.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

56.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is

clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

56.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new XOR-based CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

56.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

56.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in *Section 56.3.2.1: Global Control Register (GBL_CTRL)*) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver

channel being used, or it can be set at some fixed value determined by application, such as 1 µs. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value to generate a time stamp clock of 1 µs resolution is 60.

Note: The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

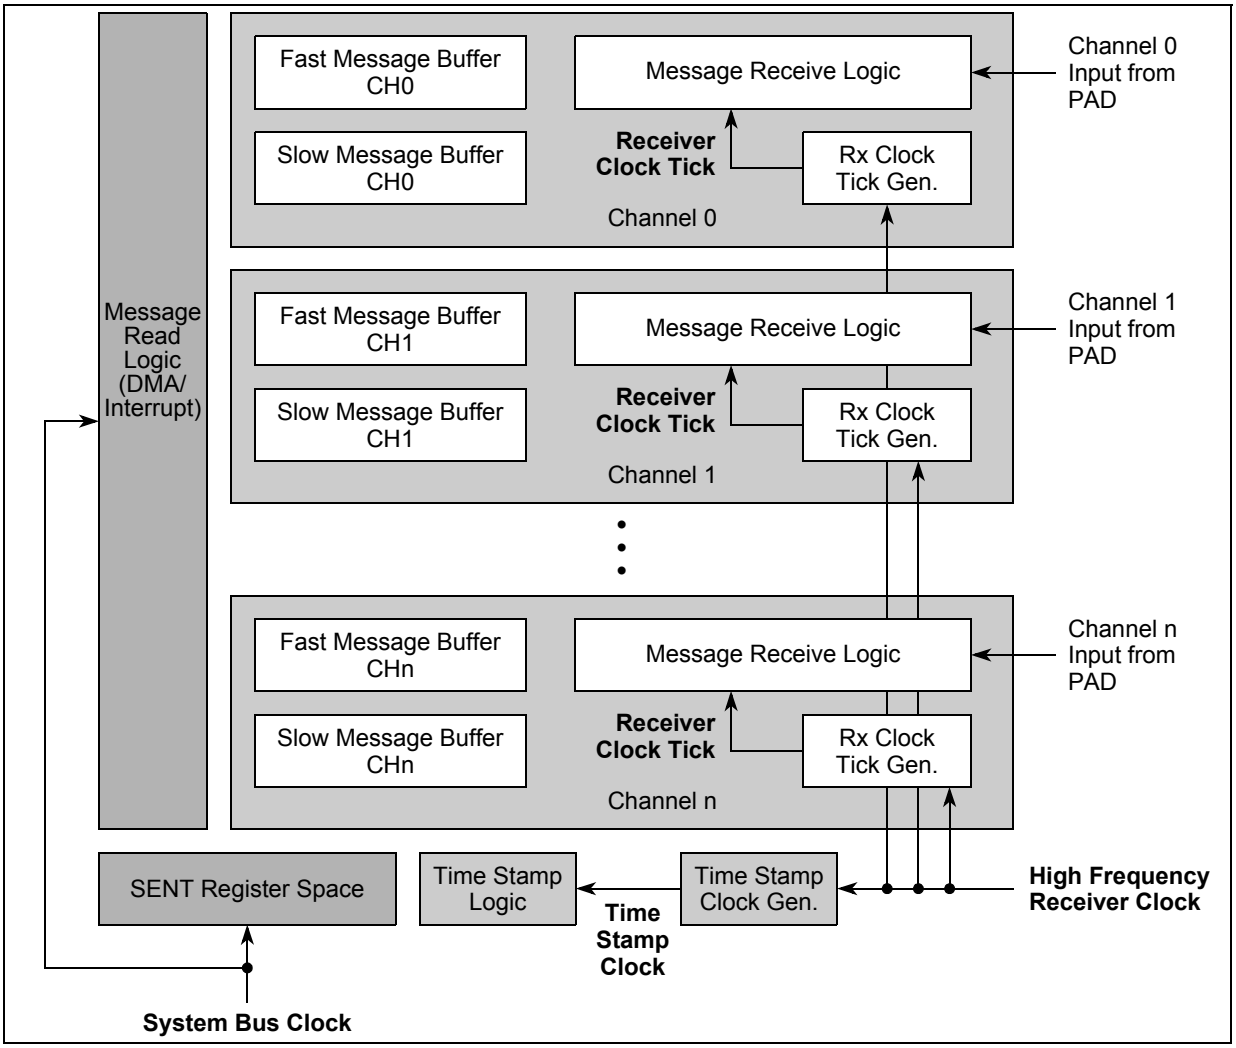
The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

56.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

56.4.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in *Section 56.3.2.20: Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). Status bit (bus_idle in *Section 56.3.2.19: Channel 'n' Status Register (n = 0 to (CH-1)) (CHn_STATUS)*) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.



56.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

56.5.1 Clocking strategy

Figure 1263 shows the clock domain in which each module is functioning.

Figure 1263. SENT Receiver module clock domains

56.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 µs receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 µs (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as 154 $\times$ 2.4 = 369.6 µs. Now since messages are arriving in parallel, 369.6 µs is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that 'N_{CHNL}' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be 369.6/N_{CHNL} µs or ~370/N_{CHNL} µs. Since the CPU or the

DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as 'T_{RD}' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

Equation 80

$$3 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370/N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

Equation 81

$$3 \times T_{RD} + T_{WAKUP} < 370/N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get

For CPU,

Equation 82

$$(3 \times N_{RD} + N_{ISR}) \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is µs)

For DMA,

Equation 83

$$3 \times N_{RD} \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is µs)

56.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula below.

Equation 84

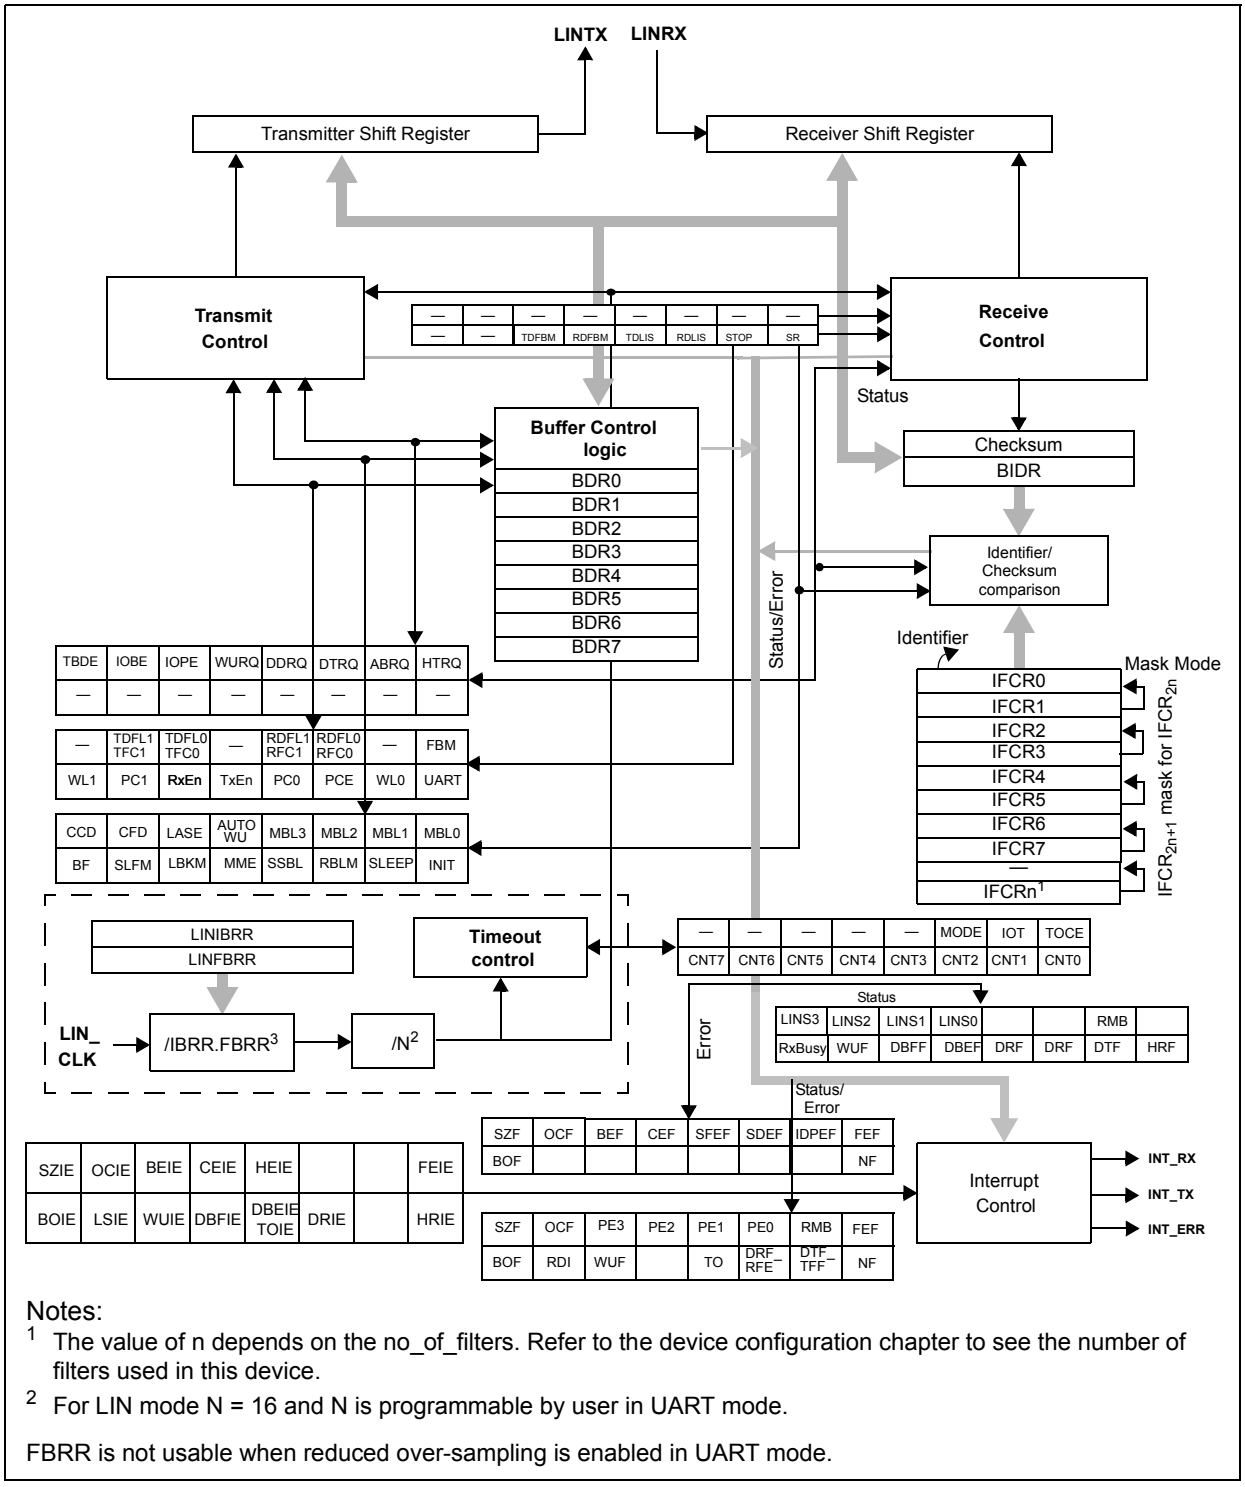
$$F_{HF_CLK} > 332 / (3 \times T_{Tx_CLK})$$

where F_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in MHz and T_{Tx_CLK} is the Transmitter or Sensor Clock Frequency in µs.

Note: T_{TX_CLK} in the above equation should be chosen based on the fastest sensor clock among all channels in the device.

57 LINFlexD

57.1 Introduction



The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, 2.1 and 2.2. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 1264. Block diagram

Notes:

1 The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.

2 For LIN mode N = 16 and N is programmable by user in UART mode.

FBRR is not usable when reduced over-sampling is enabled in UART mode.

57.2 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
  - Initialization
  - Normal
  - Sleep
- Test Mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

57.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, 2.1 and 2.2
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
  - Autonomous header handling
  - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “(2/3)*LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained.)

57.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBRR registers — see *Section 57.3.2.8, Baud rate generation*
- Separate clock for baud rate calculation (The relationship “(2/3)*LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.

- For bit rate ≤ 6.25 Mbit/s
  - Sixteen times oversampling
  - 3:1 majority voting
- For 6.25 Mbit/s < bit rate ≤ 12.5 Mbit/s
  - Reduced over sampling programmable by the user
  - 3:1 majority voting for reduced over sampling of 8
- For 12.5 Mbit/s < bit rate ≤ 25 Mbit/s
  - Reduced over sampling programmable by the user
  - 1:1 voting for all reduced over sampling of 4, 5 and 6

57.2.3 Standard features

DMA2x bus interface

57.3 Functional description

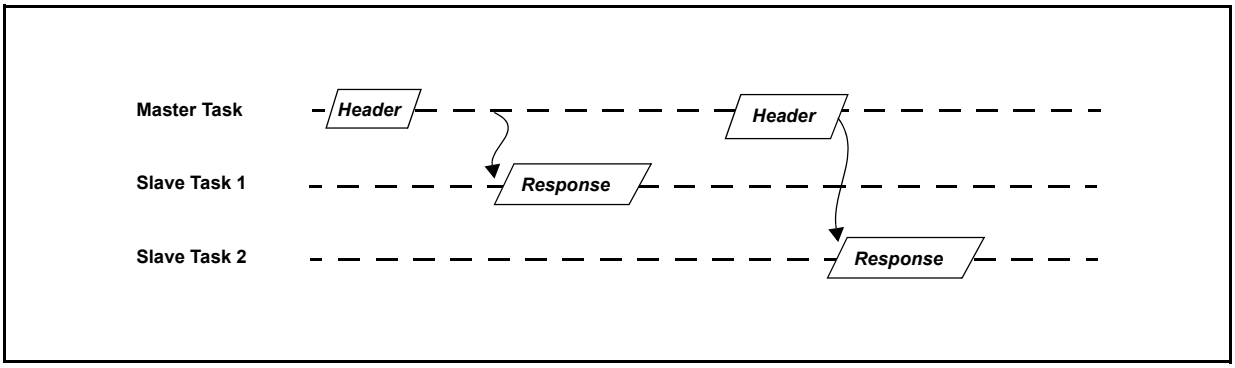
57.3.1 LIN protocol

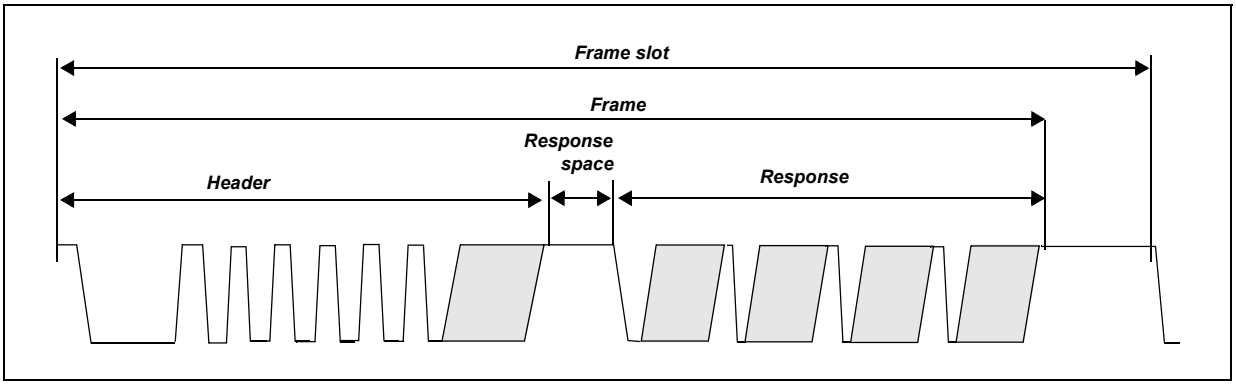
The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task — all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

57.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 1265. Frames





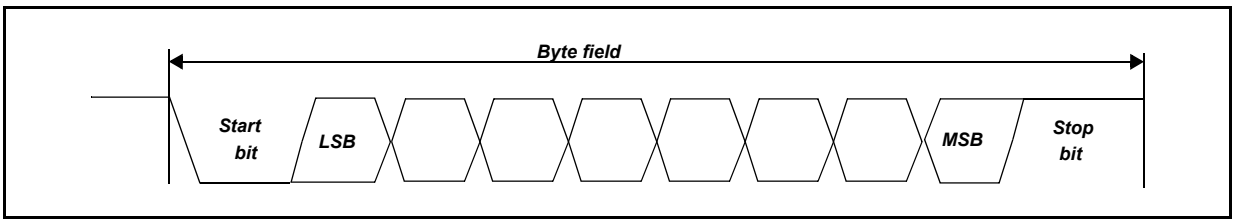


Figure 1266. Structure of LIN frame

57.3.1.2 Data field

Each byte is transmitted as shown in *Figure 1267*. The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

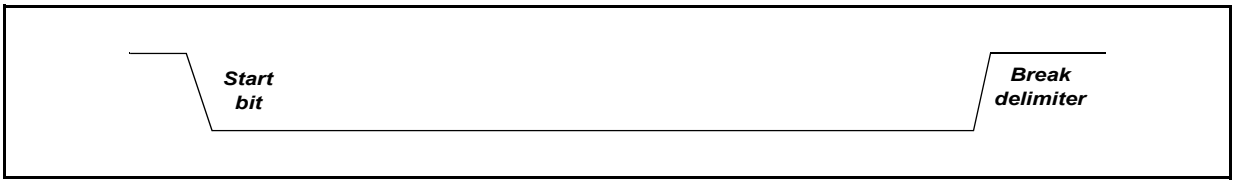

Figure 1267. Structure of byte field

57.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in *Figure 1268*. The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

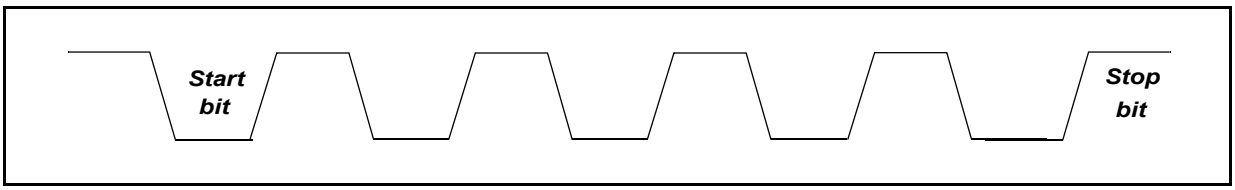

Figure 1268. Break field

57.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

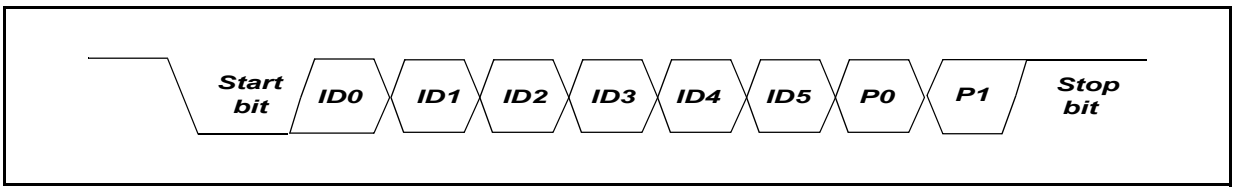

Figure 1269. Sync byte field

57.3.1.5 Identifier

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 1270. Identifier field

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

57.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it used for communication with LIN 2.0 slaves.

57.3.2 LINFlexD features

57.3.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization, Normal,** and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

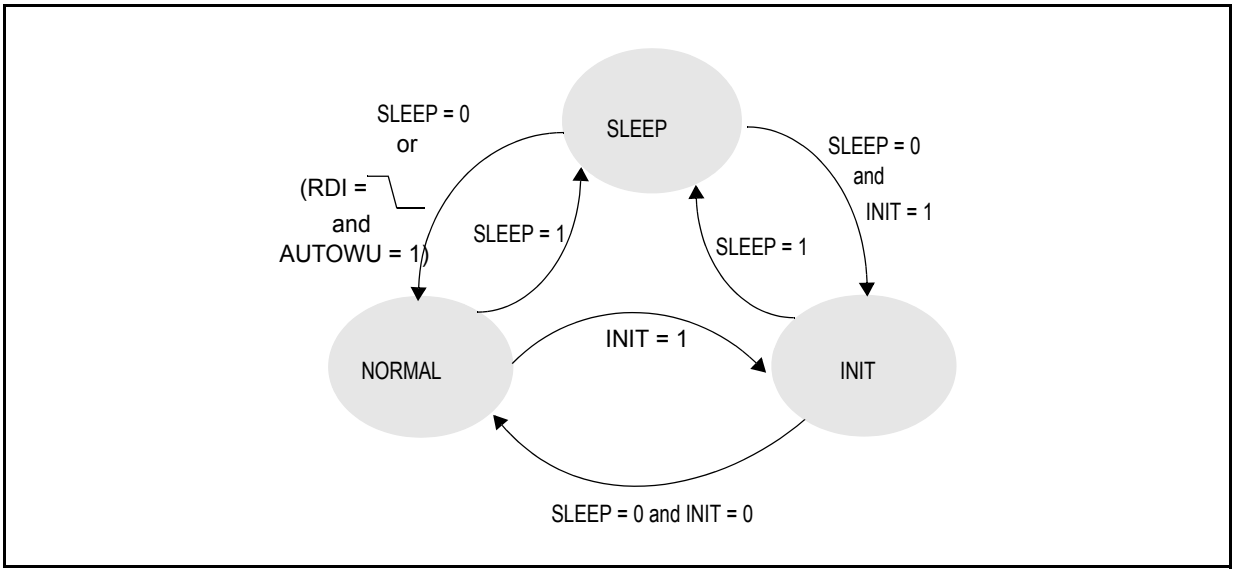
To enter this mode, software sets the INIT bit in the LINCR1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. set up the baud rate registers
2. reset the UART bit
3. select the mode (Master or Slave)
4. configure checksum control bits
5. initialize the identifier list (Slave mode)

Normal mode (NM)



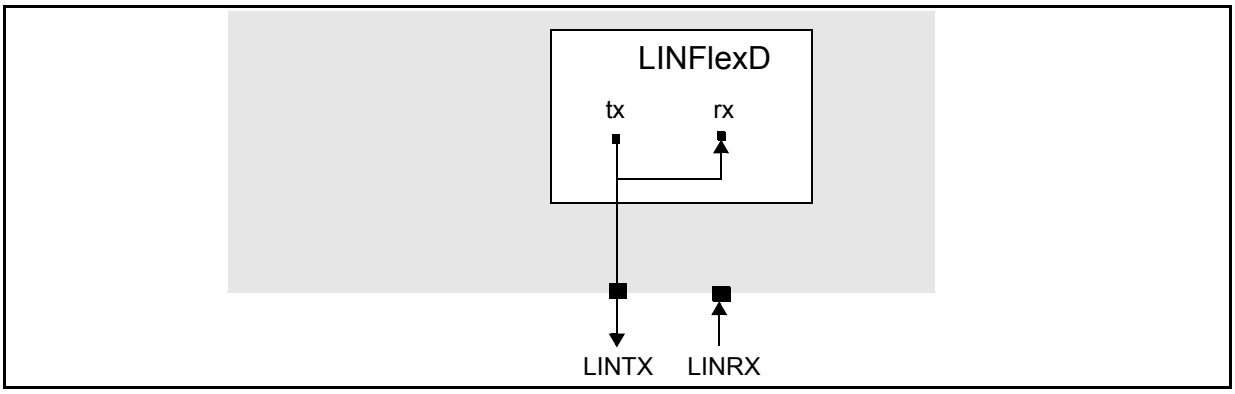
Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINCR1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 µs on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to *Section 57.3.2.10, Wakeup management*.

Figure 1271. Operating modes



57.3.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINCR1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

Figure 1272. Loop back mode

57.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

57.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. read the received ID in the BIDR register
2. fill the BDR[0:x] register
3. program the CCS and DIR bits in the BIDR register
4. specify the data field length DFL[5:0] bits in the BIDR register
5. trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BIDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

57.3.2.5 Errors

57.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- that the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,

  or

- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

   If there is an inconsistent Sync Field error, it means that:

   D > 14.0625%

   If there is no error, it means that:

   D < 14.84375%

   If 14.0625% < D < 14.84375%, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 0)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

1. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

P0 = ID0 XOR ID1 XOR ID2 XOR ID4

P1 = NOT (ID1 XOR ID3 XOR ID4 XOR ID5)

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

57.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles. Bit error is not checked during break field transmission.

Example 21.

1-bit time at 20 Kbit/s = 50 µs

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 µs

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.

Note: Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

57.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

57.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINIER.

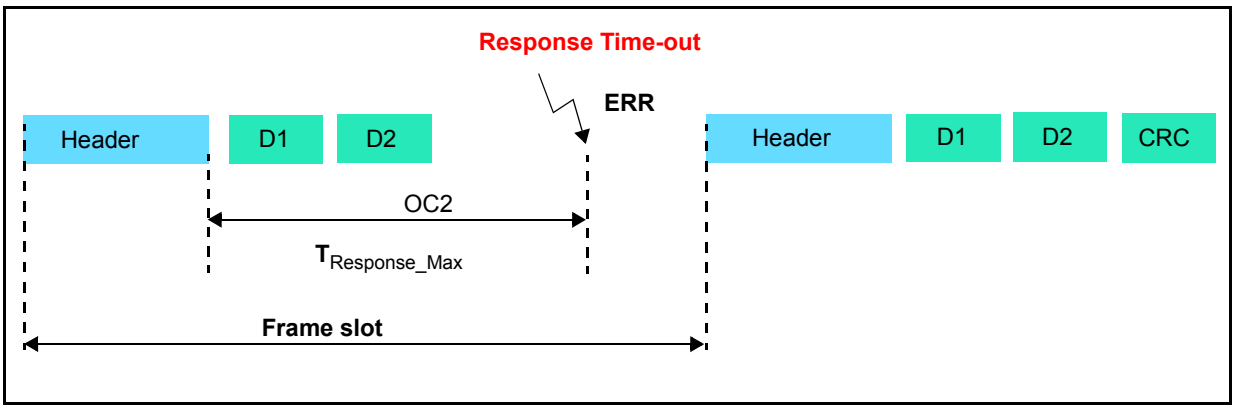
57.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

57.3.2.5.6 Timeout error

Figure 1273. Incomplete response (for example, missing checksum)



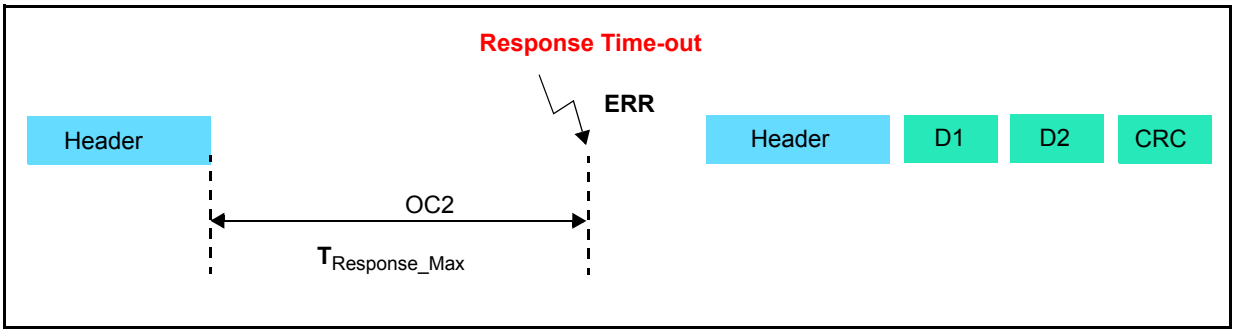


Figure 1274. No response

Response timeout mechanism

- Master mode
  - OC2 is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further OC2 update is required.
  - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the OC2 value (no change compared to earlier implementation).
  - In case of an incomplete response, timeout also occurs when the counter reaches the OC2 value (no change compared to earlier implementation).
- Slave mode
  - **Case 1**: The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, OC2 can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = 1.4 × ((DFL + 2) × 10 bit time)).
  - **Case 2**: The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = 1.4 × (9 × 10 bit time) and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:
    - At the end of the ID, OC2 is loaded with 36 (maximum possible response space) + LINFlexD_LINTCSR[CNT]
    - At the end of the first_data_byte it is reloaded again according to DFL
    - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
  - no error on the bus and timing is correct (nominal header length)
  - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error)

  Therefore there is no meaning of header timeout in master mode, so it is disabled
- Slave mode
  - header_nominal = 13 + 2 + 10 + 10 = 35 Tbit
  - header_max = 1.4 × Header_nominal = 49 Tbit
  - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is 49 × 1.14 = 56 Tbit.
  - If the counter starts after 11 Tbit, the HTO value is 56 – 11 = 45 Tbit

  The reset value of HTO is 45 and this register can only be programmed in slave mode.

  As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

  The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

57.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th, and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 4th, 5th, and 6th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see *Section 57.4.2.4, LIN Error Status Register (LINESR)*).

57.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a

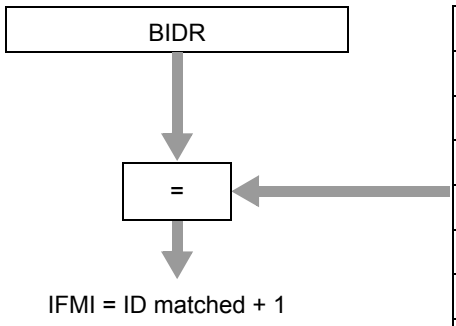
filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number 2*n* and 2*n*+1 is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals no_of_filters, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR2*n* or IFCR2*n*+1 (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than no_of_filters, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number 2*n* is the filter and 2*n*+1 acts as a mask for it. The FACT bit for filter 2*n*+1 has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.



If there is a match of identifier with the *m*th filter in any mode, then *m*+1 is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note: If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.

57.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 1257. 10-bit-shift-register sample register

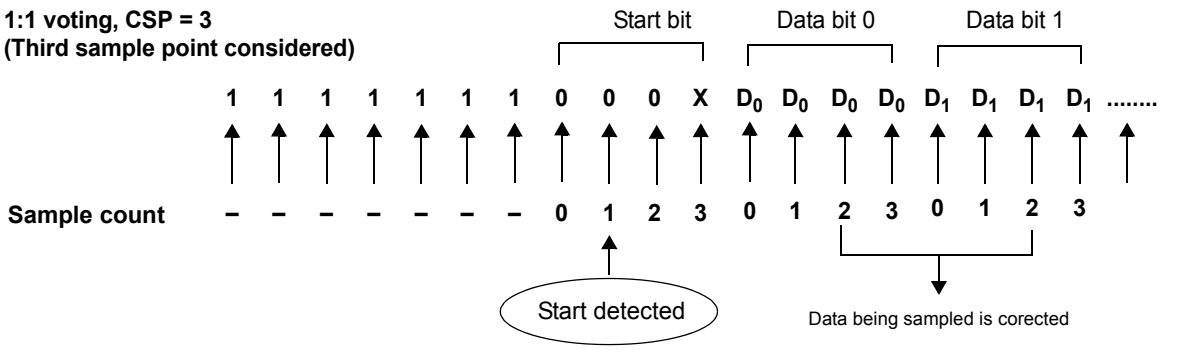
Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x(1)	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: Due to sampling during transition of the bit, the bit value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. So ‘x’ refers to an indeterministic value.

57.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

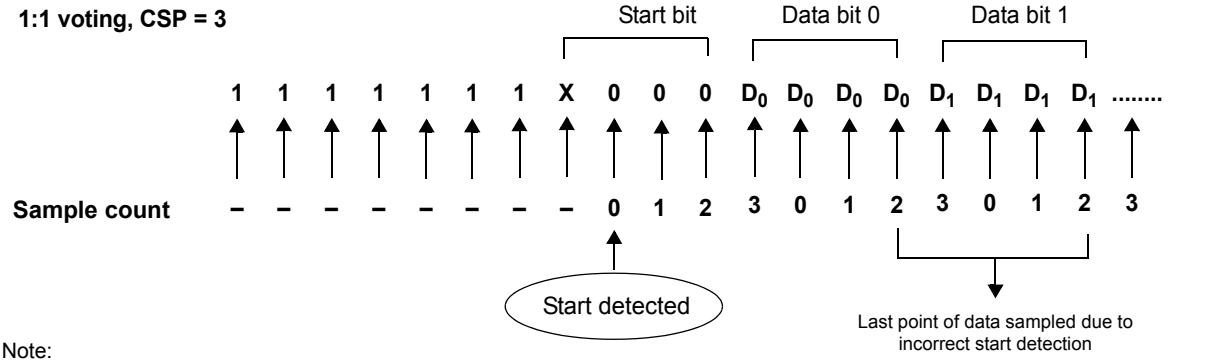
1. Refer to *Table 1257* for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '0', then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to '0' then Noise flag is set.



57.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to *Table 1257* for the status of the sample register (shift register) when count = 6
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '1', then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.

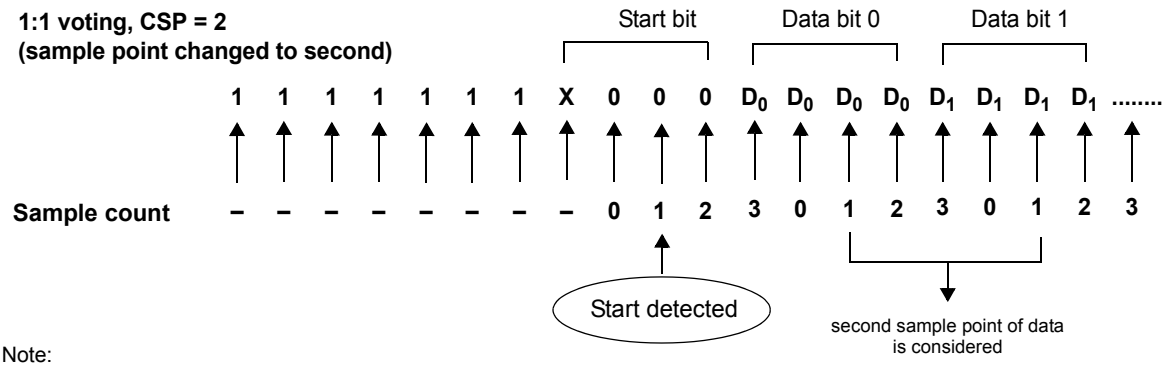


Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

Figure 1277. Start detection and sampling for over sampling rate = 4 (Case 1)

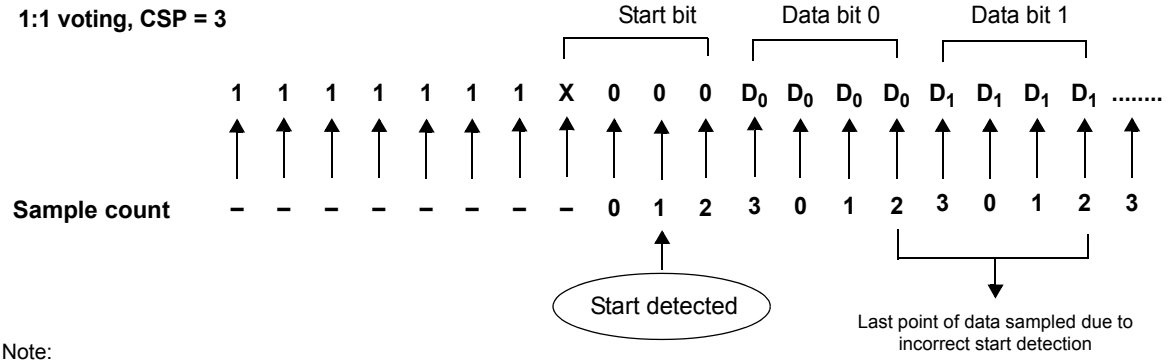
Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

Figure 1278. Start detection and sampling for over sampling rate = 4 (Case 2a)



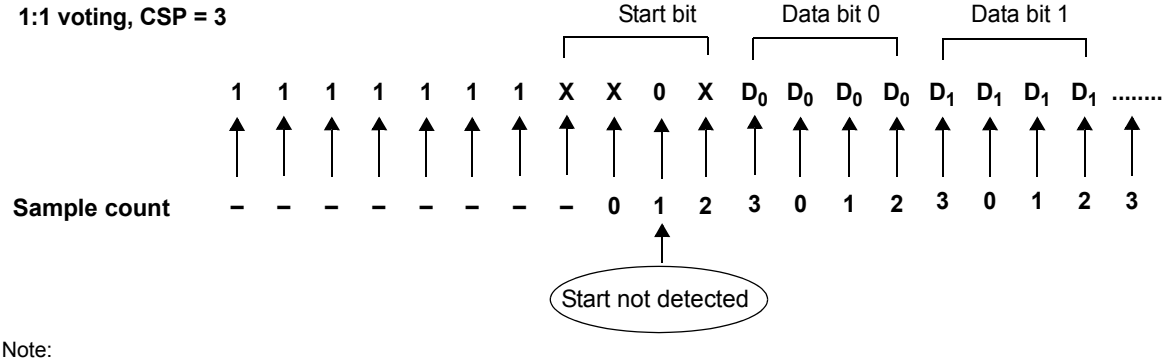
Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a ‘0’ or ‘1’ depending on the rise/fall time. Therefore ‘X’ refers to a indeterministic value.

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.



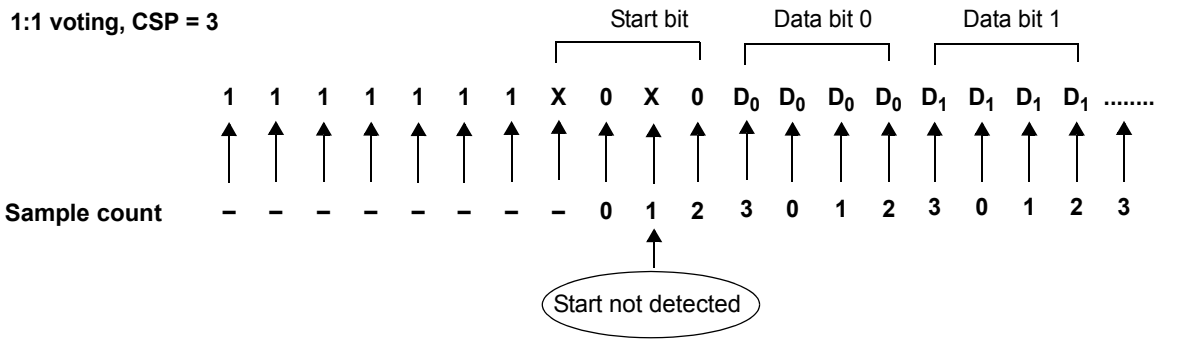
To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

Figure 1279. Start detection and sampling for over sampling rate = 4 (Case 2b)



Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

Figure 1280. Start detection and sampling for over sampling rate = 4 (Case 3)



Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

Figure 1281. Start detection and sampling for over sampling rate = 4 (Case 4)

Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

Figure 1282. Start detection and sampling for over sampling rate = 4 (Case 5)

Note:
1) D_0, D_1: Databits
2) X: Due to sampling during transition of the bit, value might be sampled as a '0' or '1' depending on the rise/fall time. Therefore 'X' refers to a non deterministic value.

57.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

Equation 85
Tx = Rx = LIN_CLK / (16 × LDIV)

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBRR.
When reduced oversampling is enabled LINFBRR is not used and LDIV contains only the integer part of LINIBRR.

Example 22.

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBRR = 11d = B h

Baud rate = 80 MHz/(16 x 1041,67) = 4.8 Kbit/s

Note: Due to design constraints the maximum baud rate achievable is 25 Mbit/s.

*Note: The relationship "(2/3)*LIN_CLK ≥ PBRIDGEx_CLK > 1/3*LIN_CLK" should also be maintained.*

57.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

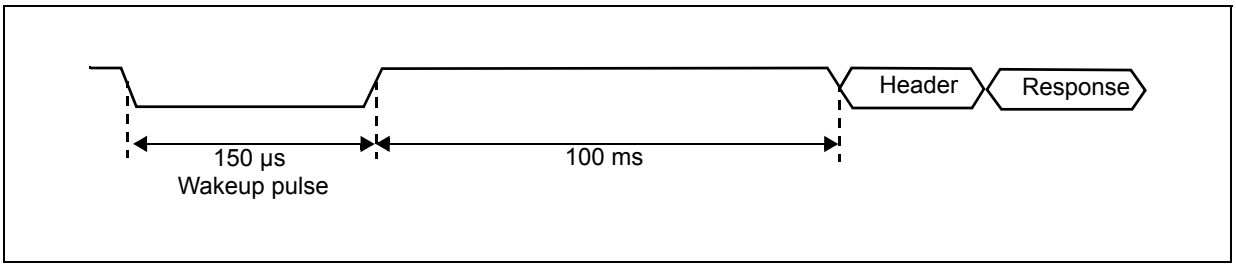
When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

57.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 µs to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 µs) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.



1. AUTOWU = 1

   On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.

2. AUTOWU = 0

   On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 1283. Wakeup sequence

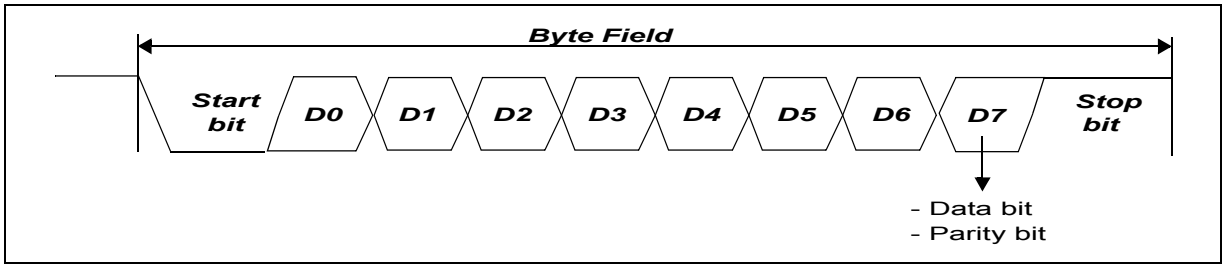
57.3.3 Timer

There is an 8 bit counter which has different behavior in different modes.

In Output Compare Mode (LINTCSR[MODE]= 1) : This counter is running even in Sleep and Initialization mode. The counter value which when matches the two software configurable output compare registers (LINOCR[OC1] or LINOCR[OC2]), generate output compare interrupt (LINESR[OCF]) provided TOCE bit in LINTCSR is set. Once an interrupt occurs subsequent interrupt is generated only when the application has soft reset the LIN IP through GCR [SR] bit to get reset the output compare flag (LINESR[OCF]).

In LIN Mode : The software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state then this counter remains in Reset state. LIN mode has no meaning if UART is enabled, hence the counter will remain in Reset state.

57.3.4 UART mode



The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames,16-bit frames,17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

57.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

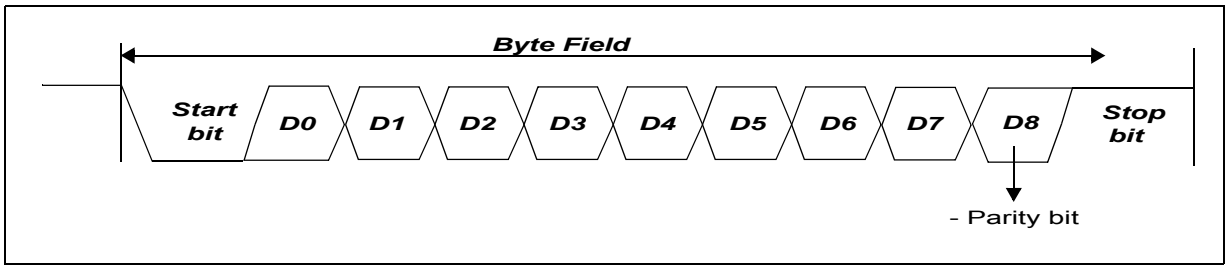


Figure 1284. UART mode 8-bit data frame

57.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

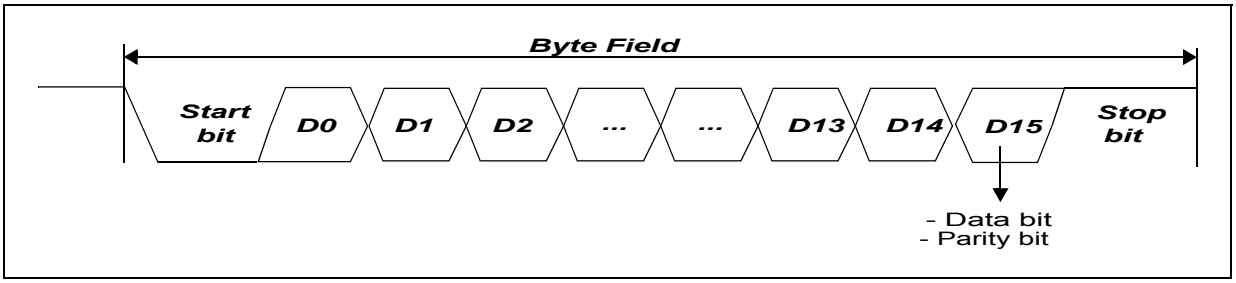

Figure 1285. UART mode 9-bit data frame

57.3.4.3 16-bit data frames

The sixteenth bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

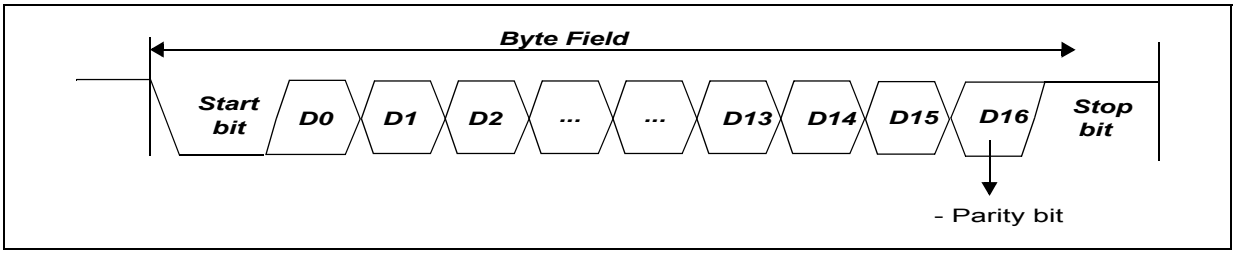

Figure 1286. UART mode 16-bit data frame

57.3.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

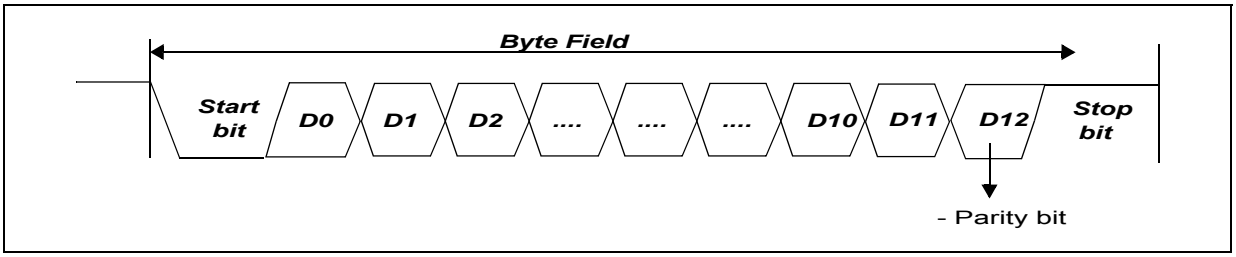

Figure 1287. UART mode 17-bit data frame

57.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception only in FIFO mode.

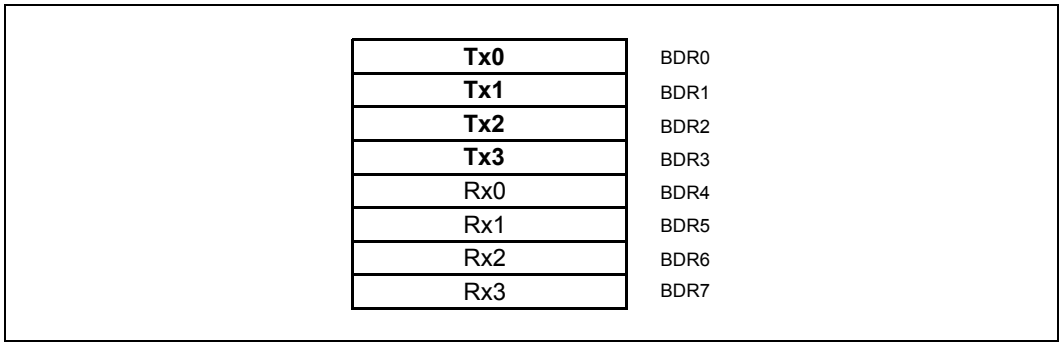

Figure 1288. UART mode 13-bit data frame

57.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in *Figure 1289*.

Figure 1289. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1.

The same applies for reception.

57.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Note: Invalid writes to BDRL which generates IPS transfer error, also triggers data transmission at the same time.

Note: When the FIFO is full, a read to DATA0 of BDRM reflects the content of DATA3 in BDRL. Proper functionality of the IP is not affected by this.

Table 1258. BDRL access in UART mode (1)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error

Table 1258. BDRL access in UART mode(Continued)(1)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

1. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register. Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

57.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception.The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 1259. BDRM access in UART mode(1)(2)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error

Table 1259. BDRM access in UART mode(1)(2)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.
2. Halfword0 refers to DATA1 and DATA0 of BDRL register. Halfword1 refers to DATA3 and DATA2 of BDRL register.

Halfword2 refers to DATA5 and DATA4 of BDRM register. Halfword3 refers to DATA7 and DATA6 of BDRM register.

- *If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.*
- *If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.*
- *If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.*
- *If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.*
- *If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.*
- *When WLS bit = 1, BDRM access depends on WL bit setting.*
- *When WLS bit = 1, WL = 0 or 1 should not be used, since this will lead to incorrect reception of data.*
- *When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.*

57.3.5 DMA interface

57.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

57.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in *Table 1260* and *Table 1261*.

Table 1260. LINFlexD control/status fields description

Register	Field	Level	Description
LINCR2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: – 1–8 bytes: normal frames – 1–64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier

Table 1260. LINFlexD control/status fields description(Continued)

Register	Field	Level	Description
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full

DMATXE[2**TX_CH_NUM] (1)		High	DMA Tx channel enable (read/write)
			In UART or LIN master mode only channel 0 can be programmed.
			In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1.
			DMATXE[x] = 0b → TX channel x disabled
			DMATXE[x] = 1b → TX channel x enabled

DMARXE[2**RX_CH_NUM] 1		High	DMA Rx channel enable (read/write)
			In UART or LIN master mode only the channel 0 can be programmed.
			In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1.
			DMARXE[x] = 0b → RX channel x disabled
			DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation.

Table 1261. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in *Table 1262*.

Table 1262. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 → 8-bit 001 → 16-bit 010 → 32-bit 011 → 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 → 8-bit 001 → 16-bit 010 →32-bit 011 → 64-bit

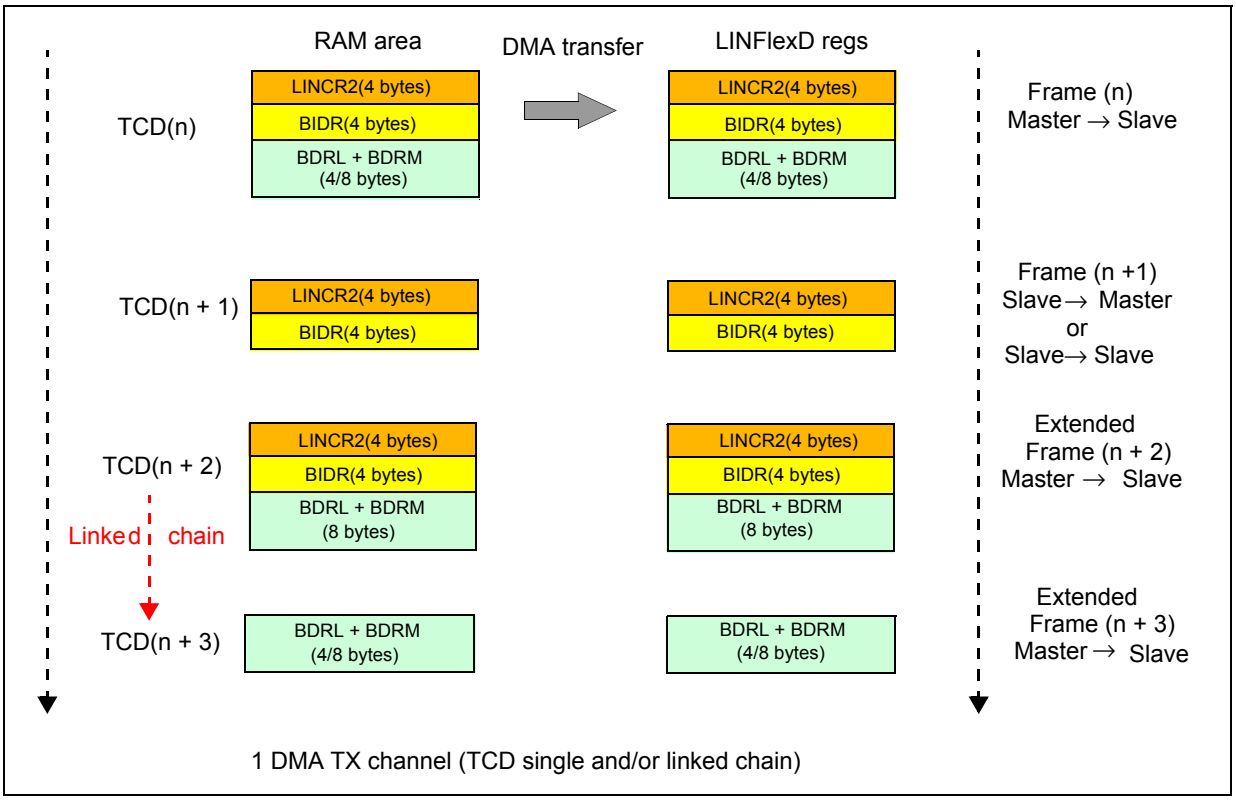

Table 1262. TCD control fields description(Continued)

TCD field	Level	Description
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

57.3.5.3 Master node — TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1290*.

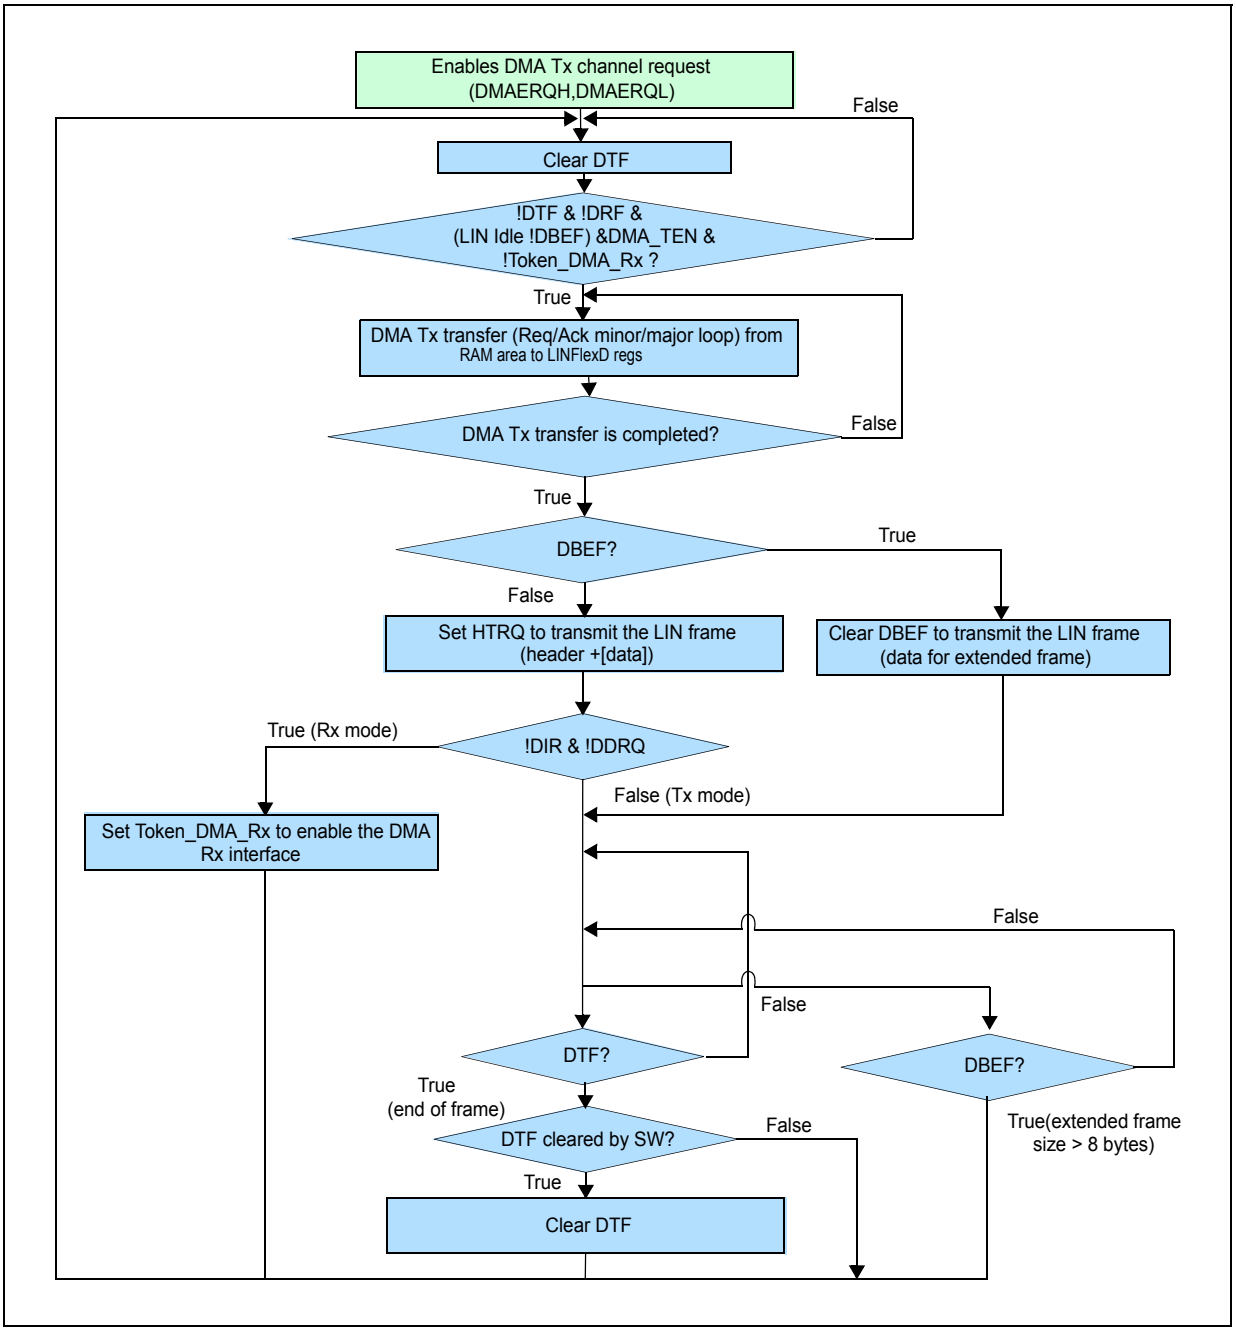
Figure 1290. Master node — TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

Table 1263 provides the register settings of the LINCR2 and BIDR for each class of LIN frame.

Table 1263. Master node — Tx mode — Register setting



LIN frame	LINCR2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in *Figure 1291*. DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in *Table 1264*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1264. TCD setting — Master node — Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4 + 4] + 0/4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned LINCR2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINCR2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

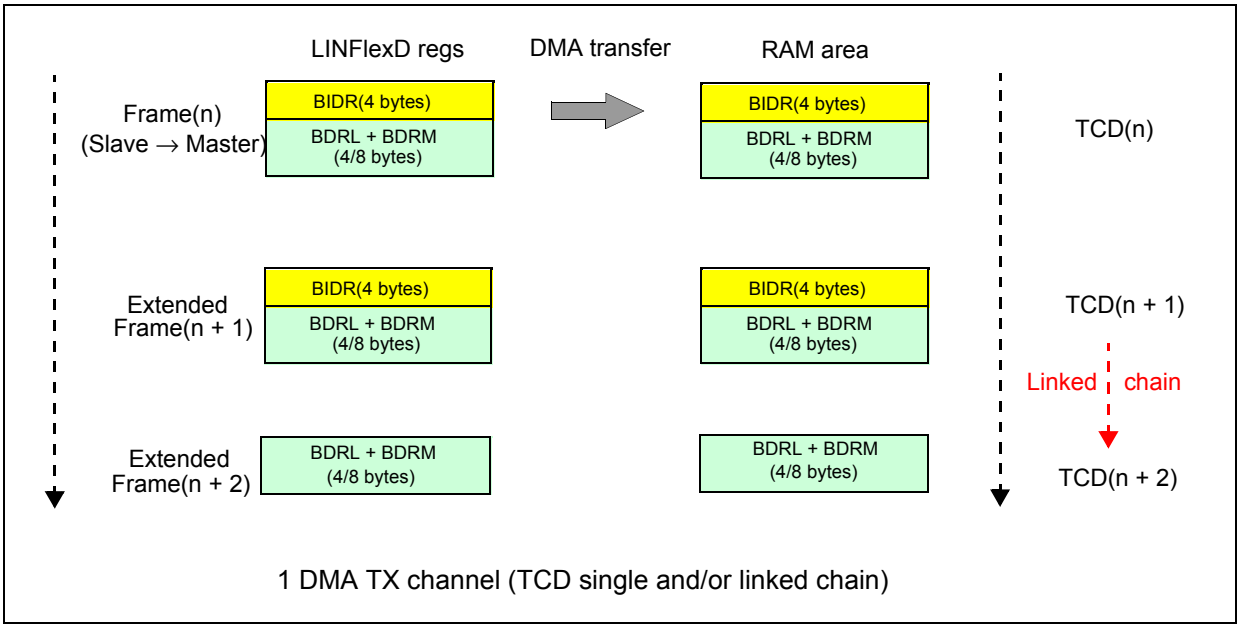


Figure 1291. Master node — DMA Tx FSM (concept scheme)

57.3.5.4 Master node — RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1292*.

Figure 1292. Master node — RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in *Figure 1293*. DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in *Table 1265*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

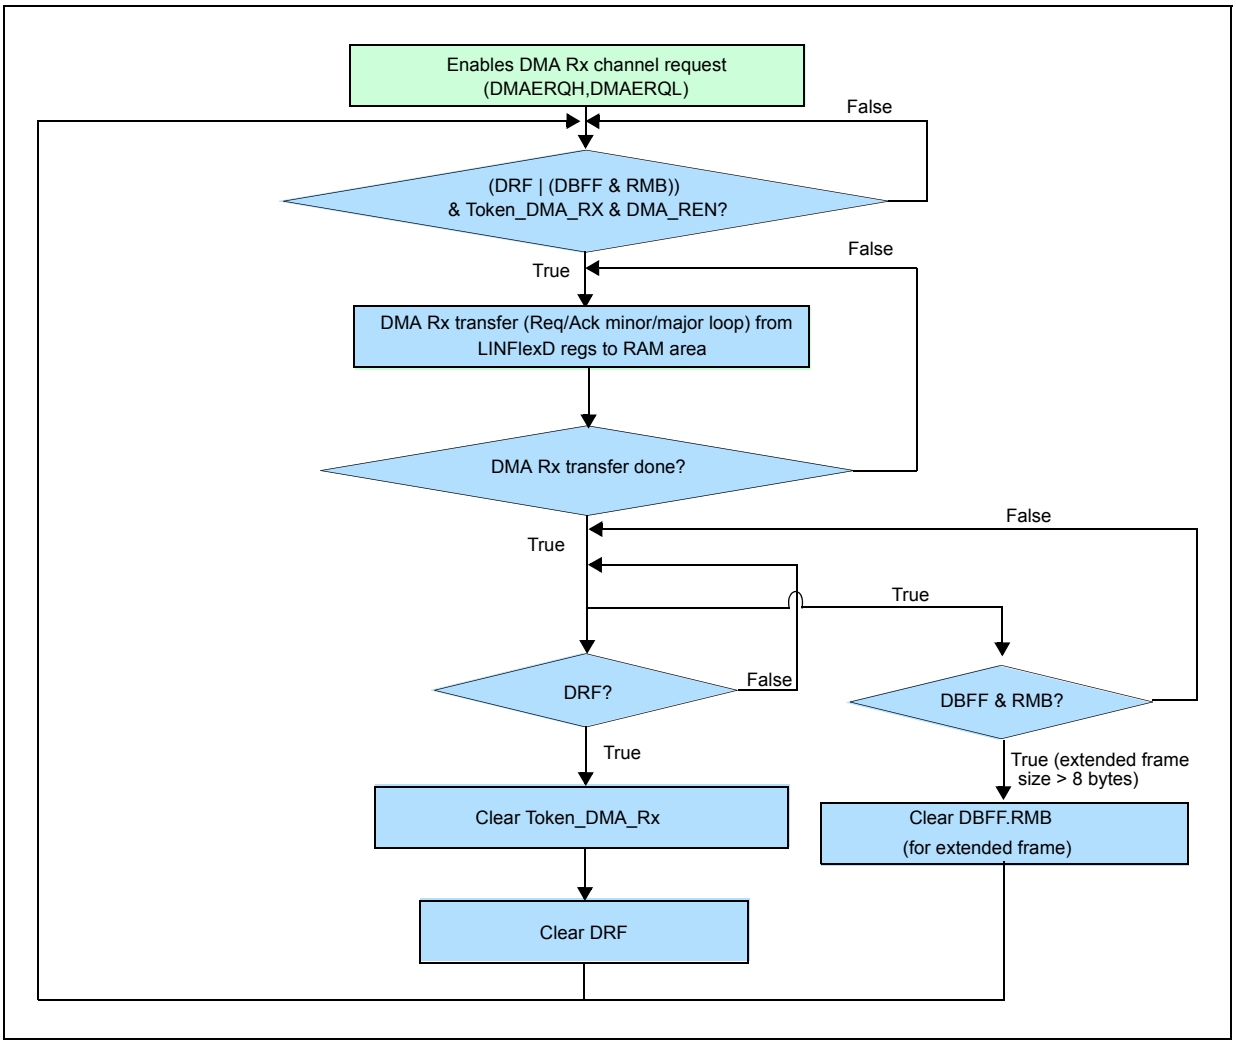

Table 1265. TCD setting — Master node — Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] +4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 1265. TCD setting — Master node — Rx mode(Continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

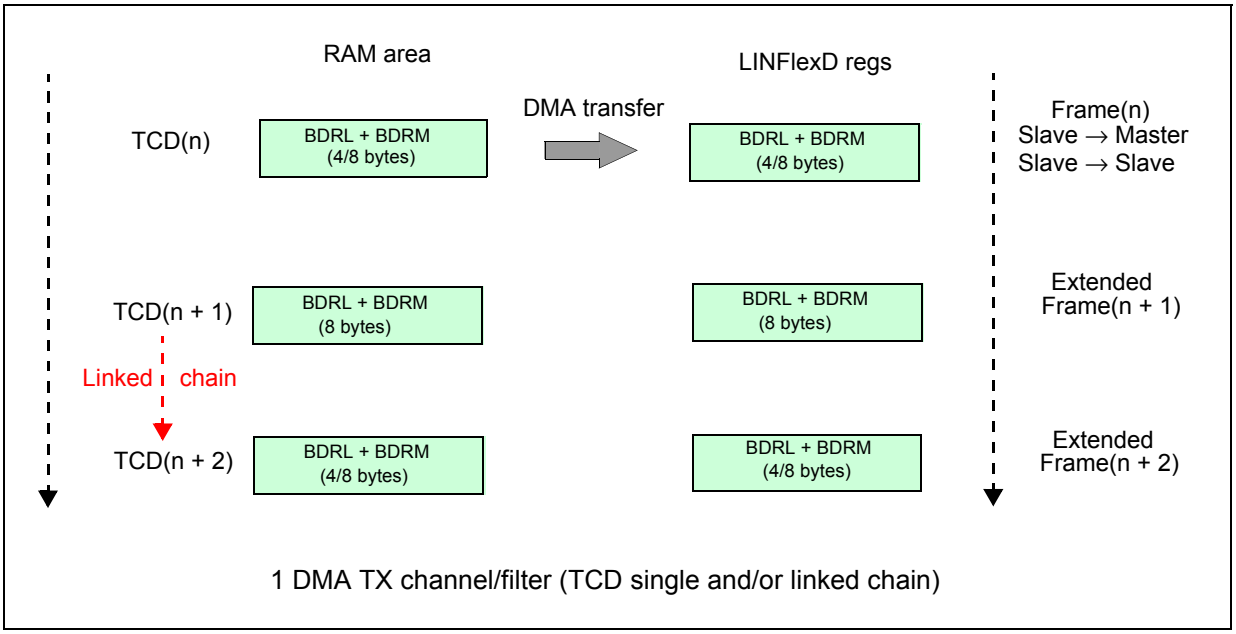

Figure 1293. Master node — DMA Rx FSM (concept scheme)

57.3.5.5 Slave node — TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1294*.

Figure 1294. Slave node — TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1266*.

Table 1266. Slave node — Tx mode — Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode – Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in *Figure 1295*. DMA TX FSM moves to Idle state if DMATXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1267*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

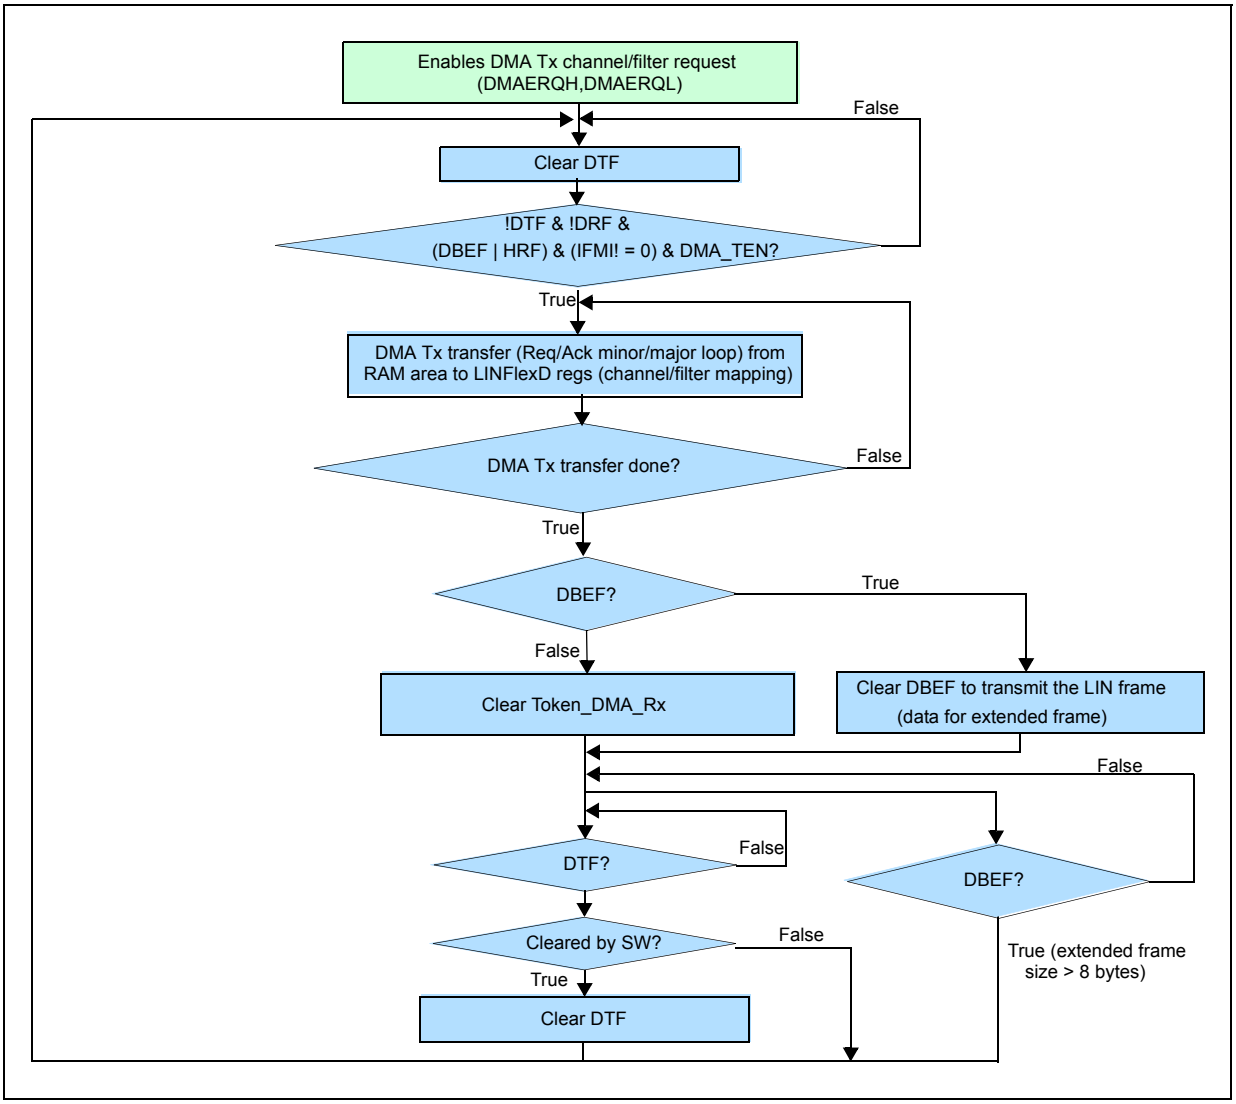

Table 1267. TCD setting — Slave node — Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 1267. TCD setting — Slave node — Tx mode(Continued)

TCD field	Value	Description

DADDR[31:0]	—	BDRL address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

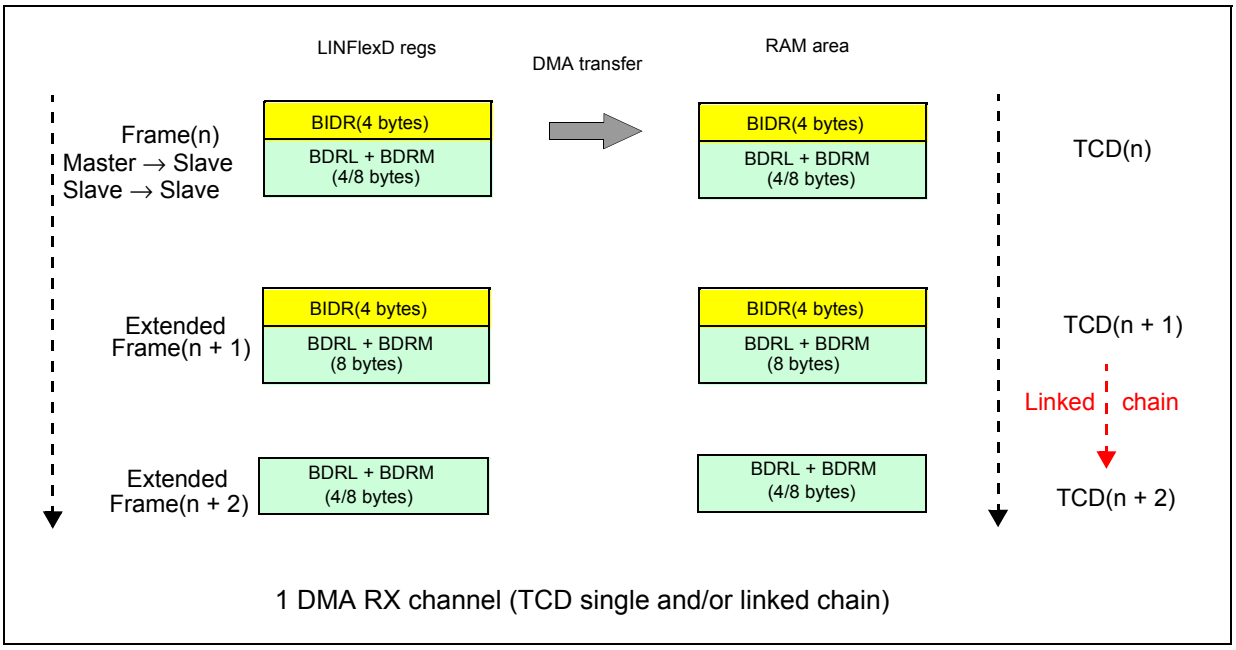

Figure 1295. Slave node — DMA Tx FSM (concept scheme)

57.3.5.6 Slave node — RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1296*.

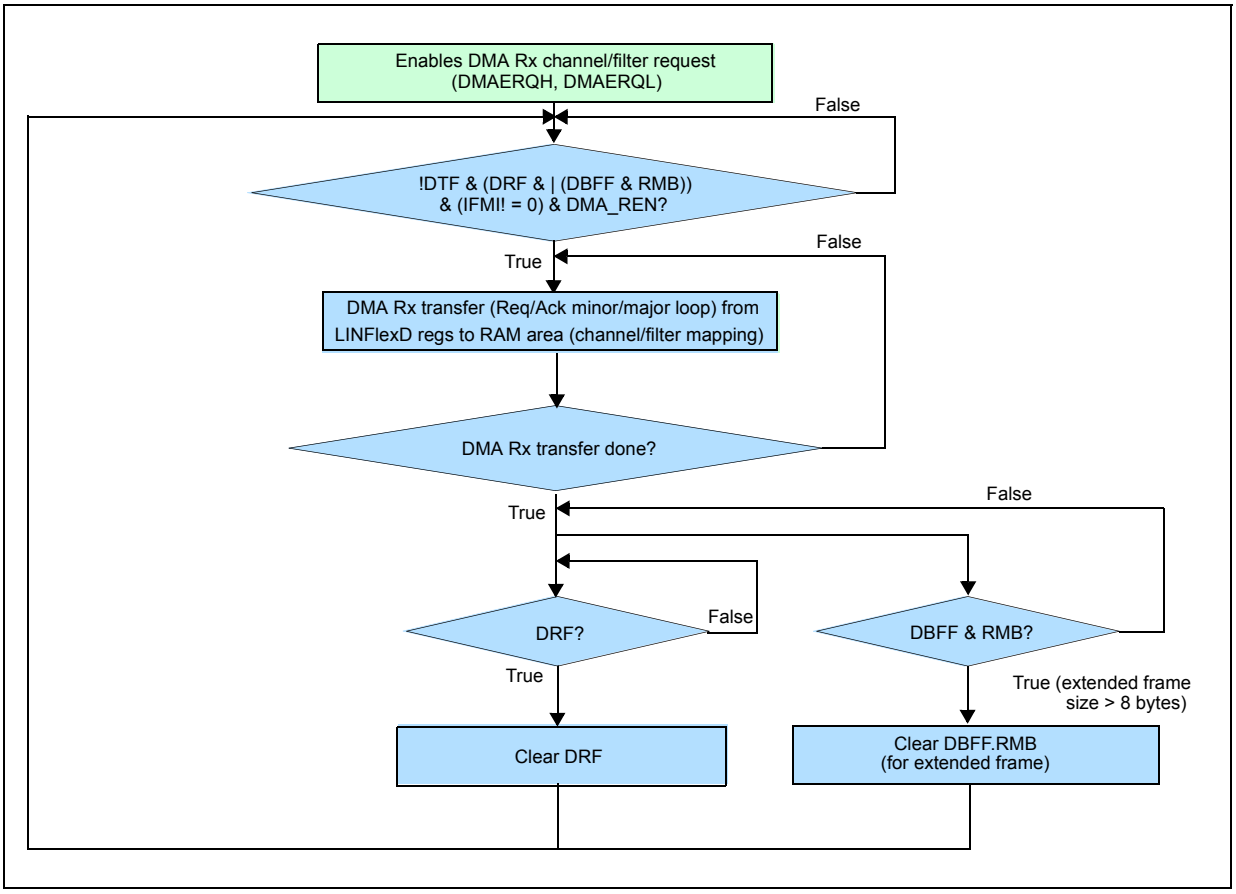
Figure 1296. Slave node — RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in *Table 1268*.

Table 1268. Slave node – Rx mode — Register setting



LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode – Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in *Figure 1297*. DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in *Table 1269*. All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1269. TCD setting — Slave node — Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—

DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

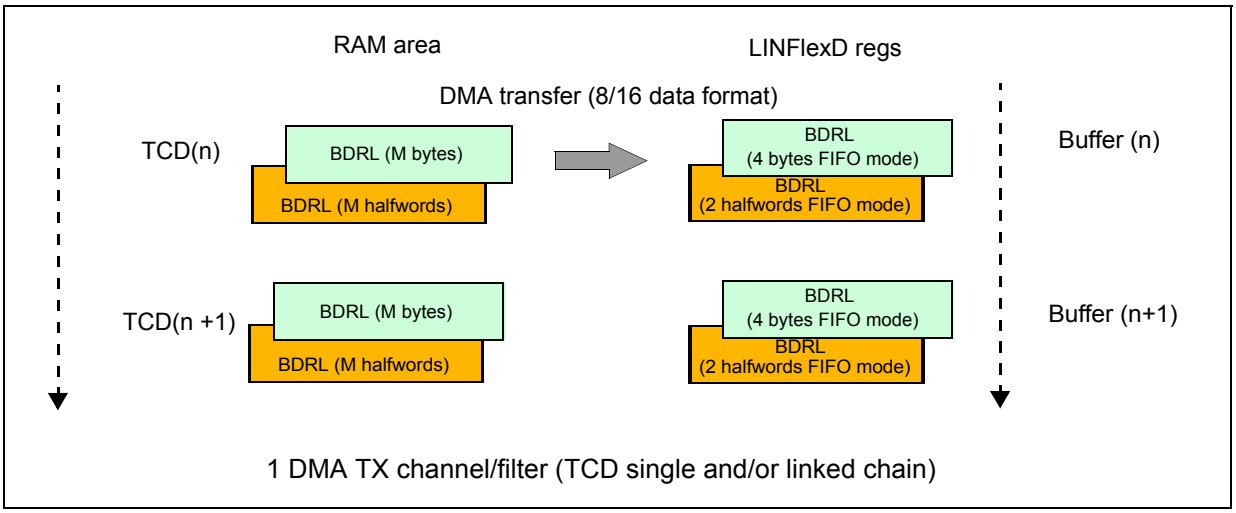

Figure 1297. Slave node — DMA Rx FSM (concept scheme)

57.3.5.7 UART — TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Figure 1298*.

Figure 1298. UART — TX memory map

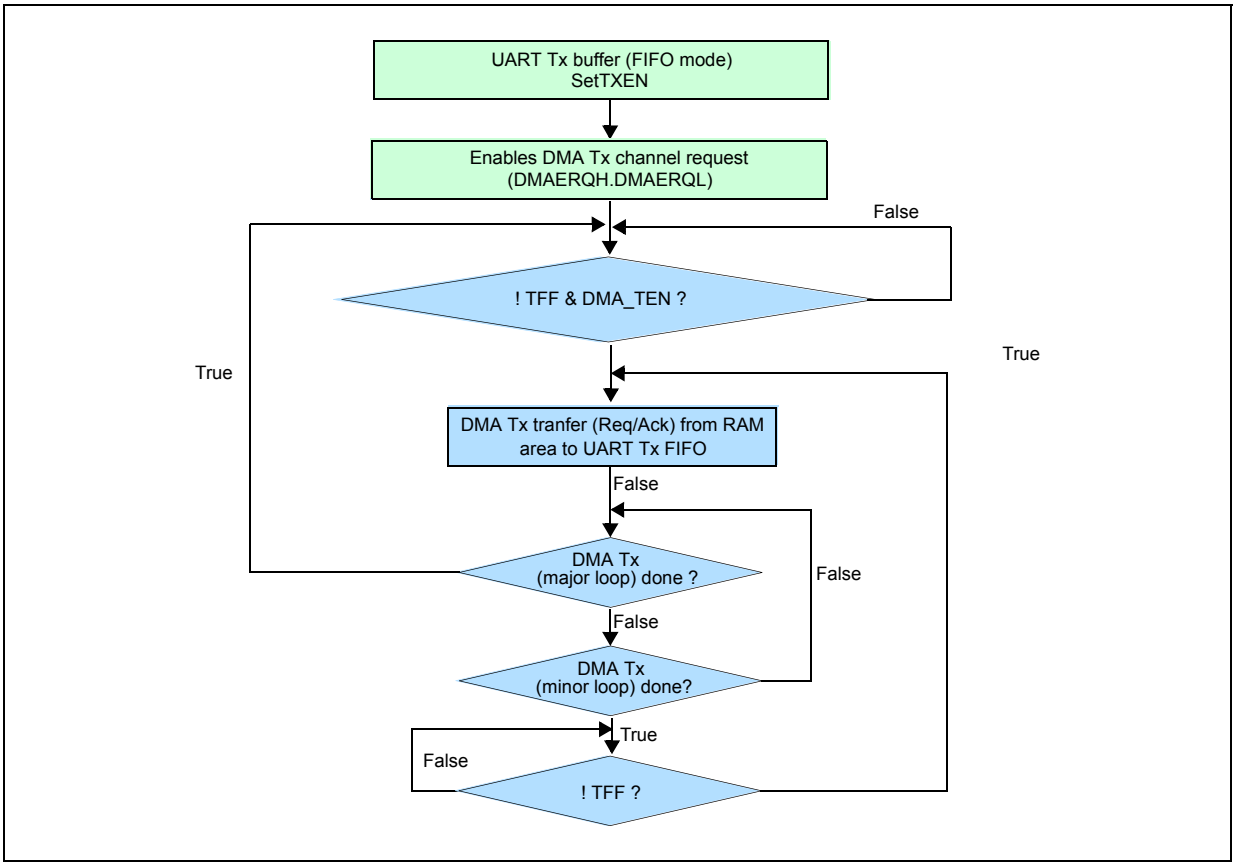
The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.



The concept FSM to control the DMA Tx interface is given in *Figure 1299*. DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in *Table 1270*. All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 1270. TCD setting — UART — Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	–M	–M × 2	—
DADDR[31:0](1)	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

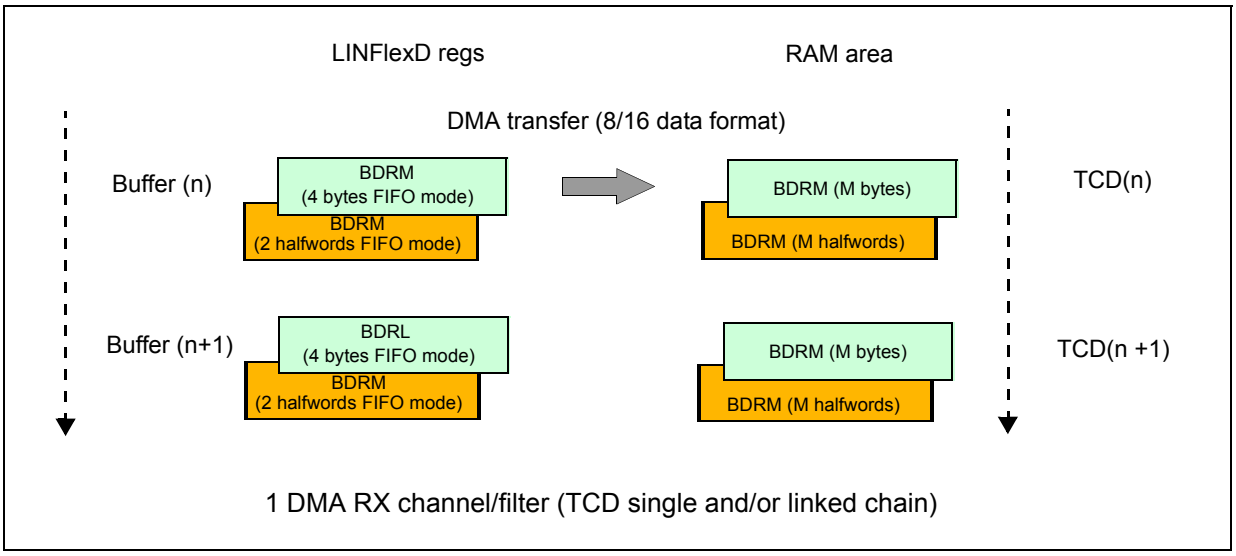


Figure 1299. UART — DMA Tx FSM (concept scheme)

57.3.5.8 UART — RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in *Table 1271*.

Figure 1300. UART — RX memory map

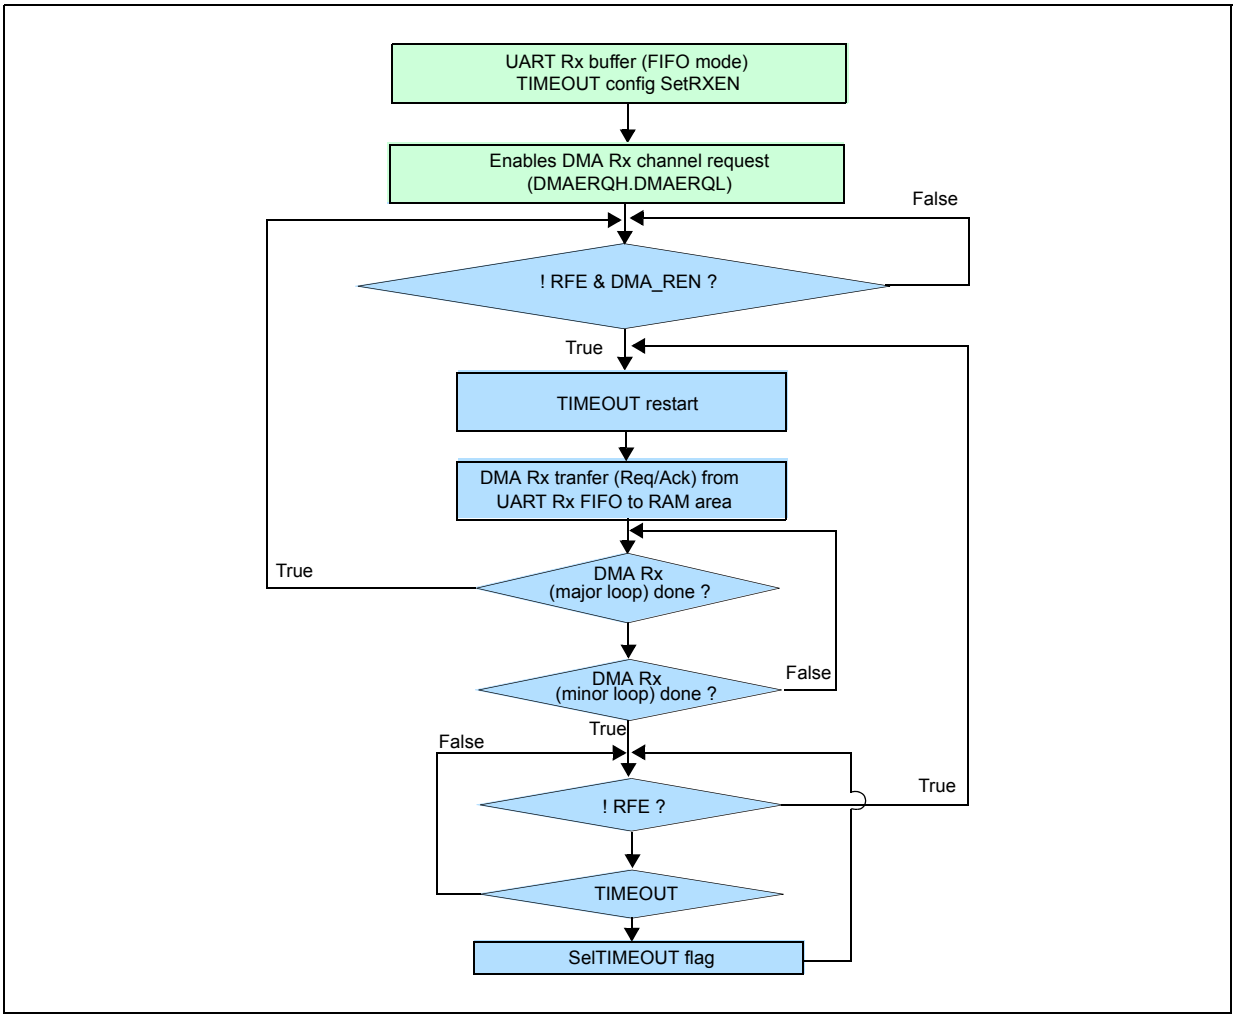
The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 µs (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.



The concept FSM to control the DMA Rx interface is given in *Figure 1301*. DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 1271. TCD setting – UART – Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0](1)	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 1301. UART — DMA Rx FSM (concept scheme)

57.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- ipd_req

  DMA peripheral request, asserted until the DMA transfer has been completed
- dma_done_lw

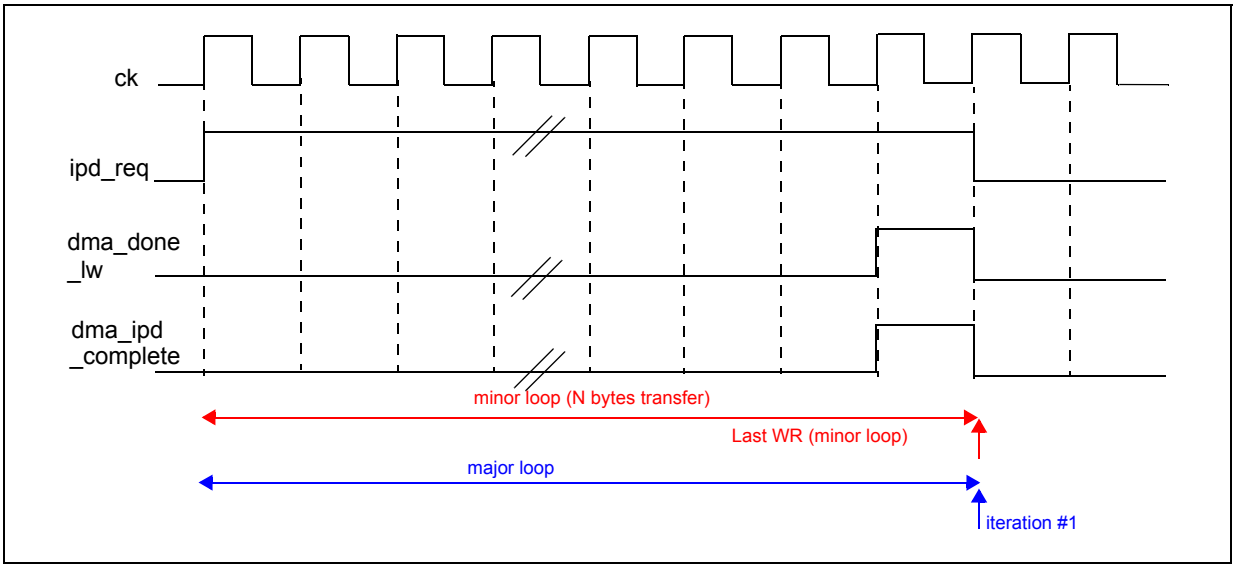
  DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected
- dma_ipd_complete

  DMA major loop finished. It is asserted for one cycle after the data phase of the last write
- dma_ipd_ack, dma_ipd_done

  Unused in this implementation

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 1302. DMA interface (major loop — single iteration)



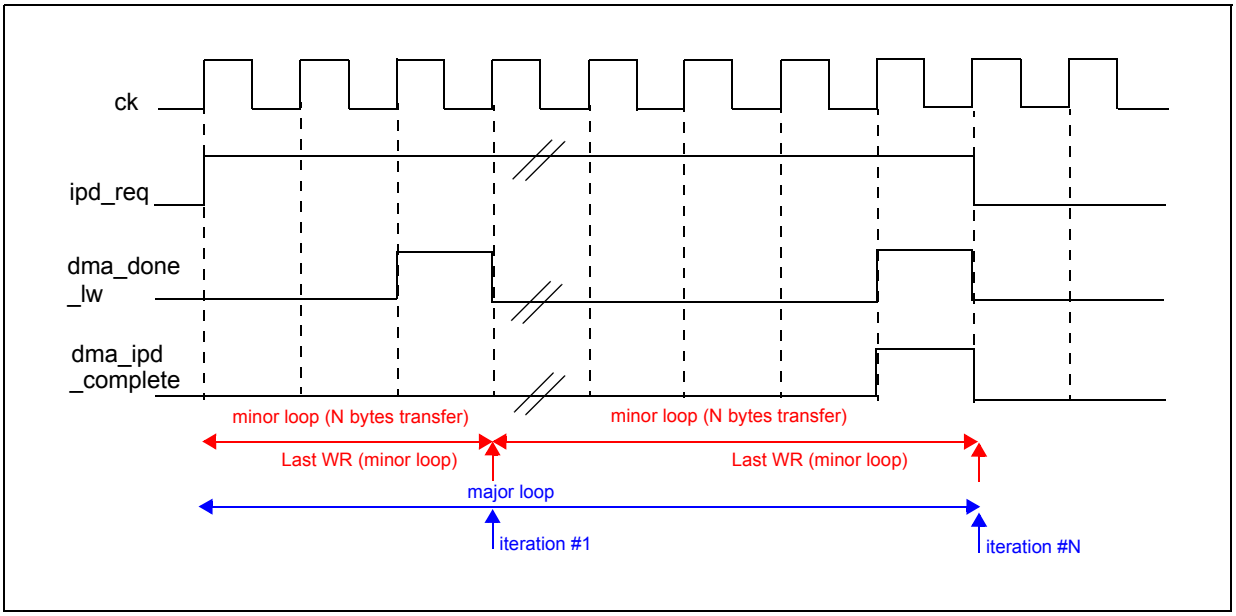


Figure 1303. DMA interface (major loop — N iteration)

57.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA

channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

57.4 Memory map and register description

57.4.1 Memory map

Table 1272 shows the LINFlexD memory/register map.

Note: In Master mode, the registers IFCR0 – IFCR15 are not present.

Note: In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in ips_xfr_err being flagged.

98[3]	DMA Tx Enable register (DMATXE)	Saf-Relv	on page 2286
9C[3]	DMA Rx Enable register (DMARXE)	Saf-Relv	on page 2287

1. No-Saf = Not safety relevant, Saf-Lat = Safety Latent, Saf-Relv = Safety Relevant, Saf-Crit = Safety Critical.
2. Refer to the device configuration chapter for the number of filters used in each instance of LINFlexD in this device.
3. The address offset depends on the no_of_filters and value of slave. Refer to the device configuration chapter for the number of filters and value of slave used in this device.

57.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

57.4.2.1 LIN Control Register 1 (LINCR1)

LINCR1 consists of control bits used to configure features of the LINFlexD.

Address 0000h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1[2]	0	0	1	0

1 This field can be read in any modes and written only in *Initialization* mode.

2 When slave = 0, this field reads '1' and cannot be programmed.

Figure 1304. LIN Control Register 1 (LINCR1)

Table 1273. LINCR1 field descriptions

Field	Description
0–15	Reserved Read returns 0
16 CCD	Checksum Calculation disable 0 Checksum calculation is done by hardware When this bit is reset the LINCFR register is read-only. 1 Checksum calculation is disabled When this bit is set the LINCFR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).

Table 1273. LINCR1 field descriptions(Continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>19
AUTOWU</td><td>Auto Wakeup
0 Sleep bit is cleared by software only
1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set
This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.</td></tr>
<tr><td>20–23
MBL[3:0]</td><td>Master Break Length
These bits choose the length of the Sync break to be generated by the master.

<table>

</table>

These bits can be programmed in Initialization mode only. They are read-only in Normal mode.</td></tr>
<tr><td>24
BF</td><td>By-pass filter
0 No IRQ if ID does not match any filter
1 A RX IRQ is generated on ID not matching any filter
This bit can be programmed during Initialization mode only.

Note: If generic slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.</td></tr>
<tr><td>25</td><td>Reserved</td></tr>
</table>

Table 1273. LINCR1 field descriptions(Continued)

Field	Description
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to *Section 57.3.2.2, Test mode*. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. **Note:** If generic *slave* = 0, then this bit will read a '1' always, and cannot be programmed.
28 SSBL	Slave Mode Sync Break Length 0 11 bit break length 1 10 bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also.

57.4.2.2 LIN Interrupt enable register (LINIER)

Address 0004h Access: User read/write

Figure 1305. LIN Interrupt enable register (LINIER)

Table 1274. LINIER field descriptions

Field	Description
0–15	Reserved Read returns 0.
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. **Note:** If generic *slave* = 0, then this bit will always read a 0 and cannot be programmed.
21–22	Reserved Read returns 0.
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR

Table 1274. LINIER field descriptions(Continued)

Field	Description
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE_TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. **Note:** If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed.

57.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Address 0008h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1306. LIN Status Register (LINSR)

Table 1275. LINSR field descriptions

Field	Description
0–11	Reserved Read returns 0
12 AUTOSYNC_COMP	Autosynchronization Completed This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers should be read in autosynchronization mode.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 1275. LINSR field descriptions(Continued)

Field	Description
16–19 LINS[3:0]	LIN state 0: Sleep mode LINFlexD is in Sleep mode, to save power consumption. 1: Init, 2: Idle This mode is entered when: – SLEEP bit and INIT bit are reset by software. – Wakeup pulse has been received on RX pin (AUTOWU set). – Previous frame transmission/reception has been completed/aborted. 3: Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. **Note:** In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle. 4: Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 5: Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 6: Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 7: Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 8: Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 9: *Checksum* Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
20–21	Reserved Read returns 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.

Table 1275. LINSR field descriptions(Continued)

Field	Description
24 RXBUSY	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. **Note:** After reset is released, RDI reflects the actual value of Rx pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin and when: – The slave is in Sleep mode – The master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flagThis bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next 8 bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** In case framing error or checksum error occurs then this flag is not set.
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. **Note:** For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: – All filters are inactive and Bypass filter (BF) bit is set – No match in any filter and Bypass filter (BF) bit is set – TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. **Note:** If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed.

57.4.2.4 LIN Error Status Register (LINESR)

Address: 000Ch Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1307. LIN error status register (LINESR)

Refer to *Section 57.3.2.5, Errors* for detailed description of all errors.

Table 1276. LINESR field descriptions

Field	Description
0–15	Reserved Read returns 0
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set, MODE bit in LINTCSR is cleared, and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINCR1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed.

Table 1276. LINESR field descriptions(Continued)

Field	Description
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. **Note:** If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed.
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. **Note:** Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set. If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed. For generic *slave* = 1,this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.
25–30	Reserved Read returns 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

57.4.2.5 UART Mode Control Register (UARTCR)

Address 0010h Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 This field can be read in any modes and written only in *Initialization* mode.
2 When TFBM = 0, the field is read/write; when TFBM = 1, the field is read-only.
3 When RFBM = 0, the field is read/write; when RFBM = 1, the field is read-only.

Figure 1308. UART Mode Control Register (UARTCR)

Table 1277. UARTCR field descriptions

Field	Description
0 MIS	Monitor Idle State 1 UARTCTO monitors the idle state of the reception line. 0 UARTCTO monitors the number of bits to be received. The default value of this bit is 0.
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: **OSR** / **CSP**: 4 / 2, 3; 5 / 2, 3, 4; 6 / 3, 4, 5; 8 / NA For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.

Table 1277. UARTCR field descriptions(Continued)

Field	Description
8 ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.
12 DTU_PCETX	Disable Timeout in UART mode 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received (num_of_frames). When num_of_frames equals NEF, Disable Timeout is set and num_of_frames gets reset to zero, restarting the timer and enabling the timeout again.
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.

Table 1277. UARTCR field descriptions(Continued)

Field	Description
16–18 TDFL_TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 15 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 1 byte x01 2 bytes x10 3 bytes x11 4 bytes TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 empty 001 1 byte 010 2 bytes 011 3 bytes 100 4 bytes Others: Reserved TDFL/TFC can be programmed and are significative only when the UART bit is set.
19–21 RDFL_RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 1 byte x01 2 bytes x10 3 bytes x11 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 Empty 001 1-byte 010 2 bytes/1.5 byte in case of WLS bit setting 011 3 bytes 100 4 bytes/2×1.5 byte in case of WLS bit setting Others: Reserved RDFL/RFC can be programmed and are significative only when the UART bit is set. **Note:** In buffer mode, RDFL should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.
22 RFBM	RFBM Rx Fifo/Buffer mode 0 Rx Buffer mode enabled 1 Rx Fifo mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx Fifo/Buffer mode 0 Tx Buffer mode enabled 1 Tx Fifo mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.

Table 1277. UARTCR field descriptions(Continued)

Field	Description
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
26 RXEN	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TXEN	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “PC1” and “PC0” to describe the functionality of word length in UART mode.
29 PCE	Parity Control Enable 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.

Table 1277. UARTCR field descriptions(Continued)

Field	Description
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 11015 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set. **Note:** The two-digit binary values are a combination of the fields “WL1” and “WL0” to describe the functionality of word length in UART mode.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

57.4.2.6 UART Mode Status Register (UARTSR)

Address 0014h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	SZF	OCF	PE				RMB	FEF	BOF	RDI	WUF	RFNE	TO	DRF_RFE[1]	DTF_TFF[2]	NF
W	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C		W1C			W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 When RFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when RFBM = 1, the field is read-only.

2 When TFBM = 0, the field can be read/cleared by software. Writing 1 clears contents; when TFBM = 1, the field is read-only.

Figure 1309. UART Mode Status Register (UARTSR)

Table 1278. UARTSR field descriptions

Field	Description
0–15	Reserved Read returns 0
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.

Table 1278. UARTSR field descriptions(Continued)

Field	Description
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. **Note:** For Baud rate above 1 Mbit/s, this flag is not usable.
18—21 PE[0:3]	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. PE[i] (where i = 0,1,2 or 3) can be equal to: 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. **Note:** Parity is checked only after a complete frame is received. When WL bits = 10 or 11, either PE[0] or PE[2] is only set. – When PE[0] is set, it indicates Parity error in either first or second byte received. – When PE[2] is set, it indicates Parity error in either third or fourth byte received.
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.

Table 1278. UARTSR field descriptions(Continued)

Field	Description
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software.The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF_RFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF_TFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

57.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Address 0018h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

1 This field can be read in any modes and written only in *Initialization* mode.

Figure 1310. LIN Time-Out Control Status Register (LINTCSR)

Table 1279. LINTCSR field descriptions

Field	Description
0–20	Reserved Read returns 0.
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event This feature is applicable only when MODE bit in LINTCSR is cleared.
23 TOCE	Time-out counter enable 0 Time-out counter disable OCF flag is not set on an output compare event. 1 Time-out counter enable OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24–31 CNT[0:7]	Counter Value These bits reflect the value of a free-running counter used for timeout. **Note:** For proper functionality of this counter, LINIBRR should be $\geq$ 5.

57.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the LINTOCR value. This register is writable by software only in Output Compare Mode.

Address 001Ch Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

[1] This reset value is valid only in Master mode.

Figure 1312. LIN Time-Out Control Register (LINTOCR)

Table 1281. LINTOCR field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–23 RTO[3:0]	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{Response_Maximum} = 1.4 \times T_{Response_Nominal}$

Table 1281. LINTOCR field descriptions(Continued)

Field	Description
24	Reserved Read returns 0.
25–31 HTO[6:0]	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is the 2Dh = 45, corresponding to $T_{Header_Maximum}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 28 (1.4 × 10 bits of sync + 1.4 × 10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

57.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

Note: This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

Address 0024h Access: User read/write

1 This field can be read in any modes and written only in *Initialization* mode.

2 This field can be read/set by software.

3 When slave = 0, this field reads ‘1’ and cannot be programmed.

Figure 1316. LIN Control Register 2 (LINCR2)

Table 1285. LINCR2 field descriptions

Field	Description
0–15	Reserved Read returns 0.
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. If generic *slave* = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.

Table 1285. LINCR2 field descriptions(Continued)

Field	Description
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. **Note:** In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.
24–31	Reserved Read returns 0.

57.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Address 0034h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1317. Buffer Identifier Register (BIDR)

Table 1286. BIDR field descriptions

Field	Description
0–15	Reserved Read returns 0.
16–21 DFL[5:0]	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1 **Note:** DFL[5:3] is provided for extended frames. Normally LIN mode will use DFL[2:0]. Identifier filters are now compatible with DFL[5:0] also.

Table 1286. BIDR field descriptions(Continued)

Field	Description
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives the data and copy them in the BDR registers 1 LINFlexD transmits the data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only This is compatible with LIN specification 1.3 and lower.
24–25	Reserved Forced to 0 by hardware.
26–31 ID[5:0]	Identifier Identifier part of the identifier field without the identifier parity. This field can be written only in Master mode (MME = ‘1’).

57.4.2.15 Buffer Data Register Least Significant (BDRL)

This register is a part of an 8-byte data buffer.

Address 0038h Access: User read/write

Figure 1320. Identifier Filter Enable Register (IFER)

Table 1289. IFER field descriptions

Field	Description
0–15	Reserved Read returns 0
16–31 FACT[15:0]	Filter active The software sets the bit FACT[x] to activate the filter x in Identifier list mode. 1. In Identifier mask mode, FACT (2n+1) have no effect on the corresponding filters as they act as mask for the Identifier 2n. 2. The length of this field depends on the value of no_of_filters. 3. The register diagram depicts the maximum no_of_filters, which can be up to 16. **Note:** Refer to device configuration chapter to see the number of filters used in the device.

57.4.2.18 Identifier Filter Match Index (IFMI)

This register contains the index corresponding to the received ID. It can be used to read or write the data directly in RAM.

Address 0044h Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

2 Refer to device configuration chapter to see the number of filters used in the device

Figure 1324. Identifier Filter Control Register (IFCR2n+1)

Table 1293. IFCR2n+1 field descriptions

Field	Description
0–15	Reserved Read returns a 0
16–21 DFL[5:0]	Data Field Length Number of data bytes in the response part of the frame. DFL[5:0] = Number of data bytes – 1
22 DIR	Direction This bit controls the direction of the data field. 0 LINFlexD receives data and copies to the BDR registers 1 LINFlexD transmits data from the BDR registers
23 CCS	Classic Checksum This bit controls the type of checksum applied on the current message. 0 Enhanced Checksum covering Identifier and Data fields This is compatible with LIN specification rev. 2.0 and higher. 1 Classic Checksum covering Data field only This is compatible with LIN specification 1.3 and lower.
24–25	Reserved Forced to 0 by hardware.
26–31 ID[5:0]	Identifier Identifier part of the identifier field without the identifier parity.

57.4.2.22 Global Control Register (GCR)

This register is read-only in Normal mode and can be programmed only in Initialization mode. This is a global control register — in other words, the register configuration will be applied in LIN mode as well as in UART mode.

Address 4C+4×no_of_filters×slave[3] Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 This field can be read in any modes and written only in *Initialization* mode.

2 This field can be written only by software in *Initialization* mode. This field reads 0 by software.

3 Refer to device configuration chapter to see the number of filters and value of slave used in the device.

Figure 1325. Global Control Register (GCR)

Table 1294. GCR field descriptions

Field	Description
0–25	Reserved Forced to 0 by hardware
26 TDFBM	Transmit data first bit MSBThis bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. 0 Transmitted data is not inverted 1 Transmitted data is inverted
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. 0 Received data is not inverted 1 Received data is inverted

Table 1294. GCR field descriptions(Continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>30
STOP</td><td>1/2 stop bit configuration
This bit controls the number of stop bit transmitted data in both UART and LIN modes.
The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload).
0 1 stop bit
1 2 stop bits</td></tr>
<tr><td>31
SR</td><td>Soft reset
SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. The following table describes, the register fields reset by SR:
<table>
<tr><th>Register</th><th>Comment</th></tr>
<tr><td>LINSR</td><td>All fields except RXbusy and AUTOSYNC_COMP are reset</td></tr>
<tr><td>LINESR</td><td>All fields are reset</td></tr>
<tr><td>LINTCSR</td><td>Only CNT[0:7] is reset</td></tr>
<tr><td>UARTSR</td><td>All fields except RFE & TFF are reset</td></tr>
<tr><td>UARTCR</td><td>Only TFC & RFC are reset</td></tr>
<tr><td>UARTCTO</td><td>All fields are reset</td></tr>
</table>
</td></tr>
</table>

57.4.2.23 UART Preset Timeout Register (UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

Address (GCR address)[1]+04h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	PTO											
W																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

[1] Depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Figure 1326. UART Preset Timeout Register (UARTPTO)

Table 1295. UARTPTO field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–31 PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A value of 0, 1 or 2 is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer to the UARTCTO register.

57.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see *Section 57.4.2.23, UART Preset Timeout Register (UARTPTO)* to monitor the number of bits received by UARTor to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGEx_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGEx_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

*Note: Due to this synchronisation, UARTCTO reflects the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) which was present on it, before 4 to 6 clock cycles of PBRIDGEx_CLK.*

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO-1
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

Address (GCR address)[1]+08h Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 Depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Figure 1327. UART Current Timeout Register (UARTCTO)

Table 1296. UARTCTO field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–31 CTO[11:0]	Current Timeout CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

57.4.2.25 DMA Tx Enable Register (DMATXE)

This register enables the DMA TX interface. This register can be written and read by software any time.

Address (GCR address)[1]+0Ch Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

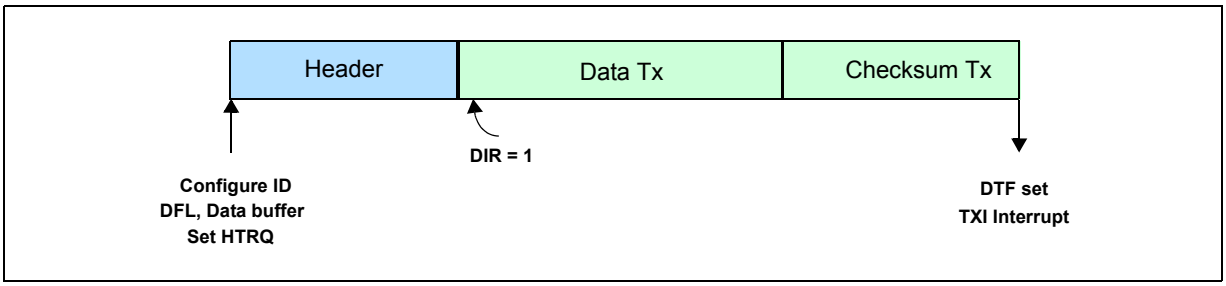
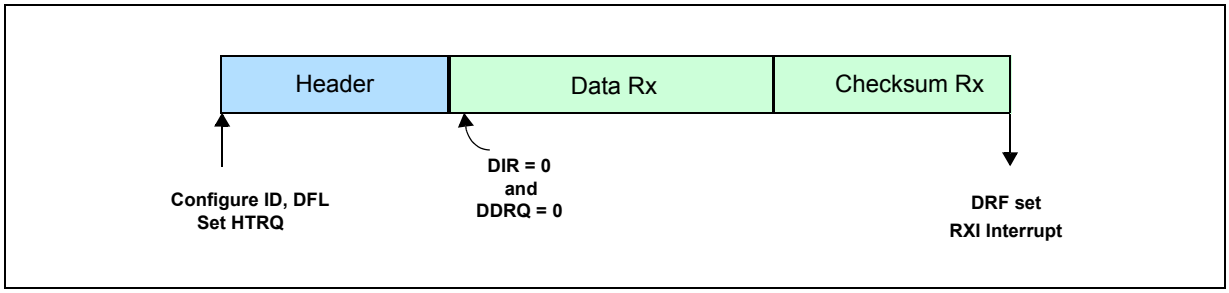
57.5 Programming considerations



The next subsections describe the various configurations in which the LINFlexD module can be used.

57.5.1 Master node

LINFlexD acts as Master when the MME bit is set.



57.5.1.1 Transmitter

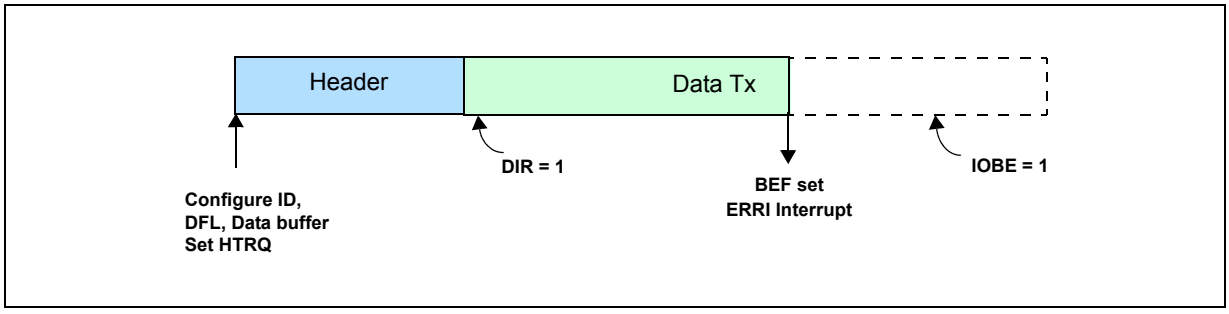
Figure 1330. Master node — transmitter configuration

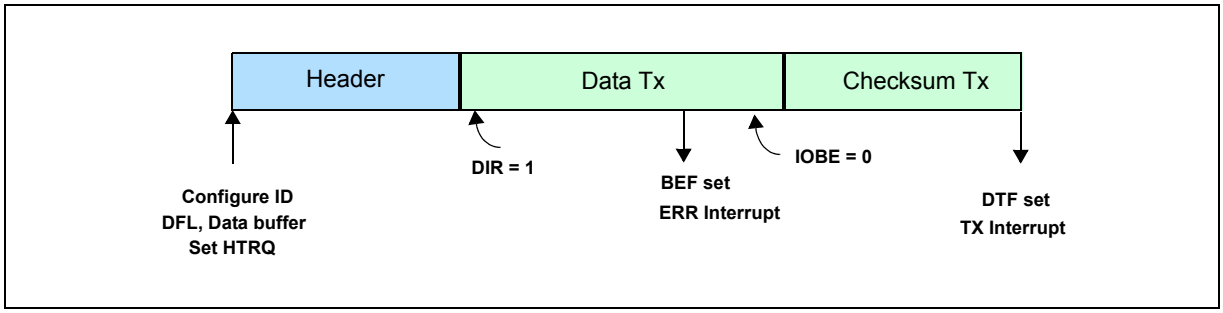
57.5.1.2 Receiver

Figure 1331. Master node — receiver configuration

57.5.1.3 Transmitter, Bit Error

Figure 1332. Master node — transmitter, bit error configuration





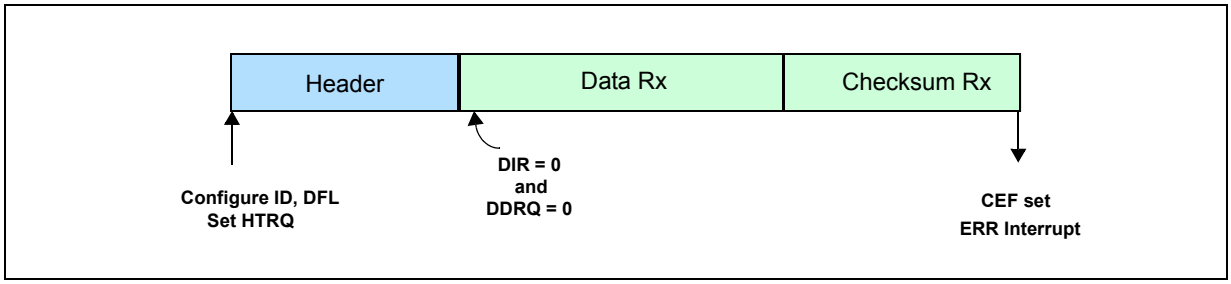


Figure 1333. Master node — transmitter, checksum error configuration

57.5.1.4 Receiver, Checksum Error

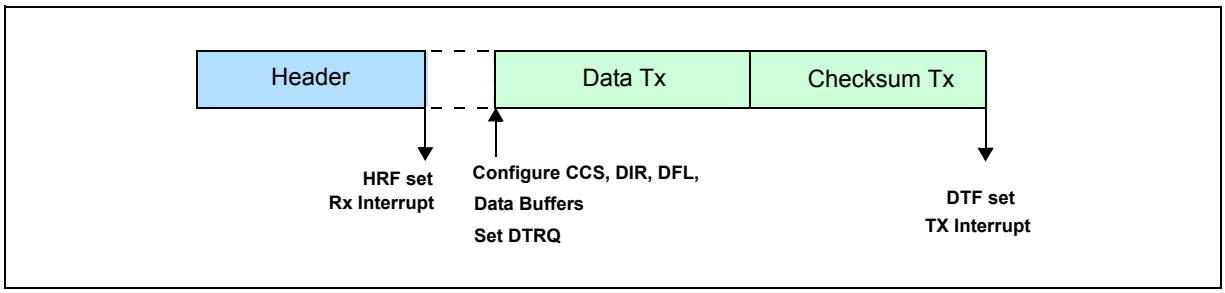

Figure 1334. Master node — receiver, checksum error configuration

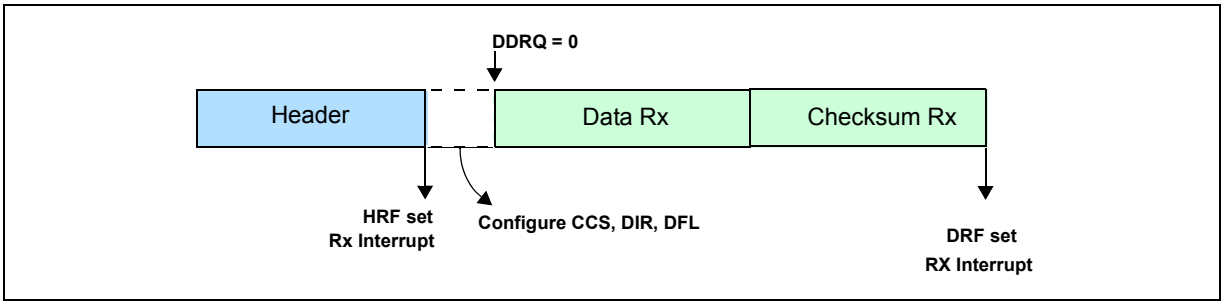
57.5.2 Slave node

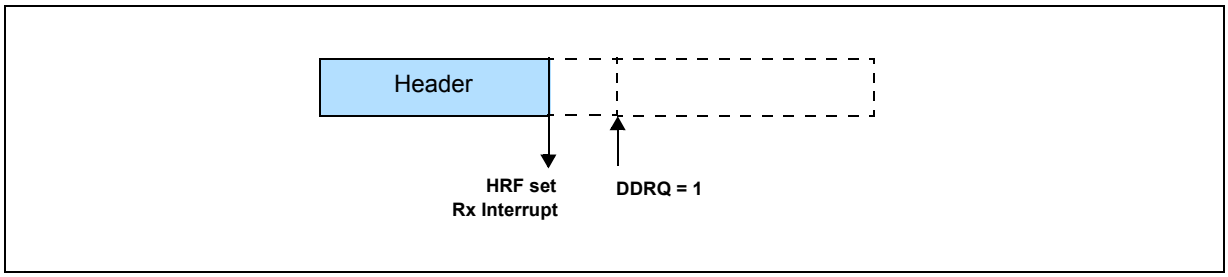
57.5.2.1 Transmitter (no identifier filters)

Figure 1335. Slave node — transmitter (no identifier filters) configuration

57.5.2.2 Receiver (no identifier filters)

Figure 1336. Slave node — receiver (no identifier filters) configuration





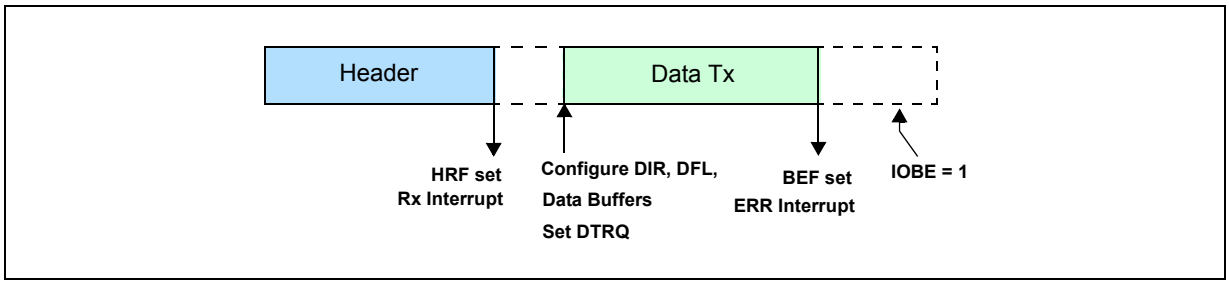


Figure 1337. Slave node — receiver (no identifier filters) configuration

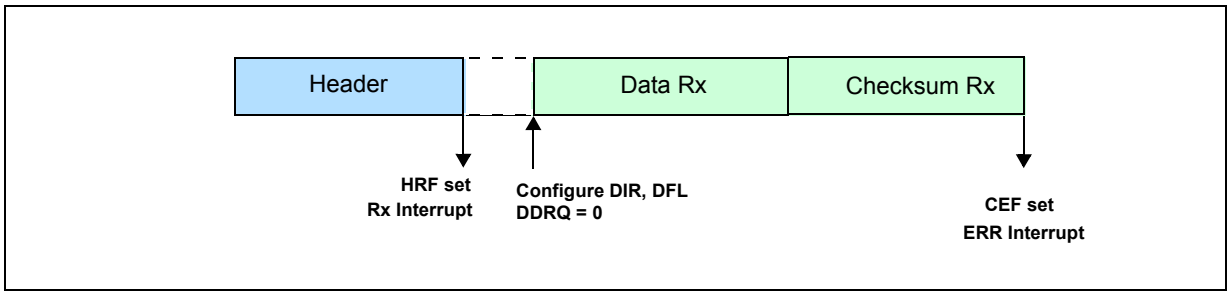

57.5.2.3 No filters, transmitter, bit error

Figure 1338. Slave node — No filters, transmitter, bit error configuration

57.5.2.4 No filters, receiver, checksum error

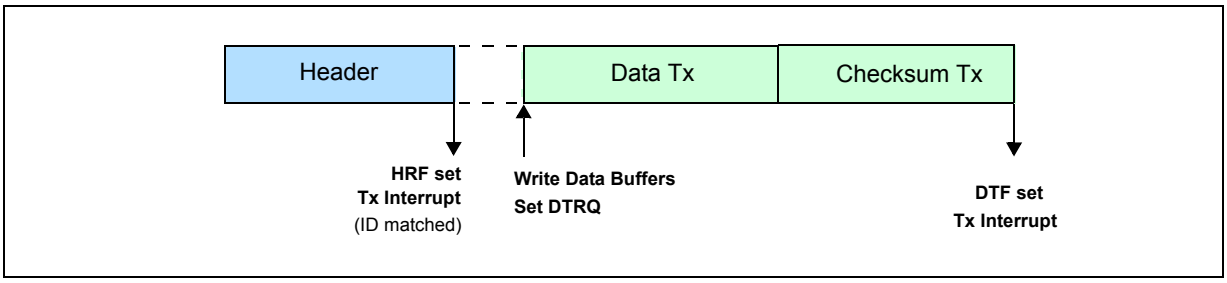

Figure 1339. Slave node — No filters, receiver, checksum error configuration

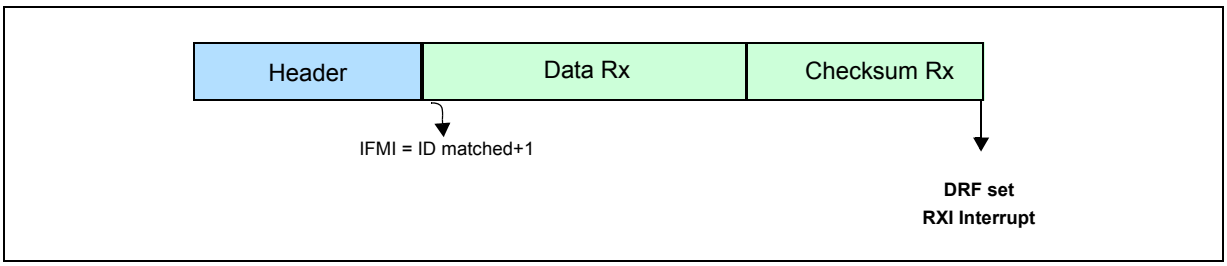
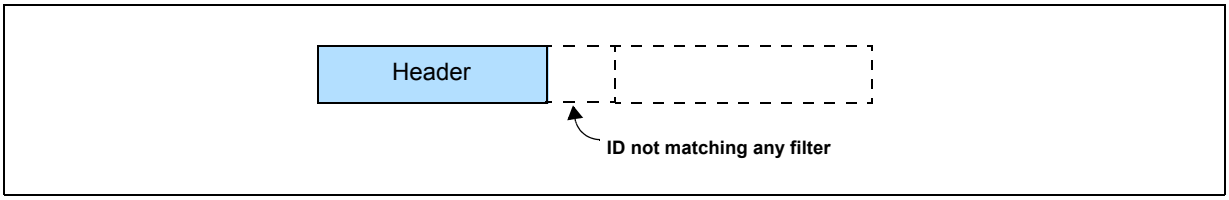
57.5.2.5 At least one TX filter, BF is reset, ID matches filter



This configuration can be used in case slave never receives data, for example, sensor.

Figure 1340. Slave node — one TX filter configuration



57.5.2.6 At least one RX filter, BF reset, ID matches filter

Figure 1341. Slave node — one RX filter configuration

57.5.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

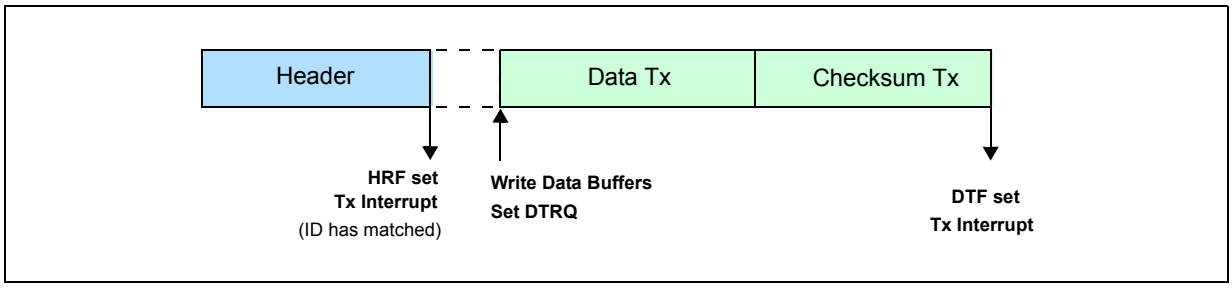
Figure 1342. RX only, TX only, RX & TX filters configuration

57.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

Figure 1343. TX filter, BF is set configuration — ID has matched



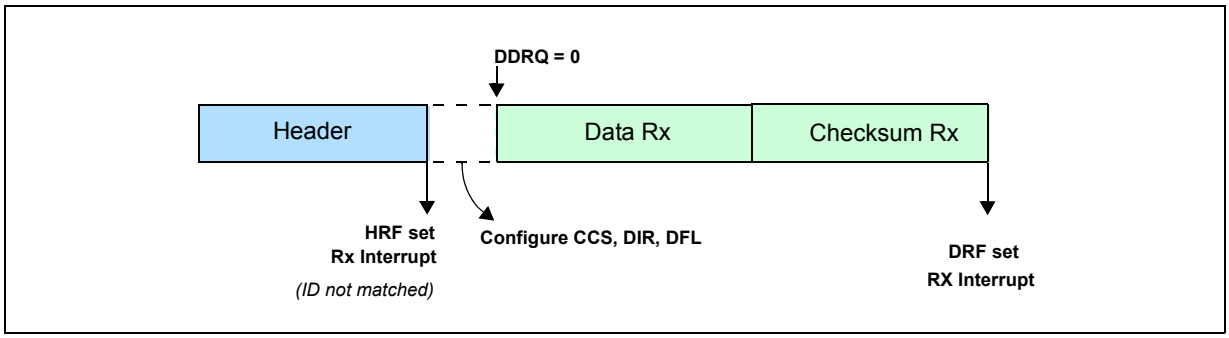


Figure 1344. TX filter, BF is set configuration — ID not matched

57.5.2.9 RX filter, BF is set

Figure 1345. RX filter, BF is set configuration — ID matched

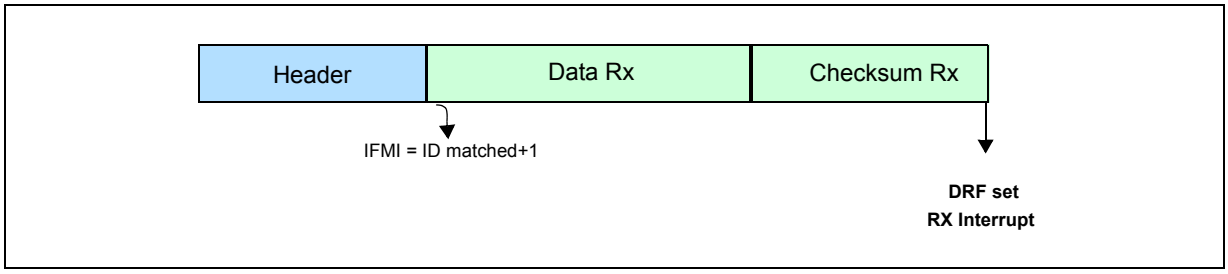

Figure 1346. RX filter, BF is set configuration — ID not matched (ID is Rx)

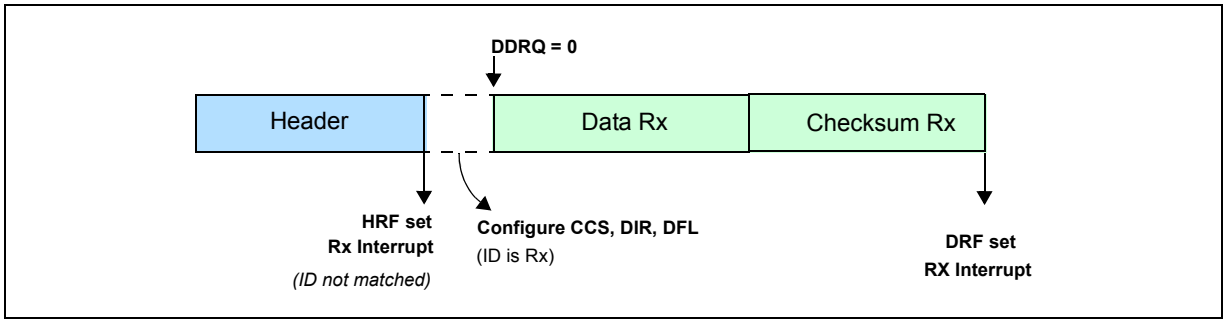

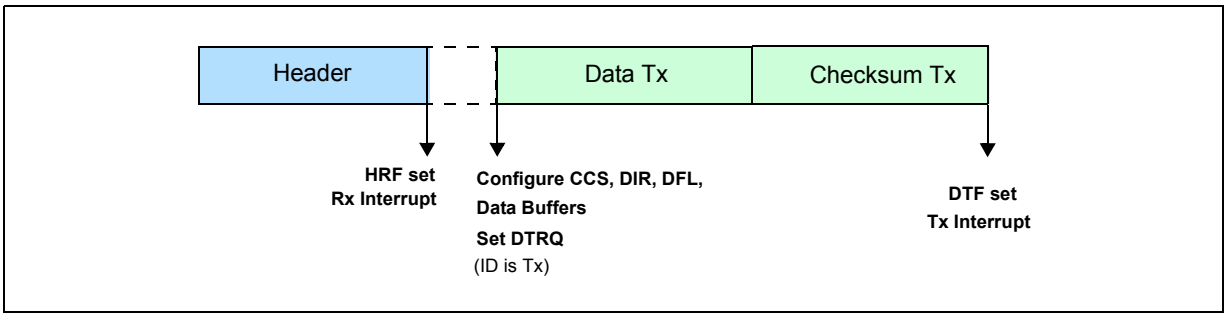

Figure 1347. RX filter, BF is set configuration — (ID is Tx)

57.5.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

Figure 1348. TX filter, RX filter, BF set configuration — (ID matched)

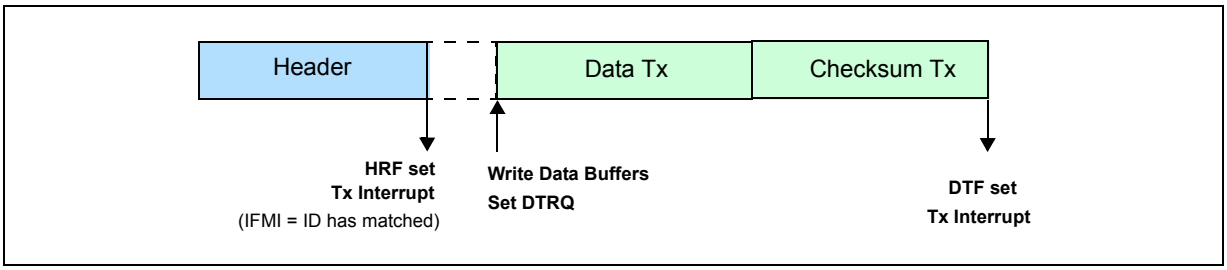

Figure 1349. TX filter, RX filter, BF set configuration — (ID matched + 1)

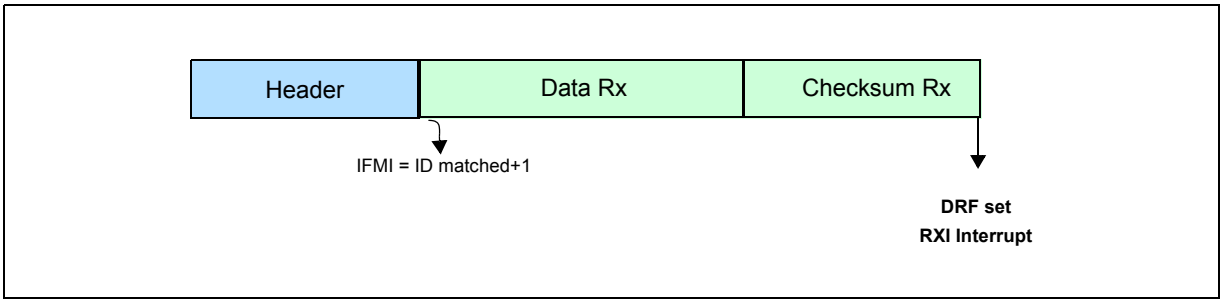

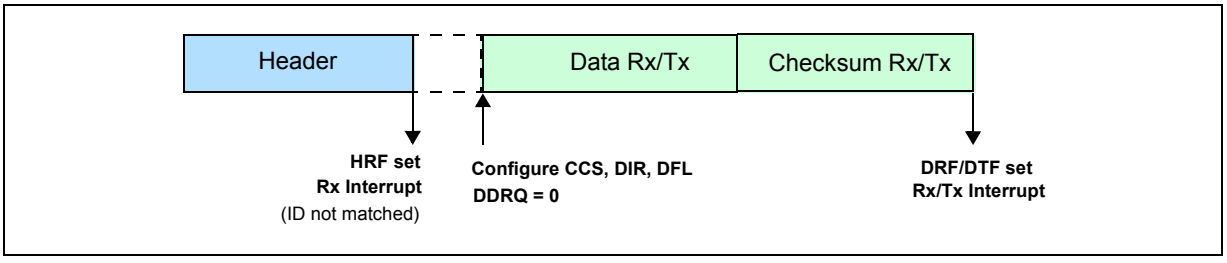

Figure 1350. TX filter, RX filter, BF set configuration — (ID not matched, RX/TX Interrupt)

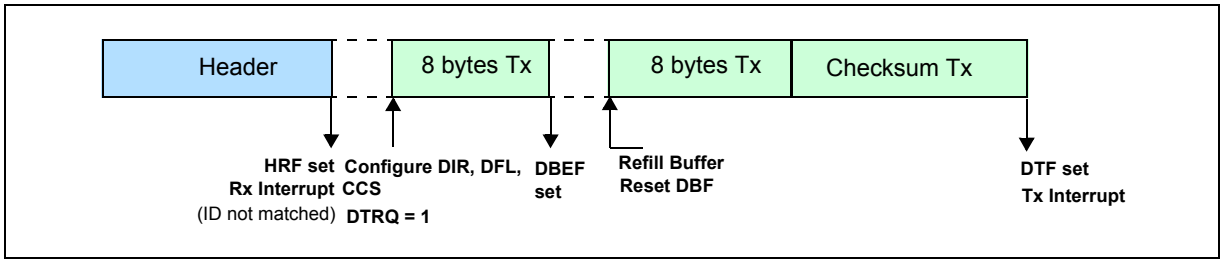
57.5.3 Extended frames

Figure 1351. Extended frames (TX Interrupt)



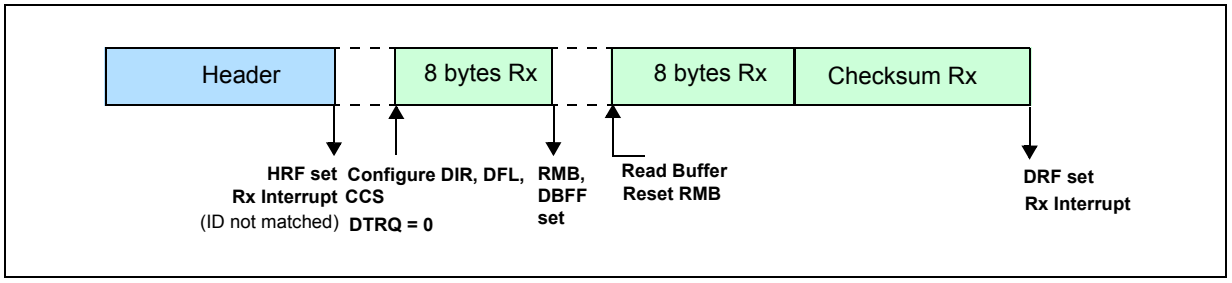


Figure 1352. Extended frames (RX Interrupt)

57.5.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

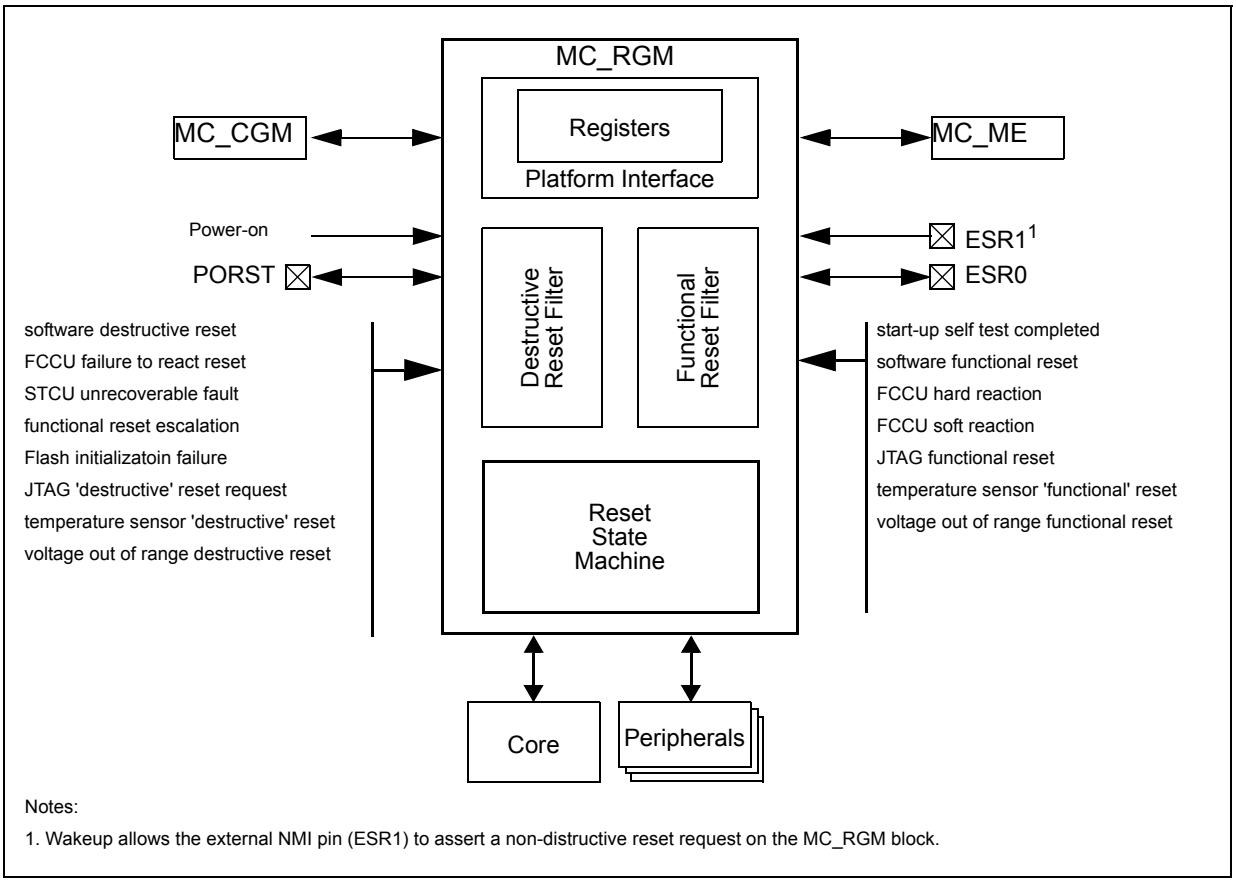
58 Reset Generation Module (MC_RGM)

58.1 Introduction



This chapter includes, but is not limited to, the funtionality, pin description, and registers of the MC_RGM module.

58.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

Figure 1358 shows the MC_RGM block diagram.

Figure 1358. MC_RGM block diagram

Notes:

1. Wakeup allows the external NMI pin (ESR1) to assert a non-distructive reset request on the MC_RGM block.

58.1.2 Features

The MC_RGM contains the following features:

- Destructive resets management.
- Functional resets management.
- Signalling of reset events after each reset sequence (reset status flags).
- Conversion of reset events to SAFE mode or interrupt request events.
- Short reset sequence configuration.
- Bidirectional reset behavior configuration.
- Configurable escalation of recurring functional resets to a *destructive* reset.
- Configurable escalation of recurring destructive resets to keep chip in reset state until next power-on reset.

58.1.3 Reset sources

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released and the state machine proceeds to the next phase until reaching the IDLE phase. At this stage, the MC_ME state machine exits RESET and enters DRUN mode.

Some reset source events can instead be converted to either a SAFE mode request to the MC_ME or an interrupt issued to the core (see *Section 58.3.1.2, Destructive Event Reset Disable (RGM_DERD) register* and *Section 58.3.1.3, Destructive Event Alternate Request (RGM_DEAR) register* for ‘destructive’ resets and *Section 58.3.1.6, Functional Event Reset Disable (RGM_FERD) register* and *Section 58.3.1.7, Functional Event Alternate Request Register (RGM_FEAR)* for ‘functional’ resets).

Destructive resets (see *Section 58.4.2, Destructive resets*) include:

- Power-on reset.
- External power-on reset.
- Software destructive reset.
- FCCU failure to react reset.
- STCU2 unrecoverable fault.
- Functional reset escalation.
- Flash initialization failure.
- JTAG destructive reset request.
- SSCM destructive reset request.
- Temperature sensor destructive reset.
- Voltage out of range destructive reset.

Functional resets (see *Section 58.4.4, Functional resets*) include:

- ESR0 external reset.
- ESR1 external reset.
- Start-up self test completed.
- Software functional reset.
- FCCU hard reaction.
- FCCU soft reaction.
- JTAG functional reset request.
- Temperature sensor functional reset.
- Voltage out of range functional reset.

58.2 External signal description

The MC_RGM interfaces to the bidirectional reset pin ESR0.

58.3 Memory map and register definition

1. individual bits cleared on writing ‘1’
2. write once: ‘0’ = enable, ‘1’ = disable.

Note: Any access to unused registers as well as write accesses to read-only registers:

- *does not change register content*
- *causes a transfer error*

58.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

The reset values of read-only fields cannot be changed.

58.3.1.1 Destructive Event Status (RGM_DES) register

This register contains the status of the destructive reset sources, including those configured to not generate a reset sequence. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Register bits are cleared on write '1'. This register is reset only on power-on.

Address 0x000 Access: User read, Supervisor read/write, Test read/write

Table 1302. RGM_DES register field descriptions

Field	Description
0–6	Reserved
7 F_VOR_DEST	Flag for voltage out of range destructive reset **Note:** This bit could become set after POR, but before software can read its value. The state of this bit should be considered indeterminate by software after initial power up. 0 No reset event has occurred since the last clear 1 A reset event has occurred
8 F_TSR_DEST	Flag for temperature sensor destructive reset 0 No reset event has occurred since the last clear 1 A reset event has occurred
9–16	Reserved

Table 1302. RGM_DES register field descriptions(Continued)

Field	Description
17 F_SSCM_DEST	Flag for SSCM destructive reset request 0 No reset event has occurred since either the last clear or the last power-on reset assertion. 1 An reset request event has occurred
18–20	Reserved
21 F_JTAG_DEST	Flag for JTAG destructive reset request 0 No reset event has occurred since the last clear 1 A reset event has occurred
22 F_FIF	Flag for Flash initialization failure 0 No reset event has occurred since the last clear 1 A reset event has occurred
23 F_EDR	Flag for functional reset escalation 0 No reset event has occurred since the last clear 1 A reset event has occurred
24–25	Reserved
26 F_SUF	Flag for STCU unrecoverable fault reset 0 No reset event has occurred since the last clear 1 A reset event has occurred
27 F_FFRR	Flag for FCCU failure to react reset 0 No reset event has occurred since the last clear 1 A reset event has occurred
28 F_SOFT_DEST	Flag for software destructive reset 0 No reset event has occurred since the last clear 1 A reset event has occurred
29	Reserved
30 F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred
31 F_POR	Flag for Power-on reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

58.3.1.2 Destructive Event Reset Disable (RGM_DERD) register

This register disables specific destructive reset sources. When a destructive reset source is disabled, the associated destructive event will trigger either a SAFE mode request or an interrupt request (see *Section 58.3.1.3, Destructive Event Alternate Request (RGM_DEAR) register*). Supervisor and test modes allow read/write access whereas read-only access is allowed in user mode. Each byte can be written only once after a destructive or power-on reset.

This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to ‘1’. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address 0x010 Access: User read, Supervisor read, Test read

23 D_EDR	Disable functional reset escalation destructive reset 0 Triggers a reset sequence
24–25	Reserved
26 D_SUF	Disable STCU unrecoverable fault destructive reset 0 Triggers a reset sequence
27 D_FFRR	Disable FCCU failure to react destructive reset 0 Triggers a reset sequence

Table 1303. RGM_DERD field descriptions(Continued)

Field	Description
28 D_SOFT_DEST	Disable software destructive reset 0 Triggers a reset sequence
29	Reserved
30 D_PORST	Disable external power-on reset 0 Triggers a reset sequence 1 Generates a SAFE mode or an interrupt request depending on the values in RGM_DEAR
31 D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

58.3.1.3 Destructive Event Alternate Request (RGM_DEAR) register

This register generates an alternate request when a reset on a destructive event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

This register is reset only on power-on.

58.3.1.5 Functional Event Status (RGM_FES) register

This register contains the status of the functional reset sources, including those configured to not generate a reset sequence. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Register bits are write ‘1’ cleared (w1c) if the triggering event has already been cleared at the source. This register is reset only on power-on.

Note: If a functional reset source is configured to generate a SAFE mode or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit to avoid multiple SAFE mode requests or interrupts for the same event. To avoid counting cycles, software can check whether the RGM_FES has been properly cleared and clear it again if this is not the case.

Address 0x300 Access: User read, Supervisor read/write, Test read/write

58.3.1.6 Functional Event Reset Disable (RGM_FERD) register

This register provides dedicated bits to disable functional reset sources.When a functional reset source is disabled, the associated functional event triggers either a SAFE mode request or an interrupt request (see *Section 58.3.1.7, Functional Event Alternate Request Register (RGM_FEAR)*). Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any destructive reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Address 0x310 Access: User read, Supervisor read/write, Test read/write

58.3.1.7 Functional Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a functional event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

This register is reset only on power-on and any destructive reset.

Address 0x320 Access: User read, Supervisor read/write, Test read/write

58.3.1.8 Functional Bidirectional Reset Enable (RGM_FBRE) register

This register enables the generation of an external reset on functional reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any destructive reset.

Address 0x330 Access: User read, Supervisor read/write, Test read/write

58.3.1.10 Functional Reset Escalation Threshold (RGM_FRET) register

This register sets the threshold for functional reset escalation to a destructive reset. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

Writing a non-zero value to the FRET field enables the functional reset escalation function. Writing any value to this register resets the functional reset counter. See *Section 58.4.6, Functional reset escalation* for details on the functional reset escalation function.

This register is reset only on power-on and any destructive reset.

Table 1311. RGM_FRET field descriptions

Field	Description
0–3	Reserved
4–7 FRET	Functional Reset Escalation Threshold If the value of this field is 0, the functional reset escalation function is disabled. Any other value is the number of functional resets which cause a destructive reset if the RGM_FRET register is not written to beforehand.

58.3.1.11 Destructive Reset Escalation Threshold (RGM_DRET) register

This register sets the threshold for destructive reset escalation, keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode.

Writing a non-zero value to the DRET field enables the destructive software reset escalation function. Writing any value to this register resets the destructive reset counter. See *Section 58.4.7, Destructive reset escalation* for details on the destructive reset escalation function.

This register is reset only on power-on.

Any other value is the number of destructive resets which keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand.

58.3.1.12 External Reset Output Extension Control (RGM_EROEC) register

This register controls the assertion of the ESR0 pin after the reset sequence has completed. Supervisor and test modes allow for read/write access, whereas read access only is allowed in user mode. The register bit is write ‘1’ cleared (w1c).

Clearing the EROEC bit causes the MC_RGM to stop asserting the ESR0 pin within two 16 MHz internal RC oscillator clock cycles. The ESR0 pin cannot be asserted by writing to this register.

This register also provides the current value sampled on ESR0 via the ERIS bit. This is useful for software to poll if, for example, ESR0 is used in the system to synchronize the application software with an external event.

This register is reset only on power-on.

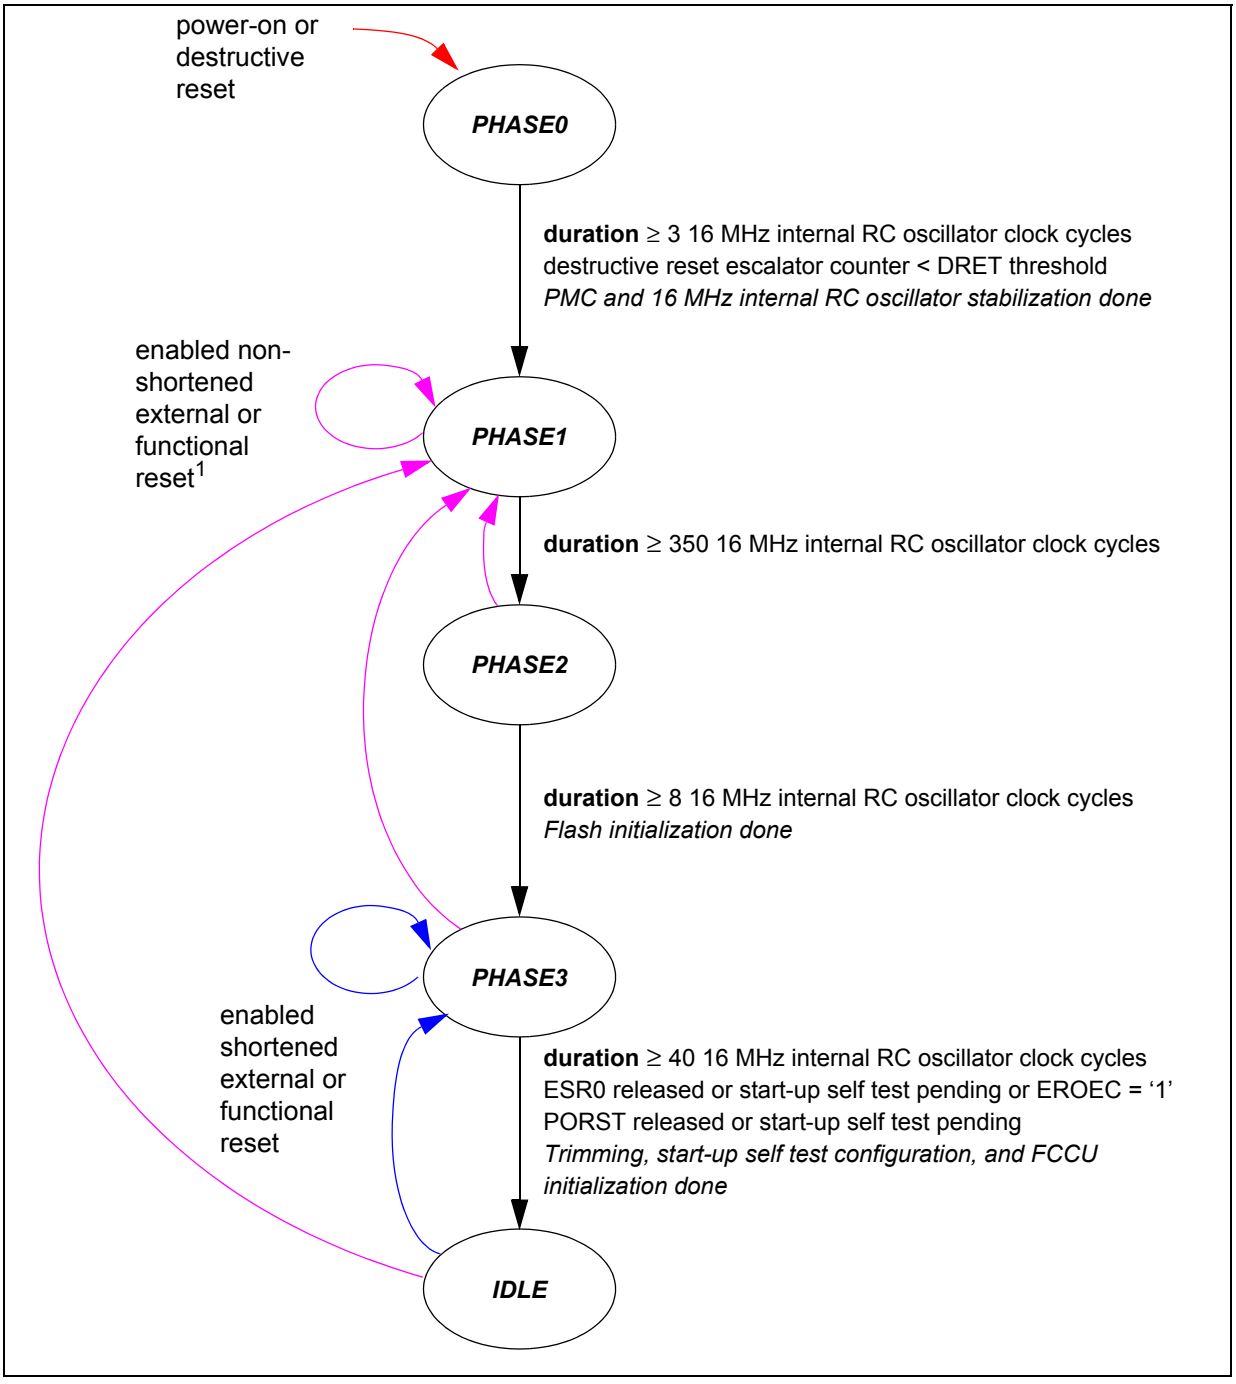
58.4 Functional description

58.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in *Table 1330*.

Table 1330. MC_RGM reset implications

Source	Modules subject to reset	External reset assertion(1)	Boot mode capture
Power-on reset	All	Yes	Yes
destructive resets	All except some clock/reset management	Yes	Yes
External reset	All except some clock/reset management and debug	Programmable (2)	Yes
functional resets	All except some clock/reset management and debug	Programmable[2]	Programmable (3)
Shortened functional resets(4)	Flip-flops except some clock/reset management and debug	Programmable[2]	Programmable[3]



1. ESR0 pin is asserted by the MC_RGM from the start of the reset sequence until the end of PHASE3.
2. The assertion of the external reset is controlled via the RGM_FBRE register.
3. The boot mode is captured if the external reset is asserted.
4. The short sequence is enabled via the RGM_FESS register.

Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence has five phases managed by a state machine which ensures that all phases are correctly processed by waiting a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in *Figure 1387*.

Figure 1387. MC_RGM State Machine

58.4.1.1 PHASE0 phase

This phase is entered immediately from any phase on a power-on or enabled destructive reset event. The reset state passes to PHASE1 when:

- All enabled destructive resets have been processed.
- All PHASE0 processes are completed: PMC and 16 MHz internal RC oscillator stabilization.
- A minimum of three 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled destructive reset event.
- The destructive reset escalator counter has not reached the RGM_DRET[DRET] threshold.

58.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or from PHASE2, PHASE3, or IDLE on a non-masked external or functional reset event that has not been configured to trigger a ‘short’ sequence. The reset state machine passes to PHASE2 when:

- All enabled, non-shortened functional resets have been processed.
- A minimum of 350 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened functional reset event.

58.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine passes to PHASE3 when:

- All PHASE2 processes are completed: Flash is initialized.
- A minimum of eight 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2.

58.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened functional reset event. The reset state machine passes to IDLE when:

- All PHASE3 processes are completed: trimming, start-up self test configuration and FCCU initialization.
- a minimum of 40 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened functional reset event.
- ESR0 is not asserted, except if a start-up self test will be executed on exit of the current reset sequence or RGM_EROEC[EROEC] is ‘1’.
- PORST is not asserted, except if a start-up self test will be executed on exit of the current reset sequence

58.4.1.5 IDLE phase

This final phase is entered from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

58.4.2 Destructive resets

A destructive reset source relates to a critical (usually hardware) error or dysfunction. When a destructive reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip, ensuring a safe start-up state for both digital and analog modules. The memory content is considered unknown.

The status flag for a given destructive reset event (RGM_DES[F_*destructive reset*]) is set when the destructive reset is asserted and Power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously so software must determine which reset source is the most critical for the application.

A destructive reset can be disabled by setting RGM_DERD[D_*destructive reset*]

Note: The RGM_DERD register can be written only once between two destructive reset events.

The chip's low-voltage detector threshold ensures that, when destructive voltage out of range (LVD and/or HVD) reset is enabled, the supply is sufficient to have the destructive event correctly propagated through the digital logic. Therefore, if a destructive reset is enabled, the MC_RGM ensures that the associated reset event is correctly triggered to the full system. However, if the destructive reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured and the reset may or may not be asserted.

An enabled destructive reset triggers a reset sequence starting from the beginning of PHASE0.

58.4.2.1 External Power-on reset—PORST

The bidirectional external Power-on reset pin PORST is a special case destructive reset.

The detection of a falling edge on PORST starts the reset sequence.

The chip asserts PORST if the reset sequence was triggered by:

- A Power-on reset.
- A destructive reset event.

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 ms after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

The reset sequence does not exit into application until PORST is no longer driven low from off-chip. When the chip is configured to execute a self-test on Power-on, destructive, and external resets, this is the exit of PHASE3 after self-test execution has completed.

58.4.3 External reset

The MC_RGM manages the external reset coming from ESR0. The detection of a falling edge on ESR0 starts the reset sequence.

The status flag associated with the external reset falling edge event (RGM_FES[F_ESR0]) is set when the external reset is asserted and the Power-on reset is not asserted.

The external reset can optionally be disabled by setting RGM_FERD[D_ESR0].

Note: The RGM_FERD register can be written only once between two destructive reset events.

An enabled external reset normally triggers a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS[SS_ESR0] is set, the external reset triggers a sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful when a Flash module reset is not desired.

The MC_RGM may also assert the external reset if the reset sequence was triggered by:

- A power-on reset.
- A destructive reset event.
- An external reset event, if configured via the RGM_FBRE register to assert the external reset
- A functional reset event configured via the RGM_FBRE register to assert the external reset.

In this case, ESR0 is asserted until all conditions for exiting PHASE3 have been met, with the exception of the ESR0 assertion check.

If the OPT_RGM_ESR0_HW bit of the “UTEST Miscellaneous” DCF client is set to ‘0’, the MC_RGM continues to assert ESR0 until the EROEC bit in the RGM_EROEC register has been cleared by software.

In addition, the MC_RGM asserts ESR0 while the start-up self test is being executed.

The ESR0 input is disabled as soon as ESR0 output is asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the ESR0 output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

If the MC_RGM stops asserting ESR0 and the 4 µs input mask period expires during the reset IDLE phase (e.g., due to the EROEC bit being cleared by software) and a new low value is detected on ESR0, an external reset falling edge event does not occur, and no new reset sequence is triggered. For a new reset sequence to trigger, ESR0 must first be deasserted.

58.4.4 Functional resets

A functional reset source relates to a less-critical (usually non-hardware) error or dysfunction, which invokes a partial reset sequence starting from PHASE1. Most digital modules are reset normally, while the state of analog modules or specific digital modules (e.g., debug modules, Flash modules) as well as the system memory content is preserved, except on a long external reset configured to execute a self-test (via DCF configuration of the STCU module).

The status flag associated with a given functional reset event (RGM_FES[F_*functional reset*]) is set when the functional reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, so software must determine which reset source is the most critical for the application.

A functional reset can be disabled by setting RGM_FERD[D_*functional reset*]

Note: The RGM_FERD register can be written only once between two Power-on reset events.

An enabled functional reset normally triggers a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a functional reset. When RGM_FESS[SS_*functional reset*] is set, the associated functional reset triggers a reset sequence starting directly from the

beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful when a Flash module reset is not desired.

58.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. It is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_DERD/FERD and RGM_DEAR/FEAR registers as shown in *Table 1331*.

Table 1331. MC_RGM Alternate Event Selection

RGM_DERD/FERD bit value	RGM_DEAR/FEAR bit value	Generated event
0	X	Reset
1	0	SAFE mode request
1	1	Interrupt request

The alternate event is cleared by deasserting the source of the request (i.e., at the reset source that caused the alternate request) and also clearing the appropriate RGM_DES/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock; if the system clock is disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

If a masked destructive reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored.

If a masked functional reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored.

58.4.6 Functional reset escalation

functional reset escalation can be used to generate a destructive reset if a number of functional or external resets has occurred between software writes to the RGM_FRET register. It is enabled by writing a non-zero value to the FRET field of this register.

Once functional reset escalation has been enabled, the MC_RGM increases a counter on each functional or external reset which causes a reset sequence (i.e., entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any Power-on or destructive reset. If the counter reaches the RGM_FRET[FRET] threshold, the MC_RGM starts a reset sequence at PHASE0 and asserts RGM_DES[F_EDR].

58.4.7 Destructive reset escalation

destructive reset escalation can be used to keep the chip in the reset state until a new Power-on triggers a reset sequence if a number of destructive resets has occurred between sowftware writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once destructive reset escalation has been enabled, the MC_RGM increases a counter on each destructive reset which causes a reset sequence (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any Power-on reset. If the counter reaches the RGM_DRET[DRET] threshold, the MC_RGM enters reset PHASE0 and stays there until the next Power-on reset occurs.

58.4.8 Individual peripheral resets

A peripheral may be reset individually without resetting the chip by setting the appropriate bit in the RGM_PRSTn registers. However, in order to prevent unexpected chip behavior, the following sequence must be observed by software.

1. Disable the module that is to be reset via the MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRSTn registers.
4. Wait at least two peripheral clock periods.
5. Clear the bit corresponding to the peripheral in the RGM_PRSTn registers.

The peripheral can be kept in reset indefinitely by not executing step 5. After the completion of step 5, the peripheral can be enabled again via the MC_ME.

59 Boot Assist Flash (BAF)

59.1 Introduction

The MCU is booted through a collaboration of several blocks, hardware, and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the boot core (CPU2 (I/O Processor (IOP)) on this device) pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. If it is FAIL_ANALYSIS, the BAF enters a loop in which it services the watchdog. The BAF does not execute further since the read access to flash memory boot sectors for the cores may be disabled if device life cycle is FAIL_ANALYSIS. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module. The package pins used by LINFlexD are the same pins used by the M_CAN module. Hence, the external PHY can be either LIN or CAN, allowing the "ASC@CAN" operation (see *Section 59.2.8, Serial boot configuration* for configuration details).

59.1.1 BAF image header

BAF image contains a 256-byte header starting from address 0040_4000h (BAF version number, see the table "BAF memory map" in the "BAF Configuration"). The header contains important information such as BAF version and production disable flag. The BAF header is explained in *Table 1332*.

Table 1332. BAF image header

Address offset	Size (bits)	Field description
0000h	32	BAF Image version
0004h	32	Reserved
0008h	32	Reserved (Part of clock Jitter Activation Constant)
000Ch	32	Clock Jitter Activation Constant
0010h–00FFh	Reserved	

59.1.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0040_4000h. The 32-bit field is explained in the following table.

Table 1333. BAF image version

Field	Description
[0:7]	Major Number: This field contains the major version number for the BAF image
[8:15]	Minor Number: This field contains the minor version number for the BAF image

Table 1333. BAF image version(Continued)

Field	Description
[16:23]	Reserved
[24:31]	Reserved

59.1.1.2 Clock Jitter Activation constant

The Clock Jitter Activation constant is a 32-bit flag, but the smallest element in flash that can be programmed is 64 bits, so the first 32 bits are reserved to allow programming of this constant. This 32-bit flag can be programmed by the customer and is used to activate the Clock Jitter feature that adds clock edge jitter to the baud rate clocks of several communications modules. As part of the BAF startup procedure, BAF copies this constant from flash to the PASS Clock Jitter Enable Register.

Table 1334. BAF Clock Jitter Activation Constant

Field	Description
[00:31]	Clock Jitter Activation Constant. The initial state of production disable flag is erased - FFFF_FFFFh. This equates to NO clock jitter.

59.2 Functional description

59.2.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of three different boot modes.

- Boot from internal flash

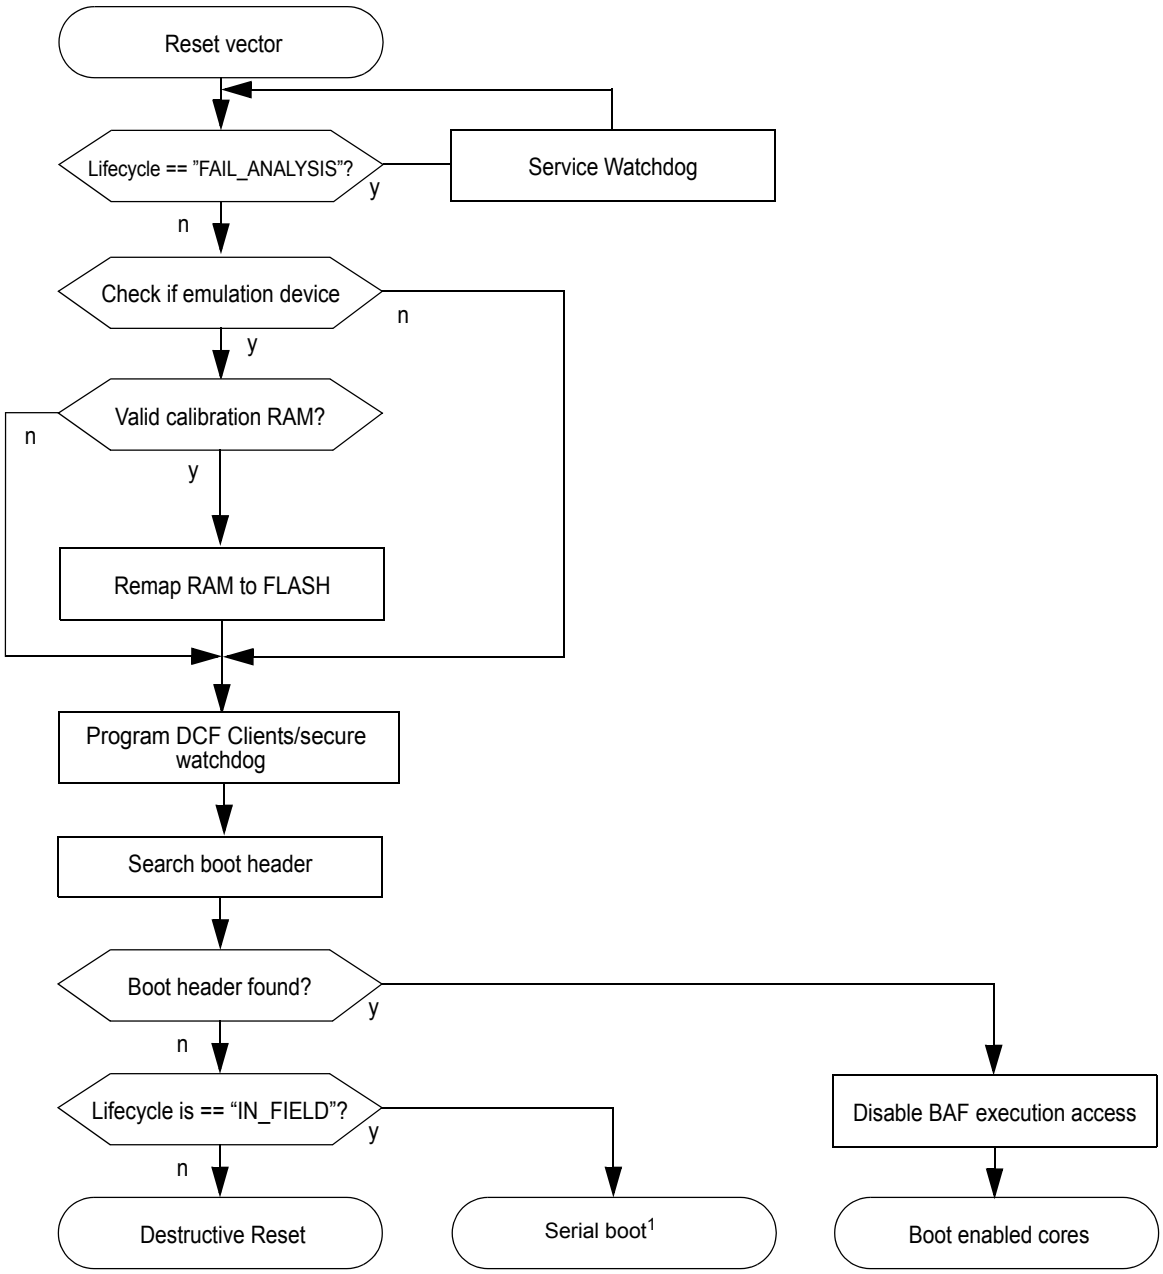
  If the internal flash contains application code with a valid boot header, the application is booted. The boot header contains flags that enable/disable individual cores and their reset vectors.
- Serial boot

  If no valid boot header is found and the current life cycle phase of the device is less than IN_FIELD, an attempt is made to download the application by a serial protocol using the LINFlexD or M_CAN module. The downloaded code is then executed by the initial boot core.
- Static mode

  The device enters power safe mode and waits for an external reset.

59.2.2 Device initialization

The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the buddy device[v] in the following way:



v. “Buddy device” refers to a companion device that is used only for system development and debug activities. It is not used in production systems.

1. BAF sets up the exception vector table to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, the BAF issues a destructive reset from the machine check exception handler if the exception is due to the reading of instructions from the BAF region. If an exception occurs during reading of the Boot header, the BAF ignores the ECC error and jumps to next boot header. If an ECC error occurs during reading of D-MEM, the BAF will still issue a destructive reset. BAF programs the Mode Entry module's MC_ME_MCTL[TARGET_MODE] to issue a destructive reset.
2. BAF uses memory of the system RAM as in the "BAF memory map" table (in *Section 7.8.2: BAF configuration*) for its stack, data and any code that executes from volatile memory. During the BAF start-up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.

59.2.3 Flow of control

Figure 1388 shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

Figure 1388. Flow of control

1 Serial boot is not available on all devices. Please check the product reference manual for details.

59.2.4 Optionally remap calibration RAM

BAF supports remapping of Calibration RAM through Soft DCF Records.

If the device is an Emulation Device (buddy device present, SIUL2_MIDR1[ED] = 1), and the external overlay RAM has valid content, then this RAM is automatically remapped over selected flash memory regions. The details of the mapping are defined by a 400-byte

configuration table at the beginning of the external overlay RAM. The layout of the table is depicted in *Table 1335*.

The content of the overlay RAM is assumed valid:

- if the BD_INIT flag in the initialization status register of the buddy device (BD_SIUL2_ISR) is set,
- and a CRC calculation over the configuration table yields the correct result,
- and the version of the calibration data matches the version of the application software in flash memory (*((uint64_t*)ADDR_SWID) = DATID).

In this case, all 32 calibration remap descriptors (PFCRDs) are setup with the values contained in the configuration table. Finally, the PFCRDE field is copied to the enable register in the PFLASH controller.

Table 1335. Remap configuration table

Address offset (hex)	Name	Contents
00	CRC_REF	CRC reference value
04	ADDR_SWID	Address of 64-bit ID value in SW FLASH
08	DATID	64-bit ID value of the calibration data
0C		
10	PFCRDE	CRD enable flags
14	LSTARTADDR0	PFCRD0, logical start address
18	PSTARTADDR0	PFCRD0, physical start address
1C	CRDSize0	PFCRD0, size
20	LSTARTADDR1	PFCRD1, logical start address
24	PSTARTADDR1	PFCRD1, physical start address
28	CRDSize1	PFCRD1, size
...	...	...
188	LSTARTADDR31	PFCRD31, logical start address
18C	PSTARTADDR31	PFCRD31, physical start address
190	CRDSize31	PFCRD31, size

The CRC calculation is performed using the CRC unit applying the CRC-32 (Ethernet protocol) polynomial. The calculation is initialized with a seed of 0000h. Then, the 100 32-bit words starting at table address offset 04h are moved to the CRC_INP register by the CPU. Finally, the content of the CRC_OUTP register is compared to the CRC_REF value.

59.2.5 Initialization of BAF DCF clients

59.2.5.1 ‘Soft’ DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (DCF Start Record), or the address specified in UTEST (Soft DCF Record Start Address). If either of the two least significant bits of the 32-bit address stored at the Soft DCF Record Start Address is set, the default start address at the DCF Start Record is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is FFFF_FFFFh). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in *Table 1336*.

The DCF clients which are used for initialization of security watchdog are explained in *Section 59.2.5.2, Security watchdog configuration*.

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in *Table 1336* provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside anywhere in the CPU address space including the BAF code block or UTEST. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in *Section 59.2.5.6, SER_BOOT_CBACK – BAF serial boot DCF client*.

Table 1336. BAF DCF client list

Address (hex)	Name	Label	Description
0000h	Security Watchdog Control Register	SEC_SWT_CR	Data to write to SWT Control Register
0001h	Security watchdog Time out register	SEC_SWT_TO	Security watchdog counter value
0002h	Security watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0003h	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog
0004h–01FFh	Reserved		
0200h	Address	ADDR	The address to which DATAX is written
0201h	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0202h	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0203h	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0204h–020Fh	Reserved		
0210h	Callback Address	CALLBACK	The address of a callback function
0211h	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0212h–7FFFh	Reserved	—	Reserved for future use.

59.2.5.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then program the security watchdog registers. BAF configures only SWT2 as security watchdog for the CPU2 (IOP) core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

59.2.5.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0000h while parsing, BAF programs the DCF client "Security watchdog control register" with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

59.2.5.2.2 Security Watchdog TImeout (SEC_SWT_TO)

The BAF parses the DCF records. While parsing, if the BAF finds a DCF record with CS14 set and address field as 0001h, the BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. The BAF checks the value obtained

from DCF records. If the value yields a timeout greater than 30 seconds, then the BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

59.2.5.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in 'fixed address execution service mode'. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0002h while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

Warning: To program the core IAC8 special purpose register, the ownership of this register should be with software. If hardware has its ownership software will not be able to write to it using mtspr instruction.

59.2.5.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to BAF which CPU will use the security watchdog. BAF parses the DCF record and if it finds a record with CS14 set and address field set as 0003h, BAF programs this DCF client. This means that BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. *Figure 1389* and *Table 1337* indicate the data layout for this client in the DCF record. This client is written once during reset. Subsequent writes are ignored.

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients are not written, data is configured erroneously.

If security watchdog is assigned to CPU0 or CPU1, relevant CPU IAC8 register is programmed along with other debug configuration registers to enable IAC8 as watch point.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). To assign the security watchdog to the Main CPU, first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

DCF Client Address 0003h

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				0				0			

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				0	0	SC1	SC0

Figure 1389. SEC_SWT_CPU bit configuration

Table 1337. SEC_SWT_CPU field description

Field	Description
[31:2]	Reserved
SC[1:0]	These two bits select the CPU which will use the security watchdog. 00 Reserved 01 Reserved 10 CPU2 (IOP) 11 Reserved

59.2.5.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0200h while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

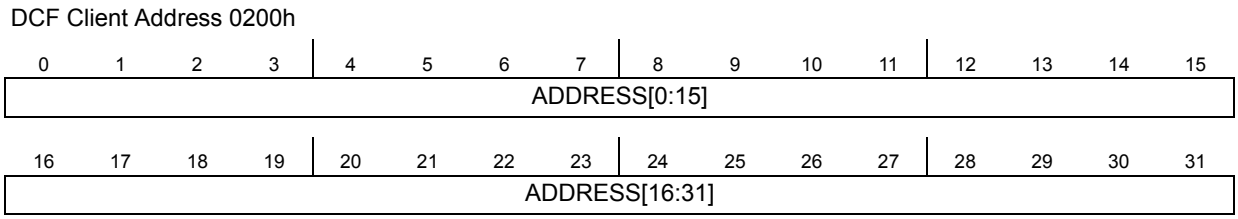


Figure 1390. BAF DCF ADDR client configuration

Table 1338. BAF DCF ADDR client description

Field	Description
ADDR[0:31]	32-Bit Address DCF client. This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU.

59.2.5.4 BAF DCF client - DATAX

59.2.5.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0201h while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to ‘0’ (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

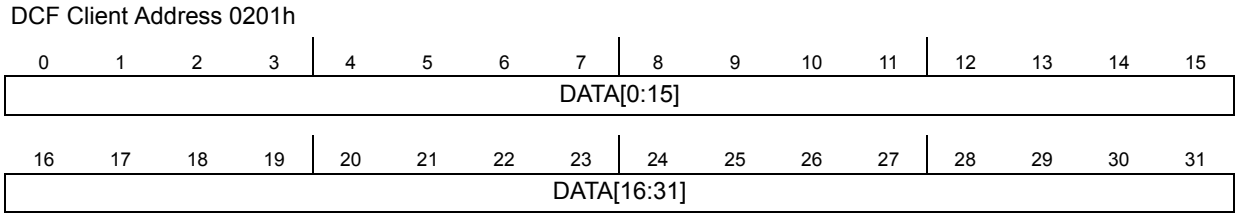

Figure 1391. DATA32 DCF client configuration

59.2.5.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0202h while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to '0' (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

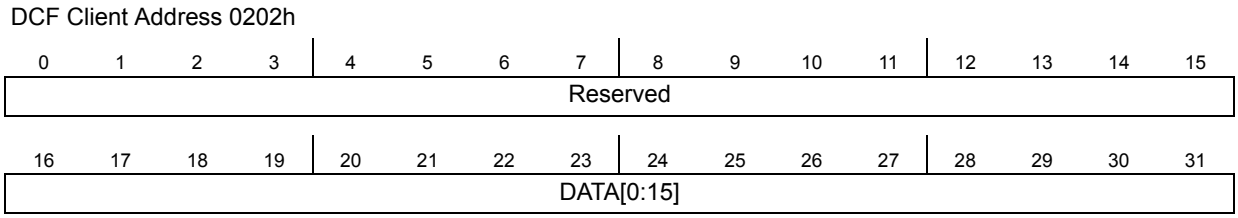

Figure 1392. DATA16 DCF Client COnfiguration

59.2.5.4.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0203h while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

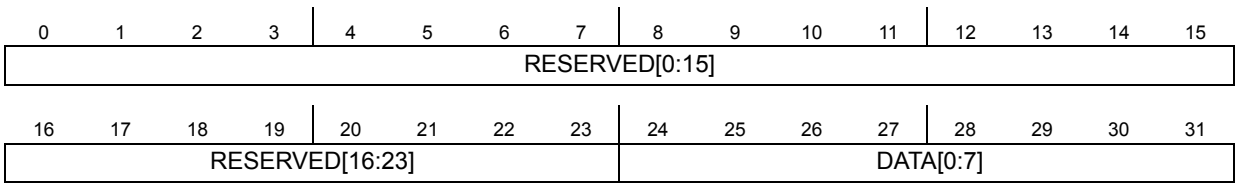

Figure 1393. DATA8 DCF Client COnfiguration

59.2.5.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0210h while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable

operations in BAF. No parameters are passed to this function and no return value is expected.

Warning: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore, several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

59.2.5.6 SER_BOOT_CBACK – BAF serial boot DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0211h while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32 bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with power.org EABI and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: No parameters are passed to the function invoked by the BAF. Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed (see *Table 1339* for details regarding return value).

Table 1339. Serial boot callback function return value definition

Return values	Description
00h	Boot from internal flash using standard search for boot record (see ‘Serial boot header and boot options’ in configuration section).
01h	Serial boot using both M_CAN and LINFlexD (in UART mode) (see ‘Serial boot header and boot options’ in configuration section).
02h–FFh	Reserved

59.2.6 Production disable activation protocol and implementation

Module failure analysis is a standard requirement. But some OEMs have an additional requirement that upon entering failure analysis mode, the MCU operation is modified in such a way that the MCU can never be used in production ECU. The chosen operational modification for production disable is to apply clock jitters to can modules so that it prevents active communications with another can device on a can network. For detail regarding production disable refer the PASS chapter.

The BAF maintains a 64-bit flag in BAF code flash region as explained in *Section 59.1.1.2: Clock Jitter Activation constant*. On every POR BAF copies the clock jitter activation constant from this flag to clock jitter enable register in PASS module to enable jitters on can baud clock. Default value of this flag is shown in *Section 59.1.1.2: Clock Jitter Activation constant*. Hence, jitter on the MCAN baud clock is disabled if the default value is used. To enable jitter on can clock the value of this flag should be modified to FFFF_FFFEh.

The BAF flash memory is write protected and locked. To enable modification of this flag and activate production disable feature, BAF implements production disable activation protocol as explained in *Table 1341: Production Disable protocol description*. BAF implements this protocol in a power.ORG EABI compliant callback routine. This callback routine can be invoked by programming a callback based soft DCF client as explained in *Section 59.2.5.5, CALLBACK – BAF callback DCF client*. The callback function address is show in *Table 1340: Production Disable Callback routine entry point*

Table 1340. Production Disable Callback routine entry point

Description	Address
Production disable protocol callback function address	0040_40E0h

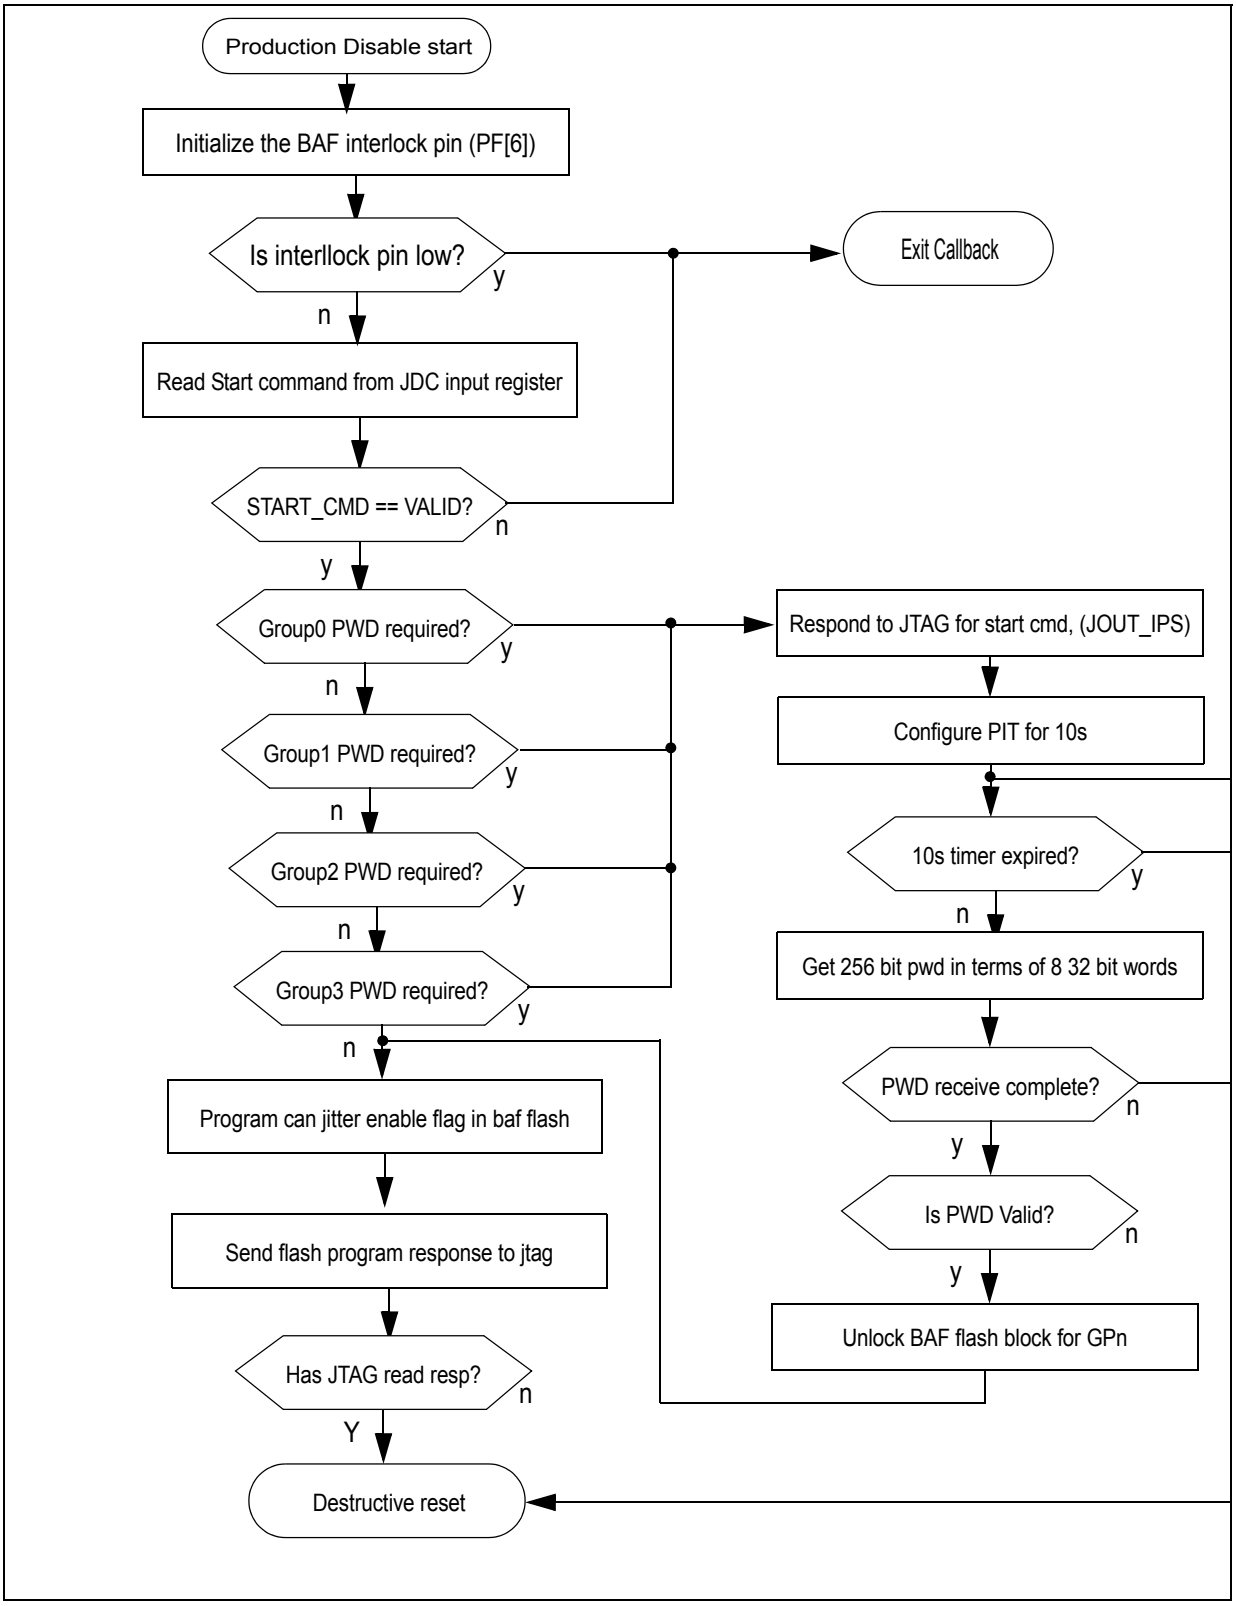

Table 1341. Production Disable protocol description

Step	Description	Tool Action/Response	MCU Action/Response
1	After power-on tool holds the MCU in reset and writes the activation code to JDC via JTAG interface. The tool pulls hardware interlock pin high, then releases reset.	Assert hardware interlock pin Write F5A0_AA55h to JDC	Starts production disable activation
2	The MCU responds by writing to the JDC an acknowledgment code and which of the 4 PASS passwords are required to unlock the BAF flash block		Write FA50_000*n*h to JDC if password for pass group n is required to unlock the BAF flash block. (n is either 0,1,2 or 3)
3	The tool reads the acknowledge from JDC module and writes the relevant password to the JDC module. MCU performs password comparison and writes error code to JDC module password provided by tool was incorrect.	Read JDC Write 256 bit password for pass group n to JDC in eight 32 bit words. (n is 0,1,2 or 3)	Write FA50_F00*n*h if password does NOT match. Once the status has been read by the tool then cause reset. (n is either 0,1,2 or 3)

Table 1341. Production Disable protocol description(Continued)

Step	Description	Tool Action/Response	MCU Action/Response
4	If more than one password is required to unlock the BAF flash block step 2 and step 3 are repeated until all relevant password has been supplied.		If password matches step 2 and step 3 are repeated for the next pass group until all pass group that lock BAF flash has been processed.
5	The MCU then attempts to program the can jitter activation constant within the BAF flash block. The can jitter activation constant flag is a write once flag. Once written it cannot be re-programed as BAF flash block is OTP. MCU write a code to JDC to signal success or failure of flash programming operation and issue reset.		Program can jitter activation constant in BAF flash block. If successful write FA51_0000h to JDC. If unsuccessful write FA51_F000h to JDC Issue reset.

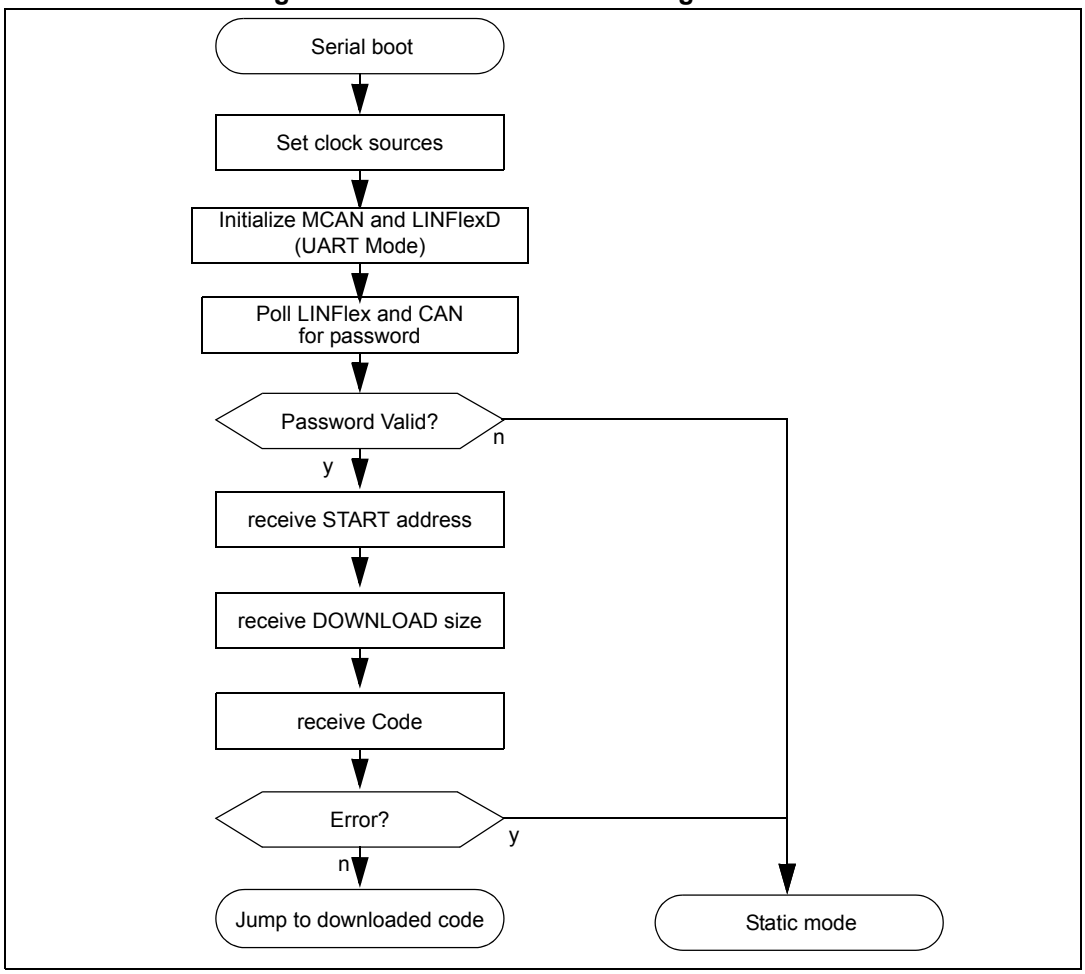

Figure 1394. Production Disable callback function flow chart

59.2.7 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above or customer selects serial boot using serial boot DCF client, then BAF determines the lifecycle status of the device. If the Life Cycle is in CUST_DELIV (Customer Delivery), it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

Figure 1395. Flow of control during serial boot

The clock source in the MC_CGM is configured and the PADs are set up for LINFlexD and M_CAN signals (see *Section 59.2.8, Serial boot configuration*), then the code is downloaded using LINFlexD or M_CAN in Serial Boot mode. In the absence of errors causing the device to be placed in Static mode, the device state is restored to resemble the out-of-reset state and the downloaded code is executed.

Serial boot allows the download of application to internal sram via LINFlexD or M_CAN interface. After downloading the application image to SRAM, the BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process both LINFlexD and M_CAN is configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid

message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and doesn't participate further in serial boot.

If a CAN message of 8 bytes with ID 11h is received on the M_CAN controller first, the BAF program

- Disables LINFlexD.
- Configures LINFlexD RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If CAN message not containing 8 bytes or NOT with ID 11h is received by M_CAN controller or a M_CAN controller generates a CAN error, it is probable that the tool is sending a LINFlexD frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error
- Continue monitoring for valid CAN messages.

If any byte from LINFlexD is received first, the BAF program:

- Checks if the first byte is FEh of the password. If not continue polling. The data may be a valid CAN message.
- If it is first byte of the password (FEh) then disable the M_CAN controller and restore to its reset state.
- Configures the M_CAN pads to their reset state.
- Transition to LINFlexD serial boot (UART mode).

59.2.7.1 Serial boot mode protocol

From a high-level perspective, the download protocol over CAN and LIN interfaces follows steps below:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes, NO_ECHO bit and VLE bit to MCU.
3. Host transmits a sequence of data bytes that are to be executed.
4. CPU2 executes code from start address provided in step 2.

Each step must be complete before the next step starts.

The exact protocol between LINFlexD andMCAN are slightly different.

NO_ECHO bit is used to select if the actual download data are to be echoed or not. If NO_ECHO bit is set, then the data will not be echoed otherwise if NO_ECHO bit is clear then the data will be echoed.

59.2.7.2 LINFlexD download protocol

The communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received 8-byte of password, 4-byte of load address and 4-byte of VLE-bit, NO_ECHO bit and 30-bit of download size to the host. The MCU echoes actual download data depending upon NO_ECHO bit.
3. The host verifies whether the echo is correct.
   – If the data is correct, the host can send the next byte of data.
   – If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded, NO_ECHO bit and the VLE bit.
4. *x* bytes of code that is downloaded to SRAM and executed (*x* must match the value specified in step 3).

59.2.7.3 MCAN download protocol

The MCAN download protocol uses very similar structure to the LINFlexD protocol, but it makes use of the message ID's provided by CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 11h as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 1h.
2. A message with 12h as the ID and and 8-byte length to send the start address, size of the code and VLE mode bit.The MCU transmits back the same data but with an ID of 2h.
3. A message with 13h as the ID is used to send data that is to be downloaded to SRAM. The MCU transmit the same data with an ID of 3h.

59.2.7.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password FEED_FACE_CAFE_BEEFh.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode(low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

59.2.7.5 Download start address, VLE bit, NO_ECHO bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bits, NO_ECHO bit and 30-bit code length as shown in *Figure 1396* and *Figure 1397*

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The NO_ECHO bit is used to indicate if download data should be echoed by the MCU. If the NO_ECHO bit is set (for example, NO_ECHO = 1), then only 8 bytes of password, 4 bytes of download address, and 4 bytes of download size are echoed, but download data is not echoed. If the NO_ECHO bit is clear, then every byte sent to the MCU must be echoed.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

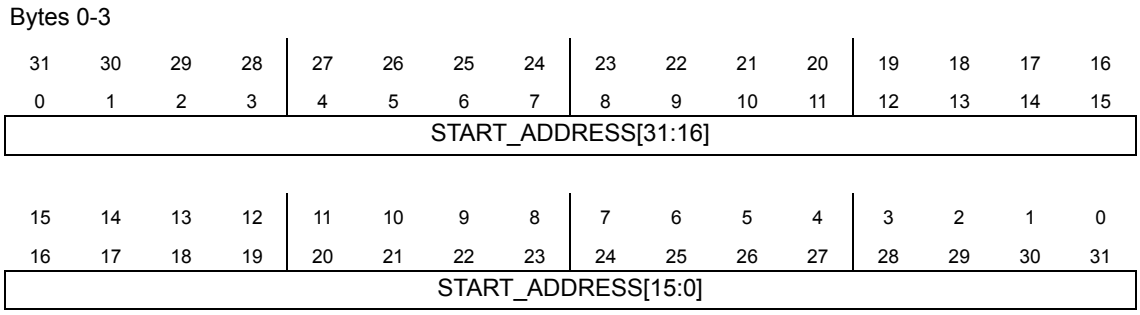

Figure 1396. Start address, VLE bit, NO_ECHO bit and download size in bytes

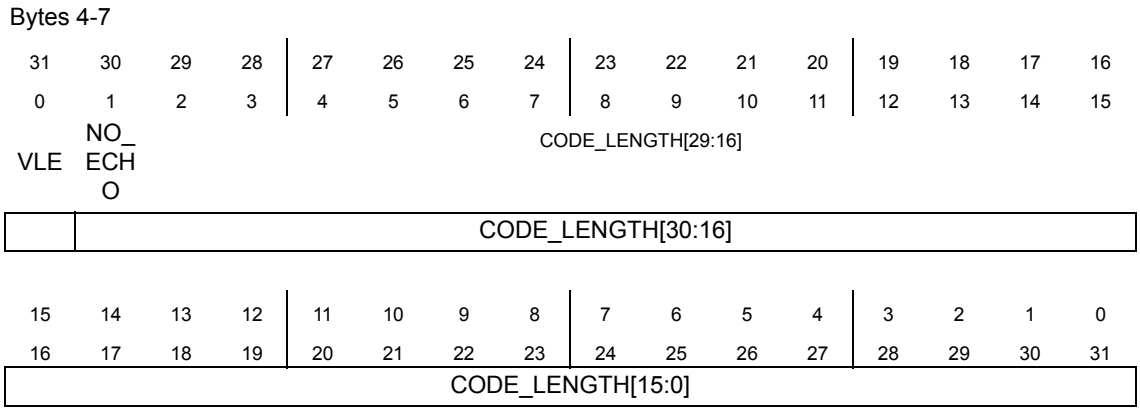

Figure 1397. Start address, VLE bit, NO_ECHO bit and download size in bytes

59.2.7.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero's and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0000_0000_0000_0000h) to the next address location. This is written to avoid possible ECC error during core prefetch.

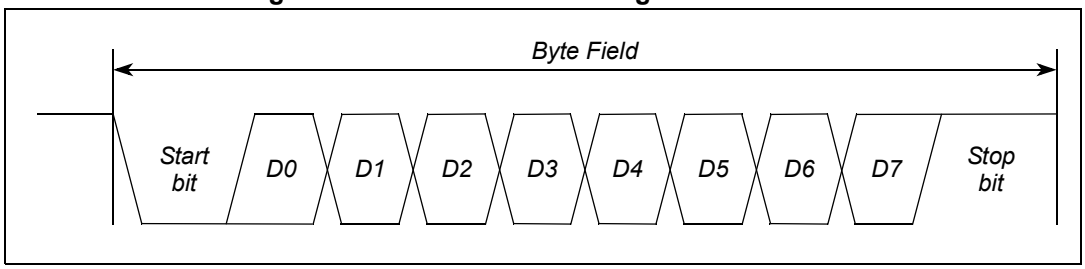
59.2.7.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

59.2.8 Serial boot configuration

59.2.8.1 LINFlexD configuration

Boot using UART protocol is implemented by LINFlexD module.



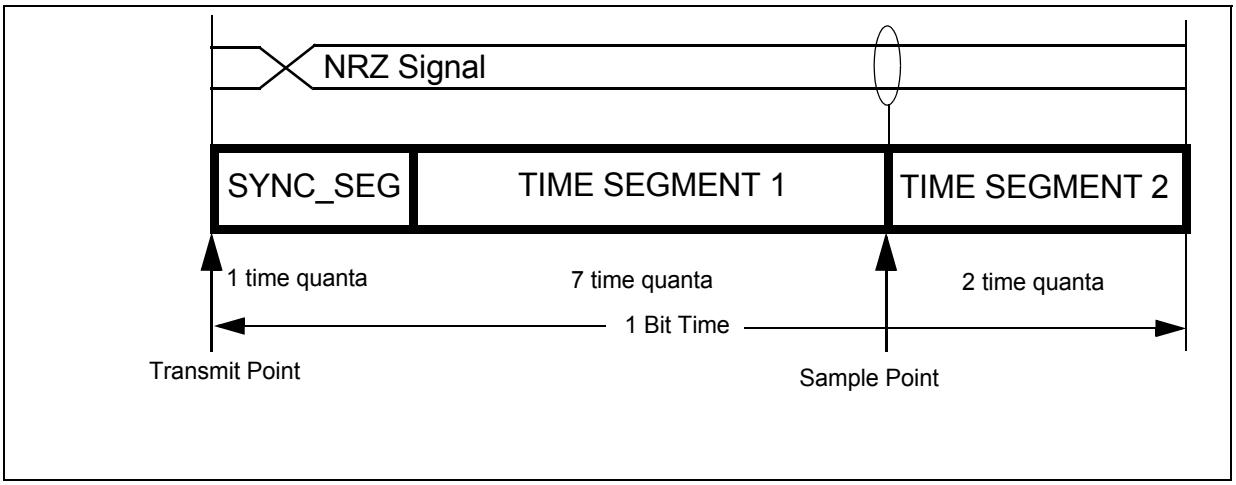
Note: See the pin configuration table in the configuration for pins used by the LINFlexD module.

When Serial Boot mode is started the LINFlexD_Rx is configured as an input and multiplexed to the LINFlexD_0 module. The LINFlexD_Tx remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD module. The application may not be using the Serial Boot Mode function, and may be using the pin used by LINFlexD_Tx as an input, which may have some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data (such as LIN or CAN). The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx pin transmission.

The LINFlexD controller is configured to operate at a baud rate of 250 kbaud with the IRCOSC as reference clock, using ane 8-bit data frame without parity bit and 1 stop bit.

Figure 1398. LINFlexD bit timing in UART mode



59.2.8.2 M_CAN configuration

The M_CAN controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11-bit identifier format detailed in CAN 2.0A specification (see *Table 1343* for baud rates).

The Bit timing is configured as shown in *Figure 1399 (M_CAN Bit Timing)*

Figure 1399. M_CAN Bit Timing

59.2.8.3 Baud rates

The LINFlexD baud rate is set to 250 kbaud with the IRCOSC as reference clock.

The M_CAN baud rate is set by the frequency of the external crystal divided by 40. *Table 1343* shows some possible baud rates.

Table 1343. M_CAN_1 baud rates

Crystal frequency	M_CAN baud rate
8 MHz	200 kbaud
12 MHz	300 kbaud
16 MHz	400 kbaud
20 MHz	500 kbaud
40 MHz	1000 kbaud

59.2.8.4 LINFlexD and M_CAN pin configuration

Please see the BAF configuration section for pin details.

59.2.8.5 Protocol summary

Table 1344 summarizes the LINFlexD protocol and BAF action during this boot mode.

Table 1344. LINFlexD serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	VLE bit + NO_ECHO bit + 30 bits of download data size in bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	If NO_ECHO bit is set, data is echoed, otherwise data is not echoed.	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	None	None	Branch to downloaded code

Table 1345 shows the M_CAN serial boot protocol.

Table 1345. M_CAN serial boot mode download protocol

Protocol steps	Host message sent	BAF response message	Action
1	CAN ID 011h + 64-bit password	CAN ID 001h + 64-bit password	Password checked against fixed password (FEED_FACE_CAFE_BEEFh). Watchdog timer is refreshed if the password check is successful.
2	CAN ID 012h + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	CAN ID 002h + 32-bit store address + 32-bit (1 VLE bit, 1 NO_ECHO bit and 30 of download data size in bytes)	Load address and size of download are stored for future use.
3	CAN ID 013h + 8 to 64 bits of raw binary data	VLE bit + 31 bit number of bytes (MSB first)	Each byte of data received is store in MCU memory, starting at the address specified in the previous step and incrementing until the amount of data received and stored, matched the size as specified in the previous step.
4	None	None	The BAF returns IO pins and CAN module to their reset state, then branches to the first address the data was stored to (As specified in step 2)
5	None	None	Branch to downloaded code

59.3 Resources

- Clocks

  Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).
- LINFlexD and M_CAN

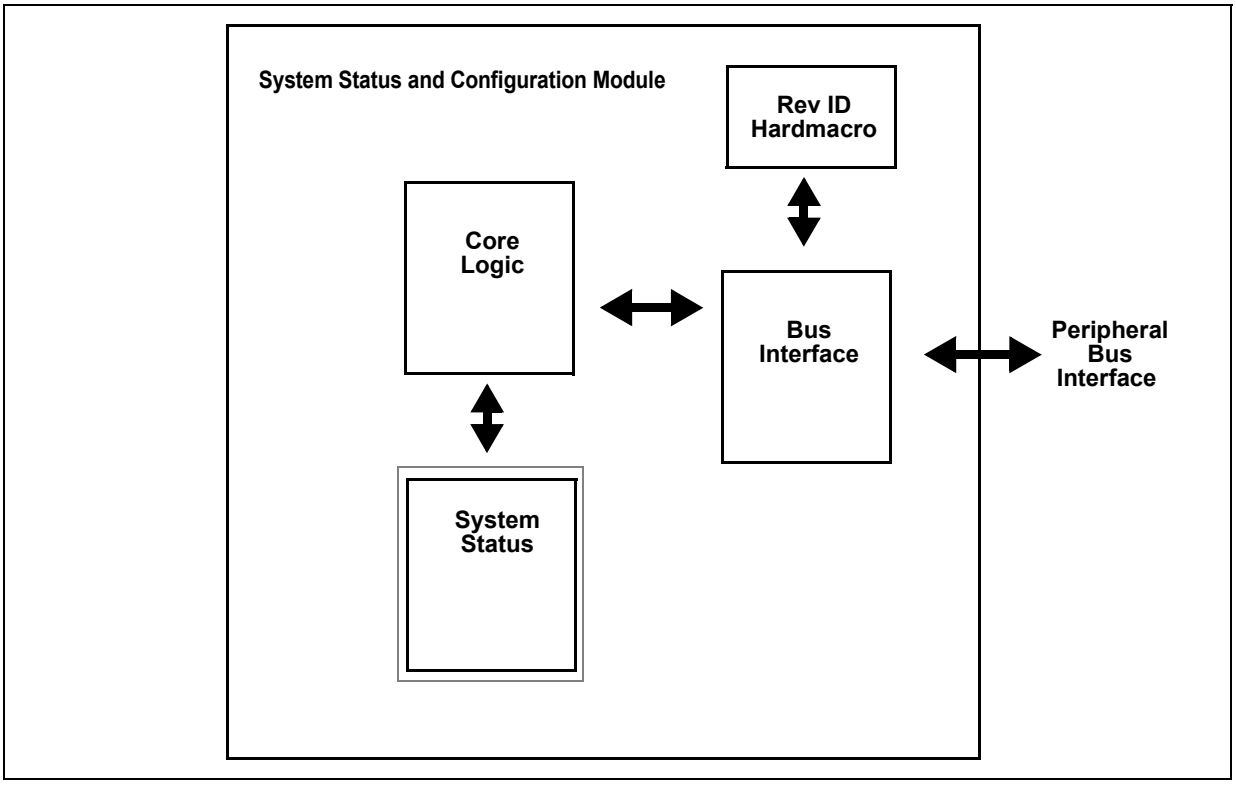
  The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted. All settings are restored before the application code in system RAM is executed.
- CRC

  The CRC module is used to validate external overlay contents, if and only if the device is an emulation device and the buddy device has been initialized.
- PFLASH

  Remapping of the external overlay memory is configured automatically under certain conditions (see *Section 59.2.4: Optionally remap calibration RAM*)
- Interrupts

  No interrupts/exceptions are used or enabled, except the Machine Check exception, to handle ECC errors.
- Security watchdog

  When SWT2 is chosen as security watchdog, SWT3 is used for task monitoring purpose.



60 System Status and Configuration Module (SSCM)

60.1 Introduction

60.1.1 Overview

The System Status and Configuration Module (SSCM) is pictured in *Figure 1400*.

Figure 1400. SSCM block diagram

60.1.2 Glossary

Table 1346. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
X	In certain contexts, such as a signal encoding, this indicates a don’t care. For example, if a field is binary coded X001b, the state of the first bit is a don’t care.
y	y is used for a place holder of 1 hex digit for unknown values.

60.1.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Determine primary boot vector
  - Decodes the Device Life Cycle

60.1.4 Modes of operation

The SSCM operates identically in all system modes.

60.2 External signal description

The SSCM has no external pins.

60.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

Table 1347 shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Note: All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit READ/WRITE to address Base + 0002h, but performing a 16-bit access to Base + 0003h is illegal.

Table 1347. SSCM memory map

Offset from SSCM_BASE	Register	Access	Reset Value	Section/ page
0000h	SSCM System Status (STATUS)	R/W	yyy0h(1)	*on page 2371*
0002h	SSCM System Memory and ID Register (MEMCONFIG)	R	yyyyh(1)	*on page 2372*
0004h	Reserved	—	—	—
0006h	SSCM Error Configuration Register (ERROR)	R/W	0000h	*on page 2372*
0008h	Reserved(2)	—	—	—
000Ah–001Ch	Reserved	—	—	—
0020h	Reserved	—	—	—
0024h	Reserved	—	—	—
0028h	Processor Start Address Register (PSA)	R	yyyy_yyyyh(1)	*on page 2373*
002Ch	Reserved	—	—	—
0030h	Reserved	—	—	—
0034h	Life Cycle Status Register (LCSTAT)	R		

Table 1347. SSCM memory map(Continued)

Offset from SSCM_BASE	Register	Access	Reset Value	Section/ page
0038h-0048h	Reserved	—	—	—
[1] See register description for reset value details. [2] No register abort on this location.				

60.3.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

60.3.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Offset 0000h Access: Read/Write

	0	1	2	3	4	5	6	7	8 9 10	11	12	13	14	15
R	0	CER	0	NXEN1	NXEN	1	0	0	BMODE	VLE	0	0	0	0
W		w1c												
Reset	0	0	0	-(2)	-(2)	1	0	0	-(2)	-(1)	0	0	0	0

[1] Reset value depends on the associated option bits in flash memory.
[2] Reset value depends on the device status after leaving reset.

Figure 1401. System Status Register (STATUS)

Table 1348. STATUS field descriptions

Field	Description
CER 1	Configuration Error. This field indicates that the SSCM has detected a configuration error while loading DCF clients (with PARITY Enabled). This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
NXEN1 3	Processor 1 Nexus enable status. 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
NXEN 4	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled

Table 1348. STATUS field descriptions(Continued)

Field	Description
BMODE 8:10	Device Boot Mode. 101 Boot from BootFlash All other values are reserved. This field is only updated during reset.
VLE 11	Variable Length Instruction Mode. When booting in Single Chip (SC) mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0 SC Boot Location contains standard PPC code 1 SC Boot Location contains VLE code

60.3.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Offset 0002h Access: Read Only

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0/1(1)	1	0/1(1)	0/1(1)	0/1(1)	0/1(1)	0

Figure 1402. System memory and ID register (MEMCONFIG)

1. Reset value reflects the JTAG ID of the device.

Table 1349. MEMCONFIG field descriptions

Field	Description
JPIN 0:9	JTAG Part ID Number
MREV 11:14	Minor Mask Revision

60.3.1.3 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Offset 0006h Access: Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1403. Error Configuration Register (ERROR)

Table 1350. ERROR field descriptions

Field	Description
PAE 14	Peripheral Bus Abort Enable. This bit enables bus aborts on any access to an off-platform peripheral slot that is not used on the device. This feature is intended to aid in debugging when developing application code. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
RAE 15	Register Bus Abort Enable. This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. This feature is intended to aid in debugging when developing application code. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception **Note:** Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the AIPS level). In this case, the PAE and RAE register bits have no effect on the abort.

60.3.1.4 Processor Start Address Register (PSA)

Offset 0028h — Access: Read Only

Figure 1405. Life Cycle Status Register (LCSTAT)

1. Reset value reflects the Pre-Life Cycle of the device.
2. Reset value is the Life Cycle of the device.

Table 1352. LCSTAT field descriptions

Field	Description
TLC 22:23	Test Life Cycle - as determined by the SSCM by reading the TLC slots. The encoding is: JDP_PROD = 01 IN_FIELD = 11 FAIL_ANALYSIS = 00
LC 29:31	Life Cycle - as determined by the SSCM by reading the LC slots. The encoding is: JDP_PROD = 110 CUST_DELIV = 011 PROD_OEM = 010 IN_FIELD = 111 FAIL_ANALYSIS = 000

60.4 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

60.4.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. *Table 1353* shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Table 1353. DCF start record

0:31
05AA 55AFh

0:31
0000 0000h

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See *Table 1354*. In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Table 1354. Format of a DCF data record

0:31
WDATA[31:0]

0:14	15:29	30	31
CS[14:0]	ADDR[16:2]	PRTY	STOP

The stop record indicates that processing should stop. The general format of the stop record is shown in *Table 1355*. Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

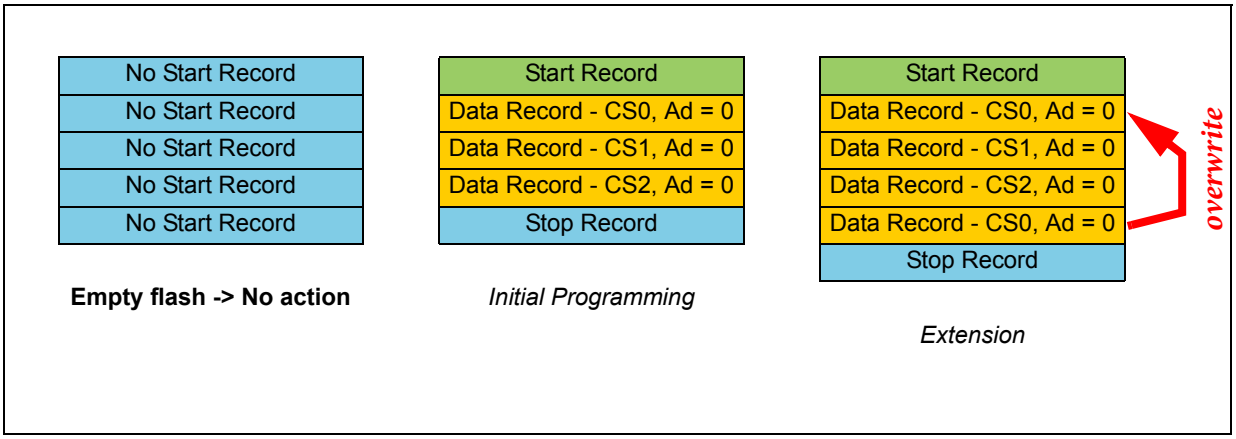
Table 1355. DCF stop record

0:31
rsvd

0:30	31
rsvd	1

If *n* data records are to be stored in UTEST, the data structure must be as shown in *Table 1356*.

Table 1356. Series of DCF records in UTEST



ADDR offset	DATA			
00h	05AA 55AFh			
04h	0000 0000h			STOP=0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			

Table 1356. Series of DCF records in UTEST(Continued)

ADDR offset	DATA	
8n - 1 + 0h	reserved	
8n - 1 + 4h	reserved	1
8n + 0h		
8n + 4h		

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in *Figure 1406*.

Figure 1406. Appending DCF records

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

60.4.2 ECC error monitoring

During flash memory scanning (such as Life Cycle, DCF records, or RCHW), the SSCM will monitor the flash memory status signals for ECC and other unexpected access errors. If such an error occurs the SSCM will request a reset.

60.4.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Boot Assisted by Flash (BAF) – the device will boot from UTest NVM Flash Block, (interface with the HSM if available) and perform device setup.

If booting is not possible with the selected configuration (for example, no Boot ID is found in the selected boot location) then the device will enter serial boot mode.

60.4.4 BAF configuration

By default the device will boot from BAF.

In BAF mode the boot core will start to execute the BAF code at the location shown in the SSCM section of the “Device Configuration” chapter. The BMODE field in the SSCM status register will be set to the value 101b. Details of the BAF operation are described in the BAF chapter.

Note: Combinations of bits not listed in Table 75 are not supported.

60.4.5 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from UTEST flash memory area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- JDP Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 128 bits each, at fixed locations in UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses:

Table 1357. Life Cycle slots

LC Slot		LC slot value
Valid Field (64 Bits)	Invalid Field (64 Bits)	
Erased	Erased	Erased
Marked	Erased	Active
Marked	Marked	Inactive
Any other values		Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh, “Erased” is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. *Table 1358* shows how the slots are arranged in memory.

Table 1358. Life Cycle Slots in Memory

Offset	LC Slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in *Table 1359*. The priority of the entries is from top to bottom, so the first row which applies determines the resulting Life Cycle.

Table 1359. Life Cycle Slots

TLC = JDP_PROD (1)	LC Slot 0 JDP_PROD(1),(2)	LC Slot 1 CUST_DEL(1),(2)	LC Slot 2 OEM_PROD(1),(2)	LC Slot 3 IN_FIELD(1),(2)	LC Slot 4 FA(1),(2)	Resulting Life Cycle
*	**Active**	Erased	Erased	Erased	Erased	JDP Production
*	*Inactive*	**Active**	Erased	Erased	Erased	Customer Delivery
*	*Inactive*	*Inactive*	**Active**	Erased	Erased	OEM Production
*	*Inactive*	*Inactive*	*Inactive*	**Active**	Erased	In Field
*	*Inactive*	*Inactive*	*Inactive*	*Inactive*	**Active**	FA
No	Erased	Erased	Erased	Erased	Erased	System Reset
No	*	*	*	*	Erased	In Field
No	*	*	*	*	Not Erased(3)	System Reset
Yes	*	*	*	*	*	JDP Production

1. '*' = don't care condition.
2. 'Erased' = slot returns all 1's
3. Any value other than FFFF_FFFF_FFFF_FFFFh.

60.5 Initialization and application information

60.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (see *Section 60.3.1, Register descriptions*).

60.6 Additional safety measures

60.6.1 Spurious reset protection

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the MC_RGM. In case of a spurious reset the SSCM will not interfere

with the flash memory bus or overwrite configuration registers. However, status internal to the SSCM will be lost.

61 Power Management Controller digital interface (PMC_dig)

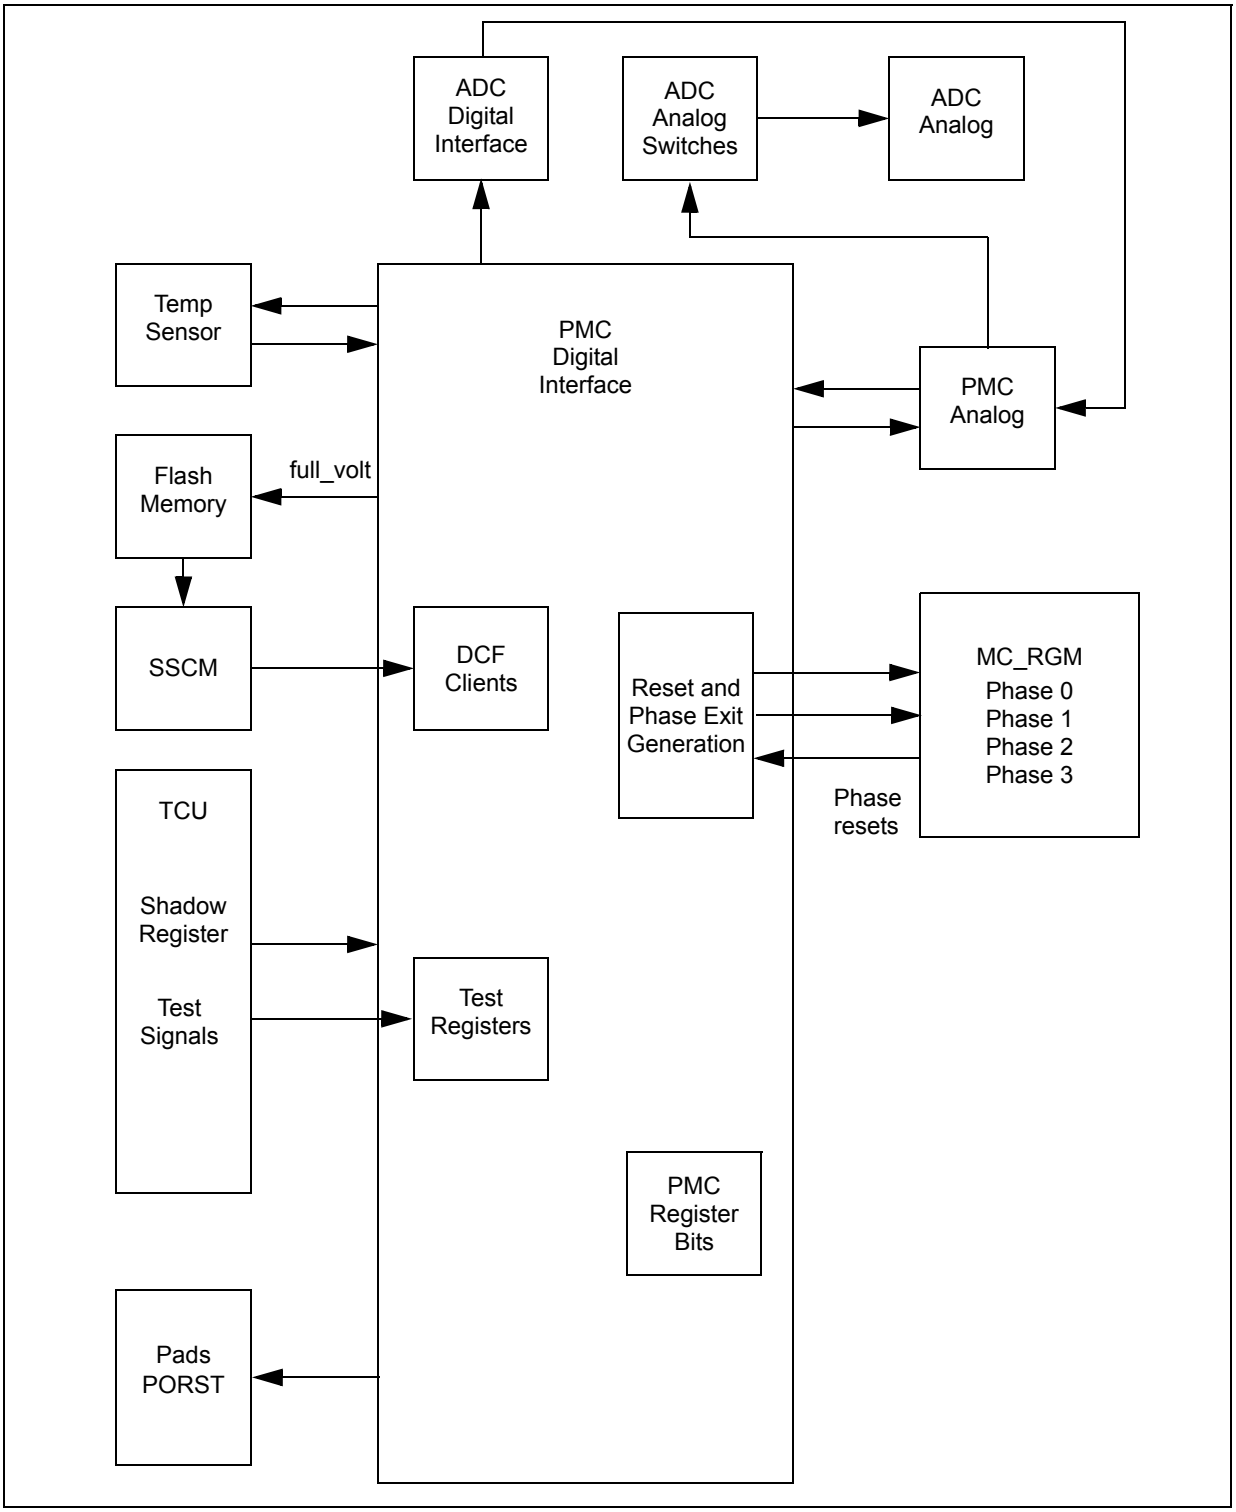
61.1 Introduction

The power management controller (PMC) consists of two blocks: an analog block and a digital block, which is described here.

The digital block:

- Contains the registers and digital logic required to generate the enable signals, trim control bits, POR reset generation and test logic for the analog block.
- Contains the controls for PMC analog outputs to be sensed with the ADC module.
- Contains the enable signals, trim bits, and other registers regarding the temperature sensor.
- Interfaces to the Reset Generation Module (MC_RGM) block, which receives the LVD values during POR to use for phase transition conditions.
- Has a custom interface to Flash memory via the SSCM (and DCF client blocks) which loads the trim values during initial POR.

Caution: Do not assert the TESTPIN or the system LVDs/HVDs will be deactivated.



The PMC digital block generates a transfer error event to the system if the selected address exceeds the highest address in the PMC digital memory map, but not if an unused address within the PMC digital memory space is accessed.

Note: The power domains measured by an LVD or HVD may not be left unpowered. They must always be connected and in a valid operating range before the device can exit Power-on reset.

61.2 Block diagram

The block diagram for the PMC is shown in *Figure 1407*.

Figure 1407. Digital PMC block diagram

61.3 Memory map and register definition

Table 1360 shows the PMC memory map. The PMC includes many registers for configuring and monitoring LVD monitors and some other control registers.

Table 1361. GR_S field descriptions

Field	Description
0–4	Reserved.
5 TS3	TS3 over-temperature detect flag—high temperature sensor input 3 (165 °C). Read-only over-temperature status flag asserted when the temperature exceeds its threshold and cleared when the temperature falls below this threshold. 0 Currently no occurrence. 1 Temperature Sensor is currently above the hot temperature threshold.
6 TS2	TS2 over temperature detect flag—high temperature sensor input 2 (150 °C). Read-only over-temperature status flag asserted when the temperature exceeds its threshold and cleared when the temperature falls below this threshold. 0 Currently no occurrence. 1 Temperature Sensor is currently above the temperature threshold.

Table 1361. GR_S field descriptions(Continued)

Field	Description
7 TS0	TS0 under-temperature detect flag—low temperature sensor input 0 (–40 °C). Read-only under-temperature status asserted when the temperature falls below its threshold and cleared when all the temperature rises above this threshold. 0 Currently no occurrence. 1 Temperature Sensor is currently below the cold temperature threshold.
8–15	Reserved.
16 VD15	VD15 high-voltage detect flag—high voltage 6.00 V supplies. Read-only high-voltage status flag asserted when any of the supplies rise above their HVD thresholds and cleared when all the supplies fall below these thresholds. All the 6.00 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected.
17 VD14	VD14 low-voltage detect flag—high voltage 4.00 V supplies. Read-only low-voltage status flag asserted when any of the supplies fall below the LVD threshold and cleared when all the supplies rise above the corresponding LVD threshold. All the 4.00 V supplies are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected.
18–20	Reserved.
21 VD10	VD10 low-voltage detect flag—high voltage 3.00 V supplies. Read-only low-voltage status flag asserted when the supply falls below its LVD threshold and cleared when the supply rises above its LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected.
22 VD9	VD9 low-voltage detect flag—high voltage 2.8 V supplies. Read-only bit is the low-voltage status flag asserted when any of the supplies fall below the LVD threshold and cleareds when all the supplies rise above the LVD threshold. All of the 2.8 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected.
23 VD8	VD8 high-voltage detect flag—low voltage 1.45 V supplies. Read-only high-voltage status flag asserted when any of the supplies rise above the HVD threshold and cleared when all the supplies fall below the HVD threshold. All the 1.45 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected.
24 VD7	VD7 high-voltage detect flag—low voltage 1.40 V supplies. Read-only high-voltage status flag asserted when any of the supplies rise above the HVD threshold and cleared when all the supplies fall below the HVD threshold. All the 1.40 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected.
25–26	Reserved.

Table 1361. GR_S field descriptions(Continued)

Field	Description
27 VD4	VD4 low-voltage detect flag— low voltage 1.14 V PLL, Flash, and hot point supply. Read-only low-voltage status flag asserted when the supply falls below its LVD threshold and cleared when the supply rises above its LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected.
28 VD3	VD3 low-voltage detect flag—low voltage 1.14 V core logic supply. Read-only low-voltage status flag asserted when any of the VD3 supplies fall below the corresponding LVD threshold and cleared when the supplies rise above the corresponding LVD threshold. All the 1.14 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected.
29–31	Reserved.

61.3.1.2 Pending Gauge Status register (GR_P)

This configuration register reflects the Event Pending register in a format that includes one bit for each voltage detect signal. These read-only bits indicate whether a voltage level event has occurred at any time in the past. They are cleared by writing ‘1’ in the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they are set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

Field	Description
0–4	Reserved.
5 VD15_F	VD15_F high-voltage detect flag—high voltage 6 V Flash supply. 0 No occurrence has happened, or EPR_VD15[HVD15_F] has been cleared. 1 HVD occurrence detected.
	Reserved.
7 VD15_C	VD15_C high-voltage detect flag—high voltage 6 V Core cold point supply. 0 No occurrence has happened, or EPR_VD15[HVD15_C] has been cleared. 1 HVD occurrence detected.
8–9	Reserved.
10 VD14_IM	VD14_IM low-voltage detect flag—high voltage 4 V I/O Main supply. 0 No occurrence has happened, or EPR_VD14[LVD14_IM] has been cleared. 1 LVD occurrence detected.
11–14	Reserved.
15 VD10_A	VD10_A low-voltage detect flag—high voltage 3 V ADC supply. 0 No occurrence has happened, or EPR_VD10[LVD10_A] has been cleared. 1 LVD occurrence detected.
16 VD10_C	VD10_C low-voltage detect flag—high voltage 3 V Core supply. 0 No occurrence has happened, or EPR_VD10[LVD10_C] has been cleared. 1 LVD occurrence detected.
17 VD9_O	VD9_O low-voltage detect flag—high voltage 2.8 V Oscillator supply. 0 No occurrence has happened, or EPR_VD9[LVD9_OR] has been cleared. 1 LVD occurrence detected.
18	Reserved.
19 VD9_IF	VD9_IF low-voltage detect flag— high voltage 2.8 V I/O Flexray supply. 0 No occurrence has happened, or EPR_VD9[LVD9_IF] has been cleared. 1 LVD occurrence detected.
20 VD9_IJ	VD9_IJ low-voltage detect flag—high voltage 2.8 V I/O JTAG supply. 0 No occurrence has happened, or EPR_VD9[LVD9_IJ] has been cleared. 1 LVD occurrence detected.
21 VD9_IM	VD9_IM low-voltage detect flag—high voltage 2.8 V I/O Main supply. 0 No occurrence has happened, or EPR_VD9[LVD9_IM] has been cleared. 1 LVD occurrence detected.
22 VD9_F	VD9_F low-voltage detect flag—high voltage 2.8 V Flash supply. 0 No occurrence has happened, or EPR_VD9[LVD9_F] has been cleared. 1 LVD occurrence detected.
23	Reserved.
24 VD9_C	VD9_C low-voltage detect flag—high voltage 2.8 V cold point supply. 0 No occurrence has happened, or EPR_VD9[LVD9_C has been cleared. 1 LVD occurrence detected.
25 VD8_C	VD8_C high-voltage detect flag—low voltage 1.45 V cold point supply. 0 No occurrence has happened, or EPR_VD8[HVD8_C] has been cleared. 1 HVD occurrence detected.

Table 1362. GR_P field descriptions(Continued)

Field	Description
25 VD8_F	VD8_F high-voltage detect flag—low voltage 1.45 V Flash supply. 0 No occurrence has happened, or EPR_VD8[HVD8_F] has been cleared. 1 HVD occurrence detected.
27 VD7_C	VD7_C high-voltage detect flag—low voltage 1.4 V cold point supply. 0 No occurrence has happened, or EPR_VD7[HVD7_C] has been cleared. 1 HVD occurrence detected.
28 VD4_C	VD4_C low-voltage detect flag—low voltage 1.14 V cold point supply. 0 No occurrence has happened, or EPR_VD4[LVD4_C] has been cleared. 1 LVD occurrence detected.
29 VD3_P	VD3_P low-voltage detect flag—low voltage 1.14 V PLL supply. 0 No occurrence has happened, or EPR_VD3[LVD3_P] has been cleared. 1 LVD occurrence detected.
30 VD3_F	VD3_F low-voltage detect flag—low voltage 1.14 V Flash supply. 0 No occurrence has happened, or EPR_VD3[LVD3_F] has been cleared. 1 LVD occurrence detected.
31 VD3_C	VD3_C low-voltage detect flag—low voltage 1.14 V Core hot point supply. 0 No occurrence has happened, or EPR_VD3[LVD3_C] has been cleared. 1 LVD occurrence detected.

61.3.1.3 Interrupt Enable Pending register (IE_P)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending registers in a similar format to the Pending Gauge Status register (GR_P). These bits toggle whether an interrupt occurs when the voltage event is seen:

Writing ‘1’ to the MSB (IE_P[IE_EN]) enables all of the voltage detect bits in the register to be read or written at any time.

23	Reserved.
24 VD9IE_C	VD9IE_C Interrupt Enable. 0 No interrupt occurs. 1 An interrupt occurs on a voltage detect event.

Table 1363. IE_P field descriptions(Continued)

Field	Description
25 VD8IE_C	VD8IE_C Interrupt Enable. 0 No interrupt occurs. 1An interrupt occurs on a voltage detect event.
25 VD8IE_F	VD8IE_F Interrupt Enable. 0 No interrupt occurs. 1An interrupt occurs on a voltage detect event.
27 VD7IE_C	VD7IE_C Interrupt Enable. 0 No interrupt occurs. 1 An interrupt occurs on a voltage detect event.
28 VD4IE_C	VD4IE_C Interrupt Enable. 0 No interrupt occurs. 1An interrupt occurs on a voltage detect event.
29 VD3IE_P	VD3IE_P Interrupt Enable. 0 No interrupt occurs. 1 An interrupt occurs on a voltage detect event.
30 VD3IE_F	VD3IE_F Interrupt Enable. 0 No interrupt occurs. 1 An interrupt occurs on a voltage detect event.
31 VD3IE_C	VD3IE_C Interrupt Enable. 0 No interrupt occurs. 1 An interrupt occurs on a voltage detect event.

61.3.1.4 Event Pending register (EPR_VD2)

This register indicates the present and past state of the voltage detect signals. If the voltage detect event crosses the trigger threshold after the last clearing event, the flag bit is set. Write ’1’ to clear the flag. Since this voltage event can only be seen when the LVD096 signals assert, these flags can only be seen in test modes that disable these PORs.

61.3.1.43 Temperature Sensor Configuration register (CTL_TD)

The Temperature Sensor register (CTL_TD) contains two enables that must both be set in order for the Temperature Sensor to be operable. It also includes two 4-bit signed trim adjustment register fields that are used to modify both Temperature Sensor trim values (one bus for over-temperature and one bus for under-temperature). Finally, this register includes Interrupt Enables (IE) for each of the Temperature Sensor EPR bits.

TRIM_ADJ_OVER and TRIM_ADJ_UNDER are used to introduce additional hysteresis into the Temp Sensor events.

For instance, the TRIM_ADJ_OVER bits could be written to 11111 (-7) and the Temperature Sensor event set as an interrupt. When this interrupt triggers, the TRIM_ADJ_OVER bits could be updated to 0111 (+7), the interrupt cleared, and the Temperature Sensor event set as a reset.

In this way, a *warning* interrupt could be established before a *shutdown* event (at a higher temperature).

Care must be taken to include a timeout during the clearing of the interrupt described in the example above. The Temperature Sensor has hysteresis and a timeout may be necessary to indicate if the interrupt flag has not cleared in a reasonable amount of time. If this is the case, then an error should be generated.

18 TS0IE	TS0IE Interrupt Enable—Temperature Sensor input 0. The MSB in IE_P must be set to access this bit. 0 No interrupt occurs. 1 An interrupt occurs.
19	Reserved.
20–23 TRIM_ADJ_OVER	TRIM_ADJ_OVER[3:0]—Customer adjustable over trim register. These bits are a signed binary number that is added to the over temperature trim (NT_TD2) value. The TRIM value is protected from overflows and underflows due to this addition.
24–25	Reserved.
26–29 TRIM_ADJ_UNDER	TRIM_ADJ_UNDER[3:0]—Customer adjustable under trim register. These bits are a signed binary number that is added to the under temperature trim value (NT_TD0). The TRIM value is protected from overflows and underflows due to this addition.
30 DOUT_EN	DOUT_EN. Digital Output Enable.
31 AOUT_EN	AOUT_EN. Analog Output Enable.

61.3.1.44 Temp Sensor FCCU Event Enable register (FEE_TD)

This Temp Sensor FCCU Event Enable register controls whether the temperature sensor detect signal event causes an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit (EPR_TD) is enabled, the temperature sensor detect assertion causes an FCCU event to be generated when the selected temperature exceeds the desired value.

61.3.1.45 Voltage Detect User Mode Test register (VD_UTST)

This register is used for testing of the LVDs and HVDs during user mode. LVD self test works only when LVD/HVD is deasserted. When LVD/HVD is asserted, the self test will flag an error. Therefore, the status of all LVD's should be verifed before the self test is actuated.

61.3.1.47 Voltage Regulator 1.2 V Control register (VREG1P2_CTRL)

This register is used to enable by USER the Auxiliary Regulator (also known as Spike or VREG1P2 Regulator) during an intentional power down event. The VREG1P2_ENB_USER bit register is OR'd with the VREG1P2_ENB_TEST. If it is permitted and the VREG1P2_ENB_USER bit is a 0, the Auxiliary Regulator is enabled. The final result is readable on the VREG1P2_ENB bit.

The VREG1P2_ENB_USER bit is writeable both by DCF load and by IPS write.

Offset: PMC_BASE + 0x034C Access: User read/write

Field	Description
0–25	Reserved.
30 VREG1P2_ENB	VREG1P2_ENB is a Read-only bit. This bit shows if the AUX Regulator (VREG1P2) is disabled or not. During Power Down, the AUX regulator is disabled when this bit is set. VREG1P2_ENB is used to control the AUX regulator. 0 The VREG1P2 is enabled. 1 The VREG1P2 is disabled.
31 VREG1P2_ENB_ USER	This bit controls if the AUX Regulator (Vreg1p2) is disabled or not in user mode. VREG1P2_ENB_USER bit is writeable by both IPS and DCF To know if the VREG1P2 is enabled or disabled the VREG1P2_ENB bit has to be read. By default VREG1P2_ENB_USER is 1. 0 User request to enable the VREG1P2. 1 User request to disable the VREG1P2.

61.3.1.48 Module Control Register (MCR)

This register is used to enable and disable the PMC analog block busses: ADC_CH_SEL and TEST_MODE buses. The TEST_MODE enables User Self Test bus. For additional details, see chapter “Power management“. The proper procedure to enable these busses would be to write the value to the register containing the bus, then write this enable high, evaluate the test associated with this bus, and then write this bus enable bit low. After that, any further tests can be continued.

TEST_PIN displays only the test pin value from analog PMC.

Offset: PMC_BASE + 0x0350 Access: User read/write

Table 1408. MCR field descriptions

Field	Description
0–16	Reserved.
171 USER_SELF_TEST_EN	This bit allows the VD_UTST bits in the VD_UTST register to be enabled. This bit should be set after the VD_UTST bus has been updated, and cleared after the test has completed. The VD_UTST bus should not be updated while the USER_SELF_TEST_EN is enabled (high). 0 The VD_UTST bus is not enabled in the PMC analog. 1 The VD_UTST bus is enabled in the PMC analog.
18–23	Reserved.
24 TEST_PIN	This Read Only Bit indicates the current value of the Test Pin and it displays the test pin value from analog PMC. 0 Test Pin is not asserted. 1 Test Pin is asserted.
25–31	Reserved.

61.4 Analog PMC interface

The outputs from the PMC digital to the PMC analog circuit consist of trim registers for each LVD circuit, an enable for each LVD (tied to the enabled state), and ADC channel select controls. The ADC channel select controls are described in more detail in the ADC interface section of this chapter, and in the Successive Approximation register Analog-to-Digital Converter (SARADC) Ditigal Interface chapter.

The signals from the PMC analog to the PMC digital logic are the POR and LVD event indication signals (both active high and active low, but only active low are used). These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There is a settling time for the analog voltage detect circuits specified at 5 microseconds. The PMC digital counts clock edges after the loading of new flash trim values to verify that this time has passed. This time can vary from 5 microseconds to 11.4 microseconds.

61.5 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of two enables: an analog and digital enable, a set of mode registers, two 7-bit trim registers (sometimes referenced as one 14-bit trim register), and an overtemp threshold select control.

The Temperature Sensor outputs three signals to the PMC digital logic: over_temp1, over_temp2, and under_temp signals. These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There are two 4-bit signed registers (TRIM_ADJ_OVER[3:0] and TRIM_ADJ_UNDER[3:0]) that software uses to adjust the value of the Temp Sensor Trim values. The fourth bit of these registers indicates the sign.

TRIM_ADJ_OVER is added to TS2_TRIM and TRIM_ADJ_UNDER is added to TS0_TRIM. This addition is protected from overflow and underflow (the TRIM value remains at max or min value).

The test interface is discussed in the test section.

For more information regarding the Temperature Sensor function, please refer to the Temperature Sensor chapter.

61.6 Power On Reset (MC_RGM Phase Gates)

The PMC digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMC and Temperature Sensor Analog blocks.

There are two signals for each the PMC and Temp Sensor blocks: one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMC digital logic also indicates when the RGM may allow transition to the next POR phase.

The digital PMC also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMC digital logic uses all the enabled Voltage Detects to determine whether it may exit Phase 3. Once all the enabled HVD/LVDs have become deasserted and the time for the LVD/HVD circuits to adjust to new trim values has elapsed, the signal is sent to the RGM that the necessary voltage levels to exit Phase 3 have been achieved.

There are eight POR signals: POR_VDDREG, POR_VDDC, POR081_C, LVD085_C, LVD096_C, LVD096_F, POR240_F, and POR240_C.

61.7 Flash interface (DCF client usage)

The PMC digital is updated during POR from the Flash block via a DCF client. This update operation loads several pieces of data, most of which being trim values applied to analog modules (PMC, Temperature Sensor, and ADC Bandgap).

The trim bits that are loaded from the flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

A DCF client is used to interface to the Flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips. If any issues occur during any of the DCF data loads (like a second write of different data), the DCF client indicates an error to the FCCU.

The updated values for the REE and RES bits are also loaded during the DCF single read proces. See *Section 61.3.1.41: Reset Event Enable register (REE_TD)* for more information regarding the REE/RES bits load from flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (allowing the bits to be rewriteable), but the reset value of the REE register bits are all high (enabling resets out of POR).

The loaded REE DCF bits are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the destructive reset signal.

For more information regarding the DCF records, please refer to the DCF chapter.

The trim data is read out of the Flash's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the Flash indicates this to the PMC digital via the SSCM module.

Once the PMC trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the Flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD/HVD signals must indicate that a valid voltage has been reached before the voltage indication will be sent to the Flash.

For more information regarding the Flash differential reads and voltage levels required, please refer to the Flash chapter.

61.8 Other module interfaces

The FCCU block receives several signals to indicate a fault has occurred. The first is a safety error from the DCF interface indicating that some error has happened during the load of the trim data from the flash during POR. All of the DCF client safety error signals are combined in the PMC digital logic and then sent to the FCCU.

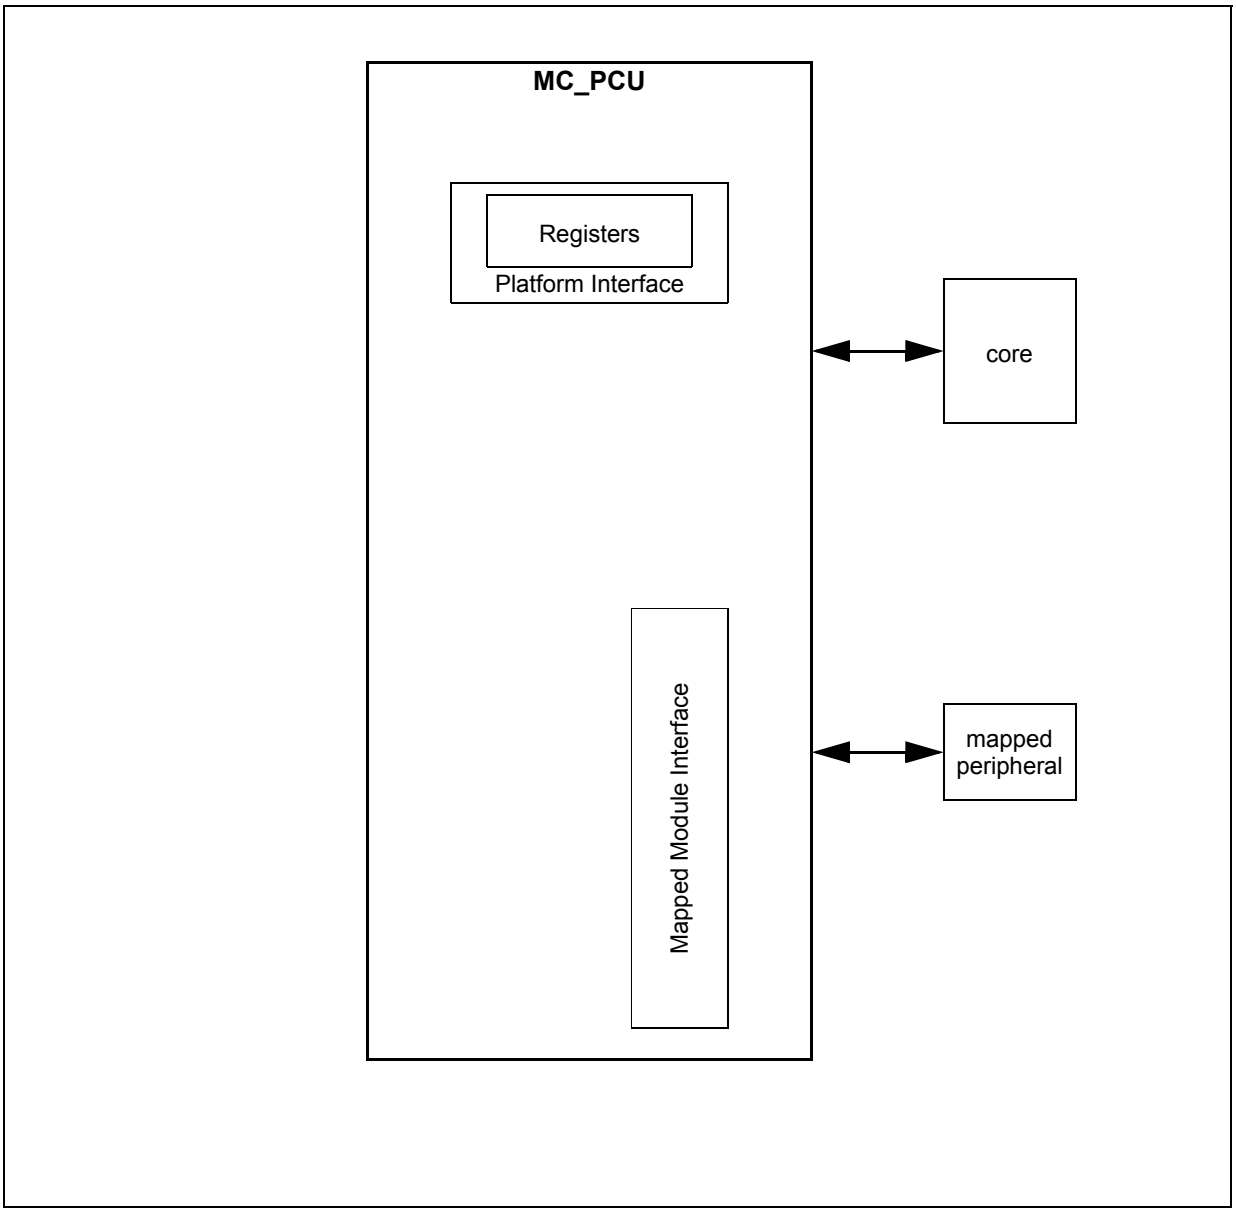
The second set of signals indicate that an HVD, LVD, or temperature event has occurred.

The LVDs sent to the FCCU are: LVD108_C, LVD108_F, LVD108_P, LVD112_C, LVD270_C, LVD270_F, LVD270_IM, LVD270_IJ, LVD270_IF, LVD270_O, LVD295_C, LVD295_A, LVD400_IM.

The HVDs sent to the FCCU are: HV140_C, HVD145_F, HVD145_C, HVD600_C, HVD600_F.

The Temp Sensor outputs tmpsns3, tmpsns2, and tmpsns0 are all combined and sent to the FCCU. For more information regarding the FCCU block and these signals, please refer to the FCCU chapter.

62 Power Control Unit (MC_PCU)



62.1 Introduction

62.1.1 Overview

The power control unit (MC_PCU) acts as a bridge for mapping the PMC peripheral to the MC_PCU address space.

Figure 1456 shows the MC_PCU block diagram.

Figure 1456. MC_PCU block diagram

62.1.2 Features

The MC_PCU includes the following feature:

- maps the PMC registers to the MC_PCU address space

62.2 External signal description

The MC_PCU has no connections to any external pins.

62.3 Memory map and register definition

62.3.1 Memory map

Table 1409. MC_PCU register description

Offset address	Register	Access	Reset value	Location
0x0040	Power Domain Status Register (PCU_PSTAT)	read	0x0000_0001	*on page 2432*

Note: Any access to unused registers as well as write accesses to read-only registers will:

- *not change register content*
- *cause a transfer error*

62.3.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the **PD0** field of the **PCU_PSTAT** register may be accessed as a word at address 0x0040, as a half-word at address 0x0042, or as a byte at address 0x0043.

62.3.2.1 Power Domain Status Register (PCU_PSTAT)

This register reflects the power status of all available power domains.

Address 0x0040 Access: User read, Supervisor read, Test read

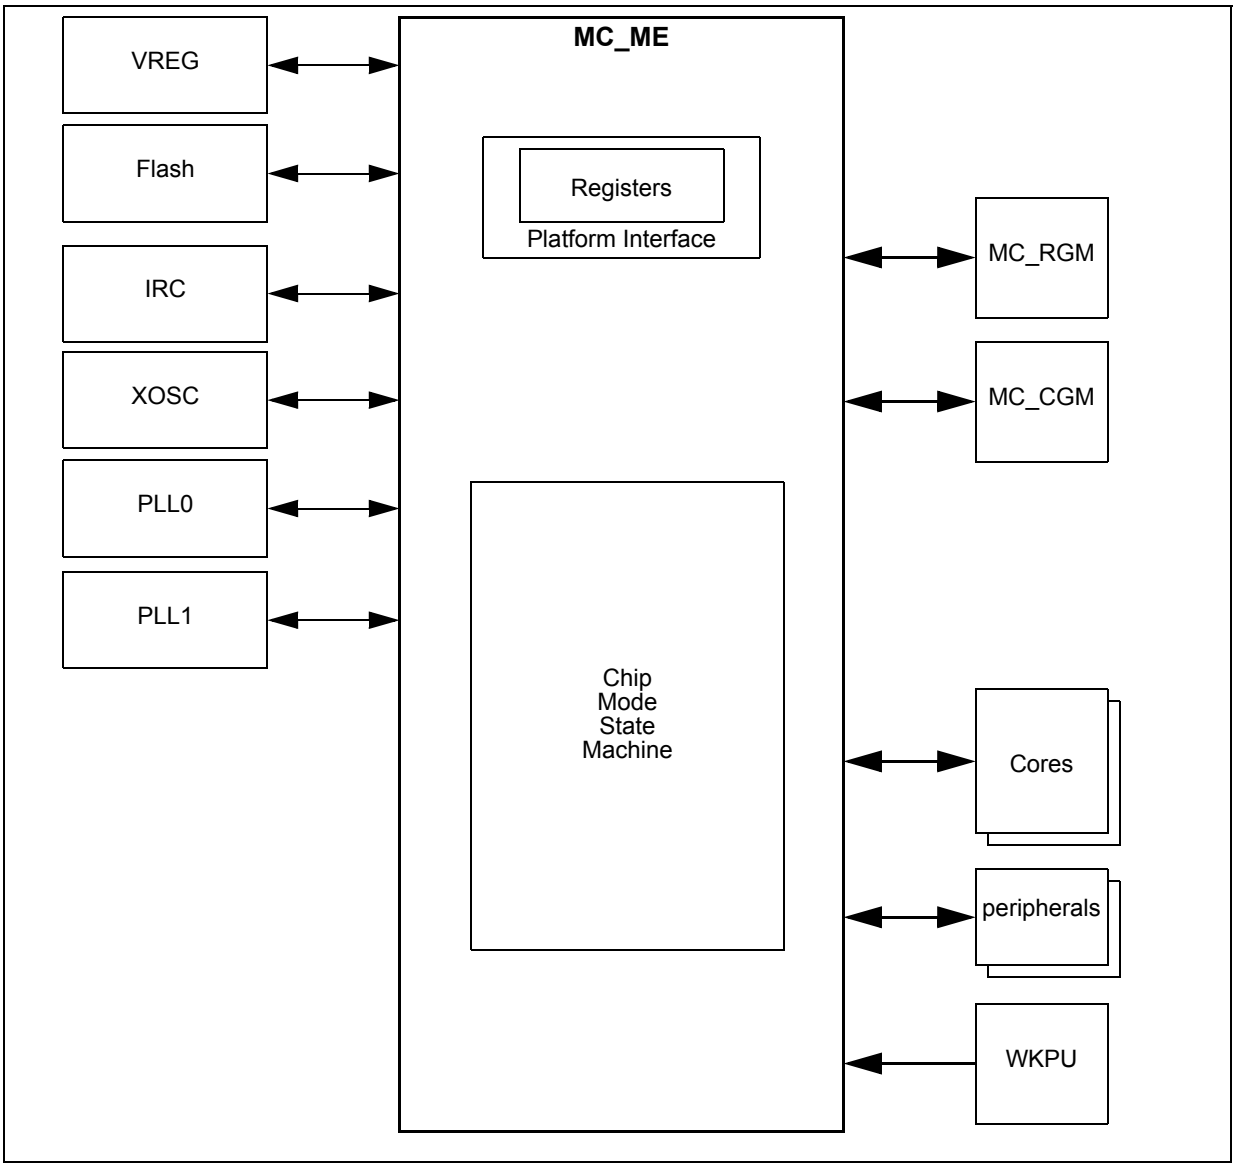
63 Mode Entry Module (MC_ME)



63.1 Introduction

63.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

Figure 1458 shows the MC_ME block diagram.

Figure 1458. MC_ME block diagram

63.1.2 Features

The MC_ME includes the following features:

- ME_ME register control of available modes.
- ME_*mode*_MC register definition of various chip mode configurations.
- ME_MCTL register control of the implemented chip mode.
- ME_GS register current mode capture and resource status.
- Optional generation of various mode transition interrupts.
- Status bits for each cause of invalid mode transitions.
- Peripheral clock gating control based on ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers.
- Additional core clock gating and boot address control based on the ME_CCTLn and ME_CADDRn registers.
- Capture of current peripheral and additional core clock gated/enabled status.
- Progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa.

63.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system.

The operating modes controlled by the MC_ME are divided into:

- System modes *RESET*, *DRUN*, *SAFE*, and *TEST*. These modes assist system configuration and monitoring.
- User modes *RUN0…3*, *HALT0*, and *STOP0* which can be configured according to energy management and available processing power requirements.

DRUN, *SAFE*, *TEST*, and *RUN0…3* are the chip software running modes.

Table 1411 describes the MC_ME modes.

Table 1411. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	System reset assertion from MC_RGM	System reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAM is executed when present.	– System reset deassertion from MC_RGM – Software request from *SAFE*, *TEST* and *RUN0…3*	– System reset assertion – *RUN0…3*, *TEST* via software – *SAFE* via software or hardware failure

Table 1411. MC_ME mode descriptions(Continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined configuration from which the system may try to recover.	– Hardware failure – Software request from *DRUN*, *TEST*, and *RUN0…3*	– System reset assertion – *DRUN* via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	Software request from *DRUN*	– System reset assertion – *DRUN* via software
RUN0…3	These are software running modes where most processing activity is done. The run modes allow varying system clock & power configurations.	– Software request from *DRUN* or other *RUN0…3* – Interrupt event from *HALT0* – Interrupt or wakeup event from *STOP0*	– System reset assertion – *SAFE* via software or hardware failure – Other *RUN0…3* modes – *HALT0*, *STOP0* via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals like clock sources, Flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.	Software request from *RUN0…3*	– System reset assertion – *SAFE* on hardware failure – *RUN0…3* on interrupt event(1)
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	Software request from *RUN0…3*	– System reset assertion – *SAFE* on hardware failure – *RUN0…3* on interrupt event or wakeup event[1]

1. If the user does not want the part to be woken up from certain Interrupt events, then the user needs to explicitly disable those interrupts in the respective peripherals. Disabling the respective interrupt channels in the Interrupt Controller will not suffice.

63.2 External signal description

The MC_ME has no connections to any external pins.

63.3 Memory map and register definition

The MC_ME contains registers for:

- Mode selection and status reporting.
- Mode configuration.
- Mode transition interrupts status and mask control.
- Scalable number of peripheral sub-mode selection and status reporting.
- Scalable number of additional core enabling and disabling control and status reporting.

Note: Access to unused registers or attempted writes to read-only registers do not change register content and cause a transfer error.

63.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the *ME_RUN_PC0* register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

The reset values and associated behavior of read-only fields cannot be changed.

63.3.2.1 Global Status register (ME_GS)

Address 0x000 Access: User read, Supervisor read, Test read

Figure 1459. Global Status register (ME_GS)

This register contains global mode status.

Table 1413. Global Status register (ME_GS) field descriptions

Field	Description
S_CURRENT_MODE	Current chip mode status. 0000 *RESET* 0001 *TEST* 0010 *SAFE* 0011 *DRUN* 0100 *RUN0* 0101 *RUN1* 0110 *RUN2* 0111 *RUN3* 1000 *HALT0* 1001 Reserved 1010 *STOP0* 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
S_MTRANS	Mode transition status. 0 Mode transition process is not active 1 Mode transition is ongoing
S_PDO	Output power-down status. This bit specifies output power-down status of I/Os and is asserted whenever outputs of pads are forced to high impedance state or the pads power-sequence driver(1) is switched off. 0 No automatic safe gating of I/Os used and pads power-sequence driver is enabled 1 In *STOP0* mode, the pad power sequence driver is disabled to reduce power consumption but the state of the output remains functional.

Table 1413. Global Status register (ME_GS) field descriptions(Continued)

Field	Description
S_MVR	Main voltage regulator status. 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
S_FLA	Flash availability status. 00 Flash is not available 01 Flash is in Power-down mode 10 Flash is in Low-power mode 11 Flash is in Normal mode and available for use
S_PLL1	Secondary PLL status. 0 Secondary PLL is not stable 1 Secondary PLL is providing a stable clock
S_PLL0	Primary PLL status. 0 Primary PLL is not stable 1 Primary PLL is providing a stable clock
S_XOSC	External crystal oscillator status. 0 External crystal oscillator is not stable 1 External crystal oscillator is providing a stable clock
S_IRC	16 MHz internal RC oscillator status. 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
S_SYSCLK	System clock switch status. These bits specify the system clock currently used by the system. 0000 16 MHz internal RC oscillator 0001 External crystal oscillator 0010 Primary PLL (PHI) 0011 Reserved 0100 Secondary PLL 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 System clock is disabled

1. Power-sequence drivers control pad slopes during *RUN* modes and are disabled in certain System or User modes to further reduce power consumption

63.3.2.2 Mode Control register (ME_MCTL)

Address 0x004 Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1
W	KEY															
Reset	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1

Figure 1460. Mode Control register (ME_MCTL)

This register is used to trigger software-controlled mode changes.

Depending on the modes enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_*mode*_MC registers must reflect this for successful mode requests.

Note: Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.

Table 1414. Mode Control register (ME_MCTL) field descriptions

Field	Description
TARGET_MODE	Target chip mode. These bits provide the target chip mode to be entered by software programming. To enter a mode via software, the write operation must be performed twice: first time with key and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. While exiting from the *HALT0* or *STOP0* modes on hardware exit events, these are updated with the appropriate *RUN0…3* mode value. 0000 RESET (triggers a 'functional' reset event) 0001 *TEST* 0010 *SAFE* 0011 *DRUN* 0100 *RUN0* 0101 *RUN1* 0110 *RUN2* 0111 *RUN3* 1000 *HALT0* 1001 Reserved 1010 *STOP0* 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 *RESET* (triggers a 'destructive' reset event)
KEY	Control key. These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access always returns the inverted key. KEY:0101101011110000 (0x5AF0) INVERTED KEY:1010010100001111 (0xA50F)

63.3.2.3 Mode Enable register (ME_ME)

Address 0x008 Access: User read, Supervisor read/write, Test read/write

Figure 1462. Interrupt Status register (ME_IS)

This register provides the current interrupt status.

Table 1416. Interrupt Status register (ME_IS) field descriptions

Field	Description
I_ICONF_CC	Invalid mode configuration interrupt (core configuration). This bit is set if a write access to one of the ME_CCTL*n* registers is attempted while a mode transition is in progress. 0 No write to an ME_CCTL*n* register was attempted during an ongoing mode transition 1 A write to an ME_CCTL*n* register was attempted during an ongoing mode transition
I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage). This bit is set during a mode transition if a clock required by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending

Table 1416. Interrupt Status register (ME_IS) field descriptions(Continued)

Field	Description
I_ICONF	Invalid mode configuration interrupt. This bit is set whenever a write operation to ME_<*mode*>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending
I_IMODE	Invalid mode interrupt . This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
I_SAFE	*SAFE* mode interrupt. This bit is set whenever the chip enters *SAFE* mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No *SAFE* mode interrupt occurred 1 *SAFE* mode interrupt is pending
I_MTC	Mode transition complete interrupt . This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit is not set while entering low-power modes *HALT0*, or *STOP0*. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

63.3.2.5 Interrupt Mask register (ME_IM)

Figure 1464. Invalid Mode Transition Status register (ME_IMTS)

This register provides the status bits for the possible causes of an invalid mode interrupt.

Table 1418. Invalid Mode Transition Status register (ME_IMTS) field descriptions

Field	Description
S_MRIG	Mode Request Ignored Status - This bit is set whenever a new mode is requested while a transition to some other mode is in progress. This bit is also set when if a transition to some other mode is requested while a wakeup event is active. It is cleared by writing 1 to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
S_MTI	Mode Transition Illegal status. This bit is set whenever a new mode is requested while another mode transition process is active (S_MTRANS is '1'). Refer to *Section 63.4.5, Mode transition interrupts* for exceptions to this behavior. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
S_MRI	Mode Request Illegal status. This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a '1' to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
S_DMA	Disabled Mode Access status. This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
S_NMA	Non-existing Mode Access status. This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
S_SEA	*SAFE* Event Active status. This bit is set whenever the chip is in *SAFE* mode, *SAFE* event bit is pending and a new mode requested other than *RESET*/*SAFE* modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than *RESET*/*SAFE* while *SAFE* event is pending 1 New mode requested other than *RESET*/*SAFE* while *SAFE* event is pending

63.3.2.7 Debug Mode Transition Status register (ME_DMTS)

Figure 1465. Debug Mode Transition Status register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS[S_MTRANS] is taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Some ME_DMTS bits may still be asserted after the mode transition has completed.

Table 1419. Debug Mode Transition Status register (ME_DMTS) field descriptions

Field	Description
PREVIOUS_MODE	Previous chip mode. These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 *RESET* 0001 *TEST* 0010 *SAFE* 0011 *DRUN* 0100 *RUN0* 0101 *RUN1* 0110 *RUN2* 0111 *RUN3* 1000 *HALT0* 1001 Reserved 1010 *STOP0* 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
MPH_BUSY	**MC_ME/MC_PCU Handshake Busy indicator**. This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has power-up/down sequencing. 0 Handshake is not busy 1 Handshake is busy
PMC_PROG	**MC_PCU Mode Change in Progress indicator**. This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
DBG_MODE	Debug mode indicator. This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
CCKL_PROG	**Core Clock Enable/Disable in Progress**. This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
PCS_PROG	**Progressive System Clock Switching in Progress**. This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
SMR	*SAFE* mode request from MC_RGM is active indicator. This bit is set if a hardware *SAFE* mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A *SAFE* mode request is not active 1 A *SAFE* mode request is active

Table 1419. Debug Mode Transition Status register (ME_DMTS) field descriptions(Continued)

Field	Description
VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator. This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator. This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
IRC_SC	IRC State Change during mode transition indicator. This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator completes its state change. 0 No state change is taking place 1 A state change is taking place
SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator. This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. A secondary clock source is a clock source other than IRC. 0 No state change is taking place 1 A state change is taking place
SYSCLK_SW	System Clock Switching pending status. 0 No system clock source switching is pending 1 A system clock source switching is pending
FLASH_SC	FLASH State Change during mode transition indicator. This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the FLASH completes its state change. 0 No state change is taking place 1 A state change is taking place
CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224…255(1). This bit is set when any peripheral appearing in ME_PS7 is requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192…2232[1]. This bit is set when any peripheral appearing in ME_PS6 is requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1419. Debug Mode Transition Status register (ME_DMTS) field descriptions(Continued)

Field	Description
CDP_PRPH_160_191	**Clock Disable Process Pending status for Peripherals 160…191**[1]. This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128…159[1]. This bit is set when any peripheral appearing in ME_PS4 is requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_96_127	**Clock Disable Process Pending status for Peripherals 96…127**[1]. This bit is set when any peripheral appearing in ME_PS3 is requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_64_95	**Clock Disable Process Pending status for Peripherals 64…95**[1]. This bit is set when any peripheral appearing in ME_PS2 is requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_32_63	**Clock Disable Process Pending status for Peripherals 32…63**[1]. This bit is set when any peripheral appearing in ME_PS1 is requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_0_31	**Clock Disable Process Pending status for Peripherals 0…31**[1]. This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the ME_PCTL*n* register. Refer to *Table 1412* for the ME_PCTL*n* locations actually occupied, which in turn indicates which peripherals are reported in the ME_DMTS register.

Figure 1472. STOP0 Mode Configuration register (ME_STOP0_MC)

This register configures system behavior during *STOP0* mode. Byte write accesses are not allowed to this register. Refer to *Table 1420* for details.

Table 1420. Mode Configuration Registers (ME_*mode*_MC) field descriptions

Field	Description
PWRLVL	**Power level** . These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
PDO	I/O output power-down control. This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power-sequence driver(1) is enabled 1 In *SAFE*/*TEST* modes, outputs of pads are forced to high impedance state and pads power-sequence driver is disabled. The inputs are level unchanged. In *STOP0* mode, only the pad power-sequence driver is disabled, but the state of the output remains functional.
MVRON	Main voltage regulator control. This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
FLAON	Flash power-down control. This bit specifies the operating mode of the code flash after entering this mode. 00 Reserved 01 Flash is in Power-down mode 10 Flash is in Low-power mode 11 Flash is in Normal mode
PLL1ON	Secondary PLL control. 0 Secondary PLL is switched off 1 Secondary PLL is switched on

Table 1420. Mode Configuration Registers (ME_*mode*_MC) field descriptions(Continued)

Field	Description
PLL0ON	Primary PLL control. 0 Primary PLL is switched off 1 Primary PLL is switched on
XOSCON	External crystal oscillator control. 0 External crystal oscillator is switched off 1 External crystal oscillator is switched on **Note:** The XOSCON value is set according to the chip configuration.
IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
SYSCLK	System clock switch control. These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 External crystal osc. 0010 Primary PLL (PHI) 0011 Reserved 0100 Secondary PLL 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 System clock is disabled in *TEST* mode, reserved in all other modes

1. Power-sequence drivers control pad slopes during *RUN* modes and are disabled in certain System or User modes to further reduce power consumption

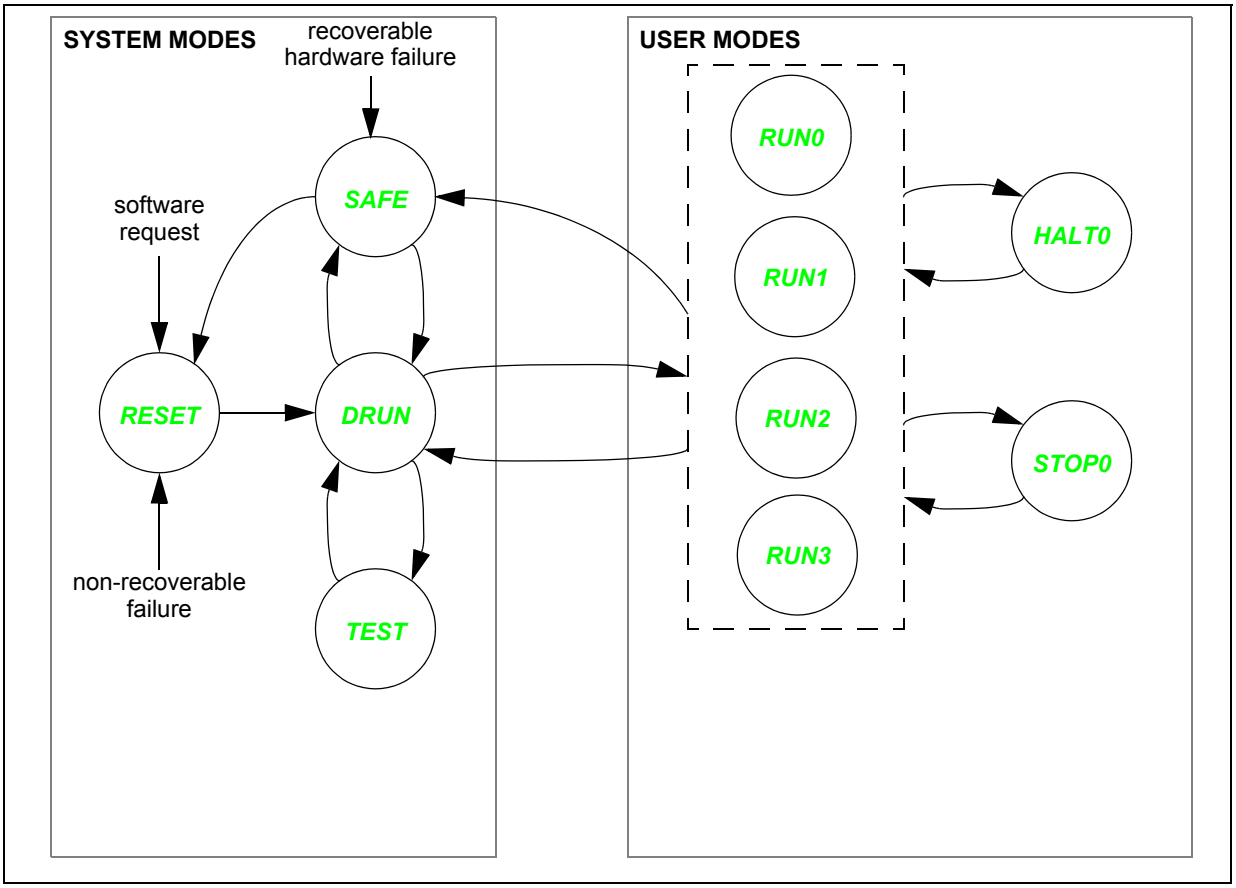
63.4 Functional description

63.4.1 Mode transition request

The transition from one mode to another is normally handled by software access to the mode control register ME_MCTL. In special cases, mode transition is automatically managed by hardware. To switch from one mode to another, the application should access the ME_MCTL register twice:

1. The first time by writing 0x5AF0 to the KEY field and the new mode to the TARGET_MODE field.
2. The second time with the inverted value 0xA50F to the KEY field and the new mode to the TARGET_MODE field.



Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_*mode*_MC register.The mode transition request may require a number of cycles depending on the programmed configuration. Refer to ME_GS[S_CURRENT_MODE] and ME_GS[S_MTRANS] to verify that the mode has been correctly entered and the transition process has completed.

For a description of valid mode requests, refer to *Section 63.4.5, Mode transition interrupts*.

Modification to the configuration register of the current mode has no effect until the next request to enter this mode. Transition requests such as *RUN0…3* → *RUN0…3*, *DRUN* → *DRUN*, *SAFE* → *SAFE*, and *TEST* → *TEST* are considered valid requests. As soon as the mode request is validated, the S_MTRANS bit is set until the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: Poll the ME_GS[S_MTRANS] bit after requesting a transition to HALT0 or STOP0 modes.

Figure 1491. MC_ME mode diagram

63.4.2 Modes details

63.4.2.1 *RESET* mode

The chip enters this mode:

- From *SAFE*, *DRUN*, *RUN0…3*, or *TEST* mode when ME_MCTL[TARGET_MODE] is written with either '0000' for a functional reset or '1111' for a destructive reset.
- From any mode due to a system reset by the MC_RGM because of a non-recoverable hardware failure (see the MC_RGM chapter for details).

Transition to this mode is instantaneous and the system remains in this mode until the reset sequence is finished. The mode configuration information is in the ME_RESET_MC register. It is a pre-defined configuration with the 16 MHz internal RC oscillator as the system clock.

DRUN mode

The chip enters this mode:

- Automatically from *RESET* mode after completion of the reset sequence.
- From *RUN0…3*, *SAFE*, or *TEST* mode when ME_MCTL[TARGET_MODE] is written with '0011'.

A DRUN mode transition request is generated when one of the above events has occurred. The mode configuration information is in the ME_DRUN_MC register and the Flash, all clock sources, and the system clock configuration can be controlled by software. After

system reset, software execution starts with the default configuration selecting the 16 MHz internal RC oscillator as the system clock. The clock source configuration (except system clock source 0) can be loaded into the ME_DRUN_MC register during *PHASE3* of the reset sequence from Flash memory.

This mode is used by software to initialize all registers as per the system needs.

Note: Ensure that the code executes from RAM before changing to this mode if the Flash is configured to be in Low-power or Power-down states in this mode.

63.4.2.2 *SAFE* mode

The chip enters this mode:

- From any mode except *RESET* when ME_MCTL[TARGET_MODE] is written with '0010'
- From any mode except *RESET* due to a *SAFE* mode request generated by the MC_RGM because of a potentially recoverable hardware failure in the system (see the MC_RGM chapter for details)

Note: A hardware SAFE mode request during RESET is processed immediately after normal completion of the reset sequence or several system clock cycles after DRUN entry, depending on the timing of the request. It does not influence the execution of the reset sequence itself.

A *SAFE* mode transition request is generated when one of the above events has occurred. The mode configuration information is in the ME_SAFE_MC register and has a pre-defined configuration with the 16 MHz internal RC oscillator selected as the system clock.

If *SAFE* mode is requested by software while another mode transition is in progress, the new target mode becomes *SAFE* mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the *SAFE* mode causes an invalid mode interrupt.

Note: If software requests transiton to SAFE mode and subsequently requests transition back to the parent mode before the transition is completed, the final mode after transition is SAFE mode and an invalid mode transition interrupt is generated.

The system remains in *SAFE* mode while a *SAFE* event is active and any software mode request during this time is ignored and lost.

This mode is used by software to assess failure severity and either:

- Re-initialize the chip via the *DRUN* mode.
- Completely reset the chip via the *RESET* mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the ME_SAFE_MC[PDO] bit should be set. The pads' power-sequence driver cell is also disabled. The input levels remain unchanged.

63.4.2.3 *TEST* mode

The chip enters this mode from *DRUN* mode when ME_MCTL[TARGET_MODE] is written with "0001".

A TEST mode transition request is generated when the above event has occurred. The mode configuration information is in the ME_TEST_MC register. All system resources are configurable in this mode except for the main voltage regulator. The clock to the whole

system can be stopped by programming the SYSCLK bit field to ‘1111’, which leaves chip reset as the only way to exit this mode.

This mode is used by software to execute software test routines.

Note: Ensure that code executes from RAM before changing to this mode if the flash is configured to be in Low-power or Power-down states in this mode.

63.4.2.4 *RUN0…3* modes

The chip enters one of these modes:

- From *DRUN*, *SAFE*, or another *RUN0…3* mode when ME_MCTL[TARGET_MODE] is written with ‘0100…0111’.
- From *HALT0* mode due to an interrupt event.
- From *STOP0* mode due to an interrupt or wakeup event.

a *RUN0…3* mode transition request is generated when one of the above events has occurred. The mode configuration information is in the ME_RUN0…3_MC registers and the Flash, all clock sources, and the system clock configuration can be controlled by software.

These modes are used by software to execute application routines

Note: Ensure that code executes from RAM before changing to this mode if the Flash is configured to be in Low-power or Power-down states in this mode.

63.4.2.5 *HALT0* mode

The chip enters this mode from one of the *RUN0…3* modes when when ME_MCTL[TARGET_MODE] is written with ‘1000’.

A *HALT0* mode transition request is generated when one of the above events has occurred. The mode configuration information is in the ME_HALT0_MC register and should be programmed according to the system needs as it is quite configuarable. The Flash can be put in Low-power or Power-down modes as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted (an invalid mode interrupt is *not* generated) with the resultant mode being:

- The current mode.
- *SAFE* (on *SAFE* mode request).
- *DRUN* (on reset).

This mode is used by software when it is required to react quickly (i.e., within a few system clock cycles of an interrupt event), or as a first-level Low-power mode with:

- The core clocks frozen
- The additional core clocks frozen.
- Only a few peripherals running.

Note: Clear the ME_GS[S_MTRANS] bit on HALT0 mode exit to ensure that the previous RUN0…3 mode configuration is fully restored before executing critical code.

63.4.2.6 *STOP0* mode

The chip enters this mode from one of the *RUN0…3* modes when ME_MCTL[TARGET_MODE] is written with ‘1010’.

A *STOP0* mode transition request is generated when the above event has occurred. The mode configuration information is in the ME_STOP0_MC register and should be programmed according to the system needs. The following clock sources are switched off in this mode:

- The primary PLL.
- The secondary PLL.

The Flash can be put in Power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode and invalid mode transition interrupt will be generated. The reason for this interrupt is S_MRIG (Mode request ignored). If transition to SAFE (on SAFE mode request) is in progress, transition request to STOP0 modes will also generate S_MRIG (Mode request ignored) interrupt. In case of transition to DRUN (on reset), no interrupt is generated.

This mode is used by software when there is no need to react quickly (e.g., allow for system clock source to be re-started), or as an advanced Low-power mode with:

- The core clock frozen.
- The additional core clocks frozen.
- Almost all peripherals stopped.

Set ME_STOP0_MC[PDO] if the pads power-sequence driver cell needs to be disabled while entering this mode. The state of the outputs is kept.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting *STOP0* mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: Clear the ME_GS[S_MTRANS] bit on STOP0 mode exit to ensure that the previous RUN0…3 mode configuration is fully restored before executing critical code.

63.4.3 Mode transition process

Mode transition proceeds along the following pre-defined steps depending on the current chip mode and the requested target mode. The steps do not all need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

63.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must satisfy a set of rules to initiate the process or it is ignored and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. Refer to *Section 63.4.5, Mode transition interrupts* for details.

- ME_MCTL[TARGET_MODE] is automatically updated for mode transitions originating from hardware events such as a *RESET*, a *SAFE* mode request or interrupt requests and wakeup events to exit Low-power modes. The mode change process start is indicated by ME_GS[S_MTRANS].
- A *RESET* mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The *RESET*

mode request has the highest priority and the MC_ME is kept in *RESET* mode during the entire reset sequence.

- *SAFE* mode request has the next highest priority after *RESET*. It is generated by:
  - Software, via the ME_MCTL register from all software running modes.
  - The MC_RGM after the detection of system hardware failures, which may occur in any mode.

63.4.3.2 Target mode configuration loading

On completion of the *Target mode request* step, the target mode configuration from the ME_*target mode*_MC register is loaded to start the resources (voltage sources, clock sources, Flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in *Table 1432*. A '√' indicates that a given resource is configurable for a given mode.

Table 1432. MC_ME resource control overview

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0…3	HALT0	STOP0
IRC	on	√ on	on	on	on	on	on
XOSC	off	√ off	off	√ off	√ off	√ off	√ off
PLL0	off	√ off	off	√ off	√ off	√ off	off
PLL1	off	√ off	off	√ off	√ off	√ off	√ off
FLASH	normal	√ normal	normal	√ normal	√ normal	√ low-power	√ power-down
MVREG	on	on	on	on	on	on	on
PDO	off	√ off	√ on	off	off	off	√ off

63.4.3.3 Peripheral clocks disable

On completion of the *Target mode request* step and system clock frequency ramp-down of the *System clock switching* step, the MC_ME requests each peripheral to enter its stop mode when the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0…7 and ME_LP_PC0…7, and the peripheral control registers ME_PCTLn

Each peripheral acknowledges its stop mode request after closing its internal activity and the MC_ME then disables the corresponding clock(s).

For a *SAFE* mode transition request, the MC_ME does not wait for the peripherals to acknowledge stop requests; the SAFE mode clock gating configuration is immediately applied regardless of the status of the peripherals' stop acknowledgement. Refer to *Section 63.4.6, Peripheral clock gating* for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters *SAFE* mode.

63.4.3.4 Processor Low-power mode entry

If mode transition is to *HALT0*, *STOP0* mode on completion of the *Peripheral clocks disable* step, the MC_ME requests each processor to enter its stopped state. Each processor acknowledges its stop state request bit after completing all outstanding bus transactions.

If mode transition is from a non Low-power mode to another non Low-power mode on completion of the *Peripheral clocks disable* step, the MC_ME requests each processor which is disabled in the ME_CCTLn registers to enter its stopped state. The processor acknowledges its stop state request bit after completing all outstanding bus transactions.

63.4.3.5 Processor clocks disable

When all processors disabled in the ME_CCTLn registers are in their appropriate stopped state on completion of the *Processor Low-power mode entry* step, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to run in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non Low-power modes.

Caution: Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

63.4.3.6 System clock disable

If all processor clocks have been disabled on completion of the *Processor clocks disable* step, the system clock used for non-processor system functions and memory is disabled.

63.4.3.7 Clock sources switch on

On completion of the *Processor Low-power mode entry* step, the MC_ME switches on all clock sources based on the *clock source*ON bits of the ME_*current mode*_MC and ME_*target mode*_MC registers. The following clock sources may be switched on:

- The 16 MHz internal RC oscillator.
- The external crystal oscillator.
- The primary PLL.
- The secondary PLL.

After the clock sources required by the target mode are switched on, all further clock-dependant mode transition steps wait (the duration depends on the type of source clock) for the stable status of the respective clocks. The availability status of these clocks is updated in the S_*clock source* bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock, which might require one of these clocks before switching to a different target clock.

63.4.3.8 Flash module switch on

On completion of the *Target mode request* step, the MC_ME may request the Flash to exit from its Low-power or Power-down mode based on the FLAON bit field of the ME_*current mode*_MC and ME_*target mode*_MC registers. When the Flash is available for access, the S_FLA bit field of the ME_GS register is updated to '11' by hardware.

Warning: Do not switch the FLASH from Low-power mode to Power-down mode or from Power-down mode to Low-power mode even if The MC_ME does not prevent or flag it.

63.4.3.9 Pad outputs on

If the PDO bit of the ME_*target mode*_MC register is cleared on completion of the *Target mode request* step, then:

- All pad outputs are enabled to return to their previous state.
- I/O pads power-sequence driver is switched on.

63.4.3.10 Peripheral clocks enable

The MC_ME enables the clocks for selected modules based on:

- The current and target chip modes.
- The peripheral configuration registers ME_RUN_PC0…7.
- ME_LP_PC0…7.
- The peripheral control registers ME_PCTLn.

This step is executed only after the*Target mode request* process is completed and the value of ME_*target mode*_MC[PWRLVL] is satisfied.

63.4.3.11 System and processor clocks enable

On completion of the *Flash module switch on* step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the reset of all processors which are configured in the ME_CCTLn registers to run in the target mode and which have their ME_CADDRn[RMC] bits set to '1'. The core reset outputs remain asserted until the end of the mode transition indicated by the ME_GS[S_MTRANS] bit, at which time they are deasserted.

If the value of ME_*target mode*_MC[PWRLVL] differs to ME_*current mode*_MC[PWRLVL], the mode change handshake is not initiated until after the system clock frequency ramp-down step of the *System clock switching* process is completed.

63.4.3.12 Processor Low-power mode exit

On completion of the *System and processor clocks enable* step, the MC_ME requests all processors configured in the ME_CCTLn registers to be disabled in the current mode and to run in the target mode.

63.4.3.13 System clock switching

If the target and current system clock configurations differ in the SYSCLK bit field of the ME_*current mode*_MC and ME_*target mode*_MC registers, the following method is implemented for clock switching:

- The target clock configuration for the 16 MHz internal RC oscillator takes effect only after the clock stabilizes and the hardware sets ME_GS[S_IRC] bit.
- The target clock configuration for the external crystal oscillator takes effect only after the clock stabilizes and the hardware sets ME_GS[S_XOSC] bit.
- The target clock configuration for the primary PLL (PHI) takes effect only after the clock stabilizes and the hardware sets ME_GS[S_PLL0] bit .
- The target clock configuration for the secondary PLL takes effect only after the clock stabilizes and the hardware sets ME_GS[S_PLL1] bit.
- To disable the clock, set the SYSCLK bit field with '1111'. This is possible only in *TEST* mode.

Progressive clock switching is performed if ME_*target mode*_MC[PWRLVL] is not equal to ME_*current mode*_MC[PWRLVL].

The current system clock configuration can be read from the ME_GS[S_SYSCLK] bit, which is updated after every system clock switching. The system uses the previous clock configuration until the target clock is available.

System clock switching starts only after:

- the *Clock sources switch on* process has completed if the target system clock source is one of the following:
  - The 16 MHz internal RC oscillator.
  - The external crystal oscillator.
  - The primary PLL.
- the *Peripheral clocks disable* process has completed in order to ensure that a system clock frequency change does not lead to unpredictable peripheral behavior before peripherals have been cleanly turned off.

An overview of system clock source selection possibilities for each mode is shown in *Table 1433*. A '√' indicates that a given clock source is selectable for a given mode.

Table 1433. MC_ME system clock selection overview

System clock source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0…3	HALT0	STOP0
16 MHz internal RC oscillator	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)	√ (default)
external crystal oscillator		√		√	√	√	√
primary PLL (PHI)		√		√	√	√	√

Table 1433. MC_ME system clock selection overview(Continued)

System clock source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0…3	HALT0	STOP0
secondary PLL		√		√	√		
system clock is disabled		√(1)					

1. Disabling the system clock during ***TEST*** mode will require a reset in order to exit ***TEST*** mode.

63.4.3.14 Pad switch off

If the ME_*target mode*_MC[PDO] bit is '1', the outputs of the pads are forced to the high impedance state when the target mode is *SAFE* or *TEST.*

This step is executed only after the *Peripheral clocks disable* process has completed.

63.4.3.15 Clock sources switch off

If a given clock source is to be switched off based on the chip mode and the clock source bits of the ME_*mode*_MC registers, the MC_ME requests the clock source to power down and updates its availability status ME_GS[S_*clock source*] bit to '0'. The following clock sources may be switched off at this step:

- The 16 MHz internal RC oscillator.
- The external crystal oscillator.
- The primary PLL.
- The secondary PLL.

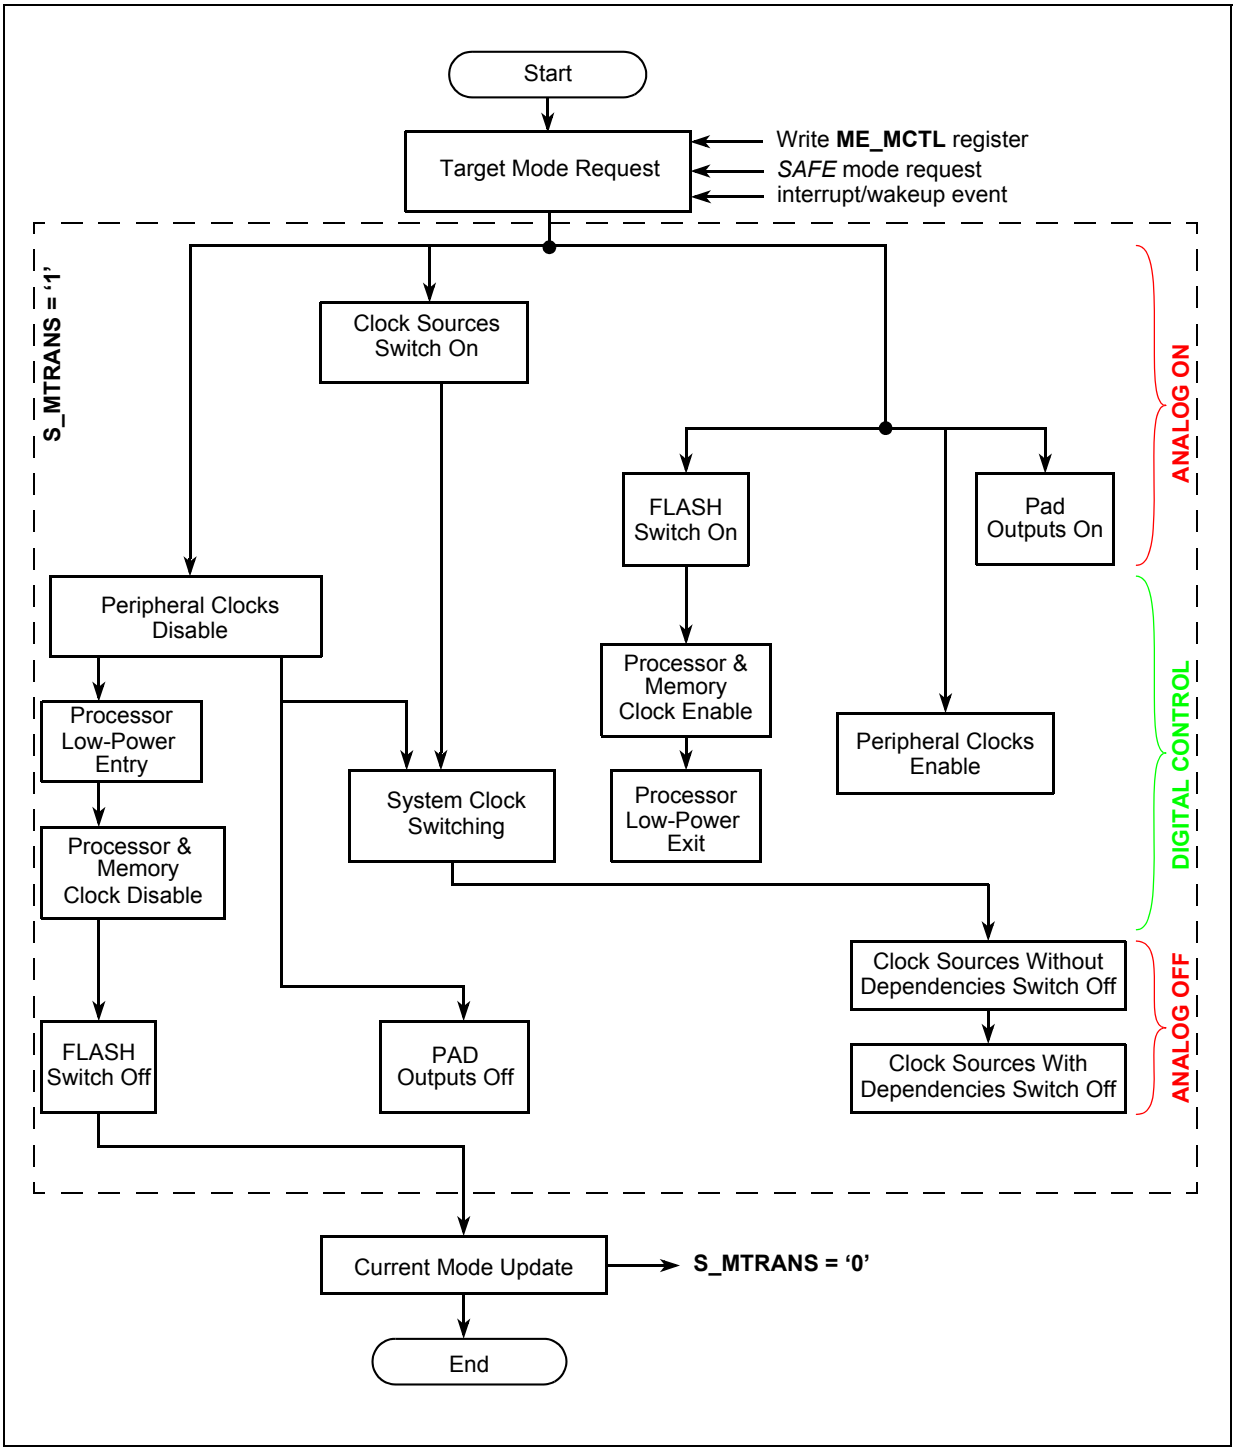
For the clock sources related to the system clock, this step is executed only after the *System clock switching* process has completed.

63.4.3.16 Flash switch off

If the Flash is to be put in Low-power or Power-down mode based on the FLAON bit field of the ME_*current mode*_MC and ME_*target mode*_MC registers, the MC_ME requests the Flash to enter the corresponding power mode and waits for the Flash to acknowledge. The power mode status of the Flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the *Processor clocks disable* and *System clock disable* processes have completed.

63.4.3.17 Current mode update

The current mode status ME_GS[S_CURRENT_MODE] bit is updated with the target mode ME_MCTL[TARGET_MODE] bit when:



- All the updated status bits in the ME_GS register match the configuration specified in the ME_*target mode*_MC register.
- Power sequences are done.
- Clock disable and enable processes are finished.
- Processor Low-power mode (stop) entry and exit processes are finished.

Note: To ensure that the SAFE mode is entered as quickly as possible, it only waits for the ME_GS[S_IRC] bit to be set, without waiting for the clock disable or enable process to finish.

Software can monitor the mode transition status via the ME_GS[S_MTRANS] bit. Mode transition latency varies depending on the requirements of the target mode and the availability of the resources prior to the new mode request.

If a mode transition is taking longer than expected, the ME_DMTS register can indicate which process is still in progress.

Figure 1492. MC_ME transition diagram

63.4.4 Protection of mode configuration registers

While programming the mode configuration registers ME_*mode*_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz internal RC oscillator is selected as the system clock, IRC must be on.
- If the external crystal oscillator clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration '00' for the FLAON bit field is reserved.
- System clock configurations marked as 'reserved' may not be selected.
- Configuration '1111' for the SYSCLK bit field is allowed only for *TEST* mode and only in this case may all system clock sources be turned off.

Warning: If the system clock is stopped during TEST mode, the chip can exit only via a system reset.

63.4.5 Mode transition interrupts

The MC_ME provides interrupts for:

- Incorrectly configuring a mode.
- Requesting an invalid mode transition.
- A *SAFE* mode transition not deriving from a software request.
- When a mode transition has completed.

63.4.5.1 Invalid mode configuration interrupt

Whenever an attempted ME_*mode*_MC register write operation violates the protection rules in *Section 63.4.4, Protection of mode configuration registers*, the interrupt pending ME_IS[I_ICONF] bit is set and an interrupt request is generated if the ME_IM[M_ICONF] mask bit is '1'.

During a mode transition, if an ME_*target mode*_MC clock source is set to 'off' and a peripheral requiring this clock has been enabled via the ME_RUN_PC0…7, ME_LP_PC0…7 and ME_PCTLn registers, the interrupt pending ME_IS[I_ICONF_CU] bit of the register is set and an interrupt request is generated if the ME_IM[M_ICONF_CU] mask bit is '1'.

If an ME_CCTLn or ME_CADDRn write attempt is made after a mode change request via the second write to the ME_CTL register and before the completion of that mode transition (ME_GS[S_MTRANS] bit deassertion), the interrupt pending ME_IS[I_ICONF_CC] bit is set and an interrupt request is generated if the ME_IM[M_ICONF_CC] mask bit is '1'.

63.4.5.2 Invalid mode transition interrupt

The mode transition request is considered invalid under the following conditions:

- If the target mode requested is other than *RESET* or *SAFE* while the system is in *SAFE* mode and the *SAFE* mode request from MC_RGM is still active, then this new mode request is invalid and the ME_IMTS[S_SEA] bit is set.
- If the ME_MCTL[TARGET_MODE] bit is written with a non-existent mode value, an invalid mode transition event is generated and the ME_IMTS[S_NMA] bit is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled in the ME_ME register, their respective configurations are reserved and any access to the ME_MCTL register with those values results in an invalid mode transition request. When a disabled mode is requested, the ME_IMTS[S_DMA] bit is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status ME_IMTS[S_MRI] bit is set. This condition is only detected when the proper key mechanism is followed while writing the ME_MCTL register, otherwise the write operation is ignored.
- If further new mode requests occur while a mode transition is in progress (ME_GS[S_MTRANS] bit is '1'), the mode transition illegal status ME_IMTS[S_MTI] bit is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register, otherwise the write operation is ignored.

Note: The priority implemented for simultaneous invalid mode transition status bits of the ME_IMTS register, from highest to lowest, is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

The mode transition request is not considered as invalid under the following conditions:

- A new *RESET* or *SAFE* mode request is allowed irrespective of the mode transition status.
- As exit from *HALT0* and *STOP0* modes depends on the system interrupts which can occur at any instant, requests to return to *RUN0…3* modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a period of time determined by. The parent mode is the chip mode before a valid mode request was made.
- Self-transition requests (e.g., *RUN0* → *RUN0*) are not considered as invalid even when the mode transition process is active (i.e., S_MTRANS is '1'). If the system is not able to enter the respective RUN0…3 mode properly (all status bits of the ME_GS register match configuration bits in the ME_*mode*_MC register) during the Low-power mode exit process, then software can only request the *SAFE* or *RESET* mode. It is not possible to request any other mode or to return to the Low-power mode.

Whenever an invalid mode request is detected, the interrupt pending ME_IS[I_IMODE] bit is set and an interrupt request is generated if the ME_IM[M_IMODE] mask bit is '1'.

63.4.5.3 *SAFE* mode transition interrupt

When the system enters *SAFE* mode as a result of a request from the MC_RGM due to a hardware failure, the interrupt pending ME_IS[I_SAFE] bit is set and an interrupt is generated if the ME_IM[M_SAFE] mask bit is '1'.

The *SAFE* mode interrupt pending bit can be cleared only when the request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in this mode, any new *SAFE* mode requests by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the interrupt pending bit is not set when *SAFE* mode is entered via a software request (i.e., programming of ME_MCTL register).

63.4.5.4 Mode transition complete interrupt

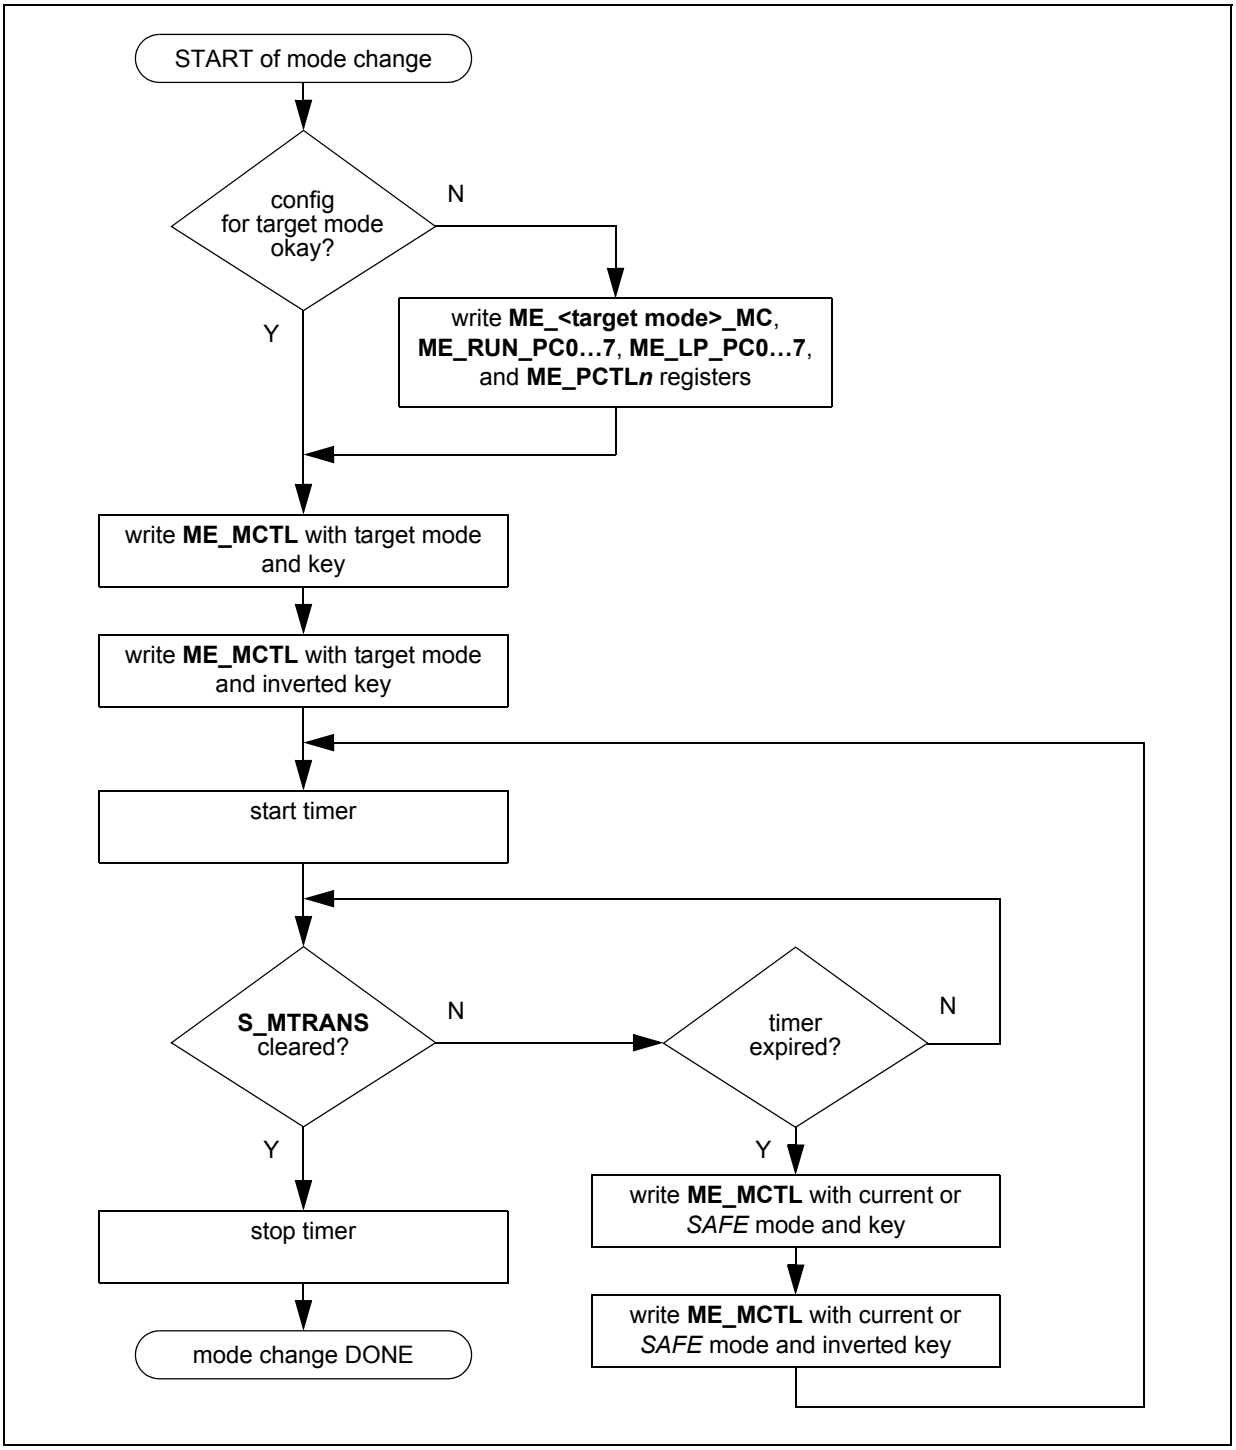
When the system fully completes a mode transition (ME_GS[S_MTRANS] bit transits from '1' to '0'), the interrupt pending ME_IS[I_MTC] bit is set and an interrupt request is generated if the ME_IM[M_MTC] mask bit is '1'. The interrupt bit I_MTC is not set when entering Low-power modes *HALT0* and *STOP0* to avoid the same event requesting the immediate exit of these Low-power modes.

63.4.6 Peripheral clock gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0…7 are chosen only during the software run modes DRUN, TEST, SAFE, and RUN0…3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is handled by the ME_PCTLn[RUN_CFG] bit.

The Low-power peripheral configuration registers ME_LP_PC0…7 are chosen only during the Low-power modes *HALT0* and *STOP0*. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is handled by the ME_PCTLn[LP_CFG] bit.



Any modifications to the ME_RUN_PC0…7, ME_LP_PC0…7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the chip enters a debug session during any mode, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits.

63.4.7 Application example

Figure 1493 shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

Figure 1493. MC_ME application example flow diagram

64 e200z410Dn3 Core Debug Support

This chapter describes the debug features of the e200z410Dn3 core.

64.1 Overview

Internal debug support in the e200z410Dn3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z410Dn3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z410Dn3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

64.1.1 Software debug facilities

e200z410Dn3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

64.1.1.1 *PowerISA 2.06* compatibility

The e200z410Dn3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

64.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z410Dn3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See *Section 64.1.4: Sharing debug resources by software/hardware*.) A data trace port is also provided.

64.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z410Dn3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the “Data Trace Control Register (DTC)” section in the Core (e200z410Dn3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

64.1.3 Hardware debug facilities

The e200z410Dn3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z410Dn3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

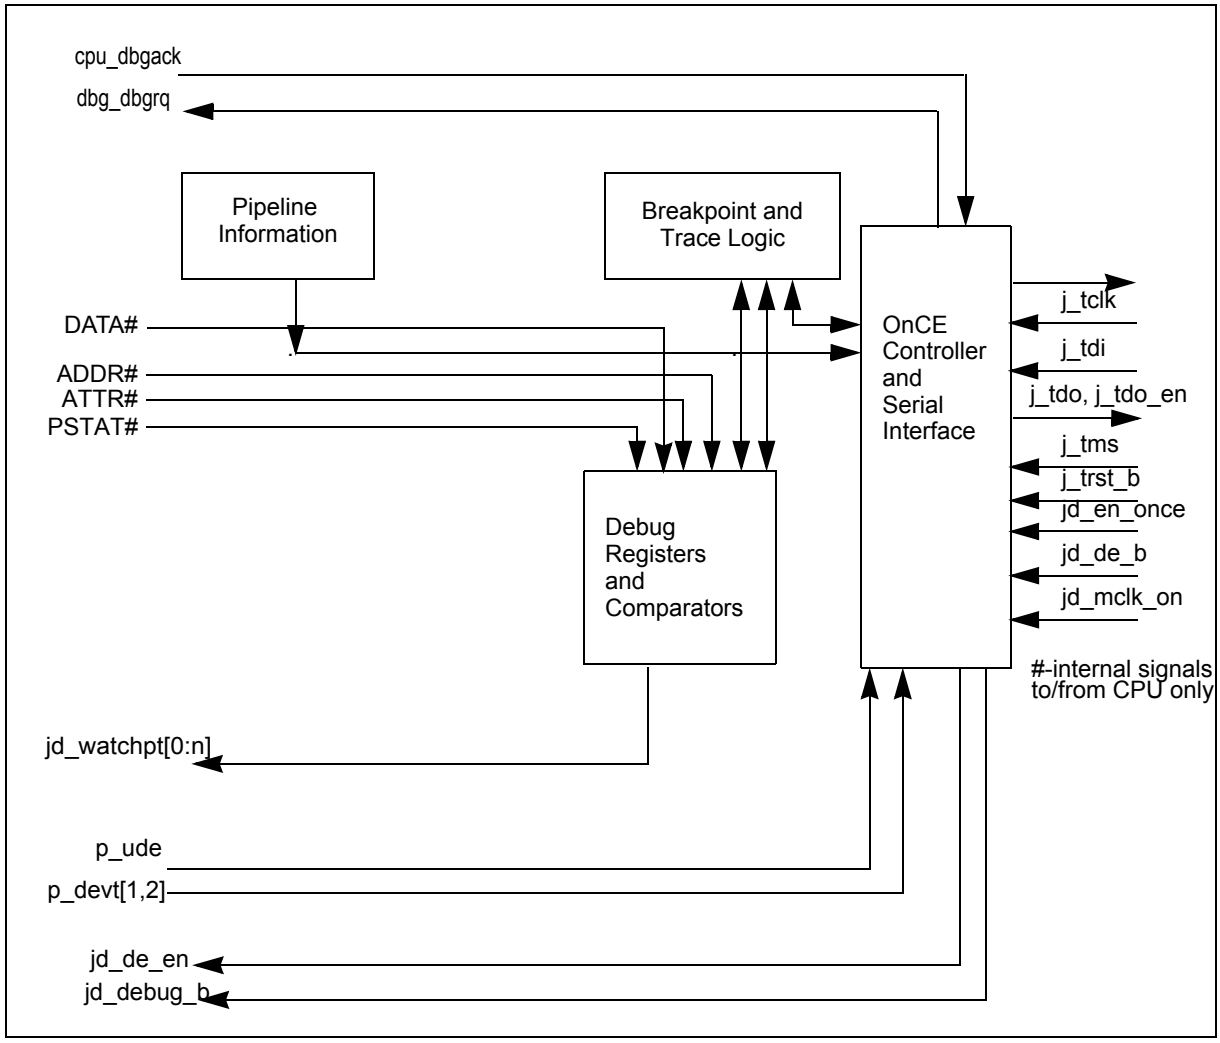
Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in *Section 64.3: Debug registers* are reserved for use by the external debugger. The same events described in *Section 64.2: Software debug events and exceptions* are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via

EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

64.1.4 Sharing debug resources by software/hardware



Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

64.1.4.1 Simultaneous hardware and software debug event handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1494 shows the e200z410Dn3 debug resources.

Figure 1494. e200z410Dn3 debug resources

64.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z410Dn3 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in *Section 64.2.11: External debug event*.
- The Performance Monitor Interrupt event PMI, which is described in *Section 64.2.13: Performance Monitor Interrupt debug event*.

The e200z410Dn3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

64.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

64.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z410Dn3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note: DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note: DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*Note: DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*Note: DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Note: Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.*

64.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 1434 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0.

Table 1434. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.

Table 1434. DAC events and resultant updates(Continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1434. DAC events and resultant updates(Continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

64.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

64.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}.

When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

64.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

64.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

64.2.7 Interrupt Taken debug event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

64.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

64.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

64.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

64.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to ‘1’ to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

64.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to ‘1’ to record the debug exception. This debug event is an asynchronous event.

64.2.13 Performance Monitor Interrupt debug event

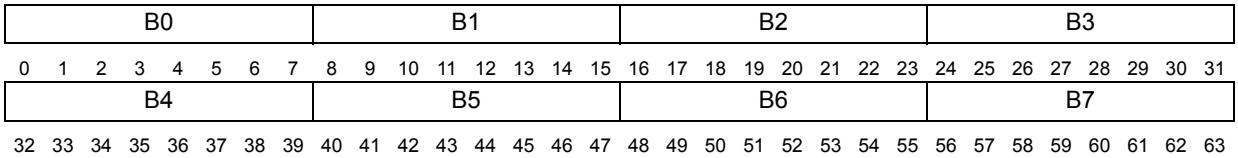
A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

64.3.1 Debug Address and Value registers



Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 1495*) corresponds to the byte data value transferred to/from memory byte offset 0, 8, ..., and the least significant byte of the register (labeled B7 in *Figure 1495*) corresponds to byte offset 7, F, ... When enabled for performing data value comparisons,

each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z410Dn3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

SPR 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset: Unaffected

Figure 1495. DVC1, DVC2 registers

64.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z410Dn3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

64.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z410Dn3 adds some implementation specific bits to this register, as seen in *Figure 1496*.

EDM	IDM	RST	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC2	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0	CIRPT	CRET	0
0	1	2 3	4	5	6	7	8	9	10	11	12 13	14 15	16	17	18	19	20	21	22	23 24	25	26	27 28 29 30 31

SPR - 308; Read/Write; Reset(1) - 0x0

Figure 1496. Debug Control Register 0 (DBCR0) register

1. $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

Table 1435 provides bit definitions for Debug Control Register 0.

Table 1435. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0.
		Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to ‘1’ before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to ‘1’, all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled

Table 1435. DBCR0 field descriptions (Continued)

Bit	Name	Description
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled 1 IAC1 debug events are enabled
9	IAC2	Instruction Address Compare 2 Debug Event Enable 0 IAC2 debug events are disabled 1 IAC2 debug events are enabled
10	IAC3	Instruction Address Compare 3 Debug Event Enable 0 IAC3 debug events are disabled 1 IAC3 debug events are enabled
11	IAC4	Instruction Address Compare 4 Debug Event Enable 0 IAC4 debug events are disabled 1 IAC4 debug events are enabled
12:13	DAC1	Data Address Compare 1 Debug Event Enable 00 DAC1 debug events are disabled 01 DAC1 debug events are enabled only for store-type data storage accesses 10 DAC1 debug events are enabled only for load-type data storage accesses 11 DAC1 debug events are enabled for load-type or store-type data storage accesses
14:15	DAC2	Data Address Compare 2 Debug Event Enable 00 DAC2 debug events are disabled 01 DAC2 debug events are enabled only for store-type data storage accesses 10 DAC2 debug events are enabled only for load-type data storage accesses 11 DAC2 debug events are enabled for load-type or store-type data storage accesses

64.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in *Figure 1498*.

SPR - 310; Read/Write; Reset(1) - 0x0

Figure 1498. DBCR2 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1437 provides bit definitions for Debug Control Register 2.

Table 1437. DBCR2 field descriptions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1

Table 1437. DBCR2 field descriptions (Continued)

Bit	Name	Description
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.

Table 1437. DBCR2 field descriptions (Continued)

Bit	Name	Description
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.

Table 1437. DBCR2 field descriptions (Continued)

Bit	Name	Description
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

64.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 1499*.

0	DVC1C	0	DVC2C	0	0	DAC1XMH	0	DAC2XMH	DAC1XM	DAC2XM	DAC1CFG	DAC2CFG
0	1	2	3	4 – 5	6	7	8	9	10 – 11	12	13	14	15	16 – 19	20 – 23	24 – 27	28 – 31

SPR - 563; Read/Write; Reset(1) - 0x0

Figure 1499. DBCR4 register

1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1438 provides bit definitions for Debug Control Register 4.

Table 1438. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1438. DBCR4 field descriptions (Continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01*xx* Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01*xx* Reserved 1*xxx* Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

64.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 1500*

IAC5US	IAC5ER	IAC6US	IAC6ER	IAC56M	0	IAC7US	IAC7ER	IAC8US	IAC8ER	IAC78M	0

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1442 provides bit definitions for Debug Control Register 8.

Table 1442. DBCR8 field descriptions

Bit	Name	Description
0:1	DAC3US	Data Address Compare 3 User/Supervisor Mode 00 DAC3 debug events not affected by MSR_{PR} 01 Reserved 10 DAC3 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC3 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC3ER	Data Address Compare 3 Effective/Real Mode 00 DAC3 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC3 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC3 debug events are based on effective address and can only occur if MSR_{DS}=1
4:5	DAC4US	Data Address Compare 4 User/Supervisor Mode. 00 DAC4 debug events not affected by MSR_{PR} 01 Reserved 10 DAC4 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC4 debug events can only occur if MSR_{PR}=1 (User mode)
6:7	DAC4ER	Data Address Compare 4 Effective/Real Mode 00 DAC4 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC4 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC4 debug events are based on effective address and can only occur if MSR_{DS}=1

Table 1442. DBCR8 field descriptions (Continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

64.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 1504*.

IDE	UDE	MRR	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 1504. Debug Status Register (DBSR)

Table 1443 provides bit definitions for the Debug Status Register.

Table 1443. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred

Table 1443. DBSR field descriptions (Continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 1505*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 600; Read/Write; Reset - unaffected

Figure 1505. Debug Data Effective Address Register (DDEAR)

64.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in *Figure 1506*.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b**, reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 1506. External Debug Resource Allocation Control (EDBRAC0) register

Table 1443 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 1444. EDBRAC0 field descriptions

Bit	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored. 0 Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable.
2	RST	Reset Field Control 0 $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 Event owned by hardware debug. 1 Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 Event owned by software debug. $DBCR0_{TRAP}$ is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 Event owned by software debug. IAC1 control fields are software readable/writable.

Table 1444. EDBRAC0 field descriptions (Continued)

Bit	Name	Description
9	IAC2	Instruction Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 Event owned by software debug. DAC1 control fields are software readable/writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1444. EDBRAC0 field descriptions (Continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable. **Note:** This bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors that have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** This bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored. 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in *Table 1445* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

64.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z410Dn3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 1507*.

DQTAG	0	DEVNT

64.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this

register. See the “Data Acquisition Messaging” section in the Core (e200z410Dn3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 1508*.

DDAM

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 576; Reset(1): 0x0

Figure 1508. Debug Data Acquisition Message (DDAM) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1447 provides bit definitions for the Debug Data Acquisition Message Register.

Table 1447. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

64.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit

checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 1438*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack

limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 1438* and *Table 1441* in *Section 64.3.2: Debug Control and Status registers*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

64.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 64.2: Software debug events and exceptions* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

*Note: It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*Note: $EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

64.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

64.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 1509*.

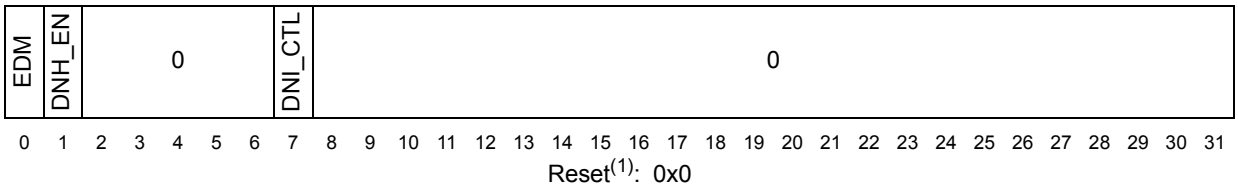

Figure 1509. External Debug Control Register 0 (EDBCR0)

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 1448 provides bit definitions for External Debug Control Register 0.

Table 1448. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	**dnh** Instruction Enable 0 Execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 Execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE}=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. **Note:** This control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1.
8:31	—	Reserved

64.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 1510*.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9 10 11	12	13	14	15	16	17 18 19 20	21	22	23	24	25	26	27	28 29 30	31

Read/Write; Reset(1) - 0x0000_0000

Figure 1510. External Debug Status Register 0 (EDBSR0)

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$=0.

Table 1449 provides bit definitions for External Debug Status Register 0.

Table 1449. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$

Table 1449. EDBSR0 field descriptions(Continued)

Bit	Name	Description
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A ‘1’ stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 1511*.

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

22:31	—	Reserved

64.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 1512*.

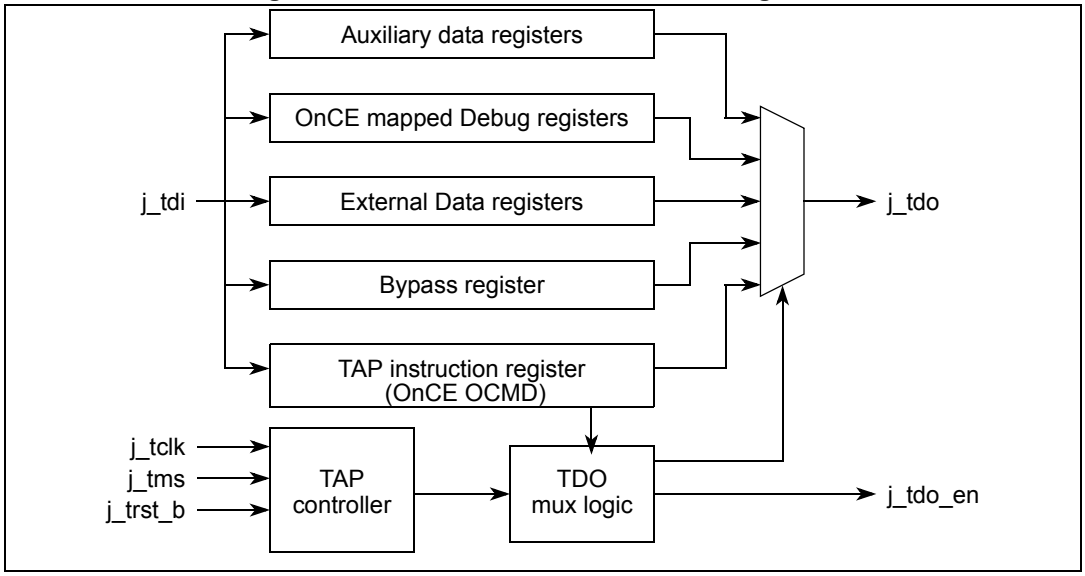
Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

Read/Write; Reset: unaffected

Figure 1512. External Debug Data Effective Address Register (EDDEAR)

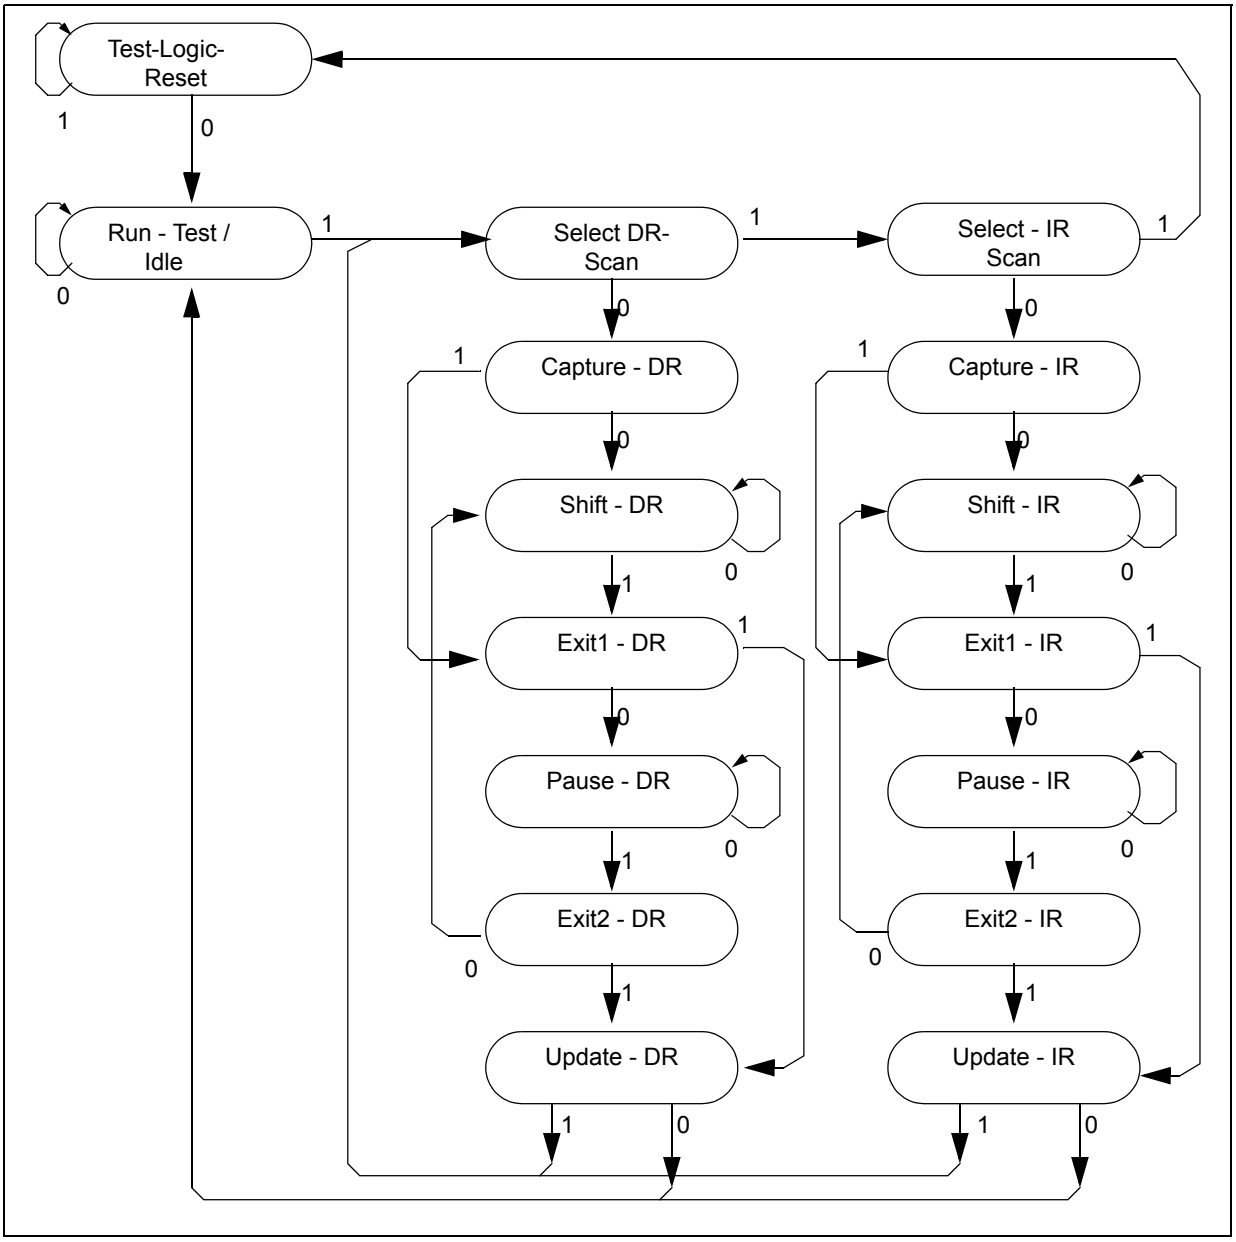
64.5.2 OnCE introduction



The e200z410Dn3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z410Dn3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.



The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1513. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1514. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 64.5.6.1: OnCE Status register*) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will

indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See *Section 64.5.6.2: OnCE Command (OCMD) register*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

64.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

Table 1451 details the primary JTAG/OnCE interface signals.

Table 1451. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en(1)	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z410Dn3) Core Complex Overview.

64.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

64.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

64.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

64.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

64.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

64.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

64.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

64.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z410Dn3 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

64.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See *Section 64.5.6.2: OnCE Command (OCMD) register* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

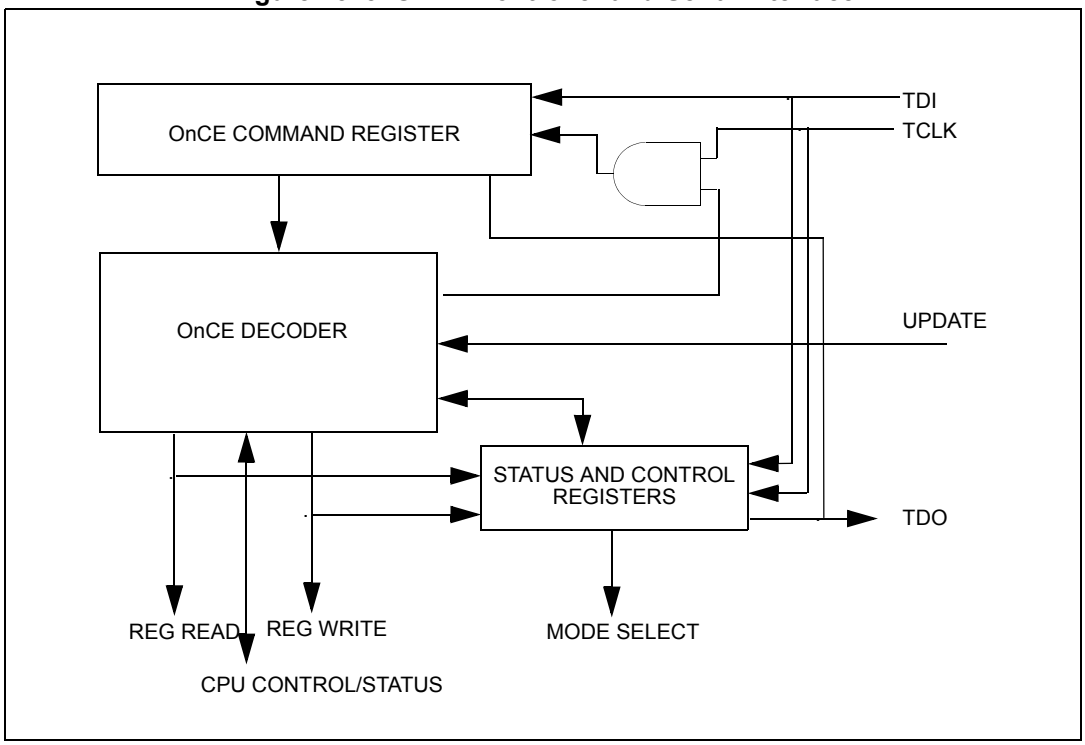
64.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z410Dn3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

64.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 1458* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

64.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)



This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

64.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 1515* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1515. OnCE Controller and Serial Interface

64.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 1516. OnCE Status register

Table 1452 provides bit definitions for the OnCE Status register.

Table 1452. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

64.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 1517*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as

such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

R/W	GO	EX	RS[0:6]

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test_Logic_Reset state

Figure 1517. OnCE Command (OCMD) register

Table 1453 provides bit definitions for the OCMD.

Table 1453. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 64.5.9.6: Exiting Debug mode and interrupt blocking*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1453. OCMD field descriptions (Continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. **Note:** If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 64.5.9.6: Exiting Debug mode and interrupt blocking*.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 1454* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 1454 indicates the OnCE register addresses.

1. Causes assertion of the j_en_once_regsel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

64.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z410Dn3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see *Section 64.7: MPU operation during debug*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 1518*.

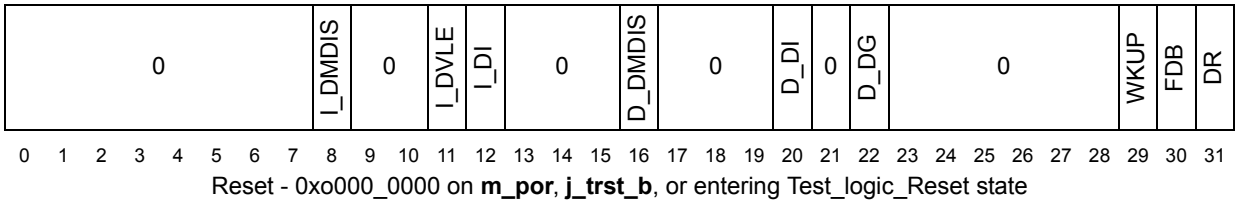

Figure 1518. OnCE Control Register (OCR)

Table 1455 provides bit definitions for the OnCE Control Register.

Table 1455. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Data accesses during a debug session.
21	—	Reserved

Table 1455. OCR field descriptions (Continued)

Bit	Name	Description
22	D_DG	Data Side Debug 'G' Attribute Bit This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the '**bkpt**' pseudo-instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. **Note:** This bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

64.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z410Dn3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z410Dn3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z410Dn3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 1456 provides a list of access requirements for OnCE registers.

Table 1456. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 $_{EDM}$ = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*(1)

PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

64.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See *Section 64.5.5.1: OnCE Enable (jd_en_once)*.

64.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z410Dn3 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z410Dn3 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

64.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

64.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

64.5.8.4 Debug request during Waiting, Halted, or Stopped state

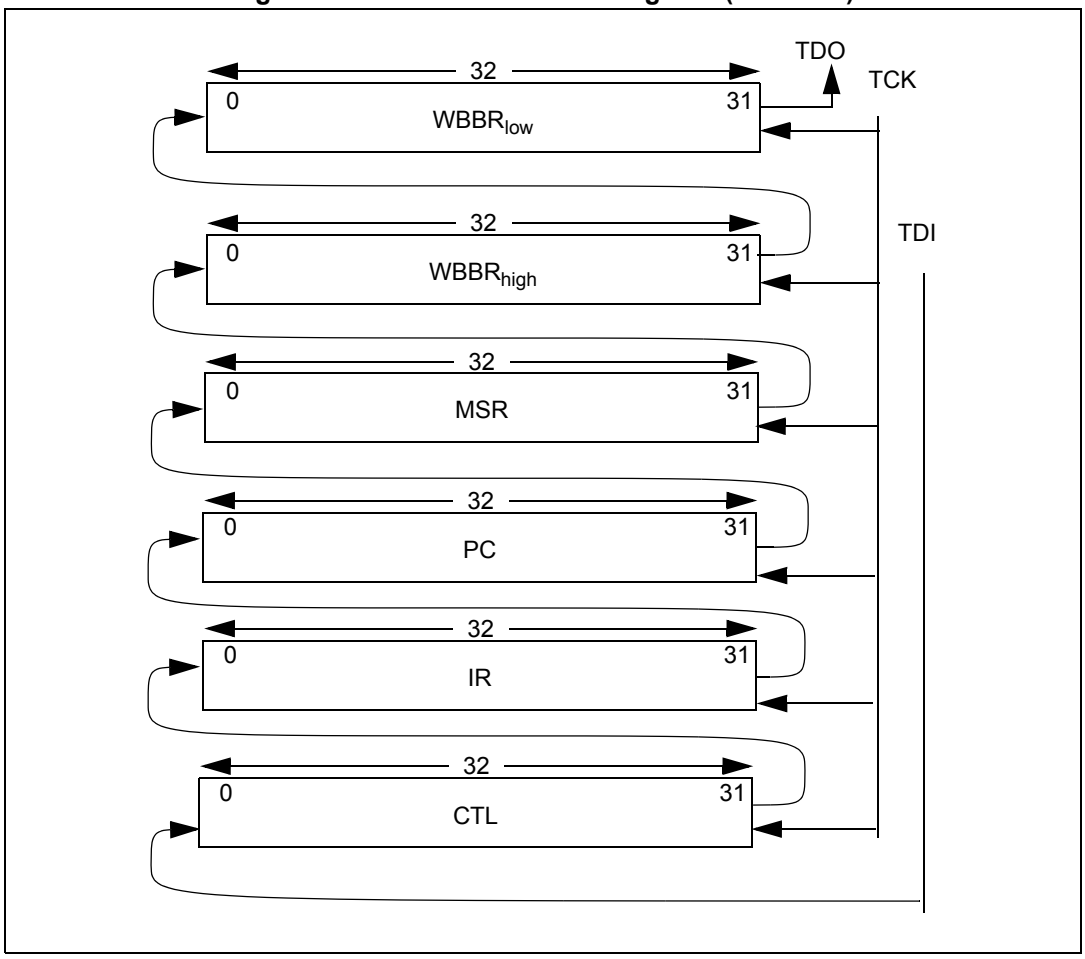
Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be

used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

64.5.8.5 Software request during normal activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z410Dn3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.



64.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z410Dn3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

Note: A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 1519* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1519. CPU Scan Chain Register (CPUSCR)

64.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

64.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the

external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

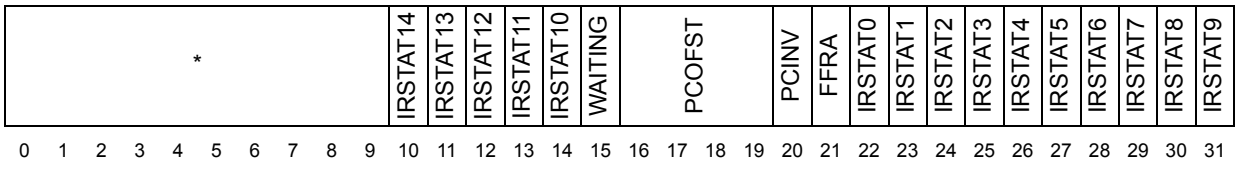


Figure 1520. Control State Register (CTL)

Table 1457. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See *Section 64.5.5.3: OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.

Table 1457. CTL field descriptions (Continued)

Bit	Name	Description
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. **Note:** not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of $WBBR_{lo}$ used as operand value.

Table 1457. CTL field descriptions (Continued)

Bit	Name	Description
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to ‘0’, and the IR set to the value of the

desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to ‘0’s if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to ‘0’ to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

64.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

64.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori**

instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 64.5.9.2: Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

64.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

64.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

64.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

64.6 Watchpoint support

e200z410Dn3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based

events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes. (See the “Watchpoint Trace Messaging” section in the Core (e200z410Dn3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1458 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1458. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status

Table 1458. Watchpoint output signal assignments(Continued)

Signal Name	Type	Description
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a ‘0’ to a ‘1’ while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$

Table 1458. Watchpoint output signal assignments(Continued)

Signal Name	Type	Description
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

64.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (*Section 64.5.6.3: OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 64.5.6.3: OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

64.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

64.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 64.5.9.2: Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 64.5.9.2: Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 64.5.9.2: Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

65 e200z225Bn3 Core Debug Support

This chapter describes the debug features of the e200z225Bn3 core.

65.1 Overview

Internal debug support in the e200z225Bn3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z225Bn3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z225Bn3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

65.1.1 Software debug facilities

e200z225Bn3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 ($DBCR0_{IDM}$). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When $DBCR0_{IDM}$ is cleared (and $EDBCR0_{EDM}$ is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when $DBCR0_{IDM}$ is cleared (or is overridden by $EDBCR0_{EDM}$ being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

65.1.1.1 *PowerISA 2.06* compatibility

The e200z225Bn3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

65.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z225Bn3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See *Section 65.1.4: Sharing debug resources by software/hardware*.) A data trace port is also provided.

65.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z225Bn3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the “Data Trace Control Register (DTC)” section in the Core (e200z225Bn3) Nexus 3 Module chapter. The data trace port will report aligned accesses, and most misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0. Also, for accesses generated by a LSP load/store instruction using circular addressing mode that crosses a buffer boundary, the two portions of the misaligned access will be reported separately, since otherwise it is not possible to correctly correlate the data with the initial access address.

65.1.3 Hardware debug facilities

The e200z225Bn3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z225Bn3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

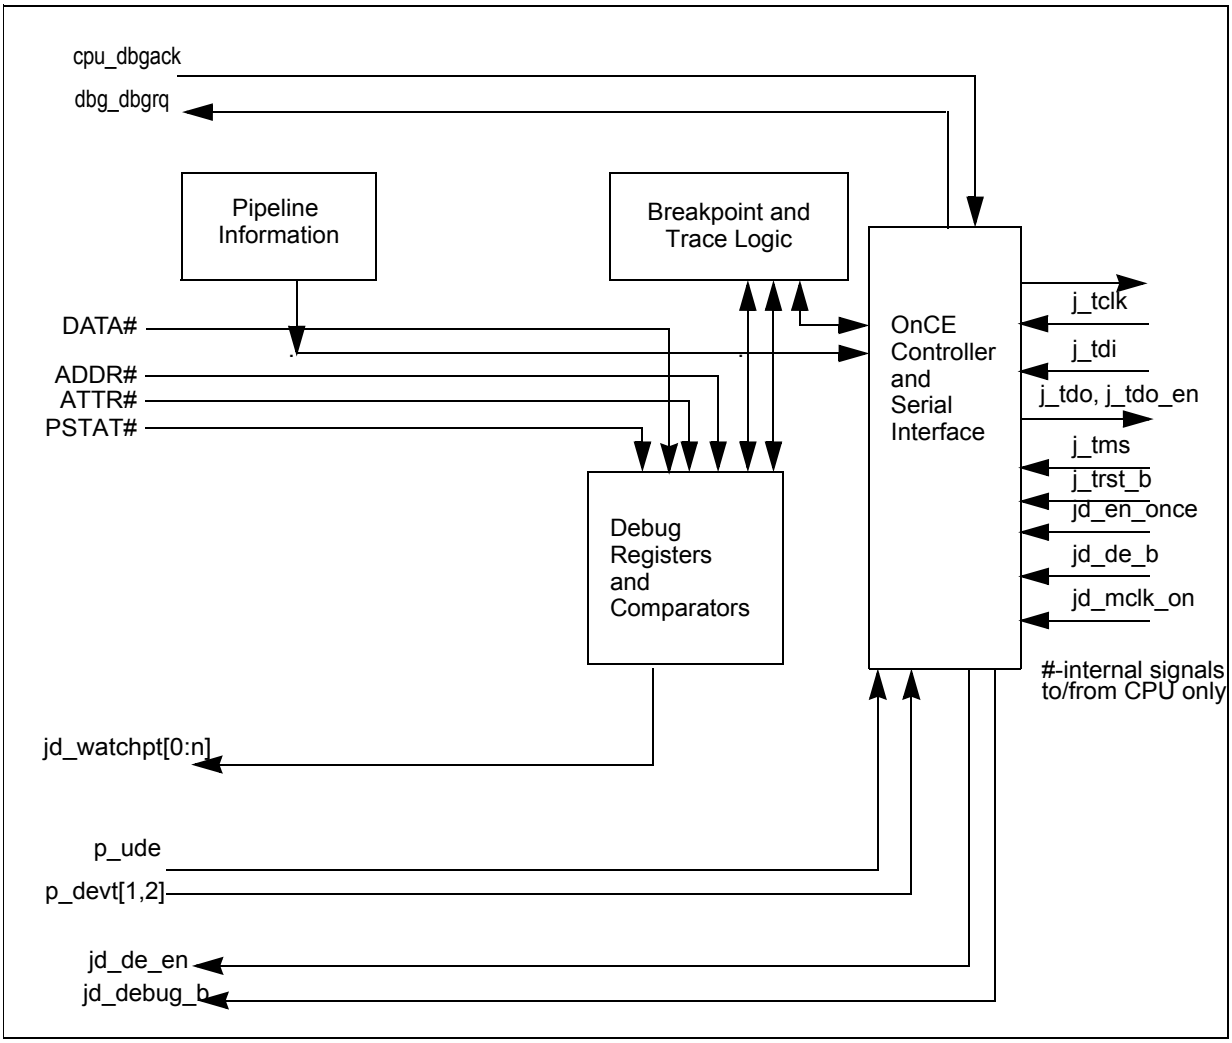
Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 ($EDBCR0_{EDM}$), which is also aliased to $DBCR0_{EDM}$. Setting $EDBCR0_{EDM}$ overrides the Internal Debug mode enable bit $DBCR0_{IDM}$ unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting $EDBCR0_{EDM}$=1, the control registers and resources described in *Section 65.3: Debug registers* are reserved for use by the external debugger. The same events described in *Section 65.2: Software debug events and*

exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. $EDBCR0_{EDM}$, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

65.1.4 Sharing debug resources by software/hardware



Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When $EDBCR0_{EDM}$ is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when $DBCR0_{IDM}$=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when $EDBCR0_{EDM}$=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

65.1.4.1 Simultaneous hardware and software debug event handing

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1521 shows the e200z225Bn3 debug resources.

Figure 1521. e200z225Bn3 debug resources

65.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}$=1) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in EDBRAC0). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers (DBCR0–8). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE}, a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when MSR_{DE}=0 and $DBCR0_{IDM}$=1. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE}. A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while MSR_{DE}=0, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z225Bn3 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in *Section 65.2.11: External debug event*.
- The Performance Monitor Interrupt event PMI, which is described in *Section 65.2.13: Performance Monitor Interrupt debug event*.

The e200z225Bn3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

65.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

65.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load or store operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z225Bn3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

Note: If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note: DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

*Note: DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.*

*Note: DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.*

*Note: Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.*

65.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class

instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

Table 1459 outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0.

Table 1459. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.

Table 1459. DAC events and resultant updates(Continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. **Note:** in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

Table 1459. DAC events and resultant updates(Continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. **Note:** in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.
DVC DACx	Any instruction (no exception)	DACy, or DVC DAC_y Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. **Note:** in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.

65.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

65.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled ($DBCR0_{TRAP}$=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}.

When a Trap debug event occurs, the $DBSR_{TRAP}$ bit is set to 1 to record the debug exception.

65.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled ($DBCR0_{BRT}$=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus $DBSR_{IDE}$ can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the $DBSR_{BRT}$ bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

65.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled ($DBCR0_{ICMP}$=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The ***se_sc*** instruction does not fall into the category of an instruction whose execution is suppressed, since the instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in DSRR0.

Instruction Complete debug events are not recognized if MSR_{DE}=0 at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed (SRR0 points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with SRR0 pointing to the instruction following the instruction that generated the EFPU Round exception, and DSRR0 will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}$=1, this circumstance can also occur when $EDBCR0_{EDM}$=1 and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}$=1, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while MSR_{DE}=1.

65.2.7 Interrupt Taken debug event

An Interrupt Taken debug event (IRPT) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}$=1) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using SRR0/1) cause an Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the non-critical interrupt handler.

65.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event (CIRPT) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}$=1) and a critical interrupt occurs. Only critical class interrupts (an interrupt using CSRR0/1) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in DSRR0 will be the address of the critical interrupt handler.

65.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}$=1) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

65.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}$=1) and an attempt is made to execute an **se_rfci** instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If MSR_{DE}=0 at the time of the execution of the **se_rfci** (i.e. before the MSR is updated by the **se_rfci**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If MSR_{DE}=1 at the time of the execution of the **se_rfci**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfci** instruction.

65.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}$=1 or $DBCR0_{DEVT2}$=1), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to ‘1’ to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

65.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to ‘1’ to record the debug exception. This debug event is an asynchronous event.

65.2.13 Performance Monitor Interrupt debug event

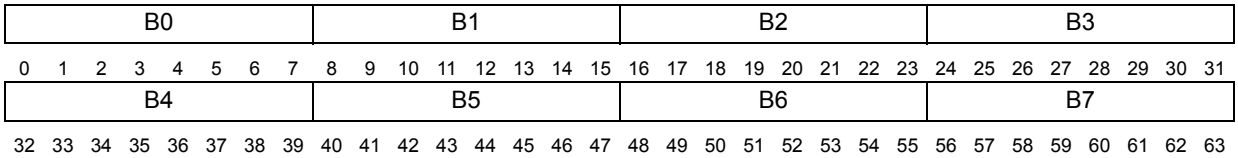
A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}$=1), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

65.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register EDBRAC0, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in EDBRAC0 corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not "owned" by software is not guaranteed to be consistent if accessed (read) by software with a **mfspr** instruction, other than the $DBCR0_{EDM}$ bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

65.3.1 Debug Address and Value registers



Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in *Figure 1522*) corresponds to the byte data value transferred to/from memory byte offset 0, 8, ..., and the least significant byte of the register (labeled B7 in *Figure 1522*) corresponds to byte offset 7, F, ... When enabled for performing data value comparisons,

each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z225Bn3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfspr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

SPR 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset: Unaffected

Figure 1522. DVC1, DVC2 registers

65.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z225Bn3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

65.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z225Bn3 adds some implementation specific bits to this register, as seen in *Figure 1523*.

EDM	IDM	RST	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC2	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0	CIRPT	CRET	0
0	1	2 3	4	5	6	7	8	9	10	11	12 13	14 15	16	17	18	19	20	21	22	23 24	25	26	27 28 29 30 31

SPR - 308; Read/Write; Reset(1) - 0x0

Figure 1523. Debug Control Register 0 (DBCR0) register

1. $DBCR0_{EDM}$ is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if $DBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $DBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b,** and only software-owned resources indicated by EDBRAC0 and the $DBCR0_{RST}$ field will be reset by **p_reset_b**. The $DBCR0_{RST}$ field will always be reset by **p_reset_b** regardless of the value of $DBCR0_{EDM}$.

Table 1460 provides bit definitions for Debug Control Register 0.

Table 1460. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCR0–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0.
		Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to ‘1’ before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to ‘1’, all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If MSR_{DE}=1, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 **p_dbrstc[1]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 **p_dbrstc[0]** pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled

Table 1460. DBCR0 field descriptions (Continued)

Bit	Name	Description
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled 1 IAC1 debug events are enabled
9	IAC2	Instruction Address Compare 2 Debug Event Enable 0 IAC2 debug events are disabled 1 IAC2 debug events are enabled
10	IAC3	Instruction Address Compare 3 Debug Event Enable 0 IAC3 debug events are disabled 1 IAC3 debug events are enabled
11	IAC4	Instruction Address Compare 4 Debug Event Enable 0 IAC4 debug events are disabled 1 IAC4 debug events are enabled
12:13	DAC1	Data Address Compare 1 Debug Event Enable 00 DAC1 debug events are disabled 01 DAC1 debug events are enabled only for store-type data storage accesses 10 DAC1 debug events are enabled only for load-type data storage accesses 11 DAC1 debug events are enabled for load-type or store-type data storage accesses
14:15	DAC2	Data Address Compare 2 Debug Event Enable 00 DAC2 debug events are disabled 01 DAC2 debug events are enabled only for store-type data storage accesses 10 DAC2 debug events are enabled only for load-type data storage accesses 11 DAC2 debug events are enabled for load-type or store-type data storage accesses
16	RET	Return Debug Event Enable 0 RET debug events are disabled 1 RET debug events are enabled
17	IAC5	Instruction Address Compare 5 Debug Event Enable 0 IAC5 debug events are disabled 1 IAC5 debug events are enabled
18	IAC6	Instruction Address Compare 6 Debug Event Enable 0 IAC6 debug events are disabled 1 IAC6 debug events are enabled

65.3.2.3 Debug Control Register 2 (DBCR2)

Debug Control Register 2 is used to configure Data Address Compare and Data Value Compare operation.The DBCR2 register is shown in *Figure 1525*.

SPR - 310; Read/Write; Reset(1) - 0x0

Figure 1525. DBCR2 register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1462 provides bit definitions for Debug Control Register 2.

Table 1462. DBCR2 field descriptions

Bit	Name	Description
0:1	DAC1US	Data Address Compare 1 User/Supervisor Mode 00 DAC1 debug events not affected by MSR_{PR} 01 Reserved 10 DAC1 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC1 debug events can only occur if MSR_{PR}=1 (User mode)
2:3	DAC1ER	Data Address Compare 1 Effective/Real Mode 00 DAC1 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC1 debug events are based on effective address and can only occur if MSR_{DS}=1

Table 1462. DBCR2 field descriptions (Continued)

Bit	Name	Description
4:5	DAC2US	Data Address Compare 2 User/Supervisor Mode 00 DAC2 debug events not affected by MSR_{PR} 01 Reserved 10 DAC2 debug events can only occur if MSR_{PR}=0 (Supervisor mode) 11 DAC2 debug events can only occur if MSR_{PR}=1. (User mode)
6:7	DAC2ER	Data Address Compare 2 Effective/Real Mode 00 DAC2 debug events are based on effective address 01 Unimplemented (Book E real address compare), no match can occur 10 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=0 11 DAC2 debug events are based on effective address and can only occur if MSR_{DS}=1
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies *Exact Address Compare* since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.

Table 1462. DBCR2 field descriptions (Continued)

Bit	Name	Description
12:13	DVC1M	Data Value Compare 1 Mode When $DBCR4_{DVC1C}$=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC1C}$=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.
14:15	DVC2M	Data Value Compare 2 Mode When $DBCR4_{DVC2C}$=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. **Note:** Inactive byte lanes of the memory access are automatically masked. When $DBCR4_{DVC2C}$=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved **Note:** Inactive byte lanes of the memory access are automatically masked.

Table 1462. DBCR2 field descriptions (Continued)

Bit	Name	Description
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1*xxxxxxx* Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. *x*1*xxxxxx* Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. *xx*1*xxxxx* Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. *xxx*1*xxxx* Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. *xxxx*1*xxx* Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. *xxxxx*1*xx* Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. *xxxxxx*1*x* Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. *xxxxxxx*1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

65.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in *Figure 1526*.

0	DVC1C	0	DVC2C	0	0	DAC1XMH	0	DAC2XMH	DAC1XM	DAC2XM	DAC1CFG	DAC2CFG
0	1	2	3	4 5 6 7 8 9 10 11	12	13	14	15	16 17 18 19	20 21 22 23	24 25 26 27	28 29 30 31

SPR - 563; Read/Write; Reset(1) - 0x0

Figure 1526. DBCR4 register

1. DBCR4 is reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1463 provides bit definitions for Debug Control Register 4.

Table 1463. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH || DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH || DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1463. DBCR4 field descriptions (Continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}$=00 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}$=00 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}$=00 0011 Reserved 01*xx* Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}$=0; when $DBCR0_{DAC1}$!=00, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}$=00 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}$=00 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}$=00 0011 Reserved 01*xx* Reserved 1*xxx* Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. **Note:** Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}$=00. When $DBCR0_{DAC2}$!=00, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.

65.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in *Figure 1527*

IAC5US	IAC5ER	IAC6US	IAC6ER	IAC56M	0	IAC7US	IAC7ER	IAC8US	IAC8ER	IAC78M	0
0 1	2 3	4 5	6 7	8 9	10 11 12 13 14 15	16 17	18 19	20 21	22 23	24 25	26 27 28 29 30 31

Table 1467. DBCR8 field descriptions (Continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

65.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr** *DBSR,RS*. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}$=1). When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1, $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}$=1 and $EDBRAC0_{IDM}$=1), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in *Figure 1531*.

IDE	UDE	MRR	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 304; Read/Clear; Reset - 0x1000_0000

Figure 1531. Debug Status Register (DBSR)

Table 1468 provides bit definitions for the Debug Status Register.

Table 1468. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if MSR_{DE}=0 and $DBCR0_{IDM}$=1 and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a Return debug event occurred

Table 1468. DBSR field descriptions (Continued)

Bit	Name	Description
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UDI}$=1
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load or store operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in *Figure 1532*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR - 600; Read/Write; Reset - unaffected

Figure 1532. Debug Data Effective Address Register (DDEAR)

65.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}$=1. EDBRAC0 settings are ignored when $EDBCR0_{EDM}$=0.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}$=1 update DBSR, causing debug interrupts to occur if MSR_{DE}=1. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled (MSR_{DE}=1 $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=0, or MSR_{DE}=1, $DBCR0_{IDM}$=1 and $EDBCR0_{EDM}$=1 and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}$=1). When $EDBCR0_{EDM}$=1, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}$=1, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in DBCR0–8 or MPU0CSR0 are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in *Figure 1533*.

0	IDM	RST	UDE	ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC34	DAC2	0	RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	DNI	DQM	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 638; Read-only by Software; Reset - Unaffected by **p_reset_b**, reset to 0x00000180 by **m_por** or while in the test-logic-reset OnCE controller state

Figure 1533. External Debug Resource Allocation Control (EDBRAC0) register

Table 1469 provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 1469. EDBRAC0 field descriptions

Bit	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control. When $EDBRAC0_{IDM}$=1, software writes to hardware-owned bits in DBCR0–8 via **mtspr** are ignored. 0 Internal Debug mode may not be enabled by software. $DBCR0_{IDM}$ is owned exclusively by hardware. **mtspr** DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 Internal Debug mode may be enabled by software. $DBCR0_{IDM}$ is owned by software. $DBCR0_{IDM}$ is software readable/writable.
2	RST	Reset Field Control 0 $DBCR0_{RST}$ owned exclusively by hardware debug. No **mtspr** access by software to $DBCR0_{RST}$ field. 1 $DBCR0_{RST}$ accessible by software debug. $DBCR0_{RST}$ is software readable/writable.
3	UDE	Unconditional Debug Event 0 Event owned by hardware debug. 1 Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{ICMP}$ field. 1 Event owned by software debug. $DBCR0_{ICMP}$ is software readable/writable.
5	BRT	Branch Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{BRT}$ field. 1 Event owned by software debug. $DBCR0_{BRT}$ is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{IRPT}$ field. 1 Event owned by software debug. $DBCR0_{IRPT}$ is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{TRAP}$ field. 1 Event owned by software debug. $DBCR0_{TRAP}$ is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC1 control and status fields. 1 Event owned by software debug. IAC1 control fields are software readable/writable.

Table 1469. EDBRAC0 field descriptions (Continued)

Bit	Name	Description
9	IAC2	Instruction Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC2 control and status fields. 1 Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC3 control and status fields. 1 Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC4 control and status fields. 1 Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC1 control and status fields. 1 Event owned by software debug. DAC1 control fields are software readable/writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No **mtspr** access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{RET}$ field. 1 Event owned by software debug. $DBCR0_{RET}$ is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1469. EDBRAC0 field descriptions (Continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT1}$ field. 1 Event owned by software debug. $DBCR0_{DEVT1}$ is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{DEVT2}$ field. 1 Event owned by software debug. $DBCR0_{DEVT2}$ is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No **mtpmr** access by software to the PMRs. Performance monitor interrupts set $EDBSR0_{PMI}$ regardless of the setting of $PMGC0_{UDI}$ 1 Event owned by software debug. PMRs are software readable/writable. **Note:** This bit is reset to '1'.
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No **mpuwe** access by software to region descriptors that have the DEBUG control bit set to '1' or to the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits, unless the CPU is in a debug session (**jd_debug_b** is asserted). MPU debug events set $EDBSR0_{MPU}$, and if not masked by $EDBSRMSK0_{MPU}$, one of $EDBSR0_{IAC}$, $EDBSR0_{DACR}$, or $EDBSR0_{DACW}$. MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (**jd_debug_b** is asserted). 1 Event owned by software debug. All region descriptors and the $MPU0CSR0_{DRDEN,DWDEN,IDEN}$ control bits are software readable/writable. **Note:** This bit is reset to '1'.
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CIRPT}$ field. 1 Event owned by software debug. $DBCR0_{CIRPT}$ is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No **mtspr** access by software to $DBCR0_{CRET}$ field. 1 Event owned by software debug. $DBCR0_{CRET}$ is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an **e_dni** or **se_dni** instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an **e_dni** or **se_dni** instruction results in either a debug interrupt ($DBCR0_{IDM}$=1 and MSR_{DE}=1) or a nop ($DBCR0_{IDM}$=0 or MSR_{DE}=0). **Note:** DNI events are not blocked during a debug session
28	DQM	Data Acquisition Messaging Registers 0 $DEVENT_{DQTAG}$ and DDAM register are exclusively owned by hardware debug. No **mtspr** access by software to $DEVENT_{DQTAG}$ field or DDAM register. Attempted access by software is ignored. 1 $DEVENT_{DQTAG}$ and DDAM register are owned by software. Software has read/write access to $DEVENT_{DQTAG}$ field and DDAM register.
29:31	—	Reserved

Table 1470 shows which resources are controlled by EDBRAC0 settings.

1. IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}$=1. Only software-owned bits or fields as shown in *Table 1470* are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

65.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the “Data Acquisition ID Tag Field” section in the Core (e200z225Bn3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in *Figure 1534*.

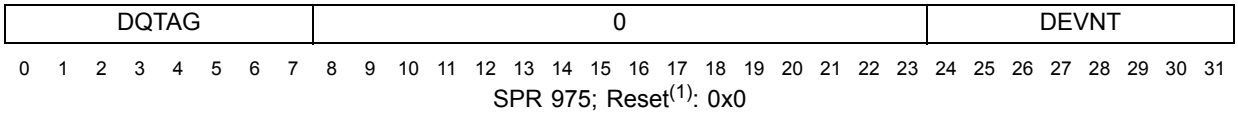

Figure 1534. Debug Event Select register (DEVENT) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b.** Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

Table 1471 provides bit definitions for the Debug Event Register.

Table 1471. DEVENT field descriptions

Bit	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.

65.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the “Data Acquisition Messaging” section in the Core (e200z225Bn3) Nexus 3 Module chapter for details.

The DDAM register is shown in *Figure 1535*.

DDAM

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 576; Reset(1): 0x0

Figure 1535. Debug Data Acquisition Message (DDAM) register

1. Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}$=0, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}$=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

Table 1472 provides bit definitions for the Debug Data Acquisition Message Register.

Table 1472. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

65.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in *Table 1463*. Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the $DBCR4_{DAC1CFG}$ field to '1000' or the $DBCR8_{DAC3CFG}$ field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '10', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the $DBCR4_{DAC1CFG}$ field is set to '1000' with $DBCR2_{DAC1US}$ set to '00' or '01', or the $DBCR7_{DAC3CFG}$ field is set to '1000' with $DBCR8_{DAC3US}$ set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the $EDBSR0_{IDE}$ status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in *Table 1463* and *Table 1466* in *Section 65.3.2: Debug Control and Status registers*. Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

65.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the $EDBCR0_{EDM}$/$DBCR0_{EDM}$ bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When $EDBCR0_{EDM}$ is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of *Section 65.2: Software debug events and exceptions* refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of $EDBCR0_{EDM}$ to '1', other bits in DBCR0 will remain unchanged. After $EDBCR0_{EDM}$ has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

*Note: It is intended for the CPU to remain in external debug mode ($EDBCR0_{EDM}$=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

*Note: $EDBCR0_{EDM}$ operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if $EDBCR0_{EDM}$ was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug

Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the $EDBCR0_{EDM}$ bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

65.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

65.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software, However, the state of $EDBCR0_{EDM}$ is reflected as a read-only bit in $DBCR0_{EDM}$ to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in *Figure 1536*.

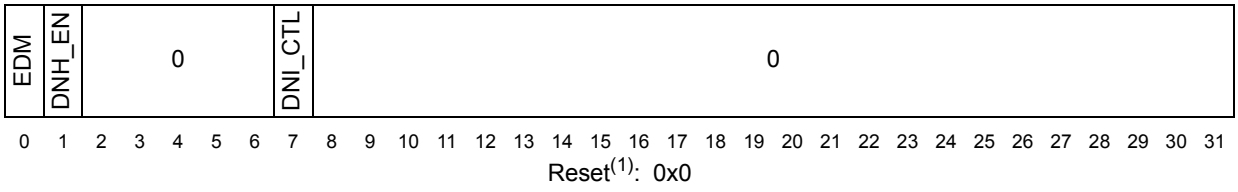

Figure 1536. External Debug Control Register 0 (EDBCR0)

1. EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 1473 provides bit definitions for External Debug Control Register 0.

Table 1473. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset **p_reset_b**. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	**dnh** Instruction Enable 0 Execution of **e_dnh** and **se_dnh** instructions cause illegal instruction exceptions to occur. 1 Execution of **e_dnh** and **se_dnh** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	**dni** Instruction Control 0 When the **dni** resource is owned by hardware, the MSR_{DE} bit is cared, and when MSR_{DE}=0, execution of **e_dni** and **se_dni** instructions are nop'ed and no entry into debug mode occurs. 1 When the **dni** resource is owned by hardware, the MSR_{DE} bit is don't-cared, and execution of **e_dni** and **se_dni** instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR_{DE}. **Note:** This control bit is only used when the dni resource is owned by hardware via control in $EDBRAC0_{DNI}$, and thus also only when EDM=1.
8:31	—	Reserved

65.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in *Figure 1537*.

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0
0	1	2	3	4	5	6	7	8	9 10 11	12	13	14	15	16	17 18 19 20	21	22	23	24	25	26	27	28 29 30	31

Read/Write; Reset(1) - 0x0000_0000

Figure 1537. External Debug Status Register 0 (EDBSR0)

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while $EDBCR0_{EDM}$=0.

Table 1474 provides bit definitions for External Debug Status Register 0.

Table 1474. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $EDBCR0_{EDM}$=1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $EDBRAC0_{PMI}$=0 regardless of the setting of $PMGC0_{UDI}$

Table 1474. EDBSR0 field descriptions(Continued)

Bit	Name	Description
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if $EDBSRMSK0_{MPU}$ is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If $EDBSRMSK0_{MPU}$ is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by $EDBCR0_{DNH_EN}$. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3‘b000 and $EDBSR0_{IDE}$ is set to 1. Normally set to 3‘b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

65.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A ‘1’ stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in *Figure 1538*.

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

65.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load or store operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of $EDBSR0_{DAC\{R,W\}}$ bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the $EDBSR0_{DAC\{R,W\}}$ bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in *Figure 1539*.

Data Effective Address

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

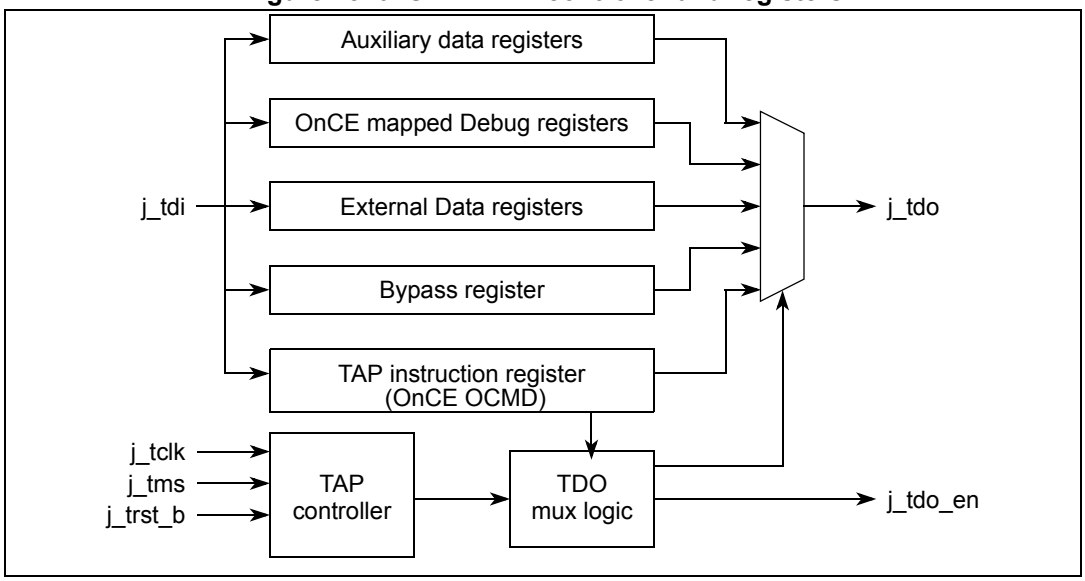
Figure 1539. External Debug Data Effective Address Register (EDDEAR)

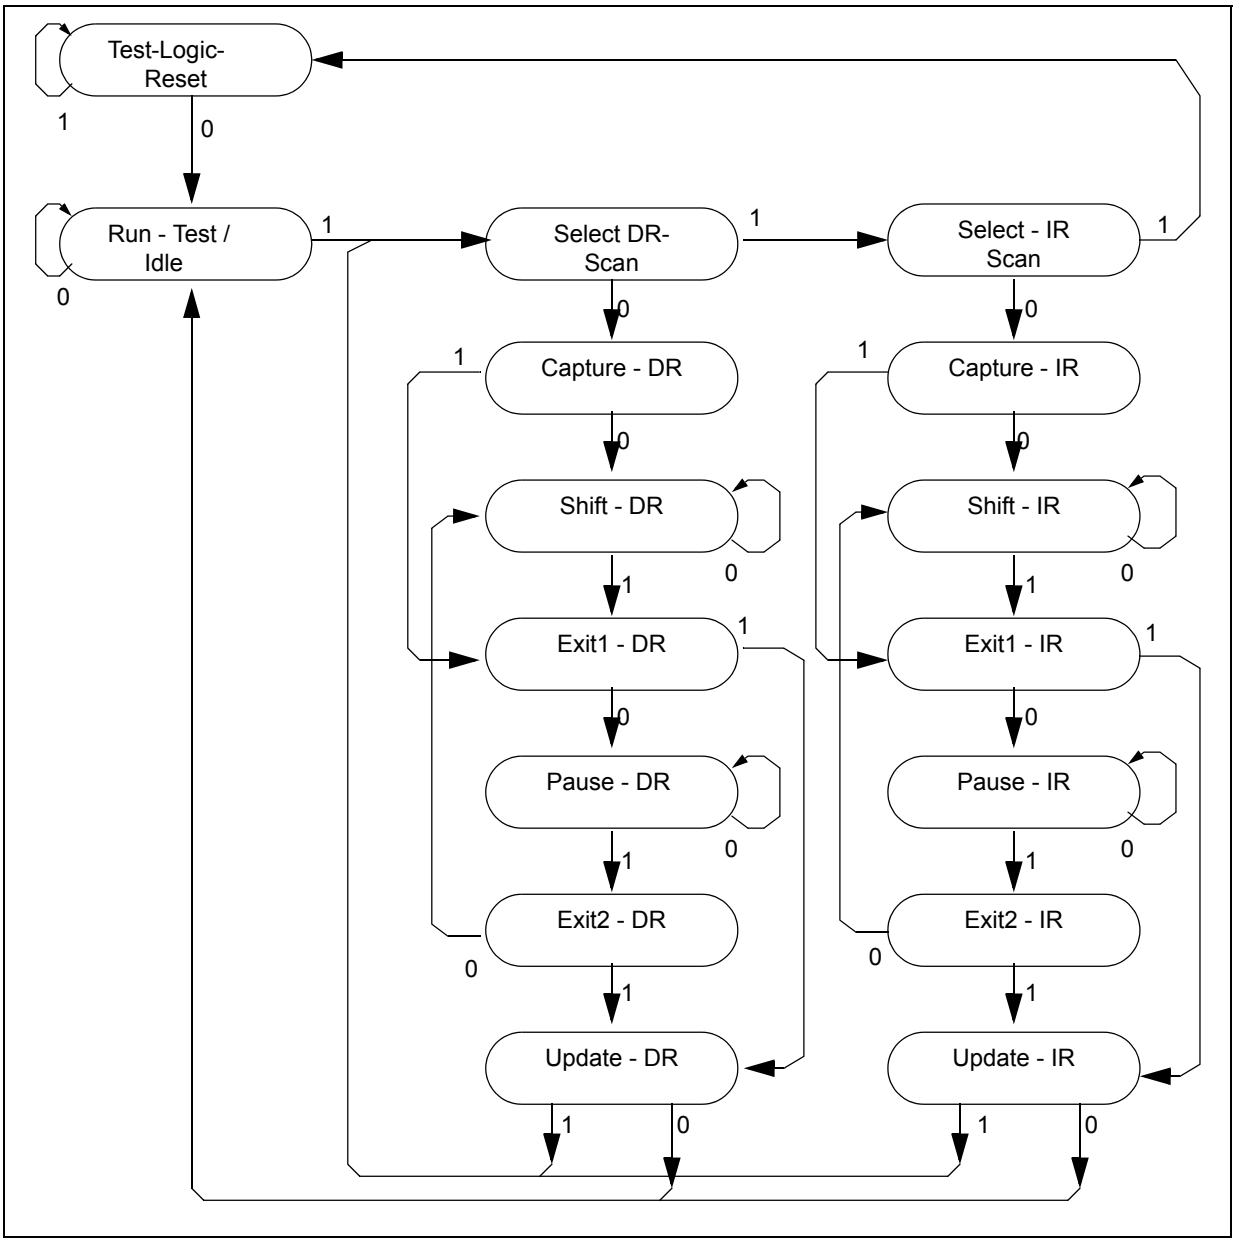
65.5.2 OnCE introduction



The e200z225Bn3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z225Bn3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.



The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1540. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1541. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), *Section 65.5.6.1: OnCE Status register*) by assertion of one or more debug requests, begins a *debug session*. The

jd_debug_b output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in the debug state. Instructions may the be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See *Section 65.5.6.2: OnCE Command (OCMD) register*). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

65.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

Table 1476 details the primary JTAG/OnCE interface signals.

Table 1476. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en(1)	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z225Bn3) Core Complex Overview.

65.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

65.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

65.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

65.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

65.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

65.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

65.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a “Bypass” command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regsel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

65.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z225Bn3 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

65.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See *Section 65.5.6.2: OnCE Command (OCMD) register* for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

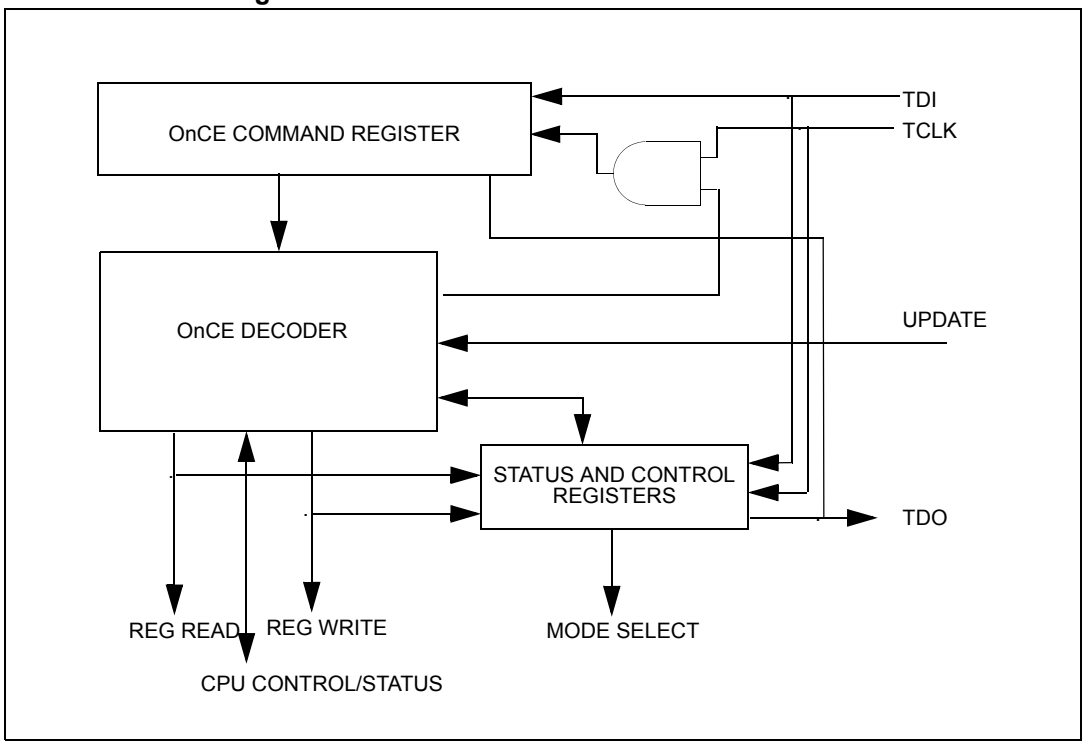
65.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU’s **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z225Bn3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

65.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to *Table 1483* for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

65.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)



This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

65.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. *Figure 1542* is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1542. OnCE Controller and Serial Interface

65.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

Figure 1543. OnCE Status register

Table 1477 provides bit definitions for the OnCE Status register.

Table 1477. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK **m_clk** Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the **jd_mclk_on** input signal after capture by **j_tclk**.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the inverted logic level on the CPU **p_reset_b** input after capture by **j_tclk**.
4	HALT	HALT Mode This bit reflects the logic level on the CPU **p_halted** output after capture by **j_tclk**.
5	STOP	STOP Mode This bit reflects the logic level on the CPU **p_stopped** output after capture by **j_tclk**.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU **p_waiting** output after capture by **j_tclk**.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

65.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in *Figure 1544*. The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as

such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test_Logic_Reset state

Figure 1544. OnCE Command (OCMD) register

Table 1478 provides bit definitions for the OCMD.

Table 1478. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. **Note:** The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on **j_tdo** during the first 32 clocks of Shift-DR. 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored.The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 65.5.9.6: Exiting Debug mode and interrupt blocking*. 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1478. OCMD field descriptions (Continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to “No Register Selected”. Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. **Note:** If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and $EDBCR0_{EDM}$=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode *without* execution of an instruction, even though the EX bit was set. **Note:** Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See *Section 65.5.9.6: Exiting Debug mode and interrupt blocking*.
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. *Table 1479* indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

Table 1479 indicates the OnCE register addresses.

111 1110	Enable_OnCE(1)
111 1111	Bypass

1. Causes assertion of the j_en_once_regsel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the $EDBCR0_{EDM}$ bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of $EDBCR0_{EDM}$. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

65.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z225Bn3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see *Section 65.7: MPU operation during debug*). The control bits are read/write. These bits are only effective while OnCE is enabled (**jd_en_once** asserted). The OCR is shown in *Figure 1545*.

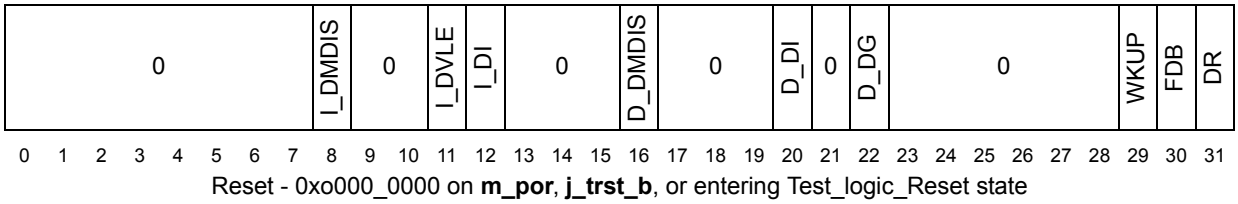

Figure 1545. OnCE Control Register (OCR)

Table 1480 provides bit definitions for the OnCE Control Register.

Table 1480. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug ‘VLE’ Attribute Bit This bit is used to provide the ‘VLE’ attribute bit to be used during a debug session. **Note:** This bit is ignored, since VLE is always enabled.
12	I_DI	Instruction Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to‘1’ to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug ‘I’ Attribute Bit This bit is used to provide the ‘I’ attribute bit to be used for Data accesses during a debug session.
21	—	Reserved

Table 1480. OCR field descriptions (Continued)

Bit	Name	Description
22	D_DG	Data Side Debug ‘G’ Attribute Bit This bit is used to provide the ‘G’ attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the **p_wakeup** output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the **m_clk** input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the ‘**bkpt**’ pseudo-instruction will cause the processor to enter debug mode, as if the **jd_de_b** input had been asserted. This bit is qualified with $EDBCR0_{EDM}$, which must be set for FDB to take effect. **Note:** This bit has no effect on **e_dnh** or **se_dnh** instruction operation.
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

65.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z225Bn3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z225Bn3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z225Bn3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the OCR_{WKUP} control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

Table 1481 provides a list of access requirements for OnCE registers.

Table 1481. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires $EDBCR0_{EDM}$ = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*(1)	
DBCR0	Y	Y	Y	N	*1	*$EDBCR0_{EDM}$ access only requires **jd_en_once** asserted
DBCR1–8	Y	Y	Y	N	*1	
DEVENT	Y	Y	Y	N	*1	
EDBRAC0 (DBERC0)	Y	N	Y	N	*1	
DBSR	Y	Y	Y	N(2)	*1	
EDBCR0	Y	N	N	N	N

IAC1–8	Y	Y	Y	N	*1	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while **jd_en_once** is asserted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

65.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See *Section 65.5.5.1: OnCE Enable (jd_en_once)*.

65.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z225Bn3 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z225Bn3 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

65.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

65.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

65.5.8.4 Debug request during Waiting, Halted, or Stopped state

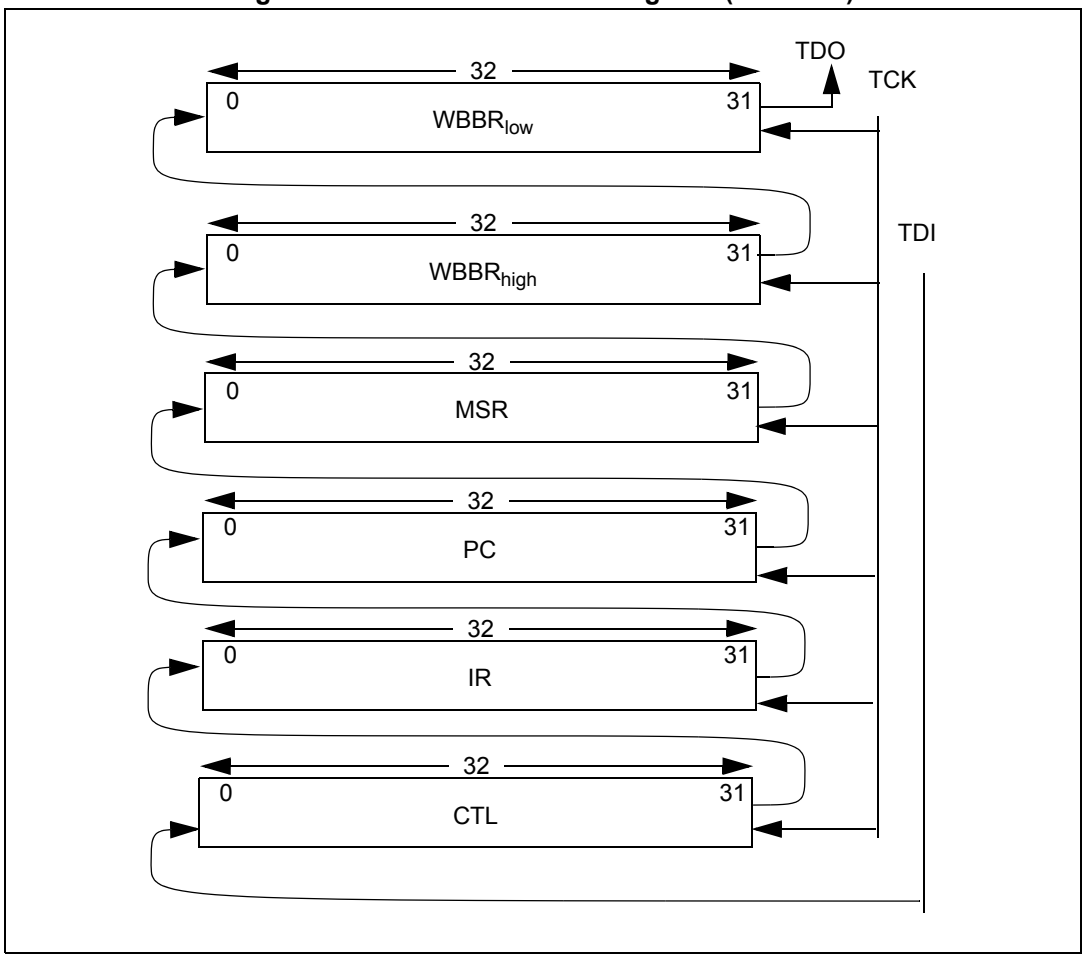
Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting, p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

65.5.8.5 Software request during normal activity

Upon executing a '**bkpt'** pseudo-instruction (for e200z225Bn3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit

is true), and $EDBCR0_{EDM}$=1, the CPU enters the debug mode after the instruction following the '**bkpt'** pseudo-instruction has entered the instruction register.



65.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by $EDBCR0_{DNH_EN}$, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is ***not*** conditioned on $EDBCR0_{EDM}$, allowing for debug of software debug handlers as well as other software. For e200z225Bn3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

65.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

Note: A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. *Figure 1546* shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1546. CPU Scan Chain Register (CPUSCR)

65.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

65.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the operations performed during the debug session and should normally be restored by the

external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

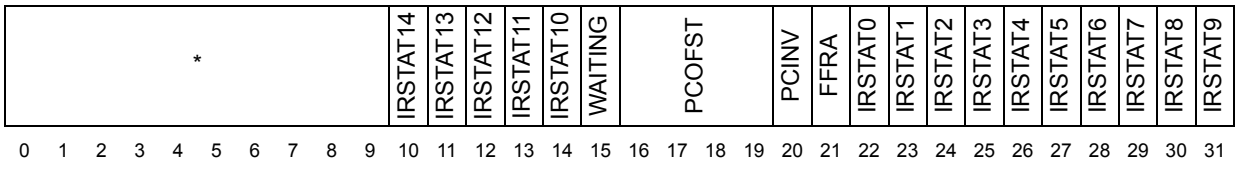


Figure 1547. Control State Register (CTL)

Table 1482. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See *Section 65.5.5.3: OnCE Debug output (jd_debug_b)*, which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.

Table 1482. CTL field descriptions (Continued)

Bit	Name	Description
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBRlo to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR.For most LSP instructions using rA||rB as a 64-bit source operand, WBBRhi, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBRlo with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0No action. 1 Content of $WBBR_{lo}$ or $WBBR_{hi,lo}$used as operand value.

Table 1482. CTL field descriptions (Continued)

Bit	Name	Description
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. **Note:** This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to ‘0’, and the IR set to the value of the

desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

65.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

65.5.9.4 Write-Back Bus Register ($WBBR_{low}$, $WBBR_{high}$)

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. $WBBR_{low}$ holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. For LSP instructions that generate 64-bit results, $WBBR_{low}$ holds the low-order 32 bits of the result. $WBBR_{high}$ holds the updated effective address calculated by a load with update instruction. For LSP instructions that generate 64-bit results, $WBBR_{high}$ holds the high-order 32 bits of the result. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into $WBBR_{low}$. The contents

of $WBBR_{low}$ can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the $WBBR_{low}$ to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to *Section 65.5.9.2: Control State Register (CTL)* for more detail on the CTL_{FFRA} bit.)

$WBBR_{low}$ and $WBBR_{high}$ are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

65.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used.This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

65.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

65.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

65.6 Watchpoint support

e200z225Bn3 supports the generation and signalling of watchpoints when operating in internal debug mode ($DBCR0_{IDM}$=1) or in external debug mode ($EDBCR0_{EDM}$=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with $EDBCR0_{EDM}$ or $DBCR0_{IDM}$.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVNT-based and DTC-based

watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31])** for various development control purposes. (See the “Watchpoint Trace Messaging” section in the Core (e200z225Bn3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

Table 1483 shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1483. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status

Table 1483. Watchpoint output signal assignments(Continued)

Signal Name	Type	Description
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a ‘1’ is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever **p_pm_event** transitions from a ‘0’ to a ‘1’ while **m_clk** is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on $PMLCa0_{PMP}$
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on $PMLCa1_{PMP}$

Table 1483. Watchpoint output signal assignments(Continued)

Signal Name	Type	Description
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on $PMLCa2_{PMP}$
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on $PMLCa3_{PMP}$
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

65.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR (*Section 65.5.6.3: OnCE Control Register (OCR)* for more detail.

Normal operation of the MPU may be modified during a ‘debug session’ via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR (*Section 65.5.6.3: OnCE Control Register (OCR)* for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

65.8 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR}, OCR_{WKUP}, are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2: Control State Register (CTL)*), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with "no-register selected", Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2: Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the $EDBCR0_{EDM}$ bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in *Section 65.5.9.2: Control State Register (CTL)*), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

66 Debug and Calibration Interface (DCI)

66.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only.

66.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

66.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

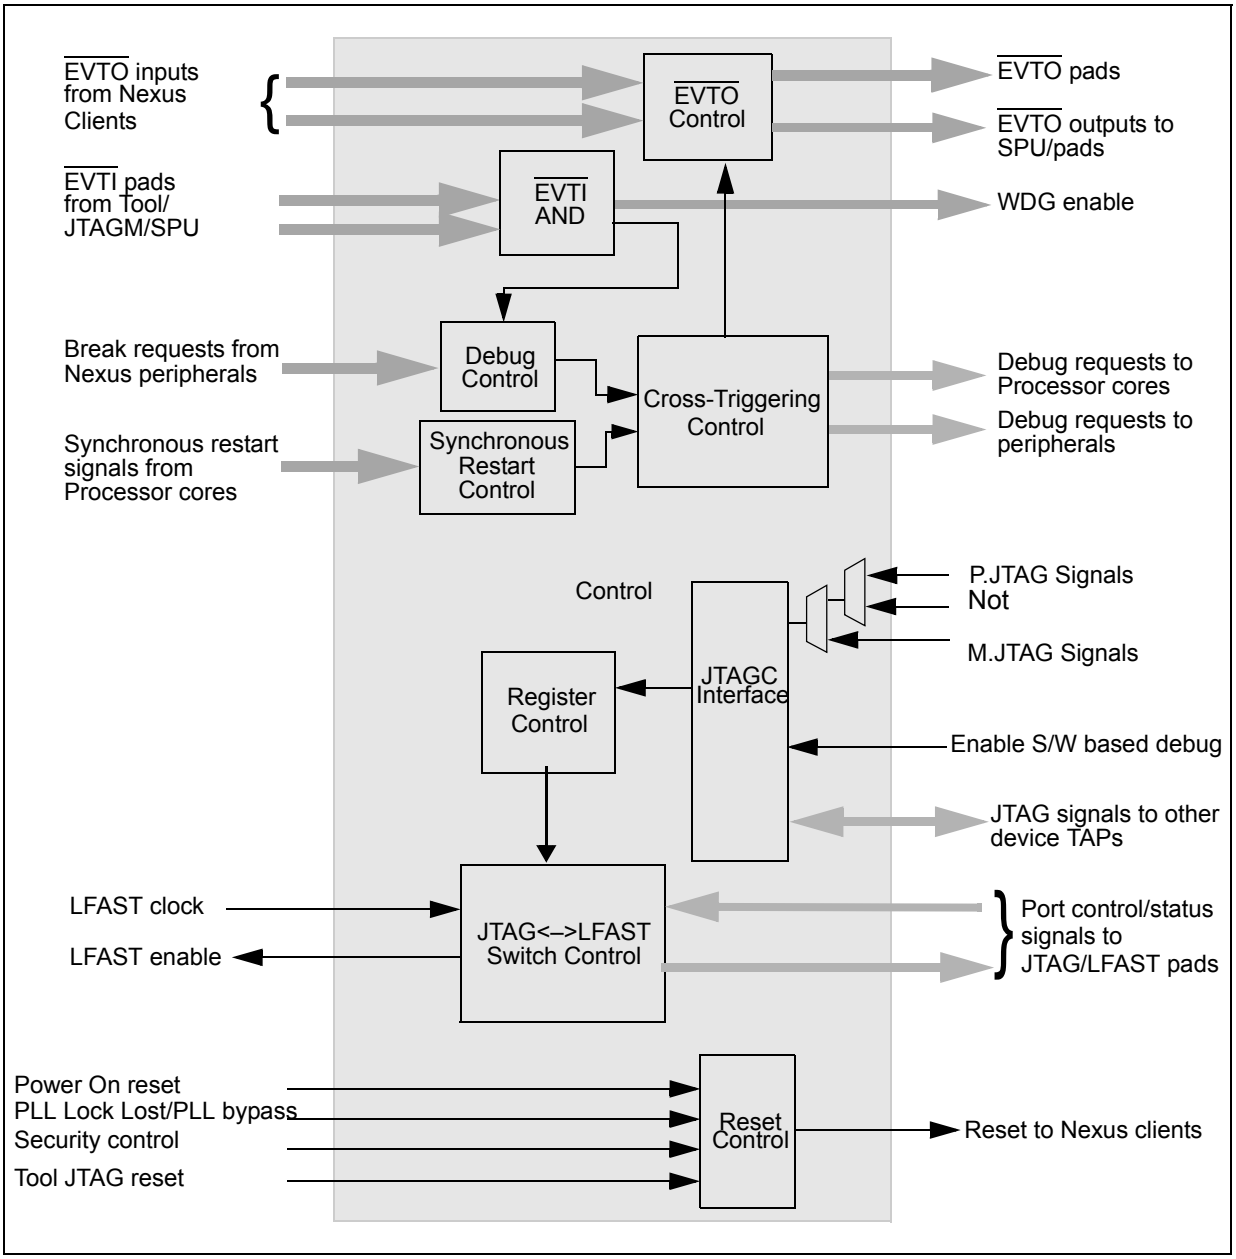
When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU, etc. The DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

Figure 1548 shows the DCI block diagram.

Figure 1548. DCI block diagram



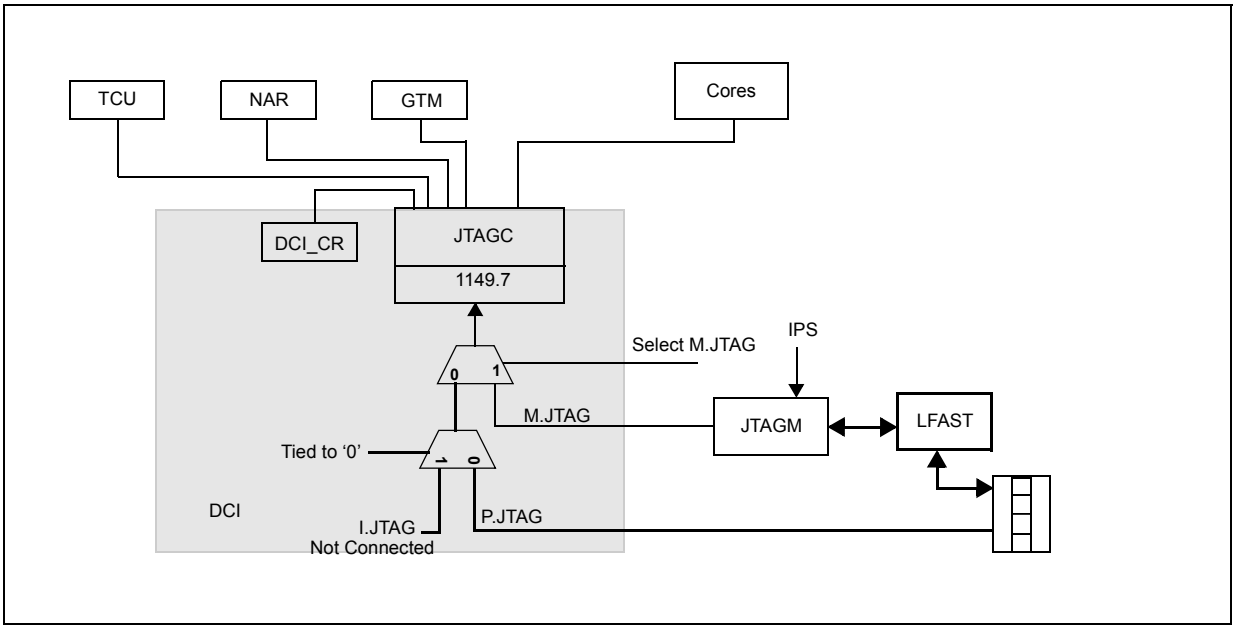


Figure 1549 shows the DCI configuration for the standard production package.

Figure 1549. DCI in a standard configuration

66.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 1484 shows a summary of the configuration options.

Table 1484. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

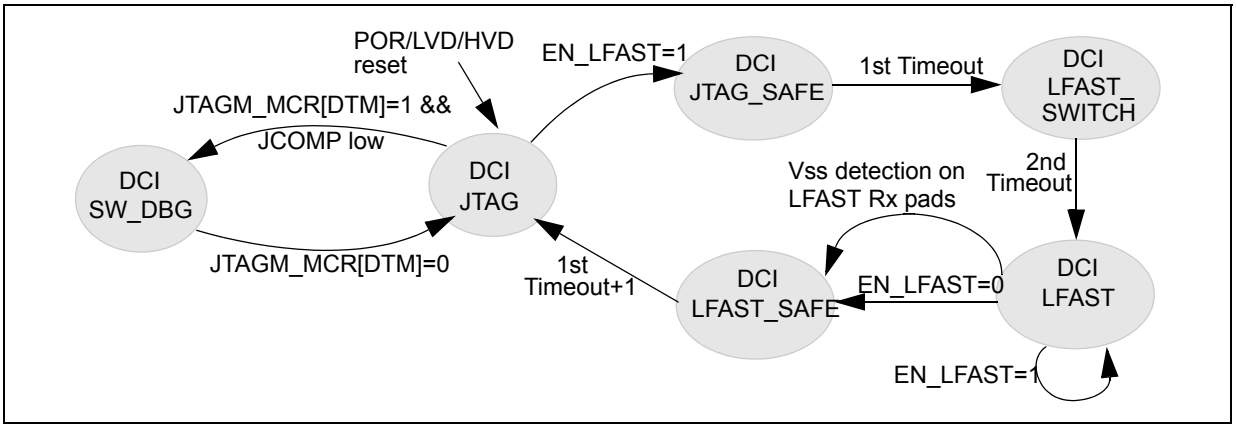
The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the

JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 66.1.3.1, Port sharing between JTAG and LFAST modes*. During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 1485* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1485. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

Figure 1550 shows the DCI mode switching operation.

Figure 1550. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

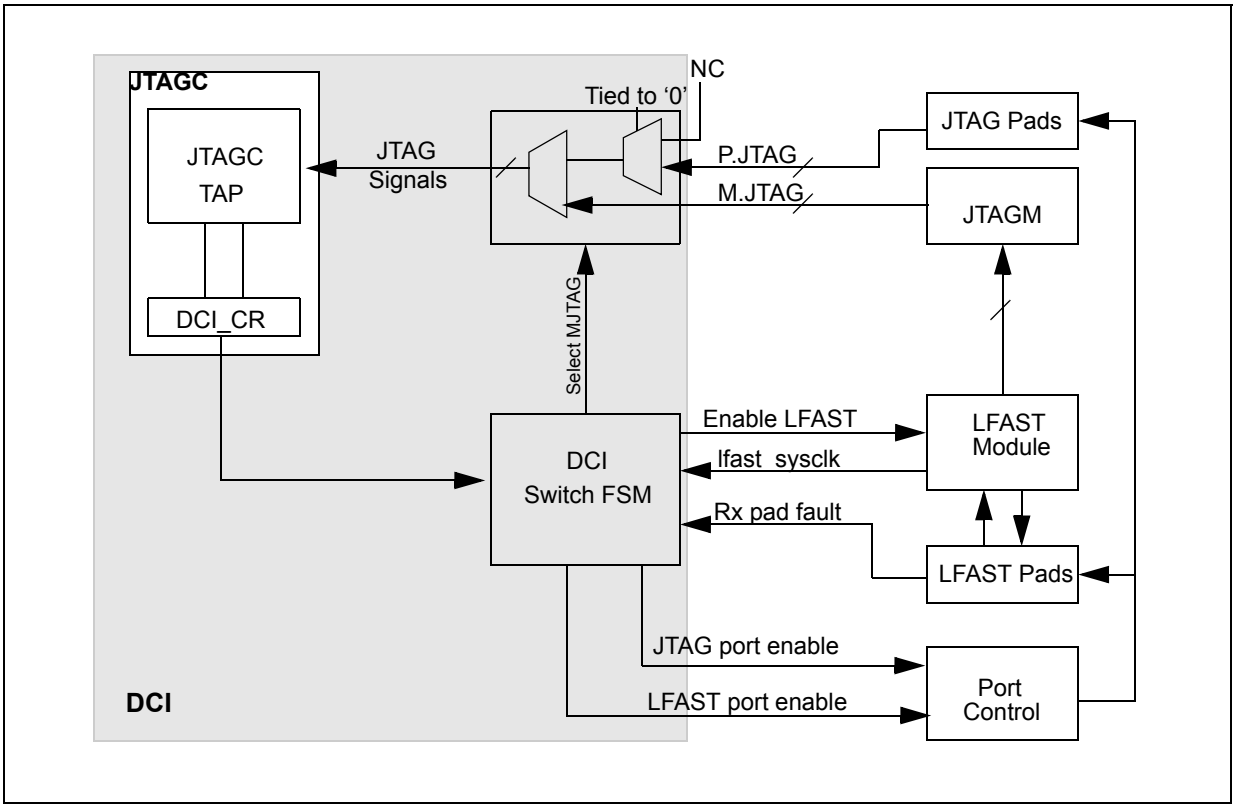


Table 1486 contains the operating mode descriptions.

Table 1486. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

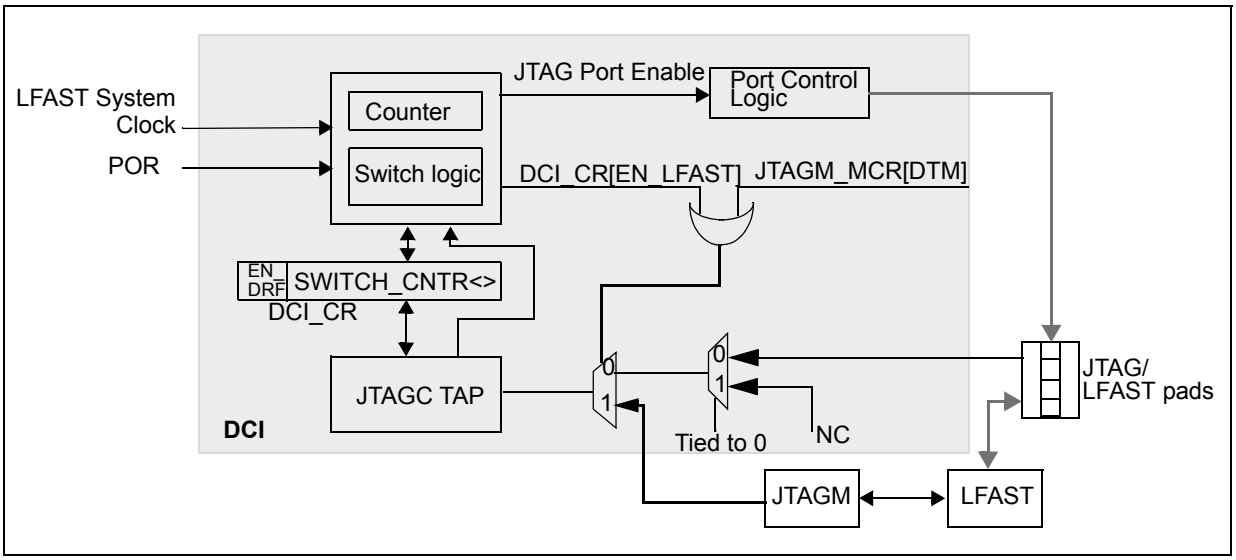
Figure 1551 shows a block diagram of the JTAG/LFAST connections.

Figure 1551. DCI JTAG/LFAST switch integration

66.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.



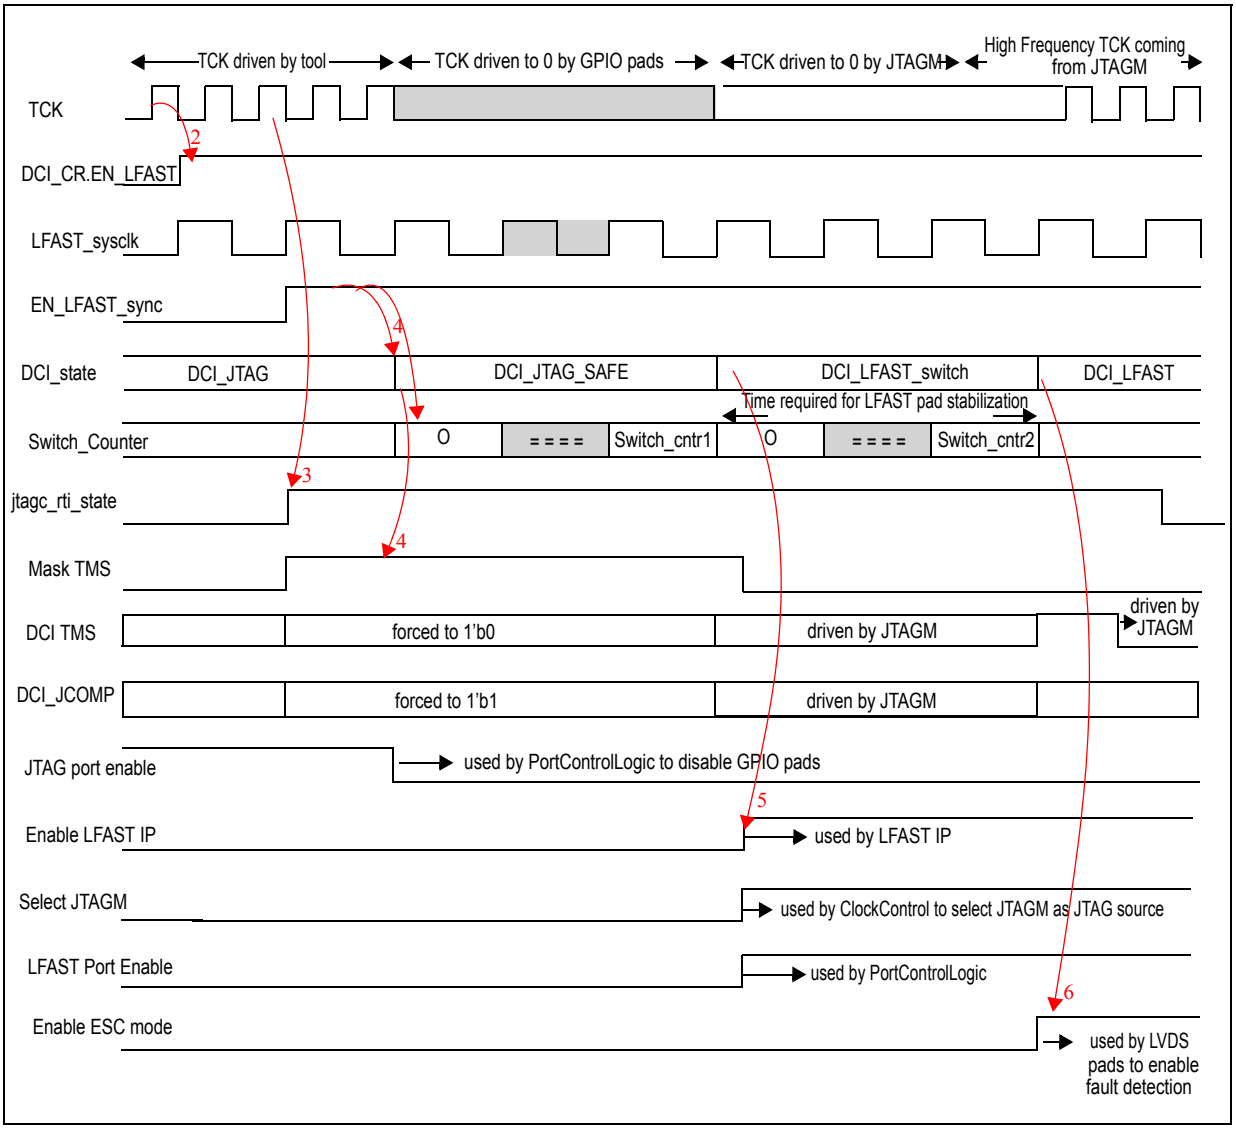
As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 1552*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to

change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 1552. DCI switching between JTAG and LFAST modes



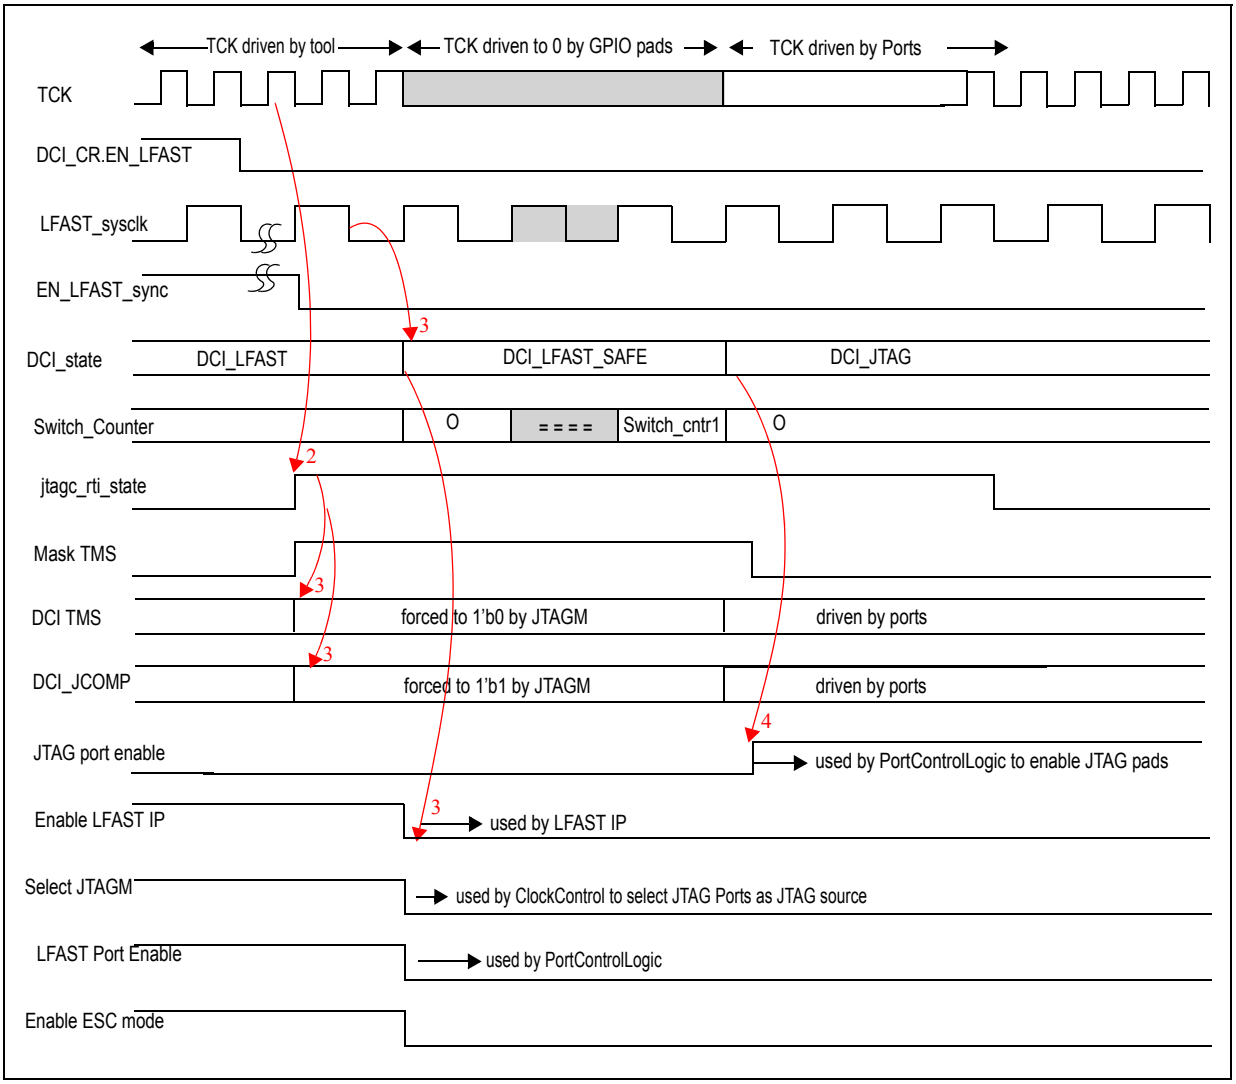
66.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   - EN_LFAST
   - SWITCH_CNTR1
   - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 1553 shows the timing sequence.

Figure 1553. DCI JTAG to LFAST switching diagram



66.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 1490 and *Table 1492* summarize the MCU and tool behaviors. *Figure 1554* shows the timing sequence.

Figure 1554. DCI LFAST to JTAG switching diagram

66.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

66.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

There is a software programmable bit, MCR[jtagm_JCOMP], present in JTAGM block which, when programmed to 0, asserts reset for the JTAGC block, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

Note: If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

66.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.If Debug_Enable is de-asserted by the SoC security modules, then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1487. Nexus reset truth table

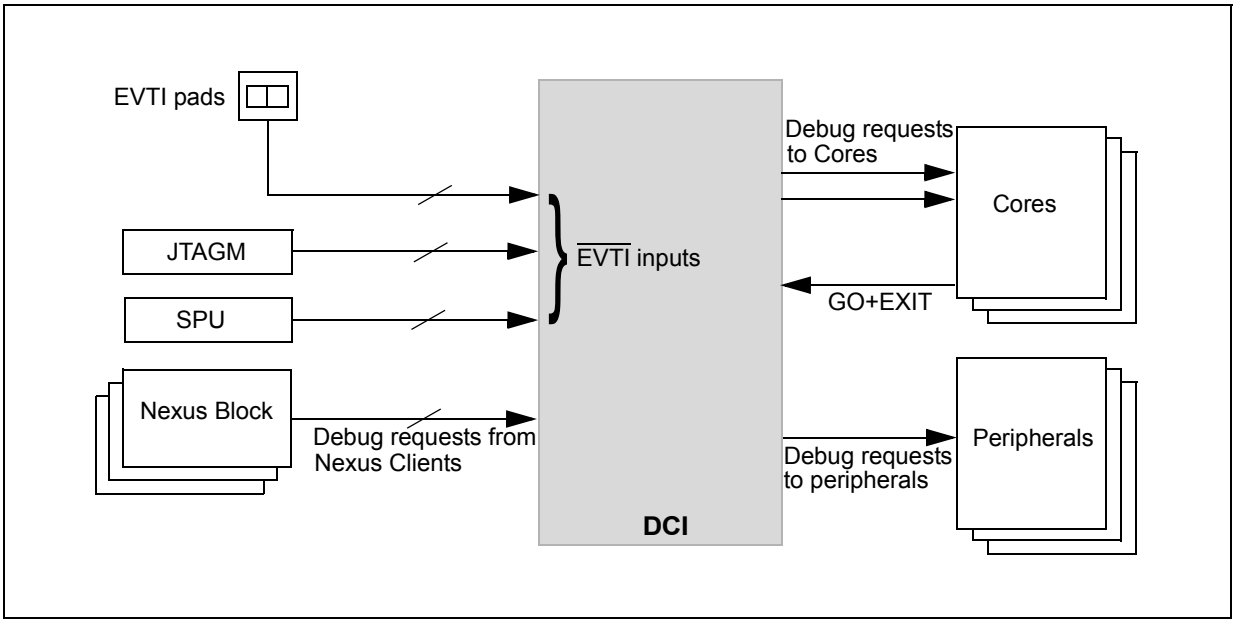
POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

66.1.3.5 System watchdog control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

66.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.



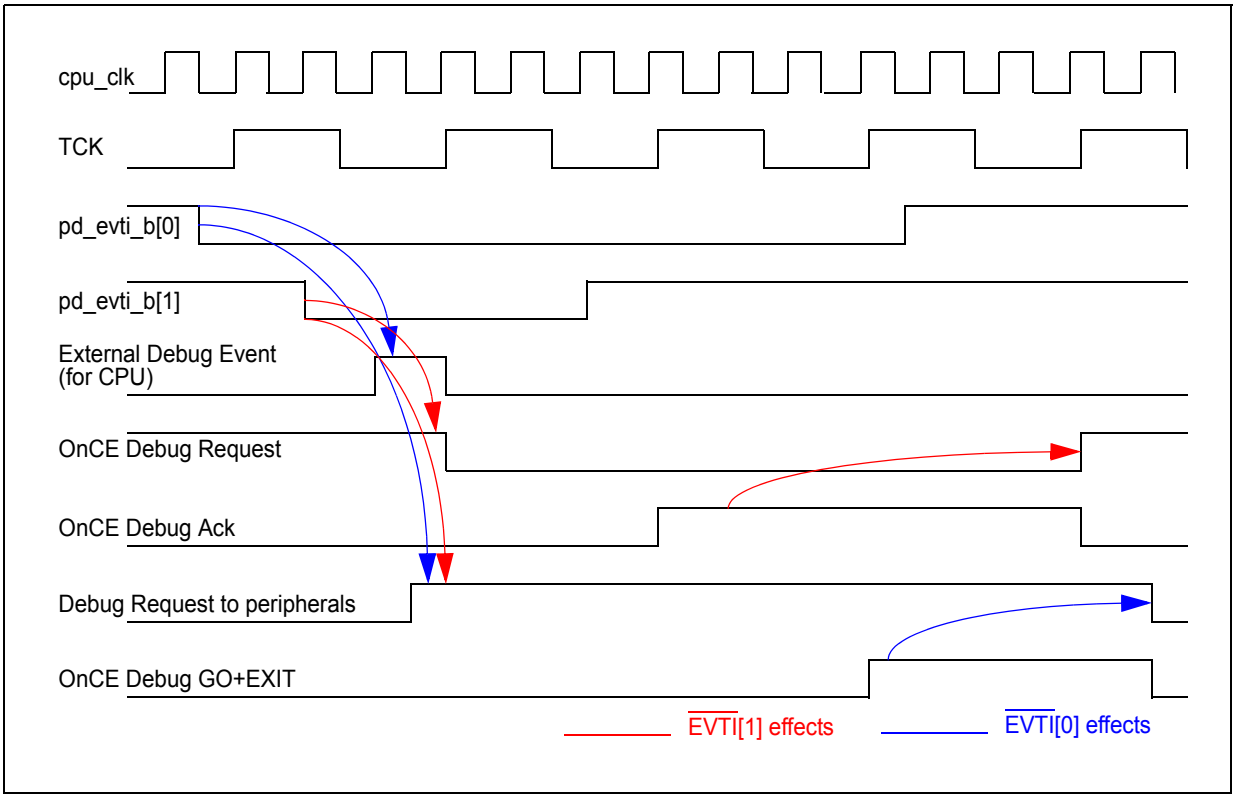
There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[1:0] signals from EVTI pads
- $\overline{\text{EVTI}}$[1:0] signals from JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1555. DCI debug control mechanism



The various sources of $\overline{\text{EVTI}}$[1:0] inputs are synchronized and logically ANDed in the DCI to generate two debug requests $\overline{\text{DCI_EVTI}}$[1:0] for the processor cores and non-CPU peripherals.Of these two inputs, $\overline{\text{EVTI}}$[0] is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\overline{\text{EVTI}}$[1], is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 1556 shows the timing sequence.

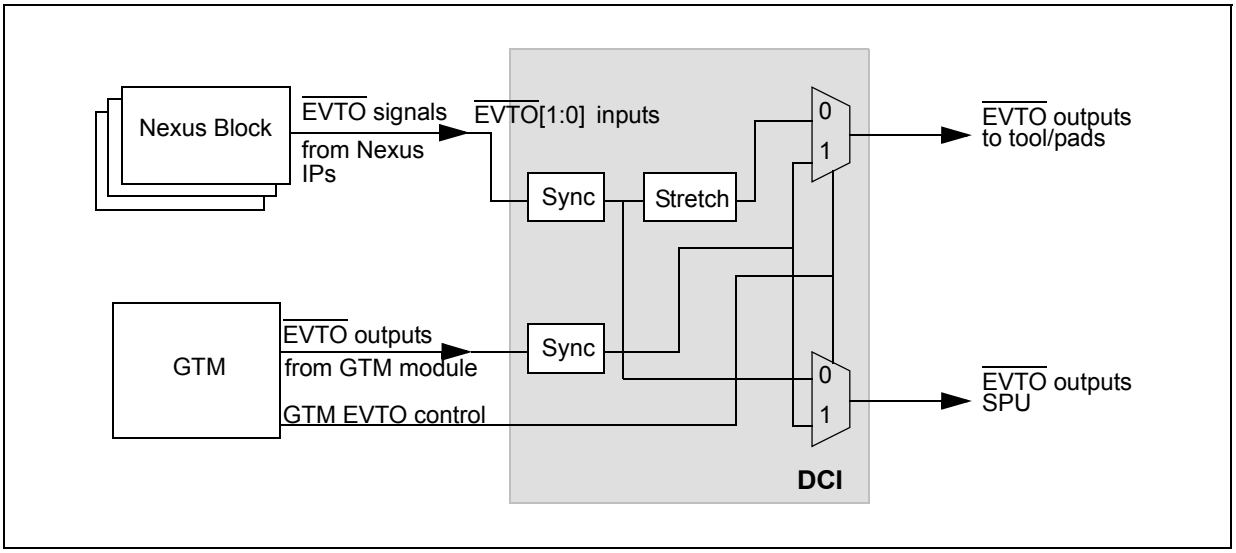
Figure 1556. DCI debug signal generation

66.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

66.1.3.8 Synchronous restart control



The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

66.1.3.9 EVTO management

The EVTO management block diagram is presented in *Figure 1557*.

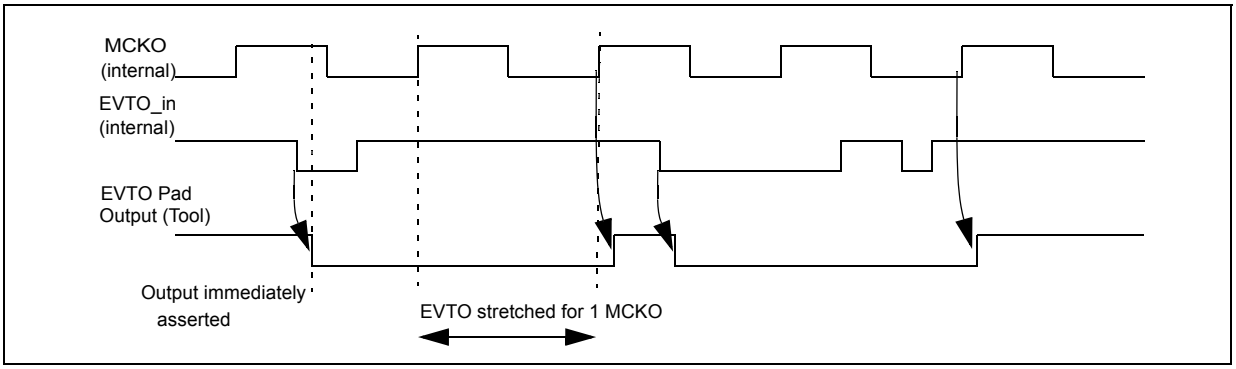


Figure 1557. DCI EVTO management

The DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce EVTO[1:0] signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[1:0] signals from any Nexus client, the DCI immediately asserts EVTO[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool(*Figure 1558*). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 1558. DCI EVTO timing diagram

66.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.
- Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

66.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

66.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

66.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 1559* shows the format of the DCI_CR.

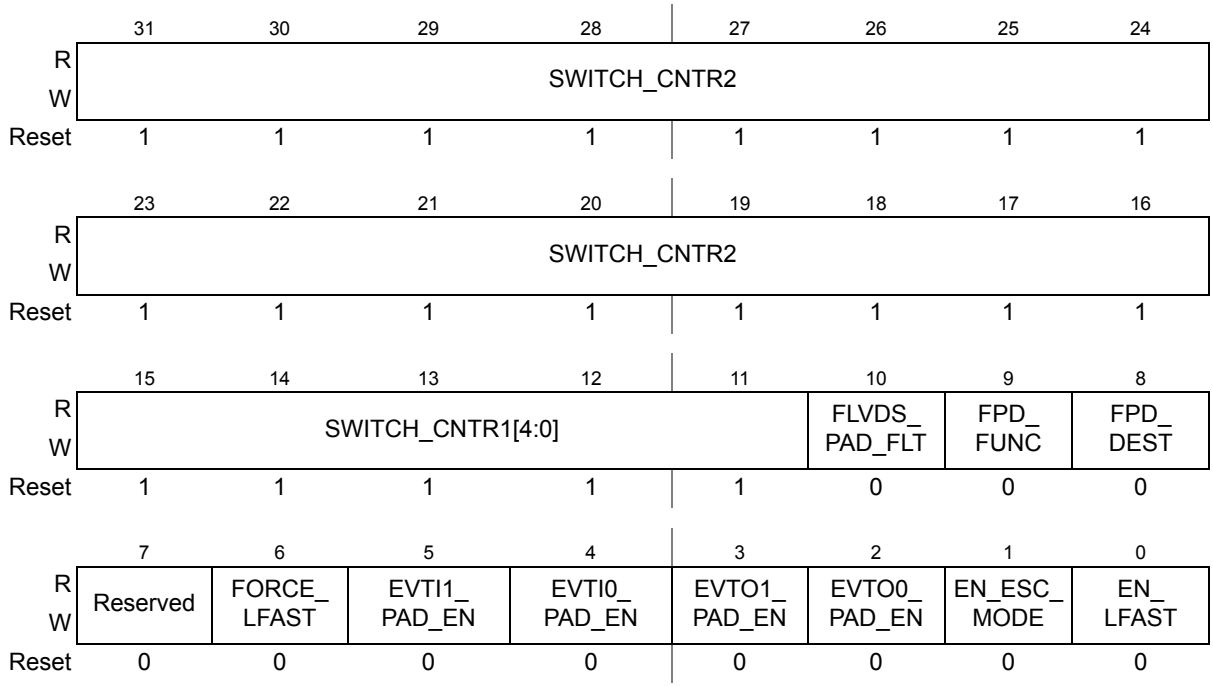

Figure 1559. DCI control register (DCI_CR)

The DCI_CR is described in *Table 1488*.

Table 1488. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2. Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32 × T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)

Table 1488. DCI_CR field descriptions(Continued)

Field	Description
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled
4 EVTI0_PAD_EN(1)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}$[1] pad 0 $\overline{\text{EVTO}}$[1] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[1] pad output enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}$[0] pad 0 $\overline{\text{EVTO}}$[0] pad output not enabled (default) 1 $\overline{\text{EVTO}}$[0] pad output enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(1)	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

66.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

66.4 Functional description

66.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 1489* and *Table 1490* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 1491* and *Table 1492* contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1489. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN
TMS	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxP
TDO	Hi-Z	Logic Output	Logic Output	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxP
JCOMP	Logic Input	Logic Input	Logic Input Latch	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxN

Mode Escape	Inhibit	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable
LFAST_ SYSCLK _EN	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable	Enable

Table 1490. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don't Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 1491. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 1492. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

66.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 1493* and *Table 1494* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

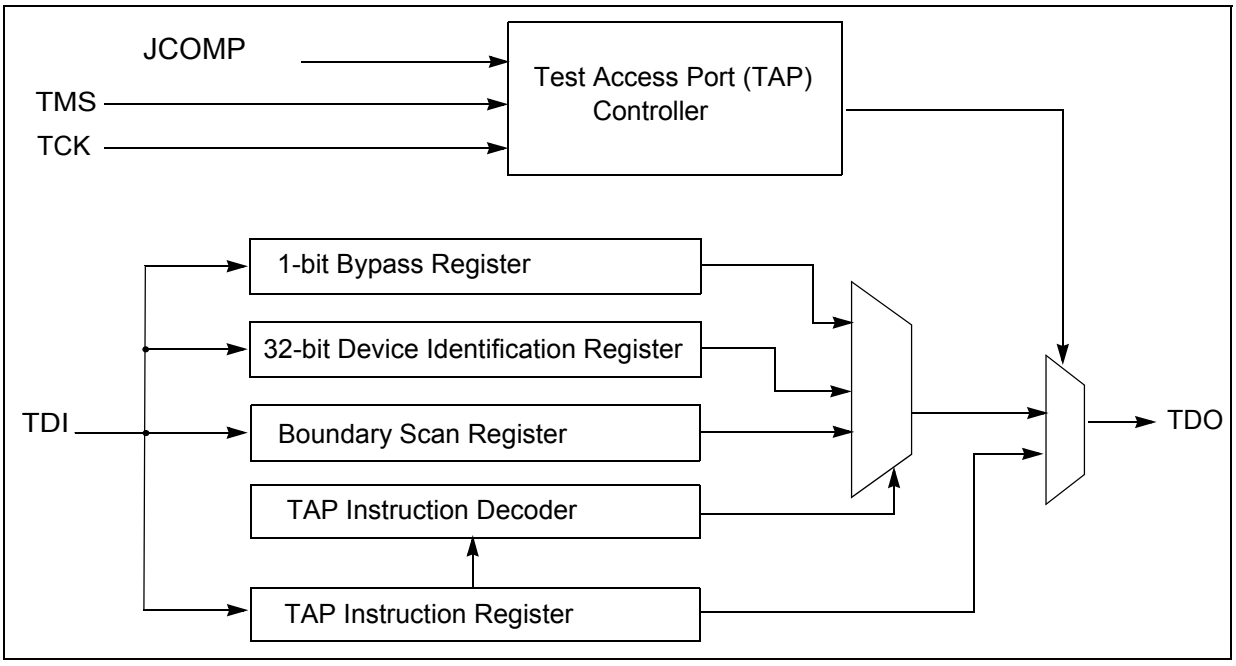
Table 1493. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 1494. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low
TDI	LVDS TxN	Don’t Care
TMS	LVDS TxP	Don’t Care
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don’t Care

67 JTAG Controller (JTAGC)



67.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

67.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1560. JTAG (IEEE 1149.1) block diagram

67.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1498* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

67.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

67.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

67.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 67.4.4: JTAGC block instructions*.

67.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

67.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1495. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

67.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

67.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

67.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 67.4.3: TAP controller state machine*.

67.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

67.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

67.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

67.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 1561. 6-bit instruction register

67.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

67.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

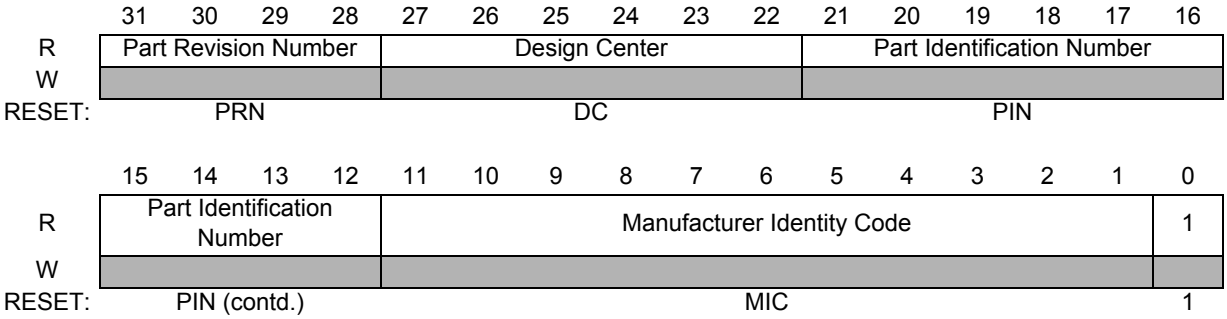


Figure 1562. Device identification register

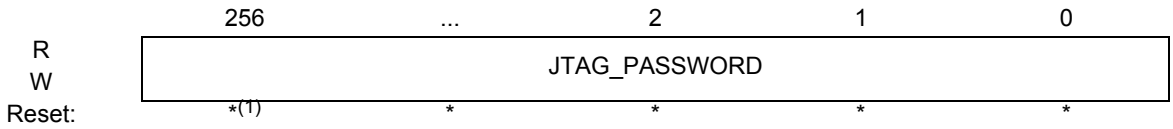


The following table describes the device identification register functions.

Table 1496. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. Value is 0x307.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x020.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

67.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1563. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1497. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

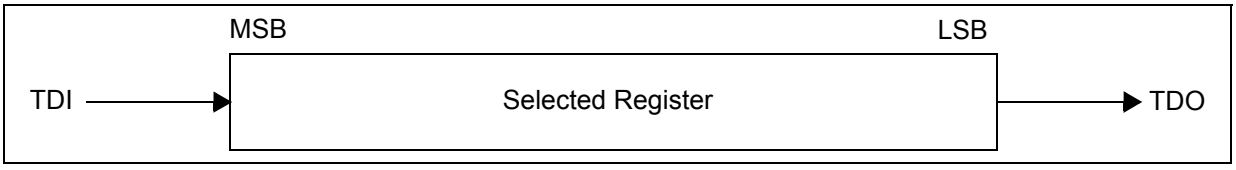
67.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 67.4.5: Boundary scan*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

67.4 Functional description

This section explains the JTAGC functional description.

67.4.1 JTAGC reset configuration



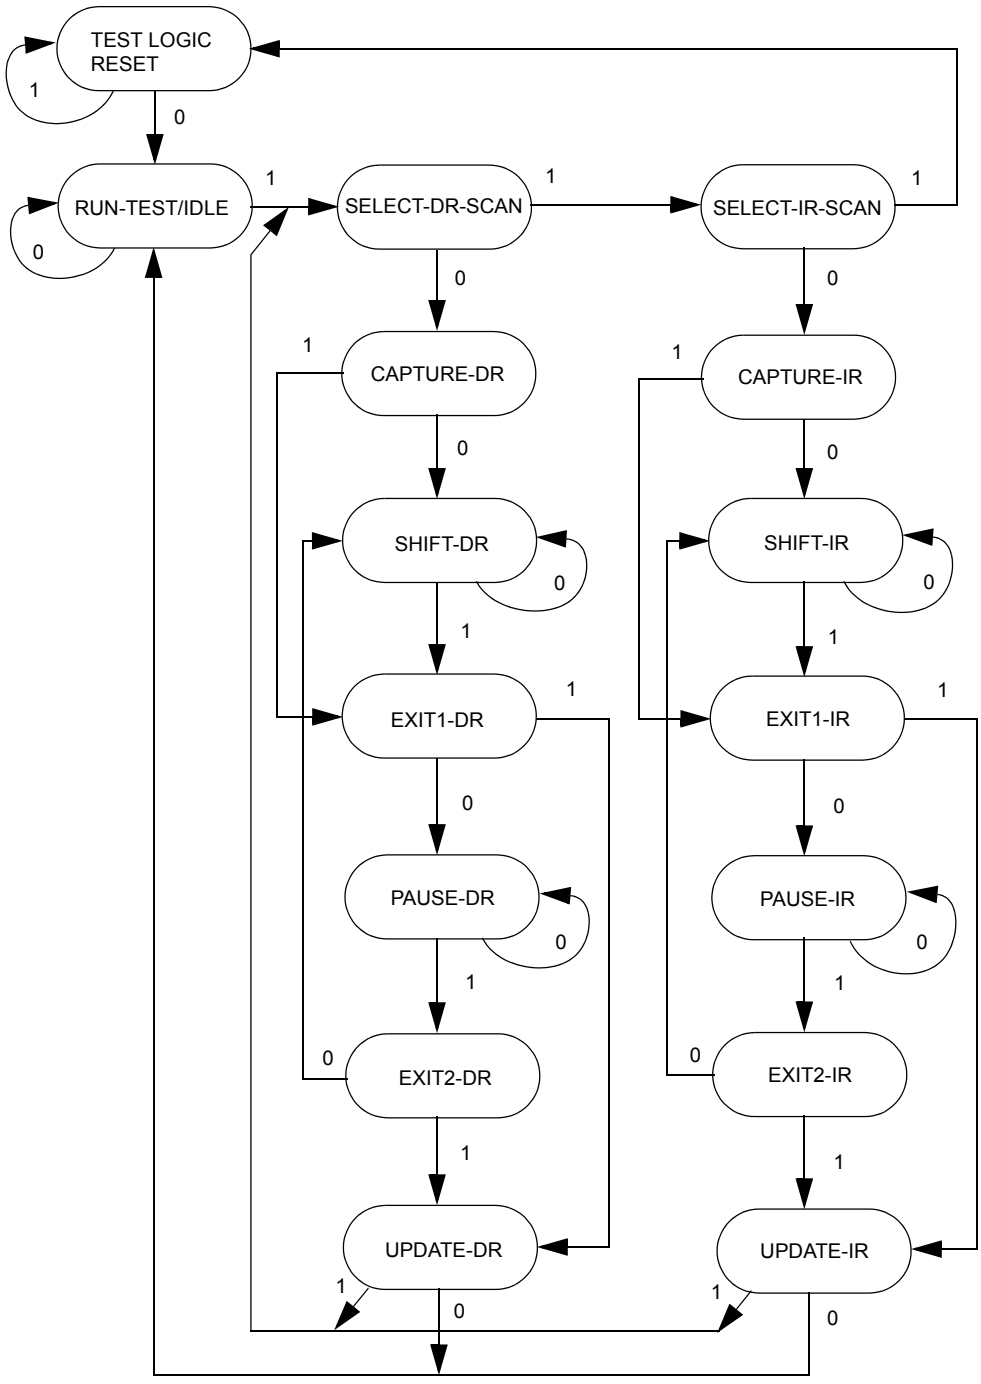
While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

67.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 67.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

Figure 1564. Shifting data through a register



67.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a

sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 1565. IEEE 1149.1-2001 TAP controller finite state machine

The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

67.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

67.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

67.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1498. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NR_PD	100001	Enables access to the NAR TAP controller on PD

Table 1498. 6-bit JTAG instructions(Continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100010	Reserved
Reserved	100011	Reserved
Reserved	100100	Reserved
Factory test reserved	100101	Intended for factory test only
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller
Reserved	100111	Reserved
ACCESS_AUX_CORE_0	101000	Enabled access to E200 Core 0
Reserved	101001	Reserved
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
ACCESS_AUX_GTM	110011	Enables access to GTM TAP controller
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
Reserved	110110	Reserved
Reserved	110111	Reserved
Reserved	111000	Reserved
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL(1)	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved(2)	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

67.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

67.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

67.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

67.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

67.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

67.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

67.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

67.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

67.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

67.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

67.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

68.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

68.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- Compliant
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- Extended
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the “Standard Protocol” — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- Advanced
  - Two-pin operation using the “Advanced Protocol” — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

68.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

68.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in *Table 1500*. Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

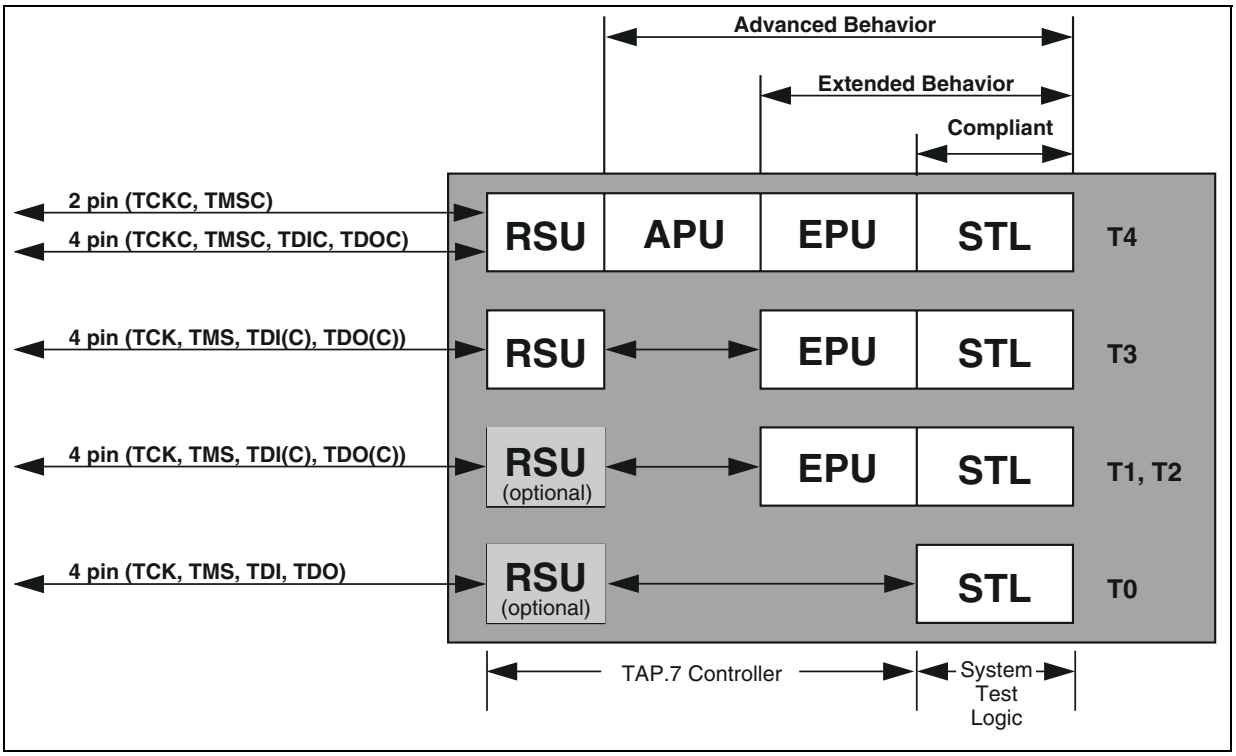
The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMSC, TDIC, TDOC, and nTRST pins.

Table 1500. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4



68.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in *Figure 1566*. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

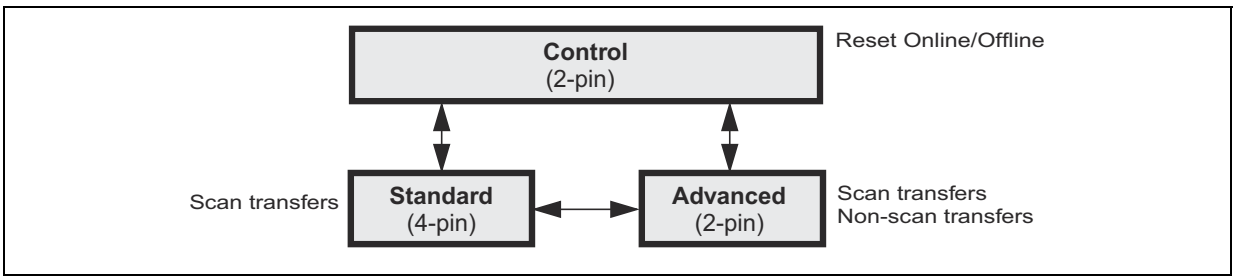


Figure 1566. TAP.7 Controller Architecture

68.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in *Figure 1567*.

Figure 1567. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in *Table 1501*.

Table 1501. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

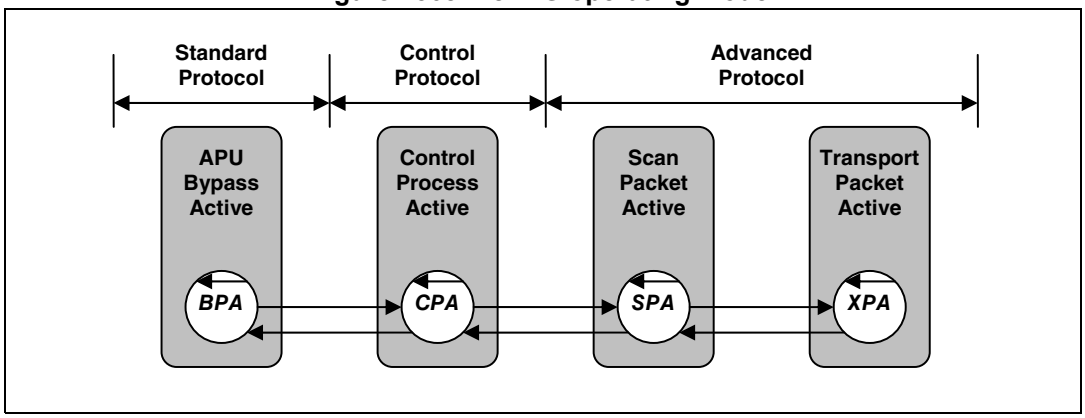
The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

68.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

68.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.



68.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

68.3.6 Operating models

Figure 1568 illustrates a simplified view of the CJTAG operating model.

Figure 1568. CJTAG operating model

68.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

68.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

68.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

68.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

68.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

68.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

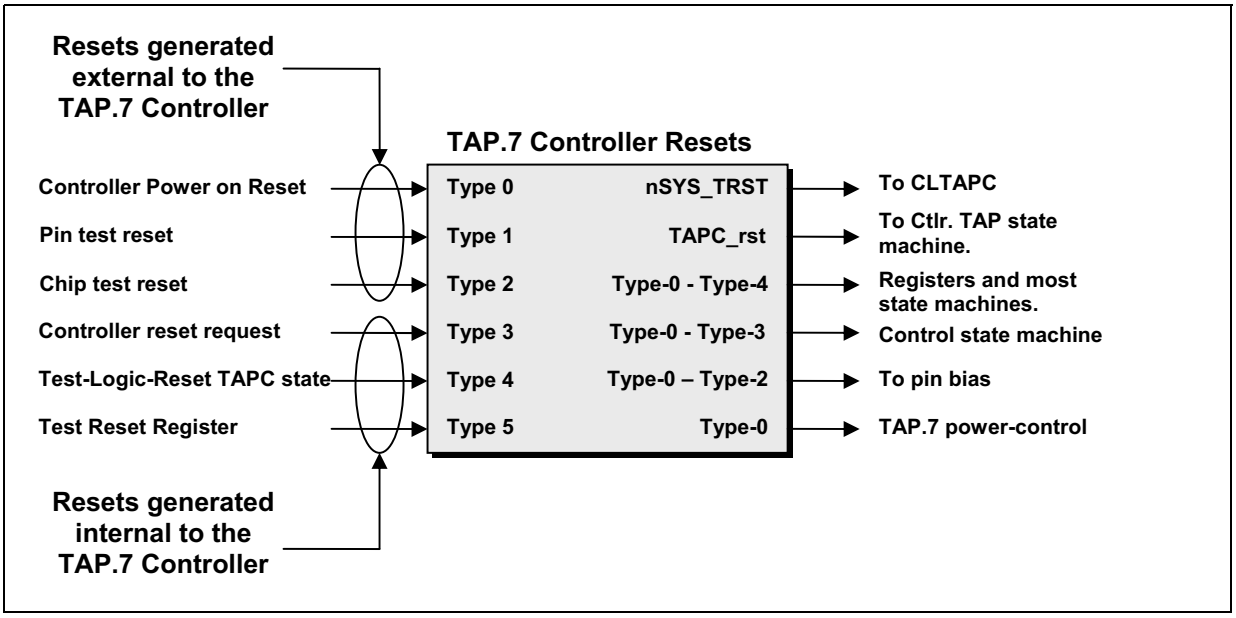
68.5 Ancillary services

68.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine



68.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 1569. Conceptual view of the EPU reset logic and state machines

68.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

68.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

68.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

68.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

68.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

68.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

68.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 1570. Reset state machine

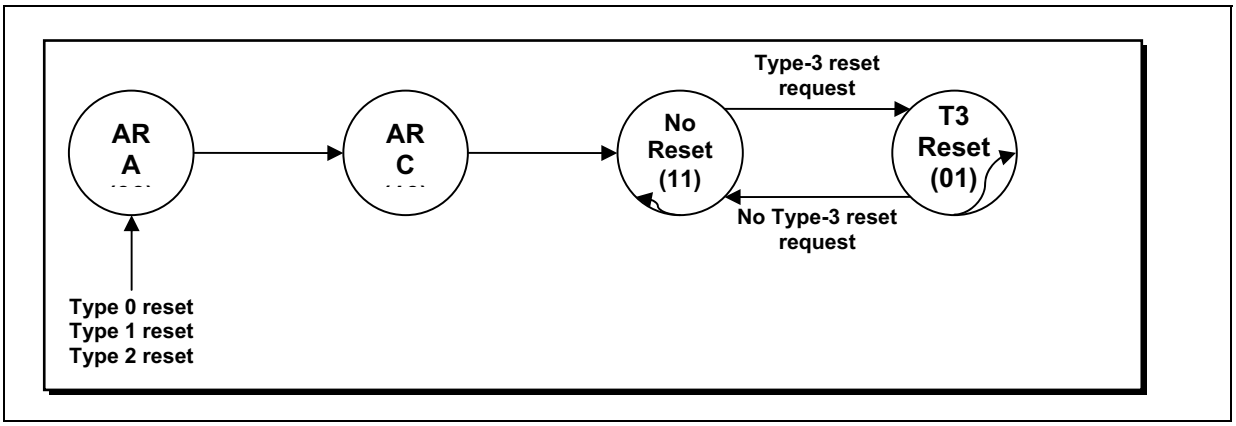


Table 1502. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in *Table 1503*.

Table 1503. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	—	—	—	—	—	—
Type-4	—	Yes	Yes	—	—	—	—
Type-3	Yes	Yes	Yes	Yes	Yes	—	—
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	—
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	—
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

68.5.3 Start-up Options

68.5.3.1 Overview

The TAP.7 start-up options are shown in *Table 1504*. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 1504. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to *Run-Test/Idle*

68.5.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

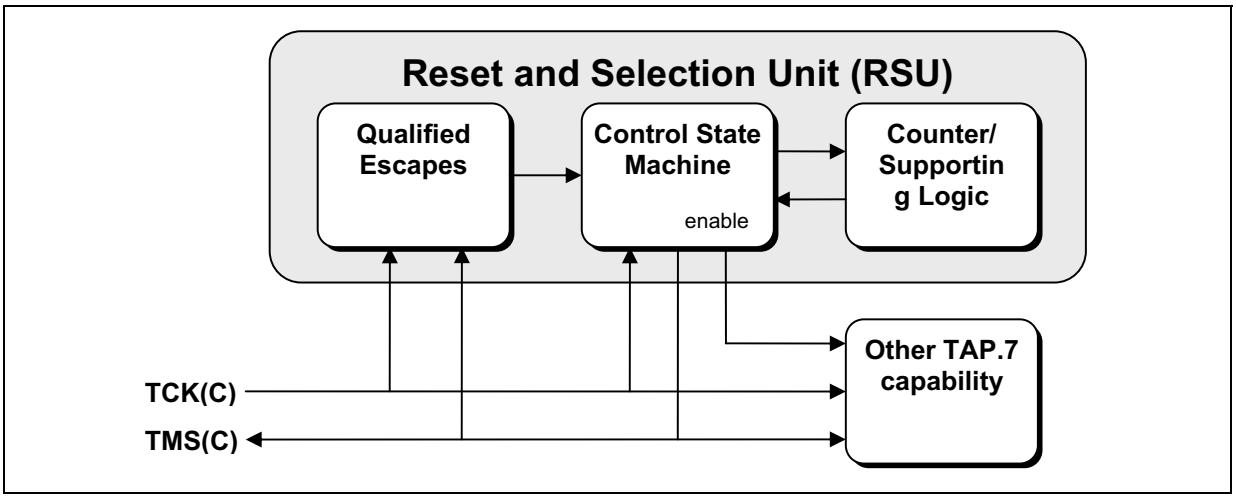
- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 1505. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMSC pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

68.5.4 RSU operation



The RSU uses TCKC and TMSC with the control protocol for configuration control.

68.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is

Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in *Figure 1571*.

Figure 1571. Conceptual view of technology selection mechanism

68.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

68.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges)– Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges)– Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

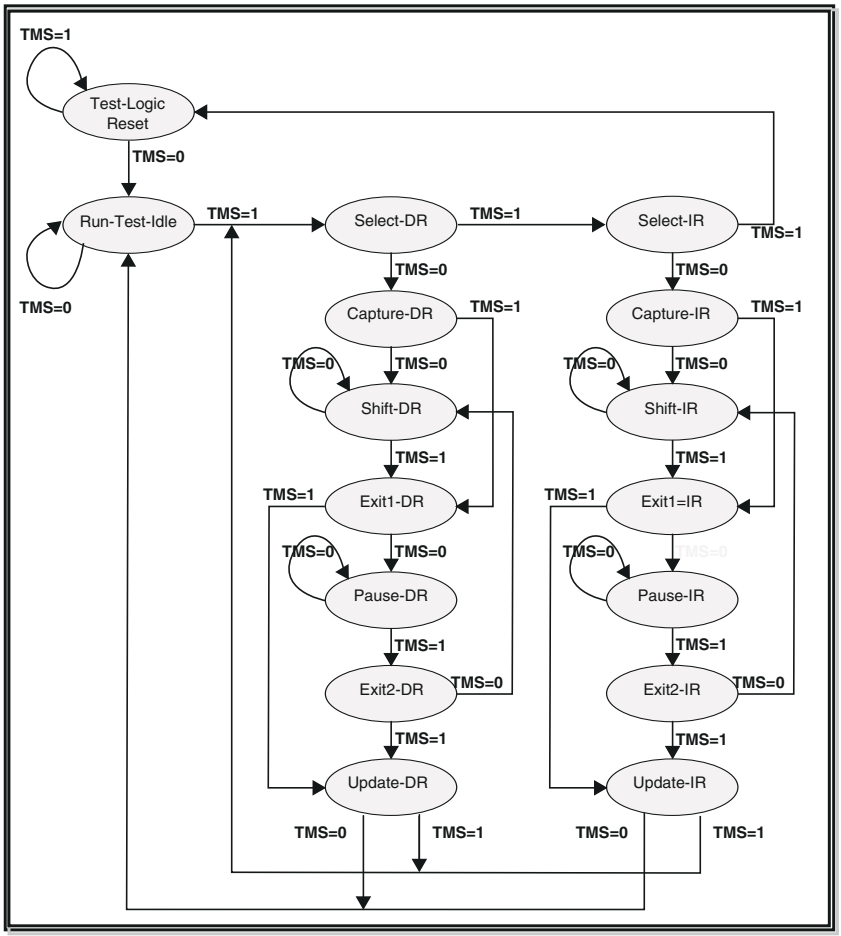
The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

68.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.



68.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

68.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 1572. Falling edge TAP controller state machine

68.6 EPU (Extended Protocol Unit) Operation

68.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

68.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

68.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be

incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

68.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

68.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

68.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

68.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

68.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "***TAP.7 ZBSs***". ZBSs that are intended for other uses are henceforth called "***Other ZBSs***". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

68.6.2 EPU Registers

68.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose.

These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

68.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers.There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

Table 1506. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge

Table 1506. TAP.7 controller register list (managed with commands)(Continued)

Register type	Global/ local	Width	Register mnemonic	Name
Read-only	Local	32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
M = Mandatory register O = Optional register				

68.6.2.3 Registers

68.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

68.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the “System Path” (STL) is used.

- 1 – Suspend use of control levels. Enables “System Path.”
- 0 – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

68.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- 1 – Inhibit ZBS detection.
- 0 – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

68.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 1507. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state

Table 1507. Scan Format Register Values(Continued)

TAPC.7 Class	SCNFMT	Description
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

68.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

68.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a

new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the “Global Register.”

68.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

68.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

68.6.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0x** – TDI and TDO have JTAG function.
- **1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

68.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

68.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

68.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

68.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 1508. RDBACK register format

Bit	Width	Register Mnemonic	Name

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

68.6.3 EPU Commands

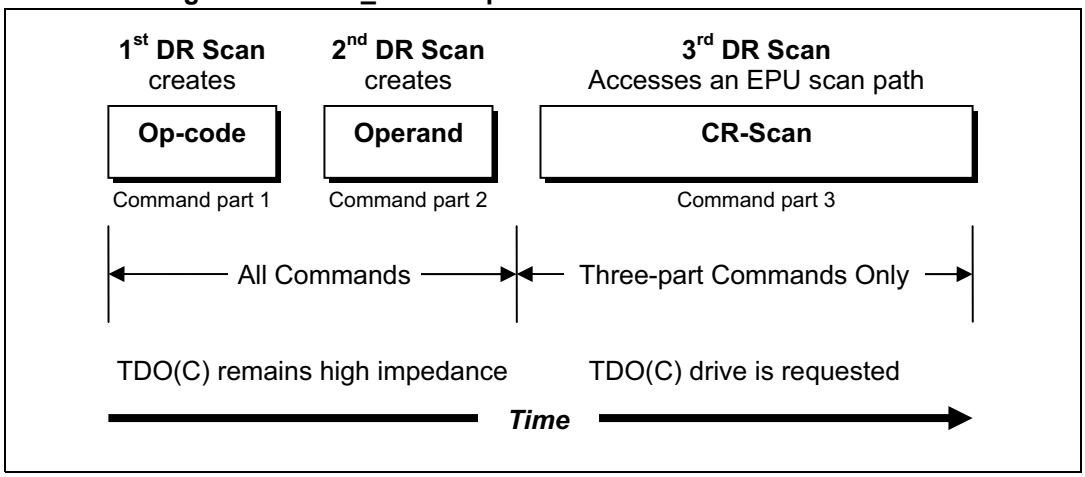
There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

68.6.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.



68.6.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

68.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in *Figure 1573*.

Figure 1573. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a ***Control-Register Scan*** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

68.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in *Table 1511*.

Table 1511. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	—	M	M	M
	0x04	STDCST	Store Data Channel State	—	—	—	—
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	—	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate(1)	0x0A	CIDA	Allocate Controller ID	—	—	M	M
	0x0B	CIDD	De-allocate Controller ID	—	—	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	—	—	—	—

1. Enumerate commands are not currently supported by the CJTAG module.

68.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

68.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

68.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

68.6.3.5 Command Definitions

68.6.3.5.1 Store Commands

68.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 1512. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	**Operand**	**bbb**		**x**	**y**	**Description**
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	—	SGC = y
				1	—	CGM = y
		010	RdyCtl	—	—	RDYC = xy
		011	DlyCtl	—	—	DLYC = xy
		100	ScnFunc	0	—	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	—	—	Reserved
		110		—	—	
		111		—	—	

68.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 1513. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	—	SREDGE = v
			001	—	Reserved
			010	—	TRESET = v
			011 – 111	—	Reserved
		1	—	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

68.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 1514. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	Operand	c	bb	CAPE	Description
00010	c bb vv	0	00	—	Reserved
			01	—	STCKDC = vv
			10	—	APFC = vv
			11	—	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

68.6.3.5.1.4 Store Scan Format (STFMT)

Table 1515. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

68.6.3.5.2 Select Commands

68.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 1516. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	**Operand**	**m**	**Description**
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

68.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 1517. Make Scan Group Candidate (MSC)

MSC		Make Scan Group Candidate	
Opcode	**Operand**	**m**	**Description**
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

68.6.3.5.3 Scan Commands

68.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 1518. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	**Operand**	**CR-Scan**	**yyyyy**	**Description**	**R/W**
01000	yyyyy	—	0	Scan Group Candidate (SGC)	Write only
		—	1	Conditional Group Member (CGM)	Write only
		—	2	CNFG[0]	Read only
		—	3	CNFG[1] (not implemented)	Read only
		—	4	CNFG[2] (not implemented)	Read only
		—	5	CNFG[3] (not implemented)	Read only
		—	6	Functional reset requested (FRESETR) (not implemented)	Read only
		—	7	Series topology detect	Write only
		—	15 – 8	Reserved	Read only

68.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

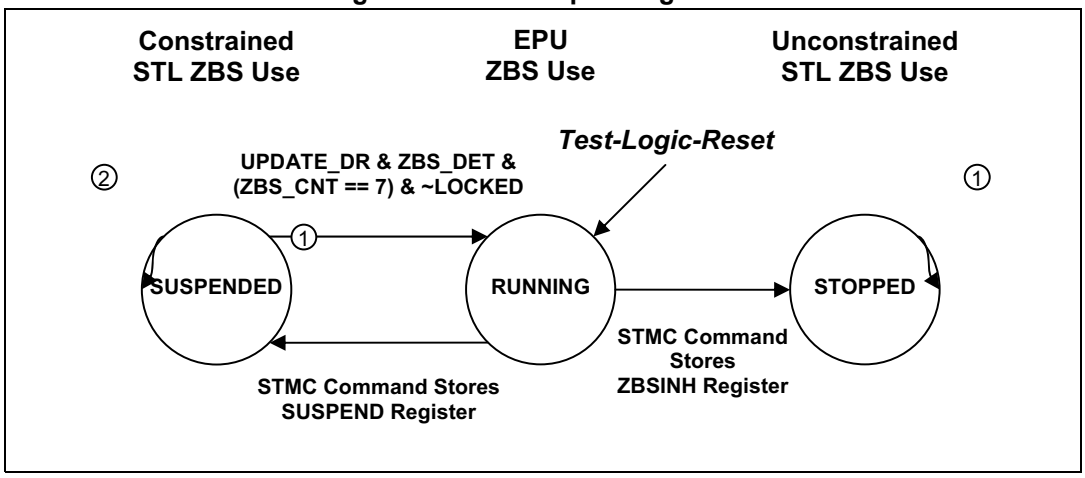


Table 1519. Scan String (SCNS)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01001	yyyyy	—	0	RDBACK[0] Register [31:0]	Read only
		—	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		—	2	CNFG[0] Register [31:0]	Read only
		—	3	CNFG[1] Register [31:0] (not implemented)	Read only
		—	4	CNFG[2] Register [31:0] (not implemented)	Read only
		—	5	CNFG[3] Register [31:0] (not implemented)	Read only
		—	6–7	Reserved (read logic 0)	Read only
		—	31–8	Private – available for customization	

68.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in *Figure 1574*.

Figure 1574. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in *Table 1520*. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 1520. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

68.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

68.7 APU (Advanced Protocol Unit) Operation

68.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMSC signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine

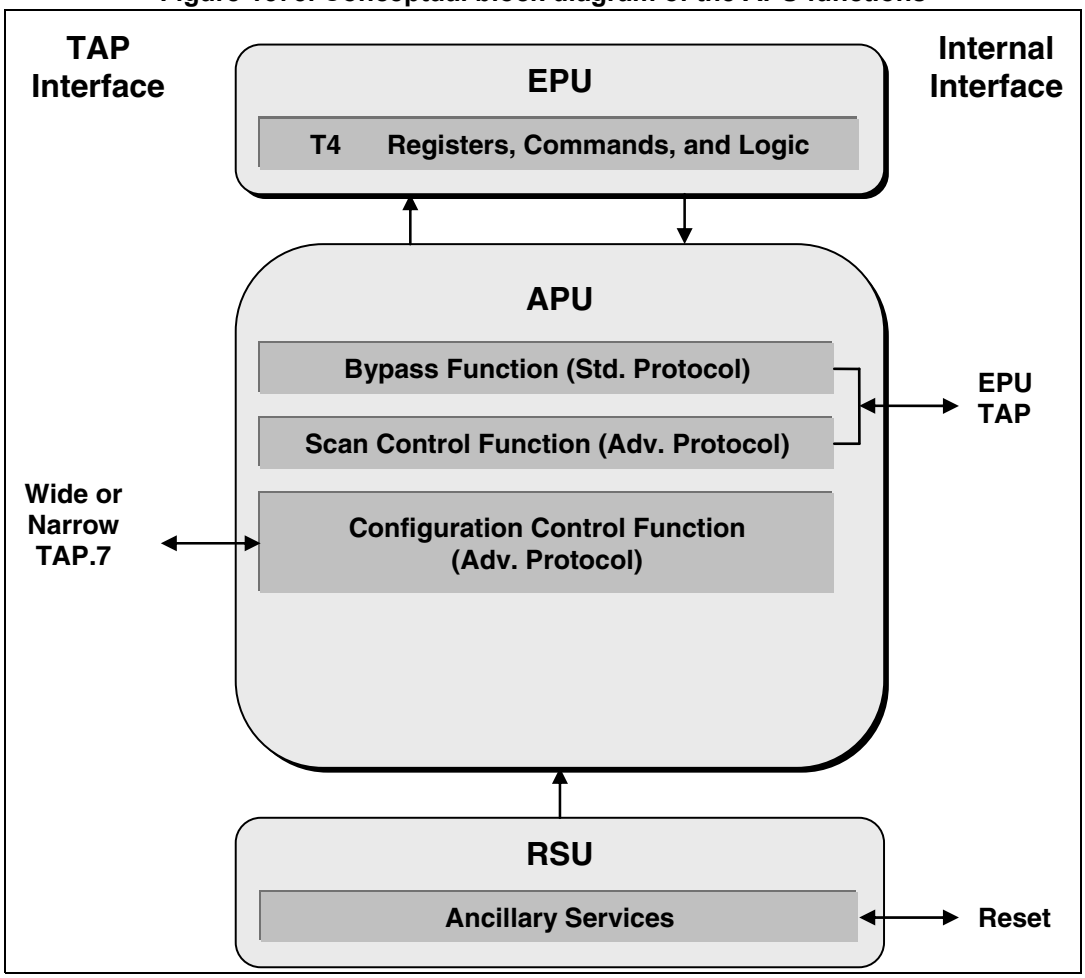
state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.



The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

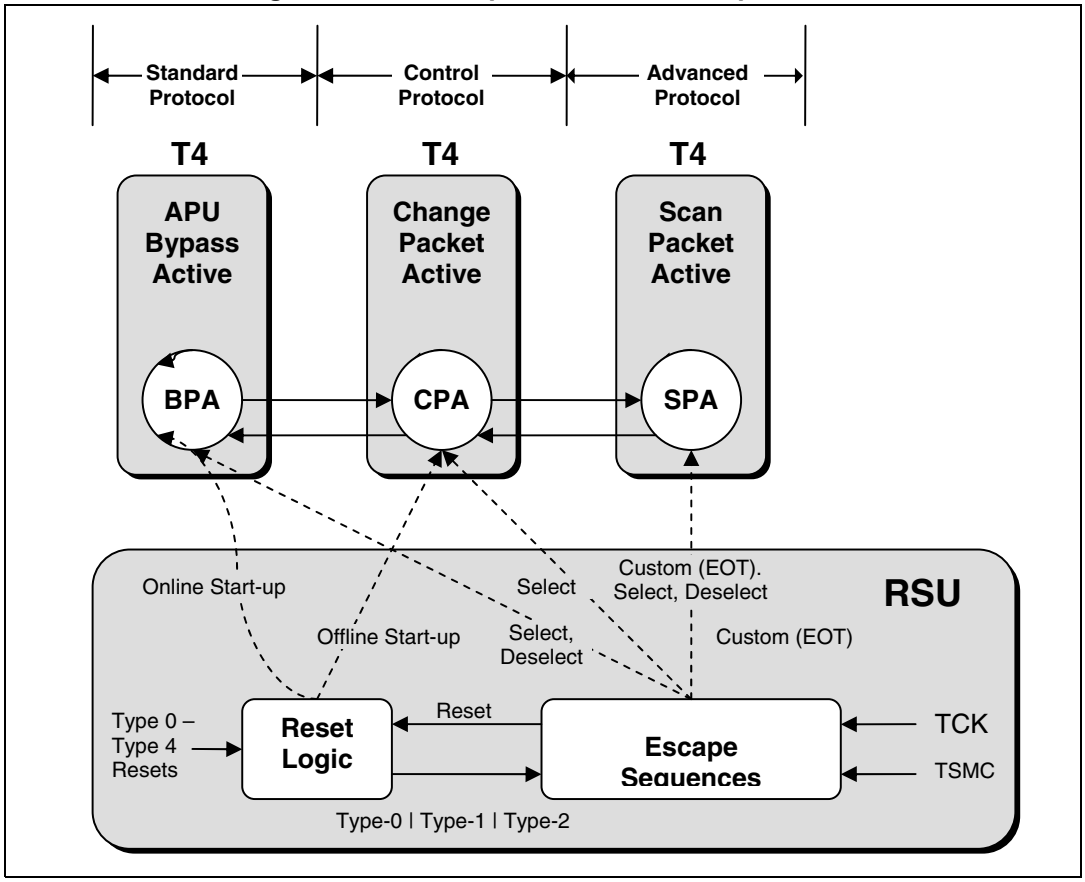
The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 1575. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.



When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure

(ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

68.7.2 Operation

The conceptual view of the APU operation is shown in *Figure 1576*.

Figure 1576. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMSC pin.

APU operating states:

- ***BPA*** – **B**y**P**ass **A**ctive
- ***CPA*** – **C**hange **P**acket **A**ctive
- ***SPA*** – **S**can **P**acket **A**ctive

68.7.2.1 BPA

The *BPA* state allocates the use of the TMSC pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

68.7.2.2 CPA

The *CPA* state allocates the use of the TMSC pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

68.7.2.3 SPA

The SPA state allocates the use of the TMSC pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

68.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMSC pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

68.7.4 Signal behaviors

The TCKC signal:

- The test clock

The TMSC signal:

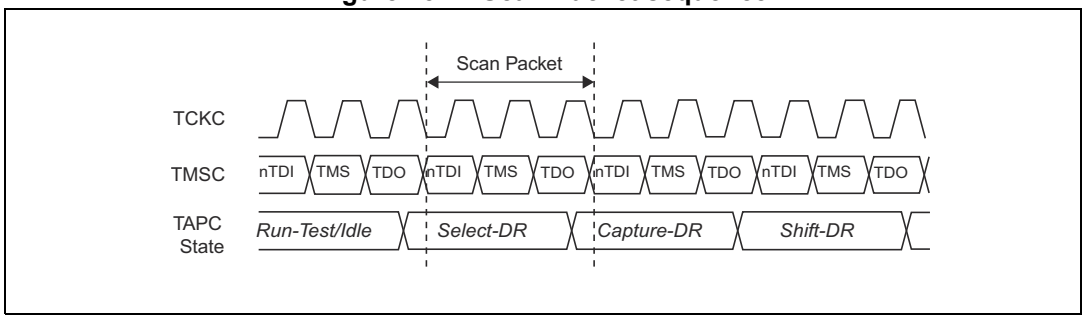
- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

68.7.5 APU Functions

68.7.5.1 Bypass Active (BPA) Function



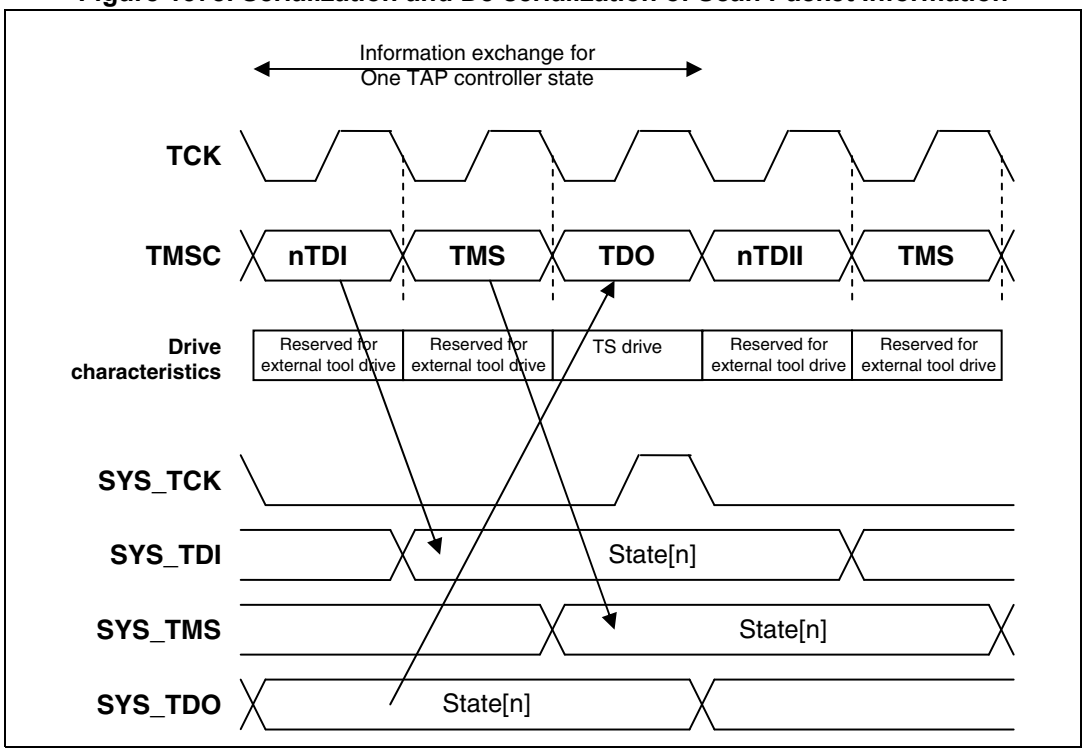
When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7

or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

68.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 1577. Scan Packet sequence



A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan

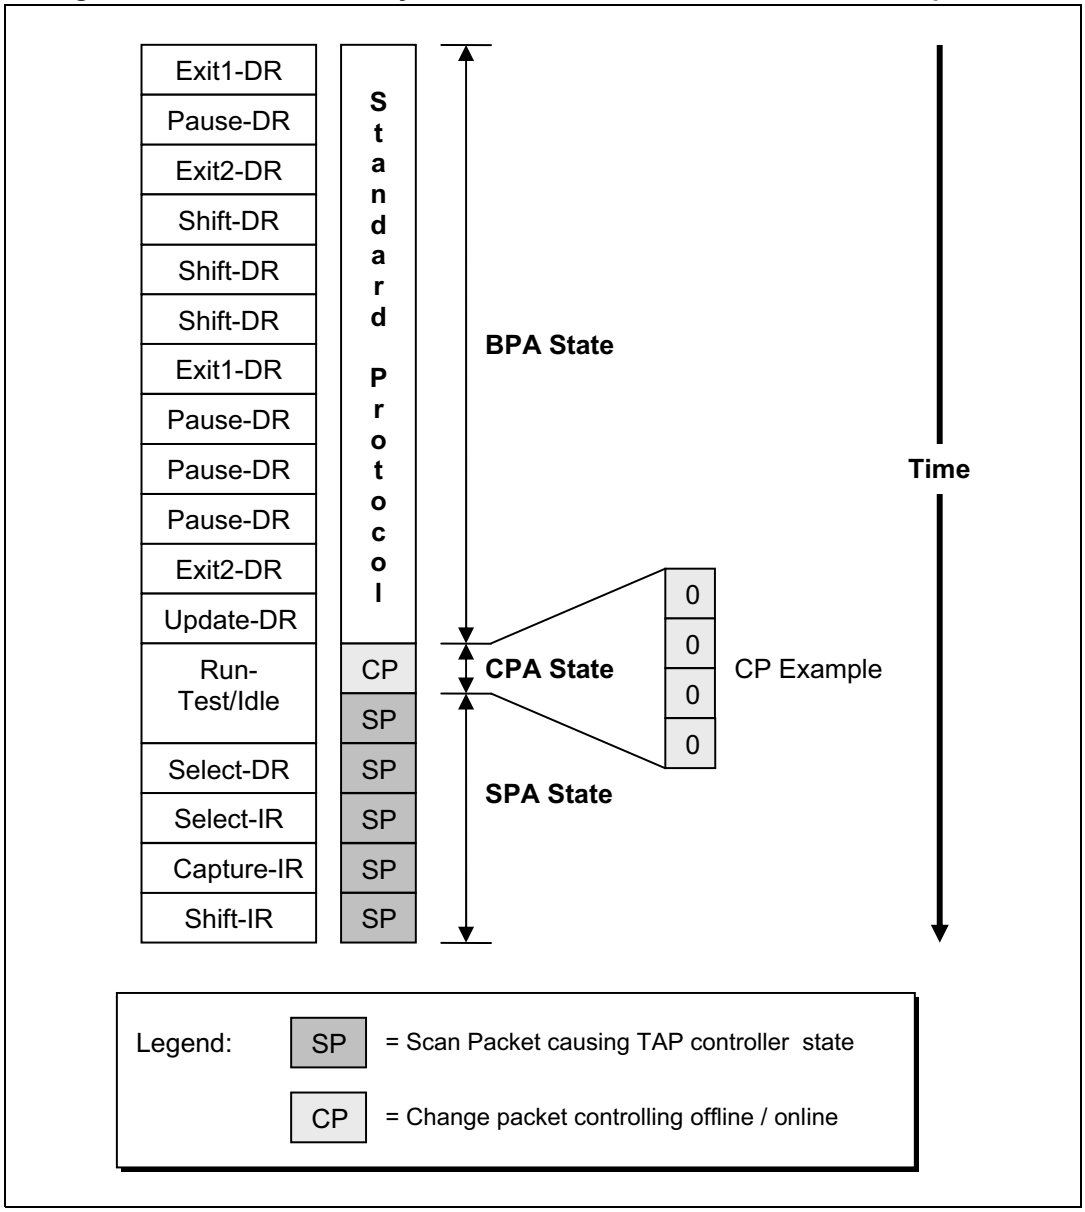
formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 1578. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.



With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

68.7.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

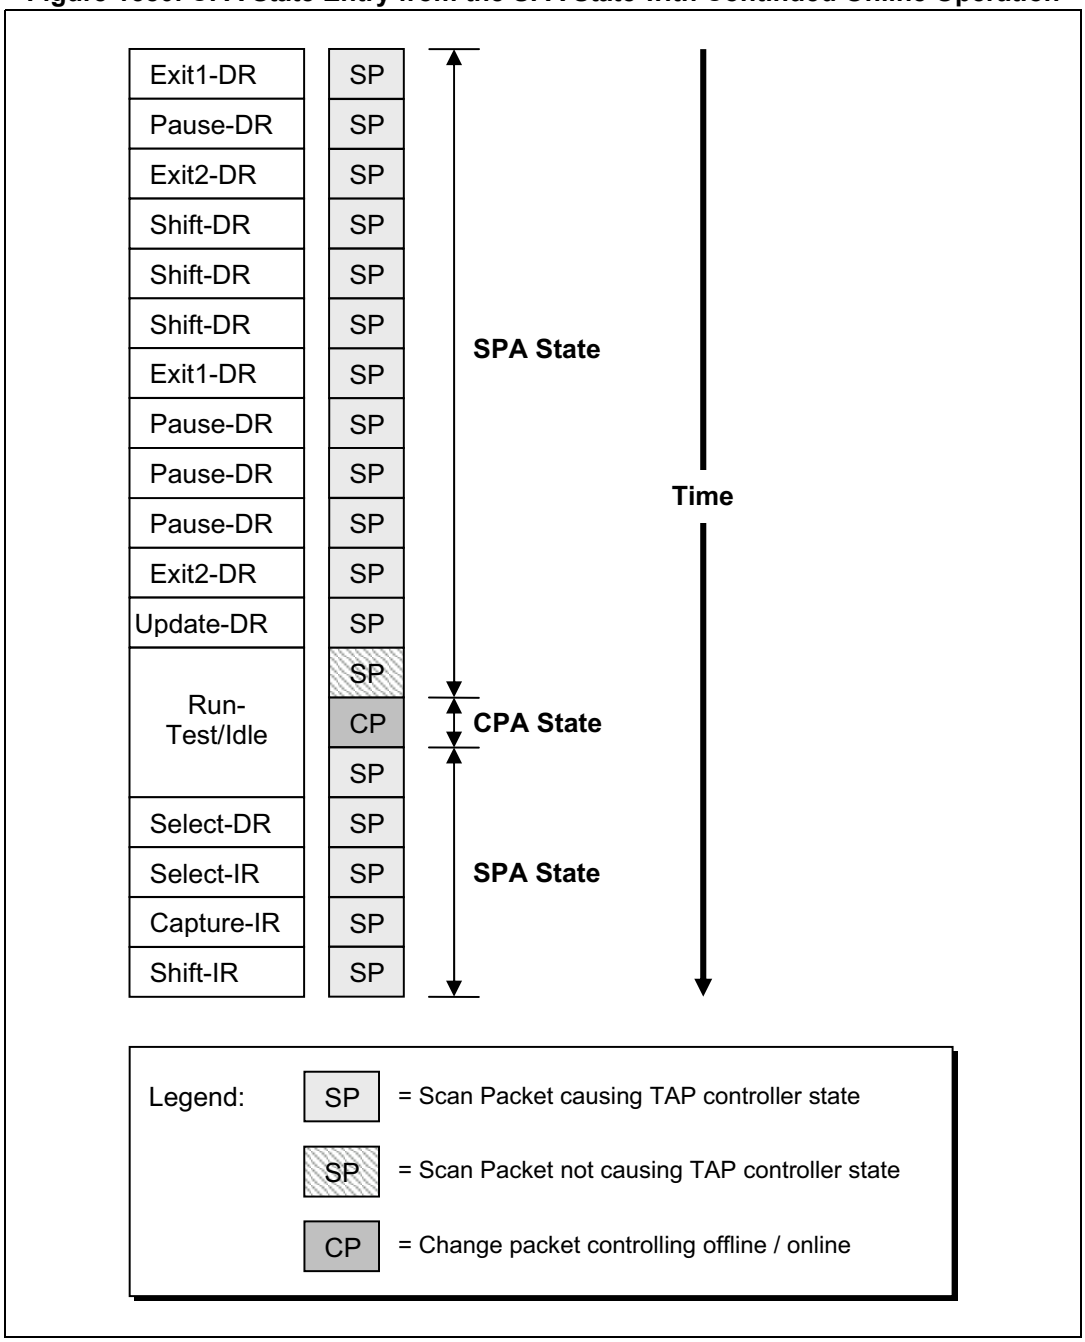


Figure 1579. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been

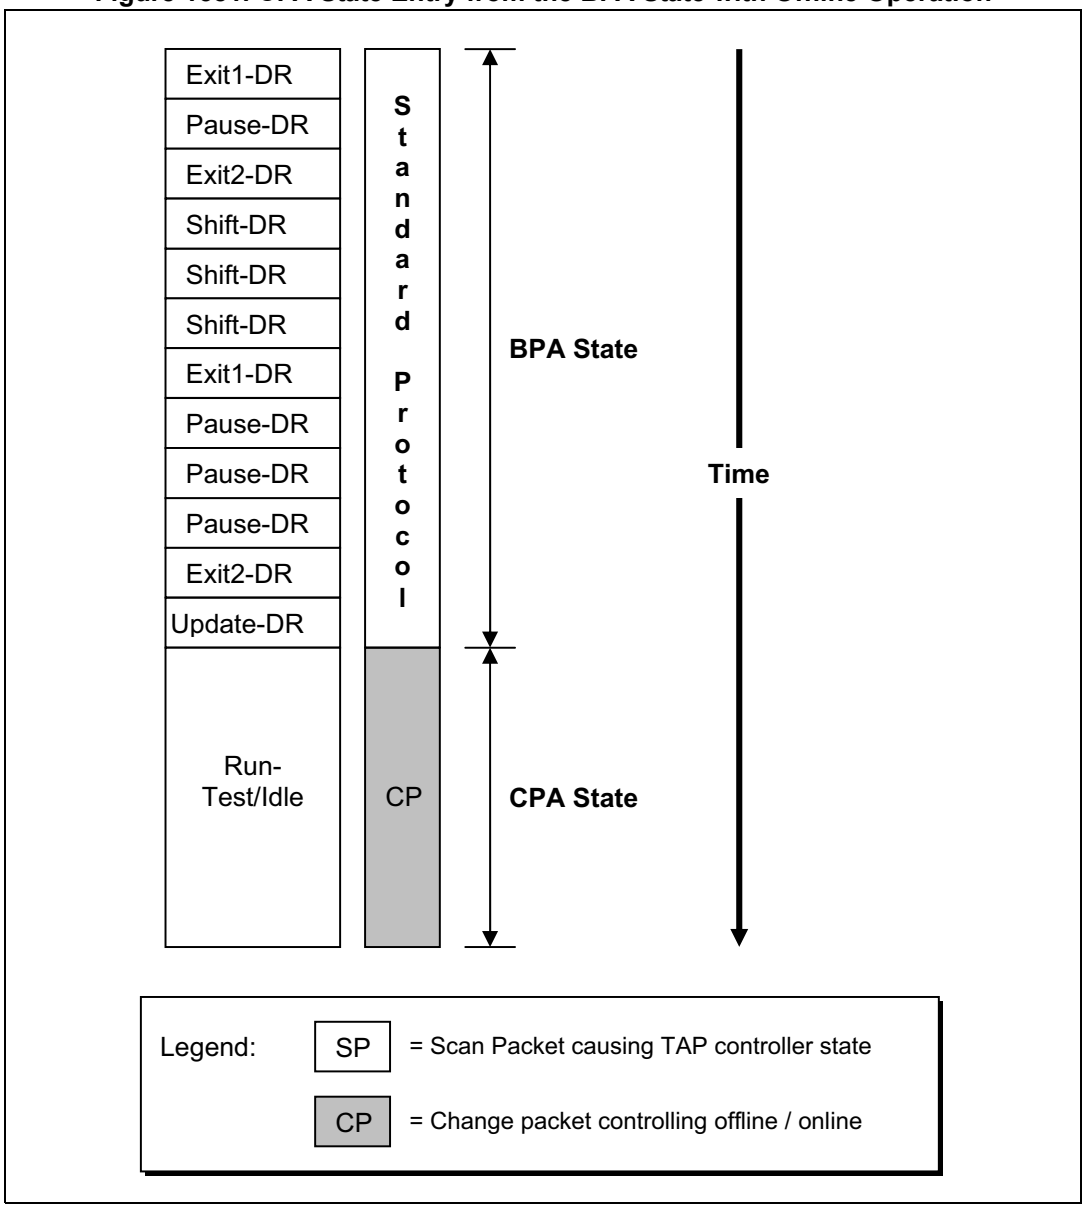
fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 1580. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state

to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 1581. CPA State Entry from the BPA State with Offline Operation



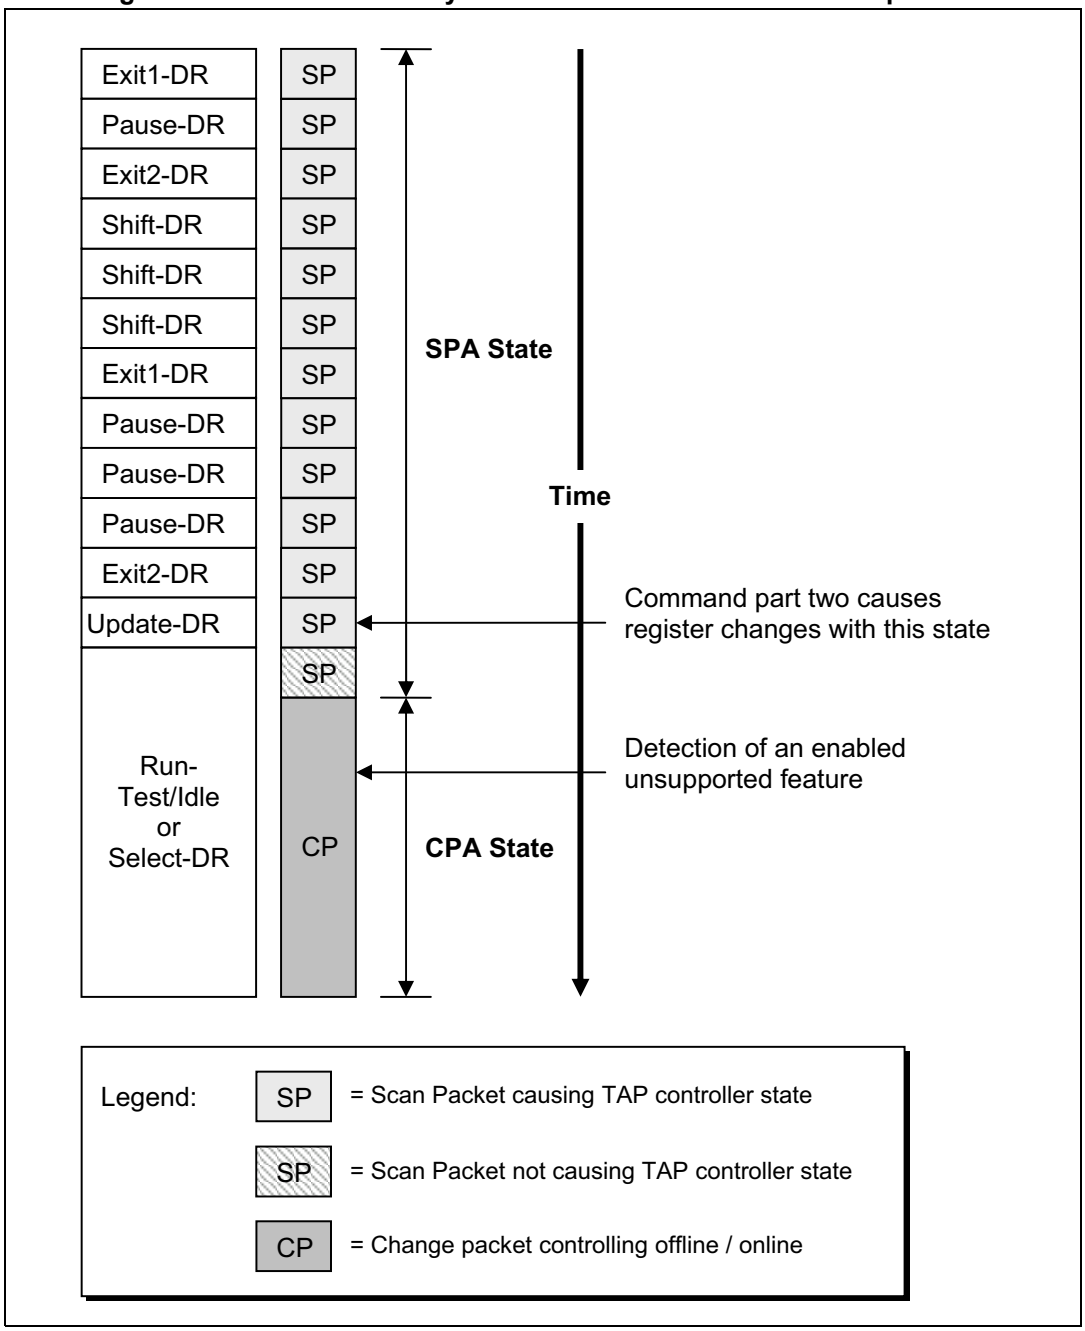


Figure 1582. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

68.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP_END
  - **01** – CP_NOP (extends the body by 1-bit)
  - **10** – CP_NOP (extends the body by 1-bit)
  - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the post amble bit.
- **Post amble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Post amble. This can be as simple as four logic zero values.

68.7.7 Scan Packet

A Scan Packet defines the period of TMSC pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

68.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

68.7.8.1 Payload Element Content

68.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain and input bit frame, an output bit frame, or both. When an input bet frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

68.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in *Table 1521*.

Table 1521. Factors determining the SP payload content

Scan format	Payload content determined by the:	
	TAPC state	Header
MScan	—	—
OScan	Yes	—

68.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

68.7.8.3 Scan Formats

68.7.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- MScan **–** Maximum flexibility.
- OScan0-7 – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in *Table 1522* and *Table 1524*, respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

68.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

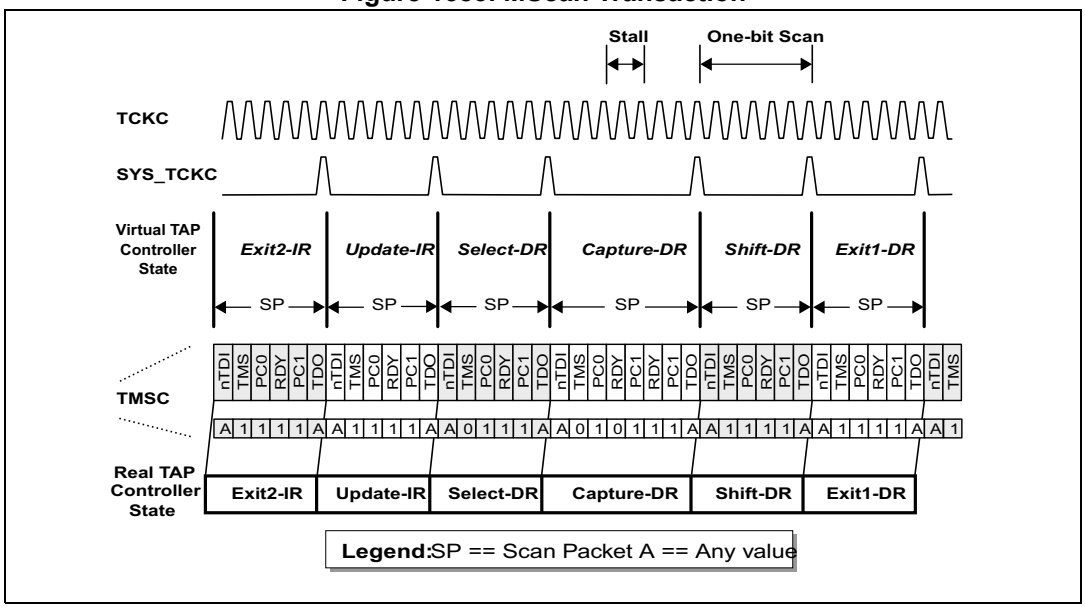

Table 1522. MScan scan format use case summary

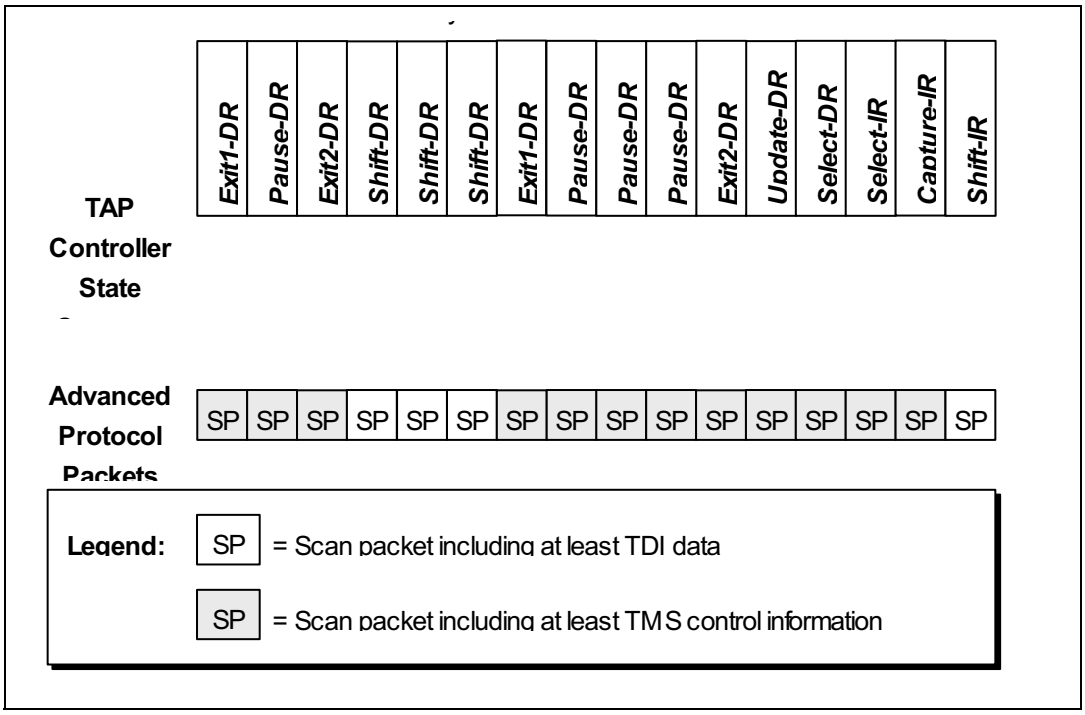
Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation			

Table 1523. MScan Scan Packet content

	Non-shift TAP controller states							Shift TAP controller states					
MScan	nTDI	TMS	PC0	RDY	PC1	TDO		nTDI	TMS	PC0	RDY	PC1	TDO

Figure 1583. MScan Transaction



68.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states

and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 1584. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- OScan0 – OScan3: Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in *Table 1524*.

Table 1524. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		
OScan4	Stalls	↓	Best	External tool or TS
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- Optimization I: OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- Optimization II: OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- Optimization III: OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- Optimization IV: OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 1525. OScan Scan Format "Payload"

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO

68.8 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

68.8.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in *Section 68.6.1.4, Control levels*.

After the control level is set tocontrol level 2, TAP.7 commands can be executed as described in *Section 68.6.3, EPU Commands*. Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in *Section 68.7.5.3, Control Process Active (CPA) Function* and *Section 68.7.6, Configuration Change Packets (CP)*. Loading a change packet body value of 00 (CP_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in *Section 68.6.3.5.1.3, Store Conditional 2-bit (STC2)*.

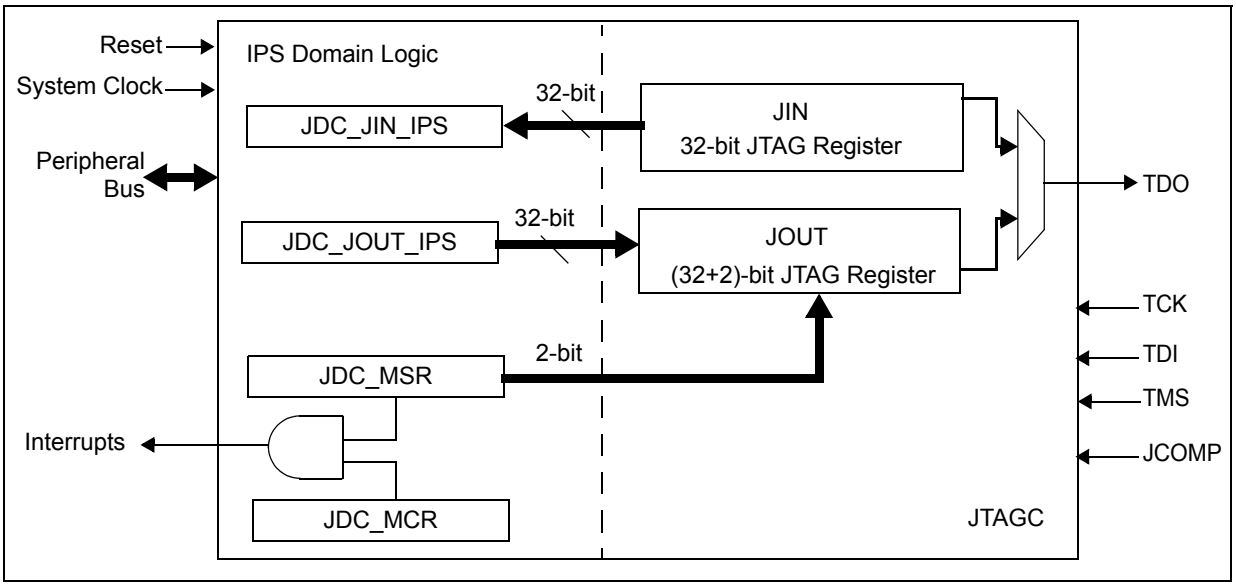
69 JTAG Data Communication (JDC)

69.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

69.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.



The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JDC_JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JDC_JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JDC_JIN_IPS register, and when new data has been written to the JDC_JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (JDC_MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in *Figure 1585*.

Figure 1585. JDC block diagram

69.3 Register definition

Table 1526 shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1526. JDC memory map

Address offset (hex)	Register	Access	Reset value	Section/page

Figure 1587. Module Status Register (JDC_MSR)

The JDC_MSR is described in *Table 1528*.

Table 1528. JDC_MSR register field descriptions

Field	Description
JIN_RDY	JIN Ready (read only). 0 Cleared upon software read of JDC_JIN_IPS contents via IPS 1 Set when new data is written to the JDC_JIN_IPS register
JIN_INT	JIN Interrupt. 0 Cleared by writing logic 1 1 Set when new data is written to the JDC_JIN_IPS register
JOUT_RDY	JOUT Ready (read only). 0 Cleared upon tool read of JOUT register via JTAG port 1 Set when new data is written to the JDC_JOUT_IPS register
JOUT_INT	JOUT Interrupt. 0 Cleared by writing logic 1 1 Set when JOUT_RDY bit is cleared by tool reading JOUT register

69.3.1.3 JTAG output IPS data register (JDC_JOUT_IPS)

The JDC_JOUT_IPS register holds data written via IPS. The JDC_JOUT_IPS contents are ported out and captured into the JOUT register to be read via the JTAG port. *Figure 1588* shows the format of the JDC_JOUT_IPS register. This register is reset by system destructive reset.

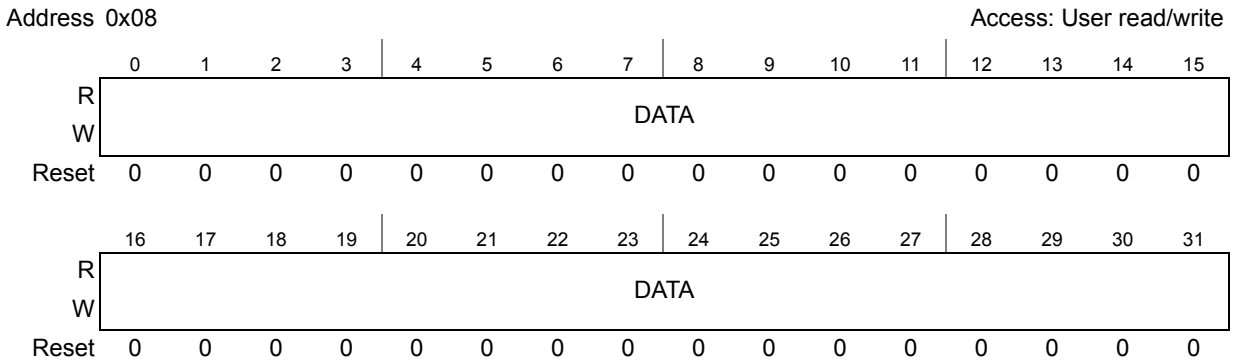

Figure 1588. JDC_JOUT_IPS register

The JDC_JOUT_IPS register is described in *Table 1529*.

Table 1529. JDC_JOUT_IPS register field descriptions

Field	Description
DATA	Contains JOUT_IPS data.

69.3.1.4 JTAG input IPS data register (JDC_JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JDC_JIN_IPS register, where it can be read via IPS. *Figure 1589* shows the format of the JDC_JIN_IPS register. This register is reset by system destructive reset.

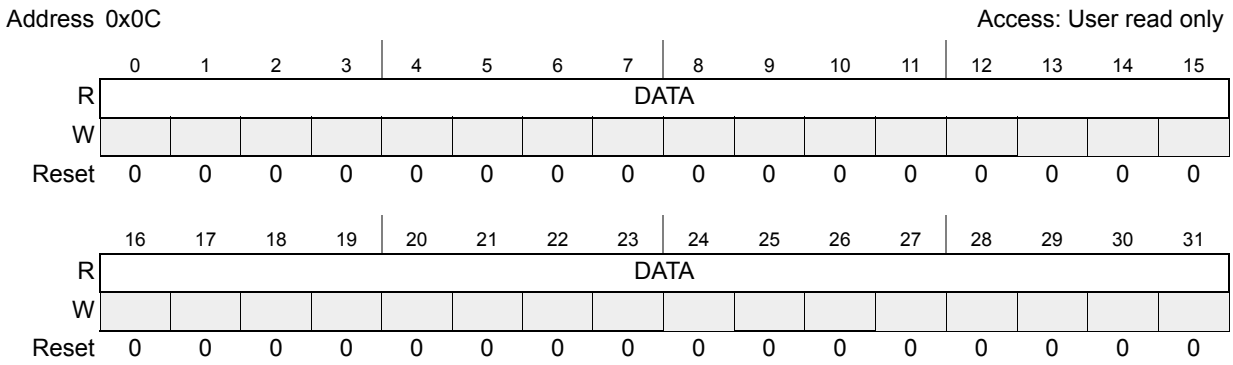

Figure 1589. JDC_JIN_IPS register

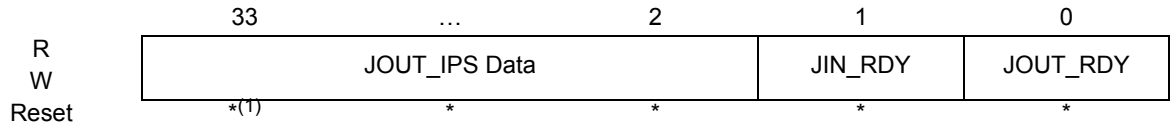
The JDC_JIN_IPS register is described in *Table 1530*.

Table 1530. JDC_JIN_IPS register field descriptions

Field	Description
DATA	Contains JIN_IPS data.



69.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JDC_JIN_IPS register. The other

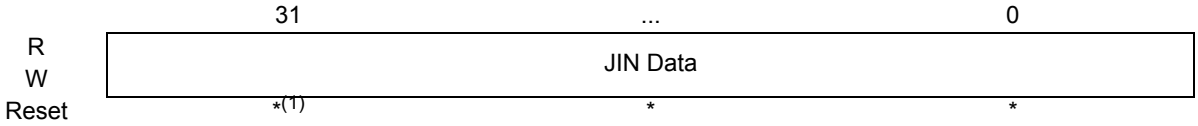
JTAG register captures data from the JDC_JOUT_IPS register and ready status from the JDC_MSR to be shifted out via the JTAG port.

69.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JDC_JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. *Figure 1590* shows the format of the JOUT register. This register is reset by system destructive reset and JTAG reset.

1. The reset value of the JOUT register is 34'b0.

Figure 1590. JOUT JTAG register



The JOUT register is described in *Table 1531*.

Table 1531. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JDC_JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from JDC_MSR
JOUT_RDY	State of JOUT_RDY bit from JDC_MSR

69.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JDC_JIN_IPS register to be read via IPS. *Figure 1591* shows the format of the JIN register. This register is reset by system destructive reset and JTAG reset.

1. The reset value of the JIN register is 32'b0.

Figure 1591. JIN JTAG Register

The JIN register is described in *Table 1532*.

Table 1532. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

69.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JDC_JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the JDC_MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JDC_JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JDC_JIN_IPS register upon exit of the Update-DR state. An update of the JDC_JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the JDC_MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JDC_JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

69.4.1 IPS register access

IPS access is available to the registers described in *Section 69.3.1: Register descriptions*.

69.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

69.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in *Table 1533*. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1533. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JDC_JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JDC_JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

70 JTAG Master (JTAGM)

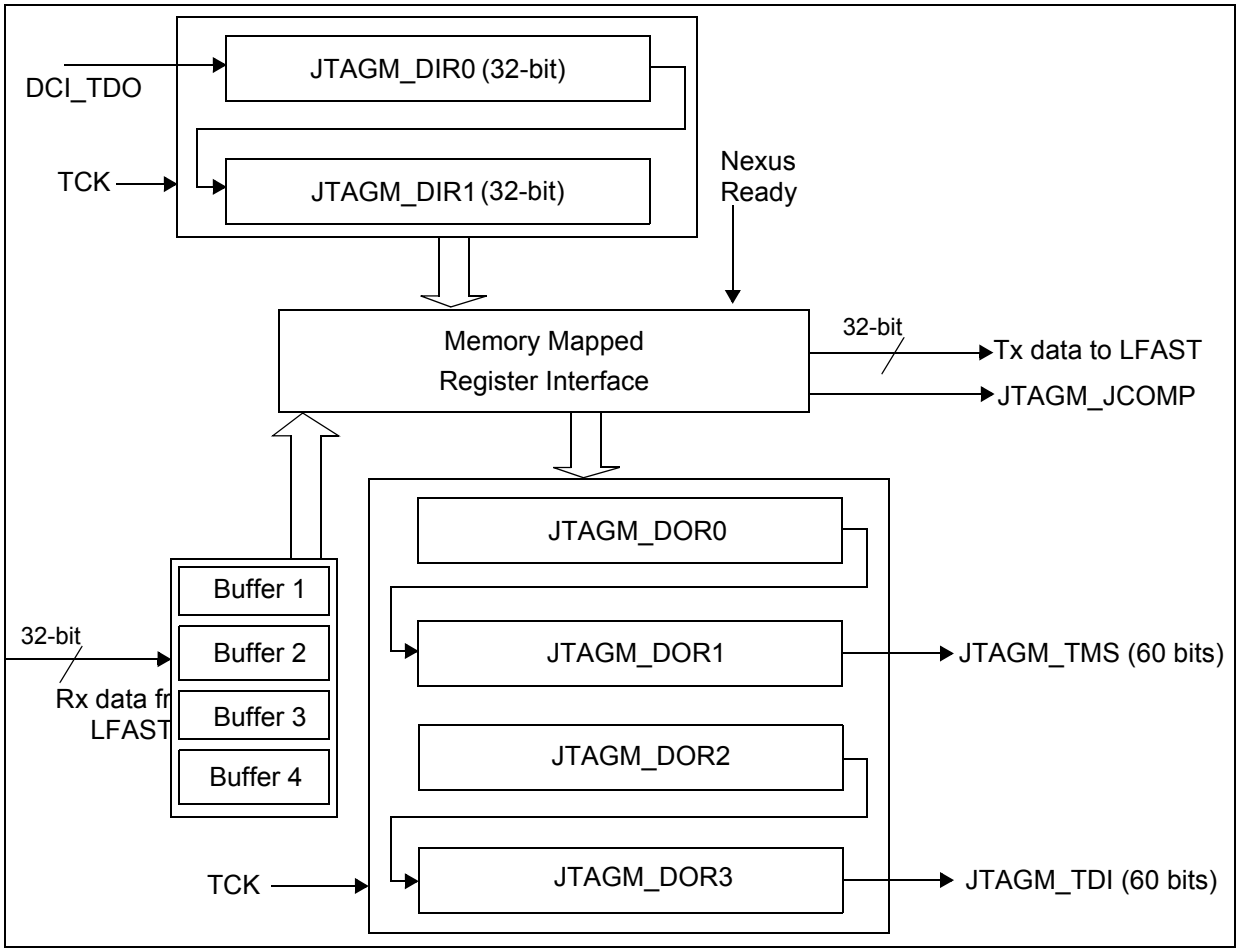
70.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

70.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RXCRC receive register
- Two data input registers

All these registers, described in detail in *Section 70.4: Memory map and register definition*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

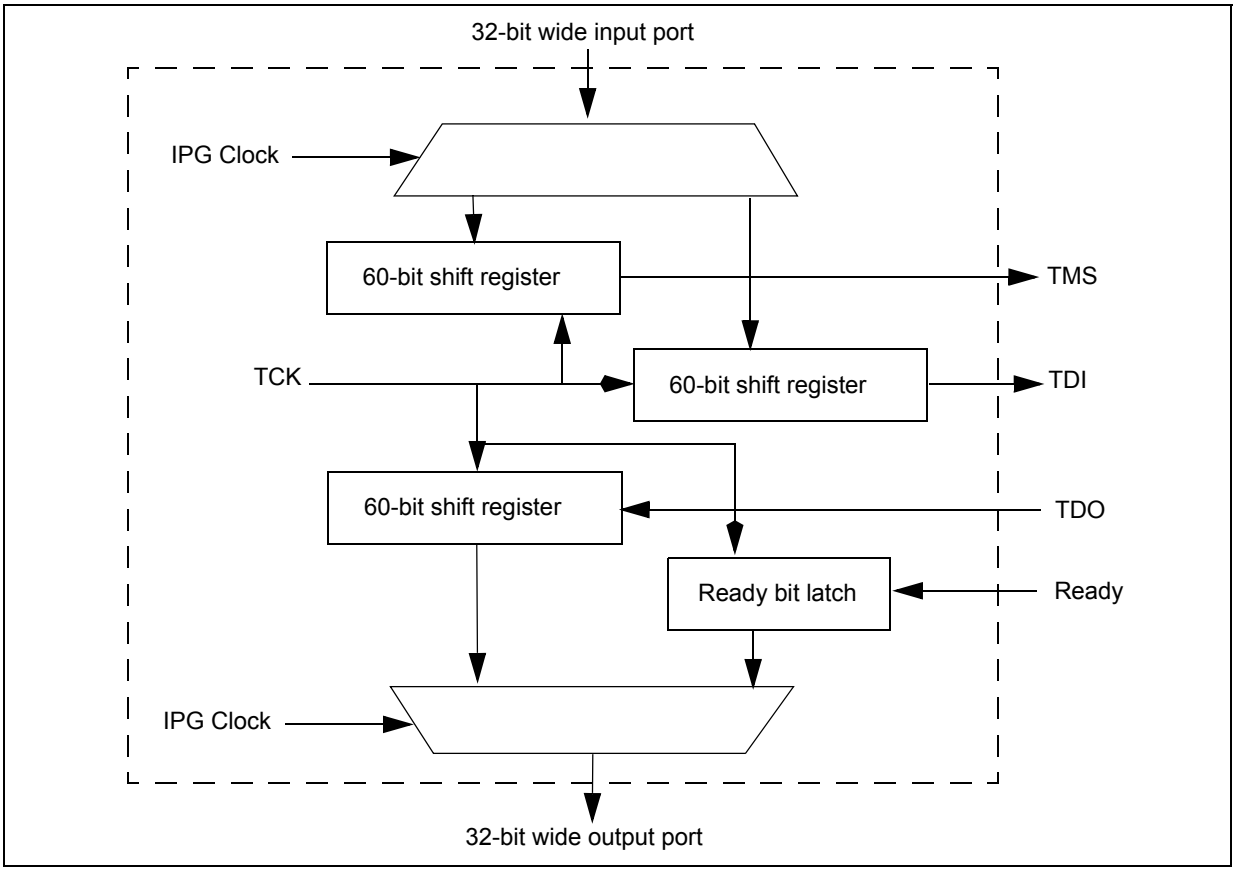
Figure 1592 shows the block diagram of the JTAGM.

Figure 1592. JTAGM block diagram

70.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST



70.2 Functional description

70.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60

TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain. *Figure 1593* shows the flow diagram of the LFAST to DCI connection.

Figure 1593. LFAST-to-DCI flow diagram

70.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[JTAGM_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[JTAGM_JCOMP]:

- Do not clear the JTAM_MCR[JTAGM_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the JTAGM_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

70.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

70.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

70.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

70.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

70.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

70.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

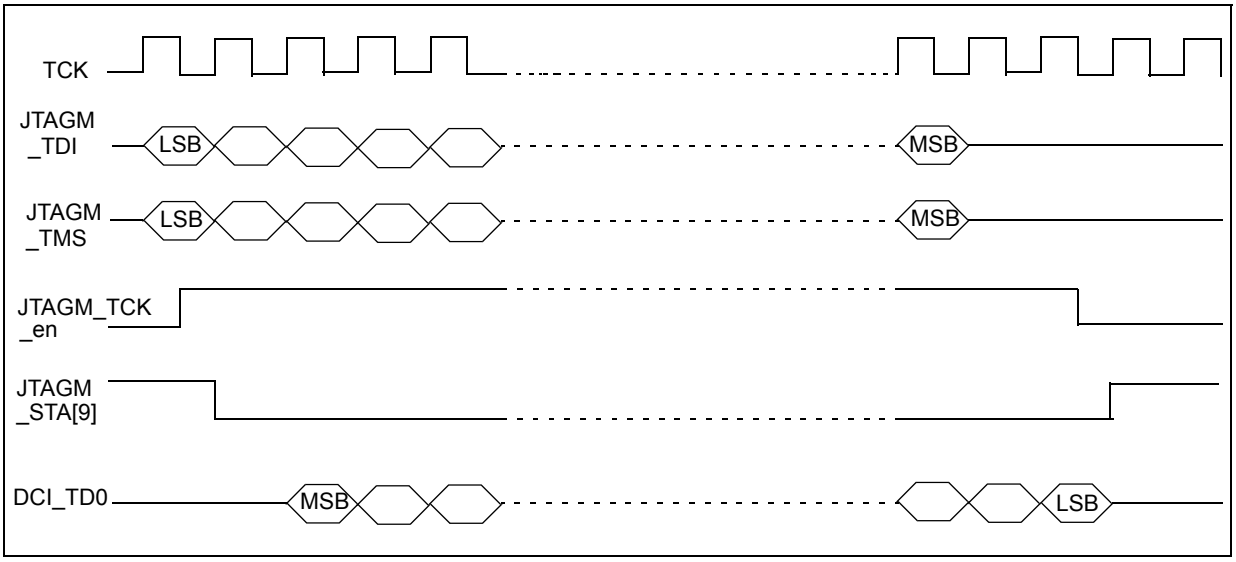
The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the EVTI0_ASSERT bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the EVTI1_ASSERT bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

70.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 70.2.5.1: Status register ready bit*). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (the least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

70.2.8 JTAGM to DCI serial interface

Figure 1594 shows the data transfer timings between JTAGM and DCI.

Figure 1594. JTAGM to DCI serial interface diagram

70.2.9 JTAGM data handling and CRC calculation in LFAST mode

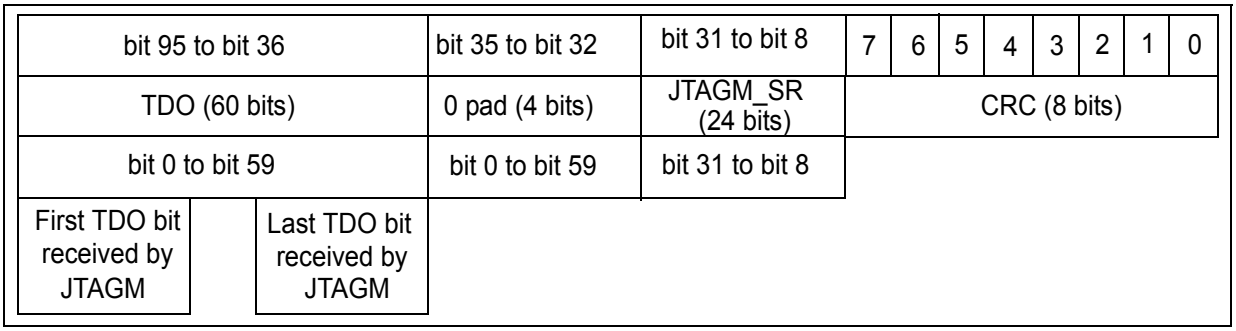


Figure 1595 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 1595. Bit ordering for LFAST to JTAGM transfer

bit 127 to bit 68		bit 67 to bit 8		7	6	5	4	3	2	1	0
TMS (60 bits)		TDI (60 bits)		CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59									
Last TMS bit transmitted by JTAGM	First TMS bit transmitted by JTAGM	Last TDI bit transmitted by JTAGM	First TDI bit transmitted by JTAGM								

Figure 1596 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 1596. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 1596*).

70.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

70.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

70.4 Memory map and register definition

Table 1534 contains the memory map of the JTAGM registers.

Table 1534. Memory map

Offset	Register	Location

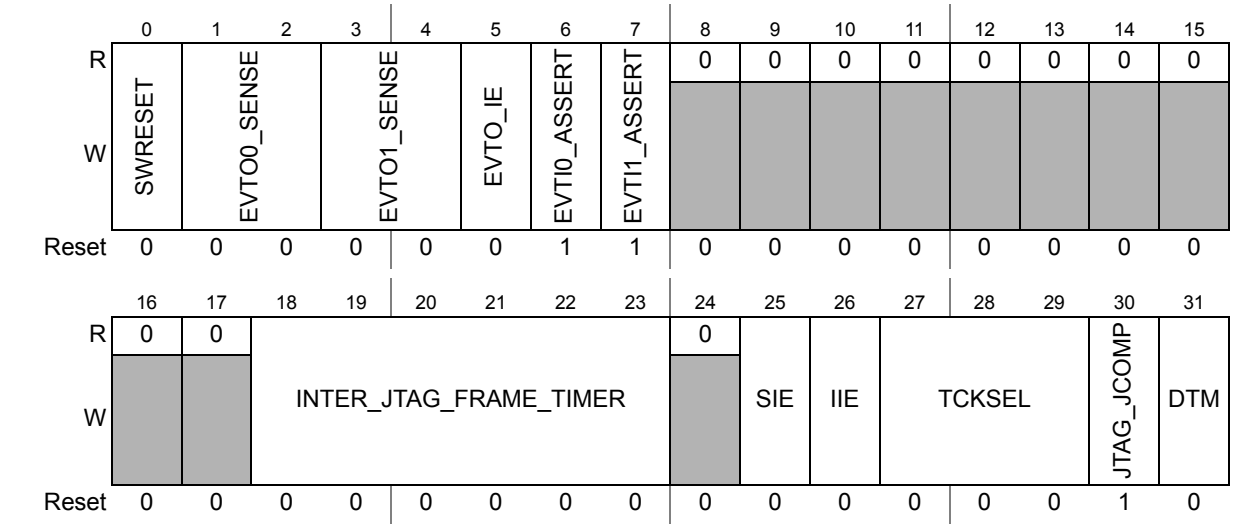

Figure 1597. JTAGM_MCR register

The JTAGM_MCR register is described in *Table 1535*.

Table 1535. JTAGM_MCR register field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit. Writing a 0 has no effect. **Note:** After being written to “1”, this bit is auto cleared within 3 TCK cycles.
1–2 EVTO0_SENSE	Determines JTAGM response to activity on $\overline{\text{EVTO}}$0 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$0 edges (default setting) 01 EVTO0_EDGE status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$0 10 EVTO0_EDGE status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$0 11 EVTO0_EDGE status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$0
3–4 EVTO1_SENSE	Determines JTAGM response to activity on $\overline{\text{EVTO}}$1 line 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$1 edges (default setting) 01 EVTO1_EDGE status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$1 10 EVTO1_EDGE status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$1 11 EVTO1_EDGE status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$1
5 EVTO_IE	Enables $\overline{\text{EVTO}}$ triggered JTAGM interrupt 0 No JTAGM interrupt is generated In response to any $\overline{\text{EVTO}}$0 or $\overline{\text{EVTO}}$1 activity 1 JTAGM interrupt is generated when EVTO0_EDGE or EVTO1_EDGE are set
6 EVTI0_ASSERT	EVTI0 Assert. 0 Asserted the $\overline{\text{EVTO}}$0 from the JTAGM module 1 Deasserts the $\overline{\text{EVTO}}$0 from the JTAGM module
7 EVTI1_ASSERT	EVTI1 Assert. 0 Asserted the $\overline{\text{EVTO}}$1 from the JTAGM module 1 Deasserts the $\overline{\text{EVTO}}$1 from the JTAGM module **Note:** In the SW mode (when DTM =1), regardless of the state of “EVTI1_ASSERT” bit the internall “evti” signal remains de-asserted . Though this bit can be written , yet writing to this bit has no effect.
8–17	Reserved
18–23 INTER_JTAG_ FRAME_TIMER	TCK delay. 0000000 TCK delay 0000011 TCK delay ... 11111163 TCK delay
24	Reserved
25 SIE	SPU Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU 1 JTAGM generates an interrupt to the CPU if the SPU interrupt request is asserted
26 IIE	Idle Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU upon completion of a 60-bit JTAG transfer 1 JTAGM generates an interrupt to the CPU upon completion of a 60-bit JTAG transfer

Table 1535. JTAGM_MCR register field descriptions(Continued)

Field	Description
27–29 TCKSEL	TCK Divider division factor control value. (TCK Divider divides the clock input to JTAGM IP to generate TCK out(input to DCI)). 000 TCK Divider division factor is 1 001 TCK Divider division factor is 2 010 TCK Divider division factor is 3 ... 111 TCK Divider division factor is 8 **Note:** It should be taken care that the maximum frequency of TCK input to DCI, should be equal or less than half of system clock.
30 JTAGM_JCOMP	JTAG reset. 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data for JTAG transferred by LFAST 1 Data for JTAG transferred by software

70.4.1.2 Status register (JTAGM_SR)

The functionality of some of the SR bits changes depending on the setting of the DTM bit in the MCR. These differences are described in the field descriptions table.

Figure 1598. JTAGM_SR register

The JTAGM_SR register is described in *Table 1536*.

Table 1536. JTAGM_SR register field descriptions

Field	Description
0 OVERRUN	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1	Reserved
2 TXGOOD	Status information from the LFAST to be used by software: Indicates either data frame or ping frame was transmitted successfully
3 TXERROR	Status information from the LFAST to be used by software: Indicates Tx data Interface not enabled and a frame is ready to be transmitted
4 RXOVFL	Status information from the LFAST to be used by software: Indicates Rx data FIFO overflow
5 INVFPS	Status information from the LFAST to be used by software: Indicates reception of frame with invalid frame payload size
6 INVICLC	Status information from the LFAST to be used by software: Indicates reception of frame with invalid ICLC code
7 ILLLCT	Status information from the LFAST to be used by software: Indicates reception of illegal LCT frame
8	Reserved
9 LVDSEN	DCI status: DCI LVDS port enable
10 JTAGEN	DCI status: DCI JTAG port enable
11 LVDSSAFE	DCI status: DCI LVDS safe mode
12 JTAGSAFE	DCI status: DCI JTAG safe mode
13 LVDSESC	DCI status: DCI LVDS escape mode
14 LFASTEN	DCI status: DCI enable LFAST
15 TOOL	DCI status: DCI tool present, set when a debug tool is connected
16 EVTO0_EDGE	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$0
17 EVTO1_EDGE	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1

Table 1536. JTAGM_SR register field descriptions(Continued)

Field	Description
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
20 CRC_ERR	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 NEXUS_ERR	Nexus error bit. It is set when there is an error, else it is 0.
22 IDLE	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode (DTM = 0), this bit has no effect and should not be used.
24–31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode (DTM = 0): Bit 24–31 reads the CRC. Write has no effect. SW Mode (DTM = 1): – Bit 24–31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears EVTO0_EDGE, bit 16 – Writing 1 on bit 25 clears EVTO1_EDGE, bit 17

70.4.1.3 Data out register 0 (JTAGM_DOR0)

Figure 1599 shows the format of the JTAGM_DOR0.

28–31	Reserved

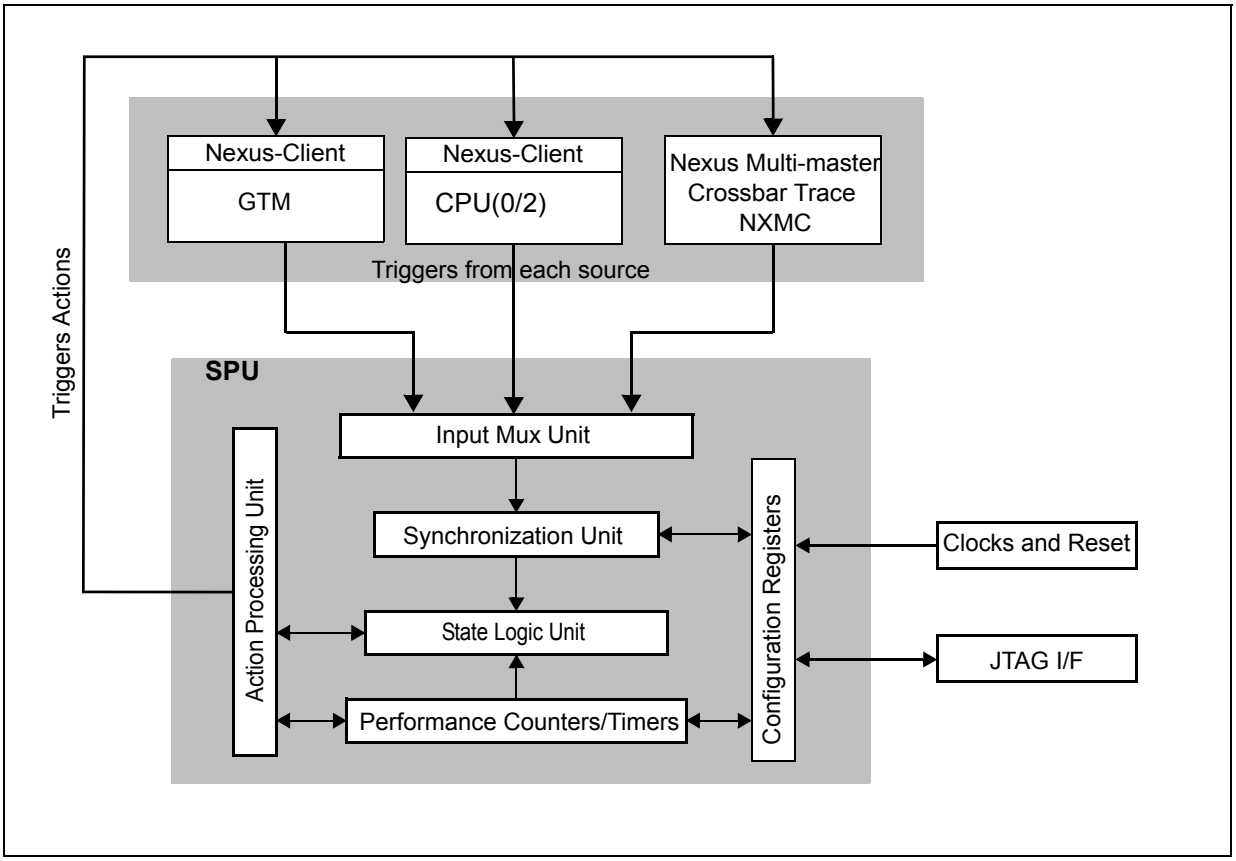
71 Sequence Processing Unit (SPU)

71.1 Introduction



The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores, GTM, or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

71.1.1 SPU block diagram

Figure 1606 shows a top-level block diagram of the SPU.

Figure 1606. SPU block diagram

71.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, GTM, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes, but one of the inputs is permanently connected to a high level so users can only choose 63 of the inputs. Of these 63 inputs, users can select 16 inputs for each SLU, shown in *Figure 1643*.

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in *Figure 1644*. The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in *Figure 1645* and *Figure 1646*. At a given time, a maximum of four

sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU0 writes to VariableB. If CPU0 writes a value to VariableB which is 0x100, then enable trace for the GTM and halt CPU0.

The SPU consists of the following sub-blocks:

- Input Mux Unit—receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64 $\times$ 1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in *Figure 1643*.
- State Logic Units (SLU)—responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted and, coupled with DeMorgan's law, allows for generalized signal combinations. This is shown in *Figure 1644*.
- Action Processing Unit—takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers—The SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

71.1.3 Features

The features of the SPU are as follows:

- clients:
  - 2 CPUs
  - 1 GTM
  - 2 System Bus clients(NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
  - Up to 4 user programmable number of active/simultaneous sequences
  - Up to 8 user programmable states that can be split between all four sequences
  - Each state can only be used in one unique sequence
  - A sequence can consist of a single state or any number of states up to 8
- State logic
  - Each state logic consist of sum of products (SOP)
  - SOP consist of four 4-input AND gates, and one 4-input OR gate
  - Optional inversion on one input of each AND gate of each state logic
  - Optional inversion on output of each AND gate.
  - Optional inversion on output of OR gate of each state
  - States are joined together with if-then-else statement to create a sequence
- SLU events
  - Up to 8 user programmable derived events/actions
  - Any state can optionally trigger of 1 to 4 actions based on a true condition
  - Any state can optionally trigger of 1 to 4 actions based on a false condition
  - User selection of trigger actions generated in response to each programmed trigger
- SPU counters/timers
  - 16 32-bit counters/timers
  - Timer/counter configurability selection via a register
  - Start/increment when used as timer/counter respectively
  - Reset when used as timer/counter respectively
  - Counter value compare match
  - Counter overflow event status
  - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
  - Range support using two counters
  - Use of counter/timer registers to generate counted or timed triggers
  - Use of counter/timer registers to capture system performance statistics
  - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
  - Access to timer/counter values via JTAG

- Prescaler for timer mode only
  - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
  - SPU to/from CPU (fastest clock)
  - SPU to/from NXMC
  - SPU to/from GTM
  - SPU to/from NAR
  - SPU to/from DCI
  - SPU to/from JTAGM
- Interfaces
  - CPU
  - GTM
  - System bus
  - NAR
  - DCI
- Configuration registers—32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions—SPU block triggers various actions based on the derived events, these actions are defined in *Section 71.2: SPU actions*

71.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Capture counter/timer Values[0–15]—place the specified counter/timer value into the trace stream for counters[0–15]
- Halt1—single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2—single signal (EVTI1) that can be used to halt a pre-configured DCI group2

- Generate a watchpoint trigger for a respective ID field the NXMC (global timestamp must be enabled from the NAR)
- Capture the global timebase and place it into the trace stream with a watchpoint ID field of respective watchpoints at the NXMC (send TIMESTAMPx where x is related to an watchpoint ID field of NXMC only)

- Single interrupt for INTC to interrupt a CPU—de-assert (cleared) via JTAGM]
- Generate a pulse on the EVTO pin—output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source—Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals)—four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

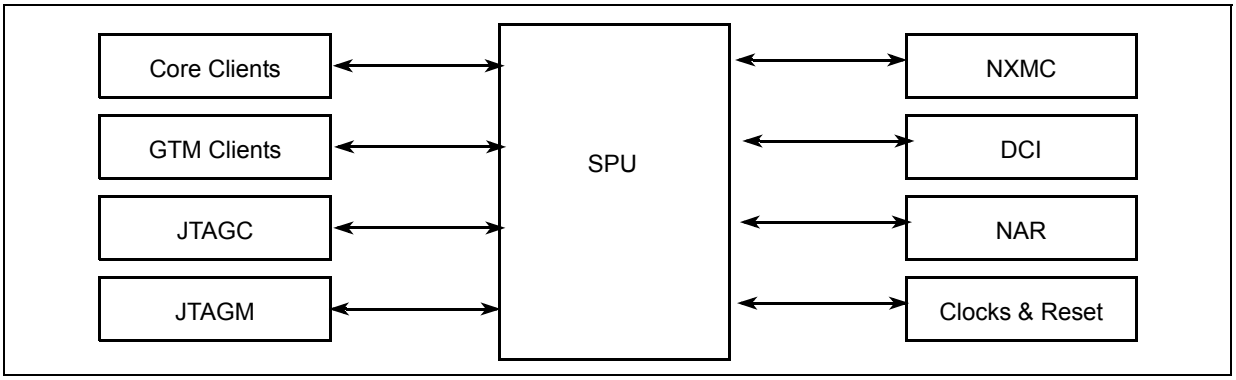
In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

71.3 Operation mode

71.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state:



- All events/inputs are disabled such that no counting or other actions occur.
- All the SPU control registers are accessible.

The user must configure the control registers before enabling the SPU via the SPU Enable/Disable register.

71.4 SPU module interface

The SPU is connected to many clients such as the cores, GTM, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in *Figure 1607*.

Figure 1607. SPU module interface

71.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

Table 1544 lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 1–0x49) registers is 4'h3
- Instruction to enable the Counter Control Unit (second set of registers with offsets 1–72) is 4'h2

Table 1544. SPU register summary

Offset (hex)	Register	Access	Reset Value	Location

71.5.1 Register descriptions

71.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8 × 1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in *Figure 1643*.

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

71.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

Figure 1608 shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see the device-specific chapter that describes how the modules are configured.

71.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in *Section 71.5.1.1: Level1 input Mux configurations registers*) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8 × 1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64 × 1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the *Figure 1643* for State0. Similar logic is provided for States 1–7.

Figure 1622. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

71.5.1.3 Sequence unit registers

71.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left

unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. *Figure 1627* shows the format of the IOICn register where the state number, n = 0–7.

Offset 0x37 (State0), 0x38 (State1), 0x39 (State2), 0x3A (State3), 0x3B (State4), 0x3C (State5), 0x3D (State6), 0x3E (State7)

71.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. *Figure 1628* shows the format of the SCTRL register.

31	Reserved. Read returns 0.

1. Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.

71.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

Figure 1629 shows the format of the SnGC register where the state number, n = 0–7.

71.5.1.6 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions, listed in *Section 71.2: SPU actions*. The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. *Table 1559* shows the bit mapping for all the possible actions divided in three groups: client based, counter based, system related.

Table 1559. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]

71.5.1.6.5 Trace group configuration registers (DTMGC, PTMGC, OTMGC and WTMGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace—clients are configured with the DTM trace group configuration (DTMGC) register
- PTM trace—clients are configured with the PTM trace group configuration (PTMGC) register
- OTM trace—clients are configured with the OTM trace group configuration (OTMGC) register
- WTM trace—clients are configured with the WTM trace group configuration (WTMGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

Figure 1636 shows the format of the trace group configuration registers.

Field	Description
31–0 COMPARE_VAL	Compare value. This value is compared with the corresponding counter/timer value to generate an event for the SPU.

71.5.1.9 Status registers

71.5.1.9.1 Counter compare status (CCOMS)

The counter compare status register shows the status of the comparisons for all the counters. The bits in this register can be cleared by writing a 1 to them. *Figure 1640* shows the format of the CCOMS register. All of the CC fields in the CCOMS register have the same description as shown in *Table 1568*.

Note: Counter compare values and other settings are not recommended to change dynamically, so w1c on CCOMS should be performed in either condition:

1. Counter is in disabled state (ENABLE bit of CCTRLn set to 0).
2. SW-Reset bit (SW_RESET) is set.

71.5.1.9.3 Counter capture status (CCAPS)

Whenever a counter value is captured, the corresponding capture status register bit for that counter is set. If the counter capture value causes a FIFO overflow, the captured value is lost and the status bit is not set. The bits in this register can be cleared by writing a 1 to them. *Figure 1642* shows the format of the CCAPS register.

All of the CC fields in the CCAPS register have the same description as shown in *Table 1570*.

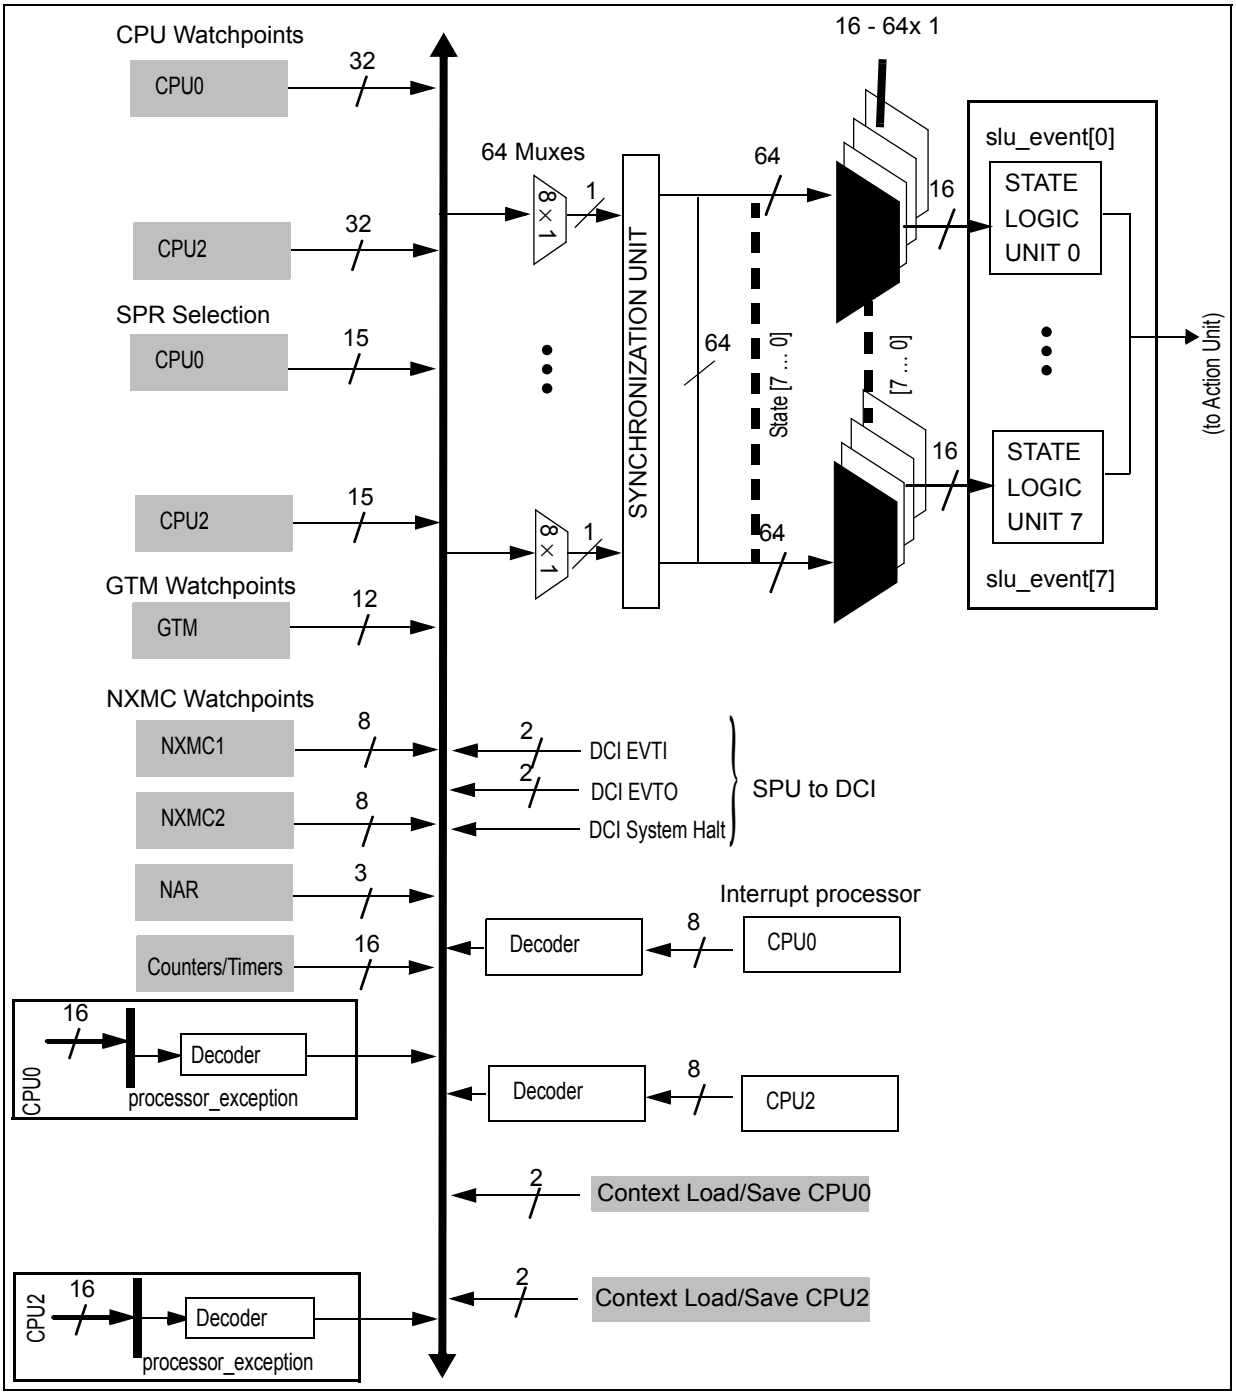
71.6 Functional description

71.6.1 Input Mux unit



The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in *Table 1643*.

- Level 1 Muxing—At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8 × 1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in *Figure 1643*.
- Level 2 Muxing—At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.

  At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16 × 8 banks of 64:1 mux are required. The selection mechanism is shown in *Figure 1643*.

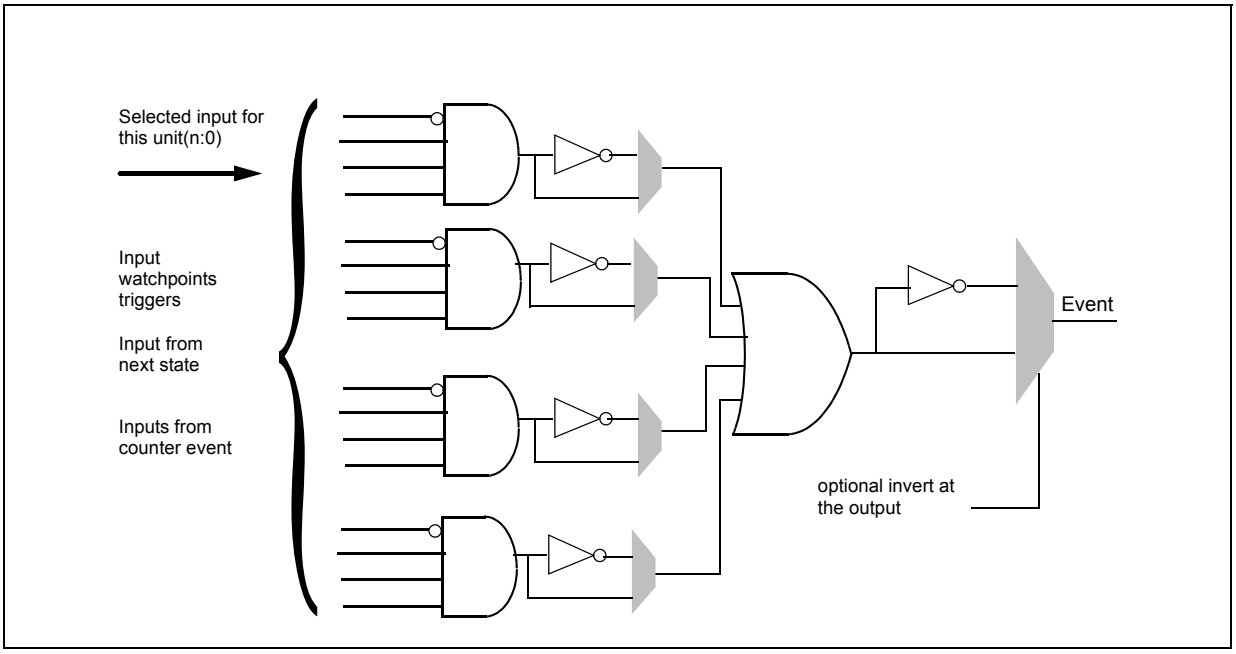
Figure 1643. Input Mux unit block diagram

71.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input condition as shown in *Table 1571*. The CPU exception vector values from the CPUs must

be byte swapped before they are programmed to the CPUn field of the CnPEVP (n = 0–1) registers as shown in *Table 1571*.

Table 1571. Processor exception processing conditions



CPU exception vector	CnPEVP register CPUn field value	Exception condition
0x0000	0x0000	Critical Input—autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input—autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	External input—vectored
0xVVVV3, low two bits = 01	0xVVVV3, high two bits = 01	Critical input—vectored

71.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in *Figure 1644*.

Figure 1644. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

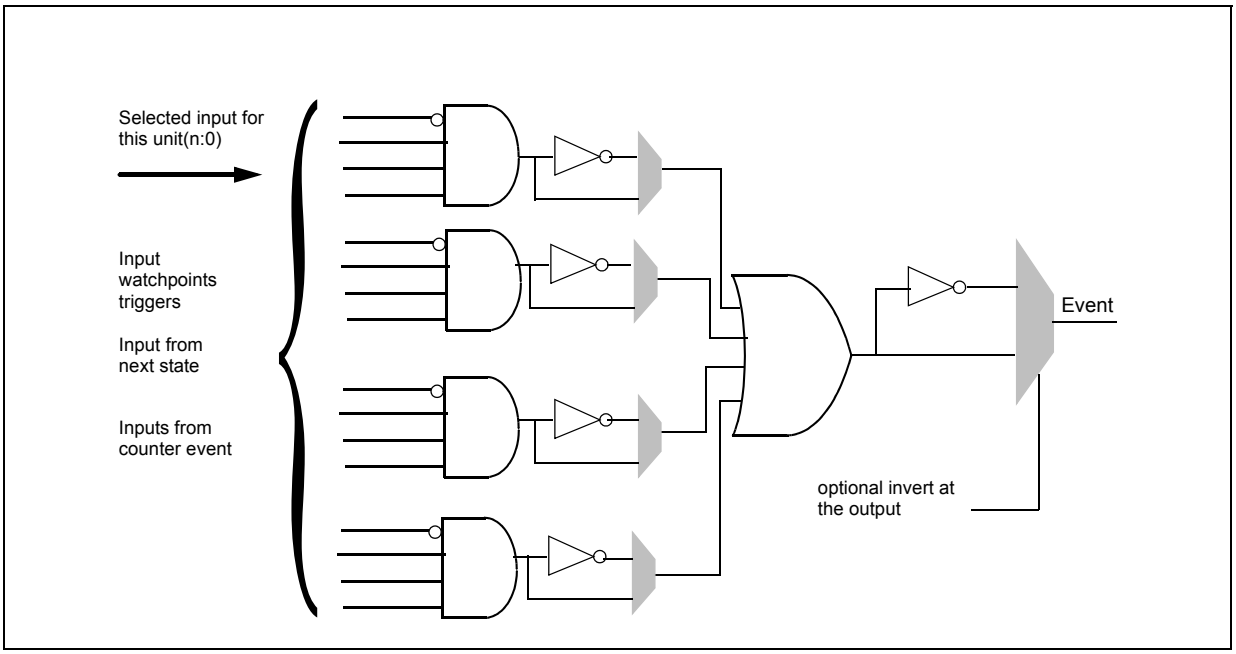
An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

71.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn be designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.



For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in *Figure 1645*:

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic

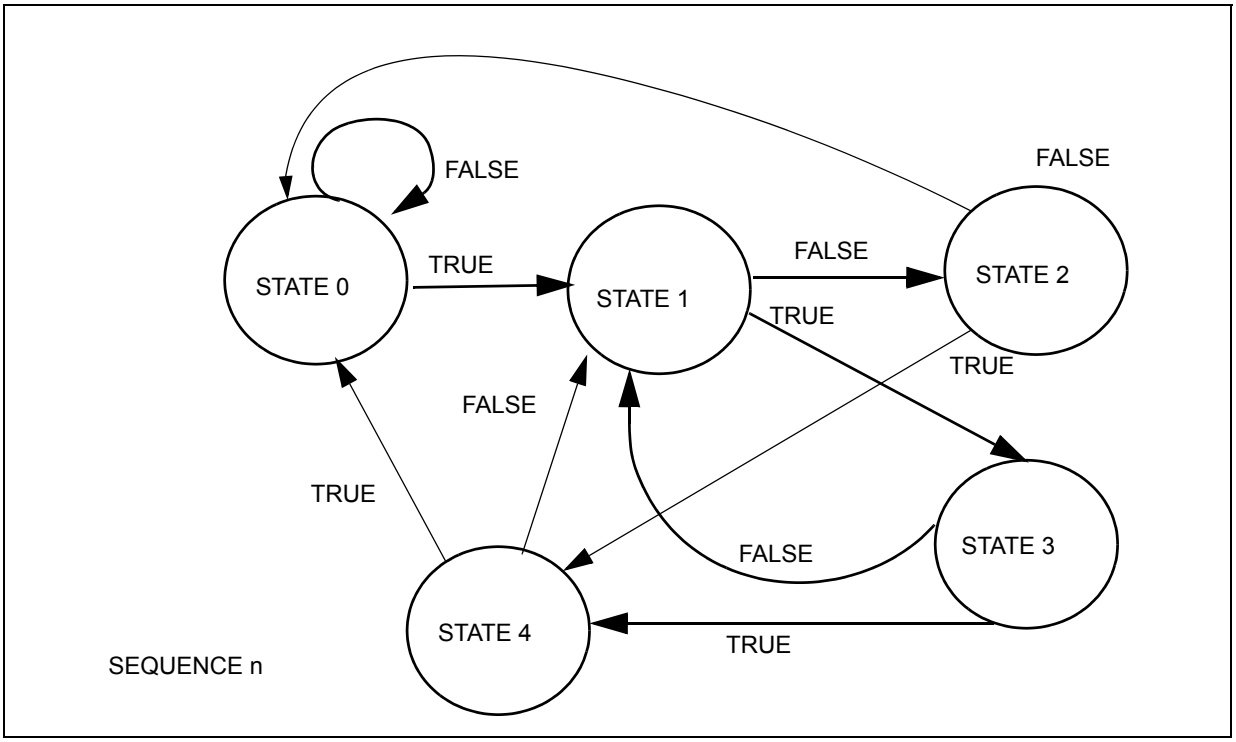


Figure 1645. Example of a simple configurable if-then-else sequence

71.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in *Figure 1646*.

Figure 1646. Complex sequence example

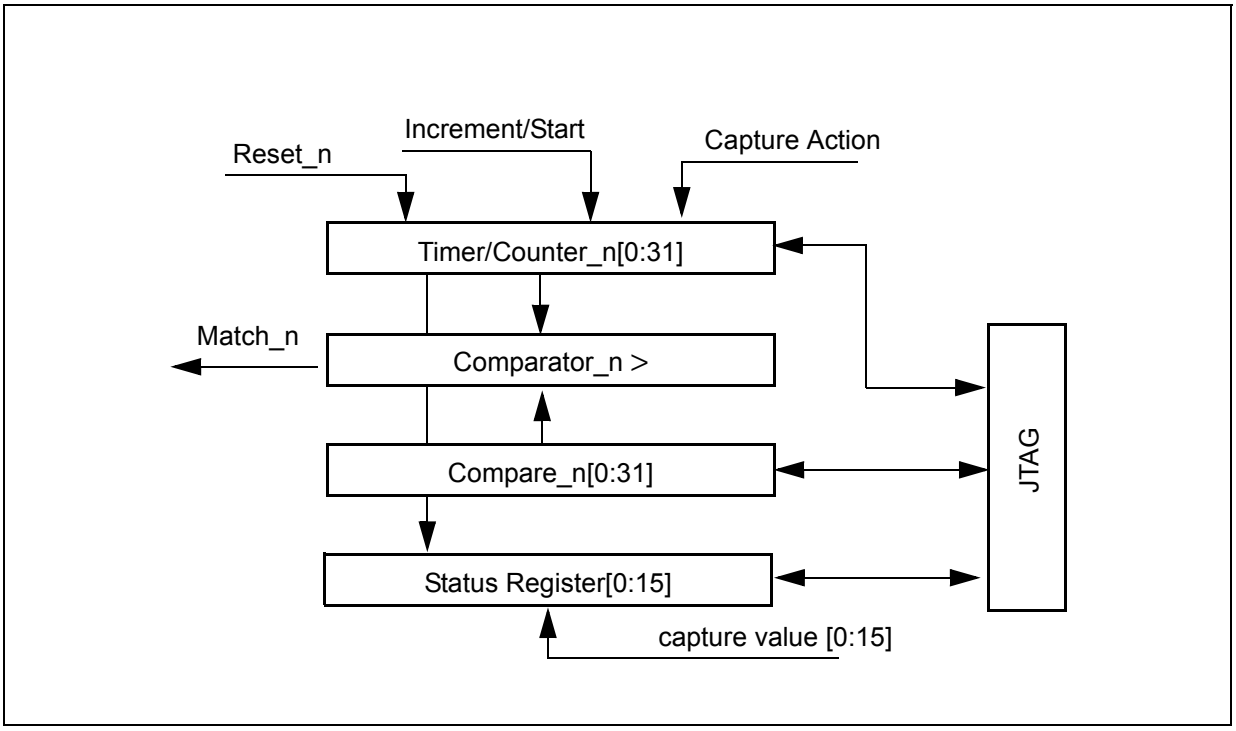
71.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered and stop the trace signal on the 12th occurance of the function. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
  - If the value of counter[0] is less than 12, then the sequence moves back to State0.
  - If the value of couner[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

71.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:



- States—each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register.
- Sequence status—each sequence has a field indicating the active state of the state machine. This is a read only field.

71.6.5 Performance counters/timers unit

The 32-bit SPU counters may be used to delay events, count distances, count latencies or count events as shown in *Figure 1647*. Each counter can be configured as either a counter or a timer via the configuration register. The basic counting operation is straightforward: once enabled (default is disabled mode), the counter increments using the platform clock whenever the selected input is driven to a logic 1.

Access (via the JTAG interface) to each of the counter/timer registers allows the configuration of the timer/counter, the compare registers and global SPU timer/counter status registers. These registers are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 1647. Counters/timers overview

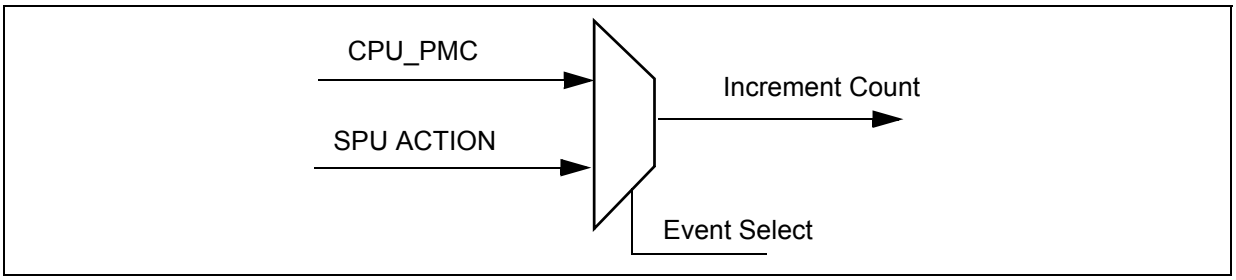
71.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register, which is accessible to users via JTAG interface. These status registers are if type write 1 to clear (W1C).

There are two classes of signals, actions and events:

- Actions—each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the

operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.



On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.

- Events—on a match event where a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

71.6.5.2 Counter input selection at SPU level

Counter increment inputs derive from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in *Figure 1648*. These inputs include signals from the primary SPU muxes or SPU events of counters.

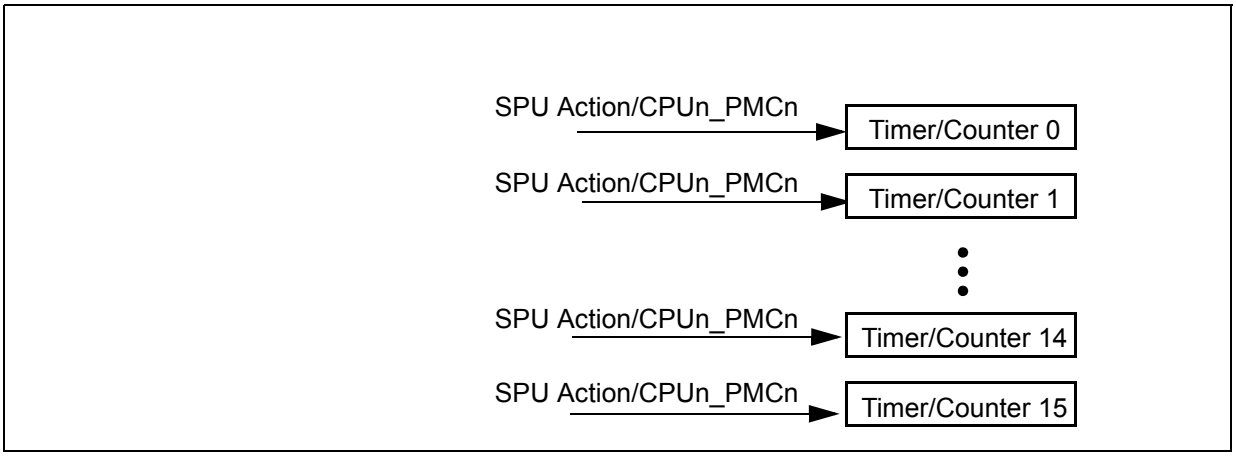


Figure 1648. Input selection for count increment

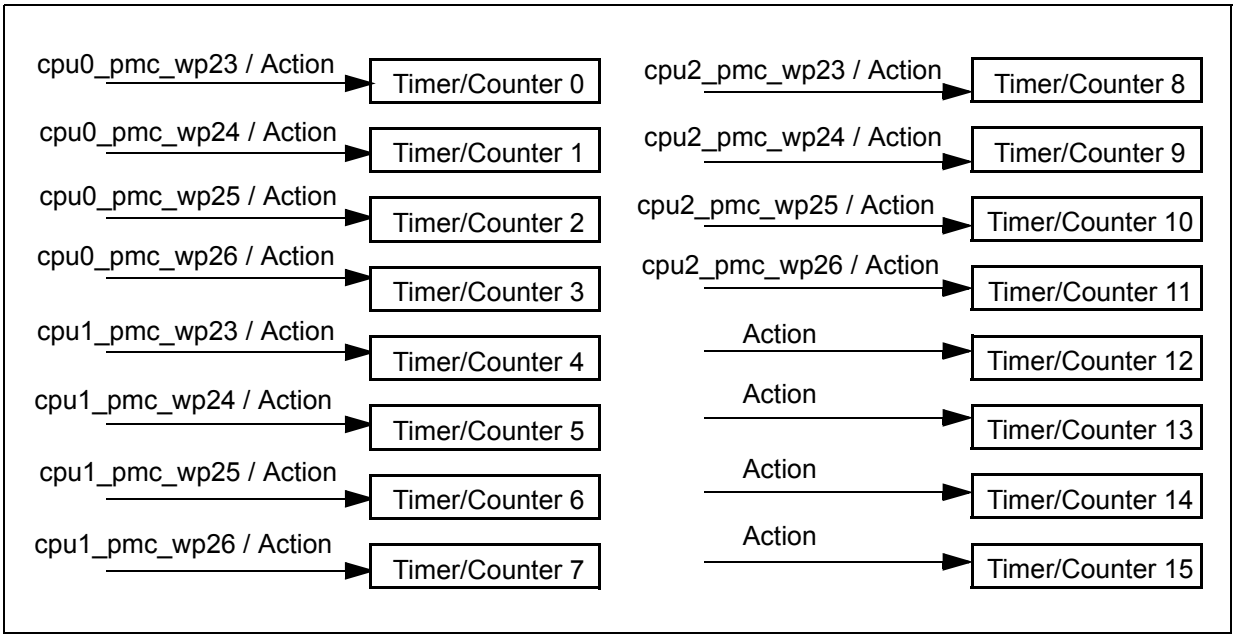
71.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in *Figure 1649*.

Figure 1649. SPU counters increment assignment



71.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPUn) are routed to the SPU debug unit.

The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the *Figure 1650*.

Figure 1650. CPU PMC mapping inside the SPU unit

71.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-than) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the *Section 71.2: SPU actions*. The actions triggers are mapped to the events by programming the set of SPU group action control for events registers**.** Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

71.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers registers, defined in *Table 1564*, are available where the user can group the different traces from same or different clients.

71.6.8 Format for CKSRC & CKDATA Values

The format of the CKSRC is defined for the SPU Peripheral (as In-Circuit trace client):

Table 1572. CKSRC format

ICT CLIENTS	CKSRC Value
SPU Counter Trace Client	b00_0000
Reserved	b00_0001 -- b11_1111

The format for the CKDATA field for the SPU Counter trace client is:

Table 1573. CKDATA format

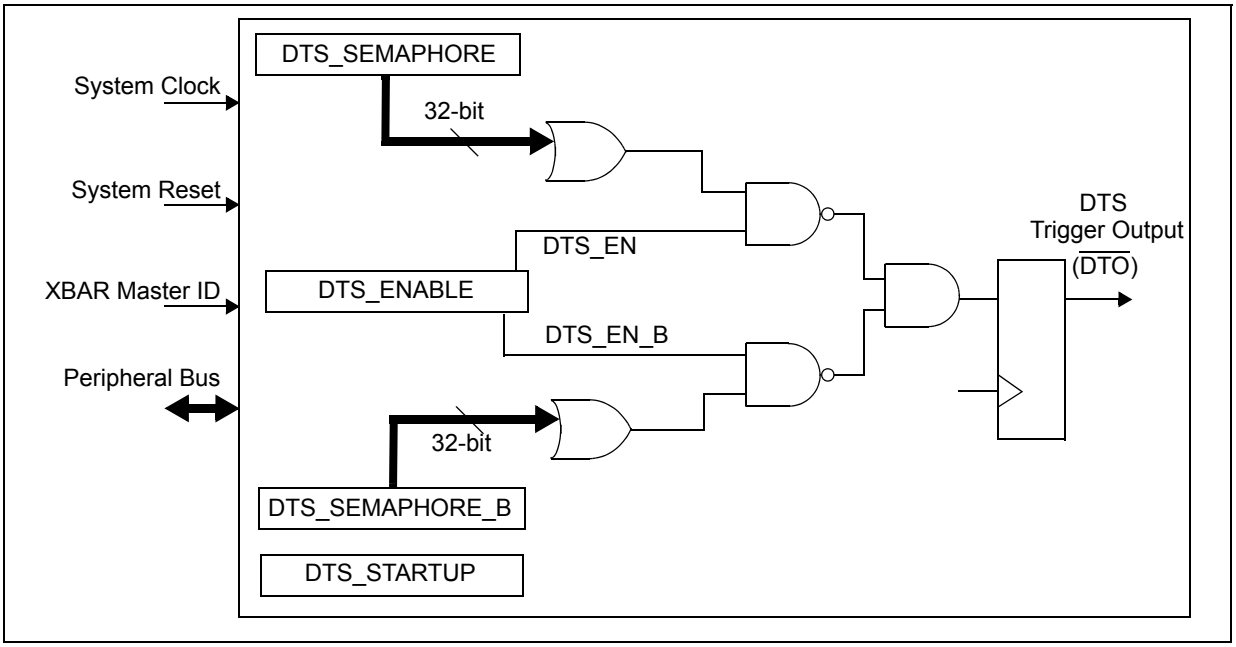
CKDATA	
CKDATA[CTR_Index]	CKDATA[CTR_VALUE]
4 bits	32-bits

72 Development Trigger Semaphore (DTS)

72.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.



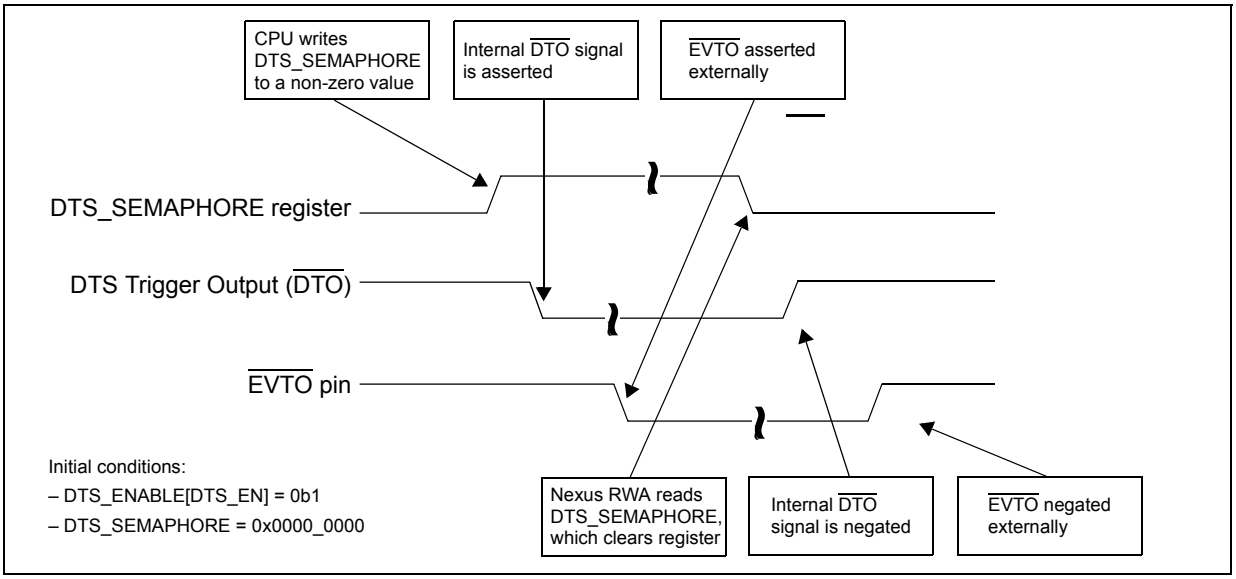
72.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output ($\overline{\text{DTO}}$). The registers are as follows:

- DTS_SEMAPHORE register—Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_SEMAPHORE_B register—Any bit in this 32-bit register, when set to a value of logic ‘1’, causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_STARTUP register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in *Figure 1651*.

Figure 1651. DTS block diagram



The DTS Trigger Output ($\overline{\text{DTO}}$) signal is connected to one of the $\overline{\text{EVTO}}$ inputs of the Debug and Calibration Interface (DCI). The other $\overline{\text{EVTO}}$ inputs are connected to the other Nexus modules in the device. $\overline{\text{DTO}}$ is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled (DTS_ENABLE[DTS_EN] = 0b1 or DTS_ENABLE[DTS_EN_B] = 0b1), all other Nexus $\overline{\text{EVTO}}$ functions associated should be disabled by the tool and $\overline{\text{EVTO}}$ becomes the $\overline{\text{DTO}}$. Unlike the $\overline{\text{EVTO}}$ function that only asserts for one clock, the $\overline{\text{DTO}}$ function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 1652 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMPAHORE register and the clearing of the register caused by a Nexus read.

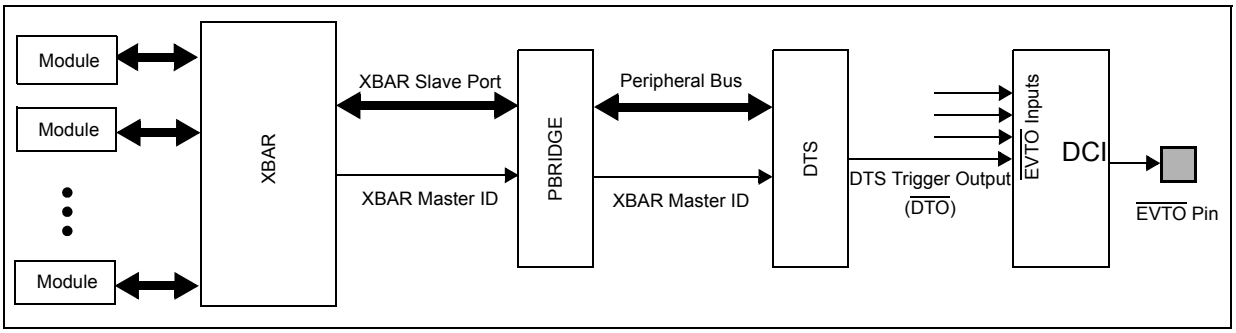


Figure 1652. $\overline{\text{DTO}}$ event sequence example

72.3 DTS device connections

Figure 1653 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 1653. DTS device connections

The registers have limited access as described in *Section 72.3.1: DTS register access*. Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

72.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in *Table 1574*. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 1574. DTS register access effects

Register	32-bit read				32-bit write			
	RWA(1)	Core	eDMA	FlexRay (2)	RWA[1]	Core	eDMA	FlexRay[2]
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear(3)	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear[3]	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool
2. FlexRay or other master
3. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: The XBAR Master ID should not be confused with the Master Port number of the XBAR. See Chapter 17: Crossbar Switch (XBAR), for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

72.4 Memory map and register definition

Table 1575 shows the memory map of the DTS module registers.

Table 1575. DTS memory map

Offset	Register	Access	Reset Value	Section/Page
0x0	ENABLE—DTS Output Enable Register	Restricted R/W(1)	0x0000_0000	*72.4.1.1/2804*
0x4	STARTUP—DTS Startup Register	Restricted R/W[1]	0x0000_0000	*72.4.1.2/2804*
0x8	SEMAPHORE—DTS Semaphore Register	Restricted R/W[1]	0xFFFF_FFFF	*72.4.1.3/2805*
0xC	SEMAPHORE_B—DTS Semaphore Extension	Restricted R/W[1]	0xFFFF_FFFF	*72.4.1.4/2806*

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

72.4.1 Register descriptions

72.4.1.1 DTS output enable register (ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{\text{DTO}}$) and whether $\overline{\text{DTO}}$ is active on the $\overline{\text{EVTO}}$ output pin of the device. *Figure 1654* shows the format of the DTS_ENABLE register.

Note: Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

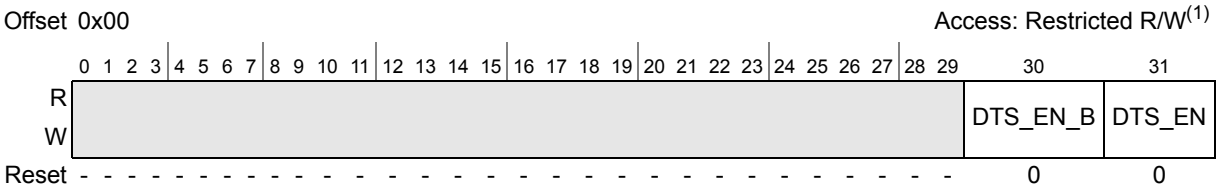

Figure 1654. DTS_ENABLE register

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

The DTS_ENABLE register is described in *Table 1576*.

Table 1576. DTS_ENABLE register field descriptions

Field	Description
DTS_EN	DTS Enable. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).
DTS_EN_B	DTS Enable B. Controls whether the $\overline{\text{DTO}}$ signal is routed to the $\overline{\text{EVTO}}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{\text{RESET}}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal ($\overline{\text{DTO}}$).

72.4.1.2 DTS startup register (STARTUP)

Figure 1655 shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller.

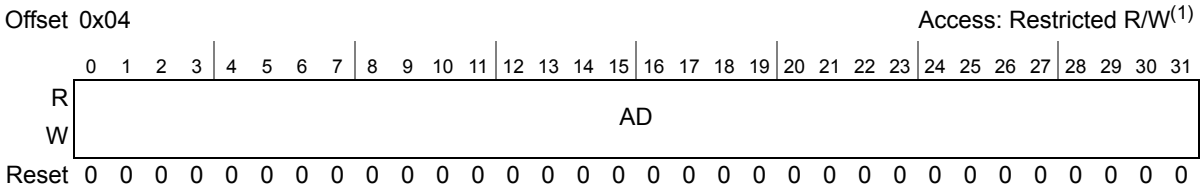

Figure 1655. DTS_STARTUP register

1. The DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

The DTS_STARTUP register is described in *Table 1577*.

Table 1577. DTS_STARTUP register field descriptions

Field	Description
AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

72.4.1.3 DTS semaphore register (SEMAPHORE)

Figure 1656 shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the $\overline{\text{DTO}}$ signal on the device $\overline{\text{EVTO}}$ pin. A one in any bit of this register causes the $\overline{\text{DTO}}$ signal on the $\overline{\text{EVTO}}$ pin to be driven low. The intended use of this register is for the $\overline{\text{DTO}}$ signal to notify tools that data is available. Individual bits are used to identify the specific data.

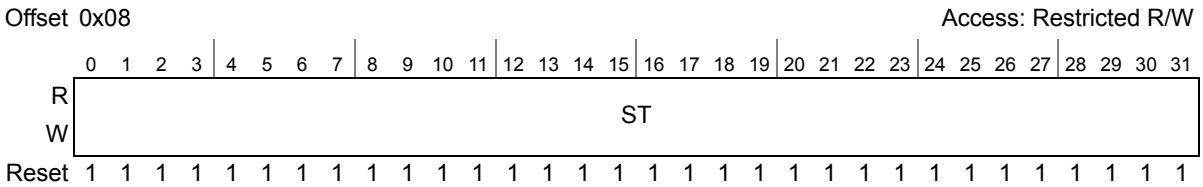

Figure 1656. DTS_SEMAPHORE register

The DTS_SEMAPHORE register is described in *Table 1578*.

Table 1578. DTS_SEMAPHORE register field descriptions

Field	Description
ST	Semaphore Trigger. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.4.1.4 DTS semaphore extension (SEMAPHORE_B)

Figure 1657 shows the format of the DTS_SEMAPHORE_B register. The DTS_SEMAPHORE_B register is used by software to assert the DTO signal on the device EVTO pin. A one in any bit of this register causes the DTO signal on the EVTO pin to be driven low. The intended use of this register is for the DTO signal to notify tools that data is available. Individual bits are used to identify the specific data.

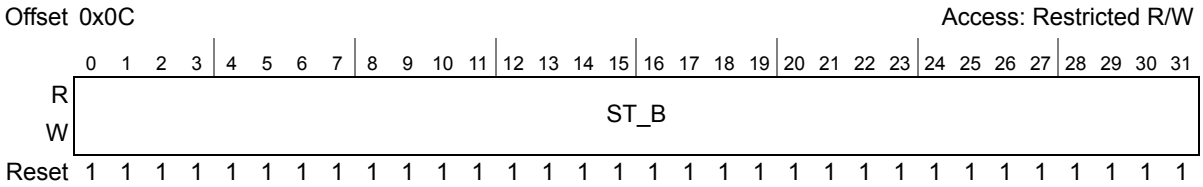

Figure 1657. DTS_SEMAPHORE_B register

The DTS_SEMAPHORE_B register is described in *Table 1579*.

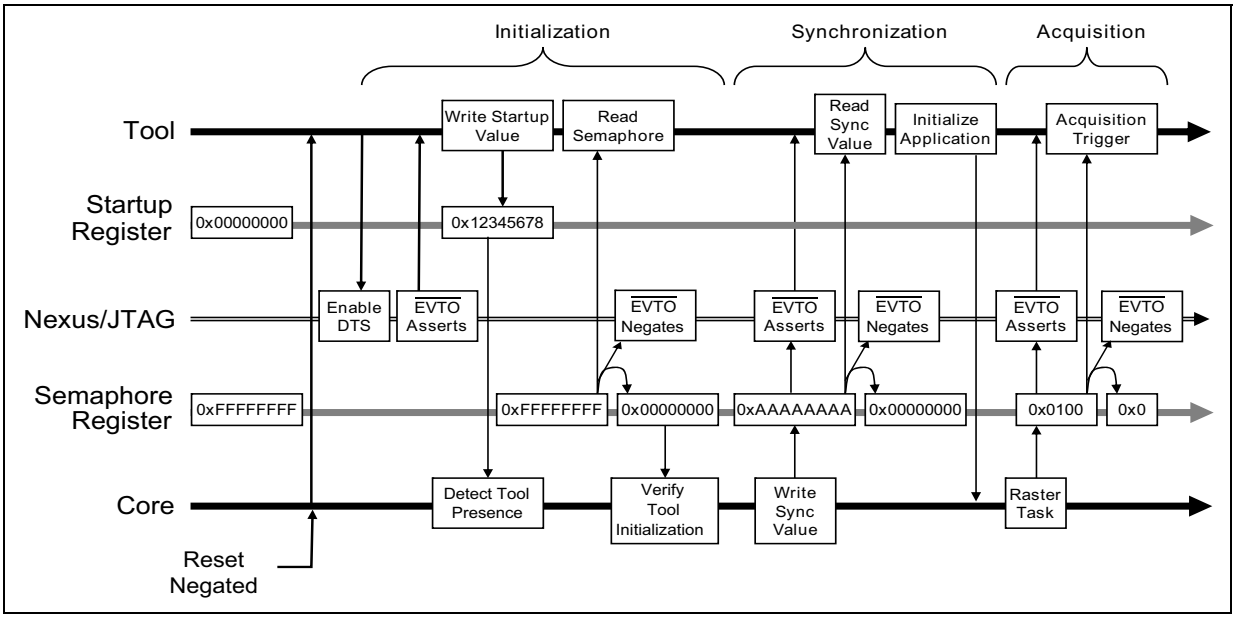
Table 1579. DTS_SEMAPHORE_B register field descriptions

Field	Description
ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical ‘1’ to a bit, the bit is set. A write of ‘0’ by the core or DMA does not change the state of the bit. – All register bits are set to ‘1’ by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by

enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.



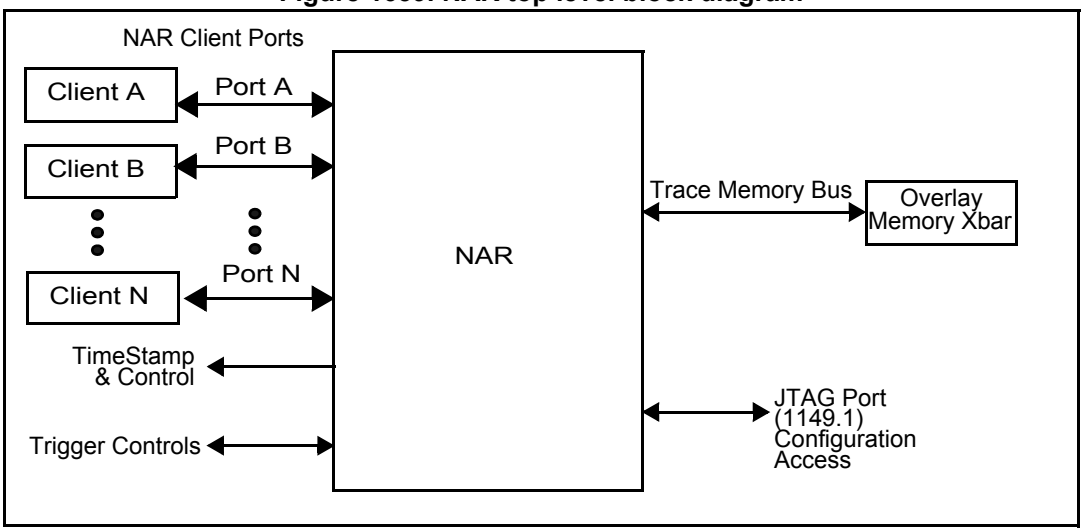
In this type of application the DTS_SEMAPHORE register and DTS Trigger Output ($\overline{DTO}$) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note: It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

Figure 1658 shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 1658. DTS startup sequence example



73 Nexus Aurora Router (NAR)

73.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 1659*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 1659. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

73.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

73.3 Features

The NAR supports the following features:

- Connects 7 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domians.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

73.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 1580. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	*on page 2811*
NAR_ST—NAR Status Register	R	1	*on page 2813*

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1660. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 1581. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 73.5.2.2, Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). **Note:** Some clients may only support timestamps on every message. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 Reserved 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9	Reserved and must be written with 0s.

Table 1581. NAR_CR field descriptions(Continued)

Field	Description
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 Aurora out is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2	Reserved and must be written with 0.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

73.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 1661. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 1582. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 1596* for coding
23–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)

73.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 73.5.6, Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

73.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

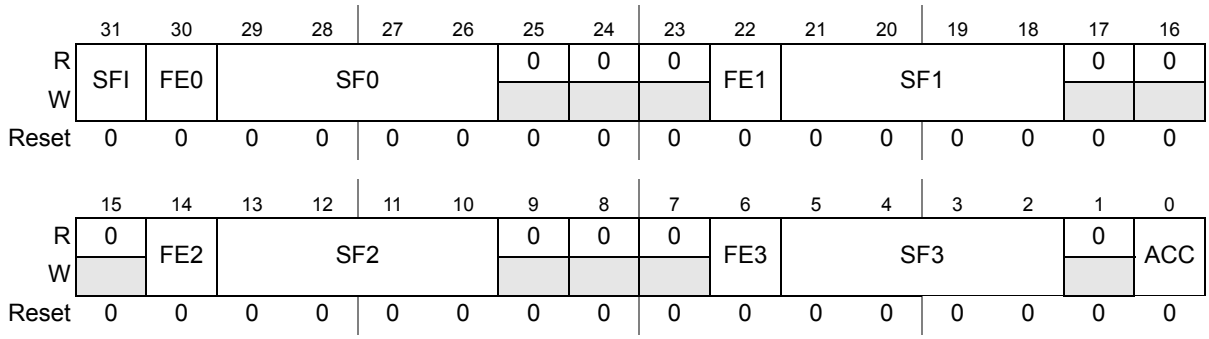

Figure 1662. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1583. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 73.5.6, Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 73.5.6, Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 73.5.6, Output arbitration* for an example.

Table 1583. NAR_SFR field descriptions(Continued)

Field	Description
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 73.5.6, Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

73.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 73.5.6, Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 73.5.6, Output arbitration* for an example.

73.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

73.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Figure 1665. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 1585. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 1586. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

73.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes),

so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

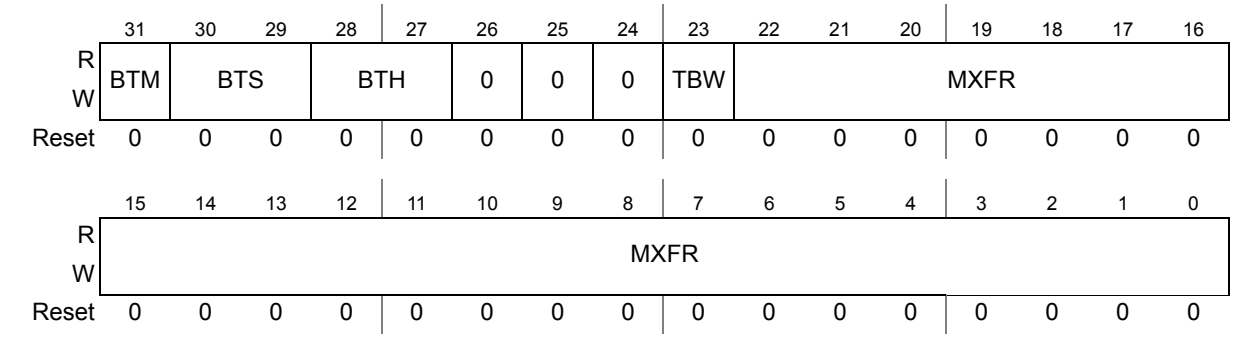

Figure 1666. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 1587. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

73.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 73.5.4, Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be

suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

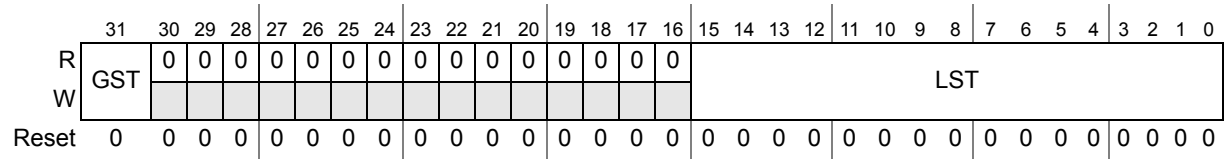

Figure 1667. Suppress trigger control registers (NAR_STCR1–4)

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1588. NAR_STCR field descriptions

Field	Description

73.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more

client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

73.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Register index: C

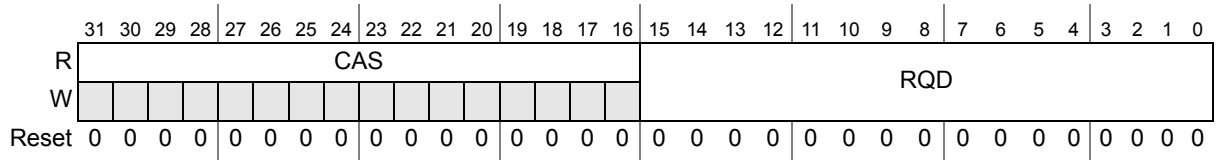

Figure 1669. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

73.4.6 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Register index: E

The NAR_AHFPAR is described in the following table.

Table 1591. NAR_AHFPAR field description

Field	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See *Section 73.5.12: Overlay and internal trace memory full status generation* **Note:** This is used in PD as it has memory ranges from 1K to 15K

73.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

73.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 73.5.4, Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

73.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 1592. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

73.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

73.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

73.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

73.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

73.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 1593. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.

Table 1593. NAR transmit operations(Continued)

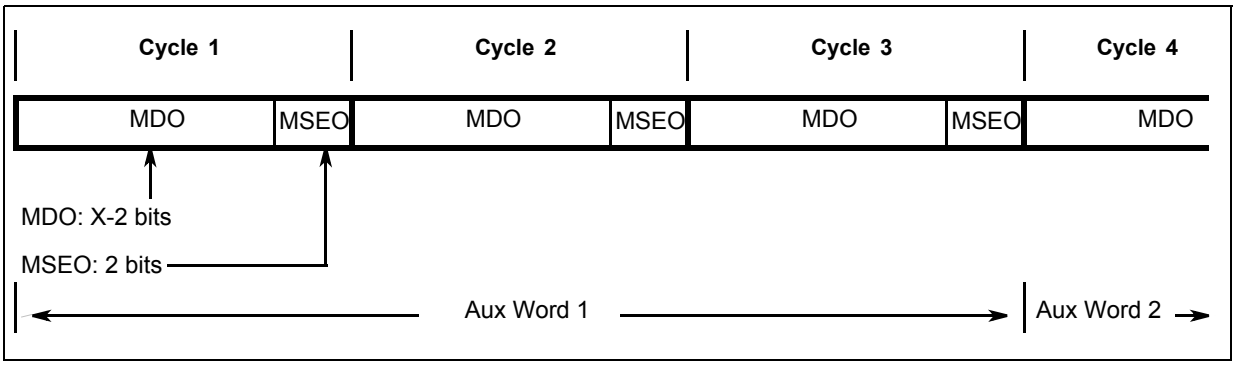
Operation	Description
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

73.5.3 Data reception and arbitration

The NAR supports 7 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn $\times$ 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment.

Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 1671. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

73.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only

supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

73.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

73.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0)

or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

73.5.7 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

73.5.7.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

73.5.7.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data

interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

73.5.8 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

73.5.9 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 $\times$ 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

73.5.10 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 1597*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 1594. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 1595*
	12	12	fixed	ECODE	See *Table 1596*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC[2]	NAR source ID
	6	6	fixed	WPHIT	See *Table 1597*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

73.5.10.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 1595. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 1596*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 1596*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 1596*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 1596. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

73.5.10.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

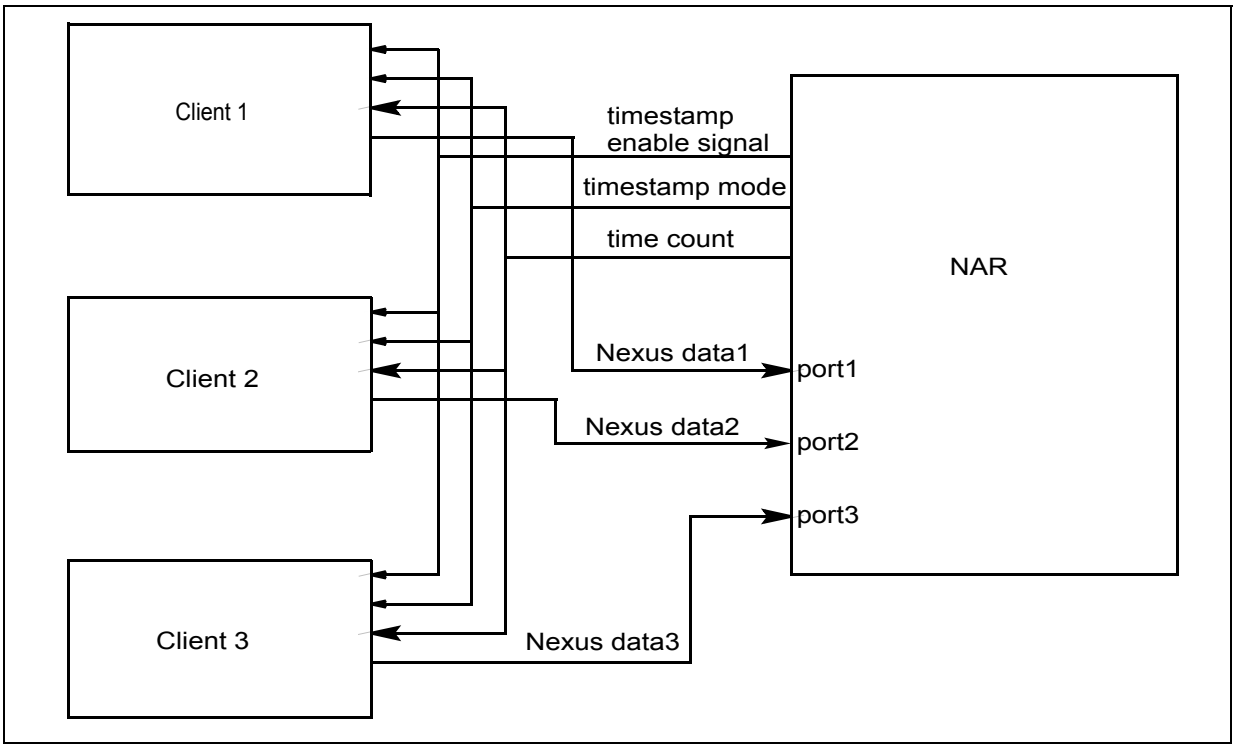


Table 1597. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

73.5.11 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 1672*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 1672. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

73.5.12 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

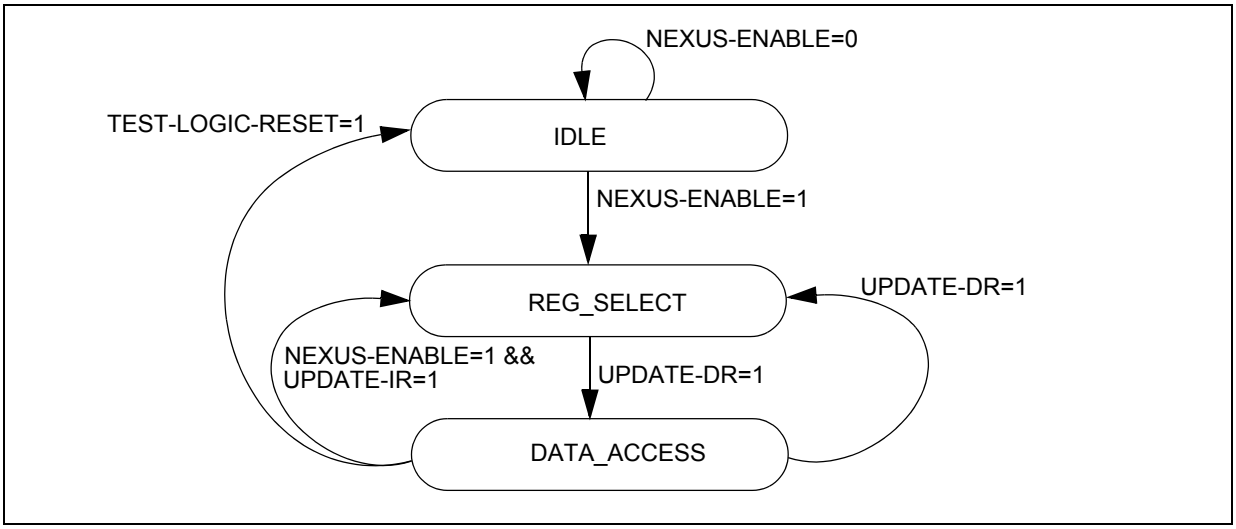
73.5.13 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 1598*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 1673. Nexus controller state machine



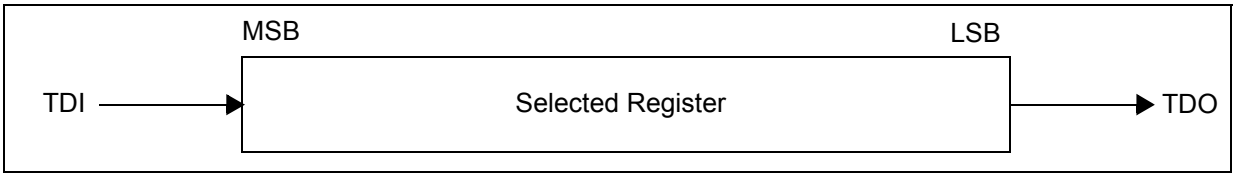


Table 1598. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 1674. Shifting data into register

73.5.13.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

73.5.13.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 1673*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 1599. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

73.5.13.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 1675*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 1580*.

MSB	LSB
7-bit register index	R/W

Figure 1675. Nexus command format for register selection

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 1600. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

73.5.14 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR

  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

73.5.14.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

73.5.14.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

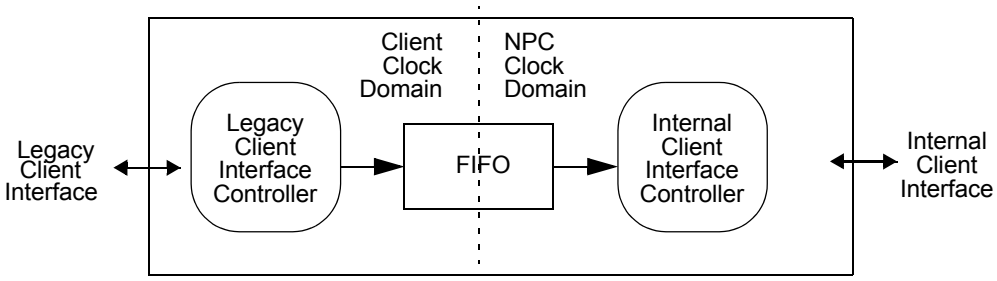
73.5.14.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

73.5.15 Legacy client interface controller



This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in *Figure 1676*.

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of paramaterizeable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

Figure 1676. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how may spaces are freed in receive queue.

73.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue,

whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 73.5.2.1, Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

73.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 73.5.6, Output arbitration*.

74 e200z410Dn3 Nexus 3 Module

The e200z410Dn3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

74.1 Introduction

74.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

74.1.2 Terms and Definitions

Table 1601 contains a set of terms and definitions associated with the Nexus 3 module.

Table 1601. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1601. Terms and Definitions(Continued)

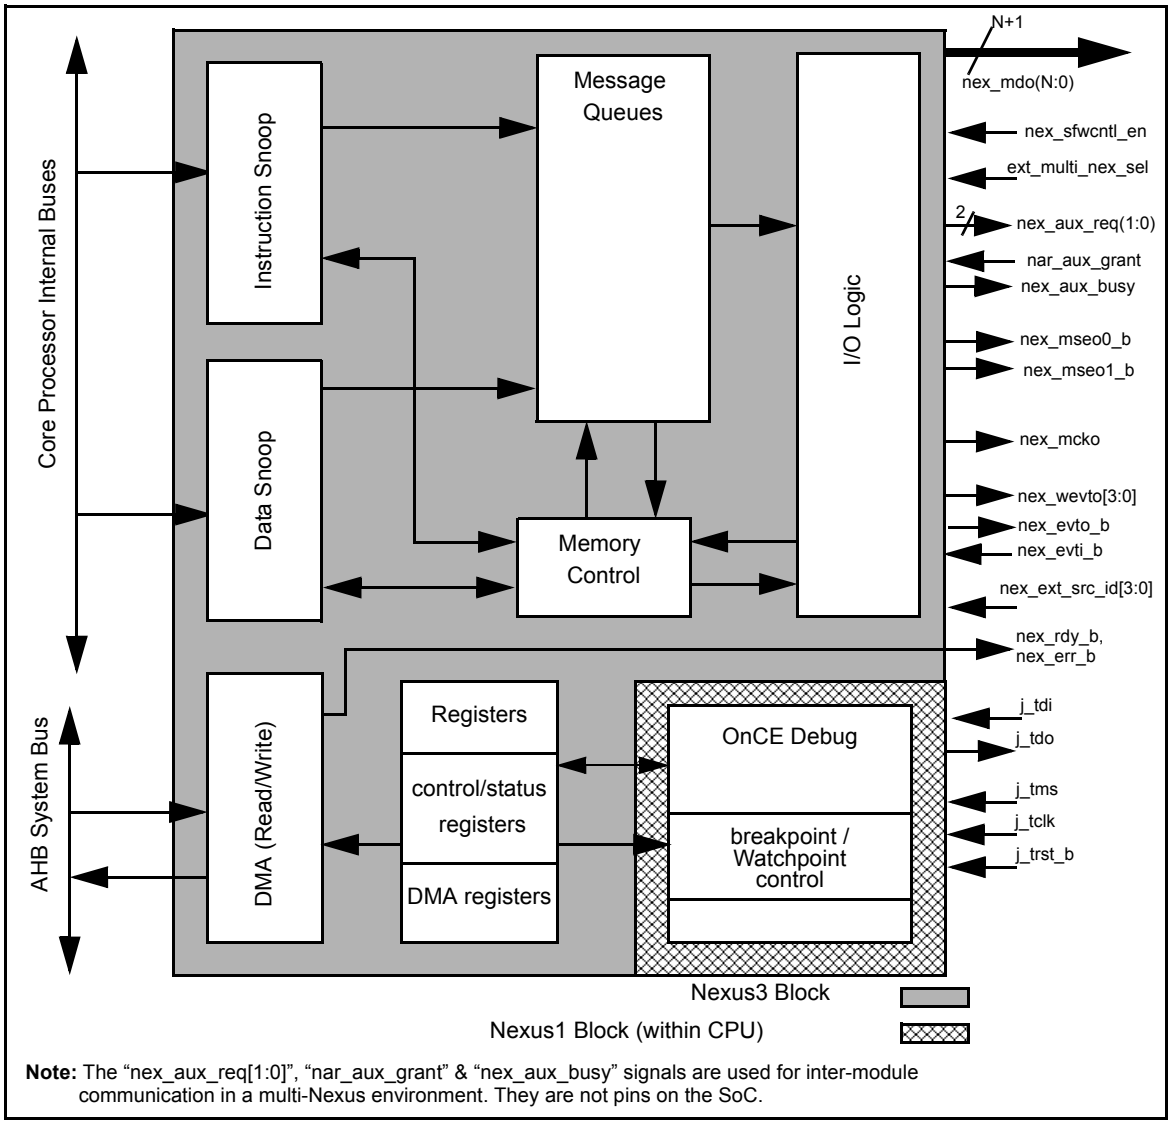
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

74.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)

  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

74.1.4 Functional Block Diagram

Figure 1677. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

74.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the **nex_evti_b** input signal is asserted at the time that **j_trst_b** is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

74.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

74.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 1602*.

Table 1602. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1607*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1602. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1607*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1602. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1607*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1607*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 1605*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See *Section 74.12.4: Resource Full Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1602. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 74.12.1: Branch Trace Messaging types*)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See *Section 74.12.1: Branch Trace Messaging types*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to *Table 1606*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See *Section 74.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See *Section 74.12.5: Program Correlation Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 74.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 1603 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1603. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 1604 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1604. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 1605 shows the encodings used for resource codes for certain messages.

Table 1605. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 1606 shows the event code encodings used for certain messages.

Table 1606. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 1607 shows the data trace size encodings used for certain messages.

Table 1607. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

74.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 74.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 74.6: Nexus 3 Register Access via Software*for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 1608 details the register map for the Nexus 3 module.

Table 1608. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.

2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

74.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Reserved				CS			
7	6	5	4	3	2	1	0

Nexus Reg# 0x1; Read-only; Reset: 0x0

Figure 1678. Client Select Control (CSC) register

Table 1609. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

74.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

OPC	0	MCK_EN	MCK_DIV	0
31	30	29	28 27 26	25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# PCR_INDEX; Read/Write; Reset: 0x0

Bit	Name	Description
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

74.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 1680* and its fields are described in *Table 1611*.

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 74.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 74.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

74.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z410Dn3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 1681* and its fields are described in *Table 1612*.

1. Refer to *Table 1606* for implemented EVCODEs.

74.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

Figure 1684. Development Status (DS) register

25:0	—	Reserved for future functionality (read as 0)

74.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For

example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z410Dn3) Core Debug Support chapter.

74.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0
31 30	29 28	27 26	25 24	23 22 21 20 19 18 17 16	15	14	13	12	11 10 9 8	7	6	5	4	3	2 1 0

Nexus Reg# 0xD; DCR: 376; Read/Write; Reset: 0x0

Figure 1692. Data Trace Control (DTC) register

The following table details the Data Trace Control register fields.

Table 1623. DTC field descriptions

Bits	Name	Description
31:30	RWT1	Read/Write Trace 1 00 No trace enabled *x*1 Enable Data Read Trace 1*x* Enable Data Write Trace

Nexus Reg# 0x15; DCR: 408; Read/Write; Reset: 0x0

Figure 1700. Data Trace End Address 4 register

Table 1624 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1624. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

74.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 1626*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Figure 1701. Read/Write Access Control/Status (RWCS) register

1. ERR and DV are read-only

Table 1625. RWCS field descriptions

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access

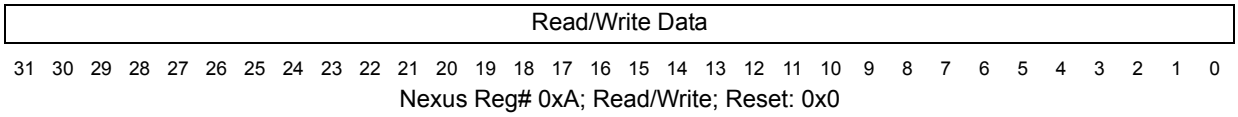
RWCS[1]	ERR (2)	Read/Write Access Error (see *Table 1626*)
RWCS[0]	DV[2]	Read/Write Access Data Valid (see *Table 1626*)



1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 1626. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

74.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 1702. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 1627* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1627. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data) second RWD pass (high order data)	0 0 0	0 1 1	X X	X X	X X	X X

1. "X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 1628 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1628. RWD byte lane mapping

1. "—" indicates byte lanes that will contain unused data.

74.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 1703. Read/Write Access Address (RWA) register

74.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 1608*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 74.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 1608*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1704. JTAG DR format

(7 bits)	(1 bit)
Nexus Register Index	R/W

RESET Value: 0x00

Table 1629. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 1608*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

74.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 1608* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

74.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

74.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

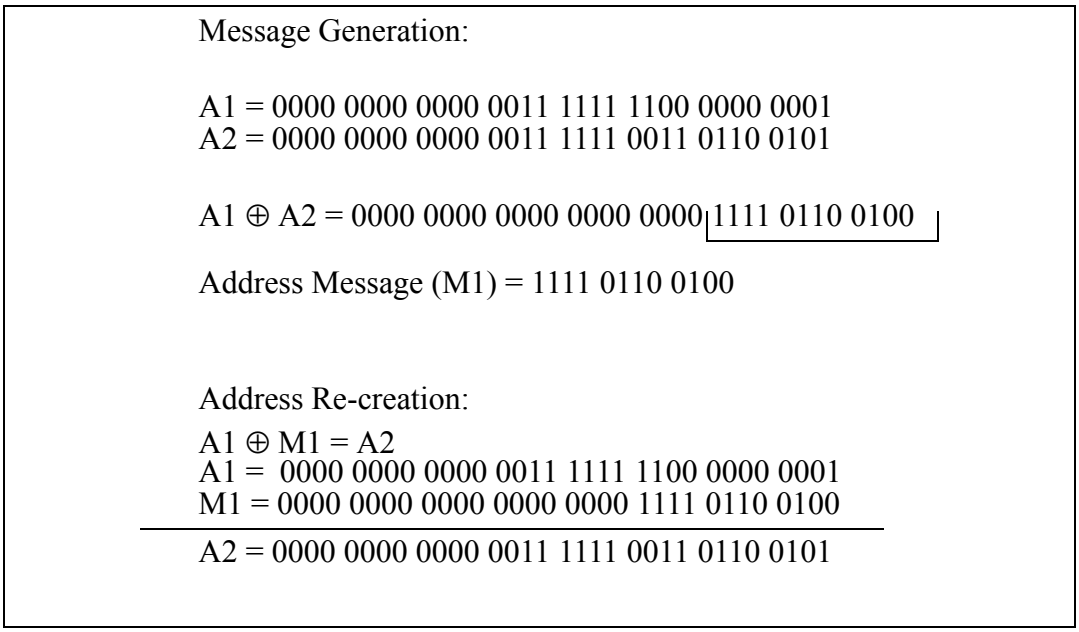
74.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

74.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant ‘1’. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 1705. Relative address generation and recreation

74.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

74.7.5 Timestamp Field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the **nex_tsen** input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of **nex_tsmode[0:1]** and the timestamp value is based on the **nex_timebase[0:29]** inputs. These signals are first synchronized to the **nex_clk** clock domain, and for **nex_timebase[0:29]**, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they the message queues. Leading zeros in the timestamp value are removed. *Table 1630* shows the **nex_tsmode[0:1]** encodings used for the timestamp mode.

Table 1630. nex_tsmode[0:1] Timestamp mode encoding

nex_tsmode[0:1]	Timestamp mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

74.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

74.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

74.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 74.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

74.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue

and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 74.8.1: Message Queue Overrun*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

74.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under circumstance: More than three messages are generated in the same cycle.

Table 1631 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 1631*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 1631. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)

Table 1631. Message Type Priority and Message Dropped Responses(Continued)

Message Type	Message	Priority	Message Dropped Response
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	None

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

74.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

74.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

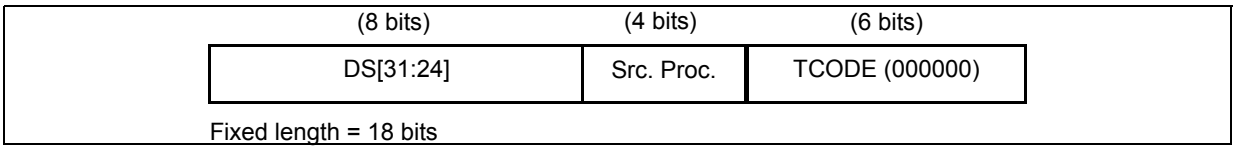
74.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

74.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



74.8.9 Data Trace Message Priority Loss Response

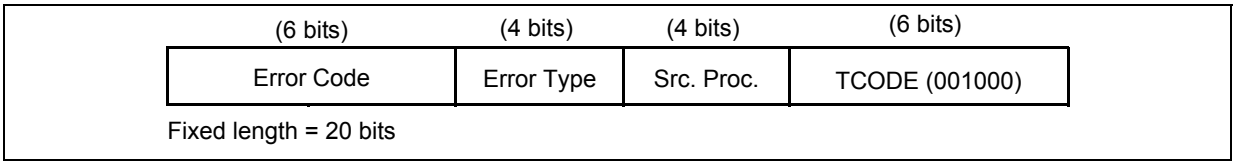
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

74.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 1706. Debug Status message format

74.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see *Table 1603* and *Table 1604*):

Figure 1707. Error message format

74.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

74.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

74.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z410Dn3) processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

Nexus 3 Process ID

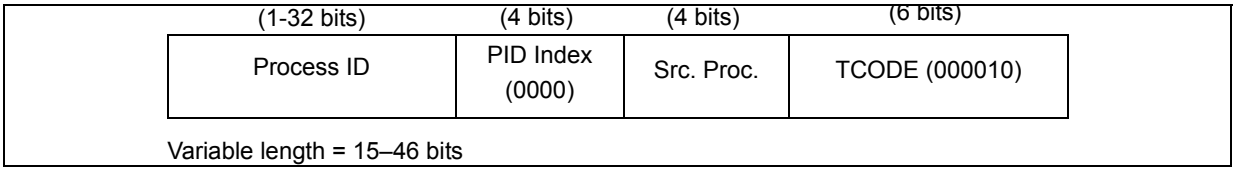
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR — 517; Read/Write; Reset: 0

Figure 1708. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.



There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will

indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 1709. Ownership Trace Message format

74.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z410Dn3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z410Dn3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

74.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

74.12.1.1 Indirect Branch Message instructions

Table 1632 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1632. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

74.12.1.2 Direct Branch Message Instructions

Table 1633 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1633. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

74.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

74.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

74.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

74.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

Figure 1710. Indirect branch message (history) format

(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

74.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Figure 1711. Indirect branch message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

74.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 1712. Direct branch message format

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

74.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

74.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

74.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1634. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

74.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

74.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 1713. Resource Full Message format

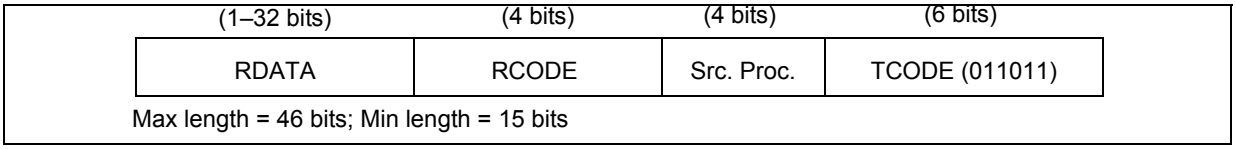


Table 1635 shows the RCODE encodings and RDATA information used for Resource Full Messages.

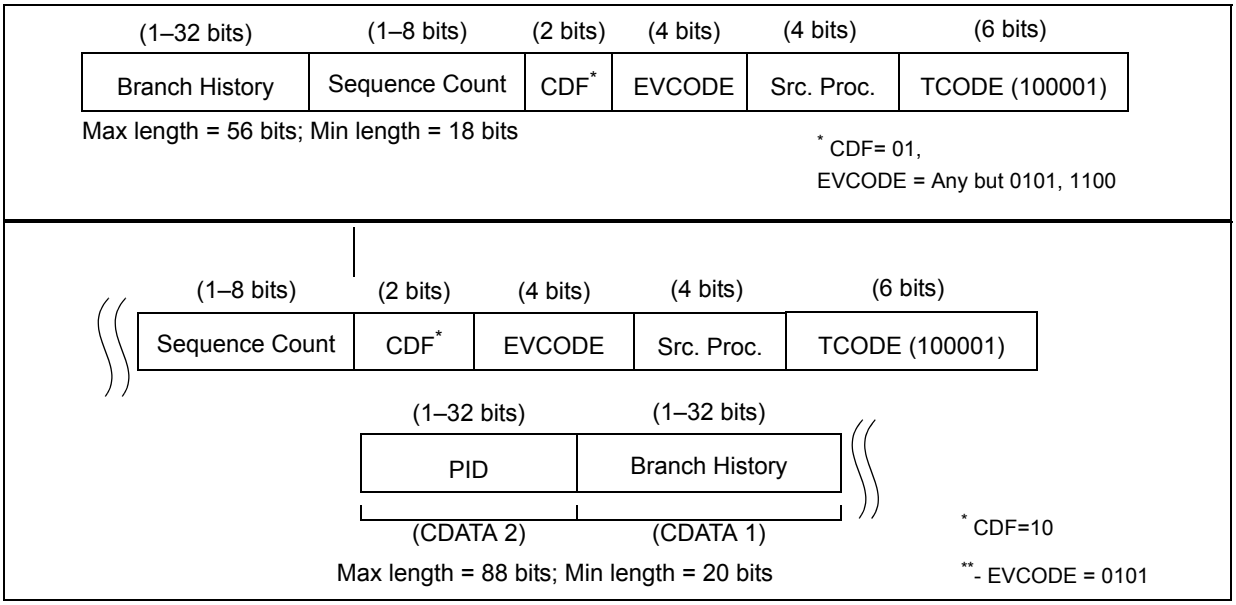
Table 1635. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

74.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 1606* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 1714. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

74.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

74.12.6 Program Trace Overflow Error messages

an Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

74.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1636*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ ‘1’ with $DC4_{PTMARK}$=‘1’.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 1715. .Program Trace Synchronization message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

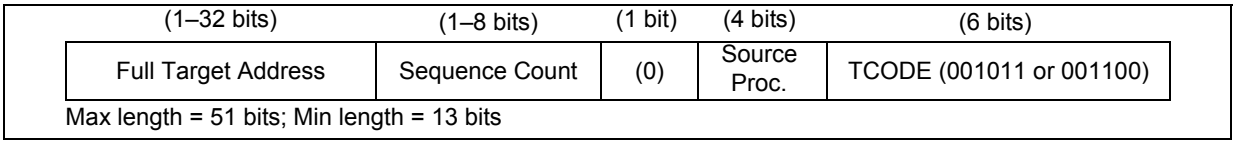
Exception conditions that result in Program Trace Synchronization are summarized in *Table 1636*.

Table 1636. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

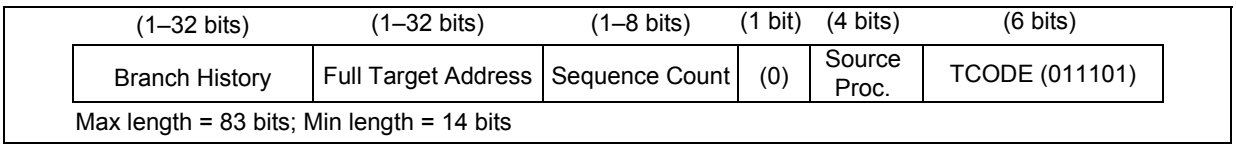
74.12.8 Program Trace Direct/Indirect Branch with Sync messages



Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1636*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.



The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 1716. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 1717. Indirect Branch History w/ Sync message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 1637*.

Table 1637. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

74.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

74.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)

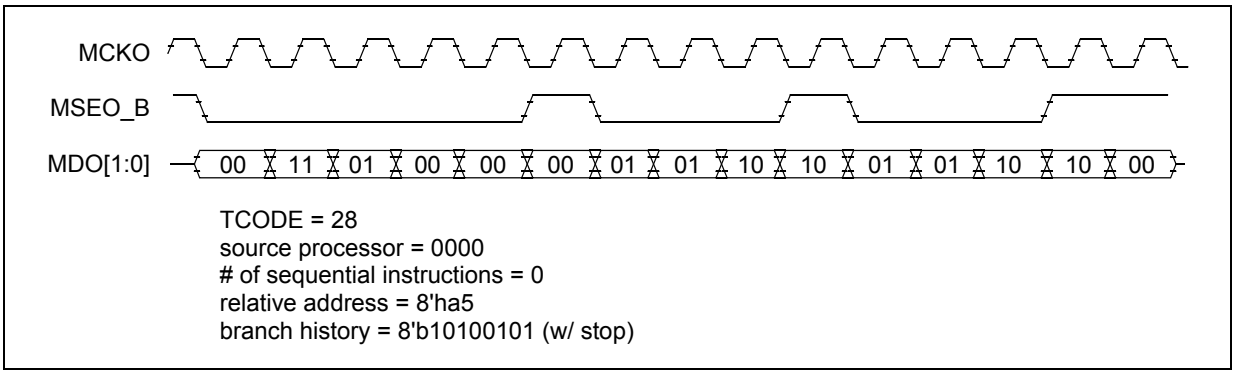

Figure 1720. Program Trace — Direct Branch (traditional) & Error messages

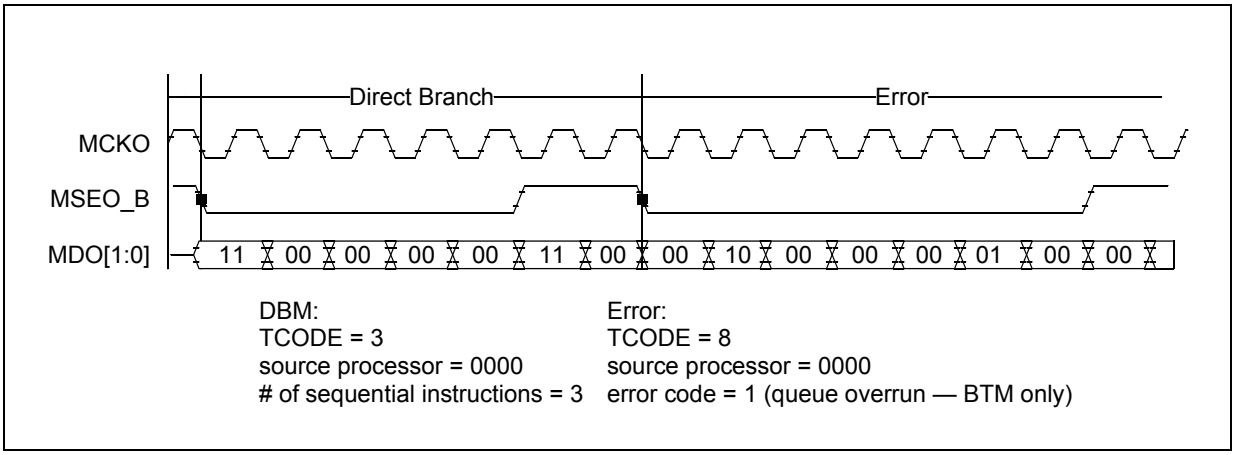

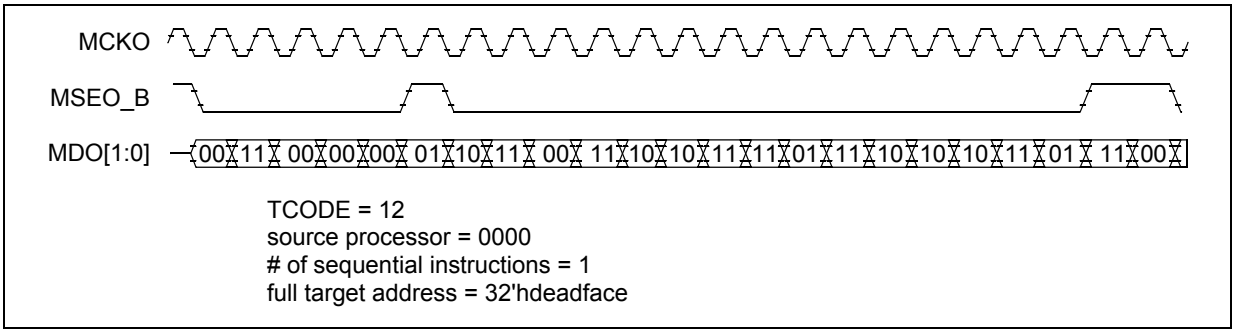

Figure 1721. Program Trace — Indirect Branch w/ Sync message

74.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

74.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z410Dn3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

74.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

74.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 1722. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

74.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 1723. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

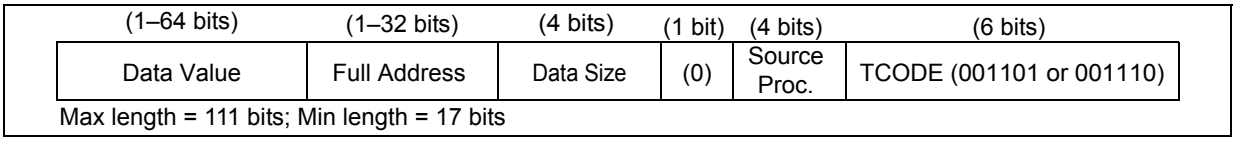
If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

*Note: * Core (e200z410Dn3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.*

*Note: For Core (e200z410Dn3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

Note: The debug/development tool will need to distinguish the two cases based on the family of processor.

74.13.2.3 Data Trace Synchronization messages



A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 1638*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization

messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 1724. Data Write/Read with Sync message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in *Table 1638*.

Table 1638. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

74.13.3 DTM operation

74.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address

range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

74.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

74.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

74.13.3.4 Bus cycle special cases

Table 1639. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary): both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction within data trace range – 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction within data trace range – 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction out of data trace range – 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction out of data trace range – 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

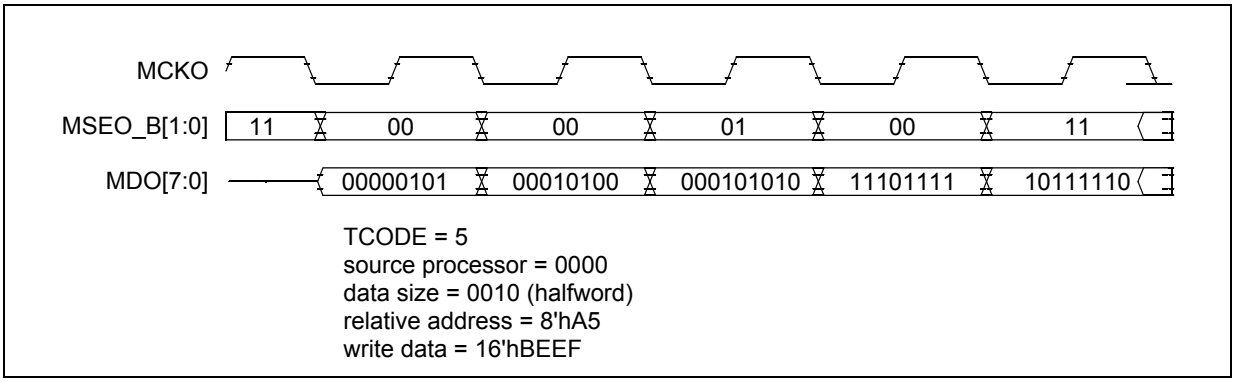
Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the

addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z410Dn3) Core Debug Support chapter.)

Note: A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

74.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 1725. Data Trace — Data Write message



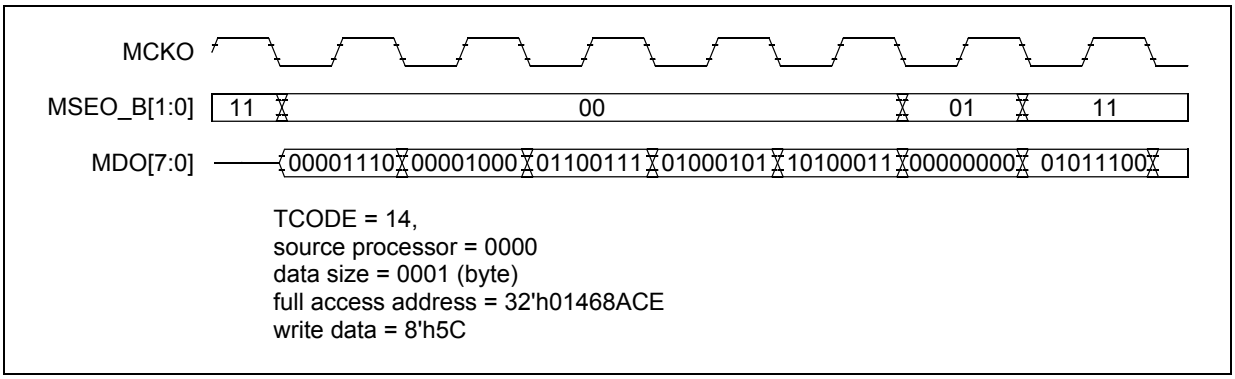


Figure 1726. Data Trace — Data Read w/ Sync message

74.14 Data Acquisition messaging

this section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

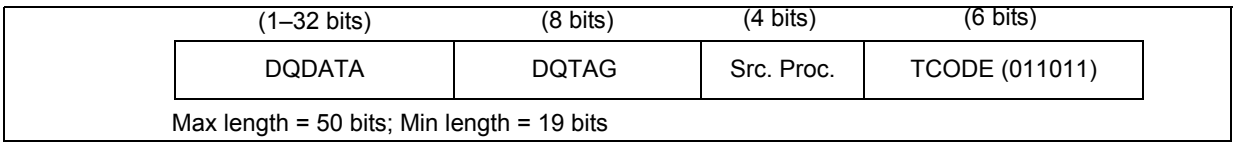
74.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the

DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

74.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.



74.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

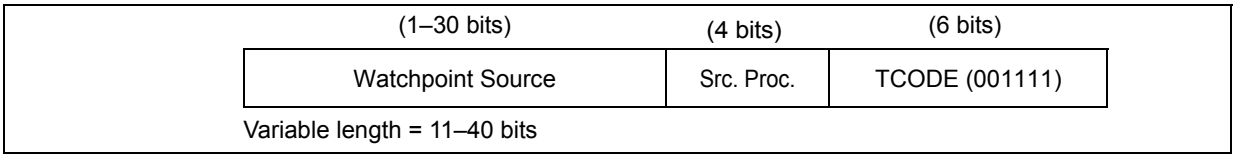
There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z410Dn3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 1727. .Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

74.15 Watchpoint Trace messaging



Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z410Dn3) Core Debug Support chapter for details on watchpoint initialization.

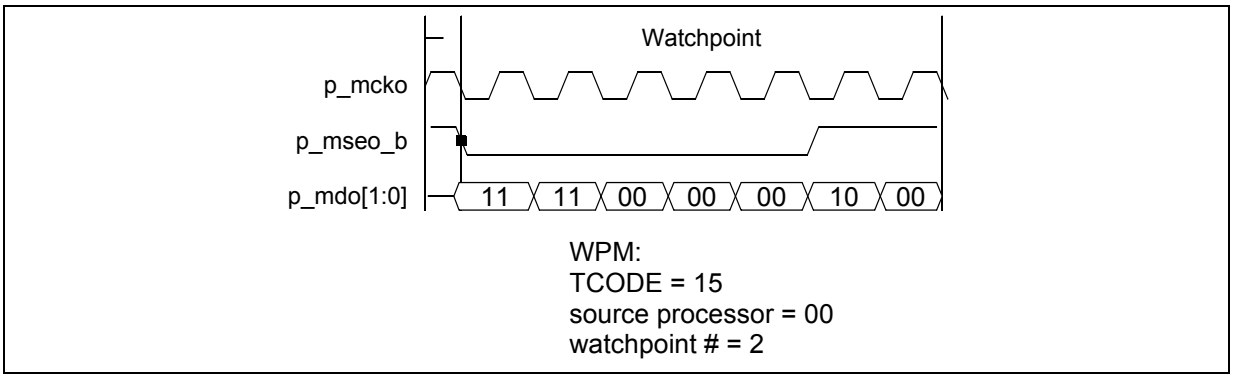
When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 1643* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 1728. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.



The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 1640. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging

74.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1729. Watchpoint Message & Watchpoint Error message

74.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 1641* details the external hardware trigger signals.

Table 1641. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 1641. External Hardware Trigger Signals(Continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

74.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

74.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 1643* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

*Note: Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

74.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 74.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 74.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

74.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 1643* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*.

*Note: Only the **nex_ahb_start**, **nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

74.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 74.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see *Table 1643* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 1643* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 74.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 74.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

74.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

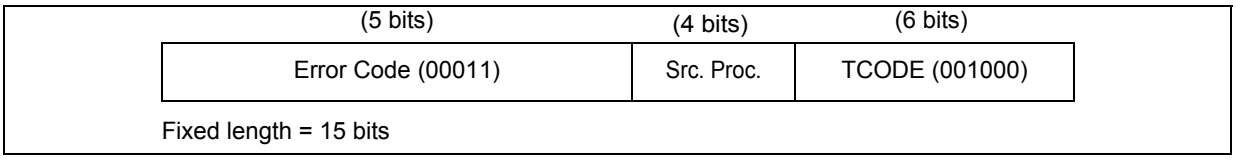
74.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

74.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

74.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 1730. Error message format

74.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

74.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 1643*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 74.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z410Dn3) Core Debug Support chapter.

Table 1642. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 1643*.

Table 1643. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2’b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2’b01

Table 1643. Nexus 3 auxiliary pins(Continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 74.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

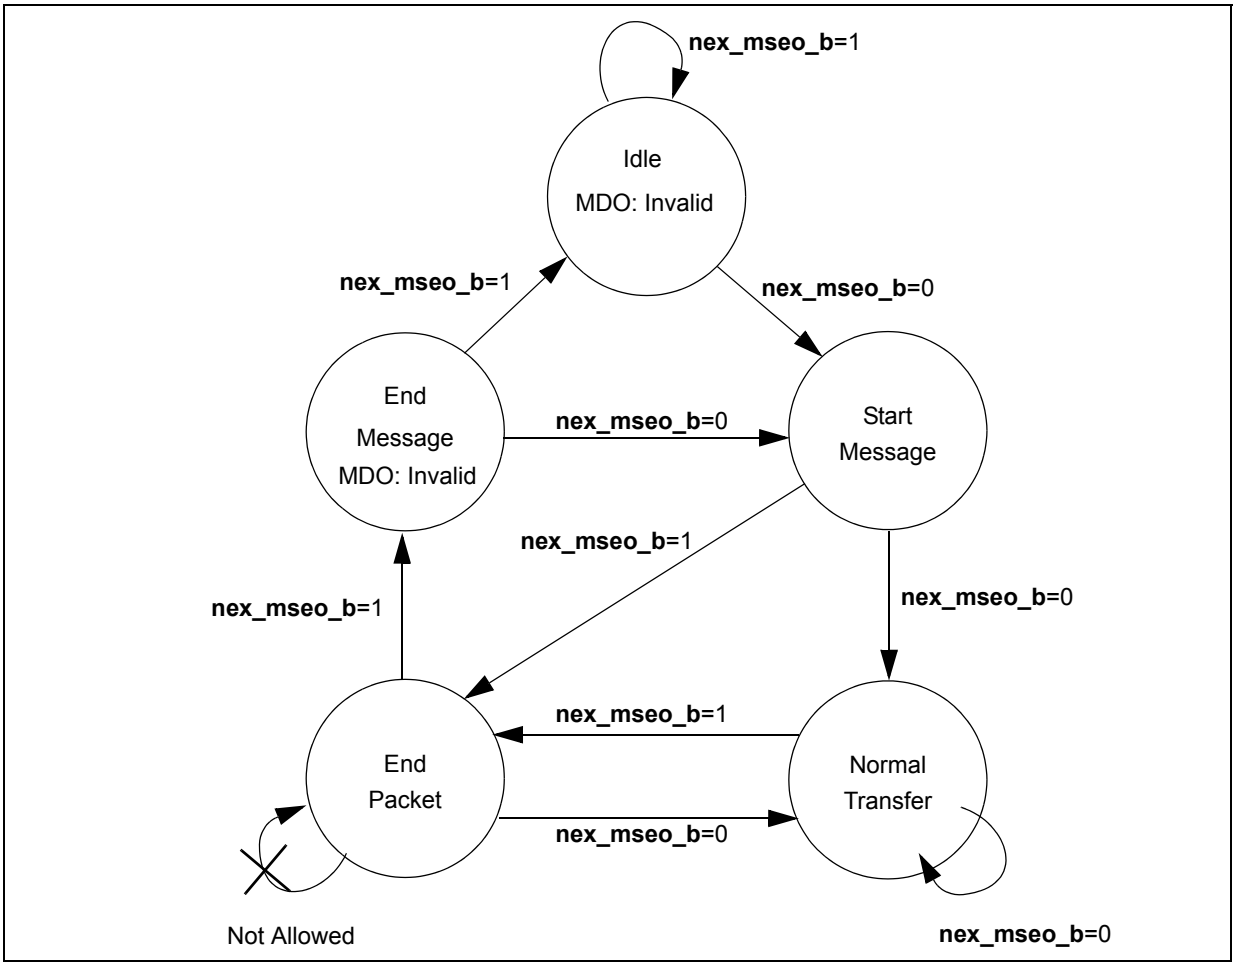
Table 1644. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 1646*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

74.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 1645*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



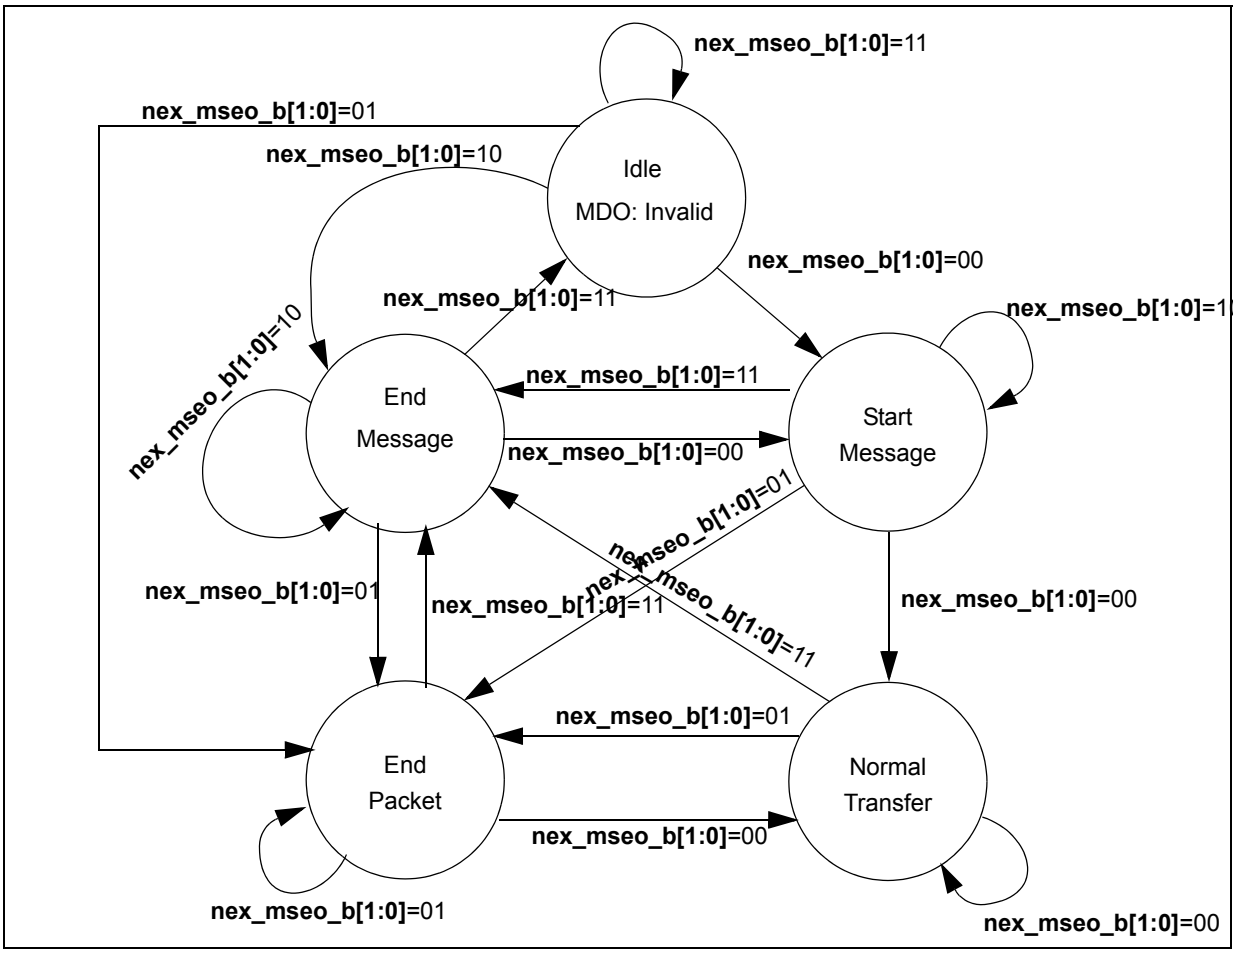
Single pin MSEO is not supported on the SPC574Kx.

Table 1645. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 1731 illustrates the state diagram for single pin MSEO transfers.

Figure 1731. Single pin MSEO transfers



Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the

minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 1732 illustrates the state diagram for dual pin MSEO transfers.

Figure 1732. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note: The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

74.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

74.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 1646* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 74.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 1646. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

74.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 1647 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 1648* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1647. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1648. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1649 and *Table 1650* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1649. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1650. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1651 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 1652* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 1651. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)

Table 1651. Data write message example (8 MDO / 1 MSEO)(Continued)

Clock	nex_mdo[7:0]								nex_mseo_b	State
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 1652. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

74.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC574Kx Data Sheet.

74.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

74.23.1 JTAG sequence for accessing internal Nexus registers

Table 1653. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value

Table 1653. Accessing internal Nexus 3 registers via JTAG/OnCE(Continued)

Step #	TMS Pin	Description
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

74.23.2 JTAG sequence for read access of memory-mapped resources

Table 1654. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

74.23.3 JTAG sequence for write access of memory-mapped resources

Table 1655. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

75 e200z225Bn3 Nexus 3 Module

The e200z225Bn3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

75.1 Introduction

75.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

75.1.2 Terms and Definitions

Table 1656 contains a set of terms and definitions associated with the Nexus 3 module.

Table 1656. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design.
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1656. Terms and Definitions(Continued)

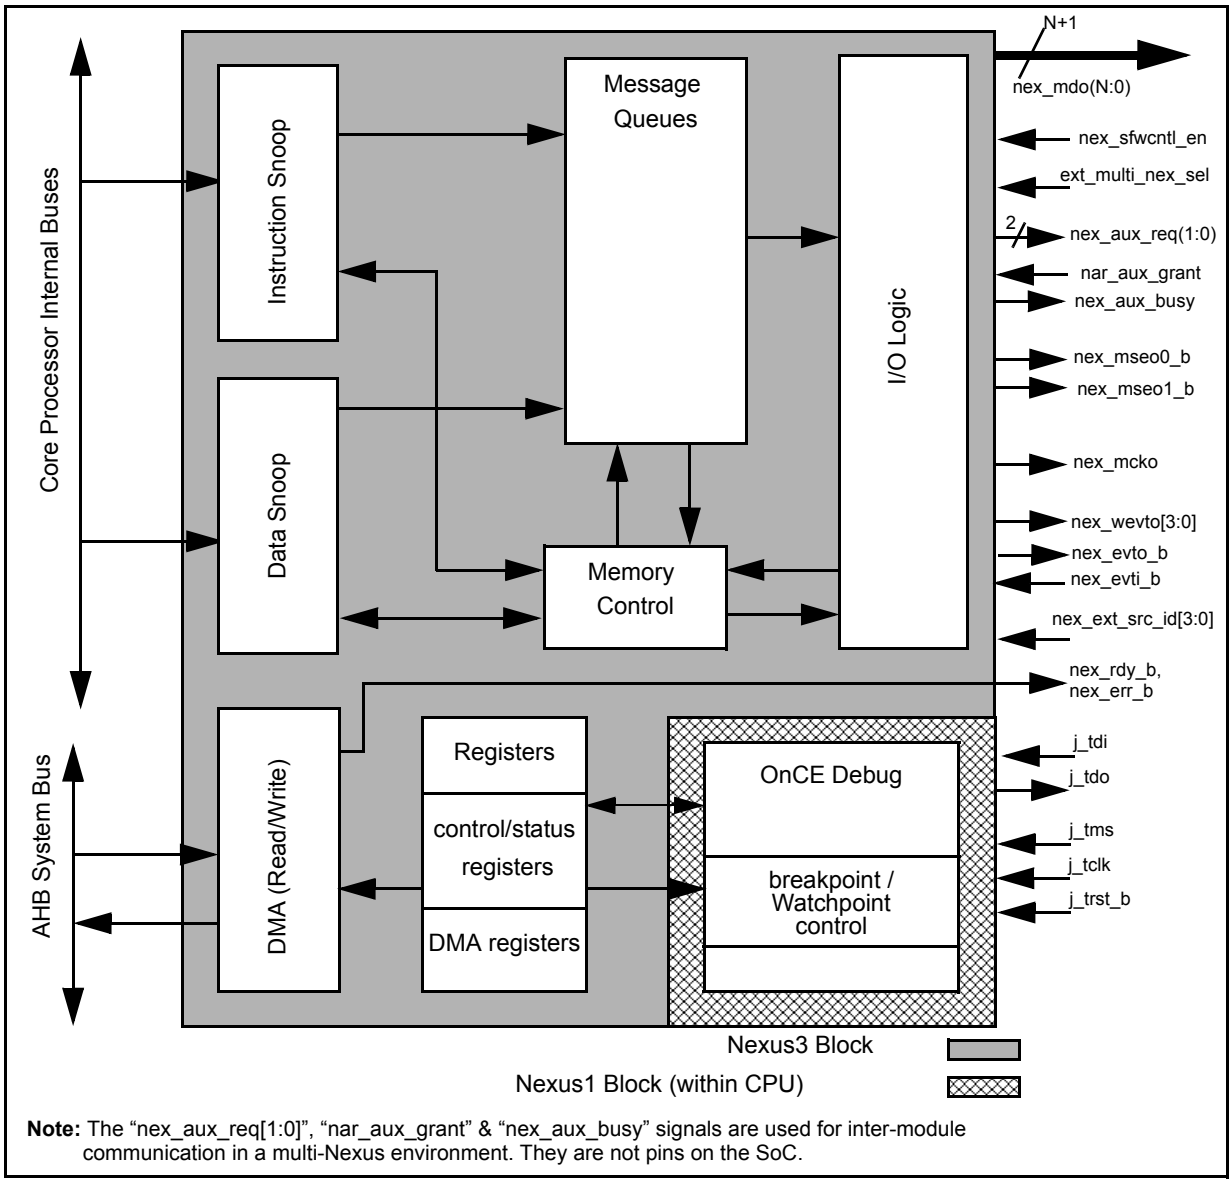
Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

75.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated. An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.
- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
  - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
  - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
  - One (1) Read/Write Ready pin (**nex_rdy_b**) pin

  - One (1) Read/Write Error pin (**nex_err_b**) pin
  - One (1) Watchpoint Event output pin (**nex_evto_b**)
  - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
  - One (1) Event In pin (**nex_evti_b**)
  - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)



Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

Note: In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

75.1.4 Functional Block Diagram

Figure 1733. Nexus 3 functional block diagram

Note: The “nex_aux_req[1:0]”, “nar_aux_grant” & “nex_aux_busy” signals are used for inter-module communication in a multi-Nexus environment. They are not pins on the SoC.

75.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the **nex_evti_b** input signal is asserted at the time that **j_trst_b** is initially negated, or is asserted during the Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test_Logic_Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

75.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

75.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in *Table 1657*.

Table 1657. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1657. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1662*)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1662*)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from $DEVENT_{DQTAG}$ register field
	1	32	DQDATA	variable	exported data taken from DDAM register
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1657. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1657. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1662*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to *Table 1662*)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to *Table 1660*) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See *Section 75.12.4: Resource Full Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1657. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see *Section 75.12.1: Branch Trace Messaging types*)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See *Section 75.12.1: Branch Trace Messaging types*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Table 1657. Supported TCODEs(Continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to *Table 1661*)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See *Section 75.12.5: Program Correlation Messages*.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See *Section 75.12.5: Program Correlation Messages*.)
	0	30	TSTAMP	variable	TImestamp value (optionally generated field)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in Section 75.12.1: Branch Trace Messaging types. If the Branch History method is selected, the shaded TCODES above will not be messaged out.

Table 1658 shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1658. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

Table 1659 shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1659. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

Table 1660 shows the encodings used for resource codes for certain messages.

Table 1660. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

Table 1661 shows the event code encodings used for certain messages.

Table 1661. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via **mtspr PID0/NPIDR**
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to MSR_{PMM} = 0 and $DC4_{PTMARK}$= 1
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

Table 1662 shows the data trace size encodings used for certain messages.

Table 1662. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte

Table 1662. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)(Continued)

DTM Size Encoding	Transfer Size
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

75.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See *Section 75.5: Nexus 3 Register Access via JTAG/OnCE* and *Section 75.6: Nexus 3 Register Access via Software*for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

Table 1663 details the register map for the Nexus 3 module.

Table 1663. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/ Write	Read Address	Write Address	DCR #(1)
Client Select Control (CSC)(2)	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtdcr** instructions use these values for the DCR number. Software writes to these registers via **mtdcr** when **nex_sfwcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

75.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Nexus Reg# 0x1; Read-only; Reset: 0x0

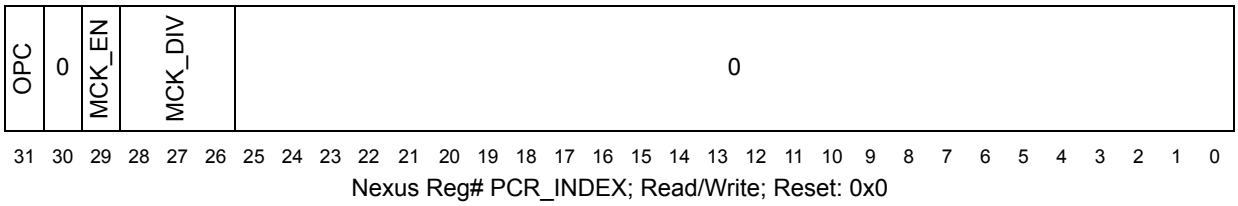

Figure 1734. Client Select Control (CSC) register

Table 1664. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0*xx* Nexus client (SoC level)

75.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Nexus Reg# PCR_INDEX; Read/Write; Reset: 0x0

Figure 1735. Port Configuration Register (PCR)

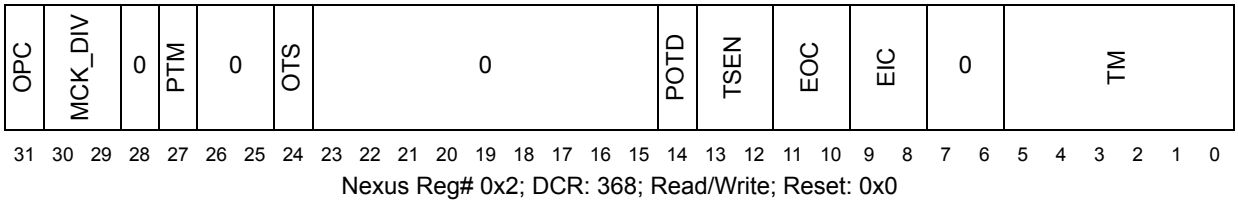

Table 1665. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# **nex_mdo[n:0]** pins defined by SOC) 1 Full Port Mode configuration (max# **nex_mdo[n:0]** pins defined by SOC)
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 **nex_mcko** is disabled 1 **nex_mcko** is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 **nex_mcko** is 1x processor clock freq. 001 **nex_mcko** is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 **nex_mcko** is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 **nex_mcko** is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

75.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in *Figure 1736* and its fields are described in *Table 1666*.

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to *Section 75.4.7: Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers* for more information on watchpoint triggering. Refer to *Section 75.16: External Hardware Trigger Controls* for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) MUST ONLY be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

75.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z225Bn3) Core Debug Support chapter.

Development Control Register 2 is shown in *Figure 1737* and its fields are described in *Table 1667*.

75.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Nexus Reg# 0x4; DCR: 409; Read-only; Reset: 0x0

25:0	—	Reserved for future functionality (read as 0)

75.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4’b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For

example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z225Bn3) Core Debug Support chapter.

75.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

RWT1	RWT2	RWT3	RWT4	0	STDC1	STDC2	STDC3	STDC4	0	RC1	RC2	RC3	RC4	DI	0
31 30	29 28	27 26	25 24	23 22 21 20 19 18 17 16	15	14	13	12	11 10 9 8	7	6	5	4	3	2 1 0

Nexus Reg# 0x15; DCR: 408; Read/Write; Reset: 0x0

Figure 1756. Data Trace End Address 4 register

Table 1679 illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1679. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating "within range," and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating "outside of range."

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when DTC_{DI} = 1, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

75.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per *Table 1681*.

AC	RW	SZ	MAP	PR	ATTR	0	CNT	ERR	DV
31	30	29 28 27	26 25 24	23 22	21 20 19 18	17 16	15 14 13 12 11 10 9 8 7 6 5 4 3 2	1	0

Nexus Reg# 0x7; Read/Write(1); Reset: 0x0

Figure 1757. Read/Write Access Control/Status (RWCS) register

1. ERR and DV are read-only

Table 1680. RWCS field descriptions

Bits	Name	Description

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 1681. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

75.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Read/Write Data

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0xA; Read/Write; Reset: 0x0

Figure 1758. Read/Write Access Data (RWD) register

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. *Table 1682* shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1682. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	*x x x*	0 0 0	—	—	—	X
Half	*x x* 0	0 0 1	—	—	X	X
Word	*x* 0 0	0 1 0	X	X	X	X
Doubleword first RWD pass (low order data) second RWD pass (high order data)	0 0 0	0 1 1	X X	X X	X X	X X

1. "X" indicates byte lanes with valid data
"—" indicates byte lanes that will contain unused data.

Table 1683 shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1683. RWD byte lane mapping

1. "—" indicates byte lanes that will contain unused data.

75.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Read/Write Address

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

Figure 1759. Read/Write Access Address (RWA) register

75.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction ("*NEXUS3-ACCESS*") into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in *Table 1663*.

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See *Section 75.23: IEEE 1149.1 (JTAG) RD/WR sequences*.)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see *Table 1663*), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1760. JTAG DR format

(7 bits)	(1 bit)
Nexus Register Index	R/W

RESET Value: 0x00

Table 1684. JTAG DR field descriptions

Nexus Register Index	Selected from values in *Table 1663*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the "Capture-DR" state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the "Update-DR" state.

75.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. *Table 1663* shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

75.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

75.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

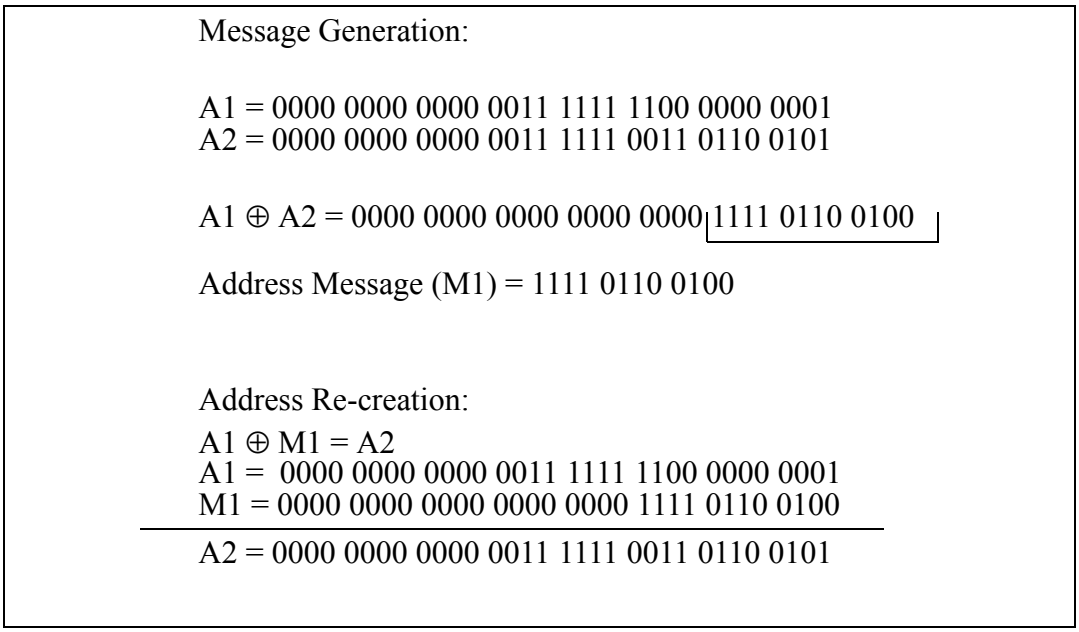
75.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

75.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant ‘1’. To recreate the original address, the relative address is XORed with the previously decoded address.



The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) =0x0003FC01, New Address (A2) = 0x0003F365

Figure 1761. Relative address generation and recreation

75.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

75.7.5 Timestamp Field (TSTAMP)

Timestamps may be optionally applied to messages. Enabling of timestamping is controlled by the **nex_tsen** input signal. The timestamping mode (timestamp frequency of occurrence) is controlled by the value of **nex_tsmode[0:1]** and the timestamp value is based on the **nex_timebase[0:29]** inputs. These signals are first synchronized to the **nex_clk** clock domain, and for **nex_timebase[0:29]**, a gray-code to binary value conversion is performed. The timestamp value is applied to messages as they the message queues. Leading zeros in

the timestamp value are removed. *Table 1685* shows the **nex_tsmode[0:1]** encodings used for the timestamp mode.

Table 1685. nex_tsmode[0:1] Timestamp mode encoding

nex_tsmode[0:1]	Timestamp mode
00	Timestamp applied to every message
01	Timestamp applied to every 4th message
10	Timestamp applied to every 16th message
11	Timestamp applied to every 64th message

75.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

75.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

75.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to *Section 75.4.9: Nexus Overrun Control (OVCR) register*, for complete programming options.

75.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in *Section 75.8.1: Message Queue Overrun*. Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

75.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

Table 1686 lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in *Table 1686*.

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 1686. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A(1)
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A[1]
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message(2)

Table 1686. Message Type Priority and Message Dropped Responses(Continued)

Message Type	Message	Priority	Message Dropped Response
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	None

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

75.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

75.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

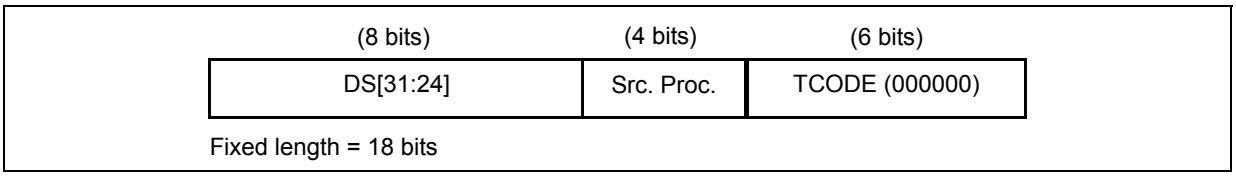
75.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

75.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.



75.8.9 Data Trace Message Priority Loss Response

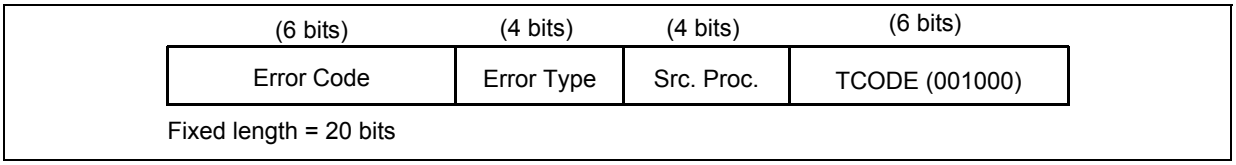
If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

75.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Figure 1762. Debug Status message format

75.10 Error messages



Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see *Table 1658* and *Table 1659*):

Figure 1763. Error message format

75.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

75.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

75.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z225Bn3) processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr**/**mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr**/**mtspr** instructions. This register is accessible in user or supervisor mode.

Nexus 3 Process ID

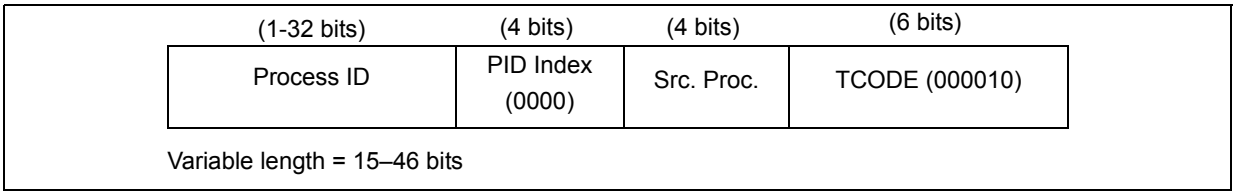
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR — 517; Read/Write; Reset: 0

Figure 1764. Nexus 3 Process ID Register (NPIDR)

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the $DC1_{OTS}$ control bit.



There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and $DC1_{OTS}$ indicates PID0 should be used, or when the NPIDR register is written to by the processor and $DC1_{OTS}$ indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will

indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting $DC1_{POTD}$.

Ownership trace information is messaged out in the following format:

Figure 1765. Ownership Trace Message format

75.12 Program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z225Bn3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z225Bn3) processors is accomplished by snooping the internal address bus, attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

75.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Certain instructions (**zvselh**) (**evsel**) generate a pair of predicate bits that are both reported as consecutive bits in the history field. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

75.12.1.1 Indirect Branch Message instructions

Table 1687 shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1687. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	**bcctr**, **bcctrl**, **bclr**, **bclrl, se_bctr, se_bctrl, se_blr, se_blrl**
System Call / Trap exceptions taken	**se_sc, tw**
Return from interrupts / exceptions	**se_rfi, se_rfci, se_rfdi**
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

75.12.1.2 Direct Branch Message Instructions

Table 1688 shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1688. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	**b**, **ba**, **bl**, **bla**, **bc**, **bca**, **bcl**, **bcla, se_b. se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync**

75.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. Certain instructions (**zvselh**) (**evsel**) generate a pair of predicate bits that are both reported as consecutive bits in the history field.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

75.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events”

that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

75.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

75.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If $DC1_{PTM}$ is set to '1', indirect branch information is messaged out in the following format:

Figure 1766. Indirect branch message (history) format

(1-32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

75.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

Figure 1767. Indirect branch message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

75.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

Figure 1768. Direct branch message format

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

75.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

75.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

75.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **zvselh** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1689. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	**bcctr, bcctrl, bclr, bclrl**
Not taken direct branches	0	**b, ba, bc, bca, bla, bcla, bl, bcl**
Taken direct branches	1	**b, ba, bc, bca, bla, bcla, bl, bcl**(1)

Table 1689. Branch/Predicate history events(Continued)

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
zvselh instruction	00,01,10, or 11	zvselh
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

75.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of ‘0’ indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of ‘1’ indicates that the preceding instruction count and history information should be interpreted in a VLE context.

75.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Figure 1769. Resource Full Message format

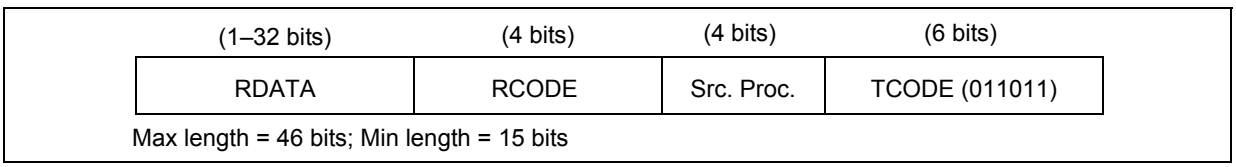


Table 1690 shows the RCODE encodings and RDATA information used for Resource Full Messages.

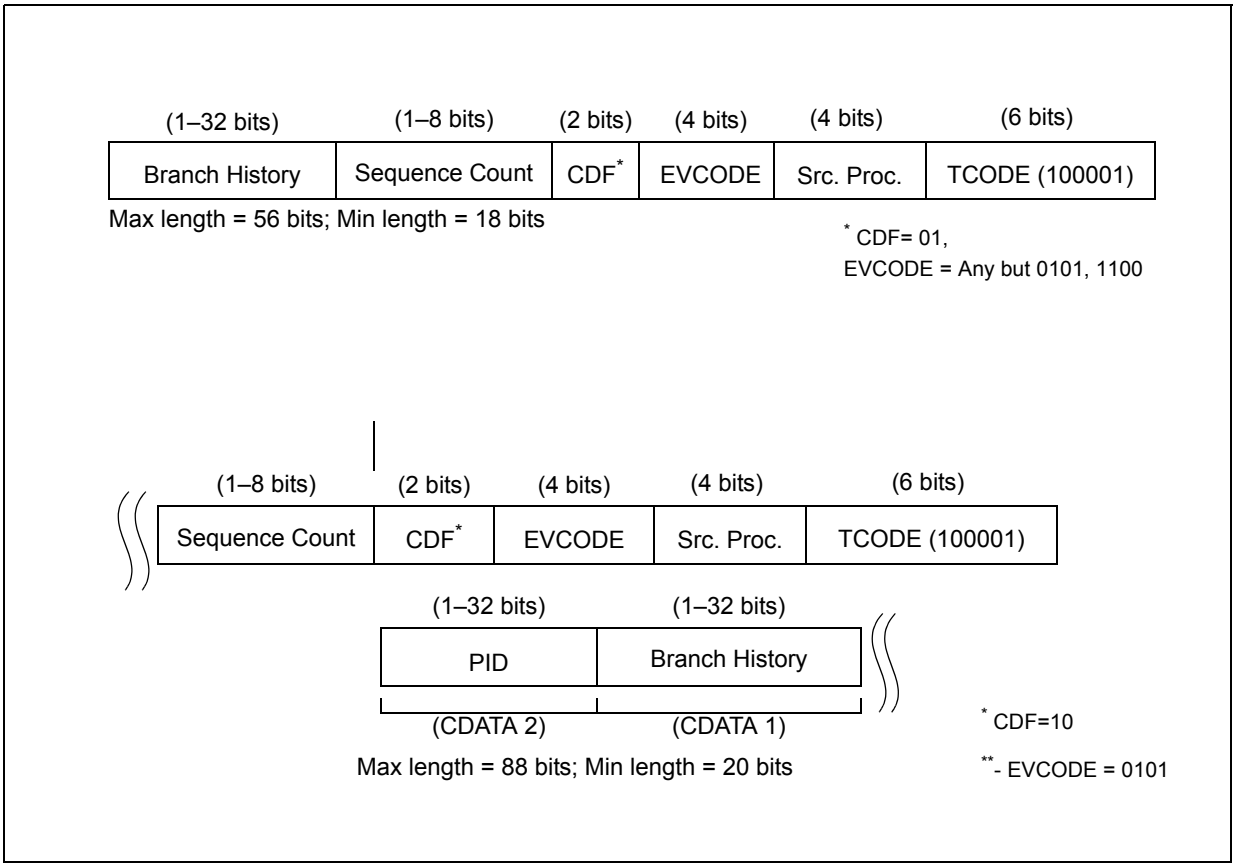
Table 1690. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch HIstory. This type of packet is terminated by a stop bit set to 1 after the last history bit.

75.12.5 Program Correlation Messages



Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl**/**bcl**/**bla**/**bcla**-type instructions)
- When program trace becomes masked due to MSR_{PMM}=‘0’ and $DC4_{PTMARK}$=‘1’.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to *Table 1661* for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 1770. Program Correlation message formats

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

75.12.6 Program Trace Overflow Error messages

an Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

75.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1691*):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow$ '1' with $DC4_{PTMARK}$='1'.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

Figure 1771. Program Trace Synchronization message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Program Trace Synchronization are summarized in *Table 1691*.

Table 1691. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (**p_reset_b**), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.

Table 1691. Program Trace exception summary(Continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

75.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see *Table 1691*):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

Figure 1772. Direct/Indirect Branch with Sync message format

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

Figure 1773. Indirect Branch History w/ Sync message format

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in *Table 1692*.

Table 1692. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync.Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the *next* Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG}→OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

75.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of $DC4_{PTMARK}$

75.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)

Figure 1774. Program Trace — Indirect Branch message (Traditional)

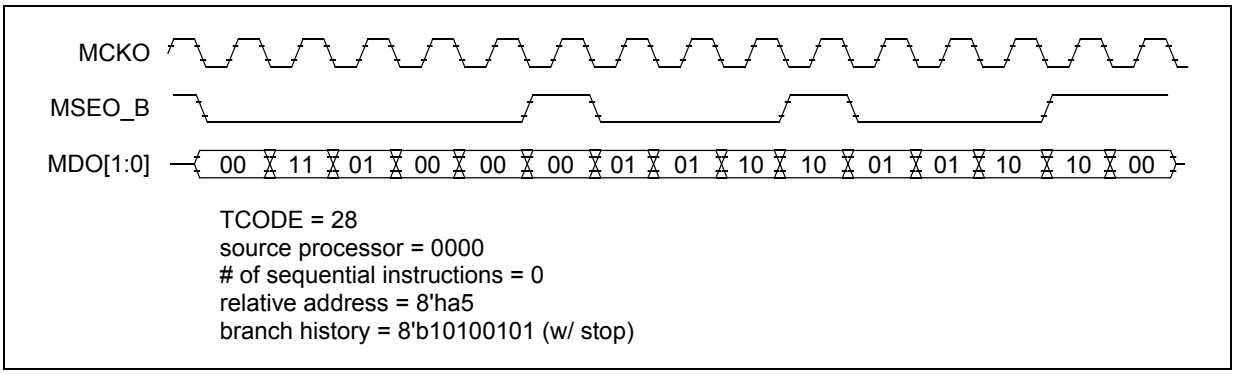

Figure 1776. Program Trace — Direct Branch (traditional) & Error messages

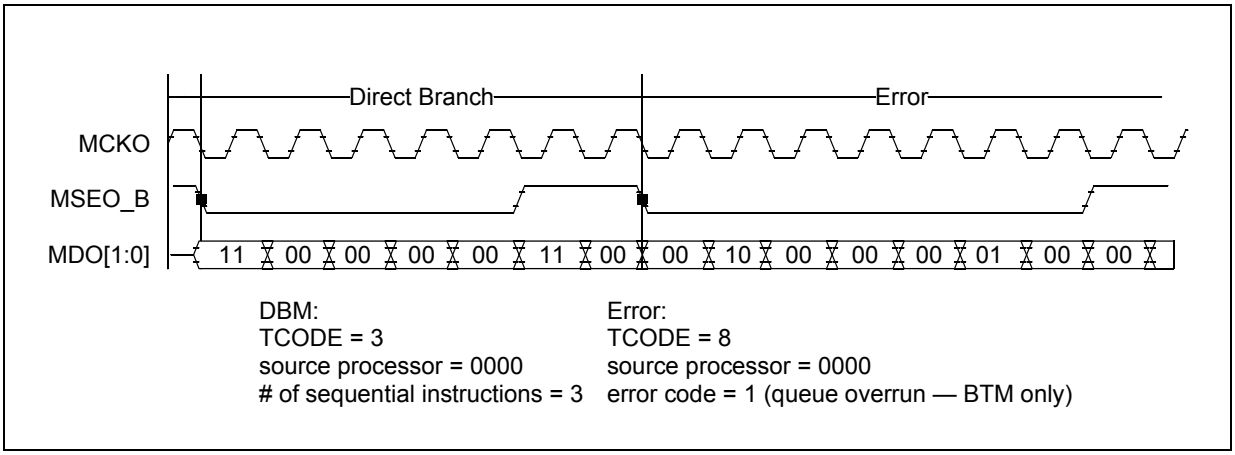

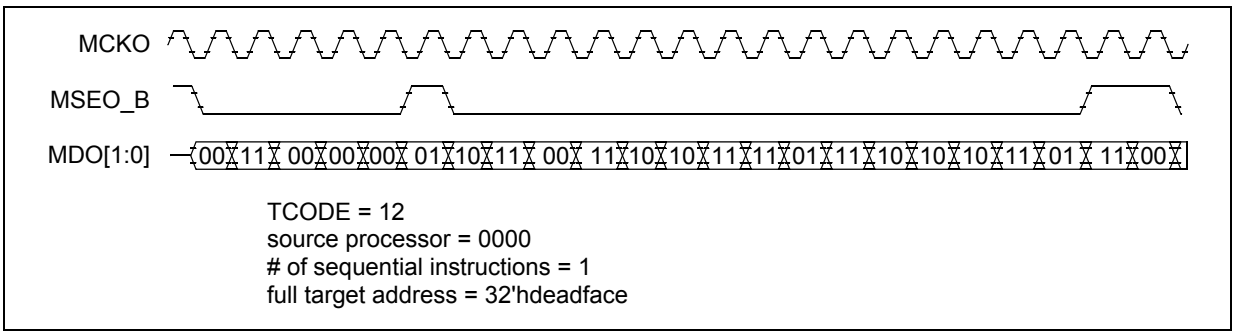

Figure 1777. Program Trace — Indirect Branch w/ Sync message

75.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

75.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z225Bn3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

75.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

75.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

Figure 1778. Data Write message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 1779. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

*Note: * Core (e200z225Bn3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.*

*Note: For Core (e200z225Bn3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.*

Note: The debug/development tool will need to distinguish the two cases based on the family of processor.

75.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see *Table 1693*):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 1780. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

Exception conditions that result in Data Trace Synchronization are summarized in *Table 1693*.

Table 1693. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (**j_trst_b**), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.

Table 1693. Data Trace Exception summary(Continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a **nex_evti_b** assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM)→ Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

75.13.3 DTM operation

75.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

75.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

75.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and $DC4_{DTMARK}$.

75.13.3.4 Bus cycle special cases

Table 1694. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{TEA}$)(1)	Data Trace Message discarded
Bus cycle completed without error[1]	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored

Table 1694. Bus cycle special cases(Continued)

Special case	Action
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC_{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary): both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction within data trace range – 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction within data trace range – 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction out of data trace range – 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary): – 1st transaction out of data trace range – 2nd transaction within range, receives a bus error	Data Trace Message discarded

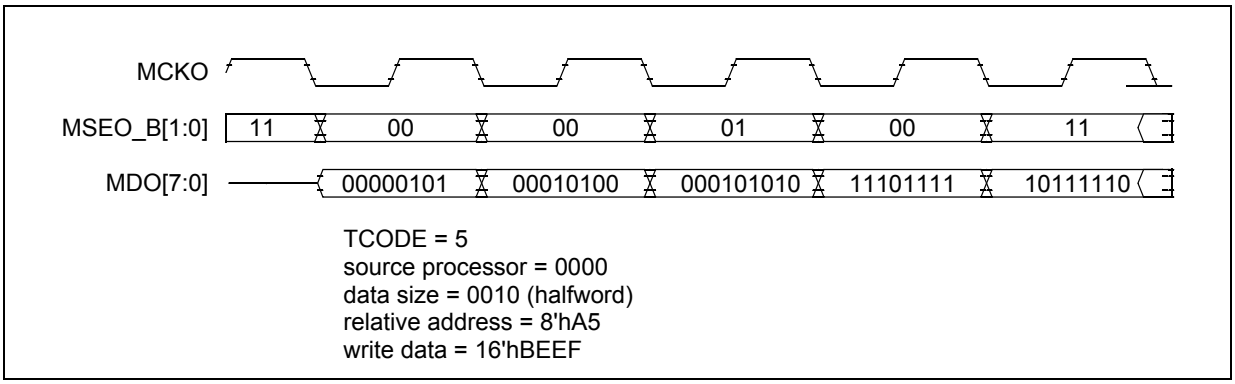
1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0, or unless the misaligned access wraps over the end of a circular buffer when using the LSP specialized load or store with circular addressing. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z225Bn3) Core Debug Support chapter.)

Note: A store to the store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

75.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 1781. Data Trace — Data Write message



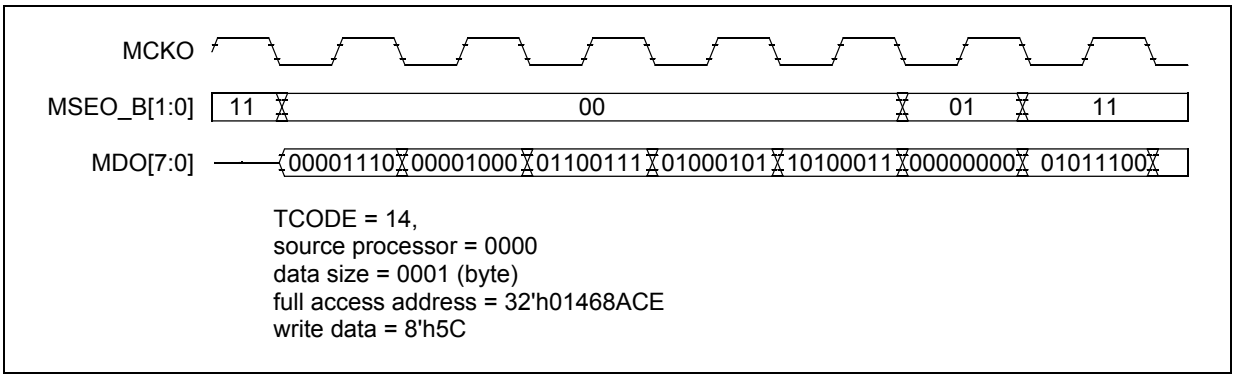


Figure 1782. Data Trace — Data Read w/ Sync message

75.14 Data Acquisition messaging

this section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

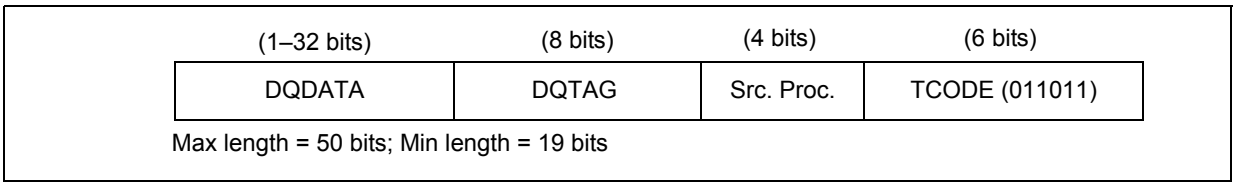
Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

75.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

75.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.



75.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

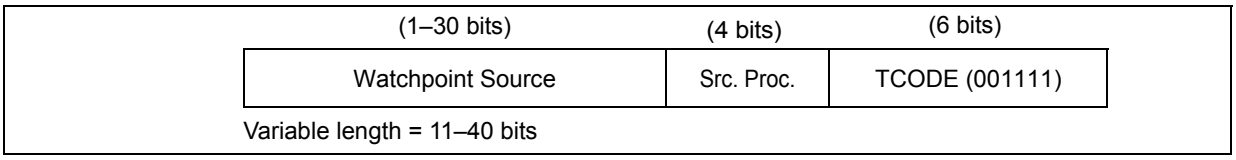
There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z225Bn3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

Figure 1783. .Data Acquisition message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.

75.15 Watchpoint Trace messaging



Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z225Bn3) Core Debug Support chapter for details on watchpoint initialization.

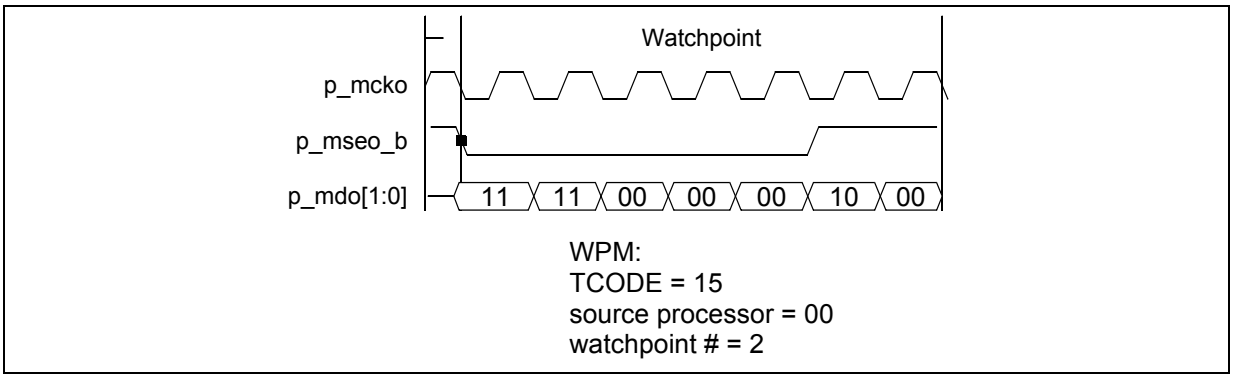
When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the $WMSK_{WEM}$ field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See *Table 1698* for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 1784. Watchpoint message format

If timestamping is enabled, the TSTAMP field is appended to the end of the message and adds up to 30 additional bits.



The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 1695. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
*xxxxxxxxxxxxxxxxxxxxxxxxxxxxx*1	Watchpoint #0 enabled for WTM

75.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1785. Watchpoint Message & Watchpoint Error message

75.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect. *Table 1696* details the external hardware trigger signals.

Table 1696. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 1696. External Hardware Trigger Signals(Continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

75.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6‘b000011 accordingly. The $RWCS_{ATTR}$ field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

75.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'1 (write access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see *Table 1698* for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

*Note: Only the **nex_ahb_start, nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

75.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 75.17.1: Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in *Section 75.17.1: Single write access* until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

75.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure as follows:
   a) Read Address → 32h'xxxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*. Configure the bits as follows:
   a) Access Control (AC) → 1b'1 (to indicate start access)
   b) Map Select (MAP) → 3b'000 (primary memory map)
   c) Access Priority (PR) → 2b'11 (highest priority)
   d) Read/Write (RW) → 1b'0 (read access)
   e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
   f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see *Table 1698* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*.

*Note: Only the **nex_ahb_start**, **nex_rdy_b,** and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.*

75.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 75.17.3: Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see *Table 1698* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see *Table 1698* for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in *Section 75.5: Nexus 3 Register Access via JTAG/OnCE*.
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in *Section 75.17.3: Single read access* until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

75.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

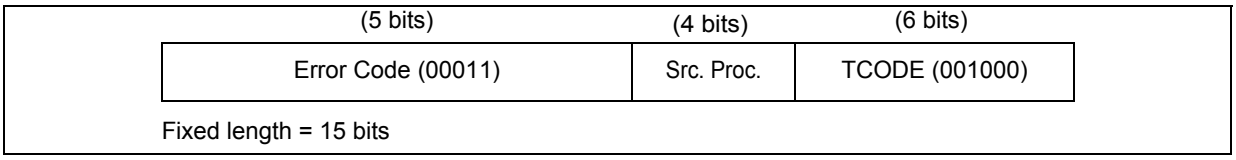
75.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

75.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.



1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
   a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
   b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

75.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

Figure 1786. Error message format

75.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

75.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in *Table 1698*. The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see *Section 75.5: Nexus 3 Register Access via JTAG/OnCE* for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z225Bn3) Core Debug Support chapter.

Table 1697. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (**j_tdo**) pin is the serial output for test instructions and data. **j_tdo** is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. **j_tdo** changes on the falling edge of **j_tclk**.
j_tdi	I	The Test Data Input (**j_tdi**) pin receives serial test instruction and data. TDI is sampled on the rising edge of **j_tclk**.
j_tms	I	The Test Mode Select (**j_tms**) input pin is used to sequence the OnCE controller state machine. **j_tms** is sampled on the rising edge of **j_tclk**.
j_tclk	I	The Test Clock (**j_tclk**) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (**j_trst_b**) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in *Table 1698*.

Table 1698. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (**nex_mcko**) is a free running output clock to development tools for timing of **nex_mdo[n:0]** & **nex_mseo_b[1:0]** pin functions. **nex_mcko** is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (**nex_mdo[n:0])** are output pins used for OTM, BTM, and DTM. External latching of **nex_mdo[n:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**).
nex_mseo_b[1:0]	O	Message Start/End Out (**nex_mseo_b[1:0]**) are output pins that indicate when a message on the **nex_mdo[n:0]** pins has started, when a variable length packet has ended, and when the message has ended. External latching of **nex_mseo_b[1:0]** shall occur on the rising edge of the Nexus3 clock (**nex_mcko**). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (**nex_rdy_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_rdy_b** remains deasserted
nex_err_b	O	Error (**nex_err_b**) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, **nex_err_b** remains deasserted
nex_evto_b	O	Event Out (**nex_evto_b**) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. **nex_evto_b** is held asserted for one (1) cycle of **nex_mcko**: 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2’b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2’b01

Table 1698. Nexus 3 auxiliary pins(Continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evti_b	I	Event In (**nex_evti_b**) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (**nex_wevto[3:0]**) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. **nex_wevto[3:0]** is held asserted for one (1) cycle of **nex_mcko**.
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to *Section 75.20: Auxiliary port arbitration*, for detail on Nexus port arbitration.

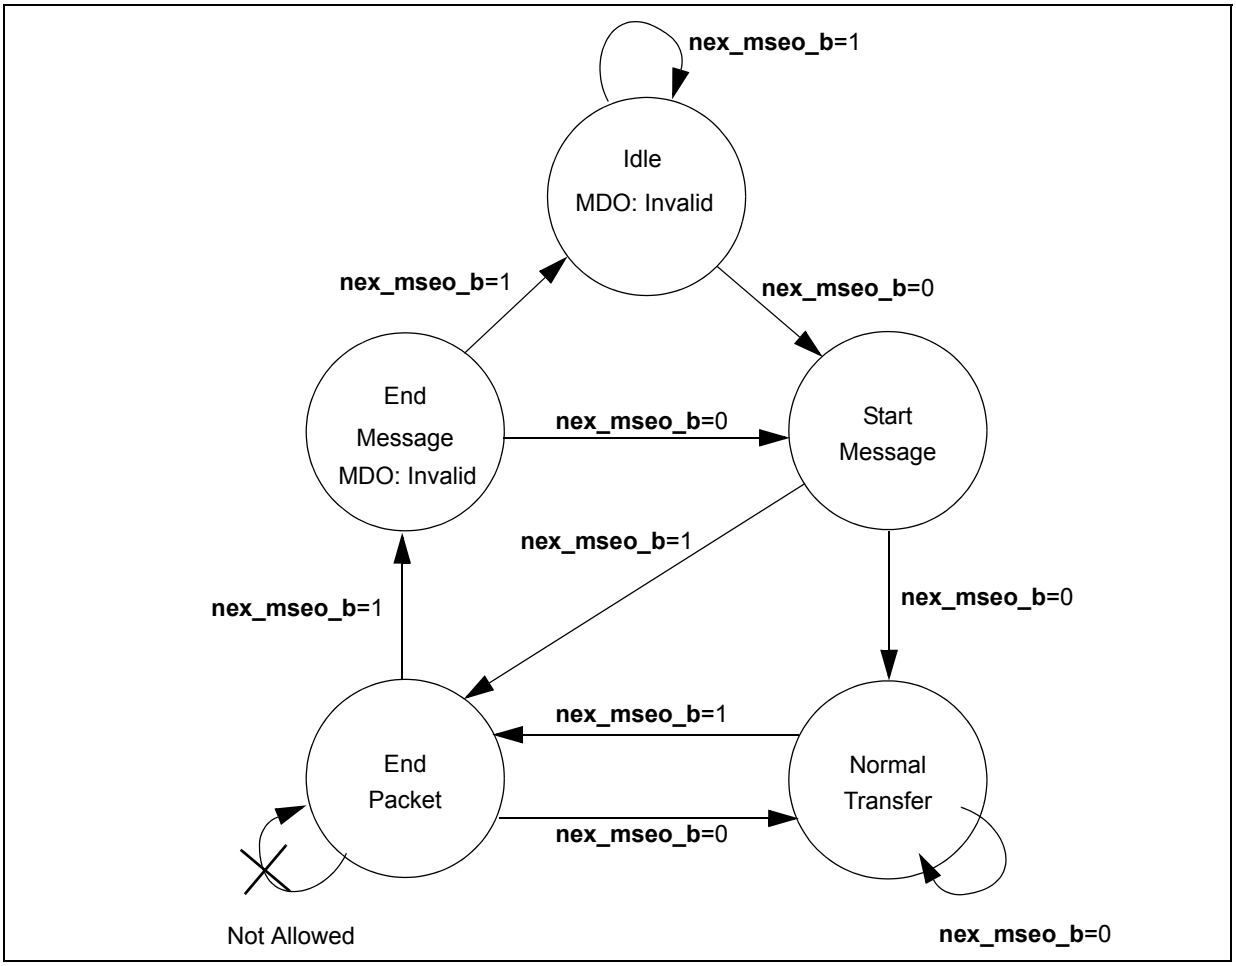
Table 1699. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (**nex_aux_req[1:0]**) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See *Table 1701*.)
nex_aux_busy	O	Nexus Auxiliary Busy (**nex_aux_busy**) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (**nar_aux_grant**) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (**ext_multi_nex_sel**) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

75.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in *Table 1700*. Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).



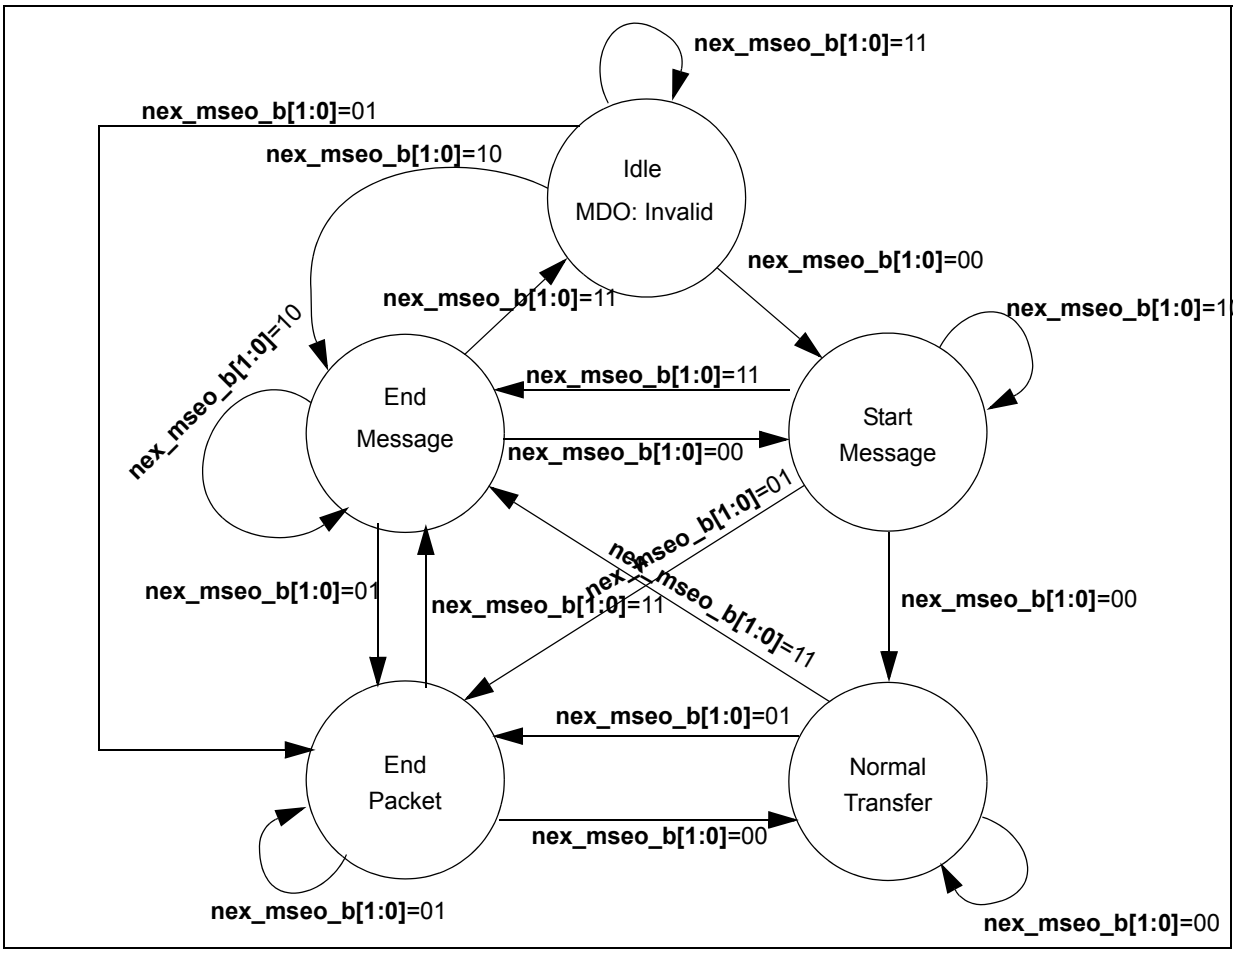
Single pin MSEO is not supported on the SPC574Kx.

Table 1700. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 1787 illustrates the state diagram for single pin MSEO transfers.

Figure 1787. Single pin MSEO transfers



Note that the "End Message" state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive "End Packet" messages. This implies the

minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive '1's on the **nex_mseo_b** pin before the actual end of message.

Figure 1788 illustrates the state diagram for dual pin MSEO transfers.

Figure 1788. Dual pin MSEO transfers

The dual pin MSEO option is more robust that the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive "End Packet" states. This can be an advantage when small, variable sized packets are transferred.

Note: The "End Message" state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

75.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

  For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

75.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level.The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in *Table 1701* below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in *Section 75.18.2: Pin protocol*. The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 1701. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

75.21 Examples

The following are examples of Program Trace and Data Trace Messages.

Table 1702 illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. *Table 1703* illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1702. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1703. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	MAP	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1704 and *Table 1705* illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1704. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1705. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

Table 1706 illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and *Table 1707* illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 1706. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)

Table 1706. Data write message example (8 MDO / 1 MSEO)(Continued)

Clock	nex_mdo[7:0]								nex_mseo_b	State
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 1707. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

75.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC574Kx Data Sheet.

75.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

75.23.1 JTAG sequence for accessing internal Nexus registers

Table 1708. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value

Table 1708. Accessing internal Nexus 3 registers via JTAG/OnCE(Continued)

Step #	TMS Pin	Description
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

75.23.2 JTAG sequence for read access of memory-mapped resources

Table 1709. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

75.23.3 JTAG sequence for write access of memory-mapped resources

Table 1710. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of **nex_rdy_b** or **nex_err_b** pin
8	—	If CNT > 0, go back to Step #5

76 Nexus Crossbar Multi-Master Client (NXMC)

76.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA, Ethernet and FlexRay start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools.This also provides the capability of sending user defined messages for the peripherals attached to it.

76.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2011 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers.
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
  - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
  - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

76.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in *Table 1712*.

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see *Section 76.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details). A separate JTAG TAP controller is instantiated within the NXMC. *Table 1711* describes the JTAG pins.

Table 1711. JTAG pins for NXMC

JTAG port	Input/ output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 1712. NXMC auxiliary pins

Auxiliary port	Input/ output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and EOC = 2'b00 – system-level debug mode was entered (ipg_debug) and EOC = 2'b01 $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see *Section 76.5.2: Enabling NXMC operation*), assertion initiates data trace synchronization messages (provided data trace is enabled).

76.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2011 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in *Table 1713*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 1713. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1714*)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1714*)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See *Table 1715*)
	14	14	ECODE	fixed	Error code (See *Table 1716*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1714*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1713. Supported public TCODEs(Continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See *Table 1714*)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See *Table 1728*)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1714. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 1715. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved

Table 1715. Error Type (ETYPE) encodings (applicable to all error messages)(Continued)

ETYPE	Description
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

76.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See *Section 76.5.1: IEEE 1149.1 (JTAG) Test Access Port* for details. The complete list of registers is shown in *Table 1717*.

Table 1717. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	$2	R/W	$04	$05
Development Control 2 (DC2)	$3	R/W	$06	$07
Watchpoint Trigger (WT)	$B	R/W	$16	$17

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.
2. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

76.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. *Figure 1791* shows the format of the WT register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19:0	Reserved for future functionality (read as 0)

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

76.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. *Figure 1792* shows the format of the DTC register.

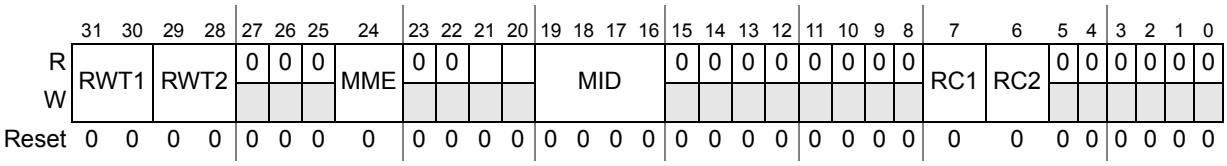

Figure 1792. Data trace control (DTC) register

The DTC register is described in *Table 1721*.

Table 1721. DTC field description

Field	Description
31:30 RWT1	Read/Write Trace 1. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
29:28 RWT2	Read/Write Trace 2. 00 No trace messages generated x1 Enable data read trace 1x Enable data write trace
27:25	Reserved for future functionality
24 MME	Multi Master Tracing enable. 0 Tracing enabled only for Master with ID = MID (DTC[19:16]) 1 Tracing enabled for all the Masters
23:20	Reserved for future functionality
19:16 MID	ID of the system bus Master to be traced[1]

Table 1721. DTC field description(Continued)

Field	Description
15:8	Reserved for future functionality
7 RC1	Range Control 1. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
6 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

76.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. *Figure 1793* shows the format of the DTSA1 and DTSA2 registers.

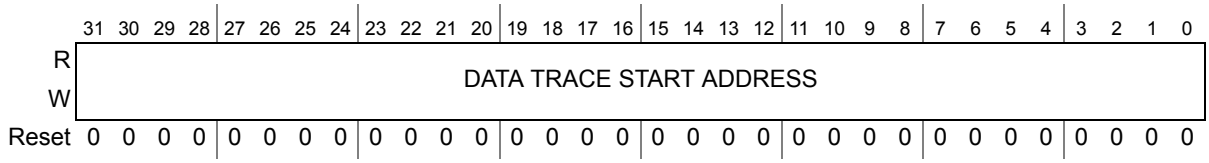

Figure 1793. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

76.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. *Figure 1794* shows the format of the DTEA1 and DTEA2 registers.

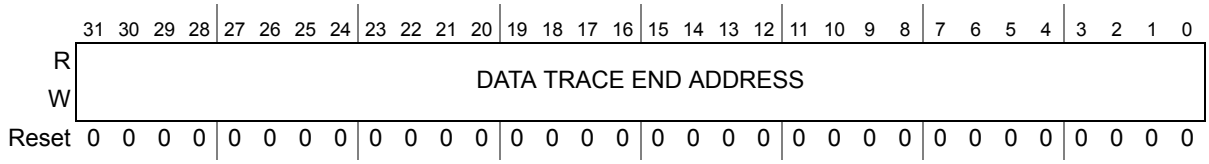

Figure 1794. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

Table 1722 illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1722. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

Note: When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

76.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. *Figure 1795* shows the format of the BWC1 register.

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWE1		BRW1		0	0	0	0	0	0	0	0	0	0	BWR1		BWT1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

15 BWT2	Breakpoint/Watchpoint #2 Type. 0 Reserved 1 Watchpoint #2 on data accesses
14:0	Reserved for future functionality (read as 0)

76.4.1.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. *Figure 1797* shows the format of the BWA1 and BWA2 registers.

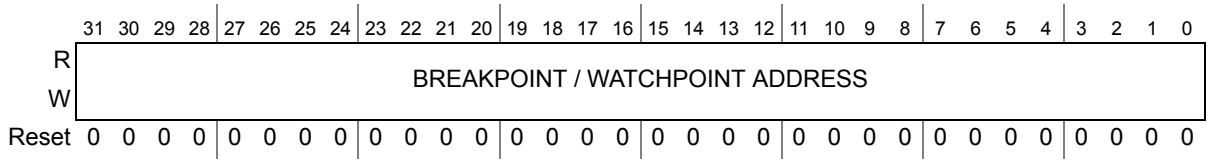

Figure 1797. Breakpoint /watchpoint address registers 1 and 2

76.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in *Table 1717*. For unimplemented registers, the NXMC module drives

TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

76.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion, after the JTAG ID register has been read by the tool.

76.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in *Section 76.5.4: NXMC register access via JTAG*.

76.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

76.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

76.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 1717*.

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see *Table 1717*), and the direction (read/write). This is achieved by loading

an 8-bit value into the JTAG Data Register (DR). This register has the format shown in *Figure 1798* and *Table 1725*.

Figure 1798. JTAG DR for Nexus register access

Table 1725. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 1717*
Read/Write (R/W)	0Read 1Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

76.6 Functional description

76.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2011 standard.

76.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

76.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

76.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in *Figure 1799*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

Figure 1799. DTM message format for DATA width = 64 bits

TSTAMP is another optional field which is inserted based on the controls received from the NAR, see *Section 76.6.4: Timestamping feature*.

76.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

76.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in *Figure 1800*. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

Figure 1800. DTM error message format (fixed length = 48 bits)

76.6.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see *Table 1726*):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message.This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in *Figure 1801*. The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Figure 1801. Data write/read with synchronization message format

Exception conditions that result in data trace synchronization are summarized in *Table 1726*.

Table 1726. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.

Table 1726. Data trace exception summary(Continued)

Exception condition	Exception handling
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM>ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

76.6.1.3 DTM operation

76.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

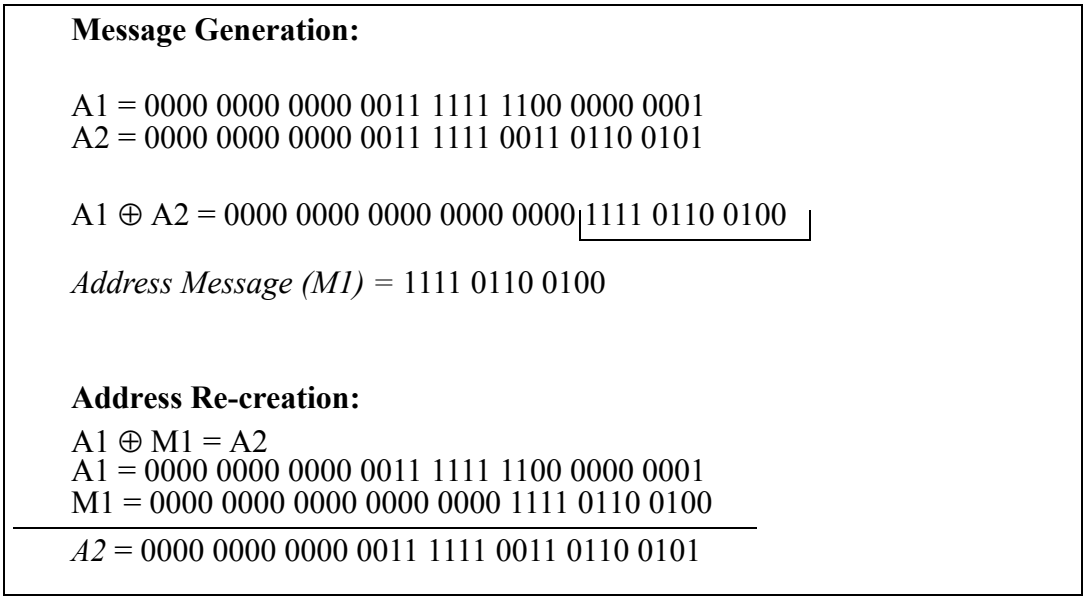
- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

76.6.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority (WPM > ICTM > DTM).



76.6.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2011 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address

transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address (A1) = 0x0003FC01, the new address (A2) = 0x0003F365 as shown in *Figure 1802*.

Figure 1802. Relative addressing example

76.6.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

76.6.1.7 System bus cycle special cases

The system bus cycle special cases are shown in *Table 1727*.

Table 1727. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

76.6.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in *Section 76.6.1.2.1: Data write and data read messages* for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

76.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2011. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

76.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in *Section 76.6.1.8: System bus multi-master tracing*).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level.The watchpoints are described in the device-specific chapter that describes how the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in *Figure 1803* and *Table 1728*.

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Figure 1803. Watchpoint message format (fixed length = 18 bits)

Table 1728. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1[1]	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

76.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in *Figure 1804*.

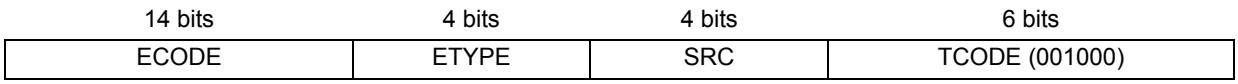


Figure 1804. Error message format (fixed length = 28 bits)

76.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

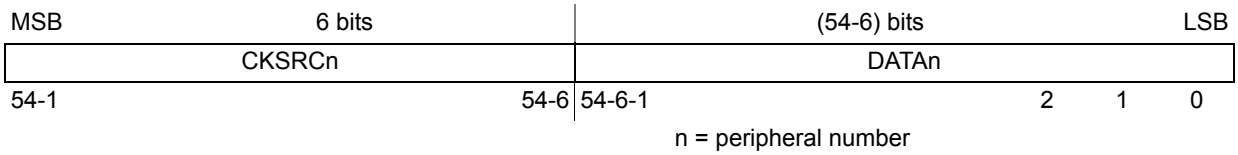

Figure 1805. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

76.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in *Figure 1806*. The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

1–44 bits	6 bits	4 bits	6 bits
CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 1806. Peripheral message format (max length = 60 bits, min length = 17 bits)

76.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in *Figure 1807*.

14 bits	4 bits	4 bits	6 bits
ECODE(CKSRCn,ErrCODE)	ETYPE	SRC	TCODE (001000)

Figure 1807. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in *Table 1715* and *Table 1716*.

76.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. *Figure 1808* shows an example of ICTM message with a TSTAMP field.

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

Figure 1808. Message with TSTAMP field example

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

1. All tracing (DTM/WPM/ICTM) must be disabled
2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
3. Change the timestamp enable indication to assert/deassert
4. Enable the required tracing controls (via TM, PME0 etc. control bits)

77 Cyclic Redundancy Check (CRC) Unit

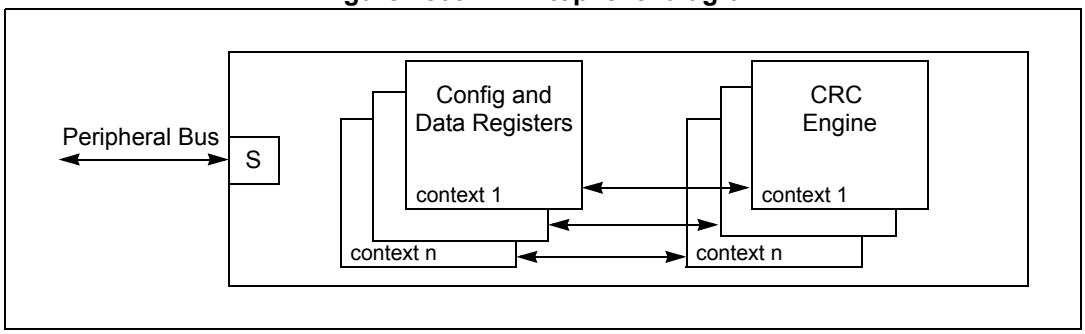
77.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

77.2 Main features

- 1 to 16 contextsfor the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 4 hard-wired polynomials (two CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

Note: Refer to the chip configuration chapter for number of contexts used in this application.



77.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet
- CRC-8-H2F Autosar polynomial

77.3 Block diagram

The top level diagram of the CRC module is given in *Figure 1809*. Refer to the chip configuration chapter for number of contexts in this module.

Figure 1809. CRC top level diagram

77.4 Signal description

The CRC module does not generate any external signals.

77.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

77.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

77.5.1 Register description

Table 1729 shows the memory map for the CRC registers.

Table 1729. CRC unit memory map(1)

Offset from CRCU_BASE	Register	Register classification(2)	Location
000h + (N-1)*10h	CRC Configuration Register (CRC_CFG)	Saf-Lat	*on page 3023*
004h + (N-1)*10h	CRC Input Register (CRC_INP)	Saf-Relv	*on page 3024*

Table 1729. CRC unit memory map(1)(Continued)

Offset from CRCU_BASE	Register	Register classification(2)	Location
008h + (N-1)*10h	CRC Current Status Register (CRC_CSTAT)	Saf-Relv	*on page 3025*

Figure 1813. CRC Output Register (CRC_OUTP)

Table 1733. CRC_OUTP field descriptions

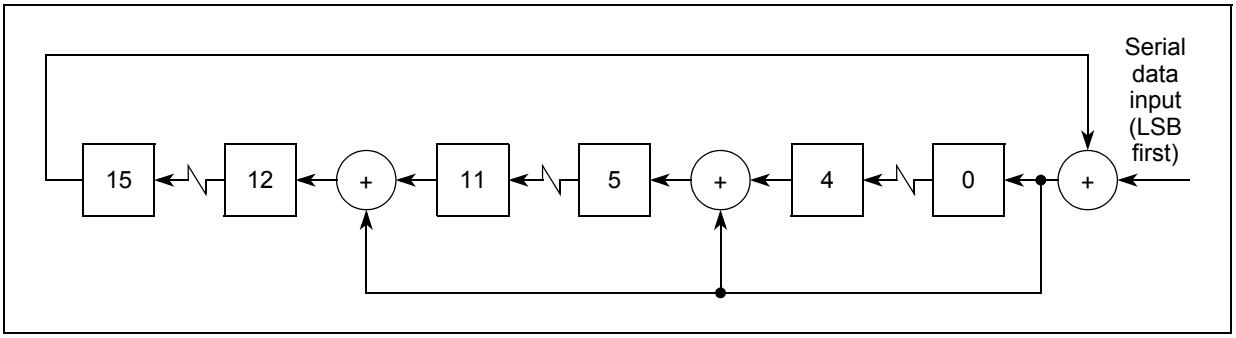
Field	Description
OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

77.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less than or equal to the number of contexts.

- The standard generator polynomials are given in *Equation 86*, *Equation 87*, and *Equation 88* for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.



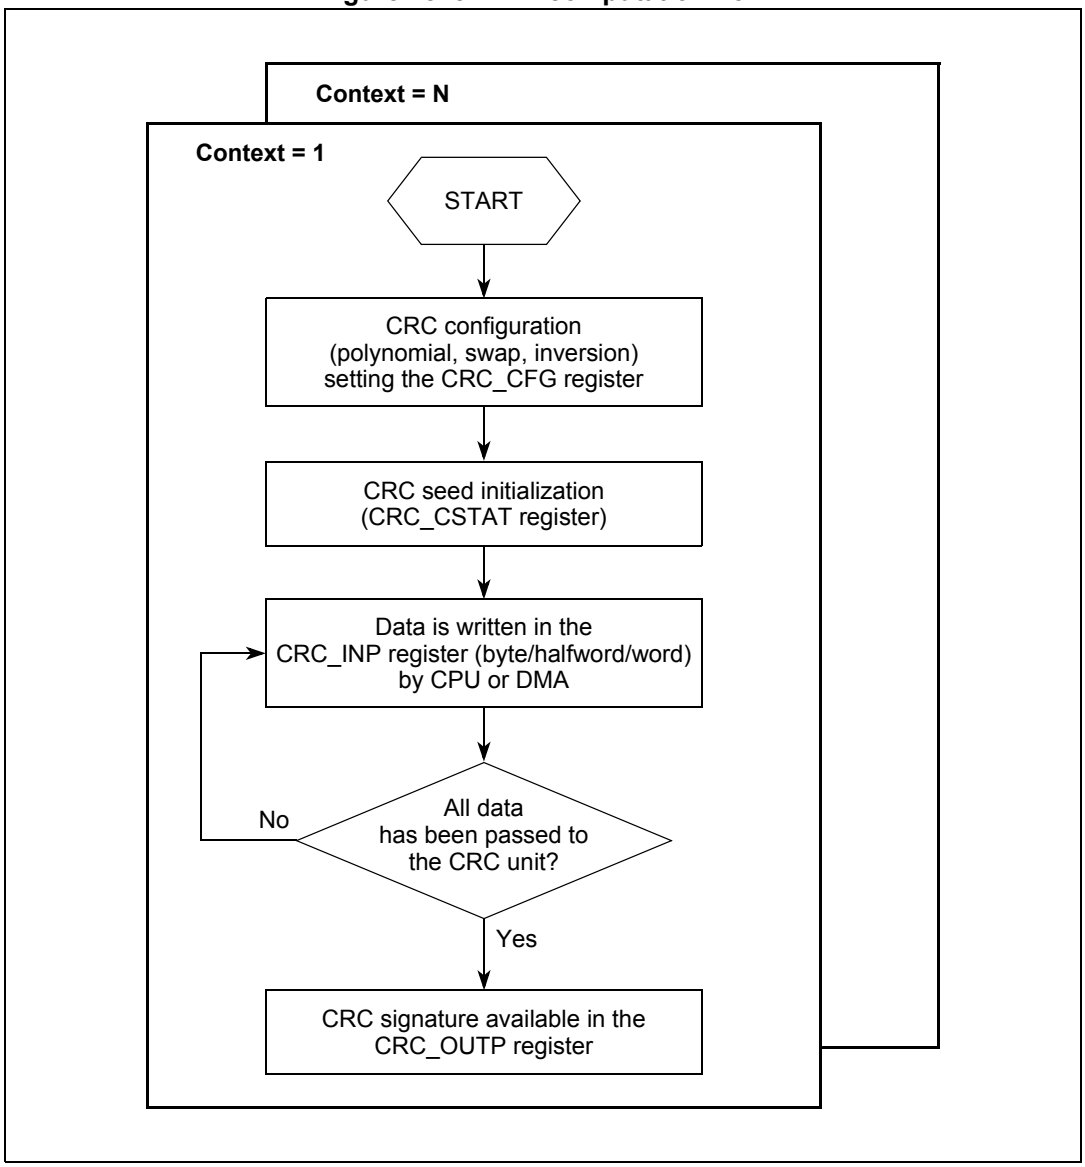
Equation 86 CRC8 VDA CAN:
$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 87 CRC-CCITT (x.25 protocol):
$$x^{16} + x^{12} + x^5 + 1$$

Equation 88 CRC-32 (Ethernet protocol):
$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Equation 89 CRC-8-H2F (Autosar 4.0 protocol)
$$x^5 + x^3 + x^2 + x + 1$$

Figure 1814. CRC-CCITT engine concept scheme



The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in *Figure 1814* for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (MSB → LSB, LSB → MSB) and/or bit inversion of the final CRC signature can be applied (CRC_OUTP register) before transmitting the CRC.

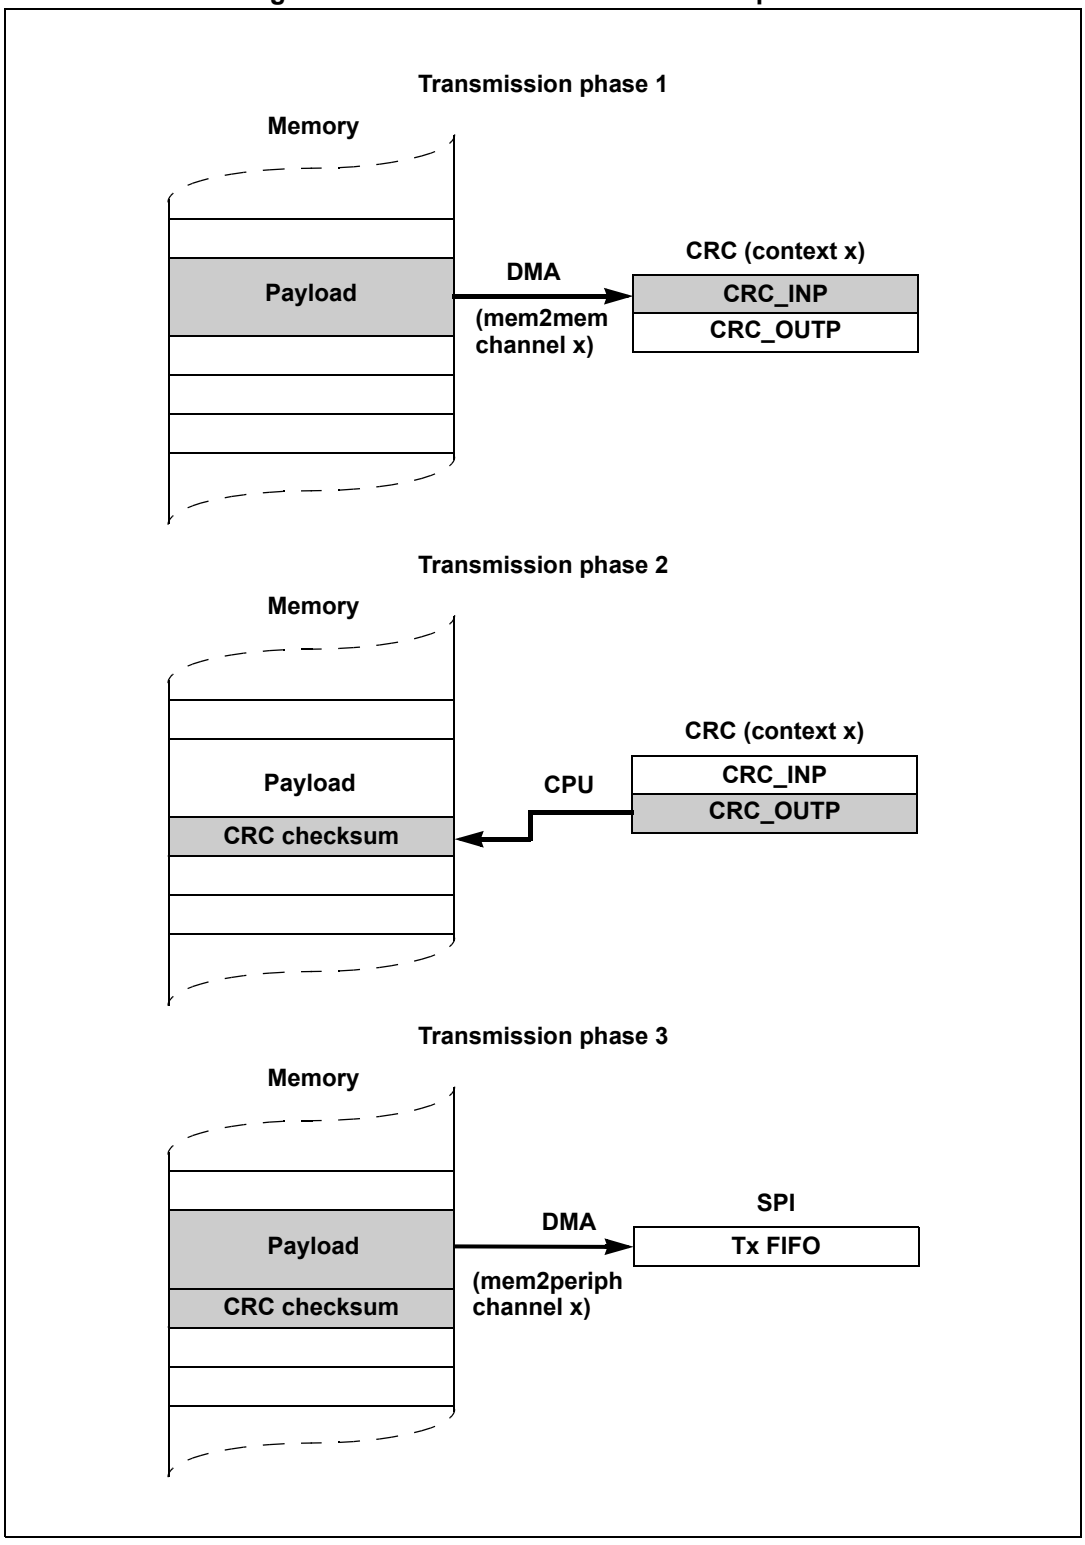
Use of the CRC module is summarized in the flow chart given in *Figure 1815*.

Figure 1815. CRC computation flow

77.7 Use cases

77.7.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:



- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has *n* channels (greater than or equal to the number of contexts) configurable for the following types of data transfer — mem2mem, periph2mem, mem2periph — then this sequence, as shown in *Figure 1816*, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x, channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 1816. DMA-CRC transmission sequence

77.7.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16 and CRC-32. Both can be applied together.
- SWAP_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP_BITWISE has priority over SWAP_BYTEWISE when both are applied together
- When generating CRC-32 for the Ethernet standard the user needs to set SWAP_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP_BITWISE bit

78 Memory Error Management Unit (MEMU)

78.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on:

- System RAM
- Peripheral RAM
- Flash memory

When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
  - Single Bit error in the data part that is detected via ECC for a system RAM or peripheral RAM or flash memory.
  - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
  - Multiple bit error that is detected via ECC for a system RAM or peripheral RAM or flash memory.
  - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
  - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the chip-specific MEMU information.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

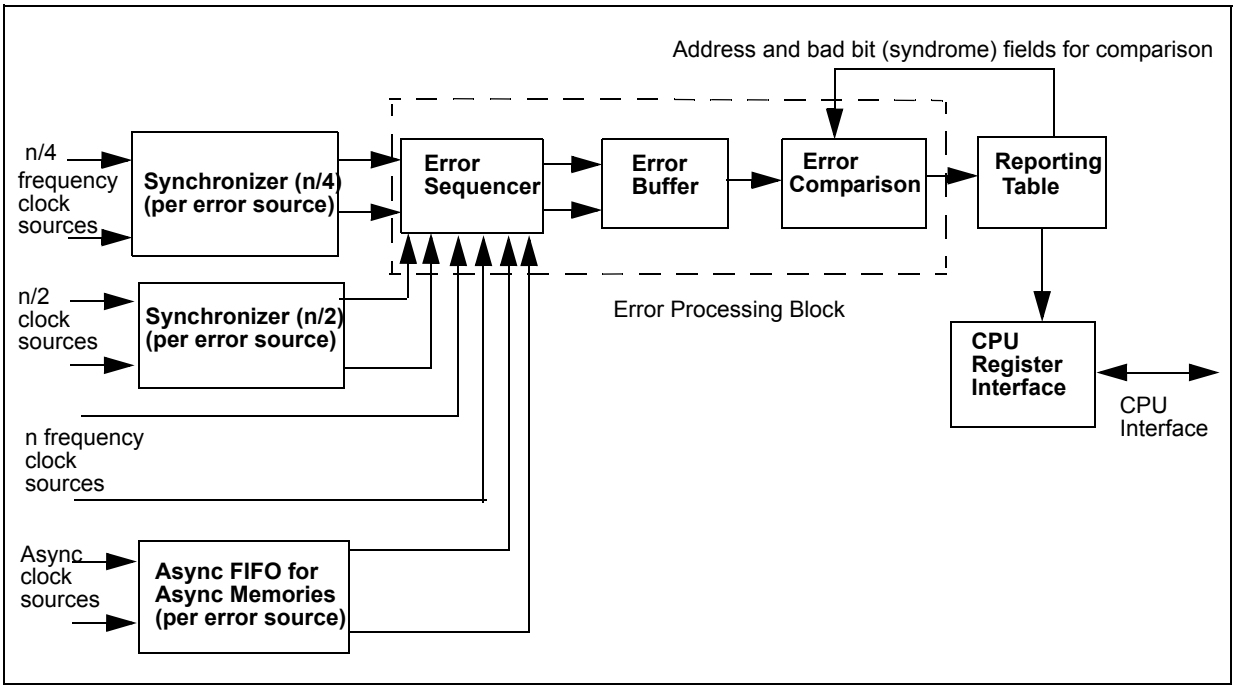
MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has multiple instances of the basic reporting block; one each for:

- System RAM ECC and MBIST
- Peripheral RAM ECC
- Flash memory ECC

Each instance has two reporting tables. Correctable errors are reported in one table while the uncorrectable are reported in the other.

See *Section 78.4, Design overview* for the reporting block details.



78.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per reporting block (system RAM ECC and MBIST or peripheral RAM ECC or flash memory ECC): The number of error sources are chip-specific; see the chip-specific MEMU information.
- Support for error reporting from the following category of error sources (both for ECC and MBIST):
  - System RAM
  - Peripheral RAM
  - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

78.3 Block diagram

Figure 1817. MEMU block diagram

78.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power-on reset. The user software can write known error addresses into the reporting table to prevent reporting of those errors addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See *Section 78.7.3, Handling overflows (Multiple error reporting)* for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

   For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits/syndrome) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

   For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

   This block is used to process the incoming errors coming from the device.

   – Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.

   – All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.

   – While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit/syndrome (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.

   – While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error UCE) is also compared, hence even if the Error Address and the Bad bit/syndrome fields (Depending on whether the incoming

error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique

– Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)

– Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (<=5 unless the error gets temporarily stored in the error buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

   This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table.If the entry is not unique it is not stored and discarded.

   The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

   The CPU can clear the flags signaling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. *Section 78.6.2.4, System RAM correctable error reporting table status register (SYS_RAM_CERR_STSn)* or *Section 78.6.2.6, System RAM uncorrectable error reporting table status register (SYS_RAM_UNCERR_STS)*). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

   The reporting table sizes are chip-specific; see the chip-specific MEMU information.

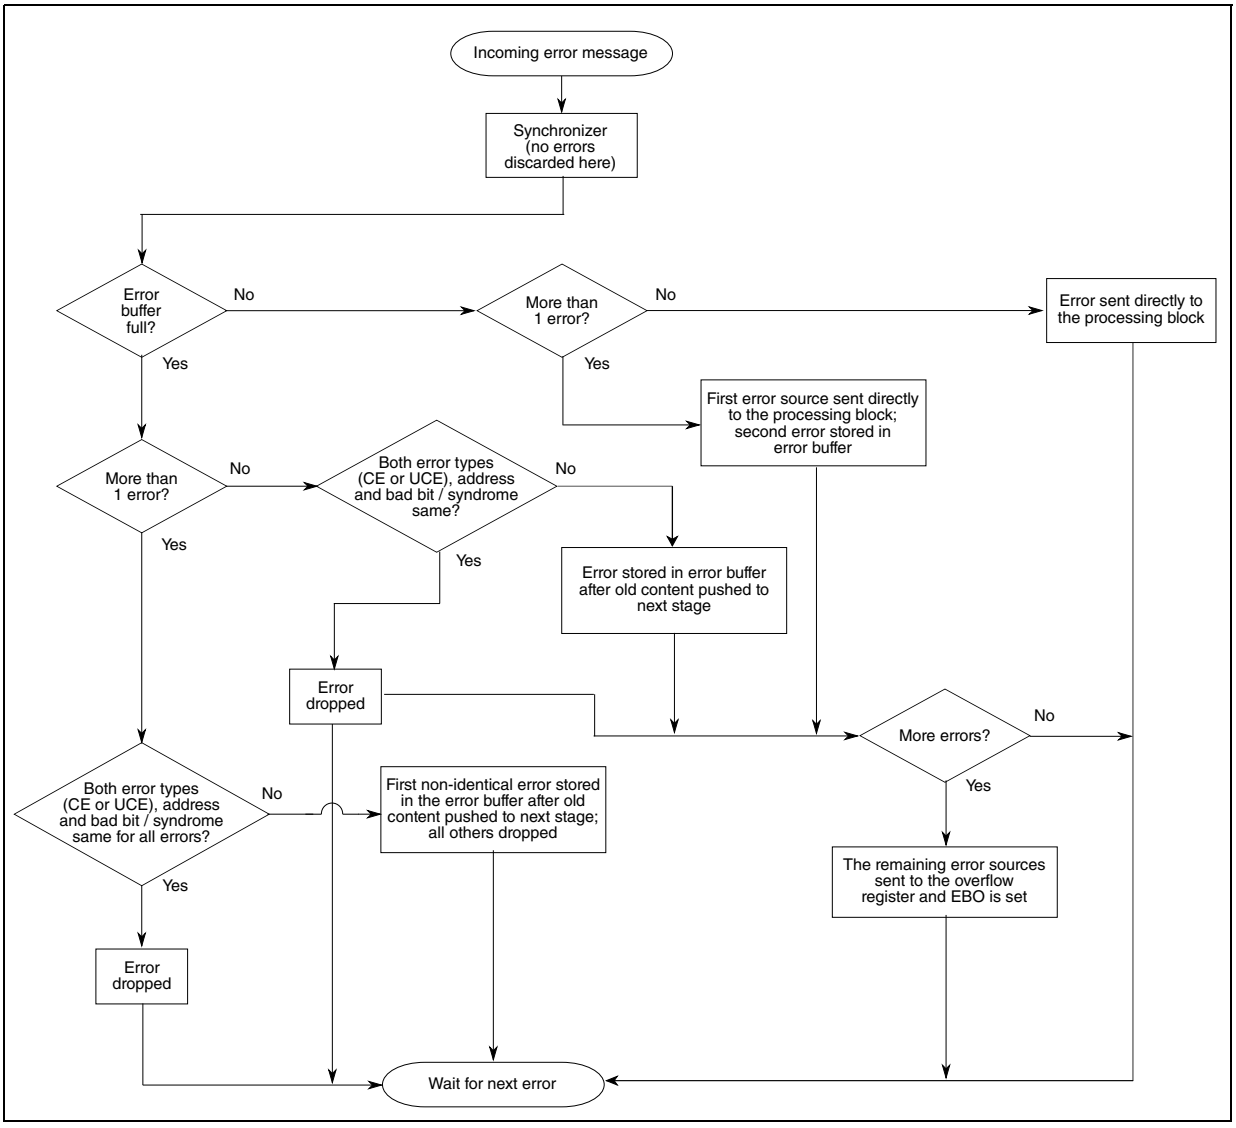
4. Register block

   The CPU register programming interface provides the memory-mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signaled to the CPU and the CPU command will be completed in the next clock cycle.

   The software, in principle, is not supposed to write VLD to 1 if it is already 1.

   The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 1818. MEMU error buffer uniqueness check flow chart



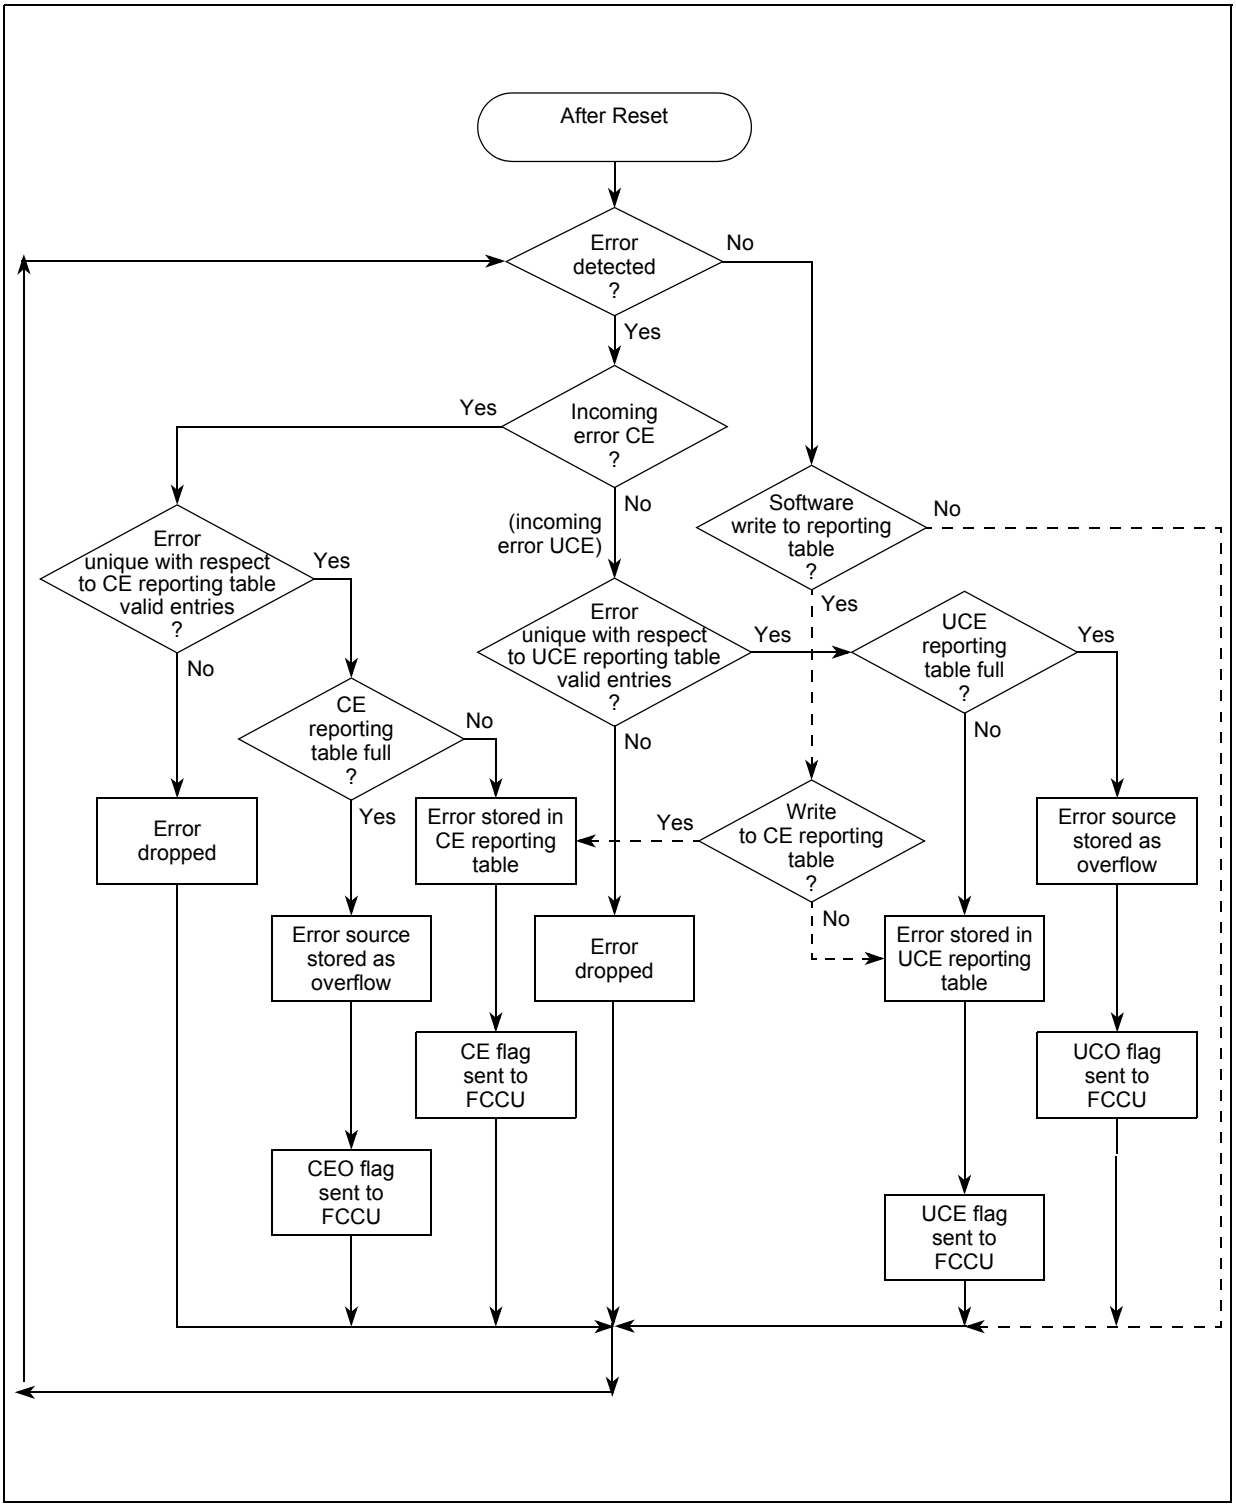


Figure 1819. MEMU reporting table uniqueness check flow chart

78.5 External signal description

MEMU has no external signals.

78.6 Memory map and register definition

78.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit,16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

Table 1734. MEMU memory map

Offset or address	Register	Access	Reset value	Section/ page

0x0628 + (2–1) × 8	Peripheral RAM uncorrectable error reporting table status register (PERIPH_RAM_UNCERR_STS)	R/W	0000_0000	*78.6.2.11/3048*
0x062C + (2–1) × 8	Peripheral RAM uncorrectable error reporting table address register (PERIPH_RAM_UNCERR_ADDR)	R/W	0000_0000	*78.6.2.12/3049*
0x0630 + n × 0x4 + (2–1) × 0x8 (n = 0 to 25÷32 – 1)[1]	Peripheral RAM concurrent overflow registers[1] (PERIPH_RAM_OFLWn)	w1c	0000_0000	*78.6.2.13/3050*
0x0C20 + n × 0x8 (n = 0 to 20–1)	Flash memory correctable error reporting table status registers (FLASH_CERR_STSn)	R/W	0000_0000	*78.6.2.14/3050*
0x0C24 + n × 0x8 (n = 0 to 20–1)	Flash memory correctable error reporting table address registers (FLASH_CERR_ADDRn)	R/W	0000_0000	*78.6.2.15/3051*
0x0C28 + (20–1) × 8	Flash memory uncorrectable error reporting table status register (FLASH_UNCERR_STS)	R/W	0000_0000	*78.6.2.16/3051*
0x0C2C + (20–1) × 8	Flash memory uncorrectable error reporting table address register (FLASH_UNCERR_ADDR)	R/W	0000_0000	*78.6.2.17/3052*
0x0C30 + n × 0x4 + (20–1) × 0x8 (n = 0 to 3÷32 – 1)[1]	Flash memory concurrent overflow registers[1] (FLASH_OFLWn)	w1c	0000_0000	*78.6.2.18/3053*

1. In this calculation, round any fractional result of the division to the next highest integer. For example, if the division is 94 ÷ 32 = 2.9375 or 66 ÷ 32 = 2.0625, round the result to 3.

2. The corresponding error sources for the Concurrent Overflow Register (OFLW) are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

Table 1735. CTRL field descriptions

Field	Description
SWR	Software Reset bit. Setting this will clear status flags and overflow register. However, the reporting table registers are not cleared. This bit will auto clear on next clock cycle. 0 No reset. 1 Reset asserted.

78.6.2.2 Error flag register (ERR_FLAG)

Bits in the ERR_FLAG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO,F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a ‘1’. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Figure 1821. Error flag register (ERR_FLAG)

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 1736. ERR_FLAG field descriptions

Field	Description
PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.

Table 1736. ERR_FLAG field descriptions(Continued)

Field	Description
PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0No Overflow. 1Overflow in the internal error processing buffer detected.
F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module). 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.

Table 1736. ERR_FLAG field descriptions(Continued)

Field	Description
SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – A new System RAM ECC and MBIST uncorrectable error is detected – A new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

78.6.2.3 Debug register (DEBUG)

This register is used to check the connections between MEMU & FCCU.

The error output of the MEMU towards FCCU shall stay set if forced until reset by SW via the MEMU in the normal way.

Field	Description
OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in *Section 78.7.3, Handling overflows (Multiple error reporting)*, occurs.

78.7 Functional description

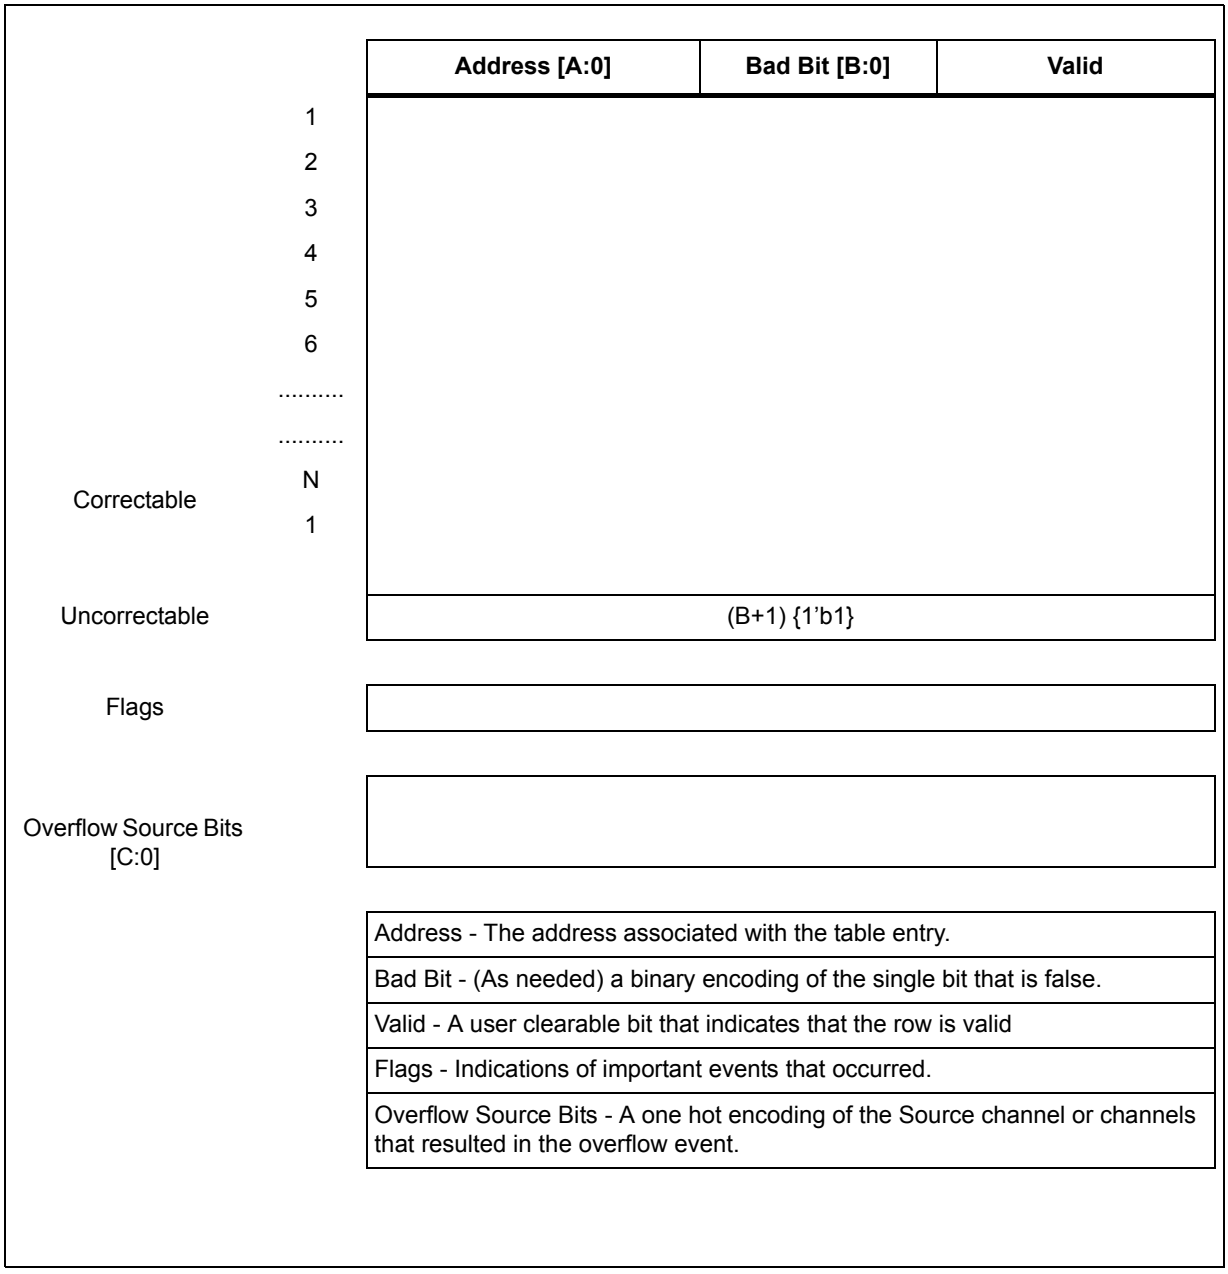
In this section, the term “bad bit” and “syndrome” are equivalent, and are used to indicate the position of the bit in error.

78.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = ‘1’ for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address.The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows:



1) Check that the VLD bit is not set,
2) Write an invalid address/bad bit information,
3) Set VLD bit,
4) Check that the address still has an invalid value,
5) Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 5th step, and the MEMU writes an errorwith the same address that Software wants to program, both the errors will be stored in the reporting table (i.e. duplicate entries).

78.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

Figure 1838. Generic representation of the reporting table of one MEMU reporting block

78.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

a) Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)

– More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow.The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together with two (or more) additional errors at the same cycle it can get flagged as an overflow.

b) Correctable/Uncorrectable Error Overflow–Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).

– An ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.

c) The Overflows will be stored in the bit-wise order i.e., if the error bit 31 reports an error, the bit 31 of the overflow register will be set to ‘1’.

79 Indirect Memory Access (IMA)

79.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading and/or modifying data, including ECC check bits. This capability is useful for test activities, e.g., verifying ECC functionality.

The SPC574Kx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. See the Device Configuration chapter for details.

79.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no back doors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed—I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

79.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control Register (CDACNTL)
- Cache Debug Access Data Register (CDADATA)

These registers are summarized in the following sections.

79.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control Register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

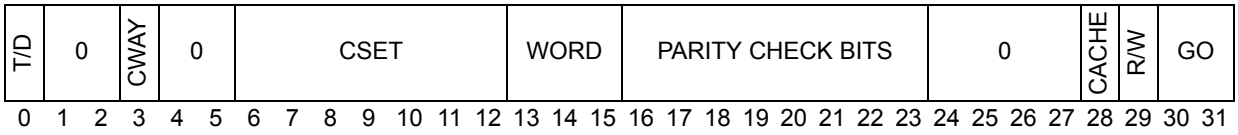


Figure 1839. Cache Debug Access Control Register (CDACNTL)

The CDACNTL bits are described in *Table 1753*.

Table 1753. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1–2	—	Reserved - read as zeros
3	CWAY	Cache Way. Specifies the cache way to be selected
4–5	—	Reserved - read as zeros
6–12	CSET	Cache Set. Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13–15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set
16–23	PARITY CHECK BITS	Parity check bits (I or D-cache) D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24–27	—	Reserved - read as zeros
28	CACHE	Cache Select. Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30–31	GO	GO command bits 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

79.2.1.2 Cache Debug Access Data Register (CDADATA)

The Cache Debug Access Data Register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

TAG or DATA

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

Figure 1840. Cache Debug Access Data Register (CDADATA)

The CDADATA bits are described in *Table 1754*.

Table 1754. CDADATA field descriptions

Bits	Name	Description
0–31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19 Tag compare bits 20–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26–28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0-not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20 Tag compare bits 21–22 Reserved 23 Valid bit 24 R bit 25 SO bit 26 SW bit 27 UW bit 28 Reserved 29–31 Lockout bits. These three bits should have the same value, 1-Locked out, 0-not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23byte 2 24–31byte 3

79.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status Register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

79.2.2.1 e2eECC Error Control/Status Register 0 (E2EECSR0)

The e2eECC Error Control/Status Register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

0	RCHKBIT	0	WRC	INVC	0	WCHKBIT/CHKINVT
0 1 2 3	4 5 6 7 8 9 10 11	12 13 14 15	16 17	18 19	20 21 22 23	24 25 26 27 28 29 30 31

Figure 1841. e2eECC Error Control/Status Register 0 (E2EECSR0)

The E2EECSR0 bits are described in *Table 1755*.

Table 1755. CDACNTL field descriptions

Bits	Name	Description
0–3	—	Reserved - read as zeros
4–11	RCHKBIT	Read Checkbits. This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12–15	—	Reserved - read as zeros
16–17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
18–19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved **Note:** Checkbit substitution has priority over Error injection
20–23	—	Reserved - read as zeros
24–31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask. This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

79.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Please note the following restrictions on memory access via IMA:

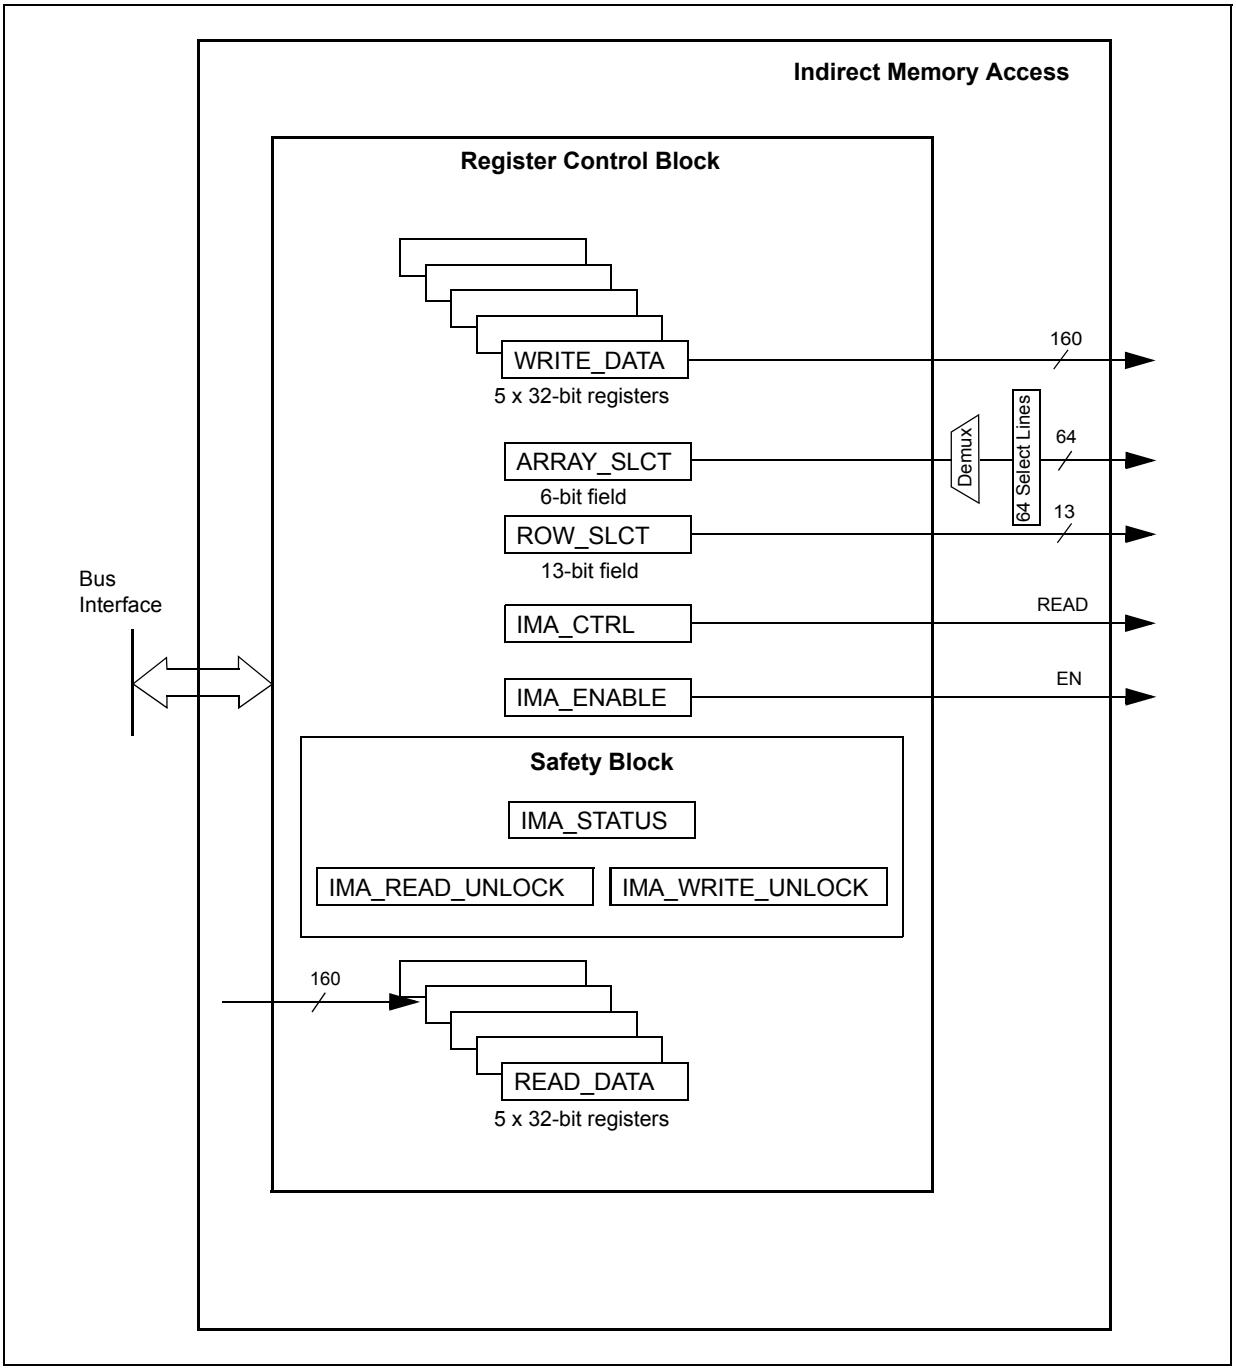
- ECC must be disabled prior to IMA write access. If ECC is enabled and a write access is attempted to ECC-bits, the write access is blocked and an error signal is forwarded to the FCCU and the corresponding error flag is set. Read access is always allowed.
- The IMA must be unlocked for reads

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

79.3.1 Features



The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
  - Reads return random data.
  - Writes have no effect.
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

79.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it to.

Figure 1842. IMA block diagram

79.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 1756. IMA memory map

Offset or Address	Register	Access	Reset Value	Section/Page
0000_0000	IMA Control Register (IMA_CTRL)	R/W(1)	0x0000_0000	*79.3.3.1/3063*
0000_0004	IMA Enable Access Register (IMA_ENABLE)	R/W	0x0000_0000	*79.3.3.2/3064*

0000_0014	IMA Read Unlock Register (IMA_READ_UNLOCK)	R/W	0x0000_0000	*79.3.3.6/3067*
0000_002C	IMA RAM Write Data Register 4 (IMA_WRITE_DATA_4)	R/W	0x0000_0000	*79.3.3.7/3067*
0000_0030	IMA RAM Write Data Register 3 (IMA_WRITE_DATA_3)	R/W	0x0000_0000	*79.3.3.7/3067*
0000_0034	IMA RAM Write Data Register 2 (IMA_WRITE_DATA_2)	R/W	0x0000_0000	*79.3.3.7/3067*
0000_0038	IMA RAM Write Data Register 1 (IMA_WRITE_DATA_1)	R/W	0x0000_0000	*79.3.3.7/3067*
0000_003C	IMA RAM Write Data Register 0 (IMA_WRITE_DATA_0)	R/W	0x0000_0000	*79.3.3.7/3067*
0000_004C	IMA RAM Read Data Register 4 (IMA_READ_DATA_4)	R	0x0000_0000	*79.3.3.8/3068*
0000_0050	IMA RAM Read Data Register 3 (IMA_READ_DATA_3)	R	0x0000_0000	*79.3.3.8/3068*
0000_0054	IMA RAM Read Data Register 2 (IMA_READ_DATA_2)	R	0x0000_0000	*79.3.3.8/3068*
0000_0058	IMA RAM Read Data Register 1 (IMA_READ_DATA_1)	R	0x0000_0000	*79.3.3.8/3068*
0000_005C	IMA RAM Read Data Register 0 (IMA_READ_DATA_0)	R	0x0000_0000	*79.3.3.8/3068*

1. Note that R/W registers may contain some read-only or write-only bits.

79.3.3.1 IMA Control Register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Offset 0x00 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Field	Description
0–30	Reserved
31 READ	IMA Read. This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

79.3.3.2 IMA Enable Access Register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: Back to back writes to the enable bit is not valid. It will still generate a two clock enable pulse and will be considered as a single access initiation.

Offset 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W

Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Figure 1845. IMA Status Register (IMA_STATUS)

Table 1759. IMA_STATUS field descriptions

Field	Description
0–22	Reserved
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
24–30	Reserved
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

79.3.3.4 IMA RAM Select Register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, i.e., accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. See the Device Configuration chapter for details.

Offset 0x0C Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	ROW_SLCT												
W

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1846. IMA RAM SELECT Register (IMA_SLCT)

Table 1760. IMA_SLCT field descriptions

Field	Description
0–2	Reserved
2–15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is an 8 KB word RAM.
16–25	Reserved
26–31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

79.3.3.5 IMA Write Unlock Register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

Offset 0x10 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1761. IMA_WRITE_UNLOCK field descriptions

Field	Description
0–31 WRITE_KEY	Key to unlock the IMA. – 0x04A43F95 is the first key that has to be written to start the unlock process. – 0xE4A9EBF7 is the second key that has to be written to unlock the IMA.

79.3.3.6 IMA Read Unlock Register (IMA_READ_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The READ_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for reads.

Offset 0x14 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

79.3.3.7 IMA RAM Write Data Register n (IMA_WRITE_DATA_n)

The IMA_WRITE_DATA_n registers hold the data values to be written to the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

Offset 0x2C (WRITE_DATA_4)
0x30 (WRITE_DATA_3)
0x34 (WRITE_DATA_2)
0x38 (WRITE_DATA_1)
0x3C (WRITE_DATA_0)

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1763. IMA_WRITE_DATA_n field descriptions

Field	Description
0–31 WRITEn	Contains data to be written to RAM. – WRITE_DATA_4[WRITE_4] contains write data bits[159:128] – WRITE_DATA_3[WRITE_3] contains write data bits[127:96] – WRITE_DATA_2[WRITE_2] contains write data bits[95:64] – WRITE_DATA_1[WRITE_1] contains write data bits[63:32] – WRITE_DATA_0[WRITE_0] contains write data bits[31:0]

79.3.3.8 IMA RAM Read Data Register n (IMA_READ_DATA_n)

The IMA_READ_DATA_n registers hold the data values read from the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_n registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

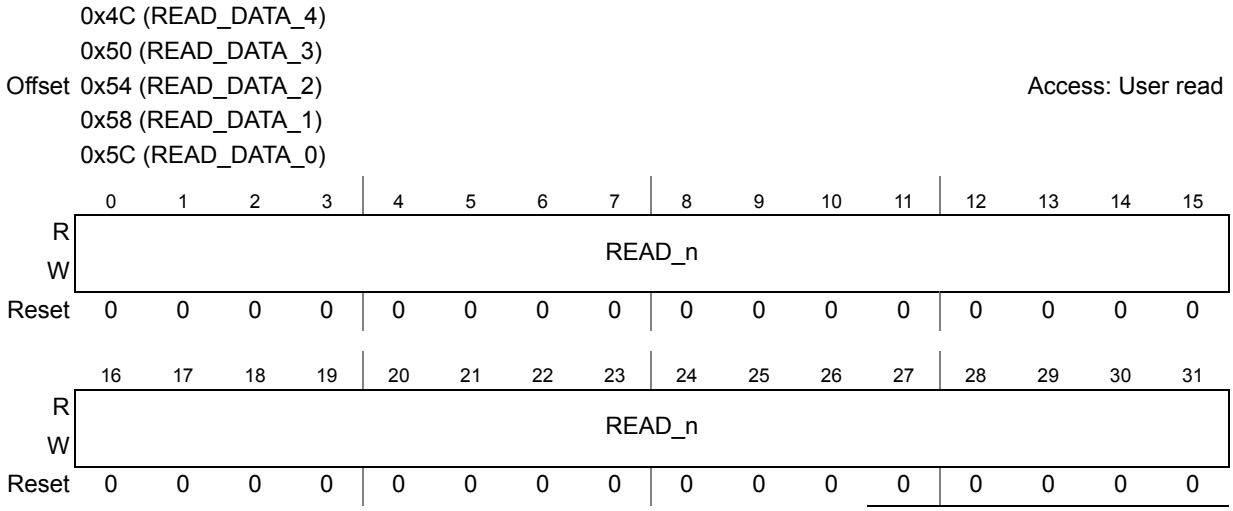

Figure 1850. IMA READ_DATA_n Register (IMA_READ_DATA_n)

Table 1764. IMA_READ_DATA_n field descriptions

Field	Description
0–31 WRITEn	Contains data to be written to RAM. – READ_DATA_4[READ_4] contains read data bits[159:128] – READ_DATA_3[READ_3] contains read data bits[127:96] – READ_DATA_2[READ_2] contains read data bits[95:64] – READ_DATA_1[READ_1] contains read data bits[63:32] – READ_DATA_0[READ_0] contains read data bits[31:0]

79.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

79.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

79.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

79.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Please consult the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

79.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, please read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

79.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY
2. Write 0x14081B56 to READ_KEY

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY

79.3.4.3.3 Unlocking writes

(The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY
2. Write 0xE4A9EBF7 to WRITE_KEY

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

79.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY

based locking method. However, usage of this feature is entirely SOC specific.

79.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[READ] has to be cleared for writes.

The following sections shows the different accesses that are available depending on the options.

79.3.4.5.1 Read access

Read Accesses are to expected to follow the sequence below

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

79.3.4.5.2 Write access

Write Accesses are to expected to follow the sequence below

1. Unlock Write Access by performing appropriate consecutive writes to WRITE_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

79.3.5 Application information

Warning: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

80 Fault Collection and Control Unit (FCCU)

80.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (e.g. RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal reactions (independently configurable for each RF):
  - No reset reaction
  - IRQ
  - Short functional reset
  - Long functional reset
  - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- Watchdog timer for the reconfiguration phase
- The FCCU's configuration is lockable in two ways:
  - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (ie., other than 0XBC). Key to lock the FCCU permanently is 0XFF, written in the FCCU_TRANS_LOCK register.
- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol i.e. dual rail and time switching.
- After power-on the error out pins have high impedance[w]. FCCU goes to operational state only on software request.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only). T_min = 250 µs + delta_T, with delta_T parameter being configurable by SW up to 10 ms.
- The overall error detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 safe (IRCOSC) clock cycles.

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for

w. Actual value depends on the SoC settings at pad level

application/test/debugging purposes. FCCU is designed for assuming that the system clock is faster then IRC clock.

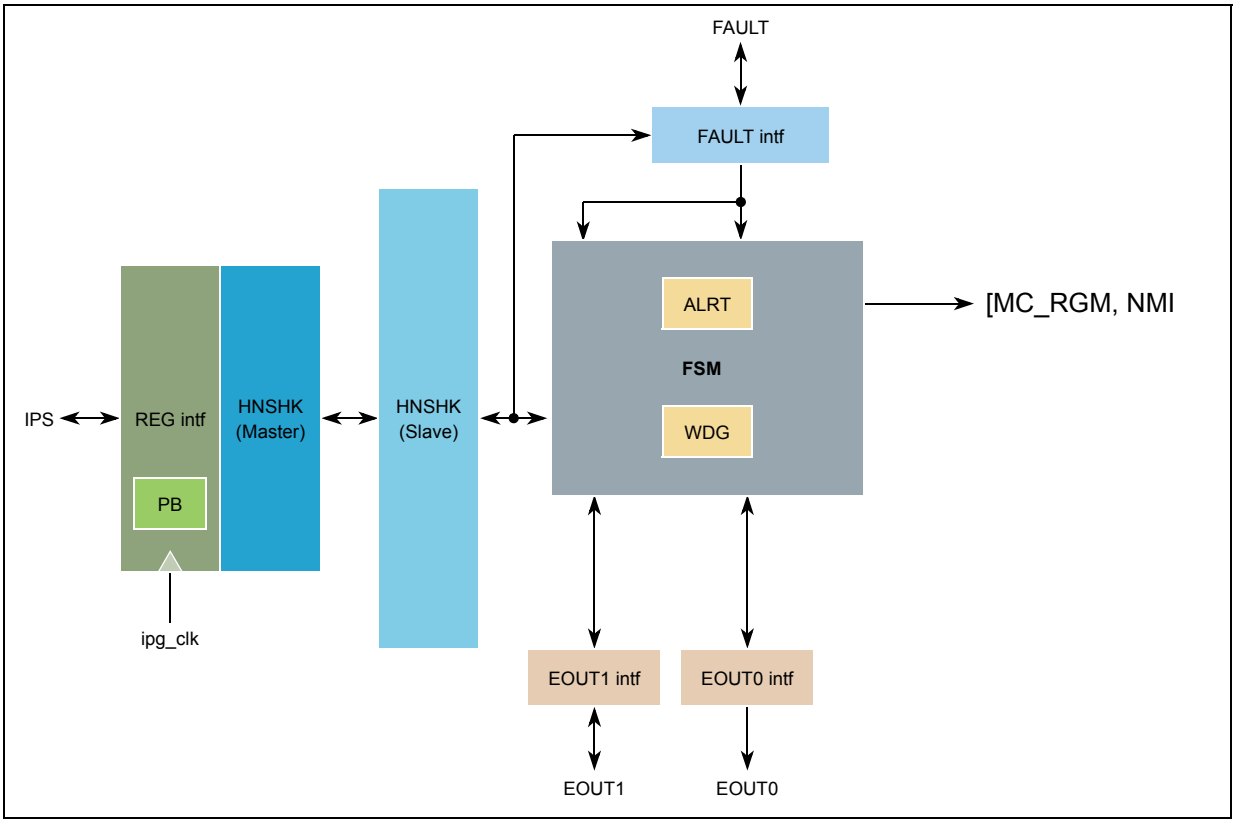
80.1.1 Acronyms and abbreviations

Table 1765. Acronyms and abbreviations

Term	Description
UF	Unrecoverable fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC	MC_CGM, MC_ME, MC_PCU, and MC_RGM modules
RF	Recoverable fault
NMI	Non-maskable interrupts
NVM	Nonvolatile memory
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

80.2 Main features

- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; see the implementation-specific details)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU.
- Internal (SoC) reactions (alarm state): interrupt request
- Internal (SoC) reactions (fault state): long functional reset request pulse, short functional reset request pulse, NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Configuration lock



80.2.1 Standard features

- IPS (slave bus signals) bus interface

80.3 Block diagram

The top-level diagram of the FCCU module is given in *Figure 1851*.

Figure 1851. FCCU block diagram

The FCCU module includes the submodules listed in *Table 1766*.

Table 1766. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: – Watchdog timer (WDG) – Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

80.4 Signal description

80.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in *Section 80.5.9: EOUT interface*.

For the availability of these signals on a chip, see the device configuration chapter.

80.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the register address space of the peripheral. Note that if some registers are not implemented (e.g. FCCU_CFS_CFGx registers), they generate no bus transfer error when accessed in writing.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access executed on configuration registers, when the fccu is not in the CONFIG state. Configuration registers are those registers which can be written only in CONFIG state. Please see *Table 1775*.
- any write executed on FCCU_CFG_TO register, when the fccu is in the CONFIG state.
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

80.5 Functional description

80.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is ‘0’. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in a external module at the FCCU. The FCCU state transitions are

consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.

- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

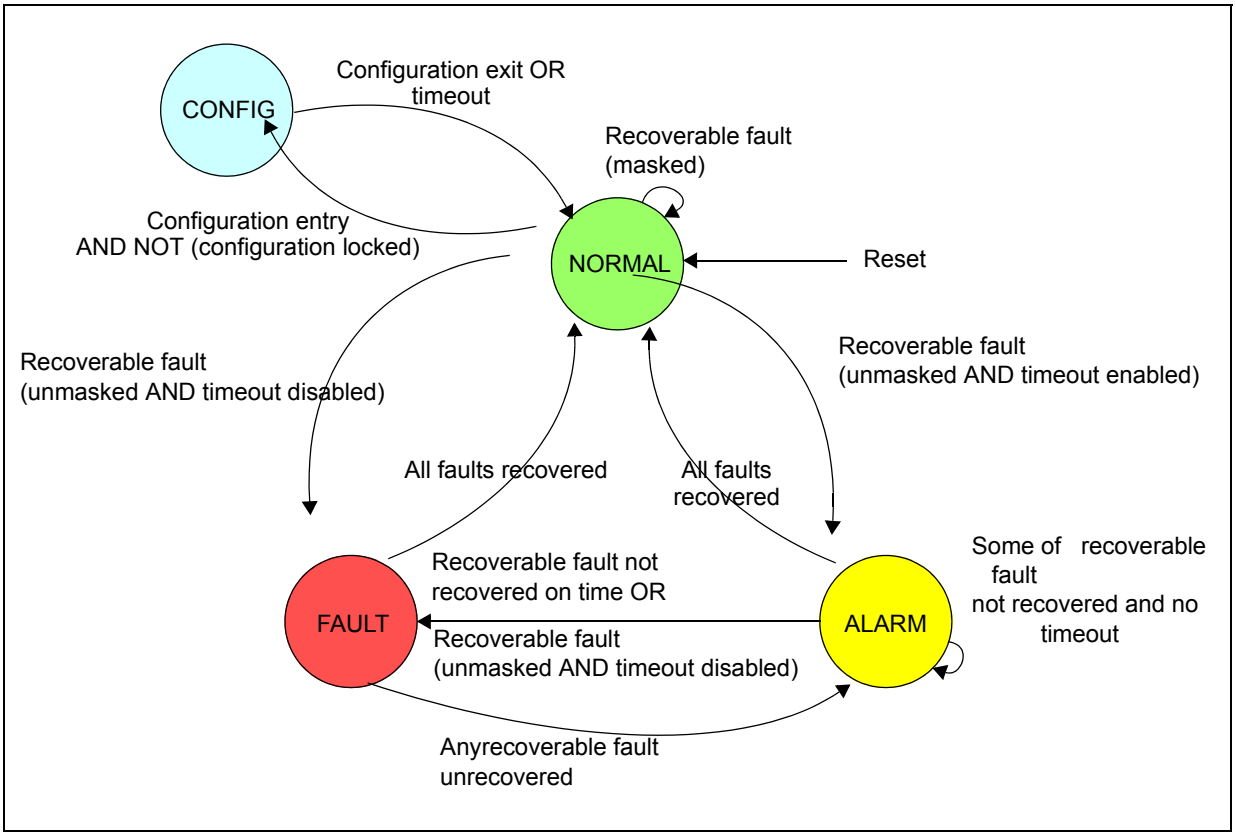
80.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in *Figure 1852*.

Basically four states are identified with the following meaning:

- CONFIG: The configuration state is used only to modify the default configuration of the FCCU. A sub-set of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, time-out, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
  The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (ie., other than 0XBC). Key to lock the FCCU permanently is 0XFF, written in the FCCU_PERMNT_LOCK register.After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
  The CONFIG to NORMAL state transition can be executed by SW or automatically following a time-out condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writeable only in CONFIG mode) are reset to their default values. Also, FCCU_CFG_TO and FCCU_EINOUT are reset to their default values, although they do not meet the condition of being a configuration register. The movement to NORMAL is made.
  The incoming faults, occurring during the configuration phase (CONFIG state) are

anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.



- NORMAL: This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following one of the following events:
  - unmasked recoverable faults with the time-out disabled → the FCCU moves to the FAULT state
  - unmasked recoverable faults with the time-out enabled → the FCCU moves to the ALARM state
  - masked recoverable faults → the FCCU stays in NORMAL state
- ALARM: the FCCU moves into the ALARM state when a unmasked recoverable fault occurs and the time-out is enabled. The transition to the ALARM state goes along with an interrupt (irq_alarm), if enabled. By definition, this fault may be recovered within a programmable time-out period, before it generates a transition to the FAULT state. The time-out is re-initialized if the FCCU state moves to the NORMAL state. The time-out restarts following the recovery from the FAULT state.
- FAULT: the FCCU moves into the FAULT state when one of the following condition occurs:
  - time-out related to a recoverable fault when the FCCU is in the ALARM state
  - unmasked recoverable faults with the time-out disabled

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 1852. FCCU state diagram

80.5.3 Reset interface

The FCCU has two input resets, as described in *Table 1767* and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In *Table 1768* for each type of fault reaction (hard, soft or self-checking), the respective output reset (rst_lfunc_b, rst_sfunc_b) is activated. In *Table 1769* for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit is responsible to generate the corresponding input reset as described in *Table 1768* and *Table 1769*. *Table 1768* and *Table 1769* describe a typical reset strategy at system level. *Table 1770* summarizes the MC actions corresponding to each reset generated by FCCU.

Table 1767. Input reset

Input reset	Description
ipg_hard_asynch_rst_clk_b	Global reset of the FCCU (synchronous to the system clock)
ipg_hard_asynch_rst_clk_safe_b	Global reset of the FCCU (synchronous to the IRCOSC)

Table 1768. Reset reactions

FAULT reaction	Active reset	ipg_hard_asynch_rst_*_b
Hard	rst_lfunc_b	disabled
Soft	rst_sfunc_b	disabled

Table 1769 shows the Reset sources.

Table 1769. Reset sources

Reset source	ipg_hard_asynch_rst_*_b
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 1770. MC actions

Active reset	MC action
rst_lfunc_b	Long functional reset (FLASH + digital modules excluded FCCU, STCU)
rst_sfunc_b	Short functional reset (digital modules excluded FCCU, STCU)

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for 2 IRCOSC clock periods.

80.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (and recoverable) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a recoverable fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any recoverable fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the recoverable faults that causes a ALARM to FAULT state transition. In this case the NCT timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

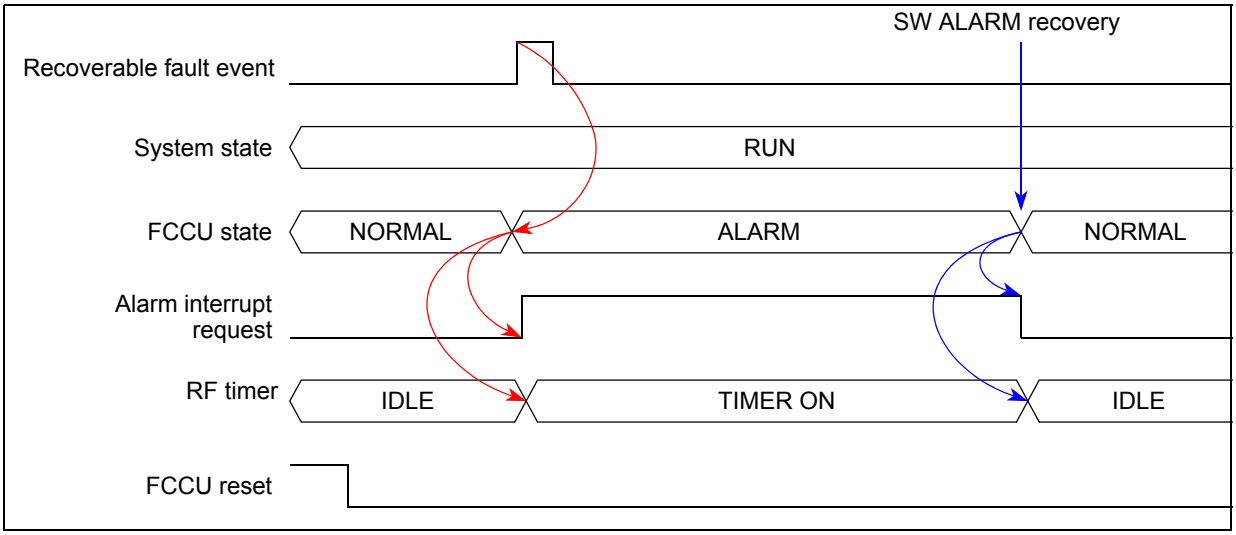
80.5.5 Fault recovery

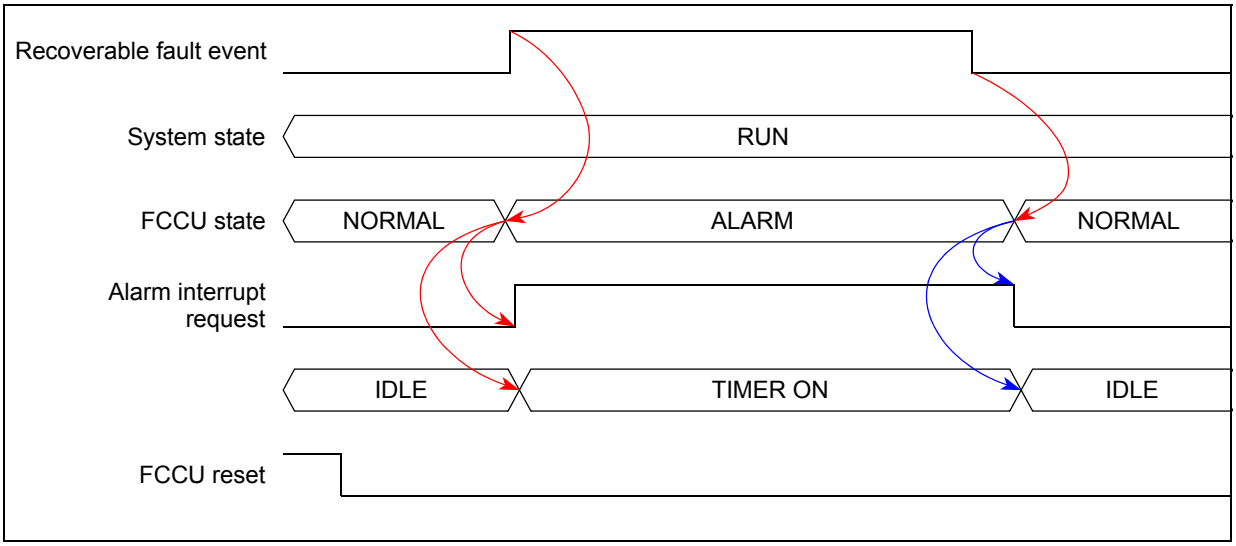
The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a recoverable FAULT management (ALARM state), see *Figure 1853* and *Figure 1854*, is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if configured)
  - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)—FCCU state transition ALARM → NORMAL

Figure 1853. Recoverable FAULT (ALARM state) recovery (a)





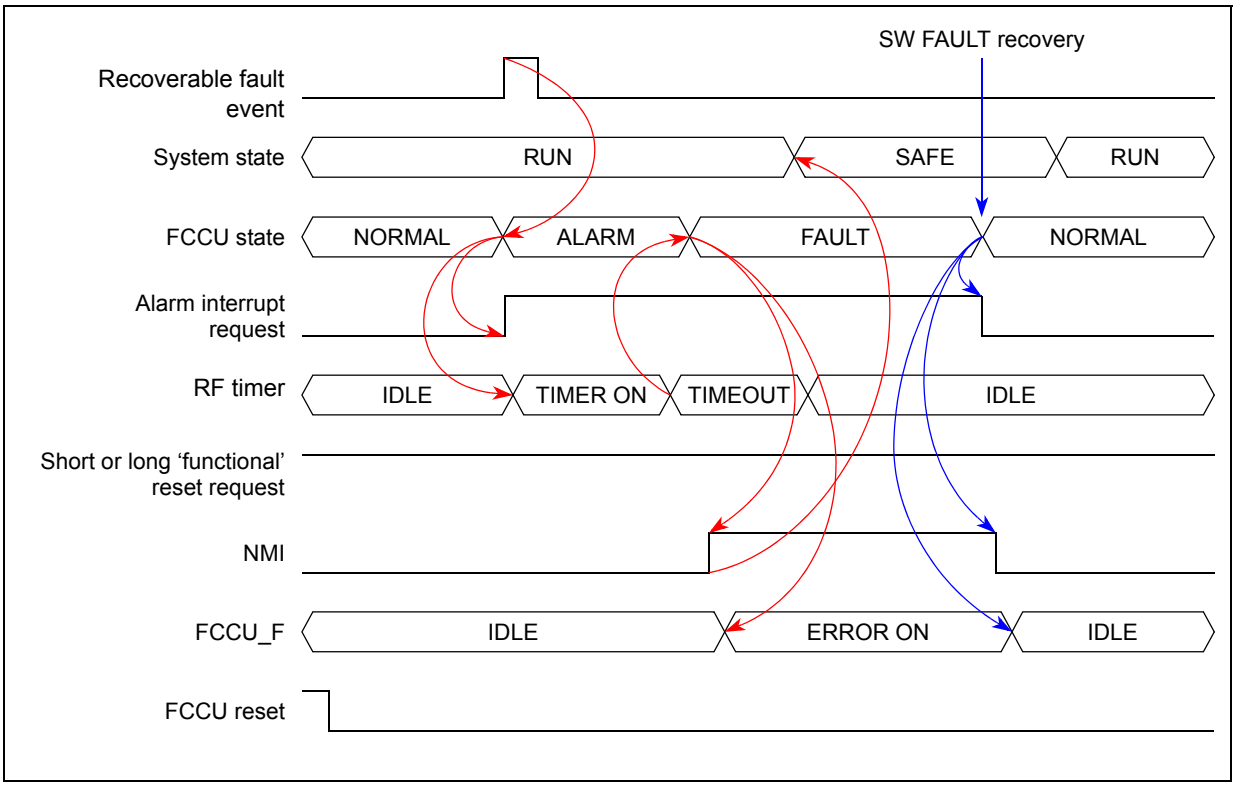


Figure 1854. Recoverable FAULT (ALARM state) recovery (b)

A typical sequence related to a recoverable FAULT management (ALARM → FAULT state), see *Figure 1855*, is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
  - alarm interrupt request (if enabled)
  - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT — xNMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)
  - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
  - system state transition: SAFE → RUN

Figure 1855. Recoverable FAULT (ALARM -> FAULT state) recovery

80.5.6 NMI interface

The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (mc_state[3:0]) = RESET

and unmasked when a SW change request of the MC state is triggered (sw_mode_change_req = 1).

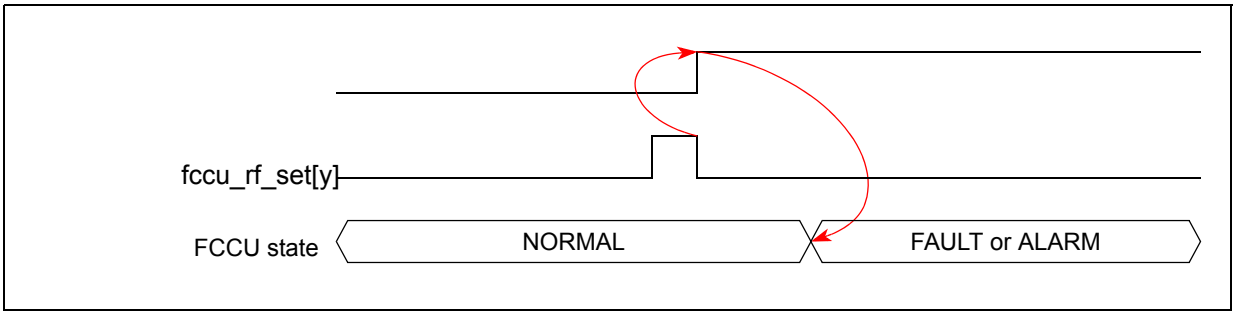
80.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple programmable edge sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism, in order to generate fake faults directly in the FAULT root, an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1856*. The fault injection is executed by a write operation in the FCCU_RFF register. The reaction following a fake recoverable fault cannot be masked. The fault injection mechanism is optional; see the implementation-specific details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (fccu_rf_clr[]) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in *Figure 1857*. The fault clearing is executed when the SW “clears” the status (flag) bits of the FCCU_RF_Sx. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 1856. FAULT injection



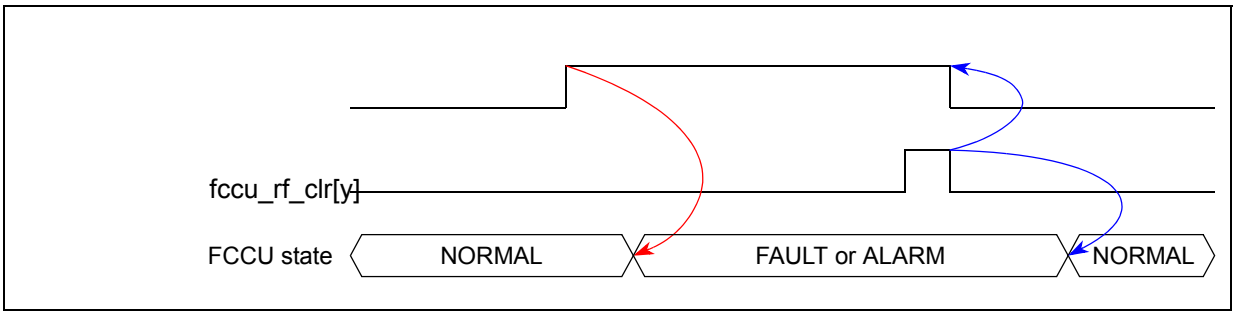


Figure 1857. FAULT clearing

80.5.8 STCU interface

The STCU interface includes:

- a set of signals resulting from the self-checking procedure connected externally at these FCCU faults:
  - recoverable

  The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- a mask (fccu_eout_msk[1:0]) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

a) STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible to provide a reaction.

b) STCU completes the self testing procedure with low severity failures. The FCCU is responsible to provide the proper reactions according to the fault occurred.

c) STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 1858. STCU-FCCU (case a)

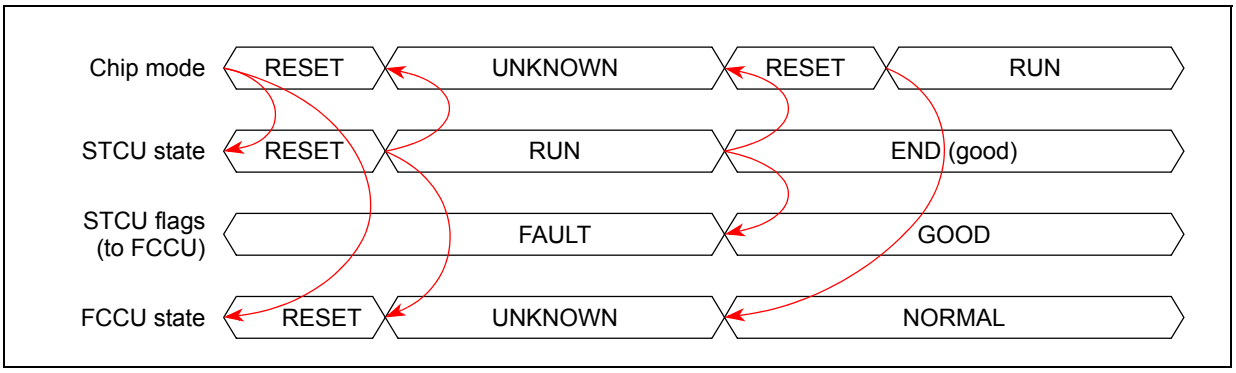

Figure 1859. STCU-FCCU (case b)

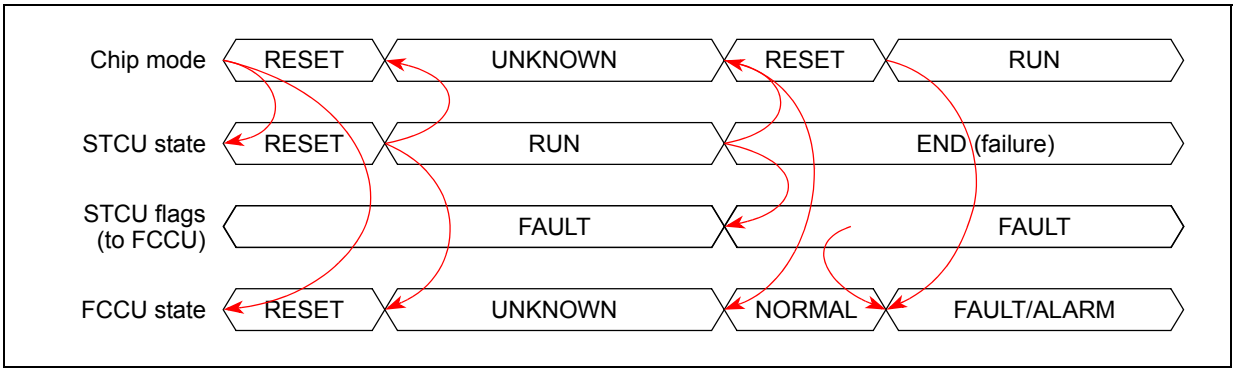

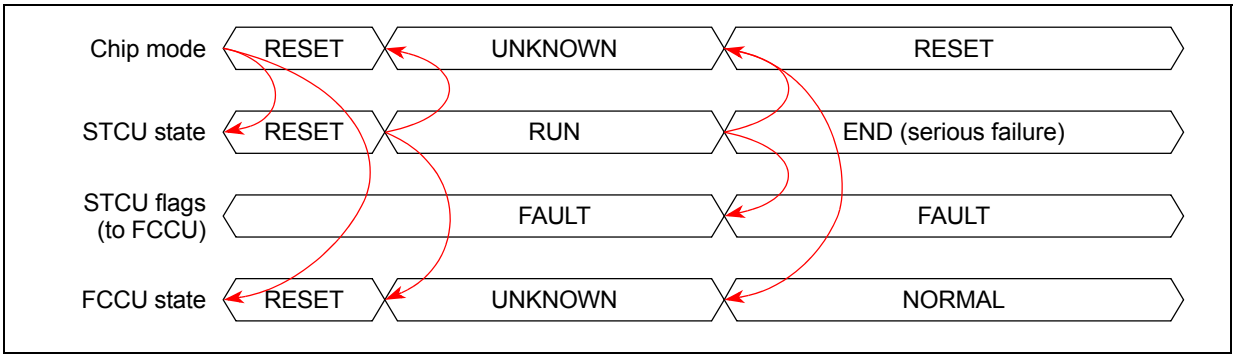

Figure 1860. STCU-FCCU (case c)

80.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (see table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z only when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic '0'). The selection to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS fields in the FCCU_CFG register. For example, for PS = 0, fcc_eout[0] = 0 and fcc_eout[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual-rail or time-switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to ERROR or viceversa and CONFIG to NORMAL). The EOUT protocol transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.
- fast switching mode: The EOUT protocol transition (NORMAL to ERROR or viceversa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occurs in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18}. With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual-rail or time-switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK ie. an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset and software bit FCCU_RST in RGM_PRST5 should not influence the state of the failure indication ie pins.

Note: The transition from error to config state is not possible but is shown to display the behavior in all four states — reset, normal, error, and config.

Table 1771. FCCU error pin behavior on STATE transitions(1)

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled | enabled						with Fault disabled | enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA | OK	NA | 1	NA | OK	OK	1	OK	NA | OK	NA | 1	NA | OK
Enabled	NA | NOK	NA | 1	NA | NOK	OK	1	OK	NA | OK	NA | 1	NA | OK

1. Table valid only after SW has written fccu_set_after_reset bit to 1.

Note: FCCU remains in NORMAL state when fault is disabled hence, "NA" (Not Applicable) appears in the above table.

80.5.9.1 Dual-rail protocol

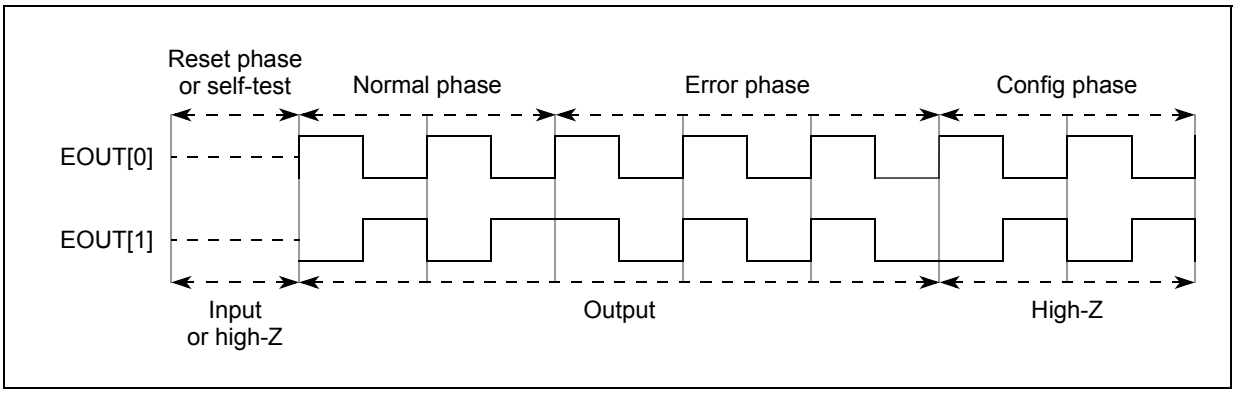
Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in *Table 1772* and the related timing diagram is given in *Figure 1861* and *Figure 1862*.

Table 1772. Dual-rail encoding

Logical state	Dual-rail encoding (output pins fccu_eout[1:0])	Note
non-faulty	10	toggling
non-faulty	01	

Table 1772. Dual-rail encoding(Continued)

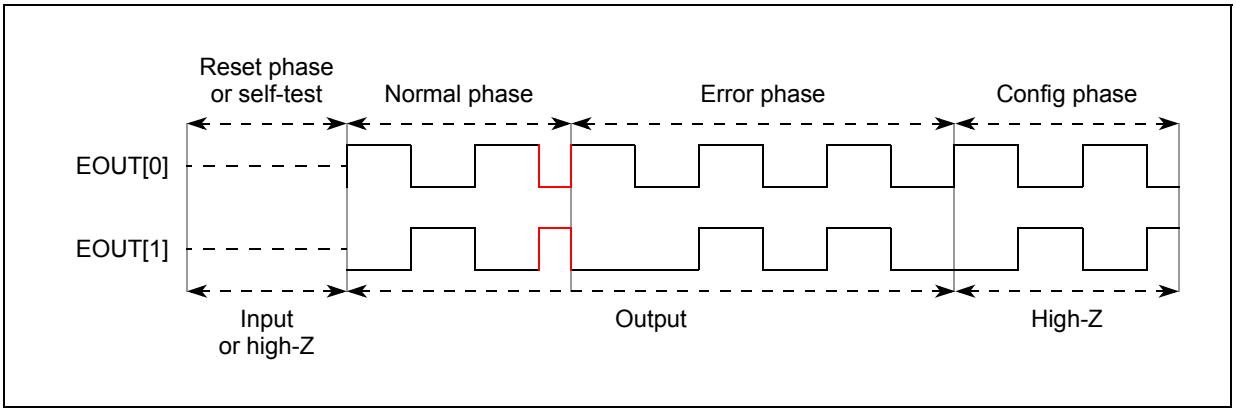
Logical state	Dual-rail encoding (output pins fccu_eout[1:0])	Note
faulty	00	toggling
faulty	11	
reset	Hi impedence(1)	no toggling
configuration	same as NORMAL(2)	toggling



1. Final value depends on the SoC settings at pad level
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, output will show “non-faulty” signal. Output pins #0, #1 will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as “high impedance”(x).



Note: Figure 1861 and Figure 1862 are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 1861. Dual-rail protocol (slow switching mode)

x. Actual value depends on the SOC settings at pad level

Figure 1862. Dual-rail protocol (fast switching mode)

80.5.9.2 Time-switching protocol

The encoding scheme is given in *Table 1773* and the related timing diagram is given in *Figure 1863*.

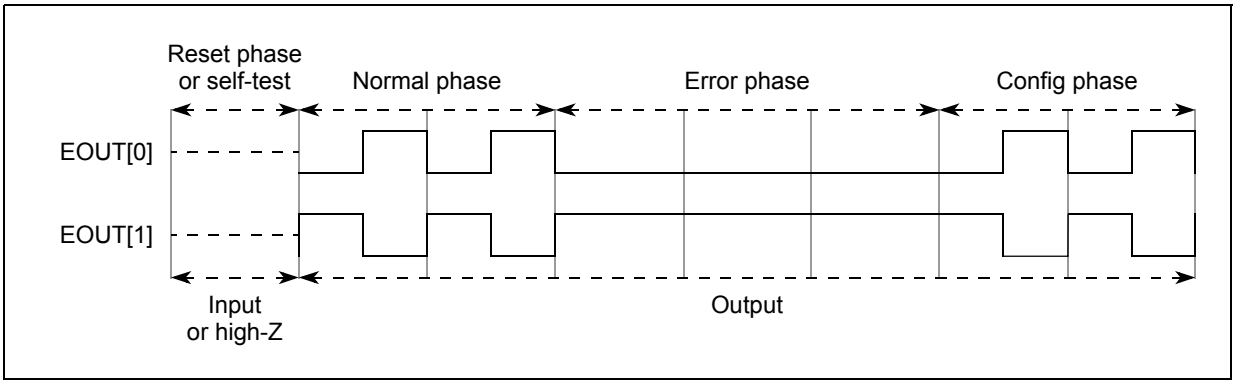
Table 1773. Time-switching encoding

Logical state	Time-switching encoding (output pins fccu_eout[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z (1)	no toggling
configuration	same as NORMAL(2)	toggling

1. Final value depends on the SOC settings at pad level
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.

As long as FCCU is in NORMAL or ALARM state, outputs will show “non-faulty” signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin fccu_eout[0] is set as low.



In Time Switching mode the second output (fccu_eout[1]) is the inverted signal of first output (fccu_eout[0]).

In the RESET phase the output pins are set as “high impedance”(y).

Note: Figure 1863 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

y. Actual value depends on the SOC settings at pad level

Figure 1863. Time-switching protocol

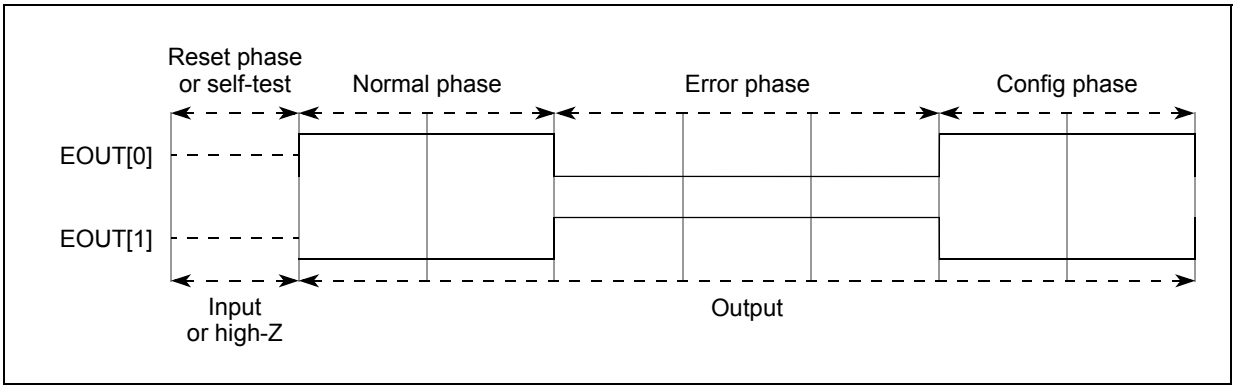
80.5.9.3 Bi-stable protocol

The encoding scheme is given in *Table 1774* and the related timing diagram is given in *Figure 1864*.

Table 1774. Bi-stable encoding

Logical state	Bi-stable encoding (output pins fccu_eout[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z (1)	no toggling
configuration	same as NORMAL(2)	no toggling

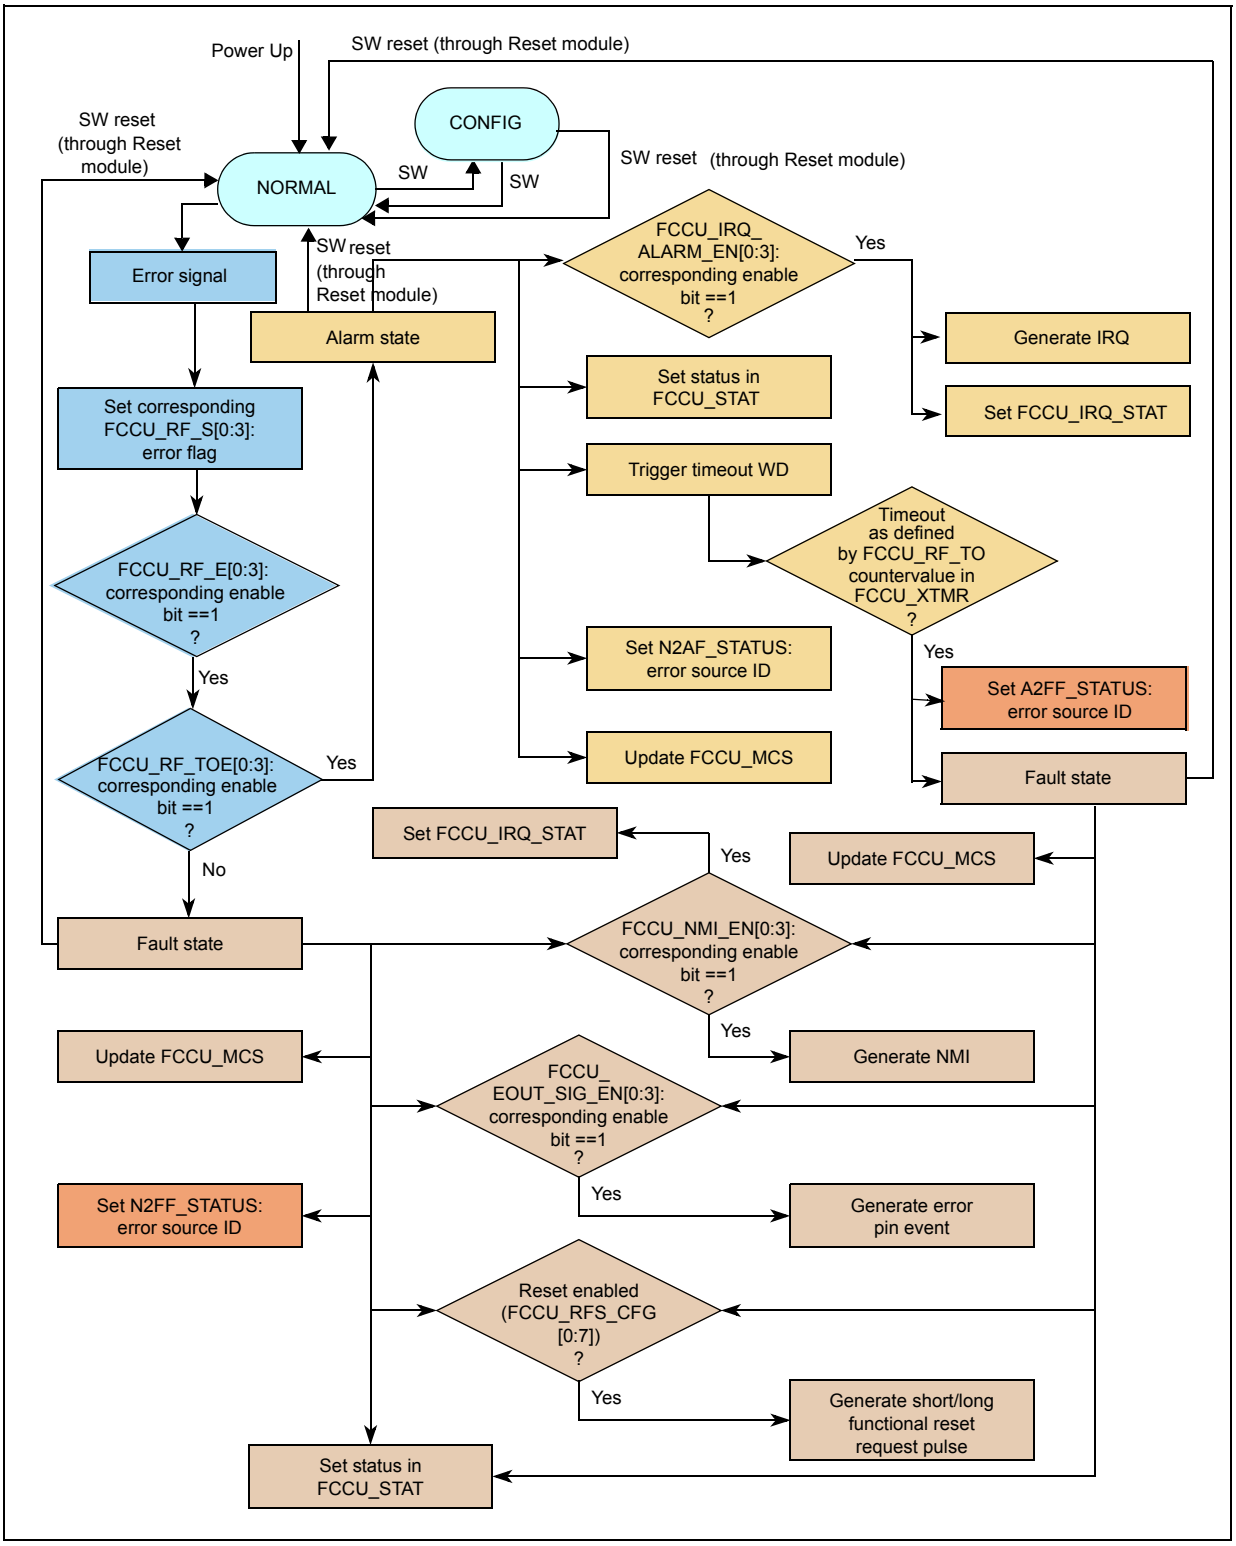
1. Final value depends on the SOC settings at pad level
2. Till FCCU_SET_AFTER_RESET is written, the Error indicating pads are driven to High impedance from FCCU's side. That bit is write-able only after the FCCU enters CONFIG state. Hence on entry to CONFIG state, user may still see high impedance.



In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (fccu_eout[1]) is the inverted signal of first output (fccu_eout[0]).

In the RESET phase the output pins are set as “high impedance”(z).

Note: Figure 1864 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.



z. Actual value depends on the SOC settings at pad level

Figure 1864. Bi-stable protocol

80.5.10 Error signal flow for RF case

Figure 1865. Error signal flow

80.6 Register description

The FCCU registers are listed in *Table 1775*. Any address offset not explicitly mentioned in *Table 1775* is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the *Table 1775*) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

Table 1775. FCCU register set

2. No-Saf = Not Safety Relevant, Saf-Relv = Safety Relevant, Saf-Lat = Safety Latent.

80.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state
- moving the FCCU state from the CONFIG state into the NORMAL state
- reading or to clear the RF status register
- reading the FCCU FSM status register
- reading or to clear the FCCU freeze registers
- reading the ALARM timer
- reading the Watchdog timer
- configure the glitch filter present on location given by FILTER_POSITION parameter

Some critical operations requires a key as defined in the FCCU_CTRLK register.

DEBUG	Debug mode entry 0: Normal operation 1: Put FCCU into debug mode When ipg_debug signal is asserted and this bit is set, FCCU moves into debug state and FCCU's FSM remains in the same state.

Table 1776. FCCU_CTRL field descriptions(Continued)

Field	Description
OPS	Operation status 00: Idle 01: In progress 10: Aborted 11: Successful This bit can be read and cleared (via OP15 operation) by the software.

Table 1776. FCCU_CTRL field descriptions(Continued)

Field	Description
OPR	*Operation run* 00000: No operation [OP0] 00001: Set the FCCU into the CONFIG state [OP1] 00010: Set the FCCU into the NORMAL state [OP2] 00011: Read the FCCU state (see the FCCU_STAT register) [OP3] 00100: Read the FCCU frozen status flags (see the N2AF_STATUS register) [OP4] 00101: Read the FCCU frozen status flags (see the A2FF_STATUS register) [OP5] 00110: Read the FCCU frozen status flags (see the N2FF_STATUS register) [OP6] 00111: Read the FCCU frozen status flags (see the F2AF_STATUS register) [OP7] 01000: Read the FCCU frozen status flags (see the FCCU_SCFS register) [OP8] 01001: Reserved 01010: Read the RF status register (see the FCCU_RF_S register) [OP10] 01011: Reserved 01100: RF status clear operation in progress (see the FCCU_RF_S register) [OP12] 01101: Clear the freeze status registers (see the freeze registers) [OP13] 01110: CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111: Clear the operation status (OPS=Idle) [OP15] 10000: Reserved 10001: Read the ALARM timer (see the FCCU_XTMR register) [OP17] 10010: RESERVED 10011: Read the CFG timer (see the FCCU_XTMR register) [OP19] 10100: Read the Error Pin low counter value (see *Section 80.6.21: FCCU XTMR Register (FCCU_XTMR)*) [OP20] 10101–11111: Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state /= NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution

80.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: There should not be any other operation in between the above steps.

The FCCU_CTRLK register is not readable, a 0000_0000h value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

1 Writable only in the CONFIG state.

Figure 1868. FCCU Configuration Register (FCCU_CFG)

Table 1778. FCCU_CFG field descriptions

Field	Description
FCCU_SET_ AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0: FCCU's Error indication stops functioning and error pins are in HI-Z state(1). 1: write to start FCCU functioning. After power-on the error out pins shall be in high impedance[1]. They will go to normal state only on software request ie. this bit is set to '1'. It is SW's responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
FCCU_SET_ CLEAR	Error pin state can be controlled by these bits 01: Error Pin goes in Faulty state. 11 write: Error Pin goes OK state (write not possible when FCCU already in the T min timer phase or if FSM enters in FAULT state by capture of a fault. 00, 10: FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z[1]. Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM except for the case of '11' mentioned above. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state.
OD	Open Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s) 0: push-pull 1: OD

Table 1778. FCCU_CFG field descriptions(Continued)

Field	Description
SM	*Switching mode* 0: EOUT protocol (dual-rail, time-switching) slow switching mode. 1: EOUT protocol (dual-rail, time-switching) fast switching mode. SM has no effect on the bi-stable protocol.
PS	*Polarity selection* 0: fcc_eout[1] active high, fcc_eout[0] active low 1: fcc_eout[1] active low, fcc_eout[0] active high This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non-toggling in Error phase.
FOM	*Fault Output Mode selection* 000: Dual-Rail (default state) [fccu_eout[1:0]= outputs] 001: Time Switching [fccu_eout[1:0]= output to be used] 010: Bi-Stable 011: Reserved 100: Reserved 101: Test0 (controlled by FCCU_EOUT register) [fccu_eout[0]= input, fccu_eout[1]= output] 110: Test1 (controlled by FCCU_EOUT register) [fccu_eout[0]= output, fccu_eout[1]= output] 111: Test2 (controlled by FCCU_EOUT register) [fccu_eout[0]= output, fccu_eout[1]= input] **Note:** In Test*x* mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.

1. Actual value depends on the SOC settings at pad level.

80.6.4 FCCU RF Configuration Registers (FCCU_RF_CFG[0:3])

The FCCU_RF_CFGx registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

Offset: 01Ch–28h (4 registers) Access: User read/write[1]

28h	FCCU_RF_CFG3	RFC[127:96]

80.6.5 FCCU RFS Configuration Registers (FCCU_RFS_CFG[0:7])

The FCCU_RFS_CFGx registers contain the configuration of each recoverable fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

These registers are writable only in the CONFIG state.

Offset: 04Ch–068h (8 registers) Access: User read/write[1]

80.6.6 FCCU RF Status Register (FCCU_RF_S[0:3])

The FCCU_RF_Sx register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for theRF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the time-out (FCCU_TO register) is elapsed before to recovery the fault.

The time-out is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register.
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_RF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (see *Section 80.5.7: FAULT interface*).

Note: There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_RF_Sx register.

In case of reconfiguration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_RF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

Offsets: 080h–08Ch (4 registers) Access: User read/write

8Ch	FCCU_RF_S3	RFS[127:96]

80.6.7 FCCU RF Key Register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_Sx register.

The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register.
2. Clear the status (flag) bit RFSx.

The key must be written for each FCCU_RF_Sx clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0000_0000h value is always returned in case of read operation.

80.6.8 FCCU RF Enable Registers (FCCU_RF_E[0:3])

The FCCU_RF_Ex registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_Sx register is anyway set (for debugging purposes), only the reaction is masked.

These registers are writable only in the CONFIG state.

Offsets: 094h–0A0h (4 registers) Access: User read/write[1]

98h	FCCU_RF_E1	RFE[63:32]
9Ch	FCCU_RF_E2	RFE[95:64]
A0h	FCCU_RF_E3	RFE[127:96]

80.6.9 FCCU RF Timeout Enable Registers (FCCU_RF_TOE[0:3])

The FCCU_RF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFEx and RFTOEx are set). In case the respective time-out is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFEx is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the time-out value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

Offsets: 0A4h–0B0h (4 registers) Access: User read/write[1]

A4h	FCCU_RF_TOE0	RFTOE[31:0]
A8h	FCCU_RF_TOE1	RFTOE[63:32]
ACh	FCCU_RF_TOE2	RFTOE[95:64]
B0h	FCCU_RF_TOE3	RFTOE[127:96]

80.6.10 FCCU RF Time-out Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state. The alarm time-outs value should be programmed less than the FOSU_COUNT, else destructive resets may be generated by FOSU time-out.

This register is writable only in the CONFIG state.

Field	Description
TO	*Recoverable fault timeout* $\text{Timeout} = (\text{TO}) \times T_{\text{RC16MHz}}$

80.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the time-out, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for all the configuration register is restored. Configuration registers are those registers which can be written only in CONFIG state. Please see *Table 1775*. The watchdog time-out is clocked with the RC oscillator clock (16 MHz). The default time-out value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog time-out the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

80.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the fccu_eout[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the fccu_eout[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the fccu_ein[1:0] inputs level

Table 1792 shows Bi-stable encoding.

Table 1792. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

EOUT0	*Error out 0 (significative only if the FCCU_CFG.FOM = Test1 or Test2 => fccu_eout[0] configured in output mode)* 0: force fccu_eout[0] = 0 1: force fccu_eout[0] = 1 The EOUT0 set/clear the respective fccu_eout[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a “don’t care” value.

80.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine (FSM) operates by the RC oscillator clock (ipg_clk_safe) asynchronous with the system clock (ipg_clk). The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

Figure 1878. FCCU Status Register (FCCU_STAT)

Table 1794. FCCU_STAT field descriptions

Field	Description
ESTAT	Current Error Pin Status. SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in non-faulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0: System is OPERATIONAL (OK). 1: System is in FAULT state.This state is taken from the FCCU Eout logic (ie., as late as possible).
PhysicErrorPin	PhysicErrorPin: Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0 1: Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol.
STATUS	FCCU Status 000: NORMAL state 001: CONFIG state 010: ALARM state 011: FAULT state Other: UNKNOWN state

80.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the "recoverable" source (fccu_rf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

80.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the time-out trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

80.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a “ recoverable fault” in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in *Section 80.5.7: FAULT interface*. The reaction following a fake recoverable fault cannot be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

80.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration time-out error
- Alarm interrupt
- NMI interrupt

The external interrupt line “irq_misc” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

80.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

ETMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it goes high at the end of the T_min period from the last fault trigger.

The SW application executes the timer read operation by the following sequence:

1. Set any of the following operations into the FCCU_CTRL.OPR field:
   – OP17
   – OP19
2. OP20Wait for the completion of the operation (FCCU_CTRL.OPS field)
3. Read the FCCU_XTMR register

Table 1802 shows Timer state/value.

Table 1802. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count

Table 1803. FCCU_XTMR field descriptions

Field	Description
XTMR	Alarm/Watchdog/Safe request timer The current timer value is measured in IRCOSC clock cycles. These bits can be read by the software.

80.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in

the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

Offset: 0ECh Access: User read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1887. FCCU MCS Register (FCCU_MCS)

Table 1804. FCCU_MCS field descriptions

Field	Description
VLx	Valid It indicates that the correspondent MCSx and FSx fields are valid. 0: MCSx, FSx fields are not significative 1: MCSx, FSx fields are significative
FSx	Fault status It indicates that the correspondent MCSx field has been captured when the FCCU is in FAULT state. 0: MCSx field captured in any state different from the FAULT state 1: MCSx field captured in FAULT state
MCSx	MCSx: *State of MC modules* The MCSx is the state of MC modules. MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual.

80.6.23 FCCU Transient Register (FCCU_TRANS_LOCK)

The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.

Offset: 0F0h Access: Supervisor write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

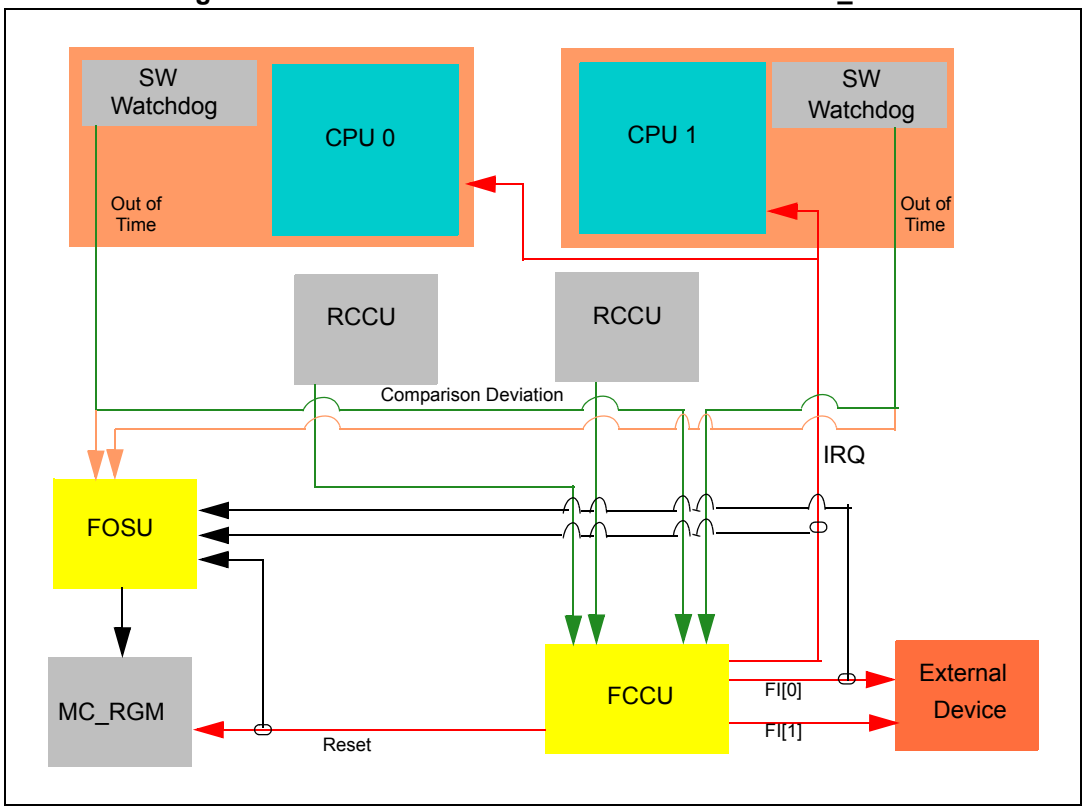
80.8 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (i.e., FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a "static" input in the sense that it does not change after FCCU configuration. This signal is automatically de-asserted whenever the FCCU moves to CONFIG state and hence FOSU shall not be able to monitor faults occurring in CONFIG state. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted (that is, an enabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state. Also, the case of a continuously incoming disabled fault being enabled later, is not monitored.

The FOSU contains a timer with a duration of FOSU_COUNT,driven by the IRCOSC.The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one for the faults which occurred):



- Reset : Long or short functional reset
- IRQ : NMI or Alarm
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still ‘stuck’ in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static “fccu program to do nothing” signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indicator output is connected to one of the MC_RGM's ‘destructive’ reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU (ipg_hard_asynch_rst_clk_safe_b), which is asserted on power-on, ‘destructive’, and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

Note: FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction. All intermediate faults are masked (not monitored) during this timeout cycle.

Figure 1894. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

80.9 Use cases and limitations

80.9.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.
   Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.
4. Software reset is optional.
5. If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and as a result, FOSU will generate destructive reset request on its timeout.

80.9.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, following steps could be followed to configure FCCU:
   a) Check and clear any pending fault status
   b) Verify FCCU is in NORMAL state, else repeat step(a) above
   c) Configure FCCU
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
   a) If active, wait for the Error out Tmin to expire
   b) Check and clear fault status
   c) Error pin moves to “non faulty” state, once fault status is cleared and Tmin expires
   d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state
   e) Read and verify default value in FCCU_RF_Ex to ascertain reset of FCCU
   f) Check and clear any new pending fault status until FCCU is in NORMAL state
   g) Reconfigure FCCU

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

81 Self-Test Control Unit (STCU2)

81.1 Introduction

Note: For the chip-specific implementation details of this module's instances, see the chip configuration information.

Self-Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the Self-Test sequence applied both during the Off-line and/or On-line conditions. The hardware can manage the Logic Built-in Self-Test (LBIST) and the SRAM or ROM Built-in Self-Test (MBIST) blocks of the device. The STCU2 includes the SSCM DCF bus to load the Self-Test parameters (LBIST or MBIST scheduling activity, LBIST setup, Unrecoverable Faults (UF) or Recoverable Faults (RF) management, CRC and MISR expected values, PLL management, and so on) from flash memory during the Off-line Self-Test phase. This interface is only able to write the configuration parameters and start the Self-Test execution once the STCU2 global reset has been applied. Register access by software is granted by an IPS interface to check the results of the Off-line Self-Test and to load or check the execution of the On-line Self-Test.

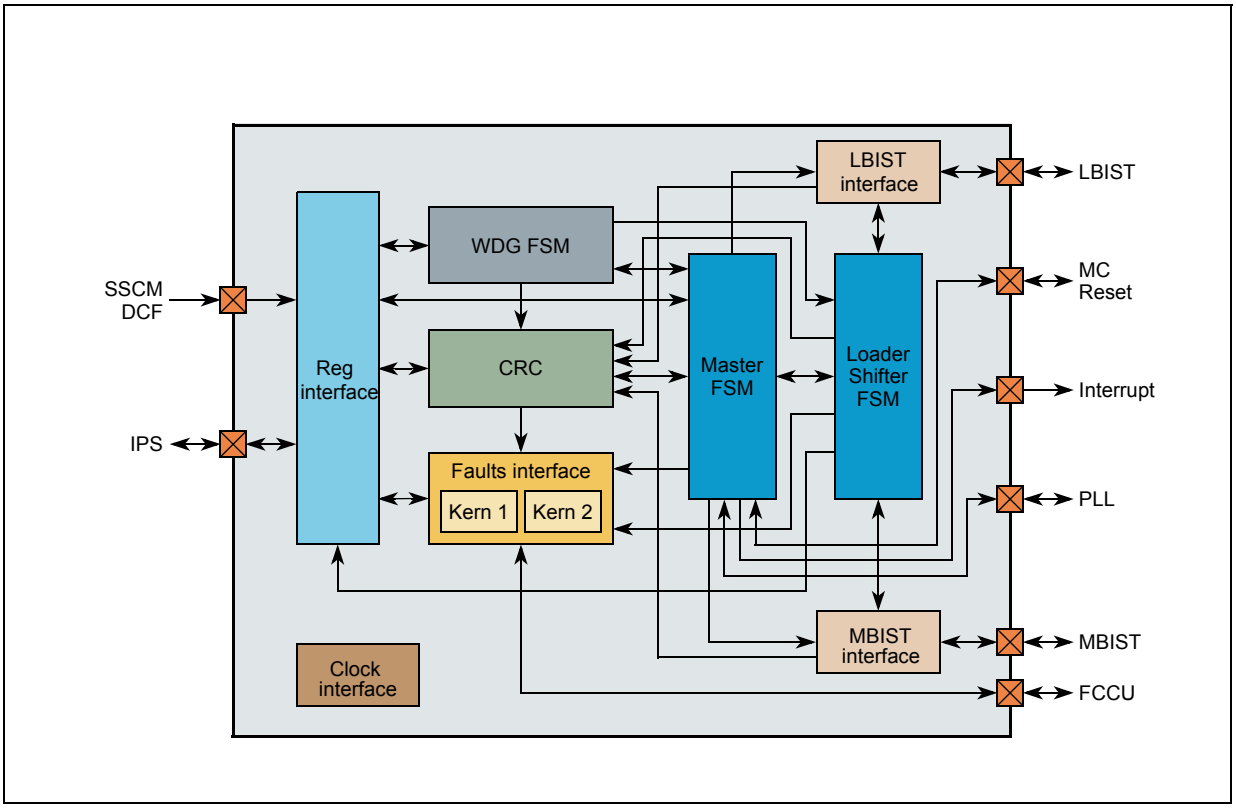
The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the Self-Test run to increase the STCU2's Self-Checking capability.
- A programmable Watchdog timer (WDG) to check the LBIST and MBIST Self-Test operations have completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out.
- Direct PLL control during the Off-line Self-Test sequence.
- Two interrupt lines enabled only during the On-line Self-Test to simplify the software handling of Self-Test execution end.
- Two sets of registers to separately collect the LBIST or MBIST results during Off-line and On-line Self-Test.

To increase the security of this module, a different Security Key sequence is also required during Off-line and On-line Self-Test to unlock write access to the STCU2 registers. The STCU2 also implements two switch off power-saving mechanisms:

- The global STCU2 clock after Self-Test sequence is completed.
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

81.2 Main features



- Double registers interface (SSCM DCF with priority over IPS).
- SSCM DCF write once register interface.
- IPS read and write (depending on SSCM enable parameters and STCU_CFG.WRP bit) register interface.
- Programmable scheduler for LBIST or MBIST execution.
- LBIST concurrent/sequential execution.
- MBIST concurrent/sequential execution.
- Programmable LBIST delayed concurrent start.
- Hardware capability to enable or disable the execution of hardware selected LBIST or MBIST
- 32-bit CRC for STCU2 Self-Checking capability (enabled by STCU_CFG.CRCEN bit)
- On-line hardware and software Self-Test sequence abort capability.
- Programmable Internal clock prescaler to reduce Internal and MBIST or LBIST TCK clocks.
- Programmable PLL direct control during Off-line Self-Test sequence.
- PLL Lock signal monitoring during Off-line and On-line Self-Test.
- LBIST or MBIST dedicated On-line interrupt source generation.
- Programmable WDG Timer for Self-Check MBIST or LBIST Time Execution.
- Hard-coded WDG time-out to flag Off-line initialization errors.
- Hard-coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence.
- LBIST and SRAM or ROM MBIST Off-line status flags.
- STCU2 internal errors Off-line status flag.
- LBIST and SRAM or ROM MBIST On-line status flags
- STCU2 internal errors On-line Status flag.
- On-line hardware and software abort status flag
- LBIST and SRAM or ROM MBIST Off-line or On-line programmable failure severity (UF/RF).
- STCU2 internal errors Off-line or On-line programmable failure severity (UF/RF).
- STCU2 errors (UF/RF) lines for FCCU signaling.
- Redundant UF/RF generation logic to improve safety.
- FCCU UF/RF faults injection mechanism.
- CRCE register access to perform redundant check by software
- LBIST MISRE registers access to perform redundant software checks.
- Self-Test Bypass capability.
- Protection mechanism of the Global write register based on Double Security Key.
- STCU2 Global Auto Power-saving when:
  - Self-Test is completed.
  - bypass mode is selected.
  - WDT time-out is detected.
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU_CFG.WRP bit is active).

- STCU2 ITF/WDG Auto Power-saving when hard-coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU_CFG[WRP] bit is active).

81.3 Block diagram

A top level diagram of the STCU2 module is given in *Figure 1895*.

Figure 1895. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- **Reg interface**: This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- **CRC**: This module is the core of the Self-Checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- ***Fault interface***: This module collects the error conditions respective to LBIST or MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set or Clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- ***Clock Block***: This module manages the internal and the LBIST or MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.

- **WDG FSM:** This module includes two different Watchdogs:
  - A hard-coded Watchdog used to Auto Lock the STCU2 access, forcing a reset condition on the Double Security Key registers.
  - A dual function Watchdog:

    After a reset event initializes the STCU2, it is used as a hard-coded Watchdog time-out.

    During LBIST or MBIST runs, it is used as a programmable Watchdog timer to check the LBIST or MBIST have completed in the designated time slot.
- **STCU2 Master FSM**: This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the respective state machine used to program the LBIST or MBIST registers and read back the data to be checked at the end of each Self Test operation.
- **LBIST interface**: This module includes the interface between the LBIST engines and the STCU2 controllers of the device.
- **MBIST interface**: This module includes the interface between the MBIST controller and STCU2 controllers.

81.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers.
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers.
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers.
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode under the following circumstances:

- The Self-Test sequence parameters are loaded before Off-line Self-Test is executed.
- The IPS access on some specific registers (see *Section 81.5, Register description*) is allowed by software only when the bit STCU_CFG[WRP] is cleared.
- Write operations are not supported and all STCU2 registers can only be read in all other circumstances except for the following rw bits: STCU_CFG[WRP], STCU_ERR_STAT[UFSF] and STCU_ERR_STAT[RFSF]. See the respective register descriptions for additional details.

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral.
- Any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other accesses to STCU2 registers).
- Any write operation performed on a register when the Double Security keys have not been applied.
- Any write operation performed on registers when the STCU_CFG[WRP] bit is set and the access is performed through software (IPS interface).
- Any write operation performed through software (IPS interface) on row registers.
- Any write operation performed Off-line on registers where writes are only allowed during the On-line Self-Test phase when STCU_CFG[WRP] = 1.
- Any write operation performed on Read Only registers.

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

A transfer error is not generated for write operations to bits marked *Reserved*.

For more details regarding register protection features, see *Section 81.5, Register description*.

81.4 Functional description

81.4.1 FSM description

The module has three state machines that work together:

- Master State Machine: the core unit of the STCU2 module; it coordinates all the Self-Test operations and the other State Machines.
- Loader/Shifter State Machine: used to program the MBIST and the LBIST parameters and to retrieve the respective results depending on the parameters stored in the STCU2 registers and under the control of the Master State Machine.
- Watchdog State Machine: evaluates all the schedule time for MBIST and LBIST and the time-outs in case of incorrect STCU2 programming.

81.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status, forcing the Off-line Self-Test condition and the cleaning up of all the registers and state machines of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the STCU_LBRMSW register reported in the following subsections.

81.4.2.1 Off-line reset generation

At the end of the Off-line Self-Test execution, the STCU2 raises the global functional reset.

81.4.2.2 On-line reset generation (only MBIST)

The On-line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences respective to the write operations performed by the MBIST execution other than prevent any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

81.4.2.3 On-line Reset generation (LBIST enabled)

At the end of the execution, the On-line execution of the LBIST generates two possible types of reset depending on the status of the STCU_LBRMSW register. See *Section 81.5.16, STCU2 On-line LBIST Reset Management (STCU_LBRMSW)*.

If all the selected LBISTs do not require the global functional reset, only the partitions subjected to LBIST are cleaned up applying a pulse on the dedicated reset line. If at least one of the selected LBISTs requires the global functional reset, the global functional reset is raised at the end of the On-line Self-Test execution.

Note: If an ABORT condition is detected by STCU2 during the On-line Self-Test execution, regardless of the value of the STCU_LBRMSW register, only the respective reset line is pulsed to prevent any potential dangerous system level operations.

81.4.3 LBIST and MBIST scheduling

The STCU2 module is designed to be very flexible, allowing the programming of the parallel or serial execution of the MBIST or LBIST depending on the power, timing and coverage constraints. The limitation in the programming flexibility is described in *Section 81.7.4, Design implementation information*.

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG[PTR]. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped at the address 10h, the second on 11h and so on. The additional pointers are in the bitfield STCU_LB_CTRL*x*[PTR] for LBIST*x* (where *x* is the selected LBIST) and STCU_MB_CTRL*y*[PTR] for MBIST (where *y* is the selected MBIST), and have to be filled depending on the selected sequence of run. The additional bitfields STCU_LB_CTRL[CSM] and STCU_MB_CTRL[CSM] provide the flexibility to run the chosen set of the LBIST or MBIST concurrently or sequentially, or to close the linked list by setting the NIL pointer. For more details, see *Section 81.5.33, STCU2 LBIST Control Register (STCU_LB_CTRLn)* and *Section 81.5.45, STCU2 MBIST Control Register (STCU_MB_CTRL)*.

81.4.4 ABORT management

The STCU2 module provides two mechanisms to perform the On-line Self-Test execution abort. When the abort is detected in both cases, the On-line Self-Test operation stops running and the status of the currently running MBIST or LBIST is saved in the respective registers to provide intermediate results that might be useful in case of debug or a concurrent run. For an LBIST run, see *Section 81.4.2, Reset management*, regarding reset specific management when abort is detected. The following sections describe the differences between the two mechanisms.

81.4.4.1 Hardware ABORT management

The STCU2 enters this abort condition as a consequence of a Functional reset that requires the Self-Test execution to stop.

When hardware abort is detected, the STCU_ERR_STAT[ABORTHW] bit is set. This flag allows the software to diagnose what occurred during the On-line Self-Test execution run.

81.4.4.2 Software ABORT management

The STCU2 enters the abort condition because the software set the bit RUNSW_ABORT in the STCU_RUNSW register. To allow the software to understand when STCU2 completes the abort sequence, this bit is kept active until the abort sequence is completed and the STCU2 clears this bit as described in *Section 81.5.2, STCU2 Run Software Register (STCU_RUNSW)*.

When software abort is raised, the STCU_ERR_STAT[ABORTSW] bit is set. Even if the abort condition is forced by software operation, this flag allows the diagnosis of what has happened during the On-line Self-Test execution run.

81.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-line Self-Test operations depending on the status of the STCU_RUN[MBPLLEN] and STCU_RUN[LBPLLEN] as described in *Section 81.5.2, STCU2 Run Software Register (STCU_RUNSW)*.

When STCU_RUN[RUN] is set to start the Off-line Self-Test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed in the STCU_PLL_CFG register.

When the STCU_RUN[MBPLLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock occurs, the STCU forces the clock to switch to the PLL output clock, allowing the MBIST to proceed at the PLL output frequency. At the end of the MBIST run, the clock source reverts to the original one. The same behavior applies when STCU_RUN[LBPLLEN] is active and LBIST is currently selected.

81.4.6 Interrupt interface

There are two interrupt sources:

- One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1)
- One triggered by LBIST (enabled by programming STCU_RUNSW[LBIE] = 1)

As described in *Section 81.5.2, STCU2 Run Software Register (STCU_RUNSW)*, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential runs in the same session, the number of interrupts generated is equivalent to the number of sequential sessions, thus providing fine granularity with respect the completed run.

The bits LBIFLG and MBIFLG in the *STCU2 Interrupt Flag Register (STCU_INT_FLG)* register flag these interrupt conditions and allow the clearing of interrupt requests. These two interrupt bits have to be cleared by writing the respective bit to 1 to enable the next interrupt request.

81.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism to the system, indicating the occurrence of an Unrecoverable Failure (UF) or a Recoverable Failure (RF) during the Self-Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. The FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set and clear mechanism works.

81.4.8 Watchdogs

The STCU2 implements three different Watchdogs to ensure that operations are finished on time.

81.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes:

- Program and run the Self-Test sequence (Safety mode).
- Bypass the Self-Test sequence by setting the STCU_RUN[BYP] bit.

If there are faults during the initialization phase which prevent the selection of one of these two operating modes, a hard-coded Watchdog time-out flags the incorrect behavior. See *Section 81.5.6, STCU2 Watchdog Register Granularity (STCU_WDG)* for more details.

81.4.8.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time is configured as described in *Section 81.5.6, STCU2 Watchdog Register Granularity (STCU_WDG)* to account for the overall execution time of the Self-Test sequence. If the selected LBISTs or MBISTs are not yet completed:

- During an Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTO] and STCU_MBEL/M/H or STCU_LBE registers.
- During an On-line Self-Test, the current LBISTs or MBISTs execution is interrupted and a failure is flagged in STCU_ERR_STAT[WDTOSW] and STCU_MBELSW/MSW/HSW or STCU_LBESW.

In case of multiple sequential runs in the same On-line or Off-line session and the time-out occurs in the middle of a sequential run, the next sequential run is skipped and the execution ends with the current updated status of the registers reported above.

In all cases, the STCU2 reset generation is managed in one of the modes described in *Section 81.4.2, Reset management*.

81.4.8.3 Write access time-out

The access on the STCU2 registers during the Self-Test configuration phase (both On-line or Off-line) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware Watchdog that, after 1024 STCU2 clock cycles, locks access and requires reinsertion of the STCU_SKC keys.

This feature is particularly useful if STCU_CFG[WRP] = 0 during the software Self-Test configuration as the software application may enable write access to the STCU2 registers.

81.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomy to evaluate the signature of the most important and critical internal signals. This feature is switched off by default but it can be turned on setting the STCU_CFG[CRCEN] bit. Once this bit is set, the expected signature has to be programmed in the STCU_CRCE register. At the end of the Self-Test execution, the STCU2 updates the content of the STCU_CRCR register with the evaluated signature and compares this value with the expected one previously programmed in STCU_CRCE. In case of mismatches, a UF/RF condition is flagged depending on the fault mapping selected in the STCU_ERR_FM register.

81.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without CPU intervention after a reset trigger event initializes the STCU2. This bus interface has priority over the IPS.

81.4.11 LBIST/MBIST execution restriction

The STCU2 provides the capability of preventing the execution of selected LBISTs or MBISTs. The list of LBISTs or MBISTs with this restriction is Hardware defined at design phase and cannot be changed by software. The activation of the restriction is controlled by a system signal which has to be carefully generated in order to fulfill the system requirements.

81.5 Register description

The STCU2 registers are listed in *Table 1815*.

Table 1815. STCU2 register set

81.5.1 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the Off-line Self-Test procedure if some configuration bits are required *only* during this Self-Test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Offset: 0000h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1896. STCU2 Run Register (STCU_RUN)

Table 1816. STCU_RUN field descriptions

Field	Description
BYP	Bypass mode 0 Off-line Self-Test is active. If the STCU_RUN[RUN] bit is not set before the hard-coded WDG Time-out, the WDTO error is generated in the STCU_ERR_STAT register. 1 Off-line Self-Test is bypassed and access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
MBPLLEN	Off-line MBIST with PLL Enabled 0 Off-line MBIST is executed without using the on-chip PLL. 1 Off-line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined in STCU_PLL_CFG register.
LBPLLEN	Off-line LBIST with PLL Enabled 0 Off-line LBIST is executed without using the on-chip PLL. 1 Off-line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined in STCU_PLL_CFG register.
RUN	RUNThe RUN bit is automatically cleared by the STCU2 when the Off-line Self-Test procedure has been completed. 0 Idle 1 Off-line Self-Test procedure is running

81.5.2 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the On-line Self-Test procedure if some configuration bits are required *only* during this Self-Test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0.
- On-line Self-Test phase is active. The On-line condition starts when the Off-line condition finishes. In this condition, the system is alive and the SW can program the STCU.

Figure 1897. STCU2 Run Software Register (STCU_RUNSW)

Table 1817. STCU_RUNSW field descriptions

Field	Description
MBIE	MBIST Interrupt Enable 0 Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1 At the end of the software MBIST execution phase of the concurrent selected memories, the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are concluded. If there is a sequence of concurrent runs in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[MBIFG] bit in between.
LBIE	LBIST Interrupt Enable 0 Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1 At the end of the software LBIST execution phase of the concurrent selected LBIST, the STCU2 forces an interrupt request to notify LBIST of the concurrent selected partitions are concluded. If there is a sequence of concurrent run in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software clears the STCU_INT_FLG[LBIFG] bit in between.
MBSWPLLEN	On-line MBIST with PLL Enabled 0 On-line MBIST is executed without using the on-chip PLL. 1 On-line MBIST is executed using the PLL configuration provided by software. STCU2 does not take PLL control but monitors the PLL lock signal to check if PLL is working correctly.
LBSWPLLEN	On-line LBIST with PLL Enabled 0 On-line LBIST is executed without using the on-chip PLL. 1 On-line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
RUNSW_ABORT	Software abort of the Self-Test currently running This bit is automatically cleared by the STCU2 when the software Self-Test abort sequence has been completed. 0 On-line Self-Test abort is not requested. 1 On-line Self-Test abort is requested.
RUNSW	RUNSWThe RUNSW bit is automatically cleared by the STCU2 when the On-line Self-Test procedure has been completed. 0 Idle 1 On-line Self-Test procedure is running

81.5.3 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed for write access to the other STCU2 registers. In order to unlock the STCU2 access after an STCU2 asynchronous reset or the end of the STCU2 run, the software (IPS bus) or the SSCM interfaces must apply the following sequence:

- Write Key1 in the STCU_SKC register.
- Write Key2 in the STCU_SKC register.

Depending on the Off-line or On-line test step, the two keys will be different. Byte write operation is not allowed as the full key has to be recognized as one unit.

Note: Note that after the Self-Test sequence has been completed or the Bypass feature has been enabled (by setting the STCU_RUN[BYP] bit), the SSCM interface is no longer available.

In case of invalid access or sequence (Keys1 and 2 must be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

If the STCU2 register access lasts more cycles than defined in the hard-coded WDG time-out, STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case the correct sequence must be applied in order to re-enable write access to the STCU2 and the WDG and Register ITF clocks.

To extend the STCU2 register access cycles before the hard-coded WDG time-out expires, only Key2 needs to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. Key1 must not be applied or a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked until the correct sequence is applied.

The STCU_SKC register is not readable; any attempts to read this register always returns the value 00000000h.

81.5.4 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the Off-line and On-line Test steps.

Access to this register is described in *Figure 1899*. It also depends on the state of the WRP bit as follows:

- When WRP = 0, the register can be written during the On-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - If software operations write to other register bits, a transfer error is raised if the value of the selected byte that is written differs from the current status of the register. This function is implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

[1] You can always read this field. In the Off-line Self-Test phase, you can always write to this field. In the On-line Self-Test phase, you can write to this field only when WRP = 0.

Figure 1899. STCU2 Configuration Register (STCU_CFG)

Table 1819. STCU_CFG field descriptions

Field	Description
PTR	LBIST or MBIST pointer. PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the Self-Test procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0, then the LBIST0 is initially scheduled. 0h to (LBIST -1) – pointer to LBIST 10h to (10h + MBIST -1) – pointer to MBIST 7Fh – pointer to NIL. No BIST execution.
LB_DELAY	Delay LBIST run. LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected to be executed concurrently with the purpose of smoothing the power consumption transient. 00h No delay 01h 001 × 16 STCU2 Core clock cycles(1) 02h 002 × 16 STCU2 Core clock cycles 03h 003 × 16 STCU2 Core clock cycles ... FDh 253 × 16 STCU2 Core clock cycles FEh 254 × 16 STCU2 Core clock cycles FFh 255 × 16 STCU2 Core clock cycles
WRP	Write Protection. 0 Specific STCU2 registers can be written through IPS bus interface after Off-line Self-Test sequence has completed. 1 Specific STCU2 registers cannot be written though IPS even after Off-line Self-Test sequence has completed, thus preventing any user application write operation.
CRCEN	CRC Enable comparison. 0 The CRC comparison is not performed and the STCU_ERR_STAT[CRCS][SW] and STCU_ERR_STAT[UF/RF] global flags are not updated in case of mismatches between STCU2[CRCE] and STCU2[CRCR] values . 1 The CRC comparison is performed and the status is updated in the respective flags of the STCU_ERR_STAT register
PMOSEN	MBIST PMOS Test Enable. 0 MBIST PMOS Test is not enabled 1 MBIST PMOS Test is enabled

Table 1819. STCU_CFG field descriptions(Continued)

Field	Description
MBU	MBIST MBU Test Enabled. 0 MBIST Full algo or reduced one without PMOS test (PMOSEN set to 0) is applied. 1 MBIST simplified Multi Bit Upset algo is used to check the RAM. If a ROM is selected, the applied algo will be Standard one without PMOS Test. ***This bit overwrites the PMOSEN feature***.
CLK_CFG	Logic, Memory Bist and STCU2 core CLK Clock configuration. CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are: 000 sys_clk 001 sys_clk/2 010 sys_clk/3 ... 101 sys_clk/6 110 sys_clk/7 111 sys_clk/8

1. STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE Clock Frequency value.

81.5.5 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the Off-line LBISTs or MBISTs are performed and STCU_RUN[MBPLLEN] = 1 or STCU_RUN[LBPLLEN] = 1.

In the On-line state, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issues.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is active.

Offset: 0010h Access: User read/write

Figure 1900. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Table 1820. STCU_PLL_CFG field descriptions

Field	Description
PLLODF	PLL Output Division Factor. The value of this field drives the Output Division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLODF value and the respective PLL's Output Division factor.
PLLIDF	PLL Input Division Factor. The value of this field drives the Input Division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLIDF value and the respective PLL's Input Division factor.
PLLLDF	PLL Loop Division Factor. The value of this field drives the Loop Division factor of the PLL embedded in the device. Refer to the PLL specifications to define the exact mapping between the PLLLDF value and the respective PLL's Loop Division factor.

81.5.6 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget for LBIST and MBIST execution, providing protection against dead-locks or infinite loop conditions during the Self-Test procedure. When the Off-line Self-Test sequence is not run and the STCU_RUN[BYP] bit is not set, the bits 15...0 define the time-out before the STCU_ERR[WDTO] bit is set and the STCU2 core clock is switched off.

When the Off-line or On-line Self-Test sequence is run, it defines the time-out of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Offset: 0014h Access: User read/write

1. STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE Clock Frequency value.

81.5.7 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST and LBIST interrupt pending bits. These bits are effective only during the On-line Self-Test phase and are managed only when the respective control bits in the STCU_RUNSW register (MBIE and LBIE) are enabled.

Offset: 0018h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Field	Description
MBIFLG	MBIST Interrupt Flag. 0 No interrupt is pending. 1 An interrupt highlighting that the On-line execution of the concurrent scheduled MBIST is completed is pending. Write 1 to clear the bit.
LBIFLG	LBIST Interrupt Flag. 0 No interrupt is pending 1 An interrupt highlighting that the On-line execution of the concurrent scheduled LBIST is completed is pending. Write 1 to clear the bit.

81.5.8 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2 critical signals. When STCU_CFG[CRCEN] = 1, it provides the Self Check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

Equation 90 CRC-32 (ethernet protocol)

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

Field	Description
CRCE	CRC expected signature

81.5.9 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the Off-line and On-line Self-Test sequence. It may be used for diagnoses and also for additional checking with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Field	Description
CRCR	Read CRC signature

81.5.10 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags respective to the STCU2 internal error conditions that occurred during configuration or the On-line and Off-line Self-Test execution.

The Unrecoverable Faults Status Flag (UFSF) and Recoverable Faults Status Flag (RFSF) can be set and cleared using the FCCU dedicated channels as described in *Section 81.7.4, Design implementation information*.

Access to this register is described in *Figure 1905* and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality is implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set and clean capability.

Offset: 0024h Access: User read/write

[1] You can always read this field. The content of this field is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Figure 1905. STCU2 Error Register (STCU_ERR_STAT)

Table 1825. STCU_ERR_STAT field descriptions

Field	Description
ABORTHW	On-line hardware abort flag. 0 No hardware abort was requested during the On-line Self-Test sequence 1 A hardware abort was detected during the On-line Self-Test sequence
ABORTSW	On-line software abort flag. 0 No software abort was requested during the On-line Self-Test sequence 1 A software abort was detected during the On-line Self-Test sequence
LOCKESW	On-line LOCK Error. 0 If PLL is enabled, it is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the On-line Self-Test sequence execution. The On-line Self-Test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW[LBSWPLLEN] is set and/or during the MBIST run when STCU_RUNSW[MBSWPLLEN] = 1.
WDTOSW	On-line Watchdog time-out. 0 LBIST and MBIST time slots have completed within the assigned watchdog time. 1 LBIST and MBIST time slot have not completed in the assigned watchdog time or there are internal mismatches i n the End of Execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished

Table 1825. STCU_ERR_STAT field descriptions(Continued)

Field	Description
CRCSSW	On-line CRC Status. This flag is activated *only* when On-line Self-Test is performed and STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] set to 0) 1 Failed CRC comparison
ENGESW	On-line Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned Serial bend status of the selected MBIST and the global BEND flag are not aligned
INVPSW	On-line Invalid Pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)
UFSF	Unrecoverable Faults Status Flag This flag report the global status of the UF. 0 No errors that trigger the Unrecoverable Faults condition 1 There are errors that trigger the Unrecoverable Faults condition
RFSF	Recoverable Faults Status Flag 0 No errors that trigger the Recoverable Faults condition 1 There are errors that trigger the Recoverable Faults condition
LOCKE	Off-line LOCK Error 0 The PLL is correctly locked during the Self-Test sequence 1 When the PLL is enabled, this flag highlights an unexpected PLL unlock event during the Off-line Self-Test sequence execution. The On-line Self-Test run is stopped and the status of the current running LBISTs or MBISTs is saved in the respective registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLLEN] = 1 and/or during the MBIST run when STCU_RUN[MBPLLEN] = 1.
WDTO	Off-line Watchdog time-out. 0 LBIST and MBIST time slot have been completed within the assigned watchdog time. 1 LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_RUN[BYP] bit are not set before the Watchdog reach the End of Count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished

Table 1825. STCU_ERR_STAT field descriptions(Continued)

Field	Description
CRCS	Off-line CRC status. This flag is activated *only* when Off-line Self-Test is performed STCU_CFG[CRCEN] is set to 1, otherwise it is always forced to 0. This prevents the generation of the respective STCU_ERR_STAT[UFSF/RFSF] bits. In both the cases, the content of the STCU_CRCR register reports the current evaluated CRC. 0 Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEN] programmed to 0) 1 Failed CRC comparison
ENGE	Off-line Engine Error. 0 Valid Engine execution 1 Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
INVP	Off-line Invalid pointer. 0 Valid linked pointer list 1 Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in LBIST or MBIST linking (execution generates an infinite loop)

81.5.11 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described in the STCU_ERR_STAT register in terms of Unrecoverable or Recoverable Faults. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions are true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

81.5.16 STCU2 On-line LBIST Reset Management (STCU_LBRMSW)

The STCU_LBRMSW register defines the On-line reset mapping for each LBIST. Global or specific functional resets can be programmed depending on the On-line Self Test requirements and top level integration architecture.

The size of the register depends on the number of LBISTs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

Offset: 003Ch Access: User read/write

81.5.17 STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)

The STCU_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault. The size of the register depends on the number of LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

81.5.29 STCU2 On-line MBIST End Flag High Register (STCU_MBEHSW)

The STCU_MBEHSW register includes the End Flag respective to the execution of the selected On-line MBIST in the range NMCUT = 64..95. The size of the register depends on the number of RAMs/ROMs subject to BIST. The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Figure 1928. STCU2 LBIST Control Register (STCU_LB_CTRLn)

1. Value of NLBIST is 8

Table 1848. STCU_LB_CTRLn field descriptions

Field	Description
CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it is scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer, the CSM bit has to be set Sequential (0) to define this is the end of the list. The Self-Test procedure is stopped when the current LBIST has been completed. – 0h to (NLBIST -1) — pointer to LBIST – 10h to (10h + MBIST -1b) — pointer to MBIST – 7Fh — pointer to NIL. No BIST execution. – others — invalid pointer, an error is set in the STCU_ERR register.
PRPGEN	Enable PRPG Loading 0Default LBIST value of the PRPG is used during LBIST run 1LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
SHS	Shift speed 000 Shift at full rate (bist_clk) 001 Shift at 1/2 rate (bist_clk) 010 Shift at 1/3 rate (bist_clk) 011 Shift at 1/4 rate (bist_clk) 100 Shift at 1/5 rate (bist_clk) 101 Shift at 1/6rate (bist_clk) 110 Shift at 1/7rate (bist_clk) 111 Shift at 1/8 rate (bist_clk)

Table 1848. STCU_LB_CTRLn field descriptions(Continued)

Field	Description
SCEN_OFF	Scan enable OFF SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles ... 1111 15 delay cycles
SCEN_ON	Scan enable ON SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000 0 delay cycles 0001 1 delay cycles ... 111115 delay cycles
PFT	Past Flush Test The LBIST controller, by default apply 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence. 0Apply Flush Test Patterns 1Skip Flush Test Patterns
CWS	Capture window size 000 illegal 001 controller waits 1 shift cycle for capture to finish 010 controller waits 2 shift cycles for capture to finish ... 111 controller waits 7 shift cycles for capture to finish

81.5.34 STCU2 LBIST PC Stop Register (STCU_LB_PCSn)

The STCU_LB_PCSn register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

Figure 1936. STCU2 On-line LBIST MISR Expected Low Register (STCU_LB_MISRELSWn)

1. Value of NLBIST is 8

Table 1856. STCU_LB_MISRELSWn field descriptions

Field	Description
MISRESW*x*	On-line MISR Expected low Bits. This field defines the low part (31..0) of the Expected MISR.

81.5.42 STCU2 On-line LBIST MISR Expected High Register (STCU_LB_MISREHSWn)

The STCU_LB_MISREHSWn register defines the MSB part (63..32) of the Expected MISR of the On-line LBIST controller. The size of the register depends on the number of MISR bits of the respective LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

Offset: 0124h + (NLBIST[1] – 1) × 40h Access: User read/write

Table 1857. STCU_LB_MISREHSWn field descriptions

Field	Description
MISRESW*x*	On-line MISR Expected high Bits. This field defines the high part (63..32) of the Expected MISR.

81.5.43 STCU2 On-line LBIST MISR Read Low Register (STCU_LB_MISRRLSWn)

The STCU_LB_MISRRLSWn register report the LSB part (31..0) of the MISR obtained at the end of the On-line LBIST controller execution. The size of the register depends on the number of MISR bits of the respective LBIST.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Offset: 0128h + (NLBIST[1] – 1) × 40h Access: User read

1. Value of NLBIST is 8

Table 1858. STCU_LB_MISRRLSWn field descriptions

Field	Description
MISRRSW*x*	On-line MISR Read Low Bin. This field is equivalent to the Low Bits (31..0) of the MISR obtained at the end of the Off-line LBIST execution.

81.5.44 STCU2 On-line LBIST MISR Read High Register (STCU_LB_MISRRHSWn)

The STCU_LB_MISRRHSWn register report the MSB part (63..32) of the MISR obtained at the end of each On-line LBIST controller execution. The size of the register depends on the number of MISR bits of the respective LBIST.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Table 1859. STCU_LB_MISRRHSWn field descriptions

Field	Description
MISRRSW*x*	On-line MISR Read High Bits. This field is equivalent to the Low Bits (63..32) of the MISR obtained at the end of the Off-line LBIST execution.

81.5.45 STCU2 MBIST Control Register (STCU_MB_CTRL)

The STCU_MB_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active.
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0.

Offset: 0600h + (NMCUT – 1) × 4h(1) Access: User read/write

Figure 1940. STCU2 MBIST Control Register (STCU_MB_CTRL)

1. Value of NMCUT is 42.

Table 1860. STCU_MB_CTRL field descriptions

Field	Description
CSM	Concurrent/sequential mode 0 Sequential mode 1 Concurrent mode
PTR	Next LBIST or MBIST pointer PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it's scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer, the CSM bit has to be set Sequential (0) to define this is the end of the list. The Self-Test procedure is stopped when the current MBIST has been completed. – 0h to (LBIST -1) — pointer to LBIST – 10h to (10h + MBIST -1b) — pointer to MBIST – 7Fh — pointer to NIL. No BIST execution. – others — invalid pointer, an error is set in the STCU_ERR register.

81.6 Register map

The following STCU2 register map shows a full implementation case. If fewer LBISTs or MBISTs are implemented, note of the following:

- The size of the STCU_LBS, STCU_LBSSW, STCU_LBE, STCU_LBESW, STCU_LBRMSW, STCU_LBUFM depends on the number of LBIST.
- The size of STCU_MBSL, STCU_MBSLSW, STCU_MBEL, STCU_MBELSW, STCU_MBUFML depends on the number of RAMs or ROMs subject to BIST.
- The size of STCU_MBSM, STCU_MBSMSW, STCU_MBEM, STCU_MBEMSW, STCU_MBUFMM depends on the number of RAMs or ROMs subject to BIST only when the respective value is greater than 32, otherwise these registers are not implemented.
- The size of the STCU_MBSH, STCU_MBSHSW, STCU_MBEH, STCU_MBEHSW, STCU_MBUFMH depends on the number of RAMs or ROMs subject to BIST only

when the respective value is greater than 64, otherwise these registers are not implemented;

- The number of STCU_LB_CTRL, STCU_LB_PCS, STCU_LB_PRPGL, STCU_LB_PRPGH, STCU_LB_MISREL, STCU_LB_MISRELSW, STCU_LB_MISREH, STCU_LB_MISREHSW, STCU_LB_MISRRL, STCU_LB_MISRRLSW, STCU_LB_MISRRH and STCU_LB_MISRRHSW depends on the number of LBISTs.
- The size of each STCU_LB_MISREL, STCU_LB_MISRELSW and STCU_LB_MISRRL, STCU_LB_MISRRLSW depends on the number of MISR bits of the respective LBIST.
- The size of each STCU_LB_MISREH, STCU_LB_MISREHSW, and STCU_LB_MISRRH, STCU_LB_MISRRHSW, depends on the number of MISR bits of the respective LBIST only when the respective value is greater than 32, otherwise the registers are not implemented.
- The size of STCU_LB_PRPGL and STCU_LB_PRPGH depends on the number of PRPG bits of the respective LBIST.
- The number of STCU_MB_CTRL depends on the number of RAMs or ROMs subject to BIST.

81.7 Use cases and limitations

The STCU2 module is designed to give high flexibility during the On-line and Off-line Self-Test. This section shows the programming operations that have to be performed to correctly use this module in three typical use cases:

- Off-line Self-Test sequence after a reset trigger event.
- Bypass mode of the Self-Test sequence after a reset trigger event.
- On-line Self-Test sequence.

81.7.1 Off-line Self-Test sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and LBIST or MBIST execution parameters stored in the NVM memory. The target is to cover the amount of

physical defects in the digital logic and in the System RAMs or ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-line STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register.
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFML/M/H registers.
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register.
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, the STCU_LB_PRPGL/H can also be programmed to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,
  - the CRCREN bit to enable the self-checking feature,
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison has been enabled, program the CRCE value expected at the end of the Off-line Self-Test sequence in the STCU_CRCE register
- If PLL usage IS enabled, program the STCU_PLL_CFG value to set the required system frequency.
- Program the RUN bit in the STCU_RUN register to enable the Off-line Self-Test execution and the L/MBPLLEN bits to enable the PLL during LBIST or MBIST execution according to STCU_PLL_CFG register content.
- Start the Off-line Self-Test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- The STCU2 switches-off the core clock at the end of the Self-Test run and releases the PLL control if this feature is enabled.
- The STCU2 resets the STCU_RUN[RUN] bit and the device exits the boot sequence. If there are failures, the STCU2 flags these failures to the FCCU by raising one or both of the stcu_ncf and stcu_cf lines.
- The software application read the STCU_LBS flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application read the STCU_LBE flag register to check the LBIST still on-going when UF or RF are detected.
- The software application read the STCU_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAM or ROM Memory BIST when UF or RF

are detected.

- The software application read the STCU_MBEL/M/H flag registers, depending on the number of memories, to check the RAM or ROM Memory BIST still running when UF or RF are detected.
- The software application read the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- For each LBIST, the software application reads the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after Off-line Self-Test execution has successfully completed are an additional safety layer added to improve the already implemented Auto Self-Test feature included in STCU2.

81.7.2 On-line Self-Test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the LBIST or MBIST execution. Since the On-line operations clean up the content of the respective Digital Logic (LBIST) or RAM (MBIST), activation of this mode requires caution. Follow this sequence:

- Unlock the On-line STCU2 access writing the Key1/Key2 sequence in the STCU_SKC register.
- Check and clear the STCU_CFG[WRP] bit to open the IPS access on the STCU2 On-line Self-Test registers.
- The LBIST, MBIST and STCU2 internal fault reaction should already be programmed during the Off-line Self-Test sequence. If they have not been programmed or there is a need to change them, they can be overwritten by setting the registers: STCU_LBUFM, STCU_MBUFML/M/H and STCU_ERR_FM.
- Program the Reset management during On-line LBIST execution setting the STCU_LBRMSW register.
- The STCU_LB_CTRL, STCU_LB_PCS should already be programmed during Off-line Self-Test sequence. If they have not been programmed or there is a need to change them, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed.
- Overwrite/Program the STCU_WDG register to define the time budget assigned for LBIST or MBIST execution.
- Overwrite/Program the STCU_CFG register to define:
  - the core and LBIST or MBIST TCK clock prescaling factor setting the CLK_CFG bits,
  - the LB_DELAY field to delay the LBIST start when many LBISTs are running simultaneously to mitigate the potential transient power issue during the start-up phase,
  - the PMOSEN or CHKBRD to define the algorithm to be used during MBIST run,

  - the CRCREN bit to enable the self-checking feature
  - set the pointer to the first LBIST/NMCUT to be executed.
- If the internal CRC comparison is enabled, overwrite/program the CRCE value expected at the end of the On-line Self-Test sequence in the STCU_CRCE register.
- Program the STCU_RUNSW[RUNSW] bit to enable the On-line Self-Test execution, the L/MBIE to enable the Interrupt requests, and the L/MBSWPLLEN bits to enable the PLL lock signal monitor during LBIST or MBIST execution.
- Start the On-line Self-Test depending on PLL management and LBIST or MBIST execution order.
- Wait the WDGEOC execution run time specified in the STCU_WDG register.
- If the L/MBIE are enabled, an interrupt is generated at the end of all the LBIST or MBIST runs. The software application has to manage these interrupt signals and clean up the respective flagS (L/MBIFLG) in the STCU_INT_FLG register.
- The STCU2 switches off the core clock at the end of the Self-Test run.
- The activated functional reset is managed by the STCU_LBRMSW.
- If at least one of the selected LBISTs enables the Global functional reset, the STCU2 requests a functional reset which restarts the system. If all the selected LBISTs enable their own dedicated functional reset, only these local reset lines are applied and only the respective LBIST partitions are cleaned up.
- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of errors, the STCU2 flags the failure to the FCCU by rising one or both of the stcu_ncf and stcu_cf lines.
- The software application reads the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions are detected.
- The software application reads the STCU_LBESW flag register to check the LBIST is still running when UFs or RFs are detected.
- The software application reads the STCU_MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UFs or RFs are detected.
- The software application reads the STCU_MBELSW/MSW/HSW flag registers, depending on the number of memories, to check the RAMs/ROMs Memory BIST is still running when UFs or RFs are detected.
- The software application reads the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UFs or RFs are detected.
- If the CRCEN bit is enabled, the software application reads the CRCE and CRCR registers to check the coherence with the STCU_ERR[CRCSSW] bit.
- For each LBIST, the software application reads the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after On-line Self-Test execution has successfully completed are an additional safety layer added to improve the already implemented Auto Self-Test feature included in the STCU2.

81.7.3 Bypass USER Mode

In this mode, the USER application parameters stored in Flash and read by SSCM are written to skip the Self-Test procedure after a reset trigger event is applied. It might be useful if the device is not configured for Safety applications. Follow this sequence:

1. Unlock the STCU2 access writing the Off-line Key1/Key2 sequence in the STCU_SKC register.
2. Set the BYP bit in the STCU_RUN register.

After the BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

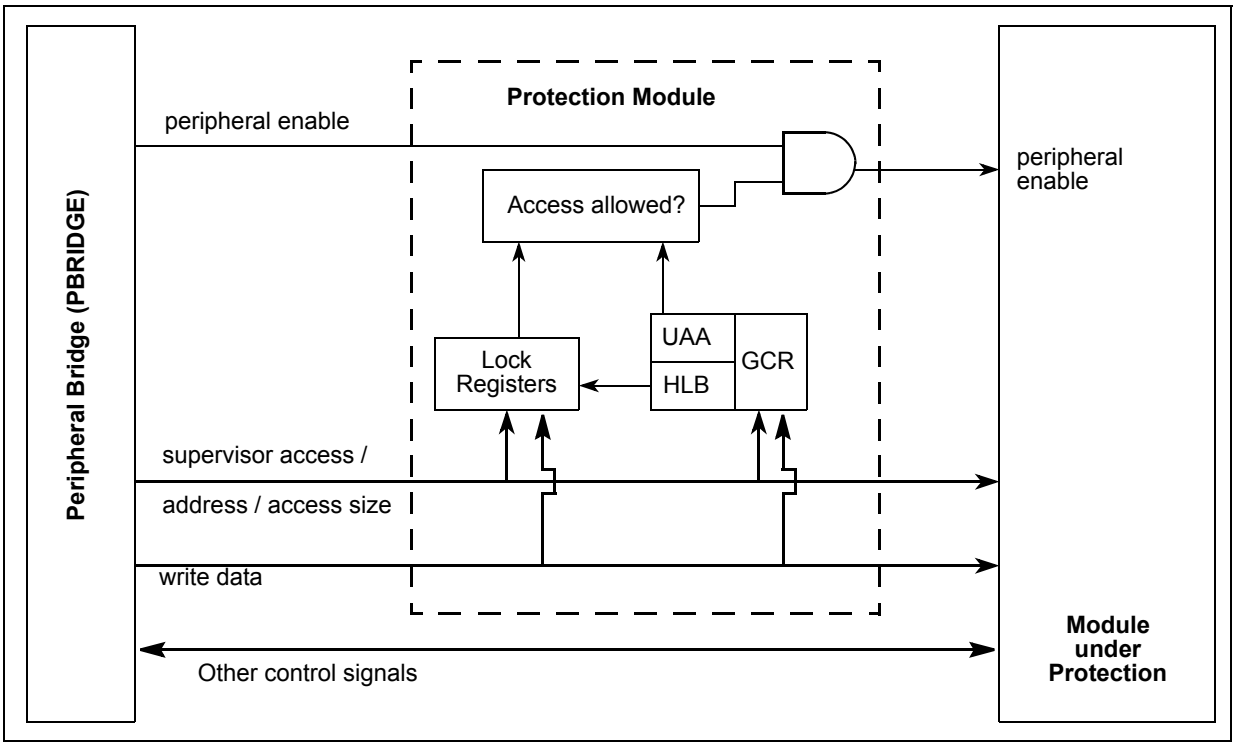
81.7.4 Design implementation information

The following list reports the limitations regarding the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the On/Off-line Self-Test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- As the software has full control of the system while applications are running during the On-line Self-Test, the STCU2 may not take control of the PLL, but only monitor the lock signal to flag incorrect unlock events.

82 Register Protection (REG_PROT)

82.1 Introduction



82.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Please see the device reference manual for device-specific details of the protected registers and bytes.

The protection module is located between the module under protection and the peripheral bridge (PBRIDGE). This is shown in *Figure 1941*.

Figure 1941. REG_PROT Block Diagram

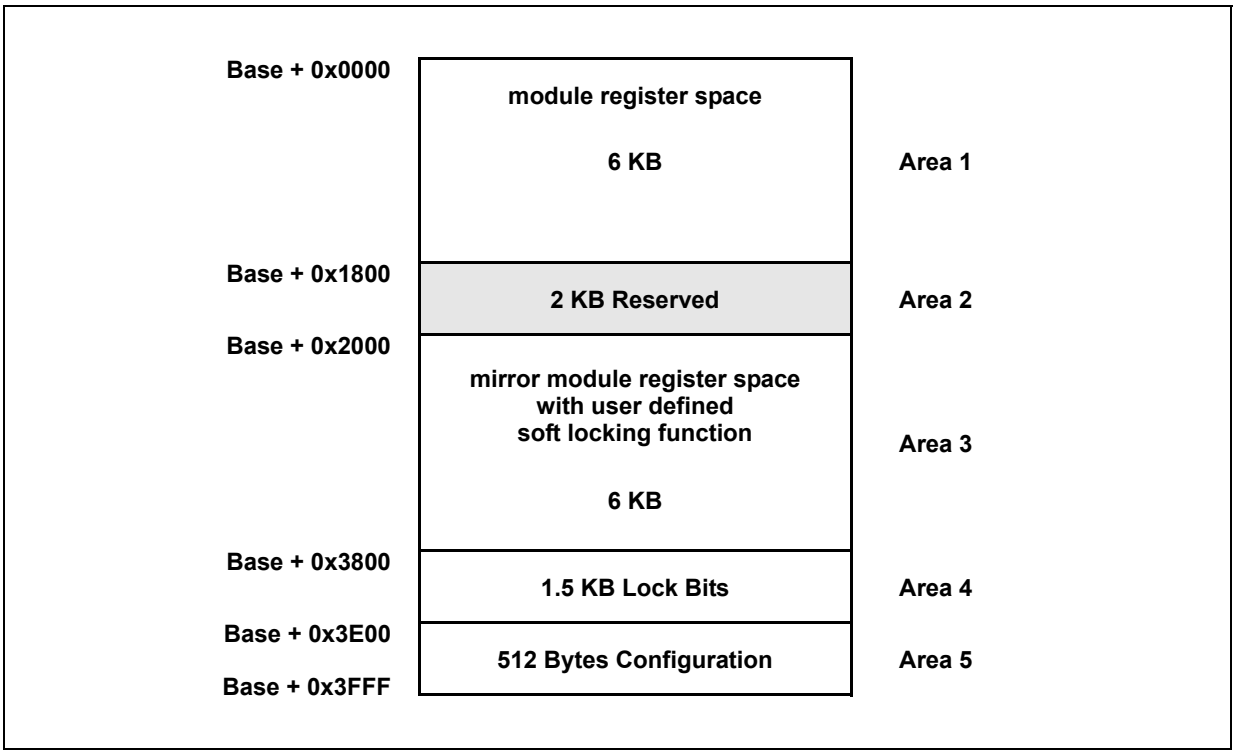
82.1.2 Features

Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

82.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.



82.2 External signal description

There are no external signals.

82.3 Memory map and register definition

This section provides a detailed description of the memory map of a module with register protection. The original 16 KB module memory space is divided into five areas as shown in *Figure 1942*.

Figure 1942. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated

Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-bit registers in Areas 4 and 5 will result in a transfer error.

82.3.1 Memory map

Figure 1862 shows the memory map for a module which is protected via a REG_PROT module.

Table 1862. REG_PROT Memory Map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	*on page 3194*
0x0001	Module Register 1 (MR1)	*on page 3194*
0x0002	Module Register 2 (MR2)	*on page 3194*
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	*on page 3194*
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	*on page 3194*
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	*on page 3194*
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	*on page 3194*
0x3800	Soft Lock Bit Register 0 (SLBR0): Soft Lock Bits 0-3	*on page 3194*
0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	*on page 3194*
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	*on page 3194*
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	*on page 3196*

Note: Reserved registers in area #1 will be handled as specified in the protected module's documentation.

82.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

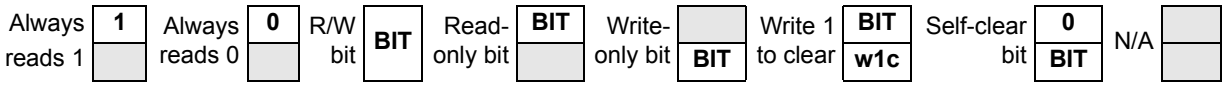


Figure 1943. Key to Register Fields

82.3.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

82.3.2.2 Module Register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR*n*.SLB*m*, according to the mapping described in *Table 1864*.

82.3.2.3 Soft Lock Bit Register (SLBR0-1535)

The Soft Lock Bit Registers hold the Soft Lock Bits for the protected registers in memory area #1, which is the normal register address space of the protected module. Each SLB register has a four Soft Lock Bits (SLB)-SLB3), each of which controls write access to a byte in memory area #1. Each Soft Lock Bit also has a corresponding Write Enable bit in the same register that controls whether the Soft Lock Bit can be written. The following table shows the mapping between the Soft Lock Bits to the bytes in memory area

Table 1863. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

- As many as 1536 Soft Lock Bit Registers (SLBRn) may be implemented, depending on the number of protected module register bytes.
- Access in User Mode is read-only; in Supervisor Mode access is read/write.

Address 0x3800-0x3DFF

Access: Read always
Supervisor write

	0	1	2	3	4	5	6	7
R	0	0	0	0	SLB0	SLB1	SLB2	SLB3

Reset	0	0	0	0	0	0	0	0

Figure 1944. Soft Lock Bit Register (SLBR*n*)

Table 1864. SLBR*n* field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified

Table 1864. SLBR*n* field descriptions(Continued)

Field	Description
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR*n* register: SLB0 can block accesses to MR[n *4 + 0] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writeable
5 SLB1	Soft Lock Bits for one MR*n* register: SLB1 can block accesses to MR[n *4 + 1] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writeable
6 SLB2	Soft Lock Bits for one MR*n* register: SLB2 can block accesses to MR[n *4 + 2] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writeable
7 SLB3	Soft Lock Bits for one MR*n* register: SLB3 can block accesses to MR[n *4 + 3] 1 Associated MR*n* byte is locked against write accesses 0 Associated MR*n* byte is unprotected and writeable

82.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Note: Access in User Mode is read-only; in Supervisor Mode access is read/write.

Offset 0x3FFC

Access: Read Always
Supervisor write

Figure 1945. Global Configuration Register (GCR)

Table 1865. GCR field descriptions

Field	Description
0 HLB	Hard Lock Bit. This register can not be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and can not be modified 0 All SLB bits are accessible and can be modified.
1 - 7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.
9 - 31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

82.4 Functional description

The following sections describe the functional characteristics of the Register Protection module.

82.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depends on the SoC and/or module.

For all addresses that are protected there are SLBR*n*.SLB*m* bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding SLBR*n*.SLB*m* bit is always 0b0 no matter what software is writing to.

82.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding SLBR*n*.SLB*m* bit needs to be changed. This can be done using the following methods:

- Modify the SLBR*n*.SLB*m* directly by writing to area #4
- Set the SLBR*n*.SLB*m* bit(s) by writing to the mirror module space (area #3)

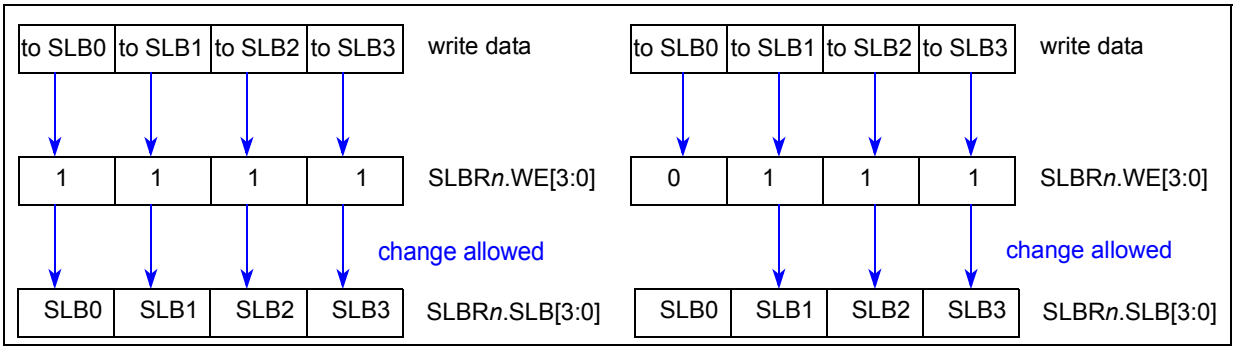
Both methods are explained in the following sections.

82.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each SLBR*n*.SLB*m* bit has a mask bit SLBR*n*.WE*m* which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 1946 shows two modification examples. In the left example there is a write access to the SLBR*n* register specifying a mask value which allows modification of all SLBR*n*.SLB*m* bits. The example on the right specifies a mask which only allows modification of the bits SLBR*n*.SLB[3:1].

Figure 1946. Change lock settings directly via Area #4



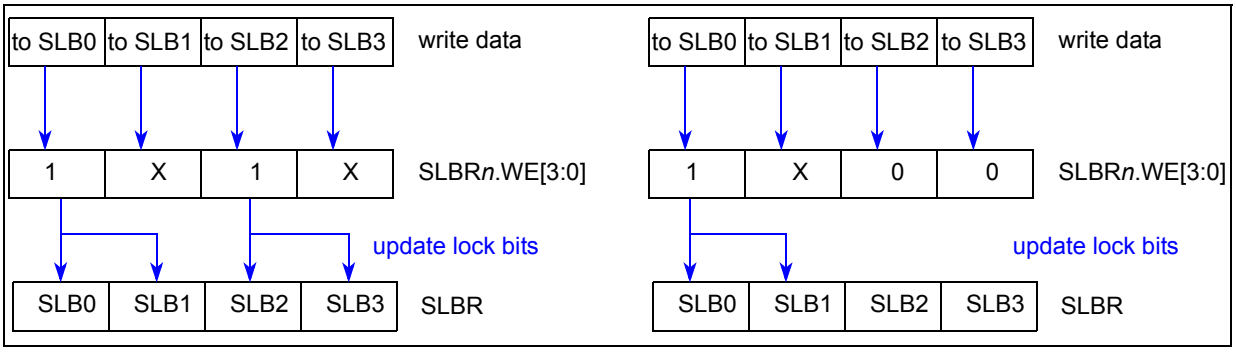


Figure 1946 shows four registers that can be protected 8-bit wise. In *Figure 1947* registers with 16-bit protection and in *Figure 1948* registers with 32-bit protection are shown:

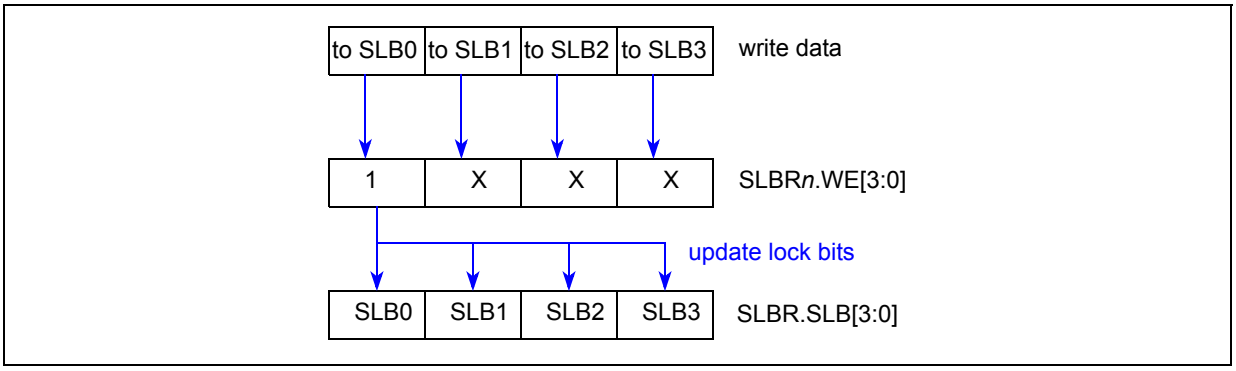
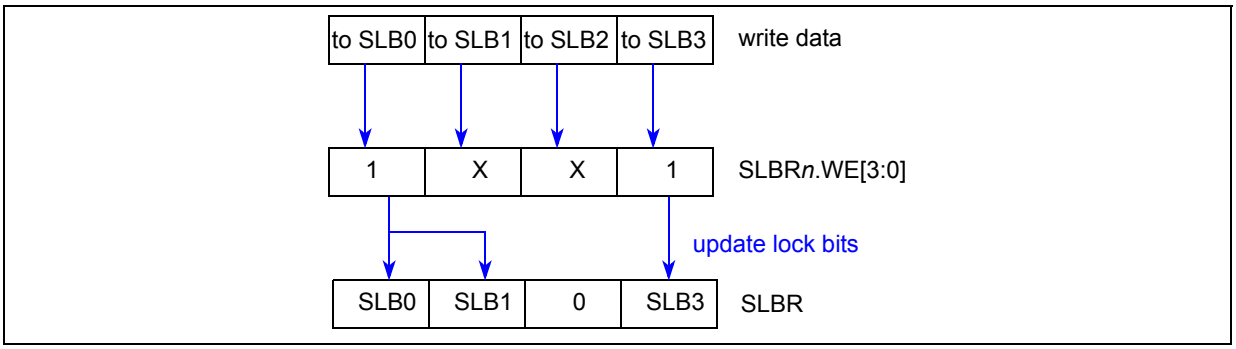
Figure 1947. Change lock settings for 16-bit protected addresses



On the right side of *Figure 1947* it is shown that the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[1] also. This is done as the address reflected by SLBR*n*.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBR*n*.WE[0] must be set while SLBR*n*.WE[1] does not matter. As the enable bits SLBR*n*.WE[3:2] are cleared the lock bits SLBR*n*.SLB[3:2] remain unchanged.

In the example on the left side of *Figure 1947* the data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] and the data written to SLBR*n*.SLB[2] is mirrored to SLBR*n*.SLB[3] as for both registers the write enables are set.

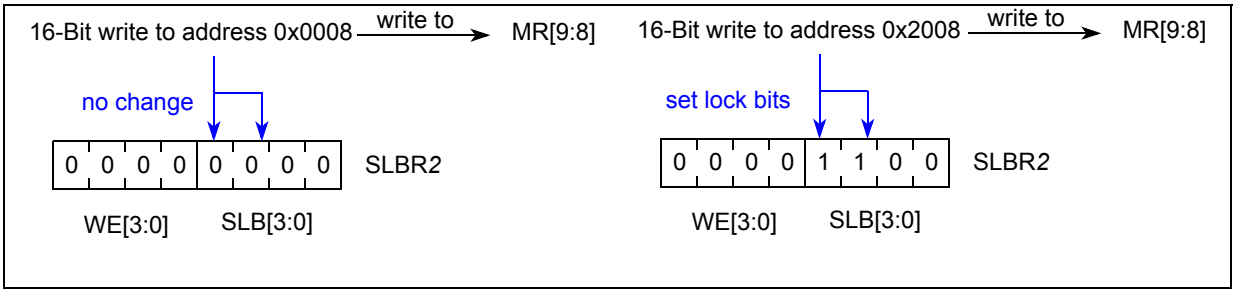


In *Figure 1948* a 32-bit wise protected register is shown. When SLBR*n*.WE[0] is set the data written to SLBR*n*.SLB[0] is automatically written to SLBR*n*.SLB[3:1] also. Otherwise SLBR*n*.SLB[3:0] remains unchanged.

Figure 1948. Change lock settings for 32-bit protected addresses

In *Figure 1949* an example is shown which has a mixed protection size configuration:

Figure 1949. Change lock settings for mixed protection

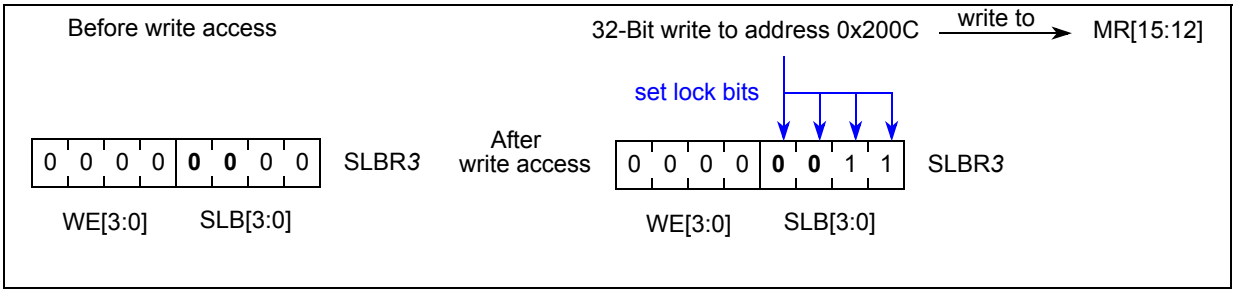


The data written to SLBR*n*.SLB[0] is mirrored to SLBR*n*.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBR*n*.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBR*n*.SLB[3] is written to SLBR*n*.SLB[3].

82.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. *Figure 1950* shows one example:

Figure 1950. Enable Locking Via Mirror Module Space (Area #3)



When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of *Figure 1947*).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of *Figure 1947*).

Figure 1951 shows an example where some addresses are protected and some are not:

Figure 1951. Enable locking for protected and unprotected addresses

In the example in *Figure 1951* addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

82.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in *Section 82.4.2.1, Change lock settings directly via Area #4* and *Section 82.4.2.2, Enable locking via mirror module space (Area #3)* is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there is a system reset.

82.4.3 Access errors

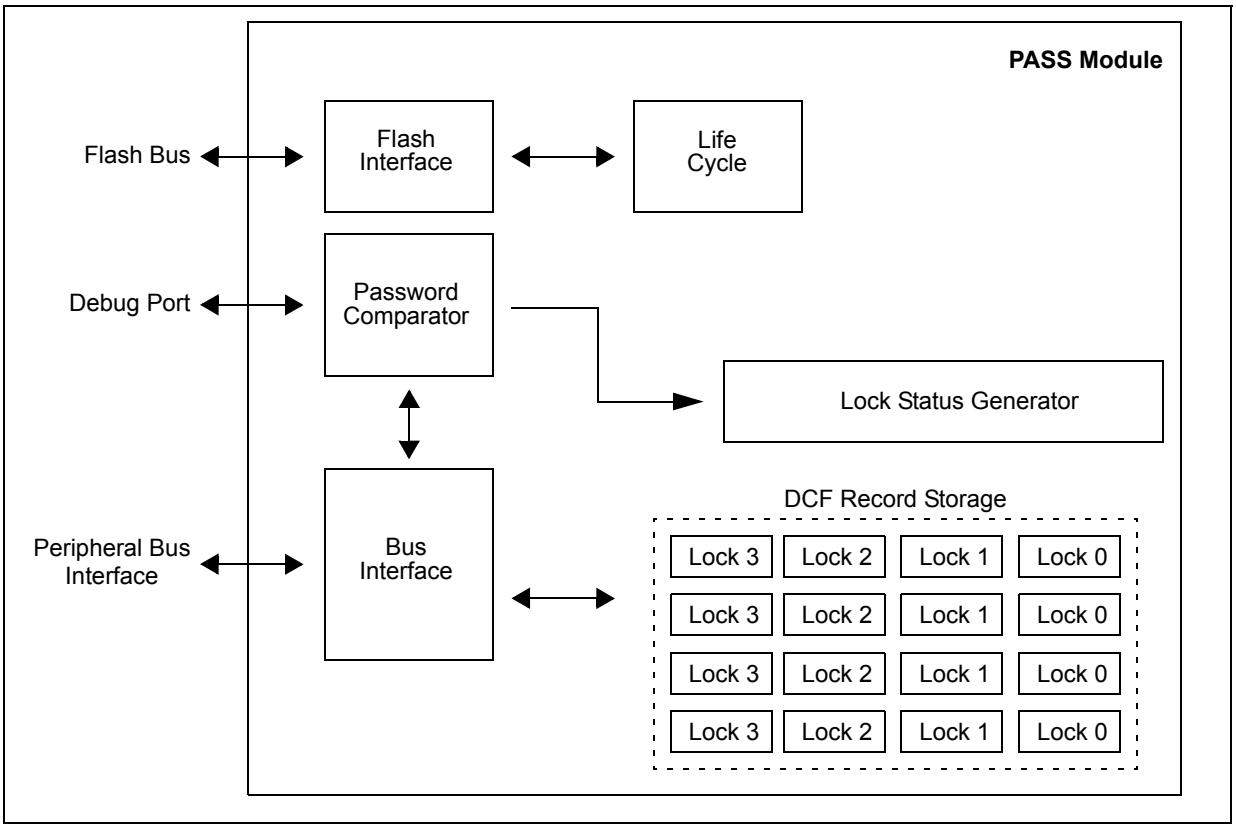
The protection module generates transfer errors under several circumstances. For the area definition refer to *Figure 1942*

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set.

82.5 Initialization/application information

82.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See *Section 82.3.2, Register descriptions*). In summary, after reset, locking for all MR*n* registers is disabled. The registers can be accessed in Supervisor Mode only.



83 Password and Device Security Module (PASS)

83.1 Introduction

83.1.1 Overview

The Password and device security (PASS) module shown in *Figure 1952*, receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 1952. PASS module block diagram

83.1.2 Features

The PASS includes these distinctive features:

- Life cycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Fuse Bypass Configuration and Password Comparison

83.1.3 Modes of operation

The PASS operates identically in all system modes.

83.2 External signal description

The PASS has 1 external pin that is used for Production Disable control.

83.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the PASS. (DCF clients are described in *Section 83.4, DCF clients*.)

Table 1866 shows the memory map for the PASS. Note that all addresses are offsets: the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual .

Table 1866. PASS memory map

1. Reset value depends on life cycle status.
2. Reset value depends on password group lock state.

Note: Non-implemented registers generate bus aborts if enabled by the SOC.

83.3.1 Register descriptions

The following registers are available in the PASS. The shaded bits are reserved for future use. For future compatibility, only write ‘0’ to these bits; they always read ‘0’.

83.3.1.1 Life Cycle Status register (LCSTAT)

The Life Cycle Status Register reflects the production status and censorship status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Offset 0x0000 Access: Software Read

Figure 1953. Life Cycle Status register (LCSTAT)

1. Reset value depends on the Censorship DCF client

PASS_LCSTAT register functions are as shown in *Table 1867*.

Table 1867. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the state of the Censorship DCF Client. The bit can be set (or cleared) via DCF Record in UTEST Flash. See section *Section 83.6.4, Censoring and uncensoring the device*. 1 Device is censored 0 Device is uncensored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit.
2 FBE	Fuse Bypass enable. This field indicates whether the Fuse Bypass DCF Client is set to Fuse Bypass Enable. 1 Fuse Bypass Enable (Fuse can be bypassed with password) 0 No Fuse Bypass (Fuse must be blown)
3–28	Reserved. This read-only bit is reserved and always has the value of 0.
29-–31 LIFE	The life cycle setting is manipulated externally (SSCM). Pass displays a 3-bit input life cycle. 011 Customer Delivery 010 OEM Production 111 In Field 001 reserved 000 Failure Analysis mode

83.3.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

Offset 0x0008

Access: Software Read/Write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1956. CIN*n* register

CIN register functions are as shown in *Table 1870*.

Table 1870. CIN register field descriptions

Field	Description
0–31 PW32	32 bits of the 256-bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7—in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

83.3.1.5 Clock Jitter Enable (CJE)

Software accessible one time writable register. This register stores the jitter enable status for the Pseudo Random Clock Divider Module (PRCD). The default value of this register if '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial communications modules includes large amounts of pseudo random clock edge jitter, making the serial communications modules unusable. For details about which serial communications modules are affected, see the clocking section of the Reference Manual.

For more information on Production disable, see *Section 83.5.4, Production Disable*

Debug access is blocked when Production disable bit[0] (Gated Debug Enable) is asserted, the Chip is *In Field* and Clock Jitter is not enabled.

Offset 0x00D0

1–31	This read-only bit is reserved and always has the value of 1.

83.3.1.6 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

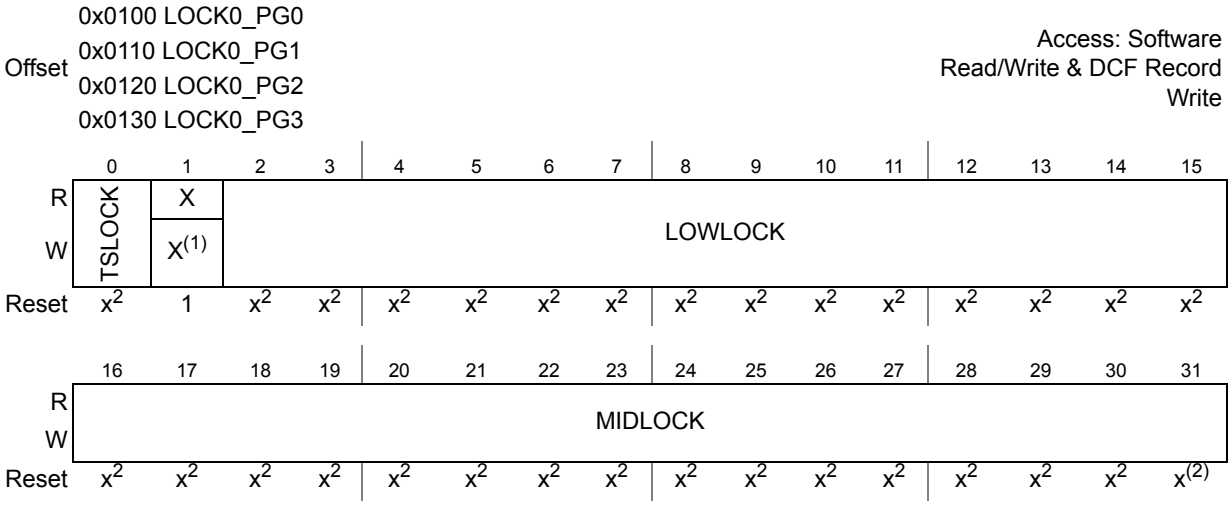

Figure 1958. LOCK0_PG*n* register

1. This bit is not implemented and its value has no impact on the system.
2. If no DCF records have been written to change the lock state, the bit will reset to '1'.

LOCK0_PG*n* register functions are as shown in *Table 1872*.

Table 1872. LOCK0_PG*n* register field descriptions

Field	Description
0 TSLOCK	UTEST NVM Lock. This bit is used to lock the UTEST NVM block from programs (erase protection not needed since UTEST NVM is OTP and not erasable).
1	This bit is reserved and has no impact on the system.
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the *Customer Delivery* life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. . However, unless the life cycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

When Production Disable register bit[1](BAF PLock Hardware Interlock enable) is asserted and life cycle is *In Field*, then the external signal is ORed with BAF_plock(low_lock[0]) of LOCK0_PGx.

83.3.1.7 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to *OEM Production* or older.

Figure 1959. LOCK1_PG*n* register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

LOCK1_PG*n* register functions are as shown in *Table 1873*.

Table 1873. LOCK1_PG*n* register field descriptions

Field	Description
0–15	This bit is reserved and always has the value 0.
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written, is '1', which indicates a block is locked.

During the *Customer Delivery* life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

83.3.1.8 Password Group *n* - Lock 2 status register (LOCK2_PG*n*)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to *OEM Production* or older.

Figure 1960. LOCK2_PG*n* register

1. If no DCF records have been written to change the lock state, the bit resets to '1'.

Note: Lock registers can only be accessed with 32-bit operations.

LOCK2_PG*n* register functions are as shown in *Table 1874*.

Table 1874. LOCK2_PG*n* register field descriptions

Field	Description
0–31 L_256LCK	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is ‘1’, which indicates a block is locked.

During the *Customer Delivery* life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.. However, unless the life cycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

83.3.1.9 Password Group *n* - Lock 3 status register (LOCK3_PG*n*)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit is cleared and the Lock registers become writable.

The LOCK bits do not come into effect before the life cycle matures to *OEM Production* or older.

Figure 1961. LOCK3_PG*n* Register

1. Not all devices include this field. See the device reference manual's chip configuration chapter for details.
2. Reset value depends on life cycle. If life cycle is *Customer delivery* or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

LOCK3_PG*n* register functions are as shown in *Table 1875*.

Table 1875. LOCK3_PG*n* register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than *Customer Delivery*. Before that the value of the bit is always 0. This bit is only updatable from SW path. It cannot be updated from DCF loading from Flash. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is *Customer Delivery* or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface LockThe default value of this bit would be '1' if not upfated from flash. 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3	Reserved
4-7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8–10	Reserved

Table 1875. LOCK3_PG*n* register field descriptions(Continued)

Field	Description

13 RL2	Read Lock Region 2 lock bit. Note that not all devices include this field. See the device reference manual's chip configuration chapter for details. The default value of this bit would be '1' if not upfated from flash. 0Region 2 is not protected 1Region 2 is protected
14 RL1	Read Lock Region 1 lock bit. Note that not all devices include this field. See the device reference manual's chip configuration chapter for details. The default value of this bit would be '1' if not upfated from flash. 0Region 1 is not protected 1Region 1 is protected
15 RL0	Read Lock Region 0 lock bit. Note that not all devices include this field. See the device reference manual's chip configuration chapter for details. The default value of this bit would be '1' if not upfated from flash. 0Region 0 is not protected 1Region 0 is protected
16–31 U_256LCK	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the *Customer Delivery* life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.. However, unless the life cycle is older than *OEM Production*, the Flash blocks are always unlocked regardless of the values in the password groups.

For operation of the region read protect feature, refer to .

Once a censored device enters the *Failure Analysis* life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0]is read unlocked in Failure Analysis lifecycle.

83.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual .

Table 1876. PASS DCF clients

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section/Page
Censorship					
None	Censorship	None	0x0000_0000	0x00B0	*83.4.1/3215*

Field	Description
0–15	Reserved.
16:31	Censorship If this value is 0x55AA the MCU is NOT censored If this value is anything other that 0x55AA, the MCU is censored

83.4.2 Production Disable

Production Disable is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable and Hardware Interlock aspects of the Production Disable feature.

The DCF client implements 2 bits with a default value of ‘0’. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, see *Section 83.5.4, Production Disable*

DCF Client Address: 0x00C0 Production Disable Access: DCF Record Write Once Only

Figure 1963. Production Disable DCF client

Table 1878. Production Disable DCF Client field descriptions

Field	Description
0–29	This bit is reserved and always has the value 0.
30 HI	Hardware Interlock 0 BAF Flash block programming is controlled by PASS_LOCK0[BAF] bits 1 BAF Flash block is locked for programming while external hardware pin is asserted ‘0’
31 DD	Debug disable. 0 Debug Interface is Enabled and Disabled using Censorship, JTAG password & PASS_LOCK3[DBL] bit as described elsewhere 1 Debug Interface is disabled while Clock Jitter is NOT enabled

83.4.2.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the Life cycle is *In Field* or beyond, overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit. All Debug access is blocked while Clock Jitter is *not* enabled.

Once Clock Jitter *is* enabled, the Debug interface is *not* disabled and can be enabled temporarily or permanently using Censorship, JTAG password or the PASS_LOCK3[DBL] bit.

83.4.2.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the life cycle is *In Field* or beyond, prevents programming of the BAF Flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

83.4.3 Fuse Bypass DCF Client

This DCF client is used to configure the password protected Fuse bypass feature. See *Section 83.5.5, Fuse Bypass* for details.

The Fuse Bypass DCF Client is not directly readable in software, but the state of the Fuse Bypass bit can be read in the LCSTAT register (*Section 83.3.1.1, Life Cycle Status register (LCSTAT)*).

The DCF client is written during Destructive Reset Phase 3 and compared during Functional Reset Phase 3 - if this compare does not match the data already written, the logic will decode No fuse bypass.

DCF Client Address: 0x00E0 Fuse Bypass — Access: DCF Record Write Once Only

Table 1879. Fuse Bypass register field descriptions

Field	Description
0–30	Reserved
31 FB	Fuse Bypass enable 0 The Fuse can NOT be Bypassed 1 Bypass of the fuse is possible with a password

83.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

83.5.1 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access; and flash memory read protection.

The MCU can be Censored by writing a DCF Record to flash that writes to the Censorship DCF client (See *Section 83.4.1, Censorship*).

83.5.2 Debug Interface Access

The debug interface in fully enabled in Customer_Delivery Lifecycle. But from OEM_Production lifecycle, it can be blocked using censorship and selectively by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS_LOCK3 register (See *Section 83.3.1.9, Password Group n - Lock 3 status register (LOCK3_PGn)*). Both these debug enabling options are further conditioned by lifecycle and Production Disable.

The table below describes all options for enabling/blocking Debug Interface access

Table 1880. Debug Interface Enable Truth Table

Input Conditions						Outcome
Lifecycle	**Production Disable mode**	**Clock Jitter Enable**	**Censorship**	**Debug Enable (LOCK3[DBL] bit)**	**JTAG Password**	**Debug Interface Enable**
Customer Delivery	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled
OEM Production	Don't Care	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
In Field	Off	Don't Care	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
	On	Jitter Enabled	Not censored	Don't Care	Don't Care	Enabled
			Censored	Unlocked (DBL=0)	Don't Care	Enabled
				Locked (DBL=1)	Matched	Enabled
					Not Matched	Blocked
		Jitter disabled	Don't Care	Don't Care	Don't Care	Blocked
Failure Analysis	Don't Care	Don't Care	Don't Care	Don't Care	Don't Care	Enabled

If the device is censored, then access is possible via JTAG password.

83.5.2.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, can to be written by an external tool. If that password matches the JTAG password

stored in UTEST flash, Debug Interface Access is enabled (according to the table above) until the next destructive reset.

83.5.3 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Lifecycle, Censorship and whether the Debug Interface access is enabled or blocked. *Table 1881: Flash Memory Read Protection Truth Table* describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but becomes read protected when a Debug tool is attached and enabled (JTAG password or LOCK3[DBL] bit).

The flash memory is also read protected when the lifecycle status is *Failure_Analysis*. This lifecycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

Table 1881. Flash Memory Read Protection Truth Table

INPUTS				OUTPUTS	
Lifecycle	**Censorship**	**Debug Interface Enable from HSM**	**Lock3[RLx]**	**Read Protected RL[0] (UTEST)**	**Read Protected RL[4:1] (Other Regions)**
JDP Production / Customer Delivery	Don't Care	Don't Care	Don't Care	Readable	Readable
OEM Production / IN Field	Uncensored	Don't Care	Don't Care	Readable	Readable
	Censored	Blocked	Don't Care	Readable	Readable
		Enabled	Locked (1)	Read Blocked	Read Blocked
			Unlocked (0)	Readable	Readable
Failure Analysis	Uncensored	Don't Care	Don't Care	Readable	Readable

83.5.4 Production Disable

83.5.4.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (normally CAN and FlexRay). This jitter means those serial communications modules are not able to communicate on the network.

As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted.

83.5.4.2 Enabling

The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. Bit 1 enables the Hardware Interlock pin. See *Section 83.4.2, Production Disable* for details.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state of both features is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential, but ensures the feature can not be Enabled accidentally.

83.5.4.3 Activation

The BAF code is always the first code executed out of reset. As part of the normal boot sequence, The BAF code copies the ‘Clock Jitter Activation’ constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (See *Section 83.3.1.5, Clock Jitter Enable (CJE)* for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF Flash is 0xFFFF_FFFF (erased state)

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF Flash should be programmed to make the most significant bit ‘0’. After the next reset, the BAF copies this updated value to the Clock Jitter Register and the feature is activated.

The BAF Flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF Flash block can further be protected from programming by an external hardware pin. If the Hardware Interlock feature is enabled, while this pin is logic ‘0’ the BAF Flash block can not be programmed.

83.5.4.4 Clock jitter Truth table

Table 1882 shows the relationship between Lifecycle, Production Disable & Clock Jitter enable input conditions versus the state of the Baud Rate Clock.

Table 1882. Clock Jitter Truth Table

Lifecycle	Production Disable[Debug Disable]	Clock Jitter Enable	Baud Rate Clock State
JDP_Production Customer_Delivery In_Field	Don't Care	0b1xxxxxxx_(24 more x)	Normal - No Jitter
		0b0xxxxxxx_(24 more x)	Jitter
Failure_Analysis	Off [0]	0b1xxxxxxx_(24 more x)	Normal - No Jitter
		0b0xxxxxxx_(24 more x)	Jitter
	On[1]	Don't Care	Jitter

83.5.5 Fuse Bypass

83.5.5.1 Fuse

Some devices include an additional security feature, whereby a silicon fuse is used to gate access to flash test mode when the device is in Failure_Analysis lifecycle. The fuse must be blown, creating physical damage to the silicon, before access is granted to Flash Test Mode. The PASS implements a configurable feature to bypass the requirement to blow the fuse to enter flash test mode, by entering a password instead. This feature is called Fuse Bypass

83.5.5.1.1 Use Case: No Fuse Bypass

Customers who want no alternative to the Fuse to enter Flash Test Mode in FA life cycle:

- During customer assembly, customer programmes DCF Record in UTEST to write this DCF client with 0.
- And as a back-up, during customer assembly, the customer could programme the Fuse Bypass Password to a random value.

83.5.5.1.2 Use Case: Fuse Bypass Password

Customers that require a password to enter Flash Test Mode in FA life cycle, but don't require the added sophistication of blowing a fuse:

- During customer assembly, customer programmes DCF Record in UTEST to write this DCF client with 1.
- During customer assembly, the customer programmes the Fuse Bypass Password into Flash
- The customer maintains a system for retrieving these passwords for the life of the module
- If the part is returned to JDP for FA, the customer must provide the Fuse Bypass password that was originally programmed into the device.
- If the password is lost or irretrievable, the customer must accept that FA can only be performed if the die is removed from the package and the fuse blown.

83.5.5.1.3 Use Case: No Fuse. No password

Customers that are less concerned with security and will accept neither fuse nor password to enter Flash Test Mode in FA life cycle:

- Customer need do nothing special for this mode in customer assembly.
- When the part is returned to JDP for FA, The DCF Client is still in the default state of 1. This is Fuse Bypass.
- The Fuse Bypass password should still be in the erased state (All 1). The tester can enter all 1 as the password to gain access to Flash Test Mode

83.5.5.2 Fuse Bypass Password

The Fuse Bypass Password is a password entered by the JDP via JTAG interface, during device FA, to gain access to Flash Test Mode. Flash Test Mode is required to perform Vt Distribution analysis and other tests on an MCU. This password is only functional during FA life cycle. During other life cycles, Flash Test Mode is either available; completely blocked; or requires the Retest Password. Flash blocks that are assigned as sealed during production are locked against any form of Flash test, including reading, erasing and Vt Distribution analysis.

83.5.5.2.1 Fuse Bypass Password Generation

The Fuse Bypass password is created by the customer during their module assembly process. It must be programmed into UTEST Flash while in CUSTOMER_DELIVERY life cycle.

When an MCU is returned to JDP for FA, the MCU must be in FA life cycle and this password must also be provided to JDP to allow access to Flash Test Mode without blowing the fuse. Therefore the customer should develop a process for managing Fuse Bypass passwords for the life of the module.

If the password is not available when a device is returned for FA, JDP must remove the die from the package and blow the fuse before entry is possible to Flash Test Mode and Flash FA can be undertaken.

83.5.5.2.2 Fuse Bypass Password Storage

The Fuse Bypass password is 224 bits (28 bytes) wide and is to be stored in UTEST Flash at a fixed location. See the device reference manual for the address of the Fuse Bypass password.

The password region of UTEST Flash is readable only when in CUSTOMER_DELIVERY life cycle. In any life cycle after this (including FA life cycle), this region is read protected.

83.5.5.2.3 Fuse Bypass Password Challenge Entry

The Fuse Bypass password challenge in entered by an external tool to the password register in JTAGC

As the Fuse Bypass Password is 224 bits; and the JTAGC password register is 256, only the least significant 224 bits of the register are used.

83.5.5.2.4 Fuse Bypass Password Compare

The Fuse Bypass Password challenged, is compared against the password stored in UTEST Flash. Only the least significant 224 bits are compared as the most significant 32 bits of the Flash page contain different data not related to Fuse Bypass.

If the password matches, Flash Test Mode access is allowed until the next POR reset.

There are no passwords that the hardware will detect as illegal. All 0 and all 1 are valid passwords.

83.6 Initialization/application information

83.6.1 Reset

The reset state of each individual bit is shown within the Register Description section (see *Section 83.3.1, Register descriptions*). However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

83.6.2 Modifying Life Cycle (maturing the device)

The life cycle can be modified by an external life cycle management device like SSCM. It is no longer controlled through the PASS module.

83.6.3 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

Table 1883. CS/ADDR Values for Lock Registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0xxxxx(1)_0100
Lock1	0xxxxx(1)_0104
Lock2	0xxxxx(1)_0108
Lock3	0xxxxx(1)_010C
PW Group 1	
Lock0	0xxxxx(1)_0110
Lock1	0xxxxx(1)_0114
Lock2	0xxxxx(1)_0118
Lock3	0xxxxx(1)_011C
PW Group 2	
Lock0	0xxxxx(1)_0120
Lock1	0xxxxx(1)_0124
Lock2	0xxxxx(1)_0128

Table 1883. CS/ADDR Values for Lock Registers(Continued)

Register	DCF CS/ADDR
Lock3	0xxxxx(1)_012C
PW Group3	
Lock0	0xxxxx(1)_0130
Lock1	0xxxxx(1)_0134
Lock2	0xxxxx(1)_0138
Lock3	0xxxxx(1)_013C

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See Device reference manual for the Client Select assignment

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in *Table 1884*.

Table 1884. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x0C	0xxxxx(1)_0110	
0x10	0xFFFF_FFFF	Stop Record
0x14	0xFFFF_FFFF	
...	...	

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See Device reference manual for the Client Select assignment

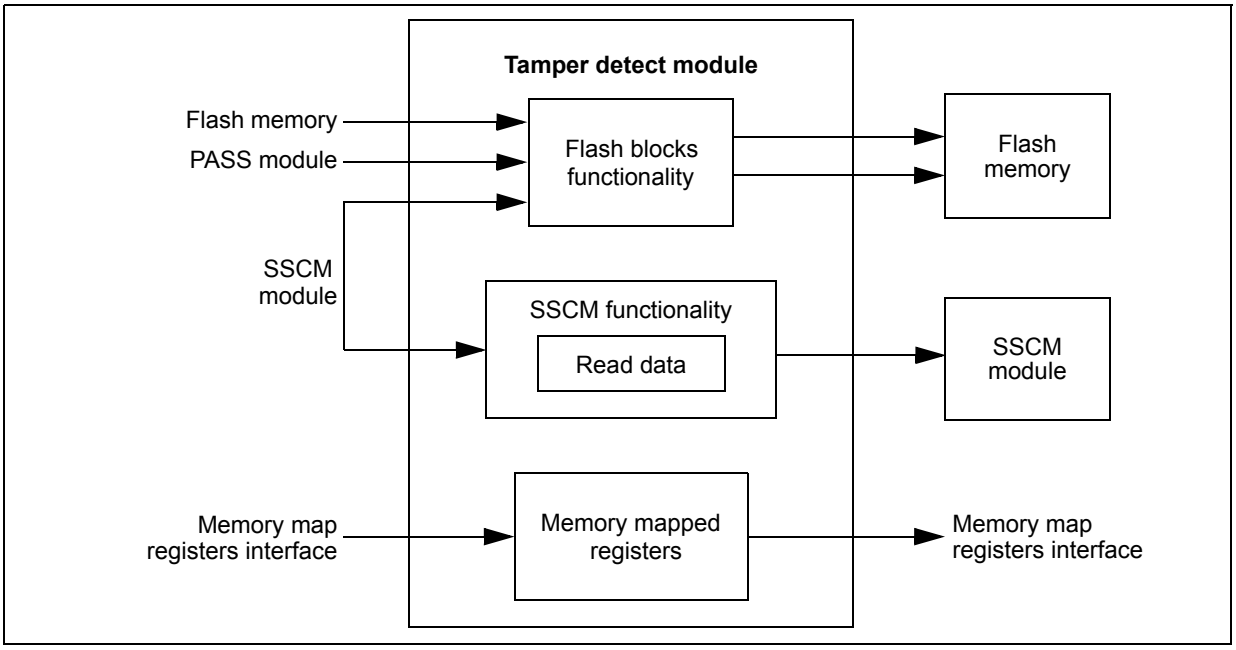
83.6.4 Censoring and uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTEST Flash, apart from the available space for DCF records. It is possible to censor and un-censor multiple times.

The DCF Client Select / Address for the Censorship DCF client, is a concatenation of the DCF Client Select (assigned outside of PASS, and is defined in the Device Reference Manual) and the address 0x00B0. Therefore 0xxxxx_00B0. In order to un-censor the device, the data field of the record needs to be written with 0x----55AA (upper 16 bits are not compared). Any other value censors the device.

On delivery the device is uncensored.

84 Tamper Detection Module (TDM)



84.1 Overview

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

Figure 1965 shows the block diagram of the TDM and its interface to other system components.

Figure 1965. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are:

- OTP (One-Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information (via the DCF bus).

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

Note: The TDM is one of several modules that provide an integrated set of security functions within the chip and there is overlap among some of those functions. In the case of OTP

assignments for flash blocks, the TDM settings cannot override security settings implemented using the PASS module. If the PASS module has security configuration settings for a flash block, those settings have priority over TDM settings.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a mean to verify whether the block is part of any TDRs. The memory map registers interface provides a mean to the user to read information of the TDM registers.

84.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records[aa]
- The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory Map Registers Interface for reading via software of specific registers.

84.3 External signal description

There are no external signals driving or being driven by the TDM.

84.4 DCF client

It is important to understand the role of DCF records and DCF clients and how the affect TDM functions.

aa. The Tamper Region Override DCF record is a “write one only” DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

DCF records contain configuration data processed during device boot. Those records are permanently stored in a dedicated block of on-chip flash memory. TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

A DCF client is an internal register within a module that corresponds to a specific type of DCF record. The register contains data from all instances of that record type considered to be valid. Although multiple instances of a record type may exist, whether each is considered valid depends on the strategy associated with that record type. For example, if a record type is defined as “write once”, multiple instances of that record type can be created but only the first (lowest address within the DCF record address space) is processed. Subsequent records are ignored.

If a DCF record type is defined as “write 1 only”, and the default value is all zeros, bits can only be changed from 0 to 1. The OTP_ENn (OTP Enable) DCF records are an example of this strategy. Multiple records of this type can be written but bits can only be changed from 0 to 1. The effect is that all records of this type are processed, since it is not also defined as "write once", and the configuration is cumulative. Since bits within that record can only be changed from 0 to 1, after a block has been configured as OTP by creating the appropriate DCF record, that cannot be reversed.

As stated previously, DCF clients are internal registers. They are not memory mapped and are therefore inaccessible for reads or writes by software. Although these registers are inaccessible to software, understanding their function is critical to being able to define the DCF records required to properly implement tamper detection on this chip.

Use the information in the following sections in conjunction with the generic Tamper Detect DCF record definitions provided in the “Device Configuration Format (DCF) Records” chapter to design and appropriate tamper detection scheme.

Note: Reserved bits are read as 0s. Attempts to write to reserved bits can generate unpredictable results for DCF clients.

Table 1885 gives an overview on the TDM DCF clients implemented.

Table 1885. DCF client address map

DCF Client Name	Description	Strategy
Diary Base Address	Stores the base address of the tamper detection diary	write-once, write 1 to 0 only
Tamper Region Override	Stores information of which TDR is to be overridden	write 0 to 1 only

Table 1885. DCF client address map(Continued)

DCF Client Name	Description	Strategy
OTPEN[nb] (OTP Enable)	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	write 0 to 1 only
TDR[n]_LOCK[m] Region Assignment	Stores information of which flash block is assigned to a TDR. – n specifies a TDR – m specifies the flash blocks as per the LOCK registers of the flash memory.	write 0 to 1 only

84.4.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. *Figure 1966* shows the diagram for this register.

Warning: This DCF client is implemented as Write Once and is writable from 1 to 0 only. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0000 Access: DCF write

26–31 TOE*[5:0]*	TDR Override Enable. Each TOE field, where *n* represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written. 1 Diary override. The diary for this TDR can be erased WITHOUT writing to the diary.

84.4.3 One Time Programmable Enable (OTPEN0) DCF client

This DCF Client holds the OTP information for the Low and Mid blocks of the flash memory. This register mirrors the LOCK0 register of the flash memory. *Figure 1968* shows the diagram for this register.

Warning: **This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to OTP irreversible.**

DCF Client Address: 0x0008 Access: DCF write

The same mapping also applies to control similar functions in the embedded flash memory module. 0 Corresponding flash blocks are not assigned as OTP 1 Corresponding flash blocks are assigned as OTP

84.4.7 Tamper Region Assignment DCF client (TDR*n*_LOCK0)

This DCF client holds the assignment information of the flash blocks to a specific TDR. Each flash block can be assigned to any of the TDR (*n* varies from zero to 5). This DCF client however holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. Therefore, the diagram of this register mirrors the LOCK0 register in the flash memory. *Figure 1972* depicts the TDRn_LOCK0 DCF client.

Warning: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored, making the assignment of a flash block to a TDR irreversible unless the entire TDR is overridden.

DCF client Address: 0x14+((n x 4) + 0) Access: DCF write

84.5 Memory Map and Registers

Note: The Tamper Detection Module's memory-mapped registers are read-only. Any attempted write generates a transfer error.

Table 1896. TDM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	TDR Status Register (TDM_TDRSR)	32	R	0000_003Fh	*84.5.1/3237*
4	Last Flash Programmed Address Register (TDM_LFPAR)	32	R	0000_0000h	*84.5.2/3239*
8	Diary Base Address (TDM_DBA)	32	R	Undefined	*84.5.3/3240*

84.5.1 TDR Status Register (TDM_TDRSR)

This register holds information for the status of each TDR. There is one bit in the register for each TDR. The status bit is a combination of the unlock state and the TDR AND the TDR Override bit. The default state of each status bit is ‘1’, meaning that erase operation is disabled for all flash blocks associated to the TDRs is disabled. The status bit for a TDR is set to ‘0’ (Indicating that erase operation for all flash blocks associated to the TDR can be

erased), if either a successful programming operation to the TDR diary region has been performed OR the TDR Override bit for that TDR is set.

TDRSR is a read-only register and writes have no effect. Write operations result in a transfer error.

Note: This register is not defined in all devices. See the chip configuration chapter of the Reference Manual for details.

Table 1897. TDM_TDRSR field descriptions

Field	Description
0–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 TDRSR5	Represents the status of TDR 5 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
27 TDRSR4	Represents the status of TDR 4 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
28 TDRSR3	Represents the status of TDR 3 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

Table 1897. TDM_TDRSR field descriptions(Continued)

Field	Description
29 TDRSR2	Represents the status of TDR 2 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
30 TDRSR1	Represents the status of TDR 1 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.
31 TDRSR0	Represents the status of TDR 0 in conjunction with the Diary Override Enable status. 0 TDR is unlocked. Blocks assigned to this TDR are NOT blocked for erasing by the TDM module. This unlock state is achieved by a successful programming operation to the correct diary region or this TDR has been permanently unlocked by a DCF record that writes to the Tamper Region Override DCF register or a successful software override operation. 1 TDR is locked. Erase of blocks assigned to this TDR is not possible.

84.5.2 Last Flash Programmed Address Register (TDM_LFPAR)

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Note: This register is not defined in all devices. See the chip configuration chapter of the Reference Manual for details.

Offset: 0x04 Access: User read

Figure 1978. Diary Base Address Register (TDM_DBA)

Table 1899. TDM_DBA field descriptions

Field	Description
0–31 DBA	Diary Base Address. These bits represent the address of the diary location in the flash. **Note:** The diary base address is established via the DBA DCF record. The reset value of this register is determined by that record.

84.6 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

84.6.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Dairy is defined by a DCF Record .

The diary is divided into6 parts where each part consists of 256 × 64-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 × 32-bit internal hardware registers that are initialized by DCF records that define the tamper region . These registers mirror exactly the LOCK registers bits from the flash module.

Each TDRn_LOCK*m* register is loaded at boot time by the SSCM , which defines if the associated flash block is Locked for Erase in a particular TDR:

- ’1’ means the flash block is locked for erase
- ’0’ means the flash block is not locked for erase

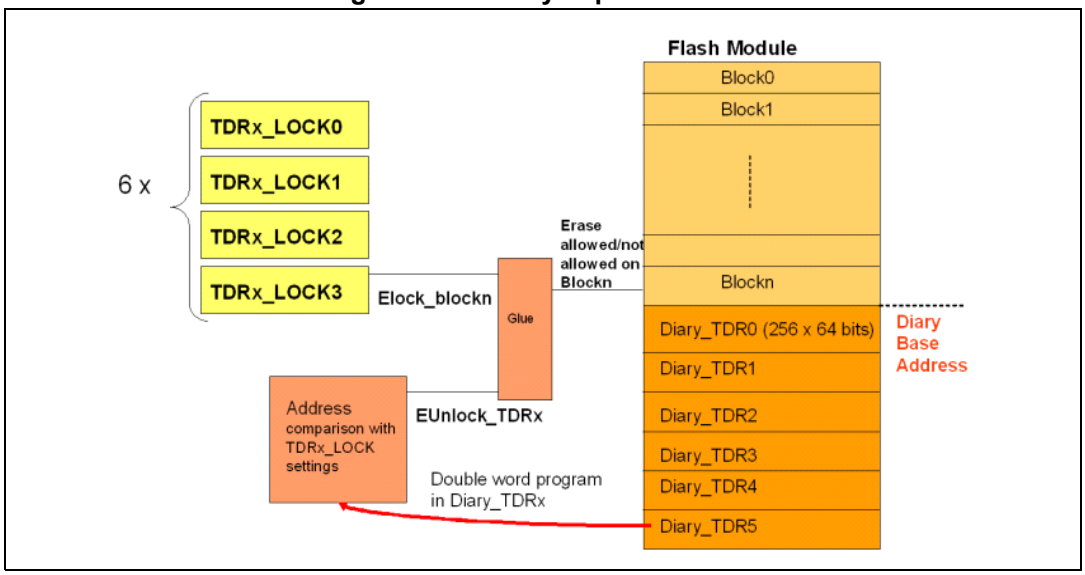
Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR.As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data was written to the correct TDR Diary Location and then unlocks the blocks for erase operation for the corresponding TDR. TDM ensures that this erase operation on unlocked blocks is allowed until the next program operation on any block, other than Diary, is performed with program completion interrupt enabled or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programmed in the diary. If diary is detected to be full, TDM provides a mean to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programmed in the diary location is flexible, and may include count information or other important customer information.



Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from “override tamper region lock” DCF record (see *Section 84.6.3: Diary*) has priority over the settings in the TDRn_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR*n*_LOCK*m* bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCK*x*_PG*n* registers have priority over TDRn_LOCKm settings. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in *Figure 1979*.

Figure 1979. Diary implementation

Note: The settings in the Tamper Region Override Register have priority over the TDRn_LOCKm Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same block are programmed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

84.6.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 × 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as TDRn_LOCKm where n is the number of a tamper region, that is, 0-5 and m varies from 0-3 as flash contains four Lock registers .

In these DCF records:

- ’1’ means that the corresponding flash block is assigned to this TDR
- ’0’ means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTEST flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

Note: No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

84.6.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming

operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of two-hundred and fifty-six 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

84.6.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore the diary can hold a maximum of 256 × 8 byte entries.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is ‘0’.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 4 KB boundary. Therefore the least significant 12 bits of the base address must all be ‘0’.

The Base address of the diary is represented by:

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

84.6.5 Diary Base Address Verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked" .See *Section 84.5.1: TDR Status Register (TDM_TDRSR)* for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See *Section 84.5.1: TDR Status Register (TDM_TDRSR)*. The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See *Section 84.5.2: Last Flash Programmed Address Register (TDM_LFPAR)*.

84.6.5.0.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to ‘0’ in each 64-bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to ‘0’; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to ‘1’. Writes to ‘0’ are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to ‘1’. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

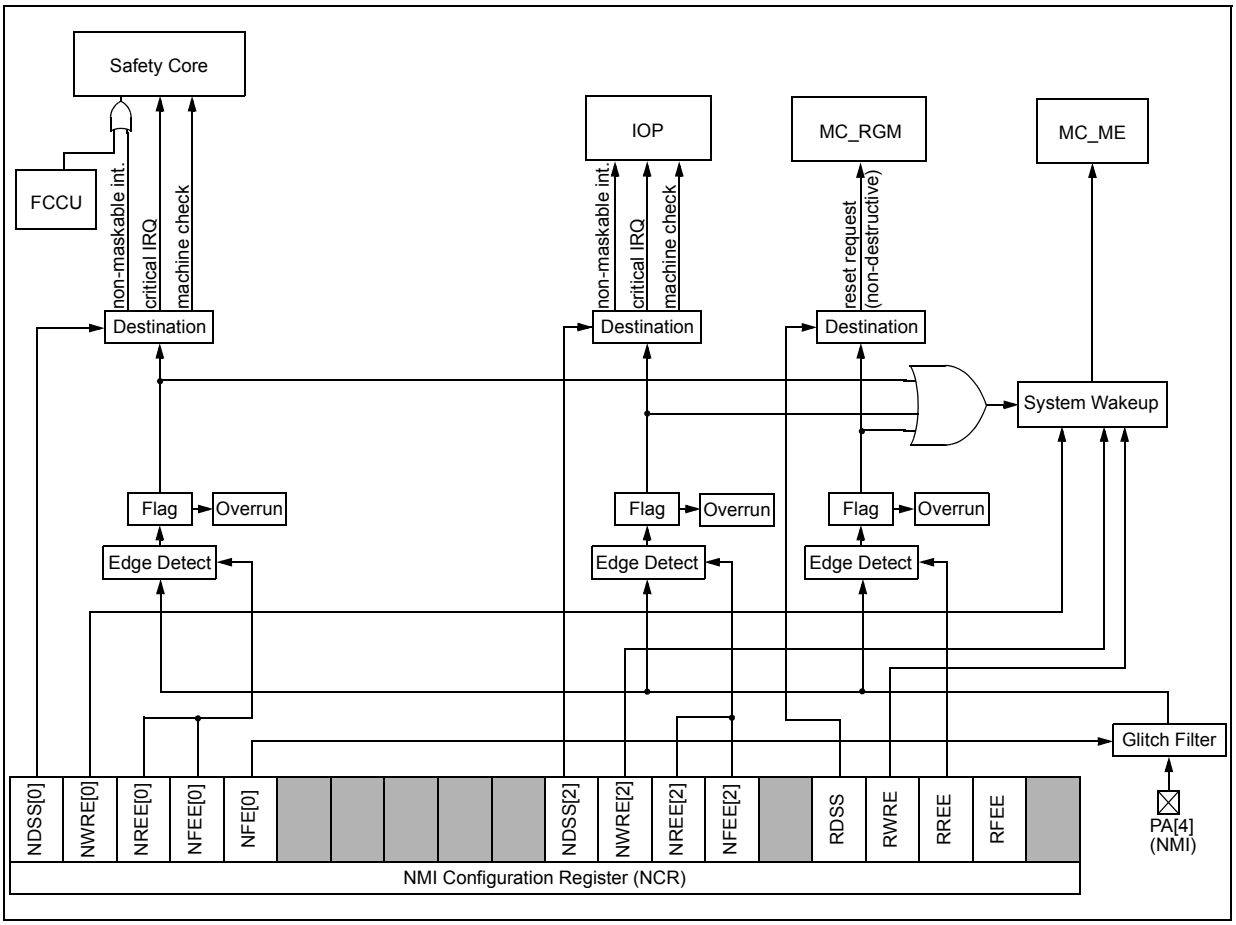
84.6.6 One Time Programmable (OTP)

84.6.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (that is, flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.



85 Wakeup Unit (WKPU)

85.1 Introduction

85.1.1 Overview

The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. This NMI external source can also generate a functional reset event to the MC_RGM. *Figure 1980* is a block diagram of the WKPU and its interfaces to other system components.

Figure 1980. WKPU block diagram

85.1.2 Features

The WKPU supports these distinctive features:

- one external NMI source
- one analog glitch filter
- independent interrupt destination for each core (safety core and IOP):
  - non-maskable interrupt
  - critical interrupt
  - machine check request
- 15 I/O external interrupts: 4–14 and 16–19 wakeup lines
- active edge selection control for events to each core and functional reset event to MC_RGM
- configurable wakeup event from low power mode to the MC_ME
- configurable wakeup event to exit from STOP mode to the MC_ME
- WKPU register configuration lock

85.2 External signal description

Active-edge-selectable, alternate-function pin PA[4] triggers the wakeup unit. See “Signal Description” chapter for further pin details.

85.3 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

85.3.1 Memory map

Table 1900 gives an overview of the WKPU registers.

Table 1900. WKPU memory map

Address offset	Register	Size (bits)	Supported access sizes (bits)	Location
0x0000	NMI Status Flag Register (NSR)	32	32/16/8	*on page 3247*
0x0004	Reserved			
0x0008	NMI Configuration Register (NCR)	32	32/16/8	*on page 3249*
0x0014	Wakeup/Interrupt Status Flag Register (WISR)	32	32	*on page 3250*
0x0018	Interrupt Request Enable Register (IRER)	32	32	*on page 3251*
0x001C	Wakeup Request Enable Register (WRER)	32	32	*on page 3251*
0x0020 – 0x0027	Reserved			
0x0028	Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)	32	32	*on page 3252*

Table 1900. WKPU memory map(Continued)

Address offset	Register	Size (bits)	Supported access sizes (bits)	Location
0x002C	Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)	32	32	on page 3252
0x0030	Wakeup/Interrupt Filter Enable Register (WIFER)	32	32	on page 3253
0x0034	Wakeup/Interrupt Pullup Enable Register (WIPUER)	32	32	on page 3253
0x0038 – 0x3FFF	Reserved			

Note: Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

85.3.2 Register descriptions

This section describes in address order all the WKPU registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

85.3.2.1 NMI Status Flag Register (NSR)

This register holds the status flags of the NMI external source pin and reset request. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI or reset request event is detected. The overrun flag is set whenever an NMI or reset request event is detected and the status flag is set (i.e. has not yet been cleared). The reset request overrun is a don't-care since the device will be reset on the first event.

The status flags are set independently of the NDSS/RDSS bits. Therefore, these flags can set but not generate a non-maskable interrupt or system wakeup if NWRE/RWRE = 0 or if NDSS is set to "no request".

Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

Note: NIF is set when: NMI Destination Source Select is disabled (NDSS = 11) and NMI System Wakeup Request is disabled (NWRE = 0) and an NMI input event is seen (pad4 is toggled).

Note: Also see notes in Section 85.3.2.2, NMI Configuration Register (NCR).

Address: 0x0000 Access: User read/write (write 1 to clear)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 1981. NMI Status Flag Register (NSR)

Table 1901. NSR field descriptions

Field	Description
NIF[x(1)]	NMI Status Flag x This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE[x] or NFEE[x] set), an NMI input event will set NIF[x]. NIF[x] causes an interrupt request based on the NMI destination, as configured by the NDSS bits, and/or a system wakeup request based on the NWRE bit configuration. 1 An event as defined by NREE[x] and NFEE[x] has occurred 0 No event has occurred on the pad
NOVF[x1]	NMI Overrun Status Flag x This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF[x] value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF[x] causes an interrupt request based on the NMI destination, as configure by the NDSS bits, and/or a system wakeup request based on the NWRE bit configuration. 1 An overrun has occurred on NMI input x 0 No overrun has occurred on NMI input x
RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (i.e., if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An event as defined by RREE and RFEE has occurred 0 No event has occurred on the pad
ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is ‘00’. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short “functional” reset. 1 An overrun has occurred on NMI input 0 No overrun has occurred on NMI input

1. Index ‘x’ designates the core: 0 is the safety core and 2 is the IOP.

85.3.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Address: 0x0008 Access: User read/write

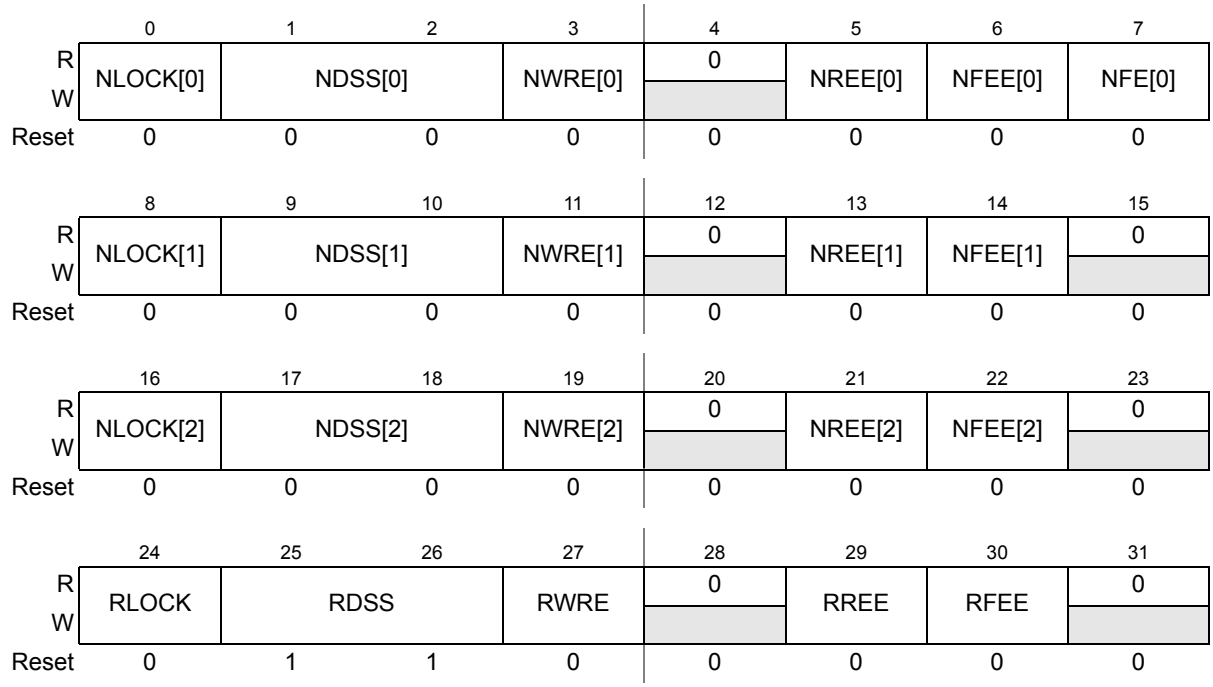

Figure 1982. NMI Configuration Register (NCR)

Table 1902. NCR field descriptions

Field	Description
NLOCK[x(1)]	NMI Configuration Lock Register x Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
NDSS[x1]	NMI Destination Source Select x 00 Non-maskable interrupt. A non-maskable interrupt will occur if NIF[x] or NOVF[x] is set. 01 Critical interrupt. A critical interrupt will occur if NIF[x] or NOVF[x] is set. 10 Machine check request. A machine check request will occur if NIF[x] or NOVF[x] is set. 11 No reaction
NWRE[x1]	NMI System Wakeup Request Enable x 1 A set NIF[x] bit or set NOVF[x] bit causes a system wakeup request 0 System wakeup requests from the corresponding NIF[x] bit are disabled
NREE[x1]	NMI Rising-edge Events Enable x 1 Rising-edge event is enabled 0 Rising-edge event is disabled
NFEE[x1]	NMI Falling-edge Events Enable x 1 Falling-edge event is enabled 0 Falling-edge event is disabled

Table 1902. NCR field descriptions(Continued)

Field	Description
NFE[0]	NMI Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled 0 Filter is disabled
RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
RDSS	Reset Destination Source Select 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request 0 System wakeup requests from the corresponding RIF bit are disabled
RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled 0 Rising-edge event is disabled
RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled 0 Falling-edge event is disabled

1. Index ‘x’ designates the core: 0 is the safety core and 2 is the IOP.

Note: Writing a ‘0’ to both NREE[x] and NFEE[x] disables the NMI functionality completely (i.e., no system wakeup or interrupt is generated on any pad activity).

Note: Writing to the NCR when NIF = 1 or NOVF = 1 causes an interrupt to the destination source/system wakeup to be generated independent of an NMI wakeup event.

85.3.2.3 Wakeup/Interrupt Status Flag Register (WISR)

This register holds the wakeup/interrupt flags.

Address: 0x0014 Access: User read/write (write 1 to clear)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	EIF[19]	EIF[18]	EIF[17]	EIF[16]	0	EIF[14:4]											0	0	0	0
W														w1c	w1c			w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1983. Wakeup/Interrupt Status Flag Register (WISR)

Table 1903. WISR field descriptions

Field	Description
EIF[x]	External Wakeup/Interrupt Status Flag x. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER[x]), EIF[x] causes an interrupt request. 1An event as defined by WIREER and WIFEER has occurred 0 No event has occurred on the pad

Note: Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Note: The external interrupts are listed in the "I/O signal description and input multiplexing" table which is contained in a Microsoft Excel® workbook attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

85.3.2.4 Interrupt Request Enable Register (IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

Address: 0x0018 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

85.3.2.8 Wakeup/Interrupt Filter Enable Register (WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

Address: 0x0030 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

85.4 Functional description

This section provides a complete functional description of the WKPU features.

85.4.1 Non-maskable interrupts

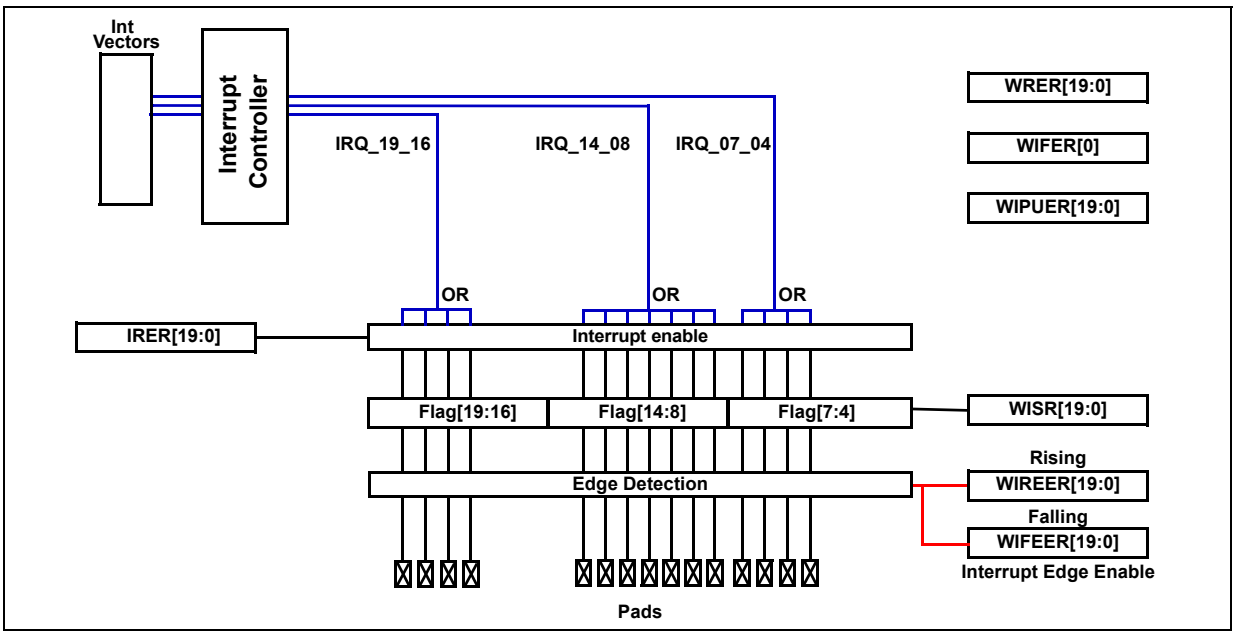
The WKPU allows the external NMI pin (ESR1) to assert the non-maskable interrupts of the cores on the device. These interrupts include non-maskable interrupts, critical interrupts, or machine check requests to any of the cores including the main core, IOP, and safety core. The safety core's non-maskable interrupt line from the WKPU is combined with the FCCU internal NMI interrupt event arising due to fault management logic.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See *Table 1902* for details.

The enabling of rising edge, falling edge, or either edge reaction to the NMI pin is independent for each core, and is controlled by NFEE[2:0] and NREE[2:0] bits in the NCR.

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The NMI supports a status flag and an overrun flag, which are located in the NSR. See *Section 85.3.2.1, NMI Status Flag Register (NSR)* for more information.



85.4.2 External Wakeups/Interrupts

The WKPU supports 13 external wakeup/interrupts which can be allocated to any pad necessary at the SoC level. This allocation is fixed per SoC.

The WKPU supports 3 interrupt vectors to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

Refer to *Figure 1990* for an overview of the external interrupt implementation.

Figure 1990. External Interrupt Pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

85.4.2.1 External Interrupt Management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (*Figure 1984*). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.

Note: Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (i.e., no system wakeup or interrupt will be generated on any activity on that pad).

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

85.4.3 Reset management

The WKPU allows the external NMI pin (ESR1) to assert a non-destructive reset request to the MC_RGM block. The ESR1 reset request can be reconfigured in the MC_RGM to

generate a SAFE mode or interrupt request (see *Chapter 58: Reset Generation Module (MC_RGM)* for details).

The enabling of rising edge, falling edge, or either-edge reaction to the NMI pin is independent for the reset request, and is controlled by the RFEE/RREE bits in the NCR.

Reset request supports a status flag and an overrun flag, which are located in the NSR. See *Section 85.3.2.1, NMI Status Flag Register (NSR)* for more information.

85.4.4 System wakeup

The WKPU allows the external NMI pin (ESR1) to assert a system wakeup from STOP to the MC_ME block on the device. The system wakeup enable is asserted in the NCR by any of the NWRE/RWRE bits.

85.4.5 Glitch filter

An analog glitch filter is placed between the NMI pin (ESR1) and the WKPU block. The filter is enabled by the NFE[0] bit in the NCR. See the device data sheet for the glitch filter electrical specifications.

85.4.5.1 Edge detect

Each NMI and reset request can be enabled or disabled independently. This can be performed using the single NCR laid out to contain all configuration bits for a given NMI in a single byte (see *Figure 1982*). The user can configure interrupts with an active rising edge, an active falling edge, or either edge being active. Disabling both edge events results in no interrupt or reset being propagated from the WKPU block.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits. The active reset request edge is controlled by the RREE and RFEE bits.

Note: After reset, NREE/RREE and NFEE/RFEE are set to '0', therefore the NMI functionality and reset request is disabled after reset and must be enabled explicitly by software.

85.5 Initialization information

This section discusses initialization for the following features:

- glitch filter and pad configuration
- non-maskable interrupt initialization
- reset request

85.5.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

Note: When enabling the glitch filter, do not enable the rising-/falling-edge events bits (NREE[x], NFEE[x], RREE, RFEE) in the same register write.

85.5.2 Non-maskable interrupt initialization

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. mask interrupts by clearing the NIF[n] and NOVF[n] bits in WKPU_NSR
2. clear WKPU_NCR bit NFEE[n] and NREE[n], preferably by writing 0 to all bits in this register
3. enable the analog glitch filter as desired by writing the NFE[0] bit in the WKPU_NCR
4. configure the appropriate SIUL2_MSCR for the desired NMI interrupt pin(s) as follows:
   - clear the ODC bits to disable output
   - set the IBE bit to enable the pin's input buffer
   - if the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits

Note: NMI interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

5. write appropriate bit values to the WKPU_NCR to configure:
   - NMI source (NDSS[n])
   - wakeup request (NWRE[n])
   - glitch filter (NFE[0])
   - rising/falling edge events enable (NFEE[n] and NREE[n])
   - NMI configuration lock (NLOCK[n])

85.5.3 Reset request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization the user must do the following:

1. mask reset requests by clearing the RIF and ROVF bits in WKPU_NSR
2. clear WKPU_NCR bit RFEE and RREE, preferably by writing 0 to all bits in this register
3. enable the analog glitch filter as desired by writing the NFE[0] bit in the WKPU_NCR
4. configure the appropriate SIUL2_MSCR for the NMI reset request pin(s) as follows:
   - clear the ODC bits to disable output
   - set the IBE bit to enable the pin's input buffer
   - if the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits

Note: NMI reset request pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external reset request inputs are desired since false reset requests could be detected (such as from a GPIO configuration).

5. write appropriate bit values to the WKPU_NCR to configure:
   - reset destination source (RDSS])
   - reset wakeup request (RWRE)
   - glitch filter (NFE[0])
   - rising/falling edge events enable (RFEE and RREE)
   - reset configuration lock (RLOCK)

86 Emulation and Debug Device Introduction

The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD).

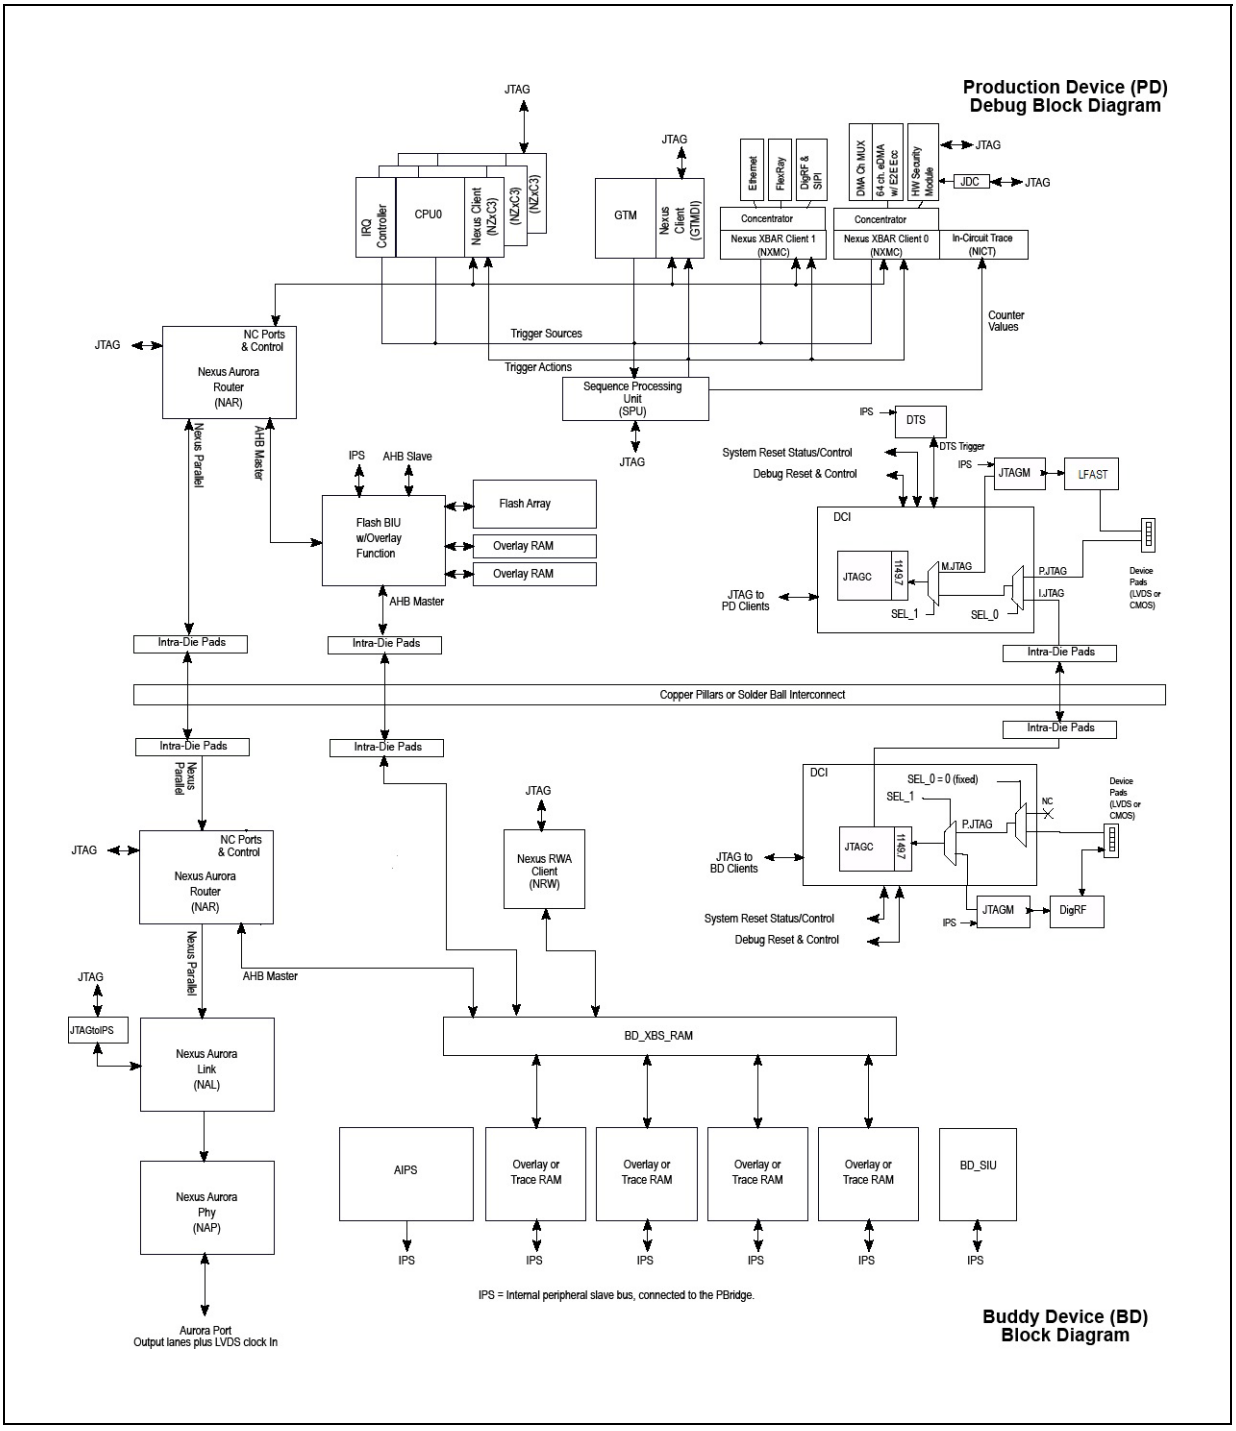
86.1 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications for four cylinder engines. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface—Allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the DCI, JTAGM and LFAST functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2011 Nexus Aurora standard)
- 1 MB on-chip SRAM usable as calibration overlay or trace RAM—entire SRAM contents are maintained as long as ED debug supply is maintained

86.2 Feature summary

On-chip modules available on the BD include the following features:



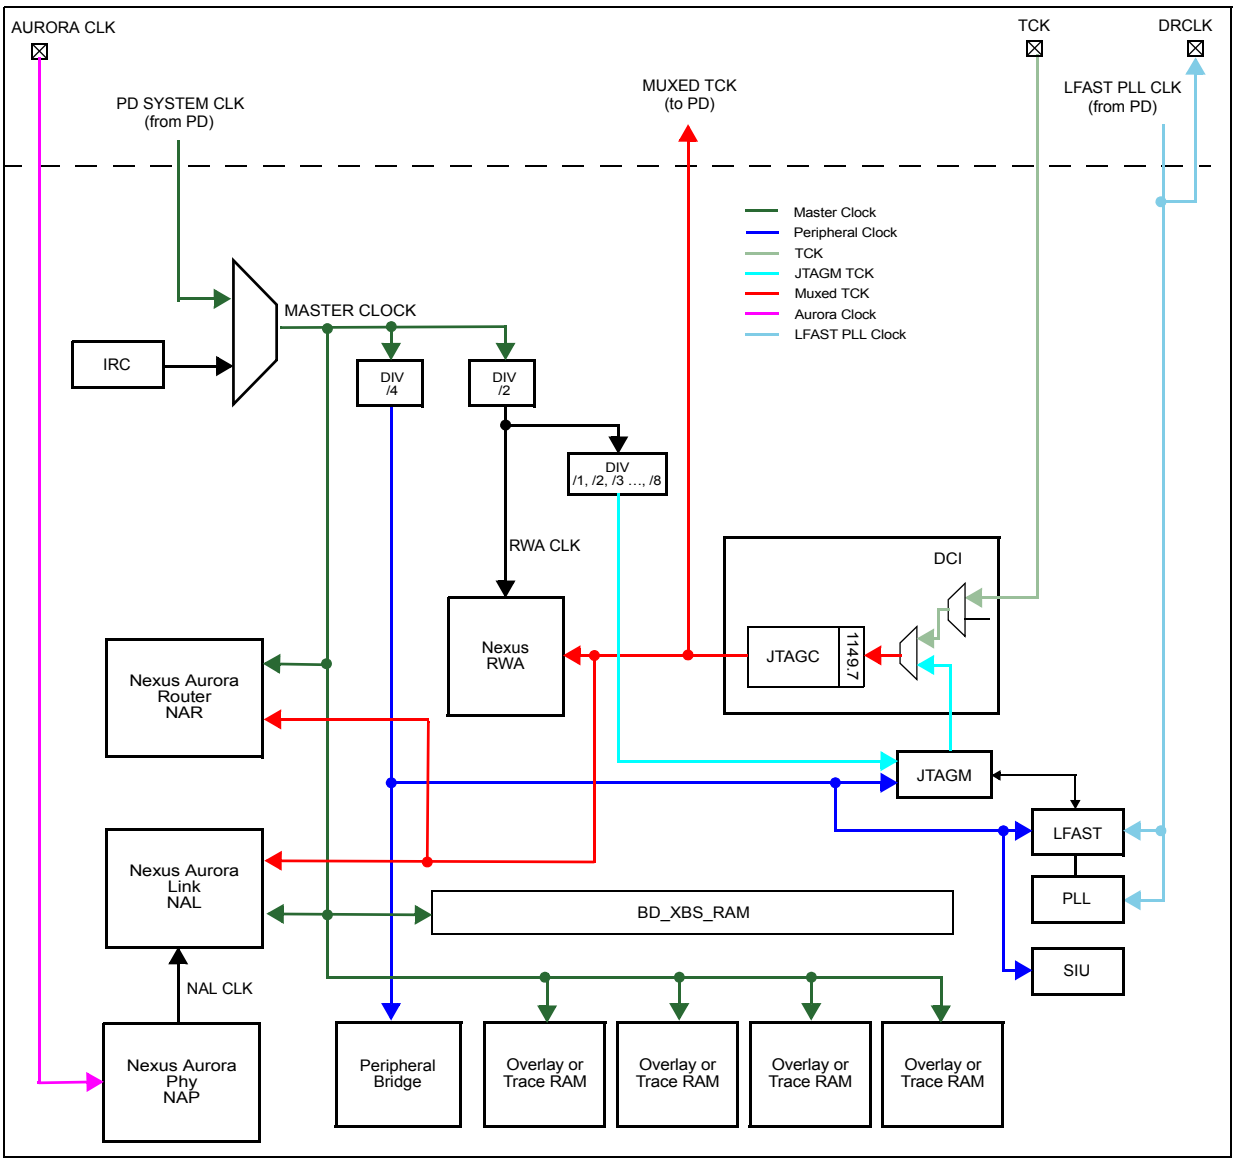
- 1 MB on-chip SRAM
  - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
  - Includes ECC
  - Implemented as 4 × 256 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
  - 64-bit data width with ECC checkbits
  - Supports “Early Write” AHB protocol (AHB-EW) for one clock trace data writes
  - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources—Memory-mapped resources include buddy device SRAM and AIPS resources
- Aurora trace port
  - 1.25 Gbit/s maximum data rate per lane
  - Support for up to 8-lane LVDS data out
    - Two lanes supported in ED package

  - Port operates in 2-lane width
  - One lane LVDS reference clock in
  - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2011 standard.
- Debug and Calibration Interface—Supports both JTAG (1149.1 and 1149.7) and LFAST modes
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Self test capability

86.3 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

Figure 1991. Emulation and debug device architecture



86.4 Clocking

Figure 1992 shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- LFAST PLL reference clock coming from the PD (BD LFAST PLL clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Aurora PHY clock coming from differential LVDS pins in the ED

Figure 1992. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible register and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of ±30%.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 160 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4)—provides the clock to memory mapped registers and other low-speed logic
- Nexus RWA clock (divided by 2)—provides the clock to the Nexus Read Write Access module
- JTAGM TCK (divided by 1, 2, …, 8)—provides a high speed TCK clock to the JTAGM module

The LFAST PLL clock from the PD (also referred to as lfast_sysclk) feeds the LFAST PLL, but it can also directly clock the LFAST in the low data rate mode. This clock is also made available as an output clock to the DRCLK package pin.

The internal TCK clock (referred to as muxed clock in *Figure 1992*) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock can come from two sources (see the Buddy Device–Debug and Calibration Interface (DCI) chapter):

- TCK package pin, when using 1149.1 or 1149.7 access
- Divided down version of the master clock to be used in LFAST/JTAGM debug accesses

Note: The division factor for the LFAST/JTAGM clock is defined by the TCKSEL field of the JTAGM_MCR (refer to the JTAGM chapter for more details). However the division factor described there applies to an already divided-by-2 clock, as shown in Figure 1992.

When the PD is unpowered, access through LFAST/JTAGM is not possible. In this case, JTAG accesses can be done only by 1149.1 or 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

In the LFAST/JTAGM mode of operation, both RWA clock and internal TCK are synchronous to each other, therefore they can both be the same frequency. This means that TCK frequency can be half of the master clock frequency. *Table 1910* summarizes the frequency restrictions on the Nexus RWA accesses.

Table 1910. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	160	160	27.7	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns)
Powered, out of reset, PLL engaged	LFAST/JTAGM	160	160	100	—

86.5 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described by *Table 1911*:

1. BD power-on reset—asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset—asserts two clock rising edges after assertion of PHASE3 reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset—asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.
4. JTAG controller reset—asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ, TEST_LEAKAGE, EZPORT boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset—asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In *Table 1911*, an ‘X’ indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins. When the debug interface is running through the LFAST interface or by software through JTAGM, those blocks are not reset by the mentioned reset sources.

Table 1911. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X

Table 1911. Reset sources and functional blocks(Continued)

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
JTAGM	X	—	JTAG mode only	JTAG mode only	—
LFAST	X	—	JTAG mode only	JTAG mode only	—
NAR	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

Note: The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

86.6 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as LFAST, JTAGM, XBAR configuration, etc. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 1912. BD memory map

Start address	End address	Allocated size (KB)	Description
BD overlay RAM			
0x0C00_0000	0x0C0F_FFFF	1024	Extended overlay RAM

87 Buddy Device—Crossbar and RAM (BD_XBS_RAM)

Within the buddy device (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note: Throughout this description, the term "overlay RAM" is applied to the BD memory, even though this memory can be used for both overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
  - Bus masters include the BD's Nexus Aurora Router (BD-NAR), the production device's flash controller (PFLASH) and the BD's Nexus Read/Write Access Client (RWA)
  - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge (AIPS-Lite) bus controller
    - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
    - End-to-End ECC32 address and data protection
    - ECC scheme based on 29-bit address and 32-bit data
    - Overlay RAM supports a 64-bit "early write" datapath and a 128-bit read datapath
- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note: Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

87.1 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit "early write" datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, m0 > m1 > m2 (PFLASH > BD-NAR > Nexus RWA). Each slave port is "parked" on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

87.2 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

e2eECC64[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0] ^ ecc_data_lower[7:0]

where `ecc_addr` is H-matrix evaluation of the 29-bit access address (addr[31:3]), `ecc_data_upper` is the H-matrix evaluation of the upper data word (data[63:32]) and `ecc_data_lower` is the comparable evaluation of the lower data word (data[31:0]).

For the BD RAM definition, the following (re)definitions apply:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

e2eECC32_upper[7:0] = ecc_addr[7:0] ^ ecc_data_upper[7:0]; data_lower[31:00] = 0

e2eECC32_lower[7:0] = ecc_addr[7:0] ^ ecc_data_lower[7:0]; data_upper[63:32] = 0

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in *Table 1913*. A '*' in *Table 1913* indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the hwchkbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

1. Bit numbering is AHB convention, bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

Figure 1993 through *Figure 1996* show an alternative representation of the ECC32 encode process, written as a C language function.

Figure 1993. C language encodeECC32_upper function description (Part 1 of 4)

              ^ (((data_a2_is_one  >> 13) & 1) ? 0x2c : 0x0)      /* data[13] */
              ^ (((data_a2_is_one  >> 12) & 1) ? 0x51 : 0x0)      /* data[12] */
              ^ (((data_a2_is_one  >> 11) & 1) ? 0xe0 : 0x0)      /* data[11] */
              ^ (((data_a2_is_one  >> 10) & 1) ? 0xa2 : 0x0)      /* data[10] */
              ^ (((data_a2_is_one  >>  9) & 1) ? 0x1c : 0x0)      /* data[ 9] */
              ^ (((data_a2_is_one  >>  8) & 1) ? 0x31 : 0x0)      /* data[ 8] */

              ^ (((data_a2_is_one  >>  7) & 1) ? 0x8c : 0x0)      /* data[ 7] */
              ^ (((data_a2_is_one  >>  6) & 1) ? 0x4a : 0x0)      /* data[ 6] */
              ^ (((data_a2_is_one  >>  5) & 1) ? 0x4c : 0x0)      /* data[ 5] */
              ^ (((data_a2_is_one  >>  4) & 1) ? 0x15 : 0x0)      /* data[ 4] */
              ^ (((data_a2_is_one  >>  3) & 1) ? 0x83 : 0x0)      /* data[ 3] */
              ^ (((data_a2_is_one  >>  2) & 1) ? 0x9e : 0x0)      /* data[ 2] */
              ^ (((data_a2_is_one  >>  1) & 1) ? 0x43 : 0x0)      /* data[ 1] */
              ^  ((data_a2_is_one         & 1) ? 0xc1 : 0x0);     /* data[ 0] */

      return(ecc);
}
```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

88 Buddy Device—System Integration Unit Lite (BD_SIUL2)

88.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

These registers are also indirectly accessible by software via BD_JTAGM in software debug mode.

88.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type
- A version field that is changed for every major mask revision of the BD
- A parameterized field that indicates the amount of extended overlay RAM included
  - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants)

88.3 Device status information

88.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically
  - BD_INIT is not cleared by external BD reset input
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or calibration software sets BD_INIT
- After PD POR, the BAF executes and reads BD_INIT
  - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap
  - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used.)

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

88.3.2 PD reset status

The IPS accessible BD_SIU_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

88.4 Memory map

Table 1914 gives an overview of the BD_SIUL2 registers.

Table 1914. BD_SIUL2 register summary

Offset	Register	Access	Reset Value	Section/Page
0x0000	BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)	R	0x57BD_0000	*88.4.1.1/-3276*

88.4.1 Register descriptions

This section describes in address order all the BD_SIUL2 registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Note: All registers support 32-bit accesses only.

88.4.1.1 BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)

The BD_SIUL2_DIDR1 contains the part number and mask number.

Offset BD_SIUL2_BASE + 0x00 Access: User read

Field	Description
0–11	Reserved.
12–15 RAM_SIZE	RAM Size. Read-only, indicates the amount of overlay RAM available in the device, with resolution of 256K byte steps 0000 0.25M byte. 0001 0.5M byte. 0010 0.75M byte. 0011 1M byte. 0100 1.25M byte. 0101 1.5M byte. 0110 1.75M byte. 0111 2M byte. 1000 2.25M byte. 1001 2.5M byte. 1010 2.75M byte. 1011 3M byte. 1100 3.25M byte. 1101 3.5M byte. 1110 3.75M byte. 1111 4M byte.
16–23 PARTNUM	Device Part Number. Read-only, mask programmed complement to the part number of the device. For the BD 1M byte part with part number 57BD1, BD_SIUL2_DIDR1.PARTNUM=57BD, and BD_SIUL2_DIDR2.PARTNUM=1. 01 1 (BD1M) 02 2 (BD2M)
24–31	Reserved.

88.4.1.3 BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset)
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT
  - If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap
  - If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used)

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

Offset BD_SIUL2_BASE + 0x100 Access: User read/write

Field	Description
0–28	Reserved.
29 PD_RST	PD Reset Flag. Read-only, indicates if PD has finished the reset sequence. 0 PD reset sequence not completed. 1 PD reset sequence completed.
30 PD_TRIM	PD Trim Flag. Read-only, indicates if PD has finished trimming phase during the reset sequence. 0 PD trimming phase not completed. 1 PD trimming phase completed.
31 PD_POR	PD POR Flag. Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed. 1 PD is powered and power on reset has completed.

89 Buddy Device—Debug and Calibration Interface (DCI)

89.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

89.1.1 Features

The ED DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

89.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

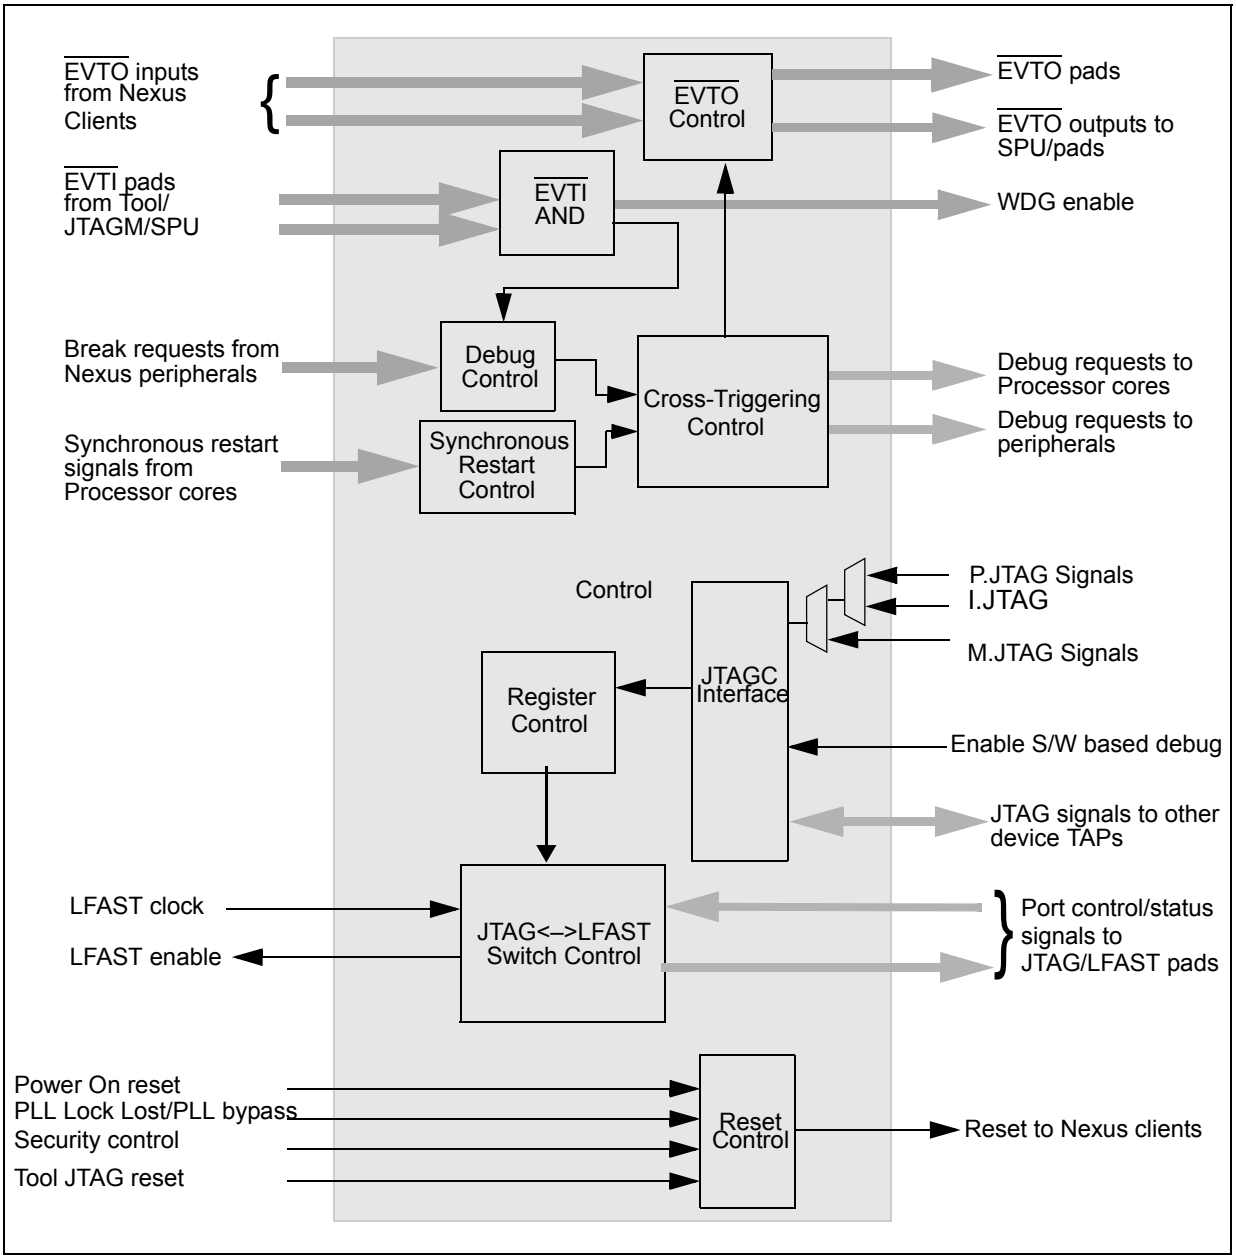
- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.

  - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.

  - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.



When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The ED DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU, etc. The ED DCI also provides the Event Out ($\overline{\text{EVTO}}$) signals to the debug tool in case of the occurrence of any internal debug event.

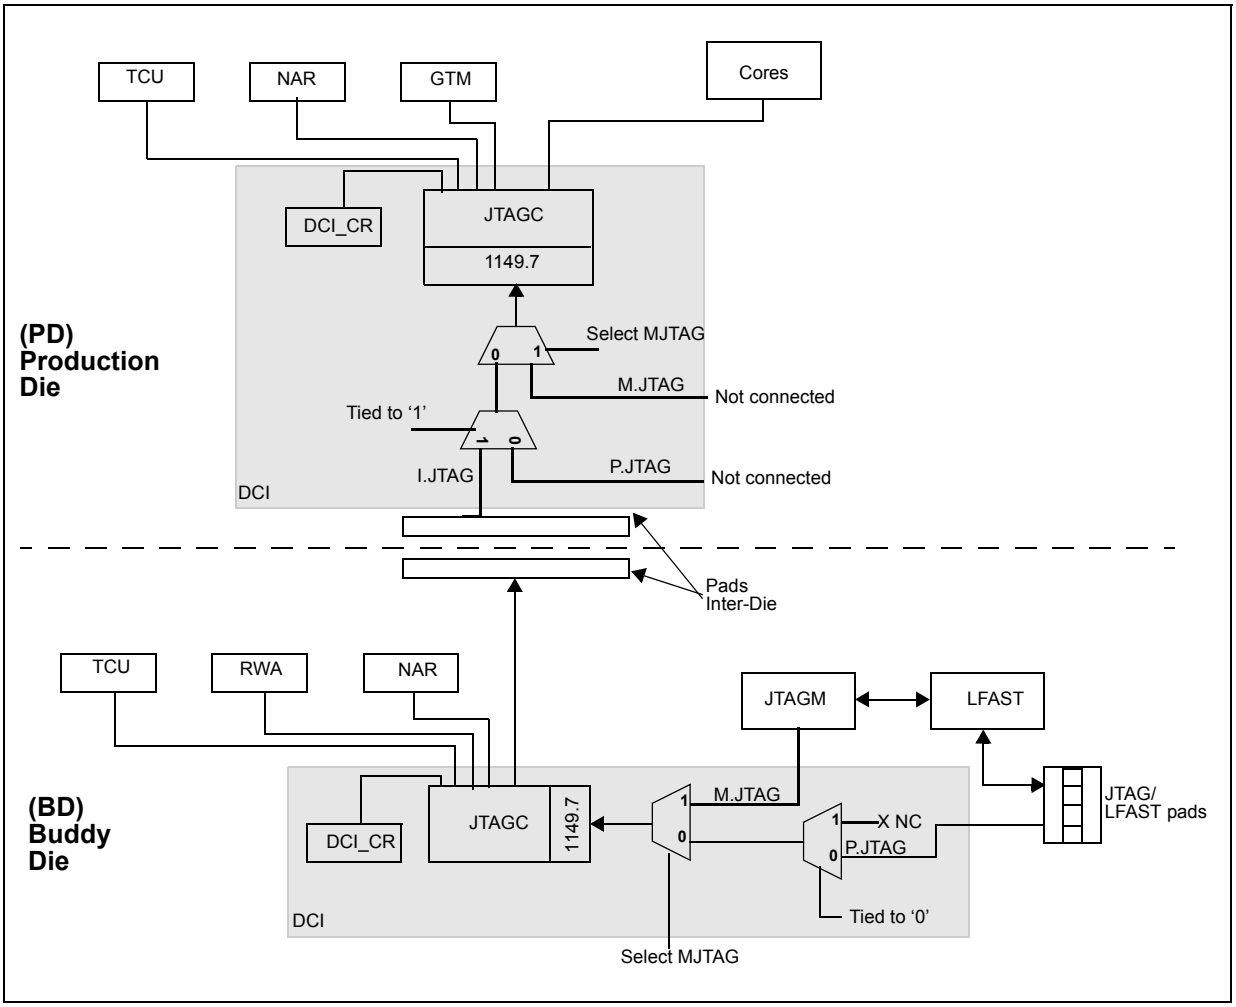


Figure 2001 shows the DCI block diagram.

Figure 2001. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in *Figure 2002*. In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

Figure 2002. DCI in an emulation configuration

89.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 1919 shows a summary of the configuration options.

Table 1919. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

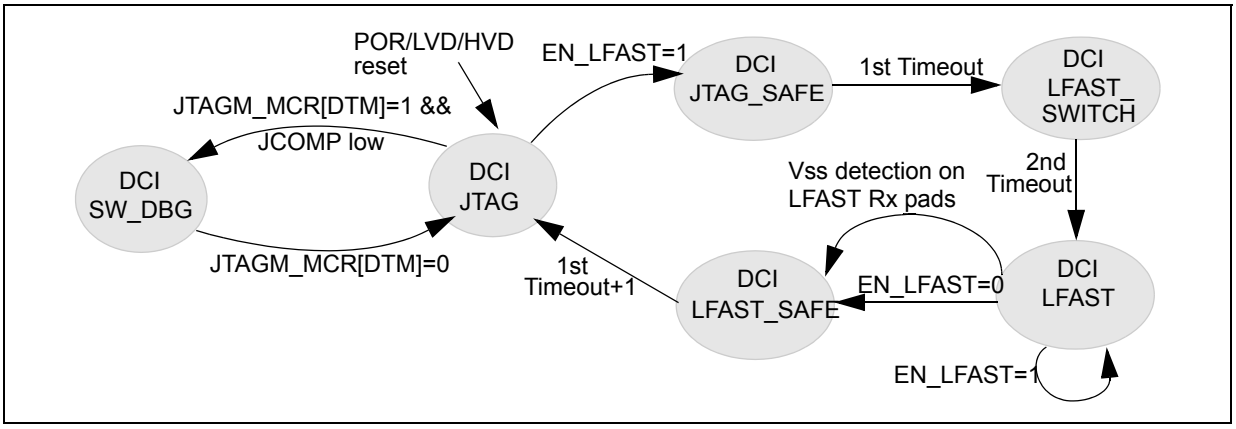
The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the BD LFAST and BD JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed.Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in *Section 89.1.3.1: Port sharing between JTAG and LFAST modes.* During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. *Table 1920* shows the port mapping.



When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1’b0). There is no change in port values if no debug tool is connected.

Table 1920. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

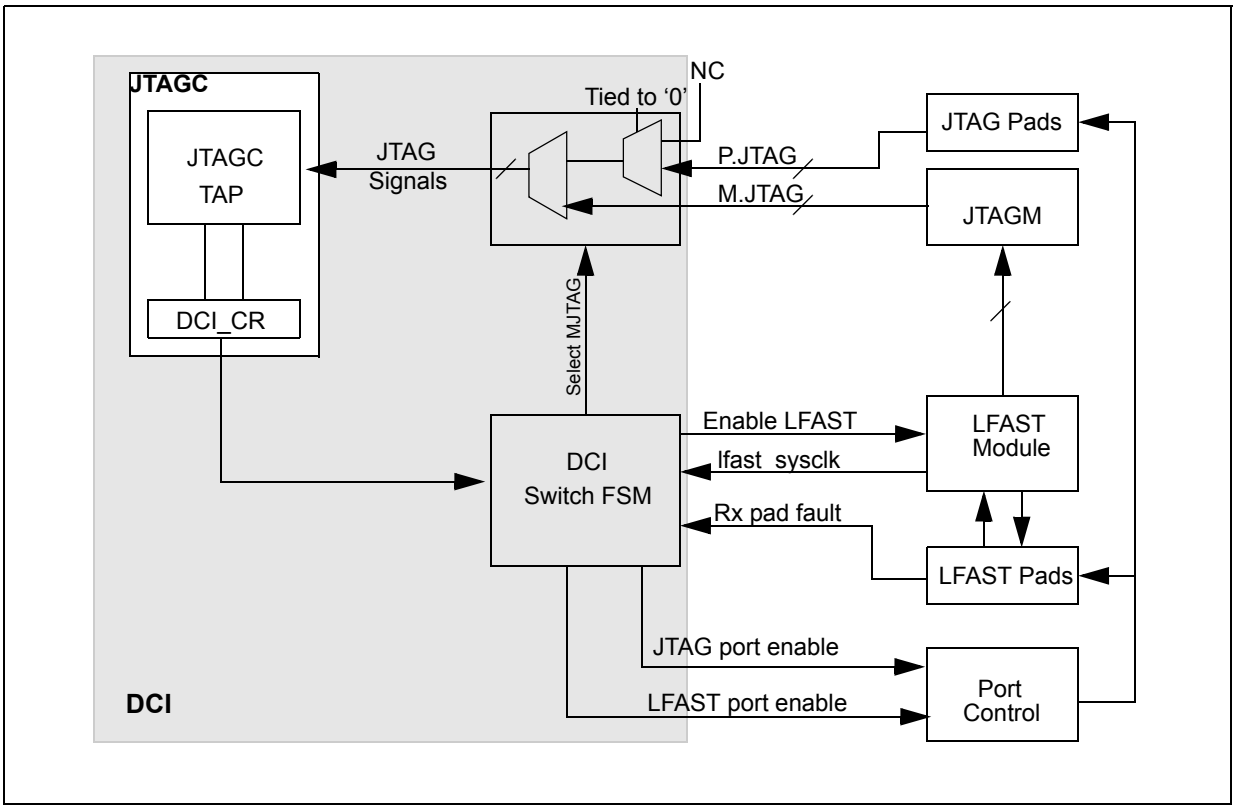
Figure 2003 shows the DCI mode switching operation.

Figure 2003. DCI operating modes state diagram

Note: JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

Table 1921 contains the operating mode descriptions.

Table 1921. DCI operating modes



Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.

Table 1921. DCI operating modes(Continued)

Mode	Description
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

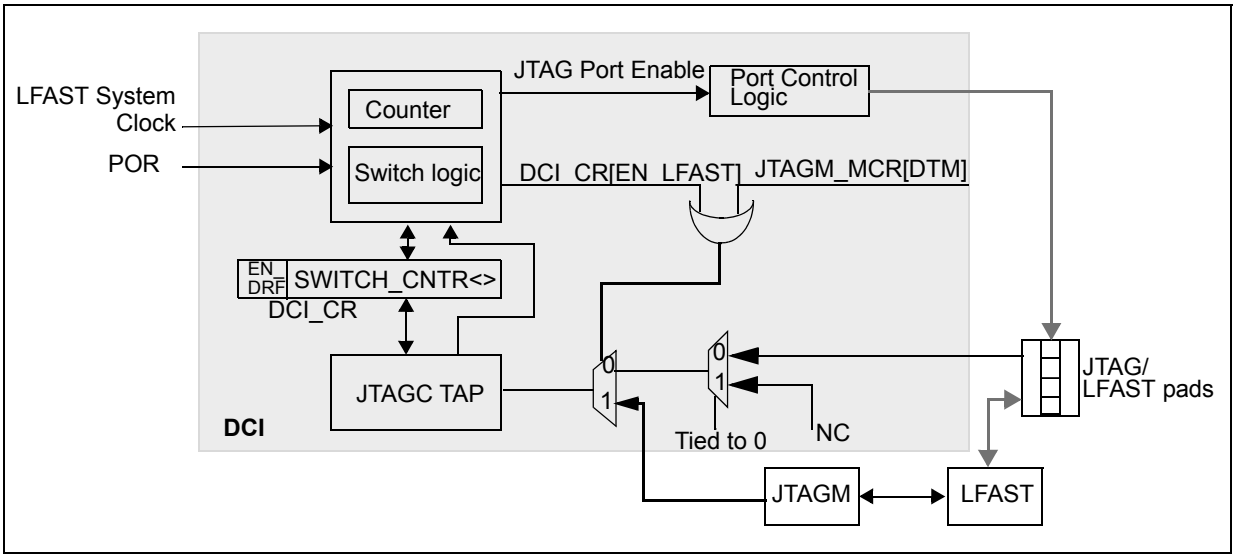
Figure 2004 shows a block diagram of the JTAG/LFAST connections.

Figure 2004. DCI JTAG/LFAST switch integration

89.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch

from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):



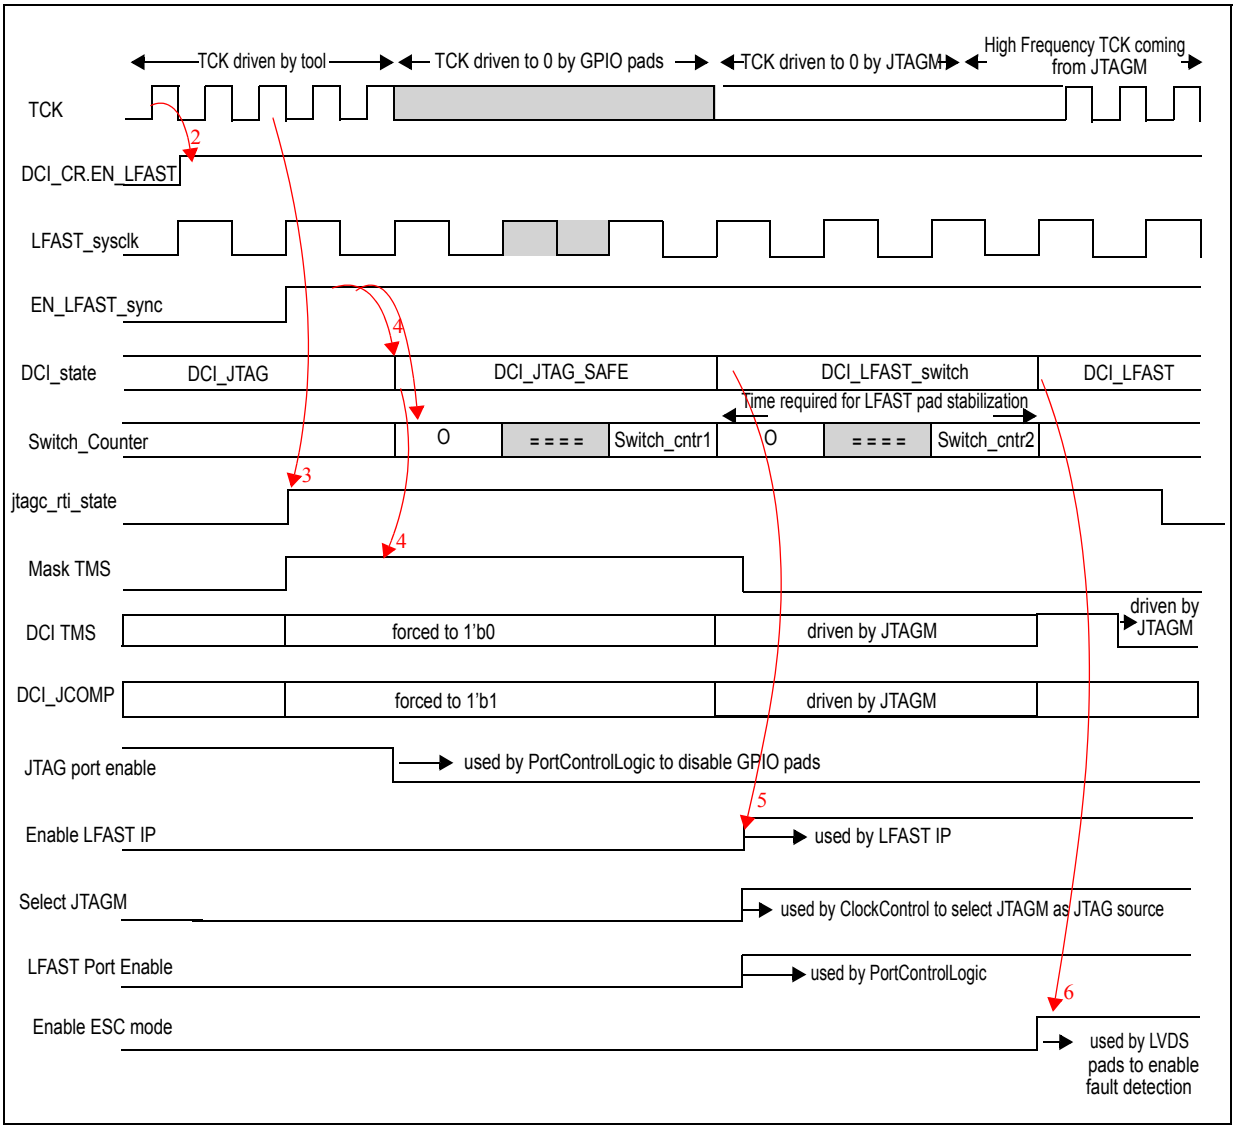
- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure.The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in *Figure 2005*.

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 2005. DCI switching between JTAG and LFAST modes



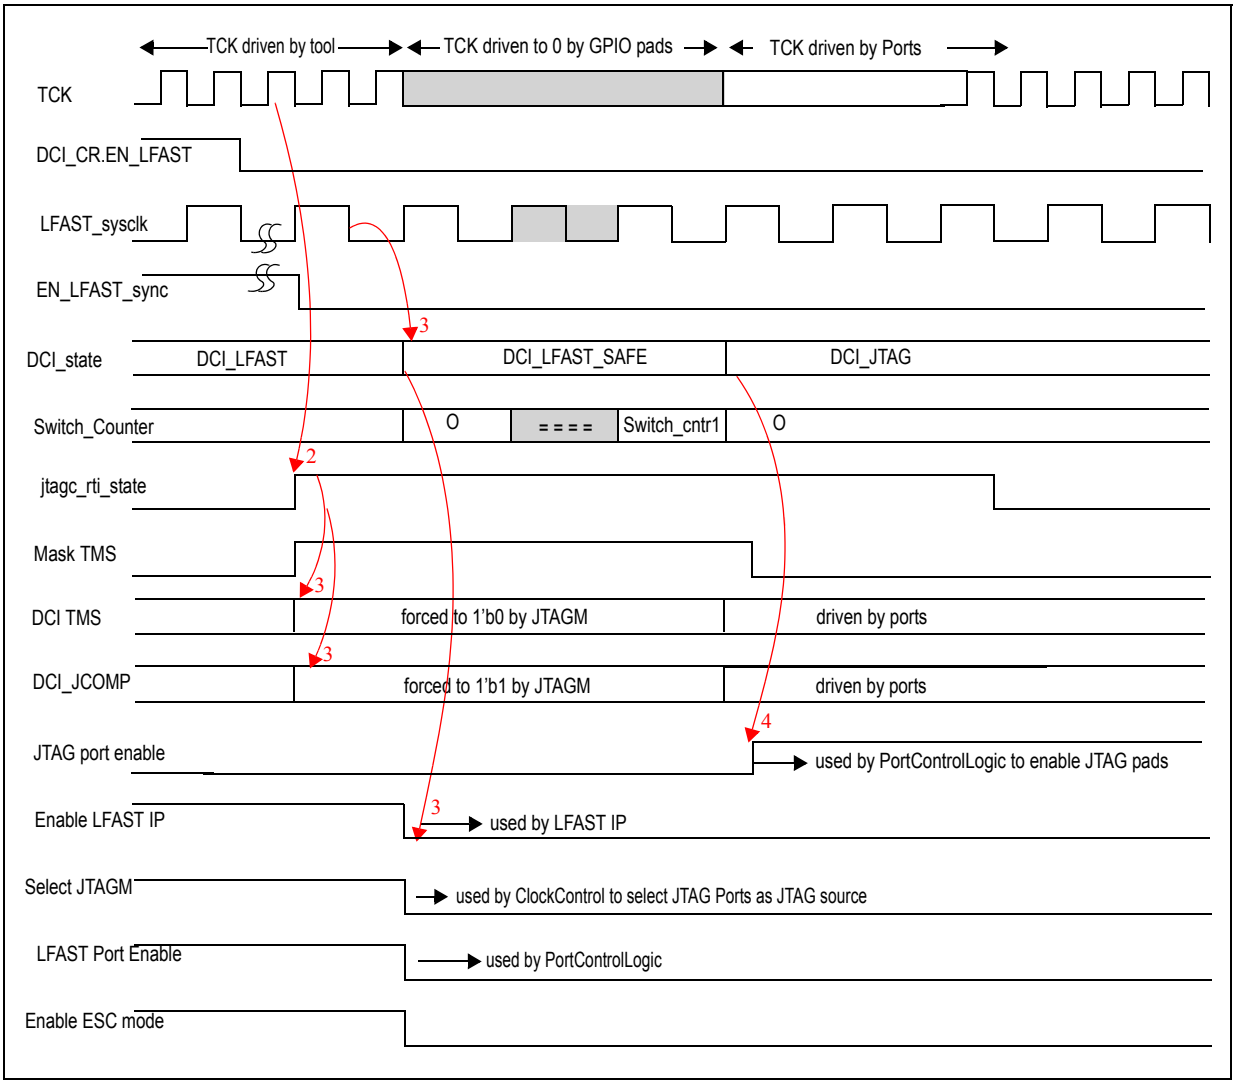
89.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
   – EN_LFAST
   – SWITCH_CNTR1
   – SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 2006 shows the timing sequence.

Figure 2006. DCI JTAG to LFAST switching diagram



89.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 1924 and *Table 1928* summarize the MCU and tool behaviors. *Figure 2007* shows the timing sequence.

Figure 2007. DCI LFAST to JTAG switching diagram

89.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

89.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

There is a software programmable bit, MCR[jtagm_JCOMP], present in JTAGM block which, when programmed to 0, asserts reset for the JTAGC block, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

Note: If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

89.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset.The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1922. Nexus reset truth table

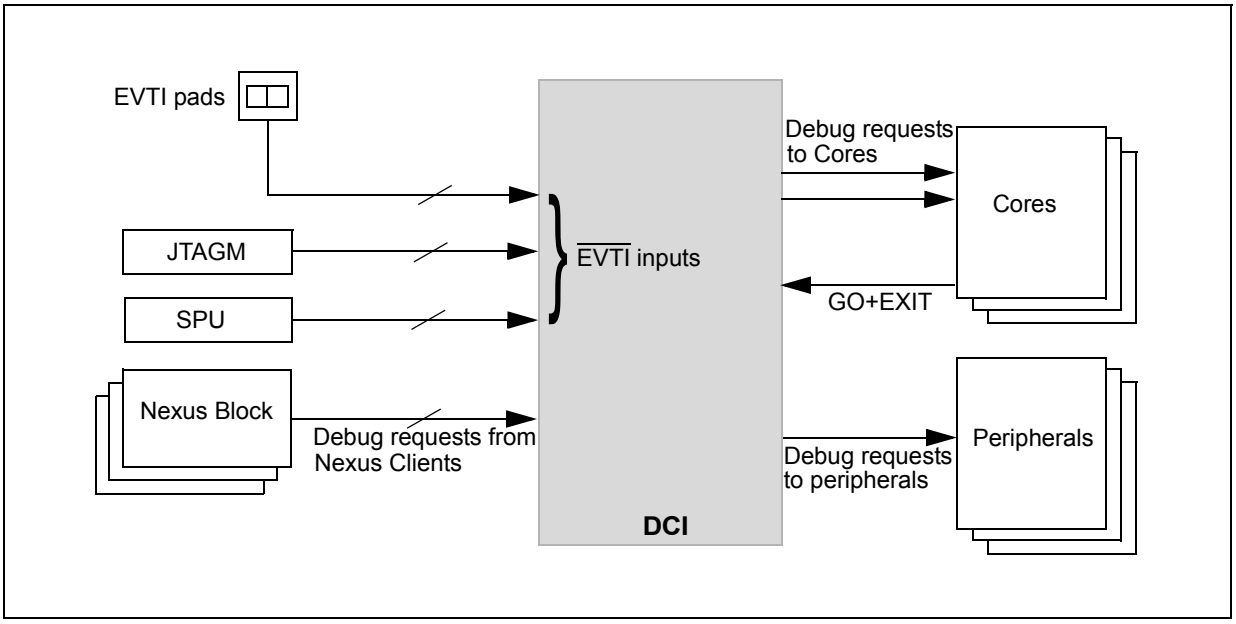
POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

89.1.3.5 System watchdog control

The BD DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the $\overline{\text{EVTI}}$[0] pin is used. If the $\overline{\text{EVTI}}$[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the $\overline{\text{EVTI}}$[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the $\overline{\text{EVTI}}$[0] pin.

89.1.3.6 Break control

The PD DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.



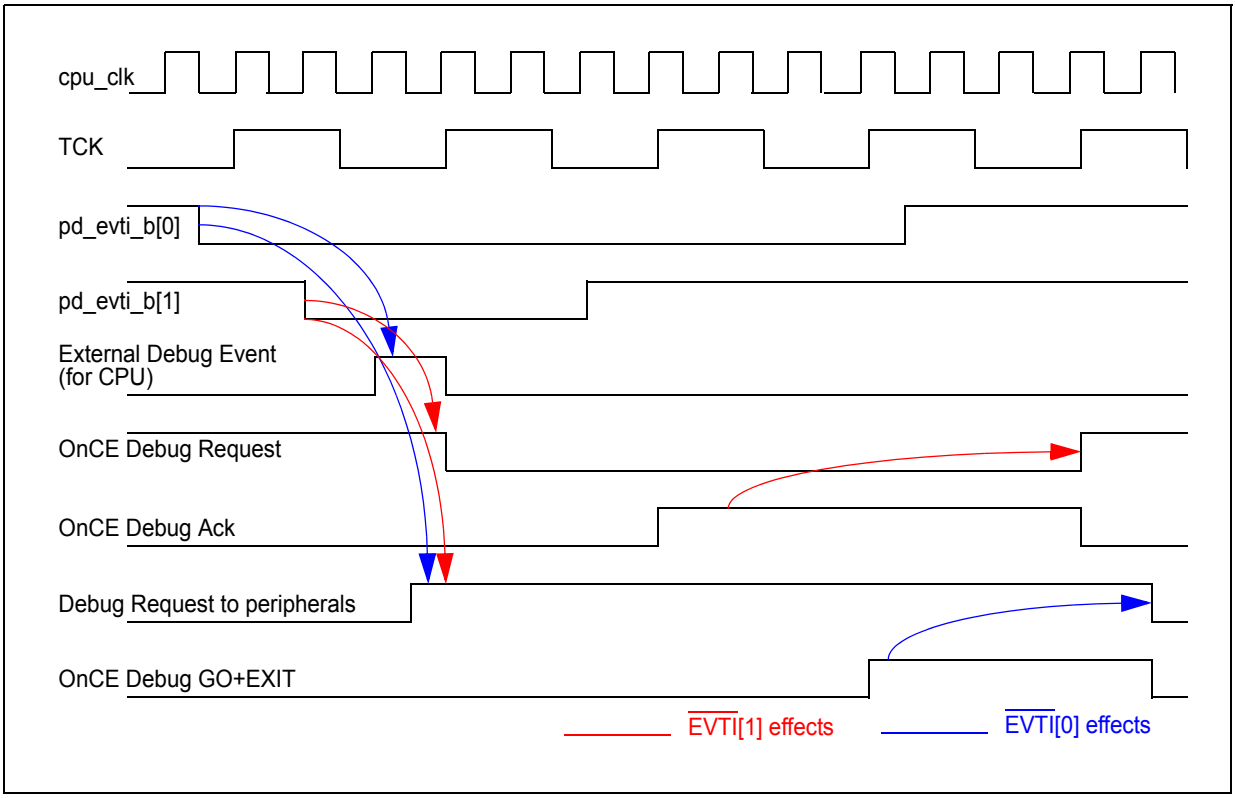
There are various different input sources that provide debug requests:

- $\overline{\text{EVTI}}$[1:0] signals from BD EVTI pads provided to the PD DCI via intra-die pads
- $\overline{\text{EVTI}}$[1:0] signals from BD JTAGM
- $\overline{\text{EVTI}}$[1:0] signals from the Sequence Processing Unit (SPU)

The PD DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor cores
- All break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 2008. DCI debug control mechanism



The various sources of $\overline{\text{EVTI}}$[1:0] inputs are synchronized and logically ANDed in the DCI to generate two debug requests DCI_$\overline{\text{EVTI}}$[1:0] for the processor cores and non-CPU peripherals.Of these two inputs, $\overline{\text{EVTI}}$[0] is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\overline{\text{EVTI}}$[1], is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted.The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command.The $\overline{\text{EVTI}}$[1:0] signals coming from the pads are enabled for debug control using DCI_CR[5:4] bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

Figure 2009 shows the timing sequence.

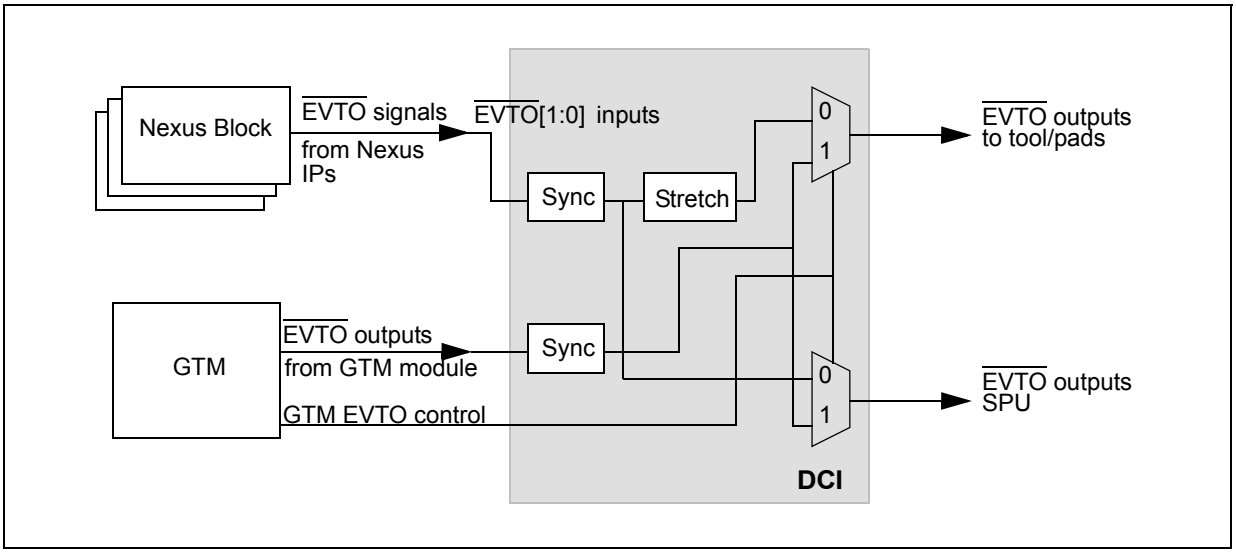
Figure 2009. DCI debug signal generation

89.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

89.1.3.8 Synchronous restart control



The PD DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

89.1.3.9 EVTO management

The EVTO management block diagram is presented in *Figure 2010*.

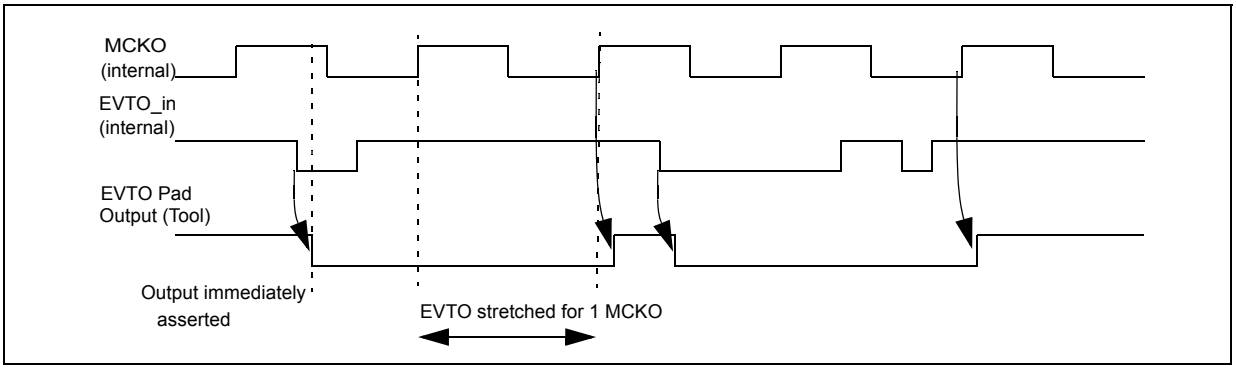


Figure 2010. DCI EVTO management

The PD DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce EVTO[1:0] signals. The PD DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[1:0] signals from any Nexus client, the DCI immediately asserts EVTO[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool(*Figure 2011*). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The PD DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 2011. DCI EVTO timing diagram

89.1.3.10 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

89.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

89.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

89.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. *Figure 2012* shows the format of the DCI_CR.

In an ED which has both PD and BD instances of the DCI, all bits controlling the switch between LFAST and JTAGM must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

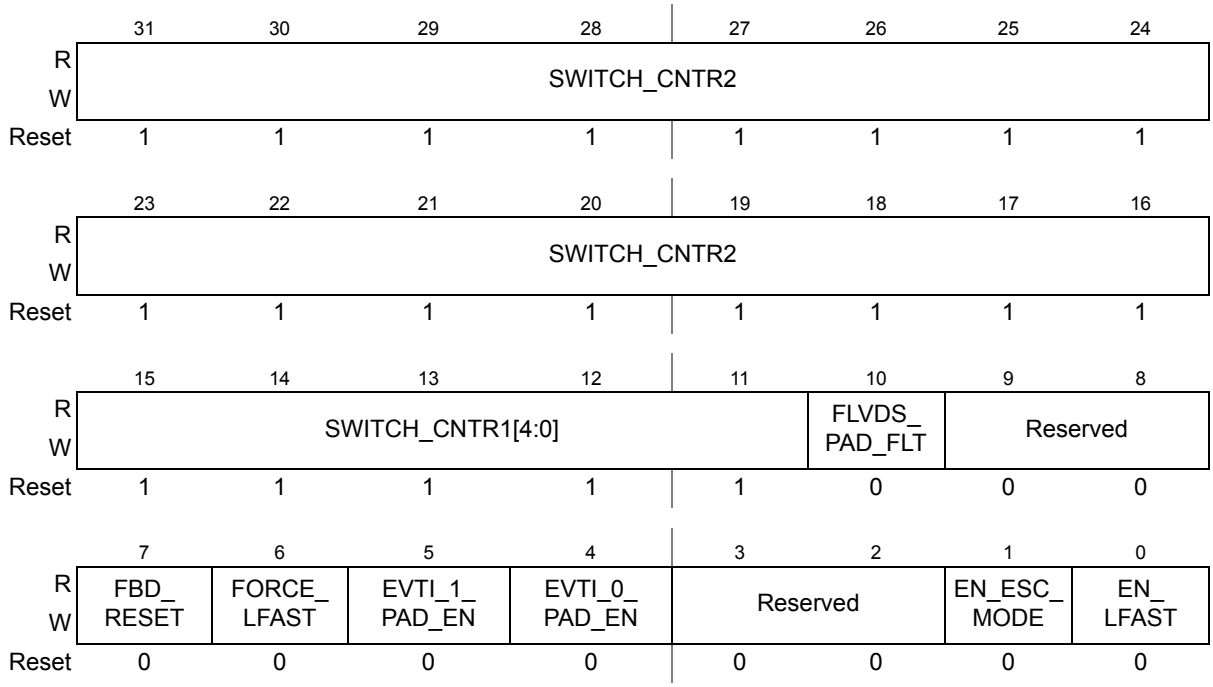

Figure 2012. DCI control register (DCI_CR)

The DCI_CR is described in *Table 1923*.

Table 1923. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2. Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = 32,768×T_{lfast_sysclk}
15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = 32 × T_{lfast_sysclk}
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
7 FBD_RESET	Force Reset 0 Do not force Reset 1 Force Reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN(1)	$\overline{\text{EVTI}}$[1] feature enable 0 $\overline{\text{EVTI}}$[1] disabled (default) 1 $\overline{\text{EVTI}}$[1] enabled

Table 1923. DCI_CR field descriptions(Continued)

Field	Description
4 EVTI0_PAD_EN(2)	$\overline{\text{EVTI}}$[0] feature enable 0 $\overline{\text{EVTI}}$[0] disabled (default) 1 $\overline{\text{EVTI}}$[0] enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST(2)	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

89.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

89.4 Functional description

89.4.1 DCI mode transition

After power-on reset, the BD DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. *Table 1924* and *Table 1925* show the steps and expected states for the MCU and tool for JTAG to LFAST switching. *Table 1926* and *Table 1927* contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1924. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN

TDO	Hi-Z	Logic Output	Logic Output	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxP

Table 1924. MCU operation (JTAG to LFAST switching)(Continued)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
JCOMP	Logic Input	Logic Input	Logic Input Latch	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxN
TCK	Logic Input	Logic Input	Logic Input	Hi-Z	Logic Output	Logic Output	Logic Output
Mode Escape	Inhibit	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable
LFAST_SYSCLK_EN	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable	Enable

Table 1925. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode)(1)	DCI_CR [EN_ LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don’t Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don’t Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 1926. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 1927. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

89.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the BD LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the BD DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. *Table 1928* and *Table 1929* contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 1928. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 1929. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low
TDI	LVDS TxN	Don’t Care

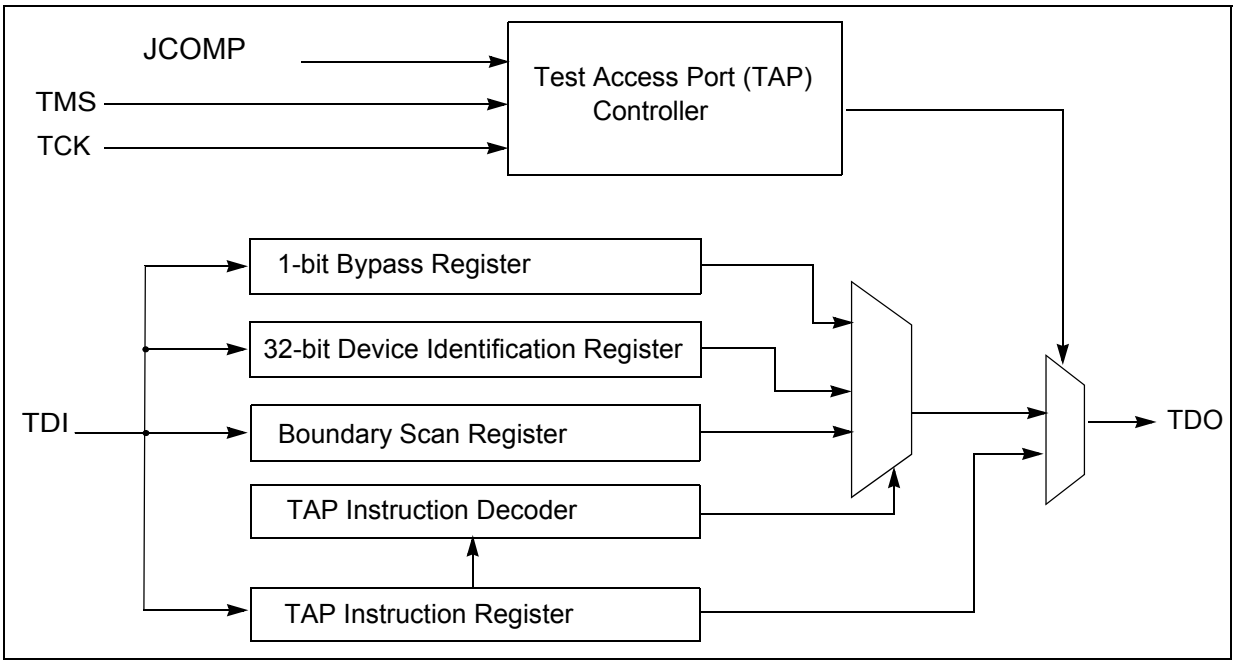
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don’t Care

90 Buddy Device—JTAG Controller (JTAGC)



90.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

90.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 2013. JTAG (IEEE 1149.1) block diagram

90.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to *Table 1933* for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

90.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

90.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

90.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in *Section 90.4.4: JTAGC block instructions*.

90.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

90.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1930. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z(1)	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

90.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

90.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

90.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in *Section 90.4.3: TAP controller state machine*.

90.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

90.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

90.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

90.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 2014. 6-bit instruction register

90.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

90.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

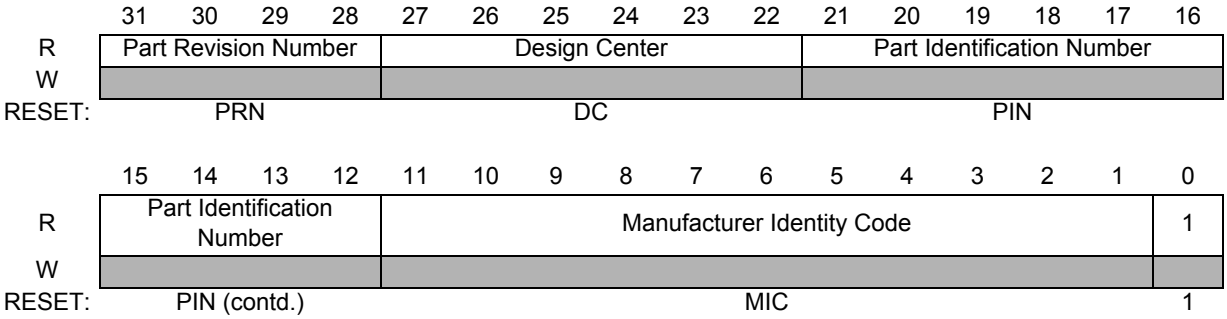


Figure 2015. Device identification register

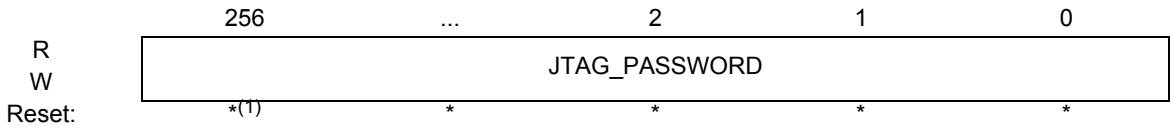


The following table describes the device identification register functions.

Table 1931. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. Value is 0x381.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x020.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

90.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 2016. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1932. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

90.3.5 Boundary scan register

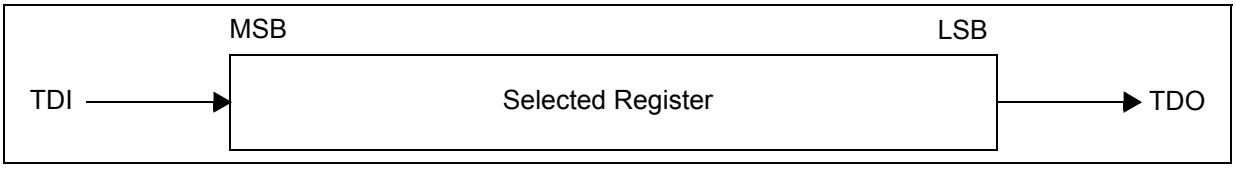
The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in *Section 90.4.5: Boundary scan*. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

90.4 Functional description

This section explains the JTAGC functional description.

90.4.1 JTAGC reset configuration



While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

90.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to *Section 90.4.4.8: ACCESS_AUX_x instructions*.

Data is shifted between TDI and TDO though the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

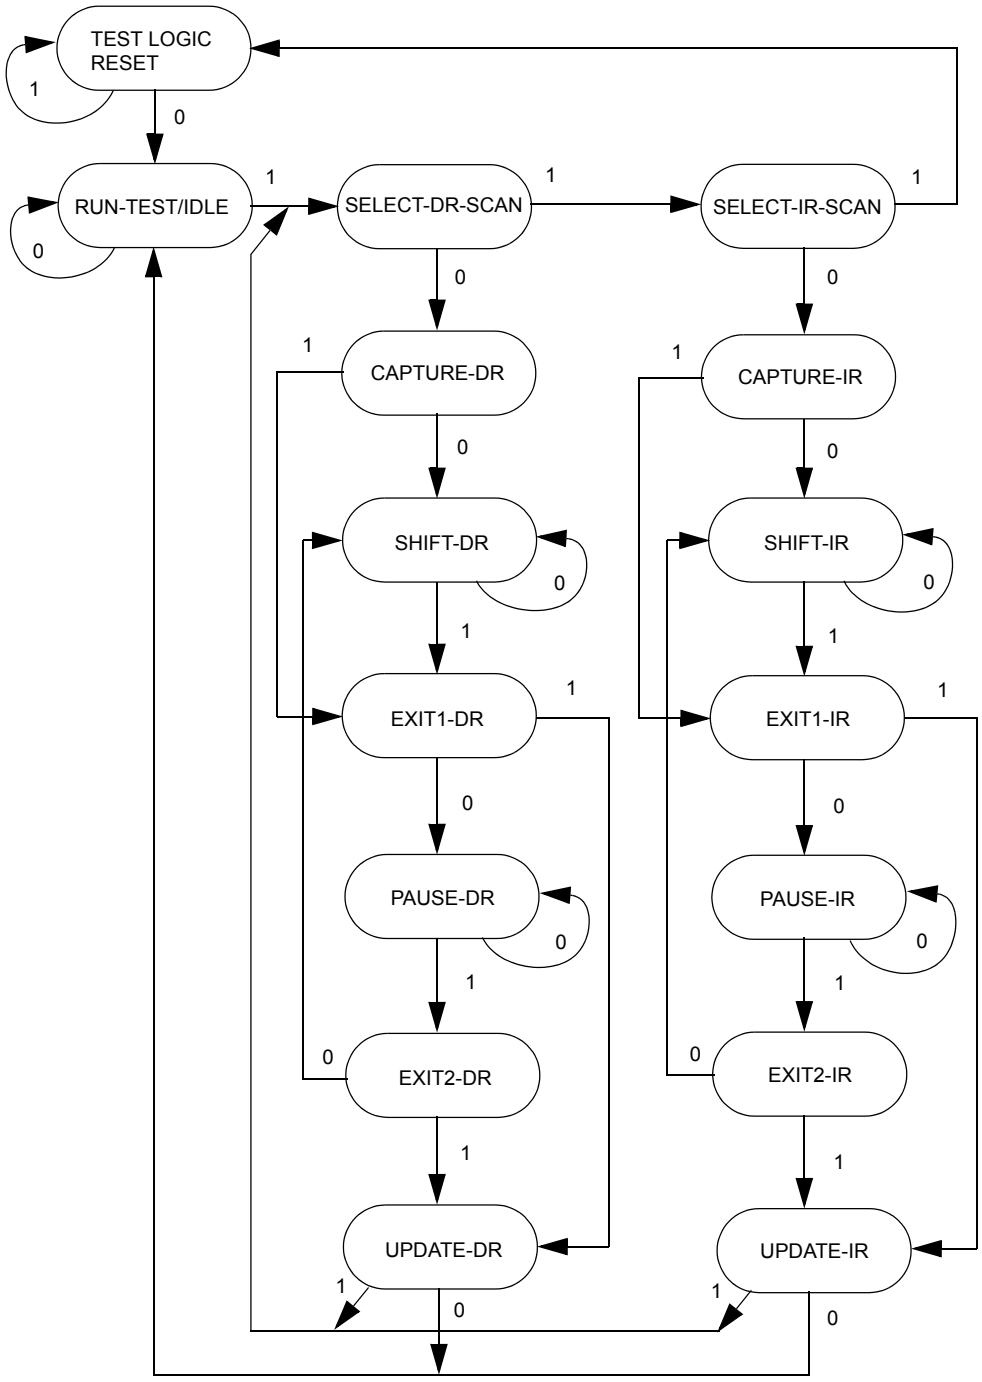


Figure 2017. Shifting data through a register

90.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

Figure 2018. IEEE 1149.1-2001 TAP controller finite state machine

The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

90.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

90.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

90.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1933. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
Reserved	001111	Reserved
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NR_BD	100000	Enables access to the NAR TAP controller on BD
Reserved	100001	Reserved

Table 1933. 6-bit JTAG instructions(Continued)

Instruction	Code[5:0]	Instruction Summary
ACCESS_AUX_NAL	100010	Enables access to the NAL TAP controller
ACCESS_AUX_RWA_BD	100011	Enables access to the RWA TAP controller
Reserved	100100	Reserved
Factory test reserved	100101	Intended for factory test only
Reserved	100110	Reserved
Reserved	100111	Reserved
Reserved	101000	Reserved
Reserved	101001	Reserved
Reserved	101010	Reserved
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
Reserved	110011	Reserved
Reserved	110100	Reserved
Reserved	110101	Reserved
Reserved	110110	Reserved
Reserved	110111	Reserved
Reserved	111000	Reserved
Reserved	111001	Reserved
Reserved	111010	Reserved
Reserved	111011	Reserved
Reserved	111100	Reserved
Reserved	111101	Reserved
ACCESS_AUX_DCI_PD	111110	Enables access to pass control from BD to PD
BYPASS	111111	Selects bypass register for data operations
Reserved(1)	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

90.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

90.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

90.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

90.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

90.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

90.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

90.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

90.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

90.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

90.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

90.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

91 Buddy Device—JTAG Master (JTAGM)

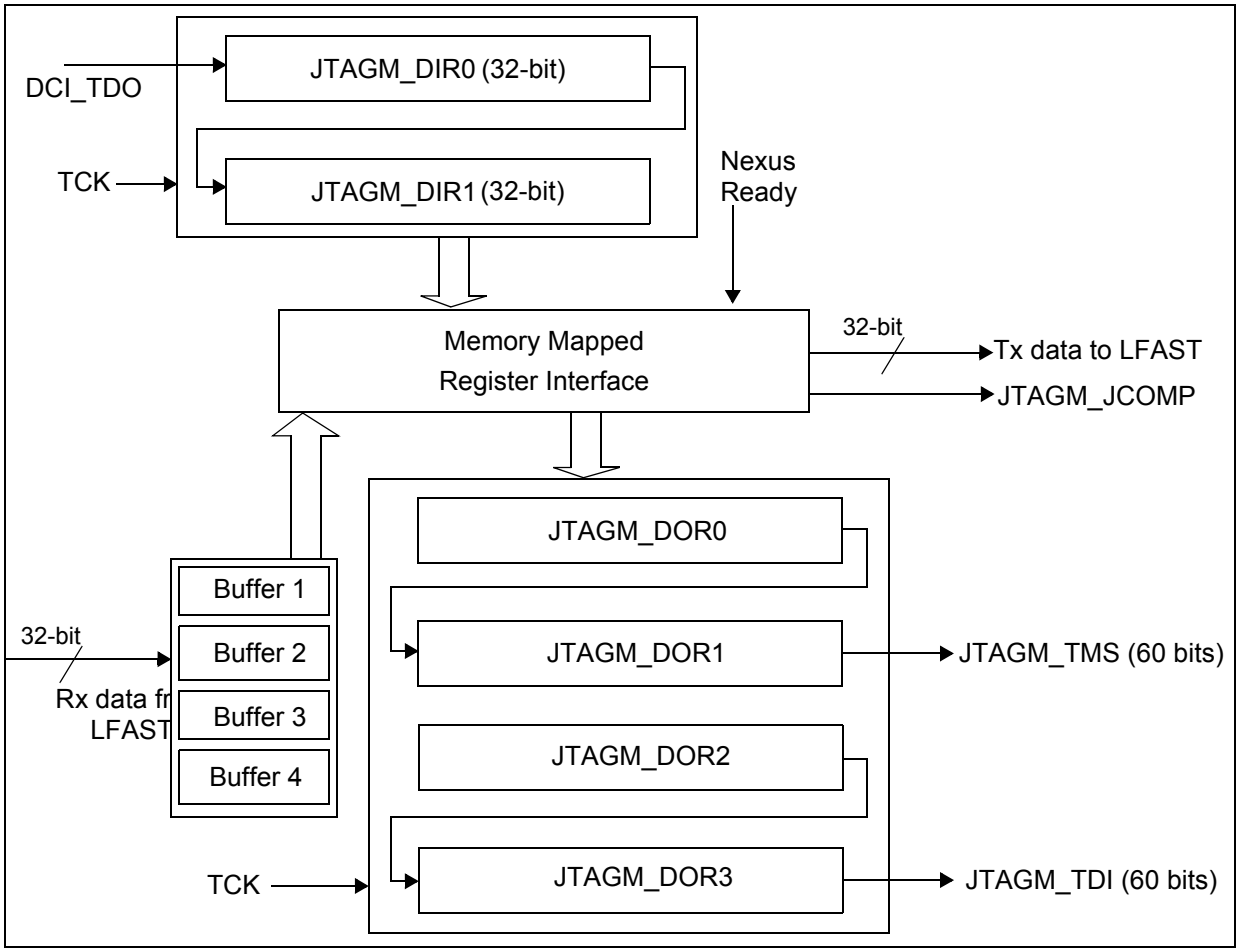
91.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

91.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:



- Configuration register
- Status register
- Four data output registers
- RXCRC receive register
- Two data input registers

All these registers, described in detail in *Section 91.4: Memory map and register definition*, are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

Figure 2019 shows the block diagram of the JTAGM.

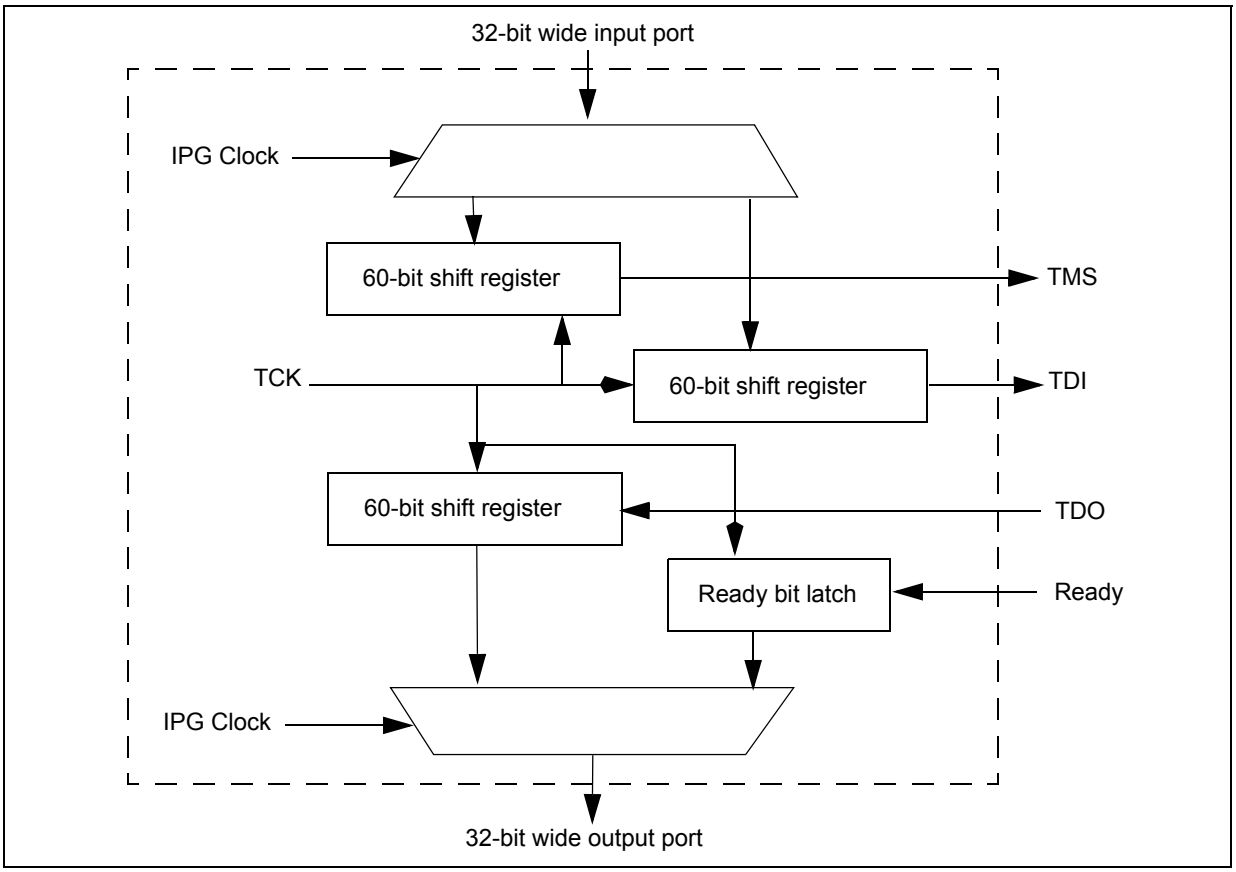
Figure 2019. JTAGM block diagram

91.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

91.2 Functional description



91.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 2020 shows the flow diagram of the LFAST to DCI connection.

Figure 2020. LFAST-to-DCI flow diagram

91.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[JTAGM_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[JTAGM_JCOMP]:

- Do not clear the JTAM_MCR[JTAGM_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the JTAGM_JCOMP bit):
  - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
  - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

91.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

91.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

91.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

91.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

91.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

91.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

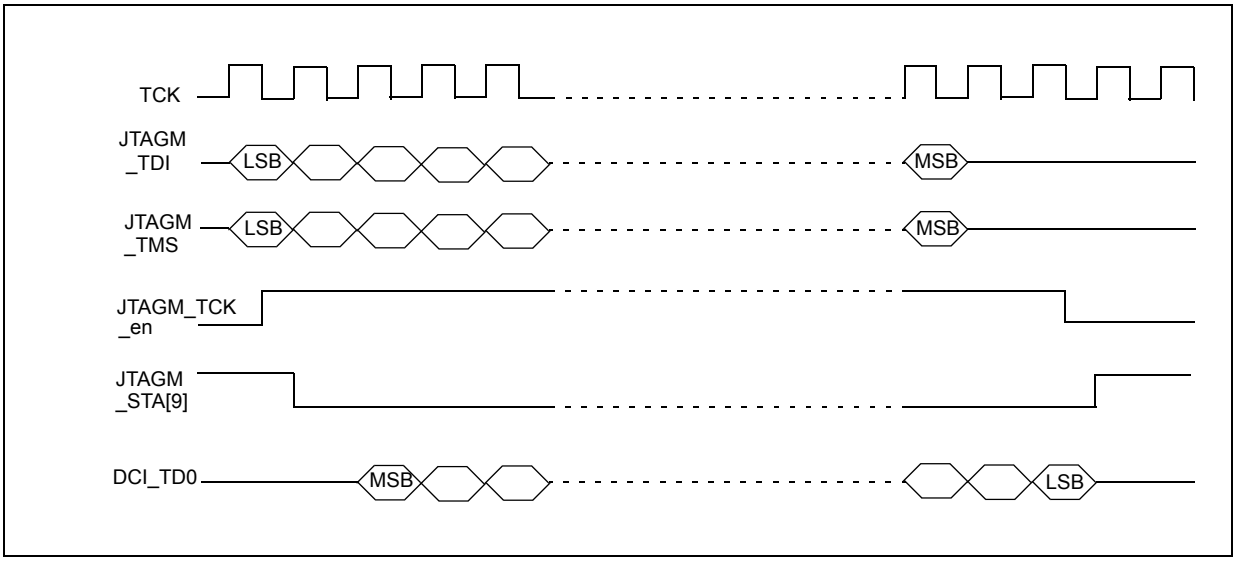
The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the EVTI0_ASSERT bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the EVTI1_ASSERT bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

91.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in *Section 91.2.5.1: Status register ready bit*). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (the least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).



The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

91.2.8 JTAGM to DCI serial interface

Figure 2021 shows the data transfer timings between JTAGM and DCI.

Figure 2021. JTAGM to DCI serial interface diagram

91.2.9 JTAGM data handling and CRC calculation in LFAST mode

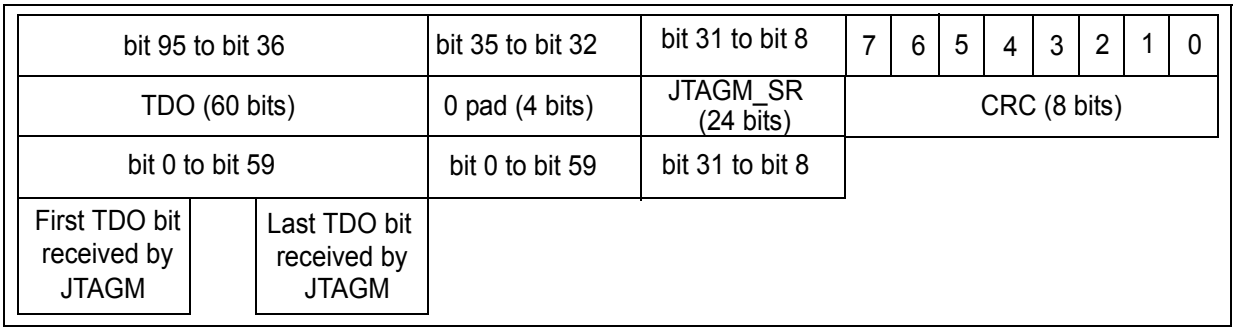


Figure 2022 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 2022. Bit ordering for LFAST to JTAGM transfer

bit 127 to bit 68		bit 67 to bit 8		7	6	5	4	3	2	1	0
TMS (60 bits)		TDI (60 bits)		CRC (8 bits)							
bit 0 to bit 59		bit 0 to bit 59									
Last TMS bit transmitted by JTAGM	First TMS bit transmitted by JTAGM	Last TDI bit transmitted by JTAGM	First TDI bit transmitted by JTAGM								

Figure 2023 shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 2023. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in *Figure 2023*).

91.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

91.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

91.4 Memory map and register definition

Table 1934 contains the memory map of the JTAGM registers.

Table 1934. Memory map

Offset	Register	Location
0x00	Module Configuration Register (JTAGM_MCR)	*on page 3321*
0x04	Status Register (JTAGM_SR)	*on page 3323*

91.4.1 Register descriptions

91.4.1.1 Module configuration register (JTAGM_MCR)

Figure 2024 shows the format of the JTAGM_MCR. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. The only exception is the SIE bit, which always needs to be programmed in the Production Device instance of the JTAGM, regardless of being ED or not.

Figure 2024. JTAGM_MCR register

The JTAGM_MCR register is described in *Table 1935*.

Table 1935. JTAGM_MCR register field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit. Writing a 0 has no effect. **Note:** After being written to “1”, this bit is auto cleared within 3 TCK cycles.
1–2 EVTO0_SENSE	Determines JTAGM response to activity on $\overline{\text{EVTO}}$0 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$0 edges (default setting) 01 EVTO0_EDGE status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$0 10 EVTO0_EDGE status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$0 11 EVTO0_EDGE status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$0
3–4 EVTO1_SENSE	Determines JTAGM response to activity on $\overline{\text{EVTO}}$1 line 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO}}$1 edges (default setting) 01 EVTO1_EDGE status bit is set whenever a falling edge is detected on $\overline{\text{EVTO}}$1 10 EVTO1_EDGE status bit is set whenever a rising edge is detected on $\overline{\text{EVTO}}$1 11 EVTO1_EDGE status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO}}$1
5 EVTO_IE	Enables $\overline{\text{EVTO}}$ triggered JTAGM interrupt 0 No JTAGM interrupt is generated In response to any $\overline{\text{EVTO}}$0 or $\overline{\text{EVTO}}$1 activity 1 JTAGM interrupt is generated when EVTO0_EDGE or EVTO1_EDGE are set
6 EVTI0_ASSERT	EVTI0 Assert. 0 Asserted the $\overline{\text{EVTO}}$0 from the JTAGM module 1 Deasserts the $\overline{\text{EVTO}}$0 from the JTAGM module
7 EVTI1_ASSERT	EVTI1 Assert. 0 Asserted the $\overline{\text{EVTO}}$1 from the JTAGM module 1 Deasserts the $\overline{\text{EVTO}}$1 from the JTAGM module **Note:** In the SW mode (when DTM =1), regardless of the state of “EVTI1_ASSERT” bit the internall “evti” signal remains de-asserted . Though this bit can be written , yet writing to this bit has no effect.
8–17	Reserved
18–23 INTER_JTAG_ FRAME_TIMER	TCK delay. 000000 0 TCK delay 000001 1 TCK delay ... 111111 63 TCK delay
24	Reserved
25 SIE	SPU Interrupt Enable.(1) 0 JTAGM does not generate an interrupt to the CPU 1 JTAGM generates an interrupt to the CPU if the SPU interrupt request is asserted
26 IIE	Idle Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU upon completion of a 60-bit JTAG transfer 1 JTAGM generates an interrupt to the CPU upon completion of a 60-bit JTAG transfer

Table 1935. JTAGM_MCR register field descriptions(Continued)

Field	Description
27–29 TCKSEL	TCK Divider division factor control value. (TCK Divider divides the clock input to JTAGM IP to generate TCK out(input to DCI)). 000 TCK Divider division factor is 1 001 TCK Divider division factor is 2 010 TCK Divider division factor is 3 ... 111 TCK Divider division factor is 8 **Note:** It should be taken care that the maximum frequency of TCK input to DCI, should be equal or less than half of system clock.
30 JTAGM_JCOMP	JTAG reset. 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data for JTAG transferred by LFAST 1 Data for JTAG transferred by software

1. The BD JTAGM instance does not receive signals from the SPU. If required, this feature needs to be enabled in the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

91.4.1.2 Status register (JTAGM_SR)

The functionality of some of the SR bits changes depending on the setting of the DTM bit in the MCR. These differences are described in the field descriptions table.

In the ED, all bits of this register need to be accessed in the BD instance of the JTAGM. The exceptions are the bits related to the SPU interrupts (SPU_INT, SPU_INT_CLR), which always need to be accessed from the PD JTAGM, regardless of being ED or not.

Figure 2025. JTAGM_SR register

The JTAGM_SR register is described in *Table 1936*.

Table 1936. JTAGM_SR register field descriptions

Field	Description
0 OVERRUN	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1	Reserved
2 TXGOOD	Status information from the LFAST to be used by software: Indicates either data frame or ping frame was transmitted successfully
3 TXERROR	Status information from the LFAST to be used by software: Indicates Tx data Interface not enabled and a frame is ready to be transmitted
4 RXOVFL	Status information from the LFAST to be used by software: Indicates Rx data FIFO overflow
5 INVFPS	Status information from the LFAST to be used by software: Indicates reception of frame with invalid frame payload size
6 INVICLC	Status information from the LFAST to be used by software: Indicates reception of frame with invalid ICLC code
7 ILLLCT	Status information from the LFAST to be used by software: Indicates reception of illegal LCT frame
8	Reserved
9 LVDSEN	DCI status: DCI LVDS port enable
10 JTAGEN	DCI status: DCI JTAG port enable
11 LVDSSAFE	DCI status: DCI LVDS safe mode
12 JTAGSAFE	DCI status: DCI JTAG safe mode
13 LVDSESC	DCI status: DCI LVDS escape mode
14 LFASTEN	DCI status: DCI enable LFAST
15 TOOL	DCI status: DCI tool present, set when a debug tool is connected
16 EVTO0_EDGE	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$0 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO}}$0
17 EVTO1_EDGE	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO}}$1 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO}}$1

Table 1936. JTAGM_SR register field descriptions(Continued)

Field	Description
18 SPU_INT_CLR	Write 1 clears the SPU_INT[1] This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.(1)
20 CRC_ERR	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 NEXUS_ERR	Nexus error bit. It is set when there is an error, else it is 0.
22 IDLE	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read **Note:** In LFAST mode (DTM = 0), this bit has no effect and should not be used.
24–31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode (DTM = 0): Bit 24–31 reads the CRC. Write has no effect. SW Mode (DTM = 1): – Bit 24–31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears EVTO0_EDGE, bit 16 – Writing 1 on bit 25 clears EVTO1_EDGE, bit 17

1. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

91.4.1.3 Data out register 0 (JTAGM_DOR0)

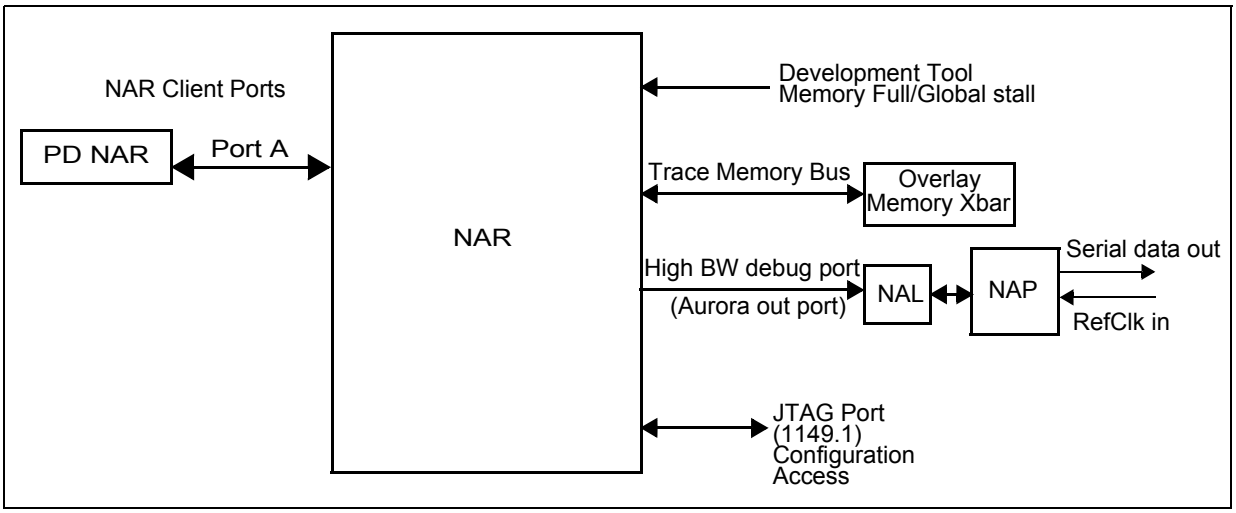
0–27 TDO_HIGH	Higher word of data received on TDO, bits 32–59
28–31	Reserved



92 Buddy Device—Nexus Aurora Router (NAR)

92.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in *Figure 2033*. Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

Figure 2033. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora

formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

- Aurora type interface with clock domain transfer at the same frequency

92.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

92.3 Features

The NAR supports the following features:

- Connects 1 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

92.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 1944. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	*on page 3331*
NAR_ST—NAR Status Register	R	1	*on page 3333*

Figure 2034. NAR control register (NAR_CR)

The NAR_CR is described in the following table.

Table 1945. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See *Section 92.5.2.2: Disabled* for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). **Note:** Some clients may only support timestamps on every message. 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 1/2 of queue is dedicated to alternate partition 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.

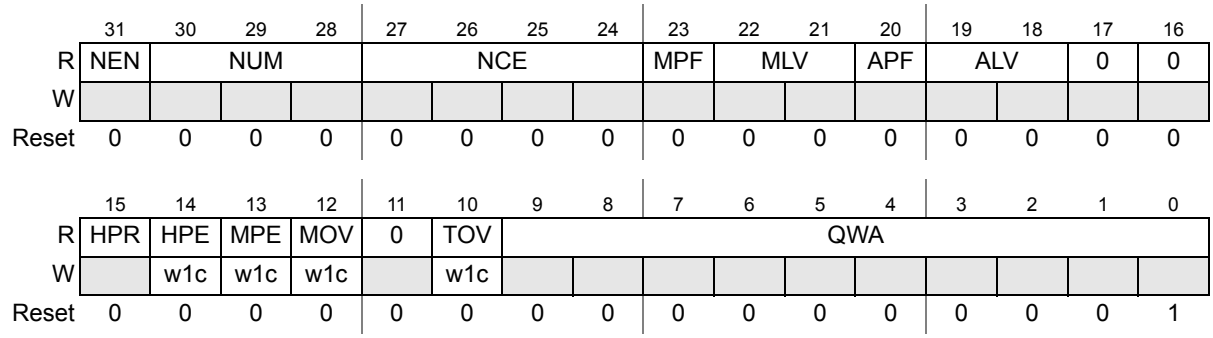

Table 1945. NAR_CR field descriptions(Continued)

Field	Description
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications. 00 No message select port. 0–1 port is active. 01 HBDP is the MSP 10 Trace memory bus is the MSP 11 Reserved
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 HBDP is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2 FSD	Frame Serial Data. 0 Framing disabled. Data is streamed through the Aurora out port. 1 Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

92.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				MPF	MLV		APF	ALV		0	0

R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Figure 2035. NAR status register (NAR_ST)

The NAR_ST register is described in the following table.

Table 1946. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See *Table 1961* for coding
23 MPF	MSP Partition Full. 0 MSP partition not full 1 MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled i.e. the main queue is partitioned. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%
20 APF	ALT Partition Full. 0 ALT partition not full 1 ALT partition full
19–18 ALV	ALT Partition Queue Level. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level <100%

Table 1946. NAR_ST field descriptions(Continued)

Field	Description
17–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)

92.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See *Section 92.5.6: Output arbitration*, for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

92.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 2

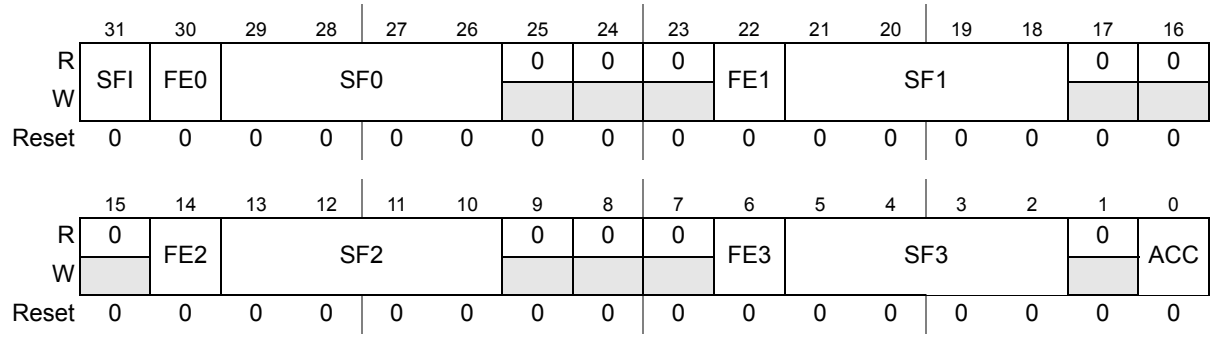

Figure 2036. Source filter register (NAR_SFR)

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SFn), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1947. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3

Table 1947. NAR_SFR field descriptions(Continued)

Field	Description
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

92.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Register index: 3

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See *Section 92.5.6: Output arbitration* for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See *Section 92.5.6: Output arbitration* for an example.

92.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

92.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 2039. Trace memory base address register NAR_TBALO

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 1949. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 1950. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

92.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Register index: 6

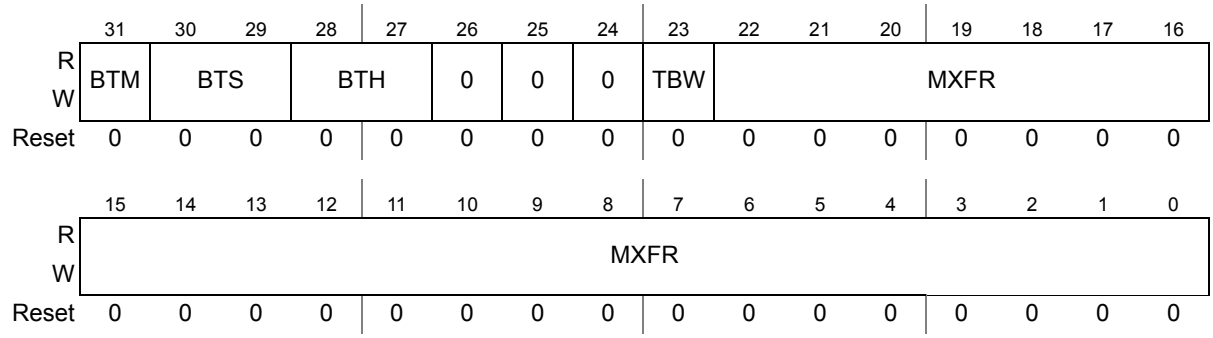

Figure 2040. Trace memory bus control register (NAR_TCR)

The NAR_TCR is described in the following table.

Table 1951. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

92.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in *Section 92.5.4: Suppress mode*. The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each

Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Register index: 7–A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

92.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status

(NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

15–0	Reserved

92.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note: Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Register index: C

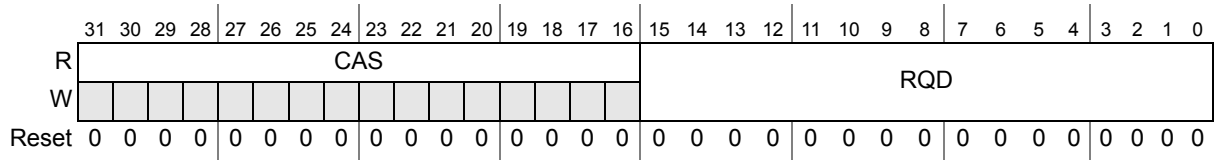

Figure 2043. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1954. NAR_CDR field descriptions

Field	Description
31–16 CAS	Client Activity Status. xxxxxxxxxxxxxxx1 Client 1 is active with new data xxxxxxxxxxxxxx1x Client 2 is active with new data xxxxxxxxxxxxx1xx Client 3 is active with new data xxxxxxxxxxxx1xxx Client 4 is active with new data xxxxxxxxxxx1xxxx Client 5 is active with new data xxxxxxxxxx1xxxxx Client 6 is active with new data xxxxxxxxx1xxxxxx Client 7 is active with new data xxxxxxxx1xxxxxxx Client 8 is active with new data xxxxxxx1xxxxxxxx Client 9 is active with new data xxxxxx1xxxxxxxxx Client 10 is active with new data xxxxx1xxxxxxxxxx Client 11 is active with new data xxxx1xxxxxxxxxxx Client 12 is active with new data xxx1xxxxxxxxxxxx Client 13 is active with new data xx1xxxxxxxxxxxxx Client 14 is active with new data x1xxxxxxxxxxxxxx Client 15 is active with new data 1xxxxxxxxxxxxxxx Client 16 is active with new data All other options Reserved

Figure 2044. Nexus Aurora Phy control register (NAR_NAPCR)

The NAR_NAPCR is described in the following table.

Table 1955. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. This field is device specific. For a description of this field see the Calibration and Debug configuration chapter which describes how the modules are configured.
11–8 LVDS_TXOPT	This is an internal characterization field.
7 LVDS_RX_TERM_EN	This is an internal characterization field.
6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

92.4.7 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	GSE	0	0	0	GLOBAL_STALL_COUNT				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0				

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 2045. Trace memory fill level and partition configuration register (NAR_AHFPAR)

The NAR_AHFPAR is described in the following table.

Table 1956. NAR_AHFPAR field description

Field	Description
31-25	Reserved and must be written with 0s
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on selected dci_evti event to generate a global stall. Selection of dci_evti is SoC specific
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See Section 92.5.13
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Section 92.5.14 **Note:** This is used in BD as it has memory ranges from 65K to 983K
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Section 92.5.14 **Note:** This is used in PD as it has memory ranges from 1K to 15K

92.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

92.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see *Section 92.5.4: Suppress mode*. Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

92.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 1957. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled

Table 1957. NAR operational modes truth table(Continued)

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

92.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

92.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

92.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

92.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

92.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 1958. NAR transmit operations

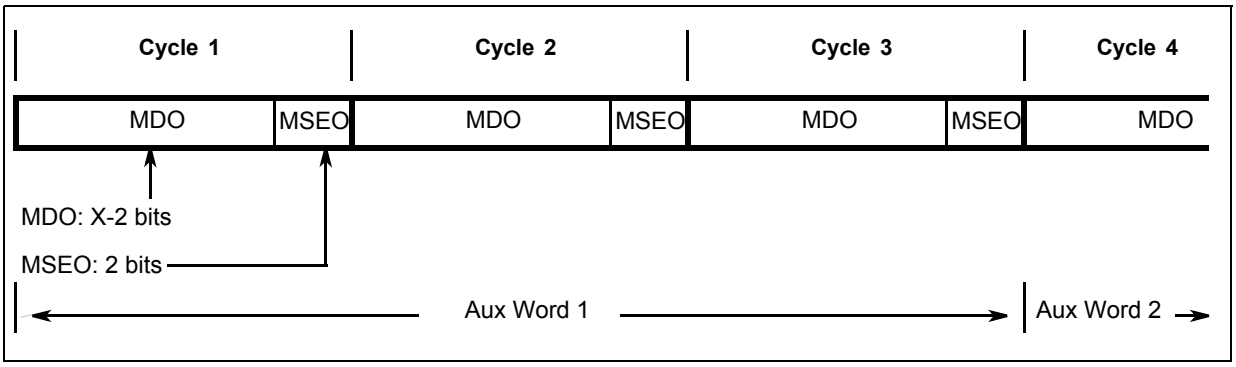
Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8 × 32-bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8 × 32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

92.5.3 Data reception and arbitration

The BD NAR supports 1 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (Bn) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.



When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never

sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire Bn × 32 data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2046. AUX bus parsing

Each AUX word consists of Bn cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request

level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

92.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then

all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

92.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

92.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

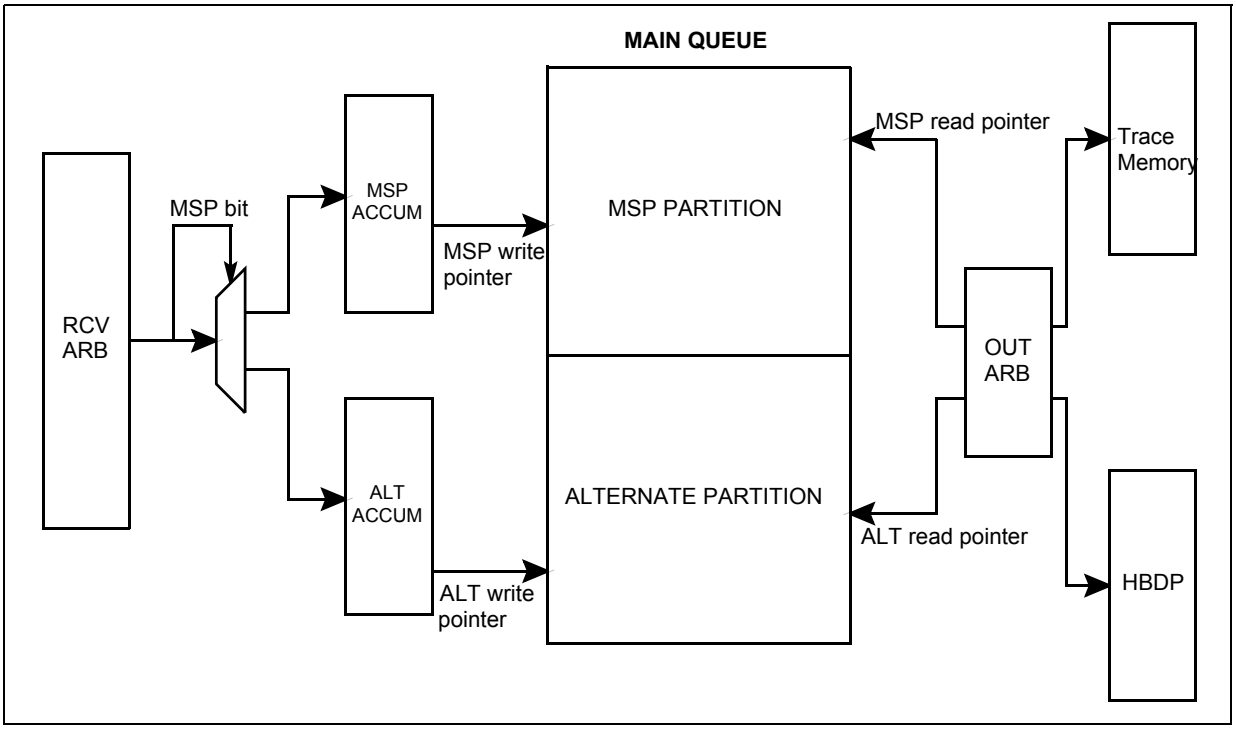
If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is ~(data_trace) AND (source = 13)HBDP



Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

92.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in *Figure 2047*. Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

Figure 2047. Queue partitioning

92.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

92.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16 × 4-bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4 × 16-bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = 16 × number of lanes).

92.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and

resizing in the likely case where the trace memory bus width does not equal the queue entry size.

92.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

92.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory

bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be 0x100 × 0x40 = 0x4000 bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

92.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- Device_ID—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in *Table 1962*.
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
  - HBDP error
  - Illegal configuration
  - Stall Error
  - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 1959. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message(1)	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC(2)	NAR source ID
	4	4	fixed	ETYPE	See *Table 1960*
	12	12	fixed	ECODE	See *Table 1961*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message(3)	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC2	NAR source ID
	6	6	fixed	WPHIT	See *Table 1962*
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

92.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 1960. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see *Table 1961*.
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes.(1)
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See *Table 1961*	The specific configuration error is conveyed in bits 0–3 of the ECODE field (*Table 1961*), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 1961. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

92.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

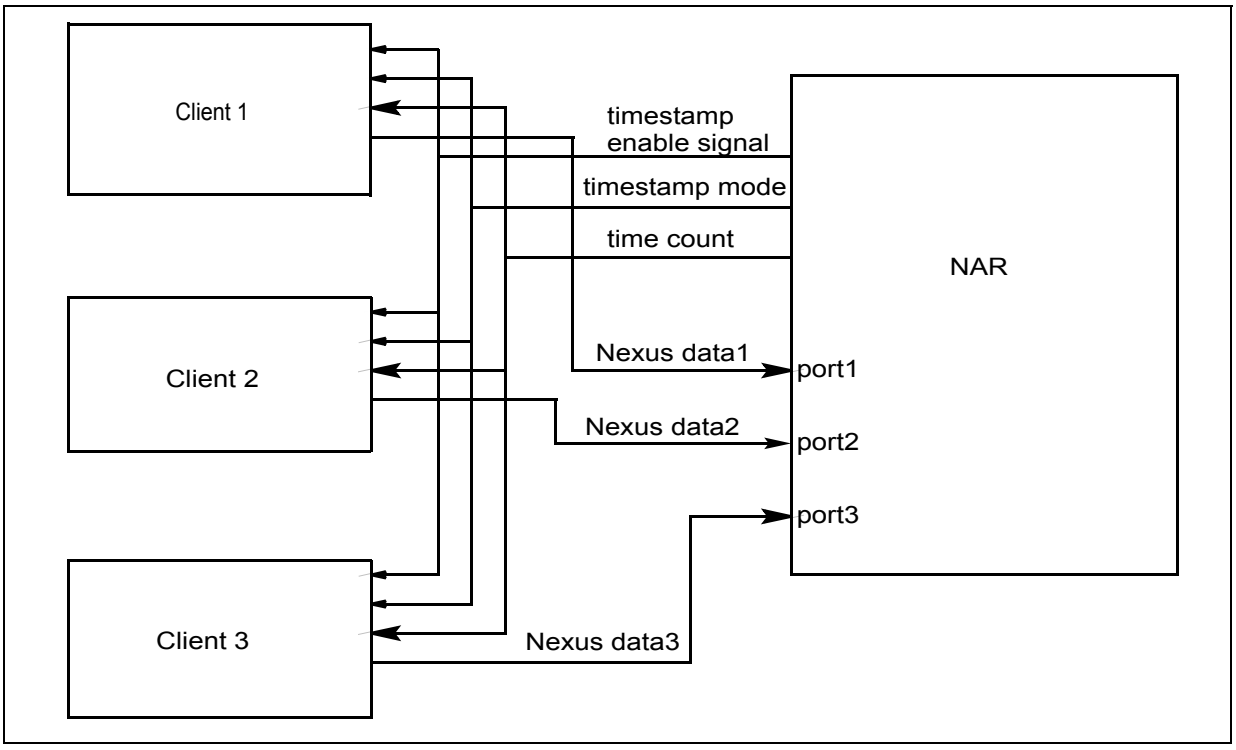


Table 1962. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

92.5.12 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in *Figure 2048*. The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2048. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

92.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to NAR block. The selected dci_evti signal carries this information. Selection between dct_evti[0] or dci_evti[1] signal is SoC specific which can be found in SoC configuration chapter. NAR detects the falling edge of selected dci_evti signal and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

92.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to

trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
  - AHB start (base) address—Base address = 0x0D00_0000 (i.e.TBAHI = 0x0, TBALO = 0x0D00_0000
  - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
  - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is (0xC0 $\times$ 0x40) = 0x3000 bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
  - Number of 1K blocks in 0x3000 bytes = (3000 right shift by 10 bits) = C = 12
  - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- NAR_AHFPAR[3:0] = (NAR_TBALO[13:10] + 0xB) = (0x7+0xB) 0x2 (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

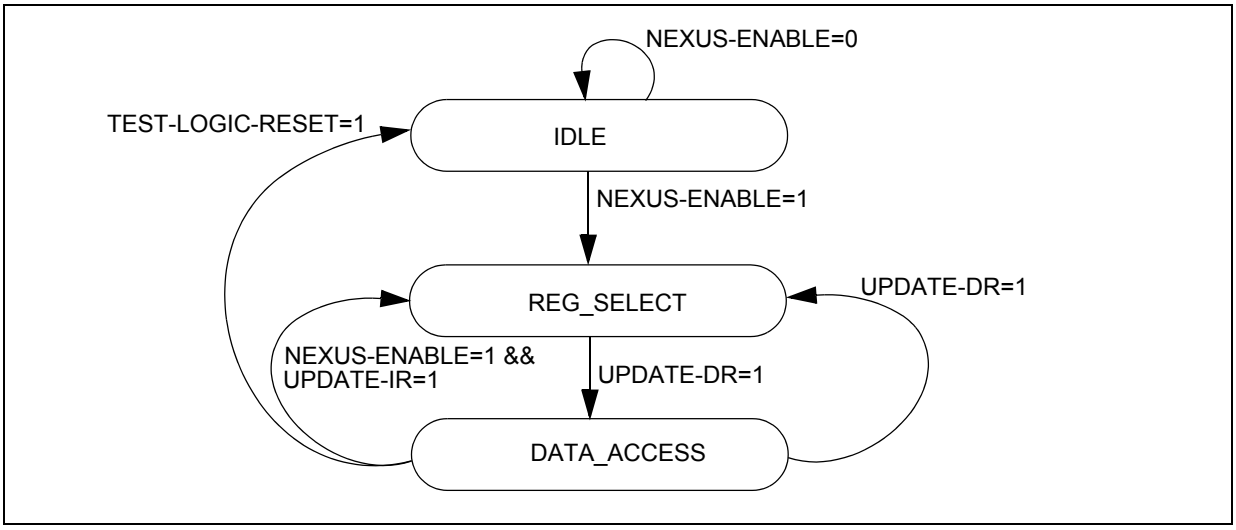
92.5.15 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in *Table 1963*. Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2049. Nexus controller state machine



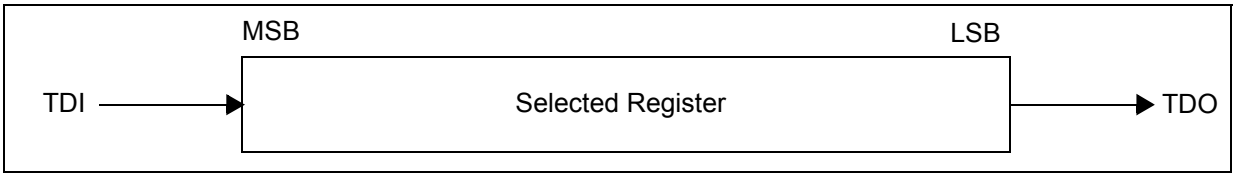


Table 1963. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2050. Shifting data into register

92.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

92.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in *Figure 2049*, transitions to the REG_SELECT state. The Nexus

controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 1964. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

92.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in *Figure 2051*. The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in *Table 1944*.

Figure 2051. Nexus command format for register selection

MSB	LSB
7-bit register index	R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state.When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state.When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 1965. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

92.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
  - Early Write (for higher BW in special module)
  - Configurable 32/64-bit address bus width
  - 64-bit data bus width
  - Transfer Types
  - IDLE, NONSEQ, SEQ
  - Single Transfers
  - Burst Transfers
  - Configurable support for INCR
  - Configurable support for INCR4, INCR8, INCR16, WRAP4
  - Response Type
  - OKAY, ERROR

  - Transfer Size
  - Byte, Half Word, Word, Double-Word
  - Protection Control
  - Cacheable/ Non Cacheable Access Control
  - User/Privilege Access
- Endianess Support
  - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
  - Total of two transactions (One plus one ongoing)

92.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

92.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

92.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

92.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width $\times$ 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as Bn $\times$ 32, where 32 = MDO bits + 2 MSEO bits and Bn is the number of beats.

Thus:Aurora data width = the Nexus client data

Aurora width $\times$ 16 = Bn $\times$ 32

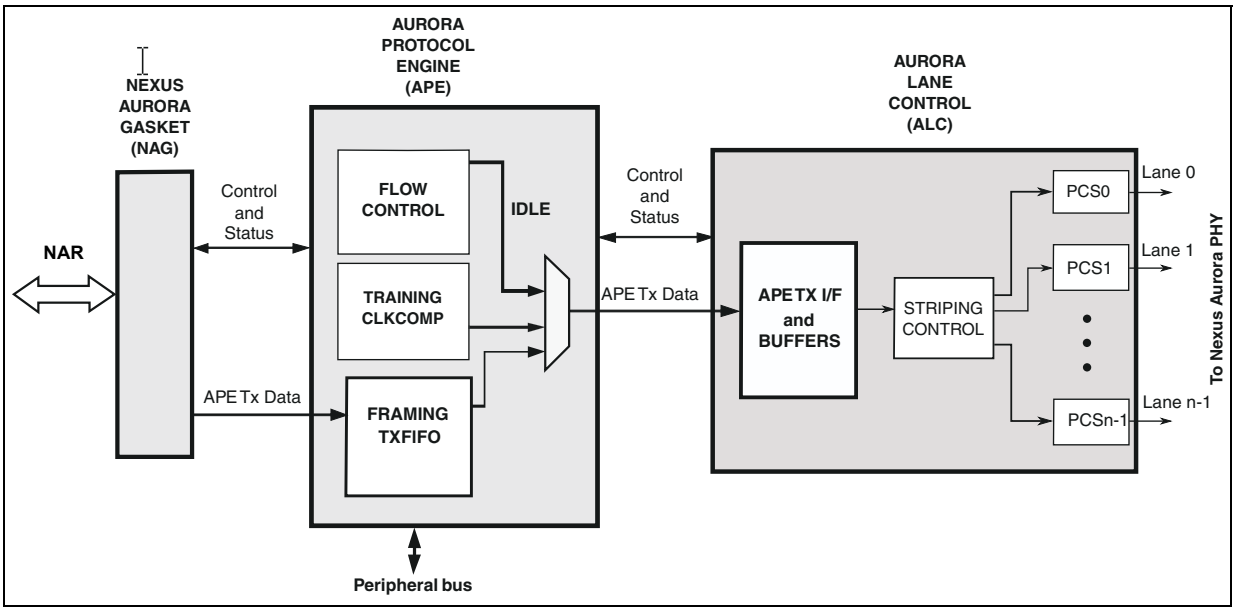
Aurora width = 2 $\times$ Bn.

This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block. The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

92.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in *Section 92.5.2.1: Reset*.

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.



92.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in *Section 92.5.6: Output arbitration*.

93 Buddy Device—Nexus Aurora Link (NAL)

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. *Figure 2052* details the NAL block diagram. The number of lanes, n, is 2.

Figure 2052. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Controller (NAR); messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. *Table 1966* lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 1966. NAL and NAP feature summary

Sub-component	Feature
NAR Aurora Gasket (NAG)	– Transmit FIFO to buffer data as it crosses the NAR / NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. – Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	– Link training – Per the Aurora Protocol specification, clock-compensation, and data framing – Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	– Striping of data stream from the Aurora core across all available lanes in two-byte chunks – PCS functionality for NAL
Nexus Aurora PHY (NAP)	– Physical transmission of serial data to device pins – External clock source for SerDes clock domain

93.1 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each packet is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each payload transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

Note: Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

93.2 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

93.3 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note: Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

93.4 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. There are several registers to control both transmit and receive functionality. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 1967. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0h	NAL General Status Register (NAL_GSR)	32	R	0000_8000h

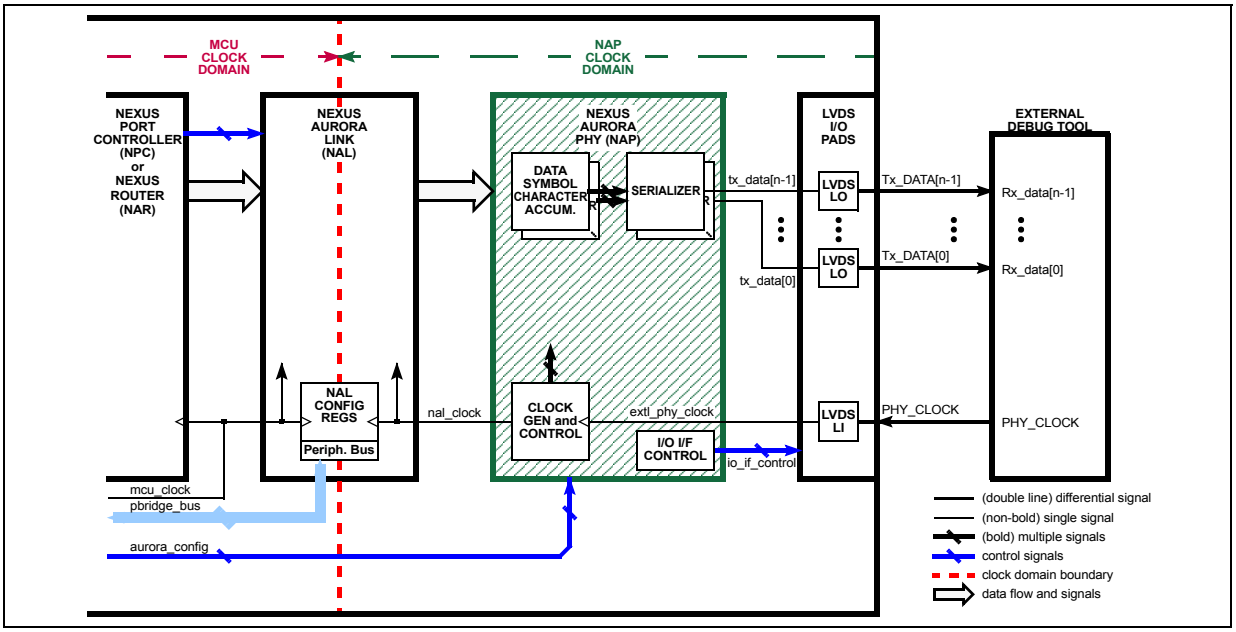
94 Buddy Device—Nexus Aurora PHY (NAP)

94.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.



Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

Figure 2056 shows a high level block diagram of the High Speed Nexus Interface and the NAP.

Figure 2056. High speed Nexus interface block diagram

94.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

94.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

94.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

94.1.2.2 Disabled/enabled

The NAP is disabled when it comes out of reset if the device is configured for pure device functional mode operation with Nexus trace messaging inhibited. The Aurora LVDS transmit lanes also remain powered down. In addition, any time the NAP block enable is negated the NAP is disabled and the LVDS transmit lanes powered down. Conversely, if the NAP is enabled when it comes out of reset or enabled sometime later after reset is negated, the NAP channels become active and the LVDS output lanes are enabled and can begin to transmit Nexus trace data after the startup time.

94.1.2.3 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

94.1.2.4 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 2 Transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

94.2 External signal description

The external signals of the NAP are listed in *Table 1971*. Each of the NAP signals consists of a positive and negative differential pair.

Table 1971. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1

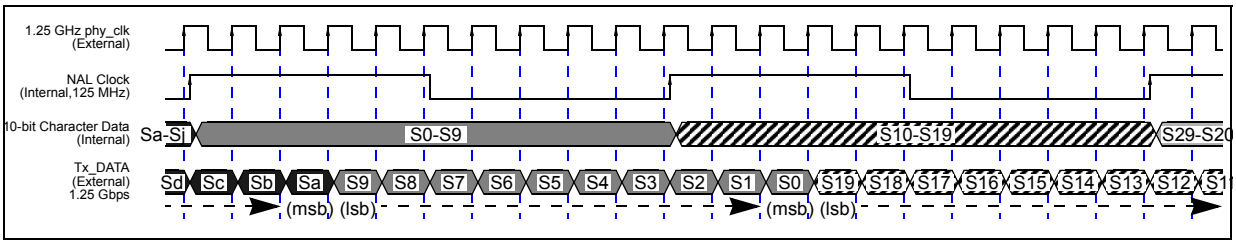
94.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

94.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

94.4.1 Data symbol character accumulator



The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

94.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

Figure 2057 shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

Figure 2057. Serializer timing diagram

94.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

94.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

95 Buddy Device—Nexus Read Write Access (RWA)

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in *Section 95.2, Nexus register access via JTAG*. The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

95.1 Register definition

Table 1972 details the register map for the RWA module.

Table 1972. RWA register map

Register	Nexus access opcode	Read/ write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

95.1.1 Register descriptions

95.1.1.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in *Table 1974*.

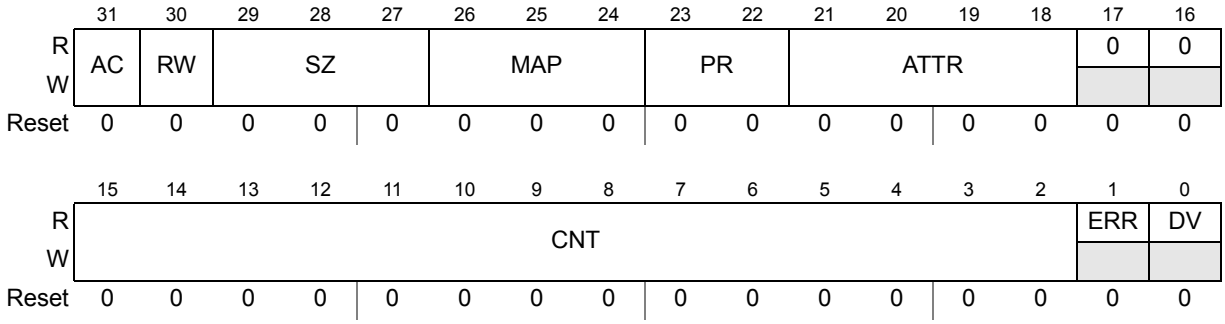


Figure 2058. Read/Write access control/status (RWCS) register

Table 1973. RWCS fields

Field	Description
31 AC	Access Control. 0 End access/ Access has completed 1 Start access
30 RW	Read/Write Select. 0 Read access 1 Write access
29:27 SZ	Word Size. 000 8-bit (byte) 001 16-bit (half-word) 010 32-bit (word) 011 Reserved (default to word) 100 Reserved (default to word) 101 Reserved (default to word) 110 Reserved (default to word) 111 Reserved (default to word)
26:24 MAP	MAP Select. 000 Primary memory map 001 Reserved 010 Reserved 011 Reserved 100 Reserved 101 Reserved 110 Reserved 111 Reserved
23:22 PR	Read/Write Access Priority. 00 Reserved (default to highest priority) 01 Reserved (default to highest priority) 10 Reserved (default to highest priority) 11 Highest access priority

Table 1973. RWCS fields(Continued)

Field	Description
21:18 ATTR	Access Attributes. RWA accesses are run as privileged data non-cacheable accesses by default, and drive the p_d_hprot[5:0] bus access attributes to 6'b000011 accordingly. This field is provided to allow a portion of these default values to be modified when performing read or write accesses using the RWA as shown in *Table 1975*. hprot[1] must be set to one. 0xxx Reserved 1xxx Reserved x0xx p_d_hprot[4] driven to 0 for accesses x1xx p_d_hprot[4] driven to 1 for accesses xx0x p_d_hprot[3] driven to 0 for accesses xx1x p_d_hprot[3] driven to 1 for accesses xxx0 p_d_hprot[2] driven to 0 for accesses xxx1 p_d_hprot[2] driven to 1 for accesses
17:16	Reserved for future functionality.
15:2 CNT	Access Control Count. Number of accesses of word size SZ.
1 ERR	Read/Write Access Error (see *Table 1974*).
0 DV	Read/Write Access Data Valid (see *Table 1974*).

Table 1974. Read/Write access status bit encoding

Read action	Write action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

Table 1975. Protection encoding

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
0	0	0	Cache-inhibited
0	0	1	Guarded, not cache-inhibited
0	1	0	Reserved
0	1	1	Reserved
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

95.1.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.

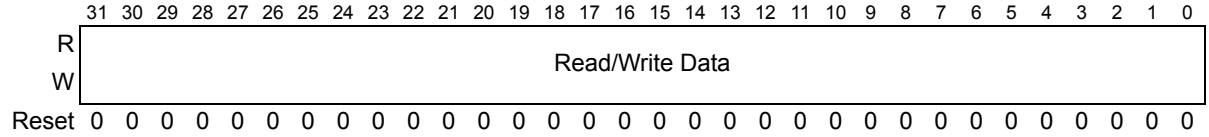

Figure 2059. Read/write access data (RWD) register

Read/write accesses to the memory require that the debug firmware properly retrieve/place the data in the RWD. *Table 1976* shows the proper placement of data into the RWD.

Table 1976. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD(1)			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

Table 1977 shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 1977. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—-	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—-	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]

Table 1977. RWD byte lane mapping(Continued)

Transfer size and byte offset	RWA(2:0)	RWD(1)			
		31:24	23:16	15:8	7:0
Word @000	0 0 0	XBAR[31:24]	XBAR[23:16]	XBAR[15:8]	XBAR[7:0]
Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

95.1.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.

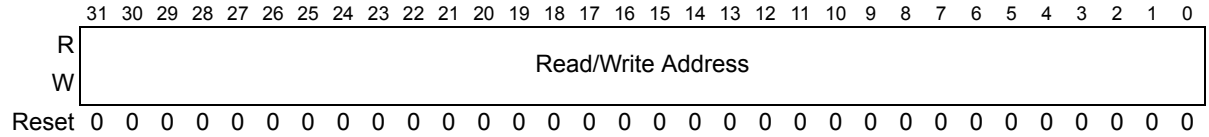

Figure 2060. Read/write access address (RWA) register

95.2 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in *Table 1972*.

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in *Table 1972*. This is achieved by loading an 8-bit value into the JTAG data register (DR).

   This register has the following format:

Figure 2061. JTAG DR for Nexus register access

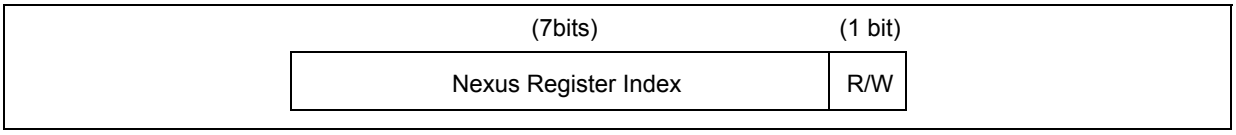

Table 1978. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in *Table 1972*
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
   a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
   b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

95.3 Memory access examples

The following subsections describe the steps which are required to access memory.

95.3.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Write Address = 32h'xxxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b'1 (to indicate start access)
   – Map Select (MAP) = 3b'000 (primary memory map)
   – Access Priority (PR) = 2b'00 (lowest priority)
   – Read/Write (RW) = 1b'1 (write access)
   – Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
   – Write Data = 32h'xxxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1'b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

95.3.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in *Section 95.3.1, Single write access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in *Section 95.3.1, Single write access* until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note: The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

95.3.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
   – Read Address = 32h'xxxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
   – Access Control (AC) = 1b'1 (to indicate start access)
   – Map Select (MAP) = 3b'000 (primary memory map)
   – Access Priority (PR) = 2b'00 (lowest priority)
   – Read/Write (RW) = 1b'0 (read access)
   – Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
   – Access Count (CNT) = 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

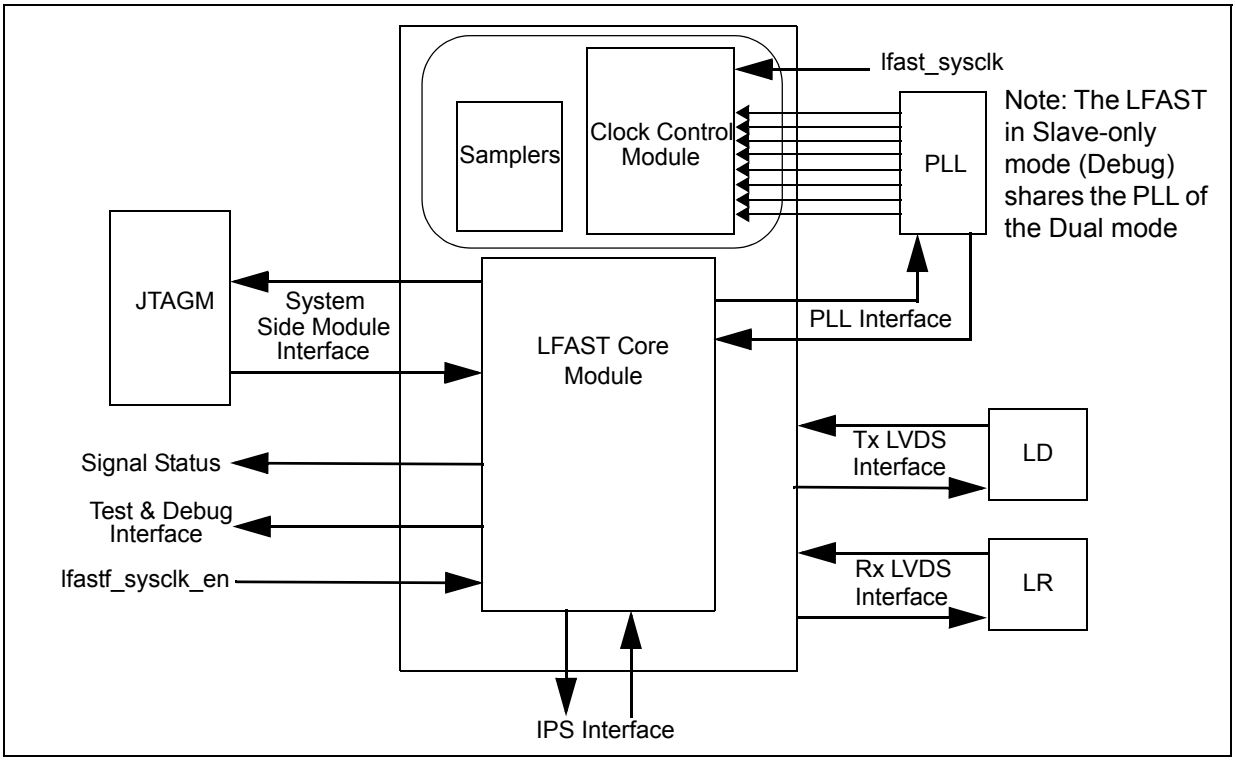
3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

95.3.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in *Section 95.3.3, Single read access* to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.
4. Repeat Steps 3 and 4 in *Section 95.3.3, Single read access* until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note: The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

96 Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug



96.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

96.2 Block diagram

Figure 2062 depicts LFAST interaction with other modules on the device.

Figure 2062. LFAST block diagram

96.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
  - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
  - Reference clock of the LFAST master and slave
- txdatap/txdatan
  - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
  - Differential receive (Rx) interface pair

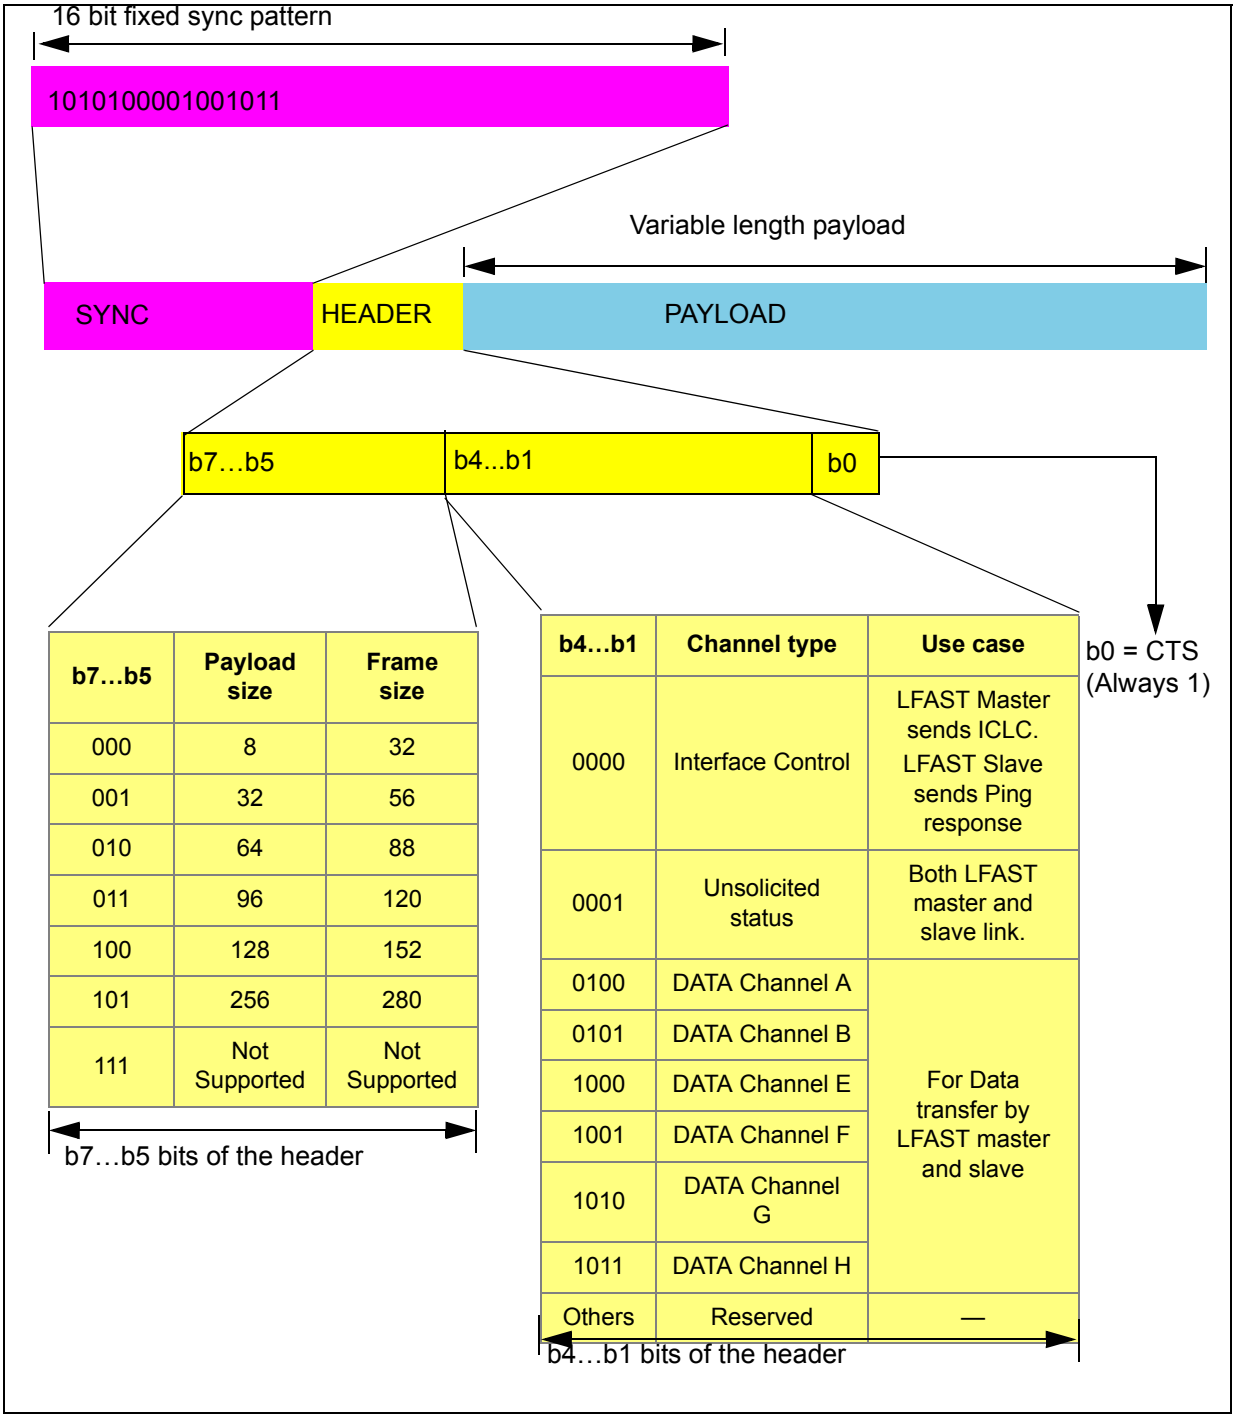
LFAST interface is an asynchronous high speed LVDS interface.

96.3.1 LFAST operating data rates

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps (lfast_sysclk ÷ 4 or lfast_sysclk ÷ 2) is referred to as low data rate, and the high data rate is in the Data Sheet.

96.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.



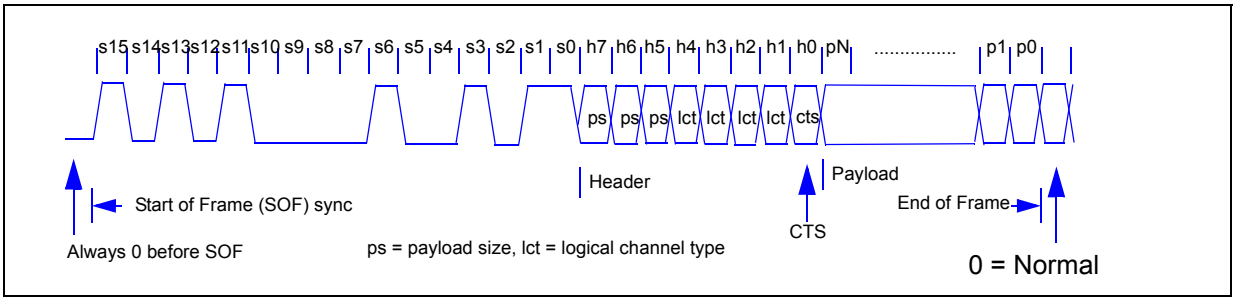
A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See *Figure 2063* for details of the LFAST frame.

Figure 2063. LFAST frame structure



b7…b5	Payload size	Frame size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
111	Not Supported	Not Supported

b4…b1	Channel type	Use case
0000	Interface Control	LFAST Master sends ICLC. LFAST Slave sends Ping response
0001	Unsolicited status	Both LFAST master and slave link.
0100	DATA Channel A	For Data transfer by LFAST master and slave
0101	DATA Channel B	
1000	DATA Channel E	
1001	DATA Channel F	
1010	DATA Channel G	
1011	DATA Channel H	
Others	Reserved	—

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 2064. Serial frame structure

The frame structure is shown in *Figure 2064* and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto-correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to *Table 1979*.

Table 1979. Header payload sizes

b7-b5 (bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

96.5 Features

- Supports slave only mode.
- Supports asynchronous data transfer rates up to the maximum data rated shown in the product Data Sheet.
- Transmits and receives data and unsolicited frames.
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports flow control using sliding window protocol.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation.
- Supports for detection of unsupported channel number and unsupported payload size.

96.6 Memory map and register definition

All registers are 32 bits wide.

96.6.1 Memory map

Table 1980. LFAST memory map

The conventions in *Figure 2065* and *Table 1981* serve as a key for the register summary and individual register diagrams.

Figure 2065. Key to Register Fields

Table 1981 provides a key for register figures and tables and the register summary.

Table 1981. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bits value (other than a hardware reset).
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but its cleared by the H/W once the operation defined by the bit is over
Reset Values	
0	Resets to zero.
1	Resets to one.
[*signal_name*]	Reset value is determined by polarity of indicated signal.

96.6.2 Register descriptions

96.6.2.1 Mode Configuration Register (MCR)

[1] Set by user software and cleared by system hardware.

Figure 2066. Mode Configuration Register (MCR)

Table 1982. MCR field descriptions

Field	Description
0-14	Reserved
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode. Refer to *Section 96.10.2: Slow speed clock* for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
19-26	Reserved
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28-29	Reserved
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

96.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Offset: 0004h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DRMD[1]
W

R	0	0	0	0	0	0	0	RDR	0	0	0	0	0	0	0	TDR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1 Only writable when MCR[DRFEN] = 0.

Figure 2067. Speed Control Register (SCR)

Table 1983. SCR field descriptions

Field	Description
0-14	Reserved
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. This bit should not be modified by S/W and left as SCR[DRMD] =1.
16 - 22	Reserved
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. This bit should not be modified by S/W.
24-30	Reserved
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. This bit should not be modified by S/W.

96.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Offset: 0008h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	SMPSEL[1]								0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

[1] Only writable only when MCR[RXEN] = 0.

Figure 2068. Correlator Control Register (COCR)

Table 1984. COCR field descriptions

Field	Description
0-7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8-27	Reserved
28-30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation … 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 08 phases 14 phases

96.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Offset: 000Ch Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1 Writable only when TMCR[LPON] = 0.

Figure 2069. Test Mode Control Register (TMCR)

Table 1985. TMCR field descriptions

Field	Description
0-5	Reserved
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by H/W on reception of an ICLC command. 1Clock Test mode enabled 0Clock Test mode disabled
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1Loopback mode is enabled 0Loopback mode is disabled
8-12	Reserved
13-15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by S/W)
16-31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPFPDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. … FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

96.6.2.5 Auto Loopback Control Register (ALCR)

Offset: 0010h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Figure 2075. LVDS Control Register (LCR)

Table 1991. LCR field description

Field	Description
0-7	Reserved
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
13 SWONLD	SW signal to turn ON the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
15 SWONLR	SW signal to turn ON the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.

Table 1991. LCR field description(Continued)

Field	Description
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode.
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable. 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable.. The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
19-25	Reserved
26 LVRXOP_TR	Used to enable or disable the on-chip receiver termination resistor in LFAST mode (applies to LVDS pad use for LFAST only): 0Disable on-chip LFAST receiver termination 1Enable on-chip LFAST receiver termination
27	Reserved
28 LVRXOP_BR	Used to set the bias current for the receiver in LFAST mode. It is recommended to always write 1 to this bit when using the LFAST interface. Writing 0 will allow for a small power savings during lower baud rates (applies to LVDS pad use for LFAST only): 0 Use for LFAST receiver baud rates less than maximum baud rate 1 Required for LFAST receiver maximum baud rate
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Clock Sync Select. This bit is used to adjust the LVDS data sampling to the duty cycle of the clock. It is recommended that a value of zero is used in all cases. A value of one is reserved for specific devices/revisions with different clock timing. 0 normal clock used to sample the LVDS data 1 adjusted clock used to sample the LVDS data
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

Table 2001. UNSRDRn field descriptions

Field	Description
0-31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

96.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements[ab]. All registers of the LFAST module are classified as non-safety relevant.

96.7 Functional description

96.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

96.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCR are programed according to the LVDS parameter in the device datasheet.
2. The PLLCR[ac] is programed with the configuration parameters of the PLL.
3. The LCR is programed with the configuration parameters of the LVDS.
4. MCR[DATAEN] fields is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 31h is received H/W writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 00h frame is received and H/W writes RIISR[ICPRF] = 1.

ab. See the “Functional Safety” chapter for register classification details.

ac. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 02h is received and H/W writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 80h is received and H/W writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 10h is received and H/W writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 00h is received and H/W writes RIISR[ICPRF] = 1.

96.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

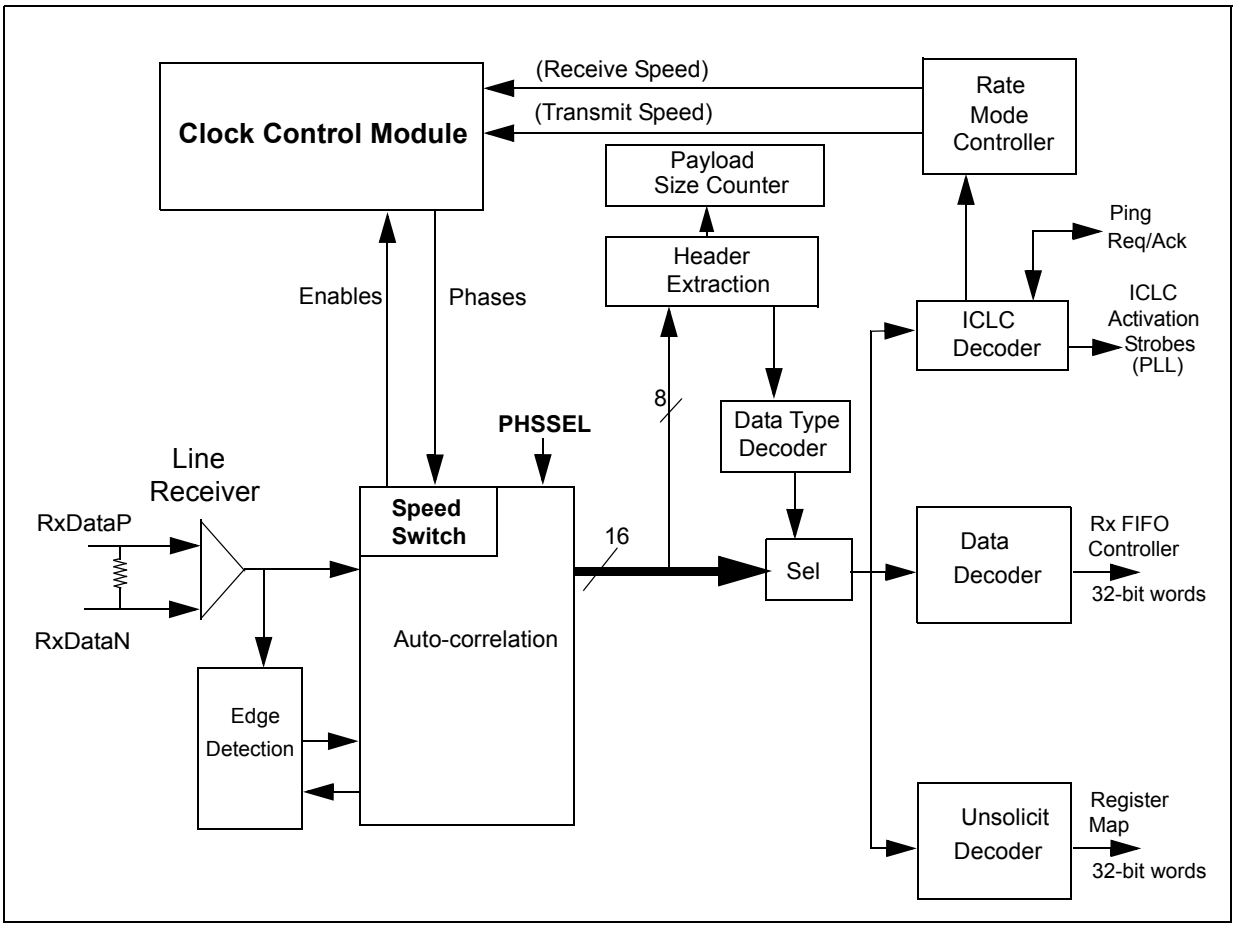
LFAST interface enable (lfast_sysclk_en) negation:

1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then S/W writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

1. The LD LVDS pad is power up, if all conditions are met:
   - LCR[SWOFFLD] = 0.
   - LCR[SWONLD] = 1.
   - MCR[TXEN] = 1.
   - When frame ICR[ICLCPLD] = 31h is received.
2. LR LVDS pad is powered up if all conditions are met:
   - LCR[SWOFFLR] = 0.
   - LCR[SWONLR] = 1.
   - MCR[RXEN] = 1.

96.7.3 Line Receiver (LR)



96.7.3.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto-correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

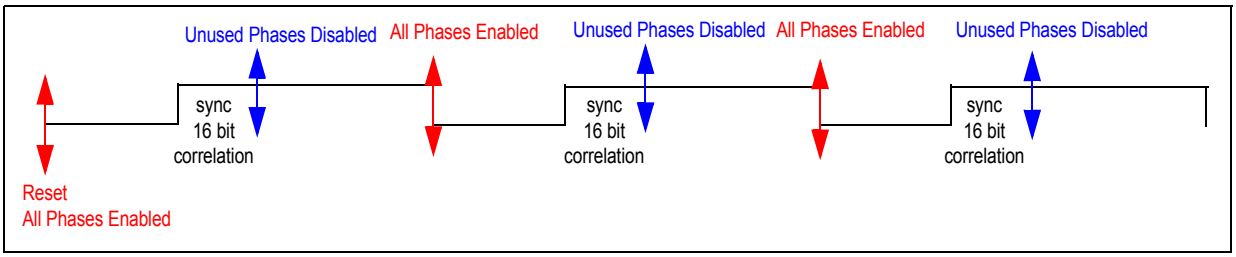
After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 2086 shows the block diagram of Uplink Controller.

Figure 2086. Top Level Receive Controller

96.7.3.2 Edge-Detection & Auto-correlation

The edge-detection and auto-correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.



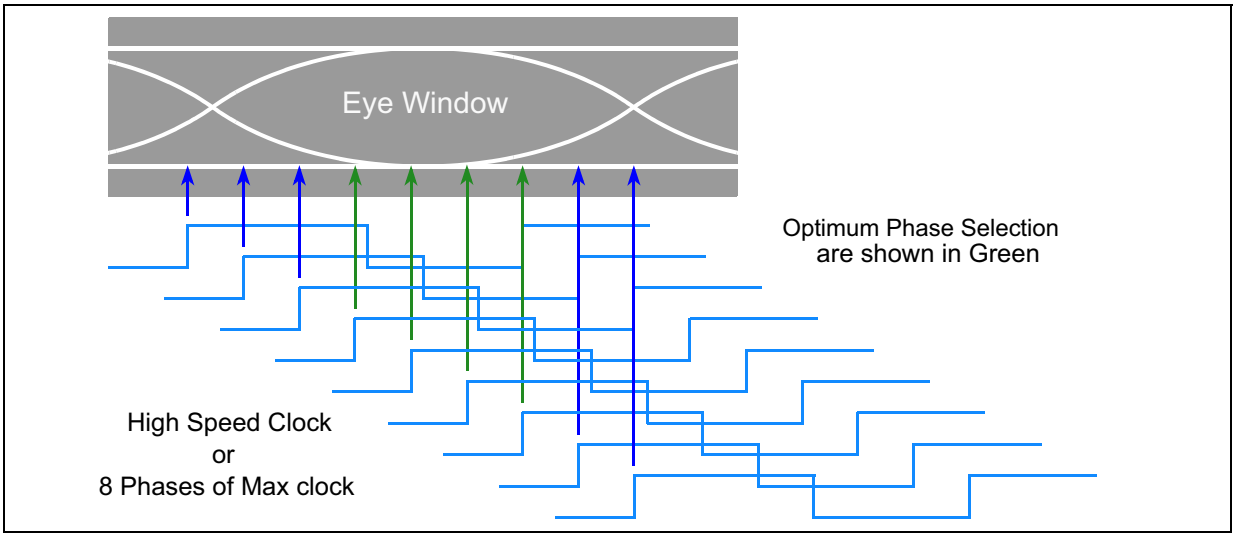
96.7.3.2.1 Auto-correlation modes

96.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization

pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

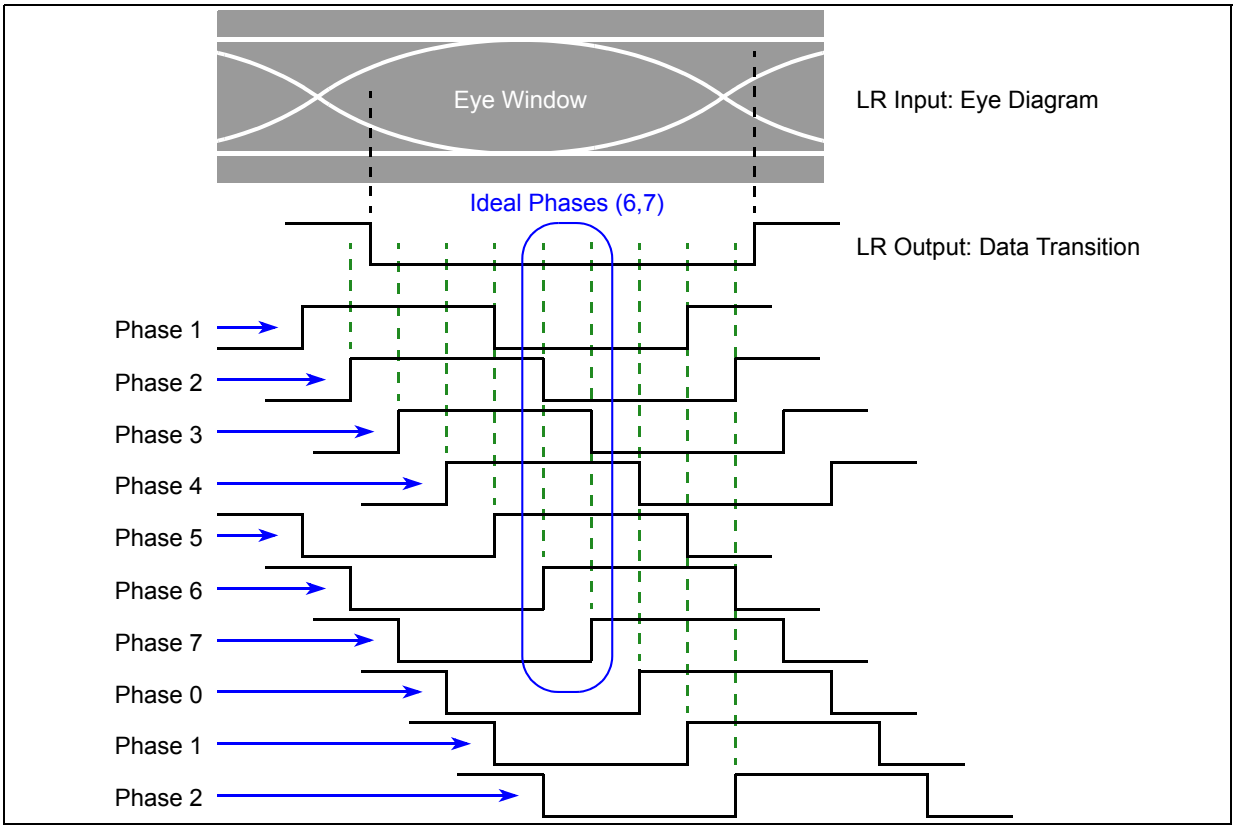
Figure 2087. Hunt Correlation mode



96.7.3.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

96.7.3.2.3 Auto-correlation



The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto-correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in *Figure 2088*.

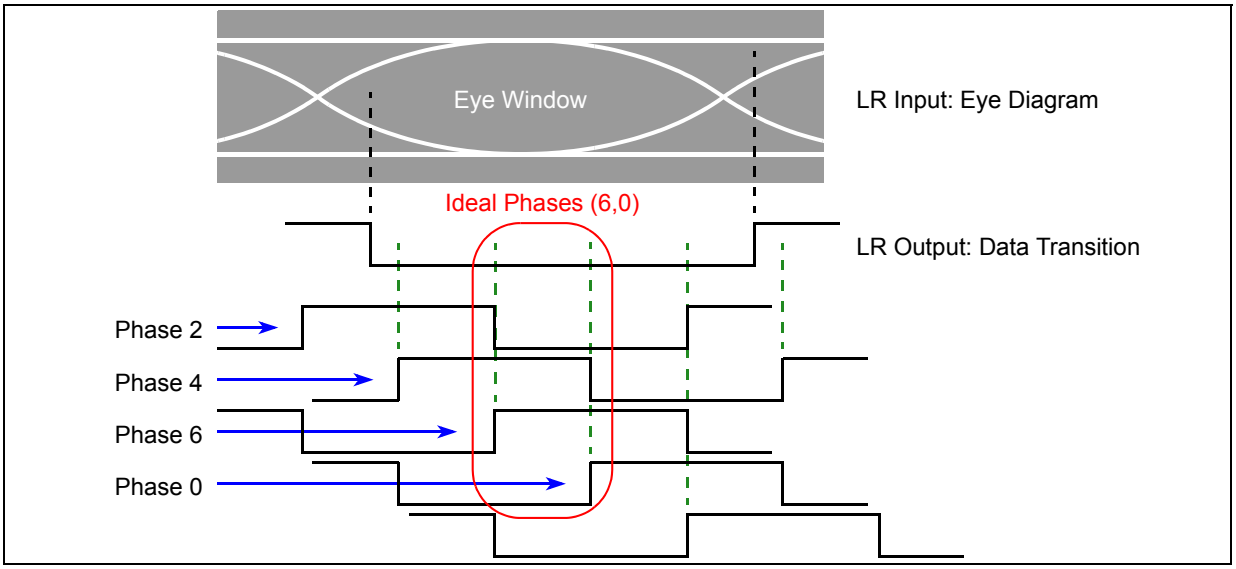
Figure 2088. High Speed 8 Phase Selection

The objective of the auto-correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in *Figure 2089*.

Figure 2089. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in *Figure 2090* and *Figure 2091*.

Figure 2090. High Speed 4 Phase Clock Alignment Example



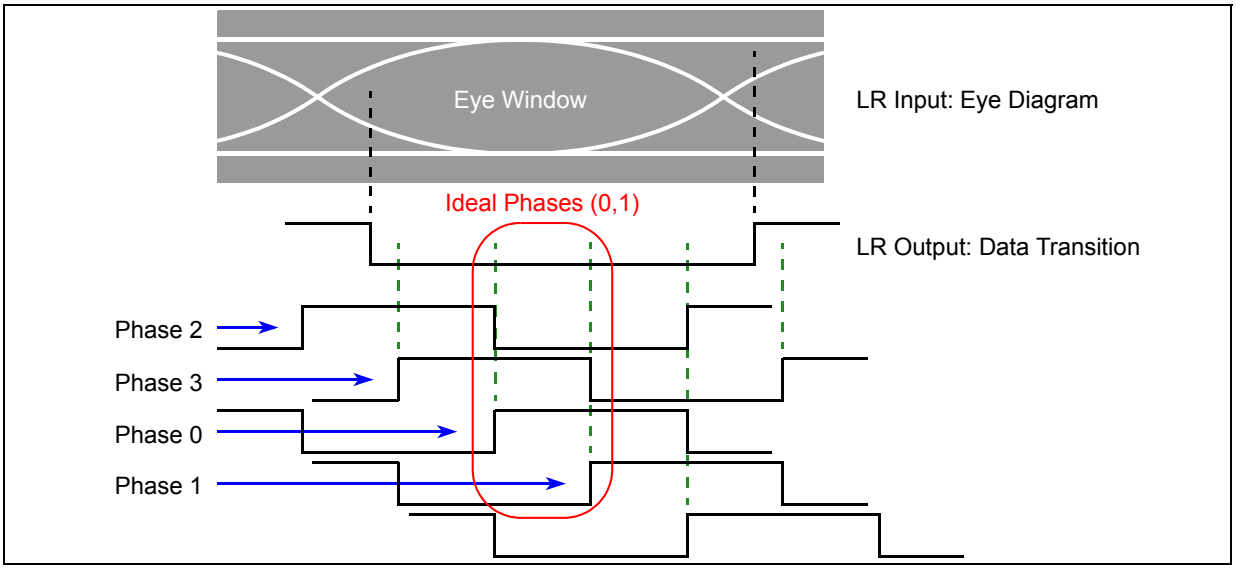


Figure 2091. Low speed 4 phase clock alignment example

The auto-correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to a intermediate phase as shown in *Table 2002*, *Table 2003*, and *Table 2004* before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 2002. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 2003. High speed 4 phase selection - sampling procedure

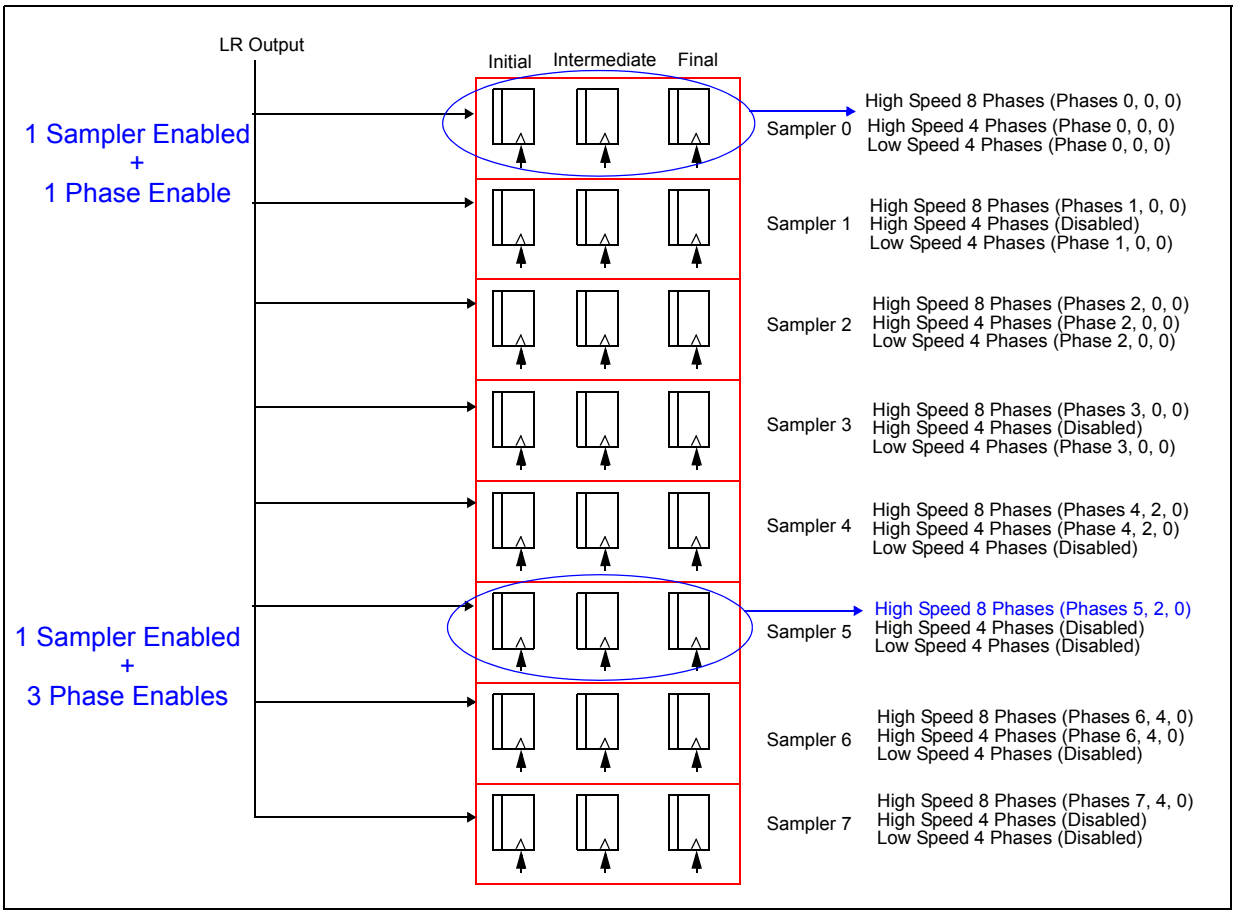
Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See *Table 2003*, Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 2004. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See *Table 2004*, Samplers 4, 5, 6, 7 are disabled.The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.



96.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto-correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in *Figure 2092*.

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (e.g Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

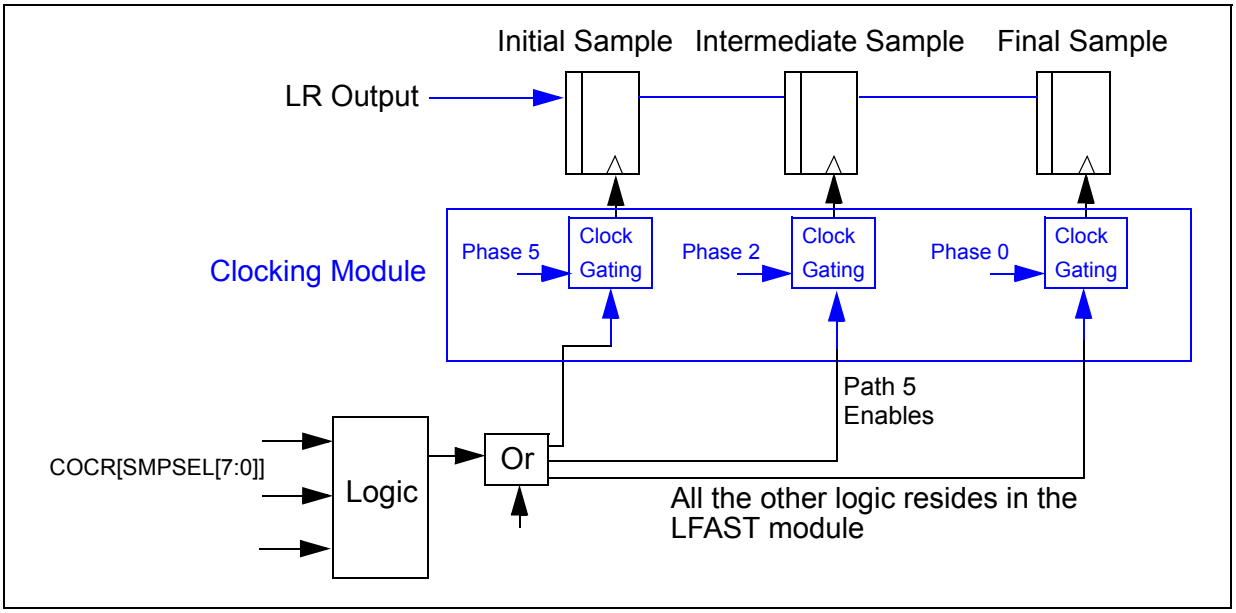


Figure 2092. Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in *Figure 2093*.

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

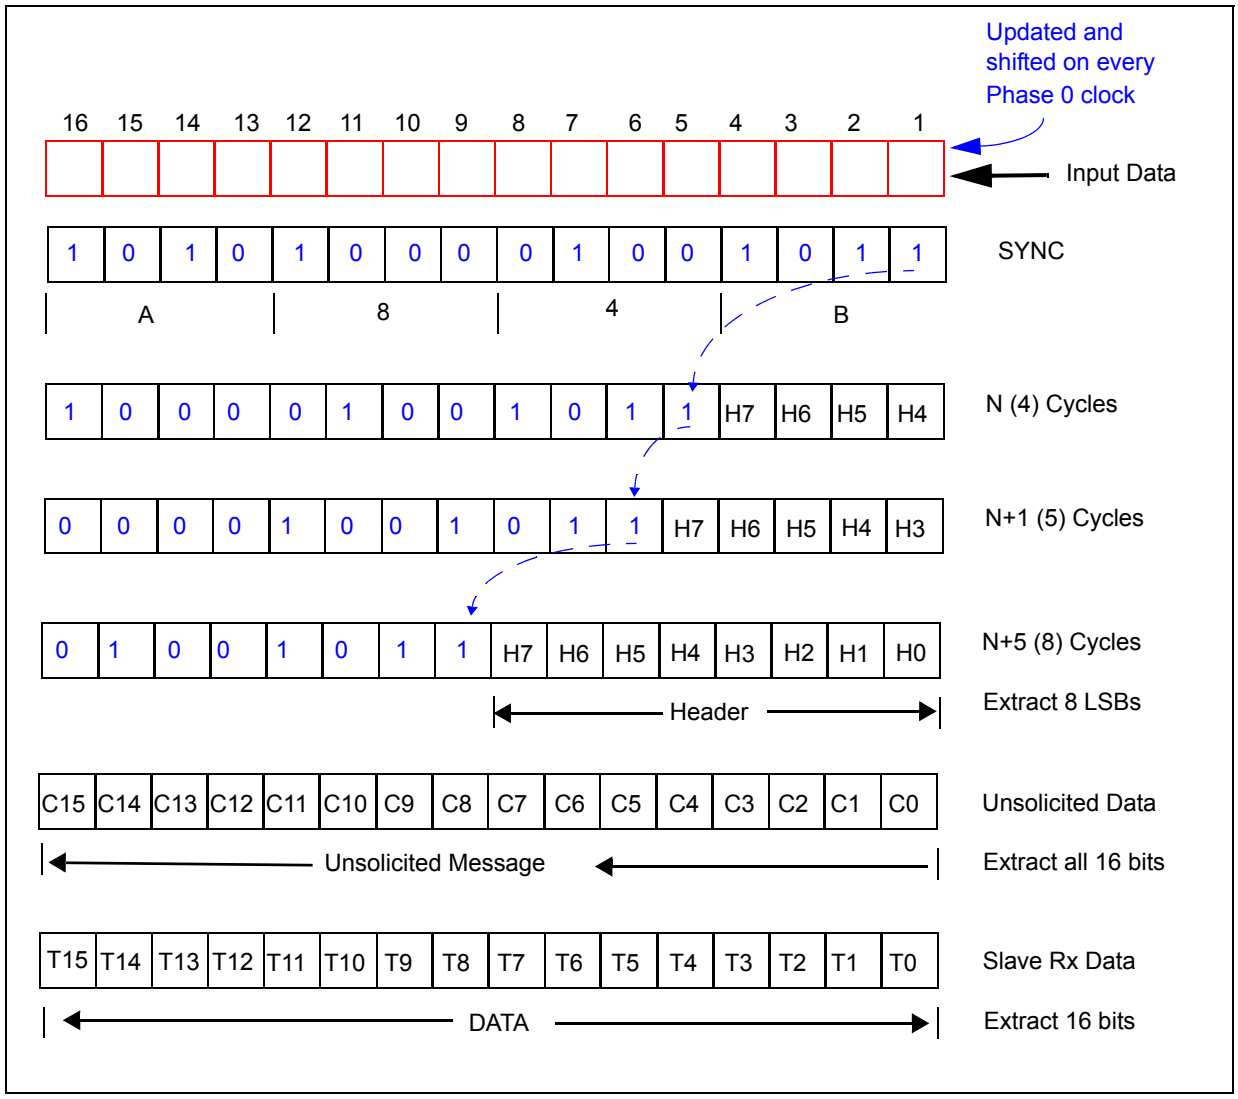

Figure 2093. Sampler 5 Logic

96.7.3.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in *Figure 2094*.

Figure 2094. Extracting Header and Payload from the 16-bit output from Auto-correlation.

96.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown
  The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a Vdd level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep
  The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- Normal
  In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 2005. Line Receiver State

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SWOFFLR] or LCR{SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

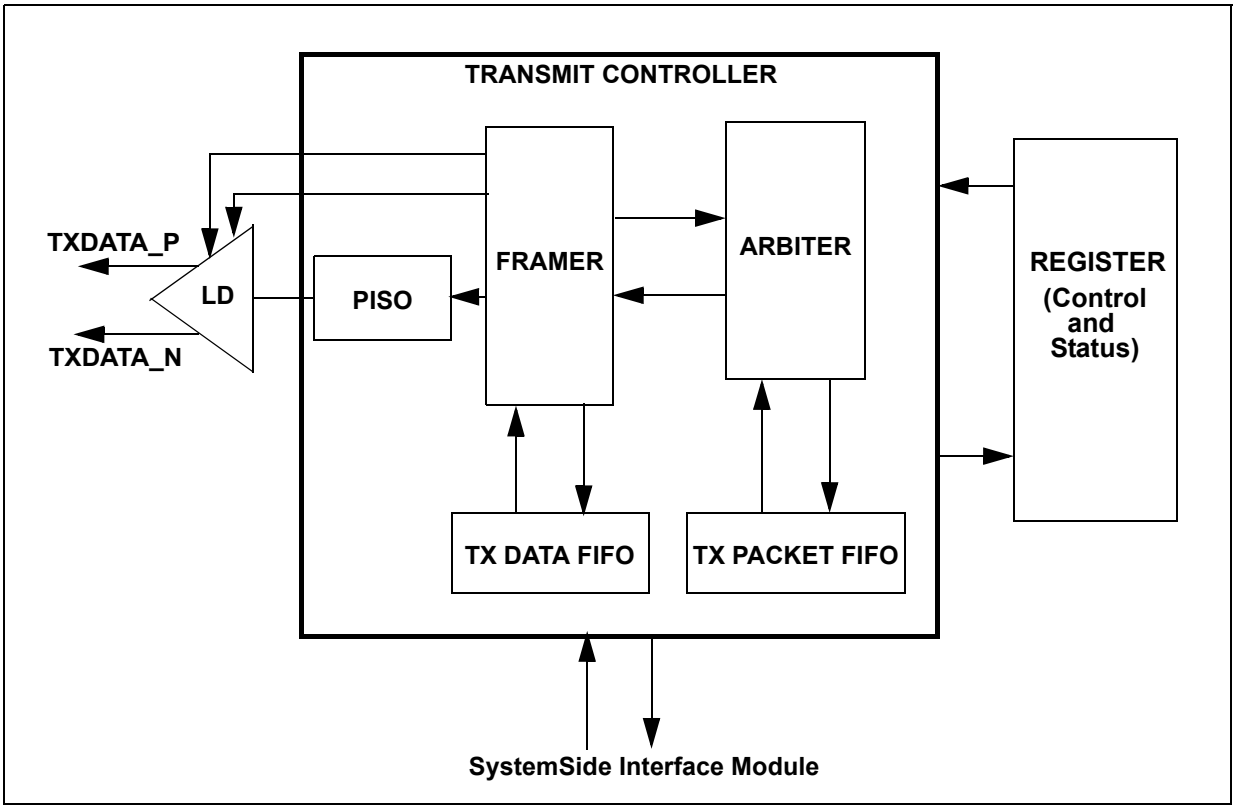
96.7.4 Transmit Controller

96.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, ping etc. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Receive Controller and the ping response from the register block.

The Tx interface has two speed modes:



- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in *Figure 2095*.

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 2095. Transmit Controller Connections

96.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- S/W programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in *Table 2006*.

Table 2006. Priority Levels for the Transmit Controller

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

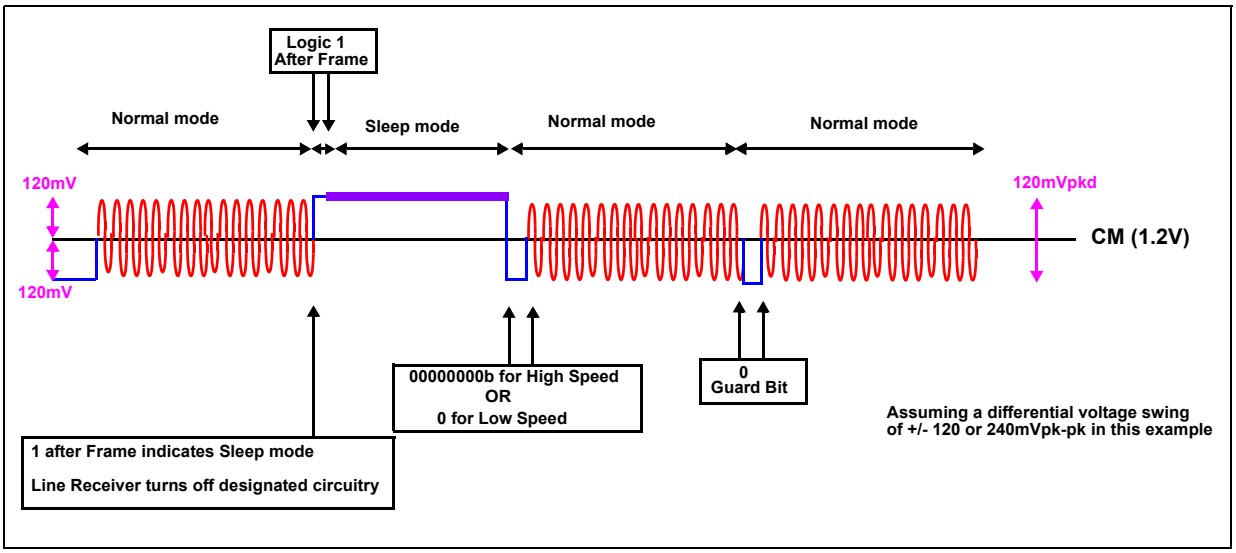
Table 2006. Priority Levels for the Transmit Controller(Continued)

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received **Note:** Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCR[DRCNT].

96.7.4.3 Line Driver digital connections

96.7.4.3.1 Line Driver states



The LD has the following states:

- Shutdown
  The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling

time is required before the LD may be used for communication.The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep
  The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely.In the sleep state the LD outputs are connected to Vcm (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a predefined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

Figure 2096. Example of Sleep mode

As shown in *Figure 2096* before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal
  In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 2007. Line Driver States

LD State	LFAST Slave Triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

96.7.5 Frames supported

Table 2008 provides the frames supported and their permissible payload sizes

Table 2008. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b,1000b – 1011b Tx – All	YES	YES	TX: 96 RX:128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO(1)	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

96.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

96.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

96.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO.Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

96.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.

96.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[RXEN] and MCR[DRFEN] bits should be set to enable the data frame reception.When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT**]**. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

96.7.6.2 Unsolicited flow

96.7.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

96.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
   - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
     - UNSTCR[USNDRQ] = 0
     - TISR[TXUNSF] = 1.
   - If UNSTCR[USNDRQ] = 0 then:
     - Program the unsolicited payload in UNSTDR0–UNSTDR8, and can be written up to a payload of frame of a maximum of 288 bits.
     - Program the unsolicited frame header in UNSTCR[UNSHDR].
     - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

96.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDR0–UNSTDR8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

96.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

96.7.6.3.1 .ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

96.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame.The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

96.7.6.3.1.2 Start PLL ICLC

The Start PLL ICLC command will write bit RIISR[ICPONF] = 1.

96.7.6.3.1.3 Stop PLL ICLC

The Stop PLL ICLC command will write RIISR[ICPOFF] = 1.

96.7.6.3.1.4 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

96.7.6.3.1.5 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

96.7.6.3.1.6 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

96.7.6.3.1.7 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

96.7.6.3.1.8 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

96.7.6.3.1.9 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

96.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

96.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

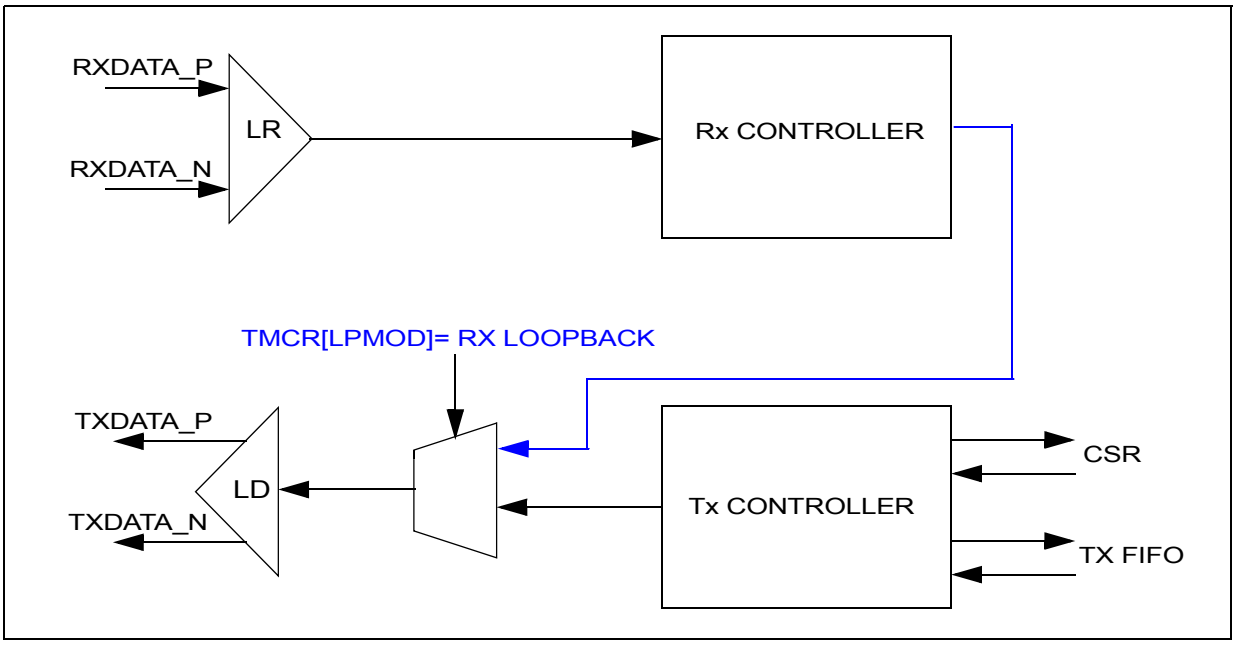
- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 2009. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.



In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

96.7.7.1.1 Rx Loopback mode

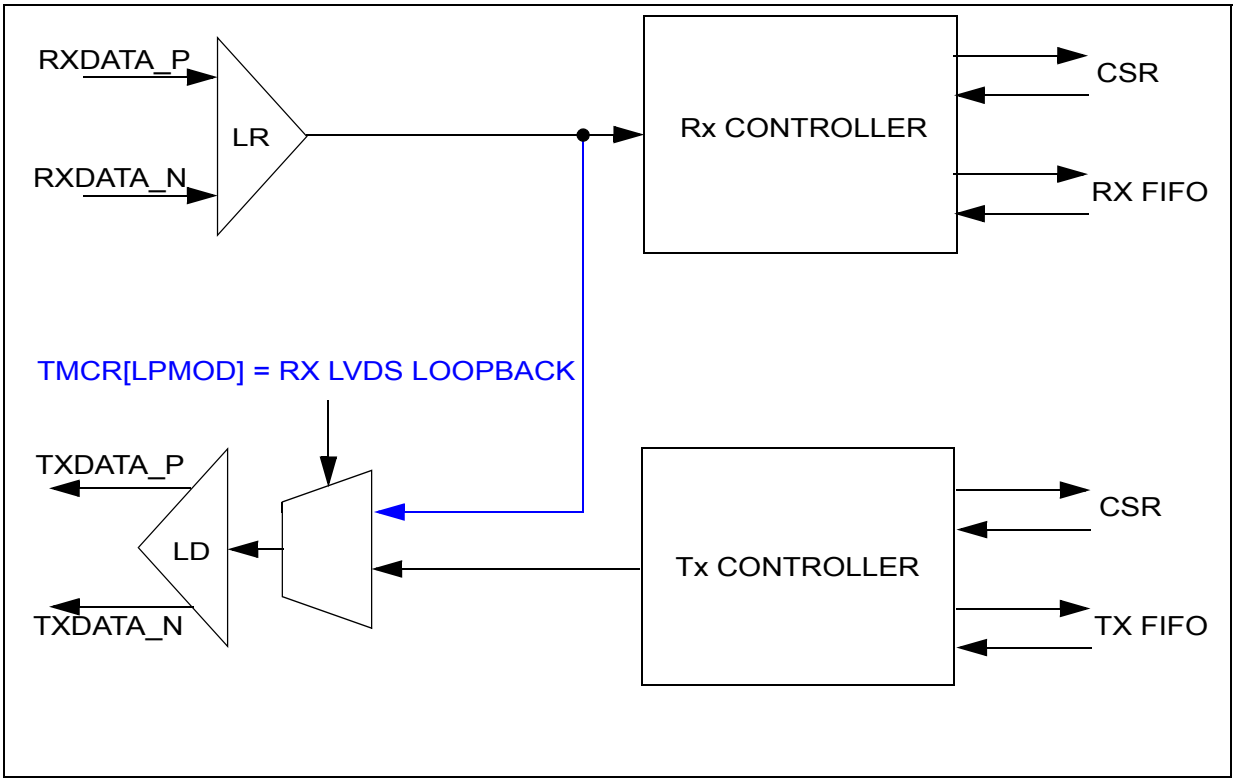
For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 2097. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
   – S/W programs TMCR[LPON] = 1.
   – For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:



- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

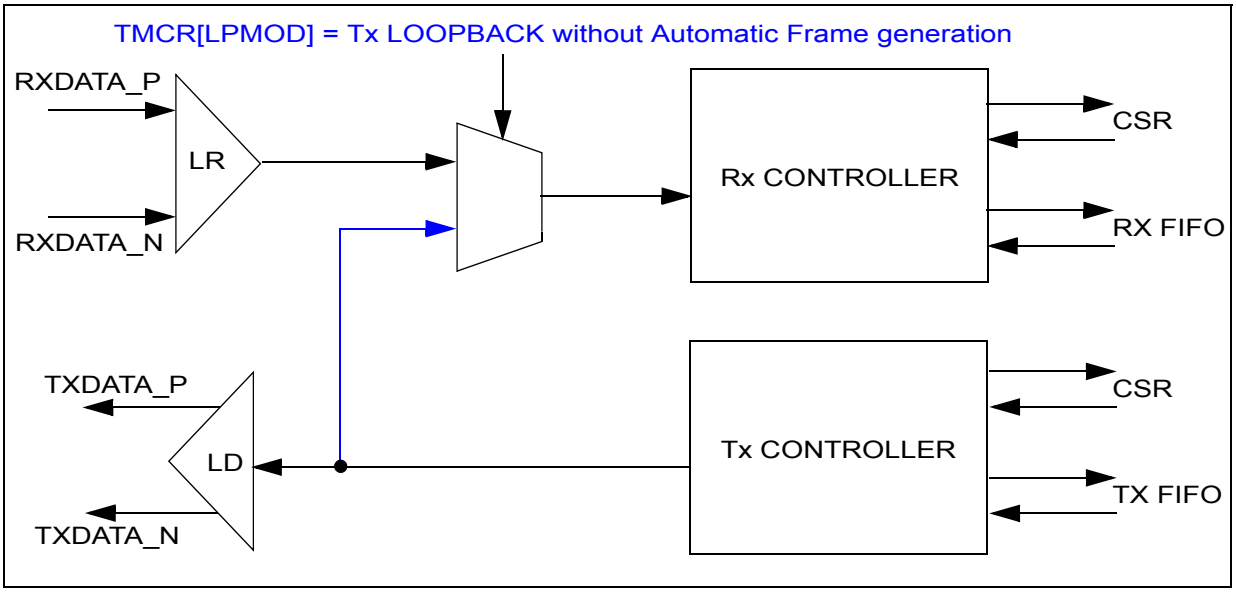
96.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 2098. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
   – S/W writes TMCR[LPON] = 1.
   – For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.



Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
  – Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.
  – Deassertion of the LFAST interface enable (lfast_sysclk_en).

96.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 2099. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
   – S/W programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

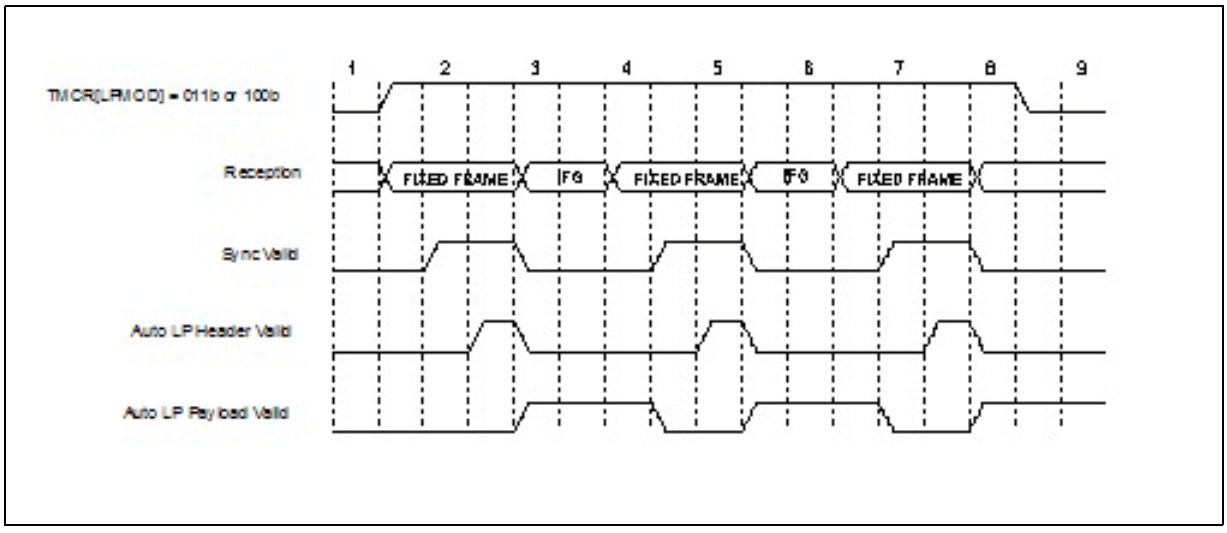
Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

96.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.



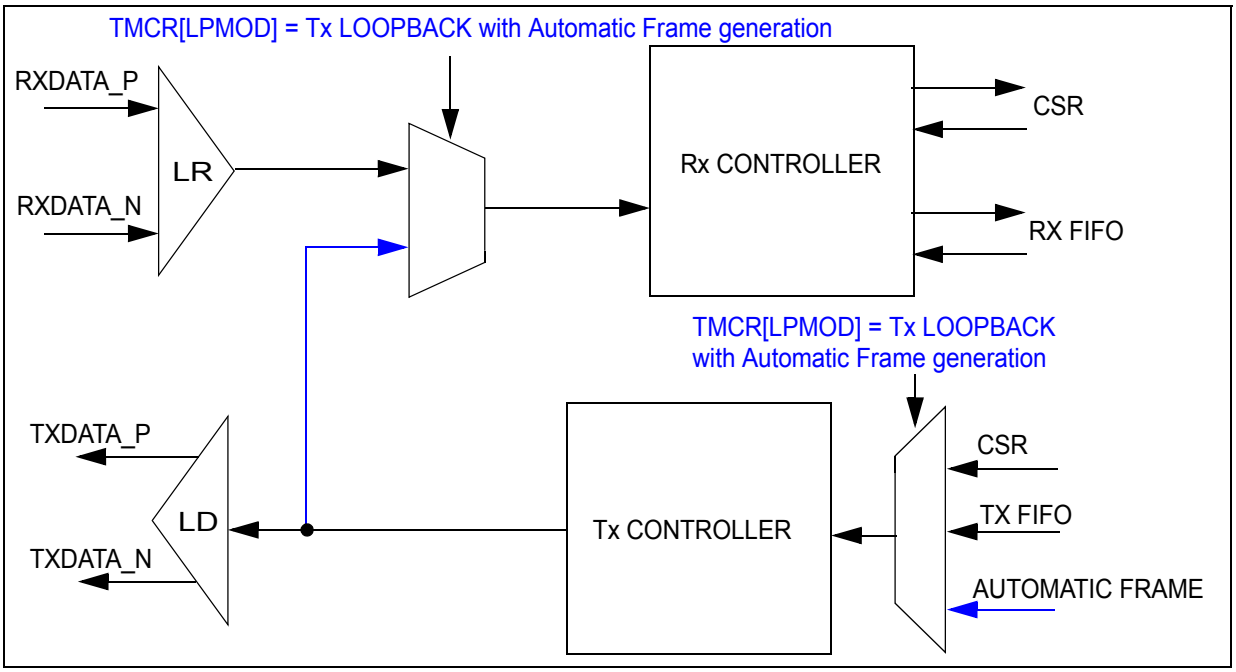
The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 2100. Automatic Loopback Test status signal timings



The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

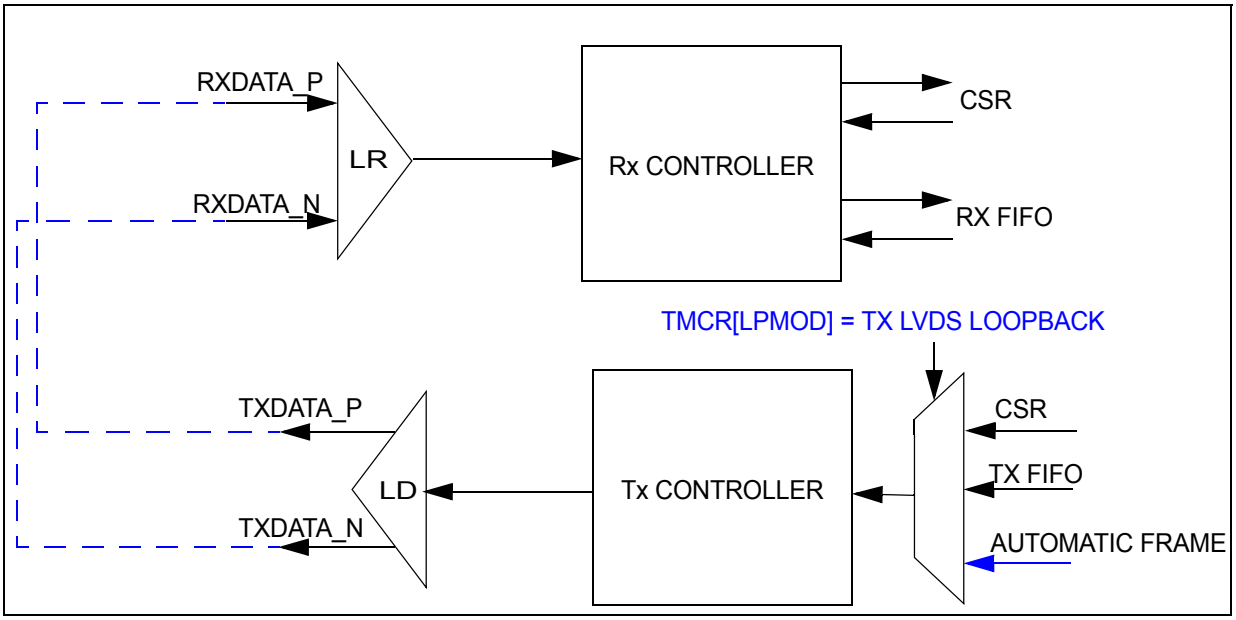
96.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

Figure 2101. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
   - S/W programs TMCR[LPON] = 1.
   - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from the LFAST Master.



Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

96.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 2102. Tx LVDS Loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
   – S/W programs TMCR[LPON] = 1.
   – For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

96.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by any of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

96.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has it own dedicated buffer, and they are not shared between each other.

Table 2010. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer (in bits)	Rx Buffer (in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet(1)	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

1. Ping response packet

96.9 Resets

The various blocks in LFAST are reset as described in *Table 2011*.

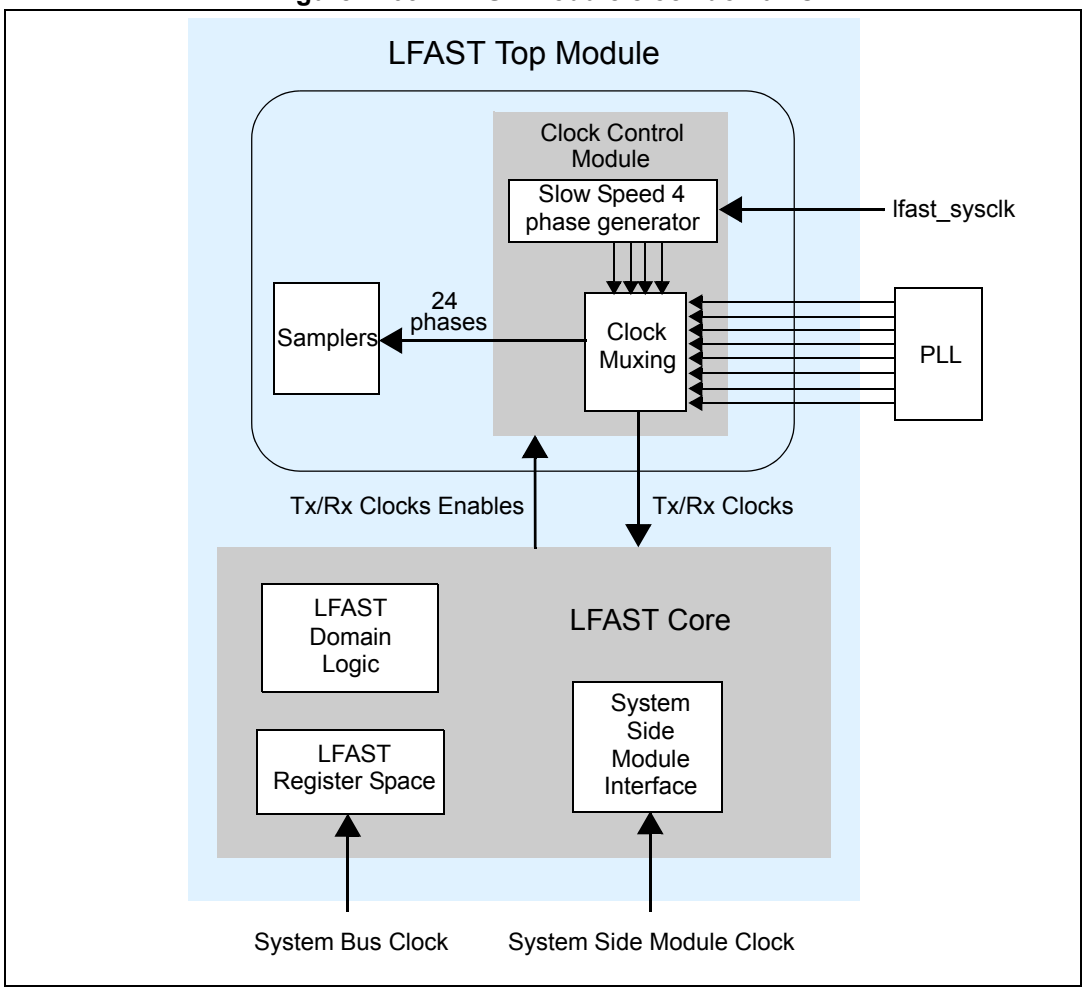
Table 2011. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space

Table 2011. Recommended receive exception handling mechanism

Reset	Blocks Reset
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

96.10 Clocks



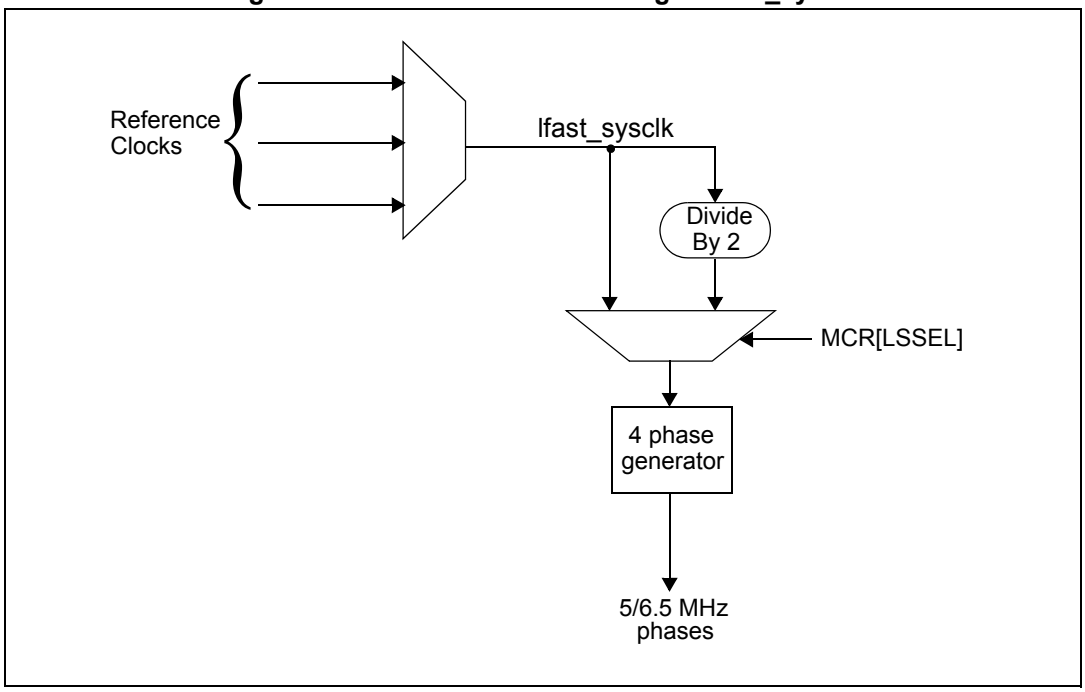
The LFAST mainly works on three clocks:

- System Bus Clock, used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

96.10.1 Clocking strategy

Figure 2103 shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 2103. LFAST module clock domains



96.10.2 Slow speed clock

96.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in *Figure 2104*, *Figure 2105* and *Figure 2106*.

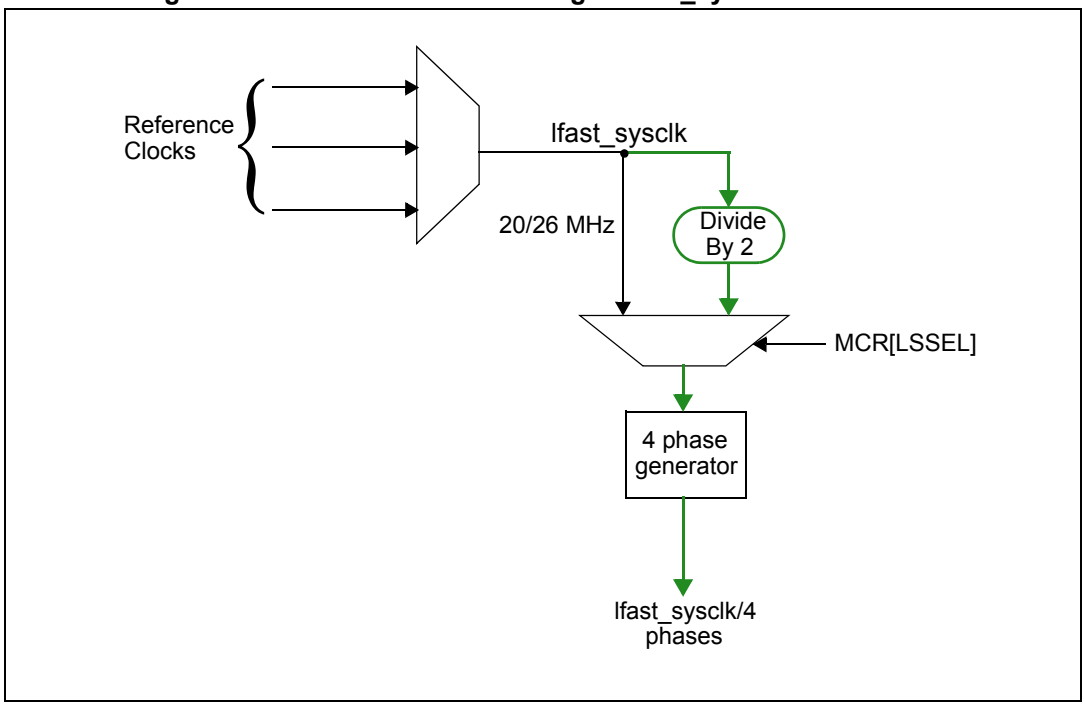


Figure 2104. External clock muxing of lfast_sysclk

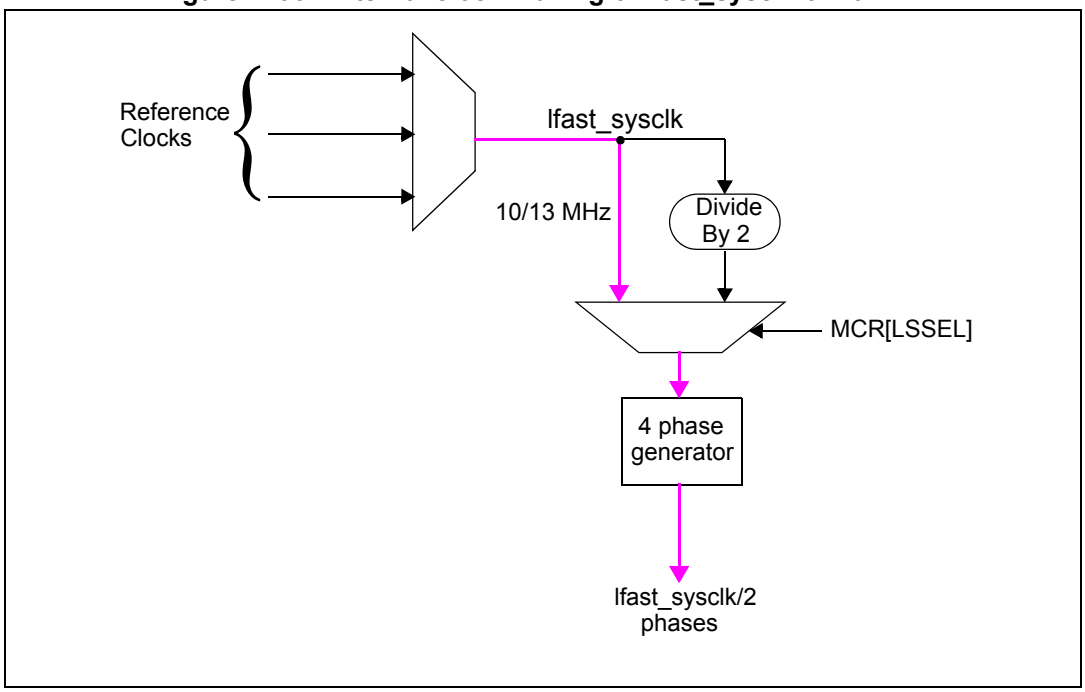
All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in *Figure 2104*.



The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2105* (selected clock path shown in green).

Figure 2105. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, lfast_sysclk is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/2 when MCR[LSSEL] = 0. If lfast_sysclk is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in *Figure 2106* (selected clock path selected shown in magenta).

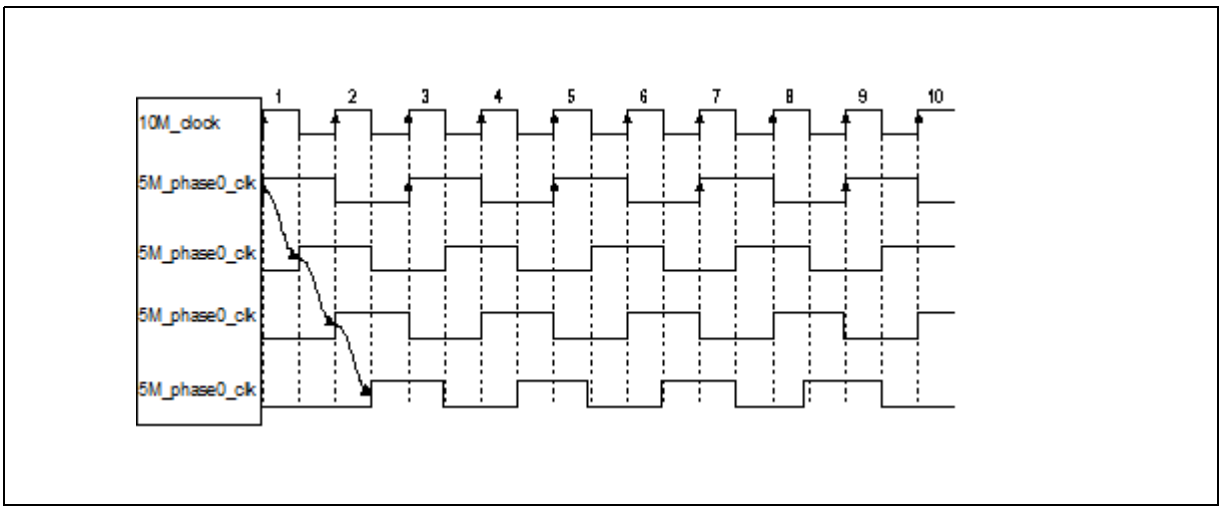


Figure 2106. External clock muxing of lfast_sysclk of 10 MHz

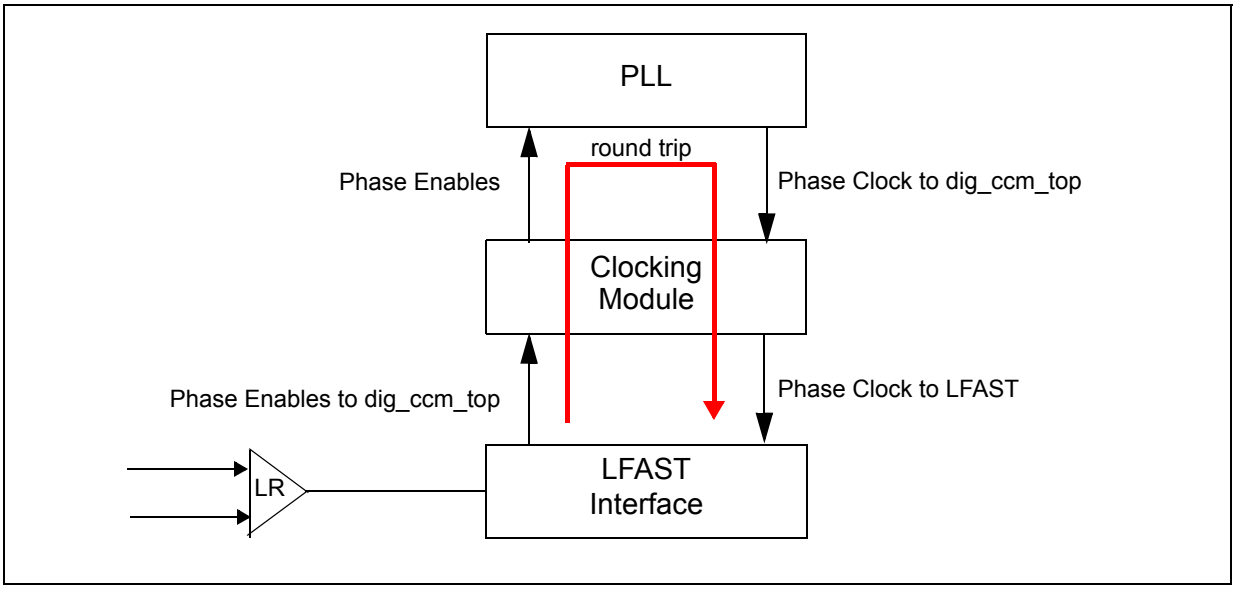
96.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated. *Figure 2107* Shows 4 phases getting generated using lfast_sysclk.

Figure 2107. Slow speed 4 phases generation



96.10.3 Rx controller clocks

96.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in *Figure 2108*.

Figure 2108. Clock Enables and Clock Paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to

the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

96.10.3.2 Clock module requirements for low speed phases

96.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

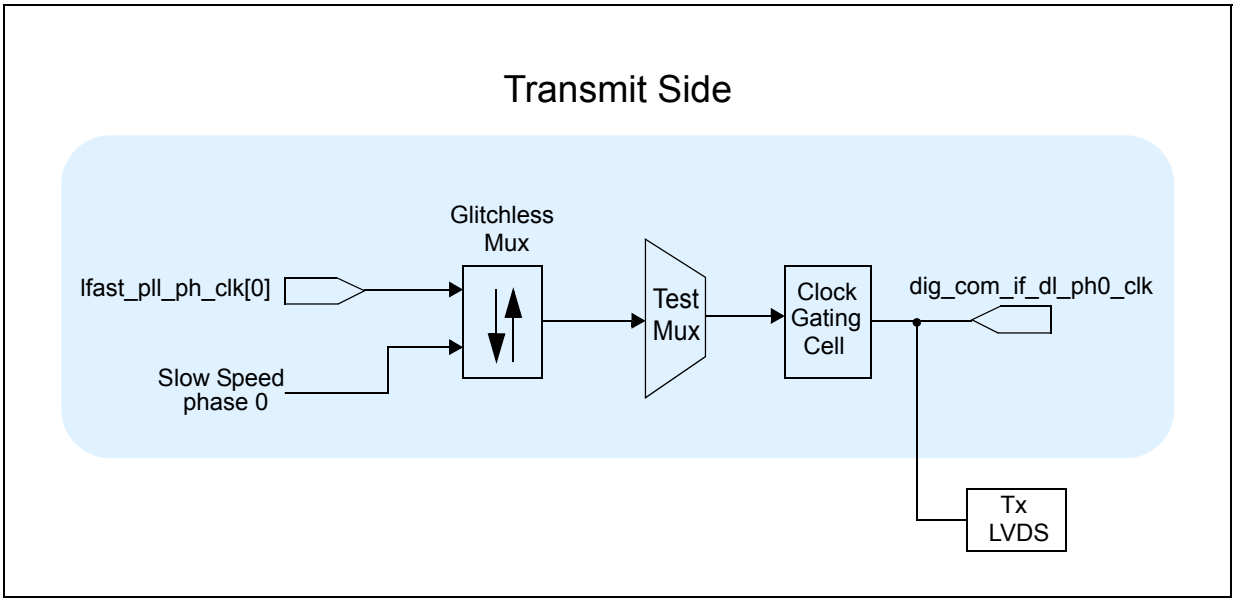
Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq × 8 MHz clock from the PLL is not needed.

Table 2012. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

96.10.4 Tx controller clocks

96.10.4.1 Clocking module requirements for speed phases



The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See *Table 2013*.

Table 2013. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

96.10.4.2 Transmit clock muxing

Figure 2109. Transmit Clocks Muxing

96.10.4.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

Appendix A Acronyms and abbreviations

Table 2014 lists acronyms and abbreviations used in this document.

Table 2014. Acronyms and abbreviations

Term	Meaning
ATX	Analog test module
APU	– Advanced protocol unit – Auxiliary processing unit
AUTOSAR	Automotive Open System Architecture
BAF	Boot assist flash
BIST	Built-in self test
CAN	Controller area network
CCCU	Clock calibration on CAN unit
CF	Critical fault
CGM	Clock generation module
CMU	Clock monitoring unit
CPU	Central processing unit
CQM	Clock quality monitor
CRC	Cyclic redundancy check
DMA	Direct memory access
DMAMUX	Direct memory access controller multiplexer
DSPI	Deserial serial peripheral interface
DTS	Development tool semaphore
ECC	Error correction code
EMI	Electromagnetic interference
EOUT	Error out
ESD	Electromagnetic static discharge
FCCU	Fault control and collection unit
FEC	Fast Ethernet controller
FLEXRAY	Automotive network communications protocol
FMPLL	Frequency-modulated phase-locked loop
FOSU	FCCU output supervision unit
FPEC	Flash program erase controller
FSM	Finite state machine
GPIO	General-purpose I/O
GTM	Generic timer module

Table 2014. Acronyms and abbreviations(Continued)

Term	Meaning
HW	Hardware
ID	LIN identifier field
IEEE	Institute of Electrical and Electronics Engineers
IIC	Inter-integrated circuit (I^2C)
IMA	Indirect memory access
INTC	Interrupt controller
INTF	Interface
IP	Intellectual propriety
IPS	– Internal peripheral system – IPI-SkyBlue slave bus
IRQ	Interrupt request
JDC	JTAG data communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
LBIST	Logic built-in self test
LFAST	LVDS Fast Asynchronous Serial Transmission
LIN	Local interconnect network
LINFlexD	Local interconnect network controller
LWB	Late-write buffer
MBIST	Memory built-in self test
MC	MC_CGM, MC_ME, MC_PCU, and MC_RGM modules
ME	Mode entry module (MC_ME)
MEMU	Memory error management unit
MFD	Multiplication factor divider
Mux	Multiplex
NCF	Non-critical fault
NMI	Non-maskable interrupts
NVM	Nonvolatile memory
OSC	Oscillator
OTP	One time programmable
PASS	Password and device security module
PCM	Platform configuration module
PCU	Power control unit
PFLASH	Flash controller
PIT	Periodic interrupt timer

Table 2014. Acronyms and abbreviations(Continued)

Term	Meaning
PLL	Phase-locked loop
PMC	Power management controller
PRAM	Platform RAM controller
PSI5	Peripheral sensor interface
PWD	Password
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
RCOSC	RC oscillator
RF	Recoverable fault
RFD	Reduced frequency divider
RGM	Reset generation module
RMW	Read-modify-write
RTL	Register transfer language
RWW	Read-while-write (operation)
Rx	Receive
SAG	Safety application guide
SAR ADC	Successive approximation register analog-to-digital converter
SD ADC	Sigma-delta analog-to-digital converter
SEMA4	Semaphore
SENT	Single edge nibble transmission
SIL	Safety integrity level
SIPI	System interprocessor interface
SIUL	System integration unit lite
SMPU	System memory protection unit
SoC	System-on-chip
SOR	Sphere of redundancy
SSCM	System status and configuration module
STCU	Self-test control unit
STM	System timer module
SW	Software
SWT	Software watchdog timer
TBD	To be defined
TCD	Transfer control descriptor
TSENS	Temperature sensor
TTCAN	Time triggered CAN

Table 2014. Acronyms and abbreviations(Continued)

Term	Meaning
Tx	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
UF	Unrecoverable fault
VCO	Voltage controlled oscillator
WDG	Watchdog timer
WKPU	Wakeup unit
WS	Wait state
XBAR	Crossbar

Revision history

Table 2015. Revision history

Date	Rev.	Changes
28-Oct-2011	1	Initial release
30-Aug-2012	2	Changes since Rev. 1 initial release: Editorial and formatting changes throughout reference manual Chapter 1, Preface Replaced “Acronyms and abbreviations” table with a reference to RM *Appendix A: Acronyms and abbreviations* Added Section 1.4, Register conventions Chapter 2, Introduction Replaced instances of “DigRF” with new module name “LFAST” Updated Section 2.1.1, Target applications Updated Section 2.1.2, Overall architecture Section 2.1.4, I/O processor: removed content linking instruction cache and data cache to IOP (I-Cache and D-Cache are not present on IOP) Updated Section 2.2, Features summary Updated Table 6 (MPC5744K/SPC574K72 device feature summary) and changed title (was “SPC57 device feature summary”) Updated Figure 2 (Block diagram) Updated Figure 3 (Periphery allocation) Chapter 3, Embedded memories Occurrences of “emulation device” changed to one of: “Emulation and Debug Device (ED)” or “emulation and debug device” or “ED” Section 3.1, Overview: removed AMU Section 3.2.2, Overlay SRAM: amended note Section 3.2.3, Processor core local SRAM: changed “supports zero single-cycle latency” to “supports zero wait-state, single-cycle latency” Section 3.3.2, Flash memory array: replaced “2 MB flash memory array” with “2.5 MB flash memory array” Section 3.3.2.1, Features: removed footnote Section 3.3.2.2, Flash organization: changed number of flash module partitions (was four; is three); removed footnote “Implementation is eight 16K blocks but for final silicon only four 16KB blocks are confirmed”. Figure 4 (K2 flash memory block diagram): replaced “2 MB Flash Memory Array” with “2.5 MB Flash Memory Array” Added Figure 5 (Flash memory segmentation and read-while-write partitioning) Table 4 (ECC comparison of data write-then-read sequence)—Row “Bus master initiates data write”, “End-to-End ECC (e2eECC)” column: added “for the computationnal shell or 32-bit data field for the peripheral shell” *Chapter 4: Signal description* *Chapter 5: Memory map* All references to “DigRF” changed to “LFAST” Updated *Table 13: Overview memory map* Updated *Table 14: Peripheral (PBRIDGE_A, PBRIDGE_B) memory map* Updated *Table 15: Flash memory and overlay RAM map* Updated *Table 18: UTEST flash memory map*

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 6, Functional Safety Extensive updates throughout chapter *Chapter 2: Device Configuration* Replaced instances of "DigRF" with new module name "LFAST" *Table 19: Reference links to related information*: replaced link to device configuration chapter section "Fast Ethernet Controller (FEC) configuration" with link to Chapter 48, Fast Ethernet Controller (FEC) Added new sections: Section 2.3.4.1.4, Master Access permissions for SMPU0 and Section 2.3.4.2.4, Master Access permissions for SMPU1 In *Table 31: Interrupt sources*: – for IRQs 226–231 and 239, changed PIT1 to PIT0 and PIT_1 to PIT_0 – for IRQs 240 and 241, changed PIT0 to PIT1 and PIT_0 to PIT_1 – for IRQ 677, changed the description to "TTCAN0 Line0 combined interrupt Rx FIFO 0 New Message" – for IRQ 678, changed the description to "TTCAN0 Line1 combined interrupt" – for IRQ 688, changed the description to "MCAN1 Line0 combined interrupt" – for IRQ 689, changed the description to "MCAN1 Line1 combined interrupt" – for IRQs 781–788, changed MCS1 to MCS0 – for IRQs 789–796, changed MCS2 to MCS1 – replaced the definitions for IRQs 797–828 – added entries for IRQs 946–961 *Table 44: Timers*: "GTM122 Integration Module Configuration" updated to read "GTM122 Generic Timer Module" *Table 51: PIT0 memory map*: Timer Channel [0:7] updated to Timer Channel [0:5] Updated Table 62 (CAN bus controllers) Added Section 7.9.3, Indirect Memory Access (IMA) *Table 88: FCCU output signals*: – updated "FI[0]" to "EOUT[0], FI[0], ERROR0" – updated "FI[1]" to "EOUT[1], FI[1], ERROR1" Section 2.9.10.1, PASS_LOCKn_PGn register bit mapping: removed reference (link) to "Chapter 37, Flash Memory Programming and Configuration" (chapter does not exist in this reference manual) Chapter 8, Reset and Boot Modified several sections regarding DCF records for better clarity Replaced all references to "emulation device" with "emulation and debug device" Section 8.1, Introduction: replaced "e200_z425" with "e200_z225" as referenced IOP core Section 8.2.3, Mode Entry module: reworded last sentence Added note to Section 8.3.5, PHASE2[DEST] Phase: flash initial configuration Added note to Section 8.3.7, IDLE[DEST] Phase: self test execution Table 118 (Module status during reset phases): updated DEVICE CONFIG module – phase P3 [[FUNC]] (was HOLD; is LOAD/HOLD); updated note under table Chapter 9, Device Configuration Format (DCF) Records Extensive updates throughout chapter Chapter 10, Power management Extensive updates throughout chapter

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 11, Security Replaced "K2 devices" with "All SPC57xx family devices" in first sentence of chapter Section 11.1, Basic security: added "Flash erase counter and tamper detector" to memory security features *Chapter 7: Calibration and Debug* Replaced instances of "DigRF" with new module name "LFAST" Updated Section 7.1, Core debug support Section 7.2.1, Debug and Calibration Interface (DCI): added NXMC to the list of modules which receive ipg_debug (following the sentence "The DCI sends the system debug signal, ipg_debug...") *Table 14: PD DCI signals*: updated the "SPU" value of the following signals: – EVTI[0]: value changed to "O" from "I/O" – EVTI[1]: value changed to "O" from "I/O" – EVTO[0]: value changed to "I" from "I/O" – EVTO[1]: value changed to "I" from "I/O" – row EVTI[1], column Cores: data changed from "I" to "—" Section 12.2.1.1, DCI EVTx pin multiplexing control register (DCI_PINCR): – changed bits 1 and 9 to reserved – added EVTO1D field to bit 15 – added EVTI1D field to bit 7 – updated field descriptions Updated Section 12.3, Calibration interface Updated Section 7.3.2, Debug LFAST Added Section 7.4, Debug over CAN Updated Section 7.5, Nexus Aurora interface *Chapter 8: Core Complex Overview* Replaced instances of "ICache" and "I CACHE" with "I-Cache" Replaced instances of "DCache" and "D CACHE" with "D-Cache" Replaced instance of "Instruction or Data MEM" with "Instruction or Data memories" Section 8.3, Features: • e200z225n3 core – updated DMEM size (was 32 KB; is 48 KB) • e200z420n3 core – updated I-Cache size (was 8 KB; is 4 KB) and D-Cache size (was 4 KB; is 2 KB) Added Section 8.4.4, EFPU2 Floating-Point Unit features Added Section 8.4.9, Performance Monitor Unit Features Chapter 15, Core e200z420n3 description Extensive updates throughout chapter Chapter 15, Core e200z225n3 description Table 160 (Exceptions and conditions): updated causing conditions content for interrupt types "EFPU Data Exception" and "EFPU Round Exception" Table 163 (Machine Check Syndrome Register (MCSR) field descriptions)—in footnote 4, changed "Zen Z420n3" to "e200z225n3"; in "Reserved" rows, added em dash (—) to empty cells in "Exception type" column

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Table 181 (MAS0—MPU Read/Write and Replacement Control): removed sentence "The guarded attribute is used as described in Section 13.6.6, Guarded Accesses" from description of bit 30 (referenced section does not exist) Figure 72 (e200z225n3 Supervisor Mode Programmer's Model SPRs): in footnote 1, replaced "These core-specific registers" with "These Zen-specific registers" Figure 73 (e200z225n3 Supervisor Mode Programmer's Model DCRs and PMRs): in footnote 1, replaced "These core-specific registers" with "These Zen-specific registers" Figure 93 (IMEM Control Register 0 (IMEMCTL0)): corrected name of bit 30 (was ICECE; is ICPECE) Section 15.3, Single-issue operation: changed title (was "Dual-issue operation") Section 15.7, Local memories: removed table "DMEMCTL0 field descriptions" *Chapter 2: System Integration Unit Lite2 (SIUL2)* Replaced instances of "Single Configuration Register" with "Signal Configuration Register" Updated *Table 39: SIUL2 memory map* Section 2.2.2.12.4, Module-port MSCR assignments and SSS values: removed table "Peripheral and input multiplexing assignments"; added reference to consult *Chapter 4: Signal description* Section 2.2.2.1, SIUL2 MCU ID Register #1 (SIUL2_MIDR1) – changed part number of field "PARTNUM" – changed description of field "ED" – changed description of field "PKG" *Table 40: SIUL2_MIDR1 field descriptions*: updated the default value of PARTNUM field (was 5744; is 5743) Section 2.2.2.2, SIUL2 MCU ID Register #2 (SIUL2_MIDR2): fixed conflicting footnote cross references Section 2.2.2.9, SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31): modified register address range (was 0x0040 - 0x00BC; is 0x0040 - 0x00BF) Added Section 16.2.2.11, User Defined Register (SIUL_UDR0 – SIUL_UDR63) Section 2.2.2.12.2, Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR_512–SIUL2_MSCR_1023): updated register address Figure 47 (External interrupt pad diagram): updated IRE[31:0] to read DIRER[31:0] Chapter 17, Crossbar Switch (XBAR) Table 244 (XBAR memory map): changed access to "R" of all *_PRS*n* registers Edited Section 17.1.2.1, XBAR Priority Registers Slave (XBAR_PRSn) to reflect that all *_PRS*n* regs are read-only Figure 151 (XBAR Control Register (XBAR_CRSn)): changed reset value of XBARx_CRSn[HPE7–HPE0] to xFF Chapter 18, Crossbar Integrity Checker (XBIC) Section 18.6, Functional description: – defined the cycle in which XBIC check is performed – elaborated about the persistent nature of the error injection function

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 19, Peripheral Bridge Section 19.1, Introduction: deleted instance of "supports up to 320 peripherals and" Section 19.1.1, Features: deleted bullets "Direct support for up to 64 on-platform peripherals and 256 off-platform peripherals" and "Support for 8-, 16-, and 32-bit width peripheral slots" Revised Section 19.1.2, General operation Table 254 (Peripheral bridge memory map): – corrected title (was "SCM memory map") – removed columns "Access" and "Reset Value" (this information is provided in the register bitmaps) Chapter 20, System Memory Protection Unit (SMPU) Removed all instances of HSM and associated content Reorganized hierarchy of sections preceding Section 20.4.2, Register descriptions Table 260 (SMPUx memory map): updated all EDR reset values to 0000_0080h Figure 173 (Region Descriptor n, Word 3 (SMPUx_RGDn_WORD3)): changed access for field FMT from read/write to read-only Table 268 (SMPUx_RGDn_WORD3 field descriptions): reworded note in RO field description Section 20.4.2.7, Region Descriptor n, Word 2 Format 0 (SMPUx_RGD_WORD2_FMT0): – changed "rights of the memory region" to "rights of the memory region on a per master basis" – changed "there are two flags" to "there are two flags per logical bus master" Figure 172 (Region Descriptor n, Word 2 Format 0 (SMPUx_RGDn_WORD2_FMT0)): deleted address "A3F1_0000h base + 408h offset + (16d × n), where n = 0d to 11d" Section 20.5, Functional description: removed "Power Management" subsection Chapter 21, Intelligent AHB Gasket (IAHBG) Removed section "Reset and timing mode changes" Added Section 21.2.4, 64->32 Interface and Section 21.2.5, 32->64 Interface Chapter 22, Semaphores2 (SEMA42) Section 22.2, Memory map/register definition: corrected the representation of RSTGT (is one register at offset 0x0040) Chapter 23, Interrupt Controller (INTC) Section 23.3, Features – replaced "Three INTC clock cycles" with "3 INTC clock cycles" – deleted phrase "so just say 3 INTC clock cycles from int request in to int request to CPU" Table 275 (INTC memory map): revised to represent the fact that each PSR is 16 bits wide, containing a PRC_SEL and PRI field Section 23.4.1, Software vector mode: deleted "Furthermore, the interrupt vector to the processor is driven as all zeroes. The interrupt acknowledge signal from the associated processor is ignored." Section 23.4.2, Hardware vector mode: deleted the paragraph beginning with "The processor negates the interrupt request..." Section 23.5.1, Memory map: deleted "IPS" from the note

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Section 23.5.2.6, INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–INTC_SSCIR31): removed figure "INTC Software Set/Clear Interrupt Register 28–31 (INTC_SSCIR28_31)" and adjusted explanatory text to refer to Figure 197 (INTC Software Set/Clear Interrupt Registers (INTC_SSCIRn)) Section 23.5.2.7, INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023): revised to represent the fact that each PSR is 16 bits wide, containing a PRC_SEL and PRI field; updated notes Section 23.6.1, Interrupt request sources: replaced instance of "PRI value in either the <<<?>>>INTC_CPRn" with "PRI value in the associated INTC_CPRn" Section 23.6.1.3, Unique vector for each interrupt request source: rewrote second sentence (was "...are assigned vectors..."; is "...are assigned vectors 0–...") Chapter 24, Enhanced Direct Memory Access (eDMA) Changed channel quantity to 32 (was 64) and modified all relevant tables accordingly Changed channel group quantity to 2 (was 4) Removed registers signaling the high portions of the control function (registers with "H" suffix) Section 24.3, Memory map/register definition: throughout register descriptions, for the NOP field, changed 6–0 to 1–7 in field description of bits to ignore Section 24.3.1, Control Register (DMA_CR): in note, reworded "For proper operation, writes to the CR register must only be performed" to read "Writes to the DMA_CR must be performed only" Section 24.3.15, Hardware Request Status Register Low (DMA_HRSL): changed "the presence of an error for each channel" to "the presence of a qualified hardware service request for each channel" Figure 211 (Channel n Priority Register (DMA_DCHPRIn)): changed reset values of fields ECP and DPA from 'x' to '0' In Section 24.4.1, eDMA microarchitecture (Data path subsection): changed "16" to "32" in the sentence "It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment." Section 24.5.7, Dynamic programming: – replaced subsection "Dynamic channel linking and dynamic scatter/gather" with new subsections Section 24.5.7.2, Dynamic channel linking and Section 24.5.7.3, Dynamic scatter/gather – deleted sentence "This section provides recommended methods to change the programming model during channel execution" Table 286 (DMA memory map): – inserted "Reserved" rows at FC0A_0008, FC0A_0010, FC0A_0020, FC0A_0028, and FC0A_0030 – updated end address of "Reserved" row at FC0A_0150 – updated end address of "Reserved" row at FC0A_1400 – removed DMA_ERQH, DMA_EEIH, DMA_INTH, DMA_ERRH, and DMA_HRSH – changed column "Offset from DMA_BASE" to "Absolute Address (hex)" – corrected link in location column for all instances of TCDn Signed Source Address Offset (DMA_TCDn_SOFF) register Section 24.5.7.1, Dynamic priority changing: changed instance of "change the channel priorities" to "then change the channel priorities"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Figure 231 (TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_CITER_ELINKYES)): added register address Figure 237 (TCD Control and Status (DMA_TCDn_CSR)): added register address Chapter 25, Direct Memory Access Multiplexer (DMAMUX) Replaced instances of "Block Guide" with "chapter" Deleted content referencing verification features DCM_FN_xxx and DCM_IP_xxx Section 25.1, Introduction (including all subsections): updated to show 57 peripheral slots/sources (was 21), 5 always-on slots (was 4), and 5 triggered peripheral slots (was 4) Section 25.4.1, DMA channels with periodic triggering capability: replaced "the first 4 channels of the DMA Mux" with "the first 5 channels of the DMA Mux" Figure 245 (DMAMUX triggered channels): updated to show 57 sources (was 21), 5 always-on slots (was 4), 5 triggered peripheral slots (was 4), and DMA channels 0–4 (was 0–4) Section 25.4.3, "Always Enabled" DMA Sources: replaced "there are 4 additional DMA sources" with "there are 5 additional DMA sources" Section 25.5.2, Enabling and configuring sources: replaced "the first 4 DMA channels" with "the first 5 DMA channels" Chapter 26, Clocking Changed "Emulation Device" to "Emulation and Debug Device" Replaced instances of "DigRF" with new module name "LFAST" Replaced instances of "Checker Core_0" with "Checker Core_0s" Updated hex number format from a '0x' prefix to an 'h' suffix Section 26.1, Introduction: – updated the number of CPUs in computational shell (was 3; is 2) – removed instance of Main Core_1 Update Section 26.2, Clock generation Updated Figure 248 (Clock generation) Section 26.2.1, MC_CGM registers: updated notes Updated Table 330 ([SCG18.301][Covers: Saf1425]MC_CGM relationship to clocks[end]) Table 331 (Maximum system level clock frequencies): removed "Main Core_1" Updated Figure 249 (K2 Dual PLL digital interface block diagram) Updated Figure 250 (Clock distribution) Section 26.6.3, Ethernet clocking: removed content describing MII Ethernet interface mode Updated Figure 252 (Device Ethernet clocking) Updated Section 26.6.4, FlexRay clocking Added Section 26.6.5, M_TTCAN/M_CAN clocking Added Section 26.6.6.1, System Clock/GTM output clock/Ethernet clock pin muxing Added Figure 255 (CMU0 block diagram) Added Figure 256 (CMU[1:10] block diagram) Updated Table 338 (Clock input sources) Figure 257 (Loss of clock logic): updated External Oscillator frequency (was 8 - 44 MHz; is 8 - 40 MHz) Correction to Figure 251 (Device LFAST clocking): TCK/DRCLK maps to PA[6] (was PA[5]) Table 339 (CMU register availability): removed CMU_ISR[FLCI]

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 27, Dual PLL Digital Interface (PLLDIG) Section 27.3, Block Diagram: removed "Dual PLL Digital Interface block diagram" (diagram is in the "Clocking" chapter) Section 27.3, Features: updated "Lock detect circuitry" bullet Section 27.4, Modes of operation: updated and amended bullet list of PLL operation modes; added note "Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<mode>_MC)." Section 27.5.1, Bypass mode with reference, both PLLs disabled: updated content and added note "The PLLs may be enabled (locked) or disabled in bypass mode." Section 27.6, Memory map and register definition: removed subsection "Register conventions" Section 27.5.2, Register descriptions: replaced the dimensioned registers PLLnCR, PLLnSR and PLLnDV with the non-dimensioned versions PLL0CR, PLL1CR, PLL0SR, PLL1SR, PLL0DV and PLL1DV Updated Section 27.6.3, Register classification for safety requirements Section 27.7.1, Input clock frequency: removed table "Input clock frequency at the pre-divider input" Updated Section 27.6.2, Clock configuration Renamed Section 27.6.3, Loss of lock (was "Loss of lock detection") Section 27.6.4, Frequency modulation: – promoted section heading to level 3 (was level 4) – added footnote describing PLL1 power down configuration "By writing MC_ME_<mode>_MC[PLL1ON] = 0b" – added footnote describing PLL1 power up configuration "By writing MC_ME_<mode>_MC[PLL1ON] = 1b" Section 27.7, Initialization information: appended both instances of "Provide a power down pulse..." with "(controlled by configuring the appropriate MC_ME_<mode>_MC register)" Chapter 28, Clock Monitor Unit (CMU) Section 28.1, Introduction: updated to discuss the CMU driving the FCCU error inputs instead of MC_RGM Updated Figure 267 (Clock Monitor Unit diagram) Table 343 (CMU_FDR field descriptions): updated CMU_FDR[FD] field description by changing CMU_MCR[MD] to CMU_MDR[MD] in the included formula Added note to end of Section 28.4.1.5, CMU Interrupt Status Register (CMU_ISR) Section 28.5.1, Frequency meter: removed the text "(for example, when the RTC module (Real Time Counter) is clocked by the metered clocks)" Table 351 (CMU memory map): removed table footnotes *Chapter 29: Clock Generation Module (MC_CGM)* Extensive updates throughout chapter Chapter 30, OSC Digital Interface (XOSC) Table 403 (XOSC configurations): removed UTEST references Section 30.3.1.1, XOSC control register (XOSC_CTL): – updated the reset value of M_OSC to '0' – added footnote "These bits can be written with any value, but writes are ignored. A read returns last written value" to bits 19:23."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 31, IRCOSC digital interface Updated instances of RCOSC to IRCOSC Updated the representation for hex numbers by removing the '0x' prefix and adding an 'h' suffix Table 417 (IRCOSC memory map): – removed "Register classification" column (This information is in the "Functional Safety" chapter.) – added "Access" and "Reset value" columns Section 31.3.1.1, IRCOSC Control register (IRCOSC_CTL): updated bits 19:24 to show that they can be written, but writes have no effect. Reads return previously written value. Figure 332 (Control register (CTL)): added footnote to bit 7 stating "These bits can be written with any value, but writes are ignored. A read returns last written value." Chapter 32, RAM controller (PRAM) Updated Section 32.1, Introduction Figure 346 (Simplified platform block diagram): – changed color of arrow between PRAM CTL and PFLASH CTL to red – added note indicating that connection PRAM CTL to Flash CTL is not supported on all devices Figure 347 (Platform RAM Configuration Register 1 (PRCR1)): register nmemonic changed (was PFCR1) Section 32.3, Functional description: removed subsection "Max address" Updated Section 32.3.1.1, Reads Removed section "Unaligned reads" Section 32.3.2, Writes: removed subsection "Late write hits" Updated Section 32.3.2.1, 64-bit writes Updated Section 32.3.2.2, Less than 64-bit writes Updated Section 32.3.2.3, Unaligned writes Section 32.4, Initialization/application information: removed VLE assembly instructions code example Figure 338 (RAM controller transaction monitor block diagram): removed "(PRAM_E2E_ECC_64)" from title Section 32.5.1, Hsiao ECC algorithm: "flash memory" changed to "system RAM" Section 32.5.1.1, E2EECC considerations on less-than-64-bit write transactions: changed "...such that faults in the RAM controller datapath and control logic are covered by e2eECC" to "...such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC" Updated Section 32.5.2, Transaction monitor Chapter 33, Flash memory controller (PFLASH Controller) Updated chapter title (was "Flash memory controller") Updated Section 33.1, Introduction Figure 350 (Platform-centric block diagram with flash memory controller): removed CoreB and associated connectivity; renamed CoreA as Core0

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Table 426 (Flash memory controller memory map): – corrected register name—was "Platform Flash Remap Configuration Register"; is "Platform Flash Calibration Remap Control Register" – corrected register name—was "Platform Flash Remap Descriptor Enable Register (PFCRDE)"; is "Platform Flash Calibration Remap Descriptor Enable Register (PFCRDE)" Table 427 (PFCR1 field descriptions): adjusted recommended RWSC values for frequency range Table 428 (PFCR2 field descriptions): added "Port1" to P1_BFEN description Table 429 (PFCR3 field descriptions): corrected description of PFCR3[BDRM] Section 33.4.1.5, PFlash Calibration Remap Control Register (PFCRCR): corrected title—was "PFlash Remap Control Register (PFCRCR)" Section 33.4.1.6, PFlash Calibration Remap Descriptor Enable Register (PFCRDE) corrected title—was "PFlash Remap Descriptor Enable Register (PFDCRDE)"; replaced instances of "PFDCRDE" with "PFCRDE" Section 33.4.1.7.1, PFlash Calibration Region Descriptor n, Word0 (PFCRDn.Word0): removed description of check performed by hardware Table 433 (PFlash Calibration Region Descriptor n, Word 0 description): adjusted bit field for LSTARTADDR—was bits 31–4; is bits 0–27 Section 33.4.1.7.2, PFlash Calibration Region Descriptor n, Word1 (PFCRDn.Word1): removed description of returning an error if PFCRDDn.Word1 is programmed with an illegal value Table 434 (PFlash Overlay Region Descriptor n, Word 1 description): adjusted bit field for PSTARTADDR—was bits 31–4; is bits 0–27 Section 33.4.1.7.3, PFlash Calibration Region Descriptor n, Word2 (PFCRDn.Word2): added MxEN fields Section 33.5.1, Basic interface protocol: removed untitled flash block organization diagram "Partition0" (correct diagram is Figure 19 (Device_Number flash mirrored space: Partition 0)) Section 33.5.7, Censorship: changed "flash space is defined by five major regions" to "flash space is defined by three major regions" Section 33.5.8, Line read buffers and prefetch operation: removed descriptions of buffer states Section 33.5.12, PFlash calibration remap support: – replaced three figure cross-references with two figure cross-references to describe portions of flash memory map available for calibration remapping – added guidelines to guarantee calibration remap access latency matches flash access latency Chapter 34, Embedded Flash Memory Removed "Chapter type/source information" table from first page Removed section "Electrical Characteristics" (electrical characteristics are available in the device datasheet) Changed Flash Macrocell size to 2720 KB and Bank0 of the Flash Macrocell size to 1280 KB Modified Figure 357 (Flash macrocell structure) Updated Section 34.1.1, Overview Updated Section 34.2.1, Flash matrix memory map Updated Table 426 (Flash Bank 0 Memory Map) Updated Table 427 (Flash Bank 1 Memory Map)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Merged table "Flash Bank 3 Memory Map" to Table 428 (Flash Bank 2 Memory Map) Table 429 (TestFlash block memory map): – added 32 byte "Customer Programmable Detection Area" – removed access type entries from "Reserved" rows Table 431 (Flash User Registers memory map): removed access type entries and reset values from "Reserved" rows Chapter 35, Decorated Storage Memory Controller (DSMC): no substantive changes *Chapter 1: Analog-to-digital converter (ADC) configuration* Extensive updates throughout chapter Chapter 38, Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface Updated Figure 422 (SDADC block diagram) Section 38.3, Features: added "Programmable wraparound mechanism" and "Programmable threshold range WDG support" features; amended "Interrupt/DMA request generation" feature Table 502 (SDADC Digital interface memory map): added SDADC_WTHHLR – WDG Threshold Register Section 38.6.2.1, Module Configuration Register (MCR): added fields 'WDGEN' and 'WRMODE' Section 38.6.2.2, Channel Selection Register (CSR): – added field 'ANCHSEL_WRAP' – added description of 'wraparound mode' in 'ANCHSEL' field Section 38.6.2.4, Status Flag Register (SFR): added fields 'ANCHSEL_CNT', 'WTHH' and 'WTHL' Section 38.6.2.5, Request Select and Enable Register (RSER): added fields 'WTHDIRS' and 'WTHDIRE' Added Section 38.6.2.10, WDG Threshold Register (WTHHLR) Section 38.7.8, Data conversion: added 'Wraparound Control Mechanism' description Section 38.7.9, Hardware triggering: added 'Wraparound Control Mechanism' description Section 38.7.10, Interrupt/DMA request support: added a desciption of 'WDG threshold crossover event' Section 38.7.12, Offset calibration support: Step 2 ("Configure the mux selection ANCHSEL field of CSR to '100' or '101' as required") expanded with two sub-steps Chapter 38, Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface Section 38.3.1, Main features: added "Normal conversion with dedicated trigger input" and "Trigger outputs on watchdog threshold crossover events" Figure 433 (SARADC block diagram): – added footnote "Test channels are mapped to internal analog channels via the SARADCB_TCCAPRx registers" – added pointers to functional equivalent of TCCAPR7 register fields ICSEL_TCH0, ICSEL_TCH1, ICSEL_TCH2, and ICSEL_TCH3

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Section 39.4.1, Normal channel conversion: added details about "enqueuing" feature Section 38.4.1.1, Start of normal conversion: added "normal trigger" as additional way to start normal conversions Section 39.4.5, Test channel connection with internal analog channel: updated third paragraph Updated Section 39.4.7, Programmable analog watchdog Section 39.5.1.1, Main Configuration Register (MCR): added new bit "WTRIGOUT" Section 39.5.1.2, Main Status Register (MSR): changed bit name "JABORT" to "JABORTCHAIN" Section 39.5.1.9, DMA Enable Register (DMAE): deleted note "In case dma_exist generic parameter is zero, this register are not implemented." Section 39.5.1.10, Internal Channel DMA Select Registers 0–2 (ICDSR0–2): deleted note "In case dma_exist generic parameter is zero, ... on this space generates transfer error." Section 39.5.1.23, Test Channel DMA Select Register (TCDSR): deleted note "In case either dma_exist generic parameter is zero or num_testch is zero, these registers are not implemented." Updated Section 39.5.1.29, Test Channel Connection with Analog Pin Registers 0–7 (TCCAPR0–7) Section 39.5.1.34, External Channel DMA Select Registers 0–3 (ECDSR0–3): deleted note "In case either dma_exist generic parameter is zero or num_extch is zero, these registers are not implemented." Figure 474 (External Channel Mapping to Internal Channel Registers 0–3 (ECMICR0–3)): corrected register name and offset address (was "TCCAPR0–7: 0x050–0x05CC"; is "ECMICR0–3: 0x5C0–0x05CC") Added Section 39.6, Start of conversion pulse delay Chapter 39, Temperature Sensor Revised Section 40.2.1, Temperature threshold detection (digital output generation) Chapter 40, Timers overview Reworded paragraph describing PIT instances; changed number of 32-bit timer channels for PIT_0 from "eight" to "six" Chapter 41, System Timer Module (STM): no substantive changes Chapter 43, Software Watchdog Timer (SWT) Section 42.1.2, Features: updated timer operation bullet Section 43.3.1.1, SWT Control Register (SWT_CR): changed field CSL (bit 28) to "Reserved" Chapter 44, Periodic Interrupt Timer (PIT): no substantive changes Chapter 44, CAN Subsystem Extensive updates throughout chapter

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 45, Serial Interprocessor Interface (SIPI) Replaced instances of "DigRF" with new module name "LFAST" Updated misaligned graphics Updated Figure 747 (SIPI header coding) showing bits 1..3 in the same group Added Section 45.5.2.9.1, CRC examples Section 49.8, Transfer API and flow charts: updated note "Read answer interrupt signals..." at end of section Figure 758 (SIPI single register write API): added note to define "TC" Added Section 45.13, SIPI control and status overview Revised Section 45.14, Memory map and register description Section 49.15.1.1, SIPI Channel Control Register (SIPI_CCRn): • moved note on 'back to back transactions' and 'priority scheduling' from end to beginning of section • added note "This register is only writable in Initialization mode (MCR[INIT] = 1)." Updated Section 49.15.1.8, SIPI Module Configuration Register (SIPI_MCR) Figure 702 (SIPI Status Register (SIPISR)): removed redundant note "Register bit can be read/cleared by software. Writing 1 clears contents." Figure 706 (SIPI Channel Error Register (SIPIERR)): removed redundant note "Register bit can be read/cleared by software. Writing 1 clears contents." Chapter 50, Deserial Serial Peripheral Interface (DSPI) Updated mention of system clock to protocol clock where appropriate Section 46.1.2, Features—updated two bullets: – was "Seperate Register and Protocol Clocking Scheme"; is "Asynchronous clocking scheme for Register and Protocol interfaces" – was "Transfers for current command frame complete (CMDTCF"; is "Transfers due from current command frame complete (CMDTCF)" Table 756 (DSPIx_MCR field descriptions): updated description of fields MDIS and XSPI Table 758 (DSPIx_CTARn field descriptions): updated description of field FMSZ Table 866 (DSPI_CTARn_SLAVE field descriptions): changed FMSZ[6] to FMSZ[5] Table 763 (DSPIx_SR field descriptions): updated description of fields TFFF and CMDTCF Updated Section 50.3.7, DSPI PUSH FIFO Register In Master Mode (DSPI_PUSHR) Table 765 (DSPIx_PUSHR field descriptions): updated description of fields PE_MASC and PP_MCSC Updated Section 50.3.8, DSPI PUSH FIFO Register In Slave Mode (DSPI_PUSHR_SLAVE) Updated Section 50.3.11, DSPI Receive FIFO Registers (DSPI_RXFRn) Table 770 (DSPIx_DSICR0 field descriptions): updated description of fields FMSZ[5] and TSBC Table 775 (DSPIx_DSICR1 field descriptions): updated description of fields TRGPRD and DPCSx Updated Section 46.4.3.3, DSI serialization Updated Section 50.5.3.5, DSI transfer initiation control Section 50.5.6, Transfer formats: updated Modified Transfer Format description Updated Section 50.5.10, Interleaved TSB (ITSB) Mode Table 899 (Differences between TSB and ITSB modes): added "Mode attribute" column

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Updated Section 46.4.13.1, Stop mode (External Stop Mode) Updated Section 46.4.13.2, Module disable mode Chapter 48, LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications Changed chapter title (was "DigRF – Interprocessor Communications") Replaced instances of "DigRF" with new module name "LFAST" Removed all instances of and references to "DIGRF3G" Figure 2 (LFAST frame structure): removed field value '110' for b7…b5 *Table 20: LCR field description*: updated description of fields LVRXOP[2] and LVLPEN Section 2.4, LFAST frame structure: changed the sentence "DigRF frames are transmitted and received across the interface using the DIGRF3G standard frame format." to "LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communition format." Section 2.6.2.16, Unsolicited Tx Control Register (UNSTCR): updated field name for UNSTCR[25:31] to UNSHDR Section 2.7.6.2.2, Unsolicited frame receive flow: - updated UNSRSR[USXDV] to UNSRSR[URXDV] - updated RISR[TXUNSF] to RISR[RXUNSF], step 3 Section 47.6.3, Register safety classification requirements: – removed "MEDC18" from title – added footnote referencing the "Functional Safety" chapter – updated "(Non-Safety critical Module)" to "(Non-Safety relevant Module)" Section 2.7.1.1, LFAST master interface startup procedure: replaced instance of "LVDS datasheet" with "LVDS parameters in the device datasheet" Section 2.7.1.2, LFAST slave interface startup procedure: replaced instance of "LVDS datasheet" with "LVDS parameters in the device datasheet" Updated Figure 1 (LFAST block diagram) Section 2.7.6.3, ICLC flow: removed "in the DIGRF3G standard" from the first sentence Chapter 48, Fast Ethernet Controller (FEC) Section 52.4, Memory map and register definition: added "Do not modify the content of reserved fields." Re-architected the register information to present the MIB block counter registers as "real" registers (each register is presented in the overall memory map and has a separate section with the typical register figure and field description). Chapter 53, FlexRay Communication Controller (FlexRay) Updated Section 49.4.2, PLL clocking Figure 1030 (Protocol Event Output Enable and StopWatch Control Register (FR_PEOER)): corrected title (was Protocol Interrupt Enable Register 1 (FR_PIER1)) Section 53.6.26, StopWatch function: added note "If cycle start and OS tick occurs... at the same cycle." Figure 1143 (StopWatch function timing diagram): replaced "ipg_clk" with "Sys_clock" (module clock)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Chapter 54, Inter-Integrated Circuit (I^2C) Section 54.2.4, Features: added following footnote to features list: "Compliant with I2C 2.0 standard with the exception that HS (high speed) mode is not supported" Figure 1156 (I^2C transaction protocol): changed "XX" to "Data" Table 1180 (Chip modes supported by the I^2C module): deleted the entry for DOZE mode (not supported on this chip) Table 1193 (I^2C high-level protocol steps): added "Acknowledment from slave" after step 2 Table 1194 (Slave address transmission process): in step 4, changed "The master must generate a STOP condition or a repeated START condition" to "The master must initiate a data transfer followed by either a STOP condition or a repeated START condition" Section 54.4.6, I^2C Bus Control Register (IBCR): deleted the IBDOZE field (that bit position is reserved) Section 54.6.5, DMA application information: changed "is configured in master mode" to "is configured in slave mode" Chapter 55, Peripheral Sensor Interface (PSI5) Extensive updates throughout chapter Added Chapter 52, Peripheral Sensor Interface-Support Module (PSI5-S) Chapter 56, SENT Receiver (SRX) Section 56.3.2.5, Slow Serial Message Ready Status Register (SRX_SMSG_RDY), first paragraph, third sentence: changed "register will get asserted on Fast Message reception" to "register will be asserted on Slow Message reception" Table 1220 (DMA_SMSG_BIT3 Field Descriptions): corrected bit numbers Table 1225 (CHn_CONFIG field descriptions): corrected bit numbers Section 56.4.8, Time stamp logic: replaced cross-reference to "Global Status Register (GBL_STATUS))" section with cross-reference to "Global Control Register (GBL_CTRL)" section Chapter 54, LINFlexD Extensive updates throughout chapter *Chapter 3: Reset Generation Module (MC_RGM)* Extensive updates throughout chapter Chapter 58, Boot Assist Flash (BAF) Extensive updates throughout chapter Chapter 60, System Status and Configuration Module (SSCM) Updated Section 57.1.1, Overview Deleted section "Conventions" Updated Section 57.1.3, Features Updated Section 60.3, Memory map and register definition Table 1368, SSCM memory map: added "Life Cycle Status Register (LCSTAT)" Updated Figure 1391 (System Status Register (STATUS)) Table 1301, STATUS field descriptions: updated description of field CER Table 1303, ERROR field descriptions: updated description of field PAE Figure 1394 (Processor Start Address Register (PSA)): updated reset values

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Added Section 60.3.1.5, Life Cycle Status Register (LCSTAT) Updated Section 57.4.1, DCF mechanism Added Section 57.4.2, ECC error monitoring Added Section 57.4.5, Life Cycle Added Section 57.6, Additional safety measures Chapter 1, Power Management Controller digital interface (PMC_dig) Extensive updates throughout chapter *Chapter 2: Power Control Unit (MC_PCU)* Extensive updates throughout chapter *Chapter 1: Mode Entry Module (MC_ME)* Extensive updates throughout chapter Chapter 13, e200z420n3 Core Debug Support Section 13.3.4, Debug Event Select register (DEVENT) register: deleted sentence "See the SoC User's Manual for more information on SoC use cases." Chapter 13, e200z225n3 Core Debug Support Section 13.3.4, Debug Event Select register (DEVENT) register: deleted sentence "See the SoC User's Manual for more information on SoC use cases." Chapter 66, Debug and Calibration Interface (DCI) Replaced instances of "DigRF" with new module name "LFAST" Updated signal names throughout Section 66.1, Introduction: replaced "5-pin DigRF (supports DigRF specification version 3.09.05) based debug tool" with "5-pin LFAST debug tool" Section 63.1.3.3, Software enabled debug and calibration mode: added a note to provide more details about simultaneous usage of SW debug and HW debug modes Updated Section 66.1.3.4, Nexus reset control Section 66.1.3.6, Break control: added bullet to debug request signals Table 1510 (DCI_CR field descriptions): added name "Enable Escape Mode" to EN_ESC_MODE description *Chapter 64: JTAG Controller (JTAGC)* Replaced all instances of "CENSOR_CTRL" with "JTAG_PASSWORD" throughout chapter Figure 1624 (JTAG (IEEE 1149.1) block diagram): removed arrow from TDI to TAP instruction decoder Chapter 65, IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) Section 68.3, Introduction: changed "Operation with both 4-pin and 2-pin star scan topologies and a 4-pin series scan topology" to "Operation with both 4-pin and 2-pin scan topologies" Section 68.3.3, 1149.7 TAP signals: deleted the references to nTRST_PD Renamed Section 68.4, CJTAG implementation summary (was "TAP.7 controller classes) and removed all content except that previously contained in "CJTAG implementation summary" Deleted the "Scan Selection Directive (SSD)" section

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Deleted content pertaining to the SSCAN function in Section 65.7.1, Overview, and Section 68.7.8, SP Format Chapter 69, JTAG Data Communication (JDC): no substantive changes Chapter 70, JTAG Master (JTAGM) Replaced instances of "DigRF" with new module name "LFAST" Added Figure 1598 (JTAGM to DCI serial interface diagram) Added Section 67.2.9, JTAGM data handling and CRC calculation in LFAST mode Figure 1526 (JTAGM_MCR register): changed the reset values of "evti0_assert" and evti1_assert" fields Table 1557 (JTAGM_MCR register field descriptions): removed DTM gating of EVTO interrupts in evto_IE field Figure 1527 (JTAGM_SR register in LFAST mode): changed the reset value of "idle" field Figure 1528 (JTAGM_SR register in SW mode): changed the reset value of "idle" field Table 1558 (JTAGM_SR register field descriptions): amended SPU_INT_CLR field description Chapter 68, Sequence Processing Unit (SPU): no substantive changes Chapter 69, LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug Changed chapter title (was "DigRF – High Speed Debug") Replaced instances of "DigRF" with new module name "LFAST" Removed all instances of and references to "DIGRF3G" Updated signal names Updated Figure 1655 (LFAST block diagram) Figure 1656 (LFAST frame structure): removed field value '110' for b7…b5 Table 1531 (LFAST memory map): updated addresses 30h to 38h from 'Reserved' to 'Reserved – Access will not generate errors' Table 1607 (LCR field description): updated description of fields LVRXOP[2] and LVLPEN Section 72.4, LFAST frame structure: changed the sentence "DigRF frames are transmitted and received across the interface using the DIGRF3G standard frame format." to "LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communition format." Figure 1652 (Unsolicited Tx Control Register (UNSTCR)): changed field name from "UHDMSG" to "UNSHDR" Section 72.6.2.17, PLL and LVDS Status Register (PLLLSR): changed fields PLLDIS and PLDCR (register bits 14:15) to reserved bits Section 69.6.3, Register safety classification requirements: – removed "MEDC18" from title – added footnote referencing the "Functional Safety" chapter – updated "(Non-Safety critical Module)" to "(Non-Safety relevant Module)" Section 69.7.1.1, LFAST slave interface startup procedure: replaced instance of "LVDS datasheet" with "LVDS parameters in the device datasheet" Section 72.7.6.2.2, Unsolicited frame receive flow: - changed instance of "UNSRSR[USXDV]" to "UNSRSR[URXDV]" - changed "RISR[TXUNSF]" to "RISR[RXUNSF]" in step 3

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Section 69.7.6.3.1, .ICLC data receive flow: removed subsections "Start PLL ICLC" and "Stop PLL ICLC" Updated Section 72.10, Clocks Updated Section 72.10.1, Clocking strategy Chapter 73, Development Trigger Semaphore (DTS) Changed chapter title (was "Development Tool Semaphore (DTS)") All references to JTAG removed or changed to Nexus Chapter 71, Nexus Aurora Router (NAR) Table 1642 (NAR_TBALO field descriptions): changed 512-byte block to 384-byte block in ADRLO[9] row Table 1637 (NAR_CR field descriptions): added "and must be written with 0s" to all reserved fields Figure 1712 (NAR status register (NAR_ST)): changed register reset value to 0x00000001 (QWA=1). Table 1647 (NAR_AHFPAR field description): added "and must be written with 0s" to all reserved fields Table 1650 (NAR message formats): updated footnotes Rearranged the following sections: – Section 71.5.10, Internal message generation – Section 71.5.10.1, Error conditions – Section 71.5.10.2, Watchpoint messages Chapter 14, e200z420n3 Nexus 3 Module Replaced references to 'NPC' (Nexus Port Controller) with references to 'NAR' (Nexus Aurora Router) Section 14.2, Enabling Nexus 3 Operation: added sentence about Nexus3 enabling with EVTI on TRST_B negation or during Test-Logic-Reset TAP state Section 14.3, TCODEs supported: changed standard to IEEE-ISTO 5001-2003 Added Chapter 14, e200z225n3 Nexus 3 Module Chapter 74, GTM Development Interface (GTMDI) Promoted several subsection headings from level 4 to level 3 Removed references to MDO and MSEO and associated content; changed text from MDO to Message Data bus Revised Figure 520 (GTMDI and GTM interface) and added note regarding GTM configuration shown in that figure, which is GTM 103 Added Table 633 (GTM Sub-module instances) Table 634 (GTMDI signal properties): removed Pull information Figure 552 (MCSA/B watchpoint address 1 register (GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1)): added a note to explain fields are relative to MCS address map, not CPU map Table 670 (GTMDI_MCSA_CE and GTMDI_MCSB_CE field descriptions): in CFTE description, replaced instance of "DTC bit" with "FTC bit" Figure 557 (Data trace address range 1 register (GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1)): added a note to explain fields are relative to MCS address map, not CPU map

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Table 636 (DID field descriptions): added value to PIN field description Figure 529 (ATOM watchpoint control 1 register (GTMDI_ATOM_WPC1)): changed access for fields SSEL1 and SSEL2 (was "read only"; is "read/write") Table 645 (GTMDI_SPEA_WPC1 field descriptions): changed definition for SSEL field value '001' (was "SPE1"; is "Reserved") Table 647 (GTMDI_SPEB_WPC1 field descriptions): changed definition for SSEL field value '0111' (was "SPE0"; is "Reserved") Figure 569 (TIM selection logic): added note regarding GTM configuration shown in that figure, which is GTM 103 Table 682 (GTMDI Nexus trace message formats): – changed SRC value to 0x7 – added a footnote to explain FSCNT field – modified footnote about Watchpoint Hit message Section 47.6.9, Fetch trace minor text changes Section 47.6.9.2, Fetch trace state machine: – added info about FSCNT – added a note about the MCS multi-thread behavior Chapter 75, Nexus Crossbar Multi-Master Client (NXMC) Removed references to internal signals MDO, MSEO and MCKO throughout chapter Table 1765 (JTAG pins for NXMC): changed 'pull-up' to 'pull-down' in "TRST" row Table 1767 (Supported public TCODEs): updated Watchpoint Message "WPHIT" row Chapter 76, Cyclic Redundancy Check (CRC) Unit Changed instances of "macrocell" to "module"; changed instances of "IPS" to "peripheral bus" Section 78.1, Introduction: changed "one of two" to "one of three" Section 78.2, Main features: • changed "1 to 16 contexts" to "1 context(s)" • removed "Support for expected and actual CRC comparison" Updated Table 1783 (CRC unit memory map) and table footnotes Section 78.5.1.1, CRC Configuration Register (CRC_CFG): added field "SWAP_BYTEWISE" (bit 26) and field "SWAP_BITWISE" (bit 27)) Figure 1863 (CRC Configuration Register (CRC_CFG)): changed INV field access from "read only" to "read/write"; updated field POLYG reset values Updated Section 78.6, Functional description Equation 3: corrected CRC-32 polynomial Section 78.7, Use cases: updated content and changed title (was "Use cases and limitations") Chapter 79, Memory Error Management Unit (MEMU) Updated Table 1788 (MEMU memory map): Section 79.1, Introduction: added "Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Section 79.4, Design overview: • updated "Synchronizer block" content • updated "Error Processing block" subbullet "Generate signals to assert the necessary flags" Updated Section 79.6.2.2, Error flag register (ERR_FLAG) Section 79.6.2.13, Peripheral RAM concurrent overflow registers (PERIPH_RAM_OFLWn): deleted introductory paragraph Section 79.6.2.18, Flash memory concurrent overflow registers (FLASH_OFLWn): deleted introductory paragraph In Figure 1877 (System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDRn)), added the missing offset (as present in Table 1788 (MEMU memory map)) Section 79.7.1, Initializing MEMU: updated last paragraph Section 79.7.3, Handling overflows (Multiple error reporting): amended description of "Error buffer overflow" Chapter 80, Indirect Memory Access (IMA) Replaced all content (chapter was previously under development) Chapter 81, Fault Collection and Control Unit (FCCU) Extensive updates throughout chapter Chapter 80, Self-Test Control Unit (STCU2) Removed section "Glossary, Acronyms & Abbreviations" Replaced several instances of STCU with STCU2 Updated Section 82.4.4.1, Hardware ABORT management Section 82.4.5, PLL interface: – modified STCU2_RUN to STCU_RUN – replaced "As soon as it happens, forces the switch with the PLL output clock" with "As soon as the lock happens, the STCU forces the clock to switch to the PLL output clock" Section 82.4.8.3, Write access time-out: replaced "that after AUTOLOCK_VALUE number of clock pulses lock" with "that, after 1024 STCU2 clock cycles, lock" Section 82.5.2, STCU2 Run Software Register (STCU_RUNSW): amended description of "On-line Self-Test phase is active" condition Table 1871 (STCU_RUNSW field descriptions): replaced instances of "pll_lock" with "PLL lock signal" Updated Section 82.5.5, STCU2 PLL Configuration Register (STCU_PLL_CFG) Updated Section 82.5.11, STCU2 Error FM Register (STCU_ERR_FM) Section 82.7.1, Off-line Self-Test sequence: deleted instance of "when pll_lock is high" Section 82.7.2, On-line Self-Test Sequence: – deleted instance of "also when pll_lock is high" – replaced instance of "pll_lock monitor" with "PLL lock signal monitor" Chapter 83, Register Protection (REG_PROT) Table 1916 (REG_PROT Memory Map): – renamed column heading — was "Section/Page"; is "Location" – reformatted cross references

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Added Chapter 83, Password and Device Security Module (PASS) Added Chapter 85, Tamper Detection Module (TDM) Chapter 86, Wakeup Unit (WKPU) Revised Figure 2034 (WKPU block diagram) Section 86.1.2, Features: replaced "safety core, main core, and IOP" with "safety core and IOP" Updated Section 86.2, External signal description Section 84.3.2, Register descriptions: removed figure "Key to Register Fields" Updated Table 1956 (NSR field descriptions) Updated Table 1957 (NCR field descriptions) Section 86.4.3, Reset management: – changed "external MC_RGM block" to "MC_RGM block" – added ESR1 clarification Section 86.4.4, System wakeup: changed "external MC_ME block" to "MC_ME block" Section 86.5.3, Reset request: replaced "interrupt" with "reset request" Chapter 48, GTM122 Integration (GTMINT) Module Updated Table 693 (High level memory map) Updated Table 694 (GTMINT module memory map) Table 697 (Correspondence between the INTCLR_PTR and the interrupts outputs): added signal ipi_int_gtm_err Section 48.3.3, Error Detection on GTM Memories Accesses: added information about individual ports for each RAM to beginning of section Chapter 86, Emulation and Debug Device Introduction Replaced instances of "DigRF" with new module name "LFAST" Changed instances of "emulation device" to "emulation and debug device" throughout Section 86.2, Feature summary: updated Aurora trace port configuration width; added DWPU Added DWPU to: – Figure 2045 (Emulation and debug device architecture) – Figure 2046 (BD clock structure) – Table 1966 (Reset sources and functional blocks) Table 1958 (BD memory map): added DWPU register at start address 0x0C80_C000 (was previously "Reserved") Chapter 88, Buddy Device—Crossbar and RAM (BD_XBS_RAM) Removed "Buddy device block diagram" *Chapter 65: Buddy Device—Debug and Calibration Interface (DCI)* Replaced instances of "DigRF" with new module name "LFAST" Changed instance of "emulation device" to "emulation and debug device" Updated signal names throughout Section 65.1, Introduction: replaced "5-pin DigRF (supports DigRF specification version 3.09.05) based debug tool" with "5-pin LFAST debug tool"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: Section 88.1.3.3, Software enabled debug and calibration mode: added a note to provide more details about simultaneous usage of SW debug and HW debug modes Updated Section 65.1.3.4, Nexus reset control Section 65.1.3.6, Break control: added bullet to debug request signals *Table 1513: DCI_CR field descriptions*: added name "Enable Escape Mode" to EN_ESC_MODE description *Chapter 64: Buddy Device—JTAG Controller (JTAGC)* Replaced all instances of "CENSOR_CTRL" with "JTAG_PASSWORD" throughout chapter Figure 1542 (JTAG (IEEE 1149.1) block diagram): removed arrow from TDI to TAP instruction decoder Updated Section 89.3.5, Boundary scan register Updated Section 64.4.5, Boundary scan Updated *Table 1626: JTAG_PASSWORD register field descriptions* Chapter 89, Buddy Device—System Integration Unit Lite (BD_SIUL2) Replaced instances of "DigRF" with new module name "LFAST" Change "emulation device" to "emulation and debug device" Section 90.3.1, Initialization status: removed paragraph about BD_INIT flag Section 89.3.2, PD reset status: updated last sentence *Chapter 59: Buddy Device—JTAG Master (JTAGM)* Replaced instances of "DigRF" with new module name "LFAST" Changed instances of "emulation device" to "emulation and debug device" or "ED" Added Figure 1324 (JTAGM to DCI serial interface diagram) Added Section 91.2.9, JTAGM data handling and CRC calculation in LFAST mode Figure 1327 (JTAGM_MCR register): changed reset values of "evti0_assert" and evti1_assert" fields *Table 1344: JTAGM_MCR register field descriptions*: removed DTM gating of EVTO interrupts in evto_IE field Figure 1328 (JTAGM_SR register in LFAST mode): changed reset value of "idle" field Figure 1329 (JTAGM_SR register in SW mode): changed reset value of "idle" field *Table 1345: JTAGM_SR register field descriptions*: amended SPU_INT_CLR field description Chapter 92, Buddy Device—Nexus Aurora Router (NAR) *Table 78: NAR_TBALO field descriptions*: changed 512-byte block to 384-byte block in ADRLO[9] row Section 6.4.5, Receive queue client disable register (NAR_CDR): corrected RDQ to RQD in note *Table 73: NAR_CR field descriptions*: added "and must be written with 0s" to all reserved fields Figure 41 (NAR status register (NAR_ST)): changed register reset value to 0x00000001 (QWA=1) *Table 84: NAR_AHFPAR field description*: added "and must be written with 0s" to all reserved fields

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Changes since Rev. 1 initial release: *Table 87: NAR message formats*: updated footnotes Rearranged the following sections: – Section 92.5.11, Internal message generation – Section 92.5.11.1, Error conditions – Section 92.5.11.2, Watchpoint messages Chapter 94, Buddy Device—Nexus Aurora Link (NAL) Added note regarding clock compensation to end of Section 94.1, Transmit operation Figure 2106 (NAL block diagram): removed UFC line Section 93.4.2, NAL General Control Register (NAL_GCR): removed ALCLBE and APELBE fields Section 93.4.3, NAL Training Control Register (NAL_TCR): changed STE value '0' to 'Reserved' Chapter 95, Buddy Device—Nexus Aurora PHY (NAP) Section 95.1, Introduction: deleted "and CRC checking" Section 94.1.2, Modes of operation: changed instance of "IO Port Control" to "NAR_NAPCR" Section 95.2, External signal description: updated to add differential signals (positive and negative) Added Chapter 96, Buddy Device—Data Write Processing Unit (DWPU) Chapter 97, Buddy Device—Nexus Read Write Access (RWA) Changed "emulation device" to "emulation and debug device" Chapter 97, Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug Changed chapter title (was "Buddy Device—DigRF – High Speed Debug)") Removed all instances of DIGRF3G throughout Replaced instances of "DigRF" with new module name "LFAST" Updated signal names Updated Figure 775 (LFAST block diagram) Section 50.4, LFAST frame structure: changed the sentence "DigRF frames are transmitted and received across the interface using the DIGRF3G standard frame format" to "LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communition format" Figure 776 (LFAST frame structure): removed field value '110' for b7…b5 Table 2051 (LFAST memory map): updated addresses 30h to 38h from 'Reserved' to 'Reserved – Access will not generate errors' *Table 939: LCR field description*: updated description of fields LVRXOP[2] and LVLPEN Section 97.6.3, Register safety classification requirements: – removed "MEDC18" from title – added footnote referencing the "Functional Safety" chapter – updated "(Non-Safety critical Module)" to "(Non-Safety relevant Module)" Figure 2198 (Unsolicited Tx Control Register (UNSTCR)): changed field name from "UHDMSG" to "UNSHDR"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
30-Aug-2012	2 (cont'd)	Section 97.7.1.1, LFAST slave interface startup procedure: replaced instance of "LVDS datasheet" with "LVDS parameters in the device datasheet"; added footnote to step 2 Section 50.7.6.2.2, Unsolicited frame receive flow: - changed instance of "UNSRSR[USXDV]" to "UNSRSR[URXDV]" - changed "RISR[TXUNSF]" to "RISR[RXUNSF]" in step 3 Added *Appendix A: Acronyms and abbreviations*
14 Feb 2014	3	Throughout document: • Editorial and formatting changes • Removed module "PSI5-S" and relative content • Replaced cores "e200z420n3", "e200z419", and "e200z225n3" with "e200z410Dn3", "e200z409D", and "e200z225Bn3" respectively • Changed "PBRIDGE0" and "AIPS Bridge 0" to PBRIDGE_A, and "PBRIDGE1" and "AIPS Bridge 1" to PBRIDGE_B • Renamed all instances of "DMACHMUX" and "PRAM" to "DMAMUX" and "PRAMC" respectively • Changed "MCAN" and "TT_CAN" to "M_CAN" and "M_TT_CAN" respectively Chapter 1, Preface: unchanged Chapter 2, Introduction Section 2.2, Features summary: changed "dual issue" to "single-issue" Table 6 (MPC5744K/SPC574K72 device feature summary): changed feature "SIPI / LFAST interprocessor bus" to "Zipwire (SIPI/LFAST) interprocessor bus"; removed footnote "Includes two-user programmable CPU cores..."; changed footnote "Optional" to "Optional: refer to your provider for more information.". Figure 2 (Block diagram): changed "AIPS Bridge" to "Peripheral Bridge" Figure 3 (Periphery allocation): renamed modules "PLLDIG" (was "PLL_DIG"), "XOSC" (was "OSC"), and "RCOSC" (was "IRCOSC") Chapter 3, Embedded memories Section 3.1, Overview: removed module "AMU" from list of peripherals with embedded memories Figure 4 (K2 flash memory block diagram): updated "Flash Memory Controller" block to show cache as 4-entry, 2-way Figure 5 (Flash memory segmentation and read-while-write partitioning): added key for "Read-While-Write partition boundaries" Section 3.3.1, Flash memory controller: corrected content to state the device has 4-entry, 2-way cache *Chapter 4: Signal description* Table "Power supply and reference pins" moved to "Supply Pins" tag of Microsoft Excel® workbook file attached to document; V_{SSOSC} changed to $V_{SS_HV_OSC}$ Section 4.4.5, Generic pins: updated Microsoft Excel® workbook file attached to document (file contains I/O Signal Description and Input Multiplexing tables) *Table 1: Pin startup and reset states*: • pin ESR1: changed all instances of "weak pulldown" to "weak pull-up" • pin TDI, Startup state: changed "High-impedance" to "weak pull-up" • pin TDO, State during reset: changed "weak pullup" to "High-impedance" • pin TMS, Startup state: changed "High-impedance" to "weak pull-up"; in other two states, changed instances of "weak pulldown" to "weak pull-up

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Chapter 5: Memory map* *Table 14: Peripheral (PBRIDGE_A, PBRIDGE_B) memory map*: • Changed all CMU instance descriptions • Set "Sigma Delta (SD) ADC 2 (SDADC_2)" area to "Reserved" (address range 0xFFF10000–0xFFF13FFF) • Moved "Tamper Detection Module (TDM)" area from address 0xFFF34000 to address 0xFC0E4000 • Set "Analog Test Annex (ATX)" area to "Reserved" (address range 0xFFF74000–0xFFF77FFF) • Changed MC_CGM start address to "0xFFFB0600" (was "0xFFFB0700") *Table 18: UTEST flash memory map*: • Removed "Temperature Sensor Calibration C (TSCC)" row • Added text "flash firmware ID and parameters" to Comment of "Unique Identifier (UID)" row Chapter 6, Functional Safety Table 16 (Module classification): changed module "Sigma-Delta ADC" to "SD ADC" for "PeMos" classification Figure 6 (General view of E2E ECC): changed "I/O Bridge 1" to "PBRIDGE 0" and "I/O Bridge 2" to "PBRIDGE 1" Updated Table 17 (LBIST partitions) Table 18 (Not in LBIST partitions): • Removed "IOMUX" instance from "System" functional group • Removed "XOSC" and "IRCOSC" instances from "Clocking" functional group • Removed "NEXUS" and "NAR" instances from "Debug" functional group • Added "Analog" and "Sefety" functional groups • Changed instance "DPS" to "DTS" in "Debug" functional group Section 6.4.1.6, Redundancy Control and Checker Units (RCCUs): added sentence "Signals are arranged in..." Table 19 (FCCU failure inputs1): • Added column "Recommended recovery: Destructive reset" • Updated column "Failure description" for FCCU channels 10, 11, 18, 21, 24, 27, 30, 35, 36, 38, 44, and 53 • Updated "Error reaction path check" column for FCCU channels 18, 19, 20, 21, 24, 26 44, and 45 • Updated "Default reaction configuration after POR or destructive reset" column for FCCU channel 6 • Updated "Reference Manual related information" column for FCCU channels 25 and 38 • Removed text "XTAL Pin Floating + EXTAL Pin Floating" from footnote "CMU_0 OLR event" Section 6.4.2, Dual-core lockstep: added sentence "Thus no user-initiated dynamic enabling of LSM is possible;" to paragraph "LSM can be disabled during boot by reprogramming..." Table 19 ([SCG18.303][Covers: Saf3257]ECC RAM implementations[end]): updated addresses in ECC to "Y" for "DMA","FEC/FIFO", and "FEC/MIB" memories Section 6.4.1.5.2, Online Logical BIST (LBIST): removed note "Testing LBIST functionality is ongoing as of this writing. This information is preliminary and will be updated as more data is received."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Chapter 2: Device Configuration* Table 38 (INTC implemented registers): • Changed "INTC Software Set/Clear Interrupt Register" abbreviations to "INTC_SSCIR0–INTC_SSCIR31" (were "INTC_SSCIR0_3–INTC_SSCIR28_31") to reflect the SSCIRs redefinition to be 8 bits (instead of 32 bits) in size • Changed "INTC Priority Select Register" abbreviations to "INTC_PSR0–INTC_PSR1023" (were "INTC_PSR0_1–INTC_PSR1022_1023") *Table 31: Interrupt sources*: major updates Section 2.3.8.3, DMA channel multiplexing block diagram: renamed (was "Block diagram") *Table 34: DMAMUX peripheral DMA request to input source mapping*: • DMAMUX_1 inputs to sources 1,2 and 50 changed to "Reserved" • DMAMUX_2 inputs to source 8 changed to "PSI5_0 CH0 RX SMC" (was "PSI5_0 CH0 RX SENT"), to sources 41, 49 and 50 changed to "Reserved" • DMAMUX_3 input to source 50 changed to "Reserved", to source 42 changed to "SIUL2_REQ3" Updated introduction of Section 2.3.8.5, DMAMUX memory map *Table 36: DMAMUX memory map*: changed abbreviations of Channel configuration registers to "CHCFGn" (was "CHCONFIGn") for all DMAMUX instances Added *Table 37: Reference links to related information* Section 2.5.3, SDADC configuration: changed number of SDADC instances to two (was three) Section 2.7, System Timer Module (STM) configuration: added text "clocked with the peripheral bridge frequency (PBRIDGEx_CLK)" to the paragraph stipulating the STM instances specific to this device Section 2.7.1, Software Watchdog Timer (SWT) configuration: removed "Programmable selection of system or internal..." item from SWT features list *Table 45: System Timer Module (STM) instances*: for each instance, removed references to clocking domains in the "Description" column Section 2.8.1, FEC interface: added paragraph "The MII Management Frame Register (MMFR) is not supported on SPC572Kx." Table 58 (CAN bus controllers): • "CAN FD Support" column divided into "M_CAN Rev 3.x" and "M_TTCAN Rev 2.x" columns • Added footnote "Debug on CAN support is available..." Section 2.8.3.2, Device specific features: updated "SIPI CHIP ID" to "0AF06041h" only *Table 61: FlexRay_0 pin names*: renamed (was "Flexray pin names"); updated pin names Section 2.8.5.2, FlexRay Stopwatch timer source muxing: replaced "PIT1_CH0" with "PIT0_CH0"; removed "STM1_CMP0" *Table 65: LINFlexD instance configurations*: changed "Number of filters implemented " and "Value of autosynchronization" to '0' for Linflex instances 1, 2, 14, and 15 Added Section 2.8.8.2, LINFlexD implemented registers Added Section 2.9.2, BAF configuration: subsections moved from Boot Assist Flash (BAF) chapter Added Section 2.10, Power Management modules *Table 77: Corresponding error sources for System RAM OFLW0 register*: changed error sources for rows 13–16 and 18

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Table 78: Corresponding error sources for System RAM OFLW1 register*: changed error sources for rows 13–16 *Table 79: Corresponding error sources for System RAM OFLW2 register*: changed error sources for rows 22–29 *Table 80: Corresponding error sources for Peripheral RAM OFLW register*: changed error sources for rows 19 and 20 *Table 85: SRAM with processor Core access*: in block "Safety Core": • Added "(Main core in lock-step with Checker core)" to Block name • Changed I-Cache SRAM Words to '128', D-Cache SRAM Words to 64, ITAG SRAM Bits to 67, and DTAG SRAM Bits to 73 • Removed block "Computational Core" *Table 86: SRAM arrays accessible via IMA*: for IMA ARRAY SELECT 9, changed column cells "Block" and "Function" from "TTCAN" to "CAN Subsystem" and "Shared RAM" respectively Updated *Table 90: Availability and reset values of selected FCCU registers* *Table 92: Protected SIUL2 registers*: major updates *Table 94: Protected PMC_DIG registers*: major updates *Table 95: Protected PLL_DIG registers*: changed "PLL1" and "PLL2" to "PLL0" and "PLL1" respectively *Table 99: Protected MC_CGM registers*: added rows "CGM_SC_DIV_RC", "CGM_SC_DIV_UPD_TYPE", and "CGM_SC_DIV_UPD_TRIG" *Table 100: Protected MC_RGM registers*: removed row "RGM_STDBY"; added row "RGM_PRST0–7" Section 2.9.10.1, PASS_LOCKn_PGn register bit mapping: removed text "The mapping of various LOCK register bits..." from note Figure 26 (PASS_LOCK1_PGn Register): removed "EEPROM Block4"–"EEPROM Block7" *Table 104: PASS DCF records*: removed row of DCF client "Life Cycle (LCSTAT)" Figure 35 (TDRx_LOCK0/OTPEN0 DCF client): updated flash block mapping Figure 31 (TDRx_LOCK1/OTPEN1 DCF client): updated flash block mapping Figure 32 (TDRx_LOCK2/OTPEN2 DCF client): updated flash block mapping *Table 106: Tamper Detection Module (TDM) DCF clients*: • DCF Client OTPEN0: changed No. of Valid Bits to "9" (was "15") • DCF Client OTPEN2: changed No. of Valid Bits to "9" (was "14") Figure 36 (Debug and calibration architecture for K2 ED): • Renamed "DigRF" modules to "LFAST" • Removed "HSM" module Chapter 8, Reset and Boot Throughout chapter: changed "Phasen" to "PHASEn" and "RGM" to "MC_RGM" Section 8.3.1, Power-on and the Reset Generation Module: added sentence "The STCU is reset..." Table 118 (Module status during reset phases): updated "STCU" row; added "MEMU" and "PASS" rows. Section 8.3.3, PHASE0 Phase: analog supply initial configuration: • Correction—flash memory is not initialized during PHASE0 • Changed sentence "Core low voltage detect..." to "Gating PHASE0 must be released..." • After sentence "This phase is typically completed..." added sentence " The device is guaranteed to remain in this phase for at least 0.5 µs." Section 8.3.5, PHASE2[DEST] Phase: flash initial configuration: changed sentence "To exit PHASE2[DEST] and..." to "All PHASE2[DEST] tasks..."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Section 8.3.6, PHASE3[DEST] Phase: device configuration: added paragraph "During this phase, the internal STCU watchdog..." Chapter 9, Device Configuration Format (DCF) Records Section 9.3.1, UTEST DCF records: removed references to "STCU", "LBIST", and "MBIST" Section 9.4, DCF client table: reformatted all subsections into bulleted lists Table 121 (DCF client list): in Miscellaneous section of table, • changed reset value of DCF client "UTEST Miscellaneous" to "0x00049141" (was "0x00048141") • added rows for DCF clients "IVPR0", "IVPR2" and "JTAG Pin Config" • changed reset value of DCF client "PMC_REE bits" to "0x00000000" (was "0x00000001") Table 122 (UTEST Miscellaneous DCF Client field descriptions): • Added note "To know the capacitance values relative to the 5-bit binary combinations..." to description of field "XOSC LOAD CAP SEL" • Updated description of field "XOSC LF_EN" *11: Power management* *Section 11.1.3, SPC574Kx power management controller overview*: • Removed POR "POR041_C" • Removed HV POR "POR240_C" and "POR240_B" • Removed high voltage detector "HVD390_C" • Removed low voltage detector "LVD085_C" • Added low voltage detector "LVD096_F", and "HVD145_F" • Changed HV Low voltage detector "LVD270_B" to "LVD270_O" • Fixed typo in HV Low voltage detector list to read "LVD270_IF, LVD295_A" (was "LVD270_I, FLVD295_A") • Changed HV Low voltage detector "LVD400_C" to "LVD400_IM" • Added HV Low voltage detector "LVD295_C" *Section 11.1.3.2, SPC574Kx power management controller integration*: replaced "VDD_HV_IO" with "VDD_HV_IO_MAIN *Table 124: POR and voltage monitors description*: updated and restructured content *Figure 54 (Device PMC block diagram (simplified))*: • Under "VDD_HV_PMC", removed blocks "POR240" and "HVD390" • Above "VDD_LV", removed block "POR041" *Figure 56 (Device low voltage power-ground network)*: added power bars; changed item label "VSS_LV_CORE" to "LV_CORE"; swapped blocks "PLL0" and "PLL1". *Section 11.2.1, Low power support and STOP mode implementation*: updated content describing how peripheral modules can be enabled/disabled in STOP mode *Table 125: Voltage monitors configurability*: updated and restructured content *Section 11.6.1.1, POWERUP state*: removed table "Functional terminal state during power-up and reset" Updated *Figure 59 (Example of VDD_LV power-up sequencing)* *Figure 60 (Threshold variation during power-up sequence)*: renamed (was "Threshold variation during power-up sequence: hot point LVD enabled") and updated Removed figure "Threshold variation during power-up sequence: hot point LVD disabled"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Figure 61 (VDD_HV monitored voltages during power-up)*Figure 59 (VDD_HV monitored voltages during power-up): updated voltage detectors for Flash, ADC and I/O Main Updated Figure 60 (Threshold variation during power-up sequence—2.7V–5.5hot point LVD disabled, 4.5V–5.5V range) Chapter 11, Security: unchanged *Chapter 7: Calibration and Debug*: no substantial changes *Chapter 8: Core Complex Overview* Renamed (was "e200z4d Core Complex Overview") Section 8.2, Overview of the e200z410Dn3, e200z409D, and e200z225Bn3 cores and Section 8.3, Features: changed "dual-issue" to "single-issue" Section 8.3, Features: added "Saturation Instructions Extension" bullet list item Added Section 8.4.5, Saturation Instructions Extension features Section 8.4.7, Cache features: changed cache sizes for e200z410Dn3 to 4 KB I-Cache and 2 KB D-Cache (was 8 KB and 2 KB) Replaced chapter "Core e200z420n3 description" with *Chapter 1: Core e200z410Dn3 description* Replaced chapter "Core e200z225n3 description" with *Chapter 1: Core e200z225Bn3 description* *Chapter 2: System Integration Unit Lite2 (SIUL2)* Throughout chapter: • Added "SIUL2 SoC Configuration Register 0 (SIUL2_SCR0)" • Renamed GPIO Pad Data Out Registers to "SIUL2_GPDO0–SIUL2_GPDO511" (were "SIUL2_GPDO0_3–SIUL2_GPDO508_511") • Renamed GPIO Pad Data In Registers to "SIUL2_GPDI0–SIUL2_GPDI511" (were "SIUL2_GPDI0_3–SIUL2_GPDI508_511") • Changed reset value of registers MIDR1 and MIDR2 to "0x5744_0000" and "0xB900_4B00" respectively (were "0x5743_0000" and "0x4000_4B00") • Removed registers "SIUL2_UDR0–SIUL2_UDR63" • Renamed Parallel GPIO Pad Data In Registers to "SIUL2_PGPDO0_1–SIUL2_PGPDO30_31" (were "SIUL2_PGPDI0–SIUL2_PGPDI31") • Renamed Parallel GPIO Pad Data In Registers to "SIUL2_PGPDI0_1–SIUL2_PGPDI30_31" (were "SIUL2_MPGPDO0–SIUL2_MPGPDO31") Section 2.1.1, Overview: rephrased for clarity Section 2.1.2, Features: • Updated number of GPIO ports (is 10; was 11) • Updated number of EIRQ pins (is 10; was 9) • Updated number of programmable digital glitch filters (is 10, was 9) • Changed Independent DMA channel for each EIRQ pin to 6 DMA channels [0, 1, 2, 4, 5, 8] Section 2.2.2.1, SIUL2 MCU ID Register #1 (SIUL2_MIDR1): added list of reset values relative to each package *Table 40: SIUL2_MIDR1 field descriptions*: changed MCU Part Number (field "PARTNUM") to '5744' (was '5743')

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Figure 35 (SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0)): updated address range; updated description of field "MAXCNTx" Updated Figure 38 (MSCR I/O pin and IP block port connectivity) Figure 39 (I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_0–SIUL2_MSCR_511)): • Renamed (was "I/O Pad MSCR Register Format") • Modified field "ODC" to encompass 3 bits from 5 to 7 (was 6:7) Split table "SIUL2_MSCR field description" into two tables: *Table 51: SIUL2_MSCR_0–SIUL2_MSCR_511 field description* and *Table 53: SIUL2_MSCR_512–SIUL2_MSCR_1023 field description* *Table 52: I/O MSCR reset state exceptions*: removed row for PA[4] port; added row for PC[2] port; updated "WPDE" and "WPUE" values of PA[7] port; updated "WPUE" value of PA[9]; updated PK[12:15] to PK[14] and PM[0:8] to PM[4:6]; removed "SMC" column; added columns "SSS", "OERC" and "ODC"; in "WPUE" column or row PA[9] added footnote "When JTAG is enabled..." From Figure 39 (I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR_0–SIUL2_MSCR_511)) to Figure 45 (SIUL2 Masked Parallel GPIO Pad Data Out Register (SIUL2_MPGPDO0)): updated address ranges Section 2.2.2.13, SIUL2 GPIO Pad Data Output Registers (SIUL2_GPDO0–SIUL2_GPDO511): reorganized bitmap (was 32-bit register with four PDO fields (0-3); is 8-bit register with single PDOx field) Section 2.2.2.14, SIUL2 GPIO Pad Data Input Registers (SIUL2_GPDI0–SIUL2_GPDI511): reorganized bitmap (was 32-bit register with four PDI fields (0-3); is 8-bit register with single PDIx field) *Table 59: Interrupt source mapping to SIUL2 interrupt request output*: added "EIRQ3" in interrupt request 0 Chapter 17, Crossbar Switch (XBAR): unchanged Chapter 18, Crossbar Integrity Checker (XBIC) Section 18.1, Overview: detail added regarding new functionality: • Forward signals (master to slave) crossbar transfer integrity is checked by verifying the attribute information using an 8-bit Error Detection Code (EDC). • Added paragraph "During the data phase of the system bus pipelined protocol... All three signals are compared clock... the whole data cycle" Section 18.2, Features: added items: • "Verification of feedback information for each data phase during..." • "Programmable integrity check enable on a per-master-port basis" Section 18.5.2.1, XBIC Module Control Register (XBIC_MCR): • Changed text in functional description to "to be enabled on a per-port basis" (was "to be enable on a per-slave-port basis.") • Changed "SEn" field description to "Slave Port Enable for EDC error detect" (was "Slave Port Enable") • Added fields "ME0–ME7" to bits 8–15 Section 18.5.2.3, XBIC Error Status Register (XBIC_ESR): • Changed register functional description • Added fields "DPSE0–DPSE7" to bits 1–8 • Added fields "DPME0–DPME7" to bits 9–16 Updated Section 18.6, Functional description Chapter 19, Peripheral Bridge: no substantial changes Chapter 20, System Memory Protection Unit (SMPU): unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Chapter 21, Intelligent AHB Gasket (IAHBG): no substantial changes Chapter 22, Semaphores2 (SEMA42): unchanged Chapter 23, Interrupt Controller (INTC) Throughout chapter: added register "INTC_MPROT" Section 23.4.2, Hardware vector mode: changed "the INTVEC_PRCn field" to "the INTVEC field" Section 23.5.2, Register descriptions: changed INTC_PSRn width to 16 bits (was 8 bits) Revised Section 23.5.2.3, INTC Current Priority Register for Processor n (INTC_CPRn) to show that the PRI fields are 4 bits wide Section 23.5.2.6, INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–INTC_SSCIR31): • Reorganized bitmap (was 32-bit register with four SET and CLR fields ; is 8-bit register with single SET and CLR fields) • Changed access type of CLR field to "w1c" (was read/write) • Revised the register definition to use the field names SET (instead of SET*n*), and CLR (instead of CLR*n*). Section 23.5.2.7, INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023): revised the description of software-settable interrupts; revised section to show that the PRI fields are 4 bits wide. Revised Section 23.6.2.2, Stack (LIFO) to show the correct number of priorities on this chip Changed "SET*n*" to "SET" and "CLR*n*" to "CLR" in the following sections: • Section 23.6.1.2, Software-settable interrupt requests • Section 23.7.7.1, Scheduling a lower priority portion of an ISR • Section 23.7.7.2, Scheduling an ISR on another processor Section 23.7.10, Examining LIFO contents: added note "Reading the INTC_IACKRn acknowledges the interrupt request to the processor..." Chapter 24, Enhanced Direct Memory Access (eDMA) Table 286 (DMA memory map): added "Reserved" row for address range "FC0A_0038–FC0A_00FF" Figure 204 (Error Status Register (DMA_ES)): added field "GPE" to bit 16 Figure 218 (Interrupt Request Register Low (DMA_INTL)): changed access type of fields relative to bits 0–15 to 'w1c' Table 293 (DMA_TCDn_ATTR field descriptions): revised "SSIZE" field description Chapter 25, Direct Memory Access Multiplexer (DMAMUX): unchanged Throughout chapter: changed Channel Configuration registers to "CHCFG0–CHCFG15" (were "CHCONFIG0–CHCONFIG15") Updated Section 25.1.3, Modes of operation Removed section "Overview" Table 328 (DMAMUX memory map): updated entirely Removed table "Channel and trigger enabling" Updated Section 25.5.2, Enabling and configuring sources Chapter 26, Clocking Removed all references to CGL (Clock Gating Logic) throughout document Section 26.1, Introduction: added item "Progressive Clock Switching (PCS)" to list of clock information Updated Figure 248 (Clock generation)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Removed figure "Fractional Clock Divider (FCD) details" Table 330 ([SCG18.301][Covers: Saf1425]MC_CGM relationship to clocks[end]): moved output clock "Peripheral Core_2 (IOP_CLK)" from register "CGM_SC_DC0" row to register "CGM_SC_DC1" row Table 331 (Maximum system level clock frequencies): added "ratio" and "max ratio" columns; moved "Peripheral Core_2" to row "Peripheral Shell XBAR" Added Section 26.5.1.7, PLLDIG initialization information Updated Figure 250 (Clock distribution) Table 338 (Clock input sources): moved monitored clock "Peripheral Core_2" from "CMU1" row to "CMU2" row Table 339 (CMU register availability): changed "CMU_MDR[OLRI]" to "CMU_ISR[OLRI]" in column "Note" for register "CMU_ISR" Figure 257 (Loss of clock logic): removed interrupt connection from "CMU_0" to "INTC" Added Section 26.9, Progressive clock switching Updated Section 26.6.4, FlexRay clocking Chapter 27, Dual PLL Digital Interface (PLLDIG) Section 27.1, Introduction: removed text "PHI frequency modulated output" from the end of the second paragraph Figure 255 (PLL0 Control Register (PLL0CR)) and Figure 258 (PLL1 Control Register (PLL1CR)): added footnote "This field can be written at any time..." to reserved fields relative to bits 25–27 and 30–31 Figure 256 (PLL0 Status Register (PLL0SR)): changed reset values of bits 25 and 27 to undefined ("—") Table 337 (PLL1FD field descriptions): updated field descriptions "FRCDIV" and "DTHDIS" Section 27.6.2, Clock configuration: • Updated equations of frequencies "f_{pll1_phi}", "f_{pll0_VCO}", and "f_{pll1_VCO}" • Added sentences "However, changing the PLLnDV fields without..." and "If the updated values are able to maintain the PLL frequency..." Section 27.6.4, Frequency modulation: • Updated numbered list to reprogram the FM • Removed the Frequency Modulation configuration example Section 27.7, Initialization information: rephrased; moved PLLDIG initialization procedure to Chapter 26, Clocking Chapter 28, Clock Monitor Unit (CMU) Section 28.4.1.3, CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR): added sentence "The HFREFR is configured for the high frequency reference..." to register description Section 28.4.1.4, CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR): added sentence "The LFREFR is configured for the low frequency reference..." to register description Section 28.4.1.5, CMU Interrupt Status Register (CMU_ISR): added note "Before entering low-power stop modes, all clock frequency..." Figure 268 (CMU Control Status Register (CMU_CSR)): added footnote "Not all CMU blocks utilize this..." to fields "CKSEL1" and "SFM" Section 28.5.3, CLKMN1 supervisor: added notes for "LFREF" and "HFREF" programming considerations

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Chapter 29: Clock Generation Module (MC_CGM)* Throughout chapter: changed instances of module name prefix "CGM" to "MC_CGM" in register names; changed offset addresses of all registers *Table 385: MC_CGM memory map*: major updates *Table 401: MC_CGM_SC_DC0 field descriptions*, *Table 402: MC_CGM_SC_DC1 field descriptions*, and *Table 403: MC_CGM_SC_DC2 field descriptions*: in "DIV" field description, removed line "If DE is set to '0' (divider 1 is disabled), any write access..." Removed section "Auxiliary Clock 10 Select Control Register (CGM_AC10_SC)" and section "Auxiliary Clock 10 Select Status Register (CGM_AC10_SS) found to be duplicates. Added Section 29.3.1.11, System Clock Divider Ratio Change Register (MC_CGM_SC_DIV_RC) Added Section 29.3.1.12, Divider Update Type Register (MC_CGM_DIV_UPD_TYPE) Added Section 29.3.1.13, Divider Update Trigger Register (MC_CGM_DIV_UPD_TRIG) Added Section 29.3.1.14, Divider Update Status Register (MC_CGM_DIV_UPD_STAT) Chapter 30, OSC Digital Interface (XOSC) Updated Table 414 (XOSC configurations) Section 30.2.4, Oscillator bypass mode: • Added note "The external oscillator must be running before the XOSC..." • Added Section 30.2.4.1, Full Swing Pierce mode Figure 339 (XOSC_CTL register): removed footnotes "Software can read as well as set the OSCBYP bit." and "Software can read as well as clear the I_OSC bit." Updated Section 30.2.2, Oscillator startup delay Chapter 31, IRCOSC digital interface Updated Section 31.2, Functional description Section 31.3.1.1, IRCOSC Control register (IRCOSC_CTL): changed access type of bit field 7 to "RW" (was "RO") Section 31.3.1.2, IRCOSC Native Trimming register (IRCOSC_NT): • Added field "FT_CODE" to bits 2–7 (were "Reserved") • Added field "TX_CODE" to bits 10–15 (were "Reserved") Chapter 32, RAM controller (PRAMC): no substantial changes Chapter 33, Flash memory controller (PFLASH Controller) Section 33.4, Memory map and register definitions: renamed (was "Flash memory controller memory map"); changed access type of register "TMD" to "R/W" (was "W") Table 427 (PFCR1 field descriptions): updated field description "P0_BFEN" Table 428 (PFCR2 field descriptions): updated field description "P1_BFEN" Section 33.4.1.7.3, PFlash Calibration Region Descriptor n, Word2 (PFCRDn.Word2): set bits 0–15 to "Reserved" (were fields "M0EN–M15EN")

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Chapter 34, Embedded Flash Memory Throughout document: • For "UT0" register: register renamed to "User Test 0 Register" (was "User Test Register 0") • For UM0–UM9 registers: registers renamed to "User Multiple Input Signature x Register" (was "User Multiple Input Signature Register x") • Abbreviated Test Mode Disable Password Check Register as "TMD" register (was "TDMPC") Section 1.3.2, User register descriptions • For "LOCK0", "LOCK1", and "LOCK2" registers: "LOWLOCK", "MIDLOCK", "HIGHLOCK", and "A256KLOCK" fields now encompass all individual bits in the same regions • For "SEL0", "SEL1", and "SEL2" registers: "LOWSEL", "MIDSEL", "HIGHSEL", and "A256KSEL" fields now encompass all individual bits in the same regions • For User Multiple Input Signature registers: register names changed to "UM0–UM9", (was "UMISR0–UMISR9"); "MISR" field now encompass all individual bits in the same regions • For "OPP0", "OPP1", and "OPP2" registers: "LOWOPP", "MIDOPP", "HIGHOPP", and "A256KOPP" fields now encompass all individual bits in the same regions Figure 2 (Module Configuration Register (MCR)): changed access type of fields relative to bits 1–3 and 16–18 to "w1c" Figure 11 (User Test 0 register (UT0)): changed bit 24 to "read-only, Reserved" (was "read/write") Updated *Table 33: OPP0 field descriptions*, *Table 34: OPP1 field descriptions*, and *Table 35: OPP2 field descriptions* Section 1.3.2.13, Test Mode Disable Password Check register (TMD): reorganized bitmap (were thirty-two fields "TDMPC0–TDMPC31"; is single 32-bit field "PWD") Section 1.4.5.5.2, Factory Erase: replaced "location 0×800020" with "location UTEST at offset +0x0020" *Table 1: Flash memory partition 0 memory map*: • Changed "LLKx" to LOWLOCK[x] (where x=0–8) and "256KLKx" to "A256KLOCK[x]" (where x=0–3) in LOCK column • Changed "LSLx" to "LOWSEL[x]" (where x=1–8) and "256KSLx" to "A256KSEL[x]" (where x=0–3) in SEL column *Table 2: Flash Memory Partition 1 memory map*: changed "256KLKx" to "A256KLOCK[x]" in LOCK column and "256KSLx" to "A256KSEL[x]" in SEL column (where x=4–8) *Table 3: Flash Memory Partition 2 memory map*: changed "HLKx" to "HIGHLOCK[x]" in LOCK column and "HSLx" to "HIGHSEL[x]" in SEL column (where x=0–3) Section 1.2, Flash memory map and description: changed maximum number of 256 KB blocks from 31 to 30 Chapter 35, Decorated Storage Memory Controller (DSMC): no substantial changes Added Chapter 36, Flash Memory Programming and Configuration

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Chapter 1: Analog-to-digital converter (ADC) configuration*: unchanged Added *Table 3: SDADC_MCR[TRIGSEL] trigger channel assignments* *Table 11: SARADC_B analog test channel assignment*: added channel 35 (VDDA22A), channel 37 (BG1P20_REF), channel 59 (VDDA22A_BIS), and channel 61 (BG1P20_REF_BIS); changed channel 110 to "Reserved". Removed section "SARADC_B interface to PMC" Section 1.2.2.10, SAR ADC register definitions: added field "WTRIGOUT" to bit 16 of register "MCR" in "SARADC_B", "SARADC_0", "SARADC_2", "SARADC_4", and "SARADC_6" register definitions tables Chapter 38, Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface Section 38.3, Features: removed two items "Left/right data alignment" and "Signed/unsigned format of converted data output" Table 488 (MCR field descriptions): updated description of field "GECEN" Table 507 (SFR field descriptions): updated description of fields "WTHL", "WTHH", and "DFFF"; renamed field "CVDF" to "CDVF" Table 508 (RSER field descriptions): updated descriptions of fields "CDVEE" and "DFFDIRE" Table 510 (FCR field descriptions): updated description of field "FTHLD"; added reset value information to "FSIZE" field description Section 38.6.2.7, FIFO Control Register (FCR): added fields "FRST" to bit 15 and "FOWEN" to bit 28 Section 38.7.8, Data conversion: added description of "FIFO Flush Option" Updated Section 38.7.11, Gain calibration support Section 38.7.12, Offset calibration support: updated step 2 Added Section 38.8.1, Data conversion step Chapter 39, Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface Corrected description of field "CDATA" in Table 521 (ICDR0–95 field descriptions), Table 547 (TCDR96–127 field descriptions), and Table 567 (ECDR128–255 field descriptions) Figure 433 (SARADC block diagram): changed "Vddm" to "VDD_HV_ADV", "Vssm" to "VSS_HV_ADV", "VAREF1" to "VDD_HV_ADR", and "VAGND1" to" VSS_HV_ADR" Section 39.4.2, Injected channel conversion: added text "but the conversion is enqueued after completion..." to bulleted list item "The normal conversion chain starts when the MCR[NSTART] bit is set..." Updated Section 39.4.3, Abort conversion Updated Section 39.4.4.1, Conversion timings Section 39.4.5, Test channel connection with internal analog channel: added paragraph "After the conversion is performed on a test channel the converted data is stored at two CDR locations at the end of..." Section 39.4.6, External channel mapping to internal analog channel: added paragraph "After the conversion is performed on a external channel, the converted data is stored at two CDR locations..." Added Section 39.4.12, Stop Mode Section 39.5.1.1, Main Configuration Register (MCR): set bit 30 to "Reserved" (was field "EDCSELF")

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Figure 438 (Main Configuration Register (MCR)): • Removed footnotes "Only available with external start feature.", "Only available with normal trigger feature.", "Only available with injection trigger feature.", and "Only available with cross-triggering unit (CTU) feature." • Added two footnotes "This bit is not available on this device and is thus reserved." Section 39.5.1.3, Interrupt Status Register (ISR): added field "CTUTRGERR" to bit 26 Added Section 39.7, Initialization Information Chapter 40, Temperature Sensor Section 40.2.1, Temperature threshold detection (digital output generation): changed time to update digital outputs from 1 µs to 1 ms Updated Figure 480 (Temperature formula) Chapter 41, Timers overview: unchanged Chapter 42, System Timer Module (STM): unchanged Chapter 43, Software Watchdog Timer (SWT): unchanged Chapter 44, Periodic Interrupt Timer (PIT) Section Table 600., PITx_MCR field descriptions: renamed field relative to bit 29 to "MDIS_RTI" (was "MDIS") Chapter 45, CAN Subsystem Throughout chapter: • Removed "transmit message buffer locking mechanism" feature • Updated M_CAN registers "FBTP", "TDCV", "CCCR", "TOCV", "PSR", "IR", "IE", "ILS", "RXF0C", "RXF0S", "RXF1C", "RXF1S", "TXFQS", "TXBTO", "TXEFS", • Added M_CAN registers "RXESC" and "TXESC" • Updated M_TTCAN registers "CCCR", "IR", "NDAT2", "RXF1A" Table 692 (References): updated "M_CAN IP" version to "Revision 3.0" (was "Revision 2.0") Updated Section 48.3.1, Features Updated Section 48.3.3, Dual clock sources Section 48.3.4, Dual interrupt lines: replaced all instances of "INT" with "EINT" Section 48.3.5.2, Register map: • Updated section introduction • Updated Table 693 (M_CAN memory map) Section 48.3.5.2.3, Fast Bit Timing and Prescaler Register (FBTP): updated time quanta range to program CAN bit time to "[4…81]" (was "[4…25]") Section 48.3.5.2.3, Fast Bit Timing and Prescaler Register (FBTP): • Changed text "1024 M_CAN clock periods" to "32 M_CAN clock periods" • Added notes "The bit rate configured for the CAN FD data phase..." and "To archive high bit rates in CAN FD mode..." Table 605 (TSCC field descriptions): updated field description "TCP" Table 702 (TSCV field descriptions): updated field description "TSC"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Section 48.3.6, Message RAM: • Added text "i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored" to sentence "The configured start addresses are 32-bit word addresses" • Replaced "1216 words" with "4352 words" • Updated Figure 625 (Message RAM Configuration) • Added note "When operated in CAN FD mode the required..." • Updated Section 48.3.6.1, Rx Buffer and FIFO element • Updated Section 48.3.6.2, Tx buffer element Updated Section 48.3.7.3, CAN FD Operation Section 48.3.7.4, Transceiver Delay Compensation: added conditions for the transceiver delay compensation Added Section 48.3.7.5, Restricted Operation Mode Updated Section 48.3.10.1, Acceptance filtering Updated Figure 629 (Standard Message ID Filter Element) Updated Figure 630 (Extended Message ID Filter Element) Updated Section 45.3.10.2, Rx FIFOs Updated Section 48.3.13, Tx handling Table 756 (CCFG Register field descriptions): added text " Configured values below 4..." to field description "TQBT" Updated Table 662 (CWD field descriptions) Updated Figure 573 (CU Interrupt Register (CUIR)) Section 48.4, Time Triggered Modular CAN (M_TTCAN) core: updated section introduction Section 48.4.1, Features: added "Debug on CAN support" feature; updated size of Generic Slave Interface to 8/16/32 bit Updated Section 48.4.2, Block Diagram Updated Table 769 (BTP field descriptions) Table 770 (TTSCC Register field descriptions): updated "TSS" field description Table 771 (TTSCV Register field descriptions): updated "TSC" field description Table 775 (PSR Register field descriptions): updated "REDC" field description Table 814 (TTIR Register field descriptions): updated "SWE" field description Figure 710 (TT Cycle Time and Count Register (TTCTC)): changed reset value of field "CC" from "0x3F" to "111111" Section 48.4.6, Message RAM: • Updated section introduction • Updated Section 48.4.6.1, Rx Buffer and FIFO element • Replaced "WM" with "MM" in Section 48.4.6.3, Tx Event FIFO element • Section 48.4.6.4, Standard message ID Filter element: Updated field descriptions "SFT", "SEEC", and "SFID2" • Section 48.4.6.6, Trigger memory element: Added field "TMEX" to bit 27 Section 48.4.7.1.1, Software initialization: replaced "CCCR[INIT] = elf " with "CCCR[INIT] = '1' " Updated Section 48.4.7.3, CAN FD Operation Updated Section 48.4.7.12.6, Extended message ID filtering Added Section 48.4.7.15, Debug on CAN Support Added Section 48.4.7.16, Interface to DMA Controller Updated Section 48.4.11, Message scheduling Updated Table 835 (M_CAN message memory size) Updated Table 837 (Shared memory map vs CAN transmit, receive and filters elements) Updated Table 838 (Detailed mapping in CAN subblocks)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Chapter 46, Serial Interprocessor Interface (SIPI) Throughout chapter: added module name prefix to all register names Section 49.1.1, Scalability: added bulleted list item "The rest of this section..." Section 49.6.2, Frame format: • Updated section introduction • Updated Section 49.6.2.6.1, SIPI header coding Section 49.15.1.8, SIPI Module Configuration Register (SIPI_MCR): added fields "DOZE" and "CHNSB" to bits 1 and 27 respectively Chapter 50, Deserial Serial Peripheral Interface (DSPI) Throughout chapter: removed all instances of signal "MTRIG" and relative content; removed all instances of registers "PISR" (PISR0–PISR7) and relative content; removed "DMA request" feature content; removed DOZE mode content. Section 50.1.2, Features: removed feature "DMA request support for DDIF" Section 50.1.4.4, External Stop mode: added content relating to External Stop mode requests in DSPI Slave mode Removed section "HT — Hardware Trigger" Table 862 (DSPI_CTARn field descriptions): updated minimum valid value of field "FMSZ" (is 4; was 3) Section 50.3.6, DSPI DMA/Interrupt Request Select and Enable Register (DSPI_RSER): set bit 17 to "Reserved" (was field "DDIF_DIRS") Section 50.3.12, DSPI DSI Configuration Register 0 (DSPI_DSICR0): • Set bits 0 and 14 to "Reserved" (were fields "MTOE" and "TRRE") • Added note "This bit is reserved if the device does..." to field "TPOL" • Updated description of fields "CID" and "DCONT" Updated Section 50.5.3, Deserial Serial Interface (DSI) configuration Removed section "Multiple Transfer Operation (MTO)" Section 50.5.9.1, MSC Dual Receiver Support with PCS Switchover: added note "When using Dual receiver support, it must be ensured that..." Table 900 (Interrupt and DMA request conditions): for DSPI condition "DSI Deserialized Data Match", changed Request Type "DMA" to "—" (was Yes) Section 50.5.13, Power saving features: added note "When in Slave Mode, the module can only be put in Low Power Modes..." Section 50.5.13.1, Stop mode (External Stop Mode): added paragraph "If a DSPI block is configured in Slave mode..." Chapter 48, LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications Section 2.6.2.1, Mode Configuration Register (MCR): added figure footnote "Writable only once after the asynchronous reset." to field "MSEN" *Table 19: PLLCR field descriptions*: updated binary combination definitions in field descriptions "IPTMOD", "REFINV", "LPCFG", and "FBDIV" *Table 29: PLLLSR field descriptions*: swapped field descriptions of "LDPDS" and "LRPDS" Section 2.6.2.15, LVDS Control Register (LCR): • Set bit 29 to "Reserved" (was field "LVTXOP") • Changed "LVRXOP" field description Chapter 49, Fast Ethernet Controller (FEC) Table 948 (FEC signal descriptions): added signals "FEC_MDC" and "FEC_MDIO" to RMII mode

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Section 52.4, Memory map and register definition: • Updated section introduction • Changed field access type of all "RMON" and "IEEE" register fields from read-write to read-only Updated Section 52.4.21, Receive Descriptor Ring Start Register (ERDSR) Chapter 53, FlexRay Communication Controller (FlexRay) Section 53.5, Memory map and register description: added note to list 16-bit write accessible only registers; changed reset value of register "FR_MVR" Section 53.5.2.19, Channel A Status Error Counter Register (FR_CASERCR): renamed field "STATUS_ERR_CNT" to "CHAERSCNT" Section 53.5.2.20, Channel B Status Error Counter Register (FR_CBSERCR): renamed field "STATUS_ERR_CNT" to "CHBERSCNT" Section 53.5.2.23, Protocol Status Register 2 (FR_PSR2): renamed field "CLKCORRFAILCNT" to "CKCORFCNT" Section 53.5.2.68, Last Dynamic Transmit Slot Channel A Register (FR_LDTXSLAR): renamed field "LASTDYNTXSLOTA" to "LDYNTXSLOTA" Section 53.5.2.69, Last Dynamic Transmit Slot Channel B Register (FR_LDTXSLBR): renamed field "LASTDYNTXSLOTB" to "LDYNTXSLOTB" Chapter 54, Inter-Integrated Circuit (I^2C) Table 1093 (IBSR field descriptions): updated "SRW" field description Table 1198 (I^2C divider and hold values): revised "SDA Hold (clocks)" entries for IBC=60 through IBC=7E, and added entry for IBC=7F Added Section 54.5.6, IPG STOP mode Updated Section 51.5.7, IPG DEBUG mode Revised Figure 1166 (Flow-Chart of DMA mode master transmit) Revised Figure 1167 (Flow-Chart of DMA mode master receive) Chapter 55, Peripheral Sensor Interface (PSI5) Table 1207 (PSI5 memory map): updated "Disable mode access" of "DMA Control Register (PSI5_DCR)" from "R/W" to "R", for all channels Removed chapter "Peripheral Sensor Interface-Support Module (PSI5-S)" Chapter 56, SENT Receiver (SRX) Section 56.3.2.4, Fast Message Ready Status Register (SRX_FMSG_RDY): changed text "register will be asserted on Fast Message reception." to "register will get asserted on Slow Message reception" Section 56.3.2.5, Slow Serial Message Ready Status Register (SRX_SMSG_RDY): changed text "register will be asserted on Slow Message reception." to "register will get asserted on Fast Message reception" Throughout chapter: reorganized bitmaps to change array of fields to single field for selected registers Updated Figure 1270 (Block diagram) Section 57.3.2.5.1, Header error: in Case 2, changed "LINCR1 = 1" to "LINCR1 = 0" Updated Section 57.3.2.5.2, Bit error Section 57.3.2.5.6, Timeout error: added subheadings: "Response timeout mechanism" and "Header timeout mechanism" Added Section 57.3.2.7.1, Start detection mechanism

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Added Section 57.3.2.7.2, Delimiter detection mechanism Updated Section 57.3.4.5, 13-bit frames Updated rows of TCD fields SADDR[31:0] and DADDR[31:0] in • Table 1286 (TCD setting — Master node — Tx mode) • Table 1287 (TCD setting — Master node — Rx mode) • Table 1289 (TCD setting — Slave node — Tx mode) • Table 1291 (TCD setting — Slave node — Rx mode) • Table 1292 (TCD setting — UART — Tx mode) • Table 1293 (TCD setting – UART – Rx mode) Table 1295 (LINCR1 field descriptions): updated descriptions of fields "SLEEP" and "INIT" Section 57.4.2.2, LIN Interrupt enable register (LINIER): renamed field relative to bit 28 to "DBEIE_TOIE" (was "DBIE/TOIE") Table 1194 (LINESR field descriptions): updated "OCF" field description Section 57.4.2.3, LIN Status Register (LINSR): • Renamed field relative to bit 24 to "RXBUSY" (was "RXbusy") • Changed access type of field "AUTOSYNC_COMP" to "w1c" (was read-only) Updated Section 57.4.2.5, UART Mode Control Register (UARTCR) Updated Section 57.4.2.6, UART Mode Status Register (UARTSR) Table 1197 (LINTCSR field descriptions): updated "IOT" and "CNT" field descriptions Table 1199 (LINTOCR field descriptions): updated "HTO" field description Section 57.4.2.13, LIN Control Register 2 (LINCR2): changed access type of fields "WURQ", "DDRQ", "DTRQ", "ABRQ", and "HTRQ" from "read only" to "read/write" Updated Table 1304 (Interface signals) *Chapter 3: Reset Generation Module (MC_RGM)* Updated Figure 76 (MC_RGM block diagram) Updated *Table 284: MC_RGM register description* Figure 82 (RGM_FERD register): changed access type of fields • "D_FCCU_SOFT" to read-write (was "read-only") • "D_SOFT_FUNC" to "read-only" (was "read-write") • "D_ESR0" to "read-only" (was "read-write") Section 3.3.1.7, Functional Event Alternate Request Register (RGM_FEAR): • Added field "AR_FCCU_SOFT" to bit 25 and changed reset value to '1' • Set bits 28 and 31 to "Reserved" (were fields "AR_SOFT_FUNC" and "AR_ESR0" respectively) Section 3.3.1.9, Functional Event Short Sequence (RGM_FESS) register: renamed field relative to bit 30 to "SS_ESR1" (was SS_ESR0) Figure 90 (RGM_PRST1 register): added field "CCCU_RST" to bit 1; set bit 4 to "Reserved" (was field "ADCSD_2_RST") Added "Peripheral Reset Register" sections Chapter 58, Boot Assist Flash (BAF) Moved sections "Search boot header and boot options", "Memory map", "LINFlexD_0 and MCAN_1 pin configuration" to Section 2.9.2, BAF configuration Added Section 58.2.5.6, SER_BOOT_CBACK – BAF serial boot DCF client Updated Section 58.2.2, Device initialization Table 1341 (BAF DCF client list): added row "Serial boot Callback Address" Added Table 1344 (Serial boot callback function return value definition)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Updated Section 58.2.7, Optionally perform a serial boot to add support for CAN serial boot Modified Section 58.2.8.3, Baud rates Added: • Section 58.2.7.1, Serial boot mode protocol • Section 58.2.7.2, LINFlexD download protocol • Section 58.2.7.3, M_CAN download protocol • Section 58.2.8.2, M_CAN configuration • Section 58.2.6, Production disable activation protocol and implementation Chapter 60, System Status and Configuration Module (SSCM) Figure 1410 (Life Cycle Status Register (LCSTAT)): changed reset value of bit 0 to '0' Section 60.3.1.5, Life Cycle Status Register (LCSTAT): changed field relative to bits 22–23 to "TLC" (was field "PLC") Table 1270 (LCSTAT field descriptions): added "JDP_PROD = 110" to "LC" field description Chapter 61, Power Management Controller digital interface (PMC_dig) Updated registers "GR_S", "GR_P", "IE_P", "EPR_VD8", "REE_VD8", "RES_VD8", "FEE_VD8", "EPR_VD9", "REE_VD9", "EPR_VD9", "FEE_VD9", "EPR_VD10", "REE_VD10", "RES_VD10", "FEE_VD10", "EPR_VD15", "REE_VD15", "RES_VD15", "FEE_VD15", "VD_UTST", and "VREG1P2_CTRL" Added registers "EPR_VD2", "REE_VD10", and "MCR" Updated Table 1381 (Power Management Controller memory map) Section 61.3.1.39, Trimming register (MREG_TRIM): changed field "MREG_TRIM" width to encompass bits 27–31 Section 61.3.1.46, ADC Channel Select register (ADC_CS): changed register abbreviation "ADC_CH" to "ADC_CS" Section 61.8, Other module interfaces: updated LVDs and HVDs sent to FCCU *Chapter 2: Power Control Unit (MC_PCU)* Updated *Table 16: Power Domain Status Register (PCU_PSTAT) field descriptions* *Chapter 1: Mode Entry Module (MC_ME)* *Table 2: MC_ME register description*: added rows "SIUL Control (ME_PCTL15)" and "CCCU Control (ME_PCTL62)" *Table 3: Global Status register (ME_GS) field descriptions*: in "S_CURRENT_MODE" field description, changed description for binary combination '0111' to "*RUN3*" (was "RUN"); added footnote "Power-sequence drivers control pad slopes..." *Table 10: Mode Configuration Registers (ME_mode_MC) field descriptions*: added footnote "Power-sequence drivers control pad slopes..." Figure 16 (Peripheral Status register 0 (ME_PS0)): added field "S_SIUL_0" to bit 16 Figure 17 (Peripheral Status register 1 (ME_PS1)): added field "CCCU" to bit 1 Replaced chapter "e200z420n3 Core Debug Support" with *Chapter 13: e200z410Dn3 Core Debug Support* Replaced chapter "e200z225n3 Core Debug Support" with *Chapter 13: e200z225Bn3 Core Debug Support*

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Chapter 66, Debug and Calibration Interface (DCI) Figure 1554 (DCI operating modes state diagram): updated text in "DCI_LFAST_SAFE" to "DCI_JTAG" transition to "1st Timeout + 1" (was "1st Timeout") Section 66.1.3.10, Reset control: • Renamed DCI_CR[FPD_ESR0] bit to DCI_CR[FPD_FUNC] • Renamed DCI_CR[FPD_PORST] bit to DCI_CR[FPD_DEST] • Updated DCI_CR reset control descriptions according to bit fields renaming Section 66.3.1, DCI control register (DCI_CR): renamed fields relative to bits 8 and 9 to "FPD_FUNC" and "FPD_DEST" respectively (were "FPD_ESR0" and "FPD_PORST") *Chapter 64: JTAG Controller (JTAGC)* *Table 1645: Device identification register field descriptions*: changed definition of variable JTAGC_PIN to "0x307" (was "0x306") Chapter 68, IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG): In Section 68.6.2.3.9, Auxiliary Pin Function Control (APFC[1:0]), corrected APFC encoding value Added Section 68.8, Functional Description Chapter 69, JTAG Data Communication (JDC) Changed way to reset registers "MCR", "MSR", "JOUT_IPS", and "JIN_IPS" (by "system destructive reset") Chapter 70, JTAG Master (JTAGM) Table 1557 (JTAGM_MCR register field descriptions): • Added note "After being written to..." in descriptions of fields "SWRESET", "evti1_assert" and "TCKSEL" • Updated description of field "TCKSEL" Section 70.4.1.2, Status register (JTAGM_SR): added note "In LFAST mode (when DTM =0)..." in description of field "NR" Chapter 68, Sequence Processing Unit (SPU): unchanged Chapter 69, LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug Table 1615 (PLLLSR field descriptions): swapped field descriptions of "LDPDS" and "LRPDS" Section 72.6.2.1, Mode Configuration Register (MCR): set bit 7 to "Reserved" (was field "IPGDBG") Section 72.6.2.9, LVDS Control Register (LCR): • Set bit 29 to "Reserved" (was field "LVTXOP") • Changed "LVRXOP" field description Chapter 73, Development Trigger Semaphore (DTS): unchanged Chapter 71, Nexus Aurora Router (NAR): unchanged Replaced chapter "e200z420n3 Nexus 3 Module" with *Chapter 14: e200z410Dn3 Nexus 3 Module*

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Replaced chapter "e200z225n3 Nexus 3 Module" with *Chapter 14: e200z225Bn3 Nexus 3 Module* Chapter 74, GTM Development Interface (GTMDI) Table 636 (DID field descriptions): added "MIC" value to field description Chapter 75, Nexus Crossbar Multi-Master Client (NXMC): unchanged Chapter 76, Cyclic Redundancy Check (CRC) Unit Figure 1869 (DMA-CRC transmission sequence): changed "CPU" to "DMA" in Transmission phase 3 Chapter 79, Memory Error Management Unit (MEMU) Throughout chapter: added content relative to "syndrome"; changed all OFLW registers (and their OFLW) fields from read/write to write-1-to-clear. In Figure 1872 ([BLG_MEMU_0061][Covers: Saf1894]MEMU reporting table uniqueness check flow chart[end]), deleted the arrow from "Error dropped" to "UCE flag sent to FCCU" In Section 79.2, Features, added item "The reporting table for uncorrectable errors supports only 1 entry" Section 79.6.2.2, Error flag register (ERR_FLAG): revised paragraph between register bitmap and register field descriptions table Section 79.6.2.3, Debug register (DEBUG): added register introduction In Section 79.7, Functional description, added text explaining the equivalence of "bad bit" and "syndrome" Chapter 80, Indirect Memory Access (IMA): unchanged Chapter 81, Fault Collection and Control Unit (FCCU) Throughout chapter: added footnote "Actual value depends on the SOC settings at pad level" in selected sections; added footnote "Final value depends on the SOC settings at pad level" in selected sections Section 81.5.4, Fault priority scheme and nesting: added text "If FCCU is in ALARM state and another fault comes, which has its alarm..." Section 81.6.1, FCCU Control Register (FCCU_CTRL) : set fields relative to bits 0 and 1 to "Reserved" (were fields "FILTER_BYPASS" and "FILTER_WIDTH" respectively) Chapter 80, Self-Test Control Unit (STCU2) Throughout chapter: field "BYP" referenced as being in register STCU_RUN (was incorrectly referenced as being in register STCU_CFG) Removed section "Register description conventions" Removed section "Open issues" Chapter 83, Register Protection (REG_PROT) Section 83.3.2.3, Soft Lock Bit Register (SLBR0-1535): detail added regarding SLB function Removed section "Writing C code using the register protection scheme"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	Chapter 83, Password and Device Security Module (PASS) Throughout chapter: added "Retest Password" and "Fuse Bypass" information; changed the abbreviation of the Challenge Status Register (was "CHSTAT"; is "CSTAT") Table 1902 (PASS memory map): added "CSTAT" reset value to "0x0000_0000" Figure 1995 (Life Cycle Status register (LCSTAT)): added footnote "If no DCF records have been written, the bit resets to '1'." Figure 2000 (LOCK0_PGn register): changed reset value of field "ATSL" to 'x' (was '1'). Section 83.3.1.8, Password Group n - Lock 2 status register (LOCK2_PGn): changed the field name from "256LCK_L" to "L_256LCK" Section 83.3.1.9, Password Group n - Lock 3 status register (LOCK3_PGn), changed the field name from "256LCK_U" to "U_256LCK" Moved all DCF client information into a separate section, Section 83.4, DCF clients Re-architected Section 83.4.2, Production Disable, to include the DD and HI information as subsections Updated Section 83.4.2.2, Hardware Interlock (HI) Added Section 83.4.3, Fuse Bypass DCF Client Revised Section 83.5, Functional description Added Table 1917 (Flash Memory Read Protection Truth Table) Chapter 85, Tamper Detection Module (TDM) Throughout chapter: added register "TDM_DBA" Updated Section 85.1, Overview Section 85.2, Features: added footnote "The Tamper Region Override DCF record is a..." to item "Override TDR via DCF records" Updated Section 85.4, DCF client Figure 2030 (Last Flash Programmed Address Register (TDM_LFPAR)): changed access type of field "LFPAR" to "read only" Chapter 86, Wakeup Unit (WKPU) Throughout chapter: added registers "WISR", "IRER", "WRER", "WIREER", "WIFEER", "WIFER", and "WIPUER" Section 86.1.2, Features: added item "15 I/O external interrupts: 4–14 and 16–19 wakeup lines" Added Section 86.4.2, External Wakeups/Interrupts Chapter 48, GTM122 Integration (GTMINT) Module: unchanged Chapter 86, Emulation and Debug Device Introduction: unchanged Chapter 88, Buddy Device—Crossbar and RAM (BD_XBS_RAM): unchanged Chapter 89, Buddy Device—System Integration Unit Lite (BD_SIUL2): • Unchanged • Relocated (was chapter 90) *Chapter 65: Buddy Device—Debug and Calibration Interface (DCI)* Figure 1428 (DCI operating modes state diagram): updated text in "DCI_LFAST_SAFE" to "DCI_JTAG" transition to "1st Timeout + 1" (was "1st Timeout") *Chapter 64: Buddy Device—JTAG Controller (JTAGC)*: unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
14 Feb 2014	3 (cont'd)	*Chapter 59: Buddy Device—JTAG Master (JTAGM)* *Table 1344: JTAGM_MCR register field descriptions*: • Added note "After being written to..." in descriptions of fields "SWRESET", "evti1_assert" and "TCKSEL" • Updated description of field "TCKSEL" Section 59.4.1.2, Status register (JTAGM_SR): added note "In LFAST mode (when DTM =0)..." in description of field "NR" Chapter 92, Buddy Device—Nexus Aurora Router (NAR): unchanged Chapter 94, Buddy Device—Nexus Aurora Link (NAL): unchanged Chapter 95, Buddy Device—Nexus Aurora PHY (NAP): unchanged Chapter 96, Buddy Device—Data Write Processing Unit (DWPU): unchanged Chapter 97, Buddy Device—Nexus Read Write Access (RWA): unchanged Chapter 97, Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug Section 50.6.2.1, Mode Configuration Register (MCR): set bit 7 to "Reserved" (was field "IPGDBG") *Table 938: PLLCR field descriptions*: updated binary combination defintions in field descriptions "IPTMOD", "REFINV", "LPCFG", and "FBDIV" Section 50.6.2.10, LVDS Control Register (LCR): • Set bit 29 to "Reserved" (was field "LVTXOP") • Changed "LVRXOP" field description *Table 947: PLLLSR field descriptions*: swapped field descriptions of "LDPDS" and "LRPDS" *Appendix A: Acronyms and abbreviations*: unchanged Updated ST template

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4	Throughout document: • Editorial and formatting changes Chapter 1, Preface: unchanged Chapter 2, Introduction Section 2.2, Features summary: replaced “2 main CPUs” to “One main processor core and one checker core” Table 6 (MPC5744K/SPC574K72 device feature summary): • Added cache row to I/O processor • Added 140 MHz to Main processor frequency • Added 70 MHz to I/O processor frequency • Replaced “4 × 256 bit” with “2 x 2 x 256-bit” in Flash memory fetch accelerator • Changed feature “M_CAN/M_TTCAN “to “CAN (M_CAN/M_TTCAN)” and its description from “2/1” to “3 (2/1)” • Added RMII to Ethernet • Replaced “365 sources” with “360 sources” in Interrupt controller • Removed 1.2 V from External power supplies Chapter 3, Embedded memories: unchanged *Chapter 4: Signal description*: unchanged *Chapter 5: Memory map* *Table 14: Peripheral (PBRIDGE_A, PBRIDGE_B) memory map*: changed “CMU_0” to “CMU_PLL0” *Table 18: UTEST flash memory map*: updated BAF code comments Chapter 6, Functional Safety Throughout chapter, changed “PBRIDGE 0” and “PBRIDGE 1” to “PBRIDGE_A” and “PBRIDGE_B” respectively Section 6.4.1.5.1, BIST during boot (off-line): added sentence “Since LBIST and MBIST are destructive, a reset is performed for the tested...” in first paragraph Section 6.4.1.5.2, Online Logical BIST (LBIST): • Added sentence “Output signals from each LBIST partition are set to a defined state when...” in first paragraph • Added note about ensuring Flash is in IDLE state (i.e., no Program/Erase operations) prior to starting LBIST operation Table 17 (LBIST partitions): added rows “Concentrator eDMA“ and “Concentrator FEC“ to partition “LBIST 2” Table 18 (Not in LBIST partitions): removed “SPU” instance from “Debug” functional group Section 6.4.1.7.3, FCCU failure inputs from other modules: added footnote “All of these faults require a long functional reset.“ to introductory paragraph. Table 19 (FCCU failure inputs1): • Added footnote to column head “Recommended Recovery Mechanism“ and updated its contents for several failures. • Removed FCCU channel row 56 “Computational Core e2eECC” Section 6.4.2, Dual-core lockstep: added sentence “Furthermore, it is not a valid operation to stop main core_0 only or to reset one of the...” in last paragraph Table 19 ([SCG18.303][Covers: Saf3257]ECC RAM implementations[end]): added column “Muxing factor“ Revised entirely Section 6.4.4.4.1, Interface to ECC units

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	*Chapter 2: Device Configuration* Added Section 2.3.6.4, IPS Clock Gating Module Enable 0 (IPS_CGM_EN0) Register Section 7.3.7.2, INTC implemented registers: • Changed address offset of register INTC_SSCIR31 from "05Ch" to "05Fh" • Changed address offset range of registers INTC_PSR0–INTC_PSR1023 from "05Ch–85Ch" to "060h–85Eh" • Added note to say that access to INTC_PSRs not implemented generates an error *Table 31: Interrupt sources*: for IRQ 255, added source names; for IRQ 454, revised "RAM" to "LRAM"; for IRQ 935, changed offset from "1EA0h" to "1E9Ch". Figure 16 (DMA channel multiplexing): changed range of sources for DMAMUX_1 and DMAMUX_3 *Table 34: DMAMUX peripheral DMA request to input source mapping*: changed source 42 to "Reserved" (was "SIUL2_REQ3") for DMAMUX_3 Added Section 2.4.1.1, Calibration remapping support and Section 2.4.1.2, Wait state settings for overlay flash latency matching Section 7.6, Decorated Storage Memory Controller (DSMC): added caution note "Do NOT perform decorated accesses to any address spaces other than those explicitly listed above." Section 2.7.1, Software Watchdog Timer (SWT) configuration: added "Internal 16 MHz RC oscillator clock that is used for timer operation" in list of features *Table 46: Software Watchdog Timer (SWT) instances*: • For SWT_2, removed expression "Elapsed times recorded in timeout register are different from SWT_0." • For SWT_3, removed expression "in the peripheral clock domain. Elapsed times recorded in timeout register are different from SWT_0." Section 2.8.4.5, High speed and microsecond channel support: • Changed peripheral clock frequency from 120 MHz to 80 MHz • Added list of external pins to insert into the MSC data stream Added Section 2.9.1, Flash initialization during reset Added *Table 73: SSCM startup information addresses* Added Section 7.11.2.6, FlexRay lookup table (LUT) RAM alignment Added Section 7.11.2.7, FlexRay lookup table (LUT) RAM misalignment Added Section 2.9.7.9, Error signal flow diagram Section 2.9.8.2, Clock Monitor Unit (CMU) protected registers: changed clock monitor units for I/O Processor and Core from "CMU_IOP" and "CMU_CORE" to "CMU_PLL0" and "CMU_FXBAR", respectively Figure 28 (PASS_LOCK3_PGn Register): changed bits to Reserved (was Bit Name "256KLOCK[15:0]") Figure 33 (TDRx_LOCK3/OTPEN3 DCF client): changed bits 16–31 to Reserved (was Bit Name "256KLOCK[15:0]") *Table 106: Tamper Detection Module (TDM) DCF clients*: • Added DCF client "Software Tamper Region Override Disable" • Updated "No. of Valid Bits" of OTP_ENs Added Table 116 (LVD /HVD self test decoding) Chapter 8, Reset and Boot Section 8.4.3.9, IOP searches for boot header (state 31): moved "Checker Core_0s" to bit 2 of Boot header configuration

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 9, Device Configuration Format (DCF) Records Figure 51 (Appending DCF records): removed "overwrite" and arrow. Revised test in Warning immediately before this figure and in text immediately after it. Table 121 (DCF client list): • Removed "Flash special strategy" column • Added typical values of clients "STCU_SKC" and "STCU_RUN" • Removed all STCU PRPGH client rows • Added "STCU_MB_CTRL_41" client row • Updated client "Censorship" row • Changed LOCKn_PGm reset values to 0xFFFF_FFFF • Changed IPS read direct access to 'no' for LOCKn_PGm clients • Removed client "Life Cycle (LCSTAT)" row • Changed IPS read direct access to 'yes' for "Production Disable" client • Removed "IVPR1" client row • In BAF 'Soft' Clients section, changed DCF addresses from hexadecimal to binary Figure 54 (PMC_REE bits DCF Client): • Changed offset to 000000000011111 • Reversed bit field order and changed bit fileds "HVD8_F" to "LVD8_F", "HVD8_C" to "LVD8_C", and "LVD14_IM" to "LVD14_C" Section 9.4, DCF client table: added "UTEST" in Parity description. Section 9.4.2, Miscellaneous DCF registers: added field "ROSC_TC_EN" to bit 19 Added Figure 53 (JTAG Pin Configuration DCF Client) and Table 123 (JTAG Pin Configuration DCF Client field descriptions) *11: Power management*: unchanged Chapter 11, Security Section 11.1, Basic security: replaced word 'BAM' with 'BAF' *Chapter 7: Calibration and Debug* Table 144 (PD NAR clients): added NAR source trace ID (SRC) row *Chapter 8: Core Complex Overview*: unchanged *Chapter 1: Core e200z410Dn3 description*: unchanged *Chapter 1: Core e200z225Bn3 description*: unchanged *Chapter 2: System Integration Unit Lite2 (SIUL2)* Section 2.2.2.1, SIUL2 MCU ID Register #1 (SIUL2_MIDR1): updated reset values Section 2.2.2.11, SIUL2 SoC Configuration Register0 (SIUL2_SCR0): changed field "ASSERT_ESR0" to "ESR0_ASSERT" *Table 51: SIUL2_MSCR_0–SIUL2_MSCR_511 field description*: • Changed "when the chip enters Safe mode." to "when the FCCU state machine enters the FAULT state." in SMC field description • Added note "The input level is unknown during the ILS transition..." in ILS field description • Updated "OERC" and "INV" field descriptions *Table 53: SIUL2_MSCR_512–SIUL2_MSCR_1023 field description*: updated "INV" field description

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 17, Crossbar Switch (XBAR): unchanged Chapter 18, Crossbar Integrity Checker (XBIC): unchanged Chapter 19, Peripheral Bridge: unchanged Chapter 20, System Memory Protection Unit (SMPU): unchanged Chapter 21, Intelligent AHB Gasket (IAHBG): unchanged Chapter 22, Semaphores2 (SEMA42): unchanged Chapter 23, Interrupt Controller (INTC) Section 23.2, Block diagram: revised the stem sentence and figure title to account for all possible processor combinations Section 23.5.2.2, INTC Master Protection Register (INTC_MPROT): in the "ID" field description, added "Only the field values related to core bus masters can..." Section 23.5.2.3, INTC Current Priority Register for Processor n (INTC_CPRn): changed "PRI" field width from 4 to 6 to encompass bits 26–31 Section 23.5.2.6, INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0–INTC_SSCIR31): changed "... can write to the CLR bit and not the SET bit, otherwise ..." to "... can write to the CLR bit, otherwise ..." Section 23.5.2.7, INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023): changed "PRIn" field width from 4 to 6 to encompass bits 26–31 Section 23.7.5.2.2, Raised priority preserved: • Deleted the text "Also, during the epilog of the interrupt exception handler..." • Replaced the timing diagram and associated table of event descriptions. Completely replaced Section 23.7.10, Examining LIFO contents Chapter 24, Enhanced Direct Memory Access (eDMA): unchanged Chapter 25, Direct Memory Access Multiplexer (DMAMUX): unchanged Chapter 26, Clocking Added column "e200z2 max. internal JTAG frequency" in Table 332 (JTAG frequencies) Added Section 26.6.7, Successive Approximation Register ADC clocking *Chapter 27: Dual PLL Digital Interface (PLLDIG)* Figure 253 (PLL0 Control Register (PLL0CR)): updated reserved field (bit 21) access to RW *Table 397: PLL0DV field descriptions*: updated binary combination definitions in field description RFDPHI Figure 256 (PLL1 Control Register (PLL1CR)): updated reserved field (bit 21) access to RW *Table 400: PLL1DV field descriptions*: updated binary combination definitions in field description RFDPHI Section 27.6.2, Clock configuration: • Updated f_{pll0_phi1} equation to show the equality with f_{pll1_ref} frequency • Updated f_{pll1_phi} equation—added factor of 2 to denominator • Updated f_{pll0_VCO} equation—added factor of 2 to numerator • Updated f_{pll1_VCO} equation—removed PLL1DV[PREDIV] from denominator • Updated first note to describe the clock sources for the PLL1 reference clock

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 28, Clock Monitor Unit (CMU) Section 28.4.1.5, CMU Interrupt Status Register (CMU_ISR): added note to the "OLRI" field description, "While entering STOP mode, OLRI may be triggered..." *Chapter 29: Clock Generation Module (MC_CGM)* Figure 279 (MC_CGM_DIV_UPD_TYPE): changed field "SYS_DIV_RATIO_CHNG" to "SYS_UPD_TYPE" Chapter 30, OSC Digital Interface (XOSC): unchanged Chapter 31, IRCOSC digital interface: unchanged Chapter 32, RAM controller (PRAMC): unchanged Chapter 32, RAM controller (PRAMC): unchanged Chapter 34, Embedded Flash Memory (MP55) For registers SEL0, SEL1, and SEL2, updated all field descriptions to read "The select field must not be written when UT0[AIE] is high." (was "The select field is not writable...") Chapter 35, Decorated Storage Memory Controller (DSMC): unchanged Chapter 36, Flash Memory Programming and Configuration: unchanged *Chapter 1: Analog-to-digital converter (ADC) configuration* Throughout document: removed all "SDADC_2" instances and relative contents Section 1.2.1.3, Sigma-Delta ADC analog input multiplexing: added bulleted list to explain how the connection to the Sigma-Delta ADC inputs is controlled *Table 3: SDADC_MCR[TRIGSEL] trigger channel assignments*: assigned "GTM hardware trigger" to trigger input 4 Figure 4 (Sigma-Delta ADC simultaneous start connectivity): added block "GTM" Section 1.2.1.7, Conversion result interrupt/DMA gating signal: added sentence "A DMA or interrupt can be generated for each conversion for each ADC. The..." Added Section 1.2.1.8, Conversion Limit Watchdog Output to GTM and Section 1.2.1.9, SDADC_MCR[TRIGSEL] definitions Section 1.2.2.3, SAR ADC analog input pin multiplexing: added sentence "Analog input pins that only connect to SARADC_B use a single analog switch pad cell." In Section 1.2.2.5, SAR ADC triggering, added note to say that GTM has to generate trigger pulses which are greater than one ADC clock cycle. Updated Figure 10 (Dual analog input pin pull up/down pad cell) Added Figure 11 (Single analog input pin pull up/down pad cell) Updated *Table 11: SARADC_B analog test channel assignment* Section 1.2.2.10, SAR ADC register definitions: for all SARADC instances—renamed field of register MSR relative to bit 13 from "JABORT" to "JABORTCHAIN" Chapter 38, Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface Table 509 (OSDR field descriptions): in OSD field description, added note "Refer to the tsettling and tLATENCY parameters in the device datasheet for the..." Section 38.8.1, Data conversion step: added sentence "Refer to the tsettling and tLATENCY parameters in the device datasheet for the minimum allowed..."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 39, Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface: unchanged Chapter 40, Temperature Sensor: unchanged Chapter 41, Timers overview: unchanged Chapter 42, System Timer Module (STM): unchanged Chapter 43, Software Watchdog Timer (SWT) Removed servicing modes "fixed execution address" and "incremental execution address" Chapter 44, Periodic Interrupt Timer (PIT): unchanged Chapter 47, GTM Development Interface (GTMDI): unchanged Chapter 48, GTM122 Integration (GTMINT) Module: unchanged Chapter 48, CAN Subsystem: unchanged Chapter 49, Serial Interprocessor Interface (SIPI) Section 49.10.1, Initialization mode (INIT): removed paragraph "When in initialization mode, all message transfers are stopped. If software invokes..." Section 49.10.3, Module disable (MD): added information to disable Rx functionality Table 852, SIPI_MCR field descriptions: revised "MOEN" field description to say that future SIPI Tx transfers are disabled when this bit is negated. Table 857, SIPI_ERR field descriptions: revised binary combination descriptions for field TOE3–TOE0 Chapter 50, Deserial Serial Peripheral Interface (DSPI): unchanged *Chapter 2: LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications* Removed reference to 312/320 MHz from entire chapter and referred to as high data rate. Section 2.6.2.15, LVDS Control Register (LCR): • Added field "LVTXOP" at bit 29 • Field "LVRXOP" (bits 26–28) is now split into 3 individual bits: LVRXOP_TR (bit 26), Reserved (bit 27), and "LVRXOP_BR" (bit 28) • Updated field description "LVCKSS" Section 2.7.6.1.2, Data receive: in the first paragraph, changed "MCR[TXEN]" to "MCR[RXEN]". Chapter 52, Fast Ethernet Controller (FEC): unchanged Chapter 53, FlexRay Communication Controller (FlexRay): unchanged Chapter 54, Inter-Integrated Circuit (I^2C) In each register description, revised the register access level info. In Figure 1165 (Recommended I^2C interrupt service routine flowchart), changed "Set TXAK =1" to "Set NOACK = 1"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	In Section 54.6.3.1, Generating START, changed "IBVR" to "IBCR". Revised Section 54.6.3.2, Transmit/receive sequence to show the correct procedures for all four cases. In Section 54.6.5.3, Exiting DMA mode, system requirement considerations: • Revised the information about DMA channel linking and DMA scatter/gather process. • Added an example for a 150 MHz system. In Section 54.4.9, I^2C Bus Interrupt Config Register (IBIC), added field "BYTERXIE" In Table 1202 (Slave transmit sequence) and Table 1203 (Slave receive sequence), deleted the first step ("Use the IBFD register to select...") and adjusted the remaining step letters accordingly. In Section 54.6.3.5, Loss of arbitration, changed "generate an interrupt to CPU and set the IBAL to indicate that the attempt to engage the bus is failed" to "generate an interrupt to CPU, set the IBAL to indicate that the attempt to engage the bus is failed, and not set the TCF due to the loss of data during arbitration." Chapter 55, Peripheral Sensor Interface (PSI5) Section 55.3.2, Register description: for "PSI5_DPRL", "PSI5_DBRL", "PSI5_DBRH", "PSI5_DSRL", and "PSI5_DSRH" registers—"DPR", "DBR", and "DSR" fields now encompass all individual bits in the same regions Section 55.3.2.13, PSI5 Message Receive Register Low (PSI5_PMRRL): changed field "CRC/P" to "CRCP" Section 55.3.2.15, PSI5 Message Register Low i (PSI5_PMRLi) {i: 0 to 31}: changed field "CRC/P" to "CRCP" Section 55.3.2.17, SMC Frame Register n (PSI5_SFRn): changed field "ID[7:4]/ID[3:0]" and "ID[3:0]/DATA[15:12]" to "ID" and "IDDATA" ,respectively Section 55.3.2.27, Slot n Frame Configuration Register (PSI5_SnFCR): changed field "CRC/P" to "CRCP" Chapter 56, SENT Receiver (SRX) Throughout chapter: • In register description sections of selected registers, changed note "The following register figure..." to "Reads of bits beyond those for the supported number..." • Removed references to "SRX_DATA_CTRL2" register Section 56.3.2.1, Global Control Register (SRX_GBL_CTRL): updated binary combination descriptions of field "TSPRSC" Section 56.3.2.19, Channel 'n' Configuration Register (n = 0 to (CH-1)) (SRX_CHn_CONFIG): in "FIL_CNT" field description, changed expression "This indicates the number" to "This indicates twice the number" In Section 56.4.8, Time stamp logic, changed required prescaler value from 60 to 59 when the high frequency receiver clock is 60 MHz Section 56.3.2.6, Data Control Register 1 (SRX_DATA_CTRL1): added note "Reset value changes depending on the number of channels that are enabled on..." In Section 56.1.2.2, Low power modes, added two notes: "If the SOC requests entry to debug or stop mode..." and "The message read registers..." Removed Section "Register Classification for Safety" Section 56.4.7.6, Pause pulse diagnostic: substantial changes In Figure 1266 (Enhanced Serial Message with 4-bit ID field), changed "Data [15:12]" to "Data Field [15:12]"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	In Section 56.1.1, Features changed bulleted list item "Supports compensation ... for drift and jitter in the Transmr clocks per channel" to "Supports compensation ... for drift in the Transmitter and Receiver clocks per channel" In Section 56.3.2.17, Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX_CHn_CLK_CTRL), added note "The value provided..." to "CM_PRSC" field description In Section 56.4.6, Input programmable filter, added value of FIL_CNT in sentence "A timing diagram of the input filter when FIL_CNT is 4 …" In Section 56.3.2.1, Global Control Register (SRX_GBL_CTRL), added field "NIB_LEN_VAR_LIMIT" at bit 15 Section 56.3.2.4, Fast Message Ready Status Register (SRX_FMSG_RDY): added note "These bits are either "write 1 to clear" (w1c) or self-clearing..." in "F_RDYn" field description. Section 56.3.2.14, DMA Slow Serial Message Bit3 Read Register (SRX_DMA_SMSG_BIT3): • Changed fields "ID[7:6] / ID[3:2]" and "ID[5:4] / ID[1:0]" to "ID7_4_D3_0" • Changed field "ID[3:0]/DATA[15:12]" to "ID3_0_DATA15_12" Section 56.4.1, Initialization sequence: added note "When configuring the Single Edge Nibble Transmission (SENT)..." Section 56.4.5, Adjustment for variation in sensor (Tx) clock: added note "At ambient temperatures above 114 degree C..." Section 56.4.7.5, CRC check: added note "The Single Edge Nibble Transmitter (SENT) Receiver..." Chapter 57, LINFlexD Changed information relative to The Baud rate limitation of 5 Mbit/s. *Chapter 3: Reset Generation Module (MC_RGM)* Section 3.3.1.1, Destructive Event Status (RGM_DES) register: updated field relative to bit 28 to "F_SOFT_DEST" (was "F_SOF_DEST") *Table 285: RGM_DES register field descriptions*: revised note in "F_VOR_DEST" field description Section 3.3.1.2, Destructive Event Reset Disable (RGM_DERD) register: • Updated field relative to bit 28 to "D_SOFT_DEST" (was "D_SOF_DEST") • Added field "D_SSCM_DEST" to bit 21 *Table 286: RGM_DERD field descriptions*: added "D_POR" field description Section 3.3.1.4, 'Destructive' Bidirectional Reset Enable (RGM_DBRE) register: updated field relative to bit 28 to "BE_SOFT_DEST" (was "BE_SOF_DEST") Section 3.3.1.7, Functional Event Alternate Request Register (RGM_FEAR): set bit 28 to "Reserved" Figure 82 (RGM_FERD register): for field "D_FCCU_SOFT", changed access type from "read/write" to "read only" Chapter 58, Boot Assist Flash (BAF) Changed LINFlexD baud rate value to 250 kbaud with the IRCOSC as reference clock (was the external crystal oscillator frequency divided by 833.333) Section 58.2.8.3, Baud rates: updated the division factor for baud rate calculation from 833.33 to 80 Chapter 60, System Status and Configuration Module (SSCM): unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 61, Power Management Controller digital interface (PMC_dig) Section 61.3.1.37, Voltage Supply for I/O Segments register (VSIO): set bit 23 to *Reserved* (was field "VSIO_IM") Section 61.3.1.48, Module Control Register (MCR): set bit 16 to *Reserved* (was field "ADC_CHSEL_EN") *Chapter 2: Power Control Unit (MC_PCU)*: unchanged *Chapter 1: Mode Entry Module (MC_ME)* Added footnote "If the user does not want the part to be woken up from certain Interrupt events, then the user needs to..." to "Exit" column of rows "HALT0" and "STOP0" against "interrupt event" in *Table 1: MC_ME mode descriptions* Section 1.3.2.6, Invalid Mode Transition Status register (ME_IMTS): added field "S_MRIG" to bit 26 Section 1.3.2.16, Peripheral Status register 1 (ME_PS1): removed field "S_ADCSD_2" from bit 4 Section 1.3.2.25, Peripheral Control registers (ME_PCTLn): removed field "DBG_F" from bit 1 Section 1.4.6, Peripheral clock gating: removed infomation relative to ME_PCTLn[DBG_F] *Chapter 13: e200z410Dn3 Core Debug Support*: unchanged *Chapter 13: e200z225Bn3 Core Debug Support*: unchanged Chapter 66, Debug and Calibration Interface (DCI): unchanged *Chapter 64: JTAG Controller (JTAGC)*: unchanged Chapter 68, IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG): unchanged Chapter 69, JTAG Data Communication (JDC): unchanged Chapter 70, JTAG Master (JTAGM) Table 1557 (JTAGM_MCR register field descriptions): updated binary combination descriptions for fields EVTI0_ASSERT and EVTI0_ASSERT Revised Section 70.4.1.2, Status register (JTAGM_SR) Chapter 71, Sequence Processing Unit (SPU): unchanged Chapter 72, LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug Removed reference to 312/320 MHz from entire chapter and referred to as high data rate. Section 72.6.2.9, LVDS Control Register (LCR): • Added field "LVTXOP" at bit 29 • Field "LVRXOP" (bits 26–28) is now split into 3 individual bits: LVRXOP_TR (bit 26), Reserved (bit 27), and "LVRXOP_BR" (bit 28) • Updated field description "LVCKSS" Section 72.6.2.15, Rx Interrupt Status Register (RISR): removed fields "RXMNF" (bit 9) and "RXMXF" (bit 10)

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Section 72.7.6.1.2, Data receive: in the first paragraph, changed "MCR[TXEN]" to "MCR[RXEN]". Chapter 73, Development Trigger Semaphore (DTS): unchanged Chapter 74, Nexus Aurora Router (NAR): unchanged *Chapter 14: e200z410Dn3 Nexus 3 Module*: unchanged *Chapter 14: e200z225Bn3 Nexus 3 Module*: unchanged Chapter 77, Nexus Crossbar Multi-Master Client (NXMC): unchanged Chapter 78, Cyclic Redundancy Check (CRC) Unit: unchanged Chapter 79, Memory Error Management Unit (MEMU) Section 79.6.2.7, System RAM uncorrectable error reporting table address register (SYS_RAM_UNCERR_ADDR): in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted." Section 79.6.2.12, Peripheral RAM uncorrectable error reporting table address register (PERIPH_RAM_UNCERR_ADDR): in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted." Section 79.6.2.17, Flash memory uncorrectable error reporting table address register (FLASH_UNCERR_ADDR): in the ERR_ADD field description, deleted "This register must be READ ONLY when its corresponding valid bit is not asserted." Chapter 80, Indirect Memory Access (IMA): editorial and fomatting updates Chapter 81, Fault Collection and Control Unit (FCCU) Section 81.5.2, FSM description: changed expression "written in the FCCU_TRANS_LOCK" to "written in the FCCU_PERMNT_LOCK" Replaced "can be masked" with "cannot be masked" in Section 81.5.7, FAULT interface and Section 81.6.18, FCCU RF Fake Register (FCCU_RFF) Section 81.9.2, Recommendations to configure FCCU: in "Read and verify default value..." list item, replaced "FCCU_NCF_Ex" with "FCCU_RF_Ex" Added note "Till FCCU_SET_AFTER_RESET is written..." in Table 1826 (Dual-rail encoding), Table 1827 (Time-switching encoding), and Table 1828 (Bi-stable encoding) Chapter 82, Self-Test Control Unit (STCU2) Section 81.2, Main features: added bulleted list item "Hardware capability to enable or disable the execution of hardware selected LBIST or MBIST" Added Section 81.4.11, LBIST/MBIST execution restriction Chapter 83, Register Protection (REG_PROT): unchanged Chapter 83, Password and Device Security Module (PASS): unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Chapter 85, Tamper Detection Module (TDM) Table 1940 (DBA field descriptions): added note "Diary Base Address must be on 16K boundary" in DBA field description Throughout chapter: added registers STO_KEYn Section 85.1, Overview: • Deleted note explaining the TDM's role as one of several modules that provide an integrated set of security functions within the chip • Added note "The PASS module provides the control for erase operation for..." • Added to list of security information passed to TDM by SSCM module: "Software tamper region override" Figure 2019 (Diary Base Address (DBA) DCF client): • Updated block diagram to indicate that interaction between SSCM module and SSCM functionality within the TDM is bidirectional. • Minor editorial fixes Section 85.4, DCF client: introduction replaced with brief description of TDM DCF client funtions Section 85.6.4, Specifying the diary base address: the TDM diary base address must be on a 16 KB boundary Changed DCF client description in introductory paragraph of OTPEN0–OTPEN4 DCF client sections Chapter 86, Wakeup Unit (WKPU): unchanged Chapter 87, Emulation and Debug Device Introduction Section 87.5, Reset logic: specified "PHASE3" PD reset signal Chapter 88, Buddy Device—Crossbar and RAM (BD_XBS_RAM): unchanged Chapter 89, Buddy Device—System Integration Unit Lite (BD_SIUL2): unchanged *Chapter 65: Buddy Device—Debug and Calibration Interface (DCI)*: unchanged *Chapter 64: Buddy Device—JTAG Controller (JTAGC)*: unchanged *Chapter 59: Buddy Device—JTAG Master (JTAGM)* *Table 1345: JTAGM_SR register field descriptions*: updated binary combination descriptions for fields EVTI0_ASSERT and EVTI0_ASSERT Revised Section 59.4.1.2, Status register (JTAGM_SR) Chapter 93, Buddy Device—Nexus Aurora Router (NAR): unchanged Chapter 94, Buddy Device—Nexus Aurora Link (NAL): unchanged Chapter 95, Buddy Device—Nexus Aurora PHY (NAP): unchanged Chapter 96, Buddy Device—Data Write Processing Unit (DWPU): unchanged Chapter 97, Buddy Device—Nexus Read Write Access (RWA): unchanged *Chapter 50: Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug* Removed reference to 312/320 MHz from entire chapter and referred to as high data rate.

Table 2015. Revision history(Continued)

Date	Rev.	Changes
19 Dec 2014	4 (cont'd)	Section 50.6.2.10, LVDS Control Register (LCR): • Added field "LVTXOP" at bit 29 • Field "LVRXOP" (bits 26–28) is now split into 3 individual bits: LVRXOP_TR (bit 26), Reserved (bit 27), and "LVRXOP_BR" (bit 28) • Updated field description "LVCKSS" Section 50.6.2.16, Rx Interrupt Status Register (RISR): removed fields "RXMNF" (bit 9) and "RXMXF" (bit 10) Section 50.7.6.1.2, Data receive: in the first paragraph, changed "MCR[TXEN]" to "MCR[RXEN]". *Appendix A: Acronyms and abbreviations*: unchanged
16 Jun 2015	5	Throughout document: editorial and formatting changes Chapter 1, Preface: unchanged Chapter 2, Introduction Section 2.1.1, Target applications: added info on device safety manual Table 3 (SPC574K72 device feature summary): updated "PSI5 bus" to "PSI5" Chapter 3, Embedded memories: Section 3.1, Overview: removed "AMU" instance *Chapter 4: Signal description* *Table 3: LVDS production pin descriptions*: • Renamed (was "LVDSM pin descriptions") • Changed the signals of the port pins PA[8], PA[7], PA[9], and PA[5] in "Debug LFAST" functional block *Table 4: LVDS emulation pin descriptions*: renamed (was "LVDSF pin descriptions") *Chapter 5: Memory map* *Table 18: UTEST flash memory map*: updated "Unique Identifier (UID)" comments Chapter 6, Functional Safety Section 6.4.1.5.2, Online Logical BIST (LBIST): added note "Since LBIST/MBIST is runnng...executing code" Moved section "FCCU failure inputs from other modules" to *Chapter 2: Device Configuration* *Chapter 2: Device Configuration* Section 7.8.2.3, Default configuration: added brief explanation of how Security Watchdog is enabled. Removed section "GTM integration module configuration" Added Section 7.8.4, GTM subsystem configuration *Table 67: BAF memory organization*: changed address range of "BAF data area and stack" BAF component from"5280_0000h – 5280_01FFh" to "5280_0000h – 5280_034Fh" Section 2.8.1, FEC interface: • Removed line "The MII Management Frame Register (MMFR) is not supported on K2." • Updated note

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	*Table 86: SRAM arrays accessible via IMA*: In "ECC bits" column, replaced 36–30 with 35–30 for GTM block and replaced 31–25 with 30–25 for DPLL. Section 7.11.4.1, Available FCCU output signals: added sentence "Clearing fault(s) corresponding to.....above HVD threshold". Added Section 7.11.4.2, FCCU failure inputs from other modules: moved from the "Functional Safety" chapter Figure 25 (PASS_LOCK0_PGn Register): changed "Read Lock Region 0" to "Read Lock Region 1" Chapter 8, Reset and Boot: unchanged Chapter 9, Device Configuration Format (DCF) Records: unchanged *11: Power management*: unchanged Chapter 11, Security: : unchanged *Chapter 7: Calibration and Debug* Added note "The EVTO signal provided to the JTAGM is stretched by the DCI on..." to EVTO[0] and EVTO[1] in *Table 14: PD DCI signals* and *Table 15: BD DCI signals* *Chapter 8: Core Complex Overview*: no substantial changes *Chapter 1: Core e200z410Dn3 description*: unchanged *Chapter 1: Core e200z225Bn3 description*: unchanged *Chapter 2: System Integration Unit Lite2 (SIUL2)* *Table 51: SIUL2_MSCR_0–SIUL2_MSCR_511 field description*: updated "HYS" field description. *Table 52: I/O MSCR reset state exceptions*: updated "SSS" values for the ports PA[5]–PA[9], PB[11], and PC[2] Chapter 17, Crossbar Switch (XBAR) Revised Section 17.1.2, Memory map and register definition to show the register configurations for all eight master and slave ports (independently from a specific device and IP instances) Chapter 18, Crossbar Integrity Checker (XBIC): unchanged Chapter 19, Peripheral Bridge Section 19.1.2, General operation: added note "FlexRay access to peripherals via the peripheral bridge is not supported" Chapter 20, System Memory Protection Unit (SMPU): unchanged Chapter 21, Intelligent AHB Gasket (IAHBG): unchanged Chapter 22, Semaphores2 (SEMA42): unchanged Chapter 23, Interrupt Controller (INTC) Throughout the chapter, changed number of priorities from "16" to "64"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	Chapter 24, Enhanced Direct Memory Access (eDMA) Table 317 (DMA_TCDn_CSR field descriptions): changed "XBS" to "XBAR" in "BWC" field description. Chapter 25, Direct Memory Access Multiplexer (DMAMUX): unchanged Chapter 26, Clocking Figure 248 (Clock generation): removed "CLKOUT" output signal from "PCS" block Table 332 (JTAG frequencies): added note "Frequency can further be limited due to device implementation. Please refer to datasheet for maximum NEXUS..." *Chapter 27: Dual PLL Digital Interface (PLLDIG)*: no substantial changes Chapter 28, Clock Monitor Unit (CMU): unchanged *Chapter 29: Clock Generation Module (MC_CGM)*: unchanged Chapter 30, OSC Digital Interface (XOSC): no substantial changes Chapter 31, IRCOSC digital interface Table 419 (IRCOSC_CTL[USER_TRIM] frequency trimming calculation) : frequency trimming calculation updated to use "δf_{TRIM}" in place of "δf_{var_SW} " Chapter 32, RAM controller (PRAMC): unchanged Chapter 33, Flash memory controller (PFLASH Controller) Figure 351 (Platform Flash Configuration Register 1 (PFCR1)): renamed field "PO_IFPFEN" to "PO_IPFEN" Chapter 34, Embedded Flash Memory (MP55) Added following table in Section 1.3.2.9, Address register (ADR): • *Table 19: Flash memory partition 0 addresses mapping* • Table 456 (Flash Memory Partition 1 addresses mapping) • Table 457 (Flash Memory Partition 2 addresses mapping) Chapter 35, Decorated Storage Memory Controller (DSMC): unchanged Chapter 36, Flash Memory Programming and Configuration Section 36.3.1, Implementing secure write protection: changed the relevant fields from RL4–RL0 to RL2–RL0 *Chapter 1: Analog-to-digital converter (ADC) configuration* Updated Section 1.2.1.5.2, Sigma-Delta Mux Input Advance and Wrap Around Chapter 38, Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface: unchanged Chapter 39, Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface: unchanged Chapter 40, Temperature Sensor: unchanged Chapter 41, Timers overview: unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	Chapter 42, System Timer Module (STM): unchanged Chapter 43, Software Watchdog Timer (SWT): unchanged Chapter 44, Periodic Interrupt Timer (PIT): unchanged Added *Chapter 1: GTM Integration (GTMINT) Module* Removed Chapter "GTM122 Integration (GTMINT) Module" Added Chapter 46, Generic Timer Module (GTM122) Chapter 47, GTM Development Interface (GTMDI) Added Section 47.1, About this module Section 47.2, Introduction: added two paragraphs to introductory paragraph Chapter 48, CAN Subsystem: unchanged Chapter 49, Serial Interprocessor Interface (SIPI) Section 49.15.1.8, SIPI Module Configuration Register (SIPI_MCR): updated register access of Reserved bit field from read only zero to read/write. Chapter 50, Deserial Serial Peripheral Interface (DSPI) Table 859 (DSPI memory map): updated reset value of DSPI Status Register (DSPIx_SR) to 0201_0000h. Section 50.3.12, DSPI DSI Configuration Register 0 (DSPI_DSICR0): changed access type for all the reserved bit fields to R/W Section 50.3.17, DSPI DSI Configuration Register 1 (DSPI_DSICR1): • Renamed field "TSBCNT[5:0]" to "TSBCNT" • Updated the access value of DSI64E bit from RW to RO • Updated "TSBCNT" field description Updated Section 50.5.3.3, DSI serialization Section 50.5.3.5, DSI transfer initiation control: removed "TRRE" field instance from introductory paragraph *Chapter 2: LVDS Fast Asynchronous Serial Transmission (LFAST) – Interprocessor Communications*: unchanged Chapter 52, Fast Ethernet Controller (FEC): unchanged Chapter 53, FlexRay Communication Controller (FlexRay): unchanged Chapter 54, Inter-Integrated Circuit (I^2C): unchanged Chapter 55, Peripheral Sensor Interface (PSI5): unchanged Chapter 56, SENT Receiver (SRX) Table 1258 (SRX_GBL_CTRL field descriptions): added note "This bit should be set to 1..." into the "NIB_LEN_VAR_LIMIT" field description Table 1274 (SRX_CHn_CLK_CTRL field descriptions): in "CM_PRSC" field desciption, removed note "The value provided in this field is ... by the Receiver" In Section 56.4.4.1, Fast messages buffers, updated sentence "The receiver channel stores message in its buffer and indicates an ... new message arrives."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	Updated Section 56.4.4.2, Slow message buffers Table 1277 (Behavior of NUM_EDGES_ERR): updated "cause for extra error bits getting asserted" column for "NIB_VAL_ERR" and "FMSG_CRC_ERR" Figure 1258 (DMA Slow Serial Message Bit2 Read Register (SRX_DMA_SMSG_BIT2)): renamed field "DATA[11:8]" to "ID3_0_DATA11_8" Table 1272 (SRX_DMA_SMSG_BIT2 field descriptions): added description of field ID3_0_DATA11_8 and updated description of field DATA[7:0]. Chapter 57, LINFlexD: no substantial changes *Chapter 3: Reset Generation Module (MC_RGM)*: no substantial changes *59: Boot Assist Flash (BAF)* Added information relating to the "NO_ECHO bit" throughout the chapter *Table 1333: BAF image version*: changed description of field "[16:23]" to Reserved (was "BAF Type") *Section 59.2.1, Boot modes*: in serial boot mode, • Changed life cycle from "CUST_DEL" to "IN_FIELD" • Added "M_CAN" interface *Figure 1388 (Flow of control)*: removed block "Delay Xs" *Section 59.2.6, Production disable activation protocol and implementation*: changed the 64-bit flag in BAF code flash region value from "7FFF_FFFFh" to "FFFF_FFFEh" Chapter 60, System Status and Configuration Module (SSCM): unchanged Chapter 61, Power Management Controller digital interface (PMC_dig) Section 61.3.1.45, Voltage Detect User Mode Test register (VD_UTST): added text "LVD self test works only when LVD/HVD is deasserted. When LVD/HVD is asserted, the self test will flag an error...." to the introductory paragraph *Chapter 2: Power Control Unit (MC_PCU)*: unchanged *Chapter 1: Mode Entry Module (MC_ME)* *Table 2: MC_ME register description*: removed "ADCSD_2 Control (ME_PCTL59)" register Updated Section 63.4.2.6, STOP0 mode *Chapter 13: e200z410Dn3 Core Debug Support*: unchanged *Chapter 13: e200z225Bn3 Core Debug Support*: unchanged Chapter 66, Debug and Calibration Interface (DCI): unchanged *Chapter 64: JTAG Controller (JTAGC)*: unchanged Chapter 68, IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG): unchanged Chapter 69, JTAG Data Communication (JDC) Changed access type of register "JDC_MSR" to w1c (was RW) Section 69.2, Overview: removed sentence "The JTAG accessible registers..."

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	Section 69.3.1.3, JTAG output IPS data register (JDC_JOUT_IPS): renamed field "JOUT_IPS Data" to "DATA" Section 69.3.1.4, JTAG input IPS data register (JDC_JIN_IPS): renamed field "JIN_IPS Data" to "DATA" Chapter 70, JTAG Master (JTAGM) Section 70.4.1.1, Module configuration register (JTAGM_MCR): removed text "This register contains the status bits for the current transfer" from the introductory paragraph. Figure 1601 (JTAGM_MCR register): changed access type of fields relative to bits 1–7 from "write only" to "read/write". Figure 1604 (JTAGM_DOR1 register): changed access type of field "TMS_LOW" from "read only" to "read/write" Figure 1606 (JTAGM_DOR3 register): changed access type of field "TMS_LOW" from "read only" to "read/write" Chapter 71, Sequence Processing Unit (SPU): unchanged Chapter 72, LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug: unchanged Chapter 73, Development Trigger Semaphore (DTS): unchanged Chapter 74, Nexus Aurora Router (NAR): unchanged *Chapter 14: e200z410Dn3 Nexus 3 Module*: unchanged *Chapter 14: e200z225Bn3 Nexus 3 Module*: unchanged Chapter 77, Nexus Crossbar Multi-Master Client (NXMC): unchanged Chapter 78, Cyclic Redundancy Check (CRC) Unit: unchanged Chapter 79, Memory Error Management Unit (MEMU) Revised Figure 1871 (MEMU error buffer uniqueness check flow chart) and Figure 1872 ([BLG_MEMU_0061][Covers: Saf1894]MEMU reporting table uniqueness check flow chart[end]). In Section 79.6.2.7, System RAM uncorrectable error reporting table address register (SYS_RAM_UNCERR_ADDR), added sentence "This field must be read-only when its corresponding valid bit..." to the ERR_ADD field description. In Section 79.6.2.12, Peripheral RAM uncorrectable error reporting table address register (PERIPH_RAM_UNCERR_ADDR), added "This field must be read-only when its corresponding valid bit..." to the ERR_ADD field description. In Section 79.6.2.17, Flash memory uncorrectable error reporting table address register (FLASH_UNCERR_ADDR), added "This field must be read-only when its corresponding valid bit..." to the ERR_ADD field description. Chapter 80, Indirect Memory Access (IMA): unchanged Chapter 81, Fault Collection and Control Unit (FCCU) Section 81.5.2, FSM description: addes sentence "Also, FCCU_CFG_TO ... a configuration register." into CONFIG bulleted list item

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	Section 81.8, FCCU Output Supervision Unit: added sentence "This signal is automatically de-asserted ...in CONFIG state." into third paragraph "There is a 'do nothing' input coming..." Chapter 82, Self-Test Control Unit (STCU2) Section 82.5.12, STCU2 Off-line LBIST Status Register (STCU_LBS): updated register bitmap to show sixteen individual fields LBE0–LBE15. Chapter 83, Register Protection (REG_PROT): unchanged Chapter 84, Password and Device Security Module (PASS) Table 1921 (LCSTAT register field descriptions): in LIFE field description, added "ST Production" to binary combination "110" Table 1935 (Flash Memory Read Protection Truth Table): • Added "Censored" Censorship contents for "Failure Analysis" Lifecycle • Changed column "Read Protected RL[4:1] (Other Regions)" to "Read Protected RL[2:1] (Other Regions)"; Chapter 85, Tamper Detection Module (TDM): unchanged Chapter 86, Wakeup Unit (WKPU): unchanged Chapter 87, Emulation and Debug Device Introduction: unchanged Chapter 88, Buddy Device—Crossbar and RAM (BD_XBS_RAM): unchanged Chapter 89, Buddy Device—System Integration Unit Lite (BD_SIUL2): unchanged *Chapter 65: Buddy Device—Debug and Calibration Interface (DCI)*: unchanged *Chapter 64: Buddy Device—JTAG Controller (JTAGC)*: unchanged *Chapter 59: Buddy Device—JTAG Master (JTAGM)* Section 59.4.1.1, Module configuration register (JTAGM_MCR): removed text "This register contains the status bits for the current transfer" from the introductory paragraph. Figure 1327 (JTAGM_MCR register): changed access type of fields relative to bits 1–7 from "write only" to "read/write". Figure 1330 (JTAGM_DOR1 register): changed access type of field "TMS_LOW" from "read only" to "read/write" Figure 1332 (JTAGM_DOR3 register): changed access type of field "TMS_LOW" from "read only" to "read/write" Chapter 93, Buddy Device—Nexus Aurora Router (NAR): unchanged Chapter 94, Buddy Device—Nexus Aurora Link (NAL): unchanged Chapter 95, Buddy Device—Nexus Aurora PHY (NAP): unchanged Chapter 96, Buddy Device—Data Write Processing Unit (DWPU): unchanged Chapter 97, Buddy Device—Nexus Read Write Access (RWA): unchanged

Table 2015. Revision history(Continued)

Date	Rev.	Changes
16 Jun 2015	5 (cont'd)	*Chapter 50: Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug*: unchanged *Appendix A: Acronyms and abbreviations*: unchanged
12-Dec-2017	6	Updated I/O signal in attached xls. *Chapter 5: Memory map* *Table 11: Flash memory and overlay RAM map*: "UTEST NVM Block – no overlay" updated to "NVM Block – no overlay" *Table 14: UTEST flash memory map*: Removed Reserved area from address "0x00400308" to "0x00400347" *Chapter 7: Device Configuration* *Section 7.11.1: PMC ADC test mode:* "Channel 100" replaced by "Test Channel TCDR 110" *Figure 39: Simplified PMC ADC test multiplexer block diagram: Updated the following:* • For LVDxxx_A, "3.3V" divider updated to "3.53V" • For LVDxxx_IM, "3.3V" divider updated to "3.53V" • For LVDxxx_F, "3.3V" divider updated to "3.53V" • For LVDxxx_C, "3.3V" divider updated to "3.42V" Updated *Table 116: LVD/HVD self test decoding* Updated *Table 97: FCCU failure inputs1* *Section 7.12: Production device vs. emulation and debug device*Added note "For Global (Development tool client) stall control, dct_evti[0] is selected. " *Chapter 9: Device Configuration Format (DCF) Records* *Figure 51: Appending DCF records*: "Data Record - CS2, Ad = 1" updated to "Data Record - CS2, Ad = 0" *Chapter 11: Power management* *Table 123: Device power management controller external signals*: Added a note to parameter $V_{DD_LV_BD}$. *Section 11.1.3: SPC574Kx power management controller overview*: Removed bullet point "Safety regulator with internal ballast...." *Chapter 16: System Integration Unit Lite2 (SIUL2)* *Table 233: SIUL2_MSCR_0–SIUL2_MSCR_511 field description*: For ILS, IBE, HYS, WPDE, and WPUE, replaced text "Used only when..." with "when a pin is used...." *Chapter 26: Clocking* *Table 331: Maximum system level clock frequencies*: Added note "clock ratio is defined through..." to "PBRIDGE_A GTM Slot" *Chapter 36: Flash Memory Programming and Configuration* *Section 36.7.1: Unconditional test mode disable seal*: Replaced value "0x2D3C_4B5A" with "0x5A4B_3C2D" *Section 36.7.2: Passcode-protected test mode disable seal*: Replaced value "0x2D3C_4B5A" with "0x5A4B_3C2D"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
12-Dec-2017	6 (cont'd)	*Chapter 37: Analog-to-digital converter (ADC) configuration* *Section 37.2.2.8.1: Self Test features*: Replaced value "2.2 ms" with "2.5 ms" *Figure 414: SARADC integration diagram:* Updated the figure, from "7 external pin trigger inputs" to "9 external pin trigger inputs" *Table 495: SARADC_B analog test channel assignment*: • Updated heading from "SARADC_B input channel" to "SARADC_B TCDR input channel" • Changed the description of 106 and 115 to "Reserved" • Added 4 new columns: Value in Hexadecimal, Value in Decimal, Conversion factor, Value converted Updated *Chapter 48: CAN Subsystem* – TEST.TDCV updated to PSR.TDCV throughout the chapter – FBTP.TDCO updated to TDCR.TDCO throughout the chapter – Reset value of *Section 48.3.15.3.3: Calibration Configuration Register (CCFG)* register updated to 0x444 – *Section 48.3.5.2: Register map*: Added note "The maximum size and the minimum granularity of the configurable...." to SIDFC, XIDFC, RXF0C, RXF1C, RXBC, TXBC, and TXEFC registers. – *Section 48.3.5.2.44: Tx Event FIFO Configuration Register (TXEFC)*: Updated the description of "EFSA" field. Updated *Chapter 57: LINFlexD*: LIN protocol version 2.2 added in description. *Chapter 58: Reset Generation Module (MC_RGM)* *Section 58.4.2: Destructive resets*: Text "The memory content...STCU module" updated to "The memory content is considered unknown" *Chapter 60: System Status and Configuration Module (SSCM)* *Figure 1406: Appending DCF records*: In the "Initial Programming" block, "CS1" updated to "CS0", "CS2" updated to "CS1" and "CS0" updated to "CS2" *Chapter 61: Power Management Controller digital interface (PMC_dig)* *Table 1360: Power Management Controller memory map*: For register "VREG1P2_CTRL", reset value changed from "0x0000_0000" to "0x0000_0003" *Table 1405: VD_UTST field descriptions*: Updated description of field "VD_UTST" *Chapter 81: Self-Test Control Unit (STCU2)* *Table 1835: STCU_MBSH field descriptions*: In description of field "MBSx", "STCU_MBEL" updated to "STCU_MBEH". *Table 1834: STCU_MBSM field descriptions*: In description of field "MBSx", "STCU_MBEL" updated to "STCU_MBEM". *Table 1819: STCU_CFG field descriptions*, *Table 1821: STCU_WDG field descriptions* : For core clock cycles, added footnote "STCU2 is being clocked from PBRIDGE Clock. Please refer Clocking chapter for PBRIDGE Clock Frequency value." *Section 81.5.33: STCU2 LBIST Control Register (STCU_LB_CTRLn)* - *Section 81.5.42: STCU2 On-line LBIST MISR Expected High Register (STCU_LB_MISREHSWn)*: All registers updated with variable "n" in the name. Also specified the value of parameter "NLBIST"

Table 2015. Revision history(Continued)

Date	Rev.	Changes
12-Dec-2017	6 (cont'd)	*85: Wakeup Unit (WKPU)* *Section 85.1.2: Features*: – Added item "15 I/O external interrupts: 4–14 and 16–19 wakeup lines" *Table 1900: WKPU memory map*: added registers "WISR", "IRER", "WRER", "WIREER", "WIFEER", "WIFER", and "WIPUER" Added *Section 85.3.2.3: Wakeup/Interrupt Status Flag Register (WISR)* Added *Section 85.3.2.4: Interrupt Request Enable Register (IRER)* Added *Section 85.3.2.5: Wakeup Request Enable Register (WRER)* Added *Section 85.3.2.6: Wakeup/Interrupt Rising-Edge Event Enable Register (WIREER)* Added *Section 85.3.2.7: Wakeup/Interrupt Falling-Edge Event Enable Register (WIFEER)* Added *Section 85.3.2.8: Wakeup/Interrupt Filter Enable Register (WIFER)* Added *Section 85.3.2.9: Wakeup/Interrupt Pullup Enable Register (WIPUER)* Added *Section 85.4.2: External Wakeups/Interrupts* *Chapter 86: Emulation and Debug Device Introduction* *Section 86.2: Feature summary*: Removed feature "Data Write Processing Unit (DWPU)" *Table 1911: Reset sources and functional blocks:* Reference to DWPU removed. *Table 1912: BD memory map:* Reference to DWPU removed. Added new *Figure 1992: BD clock structure* Updated *Figure 1991: Emulation and debug device architecture*: Removed DWPU block *Chapter 92: Buddy Device—Nexus Aurora Router (NAR)* *Section 92.5.13: Global (Development tool client) stall control*: Updated the text. *Table 1956: NAR_AHFPAR field description*: Updated the description of "GSE" field.
