Reference manual

STM32MP153
advanced Arm®-based 32-bit MPUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32MP153 microprocessor memory and peripherals.

The STM32MP153 is a family of microprocessors with different packages and peripherals.

Refer to the corresponding datasheets for ordering information, mechanical and electrical device characteristics.

For information on the Arm® Cortex®-A7 and Cortex®-M4 cores, refer to the Cortex®-A7 and Cortex®-M4 *Technical Reference Manuals*.

The STM32MP153 microprocessors include ST state-of-the-art patented technology.

1 Documentation conventions

1.1 General information

The STM32MP153 devices embed an Arm®[a] Cortex®-M4 with FPU and a dual Arm® Cortex®-A7 with FPU cores.

1.2 List of abbreviations for registers

The following abbreviations[b] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- The product integrates two debug ports:
  - JTAG debug port (**JTAG-DP**) provides a 5-pin standard interface based on the Joint Test Action Group (JTAG) protocol.
  - SWD debug port (**SWD-DP**) provides a 2-pin (clock and data) interface based on the Serial Wire Debug (SWD) protocol.
- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **Double word**: data of 64-bit length.
- **Option bytes**: product configuration bits stored in internal fuses.
- **OTP**: one-time programming (fuses).
- **AHB**: advanced high-performance bus.
- **APB**: advanced peripheral bus.
- **AXI**: Advanced extensible interface protocol.
- **ECC**: error code correction.
- **DMA**: direct memory access.
- **AHBS**: AHB slave bus.
- **AXIM**: AXI interconnect matrix.

1.5 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

2 Memory and bus architecture

2.1 System architecture

2.1.1 Bus architecture

The bus architecture is organized around two interconnect matrix, which operate in different frequency domains, as described in *Figure 1*.

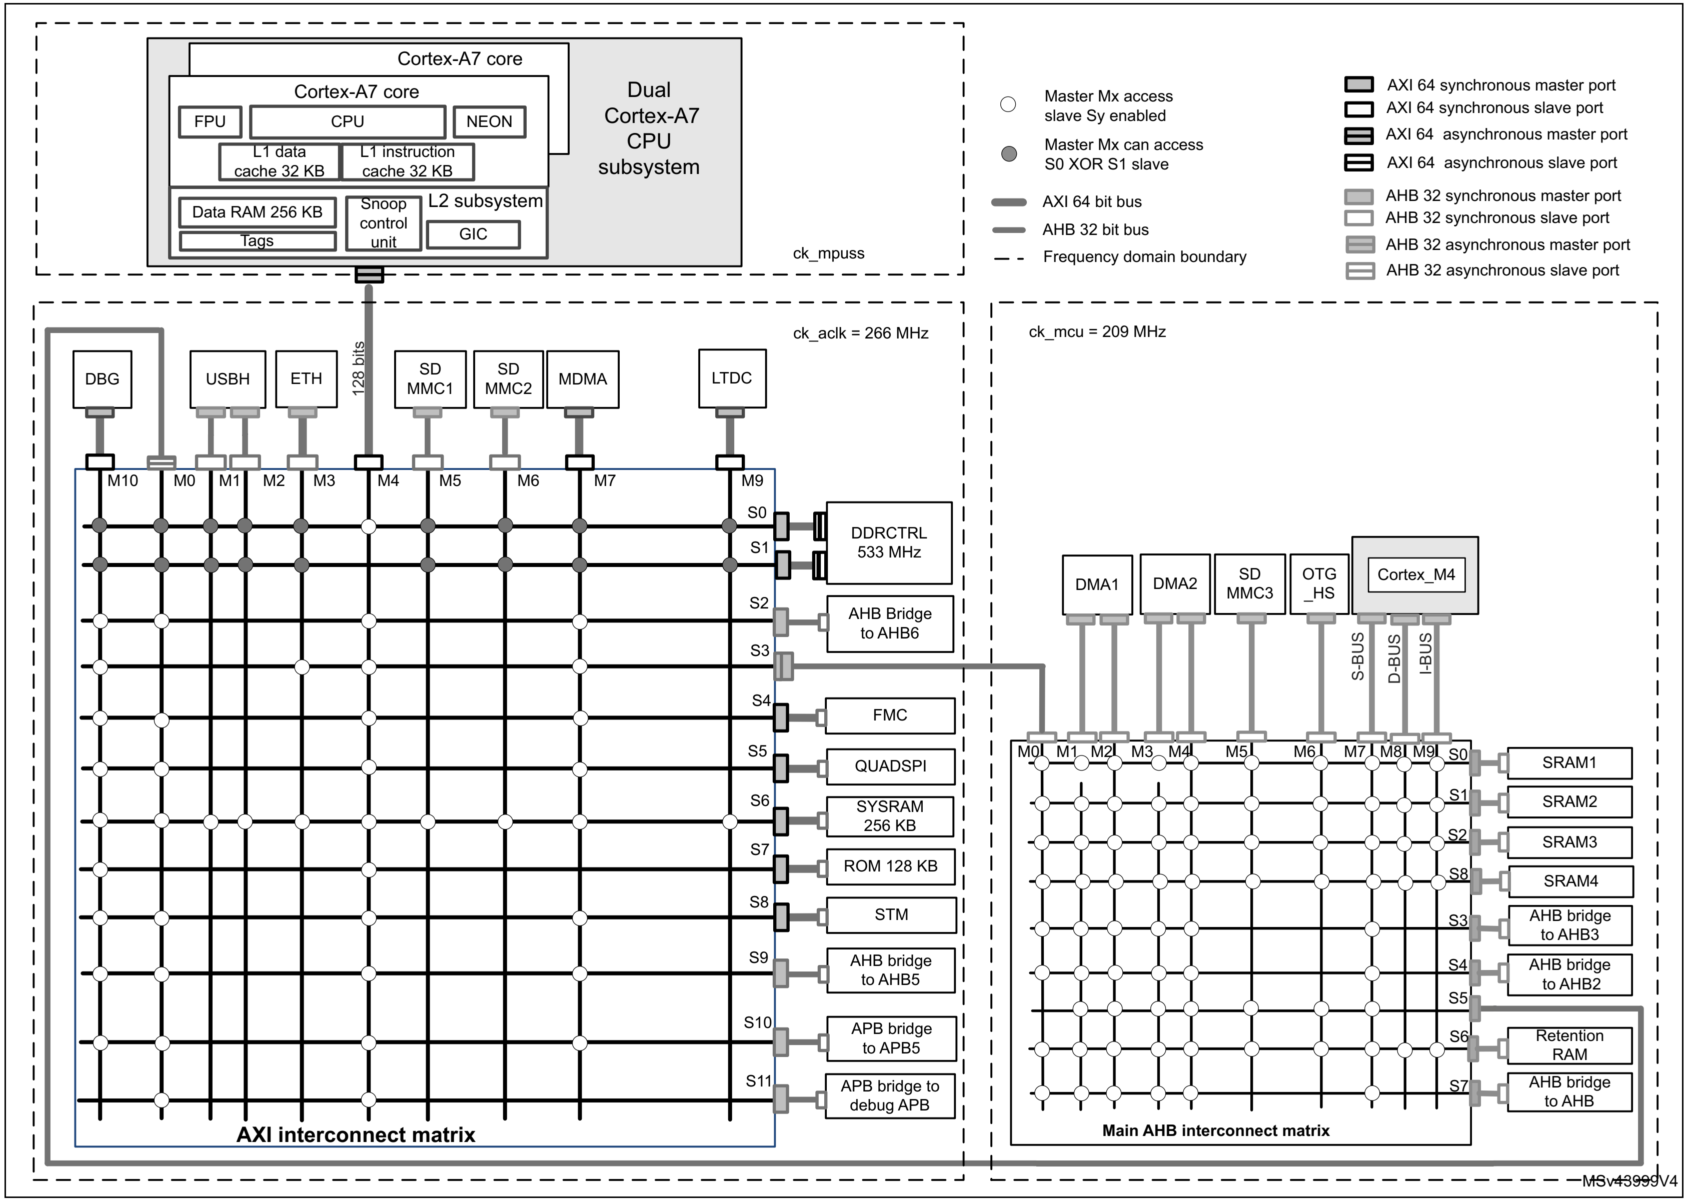
- One high speed **Arm® CoreLink™ NIC-400 network interconnect AXI-based**:
  This interconnect is dedicated to Cortex-A7 CPU subsystem and high bandwidth masters (this part of the system is called MPU-side in the following): USBH, ETH, SDMMC1/2, MDMA, LTDC.
  It manages accesses to:
  - external memories DDR (through DDRCTRL), NAND/NOR (through FMC or QUADSPI)
  - main system internal memories SYSRAM and ROM
  - main cluster of security peripherals through AHB5 bus
  - some low-speed communication peripherals through APB5 bus
  - control and configuration of the high-bandwidth masters
  - STM (system trace macrocell)
- One **multi-layer AHB interconnect** with an architecture inherited from former MCU families (this part of the system is called MCU-side in the following).
  This interconnect is dedicated to Cortex-M4 subsystem and associated masters: OTG, DMA1/2, SDMMC3.
  It manages accesses to:
  - Cortex-M4 dedicated SRAM1,2,3,4
  - most timers and low-speed communication peripherals through AHB2 bus
  - Cortex-M4 dedicated retention memory (RETRAM)
  - secondary cluster of security peripherals and camera interface through AHB3 bus
  - resources dedicated to communication with Cortex-A7 cluster: mailbox and semaphore through AHB3 bus
  - main infrastructure blocks as clock generation, power control, system configuration, and miscellaneous peripherals through AHB4 bus

AXI and multi-layer AHB matrix are connected to each other through one dedicated data-path in both directions:

- AXIM master port has access to all multi-layer AHB slaves. Some of them can become not accessible when the M4 isolation feature is activated.
- Multi-layer AHB master has access to all AXI slaves except:
  - ROM
  - slaves that can be accessed in secure mode only.

The bus architecture diagram in *Figure 1* describes the interconnect for STM32MP153 family.

Figure 1. Bus interconnect for STM32MP153



2.1.2 Memory Map organization

Introduction

For the detailed mapping of available memory and register areas, please refer to *Section 2.5: Memory organization*.

The following paragraphs describe the various resources in the system.

Embedded Memories

- **ROM**
  The 128 Kbyte embedded ROM is a fast access memory (no wait states). It is dedicated to Cortex-A7 CPU subsystem for boot code execution.This memory and the associated memory controller operate at aclk = 266 MHz.
- **Cortex-A7 CPU subsystem cache memories**
  Please refer to Cortex-A7 CPU subsystem description for cache memories characteristics.
- **SYSRAM**
  The 256 Kbyte embedded SYSRAM is a fast access static RAM, dedicated to Cortex-A7 CPU subsystem for code execution and low-latency data management. The SRAM itself is 0 wait-states. Some latency is added when data is propagated through the AXI interconnect.This memory and the associated memory controller operate at aclk = 266 MHz.
- **MCU SRAM1,2,3,4**
  The SRAM1,2,3,4 are two 128 Kbyte and two 64 Kbyte fast access static RAMs dedicated to Cortex-M4 MCU for code execution, low-latency data management, and data storage for exchange with the Cortex-A7 CPU subsystem.The SRAM1,2,3,4 are 0 wait-states. Some latency is added when data is propagated through the AHB interconnect. These memories and the associated memory controllers operate at mcu_ck = 209 MHz.
- **Retention RAM (RETRAM)**
  The RETRAM is a 64 Kbyte fast access static RAMs with specific supply providing data retention in all power modes including V_{BAT} and STANDBY. The RETRAM is 0 wait-states. Some latency is added when data is propagated through the AHB interconnect (access from MCU-side), or AXI and AHB interconnects (access from MPU-side).This memory and the associated memory controllers operate at mcu_ck = 209 MHz.
- **Backup RAM**
  The backup RAM is a 4 Kbyte static RAMs with dual-rail supply providing data backup for the whole system, whatever the power mode, with standard latency.This memory and the associated memory control operate at hclk5 = 266 MHz.
- **OTP**
  OTP is a secure one-time-programmed non volatile memory with 3072 effective bits in total. It contains system configuration information.This memory and the associated memory controllers operate at pclk5 = 133 MHz.

  OTP is auto-loaded after reset. Bits are held in shadow registers accessible at 133 MHz.

External memories support

- **DDR3/LPDDR2 controller (DDRCTRL)**

  The DDR supported types are LPDDR2, LPDDR3, DDR3/3L. Regarding external memory, 16 or 32 bits data width are possible, while internally, the DDRCTRL is connected to 64-bit data width interconnect. The maximum supported size is 1 Gbytes.

  The DDRCTRL is accessible through two AXI data ports, which have same characteristics. A system configuration register allows a given master to select which port to use, to balance traffic between the two ports.

  More information on memory characteristics and controller parametrization are available in *Section 5: DDR3/LPDDR2/LPDDR3 controller (DDRCTRL)* and *Section 7: DDR physical interface control (DDRPHYC)*.

  The DDRCTRL operates at aclk = 266 MHz. The external memory operates at up to pll2_r = 533 MHz depending on the system configuration.

- **Flexible memory controller (FMC) / QUADSPI**

  There is no internal Flash memory in the SoC. The system initial-boot-phase and self-initialization is supported by boot ROM and BSEC.

  External Flash memory is accessible through NAND configurable FMC, or through QUADSPI.

  The FMC also allows parallel connection of a SRAM/PSRAM instead of Flash memory if needed.

- **SD/SDIO/MMC card host interfaces (SDMMCx)**

  There is no internal Flash memory in the SoC. The system initial-boot-phase and self-initialization is supported by boot ROM and BSEC.

  External Flash memory such as SD card or *e*•MMC are accessible through SDMMCx

  SD, SDIO, eMMC devices are interfaced through three SDMMC controllers. Two of them are hooked to the AXIM interconnect and the third one to multi-layer AHB subsystem.

  These controllers are masters of the interconnect and originate the transfers to/from SD/SDIO/MMC memories.

Peripherals clusters

There are seven peripherals clusters in the system, briefly described hereafter.

Note: the AHBx/APBy notation means that the resources are accessed through bus AHBx, and for some of them through bus AHBx in combination with bus APBy.

- **AHB4/APB3**
  This cluster groups important system functions as clock and power control, system configuration, most GPIOs control, plus some additional timers and low-speed communication interfaces.
- **AHB3**
  This cluster groups some security blocks dedicated to Cortex-M4, camera interface and interprocessor communication resources.
- **AHB2/APB1-APB2**
  This cluster groups most of the usual MCU peripherals: timers, low-speed communication interfaces (SPI, I2C, U(S)ART, SAI), ADC, DAC, FDCAN and DFSDM.
  All those IPs are typically controlled by Cortex-M4, directly or through DMA1/2, but can also be managed by Cortex-A7 CPU subsystem as well.
- **AHB5**
  This cluster groups security blocks dedicated to Cortex-A7 and the backup RAM.
- **APB5**
  This cluster groups some low-speed secure communication blocks dedicated for Cortex-A7, in addition to BSEC and chip configuration control resources.
  Real time clock generation and anti-tamper features also belong to this cluster.
- **AHB6/APB4**
  This cluster groups most of the graphic/display resources control, as well as access to configuration registers of the fast masters: MDMA, ETHernet, SDMMC1/2,USBH.
- **Debug**
  This cluster groups all debug features including Arm® CoreSight™ infrastructure.

Memory map overview

Table 1 summarizes which master (cf *Figure 1*) can access which memory-mapped resource.

Table 1. Memory map overview STM32MP153

Resource	Cortex-A7	Cortex-M4	De-bugger	MDMA / DMA1 / DMA2	ETH	OTG / SDMMC3	USBH / SDMMC1,2 / LTDC
DDR	x	x	x	x	x	x	x

1. Cortex-A7 accesses its own debug resources through CoreSight infrastructure.
2. Cortex-A7 and debugger see the ROM, while the Cortex-M4 access RETRAM at this location.

2.2 AXI interconnect matrix (AXIM)

2.2.1 AXIM features

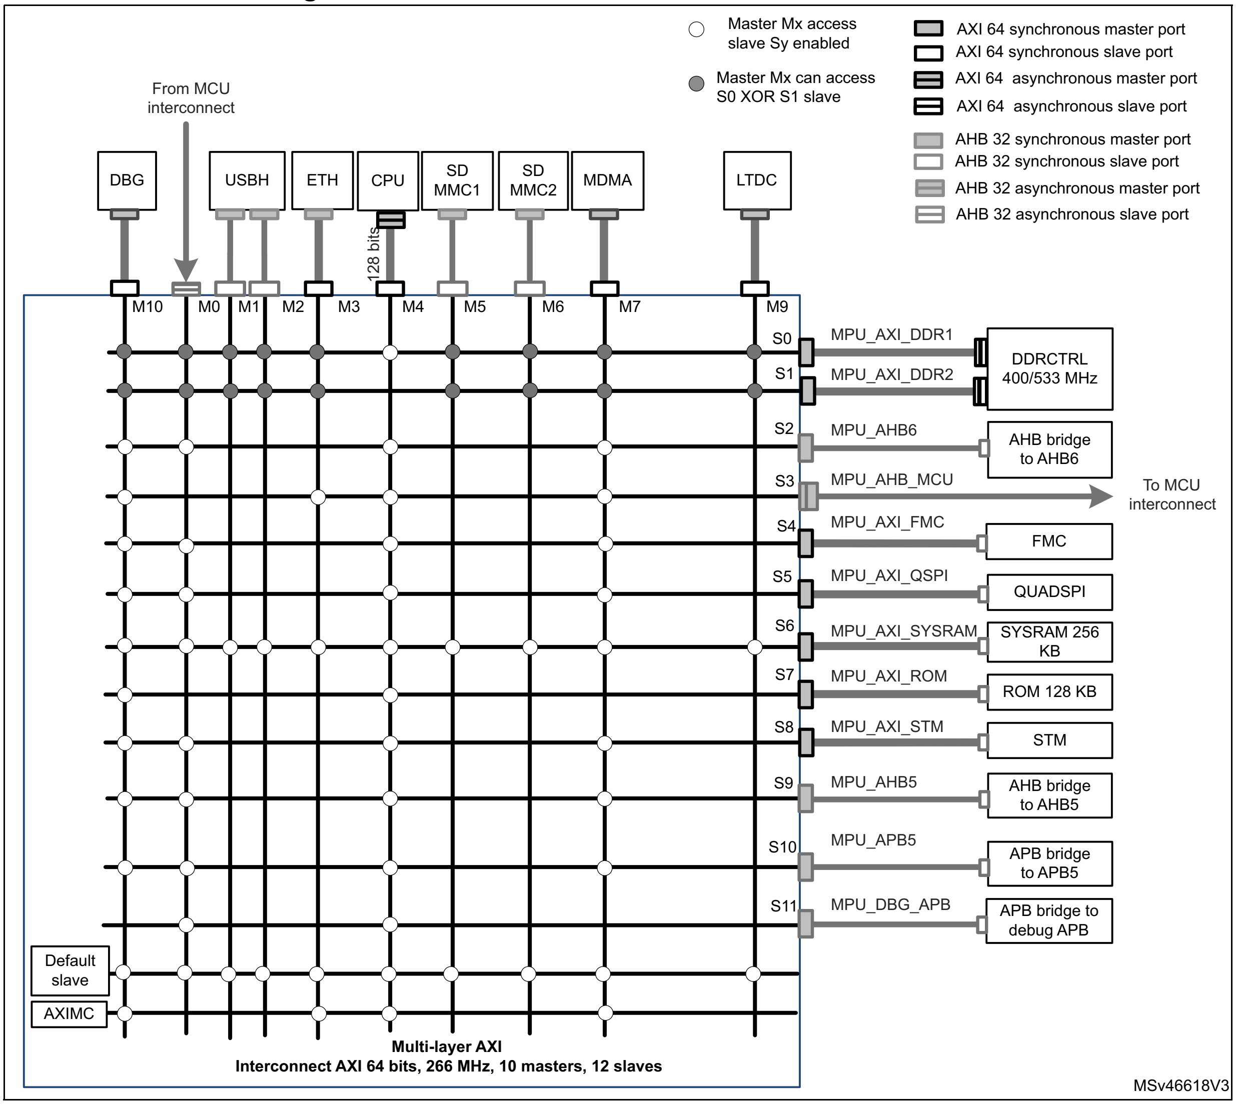
The AXIM is implemented with NIC-400 network interconnect. Its main features are:

- 10 masters, and 12 slave layers (plus 2 internal slaves), with optimized interconnect topology from masters to slaves (no full interconnect)
- Simultaneous accesses support from different masters to slaves connected to separated layers
- Protocol conversion (AXI, AHB) support
- Internal data and commands buffering for improved traffic efficiency
- QoS programming support
- Asynchronism management
- Software configuration of internal parameters (QOS, bypass,...) through user accessible registers.

2.2.2 AXIM interconnect configuration

The NIC-400 interconnect configuration is described in *Figure 2*.

Figure 2. NIC-400 interconnect AXIM for STM32MP153



2.2.3 Master ports description

- **M0**: asynchronous port connected to MCU interconnect master port
  Allows masters from the MCU subsystem to have access to all blocks in the system, except ROM and AXIMC internal slave (also known as GPV, global programmer view) which contains all NIC-400 programming registers.
- **M1/M2**: two AHB-Lite ports connected to USBHost master ports, with same capacities
  Accesses are limited to DDR and SYSRAM memories.
- **M3**: AXI4 port connected to ETHernet gigabit interface
  Accesses are limited to DDR and SYSRAM memories, plus memories located in MCU subsystem.
- **M4**: AXI3 port connected to Cortex-A7 CPU subsystem (128-bit wide)
  The asynchronism is managed inside the CPU subsystem. The conversion to 64 bits is done inside the NIC-400. The CPU subsystem is connected to DDR controller port 0 only. The user can choose to hook other masters on this layer, or leave the CPU as single master, depending on application needs.
- **M5/M6**: two AHB-Lite ports connected to SDMMC1 and SDMMC2 master ports
  Accesses are limited to DDR, and SYSRAM memories.
- **M7**: AXI4 port connected to MDMA
  MDMA is able to access all slaves in the system including the configuration ports of master IPs. It can be used to perform the entire programing of such blocks thanks to its linked list support. This master has important read issuing capabilities and is able to generate peak traffic approaching the layer theoretical max throughput.
- **M9**: AXI4 port connected to LTDC display driver
  Accesses are limited to DDR and SYSRAM memories.
- **M10**: AXI4 port connected to debug access port (DAP) AXI
  This master port has access to all slaves, except S11 going back to the DAP to avoid dual data-path in the system topology. M10 also accesses the AXIMC internal slave which contains all interconnect programming registers.

2.2.4 Master ports main characteristics

Table 2 summarizes the master ports main characteristics.

Table 2. Master ports main characteristics

Master port	Nb	Protocol	Data bus width	Synchronicity	ID width	Default QOS value(1)	Read/write issuing capability
MCU interco	M0	AHB_Lite	32	Async	1	6	1/1
USBH p1	M1	AHB_Lite	32	Sync	1	5	1/1
USBH p2	M2	AHB_Lite	32	Sync	1	5	1/1
ETH	M3	AXI4	64	Sync	4	7	1/1
CPU	M4	AXI3	128	Sync	6	12	8/8
SDMMC1	M5	AHB_Lite	32	Sync	1	4	1/1
SDMMC2	M6	AHB_Lite	32	Sync	1	4	1/1
MDMA	M7	AXI4	64	Sync	1	8	8/1
LTDC	M9	AXI4	64	Sync	4	11	2/1
DEBUG / DAP	M10	AXI4	64	Sync	1	2	1/1

1. Master priorities can be modified by software.

2.2.5 Master ports security characteristics

Table 3 lists the master ports security characteristics.

Table 3. Master ports security characteristics

Master ports	Nb	NIC input signals used for security propagation	TrustZone configuration	NSAID(1)
MCU interco	M0	HAuser(5:0)	Non-secure	0b0001 for Cortex-M4 ob0110 for DMA1 / DMA2 0b1000 for OTG
USBH p1	M1	HAuser(5:0)	Non-secure	0b0111
USBH p2	M2	HAuser(5:0)	Non-secure	0b0111
ETH	M3	ARuser(5:0) AWuser(5:0)	Non-secure	0b1010
CPU	M4	ARuser(5:0) AWuser(5:0)	Per-access	0b0000
SDMMC1	M5	HAuser(5:0)	Non-secure	0b1001
SDMMC2	M6	HAuser(5:0)	Non-secure	0b1001
MDMA	M7	ARuser(5:0) AWuser(5:0)	Per-access	0b0101
LTDC	M9	ARuser(5:0) AWuser(5:0)	Non-secure	0b0011
DEBUG / DAP	M10	ARuser(5:0) AWuser(5:0)	Per-access	0b1111

1. Master M0 transmits several NSAIDs corresponding to multi-layer AHB masters. Different masters of same type (SDMMC1/2 and USBH1/2) generate the same NSAID value.

2.2.6 Slave ports description

- **S0, S1**: AXI3 synchronous ports 0 and 1 of DDR controller. Asynchronism is managed inside the DDR controller.
- **S2**: AHB-Lite synchronous port connected to AHB6, which is the bridge to configuration ports of all masters.
- **S3**: AHB-Lite asynchronous port connected to main MCU multi-layer AHB interconnect, giving access to Cortex-A7 to all MCU peripherals.
- **S4**: AXI3 synchronous port to NAND/NOR controller
- **S5**:AXI3 synchronous port to QUADSPI controller
- **S6**:AXI3 synchronous port to SYSRAM controller
- **S7**:AXI3 synchronous port to ROM controller
- **S8**: AXI3 synchronous port to STM trace data buffer
- **S9**: AHB-Lite synchronous port to AHB5. This bridge controls access to crypto resources, secure GPI0s and backup RAM.
- **S10**: AHB-Lite synchronous port to protocol converter for APB5. APB5 is an APB3 bus supporting security signals propagation. This bus controls access to security management blocks and a set of secure peripherals.
- **S11**: AHB-Lite synchronous port to protocol converter for APB_DEBUG access located in DAP.

Internal slaves:

- **Default slave**: defines the interconnect behavior when accesses are done in a non-valid region.
- **AXIMC** (also known as GPV): contains all NIC-400 interconnect configuration registers. The interconnect configuration register set can be accessed only by two masters: Cortex-A7 CPU (software configuration in early stage of application) and DAP (debug, mainly for check).

2.2.7 Slave ports main characteristics

Table 4 lists the slave ports main characteristics.

Table 4. Slave ports main characteristics

Slave port	Nb	Protocol	Data bus width	Synchronicity	Read / write acceptance capability
DDR p0	S0	AXI4	64	Sync	20/20(1)
DDR p1	S1	AXI4	64	Sync	20/20(1)
AHB6	S2	AHB_Lite	32	Sync	1/1
Multi-layer AHB	S3	AXI4	32	Async	1/1
FMC	S4	AXI4	64	Sync	1/1
QUADSPI	S5	AXI4	64	Sync	1/1
SYSRAM	S6	AXI3	64	Sync	1/1
ROM	S7	AXI3	64	Sync	1/1
STM	S8	AXI4	64	Sync	1/1
AHB5	S9	AXI4	32	Sync	1/1
APB5	S10	AHB_Lite	32	Sync	1/1
DEBUG/DAP	S11	AHB_Lite	32	Sync	1/1

1. DDR read / write acceptance capability = CAM size (16) + internal AXI port interface FIFO (4)

2.2.8 Slave ports security characteristics

Table 5 lists the slave ports security characteristics.

Table 5. Slave ports security characteristics

Slave ports	Nb	NIC input signals used for security propagation	TrustZone configuration
DDR p0	S0	ARuser(5:0) AWuser(5:0)	Secure and non-secure
DDR p1	S1	ARuser(5:0) AWuser(5:0)	Secure and non-secure
AHB6	S2	HAuser(5:0)	Secure and non-secure
Multi-layer AHB	S3	HAuser(5:0)	Secure and non-secure
FMC	S4	ARuser(5:0) AWuser(5:0)	Secure and non-secure
QUADSPI	S5	HAuser(5:0)	Secure and non-secure
SYSRAM	S6	ARuser(5:0) AWuser(5:0)	Secure and non-secure
ROM	S7	ARuser(5:0) AWuser(5:0)	Secure and non-secure
STM	S8	ARuser(5:0) AWuser(5:0)	Secure and non-secure
AHB5	S9	ARuser(5:0) AWuser(5:0)	Secure and non-secure
APB5	S10	ARuser(5:0) AWuser(5:0)	Secure and non-secure
DEBUG/DAP	S11	HAuser(5:0)	Per-access

2.3 Multi-layer AHB interconnect

2.3.1 Multi-layer AHB features

The multi-layer AHB interconnect is an optimized version of Arm BP010 interconnect.

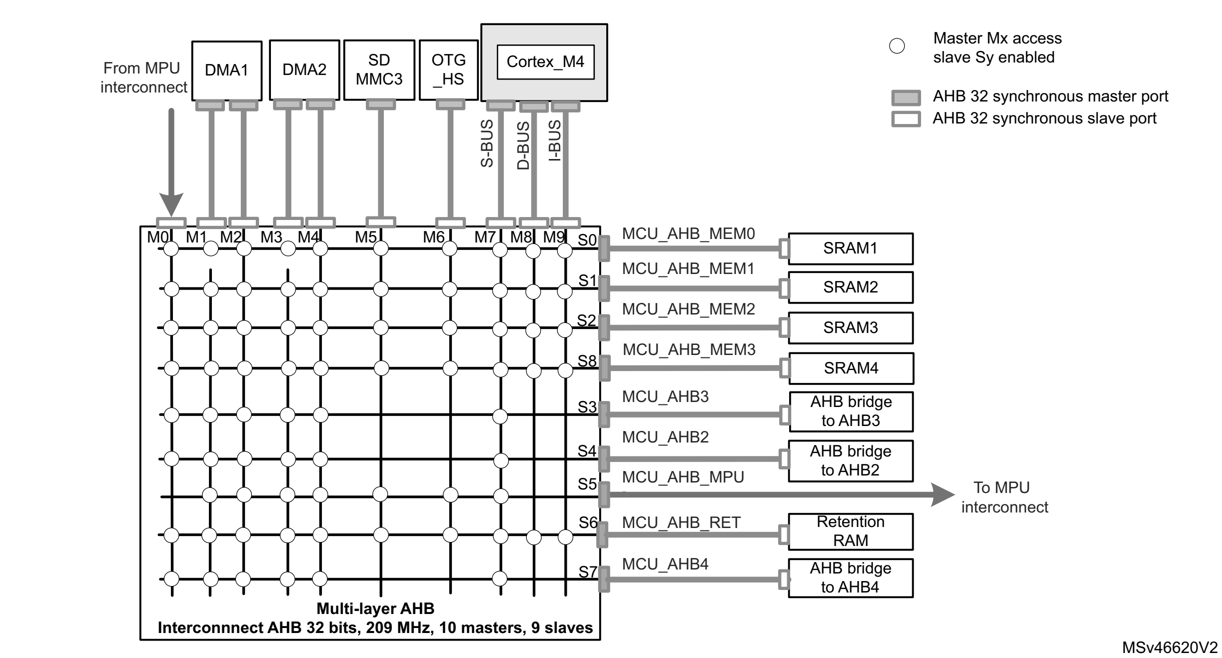
Its main features are:

- 10 masters, and 9 slave layers, all 32-bit data
- Simultaneous accesses support from different masters to slaves connected to separated layers
- Internal data and commands buffering for improved traffic efficiency

2.3.2 Multi-layer AHB interconnect configuration

The multi-layer AHB interconnect configuration is described in *Figure 3*.

Figure 3. Multi-layer AHB interconnect for STM32MP153



2.3.3 Multi-layer AHB master ports characteristics

- **M0**: AHB-Lite connected to MPU interconnect master port
  It allows masters from the MPU subsystem to have access to all slaves in the system, except the path to MPU to avoid loopback.
- **M1, M2, M3, M4**: four AHB-Lite ports connected to DMA1 and DMA2 dual-master blocks, with same capacities.
  Accesses are granted to all slaves in the subsystem: Cortex-M4 SRAMs and bridges to all peripherals.
- **M5**: AHB-Lite ports connected to SDMMC3 interface.
  Accesses are limited to Cortex-M4 RAMs, retention RAM and memories located in MPU subsystem (SYSRAM, DDR) through the main NIC-400 AXI interconnect.
- **M6**: AHB-Lite port connected to OTG interface.
  Accesses are limited to Cortex-M4 RAMs, retention RAM and memories located in MPU subsystem (SYSRAM, DDR) through the main NIC-400 AXI interconnect.
- **M7**: AHB-Lite port connected to the S-bus Cortex-M4 subsystem.
  It allows the Cortex-M4 to have access to all slaves in the system, including a number of those located in MPU subsystem through the main NIC-400 AXI interconnect.
- **M8, M9**: AHB-Lite port connected to the I-bus and D-bus of Cortex-M4 subsystem.
  It allows the Cortex-M4 to have access to slaves in the system located below 0x20 000 000, which are retention RAM and SRAM1,2,3,4. No peripherals are re-mapped below 0x20 000 000.

Table 6 lists the main characteristics of multi-layer AHB master ports.

Table 6. Multi-layer AHB master ports main characteristics

Master ports	Nb	Protocol	Data bus width	Synchronicity
AHB_MPU	M0	AHB-Lite	32	Sync
DMA1 p1	M1	AHB-Lite	32	Sync
DMA1 p2	M2	AHB-Lite	32	Sync
DMA2 p1	M3	AHB-Lite	32	Sync
DMA2 p2	M4	AHB-Lite	32	Sync
SDMMC3	M5	AHB-Lite	32	Sync
OTG	M6	AHB-Lite	32	Sync
SBUS of Cortex-M4	M7	AHB-Lite	32	Sync
DBUS of Cortex-M4	M8	AHB-Lite	32	Sync
IBUS of Cortex-M4	M9	AHB-Lite	32	Sync

2.3.4 Multi-layer AHB slave ports characteristics

- **S0, S1, S2, S8**: AHB-Lite synchronous ports to SRAM1,2,3,4.
  S1 is the slave which provides the best latency when accessed from M4 S-port.
- **S3**: AHB-Lite synchronous port to AHB3
  This bridge controls access to crypto resources and communications IPs with Cortex-A7 cluster.
- **S4**: AHB-Lite synchronous port connected to AHB2
  It is the bridge to configuration ports of all masters connected to multi-layer AHB. This port also allows to access all resources located in APB1 and APB2 clusters, and ADCs.
- **S5**: AHB-Lite synchronous port connected to main NIC-400 interconnect
  It gives access to multi-layer AHB master to most SoC peripherals.
- **S6**: AHB-Lite synchronous port to retention RAM controller
- **S7**: AHB-Lite synchronous port to AHB4
  This bridge controls access to a cluster comprising main system management utilities (clock, power), all non-secure GPIOs and a complementary set of peripherals, allowing to activate only this cluster for simple applications.

The following table lists the multi-layer AHB slave ports main characteristics.

Table 7. Multi-layer AHB slave ports main characteristics

Slave port	Nb	Protocol	Data bus width	Synchronicity	Clock ratio
SRAM1	S0	AHB-Lite	32	sync	1/1
SRAM2	S1	AHB-Lite	32	sync	1/1
SRAM3	S2	AHB-Lite	32	sync	1/1
SRAM4	S8	AHB-Lite	32	sync	1/1
AHB3	S3	AHB-Lite	32	sync	1/1
AHB2	S4	AHB-Lite	32	sync	1/1
MPU_NIC400	S5	AHB-Lite	32	sync	1/1
RETRAM	S6	AHB-Lite	32	sync	1/1
AHB4	S7	AHB-Lite	32	sync	1/1

2.4 AXIMC registers

The following register description is only about AXIM interconnect, as multi-layer AHB interconnect has no configuration registers.

x is the number of the master (Mx with x=10 means M10). Parameters of the masters vary depending on their capabilities, so the number of registers may differ from one to another.

2.4.1 AXIMC peripheral ID4 register (AXIMC_PERIPH_ID_4)

Address offset: 0x1FD0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	K4COUNT[3:0]				JEP106CON[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **K4COUNT[3:0]:** register file size

Bits 3:0 **JEP106CON[3:0]**: JEP106 continuation code

2.4.2 AXIMC peripheral ID5 register (AXIMC_PERIPH_ID_5)

Address offset: 0x1FD4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS_MERGE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS_MERGE:** Disable packing of beats to match the output data width
Unaligned transactions are not realigned to the input data word boundary.
0: normal operation
1: disable packing

2.4.14 AXIMC master x AHB conversion override functionality register (AXIMC_Mx_FN_MOD_AHB)

Address offset: 0x42028 + 0x1000 * x, (x = 0 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WR_INC_OVERRIDE	RD_INC_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WR_INC_OVERRIDE**: Converts all AHB-Lite write transactions to a series of single beat AXI transactions, and each AHB-Lite write beat is acknowledged with the AXI buffered write response.
0: override disabled
1: override enabled

Bit 0 **RD_INC_OVERRIDE**: Converts all AHB-Lite read transactions to a series of single beat AXI transactions.
0: override disabled
1: override enabled

2.4.15 AXIMC master x read priority register (AXIMC_Mx_READ_QOS)

Address offset: 0x42100 + 0x1000 * x, (x = 0 to 2)

Reset value: Block 0: 0x0000 0006

Reset value: Block 1: 0x0000 0005

Reset value: Block 2: 0x0000 0005

Refer to *Section 2.5 on page 153* for the register boundary addresses.

2.5 Memory organization

2.5.1 Introduction

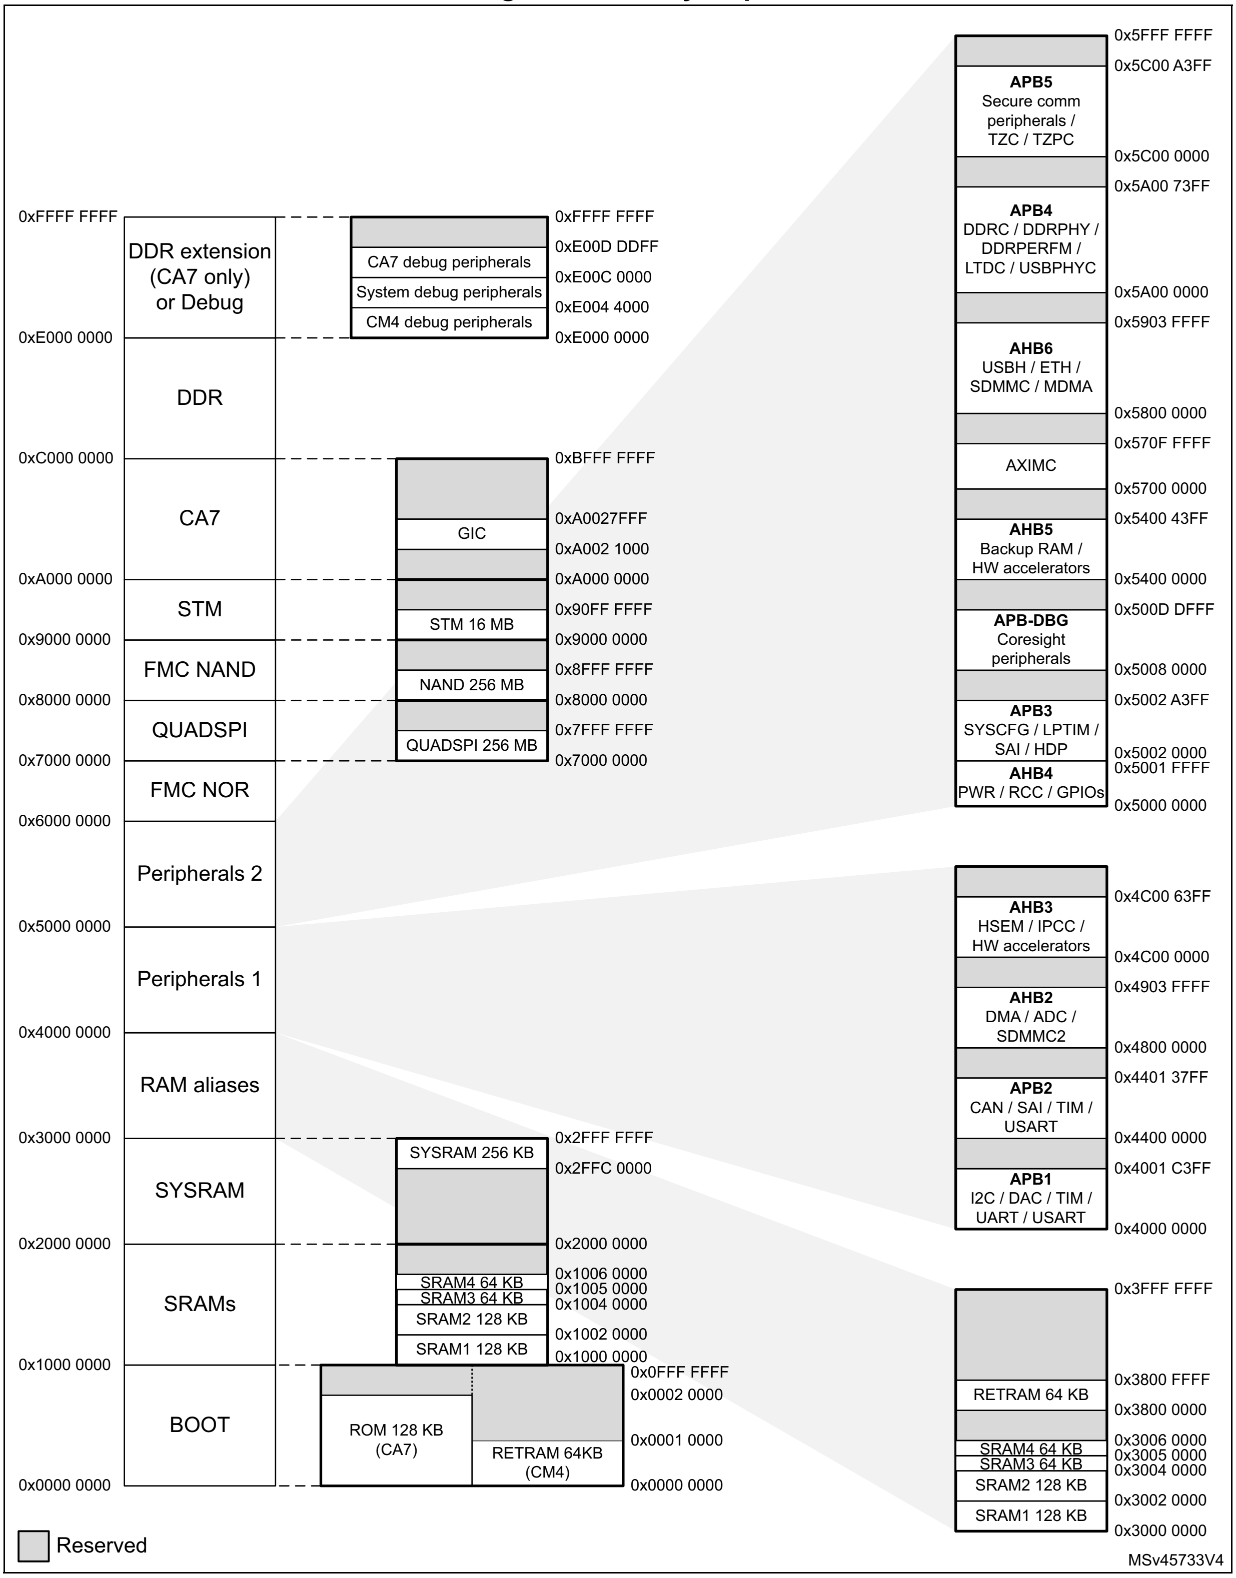
Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word’s least significant byte and the highest numbered byte the most significant.

The access to some part of the address space is master dependent, see *Section 2: Memory and bus architecture* for details.

2.5.2 Memory map and register boundary addresses

Figure 4. Memory map



All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following table.

The following table gives the boundary addresses of the peripherals available in the devices.

Peripheral mapping

Table 9. Register boundary addresses

Bus	Boundary address	Size (Bytes)	Peripheral	Peripheral Register map
Cortex-A7 internal	0xA0026000 - 0xA0027FFF	8 KB	GICV	GIC virtual CPU interface (GICV)
	0xA0024000 - 0xA0025FFF	8 KB	GICH	GIC virtual interface control, common (GICH)
	0xA0022000 - 0xA0023FFF	8 KB	GICC	GIC CPU Interface (GICC)
	0xA0021000 - 0xA0021FFF	4 KB	GICD	GIC distributor (GICD)
	0xA0000000 - 0xA0020FFF	132 KB	Reserved	-
APB5	0x5C00A400 - 0x5FFFFFFF	65495 KB	Reserved	-
	0x5C00A000 - 0x5C00A3FF	1 KB	TAMP	TAMP registers
	0x5C009400 - 0x5C009FFF	3 KB	Reserved	-
	0x5C009000 - 0x5C0093FF	1 KB	I2C6	I2C registers
	0x5C008000 - 0x5C008FFF	4 KB	STGENC	STGEN registers
	0x5C007400 - 0x5C007FFF	3 KB	Reserved	-
	0x5C007000 - 0x5C0073FF	1 KB	ETZPC	ETZPC registers
	0x5C006000 - 0x5C006FFF	4 KB	TZC	TZC registers
	0x5C005000 - 0x5C005FFF	4 KB	BSEC	BSEC registers
	0x5C004400 - 0x5C004FFF	3 KB	Reserved	-
	0x5C004000 - 0x5C0043FF	1 KB	RTC	RTC registers
	0x5C003400 - 0x5C003FFF	3 KB	Reserved	-
	0x5C003000 - 0x5C0033FF	1 KB	IWDG1	IWDG registers
	0x5C002400 - 0x5C002FFF	3 KB	Reserved	-
	0x5C002000 - 0x5C0023FF	1 KB	I2C4	I2C registers
	0x5C001400 - 0x5C001FFF	3 KB	Reserved	-
	0x5C001000 - 0x5C0013FF	1 KB	SPI6	SPI/I2S registers
	0x5C000400 - 0x5C000FFF	3 KB	Reserved	-
	0x5C000000 - 0x5C0003FF	1 KB	USART1	USART registers

Table 9. Register boundary addresses (continued)

1. Accessible by debugger only.
2. Also accessible locally by Cortex®-M4.
3. Accessible by Debugger, Cortex®-M4 and Cortex®-A7

3 Boot and security and OTP control (BSEC)

3.1 Introduction

The BSEC (boot and security and OTP control) is intended to control an OTP (one time programmable) fuse box, used for on-chip non-volatile storage for device configuration and security parameters.

3.2 BSEC main features

- 32-bit APB4 interface
- 4096 OTP bits (with 3072 effective bits)
- Valid power-supply **pwrok** input so that OTP is only operated within a VDD/VDD1 valid range
- Scratch register for communication with external agent and to store boot parameters
- Feature locking mechanism: BSEC provides 15 hardware signals, controlled by OTP to disable specific SoC features for product differentiation
- JTAG SOC interface via BSEC_JTAGIN and BSEC_JTAGOUT registers for communication channel to JTAG TAP controller.
- Two OTP regions designated as lower OTP (1 Kbits) and upper OTP (2 Kbits) having different properties
- **Lower OTP bits** (1 Kbits), with **2:1 redundancy**, are intended to store:
  - Device configuration: BSEC OTP mode and device features
  - Boot parameters
  - Engineering data and analog trim
  - Public root key (256 bits)

  All basic security features, including secure Boot with code authentication, are supported **only** with lower OTP region.
- **Upper OTP bits** (2 Kbits) with 6 bits per 32-bit word ECC support, are intended to store security sensitive information
  - ST secret keys
  - OEM secrets

  Upper OTP should only be treated by 32-bit words
- Improved resistance to hardware attacks by clock and power glitches during OTP read
- OTP bits are always read with disturbcheck.

  Every OTP word read is internally compared to an internal reference level. The disturbcheck information is provided to BSEC to qualify the OTP word value.
- Global programming locking by sticky bits
- Permanent OTP program locking per word
- OTP word programming lock by sticky bits during Boot
- Shadow OTP registers can be individually write locked by sticky bits during Boot
- Shadow OTP registers can be individually read locked by sticky bits during Boot (to prevent reloading)
- Arm® TrustZone® awareness applicable to:

- BSEC control registers
- BSEC shadow registers from lower OTP region (words 0 to 31)
- BSEC shadow registers from upper OTP region (words 32 to 95)

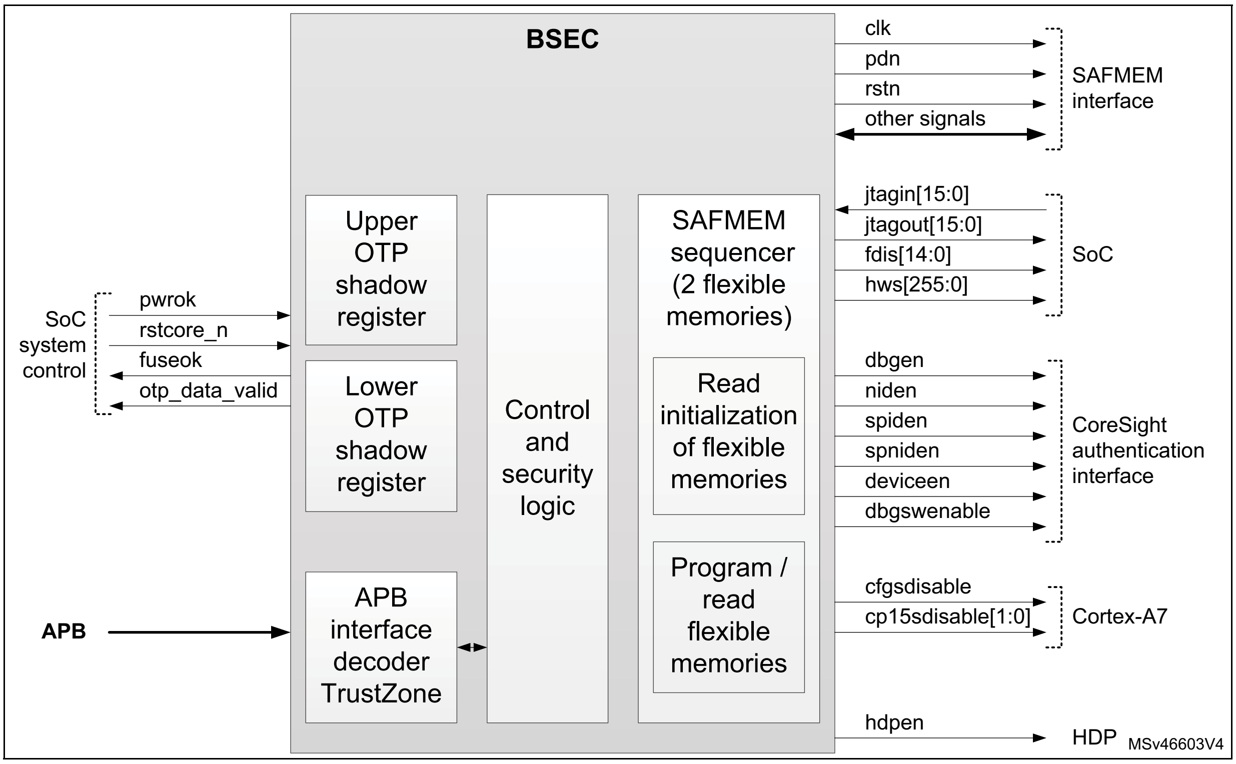
- Arm® CoreSight™ debug authentication interface with six signals:
  - **dbgen** (debug enable)
  - **devicen** (external debug enable)
  - **niden** (non-invasive debug enable)
  - **spiden** (secure privilege invasive debug enable)
  - **spniden** (secure privilege non-invasive debug enable)
  - **dbgswenable** (self hosted debug enable)
- Up to 256 hardware signals **hws[255:0]** for analog trim, factory settings and SoC RAM repair

3.3 BSEC functional description

BSEC provides an interface to the OTP (also known as anti-fuse macro) containing 3072 useful bits. BSEC also provides several registers used by the Boot process as well as mechanisms to prevent access to security sensitive information.

3.3.1 BSEC block diagram

Figure 5. BSEC block diagram



3.3.2 Interface to OTP

OTP bits are grouped in words of 32 bits each and are organized in two regions:

- the **lower region**: 32 words of 32 bits (lower 2 Kbits), using a 2:1 redundancy. SoC and Boot configuration parameters, engineering data and public root key hash are stored in this lower region.
- the **upper region**: 64 words of 32 bits (2 Kbits upper half), using ECC scheme (32 bits encoded into 38 bits). Security sensitive parameters such as secret keys are stored in this upper region.

Note: OTP bits are initially set to 0 and can be programmed once to one.
Lower OTP words, using 2:1 redundancy, can be bitwise programmed in several operations
Upper OTP words, using internal ECC, must be programmed in a single operation as a bulk 32 bits data.

The OTP bits are not directly accessible by the CPU. Instead the CPU must access shadow registers that contain copies of the OTP useful bits.

There are 96 **shadow registers: BSEC_OTP_DATA0 to BSEC_OTP_DATA95**.

These 32-bit registers are copies of actual OTP bits. Redundancy and ECC are made transparent to the user. BSEC_OTP_DATAx are also referred to OTP word #x in this document.

There are two possibilities to udpate the shadow registers:

- a system reset, where BSEC automatically copies the whole set of OTP useful bits to the shadow registers.
- an OTP read operation requested by the CPU, used after an OTP programming operation to update the corresponding shadow register.

The following OTP useful bits have a special meaning for BSEC:

- **word #0: bits 0 to 6** reserved to determine OTP security mode
- **word #1: bits 0 to 15** used to control feature disabling
- words #16 to word #23 are connected to the SoC signals hws[255:0].
  These signals are either:
  - connected to SoC peripherals (example: for analog peripheral factory trimming, or for memory repair).
  - left unconnected if OTP bits are only used by software (see *Section 4: OTP mapping (OTP)*).

3.3.3 OTP security modes

OTP word#0 bits 0 to 6 (with their potential disturbed state) are used to determine the OTP security mode.

The following OTP security modes are available:

- OTP-SECURED, including sub-modes, according to OTP word#0 as described in *Table 11*:
  - open_device
  - closed_device
- OTP-INVALID
  - In this state the upper OTP shadow registers are cleared and not accessible, the lower OTP shadow registers are not accessible, BSEC control interface is read/write accessible to secure only.

The OTP mode is made visible to software by register BSEC_OTP_STATUS.

Table 11. OTP modes definition

BSEC_OTP_DATA0 [6:0]	OTP mode	BSEC_OTP_STATUS SECURE	BSEC_OTP_STATUS INVALID
0xxx1x1	**OTP-SECURED open_device**	1	0
01x1xxx			
0xx11xx			
01xxxx1			
1xxx1x1	**OTP-SECURED closed_device**	1	0
11x1xxx			
1xx11xx			
11xxxx1			
All other values	**OTP-INVALID**	x	1

Note: The OTP mode is computed from BSEC_OTP_DATA0[6:0] only if BSEC_OTP_DISTURBED[0] is equal to zero. Otherwise the OTP mode is forced to OTP-INVALID.

3.3.4 Automatic OTP load on system-reset

On a system-reset, BSEC automatically updates all shadow registers. The OTP mode is determined during this phase.

For OTP-**SECURED** mode, all OTP words are read and BSEC_OTP_DATA**0** to BSEC_OTP_DATA**95** are updated.

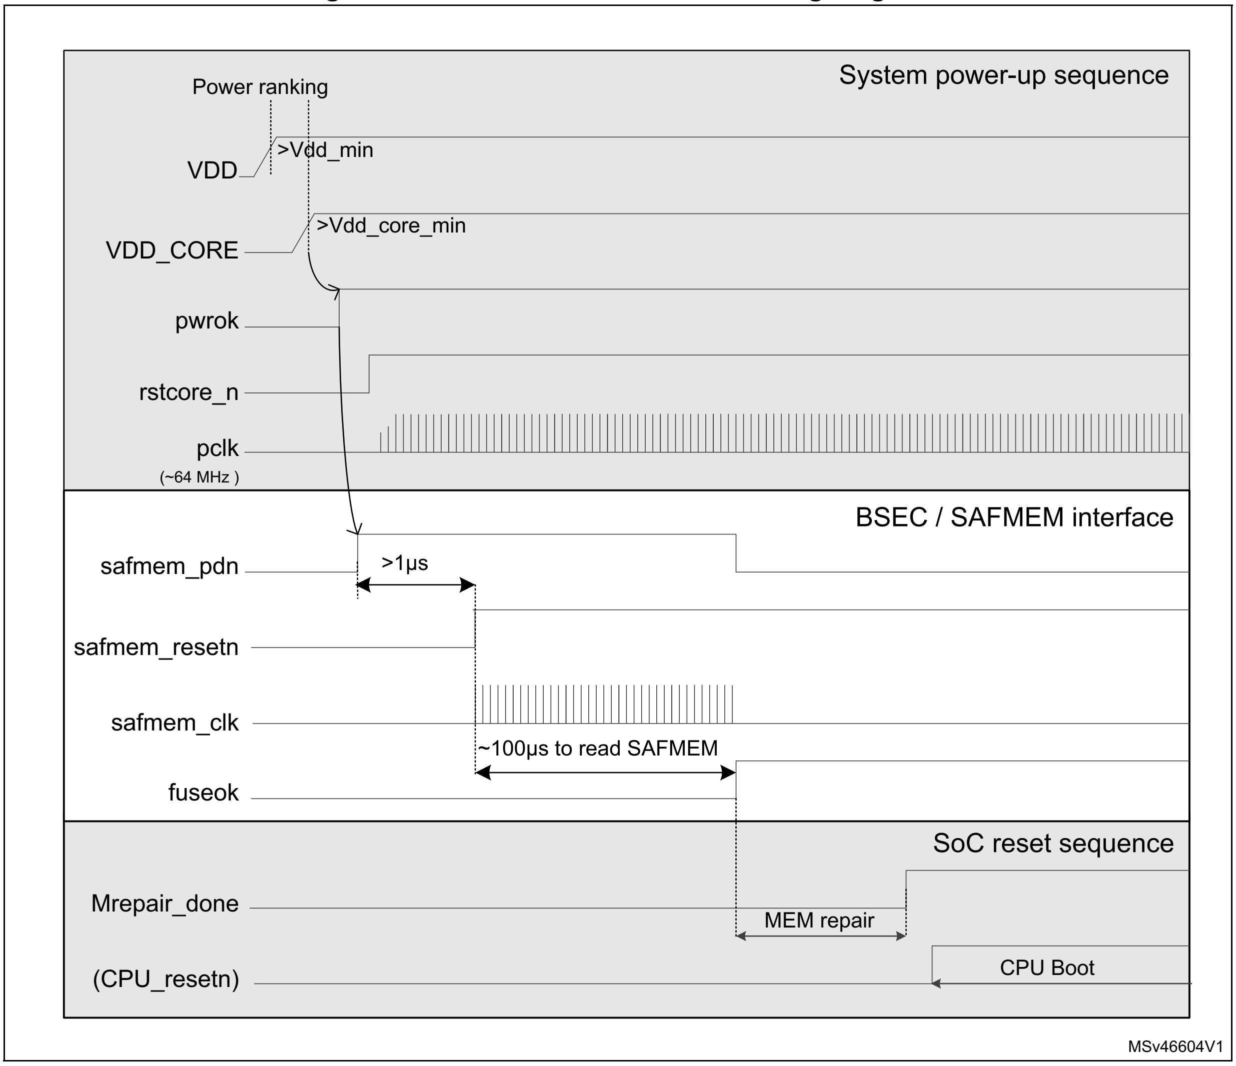
For OTP-**INVALID** mode, only BSEC_OTP_DATA**0** to BSEC_OTP_DATA**31** are updated. BSEC_OTP_DATA**32** to BSEC_OTP_DATA**95**
are set to 0.

BSEC_OTP_STATUS, BSEC_OTP_DISTURBEDx and BSEC_OTP_ERRORx registers are also updated.

fuseok signal is asserted at the end of this phase. This signal is used to release the reset to the SoC.

Note: the OTP word reading starts from word 0, in order for the BSEC to determine the OTP mode from the beginning.

Figure 6. Power-on and initial read timing diagram



3.3.5 OTP words status

- **BSEC_OTP_DISTURBEDx** registers (x = 0...2) provide the **disturbed status** for each OTP word. Any bit set to 1 means that the last reading of the corresponding word has been disturbed. Abnormal reading conditions in circuitry decoding and voltages reading have been detected.
- **BSEC_OTP_ERRORx** registers (x = 0...2) provide **error status** for each OTP word. Any bit set to 1 means that the last read operation of the word concerned revealed a redundancy or ECC check error.
- **BSEC_OTP_WRLOCKEDx** registers (x = 0...2) provide a **permanent write lock** status for each OTP word. Any bit set to 1 means that the corresponding word is permanently locked for writing.

Note: All status registers are updated during the initial read, but the disturbed and error status registers are also updated after each OTP read operation.
The first 32 OTP words implement a scheme to improve OTP robustness against hardware attacks during read as follows: Spare bits 32 to 37 are intended to support ECC and are not

used by 2:1 redundancy. They are therefore written with a simple pattern (for example OTP word address on 5 bits with even parity on the 6th bit).This pattern is checked during every OTP read. If the value read on bit 32 to 37 does not match the expected value, a disturbed information is reported to BSEC_OTP_DISTURBED0 register.

3.3.6 OTP operations

BSEC is clocked by PCLK clock source (single clock for functional and interface registers). An OTP word reading, writing (programming) or locking is called an OTP operation.

One OTP operation is performed via the BSEC_OTP_CONTROL register. It starts when the software writes a valid request to BSEC_OTP_CONTROL register and when no other operation is on going (an OTP operation cannot start until the previous one is finished).

Specific read, programming or permanent write lock operations are detailed below.

OTP read

A read operation consists in updating one of BSEC_OTP_DATA0 to BSEC_OTP_DATA95 registers with the corresponding word from OTP word.

To trigger a read operation, the software must set BSEC_OTP_CONTROL register with the word number given in ADDR field and with PROG bit set to 0.

The software can check the BUSY bit from the BSEC_OTP_STATUS register: Once cleared, this BUSY bit indicates that the read operation is complete.

When the read operation is finished, the BSEC state machine updates the “disturbed” and “error” status registers.

BSEC parameters depending on OTP content, are also updated when the corresponding OTP words are read. The OTP mode is updated when a read operation of the word 0 is performed.

Note: In OTP-INVALID mode, or if bit OTP in BSEC_OTP_LOCK register is set, words 32 to 95 cannot be read. The corresponding shadow registers are not modified.

OTP programming

A programming operation consists in programming one or several bits of an OTP word to one.

OTP word bits may be incrementally programmed to one but bits programmed to one can not be written to zero.

Lower OTP words are bitwise programmable and can be programmed incrementally to one's, upper OTP words have to be programmed in a single operation because of ECC encoding.

To trigger a programming operation, the two following steps are required:

- set the word value to write in the BSEC_OTP_WRDATA register
- set the BSEC_OTP_CONTROL register with:
  - word number given in ADDR field
  - PROG bit set to 1
  - LOCK bit set to 0.

The software checks then the BUSY bit from the BSEC_OTP_STATUS register: Once cleared, this BUSY bit indicates that the write operation is complete.

In the same register, the progfail bit is set if the write operation has failed.

Note: a programming operation to an OTP word does not update the corresponding shadow register. If needed, the software can update the shadow register with a read operation. In OTP-INVALID mode, the upper OTP (words 32 to 95) can not be programmed, regardless of bit GPLOCK in BSEC_OTP_LOCK register and regardless of registers BSEC_OTP_SPLOCK2/3.

OTP permanent write lock

A permanent write lock operation consists in forcing an OTP word to be permanently write-locked and not programmable.

For permanent write lock of an OTP word, the software must perform the same sequence as a normal programming operation with bit LOCK in BSEC_OTP_CONTROL register, with field ADDR in BSEC_OTP_CONTROL register and with BSEC_OTP_WRDATA register (see *Table 12*). After permanent lock programming, it is required to update BSEC_OTP_WRLOCKEDx registers with OTP content. In order to do this, the software must perform a word read with LOCK bit set and word address provided in BSEC_OTP_CONTROL register.

Table 12. OTP permanent write lock

OTP word to be locked	BSEC control register value		Comment
	ADDR[6:0]	WRDATA[31:0]	
0	0x00	0x0000 0003	Use 2 bits per word for lower OTPs
1	0x00	0x0000 000C	
...	...	...	
7	0x00	0x0000 C000	
8	0x01	0x0000 0003	
...	...	...	
15	0x01	0x0000 C000	
16	0x02	0x0000 0003	
...	...	...	
31	0x03	0x0000 C000	
32	0x04	0x0000 0001	Use 1 bit per word for upper OTPs
33	0x04	0x0000 0002	
...	...	...	
47	0x04	0x0000 8000	
48	0x05	0x0000 0001	
...	...	...	
63	0x05	0x0000 8000	
...	...	...	
95	0x07	0x0000 8000	

3.3.7 JTAG registers

The BSEC_JTAGIN and BSEC_JTAGOUT registers are two 16-bit registers used to communicate between software and JTAG SoC interface. This interface is used during Boot as communication channel to the external JTAG TAP controller.

3.3.8 BSEC lock registers

BSEC_OTP_LOCK register is used to lock access to security sensitive areas with sticky bits. The locks are active until the next system-reset (see *Section 3.6.5: BSEC OTP lock configuration register (BSEC_OTP_LOCK)*).

3.3.9 Debug control

The software controls the scope of the Debug by BSEC_DENABLE register. The access to this register can be locked until next system-reset with bit DENREG in BSEC_OTP_LOCK register.

BSEC_DENABLE is driving hardware signals to the SoC (such as CoreSight authentication interface and other specific control listed in *Table 13*).

For more information, see *Section 64: Debug support (DBG)*.

BSEC_DENABLE default values depends on BSEC OTP mode as shown in *Table 13*.

Table 13. BSEC_DENABLE default values after reset

Signal	OTP-SECURED open_device	OTP-SECURED closed_device	OTP-INVALID	Comment
dbgen	1	0	0	CoreSight authentication
niden	1	0	0	CoreSight authentication
spiden	0	0	0	CoreSight authentication
spniden	0	0	0	CoreSight authentication
deviceen	1	0	0	CoreSight authentication
dbgswenable	0	0	0	CoreSight authentication
hdpen	0	0	0	Hardware debug port tracing
cfgsdisable	0	0	0	Disable some of Cortex®-A7 GIC secure access
cp15sdisable[1:0]	0b00	0b00	0b00	Disable some of Cortex®-A7 CP15 secure access

3.3.10 Sticky lock register

Three sticky lock registers are used to control the reload of shadow registers, at OTP word granularity:

- BSEC_SRLOCKx (x = 0..2) to prevent reloading of selected shadow registers until next system-reset.
- BSEC_SWLOCKx (x = 0..2) to lock the write to selected shadow register from APB until next system-reset.
- BSEC_SPLOCKx (x = 0..2) to prevent programming of selected OTP words until next system-reset.

3.4 OTP layout

Lower OTP words (1 Kbits)

The lower OTP bits are stored in shadow registers BSEC_OTP_DATA0 to BSEC_OTP_DATA31 and used for general purpose and non-secret data.

These OTP are protected by a 2:1 redundancy implemented with consecutive even/odd bits.

The specific bits impacting hardware such as OTP modes, engineering, trim and memory repair are located in: CFG0, CFG1 and 8 other words (HW0 to HW7).

Upper OTP words (2 Kbits)

The upper OTP words are stored in shadow registers BSEC_OTP_DATA32 to BSEC_OTP_DATA95 and are reserved to store security sensitive information (secrets keys, certificate, RMA key). These words may also store public non-volatile information.

These upper OTP bits can be used during the Boot process to support advanced security services such as secure secret provisioning (SSP), encrypted Boot or secure storage.

The upper OTP words are protected by ECC and must be used with 32-bit word granularity.

3.4.1 DMA requests

BSEC does not support DMA hardware interface.

3.4.2 TrustZone awareness

BSEC is TrustZone aware. All APB register read and write accesses are checked for permission. *Table 14* and *Table 15* describe the permission rules depending on OTP mode and register type.

If permission check fails:

- write access is ignored and SLVERR is signaled on APB bus.
- read access returns zeros and SLVERR is signaled on APB bus.

Table 14. Write access permissions

OTP mode	Control registers[1]		Lower OTP shadow registers		Upper OTP shadow registers	
	APB secure	APB non-secure	APB secure	APB non-secure	APB secure	APB non-secure
OTP-SECURED	Yes	No	Yes	No	Yes	No
OTP-INVALID	No	No	No	No	No	No

1. BSEC control registers are any BSEC registers except BSEC_OTP_DATA0 to BSEC_OTP_DATA95.

Table 15. Read access permissions

OTP mode	Control registers[1]		Lower OTP shadow registers		Upper OTP shadow registers	
	APB secure	APB non-secure	APB secure	APB non-secure	APB secure	APB non-secure
OTP-SECURED	Yes	Yes	Yes	Yes	Yes	No
OTP-INVALID	Yes	No	No	No	No	No

1. BSEC control registers are any BSEC registers except BSEC_OTP_DATA0 to BSEC_OTP_DATA95.

3.4.3 BSEC clocking and initialization

BSEC has a single clock domain (PCLK).

- During read and programming OTPs, PCLK frequency must be ≤ 67 MHz.
- During write to shadow registers, PCLK frequency must be ≤ 67 MHz.
- During all other operations, PCLK frequency is not restricted but it is recommended to keep PCLK ≤ 67 MHz for all operations (to avoid frequency changes).
- BSEC is enforcing the correct sequencing wrt signals: CLK, PDN, and RESETN during power-up and power-down sequences.

3.5 BSEC interrupts

BSEC does **not** support any interrupt.

3.6 BSEC registers

The peripheral registers are accessed by words (32-bit).

Any write access to read-only registers are silently ignored.

Any attempt to modify locked registers (locked by sticky locks or by lock bits) are silently ignored.

3.6.1 BSEC OTP configuration register (BSEC_OTP_CONFIG)

Address offset: 0x000

Reset value: 0x0000 000E

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREAD[1:0]		PRGWIDTH[3:0]				FRC[1:0]		PWRUP
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:7 **TREAD[1:0]**: set OTP reading current level (default = 0b00)

Bits 6:3 **PRGWIDTH[3:0]**: OTP programming pulse width (default = 0b0001)

Bits 2:1 **FRC[1:0]**: OTP clock frequency range selection

00: 10 MHz ≤ frequency ≤ 20 MHz
01: 20 MHz ≤ frequency ≤ 30 MHz
10: 30 MHz ≤ frequency ≤ 45 MHz
11: 45 MHz ≤ frequency ≤ 67 MHz

Note: 0b11 is used by default. OTP *initial read is always using an internal OSC with 64 MHz max frequency. Reading* OTP *at a lower frequency than the range programmed by FRC[1:0] is possible.*

Bit 0 **PWRUP**: OTP power-up control

0: OTP powered down
1: OTP powered up

Note: After the power-on initial read of OTP*, BSEC powers down* OTP*. PWRUP bit is then cleared.*
Prior to any read or programming operation, OTP *must be powered up again by setting PWRUP bit.*
OTP *read is qualified by **pwrok** input signal, which indicates that VDD and VDD1 supplies are in valid range.*

3.6.2 BSEC OTP control register (BSEC_OTP_CONTROL)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	LOCK	PROG	Res.	ADDR[6:0]						
						rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LOCK**: OTP permanent word lock control
0: OTP normal word programming/read
1: OTP permanent write lock word programming/read

Bit 8 **PROG**: OTP operation control
0: OTP read operation
1: OTP program operation

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **ADDR[6:0]**: OTP word address
Actual OTP word address.
Words address are from 0 to 95 for BSEC
Note: the actual OTP *word address is adjusted according to the redundancy or ECC scheme.*

3.6.3 BSEC OTP write data register (BSEC_OTP_WRDATA)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
WRDATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WRDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **WRDATA[31:0]**: OTP write data

3.6.4 BSEC OTP status register (BSEC_OTP_STATUS)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PWR ON	PROG FAIL	BUSY	IN VALID	Res.	SEC URE
										r	r	r	r		r

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 Reserved, must be kept at reset value.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PWRON**: OTP power status
0: OTP in power off
1: OTP in power on
Note: used to poll pwrok signal value

Bit 4 **PROGFAIL**: last programming status
0: OTP successful last programming
1: OTP failed last programming

Bit 3 **BUSY**: OTP operation status
0: OTP idle
1: OTP operation on going
Note: bit polling is used to determine operation completion.

Bit 2 **INVALID**: OTP invalid mode
0: OTP mode is not OTP-INVALID
1: OTP mode is OTP-INVALID

Bit 1 Reserved, must be kept at reset value.

Bit 0 **SECURE**: OTP secured mode
0: OTP mode is not OTP-SECURED
1: OTP mode is OTP-SECURED

Note: The reset value of SECURE and INVALID bits depends on OTP mode.

Note: The lowest bits SECURE and INVALID must be used to identify the OTP mode instead of reading shadow register BSEC_OTP_DATA0. Precedence is INVALID > SECURE.

3.6.5 BSEC OTP lock configuration register (BSEC_OTP_LOCK)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GP LOCK	Res.	DEN REG	ROM LOCK	OTP
											rs		rs	rs	rs

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **GPLOCK**: programming sticky lock
0: programming allowed
1: programming disabled until next system reset

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DENREG**: debug enable register sticky lock
0: BSEC_DENABLE register not locked
1: BSEC_DENABLE register locked until next system reset

Bit 1 **ROMLOCK**: Upper ROM region read lock
0: Upper ROM region is accessible
1: Upper ROM region is no more accessible until next system reset
The upper ROM region is accessible only in OTP-SECURED open and OTP-SECURED closed modes and ROMLOCK bit is relevant only in these modes.

Bit 0 **OTP**: upper OTP read lock
0: upper OTP not locked
1: upper OTP cannot be reloaded until next system reset

3.6.6 BSEC debug configuration register (BSEC_DENABLE)

Address offset: 0x014

Reset value: 0x0000 0000

Note: reset value depends on OTP secure mode according to *Table 13: BSEC_DENABLE default values after reset on page 172.*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	DBG SWEN ABLE	CFGS DIS ABLE	CP15SDISABLE [1:0]		SPNID EN	SPID EN	HDPEN	DE VICE EN	NIDEN	DBG EN	Res.
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **DBGSWENABLE**: control self hosted debug enable with signal **dbgswenable**
0: Software access to all debug components is disabled
1: Software access to all debug components is enabled

Bit 9 **CFGSDISABLE**: write access to secure GIC registers disable with signal **cfgsdisable**
0: no effect, all GIC registers are accessible
1: Disable write access to some secure GIC registers

Bits 8:7 **CP15SDISABLE[1:0]**: write access to some secure Cortex®-A7 CP15 registers disable
CPDISABLE[0] applies to CPU0. CPDISABLE[1] applies to CPU1.
0: All CP15 registers are accessible
1: Disable write access to some secure CP15 registers into Cortex®-A7 corresponding CPU

Bit 6 **SPNIDEN**: secure privilege non-invasive debug enable with signal **spiden**
0: secure privilege non-invasive debug disabled
1: secure privilege non-invasive debug enabled

Bit 5 **SPIDEN**: secure privilege invasive debug enable with signal **spniden**
0: secure privilege invasive debug disabled
1: secure privilege invasive debug enabled

Bit 4 **HDPEN**: hardware debug port enable with signal **hdpen**
0: hardware debug port disabled
1: hardware debug port enabled

Bit 3 **DEVICEEN**: controls access to debug component via external debug port by signal **deviceen**
0: disabled
1: enabled

Bit 2 **NIDEN**: non-invasive debug enable with signal **niden**
0: non-invasive debug disabled
1: non-invasive debug enabled

Bit 1 **DBGEN**: debug enable with signal **dbgen**
0: disabled
1: enabled

Bit 0 Reserved, must be kept at reset value.

3.6.7 BSEC OTP disturbed status register x (BSEC_OTP_DISTURBEDx)

BSEC_OTP_DISTURBED**0** is used to report disturbed state of BSEC_OTP_DATA0 to BSEC_OTP_DATA31 (lower 1 Kbits OTP).

BSEC_OTP_DISTURBED**1** is used to report disturbed state of BSEC_OTP_DATA32 to BSEC_OTP_DATA63.

BSEC_OTP_DISTURBED**2** is used to report disturbed state of BSEC_OTP_DATA64 to BSEC_OTP_DATA95.

Address offset: 0x01C + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIS[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

DIS[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DIS[31:0]**: disturbed status of the corresponding OTP word
0: OTP word has been read correctly
1: OTP word is disturbed, either because of a read with disturbcheck failed or because the spare ECC bits [37:32] for words 0 to 31 do not match expected value. It may result from a possible hardware attack.

Note: ECC bits resilience against hardware attacks is applied only to lower OTP region.

3.6.8 BSEC OTP error status register x (BSEC_OTP_ERRORx)

BSEC_OTP_ERROR**0** is used to report error state of BSEC_OTP_DATA0 to BSEC_OTP_DATA31 (lower 1 Kbits OTP which are protected by 2:1 redundancy).

BSEC_OTP_ERROR**1** is used to report error state of BSEC_OTP_DATA32 to BSEC_OTP_DATA63 which are protected by 6-bit ECC.

BSEC_OTP_ERROR**2** is used to report error state of BSEC_OTP_DATA64 to BSEC_OTP_DATA95 which are protected by 6-bit ECC.

Address offset: 0x034 + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ERR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

ERR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ERR[31:0]**: error status of the correspond OTP word
0: OTP word has been read correctly
1: OTP word is erroneous, either because 2:1 redundancy has failed for words 0 to 31 or because ECC check has failed for words 32 to 95.

3.6.9 BSEC OTP lock status register x (BSEC_OTP_WRLOCKEDx)

BSEC_OTP_WRLOCKED**0** is used to report permanent write lock of BSEC_OTP_DATA0 to BSEC_OTP_DATA31.

BSEC_OTP_WRLOCKED**1** is used to report permanent write lock of BSEC_OTP_DATA32 to BSEC_OTP_DATA63.

BSEC_OTP_WRLOCKED**2** is used to report permanent write lock of BSEC_OTP_DATA64 to BSEC_OTP_DATA95.

Permanent write lock requires a programming sequence to lock a word (see section:*Section 3.3.6: OTP operations on page 170*).

Address offset: 0x04C + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:0 **WRLOCK[31:0]**: permanent word lock status of the correspond OTP word
0: OTP word not locked
1: OTP word permanently locked

3.6.10 BSEC OTP sticky programming lock register x (BSEC_OTP_SPLOCKx)

BSEC_OTP_SPLOCK**0** is used to lock the programming of BSEC_OTP_DATA0 to BSEC_OTP_DATA31 until next system-reset

BSEC_OTP_SPLOCK**1** is used to lock the programming of BSEC_OTP_DATA32 to BSEC_OTP_DATA63 until next system-reset

BSEC_OTP_SPLOCK**2** is used to lock the programming of BSEC_OTP_DATA64 to BSEC_OTP_DATA95 until next system-reset

Attempt to sticky program locked OTP word are silently ignored.

Address offset: 0x064 + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:0 **SPLOCK[31:0]**: lock programming for the OTP word until next power-on reset
0: OTP word not locked
1: OTP word locked for programming

3.6.11 BSEC OTP shadow write sticky lock register x (BSEC_OTP_SWLOCKx)

BSEC_OTP_SWLOCK**0** is used to prevent writing to BSEC_OTP_DATA0 to BSEC_OTP_DATA31 until next system-reset.

BSEC_OTP_SWLOCK**1** is used to prevent writing to BSEC_OTP_DATA32 to BSEC_OTP_DATA63 until next system-reset.

BSEC_OTP_SWLOCK**2** is used to prevent writing to BSEC_OTP_DATA64 to BSEC_OTP_DATA95 until next system-reset.

Write to shadow write locked BSEC_OTP_DATA word are silently ignored.

Note: Writing to OTP word 0 shadow is always prevented.

Address offset: 0x07C + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 0001, 0x0000 0000, 0x0000 0000

SWLOCK[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SWLOCK[31:0]**: lock the writing for the OTP shadow word until next power-on reset.

0: shadow word not locked

1: shadow word locked and cannot be written by software

Note: BSEC_OTP_SWLOCK0 bit 0 is forced to 1 by hardware, writing to this bit has no effect.

3.6.12 BSEC OTP shadow read sticky lock register x (BSEC_OTP_SRLOCKx)

BSEC_OTP_SRLOCK**0** is used to prevent reloading of BSEC_OTP_DATA0 to BSEC_OTP_DATA31 until next system-reset.

BSEC_OTP_SRLOCK**1** is used to prevent reloading of BSEC_OTP_DATA32 to BSEC_OTP_DATA63 until next system-reset.

BSEC_OTP_SRLOCK**2** is used to prevent reloading of BSEC_OTP_DATA64 to BSEC_OTP_DATA95 until next system-reset.

Setting SRLOCK bits or attempt to reload a locked OTP do **not** clear the corresponding BSEC_OTP_DATAx shadow register.

Note: BSEC_OTP_SRLOCK0 bit 0 is controlled by hardware according to fuse_ok, writing to this bit has no effect.

Address offset: 0x094 + 0x004 * x, (x = 0 to 2)

Reset value: 0x0000 000X, 0x0000 0000, 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SRLOCK[31:16]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SRLOCK[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SRLOCK[31:0]**: prevent reloading of the shadow word from OTP until next power-on reset.
0: OTP word not locked
1: OTP word locked and cannot be reloaded
Note: Reloading of OTP word 0 is prevented after its initial read on a system reset.

3.6.13 BSEC JTAG input register (BSEC_JTAGIN)

Address offset: 0x0AC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA[15:0]**: JTAG input data
16-bit copy from JTAG SoC register

3.6.14 BSEC JTAG output register (BSEC_JTAGOUT)

Address offset: 0x0B0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA[15:0]**: JTAG output data
16-bit copy to JTAG SoC register

3.6.15 BSEC scratch register (BSEC_SCRATCH)

Address offset: 0x0B4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: scratch data
This register is a general purpose register.

3.6.16 BSEC shadow register x (BSEC_OTP_DATAx)

The complete description of BSEC_OTP_DATAx register values and properties can be found in *Section 4: OTP mapping (OTP)*.

Several OTP directly impact BSEC behavior, such as:

- BSEC_OTP_DATA0[6:0] (see *Table 11: OTP modes definition on page 168*)

Address offset: 0x200 + 0x004 * x, (x = 0 to 95)

Reset value: 0xXXXX XXXX

The reset value depends on the actual OTP programmed value and the OTP mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: shadow register read from OTP or written by software (OTP emulation mode)
The update of shadow registers is controlled by other registers and by OTP security mode.

3.6.17 BSEC hardware configuration register (BSEC_HWCFGR)

Address offset: 0xFF0

Reset value: 0x0000 0014

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECC_USE[3:0]				SIZE[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **ECC_USE[3:0]**: protection / redundancy scheme used
0x0: No
0x1: ECC for upper OTP bits used
Others: reserved

Bits 3:0 **SIZE[3:0]**: OTP block size
0x2: 2 Kbits
0x4: 4 Kbits
0x8: 8 Kbits
Others: reserved

3.6.18 BSEC version register (BSEC_VERR)

Address offset: 0xFF4

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]**: major revision information

Bits 3:0 **MINREV[3:0]**: minor revision information

3.6.19 BSEC identification register (BSEC_IPIDR)

Address offset: 0xFF8

Reset value: 0x0010 0032

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: BSEC identification

3.6.20 BSEC size identification register (BSEC_SIDR)

Address offset: 0xFFC

Reset value: 0xA3C5 DD04

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]**: BSEC size identification

3.6.21 BSEC register map

Table 16 describes BSEC register map and reset values.

Table 16. BSEC register map and reset values

Offset	Register name and reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.5 on page 153* for the register boundary addresses.

4 OTP mapping (OTP)

The OTP bits are read or programmed by the Boot and Security and OTP control (BSEC). Before being programmed the OTP bit default is ‘0’.

The STM32MP153 device has 3072 OTP (One Time Programmable) bits which can be read-accessed in 96 words: BSEC_OTP_DATAx (x = 0 to 95):

– Lower OTP are listed in *Table 17: OTP list words 0 to 31*.

– Upper OTP are listed in *Table 18: OTP list words 32 to 95*.

The tables list the OTP word and bit field relevant properties using the following columns:

Name: OTP word synonym (for example OTP word0 is aka CFG0).

Description: OTP word or bit field description.

Prog: programming according to:

s: programmed by STMicroelectronics at factory whether product differentiations or keys.

u: available to any other software executed after bootROM.

r: programmed by bootrom (for example, during SSP process)

wplock:

n: not locked.

y: permanent programming lock by factory programming.

swprlockx: sticky lock set by boot listed as s[w][p][r][c] with character w, p, r, c according to:

w: indicates write of shadow is sticky locked,
p: indicates OTP programming is sticky locked,
r: indicates OTP reloading is sticky locked,

c: indicates OTP shadow is cleared during boot.

swprlock1: sticky lock set after boot in secured-open.

swprlock2: sticky lock set after boot in secured-closed (only possible for device with secure boot capabilities).

swprlock3: sticky lock set after boot for RMA.

Table 17. OTP list words 0 to 31

Word	Name	Bits	Description	prog	wp lock	swpr lock1	swpr lock2	swpr lock3	Detail description
0	CFG0	**OTP mode encoding**							
		0 to 5	OTP mode encoding	s	n	sw	sw	sw	-
		6	Closed_device bit[1]	u					
		7 to 31	Reserved for STMicroelectronics	s					
1	CFG1	**RPN coding**							
		0 to 7	RPN coding	s	y	sw	sw	sw	*Section 65.2: Device part number (RPN)*
		8 to 31	Reserved for STMicroelectronics						
2	CFG2	**Rerserved for STMicroelectronics**							
		0 to 3	SSP_ATTEMPTS	r	y	swprc	swprc	swprc	Set by bootROM during SSP process.
		4 to 31	Reserved for STMicroelectronics	s					-
3	CFG3	**Boot / source definition**							
		0	qspi_not_default_af	u	n	-	sw	-	0: QSPI uses default hard coded AFmux 1: QSPI uses AFmux defined in OTP
		1 to 2	emmc_if_id						0: Source is default one: SDMMC2 with default AFMux 1: SDMMC1. 2: SDMMC2 (uses non default AFmux defined in OTP)
		3 to 4	sd_if_id						0: Source is default one: SDMMC1 with default AFMux 1: SDMMC1 (uses non default AFmux defined in OTP) 2: SDMMC2
		5	no_cpu_pll						0: PLLs for CPU/AXI are enable for cold boot 1: PLLs for CPU/AXI are not enable for cold boot
		6	no_usb_dp_pullup						0: USB DP pull-up is set 1: USB DP pull-up is not set
		7 to 14	uart_instances_disabled						0b00000001 reserved. 0b00000010 disable USART2. 0b00000100 disable USART3. 0b00001000 disable UART4. 0b00010000 disable UART5. 0b00100000 disable UART6. 0b01000000 disable UART7. 0b10000000 disable USART8.
		15	no_data_cache						0: Data cache is used by bootrom. 1: Data cache is not used by bootrom.

1. This bit must never be programmed to 1 on products without secure-boot option available (refer to product datasheet). As an example, setting this bit on STM32MP15xA and STM32MP15xD products might make then permanently fail to boot. To avoid this case, it is recommended to make the OTP Word 0 permanent write locked (see *Section : OTP permanent write lock* in BSEC chapter).
2. The Public Key Hash is composed of 32 bytes: hash = byte0 byte1 byte2 ... byte31. These bytes are stored in the OTP in 8 words of 4 bytes each. The first four bytes of the hash table are stored in PKH0, the next four in PKH1, and so on. Within each word the lowest numbered byte is stored in the most significant position, and the highest numbered byte in the least significant position. Example: if hash = 00 01 02 03 04 05 06 07 08... then PKH0 = 0x00010203, PKH1 = 0x04050607, and so on.
3. This word is permanent write locked on devices without secure-boot option (see datasheet).

1. The ST Public ECDSA Chip Certificate for SSP is composed of 64 bytes: key = byte0 byte1 byte2 ... byte63. These bytes are stored in the OTP in 16 words of 4 bytes each. The first four bytes of the key table are stored in XK8, the next four in XK9, and so on. Within each word the lowest numbered byte is stored in the most significant position, and the highest numbered byte in the least significant position. Example: if key = 00 01 02 03 04 05 06 07 08 ... then XK8 = 0x00010203, XK9 = 0x04050607, and so on.

5 DDR3/LPDDR2/LPDDR3 controller (DDRCTRL)

5.1 Introduction

The DDRCTRL is a DDR-SDRAM controller and specific configuration of Synopsys uMCTL2 DDR controller v3.00a.

The DDRCTRL combined with the DDRPHYC (DDR PHY with Physical Utility Block) provides a complete memory interface solution for the DDR memory subsystem.

5.2 DDRCTRL features

- Two 64-bit AMBA® 4 AXI4 ports interface (XPI)
- AXI clock asynchronous to the controller
- Supported standards:
  - JEDEC DDR3 SDRAM specification, JESD79-3E for DDR3/3L with 32-bit interface
  - JEDEC LPDDR2 SDRAM specification, JESD209-2E for LPDDR2 with 32-bit interface
  - JEDEC LPDDR3 SDRAM specification, JESD209-3B for LPDDR3 with 32-bit interface

Warning: The STM32MP153x does not support the ODT for LPDDR3

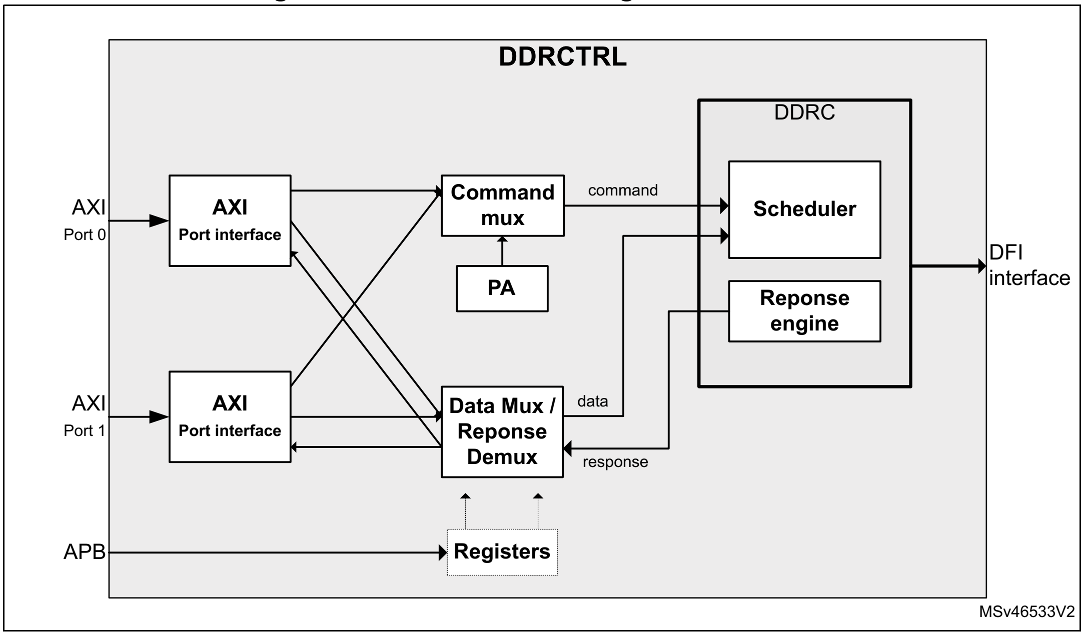
- 64-bit with DFI 2.1 compliant interface to DDRPHYC
- Advanced scheduler and SDRAM command generator
- 1:1 frequency ratio between the DDRC clock and the DDR PHY / external memory clock (aka SDR mode)
- Asynchronous clock between the AXI ports and the DDRC (the clock crossing is local to XPI's)
- Programmable full data width (32-bit) or half data width (16-bit)
- Advanced QoS support with 3 traffic class on read and 2 traffic classes on write
- Options to avoid starvation of lower priority traffic
- Guaranteed coherency for write-after-read (WAR) and read-after-write (RAW) on the AXI ports
- Programmable support for burst length options (4, 8,16)
- Write combine to allow multiple writes to the same address to be combined into a single write
- Single rank configuration
- Supports automatic SDRAM power-down entry and exit caused by a lack of transaction arrival for programmable time
- Supports automatic clock stop (LPDDR2/3) entry and exit caused by lack of transaction arrival

- Supports automatic low-power mode operation caused by a lack of transaction arrival for programmable time via hardware low-power interface
- Programmable paging policy selectable as any of the following:
  - Leave page open after accesses (Open page policy)
  - Close page when there are no further accesses available in the controller for that page
  - Auto-precharge with each access, with an optimization for page-close mode which leaves the page open after a flush for read-write and write-read collision cases
- Supports the self-refresh entry and exit as follows:
  - Automatic self-refresh entry and exit caused by lack of transaction arrival for programmable time
  - Self-refresh entry and exit under software control
- Support for deep power-down entry and exit under software control (LPDDR2)
- Support for explicit SDRAM mode register updates under software control
- Flexible address mapper logic to allow application specific mapping of row, column, bank bits
- Programmable support for 1T or 2T timing
- User-selectable refresh control options:
  - Controller-generated auto-refreshes at programmable average intervals
  - Ability to group up to 8 controller-generated refreshes together to be issued consecutively (this reduces the frequency of page closings, increasing the overall efficiency)
  - When the controller-generated refreshes are grouped, some refreshes can be issued speculatively when the controller is idle for a programmable period of time
  - Ability to disable controller-generated auto-refreshes
  - Ability to issue a refresh through direct software request
  - User-selectable ability to perform per-bank refreshes rather than all-banks refreshes for LPDDR2/3

5.3 DDRCTRL block diagram

A simplified DDRCTRL block diagram is shown in *Figure 7*.

Figure 7. DDRCTRL block diagram



5.4 DDRCTRL architecture overview

See the DDRCTRL block diagram in *Figure 7*.

- The AXI Port Interface (XPI) block provides the interface to the AXI port with the AXI bus protocol handling, data buffering and reordering for read data, data bus size / clock domain conversion and memory burst address alignment.
- The Port Arbiter (PA) block provides latency sensitive, priority based arbitration between the addresses issued by the XPI's.
- The DDR Controller (DDRC) block contains a logical CAM (Content Addressable Memory). This holds information on the commands, which is used by the scheduling algorithms to optimally schedule commands to be sent to the PHY, based on priority, bank/rank status and DDR timing constraints.
- The APB register block contains the software accessible registers
- The write data are stored until its associated command is issued to the PHY. The Write data buffer is local to DDRC.
- The read data are handled by the response engine in the DDRC and returned in the order of scheduled read commands on the HIF. the read data are stored in the read re-order buffer (local to XPI) and returned in order, to the AXI ports.

5.4.1 AXI Port Interface (XPI)

The XPI processes the AXI information: address, burst size, burst length and burst type and converts the AXI burst into read and write requests which are forwarded to the PA.

In the opposite direction, the XPI converts the responses from the DDRC into appropriate AXI responses.

Read address channel features:

- Supports any burst length for incremental bursts (<=256 byte) and burst with length <= 16 for WRAP bursts.
- The start address can be unaligned to the AXI width.
- The burst size can be less than the AXI width.
- The Read Address Queue (RAQ) is configured with dual queues (named “red” and “blue” queues)
- The clock crossing is performed in RAQ
- The depth of RAQ is set to 4.
- The generation of read request is based on AXI address and burst information and divided into packets equal to memory burst length (BL2, BL4, BL8, BL16)
- In case of an unaligned burst, the first read request is unaligned and the remaining read requests are aligned.

  In general, the re-alignment to a memory burst boundary potentially causes some data beats to be discarded (affecting bandwidth) and potentially introduces additional latency on the read data and response channel.

Write address channel features:

- The Write Address Queue (WAQ) is used to store all the addresses for write requests from a given port.
- There is a single queue for all AXI IDs from a given port.
- The write address channel behavior is similar to the read address channel.
- The clock crossing is performed in WAQ
- The depth of WAQ is set to 4.

Read data and response channels:

- The read data and response channel has a single data storage queue (RDQ)
- The clock crossing is performed in RDQ
- The depth of RDQ is set to 10
- The data from different IDs are stored in the same queue and are returned in the order of read address acceptance.
- A read reorder buffer is implemented in each port to reorder the read data for that port to the same order as the order of the AXI read commands
- The virtual channels and dynamic mapping (allow optimum reordering of read data)

5.4.2 Port arbiter (PA)

The PA arbitrates command requests from the 2 AXI ports to the HIF of the DDR Controller.

The PA is comprised of multiple tiers of arbitration stages which include:

a) Read/write arbitration (single HIF option)

b) 2 priority level arbitration based on port aging and expired-VPR/expired-VPW commands (timeout - priority0)

c) 2 priority level arbitration for read requests based on DDRC read priorities (HPR/LPR-VPR)

d) 32-priority level arbitration based on internal port aging or 16-priority level arbitration based AXI QoS inputs (programmed in AXI interconnect)

e) Round-robin arbitration to resolve ports having the same priority after passing all stages of arbitration.

Note: The port aging refers to counting down the time when a port has a request, but is not granted access to the DDRC.

The port timeout refers to when the port age becomes 0, which is also referred as the highest priority -priority0'.

The expired-VPR refers to Variable Priority Read commands whose counter has expired. The read/write credits refer to the DDRC 'Credit Mechanism' employed at the HIF interface.

5.4.3 Host Interface (HIF)

The HIF is an internal interface to the DDRCTRL (the AXI Port Interface and Port Arbiter handle all signals on this interface). It is only described for the sake of understanding QoS and multi-tier arbitration.

The read, write requests and write data are transferred from PA to DDRC using HIF interface.
The requests are throttled by:

a) A credit mechanism that ensures that the buffer space is available for any request made to the DDRC, prior to the request being made.

b) An independent stall mechanism that throttles requests when address collisions take place or when entering a self-refresh via the software self-refresh.

The read data are sent back via a common response interface

Credit mechanism:

The DDRC employs a credit mechanism to ensure that buffers do not overflow. The interface making the request to the DDRC, can only request commands for which it has been granted credits to issue.

The credits are tracked separately for the following three command types:

- High priority read (HPR)
- Low priority read (LPR)
- Write (WR)

The interface logic includes counters to track the number of credits. The credit count increments every time that the DDRC issues a credit.

The VPR commands are counted in the LPR credit bucket, the VPW commands are counted in the WR credit bucket.

Read requests:

When the LPR or HPR credit count is greater than zero, the interface can issue read requests to the DDRC

Write requests:

When the WR credit count is greater than zero, the interface can issue write requests to the DDRC.

5.4.4 DDR scheduler (DDRC)

The DDRC queues commands for scheduling and the SDRAM command generation unit. The DDRC includes 3 stores:

- HPR and LPR stores in common read CAM
- WR store in write CAM

Both CAMs are 16 entries, the HPR/LPR split is software programmable.

The DDRC allows the user to manage the Transaction Service Control (TSC) according to QoS and timeouts.

5.4.5 APB Interface (APB)

There are three classes of registers in DDRCTRL:

- Dynamic Registers
- Quasi Dynamic Registers
- Static Registers

The dynamic registers can be written at any time during operation.

The static registers can be written only when the controller is in reset.
The quasi dynamic registers can be written when the DDRCTRL is in reset or under specific conditions after the reset is done. To write the quasi dynamic registers, the DDRCTRL_SWCTL.SW_DONE bit must be set to 0 at the beginning of the programming sequence and set back to 1 at the end. After the DDRCTRL_SWSTAT.SW_DONE_ACK must be polled to acknowledge that the write action has been completed.

For more information about dynamic and quasi dynamic registers, refer to uMCTL2 Data Book [1]

5.4.6 DFI Interface (DFI)

The DDRCTRL contains a DFI MC (Memory Controller) interface, which is used to connect to a DFI compliant DDRPHYC to transfer address, control and data to the PHY.

The DFI interface is sub-divided into the following interface groups:

- Control interface
- Write data interface
- Read data interface
- Update interface
- Status interface
- Training interface (PHY-independent mode as supported by uMCTL2)
- Low-power control interface

The DDRCTRL, including its DFI interface, runs at the single data rate (SDR) clock (referred to as 1:1 frequency ratio mode in the DFI Specification), so all DFI command and address signals are equal in width to the equivalent DDR SDRAM signals. The DFI data signals are twice the width of the equivalent DDR SDRAM signals.

The DDRCTRL runs with a SDR clock and the DDRPHYC operates the SDR to DDR rate conversion on the data buses. In 1:1 frequency ratio mode, core_ddrc_core_clk and CK/CK# run at the same SDR clock frequency.

5.5 DDRCTRL functional description

5.5.1 Transaction service control (TSC) and quality of service (QoS)

The transaction service control allows the user to carefully manage the following:

- Costly read/write bus turn-around
- Priorities of read requests to generally favor high priority traffic while also preventing starvation of low priority traffic

This functionality is implemented in a simple 2-state machine for each traffic type with completely configurable controls. The states of the 2-state machine determine when reads/writes are serviced and the relative priority (high priority versus low priority reads) at any given moment.

The transactions are separated into five traffic classes: with 3 read classes and 2 write classes:

- Low priority reads (LPR)
- Variable priority reads (VPR)
- High priority reads (HPR)
- Normal priority writes (NPW)
- Variable priority writes (VPW)

The traffic classes are determined according to AXI QoS values (AxQOS[3:0]) set by the SOC AXI Interconnect (AXIM) and QoS regions settings.

The HPR and VPR/LPR are stored in a common read CAM which is split according to DDRCTRL_SCHED.lpr_num.

The VPR commands move to the expired-VPR after a timeout set by DDRCTRL_PERFVPR1.vpr_timeout. The expired -VPR goes to highest priority (Priority0).

VPW and NPW are stored in a common write CAM; the VPW commands go to the expired-VPR after timeout set by DDRC_PERFVPW1.vpw_timeout. The expired-VPW commands go to highest priority (Priority0).

Following is the list of registers related to transaction service and QoS control:

- DDRCTRL_SCHED: main scheduler control
- DDRCTRL_SCHED1: page Ccose timer
- DDRCTRL_PERFHPR1: controls HPR starvation and run_length
- DDRCTRL_PERFHPR1: controls HPR starvation and run_length
- DDRCTRL_PERFLPR1: controls LPR starvation and run_length
- DDRCTRL_PCFGR_0/1: AXI port read control for port 0/1
- DDRCTRL_PCFGW_0/1: AXI port write control for port 0/1
- DDRCTRL_PCFRQOS0_0/1 and DDRCTRL_PCFRQOS1_0/1: AXI port read QoS region mapping for port 0/1 and port timeouts.
- DDRCTRL_PCFWQOS0_0/1 and DDRCTRL_PCFWQOS1_0/1: AXI port write QoS region mapping for port 0/1 and port timeouts.

5.5.2 Paging policy options

Open page policy is set by DDRC_SCHED.pageclose = 0.

Any bank remains open until there is a need to close it because of a page miss or refresh timeout.

Intelligent precharge is a mid way between open and closed page policies, set by DDRC_SCHED.pageclose = 1 and DDRC_SCHED.pageclose_timer value to give the user control over the time waited when there are no page hits to a bank in the CAM before the auto-precharge or the explicit precharge is scheduled.

This timer allows the page to be kept open for a configurable number of clock cycles after there are no commands pending in the CAM to a bank. If there are pending commands higher up in the stream (for example XPI/PA) to the same bank/page, it gives a chance to be scheduled by the DDRCTRL as an open page command.

5.5.3 Power saving features

The DDRCTRL supports various methods to save power within the system using power saving opportunities in the SDRAM, DDRPHYC and the SOC.

Precharge Power Down: (PDN)

The DDRCTRL automatically puts SDRAM in the Precharge Power Down mode under the control of the following parameters:

- DDRCTRL_PWRCTRL.powerdown_en: to enter PDN (PDE) after a number of idle cycles
- DDRCTRL_PWRTMG.powerdown_to_x32: number of idle clocks in multiple of 32 to enter PDN
- DDRCTRL_DRAMTMG1.txp: minimum time to wait after PDN exit (PDX) to any command (DLL stays locked during PDN)

Note: During PDN refresh commands are performed and clocks must be maintained; the DDRCTRL pre-charges all banks before Precharge Power Down Exit (PDE).
The DDR3 slow power down (by setting MR0[12] =1) is not supported.

Self-Refresh: (SR)

The SR is a significant power saving opportunity for SDRAM. Furthermore during SR, the DLL's in DDRPHY C can be bypassed and the DDRCTRL clocks can be stopped.

The DDRCTRL puts SDRAM in Self Refresh (SR) in the following cases:

- Automatic SR when there are no read/write for a predefined time. This mode is controlled by:
  - DDRCTRL_PWRCTRL.selfref_en: to enter SR (SRE) after a number of idle cycle
  - DDRCTRL_PWRTMG.selfref_to_x32: number of idle clocks in multiple of 32 to enter SR.
- Software controlled SR: this mode is controlled by:
  - DDRCTRL_PWRCTRL.selfref_sw: setting this bit is referred as software self_refresh entry.
- Hardware controlled SR: this mode is supported by:
  - The FSM external to the DDRCTRL and under the control of RCC (refer to *Section 10: Reset and clock control (RCC)* for mode details). When the SoC goes into Stop mode, the DDRCTRL can put the SDRAM into self-refresh.

Deep power down: (DPD)

Note: DPD is applicable only to LPDDR2/3.
This power saving opportunity may be supported but does not present any significant interest because the SDRAM content is lost during DPD, practically DPD is not different from shutting down DDR

DDR3 DLL off mode:

The DDR3 DLL off mode may be supported at low frequencies, it requires MRS (MR1[0] =1) to disable DLL (by default DLL are on). It should use the software clock removal sequence:

```
Write 0 to DDRC_PCTRLn.port_en //to block AXI port n
Poll DDRC_PSTAT.rd_port_busy = 0
Poll DDRC_PSTAT.wr_port_busy = 0
Write 1 to DDRC_PWRCTL.selref_en // move to self-refresh
Poll DDRC_PSTAT.selfref_type = 2b10
... change AXI and DDRC clocks to lower value used w/ DLL OFF
... MRS to disable DLL
Write 0 to DDRC_PWRCTL.selref_en // exit self-refresh
Poll DDRC_PSTAT.selfref_type = 2b00
Write 1 to DDRC_PCTRLn.port_en // to unlock AXI ports
```

DDRPHY DLL bypass mode:

It is possible to disable DDRPHYC DLL's to save significant power at low frequencies; this mode must be controlled by software. The software sequence transitions SDRAM to Self-refresh during which clock frequency change is possible.

5.5.4 Address mapper

The DDRCTRL address mapper is converting the AXI port read and write request into row, bank, column SDRAM address at XPI level.

The address mapping is very flexible and defined according to DDR_ADDRMAP1 to DDR_ADDRMAP11 register settings.

The usual non interleaved Row/Bank/Column (RBC) and Bank/Row/Column (BRC) can be simply programmed according to SDRAM architecture (row/bank/column) and full or half width interface mode.

5.5.5 DRAM timing parameters

The DDRCTRL schedule commands to SDRAM according to multiple timings constrains as programmed in registers DDRCTRL_DRAMTMGn according to SDRAM JEDEC timing parameters versus frequency.

The following registers are related to timings constrains

– DDRCTRL_DRAMTMG0 to DDRCTRL_DRAMTMG14
– DDRCTRL_ODTTMG
– DDRCTRL_DFITMG0 and DDRCTRL_DFITMG1

5.5.6 SDRAM initialization sequence

The initialization is controlled by the DDRPHYC supporting a PUBL built-in initialization sequence for each DDR type and triggered by PIR registers. For more information see *Section 7: DDR physical interface control (DDRPHYC)*.

5.5.7 Refresh controls

The refresh can be issued using the auto-refresh feature in DDRCTRL or using the direct software request of the refresh command. DDRCTRL_RFSHCTL3.dis_auto_refresh selects the refresh method. When this bit is set to 1, uMCTL2 uses direct software request of refresh command. When it is set to 0, the internal auto-refresh feature is used.

Refresh using the direct software request of refresh command

Follow the steps to put the DDRCTRL in direct software request of refresh command mode:

1. Set DDRCTRL_RFSHCTL3.dis_auto_refresh bit to 1. When the register bit set, DDRCTRL checks for any pending refreshes. Any pending refreshes are issued right away using the 'critical refresh' feature inside DDRCTRL. After these refreshes are issued, all the refresh timers inside DDRCTRL are reset to 0. They are re-activated only when the auto-refresh feature is enabled.
2. The SoC core must keep track of the refresh requirements of the SDRAM.
3. The refresh command can be issued by setting the register bits DDRCTRL_DBGCMD.rank0_refresh to 1. When the refresh request is stored, the corresponding register bit is automatically cleared. The SoC core can initiate a refresh operation only if DDRCTRL_DBGSTAT.rank0_refresh_busy is low. DDRCTRL issues refresh to the SDRAM at the earliest.
4. Software-driven refresh commands are loaded into a 9-entry buffer, and are issued by DDRCTRL on the DFI as soon as it is legal to do so. If the buffer saturates, the DBGSTAT.rank0_refresh_busy remains asserted to prevent software from initiating further refreshes.

Refresh using the auto refresh feature inside DDRCTRL

The DDRCTRL provides advanced refresh controls. Besides fully-configurable refresh constraints (tRFC(min) and tREFI), it can also be programmed to gather refreshes to each rank of SDRAM to reduce the bandwidth consumed by refreshes and to increase the likelihood that refreshes can be serviced during an idle period.

The following registers are related to refresh controls:

– DDRCTRL_RFSHCTL0
– DDRCTRL_RFSHCTL3
– DDRCTRL_RFSHTMG

The purposes of refresh control are to:

- reduce the bandwidth impact of refresh cycles
- increase the likelihood of refreshes being serviced during idle periods
- provide fine-gain control of the trading-off the above benefits (to gather refreshes) versus the increased worst case latencies associated with gathering refreshes

For more information, refer to the register description; besides issuing refresh at regular intervals according to tRFC(min) and tREFI, several optimization options are possible: Burst refresh, Speculative refresh, and Per-bank refresh (applicable to LPDDR2/3).

5.5.8 ZQ calibration

This feature is applicable to all DDR types. The DDRCTRL can use the ZQ calibration command to calibrate the SDRAM RON (resistor ON) and ODT (on-die termination) values over PVT (process, voltage, temperature).

The DDRPHYC supports the RON and ODT calibration at initialization; for more information see *Section 7: DDR physical interface control (DDRPHYC)*.

The DDRCTRL may issue periodic calibrations which take less time at regular interval. (ZQCS).

The DDRCTRL may also issue a long calibration (ZQCL) after self-refresh exit

The following registers are related to ZQ calibration controls:

– DDRCTRL_ZQCTL0
– DDRCTRL_ZQCTL1
– DDRCTRL_ZQCTL2
– DDRCTRL_ZQSTAT

For more information on ZQ Calibration, refer to JEDEC specifications of the corresponding SDRAM.

5.6 DDRCTRL configuration

The DDRCTRL is a configuration of uMTCL2 with these major hardware configuration options:

– DDR mode support: DDR3/LPDDR2/LPDDR3
– Frequency ratio: 1:1
– Arbiter: include port arbiter (PA) with 2 AXI ports
– Partial write support
– CAM depth:16
– No dual HIF
– Variable priority read and variable priority write
– Dual read address queue per port

5.7 DDRCTRL registers

The DDRCTRL is configured to support DDR3/LPDDR2/LPDDR3. In the following register description section, ignore all references to other standards (mDDR, DDR2, DDR4, LPDDR4) as not being applicable.

Several register values depend on DDRCTRL configuration according to:

- Include arbiter (UMCTL2_INCL_ARB = 1)
- Partial write support (UMTCL2__PARTIAL_WR = 1)
- Variable priority read (UMCTL2_VPR_EN = 1)
- Variable priority write (UMCTL2_VPW_EN = 1)

The DDRCTRL registers are accessed only by words (32-bit).

R/W access to unmapped registers causes an APB SLVERR.

Write access to read-only registers is ignored without causing an APB SLVERR.

The Programming mode tag in the bit field describes how the field can be programmed according to:

- **Static**: the bit field is written only before DDRCTRL reset is released.
- **Dynamic**: the bit field may be written during run time.
- **Quasi-dynamic**: the bit field may be written during run time under special conditions and procedure (described in *Section 5.4.5: APB Interface (APB)*).

Quarter bus width (MSTR.data_bus_width = 10) is not supported.

For register summary see: *Table 19 on page 296*.

5.7.1 DDRCTRL master register 0 (DDRCTRL_MSTR)

Address offset: 0x000

Reset value: 0x0004 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BURST_RDWR[3:0]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DLL_OFF_MODE	Res.	DATA_BUS_WIDTH[1:0]		Res.	EN_2T_TIMING_MODE	BURSTCHOP	Res.	Res.	Res.	Res.	Res.	LPDDR3	LPDDR2	Res.	DDR3
rw		rw	rw		rw	rw						rw	rw		rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **BURST_RDWR[3:0]**: SDRAM burst length used:
- 0001 - Burst length of 2 (only supported for mDDR)
- 0010 - Burst length of 4
- 0100 - Burst length of 8
- 1000 - Burst length of 16 (only supported for mDDR, LPDDR2, and LPDDR4)

All other values are reserved.

This controls the burst size used to access the SDRAM. This must match the burst length mode register setting in the SDRAM. (For BC4/8 on-the-fly mode of DDR3 and DDR4, set this field to 0x0100) The burst length of 2 is not supported with the AXI ports when MEMC_BURST_LENGTH is 8.

The burst length of 2 is only supported when the controller is operating in 1:1 frequency mode.

For DDR3, DDR4 and LPDDR3, this must be set to 0x0100 (BL8).

For LPDDR4, this must be set to 0x1000 (BL16).

Programming mode: Static

Bit 15 **DLL_OFF_MODE**: Set to 1 when the DDRCTRL and DRAM has to be put in DLL-off mode for low frequency operation.

Set to 0 to put DDRCTRL and DRAM in DLL-on mode for normal frequency operation.

If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), dll_off_mode is not supported, and this bit must be set to '0'.

Programming mode: Quasi-dynamic Group 2

Bit 14 Reserved, must be kept at reset value.

Bits 13:12 **DATA_BUS_WIDTH[1:0]**: Selects proportion of DQ bus width that is used by the SDRAM
- 00 - Full DQ bus width to SDRAM
- 01 - Half DQ bus width to SDRAM
- 10 - Reserved
- 11 - Reserved

Programming mode: Static

Bit 11 Reserved, must be kept at reset value.

Bit 10 **EN_2T_TIMING_MODE**: If 1, then the DDRCTRL uses 2T timing. Otherwise, uses 1T timing. In 2T timing, all command signals (except chip select) are held for 2 clocks on the SDRAM bus. The chip select is asserted on the second cycle of the command

Note: 2T timing is not supported in LPDDR2/LPDDR3/LPDDR4 mode

Note: 2T timing is not supported if the configuration parameter MEMC_CMD_RTN2IDLE is set

Note: 2T timing is not supported in DDR4 geardown mode.

Note: 2T timing is not supported in Shared-AC dual channel mode and the register value is don't care.

Programming mode: Static

Bit 9 **BURSTCHOP**: When set, enable burst-chop (BC4 or 8 on-the-fly) in DDR3/DDR4. The burst-chop for Reads is exercised only in HIF configurations (UMCTL2_INCL_ARB not set) and if in full bus width mode (MSTR.data_bus_width = 00) and if MEMC_BURST_LENGTH=8 or 16. The burst-chop for writes is exercised only if partial writes enabled (UMCTL2_PARTIAL_WR=1) and if CRC is disabled (CRCPARCTL1.crc_enable = 0).

The BC4 (fixed) mode is not supported.

Programming mode: Static

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **LPDDR3**: Selects LPDDR3 SDRAM
- 1 - LPDDR3 SDRAM device in use.
- 0 - non-LPDDR3 device in use

Present only in designs configured to support LPDDR3.
Programming mode: Static

Bit 2 **LPDDR2**: Selects LPDDR2 SDRAM
- 1 - LPDDR2 SDRAM device in use.
- 0 - non-LPDDR2 device in use

Present only in designs configured to support LPDDR2.
Programming mode: Static

Bit 1 Reserved, must be kept at reset value.

Bit 0 **DDR3**: Selects DDR3 SDRAM
- 1 - DDR3 SDRAM device in use
- 0 - non-DDR3 SDRAM device in use

Only present in designs that support DDR3.
Programming mode: Static

5.7.2 DDRCTRL operating mode status register (DDRCTRL_STAT)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SELFREF_CAM_NOT_EMPTY	Res.	Res.	Res.	Res.	Res.	Res.	SELFREF_TYPE[1:0]		Res.	OPERATING_MODE[2:0]		
			r							r	r		r	r	r

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **SELFREF_CAM_NOT_EMPTY**: Self refresh with CAMs not empty. Set to 1 when Self Refresh is entered but CAMs are not drained. Cleared after exiting Self Refresh.
Programming mode: Dynamic

Bits 11:6 Reserved, must be kept at reset value.

Bits 5:4 **SELFREF_TYPE[1:0]**: Flags if Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4) is entered and if it was under Automatic Self Refresh control only or not.

- 00 - SDRAM is not in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4). If retry is enabled by CRCPARCTRL1.crc_parity_retry_enable, this also indicates SRE command is still in parity error window or retry is in-progress.
- 11 - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was caused by Automatic Self Refresh only. If retry is enabled, this guarantees SRE command is executed correctly without parity error.
- 10 - SDRAM is in Self Refresh (except LPDDR4) or SR-Powerdown (LPDDR4), which was not caused solely under Automatic Self Refresh control. It could have been caused by Hardware Low-power Interface and/or Software (PWRCTL.selfref_sw). If retry is enabled, this guarantees SRE command is executed correctly without parity error.
- 01 - SDRAM is in Self Refresh, which was caused by PHY Master Request.

Programming mode: Dynamic

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **OPERATING_MODE[2:0]**: Operating mode. This is 3-bits wide in configurations with mDDR/LPDDR2/LPDDR3/LPDDR4/DDR4 support and 2-bits in all other configurations.

Condition non-mDDR/LPDDR2/LPDDR3/LPDDR4 and non-DDR4 designs:
- 000 - Init
- 001 - Normal
- 010 - Power-down
- 011 - Self refresh

Condition mDDR/LPDDR2/LPDDR3 or DDR4 designs:
- 000 - Init
- 001 - Normal
- 010 - Power-down
- 011 - Self refresh
- 1XX - Deep power-down / Maximum Power Saving Mode

Condition LPDDR4 designs:
- 000 - Init
- 001 - Normal
- 010 - Power-down
- 011 - Self refresh / Self refresh power-down

Programming mode: Dynamic

5.7.3 DDRCTRL mode register read/write control register 0 (DDRCTRL_MRCTRL0)

Address offset: 0x010

Reset value: 0x0000 0010

Mode Register Read/Write Control Register 0.

Note: Do not enable more than one of the following fields simultaneously:

- *sw_init_int*
- *pda_en*
- *mpr_en*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR_WR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR_ADDR[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MR_TYPE
rw	rw	rw	rw												rw

Bit 31 **MR_WR**: Setting this register bit to 1 triggers a mode register read or write operation. When the MR operation is complete, the DDRCTRL automatically clears this bit. The other register fields of this register must be written in a separate APB transaction, before setting this mr_wr bit. It is recommended NOT to set this signal if in Init, Deep power-down or MPSM operating modes.

Programming mode: Dynamic

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:12 **MR_ADDR[3:0]**: Address of the mode register that is to be written to.

- 0000 - MR0
- 0001 - MR1
- 0010 - MR2
- 0011 - MR3
- 0100 - MR4
- 0101 - MR5
- 0110 - MR6
- 0111 - MR7

Don't Care for LPDDR2/LPDDR3/LPDDR4 (see MRCTRL1.mr_data for mode register addressing in LPDDR2/LPDDR3/LPDDR4)

This signal is also used for writing to control words of the register chip on RDIMMs/LRDIMMs. In that case, it corresponds to the bank address bits sent to the RDIMM/LRDIMM

In case of DDR4, the bit[3:2] corresponds to the bank group bits. Therefore, the bit[3] as well as the bit[2:0] must be set to an appropriate value which is considered both the Address Mirroring of UDIMMs/RDIMMs/LRDIMMs and the Output Inversion of RDIMMs/LRDIMMs.

Programming mode: Dynamic

Bits 11:5 Reserved, must be kept at reset value.

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **MR_TYPE**: Indicates whether the mode register operation is read or write. Only used for LPDDR2/LPDDR3/LPDDR4/DDR4.
- 0 - Write, MRCTRL register does not support MR read for LPDDR2/3
- 1 - Reserved

Programming mode: Dynamic

5.7.4 DDRCTRL mode register read/write control register 1 (DDRCTRL_MRCTRL1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR_DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MR_DATA[15:0]**: Mode register write data for all non-LPDDR2/non-LPDDR3/non-LPDDR4 modes.

For LPDDR2/LPDDR3/LPDDR4, MRCTRL1[15:0] are interpreted as

[15:8] MR Address

[7:0] MR data for writes, don't care for reads. This is 18-bits wide in configurations with DDR4 support and 16-bits in all other configurations.

Programming mode: Dynamic

5.7.5 DDRCTRL mode register read/write status register (DDRCTRL_MRSTAT)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MR_WR_BUSY
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **MR_WR_BUSY**: The SoC core may initiate a MR write operation only if this signal is low. This signal goes high in the clock after the DDRCTRL accepts the MRW/MRR request. It goes low when the MRW/MRR command is issued to the SDRAM. It is recommended not to perform MRW/MRR commands when 'MRSTAT.mr_wr_busy' is high.

- 0 - Indicates that the SoC core can initiate a mode register write operation
- 1 - Indicates that mode register write operation is in progress

Programming mode: Dynamic

5.7.6 DDRCTRL temperature derate enable register (DDRCTRL_DERATEEN)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DERATE_BYTE[3:0]				Res.	DERATE_VALUE[1:0]		DERATE_ENABLE
								rw	rw	rw	rw		rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **DERATE_BYTE[3:0]**: Derate byte
Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4
Indicates which byte of the MRR data is used for derating. The maximum valid value depends on MEMC_DRAM_TOTAL_DATA_WIDTH.
Programming mode: Static

Bit 3 Reserved, must be kept at reset value.

Bits 2:1 **DERATE_VALUE[1:0]**: Derate value
- 0 - Derating uses +1.
- 1 - Derating uses +2.

Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4
Set to 0 for all LPDDR2 speed grades as derating value of +1.875 ns is less than a core_ddrc_core_clk period.
For LPDDR3/4, if the period of core_ddrc_core_clk is less than 1.875ns, this register field should be set to 1; otherwise it should be set to 0.
Programming mode: Quasi-dynamic Group 2 and Group 4

Bit 0 **DERATE_ENABLE**: Enables derating
- 0 - Timing parameter derating is disabled
- 1 - Timing parameter derating is enabled using MR4 read value.

Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4
This field must be set to '0' for non-LPDDR2/LPDDR3/LPDDR4 mode.
Programming mode: Dynamic

5.7.7 DDRCTRL temperature derate interval register (DDRCTRL_DERATEINT)

Address offset: 0x024

Reset value: 0x0080 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR4_READ_INTERVAL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MR4_READ_INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MR4_READ_INTERVAL[31:0]**: Interval between two MR4 reads, used to derate the timing parameters.
Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4. This register must not be set to zero.
Unit: DFI clock cycle.
Programming mode: Static

5.7.8 DDRCTRL low power control register (DDRCTRL_PWRCTL)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIS_CAM_DRAIN_SELFREF	Res.	SELFREF_SW	Res.	EN_DFI_DRAM_CLK_DISABLE	DEEPPOWERDOWN_EN	POWERDOWN_EN	SELFREF_EN
								rw		rw		rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **DIS_CAM_DRAIN_SELFREF**: Indicates whether skipping CAM draining is allowed when entering Self-Refresh.

This register field cannot be modified while PWRCTL.selfref_sw==1.

- 0 - CAMs must be empty before entering SR
- 1 - CAMs are not emptied before entering SR (unsupported)

Note, PWRCTL.dis_cam_drain_selfref=1 is unsupported in this release. PWRCTL.dis_cam_drain_selfref=0 is required.

Programming mode: Dynamic

Bit 6 Reserved, must be kept at reset value.

Bit 5 **SELFREF_SW**: A value of 1 to this register causes system to move to Self Refresh state immediately, as long as it is not in INIT or DPD/MPSM operating_mode. This is referred to as Software Entry/Exit to Self Refresh.

- 1 - Software Entry to Self Refresh
- 0 - Software Exit from Self Refresh

Programming mode: Dynamic

Bit 4 Reserved, must be kept at reset value.

Bit 3 **EN_DFI_DRAM_CLK_DISABLE**: Enable the assertion of dfi_dram_clk_disable whenever a clock is not required by the SDRAM.
If set to 0, dfi_dram_clk_disable is never asserted.
Assertion of dfi_dram_clk_disable is as follows:
In DDR2/DDR3, can only be asserted in Self Refresh.
In DDR4, can be asserted in following:
- in Self Refresh.
- in Maximum Power Saving Mode
In mDDR/LPDDR2/LPDDR3, can be asserted in following:
- in Self Refresh
- in Power Down
- in Deep Power Down
- during Normal operation (Clock Stop)
In LPDDR4, can be asserted in following:
- in Self Refresh Power Down
- in Power Down
- during Normal operation (Clock Stop)
Programming mode: Dynamic

Bit 2 **DEEPPOWERDOWN_EN**: When this is 1, DDRCTRL puts the SDRAM into deep power-down mode when the transaction store is empty.
This register must be reset to '0' to bring DDRCTRL out of deep power-down mode. Controller performs automatic SDRAM initialization on deep power-down exit.
Present only in designs configured to support mDDR or LPDDR2 or LPDDR3. For non-mDDR/non-LPDDR2/non-LPDDR3, this register should not be set to 1.
For performance only
Programming mode: Dynamic

Bit 1 **POWERDOWN_EN**: If true then the DDRCTRL goes into power-down after a programmable number of cycles "maximum idle clocks before power down" (PWRTMG.powerdown_to_x32).
This register bit may be re-programmed during the course of normal operation.
Programming mode: Dynamic

Bit 0 **SELFREF_EN**: If true then the DDRCTRL puts the SDRAM into Self Refresh after a programmable number of cycles "maximum idle clocks before Self Refresh (PWRTMG.selfref_to_x32)". This register bit may be re-programmed during the course of normal operation.
Programming mode: Dynamic

5.7.9 DDRCTRL low power timing register (DDRCTRL_PWRTMG)

Address offset: 0x034

Reset value: 0x0040 2010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SELFREF_TO_X32[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T_DPD_X4096[7:0]								Res.	Res.	Res.	POWERDOWN_TO_X32[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **SELFREF_TO_X32[7:0]**: After this many clocks of the DDRC command channel being idle the DDRCTRL automatically puts the SDRAM into Self Refresh. The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.selfref_en.

Unit: Multiples of 32 DFI clocks.

For performance only.

Programming mode: Quasi-dynamic Group 4

Bits 15:8 **T_DPD_X4096[7:0]**: Minimum deep power-down time.

For mDDR, value from the JEDEC specification is 0 as mDDR exits from deep power-down mode immediately after PWRCTL.deeppowerdown_en is de-asserted.

For LPDDR2/LPDDR3, value from the JEDEC specification is 500 us.

Unit: Multiples of 4096 DFI clocks.

Present only in designs configured to support mDDR, LPDDR2 or LPDDR3.

For performance only.

Programming mode: Quasi-dynamic Group 4

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **POWERDOWN_TO_X32[4:0]**: After this many clocks of the DDRC command channel being idle the DDRCTRL automatically puts the SDRAM into power-down. The DDRC command channel is considered idle when there are no HIF commands outstanding. This must be enabled in the PWRCTL.powerdown_en.

Unit: Multiples of 32 DFI clocks

For performance only.

Programming mode: Quasi-dynamic Group 4

5.7.10 DDRCTRL hardware low power control register (DDRCTRL_HWLPCTL)

Address offset: 0x038

Reset value: 0x0000 0003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	HW_LP_IDLE_X32[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HW_LP_EXIT_IDLE_EN	HW_LP_EN
														rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HW_LP_IDLE_X32[11:0]**: Hardware idle period. The cactive_ddrc output is driven low if the DDRC command channel is idle for hw_lp_idle * 32 cycles if not in INIT or DPD/MPSM operating_mode. The DDRC command channel is considered idle when there are no HIF commands outstanding. The hardware idle function is disabled when hw_lp_idle_x32=0.

Unit: Multiples of 32 DFI clocks.

For performance only.

Programming mode: Static

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **HW_LP_EXIT_IDLE_EN**: When this bit is programmed to 1 the cactive_in_ddrc pin of the DDRC can be used to exit from the automatic clock stop, automatic power down or automatic self-refresh modes. Note, it does not cause exit of Self-Refresh that is caused by Hardware Low power interface and/or software (PWRCTL.selfref_sw).

Programming mode: Static

Bit 0 **HW_LP_EN**: Enable for hardware low power interface.

Programming mode: Quasi-dynamic Group 3

5.7.11 DDRCTRL refresh control register 0 (DDRCTRL_RFSHCTL0)

Address offset: 0x050

Reset value: 0x0021 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REFRESH_MARGIN[3:0]				Res.	Res.	Res.	REFRESH_TO_X32[4]
								rw	rw	rw	rw				rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH_TO_X32[3:0]				Res.	Res.	Res.	REFRESH_BURST[4:0]					Res.	PER_BANK_REFRESH	Res.	Res.
rw	rw	rw	rw				rw	rw	rw	rw	rw		rw		

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **REFRESH_MARGIN[3:0]**: Threshold value in number of DFI clock cycles before the critical refresh or page timer expires. A critical refresh is to be issued before this threshold is reached. It is recommended that this not be changed from the default value, currently shown as 0x2. It must always be less than internally used t_rfc_nom/32. Note that internally used t_rfc_nom is equal to RFSHTMG.t_rfc_nom_x1_x32 * 32 if RFSHTMG.t_rfc_nom_x1_sel=0. If RFSHTMG.t_rfc_nom_x1_sel=1 (for LPDDR2/LPDDR3/LPDDR4 per-bank refresh only), internally used t_rfc_nom is equal to RFSHTMG.t_rfc_nom_x1_x32. Note that, in LPDDR2/LPDDR3/LPDDR4, internally used t_rfc_nom may be divided by four if derating is enabled (DERATEEN.derate_enable=1).

Unit: Multiples of 32 DFI clocks.

Programming mode: Dynamic - Refresh Related

Bits 19:17 Reserved, must be kept at reset value.

Bits 16:12 **REFRESH_TO_X32[4:0]**: If the refresh timer (tRFCnom, also known as tREFI) has expired at least once, but it has not expired (RFSHCTL0.refresh_burst+1) times yet, then a speculative refresh may be performed. A speculative refresh is a refresh performed at a time when refresh would be useful, but before it is absolutely required. When the SDRAM bus is idle for a period of time determined by this RFSHCTL0.refresh_to_x32 and the refresh timer has expired at least once since the last refresh, then a speculative refresh is performed. Speculative refreshes continues successively until there are no refreshes pending or until new reads or writes are issued to the DDRCTRL.

For performance only.

Unit: Multiples of 32 DFI clocks.

Programming mode: Dynamic - Refresh Related

Bits 11:9 Reserved, must be kept at reset value.

Bits 8:4 **REFRESH_BURST[4:0]**: The programmed value + 1 is the number of refresh timeouts that is allowed to accumulate before traffic is blocked and the refreshes are forced to execute. Closing pages to perform a refresh is a one-time penalty that must be paid for each group of refreshes. Therefore, performing refreshes in a burst reduces the per-refresh penalty of these page closings. Higher numbers for RFSHCTL.refresh_burst slightly increases utilization; lower numbers decreases the worst-case latency associated with refreshes.

- 0 - single refresh
- 1 - burst-of-2 refresh
- 7 - burst-of-8 refresh

For information on burst refresh feature refer to section 3.9 of DDR2 JEDEC specification - JESD79-2F.pdf.

For DDR2/3, the refresh is always per-rank and not per-bank. The rank refresh can be accumulated over 8*tREFI cycles using the burst refresh feature.

In DDR4 mode, according to Fine Granularity feature, 8 refreshes can be postponed in 1X mode, 16 refreshes in 2X mode and 32 refreshes in 4X mode. If using PHY-initiated updates, care must be taken in the setting of RFSHCTL0.refresh_burst, to ensure that tRFCmax is not violated due to a PHY-initiated update occurring shortly before a refresh burst was due. In this situation, the refresh burst is delayed until the PHY-initiated update is complete.

Programming mode: dynamic - refresh related

Bit 3 Reserved, must be kept at reset value.

Bit 2 **PER_BANK_REFRESH**:

- 1 - Per bank refresh;
- 0 - All bank refresh.

Per bank refresh allows traffic to flow to other banks. Per bank refresh is not supported by all LPDDR2 devices but should be supported by all LPDDR3/LPDDR4 devices. Present only in designs configured to support LPDDR2/LPDDR3/LPDDR4

Programming mode: Static

Bits 1:0 Reserved, must be kept at reset value.

5.7.12 DDRCTRL refresh control register 3 (DDRCTRL_RFSHCTL3)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REFRESH_UPDATE_LEVEL	DIS_AUTO_REFRESH
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **REFRESH_UPDATE_LEVEL**: Toggles this signal (either from 0 to 1 or from 1 to 0) to indicate that the refresh register(s) have been updated.

refresh_update_level must not be toggled when the DDRC is in reset (core_ddrc_rstn = 0).

The refresh register(s) are automatically updated when exiting reset.

Programming mode: Dynamic

Bit 0 **DIS_AUTO_REFRESH**: When '1', disable auto-refresh generated by the DDRCTRL. When auto-refresh is disabled, the SoC core must generate refreshes using the registers DBGCMD.rankn_refresh.

When dis_auto_refresh transitions from 0 to 1, any pending refreshes are immediately scheduled by the DDRCTRL.

If DDR4 CRC/parity retry is enabled (CRCPARCTL1.crc_parity_retry_enable = 1), disable auto-refresh is not supported, and this bit must be set to '0'.

(DDR4 only) If FGR mode is enabled (RFSHCTL3.refresh_mode > 0), disable auto-refresh is not supported, and this bit must be set to '0'.

This register field is changeable on the fly.

Programming mode: Dynamic - Refresh Related

5.7.13 DDRCTRL refresh timing register (DDRCTRL_RFSHTMG)

Address offset: 0x064

Reset value: 0x0062 008C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
T_RFC_NOM_X1_SEL	Res.	Res.	Res.	T_RFC_NOM_X1_X32[11:0]											
rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LPDDR3_TREFBW_EN	Res.	Res.	Res.	Res.	Res.	T_RFC_MIN[9:0]									
rw						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **T_RFC_NOM_X1_SEL**: Specifies whether the t_rfc_nom_x1_x32 register value is x1 or x32.
Programming mode: Dynamic - Refresh Related

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **T_RFC_NOM_X1_X32[11:0]**: tREFI: Average time interval between refreshes per rank (Specification: 7.8us for DDR2, DDR3 and DDR4. See JEDEC specification for mDDR, LPDDR2, LPDDR3 and LPDDR4).

For LPDDR2/LPDDR3/LPDDR4:

- If using all-bank refreshes (RFSHCTL0.per_bank_refresh = 0), this register should be set to tREFIab
- If using per-bank refreshes (RFSHCTL0.per_bank_refresh = 1), this register should be set to tREFIpb

When the controller is operating in 1:2 frequency ratio mode, program this to (tREFI/2), no rounding up.

In DDR4 mode, tREFI value is different depending on the refresh mode. The user should program the appropriate value from the spec based on the value programmed in the refresh mode register.

Note that if RFSHTMG.t_rfc_nom_x1_sel == 1, RFSHTMG.t_rfc_nom_x1_x32 must be greater than RFSHTMG.t_rfc_min; if RFSHTMG.t_rfc_nom_x1_sel == 0, RFSHTMG.t_rfc_nom_x1_x32 * 32 must be greater than RFSHTMG.t_rfc_min; RFSHTMG.t_rfc_nom_x1_x32 must be greater than 0x1.

- Non-DDR4 or DDR4 Fixed 1x mode: RFSHTMG.t_rfc_nom_x1_x32 must be less than or equal to 0xFFE.
- DDR4 Fixed 2x mode: RFSHTMG.t_rfc_nom_x1_x32 must be less than or equal to 0x7FF.
- DDR4 Fixed 4x mode: RFSHTMG.t_rfc_nom_x1_x32 must be less than or equal to 0x3FF.

Unit: Clocks or multiples of 32 clocks, depending on RFSHTMG.t_rfc_nom_x1_sel.

Programming mode: Dynamic - Refresh Related

Bit 15 **LPDDR3_TREFBW_EN**: Used only when LPDDR3 memory type is connected. Should only be changed when DDRCTRL is in reset. Specifies whether to use the tREFBW parameter (required by some LPDDR3 devices which comply with earlier versions of the LPDDR3 JEDEC specification) or not:

- 0 - tREFBW parameter not used
- 1 - tREFBW parameter used

Programming mode: Static

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:0 **T_RFC_MIN[9:0]**: tRFC (min): Minimum time from refresh to refresh or activate.

When the controller is operating in 1:1 mode, t_rfc_min should be set to RoundUp(tRFCmin/tCK).

When the controller is operating in 1:2 mode, t_rfc_min should be set to RoundUp(RoundUp(tRFCmin/tCK)/2).

In LPDDR2/LPDDR3/LPDDR4 mode:

- If using all-bank refreshes, the tRFCmin value in the above equations is equal to tRFCab
- If using per-bank refreshes, the tRFCmin value in the above equations is equal to tRFCpb

In DDR4 mode, the tRFCmin value in the above equations is different depending on the refresh mode (fixed 1X,2X,4X) and the device density. The user should program the appropriate value from the spec based on the 'refresh_mode' and the device density that is used.

Unit: Clocks.

Programming mode: Dynamic - Refresh Related

5.7.14 DDRCTRL CRC parity control register 0 (DDRCTRL_CRCPARCTL0)

Address offset: 0x0C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DFI_ALERT_ERR_CNT_CLR	DFI_ALERT_ERR_INT_CLR	DFI_ALERT_ERR_INT_EN
													rc_w1	rc_w1	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DFI_ALERT_ERR_CNT_CLR**: DFI alert error count clear. Clear bit for DFI alert error counter. Asserting this bit, clears the DFI alert error counter, CRCPARSTAT.dfi_alert_err_cnt. When the clear operation is complete, the DDRCTRL automatically clears this bit.

Programming mode: Dynamic

Bit 1 **DFI_ALERT_ERR_INT_CLR**: Interrupt clear bit for DFI alert error. If this bit is set, the alert error interrupt on CRCPARSTAT.dfi_alert_err_int is cleared. When the clear operation is complete, the DDRCTRL automatically clears this bit.
Programming mode: Dynamic

Bit 0 **DFI_ALERT_ERR_INT_EN**: Interrupt enable bit for DFI alert error. If this bit is set, any parity/CRC error detected on the dfi_alert_n input results in an interrupt being set on CRCPARSTAT.dfi_alert_err_int.
Programming mode: Dynamic

5.7.15 DDRCTRL CRC parity status register (DDRCTRL_CRCPARSTAT)

Address offset: 0x0CC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
DFI_ALERT_ERR_CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DFI_ALERT_ERR_INT**: DFI alert error interrupt.
If a parity/CRC error is detected on dfi_alert_n, and the interrupt is enabled by CRCPARCTL0.dfi_alert_err_int_en, this interrupt bit is set. It remains set until cleared by CRCPARCTL0.dfi_alert_err_int_clr
Programming mode: Static

Bits 15:0 **DFI_ALERT_ERR_CNT[15:0]**: DFI alert error count.
If a parity/CRC error is detected on dfi_alert_n, this counter be incremented. This is independent of the setting of CRCPARCTL0.dfi_alert_err_int_en. It saturates at 0xFFFF, and can be cleared by asserting CRCPARCTL0.dfi_alert_err_cnt_clr.
Programming mode: Static

5.7.16 DDRCTRL SDRAM initialization register 0 (DDRCTRL_INIT0)

Address offset: 0x0D0

Reset value: 0x0002 004E

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SKIP_DRAM_INIT[1:0]		Res.	Res.	Res.	Res.	POST_CKE_X1024[9:0]									
rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	PRE_CKE_X1024[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **SKIP_DRAM_INIT[1:0]**: If lower bit is enabled the SDRAM initialization routine is skipped. The upper bit decides what state the controller starts up in when reset is removed

- 00 - SDRAM Initialization routine is run after power-up
- 01 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Normal Mode
- 11 - SDRAM Initialization routine is skipped after power-up. Controller starts up in Self-refresh Mode
- 10 - Reserved.

Programming mode: Quasi-dynamic Group 2

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:16 **POST_CKE_X1024[9:0]**: Cycles to wait after driving CKE high to start the SDRAM initialization sequence.

Unit: 1024 DFI clock cycles.

DDR2 typically requires a 400 ns delay, requiring this value to be programmed to 2 at all clock speeds.

LPDDR2/LPDDR3 typically requires this to be programmed for a delay of 200 us.

LPDDR4 typically requires this to be programmed for a delay of 2 us.

When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.

Programming mode: Static

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **PRE_CKE_X1024[11:0]**: Cycles to wait after reset before driving CKE high to start the SDRAM initialization sequence.

Unit: 1024 DFI clock cycles.

DDR2 specifications typically require this to be programmed for a delay of >= 200 us.

LPDDR2/LPDDR3: tINIT1 of 100 ns (min)

LPDDR4: tINIT3 of 2 ms (min)

When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.

For DDR3/DDR4 RDIMMs, this should include the time needed to satisfy tSTAB

Programming mode: Static

5.7.17 DDRCTRL SDRAM initialization register 1 (DDRCTRL_INIT1)

Address offset: 0x0D4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DRAM_RSTN_X1024[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRE_OCD_X32[3:0]			
												rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **DRAM_RSTN_X1024[8:0]**: Number of cycles to assert SDRAM reset signal during init sequence.

This is only present for designs supporting DDR3, DDR4 or LPDDR4 devices. For use with a DDR PHY, this should be set to a minimum of 1.

When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.

Unit: 1024 DFI clock cycles.

Programming mode: Static

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:0 **PRE_OCD_X32[3:0]**: Wait period before driving the OCD complete command to SDRAM.

Unit: Counts of a global timer that pulses every 32 DFI clock cycles.

There is no known specific requirement for this; it may be set to zero.

Programming mode: Static

5.7.18 DDRCTRL SDRAM initialization register 2 (DDRCTRL_INIT2)

Address offset: 0x0D8

Reset value: 0x0000 0D05

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **IDLE_AFTER_RESET_X32[7:0]**: Idle time after the reset command, tINIT4. Present only in designs configured to support LPDDR2.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: 32 DFI clock cycles.
Programming mode: Static

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **MIN_STABLE_CLOCK_X1[3:0]**: Time to wait after the first CKE high, tINIT2. Present only in designs configured to support LPDDR2/LPDDR3.
LPDDR2/LPDDR3 typically requires 5 x tCK delay.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: DFI clock cycles.
Programming mode: Static

5.7.19 DDRCTRL SDRAM initialization register 3 (DDRCTRL_INIT3)

Address offset: 0x0DC

Reset value: 0x0000 0510

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

EMR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **MR[15:0]**: DDR2: Value to write to MR register. Bit 8 is for DLL and the setting here is ignored. The DDRCTRL sets this bit appropriately.
DDR3/DDR4: Value loaded into MR0 register.
mDDR: Value to write to MR register.
LPDDR2/LPDDR3/LPDDR4 - Value to write to MR1 register
Programming mode: Quasi-dynamic Group 1 and Group 4

Bits 15:0 **EMR[15:0]**: DDR2: Value to write to EMR register. Bits 9:7 are for OCD and the setting in this register is ignored. The DDRCTRL sets those bits appropriately.
DDR3/DDR4: Value to write to MR1 register Set bit 7 to 0. If PHY-evaluation mode training is enabled, this bit is set appropriately by the DDRCTRL during write leveling.
mDDR: Value to write to EMR register.
LPDDR2/LPDDR3/LPDDR4 - Value to write to MR2 register
Programming mode: Quasi-dynamic Group 4

5.7.20 DDRCTRL SDRAM initialization register 4 (DDRCTRL_INIT4)

Address offset: 0x0E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EMR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **EMR2[15:0]**: DDR2: Value to write to EMR2 register.
DDR3/DDR4: Value to write to MR2 register
LPDDR2/LPDDR3/LPDDR4: Value to write to MR3 register
mDDR: Unused
Programming mode: Quasi-dynamic Group 4

Bits 15:0 **EMR3[15:0]**: DDR2: Value to write to EMR3 register.
DDR3/DDR4: Value to write to MR3 register
mDDR/LPDDR2/LPDDR3: Unused
LPDDR4: Value to write to MR13 register
Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.21 DDRCTRL SDRAM initialization register 5 (DDRCTRL_INIT5)

Address offset: 0x0E4

Reset value: 0x0010 0004

Res.	Res.	Res.	Res.	Res.	Res.	MAX_AUTO_INIT_X1024[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **DEV_ZQINIT_X32[7:0]**: ZQ initial calibration, tZQINIT. Present only in designs configured to support DDR3 or DDR4 or LPDDR2/LPDDR3.
DDR3 typically requires 512 SDRAM clock cycles.
DDR4 requires 1024 SDRAM clock cycles.
LPDDR2/LPDDR3 requires 1 us.
When the controller is operating in 1:2 frequency ratio mode, program this to JEDEC spec value divided by 2, and round it up to the next integer value.
Unit: 32 DFI clock cycles.
Programming mode: Static

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **MAX_AUTO_INIT_X1024[9:0]**: Maximum duration of the auto initialization, tINIT5. Present only in designs configured to support LPDDR2/LPDDR3.
LPDDR2/LPDDR3 typically requires 10 us.
Unit: 1024 DFI clock cycles.
Programming mode: Static

5.7.22 DDRCTRL DIMM control register (DDRCTRL_DIMMCTL)

Address offset: 0x0F0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIMM_ADDR_MIRR_EN	DIMM_STAGGER_CS_EN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DIMM_ADDR_MIRR_EN**: Address Mirroring Enable (for multi-rank UDIMM implementations and multi-rank DDR4 RDIMM/LRDIMM implementations).
Some UDIMMs and DDR4 RDIMMs/LRDIMMs implement address mirroring for odd ranks, which means that the following address, bank address and bank group bits are swapped: (A3, A4), (A5, A6), (A7, A8), (BA0, BA1) and also (A11, A13), (BG0, BG1) for the DDR4. Setting this bit ensures that, for mode register accesses during the automatic initialization routine, these bits are swapped within the DDRCTRL to compensate for this UDIMM/RDIMM/LRDIMM swapping. In addition to the automatic initialization routine, in case of DDR4 UDIMM/RDIMM/LRDIMM, they are swapped during the automatic MRS access to enable/disable of a particular DDR4 feature.
Note: This has no effect on the address of any other memory accesses, or of software-driven mode register accesses.
This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs.
Note: In case of x16 DDR4 DIMMs, BG1 output of MRS for the odd ranks is same as BG0 because BG1 is invalid, hence dimm_dis_bg_mirroring register must be set to 1.
- 1 - For odd ranks, implement address mirroring for MRS commands to during initialization and for any automatic DDR4 MRS commands (to be used if UDIMM/RDIMM/LRDIMM implements address mirroring)
- 0 - Do not implement address mirroring

Programming mode: Static

Bit 0 **DIMM_STAGGER_CS_EN**: Staggering enable for multi-rank accesses (for multi-rank UDIMM, RDIMM and LRDIMM implementations only). This is not supported for mDDR, LPDDR2, LPDDR3 or LPDDR4 SDRAMs.

Note: Even if this bit is set it does not take care of software driven MR commands (via MRCTRL0/MRCTRL1), where software is responsible to send them to separate ranks as appropriate.

- 1 - (DDR4) Send MRS commands to each ranks separately
- 1 - (non-DDR4) Send all commands to even and odd ranks separately
- 0 - Do not stagger accesses

Programming mode: Static.

5.7.23 DDRCTRL SDRAM timing register 0 (DDRCTRL_DRAMTMG0)

Address offset: 0x100

Reset value: 0x0F10 1B0F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	WR2PRE[6:0]							Res.	Res.	T_FAW[5:0]					
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	T_RAS_MAX[6:0]							Res.	Res.	T_RAS_MIN[5:0]					
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **WR2PRE[6:0]**:

Minimum time between write and precharge to same bank.

Unit: Clocks

Specifications: WL + BL/2 + tWR = approximately 8 cycles + 15 ns = 14 clocks @400MHz and less for lower frequencies

where:

- WL = write latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM. BST (burst terminate) is not supported at present.
- tWR = Write recovery time. This comes directly from the SDRAM specification.

Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 for this parameter.

When the controller is operating in 1:2 frequency ratio mode, 1T mode, divide the above value by 2. No rounding up.

When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value.

Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **T_FAW[5:0]**: tFAW Valid only when 8 or more banks(or banks x bank groups) are present.
In 8-bank design, at most 4 banks must be activated in a rolling window of tFAW cycles.
When the controller is operating in 1:2 frequency ratio mode, program this to (tFAW/2) and round up to next integer value.
In a 4-bank design, set this register to 0x1 independent of the 1:1/1:2 frequency mode.
Unit: Clocks
Programming mode: Quasi-dynamic Group 2 and Group 4.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **T_RAS_MAX[6:0]**: tRAS(max): Maximum time between activate and precharge to same bank. This is the maximum time that a page can be kept open
Minimum value of this register is 1. Zero is invalid.
When the controller is operating in 1:2 frequency ratio mode, program this to (tRAS(max)-1)/2. No rounding up.
Unit: Multiples of 1024 clocks.
Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **T_RAS_MIN[5:0]**: tRAS(min): Minimum time between activate and precharge to the same bank.
When the controller is operating in 1:2 frequency mode, 1T mode, program this to tRAS(min)/2. No rounding up.
When the controller is operating in 1:2 frequency ratio mode, 2T mode or LPDDR4 mode, program this to (tRAS(min)/2) and round it up to the next integer value.
Unit: Clocks.
Programming mode: Quasi-dynamic Group 2 and Group 4.

5.7.24 DDRCTRL SDRAM timing register 1 (DDRCTRL_DRAMTMG1)

Address offset: 0x104

Reset value: 0x0008 0414

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	T_XP[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	RD2PRE[5:0]						Res.	T_RC[6:0]						
		rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **T_XP[4:0]**: tXP: Minimum time after power-down exit to any operation. For DDR3, this should be programmed to tXPDLL if slow powerdown exit is selected in MR0[12].
If C/A parity for DDR4 is used, set to (tXP+PL) instead.
If LPDDR4 is selected and its spec has tCKELPD parameter, set to the larger of tXP and tCKELPD instead.
When the controller is operating in 1:2 frequency ratio mode, program this to (tXP/2) and round it up to the next integer value.
Units: Clocks.
Programming mode: Quasi-dynamic Group 2 and Group 4.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **RD2PRE[5:0]**: tRTP: Minimum time from read to precharge of same bank.
- DDR2: tAL + BL/2 + max(tRTP, 2) - 2
- DDR3: tAL + max (tRTP, 4)
- DDR4: Max of following two equations:
  tAL + max (tRTP, 4) or,
  RL + BL/2 - tRP (*).
- mDDR: BL/2
- LPDDR2: Depends on if it's LPDDR2-S2 or LPDDR2-S4:
  LPDDR2-S2: BL/2 + tRTP - 1.
  LPDDR2-S4: BL/2 + max(tRTP,2) - 2.
- LPDDR3: BL/2 + max(tRTP,4) - 4
- LPDDR4: BL/2 + max(tRTP,8) - 8

(*) When both DDR4 SDRAM and ST-MRAM are used simultaneously, use SDRAM's tRP value for calculation.

When the controller is operating in 1:2 mode, 1T mode, divide the above value by 2. No rounding up.

When the controller is operating in 1:2 mode, 2T mode or LPDDR4 mode, divide the above value by 2 and round it up to the next integer value.

Unit: Clocks.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **T_RC[6:0]**: tRC: Minimum time between activates to same bank.

When the controller is operating in 1:2 frequency ratio mode, program this to (tRC/2) and round up to next integer value.

Unit: Clocks.

Programming mode: Quasi-dynamic Group 2 and Group 4.

5.7.25 DDRCTRL SDRAM timing register 2 (DDRCTRL_DRAMTMG2)

Address offset: 0x108

Reset value: 0x0305 060D

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	WRITE_LATENCY[5:0]						Res.	Res.	READ_LATENCY[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	RD2WR[5:0]						Res.	Res.	WR2RD[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **WRITE_LATENCY[5:0]**: Set to WL

The time from write command to write data on SDRAM interface. This must be set to WL.

For mDDR, it should normally be set to 1.

Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of WL to compensate for the extra cycle of latency through the RDIMM/LRDIMM.

When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.

This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols.

Unit: clocks.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **READ_LATENCY[5:0]**: Set to RL

The time from read command to read data on SDRAM interface. This must be set to RL.

Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to adjust the value of RL to compensate for the extra cycle of latency through the RDIMM/LRDIMM.

When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.

This register field is not required for DDR2 and DDR3 (except if MEMC_TRAINING is set), as the DFI read and write latencies defined in DFITMG0 and DFITMG1 are sufficient for those protocols.

Unit: clocks.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **RD2WR[5:0]**:

DDR2/3/mDDR: RL + BL/2 + 2 - WL

DDR4: RL + BL/2 + 1 + WR_PREAMBLE - WL

LPDDR2/LPDDR3: RL + BL/2 + RU(tDQSCKmax/tCK) + 1 - WL

LPDDR4(DQ ODT is Disabled): RL + BL/2 + RU(tDQSCKmax/tCK) + WR_PREAMBLE + RD_POSTAMBLE - WL

LPDDR4(DQ ODT is Enabled) : RL + BL/2 + RU(tDQSCKmax/tCK) + RD_POSTAMBLE - ODTLon - RU(tODTon(min)/tCK)

Minimum time from read command to write command. Include time for bus turnaround and all per-bank, per-rank, and global constraints. Please see the relevant PHY databook for details of what should be included here.

Unit: Clocks.

Where:

- WL = write latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM
- RL = read latency = CAS latency
- WR_PREAMBLE = write preamble. This is unique to DDR4 and LPDDR4.
- RD_POSTAMBLE = read postamble. This is unique to LPDDR4.

For LPDDR2/LPDDR3/LPDDR4, if derating is enabled (DERATEEN.derate_enable=1), derated tDQSCKmax should be used.

When the controller is operating in 1:2 frequency ratio mode, divide the value calculated using the above equation by 2, and round it up to next integer.

Note that, depending on the PHY, if using LRDIMM, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency through the LRDIMM.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **WR2RD[5:0]**:

DDR4: CWL + PL + BL/2 + tWTR_L

LPDDR2/3/4: WL + BL/2 + tWTR + 1

Others: CWL + BL/2 + tWTR

In DDR4, minimum time from write command to read command for same bank group. In others, minimum time from write command to read command. Includes time for bus turnaround, recovery times, and all per-bank, per-rank, and global constraints.

Unit: Clocks.

Where:

- CWL = CAS write latency
- WL = Write latency
- PL = Parity latency
- BL = burst length. This must match the value programmed in the BL bit of the mode register to the SDRAM
- tWTR_L = internal write to read command delay for same bank group. This comes directly from the SDRAM specification.
- tWTR = internal write to read command delay. This comes directly from the SDRAM specification.

Add one extra cycle for LPDDR2/LPDDR3/LPDDR4 operation.

When the controller is operating in 1:2 mode, divide the value calculated using the above equation by 2, and round it up to next integer.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4

5.7.26 DDRCTRL SDRAM timing register 3 (DDRCTRL_DRAMTMG3)

Address offset: 0x10C

Reset value: 0x0050 400C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	T_MRW[9:0]										Res.	Res.	T_MRD[5:4]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
T_MRD[3:0]				Res.	Res.	T_MOD[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:20 **T_MRW[9:0]**: Time to wait after a mode register write or read (MRW or MRR).
Present only in designs configured to support LPDDR2, LPDDR3 or LPDDR4.
LPDDR2 typically requires value of 5.
LPDDR3 typically requires value of 10.
LPDDR4: Set this to the larger of tMRW and tMRWCKEL.
For LPDDR2, this register is used for the time from a MRW/MRR to all other commands.
When the controller is operating in 1:2 frequency ratio mode, program this to the above values divided by 2 and round it up to the next integer value.
For LDPDR3, this register is used for the time from a MRW/MRR to a MRW/MRR.
Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **T_MRD[5:0]**: tMRD: Cycles to wait after a mode register write or read. Depending on the connected SDRAM, tMRD represents:
DDR2/mDDR: Time from MRS to any command
DDR3/4: Time from MRS to MRS command
LPDDR2: not used
LPDDR3/4: Time from MRS to non-MRS command.
When the controller is operating in 1:2 frequency ratio mode, program this to (tMRD/2) and round it up to the next integer value.
If C/A parity for DDR4 is used, set to tMRD_PAR(tMOD+PL) instead.
Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **T_MOD[9:0]**: tMOD: Parameter used only in DDR3 and DDR4. Cycles between load mode command and following non-load mode command.

If C/A parity for DDR4 is used, set to tMOD_PAR(tMOD+PL) instead.

If MPR writes for DDR4 are used, set to tMOD + AL (or tMPD_PAR + AL if C/A parity is also used).

Set to tMOD if controller is operating in 1:1 frequency ratio mode, or tMOD/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode. Note that if using RDIMM/LRDIMM, depending on the PHY, it may be necessary to adjust the value of this parameter to compensate for the extra cycle of latency applied to mode register writes by the RDIMM/LRDIMM chip.

Also note that if using LRDIMM, the minimum value of this register is tMRD_L2 if controller is operating in 1:1 frequency ratio mode, or tMRD_L2/2 (rounded up to next integer) if controller is operating in 1:2 frequency ratio mode.

Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.27 DDRCTRL SDRAM timing register 4 (DDRCTRL_DRAMTMG4)

Address offset: 0x110

Reset value: 0x0504 0405

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	T_RCD[4:0]					Res.	Res.	Res.	Res.	T_CCD[3:0]

Res.	Res.	Res.	Res.	T_RRD[3:0]				Res.	Res.	Res.	T_RP[4:0]				
				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **T_RCD[4:0]**: tRCD - tAL: Minimum time from activate to read or write command to same bank.

When the controller is operating in 1:2 frequency ratio mode, program this to ((tRCD - tAL)/2) and round it up to the next integer value.

Minimum value allowed for this register is 1, which implies minimum (tRCD - tAL) value to be 2 when the controller is operating in 1:2 frequency ratio mode.

Unit: Clocks.

Programming mode: Quasi-dynamic Group 1 and Group 2 and Group 4

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **T_CCD[3:0]**: DDR4: tCCD_L: This is the minimum time between two reads or two writes for same bank group.

Others: tCCD: This is the minimum time between two reads or two writes.

When the controller is operating in 1:2 frequency ratio mode, program this to (tCCD_L/2 or tCCD/2) and round it up to the next integer value.

Unit: clocks.

Programming mode: Quasi-dynamic Group 2 and Group 4.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **T_RRD[3:0]**: DDR4: tRRD_L: Minimum time between activates from bank "a" to bank "b" for same bank group.

Others: tRRD: Minimum time between activates from bank "a" to bank "b"

When the controller is operating in 1:2 frequency ratio mode, program this to (tRRD_L/2 or tRRD/2) and round it up to the next integer value.

Unit: Clocks.

Programming mode: Quasi-dynamic Group 2 and Group 4.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **T_RP[4:0]**: tRP: Minimum time from precharge to activate of same bank.

When the controller is operating in 1:1 frequency ratio mode, t_rp should be set to RoundUp(tRP/tCK).

When the controller is operating in 1:2 frequency ratio mode, t_rp should be set to RoundDown(RoundUp(tRP/tCK)/2) + 1.

When the controller is operating in 1:2 frequency ratio mode in LPDDR4, t_rp should be set to RoundUp(RoundUp(tRP/tCK)/2).

Unit: Clocks.

Programming mode: Quasi-dynamic Group 2 and Group 4.

5.7.28 DDRCTRL SDRAM timing register 5 (DDRCTRL_DRAMTMG5)

Address offset: 0x114

Reset value: 0x0505 0403

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	T_CKSRX[3:0]				Res.	Res.	Res.	Res.	T_CKSRE[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	T_CKESR[5:0]						Res.	Res.	Res.	T_CKE[4:0]				
		rw	rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **T_CKSRX[3:0]**: This is the time before Self Refresh Exit that CK is maintained as a valid clock before issuing SRX. Specifies the clock stable time before SRX.

Recommended settings:

- mDDR: 1
- LPDDR2: 2
- LPDDR3: 2
- LPDDR4: tCKCKEH
- DDR2: 1
- DDR3: tCKSRX
- DDR4: tCKSRX

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **T_CKSRE[3:0]**: This is the time after Self Refresh Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after SRE.

Recommended settings:

- mDDR: 0
- LPDDR2: 2
- LPDDR3: 2
- LPDDR4: tCKELCK
- DDR2: 1
- DDR3: max (10 ns, 5 tCK)
- DDR4: max (10 ns, 5 tCK) (+ PL(parity latency)(*))

(*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL.

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **T_CKESR[5:0]**: Minimum CKE low width for Self refresh or Self refresh power down entry to exit timing in memory clock cycles.

Recommended settings:

- mDDR: tRFC
- LPDDR2: tCKESR
- LPDDR3: tCKESR
- LPDDR4: max(tCKE, tSR)
- DDR2: tCKE
- DDR3: tCKE + 1
- DDR4: tCKE + 1 (+ PL(parity latency)(*))

(*)Only if CRCPARCTL1.caparity_disable_before_sr=0, this register should be increased by PL.

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **T_CKE[4:0]**: Minimum number of cycles of CKE HIGH/LOW during power-down and self refresh.

- LPDDR2/LPDDR3 mode: Set this to the larger of tCKE or tCKESR
- LPDDR4 mode: Set this to the larger of tCKE or tSR.
- Non-LPDDR2/non-LPDDR3/non-LPDDR4 designs: Set this to tCKE value.

When the controller is operating in 1:2 frequency ratio mode, program this to (value described above)/2 and round it up to the next integer value.

Unit: Clocks.

Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.29 DDRCTRL SDRAM timing register 6 (DDRCTRL_DRAMTMG6)

Address offset: 0x118

Reset value: 0x0202 0005

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	T_CKDPDE[3:0]				Res.	Res.	Res.	Res.	T_CKDPDX[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	T_CKCSX[3:0]			
												rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **T_CKDPDE[3:0]**: This is the time after Deep Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after DPDE.

Recommended settings:

- mDDR: 0
- LPDDR2: 2
- LPDDR3: 2

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

This is only present for designs supporting mDDR or LPDDR2/LPDDR3 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **T_CKDPDX[3:0]**: This is the time before Deep Power Down Exit that CK is maintained as a valid clock before issuing DPDX. Specifies the clock stable time before DPDX.

Recommended settings:

- mDDR: 1
- LPDDR2: 2
- LPDDR3: 2

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

This is only present for designs supporting mDDR or LPDDR2 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:0 **T_CKCSX[3:0]**: This is the time before Clock Stop Exit that CK is maintained as a valid clock before issuing Clock Stop Exit. Specifies the clock stable time before next command after Clock Stop Exit.

Recommended settings:

- mDDR: 1
- LPDDR2: tXP + 2
- LPDDR3: tXP + 2
- LPDDR4: tXP + 2

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

This is only present for designs supporting mDDR or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.30 DDRCTRL SDRAM timing register 7 (DDRCTRL_DRAMTMG7)

Address offset: 0x11C

Reset value: 0x0000 0202

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	T_CKPDE[3:0]				Res.	Res.	Res.	Res.	T_CKPDX[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **T_CKPDE[3:0]**: This is the time after Power Down Entry that CK is maintained as a valid clock. Specifies the clock disable delay after PDE.

Recommended settings:

- mDDR: 0
- LPDDR2: 2
- LPDDR3: 2
- LPDDR4: tCKELCK

When using DDR2/3/4 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksre.

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

This is only present for designs supporting mDDR or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **T_CKPDX[3:0]**: This is the time before Power Down Exit that CK is maintained as a valid clock before issuing PDX. Specifies the clock stable time before PDX.

Recommended settings:

- mDDR: 0
- LPDDR2: 2
- LPDDR3: 2
- LPDDR4: 2

When using DDR2/3/4 SDRAM, this register should be set to the same value as DRAMTMG5.t_cksrx.

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

This is only present for designs supporting mDDR or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.31 DDRCTRL SDRAM timing register 8 (DDRCTRL_DRAMTMG8)

Address offset: 0x120

Reset value: 0x0000 4405

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **T_XS_DLL_X32[6:0]**: tXSDLL: Exit Self Refresh to the commands requiring a locked DLL.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
Unit: Multiples of 32 clocks.
Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.
Programming mode: Quasi-dynamic Group 2 and Group 4

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **T_XS_X32[6:0]**: tXS: Exit Self Refresh to commands not requiring a locked DLL.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
Unit: Multiples of 32 clocks.
Note: Used only for DDR2, DDR3 and DDR4 SDRAMs.
Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.32 DDRCTRL SDRAM timing register 14 (DDRCTRL_DRAMTMG14)

Address offset: 0x138

Reset value: 0x0000 00A0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **T_XSR[11:0]**: tXSR: Exit Self Refresh to any command.
When the controller is operating in 1:2 frequency ratio mode, program this to the above value divided by 2 and round up to next integer value.
Note: Used only for mDDR/LPDDR2/LPDDR3/LPDDR4 mode.
Programming mode: Quasi-dynamic Group 2 and Group 4

5.7.33 DDRCTRL SDRAM timing register 15 (DDRCTRL_DRAMTMG15)

Address offset: 0x13C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EN_DFI_LP_T_STAB	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	T_STAB_X32[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **EN_DFI_LP_T_STAB**:

- 1 - Enable using tSTAB when exiting DFI LP. Needs to be set when the PHY is stopping the clock during DFI LP to save maximum power.
- 0 - Disable using tSTAB when exiting DFI LP

Programming mode: Quasi-dynamic Group 2 and Group 4.

Bits 30:8 Reserved, must be kept at reset value.

Bits 7:0 **T_STAB_X32[7:0]**: tSTAB: Stabilization time.

It is required in the following two cases for DDR3/DDR4 RDIMM:

- When exiting power saving mode, if the clock was stopped, after re-enabling it the clock must be stable for a time specified by tSTAB
- In the case of input clock frequency change (DDR4)
- After issuing control words that refers to clock timing (Specification: 6us for DDR3, 5us for DDR4).

When the controller is operating in 1:2 frequency ratio mode, program this to recommended value divided by two and round it up to next integer.

Unit: Multiples of 32 clock cycles.

Programming mode: Quasi-dynamic Group 2 and Group 4.

5.7.34 DDRCTRL ZQ control register 0 (DDRCTRL_ZQCTL0)

Address offset: 0x180

Reset value: 0x0200 0040

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIS_AUTO_ZQ	DIS_SRX_ZQCL	ZQ_RESISTOR_SHARED	Res.	Res.	T_ZQ_LONG_NOP[10:0]										
rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	T_ZQ_SHORT_NOP[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DIS_AUTO_ZQ**:

- 1 - Disable DDRCTRL generation of ZQCS/MPC(ZQ calibration) command. Register DBGCMD.zq_calib_short can be used instead to issue ZQ calibration request from APB module.
- 0 - Internally generate ZQCS/MPC(ZQ calibration) commands based on ZQCTL1.t_zq_short_interval_x1024.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Dynamic

Bit 30 **DIS_SRX_ZQCL**:

- 1 - Disable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode.
- 0 - Enable issuing of ZQCL/MPC(ZQ calibration) command at Self-Refresh/SR-Powerdown exit. Only applicable when run in DDR3 or DDR4 or LPDDR2 or LPDDR3 or LPDDR4 mode.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Quasi-dynamic Group 2 and Group 4.

Bit 29 **ZQ_RESISTOR_SHARED**:

- 1 - Denotes that ZQ resistor is shared between ranks. Means ZQinit/ZQCL/ZQCS/MPC(ZQ calibration) commands are sent to one rank at a time with tZQinit/tZQCL/tZQCS/tZQCAL/tZQLAT timing met between commands so that commands to different ranks do not overlap.
- 0 - ZQ resistor is not shared.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Static.

Bits 28:27 Reserved, must be kept at reset value.

Bits 26:16 **T_ZQ_LONG_NOP[10:0]**: tZQoper for DDR3/DDR4, tZQCL for LPDDR2/LPDDR3, tZQCAL for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCL (ZQ calibration long)/MPC(ZQ Start) command is issued to SDRAM.

When the controller is operating in 1:2 frequency ratio mode:

DDR3/DDR4: program this to tZQoper/2 and round it up to the next integer value.

LPDDR2/LPDDR3: program this to tZQCL/2 and round it up to the next integer value.

LPDDR4: program this to tZQCAL/2 and round it up to the next integer value.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Static.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **T_ZQ_SHORT_NOP[9:0]**: tZQCS for DDR3/DD4/LPDDR2/LPDDR3, tZQLAT for LPDDR4: Number of DFI clock cycles of NOP required after a ZQCS (ZQ calibration short)/MPC(ZQ Latch) command is issued to SDRAM.

When the controller is operating in 1:2 frequency ratio mode, program this to tZQCS/2 and round it up to the next integer value.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Static.

5.7.35 DDRCTRL ZQ control register 1 (DDRCTRL_ZQCTL1)

Address offset: 0x184

Reset value: 0x0200 0100

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

T_ZQ_SHORT_INTERVAL_X1024[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:20 **T_ZQ_RESET_NOP[9:0]**: tZQReset: Number of DFI clock cycles of NOP required after a ZQReset (ZQ calibration Reset) command is issued to SDRAM.

When the controller is operating in 1:2 frequency ratio mode, program this to tZQReset/2 and round it up to the next integer value.

This is only present for designs supporting LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Static.

Bits 19:0 **T_ZQ_SHORT_INTERVAL_X1024[19:0]**: Average interval to wait between automatically issuing ZQCS (ZQ calibration short)/MPC(ZQ calibration) commands to DDR3/DDR4/LPDDR2/LPDDR3/LPDDR4 devices.

Meaningless, if ZQCTL0.dis_auto_zq=1.

Unit: 1024 DFI clock cycles.

This is only present for designs supporting DDR3/DDR4 or LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Static.

5.7.36 DDRCTRL ZQ control register 2 (DDRCTRL_ZQCTL2)

Address offset: 0x188

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ZQ_RESET
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ZQ_RESET**:

Setting this register bit to 1 triggers a ZQ Reset operation. When the ZQ Reset operation is complete, the DDRCTRL automatically clears this bit. It is recommended NOT to set this register bit if in Init, in Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) or Deep power-down operating modes.

For Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) it is scheduled after SR(except LPDDR4) or SPRD(LPDDR4) has been exited.

For Deep power down, it is not scheduled, although ZQSTAT.zq_reset_busy is de-asserted.

This is only present for designs supporting LPDDR2/LPDDR3/LPDDR4 devices.

Programming mode: Dynamic

5.7.37 DDRCTRL ZQ status register (DDRCTRL_ZQSTAT)

Address offset: 0x18C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ZQ_RESET_BUSY
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ZQ_RESET_BUSY**: SoC core may initiate a ZQ Reset operation only if this signal is low. This signal goes high in the clock after the DDRCTRL accepts the ZQ Reset request. It goes low when the ZQ Reset command is issued to the SDRAM and the associated NOP period is over. It is recommended not to perform ZQ Reset commands when this signal is high.
- 0 - Indicates that the SoC core can initiate a ZQ Reset operation
- 1 - Indicates that ZQ Reset operation is in progress

Programming mode: Dynamic

5.7.38 DDRCTRL DFI timing register 0 (DDRCTRL_DFITMG0)

Address offset: 0x190

Reset value: 0x0702 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DFI_T_CTRL_DELAY[4:0]					Res.	DFI_T_RDDATA_EN[6:0]						
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	DFI_TPHY_WRDATA[5:0]						Res.	Res.	DFI_TPHY_WRLAT[5:0]					
		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DFI_T_CTRL_DELAY[4:0]**: Specifies the number of DFI clock cycles after an assertion or de-assertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value. Note that if using RDIMM/LRDIMM, it is necessary to increment this parameter by RDIMM's/LRDIMM's extra cycle of latency in terms of DFI clock.

Programming mode: Quasi-dynamic Group 4

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DFI_T_RDDATA_EN[6:0]**: Time from the assertion of a read command on the DFI interface to the assertion of the dfi_rddata_en signal.

Refer to PHY specification for correct value.

This corresponds to the DFI parameter trddata_en. Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of trddata_en. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM.

Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_rddata_use_dfi_phy_clk.

Programming mode: Quasi-dynamic Group 1 and Group 4

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **DFI_TPHY_WRDATA[5:0]**: Specifies the number of clock cycles between when dfi_wrdata_en is asserted to when the associated write data is driven on the dfi_wrdata signal. This corresponds to the DFI timing parameter tphy_wrdata. Refer to PHY specification for correct value. Note, max supported value is 8.

Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_dfi_phy_clk.

Programming mode: Quasi-dynamic Group 4

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **DFI_TPHY_WRLAT[5:0]**: Write latency

Number of clocks from the write command to write data enable (dfi_wrdata_en). This corresponds to the DFI timing parameter tphy_wrlat.

Refer to PHY specification for correct value.Note that, depending on the PHY, if using RDIMM/LRDIMM, it may be necessary to use the adjusted value of CL in the calculation of tphy_wrlat. This is to compensate for the extra cycle(s) of latency through the RDIMM/LRDIMM.

For LPDDR4, dfi_tphy_wrlat>60 is not supported.

Unit: DFI clock cycles or DFI PHY clock cycles, depending on DFITMG0.dfi_wrdata_use_dfi_phy_clk.

Programming mode: Quasi-dynamic Group 1 and Group 4

5.7.39 DDRCTRL DFI timing register 1 (DDRCTRL_DFITMG1)

Address offset: 0x194

Reset value: 0x0000 0404

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DFI_T_WRDATA_DELAY[4:0]				
											rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	DFI_T_DRAM_CLK_DISABLE[4:0]					Res.	Res.	Res.	DFI_T_DRAM_CLK_ENABLE[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **DFI_T_WRDATA_DELAY[4:0]**: Specifies the number of DFI clock cycles between when the dfi_wrdata_en

signal is asserted and when the corresponding write data transfer is completed on the DRAM bus.

This corresponds to the DFI timing parameter twrdata_delay. Refer to PHY specification for correct value.

For DFI 3.0 PHY, set to twrdata_delay, a new timing parameter introduced in DFI 3.0.

For DFI 2.1 PHY, set to tphy_wrdata + (delay of DFI write data to the DRAM).

Value to be programmed is in terms of DFI clocks, not PHY clocks.

In FREQ_RATIO=2, divide PHY's value by 2 and round up to next integer.

If using DFITMG0.dfi_wrdata_use_dfi_phy_clk=1, add 1 to the value.

Unit: Clocks

Programming mode: Quasi-dynamic Group 4

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DFI_T_DRAM_CLK_DISABLE[4:0]**: Specifies the number of DFI clock cycles from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

Programming mode: Quasi-dynamic Group 4

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DFI_T_DRAM_CLK_ENABLE[4:0]**: Specifies the number of DFI clock cycles from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM memory devices, at the PHY-DRAM boundary. If the DFI clock and the memory clock are not phase aligned, this timing parameter should be rounded up to the next integer value.

Programming mode: Quasi-dynamic Group 4

5.7.40 DDRCTRL low power configuration register 0 (DDRCTRL_DFILPCFG0)

Address offset: 0x198

Reset value: 0x0700 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DFI_TLP_RESP[4:0]					DFI_LP_WAKEUP_DPD[3:0]				Res.	Res.	Res.	DFI_LP_EN_DPD
			rw	rw	rw	rw	rw	rw	rw	rw	rw				rw

rw	rw	rw	rw				rw	rw	rw	rw	rw				rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **DFI_TLP_RESP[4:0]**: Setting in DFI clock cycles for DFI's tlp_resp time.

Same value is used for both Power Down, Self Refresh, Deep Power Down and Maximum Power Saving modes.

DFI 2.1 specification onwards, recommends using a fixed value of 7 always.

Programming mode: Static

Bits 23:20 **DFI_LP_WAKEUP_DPD[3:0]**: Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Deep Power Down mode is entered.

Determines the DFI's tlp_wakeup time:

- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

This is only present for designs supporting mDDR or LPDDR2/LPDDR3 devices.

Programming mode: Static.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **DFI_LP_EN_DPD**: Enables DFI Low-power interface handshaking during Deep Power Down Entry/Exit.

- 0 - Disabled
- 1 - Enabled

This is only present for designs supporting mDDR or LPDDR2/LPDDR3 devices.

Programming mode: Static.

Bits 15:12 **DFI_LP_WAKEUP_SR[3:0]**: Value in DFI clpck cycles to drive on dfi_lp_wakeup signal when Self Refresh mode is entered.

Determines the DFI's tlp_wakeup time:

- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

Programming mode: Static

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **DFI_LP_EN_SR**: Enables DFI Low Power interface handshaking during Self Refresh Entry/Exit.

- 0 - Disabled
- 1 - Enabled

Programming mode: Static

Bits 7:4 **DFI_LP_WAKEUP_PD[3:0]**: Value in DFI clock cycles to drive on dfi_lp_wakeup signal when Power Down mode is entered.

Determines the DFI's tlp_wakeup time:

- 0x0 - 16 cycles
- 0x1 - 32 cycles
- 0x2 - 64 cycles
- 0x3 - 128 cycles
- 0x4 - 256 cycles
- 0x5 - 512 cycles
- 0x6 - 1024 cycles
- 0x7 - 2048 cycles
- 0x8 - 4096 cycles
- 0x9 - 8192 cycles
- 0xA - 16384 cycles
- 0xB - 32768 cycles
- 0xC - 65536 cycles
- 0xD - 131072 cycles
- 0xE - 262144 cycles
- 0xF - Unlimited

Programming mode: Static

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DFI_LP_EN_PD**: Enables DFI Low Power interface handshaking during Power Down Entry/Exit.
- 0 - Disabled
- 1 - Enabled

Programming mode: Static

5.7.41 DDRCTRL DFI update register 0 (DDRCTRL_DFIUPD0)

Address offset: 0x1A0

Reset value: 0x0040 0003

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIS_AUTO_CTRLUPD	DIS_AUTO_CTRLUPD_SRX	CTRLUPD_PRE_SRX	Res.	Res.	Res.	DFI_T_CTRLUP_MAX[9:0]									
rw	rw	rw				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	DFI_T_CTRLUP_MIN[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DIS_AUTO_CTRLUPD**: When '1', disable the automatic dfi_ctrlupd_req generation by the DDRCTRL. The core must issue the dfi_ctrlupd_req signal using register DBGCMD.ctrlupd.
When '0', DDRCTRL issues dfi_ctrlupd_req periodically.
Programming mode: Quasi-dynamic Group 3

Bit 30 **DIS_AUTO_CTRLUPD_SRX**: When '1', disable the automatic dfi_ctrlupd_req generation by the DDRCTRL at self-refresh exit.
When '0', DDRCTRL issues a dfi_ctrlupd_req before or after exiting self-refresh, depending on DFIUPD0.ctrlupd_pre_srx.
Programming mode: Static

Bit 29 **CTRLUPD_PRE_SRX**: Selects dfi_ctrlupd_req requirements at SRX:
- 0 : send ctrlupd after SRX
- 1 : send ctrlupd before SRX

If DFIUPD0.dis_auto_ctrlupd_srx=1, this register has no impact, because no dfi_ctrlupd_req is issued when SRX.
Programming mode: Static

Bits 28:26 Reserved, must be kept at reset value.

Bits 25:16 **DFI_T_CTRLUP_MAX[9:0]**: Specifies the maximum number of DFI clock cycles that the dfi_ctrlupd_req signal can assert. Lowest value to assign to this variable is 0x40.
Programming mode: Static

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **DFI_T_CTRLUP_MIN[9:0]**: Specifies the minimum number of DFI clock cycles that the dfi_ctrlupd_req signal must be asserted. The DDRCTRL expects the PHY to respond within this time. If the PHY does not respond, the DDRCTRL de-asserts dfi_ctrlupd_req after dfi_t_ctrlup_min + 2 cycles. Lowest value to assign to this variable is 0x3.

Programming mode: Static

5.7.42 DDRCTRL DFI update register 1 (DDRCTRL_DFIUPD1)

Address offset: 0x1A4

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DFI_T_CTRLUPD_INTERVAL_MIN_X1024[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DFI_T_CTRLUPD_INTERVAL_MAX_X1024[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **DFI_T_CTRLUPD_INTERVAL_MIN_X1024[7:0]**: This is the minimum amount of time between DDRCTRL initiated DFI update requests (which is executed whenever the DDRCTRL is idle). Set this number higher to reduce the frequency of update requests, which can have a small impact on the latency of the first read request when the DDRCTRL is idle. Minimum allowed value for this field is 1.

Unit: 1024 DFI clock cycles.

Programming mode: Static.

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DFI_T_CTRLUPD_INTERVAL_MAX_X1024[7:0]**: This is the maximum amount of time between DDRCTRL initiated DFI update requests. This timer resets with each update request; when the timer expires dfi_ctrlupd_req is sent and traffic is blocked until the dfi_ctrlupd_ackx is received. PHY can use this idle time to recalibrate the delay lines to the DLLs. The DFI controller update is also used to reset PHY FIFO pointers in case of data capture errors. Updates are required to maintain calibration over PVT, but frequent updates may impact performance. Minimum allowed value for this field is 1.

Note: Value programmed for DFIUPD1.dfi_t_ctrlupd_interval_max_x1024 must be greater than DFIUPD1.dfi_t_ctrlupd_interval_min_x1024.

Unit: 1024 DFI clock cycles.

Programming mode: Static.

5.7.43 DDRCTRL DFI update register 2 (DDRCTRL_DFIUPD2)

Address offset: 0x1A8

Reset value: 0x8000 0000

Bits 31:13 Reserved, must be kept at reset value.

Bits 12:8 **DFI_FREQUENCY[4:0]**: Indicates the operating frequency of the system. The number of supported frequencies and the mapping of signal values to clock frequencies are defined by the PHY.

Programming mode: Quasi-dynamic Group 1

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **DFI_INIT_START**: PHY init start request signal.When asserted it triggers the PHY init start request
Programming mode: Quasi-dynamic Group 3

Bit 4 **CTL_IDLE_EN**: Enables support of ctl_idle signal
Programming mode: Static

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DFI_INIT_COMPLETE_EN**: PHY initialization complete enable signal.
When asserted the dfi_init_complete signal can be used to trigger SDRAM initialisation
Programming mode: Quasi-dynamic Group 3

5.7.45 DDRCTRL DFI status register (DDRCTRL_DFISTAT)

Address offset: 0x1BC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **ADDRMAP_BANK_B2[5:0]**: Selects the HIF address bit used as bank address bit 2.

Valid Range: 0 to 31, and 63

Internal Base: 4

The selected HIF address bit is determined by adding the internal base to the value of this field. If unused, set to 63 and then bank address bit 2 is set to 0.

Programming mode: Static.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **ADDRMAP_BANK_B1[5:0]**: Selects the HIF address bits used as bank address bit 1.
Valid Range: 0 to 32, and 63
Internal Base: 3
The selected HIF address bit for each of the bank address bits is determined by adding the internal base to the value of this field.
If unused, set to 63 and then bank address bit 1 is set to 0.
Programming mode: Static.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **ADDRMAP_BANK_B0[5:0]**: Selects the HIF address bits used as bank address bit 0.
Valid Range: 0 to 32, and 63
Internal Base: 2
The selected HIF address bit for each of the bank address bits is determined by adding the internal base to the value of this field.
If unused, set to 63 and then bank address bit 0 is set to 0.
Programming mode: Static.

5.7.48 DDRCTRL address map register 2 (DDRCTRL_ADDRMAP2)

Address offset: 0x208

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	ADDRMAP_COL_B3[3:0]				Res.	Res.	Res.	Res.	ADDRMAP_COL_B2[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **ADDRMAP_COL_B5[3:0]**:
- Full bus width mode: Selects the HIF address bit used as column address bit 5.
- Half bus width mode: Selects the HIF address bit used as column address bit 6.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 7 .

Valid Range: 0 to 7, and 15
Internal Base: 5
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then this column address bit is set to 0.
Programming mode: Static

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ADDRMAP_COL_B4[3:0]**:
- Full bus width mode: Selects the HIF address bit used as column address bit 4.
- Half bus width mode: Selects the HIF address bit used as column address bit 5.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 6.

Valid Range: 0 to 7, and 15

Internal Base: 4

The selected HIF address bit is determined by adding the internal base to the value of this field.

If unused, set to 15 and then this column address bit is set to 0.

Programming mode: Static

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **ADDRMAP_COL_B3[3:0]**:
- Full bus width mode: Selects the HIF address bit used as column address bit 3.
- Half bus width mode: Selects the HIF address bit used as column address bit 4.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 5.

Valid Range: 0 to 7

Internal Base: 3

The selected HIF address bit is determined by adding the internal base to the value of this field.

Note, if UMCTL2_INCL_ARB=1, MEMC_BURST_LENGTH=16, Full bus width (MSTR.data_bus_width=00) and BL16 (MSTR.burst_rdwr=1000), it is recommended to program this to 0.

Programming mode: Static

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **ADDRMAP_COL_B2[3:0]**:

- Full bus width mode: Selects the HIF address bit used as column address bit 2.
- Half bus width mode: Selects the HIF address bit used as column address bit 3.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 4.

Valid Range: 0 to 7

Internal Base: 2

The selected HIF address bit is determined by adding the internal base to the value of this field.

Note, if UMCTL2_INCL_ARB=1 and MEMC_BURST_LENGTH=8, it is required to program this to 0 unless:

- in Half or Quarter bus width (MSTR.data_bus_width!=00) and
- PCCFG.bl_exp_mode==1 and either
- In DDR4 and ADDRMAP8.addrmap_bg_b0==0 or
- In LPDDR4 and ADDRMAP1.addrmap_bank_b0==0

If UMCTL2_INCL_ARB=1 and MEMC_BURST_LENGTH=16, it is required to program this to 0 unless:

- in Half or Quarter bus width (MSTR.data_bus_width!=00) and
- PCCFG.bl_exp_mode==1 and
- In DDR4 and ADDRMAP8.addrmap_bg_b0==0

Otherwise, if MEMC_BURST_LENGTH=8 and Full Bus Width (MSTR.data_bus_width==00), it is recommended to program this to 0 so that HIF[2] maps to column address bit 2.

If MEMC_BURST_LENGTH=16 and Full Bus Width (MSTR.data_bus_width==00), it is recommended to program this to 0 so that HIF[2] maps to column address bit 2.

If MEMC_BURST_LENGTH=16 and Half Bus Width (MSTR.data_bus_width==01), it is recommended to program this to 0 so that HIF[2] maps to column address bit 3.

Programming mode: Static

5.7.49 DDRCTRL address map register 3 (DDRCTRL_ADDRMAP3)

Address offset: 0x20C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	ADDRMAP_COL_B9[4:0]					Res.	Res.	Res.	ADDRMAP_COL_B8[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	ADDRMAP_COL_B7[4:0]					Res.	Res.	Res.	Res.	ADDRMAP_COL_B6[3:0]			
			rw	rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **ADDRMAP_COL_B9[4:0]**:

- Full bus width mode: Selects the HIF address bit used as column address bit 9.
- Half bus width mode: Selects the HIF address bit used as column address bit 11 (10 in LPDDR2/LPDDR3 mode).
- Quarter bus width mode: Selects the HIF address bit used as column address bit 13 (11 in LPDDR2/LPDDR3 mode).

Valid Range: 0 to 7, x, and 31. x indicate a valid value in inline ECC configuration.

Internal Base: 9

The selected HIF address bit is determined by adding the internal base to the value of this field.

Note: Per JEDEC DDR2/3/mDDR specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.

In Inline ECC configuration (MEMC_INLINE_ECC=1) and ECC is enabled (ECCCFG0.ecc_mode>0), the highest 3 column address bits must map to the highest 3 valid HIF address bits.

If column bit 9 is the highest column address bit, it must map to the highest valid HIF address bit. (x = the highest valid HIF address bit - internal base)

If column bit 9 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base)

If column bit 9 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base)

If unused, set to 31 and then this column address bit is set to 0.

Programming mode: Static.

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **ADDRMAP_COL_B8[4:0]**:

- Full bus width mode: Selects the HIF address bit used as column address bit 8.
- Half bus width mode: Selects the HIF address bit used as column address bit 9.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 11 (10 in LPDDR2/LPDDR3 mode).

Valid Range: 0 to 7, x, and 31. x indicate a valid value in inline ECC configuration.

Internal Base: 8

The selected HIF address bit is determined by adding the internal base to the value of this field.

Note: Per JEDEC DDR2/3/mDDR specification, column address bit 10 is reserved for indicating auto-precharge, and hence no source address bit can be mapped to column address bit 10.

In LPDDR2/LPDDR3, there is a dedicated bit for auto-precharge in the CA bus and hence column bit 10 is used.

In Inline ECC configuration (MEMC_INLINE_ECC=1) and ECC is enabled (ECCCFG0.ecc_mode>0), the highest 3 column address bits must map to the highest 3 valid HIF address bits.

If column bit 8 is the second highest column address bit, it must map to the second highest valid HIF address bit. (x = the highest valid HIF address bit - 1 - internal base).

If column bit 8 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base).

If unused, set to 31 and then this column address bit is set to 0.

Programming mode: Static.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **ADDRMAP_COL_B7[4:0]**:

- Full bus width mode: Selects the HIF address bit used as column address bit 7.
- Half bus width mode: Selects the HIF address bit used as column address bit 8.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 9.

Valid Range: 0 to 7, x, and 31. x indicate a valid value in inline ECC configuration.

Internal Base: 7

The selected HIF address bit is determined by adding the internal base to the value of this field.

In Inline ECC configuration (MEMC_INLINE_ECC=1) and ECC is enabled (ECCCFG0.ecc_mode>0), the highest 3 column address bits must map to the highest 3 valid HIF address bits.

If column bit 7 is the third highest column address bit, it must map to the third highest valid HIF address bit. (x = the highest valid HIF address bit - 2 - internal base).

If unused, set to 31 and then this column address bit is set to 0.

Programming mode: Static.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **ADDRMAP_COL_B6[3:0]**:

- Full bus width mode: Selects the HIF address bit used as column address bit 6.
- Half bus width mode: Selects the HIF address bit used as column address bit 7.
- Quarter bus width mode: Selects the HIF address bit used as column address bit 8.

Valid Range: 0 to 7, and 15

Internal Base: 6

The selected HIF address bit is determined by adding the internal base to the value of this field.

If unused, set to 15 and then this column address bit is set to 0.

Programming mode: Static

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **ADDRMAP_ROW_B11[3:0]**: Selects the HIF address bit used as row address bit 11.
Valid Range: 0 to 11, and 15
Internal Base: 17
The selected HIF address bit is determined by adding the internal base to the value of this field.
If unused, set to 15 and then row address bit 11 is set to 0.
Programming mode: Static

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ADDRMAP_ROW_B2_10[3:0]**: Selects the HIF address bits used as row address bits 2 to 10.
Valid Range: 0 to 11, and 15
Internal Base: 8 (for row address bit 2), 9 (for row address bit 3), 10 (for row address bit 4) etc increasing to 16 (for row address bit 10)
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
When set to 15, the values of row address bits 2 to 10 are defined by registers ADDRMAP9, ADDRMAP10, ADDRMAP11.
Programming mode: Static

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **ADDRMAP_ROW_B1[3:0]**: Selects the HIF address bits used as row address bit 1.
Valid Range: 0 to 11
Internal Base: 7
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
Programming mode: Static

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **ADDRMAP_ROW_B0[3:0]**: Selects the HIF address bits used as row address bit 0.
Valid Range: 0 to 11
Internal Base: 6
The selected HIF address bit for each of the row address bits is determined by adding the internal base to the value of this field.
Programming mode: Static

5.7.52 DDRCTRL address register 6 (DDRCTRL_ADDRMAP6)

Address offset: 0x218

Reset value: 0x0000 0000

				rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LPDDR3_6GB_12GB**:
Set this to 1 if there is an LPDDR3 SDRAM 6Gb or 12Gb device in use.
- 1 - LPDDR3 SDRAM 6Gb/12Gb device in use. Every address having row[14:13]==2'b11 is considered as invalid
- 0 - non-LPDDR3 6Gb/12Gb device in use. All addresses are valid

Present only in designs configured to support LPDDR3.
Programming mode: Static

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:24 **ADDRMAP_ROW_B15[3:0]**: Selects the HIF address bit used as row address bit 15.
Valid Range: 0 to 11, and 15
Internal Base: 21
The selected HIF address bit is determined by adding the internal base to the value of this field. If unused, set to 15 and then row address bit 15 is set to 0.
Programming mode: Static

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **ADDRMAP_ROW_B14[3:0]**: Selects the HIF address bit used as row address bit 14.
Valid Range: 0 to 11, and 15
Internal Base: 20
The selected HIF address bit is determined by adding the internal base to the value of this field. If unused, set to 15 and then row address bit 14 is set to 0.
Programming mode: Static

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **ADDRMAP_ROW_B13[3:0]**: Selects the HIF address bit used as row address bit 13.
Valid Range: 0 to 11, and 15
Internal Base: 19
The selected HIF address bit is determined by adding the internal base to the value of this field. If unused, set to 15 and then row address bit 13 is set to 0.
Programming mode: Static

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **ADDRMAP_ROW_B12[3:0]**: Selects the HIF address bit used as row address bit 12.
Valid Range: 0 to 11, and 15
Internal Base: 18
The selected HIF address bit is determined by adding the internal base to the value of this field. If unused, set to 15 and then row address bit 12 is set to 0.
Programming mode: Static

5.7.53 DDRCTRL address map register 9 (DDRCTRL_ADDRMAP9)

Res.	Res.	Res.	Res.	WR_ODT_HOLD[3:0]				Res.	Res.	Res.	WR_ODT_DELAY[4:0]				
				rw	rw	rw	rw				rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	RD_ODT_HOLD[3:0]				Res.	RD_ODT_DELAY[4:0]					Res.	Res.
				rw	rw	rw	rw		rw	rw	rw	rw	rw		

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **WR_ODT_HOLD[3:0]**:
DFI PHY clock cycles to hold ODT for a write command. The minimum supported value is 2.
Recommended values:
DDR2:
- BL8: 0x5 (DDR2-400/533/667), 0x6 (DDR2-800), 0x7 (DDR2-1066)
- BL4: 0x3 (DDR2-400/533/667), 0x4 (DDR2-800), 0x5 (DDR2-1066)

DDR3:
- BL8: 0x6

DDR4:
- BL8: 5 + WR_PREAMBLE + CRC_MODE
  WR_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)
  CRC_MODE = 0 (not CRC mode), 1 (CRC mode)

LPDDR3:
- BL8: 7 + RU(tODTon(max)/tCK)

Programming mode: Quasi-dynamic Group 1 and Group 4

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **WR_ODT_DELAY[4:0]**:
The delay, in DFI PHY clock cycles, from issuing a write command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRCTRL.
Recommended values:
DDR2:
- CWL + AL - 3 (DDR2-400/533/667), CWL + AL - 4 (DDR2-800), CWL + AL - 5 (DDR2-1066)
  If (CWL + AL - 3 < 0), DDRCTRL does not support ODT for write operation.

DDR3:
- 0x0

DDR4:
- DFITMG1.dfi_t_cmd_lat (to adjust for CAL mode)

LPDDR3:
- WL - 1 - RU(tODTon(max)/tCK))

Programming mode: Quasi-dynamic Group 1 and Group 4

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **RD_ODT_HOLD[3:0]**:
DFI PHY clock cycles to hold ODT for a read command. The minimum supported value is 2.
Recommended values:
DDR2:
- BL8: 0x6 (not DDR2-1066), 0x7 (DDR2-1066)
- BL4: 0x4 (not DDR2-1066), 0x5 (DDR2-1066)

DDR3:
- BL8 - 0x6

DDR4:
- BL8: 5 + RD_PREAMBLE
  RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)

LPDDR3:
- BL8: 5 + RU(tDQSCK(max)/tCK) - RD(tDQSCK(min)/tCK) + RU(tODTon(max)/tCK)

Programming mode: Quasi-dynamic Group 1 and Group 4

Bit 7 Reserved, must be kept at reset value.

Bits 6:2 **RD_ODT_DELAY[4:0]**:
The delay, in DFI PHY clock cycles, from issuing a read command to setting ODT values associated with that command. ODT setting must remain constant for the entire time that DQS is driven by the DDRCTRL.
Recommended values:
DDR2:
- CL + AL - 4 (not DDR2-1066), CL + AL - 5 (DDR2-1066)
If (CL + AL - 4 < 0), DDRCTRL does not support ODT for read operation.
DDR3:
- CL - CWL
DDR4:
- CL - CWL - RD_PREAMBLE + WR_PREAMBLE + DFITMG1.dfi_t_cmd_lat (to adjust for CAL mode)
WR_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)
RD_PREAMBLE = 1 (1tCK write preamble), 2 (2tCK write preamble)
If (CL - CWL - RD_PREAMBLE + WR_PREAMBLE) < 0, DDRCTRL does not support ODT for read operation.
LPDDR3:
- RL + RD(tDQSCK(min)/tCK) - 1 - RU(tODTon(max)/tCK)
Programming mode: Quasi-dynamic Group 1 and Group 4.

Bits 1:0 Reserved, must be kept at reset value.

5.7.57 DDRCTRL ODT/Rank map register (DDRCTRL_ODTMAP)

Address offset: 0x244

Reset value: 0x0000 0011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RANK0_RD_ODT	Res.	Res.	Res.	RANK0_WR_ODT
											rw				rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **RANK0_RD_ODT**: Indicates which remote ODTs must be turned on during a read from rank 0.
Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here.
Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc.
For each rank, set its bit to 1 to enable its ODT.
Programming mode: Static

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RANK0_WR_ODT**: Indicates which remote ODTs must be turned on during a write to rank 0.
Each rank has a remote ODT (in the SDRAM) which can be turned on by setting the appropriate bit here.
Rank 0 is controlled by the LSB; rank 1 is controlled by bit next to the LSB, etc.
For each rank, set its bit to 1 to enable its ODT.
Programming mode: Static

5.7.58 DDRCTRL scheduler control register (DDRCTRL_SCHED)

Address offset: 0x250

Reset value: 0x0000 0805

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	RDWR_IDLE_GAP[6:0]							GO2CRITICAL_HYSTERESIS[7:0]							
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	LPR_NUM_ENTRIES[3:0]				Res.	Res.	Res.	Res.	Res.	PAGECLOSE	PREFER_WRITE	FORCE_LOW_PRI_N
				rw	rw	rw	rw						rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **RDWR_IDLE_GAP[6:0]**: When the preferred transaction store is empty for these many clock cycles, switch to the alternate transaction store if it is non-empty.
The read transaction store (both high and low priority) is the default preferred transaction store and the write transaction store is the alternative store.
When prefer write over read is set this is reversed.
0x0 is a legal value for this register. When set to 0x0, the transaction store switching happens immediately when the switching conditions become true.
FOR PERFORMANCE ONLY
Programming mode: Static

Bits 23:16 **GO2CRITICAL_HYSTERESIS[7:0]**: UNUSED
Programming mode: Static

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **LPR_NUM_ENTRIES[3:0]**: Number of entries in the low priority transaction store is this value + 1.
(MEMC_NO_OF_ENTRY - (SCHED.lpr_num_entries + 1)) is the number of entries available for the high priority transaction store.
Setting this to maximum value allocates all entries to low priority transaction store.
Setting this to 0 allocates 1 entry to low priority transaction store and the rest to high priority transaction store.
Note: In ECC configurations, the numbers of write and low priority read credits issued is one less than in the non-ECC case. One entry each is reserved in the write and low-priority read CAMs for storing the RMW requests arising out of single bit error correction RMW operation.
Programming mode: Static

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **PAGECLOSE**: If true, bank is kept open only while there are page hit transactions available in the CAM to that bank. The last read or write command in the CAM with a bank and page hit is executed with auto-precharge if SCHED1.pageclose_timer=0. Even if this register set to 1 and SCHED1.pageclose_timer is set to 0, explicit precharge (and not auto-precharge) may be issued in some cases where there is a mode switch between write and read or between LPR and HPR. The Read and Write commands that are executed as part of the ECC scrub requests are also executed without auto-precharge.

If false, the bank remains open until there is a need to close it (to open a different page, or for page timeout or refresh timeout) - also known as open page policy. The open page policy can be overridden by setting the per-command-autopre bit on the HIF interface (hif_cmd_autopre).

The pageclose feature provids a midway between Open and Close page policies.

For performance only.

Programming mode: Quasi-dynamic Group 3

Bit 1 **PREFER_WRITE**: If set then the bank selector prefers writes over reads.

FOR DEBUG ONLY.

Programming mode: Static

Bit 0 **FORCE_LOW_PRI_N**: Active low signal. When asserted ('0'), all incoming transactions are forced to low priority. This implies that all high priority read (HPR) and variable priority read commands (VPR) are treated as low priority read (LPR) commands. On the write side, all variable priority write (VPW) commands are treated as normal priority write (NPW) commands. Forcing the incoming transactions to low priority implicitly turns off bypass path for read commands.

For performance only.

Programming mode: Static

5.7.59 DDRCTRL scheduler control register 1 (DDRCTRL_SCHED1)

Address offset: 0x254

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PAGECLOSE_TIMER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PAGECLOSE_TIMER[7:0]**: This field works in conjunction with SCHED.pageclose.
It only has meaning if SCHED.pageclose==1.
If SCHED.pageclose==1 and pageclose_timer==0, then an auto-precharge may be scheduled for last read
or write command in the CAM with a bank and page hit.
Note, sometimes an explicit precharge is scheduled instead of the auto-precharge. See SCHED.pageclose for details of when this may happen.
If SCHED.pageclose==1 and pageclose_timer>0, then an auto-precharge is not scheduled for last read
or write command in the CAM with a bank and page hit.
Instead, a timer is started, with pageclose_timer as the initial value.
There is a timer on a per bank basis.
The timer decrements unless the next read or write in the CAM to a bank is a page hit.
It gets reset to pageclose_timer value if the next read or write in the CAM to a bank is a page hit.
Once the timer has reached zero, an explicit precharge is attempted to be scheduled.
Programming mode: Static.

5.7.60 DDRCTRL high priority read CAM register 1 (DDRCTRL_PERFHPR1)

Address offset: 0x25C

Reset value: 0x0F00 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HPR_XACT_RUN_LENGTH[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

HPR_MAX_STARVE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **HPR_XACT_RUN_LENGTH[7:0]**:
Number of transactions that are serviced once the HPR queue goes critical is the smaller of:
- (a) This number
- (b) Number of transactions available.
Unit: Transaction.
For performance only.
Programming mode: Quasi-dynamic Group 3

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **HPR_MAX_STARVE[15:0]**: Number of DFI clocks that the HPR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 disables the starvation functionality; during normal operation, this function must not be disabled as it causes excessive latencies.
For performance only.
Programming mode: Quasi-dynamic Group 3

5.7.61 DDRCTRL low priority read CAM register 1 (DDRCTRL_PERFLPR1)

Address offset: 0x264

Reset value: 0x0F00 007F

W_MAX_STARVE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **W_XACT_RUN_LENGTH[7:0]**:
Number of transactions that are serviced once the WR queue goes critical is the smaller of:
- (a) This number
- (b) Number of transactions available.

Unit: Transaction.
For performance only.
Programming mode: Quasi-dynamic Group 3.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:0 **W_MAX_STARVE[15:0]**: Number of DFI clocks that the WR queue can be starved before it goes critical. The minimum valid functional value for this register is 0x1. Programming it to 0x0 disables the starvation functionality; during normal operation, this function must not be disabled as it causes excessive latencies.

For performance only.

Programming mode: Quasi-dynamic Group 3.

5.7.63 DDRCTRL debug register 0 (DDRCTRL_DBG0)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIS_COLLISION_PAGE_OPT	Res.	Res.	Res.	DIS_WC
											rw				rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DIS_COLLISION_PAGE_OPT**: When this is set to '0', auto-precharge is disabled for the flushed command in a collision case. Collision cases are write followed by read to same address, read followed by write to same address, or write followed by write to same address with DBG0.dis_wc bit = 1 (where same address comparisons exclude the two address bits representing critical word).

FOR DEBUG ONLY.

Programming mode: Static

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DIS_WC**: When 1, disable write combine.

FOR DEBUG ONLY

Programming mode: Static

5.7.64 DDRCTRL debug register 1 (DDRCTRL_DBG1)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIS_HIF	DIS_DQ
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **DIS_HIF**: When 1, DDRCTRL asserts the HIF command signal hif_cmd_stall. DDRCTRL ignores the hif_cmd_valid and all other associated request signals.

This bit is intended to be switched on-the-fly.

Programming mode: Dynamic

Bit 0 **DIS_DQ**: When 1, DDRCTRL does not de-queue any transactions from the CAM. Bypass is also disabled. All transactions are queued in the CAM. No reads or writes are issued to SDRAM as long as this is asserted.

This bit may be used to prevent reads or writes being issued by the DDRCTRL, which makes it safe to modify certain register fields associated with reads and writes (see User Guide for details). After setting this bit, it is strongly recommended to poll DBGCAM.wr_data_pipeline_empty and DBGCAM.rd_data_pipeline_empty, before making changes to any registers which affect reads and writes. This ensures that the relevant logic in the DDRC is idle.

This bit is intended to be switched on-the-fly.

Programming mode: Dynamic

5.7.65 DDRCTRL CAM debug register (DDRCTRL_DBGCAM)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	WR_DATA_PIPELINE_EMPTY	RD_DATA_PIPELINE_EMPTY	Res.	DBG_WR_Q_EMPTY	DBG_RD_Q_EMPTY	DBG_STALL	Res.	Res.	Res.	DBG_W_Q_DEPTH[4:0]				
		r	r		r	r	r				r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

			r	r	r	r	r				r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **WR_DATA_PIPELINE_EMPTY**: This bit indicates that the write data pipeline on the DFI interface is empty. This register is intended to be polled at least twice after setting DBG1.dis_dq, to ensure that all remaining commands/data have completed.

Programming mode: Dynamic.

Bit 28 **RD_DATA_PIPELINE_EMPTY**: This bit indicates that the read data pipeline on the DFI interface is empty. This register is intended to be polled at least twice after setting DBG1.dis_dq, to ensure that all remaining commands/data have completed.

Programming mode: Dynamic.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **DBG_WR_Q_EMPTY**: When 1, all the Write command queues and Write data buffers inside DDRC are empty. This register is to be used for debug purpose.

An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time.

For debug only.

Programming mode: Dynamic.

Bit 25 **DBG_RD_Q_EMPTY**: When 1, all the Read command queues and Read data buffers inside DDRC are empty. This register is to be used for debug purpose.

An example use-case scenario: When Controller enters Self-Refresh using the Low-Power entry sequence, Controller is expected to have executed all the commands in its queues and the write and read data drained. Hence this register should be 1 at that time.

For debug only.

Programming mode: Dynamic

Bit 24 **DBG_STALL**: Stall

For debug only.

Programming mode: Dynamic

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DBG_W_Q_DEPTH[4:0]**: Write queue depth

The last entry of WR queue is reserved for ECC SCRUB operation. This entry is not included in the calculation of the queue depth.

For debug only.

Programming mode: Dynamic

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBG_LPR_Q_DEPTH[4:0]**: Low priority read queue depth

The last entry of Lpr queue is reserved for ECC SCRUB operation. This entry is not included in the calculation of the queue depth.

For debug only.

Programming mode: Dynamic

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBG_HPR_Q_DEPTH[4:0]**: High priority read queue depth

For debug only.

Programming mode: Dynamic

5.7.66 DDRCTRL command debug register (DDRCTRL_DBGCMD)

Address offset: 0x30C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTRLUPD	ZQ_CALIB_SHORT	Res.	Res.	Res.	RANK0_REFRESH
										rs	rs				rs

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CTRLUPD**:

Setting this register bit to 1 indicates to the DDRCTRL to issue a dfi_ctrlupd_req to the PHY. When this request is stored in the DDRCTRL, the bit is automatically cleared. This operation must only be performed when DFIUPD0.dis_auto_ctrlupd=1.

Programming mode: Dynamic.

Bit 4 **ZQ_CALIB_SHORT**:

Setting this register bit to 1 indicates to the DDRCTRL to issue a ZQCS (ZQ calibration short)/MPC(ZQ calibration) command to the SDRAM. When this request is stored in the DDRCTRL, the bit is automatically cleared. This operation can be performed only when ZQCTL0.dis_auto_zq=1. It is recommended NOT to set this register bit if in Init, in Self-Refresh(except LPDDR4) or SR-Powerdown(LPDDR4) or Deep power-down operating modes or maximum power saving mode.

For self-refresh(except LPDDR4) or SR-powerdown(LPDDR4) it is scheduled after SR(except LPDDR4) or SPRD(LPDDR4) has been exited.

For Deep power down and maximum power saving mode, it is not scheduled, although DBGSTAT.zq_calib_short_busy is de-asserted.

Programming mode: Dynamic.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RANK0_REFRESH**:

Setting this register bit to 1 indicates to the DDRCTRL to issue a refresh to rank 0. Writing to this bit causes DBGSTAT.rank0_refresh_busy to be set. When DBGSTAT.rank0_refresh_busy is cleared, the command has been stored in DDRCTRL.

For 3DS configuration, refresh is sent to rank index 0.

This operation can be performed only when RFSHCTL3.dis_auto_refresh=1. It is recommended NOT to set this register bit if in Init or Deep power-down operating modes or Maximum Power Saving Mode.

Programming mode: Dynamic.

5.7.67 DDRCTRL status debug register (DDRCTRL_DBGSTAT)

Address offset: 0x310

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTRLUPD_BUSY	ZQ_CALIB_SHORT_BUSY	Res.	Res.	Res.	RANK0_REFRESH_BUSY
										r	r				r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CTRLUPD_BUSY**: SoC core may initiate a ctrlupd operation only if this signal is low. This signal goes high in the clock after the DDRCTRL accepts the ctrlupd request. It goes low when the ctrlupd operation is initiated in the DDRCTRL. It is recommended not to perform ctrlupd operations when this signal is high.

- 0 - Indicates that the SoC core can initiate a ctrlupd operation
- 1 - Indicates that ctrlupd operation has not been initiated yet in the DDRCTRL

Programming mode: Dynamic

Bit 4 **ZQ_CALIB_SHORT_BUSY**: SoC core may initiate a ZQCS (ZQ calibration short) operation only if this signal is low. This signal goes high in the clock after the DDRCTRL accepts the ZQCS request. It goes low when the ZQCS operation is initiated in the DDRCTRL. It is recommended not to perform ZQCS operations when this signal is high.

- 0 - Indicates that the SoC core can initiate a ZQCS operation
- 1 - Indicates that ZQCS operation has not been initiated yet in the DDRCTRL

Programming mode: Dynamic

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **RANK0_REFRESH_BUSY**: SoC core may initiate a rank0_refresh operation (refresh operation to rank 0) only if this signal is low. This signal goes high in the clock after DBGCMD.rank0_refresh is set to one. It goes low when the rank0_refresh operation is stored in the DDRCTRL. It is recommended not to perform rank0_refresh operations when this signal is high.

- 0 - Indicates that the SoC core can initiate a rank0_refresh operation
- 1 - Indicates that rank0_refresh operation has not been stored yet in the DDRCTRL

Programming mode: Dynamic

5.7.68 DDRCTRL software register programming control enable (DDRCTRL_SWCTL)

Address offset: 0x320

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rc_w1				rw				rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **RD_POISON_INTR_CLR**: Interrupt clear for read transaction poisoning. Allow 2/3 clock cycles for correct value to propagate to core logic and clear the interrupts.
Programming mode: Dynamic

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **RD_POISON_INTR_EN**: If set to 1, enables interrupts for read transaction poisoning
Programming mode: Dynamic

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RD_POISON_SLVERR_EN**: If set to 1, enables SLVERR response for read transaction poisoning
Programming mode: Dynamic

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **WR_POISON_INTR_CLR**: Interrupt clear for write transaction poisoning. Allow 2/3 clock cycles for correct value to propagate to core logic and clear the interrupts.
Programming mode: Dynamic

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **WR_POISON_INTR_EN**: If set to 1, enables interrupts for write transaction poisoning
Programming mode: Dynamic

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **WR_POISON_SLVERR_EN**: If set to 1, enables SLVERR response for write transaction poisoning
Programming mode: Dynamic

5.7.71 DDRCTRL AXI Poison status register (DDRCTRL_POISONSTAT)

Address offset: 0x370

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RD_POISON_INTR_1**: Read transaction poisoning error interrupt for port 1. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming mode: Dynamic

Bit 16 **RD_POISON_INTR_0**: Read transaction poisoning error interrupt for port 0. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's read address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register rd_poison_intr_clr, then value propagated to APB clock.
Programming mode: Dynamic

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **WR_POISON_INTR_1**: Write transaction poisoning error interrupt for port 1. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming mode: Dynamic

Bit 0 **WR_POISON_INTR_0**: Write transaction poisoning error interrupt for port 0. This register is a APB clock copy (double register synchronizer) of the interrupt asserted when a transaction is poisoned on the corresponding AXI port's write address channel. Bit 0 corresponds to Port 0, and so on. Interrupt is cleared by register wr_poison_intr_clr, then value propagated to APB clock.
Programming mode: Dynamic

5.7.72 DDRCTRL port status register (DDRCTRL_PSTAT)

Address offset: 0x3FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RD_PORT_BUSY_1	RD_PORT_BUSY_0
														r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **WR_PORT_BUSY_1**: Indicates if there are outstanding writes for AXI port 1.
Programming mode: Dynamic

Bit 16 **WR_PORT_BUSY_0**: Indicates if there are outstanding writes for AXI port 0.
Programming mode: Dynamic

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **RD_PORT_BUSY_1**: Indicates if there are outstanding reads for AXI port 1.
Programming mode: Dynamic

Bit 0 **RD_PORT_BUSY_0**: Indicates if there are outstanding reads for AXI port 0.
Programming mode: Dynamic

5.7.73 DDRCTRL port common configuration register (DDRCTRL_PCCFG)

Address offset: 0x400

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	BL_EXP_MODE	Res.	Res.	Res.	PAGEMATCH_LIMIT	Res.	Res.	Res.	GO2CRITICAL_EN
							rw				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **BL_EXP_MODE**: Burst length expansion mode. By default (i.e. bl_exp_mode==0) XPI expands every AXI burst into multiple HIF commands, using the memory burst length as a unit. If set to 1, then XPI uses half of the memory burst length as a unit.

This applies to both reads and writes. When MSTR.data_bus_width==00, setting bl_exp_mode to 1 has no effect.

This can be used in cases where Partial Writes is enabled (UMCTL2_PARTIAL_WR=1), in order to avoid or minimize t_ccd_l penalty in DDR4 and t_ccd_mw penalty in LPDDR4. Hence, bl_exp_mode=1 is only recommended if DDR4 or LPDDR4.

Note that if DBICTL.dm_en=0, functionality is not supported in the following cases:

- UMCTL2_PARTIAL_WR=0
- UMCTL2_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=8 and MSTR.burst_rdwr=1000 (LPDDR4 only)
- UMCTL2_PARTIAL_WR=1, MSTR.data_bus_width=01, MEMC_BURST_LENGTH=4 and MSTR.burst_rdwr=0100 (DDR4 only), with either MSTR.burstchop=0 or CRCPARCTL1.crc_enable=1

Functionality is also not supported if Data Channel Interleave is enabled.

Programming mode: Static.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PAGEMATCH_LIMIT**: Page match four limit. If set to 1, limits the number of consecutive same page DDRC transactions that can be granted by the Port Arbiter to four when Page Match feature is enabled. If set to 0, there is no limit imposed on number of consecutive same page DDRC transactions.

Programming mode: Static.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **GO2CRITICAL_EN**: If set to 1 (enabled), sets co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals going to DDRC based on urgent input (awurgent, arurgent) coming from AXI master. If set to 0 (disabled), co_gs_go2critical_wr and co_gs_go2critical_lpr/co_gs_go2critical_hpr signals at DDRC are driven to 1b'0.
Programming mode: Static.

5.7.74 DDRCTRL port x configuration read register (DDRCTRL_PCFGR_x)

Address offset: 0x404 + 0xB0 * x, (x = 0 to 1)

Reset value: 0x0000 4000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDWR_ORDERED_EN
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RD_PORT_PAGEMATCH_EN	RD_PORT_URGENT_EN	RD_PORT_AGING_EN	Res.	Res.	RD_PORT_PRIORITY[9:0]									
	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RDWR_ORDERED_EN**: Enables ordered read/writes. If set to 1, preserves the ordering between read transaction and write transaction issued to the same address, on a given port. In other words, the controller ensures that all same address read and write commands from the application port interface are transported to the DFI interface in the order of acceptance. This feature is useful in cases where software coherency is desired for masters issuing back-to-back read/write transactions without waiting for write/read responses. Note that this register has an effect only if necessary logic is instantiated via the UMCTL2_RDWR_ORDERED_n parameter.
Programming mode: Static.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RD_PORT_PAGEMATCH_EN**: If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register.
Programming mode: Static

Bit 13 **RD_PORT_URGENT_EN**: If set to 1, enables the AXI urgent sideband signal (arurgent). When enabled and arurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_lpr/co_gs_go2critical_hpr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register. Note that arurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).

Programming mode: Static

Bit 12 **RD_PORT_AGING_EN**: If set to 1, enables aging function for the read channel of the port.

Programming mode: Static

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **RD_PORT_PRIORITY[9:0]**: Determines the initial load value of read aging counters. These counters are parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the read aging counter sets the priority of the read channel of a given port. Port's priority increases as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel has the highest priority level (timeout condition - Priority0). For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (arqos) are enabled (timeout is still applicable). For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching. In this case, external dynamic priority input, arqos (for reads only) can still be used to set the DDRC read priority (2 priority levels: low priority read - LPR, high priority read - HPR) on a command by command basis.

Note: The two LSBs of this register field are tied internally to 2'b00.

Programming mode: Static

5.7.75 DDRCTRL port x configuration write register (DDRCTRL_PCFGW_x)

Address offset: 0x408 + 0xB0 * x, (x = 0 to 1)

Reset value: 0x0000 4000

	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **WR_PORT_PAGEMATCH_EN**: If set to 1, enables the Page Match feature. If enabled, once a requesting port is granted, the port is continued to be granted if the following immediate commands are to the same memory page (same bank and same row). See also related PCCFG.pagematch_limit register.
Programming mode: Static

Bit 13 **WR_PORT_URGENT_EN**: If set to 1, enables the AXI urgent sideband signal (awurgent). When enabled and awurgent is asserted by the master, that port becomes the highest priority and co_gs_go2critical_wr signal to DDRC is asserted if enabled in PCCFG.go2critical_en register.
Note that awurgent signal can be asserted anytime and as long as required which is independent of address handshaking (it is not associated with any particular command).
Programming mode: Static

Bit 12 **WR_PORT_AGING_EN**: If set to 1, enables aging function for the write channel of the port.
Programming mode: Static

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:0 **WR_PORT_PRIORITY[9:0]**: Determines the initial load value of write aging counters. These counters are parallel loaded after reset, or after each grant to the corresponding port. The aging counters down-count every clock cycle where the port is requesting but not granted. The higher significant 5-bits of the write aging counter sets the initial priority of the write channel of a given port. Port's priority increases as the higher significant 5-bits of the counter starts to decrease. When the aging counter becomes 0, the corresponding port channel has the highest priority level.
For multi-port configurations, the aging counters cannot be used to set port priorities when external dynamic priority inputs (awqos) are enabled (timeout is still applicable).
For single port configurations, the aging counters are only used when they timeout (become 0) to force read-write direction switching.
Note: The two LSBs of this register field are tied internally to 2'b00.
Programming mode: Static

5.7.76 DDRCTRL port x control register (DDRCTRL_PCTRL_x)

Address offset: 0x490 + 0xB0 * x, (x = 0 to 1)

				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **RQOS_MAP_REGION2[1:0]**: This bitfield indicates the traffic class of region2.
For dual address queue configurations, region2 maps to the red address queue.
Valid values are 1: VPR and 2: HPR only.
When VPR support is disabled (UMCTL2_VPR_EN = 0) and traffic class of region2 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming mode: Quasi-dynamic Group 3

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **RQOS_MAP_REGION1[1:0]**: This bitfield indicates the traffic class of region 1.
Valid values are:
- 0 : LPR,
- 1: VPR,
- 2: HPR.

For dual address queue configurations, region1 maps to the blue address queue.
In this case, valid values are
- 0: LPR and
- 1: VPR only.

When VPR support is disabled (UMCTL2_VPR_EN = 0) and traffic class of region 1 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming mode: Quasi-dynamic Group 3

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **RQOS_MAP_REGION0[1:0]**: This bitfield indicates the traffic class of region 0.
Valid values are:
- 0: LPR, 1: VPR, 2: HPR.
For dual address queue configurations, region 0 maps to the blue address queue.
In this case, valid values are:
- 0: LPR and 1: VPR only.
When VPR support is disabled (UMCTL2_VPR_EN = 0) and traffic class of region0 is set to 1 (VPR), VPR traffic is aliased to LPR traffic.
Programming mode: Quasi-dynamic Group 3

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **RQOS_MAP_LEVEL2[3:0]**: Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to arqos.
Region2 starts from (level2 + 1) up to 15.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming mode: Quasi-dynamic Group 3

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **RQOS_MAP_LEVEL1[3:0]**: Separation level1 indicating the end of region0 mapping; start of region0 is 0. Possible values for level1 are 0 to 13 (for dual RAQ) or 0 to 14 (for single RAQ) which corresponds to arqos.
Note that for PA, arqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.
All of the map_level* registers must be set to distinct values.
Programming mode: Quasi-dynamic Group 3

5.7.78 DDRCTRL port x read Q0S configuration register 1 (DDRCTRL_PCFGQOS1_x)

Address offset: 0x498 + 0xB0 * x, (x = 0 to 1)

Reset value: 0x0000 0000

				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **WQOS_MAP_REGION2[1:0]**: This bitfield indicates the traffic class of region 2.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UMCTL2_VPW_EN = 0) and traffic class of region 2 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming mode: Quasi-dynamic Group 3

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **WQOS_MAP_REGION1[1:0]**: This bitfield indicates the traffic class of region 1.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UMCTL2_VPW_EN = 0) and traffic class of region 1 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming mode: Quasi-dynamic Group 3

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **WQOS_MAP_REGION0[1:0]**: This bitfield indicates the traffic class of region 0.
Valid values are:
0: NPW, 1: VPW.
When VPW support is disabled (UMCTL2_VPW_EN = 0) and traffic class of region 0 is set to 1 (VPW), VPW traffic is aliased to NPW traffic.
Programming mode: Quasi-dynamic Group 3

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **WQOS_MAP_LEVEL2[3:0]**: Separation level2 indicating the end of region1 mapping; start of region1 is (level1 + 1). Possible values for level2 are (level1 + 1) to 14 which corresponds to awqos.

Region2 starts from (level2 + 1) up to 15.

Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.

All of the map_level* registers must be set to distinct values.

Programming mode: Quasi-dynamic Group 3

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **WQOS_MAP_LEVEL1[3:0]**: Separation level indicating the end of region0 mapping; start of region0 is 0. Possible values for level1 are 0 to 13 which corresponds to awqos.

Note that for PA, awqos values are used directly as port priorities, where the higher the value corresponds to higher port priority.

All of the map_level* registers must be set to distinct values.

Programming mode: Quasi-dynamic Group 3

5.7.80 DDRCTRL port x write Q0S configuration register 1 (DDRCTRL_PCFGWQOS1_x)

Address offset: 0x4A0 + 0xB0 * x, (x = 0 to 1)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	WQOS_MAP_TIMEOUT1[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:16 **WQOS_MAP_TIMEOUT2[10:0]**: Specifies the timeout value for write transactions in region 2.

Programming mode: Quasi-dynamic Group 3.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **WQOS_MAP_TIMEOUT1[10:0]**: Specifies the timeout value for write transactions in region 0 and 1.

Programming mode: Quasi-dynamic Group 3.

5.7.81 DDRCTRL registers summary

Refer to *Section 2.5 on page 153* for the register boundary addresses.

6 TrustZone® address space controller for DDR (TZC)

6.1 Introduction

The TZC filters read/write accesses to the DDR controller according to TrustZone access rights, and according to Non-secure master Address ID (NSAID) on up to 9 programmable regions.

Note: For more information, please refer to Arm TZC-400 TRM.

6.2 TZC features

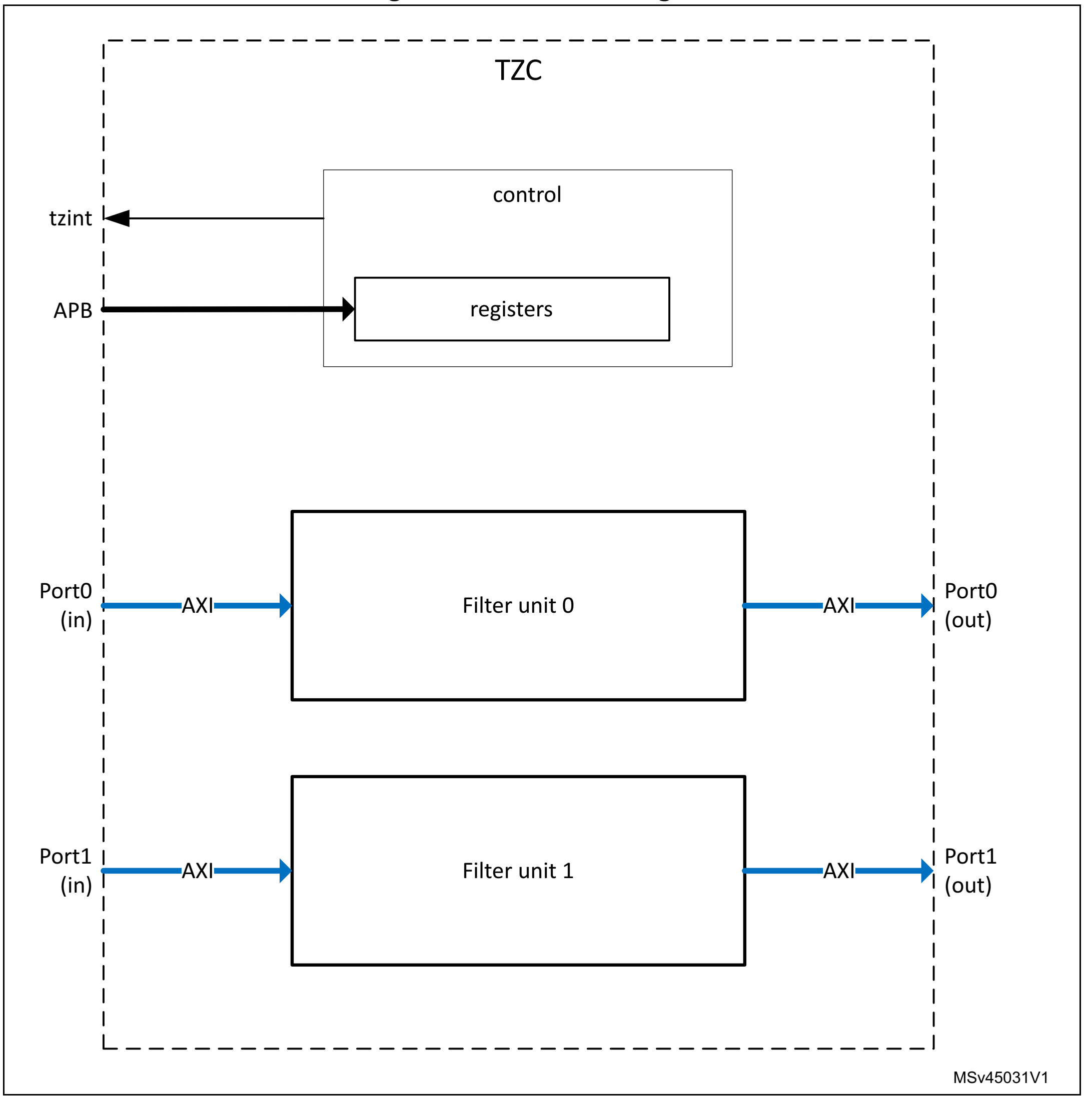
- 32-bit APB4 Interface
- TZC configuration is supported by secure master only
- 2 filter units working concurrently
- 9 regions:
  - Region 0 is always enabled and covers the whole address range
  - Regions 1 to 8 have programmable base/end address and can be assigned one or both filters.
- Secure and non-secure access permissions are programmed per region
- Non-secure accesses are filtered according to NSAID
- Regions controlled by the same filter must not overlap
- Failed permission checks are signaled with an AXI Bus error and/or interrupt
- Dual read access path with:
  - Normal path supporting 256 outstanding transactions
  - Fast path with limited outstanding capabilities using FPID signals
- Gate keeper logic to enable and disable each filter
- Speculative access

Note: Fast path and FPID signals are not used in STM32MP153x. Configured acceptance on FPID is set to minimum (8).

6.3 TZC block diagram

The TZC block diagram is shown in *Figure 8: TZC block diagram*.

Figure 8. TZC block diagram



6.4 TZC functional description

The TZC enforces the access permissions of several regions:

- region 0: always enabled and covers the whole 32-bit address space.
- regions 1 to 8: are fully programmable.

Access permissions are checked against transaction security and the transaction source:

- Transaction security is identified by AXI TrustZone protection signals: awprot[1] and arprot[1].
- The transaction source is identified by the Master NSAID. In the case of a permission fail, the fail ID is reported by the AXI ID on the AXI port. The NSAID and AXI ID are defined according to *Table 26: NSAID and AXI _ID mapping*.

A region must be granted secure access if required, regardless of the settings for non-secure reads and non-secure writes. For example, when permissions are set so that a non-secure read or non-secure write access is permitted, this does not mean that the corresponding secure read or secure write access is also automatically granted.

Table 20. NSAID and AXI _ID mapping

Master	NSAID[3:0]	ID_WIDTH	AXI_ID[10:0]
CA7 (CPU0 and 1)	0b0000	AR:6/AW:5	11'b10XXXXXX000
CM4	0b0001	0	11'b00000000001
LTDC	0b0011	4	11'b0100XXXX101
MDMA	0b0101	1	11'b0000000X000
DMA1	0b0110	0	11'b00000000001
DMA2	0b0110	0	11'b00000000001
USBH (EHCI)	0b0111	0	11'b01000000000

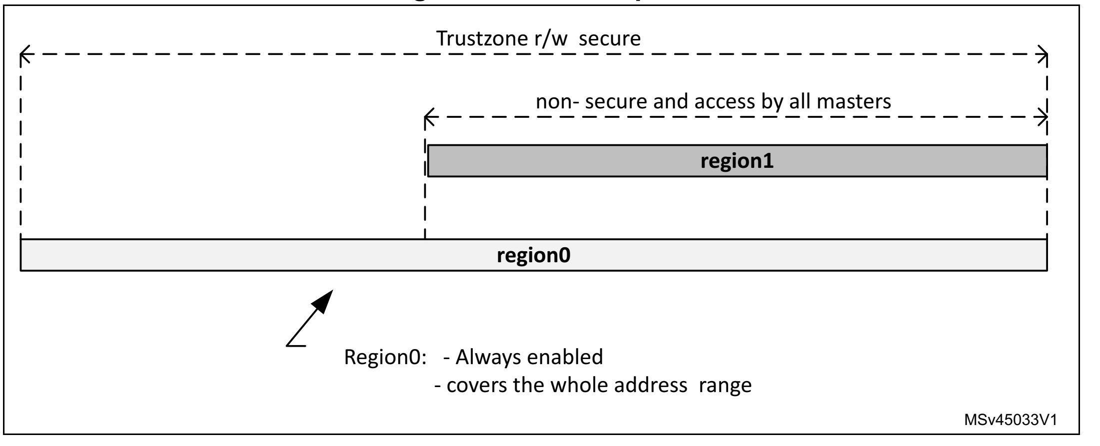
OTG	0b1000	0	11'b00000000001
SDMMC1	0b1001	0	11'b01000000011
SDMMC2	0b1001	0	11'b01000000100
SDMMC3	0b1001	0	11'b00000000001
ETH	0b1010	4	11'b0100XXXX010
DAP	0b1111	0	11'b00000000010

6.5 TZC application programming examples

A simple application example is shown *Figure 9: TZC example 1*:

Figure 9. TZC example 1



In this example the secure world has access to whole DDR range, and all non-secure masters have permission to access address ≥ base1.

It is programmed with:

- region 0
  - always enabled by default
  - covers the full address range by default
  - set region0 secure r/w access permissions
  - set region0 NSAID r/w access permission
  - enable both filters on region0

```
REGION0_ATTRIBUTE.s_wr_en = 1
REGION0_ATTRIBUTE.s_rd_en = 1
REGION0_ID_ACCESS.nsaid_we_en = 0b00000000000
REGION0_ID_ACCESS.nsaid_re_en = 0b00000000000
REGION0_ATTRIBUTE.filter_en = 0b11
```

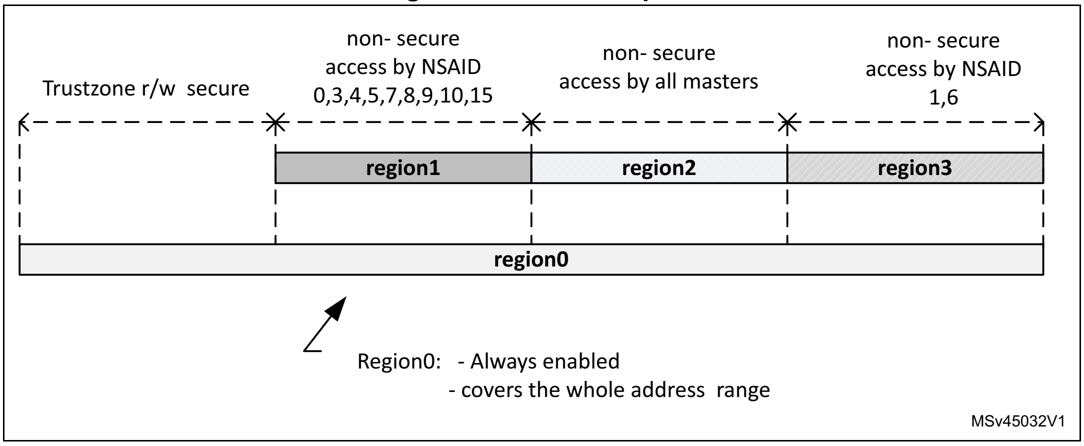
The secure world then defines the other regions (1 up to 8) and opens access to all non-secure NSAIDs.

- region1
  - define region1
  - region1 accessible by secure r/w
  - set region1 NSAID r/w permission for all NSAID
  - enable both filters on region1

```
TZC.REGION_BASE_LOW1.base_address_low = 'base1
REGION1_TOP_LOW.top_address_low = 'base1 + 'size1
REGION1_ATTRIBUTE.s_wr_en = 1
REGION1_ATTRIBUTE.s_rd_en = 1
REGION1_ID_ACCESS.nsaid_we_en = 0xFFFF
REGION1_ID_ACCESS.nsaid_re_en = 0xFFFF
REGION1_ATTRIBUTE.filter_en = 0b11
```

Another application example for the TZC is shown *Figure 10: TZC example 2*:

Figure 10. TZC example 2



In this example the secure world only has access to address ≤ base1 and non-secure masters have selective permissions to region1 and 3; region2 is shared by all non-secure masters.

It is programmed with:

- region 0
  - always enabled by default
  - covers the full address range by default
  - set region0 secure r/w access permissions
  - set region0 NSAID r/w access permission
  - enable both filters on region0

```
REGION0_ATTRIBUTE.s_wr_en = 1
REGION0_ATTRIBUTE.s_rd_en = 1
REGION0_ID_ACCESS.nsaid_we_en = 0x0000
REGION0_ID_ACCESS.nsaid_re_en = 0x0000
REGION0_ATTRIBUTE.filter_en = 0b11
```

The secure world then defines several regions (1 to 3) and opens access to the non-secure NSAID.

- region1
  - define region1
  - region1 non accessible by secure r/w
  - set region1 NSAID r/w permission for: 0,3,4,5,7,8,9,10,15
  - enable both filters on region1
    TZC.REGION_BASE_LOW1.base_address_low = 'base1

```
REGION1_TOP_LOW.top_address_low = 'base1 + 'size1
REGION1_ATTRIBUTE.s_wr_en = 0
REGION1_ATTRIBUTE.s_rd_en = 0
REGION1_ID_ACCESS.nsaid_we_en = 0x87B9
```

```
REGION1_ID_ACCESS.nsaid_re_en = 0x87B9
REGION1_ATTRIBUTE.filter_en = 0b11
```

- region2
  - define region2
  - region2 non accessible by secure r/w
  - set region2 NSAID r/w permission for: 0,1,3,4,5,6,7,8,9,10,15
  - enable both filters on region2

```
REGION2_BASE_LOW.base_address_low = 'base2
REGION2_TOP_LOW.top_address_low = 'base2 + 'size2
REGION2_ATTRIBUTE.s_wr_en = 0
REGION2_ATTRIBUTE.s_rd_en = 0
REGION2_ID_ACCESS.nsaid_we_en = 0x87FB
REGION2_ID_ACCESS.nsaid_re_en = 0x87FB
REGION2_ATTRIBUTE.filter_en = 0b11
```

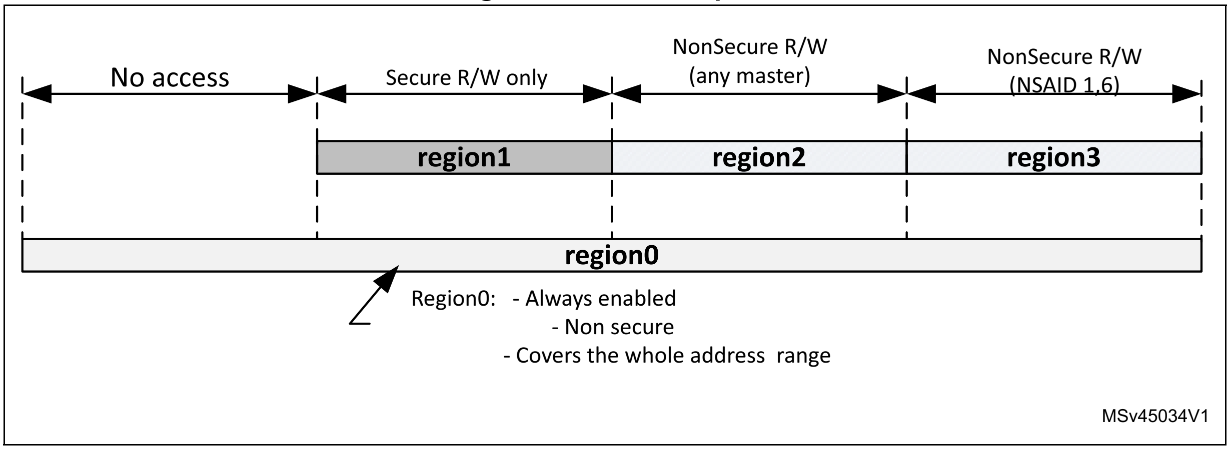
- region3
  - define region3
  - region3 non accessible by secure r/w
  - set region3 NSAID r/w permission for: 1,6
  - enable both filters on region3

```
REGION3_BASE_LOW.base_address_low = 'base3
REGION3_TOP_LOW.top_address_low = 'base3 + 'size3
REGION3_ATTRIBUTE.s_wr_en = 0
REGION3_ATTRIBUTE.s_rd_en = 0
REGION3_ID_ACCESS.nsaid_we_en = 0x0042
REGION3_ID_ACCESS.nsaid_re_en = 0x0042
REGION3_ATTRIBUTE.filter_en = 0b11
```

Note: All shared regions need to be distinct because regions must not overlap.

A third application example for the TZC is shown *Figure 11: TZC example 3*: This example uses region0 as a blanket and secure or non-secure regions are set as holes. This programming model is more convenient for trapping programming errors.

Figure 11. TZC example 3



In this example the secure world only has access to address ≤ base1 and non-secure masters have selective permissions to region2 and 3.

It is programmed with:

- region 0
  - always enabled by default
  - covers the full address range by default
  - set region0 without secure access permissions (default)
  - set region0 without NSAID r/w access permission (default)
  - enable both filters on region0

```
REGION0_ATTRIBUTE.s_wr_en = 0 (default)
REGION0_ATTRIBUTE.s_rd_en = 0 (default)
REGION0_ID_ACCESS.nsaid_we_en = 0x0000 (default)
REGION0_ID_ACCESS.nsaid_re_en = 0x0000 (default)
REGION0_ATTRIBUTE.filter_en = 0b11
```

The secure world then defines several regions (1 to 3) and opens holes for secure and non-secure access

- region1
  - define region1
  - region1 accessible by secure r/w
  - set region1 no NSAID r/w permission
  - enable both filters on region1

```
TZC.REGION_BASE_LOW1.base_address_low = 'base1
REGION1_TOP_LOW.top_address_low = 'base1 + 'size1
REGION1_ATTRIBUTE.s_wr_en = 1
REGION1_ATTRIBUTE.s_rd_en = 1
REGION1_ID_ACCESS.nsaid_we_en = 0x0000
REGION1_ID_ACCESS.nsaid_re_en = 0x0000
REGION1_ATTRIBUTE.filter_en = 0b11
```

- region2
  - define region2
  - region2 non accessible by secure r/w
  - set region2 NSAID r/w permission for all NSAID
  - enable both filters on region2

```
REGION2_BASE_LOW.base_address_low = 'base2
REGION2_TOP_LOW.top_address_low = 'base2 + 'size2
REGION2_ATTRIBUTE.s_wr_en = 0
REGION2_ATTRIBUTE.s_rd_en = 0
REGION2_ID_ACCESS.nsaid_we_en = 0xFFFF
REGION2_ID_ACCESS.nsaid_re_en = 0xFFFF
REGION2_ATTRIBUTE.filter_en = 0b11
```

- region3
  - define region3
  - region3 non accessible by secure r/w
  - set region3 NSAID r/w permission for NSAID 1,6
  - enable both filters on region3

```
REGION3_BASE_LOW.base_address_low = 'base3
```

```
REGION3_TOP_LOW.top_address_low = ‘base3 + ‘size3
REGION3_ATTRIBUTE.s_wr_en = 0
REGION3_ATTRIBUTE.s_rd_en = 0
REGION3_ID_ACCESS.nsaid_we_en = 0x0042
REGION3_ID_ACCESS.nsaid_re_en = 0x0042
REGION3_ATTRIBUTE.filter_en = 0b11
```

6.5.1 DMA requests

*Note: TZC does **not** support DMA interface.*

6.5.2 Interrupts

*Note: TZC is asserting interrupt: **tzcint** when some security checks failed.*

6.6 TZC registers

TZC registers are accessed only by words (32-bit).

6.6.1 TZC configuration register (TZC_BUILD_CONFIG)

Address offset: 0x000

Reset value: 0x0100 1F08

Provides information about TZC configuration.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	NO_OF_FILTERS[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						r	r								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	ADDRESS_WIDTH[5:0]						Res.	Res.	Res.	NO_OF_REGIONS[4:0]				
		r	r	r	r	r	r				r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **NO_OF_FILTERS[1:0]**: Number of filters
0x1: 2 filters
Others: Reserved

Bits 23:14 Reserved, must be kept at reset value.

Bits 13:8 **ADDRESS_WIDTH[5:0]**: Address width
0x1F: 32-bit address width
Others: Reserved

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NO_OF_REGIONS[4:0]**: Number fo regions
0x8: 9 regions
Others: Reserved

6.6.2 TZC action register (TZC_ACTION)

Address offset: 0x004

Reset value: 0x0000 0000

Controls interrupt and bus error response behavior when regions permission failures occur.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REACTION_VALUE[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **REACTION_VALUE[1:0]**: Permission failure reaction
Controls how TZC signals region permission failure.
0: set tzcint low and issue OKAY on the bus
1: set tzcint low and issue DECERR on the bus
2: set tzcint high and issue OKAY on the bus
3: set tzcint high and issue DECERR on the bus

6.6.3 TZC gate keeper register (TZC_GATE_KEEPER)

Address offset: 0x008

Reset value: 0x0000 0000

Provides control and status for the gate keeper in the implemented filter units.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPENSTAT[1:0]	
														r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPENREQ[1:0]	
														rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **OPENSTAT[1:0]**: Gate keeper status for each filter
Bit 17 is for filter1, bit 16 is for filter0
0: filter is opened
1: filter is closed

Bits 15:2 Reserved, must be kept at reset value.

Bits 1:0 **OPENREQ[1:0]**: Gate keeper open request
Bit 1 is for filter1, bit 0 is for filter0.
0: request filter to open
1: request filter to close

6.6.4 TZC speculation control register (TZC_SPECULATION_CTRL)

Address offset: 0x00C

Reset value: 0x0000 0000

Controls read and write access speculation.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE SPEC_ DISA BLE	READ SPEC_ DISA BLE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WRITESPEC_DISABLE**: Write access speculation disable
0: write access speculation enabled
1: write access speculation disabled

Bit 0 **READSPEC_DISABLE**: Read access speculation disable
0: read access speculation enabled
1: read access speculation disabled

6.6.5 TZC interrupt status register (TZC_INT_STATUS)

Address offset: 0x010

Reset value: 0x0000 0000

Contains the status of the interrupt signal, TZCINT, that reports access security violations or region overlap errors.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVERLAP[1:0]	
														r	r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	OVERRUN[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	STATUS[1:0]	
						r	r							r	r

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **OVERLAP[1:0]**: Overlap violation for each filter
Bit 17 is for filter 1, bit 16 is for filter 0.
0: interrupt is not asserted
1: interrupt asserted and waiting to be cleared

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **OVERRUN[1:0]**: Permission failure overrun
Two or more regions permission failures for each filter. Bit 9 is for filter 1, bit 8 is for filter 0.
0: interrupt is not asserted
1: interrupt asserted and waiting to be cleared

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **STATUS[1:0]**: Interrupt status for each filter
Bit 1 is for filter 1, bit 0 is for filter0.
0: interrupt is not asserted
1: interrupt asserted and waiting to be cleared

6.6.6 TZC interrupt clear register (TZC_INT_CLEAR)

Address offset: 0x014

Reset value: 0x0000 0000

Interrupt clear for each filter.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLEAR[1:0]	
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **CLEAR[1:0]**: Filter interrupt clear
Write “1” to clear interrupt for each filter.
bit 1: for filter 1
bit 0: for filter 0

6.6.7 TZC fail address low register x (TZC_FAIL_ADDRESS_LOWx)

Address offset: 0x020 + 0x010 * x, (x = 0 to 1)

Reset value: 0x0000 0000

Address low bits of the first failed access in the associated filter (0 to 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDR_STATUS_LOW[31:16]

ADDR_STATUS_LOW[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ADDR_STATUS_LOW[31:0]**: Fail address low bits
Low 32 address bits of the first failed access permission check in the associated filter (0 to 1).

6.6.8 TZC fail address high register x (TZC_FAIL_ADDRESS_HIGHx)

Address offset: 0x024 + 0x010 * x, (x = 0 to 1)

Reset value: 0x0000 0000

Address high bit of the first failed access in the associated filter (0 to 1).

Note: Not used with 32bit address.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:0 Reserved, must be kept at reset value.

6.6.9 TZC fail control register x (TZC_FAIL_CONTROLx)

Address offset: 0x028 + 0x010 * x, (x = 0 to 1)

Reset value: 0x0000 0000

Status information about the first access that failed a region permission check in the associated filter (0 to 1).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **DIRECTION**: Access failure direction
- 0: Read access failure
- 1: Write access failure

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **NON_SECURE**: Non-secure access failure
- 0: Secure access failure
- 1: Non-secure access failure

Bit 20 **PRIVILEGE**: Privilege access failure
- 0: Unprivileged access failure
- 1: Privileged access failure

Bits 19:0 Reserved, must be kept at reset value.

6.6.10 TZC fail ID register x (TZC_FAIL_IDx)

Address offset: 0x02C + 0x010 * x, (x = 0 to 1)

Reset value: 0x0000 0000

Contains the master AXI ARID or AWID of the first access that failed a region permission check in the associated filter unit. This occurs even if the ACTION register is set to not drive the interrupt signal.

Note: AXI ID mapping is described in Table 26: NSAID and AXI _ID mapping.

Refer to *Section 2.3 on page 101* for the register boundary addresses.

7 DDR physical interface control (DDRPHYC)

7.1 DDRPHYC features

- 32-bit DDR PHY compatible with JEDEC Standards for DDR3/3L, LPDDR2 and LPDDR3 SDRAMs.
- Dual width support: 16-bit (half-width with 2-byte lanes) or 32-bit (full-width with 4-byte lanes) DDRPHYC permits operating with SDRAMs narrower than the implemented data width.
- Operating up to 533 MHz (1066 MT/s) with DDR3/3L.
- Operating up to 533 MHz (1066 MT/s) with LPDDR2/3.
- PHY Utility Block (PUBL) to support the PHY initialization, control and calibrations.
- DFI 2.1 compliant interface to the DDRCTRL controller.
- Programmable output and ODT impedance with dynamic PVT compensation.
- Embedded dynamic drift detection in the PHY to facilitate dynamic drift compensation by the controller.
- Utilizes master and slave DLLs for a precise timing management.
- Lane-based architecture with 4-byte lanes + 1 command/address lane.
- Test modes supporting the IDDq and DLL characterization.

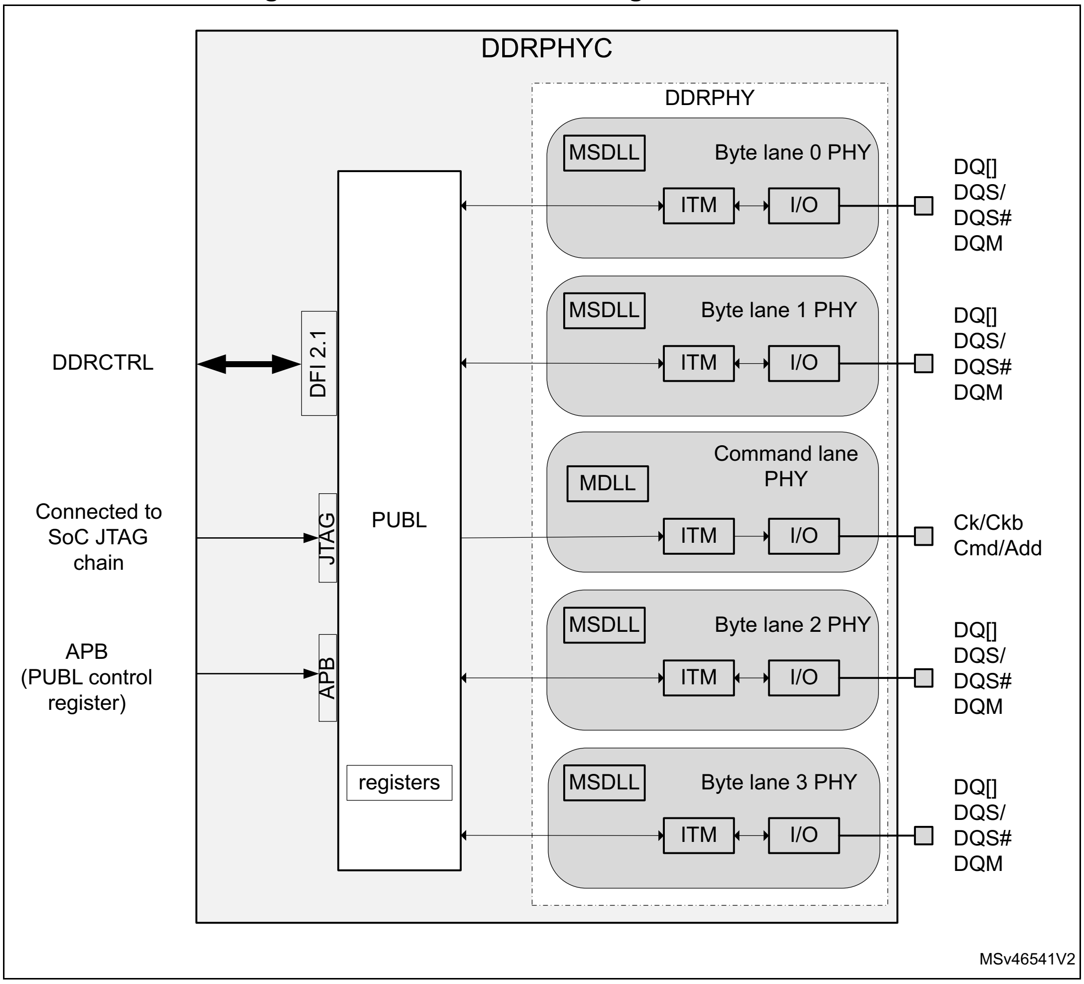
7.2 DDRPHYC block diagram

The DDRPHYC block diagram is shown in *Figure 12*.

The DDRPHYC is composed of:

- A DDRPHY physical interface which is structured into one command lane and 4-byte lanes and used to generate signals with accurate timings at the SDRAM interface.
- A PUBL (PHY Utility Block Logic) which is used to service the PHY and controlled via the APB and JTAG interfaces.

Figure 12. DDRPHYC block diagram



7.3 DDRPHYC SDRAM interface

The DDRPHYC SDRAM interfaces are listed in *Table 22*.

Table 22. DDRPHYC I/O list

Pin name	DDR3/3L	LPDDR2/3	Description
DDR_DQ31 to DDR_DQ24	Yes	Yes	Byte lane 3 DQ

DDR_BA2 to DDR_BA0	Yes	no	Bank address
DDR_CKE	Yes	Yes	CKE
DDR_CLKP	Yes	Yes	CK
DDR_CLKN	Yes	Yes	CK#
DDR_RASN	Yes	no	RAS#
DDR_CASN	Yes	no	CAS#
DDR_WEN	Yes	no	WE#
DDR_CSN	Yes	Yes	CS#
DDR_ODT	Yes	no	ODT
DDR_RESETN	Yes	no	RESET#
DDR_VREF1 to DDR_VREF3	Yes	Yes(2)	Connected to Vref= VDDQ/2
DDR_ZQ	Yes	Yes	Connected to external R =240 Ω ±1%
DDR_DTO0	Test	Test	Reserved for DLL test purposes
DDR_DTO1	Test	Test	Reserved for DLL test purposes
DDR_ATO	Test	Test	Reserved for DLL test purposes

1. For LPDDR2/3: DDR_A[9:0] are used as CA[9:0] and DDR_A[15:10] are not used.
2. DDR_VREF1: command lane reference, DDR_VREF2: byte lane 3 and 1 common reference, DDR_VREF3: byte lane 2 and 0 common reference.

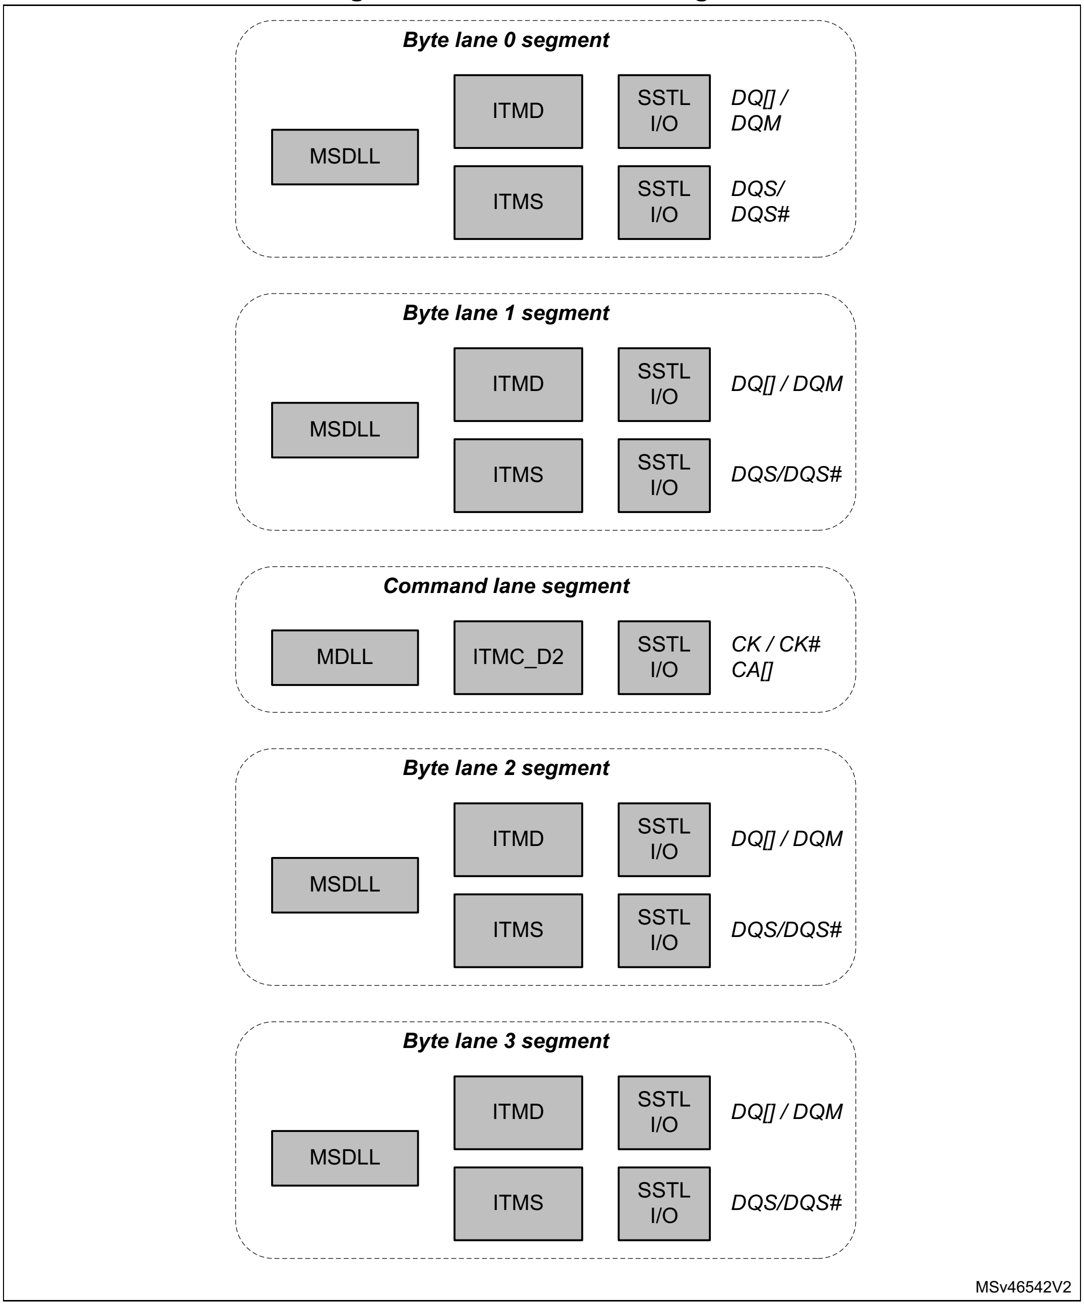
7.4 DDRPHY (DDR multiPHY IP core)

7.4.1 DDRPHY overview

The DDRPHY diagram is shown in *Figure 13*. It is implemented with a structured layout into 4-byte lanes and one address/command lane with:

- MDLL and MSDLLs to provide accurate timings with 90 deg phase shifts
- ITM: Interface timing modules, with the following types:
  - ITMD for DQ/DM signals,
  - ITMS for DQS/DQS# signals,
  - ITMC_D2 for address/command and CK/CK# signals.
- SSTL I/O’s.

Figure 13. DDRPHY block diagram



7.4.2 Delay locked loop (DLL)

The DLLs are shown in *Figure 14*

The Master DLL (MDLL) uses the input (clk_in) to generate four clock outputs, each delayed in quarter clock cycle (90°) increments. These four clock phases (clk_0, clk_90, clk_180, clk_270) are generated with very high accuracy and low jitter across a wide range of frequencies.

The Mast-Slave DLL (MSDLL) is composed of a MDLL and a slave delay pair.

The slave delay pair uses a timing reference from MDLL to provide a highly accurate 90º delay to the DQS/DQS# inputs and generate dqs_90 and dqsb_90 respectively.

DLL key features:

- Master/Slave DLL architecture for complex timing while reducing total power consumption with:
  - Master DLL for SDRAM command / address interface and general host timing.
  - Master-Slave DLL for SDRAM data lanes (DQ/DQS) for write and read data capture.
- Operating range from 100 MHz to 533 MHz.
- Optional: DLL bypass mode for LPDDR suitable for 10 MHz to 200 MHz and for low speed functional and IDDQ tests.
- Multi-phase outputs: 0deg, 90deg, 180deg 270deg.
- Extensive DLL control for fine-tuning system timings.
- Analog and digital DLL test outputs for device characterization.

Figure 14. MDLL block diagram

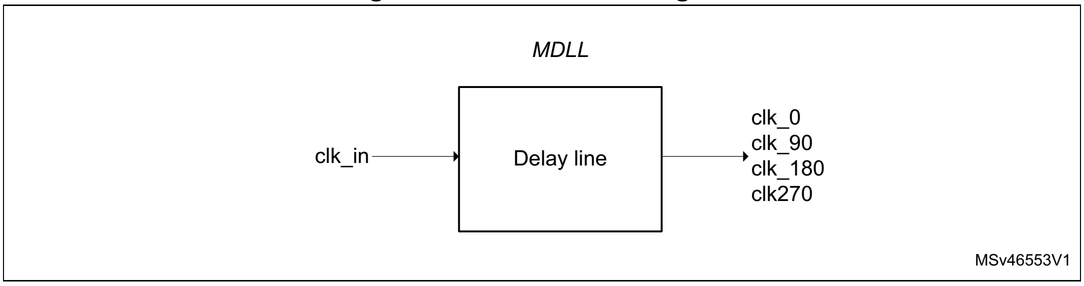


Figure 15. MSDLL block diagram

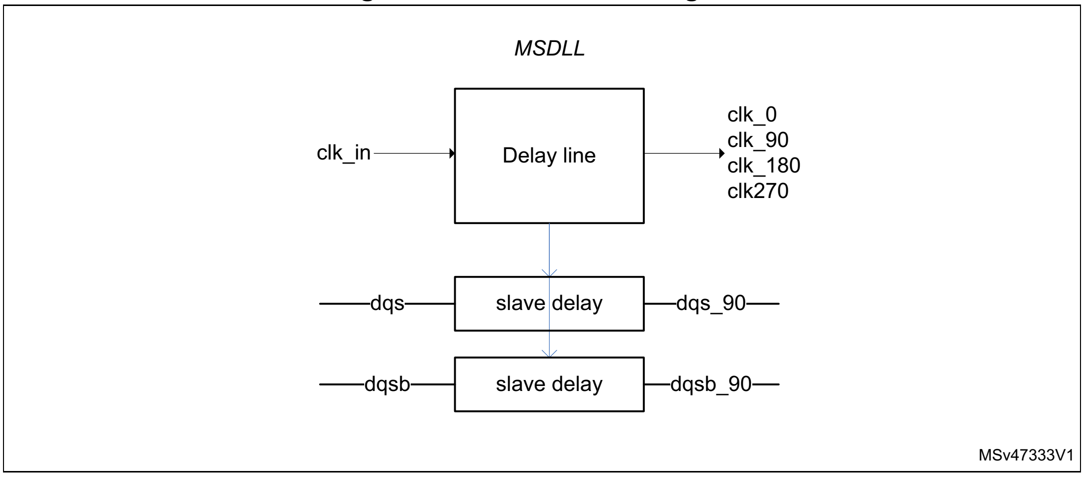

The DLL settings are controlled by a control bus dllctrl[51:0] described in *Table 23: MSDLL control bits*.

Table 23. MSDLL control bits

Control bus	Signal name	MSDLL PUBL register	MDLL PUBL register	Default	Description
dllctrl[51]	lltm	DXnDLLCR[19]	N/A	0b0	Locked loopback test mode select: 0: normal, 1: Loopback
dllctrl[50]	test_hizb_a	DXnDLLCR[18]	ACDLLCR[18]	0b0	Analog test output tri-state control 0: hiZ, 1: analog low Z

dllctrl[18:16]	bias_trm[6:4]	DLLGCR[18:16]	DLLGCR[18:16]	0b011	Master bias generator control voltage trim: VC
{dllctrl[19],dllctrl[15]}	fdtrm[1:0]	DLLGCR[19],DLLGCR[15]	DLLGCR[19],DLLGCR[15]	0b00	Master bypass fixed delay trim (-10%, 0, +10%, +20%)
dllctrl[14:12]	bias_trm[2:0]	DLLGCR[14:12]	DLLGCR[14:12]	0b111	Master bias generator frequency trim: Fmax
dllctrl[11]	test_ctrl_switch	DLLGCR[11]	N/A	0b0	Test control: Switch for analog and digital. 0: master, 1: slave
dllctrl[10:9]	test_ctrl_a[1:0]	DLLGCR[10:9]	DLLGCR[10:9]	0b00	Test control: selects the analog signal at ana test
dllctrl[8:6]	test_ctrl_d[2:0]	DLLGCR[8:6]	DLLGCR[8:6]	0b000	Test control: selects the digital signal at dig test
dllctrl[5]	test_ctrl_en	DLLGCR[5]	DLLGCR[5]	0b0	Test control enable for analog and digital test
dllctrl[4:2]	ipump_trm[2:0]	DLLGCR[4:2]	DLLGCR[4:2]	0b000	Charge pump current trim (0: max current)

7.4.3 Interface timing modules (ITMs)

The ITMs are used to generate signals with precise timing:

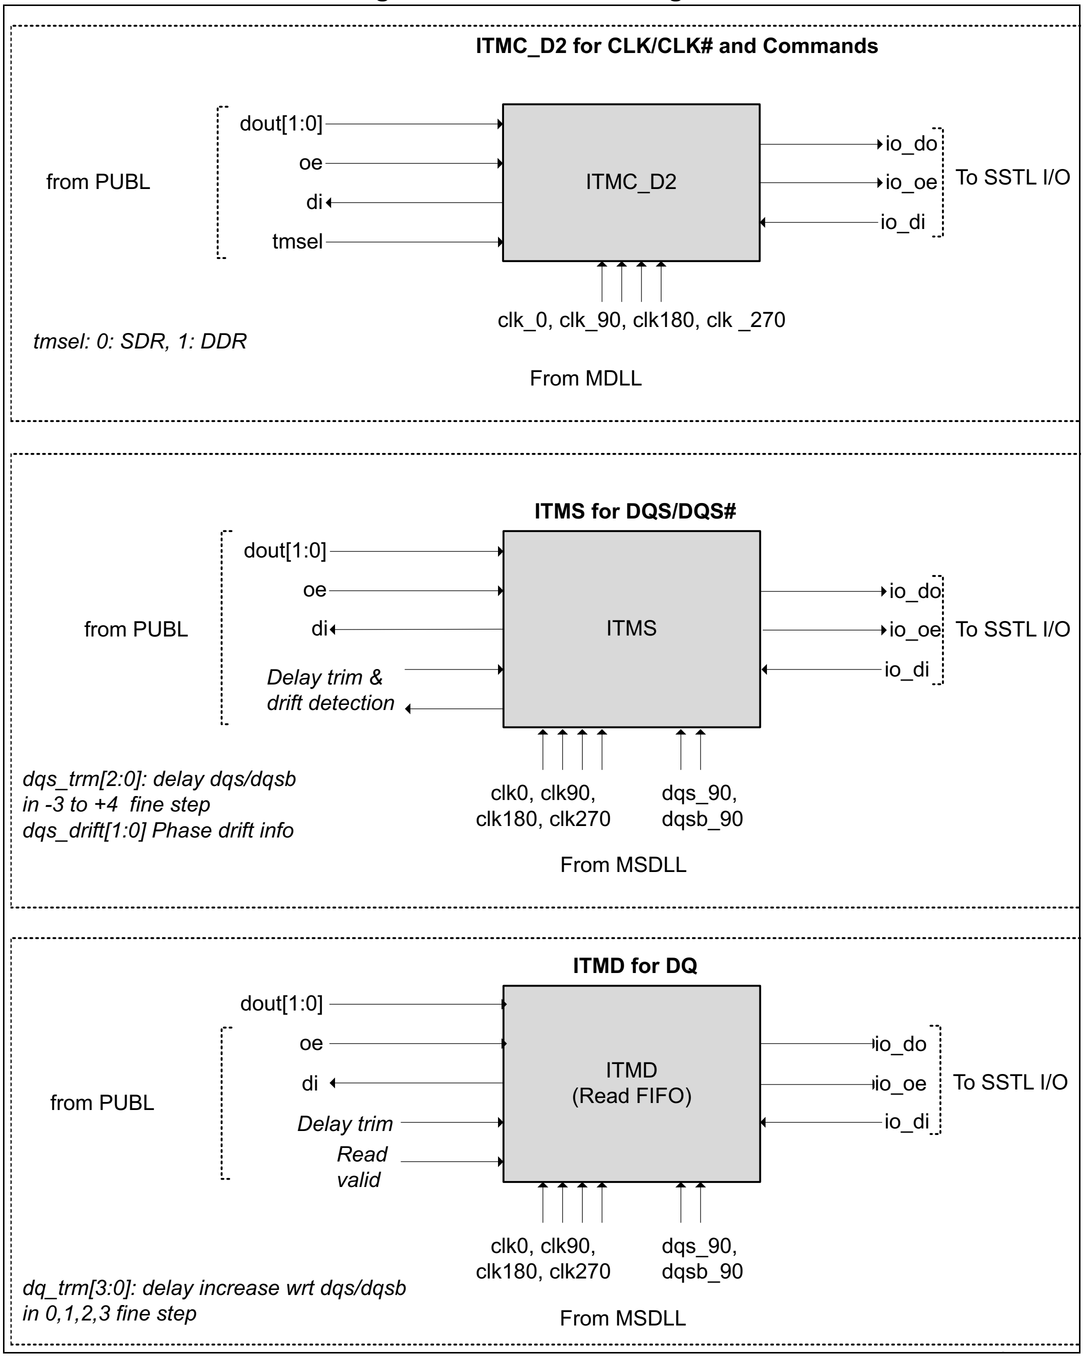
- 90deg phase delay of CK/CK# for the command / address bus
- 90deg phase delay of DQS/DQS# for write DQ/DQM byte lane outputs
- Sampling of read DQ inputs on a 90 deg phase delay of incoming DQS/DQS#

There are three types of ITM:

- ITMC_D2 for clock, address and command lanes.
- ITMS for DQS/ DQS# differential strobes.
- ITMD for DQ, DQM bytre lanes.

The ITMs are shown in *Figure 16*.

Figure 16. ITMs block diagram



The ITMC-D2 does the SDR to DDR signaling conversion for LPDDR2/3 (tmsel =1).

The ITMC_D2 connections to set timings according to SDRAM type are shown in *Figure 17* and *Figure 18*.

Figure 17. ITMC_D2 for LPDDR2/3

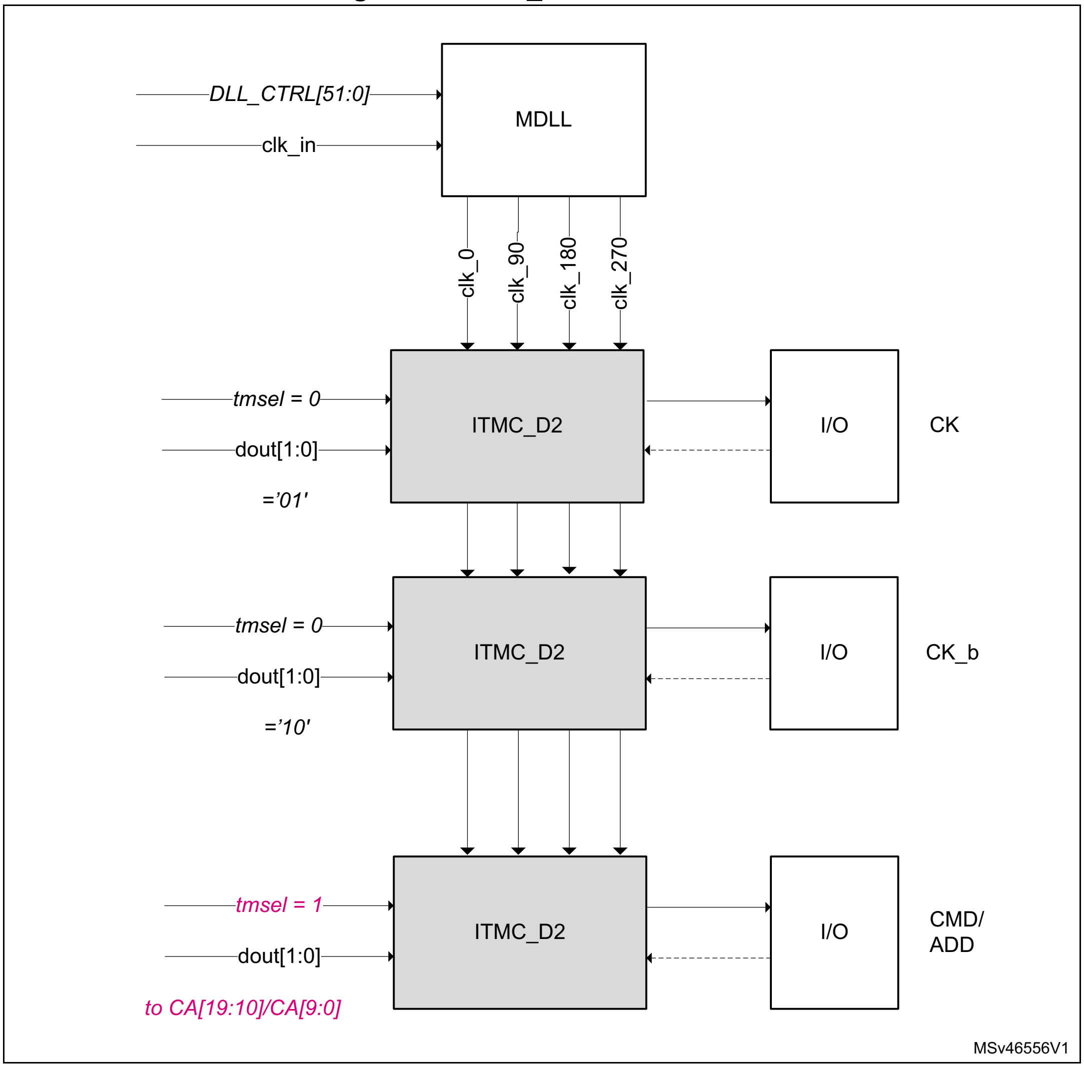


Figure 18. ITMC_D2 for DDR3/3L

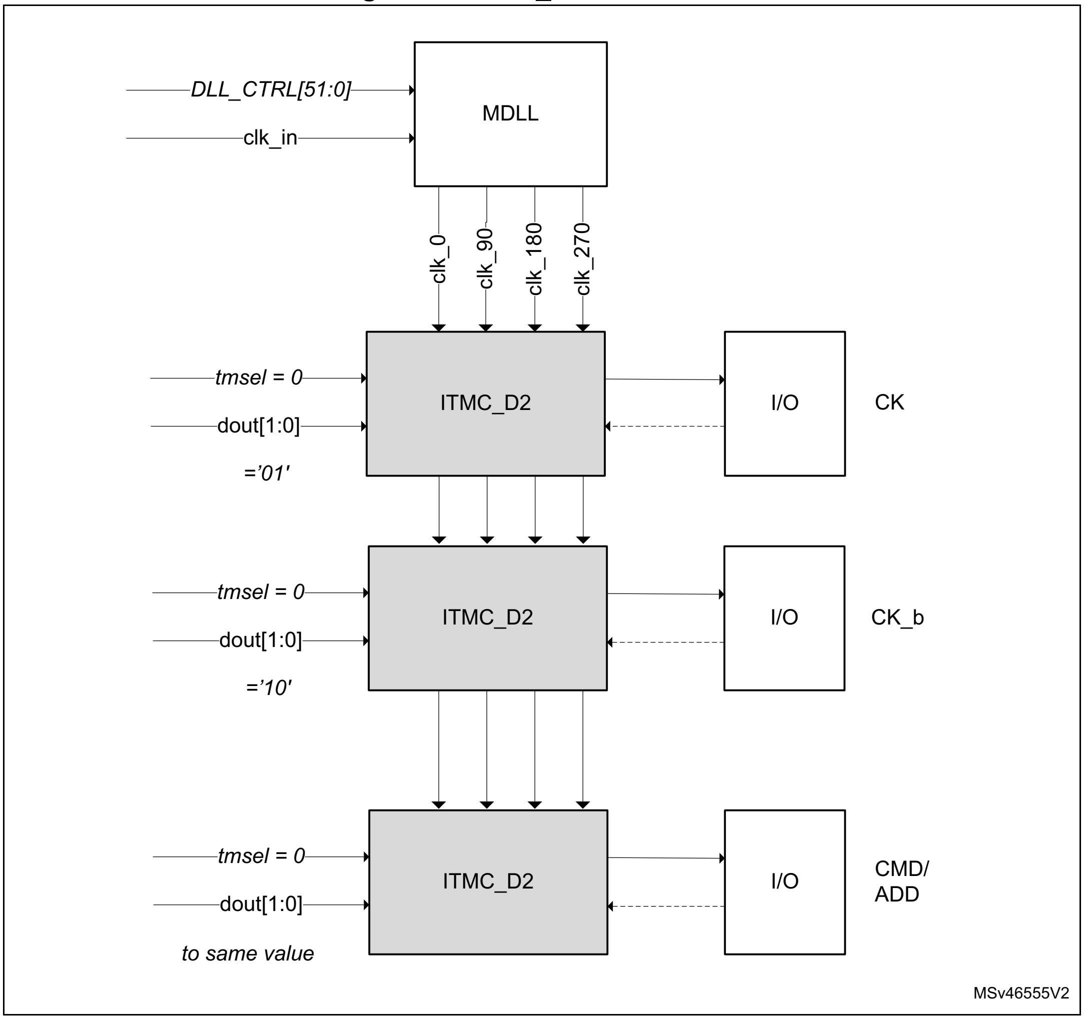


The ITMS are used for DQ strobes (DQS/DQS#) with:

- SDR to DDR signaling conversion in output direction.
- Phase select positioning
- Fine step delay
- Drift monitoring support

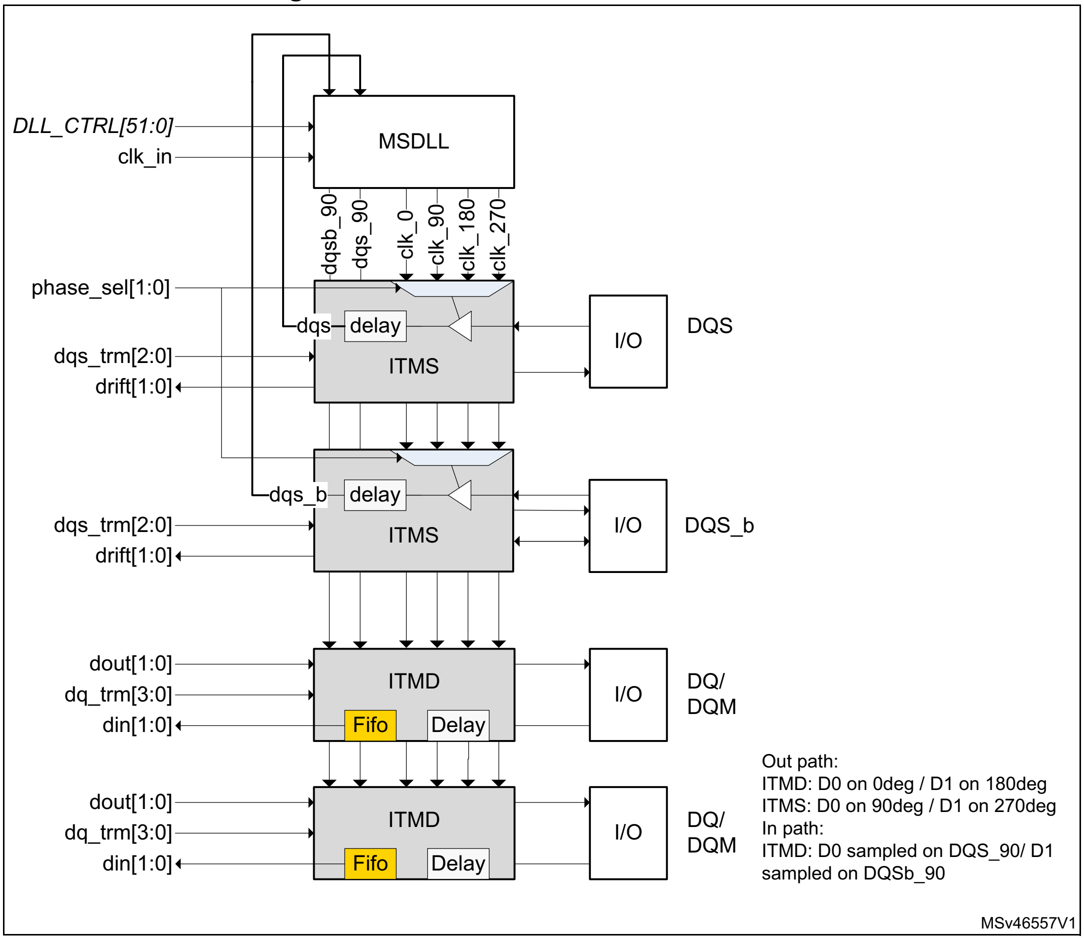
ITMS connections and timings are shown in *Figure 19*.

ITMD are used for data lanes (DQ[] and DQM) with:

- SDR to DDR signaling conversion in input and output directions.
- Sampling of incoming dq input on DQS and DQS# 90deg phases into a read FIFO
- Fine step sampling delay.

ITMD connections and timings are shown in *Figure 19*.

Figure 19. ITMS and ITMD for DQ/DQS lanes



7.4.4 SSTL IO's

SSTL IO key features:

- DDR3/DDR3L/LVCMOS operating modes
- Compatible with JEDEC standard for DDR3/DDR3L SDRAMs
- Programmable termination for DDR3/3L (ODT)
- Programmable output impedance
- PVT-compensated ODT and output impedance
- Driver and receiver power-down control
- Embedded boundary scan support logic
- PAD and internal loopback modes
- Core and I/O power down options supported
- Retention feature maintains I/O cell state during VDD power down

ZQ calibration cell:

The ZQ calibration cell provides independent calibration capability for the pull-up and pull-down ODT termination and for output impedances of the SSTL I/Os.

There are four sense blocks that provide independent sense capability for each impedance element:

– Pull-up termination impedance.

– Pull-down termination impedance.

– Pull-up output impedance.

– Pull-down output impedance.

These four elements are calibrated in series using the calibration select input ZCAL[1:0]. The calibration sequence is:

1. Output impedance pull-down.
2. Output impedance pull-up.
3. On-Die termination (ODT) pull-down.
4. ODT pull-up.

7.5 PUBL

The PUBL is intended to ease the control of the PHY features. It supports the PHY initialization, DQS gate training and programmable configuration control.

PUBL supports:

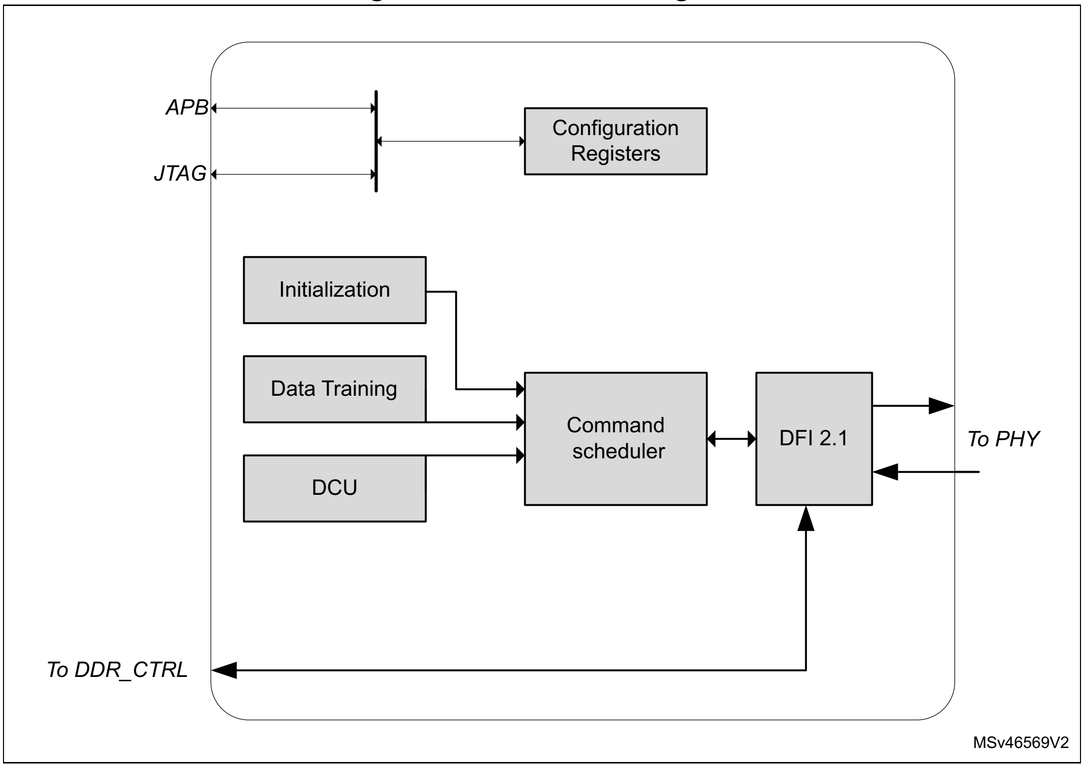
1. DDRPHY and SDRAM initialization sequences for all types of memories: DDR3/3L, LPDDR2 and LPDDR3.
2. A built-in DQS gate training (DQSTRN) to assist in programming the read DQS gate timing.
3. A DRAM Command Unit (DCU) to assist in programming the DRAM for timing calibration purposes.

The PUBL supports a DFI 2.1 interface with the DDRCTRL.

The PUBL includes configuration registers accessible via an APB interface. It also provides a JTAG interface access for test purposes.

A simplified block diagram of PUBL is shown in *Figure 20*.

Figure 20. PUBL block diagram



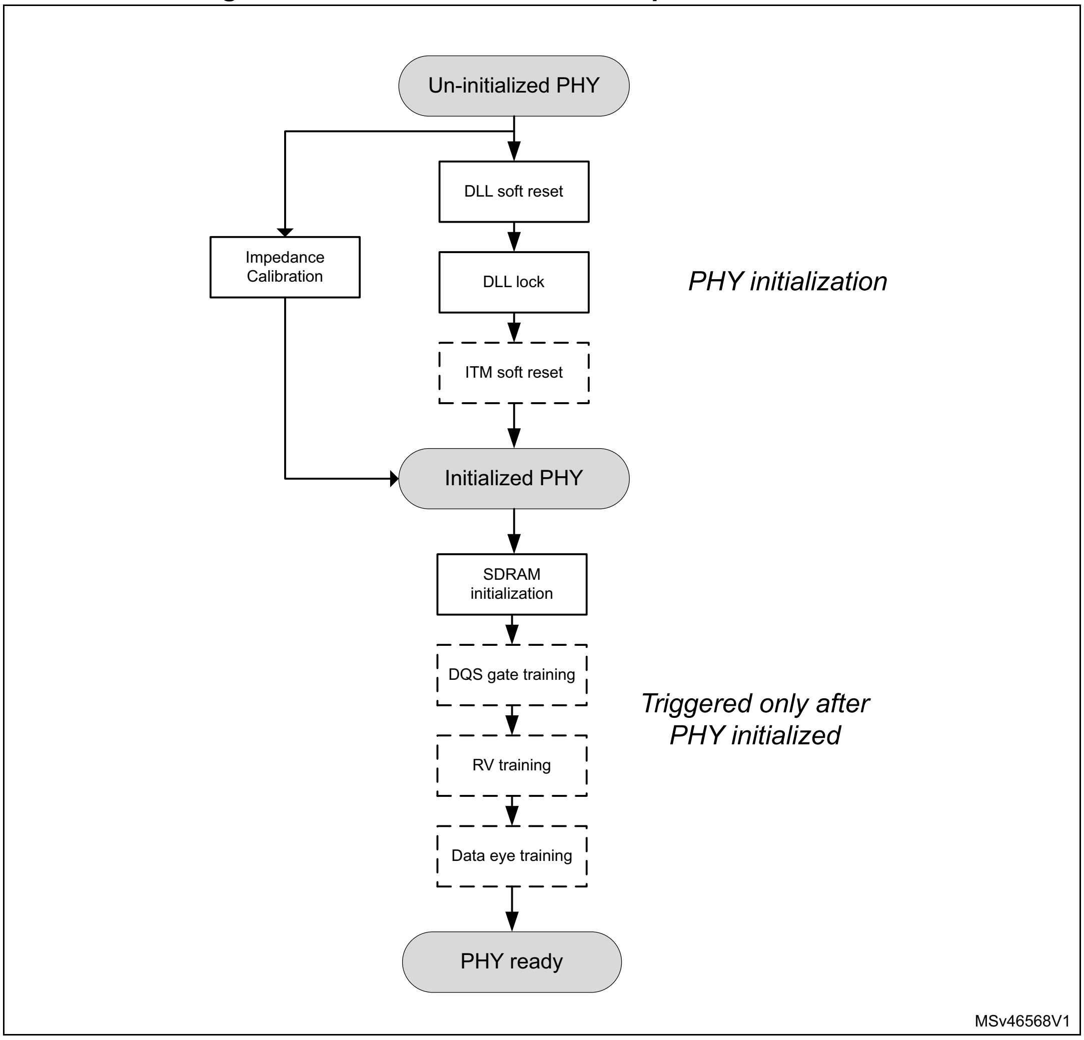
The following is a brief overview of the different design blocks and functionality of the PUBL:

- **Configuration registers**: includes all registers required to configure, control, train and self-test the PHY. The configuration block also contains registers required to initialize the DRAM.
- **Initialization**: used to automatically initialize the PHY, including locking of the DLL and calibration of I/O impedances. The initialization block also implements built-in initialization of all supported DRAMs.
- **Data training:** used to train the PHY for optimum timing margins. This includes finding the best positioning of the DQS gating window during reads, read valid generation and optimizing the read data eye.
- **DRAM command unit (DCU)**: allows the issuing of DRAM commands through the configuration port.
  This may be used to implement software DRAM initialization. It is also used for silicon debug and characterization of the PHY and the DDR interface.
- **Command scheduler**: multiplexes commands from internal PUBL blocks and the external memory controller and generates correct DRAM transactions in DFI 2.1 format. The commands from the external controller are passed to the DFI 2.1 block unmodified.
- **DFI 2.1 interface**: implements a DFI 2.1-compliant interface between the controller DDRCTRL and the PHY.

7.5.1 PHY and SDRAM initialization

Figure 21. shows a high-level diagram of the PHY initialization sequence.

Figure 21. DDRPHY initialization sequence



The initialization sequence has two phases. The first phase (shown in solid lines in *Figure 21*) happens automatically at reset and is used as follows:

1. Before and during configuration reset, the PHY is un-initialized and remains in this state until the reset is de-asserted.
2. At reset de-assertion, the PHY moves into the DLL initialization phase.
   This phase may be bypassed at any time by writing a '1' to bit LOCKBYP of the DDR PHY initialization register (DDRPHYC_PIR).
3. In parallel to DLL initialization, the impedance calibration phase also starts at reset de-assertion.
   This phase can also be bypassed by writing a '1' to the ZCALBYP bit of DDR PHY initialization register (DDRPHYC_PIR).
4. If the PHY initialization sequence was triggered by the user, a soft reset may optionally be selected to be issued to the ITMs.
   Initialization that is automatically triggered on reset does not issue a soft reset to the ITMs because the components have been already reset by the main reset.
5. Once the DLL initialization and impedance calibration phases are done and after the ITMs are reset, the PHY is initialized.

If these phases were bypassed, it is up to the user to perform them in software or trigger them at a later time before the PHY can be used.

The second phase of initialization starts after the PHY is initialized. Each step of this phase is triggered by the user (APB interface) or by DDR_CTRL:

1. The user or memory controller performs SDRAM initialization sequence (see “SDRAM Initialization”). The DRAM mode registers and necessary timing parameters must first be programmed into the PUBL **before** triggering SDRAM initialization.
2. After the SDRAM is initialized, the user or memory controller performs, or triggers the PUBL to perform, DQS gate training (see “Built-in DQS Gate Training” in *Section 7.5.6: DQS gate training (DQSTRN)*). The SDRAM must be initialized before triggering DQS gate training.
3. The user or memory controller performs, or triggers the PUBL to perform, read data valid training. PHY Initialization may be either Reset_triggered or PIR-triggered
4. The user or memory controller performs, or triggers the PUBL to perform, read data eye training.
   Note: the current version of the PUBL does not have the read eye training designed in.
5. The PHY is now ready for SDRAM read/write accesses.

The PUBL has a built-in SDRAM initialization routine that may be triggered by software or DDR_CTRL by writing to the PHY initialization register (DDRPHYC_PIR).

The initialization routine built into the PUBL is generic and does not require any knowledge of the type or configuration of external SDRAMs to be properly executed. The routine is designed with the relevant JEDEC specifications for the fastest and slowest SDRAMs supported by the PUBL to result in a universal initialization sequence. This generic sequence is applicable to DDR3 and LPDDR2 and DDR SDRAMs.

It is recommended to use the built-in PUBL routine to initialize the SDRAM. However, there may be cases such as during system debug when the built-in PUBL DRAM initialization is not triggered and DRAM initialization is performed by software or by the controller.

In these cases the system must first wait for the PHY to initialize, i.e. DLL locked and impedance calibration done, then it must write a '1' to the INIT bit of DDRPHYC_PIR with bit CTLDINIT of DDRPHYC_PIR set to '1' (for controller initialization) or '0' (for software or PUBL initialization) to inform the PUBL that DRAM initialization is done later, by software, the controller or by re-triggering on the PUBL.
The software or controller then executes the initialization sequence by sending relevant commands to the DRAM, respecting the various timing requirements of the initialization sequence.

The necessary configurations of the SDRAM must first be programmed into the PUBL before triggering SDRAM initialization.

SDRAM initialization must be triggered only after the PHY has been initialized.

All SDRAM initialization timing parameters described below are programmable in controller clock cycles in PTR1 and PTR2 registers.

The following sections describe the built in SDRAM initialization routines for different types of SDRAMs.

7.5.2 DDR3 initialization sequence

The initialization steps for DDR3 SDRAMs are as follows:

1. Optionally maintain RESET# low for a minimum of either 200 us (power-up initialization) or 100ns (power-on initialization).
   The PUBL drives RESET# low from the beginning of reset assertion and therefore this step may be skipped if enough time may already have expired to satisfy the RESET# low time.
2. After RESET# is de-asserted, wait a minimum of 500 us with CKE low.
3. Apply NOP and drive CKE high.
4. Wait a minimum of tXPR
   Caution: PUBL registers, SDRAM mode registers, and equivalent register fields inside the memory controller must be uniformly programmed. Mismatches between the register fields can cause transaction failures. Verify all register fields are consistently programmed before starting any SDRAM transaction.
5. Issue a load mode register 2 (MR2) command.
6. Issue a load mode register 3 (MR3) command.
7. Issue a load mode register (MR1) command (to set parameters and enable DLL).
8. Issue a load mode register (MR0) command to set parameters and reset DLL.
9. Issue ZQ calibration command.
10. Wait 512 SDRAM clock cycles for the DLL to lock (tDLLK) and ZQ calibration (tZQinit) to finish.
    This wait time is relative to Step 8, i.e. relative to when the DLL reset command was issued onto the SDRAM command bus.

7.5.3 LPDDR2 initialization sequence

The initialization steps for LPDDR2 SDRAMs are as follows:

1. Wait a minimum of 100 ns (tINIT1) with CKE driven low.
2. Apply NOP and set CKE high.
3. Wait a minimum of 200 us (tINIT3).
4. Issue a RESET command.
5. Wait a minimum of 1 us + 10 us (tINIT4 + tINIT5).
6. Issue a ZQ calibration command.
7. Wait a minimum of 1 us (tZQINIT).
8. Issue a Write mode register to MR1.
9. Issue a Write mode register to MR2
10. Issue a Write mode register to MR3

7.5.4 Initialization trigger and bypass

All initialization steps shown in *Figure 21* can be triggered using the PHY initialization register (DDRPHYC_PIR).
Writing a '1' to bit INIT of DDRPHYC_PIR register bit starts initialization, with the routines to be run selected by the DDRPHYC_PIR register bits. If multiple routines are selected, they are run in the order shown in *Figure 21*.

The completion of the routines is indicated in the PHY General Status Register (DDRPHYC_PGSR) with the corresponding done status bits.
The DDRPHYC_PGSR.IDONE bit indicates the overall completion of the initialization

sequence.
A status register bit is cleared (reset to '0') when the corresponding routine is re-triggered.

The de-assertion of reset automatically triggers the PUBL to perform **DLL initialization** with DLL locking and impedance calibration. Once the DLL has locked and impedance calibration has completed, the SDRAM initialization and DQS gating may be triggered or performed by software or memory controller.

Since the PUBL allows the selection of individual routines to be run when initialization is triggered using DDRPHYC_PIR register, the routines that automatically trigger on reset de-assertion have individual bypass capability.
This means that DLL locking and/or impedance calibration may be bypassed any time by writing a '1' to the corresponding bypass register bit in the DDRPHYC_PIR register. Once a routine is bypassed, it is internally registered as completed and the corresponding done status register bit is set in the PGSR register.

It is up to the user to re-trigger or perform the bypassed routines at a later time, before the PHY can be used.

Bit INITBYP of DDRPHYC_PIR register provides the option to bypass the whole initialization sequence

7.5.5 DATA training

After the DDRPHY and the external SDRAM have been successfully initialized, DDRPHY may be trained for optimum operating timing margins.
This includes:

- Training for DQS gating during reads (DQSTRN)
- Training for optimal Read Valid placement (RVTRN)

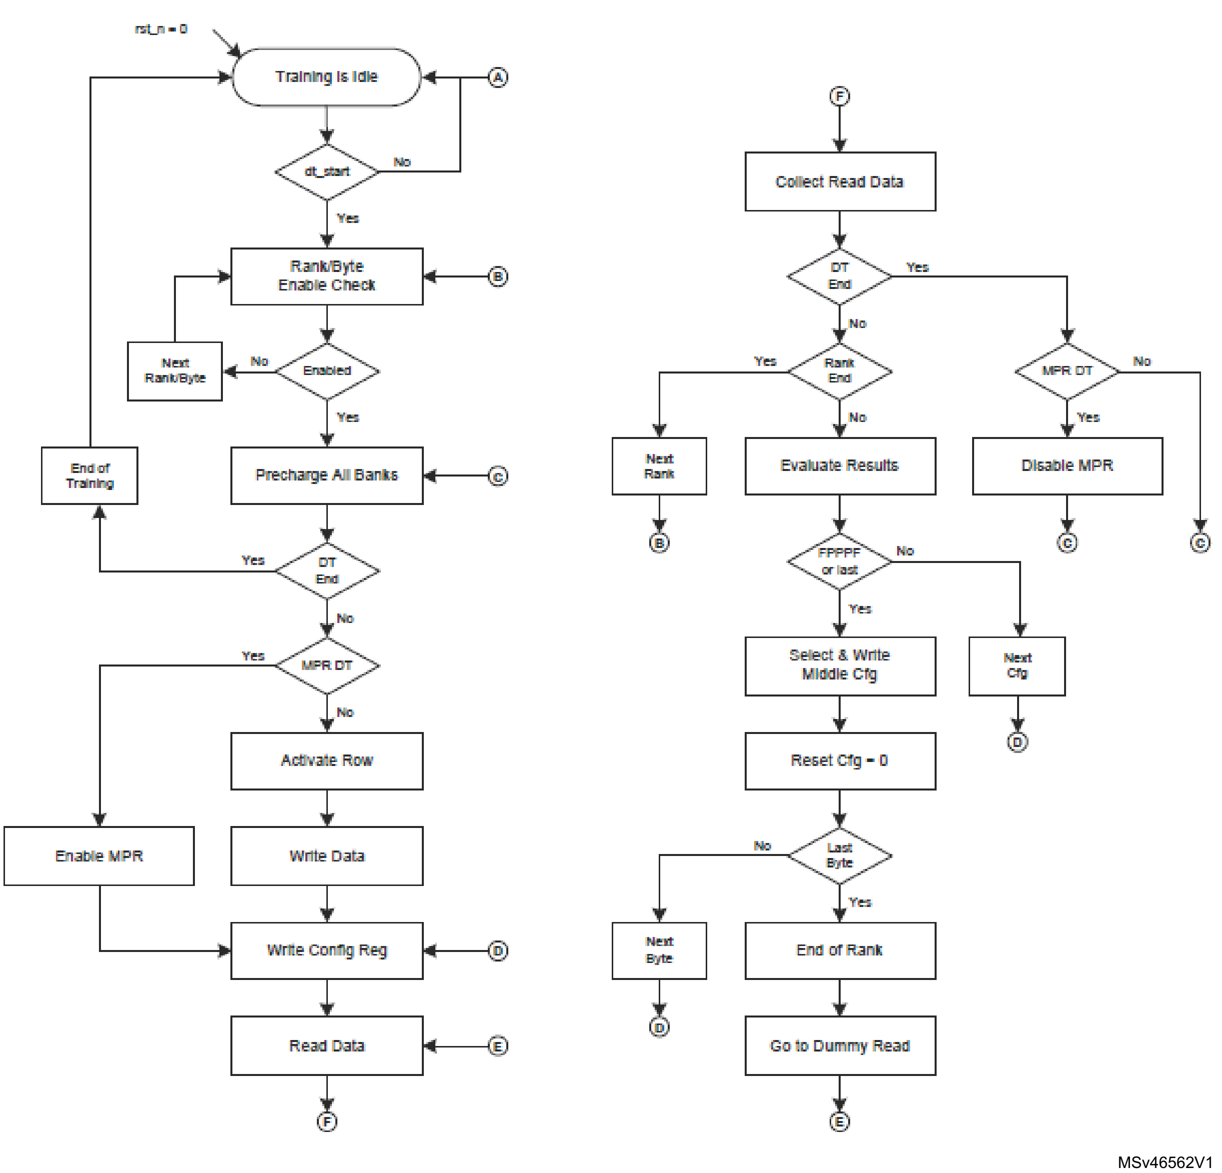
7.5.6 DQS gate training (DQSTRN)

Built-in DQS gate training:

Note: The built-in DQSTRN is mandatory and applicable only to DDR3/3L and may be using the MPR register.

The PUBL has a built-in DQS gate training routine that may be triggered by software or memory controller using the DDRPHYC_PIR register. *Figure 22* shows the detailed flow of the DQS gate training algorithm implemented in the PUB. This is followed by a description of the main phases of the training.

Figure 22. Buit-in DQS gate training flow



DQS gate training phases are as follows:

1. Data Train Idle: before and during reset, the data training state machine is in the idle state and remains in this state until the reset is de-asserted. The next configuration register values to be used for DQS gating are also reset to zero. These are the values that are written to DQS Gating System Latency (R0DGSL) and DQS Gating Phase Select (R0DGPS) fields of the DDRPHYC_DXnDQSTR register before each iteration of DQS gate training. Once reset is de-asserted, the FSM continues to remain in the idle state until data training is triggered. The FSM also remains in the idle state if data training is triggered with no ranks or bytes enabled. Otherwise the FSM goes to check if the next rank or byte is enabled.
2. Rank/byte enable check: this phase checks if the next rank/byte to be trained is enabled, otherwise it skips the rank/byte and goes to the next rank/byte. Bytes are

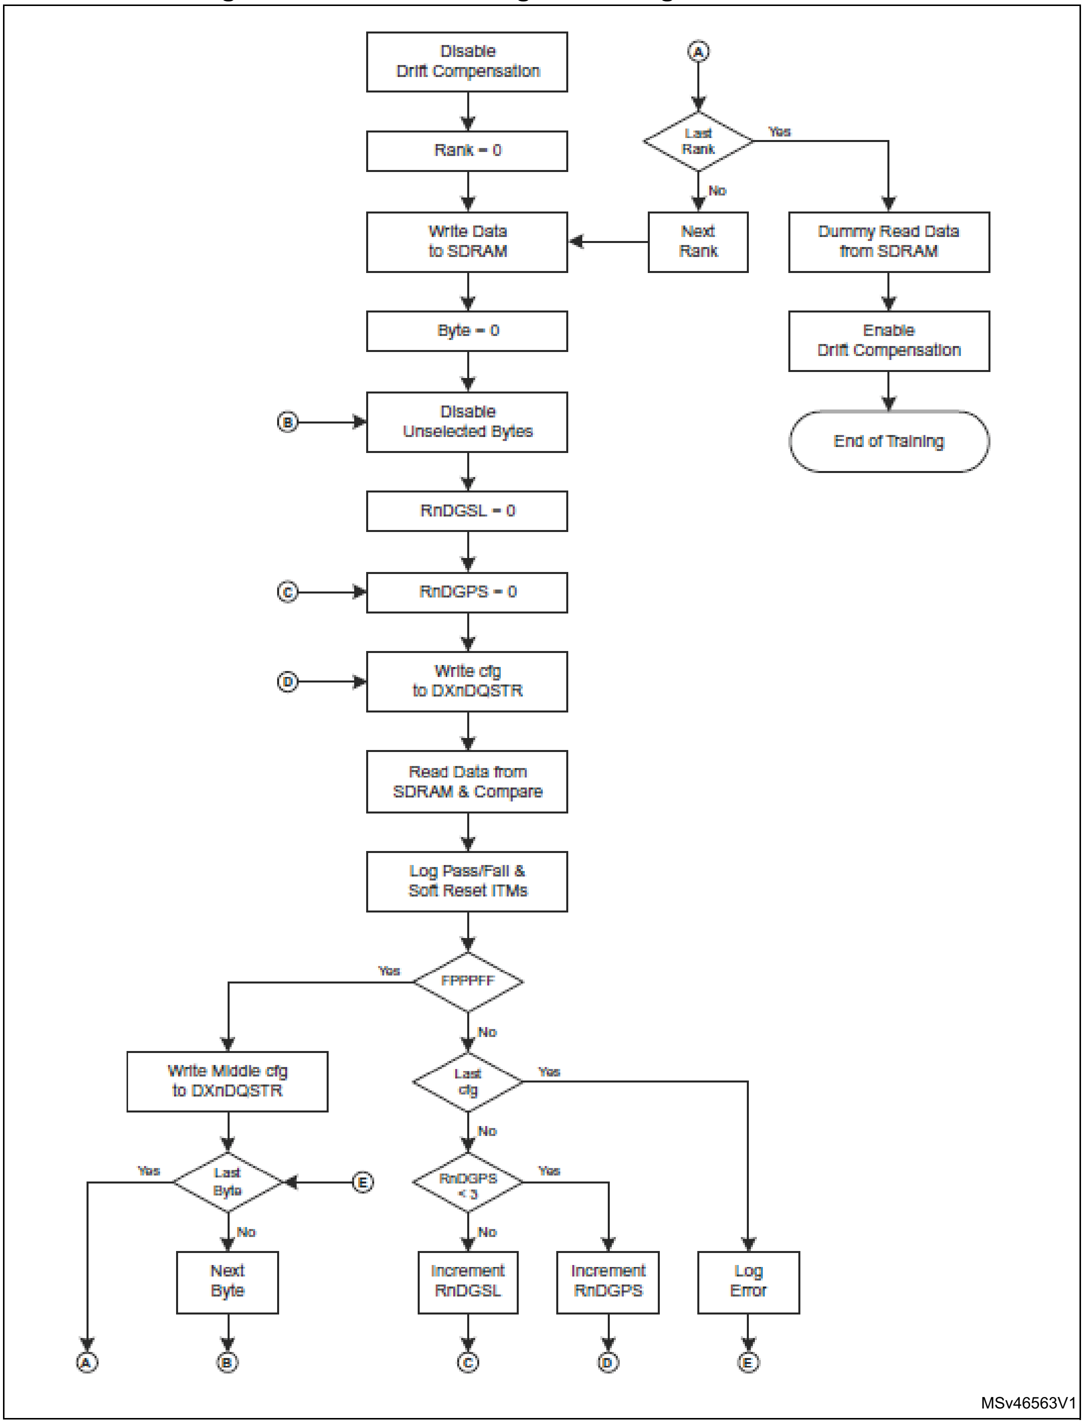
enabled/disabled using bit DXEN in DDRPHYC_DXnGCR register, and ranks are enabled/disabled using field RANKEN in DDRPHYC_DXnGCR register.

3. Precharge all banks: all banks are precharged before the beginning of training for each rank and at the end of the whole training. If the precharge is at the end of the training, the FSM goes to idle state, indicating the end of training. Otherwise it goes to prepare the DRAM for accesses, i.e. enable the MPR register if data training using MPR is selected, or activate the DRAM row to be used for write/read accesses.
4. Enable MPR: issues a load mode register command to the DRAM to enable the MPR register. This is only applicable for DDR3 DRAMs and only if the MPR bit is set in the DTAR register.
5. Activate: issues an activate command to the DRAM to open the bank row prior to writing data for training. The DRAM address used for training is user programmable in the DTAR register.
6. Write data: issues an 8-beat write to the DRAM to load data for training. The DRAM address and DRAM data used for training is user programmable in the DTAR, DTDTR0, DTDTR1 registers.
7. Write configuration register: once the data has been written to the DRAM (or MPR register has been enabled), the FSM writes the next configuration setting for the byte to the respective DQS gating register fields (DDRPHYC_R0DGSL and DDRPHYC_R0DGPS).
8. Read/collect data: this phase is executed either as a dummy read at the end of rank training or end of whole training (to reset the drift status registers in the PHY ITMs to the correct values), or it is executed as a normal read to evaluate if the DQS gate configuration is valid. After a dummy read, the FSM goes on to train the next rank or if it is the end of the whole training it goes to issue the last precharge or disable the MPR. After a read has been issued to the DRAM the FSM waits for all read data to come back. There is a time-out in case the read data does not come back. For a non-dummy read, the FSM goes on to evaluate the read data for pass/fail status.
9. Evaluate result: the read data is compared to the expected data and pass/fail status is generated and saved. If the status is such that a fail-pass-fail region (FPPPPF) has been found or if this is the last possible configuration (i.e. no passing region for this byte) the midpoint of the passing region is selected and written to (DDRPHYC_DXnDQSTR region. This signifies the end of training for the byte on the selected rank. If this is the last byte of the rank, the FSM goes on to train the next rank, otherwise it goes to the next byte of the rank. There is always a dummy read performed at the end of training all bytes of the rank.

Software DQS gate training

The DQS gate training may also be executed in software using DDRCTRL and/or the PUB DCU. *Figure 23* shows the DQS gate training software algorithm. This is followed by a description of the main phases of the training.

Figure 23. Software DQS gate training flow



The software DQS gate training phases are as follows:

1. Disable drift compensation by writing '0' to bit DFTCMP in DDRPHYC_DXnGCR register.
2. Start with rank 0, (DDRPHYC is supporting single rank only).
3. Execute a minimum of two writes to the SDRAM. Any type of data and any SDRAM address can be used for DQS gate training. It is however not recommended to use data

that is all zeroes since this may mask read data comparison. The data mask must be set to 0 to enable writing of all bytes. The number of writes must be chosen such that it results in a minimum of eight data beats at the SDRAM. This means at least two write commands when using SDRAM burst length of 4.

4. Start with byte 0 (i.e. byte 0 is selected for training).
5. Disable all the other bytes except the byte that has been selected for training. The bytes are enabled/disabled by writing 1/0 to bit DXEN in DDRPHYC_DXnGCR register. To avoid having to add programming and delay for a DLL re-lock when later re-enabling a disabled byte Lane, it is recommended to also set bit PDDISDX=0 in DDRPHYC_DXnGCR register before disabling any byte lanes. This prevents the byte Lane's DLL from going into bypass mode when a byte Lane is disabled with bit DXEN=0 in DDRPHYC_DXnGCR register.
6. Start with the selected byte DQS gating system latency (RnDGSL=0 in DXnDQSTR register).
7. Start with the selected byte DQS gating phase select (RnDGPS=0 in DXnDQSTR register).
8. Write the selected DQS gating configurations (bit R0DGSL and R0DGPS in register DXnDQSTR of the selected byte).
9. Execute reads from the SDRAM locations previously written. The number of reads must be equal to the number of writes used in Step 3. Compare the read data with the expected (written) data and log the pass/fail status as a sequence or history of flags for each trained RnDGSL/RnDGPS configuration (e.g. FFPPPPFF). A fail is either when there is a data mis-compare or when fewer data than expected is returned.

Note: A controller that is designed to always wait for the correct number of read data may need a time-out in case the trained configuration results in fewer data than expected. This is not as issue when using the PUB DCU because it does not wait for the expected number of reads; rather the read count status indicates if fewer reads were returned.

10. Once the read data has been compared and the pass/fail status logged, issue an ITM soft reset to clear the status of the read data logic in the PHY. This is important because the ITM read data FIFO pointers may be in the wrong state at the end of training an RnDGSL/RnDGPS configuration that resulted in wrong DQS gating window.
11. If two consecutive fails and some passes exist, then this is the end of the training for this rank byte. In this case, do the following:
    - Select the middle of the passes and write the values to the corresponding fields of DDRPHYC_DXnDQSTR register.

      - If this is not the last byte, then select the next byte and go to Step 5.

      - If this is the last byte but not the last rank, then select the next rank and go to Step 3.

      - If this is the last byte and the last rank, then go to Step 12 to do final clean-up before the end of the DQS gate training.
    - If the condition of two consecutive fails and some passes does not exist, then this signals that more RnDGSL/RnDGPS configurations need to be trained for this rank byte. If this is the case, do the following:

      - if R0DGPS is less than 3, then increment R0DGPS and go to Step 8

      - if R0DGPS is equal to 3 but R0DGSL is less than 7, then increment R0DGSL and go to Step 7

      - if R0DGPS is equal to 3 and R0DGSL is equal to 7, then log an error because this is a signal that something in the system is very wrong such that no passing configuration is possible for this rank byte. With such an error condition, you can either terminate the whole training to investigate the system or you can go to train the next byte.

12. Once the training of all ranks and all bytes is finished, issue one or more dummy reads to the same SDRAM locations. This flushes out the DQS drift compensation logic in the PHY and therefore avoid reporting any false drift events caused by previous DQS gating settings.
13. Once the dummy reads have completed, re-enable drift compensation by writing 1 to bit DFTCMP in DXnDQSTR register. This is the end of DQS gate training. Regular memory operations can now commence.

For details of how the PUBL DCU can be used to SDRAM accesses, please refer to *Section 7.5: PUBL*.

Note: It is not necessary to issue auto-refresh commands to the SDRAM during software DQS gate training if there is no data in the SDRAM other than the DQS gate training data. This is because the same locations are being read over and over within a relatively short period of time that should normally be less than the refresh timing requirement. However, if there is other data in the SDRAM and the training is taking longer than the required refresh timing, then refresh commands must be issued at the required intervals, interspersed relevantly with the training commands.

Read DQS gate training with low frequency LPDDR

When using LPDDR SDRAM, the built-in read DQS gate training is accurate for standard clock frequencies.

However, as the LPDDR tAC timing parameter becomes a smaller percentage of the clock period, fewer read DQS gate settings work. The read DQS gating works at low frequencies with LPDDR SDRAM, but this section provides additional guidance on how to correctly set up read DQS gating at low frequencies with LPDDR SDRAM

For all values of tAC >= (0.25*tCK), normal training can be used. When using slower speeds where tAC is less than 1 tCK, the number of data training passes may be less than ideal (as low as two) but the gate position is still satisfactory, even when aligned with rising edge of DQS. This is because there is enough margin before starting to see data fails (90 degrees of margin and at low speed is very large number).

The following lists the number of passing configurations for each of these settings and the gate position:

tAC ≥ 1.0*tCK

– Five passes, gate opening is positioned correctly 90degrees before rising edge of DQS

tAC ≥ 0.75*tCK < 1.0*tCK

– Four passes, gate opening is positioned correctly either aligned with rising edge of DQS or 90 degrees before rising edge of DQS

tAC ≥ 0.5*tCK < 0.75*tCK

– Three passes, gate opening is positioned correctly aligned with rising edge of DQS

tAC ≥ 0.25*tCK < 0.5*tCK

– Two passes, gate opening is positioned correctly aligned with rising edge of DQS

*Note: The exception to this guidance is when tAC < 0.25*tCK. In this case, no training should be performed and passive windowing should be used. Also, ensure the bits DGSL and DGPS are set to zero (DGPS is 1 by default.)*

7.5.7 Read valid training (RVTRN)

The PUBL has a built-in read valid training routine (RVTRN) that may be triggered by software or the memory controller using the DDRPHYC_PIR register.

For DDR3 RVTRN is not required

For LPDDR2/3 RVTRN is normally run at the same time as DQSTRN; it is adjusting the read valid system latency in extreme conditions with tDQSCK timings values.

7.6 PUBL timings and DFI interface

Note: This section is intended to show signals timing at the DDRPHYC interfaces and the relation between the signals at DFI and the SDRAM interface, with information about physical delays which are programmed into DDRCTRL.

7.6.1 Introduction

This section describes the timing for the interface between the controller and the PHY.

The read/write timing waveforms include four groups of signals:

1. DFI signals (dfi_*)
2. PHY clocks (ctl_clk, clk_0,clk_90, clk_180, and clk_270)
3. Controller-to-PHY interface signals (ctl_cmd, ctl_ds_oe, ctl_d_oe, ctl_d,ctl_qs_en, ctl_qs_dis, and ctl_qs_phase)
4. SDRAM signals (ck/ck_n, cmd, dqs/dqs_n, and dq).

only the important signals whose the timing needs to be controlled are shown, that are dfi_* and SDRAM signals (DDR_*).

The PHY clock group is not shown and ctl_clk is identical to dfi_clk.

From the controller-to-PHY interface signal group, only the ctl_qs_en signal is shown with the PHY passive DQS gating timing.

The read/write waveforms are given for typical PHY configurations and SDRAM latencies; the waveforms are shown for DDR3 mode.

The waveforms are mostly the same for active and the passive DQS gating, only the passive DQS gating timing is shown with the ctl_qs_en signal.

The timing waveforms shown are for write latency (WL) of 5 and read latency (RL) of 5. The timing of any latency, RWL, can be derived from these representative latencies by simply shifting the timing of (ctl_ds_oe, ctl_d_oe, ctl_d, ctl_qs_en, ctl_qs_dis, and ctl_qs_phase) relative to ctl_cmd by RWL controller clocks.

For DDR3, write latency (WL) is equal to CAS write latency (CWL) plus additive latency (AL), and read latency (RL) is equal to CAS latency (CL) plus additive latency (AL).

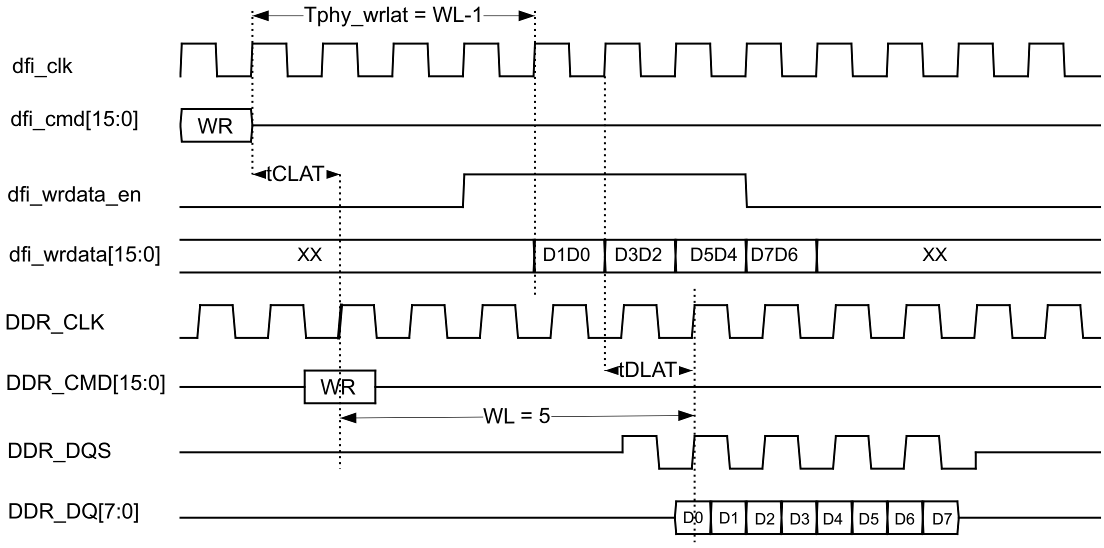
7.6.2 Write timing

Figure 24 shows the write timing for DDR3 mode with WL = 5 and BL = 8
Note that dfi_clk and ctl-clk are the same clocks, only dfi_clk is shown. The only variable in the DFI timing is the tphy_wrlat, which is the spacing between DFI write command and DFI write data enable (dfi_wrdata_en) signal.

As shown in *Table 25*, this spacing is equal to WL-1. The DFI controller always drives the write data (dfi_wrdata) one clock after it has driven the write data enable signal.
The timing of DFI write data mask (dfI_wrdata_mask) is the same as the timing of DFI write data (dfi_wrdata) and is therefore not shown in the figure. The DFI write command (dfi_cmd) is simply buffered to, and is therefore aligned with, the PHY controller command (ctl_cmd).

Figure 24 also shows the two PHY latency parameters for the command and data from the controller to the SDRAM. The command latency (tCLAT) is measured from the rising edge of the controller clock (ctl_clk) when the command is available to the PHY to the rising edge of SDRAM clock (DDR_CLK) when the command is output. Similarly, write data latency (tDLAT) is measured from the controller clock rising edge when data is available from the controller to the rising edge of data strobe (DDR_DQS) on which SDRAM data is available.

Figure 24. Write timing with WL = 5, BL = 8



Write timing: WL = 5, BL = 8

MSv46567V1

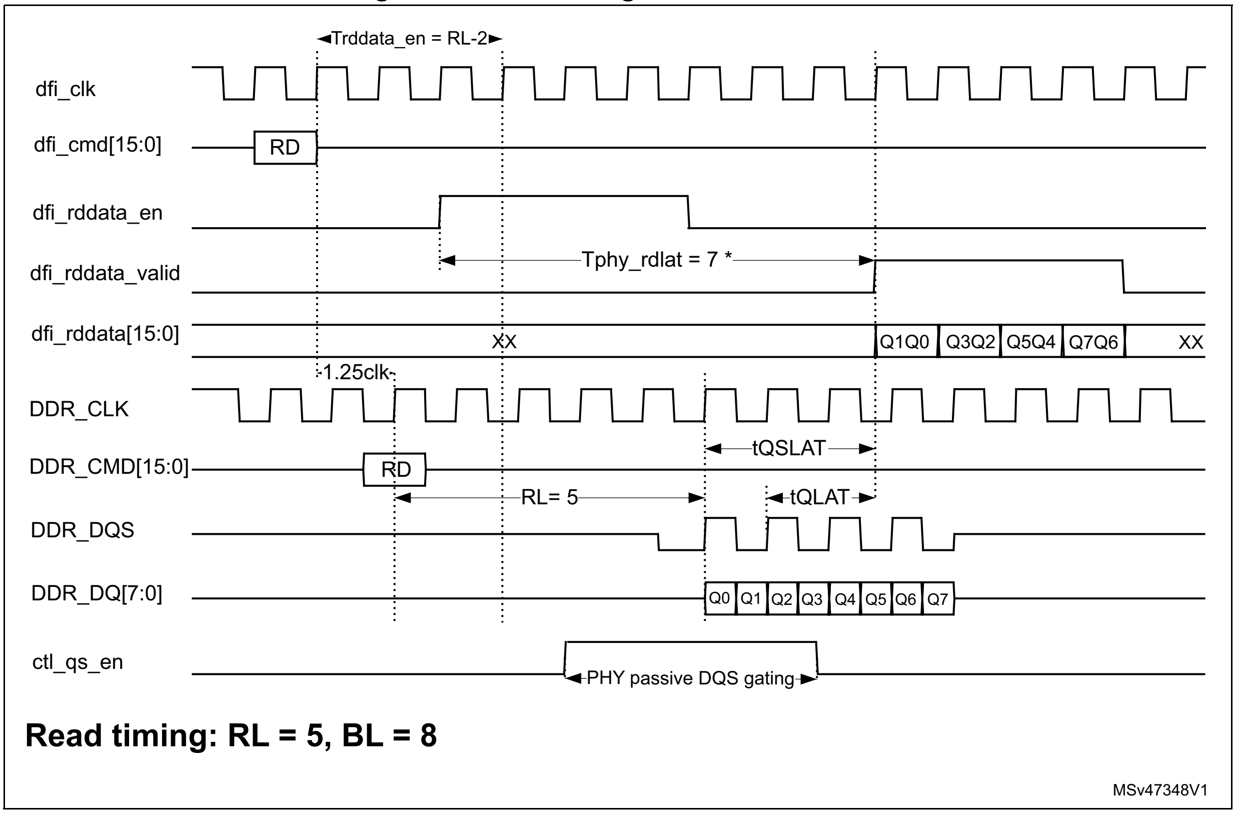
7.6.3 Read timing

Figure 25 shows the read timing for the DDR3 mode with WL = 5 and BL = 8.

Note that dfi_clk and ctl-clk are the same clocks, only dfi_clk is shown.
The only variable in the DFI timing is the trddata_en, which is the spacing between DFI read command and DFI read data enable (dfi_rddata_en) signal. As shown in *Figure 25*, this spacing is equal to RL-2.
The DFI read command (dfi_cmd) is simply buffered to, and is therefore aligned with, the PHY controller command (ctl_cmd).

The timing shown in *Figure 25* includes the timing of the read through the PHY read FIFO back to the controller. It also shows the two PHY latency parameters for the data from the SDRAM to the controller.
The data strobe latency (tQSLAT) is measured from the rising edge of the data strobe (DDR_DQS) that is coincident with the first data beat to the rising edge of the controller clock (ctl_clk same as dfi_clk) when data is sampled by the controller.
The read data latency (tQLAT) is measured from the rising edge of the data strobe (DDR_DQS) after two data beats are available to the rising edge of the controller clock (ctl_clk same as dfi_clk) when data is sampled by the controller.
The values of these parameters are described in *Table 24*. and *Table 25*.
Note that the read latencies have a variation of up to one controller clock cycle depending on the alignment of the read data strobe and the controller clock. This is because of the clock domain crossing between the read data strobe and the controller clock, which are assumed to be completely asynchronous to each other.

Figure 25. Read timing with WL = 5, BL = 8



7.6.4 DDRPHY read/write latency

Table 24: PHY latency shows the latency of commands and data through the PHY.

Refer to *Write timing on page 367* and *Read timing on page 368* for definitions and illustration of these parameters.

Table 24. PHY latency

SYMBOL	Description	Latency	Units	Note
t_{CLAT}	Command Latency	1.25	tCLK	-
t_{DLAT}	Write data Latency	1.25	tCLK	-
t_{QLAT}	Read data Latency	1-2	tCLK	1
t_{QSLAT}	Read data strobe Latency	2-3	tCLK	1

Note: The PHY Latency depends on the alignment of the read data strobe to the controller clock.

The PHY read latency parameter tphy_rdlat, i.e. the number of DFI clock cycles from the assertion of dfi_rddata_en signal to the assertion of dfi_rddata_valid is defined as:

tphy_rdlat = 3 + tQSLAT + 1 + x + y

With the no-bubbles feature enabled, the latency is:

tphy_rdlat = 3 + tQSLAT + 1 + x + y + 2

With the fixed-latency feature enabled, the latency is:

tphy_rdlat = 12

Where:

x = propagation delay of the command from the PHY macro outputs to the SDRAM

y = propagation delay of the read data from the SDRAM to the PHY macro inputs

gdqs_rsl = set of DQS gating system latency values for all ranks and all byte-lanes

The term (+3) and the term (+1) of the above equations are internal DFI logic latencies. The terms x and y include, among other things, the routing between the PHY and the I/Os, the I/O propagation delays, package delays, board delays, and other delays associated with the SDRAM that are not accounted for in the SDRAM read latency (RL) parameter.

The total read latency from the DFI read command to the DFI read data valid is

trddata_en + tphy_rdlat.

where trddata_en is described in *Table 25*.

7.6.5 DFI 2.1 overview

The DFI is an interface protocol that defines the connectivity between a DDR memory controller (DDRCTRL) and a DDR physical interface (DDRPHY) for DDR memory devices (here: DDR3 and LPDDR2).

The protocol defines the signals, signal relationships, and timing parameters required to transfer control information and data to and from the DRAM devices over the DFI.

The DDRPHYC is supporting protocol version 2.1:

Interface signal groups

DFI is subdivided into the following interface groups:

- Control interface
- Write data interface
- Read data interface
- Update interface
- Status interface
- Training interface
- Low power control interface

DFI timing parameters

The DFI defines several timing parameters with fixed values and specified as a number of DFI clock cycles. *Table 25* describes the DFI parameters applicable to DDRPHYC.

The DFI timings parameters are relevant for DDRCTL which needs to programmed accordingly.

Table 25. DFI timing parameters

Name	Description	SDR mode	Note
t_{ctrl_delay}	Specifies the number of DFI clock cycles after an assertion or deassertion of the DFI control signals that the control signals at the PHY-DRAM interface reflect the assertion or de-assertion. If the DFI clock and the memory clock are not phase-aligned, this timing parameter should be rounded up to the next integer value.	2	(1)
t_{phy_wrdata}	Specifies the number of DFI clock cycles between when the dfi_wrdata_en signal is asserted to when the associated write data is driven on the dfi_wrdata signal.	1	-
t_{phy_wrlat}	Specifies the number of DFI clocks between when a write command is sent on the DFI control interface and when the dfi_wrdata_en signal is asserted Note: In LPDDR2 mode, the following settings must be used: WL = MR2[3:0].WL + 1 (to account for tDQSS)	WL-1	(2)(3)(4)
t_{rddata_en}	Specifies the time from the assertion of a read command on the DFI to the assertion of the dfi_rddata_en signal. Note: In LPDDR2 mode, the following settings must be used: RL = MR2[3:0].RL + tDQSCK	RL-2	(2)(3)
t_{phy_rdlat}	Specifies the maximum number of cycles allowed from the assertion of the dfi_rddata_en signal to the assertion of the dfi_rddata_valid signal.	15	(5)
$t_{dram\_ck\_disable}$	Specifies the number of clocks from the assertion of the dfi_dram_clk_disable signal on the DFI until the clock to the DRAM memory devices, at the PHY-DRAM boundary, maintains a low value	2	-
$t_{dram\_ck\_enable}$	Specifies the number of clocks from the de-assertion of the dfi_dram_clk_disable signal on the DFI until the first valid rising edge of the clock to the DRAM devices at the PHYDRAM boundary.	2	-
t_{phyupd_type0}	Specifies the maximum number of DFI clocks that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type = 0.	1	(6)
t_{phyupd_resp}	Specifies the maximum number of DFI clock cycles after the assertion of the dfi_phyupd_req signal to the assertion of the dfi_phyupd_ack signal.	64	
$t_{phy\_paritylat}$	Specifies the maximum number of DFI clock cycles between when the dfi_parity_in signal is driven and when the associated dfi_parity_error is returned.	PL+6	(7)

1. Actual latencies are 1.25 but rounded up to the next integer as per DFI specification.
2. For LPDDR2 device usage the WL is the SDRAM write latency (CAS write latency + additive latency + 1) to ensure that the LPDDR2 tDQSS is accounted for. For all other DDR device usage the WL is the SDRAM write latency (CAS write latency + additive latency). If an external controller wants to run the PHY in loopback mode, i.e. if LBMODE is set, then tphy_wrlat must be set to WL-2.
3. In LPDDR2 mode, WL = MR2.WL + 1 and RL = MR2.RL + tDQSCK.
4. RL is the SDRAM read latency (CAS latency + additive latency).
5. The number includes the latency through the PHY (i.e. command latency plus read latency), plus maximum possible system latency that could be trained by the PUB.
6. This corresponds to the maximum time required for updating ITMs.
7. PL is the DIMM parity latency. it is N/A with current configuration.

7.7 PUBL registers

7.7.1 DDRPHYC revision ID register (DDRPHYC_RIDR)

Address offset: 0x000

Reset value: 0x0020 0200

Bits 7:4 **PUBMDR[3:0]**: PUB moderate rev

Bits 3:0 **PUBMNR[3:0]**: PUB minor rev

7.7.2 DDRPHYC PHY initialization register (DDRPHYC_PIR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INITBYP	ZCALBYP	LOCKBYP	CLRSR	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTLDINIT	DLLBYP	ICPC
w	w	w	w										w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	RVTRN	QSTRN	DRAMINIT	DRAMRST	ITMSRST	ZCAL	DLLLOCK	DLLSRST	INIT
							w	w	w	w	w	w	w	w	w

Bit 31 **INITBYP**: Initialization bypass
Bypasses or stops, if set, all initialization routines currently running, including PHY initialization, DRAM initialization, and PHY training.
Initialization may be triggered manually using INIT and the other relevant bits of the DDRPHYC_PIR register. This bit is self-clearing.

Bit 30 **ZCALBYP**: zcal bypass
Bypasses or stops, if set, impedance calibration of all ZQ control blocks that automatically triggers after reset.
Impedance calibration may be triggered manually using INIT and ZCAL bits of the DDRPHYC_PIR register. This bit is self-clearing.

Bit 29 **LOCKBYP**: DLL lock bypass
Bypasses or stops, if set, the waiting of DLLs to lock. DLL lock wait is automatically triggers after reset.
DLL lock wait may be triggered manually using INIT and DLLLOCK bits of the DDRPHYC_PIR register. This bit is self-clearing.

Bit 28 **CLRSR**: clear status register
Writing 1 to this bits does the following:
- Auto-clears itself. This means a following read to bit CLRSR returns 0
- Clears the DXnGSR0 bits for DTDONE, DTERR, DTIERR
- Clears bit DFTERR in DDRPHYC_PGSR register and bit DFTERR in DDRPHYC_DXnGSR1 register

This bit is primarily for debug purposes and is typically **not** needed during normal functional operation.
It can be used when bit IDONE=1 in PGSR register, to manually clear the PGSR status bits, however, the PGSR status bits (except for the DFTRR and TQ bits) are automatically cleared by starting a new init process.
The bit can also be used to manually clear the DXnGSR status bits, however, starting a new data training process automatically clears the DXnGSR status bits.

Bits 27:19 Reserved, must be kept at reset value.

Bit 18 **CTLDINIT**: Controller DRAM initialization
Indicates if set that DRAM initialization is performed by the controller. Otherwise if not set it indicates that DRAM initialization is performed using the built-in initialization sequence or using software through the configuration port.

Bit 17 **DLLBYP**: DLL bypass
A setting of 1 on this bit puts all PHY DLLs in bypass mode. A bypassed DLL is also powered down (disabled).

Bit 16 **ICPC**: Initialization complete pin configuration
Specifies how the DFI 2.1 initialization complete output pin should be used to indicate the status of initialization.
0: Asserted after PHY initialization (DLL locking and impedance calibration) is complete.
1: Asserted after PHY initialization is complete and the triggered PUBL initialization (DRAM initialization, data training, or initialization trigger with no selected initialization) is complete.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **RVTRN**:

it is expected that RVTRN and DQSTRN are run with LPDDR2/3; RVTRN is not required for DDR3

If RVTRN=1 and bit QSTRN=0, when bit INIT=1 (triggering the init process) the read DQS gate training algorithm still runs (as if bit QSTRN in DDRPHYC_PIR register was actually set to 1).

If it is necessary to run only RV training stand-alone, with no read DQS gate training, you can prevent the read DQS gate training from running by setting bit LBGDQS=1 in DDRPHYC_PGCR register.

Note: RV training cannot use multi-purpose register (MPR) and must use the user data programmed in DTDR0-1.

Bit 7 **QSTRN**: Read DQS training

Executes a PUBL training routine to determine the optimum position of the read data DQS strobe for maximum system timing margins.

Note: Read DQS training cannot use multi-purpose register (MPR) and must use the user data programmed in DTDR0-1.

Bit 6 **DRAMINIT**: DRAM initialization

Executes the DRAM initialization sequence

Bit 5 **DRAMRST**: DRAM reset (DDR3 only)

Issues a reset to the DRAM (by driving the DRAM reset pin low) and wait 200us.

This can be triggered in isolation or with the full DRAM initialization (DRAMINIT). For the latter case, the reset is issued and 200us is waited before starting the full initialization sequence.

Bit 4 **ITMSRST**: ITM reset

Soft resets the interface timing modules for the data and data strobes, i.e., it asserts the ITM soft reset (srstb) signal.

Bit 3 **ZCAL**: Impedance calibration (Driver and ODT)

Performs PHY impedance calibration.

Bit 2 **DLLLOCK**: DLL lock

Waits for the PHY DLLs to lock.

Bit 1 **DLLSRST**: DLL soft reset

Soft resets all PHY DLLs by driving the DLL soft reset pin.

Note: - Requires that ctl_clk be toggling for the DLL soft reset signal to be output from the DLL. If ctl_clk (AC DLL's cclk_0) is not guaranteed to be toggling, it is recommended to use the manual DLL soft reset bit DLLSRST of DDRPHYC_ACDLLCR, and not bit DLLSRST of DDRPHYC_PIR.

- Ensure that the minimum requirements for DLL bypass and DLL reset are observed while asserting this bit.

Bit 0 **INIT**: Initialization trigger

A write of '1' to this bit triggers the DDR system initialization, including PHY initialization, DRAM initialization, and PHY training.

The exact initialization steps to be executes are specified in bits **1 to 6** of this register. A bit setting of 1 means the step is executed as part of the initialization sequence, while a setting of ‘0’ means the step is bypassed.

The initialization trigger bit is self-clearing.

7.7.3 DDRPHYC PHY global control register (DDRPHYC_PGCR)

Address offset: 0x008

Reset value: 0x0184 2E04

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LBMODE	LBGDQS	LBDQSS	RFSHDT[3:0]				PDDISDX	ZKSEL[1:0]		RANKEN[3:0]				IODDRM[1:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LBMODE**: Loop back mode

Indicates if set that the PHY/PUB is in loopback mode

Bit 30 **LBGDQS**: Loop back DQS gating

Selects the DQS gating mode that should be used when the PHY is in loopback mode. Valid values are:

0: DQS gate training is triggered on the PUB

1: DQS gate is set manually using software

Bit 29 **LBDQSS**: Loop back DQS shift

Selects how the read DQS is shifted during loopback to ensure that the read DQS is centered into the read data eye. Valid values are:

0: PUB sets the read DQS delay to 0; DQS is already shifted 90 degrees by write path

1: The read DQS shift is set manually through software.

Bits 28:25 **RFSHDT[3:0]**: Refresh during training

A non-zero value specifies that a burst of refreshes equal to the number specified in this field should be sent to the SDRAM after training each rank except the last rank.

Bit 24 **PDDISDX**: Power down disabled byte

Indicates if set that the DLL and I/Os of a disabled byte should be powered down.

Bits 23:22 **ZKSEL[1:0]**: Impedance clock divider selection

Selects the divide ratio for the clock used by the impedance control logic. The source clock for

the divider is the configuration port clock signal (pclk), depending on which configuration port type used (see “Impedance Calibration” on page tbc).

Valid values are:

00: Divide by 2

01: Divide by 8

10: Divide by 32

11: Divide by 64

Bits 21:18 **RANKEN[3:0]**: Rank enable

Specifies the ranks that are enabled for data-training.

only Bit 0 is used and controls rank 0.

Setting the bit to ‘1’ enables the rank, and setting it to ‘0’ disables the rank.

Bits 17:16 **IODDRM[1:0]**: I/O DDR mode

Selects the DDR mode for the I/Os.

Bit 15 **IOLB**: I/O loop back select

Selects where inside the I/O the loop-back of signals happens. Not applicable to D3A I/Os. Valid values are:

0: Loopback is after output buffer; output enable must be asserted

1: Loopback is before output buffer; output enable is don't care

Bit 14 **CKINV**: CK invert

Specifies if set that CK/CK# should be inverted. Otherwise CK/CK# toggles with normal polarity.

Bits 13:12 **CKDV[1:0]**: CK disable value

Specifies the static value that should be driven on CK/CK# pair(s) when the pair(s) is disabled. CKDV[0] specifies the value for CK and CKDV[1] specifies the value for CK#.

Bits 11:9 **CKEN[2:0]**: CK enable

Controls whether the CK going to the SDRAM is enabled (toggling) or

disabled (static value defined by CKDV). One bit for each of the three CK pairs.

Bits 8:5 **DTOSEL[3:0]**: Digital test output select

Digital Test Output Select: Selects the PHY digital test output that should be driven onto PHY digital test output (DDR_DTO0) pin: Valid values are:

0000: DATX8 0 DLL digital test output

0001: DATX8 1 DLL digital test output

0010: DATX8 2 DLL digital test output

0011: DATX8 3 DLL digital test output

0100: DATX8 4 DLL digital test output

0101: DATX8 5 DLL digital test output

0110: DATX8 6 DLL digital test output

0111: DATX8 7 DLL digital test output

1000: DATX8 8 DLL digital test output

1001: AC DLL digital test output

Other: Reserved

Bits 4:3 **DFTLMT[1:0]**: DQS drift limit

Specifies the expected limit of drift on read data strobes. A drift of this value or greater is reported as a drift error through the host port error flag. Valid values are:

00: No limit (no error reported)

01: 90° drift

10: 180° drift

11: 270° or more drift

Note: Although reported through the error flag, this is not an error requiring any action. It is simply an indicator that the drift is greater than expected.

Bit 2 **DFTCMP**: DQS drift compensation

Enables or disables DQS drift compensation. Valid values are:
0: Disables data strobe drift compensation
1: Enables data strobe drift compensation
By default, drift compensation is enabled.

Note: Drift compensation is not supported under any of the following situations:
- LPDDR2/3 (bit DDRMD set to LPDDR2 in DDRPHYC_DCR register)
- Burst length 2 (bit BL in DDRPHYC_MR0 register set to burst length of 2)
- Read DQS gating using passive windowing (bit DQSCFG in DDRPHYC_PGCR register set to passive windowing)
Drift compensation must be set to disabled if any of the above are set.

Bit 1 **DQSCFG**: DQS gating configuration

Selects one of the two DQS gating schemes:
0: DQS gating is shut off using the rising edge of DQS_b (active windowing mode)
1: DQS gating blankets the whole burst (passive windowing mode).

Note: Passive windowing must be used for LPDDR2/3.

Bit 0 **ITMDMD**: ITM DDR mode

Selects whether ITMS uses DQS and DQS# or it only uses DQS.
Valid values are:
0: ITMS uses DQS and DQS#
1: ITMS uses DQS only

Note: The correct setting is always DQS and DQS#.

7.7.4 DDRPHYC PHY global status register (DDRPHYC_PGSR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						r	r	r	r	r	r	r	r	r	r

Bit 31 **TQ**: Temperature output (LPDDR only) N/A

Bits 30:10 Reserved, must be kept at reset value.

Bit 9 **RVEIRR**: Read valid training intermittent error

If set, indicates that there was an intermittent error during read valid training, such as a pass was followed by a fail then followed by another pass.

Bit 8 **RVERR**: Read valid training error

If set, indicates that a valid read valid placement could not be found during read valid training.

Bit 7 **DFTERR**: DQS drift error

If set, indicates that at least one of the read data strobes has drifted by more than or equal to the drift limit set in the PHY General Configuration Register (PGCR).

Bit 6 **DTIERR**: DQS gate training intermittent error
If set, indicates that there was an intermittent error during DQS gate training, such as a pass was followed by a fail then followed by another pass.

Bit 5 **DTERR**: DQS gate training error
If set, indicates that a valid DQS gating window could not be found during DQS gate training.

Bit 4 **DTDONE**: Data training done
Indicates, if set, that the PHY has finished doing data training.

Bit 3 **DIDONE**: DRAM initialization done
Indicates if set that DRAM initialization has completed.

Bit 2 **ZCDDONE**: zcal done
Indicates if set that impedance calibration has completed.

Bit 1 **DLDONE**: DLL lock done
Indicates if set that DLL locking has completed.

Bit 0 **IDONE**: Initialization done
Indicates if set that the DDR system initialization has completed.
This bit is set after all the selected initialization routines in DDRPHYC_PIR register have completed.

7.7.5 DDRPHYC DDR DLL global control register (DDRPHYC_DLLGCR)

Address offset: 0x010

Reset value: 0x0373 7000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DLLRSVD2[1:0]		LOCKDET	FDTRMSL[1:0]		SBIAS5_3[2:0]			BPS200	SBIAS2_0[2:0]			MBIAS[7:4]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MBIAS[3:0]				TESTSW	ATC[1:0]		DTC[2:0]			TESTEN	IPUMP[2:0]			DRES[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **DLLRSVD2[1:0]**:
These bit are connected to the DLL control bus and reserved for future use.

Bit 29 **LOCKDET**: Master lock detect enable
Note: This field is only valid for a few processes. For all other processes this field is reserved.

Bits 28:27 **FDTRMSL[1:0]**: Slave bypass fixed delay trim
00: Nominal delay
01: Nominal delay – 10%
10: Nominal delay + 10%
11: Nominal delay + 20%

Bits 26:24 **SBIAS5_3[2:0]**: Slave bias trim
Used to trim the bias for the slave DLL.

Bit 23 **BPS200**: Bypass mode frequency range
0: 0 to 100 MHz
1: 0 to 200 MHz

Bits 22:20 **SBIAS2_0[2:0]**: Slave bias trim
Used to trim the bias for the slave DLL.

Bits 19:12 **MBIAS[7:0]**: Master bias trim
Used to trim the bias for the master DLL.

Bit 11 **TESTSW**: Test switch
Selects the test signals of either the master DLL, set to 0, or the slave DLL, set to 1.

Bits 10:9 **ATC[1:0]**: Analog test control
Selects the analog signal to be output on the DLL analog test output (DDR_ATO) when TESTEN is high (Output is Vss when TESTEN is low).
The test output either comes from the master DLL or the slave DLL, depending on the setting of the test switch (TESTSW).
Both master DLL and slave DLL output similar analog test signals. Valid settings for analog test control are:
00: Replica bias output for PMOS (Vbp)
01: Replica bias output for NMOS (Vbn)
10: Filter output (Vc)
11: V_{DDCORE}

Bits 8:6 **DTC[2:0]**: Digital test control
Selects the digital signal to be output on the DLL digital test output (DTO1 pin) when TESTEN is high (Output is '0' when TESTEN is low). The DTO0 pin output masters the DLL reference clock (clk_0).
Valid settings for **master DLL** (such as, when TESTSW = '0'):
- 000: 0 output clock (clk_0)
- 001: 90 output clock (clk_90)
- 010: 180 output clock (clk_180)
- 011: 270 output clock (clk_270)
- 100: 360 internal clock (clk_360_int)
- 101: Speed-up pulse (spdup)
- 110: Slow-down pulse (slwdn)
- 111: 0 MCTL logic clock (cclk_0)

Valid settings for **slave DLL** (such as when TESTSW = '1'):
- 000: Input DQS strobe (dqs)
- 001: Input clock reference (clk_90_in)
- 010: Internal feedback clock (clk_0_out)
- 011: 90 output DQS# strobe (dqsb_90)
- 100: 90 output DQS strobe (dqs_90)
- 101: Speed-up pulse (spdup)
- 110: Slow-down pulse (slwdn)
- 111: Auto-lock enable signal

Bit 5 **TESTEN**: Test enable
Enables digital and analog test outputs selected by DTC and ATC respectively.

Bits 4:2 **IPUMP[2:0]**: Charge pump current trim
000: maximum current
111: minimum current

Bits 1:0 **DRES[1:0]**: Trim reference current versus resistor value variation
00: Rnom
01: Rnom - 20%
1x: Rnom + 20%
Note: For a few processes this field is reserved and is not used by the DLL.

7.7.6 DDRPHYC AC DLL control register (DDRPHYC_ACDLLCR)

Address offset: 0x014

Reset value: 0x4000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DLLDIS	DLLSRST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ATESTEN	Res.	Res.
rw	rw												rw

Res.	Res.	Res.	Res.	MFWDLY[2:0]			MFBDLY[2:0]			Res.	Res.	Res.	Res.	Res.	Res.
				rw	rw	rw	rw	rw	rw						

Bit 31 **DLLDIS**: DLL disable
A disabled DLL is bypassed. By default DLL is enabled.
Note: DLL bypass must only be changed when DDRPHYC clock (dphy_ker_ck) is inactive.

Bit 30 **DLLSRST**: DLL soft reset
Soft resets the AC DLL by driving the DLL soft reset pin.
Note: DLL reset must only be changed to 0 when DDRPHYC clock (dphy_ker_ck) is inactive.

Bits 29:19 Reserved, must be kept at reset value.

Bit 18 **ATESTEN**: Analog test enable
Enables the analog test signal to be output on the DLL analog test output (ATO pin). The DLL analog test output is tri-stated when this bit is '0'.

Bits 17:12 Reserved, must be kept at reset value.

Bits 11:9 **MFWDLY[2:0]**: Master DLL feed-forward delay trim
Used to trim the delay in the master DLL feed-forward path:
000: minimum delay
111: maximum delay

Bits 8:6 **MFBDLY[2:0]**: Master DLL feed-back delay trim
Used to trim the delay in the master DLL feed-back path:
000: minimum delay
111: maximum delay

Bits 5:0 Reserved, must be kept at reset value.

7.7.7 DDRPHYC PT register 0 (DDRPHYC_PTR0)

Address offset: 0x018

Reset value: 0x0022 AF9B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TITMSRST[3:0]				TDLLLOCK [11:10]	
										rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:18 **TITMSRST[3:0]**: ITM soft reset

Number of configuration clock cycles that the ITM soft reset pin must remain asserted when the soft reset is applied to the ITMs.

This must correspond to a value that is equal to or more than 8 controller clock cycles.

Default value corresponds to 8 controller clock cycles.

Bits 17:6 **TDLLLOCK[11:0]**: DLL lock time

Number of configuration clock cycles for the DLL to stabilize and lock, i.e. number of clock cycles from when the DLL reset pin is de-asserted to when the DLL has locked and is ready for use.

Default value corresponds to 5.12us at 533MHz.

Bits 5:0 **TDLLSRST[5:0]**: DLL soft reset

Number of configuration clock cycles that the DLL soft reset pin must remain asserted when the soft reset is triggered through the PHY initialization register (DDRPHYC_PIR).

This must correspond to a value that is equal to or more than 50ns or 8 controller clock cycles, whichever is bigger.

Default value corresponds to 50 ns at 533 MHz.

7.7.8 DDRPHYC PT register 1 (DDRPHYC_PTR1)

Address offset: 0x01C

Reset value: 0x0604 111D

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TDINIT0[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:19 **TDINIT1[7:0]**: tDINIT1
DRAM initialization time corresponding to the following:
DDR3 = CKE high time to first command (tRFC +10 ns or 5 tCK, whichever value is larger)
LPDDR2 = CKE low time with power and clock stable (100 ns)
LPDDR3 = CKE low time with power and clock stable (100 ns)
Default value corresponds to DDR3 360ns at 533MHz.

Bits 18:0 **TDINIT0[18:0]**: tDINIT0
DRAM initialization time corresponding to the following:
DDR3 = CKE low time with power and clock stable (500 us)
LPDDR2 = CKE high time to first command (200 us)
LPDDR3 = CKE high time to first command (200us)
Default value corresponds to DDR3 500 us at 533MHz.

7.7.9 DDRPHYC PT register 2 (DDRPHYC_PTR2)

Address offset: 0x020

Reset value: 0x042D A072

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TDINIT2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:17 **TDINIT3[9:0]**: tDINIT3
DRAM initialization time corresponding to the following:
LPDDR2 = Time from ZQ initialization command to first command (1 us)
LPDDR3 = Time from ZQ initialization command to first command (1us)
Default value corresponds to the LPDDR2/3 1 us at 533MHz.

Bits 16:0 **TDINIT2[16:0]**: tDINIT2
DRAM initialization time corresponding to the following:
DDR3 = Reset low time (200 us on power-up or 100 ns after power-up)
LPDDR2 = Time from reset command to end of auto initialization (1 us + 10 us = 11us)
LPDDR3 = Time from reset command to end of auto initialization (11us)
Default value corresponds to DDR3 200 us at 533MHz

7.7.10 DDRPHYC ACIOC register (DDRPHYC_ACIOCR)

Address offset: 0x024

Reset value: 0x3040 0812

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **ACSR[1:0]**: AC slew rate
Selects slew rate of the I/O for all address and command pins.

Bit 29 **RSTIOM**: Reset I/O mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for SDRAM Reset.

Bit 28 **RSTPDR**: RST pin power down receiver
Powers down, when set, the input receiver on the I/O for SDRAM RST# pin.

Bit 27 **RSTPDD**: RST pin power down driver
Powers down, when set, the output driver on the I/O for SDRAM RST# pin.

Bit 26 **RSTODT**: RST pin ODT
Enables, when set, the on-die termination on the I/O for SDRAM RST# pin.

Bits 25:23 Reserved, must be kept at reset value.

Bit 22 **RANKPDR**: Rank power down receiver
Powers down, when set, the input receiver on the I/O CKE, ODT, and CS# pins.
Only RANKPDR[0] is used for single rank

Bits 21:19 Reserved, must be kept at reset value.

Bit 18 **CSPDD**: CS power down driver
Powers down, when set, the output driver on the I/O for CS# pins.
Only PDD[0] is used for single rank.
CKE and ODT driver power down is controlled by DSGCR register.

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **RANKODT**: Rank ODT
Enables, when set, the on-die termination on the I/O for CKE, ODT, and CS# pins.

Bits 13:11 **CKPDR[2:0]**: CK pin power down receiver
Powers down, when set, the input receiver on the I/O for CK[0], CK[1], and CK[2] pins, respectively

Bits 10:8 **CKPDD[2:0]**: CK pin power down driver
Powers down, when set, the output driver on the I/O for CK[0], CK[1], and CK[2] pins, respectively.

Bits 7:5 **CKODT[2:0]**: CK pin ODT
Enables, when set, the on-die termination on the I/O for CK[0], CK[1], and CK[2] pins, respectively.

Bit 4 **ACPDR**: AC pins power down receivers
Powers down, when set, the input receiver on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins.

Bit 3 **ACPDD**: AC pins power down drivers
Powers down, when set, the output driver on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins

Bit 2 **ACODT**: AC pins ODT
Enables, when set, the on-die termination on the I/O for RAS#, CAS#, WE#, BA[2:0], and A[15:0] pins

Bit 1 **ACOE**: AC pins output enable
Enables, when set, the output driver on the I/O for all address and command pins

Bit 0 **ACIOM**: AC pins I/O mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for all address and command pins,

7.7.11 DDRPHYC DXCC register (DDRPHYC_DXCCR)

Address offset: 0x028

Reset value: 0x0000 0800

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
RVSEL	DQSNRST	Res.	Res.	DQSNRES[3:0]				DQSRES[3:0]				DXPDR	DXPDD	DXIOM	DXODT
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **AWDT**: Active window data train
Indicates if set that data training (DQS gate training and read valid training) should be performed with active DQS gate window.
This is just for debug purposes.
The default is to perform training with passive windowing.

Bit 15 **RVSEL**: ITMD read valid select
Selects the scheme used for ITMD read valid. Valid values are:
0: ITMD read valid signal is generated by delayed DFI read enable signal.
1: ITMD read valid is generated by the ITMD itself using asynchronous crossing.

Bit 14 **DQSNRST**: DQS reset
Indicates, if set, that the ITMS of DQS# should always be put in reset such that its output enable is always '1' and its data output is always '0'.
This is done by driving the oe_set_b and do_rst_b pins of this ITMS to '0' in order to force the unused DQS# PAD to a known state of '0' in applications that don't use DQS#.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:8 **DQSNRES[3:0]**: DQS# resistor

Selects the on-die pull-up/pull-down resistor for DQS# pins. Same encoding as DQSRES.

Note: DQS# resistor must be connected for LPDDR2.

Bits 7:4 **DQSRES[3:0]**: DQS resistor

Selects the on-die pull-down/pull-up resistor for DQS pins.
DQSRES[3] selects pull-down (when set to 0) or pull-up (when set to 1).
DQSRES[2:0] selects the resistor value as follows:
000: Open: On-die resistor disconnected
001: 688 Ω
010: 611 Ω
011: 550 Ω
100: 500 Ω
101: 458 Ω
110: 393 Ω
111: 344 Ω

Note: DQS resistor must be connected for LPDDR2

Bit 3 **DXPDR**: Data power down receiver

Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. It also powers down the PDQSR cell of all DAXT8 macros. This bit is ORed with the PDR and DQSRPD configuration bits of the individual DATX8

Bit 2 **DXPDD**: Data power down driver

Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the PDD configuration bit of the individual DATX8.

Bit 1 **DXIOM**: Data I/O mode

Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) of the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the IOM configuration bit of the individual DATX8.

Bit 0 **DXODT**: Data on die termination

Enables, when set, the on-die termination on the I/O for DQ, DM, and DQS/DQS# pins of all DATX8 macros. This bit is ORed with the ODT configuration bit of the individual DATX8.

7.7.12 DDRPHYC DSGC register (DDRPHYC_DSGCR)

Address offset: 0x02C

Reset value: 0xFA00 001F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CKEOE	RSTOE	ODTOE	CKOE	TPDOE	TPDPD	NL2OE	NL2PD	Res.	Res.	Res.	ODTPDD	Res.	Res.	Res.	CKEPDD
rw	rw	rw	rw	rw	rw	rw	rw				rw				rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FXDLAT	NOBUB	DQSGE[2:0]			DQSGX[2:0]			LPDLLPD	LPIOPD	ZUEN	BDISEN	PUREN
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **CKEOE**: CKE output enable
Sets the output driver on the I/O for SDRAM CKE pins.

Bit 30 **RSTOE**: RST output enable
Enables, when set, the output driver on the I/O for SDRAM RST# pin

Bit 29 **ODTOE**: ODT output enable
Enables, when set, the output driver on the I/O for SDRAM ODT pins.

Bit 28 **CKOE**: CK output enable
Enables, when set, the output driver on the I/O for SDRAM CK/CK# pins.

Bit 27 **TPDOE**: TPD output enable (N/A LPDDR only)

Bit 26 **TPDPD**: TPD power down driver (N/A LPDDR only)

Bit 25 **NL2OE**: Non LPDDR2 output enable
Enables, when set, the output driver on the I/O for non-LPDDR2/LPDDR3 (ODT, RAS#, CAS#, WE#, and BA) pins.
This may be used when a chip that is designed for both LPDDR2/LPDDR3 and other DDR modes is being used in LPDDR2/LPDDR3 mode.
For these pins, the I/O output enable signal (OE) is an AND of this bit and the respective output enable bit in ACIOCR or DSGCR registers.

Bit 24 **NL2PD**: Non LPDDR2 power down
Powers down, when set, the output driver and the input receiver on the I/O for non-LPDDR2/LPDDR3 (ODT, RAS#, CAS#, WE#, and BA) pins.
This may be used when a chip that is designed for both LPDDR2/LPDDR3 and other DDR modes is being used in LPDDR2/LPDDR3 mode.
For these pins, the I/O power down signal (PDD or PDR) is an OR of this bit and the respective power-down bit in ACIOCR register.

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **ODTPDD**: ODT power down driver
Powers down, when set, the output driver on the I/O for ODT pin.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **CKEPDD**: CKE power down driver
Powers down, when set, the output driver on the I/O for CKE pin.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **FXDLAT**: Fixed latency
Specified whether all reads should be returned to the controller with a fixed read latency. Enabling fixed read latency increases the read latency. Valid values are:
0: Disable fixed read latency
1: Enable fixed read latency

Bit 11 **NOBUB**: No bubble
Specified whether reads should be returned to the controller with no bubbles. Enabling no-bubble reads increases the read latency. Valid values are:
0: Bubbles are allowed during reads
1: Bubbles are not allowed during reads

Bits 10:8 **DQSGE[2:0]**: DQS gate early

Specifies the number of clock cycles for which the DQS gating must be enable dearlier than its normal position. Only applicable when using PDQSR I/O cell, passive DQS gating and no drift compensation.

This field is recommended to be set to zero for all DDR types other than LPDDR2/LPDDR3.

For LPDDR2/LPDDR3 it should be set to (tDQSCKmax - tDQSCKmin) divide by clock period and rounded up. tDQSCKmax and tDQSCKmin can be found in the LPDDR/LPDDR2 vendor datasheet.

Bits 7:5 **DQSGX[2:0]**: DQS gate extension

Specifies the number of clock cycles for which the DQS gating must be extended beyond the normal burst length width. Only applicable when using PDQSR I/O cell, passive DQS gating and no drift compensation.

This field is recommended to be set to zero for all DDR types other than LPDDR2/LPDDR3.

For LPDDR2/LPDDR3 it should be set to (tDQSCKmax- tDQSCKmin) divide by clock period and rounded up. tDQSCKmax and tDQSCKmin can be found in the LPDDR2 vendor datasheet.

Bit 4 **LPDLLPD**: Low power DLL power down

Specifies if set that the PHY should respond to the DFI low power opportunity request and power down the DLL of the PHY if the wakeup time request satisfies the DLL lock time.

For more information on requirements when enabling and disabling the DLL, refer to “bypass mode register control”

Bit 3 **LPIOPD**: Low power I/O power down

Specifies if set that the PHY should respond to the DFI low power opportunity request and power down the I/Os of the PHY.

Bit 2 **ZUEN**: zcal on DFI update request

Specifies if set that the PHY should perform impedance calibration (update) whenever there is a controller initiated DFI update request. Otherwise the PHY ignores an update request from the controller.

Bit 1 **BDISEN**: Byte disable enable

Specifies if set that the PHY should respond to DFI byte disable request. Otherwise the byte disable from the DFI is ignored in which case bytes can only be disabled using the DXnGCR register

Bit 0 **PUREN**: PHY update request enable

Specifies if set, that the PHY should issue PHY initiated DFI update request when there is DQS drift of more than ¾ of a clock cycle within one continuous (back-to-back) read burst.

By default the PHY issues PHY initiated update requests and the controller should respond otherwise the PHY may return erroneous values.

The option to disable it is provided only for silicon evaluation and testing.

7.7.13 DDRPHYC DC register (DDRPHYC_DCR)

Address offset: 0x030

Reset value: 0x0000 000B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TPD	RDIMM	UDIMM	DDR2T	NOSRA	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw											

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	DDRTYPE[1:0]		MPRDQ	PDQ[2:0]			DDR8BNK	DDRMD[2:0]		
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TPD**: Test power down (N/A LPDDR only)

If set it places the DRAM in deep power down mode.

Bit 30 **RDIMM**: Registered DIMM

Indicates if set that a registered DIMM is used. In this case, the PUBL increases the SDRAM write and read latencies (WL/RL) by 1.

This only applies to PUBL internal SDRAM transactions. Transactions generated by the controller must make its own adjustments to WL/RL when using a registered DIMM

Bit 29 **UDIMM**: Unbuffered DIMM

Indicates if set that there is address mirroring on the second rank of an un-buffered DIMM (the rank connected to CS#[1]).

In this case, the PUBL re-scrambles the bank and address when sending mode register commands to the second rank.

This only applies to PUBL internal SDRAM transactions. Transactions generated by the controller must make its own adjustments when using an un-buffered DIMM. DCR[NOSRA] must be set if address mirroring is enabled.

Bit 28 **DDR2T**: 2T timing

Indicates if set that 2T timing should be used by PUB internally generated SDRAM transactions.

Bit 27 **NOSRA**: No simultaneous rank access

Specifies if set that simultaneous rank access on the same clock cycle is not allowed. This means that multiple chip select signals should not be asserted at the same time. This may be required on some DIMM systems.

Bits 26:10 Reserved, must be kept at reset value.

Bits 9:8 **DDRTYPE[1:0]**: DDR type (LPDDR2 S4)

Selects the DDR type for the specified LPDDR mode.

Valid values for LPDDR2 are:

00: LPDDR2-S4

01: LPDDR2-S2

Others: Reserved

Bit 7 **MPRDQ**: MPR DQ

Specifies the value that is driven on non-primary DQ pins during MPR reads.
Valid values are:
0: Primary DQ drives out the data from MPR (0-1-0-1); non-primary DQs drive ‘0’
1: Primary DQ and non-primary DQs all drive the same data from MPR (0-1-0-1)

Bits 6:4 **PDQ[2:0]**: Primary DQ(DDR3 Only)

Specifies the DQ pin in a byte that is designated as a primary pin for Multi-Purpose Register (MPR) reads. Valid values are 0 to 7 for DQ[0] to DQ[7], respectively

Bit 3 **DDR8BNK**: DDR 8 banks

Indicates if set that the SDRAM used has 8 banks. tRPA = tRP+1 and tFAW are used for 8-bank DRAMs, other tRPA = tRP and no tFAW is used.

Note: A setting of 1 for DRAMs that have fewer than 8 banks still results in correct functionality but less tighter DRAM command spacing for the parameters described here.

Bits 2:0 **DDRMD[2:0]**: SDRAM DDR mode

011: DDR3
100: LPDDR2 (Mobile DDR2)
101: LPDDR3 (Mobile DDR3)
Others: Reserved

7.7.14 DDRPHYC DTP register 0 (DDRPHYC_DTPR0)

Address offset: 0x034

Reset value: 0x3092 666E

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCCD	TRC[5:0]						TRRD[3:0]				TRAS[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
TRCD[3:0]				TRP[3:0]				TWTR[2:0]			TRTP[2:0]			TMRD[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TCCD**: tCCDRead to read and write to write command delay

0: BL/2 for DDR2 and 4 for DDR3
1: BL/2 + 1 for DDR2 and 5 for DDR3

Bits 30:25 **TRC[5:0]**: tRC

Activate to activate command delay (same bank). Valid values are 2 to 42.

Bits 24:21 **TRRD[3:0]**: tRRD

Activate to activate command delay (different banks). Valid values are 1 to 8.

Bits 20:16 **TRAS[4:0]**: tRAS

Activate to precharge command delay. Valid values are 2 to 31.

Bits 15:12 **TRCD[3:0]**: tRCD

Activate to read or write delay. Minimum time from when an activate command is issued to when a read or write to the activated row can be issued. Valid values are 2 to 11.

Bits 11:8 **TRP[3:0]**: tRP
Precharge command period: The minimum time between a precharge command and any other command.
Note: Note that the controller automatically derives tRPA for 8-bank DDR2 devices by adding 1 to tRP. Valid values are 2 to 11.

Bits 7:5 **TWTR[2:0]**: tWTR
Internal write to read command delay. Valid values are 1 to 6.

Bits 4:2 **TRTP[2:0]**: tRTP
Internal read to precharge command delay. Valid values are 2 to 6. Note that even though RTP does not apply to JEDEC DDR devices, this parameter must still be set to a minimum value of 2 for DDR because the Controller always uses the DDR2 equation, AL + BL/2 + max(RTP,2) – 2, to compute the read to precharge timing (which is BL/2 for JEDEC DDR).

Bits 1:0 **TMRD[1:0]**: tMRD
Load mode cycle time: The minimum time between a load mode register command and any other command.
For DDR3 this is the minimum time between two load mode register commands.
For DDR3, the value used for tMRD is 4 plus the value programmed in these bits, i.e. tMRD value for DDR3 ranges from 4 to 7.
For LPDDR3, the value used for tMRD is 8 plus the value programmed in these bits.

7.7.15 DDRPHYC DTP register 1 (DDRPHYC_DTPR1)

Address offset: 0x038

Reset value: 0x0983 0090

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	TDQSCKMAX[2:0]			TDQSCKMIN[2:0]			TRFC[7:0]							
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	TRTODT	TMOD[1:0]		TFAW[5:0]						TRTW	TAOND[1:0]	
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:27 **TDQSCKMAX[2:0]**: tDQSCKmax
Maximum DQS output access time from CK/CK# (LPDDR2 only).
This value is used for implementing read-to-write spacing. Valid values are 1 to 7.

Bits 26:24 **TDQSCKMIN[2:0]**: tDQSCKmin
DQS output access time from CK/CK# (LPDDR2/3 only).
This value is used for computing the read latency. Valid values are 0 to 7.
This value is derived from the corresponding parameter in the SDRAM datasheet divided by the clock cycle time without rounding up.
The fractional remainder is automatically adjusted for by data training in quarter clock cycle units.
If data training is not performed then this fractional remainder must be converted to quarter clock cycle units and the gating registers (DXnDQSTR) adjusted accordingly.

Bits 23:16 **TRFC[7:0]**: tRFC

Refresh-to-Refresh: Indicates the minimum time, in clock cycles, between two refresh commands or between a refresh and an active command. This is derived from the minimum refresh interval from the datasheet, tRFC(min), divided by the clock cycle time.

The default number of clock cycles is for the largest JEDEC tRFC(min parameter value supported.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **TRTODT**: tRTODT

Read to ODT delay (DDR3 only). Specifies whether ODT can be enabled immediately after the read post-amble or one clock delay has to be added.

Valid values are:

0: ODT may be turned on immediately after read post-amble

1: ODT may not be turned on until one clock after the read post-amble

If tRTODT is set to 1, then the read-to-write latency is increased by 1 if ODT is enabled.

Bits 10:9 **TMOD[1:0]**: tMOD

Load mode update delay (DDR3 only). The minimum time between a load mode register command and a non-load mode register command.

Valid values are:

00: 12

01: 13

10: 14

11: 15

Bits 8:3 **TFAW[5:0]**: tFAW

4-bank activate period. No more than 4-bank activate commands may be issued in a given tFAW period. Only applies to 8-bank devices.

Valid values are 2 to 31.

Bit 2 **TRTW**: tRTW

Read to Write command delay.

Valid values are:

0: standard bus turn around delay

1: add 1 clock to standard bus turn around delay

This parameter allows the user to increase the delay between issuing Write commands to the SDRAM when preceded by Read commands. This provides an option to increase bus turn-around margin for high frequency systems.

Bits 1:0 **TAOND[1:0]**: tAOND/tAOFD

ODT turn-on/turn-off delays (DDR2 only). The delays are in clock cycles.

Valid values are:

00: 2/2.5

01: 3/3.5

10: 4/4.5

11: 5/5.5

Most DDR2 devices utilize a fixed value of 2/2.5. For non-standard SDRAMs, the user must ensure that the operational Write Latency is always greater than or equal to the ODT turn-on delay. For example, a DDR2 SDRAM with CAS latency set to 3 and CAS additive latency set to 0 has a Write Latency of 2. Thus 2/2.5 can be used, but not 3/3.5 or higher.

7.7.16 DDRPHYC DTP register 2 (DDRPHYC_DTPR2)

Address offset: 0x03C

Reset value: 0x1001 A0C8

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	TDLLK[9:0]										TCKE[3:1]		
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TCKE [0]	TXP[4:0]					TXS[9:0]									
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:19 **TDLLK[9:0]**: tDLLK

DLL locking time. Valid values are 2 to 1023.

Bits 18:15 **TCKE[3:0]**: tCKE

CKE minimum pulse width. Also specifies the minimum time that the SDRAM must remain in power down or self refresh mode. For DDR3 this parameter must be set to the value of tCKESR which is usually bigger than the value of tCKE. Valid values are 2 to 15.

Bits 14:10 **TXP[4:0]**: tXP

Power down exit delay. The minimum time between a power down exit command and any other command. This parameter must be set to the maximum of the various minimum power down exit delay parameters specified in the SDRAM datasheet, i.e. max(tXP, tXARD, tXARDS) for DDR2 and max(tXP, tXPDLL) for DDR3. Valid values are 2 to 31.

Bits 9:0 **TXS[9:0]**: tXS

Self refresh exit delay. The minimum time between a self refresh exit command and any other command. This parameter must be set to the maximum of the various minimum self refresh exit delay parameters specified in the SDRAM datasheet, i.e. max(tXSNR, tXSRD) for DDR2 and max(tXS, tXSDLL) for DDR3. Valid values are 2 to 1023.

7.7.17 DDRPHYC MR0 register for DDR3 (DDRPHYC_DDR3_MR0)

Address offset: 0x040

Reset value: 0x0A52

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSVD[2:0]			PD	WR[2:0]			DR	TM	CL[3:1]			BT	CL0	BL[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:13 **RSVD[2:0]**: JEDEC reserved.

Bit 12 **PD**: Power-down control

Controls the exit time for power-down modes. Refer to SDRAM datasheet for details on power-down modes. Valid values are:
0: Slow exit (DLL off)
1: Fast exit (DLL on)

Bits 11:9 **WR[2:0]**: Write recovery

This is the value of the write recovery in clock cycles. It is calculated by dividing the data sheet write recovery time, tWR (ns) by the data sheet clock cycle time, tCK (ns) and rounding up a non-integer value to the next integer.
Valid values are:
001: 5
010: 6
011: 7
100: 8
101: 10
110: 12
All other settings are reserved and should not be used.

Note: tWR (ns) is the time from the first SDRAM positive clock edge after the last data-in pair of a write command, to when a precharge of the same bank can be issued.

Bit 8 **DR**: DLL reset (autoclear)

Writing a ‘1’ to this bit resets the SDRAM DLL. This bit is self clearing, i.e. it returns back to ‘0’ after the DLL reset has been issued.

Bit 7 **TM**: Operating mode

Selects either normal operating mode (0) or test mode (1). Test mode is reserved for the manufacturer and should not be used.

Bit 3 **BT**: Burst type

Indicates whether a burst is sequential (0) or interleaved (1).

Bits 6, 5, 4, 2 **CL[3:0]:** CAS latency

The delay, in clock cycles, between when the SDRAM registers a read command to when data is available.
Valid values for CL[3:0] are:
0010: 5
0100: 6
0110: 7
1000: 8
1010: 9
1100: 10
1110: 11
Others: Reserved

Bits 1:0 **BL[1:0]**: Burst length

Determines the maximum number of column locations that can be accessed during a given read or write command.
Valid values for DDR3 are:
00: 8 (Fixed)
01: 4 or 8 (On the fly)
10: 4 (Fixed)
11: Reserved

7.7.18 DDRPHYC MR1 register for DDR3 (DDRPHYC_DDR3_MR1)

Address offset: 0x044

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	QOFF	TDQS	Res.	RTT2	Res.	LEVEL	RTT1	DIC1	AL[1:0]		RTT0	DIC0	DE
			rw	rw		rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **QOFF**: Output enable/disable

0: all outputs function as normal

1: all SDRAM outputs are disabled removing output buffer current.

This feature is intended to be used for IDD characterization of read current and should not be used in normal operation.

Bit 11 **TDQS**: Termination data strobe

When enabled (‘1’) TDQS provides additional termination resistance outputs that may be useful in some system configurations. (N/A)

Bit 10 Reserved, must be kept at reset value.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **LEVEL**: Write leveling enable (N/A)

Bits 4:3 **AL[1:0]**: Posted CAS Additive Latency:

Setting additive latency that allows read and write commands to be issued to the SDRAM earlier than normal (refer to SDRAM datasheet for details). Valid values are:

00: 0 (AL disabled)

01: CL - 1

10: CL - 2

11: Reserved

Bits 9, 6, 2 **RTT[2:0]**: On die termination
Selects the effective resistance for SDRAM on die termination.
Valid values for {RTT2,RTT1,RTT0} are:
000: ODT disabled
001: RZQ/4
010: RZQ/2
011: RZQ/6
100: RZQ/12
101: RZQ/8
Others: Reserved

Bits 5, 1 **DIC[1:0]**: Output driver impedance control
Controls the output drive strength.
Valid values for {DIC1,DIC0} are:
00: RZQ/6
01: RZQ/7
10: Reserved
11: Reserved

Bit 0 **DE**: DLL enable/disable
Enable (0) or disable (1) the DLL.
DLL must be enabled for normal operation.

7.7.19 DDRPHYC MR1 register for LPDDR2 [alternate] (DDRPHYC_LPDDR2_MR1)

Address offset: 0x044

					rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:9 **RTTWR[1:0]**: Dynamic ODT

Selects RTT for dynamic ODT.
00: Dynamic ODT off
01: RZQ/4
10: RZQ/2
11: Reserved

Bit 8 Reserved, must be kept at reset value.

Bit 7 **SRT**: Self-refresh temperature range

Selects either normal (‘0’) or extended (‘1’) operating temperature range during self-refresh.

Bit 6 **ASR**: Auto self-refresh

When enabled (‘1’), SDRAM automatically provides self-refresh power management functions for all supported operating temperature values.
Otherwise the SRT bit must be programmed to indicate the temperature range.

Bits 5:3 **CWL[2:0]**: CAS write latency

The delay, in clock cycles, between when the SDRAM registers a write command to when write data is available.
000: 5 (tCK = 2.5ns)
001: 6 (2.5ns > tCK = 1.875ns)
010: 7 (1.875ns > tCK = 1.5ns)
011: 8 (1.5ns > tCK = 1.25ns)
Others: Reserved

Bits 2:0 **PASR[2:0]**: Partial array self-refresh

Specifies that data located in areas of the array beyond the specified location are lost if self refresh is entered.
Valid settings for 8 banks are:
000: Full Array
001: Half Array (BA[2:0] = 000, 001, 010 & 011)
010: Quarter Array (BA[2:0] = 000, 001)
011: 1/8 Array (BA[2:0] = 000)
100: 3/4 Array (BA[2:0] = 010, 011, 100, 101, 110 & 111)
101: Half Array (BA[2:0] = 100, 101, 110 & 111)
110: Quarter Array (BA[2:0] = 110 & 111)
111: 1/8 Array (BA[2:0] 111)

7.7.22 DDRPHYC MR2 register for LPDDR2 [alternate] (DDRPHYC_LPDDR2_MR2)

DTROW[3:0]				DTCOL[11:0]											
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DTMPR**: Data training using MPR (DDR3 Only):

Specifies, if set, that data-training should use the SDRAM Multi-Purpose Register (MPR) register. Otherwise data-training is performed by first writing to some locations in the SDRAM and then reading the back.

Bits 30:28 **DTBANK[2:0]**: Data training bank address:

Selects the SDRAM bank address to be used during data training.

Bits 27:12 **DTROW[15:0]**: Data training row address:

Selects the SDRAM row address to be used during data training.

Bits 11:0 **DTCOL[11:0]**: Data training column address:

Selects the SDRAM column address to be used during data training.
The lower four bits of this address must always be “0000”.

7.7.29 DDRPHYC DTD register 0 (DDRPHYC_DTDR0)

Address offset: 0x058

Reset value: 0xDD22 EE11

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ZDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ZQPD**: ZCAL power down

Powers down, if set, the PZQ cell.

Bit 30 **ZCAL**: ZCAL trigger

Impedance Calibration Trigger: A write of '1' to this bit triggers impedance calibration to be performed by the impedance control logic.

The impedance calibration trigger bit is self-clearing and returns back to '0' when the calibration is complete.

Note: If ZDEN is set, then the ZCAL bit should be set to 0.

Bit 29 **ZCALBYP**: Impedance calibration bypass

Impedance Calibration Bypass: Disables, if set, impedance calibration of this ZQ control block when impedance calibration is triggered globally using the ZCAL bit of DDRPHYC_PIR. Impedance calibration of this ZQ block may be triggered manually using ZCAL.

Bit 28 **ZDEN**: Impedance override enable

Impedance Over-ride Enable: When this bit is set, it allows users to directly drive the impedance control using the data programmed in the ZQDATA field. Otherwise, the control is generated automatically by the impedance control logic.

Note: If ZDEN is set, then the ZCAL bit should be set to 0.

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:0 **ZDATA[19:0]**: Impedance override

Impedance Over-Ride Data: Data used to directly drive the impedance control.

ZDATA field mapping for **D3R I/Os** is as follows:

ZDATA[27:20] is reserved and returns zeros on reads

ZDATA[19:15] is used to select the pull-up on-die termination impedance

ZDATA[14:10] is used to select the pull-down on-die termination impedance

ZDATA[9:5] is used to select the pull-up output impedance

ZDATA[4:0] is used to select the pull-down output impedance

Note: See mPHY ST40c25 Datasheet for ZDATA encoding, default value is: ODT pulp-up/down set to hi-impedance and pull-up/down set to ~44.5 Ω for DDR3, 48.8 Ω for DDR3L, 55.5 Ω for LPDDR2 typical corner 25C

7.7.34 DDRPHYC ZQ0CR1 register (DDRPHYC_ZQ0CR1)

Address offset: 0x184

Reset value: 0x7B

7	6	5	4	3	2	1	0
ZPROG[7:4]				ZPROG[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw

Bits 7:4 **ZPROG[7:4]**: Impedance divide ratio to ext R

Impedance divide ratio: selects the external resistor divide ratio to be used to set the output impedance and the on-die termination as follows:

ZPROG[7:4] = On-die termination divide select (with RZQ = 240 Ω ±1%)

- 0x0: Reserved
- 0x1: 120 Ω
- 0x2: 96 Ω
- 0x3: 80 Ω
- 0x4: 69 Ω

ZCTRL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ZDONE**: Impedance calibration done
Indicates that impedance calibration has completed.

Bit 30 **ZERR**: Impedance calibration error
If set, indicates that there was an error during impedance calibration.

Bits 29:20 Reserved, must be kept at reset value.

Bits 19:0 **ZCTRL[19:0]**: Impedance control
Impedance Control: Current value of impedance control.
ZZCTRL field mapping for D3R I/Os is as follows:
ZCTRL[27:20] is reserved and returns zeros on reads
ZCTRL[19:15] is used to select the pull-up on-die termination impedance
ZCTRL[14:10] is used to select the pull-down on-die termination impedance
ZCTRL[9:5] is used to select the pull-up output impedance
ZCTRL[4:0] is used to select the pull-down output impedance

7.7.36 DDRPHYC ZQ0S register 1 (DDRPHYC_ZQ0SR1)

Address offset: 0x18C

Reset value: 0x00

7	6	5	4	3	2	1	0
OPU[1:0]		OPD[1:0]		ZPU[1:0]		ZPD[1:0]	
r	r	r	r	r	r	r	r

Bits 7:6 **OPU[1:0]**: opu calibration status
On-Die termination (ODT) pull-up calibration status.
00: Completed with no errors
01: Overflow error
10: Underflow error
11: Calibration in progress

Bits 5:4 **OPD[1:0]**: opd calibration status
On-Die termination (ODT) pull-down calibration status.
00: Completed with no errors
01: Overflow error
10: Underflow error
11: Calibration in progress

Bits 3:2 **ZPU[1:0]**: zpu calibration status
Output impedance pull-up calibration status. Valid status encodings are:
00: Completed with no errors
01: Overflow error
10: Underflow error
11: Calibration in progress

Bits 1:0 **ZPD[1:0]**: zpd calibration status
Output impedance pull-down calibration status. Valid status encodings are:
00: Completed with no errors
01: Overflow error
10: Underflow error
11: Calibration in progress

7.7.37 DDRPHYC byte lane n GC register (DDRPHYC_DXnGCR)

Address offset: 0x1C0 + 0x40 * n, (n = 0 to 3)

Reset value: 0x0001 0E81

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R0RVSL[1:0]		RTTOAL	RTTOH[1:0]		DQRTT	DQSRTT	DSEN[1:0]		DQSRPD	DXPDR	DXPDD	DXIOM	DQODT	DQSODT	DXEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:14 **R0RVSL[2:0]**: Read valid system latency in steps

Used to specify the read valid system latency relative to the ideal placement of the ITMD read valid signal when bit RVSEL in DDRPHYC_DXCCR register is set to 0.

Power-up default is 011 (i.e. ideal placement of the read valid signal).

The RVSL fields are initially set by the PUB during automatic read valid training but these values can be overwritten by a direct write to this register.

Valid values are:

000: read valid system latency = ideal placement - 3

001: read valid system latency = ideal placement - 2

010: read valid system latency = ideal placement - 1

011: read valid system latency = ideal placement

100: read valid system latency = ideal placement + 1

101: read valid system latency = ideal placement + 2

110: read valid system latency = ideal placement + 3

Others: Reserved

Bit 13 **RTTOAL**: RTT ON additive latency

Indicates when the ODT control of DQ/DQS SSTL I/Os is set to the value in DQODT/DQSODT during read cycles.

Valid values are:

0: ODT control is set to DQSODT/DQODT almost two cycles before read data preamble

1: ODT control is set to DQSODT/DQODT almost one cycle before read data preamble

Bits 12:11 **RTTOH[1:0]**: RTT output hold

Indicates the number of clock cycles (from 0 to 3) after the read data postamble for which ODT control should remain set to DQSODT for DQS or DQODT for DQ/DM before disabling it (setting it to ‘0’) when using dynamic ODT control.

ODT is disabled almost RTTOH clock cycles after the read postamble

Bit 10 **DQRTT**: DQ dynamic RTT control

Indicates, if set, that the ODT control of DQ/DM SSTL I/Os be dynamically controlled by setting it to the value in DQODT during reads and disabling it (setting it to ‘0’) during any other cycle.

If this bit is not set, then the ODT control of DQ SSTL I/Os is always set to the value in DQODT.

Since dynamic ODT is on by default, when using LPDDR2/LPDDR3 this bit must be set to 0 since LPDDR2/LPDDR3 does not require ODT to be on.`

Bit 9 **DQSRTT**: DQS dynamic RTT control

Indicates, if set, that the ODT control of DQS SSTL I/Os be dynamically controlled by setting it to the value in DQSODT during reads and disabling it (setting it to ‘0’) during any other cycle.

If this bit is not set, then the ODT control of DQS SSTL I/Os is always set to the value in DQSODT field.

Since dynamic ODT is on by default, when using LPDDR2/LPDDR3 this bit must be set to 0 since LPDDR2/LPDDR3 does not require ODT to be on.

Bits 8:7 **DSEN[1:0]**: Write DQS enable
Controls whether the write DQS going to the SDRAM is enabled (toggling) or disabled (static value) and whether the DQS is inverted.
DQS# is always the inversion of DQS.
These values are valid only when DQS/DQS# output enable is on, otherwise the DQS/DQS# is tristated.
Valid settings are:
00: DQS disabled (Driven to constant 0)
01: DQS toggling with normal polarity (This should be the default setting)
10: DQS toggling with inverted polarity
11: DQS disabled (Driven to constant 1)

Bit 6 **DQSRPD**: DQSR power-down
Powers down, if set, the PDQSR cell.
This bit is ORed with the common PDR configuration bit

Bit 5 **DXPDR**: Data power-down receiver
Powers down, when set, the input receiver on I/O for DQ, DM, and DQS/DQS# pins of the byte. This bit is ORed with the common PDR configuration bit

Bit 4 **DXPDD**: Data power-down driver
Powers down, when set, the output driver on I/O for DQ, DM, and DQS/DQS# pins of the byte. This bit is ORed with the common PDD configuration bit

Bit 3 **DXIOM**: Data I/O mode
Selects SSTL mode (when set to 0) or CMOS mode (when set to 1) for the I/O for DQ, DM, and DQS/DQS# pins of the byte.
This bit is ORed with the IOM configuration bit of the individual DATX8

Bit 2 **DQODT**: DQ ODT enable
Enables, when set, the on-die termination on the I/O for DQ and DM pins of the byte.
This bit is ORed with the common DATX8 ODT configuration bit

Bit 1 **DQSODT**: DQS ODT enable
Enables, when set, the on-die termination on the I/O for DQS/DQS# pin of the byte.
This bit is ORed with the common DATX8 ODT configuration bit

Bit 0 **DXEN**: DATA byte enable
Enables, if set, the DATX8 and SSTL I/Os used on the data byte.
Setting this bit to ‘0’ disables the byte, i.e. the byte SSTL I/Os are put in power-down mode and the DLL in the DATX8 is put in bypass mode.
After changing a Byte Lane from disabled to enabled, the DLL for that Byte Lane must be reset and re-locked.
Software can use bits DLLSRST and DLLLOCK of DDRPHYC_PIR register to accomplish this (reset and re-locks all DLLs in the DDR PHY).

7.7.38 DDRPHYC byte lane n GS register 0 (DDRPHYC_DXnGSR0)

Address offset: 0x1C4 + 0x40 *n, (n = 0 to 3)

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DTPASS[2:0]			Res.	Res.	Res.	Res.	DTIERR	Res.	Res.	Res.	DTERR	Res.	Res.	Res.	DTDONE
r	r	r					r				r				r

Bits 15:13 **DTPASS[2:0]**: DQS training pass count
The number of passing configurations during DQS gate training.

Bits 12:9 Reserved, must be kept at reset value.

Bit 8 **DTIERR**: DQS gate training intermittent error
If set, indicates that there was an intermittent error during DQS gate training of the byte, such as a pass was followed by a fail then followed by another pass.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **DTERR**: DQS gate training error
If set, indicates that a valid DQS gating window could not be found during DQS gate training of the byte.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DTDONE**: Data training done
Indicates, if set, that the byte has finished doing data training.

7.7.39 DDRPHYC byte lane n GS register 1 (DDRPHYC_DXnGSR1)

Address offset: 0x1C8 + 0x40 * n, (n = 0 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	RVERR	Res.	Res.	Res.	Res.	Res.	Res.	DQSDFT[1:0]		Res.	Res.	Res.	DFTERR
			r							r	r				r

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **RVPASS[2:0]**: Read valid training pass count
The number of passing configurations during read valid training.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RVIERR**: RV intermittent error for rank

If set, indicates that there was an intermittent error during read valid training of the byte, such as a pass was followed by a fail then followed by another pass.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **RVERR**: RV training error

If set, indicates that a valid read valid placement could not be found during read valid training of the byte

Bits 11:6 Reserved, must be kept at reset value.

Bits 5:4 **DQSDFT[1:0]**: DQS drift value

Used to report the drift on the read data strobe of the data byte.
Valid settings are:
00: No drift
01: 90° drift
10: 180° drift
11: 270° drift or more

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DFTERR**: DQS drift error

If set, indicates that the byte read data strobe has drifted by more than or equal to the drift limit set in the PHY General Configuration Register (PGCR).

7.7.40 DDRPHYC byte lane n DLLC register (DDRPHYC_DXnDLLCR)

Address offset: 0x1CC + 0x40 * n, (n = 0 to 3)

Reset value: 0x4000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DLLDIS**: DLL bypass

A disabled DLL is bypassed. Default ('0') is DLL enabled.

Note: DLL bypass must only be changed when DDRPHYC clock (dphy_ker_ck) is inactive.

Bit 30 **DLLSRST**: DLL reset

Soft resets the byte DLL by driving the DLL soft reset pin.

Note: DLL reset must only be changed to 0 when DDRPHYC clock (dphy_ker_ck) is inactive.

Bits 29:20 Reserved, must be kept at reset value.

Bit 19 **SDLBMODE**: Bypass slave DLL during loopback

If this bit is set, the slave DLL is put in loopback mode in which there is no 90 degrees phase shift on read DQS/DQS#. This bit must be set when operating the byte PHYs in loopback mode.

Bit 18 **ATESTEN**: Enable path to pin 'ATO'
Enables the analog test signal to be output on the DLL analog test output (DDR_ATO). The DLL analog test output is tri-stated when this bit is '0'.

Bits 17:14 **SDPHASE[3:0]**: Slave DLL phase
Selects the phase difference between the input clock and the corresponding output clock of the slave DLL. Valid settings:
0000: 90
0001: 72
0010: 54
0011: 36
0100: 108
0101: 90
0110: 72
0111: 54
1000: 126
1001: 108
1010: 90
1011: 72
1100: 144
1101: 126
1110: 108
1111: 90

Bits 13:12 **SSTART[1:0]**: Slave DLL autostart
Used to control how the slave DLL starts up relative to the master DLL locking:
0X: Slave DLL automatically starts up once the master DLL has achieved lock.
10: The automatic startup of the slave DLL is disabled; the phase detector is disabled.
11: The automatic startup of the slave DLL is disabled; the phase detector is enabled.

Bits 11:9 **MFWDLY[2:0]**: Master DLL feed-forward trim
Used to trim the delay in the master DLL feedforward path:
000: minimum delay
...
111: maximum delay

Bits 8:6 **MFBDLY[2:0]**: Master DLL feed-back trim
Used to trim the delay in the master DLL feedback path:
000: minimum delay
...
111: maximum delay

Bits 5:3 **SFWDLY[2:0]**: Slave DLL feed-forward trim
Slave Feed-Forward Delay Trim: Used to trim the delay in the slave DLL feedforward path:
000: minimum delay
...
111: maximum delay

Bits 2:0 **SFBDLY[2:0]**: Slave DLL feed-back trim
Slave Feed-Back Delay Trim: Used to trim the delay in the slave DLL feedback path:
000: minimum delay
...
111: maximum delay

7.7.41 DDRPHYC byte lane n DQT register (DDRPHYC_DXnDQTR)

Address offset: 0x1D0 + 0x40 * n, (n = 0 to 3)

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DQDLY7[3:0]				DQDLY6[3:0]				DQDLY5[3:0]				DQDLY4[3:0]

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **DQDLY7[3:0]**: DQ delay for bit 7
Used to adjust the delay of the data relative to the nominal delay that is matched to the delay of the data strobes through the slave DLL and clock tree.
The lower two bits of the DQDLY for each DQ bit controls the delay for the data clocked by DQS, while the higher two bits control the delay for the data clocked by DQS_b.
Valid settings for each 2-bit control field are:
00: nominal delay
01: nominal delay + 1 step
10: nominal delay + 2 steps
11: nominal delay + 3 steps

Bits 27:24 **DQDLY6[3:0]**: DQ delay for bit 6
idem

Bits 23:20 **DQDLY5[3:0]**: DQ delay for bit 5
Idem

Bits 19:16 **DQDLY4[3:0]**: DQ delay for bit 4

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	R0DGPS[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	R0DGSL[2:0]		
		rw	rw										rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:26 **DMDLY[3:0]**: DM delay
Used to adjust the delay of the data relative to the nominal delay that is matched to the delay of the data strobes through the slave DLL and clock tree.
The lower two bits of the DQDLY for each DQ bit controls the delay for the data clocked by DQS, while the higher two bits control the delay for the data clocked by DQS_b.
Valid settings for each 2-bit control field are:
00: nominal delay
01: nominal delay + 1 step
10: nominal delay + 2 steps
11: nominal delay + 3 steps

Bits 25:23 **DQSNDLY[2:0]**: DQS# delay
Used to adjust the delay of the data strobes relative to the nominal delay that is matched to the delay of the data bit through the slave DLL and clock tree.
Valid values are:
000: nominal delay - 3 steps
001: nominal delay - 2 steps
010: nominal delay - 1 step
011: nominal delay
100: nominal delay + 1 step
101: nominal delay + 2 steps
110: nominal delay + 3 steps
111: nominal delay + 4 steps

Note: - After changing this value, an ITM soft reset must be issued: bit ITMSRST=1 and bit INIT=1 in DDRPHYC_PIR register.

Bits 22:20 **DQSDLY[2:0]**: DQS delay

Used to adjust the delay of the data strobes relative to the nominal delay that is matched to the delay of the data bit through the slave DLL and clock tree.

Valid values are:

000: nominal delay - 3 steps
001: nominal delay - 2 steps
010: nominal delay - 1 step
011: nominal delay
100: nominal delay + 1 step
101: nominal delay + 2 steps
110: nominal delay + 3 steps
111: nominal delay + 4 steps

Note: - After changing this value, an ITM soft reset (bit ITMSRST=1 and bit INIT=1 in DDRPHYC_PIR register) must be issued.

Bits 19:14 Reserved, must be kept at reset value.

Bits 13:12 **R0DGPS[1:0]**: Rank 0 DQS gating phase select

Selects the clock used to enable the data strobes during read so that the value of the data strobes before and after the preamble/postamble are filtered out.

R0DGPS is initially set by the PUBL during automatic DQS data training and subsequently updated during data strobe drift compensation. However, these values can be overwritten by a direct write to this register, and the automatic update during DQS drift compensation can be disabled using the PHY General Configuration Register (PGCR).

Valid values are:

00: 180 clock (clk180)
01: 270 clock (clk270)
10: 360 clock (clk0)
11: 450 clock (next clk90)

Bits 11:3 Reserved, must be kept at reset value.

Bits 2:0 **R0DGSL[2:0]**: Rank 0 DQS gating system latency

Used to increase the number of clock cycles needed to expect valid DDR read data by up to five extra clock cycles.

This is used to compensate for board delays and other system delays.

Power-up default is 000 (i.e. no extra clock cycles required).

The SL fields are initially set by the PUBL during automatic DQS data training but these values can be overwritten by a direct write to this register.

Valid values are:

000: No extra clock cycles
001: 1 extra clock cycle
010: 2 extra clock cycles
011: 3 extra clock cycles
100: 4 extra clock cycles
101: 5 extra clock cycles
Others: Reserved

7.7.43 DDRPHYC register map

Refer to *Section 2.5 on page 153* for the register boundary addresses.

8 DDR performance monitor (DDRPERFM)

8.1 Introduction

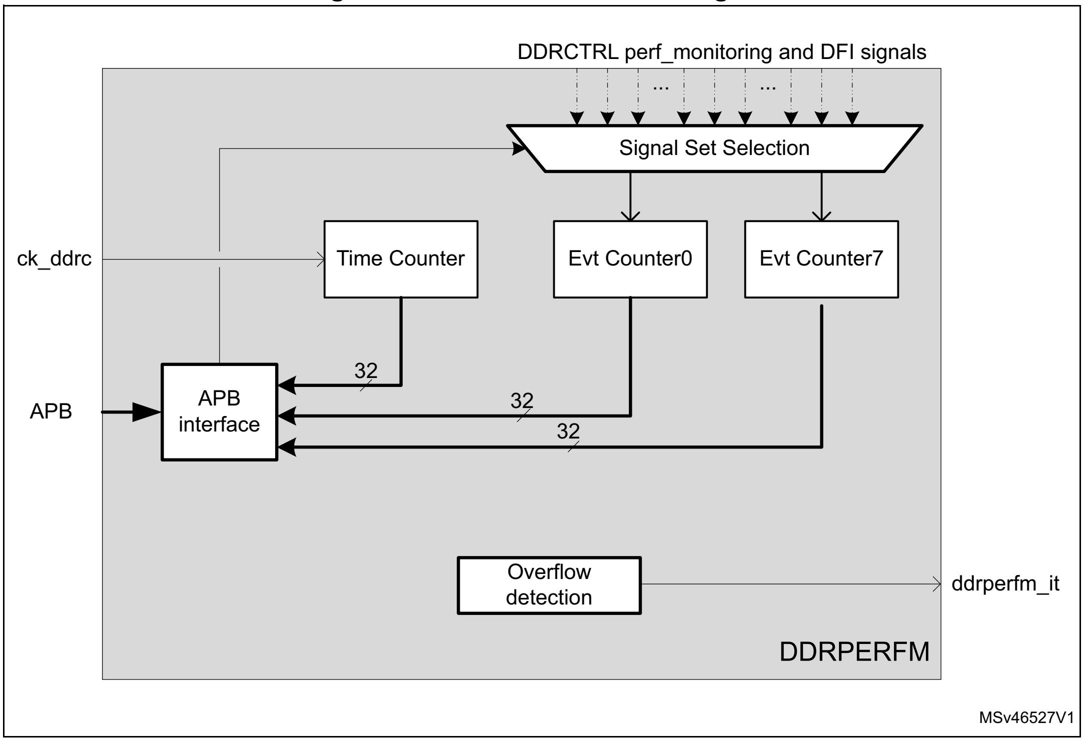
The DDRPERFM is intended to monitor DDR controller performance by counting events from a set of signals and gathering results under software control.
The DDRPERFM can be used to feedback important statistics such as the DDR utilization, read/write bandwidth, bank activation, idle state duration for some off-line analysis of the DDR system performance and for optimal parameter settings to improve the DDR utilization and for power optimization.

8.2 Features

- One 32-bit time counter (TCNT)
- Four 32-bit event counters (CNT0 to CNT3)
- Selection from 4 sets of events to be monitored
- Global Start/ Stop control
- Individual counter enable and clear
- Global counter start and stop triggered by software
- Counter overflow detection with all the counters freeze and the interrupt event generation
- APB interface

8.3 Block diagram

Figure 26. DDRPERFM block diagram



8.4 Functional description

The DDRPERFM provides information of how efficiently the DDR controller is working by reporting statistics according to the set of signals selected for monitoring.

Up to 4 signals from 4 sets of signals along with one permanent clock counter can be monitored.

The counters are started and stopped by software.

All the counters stop when one counter saturates. (The quickest it can saturate is 8.05 seconds with 533 MHz DDR)

The counters may be halted without resetting them to suspend counting.

Useful composite statistics can be derived from counter values; This information can be used by developers to tune the DDR controller settings. For example to optimize the DDR utilization or to improve the low-power mode settings.

Table 27. DDRPERFM signal sets

Set	CNT0	CNT1	CNT2	CNT3
0	perf_op_is_rd	perf_op_is_wr	perf_op_is_activate	ctl_idle
1	perf_hpr_req_with_nocredit	perf_lpr_req_with_nocredit	Reserved	cactive_ddrc
2	perf_op_is_enter_powerdown	perf_op_is_refresh	perf_selfref_mode	dfi_lp_req
3	perf_hpr_xact_when_critical	perf_lpr_xact_when_critical	perf_wr_xact_when_critical	dfi_lp_req

The signals are described hereafter:

perf_op_is_rd	Asserted for every read that is issued for commands going through CAM
perf_op_is_wr	Asserted for every write that is issued for commands going through CAM.
perf_op_is_activate	Asserted for every activate that is issued for commands going through CAM
ctl_idle	Asserted when the controller is idle for extended periods and only when there are no commands or data on the DFI interface.
perf_hpr_req_with_nocredit	Asserted when there is a High Priority Read (HPR) request (from XPI to PA) not served due to no available credit.
perf_lpr_req_with_nocredit	Asserted when there is a Low Priority Read (LPR) request (from XPI to PA) not served due to no available credit.
cactive_ddrc	DDRC Hardware Low-power clock active. Indicates that the DDRC requires its clock signal.
perf_op_is_enter_powerdown	Asserted for every entry into Power down mode
perf_op_is_refresh	Asserted for every refresh command that is issued by the controller.
perf_selfref_mode	Asserted for the entire duration for which the controller stays in Self-Refresh mode.
perf_hpr_xact_when_critical	Asserted for every High Priority Read transaction that is scheduled when the High Priority queue is in critical state.
perf_lpr_xact_when_critical	Asserted for every Low Priority Read transaction that is scheduled when the Low Priority queue is in critical state.
perf_wr_xact_when_critical	Asserted for every write transaction that is scheduled when the write queue is in critical state.
dfi_lp_req	DFI low-power opportunity request. This signal is used by the controller to inform the PHY of an opportunity to switch to a low-power mode.

8.5 Application information

8.5.1 Signal set 0: to monitor the DDR utilization

By counting the read and write commands sent to DDR over a time window, can be monitored:

- The read and write traffic (approximate) bandwidth.
- The DDR utilization.
- The DDR scheduling efficiency

Note: The DDR efficiency is measured by the ratio of read and write count to the time where the DDR is not idle.

Example:

```
read_bandwidth (Mbyte/sec)  ~= 4 * BL * freq * CNT0/TCNT
write_bandwidth (Mbyte/sec) ~= 4 * BL * freq * CNT1/TCNT
DDR_utilization = (BL/2) *(CNT0 + CNT1)/TCNT
with
   BL = 8
   freq = 533 MHz
```

The ratio of activate commands to the total of read and write commands is providing information about the bank conflict efficiency, this information can be used to select the best memory access pattern between the bank sequential or the bank interleaved.

8.5.2 Signal set 1: to monitor the HPR and LPR stores

By counting the durations where the DDRC stores are out-of-credit to fine tune the DDRCTRL scheduling and performance control:

- To better balance the store split between HPR and LPR.
- To optimize the starvation timeout.
- To optimize run-length when the store is in critical state
- To fine tune the page open/close policy.

These settings are controlled by DDRCTRL_SCHED, DDRCTRL_SCHED1, DDRCTRL_HPR1, DDRCTRL_LPR1, DDRCTRL_WR1 registers.

8.5.3 Signal set 2: to monitor the refresh and self-refresh duration

The refresh commands are sent at regular intervals when the DDR is not in self-refresh. Monitoring the PowerDown commands sent when the DDR is idle, can be used to fine tune the low-power settings controlled by DDRCTRL_PWRCTRL and DDRCTRL_PWRTMG.

8.5.4 Signal set 3: to monitor the DDR stalling

By counting the duration where any DDRC store is in critical state, it is possible to fine tune the DDRCTRL scheduling and performance control.
The queue goes to critical state when the starvation counters time out

These settings are controlled by DDRCTRL_PCFGR/W, DDRCTRL_PCFGQOS, DDRCTRL_CFGWQOS registers for each port.

8.6 DDRPERFM registers

8.6.1 DDRPERFM control register (DDRPERFM_CTL)

Address offset: 0x000

Reset value: 0x0000 0000

Note: Write-only register. A read request returns all zeros.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STOP	START
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **STOP:** stop all the counters.
0: writing a ‘0’ has no effect.
1: writing a ‘1’ stops all the counters
Writing a ‘1’ when the counters are stopped (DDRPERFM_STATUS.BUSY = 0) is ignored

Bit 0 **START:** Start counters which are enabled, the time counter (TCNT) is always enabled.
0: writing a ‘0’ has no effect.
1: writing a ‘1’ Starts counters which are enabledW
writing a ‘1’ when the counters are running (DDRPERFM_STATUS.BUSY = 1) is ignored

Caution: A simultaneous write of START and STOP bits at ‘1’ has an unpredictable effect.

8.6.2 DDRPERFM configurationl register (DDRPERFM_CFG)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEL[1:0]	
														rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN[3:0]			
												rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **SEL[1:0]:** select set of signals to be monitored (from 0 to 3) (see signal set description in *Table 27: DDRPERFM signal sets*) and counters to be enabled

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:0 **EN[3:0]:** enable counter x (from 0 to 3)
0: the corresponding counter is disabled and does not increment
1: the corresponding counter is enabled and incremented on event at each clock

Note: The time counter (TCNT) is enabled by default.

Caution: The DDRPERFM_CFG can be modified **only** when the DDRPERFM is stopped.
A write to this register is ignored when DDRPERFM_STATUS.BUSY = 1

8.6.3 DDRPERFM status register (DDRPERFM_STATUS)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TOVF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSY
r															r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COVF[3:0]			
												r	r	r	r

Bit 31 **TOVF**: total counter overflow
0: no overflow
1: counter overflow

Bits 30:17 Reserved, must be kept at reset value.

Bit 16 **BUSY:** Busy Status
0: DDRPERFM is stopped or a counter is in overflow
1: DDRPERFM is counting (at least TCNT is counting)

Bits 15:4 Reserved, must be kept at reset value.

Bits 3:0 **COVF[3:0]:** Counter x Overflow (with x from 0 to 3)
0: no overflow
1: counter overflow

Note: When any counter is in overflow, the DDRPERFM is stopped with all the counters keeping their value, the DDRPERFM needs a restart after overflowing counter has been cleared.

The counter overflow is also visible also by reading DDRPERFM_CNTx = 0xFFFF_FFFF

8.6.4 DDRPERFM counter clear register (DDRPERFM_CCR)

Address offset: 0x00C

Note: Write-only register. A read request returns all zeros

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCLR[3:0]			
												w	w	w	w

Bit 31 **TCLR**: time counter clear
0: writing a ‘0’ has no effect
1: writing a ‘1’ clears the time counter

Bits 30:4 Reserved, must be kept at reset value.

Bits 3:0 **CCLR[3:0]:** counter x Clear (with x from 0 to 3)
0: writing a ‘0’ has no effect
1: writing a ‘1’ clears the corresponding event counter x (with x from 0 to 3)

Note: A write to this register is ignored when DDRPERFM_STATUS.BUSY = 1.

8.6.5 DDRPERFM interrupt enable register (DDRPERFM_IER)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVFIE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **OVFIE**: overflow interrupt enable
0: overflow interrupt disabled
1: overflow interrupt enabled

8.6.6 DDRPERFM interrupt status register (DDRPERFM_ISR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVFF
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **OVFF**: overflow flag
This flag is set when one counter is in overflow

8.6.7 DDRPERFM interrupt clear register (DDRPERFM_ICR)

Address offset: 0x018

Note: Write-only register. A read request returns all zeros

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OVF
															w

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **OVF**: overflow flag
0: no action
1: clears the overflow flag

Note: Following a counter overflow, the programming sequence must be:
1) Clear the counter(s) by writing '1' to DDRPERFM_CCR appropriate bits
2) Clear the interrupt by writing '1' to DDRPERFM_ICR.OVF

8.6.8 DDRPERFM time counter register (DDRPERFM_TCNT)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CNT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CNT[31:0]**: total time, this is number of DDR controller clocks elapsed while DDRPERFM has been running.

Caution: The time counter must only be read when DDRPERFM is stopped.
This register is read as zero when DDRPERFM_STATUS.BUSY=1.

8.6.9 DDRPERFM event counter x register (DDRPERFM_CNTx)

Address offset: 0x030 + x * 0x008 (x = 0 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CNT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
CNT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CNT[31:0]**: event counter value.

Each counter is incrementing when the corresponding signal from the selected set is asserted. See *Table 27: DDRPERFM signal sets* .

Caution: The counters must only be read when DDRPERFM is stopped.
These registers are read as zero when DDRPERFM_STATUS.BUSY=1.

8.6.10 DDRPERFM hardware configuration register (DDRPERFM_HWCFG)

Address offset: 0x3F0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NCNT[3:0]			
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **NCNT[3:0]:** number of counters for this configuration (4)

8.6.11 DDRPERFM version register (DDRPERFM_VER)

Address offset: 0x3F4

Reset value: 0x0000 0010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]:** Major revision number.

Bits 3:0 **MINREV[3:0]:** Minor revision number.

8.6.12 DDRPERFM ID register (DDRPERFM_ID)

Address offset: 0x3F8

Reset value: 0x0014 0061

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]:** DDRPERFM unique identification.

8.6.13 DDRPERFM magic ID register (DDRPERFM_SID)

Address offset: 0x3FC

Reset value: 0xA3C5 DD01

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]:** magic ID for automatic IP discovery.

8.6.14 DDRPERFM register map

Table 28. Power control register map and reset values

Refer to *Section 2.5 on page 153* for the register boundary addresses.

9 Power control (PWR)

The power control (PWR) provides an overview of the supply architecture of the different power domains, and the control of the supply configuration.

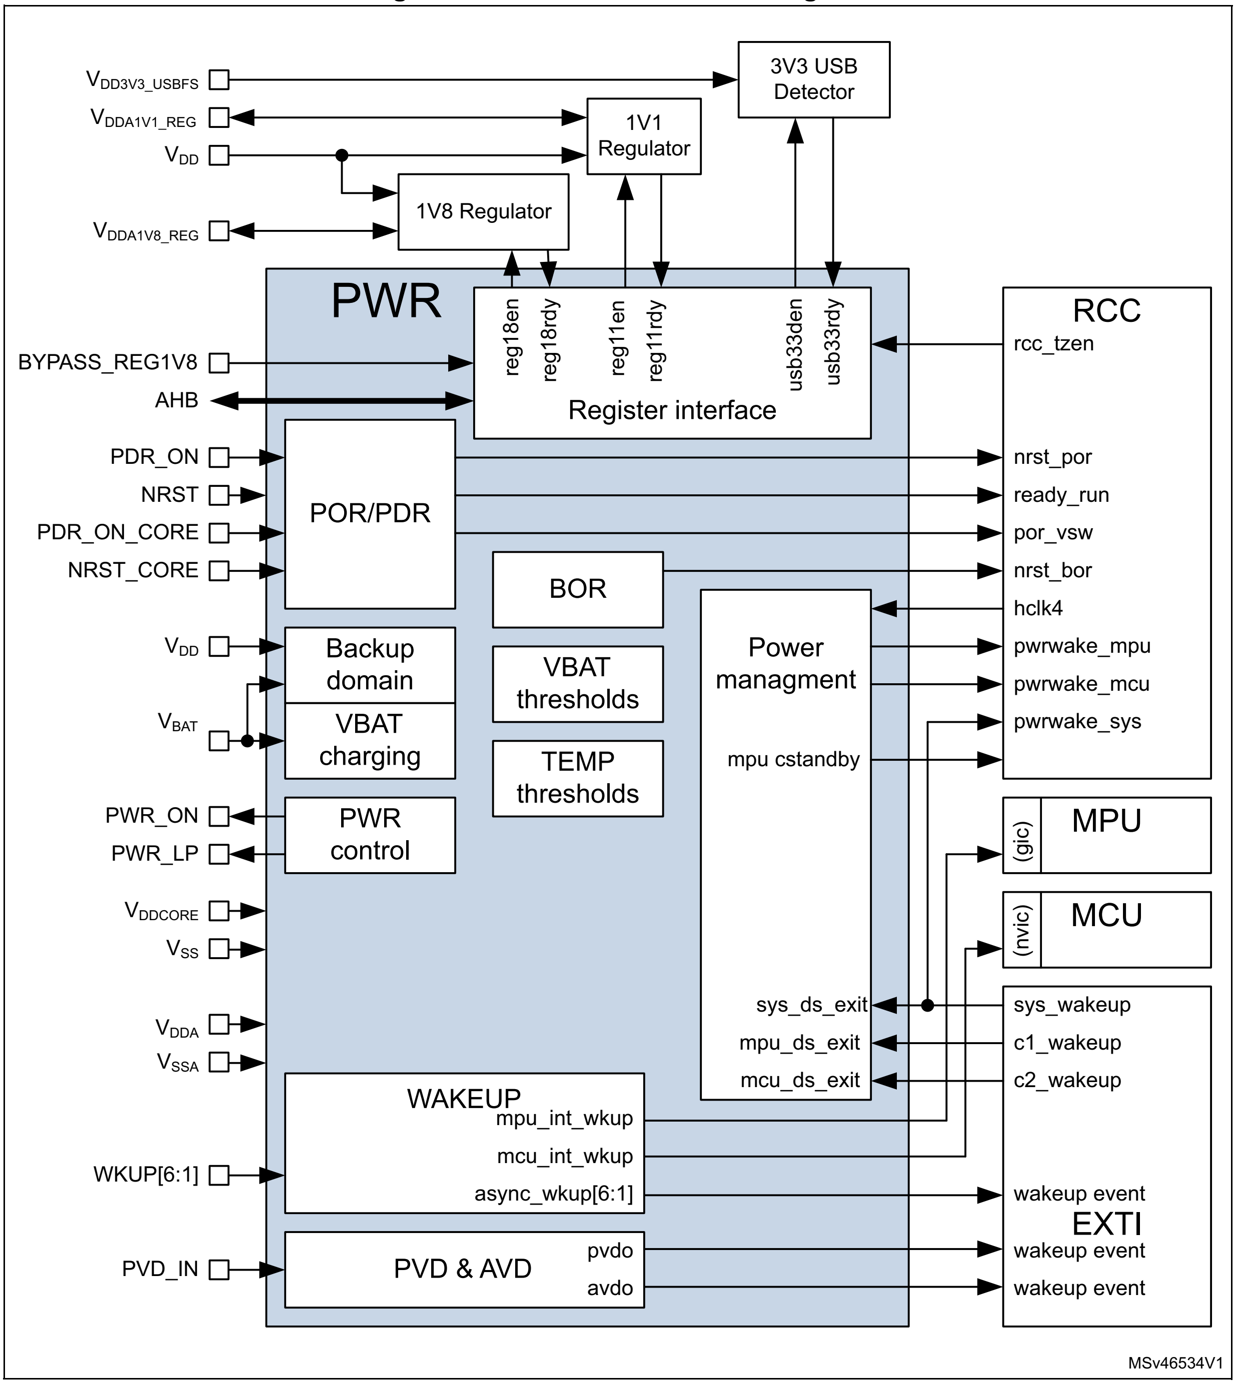
It provides an overview of the power supply supervisor features and provides the control of the V_{DDCORE} supply domain according to the operating modes. In the PWR section, the Cortex®- A7 is called MPU and the Cortex® -M4 is called MCU.

9.1 PWR main features

- System supply external regulation control
  - V_{DDCORE} supply request PWR_ON
  - V_{DDCORE} low power mode control PWR_LP
- Peripheral supply regulation
  - 1.8 V regulator (external to PWR IP)
  - 1.1 V regulator (external to PWR IP)
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - VBAT thresholds
  - Temperature thresholds
  - V_{DDCORE} monitor
- VBAT charging
- Power management
  - Operating modes
  - Low-power modes
- Register access TrustZone® security

9.2 PWR block diagram

Figure 27. Power control block diagram



9.2.1 PWR pin overview

Table 29. PWR pin overview

Pin name	I/O	Description
V_{DD}	P	Main IO and VDD domain supply input
V_{DD_PLL}	P	PLLs supply input, shall be connected to V_{DD}(not used by PWR)
V_{BAT}	P	Backup battery supply input
V_{DDCORE}	P	Core domain supply
V_{DDA}	P	Analog domain supply
V_{DDA1V8_REG}	P	1V8 regulator supply output
V_{DDA1V1_REG}	P	1V1 regulator supply output
V_{DD3V3_USBFS}	P	USB FS IO 3V3 supply input
V_{DD3V3_USBHS}	P	USB HS PHY 3V3 supply input, shall be connected to V_{DD3V3_USBFS} (not used by PWR)
V_{DDQ_DDR}	P	DDR PHY supply input (not used by PWR)
V_{SS}	P	Main ground
V_{SSA}	P	Analog ground
V_{SS_USBHS}	P	USB HS PHY ground (not used by PWR)
AHB	I/O	AHB register interface
PWR_ON	O	Core supply enable output
PWR_LP	O	Core supply Low-power Stop mode selection output
PDR_ON	I	V_{DD} Power On Reset enable
NRST	IO	Application pad reset input/output
PDR_ON_CORE	I	V_{DDCORE} Power On Reset enable
NRST_CORE	I	V_{DDCORE} reset input (to be used when V_{DDCORE} Power On Reset is disabled)
BYPASS_REG1V8	I	1V8 regulator bypass
WKUP[6:1]	I	Wakeup inputs
PVD_IN	I	PVD external input
hclk4	I	PWR AHB bus clock input from RCC
pvdo	O	Programmable voltage detector output
avdo	O	Analog voltage detector output

9.3 PWR power supplies

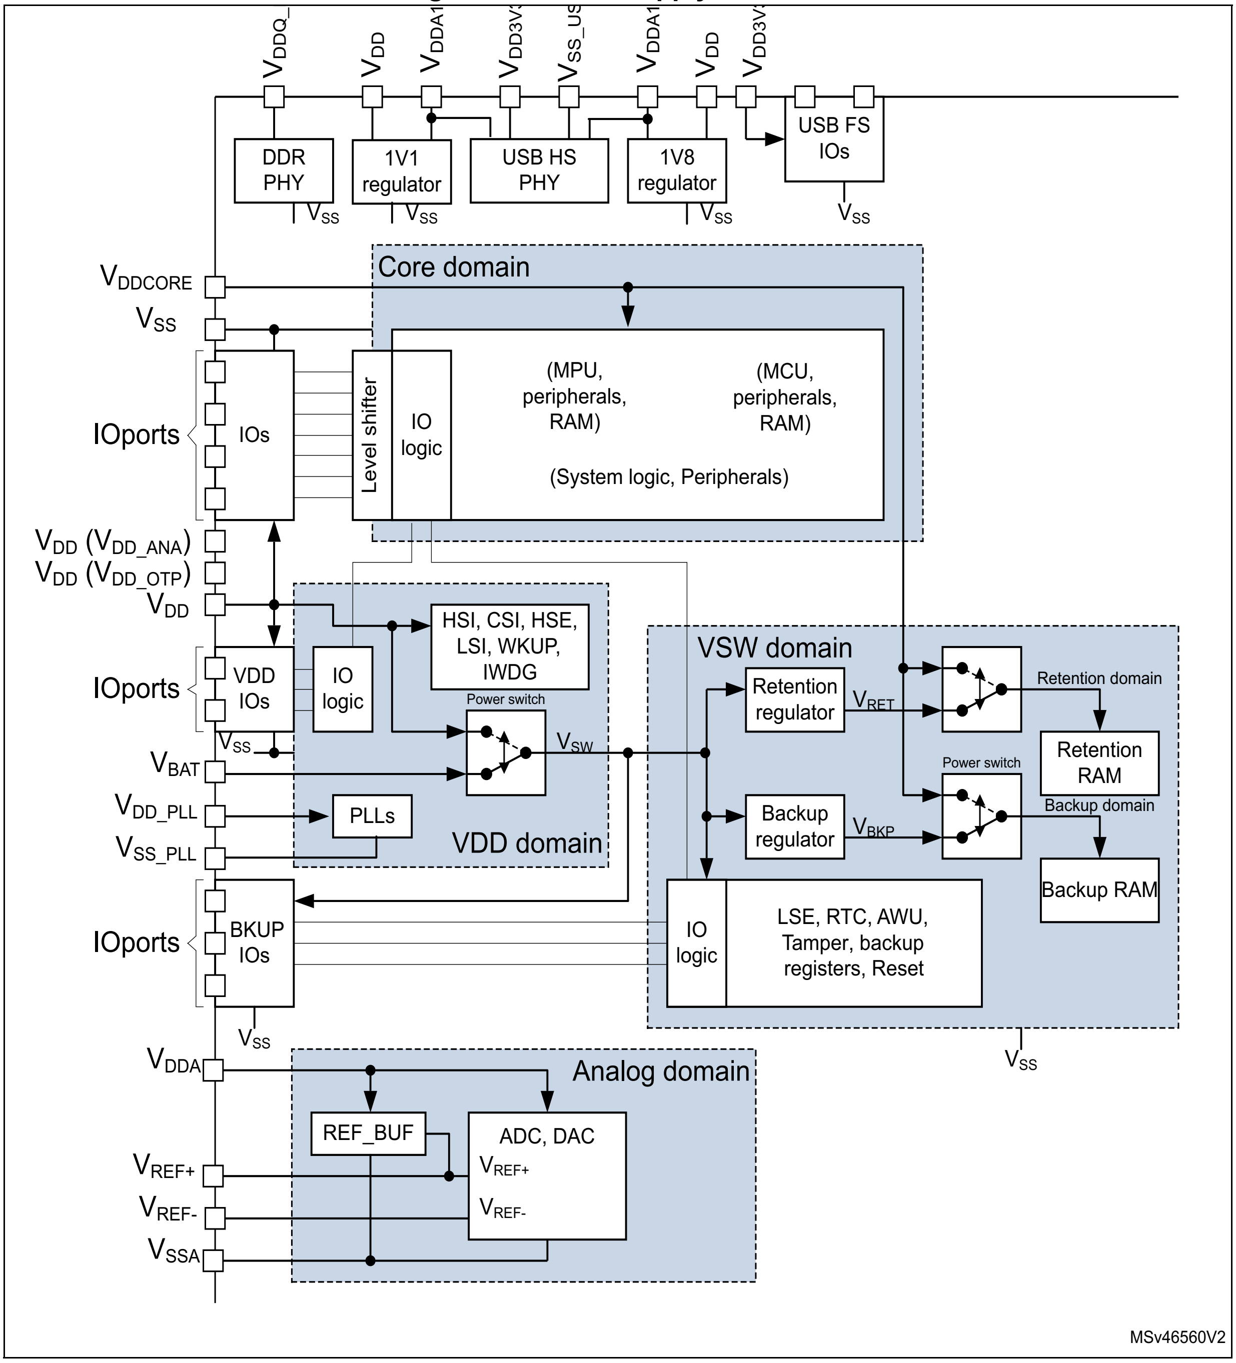
The system requires supply on V_{DD} and V_{DDCORE}, and provides independent supplies for V_{DDA}, V_{BAT}, V_{DD1V8_REG}, V_{DD1V1_REG}, V_{DD3V3_USBFS}, V_{DD3V3_USBHS} and V_{DDQ_DDR}. It provides regulated supplies for specific functions (1V8 regulator):

- V_{DD} power supply input for I/Os and system analog such as reset, power management and oscillators and PLLs.
- V_{DD_PLL} power supply input for PLLs, to be connected to the same supply as used for V_{DD}.
- V_{BAT} optional power supply input for backup domain when V_{DD} is not present (VBAT mode).
- V_{DDCORE} digital core domain supply, dependent on V_{DD} supply. VDD shall be present before V_{DDCORE}.
- V_{DDA} analog power supply input for ADCs, DACs and voltage reference buffers, independent from any other supply.
- V_{REF+} external reference voltage for ADC and DAC, independent from any other supply.
  - When the voltage reference buffer is enabled, supply output.
  - When the voltage reference buffer is disabled, independent external reference supply input.
- V_{SSA} separate analog and reference voltage ground.
- V_{DDA1V8_REG} 1V8 regulator supply, independent from any other supply.
  - When the 1V8 regulator is enabled, supply output.
  - When the 1V8 regulator is disabled, independent external supply input.
- V_{DDA1V1_REG} 1V1 regulator supply, independent from any other supply.
- V_{DD3V3_USBFS} supply input for USB FS IOs, independent from any other supply.
- V_{DD3V3_USBHS} supply input for USB HS PHY, to be connected to the same supply as used for V_{DD3V3_USBFS}.
- V_{SS_USBHS} separate USB HS PHY ground.
- V_{DDQ_DDR} supply input for DDR PHY, independent from any other supply.
- V_{SS} common ground for all supplies except for analog.

Note: Depending on the operating power supply range, some peripheral may be used with limited functionality and performance. For more details refer to section "General operating conditions" in the datasheet.

Note: An external DDR memory is to be supplied from an external regulator which is NOT controlled by the PWR. When the system enters low-power modes it is up to the firmware to control the DDR memory supply directly through the external regulator. When the system enters Standby mode the PWR_ON pin may be used by the external DDR memory regulator to power down the DDR memory supply.

Figure 28. Power supply overview



9.3.1 PWR core domain

The V_{DDCORE} core domain supply is provided from an external regulator. The V_{DDCORE} supplies all the digital circuitries except the backup domain and the standby circuitry when in Standby mode.

Following a V_{DD} power-on reset, the external regulator is enabled via PWR_ON and supplies the V_{DDCORE}.

The external regulator may operate in different modes (Main, Low-power, Off) which is used depending on the system operating modes (Run, Stop, LP-Stop, LPLV-Stop and Standby).

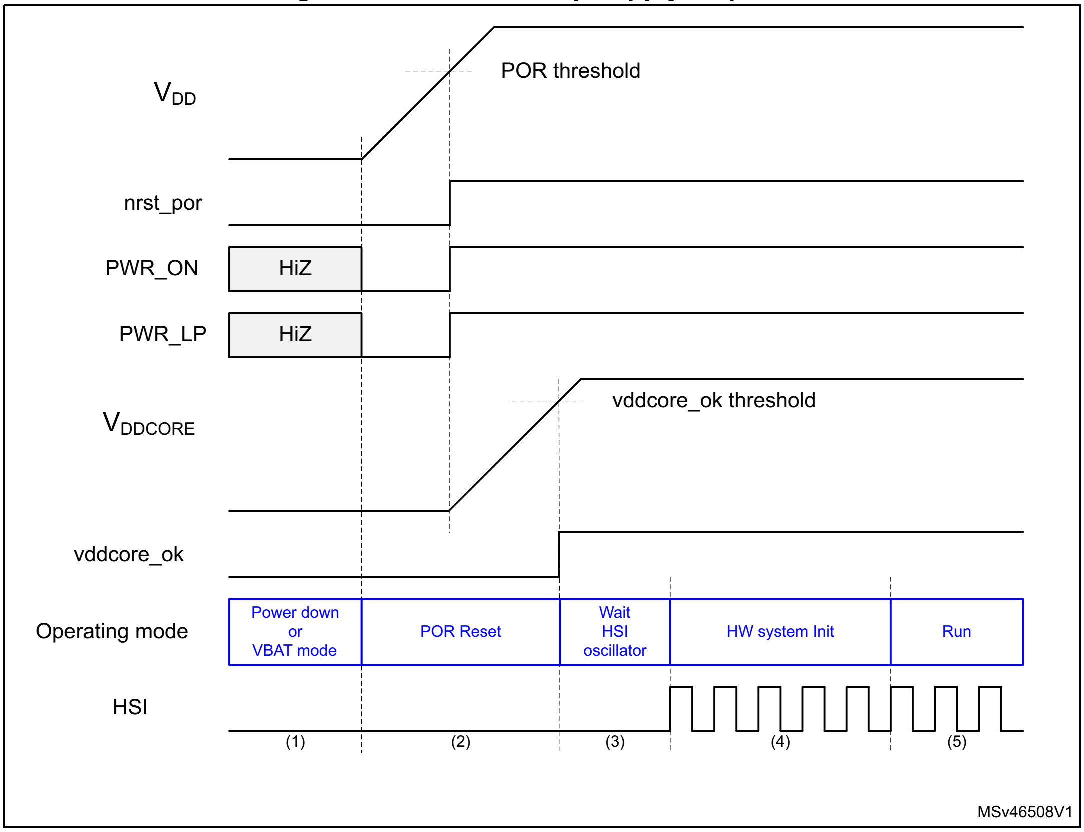
- In Run mode
  - The regulator supplies full power to the V_{DDCORE} domain (core, memories and digital peripherals), in its Main mode, both PWR_ON and PWR_LP are set high.
- In Stop mode
  - The regulator supplies the V_{DDCORE} domain to retain the content of registers and internal memories. The external regulator is kept in Main mode to allow a fast exit. The Low-power mode signaling is disabled with the LPDS register bit in *PWR control register 1 (PWR_CR1)*. Both PWR_ON and PWR_LP are kept set high.
- In LP-Stop mode
  - The regulator supplies the V_{DDCORE} domain to retain the content of registers and internal memories. The external regulator is allowed to enter Low-power mode. The Low-power mode signaling on PWR_LP is enabled with the LPDS register bit in *PWR control register 1 (PWR_CR1)*. The PWR_ON is kept set high or follows PWR_LP as selected in LPCFG in *PWR control register 1 (PWR_CR1)*, and PWR_LP is cleared to low.
- In LPLV-Stop mode
  - The regulator supplies the VDDCORE domain to retain the content of registers and internal memories. The external regulator is allowed to enter Low-power low-voltage mode. The Low-power mode signaling on PWR_LP is enabled with the LPDS register bit in *PWR control register 1 (PWR_CR1)*. The PWR_ON is kept set high or follows PWR_LP as selected in LPCFG in *PWR control register 1 (PWR_CR1)*, and PWR_LP is cleared to low. The Low-power Low-voltage mode is enabled by the LVDS register bit in *PWR control register 1 (PWR_CR1)*, the V_{DDCORE} supply level may be lowered during LPLV-Stop mode.
- In Standby mode
  - The PWR_ON and PWR_LP signals are both set low, the external regulator is switched off and the V_{DDCORE} domain is powered down. The content of the registers and memories are lost except for the backup domain and the Standby circuitry.

9.3.2 PWR supply system startup sequence

The system startup sequence is shown in *Figure 29*.

1. From power-on the POR monitors the V_{DD} supply. Once the supply is above the POR threshold level, the external Voltage regulator providing the V_{DDCORE} supply is enabled via the PWR_ON signal.
2. As long as the V_{DDCORE} is below the vddcore_ok threshold, the system is kept in reset.
3. Once the V_{DDCORE} supply is above the vddcore_ok threshold level, the system is taken out of reset, where after the HSI oscillator is enabled.
4. Once the HSI oscillator is stable, the hardware initializes the system (option bytes loading), then the Run mode is entered.

Figure 29. Device startup supply sequence

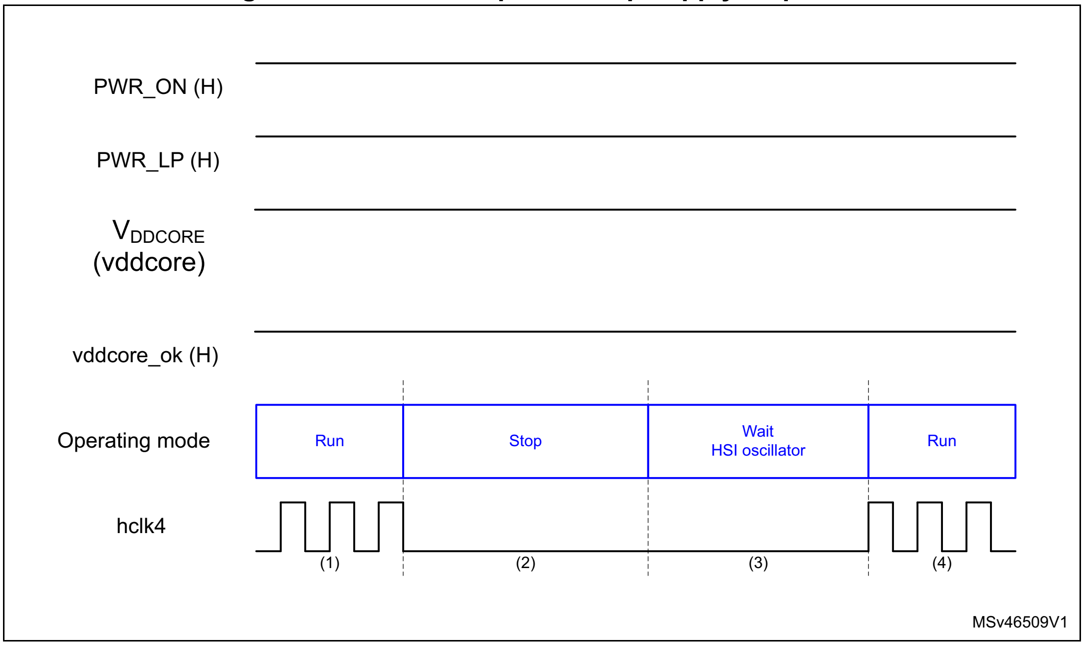


9.3.3 PWR supply Stop sequence

The system Stop mode sequence is shown in *Figure 30*. The Stop mode is entered when selected by the LPDS register bit in *PWR control register 1 (PWR_CR1)*.

1. When entering Stop mode, the hclk4 is stopped. The oscillators can be stopped in order to reduce the power consumption. For detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*.
2. In Stop mode both the PWR_ON and PWR_LP are kept high. The external regulator remains in main mode.
3. On a wakeup event, the clock restore process is performed. See RCC: *The clock restore sequence description* for more details.
4. Once the oscillator is stable, the system enters into Run mode.

Figure 30. Device low-power Stop supply sequence

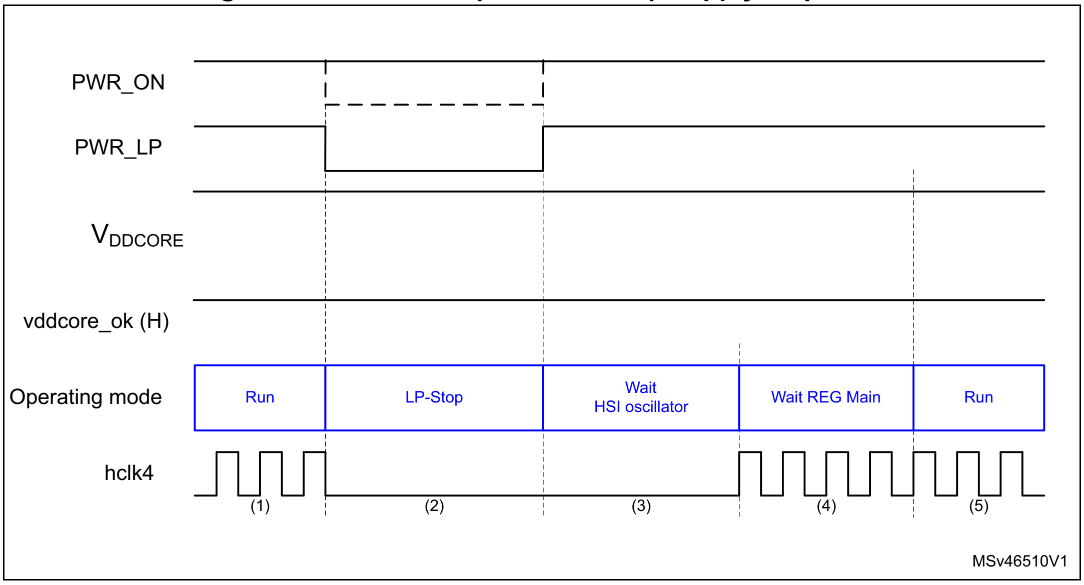


9.3.4 PWR supply LP-Stop sequence

The system LP-Stop mode sequence is shown in *Figure 31*. The LP-Stop mode is entered when selected by the LPDS register bit in *PWR control register 1 (PWR_CR1)*.

1. When entering LP-Stop mode the hclk4 is stopped. The oscillators can be stopped in order to reduce the power consumption. For detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*
2. In the LP-Stop mode the PWR_ON is either kept high (pwr_on) or follows the PWR_LP (pwr_onlp) as selected with the LPCFG register bit in *PWR control register 1 (PWR_CR1)*. The PWR_LP is asserted, signaling LP-Stop. After, the external regulator may enter Low-power mode.
3. On a wakeup event the external regulator is taken out of Low-power mode via PWR_LP, and the clock restore process is performed. See RCC: *The clock restore sequence description* for more details.
4. Once the oscillator is stable, the PWRLP_TEMPO delay is timed out to allow the external regulator to switch to main mode (see *Section 10.7.92: RCC PWR_LP delay control register (RCC_PWRLPDLYCR)*).
5. After the delay timeout the system enters into Run mode.

Figure 31. Device low-power LP-Stop supply sequence

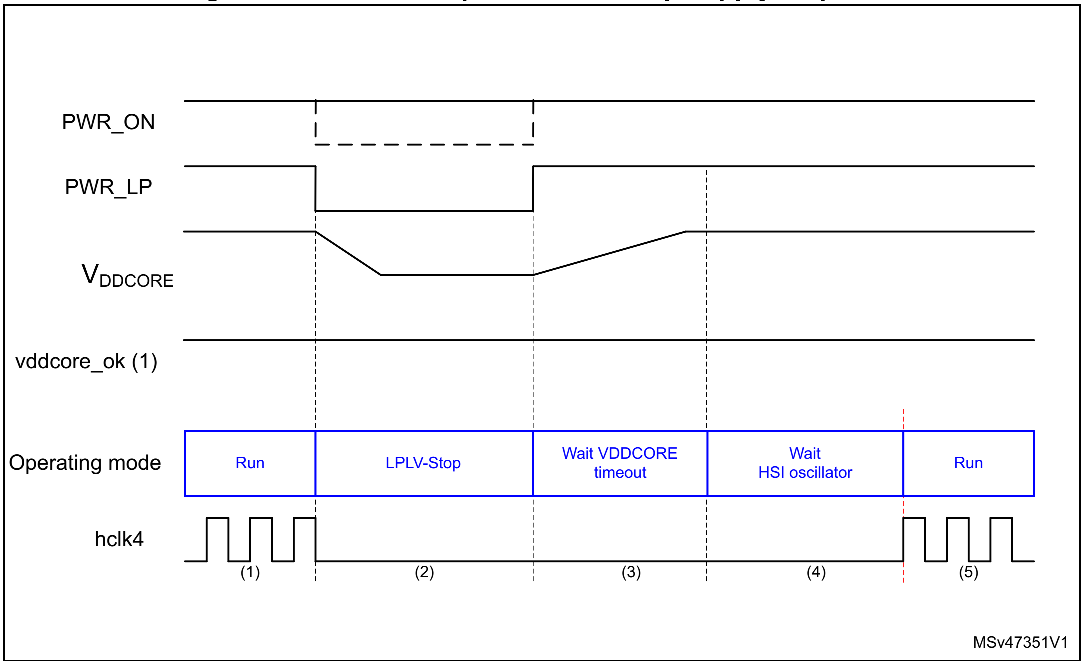


9.3.5 PWR supply LPLV-Stop sequence

The system LPLV-Stop mode sequence is shown in *Figure 32*. The LPLV-Stop mode is entered when selected by the LPDS and LVDS register bits in *PWR control register 1 (PWR_CR1)*.

1. When entering LPLV-Stop mode the hclk4 is stopped. The oscillators can be stopped in order to reduce the power consumption. For detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*.
2. In the LPLV-Stop mode the PWR_ON is either kept high (pwr_on) or follows the PWR_LP (pwr_omlp) as selected with the LPCFG register bit in *PWR control register 1 (PWR_CR1)*. The PWR_LP is asserted, signaling LPLV-Stop. After, the external regulator may enter Low-power low-voltage mode and lower the V_{DDCORE} supply.
3. On a wakeup event the external regulator is taken out of Low-power low-voltage mode via PWR_LP and a delay $t_{SEL\_VDDCORETEMPO}$, is started to wait for the V_{DDCORE} to reach the Run mode operating supply level.
4. After this delay the HSI is enabled and the clock restore process is performed. See RCC: *The clock restore sequence description* for more details.
5. Once the oscillator is stable, the system enters Run mode.

Figure 32. Device low-power LPLV-Stop supply sequence

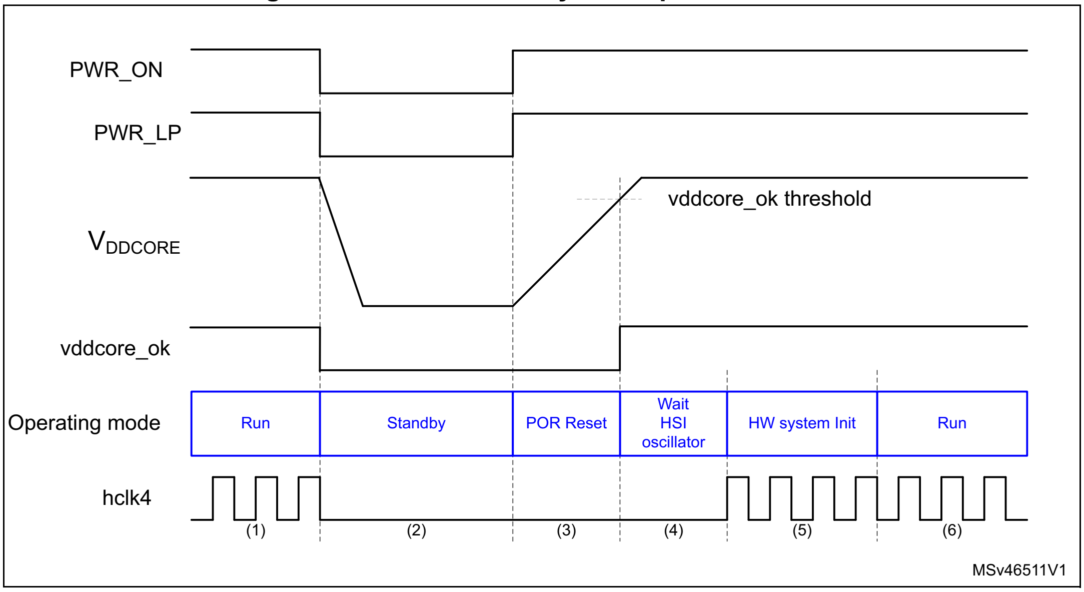


9.3.6 PWR supply Standby sequence

The system Standby mode sequence is shown in *Figure 33*.

1. When entering Standby mode, the PWR_ON signal requests the V_{DDCORE} supply to be powered off, the hclk4 is stopped. The oscillators are also stopped.
   If needed, a guaranteed minimum PWR_ON pulse low time can be defined in *PWR control register 3 (PWR_CR3)* bits POPL.
2. On a wakeup event, the external regulator is requested, via the PWR_ON signal, to switch on the V_{DDCORE} supply. As long as the V_{DDCORE} is below the vddcore_ok threshold, the system is kept in Standby.
   When a wakeup event occurs before the guaranteed minimum PWR_ON pulse low time, the external regulator is only requested to switch on the V_{DDCORE} supply till after the minimum PWR_ON pulse low time.
3. Once the V_{DDCORE} supply is above the vddcore_ok threshold level, the HSI oscillator is enabled.
4. Once the oscillator is stable, the hardware initializes the system (option bytes loading), after which Run mode is entered.

Figure 33. Device Standby mode power control.



In Standby mode when the V_{DDCORE} OK monitoring (vddcore_ok) is disabled by PDR_ON_CORE, the NRST_CORE signal shall be activated whenever V_{DDCORE} is powered down.

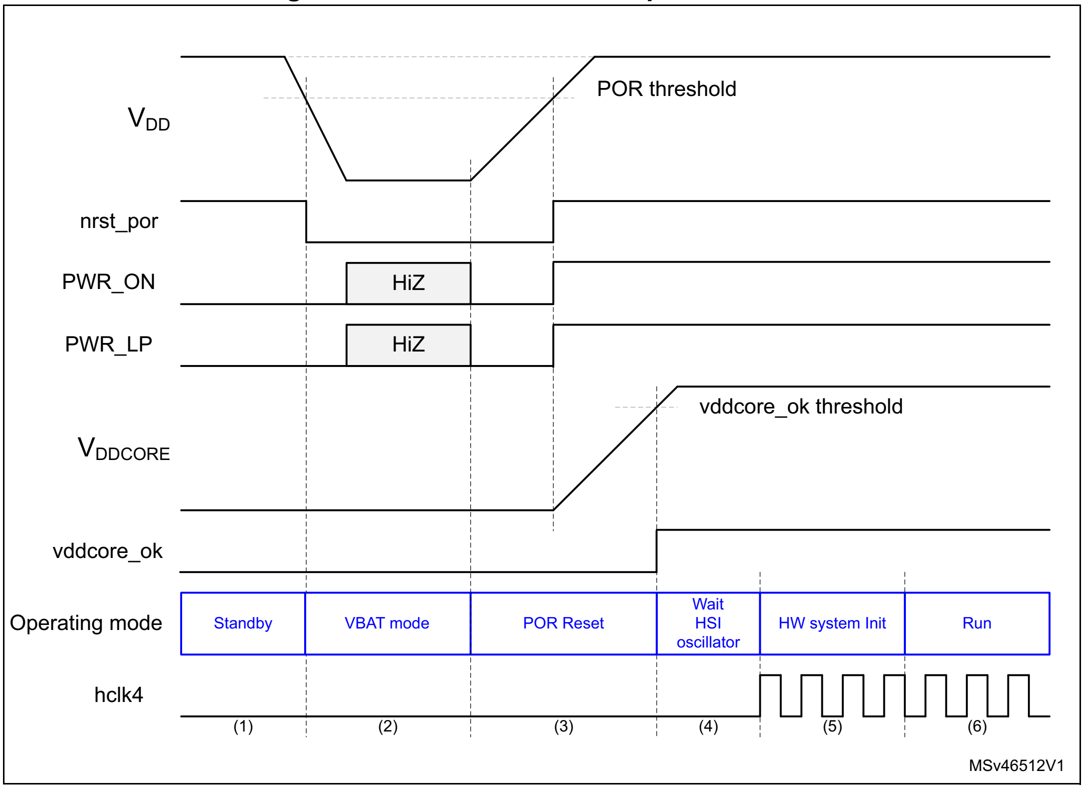
PDR_ON_CORE is reserved for STMicroelectronics production tests and must always be connected to V_{DD} in an application.

9.3.7 PWR supply VBAT sequence from Standby.

The system VBAT mode sequence after Standby is shown in *Figure 34*.

1. When in Standby mode, the device can be set in VBAT mode by powering down the V_{DD} supply. The pwr_on signal keeps requesting the V_{DDCORE} supply to be powered off.
2. When powering down V_{DD}, the device enters VBAT mode. The PWR_ON and PWR_LP signals become HiZ.
3. To exit VBAT mode, the V_{DD} supply shall be reestablished, the POR monitors the V_{DD} supply. Once the supply is above the POR threshold level the External Voltage regulator providing the V_{DDCORE} supply is enabled via the pwr_on signal:
   As long as the V_{DDCORE} is below the vddcore_ok threshold the system is kept in reset.
4. Once the V_{DDCORE} supply is above the vddcore_ok threshold level, the system is taken out of reset, where after the HSI oscillator is enabled.
5. Once the oscillator is stable, the hardware initializes the system (option bytes loading), after which Run mode is entered.

Figure 34. Device VBAT mode power control



When VBAT mode is entered from Run, Stop, LP-Stop or LPLV-Stop mode, the V_{DD} and V_{DDCORE} supplies shall both be powered down.

9.3.8 PWR V_{SW} domain

To retain the content of the V_{SW} domain (RTC, backup registers, backup RAM, and retention RAM) when V_{DD} is turned off, VBAT pin can be connected to an optional standby voltage supplied from a battery or an another source.

Switching to the V_{BAT} supply (VBAT mode) is controlled by the power-down reset (PDR) embedded in the reset block, monitoring the V_{DD} supply.

Warning: **During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR is detected, the power switch between V_{BAT} and V_{DD} remains connected to V_{BAT}.**
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (refer to the datasheet for the value of $t_{RSTTEMPO}$) and V_{DD} > V_{BAT} + 0.6 V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

When the V_{DD} supply is present, the V_{SW} domain is supplied from V_{DD}. This allows to save V_{BAT} power supply battery life time.

If no external backup battery is used in the application, it is recommended to connect VBAT externally to V_{DD}.

Whenever the V_{DD} supply is present and above the PDR threshold, the backup domain I/Os are supplied by V_{DD}, the following functions are available:

- PC14 and PC15 can be used as either GPIO (if V_{DDCORE} is present) or as LSE pins.
- PC13, PI8 and PC1 can be used as either GPIO (if V_{DDCORE} is present) or as RTC or TAMP pins.

Note: Due to the fact that the VSW switch only sinks a limited amount of current, the use of PC1, PC13 to PC15, and PI8 as GPIOs is restricted. See Datasheet for details.

When the V_{DD} supply is absent and a supply is present on VBAT, the backup domain I/Os are supplied by V_{BAT}, the following functions are available in VBAT mode:

- PC14 and PC15 can be used as LSE pins only.
- PC13, PI8 and PC1 can be used as RTC or TAMP pins.

PWR V_{SW} domain access

After a system reset the RTC registers and RTC backup registers are protected against possible unwanted write accesses. To enable access to the V_{SW} domain, proceed as follows:

1. Set the DBP bit in the *PWR control register 1 (PWR_CR1)* to enable access to the V_{SW} domain.

For more detail on RTC and backup registers access see *Section 48: Real-time clock (RTC)* in reference manual.

PWR Backup RAM

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode.

- In Run, Stop, LP-Stop and LPLV-Stop modes the backup RAM is supplied from the V_{DDCORE} supply.
- In Standby and VBAT modes, the backup RAM is supplied through the Backup regulator in the V_{SW} domain.

When the backup regulator is enabled by BREN register bit in *PWR control register 2 (PWR_CR2)*, the backup RAM content is retained even in Standby and/or VBAT mode (it can be considered as an internal EEPROM when V_{BAT} is always present). The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or VBAT modes.

When enabling the backup regulator, the readiness of the backup supply shall be checked with the BRRDY register bit in *PWR control register 2 (PWR_CR2)*, before entering Standby or VBAT mode.

The backup RAM is not mass erased by an tamper event, instead it is read protected to prevent confidential data, such as cryptographic private key, from being accessed. To re-gain access to the backup RAM after a tamper event, it needs to be first erased. The backup RAM can be erased:

- After a tamper event, by performing a dummy write with zero as data to the backup RAM.

PWR retention RAM

The retention domain includes 64 Kbytes of retention RAM accessible in 32-bit, 16-bit or 8-bit data mode.

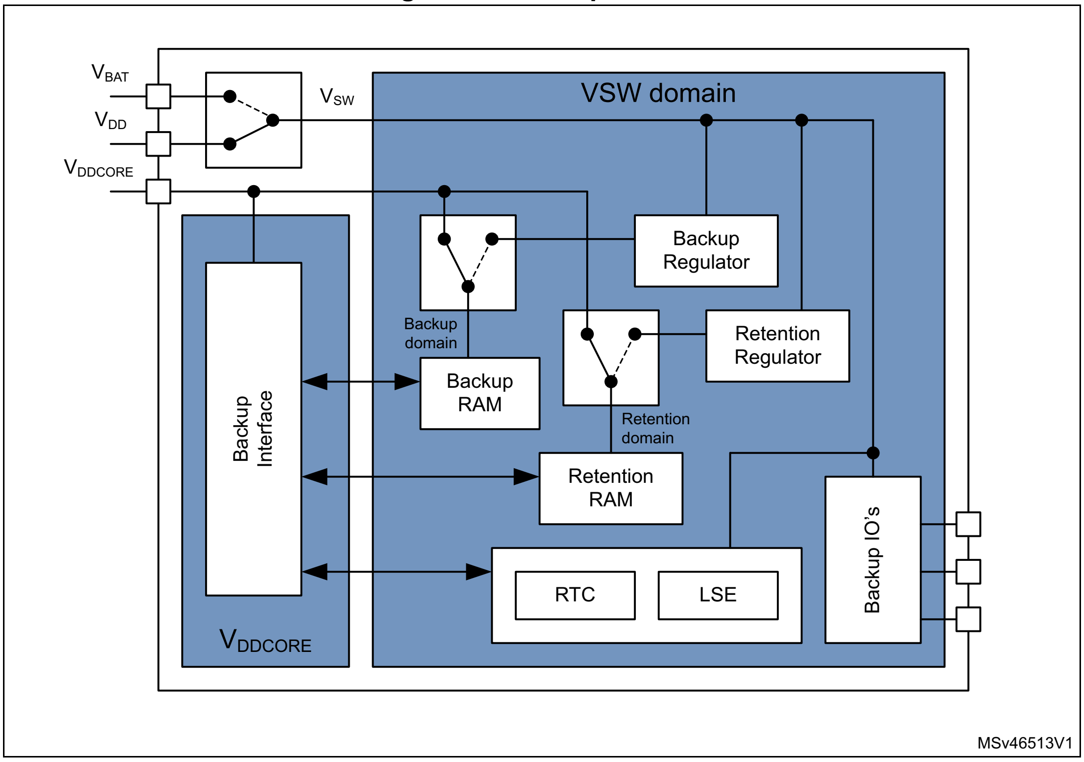
- In Run, Stop, LP-Stop and LPLV-Stop modes the retention RAM is supplied from the V_{DDCORE} supply.
- In Standby and VBAT modes, the retention RAM is supplied through the retention regulator in the V_{SW} domain.

When the retention regulator is enabled by the RREN register bit in *PWR control register 2 (PWR_CR2)*, the retention RAM content is retained even in Standby and/or VBAT mode (it can be considered as an Non-volatile memory when V_{BAT} is always present). The retention regulator can be ON or OFF depending whether the application needs the retention RAM function in Standby or VBAT modes.

When enabling the retention regulator, the readiness of the retention supply shall be checked with the RRRDY register bit in *PWR control register 2 (PWR_CR2)*, before entering Standby or VBAT mode.

In Standby and VBAT mode, when the retention supply drops below a threshold level, the RRRDY bit is reset. The retention regulator shall be disabled and then re-enabled to have the RRRDY bit set again. This function may be used to detect issues with the retention RAM integrity.

Figure 35. Backup domain



9.3.9 PWR VBAT battery charging

When V_{DD} is present, it is possible to charge the external battery on VBAT through an internal resistance between the 2 supplies.

The VBAT charging is done either through a 5 kOhm resistor, or through a 1.5 kOhm resistor depending on the VBRS bit value in *PWR control register 3 (PWR_CR3)*.

The battery charging is enabled by setting the VBE bit in *PWR control register 3 (PWR_CR3)*. It is automatically disabled when entering VBAT mode.

9.3.10 PWR analog supply

PWR separate analog V_{DDA} supply.

The analog supply domain has separate V_{DDA} and V_{SSA} pads to allow the supply to be filtered and shielded from noise on the PCB. This allows to improve the ADC and DAC conversion accuracy.

- The analog voltage supply input is available on a separate V_{DDA} pin.
- An isolated supply ground connection is provided on pin V_{SSA}.

PWR analog reference voltage V_{REF}.

To allow better accuracy on low voltage signals, the ADC and DAC have furthermore a separate reference voltage V_{REF+} pin. The user may connect a separate external reference voltage on V_{REF+}. The V_{REF+} controls the highest voltage, represented by the full scale value. The lower voltage reference V_{REF-} is connected together with V_{SSA}.

When enabled by the voltage reference buffer ENVR bit in the *Section 31.3.1: VREFBUF control and status register (VREFBUF_CSR)*, the V_{REF+} is provided from the internal voltage reference buffer. The internal voltage reference buffer can also provide a reference voltage to external components through the pin, see *Section 31: Voltage reference buffer (VREFBUF)*.

When the internal voltage reference buffer is disabled by ENVR, the V_{REF+} can also be used as a reference supply to external circuits.

9.3.11 PWR 1V8 regulator

The 1V8 regulator is supplied from the V_{DD} supply and generates the V_{DDA1V8_REG} supply. The USB HS PHY is directly connected to this supply.

The use of the integrated 1V8 regulator has to be enabled by the BYPASS_REG1V8 pin.

When enabled by the BYPASS_REG1V8 pin and the REG18EN register bit in *PWR control register 3 (PWR_CR3)*, the V_{DDA1V8_REG} is provided from the 1V8 regulator. Before using the V_{DDA1V8_REG}, the availability shall be checked with the REG18RDY register bit in *PWR control register 3 (PWR_CR3)*.

When the 1V8 regulator is disabled (bypass) by the BYPASS_REG1V8 pin or the REG18EN register bit, the V_{DDA1V8_REG} can be provided from an external supply.

For more information on the 1V8 regulator see *Section 9.3: PWR power supplies*.

9.3.12 PWR 1V1 regulator

The 1V1 regulator is supplied from the V_{DD} supply and generates the V_{DDA1V1_REG} supply. The USB HS PHY is directly connected to this supply.

The 1V1 regulator is enabled by the REG11EN register bit in *PWR control register 3 (PWR_CR3)*. Before using the supply from the 1V1 regulator, the availability shall be checked with the REG11RDY register bit in *PWR control register 3 (PWR_CR3)*.

For more information on the 1V1 regulator see *Section 9.3: PWR power supplies*.

9.4 PWR power supply supervision

The power supply level monitoring is available on the following supplies:

- V_{DD} via POR/PDR *Section 9.4.1*, BOR *Section 9.4.2*., and PVD monitor *Section 9.4.3*.
  - The POR/PDR monitoring flag is available from the PORRSTF register bit in the RCC.
  - The BOR monitoring flag is available from the BORRSTF register bit in the RCC.
  - The PVD monitoring flag is available from the PVDO register bit in *PWR control status register 1 (PWR_CSR1)*. In addition an interrupt and wakeup can be generated via the EXTI.
- V_{DDA} via AVD monitor, *Section 9.4.5*.
  - The AVD monitoring flag is available from the AVDO register bit in *PWR control status register 1 (PWR_CSR1)*. In addition an interrupt and wakeup can be generated via the EXTI.
- V_{BAT} via VBAT threshold, *Section 9.4.6*.
  - The VBAT monitoring could be enabled in *PWR control register 2 (PWR_CR2)*. The monitoring could generate tamper event via the TAMP.
- V_{DDCORE} via vddcore_ok which keeps V_{DDCORE} domain in reset as long as the level is not OK, *Section 9.5*.
  - The V_{DDCORE} OK monitoring flags are available from the SBF register bit in *PWR MCU control register (PWR_MCUCR)*, in *PWR MCU control register (PWR_MCUCR)* and from the VCORERSTF register bit in the RCC.
- V_{SW} via rst_vsw, which keeps V_{SW} domain in reset as long as the level is not OK.
  - The VSW monitoring has no flag. The VSW registers reset value could be used.
- V_{BKP} via a BRRDY in *PWR control register 2 (PWR_CR2)*
- V_{RET} via a RRRDY in *PWR control register 2 (PWR_CR2)*.
- V_{DD3V3_USBFS} via USB33RDY*PWR control register 3 (PWR_CR3)*.
- V_{DDA1V8_REG} via REG18RDY*PWR control register 3 (PWR_CR3)*
- V_{DDA1V1_REG} via REG11RDY*PWR control register 3 (PWR_CR3)*

9.4.1 PWR power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that allows a proper startup operation.

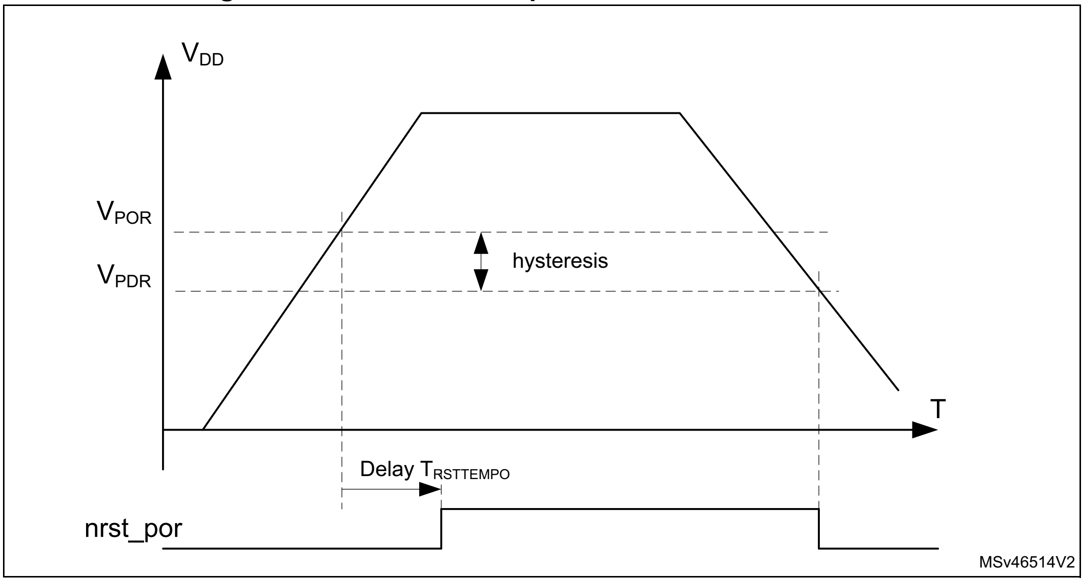
The system remains in Reset mode when V_{DD} is below a specified V_{POR} threshold, without the need for an external reset circuit. Once the V_{DD} supply level is above the V_{POR} threshold, the system is taken out of reset. More details concerning the power-on/power-down reset threshold, refer to the electrical characteristics in the datasheet.

The POR/PDR generates also an application reset (NRST).

The POR/PDR can be enabled/disabled by the device input pin PDR_ON. When disabled, the V_{DD} power on reset shall be provided on the NRST device input pin.

PDR_ON is reserved for STMicroelectronics production tests and must always be connected to V_{DD} in an application.

Figure 36. Power-on reset/power-down reset waveform



1. For the thresholds and hysteresis values, refer to the datasheet.

9.4.2 PWR brownout reset (BOR)

During power-on, the brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through the system option bytes. By default, BOR is off. When selecting another BOR threshold, this takes effect only after the option bytes are loaded by the device. The following programmable V_{BOR} thresholds can be selected:

- BOR off (VBOR0): reset threshold level for full range voltage operation.
- BOR Level 1 (VBOR1): reset threshold level for above 2.10 V typ. voltage operation.
- BOR Level 2 (VBOR2): reset threshold level for above 2.40 V typ. voltage operation.
- BOR Level 3 (VBOR3): reset threshold level for above 2.70 typ. voltage operation.

Refer to Datasheet for more information on the BOR thresholds.

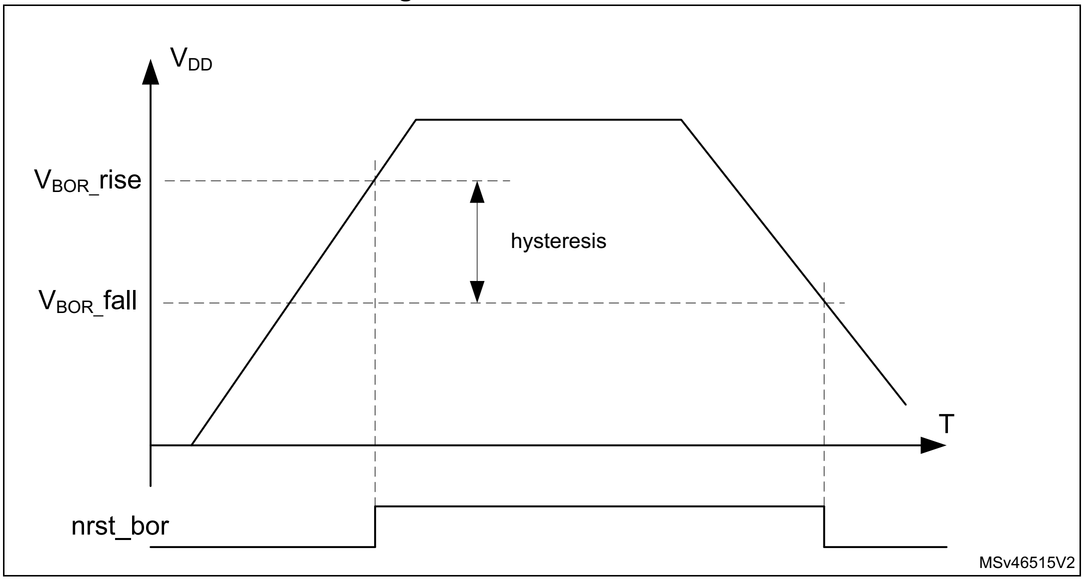
The BOR generates also an application reset (NRST).

When the BOR is enabled and the V_{DD} supply voltage drops below the selected V_{BOR} threshold, an Application reset (NRST) is generated.

The BOR can be disabled by programming the system option bytes. To disable the BOR function, V_{DD} must have been higher than V_{BOR0} to start the system option byte programming sequence. The power down is then monitored by the PDR (see *Section 9.4.1*)

The BOR threshold hysteresis for level 1, 2, and 3 is ~100 mV, for level 0 it is ~40 mV (between the rising and the falling edge of the supply voltage).

Figure 37. BOR thresholds



1. For the thresholds and hysteresis values, refer to the datasheet.

9.4.3 PWR VDDCORE OK reset

The system has an integrated circuitry that allows proper startup operation of the V_{DDCORE} domain.

The V_{DDCORE} domain remains in Reset mode when V_{DDCORE} is below the operation threshold vddcore_ok. Once the V_{DDCORE} supply level is above the operation threshold vddcore_ok, the V_{DDCORE} domain is taken out of reset. For more details concerning the V_{DDCORE} OK reset threshold, refer to the electrical characteristics of the datasheet.

The V_{DDCORE} OK detector can be enabled/disabled by the device input pin PDR_ON_CORE. When disabled, the V_{DDCORE} domain reset shall be provided on the NRST_CORE device input pin.

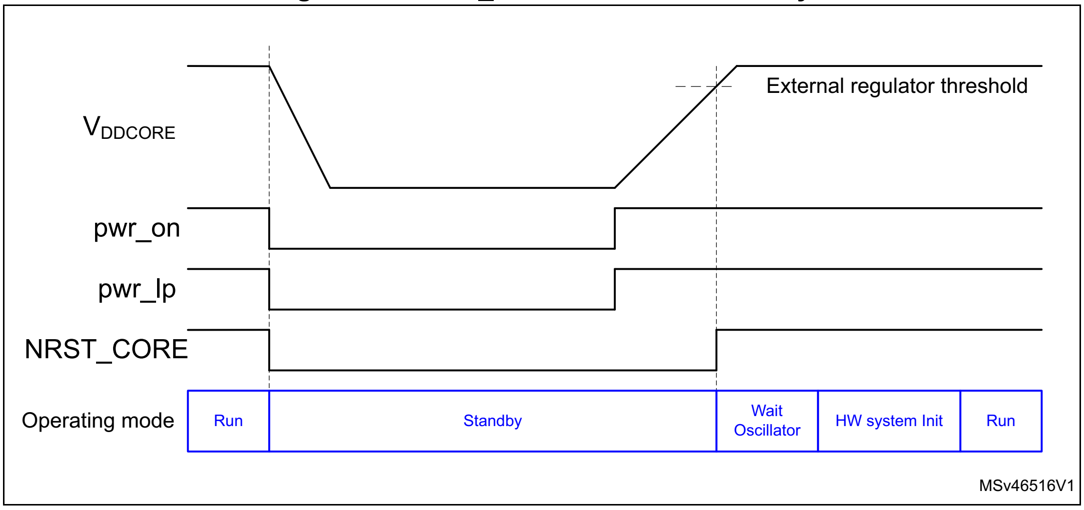
PDR_ON_CORE is reserved for STMicroelectronics production tests and must always be connected to V_{DD} in an application

When the V_{DDCORE} OK detector is disabled, the V_{DDCORE} supply level can be lowered in LPLV-Stop mode.

When the V_{DDCORE} OK detector is disabled, the NRST_CORE signal shall be used in Standby mode see *Figure 38*.

The NRST_CORE is operational irrespective of the PDR_ON_CORE state. Hence it also resets the V_{DDCORE} domain when the V_{DDCORE} OK detector is enabled by PDR_ON_CORE.

Figure 38. NRST_CORE control in Standby



9.4.4 PWR programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[2:0] bits in the *PWR control register 1 (PWR_CR1)*.

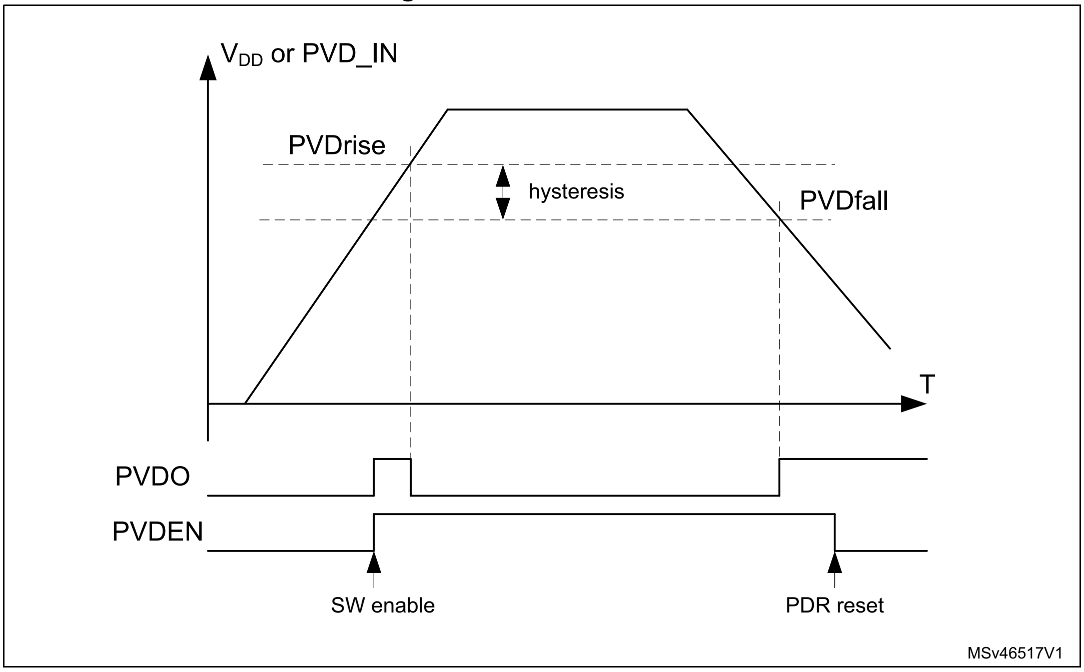
The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case, the voltage level on PVD_IN is compared to the internal VREFINT level.

The PVD is enabled by setting the PVDEN bit in *PWR control register 1 (PWR_CR1)*.

The PVD is not available in Standby mode.

A PVDO flag is available, in the *PWR control status register 1 (PWR_CSR1)*, to indicate whether V_{DD} or voltage level on PVD_IN is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The PVDO output interrupt can be generated when V_{DD} or voltage level on PVD_IN drops below the PVD threshold and/or when V_{DD} or voltage level on PVD_IN rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example, the service routine could perform emergency shutdown tasks.

Figure 39. PVD thresholds



1. For the thresholds and hysteresis values, refer to the datasheet.

9.4.5 PWR analog voltage detector (AVD)

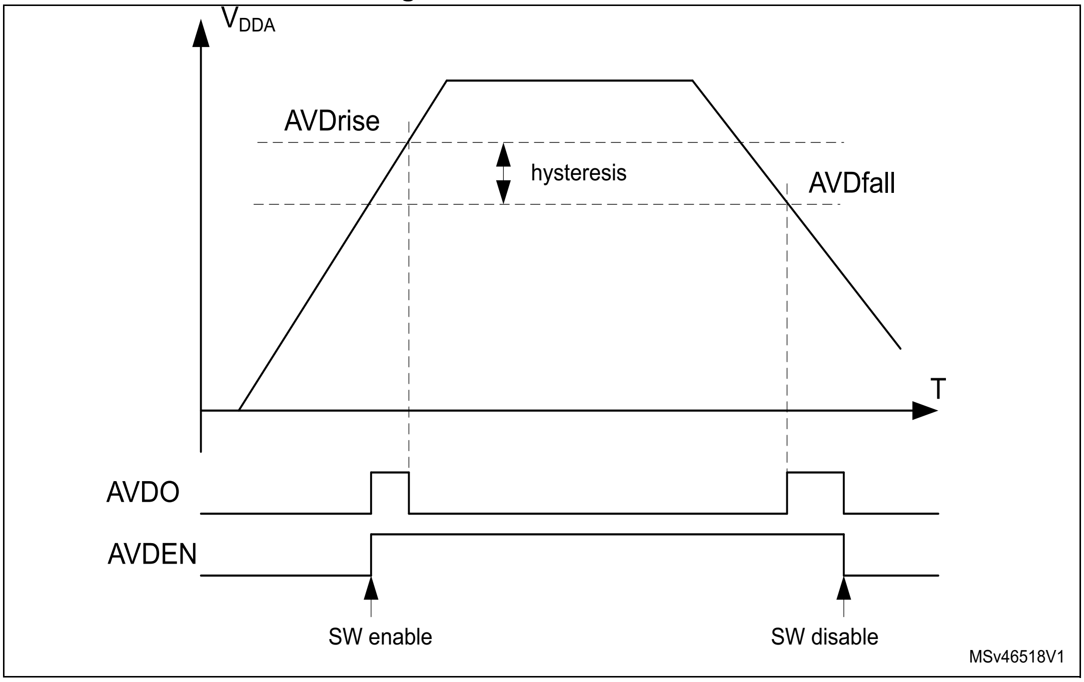
The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in *PWR control register 1 (PWR_CR1)*.

The AVD is not available in Standby mode.

An AVDO flag is available, in the *PWR control status register 1 (PWR_CSR1)*, to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example, the service routine could indicate when the V_{DDA} supply drops below a minimum level.

Figure 40. AVD thresholds



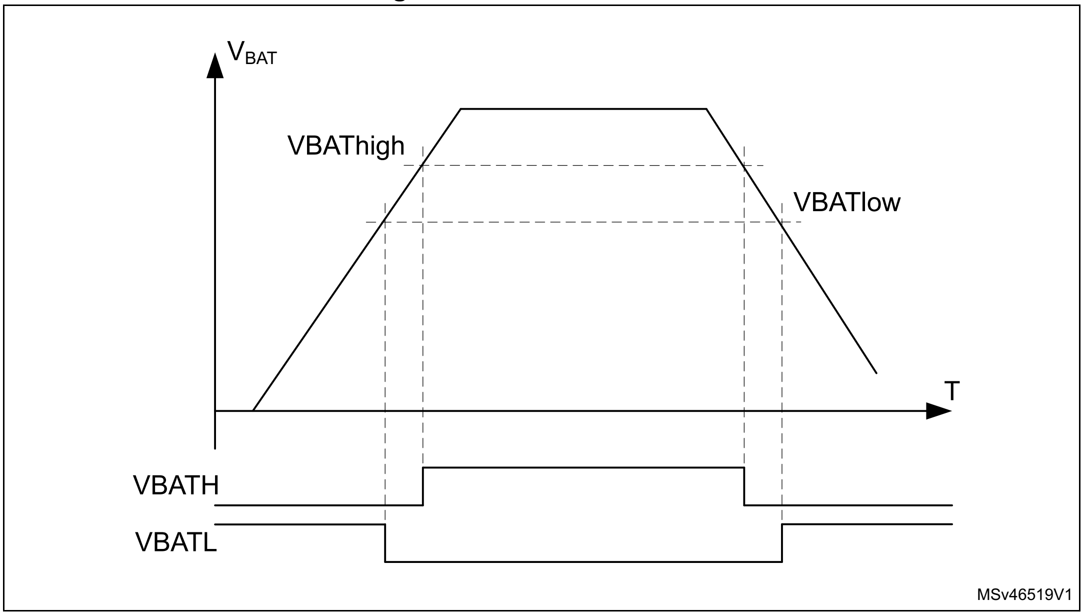
1. For the thresholds and hysteresis values, refer to the datasheet.

9.4.6 PWR battery voltage thresholds

During VBAT mode, the battery voltage V_{BAT} supply can be monitored by comparing it with two threshold levels. The VBAT supply monitor can be enabled/disabled with MONEN bit in *PWR control register 2 (PWR_CR2)*. When enabled, the battery voltage thresholds increases power consumption.

The VBATL and VBATH are available on tamper signals (see *Section 49: Tamper and backup registers (TAMP)*).

Figure 41. VBAT thresholds



1. For the thresholds and hysteresis values, refer to the datasheet.

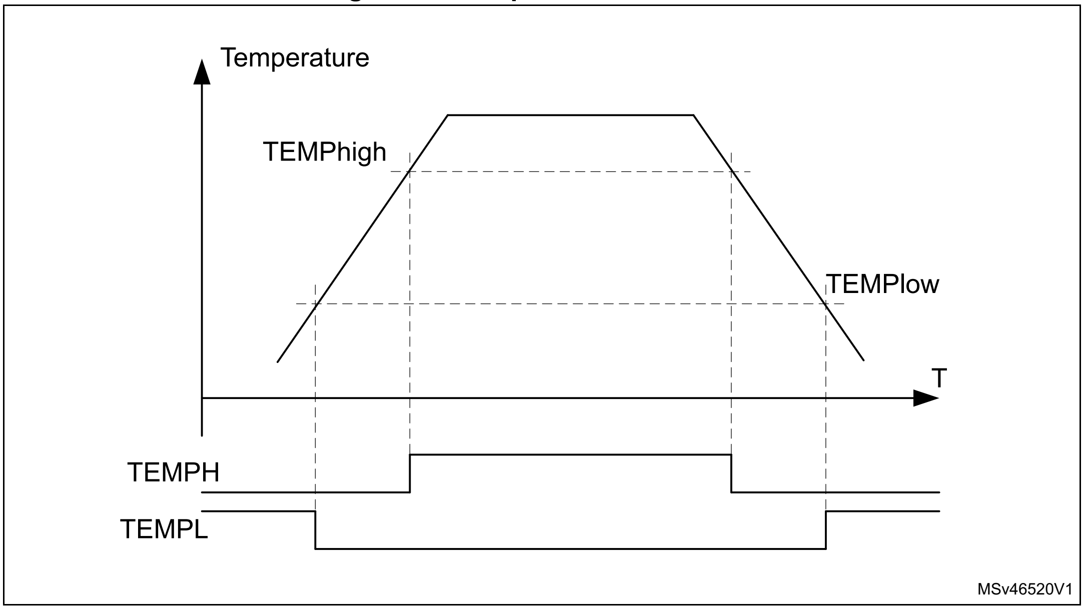
9.4.7 PWR temperature thresholds

The temperature can be monitored by comparing it with two threshold levels. TEMPH flag and TEMPL flag are available, in the *PWR control register 2 (PWR_CR2)*, to indicate if the device temperature is higher or lower than the threshold. The temperature monitor can be enabled/disabled with MONEN bit in *PWR control register 2 (PWR_CR2)*. When enabled, the temperature thresholds increases power consumption. As an example the levels could be used to trigger a routine to perform temperature control tasks.

The temperature thresholds, when enabled, are also available in Standby and VBAT modes.

The TEMPL and TEMPH are available on tamper signals (see *Section 48: Real-time clock (RTC)*).

Figure 42. Temperature thresholds



1. For the thresholds and hysteresis value, refer to the datasheet.

9.5 PWR power management

The power management controls the V_{DDCORE} supply in accordance with the system operation modes (see *Section 9.5.1: PWR operating modes*).

There is a single V_{DDCORE} domain for both the MPU and MCU systems. The system, MPU and MCU can be in one of the following operating modes:

- Run, CRun/CSleep (power On, clock On)
- Stop, LP-Stop, LPLV-Stop, CStop (power On, clock Off)
- CStandby (power On, clock Off, MPU reset).
- Standby (power Off, clock Off).

At the PWR controller level, the Dual core Cortex-A7 is seen as a single MPU.

The system operating mode depends on both MPU and MCU systems. For the system to be in Stop, LP-Stop, LPLV-Stop or Standby, both MPU and MCU need to be in CStop or CStandby, see *Table 33: System Low-power mode summary*.

The V_{DDCORE} is supplied from a single supply at a common level. The V_{DDCORE} supply level follows the system operating mode (Run, Stop, LP-Stop, LPLV-Stop and Standby).

9.5.1 PWR operating modes

Several system operating modes are available to tune the system according to the performance needs, i.e. when the MPU and MCU do not need to execute code and are waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

The operating modes allow the control of the clock distribution to the different system parts and the power of the system. The system operation mode is driven by the MPU sub-system and MCU sub-system. The MPU and MCU sub-systems may include multiple bus matrix depending on its peripheral allocation (see *Section 10: Reset and clock control (RCC)*). The following operating modes for the different system parts are defined:

- MPU and MCU sub-system modes:
  - **CRun**
    - The MPU/MCU and the MPU/MCU sub-system peripheral(s) according to RCC PERxEN are clocked.
  - **CSleep**:
    - The MPU/MCU clocks are stalled and the MPU/MCU sub-system allocated peripheral(s) clock operate according to RCC PERxLPEN. When the MPU/MCU enters CSleep with WFE, the MPU/MCU sub-system allocated peripheral(s) clock operate as in MPU/MCU CRun mode, irrespective of RCC PERxLPEN.
  - **CStop**:
    - The MPU/MCU and the MPU/MCU sub-system peripheral(s) clock are stalled. The wakeup depends on the system mode.
    1) When the system mode Run has been kept or Stop, LP-Stop or LPLV-Stop has been entered, the MPU/MCU wakes up with an interrupt or event.
    2) When the system mode Standby has been entered, the MPU/MCU wakes up with a reset.
  - **CStandby** (for MPU only)

    - The MPU and the MPU sub-system peripheral(s) clock are stalled, and the MPU always wakes up with a reset.

    1) When the system mode Run has been kept or Stop, LP-Stop or LPLV-Stop has been entered, the MPU wakes up with a local MPU reset, see *Section 10.3.3: The local resets*.

    2) When the system mode Standby has been entered, the MPU wakes up with a reset.
- System modes
  - **Run**
    The various sub-system clocks are running according to RCC configuration.
    - The MPU or MCU sub-system is in CRun or CSleep
  - **Stop**
    The LPDS bit in *PWR control register 1 (PWR_CR1)* selects Stop.
    The various sub-system clocks are stalled.
    - Both MPU and MCU sub-systems are in CStop or CStandby.
    and
    - At least one PDDS[a] bit selects Stop.
  - **LP-Stop**
    The LPDS bit in *PWR control register 1 (PWR_CR1)* selects LP-Stop. The LVDS bit in *PWR control register 1 (PWR_CR1)* selects normal voltage.

The various sub-system clocks are stalled.
- Both MPU and MCU sub-systems are in CStop or CStandby.
and
- At least one PDDS[a] bit select Stop.

– **LPLV-Stop**

  The LPDS and LVDS bits in *PWR control register 1 (PWR_CR1)* select LPLV-Stop.

  The various sub-system clocks are stalled.

  - Both MPU and MCU sub-systems are in CStop or CStandby

  and

  - At least one PDDS[a] bit selects Stop.

– **Standby**

  The system is powered down.
  - MPU sub-system is in CStandby or CStop with CSTBYDIS = 1 and MCU sub-system is in CStop
  and
  - All PDDS[a] bits select Standby.

In Run mode power consumption can be reduced by:

- Gating the clocks to the AHBx and APBx peripherals when they are unused with PERxEN (see *Section 10: Reset and clock control (RCC)*).

a. PPDS bit in the *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)* registers.

PWR MPU Low-power mode summary

The Dual Cortex-A7 core MPU system supports the following Low-power modes:

Table 30. MPU Low-power mode summary

</table>

1. For STPREQ_P[1:0] register bits functionality refer to the RCC.
2. At least one MPU processors is in WFE and the other MPU processor is in WFE or WFI.
3. Wakes up the respective processor associated with the event or interrupt.
4. All CPU processors are in WFI.
5. The MPU sub-system peripherals having a PERxLPEN bit operates accordingly.
6. The AXI bus clock may be ON due to the MCU with allocated peripherals activity.

Note: The Dual Cortex-A7 core MPU system does not support the individual processor shutdown mode from Arm.

PWR MCU Low-power mode summary

Table 31. MCU Low-power mode summary

MCU	Entry	Wakeup	Processor clock	Bus matrix clocks
CRun	-	-	ON	ON
CSleep	Arm Cortex-M4 SCR SLEEPDEEP = 0 WFE	Any MCU interrupt or event or reset	OFF	ON/OFF(1)
	Arm Cortex-M4 SCR SLEEPDEEP = 0 WFI or return from ISR	Any MCU interrupt or reset		
CStop	Arm Cortex-M4 SCR SLEEPDEEP = 1 WFE	Any MCU EXTI interrupt or event or reset		OFF/ON(2)
	Arm Cortex-M4 SCR SLEEPDEEP = 1 WFI or return from ISR	Any MCU EXTI interrupt or reset		

1. The MCU sub-system peripherals having a PERxLPEN bit operates accordingly.
2. The AHB bus clock may be ON due to the MPU activity.

PWR system Low-power modes summary

The system Low-power modes are derived from the MPU and MCU Low-power modes.

1. The DDR operation state is only presented for information. i.e. The DDR may be Off when MPU is in CRun, e.g. when executing from BOOTROM or it may be in self refresh when the system is in any of its operation modes.
2. The sys-oscillators: HSI/HSE/CSI oscillators configured ON in RCC.
3. At least 1 PDDS bit selects the Stop mode (PPDS bit in registers *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)*).

4. When the system oscillator HSI, CSI or HSE is used, the state is controlled by respective xxxKERON, else the system oscillator is OFF (see *Section 10: Reset and clock control (RCC)*).
5. Settings in *PWR control register 3 (PWR_CR3)* bits POPL have no impact on the LP-Stop and LPLV-Stop mode PWR_ON and PWR_LP pulse low time.
6. A guaranteed minimum PWR_ON and PWR_LP pulse low time can be defined in *PWR control register 3 (PWR_CR3)* bits POPL.

Table 34. Functionalities depending on system operating mode[1] (continued)

Peripheral	Run	Sleep	Stop and LP-Stop		LPLV-Stop		Standby		VBAT
			-	Wakeup capability	-	Wakeup capability	-	Wakeup capability	
HSEM	O	O	R	-	R	-	-	-	-
GPIOs	O	O	R	O	R	O	-	5 pins (10)	-

1. Legend: Y = Yes (Enable). O = Optional (Disable by default. Can be enabled by software). R = data/state retained. - = Not available; highlighted in gray for wakeup mode.
2. The SRAM clock can be gated on or off.
3. The BKPSRAM and RETSRAM content can optionally be retained when enabled.
4. Some peripherals with wakeup from Stop capability can request HSI to be enabled. In this case, HSI is woken up by the peripheral, and only feeds the peripheral which requested it. HSI is automatically put off when the peripheral does not need it anymore.
5. UART reception is functional in Stop mode, and generates a wakeup interrupt on Start, address match or received frame event.
6. I2C address detection is functional in Stop mode, and generates a wakeup interrupt in case of address match
7. SPI transmission and reception is functional in Stop mode, and generates a wakeup interrupt in case of FIFO thresholds, end of transfer, errors, ...
8. Only with LSE or LSI as kernel clock source.
9. Not present on all the product part numbers, see the related datasheet for more information.
10. The I/Os with wakeup from Standby/Shutdown capability is only available from a limited number of pins.

9.5.2 PWR power modes

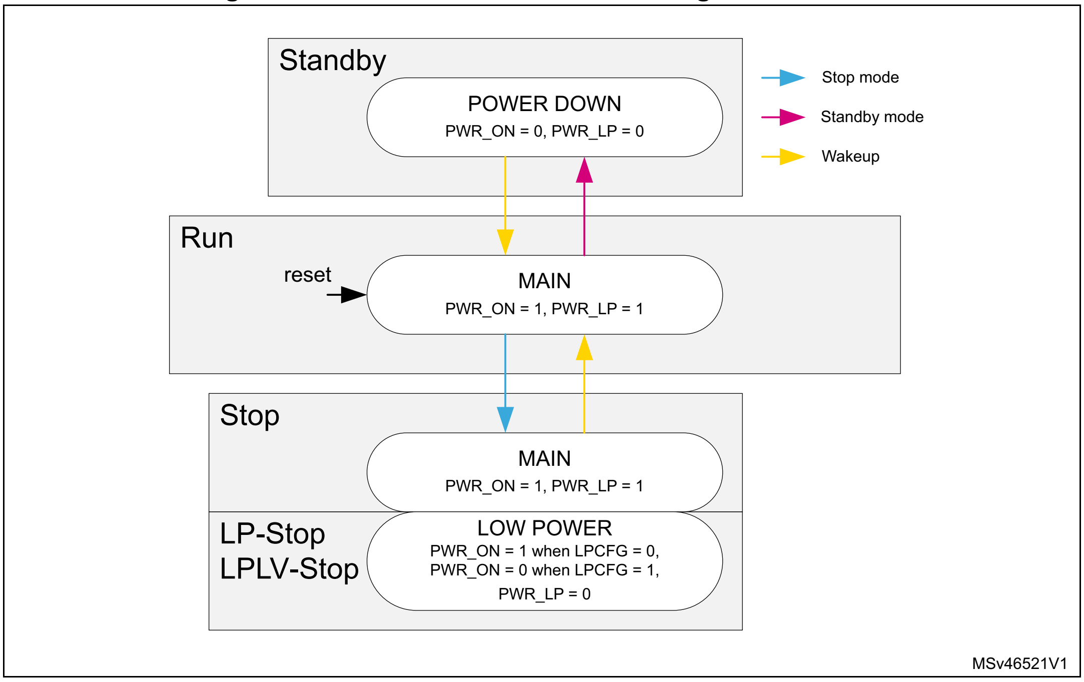
The power control handles the V_{DDCORE} supply for system Run, Stop, LP-Stop, LPLV-Stop and Standby modes. The system mode depends on the individual MPU and MCU sub-system modes (CRun, CSleep, CStop, CStandby).

- In Run mode the V_{DDCORE} is supplied.
- In Stop and LP-Stop modes the V_{DDCORE} is supplied.
- In LPLV-Stop mode the V_{DDCORE} may be supplied at a lower level.
- In Standby mode the V_{DDCORE} supply is switched off.

In system Stop mode, the PWR_LP is kept set high. In system LP-Stop mode, the PWR_LP is cleared to low, allowing an external regulator to switch between main power and Low-power mode with a reduced load capability and in LPLV-Stop mode to lower the V_{DDCORE} supply level.

In system Stop mode, the PWR_ON is kept asserted. In system LP-Stop mode, the PWR_ON is kept asserted or may be de-asserted according the register bit LPCFG in *PWR control register 1 (PWR_CR1)*, allowing an external regulator to switch between main power and Low-power mode with a reduced load capability and in LPLV-Stop mode to lower the V_{DDCORE} supply level. The definition (Power Off or Low-power mode) of the PWR_ON signal shall have be defined in the external regulator before entering LP-Stop or LPLV-Stop mode.

Figure 43. Power states and external regulator control

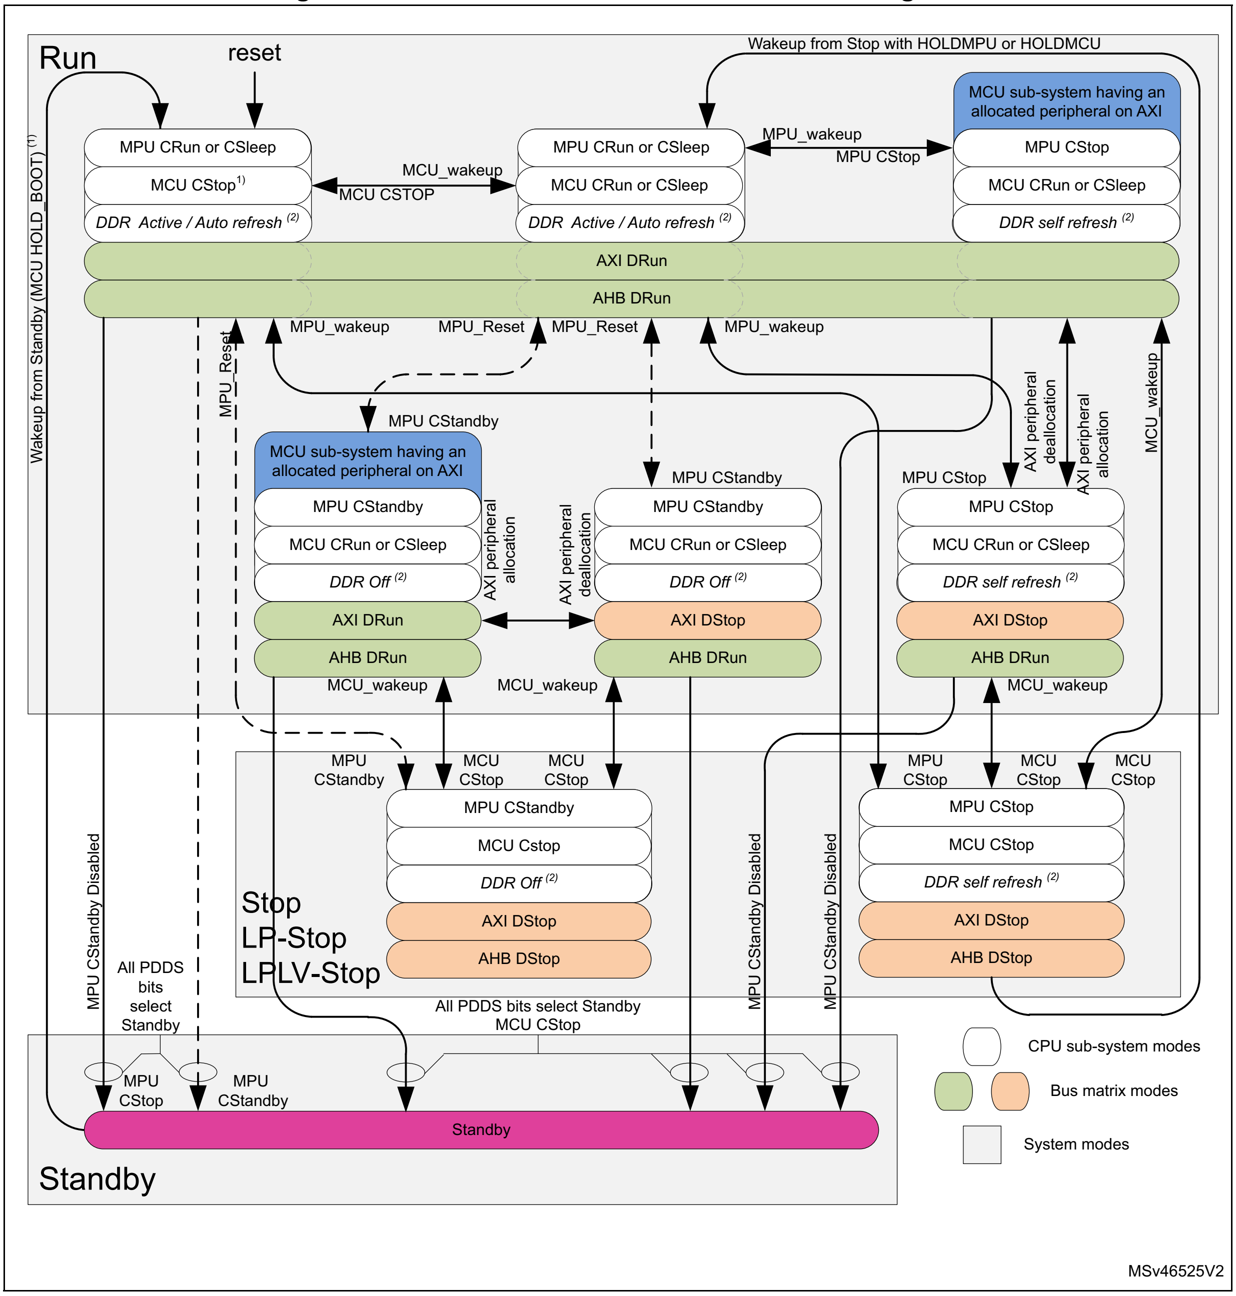


The system mode selection between Stop, LP-Stop or LPLV-Stop and Standby is controlled by the MPU PDDS /MCU PDDS bits and the MPU CSTBYDIS bits in *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)*. The system only enters Standby when both the MPU and MCU PDDS bits allow so.

Table 35. PDDS low-power mode control

MPU CSTBYDIS	MPU PDDS	MCU PDDS	System operation mode
x	0	x	Stop, LP-Stop, LPLV-Stop (with MPU in CStop)
0	1	0	Stop, LP-Stop, LPLV-Stop (with MPU in CStandby)
0	1	1	Standby (with MPU in CStandby)
1	1	1	Standby (with MPU in CStop)

Figure 44. Power control modes detailed state diagram



1. After a wakeup from Standby the MPU and MCU boot as described in *Section 10: Reset and clock control (RCC)* processor hold from standby. When ever MCU is in HOLD_BOOT it does not prevent the system to enter Stop, LP-Stop, LPLV-Stop or Standby.
2. The DDR operation state is only presented for information. i.e. The DDR may be Off when MPU is in CRun, e.g. when executing from Boot ROM.

Power control state transitions are initiated by:

- MPU or MCU going to CStop.
  - *Figure 44* Green transitions system stays in Run.
  - *Figure 44* Blue transitions system enters to Stop, LP-Stop or LPLV-Stop.
  - *Figure 44* Red transitions system enters to Standby.
- MPU going to CStandby
  - *Figure 44* Dotted Red line transitions, entered system mode depend also on MCU mode.
- EXTI wakeup event.
  - *Figure 44* Green transitions MPU or MCU wakes up as from CSleep.
  - *Figure 44* Blue transitions MPU or MCU wakes up from CStop. The STOPF is set.
- Wakeup event
  - *Figure 44* Dotted Red line transitions MPU wakes up from CStandby. The MPU SBFMPU is set.
    - When the system remained in Run no additional flags are set.
    - When the system wakes up from Stop, LP-Stop or LPLV-Stop additionally the STOPF is set.
  - *Figure 44* Red transitions MPU and MCU wakes up from Standby. The SBF is set.
- Peripheral allocation or deallocation
  - *Figure 44* Orange transitions MPU is in CStop or CStandby and MCU allocates a first or deallocates the last peripheral on the AXI bus.

The flags provided to determine from which mode the system exits are shown in *Table 34*. The MPU and MCU have their own set of flags which can be read from *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)*. The MPU and MCU have their own register reset bit CSSF to clear it's own wakeup flags. The MPU and MCU CSSF register bit is located in the same register as the MPU and MCU flags:

Table 36. Low-power mode exit flags

System mode	MPU mode	MCU mode	SBF	SBFMPU	STOPF	Comment
Run	CRun / CStop	CRun / CStop	0	0	0	System contents retained
	CStandby		0	1	0	
Stop LP-Stop LPLV-Stop	CStop	CStop	0	0	1	System contents retained, clock system stopped.
	CStandby		0	1	1	
Standby	CStandby		1	1	0	System contents lost
VBAT(1)	n.a.	n.a.	0	0	0	System contents lost

1. Exit from VBAT mode may be derived from the retained registers in the V_{SW} domain, which are not reset.

9.5.3 PWR system wakeup

From an application reset (NRST, IWDG, ...) and a wakeup from Standby, the system wakes up the MPU and the MCU is kept in HOLD. From this point the MPU BOOTROM manages the startup (see *Processor hold from Standby* in *Section 10: Reset and clock control*

(RCC)). From Stop, LP-Stop and LPLV-Stop the system can be configured to wake up the MPU or MCU independently.

9.6 PWR low-power modes

Several Low-power modes are available to save power when the MPU and/or MCU do not need to execute code (i.e. when waiting for an external event). It is up to the user to select the mode that gives the best compromise between low-power consumption, short startup time and available wakeup sources.

- Slowing down the CPU clock and/or the bus matrix clocks (see *Section 10: Reset and clock control (RCC)*)
- Controlling individual peripheral clocks (see *Section 10: Reset and clock control (RCC)*)
- Low-power modes
  - CSleep (MPU/MCU clock stopped)
  - CStop (MPU/MCU sub-system clock stopped)
  - CStandby (MPU sub-system clock stopped and wakeup via reset)
  - Stop (bus matrix clocks stalled, the oscillators can be stopped, for detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*, normal mode signaled to external regulator).
  - LP-Stop and LPLV-Stop (bus matrix clocks stalled, the oscillators can be stopped, for detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*, Low-power mode signaled to external regulator).
  - Standby (System powered down)

9.6.1 PWR slowing down the CPU clocks and/or the bus matrix clocks

In Run mode, the speed of the MPU, MCU and/or the bus matrix clocks can be reduced, for more details refer to *Section 10: Reset and clock control (RCC)*.

9.6.2 PWR controlling peripheral clocks

In Run mode, the bus clock for individual peripherals can be stopped by the RCC PERxEN register bits at any time to reduce power consumption.

To reduce power consumption in CSleep mode the individual peripheral clocks can be disabled by the RCC PERxLPEN register bit. For the peripherals still receiving a clock in CSleep mode, their clock can be slowed down before entering to CSleep mode.

9.6.3 PWR entering to low-power modes

MPU sub-system Low-power modes CSleep, CStop and CStandby are entered by the MPU when executing the WFI (Wait For Interrupt), or WFE (Wait for Event) instructions.

MCU sub-system Low-power modes CSleep and CStop are entered by the MCU when executing the WFI (Wait For Interrupt), or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M4 System Control register is set on Return from ISR.

The system may enter Stop, LP-Stop, LPLV-Stop or Standby when all EXTI wakeup sources are cleared and both the MPU and MCU are in CStop or CStandby.

9.6.4 PWR exiting from low-power modes

From CSleep mode the MPU and MCU sub-systems exit from low-power mode through any interrupt or event depending how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the GIC/NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the MPU and MCU exits from low-power mode as soon as an event occurs. The wakeup event can be generated either by:
  - GIC/NVIC IRQ interrupt.
    - For MPU, by enabling an interrupt in the peripheral control register and in the GIC.
    Only GIC interrupts with sufficient priority wake up and interrupt the MPU.
    - For MCU, when SEVONPEND = 0 in the Cortex®-M4 System Control register.
    By enabling an interrupt in the peripheral control register and in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
    Only NVIC interrupts with sufficient priority wake up and interrupt the MCU.
    - For MCU when SEVONPEND = 1 in the Cortex®-M4 System Control register.
    By enabling an interrupt in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and when enabled the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.
    All NVIC interrupts wake up the MCU, even the disabled ones.
    Only enabled NVIC interrupts with sufficient priority wake up and interrupt the MCU.
  - Event
    - For MPU and MCU configuring an EXTI line in event mode. When the MPU or MCU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It may be necessary to clear the interrupt flag in the peripheral.

From CStop, Stop, LP-Stop and LPLV-Stop modes the MPU and/or MCU sub-systems exits from low-power mode only through an enabled EXTI interrupt or event depending on how the low-power mode was entered (see above).

From CStandby mode, when the system is in Run, Stop, LP-Stop or LPLV-Stop the MPU sub-system exits from low-power mode only through an enabled EXTI interrupt. Program execution restarts with a MPU reset.

From Standby mode the MPU sub-system exits from low-power mode only through an application reset (NRST, IWDG, ...), WKUPx pins event or a RTC event. Program execution restarts in the same way as after a power on reset (option bytes loading, reset vector fetched, etc.). When the system exits Standby mode the MCU is in HOLD. From this point the MPU BOOTROM manages the startup (see *Processor hold from Standby* in *Section 10: Reset and clock control (RCC)*).

9.6.5 PWR CSleep mode

The CSleep mode applies to the MPU and/or MCU sub-systems. In CSleep mode the MPU/MCU clock is stopped. The MPU and/or MCU sub-systems peripherals clocks operate according to the PERxLPEN bits.

PWR entering to CSleep mode

The CSleep mode is entered according to *Section 9.6.3: PWR entering to low-power modes*.

- For MPU one of the STPREQ_P[1:0] register bits in (see *Section 10: Reset and clock control (RCC)*) is cleared.
- For MCU the SLEEPDEEP bit in the Cortex®-M4 System Control register is cleared.

Refer to *Table 37* for MPU and *Table 38* for MCU, for details on how to enter to CSleep mode.

PWR exiting from CSleep mode

The CSleep mode is exited according to *Section 9.6.4: PWR exiting from low-power modes*.

Refer to *Table 37* for MPU and *Table 38* for MCU, for more details on how to exit from CSleep mode.

Table 37. MPU CSleep

CSleep mode	Description
Mode entry	WFI (Wait for Interrupt) while: – STPREQ_P[1:0] = not ‘b11 (see *Section 10: Reset and clock control (RCC)*). – MPU GIC interrupts and events cleared.
	WFE (Wait for Event) while: – MPU GIC interrupts and events cleared.
Mode exit	If WFI was used for entry: – Any Interrupt enabled in GIC: Refer to *Section 20.2: GIC Interrupts* If WFE was used for entry: – Any Interrupt even when disabled in GIC: refer to *Section 20.2: GIC Interrupts* or any event: refer to *Section 9.6.4: PWR exiting from low-power modes*
Wakeup latency	None

Table 38. MCU CSleep

CSleep mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 0 (Refer to the Cortex®-M4 System Control register.) – MCU NVIC interrupts and events cleared.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 (Refer to the Cortex®-M4 System Control register.) – MCU NVIC interrupts and events cleared.

Table 38. MCU CSleep (continued)

CSleep mode	Description
Mode exit	If WFI or return from ISR was used for entry: – Any Interrupt enabled in NVIC: Refer to *Section 20.2: GIC Interrupts* If WFE was used for entry and SEVONPEND = 0: – Any event: Refer to *Section 9.6.4: PWR exiting from low-power modes* If WFE was used for entry and SEVONPEND = 1: – Any Interrupt even when disabled in NVIC: refer to *Section 20.2: GIC Interrupts* or any event: refer to *Section 9.6.4: PWR exiting from low-power modes*
Wakeup latency	None

9.6.6 PWR CStop mode

The CStop mode applies to the MPU and/or MCU sub-systems. In CStop mode the MPU/MCU clock and MPU and/or MCU sub-systems peripherals clocks are stopped.

In CStop mode, MPU and/or MCU sub-systems peripherals having a kernel clock request are still able to request their kernel clock, when selecting a clock in the RCC which is able to run in CStop mode.

PWR entering to CStop mode

The CStop mode is entered according to *Section 9.6.3: PWR entering to low-power modes*,

- For MPU when both STPREQ_P[1:0] register bits in the RCC are set and the PDDS register bit in *PWR MPU control register (PWR_MPUCR)* is cleared.
  or
  When both STPREQ_P[1:0] register bits in the RCC are set and the CSTBYDIS register bit is set and the PDDS register bit in *PWR MPU control register (PWR_MPUCR)* is set.
- For MCU when the SLEEPDEEP bit in the Cortex®-M4 System Control register is set.

Refer to *Table 39* for MPU and *Table 40* for MCU, for details on how to enter to CStop mode.

PWR exiting from CStop mode

The CStop mode is exited according to *Section 9.6.4: PWR exiting from low-power modes*.

Refer to *Table 39* for MPU and *Table 40* for MCU, for more details on how to exit from CStop mode.

Table 39. MPU CStop

CStop mode	Description
Mode entry	WFI (Wait for Interrupt) – STPREQ_P = ‘b11 and MPU PDDS = 0 or STPREQ_P = ‘b11 and MPU CSTBYDIS = 1 – MPU GIC interrupts and events cleared. – All MPU EXTI Wakeup sources are cleared.
Mode exit	EXTI Interrupt enabled in GIC: Refer to *Section 20.2: GIC Interrupts*, for the peripherals which are not stopped.
Wakeup latency	EXTI and RCC wakeup synchronization (see *Section 10: Reset and clock control (RCC)*).

Table 40. MCU CStop

CStop mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 1 (Refer to the Cortex®-M4 System Control register.) – MCU NVIC interrupts and events cleared. – All MCU EXTI Wakeup sources are cleared.
	On return from ISR while: – SLEEPDEEP = 1 and – SLEEPONEXIT = 1 (Refer to the Cortex®-M4 System Control register.) – MCU NVIC interrupts and events cleared. – All MCU EXTI Wakeup sources are cleared.
Mode exit(1)	If WFI or return from ISR was used for entry: – EXTI Interrupt enabled in NVIC: Refer to *Section 20.2: GIC Interrupts*, for peripheral which are not stopped. If WFE was used for entry and SEVONPEND = 0: – EXTI event: Refer to *Section 9.6.4: PWR exiting from low-power modes*, for peripheral which are not stopped. If WFE was used for entry and SEVONPEND = 1: – EXTI Interrupt even when disabled in NVIC: refer to *Section 20.2: GIC Interrupts* or EXTI event: refer to *Section 9.6.4: PWR exiting from low-power modes*, for peripheral which are not stopped.
Wakeup latency	EXTI and RCC wakeup synchronization (see *Section 10: Reset and clock control (RCC)*).

1. The IWDG1 and IWDG2 configured to generate a system debug wakeup event wake up the MPU and MCU, and trigger the debug CTI interface.

9.6.7 PWR CStandby mode

The CStandby mode applies only to the MPU sub-system. In CStandby mode the MPU clock and MPU sub-system peripherals clocks are stopped.

In CStandby mode, MPU sub-system peripherals having a kernel clock request are still able to request their kernel clock, when selecting a clock in the RCC which is able to run in CStop mode.

The MPU exits CStandby mode with a MPU reset.

PWR entering to CStandby mode

The CStandby mode is entered according to *Section 9.6.3: PWR entering to low-power modes*, when both MPU STPREQ_P[1:0] register bits in the RCC are set and the CSTBYDIS register bit is clear and the PDDS register bit in *PWR MPU control register (PWR_MPUCR)* is set.

Refer to *Table 41* for MPU, for details on how to enter to CStandby mode.

PWR exiting from CStandby mode

The CStandby mode is exited according to *Section 9.6.10: PWR Standby mode*.

Refer to *Table 41* for MPU, for more details on how to exit from CStandby mode.

Table 41. MPU CStandby

CStandby mode	Description
Mode entry	WFI (Wait for Interrupt) – STPREQ_P[1:0] = b’11 and MPU CSTBYDIS = 0 & PDDS = 1 – MPU GIC interrupts and events cleared. – All MPU EXTI wakeup sources are cleared.
Mode exit	EXTI Interrupt enabled in GIC: refer to *Section 20.2: GIC Interrupts*, for peripheral which are not stopped.
Wakeup latency	EXTI and RCC wakeup synchronization (see *Section 10: Reset and clock control (RCC)*).

9.6.8 PWR Stop mode

The system enters to Stop mode only when both the MPU and MCU sub-systems are in CStop mode or CStandby mode and the EXTI wakeup sources are inactive, and at least one of the MPU or MCU PDDS bit in *PWR MPU control register (PWR_MPUCR)* or *PWR MCU control register (PWR_MCUCR)* request Stop. In Stop mode, the bus matrix clocks are stalled. The oscillators can be stopped, for detailed oscillators status in Stop mode, see *Section 10.4.2: Oscillators description* and *Section 10.4.7: Clock generation in Stop and Standby modes*. For more information on the other clocks refer to RCC.

In Stop mode, the peripherals using the LSI or the LSE clock and peripherals having a kernel clock request selecting a clock source in the RCC which is able to run in Stop mode, are still able to operate.

In system Stop mode, the following features can be selected to be kept active by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by an Application reset. See *Section 46: Independent watchdog (IWDG)*.
- Real-time clock (RTC): this is configured by the RTCEN bit in the *RCC backup domain control register (RCC_BDCR)*
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the *RCC reset duration and LSI control register (RCC_RDLSICR)*.
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the *RCC backup domain control register (RCC_BDCR)*.
- Peripherals capable of running on the LSI or LSE clock.
- Peripherals having a kernel clock request.
- Internal RC oscillators (HSI, CSI) and HSE oscillator: this is configured by the corresponding xxxKERON bit in the *RCC oscillator clock enable set register (RCC_OCENSETR)*
- The ADC or DAC can also consume power during the Stop mode, unless they are disabled before entering to it. To disable them, the ADON bit in the ADC_CR2 register and the ENx bit in the DAC_CR register must both be written to 0.

PWR entering to Stop mode

The Stop mode is entered according to *Section 9.6.3: PWR entering to low-power modes*, when at least one PDDS bit in *PWR MPU control register (PWR_MPUCR)* or *PWR MCU control register (PWR_MCUCR)* requests Stop.

Refer to *Table 42* for details on how to enter to Stop mode.

If an access to a bus matrix is ongoing, the Stop mode entry is delayed until the bus matrix access is finished.

PWR exiting from Stop mode

The Stop mode is exited according to *Section 9.6.4: PWR exiting from low-power modes*.

Refer to *Table 42* for more details on how to exit from Stop mode.

When exiting from Stop mode the RCC enables HSI for the MCU, and restores the MPU and AXI bus matrix clocks. Refer to *Section 10: Reset and clock control (RCC)* Leaving Stop mode.

The STOPF status flag in *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)* registers indicate that the system has exit from Stop mode. The MPU and MCU have their own set of flag.

Table 42. Stop

Stop mode	Description
Mode entry	– When the MPU and MCU are in CStop mode or CStandby mode, or the MCU is in HOLD_BOOT, and there is no active EXTI wakeup source. – At least one PDDS bit selects Stop. – LPDS selects Stop

Table 42. Stop (continued)

Stop mode	Description
Mode exit	– On an EXTI wakeup.
Wakeup latency	Clocks restored, see RCC for more information. + EXTI and RCC wakeup synchronization and PWRLP_TEMPO (see *Section 10: Reset and clock control (RCC)*).

PWR I/O states in Stop mode

In Stop mode, all I/O pins keep their configuration.

9.6.9 PWR LP-Stop and LPLV-Stop modes

The LP-Stop mode is handled in the same way as Stop mode, when LP-Stop mode is selected by the LPDS register bit in *PWR control register 1 (PWR_CR1)*. See *Section 9.6.8: PWR Stop mode*.

Refer to *Table 43* for more details on how to enter to and exit from LP-Stop mode.

Table 43. LP-Stop

Stop mode	Description
Mode entry	– When the MPU and MCU are in CStop mode or CStandby mode, or the MCU is in HOLD_BOOT, and there is no active EXTI wakeup source. – At least one PDDS bit selects Stop. – LPDS selects LP-Stop
Mode exit	– On an EXTI wakeup.
Wakeup latency	Clocks restored, see RCC for more information. + LP-Stop timeout (external regulator to switch to main mode) + EXTI and RCC wakeup synchronization and PWRLP_TEMPO (see *Section 10: Reset and clock control (RCC)*).

The LVDS register bit in *PWR control register 1 (PWR_CR1)* allows to select whether the V_{DDCORE} supply level during LP-Stop mode is kept at the Run mode level, or is lowered (LP-Stop with low voltage mode).

In LPLV-Stop mode, the peripherals able to wake up from Stop mode (such as UART, I2C, SPI) except LPTIM (using LSE or LSI), RTC, Tamper and wakeup pins, shall all be disabled, and the DDR retention shall be enabled by DDRRETEN in *PWR control register 3 (PWR_CR3)*.

Refer to *Table 44* for more details on how to enter to and exit from LPLV-Stop mode.

Table 44. LPLV-Stop

Stop mode	Description
Mode entry	– When the MPU and MCU are in CStop mode or CStandby mode, or the MCU is in HOLD_BOOT, and there is no active EXTI wakeup source. – At least one PDDS bit selects Stop – LPDS selects low power stop – LVDS selects LPLV-Stop
Mode exit	– WKUP pins, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, Application reset (NRST, IWDG, ...).
Wakeup latency	Clocks restored, see RCC for more information. + LPLV-Stop timeout (external regulator to restore Run mode operating supply level) + EXTI and RCC wakeup synchronization.

9.6.10 PWR Standby mode

The Standby mode allows to achieve the lowest power consumption. It is based on the MPU and MCU sub-systems CStop mode and CStandby mode, as for the Stop mode, but with the V_{DDCORE} supply regulator powered off.

The system enters to Standby mode only when the MPU is in CStandby or CStop and the MCU is in CStop mode and both PDDS bits in *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)* request Standby. When the system enters to Standby mode the PWR_ON and PWR_LP pins are set low. It is expected that the External Voltage regulator providing the V_{DDCORE} supply is disabled, the complete V_{DDCORE} domain is consequently powered off. The PLLs, HSI, CSI oscillator and the HSE oscillator are also switched off, SRAM and register contents are lost except for the V_{DD}, VSW, backup domain, and retention domain (i.e. RTC registers, RTC backup register, LSE, backup RAM and Retention RAM), and Standby circuitry (see *Section 9.3.2: PWR supply system startup sequence*).

In system Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG): the IWDG is started by writing to its Key register or by hardware option. Once started it cannot be stopped except by an Application reset. See *Section 46: Independent watchdog (IWDG)*.
- Real-time clock (RTC): this is configured by the RTCEN bit in the backup domain control register (RCC_BDCR)
- Internal RC oscillator (LSI RC): this is configured by the LSION bit in the Control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE OSC): this is configured by the LSEON bit in the backup domain control register (RCC_BDCR)

PWR entering to Standby mode

The Standby mode is entered according to *Section 9.6.3: PWR entering to low-power modes*, when all PDDS bits in *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)* request Standby.

Refer to *Table 45* for more details on how to enter to Standby mode.

PWR exiting from Standby mode

The Standby mode is exited according to *Section 9.6.4: PWR exiting from low-power modes*.

Refer to *Table 45* for more details on how to exit from Standby mode.

The system exits from Standby mode when an application reset (NRST, IWDG, ...), a WKUP pin event, a RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after wakeup from Standby except for the power control and status registers *PWR control register 2 (PWR_CR2)*, *PWR control register 3 (PWR_CR3)*, the SBF bit in *PWR MPU control register (PWR_MPUCR)* and *PWR MCU control register (PWR_MCUCR)*, *PWR wakeup flag register (PWR_WKUPFR)*, and *PWR MPU wakeup enable register (PWR_MPUWKUPENR)*.

After waking up from Standby mode, program execution restarts in the same way as after a Power On reset (boot option sampling, boot vector reset fetched, etc.). The MPU starts up booting and the MCU is kept in HOLD. From this point the MPU BOOTROM manages the startup (see *Processor hold from Standby* in *Section 10: Reset and clock control (RCC)*).

The exit from Standby/CStandby status flags can be retrieved thanks to the STDBYRSTF and CSTDBYRSTF bits in *RCC MPU reset status clear register (RCC_MP_RSTSCLRR)*. Those bits are set by the BOOTROM code from the SBF/SBFMPU bits in *PWR MPU control register (PWR_MPUCR)*. The SBF/SBFMPU bits are dedicated to the BOOTROM usage and should not be used elsewhere.

Table 45. Standby

Standby mode	Description
Mode entry	– The MPU sub-system is in CStandby or CStop and MCU sub-system is in CStop mode or HOLD_BOOT, and there is no active EXTI wakeup source. – All PDDS bits select Standby. – All WKUPF bits in Power Control/Status register (PWR_WKUPFR) are cleared. – All RTC wakeup events are cleared.
Mode exit	– WKUP pins, RTC alarm (Alarm A and Alarm B), RTC wakeup, tamper event, time stamp event, application reset (such as NRST, IWDG[(1)]).
Wakeup latency	System reset phase (see *Section 10: Reset and clock control (RCC)*).

1. The IWDG1 and IWDG2 when configured to generate an Application reset and when configured to generate a system debug wakeup event, reset in both cases the system.

PWR I/O states in Standby mode

In Standby mode, all I/O pins are high impedance no pull except for:

- NRST reset pin, PWR_ON pin, and PWR_LP pin (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins, if enabled, the WKUP pin pulls can be configured by WKUPPUPD register bits in *PWR wakeup control register (PWR_WKUPCR)*.

9.6.11 PWR debug Stop

When the system enters low-power mode Stop, operation depend on the DBG_STOP configuration in the DBG module.

When the Stop mode debug is enabled, when entering Stop mode the PWR does not signal low-power mode on the PWR_ON and PWR_LP signals. This keeps the V_{DDCORE} domain to be supplied from the regulator in main mode.

When exiting from Stop mode the system MPU and logic is enabled as from normal Stop mode, the STOPF flag is set and when the MPU has entered CStandby mode the SBFMPU flag is set as well.

9.6.12 PWR debug Standby

When the system enters low-power mode Standby, operation depend on the DBG_Standby configuration in the DBG module.

When the Standby mode debug is enabled, when entering Standby mode the PWR keeps the pwr_on active, allowing the V_{DDCORE} domain to remain supplied. In Standby mode the VDDCORE domain is not reset, allowing the CPU and bus clocks to be active.

When exiting from Standby mode a reset is generated, which resets the V_{DDCORE} logic excluding the debug logic. Waking up from debug Standby mode the system MPU and MCU and logic is reset as from normal Standby mode and the SBF flag are set. When the MPU has entered CStandby mode the SBFMPU flag is set as well.

9.7 PWR WKUP pins

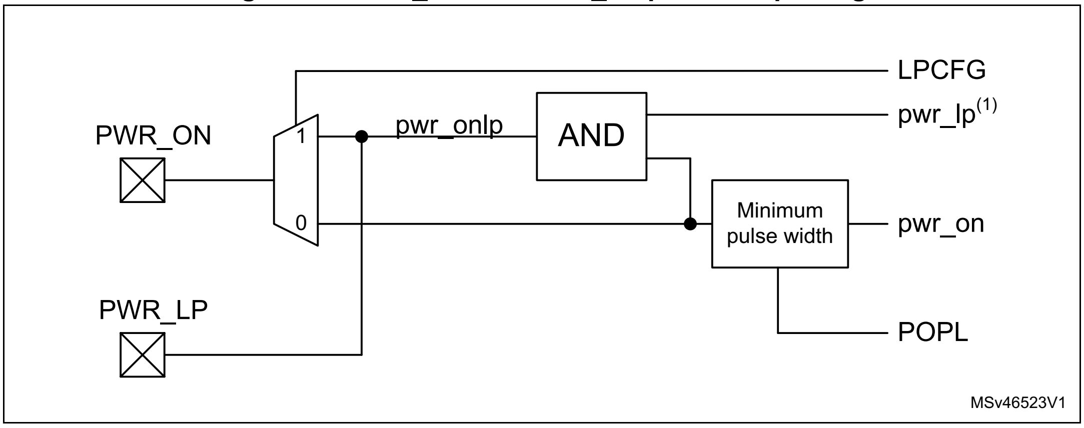
The WKUP polarity shall only be changed in WKUPP when the wakeup interrupt is disabled, in WKUPEN.

To avoid falls interrupts, the WKUPF shall be cleared with WKUPC, before enabling the wakeup interrupt in WKUPEN.

9.8 PWR_ON and PWR_LP pins

The PWR_ON pin may signal pwr_on or pwr_onlp depending the selection in LPCFG register bit in *PWR control register 1 (PWR_CR1)*. The PWR_LP pin signals pwr_onlp.

Figure 45. PWR_ON and PWR_LP pins multiplexing



1. See LPDS bit in *PWR control register 1 (PWR_CR1)*.

PWR_ON pin

When LPCFG select pwr_on signaling, the PWR_ON pad is only low in Standby mode.

When LPCFG select pwr_onlp signaling on PWR_ON, the definition (Standby, LP-Stop or LPLV-Stop) of the signal being low shall be communicated to the external power management prior entering low-power mode. The PWR_ON pad is low in Standby, LP-Stop and LPLV-Stop modes.

9.9 PWR interrupts

The PWR provides the following interrupts:

- Wakeup interrupt to MPU.
  - Enabled by WKUPEN[6:1] register bit in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)*.
  - The interrupt status flag WKUPF[6:1] are available from *PWR wakeup flag register (PWR_WKUPFR)*.
- Wakeup interrupt to MCU.
  - Enabled by WKUPEN[6:1] register bit in *PWR MCU wakeup enable register (PWR_MCUWKUPENR)*.
  - The same interrupt status flag WKUPF[6:1] as for the MPU are available from *PWR wakeup flag register (PWR_WKUPFR)*.

Other status flag associated with Stop and Standby modes and monitoring functions are also available, see *Table 46*:

Table 46. PWR status flags

Status Flag	Description	Interrupt	Clear through
STOPF	Exit from Stop mode	Wakeup from Stop mode events	CSSF
SBF[1]	Exit from Standby mode	Wakeup from Standby events.	CSSF

Table 46. PWR status flags (continued)

Status Flag	Description	Interrupt	Clear through
SBFMPU[(1)]	MPU exit CStandby mode	Wakeup from CStandby, events.	CSSF
WKUPF[6:1]	Wakeup flags	MPU and MCU wakeup from Standby and Stop events.	WKUPC[6:1]
PVDO	Programmable voltage detector	interrupt via EXTI	n.a.
AVDO	Analog voltage detector	interrupt via EXTI	n.a.
TEMPL, TEMPH	Temperature monitoring	interrupt via EXTI	n.a.
BRRDY	Backup regulator ready	no associated interrupt	n.a.
RRRDY	Retention regulator ready	no associated interrupt	n.a.
USB33RDY	USB FS 3V3 supply ready	no associated interrupt	n.a.
REG18RDY	Regulator 1V8 supply ready	no associated interrupt	n.a.
REG11RDY	Regulator 1V1 supply ready	no associated interrupt	n.a.

1. SBF and SBFMPU are dedicated to the BOOTROM usage and should not be used elsewhere. The STDBYRSTF and CSTDBYRSTF bits in *RCC MPU reset status clear register (RCC_MP_RSTSCLRR)* should be used by application code as part of reset source identification process. See *Section 10.3.13: Reset source identification*.

9.10 PWR TrustZone security

The PWR is able to secure registers from being modified by non-secure accesses. The TrustZone security is activated by the RCC TZEN register bit in *Section 10.7.2: RCC TrustZone control register (RCC_TZCR)*. At PWR level the security consist in preventing a non-secure write access to:

- Change the settings of the VBAT and TEMP Monitor, PVD and AVD.
- Change the low-power Deepsleep and RAM low-power settings.
- Change the backup domain write protection.
- Change the Backup regulator, Retention regulator, 1V8 regulator, 1V1 regulator and USB 3.3V voltage level detector settings.
- Change the backup battery charging settings.
- Change the MPU power control register settings.
- Change the Standby wakeup settings and flags.

The PWR TrustZone security enables write access security for all features simultaneously.

Table 47. Register security overview

Register name	Access type	Security[(1)]
PWR_CR1	RW	Write security
PWR_CSR1	R	Non secure
PWR_CR2	RW	Write secure
PWR_CR3	RW	Write secure

Table 47. Register security overview (continued)

Register name	Access type	Security[1]
PWR_MPUCR	RW	Write secure
PWR_MCUCR	RW	Non secure
PWR_WKUPCR	RW	Write secure[2]
PWR_WKUPFR	R	Non secure
PWR_MPUWKUPENR	RW	Write secure
PWR_MCUWKUPENR	RW	Non secure
PWR_VER	R	Non secure
PWR_ID	R	Non secure
PWR_SID	R	Non secure

1. Security is enabled with the RCC TZEN register bit.
2. Security is additionally channel wise enabled with WKUPEN bits in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* register.

9.11 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless explicitly specified differently.

9.11.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0x0000 0000

Reset on any system reset.

This register provides write access security when enabled by TZEN register bit in *Section 10: Reset and clock control (RCC)*. When security is enabled a non-secure write access generates a bus error. Secure and non-secure read accesses are granted and return the register value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALS[1:0]		AVDEN
													rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBP	PLS[2:0]			PVDEN	Res.	LVDS	LPCFG	LPDS
							rw	rw	rw	rw	rw		rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:17 **ALS[1:0]:** Analog Voltage Detector level selection.

These bits select the voltage threshold detected by the AVD.
00: 1.7V
01: 2.1V
10: 2.5V
11: 2.8V

Bit 16 **AVDEN:** Peripheral Voltage Monitor on V_{DDA} enable.

0: Peripheral Voltage Monitor on V_{DDA} disabled
1: Peripheral Voltage Monitor on V_{DDA} enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **DBP:** Disable backup domain write protection.

In reset state, the RCC_BDCR, PWR_CR2, RTC, and backup registers are protected against parasitic write access. This bit must be set to enable write access to these.
0: Write access to RTC and backup domain registers disabled.
1: Write access to RTC and backup domain registers enabled.

Bits 7:5 **PLS[2:0]:** Programmable Voltage Detector level selection.

These bits are read only when the SYSCFG register bit PVDL is set (when PVDL is set, there is no bus errors generated when writing this register).
These bits select the voltage threshold detected by the PVD.
000: 1.95 V
001: 2.1 V
010: 2.25 V
011: 2.4 V
100: 2.55 V
101: 2.7 V
110: 2.85 V
111: External voltage level on PVD_IN (compared to internal VREFINT)

Bit 4 **PVDEN:** Programmable Voltage detector enable.

This bit is read only when the SYSCFG register bit PVDL is set (when PVDL is set, there is no bus errors generated when writing this register).
0: Programmable Voltage detector disabled.
1: Programmable Voltage detector enabled.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **LVDS:** Low Voltage Deepsleep LPLV-Stop mode selection.

This bit has only effect when the low power stop mode is selected in LPDS and changes the V_{DDCORE} domain supply reset level.

0: LP-Stop mode V_{DDCORE} domain supply reset level at same level as Run mode. The V_{DDCORE} domain supply level in LP-Stop mode shall be kept at same level as Run mode.

1: LPLV-Stop mode V_{DDCORE} domain supply reset level at lower level than Run mode. Allows to lower V_{DDCORE} domain supply level in LPLV-Stop mode (see the datasheet for voltage levels).

Bit 1 **LPCFG:** PWR_ON pin configuration.

0: PWR_ON pin signals Standby mode (PWR_ON =1 in Run, Stop, LP-Stop, LPLV-Stop, and 0 in Standby).

1: PWR_ON pin signals Standby, LP-Stop and LPLV-Stop modes (PWR_ON = 1 in Run, Stop, and 0 in LP-Stop, LPLV-Stop and Standby).

Bit 0 **LPDS:** Low Power Deepsleep Stop mode selection.

0: Stop mode selected, External regulator kept in Main power mode (pwr_lp = 1).

1: low-power stop mode selected External regulator may enter Low-power mode (pwr_lp = 0). Further low power mode selection is provided by LVDS.

9.11.2 PWR control status register 1 (PWR_CSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Reset on any system reset.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **AVDO**: Analog Voltage detector Output on V_{DDA}.

This bit is set and cleared by hardware. It is valid only if AVD on V_{DDA} is enabled by the AVDEN bit.

0: V_{DDA} is equal or higher than the AVD threshold selected with the ALS[2:0] bits.

1: V_{DDA} is lower than the AVD threshold selected with the ALS[2:0] bits

Note: The AVD is disabled in Standby mode and after system reset. For this reason, this bit is equal to 0 after Standby and reset.

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: Programmable Voltage Detect Output

This bit is set and cleared by hardware. It is valid only if PVD is enabled by the PVDEN bit.

0: V_{DD} or voltage level on PVD_IN is equal or higher than the PVD threshold selected with the PLS[2:0] bits.

1: V_{DD} or voltage level on PVD_IN is lower than the PVD threshold selected with the PLS[2:0] bits.

Note: The PVD is disabled in Standby mode and after a system reset. For this reason, this bit is equal to 0 after Standby and system reset.

Bits 3:0 Reserved, must be kept at reset value.

9.11.3 PWR control register 2 (PWR_CR2)

Address offset: 0x008

Reset value: 0x0000 0000

Not reset by wakeup from Standby mode, Application reset (NRST, IWDG, ...) and V_{DD} POR, but reset only by V_{SW} POR and VSWRST.

Access 6 wait states when writing this register.

After reset the register is write-protected and the DBP bit in the *PWR control register 1 (PWR_CR1)* has to be set before it can be written. When DBP is cleared, there is no bus errors generated when writing this register.

This register shall not be accessed when the RCC VSWRST register bit in *Section 10.7.86: RCC backup domain control register (RCC_BDCR)* resets the VSW domain.

This register provides Write access security when enabled by TZEN register bit in *Section 10.7.2: RCC TrustZone control register (RCC_TZCR)*. When security is enabled a non-secure write access generates a bus error. Secure and non-secure read accesses are granted and return the register value.

When a system reset occurs during the register write cycle the written data is not guaranteed.

											rw			rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: Monitored temperature level above high threshold

0: Temperature below high threshold level, or Monitor disabled.

1: Temperature equal or above high threshold level.

Bit 22 **TEMPL**: Monitored temperature level above low threshold

0: Temperature above low threshold level, or Monitor disabled.

1: Temperature equal or below low threshold level.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **RRRDY**: Retention Regulator ready

Set by hardware to indicate that the Retention Regulator is ready. Entering Standby or VBAT mode before the Retention Regulator is ready may cause loss of Retention RAM content.

0: Retention Regulator not ready.

1: Retention Regulator ready.

Bit 16 **BRRDY**: Backup Regulator ready

Set by hardware to indicate that the Backup Regulator is ready. Entering Standby or VBAT mode before the Backup Regulator is ready may cause loss of Backup RAM content.

0: Backup Regulator not ready.

1: Backup Regulator ready.

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MONEN:** VBAT and temperature monitoring enable

When set, the V_{BAT} supply and temperature monitoring is enabled.

0: V_{BAT} and temperature monitoring disabled.

1: V_{BAT} and temperature monitoring enabled.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **RREN:** Retention regulator enable

When set, the retention regulator (used to maintain retention RAM content in Standby and VBAT modes) is enabled.

If RREN is reset, the Retention Regulator is switched off. The retention RAM can still be used in Run mode and Stop mode but its content is lost in the Standby and VBAT modes. Once set, the application must wait that the retention regulator Ready flag (RRRDY) is set to indicate that the data written into the SRAM is maintained in the Standby and VBAT modes.

0: Retention regulator disabled

1: Retention regulator enabled

Bit 0 **BREN:** Backup regulator enable

When set, the backup regulator (used to maintain backup RAM content in Standby and VBAT modes) is enabled.

If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run mode and Stop mode but its content is lost in the Standby and VBAT modes. Once set, the application must wait that the Backup Regulator Ready flag (BRRDY) is set to indicate that the data written into the SRAM is maintained in the Standby and VBAT modes.

0: Backup regulator disabled

1: Backup regulator enabled

9.11.4 PWR control register 3 (PWR_CR3)

Address offset: 0x00C

Reset value: 0x5000 0000

Not reset by wakeup from Standby mode and Application reset (such as NRST, IWDG) but only reset by V_{DD} POR.

Access 6 wait states when writing this register.

This register provides Write access security when enabled by TZEN register bit in *Section 10: Reset and clock control (RCC)*. When security is enabled a non-secure write access generates a bus error. Secure and non-secure read accesses are granted and return the register value.

When a system reset occurs during the register write cycle the written data is not guaranteed.

Bit 31 **REG11RDY**: 1V1 regulator supply ready
0: 1V1 supply not ready
1: 1V1 supply ready

Bit 30 **REG11EN**: 1V1 regulator enable
0: 1V1 regulator disabled
1: 1V1 regulator enabled (when in Standby mode the 1V1 regulator is disabled)

Bit 29 **REG18RDY**: 1V8 regulator supply ready
0: 1V8 supply not ready
1: 1V8 supply ready

Bit 28 **REG18EN**: 1V8 regulator enable
0: 1V8 regulator disabled
1: 1V8 regulator enabled, when also pin BYPASS_REG1V8 is low (when in Standby mode the 1V8 regulator is disabled).

Bit 27 Reserved, must be kept at reset value.

Bit 26 **USB33RDY**: USB 3.3V supply ready
0: USB 3.3V supply not ready
1: USB 3.3V supply ready

Bit 25 Reserved, must be kept at reset value.

Bit 24 **USB33DEN**: USB 3.3V voltage level detector enable
0: USB 3.3V voltage level detector disabled
1: USB 3.3V voltage level detector enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:17 **POPL[4:0]**: pwr_on pulse low configuration
These bits are set and cleared by software. They define the minimum guaranteed duration of the pwr_on low pulse in Standby mode (there is no impact on the LP-Stop and LPLV-Stop modes).
The LSI oscillator is automatically enabled when needed by the POPL pulse low configuration.
00000: No guaranteed minimum low time
00001: ~ 1 ms guaranteed minimum low time (1 x 32 LSI cycles)
00010: ~ 2 ms guaranteed minimum low time (2 x 32 LSI cycles)
...
11111: ~ 31 ms guaranteed minimum low time (31 x 32 LSI cycles)

Bits 16:13 Reserved, must be kept at reset value.

Bit 12 **DDRRETEN:** DDR retention enable
Set by Hardware on NRST pad reset, when the reset delay control is enabled in the RCC_MP_APRSTCR.RDCTLEN register bit, or when written ‘b1 by software, the DDR PHY puts its pads in retention.
To disable retention software shall write this bit to ‘b0.
0: DDR self-refresh retention disabled.
1: DDR self-refresh retention enabled.

Bit 11 **DDRSRDIS:** DDR self-refresh retention after standby disable
When written ‘b1, the DDR PHY pads retention, enabled due to DDRSREN, is disabled.
0: No action
1: When DDRSREN is ‘b1: Disable DDR self-refresh retention after standby mode. This bit is reset by hardware once DDR self-refresh retention has been disabled.
When DRRSREN is ‘b0 no action.

Bit 10 **DDRSREN:** DDR self-refresh in standby mode enable
When set, the DDR PHY puts its pads in retention when entering Standby mode.
0: DDR self-refresh retention when entering standby mode disabled.
1: DDR self-refresh retention when entering standby mode enabled (DDR self-refresh retention after Standby shall be disabled by DDRSRDIS).

Bit 9 **VBRS**: VBAT charging resistor selection
0: Charges VBAT through a 5 kOhm resistor.
1: Charges VBAT through a 1.5 kOhm resistor.

Bit 8 **VBE**: VBAT charging enable
0: VBAT battery charging disabled.
1: VBAT battery charging enabled.

Bits 7:0 Reserved, must be kept at reset value.

9.11.5 PWR MPU control register (PWR_MPUCR)

Address offset: 0x010

Reset value: 0x0000 0000

See individual bits for reset condition.

Access 6 wait states when writing this register.

This register provides Write access security when enabled by TZEN register bit in *Section 10: Reset and clock control (RCC)*. When security is enabled a non-secure write access generates a bus error. Secure and non-secure read accesses are granted and return the register value.

When a system reset occurs during the register write cycle the written data is not guaranteed.

r						rw		r	r	r		rw			rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **STANDBYWFIL2:** MPU system idle indication
This bit is set and reset by hardware based on the MPU operation mode.
0: MPU system CRun or CSleep
1: MPU system CStop or CStandby

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **CSSF:** Clear MPU Standby, Stop flags.(Always read as 0)
This bit is reset on any system reset.
0: No effect
1: When written, clears the MPU flags (STOPF, SBF, and SBFMPU). The register bit is cleared to 0 by hardware.

Bit 8 Reserved, must be kept at reset value.

Bit 7 **SBFMPU:** MPU Standby flag
This bit is set by hardware and cleared only by a V_{DD} POR reset or by setting the MPU CSSF bit (not reset when exit from Standby mode). This bit is cleared by the MPU Boot ROM.
0: MPU has not been in CStandby mode.
1: MPU has been in CStandby mode.

Bit 6 **SBF:** System Standby flag
This bit is set by hardware and cleared only by a V_{DD} POR reset or by setting the MPU CSSF bit (not reset when exit from Standby mode). This bit is cleared by the MPU Boot ROM.
0: System has not been in Standby mode.
1: System has been in Standby mode, system contents has been lost.

Bit 5 **STOPF:** Stop flag
This bit is set by hardware and cleared only by any system reset or by setting the MPU CSSF bit. This bit is cleared by the MPU Boot ROM.
0: System has not been in Stop mode
1: System has been in Stop mode, clock system has been stopped.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **CSTBYDIS:** MPU CStandby mode disable
This bit is reset only by a V_{DD} POR reset (not reset when exit from Standby mode).
Allows to define the use of the MPU CStandby mode. Under some conditions, this bit is cleared by the MPU Boot ROM.
0: MPU CStandby mode enabled
1: MPU CStandby mode disabled

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **PDDS:** System Power Down Deepsleep selection
This bit is reset only by a V_{DD} POR reset (not reset when exit from Standby mode).
Allows MPU to define the Deepsleep mode for the system.
0: Keeps Stop mode when MPU enters to CStop.
1: Allows Standby mode when MPU enters to CStop. When CSTBYDIS = 0 allows MPU to enter CStandby mode.

9.11.6 PWR MCU control register (PWR_MCUCR)

Address offset: 0x014

Reset value: 0x0000 0000

See individual bits for reset condition.

Access 6 wait states when writing this register.

This register is always non-secure.

When a system reset occurs during the register write cycle the written data is not guaranteed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DEEPSLEEP	Res.	Res.	Res.	Res.	Res.	CSSF	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	PDDS
r						rw			r	r					rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **DEEPSLEEP:** MCU system idle indication

This bit is set and reset by hardware based on the MCU operation mode.
0: MCU system CRun or CSleep
1: MCU system CStop

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **CSSF:** Clear MCU Standby, Stop flags (always read as 0)

This bit is reset on any system reset.
0: No effect
1: When written, clear the MCU flags (STOPF, and SBF). Register bit is cleared to 0 by hardware.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **SBF:** System Standby Flag

This bit is set by hardware and cleared only by a V_{DD} POR reset or by setting the MCU CSSF bit (not reset when exit from Standby mode).
0: System has not been in Standby mode.
1: System has been in Standby mode, system contents has been lost.

Bit 5 **STOPF:** Stop Flag

This bit is set by hardware and cleared only by any system reset or by setting the MCU CSSF bit.
0: System has not been in Stop mode.
1: System has been in Stop mode, clock system has been stopped.

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **PDDS:** System Power Down Deepsleep selection.

This bit is reset only by a V_{DD} POR reset (not reset when exit from Standby mode).
Allows MCU to define the Deepsleep mode for the system.
0: Keeps Stop mode when MCU enters to CStop.
1: Allows Standby mode when MCU enters to CStop.

9.11.7 PWR wakeup control register (PWR_WKUPCR)

Address offset: 0x020

Reset value: 0x0000 0000

Not reset by wakeup from Standby mode, but by any application reset (such as NRST, IWDG).

Access 6 wait states when writing this register (when clearing a WKUPF, the AHB write access completes after the WKUPF has cleared).

This register provides Write access security when enabled by TZEN register bit in *Section 10: Reset and clock control (RCC)*. When security is enabled a non-secure write access on individual WKUPC[6:1], WKUPP[6:1] bits and WKUPPUPD[6:1] bit pairs are discarded when the corresponding WKUPEN[6:1] bit in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is set. No bus error is generated. Secure and non-secure read accesses are granted and return the register value.

When a system reset occurs during the register write cycle the written data is not guaranteed.

		rw	rw	rw	rw	rw	rw			rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **WKUPPUPD[6:1][1:0]**: Wakeup pull configuration for WKUPn pin, n range [6:1]

These bits define the IO pad pull configuration used when WKUPENn = 1 (note that the associated GPIO port pull configuration shall be set to the same value or 00). The wakeup pin pull configuration is maintained in Standby mode.

When TZEN is enabled in the RCC and WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is set, bit pair n can only be written by a secure access, a non-secure write on this bit pair is discarded.

When TZEN is disabled in the RCC or WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is clear, bit pair n can be written by a secure and non-secure access.

00: No pulls
01: Pull-up
10: Pull-down
11: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **WKUPP[6:1]**: Wakeup Polarity bit for WKUPn pin, n range [6:1]

These bits define the polarity used for event detection on external wake-up WKUPn pin.

When TZEN is enabled in the RCC and WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is set, bit n can only be written by a secure access, a non-secure write on this bit is discarded.

When TZEN is disabled in the RCC or WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is clear, bit n can be written by a secure and non-secure access.

0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPC[6:1]:** Clear Wakeup Flag for WKUPn pin, n range [6:1]

When TZEN is enabled in the RCC and WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is set, bit n can only be written by a secure access, a non-secure write on this bit is discarded.

When TZEN is disabled in the RCC or WKUPENn in *PWR MPU wakeup enable register (PWR_MPUWKUPENR)* is clear, bit n can be written by a secure and non-secure access.

These bits are always read as 0.

0: No effect
1: Writing 1 clears the WKUPFn wakeup flag (the bit is cleared to 0 by hardware).

9.11.8 PWR wakeup flag register (PWR_WKUPFR)

Address offset: 0x024

Reset value: 0x0000 0000

Not reset by wakeup from Standby mode but by any Application reset (NRST, IWDG, ...)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPF[6:1]:** Wakeup flag for WKUPn pin before enable, n range [6:1].
This bit is set by hardware and cleared only by a NRST Reset or by setting the WKUPCn bit in the *PWR wakeup control register (PWR_WKUPCR)*
0: No wakeup event occurred
1: A wakeup event was received from WKUPCn pin

9.11.9 PWR MPU wakeup enable register (PWR_MPUWKUPENR)

Address offset: 0x028

Reset value: 0x0000 0000

Not reset by wakeup from Standby mode but by any Application reset (NRST, IWDG, ...).

Access 6 wait states when writing this register.

This register provides Write access security when enabled by TZEN register bit in *Section 10: Reset and clock control (RCC)*. When security is enabled a non-secure write access is discarded and a bus error is generated. Secure and non-secure read accesses are granted and return the register value.

When a system reset occurs during the register write cycle the written data is not guaranteed.

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPEN[6:1]**: Enable Wakeup WKUPn pin and interrupt for MPU, n range [6:1]
Each bit is set and cleared by software.
When TZEN is enabled in the RCC, these bits can only be written by a secure access, a non-secure write is discarded.
When TZEN is disabled in the RCC, these bits can be written by a secure and non-secure access.
0: An event on WKUPn pin does not wake up the system from Standby and Stop mode, nor generates an interrupt to MPU.
1: A rising or falling edge on WKUPn pin wakes up the system from Standby and Stop mode and generates an interrupt to MPU.

9.11.10 PWR MCU wakeup enable register (PWR_MCUWKUPENR)

Address offset: 0x02C

Reset value: 0x0000 0000

Not reset by wakeup from Standby mode but by any Application reset (NRST, IWDG, ...)

Access 6 wait states when writing this register.

When a system reset occurs during the register write cycle the written data is not guaranteed.

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **WKUPEN[6:1]**: Enable Wakeup WKUPn pin and interrupt for MCU, n range [6:1]
Each bit is set and cleared by software.
0: An event on WKUPn pin does not wake up the system from Standby and Stop mode, nor generate an interrupt to MCU.
1: A rising or falling edge on WKUPn pin wakes up the system from Standby and Stop mode, and generate an interrupt to MCU.

9.11.11 PWR IP version register (PWR_VER)

Address offset: 0x3F4

Reset value: 0x0000 0011

Refer to *Section 2.5 on page 153* for the register boundary addresses.

10 Reset and clock control (RCC)

The RCC block is responsible for the management of the clock and reset generation for the complete circuit.

This section often refers to operating modes defined in *Section 9.5.1: PWR operating modes*.

10.1 RCC main features

- AHB-Lite bus interface
- TrustZone aware
- Register protection function
- Reset part:
  - Generation of local and system reset
  - Bidirectional pad reset (NRST) allowing the reset of external devices, or the reset of the circuit
- Clock generation part:
  - Generation and distribution of clocks for the complete system
  - 4 separate PLLs:
    - Integer or fractional mode
    - Spread spectrum function to reduce the amount of EMI peaks
    - Possibility to change the PLL fractional ratios on-the-fly
  - Smart clock gating for reduction of power dissipation
  - 2 external oscillators:
    - HSE, supporting a wide range of crystals: 8 to 48 MHz
    - LSE, for the 32.768 kHz crystal
  - 3 Internal oscillators: HSI, CSI and LSI
  - Buffered clock outputs for external devices
  - Generation of 2 interrupts lines:
    - A dedicated interrupt line for clock security management
    - A general interrupt line for other events
- 2 Independent interrupt interfaces
- 2 Independent events to wake up processors

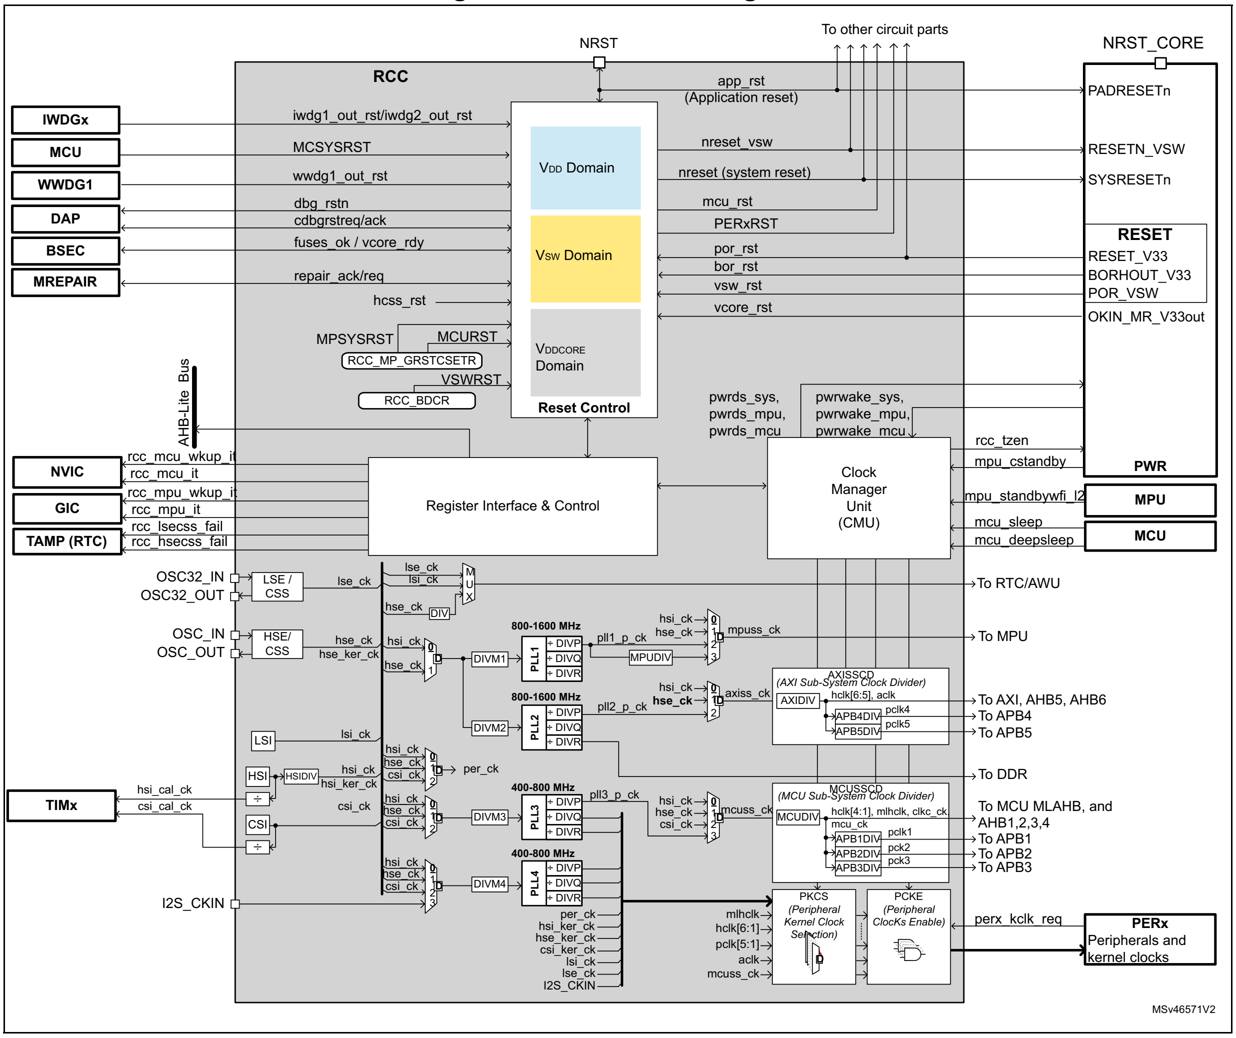
10.2 RCC block diagram

Figure 46 gives a simplified view of the RCC, and the key signals exchanged with the other blocks. Three voltage domains are present in the RCC: the V_{DD} domain (blue), the V_{SW} domain (yellow) and the V_{DDCORE} domain (gray).

For the reset part, analog comparators located into the PWR block provide all reset signals dependent of the power supplies: **por_rst**, **bor_rst**, **vcore_rst** and **vsw_rst**. Two reset sources are coming from pads: NRST and NRST_CORE. The RCC also receives resets from various other sources: watchdogs, MCU, registers... All these resets are handled by the RCC in order to reset properly all the parts of the system.

For the clock generation part, the RCC handles the generation and the gating for all the clocks according to register settings and processors modes. Note that the RCC is clocked with hclk4 clock.

Figure 46. RCC block diagram



The RCC exchanges also some signals with the PWR in order to control the entry and the exit of the system in Stop and Standby modes.

10.2.1 RCC pin overview

Table 49 lists the RCC signals connected to pads or balls.

Table 49. Pin overview

Pin Name	I/O	Description
NRST	I/O	External (application) reset, can be used to provide reset to external devices
OSC32_IN	I	32.768 kHz oscillator input or external clock input
OSC32_OUT	O	32.768 kHz oscillator output
OSC_IN	I	HSE oscillator input or external clock input
OSC_OUT	O	HSE oscillator output
MCO1	O	Output clock 1 for external devices
MCO2	O	Output clock 2 for external devices
I2S_CKIN	I	External kernel clock input for digital audio interfaces: SPI/I2S, SAI, and DFSDM
ETH_TX_CLK	I	External clock TX provided by the Ethernet PHY for MII
ETH_RX_CLK/ ETH_REF_CLK	I	External clock RX provided by the Ethernet PHY for MII, RMII, GMII and RGMII
ETH_CLK	O	Clock output for external Ethernet PHY
ETH_CLK125	I	External clock RX provided by the Ethernet PHY for GMII and RGMII
GTX_CLK	O	Clock output for external Ethernet PHY

10.3 RCC functional description - reset part

There are several sources able to generate a reset:

- Supply voltages (V_{DD} or V_{DDCORE} or V_{SW}) lower than the expected values,
- Watchdog timeout,
- MPU exit from CStandby,
- Product exit from Standby,
- External signals driving the NRST or NRST_CORE pads,
- Software commands.

The coverage (or scope) of the resets differs according to the source initiating the reset. However the following categories can be distinguished:

- The power-on/off resets,
- The application and system resets,
- The local resets.

10.3.1 The power-on/off resets

The PWR block provides some reset signals to the RCC:

- The **por_rst** signal, which is asserted when the V_{DD} supply is lower than the V_{POR} threshold.
- The **bor_rst** signal, which is asserted when the V_{DD} supply is lower than the V_{BOR} threshold.
- The **vcore_rst** signal, which is asserted when the V_{DDCORE} supply is lower than the V_{DDCORE} threshold, or when the pad NRST_CORE is asserted.
- The **vsw_rst** signal, which is asserted when the V_{SW} supply is lower than the expected threshold.

As shown in *Figure 47*, the signal provided by the PWR block, indicating that the V_{DDCORE} is valid (OKIN_MR_V33out), is used by the RCC in order to trigger the hardware system initialization sequence and the memory repair. Refer to *Section 3: Boot and security and OTP control (BSEC)* for details. When this initialization sequence is completed, then the **vcore_rst** is released allowing the processors to start.

Refer to *Table 50: Reset coverage summary* for details.

Refer to *Section 9: Power control (PWR)* for details on the generation of power-on/off resets.

10.3.2 The application and system resets

An application reset (**app_rst**) is generated from one of the following sources:

- A reset from NRST pad,
- A reset from **por_rst** signal (generally called power-on reset),
- A reset from **bor_rst** signal (generally called brownout),
- A reset from the Independent Watchdogs 1 (**iwdg1_out_rst**),
- A reset from the Independent Watchdogs 2 (**iwdg2_out_rst**),
- A software reset from the Cortex-M4 (MCU), via the AIRCR register (MCSYSRST) if the option byte OTP_MCU_SYSRST_EN allows it,
- A software reset from the RCC, when the Cortex-A7 (MPU) sets the bit MPSYSRST to '1' via *RCC global reset control set register (RCC_MP_GRSTCSETR)*,
- A failure on HSE, when the clock security system feature is activated (**hcss_rst**).

A System reset (**nreset**) is generated from one of the following sources:

- A reset from **app_rst** signal (application reset),
- A reset from **vcore_rst** signal.

Note: When the system is in Standby, the V_{DDCORE} is switched off, but V_{DD} is still present. So when the system exits from Standby, the vcore_rst signal is activated, generating a nreset reset.

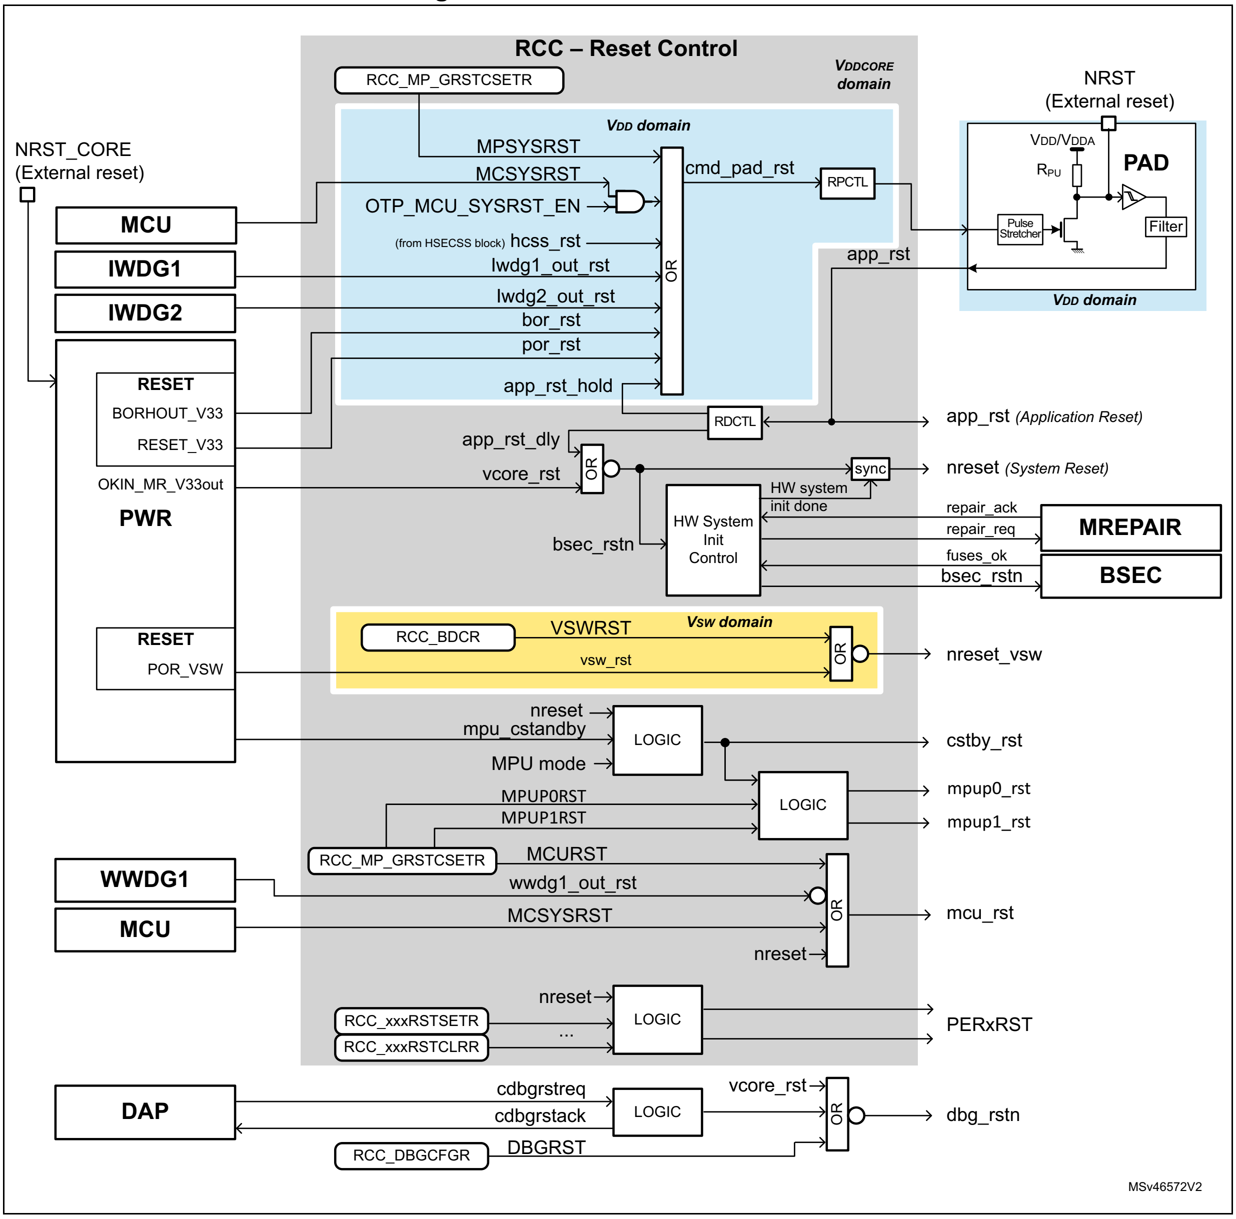
As shown in *Figure 47*, the NRST pad is activated by:

- **por_rst**, **bor_rst**,
- **iwdg1_out_rst**, **iwdg2_out_rst,**
- MPSYSRST,
- MCSYSRST when allowed by OTP_MCU_SYSRST_EN option byte. Refer to *Section 4: OTP mapping (OTP)*,
- Assertion of NRST by an external source.

A programmable reset pulse control (RPCTL) allows the application to define a minimum pulse width for the assertion of the NRST pad. Note that when the RPCTL is disabled, the reset PAD embeds a pulse stretcher which guarantees a minimum reset pulse duration of 20 µs for each internal reset source. Note that **app_rst** and **nreset** are also impacted by this function. For details on RPCTL refer to *Section 10.3.10: Reset pulse control (RPCTL)*.

Note: It is not recommended to let the NRST and NRST_CORE pins unconnected. When it is not used, connect these pins to ground via a capacitor of 10 to 100 nF.

Figure 47. Reset circuit overview



10.3.3 The local resets

The local resets are the resets which do not directly affect both processors. Here is the list of the most important local resets:

- When the MPU exits from CStandby, it is reset by a reset named **cstby_rst**. CStandby mode means that the MPU requested to go to Standby but the product did not go to Standby due to the mode of the MCU. Refer to *Section 9: Power control (PWR)* for details.

- The MPU can reset the MCU via the RCC_MP_GRSTCSETR register, by setting the bit MCURST to ‘1’.
- The MPU can reset the MPU processor 0 via the RCC_MP_GRSTCSETR register, by setting the bit MPUP0RST to ‘1’. Note that the Snoop Control Unit of the MPU (SCU) is not reset.
- The MPU can reset the MPU processor 1 via the RCC_MP_GRSTCSETR register, by setting the bit MPUP1RST to ‘1’. Note that the Snoop Control Unit of the MPU (SCU) is not reset.
- A software reset from the Cortex-M4 via the AIRCR register can be restricted only to the MCU and WWDG1 according to the value of the option byte OTP_MCU_SYSRST_EN.
- A timeout of WWDG1 will reset the MCU and WWDG1.

10.3.4 Resets generated by the CPUs

Both CPUs can generate system and local resets. The RCC offers the following possibilities:

- The MPU can generate a system reset by means of the MPSYSRST bit, located into *RCC global reset control set register (RCC_MP_GRSTCSETR)*. The MCU cannot access the MPSYSRST bit, and it cannot prevent the MPU to generate this system reset.
- The MPU can reset the MCU by means of the MCURST bit, located into *RCC global reset control set register (RCC_MP_GRSTCSETR)*. The MCU cannot prevent the MPU to generate this local reset.
- The MPU can reset its processor 0 or processor 1 independently thanks to MPUP0RST and MPUP1RST bits, located into *RCC global reset control set register (RCC_MP_GRSTCSETR)*. This feature allows the application to restart one of the MPU core without disturbing code execution of the MCU. Note that the Snoop Control Unit of the MPU (SCU) is not reset.
- The MCU can generate a system reset via the AIRCR register of the Cortex-M4, if allowed by the option byte OTP_MCU_SYSRST_EN. If the option byte does not allow, the reset scope is limited to the MCU and WWDG1. In addition an interrupt can be generated to the MPU via the EXTI block.

Warning: It is recommended to set the MCU in CSleep before performing a MCU reset via MCURST bit.

Note: Setting the bit 2 of AIRCR register located into the MCU, activates the SYSRESETREQ signal. This reset is named MCSYSRST in this document.

Note: The SYSRESETREQ signal is connected to both EXTI and GIC allowing the MPU to receive a wakeup event and an interrupt when the MCU generates a MCSYSRST request.

The MPU will be reset either by a system reset (**nreset**) or by a CStandby local reset (**cstby_rst**).

10.3.5 Watchdog reset

Three watchdogs are provided to the application:

- The IWDG1 and IWDG2 dedicated to the MPU
- The WWDG1 dedicated to the MCU

The WWDG1 can generate a MCU local reset if it not acknowledged in the expected time-window. In addition an interrupt can be generated to the MPU via the EXTI block. Refer to *Section 46.2: IWDG main features* for details.

The IWDG1 and IWDG2 generate a system reset when a timeout occurs.

10.3.6 Backup domain reset

A backup domain reset (**nreset_vsw**) is generated when one of the following events occurs:

- Software reset, triggered by setting the VSWRST bit in the *RCC backup domain control register (RCC_BDCR)*. All RTC registers and the RCC_BDCR register are set to their reset values, except the field VSWRST itself. The BKPSRAM and RETRAM are not affected.
- When the V_{SW} voltage is outside the operating range. All RTC registers and the RCC_BDCR register are set to their reset values. In this case the content of the BKPSRAM and RETRAM are no longer valid.

Refer to *Section 1.3.3: Backup domain* section of PWR block for additional information.

10.3.7 Coresight debug reset

The coresight debug components including the debug part of the MPU, can be reset in three different ways:

- Over the DAP by setting to ‘1’ the bit CDBGRSTREQ of the control/status register of the debug port. Setting the bit CDBGRSTREQ to ‘1’ asserts the debug reset request signal CDBGRSTREQ connected to the RCC. Then the RCC activates the **dbg_rstn**, a handshake signal **cdbgrstack** is provided to the DAP request. The **dbg_rstn** is active as long as the **cdbgrstreq** is to ‘1’.
- By the application setting the bit DBGRST of *RCC debug configuration register (RCC_DBGCFGR)* to ‘1’. When DBGRST is set to ‘1’, the **dbg_rstn** reset is activated, the **dbg_rstn** reset is released when DBGRST = ‘0’.
- When V_{DDCORE} power-on reset occurs (**vcore_rst**). This reset is activated after a power-on reset, or when the product exits from Standby.

10.3.8 Option bytes loading

The option bytes configuration and the memory repair sequences are triggered every time the **app_rst** or the **vcore_rst** are activated (i.e. after an application reset, or when the system exits from Standby).

10.3.9 Peripheral reset

The application can reset individually any peripherals whenever it is requested. This can be done by both processors via registers named RCC_xxxxRSTSETR and RCC_xxxxRSTCLRR, “xxxx” is the bus name where the peripheral is connected.

Note that when the secure mode is enabled, only secure accesses can reset the peripherals connected to APB5.

When a peripheral needs to be reset, it is recommended to first enable its peripheral clock by setting the corresponding peripheral enable bit to ‘1’. Refer to *Section 10.4.10: Peripheral allocation* for details.

For other peripherals, it is up to the application to assert and release the peripheral reset (respectively via RCC_xxxxRSTSETR, and RCC_xxxxRSTCLRR registers).

10.3.10 Reset pulse control (RPCTL)

The RPCTL allows the application to control the minimum activation time of the NRST PAD. This feature is particularly helpful because some external devices may request a specific duration for the activation of the NRST. In addition the reset pulse generated by the IWDGx or WWDG, may be too short for external devices.

The RPCTL is located into the V_{DD} domain, and is only reset after a power-on reset.

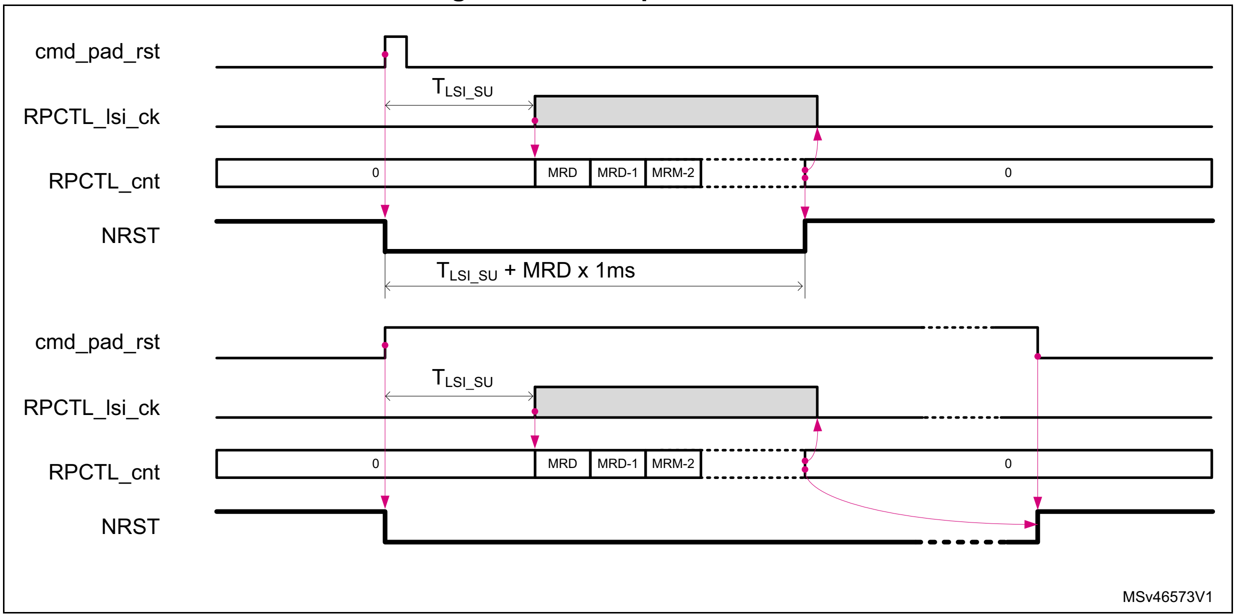
The RPCTL is controlled by the MRD[4:0] bits located in the *RCC reset duration and LSI control register (RCC_RDLSICR)*.

- If MRD = ‘0’, then the RPCTL is bypassed and the signal **cmd_pad_rst** directly drives the reset PAD. The minimum activation time in this case is given by the pulse stretcher embedded into the reset PAD (typically 20 µs).
- If MRD is different from ‘0’, when the reset is activated (rising edge of **cmd_pad_rst**), NRST is immediately driven Low at least for a duration equal to the value given by MRD[4:0]. The duration of the reset is not affected by the RPCTL in the case where the

cmd_pad_rst signal is active for a duration longer than the value programmed on MRD[4:0]. The MRD[4:0] bits allow to adjust a minimum activation time between 1 to 31 ms.

Note that the RPCTL is using the LSI clock in order to control the reset width. When the **cmd_pad_rst** goes HIGH, then the RPCTL requests the LSI clock in order to control the reset duration. If the LSI was not enabled by another function, it may take some microseconds before having the LSI ready (T_{LSI_SU}). *Figure 48* shows simplified timing diagrams.

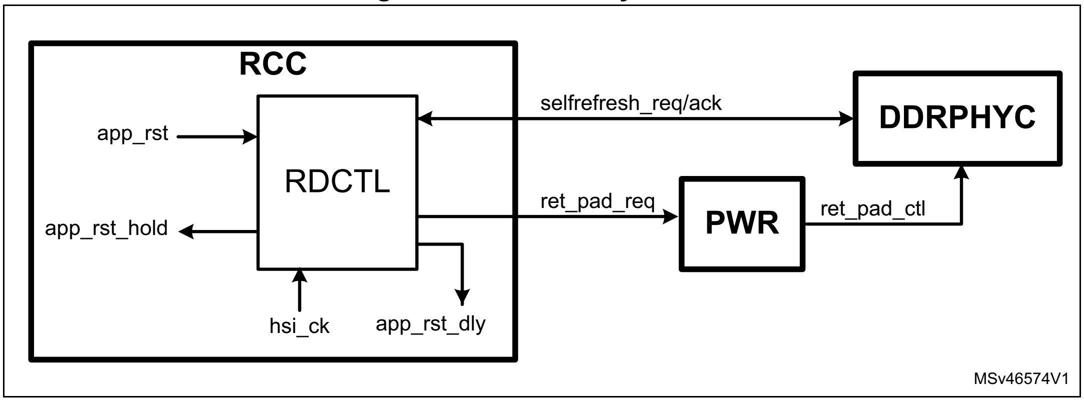
Figure 48. Reset pulse control



10.3.11 Reset delay control (RDCTL)

The RDCTL block must be used if the external DDR device needs to be set in self-refresh before generating a system reset (**nreset**) to the circuit.

Figure 49. Reset delay control



When enabled, the RDCTL performs the following operations:

If a **app_rst** occurs:

- The RDCTL keeps the **app_rst_dly** inactive and asserts the **app_rst_hold** signal in order to maintain the **cmd_pad_rst** active,
- The RDCTL activates the HSI oscillator, and waits if needed, the availability of **hsi_ck** clock,
- If the system is in Stop, LP-Stop or LPLV-Stop mode, then the **app_rst_dly** signal is activated and the **app_rst_hold** signal is released.
- Otherwise, if the system is in Run, then:
  - The timeout counter starts to count-down,
  - The RDCTL requests to the DDRPHYC to set the external DDR device into self-refresh.
  - Once the DDRPHYC confirms that the external DDR device is in self-refresh, then the RDCTL performs the following actions:
    - Freeze of the timeout counter,
    - Requests to the PWR to set the DDR pads into retention mode (**ret_pad_req**),
    - Activates the **app_rst_dly** signal,
    - Releases the **app_rst_hold** signal.
  - If the timeout counter elapses before the RDCTL receives the confirmation that the external DDR device is set to self-refresh, the **app_rst_dly** is activated, and the signal **app_rst_hold** is released.

The RDCTL can be enabled or disabled by the application via the RDCTLEN bit of *RCC application reset control register (RCC_MP_APRSTCR)*. When the RDCTL is disabled (RDCTLEN = ‘0’), the signal **app_rst_dly** is not delayed and follows **app_rst** value, in addition, the DDR pads retention request is not generated.

Caution: The bit RDCTLEN must not be set to ‘1’, at the moment where the **app_rst** is asserted. It is preferable to enable this function during the initialization phase.

The application can also program the timeout value via the RSTTO[6:0] field of *RCC application reset control register (RCC_MP_APRSTCR)*.

This timeout value can be programmed using the following formula:

$$\mathrm{RSTTO} \geq \mathrm{round}\left(\frac{8192 \times T_{ck\_ker\_dphy}}{10^{-6}}\right)$$

Where $T_{ck\_ker\_dphy}$ represents the period of the kernel clock provided to the DDRPHYC.

Caution: It is not allowed to change this field value when RDCTLEN = ‘1’.
It is not recommended to set RSTTO[6:0] to ‘0’.

After a **nreset**, the application can check if the external DDR device has been properly set in self-refresh by checking the RSTTO[6:0]. The RSTTO[6:0] gives the current value of the timeout counter. If this value is equal to ‘0’, it means that a timeout condition occurs at the last time the RDCTL has requested to the external DDR device to self-refresh.

*Note: The **hsi_ck** frequency depends on the HSIDIV value.*

10.3.12 Reset coverage summary

Table 50 gives a detailed view of reset sources and reset domains (highlighted in gray). Each line represents a reset source.

Note: It is assumed that when V_{DD} is not valid, V_{DDCORE} is not valid as well.

Table 50. Reset coverage summary (1)

	PWR_MPUCR, PWR_MCUCR Individual bits of these registers do not have the same reset condition, refer to the PWR section for details.	x	x	x	x	-	-	-	-	-	-	-	-
	PWR_WKUPCR, PWR_WKUPFR, PWR_MPUWKUPENR, PWR_MCUWKUPENR	x	-	x	-	-	-	-	-	-	-	-	-
	Other registers	x	x	x	x	-	-	-	-	-	-	-	-
RTC		-	-	-	-	-	-	-	-	-	-	-	x

Table 50. Reset coverage summary (continued)[(1)]

Reseted functions	Reset lines											
	por_rst [(2)]	vcore_rst [(3)]	app_rst [(4)]	nreset	cstby_rst	mpup1_rst	mpup0_rst	mcu_rst	dbg_rstn	bsec_rstn	PERxRST	nreset_vsw
BKPSRAM and RETRAM After a reset of the V_{SW} domain, the backup regulator of the BKPSRAM and RETRAM are disabled, this function is controlled via the PWR block, BREN and RREN bits. If the nreset_vsw reset is due to a too low V_{SW} voltage, the content of BKPSRAM and RETRAM is lost.	-	-	-	-	-	-	-	-	-	-	-	x
Other Peripherals	x	x	x	x	-	-	-	-	-	-	x	-

1. The ‘x’ means that the function is reset by the corresponding reset line, the ‘-’ means that the function is not reset by the corresponding reset line.
2. When **por_rst** is asserted, the **vcore_rst**, the **nreset**, the **app_rst**, the **bsec_rst,** the **mcu_rst** are asserted as well.
3. When **vcore_rst** is asserted, the **nreset**, the **bsec_rst,** the **mcu_rst** the **dbg_rst** are asserted as well.
4. When **app_rst** is asserted, the **nreset**, the **bsec_rst**, the **mcu_rst** are asserted as well.

Reset of the RCC registers

Table 51 lists registers having bits into a voltage domain different from V_{DDCORE}. As a consequence some of those registers are not always reset by **nreset**. The RCC registers not shown in *Table 51* are reset by the system reset (**nreset**).

Table 51. RCC registers with specific reset and specific voltages

RCC register name	Voltage domain	Reset condition	Comment
RCC_MP_BOOTCR	V_{DD}	app_rst	Shall be reset after a System reset, but not after Standby
RCC_OCENSETR, RCC_OCENCLRR, RCC_OCRDYR, RCC_HSICFGR, RCC_CSICFGR	V_{DD}	nreset	-
RCC_BR_RSTSCLRR	V_{DD}	por_rst	Only reset when a V_{DD} is removed
RCC_MC_RSTSCLRR	V_{DD}	por_rst	Only reset when a V_{DD} is removed
RCC_RDLSICR	V_{DD}	por_rst	Only reset when a V_{DD} is removed
RCC_BDCR	V_{SW}	nreset_vsw	-

10.3.13 Reset source identification

The RCC offers four registers in order to identify the root cause of resets:

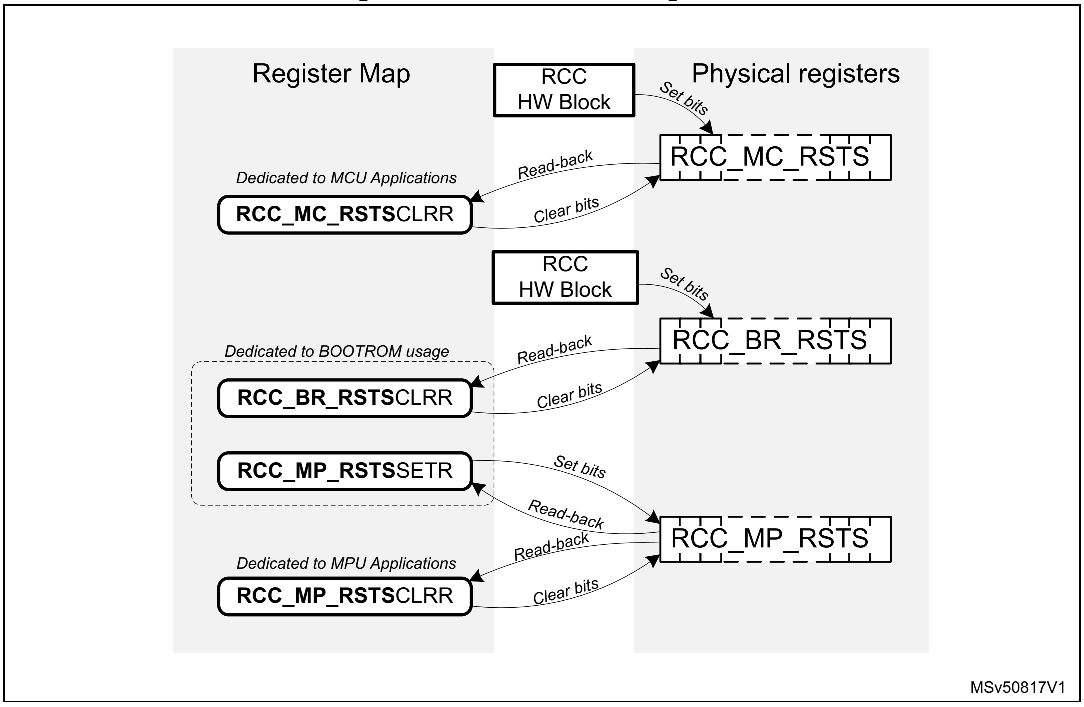
- *RCC BOOTROM reset status clear register (RCC_BR_RSTSCLRR)*,
- *RCC MCU reset status clear register (RCC_MC_RSTSCLRR),*
- *RCC MPU reset status clear register (RCC_MP_RSTSCLRR)* and
- *RCC MPU reset status set register (RCC_MP_RSTSSETR)*

The registers RCC_MP_RSTSSETR and RCC_BR_RSTSCLRR are dedicated to the BOOTROM usage, and must not be used by the application.

The register RCC_MP_RSTSCLRR is dedicated to the MPU applications, and the register RCC_MC_RSTSCLRR is dedicated to the MCU applications.

The figure hereafter is giving details on the way the reset source registers are working.

Figure 50. Reset source registers



The BOOTROM will use the RCC_BR_RSTSCLRR register in order to identify the root cause of the reset, and to define which kind of boot sequence must be performed. In addition the BOOTROM code will update the RCC_MP_RSTSCLRR register after every system reset, power-on reset or exit from Standby and CStandby. More precisely, the BOOTROM copies the content of RCC_BR_RSTSCLRR and the value of SBF and SBF_MPU flags into the RCC_MP_RSTSCLRR register, using the RCC_MP_RSTSSETR register.

Then the MPU can check and clear the reset sources by reading the RCC_MP_RSTSCLRR register. On its side, the MCU can check and clear the reset sources by reading the RCC_MC_RSTSCLRR register. Each CPU can reset the flags of their own registers.

Table 52 shows how the status bits of RCC_MC_RSTSCLRR, RCC_BR_RSTSCLRR and RCC_MP_RSTSCLRR registers behave, according to the situation generating a reset.

Table 52. Reset source identification (RCC_MP/MC/BR_RSTSCLRR, and PWR)[1]

#	Situations Generating a Reset	HCSSRSTF	WWDG1RSTF	IWDG2RSTF	IWDG1RSTF	CSTDBYRSTF [2]	STDBYRSTF [2]	MCSYSRSTF	MPUP1RSTF [3]	MPUP0RSTF [3]	MPSYSRSTF	PORRSTF	BORRSTF	VCORERSTF	PADRSTF	MCURSTF
1	Power-on reset (**por_rst**)	0	0	0	0	0	0	0	0	0	0	1	0	1	1	1
2	Brownout reset (**bor_rst**)	0	0	0	0	0	0	0	0	0	0	0	1	0	1	1
3	Pad reset from NRST	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1
4	System reset generated by MCU (MCSYSRST), when system reset is allowed by the option byte OTP_MCU_SYSRST_EN.	0	0	0	0	0	0	1	0	0	0	0	0	0	1	1
	Local reset generated by MCU (MCSYSRST), when system reset is not allowed by the option byte OTP_MCU_SYSRST_EN.	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
5	System reset generated by MPU (MPSYSRST)	0	0	0	0	0	0	0	0	0	1	0	0	0	1	1
6	MCU reset by MPU (MCURST)	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1
7	System exits from Standby	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0
8	MPU exits from CStandby	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0
9	MPU processor 0 reset generated by the MPU	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0
10	MPU processor 1 reset generated by the MPU	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0
11	WWDG1 reset (**wwdg1_out_rst**)	0	1	0	0	0	0	0	0	0	0	0	0	0	0	1
12	IWDG1 reset (**iwdg1_out_rst**)	0	0	0	1	0	0	0	0	0	0	0	0	0	1	1
13	IWDG2 reset (**iwdg2_out_rst**)	0	0	1	0	0	0	0	0	0	0	0	0	0	1	1
14	Reset due to a failure of V_{DDCORE} or assertion of NRST_CORE	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0
15	Reset due to a clock failure on HSE	1	0	0	0	0	0	0	0	0	0	0	0	0	1	1

1. The bit status at ‘1’ is highlighted in gray.
2. Those bits are located into the CC_MP_RSTSCLRR and RCC_MP_RSTSSETR registers. The BOOTROM copies the SBF bit into STDBYRSTF and the SBF_MPU bit into CSTDBYRSTF. The SBF and SBF_MPU are described into *Section 1.9.5: PWR MPU control register (PWR_MPUCR)*.
3. Bits MPUP[1:0]RSTF are not available into the RCC_MC_RSTSCLRR register.

Note: The MCSYSRSTF bit located into the RCC_BR_RSTSCLRR *and* RCC_MP_RSTSR *registers is only meaningful when the option byte OTP_MCU_SYSRST_EN allows the MCU to perform a system reset. If it is not the case the bit MCSYSRSTF is forced to ‘0’.*

10.3.14 Power-on and wakeup sequences

For detailed diagrams refer to *Section 1.3.1: Supply system startup* of the PWR block.

The time interval between the event which exits the product from a low-power mode and the moment where the CPUs are able to execute code, depends on the state of the system and its configuration. *Figure 51* shows the most usual examples.

Power-on wakeup sequence

The “power-on wakeup” sequence of *Figure 51* gives the most significant phases of the power-on sequence. It is the longest sequence as the circuit was not powered. Note that this sequence remains unchanged if VBAT was present or not.

Boot sequence from PAD reset (NRST)

The “PAD reset” gives the most important steps of the boot sequence. Note that in this case, V_{DD}/V_{DDA} have not been removed.

- The setting time is faster as the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI is not enabled when the NRST occurs, otherwise this restart delay phase is skipped.
- The option byte reloading is performed.

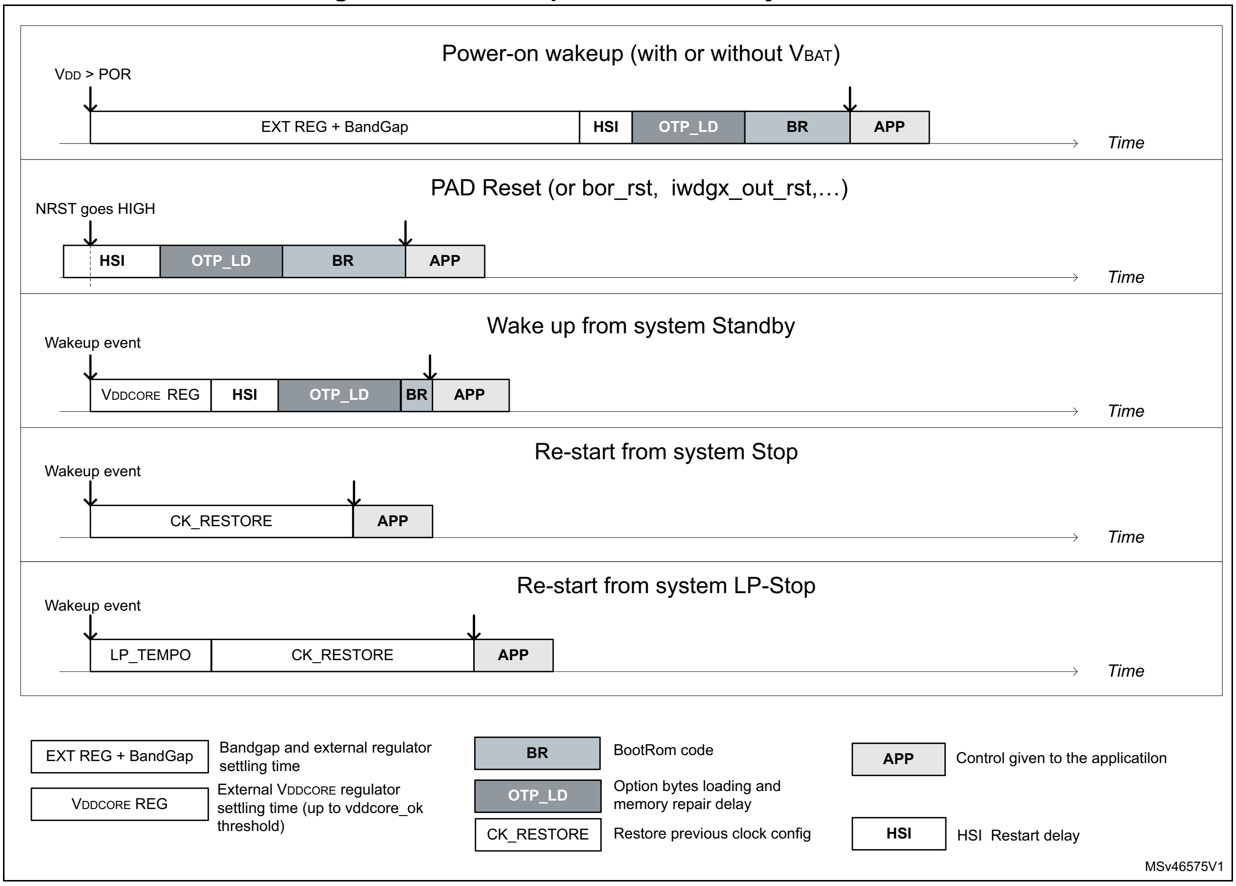
Boot sequence from system Standby

For a wake up from system Standby, as the V_{DD} is not removed, the settling time is also fast as the reference voltage is already stable. As the V_{DDCORE} was not there, the re-start delay for the HSI, and the option byte reloading cannot be skipped.

Re-start sequence from system Stop

For a re-start from system Stop, V_{DDCORE} has not been removed, so the settling time is mainly due to the re-start delay of the clock. It can be fast if the system has been programmed to restart on HSI/CSI, but it will be longer if the system restarts on HSE, and/or PLLs.

Figure 51. Boot sequences versus system states



MCU HOLD_BOOT after processor reset

The RCC allows to put the MCU on HOLD_BOOT every time the MCU is reset.

This function is controlled by the MPU via the BOOT_MCU bit located into the *RCC global control register (RCC_MP_GCR)*. The BOOT_MCU bit can only be programmed by the MPU. In addition, if the secure mode is activated, only secure MPU accesses will be allowed.

When BOOT_MCU = ‘0’, after a MCU reset, the MCU is maintained on HOLD_BOOT until the MPU sets the bit BOOT_MCU to ‘1’.

The possible reset sources for the MCU are:

- System reset (**nreset**),
- The reset generated by the MPU (MCURST),
- The WWDG1 reset (wwdg1_out_rst),
- The reset generated by the MCU itself (MCSYSRST).

Having the MCU on HOLD_BOOT, does not prevent the system to go to one of the Stop modes, or in Standby. So when the MCU is on HOLD_BOOT, the system will be in Stop mode if the MPU goes to CStop, then if the MPU allows the Standby mode, the system can go to Standby (if PDDS bits are set to ‘1’).

In conclusion, the HOLD_BOOT mode is equivalent to a MCU CStop mode. This means that when the MCU is in HOLD_BOOT, all the peripherals allocated by the MCU, will no longer be clocked, except the ones able to request a kernel clock, or working with **lse_ck** or **lsi_ck**.

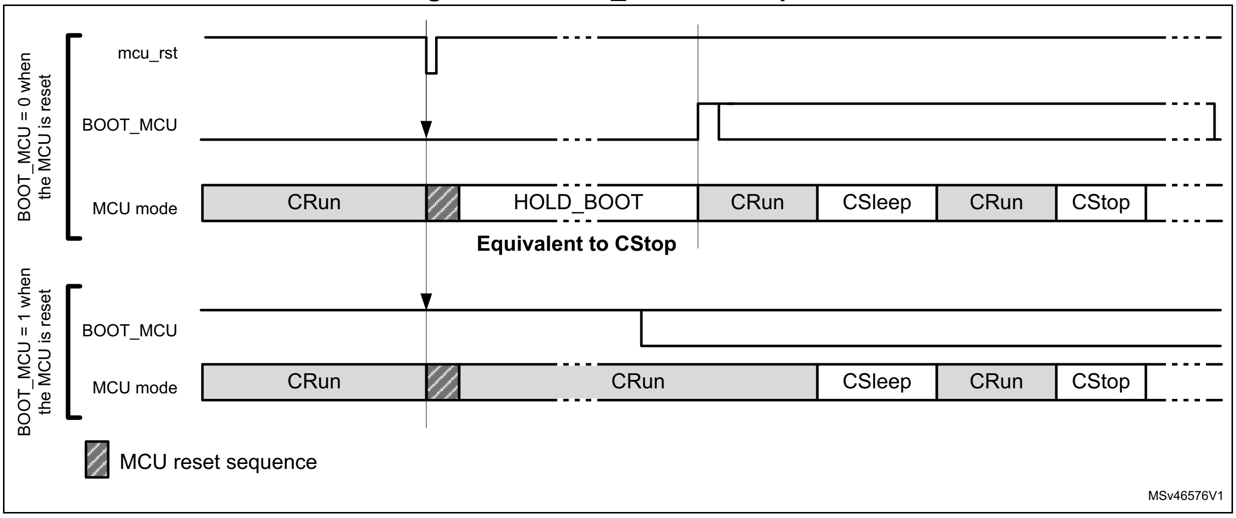
The BOOT_MCU bit is reset after a system reset, a power-on reset, or an exit from Standby (i.e. **nreset** signal).

Figure 52 shows two examples. An example where the BOOT_MCU bit is set to ‘0’, when the MCU is reset. In that case the MCU stays in HOLD_BOOT mode until the MPU sets the BOOT_MCU bit to ‘1’.

In the second example, the bit BOOT_MCU bit is set to ‘1’, when the MCU is reset. In that case the MCU switches immediately to CRun mode as soon as the MCU hardware reset sequence is completed.

Note that once the MCU is in CRun, the BOOT_MCU can be set again to ‘0’ without disturbing the MCU activity. In that way the MCU will be again set in HOLD_BOOT the next time it is reset.

Figure 52. HOLD_BOOT examples



Processor hold from Standby

The BOOTROM code provides the possibility to select which processor is allowed to restart its application code after a Standby mode. This feature is controlled via two bits: MPU_BEN and MCU_BEN.

The bits MPU_BEN and MCU_BEN can only be programmed by the MPU. In addition, if the secure mode is activated, only secure MPU accesses can change those bits. They are reset by hardware after a system reset (from IWDG, POR, BOR, PAD), but not when the product exits from Standby. Those bits are located into V_{DD} domain in order to be reset after a power-on reset. Refer to the *RCC boot control register (RCC_MP_BOOTCR)*.

After a system reset, a power-on reset, or an exit from Standby, the MCU is always maintained on HOLD_BOOT by the hardware (because BOOT_MCU bit is reset), and only the MPU is allowed to boot, thus to execute the BOOTROM code.

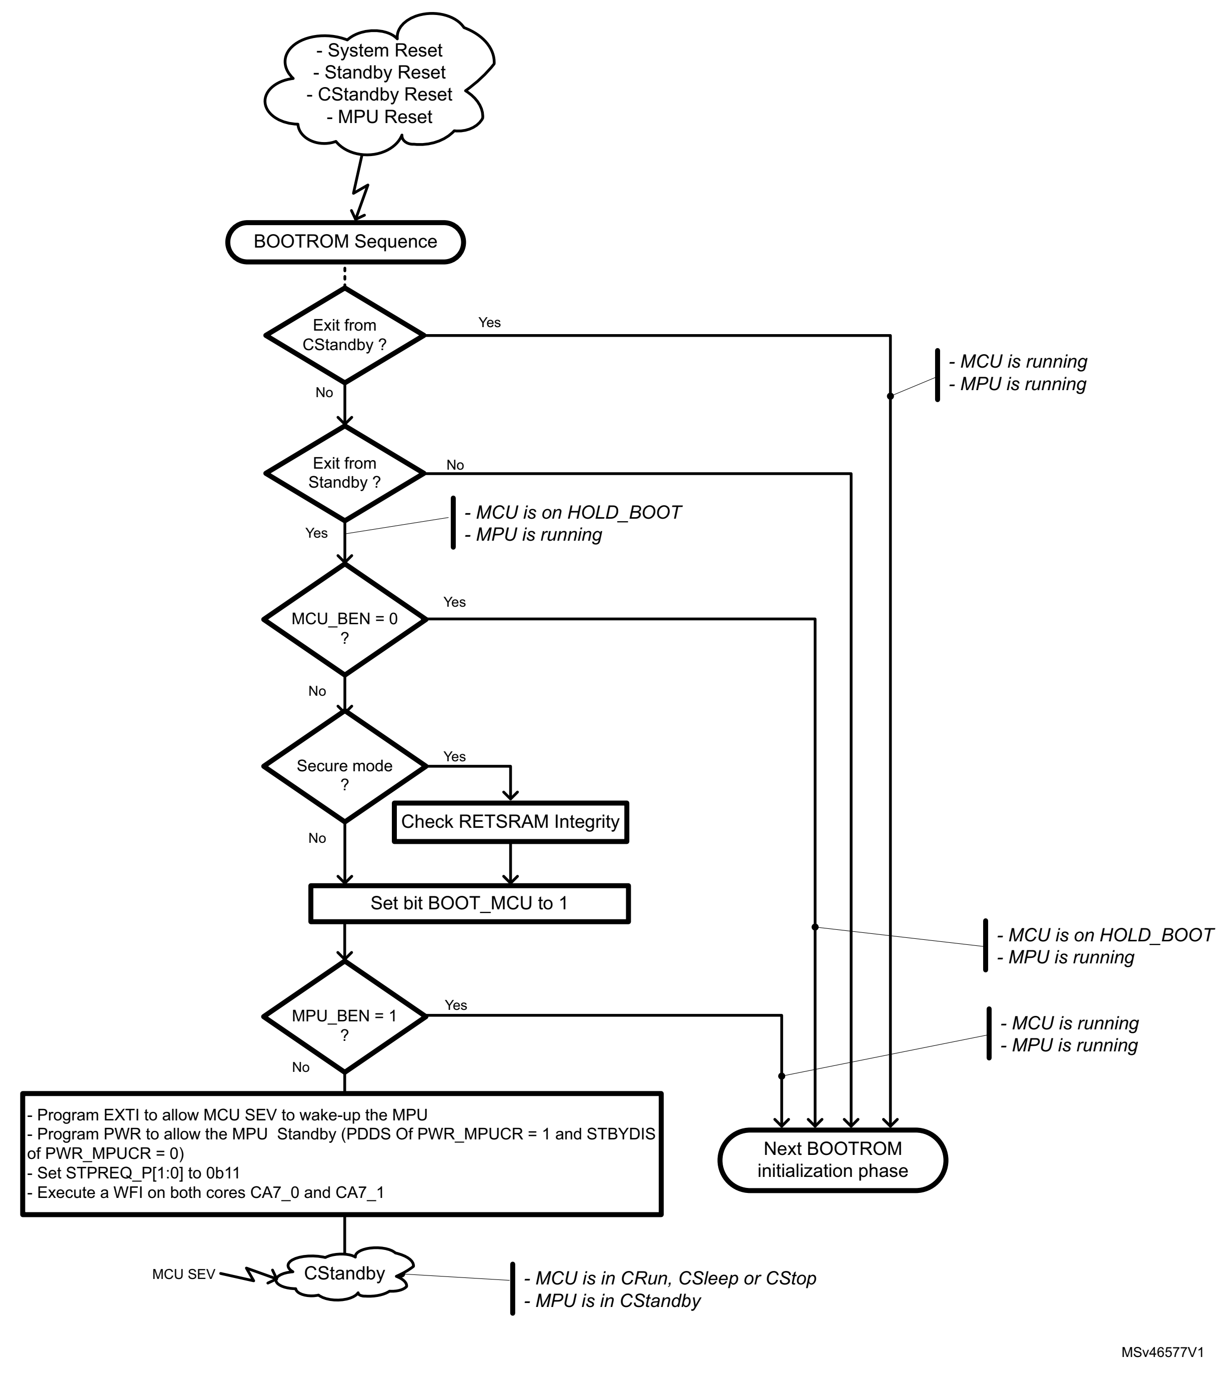
If the application wants that only the MCU restarts after a product Standby, the MPU shall set the bit MCU_BEN to ‘1’, and MPU_BEN to ‘0’ before the product goes to Standby. Then when the product exits from Standby, the BOOTROM will check the integrity of the RETRAM code (only in secure mode), and give the control to the MCU, by setting the bit BOOT_MCU to ‘1’.

Then the BOOTROM sets the MPU to CStandby. The MPU can exit from the CStandby mode by a MCU SEV event, or a system reset.

If MPU_BEN was set to ‘1’, then the BOOTROM continue its initialization phase and jumps to the application instead of going to CStandby.

Note: The SEV is a Cortex-M4 instruction which can be used to generate a pulse event on the TXEV line. This line is connected to the EXTI in order to generate an event for the MPU even if the MPU is in CStop or CStandby.

Figure 53. Hold function handled by the BOOTROM



10.4 RCC functional description - clock part

The RCC provides a high degree of flexibility to the application in the choice of the clock generators:

- The clock from HSI: High Speed Internal oscillator (~ 8, 16, 32, 64 MHz)
- The clock from HSE: High Speed External oscillator (8 to 48 MHz)
- The clock from LSE: Low Speed External oscillator (32.768 kHz)
- The clock from LSI: Low Speed Internal oscillator (~ 32 kHz)
- The clock from CSI: Low Power Internal oscillator (~4 MHz)

It offers a good flexibility for the application to select the appropriate clock for CPUs and peripherals. More especially for peripherals that need a specific clock like Ethernet, USB OTG FS and HS, SPI(I2S), SAI and SDMMC.

Each clock source can be switched on or off independently in order to optimize the power consumption.

There are mainly 4 clock paths:

- The MPU clocking
- The AXI Sub-System (AXI-SS) clocking, including the DDR interface
- The MCU, and its bus matrix
- The peripheral kernel clocks

The RCC provides up to 4 PLLs, each of them can be configured with integer or fractional ratios.

- The PLL1 is dedicated to the MPU clocking
- The PLL2 provides:
  - The clocks for the AXI-SS (including APB4, APB5, AHB5 and AHB6 bridges)
  - The clocks for the DDR interface
- The PLL3 provides:
  - The clocks for the MCU, and its bus matrix (including the APB1, APB2, APB3, AHB1, AHB2, AHB3 and AHB4)
  - The kernel clocks for peripherals
- The PLL4 is dedicated to the generation of the kernel clocks for various peripherals

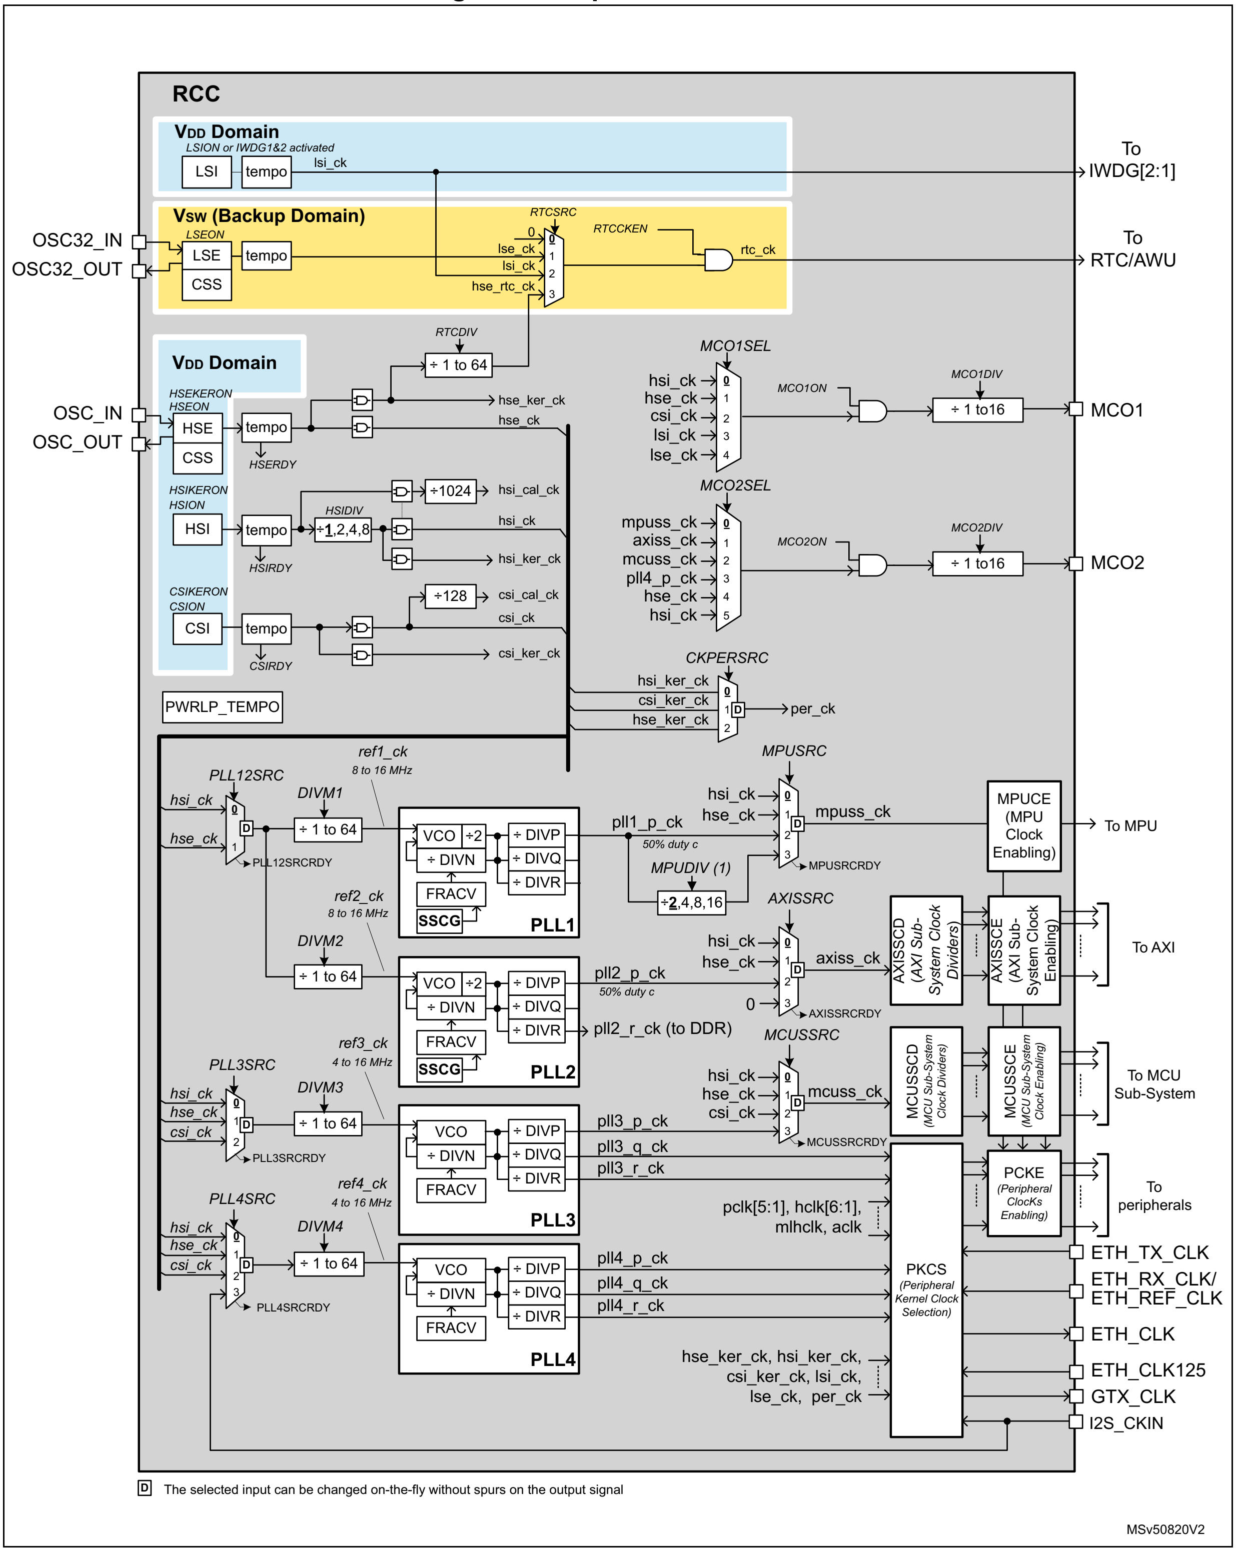
The blocks named AXISSCD, and MCUSSCD contain several prescalers used to configure the processors and bus matrix clock frequencies.

The blocks named AXISSCE, MCUSSCE and PCKE are responsible for the gating of the peripheral kernel clock, the bus interface, the cores and bus matrix clocks.

The block named PKCS (Peripheral Kernel Clock Selection) provides several dynamic switches allowing a large choice for the kernel clock distribution to peripherals.

As shown in *Figure 54*, the RCC offers 2 clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

Figure 54. Top-level clock tree



2. **X** represents the selected MUX input after a system reset.

10.4.1 Clock naming convention

The RCC is providing clocks to the complete circuit. In order to avoid misunderstanding, the following terms are used in this document:

- **The peripheral clocks:**
  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clocks can be provided to a peripheral:
  - The bus interface clocks
  - The kernel clocks

  A peripheral will receive from the RCC one or several bus interface clocks. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (example GPIOx, DMAx...).

  Some peripherals request as well a dedicated clock in order to handle the interface function. This clock is named kernel clock. For example peripherals such as SAI, need to generate specific and accurate master clock frequencies, which requests dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific need of the interface, is that the bus clock can be changed without requesting any reprogramming of the peripheral.
- **The CPU clocks**
  The CPU clock is the clock provided to the CPUs (**mcu_ck**, **mpuss_ck**).
- **The bus matrix clocks**
  The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI).

10.4.2 Oscillators description

The table hereafter shows the oscillator states versus system modes when the oscillators are enabled via registers. The term “available” means that the resource can be used if activated via registers.

Table 53. Oscillator states versus system modes

System modes	V_{DD} domain				V_{SW} domain
	HSE	HSI	CSI	LSI	LSE
Exit from system reset	OFF	ON	OFF	Available	Available
In Run	Available	Available	Available	Available	Available
In Stop, LP-Stop	Available (1)	Available (2)	Available (3)	Available	Available
In Standby, LPLV-Stop	OFF	OFF	OFF	Available	Available
In VBAT	OFF	OFF	OFF	OFF	Available

1. HSE can remain activated in (LP-)Stop mode if HSEKERON = ‘1’, or if the peripheral generates a kernel clock request.
2. HSI can remain activated in (LP-)Stop mode if HSIKERON = ‘1’, or if the peripheral generates a kernel clock request.
3. CSI can remain activated in (LP-)Stop mode if CSIKERON = ‘1’, or if the peripheral generates a kernel clock request.

The HSE oscillator

The High Speed External block can generate a clock from two possible sources:

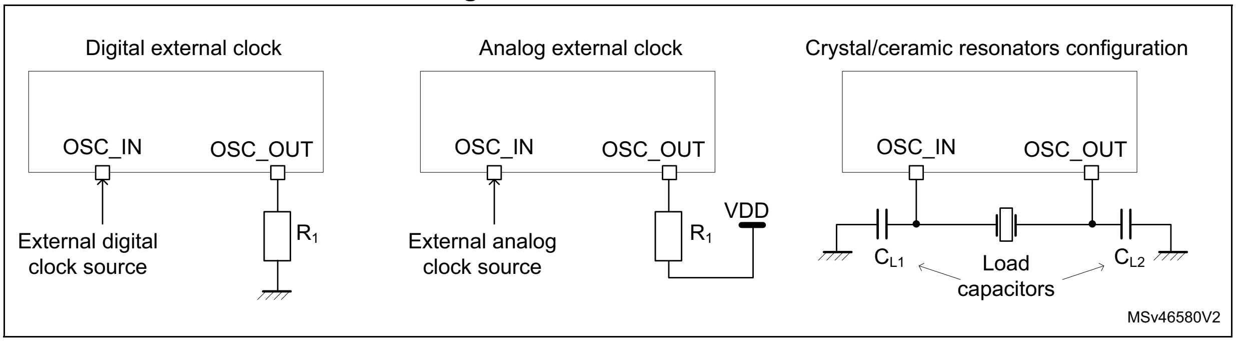
- external analog clock source
- external digital clock source
- external crystal/ceramic resonator

In order to allow the BOOTROM to detect in which configuration the HSE is used, a resistor (R1) must be connected either to the GND or to V_{DD}.

The resistor must be connected to the GND in the case where the HSE is using an external digital clock. The resistor must be connected to the V_{DD} in the case where the HSE is using an external analog clock, and removed if a crystal or ceramic resonator is used.

Refer to the datasheet for the values of C_{L1}, C_{L2} and R1.

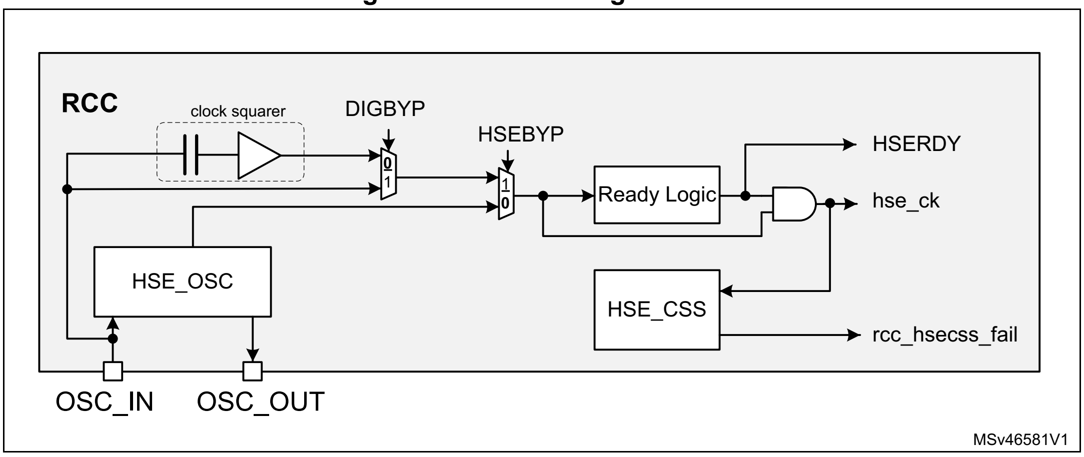
Figure 55. HSE clock source



The HSERDY flag of the *RCC oscillator clock ready register (RCC_OCRDYR)* indicates whether the HSE oscillator is stable or not. When the HSE is enabled (HSEON set to '1'), the HSERDY flag goes to '1' when 512 cycles of HSE clock have been counted. The **hse_ck** clock is not released until the HSERDY bit is set by hardware. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_MP_CIER)* or *RCC clock source interrupt enable register (RCC_MC_CIER)*.

Figure 56 shows a simplified view of the HSE clock generation.

Figure 56. HSE clock generation



Note as well that it is possible to keep the HSE enabled, when the system is in (LP-)Stop mode, see *Section 10.4.7: Clock generation in Stop and Standby modes* for additional information.

In addition, it is possible to drive the HSE clock to the MCO1 and MCO2 outputs and use it as a clock source for other application components.

External clock configuration (HSE bypass)

The HSE can accept an external clock source on OSC_IN when the bypass mode is selected (HSEBYP = ‘1’).

The external clock signal connected to OSC_IN pin can be digital or low-swing (analog). The low-swing clock signal is supported thanks to an internal clock squarer. The input signal shall have a duty cycle close to 50%.

In order to switch the HSE in external clock mode, the user shall do the following:

- Disable the HSE by writing to ‘1’ the HSEON bit of the *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.
- Check that the HSE is disabled by verifying that the bit HSERDY of *RCC oscillator clock ready register (RCC_OCRDYR)* is set to ‘0’.
- Either set the bit DIGBYP to ‘1’ if the clock provided to OSC_IN is full-swing digital signal, or set the bit DIGBYP to ‘0’ if the clock provided to OSC_IN is low-swing signal. The bit DIGBYP can be controlled via *RCC oscillator clock enable set register (RCC_OCENSETR)* and *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.
- Set the bit HSEBYP to ‘1’ by writing the HSEBYP bit of *RCC oscillator clock enable set register (RCC_OCENSETR)*.
- Enable again the HSE by writing to ‘1’ the bit HSEON of *RCC oscillator clock enable set register (RCC_OCENSETR)*, in order to activate the hse_ck.
- Check that the bit HSERDY of *RCC oscillator clock ready register (RCC_OCRDYR)* is set to ‘1’, then the HSE is ready for use.

See *Figure 55* and *Figure 56* for details. Refer to the datasheet for additional information.

External crystal/ceramic resonator configuration

The oscillator is enabled by setting the HSEBYP bit to ‘0’, and HSEON to ‘1’.

The HSE can be used when the product needs a very accurate high speed clock.

In order to select the external crystal/ceramic resonator, the application must follow the sequence hereafter:

- Disable the HSE by writing to ‘1’ the HSEON bit of the *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.
- Check that the HSE is disabled by verifying that the bit HSERDY is set to ‘0’,
- Set the bit HSEBYP to ‘0’, by writing to ‘1’ the HSEBYP bit of *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.
- Enable again the HSE by writing to ‘1’ the bit HSEON, of *RCC oscillator clock enable set register (RCC_OCENSETR)*.
- Check that the bit HSERDY is set to ‘1’, then the HSE is ready for use.

The associated hardware configuration is shown in *Figure 55*. The resonator and the load capacitors have to be placed as close as possible to the oscillator pins in order to minimize the output distortion and the start-up stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The HSI oscillator

The HSI provides the default clock to the product.

The HSI is a High Speed Internal RC oscillator which can also be used directly as a source for processors and interconnects clocks, peripheral clock, or as PLL input.

A pre-divider allows the user to select a HSI output frequency of 8, 16, 32 or 64 MHz. This pre-divider is controlled by HSIDIV located into the *RCC HSI configuration register (RCC_HSICFGR)*. A flag (HSIDIVRDY) is also available into the *RCC oscillator clock ready register (RCC_OCRDYR)* in order to check when the new division ratio is taken into account by the hardware.

Note that the HSIDIV value can be changed on-the-fly, and the HSI block will take into account the new division ratio without generating any spurs on the HSI clock.

However the following points must be considered:

- It is **not allowed** to change HSIDIV, if the HSI is currently used as reference clock for a PLL.
- If the HSI clock is currently used as kernel clock for some peripherals, the application has to ensure that the HSI frequency change will not disturb the peripherals.

The HSI has some advantages:

- No need of external crystal; could be interesting as low-cost clock source,
- Startup time faster than HSE: few microseconds,
- Reduced power consumption

The HSI precision, even with the frequency calibration is less accurate than an external crystal oscillator or ceramic resonator.

Care must be taken when the HSI is used as kernel clock for communication peripherals: the application has to take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

Note as well that it is possible to keep the HSI enabled, when the system is in (LP-)Stop mode, see *Section 10.4.7: Clock generation in Stop and Standby modes* for additional information.

The HSIRDY flag of RCC_OCRDYR register indicates whether the HSI is stable or not. At startup, the HSI output clock is not released until the HSIRDY bit is set by hardware. The HSI activation can also be controlled by the application via HSION bit located into the *RCC oscillator clock enable set register (RCC_OCENSETR)* and *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.

In addition, it is possible to drive the HSI clock to the MCO1 and MCO2 outputs and use it as a clock source for other application components.

Calibration

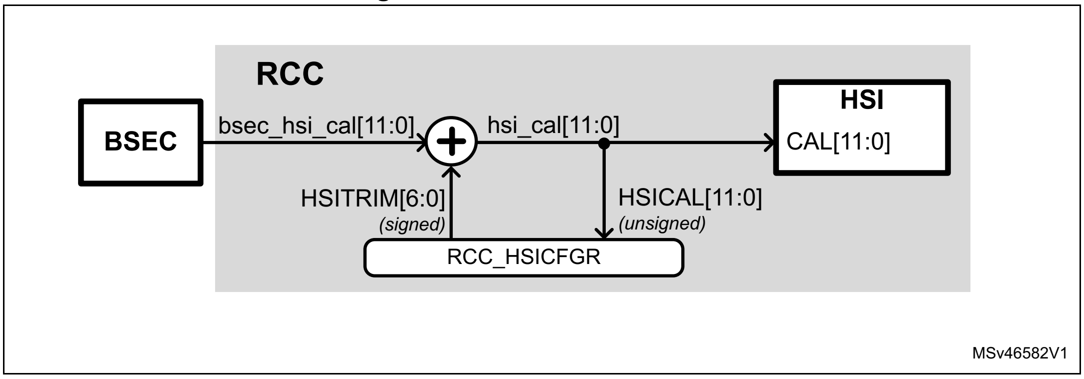
RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for an accuracy of ACC_{HSI}. Refer to the datasheet of the product for more information.

When a **app_rst** or **vcore_rst** occurred, the factory calibration value is reloaded in the HSI, and is visible on HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user can trim the HSI frequency using the HSITRIM[6:0] bits.

Bits HSICAL[11:0] and HSITRIM[6:0] are located into the *RCC HSI configuration register (RCC_HSICFGR)*.

Figure 57. HSI calibration flow



In addition the RCC provides a signal named **hsi_cal_ck** dedicated to the calibration of the HSI. This signal is connected to TIM15 and TIM12, refer to *Section 10.6.4: The clock calibration using TIMx* for additional information.

Note as well that the signal **hsi_cal_ck** is gated when the system goes to Stop.

The CSI oscillator

The CSI is a Low Power RC oscillator which can also be used directly as a source for processors and interconnects clocks, peripheral clock, or as PLL input for PLL3 and PLL4.

The CSI has some advantages:

- No need of external crystal; could be interesting as low-cost clock source,
- Startup time faster than HSE: few microseconds,
- Very low-power consumption,

Note that the CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

The CSI frequency precision, even with calibration of the frequency, is less accurate than an external crystal oscillator or ceramic resonator.

Even if the settling time of the CSI is faster than the one of the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application has to take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

Note as well that it is possible to keep the CSI enabled, when the system is in (LP-)Stop mode, see *Section 10.4.7: Clock generation in Stop and Standby modes* for additional information.

In addition, it is possible to drive the CSI clock to the MCO1 output and use it as a clock source for other application components.

The CSI can also be controlled by the application via CSION bit located into the *RCC oscillator clock enable set register (RCC_OCENSETR)* and *RCC oscillator clock enable clear register (RCC_OCENCLRR)*.

Calibration

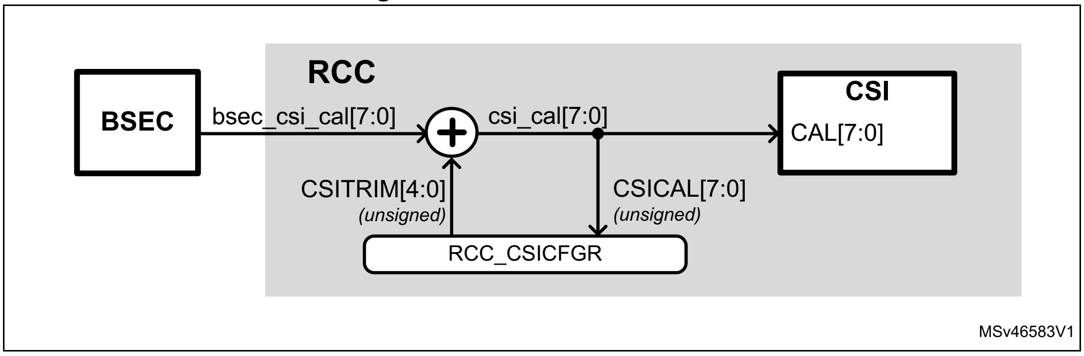
RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by ST for an accuracy of ACC_{CSI}. Refer to the datasheet of the product for more information.

When a **app_rst** or **vcore_rst** occurred, the factory calibration value is reloaded into the CSI, and is visible on CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations this may affect the RC oscillator frequency. The user can trim the CSI frequency using the CSITRIM[4:0] bits.

Bits CSICAL[7:0] and CSITRIM[4:0] are located into the *RCC CSI configuration register (RCC_CSICFGR)*.

Figure 58. CSI calibration flow



In addition the RCC provides a signal named **csi_cal_ck** dedicated to the calibration of the CSI. This signal is connected to TIM15 and TIM12, refer to *Section 10.6.4: The clock calibration using TIMx* for additional information.

Note as well that the signal **csi_cal_ck** is gated when the system goes to Stop.

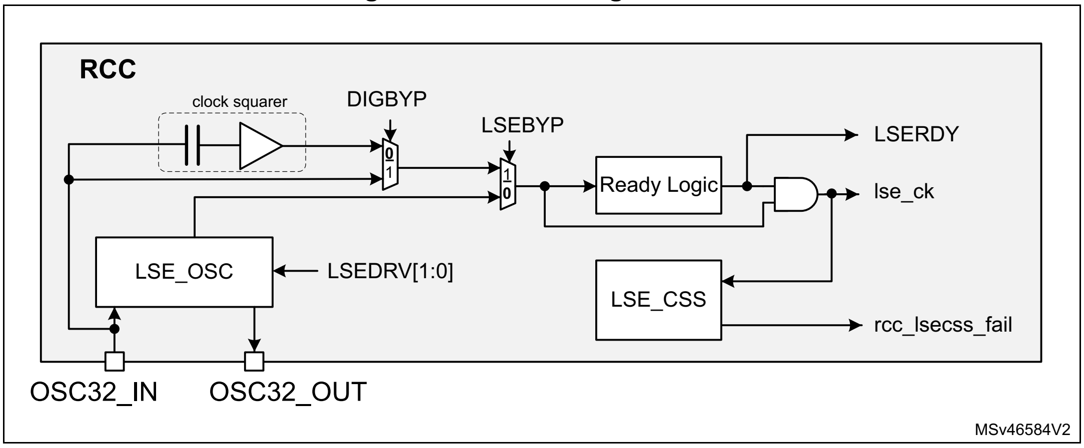
The LSE oscillator

The Low Speed External block can generate a clock from two possible sources:

- External crystal/ceramic resonator
- External user clock

The LSE function offers a LSERDY flag which indicates whether the LSE clock is available or not.

Figure 59. LSE clock generation



The LSE oscillator is switched on and off using the LSEON bit. The LSE remains enabled when the system enters in Stop, LP-Stop, LPLV-Stop, Standby or VBAT mode.

In addition, it is possible to drive the LSE clock to the MCO1 output and use it as a clock source for other application components.

External clock source (LSE bypass)

In this mode, an external clock source must be provided to OSC32_IN pin. The input clock can have a frequency up to 32.768 kHz, and be low-swing. This mode is selected by setting the LSEBYP and LSEON bits to ‘1’. In bypass mode, when the LSE is enabled (LSEON set to '1'), the LSERDY flag goes immediately to '1'.

The external clock signal can be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude, is supported thanks to an internal clock squarer. The input signal shall have a duty cycle close to 50%. The OSC32_OUT pin should be left HI-Z. Refer to the datasheet for additional information.

In order to select the external clock source, the application must follow the sequence hereafter:

- Set DBP bit of PWR_CR1 to ‘1’ in order to allow write accesses to RCC_BDCR register.
- Disable the LSE by writing to ‘0’ the LSEON bit,
- Check that the LSE is disabled by verifying that the bit LSERDY is set to ‘0’,
- Either set the bit DIGBYP to ‘1’ if the clock provided to OSC32_IN is full-swing digital signal, or set the bit DIGBYP to ‘0’ if the clock provided to OSC32_IN is low-swing signal,
- Set the bit LSEBYP to ‘1’,
- Enable again the LSE by writing to ‘1’ the bit LSEON,
- Check that the bit LSERDY is set to ‘1’, then the LSE is ready for use.
- Set DBP bit of PWR_CR1 to ‘0’ in order to write-protect accesses to RCC_BDCR register.

Note that those bits except DBP, are all located into the *RCC backup domain control register (RCC_BDCR)*.

External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage of providing a low-power but highly accurate clock source to the real-time clock peripheral (RTC) for clock/calendar or other timing functions.

In order to select the external crystal/ceramic resonator, the application must follow the sequence hereafter:

- Set DBP bit of PWR_CR1 to ‘1’ in order to allow write accesses to RCC_BDCR register.
- Disable the LSE by writing to ‘0’ the LSEON bit,
- Check that the LSE is disabled by verifying that the bit LSERDY is set to ‘0’,
- Set the bit LSEBYP to ‘0’,
- Configure LSEDRV[1:0] if needed,
- Enable again the LSE by writing to ‘1’ the bit LSEON,
- Check that the bit LSERDY is set to ‘1’, then the LSE is ready for use.
- Set DBP bit of PWR_CR1 to ‘0’ in order to write-protect accesses to RCC_BDCR register.

Note that those bits are all located into the *RCC backup domain control register (RCC_BDCR)*.

When the LSE is enabled (LSEON set to '1'), the LSERDY flag goes to '1' when 4096 cycles of LSE clock have been detected. This mechanism is also activated for an external clock source (LSEBYP = '1'). An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_MP_CIER)* or *RCC clock source interrupt enable register (RCC_MC_CIER)* when the LSE is ready.

Note: The LSE on MCO1 output is only available in Run and (LP-)Stop mode. In LPLV-Stop, Standby and VBAT mode LSE is not available from MCO1 output. When entering Standby or VBAT mode a spike may occur on MCO1.

The LSE offers a programmable driving capability (LSEDRV[1:0]) of the oscillator amplifier.It allows the application to adapt the oscillator to the characteristics of the external components. The driving capability shall be changed before enabling the LSE oscillator.

Warning: It is not allowed to change the driving capability when the LSE is enabled. The LSE behavior is not guaranteed in that case.

The LSI oscillator

The LSI acts as an low-power clock source that can be kept running when the System is in Stop, LP-Stop, LPLV-Stop or Standby mode for the independent watchdogs (IWDG) and Auto-Wakeup Unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched on and off using the LSION bit, and the LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled.

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_MP_CIER)* or *RCC clock source interrupt enable register (RCC_MC_CIER)*.

In addition, it is possible to drive the LSI clock to the MCO1 output and use it as a clock source for other application components.

Note: Note that the LSI on MCO1 output is only available in Run and (LP-)Stop mode. In LPLV-Stop and Standby mode, the LSI is not available from MCO1 output. When entering Standby mode a spike may occur on MCO1.

Bits LSION and LSIRDY are located into the *RCC reset duration and LSI control register (RCC_RDLSICR)*.

10.4.3 Clock security system (CSS)

CSS on HSE

The RCC features a clock security system allowing the application to detect if the HSE clock stops toggling due to an unexpected reason. This could be caused for example, by a hardware failure or an attack. In the case failure detection the CSS will generate a system reset, and protect sensitive data of the BKPSRAM.

The clock security system can be activated by the application software via HSECSSON bit. The HSECSSON bit can be activated even when the HSEON is set to ‘0’. The CSS on HSE will be enabled by the hardware when the HSE is enabled and ready, and HSECSSON is set to ‘1’.

The CSS on HSE is disabled when the HSE is disabled (i.e. when the system is Stop or Standby).

It is not possible to clear the bit HSECSSON by software.

The bit HSECSSON will be cleared by the hardware when a system reset occurs or when the system enters in Standby mode. The bits HSEON and HSECSSON are located into the *RCC oscillator clock enable set register (RCC_OCENSETR)*.

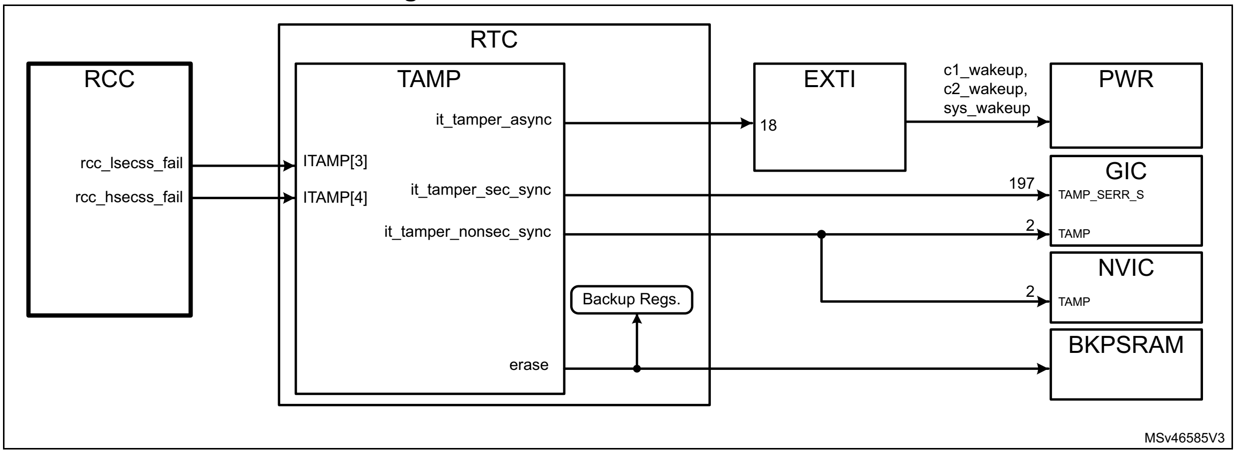
If a failure is detected on the HSE:

- The RCC generates an application reset (**app_rst** and **nreset**). The flag HCSSRSTF is set in order to allow the application to identify the reset root cause.
- A failure event is generated (**rcc_hsecss_fail**). This event is connected to the TAMP block, allowing the protection of backup registers and BKPSRAM.

Figure 60 shows the block involved in the HSE and LSE CSS function. Refer to the description of those blocks to get more details.

Note: Note that before selecting again the HSE clock, after an HSE failure, at least one the HCSSRSTF flags located into RCC BOOTROM reset status clear register (RCC_BR_RSTSCLRR) or RCC MCU reset status clear register (RCC_MC_RSTSCLRR) must be cleared. The BOOTROM performs this task by resetting the HCSSRSTF flag of the RCC_BR_RSTSCLRR *register, after an HSE failure. Then the BOOTROM reboots the circuit if the selected boot source does not require the HSE resource. Refer to BOOTROM documentation for details.*

Figure 60. LSE and HSE CSS function



CSS on LSE

The RCC features a clock security system allowing the application to detect if the LSE clock stops toggling due to an unexpected reason. This could be caused for example, by a hardware failure or an attack. In case of failure detection the CSS will generate a failure event, disable the clock provided to the RTC and protect sensitive data of the BKPSRAM.

The Clock Security System (CSS) on Low Speed External (LSE) oscillator can be activated by setting to ‘1’ the LSECSSON bit of the RCC_BDCR register.
This bit can be disabled only by hardware in the two following conditions:

- After a **nreset_vsw** reset (see *Figure 47*), or
- After a failure detection on LSE.

The activation of the CSS on LSE must be done in the following order:

1. Set the LSEON to ‘1’, and wait for LSERDY = ‘1’,
2. Select the LSE clock via the RTCSRC field,
3. Set the LSECSSON to ‘1’,

LSEON and RTCSRC are also located into the *RCC backup domain control register (RCC_BDCR)*.

The CSS on LSE is working in all system modes: Run, Stop, Standby and VBAT.

If a failure is detected on the LSE:

- The clock provided to the RTC is disabled immediately by the hardware, by setting the RTCSRC field to ‘0’.
- The values of LSEON and LSECSSON are not changed by the hardware.
- A failure event is generated (**rcc_lsecss_fail**). This event is connected to the TAMP block, allowing to wake up from Standby, and allowing the protection of backup registers and BKPSRAM.
- An interrupt flag (LSECSSF) is activated in order to generate an interrupt to the MCU or MPU if needed.

The CSS on LSE offers two flags in order to detect a failure: the flag LSECSSD located into the RCC_BDCR register, and the LSECSSF located into the *RCC clock source interrupt flag register (RCC_MP_CIFR)*.

In case of failure, the software has to do the following:

- Disable the CSS function (this step is mandatory)
  – Set the LSECSSON bit to ‘0’
  – Set the LSEON bit to ‘0’, in order to disable the LSE
  – Clear the LSECSSF bit, if interrupt was enabled for this event
- Change the clock source for the RTC if needed:
  – Set the RTCEN bit to ‘0’ to disable the RTC clock
  – Enable the new clock source for the RTC
  – Select the proper clock source via RTCSRC
  – Set the RTCEN bit to ‘1’ to enable the RTC clock

For sure, the software can take any other required actions to secure the application.

Figure 60 shows the block involved in the HSE and LSE CSS function.

Note: The clock security feature must not be re-enabled.
Before re-using the CSS function for LSE, a backup domain reset must be performed for example via the VSWRST bit in RCC backup domain control register (RCC_BDCR).

10.4.4 Clock output generation (MCO1 and MCO2)

Two micro-controller clock output (MCO) pins are available: MCO1 and MCO2. For each output, it is possible to select a clock source.The selected clock can be divided thanks to configurable prescaler. Refer to *Figure 54* for additional information on signal selection.

The MCO1 and MCO2 outputs are controlled via MCO1DIV[3:0], MCO1SEL[2:0], MCO2DIV[2:0] and MCO2SEL[2:0] located into the *RCC MCO1 configuration register (RCC_MCO1CFGR)* and *RCC MCO2 configuration register (RCC_MCO2CFGR)*.

For the different MCO pins, the corresponding GPIO port has to be programmed in alternate function mode.

The dividers MCODIV1 and MCODIV2, provide a clock with a duty cycle of 50% for divisions with even values. More generally the duty cycle is given by the following formula:

$$DC(\%) = \frac{FLOOR\left(\frac{MCODIVx + 1}{2}\right)}{(MCODIVx + 1)} \times 100$$

For MCODIVx = 0, the duty cycle is also 50%.

Note that the MCO1 and MCO2 outputs are only available in Run and (LP-)Stop modes.

Caution: The clock provided to the MCOs outputs must not exceed the maximum PAD speed, Refer to the product datasheet for information about the supported PAD speed.

10.4.5 PLLs description

The RCC features four PLLs:

Two PLLs having a VCO frequency of up to 1.6 GHz (PLL_1600):

- A PLL (PLL1) exclusively used to provide the clock to the Cortex-A7 MPU Sub-System (CA7-SS).
- A PLL (PLL2) used to the clock generation for the AXI-SS. Some outputs of this PLL are also used to generate a kernel clock to peripherals.

Two PLLs having a VCO frequency of up to 800 MHz (PLL_800):

- A PLL (PLL3) used to provide the clock to the MCU and its interconnect.
- A PLL (PLL4) Dedicated to the generation of kernel clocks to peripherals.

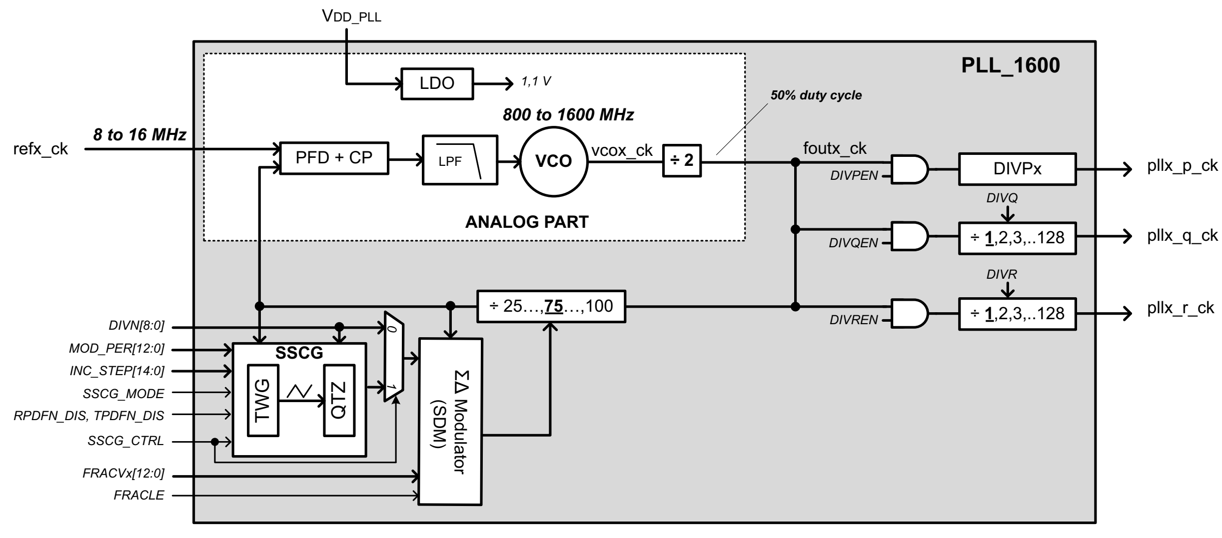
PLL_1600 main features:

- VCO range between 800 and 1600 MHz
- Input frequency range: 8 to 16 MHz
- Three working modes
  - Fractional mode, using 13-bit sigma-delta modulator. The sigma-delta modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
  - Integer mode
  - Spread spectrum mode in order to reduce EMI
- Up to 3 outputs:
  - 3 outputs with post-dividers

PLL_800 main features:

- VCO range between 400 and 800 MHz
- Input frequency range: 4 to 16 MHz
- Three working modes
  - Fractional mode, using 13-bit sigma-delta modulator. The sigma-delta modulator can be updated on-the-fly, without generating frequency overshoots on PLLs outputs.
  - Integer mode
- Up to 3 outputs:
  - 3 outputs with post-dividers

Figure 61. PLL1 and PLL2 block diagram

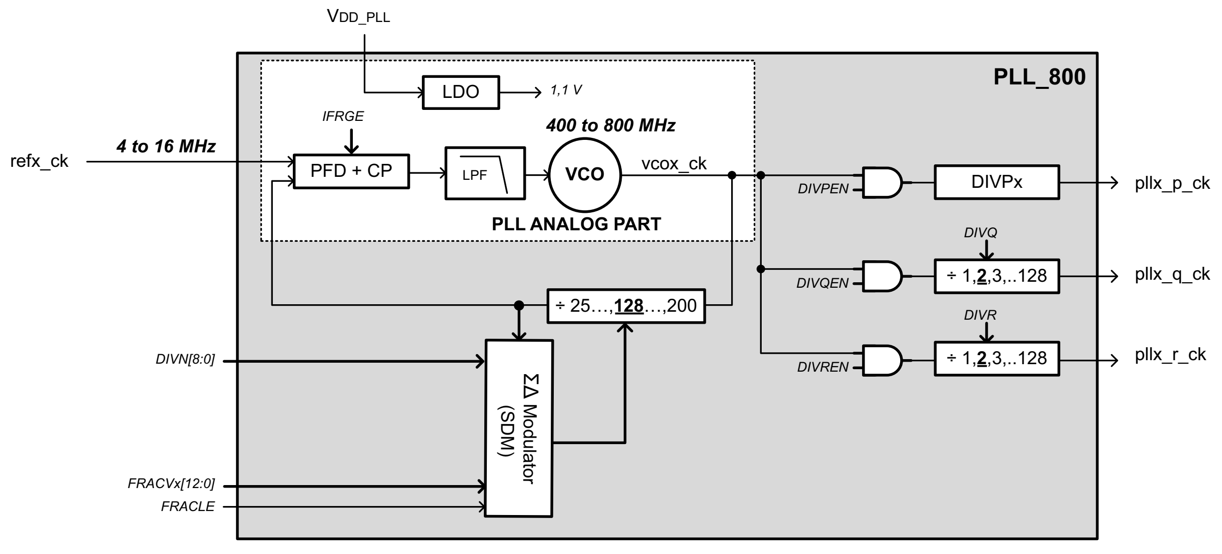


(1) It is recommended to use the values 1,2,4,6...128 for DIVP of PLL1 and PLL2

The PLL1 and PLL2 analog parts provide a dedicated outputs delivering a clean clock signal (**foutx_ck**) with a duty cycle of 50%. The **foutx_ck** clock has a frequency of F_{VCO} / 2, and is available on **pllx_p_ck, pllx_q_ck** and, **pllx_r_ck** outputs when the post-dividers are bypassed.

The MPU and DDRC are very sensitive to clock jitter and duty cycle degradation, the application shall use directly **foutx_ck** when possible.

Figure 62. PLL3 and PLL4 block diagram



(1) It is recommended to use the values 1,2,4,6...128 for DIVP of PLL3

The PLLs are controlled via RCC_PLLxCR, RCC_PLLxCFGR1, RCC_PLLxCFGR2 and RCC_PLLxFRACR registers.

The user must provide to each PLL, a clean reference clock (**refx_ck**) in the accepted input frequency range, which is:

- 8 to 16 MHz for the PLL1 and PLL2
- 4 to 16 MHz for the PLL3 and PLL4

The application has to program properly the DIVM1, DIVM2, DIVM3 and DIVM4 dividers in order to match these conditions.

In addition, the IFRGE field must be set according to the reference input frequency: it will guarantee an optimal performance of the PLL3 and PLL4.

The loop divider DIVN has to be programmed in order to get the expected frequency at VCO output. The VCO output range must be respected.

The PLLs can be enabled by setting the corresponding PLLON bit to ‘1’. The PLLxRDY bits inform the user that the PLL is ready (i.e. locked).

Warning: For the DIVP outputs of PLL1 and PLL2, only the bypass (division by 1) and even divisions are allowed.
For the DIVP output of PLL3, only the even divisions are allowed.
If those conditions are not respected the behavior of the circuit is not guaranteed.

More generally, in order to get PLLs output frequencies with a duty cycle close to 50%, DIVP, DIVQ, DIVR must select an even division.

PLL programming recommendations

This section is providing a list of recommendations to follow in order to guarantee a good usage of the PLLs. Note that programming examples are given in *Section 10.6.2: PLL programming*.

- Before enabling the PLLs, the user must ensure that the reference frequency (**refx_ck**) provided to the PLL is in the good range.
- When the PLLs are enabled, it is possible to change the values of a post-dividers (DIVP, DIVQ or DIVR) without disabling the corresponding PLL.
  Refer to *Section : Reprogramming post-dividers* for details.
- When the PLLs are enabled, changing the value of DIVMx, DIVNx, IFRGE conducts to an invalid output frequency, with the risk of crashing the system. There is no hardware protection, it is up to the application to avoid this situation.
- When one or several PLL outputs are not used, the application shall set the corresponding enable bit DIVyEN to ‘0’.
- In order to ensure the good behavior of the PLL, the bits DIVPEN, DIVQEN and DIVREN must be set to '0' before disabling the corresponding PLL. In the same way, the bits DIVPEN, DIVQEN and DIVREN can be set to '1' only if the correspond bit PLLON is already set to '1' and the PLL is ready.

*Note: The **refx_ck** clock is provided to the PLLx when the corresponding PLLON bit is set to ‘1’.*

The PLLs can work in 3 different modes:

- In integer mode
- In fractional mode
- In spread spectrum mode (only for PLL1 and PLL2)

Using the PLLs in integer mode

The PLL is working in integer mode when the sigma-delta modulator (SDM) is loaded with a '0', and the bit SSCG_CTRL = '0' where available.

In order to load '0' into the SDM, the user has to perform the following sequence:

- Write FRACV to '0', and FRACLE to '0'
- Write FRACLE to '1'

The bits FRACV[12:0] and FRACLE are located in the RCC PLLx Fractional Register (RCC_PLLxFRACR) with x = 1, 2, 3 or 4.

For the PLL1 and PLL2, the VCO frequency (F_{VCO}) is given by the following expression:

$$F_{VCO} = F_{ref\_ck} \times 2 \times (DIVN + 1)$$

And the frequency at the output of the post-dividers is given by:

$$F_{pll\_y\_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}$$

with y = P, Q or R

For the PLL3 and PLL4, the VCO frequency (F_{VCO}) is given by the following expression:

$$F_{VCO} = F_{ref\_ck} \times (DIVN + 1)$$

And the frequency at the output of the post-dividers is given by

with y = P, Q or R

$$F_{pll\_y\_ck} = \frac{F_{VCO}}{DIVy + 1}$$

Using the PLLs in fractional mode

The fractional mode is activated when the value loaded into the SDM is different from 0, and the bit SSCG_CTRL = '0' where available.

The SDM value can be updated at anytime by the application by executing the following sequence:

- Write into FRACV the new fractional value, and FRACLE to '0'
- Write FRACLE to '1'. The new FRACV value is loaded into the SDM when FRACLE bit goes from 0 to '1'.

The sigma delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

When the PLL is used in fractional mode, the DIVN divider must be initialized before enabling the PLL, but it is then possible to change the value of FRACV on-the-fly without disturbing the PLL output.

This feature can be used either to generate a specific frequency, with a good accuracy from any crystal value, or to perform a fine tuning of the frequency on-the-fly.

For the PLL1 and PLL2, the VCO frequency is given by the following expression:

$$F_{VCO} = 2 \times F_{ref\_ck} \times \left((DIVN + 1) + \frac{FRACV}{2^{13}} \right)$$

$F_{pll\_x\_ck}$ can be computed using formula of *Section : Using the PLLs in integer mode*.

For the PLL3 and PLL4, the VCO frequency is given by the following expression:

$$F_{VCO} = F_{ref\_ck} \times \left((DIVN + 1) + \frac{FRACV}{2^{13}} \right)$$

$F_{pll\_x\_ck}$ can be computed using formula of *Section : Using the PLLs in integer mode*.

Using the PLLs in spread spectrum mode

The spread spectrum mode is activated when the SDM loaded with 0, and the bit SSCG_CTRL = ‘1’. This feature is available on PLL1 and PLL2.

The spread spectrum technique consist of modulating the VCO frequency with a low-frequency signal (in our case a triangular signal), in order to spread the clock energy into a wider frequency band. As a consequence, the amount of emitted EMI peaks will be reduced.

The parameters of the spread spectrum modulation are adjusted via the following fields:

- MOD_PER[12:0]: used to adjust the modulation frequency

Note: Note that the modulation frequency is generally in the range of 20 to 50 kHz.

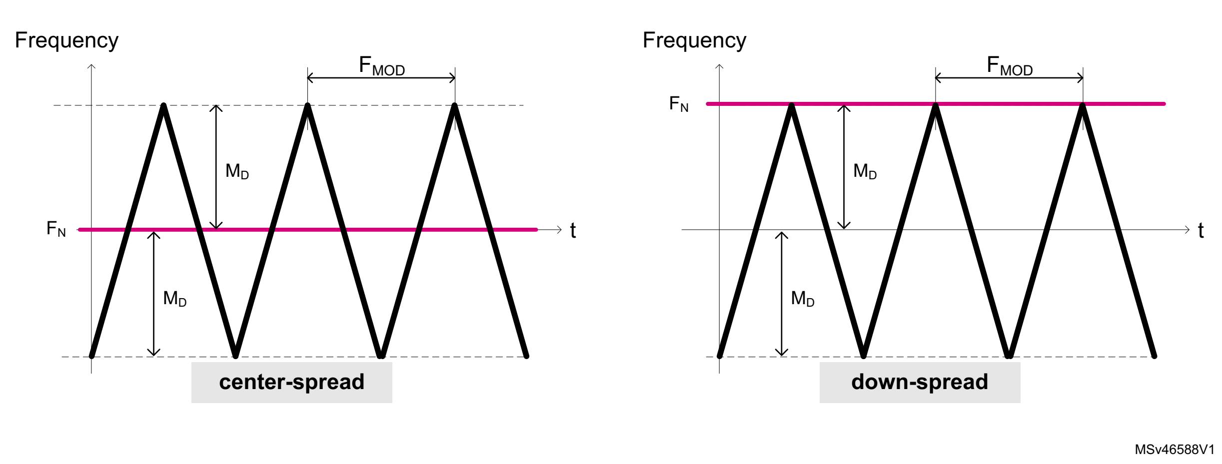
- INC_STEP[14:0]: used to adjust the modulation depth (or modulation index)
- SSCG_MODE: used to define if the modulation is centered around the VCO frequency (center-spread) or if it is lowered with respect to VCO frequency (down-spread).

The bits MOD_PER[12:0], INC_STEP[14:0] and SSCG_MODE are located in RCC PLLx Clock Spreading Generator Register (RCC_PLLxCSGR) with x=1 or 2.

Figure 63 shows the signal modulating the nominal frequency (F_N), when SSCG_MODE = 0 (center-spread) and SSCG_MODE = ‘1’ (down-spread). The nominal frequency is the frequency output by the PLL in integer mode, when no clock spreading is applied.

Setting the SSCG_MODE bit to ‘1’ (down-spread) guaranties that the PLL output frequency will not exceed the programmed frequency value when the SSCG will be enabled.

Figure 63. Spread spectrum modulation



The peak modulation depth (in percentage) is given by the following formula:

$$M_D\,(\%) = \frac{MOD\_PER \times INC\_STEP \times 100 \times 5}{(2^{15} - 1) \times (DIVN + 1)}$$

Note that MOD_PER x INC_STEP shall not exceed (2^{15}-1).

The modulation frequency (F_{mod}) is given by:

$$F_{mod} = \frac{F_{ck\_ref}}{4 \times MOD\_PER}$$

In order to use the spread spectrum feature, the user has to do the following:

- Program the PLL according to *Section : Using the PLLs in integer mode* in order to adjust the nominal frequency (F_N) according to the targeted by the application.
- Compute the MOD_PER value according to the wanted modulation frequency (F_{mod}):

$$MOD\_PER = ROUND\left(\frac{F_{ck\_ref}}{4 \times F_{mod}}\right)$$

- Compute the INC_STEP value according to the wanted modulation depth (M_D):

$$INC\_STEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MOD\_PER}\right)$$

  Check that MOD_PER x INC_STEP does not exceed (2^{15}-1).

- Then DIVP,Q or R can be adjusted, and the bit SSCG_CTRL can be set to ‘1’, and the PLL enabled.

The user can check F_{MIN},F_{MAX} and F_C as follow:

- If SSCG_MODE = ‘0’ (centered-spread)

  F_C is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_C \times (1 - M_D/100)$

  $F_{MAX} = F_C \times (1 + M_D/100)$
- If SSCG_MODE = ‘1’ (down-spread)

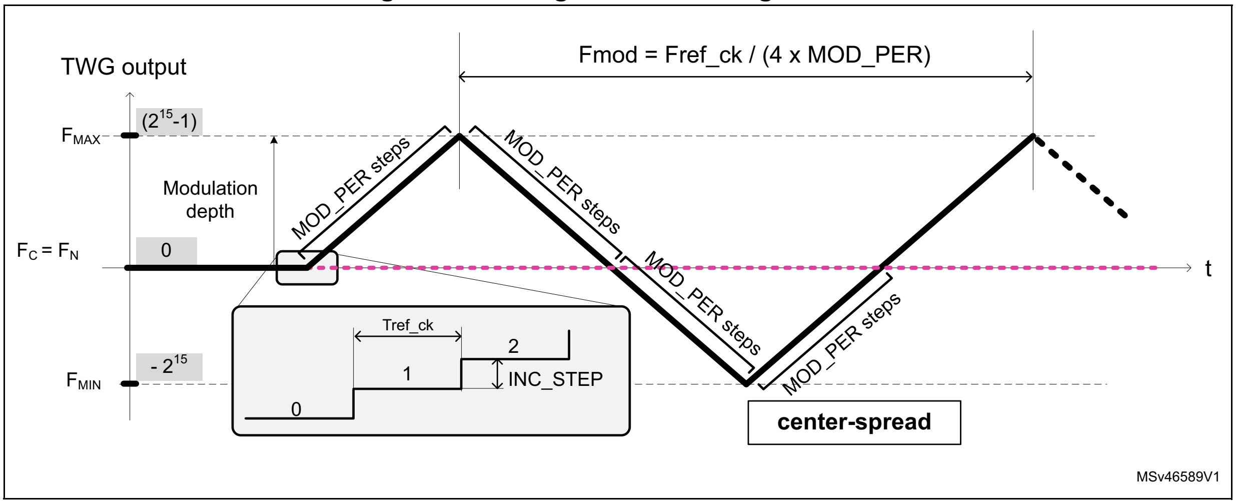
  F_{MAX} is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_{MAX} \times (1 - 2 \times M_D/100)$

  $F_C = F_{MAX} \times (1 - M_D/100)$

Figure 64 shows the digital signal generated by Triangular Waveform Generator (TWG block), and the way of MOD_PER and INC_STEP are changing the triangular waveform.

Figure 64. Triangular waveform generator



Refer to *Section : Reprogramming post-dividers* and *Section : PLL initialization procedure* for additional information on the PLL programming.

10.4.6 Sub-system clocks

The RCC handles three sub-system clocks: **mpuss_ck**, **axiss_ck** and **mcuss_ck**.

Sub-system clock selection

After a system reset, the HSI is selected as the main clock for the complete system. So the HSI is used to provide the clocks:

- **mpuss_ck**,
- **axiss_ck**,
- mcuss_ck

After a system reset, all PLLs are switched off, as well as CSI and HSE.

When the system is running, the user has the possibility to select the clock to be used for the MPU (**mpuss_ck**), for the interconnect (**axiss_ck**), and for the MCU (**mcuss_ck**).

For **mpuss_ck**, the application can select between the following sources:

- HSI
- HSE or
- pll1_p_ck
- **pll1_p_ck** / MPUDIV

For **axiss_ck**, the application can select between the following sources:

- HSI
- HSE or
- pll2_p_ck

For **mcuss_ck**, the application can select between the following sources:

- HSI
- HSE
- CSI or,
- pll3_p_ck

The clock source for **mpuss_ck** is controlled by MPUSRC located into the *RCC MPU clock selection register (RCC_MPCKSELR)*, the clock source for **axiss_ck** is controlled by AXISSRC located into the *RCC AXI sub-system clock selection register (RCC_ASSCKSELR)*, and the clock source for **mcuss_ck** is controlled by MCUSSRC located into the *RCC MCU sub-system clock selection register (RCC_MSSCKSELR)*.

Dynamic clock switches

The clock selectors shown with a square D on *Figure 65* allows to reconfigure the selected input on the fly without spurs or timing violation. This allows dynamic clock switching.

As a consequence, the switching from the original to the new input can only be performed if a clock is present on both inputs. If it is not the case, no clock will be provided. In order to recover from this situation the user has to provide a valid clock to both inputs.

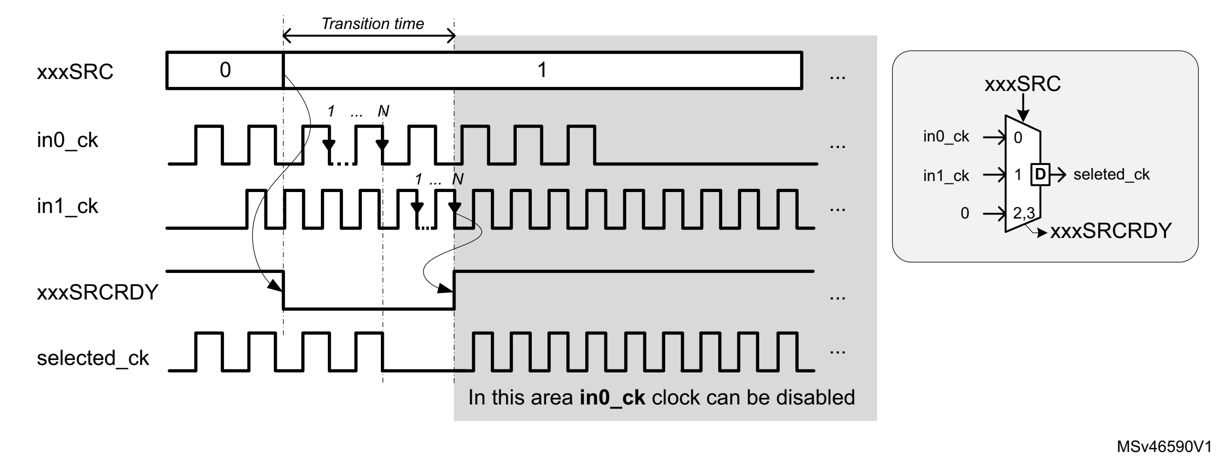
During the transition from one input to the other, the clock output will be gated, in the worst case, during 3 clock cycles of the previously selected clock and 3 clock cycles of the new selected clock. As shown in *Figure 65*, both input clocks shall be present during transition time.

Note that some dynamic switches such as the ones controlled by PLL12SRC, PLL3SRC, PLL4SRC, MPUSRC, AXISSRC and MCUSSRC provide a ready signal (xxxSRCRDY in *Figure 65*). This ready signal goes immediately to ‘0’, when the clock source is changed (xxxSRC), and goes to ‘1’ when the switch is able to provide the new selected clock. This signal can be used to check that the switch transition has been properly done.

When those switches are placed in position where no input clock is selected (position 2,3 in the example of *Figure 65*), no clock will be generated to their outputs, and the xxxSRCRDY flag will be set to ‘0’.

*Note: Note however that the xxxSRCRDY flag cannot be used to detect if a clock is generated at the switch output. For example, if the switch is already selecting the **in0_ck**, and the xxxSRCRDY flag is set to ‘1’, if the **in0_ck** is disabled, the xxxSRCRDY flag will not go to ‘0’, but stays to ‘1’ because last switch transition has been properly performed. For sure if the application changes the xxxSRC value, if the **in0_ck** is disabled the switch will not be able to selected the new input, and the xxxSRCRDY flag will remain to ‘0’.*

Figure 65. Dynamic clock switching



Hardware protection for switch transition

The switching from one clock source to another occurs only if the target clock source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switching occurs when the clock source is ready.

The status bits in the *RCC oscillator clock ready register (RCC_OCRDYR)* indicate which clock(s) is (are) ready.

Sub-system clock generation

Figure 66 shows a simplified view of the clock distribution for the CPUs and busses. All the dividers presented in the block diagram can be changed on-the-fly without generating timing violations. This feature allows the user to adapt in a very simple way, the busses frequencies to the application needs, and thus optimize the power consumption.

The MPUDIV divider located into *RCC MPU clock divider register (RCC_MPCKDIVR)* can be used to adjust dynamically the clock for the MPU.

The AXIDIV divider located into *RCC AXI clock divider register (RCC_AXIDIVR)* can be used to adjust dynamically the clock for the AXI matrix. The value of this divider also impacts the clock frequency of AHB5, AHB6, APB4 and APB5.

The APB4DIV divider located into *RCC APB4 clock divider register (RCC_APB4DIVR)* can be used to adjust dynamically the clock for the APB4 bridge.

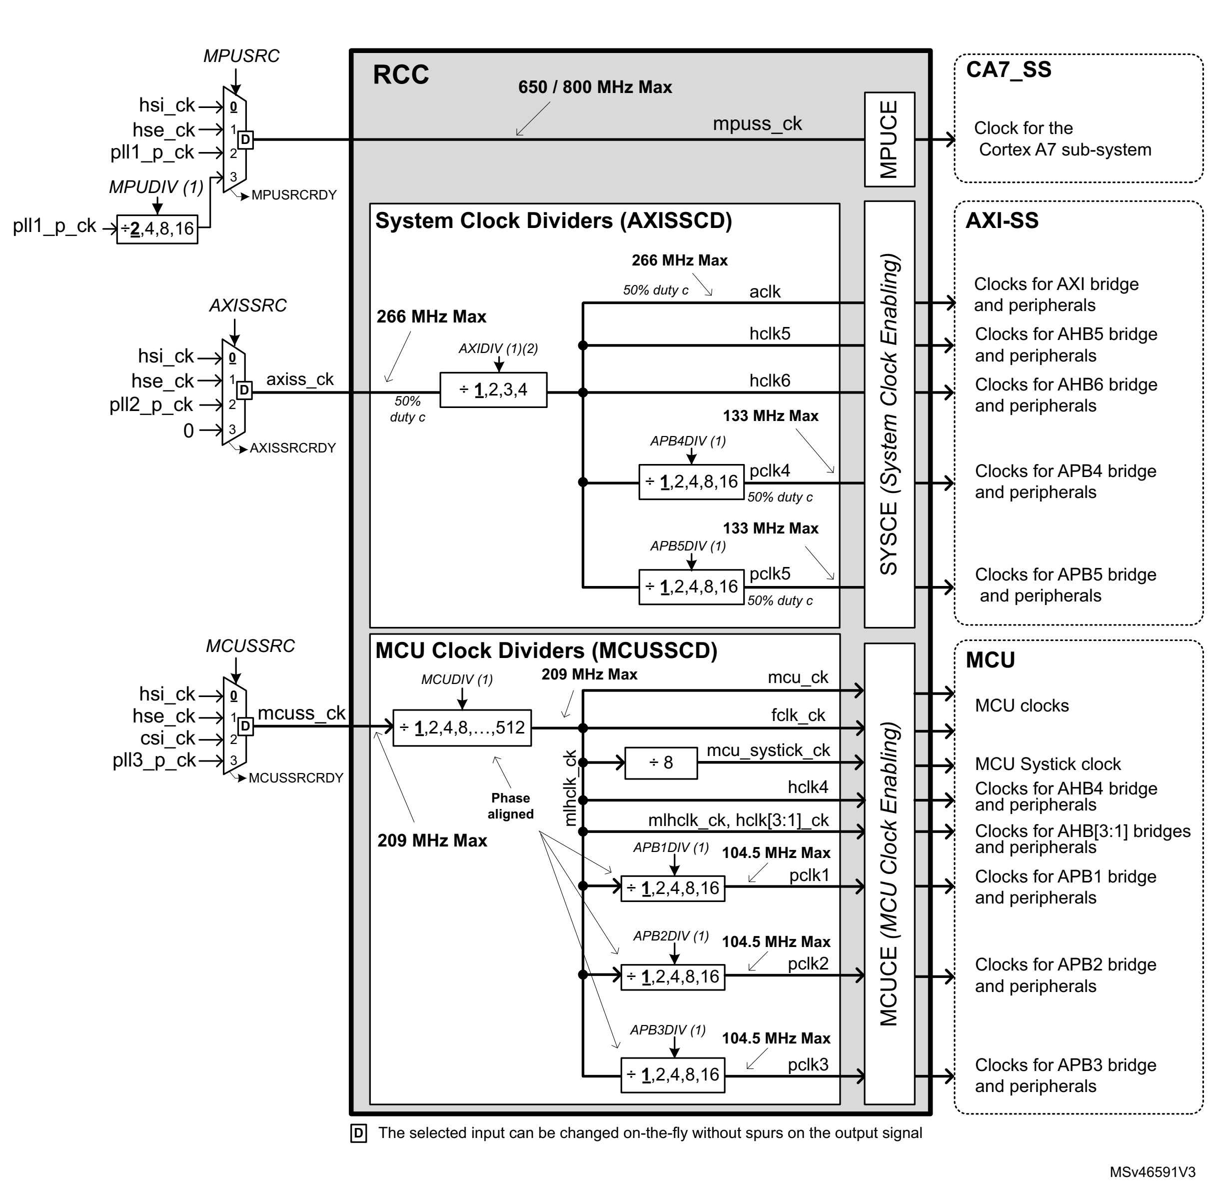
In the same way, the APB5DIV divider located into *RCC APB5 clock divider register (RCC_APB5DIVR)*, can be used to adjust dynamically the clock for the APB5 bridge.

In the MCU clock tree, the MCUDIV divider located into *RCC MCU clock divider register (RCC_MCUDIVR)*, can be used to adjust dynamically the clock for the MCU. The value of this divider also impacts the clock frequency of AHB bridges, APB1, APB2 and APB3.

The APB1DIV divider located into *RCC APB1 clock divider register (RCC_APB1DIVR)*, can be used to adjust dynamically the clock for the APB1 bridge. Similar implementation is available for APB2 and APB3.

Note that dividers having the possibility to be updated on-the-fly provides a ready bit in order to inform the application on the moment when the new division ratio is taken into account.

Figure 66. Core and busses clock generation



1. Can be changed on the fly.
2. Keeps a duty-cycle of 50% even for division by 3.
3. **X** represents the selected MUX input after a system reset.

10.4.7 Clock generation in Stop and Standby modes

The product supports three kinds of system Stop modes:

- Normal system stop mode, named Stop
- Low-power system stop mode, named LP-Stop
- Low-power, low-voltage system stop mode, named LPLV-Stop

The main differences between those stop modes is the handling of the V_{DDCORE} supply voltage:

- In Stop mode, the V_{DDCORE} supply voltage remains the same as system Run mode, with the same power capability,
- In LP-Stop mode, the V_{DDCORE} supply voltage remains the same as system Run mode, but with a limited power capability. This is usually achieved thanks to an external PMIC having 2 power modes: a high power mode (HP) for nominal cases (Run and Stop) and a low-power mode (LP) limiting the power capability for LP-Stop and LPLV-Stop modes.
- In LPLV-Stop mode, the V_{DDCORE} supply voltage is reduced, and the power capability is reduced as well,

The amount of peripherals able to wake-up the system from Stop, depends on the Stop mode activated. For example, Stop or LP-Stop modes offer a larger choice of peripherals able to wake-up the system than the LPLV-Stop mode. Please refer *Section Table 34.: Functionalities depending on system operating mode* in the PWR.

Going to Stop, LP-Stop or LPLV-Stop mode

The system can go to Stop, LP-Stop or LPLV-Stop mode, when the MPU is in CStop or CStandby, and the MCU in CStop. Refer to *Section 9.5.1: PWR operating modes*.

Note as well that before going to CStop, each processor has to mask all the interrupts except the RCC wakeup interrupts in order to ensure a safe Stop sequence entry and exit. The RCC provides two wakeup interrupts: **rcc_mpu_wkup_it** and **rcc_mcu_wkup_it** which can be enabled via their corresponding WKUPIE bit. Refer to *Section 10.5: RCC interrupts* for additional information.

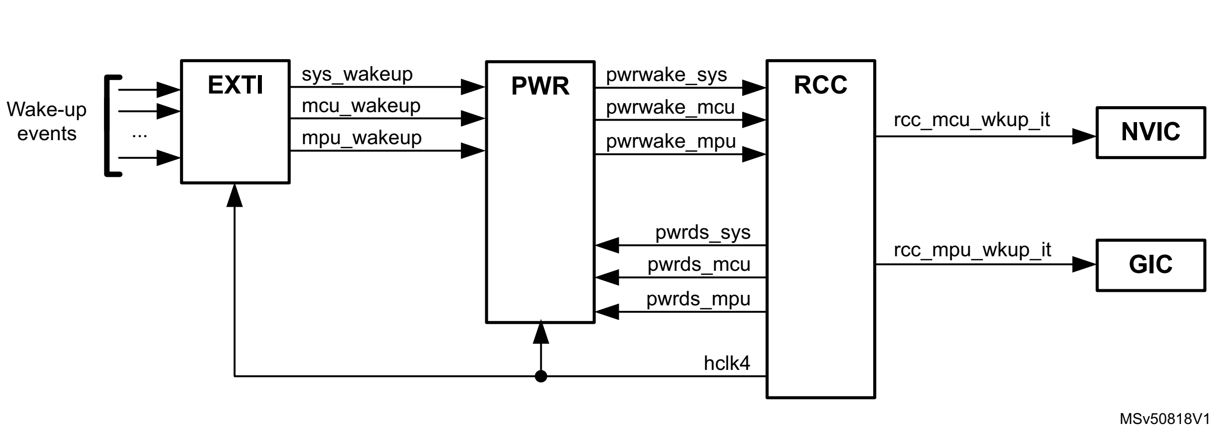
Before switching off all the clocks, the RCC waits that the DDRC enters into self-refresh mode. As a consequence, the effective entry into Stop, LP-Stop or LPLV-Stop mode, may be delayed until the DDRC allows it. Then the RCC stops all the clocks (sub-system and kernel clocks) and the following clock sources are disabled as well:

- CSI, if CSIKERON = '0',
- HSI, if HSIKERON = '0',
- HSE, if HSEKERON = '0',
- PLL1, PLL2, PLL3 and PLL4.

Note: In LPLV-Stop mode, CSI, HSI and HSE cannot be used.

Note: LSE and LSI oscillators remain active in Stop, LP-Stop and LPLV-Stop mode if enabled.

Figure 67. Key signals controlling low-power modes



In addition, the RCC informs the PWR block that the MPU and/or MCU sub-system are in CStop via signals **pwrds_mpu**, **pwrds_mcu** and **pwrds_sys** (see *Figure 46*).

- The **pwrds_mpu** is used to indicate to the PWR that the MPU is in CStop or CStandby.
- The **pwrds_mcu** is used to indicate to the PWR that the MCU is in CStop.
- The **pwrds_sys** is used to indicate to the PWR that the system is in Stop, LP-Stop or LPLV-Stop, and no longer clocked.

Note that when only one processor goes to CStop, the PLLs and oscillators generating **mpuss_ck**, **axiss_ck**, **mcuss_ck** and kernel clocks are kept activated.

During Stop, LP-Stop or LPLV-Stop mode

As explained in the previous section, in system Stop, LP-Stop or LPLV-Stop mode, all clocks, PLLs and oscillators are disabled, except LSE and LSI which are kept in their current states. However there are two specific cases in Stop and LP-Stop mode where the HSE, HSI or CSI can be enabled:

- When a dedicated peripheral is requesting a kernel clock:
  In that case the peripheral will receive the HSE, HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- When the bits HSEKERON, HSIKERON or CSIKERON are set:
  In that case the HSE, HSI or CSI are kept running during (LP-)Stop mode, but the clock is not provided to the peripherals. In that way, the clock will be available immediately when the system exits from (LP-)Stop or when a peripheral is requesting the kernel clock. Refer to *Table 54* for details.

The HSIKERON, HSEKERON and CSIKERON bits are located into the *RCC oscillator clock enable set register (RCC_OCENSETR)* and *RCC oscillator clock enable clear register (RCC_OCENCLRR)*. *Table 54* gives details on the behavior of those bits.

Note as well that the HSE, HSI and CSI outputs provide two clock paths (see *Figure 54*):

- One path for the processors and interconnects clocks (**hse_ck**, **hsi_ck** or **csi_ck**),
- One path for the peripheral kernel clocks (**hse_ker_ck**, **hsi_ker_ck** or **csi_ker_ck**).

In system (LP-)Stop mode, when a peripheral requests the kernel clock, only the path providing the peripheral kernel clock is activated, the processors and interconnects clock paths remain inactive.

Table 54. HSI, CSI and HSE states versus system modes(1)

System modes	HSION (CSION) (HSEON)	HSIKERON (CSIKERON) (HSEKERON)	Kernel clock request (2)	-	HSI State (CSI State) (HSE State)	hsi_ck (csi_ck) (hse_ck)	hsi_ker_ck (csi_ker_ck) (hse_ker_ck)
Run	0	X	1	→	ON	Gated	ON
			0	→	OFF		Gated
	1		X	→	ON	ON	ON
Stop or LP-Stop	X	X	1	→	ON (3)	Gated	ON
		0	0	→	OFF		Gated
		1	0	→	ON		ON (4)
Standby or LPLV-Stop	X	X	X	→	OFF	Gated	Gated

1. 'ON' state highlighted in gray.
2. Kernel clock request is equal '1' when the peripheral is requesting a kernel clock AND its corresponding PERxSRC is selecting the HSE, HSI or CSI oscillator, AND if its PERxEN and PERxLPEN are set to '1'. Refer to *Table 63: Peripheral clock enable details for MPU (MCU)* for details.
3. Only the oscillator selected by the PERxSRC of the peripheral requesting the kernel clock is enabled.
4. The kernel clock is provided to the PCKE block, and gated as long as the peripheral does not generate a kernel clock request.

Leaving Stop, LP-Stop or LPLV-Stop mode

The system can leave Stop, LP-Stop or LPLV-Stop mode thanks to events generated by peripherals able to work in the selected Stop mode. The exit from system Stop is generally done in the following way (see also *Figure 67*):

- A peripheral sends a wakeup interrupt to the EXTI block.
- The EXTI block generates an event to the PWR block (**sys_wakeup**).
- The PWR block signals to the external PMIC that the main power should be restored (through PWR_LP signal or optionally PWR_ON signal).
- If the PMIC was in LPLV-Stop, the PWR block waits for a nominal V_{DDCORE} voltage.
- When V_{DDCORE} reached the nominal value, then the PWR asserts the **pwrwake_sys** for the RCC.
- Thanks to this signal, the RCC provides the **hclk4** clock to the EXTI and PWR blocks and starts the clock restore sequence.
- When the **hclk4** is available, the EXTI asserts the **mpu_wakeup**, or **mcu_wakeup** signals, indicating to the PWR block which processor shall be activated.
- The PWR then asserts the **pwrwake_mpu**, or **pwrwake_mcu** signals for the RCC according to the processor to be activated.
- On the RCC side:
  - If the signal **pwrwake_mpu** is activated, the RCC asserts the **rcc_mpu_wkup_it**, and provides a clock to the MPU and AXI sub-system when those clocks are available.
  - If the signal **pwrwake_mcu** is activated, the RCC asserts the **rcc_mcu_wkup_it**, and provides the **ck_hsi** to the MCU when available.
- Then the targeted processor exits from CStop, and re-enables the interrupts of peripherals activated during Stop mode. In that way, the peripheral which has generated the wakeup event is able to generate an interrupt to the sub-system's processor.
- The RCC acknowledges the **pwrwake_mpu**, or **pwrwake_mcu** requests by de-asserting the **pwrds_mpu** or **pwrds_mcu** signals.

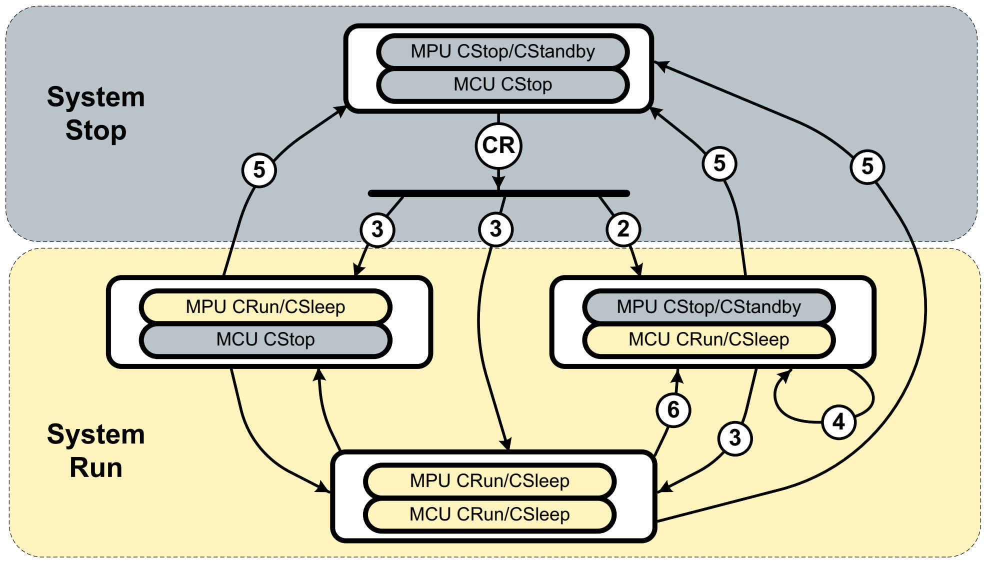
Caution: The RCC integrates a state machine able to restore the clock configuration which was used before going to one of the Stop modes. The PLL3 and PLL4 are not handled by this mechanism.

When exiting from one of the system Stop modes, the MCU always uses the **hsi_ck** as sub-system clock and the PLL3 and PLL4 are disabled. As a consequence, after a system Stop, the following bits are set to their reset value:

- HSION = '1', MCUDIV = '0', MCUSSRC = '0',
- PLL3ON = '0', DIVPEN, DIVQEN and DIVREN of PLL3 are set to '0'
- PLL4ON = '0', DIVPEN, DIVQEN and DIVREN of PLL4 are set to '0'

The RCC executes the clock restore sequence every time the system exits from Stop, LP-Stop or LPLV-Stop as shown in *Figure 68*. When the system is in Run, all oscillators and PLLs requested by the application are activated, but the sub-system clocks are only provided according to MCU and MPU modes.

Figure 68. Clock restore activation versus system mode



CR Clock restore sequence triggered by **pwrwake_sys** event. **hsi_ck** is enabled in order to generate **hclk4**. PLL1 and PLL2 are re-enabled if their respective PLLxON bit was set to ‘1’.

2 Enabling of **mcuss_ck** clock (**pwrwake_mcu**)

3 Enabling of **mpuss_ck, mcuss_ck** and **axiss_ck** clocks, if not already enabled (**pwrwake_mpu**)

4 Clock enabling of **axiss_ck**

5 Disablling of all sub-system clocks, all PLLs, and oscillators if allowed

6 Disabling of **mpuss_ck** and **axiss_ck** if not needed by MCU

Run, Crun, or Csleep — Stop, Cstop, or CStandby

MSv46592V1

Handling the PWRLP_TEMPO

The PWRLP_TEMPO is used to wait automatically that the external PMIC switches from Low-power (LP) mode to High-power (HP), before enabling power-consuming parts. The application can control the delay value via *RCC PWR_LP delay control register (RCC_PWRLPDLYCR)*. The PWRLP_TEMPO is using the **hsi_ck** clock as reference.

In order to allow a fast restart time when the MCU wakes up from system (LP-)Stop or LPLV-Stop, it is possible for the activation of the **mcuss_ck** clock to bypass the PWRLP_TEMPO delay. This is only possible when the power consumption of the MCU is low enough to be supported by the PMIC LP mode. This function is controlled by the MCTMPSKP bit of the RCC_PWRLPDLYCR register. Note that in this case, the PMIC still transitions from LP to HP mode.

Refer to *Section 10.6.5: Clock restore sequence examples* for additional information.

Warning: **When the bit MCTMPSKP is set to ‘1’, the application must ensure that the MCU did not allocate peripherals located into the AXI sub-system (i.e. on AXIM, AHB5, AHB6, APB4 or APB5). If this rule is not respected, a system reset may be generated.**

The clock restore sequence description

Every time the system exits from one of the Stop modes (**pwrwake_sys**), the RCC re-enables the requested oscillators and PLLs in order to restore the **mpuss_ck, axiss_ck** and **mcuss_ck** clocks. The sub-system clock settings are defined by the registers listed on *Table 55*.

The registers listed on *Table 55* cannot be modified during the clock restore sequence.

If the system exits from one of the Stop modes due to a wakeup event for the MPU (**pwrwake_mpu**), then the **mpuss_ck, mcuss_ck** and **axiss_ck** clocks will be re-enabled simultaneously only when both **mpuss_ck**, **mcuss_ck** and **axiss_ck** are ready.

If the system exits from one of the Stop modes due to a wakeup event for the MCU (**pwrwake_mcu**), then the **mcuss_ck,** and **axiss_ck** (if needed for MCU) clocks will be re-enabled simultaneously only when both **mcuss_ck** and **axiss_ck** are ready. The clock **mpuss_ck** and **axiss_ck** (if not needed) will remain gated even if their respective PLLs are enabled. The **axiss_ck** clock will be enabled if the MCU allocated at least one peripheral into the AXI sub-system. Note that the **mcuss_ck** is always connected to **hsi_ck** when the system exits from Stop.

More precisely, the clock restore sequence will be split into the following main steps (see also *Figure 69* and *Figure 70*):

- Set the bit CKREST = ‘1’ and AXICKRDY = ‘0’ in order to inform that a clock restore sequence will be initiated. The registers listed on *Table 55* cannot be modified during the clock restore sequence.
- Enable the oscillators which were enabled before going to one of the system Stop modes.
- When the HSI is ready, the RCC can trigger the PWRLP_TEMPO (according to PWRLP_DLY value) in order to allow a delay to the external PMIC to switch in HP mode, before doing power-consuming operations on V_{DDCORE}.
- When the oscillator used by PLL1 and PLL2 is ready, the PLLs analog parts can be powered. As the PLLs analog parts are not powered by V_{DDCORE}, it is possible to enable the VCOs, with all outputs (P, Q, and R dividers) disabled. There is no need to wait that PWRLP_TEMPO elapsed.
- Before enabling the PLL outputs, the RCC shall wait until the PWRLP_TEMPO elapsed, and the PLLs are ready. The process generating the **mcuss_ck** clock may also need to wait until the PWRLP_TEMPO elapsed when MCTMPSKP = ‘0’.
- When all the sub-system clocks are ready, then the RCC sets the bit CKREST to ‘0’. The registers listed on *Table 55* can then be modified by the application if needed.
- If the system exits from one of the Stop modes due to a wakeup event for the MCU, when **mcuss_ck,** and **axiss_ck** (if needed) clocks are ready, then the clocks can be re-enabled. The AXICKRDY bit is set to ‘1’ by the RCC if **axiss_ck** has been enabled as well.
- If the system exits from one of the Stop modes due to a wakeup event for the MPU, when **mpuss_ck, mcuss_ck,** and **axiss_ck** clocks are ready, then the clocks can be re-enabled.The AXICKRDY bit is set to ‘1’ as well.

Refer to *Section 10.6.5: Clock restore sequence examples* for additional information.

Figure 69. Clock restore process activated after system Stop

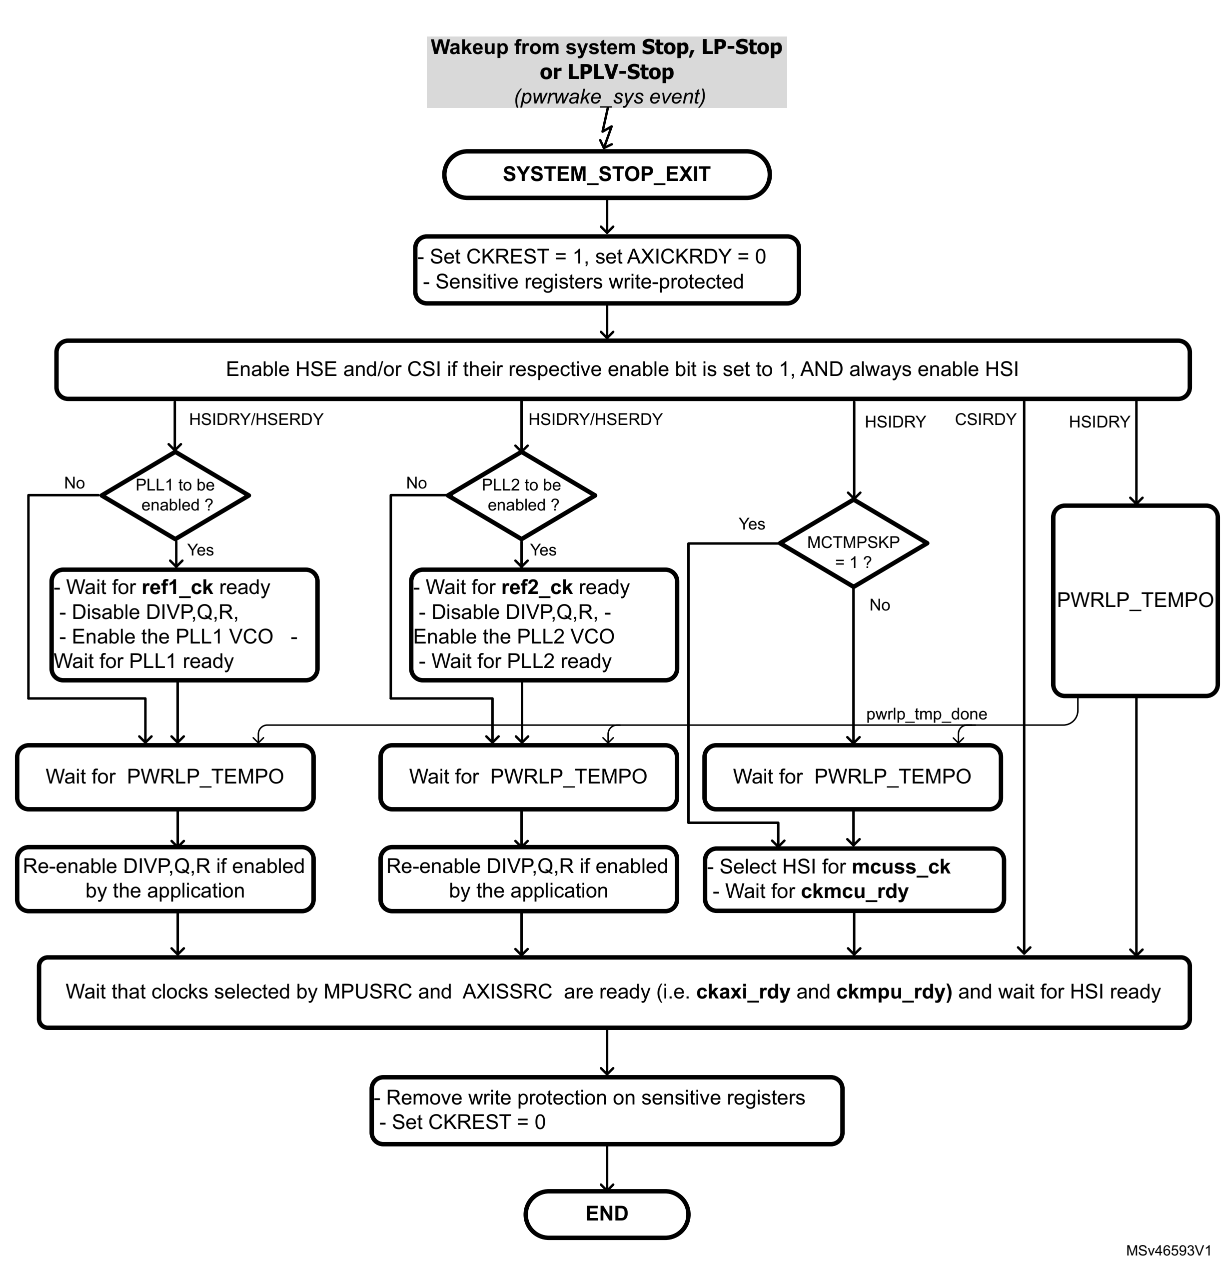


Figure 70. Wake up from CStop processes

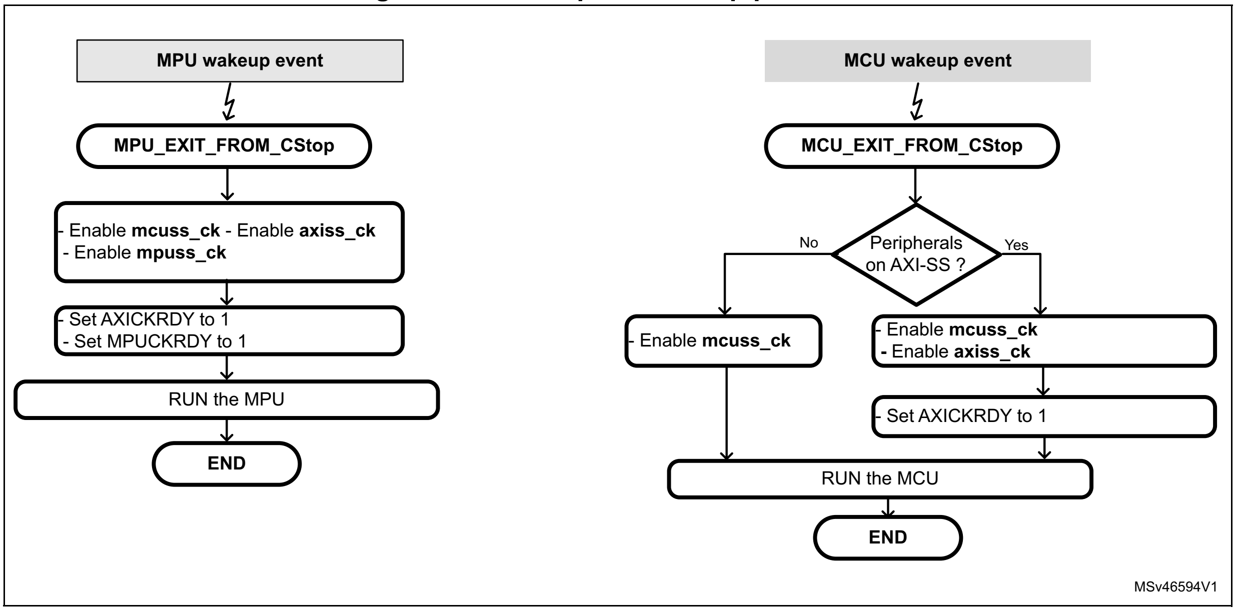

Note: Note as well that the RCC also provides a bit named AXICKRDY indicating if the ***axiss_ck*** *clock is ready to be used. This signal is particularly helpful when the MCU allocates a peripheral located into the AXI sub-system.*

Note: When the system exits from one of the Stop modes due to a wakeup event for the MCU, if the MCU has a peripheral using HSE as kernel clock, the MCU has to check that the HSE is ready before using this peripheral.

In order to avoid any unexpected behavior during the clock restore, the RCC provides a write-protection of all registers having a sensitive content for the clock restore. The application shall not attempt to write those registers when the clock restore sequence is running. If a processor attempts to write into one of the register listed in *Table 55*, the write operation is ignored, and a hard fault is generated. This situation may occur if one processor is already running while the other exits from CStop.

Note that the RCC provides a bit named CKREST in order to inform the application if a clock restore is on-going.

Table 55. Resources blocked during clock restore sequence

Resources	-	Corresponding registers write-protected during clock restore
Sub-system clock switches	→	RCC_MPCKSELR, RCC_ASSCKSELR, RCC_MSSCKSELR
PLL1 and 2 settings	→	RCC_PLL1CR, RCC_PLL1CFGR1, RCC_PLL1CFGR2, RCC_PLL1FRACR, RCC_PLL1CSGR RCC_PLL2CR, RCC_PLL2CFGR1, RCC_PLL2CFGR2, RCC_PLL2FRACR, RCC_PLL2CSGR
Reference clocks selection	→	RCC_RCK12SELR
Oscillator settings	→	RCC_OCENSETR, RCC_OCENCLRR, RCC_HSICFGR, RCC_CSICFGR
Miscs	→	RCC_PWRLPDLYCR

Going to Standby mode

The system can go to Standby mode when MPU is in CStop or CStandby, and the MCU is in CStop and both processors allowed the Standby mode. Refer to *Section 9.6: PWR low-power modes* for details

When the complete system goes to Standby mode, the RCC stops all the clocks and PLLS, with the exception of the LSI and LSE.

In addition, the RCC informs the PWR block that the MPU and MCU sub-system are in CStop via **pwrds_mpu** and **pwrds_mcu** signals (see *Figure 46*).

Then the PWR block can request to the external PMIC to switch off the V_{DDCORE} voltage. Only parts working on V_{DD} and V_{SW} are kept operating in this mode.

Leaving Standby mode

When the circuit leaves the system Standby mode, the HSI is selected as default clock for **mpuss_ck**, **axiss_ck**, **mcuss_ck**, the RCC registers are reset to their initial values except the RCC_MP_BOOTCR, RCC_BDCR, RCC_RDLSICR, RCC_BR_RSTSCLRR and RCC_MC_RSTSCLRR.

Note that a system reset is generated when the circuit exits from Standby.

10.4.8 Peripheral clock distribution

Some peripherals are designed to work with two different clock domains asynchronous each other: a clock domain synchronous to the register and bus interface (**ckg_bus_perx** clock), and a clock domain generally synchronous to the peripheral (kernel clock).

The benefit of having peripherals supporting those two clock domains is that the user has more freedom to choose optimized clock frequency for the CPUs, bus matrix, and for the kernel part of the peripheral.

As a consequence, the user can change the bus frequency without reprogramming the peripherals. For example an on-going transfer with UART will not be disturbed if its APB clock is changed on-the-fly.

For most of the peripherals, *Table 56* displays the peripheral clocks under RCC control. Note that clocks controlled by the peripherals themselves are not shown (for examples clocks from an external interfaces and the peripherals).

Table 56 show clearly (gray shaded cells) the kernel clocks provided by the RCC, and the bit field controlling the kernel clock selector. The maximum allowed frequency is given for the output of each MUX and for each bus clock.

It is up to the user to respect those requirements.

1. '**A**' Means that the kernel clock is asynchronous with respect to bus interface clock.
   '**S**' Means that the kernel clock is synchronous with respect to bus interface clock.
2. For the ADC12, if a clock with a duty cycle of 50% is needed then the max frequency is limited to 72 MHz. In order to get a duty cycle 50%, the DIVQ value shall be odd. Refer to *Section : Clock distribution for HDMI-CEC, STGEN, ADCs and DACs* for details.
   For the SDMMCx, a duty cycle of 50% in needed when supporting DDR, if the RCC cannot provide a clock with such a duty cycle, the application must use SDMMCx internal dividers.
3. The RTC switch is in the V_{SW} voltage domain

The following sections show a more detailed view of the kernel clock and bus interface clock distribution. Refer to *Section 10.4.11: Peripheral clock gating control* for details.

In order to reduce the amount of switches, some peripherals are sharing the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

Clock distribution for SAIs, SPI/I2Ss, SPDIFRX and DFSDM

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in *Figure 72* and *Figure 73*, the kernel clock of the SAIs or SPI(I2S)s can be generated by:

- The PLL3 or PLL4 in order to provide optimal flexibility on the frequency generation,
- HSE, HSI or CSI for use-cases where the current consumption is critical,
- I2S_CKIN in the case where an external clock reference need to be used.The DFSDM can share the same kernel clock as SAI1: this can be useful when the DFSDM is used for audio applications.

To work properly, the DFSDM always needs **dfsdm_clk** and **fdsdm_pclk** clocks.

The clock **dfsdm_Aclk** can be used as clock source for DFSDM_CKOUT. The clock DFSDM_CKOUT can be generated either from **dfsdm_clk** (default) or **dfsdm_Aclk**.

See *Section 32: Digital filter for sigma delta modulators (DFSDM)* for details.

Clock settings examples for PLL3

The table hereafter is showing programming examples of kernel clock generation using the PLL3. Audio frequencies with good accuracy (grey cells) can be obtained with the PLL3 in fractional or integer mode. The PLL3 is also used to provide a clock to the MCU (PLL3P output).

Table 57. Kernel clock settings examples for audio applications

Conf	F_{HSE}	F_{ref3_ck}	F_{VCO}	DIVM+1	DIVN+1	FRACV	DIVP+1	DIVQ+1	DIVR+1	PLL3P output	PLL3Q output		PLL3R output	
											Freq.	Error for 48 kHz	Freq.	Error for 44.1 kHz

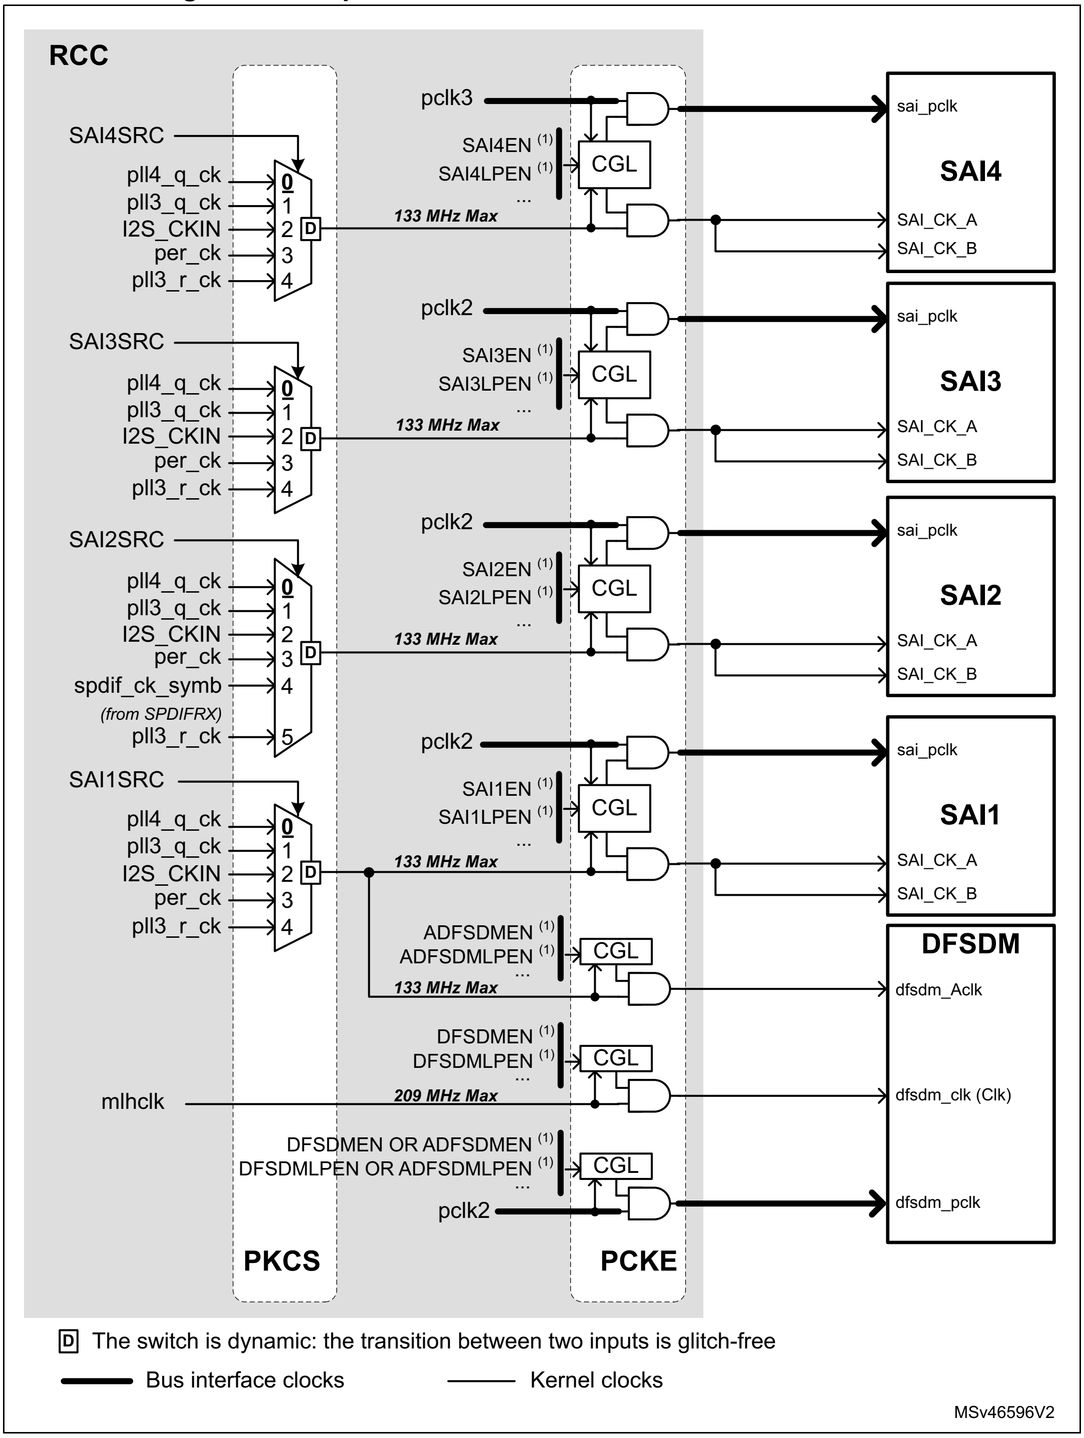
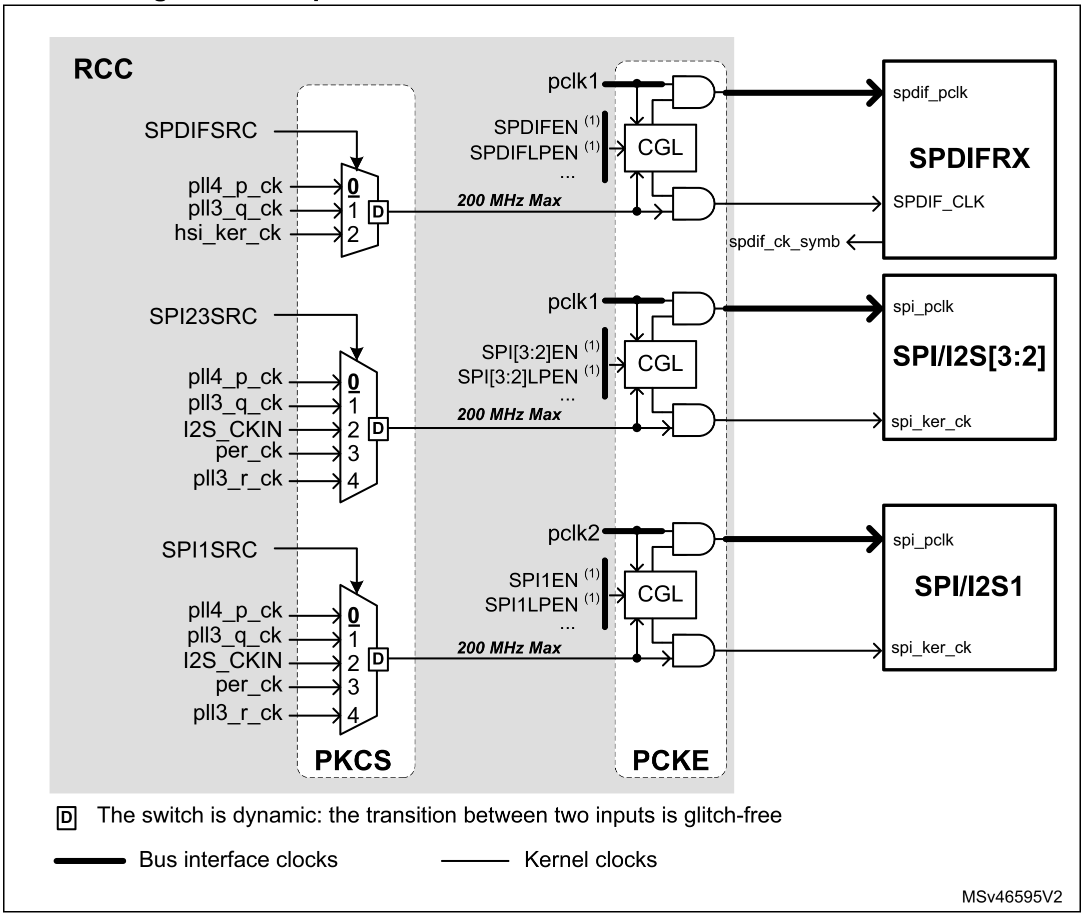
Figure 71. Peripheral clock distribution For SAIs and DFSDM



1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset

Note: The SPDIFRX does not need a specific frequency, but just a kernel clock frequency high enough to make the peripheral working properly. Refer to the description of the SPDIFRX for details.

Figure 72. Peripheral clock distribution for SPI/I2Ss and SPDIFRX



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

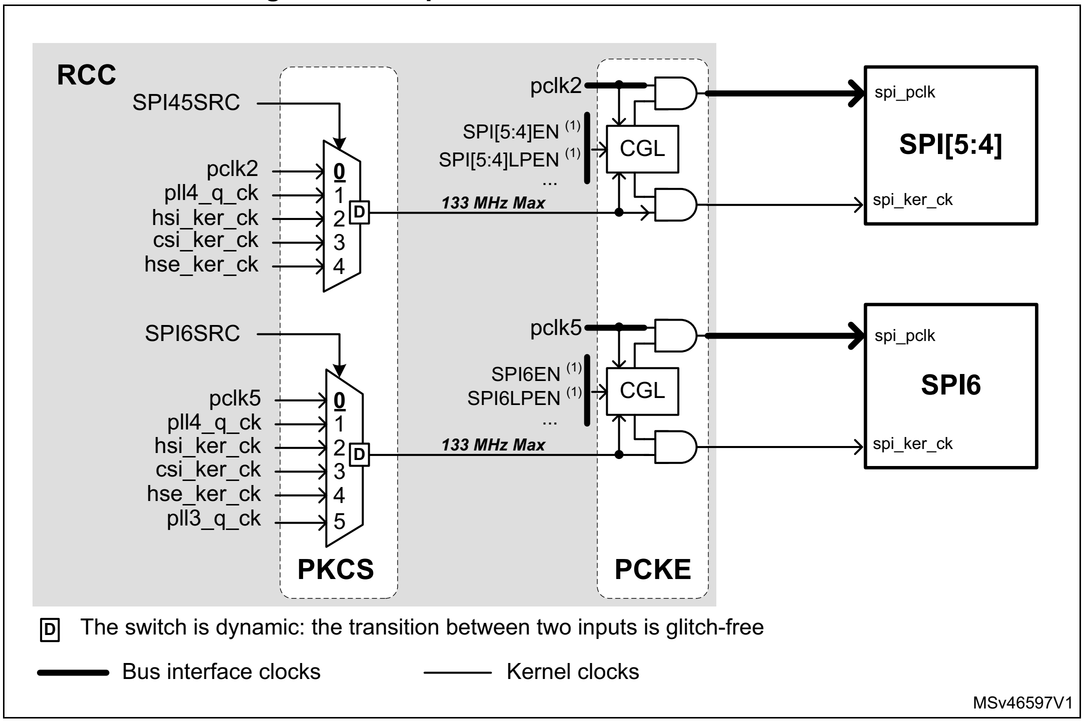
Refer to *Table 63* for details concerning the behavior of the clock gating logic (CGL).

Clock distribution for SPIs

In general, SPIs (or SPI/I2Ss used in SPI mode) do not need specific kernel clock frequencies but a clock fast enough to generate the correct data rate. For that purpose it is generally possible to select a source from:

- APB bus, which can be used to avoid the activation of an additional PLL,
- PLL4 for better flexibility if required, it allows for example to change the frequency of the MCU bus via PLL3, without affecting the speed of some serial interfaces,
- HSI, CSI for low-power use-cases.

Figure 73. Peripheral clock distribution for SPIs



1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset.

*Note: In order to provide a secure kernel clock to SPI6, the application must choose **pclk5**, **hse_ker_ck**, **hsi_ker_ck** or **csi_ker_ck**. The application can also use **pll3_q_ck**, but in that case the bit MCKPROT must be set to '1' as well. Refer to Section 10.4.14: RCC TrustZone function for usage of the MCKPROT bit.*

Refer to *Table 63* for details concerning the behavior of the clock gating logic (CGL).

Clock distribution for I2Cs, UARTs and USARTs

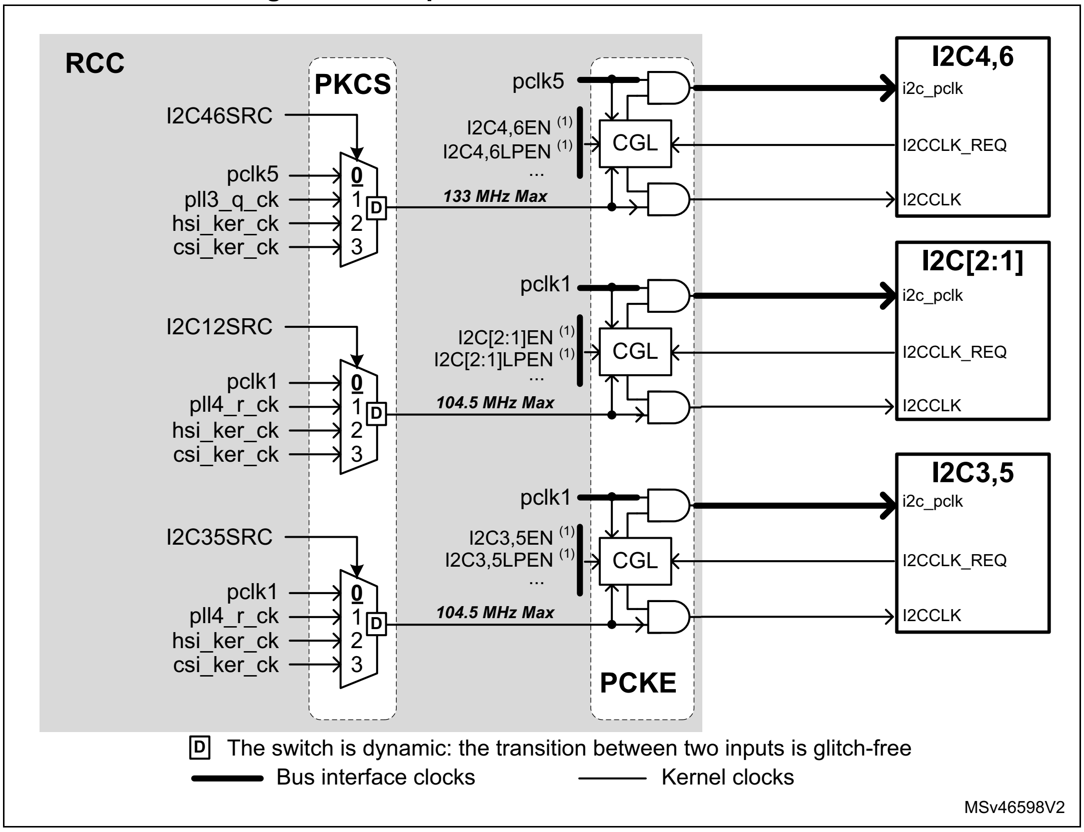
As explained for the SPI, I2Cs and UARTs do not need a specific kernel clock frequency but a clock fast enough to generate the correct baud rate, or the wanted bit clock on the serial link. For that purpose it is generally possible to select a source from:

- PLL3 which can be used to avoid the activation of an additional PLL,
- PLL4 for better flexibility if required, it allows for example to change the frequency of the MCU bus via PLL3, without affecting the speed of some serial interfaces,
- HSI, CSI for low-power use-cases, and also in the case where the peripheral has to wake up quickly from (LP-)Stop mode (i.e. UART, I2C...).

Note that UARTs also receive the LSE clock, for use-cases which do not request high baud rates.

As shown in *Figure 74*, *Figure 75* and *Figure 76* the I2Cs and UARTs provide kernel clock requests signals (I2CCLK_REQ and UCLK_REQ). These signals can be used when the system is in (LP-)Stop, in order to request the selected kernel clock to the RCC. This function only works when the **hsi_ker_ck** or **csi_ker_ck** or **hse_ker_ck** are selected. Refer to *Section 10.4.11: Peripheral clock gating control* for details.

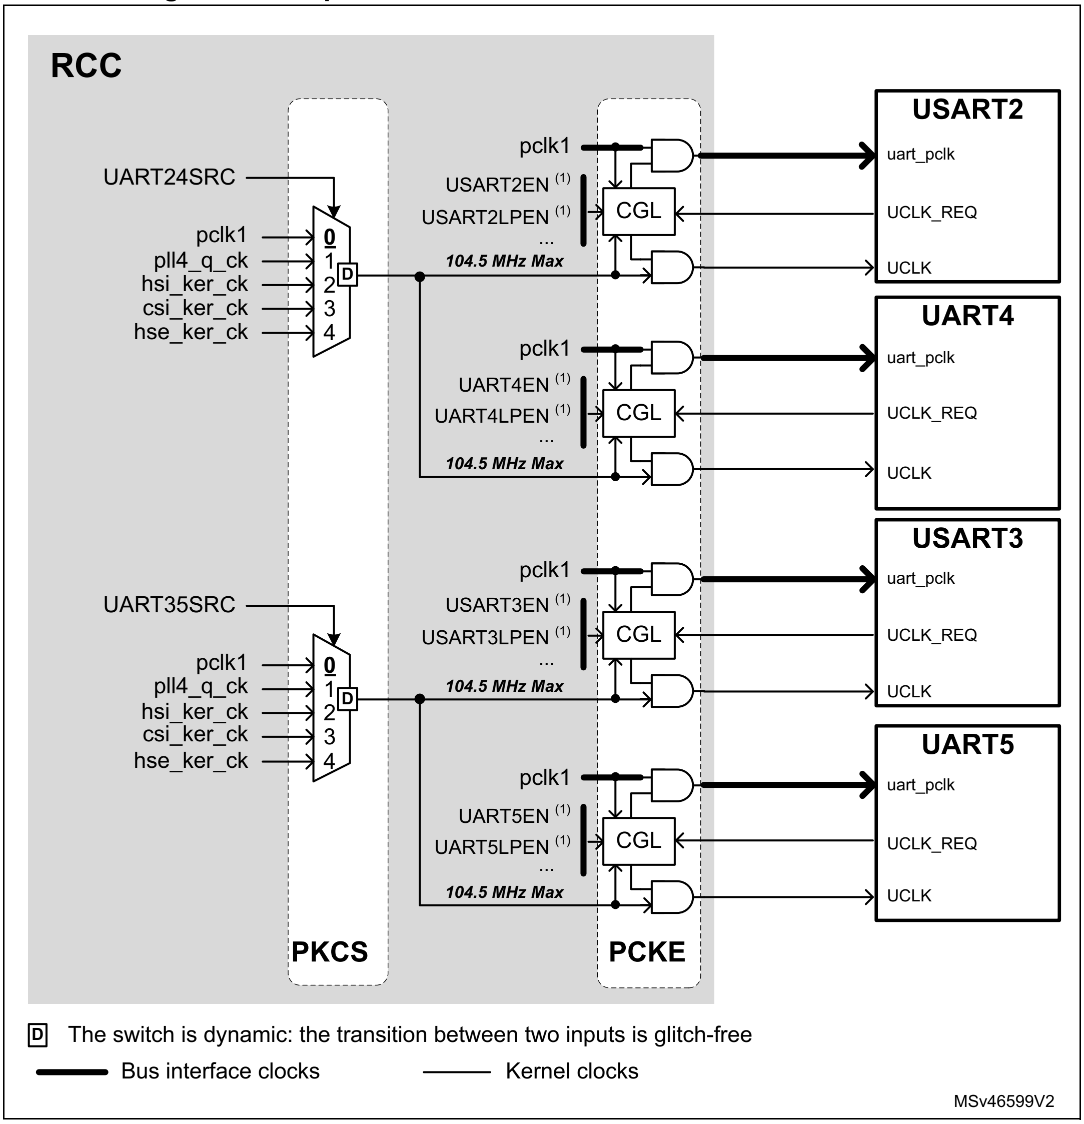
Figure 74. Peripheral clock distribution for I2Cs



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

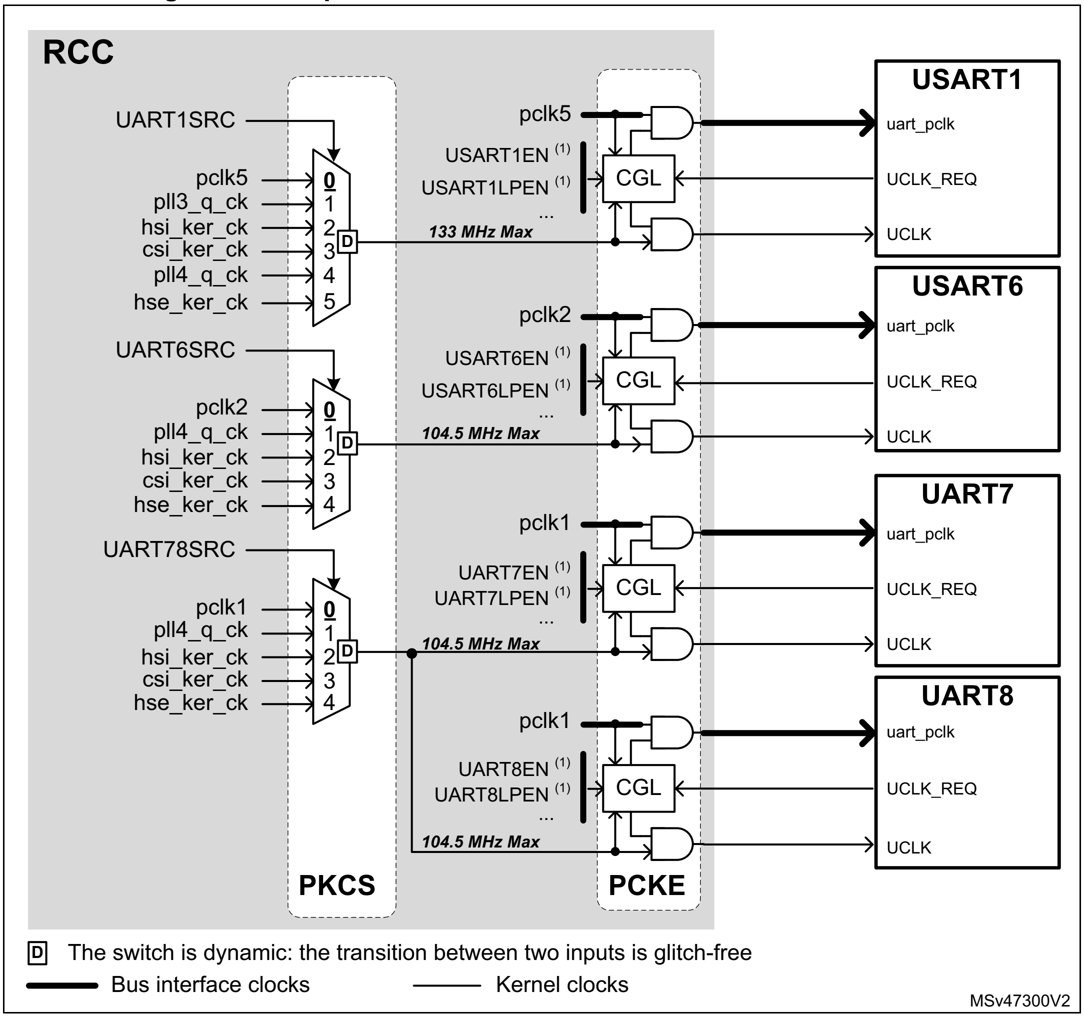
Note: *In order to provide a secure kernel clock to I2C4 and I2C6, the application must choose **pclk5**, **hsi_ker_ck** or **csi_ker_ck**. The application can also use **pll3_q_ck**, but in that case the MCKPROT bit must be set to '1' as well.*

Figure 75. Peripheral clock distribution for UARTs, and USARTs



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

Figure 76. Peripheral clock distribution for UARTs, and USARTs



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

*Note: In order to provide a secure kernel clock to USART1, the application must choose **pclk5**, **hse_ker_ck**, **hsi_ker_ck** or **csi_ker_ck**. The application can also use **pll3_q_ck**, but in that case the MCKPROT bit must be set to '1' as well.*

*Note: In order to allow the I2Cs or U(S)ARTs to work in CStop or system (LP-)Stop mode, the user must select an oscillator as kernel clock: **hse_ker_ck**, **hsi_ker_ck** or **csi_ker_ck**. The HSEKERON, HSIKERON and CSIKERON bits must be programmed according to application requirements.*

Refer to *Table 63* for details concerning the behavior of the clock gating logic (CGL).

Clock distribution for TIMs and LPTIMs

The TIMs timers are using kernel clocks (**timg[2:1]_ck**) phase aligned with the bus interface clock.

The frequency of the timers clock depends on:

- The APB prescaler corresponding to the bus where the timer is connected, and
- The bits TIMG[2:1]PRE.

The next table shows how to select the timer clock frequency.

Table 58. Ratio between clock timers and pclk

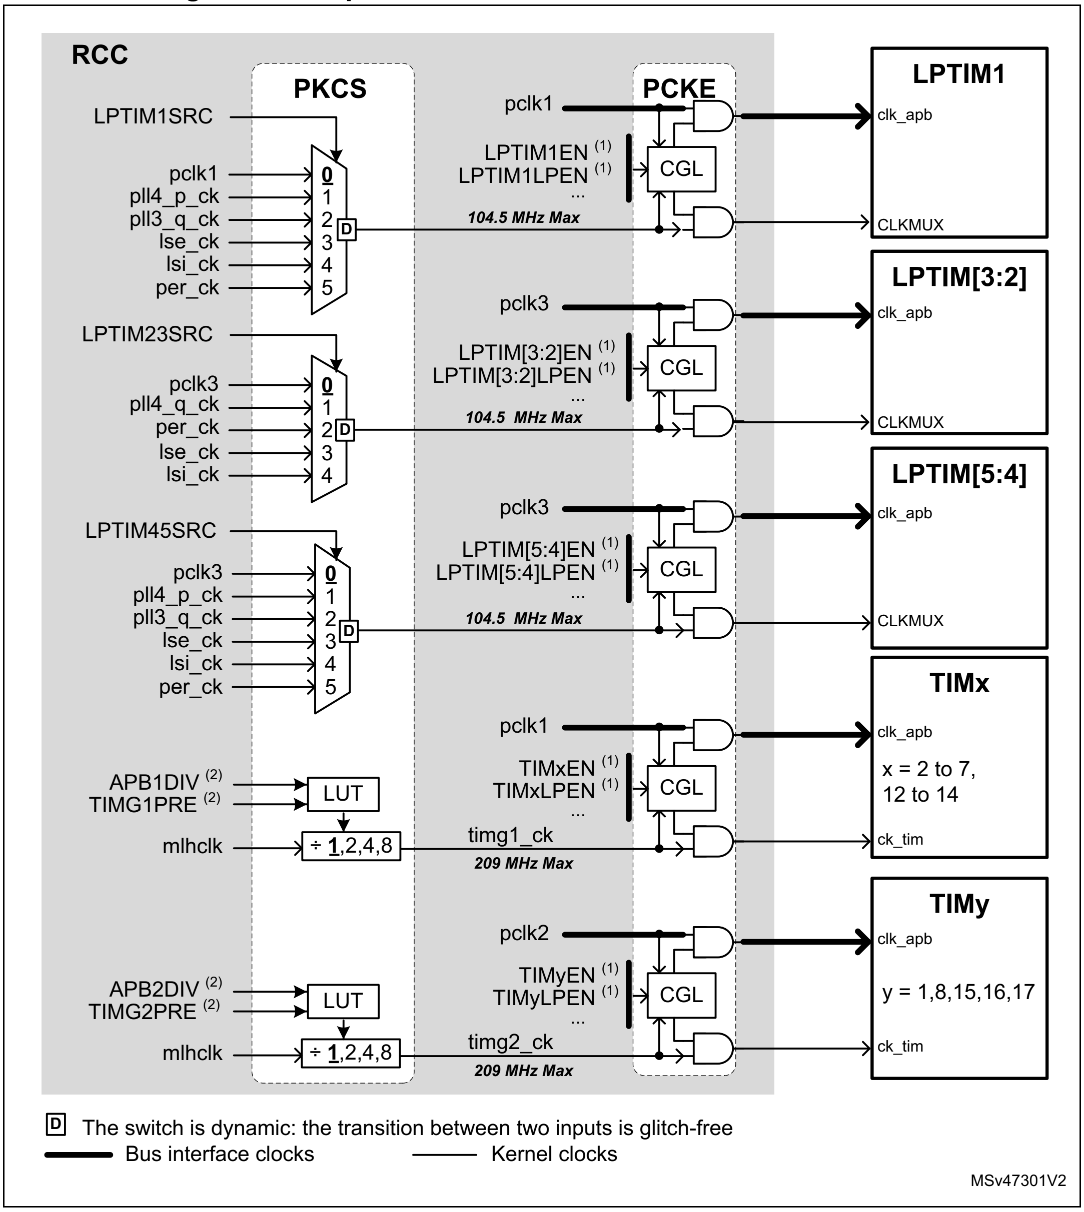
APB1DIV (1) APB2DIV	TIMG1PRE TIMG2PRE (2)	-	F_{timg1_ck} F_{timg2_ck}	F_{pclk1} F_{pclk2}	Comments
‘000’	x	→	F_{mlhclk}	F_{mlhclk}	The timer clock is equal to the bus clock.
‘001’	x	→	F_{mlhclk}	F_{mlhclk} / 2	The timer clock is 2 times faster than the bus clock.
‘010’	‘0’	→	F_{mlhclk} / 2	F_{mlhclk} / 4	
‘011’	‘0’	→	F_{mlhclk} / 4	F_{mlhclk} / 8	
‘100’	‘0’	→	F_{mlhclk} / 8	F_{mlhclk} / 16	
‘010’	‘1’	→	F_{mlhclk}	F_{mlhclk} / 4	The timer clock is 4 times faster than the bus clock.
‘011’	‘1’	→	F_{mlhclk} / 2	F_{mlhclk} / 8	
‘100’	‘1’	→	F_{mlhclk} / 4	F_{mlhclk} / 16	

1. APB1DIV and APB2DIV are located into *RCC APB1 clock divider register (RCC_APB1DIVR)* and *RCC APB2 clock divider register (RCC_APB2DIVR)*.
2. TIMG1PRE and TIMG2PRE are located into *RCC TIM group 1 prescaler register (RCC_TIMG1PRER)* and *RCC TIM group 2 prescaler register (RCC_TIMG2PRER)*.

The LPTIM timers have a kernel clock fully asynchronous with respect to their bus interface clock.

In addition, the LPTIMs can also use as reference clock **lse_ck** and **lsi_ck**, allowing them to work even when the system is in (LP-/LPLV-)Stop.

Figure 77. Peripheral clock distribution for TIMs and LPTIMs



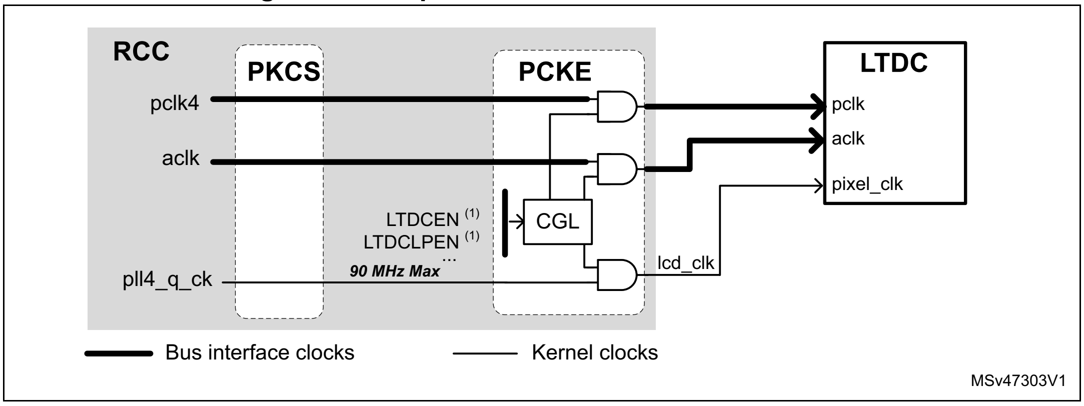
1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset.
2. Can be changed on the fly.

Refer to *Table 63* for details concerning the behavior of the clock gating logic (CGL).

Clock distribution for LTDC

The LTDC pixel clock is provided by the PLL4 (**pll4_q_ck**). The frequency of this clock shall be adjusted according to the wanted resolution and refresh rate.

Figure 78. Peripheral clock distribution for LTDC

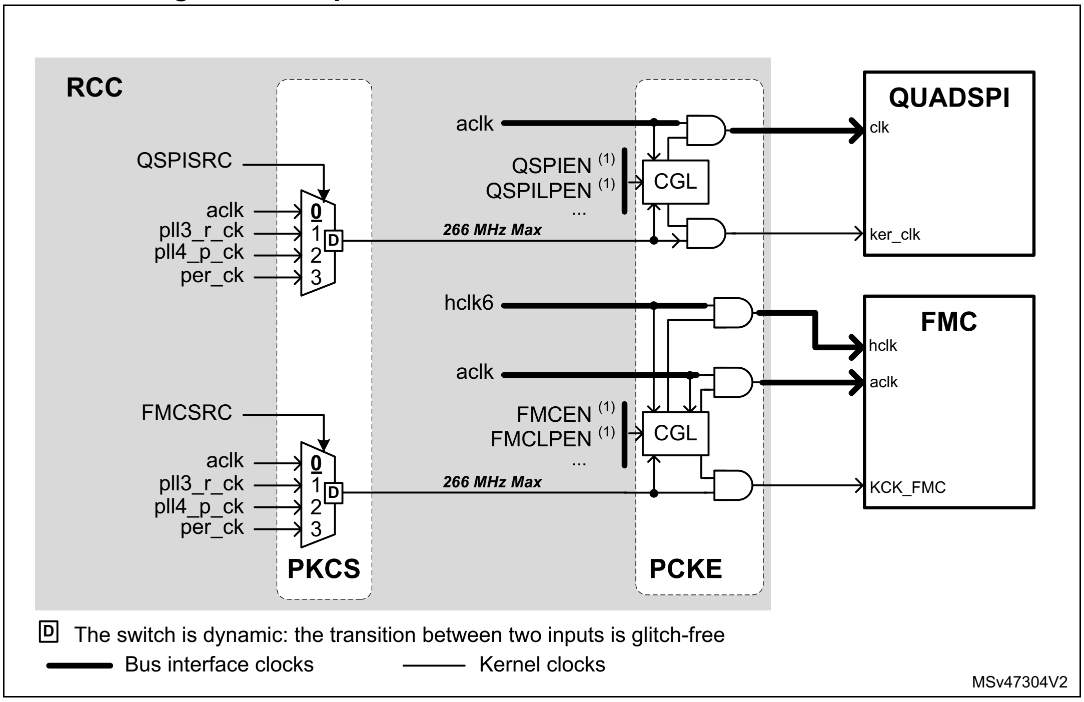


1. There is one enable bit and one low-power enable bit for MPU and MCU.

Clock distribution for SDMMCs, FMC and QUADSPI

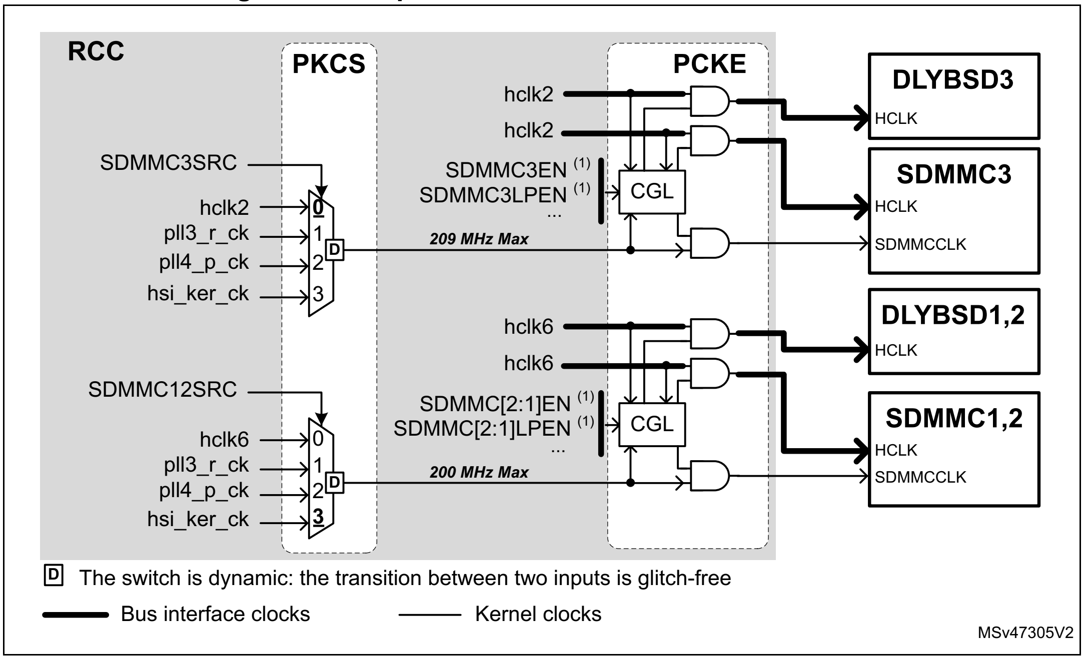
The FMC, QUADSPI can also use a clock different from the bus interface clock for more flexibility.

Figure 79. Peripheral clock distribution for QUADSPI and FMC



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

Figure 80. Peripheral clock distribution for SDMMCs



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

Clock distribution for USBH and USBO

Figure 81 shows the clock distribution for the USB blocks. The RCC has to provide a clean reference clock to the USB PHY. The USB PHY has its own PLL and generates kernel clocks for the USBH (HOST) and USBO (OTG) blocks. The USB PHY receives two different clocks thanks to the mux controlled by USBPHYSRC.

In order to get the best clock quality for the USB, it is better to select the **hse_ker_ck** clock or **hse_ker_ck**/2.

Note that the application has to provide to the USBPHY PLL the following clock reference:

- A clock frequency between 19.2 and 38.4 MHz if the USBPHY PLL is working in integer mode
- A clock frequency between 26 and 38.4 MHz if the USBPHY PLL is working in fractional mode

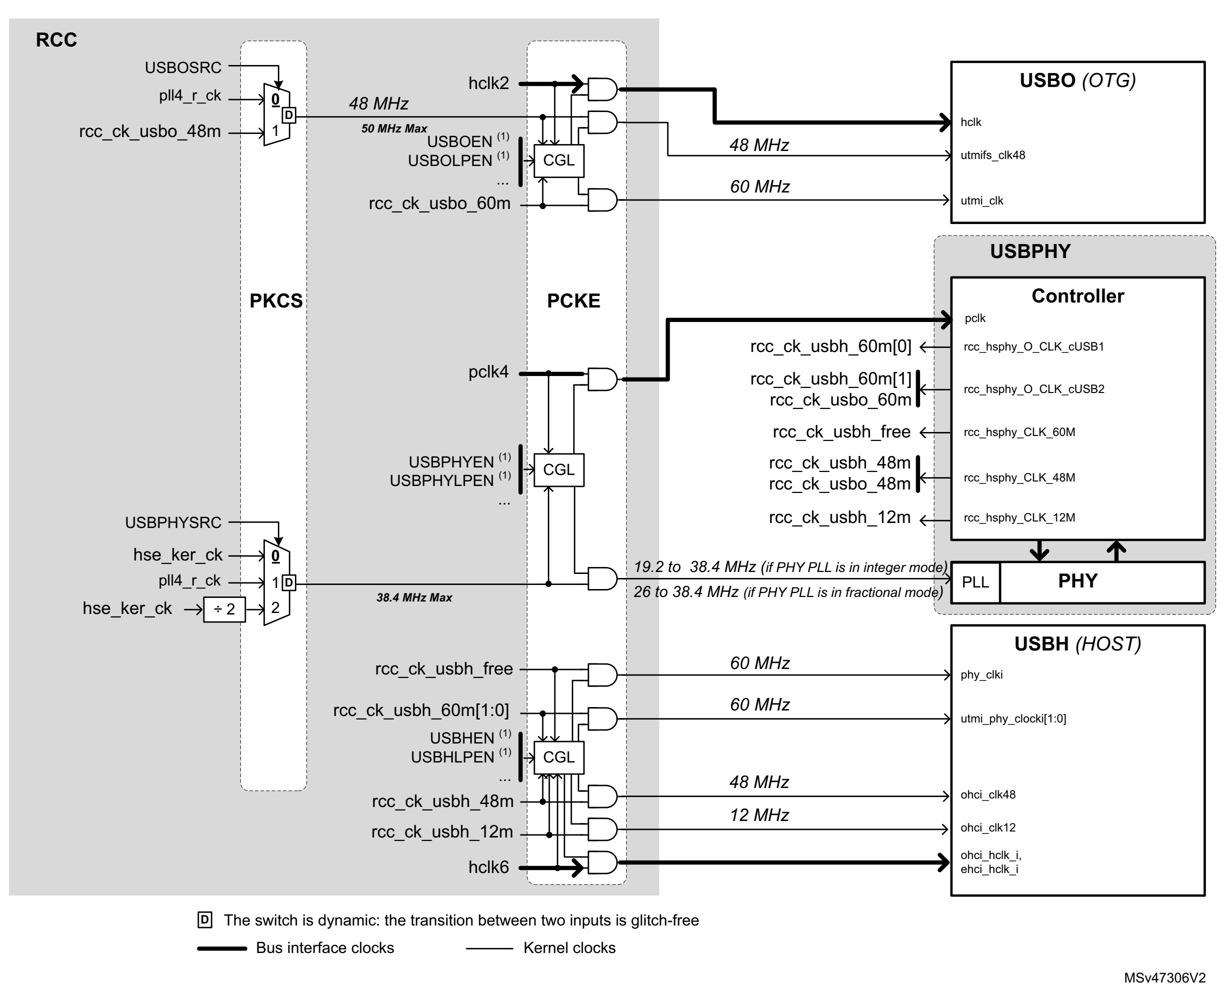
In addition, if the USBO is used in full-speed mode only, the application can choose the 48 MHz clock source to be provided to the USBO:

- A clock generated by the USBPHY; in that case the PLL of the PHY must be used.
- The **pll4_r_ck** clock; in that case there is no need to enable the PLL of the PHY.

The clock selection is performed via USBOSRC.

Those configuration bits are located into *RCC USB kernel clock selection register (RCC_USBCKSELR)*.

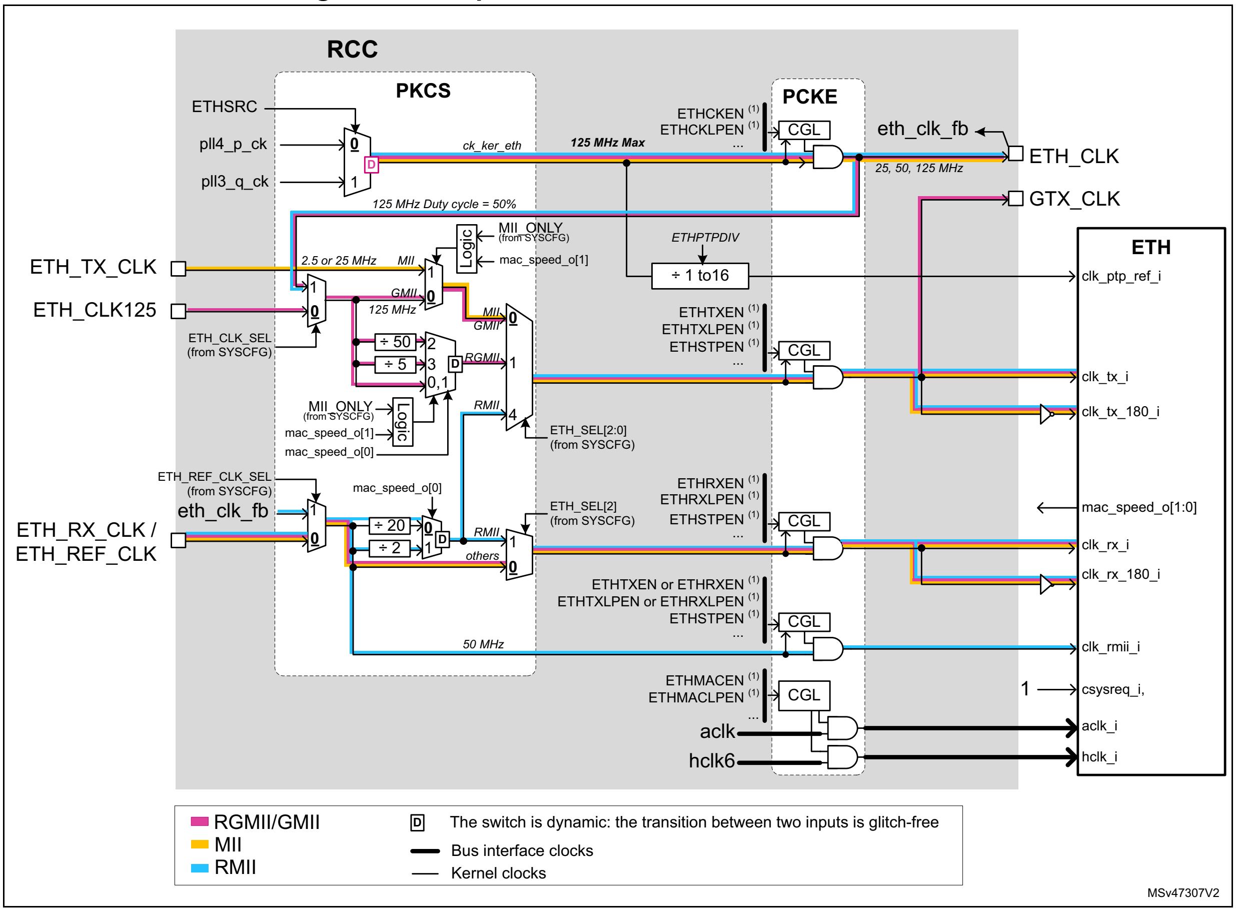
Figure 81. Peripheral clock distribution for USB



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

Clock distribution for Ethernet (ETH)

Figure 82. Peripheral clock distribution for Ethernet



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

The Ethernet clocks provided by the RCC are available on ETH_CLK pad.

The clock selection for the RX and TX path is controlled via the SYSCFG block.

The signal ETH_SEL[2:0] is provided by the SYSCFG block and defines the interface type used:

- In MII mode (orange path),
  - The transmit clock is received from the external PHY via the pad ETH_TX_CLK. The clock frequency will be 2.5 or 25 MHz.
  - The receive clock is received from the external PHY via the pad ETH_RX_CLK. The clock frequency will be 2.5 or 25 MHz
  - In this mode, the output ETH_CLK can be used to provide a reference clock (25 MHz) to the external PHY.
- In GMII mode (red path),
  - The transmit clock can be selected between an internal clock provided by the RCC, or the clock received on the ETH_CLK125 pad. This selection is controlled

via ETH_CLK_SEL from the SYSCFG.
The clock frequency is fixed to 125 MHz.
    - The receive clock is coming directly from the ETH_RX_CLK pad.
The clock frequency is fixed to 125 MHz.
    - The transmit clock is provided to the PHY via the pad GTX_CLK.
    - A reference clock of 25 MHz can also be provided to the external PHY, via ETH_CLK pad.
- In RGMII mode (red path),
    - The transmit clock can be selected between an internal clock provided by the RCC, or the clock received on the pad ETH_CLK125. This selection is controlled via ETH_CLK_SEL from the SYSCFG. The clock frequency can be adjusted dynamically to 2.5, 25 or 125 MHz according to the signal **mac_speed_o[1:0]** provided by the ETH block
    - The receive clock is coming directly from ETH_RX_CLK pad. The clock frequency will be 2.5, 25 or 125 MHz.
    - The transmit clock is provided to the PHY via the pad GTX_CLK.
    - A reference clock of 25 MHz can also be provided to the external PHY, via ETH_CLK pad.
- In RMII mode (blue path)
    - A continuous reference clock (50 MHz) can be selected between an internal clock provided by the RCC, or the clock received on ETH_REF_CLK pad. This selection is controlled via ETH_REF_CLK_SEL from the SYSCFG.
    - The transmit and receive clock frequency can be adjusted dynamically to 2.5 or 25 MHz according to the signal **mac_speed_o[0]** provided by the ETH block.
    - A continuous reference clock (50 MHz) can also be provided to the external PHY, via ETH_CLK pad.

The ETH block provides information on the MAC speed (**mac_speed_o[1:0])**, which may change dynamically.

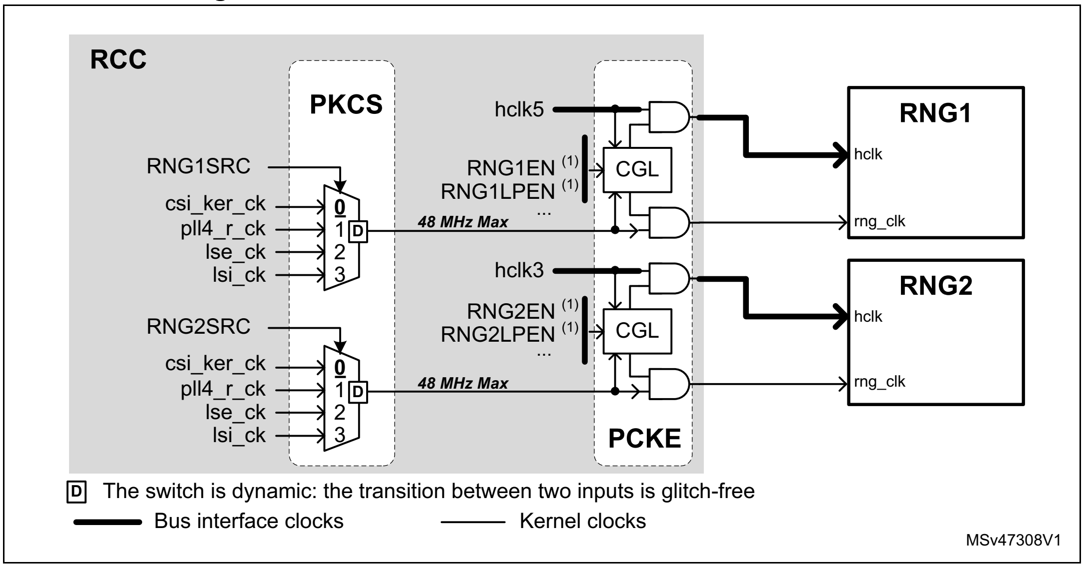
mac_speed_o[1:0] equals:
- 0x: for 1000 Mbps
- 10: for 10 Mbps
- 11: for 100 Mbps

The application can control the gating of the clocks according to the processor modes (CRun, CSleep).

In addition it is also possible to control the gating of clocks coming from PADs ETH_RX_CLK and ETH_TX_CLK in CStop and Stop modes via the ETHSTPEN bit. It is also possible to gate the GTX_CLK clock provided to the PHY during EEE LPI state via the ETH block.

Clock distribution for RNG1 and RNG2

Figure 83. Kernel clock distribution for RNG1 and RNG2

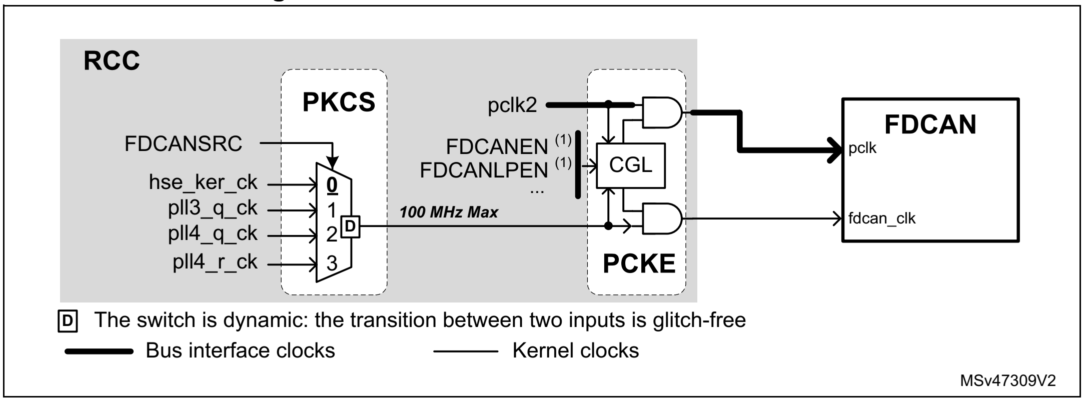


1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset.

Note: In order to provide a secure kernel clock to RNG1, the application must choose ***lse_ck****,* ***lsi_ck****, or* ***csi_ker_ck****.*

Clock distribution for FDCAN

Figure 84. Kernel clock distribution for FDCAN



1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset.

Clock distribution for HDMI-CEC, STGEN, ADCs and DACs

The handling of the STGEN block is a bit particular: It requires a single clock used as bus interface, and kernel clock. In addition, this clock may need to be activated during system (LP-)Stop mode.

Note that two asynchronous bridges are connecting the STGEN to APB4 and APB5 busses, so the RCC shall provide those APB clocks when the STGEN is enabled.

The STGEN can be accessed via two different APB ports:

- The ABP4 port allows the application to use some STGEN resources, but this interface is read-only. Enable bits are available in order to use the STGEN via the APB4: STGENROEN, STGENROLPEN and STGENROSTPEN. These bits can be modified in non-secure mode even if TrustZone is enabled (TZEN = ‘1’).
- The ABP5 port allows the application to control the STGEN, without restrictions. Enable bits are available in order to use the STGEN via the APB5: STGENEN, STGENLPEN and STGENSTPEN. These bits can only be modified by secure accesses if TrustZone is enabled (TZEN = ‘1’).

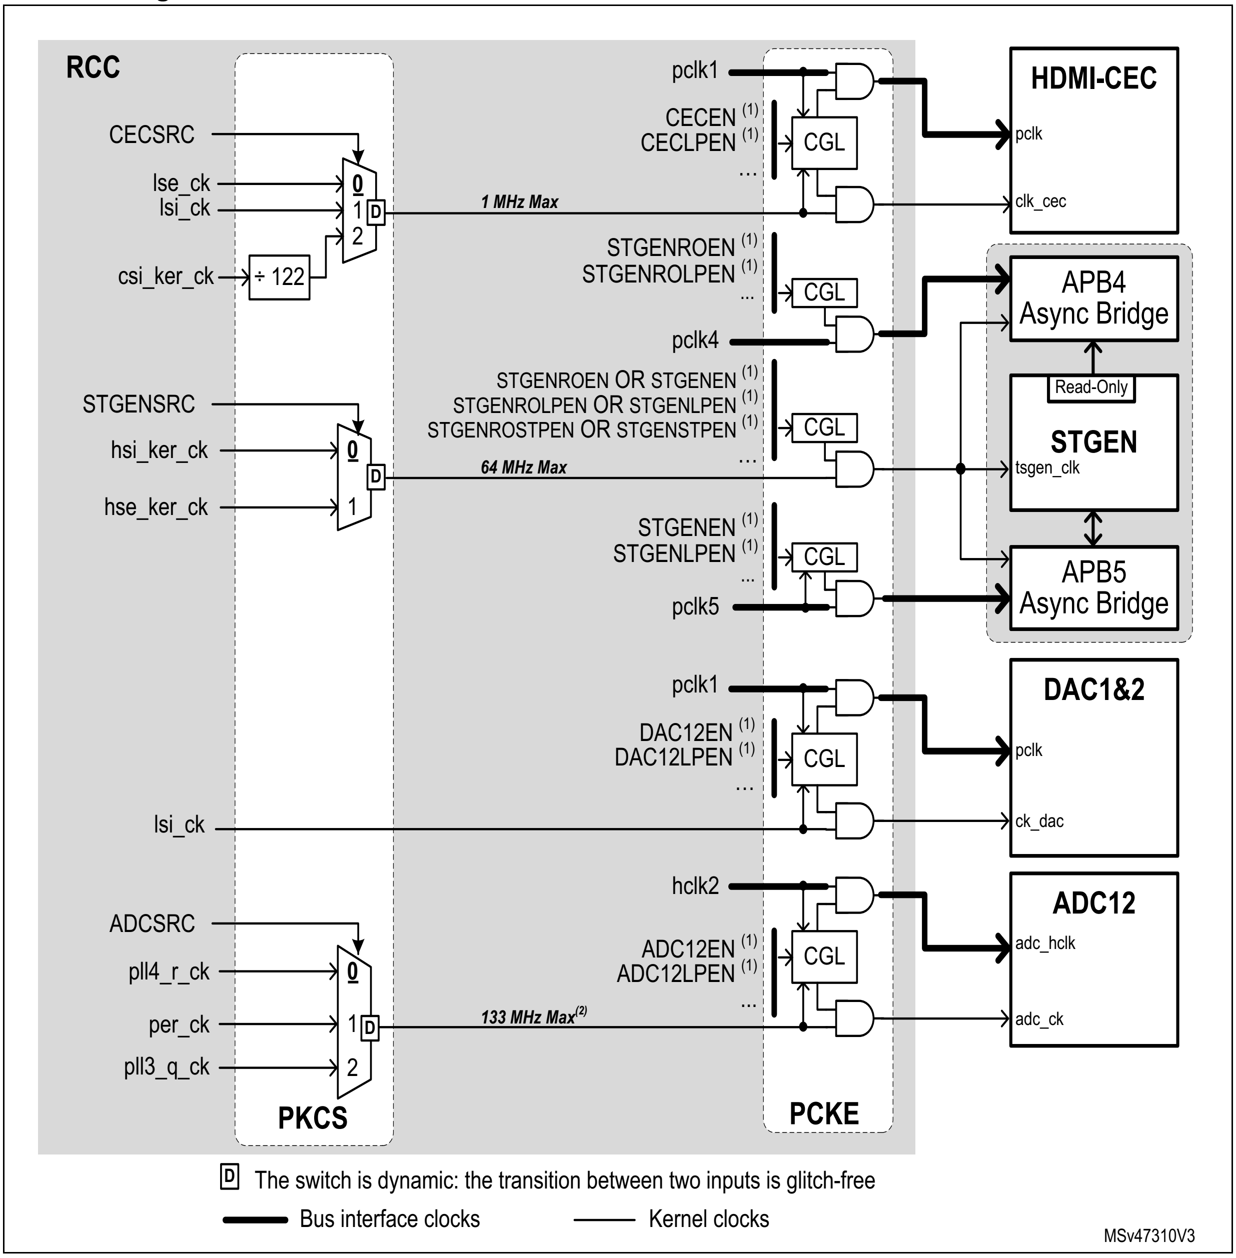
The application can select which clock can be used as STGEN clock (HSE or HSI) via the STGENSRC bit of *RCC STGEN clock selection register (RCC_STGENCKSELR)*.

In order to ensure that the clock is provided to the STGEN when the system is in (LP-)Stop mode, the application shall set the bits STGENEN, STGENLPEN and STGENSTPEN to ‘1’ or set the bits STGENROEN, STGENROLPEN and STGENROSTPEN to ‘1’. In addition, HSEKERON or HSIKERON bits must be set to ‘1’, according to the clock source selected.

The ADC12 has an embedded prescaler in order to provide to the ADC analog cell a clock with a duty cycle as close as possible to 50%.

- If the embedded ADC12 prescaler is bypassed, it is up to the RCC to provide a **clk_adc** clock with a duty cycle of 50%.
  Note that in order to get a clk_adc with a duty cycle of 50%, the post dividers (DIVQ or DIVR) must be programmed to an odd value. If hsi_ker_ck is used, HSIDIV[1:0] must be different from 0.
- If the embedded ADC12 prescaler is used, then the RCC can provide a clock at a frequency up to 133 MHz.

Figure 85. Kernel clock distribution for ADC12, DACs, STGEN and HDMI-CEC

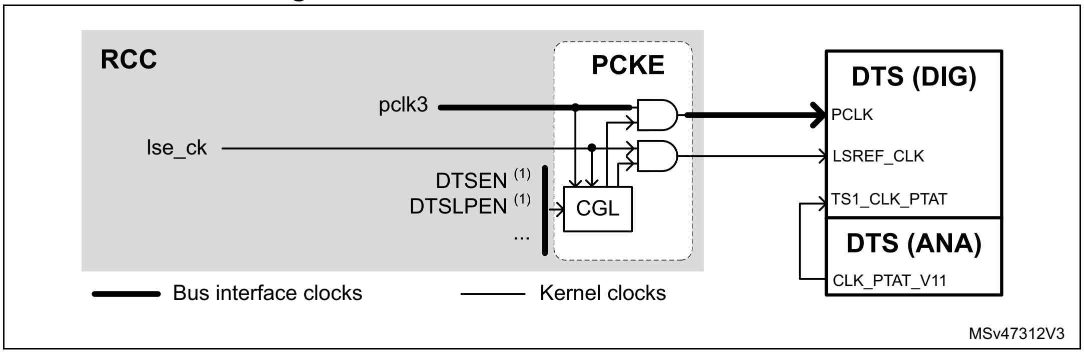


1. There is one enable bit and one low-power enable bit for MPU and MCU.
   X Represents the selected MUX input after a system reset.
2. In case ADC prescaler is bypassed, max frequency is limited by the ADC specification (see product datasheet).

Clock distribution for digital temperature sensor (DTS)

The DTS block needs an APB clock and the **lse_ck** clock. The RCC can provide the lse_ck clock to the DTS block even when the system is in (LP-)Stop. Refer to section *Section 10.4.11: Peripheral clock gating control* for additional information.

Figure 86. Kernel clock distribution for DTS



1. There is one enable bit and one low-power enable bit for MPU and MCU.

Clock distribution for RTC/AWU

The **rtc_ck** clock source can be:

- The **hse_rtc_ck** (**hse_ck** divided by a programmable prescaler),
- The **lse_ck** or,
- The **lsi_ck** clock.

The source clock is selected by programming the RTCSRC[1:0] bits in the *RCC backup domain control register (RCC_BDCR)* and the RTCDIV[5:0] bits in the *RCC RTC clock division register (RCC_RTCDIVR)*.

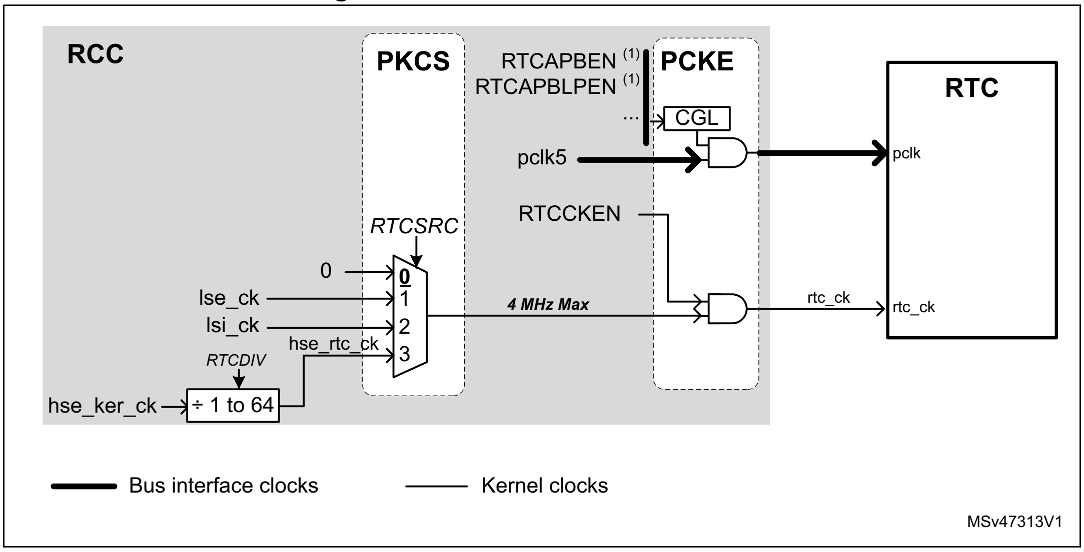
The RTCSRC[1:0] can be modified only once after a reset of the backup domain, or after a LSE failure (LSECSSD = ‘1’).

Note as well that in order to modify the RCC_BDCR register, the DBP bit in the PWR control register 1 (PWR_CR1) has to be set to ‘1’.

The LSE oscillator is in the Backup domain, whereas the other oscillators are not. As a consequence:

- If LSE is selected as the RTC clock:
  - The RTC continues to work even if the V_{DD} supply is switched off, provided the VBAT supply is maintained.
- If LSI is selected as the RTC clock:
  - The RTC state is not guaranteed if the V_{DD} supply is powered off.
  - The RTC continues to work in Stop, LP-Stop, LPLV-Stop and Standby modes.
- If the HSE clock is used as the RTC clock:
  - The RTC state is not guaranteed if the V_{DD} supply is powered off or if the V_{DDCORE} supply is powered off.
  - The RTC continues to work in (LP-)Stop mode if HSEKERON = ‘1’. Note that the clock is lost after a **nreset**.

Figure 87. Clock distribution for RTC



1. There is one enable bit and one low-power enable bit for MPU and MCU.
X Represents the selected MUX input after a system reset.

The **rtc_ck** clock is enabled via RTCCKEN bit located into the RCC_BDCR register.
The RTC bus interface clock (APB clock) is enabled via RTCAPBEN and RTCAPBLPEN bits located respectively into RCC_MP_APB5ENSETR, RCC_MC_APB5ENSETR, RCC_MP_APB5LPENSETR and RCC_MC_APB5LPENSETR registers.

The RTC bus interface clock (APB clock) is disabled via RTCAPBEN and RTCAPBLPEN bits located into RCC_MP_APB5ENCLRR, RCC_MC_APB5ENCLRR, RCC_MP_APB5LPENCLRR and RCC_MC_APB5LPENCLRR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result as the first one. Otherwise a third read access must be performed.

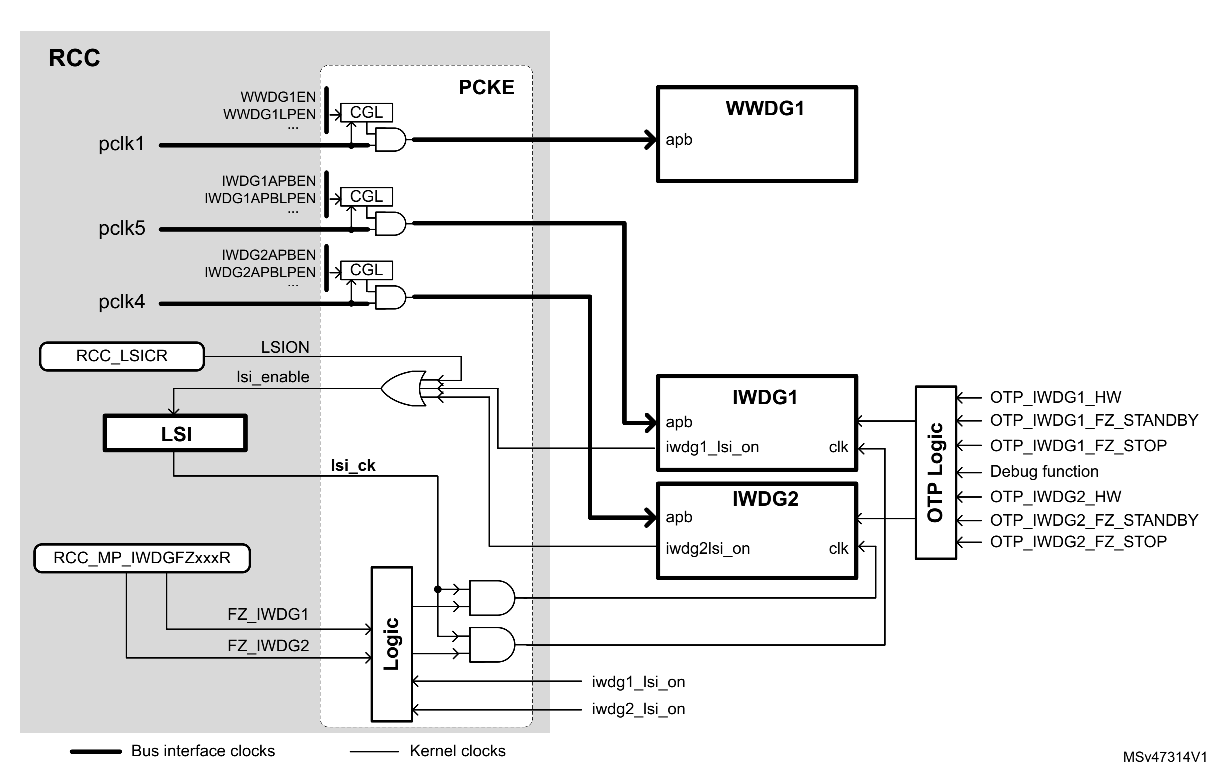
Clock distribution for watchdogs (IWDG[2:1], WWDG1)

The RCC provides the clocks for the three watchdog blocks available on the circuit:

- The two independent watchdogs (IWDG1 and IWDG2) are connected to the LSI.
- The window watchdog WWDG1 is connected to the APB1 clock.

If an independent watchdog is started by either option byte configuration or by software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator set-up delay, the clock is provided to the IWDGs.

Figure 88. Clock distribution for IWDG[2:1] and WWDG1



WWDG1 clock control

The window watchdog clock (**pclk1**) can be enabled by setting the WWDG1EN bit in RCC_MC_APB1ENSETR register. The software cannot stop WWDG1 down-counting by setting WWDG1EN bit to ‘0’. It is expected that the RCC_MC_ABP1ENSETR register is controlled by the MCU, but it is also possible for the MPU to access this register if requested by a specific application.

The WWDG1 block is frozen when the MCU goes to CStop mode.

IWDG[2:1] clock control

The independent watchdogs do not need their clock to be enabled by the RCC block. There are two ways to provide the LSI clock to the IWDG1/2:

- Enabling the IWDG1/2 by software, and use the sequences described into *Section 46.4.4: Window option*. The IWDG1/2 will request automatically the LSI clock activation to the RCC.
- Via the OTP_IWDG[2:1]_HW option bytes, which allow IWDG1 and IWDG2 to be automatically enabled after a system reset. Refer to *Section 46.4.4: Window option* configuration for watchdog for details.

Note as well that the IWDG1 and IWDG2 bus interface clocks (APB clock) must be enabled before accessing the IWDGx registers. The APB clock can be disabled when no access to IWDGx is required. The IWDGx are still counting-down even if the APB clock is disabled.

Note as well that the IWDG1 bus interface clock (APB clock) is controlled via IWDG1APBEN and IWDG1APBLPEN bits located into RCC_MP_APB5ENSETR, RCC_MP_APB5LPENSETR, RCC_MP_APB5ENCLRR and RCC_MP_APB5LPENCLRR registers.

In the same way, the IWDG2 bus interface clock (APB clock) is controlled via IWDG2APBEN and IWDG2APBLPEN bits located into RCC_MP_APB4ENSETR, RCC_MP_APB4LPENSETR, RCC_MP_APB4ENCLRR and RCC_MP_APB4LPENCLRR registers for the MPU.

The LSI clock at the IWDG[2:1] inputs can be frozen in the following situations:

- When the bits FZ_IWDG[2:1] are set (see *Handling of the IWDGs during BOOTROM code execution*). These bits are dedicated to the BOOTROM, and are used to freeze the IWDG[2:1] during BOOTROM code execution.
- When the option bytes OTP_IWDG[2:1]_FZ_STANDBY are set. In this case the corresponding IWDG[2:1] is frozen when the system goes to Standby.
- When the option bytes OTP_IWDG[2:1]_FZ_STOP are set. In this case the IWDG[2:1] are frozen when the MPU goes CStop.

Note that the IWDG[2:1] can also be frozen in debug mode.

Handling of the IWDGs during BOOTROM code execution

The BOOTROM code is always activated after a system reset, a Standby, or a CStandby reset.

As soon as the BOOTROM code is activated, the BOOTROM will freeze the IWDGs clocks. This is done by setting the FZ_IWDG1 and FZ_IWDG2 bits of *RCC IWDG clock freeze set register (RCC_MP_IWDGFZSETR)* to ‘1’.
Before giving the control to the application, the BOOTROM writes the FZ_IWDG1 and FZ_IWDG2 bits of *RCC IWDG clock freeze clear register (RCC_MP_IWDGFZCLRR)* to ‘1’ in order to unfreeze the IWDGs. In that way if the IWDGs were enabled by the application, they will be re-enabled, otherwise they remain disabled.

The access to RCC_MP_IWDGFZSETR and RCC_MP_IWDGFZCLRR registers are restricted to the MPU, and only in secure mode.

The RCC_MP_IWDGFZSETR register used to freeze the IWDGs, is very sensitive. Every time the MPU is reset (i.e. system reset: **nreset or** CStandby reset: **cstby_rst**), the hardware allows to write the RCC_MP_IWDGFZSETR register only once.

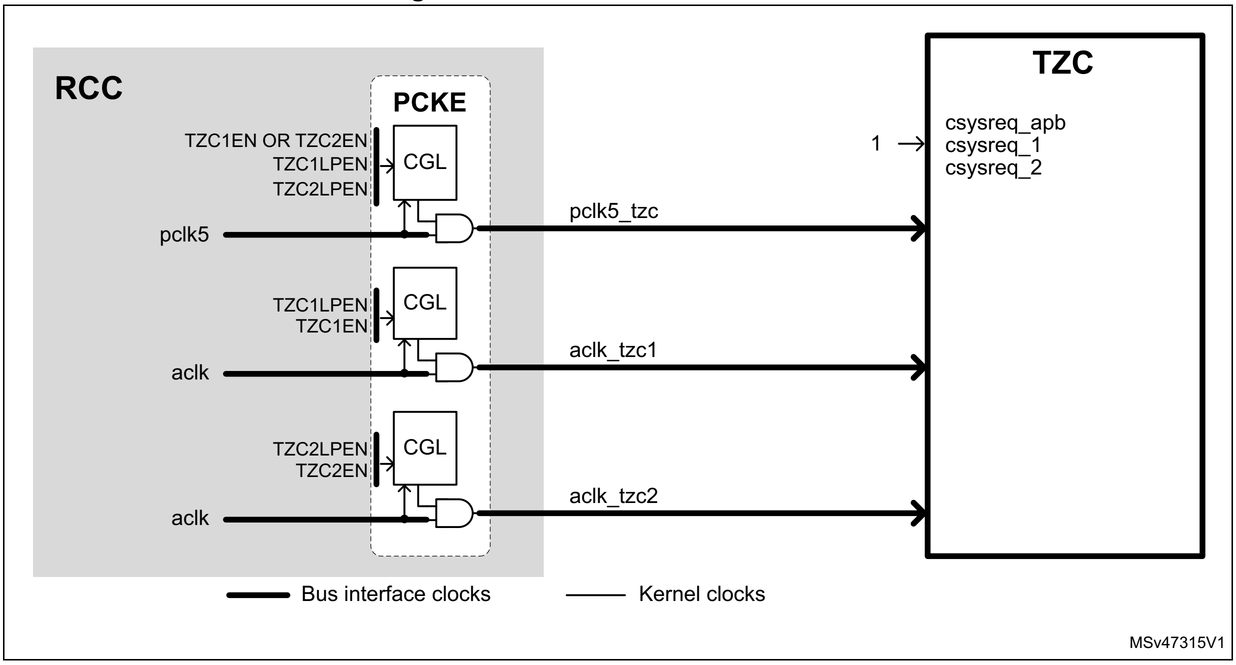
Clock distribution for TZC

The next figure shows a simplified view of the clock distribution for the TZC. The TZC receives the following clocks:

- An APB clock (**pclk5_tzc**),
- An AXI clock for AXI port 1 (**aclk_tzc1**),
- An AXI clock for AXI port 2 (**aclk_tzc2**).

The application can choose to enable the APB clock and one or both clocks of the AXI ports.

Figure 89. Clock distribution for TZC



1. There is one enable bit and one low-power enable bit for MPU and MCU.

In order to enable the TZC, the processor shall set TZC1EN and/or TZC2EN to ‘1’. If the application wants to keep the clocks active in CSleep, the corresponding bit TZC1LPEN and/or TZC2LPEN must be set to ‘1’ as well.

Each processor (MPU and MCU) have their own enable bit control on RCC_Mx_APB5ENSETR/CLRR and RCC_Mx_APB5LPENSETR/CLRR registers.

Clock distribution for DDRC and DDRPHYC

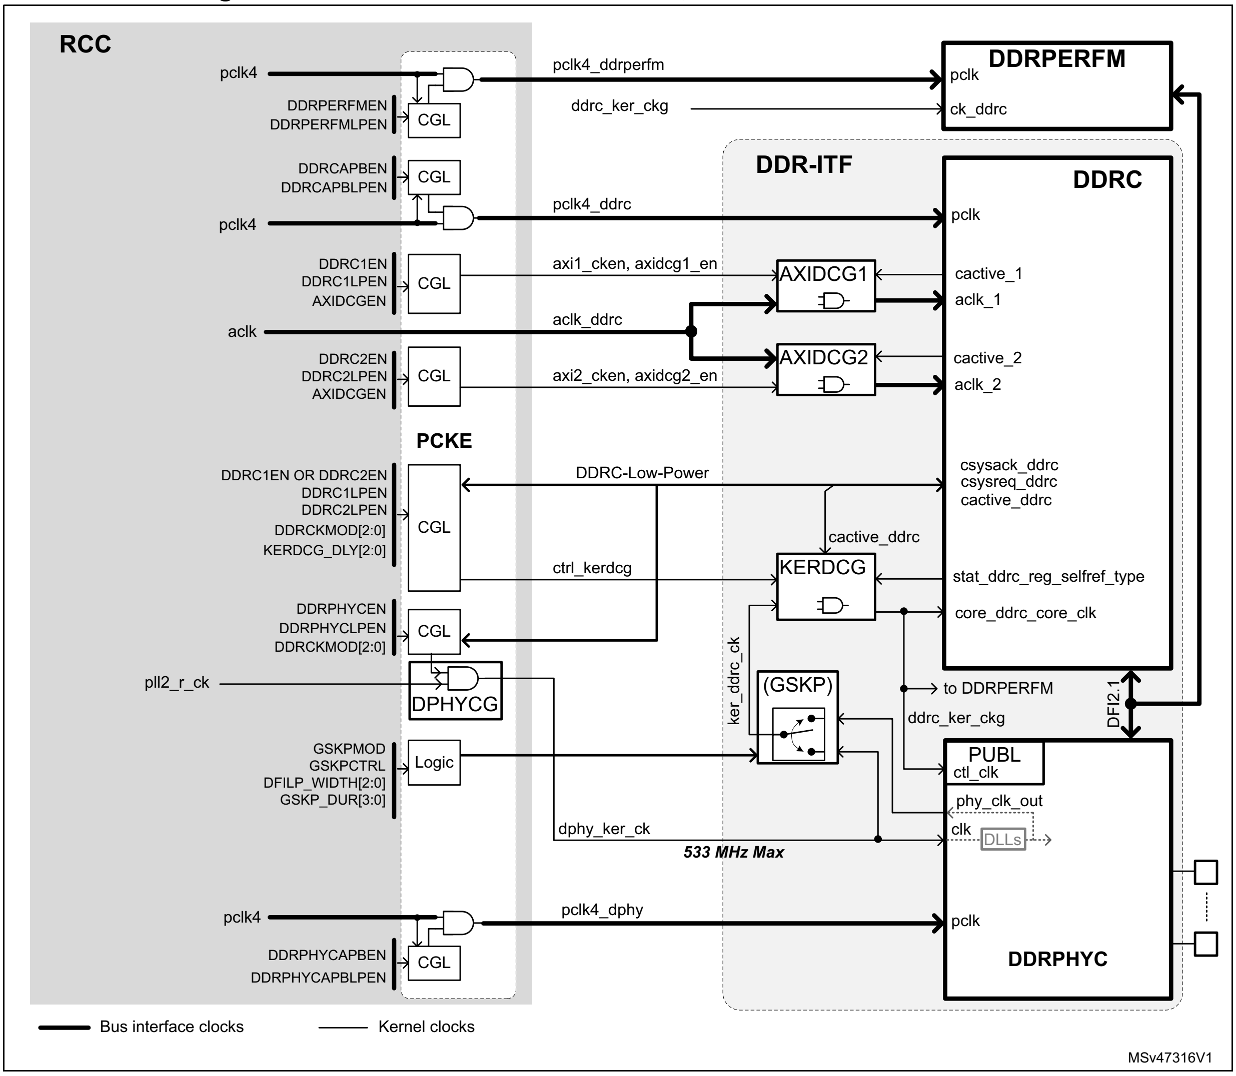
The next figure shows a simplified view of the clock distribution for the DDRC and DDRPHYC blocks. Refer to *Section 5: DDR3/LPDDR2/LPDDR3 controller (DDRCTRL)* for additional information.

The RCC needs to provide the following clocks:

- The APB clocks for the register interface (**pclk4_ddrperfm, pclk4_ddrc** and **pclk4_dphy**).
- The AXI clocks for the two AXI ports of DDRC (**aclk**).
- The kernel clock for the DDRPHYC (**dphy_ker_ck**). Note that the DDRPHYC provides the clock **ddrc_ker_ck** for the DDRC, DDRPERFM and PUBL (part of the DDRPHYC).

Note that all RCC control bits mentioned in this section are located into to the *RCC DDR interface control register (RCC_DDRITFCR)*.

Figure 90. Clock distribution for DDRC, DDRPHYC and DDRPERFM



Control of the APB clocks

The control of the APB clock gating is performed via dedicated bits:

- The DDRCAPBEN and DDRCAPBLPEN bits control the gating of the APB clock of the DDRC interface (**pclk4_ddrc**),
- The DDRPHYCAPBEN and DDRPHYCAPBLPEN bits control the gating of the APB clock of the DDRPHYC interface (**pclk4_dphy**),

Refer to *Section 10.4.11: Peripheral clock gating control* for details.

Control of the AXI clocks

The AXIDCG[2:1] blocks are handling the gating of the AXI clocks (**aclk_[2:1]**) provided to the DDRC AXI ports. The AXIDCG[2:1] bits are controlled by the RCC, and can work as follow:

- Automatic mode: the **aclk_[2:1]** clocks are gated according to **cactive_[2:1]** signals provided by the DDRC.
- Manual mode: the RCC can directly enable or disable the AXI clock generation.

The application can disable the clock of one AXI port, when not used, by setting the corresponding DDRCxEN to ‘0’.

Table 59. Gating control of the aclk_[2:1] clocks

DDRC1EN (DDRC2EN)	DDRC1LPEN (DDRC2LPEN)	AXIDCGEN	MPU mode	-	aclk_1 (aclk_2) clock	Comments
0	X	X	Any	→	OFF	The **aclk_x** is gated because DDRCxEN = ‘0’.
1	X	0	CRun	→	ON	The **aclk_x** is forced ON independently of **cactive_x** because DDRCxEN = ‘1’, AXIDCGEN = ‘0’ and MPU is in CRun
		1		→	DCG (1)	When DDRCxEN = AXIDCGEN = ‘1’, the **aclk_x** is gated automatically according to **cactive_x**.
1	0	0	CSleep	→	OFF	The **aclk_x** is gated because DDRCxLPEN = ‘0’, and AXIDCGEN = ‘0’, and the MPU is in CSleep
	1			→	ON	The **aclk_x** is forced ON independently of **cactive_x** because DDRCxEN = DDRCxLPEN = ‘1’ and AXIDCGEN = ‘0’
	X	1		→	DCG	When DDRCxEN = AXIDCGEN = ‘1’, the **aclk_x** is gated automatically according to **cactive_x**.
X	X	X	CStop or CStandby	→	OFF	The **aclk_[2:1]** are gated.

1. **DCG** means Dynamic Clock Gating according to **cactive_x** signal, highlighted in gray.

Control of the DDRC and DDRPHYC kernel clocks

The KERDCG and DPHYCG blocks are handling respectively the clock gating of the **ddrc_ker_ckg** and **dphy_ker_ck.** They are controlled by the RCC, and can work in normal, automatic or hardware low-power self-refresh mode according to the way the DDRC and the RCC are programmed.

Table 60 details the way clocks **ddrc_ker_ckg** and **dphy_ker_ck** are handled according to the value of DDRCKMOD.

Table 60. DDRCKMOD control description

<table>
<tr><th>DDRCKMOD</th><th>-</th><th>KERDCG mode</th><th>DPHYCG mode</th><th>Comment</th></tr>
<tr><td>‘000’</td><td>→</td><td>Normal</td><td>Normal</td><td>Software Self-Refresh mode (SSR): (1)
The gating of the dphy_ker_ck clock depends on the DDRPHYCEN, DDRPHYCLPEN and MPU mode.
The gating of the ddrc_ker_ckg clock depends on the DDRCxEN, DDRCxLPEN and MPU mode.</td></tr>
<tr><td>‘001’</td><td>→</td><td rowspan="2">Auto.</td><td>Normal</td><td>Automatic Self-Refresh mode (ASR1): (2) (3)
The clock ddrc_ker_ckg is gated automatically according to cactive_ddrc signal.
The gating of the dphy_ker_ck clock depends on the DDRPHYCEN, DDRPHYCLPEN and MPU mode.
DDRCxEN is still used to disable/enable the DDR interface,</td></tr>
<tr><td>‘101’</td><td>→</td><td>Auto</td><td>Full Automatic Self-Refresh mode (ASR2): (4) (3)
The clocks ddrc_ker_ckg and dphy_ker_ck are gated automatically according to cactive_ddrc signal.

DDRCxEN is still used to disable/enable the DDR interface.</td></tr>
</table>

1. This mode must be selected during DDRC and DDRPHYC initialization phase, and if the application is using the software self-refresh.
2. This mode can be used when the application wants to maintain a clock to the DLLs.
3. It is recommended to have DDRCxEN = DDRCxLPEN = DDRPHYCEN = DDRPHYCLPEN = ‘1’.
4. This mode can be used when the DLLs are in bypass.
5. It is recommended to have DDRCxEN = DDRPHYCEN = ‘1’ and DDRCxLPEN = DDRPHYCLPEN = ‘0’.

Glitch skipper (GSKP)

The RCC also needs to handle a block named Glitch Skipper (GSKP). The GSKP is performing following functions:

- The GSKP prevents low-power mode transitions shorter than 1 us. The application has to program a timeout delay via the DFILP_WIDTH[2:0] field.
- The GSKP prevents to have glitches on the clock **ddrc_ker_ck** during the re-activation of the DLLs. For that purpose, when GSKPMOD = ‘1’, the GSKP is providing the clock **dphy_ker_ck** to the DDRC for a duration given by the GSKP_DUR[3:0] field.

  The application can also control manually the clock switching via GSKPCTRL bit when GSKPMOD = ‘0’. In this case, when GSKPCTRL is set to ‘1’, the GSKP provides the clock **dphy_ker_ck** to the DDRC, and when GSKPCTRL is set to ‘0’, the GSKP will provide the clock **phy_clk_out** to the DDRC, after a delay given by GSKP_DUR[3:0].

  The DFILP_WIDTH, GSKPMOD, GSKP_DUR and GSKPCTRL fields are located in *RCC DDR interface control register (RCC_DDRITFCR)*.

DDRC Low-power Interface

The DDRC block provides a low-power interface which can used to control the entry and exit of the DDRC and DDRPHYC into low-power mode. This interface also controls the gating of the **dphy_ker_ck** and **ddrc_ker_ckg** clocks. This low-power interface is compliant to AMBA AXI protocol specification. In order to simplify the drawings, this document only shows the most significant states of the DDRC low-power interface. *Table 60* gives details on the DDRC low-power states.

The DDRC Low-power interface can be used in HSR1 and HSR2 modes in order to control:

- The generation of the DDRC and DDRPHYC kernels clocks,
- The entry/exit of the external DDR device into low-power (i.e. self-refresh).

Table 61. DDRC low-power (DDRC-LP) states description

DDRC low-power states	-	Comment
CKON	→	Normal clocked operation: The RCC provides the kernel clock(s) to the DDRC and DDRPHYC. **csysreq_ddrc**, **csysack_ddrc** and **cactive_ddrc** are all set to ‘1’
CKOFF	→	Low-power operation: The RCC does not provide the kernel clock(s) to the DDRC and DDRPHYC. **csysreq_ddrc**, **csysack_ddrc** and **cactive_ddrc** are all set to ‘0’
CKON_Rreq	→	Low-power exit initiated by the RCC: The RCC provides the kernel clock(s) to the DDRC and DDRPHYC. The RCC sets the **csysreq_ddrc** to ‘1’, and waits for **csysack_ddrc** and **cactive_ddrc** set to ‘1’ before going to state CKON.
CKON_Preq	→	Low-power exit initiated by the DDRC: The DDRC requests the kernel clock(s) by setting the **cactive_ddrc** to ‘1’. The RCC provides the kernel clock(s), sets the **csysreq_ddrc** to ‘1’, and waits for **csysack_ddrc** set to ‘1’ before going to state CKON.
CKOFF_Rreq	→	Low-power entry initiated by the RCC: The RCC requests to the DDRC to entry into low-power by setting the **csysreq_ddrc** to ‘0’. The DDRC may accept or deny the request. If a request is denied, the interface come back to CKON state, and the RCC retries a new low-power request entry. When the low-power request is accepted by the DDRC (**csysack_ddrc** and **cactive_ddrc** = ‘0’), the RCC disables the kernel clock(s). Then the states switches to CKOFF.

Self-refresh mode control

Switching the external DDR device into self-refresh is important for energy saving.

When the external DDR device is in self-refresh, the application can switch-off the clocks of the DDRC and DDRPHYC, without loosing the content of the external DDR.

When the external DDR device is in self-refresh, the application can no longer access to the content of the external DDR device.

Exiting a DDR device from self-refresh can take several microseconds and the application has to take into account this latency. This latency is due to the external DDR device, but also to the way the DLLs located into the DDRPHYC are handled.

The RCC offers 3 ways to control the clocks of the DDRC and DDRPHYC:

- The software self-refresh mode (SSR),
- The automatic self-refresh mode (ASR),
- The hardware self-refresh mode (HSR).

The behavior of the RCC is different according to the self-refresh mode selected by the application. For that purpose, the application has to program the DDRCKMOD in accordance with the configuration of the DDRC and DDRPHYC.

The software self-refresh mode (SSR)

In this mode, the application has to program directly the DDRC in order to switch the external DDR device immediately into self-refresh. Typically when the MPU wants to go to CSleep or CStop, it must ensure that the DDR resource is no longer needed, and program the DDRC in order to switch it to self-refresh.
The piece of code performing the entry and the exit of the DDRC to self-refresh must be located into the SYSRAM. This is due to the fact that some software routine need to run when the DDR device is in self-refresh.

The automatic self-refresh mode (ASR1 and ASR2)

In this mode the software does not need to program the DDRC every-time the DDRC must be set into self-refresh. The DDRC will go automatically into self-refresh mode when the DDRC is inactive for an amount of time defined into the DDRC.

Even when the MPU is in CRun mode, the DDRC may go to self-refresh if there is no activity on its AXI ports. The automatic self-refresh mode, allows the entry into self-refresh independently of the processor mode.

When the MPU goes to CSleep, if the clocks of the DDRC and optionally the clock of the DDRPHYC need to be gated, the RCC delays the gating of these clocks until the DDRC switches into self-refresh mode.

If the system needs to go to one of the Stop modes, the RCC will delay the gating of the clocks until the DDRC switches into self-refresh mode.

The ASRx modes must be used only if the DDRC has been programmed in automatic self-refresh mode, otherwise the behavior of the DDR interface is not guaranteed.

The ASRx modes only impact the gating of the DDRC and DDRPHYC kernel clocks (i.e. **ddrc_ker_ckg** and **dphy_ker_ck**).

Warning: The ASR2 mode can only be used when the DLLs of the DDRPHYC are bypassed. So only DDR devices such as LPDDR2, working at frequencies around 125 MHz can use this feature.

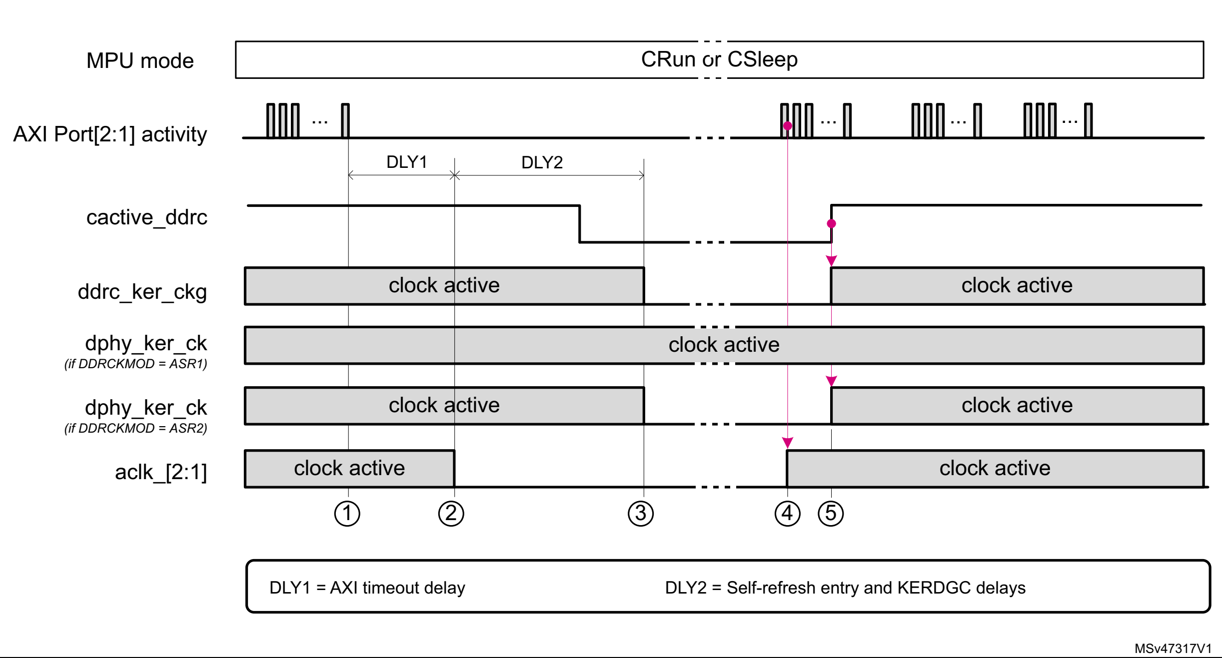
When the ASRx modes are used, at least one of the DDRCxEN bits must be set to ‘1’.

Figure 91 shows a simplified timing for the entry and exit from self-refresh.

In this example DDRCxEN = DDRCxLPEN = ‘1’, DDRPHYCEN = DDRPHYCLPEN = ‘1’, AXIDCGEN = ‘1’.

1. The activity on AXI port x is stopped, due for example, to the fact that the MPU goes to CSleep, but it could be also the case between two activity bursts.
2. When no activity is detected in the AXI port x for at least UMCTL2_AXI_LOWPWR_NOPXCNT ***aclk_x** cycles (DLY1), the AXI clock (**aclk_x**) is gated if AXIDCGEN = ‘1’.
3. When the AXI interfaces are gated, if it does not switch back to active after a delay DLY2, the clock **ddrc_ker_ckg** is gated. If the ASR1 mode is selected, the clock **dphy_ker_ck** remains enabled if DDRPHYCEN = DDRPHYCLPEN = ‘1’. If the ASR2 mode is selected, then the clock **dphy_ker_ck** is gated just after the gating of the **ddrc_ker_ckg** clock. The MPU mode can be CRun or CSleep.
4. If a transaction is performed in one of the two AXI ports, the AXI clock (**aclk_x**) is re-enabled. The AXI transaction can be caused by any master using DDR resources.
5. Few AXI clock cycles later, the DDRC sets the **cactive_ddrc** to ‘1’ in order to request the kernel clock. The DDRPHYC clock **dphy_ker_ck** and the DDRC clock **ddrc_ker_ckg** are re-enabled.The external DDR is then ready to process the pending transactions.

Figure 91. Entering and exiting self-refresh in ASR1 or ASR2 modes



The hardware self-refresh mode (HSR1 and HSR2)

The hardware self-refresh mode is using the DDRC-low-power interface (DDRC-LP) in order to request to the DDR to go or exit from low-power.

The DDRC-LP allows the exit of the DDR interface from self-refresh in the following cases:

- When the interface is enabled via DDRCxEN bits,
- When the MPU exits from CSleep or CStop,
- When the DDRC requests to exit from self-refresh. This could happen if another master is accessing one of the AXI ports.

The DDRC-LP allows the entry of the DDR interface into self-refresh in the following cases:

- When the interface is disabled via DDRCxEN bits,
- When the MPU transitions from CRun to CSleep,
- When the MPU transitions from CRun to CStop.

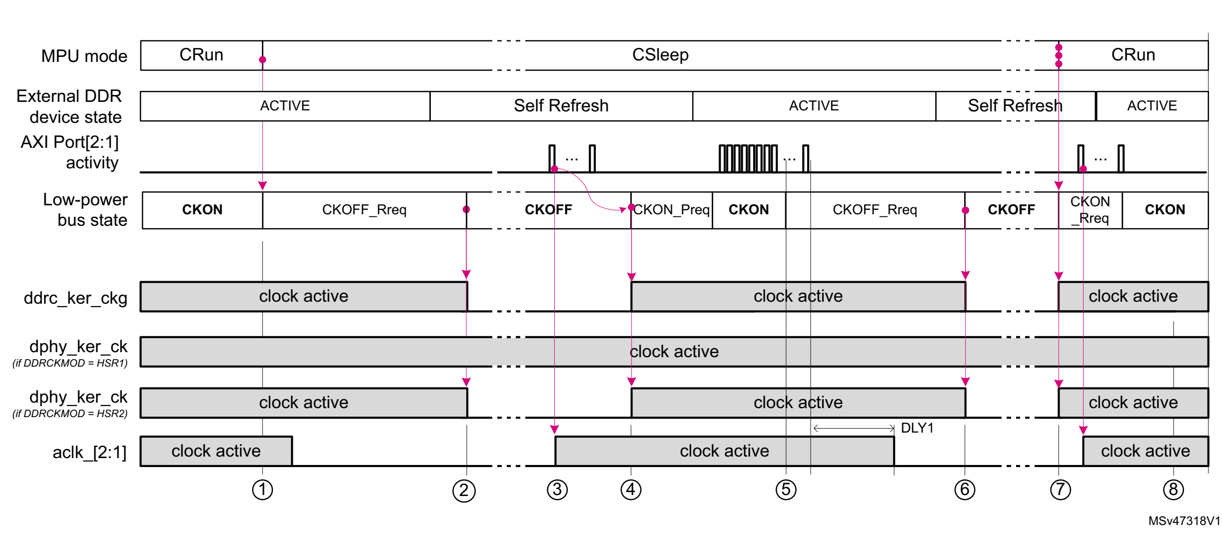
This may be less efficient in term of power saving than the automatic mode (ASR) but avoids that the DDRC goes accidentally to self-refresh when the MPU is in CRun, increasing the system performances.

Warning: The HSR2 mode can only be used when the DLLs of the DDRPHYC are bypassed. So only DDR devices such as LPDDR2, working at frequencies around 125 MHz can use this feature.

Figure 92 shows simplified timing for the self-refresh entry and exit. This is typically what will happen when the MPU goes to CSleep while some master are still enabled.

This example is based on configurations #7 and #8 of *Table 61*, with AXIDCGEN = ‘1’.

Figure 92. Entering and exiting self-refresh in HSR1 or HSR2 modes



1. When the MPU goes to CSleep, the RCC requests to the DDRC to go to self-refresh, using the DDRC Low-power bus (CKOFF_Rreq). Note as well that the AXI clock will be disabled if no transactions occur on AXI ports for a programmed delay (DLY1).
2. When all the conditions in the DDRC are met (no transaction pending, DDR in self-refresh), the DDRC acknowledges the request. Note that if the DDRC denies the request from the RCC, the RCC has to generate a new requests until it is accepted by the DDRC, or if the MPU exits from CSleep.
   When the DDRC acknowledges the low-power request, then the RCC disables the DDRC clock **ddrc_ker_ckg**. If the HSR1 mode is selected, the clock **dphy_ker_ck** remains enabled if DDRPHYCEN = DDRPHYCLPEN = ‘1’. If the HSR2 mode is selected the DDRPHYC clock **dphy_ker_ck** is disabled as well. The DDRC low-power bus is then in CKOFF state.
3. If a transaction is performed in one of the two AXI ports, the AXI clock (**aclk_x**) is re-enabled. The AXI transaction can be caused by any master using DDR resources.
4. Few AXI clock cycles later, the DDRC request to the RCC to re-enable the kernel clock, using the DDRC Low-power bus (CKON_Preq). As soon as the RCC receives the request, the DDRPHYC clock **dphy_ker_ck** and the DDRC clock **ddrc_ker_ckg** are re-enabled. The external DDR is then ready to process the pending transactions.
5. As the MPU is still in CSleep mode, the RCC will request to the DDRC to go to self-refresh, using the DDRC Low-power bus (CKOFF_Rreq). The DDRC may deny the request several times if all conditions to enter in self-refresh are not met. The RCC has to renew its request regularly until it is accepted by the DDRC. The RCC shall stop performing this request if the MPU goes to CRun meanwhile.
6. When all the conditions in the DDRC are met (no transaction pending, DDR in self-refresh), the DDRC acknowledges the request. When the DDRC acknowledges the low-power request, then the RCC disables the DDRC clock **ddrc_ker_ckg**. If the HSR1 mode is selected, the clock **dphy_ker_ck** remains enabled if DDRPHYCEN = DDRPHYCLPEN = ‘1’. If the HSR2 mode is selected the DDRPHYC clock **dphy_ker_ck** is disabled as well. The DDRC low-power bus is then in CKOFF state.

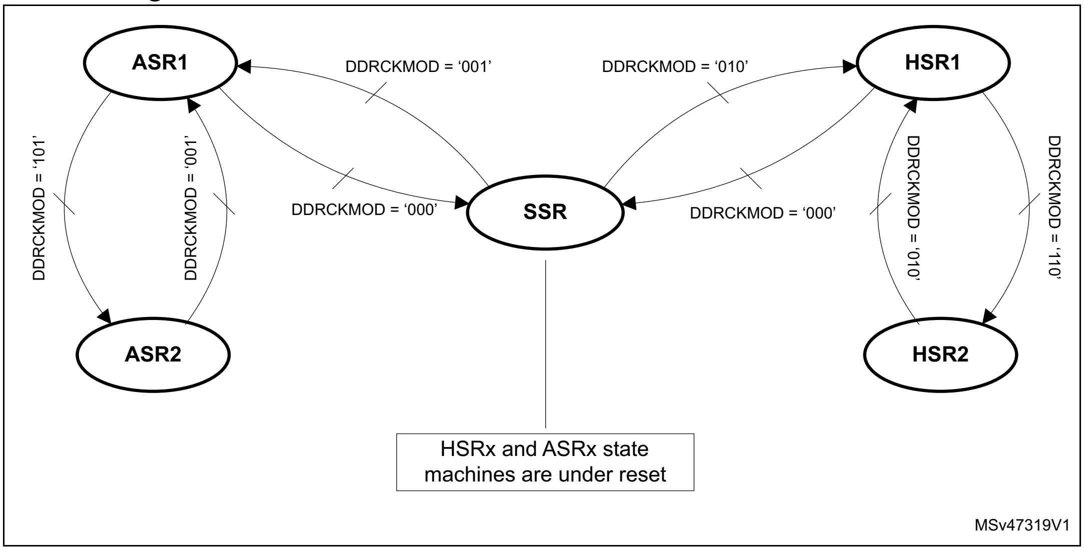
The sequence described between step 4 to step 7 may be repeated several times will the MPU is in CSleep.

7. When the MPU exits from CSleep, the RCC re-enables the DDRPHYC clock **dphy_ker_ck** and the DDRC clock **ddrc_ker_ckg**, and requests to the DDRC to exit the DDR from self-refresh, using the DDRC Low-power bus (CKON_Rreq).
8. The DDRC acknowledges the request by setting the DDRC low-power bus into CKON state. The external DDR is then ready to process the pending transactions.

Transitions between SSR, ASR and HSR

It is possible for the application to change the value of the DDRCKMOD without disabling the DDR interface. The next figure shows the allowed transition between SSR, ASR and HSR modes.

Figure 93. Allowed transitions between SSR, ASR and HSR modes



It is not allowed to transition directly:

- From ASRx to HSRx, the application needs first to set DDRCKMOD to ‘000’ (SSR), and then set the DDRCKMOD to the wanted HSR or ASR mode,
- From SSR to ASR2, the application needs first to set DDRCKMOD to ‘001’ (ASR1), and then set the DDRCKMOD to ‘101’ (ASR2 mode),
- From ASR2 to SSR, the application needs first to set DDRCKMOD to ‘001’ (ASR1), and then set the DDRCKMOD to ‘000’ (SSR mode),
- From SSR to HSR2, the application needs first to set DDRCKMOD to ‘010’ (HSR1), and then set the DDRCKMOD to ‘110’ (HSR2 mode),
- From HSR2 to SSR, the application needs first to set DDRCKMOD to ‘010’ (HSR1), and then set the DDRCKMOD to ‘000’ (SSR mode).

Recommended configurations

The bits DDRCxEN and DDRPHYC are used to enable or disable the DDR interface.

Table 62 shows the recommended RCC configurations. The application has to select the configuration adapted to its DDR configuration.

Table 62. Recommended configurations (1)

Conf #	DDRCKMOD	DDRCxEN	DDRCxLPEN	DDRPHYCEN	DDRPHYCLPEN	-	MPU CRun mode AXI clock (2)	MPU CRun mode DDRC clock	MPU CRun mode DDRPHYC clock	MPU CSleep mode AXI clock (2)	MPU CSleep mode DDRC clock	MPU CSleep mode DDRPHYC clock	Comments
1	Any	0	x	0	x	→	OFF	OFF	OFF	OFF	OFF	OFF	Interface disabled
2	SSR	1	0	1	0	→	ON	ON	ON	OFF	OFF	OFF	The gating of the DDRC and DDRPHYC clock is dependent of the MPU mode. It is up to the application software to switch the DDR interface into low-power mode, before gating the clocks.
3		1	0	1	1	→	ON	ON	ON	OFF	OFF	ON	
4		1	1	1	1	→	ON	ON	ON	ON	ON	ON	
5	ASR1	1	1	1	1	→	ON	DCG	ON	ON	DCG	ON	Only DDRC kernel clock is controlled according to automatic mode.
6	ASR2	1	1	1	0	→	ON	DCG	DCG	ON	DCG	DCG	Both DDRC and DDRPHYC kernel clocks are controlled according to automatic mode. This mode can only be used when the DLLs of the DDRPHYC are bypassed. So only DDR devices such as LPDDR2, working at frequencies around 125 MHz can use this feature.
7	HSR1	1	0	1	1	→	ON	DLP	ON	OFF	DLP	ON	The DDRC kernel clock is controlled according to DDRC-LP interface. The DDRPHYC kernel clock shall be maintained active by setting DDRPHYCEN = DDRPHYCLPEN = ‘1’
8	HSR2	1	0	1	0	→	ON	DLP	DLP	OFF	DLP	DLP	Both DDRC and DDRPHYC kernel clocks are controlled according to DDRC-LP interface. This mode can only be used when the DLLs of the DDRPHYC are bypassed. So only DDR devices such as LPDDR2, working at frequencies around 125 MHz can use this feature.

1. DCG means that the clocks are controller using dynamic clock gating, highlighted in gray.
In the case of DDRC and DDRPHYC, the clocks are gated by the **cactive_ddrc** signal.
DLP means DDRC Low-Power protocol, highlighted in blue.
2. When the bit AXIDCGEN = ‘1’, the AXI clock is gated automatically according to **cactive_[2:1]** (DCG), except when DDRCxEN = ‘0’.

In the configurations #2 to #4, the gating of the DDRC and DDRPHYC clock is dependent of the MPU mode. It is up to the application software to switch the DDR interface into low-power mode, before gating the clocks.

Configuration #2

- The APB and the kernel clocks of both DDRC and DDRPHYC are enabled when the MPU is in CRun, and disabled in CSleep.

Configuration #3

- The APB clock of DDRC is enabled when the MPU is in CRun, and disabled in CSleep.
- The APB clock of DDRPHYC is enabled when the MPU is in CRun or CSleep.
- The DDRC kernel clock (**ddrc_ker_ckg**) is enabled when the MPU is in CRun, and disabled in CSleep.
- The DDRPHYC kernel clock (**dphy_ker_ck**) is enabled when the MPU is in CRun or CSleep.

Configuration #4

- The APB clocks of DDRC and DDRPHYC are enabled when the MPU is in CRun or CSleep.
- The DDRC and DDRPHYC kernel clocks (**ddrc_ker_ckg** and **dphy_ker_ck**) are enabled when the MPU is in CRun or CSleep.

In the configurations #5 and #6, the gating of the DDRC and DDRPHYC clocks is automatic and dependent to the activity of the DDRC.

Configuration #5

- The APB clock of both DDRC and DDRPHYC are enabled when the MPU is in CRun or CSleep.
- The DDRC kernel clock (**ddrc_ker_ckg**) is gated according to **cactive_ddrc** independently of the MPU mode.
- The DDRPHYC kernel clock (**dphy_ker_ck**) is enabled independently of the MPU mode. This configuration can be interesting when the DLLs of the DDRPHYC need to remain locked.

Configuration #6

- The APB clock of both DDRC and DDRPHYC are enabled when the MPU is in CRun or CSleep.
- The DDRC and DDRPHYC kernel clocks (**ddrc_ker_ckg** and **dphy_ker_ck**) are gated according to **cactive_ddrc** independently of the MPU mode.
- This configuration saves power when the DLLs of the DDRPHYC are not used (bypassed).

In the configurations #7 to #8, the gating of the DDRC and DDRPHYC clocks is controlled by the DDRC-LP. The DDRC-LP can also request to the DDR interface to go to low-power (i.e. self-refresh).

Configuration #7

- The APB clock of DDRC is enabled when the MPU is in CRun, and disabled in CSleep.
- The APB clock of DDRPHYC are enabled when the MPU is in CRun or CSleep.
- The DDRC kernel clock (**ddrc_ker_ckg**) is gated using to the DDRC-Low-power handshake, according to the MPU mode, and DDRC requests.
- The DDRPHYC kernel clock (**dphy_ker_ck**) is enabled independently of the MPU mode. This configuration can be interesting when the DLLs of the DDRPHYC need to remain locked.

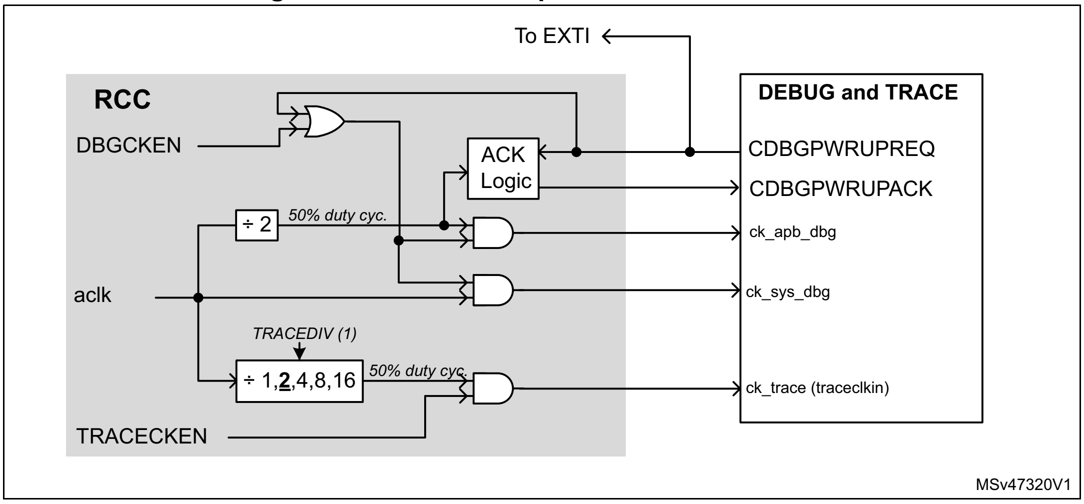
Configuration #8

- The APB clock of DDRC is enabled when the MPU is in CRun, and disabled in CSleep.
- The APB clock of DDRPHYC are enabled when the MPU is in CRun or CSleep.
- The DDRC and the DDRPHYC kernel clocks (**ddrc_ker_ckg** and **dphy_ker_ck**) are gated using to the DDRC-Low-power handshake, according to the MPU mode, and DDRC requests.

Clock distribution for DBG and trace

The clock generation for the trace and debug is controlled by the RCC via the *RCC debug configuration register (RCC_DBGCFGR)*.

Figure 94. Clock description for DBG and trace



1. X Represents the reset value after a system reset.

Clock distribution for IO compensation

The IO compensation cell is used to calibrate the I/Os slew rate. For that purpose, the RCC is providing the **csi_ck** clock to the IO compensation cell block.

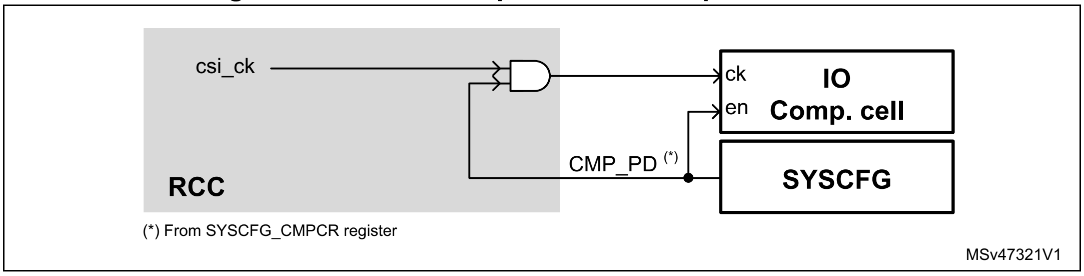
When the compensation mechanism needs to be activated, the clock must be provided to the IO compensation cell block. Meaning that the application has to set the CSION bit to ‘1’.

The **csi_ck** clock is not provided to the IO compensation cell if the CMP_PD bit is set to ‘0’. Refer to *Section 14: System configuration controller (SYSCFG)* block description for further information.

Note that the **csi_ck** clock is automatically gated when the system goes to (LP-)Stop, and if the CSIKERON bit is set to ‘0’. Setting the CSIKERON bit to ‘1’ allows to maintain the **csi_ck** clock enabled even in system (LP-)Stop.

In system Standby the **csi_ck** clock is disabled.

Figure 95. Clock description for IO compensation cell



10.4.9 General clock concept overview

The RCC handles the distribution of the CPUs, bus interface and peripheral clocks for the system, according to the operating mode of each processor. Refer to *Section 9.5.1: PWR operating modes* for details on operating modes.

Refer to *Section 10.4.1: Clock naming convention*, for details on clock definitions.

For most of the peripherals, it is possible for the application to control the activation/deactivation of their kernel and bus interface clocks. Prior to use a peripheral, the MPU or MCU has to enable it (by setting its PERxEN to '1'), and defines if this peripheral remains active in CSleep mode (by setting its PERxLPEN to '1'). This operation is called 'allocate' a peripheral to a processor. Refer to *Section 10.4.10: Peripheral allocation* for more details.

The peripheral allocation is used by the RCC to control automatically the clock gating according to the CPUs modes.

For example if the MPU enables a peripheral and decides that the kernel clock of this peripheral shall be gated when it goes to CSleep, then the state of the MCU has no effect on the clock gating of this peripheral, but the clock gating will obey to the state of the MPU. This is true if the MCU did not allocate this peripheral as well. Allocating a peripheral guarantees to a processor that this peripheral will remain accessible independently of the mode of the other processor.

Each CPU have dedicated registers in order to allocate individually the peripherals they intends to use in the application. Registers dedicated to the MPU are named RCC_MP_xxxx, the registers dedicated to the MCU are named RCC_MC_xxxx.

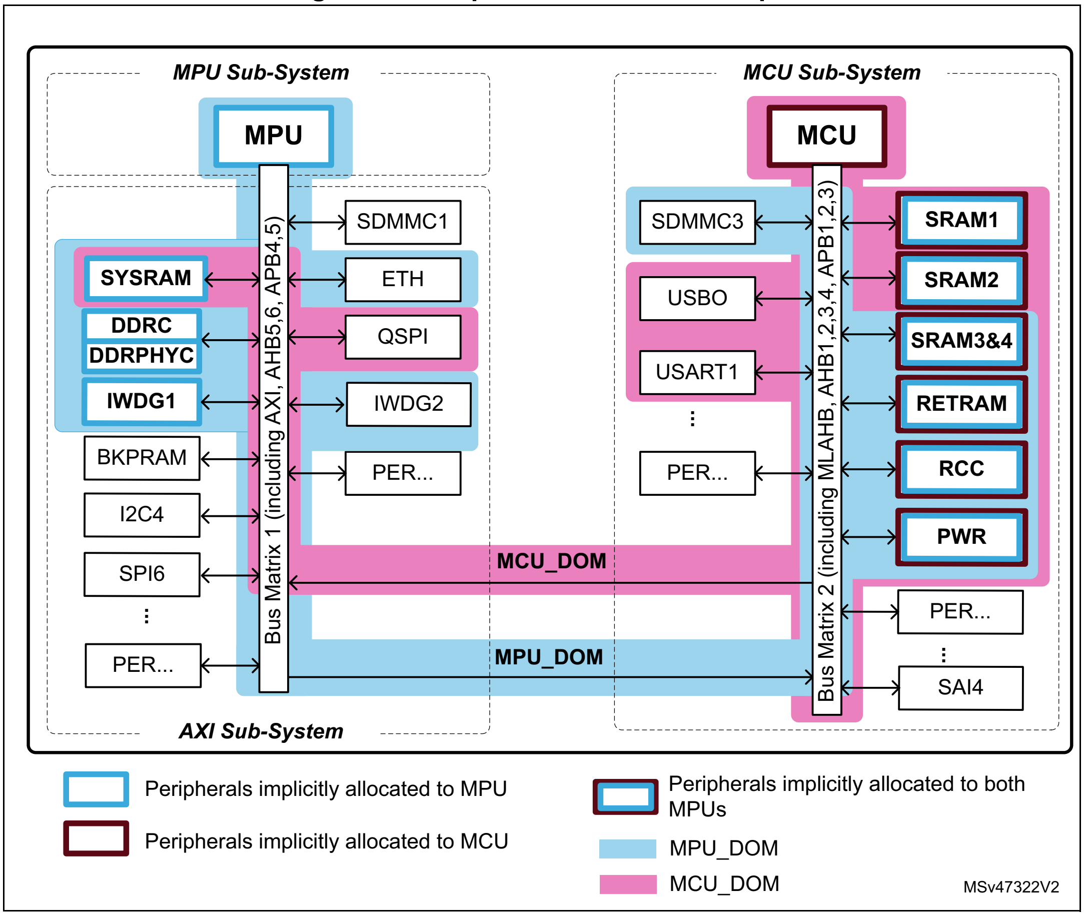
Figure 96 gives an example of peripheral allocation:

- The MPU enabled the ETH, SDMMC3, SRAM3 and RETRAM. Note that SYSRAM, DDRC, DDRPHYC and IWDG1 are implicitly allocated to MPU. The group composed by the MPU, bus matrix 1, bus matrix 2, and peripherals allocated via RCC_MP_xxxx registers are forming the MPU peripheral domain (MPU_DOM).
- The MCU enabled SYSRAM, QUADSPI, USBO and USART1. The group composed by the MCU, bus matrix 1, bus matrix 2 and peripherals allocated via RCC_MC_xxxx registers are forming the MCU peripheral domain (MCU_DOM).

Note: PWR and RCC are common resources and implicitly allocated to both MPU and MCU.

Note: As shown in Figure 96, some memories are implicitly allocated to a processor, refer to Section : Handling of memory devices for more details.

Figure 96. Peripheral allocation example



Note: MPU_DOM and MCU_DOM can be spread over the 2 domains.

When the MPU goes to CStop, then the RCC will disable automatically the bus interface and kernel clocks of all the peripherals of the MPU_DOM as well as the MPU clock. If MCU is still in CRun, then the bus matrix 1 is still clocked as MCU_DOM contains peripherals (SYSRAM, QUADSPI) physically connected to this bus matrix. The PLLs if enabled, are not disabled by the RCC as the MCU is still in running.

Then, if the MCU goes to CStop, the bus matrix 1 is no longer clocked. Note that in this scenario, the complete system can go to Stop. If both CPUs allowed the Standby mode, then the system will go to Standby.

Wakeup events will be able to exit the system from Standby or Stop.

Handling of memory devices

Both CPUs are able to access all the memory devices available in the product:

- SYSRAM,
- SRAM1, SRAM2, SRAM3, SRAM4, RETRAM,
- BKPSRAM.

As shown in *Figure 96*, SYSRAM is implicitly allocated to the MPU. So there is no enable bit for the MPU to allocate this memory. But when the MCU wants to access the SYSRAM, the memory must be enabled via *RCC AXI peripheral enable for MCU set register*

(RCC_MC_AXIMENSETR). Enabling the SYSRAM ensures that this memory will still be operating even if MPU goes to CStop.

However, the SRAM1, SRAM2, SRAM3 and SRAM4 are implicitly allocated to both MCU and MPU because the MLAHB bridge will be enabled if one of the processor is in CRun.

The RETRAM has enable bits for both MPU and MCU. By default this memory is allocated (i.e. enabled) to both processors in order to allow accesses when the system exits from Standby.

The BKPSRAM has a dedicated enable bit for each CPU in order to gate the bus interface clock. The CPUs need to enable the BKPSRAM prior to use it.

Refer to *Section 10.4.11: Peripheral clock gating control* and *Section 10.4.12: Processors and interconnect clocks gating* for details on clock enabling.

10.4.10 Peripheral allocation

Each CPU can allocate a peripheral and hence control its kernel and bus interface clock. Each CPU has dedicated registers in order to perform this peripheral allocation. A peripheral is allocated when its PERxEN bit is set to ‘1’, by the MPU and/or MCU.

The MPU can allocate or deallocate a peripheral for itself by setting the dedicated PERxEN bit on registers RCC_MP_xxxxENSETR and RCC_MP_xxxxENCLRR. The MPU can perform the same operations for the MCU via RCC_MC_xxxxENSETR and RCC_MC_xxxxENCLRR registers.

The MCU can also allocate or deallocate a peripheral for itself by setting the dedicated PERxEN bit on RCC_MC_xxxxENSETR and RCC_MC_xxxxENCLRR registers.

However, the MCU cannot allocate or deallocate a peripheral for the MPU: it can read the RCC_MP_xxxxENSETR and RCC_MP_xxxxENCLRR registers, but the RCC prevents the MCU to write them.

A similar mechanism is implemented for the control of the peripheral clocks when the CPUs are in CSleep (PERxLPEN bits).

The peripheral allocation bits (PERxEN bits) are used by the hardware in order to provide the kernel and bus interface clocks to the peripherals, but they are also used to link peripherals to a CPU (CPU sub-system). In this way, the hardware will be able to safely gate the peripheral clocks and bus matrix clocks, according to CPU states. The PWR block will also use this information in order to control properly the domain states.

Clock enabling delays

In order to avoid spurs, the clock gating logic will synchronize the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock.

- A maximum delay of 2 periods of the enabled clock may occur between the enable command, and the first rising edge of the clock. The enable command can be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.
- A maximum delay of 1.5 periods of the disabled clock may occur between the disable command, and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

Note: Both the kernel clock and the bus interface clock are affected by this re-synchronization delay.

In addition, the clock enabling delay may increase if the application is enabling for the first time, a peripheral which is not located into its sub-system. This is due to the fact that the sub-system where the peripheral is located may not have its sub-system clock ready. The sub-system clock must be switched on before the application can use this peripheral.

For example if the MCU is enabling a peripheral located into the AXI sub-system, while the MPU is in CStop, then the RCC has to provide a clock to the AXI sub-system.

In order to allocate properly a peripheral, the following sequence must be respected:

- Enable the peripheral clocks (i.e. allocate the peripheral) by writing its PERxEN bit to ‘1’ in the RCC_MP_xxxxENSETR or RCC_MC_xxxxENSETR register,
- Read back the RCC_MP_xxxxENSETR or RCC_MC_xxxxENSETR register. This operation can be considered as a dummy read,
- Then the peripheral can be used.

Note: When the bus interface clock is not active, the read or write accesses to the peripheral registers are not supported. A read access will result in reading invalid data. A write access is ignored and does not create any bus errors.

10.4.11 Peripheral clock gating control

As mentioned previously, each peripheral requires a bus interface clock, named **ckg_bus_perx** (for peripheral ‘x’). This clock is an APB, AHB or AXI clock, according to which bus the peripheral is connected.
The clock used as bus interface for peripherals located into MPU domain could be **aclk**, **hclk5, hclk6, pclk4** or **pclk5**, depending on the bus connected to each peripheral. For simplicity, those clocks are named **mpu_bus_ck**. In the same way, the signal named **mcu_bus_ck** represents **hclk[4:1]**, **pclk1**, **pclk2** or **pclk3**, depending on the bus connected to each peripheral of MCU domain.

Some peripherals (SAI, UART...) need also a dedicated clock for their communication interface, this clock is generally asynchronous with respect to the bus interface clock, and is named kernel clock (**kckg_perx**).

Both clocks can be gated according to several conditions detailed hereafter.

As shown in *Figure 97*, the enabling of the kernel and bus interface clocks of each peripheral depends on several input signals:

- MP_PERxEN, MP_PERxLPEN bits
- MC_PERxEN, and MC_PERxLPEN bits
- **mpu_mode** (see *Table 64: MPU mode details*)
- **mcu_mode** (**mcu_sleep** and **mcu_deepsleep** signals)
- The kernel clock request (**req_ker_perx**) of the peripheral itself, when the feature is available.

MP_PERxEN represents the peripheral enable (allocation) bit for the MPU. The MPU can write these bits to ‘1’ via RCC_MP_xxxxENSETR registers.

MC_PERxEN represents the peripheral enable (allocation) bit for MCU. The MCU can write these bits to ‘1’ via RCC_MC_xxxxENSETR registers.

The MPU State is a logic combination of processors states (WFI or WFE) and STPREQ_P[1:0] bits, see *Table 69* for details.

Refer to *Section 10.4.10: Peripheral allocation* for more details.

Figure 97. Peripheral kernel clock enable logic details

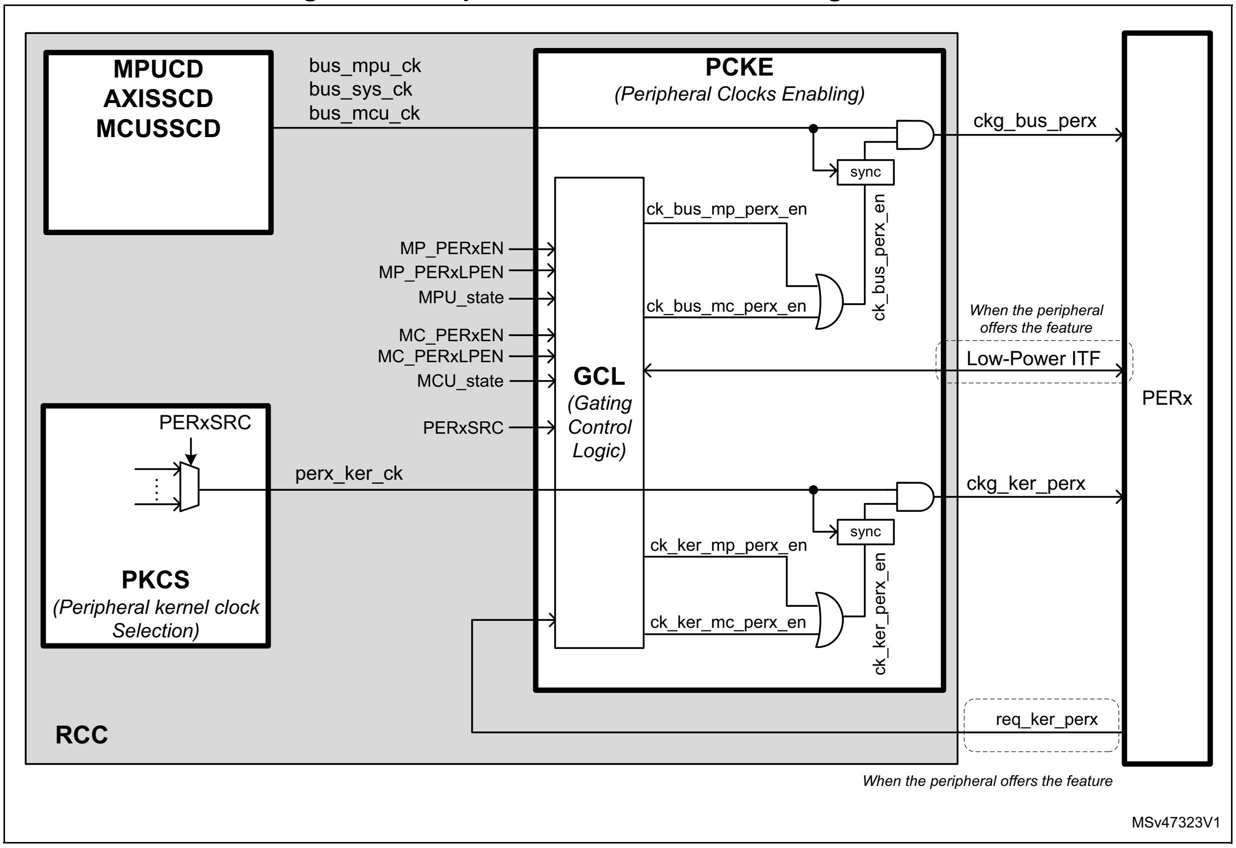


Table 63 gives the details of the enabling logic of most of the peripheral clocks for peripherals allocated by MPU (or MCU).

Table 63. Peripheral clock enable details for MPU (MCU)

MP_PERxEN (MC_PERxEN)	MP_PERxLPEN (MC_PERxLPEN)	PERxSRC	req_ker_perx	MPU State (MCU State)	-	mp_perx_en_ker_ck (mc_perx_en_ker_ck)	(mp_perx_en_bus_ck (mc_perx_en_bus_ck)	Comments
0	X	X	X	X	→	0	0	No clock provided to the peripheral, because PERxEN=0
1	X	X	X	CRun	→	1	1	Kernel and bus interface clocks are provided to the peripheral, because the MPU (MCU) is in CRun, and PERxEN='1'

Table 63. Peripheral clock enable details for MPU (MCU) (continued)

MP_PERxEN (MC_PERxEN)	MP_PERxLPEN (MC_PERxLPEN)	PERxSRC	req_ker_perx	MPU State (MCU State)	-	mp_perx_en_ker_ck (mc_perx_en_ker_ck)	(mp_perx_en_bus_ck (mc_perx_en_bus_ck)	Comments
1	0	X	X	CSleep	→	0	0	No clock provided to the peripheral, because the MPU (MCU) is in CSleep, and PERxLPEN=0
1	1	X	X		→	1	1	Kernel and bus interface clocks are provided to the peripheral, because MPU (MCU) is in CSleep, and PERxLPEN='1'
1	0	X	X	CStop	→	0	0	No clock provided to the peripheral because the PERxLPEN bit is set to '0'.
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no csi_ker_ck and no hse_ker_ck	X		→	0	0	No clock provided to the peripheral because MPU (MCU) is in CStop and **lse_ck** or **lsi_ck** or **hsi_ker_ck** or **csi_ker_ck** or **hse_ker_ck** are not selected.
1	1	lsi_ck or lse_ck	X		→	1 [(1)]	0	Kernel clock is provided to the peripheral because PERxEN = PERxLPEN='1' and **lsi_ck** or **lse_ck** are selected. The bus interface clock is no provided as the MPU (MCU) is in CStop. It is up to the application to enable the LSE or LSI if requested.
1	1	hsi_ker_ck or csi_ker_ck or hse_ker_ck	1		→	1	0	Kernel clock is provided to the peripheral because **req_ker_perx** = '1', and PERxEN = PERxLPEN='1' and **hsi_ker_ck** or **csi_ker_ck** or **hse_ker_ck** are selected. The bus interface clock is not provided as the MPU (MCU) is in CStop. If the oscillators are OFF, the RCC will enable them when a kernel clock request occurs.
1	1	hsi_ker_ck or csi_ker_ck or hse_ker_ck	0		→	0	0	No clock provided to the peripheral because MPU (MCU) is in CStop, and no kernel clock request pending

1. Note that for RNG block, the kernel clock is not delivered if the CPU to which it is allocated is in CStop, even if the clock selected is lsi_ck or lse_ck.

Note: The kernel clock request generated by the peripheral, will enable the corresponding oscillator only if the PERxSRC is selecting an oscillator: HSI, CSI or HSE.

As a summary, we can state that the kernel clock is provided to the peripherals in the following conditions:

1. When the CPU to which the peripheral is allocated is in CRun.
2. When the CPU to which the peripheral is allocated is in CSleep and PERxLPEN = ‘1’.
3. When the CPU to which the peripheral is allocated is in CStop, with PERxLPEN = ‘1’, and the peripheral is generating a kernel clock request, and the selected clock is **hsi_ker_ck** or **csi_ker_ck** or **hse_ker_ck**.
4. When the CPU to which the peripheral is allocated is in CStop, with PERxLPEN = ‘1’, and the kernel source clock of the peripheral is **lse_ck** or **lsi_ck**.

The bus interface clock will be provided to the peripherals only when the conditions 1 or 2 are met.

Note: Only some peripherals are able to request the kernel clock: I2C, U(S)ART. This feature gives to the peripheral the capability to wait for an event with an optimal power consumption.

10.4.12 Processors and interconnect clocks gating

CA7-SS (MPU) clock gating

The CA7-SS (MPU) embeds two processors. All the processors and SCU are clocked with the **mpuss_ck** clock provided by the RCC.

When one of the processor goes to Wait For Interrupt (WFI), it is set in low-power state by disabling its clocks, except for the functions used to wake up the processor from WFI.

When one of the processor goes to Wait For Event (WFE), it is set in low-power state by disabling its clocks, except for the functions used to wake up the processor from WFE.

When both processors are in WFI state, the shared L2 memory system logic can also enter in WFI, and the signal **mpu_standbywfi_l2** is asserted.

More precisely, when both processors are in WFI state, then the L2 memory system completes the pending transactions, enters in WFI state, and the signal **mpu_standbywfi_l2** is asserted. If the CStop mode has been requested via STPREQ_Px bits, the RCC disables the **mpuss_ck** clock, and the AXI interface clock (**aclk_mpu**).

Table 64 details the MPU modes according to the processor state (WFI) and RCC register values.

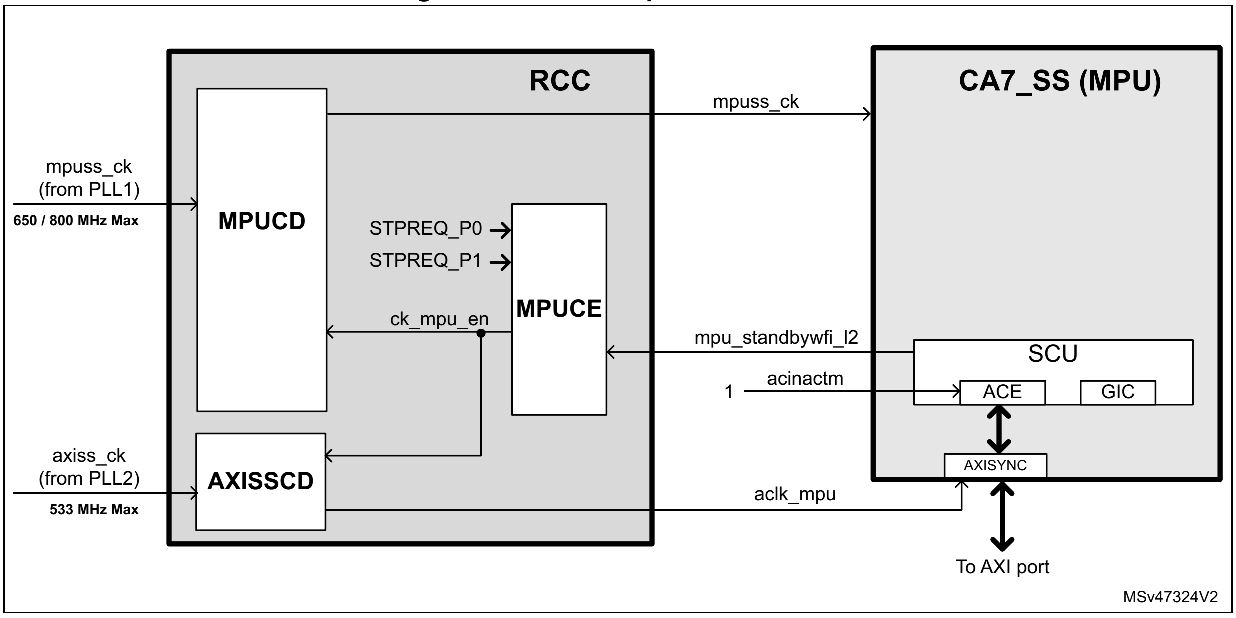
Table 64. MPU mode details (1)

STPREQ_P0 AND STPREQ_P1 (2)	proc_0 in WFI	proc_1 in WFI	-	MPU mode
-	N	-	→	CRun
	-	N	→	
0	Y	Y	→	CSleep
1	Y	Y	→	CStop

1. “-” means don’t care.
2. STPREQ_P0 AND STPREQ_P1 is a logic “AND” between both bits.
The STPREQ_P0 and STPREQ_P1 bits are located into *RCC stop request set register (RCC_MP_SREQSETR)* and *RCC stop request clear register (RCC_MP_SREQCLRR)*.

The clock **mpuss_ck** and **aclk_mpu** are gated by the RCC when the MPU state is CStop.

Figure 98. MPU low-power interface



Bus matrix and bridges clock gating

The bridges and bus matrix clocks are gated according to processors mode, and the peripheral allocated to those processors.

The tables hereafter show in which conditions the RCC is gating the clock bus matrix and bridges.

For information about convention naming, Refer to *Section 10.4.11: Peripheral clock gating control*.

Table 65. Bus clock enable details for AXIM

MPU mode (1)	MCU mode (1)	mpu_peren_axi (2)	mpu_perlpen_axi (2)	mcu_peren_axi (2)	mcu_perlpen_axi (2)	-	AXIM Clock	Description
CRun	Any	X	X	X	X	→	Clocked	The AXIM clock is generated when one of the following condition is true: – The MPU is in CRun – The MPU is in CSleep with at least a peripheral of the AXI-SS allocated by the MPU with the sleep enable bit activated (i.e. MP_ PERxEN = ‘1’ and MP_PERxLPEN = ‘1’) – The MCU is in CRun with at least a peripheral of the AXI-SS allocated (i.e. at least one MC_PERxEN = ‘1’) – The MCU is in CSleep with at least a peripheral of the AXI-SS allocated, with the sleep enable bit activated (i.e. MC_ PERxEN = ‘1’ and MC_PERxLPEN = ‘1’)
CSleep	Any	1	1	X	X	→		
Any	CRun	X	X	1	X	→		
Any	CSleep	X	X	1	1	→		
CSleep	Any	X	0	0	X	→	Gated	In all other cases, the AXIM clock is gated.
	CSleep	X	0	X	0	→		
	CStop	X	0	X	X	→		
CStop / CStandby	Any	X	X	0	X	→		
	CSleep	X	X	X	0	→		
	CStop	X	X	X	X	→		

1. “Any” means any mode. It can be CRun, CSleep, CStop, or CStandby (for MPU only).

2. **mpu_peren_axi** is set to ‘1’ when at least a peripheral connected to the AXI-SS is allocated to the MPU.
mpu_perlpen_axi is set to ‘1’ when at least a peripheral connected to the AXI-SS is allocated to the MPU, with its PERxLPEN bit set to ‘1’.
mcu_peren_axi is set to ‘1’ when at least a peripheral connected to the AXI-SS is allocated to the MCU.
mcu_perlpen_axi is set to ‘1’ when at least a peripheral connected to the AXI-SS is allocated to the MCU, with its PERxLPEN bit set to ‘1’.
The AXI-SS represents the AXIM, AHB5, AHB6, APB4, APB5.

Note: When mpu_peren_axi = ‘0’, mpu_perlpen_axi is also equal to ‘0’.

When mpu_peren_axi = mpu_perlpen_axi = ‘1’ it means that at least for one peripheral connected to the AXI-SS, MP_PERxEN = MP_PERxLPEN = ‘1’.

The same applies for MCU.

Table 66. Bus clock enable details for AHB5 and AHB6

MPU mode (1)	MCU mode (1)	mpu_peren_ahb5 (mpu_peren_ahb6) (2)	mpu_perlpen_ahb5 (mpu_perlpen_ahb6) (2)	mcu_peren_ahb5 (mcu_peren_ahb6) (2)	mcu_perlpen_ahb5 (mcu_perlpen_ahb6) (2)	-	AHB5 (AHB6) Clock	Description
CRun	Any	1	X	X	X	→	Clocked	The AHB5 (AHB6) clock is generated when one of the following condition is true: – The MPU is in CRun with at least a peripheral on AHB5 (AHB6) allocated (i.e. at least one MC_PERxEN = ‘1’) – The MPU is in CSleep with at least a peripheral on AHB5 (AHB6) allocated, with the sleep enable bit activated (i.e. MP_ PERxEN = ‘1’ and MP_PERxLPEN = ‘1’) – The MCU is in CRun with at least a peripheral on AHB5 (AHB6) allocated (i.e. at least one MC_PERxEN = ‘1’) – The MCU is in CSleep with at least a peripheral on AHB5 (AHB6) allocated, with the sleep enable bit activated (i.e. MC_ PERxEN = ‘1’ and MC_PERxLPEN = ‘1’)
CSleep	Any	1	1	X	X	→		
Any	CRun	X	X	1	X	→		
Any	CSleep	X	X	1	1	→		
Any	Any	0	X	0	X	→	Gated	In all other cases, the AHB5 (AHB6) clock is gated.
	CSleep	0	X	X	0	→		
	CStop	0	X	X	X	→		
CSleep	Any	X	0	0	X	→		
	CSleep	X	0	X	0	→		
	CStop	X	0	X	X	→		
CStop / CStandby	Any	X	X	0	X	→		
	CSleep	X	X	X	0	→		
	CStop	X	X	X	X	→		

1. “Any” means any mode. It can be CRun, CSleep, CStop, or CStandby (for MPU only).
2. **mpu_peren_ahb5** is set to ‘1’ when at least a peripheral connected to the AHB5 is allocated to the MPU.
mpu_perlpen_ahb5 is set to ‘1’ when at least a peripheral connected to the AHB5 is allocated to the MPU, with its PERxLPEN bit set to ‘1’.
mcu_peren_ahb5 is set to ‘1’ when at least a peripheral connected to the AHB5 is allocated to the MCU.
mcu_perlpen_ahb5 is set to ‘1’ when at least a peripheral connected to the AHB5 is allocated to the MCU, with its PERxLPEN bit set to ‘1’.

mpu_peren_ahb6 is set to ‘1’ when at least a peripheral connected to the AHB6 or APB4 is allocated to the MPU.
mpu_perlpen_ahb6 is set to ‘1’ when at least a peripheral connected to the AHB6 or APB4 is allocated to the MPU, with its PERxLPEN bit set to ‘1’.
mcu_peren_ahb6 is set to ‘1’ when at least a peripheral connected to the AHB6 or APB4 is allocated to the MCU.
mcu_perlpen_ahb6 is set to ‘1’ when at least a peripheral connected to the AHB6 or APB4 is allocated to the MCU, with its PERxLPEN bit set to ‘1’.

Note: The AXIMC peripheral clock and reset are controlled via RCC_MP_AHB5_xxx registers but this peripheral is not connected to the AHB5.

Due to bus topology, peripherals on the APB4 are accessible via AHB6.

Table 67. Bus clock enable details for MLAHB and AHB4

MPU mode (1)	MCU mode (1)	-	MLAHB (AHB4) Clock	Description
CRun	Any	→	Clocked	The MLAHB and AHB4 clocks are generated when one of the following condition is true: – The MPU is in CRun or CSleep – The MCU is in CRun or CSleep ==> When the system is in Run
CSleep	Any	→

CStop / CStandby	Any	X	X	0	X	→		
	CSleep	X	X	X	0	→		
	CStop	X	X	X	X	→		

1. “Any” means any mode. It can be CRun, CSleep, CStop, or CStandby (for MPU only).
2. **mpu_peren_apb1** is set to ‘1’ when at least a peripheral connected to the APB1 is allocated to the MPU.
mpu_perlpen_apb1 is set to ‘1’ when at least a peripheral connected to the APB1 is allocated to the MPU, with its PERxLPEN bit set to ‘1’.
mcu_peren_apb1 is set to ‘1’ when at least a peripheral connected to the APB1 is allocated to the MCU.
mcu_perlpen_apb1 is set to ‘1’ when at least a peripheral connected to the APB1 is allocated to the MCU, with its PERxLPEN bit set to ‘1’.

Similar properties apply for mpu_peren_apb[5:2], mpu_perlpen_apb[5:2], mcu_peren_apb[5:2] and mcu_perlpen_apb[5:2].

Remarks

The MLAHB and AHB4 are clocked as soon as one of the CPU is no longer in CStop. This is due to the fact that RCC and PWR blocks are implicitly allocated to both MPU and MCU.

The AXIM can remain clock gated when the MPU is in CStop, and the MCU has no peripheral allocated into a place needing the activated of the AXIM.

10.4.13 Low-power emulation mode

In order to ease the debugging of the circuit, the RCC is able to handle an emulation mode for the (LP-)Stop and Standby modes. Refer to *Section : Low power mode emulation in debug* of DBG section to get additional information.

Note: In debug emulation mode, the clock of the WWDG1 is frozen.

Sleep emulation mode

The Sleep emulation mode is controlled by the DBGSLEEP bit of the DBGMCU_CR register.

When a processor goes to CSleep with DBGSLEEP = ‘1’, then the processor clock, the clocks of all allocated peripherals, debug parts, and interconnect are maintained activated.

Stop emulation mode

The Stop emulation mode is controlled by the DBGSTOP bit of DBGMCU_CR register.

When a processor goes to CStop or when the system goes to Stop with DBGSTOP = ‘1’, then:

- The processor clock, clocks of all allocated peripherals, debug parts, and interconnect are maintained activated,
- the PWR will not signal low-power mode on the PWR_ON and PWR_LP signals. This will keep the V_{DDCORE} domain to be supplied from the regulator in main mode,
- When a wakeup event occurs, then the PWR and EXTI blocks behave normally.
- If it is an exit from system Stop, then the RCC will bypass (or execute very fast) the clock restore sequence as clocks are still there.

When the MPU goes to CStandby, with DBGSTOP = ‘1’, then:

- The MPU clock, clocks of all allocated peripherals, debug parts, and interconnect are maintained activated,
- The interrupt lines connected to the GIC are immediately gated in order to prevent the MPU to execute an exception before it is reset.
- The PWR will not signal the low-power mode on the PWR_ON and PWR_LP signals. This will keep the V_{DDCORE} domain supplied.
- When a wakeup event occurs, then the PWR and EXTI blocks behave normally, and the RCC generates a MPU reset.
- The interrupt lines connected to the GIC are no longer gated.

Standby emulation mode

The Standby emulation mode is controlled by the DBGSTBY bit of the DBGMCU_CR register.

When the system goes to Standby with DBGSTBY = ‘1’, then:

- The processors clocks, clocks of all allocated peripherals, debug parts, and interconnect are maintained activated,
- The interrupt lines connected to the GIC and NVIC are immediately gated in order to prevent the MPU and MCU to execute an exception before it is reset,
- The PWR will keep the PWR_ON active, allowing the V_{DDCORE} domain to remain supplied,
- When a wakeup event occurs, then the PWR and EXTI blocks behave normally, the RCC generates a reset of the complete V_{DDCORE} (**vcore_rst**), but will not reset the debug part (**dbg_rstn** not activated),
- The interrupt lines are no longer gated.

10.4.14 RCC TrustZone function

The RCC TrustZone function is controlled via two bits: TZEN and MCKPROT located into the *RCC TrustZone control register (RCC_TZCR)*.

The bit TZEN allows the RCC and the PWR to be switched in secure mode. The RCC_TZCR register is only accessible by a secure access.
When TZEN = ‘1’, some RCC and PWR registers can only be modified using secure accesses. The reading of registers is always allowed.

The MCKPROT bit allows in addition to control the secure mode for the registers controlling the generation of the **mcuss_ck** clock.

The RCC is able to protect the secure parts from being modified by non-secure accesses. At RCC level the TrustZone security consists on preventing a non-secure device from:

- Changing the settings of the HSE, HSI, CSI, LSE and LSI,
- Changing the settings of the clocks used for the MPU,
- Changing the settings of the clocks for the AXIM, AHB5 and APB5,
- Disabling the peripheral clocks of secure peripherals,
- Reseting the secure peripherals,
- Changing the kernel clock of secure peripherals.

Refer to *Table 74: Register access type versus protection and security* to get the list of impacted registers.

A non-secure write access into a register with the security is enabled will generate a hard fault. Read accesses are always allowed.

*Note: The value of TZEN bit is provided to the PWR block via the signal **rcc_tzen**.*

10.5 RCC interrupts

The RCC provides 2 independent interrupt interfaces:

- An interrupt interface dedicated to the MPU, and
- An interrupt interface dedicated to the MCU.

The interrupt interface dedicated to the MPU, can be switched into secure mode via the TZEN bit. The interrupt interface dedicated to the MCU is always in non-secure mode.

Each interrupt interface provides 2 interrupt lines:

- A general interrupt line (**rcc_mpu_it** or **rcc_mcu_it**), providing events when the PLLs are ready, or when the oscillators are ready.
- An interrupt line dedicated to the wakeup of the processors when they are in CStop (**rcc_mpu_wkup_it** or **rcc_mcu_wkup_it**).

All interrupt lines are active HIGH, and level triggered.

The enabling of the **rcc_mpu_it**, and **rcc_mpu_wkup_it** interrupts are controlled via *RCC clock source interrupt enable register (RCC_MP_CIER)*.

The enabling of the **rcc_mcu_it**, and **rcc_mcu_wkup_it** interrupts are controlled via *RCC clock source interrupt enable register (RCC_MC_CIER)*.

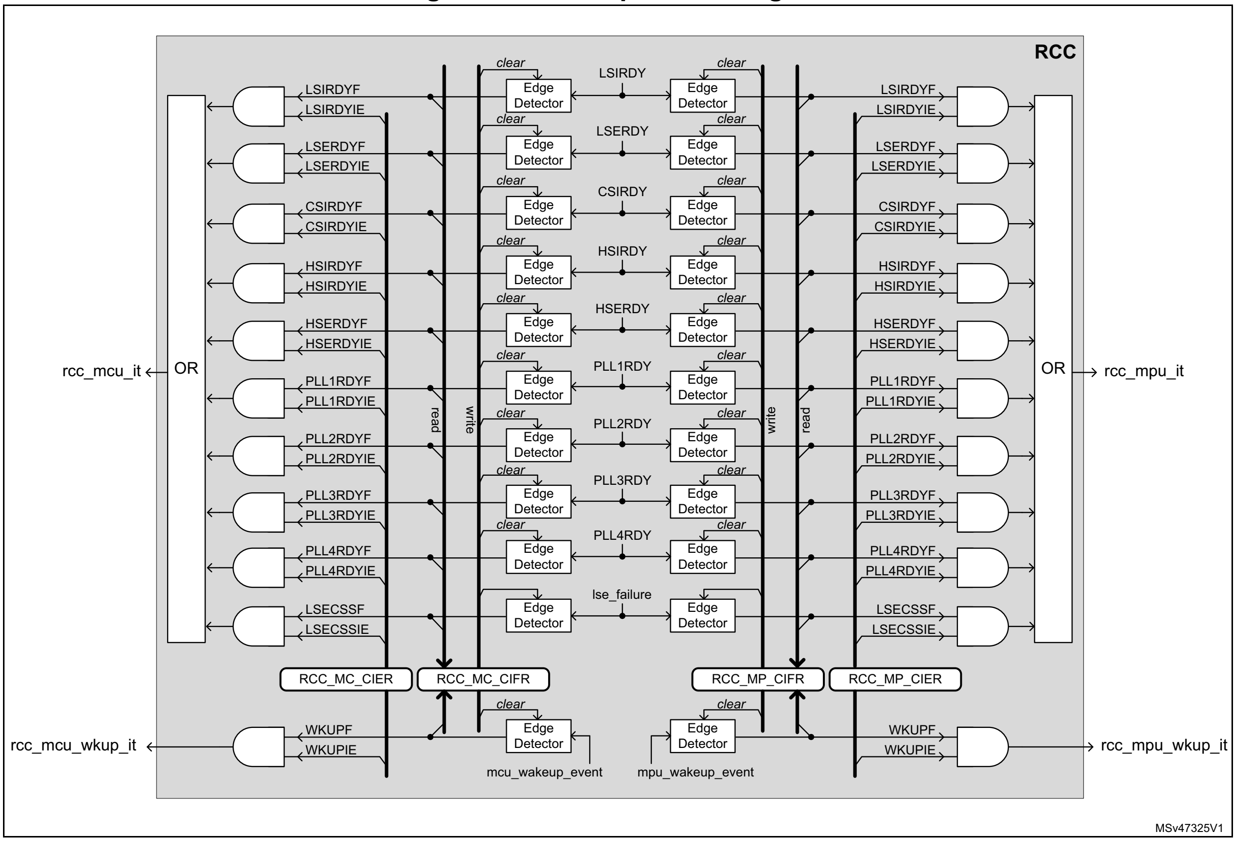
The **rcc_mpu_it** (or **rcc_mcu_it**) line is activated when an event flag is set to ‘1’, and its corresponding enable bit is set to ‘1’ as well. In order to release the **rcc_mpu_it** (or **rcc_mcu_it**) line, all the event flags which have been enabled must be cleared.

The **rcc_mpu_wkup_it** (or **rcc_mcu_wkup_it**) line is activated when the RCC has to exit the MPU (or MCU) from CStop, and if the WKUPIE bit is set to ‘1’ as well. In order to release the **rcc_mpu_wkup_it** (or **rcc_mcu_wkup_it**) line, the MPU (or MCU) shall write the WKUPF bit of the corresponding register to ‘1’.

The interrupt flags can be checked and cleared via *RCC clock source interrupt flag register (RCC_MP_CIFR)* or *RCC clock source interrupt flag register (RCC_MC_CIFR)*.

The event flags goes to ‘1’, on rising edge of the corresponding ready bit (xxxRDY).

Figure 99. Interrupt block diagram



Note: The interrupt flags are relevant even if the corresponding interrupt enable bit is not set.

Table 70 gives a summary of the interrupt sources, and the way to control them.

Table 70. Interrupt sources and control

Interrupt event flag	Description	Interrupt enable	Action to clear interrupt	Interrupt Lines
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYF to ‘1’	rcc_mcu_it, rcc_mpu_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYF to ‘1’	
HSIDRYF	HSI ready	HSIDRYIE	Set HSIRDYF to ‘1’	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYF to ‘1’	
CSIRDYF	CSI ready	CSIRDYIE	Set CSIRDYF to ‘1’	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYF to ‘1’	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYF to ‘1’	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYF to ‘1’	
PLL4RDYF	PLL4 ready	PLL4RDYIE	Set PLL4RDYF to ‘1’	
LSECSSF	LSE Clock security system failure	LSECSSIE (1)	Set LSECSSF to ‘1’	
WKUPF	Wake up from CStop event	WKUPIE	Set WKUPF to ‘1’	rcc_mpu_wkup_it, rcc_mcu_wkup_it

1. The security system feature must also be enabled (LSECSSON = ‘1’), in order to generate interrupts.

10.6 RCC application information

10.6.1 Handling dynamic clock switching

Care shall be taken when changing on the fly the clock source and clock frequency of processor and bridges:

- The application shall ensure that all the required resources remain clocked during the clock switching in order to ensure that the processor performing the transition remains properly clocked. For example if a processor is doing a clock change which needs to be performed in several steps, the processor, its memory, the bridges and the RCC must remain clocked to allow the software to perform properly the clock transition. If one of these elements is no longer clocked, the transition will not be completed and the system is blocked.
- The application shall also ensure that the frequency of the clocks provided to processors, bridges and peripherals never exceed the maximum allowed value.

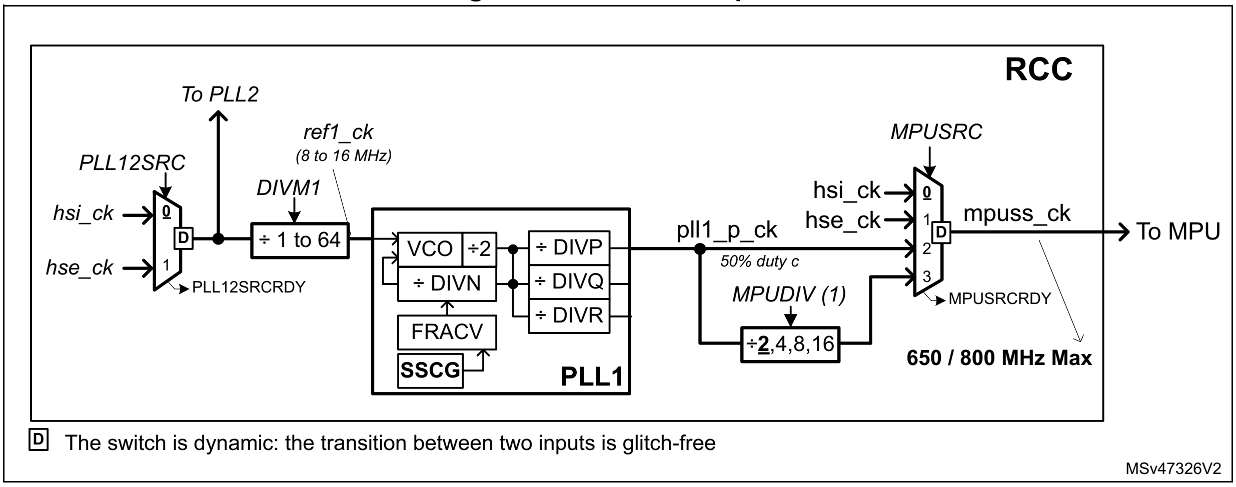
In addition, changing the clock on the interconnect can also affect the performances of some peripheral, more especially if the peripheral is using an APB, AHB or AXI clock as kernel clock.

Changing the MPU clock frequency

The MPU clock frequency can be changed in different ways:

- By changing the MPUSRC value,
- By changing the MPUDIV value,
- By changing the PLL1 settings.

Figure 100. MPU clock path



1. MPUDIV can be changed on-the-fly.
   X Represents the selected MUX input after a system reset.

Changing the MPU clock frequency via MPUSRC

If the MPU clock is changed using MPUSRC, the application has to:

- Ensure that the next clock source is ready before switching the MPUSRC to this input,
- Ensure that the switching of MPUSRC is completed before disabling the previous clock source.

So the procedure is the following:

- Enable the new wanted clock,
- Wait for this clock to be ready,
- Switch the MPUSRC to this new clock,
- Wait until the bit MPUSRCRDY = '1'
- The previous clock source can be disabled.

Changing the MPU clock frequency via MPUDIV

If the MPU clock frequency is changed using MPUDIV, the application has to take care about two things:

- Do not set MPUDIV to ‘000’ if the MPUSRC = ‘3’, otherwise the processor will no longer be clocked,
- Do not exceed the maximum allowed frequency for the **mpuss_ck**.

Changing the MPU clock frequency via PLL1

If the MPU clock frequency is changed via the PLL1, the application has to provide to the MPU a backup clock as long as the transition to the new clock frequency is not complete.

If the MPU is already using the PLL1, the following procedure must be followed:

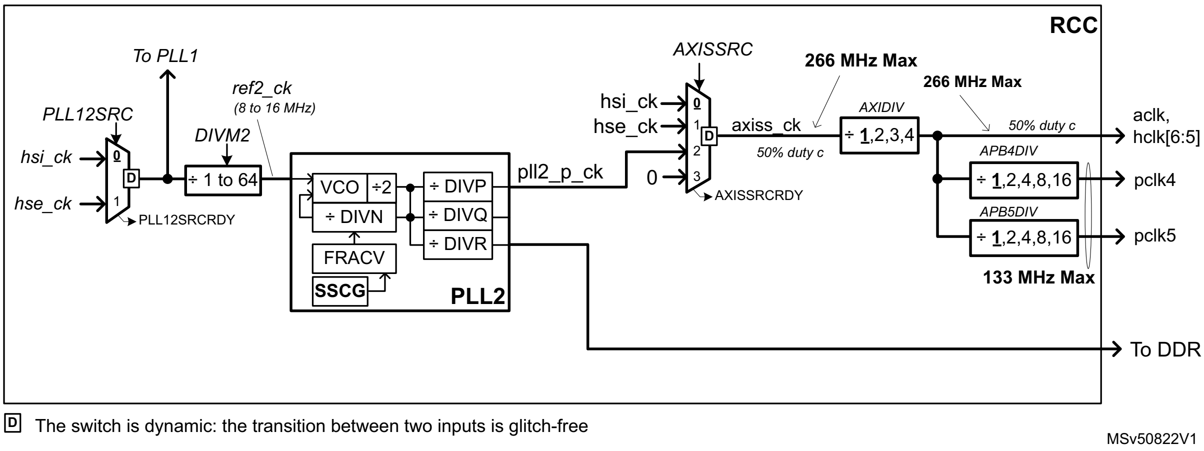
1. Enable a backup clock if not enabled: for example HSI or HSE,
2. Wait for this back-up clock to be ready,
3. Switch the MPUSRC to select this backup clock,
4. Wait for the switching transition to be complete,
5. Change the PLL settings: could be a reprogramming of VCO, which can take few tenth of microseconds due to the PLL lock (see *Section : PLL initialization procedure*), or the reprogramming of the post dividers which is simpler and faster (see *Section : Reprogramming post-dividers*),
6. Wait for the PLL1 to be ready,
7. Switch the MPUSRC to pll1_p_ck,
8. Wait for MPUSRCRDY = '1',
9. Then the back-up clock can be disabled.

Changing the axiss_ck clock source and frequency:

The AXI clock frequency can be changed in different ways:

- By changing the AXISSRC value,
- By changing the AXIDIV value,
- By changing the PLL2 settings.

Figure 101. PLL2 clock path



1. **X** Represents the selected MUX input after a system reset.

Changing axiss_ck frequency via the AXISSRC:

If the **axiss_ck** clock frequency is changed using AXISSRC, the application must do the following:

- Check that the current AXIDIV setting, with the new clock source will not exceed the maximum allowed frequency for the AXIM, AHB[6:5] and APB[5:4]. If it is the case, then:
  - Change the AXIDIV, APB4DIV and APB5DIV in order to ensure that the new clock frequency will not exceed the maximum frequency on AXIM, APB4 and APB5 busses,
  - Wait for AXIDIV, APB4DIV and APB5DIV ready, in order to avoid switching to the new clock source before the new division ratio is effective.
- Generate the new clock source, and wait that this clock source is ready,
- Switch the AXISSRC in order to select the new clock source,
- Wait for AXISSRCRDY = '1' before switching off the previous clock source.

Note: Before switching off the previous clock source be sure that this clock is not used by another sub-system.

Changing axiss_ck frequency via the AXIDIV:

The AXIDIV can be changed on the fly, by simply changing the AXIDIV value.

The application shall ensure that the frequency at the output of AXIDIV will never exceed the maximum allowed frequency for the AXIM, AHB[6:5] and APB[5:4].

The new division value may take some time before being effective, so the application shall always wait for the ready bits of the dividers (AXIDIVRDY, APB[5:4]DIVRDY) to ensure that the new division value is effective.

Changing axiss_ck frequency via the PLL2:

If the **axiss_ck** clock frequency is changed via the PLL2, the application has to generate the **axiss_ck** via a backup clock as long as the transition to the new clock frequency is not complete. If no backup clock is provided, the MPU can no longer run, as the AXI bridge will not be available.

It is possible to change only the DIVP output of the PLL2, by doing the following:

- Enable a back-up clock if not enabled: for example HSI or HSE,
- Wait for this back-up clock to be ready,
- Switch the AXISSRC to this back-up clock,
- Wait for the switching transition to be complete (AXISSRCRDY = ‘1’),
- Check that the current AXIDIV setting, with the new clock source will not exceed the maximum allowed frequency for the AXI. If it is the case, then
  – Change the AXIDIV in order to ensure that the new clock frequency will not exceed the max frequency on AXI bus,
  – Wait for AXIDIV ready, in order to avoid switching to the new clock source before the new division ratio is effective.
- Set the bit DIVPEN of PLL2 to '0',
- Change the value of DIVP,
- Set the bit DIVPEN of PLL2 to '1',
- Switch the AXISSRC to this new clock,
- Wait for AXISSRCRDY = '1',
- Then the back-up clock can be disabled.

Changing the VCO frequency of the PLL2 has more impact, because the PLL2 is also providing the clock to the DDR interface.

In order to change the PLL2 VCO frequency the application has to perform the following steps, assuming that the DDR is used to execute the application code:

- Stop or pause peripherals working with DDR,
- Load the code doing the clock transition into the SYSRAM,
- Give the control to the code located into the SYSRAM.

At this state the DDR shall no longer be used,

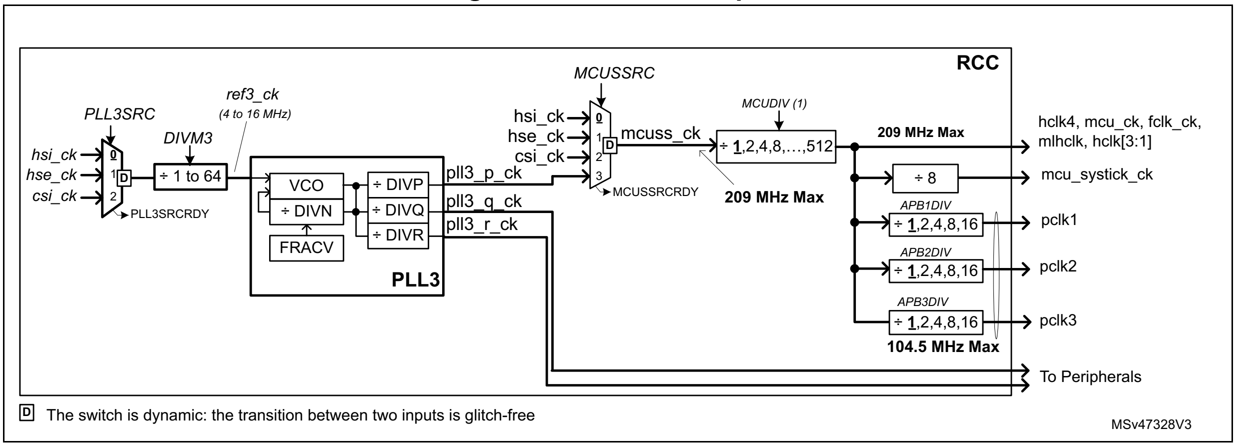
- Set the DDR in self-refresh,
- Enable a back-up clock if not enabled: for example HSI or HSE,
- Wait for this back-up clock to be ready,
- Switch the AXISSRC to this back-up temporary clock (AXISSRC = ‘0’ or ‘1’),
- Wait for the switching transition to be complete,
- Check that the current AXIDIV setting, with the new wanted clock frequency will not exceed the max allowed frequency for the AXI. If it is the case, then:
  – Change the AXIDIV in order to ensure that the new clock frequency will not exceed the max frequency on AXI bus,
  – Wait for AXIDIV ready, in order to avoid switching to the new clock source before the new division ratio is effective.
- Change the PLL settings: see *Section : PLL initialization procedure* for details. This step may take several microseconds due to the PLL lock time,
- Switch the AXISSRC to this new clock (AXISSRC = ‘2’),
- Wait for AXISSRCRDY = '1',
- Then the back-up clock can be disabled,
- The DDR controller shall be re-initialized, because the clock of the DDR interface may have changed due to the change of the frequency of the PLL2 VCO.
- Then the application can switch again on the DDR,
- The peripheral services using DDR can be re-enabled.

Changing the MCU clock source and frequency:

The MCU clock frequency (**mcuss_ck**) can be changed in different ways:

- By changing the MCUSSRC value,
- By changing the MCUDIV value,
- By changing the PLL3 settings.

Figure 102. MCU clock path



1. X Represents the selected MUX input after a system reset.

Changing MCU clock frequency via the MCUSSRC:

If the **mcuss_ck** clock is changed using MCUSSRC, the application must do the following:

- Check that the current MCUDIV setting, with the new clock source will not exceed the max allowed frequency for the MCU domain. If it is the case, then
  - Change MCUDIV, APB1DIV, APB2DIV and APB3DIV in order to ensure that the new clock frequency will not exceed the max frequency on MCU, AHB[4:1], MLAHB and APB[3:1] busses,
  - Wait for MCUDIV, APB1DIV, APB2DIV and APB3DIV ready, in order to avoid switching to the new clock source before the new division ratio is effective.
- Enable the new clock source, and wait that this clock source is ready,
- Switch the MCUSRC to the new clock source,
- Wait for MCUSSRCRDY = '1' before switching off the previous clock source.

Changing MCU clock frequency via the MCUDIV:

The MCUDIV can be changed on the fly, by simply changing the MCUDIV value.

The application shall ensure that the frequency at the output of MCUDIV will never exceed the maximum allowed frequency of the on MCU, AHB[4:1], MLAHB and APB[3:1].

The new division values may take some time before being effective, so the application shall always wait for the ready bits of the dividers (MCUDIVRDY, APB[3:1]DIVRDY) to check when the new division value is effective.

Changing MCU clock frequency via the PLL3:

If the MCU clock frequency is changed via the PLL3, the application has to provide to the MCU a backup clock as long as the transition to the new clock frequency is not complete.

If the MCU is already using the PLL3, the following procedure must be followed:

1. Enable a backup clock if not enabled: for example HSI, CSI or HSE,
2. Wait for this back-up clock to be ready,
3. Switch the MCUSSRC to select this backup clock,
4. Wait for the switching transition to be complete (MCUSSRCRDY = ‘1’)
5. Change the PLL settings: could be a reprogramming of VCO, which can take few tenth of microseconds due to the PLL lock (see *Section : PLL initialization procedure*), or the reprogramming of the post dividers which is simpler and faster (see *Section : Reprogramming post-dividers*).
6. Wait for the PLL3 to be ready,
7. Switch the MCUSSRC to select pll3_p_ck,
8. Wait for the switching transition to be complete (MCUSSRCRDY = ‘1’),
9. Then the back-up clock can be disabled.

10.6.2 PLL programming

PLL initialization procedure

The recommended initialization sequence of the PLLs for the integer and fractional mode is given hereafter:

- The PLL is supposed to be disabled: DIVPEN, DIVQEN, DIVREN, PLLON, and PLLxRDY set to '0', if it is not the case, refer to *PLL disabling procedure*.
- Enable the wanted clock source (HSE, HSI, or CSI) and wait for the ready flag.
- Select the clock source: via RCC_RCK12SELR, RCC_RCK3SELR and RCC_RCK4SELR registers.
- Wait for the clock switch to be ready.
- Initialize the pre-dividers (DIVMx) in order to provide to the PLL, a valid reference clock. DIVMx are located into the RCC_PLLxCFGR1 registers.
- Configure the PLL:
  - In integer or clock spreading mode the application shall ensure that a '0' is loaded into the SDM. This can be done as follow:

    \- Set FRACLE to '0'

    \- Write FRACV to '0'

    \- Set FRACLE to '1'
  - In fractional mode, the application shall load the SDM with the wanted value (FracInitValue) by executing a sequence similar to the integer mode, but with FRACV = FracInitValue.
  - Program the fields IFRGE (for PLL3 and 4), SSCG_CTRL(for PLL 1 and 2), DIVN, DIVP, DIVQ and DIVR.
  - If the clock spreading mode is used (for PLL1 and 2), program also the fields MOD_PER, INC_STEP and SSCG_MODE.
- Enable the PLL:
  - Set the corresponding PLLON bit to '1', and wait for PLLxRDY bit set to '1',
  - If the PLL is in fractional mode, the FRACLE bit must not be set back to '0' as long as PLLxRDY = '0'.
- When the PLLxRDY bit is equal to '1', the application can enable the wanted outputs by setting DIVPEN, DIVQEN, DIVREN to '1'.
- If the application intends to tune the PLL frequency on-the-fly (only possible in fractional mode), then:
  - Set FRACLE to '0',
    When FRACLE = '0', the sigma delta modulator is still operating with the current value,
  - Write the new value into FRACV (FracValue(n)),
  - Set FRACLE to '1', in order to latch the content of FRACV into the SDM.

Note: *When the PLLxRDY goes to '1', it means that the PLLx output frequency is within 2% of its target value.*

Reprogramming post-dividers

When the PLLs are enabled, it is possible to change the values of a post-dividers (DIVP, DIVQ or DIVR) without disabling the corresponding PLL, by performing the following sequence:

- Disable the wanted output by setting the bit DIVPEN, DIVQEN or DIVREN to '0',
- Change the value of the corresponding post-divider (DIVP, DIVQ or DIVR),
- Re-enable this output by setting the bit DIVPEN, DIVQEN or DIVREN to '1'.

Using the SSCG block

If an application needs to generate with the PLL2, a clock signal having the following characteristics

- An output frequency (**Fpll2_r_ck**), as close as possible to 533 MHz, but not more,
- With a modulation depth of 0.5% peak (M_D),
- With a frequency modulation of 25 kHz (F_{MOD}).

The assumption is that the crystal oscillator is 24 MHz (F_{hse_ck}).

DIVM2 is programmed to 2 in order to provide a reference clock of 12 MHz to the PLL2 (F_{ref2_ck}).

From a 12 MHz reference clock, it is possible to generate 528 MHz, using the division by two provided by the PLL2, in order to ensure an optimal duty cycle.

The application has to compute the following parameters:

Computing NDIV by combining the formulas given in *Section : Using the PLLs in integer mode*:

$$DIVN = \frac{F_{pll\_r\_ck}}{F_{ck\_ref}} - 1 = \frac{528}{12} - 1 = 43$$

Computing MOD_PER:

$$MOD\_PER = ROUND\left(\frac{F_{ref\_ck}}{4 \times F_{MOD}}\right) = ROUND\left(\frac{12 \times 10^6}{4 \times 25 \times 10^3}\right) = 120$$

Computing INC_STEP:

$$INC\_STEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MOD\_PER}\right) = ROUND\left(\frac{32767 \times 0.5 \times (43 + 1)}{100 \times 5 \times 120}\right) = 12$$

Check that MOD_PER x INC_STEP is lower than (2^{15}-1)

In the example, MOD_PER x INC_STEP = 1440 ==> OK

Due to rounding operations, the modulation period and the modulation depth will not completely match the target. In order to choose between center-spread or down-spread modulation we have to check if the frequency max will exceed our requirement of 533 MHz.

The real modulation depth is:

$$M_D\ (\%) = \frac{MOD\_PER \times INC\_STEP \times 100 \times 5}{(2^{15} - 1) \times (DIVN + 1)} = \frac{120 \times 12 \times 100 \times 5}{(2^{15} - 1) \times (43 + 1)} = 0.499\ \%$$

If the center-spread modulation is used, F_{MAX} will be:

$F_{MAX} = F_C$ x (1 + M_D / 100) = 528 x (1 + 0.499 / 100) = 530.6 MHz.

So the center-spread modulation can be used.

PLL disabling procedure

The recommended disabling sequence is given hereafter:

- Disable all the post-dividers: set DIVPEN, DIVQEN and DIVREN bits of PLLx to ‘0’,
- Disable the PLL: set PLLON bit of PLLx to ‘0’,
- Wait for PLLxRDY = ‘0’.

MPU frequency plan examples

The PLL1 is dedicated to the generation of the MPU clock. The application shall provide to the MPU a clock having the following characteristics:

- A duty cycle of 50%,
- A jitter as small as possible, more especially when the MPU frequency is closed to its maximum.

The table hereafter show possible frequency plans for MPU with most usual crystals.

Table 71. Clock settings examples for MPU

HSE (MHz)	PLL1						MPUSRC	mpuss_ck (MHz)	Comments
	DIVM1+1	DIVN+1	DIVP+1	F_{COMP} (MHz)	F_{VCO} (MHz)	F_{fout1_ck} (MHz)			
16	2	100	1	8	1600	800	pll1_p_ck	800	List of all possible frequencies by changing MPUDIV, with MPUSRC = ‘11’: 800, 400, 200, 100, 50 MHz
	2	81		8	1296	648		648	List of all possible frequencies by changing MPUDIV, with MPUSRC = ‘11’: 648, 324, 162, 81, 40.5 MHz
	1	40		16	1280	640		640	List of all possible frequencies by changing MPUDIV, with MPUSRC = ‘11’: 640, 320, 160, 80, 40 MHz
	2	75		8	1200	600		600	List of all possible frequencies by changing MPUDIV, with MPUSRC = ‘11’: 600, 300, 150, 75, 37.5 MHz

Table 71. Clock settings examples for MPU (continued)

HSE (MHz)	PLL1						MPUSRC	mpuss_ck (MHz)	Comments
	DIVM1+1	DIVN+1	DIVP+1	F_{COMP} (MHz)	F_{VCO} (MHz)	F_{fout1_ck} (MHz)			
19.2	2	83	1	9.6	1593.6	796.8	pll1_p_ck	796.8	All other frequencies obtained by changing MPUDIV are allowed as well.
	2	67		9.6	1286.4	643.2		643.2	
		63		9.6	1190.4	595.2		595.2	
24	3	100	1	8	1600	800	pll1_p_ck	800	All other frequencies obtained by changing MPUDIV are allowed as well.
	2	54		12	1296	648		648	
	2	50		12	1200	600		600	
26	2	61	1	13	1586	793	pll1_p_ck	793	All other frequencies obtained by changing MPUDIV are allowed as well.
	2	50		13	1300	650		650	
	2	46		13	1196	598		598	

In order to have a duty cycle as close as possible to 50%, and an optimal jitter the following rules shall be respected:

To improve the jitter:

- F_{COMP} must be as close as possible to the highest accepted input frequency range of the PLL. For PLL1 and PLL2 it is 16 MHz.
- DIVN value must be as small as possible.
- It is better to use the PLL in integer mode.

To avoid duty cycle degradation

- Prefer using DIVP,Q,R in bypass (DIVP,Q,R = ‘0’) more especially for MPU and DDRC.
- Do not use DIVP,Q,R dividers with odd values more especially the value 3.

Note: Care shall be taken when the HSI is used to provide the reference clock. The application has to take into account the accuracy of the HSI to ensure that it will not exceed the maximum allowed frequency.

AXI and DDR frequency plan examples

Table 72. Clock setting examples for AXI, DDR

HSE (MHz)	PLL2								AXIDIV+1	AXI clock (MHz)	DDR clock (MHz)
	DIVM2+1	DIVN+1	DIVP+1	DIVQ+1	DIVR+1	F_{COMP} (MHz)	F_{VCO} (MHz)	F_{fout2_ck} (MHz)			
16	1	33	2	1	1	16	1056	528	1	264	528
	1	25	2	1	1	16	800	400	1	200	400
19.2	2	55	2	1	1	9.6	1056	528	1	264	528

Table 72. Clock setting examples for AXI, DDR (continued)

HSE (MHz)	**PLL2**								**AXIDIV+1**	AXI clock (MHz)	DDR clock (MHz)
	DIVM2+1	**DIVN+1**	**DIVP+1**	**DIVQ+1**	**DIVR+1**	**F_{COMP} (MHz)**	**F_{VCO} (MHz)**	**F_{fout2_ck} (MHz)**			
24	2	44	2	1	1	12	1056	528	1	264	528
	3	50	2	1	1	8	800	400	1	200	400
	2	53	4	2	2	12	1280	640	1	160	320
	2	44	2	1	2	12	1056	528	1	264	264
	2	28	2	1	2	12	672	336	1	168	168
26	2	41	2	1	1	13	1066	533	1	266	533

10.6.3 Configuring the sub-system clocks

This examples shows the register programming sequence in order to configure properly the sub-system clocks (i.e. **mpuss_ck**, **axiss_ck** and **mcuss_ck**).

In this example, it is assumed that:

- The crystal connected to HSE is 24 MHz,
- Both MPU, and MCU are using HSE as clock source,
- The MPU is working at 600 MHz (PLL1), the MCU at 200 MHz (PLL3), and the AXI is 264 MHz (PLL2),
- It is supposed that **mpuss_ck**, **axiss_ck** and **mcuss_ck** are working with HSI (as it is the case after a system reset).

Here is a recommended programming sequence:

- Enabling of the HSE:
  – Check that HSEON and HSERDY are set to ‘0’ (this is the case after a power-on reset),
  – Set HSEON to ‘1’, and wait for HSERDY = ‘1’. When HSERDY = ‘1’, the clock **hse_ck** is ready to use.
- **refx_ck** clock settings:
  – Set PLL12SRC to ‘1’ in order to select the **hse_ck** for the MPU and AXI and wait for PLL12SRCRDY flag equal to ‘1’,
  – Set DIVM1 and DIVM2 to ‘1’ in order to set the frequency of **ref1_ck** and **ref2_ck** clocks at 12 MHz,
  – Set PLL3SRC to ‘1’ in order to select the **hse_ck** for the MCU sub-system, and wait for PLL3SRCRDY flag equal to ‘1’,
  – Set DIVM3 to 2, in order to provide **ref3_ck** clocks at 8 MHz.
- PLL1 settings and enabling:
  – Ensure that the PLL1 is disabled and all PLL outputs as well, if it is not the case, the sequence described in *Section : PLL disabling procedure*, must be executed,
  – Set DIVN to 49d, in order to have a VCO frequency of 1200 MHz, and thus to have **Ffout1_ck** = 600 MHz,
  – Set DIVP to ‘0’,
  – Set the PLL1 into integer mode:
  – - Set FRACLE to ‘0’
  – - Set FRACV to ‘0’,
  – - Then set FRACLE to ‘1’
  – Disable the clock spreading: SSCG_CTRL = ‘0’
  – Set PLLON to ‘1’
  – Wait for PLL1RDY flag set to ‘1’
  – Set DIVPEN to ‘1’.
- PLL2 settings and enabling:
  – Ensure that the PLL2 is disabled and all PLL outputs as well, if it is not the case, the sequence described in *Section : PLL disabling procedure*, must be executed,
  – Set DIVN to 43d, in order to have a VCO frequency of 1056 MHz, and thus to have **Ffout2_ck** = 528 MHz,
  – Set DIVP to ‘1’ (division by 2),
  – Set the PLL2 into integer mode:
  – - Set FRACLE to ‘0’,
  – - Set FRACV to ‘0’,
  – - Then set FRACLE to ‘1’
  – Set INC_STEP = xx, MOD_PER = yy and SSCG_MODE = ‘1’ (down-spread modulation),
  – Set SSCG_CTRL to ‘1’,
  – Set PLLON to ‘1’,
  – Wait for PLL2RDY flag set to ‘1’,
  – Set DIVPEN to ‘1’.

- PLL3 settings and enabling:
  - Ensure that the PLL3 is disabled and all PLL outputs as well, if it is not the case, the sequence described in *Section : PLL disabling procedure*, must be executed,
  - Set DIVN to 49d, in order to have a VCO frequency of 400 MHz,
  - Set DIVP to ‘1’ in order to have a division by 2,
  - Set IFRGE to ‘x1’,
  - Set the PLL3 into integer mode:
  - - Set FRACLE to ‘0’,
  - - Set FRACV to ‘0’,
  - - Then set FRACLE to ‘1’
  - Set PLLON to ‘1’,
  - Wait for PLL3RDY flag set to ‘1’,
  - Set DIVPEN to ‘1’.
- Interconnect clock settings:

  Before increasing the frequency of the **mcuss_ck**, **axiss_ck** and **mpuss_ck**, the application must ensure that the bus matrix clock dividers are properly programmed in order to avoid invalid frequencies.
  - Set MCUDIV to ‘0’ in order to provide a clock of 200 MHz to the MCU,
  - Set AXIDIV to ‘0’ in order to get the AXI frequency of 264 MHz,
  - Set APB4DIV to a value different from 0 to ensure that **Fpclk4** will be lower or equal to 133 MHz,
  - Set APB5DIV to a value bigger than 1 to ensure that **Fpclk5** will be lower or equal to 133 MHz,
  - Set APB1DIV, APB2DIV and APB3DIV to a value different from 0 to ensure that Fpclk[3:1] will be lower or equal to 100 MHz.
- Sub-system clock switching:
  - Set MPUSRC to 2, in order to select the direct DIVP output from PLL1,
  - Set AXISSRC to 2, in order to select the DIVP output from PLL2,
  - Set MCUSSRC to 3, in order to select the DIVP output from PLL3,
  - Wait for MCUSSRCRDY = ‘1’, MPUSRCRDY = ‘1’, and AXISSRCRDY = ‘1’, before disabling the HSI clock, if not used in the system.

10.6.4 The clock calibration using TIMx

It is possible to measure the frequencies of most of clock source generators by means of the input capture of TIMx.

Calibrating the HSI or CSI with the HSE

The RCC provides two dedicated signals hsi_cal_ck and csi_cal_ck in order to perform the calibration of the HSI and CSI oscillators.

The hsi_cal_ck represents the HSI oscillator output, divided by 1024. The csi_cal_ck represents the CSI oscillator output divided by 128.

The signals hsi_cal_ck and csi_cal_ck are connected to TIM12 and TIM15 input capture. For this calibration, it is expected to have the HSE used as the interconnect clock source via

PLL3. The number of interconnect clock periods between consecutive edges of the hsi_cal_ck (or csi_cal_ck) signal provides a measurement of the HSI (or CSI) clock period.

The calibration accuracy depends on the frequency ratio between the TIM15/12 clock, and the hsi_cal_ck (or csi_cal_ck) clock. The greater the ratio is, the more accurate the measurement is.

The frequency of the hsi_cal_ck is typically 62.5 kHz, and 31.25 kHz for csi_cal_ck.

For a timer clock of 50 MHz, the calibration accuracy will be about 0.13% for HSI and 0.065% for CSI.

The HSI and CSI oscillators have dedicated, user-accessible calibration bits for this purpose, see *RCC HSI configuration register (RCC_HSICFGR)* and *RCC CSI configuration register (RCC_CSICFGR)*. When the HSI or CSI are used via the PLLx, it is also possible to fine-tune the interconnect clock using the fractional divider of the PLLs.

Calibrating the HSI or CSI with the LSE

The primary purpose of having the LSE connected to a TIMx input capture is to be able to precisely measure the HSI or CSI. This requires to have the HSI or CSI used as the interconnect clock source either directly or via PLL3. The number of interconnect clock counts between consecutive edges of the LSE signal provides a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) the user can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio): the precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

The HSI and CSI oscillators have dedicated, user-accessible calibration bits for this purpose, see *RCC HSI configuration register (RCC_HSICFGR)* and *RCC CSI configuration register (RCC_CSICFGR)*. When the HSI or CSI are used via the PLLx, it is also possible to fine-tune the interconnect clock using the fractional divider of the PLLs.

Calibrating the LSI with the HSI

It is also possible to measure the LSI frequency: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation: by measuring it versus the HSI clock source, it is possible to determine its frequency with the precision of the HSI. The measured value can be used to have more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy.

10.6.5 Clock restore sequence examples

The following section shows some simplified timing examples of the execution of the clock restore sequence.

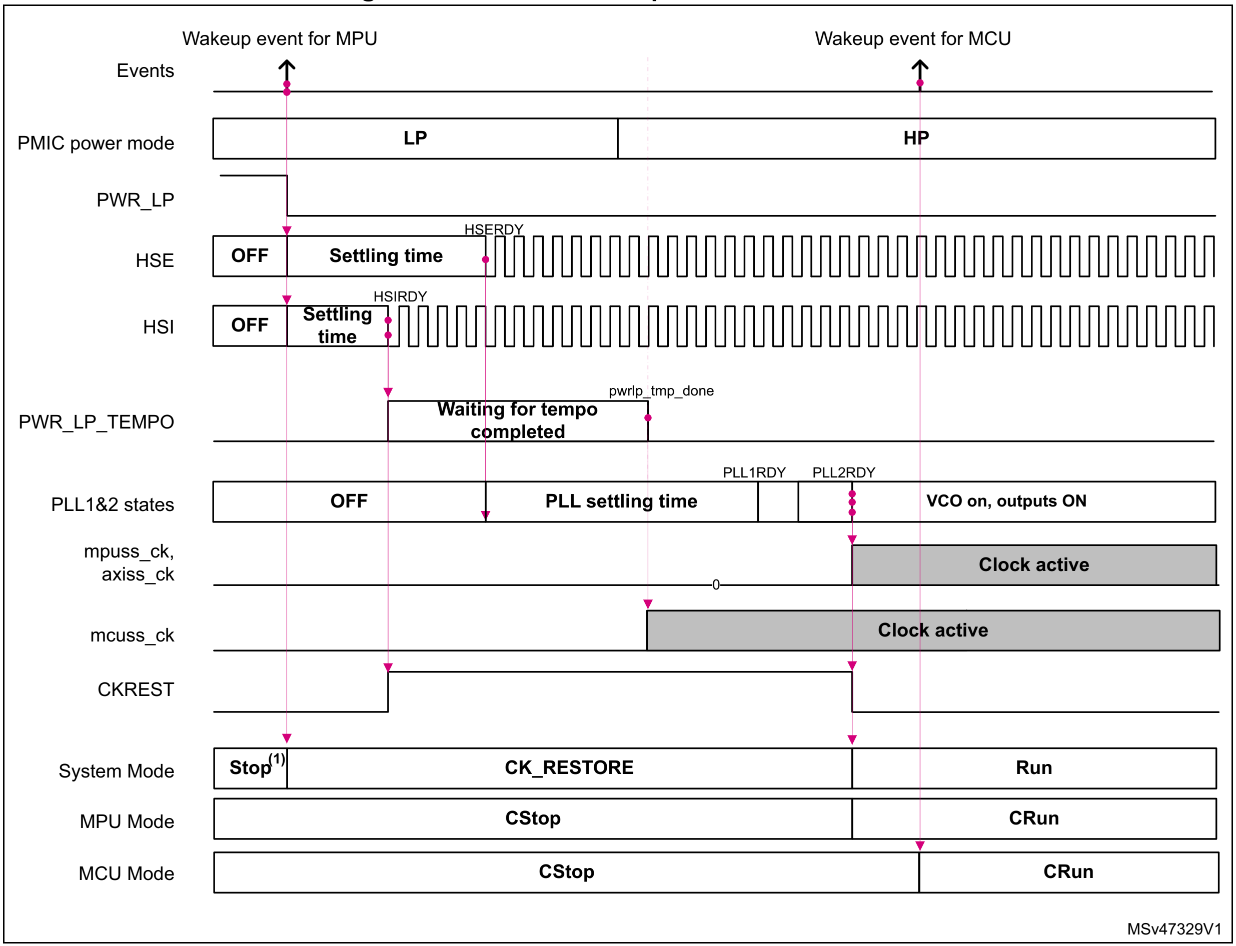
Exit from Stop due to a MPU event

In this example, the system exits from one of the Stop modes due to an event for the MPU, later on, an event for the MCU occurs.

Figure 103 is based on the following configuration:

- The **mpuss_ck** is provided by PLL1 via HSE,
- The **axiss_ck** is provided by PLL2 via HSE,
- The **mcuss_ck** is provided by HSI,
- The bit MCTMPSKP = ‘0’: need to wait for PMIC transition from LP to HP.

Figure 103. Exit from Stop due to MPU event



1. Can be Stop, LP-Stop or LPLV-Stop.

Refer to *Leaving Stop, LP-Stop or LPLV-Stop mode* for additional informations.

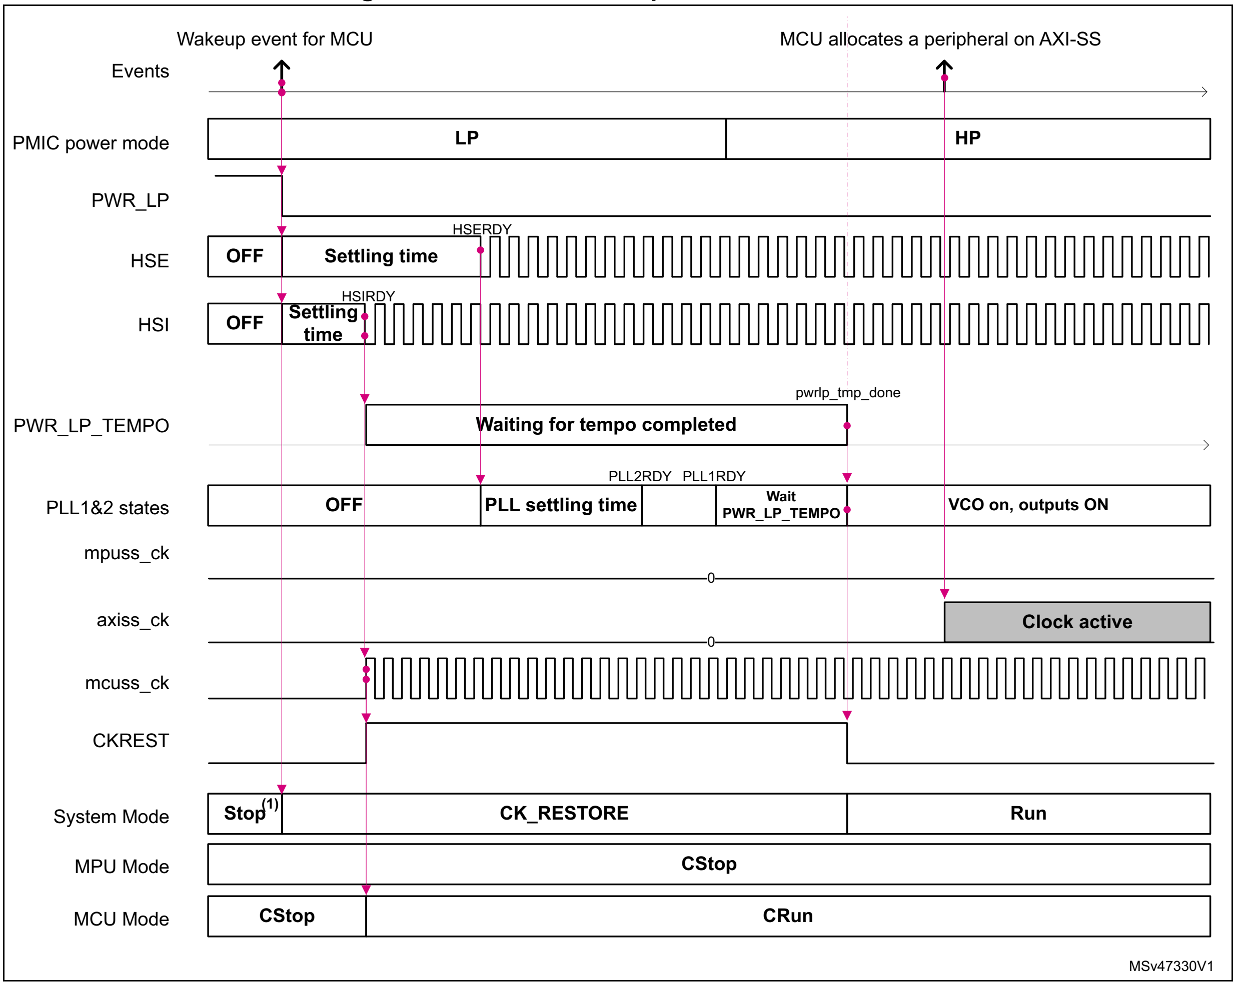
Exit from Stop due to a MCU event, example 1

In this example, the system exits from one of the Stop modes due to an event for the MCU, later the MCU allocates a peripheral on the AXI-SS.

Figure 104 is based on the following configuration:

- The **mpuss_ck** is provided by PLL1 via HSE,
- The **axiss_ck** is provided by PLL2 via HSE,
- The **mcuss_ck** is provided by HSI,
- The MCU does not have peripherals allocated into the AXI-SS,
- The bit MCTMPSKP = ‘1’: no need to wait for PMIC transition from LP to HP.

Figure 104. Exit from Stop due to MCU event



1. Can be Stop, LP-Stop or LPLV-Stop.

Refer to *Leaving Stop, LP-Stop or LPLV-Stop mode* for additional informations.

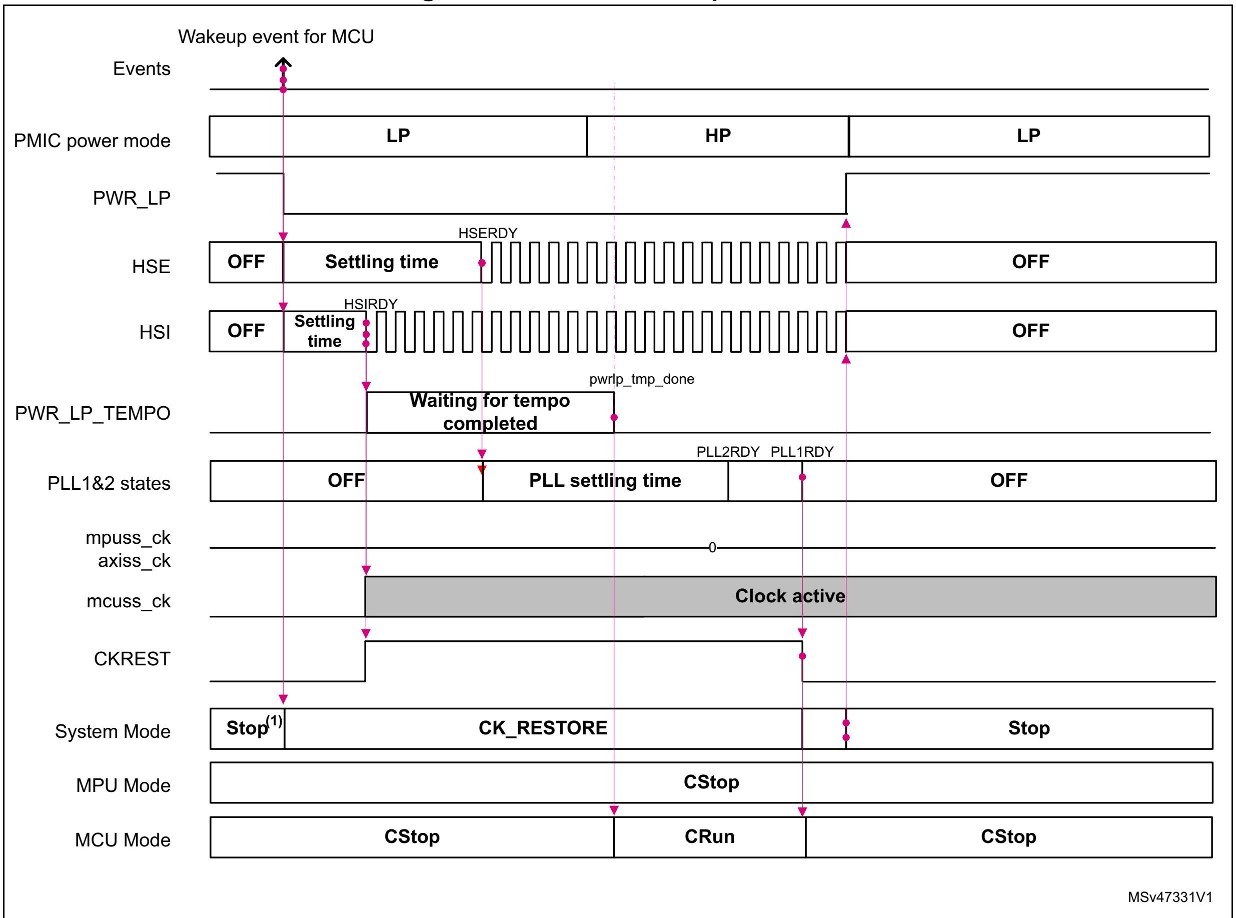
Exit from Stop due to a MCU event, example 2

In this example, the system exits from one of the Stop modes due to an event for the MCU, the MCU executes a task and goes back to CStop. Note that the MCU goes to CStop only when the bit CKREST is set to '0'.

Figure 105 is based on the following configuration:

- The **mpuss_ck** is provided by PLL1 via HSE,
- The **axiss_ck** is provided by PLL2 via HSE,
- The **mcuss_ck** is provided by HSI,
- The MCU does not have peripherals allocated into the AXI-SS,
- The bit MCTMPSKP = '0': need to wait for PMIC transition from LP to HP.

Figure 105. Exit from Stop for MCU



1. Can be Stop, LP-Stop or LPLV-Stop.

Refer to *Leaving Stop, LP-Stop or LPLV-Stop mode* for additional informations.

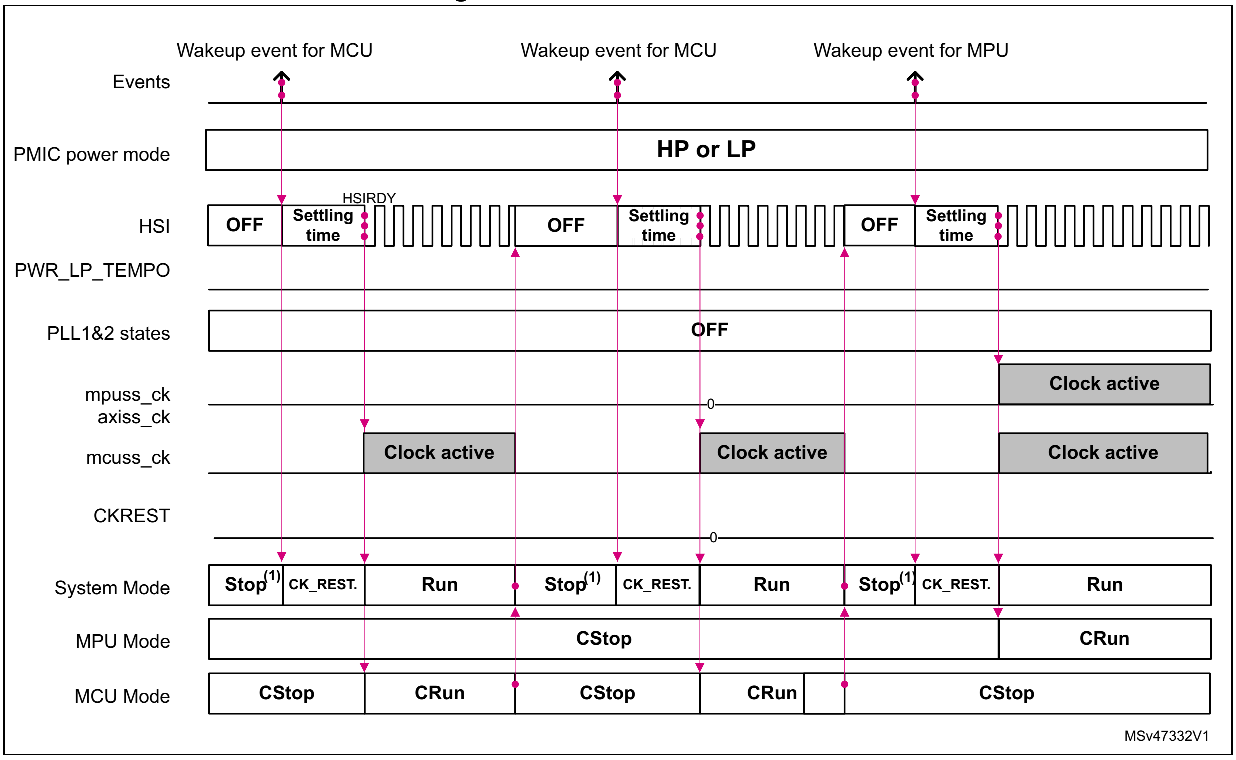
Fast clock restore

In this example, the system exits from one of the Stop modes due to an event for the MCU or MPU. In order to speed-up the occurrence of the CStop-CRun-CStop sequence, the system switch back to HSI as clock source for both MCU, MPU and AXI. In that way, the clock restore sequence is reduced to the activation of the HSI clock.

Figure 106 is based on the following configuration:

- The **mpuss_ck** is provided by HSI before going to CStop
- The **axiss_ck** is provided by HSI before going to CStop
- The **mcuss_ck** is provided by HSI
- The MCU does not have peripherals allocated into the AXI-SS.
- The field PWRLP_DLY is set to ‘0’ in order to bypass the low-power switch tempo.

Figure 106. Fast clock restore



1. Can be Stop, LP-Stop or LPLV-Stop.

Refer to *Leaving Stop, LP-Stop or LPLV-Stop mode* for additional informations.

10.7 RCC registers

The table hereafter gives a summary of the access property of each register. Some registers can be accessed by every bus master, some other can only be accessed by the MPU.

Some registers can only be accessed in secure mode, when the RCC is switched in secure mode.

Table 73 shows the register accesses ("Access Results") according to the possible register attributes. The table shall be read as follow: for a register which can be switched in secure mode ("S"), read operation are always valid, write operations in secure mode are also always valid, write operation in non-secure mode are invalid if TZEN = '1' (or when TZEN = MCKPROT = '1' for registers sensitive to those two bits).

Table 73. Access results according to register security attributes

Secure attribute (1)	TZEN or (TZEN and MCKPROT) (2)	Register access		Access results	Notifications
		Secure	Direction		
AS	x	x	R	Register is read	-
	x	Secure	W	Register is written	-
	x	Non-secure	W	Register is not written	Hard fault
S	x	x	R	Register is read	-
	x	Secure	W	Register is written	-
	0	Non-secure	W	Register is written	-
	1	Non-secure	W	Register is not written	Hard fault
NS	x	x	x	Register is read or written	-

1. "AS" means Alway Secure.
"S" means securable (depends on TZEN and MCKPROT).
"NS" means Non-Secure.

2. For registers controlling the generation of the **mcuss_ck** clock, the security is controlled by an AND between TZEN and MCKPROT.

In addition, some registers can only be modified by the MPU ("MPU Only" in *Table 74*). When the MCU writes into a register having the attribute "MPU Only", the write operation is ignored and a hard fault is triggered. Read accesses to registers having the attribute "MPU Only" are always allowed.

Table 74 gives the attributes for all RCC registers.

1. **RW** means Read or Write.
   SR means Set or Read. On the register description it is noted “RWS1”.
   CR means Clear or Read.On the register description it is noted “RWC1”.
   R means Read.
   W means Write.
2. **N** means that there is no control on the master accessing this register.
   MPU Only means that only the MPU is allowed to write this resource. The read operations are always allowed.
3. **AS** means “Always Secure”: this register can only be accessed in secure mode.
   S means “Secure”: this register can only be written in secure mode when TZEN = ‘1’ or when TZEN AND MCKPROT = ‘1’. If TZEN = ‘0’, then the register can also be written in non-secure mode. Read access is always allowed.
   NS means “Non-secure”: this register always accept non-secure access, independently of TZEN bit. Secure and non-secure accesses are accepted.

10.7.1 Register mapping

All the RCC registers can be accessed in word, half-word and byte format, unless explicitly specified differently.

All the RCC registers are reset by the **nreset** signal, unless explicitly specified differently.

The RCC register map is divided into two sections:

- An address section (lower address part) containing registers which can be switched to secure mode,
- An address section (higher address part) containing registers which cannot be switched to secure mode.

Note that the burst access mode is not supported.

10.7.2 RCC TrustZone control register (RCC_TZCR)

Address offset: 0x000

Reset value: 0x0000 0003

This register is used to switch the RCC into secure mode. This register can only be accessed in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCKPROT	TZEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCKPROT**: Protection of the generation of mcuss_ck clock (secure) Enable

Set and reset by software in order to control the security for all registers involved in the generation of the mcuss_ck clock. This bit is only significant if TZEN = '1'.

When TZEN = '1', if MCKPROT = '1', then only secure accesses are allowed to change the register controlling the mcuss_ck clock.

In all other cases, non secure accesses are allowed to those registers.

Refer to *Section 10.4.14: RCC TrustZone function* for details.

0: The registers controlling mcuss_ck clock are not protected
1: The registers controlling mcuss_ck clock are protected, if TZEN = '1' (default after reset).

Bit 0 **TZEN**: RCC TrustZone (secure) Enable

Set and reset by software in order to control the TrustZone mode. When this bit is set, the control of several RCC functions shall be controlled using secure accesses. Refer to *Section 10.4.14: RCC TrustZone function* for details.

0: No protection
1: TrustZone enabled (default after reset).

10.7.3 RCC oscillator clock enable set register (RCC_OCENSETR)

Address offset: 0x00C

Reset value: 0x0000 0001

This register is used to control the oscillators.Writing '0' to this register has no effect, writing '1' will set the corresponding bits. Reading will give the effective values of each bit.If TZEN = MCKPROT = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	HSECSSON	HSEBYP	HSEKERON	HSEON	DIGBYP	Res.	CSIKERON	CSION	Res.	Res.	HSIKERON	HSION
				rs	rs	rs	rs	rs		rs	rs			rs	rs

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **HSECSSON**: Set the HSECSSON bit

Set the Clock Security System on HSE.

This bit is “set only” (disabled by a system reset or when the system enters in Standby mode).

When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready.

0: Reading '0' means that the Clock Security System on HSE is OFF (default after reset)

1: Writing '1' enables the Clock Security System on HSE, reading '1' means that the Clock Security System on HSE is ON

Bit 10 **HSEBYP**: Set HSEBYP bit

Set by software in order to enable the bypass mode.

0: No effect

1: Set the HSEBYP bit

Bit 9 **HSEKERON**: Set HSEKERON bit

Set by software to force the HSE to ON, even in (LP-)Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of HSEON.

0: No effect

1: Set the HSEKERON bit

Bit 8 **HSEON**: Set HSEON bit

Set by software to enable the HSE.

0: No effect

1: Set HSEON bit

Bit 7 **DIGBYP**: Set DIGBYP bit

Set by software when the external clock connected to OSC_IN is a full-swing digital signal.

0: No effect

1: Set DIGBYP bit (digital bypass)

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CSIKERON**: Set CSIKERON bit

Set by software to force the CSI to ON, even in (LP-)Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.

0: No effect
1: Set the CSIKERON bit

Bit 4 **CSION**: Set CSION bit

Set by software to enable CSI clock.

0: No effect
1: Set the CSION bit

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **HSIKERON**: Set HSIKERON bit

Set by software to force the HSI to ON, even in (LP-)Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: No effect
1: Set the HSIKERON bit

Bit 0 **HSION**: Set HSION bit

Set by software to enable the HSI clock.

The HSION is also set by hardware to force the HSI to ON when the product leaves Standby mode or one of the Stop modes.

0: No effect
1: Set the HSION bit

10.7.4 RCC oscillator clock enable clear register (RCC_OCENCLRR)

Address offset: 0x010

Reset value: 0x0000 0001

This register is used to control the oscillators.Writing '0' to this register has no effect, writing '1' will clear the corresponding bits. Reading will give the effective values of the enable bits.If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1			rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSEBYP**: Clear the HSEBYP bit

Cleared by software in order to disable the bypass mode.

0: No effect

1: Clear the HSEBYP bit

Bit 9 **HSEKERON**: Clear HSEKERON bit

Cleared by software in order to allow the HSE to be switched off in one of the Stop modes.

0: No effect

1: Clear the HSEKERON bit

Bit 8 **HSEON**: Clear of HSEON bit

Cleared by software to disable the HSE clock.

0: No effect

1: Clear the HSEON bit

Bit 7 **DIGBYP**: Clear of DIGBYP bit

Cleared by software when the external clock connected to OSC_IN is a low-swing signal.

0: No effect

1: Clear the DIGBYP bit (analog bypass)

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CSIKERON**: Clear of CSIKERON bit

Cleared by software in order to allow the CSI to be switched off in one of the Stop modes.

This bit has no effect on the value of CSION.

0: No effect

1: Clear the CSIKERON bit

Bit 4 **CSION**: Clear of CSION bit

Cleared by software to disable the CSI clock.

0: CSI is OFF

1: Clear the CSION bit

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **HSIKERON**: Clear of HSIKERON bit

Cleared by software in order to allow the HSI to be switched off in one of the Stop modes.

This bit has no effect on the value of HSION.

0: No effect

1: Clear the HSIKERON bit

Bit 0 **HSION**: Clear of HSION bit

Cleared by software to disable the HSI clock.

0: No effect

1: Clear the HSION bit

10.7.5 RCC oscillator clock ready register (RCC_OCRDYR)

Address offset: 0x808

Reset value: 0x0000 0000

This is a read-only access register, It contains the status flags of oscillators. Writing has no effect.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CKREST	AXICKRDY	MPUCKRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						r	r	r							

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSERDY	Res.	Res.	Res.	CSIRDY	Res.	HSIDIVRDY	Res.	HSIRDY
							r				r		r		r

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CKREST**: Clock Restore State Machine Status

Set by hardware to indicate if the clock restore sequence is on-going.

0: The clock restore process is not on-going (default after reset)
1: The clock restore process is on-going

Bit 24 **AXICKRDY**: AXI sub-system clock ready flag

Set by hardware to indicate that the axiss_ck clock is available.

0: axiss_ck clock is not available (default after reset)
1: axiss_ck clock is available

Bit 23 **MPUCKRDY**: MPU clock ready flag

Set by hardware to indicate that the mpuss_ck clock is available.

0: mpuss_ck clock is not available (default after reset)
1: mpuss_ck clock is available

Bits 22:9 Reserved, must be kept at reset value.

Bit 8 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock is not ready (default after reset)
1: HSE clock is ready

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CSIRDY**: CSI clock ready flag

Set by hardware to indicate that the CSI oscillator is stable.

0: CSI clock is not ready (default after reset)
1: CSI clock is ready

Bit 3 Reserved, must be kept at reset value.

Bit 2 **HSIDIVRDY**: HSI divider ready flag

Set and reset by hardware.

As a write in HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF will go immediately to '0' when HSIDIV value is changed, and will be set back to '1' when the output frequency matches the value programmed into HSIDIV

0: the new division ratio is not yet propagated to hsi_ck (hsi_ker_ck) (default after reset)
1: the hsi_ck (hsi_ker_ck) clock frequency reflects the new HSIDIV value

Bit 1 Reserved, must be kept at reset value.

Bit 0 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)
1: HSI clock is ready

10.7.6 RCC debug configuration register (RCC_DBGCFGR)

Address offset: 0x80C

Reset value: 0x0000 0001

This is register contains the enable control of the debug and trace function, and the clock divider for the trace function.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

			rw			rw	rw						rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **DBGRST**: Reset of the debug function

Set and cleared by software to control the generation of the reset (dbg_rstn) for the trace and debug parts.

0: The trace and debug parts are not reset. (default after reset)

1: The trace and debug parts are under reset.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **TRACECKEN**: Clock enable for trace function

Set and cleared by software to control the generation of the trace_ck clock.

See *Section : Clock distribution for DBG and trace* for additional information.

0: The clock for the trace function is disabled (default after reset)

1: The clock for the trace function is enabled

Bit 8 **DBGCKEN**: Clock enable for debug function

Set and cleared by software to control the generation of the ck_apb_dbg clock (DEBUG APB clock), the ck_sys_dbg. See *Section : Clock distribution for DBG and trace* for additional information.

0: The enabling of the clock for the debug function is controlled by cdbgwrupreq signal from DAP. (default after reset)

1: The clock for the debug function is enabled

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **TRACEDIV[2:0]**: Clock divider for the trace clock (ck_trace)

Set and reset by software to control the ck_trace clock division factor.

It is possible to change this division ratio on-the-fly.

others: aclk / 16

0x0: aclk

0x1: aclk / 2 (default after reset)

0x2: aclk / 4

0x3: aclk / 8

10.7.7 RCC HSI configuration register (RCC_HSICFGR)

Address offset: 0x018

Reset value: 0x0000 0000

This register is used to configure the HSI. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	HSITRIM[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	HSIDIV[1:0]	
	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading during system reset

Adjusted by software through trimming bits HSITRIM.

This field represents the sum of engineering Option Byte calibration value and HSITRIM bits value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **HSITRIM[6:0]**: HSI clock trimming

Set by software to adjust calibration. HSITRIM represents a signed value.

HSITRIM field is added to the engineering Option Bytes loaded during reset phase (bsec_hsi_cal[11:0]) in order to form the calibration trimming value.

HSICAL[11:0] = HSITRIM[6:0] + bsec_hsi_cal[11:0].

0x40: bsec_hsi_cal[11:0] - 64
0x41: bsec_hsi_cal[11:0] - 63
...
0x0: bsec_hsi_cal[11:0] (default after reset)
...
0x3E: bsec_hsi_cal[11:0] + 62
0x3F: bsec_hsi_cal[11:0] + 63

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **HSIDIV[1:0]**: HSI clock divider

Set and reset by software.

These bits allows the user to select a division ratio in order to select the wanted HSI clock frequency. The bit HSIDIVRDY of *RCC oscillator clock ready register (RCC_OCRDYR)* indicates when the new division ratio is taken into account.

0x0: Division by 1, hsi_ck (hsi_ker_ck) = 64 MHz (default after reset)
0x1: Division by 2, hsi_ck (hsi_ker_ck) = 32 MHz
0x2: Division by 4, hsi_ck (hsi_ker_ck) = 16 MHz
0x3: Division by 8, hsi_ck (hsi_ker_ck) = 8 MHz

10.7.8 RCC CSI configuration register (RCC_CSICFGR)

Address offset: 0x01C

Reset value: 0x0000 1000

This register is used to fine-tune the CSI frequency. If TZEN = MCKPROT = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **CSICAL[7:0]**: CSI clock calibration
Set by hardware by option byte loading during system reset.
Adjusted by software through trimming bits CSITRIM.
This field represents the sum of engineering Option Byte calibration value and CSITRIM bits value

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **CSITRIM[4:0]**: CSI clock trimming
Set by software to adjust calibration.
CSITRIM field is added to the engineering Option Bytes loaded during reset phase (bsec_csi_cal[7:0]) in order to form the calibration trimming value.
CSICAL[7:0] = CSITRIM[4:0] + bsec_csi_cal[7:0].

Bits 7:0 Reserved, must be kept at reset value.

10.7.9 RCC MCO1 configuration register (RCC_MCO1CFGR)

Address offset: 0x800

Reset value: 0x0000 0000

This register is used to select the clock generated on MCO1 output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **MCO1ON**: Control of the MCO1 output

Set and cleared by software to enable the MCO1 output

0: The MCO1 output is disabled
1: The MCO1 output is enabled

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **MCO1DIV[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

Refer to *Section 10.4.4: Clock output generation (MCO1 and MCO2)* for details.

0x0: bypass (default after reset)
0x1: division by 2
0x2: division by 3
...
0xF: division by 16

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **MCO1SEL[2:0]**: MCO1 clock output selection

Set and cleared by software. Clock source selection may generate glitches on MCO1.

It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.

0x0: HSI clock selected (hsi_ck) (default after reset)
0x1: HSE clock selected (hse_ck)
0x2: CSI clock selected (csi_ck)
0x3: LSI clock selected (lsi_ck)
0x4: LSE oscillator clock selected (lse_ck)
others: reserved

10.7.10 RCC MCO2 configuration register (RCC_MCO2CFGR)

Address offset: 0x804

Reset value: 0x0000 0000

This register is used to select the clock generated on MCO2 output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw					rw	rw	rw	rw		rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **MCO2ON**: Control of the MCO2 output

Set and cleared by software to enable the MCO2 output

0: The MCO2 output is disabled

1: The MCO2 output is enabled

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **MCO2DIV[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

Refer to *Section 10.4.4: Clock output generation (MCO1 and MCO2)* for details.

0x0: bypass (default after reset)

0x1: division by 2

0x2: division by 3

...

0xF: division by 16

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **MCO2SEL[2:0]**: Micro-controller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2.

It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.

0x0: MPU clock selected (mpuss_ck) (default after reset)

0x1: AXI clock selected (axiss_ck)

0x2: MCU clock selected (mcuss_ck)

0x3: PLL4 clock selected (pll4_p_ck)

0x4: HSE clock selected (hse_ck)

0x5: HSI clock selected (hsi_ck)

others: reserved

10.7.11 RCC MPU clock selection register (RCC_MPCKSELR)

Address offset: 0x020

Reset value: 0x8000 0000

This register is used to select the clock source for the MPU. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bit 31 **MPUSRCRDY**: MPU clock switch status

Set and reset by hardware to indicate if the MPU clock switch transition has been properly performed.

0: The MPU switch is not ready: no clock is generated on its output
1: The MPU switch is ready: the clock switch is selecting the clock given by MPUSRC field. (default after reset)

Bits 30:2 Reserved, must be kept at reset value.

Bits 1:0 **MPUSRC[1:0]**: MPU clock switch

Set and reset by software to select the MPU sub-system clock source (mpuss_ck).

Note that MPUDIV is disabled if MPUSRC[1:0] is different from '11'.

Be sure that MPUDIV is different from '000' before setting MPUSRC to '11'.

0x0: HSI selected as MPU sub-system clock (hsi_ck) (default after reset)
0x1: HSE selected as MPU sub-system clock (hse_ck)
0x2: PLL1 selected as MPU sub-system clock (pll1_p_ck)
0x3: PLL1 via MPUDIV is selected as MPU sub-system clock (pll1_p_ck / 2 MPUDIV).

10.7.12 RCC AXI sub-system clock selection register (RCC_ASSCKSELR)

Address offset: 0x024

Reset value: 0x8000 0000

This register is used to select the clock source for the AXI sub-system. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bit 31 **AXISSRCRDY**: AXI sub-system clock switch status

Set and reset by hardware to indicate if the AXI clock switch transition has been properly performed.

0: The AXI sub-system switch is not ready or in positions higher than '011': no clock is generated on its output

1: The AXI sub-system switch is ready: the clock switch is selecting the clock given by AXISSRC field. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **AXISSRC[2:0]**: AXI sub-system clock switch

Set and reset by software to select the AXI sub-system clock source (axiss_ck).

0x0: HSI selected as AXI sub-system clock (hsi_ck) (default after reset)

0x1: HSE selected as AXI sub-system clock (hse_ck)

0x2: PLL2 selected as AXI sub-system clock (pll2_p_ck)

others: axiss_ck is gated

10.7.13 RCC MCU sub-system clock selection register (RCC_MSSCKSELR)

Address offset: 0x048

Reset value: 0x8000 0000

This register is used to select the clock source for the MCU sub-system, including the MCU itself. If TZEN = MCKPROT = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bit 31 **MCUSSRCRDY**: MCU sub-system clock switch status

Set and reset by hardware to indicate if the MCU clock switch transition has been properly performed.

0: The MCU sub-system switch is not ready or in positions higher than '011': no clock is generated on its output

1: The MCU sub-system switch is ready: the clock switch is selecting the clock given by MCUSSRC field. (default after reset)

Bits 30:2 Reserved, must be kept at reset value.

Bits 1:0 **MCUSSRC[1:0]**: MCUSS clock switch

Set and reset by software to select the MCU sub-system clock source (mcuss_ck).

Reset by hardware in order to select hsi_ck when the system exits from one of the Stop modes.

0x0: HSI selected as MCU sub-system clock (hsi_ck) (default after reset)

0x1: HSE selected as MCU sub-system clock (hse_ck)

0x2: CSI selected as MCU sub-system clock (csi_ck)

0x3: PLL3 selected as MCU sub-system clock (pll3_p_ck)

10.7.14 RCC PLL 1 and 2 reference clock selection register (RCC_RCK12SELR)

Address offset: 0x028

Reset value: 0x8000 0000

This register is used to select the reference clock for PLL1 and PLL2. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bit 31 **PLL12SRCRDY**: PLL12 reference clock switch status

Set and reset by hardware to indicate if the PLL12 clock switch transition has been properly performed.

0: The PLL12 switch is not ready or in position '1x': no clock is generated on its output

1: The PLL12 switch is ready: the clock switch is selecting the clock given by PLL12SRC field. (default after reset)

Bits 30:2 Reserved, must be kept at reset value.

Bits 1:0 **PLL12SRC[1:0]**: Reference clock selection for PLL1 and PLL2

Set and reset by software to select the PLL1 and PLL2 clock source.

In order to save power when PLL1 and PLL2 are not used, PLL12SRC must be set to '1x'.

0x0: HSI selected as PLL clock (hsi_ck) (default after reset)

0x1: HSE selected as PLL clock (hse_ck)

others: No clock send to DIVMx divider and PLLs

10.7.15 RCC PLL 3 reference clock selection register (RCC_RCK3SELR)

Address offset: 0x820

Reset value: 0x8000 0000

This register is used to select the reference clock for PLL3. If TZEN = MCKPROT = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **PLL3SRCRDY**: PLL3 reference clock switch status

Set and reset by hardware to indicate if the PLL3 clock switch transition has been properly performed.

0: The PLL3 switch is not ready or in position '11': no clock is generated on its output

1: The PLL3 switch is ready: the clock switch is selecting the clock given by PLL3SRC field. (default after reset)

Bits 30:2 Reserved, must be kept at reset value.

Bits 1:0 **PLL3SRC[1:0]**: Reference clock selection for PLL3

Set and reset by software to select the PLL3 clock source.

In order to save power, when PLL3 is not used, PLL3SRC must be set to '11'.

0x0: HSI selected as PLL clock (hsi_ck) (default after reset)

0x1: HSE selected as PLL clock (hse_ck)

0x2: CSI selected as PLL clock (csi_ck)

0x3: No clock send to DIVMx divider and PLLs

10.7.16 RCC PLL4 reference clock selection register (RCC_RCK4SELR)

Address offset: 0x824

Reset value: 0x8000 0000

This register is used to select the reference clock for PLL4.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **PLL4SRCRDY**: PLL4 reference clock switch status

Set and reset by hardware to indicate if the PLL4 clock switch transition has been properly performed.

0: The PLL4 switch is not ready or in position '11': no clock is generated on its output

1: The PLL4 switch is ready: the clock switch is selecting the clock given by PLL4SRC field. (default after reset)

Bits 30:2 Reserved, must be kept at reset value.

Bits 1:0 **PLL4SRC[1:0]**: Reference clock selection for PLL4

Set and reset by software to select the PLL4 clock source.

0x0: HSI selected as PLL clock (hsi_ck) (default after reset)

0x1: HSE selected as PLL clock (hse_ck)

0x2: CSI selected as PLL clock (csi_ck)

0x3: Signal I2S_CKIN used as reference clock

10.7.17 RCC TIM group 1 prescaler register (RCC_TIMG1PRER)

Address offset: 0x828

Reset value: 0x8000 0000

This register is used to control the prescaler value of timers located into APB1 domain. It concerns TIM2, TIM3, TIM4, TIM5, TIM6, TIM7, TIM12, TIM13 and TIM14. Refer to *Section : Sub-system clock generation* for additional information.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rw

Bit 31 **TIMG1PRERDY**: Timers clocks prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account (default after reset).

Bits 30:1 Reserved, must be kept at reset value.

Bit 0 **TIMG1PRE**: Timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 domain.

Refer to *Table 58: Ratio between clock timers and pclk*.

0: The Timers kernel clock is equal to mlhclk if APB1DIV is corresponding to a division by 1 or 2, else it is equal to 2 x Fpclk1 (default after reset)

1: The Timers kernel clock is equal to mlhclk if APB1DIV is corresponding to division by 1, 2 or 4, else it is equal to 4 x Fpclk1

10.7.18 RCC TIM group 2 prescaler register (RCC_TIMG2PRER)

Address offset: 0x82C

Reset value: 0x8000 0000

This register is used to control the prescaler value of timers located into APB2 domain. It concerns TIM1, TIM8, TIM15, TIM16, and TIM17. Refer to *Section : Sub-system clock generation* for additional information.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TIMG2PRERDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

															rw

Bit 31 **TIMG2PRERDY**: Timers clocks prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account (default after reset).

Bits 30:1 Reserved, must be kept at reset value.

Bit 0 **TIMG2PRE**: Timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB2 domain.

Refer to *Table 58: Ratio between clock timers and pclk*.

0: The Timers kernel clock is equal to mlhclk if APB2DIV is corresponding to a division by 1 or 2, else it is equal to 2 x Fpclk2 (default after reset)

1: The Timers kernel clock is equal to mlhclk if APB2DIV is corresponding to division by 1, 2 or 4, else it is equal to 4 x Fpclk2

10.7.19 RCC RTC clock division register (RCC_RTCDIVR)

Address offset: 0x044

Reset value: 0x0000 0000

This register is used to divide the HSE clock for RTC. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTCDIV[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **RTCDIV[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.

Caution: The software has to set these bits correctly to ensure that the clock supplied to the RTC is lower than 4 MHz. These bits must be configured if needed before selecting the RTC clock source.

Note that when the RTCSRC is different from 3, this divider is disabled (does not provide clock).

0x0: HSE (default after reset)
0x1: HSE/2
0x2: HSE/3
0x3: HSE/4
...
0x3E: HSE/63
0x3F: HSE/64

10.7.20 RCC MPU clock divider register (RCC_MPCKDIVR)

Address offset: 0x02C

Reset value: 0x8000 0001

This register is used to control the MPU clock prescaler. Refer to *Section : Sub-system clock generation* for additional information. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MPUDIVRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MPUDIV[2:0]		
													rw	rw	rw

Bit 31 **MPUDIVRDY**: MPU sub-system clock divider status

Set and reset by hardware to indicate if the new division factor is taken into account.

This bit significant only when MPUSRC[1:0] = '11'.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **MPUDIV[2:0]**: MPU Core clock divider

Set and reset by software to control the MPU clock division factor when the MPUSRC is set to position 3.

It is possible to change this division ratio on-the-fly. It impacts only the frequency of the MPU clock. The clocks are divided with the new prescaler factor, from 1 to 16 pll1_p_ck cycles after MPUDIV update. The application can check if the new division factor is taken into account by reading back the MPUDIVRDY flag. Note that this divider is disabled if MPUSRC[1:0] is different from '11'.

0x0: The MPUDIV is disabled; i.e. no clock generated

0x1: The mpuss_ck is equal to pll1_p_ck divided by 2 (default after reset)

0x2: The mpuss_ck is equal to pll1_p_ck divided by 4

0x3: The mpuss_ck is equal to pll1_p_ck divided by 8

others: The mpuss_ck is equal to pll1_p_ck divided by 16

10.7.21 RCC AXI clock divider register (RCC_AXIDIVR)

Address offset: 0x030

Reset value: 0x8000 0000

This register is used to control the AXI Matrix clock prescaler. Refer to *Section : Sub-system clock generation* for additional information. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AXIDIV[2:0]		
													rw	rw	rw

Bit 31 **AXIDIVRDY**: AXI sub-system clock divider status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.
1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **AXIDIV[2:0]**: AXI, AHB5 and AHB6 clock divider

Set and reset by software to control the AXI, AHB5 and AHB6 clock division factor.

It is possible to change this division ratio on-the-fly. It impacts the frequency of AXI, APB4, APB5 AHB5 and AHB6 clocks.

The clocks are divided with the new prescaler factor, from 1 to 4 axiss_ck cycles after AXIDIV update. The application can check if the new division factor is taken into account by reading back the AXIDIVRDY flag.

0x0: axiss_ck (default after reset)
0x1: axiss_ck / 2
0x2: axiss_ck / 3
others: axiss_ck / 4

10.7.22 RCC APB4 clock divider register (RCC_APB4DIVR)

Address offset: 0x03C

Reset value: 0x8000 0000

This register is used to control the APB4 clock divider. Refer to *Section : Sub-system clock generation* for additional information. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bit 31 **APB4DIVRDY**: APB4 clock divider status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **APB4DIV[2:0]**: APB4 clock divider

Set and reset by software to control the APB4 clock division factor.

It is possible to change this division ratio on-the-fly. It impacts only the frequency of APB4 clock.

The clocks are divided with the new prescaler factor, from 1 to 16 aclk cycles after APB4DIV update. The application can check if the new division factor is taken into account by reading back the APB4DIVRDY flag.

0x0: aclk (default after reset)

0x1: aclk / 2

0x2: aclk / 4

0x3: aclk / 8

others: aclk / 16

10.7.23 RCC APB5 clock divider register (RCC_APB5DIVR)

Address offset: 0x040

Reset value: 0x8000 0000

This register is used to control the APB5 clock divider. Refer to *Section : Sub-system clock generation* for additional information. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bit 31 **APB5DIVRDY**: APB5 clock divider status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **APB5DIV[2:0]**: APB5 clock divider

Set and reset by software to control the APB5 clock division factor.

It is possible to change this division ratio on-the-fly. It impacts only the frequency of APB5 clock.

The clocks are divided with the new prescaler factor, from 1 to 16 aclk cycles after APB5DIV update. The application can check if the new division factor is taken into account by reading the APB5DIVRDY flag.

0x0: aclk (default after reset)

0x1: aclk / 2

0x2: aclk / 4

0x3: aclk / 8

others: aclk / 16

10.7.24 RCC MCU clock divider register (RCC_MCUDIVR)

Address offset: 0x830

Reset value: 0x8000 0000

This register is used to control the MCU sub-system clock prescaler. Refer to *Section : Sub-system clock generation* for additional information. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCUDIV[3:0]			
												rw	rw	rw	rw

Bit 31 **MCUDIVRDY**: MCU clock prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.
1: The new division factor is taken into account. (default after reset)

Bits 30:4 Reserved, must be kept at reset value.

Bits 3:0 **MCUDIV[3:0]**: MCU clock divider

Set and reset by software to control the MCU clock division factor.

Changing this division ratio has an impact on the frequency of MCU clock, and all bus matrix clocks. The clocks are divided with the new prescaler factor, from 1 to 512 cycles of mcuss_ck, after MCUDIV update. The application can check if the new division factor is taken into account by reading back the MCUDIVRDY flag.

0x0: mcuss_ck not divided (default after reset)
0x1: mcuss_ck divided by 2
0x2: mcuss_ck divided by 4
0x3: mcuss_ck divided by 8
0x4: mcuss_ck divided by 16
0x5: mcuss_ck divided by 32
0x6: mcuss_ck divided by 64
0x7: mcuss_ck divided by 128
0x8: mcuss_ck divided by 256
others: mcuss_ck divided by 512

10.7.25 RCC APB1 clock divider register (RCC_APB1DIVR)

Address offset: 0x834

Reset value: 0x8000 0000

This register is used to control the APB1 clock prescaler. Refer to *Section : Sub-system clock generation* for additional information.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bit 31 **APB1DIVRDY**: APB1 clock prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **APB1DIV[2:0]**: APB1 clock divider

Set and reset by software to control the clock division factor.

The clocks are divided with the new prescaler factor, from 1 to 16 mlhclk cycles after APB1DIV update. The application can check if the new division factor is taken into account by reading back the APB1DIVRDY flag.

0x0: mlhclk (default after reset)
0x1: mlhclk / 2
0x2: mlhclk / 4
0x3: mlhclk / 8
0x4: mlhclk / 16
others: Not allowed

10.7.26 RCC APB2 clock divider register (RCC_APB2DIVR)

Address offset: 0x838

Reset value: 0x8000 0000

This register is used to control the APB2 clock prescaler. Refer to *Section : Sub-system clock generation* for additional information.

Bit 31 **APB2DIVRDY**: APB2 clock prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **APB2DIV[2:0]**: APB2 clock divider

Set and reset by software to control the clock division factor.

The clocks are divided with the new prescaler factor, from 1 to 16 mlhclk cycles after APB2DIV update. The application can check if the new division factor is taken into account by reading back the APB2DIVRDY flag.

0x0: mlhclk (default after reset)

0x1: mlhclk / 2

0x2: mlhclk / 4

0x3: mlhclk / 8

0x4: mlhclk / 16

others: Not allowed

10.7.27 RCC APB3 clock divider register (RCC_APB3DIVR)

Address offset: 0x83C

Reset value: 0x8000 0000

This register is used to control the APB3 clock prescaler. Refer to *Section : Sub-system clock generation* for additional information.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bit 31 **APB3DIVRDY**: APB3 clock prescaler status

Set and reset by hardware to indicate if the new division factor is taken into account.

0: The new division factor is not yet taken into account.

1: The new division factor is taken into account. (default after reset)

Bits 30:3 Reserved, must be kept at reset value.

Bits 2:0 **APB3DIV[2:0]**: APB3 clock divider

Set and reset by software to control the clock division factor.

The clocks are divided with the new prescaler factor, from 1 to 16 hclk cycles after APB3DIV update. The application can check if the new division factor is taken into account by reading back the APB3DIVRDY flag.

0x0: hclk (default after reset)

0x1: hclk / 2

0x2: hclk / 4

0x3: hclk / 8

others: hclk / 16

10.7.28 RCC PLL1 control register (RCC_PLL1CR)

Address offset: 0x080

Reset value: 0x0000 0000

This register is used to control the PLL1. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw	rw	rw		rw	r	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DIVREN**: PLL1 DIVR divider output enable
Set and reset by software to enable the pll1_r_ck output of the PLL1.
In order to save power, when the pll1_r_ck is not needed, DIVREN and DIVR must be set to '0'.
0: pll1_r_ck output is disabled (default after reset)
1: pll1_r_ck output is enabled

Bit 5 **DIVQEN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the pll1_q_ck output of the PLL1.
In order to save power, when the pll1_q_ck is not needed, DIVQEN and DIVQ must be set to '0'.
0: pll1_q_ck output is disabled (default after reset)
1: pll1_q_ck output is enabled

Bit 4 **DIVPEN**: PLL1 DIVP divider output enable
Set and reset by software to enable the pll1_p_ck output of the PLL1.
In order to save power, when the pll1_p_ck is not needed, DIVPEN and DIVP must be set to '0'.
0: pll1_p_ck output is disabled (default after reset)
1: pll1_p_ck output is enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SSCG_CTRL**: Spread Spectrum Clock Generator of PLL1 enable

Set and reset by software to enable the spread spectrum clock generator of PLL1, in order to reduce the amount of EMI peaks.

0: Clock Spreading Generator disabled (default after reset)

1: Clock Spreading Generator enabled

Bit 1 **PLL1RDY**: PLL1 clock ready flag

Set by hardware to indicate that the PLL1 is locked.

0: PLL1 unlocked (default after reset)

1: PLL1 locked

Bit 0 **PLLON**: PLL1 enable

Set and cleared by software to enable the PLL1.

Note that DIVPEN of PLL1 must be set to ‘0’ before setting PLLON to ‘0’. Please refer to *Section : PLL disabling procedure* for details.

0: PLL1 OFF (default after reset)

1: PLL1 is ON, and ref1_ck is provided to the PLL1

10.7.29 RCC PLL1 configuration register 1 (RCC_PLL1CFGR1)

Address offset: 0x084

Reset value: 0x0001 0031

This register is used to configure the PLL1. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:16 **DIVM1[5:0]**: Prescaler for PLL1
Set and cleared by software to configure the prescaler of the PLL1.
0x0: bypass
0x1: division by 2 (default after reset)
0x2: division by 3
...
0x3F: division by 64

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **DIVN[8:0]**: Multiplication factor for PLL1 VCO
Set and reset by software to control the multiplication factor of the VCO.
Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is: 800 to 1600 MHz.
VCO output frequency = Fref1_ck x 2 x (DIVN+1), when value 0 has been loaded into FRACV, with:
- Valid division ratios for DIVN: between 25 and 100
- The input frequency Fref1_ck between 8 and 16 MHz
0x18: Division ratio is 25
0x19: Division ratio is 26
...
0x31: Division ratio is 50 (default after reset)
...
0x63: Division ratio is 100
Others: wrong configurations

10.7.30 RCC PLL1 configuration register 2 (RCC_PLL1CFGR2)

Address offset: 0x088

Reset value: 0x0001 0100

This register is used to configure the PLL1. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **DIVR[6:0]**: PLL1 DIVR division factor

Set and reset by software to control the frequency of the pll1_r_ck clock.

0x0: pll1_r_ck = fout1_ck
0x1: pll1_r_ck = fout1_ck / 2 (default after reset)
0x2: pll1_r_ck = fout1_ck / 3
...
0x7F: pll1_r_ck = fout1_ck / 128

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **DIVQ[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the pll1_q_ck clock.

0x0: pll1_q_ck = fout1_ck
0x1: pll1_q_ck = fout1_ck / 2 (default after reset)
0x2: pll1_q_ck = fout1_ck / 3
...
0x7F: pll1_q_ck = fout1_ck / 128

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **DIVP[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the pll1_p_ck clock.

Odd division factors are not recommended due to duty cycle degradation.

0x0: pll1_p_ck = fout1_ck (default after reset)
0x1: pll1_p_ck = fout1_ck / 2
0x2: pll1_p_ck = fout1_ck / 3
...
0x7F: pll1_p_ck = fout1_ck / 128

10.7.31 RCC PLL1 fractional register (RCC_PLL1FRACR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register is used to fine-tune the frequency of the PLL1 VCO. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

															rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
FRACV[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FRACLE**: PLL1 fractional latch enable

Set and reset by software to latch the content of FRACV into the Sigma-Delta modulator.

In order to latch the FRACV value into the Sigma-Delta modulator, FRACLE must be set to '0', then set to '1': the transition 0 to '1' transfers the content of FRACV into the modulator. Refer to *Section : Reprogramming post-dividers* and *Section : PLL initialization procedure* for additional information on the PLL programming.

Bits 15:3 **FRACV[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is: 800 to 1600 MHz

VCO output frequency = Fref1_ck x ((DIVN+1) + (FRACV / 8192)), with

- DIVN shall be between 4 and 512
- FRACV can be between 0 and 8191
- The input frequency Fref1_ck shall be between 4 and 16 MHz

In order to change the FRACV value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit FRACLE to '0',
- write the new fractional value into FRACV,
- set the bit FRACLE to '1'.

Bits 2:0 Reserved, must be kept at reset value.

10.7.32 RCC PLL1 clock spreading generator register (RCC_PLL1CSGR)

Address offset: 0x090

Reset value: 0x0000 0000

This register is used to configure the PLL1.It is not recommended to change the content of this register when the PLL1 is enabled (PLLON = '1'). Refer to *Section : Using the PLLs in spread spectrum mode* for details. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bit 31 Reserved, must be kept at reset value.

Bits 30:16 **INC_STEP[14:0]**: Modulation Depth Adjustment for PLL1
Set and reset by software to adjust the modulation depth of the clock spreading generator.

Bit 15 **SSCG_MODE**: Spread spectrum clock generator mode
Set and reset by software to select the clock spreading mode.
0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 14 **RPDFN_DIS**: Dithering RPDF noise control
Set and reset by software.
This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a rectangular probability density function.
0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bit 13 **TPDFN_DIS**: Dithering TPDF noise control
Set and reset by software.
This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a triangular probability density function.
0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bits 12:0 **MOD_PER[12:0]**: Modulation Period Adjustment for PLL1
Set and reset by software to adjust the modulation period of the clock spreading generator.

10.7.33 RCC PLL2 control register (RCC_PLL2CR)

Address offset: 0x094

Reset value: 0x0000 0000

This register is used to control the PLL2. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bit 6 **DIVREN**: PLL2 DIVR divider output enable

Set and reset by software to enable the pll2_r_ck output of the PLL2.

In order to save power, when the pll2_r_ck is not needed, DIVREN and DIVR must be set to '0'.

0: pll2_r_ck output is disabled (default after reset)
1: pll2_r_ck output is enabled

Bit 5 **DIVQEN**: PLL2 DIVQ divider output enable

Set and reset by software to enable the pll2_q_ck output of the PLL2.

In order to save power, when the pll2_q_ck is not needed, DIVQEN and DIVQ must be set to '0'.

0: pll2_q_ck output is disabled (default after reset)
1: pll2_q_ck output is enabled

Bit 4 **DIVPEN**: PLL2 DIVP divider output enable

Set and reset by software to enable the pll2_p_ck output of the PLL2.

In order to save power, when the pll2_p_ck is not needed, DIVPEN and DIVP must be set to '0'.

0: pll2_p_ck output is disabled (default after reset)
1: pll2_p_ck output is enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SSCG_CTRL**: Clock Spreading Generator of PLL2 enable

Set and reset by software to enable the clock spreading generator of PLL2, in order to reduce the amount of EMI peaks.

0: Clock Spreading Generator disabled (default after reset)
1: Clock Spreading Generator enabled

Bit 1 **PLL2RDY**: PLL2 clock ready flag

Set by hardware to indicate that the PLL2 is locked.

0: PLL2 unlocked (default after reset)
1: PLL2 locked

Bit 0 **PLLON**: PLL2 enable

Set and cleared by software to enable the PLL2.

0: PLL2 OFF (default after reset)
1: PLL2 ON, and ref2_ck is provided to the PLL2

10.7.34 RCC PLL2 configuration register 1 (RCC_PLL2CFGR1)

Address offset: 0x098

Reset value: 0x0001 0063

This register is used to configure the PLL2. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Bit 16 **FRACLE**: PLL2 fractional latch enable

Set and reset by software to latch the content of FRACV into the Sigma-Delta modulator.

In order to latch the FRACV value into the Sigma-Delta modulator, FRACLE must be set to '0', then set to '1': the transition 0 to '1' transfers the content of FRACV into the modulator. Refer to *Section : Reprogramming post-dividers* and *Section : PLL initialization procedure* for additional information on the PLL programming.

Bits 15:3 **FRACV[12:0]**: Fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is: 800 to 1600 MHz

VCO output frequency = Fref2_ck x ((DIVN+1) + (FRACV / 8192)), with

- DIVN shall be between 4 and 512
- FRACV can be between 0 and 8191
- The input frequency Fref2_ck shall be between 4 and 16 MHz

In order to change the FRACV value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit FRACLE to '0',
- write the new fractional value into FRACV,
- set the bit FRACLE to '1'.

Bits 2:0 Reserved, must be kept at reset value.

10.7.37 RCC PLL2 clock spreading generator register (RCC_PLL2CSGR)

Address offset: 0x0A4

Reset value: 0x0000 0000

This register is used to configure the PLL2. It is not recommended to change the content of this register when the PLL2 is enabled (PLLON = '1'). Refer to *Section : Using the PLLs in spread spectrum mode* for details. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

Set and reset by software to enable the pll3_r_ck output of the PLL3.

In order to save power, when the pll3_r_ck is not needed, DIVREN and DIVR must be set to '0'.

0: pll3_r_ck output is disabled (default after reset)
1: pll3_r_ck output is enabled

Bit 5 **DIVQEN**: PLL3 DIVQ divider output enable

Set and reset by software to enable the pll3_q_ck output of the PLL3.

In order to save power, when the pll3_q_ck is not needed, DIVQEN and DIVQ must be set to '0'.

0: pll3_q_ck output is disabled (default after reset)
1: pll3_q_ck output is enabled

Bit 4 **DIVPEN**: PLL3 DIVP divider output enable

Set and reset by software to enable the pll3_p_ck output of the PLL3.

In order to save power, when the pll3_p_ck is not needed, DIVPEN and DIVP must be set to '0'.

0: pll3_p_ck output is disabled (default after reset)
1: pll3_p_ck output is enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **PLL3RDY**: PLL3 clock ready flag

Set by hardware to indicate that the PLL3 is locked.

0: PLL3 unlocked (default after reset)
1: PLL3 locked

Bit 0 **PLLON**: PLL3 enable

Set and cleared by software to enable the PLL3.

Cleared by hardware when entering Stop, LP-Stop, LPLV-Stop, or Standby mode.

Note that DIVPEN, DIVQEN and DIVREN of PLL3 must be set to ‘0’ before setting PLLON to ‘0’. refer to *Section : PLL disabling procedure* for details.

0: PLL3 OFF (default after reset)
1: PLL3 ON, and ref3_ck is provided to the PLL3

10.7.39 RCC PLL3 configuration register 1 (RCC_PLL3CFGR1)

Address offset: 0x884

Reset value: 0x0001 0031

This register is used to configure the PLL3. If TZEN = MCKPROT = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **IFRGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
x0: The PLL3 input (ref3_ck) clock range frequency is between 4 and 8 MHz (default after reset)
x1: The PLL3 input (ref3_ck) clock range frequency is between 8 and 16 MHz.
Note that if ref3_ck is equal to 8 MHz, it is recommended to set IFRGE = ‘x1’

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **DIVM3[5:0]**: Prescaler for PLL3
Set and cleared by software to configure the prescaler of the PLL3.
0x0: bypass
0x1: division by 2 (default after reset)
0x2: division by 3
...
0x3F: division by 64

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **DIVN[8:0]**: Multiplication factor for PLL3 VCO
Set and reset by software to control the multiplication factor of the VCO.
Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is between 400 and 800 MHz.

VCO output frequency = Fref3_ck x (DIVN+1), when value 0 has been loaded into FRACV, with:
- Valid division ratios for DIVN: between 25 and 200
- The input frequency Fref3_ck between 4 and 16 MHz

0x18: Division ratio is 25
0x19: Division ratio is 26
0x1A: Division ratio is 27
...
0x31: Division ratio is 50 (default after reset)
...
0xC7: Division ratio is 200
Others: wrong configurations

10.7.40 RCC PLL3 configuration register 2 (RCC_PLL3CFGR2)

Address offset: 0x888

Reset value: 0x0001 0101

This register is used to configure the PLL3. If TZEN = MCKPROT = '1', this register can only be modified in secure mode.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **DIVR[6:0]**: PLL3 DIVR division factor

Set and reset by software to control the frequency of the pll3_r_ck clock.

0x0: pll3_r_ck = vco3_ck
0x1: pll3_r_ck = vco3_ck / 2 (default after reset)
0x2: pll3_r_ck = vco3_ck / 3
...
0x7F: pll3_r_ck = vco3_ck / 128

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **DIVQ[6:0]**: PLL3 DIVQ division factor

Set and reset by software to control the frequency of the pll3_q_ck clock.

0x0: pll3_q_ck = vco3_ck
0x1: pll3_q_ck = vco3_ck / 2 (default after reset)
0x2: pll3_q_ck = vco3_ck / 3
...
0x7F: pll3_q_ck = vco3_ck / 128

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **DIVP[6:0]**: PLL3 DIVP division factor

Set and reset by software to control the frequency of the pll3_p_ck clock.

0x0: pll3_p_ck = vco3_ck
0x1: pll3_p_ck = vco3_ck / 2 (default after reset)
0x2: pll3_p_ck = vco3_ck / 3
...
0x7F: pll3_p_ck = vco3_ck / 128

10.7.41 RCC PLL3 fractional register (RCC_PLL3FRACR)

Address offset: 0x88C

Reset value: 0x0000 0000

This register is used to fine-tune the frequency of the PLL3 VCO. If TZEN = MCKPROT = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FRACLE
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACV[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FRACLE**: PLL3 fractional latch enable

Set and reset by software to latch the content of FRACV into the Sigma-Delta modulator.

In order to latch the FRACV value into the Sigma-Delta modulator, FRACLE must be set to '0', then set to '1': the transition 0 to '1' transfers the content of FRACV into the modulator. Refer to *Section : PLL initialization procedure* and *Section : Reprogramming post-dividers* for additional information on the PLL programming.

Bits 15:3 **FRACV[12:0]**: Fractional part of the multiplication factor for PLL3 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL3 VCO.

Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is between 400 and 800 MHz.

VCO output frequency = Fref3_ck x ((DIVN+1) + (FRACV / 8192)), with

- DIVN shall be between 4 and 512
- FRACV can be between 0 and 8191
- The input frequency Fref3_ck shall be between 1 and 16 MHz

In order to change the FRACV value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit FRACLE to '0',
- write the new fractional value into FRACV,
- set the bit FRACLE to '1'.

Bits 2:0 Reserved, must be kept at reset value.

10.7.42 RCC PLL4 control register (RCC_PLL4CR)

Address offset: 0x894

Reset value: 0x0000 0000

This register is used to control the PLL4.

									rw	rw	rw			r	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **DIVREN**: PLL4 DIVR divider output enable

Set and reset by software to enable the pll4_r_ck output of the PLL4.

In order to save power, when the pll4_r_ck is not needed, DIVREN must be set to '0'.

0: pll4_r_ck output is disabled (default after reset)
1: pll4_r_ck output is enabled

Bit 5 **DIVQEN**: PLL4 DIVQ divider output enable

Set and reset by software to enable the pll4_q_ck output of the PLL4.

In order to save power, when the pll4_q_ck is not needed, DIVQEN must be set to '0'.

0: pll4_q_ck output is disabled (default after reset)
1: pll4_q_ck output is enabled

Bit 4 **DIVPEN**: PLL4 DIVP divider output enable

Set and reset by software to enable the pll4_p_ck output of the PLL4.

In order to save power, when the pll4_p_ck is not needed, DIVPEN must be set to '0'.

0: pll4_p_ck output is disabled (default after reset)
1: pll4_p_ck output is enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **PLL4RDY**: PLL4 clock ready flag

Set by hardware to indicate that the PLL4 is locked.

0: PLL4 unlocked (default after reset)
1: PLL4 locked

Bit 0 **PLLON**: PLL4 enable

Set and cleared by software to enable the PLL4.

Cleared by hardware when entering Stop, LP-Stop, LPLV-Stop, or Standby mode.

Note that DIVPEN, DIVQEN and DIVREN of PLL4 must be set to ‘0’ before setting PLLON to ‘0’. refer to *Section : PLL disabling procedure* for details.

0: PLL4 OFF (default after reset)
1: PLL4 ON, and ref4_ck is provided to the PLL4

10.7.43 RCC PLL4 configuration register 1 (RCC_PLL4CFGR1)

Address offset: 0x898

Reset value: 0x0001 0031

This register is used to configure the PLL4.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **FRACLE**: PLL4 fractional latch enable

Set and reset by software to latch the content of FRACV into the Sigma-Delta modulator.

In order to latch the FRACV value into the Sigma-Delta modulator, FRACLE must be set to '0', then set to '1': the transition 0 to '1' transfers the content of FRACV into the modulator. Refer to Section: Refer to *Section : PLL initialization procedure* and *Section : Reprogramming post-dividers* for additional information.

Bits 15:3 **FRACV[12:0]**: Fractional part of the multiplication factor for PLL4 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL4 VCO.

Warning: the software has to set correctly these bits to ensure that the VCO output frequency is between its valid frequency range, which is between 400 and 800 MHz.

VCO output frequency = Fref4_ck x ((DIVN+1) + (FRACV / 8192)), with

- DIVN shall be between 4 and 512
- FRACV can be between 0 and 8191
- The input frequency Fref4_ck shall be between 1 and 16 MHz

In order to change the FRACV value on-the-fly even if the PLL is enabled, the application has to proceed as follow:

- set the bit FRACLE to '0',
- write the new fractional value into FRACV,
- set the bit FRACLE to '1'.

Bits 2:0 Reserved, must be kept at reset value.

10.7.46 RCC I2C1,2 kernel clock selection register (RCC_I2C12CKSELR)

Address offset: 0x8C0

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the I2C1 and I2C2. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

others: reserved, the kernel clock is disabled

10.7.51 RCC SAI3 kernel clock selection register (RCC_SAI3CKSELR)

Address offset: 0x8D0

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the SAI3. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **FMCSRC[1:0]**: FMC kernel clock source selection

Set and reset by software.

0x0: aclk clock selected as kernel peripheral clock (default after reset)
0x1: pll3_r_ck clock selected as kernel peripheral clock
0x2: pll4_p_ck clock selected as kernel peripheral clock
0x3: per_ck clock selected as kernel peripheral clock

10.7.67 RCC FDCAN kernel clock selection register (RCC_FDCANCKSELR)

Address offset: 0x90C

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the FDCAN block. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

Bits 1:0 **CECSRC[1:0]**: CEC-HDMI kernel clock source selection
Set and reset by software.
0x0: lse_ck clock selected as kernel peripheral clock (default after reset)
0x1: lsi_ck clock selected as kernel peripheral clock
0x2: csi_ker_ck/122 clock selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

10.7.70 RCC USB kernel clock selection register (RCC_USBCKSELR)

Address offset: 0x91C

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the USBPHY PLL of the USB HOST and USB OTG. It also controls the pre-divider for the reference clock for the USBPHY. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

											rw			rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **USBOSRC**: USB OTG kernel clock source selection
Set and reset by software.
0: pll4_r_ck clock selected as kernel peripheral clock (default after reset)
1: clock provided by the USB PHY (rcc_ck_usbo_48m) selected as kernel peripheral clock

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **USBPHYSRC[1:0]**: USB PHY kernel clock source selection
Set and reset by software.
0x0: hse_ker_ck clock selected as kernel peripheral clock (default after reset)
0x1: pll4_r_ck clock selected as kernel peripheral clock
0x2: hse_ker_ck/2 clock selected as kernel peripheral clock
other: Clock disabled

10.7.71 RCC RNG1 kernel clock selection register (RCC_RNG1CKSELR)

Address offset: 0x0CC

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the RNG1. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*. If TZEN = '1', this register can only be modified in secure mode.

Bits 1:0 **RNG2SRC[1:0]**: RNG2 kernel clock source selection

Set and reset by software.

0x0: csi_ker_ck clock selected as kernel peripheral clock (default after reset)
0x1: pll4_r_ck clock selected as kernel peripheral clock
0x2: lse_ck clock selected as kernel peripheral clock
0x3: lsi_ck clock selected as kernel peripheral clock

10.7.73 RCC common peripheral clock selection register (RCC_CPERCKSELR)

Address offset: 0x0D0

Reset value: 0x0000 0000

This register is used to select an oscillator source as kernel clock for the per_ck clock. The per_ck clock is distributed to several peripherals. Refer to *Section : Clock enabling delays*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **CKPERSRC[1:0]**: Oscillator selection for kernel clock

Set and cleared by software.

0x0: hsi_ker_ck clock selected (default after reset)
0x1: csi_ker_ck clock selected
0x2: hse_ker_ck clock selected
0x3: Clock disabled

10.7.74 RCC STGEN clock selection register (RCC_STGENCKSELR)

Address offset: 0x0D4

Reset value: 0x0000 0000

This register is used to select the peripheral clock for the STGEN block. Note that this clock is used to provide a time reference for the application. Refer to *Section : Clock enabling delays*. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **STGENSRC[1:0]**: Oscillator selection for kernel clock

Set and cleared by software.

0x0: hsi_ker_ck clock selected (default after reset)
0x1: hse_ker_ck clock selected
others: Clock disabled

10.7.75 RCC DDR interface control register (RCC_DDRITFCR)

Address offset: 0x0D8

Reset value: 0x000F D02A

This register is used to control the DDR interface, including the DDRC and DDRPHYC. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GSKP_DUR[3:0]				DFILP_WIDTH[2:0]			GSKPCTRL	GSKPMOD	DDRCKMOD[2:0]			DPHYCTLRST	DPHYRST	DPHYAPBRST	DDRCORERST

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **GSKP_DUR[3:0]**: Glitch skipper duration in automatic mode
Set and clear by software.
This field allow the application to define the amount of time where the glitch skipper is providing the clock dphy_ker_ck instead of the clock ddrc_ker_ck to the DDRC block.
This delay is equal to (GSKP_DUR + 1) x 32 x Tdphy_ker_ck
0x0: Sets a delay of 32 x Tdphy_ker_ck
0x1: Sets a delay of 2 x 32 x Tdphy_ker_ck
0x2: Sets a delay of 3 x 32 x Tdphy_ker_ck
...
0xF: Sets a delay of 16 x 32 x Tdphy_ker_ck

Bits 27:25 **DFILP_WIDTH[2:0]**: Minimum duration of low-power request command
Set and clear by software.
The low power request duration must always be bigger or equal to 1 microsecond. If this duration is not respected, the DDR interface behavior is not guaranteed. The application has to program properly DFILP_WIDTH in order to ensure a delay bigger or equal to 1 microsecond. Note that the delay is also dependent of the frequency of the dphy_ker_ck clock.
0x0: Bypass, delay disabled
0x1: Forces a delay of 160 x Tdphy_ker_ck to be used when Fdphy_ker_ck is between 120 and 160 MHz.
0x2: Forces a delay of 224 x Tdphy_ker_ck to be used when Fdphy_ker_ck is between 160 and 220 MHz.
0x3: Forces a delay of 320 x Tdphy_ker_ck to be used when Fdphy_ker_ck is between 220 and 320 MHz.
0x4: Forces a delay of 416 x Tdphy_ker_ck to be used when Fdphy_ker_ck is between 320 and 410 MHz.
Others: Forces a delay of 544 x Tdphy_ker_ck to be used when Fdphy_ker_ck is between 410 and 533MHz.

Bit 24 **GSKPCTRL**: Glitch Skipper (GSKP) control
Set and clear by software.
This has effect only if GSKPMOD = '0'.
0: The GSKP block is providing the clock phy_out_ck (provided by the DDRPHYC)
1: The GSKP block is providing the clock dphy_ker_ck (provided by the RCC)

Bit 23 **GSKPMOD**: Glitch Skipper (GSKP) Mode
Set and clear by software.
0: The GSKP block is controlled by the GSKPCTRL bit.
1: The GSKP block is controlled automatically by the DFI.

Bits 22:20 **DDRCKMOD[2:0]**: RCC mode for DDR clock control

Set and clear by software.

0x0: Normal mode: the gating of the dphy_ker_ck clock depends on the DDRPHYCEN, DDRPHYCLPEN and MPU mode. The gating of the ddrc_ker_ckg clock depends on the DDRCxEN, DDRCxLPEN and MPU mode. This mode must be selected during DDRC and DDRPHYC initialization phase, and if the application is using the software self-refresh (SSR).

0x1: Automatic Self-Refresh mode (ASR1): the clock ddrc_ker_ckg is gated automatically according to cactive_ddrc signal. The gating of the dphy_ker_ck clock depends on the DDRPHYCEN, DDRPHYCLPEN and MPU mode.
This mode can be used when the application wants to maintain a clock to the DLLs in order to avoid the re-lock sequences. In this mode it is recommended to have DDRCxEN = DDRCxLPEN = DDRPHYCEN = DDRPHYCLPEN = '1'.

0x5: Full Automatic Self-Refresh mode (ASR2): the clocks ddrc_ker_ckg and dphy_ker_ck are gated automatically according to cactive_ddrc signal.
This mode can be used when the DLLs are in bypass. In this mode it is recommended to have DDRCxEN = DDRCxLPEN = DDRPHYCEN = DDRPHYCLPEN = '1'.

0x2: Hardware Self-Refresh mode (HSR1): the gating of the ddrc_ker_ckg clock is controlled by the AXI-Low-Power interface connected to the DDRC. The gating of the dphy_ker_ck clock depends on the DDRPHYCEN, DDRPHYCLPEN and MPU mode.
This mode can be used when the application wants to maintain a clock to the DLLs. In this mode it is recommended to have DDRCxEN = DDRCxLPEN = DDRPHYCEN = DDRPHYCLPEN = '1'.

0x6: Full Hardware Self-Refresh mode (HSR2): the gating of ddrc_ker_ckg and dphy_ker_ck clocks are controlled by the AXI-Low-Power interface connected to the DDRC.
This mode can be used when the DLLs are in bypass. In this mode it is recommended to have DDRCxEN = DDRCxLPEN = DDRPHYCEN = DDRPHYCLPEN = '1'.

other: reserved

Bit 19 **DPHYCTLRST**: DDRPHYC Control reset

Set and clear by software.

0: does not reset the DDRPHYC Control
1: resets the DDRPHYC Control

Bit 18 **DPHYRST**: DDRPHYC reset

Set and clear by software.

0: does not reset the DDRPHYC
1: resets the DDRPHYC

Bit 17 **DPHYAPBRST**: DDRPHYC APB interface reset

Set and clear by software.

0: does not reset the DDRPHYC APB interface
1: resets the DDRPHYC APB interface

Bit 16 **DDRCORERST**: DDRC core reset

Set and clear by software.

0: does not reset the DDRC core
1: resets the DDRC core

Bit 15 **DDRCAXIRST**: DDRC AXI interface reset
Set and clear by software.
0: does not reset the DDRC AXI interface
1: resets the DDRC AXI interface

Bit 14 **DDRCAPBRST**: DDRC APB interface reset
Set and clear by software.
0: does not reset the DDRC APB interface
1: resets the DDRC APB interface

Bits 13:11 **KERDCG_DLY[2:0]**: AXIDCG delay
Set and clear by software.
It represents the delay between the falling edge of the cactive_ddrc signal and the moment where the KERDCG will gate the ddrc_ker_ckg.
0x0: 1 period of ddrc_ker_ck between cactive_ddrc falling edge and the gating of ddrc_ker_ckg.
0x1: 3 periods of ddrc_ker_ck between cactive_ddrc falling edge and the gating of ddrc_ker_ckg.
...
0x7: 15 periods of ddrc_ker_ck between cactive_ddrc falling edge and the gating of ddrc_ker_ckg.

Bit 10 **DDRPHYCAPBLPEN**: DDRPHYC APB clock enable during CSleep mode
Set and clear by software.
This bit is controlling the gating of pclk4_dphy clock during CSleep mode.
0: means that the APB clock is disabled in CSleep
1: means that the APB clock is enabled in CSleep

Bit 9 **DDRPHYCAPBEN**: DDRPHYC APB clock enable
Set and clear by software.
This bit is controlling the gating of pclk4_dphy clock.
0: means that the APB clock is disabled
1: means that the APB clock is enabled

Bit 8 **AXIDCGEN**: AXIDCG enable during MPU CRun mode
Set and clear by software.
When the dynamic clock gating is disabled, the clock is always provided to the DDRC if provided by the RCC.
0: means that the dynamic clock gating of AXIDCG[2:1] is disabled during MPU CRun,
1: means that the dynamic clock gating of AXIDCG{2:1] is enabled during MPU CRun

Bit 7 **DDRCAPBLPEN**: DDRC APB clock enable during CSleep mode
Set and clear by software.
This bit is controlling the gating of pclk4_ddrc clock during CSleep mode.
0: means that the APB clock is disabled in CSleep
1: means that the APB clock is enabled in CSleep

Bit 6 **DDRCAPBEN**: DDRC APB clock enable
Set and clear by software.
This bit is controlling the gating of pclk4_ddrc clock.
0: means that the APB clock is disabled
1: means that the APB clock is enabled

Bit 5 **DDRPHYCLPEN**: DDRPHYC peripheral clocks enable during CSleep mode
Set and clear by software.
This bit is controlling the gating of dphy_ker_ck and pclk4_dphy in CSleep
0: means that the peripheral clocks are disabled in CSleep
1: means that the peripheral clocks are enabled in CSleep

Bit 4 **DDRPHYCEN**: DDRPHYC peripheral clocks enable
Set and clear by software.
This bit is controlling the gating of dphy_ker_ck and pclk4_dphy
0: means that the peripheral clocks are disabled
1: means that the peripheral clocks are enabled

Bit 3 **DDRC2LPEN**: DDRC port 2 peripheral clocks enable during CSleep mode
Set and clear by software.
This bit is controlling the gating of ddrc_ker_ckg, aclk2_ddrc and pclk4_ddrc in CSleep.
0: means that the peripheral clocks are disabled in CSleep
1: means that the peripheral clocks are enabled in CSleep

Bit 2 **DDRC2EN**: DDRC port 2 peripheral clocks enable
Set and clear by software.
This bit is controlling the gating of ddrc_ker_ckg, aclk2_ddrc and pclk4_ddrc clocks.
0: Means that the DDRC peripheral clocks are disabled
1: Means that the DDRC peripheral clocks are enabled

Bit 1 **DDRC1LPEN**: DDRC port 1 peripheral clocks enable during CSleep mode
Set and clear by software.
This bit is controlling the gating of ddrc_ker_ckg, aclk1_ddrc and pclk4_ddrc in CSleep.
0: means that the peripheral clocks are disabled in CSleep
1: means that the peripheral clocks are enabled in CSleep

Bit 0 **DDRC1EN**: DDRC port 1 peripheral clocks enable
Set and clear by software.
This bit is controlling the gating of ddrc_ker_ckg, aclk1_ddrc and pclk4_ddrc clocks.
0: Means that the DDRC peripheral clocks are disabled
1: Means that the DDRC peripheral clocks are enabled

10.7.76 RCC ADC kernel clock selection register (RCC_ADCCKSELR)

Address offset: 0x928

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the ADC block. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

0x5: per_ck clock selected as kernel peripheral clock
others: the kernel clock is disabled

10.7.78 RCC LPTIM2 and 3 kernel clock selection register (RCC_LPTIM23CKSELR)

Address offset: 0x930

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the LPTIM2 and LPTIM3 blocks. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **LPTIM23SRC[2:0]**: LPTIM2 and LPTIM3 kernel clock source selection

Set and reset by software.

0x0: pclk3 clock selected as kernel peripheral clock (default after reset)
0x1: pll4_q_ck clock selected as kernel peripheral clock
0x2: per_ck clock selected as kernel peripheral clock
0x3: lse_ck clock selected as kernel peripheral clock
0x4: lsi_ck clock selected as kernel peripheral clock
others: the kernel clock is disabled

10.7.79 RCC LPTIM1 kernel clock selection register (RCC_LPTIM1CKSELR)

Address offset: 0x934

Reset value: 0x0000 0000

This register is used to control the selection of the kernel clock for the LPTIM1 block. Note that changing the clock source on-the-fly is allowed, and will not generate any timing violation, however the user has to ensure that both the previous and the new clock sources are present during the switching, and for the whole transition time. Refer to *Section : Clock enabling delays*.

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **LPTIM1SRC[2:0]**: LPTIM1 kernel clock source selection

Set and reset by software.

0x0: pclk1 clock selected as kernel peripheral clock (default after reset)
0x1: pll4_p_ck clock selected as kernel peripheral clock
0x2: pll3_q_ck clock selected as kernel peripheral clock
0x3: lse_ck clock selected as kernel peripheral clock
0x4: lsi_ck clock selected as kernel peripheral clock
0x5: per_ck clock selected as kernel peripheral clock
others: the kernel clock is disabled

10.7.80 RCC boot control register (RCC_MP_BOOTCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register is used to control the HOLD boot function when the system exits from Standby. Refer to *Section : MCU HOLD_BOOT after processor reset*. This register is reset when a system reset occurs, but not when the circuit exits from Standby (app_rst reset).

If TZEN = '1', this register can only be modified in secure mode. This register can only be accessed by the MPU.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MPU_BEN	MCU_BEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MPU_BEN**: MPU Boot Enable after Standby

Set and reset by software in order to allow or not the MPU to restart the next time the system exits from Standby. The value of this bit is used by the BOOTROM in order to allow or not the restart of the MPU application.

0: The MPU will remain on CStandby when the system exits from Standby

1: The MPU is allowed to restart when the system exits from Standby

Bit 0 **MCU_BEN**: MCU Boot Enable after Standby

Set and reset by software in order to allow or not the MCU to restart the next time the system exits from Standby. The value of this bit is used by the BOOTROM in order to allow or not the restart of the MPU application.

0: The MCU will remain on HOLD_BOOT when the system exits from Standby

1: The MCU is allowed to restart when the system exits from Standby

10.7.81 RCC stop request set register (RCC_MP_SREQSETR)

Address offset: 0x104

Reset value: 0x0000 0000

Writing '0' has no effect, reading will return the values of the bits. Writing a '1' sets the corresponding bit to '1'. The MCU cannot write to this register. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STPREQ_P1	STPREQ_P0
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **STPREQ_P1**: Stop Request for MPU processor number 1
Set by software
Indicates if the MPU processor number 1 allows the entry in CStop mode for MPU domain, when the complete MPU is in WFI.
0: Writing '0' has no effect, reading '0' means that the MPU processor number 1 does not allow the MPU domain to go to CStop
1: Writing '1' sets the STPREQ_P1 bit, reading '1' means that the MPU processor number 1 allows the MPU domain to go to CStop

Bit 0 **STPREQ_P0**: Stop Request for MPU processor number 0
Set by software
Indicates if the MPU processor number 0 allows the entry in CStop mode for MPU domain, when the complete MPU is in WFI.
0: Writing '0' has no effect, reading '0' means that the MPU processor number 0 does not allow the MPU domain to go to CStop
1: Writing '1' sets the STPREQ_P0 bit, reading '1' means that the MPU processor number 0 allows the MPU domain to go to CStop

10.7.82 RCC stop request clear register (RCC_MP_SREQCLRR)

Address offset: 0x108

Reset value: 0x0000 0000

Writing '0' has no effect, reading will return the effective values of the bits. Writing a '1' sets the corresponding bit to '0'. The MCU cannot write to this register. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

														rc_w1	rc_w1

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **STPREQ_P1**: Stop Request for MPU processor number 1

Cleared by software

Indicates if the MPU processor number 1 allows the entry in CStop mode for MPU domain, when the complete MPU is in WFI.

0: Writing '0' has no effect, reading '0' means that the MPU processor number 1 does not allow the MPU domain to go to CStop

1: Writing '1' clears the STPREQ_P1 bit, reading '1' means that the MPU processor number 1 allows the MPU domain to go to CStop

Bit 0 **STPREQ_P0**: Stop Request for MPU processor number 0

Cleared by software

Indicates if the MPU processor number 0 allows the entry in CStop mode for MPU domain, when the complete MPU is in WFI.

0: Writing '0' has no effect, reading '0' means that the MPU processor number 0 does not allow the MPU domain to go to CStop

1: Writing '1' clears the STPREQ_P0 bit, reading '1' means that the MPU processor number 0 allows the MPU domain to go to CStop

10.7.83 RCC global control register (RCC_MP_GCR)

Address offset: 0x10C

Reset value: 0x0000 0000

The register contains global control bits. If TZEN = '1', this register can only be modified in secure mode. The MCU cannot modify this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOT_MCU
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BOOT_MCU**: Allows the MCU to boot

Set and reset by software in order set the MCU in HOLD_BOOT after a reset of the MCU core. Note that the MCU core can be reset by mpu_rst or by nreset.

Refer to *Section : MCU HOLD_BOOT after processor reset* for details.

If the MCU was in HOLD_BOOT it will cause the MCU to boot.

0: The MCU will be set in HOLD_BOOT when the next MCU core reset occurs. (default after reset)

1: The MCU will not be in HOLD_BOOT mode when the next MCU core reset occurs.

10.7.84 RCC application reset control register (RCC_MP_APRSTCR)

Address offset: 0x110

Reset value: 0x0000 7F00

This register is used to control the behavior of the warm reset. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	RSTTO[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDCTLEN
	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **RSTTO[6:0]**: Reset Timeout Delay Adjust

Set and reset by software in order to define the maximum amount of time the app_rst is delayed. The timeout value is counted using hsi_ck, which can be divided according to HSIDIV.

This function is only available when the RDCTLEN = '1'.

It is not allowed to change this field value when RDCTLEN = ‘1’. Refer to *Section 10.3.11: Reset delay control (RDCTL)* for additional information of the programming of the timeout value.

0x0: The timeout function is disabled
0x1: The timeout is set to 2 x 2^{HSIDIV} us
...
0x7F: The timeout is set to 128 x 2^{HSIDIV} us (default after reset)

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **RDCTLEN**: Reset Delay Control Enable

Set and reset by software.

0: The RDCTL control block is bypassed (default after reset)
1: The RDCTL control block is enabled.

10.7.85 RCC application reset status register (RCC_MP_APRSTSR)

Address offset: 0x114

Reset value: 0x0000 0000

This register provides a status of the RDCTL. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	RSTTOV[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	r	r	r	r	r	r	r								

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:8 **RSTTOV[6:0]**: Reset Timeout Delay Value

Set by hardware in order to give the value of the timeout counter. This function is only available when the RDCTLEN = '1'.

If RSTTOS = '0' it means that a timeout occurred.

Bits 7:0 Reserved, must be kept at reset value.

10.7.86 RCC backup domain control register (RCC_BDCR)

Address offset: 0x140

Reset value: 0x0000 0020

This register is used to control the LSE function. Wait states are inserted in case of successive write accesses to this register. The number of wait states may be up to 7 cycles of AHB4 clock.

After a system reset, the register RCC_BDCR is write-protected. In order to modify this register, the DBP bit in the PWR control register 1 (PWR_CR1) has to be set to '1'. Bits of RCC_BDCR register are only reset after a backup domain reset: nreset_vsw (see *Section 10.3.6: Backup domain reset*). Any other internal or external reset will not have any effect on these bits.

This register is located into the V_{SW} domain. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
VSWRST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTCCKEN	Res.	Res.	RTCSRC[1:0]

						r	rw			rw	rw	rw	r	rw	rw

Bit 31 **VSWRST**: V Switch domain software reset

Set and reset by software.

0: Reset not activated (default after backup domain reset)

1: Resets the entire V_{SW} domain

Bits 30:21 Reserved, must be kept at reset value.

Bit 20 **RTCCKEN**: RTC clock enable

Set and reset by software.

0: rtc_ck clock is disabled (default after backup domain reset)

1: rtc_ck clock enabled

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **RTCSRC[1:0]**: RTC clock source selection

Set by software to select the clock source for the RTC. This field can be written only one time after backup domain reset.

When a LSE failure occurs, the RTCSRC is set to '0', and the software is allowed to write it again once.

This field must be written before LSECSSON is enabled.

Refer to *Section : CSS on LSE* for details.

0x0: No clock (default after backup domain reset)

0x1: LSE clock used as RTC clock

0x2: LSI clock used as RTC clock

0x3: HSE clock divided by RTCDIV value is used as RTC clock

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSD**: LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the Clock Security System on the external 32 kHz oscillator.

0: No failure detected on 32 kHz oscillator (default after backup domain reset)
1: Failure detected on 32 kHz oscillator

Bit 8 **LSECSSON**: LSE clock security system enable

Set by software to enable the Clock Security System on 32 kHz oscillator.

Refer to *Section : CSS on LSE* for details on the activation and deactivation sequences.

Once the LSECSSON bit is enabled it cannot be disabled, except after a LSE failure detection (LSECSSD = '1').

0: Clock Security System on 32 kHz oscillator OFF (default after backup domain reset)
1: Clock Security System on 32 kHz oscillator ON

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.

0x0: Lowest drive
0x1: Medium low drive
0x2: Medium high drive (default after backup domain reset)
0x3: Highest drive

Bit 3 **DIGBYP**: LSE digital bypass

Set and reset by software to select the analog or digital bypass mode.

0: The LSE is in analog bypass mode (default after backup domain reset)

1: The LSE is in digital bypass mode

Bit 2 **LSERDY**: LSE oscillator ready

Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of lse_ck clock to fall down after LSEON has been set to '0'.

0: LSE oscillator not ready (default after backup domain reset)
1: LSE oscillator ready

Bit 1 **LSEBYP**: LSE oscillator bypass

Set and reset by software to bypass oscillator in debug mode.

This bit must not be written when the LSE is enabled (LSEON = '1').

Refer to *Section : Note as well that the signal csi_cal_ck is gated when the system goes to Stop.* for details.

0: LSE oscillator not bypassed (default after backup domain reset)
1: LSE oscillator bypassed

Bit 0 **LSEON**: LSE oscillator enabled

Set and reset by software.

0: LSE oscillator OFF (default after backup domain reset)
1: LSE oscillator ON

10.7.87 RCC reset duration and LSI control register (RCC_RDLSICR)

Address offset: 0x144

Reset value: 0x0000 0000

This register is used to control the minimum NRST active duration and LSI function.

0 to 7 wait states are inserted for word, half-word and byte accesses. Wait states are inserted in case of successive accesses to this register.

This register is reset by the por_rst reset, and it is located into the V_{DD} domain. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SPARE[4:0]					EADLY[2:0]			Res.	Res.	Res.	MRD[4:0]

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LSIRDY	LSION
														r	rw

Bits 31:27 **SPARE[4:0]**: Spare bits

Set and reset by software. Reserved for future use.

Bits 26:24 **EADLY[2:0]**: External access delays

Set and reset by software.

Time to wait before the BOOTROM performs any external access (UART, USB, QUADSPI, FMC, SDMMC,...)

0x0: 10 ms (default after reset)
0x1: No extra delay added by the BOOTROM
0x2: 100 us
0x3: 200 us
0x4: 500 us
0x5: 1 ms
0x6: 2 ms
0x7: 5 ms

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **MRD[4:0]**: Minimum Reset Duration

Set and reset by software. They define the minimum guaranteed duration of the NRST low pulse. The LSI oscillator is automatically enabled when needed by the RPCTL.

0x0: NRST low pulse duration is guaranteed by the pulse stretcher of the PAD. The RPCTL is bypassed (default after reset)
0x1: The guaranteed NRST low pulse duration is about 1 ms (1 x 32 lsi_ck cycles),
0x2: The guaranteed NRST low pulse duration is about 2 ms (2 x 32 lsi_ck cycles),
...
0x1F: The guaranteed NRST low pulse duration is about 31 ms (31 x 32 lsi_ck cycles).

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready

Set and reset by hardware to indicate when the LSI is stable. This bit needs 3 cycles of lsi_ck clock to fall down after LSION has been set to '0'.

0: LSI oscillator not ready (default after reset)
1: LSI oscillator ready

Bit 0 **LSION**: LSI oscillator enabled

Set and reset by software.

This bit is used to request the activation of the LSI oscillator. Note that IWDG1 and IWDG2 can also request the activation of LSI.

0: LSI oscillator is OFF if no other requester needs it, such as IWDG[2:1] (default after reset)
1: LSI oscillator ON

10.7.88 RCC clock source interrupt enable register (RCC_MP_CIER)

Address offset: 0x414

Reset value: 0x0000 0000

This register shall be used by the MPU to control the interrupt source enable. Refer to *Section 10.5: RCC interrupts* for more details. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WKUPIE**: Wake up from CStop Interrupt Enable

Set and reset by software to enable/disable the generation of the interrupt used to wake up the MPU from CStop.

0: Wakeup interrupt disabled (default after reset)

1: Wakeup interrupt enabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **LSECSSIE**: LSE clock security system Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the Clock Security System on external 32 kHz oscillator.

0: LSE CSS interrupt disabled (default after reset)

1: LSE CSS interrupt enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4DYIE**: PLL4 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL4 lock.

0: PLL4 lock interrupt disabled (default after reset)

1: PLL4 lock interrupt enabled

Bit 10 **PLL3DYIE**: PLL3 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL3 lock.

0: PLL3 lock interrupt disabled (default after reset)

1: PLL3 lock interrupt enabled

Bit 9 **PLL2DYIE**: PLL2 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL2 lock.

0: PLL2 lock interrupt disabled (default after reset)

1: PLL2 lock interrupt enabled

Bit 8 **PLL1DYIE**: PLL1 ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CSIRDYIE**: CSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 3 **HSERDYIE**: HSE ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 2 **HSIRDYIE**: HSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

10.7.89 RCC clock source interrupt flag register (RCC_MP_CIFR)

Address offset: 0x418

Reset value: 0x0000 0000

This register shall be used by the MPU in order to read and clear the interrupt flags.Writing '0' has no effect, writing '1' will clear the corresponding flag.Refer to *Section 10.5: RCC interrupts* for more details. If TZEN = '1', this register can only be modified in secure mode.

				rc_w1	rc_w1	rc_w1	rc_w1				rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WKUPF**: Wake up from CStop Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the MPU needs to exit from CStop.

0: No wakeup interrupt pending (default after reset)

1: Wakeup interrupt pending, writing '1' clears this flag

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **LSECSSF**: LSE clock security system Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when a failure is detected on the external 32 kHz oscillator.

0: No failure detected on the external 32 kHz oscillator (default after reset)

1: A failure is detected on the external 32 kHz oscillator, writing '1' clears this flag

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4DYF**: PLL4 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL4 locks.

0: No clock ready interrupt caused by PLL4 lock (default after reset)

1: Clock ready interrupt caused by PLL4 lock, writing '1' clears this flag

Bit 10 **PLL3DYF**: PLL3 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL3 locks.

0: No clock ready interrupt caused by PLL3 lock (default after reset)

1: Clock ready interrupt caused by PLL3 lock, writing '1' clears this flag

Bit 9 **PLL2DYF**: PLL2 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL2 locks.

0: No clock ready interrupt caused by PLL2 lock (default after reset)

1: Clock ready interrupt caused by PLL2 lock, writing '1' clears this flag

Bit 8 **PLL1DYF**: PLL1 ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the PLL1 locks.
0: No clock ready interrupt caused by PLL1 lock (default after reset)
1: Clock ready interrupt caused by PLL1 lock, writing '1' clears this flag

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CSIRDYF**: CSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the CSI clock becomes stable.
0: No clock ready interrupt caused by the CSI (default after reset)
1: Clock ready interrupt caused by the CSI, writing '1' clears this flag

Bit 3 **HSERDYF**: HSE ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the HSE clock becomes stable.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE, writing '1' clears this flag

Bit 2 **HSIRDYF**: HSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the HSI clock becomes stable.
0: No clock ready interrupt caused by the HSI (default after reset)
1: Clock ready interrupt caused by the HSI, writing '1' clears this flag

Bit 1 **LSERDYF**: LSE ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the LSE clock becomes stable.
0: No clock ready interrupt caused by the LSE (default after reset)
1: Clock ready interrupt caused by the LSE, writing '1' clears this flag

Bit 0 **LSIRDYF**: LSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the LSI clock becomes stable.
0: No clock ready interrupt caused by the LSI (default after reset)
1: Clock ready interrupt caused by the LSI, writing '1' clears this flag

10.7.90 RCC clock source interrupt enable register (RCC_MC_CIER)

Address offset: 0xC14

Reset value: 0x0000 0000

This register shall be used by the MCU to control the interrupt source enable. Refer to *Section 10.5: RCC interrupts* for more details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WKUPIE**: Wake up from CStop Interrupt Enable

Set and reset by software to enable/disable the generation of the interrupt used to wake up the MCU from CStop.

0: Wak-up interrupt disabled (default after reset)

1: Wakeup interrupt enabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **LSECSSIE**: LSE clock security system Interrupt Enable

Set and reset by software to enable/disable interrupt caused by the Clock Security System on external 32 kHz oscillator.

Note that the LSE security system feature must also be enabled (LSECSSON = '1'), in order to generate interrupts.

0: LSE CSS interrupt disabled (default after reset)

1: LSE CSS interrupt enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4DYIE**: PLL4 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL4 lock.

0: PLL4 lock interrupt disabled (default after reset)

1: PLL4 lock interrupt enabled

Bit 10 **PLL3DYIE**: PLL3 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL3 lock.

0: PLL3 lock interrupt disabled (default after reset)

1: PLL3 lock interrupt enabled

Bit 9 **PLL2DYIE**: PLL2 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL2 lock.

0: PLL2 lock interrupt disabled (default after reset)

1: PLL2 lock interrupt enabled

Bit 8 **PLL1DYIE**: PLL1 ready Interrupt Enable

Set and reset by software to enable/disable interrupt caused by PLL1 lock.

0: PLL1 lock interrupt disabled (default after reset)

1: PLL1 lock interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CSIRDYIE**: CSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 3 **HSERDYIE**: HSE ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 2 **HSIRDYIE**: HSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready Interrupt Enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

10.7.91 RCC clock source interrupt flag register (RCC_MC_CIFR)

Address offset: 0xC18

Reset value: 0x0000 0000

This register shall be used by the MCU in order to read and clear the interrupt flags.Writing '0' has no effect, writing '1' will clear the corresponding flag.Refer to *Section 10.5: RCC interrupts* for more details.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **WKUPF**: Wake up from CStop Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the MCU needs to exit from CStop.

0: No wakeup interrupt pending (default after reset)

1: Wakeup interrupt pending, writing '1' clears this flag

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **LSECSSF**: LSE clock security system Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when a failure is detected on the external 32 kHz oscillator.

0: No failure detected on the external 32 kHz oscillator (default after reset)

1: A failure is detected on the external 32 kHz oscillator, writing '1' clears this flag

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **PLL4DYF**: PLL4 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL4 locks.

0: No clock ready interrupt caused by PLL4 lock (default after reset)

1: Clock ready interrupt caused by PLL4 lock, writing '1' clears this flag

Bit 10 **PLL3DYF**: PLL3 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL3 locks.

0: No clock ready interrupt caused by PLL3 lock (default after reset)

1: Clock ready interrupt caused by PLL3 lock, writing '1' clears this flag

Bit 9 **PLL2DYF**: PLL2 ready Interrupt Flag

Reset by software by writing this flag to '1'.

Set by hardware when the PLL2 locks.

0: No clock ready interrupt caused by PLL2 lock (default after reset)

1: Clock ready interrupt caused by PLL2 lock, writing '1' clears this flag

Bit 8 **PLL1DYF**: PLL1 ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the PLL1 locks.
0: No clock ready interrupt caused by PLL1 lock (default after reset)
1: Clock ready interrupt caused by PLL1 lock, writing '1' clears this flag

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CSIRDYF**: CSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the CSI clock becomes stable.
0: No clock ready interrupt caused by the CSI (default after reset)
1: Clock ready interrupt caused by the CSI, writing '1' clears this flag

Bit 3 **HSERDYF**: HSE ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the HSE clock becomes stable.
0: No clock ready interrupt caused by the HSE (default after reset)
1: Clock ready interrupt caused by the HSE, writing '1' clears this flag

Bit 2 **HSIRDYF**: HSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the HSI clock becomes stable.
0: No clock ready interrupt caused by the HSI (default after reset)
1: Clock ready interrupt caused by the HSI, writing '1' clears this flag

Bit 1 **LSERDYF**: LSE ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the LSE clock becomes stable.
0: No clock ready interrupt caused by the LSE (default after reset)
1: Clock ready interrupt caused by the LSE, writing '1' clears this flag

Bit 0 **LSIRDYF**: LSI ready Interrupt Flag
Reset by software by writing this flag to '1'.
Set by hardware when the LSI clock becomes stable.
0: No clock ready interrupt caused by the LSI (default after reset)
1: Clock ready interrupt caused by the LSI, writing '1' clears this flag

10.7.92 RCC PWR_LP delay control register (RCC_PWRLPDLYCR)

Address offset: 0x41C

Reset value: 0x0000 0000

This register is used to program the delay between the moment where the system exits from one of the Stop modes, and the moment where it is allowed to enable the PLLs and provide a clock to bridges and processors. If TZEN = '1', this register can only be modified in secure mode. Write access to this register is not allowed during the clock restore sequence. See *Section : The clock restore sequence description* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCTMPSKP	Res.	Res.	PWRLP_DLY[21:16]					
							rw			rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PWRLP_DLY[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **MCTMPSKP**: Skip the PWR_DLY for MCU
Set and Reset by software.
This bit is used by the clock restore sequence to skip the PWRLP_TEMPO Delay for the restore of the mcuss_ck when the system exits from one of the Stop modes.
0: The clock restore sequence of the MCU waits for the PWRLP_TEMPO delay before activating power consuming elements (default after reset)
1: The clock restore sequence of the MCU runs the PWRLP_TEMPO delay but did not wait for the delay to elapse before activating power consuming elements

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:0 **PWRLP_DLY[21:0]**: PWRLP_TEMPO value
Set and Reset by software.
This register contains the delay value to be observed before activating the PLLs and interconnect clocks, after one of the system Stop.
The delay is counted with the HSI clock. The user has to take into account HSIDIV value.
The delay value is given by the following formula: PWRLP_DLY[21:0] / FHSI
0x0: The PWRLP_TEMPO delay is bypassed (default after reset)
0x1: A PWRLP_TEMPO delay of one period of HSI (at 64 MHz) is observed
...
0x3FFFFF: A PWRLP_TEMPO delay of about 65.5 milliseconds is observed

10.7.93 RCC APB1 peripheral reset set register (RCC_APB1RSTSETR)

Address offset: 0x980

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Bit 31 **MDIOSRST**: MDIOS block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DAC12RST**: DAC1 and 2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECRST**: HDMI-CEC block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 26 **SPDIFRST**: SPDIFRX block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 25 Reserved, must be kept at reset value.

Bit 24 **I2C5RST**: I2C5 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 23 **I2C3RST**: I2C3 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 22 **I2C2RST**: I2C2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 21 **I2C1RST**: I2C1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8RST**: UART8 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 18 **UART7RST**: UART7 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 17 **UART5RST**: UART5 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 16 **UART4RST**: UART4 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 15 **USART3RST**: USART3 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 14 **USART2RST**: USART2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3RST**: SPI3 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 11 **SPI2RST**: SPI2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 8 **TIM14RST**: TIM14 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 7 **TIM13RST**: TIM13 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 6 **TIM12RST**: TIM12 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 5 **TIM7RST**: TIM7 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 4 **TIM6RST**: TIM6 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 3 **TIM5RST**: TIM5 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 2 **TIM4RST**: TIM4 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 1 **TIM3RST**: TIM3 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 0 **TIM2RST**: TIM2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

10.7.94 RCC APB1 peripheral reset clear register (RCC_APB1RSTCLRR)

Address offset: 0x984

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 17 **UART5RST**: UART5 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 16 **UART4RST**: UART4 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 15 **USART3RST**: USART3 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 14 **USART2RST**: USART2 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3RST**: SPI3 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 11 **SPI2RST**: SPI2 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 8 **TIM14RST**: TIM14 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 7 **TIM13RST**: TIM13 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 6 **TIM12RST**: TIM12 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 5 **TIM7RST**: TIM7 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 4 **TIM6RST**: TIM6 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 3 **TIM5RST**: TIM5 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 2 **TIM4RST**: TIM4 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 1 **TIM3RST**: TIM3 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

Bit 0 **TIM2RST**: TIM2 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' release the block reset, reading '1' means that the block reset is asserted

10.7.95 RCC APB2 peripheral reset set register (RCC_APB2RSTSETR)

Address offset: 0x988

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANRST**: FDCAN block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **DFSDMRST**: DFSDM block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3RST**: SAI3 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 17 **SAI2RST**: SAI2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 16 **SAI1RST**: SAI1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6RST**: USART6 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5RST**: SPI5 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 9 **SPI4RST**: SPI4 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 8 **SPI1RST**: SPI/I2S1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17RST**: TIM17 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 3 **TIM16RST**: TIM16 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 2 **TIM15RST**: TIM15 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 1 **TIM8RST**: TIM8 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 0 **TIM1RST**: TIM1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

10.7.96 RCC APB2 peripheral reset clear register (RCC_APB2RSTCLRR)

Address offset: 0x98C

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANRST**: FDCAN block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **DFSDMRST**: DFSDM block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3RST**: SAI3 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 17 **SAI2RST**: SAI2 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 16 **SAI1RST**: SAI1 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6RST**: USART6 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5RST**: SPI5 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 9 **SPI4RST**: SPI4 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 8 **SPI1RST**: SPI/I2S1 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17RST**: TIM17 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 3 **TIM16RST**: TIM16 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 2 **TIM15RST**: TIM15 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 1 **TIM8RST**: TIM8 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 0 **TIM1RST**: TIM1 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

10.7.97 RCC APB3 peripheral reset set register (RCC_APB3RSTSETR)

Address offset: 0x990

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Bit 16 **DTSRST**: DTS block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **VREFRST**: VREF block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 12 Reserved, must be kept at reset value.

Bit 11 **SYSCFGRST**: SYSCFG block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **SAI4RST**: SAI4 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **LPTIM5RST**: LPTIM5 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 2 **LPTIM4RST**: LPTIM4 block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 1 **LPTIM3RST**: LPTIM3 block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 0 **LPTIM2RST**: LPTIM2 block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

10.7.98 RCC APB3 peripheral reset clear register (RCC_APB3RSTCLRR)

Address offset: 0x994

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **VREFRST**: VREF block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 12 Reserved, must be kept at reset value.

Bit 11 **SYSCFGRST**: SYSCFG block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **SAI4RST**: SAI4 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **LPTIM5RST**: LPTIM5 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 2 **LPTIM4RST**: LPTIM4 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 1 **LPTIM3RST**: LPTIM3 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 0 **LPTIM2RST**: LPTIM2 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

10.7.99 RCC AHB2 peripheral reset set register (RCC_AHB2RSTSETR)

Address offset: 0x998

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SDMMC3RST**: SDMMC3 and the SDMMC3 delay (DLYBSD3) block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **USBORST**: USBO block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **ADC12RST**: ADC1 and 2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **DMAMUXRST**: DMAMUX block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 1 **DMA2RST**: DMA2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 0 **DMA1RST**: DMA1 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

10.7.100 RCC AHB2 peripheral reset clear register (RCC_AHB2RSTCLRR)

Address offset: 0x99C

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **USBORST**: USBO block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **ADC12RST**: ADC1 and 2 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **DMAMUXRST**: DMAMUX block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 1 **DMA2RST**: DMA2 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 0 **DMA1RST**: DMA1 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

10.7.101 RCC AHB3 peripheral reset set register (RCC_AHB3RSTSETR)

Address offset: 0x9A0

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **IPCCRST**: IPCC block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 11 **HSEMRST**: HSEM block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **CRC2RST**: CRC2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 6 **RNG2RST**: RNG2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 5 **HASH2RST**: HASH2 block reset
Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 4 **CRYP2RST**: CRYP2 (3DES/AES2) block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIRST**: DCMI block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

10.7.102 RCC AHB3 peripheral reset clear register (RCC_AHB3RSTCLRR)

Address offset: 0x9A4

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **IPCCRST**: IPCC block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 11 **HSEMRST**: HSEM block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **CRC2RST**: CRC2 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 6 **RNG2RST**: RNG2 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 5 **HASH2RST**: HASH2 block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 4 **CRYP2RST**: CRYP2 (3DES/AES2) block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMIRST**: DCMI block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

10.7.103 RCC AHB4 peripheral reset set register (RCC_AHB4RSTSETR)

Address offset: 0x9A8

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral.

Set by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCRST**: FMC block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ETHMACRST**: ETH block reset

Set by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' asserts the block reset, reading '1' means that the block reset is asserted

Bits 9:0 Reserved, must be kept at reset value.

10.7.112 RCC AHB6 peripheral reset clear register (RCC_AHB6RSTCLRR)

Address offset: 0x19C

Reset value: 0x0000 0000

This register is used to release the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' releases the reset of the corresponding peripheral.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **USBHRST**: USBH block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **CRC1RST**: CRC1 block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **SDMMC2RST**: SDMMC2 and the SDMMC2 delay (DLYBSD2) block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 16 **SDMMC1RST**: SDMMC1 and the SDMMC1 delay (DLYBSD1) block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPIRST**: QUADSPI and the QUADSPI delay block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCRST**: FMC block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bit 11 Reserved, must be kept at reset value.

Bit 10 **ETHMACRST**: ETH block reset

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

Bits 9:0 Reserved, must be kept at reset value.

10.7.113 RCC AHB6 secure peripheral reset set register (RCC_TZAHB6RSTSETR)

Address offset: 0x1A0

Reset value: 0x0000 0000

This register is used to activate the reset of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' activates the reset of the corresponding peripheral. If TZEN = '1', this register can only be modified in secure mode.

Bit 0 **MDMARST**: MDMA block reset
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the block reset is released
1: Writing '1' releases the block reset, reading '1' means that the block reset is asserted

10.7.115 RCC global reset control set register (RCC_MP_GRSTCSETR)

Address offset: 0x404

Reset value: 0x0000 0000

This register is used by the MPU in order to generate either a MCU reset or a system reset or a reset of one of the two MPU processors. Writing '0' has no effect, reading returns the effective values of the corresponding bits. Writing a '1' activates the reset. The MCU cannot modify this register. If TZEN = '1', this register can only be modified in secure mode.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MPUP1RST	MPUP0RST	Res.	Res.	MCURST	MPSYSRST
										rs	rs			rs	rs

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **MPUP1RST**: MPU processor 1 reset

Set by software, cleared by hardware when the reset command is completed.

Note that the Snoop Control Unit of the MPU (SCU) is not reset.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' generate a reset of the MPU processor 1, reading '1' means that the block reset is asserted

Bit 4 **MPUP0RST**: MPU processor 0 reset

Set by software, cleared by hardware when the reset command is completed.

Note that the Snoop Control Unit of the MPU (SCU) is not reset.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' generate a reset of the MPU processor 0, reading '1' means that the block reset is asserted

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **MCURST**: MCU reset

Set by software, cleared by hardware when the reset command is completed.

It is recommended to set the MCU to CSleep before setting the MCURST bit to ‘1’.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' generate a reset of the MCU core, reading '1' means that the block reset is asserted

Bit 0 **MPSYSRST**: System reset

Set by software, cleared by hardware.

0: Writing '0' has no effect, reading '0' means that the block reset is released

1: Writing '1' generate a system reset, see *Figure 47*.

10.7.116 RCC APB1 peripheral enable for MPU set register (RCC_MP_APB1ENSETR)

Address offset: 0xA00

Reset value: 0x0000 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MPU. Writing '0' has no effect, reading will return the effective value of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 31 **MDIOSEN**: MDIOS peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DAC12EN**: DAC1 and 2 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECEN**: HDMI-CEC peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 26 **SPDIFEN**: SPDIFRX peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 25 Reserved, must be kept at reset value.

Bit 24 **I2C5EN**: I2C5 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 23 **I2C3EN**: I2C3 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 22 **I2C2EN**: I2C2 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 21 **I2C1EN**: I2C1 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8EN**: UART8 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 18 **UART7EN**: UART7 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 17 **UART5EN**: UART5 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 16 **UART4EN**: UART4 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 15 **USART3EN**: USART3 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 14 **USART2EN**: USART2 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3EN**: SPI3 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 11 **SPI2EN**: SPI2 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 8 **TIM14EN**: TIM14 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 7 **TIM13EN**: TIM13 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 6 **TIM12EN**: TIM12 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 5 **TIM7EN**: TIM7 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 4 **TIM6EN**: TIM6 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 3 **TIM5EN**: TIM5 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 2 **TIM4EN**: TIM4 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 1 **TIM3EN**: TIM3 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 0 **TIM2EN**: TIM2 peripheral clocks enable
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.117 RCC APB1 peripheral enable for MCU set register (RCC_MC_APB1ENSETR)

Address offset: 0xA80

Reset value: 0x0000 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MCU. Writing '0' has no effect, reading will return '0'. Writing a '1' sets the corresponding bit to '1'.

Bit 31 **MDIOSEN**: MDIOS peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DAC12EN**: DAC1 and 2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECEN**: HDMI-CEC peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 26 **SPDIFEN**: SPDIFRX peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 25 Reserved, must be kept at reset value.

Bit 24 **I2C5EN**: I2C5 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 23 **I2C3EN**: I2C3 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 22 **I2C2EN**: I2C2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 21 **I2C1EN**: I2C1 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8EN**: UART8 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 18 **UART7EN**: UART7 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 17 **UART5EN**: UART5 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 16 **UART4EN**: UART4 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 15 **USART3EN**: USART3 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 14 **USART2EN**: USART2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3EN**: SPI3 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 11 **SPI2EN**: SPI2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 8 **TIM14EN**: TIM14 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 7 **TIM13EN**: TIM13 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 6 **TIM12EN**: TIM12 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 5 **TIM7EN**: TIM7 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 4 **TIM6EN**: TIM6 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 3 **TIM5EN**: TIM5 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 2 **TIM4EN**: TIM4 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 1 **TIM3EN**: TIM3 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 0 **TIM2EN**: TIM2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.119 RCC APB1 peripheral enable for MCU clear register (RCC_MC_APB1ENCLRR)

Address offset: 0xA84

Reset value: 0x0000 0000

This register is used to clear the peripheral clock enable bit of the corresponding peripheral. It shall be used to deallocate a peripheral from MCU. Writing '0' has no effect, reading will return '0'. Writing a '1' sets the corresponding bit to '0'.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANEN**: FDCAN and CANRAM peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ADFSDMEN**: Audio DFSDM peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 20 **DFSDMEN**: DFSDM peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3EN**: SAI3 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 17 **SAI2EN**: SAI2 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 16 **SAI1EN**: SAI1 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6EN**: USART6 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5EN**: SPI5 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 9 **SPI4EN**: SPI4 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 8 **SPI1EN**: SPI/I2S1 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17EN**: TIM17 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 3 **TIM16EN**: TIM16 peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 2 **TIM15EN**: TIM15 peripheral clocks enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 1 **TIM8EN**: TIM8 peripheral clocks enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 0 **TIM1EN**: TIM1 peripheral clocks enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.123 RCC APB2 peripheral enable for MCU clear register (RCC_MC_APB2ENCLRR)

Address offset: 0xA8C

Reset value: 0x0000 0000

This register is used to clear the peripheral clock enable bit of the corresponding peripheral. It shall be used to deallocate a peripheral from MCU. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '0'.

1: Writing '1' enables the APB clock, reading '1' means that the APB clock is enabled

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **LTDCEN**: LTDC peripheral clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled

1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.129 RCC APB4 peripheral enable for MPU set register (RCC_MP_APB4ENSETR)

Address offset: 0x200

Reset value: 0x0000 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MPU. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 8 **BKPSRAMEN**: BKPSRAM clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **RNG1EN**: RNG1 peripheral clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 5 **HASH1EN**: HASH1 peripheral clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bit 4 **CRYP1EN**: CRYP1 (3DES/AES1) peripheral clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **GPIOZEN**: GPIOZ Secure peripheral clocks enable

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' enables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.137 RCC AHB5 peripheral enable for MPU set register (RCC_MP_AHB5ENSETR)

Address offset: 0x210

Reset value: 0x0001 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MPU. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. If TZEN = '1', this register can only be modified in secure mode.

0: Writing '0' has no effect, reading '0' means that eth_ker_ck clock is disabled
1: Writing '1' disables the eth_ker_ck clock, reading '1' means that the eth_ker_ck clock is enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:1 Reserved, must be kept at reset value.

Bit 0 **MDMAEN**: MDMA peripheral clocks enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled
1: Writing '1' disables the peripheral clocks, reading '1' means that the peripheral clocks are enabled

10.7.144 RCC AHB6 secure peripheral enable for MPU set register (RCC_MP_TZAHB6ENSETR)

Address offset: 0x220

Reset value: 0x0000 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MPU. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. If TZEN = '1', this register can only be modified in secure mode.

10.7.154 RCC AHB4 peripheral enable for MPU set register (RCC_MP_AHB4ENSETR)

Address offset: 0xA28

Reset value: 0x0000 0000

This register is used to set the peripheral clock enable bit of the corresponding peripheral to '1'. It shall be used to allocate a peripheral to the MPU. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 28 Reserved, must be kept at reset value.

Bit 27 **CECLPEN**: HDMI-CEC peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 26 **SPDIFLPEN**: SPDIFRX peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 25 Reserved, must be kept at reset value.

Bit 24 **I2C5LPEN**: I2C5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 23 **I2C3LPEN**: I2C3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 22 **I2C2LPEN**: I2C2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 21 **I2C1LPEN**: I2C1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8LPEN**: UART8 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 18 **UART7LPEN**: UART7 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **UART5LPEN**: UART5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **UART4LPEN**: UART4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 **USART3LPEN**: USART3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 14 **USART2LPEN**: USART2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3LPEN**: SPI3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **SPI2LPEN**: SPI2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **TIM14LPEN**: TIM14 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 7 **TIM13LPEN**: TIM13 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 6 **TIM12LPEN**: TIM12 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 5 **TIM7LPEN**: TIM7 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 4 **TIM6LPEN**: TIM6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM5LPEN**: TIM5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM4LPEN**: TIM4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM3LPEN**: TIM3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM2LPEN**: TIM2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.165 RCC APB1 sleep clock enable for MCU set register (RCC_MC_APB1LPENSETR)

Address offset: 0xB80

Reset value: 0xBDEF DBFF

This register is used by the MCU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 21 **I2C1LPEN**: I2C1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8LPEN**: UART8 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 18 **UART7LPEN**: UART7 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **UART5LPEN**: UART5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **UART4LPEN**: UART4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 **USART3LPEN**: USART3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 14 **USART2LPEN**: USART2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3LPEN**: SPI3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **SPI2LPEN**: SPI2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **TIM14LPEN**: TIM14 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 7 **TIM13LPEN**: TIM13 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 6 **TIM12LPEN**: TIM12 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 5 **TIM7LPEN**: TIM7 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 4 **TIM6LPEN**: TIM6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM5LPEN**: TIM5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM4LPEN**: TIM4 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM3LPEN**: TIM3 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM2LPEN**: TIM2 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.166 RCC APB1 sleep clock enable MPU clear register (RCC_MP_APB1LPENCLRR)

Address offset: 0xB04

Reset value: 0xADEF DBFF

This register is used by the MPU in order to clear the PERxLPEN bits of the corresponding peripherals located into the APB1 bus. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '0'.

Bit 31 **MDIOSLPEN**: MDIOS peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 30 Reserved, must be kept at reset value.

Bit 29 **DAC12LPEN**: DAC1 and 2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 28 **WWDG1LPEN**: WWDG1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 27 **CECLPEN**: HDMI-CEC peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 26 **SPDIFLPEN**: SPDIFRX peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 25 Reserved, must be kept at reset value.

Bit 24 **I2C5LPEN**: I2C5 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 23 **I2C3LPEN**: I2C3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 22 **I2C2LPEN**: I2C2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 21 **I2C1LPEN**: I2C1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 Reserved, must be kept at reset value.

Bit 19 **UART8LPEN**: UART8 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 18 **UART7LPEN**: UART7 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **UART5LPEN**: UART5 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **UART4LPEN**: UART4 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 **USART3LPEN**: USART3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 14 **USART2LPEN**: USART2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **SPI3LPEN**: SPI3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **SPI2LPEN**: SPI2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **TIM14LPEN**: TIM14 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 7 **TIM13LPEN**: TIM13 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 6 **TIM12LPEN**: TIM12 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 5 **TIM7LPEN**: TIM7 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 4 **TIM6LPEN**: TIM6 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM5LPEN**: TIM5 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM4LPEN**: TIM4 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM3LPEN**: TIM3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM2LPEN**: TIM2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.168 RCC APB2 sleep clock enable for MPU set register (RCC_MP_APB2LPENSETR)

Address offset: 0xB08

Reset value: 0x0137 271F

This register is used by the MPU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

		rs			rs	rs	rs				rs	rs	rs	rs	rs

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANLPEN**: FDCAN and CANRAM peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ADFSDMLPEN**: Audio DFSDM peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 **DFSDMLPEN**: DFSDM peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3LPEN**: SAI3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **SAI2LPEN**: SAI2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SAI1LPEN**: SAI1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6LPEN**: USART6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5LPEN**: SPI5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 9 **SPI4LPEN**: SPI4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **SPI1LPEN**: SPI/I2S1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17LPEN**: TIM17 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM16LPEN**: TIM16 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM15LPEN**: TIM15 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM8LPEN**: TIM8 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM1LPEN**: TIM1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.169 RCC APB2 sleep clock enable for MCU set register (RCC_MC_APB2LPENSETR)

Address offset: 0xB88

Reset value: 0x0137 271F

This register is used by the MCU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANLPEN**: FDCAN and CANRAM peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ADFSDMLPEN**: Audio DFSDM peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 **DFSDMLPEN**: DFSDM peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3LPEN**: SAI3 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **SAI2LPEN**: SAI2 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SAI1LPEN**: SAI1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6LPEN**: USART6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5LPEN**: SPI5 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 9 **SPI4LPEN**: SPI4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **SPI1LPEN**: SPI/I2S1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17LPEN**: TIM17 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM16LPEN**: TIM16 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM15LPEN**: TIM15 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM8LPEN**: TIM8 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM1LPEN**: TIM1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.170 RCC APB2 sleep clock enable for MPU clear register (RCC_MP_APB2LPENCLRR)

Address offset: 0xB0C

Reset value: 0x0137 271F

This register is used by the MPU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 24 **FDCANLPEN**: FDCAN and CANRAM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ADFSDMLPEN**: Audio DFSDM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 **DFSDMLPEN**: DFSDM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3LPEN**: SAI3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **SAI2LPEN**: SAI2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SAI1LPEN**: SAI1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6LPEN**: USART6 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5LPEN**: SPI5 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 9 **SPI4LPEN**: SPI4 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **SPI1LPEN**: SPI/I2S1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17LPEN**: TIM17 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM16LPEN**: TIM16 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM15LPEN**: TIM15 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM8LPEN**: TIM8 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM1LPEN**: TIM1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.171 RCC APB2 sleep clock enable for MCU clear register (RCC_MC_APB2LPENCLRR)

Address offset: 0xB8C

Reset value: 0x0137 271F

This register is used by the MCU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **FDCANLPEN**: FDCAN and CANRAM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **ADFSDMLPEN**: Audio DFSDM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 20 **DFSDMLPEN**: DFSDM peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 19 Reserved, must be kept at reset value.

Bit 18 **SAI3LPEN**: SAI3 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 17 **SAI2LPEN**: SAI2 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SAI1LPEN**: SAI1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **USART6LPEN**: USART6 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **SPI5LPEN**: SPI5 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 9 **SPI4LPEN**: SPI4 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 8 **SPI1LPEN**: SPI/I2S1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TIM17LPEN**: TIM17 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **TIM16LPEN**: TIM16 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **TIM15LPEN**: TIM15 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 **TIM8LPEN**: TIM8 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 0 **TIM1LPEN**: TIM1 peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.172 RCC APB3 sleep clock enable for MPU set register (RCC_MP_APB3LPENSETR)

Address offset: 0xB10

Reset value: 0x0003 290F

This register is used by the MPU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 0 **LTDCLPEN**: LTDC peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.178 RCC APB4 sleep clock enable for MCU clear register (RCC_MC_APB4LPENCLRR)

Address offset: 0x384

Reset value: 0x0011 0111

This register is used by the MCU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **STGENROSTPEN**: STGEN Read-Only Interface clock enable during CStop mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CStop
1: Writing '1' disables the clock in CStop, reading '1' means that the clock are enabled in CStop

Bit 20 **STGENROLPEN**: STGEN Read-Only Interface peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **USBPHYLPEN**: USBPHYC peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **DDRPERFMLPEN**: DDRPERFM APB clock enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the APB clock is disabled in CSleep
1: Writing '1' disables the APB clock in CSleep, reading '1' means that the APB clock is enabled in CSleep

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **LTDCLPEN**: LTDC peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.179 RCC APB4 sleep clock enable for MPU clear register (RCC_MP_APB4LPENCLRR)

Address offset: 0x304

Reset value: 0x0011 8111

This register is used by the MPU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 21 **STGENSTPEN**: STGEN Controller part, peripheral clocks enable during CStop mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CStop
1: Writing '1' enables the peripheral clocks in CStop, reading '1' means that the peripheral clocks are enabled in CStop

Bit 20 **STGENLPEN**: STGEN Controller part, peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BSECLPEN**: BSEC peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **TZPCLPEN**: TZPC peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 12 **TZC2LPEN**: TZC AXI port 2 peripheral clocks enable during CSleep mode
Set by software. See *Section : Clock distribution for TZC* for details.
0: Writing '0' has no effect, reading '0' means that the clocks are disabled for AXI port 2 in CSleep
1: Writing '1' enables the pclk5 and aclk_tzc2 clocks in CSleep, reading '1' means that the clocks are enabled for AXI port 2 in CSleep

Bit 11 **TZC1LPEN**: TZC AXI port 1 peripheral clocks enable during CSleep mode
Set by software. See *Section : Clock distribution for TZC* for details.
0: Writing '0' has no effect, reading '0' means that the clocks are disabled for AXI port 1 in CSleep
1: Writing '1' enables the pclk5 and aclk_tzc1 clocks in CSleep, reading '1' means that the clocks are enabled for AXI port 1 in CSleep

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **RTCAPBLPEN**: RTC APB clock enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **USART1LPEN**: USART1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 3 **I2C6LPEN**: I2C6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 2 **I2C4LPEN**: I2C4 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 1 Reserved, must be kept at reset value.

Bit 0 **SPI6LPEN**: SPI6 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.181 RCC APB5 sleep clock enable for MPU set register (RCC_MP_APB5LPENSETR)

Address offset: 0x308

Reset value: 0x0011 B91D

This register is used by the MPU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. If TZEN = '1', this register can only be modified in secure mode.

Bit 21 **STGENSTPEN**: STGEN Controller part, peripheral clocks enable during CStop mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CStop

1: Writing '1' enables the peripheral clocks in CStop, reading '1' means that the peripheral clocks are enabled in CStop

Bit 20 **STGENLPEN**: STGEN Controller part, peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BSECLPEN**: BSEC peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 **IWDG1APBLPEN**: IWDG1 APB clock enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the APB clock is disabled in CSleep

1: Writing '1' enables the APB clock in CSleep, reading '1' means that the APB clock is enabled in CSleep

Bit 14 Reserved, must be kept at reset value.

Bit 13 **TZPCLPEN**: TZPC peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 12 **TZC2LPEN**: TZC AXI port 2 peripheral clocks enable during CSleep mode

Set by software. See *Section : Clock distribution for TZC* for details.

0: Writing '0' has no effect, reading '0' means that the clocks are disabled for AXI port 2 in CSleep

1: Writing '1' enables the pclk5 and aclk_tzc2 clocks in CSleep, reading '1' means that the clocks are enabled for AXI port 2 in CSleep

Bit 11 **TZC1LPEN**: TZC AXI port 1 peripheral clocks enable during CSleep mode

Set by software. See *Section : Clock distribution for TZC* for details.

0: Writing '0' has no effect, reading '0' means that the clocks are disabled for AXI port 1 in CSleep

1: Writing '1' enables the pclk5 and aclk_tzc1 clocks in CSleep, reading '1' means that the clocks are enabled for AXI port 1 in CSleep

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **RTCAPBLPEN**: RTC APB clock enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 7:5 Reserved, must be kept at reset value.

1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.184 RCC AHB5 peripheral enable for MPU set register (RCC_MP_AHB5LPENSETR)

Address offset: 0x310

Reset value: 0x0000 0171

This register is used by the MPU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. If TZEN = '1', this register can only be modified in secure mode.

Bit 20 **CRC1LPEN**: CRC1 peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay (DLYBSD2) block peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay (DLYBSD1) block peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPILPEN**: QUADSPI peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCLPEN**: FMC peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **ETHSTPEN**: ETH peripheral clock enable during CStop mode

Allows the ETH block to receive the clock coming from pads ETH_TX_CLK and ETH_RX_CLK during CStop.

Set by software.

0: Writing '0' has no effect, reading '0' means that the ETH RX and TX kernel clocks are gated in CStop

1: Writing '1' enables the ETH RX and TX kernel clocks in CStop, reading '1' means that the ETH RX and TX kernel clocks are enabled in CStop

Bit 10 **ETHMACLPEN**: Enable of the bus interface clocks for ETH block during CSleep mode

The bus interface clocks for ETH are hclk6 and aclk.

Set by software.

0: Writing '0' has no effect, reading '0' means that the bus interface clocks are disabled in CSleep

1: Writing '1' enables the bus interface clocks in CSleep, reading '1' means that the bus interface clocks are enabled in CSleep

Bit 9 **ETHRXLPEN**: Enable of the Ethernet Reception Clock during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the reception clock is disabled in CSleep

1: Writing '1' enables the reception clock in CSleep, reading '1' means that the reception clock is enabled in CSleep

Bit 8 **ETHTXLPEN**: Enable of the Ethernet Transmission Clock during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the transmission clock is disabled in CSleep

1: Writing '1' enables the transmission clock in CSleep, reading '1' means that the transmission clock is enabled in CSleep

Bit 7 **ETHCKLPEN**: Enable of the Ethernet clock generated by the RCC (eth_ker_ck) during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that eth_ker_ck clock is disabled in CSleep

1: Writing '1' enables the eth_ker_ck clock in CSleep, reading '1' means that the eth_ker_ck clock is enabled in CSleep

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **MDMALPEN**: MDMA peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.189 RCC AHB6 sleep clock enable for MCU set register (RCC_MC_AHB6LPENSETR)

Address offset: 0x398

Reset value: 0x0113 57A1

This register is used by the MCU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 17 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay (DLYBSD2) block peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay (DLYBSD1) block peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPILPEN**: QUADSPI peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCLPEN**: FMC peripheral clocks enable during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **ETHSTPEN**: ETH peripheral clock enable during CStop mode
Allows the ETH block to receive the clock coming from pads ETH_TX_CLK and ETH_RX_CLK during CStop.
Set by software.
0: Writing '0' has no effect, reading '0' means that the ETH RX and TX kernel clocks are gated in CStop
1: Writing '1' enables the ETH RX and TX kernel clocks in CStop, reading '1' means that the ETH RX and TX kernel clocks are enabled in CStop

Bit 10 **ETHMACLPEN**: Enable of the bus interface clocks for ETH block during CSleep mode
The bus interface clocks for ETH are hclk6 and aclk.
Set by software.
0: Writing '0' has no effect, reading '0' means that the bus interface clocks are disabled in CSleep
1: Writing '1' enables the bus interface clocks in CSleep, reading '1' means that the bus interface clocks are enabled in CSleep

Bit 9 **ETHRXLPEN**: Enable of the Ethernet Reception Clock during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the reception clock is disabled in CSleep
1: Writing '1' enables the reception clock in CSleep, reading '1' means that the reception clock is enabled in CSleep

Bit 8 **ETHTXLPEN**: Enable of the Ethernet Transmission Clock during CSleep mode
Set by software.
0: Writing '0' has no effect, reading '0' means that the transmission clock is disabled in CSleep
1: Writing '1' enables the transmission clock in CSleep, reading '1' means that the transmission clock is enabled in CSleep

Bit 7 **ETHCKLPEN**: Enable of the Ethernet clock generated by the RCC (eth_ker_ck) during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that eth_ker_ck clock is disabled in CSleep
1: Writing '1' enables the eth_ker_ck clock in CSleep, reading '1' means that the eth_ker_ck clock is enabled in CSleep

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **MDMALPEN**: MDMA peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.190 RCC AHB6 sleep clock enable for MPU clear register (RCC_MP_AHB6LPENCLRR)

Address offset: 0x31C

Reset value: 0x0113 57A1

This register is used by the MPU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Cleared by software.

0: Writing '0' has no effect, reading '0' means that eth_ker_ck clock is disabled in CSleep

1: Writing '1' disables the eth_ker_ck clock in CSleep, reading '1' means that the eth_ker_ck clock is enabled in CSleep

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **MDMALPEN**: MDMA peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.191 RCC AHB6 sleep clock enable for MCU clear register (RCC_MC_AHB6LPENCLRR)

Address offset: 0x39C

Reset value: 0x0113 57A1

This register is used by the MCU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Bit 24 **USBHLPEN**: USBH peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **CRC1LPEN**: CRC1 peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay (DLYBSD2) block peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 16 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay (DLYBSD1) block peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 15 Reserved, must be kept at reset value.

Bit 14 **QSPILPEN**: QUADSPI peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 13 Reserved, must be kept at reset value.

Bit 12 **FMCLPEN**: FMC peripheral clocks enable during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 11 **ETHSTPEN**: ETH peripheral clock enable during CStop mode
Allows the ETH block to receive the clock coming from pads ETH_TX_CLK and ETH_RX_CLK during CStop.
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the ETH RX and TX kernel clocks are gated in CStop
1: Writing '1' disabled the ETH RX and TX kernel clocks in CStop, reading '1' means that the ETH RX and TX kernel clocks are enabled in CStop

Bit 10 **ETHMACLPEN**: Disable of the bus interface clocks for ETH block during CSleep mode
The bus interface clocks for ETH are hclk6 and aclk.
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the bus interface clocks are disabled in CSleep
1: Writing '1' disables the bus interface clocks in CSleep, reading '1' means that the bus interface clocks are enabled in CSleep

Bit 9 **ETHRXLPEN**: Disable of the Ethernet Reception Clock during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the reception clock is disabled in CSleep
1: Writing '1' disables the reception clock in CSleep, reading '1' means that the reception clock is enabled in CSleep

Bit 8 **ETHTXLPEN**: Disable of the Ethernet Transmission Clock during CSleep mode
Cleared by software.
0: Writing '0' has no effect, reading '0' means that the transmission clock is disabled in CSleep
1: Writing '1' disables the transmission clock in CSleep, reading '1' means that the transmission clock is enabled in CSleep

Bit 7 **ETHCKLPEN**: Disable of the Ethernet clock generated by the RCC (eth_ker_ck) during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that eth_ker_ck clock is disabled in CSleep
1: Writing '1' disables the eth_ker_ck clock in CSleep, reading '1' means that the eth_ker_ck clock is enabled in CSleep

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **MDMALPEN**: MDMA peripheral clocks enable during CSleep mode

Cleared by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep
1: Writing '1' disables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.192 RCC AHB6 secure sleep clock enable for MPU set register (RCC_MP_TZAHB6LPENSETR)

Address offset: 0x320

Reset value: 0x0000 0001

This register is used by the MPU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. If TZEN = '1', this register can only be modified in secure mode.

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **CRC2LPEN**: CRC2 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 6 **RNG2LPEN**: RNG2 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 5 **HASH2LPEN**: HASH2 peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bit 4 **CRYP2LPEN**: CRYP2 (3DES/AES2) peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **DCMILPEN**: DCMI peripheral clocks enable during CSleep mode

Set by software.

0: Writing '0' has no effect, reading '0' means that the peripheral clocks are disabled in CSleep

1: Writing '1' enables the peripheral clocks in CSleep, reading '1' means that the peripheral clocks are enabled in CSleep

10.7.200 RCC AHB3 sleep clock enable for MPU clear register (RCC_MP_AHB3LPENCLRR)

Address offset: 0xB24

Reset value: 0x0000 18F1

This register is used by the MPU in order to clear the PERxLPEN bit of the corresponding peripheral. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

10.7.207 RCC AXI sleep clock enable for MCU set register (RCC_MC_AXIMLPENSETR)

Address offset: 0xBB0

Reset value: 0x0000 0001

This register is used by the MCU in order to set the PERxLPEN bit of the corresponding peripheral to '1'. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

10.7.214 RCC BOOTROM reset status clear register (RCC_BR_RSTSCLRR)

Address offset: 0x400

Reset value: 0x0000 0015

This register is used by the BOOTROM to check the reset source. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' clears the corresponding bit to '0'. In order to identify the reset source, the MPU application must use *RCC MPU reset status clear register (RCC_MP_RSTSCLRR)*, and the MCU application must use the *RCC MCU reset status clear register (RCC_MC_RSTSCLRR)*. Refer to *Section 10.3.13: Reset source identification* for details.

This register except MPUP[1:0]RSTF flags is located into V_{DD} domain, and is reset by por_rst reset. The MPUP[1:0]RSTF flags are located into V_{DDCORE} and are reset by nreset. If TZEN = '1', this register can only be modified in secure mode.

	rc_w1	rc_w1				rc_w1	rc_w1	rc_w1	rc_w1		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **MPUP1RSTF**: MPU processor 1 reset flag

Cleared by software, set by hardware when a MPU processor 1 reset occurred.

0: Writing '0' has no effect, reading '0' means that no MPU processor 1 reset occurred (default after nreset reset)

1: Writing '1' clears the MPUP1RSTF flag, reading '1' means that MPU processor 1 reset occurred

Bit 13 **MPUP0RSTF**: MPU processor 0 reset flag

Cleared by software, set by hardware when a MPU processor 0 reset occurred.

0: Writing '0' has no effect, reading '0' means that no MPU processor 0 reset occurred (default after nreset reset)

1: Writing '1' clears the MPUP0RSTF flag, reading '1' means that MPU processor 0 reset occurred

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 **IWDG2RSTF**: IWDG2 reset flag

Cleared by software, set by hardware when a IWDG2 reset occurred.

0: Writing '0' has no effect, reading '0' means that no IWDG2 reset occurred (default after por_rst reset)

1: Writing '1' clears the IWDG2RSTF flag, reading '1' means that a IWDG2 reset occurred

Bit 8 **IWDG1RSTF**: IWDG1 reset flag

Cleared by software, set by hardware when a IWDG1 reset occurred.

0: Writing '0' has no effect, reading '0' means that no IWDG1 reset occurred (default after por_rst reset)

1: Writing '1' clears the IWDG1RSTF flag, reading '1' means that a IWDG1 reset occurred

Bit 7 **MCSYSRSTF**: MCU System reset flag

Cleared by software, set by hardware when a MCU system reset occurred.

Note that for the RCC_BR_RSTSCLRR register, this bit is forced to '0' when the option byte OTP_MCU_SYSRST_EN does not allow the MCU to perform a system reset.

0: Writing '0' has no effect, reading '0' means that no system reset generated by the MCU occurred (default after por_rst reset)

1: Writing '1' clears the MCURSTF flag, reading '1' means that a system reset generated by the MCU occurred

Bit 6 **MPSYSRSTF**: MPU System reset flag

Cleared by software, set by hardware when a MPU system reset occurred.

0: Writing '0' has no effect, reading '0' means that no system reset generated by the MPU occurred (default after por_rst reset)

1: Writing '1' clears the MCURSTF flag, reading '1' means that a system reset generated by the MPU occurred

Bit 5 Reserved, must be kept at reset value.

Bit 4 **VCORERSTF**: V_{DDCORE} reset flag

Cleared by software, set by hardware when a reset occurred because V_{DDCORE} is lower than the expected value.

0: Writing '0' has no effect, reading '0' means that V_{DDCORE} is not the origin of the reset

1: Writing '1' clears the VCORERSTF flag, reading '1' means that V_{DDCORE} is the origin of the reset (default after por_rst reset)

Bit 3 **HCSSRSTF**: HSE CSS reset flag

Cleared by software, set by hardware when a failure is detected on HSE.

0: Writing '0' has no effect, reading '0' means that no HSE CSS reset occurred (default after por_rst reset)

1: Writing '1' clears the HCSSRSTF flag, reading '1' means that a HSE CSS reset occurred

Bit 2 **PADRSTF**: NRST reset flag

Cleared by software, set by hardware when a PAD reset occurred.

0: Writing '0' has no effect, reading '0' means that no PAD reset occurred (default after por_rst reset)

1: Writing '1' clears the PADRSTF flag, reading '1' means that a PAD reset occurred

Bit 1 **BORRSTF**: BOR reset flag

Cleared by software, set by hardware when a BOR reset occurred.

0: Writing '0' has no effect, reading '0' means that no BOR reset occurred (default after por_rst reset)

1: Writing '1' clears the BORRSTF flag, reading '1' means that a BOR reset occurred

Bit 0 **PORRSTF**: POR/PDR reset flag

Cleared by software, set by hardware when a POR/PDR reset occurred.

0: Writing '0' has no effect, reading '0' means that no POR/PDR reset occurred

1: Writing '1' clears the PORRSTF flag, reading '1' means that a POR/PDR reset occurred (default after por_rst reset)

10.7.215 RCC MCU reset status clear register (RCC_MC_RSTSCLRR)

Address offset: 0xC00

Reset value: 0x0000 0015

This register is used by the MCU to check the reset source. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' clears the corresponding bit to '0' .Refer to *Section 1.3.12: Reset Source Identification* for details.This register is located into V_{DD} domain, and is reset by por_rst reset.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **WWDG1RSTF**: WWDG1 reset flag

Cleared by software, set by hardware when a WWDG1 reset occurred.

0: Writing '0' has no effect, reading '0' means that no WWDG1 reset occurred (default after por_rst reset)

1: Writing '1' clears the WWDG1RSTF flag, reading '1' means that a WWDG1 reset occurred

Bit 9 **IWDG2RSTF**: IWDG2 reset flag

Cleared by software, set by hardware when a IWDG2 reset occurred.

0: Writing '0' has no effect, reading '0' means that no IWDG2 reset occurred (default after por_rst reset)

1: Writing '1' clears the IWDG2RSTF flag, reading '1' means that a IWDG2 reset occurred

Bit 8 **IWDG1RSTF**: IWDG1 reset flag

Cleared by software, set by hardware when a IWDG1 reset occurred.

0: Writing '0' has no effect, reading '0' means that no IWDG1 reset occurred (default after por_rst reset)

1: Writing '1' clears the IWDG1RSTF flag, reading '1' means that a IWDG1 reset occurred

Bit 7 **MCSYSRSTF**: MCU System reset flag

Cleared by software, set by hardware when a MCU system reset occurred.

Note that for the RCC_BR_RSTSCLRR register, this bit is forced to '0' when the option byte OTP_MCU_SYSRST_EN does not allow the MCU to perform a system reset.

0: Writing '0' has no effect, reading '0' means that no system reset generated by the MCU occurred (default after por_rst reset)

1: Writing '1' clears the MCURSTF flag, reading '1' means that a system reset generated by the MCU occurred

Bit 6 **MPSYSRSTF**: MPU System reset flag

Cleared by software, set by hardware when a MPU system reset occurred.

0: Writing '0' has no effect, reading '0' means that no system reset generated by the MPU occurred (default after por_rst reset)

1: Writing '1' clears the MCURSTF flag, reading '1' means that a system reset generated by the MPU occurred

Bit 5 **MCURSTF**: MCU reset flag

Cleared by software, set by hardware when a MCU reset occurred.

0: Writing '0' has no effect, reading '0' means that no MCU reset occurred (default after por_rst reset)

1: Writing '1' clears the MCURSTF flag, reading '1' means that a MCU reset occurred

Bit 4 **VCORERSTF**: V_{DDCORE} reset flag

Cleared by software, set by hardware when a reset occurred because V_{DDCORE} is lower than the expected value.

0: Writing '0' has no effect, reading '0' means that V_{DDCORE} is not the origin of the reset

1: Writing '1' clears the VCORERSTF flag, reading '1' means that V_{DDCORE} is the origin of the reset (default after por_rst reset)

Bit 3 **HCSSRSTF**: HSE CSS reset flag

Cleared by software, set by hardware when a failure is detected on HSE.

0: Writing '0' has no effect, reading '0' means that no HSE CSS reset occurred (default after por_rst reset)

1: Writing '1' clears the HCSSRSTF flag, reading '1' means that a HSE CSS reset occurred

Bit 2 **PADRSTF**: NRST reset flag

Cleared by software, set by hardware when a PAD reset occurred.

0: Writing '0' has no effect, reading '0' means that no PAD reset occurred (default after por_rst reset)

1: Writing '1' clears the PADRSTF flag, reading '1' means that a PAD reset occurred

Bit 1 **BORRSTF**: BOR reset flag

Cleared by software, set by hardware when a BOR reset occurred.

0: Writing '0' has no effect, reading '0' means that no BOR reset occurred (default after por_rst reset)

1: Writing '1' clears the BORRSTF flag, reading '1' means that a BOR reset occurred

Bit 0 **PORRSTF**: POR/PDR reset flag

Cleared by software, set by hardware when a POR/PDR reset occurred.

0: Writing '0' has no effect, reading '0' means that no POR/PDR reset occurred

1: Writing '1' clears the PORRSTF flag, reading '1' means that a POR/PDR reset occurred (default after por_rst reset)

10.7.216 RCC MPU reset status clear register (RCC_MP_RSTSCLRR)

Address offset: 0x408

Reset value: 0x0000 0000

This register is used by the MPU to check the reset source. This register is updated by the BOOTROM code, after a power-on reset (por_rst), a system reset (nreset), or an exit from Standby or CStandby.

Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' clears the corresponding bit to '0'.

Refer to *Section 10.3.13: Reset source identification* for details.

The register is located in V_{DDCORE}.

If TZEN = '1', this register can only be modified in secure mode.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **SPARE**: Spare bits

Set and reset by software. Reserved for future use.

Bit 14 **MPUP1RSTF**: MPU processor 1 reset flag

Cleared by software, set by the BOOTROM code when a MPU processor 1 reset occurred.

0: No MPU processor 1 reset occurred (default after nreset reset)
1: MPU processor 1 reset occurred

Bit 13 **MPUP0RSTF**: MPU processor 0 reset flag

Cleared by software, set by the BOOTROM code when a MPU processor 0 reset occurred.

0: No MPU processor 0 reset occurred (default after nreset reset)
1: MPU processor 0 reset occurred

Bit 12 **CSTDBYRSTF**: MPU CStandby reset flag

Cleared by software, set by the BOOTROM code when the MPU exits from CStandby.

0: MPU has not been in CStandby mode
1: MPU has been in CStandby mode

Bit 11 **STDBYRSTF**: System Standby reset flag

Cleared by software, set by the BOOTROM code when exiting from system Standby.

0: System has not been in Standby mode
1: System has been in Standby mode

Bit 10 Reserved, must be kept at reset value.

Bit 9 **IWDG2RSTF**: IWDG2 reset flag

Cleared by software, set by the BOOTROM code when a IWDG2 reset occurred.

0: No IWDG2 reset occurred
1: An IWDG2 reset occurred

Bit 8 **IWDG1RSTF**: IWDG1 reset flag

Cleared by software, set by the BOOTROM code when a IWDG1 reset occurred.

0: No IWDG1 reset occurred
1: An IWDG1 reset occurred

Bit 7 **MCSYSRSTF**: MCU System reset flag

Cleared by software, set by the BOOTROM code when a MCU system reset occurred.

0: No system reset generated by the MCU occurred
1: A system reset generated by the MCU occurred

Bit 6 **MPSYSRSTF**: MPU System reset flag
Cleared by software, set by the BOOTROM code when a MPU system reset occurred.
0: No system reset generated by the MPU occurred
1: A system reset generated by the MPU occurred

Bit 5 Reserved, must be kept at reset value.

Bit 4 **VCORERSTF**: V_{DDCORE} reset flag
Cleared by software, set by the BOOTROM code when a reset occurred because V_{DDCORE} is lower than the expected value.
0: V_{DDCORE} is not the origin of the reset
1: V_{DDCORE} is the origin of the reset

Bit 3 **HCSSRSTF**: HSE CSS reset flag
Cleared by software, set by the BOOTROM code when a failure is detected on HSE.
0: No HSE CSS reset occurred
1: A HSE CSS reset occurred

Bit 2 **PADRSTF**: NRST reset flag
Cleared by software, set by the BOOTROM code when a PAD reset occurred.
0: No PAD reset occurred
1: A PAD reset occurred

Bit 1 **BORRSTF**: BOR reset flag
Cleared by software, set by the BOOTROM code when a BOR reset occurred.
0: No BOR reset occurred
1: A BOR reset occurred

Bit 0 **PORRSTF**: POR/PDR reset flag
Cleared by software, set by the BOOTROM code when a POR/PDR reset occurred.
0: No POR/PDR reset occurred
1: A POR/PDR reset occurred

10.7.217 RCC MPU reset status set register (RCC_MP_RSTSSETR)

Address offset: 0x420

Reset value: 0x0000 0000

This register is dedicated to the BOOTROM code in order to update the reset source. This register is updated by the BOOTROM code, after a power-on reset (por_rst), a system reset (nreset), or an exit from Standby or CStandby. The application software shall not use this register. In order to identify the reset source, the MPU application must use *RCC MPU reset status clear register (RCC_MP_RSTSCLRR)*, and the MCU application must use the *RCC MCU reset status clear register (RCC_MC_RSTSCLRR)*.

Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'.

Refer to *Section 10.3.13: Reset source identification* for details.

The register is located in V_{DDCORE}.

If TZEN = '1', this register can only be modified in secure mode.

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **SPARE**: Spare bits
Set and reset by software. Reserved for future use.

Bit 14 **MPUP1RSTF**: MPU processor 1 reset flag
Set by the BOOTROM code when a MPU processor 1 reset occurred.
0: No MPU processor 1 reset occurred (default after nreset reset)
1: MPU processor 1 reset occurred

Bit 13 **MPUP0RSTF**: MPU processor 0 reset flag
Set by the BOOTROM code when a MPU processor 0 reset occurred.
0: No MPU processor 0 reset occurred (default after nreset reset)
1: MPU processor 0 reset occurred

Bit 12 **CSTDBYRSTF**: MPU CStandby reset flag
Set by the BOOTROM code when the MPU exits from CStandby.
0: MPU has not been in CStandby mode
1: MPU has been in CStandby mode

Bit 11 **STDBYRSTF**: System Standby reset flag
Set by the BOOTROM code when exiting from system Standby.
0: System has not been in Standby mode
1: System has been in Standby mode

Bit 10 Reserved, must be kept at reset value.

Bit 9 **IWDG2RSTF**: IWDG2 reset flag
Set by the BOOTROM code when a IWDG2 reset occurred.
0: No IWDG2 reset occurred
1: An IWDG2 reset occurred

Bit 8 **IWDG1RSTF**: IWDG1 reset flag
Set by the BOOTROM code when a IWDG1 reset occurred.
0: No IWDG1 reset occurred
1: An IWDG1 reset occurred

Bit 7 **MCSYSRSTF**: MCU System reset flag
Set by the BOOTROM code when a MCU system reset occurred.
0: No system reset generated by the MCU occurred
1: A system reset generated by the MCU occurred

Bit 6 **MPSYSRSTF**: MPU System reset flag
Set by the BOOTROM code when a MPU system reset occurred.
0: No system reset generated by the MPU occurred
1: A system reset generated by the MPU occurred

Bit 5 Reserved, must be kept at reset value.

Bit 4 **VCORERSTF**: V_{DDCORE} reset flag
Set by the BOOTROM code when a reset occurred because V_{DDCORE} is lower than the expected value.
0: V_{DDCORE} is not the origin of the reset
1: V_{DDCORE} is the origin of the reset

Bit 3 **HCSSRSTF**: HSE CSS reset flag
Set by the BOOTROM code when a failure is detected on HSE.
0: No HSE CSS reset occurred
1: A HSE CSS reset occurred

Bit 2 **PADRSTF**: NRST reset flag
Set by the BOOTROM code when a PAD reset occurred.
0: No PAD reset occurred
1: A PAD reset occurred

Bit 1 **BORRSTF**: BOR reset flag
Set by the BOOTROM code when a BOR reset occurred.
0: No BOR reset occurred
1: A BOR reset occurred

Bit 0 **PORRSTF**: POR/PDR reset flag
Set by the BOOTROM code when a POR/PDR reset occurred.
0: No POR/PDR reset occurred
1: A POR/PDR reset occurred

10.7.218 RCC IWDG clock freeze set register (RCC_MP_IWDGFZSETR)

Address offset: 0x40C

Reset value: 0x0000 0000

This register is used by the BOOTROM in order to freeze the IWDGs clocks. After a system reset or Standby reset (nreset), or a CStandby reset (cstby_rst) the MPU is allowed to write it once.Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' sets the corresponding bit to '1'. The MCU cannot modify this register. If TZEN = '1', this register can only be modified in secure mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FZ_IWDG2	FZ_IWDG1
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **FZ_IWDG2**: Freeze the IWDG2 clock

Set once by the BOOTROM software after a system reset or Standby reset, or a CStandby reset, in order to freeze the IWDG2.

0: Writing '0' has no effect, reading '0' means that the IWDG2 clock is not frozen (default after reset)

1: Writing '1' freeze the IWDG2 clock, reading '1' means that the IWDG2 clock is frozen

Bit 0 **FZ_IWDG1**: Freeze the IWDG1 clock

Set once by the BOOTROM software after a system reset or Standby reset, or a CStandby reset, in order to freeze the IWDG1.

0: Writing '0' has no effect, reading '0' means that the IWDG1 clock is not frozen (default after reset)

1: Writing '1' freeze the IWDG1 clock, reading '1' means that the IWDG1 clock is frozen

10.7.219 RCC IWDG clock freeze clear register (RCC_MP_IWDGFZCLRR)

Address offset: 0x410

Reset value: 0x0000 0000

This register is used by the BOOTROM in order to unfreeze the IWDGs clocks. Writing '0' has no effect, reading will return the effective values of the corresponding bits. Writing a '1' clears the corresponding bit to '0'. The MCU cannot modify this register. If TZEN = '1', this register can only be modified in secure mode.

														rc_w1	rc_w1

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **FZ_IWDG2**: Unfreeze the IWDG2 clock

Cleared by the BOOTROM software, in order to unfreeze the IWDG2.

0: Writing '0' has no effect, reading '0' means that the IWDG2 clock is not frozen (default after reset)

1: Writing '1' unfreeze the IWDG2 clock, reading '1' means that the IWDG2 clock is frozen

Bit 0 **FZ_IWDG1**: Unfreeze the IWDG1 clock

Cleared by the BOOTROM software, in order to unfreeze the IWDG1.

0: Writing '0' has no effect, reading '0' means that the IWDG1 clock is not frozen (default after reset)

1: Writing '1' unfreeze the IWDG1 clock, reading '1' means that the IWDG1 clock is frozen

10.7.220 RCC version register (RCC_VERR)

Address offset: 0xFF4

Reset value: 0x0000 0011

This register gives the IP version

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.5 on page 153* for the register boundary addresses.

11 Hardware semaphore (HSEM)

11.1 Introduction

The hardware semaphore block provides 32 (32-bit) register based semaphores.

The semaphores can be used to ensure synchronization between different processes running between different cores. The HSEM provides a non-blocking mechanism to lock semaphores in an atomic way. The following functions are provided:

- Semaphore lock, in two ways:
  - 2-step lock: by writing COREID and PROCID to the semaphore, followed by a read check
  - 1-step lock: by reading the COREID from the semaphore
- Interrupt generation when a semaphore is unlocked
  - Each semaphore may generate an interrupt on one of the interrupt lines
- Semaphore clear protection
  - A semaphore is only unlocked when COREID and PROCID match
- Global semaphore clear per COREID

11.2 Main features

The HSEM includes the following features:

- 32 (32-bit) semaphores
- 8-bit PROCID
- 4-bit COREID
- One interrupt line per processor
- Lock indication

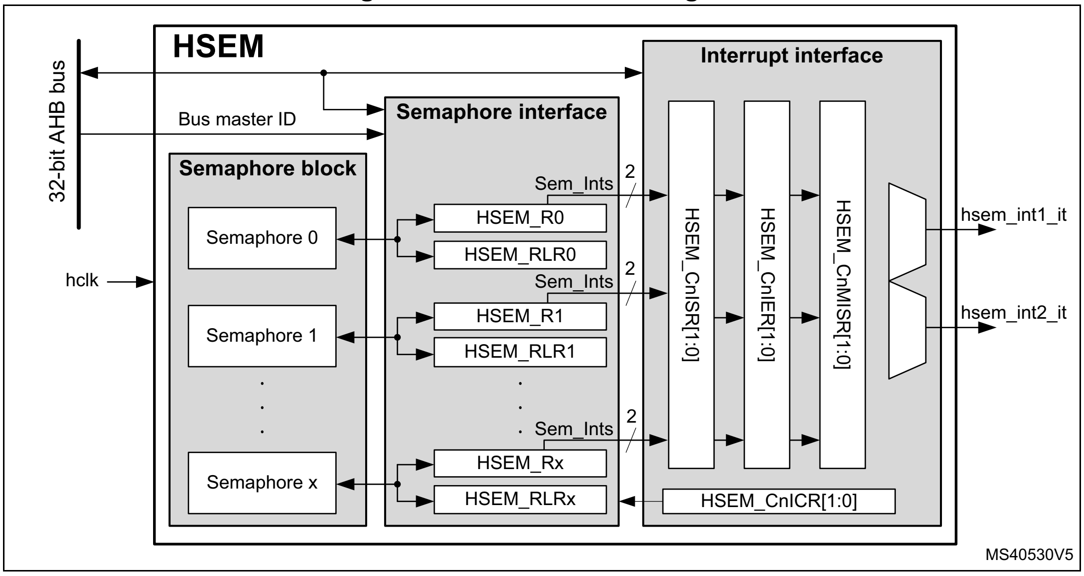
11.3 Functional description

11.3.1 HSEM block diagram

As shown in *Figure 107*, the HSEM is based on three sub-blocks:

- the semaphore block containing the semaphore status and IDs
- the semaphore interface block providing AHB access to the semaphore via the HSEM_Rx and HSEM_RLRx registers
- the interrupt interface block providing control for the interrupts via HSEM_CnISR, HSEM_CnIER, HSEM_CnMISR, and HSEM_CnICR registers.

Figure 107. HSEM block diagram



11.3.2 HSEM internal signals

Table 76. HSEM internal input/output signals

Signal name	Signal type	Description
AHB bus	Digital input/output	AHB register access bus
BusMasterID	Digital input	AHB bus master ID
hsem_intn_it	Digital output	Interrupt n line (n = 1 to 2)

11.3.3 HSEM lock procedures

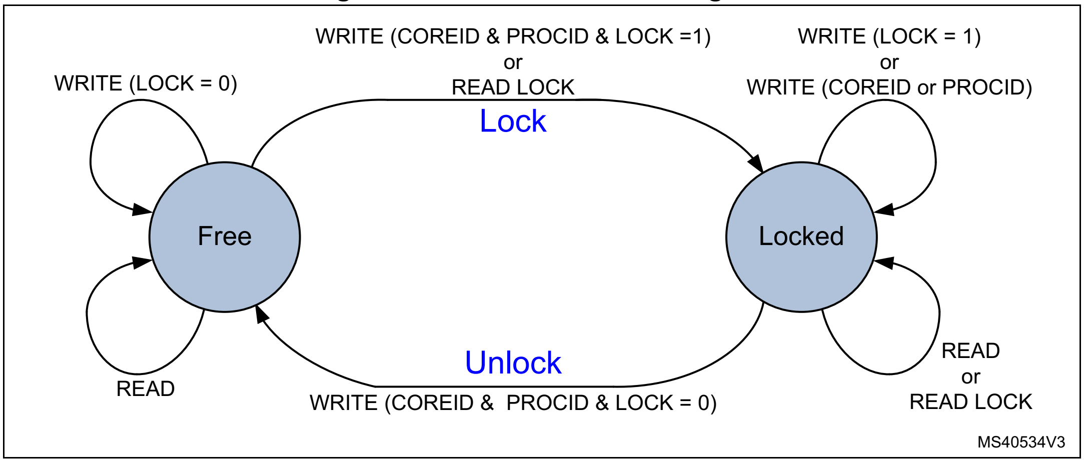
There are two lock procedures, namely 2-step (write) lock and 1-step (read) lock. The two procedures can be used concurrently.

The semaphore is free when its LOCK bit is 0. In this case, the COREID and PROCID are also 0. When the LOCK bit is 1, the semaphore is locked and the COREID indicates which AHB bus master ID has locked it. The PROCID indicates which process of that AHB bus master ID has locked the semaphore.

When write locking a semaphore, the written COREID must match the AHB bus master ID , and the PROCID is written by the AHB bus master software process taking the lock.

When read locking the semaphore, the COREID is taken from the AHB bus master ID, and the PROCID is forced to 0 by hardware. There is no PROCID available with read lock.

Figure 108. Procedure state diagram



2-step (write) lock procedure

The 2-step lock procedure consists in a write to lock the semaphore, followed by a read to check if the lock has been successful, carried out from the HSEM_Rx register.

- Write semaphore with PROCID and COREID, and LOCK = 1. The COREID data written by software must match the AHB bus master information, that is, a AHB bus master ID = 1 writes data COREID = 1.

  Lock is put in place when the semaphore is free at write time.
- Read-back the semaphore

  The software checks the lock status, if PROCID and COREID match the written data, then the lock is confirmed.
- Else retry (the semaphore has been locked by another process, AHB bus master ID).

A semaphore can only be locked when it is free.

A semaphore can be locked when the PROCID = 0.

Consecutive write attempts with LOCK = 1 to a locked semaphore are ignored.

1-step (read) lock procedure

The 1-step procedure consists in a read to lock and check the semaphore in a single step, carried out from the HSEM_RLRx register.

- Read lock semaphore with the AHB bus master COREID.
- If read COREID matches and PROCID = 0, then lock is put in place. If COREID matches and PROCID is not 0, this means that another process from the same COREID has locked the semaphore with a 2-step (write) procedure.
- Else retry (the semaphore has been locked by another process, AHB bus master ID).

A semaphore can only be locked when it is free. When read locking a free semaphore, PROCID is 0. Read locking a locked semaphore returns the COREID and PROCID that locked it. All read locks, including the first one that locks the semaphore, return the COREID that locks or locked the semaphore.

Note: The 1-step procedure must not be used when running multiple processes of the same AHB bus master ID. All processes using the same semaphore read the same status. When only one process locks the semaphore, each process of that AHB bus master ID reads the semaphore as locked by itself with the COREID.

11.3.4 HSEM write/read/read lock register address

For each semaphore, two AHB register addresses are provided, separated in two banks of 32-bit semaphore registers, spaced by a 0x80 address offset.

In the first register address bank the semaphore can be written (locked/unlocked) and read through the HSEM_Rx registers.

In the second register address bank the semaphore can be read (locked) through the HSEM_RLRx registers.

11.3.5 HSEM unlock procedures

Unlocking a semaphore is a protected process, to prevent accidental clearing by a AHB bus master ID or by a process not having the semaphore lock right. The procedure consists in writing to the semaphore HSEM_Rx register with the corresponding COREID and PROCID and LOCK = 0. When unlocked, the COREID, and the PROCID are all 0.

When unlocked, an interrupt may be generated to signal the event. To this end, the semaphore interrupt must be enabled.

The unlock procedure consists in a write to the semaphore HSEM_Rx register with matching COREID regardless on how the semaphore has been locked (1- or 2-step).

- Write semaphore with PROCID, COREID, and LOCK = 0
- If the written data matches the semaphore PROCID and COREID and the AHB bus master ID , the semaphore is unlocked and an interrupt may be generated when enabled, else write is ignored, semaphore remains locked and no interrupt is generated (the semaphore is locked by another process, AHB bus master ID or the written data does not match the AHB bus master signaling).

Note: Different processes of the same AHB bus master ID can write any PROCID value. Preventing other processes of the same AHB bus master ID from unlocking a semaphore must be ensured by software, handling the PROCID correctly.

11.3.6 HSEM COREID semaphore clear

All semaphores locked by a COREID can be unlocked at once by using the HSEM_CR register. Write COREID and correct KEY value in HSEM_CR. All locked semaphores with a matching COREID are unlocked, and may generate an interrupt when enabled.

Note: This procedure may be used in case of an incorrect functioning AHB bus master ID, where another AHB bus master can unlock the locked semaphores by writing the COREID of the incorrect functioning processor into the HSEM_CR register with the correct KEY value. This unlocks all locked semaphores with a matching COREID.

An interrupt may be generated for the unlocked semaphore(s). To this end, the semaphore interrupt must be enabled in the HSEM_CnIER registers.

11.3.7 HSEM interrupts

An interrupt line hsem_intn_it per processor allows each semaphore to generate an interrupt.

An interrupt line provides the following features per semaphore:

- interrupt enable
- interrupt clear
- interrupt status
- masked interrupt status

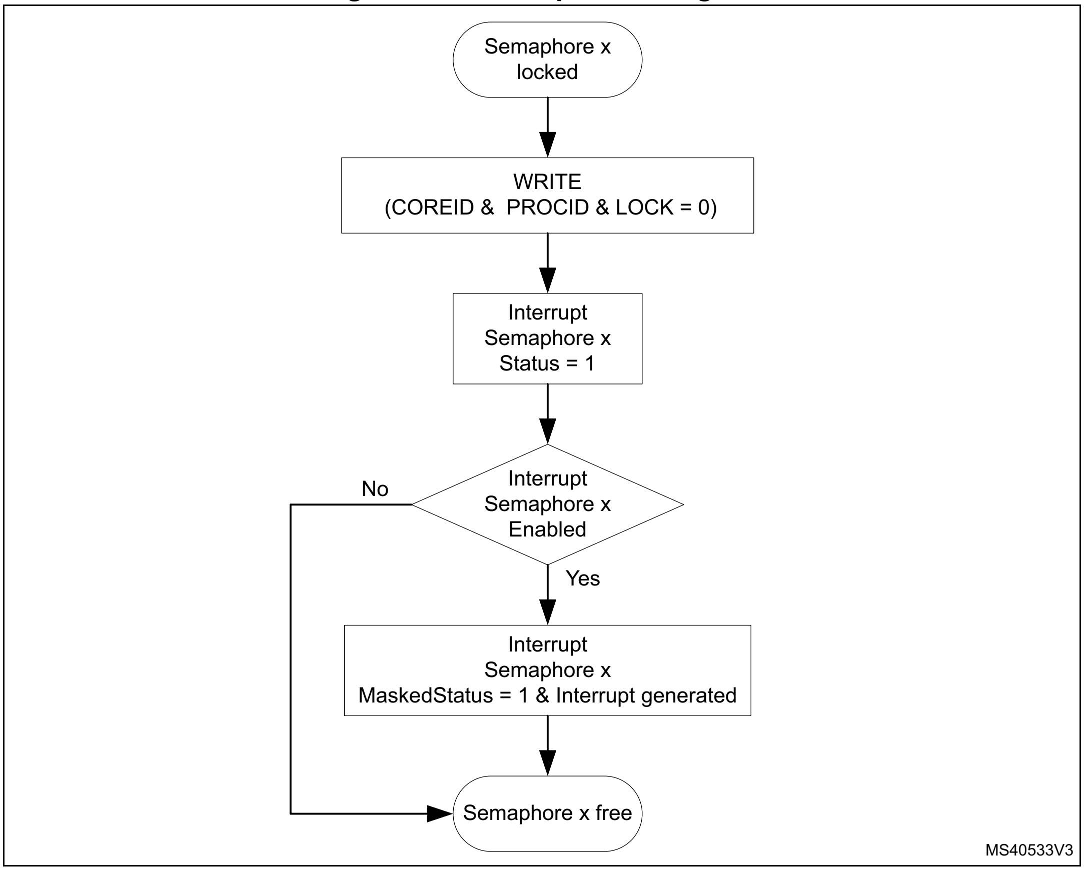
With the interrupt enable (HSEM_CnIER) the semaphores affecting the interrupt line can be enabled. Disabled (masked) semaphore interrupts do not set the masked interrupt status MISF for that semaphore, and do not generate an interrupt on the interrupt line.

The interrupt clear (HSEM_CnICR) clears the interrupt status ISF and masked interrupt status MISF of the associated semaphore for the interrupt line.

The interrupt status (HSEM_CnISR) mirrors the semaphore interrupt status ISF before the enable.

The masked interrupt status (HSEM_CnMISR) only mirrors the semaphore enabled interrupt status MISF on the interrupt line. All masked interrupt status MISF of the enabled semaphores need to be cleared to clear the interrupt line.

Figure 109. Interrupt state diagram



The procedure to get an interrupt when a semaphore becomes free is described hereafter.

Try to lock semaphore x

- If the semaphore lock is obtained, no interrupt is needed.
- If the semaphore lock fails:
- Clear pending semaphore x interrupt status for the interrupt line in HSEM_CnICR.
  Re-try to lock the semaphore x again:
  - If the semaphore lock is obtained, no interrupt is needed (semaphore has been freed between first try to lock and clear semaphore interrupt status).
  - If the semaphore lock fails, enable the semaphore x interrupt in HSEM_CnIER.

On semaphore x free interrupt, try to lock semaphore x

- If the semaphore lock is obtained:
  Disable the semaphore x interrupt in HSEM_CnIER.
  Clear pending semaphore x interrupt status in HSEM_CnICR.
- If the semaphore x lock fails:
  Clear pending semaphore x interrupt status in HSEM_CnICR.
  Try again to lock the semaphore x:
  - If the semaphore lock is obtained (semaphore has been freed between first try to lock and semaphore interrupt status clear), disable the semaphore interrupt in HSEM_CnIER.

– If the semaphore lock fails, wait for semaphore free interrupt.

Note: An interrupt does not lock the semaphore. After an interrupt, either the AHB bus master or the process must still perform the lock procedure to lock the semaphore.

It is possible to have multiple AHB bus masters informed by the semaphore free interrupts. Each AHB bus master gets its interrupt, and the first one to react locks the semaphore.

11.3.8 AHB bus master ID verification

The HSEM allows only authorized AHB bus master IDs to lock and unlock semaphores.

- The AHB bus master 2-step lock write access to the semaphore HSEM_Rx register is checked against the valid bus master IDs.
  – Accesses from unauthorized AHB bus master IDs are discarded and do not lock the semaphore.
- The AHB bus master 1-step lock read access from the semaphore HSEM_RLRx register is checked against the valid bus master IDs.
  – An unauthorized AHB bus master ID read from HSEM_RLRx returns all 0.
- The semaphore unlock write access to the HSEM_CR register is checked against the valid bus master IDs. Only the valid bus master IDs can write to the HSEM_CR register and unlock any of the COREID semaphores.
  – Accesses from unauthorized AHB bus master IDs are discarded and do not clear the COREID semaphores.

Table 77 details the relation between bus master/processor and COREID.

Table 77. Authorized AHB bus master IDs

Bus master 0 (processor1)	Bus master 1 (processor2)
COREID = 1	COREID = 2

Note: Accesses from unauthorized AHB bus master IDs to other registers are granted.

11.4 HSEM registers

Registers must be accessed using word format. Byte and half-word accesses are ignored and have no effect on the semaphores, they generate a bus error.

11.4.1 HSEM register semaphore x (HSEM_Rx)

Address offset: 0x000 + 0x4 * x (x = 0 to 31)

Reset value: 0x0000 0000

The HSEM_Rx must be used to perform a 2-step write lock, read back, and for unlocking a semaphore. Only write accesses with authorized AHB bus master IDs are granted. Write accesses with unauthorized AHB bus master IDs are discarded.

				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK:** Lock indication

This bit can be written and read by software.

0: On write free semaphore (only when COREID and PROCID match), on read semaphore is free.

1: On write try to lock semaphore, on read semaphore is locked.

Bits 30:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **COREID[3:0]:** Semaphore COREID

Written by software

- When the semaphore is free and the LOCK bit is at the same time written to 1 and the COREID matches the AHB bus master ID.
- When the semaphore is unlocked (LOCK written to 0 and AHB bus master ID matched COREID, the COREID is cleared to 0.
- When the semaphore is unlocked (LOCK bit written to 0 or AHB bus master ID does not match COREID, the COREID is not affected.
- Write when LOCK bit is already 1 (semaphore locked), the COREID is not affected.
- An authorized read returns the stored COREID value.

Bits 7:0 **PROCID[7:0]:** Semaphore PROCID

Written by software

-When the semaphore is free and the LOCK is written to 1, and the COREID matches the AHB bus master ID, PROCID is set to the written data.
- When the semaphore is unlocked, LOCK written to 0 and AHB bus master ID matched COREID, the PROCID is cleared to 0.
- When the semaphore is unlocked, LOCK bit written to 0 and AHB bus master ID does not match COREID, the PROCID is not affected.
- Write when LOCK bit is already 1 (semaphore locked), the PROCID is not affected.
- An authorized read returns the stored PROCID value.

11.4.2 HSEM read lock register semaphore x (HSEM_RLRx)

Address offset: 0x080 + 0x4 * x (x = 0 to 31)

Reset value: 0x0000 0000

Accesses the same physical bits as HSEM_Rx. The HSEM_RLRx must be used to perform a 1-step read lock. Only read accesses with authorized AHB bus master IDs are granted. Read accesses with unauthorized AHB bus master IDs are discarded and return 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**

				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **LOCK:** Lock indication

This bit is read only by software at this address.

- When the semaphore is free:

A read with a valid AHB bus master ID locks the semaphore and returns 1.

- When the semaphore is locked:

A read with a valid AHB bus master ID returns 1 (the COREID and PROCID reflect the already locked semaphore information).

Bits 30:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **COREID[3:0]:** Semaphore COREID

This field is read only by software at this address.

On a read, when the semaphore is free, the hardware sets the COREID to the AHB bus master ID reading the semaphore. The COREID of the AHB bus master locking the semaphore is read.

On a read when the semaphore is locked, this field returns the COREID of the AHB bus master that has locked the semaphore.

Bits 7:0 **PROCID[7:0]:** Semaphore processor ID

This field is read only by software at this address.

- On a read when the semaphore is free:

A read with a valid AHB bus master ID locks the semaphore and hardware sets the PROCID to 0.

- When the semaphore is locked:

A read with a valid AHB bus master ID returns the PROCID of the AHB bus master that has locked the semaphore.

11.4.3 HSEM interrupt enable register (HSEM_CnIER)

Address offset: 0x100 + 0x010 * (n - 1), (n = 1 to 2)

Reset value: 0x0000 0000

ISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ISF[31:0]:** Interrupt semaphore x status bit before enable (mask) (x = 0 to 31)
This bit is set by hardware, and reset only by software. This bit is cleared by software writing the corresponding HSEM_CnICR bit.
0: Interrupt semaphore x status, no interrupt pending
1: Interrupt semaphore x status, interrupt pending

11.4.6 HSEM interrupt status register (HSEM_CnMISR)

Address offset: 0x10C + 0x010 * (n - 1), (n = 1 to 2)

Reset value: 0x0000 0000

MISF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **MISF[31:0]:** Masked interrupt(n) semaphore x status bit after enable (mask) (x = 0 to 31)
This bit is set by hardware and read only by software. This bit is cleared by software writing the corresponding HSEM_CnICR bit. This bit is read as 0 when semaphore x status is masked in HSEM_CnIER bit x.
0: interrupt(n) semaphore x status after masking not pending
1: interrupt(n) semaphore x status after masking pending

11.4.7 HSEM clear register (HSEM_CR)

Address offset: 0x140

Reset value: 0x0000 0000

Only write accesses with authorized AHB bus master IDs are granted. Write accesses with unauthorized AHB bus master IDs are discarded.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	COREID[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
				w	w	w	w								

Bits 31:16 **KEY[15:0]:** Semaphore clear key
This field can be written by software and is always read 0.
If this key value does not match HSEM_KEYR.KEY, semaphores are not affected.
If this key value matches HSEM_KEYR.KEY, all semaphores matching the COREID are cleared to the free state.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **COREID[3:0]:** COREID of semaphores to be cleared
This field can be written by software and is always read 0.
This field indicates the COREID for which the semaphores are cleared when writing the HSEM_CR.

Bits 7:0 Reserved, must be kept at reset value.

11.4.8 HSEM clear semaphore key register (HSEM_KEYR)

Address offset: 0x144

Reset value: 0x0000 0000

Refer to *Section 2.5: Memory organization* for the register boundary addresses.

12 Inter-processor communication controller (IPCC)

12.1 Introduction

The inter-processor communication controller (IPCC) is used for communicating data between two processors.

The IPCC block provides a nonblocking signaling mechanism to post and retrieve communication data in an atomic way. It provides the signaling for twelve channels:

- six channels in the direction from processor 1 to processor 2
- six channels in the opposite direction

It is then possible to have two different communication types in each direction.

The IPCC communication data must be located in a common memory, which is not part of the IPCC block.

12.2 IPCC main features

- Status signaling for the twelve channels
  – Channel occupied/free flag, also used as lock
- Two interrupt lines per processor
  – One for RX channel occupied (communication data posted by sending processor)
  – One for TX channel free (communication data retrieved by receiving processor)
- Interrupt masking per channel
  – Channel occupied mask
  – Channel free mask
- Two channel operation modes
  – Simplex (each channel has its own communication data memory location)
  – Half duplex (a single channel associated to a bidirectional communication data information memory location)

12.3 IPCC functional description

The IPCC communication data is located in a common memory, which is not part of the IPCC block. The address location of the communication data must be known or located in a known common area that, as already stated, is not part of the IPCC block.

For each communication, the IPCC block provides a channel status flag CHnF.

- When 0, the channel status flag CHnF indicates that the associated IPCC channel is free (the receiving processor has retrieved communication data), and can be accessed by the sending processor.
- When 1, the channel status flag CHnF indicates that the associated IPCC channel is occupied (the sending processor has posted communication data) and can be accessed by the receiving processor.

The channel operation mode must be known to both processors. A common parameter can be used to indicate the channel transfer mode and must also be located in a known common area. This parameter is not available from the IPCC.

12.3.1 IPCC block diagram

The IPCC (see *Figure 110*) consists of the following subblocks:

- Status block, containing the channel status
- IPCC interface block, providing AHB access to the channel status registers
- Interrupt interface block, providing control for the interrupts

Figure 110. IPCC block diagram

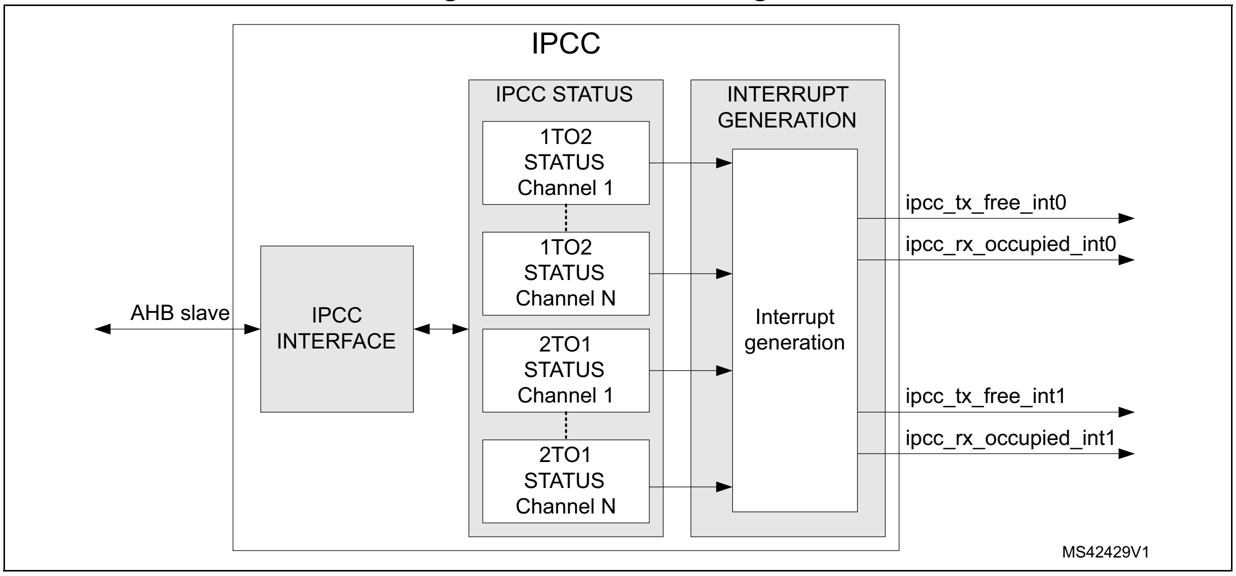

Table 79. IPCC interface signals

Signal		Description
Name	Type	
AHB slave	I/O	AHB register access bus
ipcc_tx_free_int1	O	TX free interrupt to processor 1
ipcc_rx_occupied_int1	O	RX occupied interrupt to processor 1
ipcc_tx_free_int2	O	TX free interrupt to processor 2
ipcc_rx_occupied_int2	O	RX occupied interrupt to processor 2

12.3.2 IPCC Simplex channel mode

In Simplex channel mode, a dedicated memory location (used to transfer data in a single direction) is assigned to the communication data. The associated channel N control bits (see *Table 80*) are used to manage the transfer from the sending to the receiving processor.

Table 80. Bits used for the communication

Processor	A	B
SEND A = 1 RECEIVE B = 2	IPCC_C1CR.TXFIE IPCC_C1MR.CHnFM IPCC_C1SCR.CHnS IPCC_C1TOC2SR.CHnF	IPCC_C2CR.RXOIE IPCC_C2MR.CHnOM IPCC_C2SCR.CHnC
SEND A = 2 RECEIVE B = 1	IPCC_C2CR.TXFIE IPCC_C2MR.CHnFM IPCC_C2SCR.CHnS IPCC_C2TOC1SR.CHnF	IPCC_C1CR.RXOIE IPCC_C1MR.CHnOM IPCC_C1SCR.CHnC

Once the sending processor has posted the communication data in the memory, it sets the channel status flag CHnF to occupied with CHnS.

Once the receiving processor has retrieved the communication data from the memory, it clears the channel status flag CHnF back to free with CHnC.

Figure 111. IPCC Simplex channel mode transfer timing

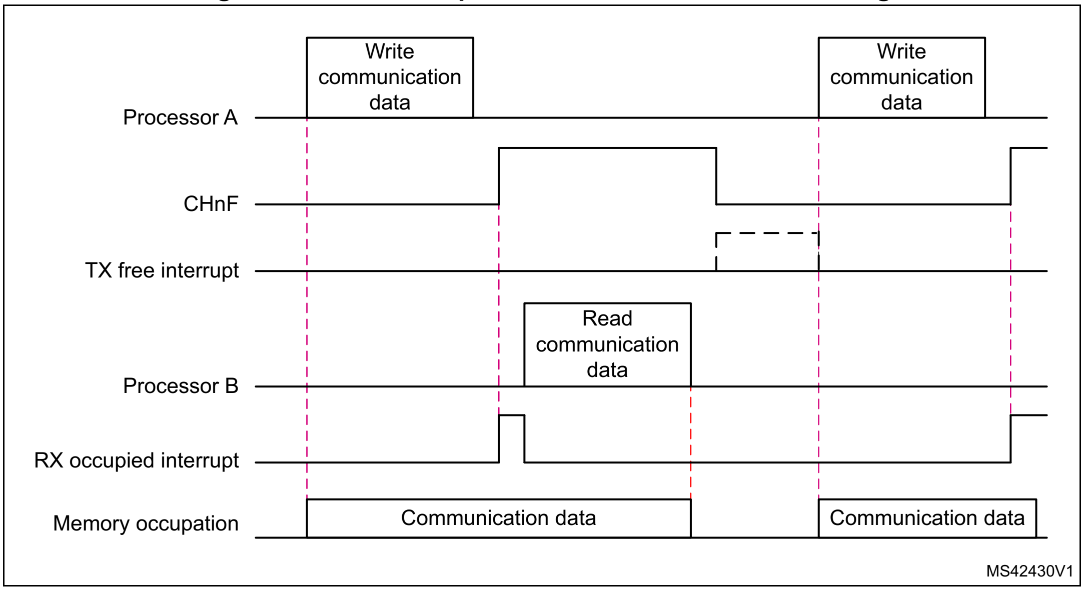

Figure 112. IPCC Simplex - Send procedure state diagram

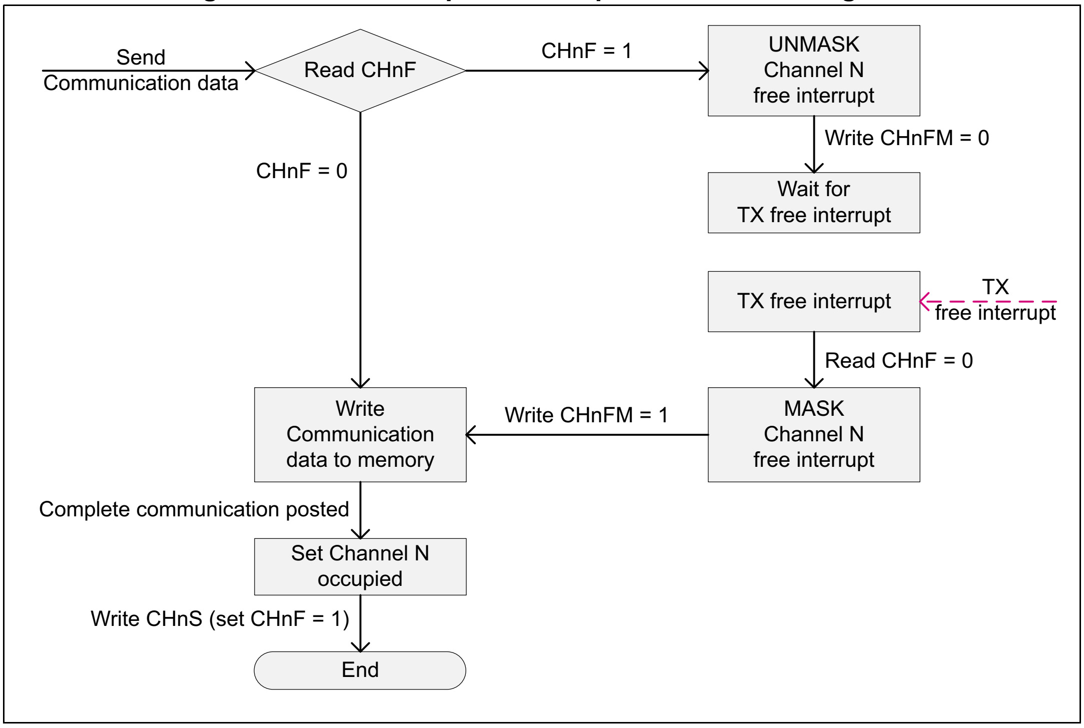
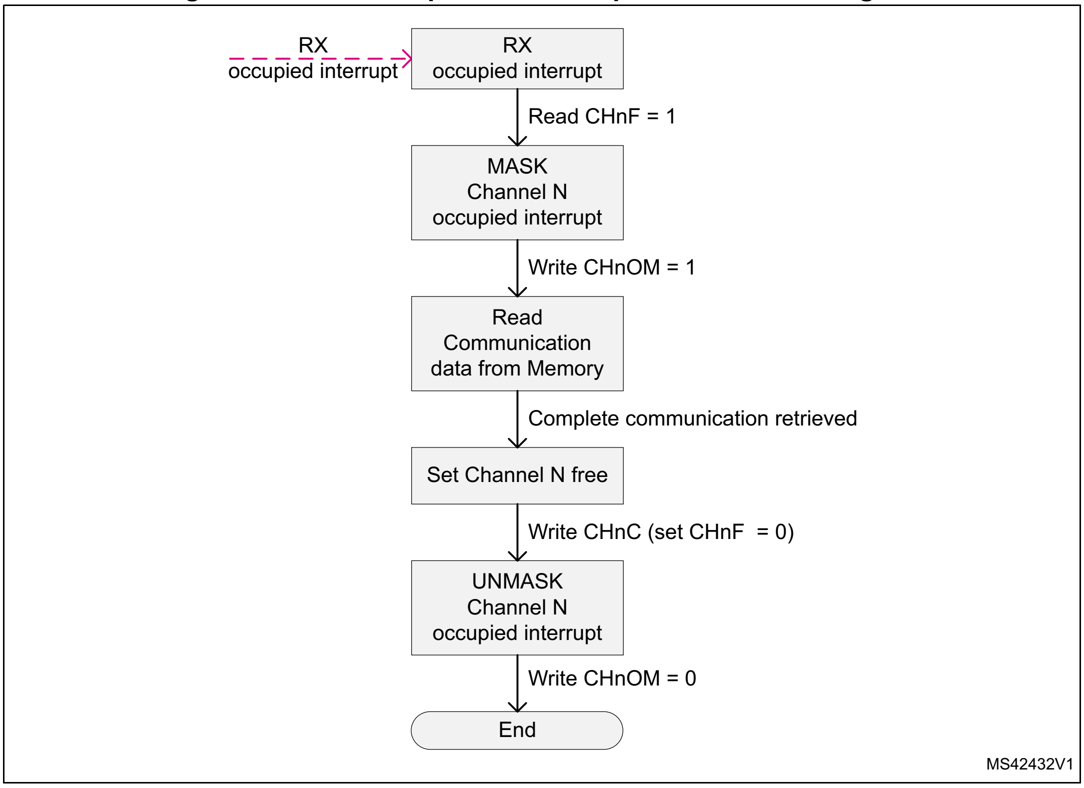


To send communication data:

- The sending processor checks the channel status flag CHnF:
  - When CHnF = 0, the channel is free (last communication data retrieved by the receiving processor), and the new communication data can be written.
  - When CHnF = 1, the channel is occupied (last communication data not retrieved by the receiving processor), and the sending processor unmasks the channel free interrupt (CHnFM = 0).
  - On a TX free interrupt, the sending processor checks which channel became free and masks the channel free interrupt (CHnFM = 1). Then the new communication can take place.
- Once the complete communication data is posted, the channel status is set to occupied with CHnS. This gives memory access to the receiving processor and generates the RX occupied interrupt.

Figure 113. IPCC Simplex - Receive procedure state diagram



To receive a communication, the channel occupied interrupt is unmasked (CHnOM = 0):

- On an RX occupied interrupt, the receiving processor checks which channel became occupied, masks the associated channel occupied interrupt (CHnOM) and reads the communication data from memory.
- Once the complete communication data is retrieved, the channel status is cleared to free with CHnC. This gives memory access back to the sending processor and may generate the TX free interrupt.
- Once the channel status is cleared, the channel occupied interrupt is unmasked (CHnOM = 0).

12.3.3 IPCC Half-duplex channel mode

The Half-duplex channel mode is used when one processor sends a communication and the other processor sends a response to each communication (ping-pong).

In Half-duplex channel mode, a single dedicated memory location is assigned to communication data and response, and is used to transfer data in both directions. The sending processor channel status flag CHnF is assigned to the channel and used by both processors (see *Table 80*).

Once the processor A posts communication data into memory, it sets the processor A channel status flag CHnF to occupied with CHnS (giving memory access to processor B).

Once the processor B retrieves communication data from memory, it does not change the channel status flags. The memory access is kept by processor B for the response.

Once the processor B posts the response into memory, it clears the channel status flag CHnF to free with CHnC (giving memory access back to processor A).

Once the processor A retrieves the response from the memory, it does not change the channel status flags. The memory location access is kept by processor A for the next communication data.

Figure 114. IPCC Half-duplex channel mode transfer timing

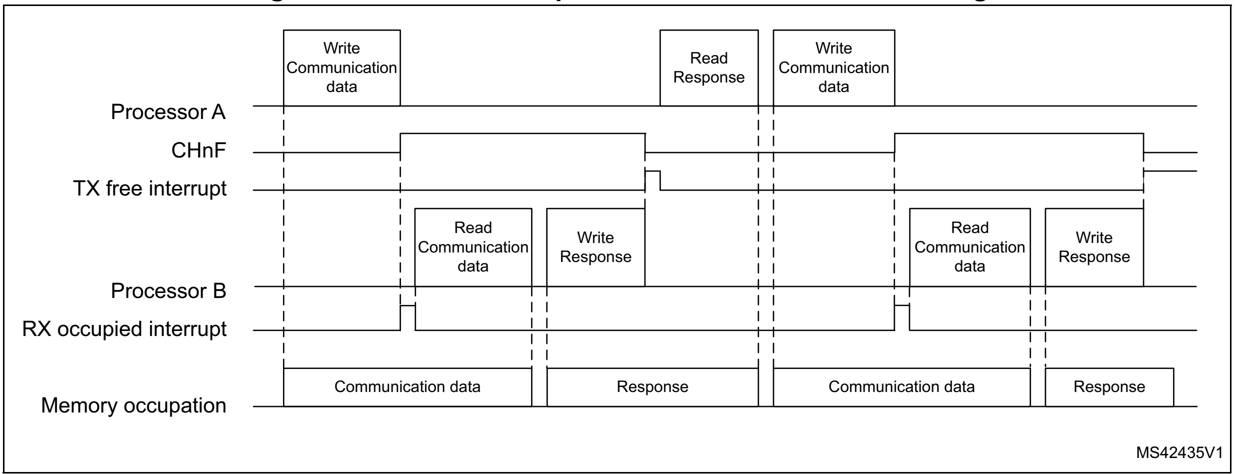


Figure 115. IPCC Half-duplex - Send procedure state diagram

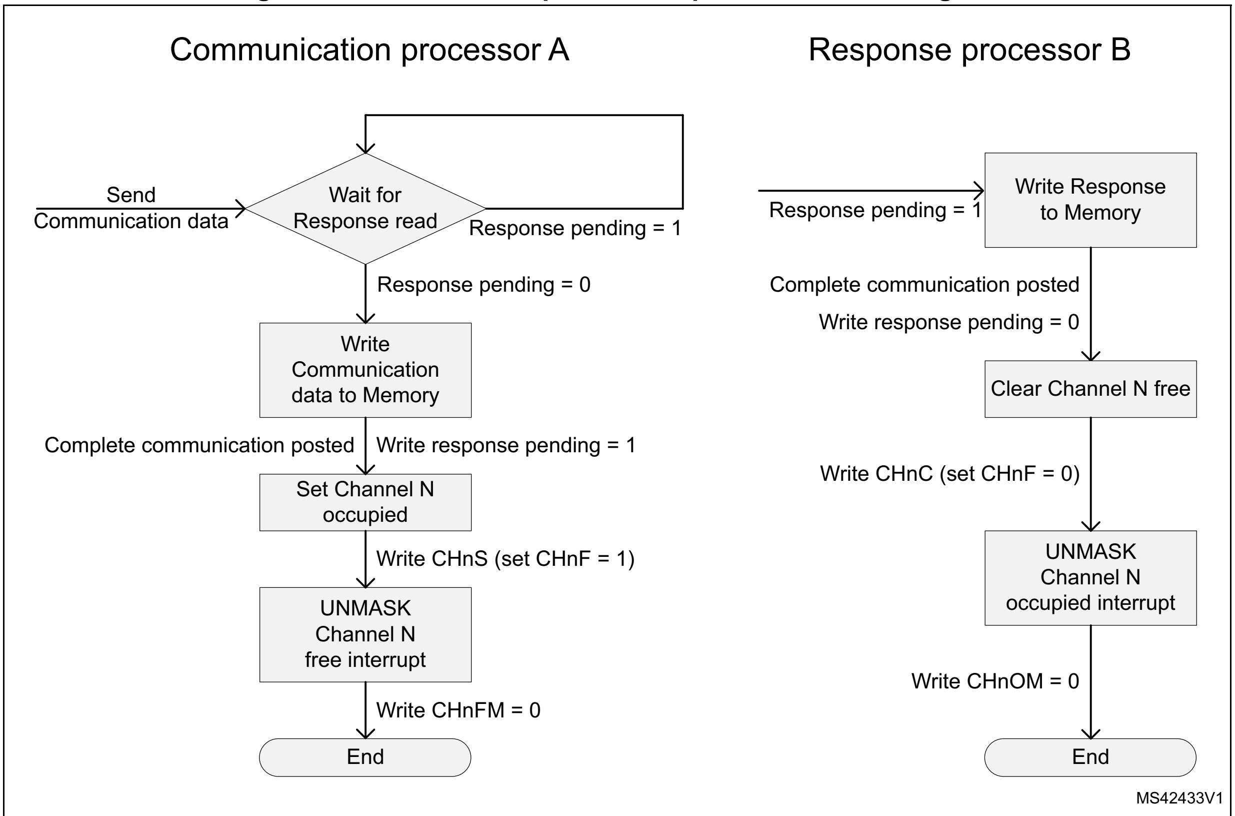


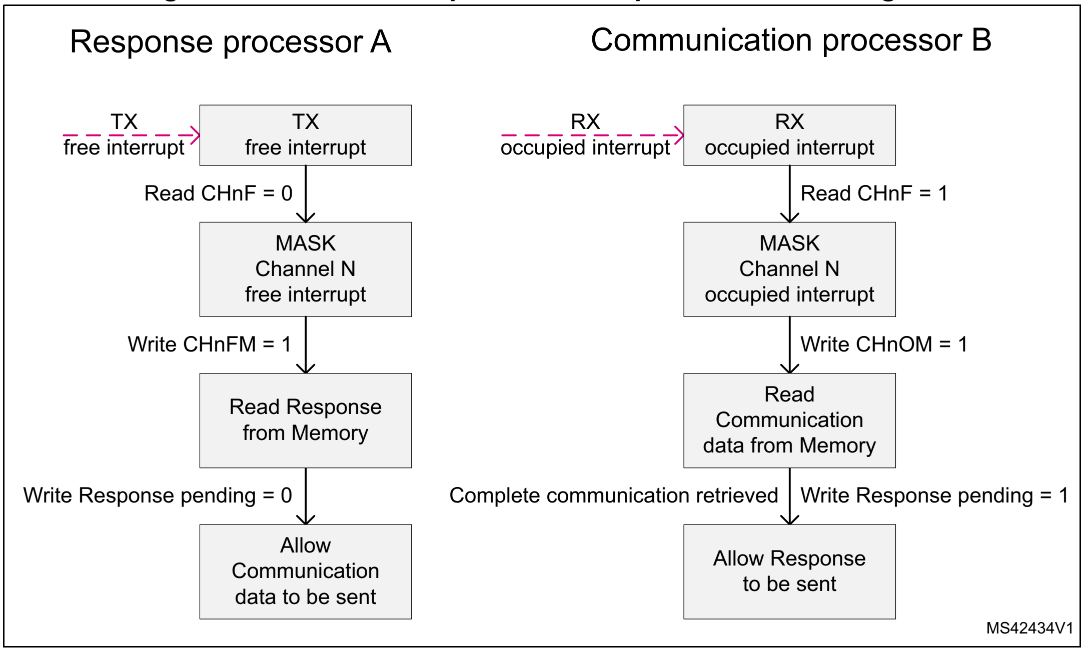
To send communication data:

- The sending processor waits for its response pending software variable to get 0.
  – Once the response pending software variable is 0 the communication data is posted.
- Once the complete communication data has been posted, the channel status flag CHnF is set to occupied with CHnS, and the response pending software variable is set to 1 (this gives memory access and generates the RX occupied interrupt to the receiving processor).
- Once the channel status flag CHnF is set, the channel free interrupt is unmasked (CHnFM = 0).

To send a response:

- The receiving processor waits for its response pending software variable to get 1.
  – Once the response pending software variable is 1, the response is posted.
- Once the complete response is posted, the channel status flag CHnF is cleared to free with CHnC, and the response pending software variable is set to 0 (this gives memory access and generates the TX free interrupt to the sending processor).
- Once the channel status flag CHnF is cleared, the channel occupied interrupt is unmasked (CHnOM = 0).

Figure 116. IPCC Half-duplex - Receive procedure state diagram



To receive communication data the channel occupied interrupt is unmasked (CHnOM = 0):

- On an RX occupied interrupt, the receiving processor checks which channel became occupied, masks the associated channel occupied interrupt (CHnOM) and reads the communication data from the memory.
- Once the complete communication data is retrieved, the response pending software variable is set. The channel status is not changed, access to the memory is kept to post the subsequent response.

To receive the response the channel free interrupt is unmasked (CHnFM = 0):

- On a TX free interrupt, the sending processor checks which channel became free, masks the associated channel free interrupt (CHnFM) and reads the response from the memory.
- Once the complete response is retrieved, the response pending software variable is cleared. The channel status is not changed, access to the memory is kept to post the subsequent communication data.

12.3.4 IPCC interrupts

There are four interrupt lines :

- two RX channel occupied interrupts, one for each processor:
  - Interrupt enable RXOIE per processor
  - Individual mask CHnOM per channel
- two TX channel free interrupts, one for each processor
  - Interrupt enable TXFIE per processor
  - Individual mask CHnFM per channel

The RX occupied interrupt is used by the receiving processor and indicates when an unmasked channel status indicates occupied (CHnF = 1).

The TX free interrupt is used by the sending processor, and indicates when an unmasked channel status indicates free (CHnF = 0).

A secure channel only generates a secure interrupt, and only in the case when the channel is secure unmasked and global secure enabled.

A non-secure channel only generates a non-secure interrupt, and only in the case when the channel is non-secure unmasked and global non-secure enabled.

12.4 IPCC registers

The peripheral registers must be accessed by words (32-bit). Byte (8-bit) and half-word (16-bit) accesses are not permitted and do not generate a bus error.

12.4.1 IPCC processor 1 control register (IPCC_C1CR)

Address offset: 0x000

Reset value: 0x0000 0000

13 General-purpose I/Os (GPIO)

13.1 Introduction

Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR) and a 32-bit set/reset register (GPIOx_BSRR). In addition all GPIOs have a 32-bit locking register (GPIOx_LCKR) and two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

13.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Locking mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

13.3 GPIO functional description

Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers have to be accessed as 32-bit words, half-words or bytes. The purpose of the GPIOx_BSRR register is to allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 117 and *Figure 118* show the basic structures of a standard and a 5-Volt tolerant I/O port bit, respectively. *Table 82* gives the possible port bit configurations.

Figure 117. Basic structure of an I/O port bit

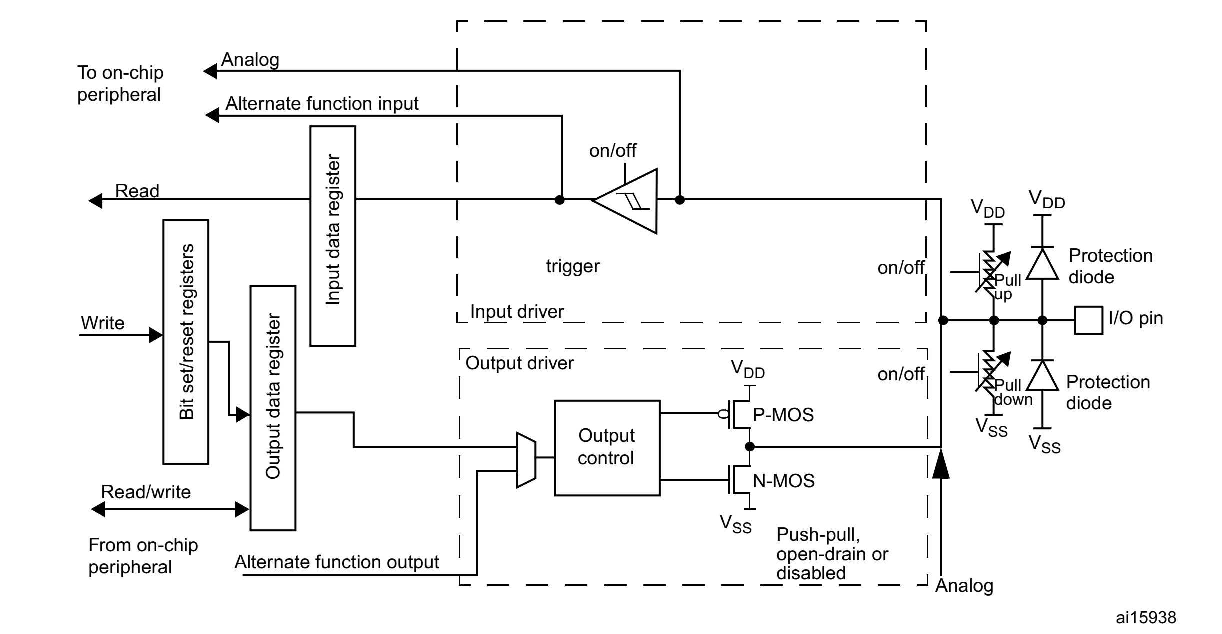

Figure 118. Basic structure of a 5-Volt tolerant I/O port bit

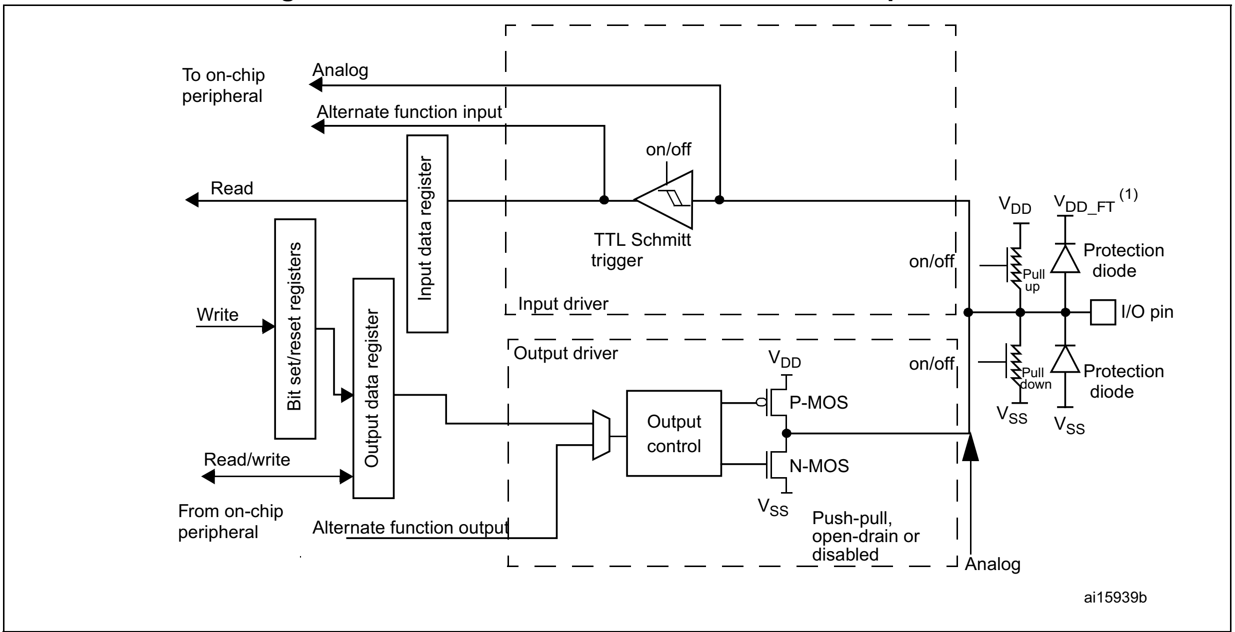


1. V_{DD_FT} is a potential specific to five-volt tolerant I/Os and different from V_{DD}.

Table 82. Port bit configuration table[(1)]

MODE(i) [1:0]	OTYPER(i)	OSPEED(i) [1:0]		PUPD(i) [1:0]		I/O configuration	
01	0	SPEED [1:0]		0	0	GP output	PP
	0			0	1	GP output	PP + PU
	0			1	0	GP output	PP + PD
	0			1	1	Reserved	
	1			0	0	GP output	OD
	1			0	1	GP output	OD + PU
	1			1	0	GP output	OD + PD
	1			1	1	Reserved (GP output OD)	
10	0	SPEED [1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0	Input/output	Analog, PD
	x	x	x	1	1	Reserved	

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in input floating mode.

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not depending on the value in the GPIOx_PUPDR register.

13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there can be no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to sixteen alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.
- Cortex-M4 with FPU EVENTOUT is mapped on AF15

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user has to proceed as follows:

- **System function:** MCOx pins have to be configured in alternate function mode.
- **GPIO:** configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function:**
  – Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  – Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDER registers, respectively.
  – Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
  – For the ADC and DAC, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC and DAC registers.
  – For the additional functions like OTG_ID, OTG_FS_DP/DM, RTC_OUT, RTC_LSCO, TAMP_xxx, WKUPx and oscillators, configure the required function in the related OTG, RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers. For details about I/O control by the RTC, refer to *Section 48.3: RTC functional description*.
- EVENTOUT
  – Configure the I/O pin used to output the core EVENTOUT signal by connecting it to AF15.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (GPIOx_IDR and GPIOx_ODR). GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

See *Section 13.4.5: GPIO port input data register (GPIOx_IDR) (x = A to K, Z)* and *Section 13.4.6: GPIO port output data register (GPIOx_ODR) (x = A to K, Z)* for the register descriptions.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register which allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, bit BS(i) **sets** the corresponding ODR(i) bit. When written to 1, bit BR(i) **resets** the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: it is possible to modify one or more bits in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

It is possible to freeze the GPIO control registers by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write / read sequence has to be applied. When the right LOCK sequence is applied to bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence has been applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence (refer to *Section 13.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K, Z)*) can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 has to be set at the same time as the [15:0] bits.

For more details refer to LCKR register description in *Section 13.4.8: GPIO port configuration lock register (GPIOx_LCKR) (x = A to K, Z)*.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin refer to the device datasheet.

13.3.8 External interrupt/wakeup lines

All ports have external interrupt capability. To use external interrupt lines, the port must not be configured in analog mode.

Refer to *Section 23: Extended interrupt and event controller (EXTI).*

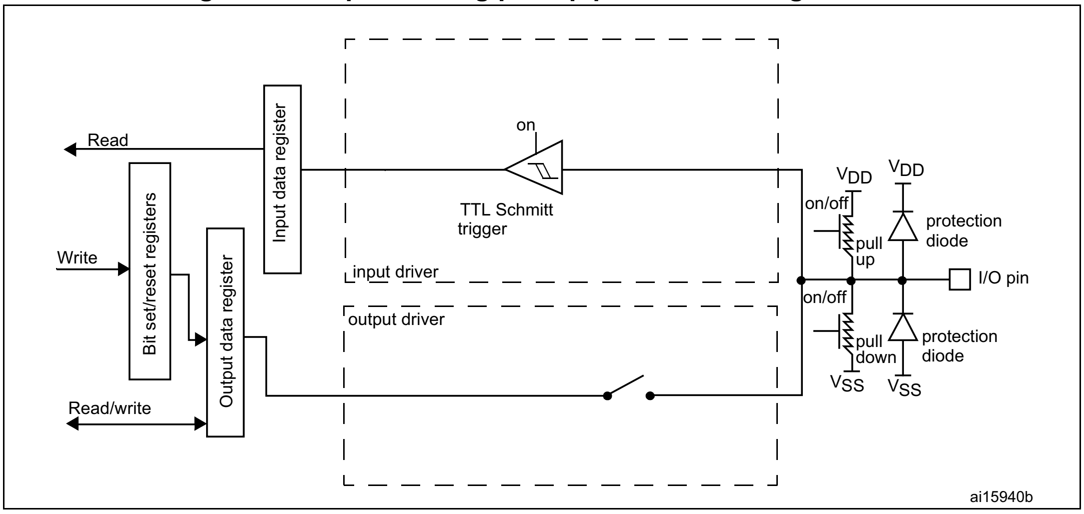
13.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register provides the I/O state

Figure 119 shows the input configuration of the I/O port bit.

Figure 119. Input floating/pull up/pull down configurations



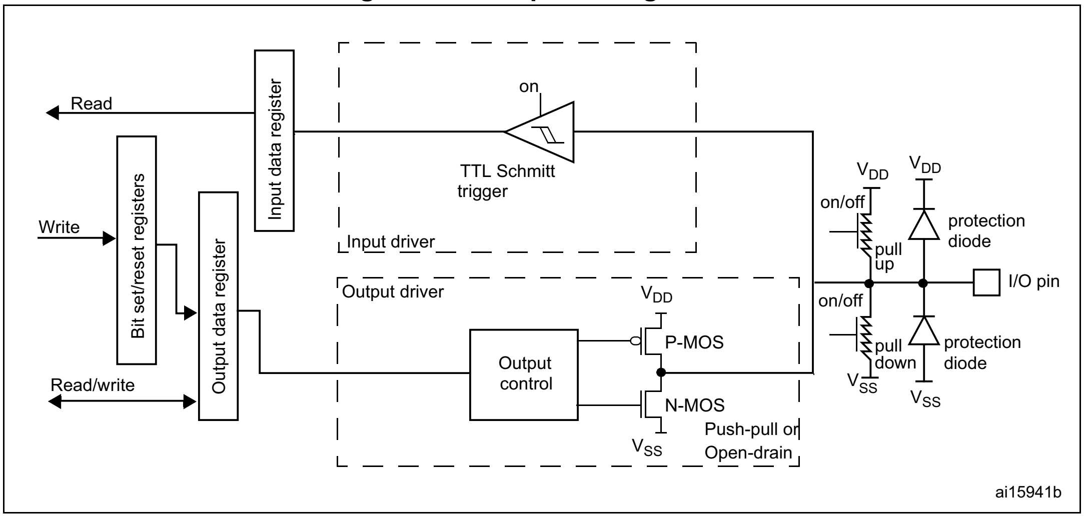
13.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open drain mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register leaves the port in Hi-Z (the P-MOS is never activated)
  - Push-pull mode: A “0” in the Output register activates the N-MOS whereas a “1” in the Output register activates the P-MOS
- The Schmitt trigger input is activated
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state
- A read access to the output data register gets the last written value

Figure 120 shows the output configuration of the I/O port bit.

Figure 120. Output configuration



13.3.11 I/O compensation cell

This cell is used to control the I/O commutation slew rate (t_{fall} / t_{rise}) to reduce the I/O noise on power supply.

The cell is split into two blocks:

- The first block provides an optimal code for the current PVT. The code stored in this block can be read when the READY flag of the SYSCFG_CMPCR is set.
- The second block controls the I/O slew rate.The user selects the code to be applied automatically or to program it by software.

The I/O compensation cell features 2 voltage ranges: 1.62 to 2.0 V and 2.7 to 3.6 V.

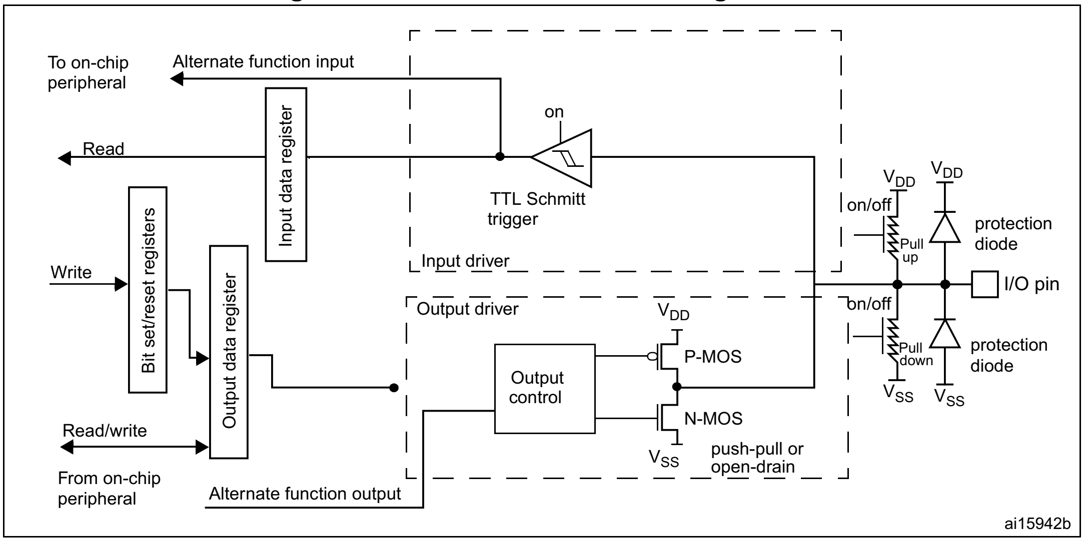
13.3.12 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data)
- The Schmitt trigger input is activated
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle
- A read access to the input data register gets the I/O state

Figure 121 shows the Alternate function configuration of the I/O port bit.

Figure 121. Alternate function configuration



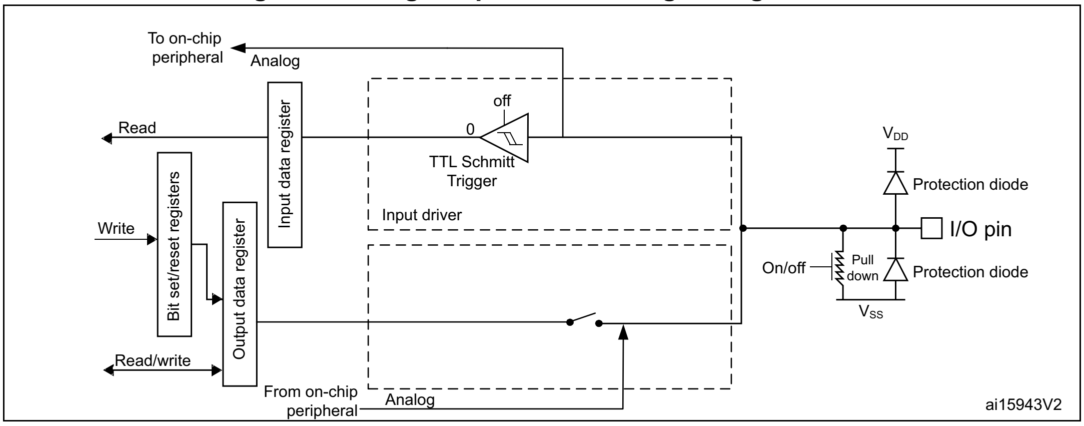
13.3.13 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up resistor is disabled by hardware.
- The weak pull-down resistor is activated or not depending on GPIOx_PUPDR value.
- Read access to the input data register gets the value “0”.

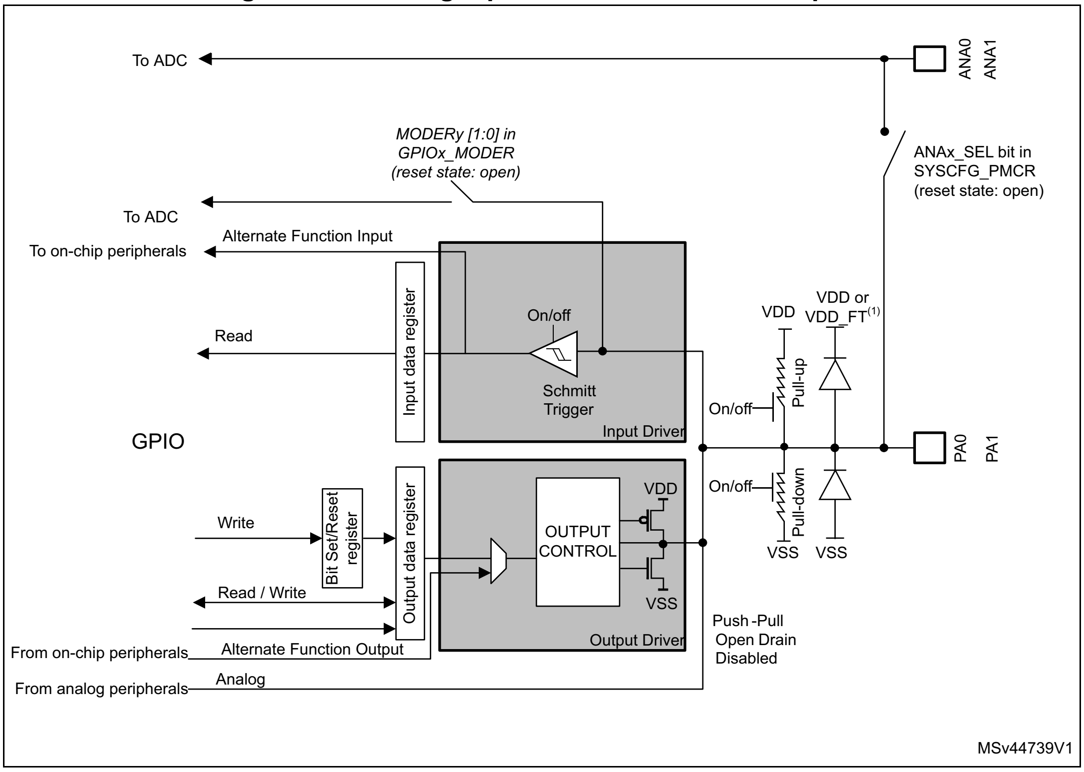
Figure 122 shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 122. High impedance-analog configuration



Some pins/balls are directly connected to ANA0 and ANA1 ADC analog inputs (see *Figure 123*): there is a direct path between ANA0/ANA1 and PA0/PA1 pins/balls, through an analog switch (refer to *Section 14.3.2: SYSCFG peripheral mode configuration set register (SYSCFG_PMCSETR)* for details on how to configure analog switches).

Figure 123. Analog inputs connected to ADC inputs



1. VDD_FT is a potential specific to 5V tolerant I/Os. It is distinct from VDD.

13.3.14 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched OFF (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched ON (by setting the HSEON or LSEON bit in the RCC_CSR register) the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect. This is also true in External clock mode.

13.3.15 Using the GPIO pins in the backup supply domain

The PC13, PC14, PC15, and PI8 GPIO functionality is lost when the core supply domain is powered off (for example, when the device enters standby mode).

In this case, if their GPIO configuration (including GPIO pull-up/pull-down and open-drain settings) is not bypassed by any RTC, TAMP, or PWR (WKUP) configuration, these pins are forced into analog mode.

For details about I/O control by the RTC, refer to *Section 48.3: RTC functional description*.

13.3.16 TrustZone security (only for GPIOZ)

The TrustZone security is always activated On GPIOZ. Each I/O pin of GPIOZ port can be individually configured as secure through the GPIOZ_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function AFI, AFO, mode selection, I/O data are secure against a non-secure access:

- Input data are not redirected to another peripheral
- Output data are not replaced by another peripheral
- Secure I/O data can not be redirected to a non-secure I/O whatever the I/O is configured as alternate function or though peripherals as analog, USB, RTC, wakeup pins in PWR controller
- Non-secure I/O data can not be redirected to a secure peripheral

After reset, all GPIOZ I/O pins are secure.

Table 83 gives a summary of the I/O port secured bits following the security configuration bit in the GPIOZ_SECCFGR register.

- Secured bits: read and write operations are only allowed by a secure access. Non-secure read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Non-secure bits: no restriction. Read and write operations are allowed by both secure and non-secure accesses.

Table 83. GPIO secured bits(1)

Secure configuration bit	Secured bit	Register name	Non-secure access on secure bits
SECy = 1 in GPIOx_SECCFGR	MODEy[1:0]	GPIOx_MODER	RAZ/WI
	OTy	GPIOx_OTYPER	
	OSPEEDy[1:0]	GPIOx_OSPEEDR	
	PUPDy[1:0]	GPIOx_PUPDR	
	IDy	GPIOx_IDR	
	ODy	GPIOx_ODR	
	BSy	GPIOx_BSRR	
	LCKy	GPIOx_LCKR	
	AFSELy[3:0]	GPIOx_AFRL	
	BRy	GPIOx_AFRH	
		GPIOx_BRR	

1. GPIOx, x= Z, and y=0..7.

13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

For a summary of register bits, register address offsets and reset values, refer to *Table 84*.

The peripheral registers can be written in word, half word or byte mode.

13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to K, Z)

Address offset:0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODER15[1:0]		MODER14[1:0]		MODER13[1:0]		MODER12[1:0]		MODER11[1:0]		MODER10[1:0]		MODER9[1:0]		MODER8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODER7[1:0]		MODER6[1:0]		MODER5[1:0]		MODER4[1:0]		MODER3[1:0]		MODER2[1:0]		MODER1[1:0]		MODER0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODER[15:0][1:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O mode.
00: Input mode
01: General purpose output mode
10: Alternate function mode
11: Analog mode

13.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to K, Z)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OT15	OT14	OT13	OT12	OT11	OT10	OT9	OT8	OT7	OT6	OT5	OT4	OT3	OT2	OT1	OT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OT[15:0]:** Port x configuration I/O pin y (y = 15 to 0)
These bits are written by software to configure the I/O output type.
0: Output push-pull (reset state)
1: Output open-drain

13.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to K, Z)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OSPEEDR15[1:0]		OSPEEDR14[1:0]		OSPEEDR13[1:0]		OSPEEDR12[1:0]		OSPEEDR11[1:0]		OSPEEDR10[1:0]		OSPEEDR9[1:0]		OSPEEDR8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OSPEEDR7[1:0]		OSPEEDR6[1:0]		OSPEEDR5[1:0]		OSPEEDR4[1:0]		OSPEEDR3[1:0]		OSPEEDR2[1:0]		OSPEEDR1[1:0]		OSPEEDR0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDR[15:0][1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed
01: Medium speed
10: High speed
11: Very high speed

Note: Refer to the product datasheets for the values of OSPEEDRy bits versus V_{DD} range and external load.

13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to K, Z)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PUPDR15[1:0]		PUPDR14[1:0]		PUPDR13[1:0]		PUPDR12[1:0]		PUPDR11[1:0]		PUPDR10[1:0]		PUPDR9[1:0]		PUPDR8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PUPDR7[1:0]		PUPDR6[1:0]		PUPDR5[1:0]		PUPDR4[1:0]		PUPDR3[1:0]		PUPDR2[1:0]		PUPDR1[1:0]		PUPDR0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDR[15:0][1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down
01: Pull-up
10: Pull-down
11: Reserved

13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to K, Z)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR15	IDR14	IDR13	IDR12	IDR11	IDR10	IDR9	IDR8	IDR7	IDR6	IDR5	IDR4	IDR3	IDR2	IDR1	IDR0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDR[15:0]:** Port x input data I/O pin y (y = 15 to 0)
These bits are read-only. They contain the input value of the corresponding I/O port.

13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to K, Z)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ODR15	ODR14	ODR13	ODR12	ODR11	ODR10	ODR9	ODR8	ODR7	ODR6	ODR5	ODR4	ODR3	ODR2	ODR1	ODR0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODR[15:0]:** Port output data I/O pin y (y = 15 to 0)
These bits can be read and written by software.
Note: For atomic bit set/reset, the ODR bits can be individually set and/or reset by writing to the GPIOx_BSRR register (x = A..F).

13.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to K, Z)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BR[15:0]:** Port x reset I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODRx bit
1: Resets the corresponding ODRx bit
Note: If both BSx and BRx are set, BSx has priority.

Bits 15:0 **BS[15:0]:** Port x set I/O pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODRx bit
1: Sets the corresponding ODRx bit

13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to K, Z)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

LOCK key write sequence:

WR LCKR[16] = ‘1’ + LCKR[15:0]

WR LCKR[16] = ‘0’ + LCKR[15:0]

WR LCKR[16] = ‘1’ + LCKR[15:0]

RD LCKR

RD LCKR[16] = ‘1’ (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the lock.

After the first lock sequence on any bit of the port, any read access on the LCKK bit returns ‘1’ until the next MCU reset or peripheral reset.

Bits 15:0 **LCK[15:0]:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is ‘0.

0: Port configuration not locked

1: Port configuration locked

13.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to K, Z)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BR[15:0]:** Port x reset IO pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODx bit
1: Reset the corresponding ODx bit

13.4.12 GPIO secure configuration register (GPIOZ_SECCFGR)

This register provides access security control and can be written only by a secure access. It is used to configure a selected I/O as secure. A non-secure write access to this register is discarded. Read returns the current GPIOZ pin security setting.

Address offset: 0x30

Reset value: 0x0000 00FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.5 on page 153* for the register boundary addresses.

14 System configuration controller (SYSCFG)

The system configuration controller is mainly used to manage the compensation cell and other IOs and system related settings. This section applies to the whole STM32MP153 family, unless otherwise specified.

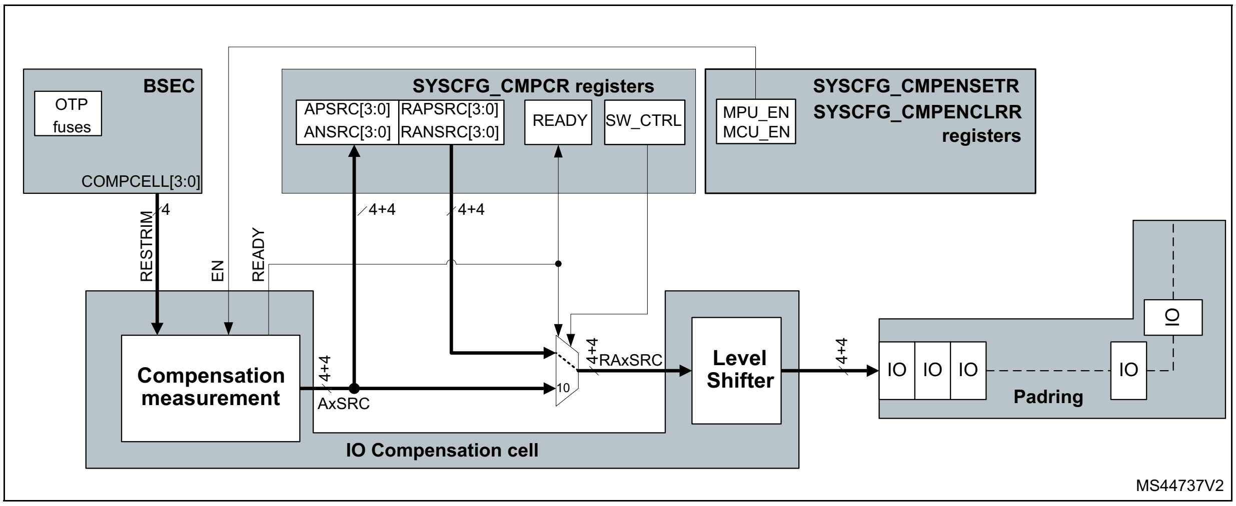
14.1 I/O compensation cell

By default the I/O compensation cell is not used. However when the I/O output buffer speed is configured in 50 MHz mode and above, it is recommended to use the compensation cell for a slew rate control on I/O $t_{f(IO)out}/t_{r(IO)out}$ commutation to reduce the I/O noise on the power supply.

Note: When enabled, the compensation cell has only impact on I/Os with GPIOx_OSPEEDRy = 0b10 or 0b11.

When the compensation cell is enabled, a READY flag is set to indicate that the compensation cell is ready and can be used, the compensation value is then continuously updated.

Figure 124. I/O compensation control overview



Sequence to enable IO compensation:

1. Ensure the CSI oscillator is enabled and ready (in RCC)
2. Set SYSCFG_CMPENSETR.MCU_EN or MPU_EN=1
3. Wait SYSCFG_CMPCR.READY = 1
4. Set SYSCFG_CMPCR.SW_CTRL = 0

Sequence to disable the IO compensation, holding the current compensation value (e.g. before going to STOP):

1. Copy actual value of SYSCFG_CMPCR.APSRC[3:0]/ANSRC[3:0] in SYSCFG_CMPCR.RAPSRC[3:0]/RANSRC[3:0]
2. Set SYSCFG_CMPCR.SW_CTRL = 1
3. Set SYSCFG_CMPENCLRR.MCU_EN and MPU_EN=1

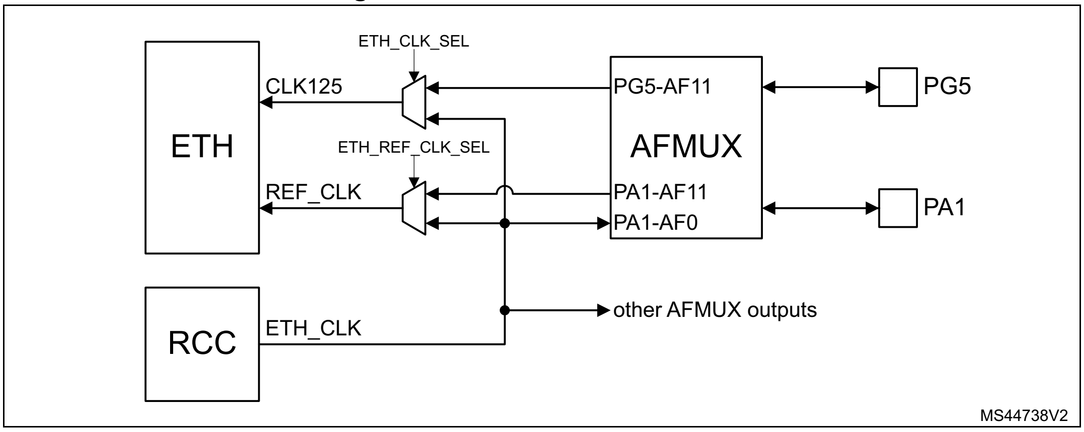
Note: the CSI oscillator is disabled automatically in Stop mode if not requested for other usages, and the CSI is always OFF in Standby mode.

14.2 Ethernet clock source

Depending on the external ethernet PHY, the ETH_CLK clock can have various usage:

- The GMII and RGMII clocks: PG5 can be used to receive either 125 MHz from PHY or internally the ETH_CLK clock at 125 MHz (ETH_CLK can be fed externally to another pin if needed).
- The RMII clock: the ETH_CLK clock at 50 MHz can be output on PA1 and at the same time used by the PHY for REF_CLK.
- ALL: the ETH_CLK clock can be used for the PHY reference clock.

Figure 125. Ethernet clock source



The ethernet clock source is controlled through the SYSCFG_PMCSETR/CLRR registers.

14.3 SYSCFG registers

14.3.1 SYSCFG boot pins control register (SYSCFG_BOOTR)

Address offset: 0x000

Reset value: 0x0000 000X

This register is used to know the state of BOOT pins and to control pull-up to reduce the static power consumption on the pin set to high level.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BOOT2_PD	BOOT1_PD	BOOT0_PD	Res.	BOOT2	BOOT1	BOOT0
									rw	rw	rw		r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **BOOT2_PD:** BOOT2 pin pull-down disable. This is used to save power in case the BOOT2 pin is connected to VDD.
- 0: (enabled) pull-down enabled. The BOOT2 pin can be left open and will take a value of 0 if open.
- 1: (disabled) pull-down disabled. The BOOT2 pin must not be left open.

Bit 5 **BOOT1_PD:** BOOT1 pin pull-down disable. This is used to save power in case the BOOT1 pin is connected to VDD
- 0: (enabled) pull-down enabled. The BOOT1 pin can be left open and will take a value of 0 if open.
- 1: (disabled) pull-down disabled. The BOOT1 pin must not be left open.

Bit 4 **BOOT0_PD:** BOOT0 pin pull-down disable. This is used to save power in case the BOOT0 pin is connected to VDD
- 0: (enabled) pull-down enabled. The BOOT0 pin can be left open and will take a value of 0 if open.
- 1: (disabled) pull-down disabled. The BOOT0 pin must not be left open.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **BOOT2:** BOOT2 pin value
- 0: (low) BOOT2 pin connected to VSS (or left open if BOOT2_PD=0)
- 1: (high) BOOT2 pin connected to VDD

Bit 1 **BOOT1:** BOOT1 pin value
- 0: (low) BOOT1 pin connected to VSS (or left open if BOOT1_PD=0)
- 1: (high) BOOT1 pin connected to VDD

Bit 0 **BOOT0:** BOOT0 pin value
- 0: (low) BOOT0 pin connected to VSS (or left open if BOOT0_PD=0)
- 1: (high) BOOT0 pin connected to VDD

14.3.2 SYSCFG peripheral mode configuration set register (SYSCFG_PMCSETR)

Address offset: 0x004

Reset value: 0x0000 0000

						rs	rs			rs	rs	rs	rs	rs	rs

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **ANA1_SEL**: controls analog connection between the ANA1 and PA1 pin.
Set by software.
0: Writing '0' has no effect, reading '0' means no connection. For best ADC performance the ANA1 input must be used for package having ANA1 pin present.
1: Writing '1' set this bit, reading '1' means ANA1 internally connected to PA1. Must only be used on package not having ANA1 pin.

Bit 24 **ANA0_SEL**: controls analog connection between ANA0 and PA0 pin.
Set by software.
0: Writing '0' has no effect, reading '0' means no connection. For best ADC performance ANA0 input must be used for package having ANA0 pin present.
1: Writing '1' set this bit, reading '1' means ANA0 internally connected to PA0. Must only be used on package not having ANA0 pin.

Bits 23:21 **ETH_SEL[2:0]**: Ethernet PHY interface selection.
Set by software. Writing bit as '0' has no effect, set individual bits by writing '1', reading means
000: GMII or MII
001: RGMII
010: Reserved
011: Reserved
100: RMII
101: Reserved
110: Reserved
111: Reserved
Note: Configuration must be done while the ETH is under reset and before enabling the ETH clocks

Bit 20 **ETH_SELMII**: controls MII or GMII when ETH_SEL[2:0] = 0b000.
Set by software.
0: (GMII) Writing '0' has no effect, reading '0' means MII/GMII clock mux controlled by ETH GMAC (GMII PHY use case)
1: (MII) Writing '1' set this bit, reading '1' means MII/GMII clock mux forced in MII mode (MII PHY use case)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **ETH_REF_CLK_SEL**: Ethernet 50MHz RMII clock selection.

Set by software.

0: Writing '0' has no effect, reading '0' means External clock is used. Need selection of AFMux. Could be used with all PHY

1: Writing '1' set this bit, reading '1' means Internal clock ETH_CLK1 from RCC is used regardless AFMux. Could be used only with RMII PHY.

Bit 16 **ETH_CLK_SEL**: Gigabit Ethernet 125 MHz clock selection. Only useful for GMII or RGMII PHY

Set by software.

0: Writing '0' has no effect, reading '0' means External clock is used. Need selection of AFMux

1: Writing '1' set this bit, reading '1' means Internal clock ETH_CLK1 from RCC is used regardless AFMux

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **ANASWVDD**: GPIO analog switches control voltage selection

Set by software.

0: Writing '0' has no effect, reading '0' means IOs analog switches supplied by VDDA (**EN_BOOSTER**=0) or Booster output (**EN_BOOSTER**=1)

1: Writing '1' set this bit, reading '1' means IOs analog switches supplied by VDD (regardless **EN_BOOSTER** bit, which should be cleared to avoid unwanted power consumption). Useful to avoid using Booster (add current consumption) when VDDA < 2.7V, but VDD > 2.7V. When both VDD < 2.7V and VDDA < 2.7V, the Booster is still needed to get full AC performances from IOs analog switches.

Bit 8 **EN_BOOSTER**: Pad Booster enable.

Set by software.

used to reduce the Total Harmonic Distortion of the IOs analog switches when VDDA and VDD supplies are below 2.7V. Activating the booster allows to guaranty the AC performance on IOs analog switches. When activated the performance of the analog switch is the same on the full voltage range. This bit is only useful when **ANASWVDD**=0

0: Writing '0' has no effect, reading '0' means Booster is disabled

1: Writing '1' set this bit, reading '1' means Booster is enabled. Note that this will add a current consumption on VDD

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **I2C6_FMP**: Fast Mode Plus (FM+) enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C6 usage is possible up to 400 kHz

1: Writing '1' set this bit, reading '1' means the I2C6 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 4 **I2C5_FMP**: Fast Mode Plus (FM+) Enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C5 usage is possible up to 400 kHz

1: Writing '1' set this bit, reading '1' means the I2C5 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 3 **I2C4_FMP**: Fast Mode Plus (FM+) Enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C4 usage is possible up to 400 kHz

1: Writing '1' set this bit, reading '1' means the I2C4 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1MHz.

Bit 2 **I2C3_FMP**: Fast Mode Plus (FM+) Enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C3 usage is possible up to 400kHz

1: Writing '1' set this bit, reading '1' means the I2C3 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 1 **I2C2_FMP**: Fast Mode Plus (FM+) Enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C2 usage is possible up to 400 kHz

1: Writing '1' set this bit, reading '1' means the I2C2 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 0 **I2C1_FMP**: Fast Mode Plus (FM+) Enable

Set by software.

0: Writing '0' has no effect, reading '0' means I2C1 usage is possible up to 400 kHz

1: Writing '1' set this bit, reading '1' means the I2C1 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

14.3.3 SYSCFG peripheral mode configuration clear register (SYSCFG_PMCCLRR)

Address offset: 0x044

Reset value: 0x0000 0000

						rc_w1	rc_w1			rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **ANA1_SEL**: controls analog connection between the ANA1 and PA1 pin.
Cleared by software.
0: Writing '0' has no effect, reading '0' means no connection. For best ADC performance the ANA1 input must be used for package having ANA1 pin present.
1: Writing '1' clear this bit, reading '1' means ANA1 internally connected to PA1. Must only be used on package not having ANA1 pin.

Bit 24 **ANA0_SEL**: controls analog connection between ANA0 and PA0 pin.
Cleared by software.
0: Writing '0' has no effect, reading '0' means no connection. For best ADC performance ANA0 input must be used for package having ANA0 pin present.
1: Writing '1' clear this bit, reading '1' means ANA0 internally connected to PA0. Must only be used on package not having ANA0 pin.

Bits 23:21 **ETH_SEL[2:0]**: Ethernet PHY interface selection.
Cleared by software. Writing bit as '0' has no effect, clear individual bits by writing ‘1’, reading means
000: GMII or MII
001: RGMII
010: Reserved
011: Reserved
100: RMII
101: Reserved
110: Reserved
111: Reserved
Note: Configuration must be done while the ETH is under reset and before enabling the ETH clocks

Bit 20 **ETH_SELMII**: controls MII or GMII when ETH_SEL[2:0] = 0b000.
Cleared by software.
0: (GMII) Writing '0' has no effect, reading '0' means MII/GMII clock mux controlled by ETH GMAC (GMII PHY use case)
1: (MII) Writing '1' clear this bit, reading '1' means MII/GMII clock mux forced in MII mode (MII PHY use case)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **ETH_REF_CLK_SEL**: Ethernet 50MHz RMII clock selection.
Cleared by software.
0: Writing '0' has no effect, reading '0' means External clock is used. Need selection of AFMux. Could be used with all PHY
1: Writing '1' clear this bit, reading '1' means Internal clock ETH_CLK1 from RCC is used regardless AFMux. Could be used only with RMII PHY.

Bit 16 **ETH_CLK_SEL**: Gigabit Ethernet 125 MHz clock selection. Only useful for GMII or RGMII PHY
Cleared by software.
0: Writing '0' has no effect, reading '0' means External clock is used. Need selection of AFMux
1: Writing '1' clear this bit, reading '1' means Internal clock ETH_CLK1 from RCC is used regardless AFMux

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **ANASWVDD**: GPIO analog switches control voltage selection

Cleared by software.

0: Writing '0' has no effect, reading '0' means IOs analog switches supplied by VDDA (**EN_BOOSTER**=0) or Booster output (**EN_BOOSTER**=1)

1: Writing '1' clear this bit, reading '1' means IOs analog switches supplied by VDD (regardless **EN_BOOSTER** bit, which should be cleared to avoid unwanted power consumption). Useful to avoid using Booster (add current consumption) when VDDA < 2.7V, but VDD > 2.7V.

Bit 8 **EN_BOOSTER**: Pad Booster enable.

Cleared by software.

used to reduce the Total Harmonic Distortion of the IOs analog switches when VDDA and VDD supplies are below 2.7V. Activating the booster allows to guaranty the AC performance on IOs analog switches. When activated the performance of the analog switch is the same on the full voltage range. This bit is only useful when **ANASWVDD**=0

0: Writing '0' has no effect, reading '0' means Booster is disabled

1: Writing '1' clear this bit, reading '1' means Booster is enabled. Note that this will add a current consumption on VDD.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **I2C6_FMP**: Fast Mode Plus (FM+) enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means I2C6 usage is possible up to 400 kHz

1: Writing '1' clear this bit, reading '1' means the I2C6 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 4 **I2C5_FMP**: Fast Mode Plus (FM+) Enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means I2C5 usage is possible up to 400 kHz

1: Writing '1' clear this bit, reading '1' means the I2C5 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 3 **I2C4_FMP**: Fast Mode Plus (FM+) Enable

Cleared by software.

0: Writing '0' has no effect, reading '0' means I2C4 usage is possible up to 400 kHz

1: Writing '1' clear this bit, reading '1' means the I2C4 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1MHz.

Bit 2 **I2C3_FMP**: Fast Mode Plus (FM+) Enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means I2C3 usage is possible up to 400kHz
1: Writing '1' clear this bit, reading '1' means the I2C3 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 1 **I2C2_FMP**: Fast Mode Plus (FM+) Enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means I2C2 usage is possible up to 400 kHz
1: Writing '1' clear this bit, reading '1' means the I2C2 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

Bit 0 **I2C1_FMP**: Fast Mode Plus (FM+) Enable
Cleared by software.
0: Writing '0' has no effect, reading '0' means I2C1 usage is possible up to 400 kHz
1: Writing '1' clear this bit, reading '1' means the I2C1 SCL & SDA pads in Fast Mode Plus (FM+), as soon as the correspondent alternate function is selected. The pad low drive is enhanced to allow usage up to 1 MHz.

14.3.4 SYSCFG IO control set register (SYSCFG_IOCTRLSETR)

Address offset: 0x018

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSLVEN_SPI**: High Speed Low Voltage Pad mode Enable.
Set by software.
Controls the speed of _h and _e pads when a SPIy_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' enables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 3 **HSLVEN_SDMMC**: High Speed Low Voltage Pad mode Enable.
Set by software.
Controls the speed of _h and _e pads when a SDMMCy_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' enables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 2 **HSLVEN_ETH**: High Speed Low Voltage Pad mode Enable.
Set by software.
Controls the speed of _h and _e pads when a ETH_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' enables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 1 **HSLVEN_QUADSPI**: High Speed Low Voltage Pad mode Enable.
Set by software.
Controls the speed of _h and _e pads when a QUADSPI_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' enables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 0 **HSLVEN_TRACE**: High Speed Low Voltage Pad mode Enable.
Set by software.
Controls the speed of _h and _e pads when a TRACEx signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' enables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

1. This bit is not taken into account if the OTP bit **(product_below_2V5)** is 0 (default)
2. Enabling High Speed mode while VDD > 2.7V can damage the IC. See pad characteristics for details.

Danger: **Enabling High Speed mode while VDD > 2.7V can damage the IC.**
See pad characteristics for details

14.3.5 SYSCFG IO control clear register (SYSCFG_IOCTRLCLRR)

Address offset: 0x058

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **HSLVEN_SPI**: High Speed Low Voltage Pad mode Enable.
Cleared by software.
Controls the speed of _h and _e pads when a SPIy_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' disables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 3 **HSLVEN_SDMMC**: High Speed Low Voltage Pad mode Enable.
Cleared by software.
Controls the speed of _h and _e pads when a SDMMCy_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' disables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 2 **HSLVEN_ETH**: High Speed Low Voltage Pad mode Enable.
Cleared by software.
Controls the speed of _h and _e pads when a ETH_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' disables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 1 **HSLVEN_QUADSPI**: High Speed Low Voltage Pad mode Enable.
Cleared by software.
Controls the speed of _h and _e pads when a QUADSPI_x signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' disables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

Bit 0 **HSLVEN_TRACE**: High Speed Low Voltage Pad mode Enable.
Cleared by software.
Controls the speed of _h and _e pads when a TRACEx signal is selected in AFMUX.
0: Writing '0' has no effect, reading '0' means High Speed mode disabled
1: Writing '1' disables High Speed mode, reading '1' means High Speed mode enabled(1)(2)

1. This bit is not taken into account if the OTP bit **(product_below_2V5)** is 0 (default)
2. Enabling High Speed mode while VDD > 2.7V can damage the IC. See pad characteristics for details.

Danger: **Enabling High Speed mode while VDD > 2.7V can damage the IC.**
See pad characteristics for details

					rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **AXI_M10:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 9 **AXI_M9:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 8 **AXI_M8:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 7 **AXI_M7:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 6 **AXI_M6:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 5 **AXI_M5:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 4 Reserved, must be kept at reset value.

Bit 3 **AXI_M3:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning

0: (S0) Master access DDR through Slave S0

1: (S1) Master access DDR through Slave S1

Bit 2 **AXI_M2:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning
0: (S0) Master access DDR through Slave S0
1: (S1) Master access DDR through Slave S1

Bit 1 **AXI_M1:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning
0: (S0) Master access DDR through Slave S0
1: (S1) Master access DDR through Slave S1

Bit 0 **AXI_M0:** controls which slave port is used by the master to access the DDR. Allows the performance/latency tuning
0: (S0) Master access DDR through Slave S0
1: (S1) Master access DDR through Slave S1

14.3.7 SYSCFG compensation cell control register (SYSCFG_CMPCR)

Address offset: 0x020

Reset value: 0xXX87 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
APSRC[3:0]				ANSRC[3:0]				RAPSRC[3:0]				RANSRC[3:0]			
r	r	r	r	r	r	r	r	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	READY	Res.	Res.	Res.	Res.	Res.	Res.	SW_CTRL	Res.
							r							rw	

Bits 31:28 **APSRC[3:0]**: PMOS I/O Compensation value provided by compensation cell.
Value sent to IOs compensation when SW_CTRL = 0 and READY = 1

Bits 27:24 **ANSRC[3:0]**: NMOS I/O Compensation value provided by compensation cell.
Value sent to IOs when SW_CTRL = 0 and READY = 1

Bits 23:20 **RAPSRC[3:0]**: PMOS I/O Compensation value sent to IOs when SW_CTRL = 1
0000: reserved
0001: maximum compensation of fast conditions
....
1000: compensation for typical conditions
....
1110: maximum compensation of slow conditions
1111: reserved
Note: If compensation is needed, it is recommended to use automatic compensation

Bits 19:16 **RANSRC[3:0]**: NMOS I/O Compensation value sent to IOs when SW_CTRL = 1
0000: reserved
0001: maximum compensation of slow conditions
....
0111: compensation for typical conditions
....
1110: maximum compensation of fast conditions
1111: reserved
Note: If compensation is needed, it is recommended to use automatic compensation

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **READY**: Compensation cell ready flag
0: I/O compensation cell not ready.
1: I/O compensation cell ready, the values of APSRC[3:0] and ANSRC[3:0] are valid

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **SW_CTRL**: Compensation Software Control
0: IO compensation values come from compensation values in ANSRC[3:0] and APSRC[3:0]
1: IO compensation values come from RANSRC[3:0] and RAPSRC[3:0] register values
Note: SW_CTRL = 0 is not taken into account until READY = 1.
This means that whenever SW_CTRL, the RANSRC[3:0] and RAPSRC[3:0] are used for IO compensation when the compensation cell is in power down (MCU_EN = 0 and MPU_EN = 0, which is the case after a reset).

Bit 0 Reserved, must be kept at reset value.

14.3.8 SYSCFG compensation cell enable set register (SYSCFG_CMPENSETR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCU_EN	MPU_EN
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCU_EN**: Compensation cell enable

Set by software.

0: (power_down) Writing '0' has no effect, reading ‘0’ mean I/O compensation cell in power-down mode if MPU_EN=0

1: (enabled) Writing '1' enable I/O compensation cell, reading ‘1’ mean /O compensation cell is enabled

Note: The CSI oscillator must be enabled and ready (controlled in RCC) before MPU_EN could be set to 1. Similarly, the CSI oscillator could be disabled only if MPU_EN and MCU_EN are set to 0.

Bit 0 **MPU_EN**: Compensation cell enable

Set by software.

0: (power_down) Writing '0' has no effect, reading ‘0’ mean I/O compensation cell in power-down mode if MCU_EN=0

1: (enabled) Writing '1' enable I/O compensation cell, reading ‘1’ mean /O compensation cell is enabled

Note: The CSI oscillator must be enabled and ready (controlled in RCC) before MPU_EN could be set to 1. Similarly, the CSI oscillator could be disabled only if MPU_EN and MCU_EN are set to 0.

14.3.9 SYSCFG compensation cell enable clear register (SYSCFG_CMPENCLRR)

Address offset: 0x028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCU_EN	MPU_EN
														rc_w1	rc_w1

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MCU_EN**: Compensation cell enable

Cleared by software.

0: (power_down) Writing '0' has no effect, reading ‘0’ mean I/O compensation cell in power-down mode if MPU_EN=0

1: (enabled) Writing '1' clear MCU_EN bit, reading ‘1’ mean /O compensation cell is enabled

Note: The CSI oscillator must be enabled and ready (controlled in RCC) before MPU_EN could be set to 1. Similarly, the CSI oscillator could be disabled only if MPU_EN and MCU_EN are set to 0.

Bit 0 **MPU_EN**: Compensation cell enable

Cleared by software.

0: (power_down) Writing '0' has no effect, reading ‘0’ mean I/O compensation cell in powerdown mode if MCU_EN=0

1: (enabled) Writing '1' clear MPU_EN bit, reading ‘1’ mean /O compensation cell is enabled

Note: The CSI oscillator must be enabled and ready (controlled in RCC) before MPU_EN could be set to 1. Similarly, the CSI oscillator could be disabled only if MPU_EN and MCU_EN are set to 0.

14.3.10 SYSCFG control timer break register (SYSCFG_CBR)

Address offset: 0x02C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDL	Res.	CLL
													rs		rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **PVDL**: PVD lock enable bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection to TIM1/8/15/16/17 Break input, as well as the PVDE and PLS[2:0] in the PWR_CR1 register.

0: PVD interrupt disconnected from TIM1/8/15/16/17 Break input. PVDE and PLS[2:0] bits can be programmed by the application.

1: PVD interrupt connected to TIM1/8/15/16/17 Break input. PVDE and PLS[2:0] bits are read only.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CLL**: Cortex-M4 LOCKUP (Hardfault) output enable bit

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the connection of Cortex-M4 LOCKUP (Hardfault) output to TIM1/8/15/16/17 Break input

0: Cortex-M4 LOCKUP output disconnected from TIM1/8/15/16/17 Break inputs

1: Cortex-M4 LOCKUP output connected to TIM1/8/15/16/17 Break inputs

14.3.11 SYSCFG version register (SYSCFG_VERR)

Address offset: 0x03F4

Reset value: 0x0000 0020

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]:** Major revision
These bits return the SYSCFG major revision.
Major revision is 2.

Bits 3:0 **MINREV[3:0]:** Minor revision
These bits return the SYSCFG minor revision.
Minor revision is 0.

14.3.12 SYSCFG identification register (SYSCFG_IPIDR)

Address offset: 0x03F8

Reset value: 0x0003 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]

15 Extended TrustZone® protection controller (ETZPC)

15.1 ETZPC introduction

The ETZPC configures TrustZone security in a SoC having bus masters and slaves with programmable-security attributes (securable resources) such as:

- On-chip RAM/ROM with programmable secure region size
- AHB and APB peripherals to be made secure
- AHB and APB peripherals to be set as isolated

15.2 ETZPC features

- 32-bit APB4 interface
- ETZPC is always Write-secure
- Register set to control SoC security settings for:
  - securable on-chip RAM and ROM secure region size
  - access rights for securable AHB and APB peripherals
  - resource isolation to Cortex-M4 domain for AHB and APB peripherals
- Locking of the security configuration per memory region and per peripheral
- Configurable memory region size in 4-Kbyte steps.

15.3 Extended TrustZone architecture and ETZPC

- The Arm TrustZone model supports the isolation between:
  - A secure world, where security sensitive applications are run and critical resources are located; secure transactions are signaled with AxPROT[1] = 0 on the AXI bus
  - A non-secure or public world (Linux user space); non-secure transactions are signaled with AxPROT[1] = 1 on the AXI bus.
  - The STM32MP153 TrustZone architecture is extended beyond AXI and Cortex-A with AXI/AHB sideband signals to propagate the secure/non-secure transaction attributes to AHB and APB agents.
- AHB and APB peripherals are categorized as:
  - **secure**:
    These peripherals are protected by an AHB/APB firewall stub used to reject any non-secure access.
    Non secure writes are ignored with a Bus error.
    Non secure reads do not proceed to the peripheral, zeros are returned on the bus with a bus error.
  - **securable**:
    These peripherals are protected by an AHB/APB firewall, which is controlled by ETZPC to define its security mode.
    When the peripheral is configured as secure by ETZPC: non-secure writes are ignored with a Bus error, non-secure reads do not proceed to the peripheral, and zeros are returned on the bus with a Bus error. Only secure reads and writes can

proceed to the peripheral.
When the peripheral is configured as non-secure by the ETZPC, both secure and non-secure reads and writes can proceed to the peripheral.

– **non-secure:**
These peripherals are connected directly to AHB/APB and both secure and non-secure read and write can proceed to the peripheral.

– **TrustZone-aware**:
These peripherals are connected directly to the AHB or APB4 bus and implement a specific TrustZone behavior, for example a subset of registers can be made secure according to the peripheral state, or to its programming interface.

Note: The Bus error is conditioned to interconnect clocking (for example, illicit access to an un-clocked peripheral does not generate a bus error).

- AXI bus masters drive the AxPROT[1] signal according to their secure state; an AXI bus master can be:
  a) non-secure (in which case AxPROT[1]=1)
  b) TrustZone capable (Cortex-A7,MDMA) in which case AxPROT[1] is driven low when the bus master is in secure state.
- AHB bus masters are normally non-secure.

  It is expected that the ETZPC is programmed during secure BOOT and not changed later:
  – The TZMA secure region size can only be changed by secure software.

Note: Before releasing a RAM region to the non-secure world by programming the TZMA to decrease the secure region size, the RAM should be cleared.

15.4 ETZPC functional description

The ETZPC consists of a set of registers to control securable IPs through:

- **r0size[]** bits to define each TZMA secure region size.
  decprot[1:0] bits to control each AHB/APB securable peripheral access permissions as:
  - decprot[1:0] = 00: the peripheral is secure; read/write accesses are allowed by the secure world only.
  - decprot[1:0] = 01: the peripheral is write secure; read accesses are allowed by both secure and non-secure worlds, but write accesses are allowed by the secure world only.
  - decprot[1:0] = 10: The peripheral is non-secure and certain MCU peripherals are isolated, according to *Table 91: decprot bits for isolable peripherals (type 2) and behavior*.
  - decprot[1:0] = 11: the peripheral is non-secure; both read and write access are allowed by both the secure and non-secure worlds.

By default, after reset, memory regions are secure and all peripherals are read/ write secure.

r0size[] and **decprot[]** can be individually locked to prevent security configuration changes until next reset.

15.5 STM32MP153 security architecture

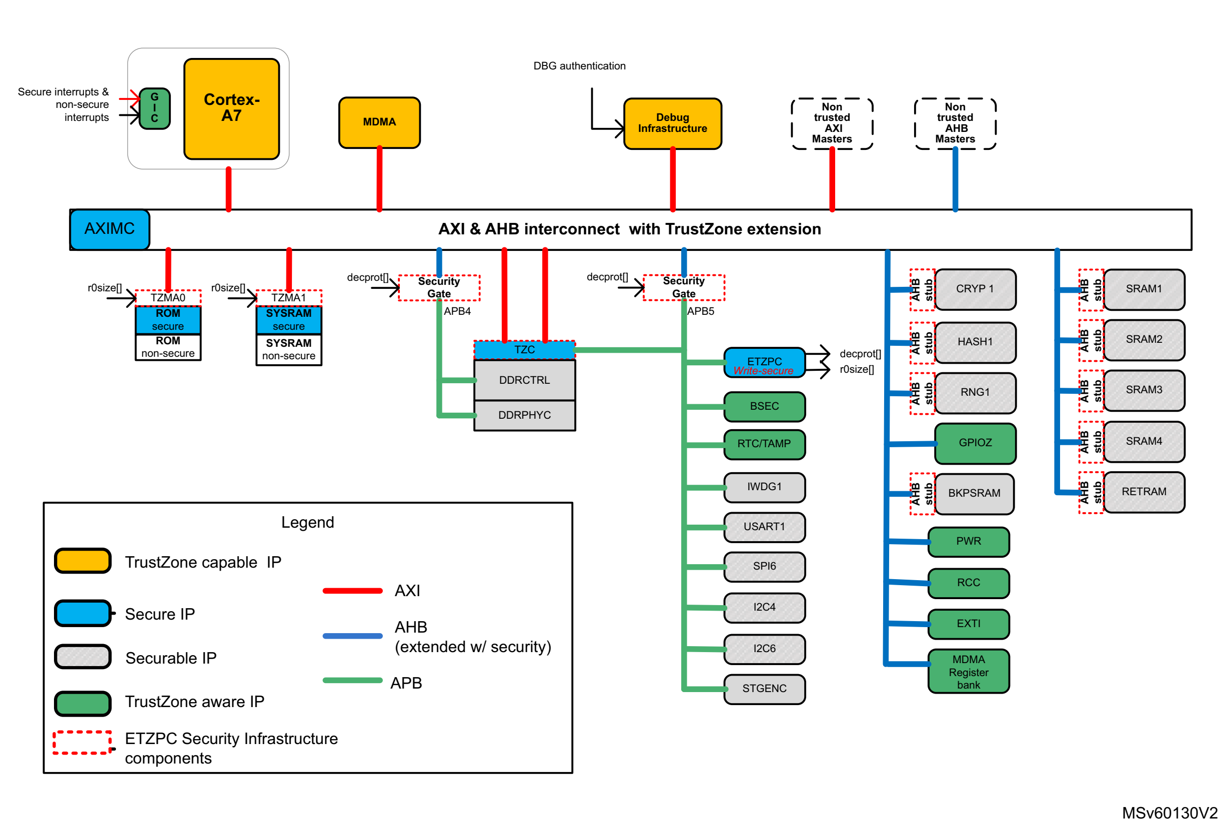
IP security properties can be classified as:

- TrustZone capable bus master IPs, as listed in *Table 89*.
- TrustZone aware peripherals, whose behavior is conditioned to transaction security, as listed in *Table 87*.
- TrustZone securable peripherals which rely on some AHB stub or on the AHB2APB bridge to control IP access according to decprot[] bits and transaction security. These are listed in *Table 86: STM32MP153 secure and securable peripherals* with type P.
- TrustZone secure (always secure) peripherals, as listed in *Table 86: STM32MP153 secure and securable peripherals* with type S or WS (write secure).

Note: Debug access port (DAP) security properties are set via the DBG authentication interface.

The STM32MP153 security architecture is shown in *Figure 126*.

Figure 126. STM32MP153 security architecture



The STM32MP153 security architecture is based on an extended version of Arm TrustZone with:

- TrustZone extension to AHB
- AHB stubs to protect securable AHB peripherals
- AHB2APB bridge using PPROT[1] signal propagation to TrustZone aware IPs listed in *Table 87*
- AHB2APB bridge to protect the securable APB peripherals listed in *Table 86: STM32MP153 secure and securable peripherals*
- TZMA firewalls for ROM and SYSRAM shown in *Table 88*

Table 86. STM32MP153 secure and securable peripherals

IP	Type(1)	Bus	comment
DDRPHYC	P	APB4	DDR PHY
DDRCTRL	P	APB4	DDR controller
CRYP1	P	AHB	CRYP1
HASH1	P	AHB	HASH1
RNG1	P	AHB	RNG1
I2C4	P	APB5	I2C for secure applications
I2C6	P	APB5	I2C for secure applications

Table 86. STM32MP153 secure and securable peripherals (continued)

IP	Type[1]	Bus	comment
SPI6	P	APB5	SPI for secure applications
USART1	P	APB5	USART for secure applications
IWDG1	P	APB5	Secure Independent Watchdog
BKPSRAM	P	AHB	BKPSRAM (4 Kbytes)
STGENC	P	APB5	System Timer GENerator (STGEN) Control port
TZC	S	APB5	TrustZone address space controller
ETZPC	WS	APB5	TrustZone protection controller (this IP)
SRAM1/2/3/4	P	AHB	SRAM1/2/3/4
RETRAM	P	AHB	RETRAM
AXIM	S	AXI	GPV local to AXIM

1. P: securable peripherals, S: R/W secure peripheral, WS: Write secure peripheral.

Table 87. STM32MP153 TrustZone-aware peripherals

IP	Bus	comment
BSEC	APB5	BSEC includes a subset of secure registers
MDMA	AHB	MDMA supports security per channel and its slave port is made TrustZone aware to forbid non-secure access to secure channels
GPIOZ	AHB	GPIOz is TrustZone-aware and supporting pin level security
RCC	AHB	RCC includes sensitive registers which are write secure
PWR	AHB	PWR includes sensitive registers which are write secure
EXTI	AHB	EXTI includes sensitive registers which are write secure
RTC and Tamper	APB	RTC/TAMP includes a subset of secure registers

For more information about IP security features refer to the corresponding IP section.

Table 88. STM32MP153 memory firewalls

On-chip memory	IP	comment
ROM	TZMA0	ROM can be partitioned into secure/non-secure regions on a 4 Kbyte boundary, the lower region is secure with 0 K, 4 K, 8 K, and so on up to 128 Kbyte size. After system reset all ROM is secure.
SYSRAM	TZMA1	SYSRAM can be partitioned into secure/non-secure regions at a 4 Kbyte boundary, the lower region is secure with 0 K, 4 K, 8 K, and so on up to 256 Kbyte size. After system reset all SYSRAM is secure.

Table 89. STM32MP153 TrustZone-capable bus masters

IP	I/F	comment
Cortex-A7	AXI	Cortex-A7 is TrustZone capable.
MDMA	AXI	MDMA channels can be set as secure or non-secure.
DAP AXI-AP	AXI	AXI-AP is made TustZone aware according to debug authentication interface (spiden, spniden) controlled by the BSEC.

15.6 STM32MP153 MCU resource isolation

The ETZPC can be used to define a set of resources to be accessed only by the Cortex-M4 domain (MCU resource isolation). Besides the Cortex-M4, the domain may also include several DMA masters assigned to the MCU isolation domain.

Resources and DMA masters that can be assigned to MCU isolation domains are listed in *Table 93: Programmable options according to resource type* with type =2 and type =3. This concerns a large set of resources, with access restricted to the Cortex-M4 and DMA master under its control for application safety purposes.

Resource isolation is programmed by the decprot[] bits and access filtering using AHB stubs and AHB2APB firewalling according to the Master IDs. Because security and MCU resource isolation peripherals are not orthogonal, the resources listed in *Table 93* are of 3 types as follows:

- **type 1**: securable peripherals
  – the decprot[] bits define access rules according to*Table 90*
  – failed access are reported with a bus error
- **type 2**: isolable only peripherals
  – the decprot[] bits define access rules according to *Table 91*
  – failed access are reported with a bus error
- **type 3**: peripherals which are both securable and isolable
  – the decprot[] bits define access rules according to *Table 92*
  – failed access are reported with a bus error.

Any resource not listed in *Table 93: Programmable options according to resource type* is accessible by any bus master (for example, non secured).

The debug AXI-AP is non-secure but able to access MCU resources.

Table 90. decprot bits for securable peripherals (type 1) and behavior

decprot[1:0]	Comment
0b00	The peripheral is RW secure. Default after reset.
0b01	The peripheral is write-secure (for example.only write secure are allowed, read can be secure or non-secure).
0b10	Reserved. (Undefined behavior but does not weaken security.)
0b11	The peripheral is not secure (read and write by secure and non-secure means).

Table 91. decprot bits for isolable peripherals (type 2) and behavior

decprot[1:0]	Comment
0b0x	Reserved. (Undefined behavior but does not weaken security).
0b10	Peripheral RW access only by the Cortex-M4 domain. (Cortex-A7 and other bus masters not in the Cortex-M4 domains are denied whether secure or non secure).
0b11	The peripheral is not secure (read and write by secure and non-secure means). Default after reset.

Table 92. decprot bits for securable and Isolable Peripherals (type 3) and behavior

decprot[1:0]	Comment
0b00	The peripheral is RW secure.
0b01	The peripheral is write-secure (for example, only secure writes are allowed, read can be secure or non-secure).
0b10	Peripheral RW access only by Cortex-M4 domain. (Cortex-A7 and other Bus master not in Cortex-M4 domains are denied whether secure or non secure).
0b11	The peripheral is not secure (read and write by secure and non secure means). Default after reset.

Programmable values of decprot[] bits according to resource type are summarized in *Table 93*

Table 93. Programmable options according to resource type

Resource type	0b00 (secured)	0b01 (Write secured)	0b10 (MCU isolation)	0b11 (non-secured)
1: Securable	Prog (default)	Prog	No	Prog
2: MCU isolation	No	No	Prog	Prog (default)
3: Securable and MCU Isolation	Prog	Prog	Prog	Prog (default)

Note: Default after reset indicated by "".*

Bus master and MCU resource isolation:

Bus masters listed in *Table 94: DECPROT assignment* (DMA1, DMA2, OTG, SDMMC3, ETH1) may be assigned to the MCU isolation domain according to their control port decprot[] bit programming value. In this case they have granted access to other MCU isolated resources.

Failed access behaviors:

Whether it is a security or isolation violation, failed writes are ignored and failed reads are returned as zeros. Furthermore a bus error is asserted to either raise an exception with the Cortex CPUs, or to be flagged by an interrupt with DMA IPs.

Note: *The only exception is GPIOZ (Tz-aware IP), which fails silently.*

Any write access to ETZPC locked settings is also silently ignored.

All peripherals concerned by security and MCU resource isolation, and controlled by the ETZPC are listed in *Table 94* with the corresponding IP decprot[] bits.

Table 94. DECPROT assignment

Index	decprot bits	IP	Bus	Default	Bus master	Type	Attributes
0	DECPROT0[1:0]	STGENC	APB5	0b00	-	1	Securable
1	DECPROT0[3:2]	BKPSRAM	AHB5	0b00	-	1	Securable
2	DECPROT0[5:4]	IWDG1	APB5	0b00	-	1	Securable
3	DECPROT0[7:6]	USART1	APB5	0b00	-	1	Securable

95	DECPROT5[31:30]	-		0b11	-	-	Reserved

1. FDCAN use one decprot[] for several APB regions
2. USBPHYC associated to OTG cannot be isolated

15.7 ETZPC registers

The ETZPC registers are accessed only by word (32-bit).

ETZPC registers are write-secure (that is, read accesses are allowed by secure and non-secure domains, write accesses are allowed by the secure domain only).

The ETZPC_DECPROTx registers are used to control security and resource isolation for all peripherals listed in *Table 94: DECPROT assignment* according to the index (from 0 to 95).

Caution: The ETZPC is programmed during early boot, it should not be changed afterwards, lock bits can enforce this; propagation of the ETZPC decprot[] bits takes some delay, two APB cycles must be observed before security rule is applied.

15.7.1 ETZPC ROM secure size definition (ETZPC_TZMA0_SIZE)

Address offset: 0x000

Reset value: 0x0000 03FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs															
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	R0SIZE[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: To lock r0size settings of the TZMA

0: r0size[] can be written

1: r0size[] cannot be modified until the next reset, therefore the write to r0size is silently ignored (for example no APB SLVERR).

Bits 30:10 Reserved, must be kept at reset value.

Bits 9:0 **R0SIZE[9:0]**

Defines the size of the secure ROM at the lower values, and non-secure ROM at the higher values:

0x000: all ROM is non-secure

0x001: 4 Kbyte ROM secure

0x002: 8 Kbyte ROM secure

....

0x020 to 0x3FF: 128 Kbyte ROM secure (for example all ROM secure)

15.7.2 ETZPC RAM secure size definition (ETZPC_TZMA1_SIZE)

Address offset: 0x004

Reset value: 0x0000 03FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs															
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	R0SIZE[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: To lock r0size settings of the TZMA

0: r0size[] can be written

1: r0size[] can not be modified until next reset, therefore the write to r0size is silently ignored (for example APB SLVERR)

Bits 30:10 Reserved, must be kept at reset value.

Bits 9:0 **R0SIZE[9:0]:** Defines the size of the secure RAM at the lower values, and non-secure RAM at the higher values:

0x000: all RAM is non-secure

0x001: 4 Kbyte RAM secure

0x002: 8 Kbyte RAM secure

....

0x040 to 0x3FF: 256 Kbyte RAM secure (for example all RAM secure)

15.7.3 ETZPC securable peripheral control register x (ETZPC_DECPROTx)

Address offset: 0x010 + 0x004 * (x- 0) (x = 0 to 5)

Reset value: 0x0000 0000, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF, 0xFFFF FFFF

Register reset values according to values in *Table 94: DECPROT assignment* column *Default*, see also register map.

Define security and isolation for peripheral at index (16 * x + y) in *Table 94* according to ETZPC_DECPROTx with (x = 0 to 5) and (y= 0 to 15) according to DECPROTy[1:0]:

- 00: read and write secure
- 01: read non-secure and write secure
- 10: non-secure but MCU isolated
- 11: non-secure.

Permissible values of DECPROTy[1:0] are according to *Table 94* column *Attributes*.

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bit 31 **LOCK31:** Lock of security for peripheral with index (32 * x + 31) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 30 **LOCK30**: Lock of security for peripheral with index (32 * x + 30) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 29 **LOCK29**: Lock of security for peripheral with index (32 * x + 29) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 28 **LOCK28**: Lock of security for peripheral with index (32 * x + 28) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 27 **LOCK27**: Lock of security for peripheral with index (32 * x + 27) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 26 **LOCK26**: Lock of security for peripheral with index (32 * x + 26) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 25 **LOCK25**: Lock of security for peripheral with index (32 * x + 25) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 24 **LOCK24**: Lock of security for peripheral with index (32 * x + 24) as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 23 **LOCK23**: Lock of security for peripheral with index (32 * x + 23) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 22 **LOCK22**: Lock of security for peripheral with index (32 * x + 22) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 21 **LOCK21**: Lock of security for peripheral with index (32 * x + 21) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 20 **LOCK20**: Lock of security for peripheral with index (32 * x + 20) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 19 **LOCK19**: Lock of security for peripheral with index (32 * x + 19) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 18 **LOCK18**: Lock of security for peripheral with index (32 * x + 18) as defined by *Table 94*.
0: not locked
1: decprot[] bits are locked until next reset

Bit 17 **LOCK17**: Lock of security for peripheral with index (32 * x + 17) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 16 **LOCK16**: Lock of security for peripheral with index (32 * x + 16) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 15 **LOCK15:** Lock of security for peripheral with index (32 * x + 15) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 14 **LOCK14**: Lock of security for peripheral with index (32 * x + 14) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 13 **LOCK13**: Lock of security for peripheral with index (32 * x + 13) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 12 **LOCK12**: Lock of security for peripheral with index (32 * x + 12) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 11 **LOCK11**: Lock of security for peripheral with index (32 * x + 11) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 10 **LOCK10**: Lock of security for peripheral with index (32 * x + 10) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 9 **LOCK9**: Lock of security for peripheral with index (32 * x + 9) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 8 **LOCK8**: Lock of security for peripheral with index (32 * x + 8) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 7 **LOCK7**: Lock of security for peripheral with index (32 * x + 7) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 6 **LOCK6**: Lock of security for peripheral with index (32 * x + 6) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 5 **LOCK5**: Lock of security for peripheral with index (32 * x + 5) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 4 **LOCK4**: Lock of security for peripheral with index (32 * x + 4) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 3 **LOCK3**: Lock of security for peripheral with index (32 * x + 3) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 2 **LOCK2**: Lock of security for peripheral with index (32 * x + 2) as defined by *Table 94*.
0: not locked
1: decprot[] bits are locked until next reset

Bit 1 **LOCK1**: Lock of security for peripheral with index (32 * x + 1) as defined by *Table 94*.
0: not locked
1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

Bit 0 **LOCK0**: Lock of security for peripheral with index 32 * x as defined by *Table 94*.

0: not locked

1: peripheral decprot[] bits are locked until next reset, therefore the write to decprot[] is silently ignored (for example no APB SLVERR)

15.7.5 ETZPC HW configuration register (ETZPC_HWCFGR)

Address offset: 0x3F0

Reset value: 0x0000 6002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CHUNKS1N4[7:0]								NUM_AHB_SEC[7:0]

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
NUM_PER_SEC[7:0]								NUM_TZMA[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **CHUNKS1N4[7:0]**: TZMA size steps (0: 4 Kbytes, 1: 1 Kbyte)

Bits 23:16 **NUM_AHB_SEC[7:0]**: Number of securable AHB masters

Bits 15:8 **NUM_PER_SEC[7:0]**: Number of securable peripherals

Bits 7:0 **NUM_TZMA[7:0]**: Number of TZMA instances

15.7.6 ETZPC version register (ETZPC_VERR)

Address offset: 0x3F4

Reset value: 0x0000 0021

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAJREV[3:0]				MINREV[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **MAJREV[3:0]:** Major revision

This field returns the major revision of the ETZPC

Bits 3:0 **MINREV[3:0]:** Minor revision

This field returns the minor revision of the ETZPC

15.7.7 ETZPC identification register (ETZPC_IDR)

Address offset: 0x3F8

Reset value: 0x0010 0061

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ID[31:0]**: Identification code.
This field returns the Identification code of ETZPC

15.7.8 ETZPC size identification register (ETZPC_SIDR)

Address offset: 0x3FC

Reset value: 0xA3C5 DD01

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]**: Size and ID.
This field returns the size and ID of ETZPC

15.7.9 ETZPC register map

The table below provides the ETZPC register map and reset values.

Table 95. ETZPC register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.5 on page 153* for the register boundary addresses.

16 Block interconnects

16.1 Peripheral interconnects

16.1.1 Introduction

Several peripherals have direct interconnections between them. This allows autonomous communication and synchronization between peripherals, saving processor resources and reducing power supply consumption.

In addition, these hardware connections remove software latency and allow the design of a predictable system.

This also saves pins and GPIOs.

Depending on the peripheral, these interconnections can operate in Run, CSleep or Stop modes.

16.1.2 Connection overview

There are several types of connections, as listed below.

Asynchronous connections (A)

The source output signal is sampled by the destination clock, leading to the possible introduction of jitter in the latency between the source output event and the destination event detection.

Synchronous connections (S)

Both source and destination are synchronous (they run on the same clock), and the latency from the source to the destination is deterministic. No jitter is introduced.

Break/fault connection for TIM outputs (B)

The source output signal disables the timer outputs through a pure combinatorial logic path, without any latency.

17 MDMA controller (MDMA)

17.1 MDMA introduction

The master direct memory access (MDMA) is used in order to provide high-speed data transfer between memory and memory, or between peripherals and memory. Data can be quickly moved by the MDMA without any CPU action. This keeps the CPU resources free for other operations.

The MDMA controller provides a master AXI interface for main memory and peripheral register access (system access port).

The MDMA works in conjunction with the standard DMA controllers (DMA1 or DMA2). It offers up to 32 channels, each dedicated to manage memory access requests from one of the DMA stream memory buffer or other peripherals (with integrated FIFO).

17.2 MDMA main features

- AXI master bus architecture.
- 32 channels
- Up to 40 hardware trigger sources
- Each channel request can be selected among any of the request sources. This selection is software-configurable and allows several peripherals to initiate DMA requests. The trigger selection can be automatically changed at the end of one block transfer.
- All channels are identical and can be connected either to a standard DMA or a peripheral request (acknowledge by data read/write) system or to a peripheral request/acknowledge system
- Each channel also supports software trigger.
- One 256-level memory buffer, split in two 128-level first-in, first-out (FIFO), that is used to store temporary the data to be transferred (in burst or single transfer mode), for one or two consecutive buffers. The FIFO stores the data that are transferred during the current channel block transfer (up to the block transfer size). The second FIFO can be used for the next buffer to be transferred, either for the same channel or for the next channel transfer.
- The priorities between DMA channels are software-programmable (four levels consisting of very-high, high, medium, low) or hardware in case of equality (for example, channel 0 has priority over channel 1)
- Independent source and destination transfer width (byte, half-word, word, double-word): when the data widths of the source and destination are not equal, the MDMA can pack/unpack the necessary data to optimize the bandwidth.
- The size and address increment for both source and destination can be independently selected.

Note: Based on this separation, some more advanced packing/unpacking operations are available at software level. As an example, 2 x 16-bit data blocks can be interleaved together using two MDMA channels, in the destination memory, by simply programming the two channels with an increment step of 4 bytes and a data size of 16 bits + a start address shifted by two between the two channels.

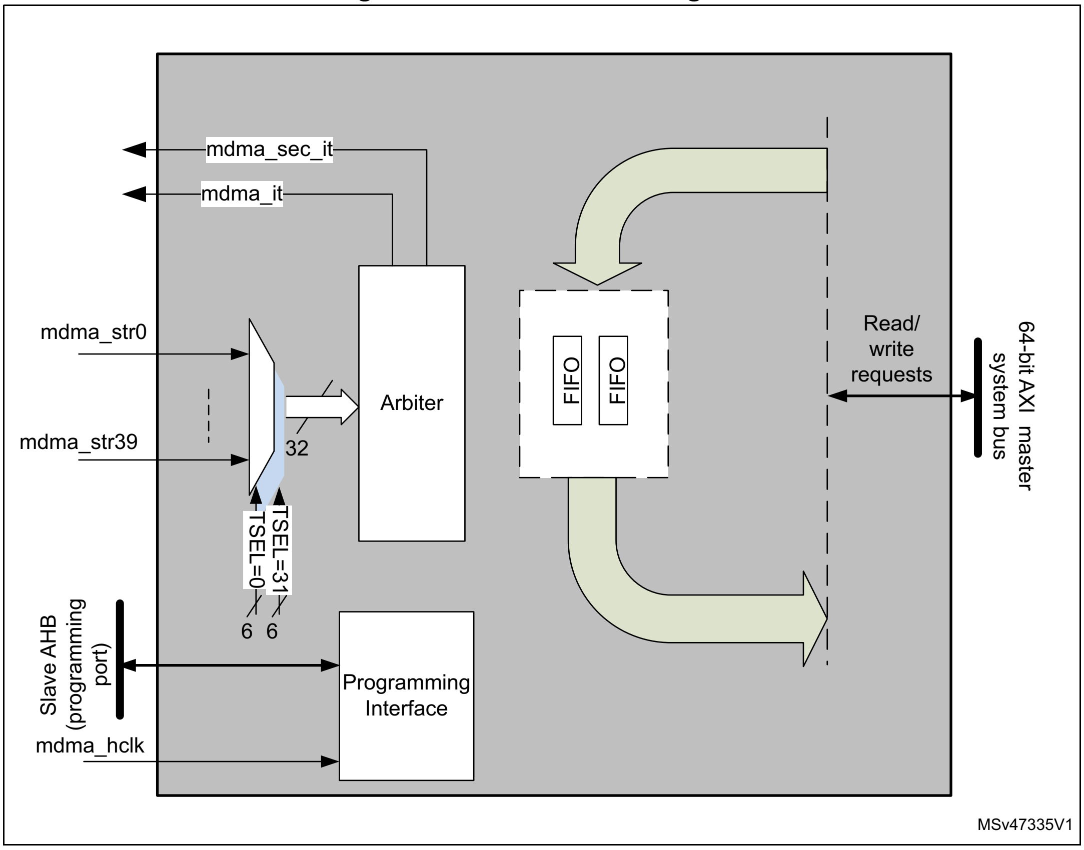
- Incrementing, decrementing or non incrementing/fixed addressing for source and destination
- Data packing/unpacking is always done respecting the little endian convention: lower address in a data entity (double-word, word, or half-word) contains always the lowest significant byte. This is independent of the address increment/decrement mode of both source and destination.
- Supports incremental burst transfers. The size of the burst is software-configurable, up to 128 bytes. For larger data sizes the burst length is limited, as to respect the maximum 128 bytes data burst size (such as 16 x 64 bits or 32 x 32 bits).
- For the TCM memory accesses, the burst access is only allowed when the increment and data size are identical and lower than or equal to 32 bits.
- Five event flags (MDMA channel transfer complete, MDMA block transfer complete, MDMA block repeat transfer Complete, MDMA buffer transfer Complete, MDMA transfer error) are available and can generate interrupts.

17.3 MDMA functional description

17.3.1 MDMA block diagram

The figure below shows the block diagram of the MDMA.

Figure 127. MDMA block diagram



17.3.2 MDMA internal signals

The table below shows the internal MDMA signals.

Table 99. MDMA internal input/output signals

Signal name	Signal type	Description
mdma_hclk	Digital input	MDMA AHB clock
mdma_it	Digital output	MDMA interrupt
mdma_sec_it	Digital output	MDMA secure interrupt
mdma_str[0:39]	Digital input	MDMA stream request

17.3.3 MDMA overview

The MDMA performs a direct memory transfer: as an AXI master, the MDMA can take the control of the AXI bus matrix to initiate AXI transactions.

The MDMA can carry out the following transactions:

- memory-to-memory (software triggered)
- peripheral-to-memory
- memory-to-peripheral

For the last two transaction types, the memory can also be replaced by a memory-mapped peripheral, which has no control over the MDMA flow. When these types of transaction are used and the request comes from a standard DMA (DMA1 or DMA2), the peripheral register access is replaced by a memory access to the memory buffer used by this DMA.

Note: Non-incrementing/decrementing mode is not used for memory accesses.

The source and destination are simply defined by the address (peripherals being memory-mapped also).

The AHB slave port is used to program the MDMA (it supports 8-,16-, and 32-bit accesses).

The size of the data array to be transferred for a single request is one of the following:

- buffer transfer size
- block size
- repeated block
- complete channel data (until the linked-list pointer for the channel is null)

The choice of the size is done through the TRGM[1:0] (Trigger mode) selection field.

The user must choose one of them based on the data array size available (usually in the DMA1/2 memory buffer) and the “real time” requirements for other MDMA channels (knowing that a buffer transfer is the minimum data aggregate to be transferred by the MDMA without doing a new arbitration between MDMA channel requests).

For each channel, there are three key data array sizes:

- Burst size: this is the length of the data transfer which can be performed in burst mode. This burst length defines the maximum transfer length which cannot be interrupted at bus arbitration level and can block other masters from accessing the bus.
- Buffer transfer size: this is the length of the data array to be transferred, on a channel, before checking for MDMA requests on other channels. This is the data array transfer lengths which cannot be interrupted at MDMA level (from other channel requests).
- Block size: this value has two meanings which can be used together:
  - main: this is length of the data block which is described in a block structure of the MDMA linked list (corresponds to one entry in the linked list)
  - selectable: when TRGM[1:0] equals 01, this is the length of the data array which is transferred on a single MDMA request activation (for the respective channel)

17.3.4 MDMA channel

Each MDMA channel provides an unidirectional transfer link between a source and a destination.

Each channel can perform transfer of the following types:

- Single block transfer: one block is transferred. At the end of the block, the MDMA channel is disabled and an end-of-channel transfer interrupt is generated.
- Repeated block transfer: a number of blocks is transferred before disabling the channel.
- Linked-list transfer: when the transfer of the current data block (or last block in a repeat) is completed, a new block control structure is loaded from memory and a new block transfer is started.

The minimum amount of data to be transferred for each request (buffer size, up to 128 bytes) is programmable. The total amount of data in a block, is programmable up to 64 Kbytes. This value is decremented after each transfer. When this counter reaches zero, the end of the block is reached and an action is taken based on the repeat counter (for repeated block transfer) and/or linked-list structure value.

Note: If the block length is not a multiple of the buffer length, the last buffer transfer in the block is shorter, covering the remaining bytes to be transferred in the current block.

If the link structure address points to a valid memory address, the MDMA reloads the whole channel descriptor structure register contents from memory at this address. Then, a new block transfer is then executed (on the next MDMA channel request) based on this information.

If the link structure address is 0x0, at the end of the current/repeated block transfer, the MDMA channel is disabled and the end-of-channel transfer interrupt is generated.

17.3.5 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The source/destination addresses can be fixed (such as FIFO/single data register peripherals) or incremented/decremented. The transfer can be done in single access or in burst mode (programmable).

17.3.6 Pointer update

The source and destination memory pointers can optionally be automatically post-incremented/decremented, or kept constant after each transfer depending on the SINC[1:0] and DINC[1:0] bitfields in the MDMA_CxCR register.

Disabling the increment mode is useful when the peripheral source or destination data are accessed through a single register/FIFO mode.

If the increment/decrement mode is enabled, the address of the next data transfer is the address of the previous one incremented/decrement by 1, 2, 4 or 8 depending on the increment size programmed in SINCOS[1:0] or DINCOS[1:0] in MDMA_CxCR.

In order to optimize the packing operation, the increment offset size and the data size are programmable independently.

17.3.7 MDMA buffer transfer

This is the minimum logical amount of data (up to 128 bytes) which is transferred on an MDMA request event, on one channel.

An MDMA buffer transfer consists of a sequence of a given number of data transfers (done as single or burst data transfers). The number of data items to be transferred and their width (8, 16, 32, or 64 bits) are software programmable. The length of the burst used for data transfers is also programmable, independently.

After an event requiring a data array to be transferred, the DMA/peripheral sends a request signal to the MDMA, which serves the request depending on the channel priorities.

The request is acknowledged either by writing the mask data value to the address given mask address, when these registers are set or by hardware ACK signal.

If the mask address register is not set (0x00 value), the request can be reset by simply reading/writing the data to the peripheral. In this case, if the request is done by a destination peripheral, the write must be set as non bufferable, in order to avoid a false new MDMA request.

The total amount of data to be transferred, on the current channel, following a MDMA request, is determined by the TRGM[1:0] field.

If TRGM[1:0] equals 00, a single buffer is transferred, then the MDMA waits for another request on the same channel.

Note: In this case, the hardware request for the currently active channel (data in the FIFO) is not considered again until the end of the write phase for this channel. Even if the channel is still active at the end of the read phase, another channel (even with lower priority) can start the read phase. Lower priority channels can be interleaved with current channel transfer.

If TRGM[1:0] is different from 00 (multiple buffers need to be transferred), the mdma_strx for the current channel remains active (internally memorized) until the whole transfer defined by TRGM (block, repeated block or whole channel/linked list data) is completed.
After transferring an individual buffer, the MDMA enters in a new arbitration phase (between new external requests and internally memorized ones). If no other higher priority, the channel request is active, and a new buffer transfer is started for the same channel.

Note: When TRGM[1:0] is different from 00, a larger array of data is transferred for a single request. But, as the channel arbitration is done after each buffer transfer, no higher level MDMA requests are blocked for the more than a buffer transfer period, on any lower priority channel.

17.3.8 Request arbitration

An arbiter manages the MDMA channel requests based on their priority. When the MDMA is idle and after the end of each buffer transfer, all MDMA requests (hardware or software) are checked for all enabled channels.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the MDMA_CxCR register. There are four levels:
  - Very high priority
  - High priority
  - Medium priority
  - Low priority
- Hardware: at hardware level, the channel priority is fixed. If two requests have the same software priority level, the channel with the lower number takes priority over the stream with the higher number. For example, Channel 2 takes priority over Channel 4 when they have the same software priority level.

17.3.9 FIFO

A FIFO structure is used to temporarily store data coming from the source before writing them to the destination. There is a central FIFO structure which is used for all channels.

In order to maximize data bandwidth and bus usage, the following mechanisms are used, allowing multiple read/write operation to be executed in parallel.

- During a buffer transfer, as soon as the FIFO contains enough data for a destination burst transfer, the write operation starts.
- When the complete data for a buffer transfer has been read into the FIFO, the arbitration procedure is started. Following that, the next buffer data to be transferred can be read to the FIFO.

When an active channel is disabled due to an error, during a buffer transfer, the remaining data in the internal FIFO is discarded.

17.3.10 Block transfer

A block is a “contiguous” array of data, up to 64 Kbytes, which is transferred by successive buffer transfers.

Each block of data is defined by the start address and the block length. When a block transfer is completed, one of the following three actions can be executed:

- The block is part of a repeated block transfer: the block length is reloaded and new block start address is computed (based on the information in MDMA_CxBRUR).
- It is a single block or the last block in a repeated block transfer: the next block information is loaded from the memory (using the linked list address information, from MDMA_CxLAR).
- It is the last block which needs to be transferred for the current MDMA channel (MDMA_CxLAR = 0): the channel is disabled and no further MDMA requests are accepted for this channel.

17.3.11 Block repeat mode

The block repeat mode is used to repeat a block transfer, with different start addresses for source and destination.

When the repeat block mode is active (repeat counter ≠ 0), at the end of the current block transfer, the block parameters are updated (BNDT value reloaded and SAR/DAR values updated according to BRSUM/BRDUM configuration), and the repeat counter decremented by one.

When the repeat block counter reaches 0, this last block is treated as a single block transfer.

17.3.12 Linked-list mode

The linked-list mode allows a new MDMA configuration to be loaded (MDMA_CxTCR, MDMA_CxBNDTR, MDMA_CxSAR, MDMA_CxDAR, MDMA_CxBRUR, MDMA_CxLAR, MDMA_CxTBR, MDMA_CxMAR and MDMA_CxMDR registers), from the address given in MDMA_CxLAR. This address must address a memory mapped on the AXI system bus.

Following this operation, the channel is ready to accept new requests, as defined in the block/repeated block modes above, or continue the transfer if TRGM[1:0] = 11.

The trigger source can be automatically changed, when loading the MDMA_CxTBR value.

The TRGM and SWRM values must not be changed when TRGM[1:0] = 11.

17.3.13 MDMA transfer completion

Different events can generate an end of transfer by setting the CTCIF bit in the status register (MDMA_CxISR):

- The MDMA_CxBNDTR counter has reached zero, the Block Repeat Counter is 0 and the Link list pointer address is 0
- The channel is disabled before the end of transfer (by clearing the EN bit in MDMA_CxCR) and all the remaining data have been transferred from the FIFO to the destination

17.3.14 MDMA transfer suspension

At any time, a MDMA transfer can be suspended in order to be to be restarted later on or to be definitively disabled before the end of the MDMA transfer.

There are two cases:

- The channel is disabled, with no later-on restart from the point where it was stopped. There is no particular action to do, besides clearing the EN bit in the MDMA_CxCR register to disable the channel. The stream can take time to be disabled (on going buffer transfer is completed first). The transfer complete interrupt flag is set in order to indicate the end of transfer. The value of the EN bit in MDMA_CxCR is now 0 to confirm the channel interruption. The MDMA_CxNDTR register contains the number of remaining data items when the channel was stopped. The software can then determine how many data items have been transferred before the channel was interrupted.
- The channel is suspended before the number of remaining bytes to be transferred in the MDMA_CxBNDTR register reaches zero. The aim is to restart the transfer later by re-enabling the channel. The channel transfer complete interrupt flag CTCIF is set in order to indicate the end of transfer. If the MDMA_CxBNDTR, MDMA_CxSAR and

MDMA_CxDAR registers are not modified by software, the transfer continues when the channel is re-enabled. CTCIF must also be reset before restarting the channel.

Note: If the completed buffer is the last of the block, the configuration registers are also updated before disabling the channel, in order to be correctly prepared for a soft restart.

Before reprogramming the channel, the software must wait the MDMA_CTCIF register is set, in order to guarantee that any ongoing operation has been completed.

17.3.15 Error management

The MDMA can detect the following errors and the transfer error interrupt flag (TEIF) is set:

- when a bus error occurs during a MDMA read/write access
- when an address alignment does not correspond to the data size
- when the block size is not a multiple of the data size (for source and/or destination): this error is activated on the last transfer and the error address points to the last transfer (which cannot be done)

17.4 MDMA interrupts

For each MDMA channel, an interrupt can be produced on the following events:

- Channel transfer completed
- Block-transfer completed
- Block-transfer repeat completed
- Buffer transfer completed
- Transfer error

Separate interrupt enable control bits are available for flexibility as shown in the table below.

Table 100. MDMA interrupt requests

Interrupt event	Event flag	Enable control bit
Channel transfer completed	CTCIF	CTCIE
Block-transfer repeat completed	BTRIF	BTRIE
Block-transfer completed	BTIF	BTIE
Buffer transfer completed	TCIF	TCIE
Transfer error	TEIF	TEIE

Note: Before setting an enable control bit to 1, the corresponding event flag must be cleared, otherwise an interrupt may be immediately generated, if the bit is already set.

When at least one interrupt flag and the respective enable control bit are set, the channel interrupt bit is set in the MDMA_SGISR. The interrupt output or the secure interrupt output is also activated. This generates an interrupt if the respective interrupt channel is enabled in the NVIC.

17.5 MDMA registers

The MDMA registers can be accessed in word, half-word, or byte format.

17.5.1 MDMA global interrupt status register (MDMA_GISR0)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GIF31	GIF30	GIF29	GIF28	GIF27	GIF26	GIF25	GIF24	GIF23	GIF22	GIF21	GIF20	GIF19	GIF18	GIF17	GIF16
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

GIF15	GIF14	GIF13	GIF12	GIF11	GIF10	GIF9	GIF8	GIF7	GIF6	GIF5	GIF4	GIF3	GIF2	GIF1	GIF0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **GIF[31:0]**: Channel x global interrupt flag (x = 31 to 0)

This bitfield is set and reset by hardware. It is a logical OR of all channel x interrupt flags (CTCIF, BTIF, BRTIF, TEIF) which are enabled in MDMA_CTCIEx, MDMA_BTIEx, MDMA_BRTIEx, and MDMA_TEIEx.

0: No interrupt generated by channel x

1: Interrupt generated by channel x

17.5.2 MDMA secure global interrupt status register (MDMA_SGISR0)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
GIF31	GIF30	GIF29	GIF28	GIF27	GIF26	GIF25	GIF24	GIF23	GIF22	GIF21	GIF20	GIF19	GIF18	GIF17	GIF16
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GIF15	GIF14	GIF13	GIF12	GIF11	GIF10	GIF9	GIF8	GIF7	GIF6	GIF5	GIF4	GIF3	GIF2	GIF1	GIF0
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **GIF[31:0]**: Channel x global interrupt flag (x = 31 to 0)

This bitfield is set and reset by hardware. It is a logical OR of all channel x interrupt flags (CTCIF, BTIF, BRTIF, TEIF) which are enabled in MDMA_CTCIEx, MDMA_BTIEx, MDMA_BRTIEx, and MDMA_TEIEx).

0: No interrupt generated by channel x

1: Interrupt generated by channel x

17.5.3 MDMA channel x interrupt status register (MDMA_CxISR)

Address offset: 0x40 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRQA
															r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TCIF	BTIF	BRTIF	CTCIF	TEIF
											r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **CRQA**: Channel x request active flag

This bit is set by software writing 1 to SWRQx in MDMA_CxCR, in order to request an MDMA transfer, and the channel x is enabled.

This bit is also set by hardware when the channel request becomes active, and the channel is enabled. The hardware request memorized until it is served.

This bit is cleared by hardware when the channel x request is completed (after the source write phase of the last buffer transfer due for the current request).

0: The MDMA transfer mdma_strx is inactive for channel x.

1: The MDMA transfer mdma_strx is active for channel x

Note: This bit is also reset by hardware when the channel is disabled (in case of transfer error, or when reaching the end of the channel data transfer - repeat block = 0 and linked list pointer null-, or by software programming the channel enable bit to 0 before that).

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **TCIF**: Channel x buffer transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No buffer transfer complete event on channel x

1: A buffer transfer complete event occurred on channel x

TC is set when a single buffer is transferred. It is activated on each channel transfer request. This can be used as a debug feature (without interrupt), indicating that (at least) an MDMA buffer transfer has been generated since the last flag reset.

Bit 3 **BTIF**: Channel x block transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No block transfer complete event on channel x

1: A block transfer complete event occurred on channel x.

Bit 2 **BRTIF**: Channel x block repeat transfer complete interrupt flag

This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.

0: No block repeat transfer complete event on channel x

1: A block repeat transfer complete event occurred on channel x

Bit 1 **CTCIF**: Channel x channel transfer complete interrupt flag
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.
0: No channel transfer complete event on channel x
1: A channel transfer complete event occurred on channel x
CTC is set when the last block was transferred and the channel has been automatically disabled.
CTC is also set when the channel is suspended, as a result of writing EN bit to 0.

Bit 0 **TEIF**: Channel x transfer error interrupt flag
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in MDMA_IFCRy.
0: No transfer error on stream x
1: A transfer error occurred on stream x

17.5.4 MDMA channel x interrupt flag clear register (MDMA_CxIFCR)

Address offset: 0x44 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CLTCIF	CBTIF	CBRTIF	CCTCIF	CTEIF
											w	w	w	w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CLTCIF**: Clear buffer transfer complete Interrupt flag for channel x
Writing 1 into this bit clears TCIF in MDMA_ISRy.

Bit 3 **CBTIF**: Channel x clear block transfer complete interrupt flag
Writing 1 into this bit clears BTIF in MDMA_ISRy.

Bit 2 **CBRTIF**: Channel x clear block repeat transfer complete interrupt flag
Writing 1 into this bit clears BRTIF in MDMA_ISRy.

Bit 1 **CCTCIF**: Clear channel transfer complete interrupt flag for channel x
Writing 1 into this bit clears CTCIF in MDMA_ISRy.

Bit 0 **CTEIF**: Channel x clear transfer error interrupt flag
Writing 1 into this bit clears TEIF in MDMA_ISRy.

17.5.5 MDMA channel x error status register (MDMA_CxESR)

Address offset: 0x48 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	BSE	ASE	TEMD	TELD	TED	TEA[6:0]						
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **BSE**: Block size error

This bit is set by hardware, when the block size is not an integer multiple of the data size either for source or destination. TED indicates whether the problem is on the source or destination. This bit is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No block size error

1: Programmed block size is not an integer multiple of the data size.

Bit 10 **ASE**: Address size error

This bit is set by hardware, when the programmed address is not aligned with the data size. TED indicates whether the problem is on the source or destination. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No address size error

1: Programmed address is not coherent with the data size.

Bit 9 **TEMD**: Transfer error mask data

This bit is set by hardware, in case of a transfer error while writing the mask data. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No mask write access error

1: The last transfer error on the channel was a related to a write of the mask data.

Bit 8 **TELD**: Transfer error link data

This bit is set by hardware, in case of a transfer error while reading the block link data structure. It is cleared by software writing 1 to CTEIF in MDMA_IFCRy.

0: No link data read access error

1: The last transfer error on the channel was a related to a read of the link data structure.

Bit 7 **TED**: Transfer error direction

This bit is set and cleared by hardware, in case of an MDMA data transfer error.

0: The last transfer error on the channel was a related to a read access.

1: The last transfer error on the channel was a related to a write access.

Bits 6:0 **TEA[6:0]**: Transfer error address

These bits are set and cleared by hardware in case of an MDMA data transfer error. They are used in conjunction with TED. This field indicates the 7 LSB bits of the address which generated a transfer/access error.

This field can be used by software to retrieve the failing address, by adding this value (truncated to the buffer transfer length size) to the current SAR/DAR value.

Note: The SAR/DAR current value does not reflect this last address due to the FIFO management system. The SAR/DAR are only updated at the end of a (buffer) transfer (of TLEN+1 bytes).

This field is not set in case of a link data error.

17.5.6 MDMA channel x control register (MDMA_CxCR)

This register is used to control the concerned channel.

Address offset: 0x4C + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWRQ
															w
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	WEX	HEX	BEX	Res.	Res.	Res.	SM	PL[1:0]		TCIE	BTIE	BRTIE	CTCIE	TEIE	EN
	rw	rw	rw				rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SWRQ**: Software request

Writing 1 into this bit sets the CRQA in MDMA_ISRy, activating the request on channel x.

Note: Either the whole MDMA_CxCR register or the 8-/16-bit register at the address offset: 0x4E + 0x40 × channel number, can be used for SWRQ activation.

In case of software request, acknowledge is not generated (neither hardware signal, nor MDMA_CxMAR write access).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **WEX**: Word endianness exchange

This bit is set and cleared by software.
0: Little endianness preserved for words
1: Word order exchanged in double word
When this bit is set, the word order in the destination double word is reversed: higher address word contains the data read from the lower address of the source.
If the destination is not a double word, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bit 13 **HEX**: Half-word endianness exchange

This bit is set and cleared by software.
0: Little endianness preserved for half words
1: half-word order exchanged in each word
When this bit is set, the half-word order in each destination word is reversed: higher address half-word contains the data read from the lower address of the source.
If destination length is shorter than word, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bit 12 **BEX**: Byte endianness exchange

This bit is set and cleared by software.
0: Little endianness preserved for bytes
1: byte order exchanged in each half-word
When this bit is set, the byte order in each destination half-word is reversed: higher address word contains the data read from the lower address of the source.
If destination is byte, do not care of this bit value.

Note: This bit is protected and can be written only if EN is 0.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SM**: Secure mode enable

This bit is set and cleared by software. It can only be written when the AHB slave port is in secure mode.

0: Secure mode disabled

1: Secure mode enable

When this bit is read as 0, the software can program the configuration bits related to the current channel independently of the secure mode of the AHB slave interface.

When this bit is set to 1, all registers of the current channel are write protected when the secure mode of the AHB slave port is not active. All MDMA master transactions are done in secure mode.

Note: This bit is protected and can be written only if EN is 0.

Bits 7:6 **PL[1:0]**: Priority level

These bits are set and cleared by software.

00: Low

01: Medium

10: High

11: Very high

Note: These bits are protected and can be written only if EN is 0.

Bit 5 **TCIE**: Buffer transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

Bit 4 **BTIE**: Block transfer interrupt enable

This bit is set and cleared by software.

0: BT complete interrupt disabled

1: BT complete interrupt enabled

Bit 3 **BRTIE**: Block repeat transfer interrupt enable

This bit is set and cleared by software.

0: BT interrupt disabled

1: BT interrupt enabled

Bit 2 **CTCIE**: Channel transfer complete interrupt enable

This bit is set and cleared by software.

0: TC interrupt disabled

1: TC interrupt enabled

Bit 1 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.

0: TE interrupt disabled

1: TE interrupt enabled

Bit 0 **EN**: Channel enable/flag channel ready when read low

This bit is set and cleared by software.

0: Channel disabled

1: Channel enabled

This bit can be cleared by hardware:

- on a MDMA end of transfer (stream ready to be configured)
- if a transfer error occurs on the AXI master buses (bus error/HardFault)
- if another error condition is encountered (data alignment, block/data size incompatibility)

When this bit is reset by software, the ongoing buffer transfer (if any) is completed.
All status/configuration registers keep their current values. If the channel is re-enabled without writing these registers, the channel continues from the point where it was interrupted.

When this bit is read as 0, the software is allowed to program the configuration registers.
It is forbidden to write these registers when the EN bit is read as 1 (writes are ignored).

Note: When this bit is reset by software, it is recommended to wait for the CTCIF = 1, in order to ensure that any ongoing buffer transfer has been completed, before reprogramming the channel.

17.5.7 MDMA channel x transfer configuration register (MDMA_CxTCR)

Address offset: 0x50 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

This register is used to configure the concerned channel. In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from the memory (from address given by current LAR[31:0] + 0x00).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BWM	SWRM	TRGM[1:0]		PAM[1:0]		PKE	TLEN[6:0]							DBURST[2:1]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
DBURST[0]	SBURST[2:0]			DINCOS[1:0]		SINCOS[1:0]		DSIZE[1:0]		SSIZE[1:0]		DINC[1:0]		SINC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BWM**: Bufferable write mode

This bit is set and cleared by software.

0: The destination write operation is non-bufferable.

1: The destination write operation is bufferable.

Note: This bit is protected and can be written only if EN is 0.

All MDMA destination accesses are non-cacheable.

Bit 30 **SWRM**: Software request mode

This bit is set and cleared by software. If an hardware or software request is currently active, the bit change is delayed until the current transfer is completed.

0: Hardware request are taken into account: the transfer is initiated as defined by TRGM value and acknowledged by the MDMA ACKx signal. If the MDMA_CxMAR contains a valid address, the MDMA_CxMDR value is also written at MDMA_CxMAR address.

1: Hardware request are ignored. Transfer is triggered by software writing 1 to the SWRQ bit.

Note: This bit is protected and can be written only if EN is 0.

Bits 29:28 **TRGM[1:0]**: Trigger mode

These bits are set and cleared by software.

00: Each MDMA request (software or hardware) triggers a buffer transfer.

01: Each MDMA request (software or hardware) triggers a block transfer.

10: Each MDMA request (software or hardware) triggers a repeated block transfer (if the block repeat is 0, a single block is transferred).

11: Each MDMA request (software or hardware) triggers the transfer of the whole data for the respective channel (for example linked list) until the channel reach the end and it is disabled.

Note: If TRGM is 11 for the current block, all values loaded at the end of the current block through the linked-list mechanism must keep the same value (TRGM = 11), and the same SWRM value, otherwise the result is undefined.

These bits are protected and can be written only if EN is 0.

Bits 27:26 **PAM[1:0]**: Padding/alignment mode

These bits are set and cleared by software.

00: Right aligned, padded with 0s (default). If source data is larger than destination size, only LSB part of the source is written to the destination address. The reminder part is discarded.

01: Right aligned, sign extended

10: Left aligned (padded with 0s). if source data is larger than destination size, only MSB part of the source is written to the destination address. The reminder part is discarded.

11: Reserved

Note: When PKE = 1 or DSIZE=SSIZE, these bits are ignored.

These bits are protected and can be written only if EN is 0.

Bit 25 **PKE**: Pack enable

This bit is set and cleared by software.

0: The source data is written to the destination as is. If source size is smaller than destination, it is padded according to the PAM value. If source data size is larger than destination one, it is truncated. The alignment is done according to the PAM[1:0] value.

1: The source data is packed/unpacked into the destination data size. All data are right aligned, in little-endian mode.

Note: This bit is protected and can be written only if EN is 0.

Bits 24:18 **TLEN[6:0]**: Buffer transfer length (number of bytes - 1)

These bits are set and cleared by software. TLEN + 1 value represents the number of bytes to be transferred in a single transfer.

The transfer length must be a multiple of the data size (for both source and destination)

When the source/destination sizes are different and padding/truncation is used, TLEN + 1 refers to the source data array size.

Note: These bits are protected and can be written only if EN is 0.

DBURST value must be programmed in order to ensure that the burst size is lower than the transfer size.

Bits 17:15 **DBURST[2:0]**: Destination burst transfer configuration

These bits are set and cleared by software.

000: Single transfer

N: burst of 2^N beats

DBURST value must be programmed as to ensure that the burst size is lower than the transfer length. If this is not ensured, the result is unpredictable.

Note: These bits are protected and can be written only if EN is 0.

When DINC = 00, DBURST must be maximum 100 (burst of 16), else the result is unpredictable.

Bits 14:12 **SBURST[2:0]**: Source burst transfer configuration

These bits are set and cleared by software.

000: single transfer

N: burst of 2^N beats

SBURST value must be programmed as to ensure that the burst size is lower than the transfer length. If this is not ensured, the result is unpredictable.

Note: These bits are protected and can be written only if EN is 0.

When SINC = 00, SBURST must be maximum 100 (burst of 16), else the result is unpredictable.

Bits 11:10 **DINCOS[1:0]**: Destination increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit DINC[1:0] = 00.

Note: If DINCOS < DSIZE and DINC ≠ 00, the result is unpredictable.

These bits are protected and can be written only if EN = 0.

Bits 9:8 **SINCOS[1:0]**: Source increment offset size

These bits are set and cleared by software.

00: byte (8-bit)

01: half-word (16-bit)

10: word (32-bit)

11: Double-Word (64-bit) -

This bits have no meaning if bit SINC[1:0] = 00.

Note: If SINCOS < SSIZE and SINC ≠ 00, the result is unpredictable.

These bits are protected and can be written only if EN = 0.

Bits 7:6 **DSIZE[1:0]**: Destination data size

These bits are set and cleared by software.

00: Byte (8 bits)

01: Half-word (16 bits)

10: Word (32 bits)

11: Double-word (64 bits)

Note: If DINCOS < DSIZE and DINC ≠ 00, the result is unpredictable.

These bits are protected and can be written only if EN = 0.

Bits 5:4 **SSIZE[1:0]**: Source data size

These bits are set and cleared by software.

00: Byte (8 bits)

01: Half-word (16 bits)

10: Word (32 bits)

11: Double-word (64 bits)

Note: If SINCOS < SSIZE and SINC ≠ 00, the result is unpredictable.

These bits are protected and can be written only if EN is 0.

Bits 3:2 **DINC[1:0]**: Destination increment mode
These bits are set and cleared by software.
00: Destination address pointer is fixed.
10: Destination address pointer is incremented after each data transfer (increment is done according to DINCOS).
11: Destination address pointer is decremented after each data transfer (increment is done according to DINCOS).
These bits are protected and can be written only if EN = 0.

Bits 1:0 **SINC[1:0]**: Source increment mode
These bits are set and cleared by software.
00: Source address pointer is fixed.
10: Source address pointer is incremented after each data transfer (increment is done according to SINCOS).
11: Source address pointer is decremented after each data transfer (decrement is done according to SINCOS).
These bits are protected and can be written only if EN = 0.

17.5.8 MDMA channel x block number of data register (MDMA_CxBNDTR)

Address offset: 0x54 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from the memory (from address given by current LAR[31:0] + 0x04).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRC[11:0]												BRDUM	BRSUM	Res.	BNDT[16]
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 **BRC[11:0]**: Block repeat count
This field contains the number of repetitions of the current block (0 to 4095). When the channel is enabled, this register is read-only, indicating the remaining number of blocks, excluding the current one. This register decrements after each complete block transfer.
Once the last block transfer has completed, this register can either stay at zero or be reloaded automatically from memory (in linked-list mode, meaning link address valid).
Note: These bits are protected and can be written only if EN = 0.

Bit 19 **BRDUM**: Block repeat destination address update mode
0: At the end of a block transfer, the MDMA_DAR register is updated by adding the DUV to the current DAR value (current destination address).
1: At the end of a block transfer, the MDMA_DAR register is updated by subtracting the DUV from the current DAR value (current destination address).
Note: These bits are protected and can be written only if EN = 0.

Bit 18 **BRSUM**: Block repeat source address update mode

0: At the end of a block transfer, the MDMA_SAR register is updated by adding the SUV to the current SAR value (current source address).

1: At the end of a block transfer, the MDMA_SAR register is updated by subtracting the SUV from the current SAR value (current source address).

Note: These bits are protected and can be written only if EN = 0.

Bit 17 Reserved, must be kept at reset value.

Bits 16:0 **BNDT[16:0]**: Block number of data bytes to transfer

Number of bytes to be transferred (0 up to 65536) in the current block. When the channel is enabled, this register is read-only, indicating the remaining data items to be transmitted. During the channel activity, this register decrements, indicating the number of data items remaining in the current block.

Once the block transfer has completed, this register can either stay at zero or be reloaded automatically with the previously programmed value if the channel is configured in block repeat mode.

If the value of this register is zero, no transaction can be served even if the stream is enabled.

Note: If the BNDT value is not an integer multiple of the TLEN + 1 value, the last transfer is shorter and contains only the remaining data in the block.

The block size must be a multiple of the source and destination data size. If this is not true, an error is set and the no data are written

These bits are protected and can be written only if EN = 0.

17.5.9 MDMA channel x source address register (MDMA_CxSAR)

Address offset: 0x58 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x08).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SAR[31:0]**: Source address

These bits represent the base address of the peripheral data register from/to which the data is read. They must be aligned with the SSIZE (SAR[1:0] = 00 when SSIZE = 10), but may be unaligned with the SINCOS.

During the channel activity, this register is updated, reflecting the current address from which the data is read next.

When the block repeat mode is active, when a block transfer is completed, the source address is updated by adding/subtracting the SAU value to the current value (already updated after the last transfer in the block).

When the linked-list mode is active, at the end of a block (repeated or not) transfer, the SAR value is loaded from memory (from address LSA + m).

Note: These bits are write-protected and can be written only when bit EN = 0.

17.5.10 MDMA channel x destination address register (MDMA_CxDAR)

Address offset: 0x5C + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x0C).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DAR[31:0]**: Destination address

Base address of the destination address to which the data is written. Must be aligned with the DSIZE (for example DAR[0] = 0 when DSIZE=01), but may be unaligned with the DINCOS.

During the channel activity, this register is updated, reflecting the current address to which the data is written next.

When the block repeat mode is active, when a block transfer is completed, the Destination address is updated by adding/subtracting the DAU value to the current value (after the last transfer in the block).

When the linked-list mode is active, at the end of a block (repeated or not) transfer, the DAR value is loaded from memory (from address LSA + m).

Note: These bits are write-protected and can be written only when bit EN = 0.

17.5.11 MDMA channel x block repeat address update register (MDMA_CxBRUR)

Address offset: 0x60 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x10).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUV[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **DUV[15:0]**: Destination address update value

This value is used to update (by addition or subtraction) the current destination address at the end of a block transfer. It must be an integer multiple of DSIZE, in order to keep DAR aligned to DSIZE (DAR[1:0] = 00 when DSIZ E =10).

If this value is 0, the next repetition of the block transfer continues to the next address.

When the block repeat mode is not active (BRC = 0), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

This field must be programmed to 0 when DINC[1:0] = 00.

Bits 15:0 **SUV[15:0]**: Source address update value

This value is used to update (by addition or subtraction) the current source address at the end of a block transfer. It must be an integer multiple of SSIZE, in order to keep SAR aligned to SSIZE (SAR[1:0] = 00 when SSIZE = 10).

If this value is 0, the next repetition of the block transfer continues from the next address.

When the block repeat mode is not active (BRC=0), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

This field must be programmed to 0 when SINC[1:0] = 00.

17.5.12 MDMA channel x link address register (MDMA_CxLAR)

Address offset: 0x64 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x14).

Note: The new value is only taken into account after all registers are updated, for the next end of block.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LAR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r	r	r

Bits 31:0 **LAR[31:0]**: Link address register

At the end of a (repeated) block transfer, the current channel configuration registers (MDMA_CxTCR, MDMA_CxBNDTR, MDMA_CxSAR, MDMA_CxDAR, MDMA_CxBRUR, MDMA_CxMAR, MDMA_CxMDR and MDMA_CxLAR itself) are loaded with the data structure found at this address.

If the value of this register is 0, no register update takes place, the channel is disabled and CTCIF is set, indicating the end of the transfer for this channel.

The channel configuration (LAR address) must be in the AXI address space.

LAR value must be aligned at a double-word address (LAR[2:0] = 0x0).

Note: These bits are write-protected and can be written only when bit EN = 0.

17.5.13 MDMA channel x trigger and bus selection register (MDMA_CxTBR)

Address offset: 0x68 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x18).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TSEL[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TSEL[5:0]**: Trigger selection

This field selects the hardware trigger (RQ) input for channel x. The ACK is sent on the ACK output having the same index value.

When SWRM bit is set (software request selected), this field is ignored.

Note: These bits are write-protected and can be written only when bit EN = 0.

If multiple channels are triggered by the same event (have the same TSEL value), all of them are triggered in parallel. Only the channel with the lowest index acknowledges the request (as software or hardware acknowledge).

17.5.14 MDMA channel x mask address register (MDMA_CxMAR)

Address offset: 0x70 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In linked-list mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x20).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MAR[31:0]**: Mask address

When an ACK signal is generated, a write of the MDR value is also done to this address. This is used to clear the RQ signal generated by the DMA2 by writing to its interrupt clear register.

If the value of this register is 0, this function is disabled.

Note: These bits are write-protected and can be written only when bit EN = 0.

17.5.15 MDMA channel x mask data register (MDMA_CxMDR)

Address offset: 0x74 + 0x40 * x, (x = 0 to 31)

Reset value: 0x0000 0000

In Linked List mode, at the end of a block (single or last block in repeated block transfer mode), this register is loaded from memory (from address given by current LAR[31:0] + 0x24).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
MDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MDR[31:0]**: Mask data

When an ACK signal is generated, a write of the MDR value is also done to the address defined by the MDMA_MAR register. This is used to clear the RQ signal generated by the DMA2 by writing to its interrupt clear register.

Note: These bits are write-protected and can be written only when bit EN = 0.

17.5.16 MDMA register map

Table 101. MDMA register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.5* for the register boundary addresses.

18 Direct memory access controller (DMA)

18.1 DMA introduction

Direct memory access (DMA) is used in order to provide high-speed data transfer between peripherals and memory and between memory and memory. Data can be quickly moved by DMA without any CPU action. This keeps CPU resources free for other operations.

The DMA controller combines a powerful dual AHB master bus architecture with independent FIFO to optimize the bandwidth of the system, based on a complex bus matrix architecture.

The two DMA controllers (DMA1, DMA2) have 8 streams each, dedicated to managing memory access requests from one or more peripherals.

Each DMA stream is driven by one DMAMUX output channel (request). Any DMAMUX output request can be individually programmed in order to select the DMA request source signal, from any of the 116 available request input signals.

Refer to the *Section 19.3: DMAMUX implementation* for more information about the DMA requests and streams mapping.

Each DMA controller has an arbiter for handling the priority between DMA requests.

18.2 DMA main features

The main DMA features are:

- Dual AHB master bus architecture, one dedicated to memory accesses and one dedicated to peripheral accesses
- AHB slave programming interface supporting only 32-bit accesses
- 8 streams for each DMA controller, up to 116 channels (requests) per stream
- Four-word depth 32 first-in, first-out memory buffers (FIFOs) per stream, that can be used in FIFO mode or direct mode:
  - FIFO mode: with threshold level software selectable between 1/4, 1/2 or 3/4 of the FIFO size
  - Direct mode: each DMA request immediately initiates a transfer from/to the memory. When it is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads only one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.
- Each stream can be configured to be:
  - a regular channel that supports peripheral-to-memory, memory-to-peripheral and memory-to-memory transfers
  - a double buffer channel that also supports double buffering on the memory side
- Priorities between DMA stream requests are software-programmable (four levels consisting of very high, high, medium, low) or hardware in case of equality (for example, request 0 has priority over request 1)
- Each stream also supports software trigger for memory-to-memory transfers

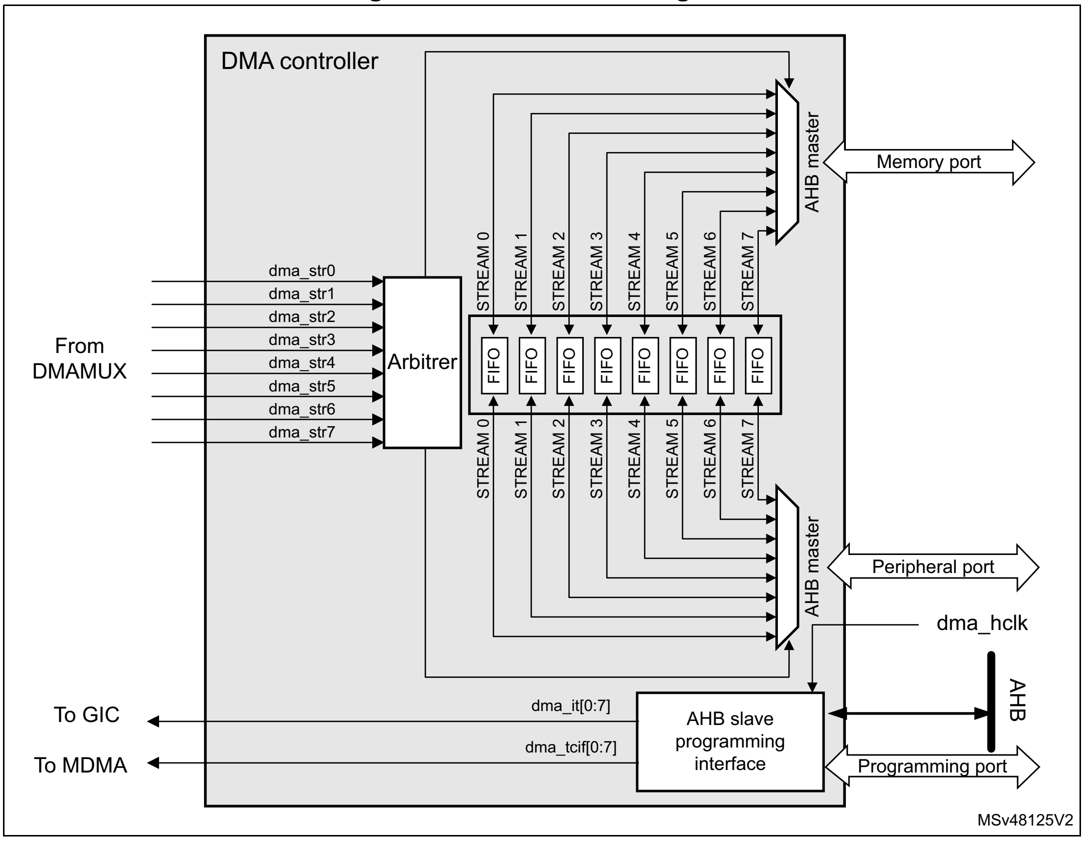
- Each stream request can be selected among up to 116 possible channel requests. This selection is software-configurable by the DMAMUX and allows 108 peripherals to initiate DMA requests
- The number of data items to be transferred can be managed either by the DMA controller or by the peripheral:
  - DMA flow controller: the number of data items to be transferred is software-programmable from 1 to 65535
  - Peripheral flow controller: the number of data items to be transferred is unknown and controlled by the source or the destination peripheral that signals the end of the transfer by hardware
- Independent source and destination transfer width (byte, half-word, word): when the data widths of the source and destination are not equal, the DMA automatically packs/unpacks the necessary transfers to optimize the bandwidth. This feature is only available in FIFO mode
- Incrementing or non-incrementing addressing for source and destination
- Supports incremental burst transfers of 4, 8 or 16 beats. The size of the burst is software-configurable, usually equal to half the FIFO size of the peripheral
- Each stream supports circular buffer management
- 5 event flags (DMA half transfer, DMA transfer complete, DMA transfer error, DMA FIFO error, direct mode error) logically ORed together in a single interrupt request for each stream

18.3 DMA functional description

18.3.1 DMA block diagram

The figure below shows the block diagram of a DMA.

Figure 128. DMA block diagram



18.3.2 DMA overview

The DMA controller performs direct memory transfer: as an AHB master, the DMA controller can take the control of the AHB bus matrix to initiate AHB transactions.

The DMA controller carries out the following transactions:

- peripheral-to-memory
- memory-to-peripheral
- memory-to-memory

The DMA controller provides two AHB master ports: the AHB memory port, intended to be connected to memories and the AHB peripheral port, intended to be connected to peripherals. However, to allow memory-to-memory transfers, the AHB peripheral port must also have access to the memories.

The AHB slave port is used to program the DMA controller (it supports only 32-bit accesses).

18.3.3 DMA transactions

A DMA transaction consists of a sequence of a given number of data transfers. The number of data items to be transferred and their width (8-bit, 16-bit or 32-bit) are software-programmable.

Each DMA transfer consists of three operations:

- a loading from the peripheral data register or a location in memory, addressed through the DMA_SxPAR or DMA_SxM0AR register
- a storage of the data loaded to the peripheral data register or a location in memory addressed through the DMA_SxPAR or DMA_SxM0AR register
- a post-decrement of the DMA_SxNDTR register, containing the number of transactions that still have to be performed

After an event, the peripheral sends a request signal to the DMA controller. The DMA controller serves the request depending on the channel priorities. As soon as the DMA controller accesses the peripheral, an Acknowledge signal is sent to the peripheral by the DMA controller. The peripheral releases its request as soon as it gets the Acknowledge signal from the DMA controller. Once the request has been deasserted by the peripheral, the DMA controller releases the Acknowledge signal. If there are more requests, the peripheral can initiate the next transaction.

18.3.4 DMA request mapping

The DMA request mapping from peripherals to DMA streams is described in *Section 19.3: DMAMUX implementation*.

18.3.5 Arbiter

An arbiter manages the 8 DMA stream requests based on their priority for each of the two AHB master ports (memory and peripheral ports) and launches the peripheral/memory access sequences.

Priorities are managed in two stages:

- Software: each stream priority can be configured in the DMA_SxCR register. There are four levels:
  – Very high priority
  – High priority
  – Medium priority
  – Low priority
- Hardware: If two requests have the same software priority level, the stream with the lower number takes priority over the stream with the higher number. For example, stream 2 takes priority over stream 4.

18.3.6 DMA streams

Each of the eight DMA controller streams provides a unidirectional transfer link between a source and a destination.

Each stream can be configured to perform:

- Regular type transactions: memory-to-peripherals, peripherals-to-memory or memory-to-memory transfers
- Double-buffer type transactions: double buffer transfers using two memory pointers for the memory (while the DMA is reading/writing from/to a buffer, the application can write/read to/from the other buffer).

The amount of data to be transferred (up to 65535) is programmable and related to the source width of the peripheral that requests the DMA transfer connected to the peripheral AHB port. The register that contains the amount of data items to be transferred is decremented after each transaction.

18.3.7 Source, destination and transfer modes

Both source and destination transfers can address peripherals and memories in the entire 4-Gbyte area, at addresses comprised between 0x0000 0000 and 0xFFFF FFFF.

The direction is configured using the DIR[1:0] bits in the DMA_SxCR register and offers three possibilities: memory-to-peripheral, peripheral-to-memory or memory-to-memory transfers.

The table below describes the corresponding source and destination addresses.

Table 102. Source and destination address

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR
01	Memory-to-peripheral	DMA_SxM0AR	DMA_SxPAR
10	Memory-to-memory	DMA_SxPAR	DMA_SxM0AR
11	Reserved	-	-

When the data width (programmed in the PSIZE or MSIZE bits in the DMA_SxCR register) is a half-word or a word, respectively, the peripheral or memory address written into the DMA_SxPAR or DMA_SxM0AR/M1AR registers has to be aligned on a word or half-word address boundary, respectively.

Peripheral-to-memory mode

Figure 129 describes this mode.

When this mode is enabled (by setting the bit EN in the DMA_SxCR register), each time a peripheral request occurs, the stream initiates a transfer from the source to fill the FIFO.

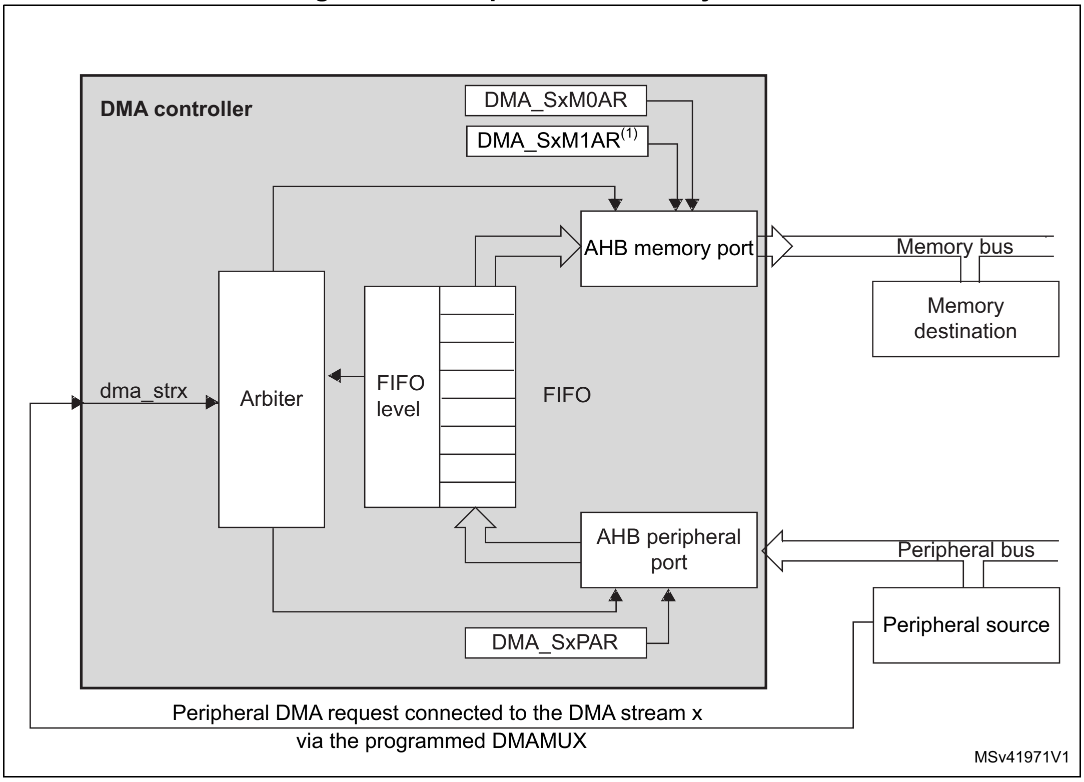
When the threshold level of the FIFO is reached, the contents of the FIFO are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is 0), the threshold level of the FIFO is not used: after each single data transfer from the peripheral to the FIFO, the corresponding data are immediately drained and stored into the destination.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Figure 129. Peripheral-to-memory mode



1. For double-buffer mode.

Memory-to-peripheral mode

Figure 130 describes this mode.

When this mode is enabled (by setting the EN bit in the DMA_SxCR register), the stream immediately initiates transfers from the source to entirely fill the FIFO.

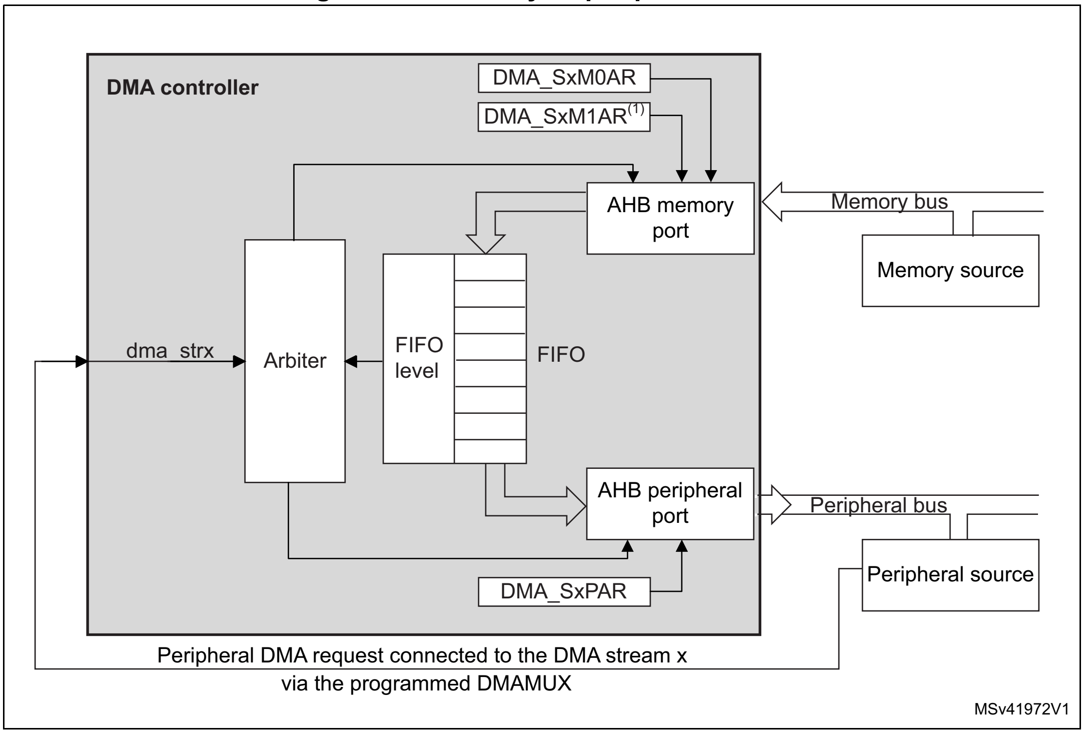
Each time a peripheral request occurs, the contents of the FIFO are drained and stored into the destination. When the level of the FIFO is lower than or equal to the predefined threshold level, the FIFO is fully reloaded with data from the memory.

The transfer stops once the DMA_SxNDTR register reaches zero, when the peripheral requests the end of transfers (in case of a peripheral flow controller) or when the EN bit in the DMA_SxCR register is cleared by software.

In direct mode (when the DMDIS value in the DMA_SxFCR register is 0), the threshold level of the FIFO is not used. Once the stream is enabled, the DMA preloads the first data to transfer into an internal FIFO. As soon as the peripheral requests a data transfer, the DMA transfers the preloaded value into the configured destination. It then reloads again the empty internal FIFO with the next data to be transfer. The preloaded data size corresponds to the value of the PSIZE bitfield in the DMA_SxCR register.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Figure 130. Memory-to-peripheral mode



1. For double-buffer mode.

Memory-to-memory mode

The DMA channels can also work without being triggered by a request from a peripheral. This is the memory-to-memory mode, described in *Figure 131*.

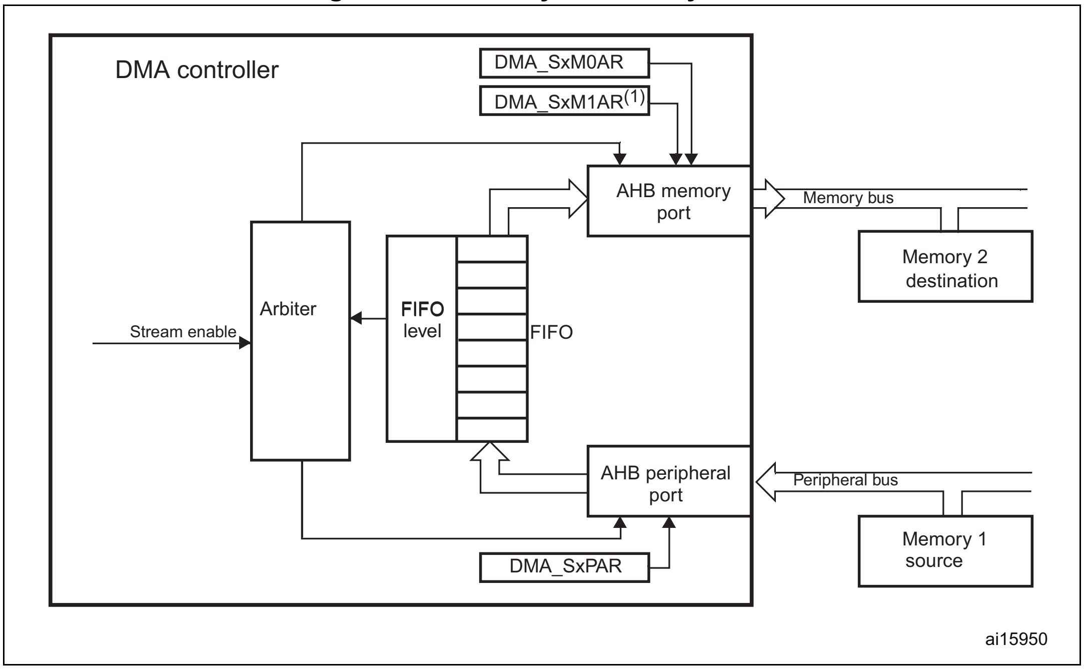
When the stream is enabled by setting the Enable bit (EN) in the DMA_SxCR register, the stream immediately starts to fill the FIFO up to the threshold level. When the threshold level is reached, the FIFO contents are drained and stored into the destination.

The transfer stops once the DMA_SxNDTR register reaches zero or when the EN bit in the DMA_SxCR register is cleared by software.

The stream has access to the AHB source or destination port only if the arbitration of the corresponding stream is won. This arbitration is performed using the priority defined for each stream using the PL[1:0] bits in the DMA_SxCR register.

Note: When memory-to-memory mode is used, the circular and direct modes are not allowed.

Figure 131. Memory-to-memory mode



1. For double-buffer mode.

18.3.8 Pointer incrementation

Peripheral and memory pointers can optionally be automatically post-incremented or kept constant after each transfer depending on the PINC and MINC bits in the DMA_SxCR register.

Disabling the increment mode is useful when the peripheral source or destination data is accessed through a single register.

If the increment mode is enabled, the address of the next transfer is the address of the previous one incremented by 1 (for bytes), 2 (for half-words) or 4 (for words) depending on the data width programmed in the PSIZE or MSIZE bits in the DMA_SxCR register.

In order to optimize the packing operation, it is possible to fix the increment offset size for the peripheral address whatever the size of the data transferred on the AHB peripheral port. The PINCOS bit in the DMA_SxCR register is used to align the increment offset size with the data size on the peripheral AHB port, or on a 32-bit address (the address is then incremented by 4). The PINCOS bit has an impact on the AHB peripheral port only.

If the PINCOS bit is set, the address of the following transfer is the address of the previous one incremented by 4 (automatically aligned on a 32-bit address), whatever the PSIZE value. The AHB memory port, however, is not impacted by this operation.

18.3.9 Circular mode

The circular mode is available to handle circular buffers and continuous data flows (e.g. ADC scan mode). This feature can be enabled using the CIRC bit in the DMA_SxCR register.

When the circular mode is activated, the number of data items to be transferred is automatically reloaded with the initial value programmed during the stream configuration phase, and the DMA requests continue to be served.

Note: In the circular mode, it is mandatory to respect the following rule in case of a burst mode configured for memory:

DMA_SxNDTR = Multiple of ((Mburst beat) × (Msize)/(Psize)), where:

- *(Mburst beat) = 4, 8 or 16 (depending on the MBURST bits in the DMA_SxCR register)*
- *((Msize)/(Psize)) = 1, 2, 4, 1/2 or 1/4 (Msize and Psize represent the MSIZE and PSIZE bits in the DMA_SxCR register. They are byte dependent)*
- *DMA_SxNDTR = Number of data items to transfer on the AHB peripheral port*

For example: Mburst beat = 8 (INCR8), MSIZE = 00 (byte) and PSIZE = 01 (half-word), in this case: DMA_SxNDTR must be a multiple of (8 × 1/2 = 4).

If this formula is not respected, the DMA behavior and data integrity are not guaranteed.

NDTR must also be a multiple of the Peripheral burst size multiplied by the peripheral data size, otherwise this could result in a bad DMA behavior.

18.3.10 Double-buffer mode

This mode is available for all the DMA1 and DMA2 streams.

The double-buffer mode is enabled by setting the DBM bit in the DMA_SxCR register.

A double-buffer stream works as a regular (single buffer) stream with the difference that it has two memory pointers. When the double-buffer mode is enabled, the circular mode is automatically enabled (CIRC bit in DMA_SxCR is not relevant) and at each end of transaction, the memory pointers are swapped.

In this mode, the DMA controller swaps from one memory target to another at each end of transaction. This allows the software to process one memory area while the second memory area is being filled/used by the DMA transfer. The double-buffer stream can work in both directions (the memory can be either the source or the destination) as described in Table 103.

*Note: In double-buffer mode, it is possible to update the base address for the AHB memory port on-the-fly (*DMA_SxM0AR or DMA_SxM1AR*) when the stream is enabled, by respecting the following conditions:*

- *When the CT bit is 0 in the DMA_SxCR register, the DMA_SxM1AR register can be written. Attempting to write to this register while CT = 1 sets an error flag (TEIF) and the stream is automatically disabled.*
- *When the CT bit is 1 in the DMA_SxCR register, the DMA_SxM0AR register can be written. Attempting to write to this register while CT = 0, sets an error flag (TEIF) and the stream is automatically disabled.*

To avoid any error condition, it is advised to change the base address as soon as the TCIF flag is asserted because, at this point, the targeted memory must have changed from *memory 0 to 1 (or from 1 to 0) depending on the value of CT in the DMA_SxCR register in accordance with one of the two above conditions.*

For all the other modes (except the double-buffer mode), the memory address registers are write-protected as soon as the stream is enabled.

Table 103. Source and destination address registers in double-buffer mode (DBM = 1)

Bits DIR[1:0] of the DMA_SxCR register	Direction	Source address	Destination address
00	Peripheral-to-memory	DMA_SxPAR	DMA_SxM0AR / DMA_SxM1AR
01	Memory-to-peripheral	DMA_SxM0AR / DMA_SxM1AR	DMA_SxPAR
10	Not allowed(1)		
11	Reserved	-	-

1. When the double-buffer mode is enabled, the circular mode is automatically enabled. Since the memory-to-memory mode is not compatible with the circular mode, when the double-buffer mode is enabled, it is not allowed to configure the memory-to-memory mode.

18.3.11 Programmable data width, packing/unpacking, endianness

The number of data items to be transferred has to be programmed into DMA_SxNDTR (number of data items to transfer bit, NDT) before enabling the stream (except when the flow controller is the peripheral, PFCTRL bit in DMA_SxCR is set).

When using the internal FIFO, the data widths of the source and destination data are programmable through the PSIZE and MSIZE bits in the DMA_SxCR register (can be 8-, 16- or 32-bit).

When PSIZE and MSIZE are not equal:

- The data width of the number of data items to transfer, configured in the DMA_SxNDTR register is equal to the width of the peripheral bus (configured by the PSIZE bits in the DMA_SxCR register). For instance, in case of peripheral-to-memory, memory-to-peripheral or memory-to-memory transfers and if the PSIZE[1:0] bits are configured for half-word, the number of bytes to be transferred is equal to 2 × NDT.
- The DMA controller only copes with little-endian addressing for both source and destination. This is described in *Table 104*.

This packing/unpacking procedure may present a risk of data corruption when the operation is interrupted before the data are completely packed/unpacked. So, to ensure data coherence, the stream may be configured to generate burst transfers: in this case, each group of transfers belonging to a burst are indivisible (refer to *Section 18.3.12*).

In direct mode (DMDIS = 0 in the DMA_SxFCR register), the packing/unpacking of data is not possible. In this case, it is not allowed to have different source and destination transfer data widths: both are equal and defined by the PSIZE bits in the DMA_SxCR register. MSIZE bits are not relevant.

Table 104. Packing/unpacking and endian behavior (bit PINC = MINC = 1)

AHB memory port width	AHB peripheral port width	Number of data items to transfer (NDT)	Memory transfer number	Memory port address / byte lane	Peripheral transfer number	Peripheral port address / byte lane	
						PINCOS = 1	PINCOS = 0
8	8	4	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
8	16	2	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
8	32	1	1 2 3 4	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]	1	0x0 / B3|B2|B1|B0[31:0]	0x0 / B3|B2|B1|B0[31:0]
16	8	4	1 2	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
16	16	2	1 2	0x0 / B1|B0[15:0] 0x2 / B1|B0[15:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
16	32	1	1 2	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]	1	0x0 / B3|B2|B1|B0[31:0]	0x0 / B3|B2|B1|B0[31:0]
32	8	4	1	0x0 / B3|B2|B1|B0[31:0]	1 2 3 4	0x0 / B0[7:0] 0x4 / B1[7:0] 0x8 / B2[7:0] 0xC / B3[7:0]	0x0 / B0[7:0] 0x1 / B1[7:0] 0x2 / B2[7:0] 0x3 / B3[7:0]
32	16	2	1	0x0 /B3|B2|B1|B0[31:0]	1 2	0x0 / B1|B0[15:0] 0x4 / B3|B2[15:0]	0x0 / B1|B0[15:0] 0x2 / B3|B2[15:0]
32	32	1	1	0x0 /B3|B2|B1|B0 [31:0]	1	0x0 / B3|B2|B1|B0 [31:0]	0x0 / B3|B2|B1|B0[31:0]

Note: Peripheral port may be the source or the destination (it can also be the memory source in the case of memory-to-memory transfer).

PSIZE, MSIZE and NDT[15:0] must be configured so as to ensure that the last transfer is not incomplete. This can occur when the data width of the peripheral port (PSIZE bits) is lower than the data width of the memory port (MSIZE bits). This constraint is summarized in the table below.

Table 105. Restriction on NDT versus PSIZE and MSIZE

PSIZE[1:0] of DMA_SxCR	MSIZE[1:0] of DMA_SxCR	NDT[15:0] of DMA_SxNDTR
00 (8-bit)	01 (16-bit)	Must be a multiple of 2
00 (8-bit)	10 (32-bit)	Must be a multiple of 4
01 (16-bit)	10 (32-bit)	Must be a multiple of 2

18.3.12 Single and burst transfers

The DMA controller can generate single transfers or incremental burst transfers of 4, 8, or 16 beats.

The size of the burst is configured by software independently for the two AHB ports by using the MBURST[1:0] and PBURST[1:0] bits in the DMA_SxCR register.

The burst size indicates the number of beats in the burst, not the number of bytes transferred.

To ensure data coherence, each group of transfers that form a burst are indivisible: AHB transfers are locked and the arbiter of the AHB bus matrix does not degrant the DMA master during the sequence of the burst transfer.

Depending on the single or burst configuration, each DMA request initiates a different number of transfers on the AHB peripheral port:

- When the AHB peripheral port is configured for single transfers, each DMA request generates a data transfer of a byte, half-word or word depending on the PSIZE[1:0] bits in the DMA_SxCR register
- When the AHB peripheral port is configured for burst transfers, each DMA request generates 4,8 or 16 beats of byte, half word or word transfers depending on the PBURST[1:0] and PSIZE[1:0] bits in the DMA_SxCR register.

The same as above has to be considered for the AHB memory port considering the MBURST and MSIZE bits.

In direct mode, the stream can only generate single transfers and the MBURST[1:0] and PBURST[1:0] bits are forced by hardware.

The address pointers (DMA_SxPAR or DMA_SxM0AR registers) must be chosen so as to ensure that all transfers within a burst block are aligned on the address boundary equal to the size of the transfer.

The burst configuration has to be selected in order to respect the AHB protocol, where bursts **must not** cross the 1 Kbyte address boundary because the minimum address space that can be allocated to a single slave is 1 Kbyte. This means that the 1-Kbyte address boundary **must not** be crossed by a burst block transfer, otherwise an AHB error is generated, that is not reported by the DMA registers.

18.3.13 FIFO

FIFO structure

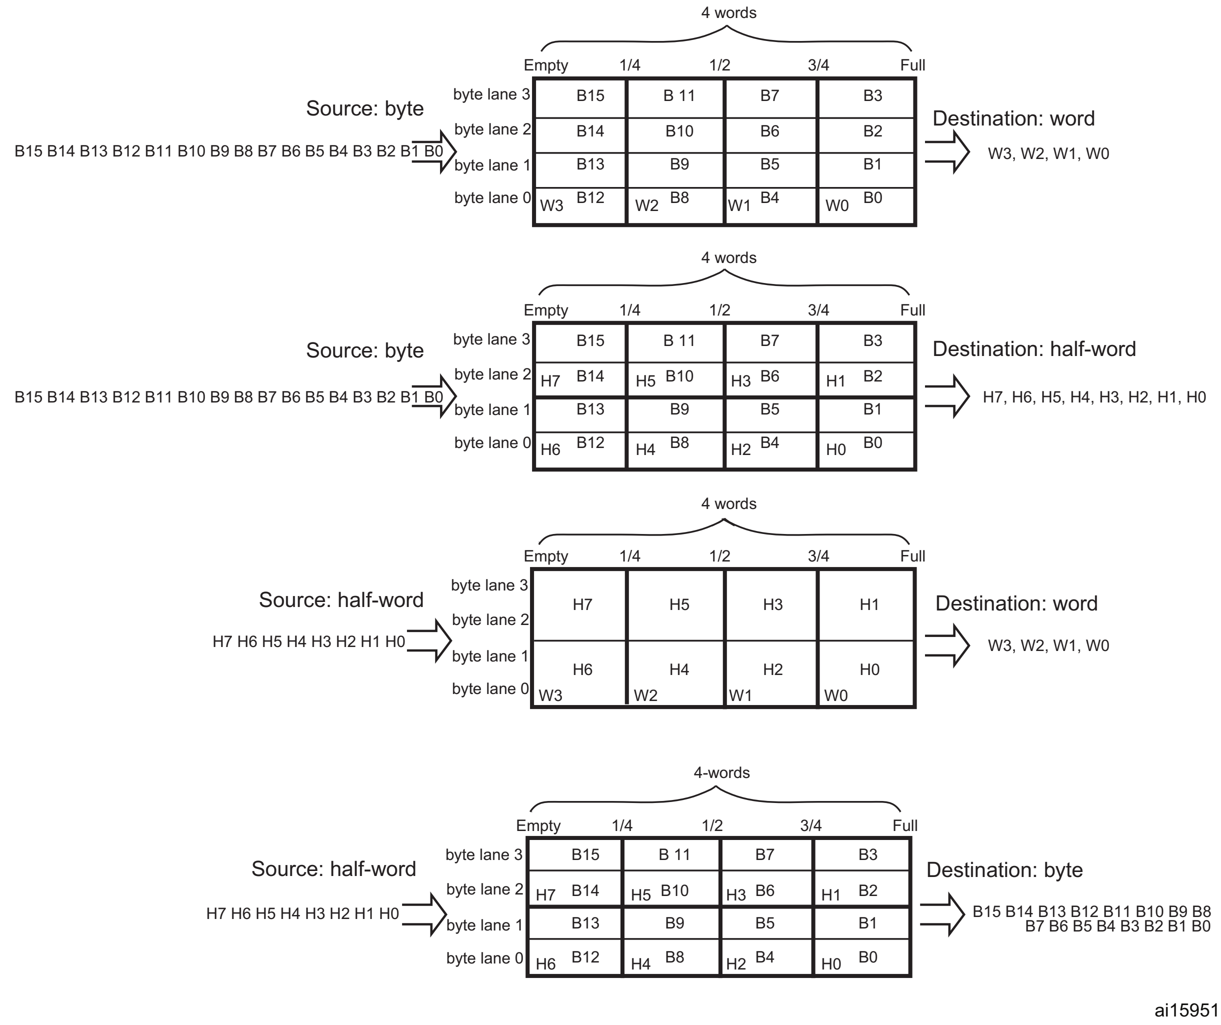
The FIFO is used to temporarily store data coming from the source before transmitting them to the destination.

Each stream has an independent 4-word FIFO and the threshold level is software-configurable between 1/4, 1/2, 3/4 or full.

To enable the use of the FIFO threshold level, the direct mode must be disabled by setting the DMDIS bit in the DMA_SxFCR register.

The structure of the FIFO differs depending on the source and destination data widths, and is described in the figure below.

Figure 132. FIFO structure



FIFO threshold and burst configuration

Caution is required when choosing the FIFO threshold (bits FTH[1:0] of the DMA_SxFCR register) and the size of the memory burst (MBURST[1:0] of the DMA_SxCR register). The content pointed by the FIFO threshold must exactly match an integer number of memory burst transfers. If this is not in the case, a FIFO error (flag FEIFx of the DMA_HISR or DMA_LISR register) is generated when the stream is enabled, then the stream is automatically disabled. The allowed and forbidden configurations are described in the table below. The forbidden configurations are highlighted in gray in the table.

Table 106. FIFO threshold configurations

<table>
<tr><th>MSIZE</th><th>FIFO level</th><th>MBURST = INCR4</th><th>MBURST = INCR8</th><th>MBURST = INCR16</th></tr>
<tr><td rowspan="4">Byte</td><td>1/4</td><td>1 burst of 4 beats</td><td>Forbidden</td><td rowspan="3">Forbidden</td></tr>
<tr><td>1/2</td><td>2 bursts of 4 beats</td><td>1 burst of 8 beats</td></tr>
<tr><td>3/4</td><td>3 bursts of 4 beats</td><td>Forbidden</td></tr>
<tr><td>Full</td><td>4 bursts of 4 beats</td><td>2 bursts of 8 beats</td><td>1 burst of 16 beats</td></tr>
<tr><td rowspan="4">Half-word</td><td>1/4</td><td>Forbidden</td><td rowspan="3">Forbidden</td><td rowspan="8">Forbidden</td></tr>
<tr><td>1/2</td><td>1 burst of 4 beats</td></tr>
<tr><td>3/4</td><td>Forbidden</td></tr>
<tr><td>Full</td><td>2 bursts of 4 beats</td><td>1 burst of 8 beats</td></tr>
<tr><td rowspan="4">Word</td><td>1/4</td><td rowspan="3">Forbidden</td><td rowspan="4">Forbidden</td></tr>
<tr><td>1/2</td></tr>
<tr><td>3/4</td></tr>
<tr><td>Full</td><td>1 burst of 4 beats</td></tr>
</table>

In all cases, the burst size multiplied by the data size must not exceed the FIFO size (data size can be: 1 (byte), 2 (half-word) or 4 (word)).

Incomplete burst transfer at the end of a DMA transfer may happen if one of the following conditions occurs:

- For the AHB peripheral port configuration: the total number of data items (set in the DMA_SxNDTR register) is not a multiple of the burst size multiplied by the data size.
- For the AHB memory port configuration: the number of remaining data items in the FIFO to be transferred to the memory is not a multiple of the burst size multiplied by the data size.

In such cases, the remaining data to be transferred is managed in single mode by the DMA, even if a burst transaction is requested during the DMA stream configuration.

Note: When burst transfers are requested on the peripheral AHB port and the FIFO is used (DMDIS = 1 in the DMA_SxCR register), it is mandatory to respect the following rule to avoid permanent underrun or overrun conditions, depending on the DMA stream direction:

If (PBURST × PSIZE) = FIFO_SIZE (4 words), FIFO_Threshold = 3/4 is forbidden with PSIZE = 1, 2 or 4 and PBURST = 4, 8 or 16.

This rule ensures that enough FIFO space at a time is free to serve the request from the peripheral.

FIFO flush

The FIFO can be flushed when the stream is disabled by resetting the EN bit in the DMA_SxCR register and when the stream is configured to manage peripheral-to-memory or memory-to-memory transfers. If some data are still present in the FIFO when the stream is disabled, the DMA controller continues transferring the remaining data to the destination (even though stream is effectively disabled). When this flush is completed, the transfer complete status bit (TCIFx) in the DMA_LISR or DMA_HISR register is set.

The remaining data counter DMA_SxNDTR keeps the value in this case to indicate how many data items are currently available in the destination memory.

Note that during the FIFO flush operation, if the number of remaining data items in the FIFO to be transferred to memory (in bytes) is less than the memory data width (for example 2 bytes in FIFO while MSIZE is configured to word), data is sent with the data width set in the MSIZE bit in the DMA_SxCR register. This means that memory is written with an undesired value. The software may read the DMA_SxNDTR register to determine the memory area that contains the good data (start address and last address).

If the number of remaining data items in the FIFO is lower than a burst size (if the MBURST bits in DMA_SxCR register are set to configure the stream to manage burst on the AHB memory port), single transactions are generated to complete the FIFO flush.

Direct mode

By default, the FIFO operates in direct mode (DMDIS bit in the DMA_SxFCR is reset) and the FIFO threshold level is not used. This mode is useful when the system requires an immediate and single transfer to or from the memory after each DMA request.

When the DMA is configured in direct mode (FIFO disabled), to transfer data in memory-to-peripheral mode, the DMA preloads one data from the memory to the internal FIFO to ensure an immediate data transfer as soon as a DMA request is triggered by a peripheral.

To avoid saturating the FIFO, it is recommended to configure the corresponding stream with a high priority.

This mode is restricted to transfers where:

- the source and destination transfer widths are equal and both defined by the PSIZE[1:0] bits in DMA_SxCR (MSIZE[1:0] bits are not relevant)
- burst transfers are not possible (PBURST[1:0] and MBURST[1:0] bits in DMA_SxCR are don’t care)

Direct mode must not be used when implementing memory-to-memory transfers.

18.3.14 DMA transfer completion

Different events can generate an end of transfer by setting the TCIFx bit in the DMA_LISR or DMA_HISR status register:

- In DMA flow controller mode:
  – The DMA_SxNDTR counter has reached zero in the memory-to-peripheral mode.
  – The stream is disabled before the end of transfer (by clearing the EN bit in the DMA_SxCR register) and (when transfers are peripheral-to-memory or memory-

    to-memory) all the remaining data have been flushed from the FIFO into the memory.
- In Peripheral flow controller mode:
    - The last external burst or single request has been generated from the peripheral and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory
    - The stream is disabled by software, and (when the DMA is operating in peripheral-to-memory mode) the remaining data have been transferred from the FIFO into the memory

Note: The transfer completion is dependent on the remaining data in FIFO to be transferred into memory only in the case of peripheral-to-memory mode. This condition is not applicable in memory-to-peripheral mode.

If the stream is configured in non-circular mode, after the end of the transfer (that is when the number of data to be transferred reaches zero), the DMA is stopped (EN bit in DMA_SxCR register is cleared by Hardware) and no DMA request is served unless the software reprograms the stream and re-enables it (by setting the EN bit in the DMA_SxCR register).

18.3.15 DMA transfer suspension

At any time, a DMA transfer can be suspended to be restarted later on or to be definitively disabled before the end of the DMA transfer.

There are two cases:

- The stream disables the transfer with no later-on restart from the point where it was stopped. There is no particular action to do, except to clear the EN bit in the DMA_SxCR register to disable the stream. The stream may take time to be disabled (ongoing transfer is completed first). The transfer complete interrupt flag (TCIF in the DMA_LISR or DMA_HISR register) is set in order to indicate the end of transfer. The value of the EN bit in DMA_SxCR is now 0 to confirm the stream interruption. The DMA_SxNDTR register contains the number of remaining data items at the moment when the stream was stopped so that the software can determine how many data items have been transferred before the stream was interrupted.
- The stream suspends the transfer before the number of remaining data items to be transferred in the DMA_SxNDTR register reaches 0. The aim is to restart the transfer later by re-enabling the stream. In order to restart from the point where the transfer was stopped, the software has to read the DMA_SxNDTR register after disabling the stream by writing the EN bit in DMA_SxCR register (and then checking that it is at 0) to know the number of data items already collected. Then:
    - The peripheral and/or memory addresses have to be updated in order to adjust the address pointers
    - The SxNDTR register has to be updated with the remaining number of data items to be transferred (the value read when the stream was disabled)
    - The stream may then be re-enabled to restart the transfer from the point it was stopped

Note: A transfer complete interrupt flag (TCIF in DMA_LISR or DMA_HISR) is set to indicate the end of transfer due to the stream interruption.

18.3.16 Flow controller

The entity that controls the number of data to be transferred is known as the flow controller. This flow controller is configured independently for each stream using the PFCTRL bit in the DMA_SxCR register.

The flow controller can be:

- The DMA controller: in this case, the number of data items to be transferred is programmed by software into the DMA_SxNDTR register before the DMA stream is enabled.
- The peripheral source or destination: this is the case when the number of data items to be transferred is unknown. The peripheral indicates by hardware to the DMA controller when the last data are being transferred. This feature is only supported for peripherals that are able to signal the end of the transfer.

When the peripheral flow controller is used for a given stream, the value written into the DMA_SxNDTR has no effect on the DMA transfer. Actually, whatever the value written, it is forced by hardware to 0xFFFF as soon as the stream is enabled, to respect the following schemes:

- Anticipated stream interruption: EN bit in DMA_SxCR register is reset to 0 by the software to stop the stream before the last data hardware signal (single or burst) is sent by the peripheral. In such a case, the stream is switched off and the FIFO flush is triggered in the case of a peripheral-to-memory DMA transfer. The TCIFx flag of the corresponding stream is set in the status register to indicate the DMA completion. To know the number of data items transferred during the DMA transfer, read the DMA_SxNDTR register and apply the following formula:
  - Number_of_data_transferred = 0xFFFF – DMA_SxNDTR
- Normal stream interruption due to the reception of a last data hardware signal: the stream is automatically interrupted when the peripheral requests the last transfer (single or burst) and when this transfer is complete. the TCIFx flag of the corresponding stream is set in the status register to indicate the DMA transfer completion. To know the number of data items transferred, read the DMA_SxNDTR register and apply the same formula as above.
- The DMA_SxNDTR register reaches 0: the TCIFx flag of the corresponding stream is set in the status register to indicate the forced DMA transfer completion. The stream is automatically switched off even though the last data hardware signal (single or burst) has not been yet asserted. The already transferred data is not lost. This means that a maximum of 65535 data items can be managed by the DMA in a single transaction, even in peripheral flow control mode.

Note: When configured in memory-to-memory mode, the DMA is always the flow controller and the PFCTRL bit is forced to 0 by hardware.

The circular mode is forbidden in the peripheral flow controller mode.

18.3.17 Summary of the possible DMA configurations

The table below summarizes the different possible DMA configurations. The forbidden configurations are highlighted in gray in the table.

Table 107. Possible DMA configurations

DMA transfer mode	Source	Destination	Flow controller	Circular mode	Transfer type	Direct mode	Double-buffer mode
Peripheral-to-memory	AHB peripheral port	AHB memory port	DMA	Possible	single	Possible	Possible
					burst	Forbidden	
			Peripheral	Forbidden	single	Possible	Forbidden
					burst	Forbidden	
Memory-to-peripheral	AHB memory port	AHB peripheral port	DMA	Possible	single	Possible	Possible
					burst	Forbidden	
			Peripheral	Forbidden	single	Possible	Forbidden
					burst	Forbidden	
Memory-to-memory	AHB peripheral port	AHB memory port	DMA only	Forbidden	single	Forbidden	Forbidden
					burst		

18.3.18 Stream configuration procedure

The following sequence must be followed to configure a DMA stream x (where x is the stream number):

1. If the stream is enabled, disable it by resetting the EN bit in the DMA_SxCR register, then read this bit in order to confirm that there is no ongoing stream operation. Writing this bit to 0 is not immediately effective since it is actually written to 0 once all the current transfers are finished. When the EN bit is read as 0, this means that the stream is ready to be configured. It is therefore necessary to wait for the EN bit to be cleared before starting any stream configuration. All the stream dedicated bits set in the status register (DMA_LISR and DMA_HISR) from the previous data block DMA transfer must be cleared before the stream can be re-enabled.
2. Set the peripheral port register address in the DMA_SxPAR register. The data is moved from/ to this address to/ from the peripheral port after the peripheral event.
3. Set the memory address in the DMA_SxMA0R register (and in the DMA_SxMA1R register in the case of a double-buffer mode). The data is written to or read from this memory after the peripheral event.
4. Configure the total number of data items to be transferred in the DMA_SxNDTR register. After each peripheral event or each beat of the burst, this value is decremented.
5. Use DMAMUX to route a DMA request line to the DMA channel.
6. If the peripheral is intended to be the flow controller and if it supports this feature, set the PFCTRL bit in the DMA_SxCR register.
7. Configure the stream priority using the PL[1:0] bits in the DMA_SxCR register.
8. Configure the FIFO usage (enable or disable, threshold in transmission and reception)

9. Configure the data transfer direction, peripheral and memory incremented/fixed mode, single or burst transactions, peripheral and memory data widths, circular mode, double-buffer mode and interrupts after half and/or full transfer, and/or errors in the DMA_SxCR register.
10. Activate the stream by setting the EN bit in the DMA_SxCR register.

As soon as the stream is enabled, it can serve any DMA request from the peripheral connected to the stream.

Once half the data have been transferred on the AHB destination port, the half-transfer flag (HTIF) is set and an interrupt is generated if the half-transfer interrupt enable bit (HTIE) is set. At the end of the transfer, the transfer complete flag (TCIF) is set and an interrupt is generated if the transfer complete interrupt enable bit (TCIE) is set.

Warning: To switch off a peripheral connected to a DMA stream request, it is mandatory to, first, switch off the DMA stream to which the peripheral is connected, then to wait for EN bit = 0. Only then can the peripheral be safely disabled.

18.3.19 Error management

The DMA controller can detect the following errors:

- **Transfer error**: the transfer error interrupt flag (TEIFx) is set when:
  - a bus error occurs during a DMA read or a write access
  - a write access is requested by software on a memory address register in double-buffer mode whereas the stream is enabled and the current target memory is the one impacted by the write into the memory address register (refer to *Section 18.3.10: Double-buffer mode*)
- **FIFO error**: the FIFO error interrupt flag (FEIFx) is set if:
  - a FIFO underrun condition is detected
  - a FIFO overrun condition is detected (no detection in memory-to-memory mode because requests and transfers are internally managed by the DMA)
  - the stream is enabled while the FIFO threshold level is not compatible with the size of the memory burst (refer to *Table 106: FIFO threshold configurations*)
- **Direct mode error**: the direct mode error interrupt flag (DMEIFx) can only be set in the peripheral-to-memory mode while operating in direct mode and when the MINC bit in the DMA_SxCR register is cleared. This flag is set when a DMA request occurs while the previous data have not yet been fully transferred into the memory (because the memory bus was not granted). In this case, the flag indicates that two data items were be transferred successively to the same destination address, which could be an issue if the destination is not able to manage this situation

In direct mode, the FIFO error flag can also be set under the following conditions:

- In the peripheral-to-memory mode, the FIFO can be saturated (overrun) if the memory bus is not granted for several peripheral requests.
- In the memory-to-peripheral mode, an underrun condition may occur if the memory bus has not been granted before a peripheral request occurs.

If the TEIFx or the FEIFx flag is set due to incompatibility between burst size and FIFO threshold level, the faulty stream is automatically disabled through a hardware clear of its EN bit in the corresponding stream configuration register (DMA_SxCR).

If the DMEIFx or the FEIFx flag is set due to an overrun or underrun condition, the faulty stream is not automatically disabled and it is up to the software to disable or not the stream by resetting the EN bit in the DMA_SxCR register. This is because there is no data loss when this kind of errors occur.

When the stream's error interrupt flag (TEIF, FEIF, DMEIF) in the DMA_LISR or DMA_HISR register is set, an interrupt is generated if the corresponding interrupt enable bit (TEIE, FEIE, DMEIE) in the DMA_SxCR or DMA_SxFCR register is set.

Note: When a FIFO overrun or underrun condition occurs, the data is not lost because the peripheral request is not acknowledged by the stream until the overrun or underrun condition is cleared. If this acknowledge takes too much time, the peripheral itself may detect an overrun or underrun condition of its internal buffer and data might be lost.

18.4 DMA interrupts

For each DMA stream, an interrupt can be produced on the following events:

- Half-transfer reached
- Transfer complete
- Transfer error
- FIFO error (overrun, underrun or FIFO level error)
- Direct mode error

Separate interrupt enable control bits are available for flexibility as shown in the table below.

Table 108. DMA interrupt requests

Interrupt event	Event flag	Enable control bit
Half-transfer	HTIF	HTIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE
FIFO overrun/underrun	FEIF	FEIE
Direct mode error	DMEIF	DMEIE

Note: Before setting an enable control bit EN = 1, the corresponding event flag must be cleared, otherwise an interrupt is immediately generated.

18.5 DMA registers

The DMA registers have to be accessed by words (32 bits).

18.5.1 DMA low interrupt status register (DMA_LISR)

Address offset: 0x000

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[3:0]**: Stream x transfer complete interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No transfer complete event on stream x
1: A transfer complete event occurred on stream x.

Bits 26, 20, 10, 4 **HTIF[3:0]**: Stream x half transfer interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No half transfer event on stream x
1: An half transfer event occurred on stream x.

Bits 25, 19, 9, 3 **TEIF[3:0]**: Stream x transfer error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No transfer error on stream x
1: A transfer error occurred on stream x.

Bits 24, 18, 8, 2 **DMEIF[3:0]**: Stream x direct mode error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No direct mode error on stream x
1: A direct mode error occurred on stream x.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[3:0]**: Stream x FIFO error interrupt flag (x = 3 to 0)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_LIFCR register.
0: No FIFO error event on stream x
1: A FIFO error event occurred on stream x.

18.5.2 DMA high interrupt status register (DMA_HISR)

Address offset: 0x004

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **TCIF[7:4]**: Stream x transfer complete interrupt flag (x = 7 to 4)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.
0: No transfer complete event on stream x
1: A transfer complete event occurred on stream x.

Bits 26, 20, 10, 4 **HTIF[7:4]**: Stream x half transfer interrupt flag (x = 7 to 4)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.
0: No half transfer event on stream x
1: An half transfer event occurred on stream x.

Bits 25, 19, 9, 3 **TEIF[7:4]**: Stream x transfer error interrupt flag (x = 7 to 4)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.
0: No transfer error on stream x
1: A transfer error occurred on stream x.

Bits 24, 18, 8, 2 **DMEIF[7:4]**: Stream x direct mode error interrupt flag (x = 7 to 4)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.
0: No direct mode error on stream x
1: A direct mode error occurred on stream x.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **FEIF[7:4]**: Stream x FIFO error interrupt flag (x = 7 to 4)
This bit is set by hardware. It is cleared by software writing 1 to the corresponding bit in DMA_HIFCR register.
0: No FIFO error event on stream x
1: A FIFO error event occurred on stream x.

18.5.3 DMA low interrupt flag clear register (DMA_LIFCR)

Address offset: 0x008

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[3:0]**: Stream x clear transfer complete interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA_LISR register.

Bits 26, 20, 10, 4 **CHTIF[3:0]**: Stream x clear half transfer interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA_LISR register

Bits 25, 19, 9, 3 **CTEIF[3:0]**: Stream x clear transfer error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA_LISR register.

Bits 24, 18, 8, 2 **CDMEIF[3:0]**: Stream x clear direct mode error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA_LISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[3:0]**: Stream x clear FIFO error interrupt flag (x = 3 to 0)
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA_LISR register.

18.5.4 DMA high interrupt flag clear register (DMA_HIFCR)

Address offset: 0x00C

Reset value: 0x0000 0000

Bits 31:28, 15:12 Reserved, must be kept at reset value.

Bits 27, 21, 11, 5 **CTCIF[7:4]**: Stream x clear transfer complete interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding TCIFx flag in the DMA_HISR register.

Bits 26, 20, 10, 4 **CHTIF[7:4]**: Stream x clear half transfer interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding HTIFx flag in the DMA_HISR register.

Bits 25, 19, 9, 3 **CTEIF[7:4]**: Stream x clear transfer error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding TEIFx flag in the DMA_HISR register.

Bits 24, 18, 8, 2 **CDMEIF[7:4]**: Stream x clear direct mode error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding DMEIFx flag in the DMA_HISR register.

Bits 23, 17, 7, 1 Reserved, must be kept at reset value.

Bits 22, 16, 6, 0 **CFEIF[7:4]**: Stream x clear FIFO error interrupt flag (x = 7 to 4)
Writing 1 to this bit clears the corresponding CFEIFx flag in the DMA_HISR register.

18.5.5 DMA stream x configuration register (DMA_SxCR)

This register is used to configure the concerned stream.

Address offset: 0x010 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

PINCOS	MSIZE[1:0]		PSIZE[1:0]		MINC	PINC	CIRC	DIR[1:0]		PFCTRL	TCIE	HTIE	TEIE	DMEIE	EN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:23 **MBURST[1:0]**: Memory burst transfer configuration
These bits are set and cleared by software.
00: Single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN = 0.
In direct mode, these bits are forced to 0x0 by hardware as soon as bit EN = 1.

Bits 22:21 **PBURST[1:0]**: Peripheral burst transfer configuration
These bits are set and cleared by software.
00: Single transfer
01: INCR4 (incremental burst of 4 beats)
10: INCR8 (incremental burst of 8 beats)
11: INCR16 (incremental burst of 16 beats)
These bits are protected and can be written only if EN = 0.
In direct mode, these bits are forced to 0x0 by hardware.

Bit 20 **TRBUFF**: Enable the DMA to handle bufferable transfers
0: Bufferable transfers not enabled
1: Bufferable transfers enabled

Note: This bit must be set to 1 if the DMA stream manages UART/USART transfers.

Bit 19 **CT**: Current target (only in double-buffer mode)
This bit is set and cleared by hardware. It can also be written by software.
0: Current target memory is memory 0 (addressed by the DMA_SxM0AR pointer).
1: Current target memory is memory 1 (addressed by the DMA_SxM1AR pointer).
This bit can be written only if EN = 0 to indicate the target memory area of the first transfer. Once the stream is enabled, this bit operates as a status flag indicating which memory area is the current target.

Bit 18 **DBM**: Double-buffer mode
This bit is set and cleared by software.
0: No buffer switching at the end of transfer
1: Memory target switched at the end of the DMA transfer
This bit is protected and can be written only if EN = 0.

Bits 17:16 **PL[1:0]**: priority level
These bits are set and cleared by software.
00: Low
01: Medium
10: High
11: Very high
These bits are protected and can be written only if EN = 0.

Bit 15 **PINCOS**: Peripheral increment offset size
This bit is set and cleared by software
0: The offset size for the peripheral address calculation is linked to the PSIZE.
1: The offset size for the peripheral address calculation is fixed to 4 (32-bit alignment).
This bit has no meaning if bit PINC = 0.
This bit is protected and can be written only if EN = 0.
This bit is forced low by hardware when the stream is enabled (EN = 1) if the direct mode is selected or if PBURST are different from 00.

Bits 14:13 **MSIZE[1:0]**: Memory data size
These bits are set and cleared by software.
00: Byte (8-bit)
01: Half-word (16-bit)
10: Word (32-bit)
11: Reserved
These bits are protected and can be written only if EN = 0.
In direct mode, MSIZE is forced by hardware to the same value as PSIZE as soon as EN = 1.

Bits 12:11 **PSIZE[1:0]**: Peripheral data size
These bits are set and cleared by software.
00: Byte (8-bit)
01: Half-word (16-bit)
10: Word (32-bit)
11: Reserved
These bits are protected and can be written only if EN = 0.

Bit 10 **MINC**: Memory increment mode
This bit is set and cleared by software.
0: Memory address pointer fixed
1: Memory address pointer incremented after each data transfer (increment is done according to MSIZE)
This bit is protected and can be written only if EN = 0.

Bit 9 **PINC**: Peripheral increment mode

This bit is set and cleared by software.
0: Peripheral address pointer fixed
1: Peripheral address pointer incremented after each data transfer (increment done according to PSIZE)
This bit is protected and can be written only if EN = 0.

Bit 8 **CIRC**: Circular mode

This bit is set and cleared by software and can be cleared by hardware.
0: Circular mode disabled
1: Circular mode enabled
When the peripheral is the flow controller (bit PFCTRL = 1), and the stream is enabled (EN = 1), then this bit is automatically forced by hardware to 0.
It is automatically forced by hardware to 1 if the DBM bit is set, as soon as the stream is enabled (EN = 1).

Bits 7:6 **DIR[1:0]**: Data transfer direction

These bits are set and cleared by software.
00: Peripheral-to-memory
01: Memory-to-peripheral
10: Memory-to-memory
11: Reserved
These bits are protected and can be written only if EN = 0.

Bit 5 **PFCTRL**: Peripheral flow controller

This bit is set and cleared by software.
0: DMA is the flow controller.
1: The peripheral is the flow controller.
This bit is protected and can be written only if EN = 0.
When the memory-to-memory mode is selected (bits DIR[1:0] = 10), then this bit is automatically forced to 0 by hardware.

Bit 4 **TCIE**: Transfer complete interrupt enable

This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 3 **HTIE**: Half transfer interrupt enable

This bit is set and cleared by software.
0: HT interrupt disabled
1: HT interrupt enabled

Bit 2 **TEIE**: Transfer error interrupt enable

This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 1 **DMEIE**: Direct mode error interrupt enable

This bit is set and cleared by software.
0: DME interrupt disabled
1: DME interrupt enabled

Bit 0 **EN**: Stream enable/flag stream ready when read low
This bit is set and cleared by software.
0: Stream disabled
1: Stream enabled
This bit is cleared by hardware:
– on a DMA end of transfer (stream ready to be configured)
– if a transfer error occurs on the AHB master buses
– when the FIFO threshold on memory AHB port is not compatible with the burst size
When this bit is read as 0, the software is allowed to program the configuration and FIFO bits registers. It is forbidden to write these registers when the EN bit is read as 1.
Note: Before setting EN bit to 1 to start a new transfer, the event flags corresponding to the stream in DMA_LISR or DMA_HISR register must be cleared.

18.5.6 DMA stream x number of data register (DMA_SxNDTR)

Address offset: 0x014 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

NDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **NDT[15:0]**: Number of data items to transfer (0 up to 65535)
This bitfield can be written only when the stream is disabled. When the stream is enabled, this bitfield is read-only, indicating the remaining data items to be transmitted. This bitfield decrements after each DMA transfer.
Once the transfer is completed, this bitfield can either stay at zero (when the stream is in normal mode), or be reloaded automatically with the previously programmed value in the following cases:
– when the stream is configured in circular mode
– when the stream is enabled again by setting EN bit to 1
If the value of this bitfield is zero, no transaction can be served even if the stream is enabled.

18.5.7 DMA stream x peripheral address register (DMA_SxPAR)

Address offset: 0x018 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PAR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PAR[31:0]**: Peripheral address
Base address of the peripheral data register from/to which the data is read/written.
These bits are write-protected and can be written only when bit EN = 0 in DMA_SxCR.

18.5.8 DMA stream x memory 0 address register (DMA_SxM0AR)

Address offset: 0x01C + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

M0A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **M0A[31:0]**: Memory 0 address
Base address of memory area 0 from/to which the data is read/written.
These bits are write-protected. They can be written only if:
- the stream is disabled (EN = 0 in DMA_SxCR) or
- the stream is enabled (EN = 1 in DMA_SxCR) and CT = 1 in DMA_SxCR (in double-buffer mode).

18.5.9 DMA stream x memory 1 address register (DMA_SxM1AR)

Address offset: 0x020 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

M1A[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **M1A[31:0]**: Memory 1 address (used in case of double-buffer mode)
Base address of memory area 1 from/to which the data is read/written.
This bitfield is used only for the double-buffer mode.
These bits are write-protected. They can be written only if:
- the stream is disabled (EN = 0 in DMA_SxCR) or
- the stream is enabled (EN = 1 in DMA_SxCR) and bit CT = 0 in DMA_SxCR .

18.5.10 DMA stream x FIFO control register (DMA_SxFCR)

Address offset: 0x024 + 0x18 * x, (x = 0 to 7)

Reset value: 0x0000 0021

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FEIE	Res.	FS[2:0]			DMDIS	FTH[1:0]	
								rw		r	r	r	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **FEIE**: FIFO error interrupt enable
This bit is set and cleared by software.
0: FE interrupt disabled
1: FE interrupt enabled

Bit 6 Reserved, must be kept at reset value.

Bits 5:3 **FS[2:0]**: FIFO status
These bits are read-only.
000: 0 < fifo_level < 1/4
001: 1/4 ≤ fifo_level < 1/2
010: 1/2 ≤ fifo_level < 3/4
011: 3/4 ≤ fifo_level < full
100: FIFO is empty.
101: FIFO is full.
Others: Reserved (no meaning)
These bits are not relevant in the direct mode (DMDIS = 0).

Bit 2 **DMDIS**: Direct mode disable
This bit is set and cleared by software. It can be set by hardware.
0: Direct mode enabled
1: Direct mode disabled
This bit is protected and can be written only if EN = 0.
This bit is set by hardware if the memory-to-memory mode is selected (DIR = 10 in DMA_SxCR), and EN = 1 in DMA_SxCR because the direct mode is not allowed in the memory-to-memory configuration.

Bits 1:0 **FTH[1:0]**: FIFO threshold selection
These bits are set and cleared by software.
00: 1/4 full FIFO
01: 1/2 full FIFO
10: 3/4 full FIFO
11: Full FIFO
These bits are not used in the direct mode when the DMIS = 0.
These bits are protected and can be written only if EN = 0.

18.5.11 DMA hardware configuration 2 register (DMA_HWCFGR2)

Address offset: 0x3EC

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					r	r	r				r			r	r

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **CHSEL_WIDTH[2:0]**: Width of the CHSEL field of any DMA_SxCR register common to all streams

In [0..6] range:
0: No programmable selection
1: 2 channels programmable selection
2: Up to 8 channels programmable selection
3: Up to 16 channels programmable selection
4: Up to 32 channels programmable selection
5: Up to 64 channels programmable selection
6: Up to 128 channels programmable selection

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **WRITE_BUFFERABLE**:

0: DMA acknowledge signal is de-asserted one cycle after occurred both 1) the last cycle of the data phase of the bus access on its AHB peripheral master port and 2) the de-assertion of the peripheral request
1: DMA acknowledge signal is de-asserted exactly one cycle after the last cycle of the data phase of the bus access on its AHB peripheral master port
In any case, DMA acknowledge signal is asserted one cycle after the address phase of the bus access on its AHB peripheral master port.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **FIFO_SIZE[1:0]**: FIFO size, common to all streams

In [0..3] range:
0: 2-word FIFO
1: 4-word FIFO
2: 8-word FIFO
3: 16-word FIFO

18.5.12 DMA hardware configuration 1 register (DMA_HWCFGR1)

Address offset: 0x3F0

Reset value: 0x2222 2222

Refer to *Section 2.5* for the register boundary addresses.

19 DMA request multiplexer (DMAMUX)

19.1 Introduction

A peripheral indicates a request for DMA transfer by setting its DMA request signal. The DMA request is pending until served by the DMA controller that generates a DMA acknowledge signal, and the corresponding DMA request signal is deasserted.

In this document, the set of control signals required for the DMA request/acknowledge protocol is not explicitly shown or described, and it is referred to as DMA request line.

The DMAMUX request multiplexer enables routing a DMA request line between the peripherals and the DMA controllers of the product. The routing function is ensured by a programmable multi-channel DMA request line multiplexer. Each channel selects a unique DMA request line, unconditionally or synchronously with events from its DMAMUX synchronization inputs. The DMAMUX may also be used as a DMA request generator from programmable events on its input trigger signals.

The number of DMAMUX instances and their main characteristics are specified in *Section 19.3.1*.

The assignment of DMAMUX request multiplexer inputs to the DMA request lines from peripherals and to the DMAMUX request generator outputs, the assignment of DMAMUX request multiplexer outputs to DMA controller channels, and the assignment of DMAMUX synchronizations and trigger inputs to internal and external signals depend upon product implementation. They are detailed in *Section 19.3.2*.

19.2 DMAMUX main features

- 16-channel programmable DMA request line multiplexer output
- 8-channel DMA request generator
- 8 trigger inputs to DMA request generator
- 8 synchronization inputs
- Per DMA request generator channel:
  - DMA request trigger input selector
  - DMA request counter
  - Event overrun flag for selected DMA request trigger input
- Per DMA request line multiplexer channel output:
  - 108 input DMA request lines from peripherals
  - One DMA request line output
  - Synchronization input selector
  - DMA request counter
  - Event overrun flag for selected synchronization input
  - One event output, for DMA request chaining
- Identification registers, with associated IP revision and hardware configuration.

19.3 DMAMUX implementation

19.3.1 DMAMUX instantiation

DMAMUX is instantiated with the hardware configuration parameters listed in the following table.

Table 110. DMAMUX instantiation

Feature	DMAMUX
Number of DMAMUX output request channels	16
Number of DMAMUX request generator channels	8
Number of DMAMUX request trigger inputs	8
Number of DMAMUX synchronization inputs	8
Number of DMAMUX peripheral request inputs	108

19.3.2 DMAMUX mapping

The mapping of resources to DMAMUX is hardwired.

DMAMUX is used with DMA1 and DMA2:

- DMAMUX channels 0 to 7 are connected to DMA1 channels 0 to 7
- DMAMUX channels 8 to 15 are connected to DMA2 channels 0 to 7

Table 111. DMAMUX: assignment of multiplexer inputs to resources

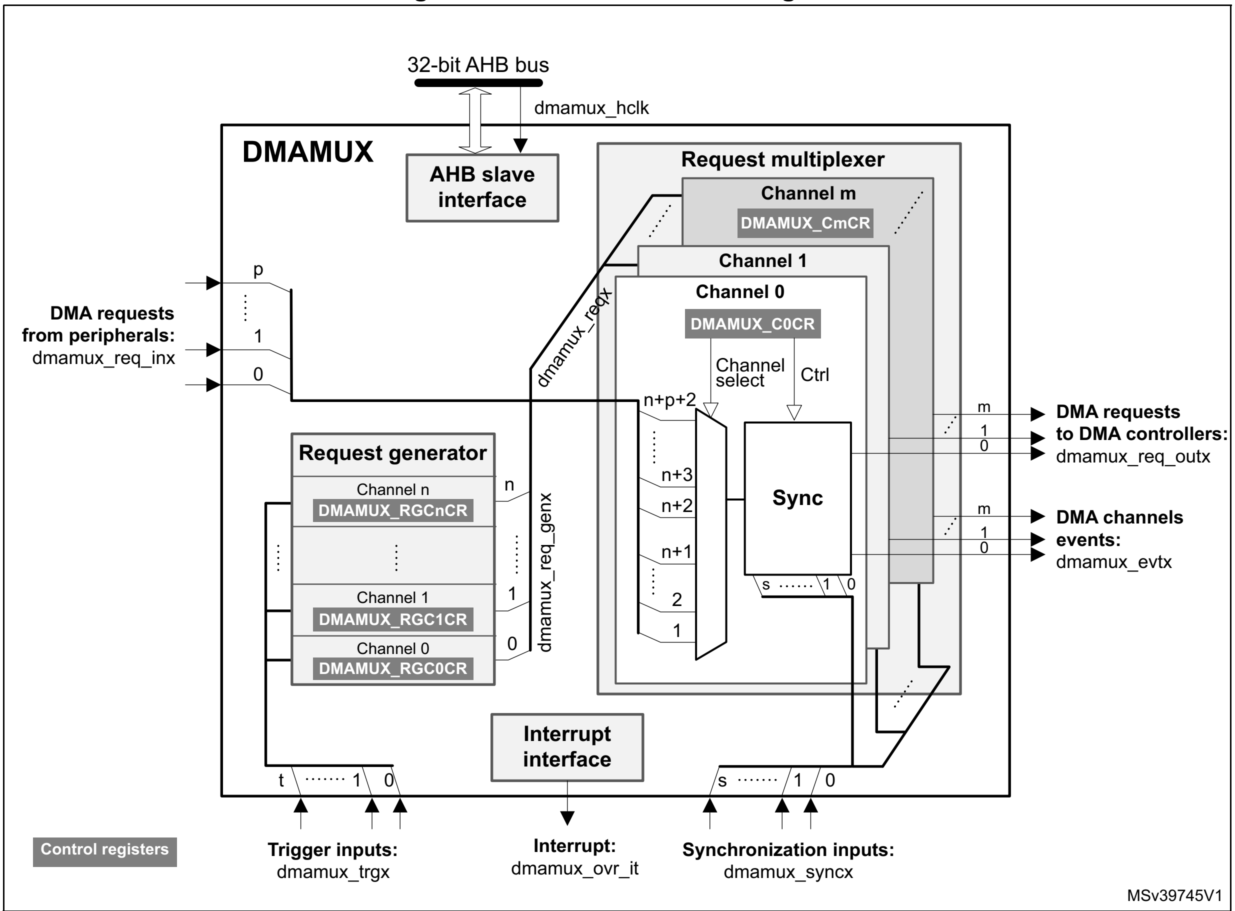
19.4 DMAMUX functional description

19.4.1 DMAMUX block diagram

Figure 133 shows the DMAMUX block diagram.

Figure 133. DMAMUX block diagram



DMAMUX features two main sub-blocks: the request line multiplexer and the request line generator.

The implementation assigns:

- DMAMUX request multiplexer sub-block inputs (dmamux_reqx) from peripherals (dmamux_req_inx) and from channels of the DMAMUX request generator sub-block (dmamux_req_genx)
- DMAMUX request outputs to channels of DMA controllers (dmamux_req_outx)
- Internal or external signals to DMA request trigger inputs (dmamux_trgx)
- Internal or external signals to synchronization inputs (dmamux_syncx)

19.4.2 DMAMUX signals

Table 114 lists the DMAMUX signals.

Table 114. DMAMUX signals

Signal name	Description
dmamux_hclk	DMAMUX AHB clock
dmamux_req_inx	DMAMUX DMA request line inputs from peripherals
dmamux_trgx	DMAMUX DMA request triggers inputs (to request generator sub-block)
dmamux_req_genx	DMAMUX request generator sub-block channels outputs
dmamux_reqx	DMAMUX request multiplexer sub-block inputs (from peripheral requests and request generator channels)
dmamux_syncx	DMAMUX synchronization inputs (to request multiplexer sub-block)
dmamux_req_outx	DMAMUX requests outputs (to DMA controllers)
dmamux_evtx	DMAMUX events outputs
dmamux_ovr_it	DMAMUX overrun interrupts

19.4.3 DMAMUX channels

A DMAMUX channel is a request multiplexer channel that can include, depending upon the selected input of the request multiplexer, an additional DMAMUX request generator channel.

A DMAMUX request multiplexer channel is connected and dedicated to a single channel of DMA controller(s).

Channel configuration procedure

Follow the sequence below to configure a DMAMUX x channel and the related DMA channel y:

1. Set and configure completely the DMA channel y, except enabling the channel y.
2. Set and configure completely the related DMAMUX y channel.
3. Last, activate the DMA channel y by setting the EN bit in the DMA y channel register.

19.4.4 DMAMUX request line multiplexer

The DMAMUX request multiplexer with its multiple channels ensures the actual routing of DMA request/acknowledge control signals, named DMA request lines.

Each DMA request line is connected in parallel to all the channels of the DMAMUX request line multiplexer.

A DMA request is sourced either from the peripherals, or from the DMAMUX request generator.

The DMAMUX request line multiplexer channel x selects the DMA request line number as configured by the DMAREQ_ID field in the DMAMUX_CxCR register.

Note: The null value in the field DMAREQ_ID corresponds to no DMA request line selected.

Caution: A same non-null DMAREQ_ID cannot be programmed to different x and y DMAMUX request multiplexer channels (via DMAMUX_CxCR and DMAMUX_CyCR), except when the application guarantees that the two connected DMA channels are not simultaneously active.

On top of the DMA request selection, the synchronization mode and/or the event generation may be configured and enabled, if required.

Synchronization mode and channel event generation

Each DMAMUX request line multiplexer channel x can be individually synchronized by setting the synchronization enable (SE) bit in the DMAMUX_CxCR register.

DMAMUX has multiple synchronization inputs. The synchronization inputs are connected in parallel to all the channels of the request multiplexer.

The synchronization input is selected via the SYNC_ID field in the DMAMUX_CxCR register of a given channel x.

When a channel is in this synchronization mode, the selected input DMA request line is propagated to the multiplexer channel output, once a programmable rising/falling edge is detected on the selected input synchronization signal, via the SPOL[1:0] field of the DMAMUX_CxCR register.

Additionally, internally to the DMAMUX request multiplexer, there is a programmable DMA request counter, which can be used for the channel request output generation, and for an event generation. An event generation on the channel x output is enabled through the EGE bit (event generation enable) of the DMAMUX_CxCR register.

As shown in *Figure 135*, upon the detected edge of the synchronization input, the pending selected input DMA request line is connected to the DMAMUX multiplexer channel x output.

Note: If a synchronization event occurs while there is no pending selected input DMA request line, it is discarded. The following asserted input request lines is not connected to the DMAMUX multiplexer channel output until a synchronization event occurs again.

From this point on, each time the connected DMAMUX request is served by the DMA controller (a served request is deasserted), the DMAMUX request counter is decremented. At its underrun, the DMA request counter is automatically loaded with the value in the NBREQ field of the DMAMUX_CxCR register and the input DMA request line is disconnected from the multiplexer channel x output.

Thus, the number of DMA requests transferred to the multiplexer channel x output following a detected synchronization event, is equal to the value in the NBREQ field, plus one.

Note: The NBREQ field value can be written by software only when both synchronization enable bit (SE) and event generation enable bit (EGE) of the corresponding multiplexer channel x are disabled.

Figure 134. Synchronization mode of the DMAMUX request line multiplexer channel

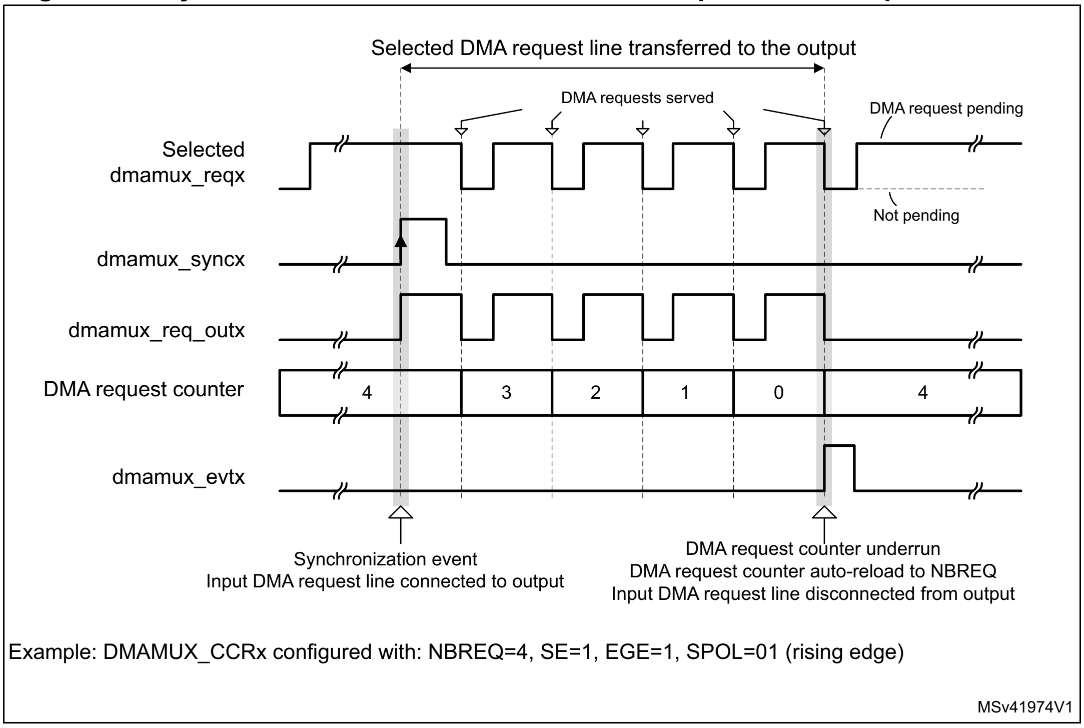


Figure 135. Event generation of the DMA request line multiplexer channel

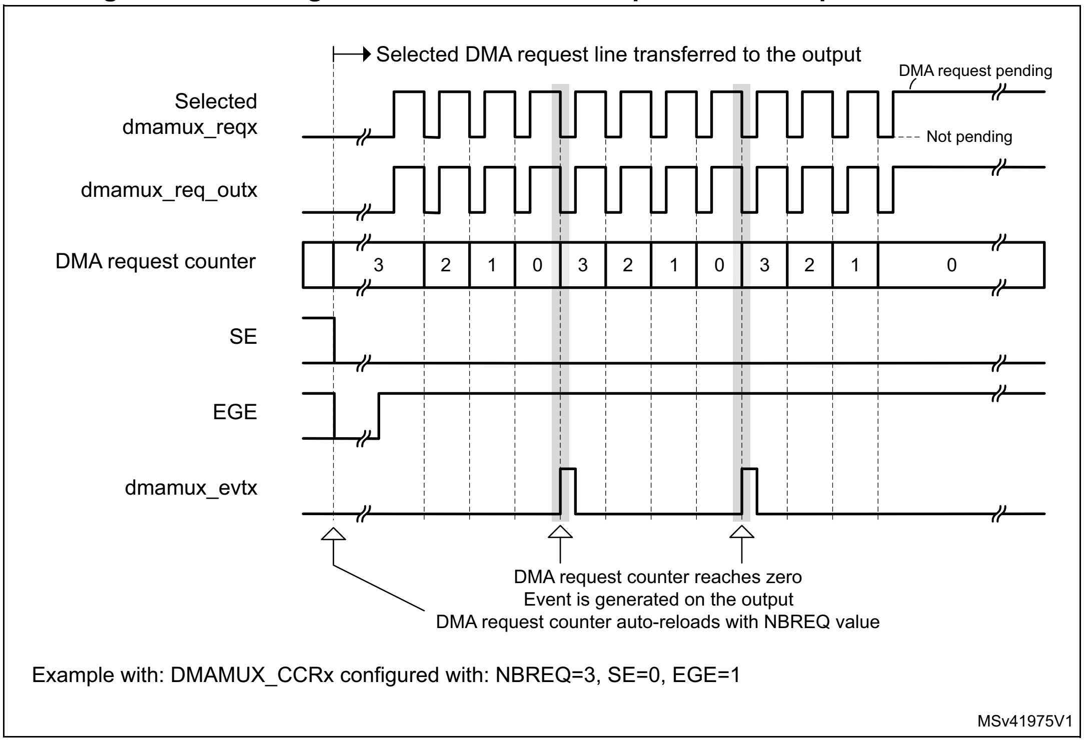

If EGE is enabled, the multiplexer channel generates a channel event, as a pulse of one AHB clock cycle, when its DMA request counter is automatically reloaded with the value of the programmed NBREQ field, as shown in *Figure 134* and *Figure 135*.

Note: If EGE is enabled and NBREQ = 0, an event is generated after each served DMA request.

Note: A synchronization event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_CxCR register, the synchronization events are masked during three AHB clock cycles.

Synchronization overrun and interrupt

If a new synchronization event occurs before the request counter underrun (the internal request counter programmed via the NBREQ field of the DMAMUX_CxCR register), the synchronization overrun flag bit SOFx is set in the DMAMUX_CSR register.

Note: The request multiplexer channel x synchronization must be disabled (DMAMUX_CxCR.SE = 0) when the use of the related channel of the DMA controller is completed. Else, upon a new detected synchronization event, there is a synchronization overrun due to the absence of a DMA acknowledge (that is, no served request) received from the DMA controller.

The overrun flag SOFx is reset by setting the associated clear synchronization overrun flag bit CSOFx in the DMAMUX_CFR register.

Setting the synchronization overrun flag generates an interrupt if the synchronization overrun interrupt enable bit SOIE is set in the DMAMUX_CxCR register.

19.4.5 DMAMUX request generator

The DMAMUX request generator produces DMA requests following trigger events on its DMA request trigger inputs.

The DMAMUX request generator has multiple channels. DMA request trigger inputs are connected in parallel to all channels.

The outputs of DMAMUX request generator channels are inputs to the DMAMUX request line multiplexer.

Each DMAMUX request generator channel x has an enable bit GE (generator enable) in the corresponding DMAMUX_RGxCR register.

The DMA request trigger input for the DMAMUX request generator channel x is selected through the SIG_ID (trigger signal ID) field in the corresponding DMAMUX_RGxCR register.

Trigger events on a DMA request trigger input can be rising edge, falling edge or either edge. The active edge is selected through the GPOL (generator polarity) field in the corresponding DMAMUX_RGxCR register.

Upon the trigger event, the corresponding generator channel starts generating DMA requests on its output. Each time the DMAMUX generated request is served by the connected DMA controller (a served request is deasserted), a built-in (inside the DMAMUX request generator) DMA request counter is decremented. At its underrun, the request generator channel stops generating DMA requests and the DMA request counter is automatically reloaded to its programmed value upon the next trigger event.

Thus, the number of DMA requests generated after the trigger event is GNBREQ + 1.

Note: The GNBREQ field value can be written by software only when the enable GE bit of the corresponding generator channel x is disabled.

There is no hardware write protection.

A trigger event (edge) is detected if the state following the edge remains stable for more than two AHB clock cycles.

Upon writing into DMAMUX_RGxCR register, the trigger events are masked during three AHB clock cycles.

Trigger overrun and interrupt

If a new DMA request trigger event occurs before the DMAMUX request generator counter underrun (the internal counter programmed via the GNBREQ field of the DMAMUX_RGxCR register), and if the request generator channel x was enabled via GE, then the request trigger event overrun flag bit OFx is asserted by the hardware in the DMAMUX_RGSR register.

Note: The request generator channel x must be disabled (DMAMUX_RGxCR.GE = 0) when the usage of the related channel of the DMA controller is completed. Else, upon a new detected trigger event, there is a trigger overrun due to the absence of an acknowledge (that is, no served request) received from the DMA.

The overrun flag OFx is reset by setting the associated clear overrun flag bit COFx in the DMAMUX_RGCFR register.

Setting the DMAMUX request trigger overrun flag generates an interrupt if the DMA request trigger event overrun interrupt enable bit OIE is set in the DMAMUX_RGxCR register.

19.5 DMAMUX interrupts

An interrupt can be generated upon:

- a synchronization event overrun in each DMA request line multiplexer channel
- a trigger event overrun in each DMA request generator channel

For each case, per-channel in.dividual interrupt enable, status, and clear flag register bits are available.

Table 115. DMAMUX interrupts

Interrupt signal	Interrupt event	Event flag	Clear bit	Enable bit
dmamuxovr_it	Synchronization event overrun on channel x of the DMAMUX request line multiplexer	SOFx	CSOFx	SOIE
	Trigger event overrun on channel x of the DMAMUX request generator	OFx	COFx	OIE

19.6 DMAMUX registers

Refer to the table containing register boundary addresses for the DMAMUX base address.

DMAMUX registers may be accessed per byte (8-bit), half-word (16-bit), or word (32-bit). The address must be aligned with the data size.

19.6.1 DMAMUX request line multiplexer channel x configuration register (DMAMUX_CxCR)

Address offset: 0x000 + 0x04 * x (x = 0 to 15)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	SYNC_ID[2:0]			NBREQ[4:0]					SPOL[1:0]		SE

Res.	Res.	Res.	Res.	Res.	Res.	EGE	SOIE	Res.	DMAREQ_ID[6:0]						
						rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **SYNC_ID[2:0]**: Synchronization identification
Selects the synchronization input (see *Table 113: DMAMUX: assignment of synchronization inputs to resources*).

Bits 23:19 **NBREQ[4:0]**: Number of DMA requests minus 1 to forward
Defines the number of DMA requests to forward to the DMA controller after a synchronization event, and/or the number of DMA requests before an output event is generated.
This field must only be written when both SE and EGE bits are low.

Bits 18:17 **SPOL[1:0]**: Synchronization polarity
Defines the edge polarity of the selected synchronization input:
00: No event (no synchronization, no detection).
01: Rising edge
10: Falling edge
11: Rising and falling edges

Bit 16 **SE**: Synchronization enable
0: Synchronization disabled
1: Synchronization enabled

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **EGE**: Event generation enable
0: Event generation disabled
1: Event generation enabled

Bit 8 **SOIE**: Synchronization overrun interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bits 6:0 **DMAREQ_ID[6:0]**: DMA request identification
Selects the input DMA request. See the DMAMUX table about assignments of multiplexer inputs to resources.

19.6.2 DMAMUX request line multiplexer interrupt channel status register (DMAMUX_CSR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SOF[15:0]**: Synchronization overrun event flag
The flag is set when a synchronization event occurs on a DMA request line multiplexer channel x, while the DMA request counter value is lower than NBREQ.
The flag is cleared by writing 1 to the corresponding CSOFx bit in DMAMUX_CFR register.

19.6.3 DMAMUX request line multiplexer interrupt clear flag register (DMAMUX_CFR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CSOF[15:0]**: Clear synchronization overrun event flag
Writing 1 in each bit clears the corresponding overrun flag SOFx in the DMAMUX_CSR register.

19.6.4 DMAMUX request generator channel x configuration register (DMAMUX_RGxCR)

Address offset: 0x100 + 0x04 * x (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GNBREQ[4:0]					GPOL[1:0]		GE
								rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	OIE	Res.	Res.	Res.	Res.	Res.	SIG_ID[2:0]		
							rw						rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:19 **GNBREQ[4:0]**: Number of DMA requests to be generated (minus 1)

Defines the number of DMA requests to be generated after a trigger event. The actual number of generated DMA requests is GNBREQ +1.

Note: This field must be written only when GE bit is disabled.

Bits 18:17 **GPOL[1:0]**: DMA request generator trigger polarity

Defines the edge polarity of the selected trigger input

00: No event, i.e. no trigger detection nor generation.

01: Rising edge

10: Falling edge

11: Rising and falling edges

Bit 16 **GE**: DMA request generator channel x enable

0: DMA request generator channel x disabled

1: DMA request generator channel x enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **OIE**: Trigger overrun interrupt enable

0: Interrupt on a trigger overrun event occurrence is disabled

1: Interrupt on a trigger overrun event occurrence is enabled

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **SIG_ID[2:0]**: Signal identification

Selects the DMA request trigger input used for the channel x of the DMA request generator

19.6.5 DMAMUX request generator interrupt status register (DMAMUX_RGSR)

Address offset: 0x140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **OF[7:0]**: Trigger overrun event flag

The flag is set when a new trigger event occurs on DMA request generator channel x, before the request counter underrun (the internal request counter programmed via the GNBREQ field of the DMAMUX_RGxCR register).

The flag is cleared by writing 1 to the corresponding COFx bit in the DMAMUX_RGCFR register.

19.6.6 DMAMUX request generator interrupt clear flag register (DMAMUX_RGCFR)

Address offset: 0x144

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **COF[7:0]**: Clear trigger overrun event flag

Writing 1 in each bit clears the corresponding overrun flag OFx in the DMAMUX_RGSR register.

19.6.7 DMAMUX size identification register (DMAMUX_SIDR)

Address offset: 0x3FC

Reset value: 0xA3C5 DD01

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SID[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
SID[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SID[31:0]:** Size identification
This register identifies an IP size of 1 KB address space.

19.6.8 DMAMUX IP identification register (DMAMUX_IPIDR)

Address offset: 0x3F8

Reset value: 0x0010 0011

This register identifies the IP.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ID[31:16]

1. - The absence of parenthesis around EXTI event numbers indicates that the EXTI output is connected to the NVIC. The EXTI configuration may impact the interrupt line state (i.e. EXTI may mask the interrupt).
   - The presence of parenthesis () around EXTI event numbers indicates that the EXTI output is not connected to the NVIC. The EXTI configuration cannot impact the interrupt line state.
   See *Section 23: Extended interrupt and event controller (EXTI)* for details.
2. Check device datasheet for availability.

20.2 GIC Interrupts

Table 118. STM32MP153 interrupt mapping for Cortex®-A7 GIC

Num	ID	Acronym	Description	EXTI event (1)
SGI (Rising Edge triggered)				
0	0	SGI0	software generated interrupt 0 (recommended non-secure)	-
1	1	SGI1	software generated interrupt 1 (recommended non-secure)	-
2	2	SGI2	software generated interrupt 2 (recommended non-secure)	-
3	3	SGI3	software generated interrupt 3 (recommended non-secure)	-
4	4	SGI4	software generated interrupt 4 (recommended non-secure)	-
5	5	SGI5	software generated interrupt 5 (recommended non-secure)	-
6	6	SGI6	software generated interrupt 6 (recommended non-secure)	-
7	7	SGI7	software generated interrupt 7 (recommended non-secure)	-
8	8	SGI8	software generated interrupt 8 (recommended secure)	-
9	9	SGI9	software generated interrupt 9 (recommended secure)	-
10	10	SGI10	software generated interrupt 10 (recommended secure)	-
11	11	SGI11	software generated interrupt 11 (recommended secure)	-
12	12	SGI12	software generated interrupt 12 (recommended secure)	-
13	13	SGI13	software generated interrupt 13 (recommended secure)	-
14	14	SGI14	software generated interrupt 14 (recommended secure)	-
15	15	SGI15	software generated interrupt 15 (recommended secure)	-

Table 118. STM32MP153 interrupt mapping for Cortex®-A7 GIC (continued)

Num	ID	Acronym	Description	EXTI event (1)
PPI (Active Low level sensitive)				
-	16 to 24	-	Reserved	-
-	25	PPI6	Virtual maintenance interrupt.	-
-	26	PPI5	Hypervisor timer event.	-
-	27	PPI4	Virtual timer event.	-
-	28	PPI0	Legacy nFIQ signal. Not used.	-
-	29	PPI1	Secure physical timer event.	-
-	30	PPI2	Non-secure physical timer event.	-
-	31	PPI3	Legacy nIRQ signal. Not used.	-
SPI (active high level sensitive or rising edge triggered)				
0	32	WWDG1_IT	Window watchdog 1 early wakeup interrupt	-
1	33	PVD_AVD	PVD & AVD detector through EXTI	16
2	34	TAMP	Tamper interrupt (include LSECSS interrupts)	(18)
3	35	RTC_WKUP_ALARM	RTC wakeup timer and alarms (A and B) interrupt	(19)
4	36	TZC_IT	TrustZone DDR address space controller	-
5	37	RCC	RCC global interrupt	-
6	38	EXTI0	EXTI line 0 interrupt	0
7	39	EXTI1	EXTI line 1 interrupt	1
8	40	EXTI2	EXTI line 2 interrupt	2
9	41	EXTI3	EXTI line 3 interrupt	3
10	42	EXTI4	EXTI line 4 interrupt	4
11	43	DMA1_STR0	DMA1 stream0 global interrupt	-
12	44	DMA1_STR1	DMA1 stream1 global interrupt	-
13	45	DMA1_STR2	DMA1 stream2 global interrupt	-
14	46	DMA1_STR3	DMA1 stream3 global interrupt	-
15	47	DMA1_STR4	DMA1 stream4 global interrupt	-
16	48	DMA1_STR5	DMA1 stream5 global interrupt	-
17	49	DMA1_STR6	DMA1 stream6 global interrupt	-
18	50	ADC1	ADC1 global interrupt	-
19	51	FDCAN1_IT0	FDCAN1 interrupt 0	-
20	52	FDCAN2_IT0	FDCAN2 interrupt 0	-
21	53	FDCAN1_IT1	FDCAN1 interrupt 1	-
22	54	FDCAN2_IT1	FDCAN2 interrupt 1	-

1. - The absence of parenthesis around EXTI event numbers indicates that the EXTI output is connected to the GIC. The EXTI configuration may impact the interrupt line state (i.e. EXTI may mask the interrupt).
   - The presence of parenthesis () around EXTI event numbers indicates that the EXTI output is not connected to the GIC. The EXTI configuration cannot impact the interrupt line state.
   See *Section 23: Extended interrupt and event controller (EXTI)* for details.
2. Check device datasheet for availability.

20.3 EXTI events

Table 119. STM32MP153 EXTI Events

Event Input	Source	Event type	Wakeup target	Connection to rxev[(1)]	TrustZone
0	EXTI[0]	Configurable	MPU & MCU	Yes	Yes
1	EXTI[1]	Configurable	MPU & MCU	Yes	Yes

1. rxev is only present on MCU core.

21 Nested Vectored Interrupt Controllers (NVIC)

21.1 NVIC features

The nested vector interrupt controller NVIC includes the following features:

- 150 maskable interrupt channels
- 16 programmable priority levels (4 bits of interrupt priority are used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the Cortex-M4 processor core are closely coupled, which enables low latency interrupt processing and efficient processing of late arriving interrupts.

All the interrupts including the Cortex-M4 core exceptions are managed by the NVIC. For more information on exceptions and NVIC programming, refer to Cortex®-M4 programming manual PM0214.

21.2 SysTick calibration value register

As the Systick is not running on a fixed frequency, there is no SystTick calibration value available. The SysTick reload counter should be set according to the required time base and the mcu_ck frequency value set in RCC.

21.3 Interrupt and exception vectors

See the interrupt tables for STM32MP153 devices in *Interrupt list* section.

22 Global interrupt controller (GIC)

22.1 Introduction

The following Arm® specifications provides additional details on the GIC:

- Arm® Generic Interrupt Controller - Architecture Specification v2.0
- Cortex®-A7 MPCore Technical Reference Manual Revision: r0p5

22.2 GIC main features

The integrated GIC collates and arbitrates from a large number of interrupt sources.

It provides:

- Masking of interrupts
- Prioritization of interrupts
- Distribution of the interrupts to the target processors
- Tracking the status of interrupts
- Generation of interrupts by software
- Support for security extensions
- Support for virtualization extensions

22.3 GIC functional description

The GIC is a single functional unit located in the Cortex-A7 MPCore processor. The GIC consists of a shared distributor block and several CPU interfaces. For each processor in the multiprocessor device, there is:

- one CPU interface
- a virtual interface control
- a virtual CPU interface.

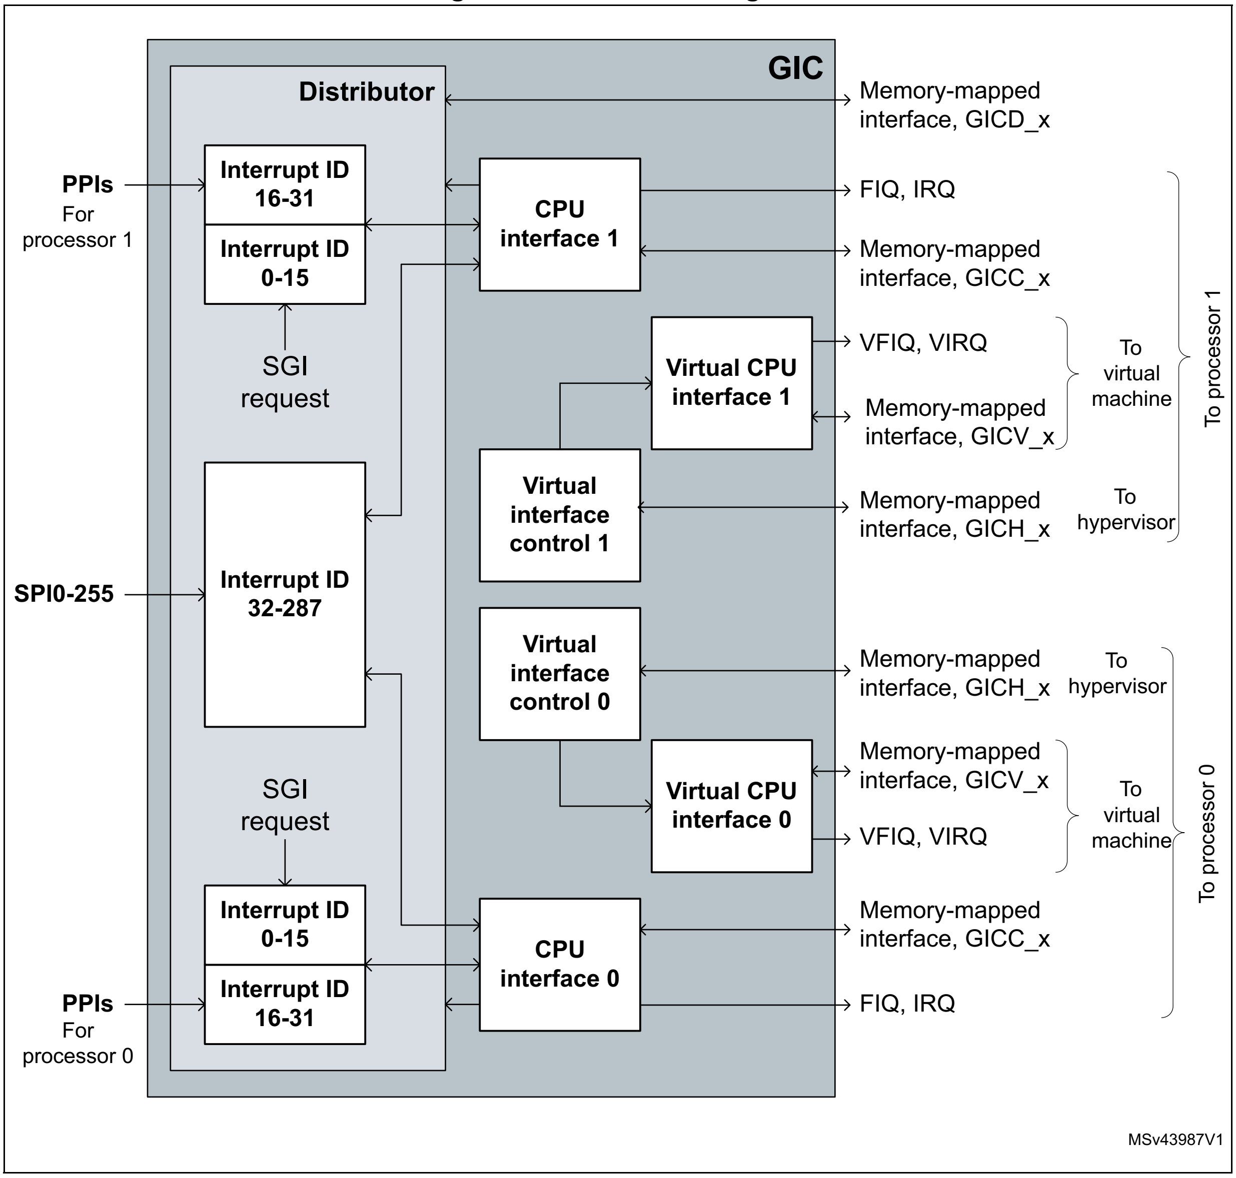
The GIC registers are memory-mapped, and the base address is visible into the configuration base address (CBAR) for each processor in the cluster.

Memory regions used for these registers must be marked as device or strongly-ordered in the translation tables.

Memory regions marked as normal memory cannot access any of the GIC registers, instead access caches or external memory as required.

Figure 136 shows the GIC block diagram.

Figure 136. GIC block diagram



22.4 Interrupt sources

All interrupt sources are identified by a unique ID.

The Cortex-A7 MPCore processor has the following interrupt sources:

22.4.1 Software generated interrupts (SGI)

SGIs are generated by writing to the software generated interrupt register (GICD_SGIR). A maximum of 16 SGIs, ID0-ID15, can be generated for each processor interface. An SGI has edge-triggered properties. The software triggering of the interrupt is equivalent to the edge transition of the interrupt signal on a peripheral input.

Arm recommends to use SGI ID0-ID7 for non-secure interrupts and SGI ID8-ID15 for secure interrupts.

22.4.2 Private peripheral interrupts (PPI)

A PPI is an interrupt generated by a peripheral that is specific to a single processor. There are seven PPIs for each CPU interface:

Legacy nFIQ signal (PPI0) - NOT USED

When the GIC interrupt bypass is in effect, such as after reset, the external nFIQ signal bypasses the interrupt distributor logic and directly drives the interrupt request to the corresponding processor.

When a processor uses the GIC rather than the external nFIQ signal, by enabling its own CPU interface, the nFIQ signal is treated like other interrupt lines and uses ID28. The interrupt is active-low level-sensitive.

Secure physical timer event (PPI1)

This is the event generated from the secure physical timer and uses ID29. The interrupt is level-sensitive.

Non-secure physical timer event (PPI2)

This is the event generated from the non-secure physical timer and uses ID30. The interrupt is level-sensitive.

Legacy nIRQ signal (PPI3) - NOT USED

When the GIC interrupt bypass is in effect, such as after reset, the external nIRQ signal bypasses the interrupt distributor logic and directly drives the interrupt request to the corresponding processor.

When a processor uses the GIC rather than the external nIRQ signal, by enabling its own CPU interface, the nIRQ signal is treated like other interrupt lines and uses ID31. The interrupt is active-low level-sensitive.

Virtual timer event (PPI4)

This is the event generated from the virtual timer and uses ID27. The interrupt is level-sensitive.

Hypervisor timer event (PPI5)

This is the event generated from the physical timer in hypervisor mode and uses ID26. The interrupt is level-sensitive.

Virtual maintenance interrupt (PPI6)

The virtualization extensions support in the Arm Generic Interrupt Controller Architecture Specification, permits for a maintenance interrupt to be generated under several conditions. The virtual maintenance interrupt uses ID25. The interrupt is level-sensitive.

22.4.3 Shared peripheral interrupts (SPI)

SPIs are triggered by events generated on associated interrupt input lines. The GIC supports up to 256 SPIs corresponding to the external IRQS signal.

SPIs start at ID32. The SPIs can be configured to be edge-triggered or active-high level-sensitive.

22.4.4 Interrupt priority formats

The Cortex-A7 MPCore processor implements a 5-bit version of the interrupt priority field for 32 interrupt priority levels.

22.5 GIC distributor (GICD)

The GIC distributor (GICD) centralizes all interrupt sources, determines the priority of each interrupt, and, for each CPU interface, forwards the interrupt with the highest priority to the interface for priority masking and preemption handling.

The GICD provides a programming interface for:

- globally enabling the forwarding of interrupts to the CPU interfaces
- enabling or disabling each interrupt
- setting the priority level of each interrupt
- setting the target processor list of each interrupt
- setting each peripheral interrupt to be level-sensitive or edge-triggered
- setting each interrupt as either group 0 or group 1
- sending an SGI to one or more target processors
- visibility of the state of each interrupt
- a mechanism for software to set or clear the pending state of a peripheral interrupt.

The GICD_IPRIORITYRx, GICD_ITARGETSRx, GICD_CPENDSGIRx, and GICD_SPENDSGIRx registers are byte-accessible and halfword-accessible.

All other registers are word-accessible.

22.5.1 GICD control register (GICD_CTLR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLEGRP1	ENABLEGRP0
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **ENABLEGRP1:** enable group 1 interrupts
Global enable for forwarding pending group 1 interrupts from the GICD to the CPU interfaces

Bit 0 **ENABLEGRP0**: enable group 0 interrupts
Global enable for forwarding pending group 0 interrupts from the GICD to the CPU interfaces

22.5.2 GICD control non-secure access register (GICD_CTLRNS)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENABLE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ENABLE**:
Global enable for forwarding pending group 1 interrupts from the GICD to the CPU interfaces

22.5.3 GICD interrupt controller type register (GICD_TYPER)

Address offset: 0x004

Reset value: 0x0000 FC28

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
LSPI[4:0]					SECURITYEXTN	Res.	Res.	CPUNUMBER[2:0]			ITLINESNUMBER[4:0]				
r	r	r	r	r	r			r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:11 **LSPI[4:0]**: lockable shared peripheral interrupt
Returns the number of LSPIs that the interrupt controller contains (0b1111 = 31 LSPIs, these are the interrupts of IDs 32-62).

Bit 10 **SECURITYEXTN**: security extension
Indicates whether the GIC implements the security extensions. This bit always returns a value of 1, indicating that the security extensions are implemented.

Bits 9:8 Reserved, must be kept at reset value.

Bits 7:5 **CPUNUMBER[2:0]**: number of processors interfaces
Indicates the number of implemented processors interfaces in the GIC (0b001 = 2 processors)

Bits 4:0 **ITLINESNUMBER[4:0]**: number of interrupt lines
Indicates the number of interrupts that the GIC supports (0b01000 = Up to 288 interrupts, 256 external interrupts)

22.5.4 GICD implementer identification register (GICD_IIDR)

Address offset: 0x008

Reset value: 0x0100 143B

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRODUCTID[7:0]								Res.	Res.	Res.	Res.	VARIANT[3:0]

Bits 31:0 **SPISRx[31:0]**: shared peripheral interrupt

22.5.22 GICD software generated interrupt register (GICD_SGIR)

Address offset: 0xF00

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	TARGETLISTFILTER[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	CPUTARGETLIST[1:0]	
						w	w							w	w
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
NSATT	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SGIINTID[3:0]			
w												w	w	w	w

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **TARGETLISTFILTER[1:0]**: target list filter

Determines how the distributor must process the requested SGI

0: Forward the interrupt to the CPU interfaces specified in the CPUTARGETLIST field

1: Forward the interrupt to all CPU interfaces except the processor which requested the interrupt

2: Forward the interrupt only to the CPU interface of the processor which requested the interrupt

3: Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **CPUTARGETLIST[1:0]**: CPU target list

When TARGETLISTFILTER = 0b00, defines the CPU interfaces to which the GICD must forward the interrupt. Each bit of CPUTARGETLIST[1:0] refers to the corresponding CPU interface. If this field is 0 when TARGETLISTFILTER is 0b00, the GICD does not forward the interrupt to any CPU interface.

Bit 15 **NSATT**: non-secure attribute

It specifies the required security value of the SGI:

0 - Forward the SGI specified in the SGIINTID field to a specified CPU interface only if the SGI is configured as group 0 on that interface.

1 - Forward the SGI specified in the SGIINTID field to a specified CPU interfaces only if the SGI is configured as group 1 on that interface.

This field is writable only by a secure access. Any non-secure write to the GICD_SGIR generates an SGI only if the specified SGI is programmed as group 1.

Bits 14:4 Reserved, must be kept at reset value.

Bits 3:0 **SGIINTID[3:0]**: SGI interrupt ID

The value of this field is the interrupt ID of the SGI to forward to the specified CPU interfaces, in the range 0-15 (for example: a value of 0b0011 specifies interrupt ID 3).

22.5.23 GICD SGI clear-pending register x (GICD_CPENDSGIRx)

Address offset: 0xF10 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0000

For SGI x * 4 to SGI x * 4 + 3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SGI_CLEAR_PENDING3[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	SGI_CLEAR_PENDING2[1:0]	
						rw	rw							rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	SGI_CLEAR_PENDING1[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	SGI_CLEAR_PENDING0[1:0]	
						rw	rw							rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **SGI_CLEAR_PENDING3[1:0]**: clear-pending state for SGI [x * 4 + 3]
Writing a 1 clears the pending state of the SGI [x * 4 + 3] for the corresponding source processor, and no longer targets the processor performing the write.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 3] is pending, from the corresponding source processor, on the reading processor.

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **SGI_CLEAR_PENDING2[1:0]**: clear-pending state for SGI [x * 4 + 2]
Writing a 1 clears the pending state of the SGI [x * 4 + 2] for the corresponding source processor, and no longer targets the processor performing the write.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 2] is pending, from the corresponding source processor, on the reading processor.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **SGI_CLEAR_PENDING1[1:0]**:clear-pending state for SGI [x * 4 + 1]
Writing a 1 clears the pending state of the SGI [x * 4 + 1] for the corresponding source processor, and no longer targets the processor performing the write.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 1] is pending, from the corresponding source processor, on the reading processor.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **SGI_CLEAR_PENDING0[1:0]**: clear-pending state for SGI [x * 4]
Writing a 1 clears the pending state of the SGI [x * 4] for the corresponding source processor, and no longer targets the processor performing the write.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4] is pending, from the corresponding source processor, on the reading processor.

22.5.24 GICD SGI set-pending register x (GICD_SPENDSGIRx)

Address offset: 0xF20 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0000

For SGI x * 4 to SGI x * 4 + 3

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw							rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **SGI_SET_PENDING3[1:0]**: set-pending state for SGI [x * 4 + 3]
Writing a 1 sets the pending state of the SGI [x * 4 + 3] for the corresponding source processor.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 3] is pending, from the corresponding source processor, on the reading processor.

Bits 23:18 Reserved, must be kept at reset value.

Bits 17:16 **SGI_SET_PENDING2[1:0]**: set-pending state for SGI [x * 4 + 2]
Writing a 1 sets the pending state of the SGI [x * 4 + 2] for the corresponding source processor.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 2] is pending, from the corresponding source processor, on the reading processor.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **SGI_SET_PENDING1[1:0]**: set-pending state for SGI [x * 4 + 1]
Writing a 1 sets the pending state of the SGI [x * 4 + 1] for the corresponding source processor.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4 + 1] is pending, from the corresponding source processor, on the reading processor.

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **SGI_SET_PENDING0[1:0]**: set-pending state for SGI [x * 4]
Writing a 1 sets the pending state of the SGI [x * 4] for the corresponding source processor.
Writing a 0 has no effect.
Reading a bit identifies whether the SGI [x * 4] is pending, from the corresponding source processor, on the reading processor.

Refer to *Section 2.5 on page 153* for the register boundary addresses.

22.6 GIC CPU Interface (GICC)

Each CPU interface provides a programming interface for:

- enabling the signaling of interrupt requests by the CPU interface
- acknowledging an interrupt
- indicating completion of the processing of an interrupt
- setting an interrupt priority mask for the processor
- defining the preemption policy for the processor
- determining the highest priority pending interrupt for the processor.

All the registers are word-accessible.

22.6.1 GICC control register (GICC_CTLR)

Address offset: 0x000

Reset value: 0bxxxx xxxx xxxx xxxx xxxx x000 0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	EOIMODENS	EOIMODES	IRQBYPDISGRP1	FIQBYPDISGRP1	IRQBYPDISGRP0	FIQBYPDISGRP0	CBPR	FIQEN	ACKCTL	ENABLEGRP1	ENABLEGRP0
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **EOIMODENS**: Alias of EOIMODENS from the non-secure copy of this register.

Bit 9 **EOIMODES**:EOI mode for secure accesses

Controls the behavior of accesses to GICC_EOIR and GICC_DIR registers. This control applies only to secure accesses.

Bit 8 **IRQBYPDISGRP1**: Alias of IRQBYPDISGRP1 from the non-secure copy of this register.

Bit 7 **FIQBYPDISGRP1**: Alias of FIQBYPDISGRP1 from the non-secure copy of this register.

Bit 6 **IRQBYPDISGRP0**: IRQ bypass disable for group 0 interrupts

When the signaling of IRQs by the CPU interface is disabled, this bit partly controls whether the bypass IRQ signal is signaled to the processor.

Bit 5 **FIQBYPDISGRP0**: FIQ bypass disable for group 0 interrupts

When the signaling of FIQs by the CPU interface is disabled, this bit partly controls whether the bypass FIQ signal is signaled to the processor.

Bit 4 **CBPR**: BPR control

Controls whether the GICC_BPR provides common control to group 0 and group 1 interrupts.

Bit 3 **FIQEN**: FIQ enable for group 0 interrupts
Controls whether the CPU interface signals group 0 interrupts to a target processor using the FIQ or the IRQ signal.
The GIC always signals group 1 interrupts using the IRQ signal.

Bit 2 **ACKCTL**: Acknowledge control
When the highest priority pending interrupt is a group 1 interrupt, this bit determines both:
- whether a read of GICC_IAR acknowledges the interrupt, or returns a spurious interrupt ID
- whether a read of GICC_HPPIR returns the ID of the highest priority pending interrupt, or returns a spurious interrupt ID.
Arm deprecates use of this bit and strongly recommends using a software model where this bit is set to 0.

Bit 1 **ENABLEGRP1**: Enable group 1 interrupts
It enables for the signaling of group 1 interrupts by the CPU interface to the connected processor.

Bit 0 **ENABLEGRP0**: Enable group 0 interrupts
It enables for the signaling of group 0interrupts by the CPU interface to the connected processor.

22.6.2 GICC control non-secure access register (GICC_CTLRNS)

Address offset: 0x000

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xx0x x00x xxx0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	EOIMODENS	Res.	Res.	IRQBYPDISGRP1	FIQBYPDISGRP1	Res.	Res.	Res.	Res.	ENABLEGRP1
						rw			rw	rw					rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **EOIMODENS**: EOI mode for non- secure accesses
It controls the behavior of accesses to GICC_EOIR and GICC_DIR registers.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **IRQBYPDISGRP1**: IRQ bypass for group 1 interrupts
When the signaling of IRQs by the CPU interface is disabled, this bit partly controls whether the bypass IRQ signal is signaled to the processor.

Bit 5 **FIQBYPDISGRP1**: FIQ bypass disable for group 1 interrupts
When the signaling of FIQs by the CPU interface is disabled, this bit partly controls whether the bypass FIQ signal is signaled to the processor.

Bits 4:1 Reserved, must be kept at reset value.

Bit 0 **ENABLEGRP1**: Enable group1 interrupts
Enable for the signaling of group 1 interrupts by the CPU interface to the connected processor.

22.6.3 GICC input priority mask register (GICC_PMR)

Address offset: 0x004

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx 0000 0xxx

15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIORITY[4:0]					Res.	Res.	Res.
								rw	rw	rw	rw	rw			

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:3 **PRIORITY[4:0]**: priority mask level for the CPU interface
If the priority of an interrupt is higher than the value indicated by this field, the interface signals the interrupt to the processor.

Bits 2:0 Reserved, must be kept at reset value.

22.6.4 GICC binary point register (GICC_BPR)

Address offset: 0x008

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx xxxx x010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BINARY_POINT[2:0]		
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **BINARY_POINT[2:0]**:
The value of this field controls how the 8-bit interrupt priority field is split into a group priority field. It is used to determine interrupt preemption and a sub-priority field. Minimum value is 2.

22.6.5 GICC binary point non-secure access register (GICC_BPRNS)

Address offset: 0x008

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx xxxx x011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BINARY_POINT[2:0]		
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **BINARY_POINT[2:0]**:
The value of this field controls how the 8-bit interrupt priority field is split into a group priority field. It is used to determine interrupt preemption and a sub-priority field. Minimum value is 3.

22.6.6 GICC interrupt acknowledge register (GICC_IAR)

Address offset: 0x00C

Reset value: 0bxxxx xxxx xxxx xxxx xxxx x011 1111 1111

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CPUID	INTERRUPT_ID[9:0]									
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **CPUID**:
For SGIs in a multiprocessor implementation, this field identifies the processor that requested the interrupt. It returns the number of the CPU interface that made the request.
For example, a value of 1 means the request was generated by a write to the GICD_SGIR on CPU interface 1.

Bits 9:0 **INTERRUPT_ID[9:0]**: The interrupt ID

22.6.7 GICC end of interrupt register (GICC_EOIR)

Address offset: 0x010

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	CPUID	EOIINTID[9:0]									
					w	w	w	w	w	w	w	w	w	w	w

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **CPUID**:
On a multiprocessor implementation, if the write refers to an SGI, this field contains the CPUID value from the corresponding GICC_IAR access.

Bits 9:0 **EOIINTID[9:0]**:
It contains the interrupt ID value from the corresponding GICC_IAR access.

22.6.8 GICC running priority register (GICC_RPR)

Address offset: 0x014

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx 1111 1111

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIORITY[4:0]					Res.	Res.	Res.
								r	r	r	r	r			

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:3 **PRIORITY[4:0]**: current running priority on the CPU interface

Bits 2:0 Reserved, must be kept at reset value.

22.6.9 GICC highest priority pending interrupt register (GICC_HPPIR)

Address offset: 0x018

Reset value: 0bxxxx xxxx xxxx xxxx xxx0 0011 1111 1111

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	CPUID	PENDINTID[9:0]									
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **CPUID**:

On a multiprocessor implementation, if the PENDINTID field returns the ID of an SGI, this field contains the CPUID value for that interrupt. This identifies the processor that generated the interrupt.

Bits 9:0 **PENDINTID[9:0]**: interrupt ID of the highest-priority pending interrupt

22.6.10 GICC aliased binary point register (GICC_ABPR)

Address offset: 0x01C

Reset value: 0bxxxx xxxx xxxx xxxx xxxx xxxx xxxx x011

GICC_ABPR is an alias of the non-secure GICC_BPR. When GICC_CTLR.CBPR is set to 0, a secure access to this register is equivalent to a non-secure access to GICC_BPR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BINARY_POINT[2:0]		
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **BINARY_POINT[2:0]**:

The value of this field controls how the 8-bit interrupt priority field is split into a group priority field. It is used to determine interrupt preemption, and a subpriority field. Minimun value is 3.

22.6.11 GICC aliased interrupt acknowledge register (GICC_AIAR)

Address offset: 0x020

Reset value: 0bxxxx xxxx xxxx xxxx xxxx x011 1111 1111

GICC_AIAR is an alias of the non-secure view of GICC_IAR. A secure access to this register is identical to a non-secure access to GICC_IAR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	CPUID	INTERRUPT_ID[9:0]									
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **CPUID**:

For SGIs in a multiprocessor implementation, this field identifies the processor that requested the interrupt. It returns the number of the CPU interface that made the request.
