Reference manual

STM32H7Rx/7Sx Arm®-based 32-bit MCUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32H7R3, STM32H7S3, STM32H7R7, and STM32H7S7 memory and peripherals.

Microcontrollers of the STM32H7R3/7S3 and STM32H7R7/7S7 lines have different memory sizes, packages, and peripherals. They are referred to as STM32H7Rx/7Sx hereafter.

For ordering information, mechanical, and electrical device characteristics refer to the corresponding datasheets.

For information on the Arm® Cortex®-M7 with FPU core, refer to the corresponding Arm technical reference manual available from www.arm.com.

STM32H7Rx/7Sx microcontrollers include ST state-of-the-art patented technology.

2.5 Flash memory overview 163

2.6 Boot configuration 163

3 RAMECC monitoring (RAMECC) 165

3.1 Introduction 165

3.2 RAMECC main features . . . 165
3.3 RAMECC functional description . . . 165
3.3.1 RAMECC internal signals . . . 167
3.3.2 RAMECC monitor mapping . . . 168
3.3.3 ECC fault injection test on SRAM1, SRAM3, and TCM . . . 169
3.3.4 Read access latency . . . 169
3.4 RAMECC low-power modes . . . 169
3.5 RAMECC interrupts . . . 170
3.6 RAMECC registers . . . 171
3.6.1 RAMECC interrupt enable register (RAMECC_IER) . . . 171
3.6.2 RAMECC monitor x configuration register (RAMECC_MxCR) . . . 172
3.6.3 RAMECC monitor x status register (RAMECC_MxSR) . . . 174
3.6.4 RAMECC monitor x failing address register (RAMECC_MxFAR) . . . 174
3.6.5 RAMECC monitor x failing data low register (RAMECC_MxFDRL) . . . 175
3.6.6 RAMECC monitor x failing data high register (RAMECC_MxFDRH) . . . 175
3.6.7 RAMECC monitor x failing ECC error code register (RAMECC_MxFECR) . . . 176
3.6.8 RAMECC register map . . . 177

4 System security . . . 178
4.1 Key security features . . . 178
4.2 Secure install . . . 179
4.3 Secure boot . . . 180
4.3.1 Unique boot entry . . . 180
4.3.2 Security services in system flash memory . . . 181
4.4 Secure update . . . 183
4.5 Resource isolation using hide protect levels . . . 183
4.5.1 Temporal isolation using secure hide protection (HDP) . . . 183
4.6 Secure execution . . . 184
4.6.1 Memory protection unit (MPU) . . . 184
4.6.2 Embedded flash memory write protection . . . 184
4.6.3 Tamper detection and response . . . 184
4.7 Secure storage . . . 187

4.7.1 Hardware secret key management . . . 188
4.7.2 Unique ID . . . 189
4.8 Crypto engines . . . 189
4.8.1 Crypto engines features . . . 189
4.8.2 Secure AES co-processor (SAES) . . . 190
4.8.3 Memory cipher engine (MCE) . . . 190
4.9 Product life cycle . . . 191
4.9.1 Product configurations and security services . . . 192
4.9.2 Recommended product settings . . . 193
4.10 System memory . . . 193
4.10.1 Introduction . . . 193
4.10.2 RSS user functions . . . 193

5 Embedded flash memory (FLASH) . . . 200
5.1 Introduction . . . 200
5.2 FLASH main features . . . 200
5.3 FLASH functional description . . . 201
5.3.1 FLASH block diagram . . . 201
5.3.2 FLASH internal signals . . . 202
5.3.3 FLASH architecture and integration in the system . . . 202
5.3.4 Flash memory architecture and usage . . . 204
5.3.5 Flash hide protection schemes . . . 208
5.3.6 Overview of FLASH operations . . . 209
5.3.7 FLASH read operations . . . 210
5.3.8 FLASH program operations . . . 212
5.3.9 FLASH erase operations . . . 216
5.3.10 Flash memory error protections . . . 218
5.3.11 FLASH one-time programmable area . . . 219
5.3.12 FLASH read-only area . . . 221
5.3.13 FLASH reset and clocks . . . 221
5.4 FLASH option bytes . . . 222
5.4.1 About option bytes . . . 222
5.4.2 Option byte loading . . . 222
5.4.3 Option byte words modification . . . 223
5.4.4 Option byte key management . . . 225
5.4.5 Option byte user words overview . . . 226

5.4.6 Description of user option byte word 228
5.4.7 Description of security option bytes 229
5.5 FLASH protection mechanisms 231
5.5.1 FLASH configuration protection 231
5.5.2 Write protection 232
5.5.3 Life cycle management 233
5.5.4 Hide protected system flash area 234
5.5.5 Hide protected user flash area 234
5.6 FLASH low-power modes 237
5.6.1 Introduction 237
5.6.2 Managing the FLASH domain switching to Stop or Standby 237
5.7 FLASH error management 238
5.7.1 Introduction 238
5.7.2 Write protection error (WRPERRF) 238
5.7.3 Programming sequence error (PGSERRF) 239
5.7.4 Strobe error (STRBERRF) 239
5.7.5 Inconsistency error (INCERRF) 240
5.7.6 Error correction code error (SNECCERRF/DBECCERRF) 240
5.7.7 Read secure error (RDSERRF) 241
5.7.8 CRC read error (CRCRDERRF) 241
5.7.9 Option byte change error (OPTERRF) 241
5.7.10 Key valid error (KVEF) 242
5.7.11 Key transfer error (KTEF) 242
5.7.12 Option byte loading error (OBLERRF) 242
5.7.13 Miscellaneous HardFault errors 243
5.8 FLASH interrupts 243
5.9 FLASH registers 245
5.9.1 FLASH access control register (FLASH_ACR) 245
5.9.2 FLASH control key register (FLASH_KEYR) 246
5.9.3 FLASH control register (FLASH_CR) 246
5.9.4 FLASH status register (FLASH_SR) 249
5.9.5 FLASH interrupt enable register (FLASH_IER) 251
5.9.6 FLASH interrupt status register (FLASH_ISR) 252
5.9.7 FLASH interrupt clear register (FLASH_ICR) 254
5.9.8 FLASH CRC control register (FLASH_CRCCR) 255
5.9.9 FLASH CRC start address register . . . . . (FLASH_CRCSADDR) 256

5.9.10 FLASH CRC end address register (FLASH_CRCEADDR) 257
5.9.11 FLASH CRC data register (FLASH_CRCDATAR) 257
5.9.12 FLASH ECC single error fail address (FLASH_ECCSFADDR) 258
5.9.13 FLASH ECC double error fail address (FLASH_ECCDFADDR) 258
5.9.14 FLASH options key register (FLASH_OPTKEYR) 259
5.9.15 FLASH options control register (FLASH_OPTCR) 259
5.9.16 FLASH options interrupt status register (FLASH_OPTISR) 260
5.9.17 FLASH options interrupt clear register (FLASH_OPTICR) 261
5.9.18 FLASH option byte key control register (FLASH_OBKCR) 262
5.9.19 FLASH option bytes key data register x (FLASH_OBKDRx) 263
5.9.20 FLASH non-volatile status register (FLASH_NVSR) 263
5.9.21 FLASH security status register programming (FLASH_NVSRP) 264
5.9.22 FLASH RoT status register (FLASH_ROTSR) 265
5.9.23 FLASH RoT status register programming (FLASH_ROTSRP) 266
5.9.24 FLASH OTP lock status register (FLASH_OTPLSR) 266
5.9.25 FLASH OTP lock status register programming (FLASH_OTPLSRP) 267
5.9.26 FLASH write protection status register (FLASH_WRPSR) 267
5.9.27 FLASH write protection status register programming (FLASH_WRPSRP) 268
5.9.28 FLASH hide protection status register (FLASH_HDPSR) 268
5.9.29 FLASH hide protection status register programming (FLASH_HDPSRP) 269
5.9.30 FLASH epoch status register (FLASH_EPOCHSR) 270
5.9.31 FLASH RoT status register programming (FLASH_EPOCHSRP) 270
5.9.32 FLASH option byte word 1 status register (FLASH_OBW1SR) 271
5.9.33 FLASH option byte word 1 status register programming (FLASH_OBW1SRP) 272
5.9.34 FLASH option byte word 2 status register (FLASH_OBW2SR) 273
5.9.35 FLASH option byte word 2 status register programming (FLASH_OBW2SRP) 274
5.9.36 FLASH register map 275

6 Power control (PWR) 279

6.1 Introduction 279
6.2 PWR main features 279
6.3 PWR block diagram 280
6.3.1 PWR pins and internal signals 281
6.4 Power supplies 283

6.4.1 System supply startup . . . 287
6.4.2 Core domain . . . 290
6.4.3 PWR external supply . . . 292
6.4.4 Backup domain . . . 292
6.4.5 VBAT battery charging . . . 294
6.4.6 Analog supply . . . 295
6.4.7 USB regulator . . . 296
6.5 Power supply supervision . . . 297
6.5.1 Power-on reset (POR)/power-down reset (PDR) . . . 297
6.5.2 Brownout reset (BOR) . . . 298
6.5.3 Programmable voltage detector (PVD) . . . 299
6.5.4 Analog voltage detector (AVD) . . . 300
6.5.5 Battery voltage thresholds . . . 301
6.5.6 Temperature thresholds . . . 302
6.5.7 VCORE maximum voltage level detector . . . 303
6.6 Power management . . . 304
6.6.1 Operating modes . . . 304
6.6.2 Voltage scaling . . . 305
6.6.3 Power management examples . . . 306
6.7 Low-power modes . . . 309
6.7.1 Slowing down system clocks . . . 310
6.7.2 Controlling peripheral clocks . . . 310
6.7.3 Entering low-power modes . . . 310
6.7.4 Exiting from low-power modes . . . 310
6.7.5 Sleep mode . . . 312
6.7.6 Stop mode . . . 312
6.7.7 Standby mode . . . 315
6.7.8 Monitoring low-power modes . . . 317
6.8 PWR registers . . . 318
6.8.1 PWR control register 1 (PWR_CR1) . . . 318
6.8.2 PWR control status register 1 (PWR_SR1) . . . 320
6.8.3 PWR control status register 1 (PWR_CSR1) . . . 321
6.8.4 PWR control register 2 (PWR_CSR2) . . . 323
6.8.5 PWR CPU control register 3 (PWR_CSR3) . . . 326
6.8.6 PWR control status register 4 (PWR_CSR4) . . . 327
6.8.7 PWR wake-up clear register (PWR_WKUPCR) . . . 328
6.8.8 PWR wake-up flag register (PWR_WKUPFR) . . . 329

6.8.9 PWR wake-up enable and polarity register (PWR_WKUPEPR) 330
6.8.10 PWR USB Type-C and Power Delivery register (PWR_UCPDR) 331
6.8.11 PWR apply pull configuration register (PWR_APCR) 332
6.8.12 PWR port N pull-up control register (PWR_PUCRN) 334
6.8.13 PWR port N pull-down control register (PWR_PDCRN) 335
6.8.14 PWR port O pull-up control register (PWR_PUCRO) 336
6.8.15 PWR port O pull-down control register (PWR_PDCRO) 337
6.8.16 PWR port P pull-down control register (PWR_PDCRP) 338
6.8.17 PWR register map 339

7 Reset and clock control (RCC) 341

7.1 RCC main features 341
7.2 RCC block diagram 342
7.3 RCC pins and internal signals 343
7.4 RCC reset block functional description 345
7.4.1 Reset from PWR block 345
7.4.2 The system and application resets (sys_rst and nreset) 347
7.4.3 The NRST reset 347
7.4.4 Low-power mode security reset (lpwr_rst) 347
7.4.5 Backup domain reset 348
7.4.6 Coresight debug reset 348
7.4.7 Option bytes loading 349
7.4.8 Peripheral resets 349
7.4.9 Reset coverage summary 349
7.4.10 Reset source identification 351
7.4.11 Power-on and wake-up sequences 351
7.5 RCC clock block functional description 353
7.5.1 Clock naming convention 355
7.5.2 Oscillators description 355
7.5.3 Clock security system (CSS) 365
7.5.4 Clock output generation (MCO1/MCO2) 368
7.5.5 PLL description 370
7.5.6 System clock (**sys_ck**) 376
7.5.7 Clock protection 379
7.5.8 Clock generation in Stop and Standby modes 380
7.5.9 Peripheral clock distribution 382
7.5.10 General clock concept overview 411

7.5.11 Peripheral allocation . . . 412
7.5.12 Peripheral clock gating control . . . 413
7.5.13 CPU and bus matrix clock gating control . . . 416
7.5.14 Low-power emulation modes . . . 417
7.6 RCC interrupts . . . 418
7.7 RCC Programming examples . . . 419
7.7.1 PLL programming procedure . . . 419
7.7.2 Frequency configuration examples . . . 421
7.8 RCC registers . . . 424
7.8.1 RCC source control register (RCC_CR) . . . 424
7.8.2 RCC clock protection register (RCC_CKPROTR) . . . 428
7.8.3 RCC HSI calibration register (RCC_HSICFGR) . . . 429
7.8.4 RCC clock recovery RC register (RCC_CRRCR) . . . 430
7.8.5 RCC CSI calibration register (RCC_CSICFGR) . . . 430
7.8.6 RCC clock configuration register (RCC_CFGR) . . . 431
7.8.7 RCC CPU domain clock configuration register (RCC_CDCFGR) . . . 434
7.8.8 RCC AHB clock configuration register (RCC_BMCFGR) . . . 435
7.8.9 RCC APB clocks configuration register (RCC_APBCFGR) . . . 436
7.8.10 RCC PLLs clock source selection register (RCC_PLLCKSELR) . . . 438
7.8.11 RCC PLLs configuration register (RCC_PLLCFGR) . . . 440
7.8.12 RCC PLL1 dividers configuration register 1 (RCC_PLL1DIVR1) . . . 443
7.8.13 RCC PLL1 dividers configuration register 2 (RCC_PLL1DIVR2) . . . 445
7.8.14 RCC PLL1 fractional divider register (RCC_PLL1FRACR) . . . 445
7.8.15 RCC PLL1 Spread Spectrum Clock Generator register (RCC_PLL1SSCGR) . . . 447
7.8.16 RCC PLL2 dividers configuration register 1 (RCC_PLL2DIVR1) . . . 448
7.8.17 RCC PLL2 dividers configuration register 2 (RCC_PLL2DIVR2) . . . 450
7.8.18 RCC PLL2 fractional divider register (RCC_PLL2FRACR) . . . 451
7.8.19 RCC PLL2 Spread Spectrum Clock Generator register (RCC_PLL2SSCGR) . . . 452
7.8.20 RCC PLL3 dividers configuration register 1 (RCC_PLL3DIVR1) . . . 453
7.8.21 RCC PLL3 dividers configuration register 2 (RCC_PLL3DIVR2) . . . 455
7.8.22 RCC PLL3 fractional divider register (RCC_PLL3FRACR) . . . 455
7.8.23 RCC PLL3 Spread Spectrum Clock Generator register (RCC_PLL3SSCGR) . . . 457
7.8.24 RCC AHB peripheral kernel clock selection register (RCC_CCIPR1) . 458
7.8.25 RCC APB1 peripherals kernel clock selection register (RCC_CCIPR2) . . . 461

7.8.26 RCC APB2 peripherals kernel clock selection register (RCC_CCIPR3) 463
7.8.27 RCC APB4,5 peripherals kernel clock selection register (RCC_CCIPR4) 465
7.8.28 RCC clock source interrupt enable register (RCC_CIER) 467
7.8.29 RCC clock source interrupt flag register (RCC_CIFR) 468
7.8.30 RCC clock source interrupt clear register (RCC_CICR) 470
7.8.31 RCC Backup domain control register (RCC_BDCR) 472
7.8.32 RCC clock control and status register (RCC_CSR) 474
7.8.33 RCC AHB1 peripheral reset register (RCC_AHB1RSTR) 475
7.8.34 RCC AHB2 peripheral reset register (RCC_AHB2RSTR) 476
7.8.35 RCC AHB3 peripheral reset register (RCC_AHB3RSTR) 477
7.8.36 RCC AHB4 peripheral reset register (RCC_AHB4RSTR) 478
7.8.37 RCC AHB5 peripheral reset register (RCC_AHB5RSTR) 480
7.8.38 RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1) 482
7.8.39 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2) 485
7.8.40 RCC APB2 peripheral reset register (RCC_APB2RSTR) 486
7.8.41 RCC APB4 peripheral reset register (RCC_APB4RSTR) 488
7.8.42 RCC APB5 peripheral reset register (RCC_APB5RSTR) 490
7.8.43 RCC AXI clocks gating disable register (RCC_CKGDISR) 491
7.8.44 RCC Reset status register (RCC_RSR) 495
7.8.45 RCC AHB1 clock enable register (RCC_AHB1ENR) 497
7.8.46 RCC AHB2 clock enable register (RCC_AHB2ENR) 499
7.8.47 RCC AHB3 clock enable register (RCC_AHB3ENR) 500
7.8.48 RCC AHB4 clock enable register (RCC_AHB4ENR) 501
7.8.49 RCC AHB5 clock enable register (RCC_AHB5ENR) 503
7.8.50 RCC APB1 clock enable register 1 (RCC_APB1ENR1) 505
7.8.51 RCC APB1 clock enable register 2 (RCC_APB1ENR2) 508
7.8.52 RCC APB2 clock enable register (RCC_APB2ENR) 509
7.8.53 RCC APB4 clock enable register (RCC_APB4ENR) 510
7.8.54 RCC APB5 clock enable register (RCC_APB5ENR) 513
7.8.55 RCC AHB5 low-power clock enable register (RCC_AHB5LPENR) . . . 514
7.8.56 RCC AHB1 low-power clock enable register (RCC_AHB1LPENR) . . . 516
7.8.57 RCC AHB2 low-power clock enable register (RCC_AHB2LPENR) . . . 518
7.8.58 RCC AHB3 low-power clock enable register (RCC_AHB3LPENR) . . . 519
7.8.59 RCC AHB4 low-power clock enable register (RCC_AHB4LPENR) . . . 520
7.8.60 RCC APB1 low-power clock enable register 1 (RCC_APB1LPENR1) 522
7.8.61 RCC APB1 low-power clock enable register 2 (RCC_APB1LPENR2) 525

7.8.62 RCC APB2 low-power clock enable register (RCC_APB2LPENR) . . . 526
7.8.63 RCC APB4 low-power clock enable register (RCC_APB4LPENR) . . . 528
7.8.64 RCC APB5 low-power clock enable register (RCC_APB5LPENR) . . . 530
7.9 RCC register map . . . 531

8 System configuration, boot and security (SBS) . . . 540
8.1 SBS introduction . . . 540
8.2 SBS main features . . . 540
8.3 SBS functional description . . . 541
8.3.1 SBS block diagram . . . 541
8.3.2 SBS internal signals . . . 541
8.3.3 SBS reset and clocks . . . 541
8.3.4 SBS hide protection management . . . 542
8.3.5 SBS boot control . . . 542
8.3.6 SBS debug management . . . 543
8.3.7 SBS voltage booster for I/O analog switches . . . 544
8.3.8 SBS I/O compensation cell management . . . 544
8.3.9 SBS registers access control . . . 545
8.3.10 SBS error management . . . 546
8.4 SBS interrupts . . . 546
8.5 SBS registers . . . 546
8.5.1 SBS boot status register (SBS_BOOTSR) . . . 546
8.5.2 SBS hide protection control register (SBS_HDPLCR) . . . 547
8.5.3 SBS hide protection status register (SBS_HDPLSR) . . . 547
8.5.4 SBS debug control register (SBS_DBGCR) . . . 548
8.5.5 SBS debug lock register (SBS_DBGLOCKR) . . . 548
8.5.6 SBS RSS command register (SBS_RSSCMDR) . . . 549
8.5.7 SBS product mode and configuration register (SBS_PMCR) . . . 549
8.5.8 SBS FPU interrupt mask register (SBS_FPUIMR) . . . 550
8.5.9 SBS memory erase status register (SBS_MESR) . . . 551
8.5.10 SBS I/O compensation cell control and status register (SBS_CCCSR) . . . 551
8.5.11 SBS compensation cell for I/Os value register (SBS_CCVALR) . . . 554
8.5.12 SBS compensation cell for I/Os software value register (SBS_CCSWVALR) . . . 555
8.5.13 SBS break lockup register (SBS_BKLOCKR) . . . 556
8.5.14 SBS external interrupt configuration register x (SBS_EXTICRx) . . . 558

8.5.15 SBS register map . . . 559

9 Clock recovery system (CRS) . . . 561

9.1 CRS introduction . . . 561
9.2 CRS main features . . . 561
9.3 CRS implementation . . . 561
9.4 CRS functional description . . . 562
9.4.1 CRS block diagram . . . 562
9.4.2 CRS internal signals . . . 562
9.4.3 Synchronization input . . . 563
9.4.4 Frequency error measurement . . . 563
9.4.5 Frequency error evaluation and automatic trimming . . . 564
9.4.6 CRS initialization and configuration . . . 565
9.5 CRS in low-power modes . . . 566
9.6 CRS interrupts . . . 566
9.7 CRS registers . . . 566
9.7.1 CRS control register (CRS_CR) . . . 566
9.7.2 CRS configuration register (CRS_CFGR) . . . 568
9.7.3 CRS interrupt and status register (CRS_ISR) . . . 569
9.7.4 CRS interrupt flag clear register (CRS_ICR) . . . 571
9.7.5 CRS register map . . . 571

10 General-purpose I/Os (GPIO) . . . 573

10.1 Introduction . . . 573
10.2 GPIO main features . . . 573
10.3 GPIO functional description . . . 573
10.3.1 General-purpose I/O (GPIO) . . . 575
10.3.2 I/O pin alternate function multiplexer and mapping . . . 576
10.3.3 I/O port control registers . . . 576
10.3.4 I/O port data registers . . . 577
10.3.5 I/O data bitwise handling . . . 577
10.3.6 GPIO locking mechanism . . . 577
10.3.7 I/O alternate function input/output . . . 577
10.3.8 External interrupt/wake-up lines . . . 578
10.3.9 Input configuration . . . 578
10.3.10 Output configuration . . . 579

10.3.11 Alternate function configuration . . . 579
10.3.12 Analog configuration . . . 580
10.3.13 Using the HSE or LSE oscillator pins as GPIOs . . . 580
10.3.14 Using the GPIO pins in the RTC supply domain . . . 581
10.3.15 Privileged and unprivileged modes . . . 581
10.3.16 High-speed low-voltage mode (HSLV) . . . 581
10.3.17 I/O compensation cell . . . 582
10.4 GPIO registers . . . 582
10.4.1 GPIO port mode register (GPIOx_MODER) (x=A to H, M to P) . . . 582
10.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to G, M to P) . . . 583
10.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to G, M to P) . . . 583
10.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to G, M to P) . . . 584
10.4.5 GPIO port input data register (GPIOx_IDR) (x = A to G, M to P) . . . 584
10.4.6 GPIO port output data register (GPIOx_ODR) (x = A to G, M to P) . . . 585
10.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to G, M to P) . 585
10.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to G, M to P) . . . 586
10.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to G, M to P) . . . 587
10.4.10 GPIO alternate function high register (GPIOx_AFRH) (x = A to G, M to P) . . . 588
10.4.11 GPIO port bit reset register (GPIOx_BRR) (x = A to G, M to P) . . . 589
10.4.12 GPIO register map . . . 590

11 Peripheral interconnect . . . 592
11.1 Introduction . . . 592
11.2 Connection summary . . . 592
11.3 Interconnection details . . . 594
11.3.1 Master to slave interconnection for timers . . . 594
11.3.2 Triggers to ADCs . . . 595
11.3.3 ADC analog watchdogs as triggers to timers . . . 596
11.3.4 Triggers on ADF1 . . . 596
11.3.5 Internal input and clock sources to timers . . . 596
11.3.6 Triggers to low-power timers . . . 597
11.3.7 RTC wake-up as inputs to timers . . . 598

11.3.8 USB OTG SOF as trigger to timers . . . 598
11.3.9 System errors as break signals to timers . . . 598
11.3.10 Triggers to GPDMA/HPDMA . . . 599
11.3.11 Internal analog signals to analog peripherals . . . 599
11.3.12 ADC data filtering by the ADF1 . . . 600
11.3.13 Internal tamper sources . . . 600
11.3.14 Output from tamper to RTC . . . 601
11.3.15 Encryption keys to AES/SAES . . . 601

12 General purpose direct memory access controller (GPDMA) . . . 602

12.1 GPDMA introduction . . . 602
12.2 GPDMA main features . . . 602
12.3 GPDMA implementation . . . 603
12.3.1 GPDMA channels . . . 603
12.3.2 GPDMA in low-power modes . . . 604
12.3.3 GPDMA requests . . . 604
12.3.4 GPDMA block requests . . . 607
12.3.5 GPDMA channels with peripheral early termination . . . 607
12.3.6 GPDMA triggers . . . 608
12.4 GPDMA functional description . . . 610
12.4.1 GPDMA block diagram . . . 610
12.4.2 GPDMA channel state and direct programming without any linked-list 610
12.4.3 GPDMA channel suspend and resume . . . 611
12.4.4 GPDMA channel abort and restart . . . 612
12.4.5 GPDMA linked-list data structure . . . 613
12.4.6 Linked-list item transfer execution . . . 616
12.4.7 GPDMA channel state and linked-list programming in run-to-completion mode . . . 617
12.4.8 GPDMA channel state and linked-list programming in link step mode 620
12.4.9 GPDMA channel state and linked-list programming . . . 627
12.4.10 GPDMA FIFO-based transfers . . . 629
12.4.11 GPDMA transfer request and arbitration . . . 636
12.4.12 GPDMA triggered transfer . . . 640
12.4.13 GPDMA circular buffering with linked-list programming . . . 641
12.4.14 GPDMA transfer in peripheral flow-control mode . . . 643
12.4.15 GPDMA privileged/unprivileged channel . . . 644
12.4.16 GPDMA error management . . . 644

12.5 GPDMA in debug mode 646
12.6 GPDMA in low-power modes 646
12.7 GPDMA interrupts 647
12.8 GPDMA registers 648
12.8.1 GPDMA privileged configuration register (GPDMA_PRIVCFGR) 648
12.8.2 GPDMA configuration lock register (GPDMA_RCFGLOCKR) 649
12.8.3 GPDMA masked interrupt status register (GPDMA_MISR) 649
12.8.4 GPDMA channel x linked-list base address register (GPDMA_CxLBAR) 650
12.8.5 GPDMA channel x flag clear register (GPDMA_CxFCR) 650
12.8.6 GPDMA channel x status register (GPDMA_CxSR) 651
12.8.7 GPDMA channel x control register (GPDMA_CxCR) 653
12.8.8 GPDMA channel x transfer register 1 (GPDMA_CxTR1) 655
12.8.9 GPDMA channel x transfer register 2 (GPDMA_CxTR2) 658
12.8.10 GPDMA channel x block register 1 (GPDMA_CxBR1) 662
12.8.11 GPDMA channel x alternate block register 1 (GPDMA_CxBR1) 663
12.8.12 GPDMA channel x source address register (GPDMA_CxSAR) 666
12.8.13 GPDMA channel x destination address register (GPDMA_CxDAR) . . 667
12.8.14 GPDMA channel x transfer register 3 (GPDMA_CxTR3) 668
12.8.15 GPDMA channel x block register 2 (GPDMA_CxBR2) 669
12.8.16 GPDMA channel x linked-list address register (GPDMA_CxLLR) 670
12.8.17 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR) 672
12.8.18 GPDMA register map 673

13 High-performance direct memory access controller (HPDMA) 675
13.1 HPDMA introduction 675
13.2 HPDMA main features 675
13.3 HPDMA implementation 676
13.3.1 HPDMA channels 676
13.3.2 HPDMA in low-power modes 677
13.3.3 HPDMA requests 677
13.3.4 HPDMA block requests 678
13.3.5 HPDMA channels with peripheral early termination 678
13.3.6 HPDMA triggers 678
13.4 HPDMA functional description 681
13.4.1 HPDMA block diagram 681

13.4.2 HPDMA channel state and direct programming without any linked-list . . . 681
13.4.3 HPDMA channel suspend and resume . . . 682
13.4.4 HPDMA channel abort and restart . . . 683
13.4.5 HPDMA linked-list data structure . . . 684
13.4.6 Linked-list item transfer execution . . . 687
13.4.7 HPDMA channel state and linked-list programming in run-to-completion mode . . . 688
13.4.8 HPDMA channel state and linked-list programming in link step mode . . . 692
13.4.9 HPDMA channel state and linked-list programming . . . 699
13.4.10 HPDMA FIFO-based transfers . . . 701
13.4.11 HPDMA transfer request and arbitration . . . 717
13.4.12 HPDMA triggered transfer . . . 721
13.4.13 HPDMA circular buffering with linked-list programming . . . 722
13.4.14 HPDMA transfer in peripheral flow-control mode . . . 724
13.4.15 HPDMA privileged/unprivileged channel . . . 725
13.4.16 HPDMA error management . . . 725
13.5 HPDMA in debug mode . . . 727
13.6 HPDMA in low-power modes . . . 727
13.7 HPDMA interrupts . . . 728
13.8 HPDMA registers . . . 729
13.8.1 HPDMA privileged configuration register (HPDMA_PRIVCFGR) . . . 729
13.8.2 HPDMA configuration lock register (HPDMA_RCFGLOCKR) . . . 730
13.8.3 HPDMA masked interrupt status register (HPDMA_MISR) . . . 730
13.8.4 HPDMA channel x linked-list base address register (HPDMA_CxLBAR) . . . 731
13.8.5 HPDMA channel x flag clear register (HPDMA_CxFCR) . . . 732
13.8.6 HPDMA channel x status register (HPDMA_CxSR) . . . 733
13.8.7 HPDMA channel x control register (HPDMA_CxCR) . . . 734
13.8.8 HPDMA channel x transfer register 1 (HPDMA_CxTR1) . . . 737
13.8.9 HPDMA channel x transfer register 2 (HPDMA_CxTR2) . . . 740
13.8.10 HPDMA channel x block register 1 (HPDMA_CxBR1) . . . 744
13.8.11 HPDMA channel x alternate block register 1 (HPDMA_CxBR1) . . . 745
13.8.12 HPDMA channel x source address register (HPDMA_CxSAR) . . . 748
13.8.13 HPDMA channel x destination address register (HPDMA_CxDAR) . . 749
13.8.14 HPDMA channel x transfer register 3 (HPDMA_CxTR3) . . . 750
13.8.15 HPDMA channel x block register 2 (HPDMA_CxBR2) . . . 751

13.8.16 HPDMA channel x linked-list address register (HPDMA_CxLLR) 752
13.8.17 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR) 754
13.8.18 HPDMA register map 755

14 Chrom-GRC (GFXMMU) 757
14.1 Introduction 757
14.2 GFXMMU main features 757
14.3 GFXMMU functional and architectural description 757
14.3.1 GFXMMU block diagram 757
14.3.2 GFXMMU internal signals 758
14.3.3 Virtual memory 758
14.3.4 Packing and unpacking 760
14.3.5 MMU architecture 761
14.4 GFXMMU interrupts 764
14.5 GFXMMU registers 765
14.5.1 GFXMMU configuration register (GFXMMU_CR) 765
14.5.2 GFXMMU status register (GFXMMU_SR) 767
14.5.3 GFXMMU flag clear register (GFXMMU_FCR) 767
14.5.4 GFXMMU default value register (GFXMMU_DVR) 768
14.5.5 GFXMMU default alpha register (GFXMMU_DAR) 768
14.5.6 GFXMMU buffer x configuration register (GFXMMU_BxCR) 769
14.5.7 GFXMMU LUT entry x low (GFXMMU_LUTxL) 769
14.5.8 GFXMMU LUT entry x high (GFXMMU_LUTxH) 770

17.7.2 ICACHE status register (ICACHE_SR) 819
17.7.3 ICACHE interrupt enable register (ICACHE_IER) 820
17.7.4 ICACHE flag clear register (ICACHE_FCR) 820
17.7.5 ICACHE hit monitor register (ICACHE_HMONR) 821
17.7.6 ICACHE miss monitor register (ICACHE_MMONR) 821

17.7.7 ICACHE register map 822

18 Graphic timer (GFXTIM) 823

18.1 Introduction 823

18.2 GFXTIM main features 823

18.3 GFXTIM functional description 823

18.3.1 Block diagram 823

18.3.2 GFXTIM pins and internal signals 824

18.3.3 Clock generator 825

18.3.4 Example of clock generator configuration 827

18.3.5 Absolute timers 831

18.3.6 Relative timers 832

18.3.7 Tearing-effect detection 833

18.3.8 Event generator 833

18.3.9 Watchdog timer 834

18.4 GFXTIM interrupts 835

18.5 GFXTIM registers 836

18.5.1 GFXTIM configuration register (GFXTIM_CR) 836

18.5.2 GFXTIM clock generator configuration register (GFXTIM_CGCR) . . . 837

18.5.3 GFXTIM timers configuration register (GFXTIM_TCR) 839

18.5.4 GFXTIM timers disable register (GFXTIM_TDR) 840

18.5.5 GFXTIM events control register (GFXTIM_EVCR) 841

18.5.6 GFXTIM events selection register (GFXTIM_EVSR) 841

18.5.7 GFXTIM watchdog timer configuration register (GFXTIM_WDGTCR) 843

18.5.8 GFXTIM interrupt status register (GFXTIM_ISR) 845

18.5.9 GFXTIM interrupt clear register (GFXTIM_ICR) 846

18.5.10 GFXTIM interrupt enable register (GFXTIM_IER) 848

18.5.11 GFXTIM timers status register (GFXTIM_TSR) 850

18.5.12 GFXTIM line clock counter reload register (GFXTIM_LCCRR) 851

18.5.13 GFXTIM frame clock counter reload register (GFXTIM_FCCRR) 851

18.5.14 GFXTIM absolute time register (GFXTIM_ATR) 851

18.5.15 GFXTIM absolute frame counter register (GFXTIM_AFCR) 852

18.5.16 GFXTIM absolute line counter register (GFXTIM_ALCR) 852

18.5.17 GFXTIM absolute frame counter compare 1 register (GFXTIM_AFCC1R) 853

18.5.18 GFXTIM absolute line counter compare 1 register (GFXTIM_ALCC1R) . . . 853
18.5.19 GFXTIM absolute line counter compare 2 register (GFXTIM_ALCC2R) . . . 853
18.5.20 GFXTIM relative frame counter 1 register (GFXTIM_RFC1R) . . . 854
18.5.21 GFXTIM relative frame counter 1 reload register (GFXTIM_RFC1RR) . . . 854
18.5.22 GFXTIM relative frame counter 2 register (GFXTIM_RFC2R) . . . 855
18.5.23 GFXTIM relative frame counter 2 reload register (GFXTIM_RFC2RR) . . . 855
18.5.24 GFXTIM watchdog counter register (GFXTIM_WDGCR) . . . 855
18.5.25 GFXTIM watchdog reload register (GFXTIM_WDGRR) . . . 856
18.5.26 GFXTIM watchdog pre-alarm register (GFXTIM_WDGPAR) . . . 856
18.5.27 GFXTIM register map . . . 856

19 Nested vectored interrupt controller (NVIC) . . . 859

19.1 NVIC features . . . 859
19.1.1 SysTick calibration value register . . . 859
19.1.2 Interrupt and exception vectors . . . 860

20 Extended interrupt and event controller (EXTI) . . . 867

20.1 EXTI main features . . . 867
20.2 EXTI block diagram . . . 867
20.2.1 EXTI connections between peripherals and CPU . . . 868
20.3 EXTI functional description . . . 869
20.3.1 EXTI configurable event input - CPU wake-up . . . 870
20.3.2 EXTI direct event input - CPU wake up . . . 871
20.4 EXTI event input mapping . . . 872
20.5 EXTI functional behavior . . . 874
20.5.1 EXTI CPU interrupt procedure . . . 875
20.5.2 EXTI CPU event procedure . . . 875
20.5.3 EXTI CPU wake-up procedure . . . 875
20.5.4 EXTI software interrupt/event trigger procedure . . . 875
20.6 EXTI registers . . . 876
20.6.1 EXTI rising trigger selection register (EXTI_RTSR1) . . . 876
20.6.2 EXTI falling trigger selection register (EXTI_FTSR1) . . . 876
20.6.3 EXTI software interrupt event register (EXTI_SWIER1) . . . 877
20.6.4 EXTI rising trigger selection register (EXTI_RTSR2) . . . 877

20.6.5 EXTI falling trigger selection register (EXTI_FTSR2) 878
20.6.6 EXTI software interrupt event register (EXTI_SWIER2) 879
20.6.7 EXTI interrupt mask register (EXTI_IMR1) 880
20.6.8 EXTI event mask register (EXTI_EMR1) 881
20.6.9 EXTI pending register (EXTI_PR1) 881
20.6.10 EXTI interrupt mask register (EXTI_IMR2) 882
20.6.11 EXTI event mask register (EXTI_EMR2) 882
20.6.12 EXTI pending register (EXTI_PR2) 883
20.6.13 EXTI interrupt mask register (EXTI_IMR3) 884
20.6.14 EXTI event mask register (EXTI_EMR3) 884
20.6.15 EXTI register map 885

23.9.4 Low-power modes . . . 982
23.9.5 SDRAM controller registers . . . 985
23.9.6 FMC register map . . . 991

24 Extended-SPI interface (XSPI) . . . 994
24.1 Introduction . . . 994
24.2 XSPI main features . . . 994
24.3 XSPI implementation . . . 995
24.4 XSPI functional description . . . 996
24.4.1 XSPI block diagram . . . 996
24.4.2 XSPI pins and internal signals . . . 1000
24.4.3 Clock constraints . . . 1001
24.4.4 XSPI interface to memory modes . . . 1001
24.4.5 XSPI regular-command protocol . . . 1001
24.4.6 XSPI regular-command protocol signal interface . . . 1005
24.4.7 HyperBus protocol . . . 1010
24.4.8 Specific features . . . 1015
24.4.9 XSPI operating modes introduction . . . 1017
24.4.10 XSPI indirect mode . . . 1017
24.4.11 XSPI automatic status-polling mode . . . 1019
24.4.12 XSPI memory-mapped mode . . . 1019
24.4.13 XSPI configuration introduction . . . 1020
24.4.14 XSPI system configuration . . . 1020
24.4.15 XSPI device configuration . . . 1021
24.4.16 XSPI regular-command mode configuration . . . 1023
24.4.17 XSPI HyperBus protocol configuration . . . 1026
24.4.18 XSPI error management . . . 1026
24.4.19 XSPI high-speed interface and calibration . . . 1027
24.4.20 XSPI BUSY and ABORT . . . 1028
24.4.21 XSPI reconfiguration or deactivation . . . 1028
24.4.22 NCS behavior . . . 1029
24.4.23 Software control of two external memories . . . 1030

24.5 Address alignment and data number 1031
24.6 XSPI interrupts 1032
24.7 XSPI registers 1033
24.7.1 XSPI control register (XSPI_CR) 1033
24.7.2 XSPI device configuration register 1 (XSPI_DCR1) 1036
24.7.3 XSPI device configuration register 2 (XSPI_DCR2) 1037
24.7.4 XSPI device configuration register 3 (XSPI_DCR3) 1038
24.7.5 XSPI device configuration register 4 (XSPI_DCR4) 1039
24.7.6 XSPI status register (XSPI_SR) 1039
24.7.7 XSPI flag clear register (XSPI_FCR) 1040
24.7.8 XSPI data length register (XSPI_DLR) 1041
24.7.9 XSPI address register (XSPI_AR) 1041
24.7.10 XSPI data register (XSPI_DR) 1042
24.7.11 XSPI polling status mask register (XSPI_PSMKR) 1043
24.7.12 XSPI polling status match register (XSPI_PSMAR) 1043
24.7.13 XSPI polling interval register (XSPI_PIR) 1044
24.7.14 XSPI communication configuration register (XSPI_CCR) 1044
24.7.15 XSPI timing configuration register (XSPI_TCR) 1046
24.7.16 XSPI instruction register (XSPI_IR) 1047
24.7.17 XSPI alternate bytes register (XSPI_ABR) 1047
24.7.18 XSPI low-power timeout register (XSPI_LPTR) 1047
24.7.19 XSPI wrap communication configuration register (XSPI_WPCCR) 1048
24.7.20 XSPI wrap timing configuration register (XSPI_WPTCR) 1050
24.7.21 XSPI wrap instruction register (XSPI_WPIR) 1051
24.7.22 XSPI wrap alternate byte register (XSPI_WPABR) 1051
24.7.23 XSPI write communication configuration register (XSPI_WCCR) 1051
24.7.24 XSPI write timing configuration register (XSPI_WTCR) 1053
24.7.25 XSPI write instruction register (XSPI_WIR) 1054
24.7.26 XSPI write alternate byte register (XSPI_WABR) 1054
24.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR) 1055
24.7.28 XSPI full-cycle calibration configuration (XSPI_CALFCR) 1055
24.7.29 XSPI DLL master calibration configuration (XSPI_CALMR) 1056
24.7.30 XSPI DLL slave output calibration configuration (XSPI_CALSOR) 1057
24.7.31 XSPI DLL slave input calibration configuration (XSPI_CALSIR) 1058
24.7.32 XSPI register map 1058

25 XSPI I/O manager (XSPIM) 1062
25.1 Introduction 1062
25.2 XSPIM main features 1062
25.3 XSPIM implementation 1062
25.4 XSPIM functional description 1062
25.4.1 XSPIM block diagram 1062
25.4.2 XSPIM input/output pins 1063
25.4.3 XSPIM matrix 1063
25.4.4 XSPIM multiplexed mode 1064
25.5 Use cases description 1064
25.5.1 XSPIs direct octal mode 1065
25.5.2 XSPI direct 16-bit mode 1065
25.5.3 XSPI dual-octal mode 1066
25.5.4 XSPI swapped mode 1067
25.5.5 Two XSPIs multiplexed mode to Port 1 accessing two external memories 1067
25.5.6 Two XSPIs multiplexed mode to Port 2 accessing two external memories 1068
25.5.7 XSPI1 and XSPI2 drive a single external memory 1069
25.5.8 A single XSPI drives two external memories 1069
25.6 XSPIM registers 1071
25.6.1 XSPIM control register (XSPIM_CR) 1071
25.6.2 XSPIM register map 1072

26 Delay block (DLYB) 1073
26.1 Introduction 1073
26.2 DLYB main features 1073
26.3 DLYB functional description 1073
26.3.1 DLYB diagram 1073
26.3.2 DLYB pins and internal signals 1074
26.3.3 General description 1074
26.3.4 Delay line length configuration procedure 1075
26.3.5 Output clock phase configuration procedure 1075
26.4 DLYB registers 1076
26.4.1 DLYB control register (DLYB_CR) 1076
26.4.2 DLYB configuration register (DLYB_CFGR) 1077

26.4.3 DLYB register map 1077

27 Analog-to-digital converters (ADC1/2) 1078

27.1 Introduction 1078

27.2 ADC main features 1078

27.3 ADC implementation 1080

27.4 ADC functional description 1081

27.4.1 ADC block diagram 1081

27.4.2 ADC pins and internal signals 1082

27.4.3 ADC clocks 1085

27.4.4 ADC connectivity 1087

27.4.5 Slave AHB interface 1089

27.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) 1089

27.4.7 Single-ended and differential input channels 1090

27.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT) 1090

27.4.9 ADC on-off control (ADEN, ADDIS, ADRDY) 1093

27.4.10 Constraints when writing the ADC control bits 1094

27.4.11 Channel selection (SQRx, JSQRx) 1095

27.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2) 1096

27.4.13 Single conversion mode (CONT = 0) 1098

27.4.14 Continuous conversion mode (CONT = 1) 1098

27.4.15 Starting conversions (ADSTART, JADSTART) 1099

27.4.16 ADC timing 1100

27.4.17 Stopping an ongoing conversion (ADSTP, JADSTP) 1101

27.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN) 1102

27.4.19 Injected channel management 1104

27.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 1105

27.4.21 Queue of context for injected conversions 1106

27.4.22 Programmable resolution (RES) - fast conversion mode 1114

27.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP) . 1115

27.4.24 End of conversion sequence (EOS, JEOS) 1115

27.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers) 1116

27.4.26 Data management 1118

27.4.27 Managing conversions using the ADF 1124

27.4.28 Dynamic low-power features 1125

27.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx) 1130
27.4.30 Oversampler 1134
27.4.31 Dual ADC modes 1141
27.4.32 Temperature sensor 1154
27.4.33 VBAT supply monitoring 1156
27.4.34 Monitoring the internal voltage reference 1157
27.4.35 Monitoring the supply voltage 1158
27.5 ADC in low-power modes 1159
27.6 ADC interrupts 1159
27.7 ADC registers (for each ADC) 1161
27.7.1 ADC interrupt and status register (ADC_ISR) 1161
27.7.2 ADC interrupt enable register (ADC_IER) 1163
27.7.3 ADC control register (ADC_CR) 1165
27.7.4 ADC configuration register (ADC_CFGR) 1168
27.7.5 ADC configuration register 2 (ADC_CFGR2) 1173
27.7.6 ADC sample time register 1 (ADC_SMPR1) 1175
27.7.7 ADC sample time register 2 (ADC_SMPR2) 1176
27.7.8 ADC watchdog threshold register 1 (ADC_TR1) 1177
27.7.9 ADC watchdog threshold register 2 (ADC_TR2) 1178
27.7.10 ADC watchdog threshold register 3 (ADC_TR3) 1179
27.7.11 ADC regular sequence register 1 (ADC_SQR1) 1179
27.7.12 ADC regular sequence register 2 (ADC_SQR2) 1180
27.7.13 ADC regular sequence register 3 (ADC_SQR3) 1181
27.7.14 ADC regular sequence register 4 (ADC_SQR4) 1182
27.7.15 ADC regular data register (ADC_DR) 1183
27.7.16 ADC injected sequence register (ADC_JSQR) 1183
27.7.17 ADC offset y register (ADC_OFRy) 1186
27.7.18 ADC injected channel y data register (ADC_JDRy) 1187
27.7.19 ADC analog watchdog 2 configuration register (ADC_AWD2CR) . . . 1188
27.7.20 ADC analog watchdog 3 configuration register (ADC_AWD3CR) . . . 1188
27.7.21 ADC Differential mode selection register (ADC_DIFSEL) 1189
27.7.22 ADC calibration factors (ADC_CALFACT) 1190
27.7.23 ADC option register (ADC_OR) 1190
27.8 ADC common registers 1191
27.8.1 ADC common status register (ADC_CSR) 1191
27.8.2 ADC common control register (ADC_CCR) 1193

27.8.3 ADC common regular data register for dual mode (ADC_CDR) 1196
27.8.4 ADC hardware configuration register (ADC_HWCFGR0) 1196
27.8.5 ADC version register (ADC_VERR) 1197
27.8.6 ADC identification register (ADC_IPDR) 1197
27.8.7 ADC size identification register (ADC_SIDR) 1198
27.9 ADC register map 1199

28 Digital temperature sensor (DTS) 1203
28.1 Introduction 1203
28.2 DTS main features 1203
28.3 DTS functional description 1204
28.3.1 DTS block diagram 1204
28.3.2 DTS internal signals 1204
28.3.3 DTS block operation 1205
28.3.4 Operating modes 1205
28.3.5 Calibration 1205
28.3.6 Prescaler 1205
28.3.7 Temperature measurement principles 1206
28.3.8 Sampling time 1207
28.3.9 Quick measurement mode 1207
28.3.10 Trigger input 1208
28.3.11 On-off control and ready flag 1208
28.3.12 Temperature measurement sequence 1209
28.4 DTS low-power modes 1210
28.5 DTS interrupts 1210
28.5.1 Temperature window comparator 1210
28.5.2 Synchronous interrupt 1210
28.5.3 Asynchronous wakeup 1210
28.6 DTS registers 1211
28.6.1 Temperature sensor configuration register 1 (DTS_CFGR1) 1211
28.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1) 1213
28.6.3 Temperature sensor ramp value register (DTS_RAMPVALR) 1213
28.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1) 1214
28.6.5 Temperature sensor data register (DTS_DR) 1214
28.6.6 Temperature sensor status register (DTS_SR) 1215
28.6.7 Temperature sensor interrupt enable register (DTS_ITENR) 1216

28.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR) 1217
28.6.9 Temperature sensor option register (DTS_OR) 1218
28.6.10 DTS register map 1219

29 Voltage reference buffer (VREFBUF) 1220
29.1 Introduction 1220
29.2 VREFBUF implementation 1220
29.3 VREFBUF functional description 1220
29.4 VREFBUF trimming 1221
29.5 VREFBUF registers 1222
29.5.1 VREFBUF control and status register (VREFBUF_CSR) 1222
29.5.2 VREFBUF calibration control register (VREFBUF_CCR) 1223
29.5.3 VREFBUF register map 1223

30 Audio digital filter (ADF) 1224
30.1 ADF introduction 1224
30.2 ADF main features 1224
30.3 ADF implementation 1225
30.4 ADF functional description 1226
30.4.1 ADF block diagram 1226
30.4.2 ADF pins and internal signals 1226
30.4.3 Serial input interface (SITF) 1227
30.4.4 ADC slave interface (ADCITF) 1231
30.4.5 Clock generator (CKGEN) 1232
30.4.6 Bitstream matrix (BSMX) 1234
30.4.7 Digital filter processing (DFLT) 1235
30.4.8 Digital filter acquisition modes 1245
30.4.9 Start-up sequence examples 1253
30.4.10 Sound activity detection (SAD) 1254
30.4.11 Data transfer to memory 1262
30.4.12 Autonomous mode 1265
30.4.13 Register protection 1265
30.5 ADF low-power modes 1266
30.6 ADF interrupts 1266
30.7 ADF application information 1268
30.7.1 ADF configuration examples for audio capture 1268

30.7.2 Programming examples . . . 1269
30.7.3 Connection examples . . . 1271
30.7.4 Global frequency response . . . 1272
30.7.5 Total ADF gain . . . 1273
30.7.6 How to compute SAD thresholds . . . 1276
30.8 ADF registers . . . 1280
30.8.1 ADF global control register (ADF_GCR) . . . 1280
30.8.2 ADF clock generator control register (ADF_CKGCR) . . . 1281
30.8.3 ADF serial interface control register 0 (ADF_SITF0CR) . . . 1283
30.8.4 ADF bitstream matrix control register 0 (ADF_BSMX0CR) . . . 1284
30.8.5 ADF digital filter control register 0 (ADF_DFLT0CR) . . . 1285
30.8.6 ADF digital filer configuration register 0 (ADF_DFLT0CICR) . . . 1287
30.8.7 ADF reshape filter configuration register 0 (ADF_DFLT0RSFR) . . . 1288
30.8.8 ADF delay control register 0 (ADF_DLY0CR) . . . 1289
30.8.9 ADF DFLT0 interrupt enable register (ADF_DFLT0IER) . . . 1290
30.8.10 ADF DFLT0 interrupt status register 0 (ADF_DFLT0ISR) . . . 1291
30.8.11 ADF SAD control register (ADF_SADCR) . . . 1292
30.8.12 ADF SAD configuration register (ADF_SADCFGR) . . . 1294
30.8.13 ADF SAD sound level register (ADF_SADSDLVR) . . . 1295
30.8.14 ADF SAD ambient noise level register (ADF_SADANLVR) . . . 1296
30.8.15 ADF digital filter data register 0 (ADF_DFLT0DR) . . . 1296
30.8.16 ADF register map . . . 1296

31 Digital camera interface pixel pipeline (DCMIPP) . . . 1299
31.1 Introduction . . . 1299
31.2 DCMIPP main features . . . 1301
31.3 DCMIPP functional description . . . 1302
31.3.1 DCMIPP block diagram . . . 1302
31.3.2 DCMIPP pads and internal signals . . . 1302
31.3.3 DCMIPP reset and clocks . . . 1303
31.3.4 DCMIPP maximum resolution . . . 1305
31.3.5 DCMIPP minimum requirements for frame structure . . . 1305
31.3.6 Description of DCMIPP pixel format support . . . 1305
31.4 DCMIPP input and flow control . . . 1306
31.4.1 Parallel input interface . . . 1306
31.4.2 Frame counter . . . 1310
31.4.3 Frame control . . . 1310

31.4.4 Pipe deactivation . . . 1314
31.5 Pipe0 (dump pipe) . . . 1315
31.5.1 Overview . . . 1315
31.5.2 Decimation . . . 1315
31.5.3 Crop/statistics selection/suppression . . . 1316
31.5.4 Dump counter . . . 1317
31.5.5 Double buffer mode . . . 1318
31.5.6 Pixel packing . . . 1318
31.5.7 Overrun detection . . . 1319
31.6 Pixel format description . . . 1320
31.6.1 Parallel interface formats . . . 1320
31.6.2 Dump pipe formats . . . 1322
31.6.3 AXI IP-Plug . . . 1323
31.7 Shadow registers . . . 1325
31.8 DCMIPP low power modes . . . 1326
31.9 DCMIPP interrupts . . . 1327
31.9.1 Free-running DCMIPP . . . 1327
31.9.2 Interrupts . . . 1327
31.9.3 Event pins . . . 1329
31.10 DCMIPP registers . . . 1330
31.10.1 DCMIPP IP-Plug global register 1 (DCMIPP_IPGR1) . . . 1330
31.10.2 DCMIPP IP-Plug global register 2 (DCMIPP_IPGR2) . . . 1331
31.10.3 DCMIPP IP-Plug global register 3 (DCMIPP_IPGR3) . . . 1331
31.10.4 DCMIPP IP-Plug identification register (DCMIPP_IPGR8) . . . 1331
31.10.5 DCMIPP IP-Plug Clientx register 1 (DCMIPP_IPCxR1) . . . 1332
31.10.6 DCMIPP IP-Plug Clientx register 2 (DCMIPP_IPCxR2) . . . 1333
31.10.7 DCMIPP IP-Plug Clientx register 3 (DCMIPP_IPCxR3) . . . 1333
31.10.8 DCMIPP parallel interface control register (DCMIPP_PRCR) . . . 1334
31.10.9 DCMIPP parallel interface embedded synchronization code register (DCMIPP_PRESCR) . . . 1335
31.10.10 DCMIPP parallel interface embedded synchronization unmask register (DCMIPP_PRESUR) . . . 1336
31.10.11 DCMIPP parallel interface interrupt enable register (DCMIPP_PRIER) . . . 1337
31.10.12 DCMIPP parallel interface status register (DCMIPP_PRSR) . . . 1337
31.10.13 DCMIPP parallel interface interrupt clear register (DCMIPP_PRFCR) . . . 1338

31.10.14 DCMIPP common configuration register (DCMIPP_CMCR) 1338
31.10.15 DCMIPP common frame counter register (DCMIPP_CMFRCR) 1339
31.10.16 DCMIPP common interrupt enable register (DCMIPP_CMIER) 1339
31.10.17 DCMIPP common status register 1 (DCMIPP_CMSR1) 1340
31.10.18 DCMIPP common status register 2 (DCMIPP_CMSR2) 1341
31.10.19 DCMIPP common interrupt clear register (DCMIPP_CMFCR) 1343
31.10.20 DCMIPP Pipe0 flow selection configuration register (DCMIPP_P0FSCR) 1344
31.10.21 DCMIPP Pipe0 flow control configuration register (DCMIPP_P0FCTCR) 1344
31.10.22 DCMIPP Pipe0 statistic/crop start register (DCMIPP_P0SCSTR) . . . 1345
31.10.23 DCMIPP Pipe0 statistic/crop size register (DCMIPP_P0SCSZR) . . . 1345
31.10.24 DCMIPP Pipe0 dump counter register (DCMIPP_P0DCCNTR) 1346
31.10.25 DCMIPP Pipe0 dump limit register (DCMIPP_P0DCLMTR) 1347
31.10.26 DCMIPP Pipe0 pixel packer configuration register (DCMIPP_P0PPCR) 1347
31.10.27 DCMIPP Pipe0 pixel packer Memory0 address register 1 (DCMIPP_P0PPM0AR1) 1348
31.10.28 DCMIPP Pipe0 pixel packer Memory0 address register 2 (DCMIPP_P0PPM0AR2) 1349
31.10.29 DCMIPP Pipe0 interrupt enable register (DCMIPP_P0IER) 1349
31.10.30 DCMIPP Pipe0 status register (DCMIPP_P0SR) 1350
31.10.31 DCMIPP Pipe0 interrupt clear register (DCMIPP_P0FCR) 1351
31.10.32 DCMIPP Pipe0 current flow control configuration register (DCMIPP_P0CFCTCR) 1352
31.10.33 DCMIPP Pipe0 current statistic/crop start register (DCMIPP_P0CSCSTR) 1352
31.10.34 DCMIPP Pipe0 current statistic/crop size register (DCMIPP_P0CSCSZR) 1353
31.10.35 DCMIPP Pipe0 current pixel packer configuration register (DCMIPP_P0CPPCR) 1354
31.10.36 DCMIPP Pipe0 current pixel packer Memory0 address register 1 (DCMIPP_P0CPPM0AR1) 1355
31.10.37 DCMIPP Pipe0 current pixel packer Memory0 address register 2 (DCMIPP_P0CPPM0AR2) 1355
31.11 DCMIPP register map 1357

32 Parallel synchronous slave interface (PSSI) 1360

32.1 Introduction 1360
32.2 PSSI main features 1360

32.3 PSSI functional description . . . 1360
32.3.1 PSSI block diagram . . . 1361
32.3.2 PSSI pins and internal signals . . . 1361
32.3.3 PSSI clock . . . 1362
32.3.4 PSSI data management . . . 1362
32.3.5 PSSI optional control signals . . . 1364
32.4 PSSI interrupts . . . 1367
32.5 PSSI registers . . . 1367
32.5.1 PSSI control register (PSSI_CR) . . . 1367
32.5.2 PSSI status register (PSSI_SR) . . . 1369
32.5.3 PSSI raw interrupt status register (PSSI_RIS) . . . 1370
32.5.4 PSSI interrupt enable register (PSSI_IER) . . . 1371
32.5.5 PSSI masked interrupt status register (PSSI_MIS) . . . 1371
32.5.6 PSSI interrupt clear register (PSSI_ICR) . . . 1372
32.5.7 PSSI data register (PSSI_DR) . . . 1372
32.5.8 PSSI register map . . . 1373

33 LCD-TFT display controller (LTDC) . . . 1374
33.1 Introduction . . . 1374
33.2 LTDC main features . . . 1374
33.3 LTDC functional description . . . 1375
33.3.1 LTDC block diagram . . . 1375
33.3.2 LTDC pins and internal signals . . . 1375
33.3.3 LTDC reset and clocks . . . 1376
33.4 LTDC programmable parameters . . . 1378
33.4.1 LTDC global configuration parameters . . . 1378
33.4.2 Layer programmable parameters . . . 1380
33.5 LTDC interrupts . . . 1384
33.6 LTDC programming procedure . . . 1385
33.7 LTDC registers . . . 1386
33.7.1 LTDC synchronization size configuration register (LTDC_SSCR) . . . 1386
33.7.2 LTDC back porch configuration register (LTDC_BPCR) . . . 1386
33.7.3 LTDC active width configuration register (LTDC_AWCR) . . . 1387
33.7.4 LTDC total width configuration register (LTDC_TWCR) . . . 1388
33.7.5 LTDC global control register (LTDC_GCR) . . . 1388
33.7.6 LTDC shadow reload configuration register (LTDC_SRCR) . . . 1390

33.7.7 LTDC background color configuration register (LTDC_BCCR) 1390
33.7.8 LTDC interrupt enable register (LTDC_IER) 1391
33.7.9 LTDC interrupt status register (LTDC_ISR) 1392
33.7.10 LTDC interrupt clear register (LTDC_ICR) 1392
33.7.11 LTDC line interrupt position configuration register (LTDC_LIPCR) . . 1393
33.7.12 LTDC current position status register (LTDC_CPSR) 1393
33.7.13 LTDC current display status register (LTDC_CDSR) 1394
33.7.14 LTDC layer x control register (LTDC_LxCR) 1394
33.7.15 LTDC layer x window horizontal position configuration register (LTDC_LxWHPCR) 1395
33.7.16 LTDC layer x window vertical position configuration register (LTDC_LxWVPCR) 1396
33.7.17 LTDC layer x color keying configuration register (LTDC_LxCKCR) 1397
33.7.18 LTDC layer x pixel format configuration register (LTDC_LxPFCR) 1397
33.7.19 LTDC layer x constant alpha configuration register (LTDC_LxCACR) 1398
33.7.20 LTDC layer x default color configuration register (LTDC_LxDCCR) 1398
33.7.21 LTDC layer x blending factors configuration register (LTDC_LxBFCR) 1399
33.7.22 LTDC layer x color frame buffer address register (LTDC_LxCFBAR) 1400
33.7.23 LTDC layer x color frame buffer length register (LTDC_LxCFBLR) 1400
33.7.24 LTDC layer x color frame buffer line number register (LTDC_LxCFBLNR) 1401
33.7.25 LTDC layer x CLUT write register (LTDC_LxCLUTWR) 1401
33.7.26 LTDC register map 1402

34 JPEG codec (JPEG) 1405

34.1 Introduction 1405
34.2 JPEG codec main features 1405
34.3 JPEG codec block functional description 1406
34.3.1 General description 1406
34.3.2 JPEG internal signals 1406
34.3.3 JPEG decoding procedure 1407
34.3.4 JPEG encoding procedure 1409
34.4 JPEG codec interrupts 1412

34.5 JPEG codec registers 1412
34.5.1 JPEG codec control register (JPEG_CONFR0) 1412
34.5.2 JPEG codec configuration register 1 (JPEG_CONFR1) 1413
34.5.3 JPEG codec configuration register 2 (JPEG_CONFR2) 1414
34.5.4 JPEG codec configuration register 3 (JPEG_CONFR3) 1414
34.5.5 JPEG codec configuration register x (JPEG_CONFRx) 1415
34.5.6 JPEG control register (JPEG_CR) 1416
34.5.7 JPEG status register (JPEG_SR) 1417
34.5.8 JPEG clear flag register (JPEG_CFR) 1418
34.5.9 JPEG data input register (JPEG_DIR) 1419
34.5.10 JPEG data output register (JPEG_DOR) 1419
34.5.11 JPEG quantization memory x (JPEG_QMEMx_y) 1420
34.5.12 JPEG Huffman min (JPEG_HUFFMINx_y) 1420
34.5.13 JPEG Huffman min x (JPEG_HUFFMINx_y) 1421
34.5.14 JPEG Huffman base (JPEG_HUFFBASEx) 1421
34.5.15 JPEG Huffman symbol (JPEG_HUFFSYMBx) 1422
34.5.16 JPEG DHT memory (JPEG_DHTMEMx) 1423
34.5.17 JPEG Huffman encoder ACx (JPEG_HUFFENC_ACx_y) 1423
34.5.18 JPEG Huffman encoder DCx (JPEG_HUFFENC_DCx_y) 1424
34.5.19 JPEG codec register map 1425

35 True random number generator (RNG) 1427
35.1 Introduction 1427
35.2 RNG main features 1427
35.3 RNG functional description 1428
35.3.1 RNG block diagram 1428
35.3.2 RNG internal signals 1428
35.3.3 Random number generation 1428
35.3.4 RNG initialization 1431
35.3.5 RNG operation 1432
35.3.6 RNG clocking 1434
35.3.7 Error management 1434
35.3.8 RNG low-power use 1435
35.4 RNG interrupts 1436
35.5 RNG processing time 1436
35.6 RNG entropy source validation 1437

35.6.1 Introduction . . . 1437
35.6.2 Validation conditions . . . 1437
35.7 RNG registers . . . 1438
35.7.1 RNG control register (RNG_CR) . . . 1438
35.7.2 RNG status register (RNG_SR) . . . 1440
35.7.3 RNG data register (RNG_DR) . . . 1441
35.7.4 RNG noise source control register (RNG_NSCR) . . . 1442
35.7.5 RNG health test control register (RNG_HTCR) . . . 1443
35.7.6 RNG register map . . . 1443

36 Secure AES coprocessor (SAES) . . . 1444
36.1 Introduction . . . 1444
36.2 SAES main features . . . 1444
36.3 SAES implementation . . . 1445
36.4 SAES functional description . . . 1445
36.4.1 SAES block diagram . . . 1445
36.4.2 SAES internal signals . . . 1446
36.4.3 SAES reset and clocks . . . 1447
36.4.4 SAES symmetric cipher implementation . . . 1447
36.4.5 SAES encryption or decryption typical usage . . . 1448
36.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication . . . 1450
36.4.7 SAES ciphertext stealing and data padding . . . 1450
36.4.8 SAES suspend and resume operations . . . 1451
36.4.9 SAES basic chaining modes (ECB, CBC) . . . 1451
36.4.10 SAES counter (CTR) mode . . . 1456
36.4.11 SAES Galois/counter mode (GCM) . . . 1458
36.4.12 SAES Galois message authentication code (GMAC) . . . 1462
36.4.13 SAES counter with CBC-MAC (CCM) . . . 1464
36.4.14 SAES operation with wrapped keys . . . 1469
36.4.15 SAES operation with shared keys . . . 1473
36.4.16 SAES data registers and data swapping . . . 1474
36.4.17 SAES key registers . . . 1477
36.4.18 SAES initialization vector registers . . . 1478
36.4.19 SAES error management . . . 1478
36.5 SAES interrupts . . . 1480
36.6 SAES DMA requests . . . 1481

36.7 SAES processing latency 1481
36.8 SAES registers 1483
36.8.1 SAES control register (SAES_CR) 1483
36.8.2 SAES status register (SAES_SR) 1486
36.8.3 SAES data input register (SAES_DINR) 1487
36.8.4 SAES data output register (SAES_DOUTR) 1488
36.8.5 SAES key register 0 (SAES_KEYR0) 1488
36.8.6 SAES key register 1 (SAES_KEYR1) 1489
36.8.7 SAES key register 2 (SAES_KEYR2) 1489
36.8.8 SAES key register 3 (SAES_KEYR3) 1489
36.8.9 SAES initialization vector register 0 (SAES_IVR0) 1490
36.8.10 SAES initialization vector register 1 (SAES_IVR1) 1490
36.8.11 SAES initialization vector register 2 (SAES_IVR2) 1490
36.8.12 SAES initialization vector register 3 (SAES_IVR3) 1491
36.8.13 SAES key register 4 (SAES_KEYR4) 1491
36.8.14 SAES key register 5 (SAES_KEYR5) 1491
36.8.15 SAES key register 6 (SAES_KEYR6) 1492
36.8.16 SAES key register 7 (SAES_KEYR7) 1492
36.8.17 SAES suspend registers (SAES_SUSPRx) 1492
36.8.18 SAES interrupt enable register (SAES_IER) 1493
36.8.19 SAES interrupt status register (SAES_ISR) 1494
36.8.20 SAES interrupt clear register (SAES_ICR) 1495
36.8.21 SAES register map 1495

37 Cryptographic processor (CRYP) 1498
37.1 Introduction 1498
37.2 CRYP main features 1498
37.3 CRYP implementation 1499
37.4 CRYP functional description 1500
37.4.1 CRYP block diagram 1500
37.4.2 CRYP internal signals 1501
37.4.3 CRYP reset and clocks 1501
37.4.4 CRYP symmetric cipher implementation 1501
37.4.5 CRYP encryption/ decryption typical usage 1502
37.4.6 CRYP authenticated encryption, decryption, and cipher-based message authentication 1505
37.4.7 CRYP ciphertext stealing and data padding 1505

37.4.8 CRYP suspend and resume operations 1506
37.4.9 CRYP basic chaining modes (ECB, CBC) 1506
37.4.10 CRYP counter mode (CTR) 1511
37.4.11 CRYP AES Galois/counter mode (GCM) 1513
37.4.12 CRYP AES Galois message authentication code (GMAC) 1519
37.4.13 CRYP AES Counter with CBC-MAC (CCM) 1520
37.4.14 AES key sharing with secure AES co-processor 1525
37.4.15 CRYP data registers and data swapping 1526
37.4.16 CRYP key registers 1529
37.4.17 CRYP initialization vector registers 1529
37.4.18 CRYP error management 1530
37.5 CRYP interrupts 1530
37.6 CRYP DMA requests 1531
37.7 CRYP processing time 1532
37.8 CRYP registers 1533
37.8.1 CRYP control register (CRYP_CR) 1533
37.8.2 CRYP status register (CRYP_SR) 1535
37.8.3 CRYP data input register (CRYP_DINR) 1537
37.8.4 CRYP data output register (CRYP_DOUTR) 1537
37.8.5 CRYP DMA control register (CRYP_DMACR) 1538
37.8.6 CRYP interrupt mask set/clear register (CRYP_IMSCR) 1538
37.8.7 CRYP raw interrupt status register (CRYP_RISR) 1539
37.8.8 CRYP masked interrupt status register (CRYP_MISR) 1539
37.8.9 CRYP key register 0L (CRYP_K0LR) 1540
37.8.10 CRYP key register 0R (CRYP_K0RR) 1541
37.8.11 CRYP key register 1L (CRYP_K1LR) 1541
37.8.12 CRYP key register 1R (CRYP_K1RR) 1541
37.8.13 CRYP key register 2L (CRYP_K2LR) 1542
37.8.14 CRYP key register 2R (CRYP_K2RR) 1542
37.8.15 CRYP key register 3L (CRYP_K3LR) 1543
37.8.16 CRYP key register 3R (CRYP_K3RR) 1543
37.8.17 CRYP initialization vector register 0L (CRYP_IV0LR) 1543
37.8.18 CRYP initialization vector register 0R (CRYP_IV0RR) 1544
37.8.19 CRYP initialization vector register 1L (CRYP_IV1LR) 1544
37.8.20 CRYP initialization vector register 1R (CRYP_IV1RR) 1545
37.8.21 CRYP context swap GCM-CCM registers (CRYP_CSGCMCCMxR) 1545
37.8.22 CRYP context swap GCM registers (CRYP_CSGCMxR) 1546

37.8.23 CRYP register map 1546

38 Hash processor (HASH) 1548

38.1 Introduction 1548

38.2 HASH main features 1548

38.3 HASH implementation 1549

38.4 HASH functional description 1549

38.4.1 HASH block diagram 1549

38.4.2 HASH internal signals 1549

38.4.3 About secure hash algorithms 1550

38.4.4 Message data feeding 1550

38.4.5 Message digest computing 1551

38.4.6 Message padding 1553

38.4.7 HMAC operation 1554

38.4.8 HASH suspend/resume operations 1556

38.4.9 HASH DMA interface 1558

38.4.10 HASH error management 1559

38.4.11 HASH processing time 1559

38.5 HASH interrupts 1560

38.6 HASH registers 1560

38.6.1 HASH control register (HASH_CR) 1560

38.6.2 HASH data input register (HASH_DIN) 1562

38.6.3 HASH start register (HASH_STR) 1563

38.6.4 HASH digest registers 1564

38.6.5 HASH interrupt enable register (HASH_IMR) 1566

38.6.6 HASH status register (HASH_SR) 1566

38.6.7 HASH context swap registers 1567

38.6.8 HASH register map 1568

39 Memory cipher engine (MCE) 1570

39.1 Introduction 1570

39.2 MCE main features 1570

39.3 MCE implementation 1571

39.4 MCE functional description 1572

39.4.1 MCE block diagram 1572

39.4.2 MCE internal signals 1572

39.4.3 MCE programming 1573
39.4.4 MCE reset and clocks 1574
39.4.5 MCE block cipher encryption mode 1574
39.4.6 MCE stream cipher encryption mode 1576
39.4.7 MCE AXI traffic management 1577
39.4.8 MCE encryption disable options 1577
39.4.9 MCE error management 1578
39.5 MCE interrupts 1578
39.6 MCE registers 1579
39.6.1 MCE configuration register (MCE_CR) 1579
39.6.2 MCE status register (MCE_SR) 1579
39.6.3 MCE illegal access status register (MCE_IASR) 1580
39.6.4 MCE illegal access clear register (MCE_IACR) 1581
39.6.5 MCE illegal access interrupt enable register (MCE_IAIER) 1581
39.6.6 MCE privileged configuration register (MCE_PRIVCFGR) 1582
39.6.7 MCE illegal access error status register (MCE_IAESR) 1582
39.6.8 MCE illegal address register (MCE_IADDR) 1583
39.6.9 MCE region x configuration register (MCE_REGCRx) 1583
39.6.10 MCE start address for region x register (MCE_SADDRx) 1585
39.6.11 MCE end address for region x register (MCE_EADDRx) 1585
39.6.12 MCE attribute for region x register (MCE_ATTRx) 1586
39.6.13 MCE master key x (MCE_MKEYRx) 1586
39.6.14 MCE fast master key x (MCE_FMKEYRx) 1586
39.6.15 MCE cipher context z configuration register (MCE_CCzCFGR) 1587
39.6.16 MCE cipher context z nonce register 0 (MCE_CCzNR0) 1589
39.6.17 MCE cipher context z nonce register 1 (MCE_CCzNR1) 1589
39.6.18 MCE cipher context z key register 0 (MCE_CCzKEYR0) 1590
39.6.19 MCE cipher context z key register 1 (MCE_CCzKEYR1) 1590
39.6.20 MCE cipher context z key register 2 (MCE_CCzKEYR2) 1591
39.6.21 MCE cipher context z key register 3 (MCE_CCzKEYR3) 1591
39.6.22 MCE register map 1592

40 Public key accelerator (PKA) 1594
40.1 Introduction 1594
40.2 PKA main features 1594

40.3 PKA functional description 1595
40.3.1 PKA block diagram 1595
40.3.2 PKA internal signals 1595
40.3.3 PKA reset and clocks 1595
40.3.4 PKA public key acceleration 1596
40.3.5 Typical applications for PKA 1598
40.3.6 PKA procedure to perform an operation 1600
40.3.7 PKA error management 1601
40.4 PKA operating modes 1602
40.4.1 Introduction 1602
40.4.2 Montgomery parameter computation 1603
40.4.3 Modular addition 1603
40.4.4 Modular subtraction 1604
40.4.5 Modular and Montgomery multiplication 1604
40.4.6 Modular exponentiation 1605
40.4.7 Modular inversion 1607
40.4.8 Modular reduction 1607
40.4.9 Arithmetic addition 1608
40.4.10 Arithmetic subtraction 1608
40.4.11 Arithmetic multiplication 1609
40.4.12 Arithmetic comparison 1609
40.4.13 RSA CRT exponentiation 1609
40.4.14 Point on elliptic curve Fp check 1610
40.4.15 ECC Fp scalar multiplication 1611
40.4.16 ECDSA sign 1612
40.4.17 ECDSA verification 1614
40.4.18 ECC complete addition 1615
40.4.19 ECC double base ladder 1615
40.4.20 ECC projective to affine 1616
40.5 Example of configurations and processing times 1617
40.5.1 Supported elliptic curves 1617
40.5.2 Computation times 1619
40.6 PKA interrupts 1621
40.7 PKA registers 1622
40.7.1 PKA control register (PKA_CR) 1622
40.7.2 PKA status register (PKA_SR) 1624

40.7.3 PKA clear flag register (PKA_CLRFR) 1625
40.7.4 PKA RAM 1625
40.7.5 PKA register map 1626

41 Advanced-control timers (TIM1) 1627
41.1 TIM1 introduction 1627
41.2 TIM1 main features 1628
41.3 TIM1 functional description 1629
41.3.1 Block diagram 1629
41.3.2 TIM1 pins and internal signals 1630
41.3.3 Time-base unit 1634
41.3.4 Counter modes 1636
41.3.5 Repetition counter 1648
41.3.6 External trigger input 1649
41.3.7 Clock selection 1650
41.3.8 Capture/compare channels 1654
41.3.9 Input capture mode 1656
41.3.10 PWM input mode 1657
41.3.11 Forced output mode 1658
41.3.12 Output compare mode 1659
41.3.13 PWM mode 1660
41.3.14 Asymmetric PWM mode 1668
41.3.15 Combined PWM mode 1669
41.3.16 Combined 3-phase PWM mode 1670
41.3.17 Complementary outputs and dead-time insertion 1671
41.3.18 Using the break function 1674
41.3.19 Bidirectional break inputs 1680
41.3.20 Clearing the tim_ocxref signal on an external event 1681
41.3.21 6-step PWM generation 1682
41.3.22 One-pulse mode 1683
41.3.23 Retriggerable One-pulse mode 1685
41.3.24 Pulse on compare mode 1686
41.3.25 Encoder interface mode 1688
41.3.26 Direction bit output 1705
41.3.27 UIF bit remapping 1706
41.3.28 Timer input XOR function 1706
41.3.29 Interfacing with Hall sensors 1706

41.3.30 Timer synchronization 1708
41.3.31 ADC triggers 1713
41.3.32 DMA burst mode 1713
41.3.33 TIM1 DMA requests 1714

46.7.2 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3) . . . 2092
46.7.3 LPTIMx interrupt and status register [alternate] (LPTIMx_ISR) (x = 1 to 3) . . . 2094
46.7.4 LPTIMx interrupt clear register (LPTIMx_ICR)(x = 4 to 5) . . . 2096
46.7.5 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3) . . . 2097
46.7.6 LPTIMx interrupt clear register [alternate] (LPTIMx_ICR) (x = 1 to 3) . . . 2098
46.7.7 LPTIMx interrupt enable register (LPTIMx_DIER)(x = 4 to 5) . . . 2099
46.7.8 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3) . . . 2101
46.7.9 LPTIMx interrupt enable register [alternate] (LPTIMx_DIER) (x = 1 to 3) . . . 2102
46.7.10 LPTIM configuration register (LPTIM_CFGR) . . . 2104
46.7.11 LPTIM control register (LPTIM_CR) . . . 2107
46.7.12 LPTIM compare register 1 (LPTIM_CCR1) . . . 2108
46.7.13 LPTIM autoreload register (LPTIM_ARR) . . . 2109

46.7.14 LPTIM counter register (LPTIM_CNT) 2109
46.7.15 LPTIM configuration register 2 (LPTIM_CFGR2) 2110
46.7.16 LPTIM repetition register (LPTIM_RCR) 2111
46.7.17 LPTIM capture/compare mode register 1 (LPTIM_CCMR1) 2111
46.7.18 LPTIM compare register 2 (LPTIM_CCR2) 2114
46.7.19 LPTIM register map 2114

47 System window watchdog (WWDG) 2117

47.1 Introduction 2117
47.2 WWDG main features 2117
47.3 WWDG implementation 2117
47.4 WWDG functional description 2118
47.4.1 WWDG block diagram 2118
47.4.2 WWDG internal signals 2118
47.4.3 Enabling the watchdog 2119
47.4.4 Controlling the down-counter 2119
47.4.5 How to program the watchdog timeout 2119
47.4.6 Debug mode 2120
47.5 WWDG interrupts 2121
47.6 WWDG registers 2121
47.6.1 WWDG control register (WWDG_CR) 2121
47.6.2 WWDG configuration register (WWDG_CFR) 2122
47.6.3 WWDG status register (WWDG_SR) 2122
47.6.4 WWDG register map 2123

48 Independent watchdog (IWDG) 2124

48.1 Introduction 2124
48.2 IWDG main features 2124
48.3 IWDG implementation 2124
48.4 IWDG functional description 2125
48.4.1 IWDG block diagram 2125
48.4.2 IWDG internal signals 2126
48.4.3 Software and hardware watchdog modes 2126
48.4.4 Window option 2127
48.4.5 Debug 2130
48.4.6 Register access protection 2130

48.5 IWDG low power modes . . . 2131
48.6 IWDG interrupts . . . 2131
48.7 IWDG registers . . . 2133
48.7.1 IWDG key register (IWDG_KR) . . . 2134
48.7.2 IWDG prescaler register (IWDG_PR) . . . 2134
48.7.3 IWDG reload register (IWDG_RLR) . . . 2135
48.7.4 IWDG status register (IWDG_SR) . . . 2135
48.7.5 IWDG window register (IWDG_WINR) . . . 2137
48.7.6 IWDG early wake-up interrupt register (IWDG_EWCR) . . . 2137
48.7.7 IWDG register map . . . 2139

49 Real-time clock (RTC) . . . 2140
49.1 Introduction . . . 2140
49.2 RTC main features . . . 2140
49.3 RTC functional description . . . 2140
49.3.1 RTC block diagram . . . 2140
49.3.2 RTC pins and internal signals . . . 2142
49.3.3 GPIOs controlled by the RTC and TAMP . . . 2143
49.3.4 RTC privilege protection modes . . . 2146
49.3.5 Clock and prescalers . . . 2147
49.3.6 Real-time clock and calendar . . . 2148
49.3.7 Calendar ultra-low power mode . . . 2149
49.3.8 Programmable alarms . . . 2149
49.3.9 Periodic auto-wake-up . . . 2149
49.3.10 RTC initialization and configuration . . . 2150
49.3.11 Reading the calendar . . . 2153
49.3.12 Resetting the RTC . . . 2154
49.3.13 RTC synchronization . . . 2154
49.3.14 RTC reference clock detection . . . 2155
49.3.15 RTC smooth digital calibration . . . 2156
49.3.16 Timestamp function . . . 2158
49.3.17 Calibration clock output . . . 2158
49.3.18 Tamper and alarm output . . . 2159
49.4 RTC low-power modes . . . 2159
49.5 RTC interrupts . . . 2160
49.6 RTC registers . . . 2160

49.6.1 RTC time register (RTC_TR) . . . 2161
49.6.2 RTC date register (RTC_DR) . . . 2162
49.6.3 RTC subsecond register (RTC_SSR) . . . 2163
49.6.4 RTC initialization control and status register (RTC_ICSR) . . . 2163
49.6.5 RTC prescaler register (RTC_PRER) . . . 2165
49.6.6 RTC wake-up timer register (RTC_WUTR) . . . 2166
49.6.7 RTC control register (RTC_CR) . . . 2166
49.6.8 RTC privilege mode control register (RTC_PRIVCFGR) . . . 2170
49.6.9 RTC write protection register (RTC_WPR) . . . 2172
49.6.10 RTC calibration register (RTC_CALR) . . . 2172
49.6.11 RTC shift control register (RTC_SHIFTR) . . . 2174
49.6.12 RTC timestamp time register (RTC_TSTR) . . . 2175
49.6.13 RTC timestamp date register (RTC_TSDR) . . . 2176
49.6.14 RTC timestamp subsecond register (RTC_TSSSR) . . . 2176
49.6.15 RTC alarm A register (RTC_ALRMAR) . . . 2177
49.6.16 RTC alarm A subsecond register (RTC_ALRMASSR) . . . 2178
49.6.17 RTC alarm B register (RTC_ALRMBR) . . . 2179
49.6.18 RTC alarm B subsecond register (RTC_ALRMBSSR) . . . 2180
49.6.19 RTC status register (RTC_SR) . . . 2181
49.6.20 RTC masked interrupt status register (RTC_MISR) . . . 2183
49.6.21 RTC status clear register (RTC_SCR) . . . 2184
49.6.22 RTC alarm A binary mode register (RTC_ALRABINR) . . . 2185
49.6.23 RTC alarm B binary mode register (RTC_ALRBBINR) . . . 2185
49.6.24 RTC register map . . . 2187

50 Tamper and backup registers (TAMP) . . . 2189

50.1 Introduction . . . 2189
50.2 TAMP main features . . . 2189
50.3 TAMP functional description . . . 2190
50.3.1 TAMP block diagram . . . 2190
50.3.2 TAMP pins and internal signals . . . 2191
50.3.3 GPIOs controlled by the RTC and TAMP . . . 2193
50.3.4 TAMP register write protection . . . 2194
50.3.5 Backup registers protection zones . . . 2194
50.3.6 TAMP privilege protection modes . . . 2194
50.3.7 Boot hardware key (BHK) . . . 2195
50.3.8 Tamper detection . . . 2195

50.3.9 TAMP backup registers and other device secrets erase 2195
50.3.10 Tamper detection configuration and initialization 2197
50.4 TAMP low-power modes 2203
50.5 TAMP interrupts 2204
50.6 TAMP registers 2204
50.6.1 TAMP control register 1 (TAMP_CR1) 2204
50.6.2 TAMP control register 2 (TAMP_CR2) 2206
50.6.3 TAMP control register 3 (TAMP_CR3) 2209
50.6.4 TAMP filter control register (TAMP_FLTCR) 2210
50.6.5 TAMP active tamper control register 1 (TAMP_ATCR1) 2211
50.6.6 TAMP active tamper seed register (TAMP_ATSEEDR) 2214
50.6.7 TAMP active tamper output register (TAMP_ATOR) 2214
50.6.8 TAMP active tamper control register 2 (TAMP_ATCR2) 2215
50.6.9 TAMP configuration register (TAMP_CFGR) 2218
50.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR) 2219
50.6.11 TAMP interrupt enable register (TAMP_IER) 2220
50.6.12 TAMP status register (TAMP_SR) 2222
50.6.13 TAMP masked interrupt status register (TAMP_MISR) 2224
50.6.14 TAMP status clear register (TAMP_SCR) 2226
50.6.15 TAMP monotonic counter 1 register (TAMP_COUNT1R) 2228
50.6.16 TAMP resources protection configuration register (TAMP_RPCFGR) 2228
50.6.17 TAMP backup x register (TAMP_BKPxR) 2229
50.6.18 TAMP register map 2230

51 Inter-integrated circuit interface (I2C) 2232
51.1 Introduction 2232
51.2 I2C main features 2232
51.3 I2C implementation 2233
51.4 I2C functional description 2233
51.4.1 I2C block diagram 2234
51.4.2 I2C pins and internal signals 2234
51.4.3 I2C clock requirements 2235
51.4.4 I2C mode selection 2235
51.4.5 I2C initialization 2236
51.4.6 I2C reset 2240
51.4.7 I2C data transfer 2241

51.4.8 I2C target mode . . . 2243
51.4.9 I2C controller mode . . . 2252
51.4.10 I2C_TIMINGR register configuration examples . . . 2263
51.4.11 SMBus specific features . . . 2265
51.4.12 SMBus initialization . . . 2267
51.4.13 SMBus I2C_TIMEOUTR register configuration examples . . . 2269
51.4.14 SMBus target mode . . . 2270
51.4.15 SMBus controller mode . . . 2273
51.4.16 Wake-up from Stop mode on address match . . . 2276
51.4.17 Error conditions . . . 2277
51.5 I2C in low-power modes . . . 2279
51.6 I2C interrupts . . . 2279
51.7 I2C DMA requests . . . 2280
51.7.1 Transmission using DMA . . . 2280
51.7.2 Reception using DMA . . . 2280
51.8 I2C debug modes . . . 2280
51.9 I2C registers . . . 2281
51.9.1 I2C control register 1 (I2C_CR1) . . . 2281
51.9.2 I2C control register 2 (I2C_CR2) . . . 2284
51.9.3 I2C own address 1 register (I2C_OAR1) . . . 2286
51.9.4 I2C own address 2 register (I2C_OAR2) . . . 2286
51.9.5 I2C timing register (I2C_TIMINGR) . . . 2287
51.9.6 I2C timeout register (I2C_TIMEOUTR) . . . 2288
51.9.7 I2C interrupt and status register (I2C_ISR) . . . 2289
51.9.8 I2C interrupt clear register (I2C_ICR) . . . 2292
51.9.9 I2C PEC register (I2C_PECR) . . . 2293
51.9.10 I2C receive data register (I2C_RXDR) . . . 2293
51.9.11 I2C transmit data register (I2C_TXDR) . . . 2294
51.9.12 I2C register map . . . 2295

52 Improved inter-integrated circuit (I3C) . . . 2296
52.1 Introduction . . . 2296
52.2 I3C main features . . . 2296
52.3 I3C implementation . . . 2298
52.3.1 I3C instantiation . . . 2298
52.3.2 I3C wake-up from low-power mode(s) . . . 2298

52.3.3 I3C FIFOs . . . 2298
52.3.4 I3C triggers . . . 2298
52.3.5 I3C interrupt(s) . . . 2298
52.3.6 I3C MIPI® support . . . 2299
52.4 I3C block diagram . . . 2300
52.5 I3C pins and internal signals . . . 2300
52.6 I3C reset and clocks . . . 2301
52.6.1 I3C reset . . . 2301
52.6.2 I3C clocks and requirements . . . 2301
52.7 I3C peripheral state and programming . . . 2303
52.7.1 I3C peripheral state . . . 2303
52.7.2 I3C controller state and programming sequence . . . 2303
52.7.3 I3C target state and programming sequence . . . 2308
52.8 I3C registers and programming . . . 2312
52.8.1 I3C register set, as controller/target . . . 2312
52.8.2 I3C registers and fields use versus peripheral state, as controller . . . 2313
52.8.3 I3C registers and fields usage versus peripheral state, as target . . . 2316
52.9 I3C bus transfers and programming . . . 2318
52.9.1 I3C command set (CCCs), as controller/target . . . 2318
52.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller . . . 2322
52.9.3 I3C broadcast ENTDAA CCC transfer, as controller . . . 2324
52.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller . . . 2324
52.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target . . . 2326
52.9.6 I3C broadcast ENTDAA CCC transfer, as target . . . 2328
52.9.7 I3C broadcast DEFTGTS CCC transfer, as target . . . 2329
52.9.8 I3C broadcast DEFGRPA CCC transfer, as target . . . 2330
52.9.9 I3C direct GETSTATUS CCC response, as target . . . 2331
52.9.10 I3C private read/write transfer, as controller . . . 2332
52.9.11 I3C private read/write transfer, as target . . . 2333
52.9.12 Legacy I2C read/write transfer, as controller . . . 2334
52.9.13 I3C IBI transfer, as controller/target . . . 2335
52.9.14 I3C hot-join request transfer, as controller/target . . . 2336
52.9.15 I3C controller-role request transfer, as controller/target . . . 2337
52.10 I3C FIFOs management, as controller . . . 2338
52.10.1 C-FIFO management, as controller . . . 2338

52.10.2 TX-FIFO management, as controller 2339
52.10.3 RX-FIFO management, as controller 2342
52.10.4 S-FIFO management, as controller 2344
52.11 I3C FIFOs management, as target 2346
52.11.1 RX-FIFO management, as target 2346
52.11.2 TX-FIFO management, as target 2347
52.12 I3C error management 2350
52.12.1 Controller error management 2350
52.12.2 Target error management 2352
52.13 I3C wake-up from low-power mode(s) 2353
52.13.1 Wake-up from Stop 2353
52.14 I3C in low-power modes 2356
52.15 I3C interrupts 2357
52.16 I3C registers 2358
52.16.1 I3C message control register (I3C_CR) 2358
52.16.2 I3C message control register [alternate] (I3C_CR) 2360
52.16.3 I3C configuration register (I3C_CFGR) 2362
52.16.4 I3C receive data byte register (I3C_RDR) 2367
52.16.5 I3C receive data word register (I3C_RDWR) 2367
52.16.6 I3C transmit data byte register (I3C_TDR) 2368
52.16.7 I3C transmit data word register (I3C_TDWR) 2369
52.16.8 I3C IBI payload data register (I3C_IBIDR) 2371
52.16.9 I3C target transmit configuration register (I3C_TGTTDR) 2372
52.16.10 I3C status register (I3C_SR) 2373
52.16.11 I3C status error register (I3C_SER) 2374
52.16.12 I3C received message register (I3C_RMR) 2376
52.16.13 I3C event register (I3C_EVR) 2377
52.16.14 I3C interrupt enable register (I3C_IER) 2381
52.16.15 I3C clear event register (I3C_CEVR) 2383
52.16.16 I3C own device characteristics register (I3C_DEVR0) 2385
52.16.17 I3C device x characteristics register (I3C_DEVRx) 2387
52.16.18 I3C maximum read length register (I3C_MAXRLR) 2389
52.16.19 I3C maximum write length register (I3C_MAXWLR) 2390
52.16.20 I3C timing register 0 (I3C_TIMINGR0) 2391
52.16.21 I3C timing register 1 (I3C_TIMINGR1) 2392
52.16.22 I3C timing register 2 (I3C_TIMINGR2) 2394

52.16.23 I3C bus characteristics register (I3C_BCR) 2395
52.16.24 I3C device characteristics register (I3C_DCR) 2396
52.16.25 I3C get capability register (I3C_GETCAPR) 2397
52.16.26 I3C controller-role capability register (I3C_CRCAPR) 2398
52.16.27 I3C get max data speed register (I3C_GETMXDSR) 2399
52.16.28 I3C extended provisioned ID register (I3C_EPIDR) 2401
52.16.29 I3C register map 2402

53 Universal synchronous/asynchronous receiver transmitter (USART/UART) 2405

53.1 Introduction 2405
53.2 USART main features 2405
53.3 USART extended features 2406
53.4 USART implementation 2406
53.5 USART functional description 2408
53.5.1 USART block diagram 2408
53.5.2 USART pins and internal signals 2408
53.5.3 USART clocks 2410
53.5.4 USART character description 2410
53.5.5 USART FIFOs and thresholds 2413
53.5.6 USART transmitter 2413
53.5.7 USART receiver 2416
53.5.8 USART baud rate generation 2423
53.5.9 Tolerance of the USART receiver to clock deviation 2425
53.5.10 USART auto baud rate detection 2426
53.5.11 USART multiprocessor communication 2428
53.5.12 USART Modbus communication 2430
53.5.13 USART parity control 2431
53.5.14 USART LIN (local interconnection network) mode 2432
53.5.15 USART synchronous mode 2434
53.5.16 USART single-wire half-duplex communication 2438
53.5.17 USART receiver timeout 2438
53.5.18 USART smartcard mode 2439
53.5.19 USART IrDA SIR ENDEC block 2443
53.5.20 Continuous communication using USART and DMA 2446
53.5.21 RS232 hardware flow control and RS485 driver enable 2448
53.5.22 USART low-power management 2451

53.6 USART in low-power modes 2454
53.7 USART interrupts 2454
53.8 USART registers 2457
53.8.1 USART control register 1 (USART_CR1) 2457
53.8.2 USART control register 1 [alternate] (USART_CR1) 2461
53.8.3 USART control register 2 (USART_CR2) 2464
53.8.4 USART control register 3 (USART_CR3) 2468
53.8.5 USART control register 3 [alternate] (USART_CR3) 2472
53.8.6 USART baud rate register (USART_BRR) 2476
53.8.7 USART guard time and prescaler register (USART_GTPR) 2476
53.8.8 USART receiver timeout register (USART_RTOR) 2477
53.8.9 USART request register (USART_RQR) 2478
53.8.10 USART interrupt and status register (USART_ISR) 2479
53.8.11 USART interrupt and status register [alternate] (USART_ISR) 2485
53.8.12 USART interrupt flag clear register (USART_ICR) 2490
53.8.13 USART receive data register (USART_RDR) 2491
53.8.14 USART transmit data register (USART_TDR) 2492
53.8.15 USART prescaler register (USART_PRESC) 2492
53.8.16 USART register map 2493

54 Low-power universal asynchronous receiver transmitter (LPUART) 2495
54.1 Introduction 2495
54.2 LPUART main features 2495
54.3 LPUART implementation 2496
54.4 LPUART functional description 2498
54.4.1 LPUART block diagram 2498
54.4.2 LPUART pins and internal signals 2499
54.4.3 LPUART clocks 2500
54.4.4 LPUART character description 2500
54.4.5 LPUART FIFOs and thresholds 2502
54.4.6 LPUART transmitter 2502
54.4.7 LPUART receiver 2506
54.4.8 LPUART baud rate generation 2510
54.4.9 Tolerance of the LPUART receiver to clock deviation 2511
54.4.10 LPUART multiprocessor communication 2512
54.4.11 LPUART parity control 2514

54.4.12 LPUART single-wire half-duplex communication 2515
54.4.13 Continuous communication using DMA and LPUART 2515
54.4.14 RS232 hardware flow control and RS485 driver enable 2518
54.4.15 LPUART low-power management 2520
54.5 LPUART in low-power modes 2523
54.6 LPUART interrupts 2524
54.7 LPUART registers 2525
54.7.1 LPUART control register 1 (LPUART_CR1) 2525
54.7.2 LPUART control register 1 [alternate] (LPUART_CR1) 2528
54.7.3 LPUART control register 2 (LPUART_CR2) 2531
54.7.4 LPUART control register 3 (LPUART_CR3) 2533
54.7.5 LPUART control register 3 [alternate] (LPUART_CR3) 2536
54.7.6 LPUART baud rate register (LPUART_BRR) 2539
54.7.7 LPUART request register (LPUART_RQR) 2539
54.7.8 LPUART interrupt and status register (LPUART_ISR) 2540
54.7.9 LPUART interrupt and status register [alternate] (LPUART_ISR) . . . 2544
54.7.10 LPUART interrupt flag clear register (LPUART_ICR) 2547
54.7.11 LPUART receive data register (LPUART_RDR) 2548
54.7.12 LPUART transmit data register (LPUART_TDR) 2549
54.7.13 LPUART prescaler register (LPUART_PRESC) 2549
54.7.14 LPUART register map 2550

55 Serial peripheral interface (SPI) 2552
55.1 Introduction 2552
55.2 SPI main features 2552
55.3 SPI implementation 2553
55.4 SPI functional description 2554
55.4.1 SPI block diagram 2554
55.4.2 SPI pins and internal signals 2555
55.4.3 SPI communication general aspects 2556
55.4.4 Communications between one master and one slave 2556
55.4.5 Standard multislave communication 2559
55.4.6 Multimaster communication 2562
55.4.7 Slave select (SS) pin management 2562
55.4.8 Ready pin (RDY) management 2566
55.4.9 Communication formats 2566

55.4.10 Configuring the SPI . . . 2568
55.4.11 Enabling the SPI . . . 2569
55.4.12 SPI data transmission and reception procedures . . . 2570
55.4.13 Disabling the SPI . . . 2574
55.4.14 Communication using DMA (direct memory addressing) . . . 2575
55.5 SPI specific modes and control . . . 2577
55.5.1 TI mode . . . 2577
55.5.2 SPI error flags . . . 2577
55.5.3 CRC computation . . . 2581
55.6 SPI in low-power modes . . . 2582
55.7 SPI interrupts . . . 2582
55.8 I2S main features . . . 2584
55.9 I2S functional description . . . 2584
55.9.1 I2S general description . . . 2584
55.9.2 Pin sharing with SPI function . . . 2585
55.9.3 Bitfields usable in I2S/PCM mode . . . 2585
55.9.4 Slave and master modes . . . 2586
55.9.5 Supported audio protocols . . . 2586
55.9.6 Additional serial interface flexibility . . . 2592
55.9.7 Startup sequence . . . 2594
55.9.8 Stop sequence . . . 2596
55.9.9 Clock generator . . . 2597
55.9.10 Internal FIFOs . . . 2599
55.9.11 FIFO status flags . . . 2600
55.9.12 Handling of underrun situation . . . 2600
55.9.13 Handling of overrun situation . . . 2601
55.9.14 Frame error detection . . . 2602
55.9.15 DMA interface . . . 2604
55.9.16 Programing examples . . . 2604
55.10 I2S interrupts . . . 2607
55.11 SPI/I2S registers . . . 2607
55.11.1 SPI/I2S control register 1 (SPI_CR1) . . . 2607
55.11.2 SPI/I2S control register 2 (SPI_CR2) . . . 2609
55.11.3 SPI/I2S configuration register 1 (SPI_CFG1) . . . 2610
55.11.4 SPI/I2S configuration register 2 (SPI_CFG2) . . . 2613
55.11.5 SPI/I2S interrupt enable register (SPI_IER) . . . 2615

55.11.6 SPI/I2S status register (SPI_SR) . . . 2616
55.11.7 SPI/I2S interrupt/status flags clear register (SPI_IFCR) . . . 2619
55.11.8 SPI/I2S transmit data register (SPI_TXDR) . . . 2620
55.11.9 SPI/I2S receive data register (SPI_RXDR) . . . 2620
55.11.10 SPI/I2S polynomial register (SPI_CRCPOLY) . . . 2621
55.11.11 SPI/I2S transmitter CRC register (SPI_TXCRC) . . . 2621
55.11.12 SPI/I2S receiver CRC register (SPI_RXCRC) . . . 2622
55.11.13 SPI/I2S underrun data register (SPI_UDRDR) . . . 2623
55.11.14 SPI/I2S configuration register (SPI_I2SCFGR) . . . 2623
55.11.15 SPI/I2S register map . . . 2625

56 Serial audio interface (SAI) . . . 2627

56.1 Introduction . . . 2627
56.2 SAI main features . . . 2627
56.3 SAI implementation . . . 2628
56.4 SAI functional description . . . 2629
56.4.1 SAI block diagram . . . 2629
56.4.2 SAI pins and internal signals . . . 2630
56.4.3 Main SAI modes . . . 2631
56.4.4 SAI synchronization mode . . . 2632
56.4.5 Audio data size . . . 2633
56.4.6 Frame synchronization . . . 2633
56.4.7 Slot configuration . . . 2636
56.4.8 SAI clock generator . . . 2638
56.4.9 Internal FIFOs . . . 2641
56.4.10 PDM interface . . . 2643
56.4.11 AC’97 link controller . . . 2651
56.4.12 SPDIF output . . . 2653
56.4.13 Specific features . . . 2656
56.4.14 Error flags . . . 2660
56.4.15 Disabling the SAI . . . 2663
56.4.16 SAI DMA interface . . . 2663
56.5 SAI interrupts . . . 2664
56.6 SAI registers . . . 2666
56.6.1 SAI global configuration register (SAI_GCR) . . . 2666
56.6.2 SAI configuration register 1 (SAI_ACR1) . . . 2666

56.6.3 SAI configuration register 2 (SAI_ACR2) 2669
56.6.4 SAI frame configuration register (SAI_AFRCR) 2671
56.6.5 SAI slot register (SAI_ASLOTR) 2672
56.6.6 SAI interrupt mask register (SAI_AIM) 2673
56.6.7 SAI status register (SAI_ASR) 2674
56.6.8 SAI clear flag register (SAI_ACLRFR) 2676
56.6.9 SAI data register (SAI_ADR) 2677
56.6.10 SAI configuration register 1 (SAI_BCR1) 2678
56.6.11 SAI configuration register 2 (SAI_BCR2) 2680
56.6.12 SAI frame configuration register (SAI_BFRCR) 2682
56.6.13 SAI slot register (SAI_BSLOTR) 2683
56.6.14 SAI interrupt mask register (SAI_BIM) 2684
56.6.15 SAI status register (SAI_BSR) 2686
56.6.16 SAI clear flag register (SAI_BCLRFR) 2688
56.6.17 SAI data register (SAI_BDR) 2689
56.6.18 SAI PDM control register (SAI_PDMCR) 2689
56.6.19 SAI PDM delay register (SAI_PDMDLY) 2690
56.6.20 SAI register map 2692

57 SPDIF receiver interface (SPDIFRX) 2694

57.1 SPDIFRX interface introduction 2694
57.2 SPDIFRX main features 2694
57.3 SPDIFRX functional description 2694
57.3.1 SPDIFRX pins and internal signals 2695
57.3.2 S/PDIF protocol (IEC-60958) 2696
57.3.3 SPDIFRX decoder (SPDIFRX_DC) 2698
57.3.4 SPDIFRX tolerance to clock deviation 2702
57.3.5 SPDIFRX synchronization 2702
57.3.6 SPDIFRX handling 2704
57.3.7 Data reception management 2706
57.3.8 Dedicated control flow 2708
57.3.9 Reception errors 2709
57.3.10 Clocking strategy 2711
57.3.11 Symbol clock generation 2711
57.3.12 DMA interface 2713
57.3.13 Interrupt generation 2714
57.3.14 Register protection 2715

57.4 Programming procedures . . . 2715
57.4.1 Initialization phase . . . 2716
57.4.2 Handling of interrupts coming from SPDIFRX . . . 2717
57.4.3 Handling of interrupts coming from DMA . . . 2717
57.5 SPDIFRX interface registers . . . 2718
57.5.1 SPDIFRX control register (SPDIFRX_CR) . . . 2718
57.5.2 SPDIFRX interrupt mask register (SPDIFRX_IMR) . . . 2720
57.5.3 SPDIFRX status register (SPDIFRX_SR) . . . 2721
57.5.4 SPDIFRX interrupt flag clear register (SPDIFRX_IFCR) . . . 2723
57.5.5 SPDIFRX data input register (SPDIFRX_FMT0_DR) . . . 2724
57.5.6 SPDIFRX data input register (SPDIFRX_FMT1_DR) . . . 2724
57.5.7 SPDIFRX data input register (SPDIFRX_FMT2_DR) . . . 2725
57.5.8 SPDIFRX channel status register (SPDIFRX_CSR) . . . 2726
57.5.9 SPDIFRX debug information register (SPDIFRX_DIR) . . . 2726
57.5.10 SPDIFRX interface register map . . . 2727

58 Management data input/output (MDIOS) . . . 2728
58.1 MDIOS introduction . . . 2728
58.2 MDIOS main features . . . 2728
58.3 MDIOS functional description . . . 2729
58.3.1 MDIOS block diagram . . . 2729
58.3.2 MDIOS pins and internal signals . . . 2729
58.3.3 MDIOS protocol . . . 2729
58.3.4 MDIOS enabling and disabling . . . 2730
58.3.5 MDIOS data . . . 2731
58.3.6 MDIOS APB frequency . . . 2732
58.3.7 Write/read flags and interrupts . . . 2732
58.3.8 MDIOS error management . . . 2733
58.3.9 MDIOS in Stop mode . . . 2734
58.3.10 MDIOS interrupts . . . 2734
58.4 MDIOS registers . . . 2734
58.4.1 MDIOS configuration register (MDIOS_CR) . . . 2734
58.4.2 MDIOS write flag register (MDIOS_WRFR) . . . 2735
58.4.3 MDIOS clear write flag register (MDIOS_CWRFR) . . . 2736
58.4.4 MDIOS read flag register (MDIOS_RDFR) . . . 2736
58.4.5 MDIOS clear read flag register (MDIOS_CRDFR) . . . 2737

58.4.6 MDIOS status register (MDIOS_SR) 2737
58.4.7 MDIOS clear flag register (MDIOS_CLRFR) 2738
58.4.8 MDIOS input data register x (MDIOS_DINRx) 2738
58.4.9 MDIOS output data register x (MDIOS_DOUTRx) 2739
58.4.10 MDIOS register map 2739

59 Secure digital input/output MultiMediaCard interface (SDMMC) . . 2741

59.1 SDMMC main features 2741
59.2 SDMMC implementation 2741
59.3 SDMMC bus topology 2742
59.4 SDMMC operation modes 2744
59.5 SDMMC functional description 2745
59.5.1 SDMMC block diagram 2745
59.5.2 SDMMC pins and internal signals 2745
59.5.3 General description 2746
59.5.4 SDMMC adapter 2748
59.5.5 SDMMC AHB slave interface 2770
59.5.6 SDMMC AHB master interface 2771
59.5.7 AHB and SDMMC_CK clock relation 2774
59.6 Card functional description 2774
59.6.1 SD I/O mode 2774
59.6.2 CMD12 send timing 2782
59.6.3 Sleep (CMD5) 2786
59.6.4 Interrupt mode (Wait-IRQ) 2787
59.6.5 Boot operation 2788
59.6.6 Response R1b handling 2791
59.6.7 Reset and card cycle power 2792
59.7 Hardware flow control 2793
59.8 Ultra-high-speed phase I (UHS-I) voltage switch 2793
59.9 SDMMC interrupts 2796
59.10 SDMMC registers 2798
59.10.1 SDMMC power control register (SDMMC_POWER) 2798
59.10.2 SDMMC clock control register (SDMMC_CLKCR) 2799
59.10.3 SDMMC argument register (SDMMC_ARGR) 2801
59.10.4 SDMMC command register (SDMMC_CMDR) 2801
59.10.5 SDMMC command response register (SDMMC_RESPCMDR) 2803

59.10.6 SDMMC response x register (SDMMC_RESPxR) 2804
59.10.7 SDMMC data timer register (SDMMC_DTIMER) 2804
59.10.8 SDMMC data length register (SDMMC_DLENR) 2805
59.10.9 SDMMC data control register (SDMMC_DCTRL) 2806
59.10.10 SDMMC data counter register (SDMMC_DCNTR) 2807
59.10.11 SDMMC status register (SDMMC_STAR) 2808
59.10.12 SDMMC interrupt clear register (SDMMC_ICR) 2811
59.10.13 SDMMC mask register (SDMMC_MASKR) 2813
59.10.14 SDMMC acknowledgment timer register (SDMMC_ACKTIMER) . . . 2816
59.10.15 SDMMC DMA control register (SDMMC_IDMACTRLR) 2816
59.10.16 SDMMC IDMA buffer size register (SDMMC_IDMABSIZER) 2817
59.10.17 SDMMC IDMA buffer base address register (SDMMC_IDMABASER) 2818
59.10.18 SDMMC IDMA linked list address register (SDMMC_IDMALAR) . . . 2818
59.10.19 SDMMC IDMA linked list memory base register (SDMMC_IDMABAR) 2819
59.10.20 SDMMC data FIFO registers x (SDMMC_FIFORx) 2820
59.10.21 SDMMC register map 2820

60 FD controller area network (FDCAN) 2823

60.1 Introduction 2823
60.2 FDCAN main features 2825
60.3 FDCAN functional description 2826
60.3.1 FDCAN block diagram 2826
60.3.2 FDCAN pins and internal signals 2827
60.3.3 Bit timing 2828
60.3.4 Operating modes 2829
60.3.5 Error management 2838
60.3.6 Message RAM 2839
60.3.7 FIFO acknowledge handling 2848
60.3.8 FDCAN Rx FIFO element 2848
60.3.9 FDCAN Tx buffer element 2850
60.3.10 FDCAN Tx event FIFO element 2852
60.3.11 FDCAN standard message ID filter element 2853
60.3.12 FDCAN extended message ID filter element 2854
60.4 FDCAN registers 2856
60.4.1 FDCAN core release register (FDCAN_CREL) 2856

60.4.2 FDCAN endian register (FDCAN_ENDN) 2856
60.4.3 FDCAN data bit timing and prescaler register (FDCAN_DBTP) 2856
60.4.4 FDCAN test register (FDCAN_TEST) 2857
60.4.5 FDCAN RAM watchdog register (FDCAN_RWD) 2858
60.4.6 FDCAN CC control register (FDCAN_CCCR) 2859
60.4.7 FDCAN nominal bit timing and prescaler register (FDCAN_NBTP) . 2860
60.4.8 FDCAN timestamp counter configuration register (FDCAN_TSCC) . 2862
60.4.9 FDCAN timestamp counter value register (FDCAN_TSCV) 2862
60.4.10 FDCAN timeout counter configuration register (FDCAN_TOCC) . . . 2863
60.4.11 FDCAN timeout counter value register (FDCAN_TOCV) 2864
60.4.12 FDCAN error counter register (FDCAN_ECR) 2864
60.4.13 FDCAN protocol status register (FDCAN_PSR) 2865
60.4.14 FDCAN transmitter delay compensation register (FDCAN_TDCR) . . 2867
60.4.15 FDCAN interrupt register (FDCAN_IR) 2867
60.4.16 FDCAN interrupt enable register (FDCAN_IE) 2870
60.4.17 FDCAN interrupt line select register (FDCAN_ILS) 2872
60.4.18 FDCAN interrupt line enable register (FDCAN_ILE) 2873
60.4.19 FDCAN global filter configuration register (FDCAN_RXGFC) 2873
60.4.20 FDCAN extended ID and mask register (FDCAN_XIDAM) 2875
60.4.21 FDCAN high-priority message status register (FDCAN_HPMS) 2875
60.4.22 FDCAN Rx FIFO 0 status register (FDCAN_RXF0S) 2876
60.4.23 CAN Rx FIFO 0 acknowledge register (FDCAN_RXF0A) 2877
60.4.24 FDCAN Rx FIFO 1 status register (FDCAN_RXF1S) 2877
60.4.25 FDCAN Rx FIFO 1 acknowledge register (FDCAN_RXF1A) 2878
60.4.26 FDCAN Tx buffer configuration register (FDCAN_TXBC) 2878
60.4.27 FDCAN Tx FIFO/queue status register (FDCAN_TXFQS) 2879
60.4.28 FDCAN Tx buffer request pending register (FDCAN_TXBRP) 2879
60.4.29 FDCAN Tx buffer add request register (FDCAN_TXBAR) 2880
60.4.30 FDCAN Tx buffer cancellation request register (FDCAN_TXBCR) . . 2881
60.4.31 FDCAN Tx buffer transmission occurred register (FDCAN_TXBTO) 2881
60.4.32 FDCAN Tx buffer cancellation finished register (FDCAN_TXBCF) . . 2882
60.4.33 FDCAN Tx buffer transmission interrupt enable register (FDCAN_TXBTIE) 2882
60.4.34 FDCAN Tx buffer cancellation finished interrupt enable register (FDCAN_TXBCIE) 2883
60.4.35 FDCAN Tx event FIFO status register (FDCAN_TXEFS) 2883
60.4.36 FDCAN Tx event FIFO acknowledge register (FDCAN_TXEFA) . . . 2884
60.4.37 FDCAN CFG clock divider register (FDCAN_CKDIV) 2884

60.4.38 FDCAN register map 2885

61 USB on-the-go full-speed (OTG_FS) 2889

61.1 Introduction 2889

61.2 OTG_FS main features 2890

61.2.1 General features 2890

61.2.2 Host-mode features 2891

61.2.3 Peripheral-mode features 2891

61.3 OTG_FS implementation 2892

61.4 OTG_FS functional description 2893

61.4.1 OTG_FS block diagram 2893

61.4.2 OTG_FS pin and internal signals 2893

61.4.3 OTG_FS core 2894

61.4.4 Embedded full-speed OTG PHY connected to OTG_FS 2894

61.4.5 OTG detections 2895

61.5 OTG_FS dual role device (DRD) 2895

61.5.1 ID line detection 2895

61.6 OTG_FS as a USB peripheral 2896

61.6.1 Peripheral states 2896

61.6.2 Peripheral endpoints 2897

61.7 OTG_FS as a USB host 2899

61.7.1 USB host states 2900

61.7.2 Host channels 2901

61.7.3 Host scheduler 2903

61.8 OTG_FS SOF trigger 2904

61.8.1 Host SOFs 2904

61.8.2 Peripheral SOFs 2904

61.9 OTG_FS low-power modes 2905

61.10 OTG_FS Dynamic update of the OTG_HFIR register 2906

61.11 OTG_FS data FIFOs 2906

61.11.1 Peripheral FIFO architecture 2907

61.11.2 Host FIFO architecture 2908

61.11.3 FIFO RAM allocation 2909

61.12 OTG_FS system performance 2911

61.13 OTG_FS interrupts 2911

61.14 OTG_FS control and status registers 2913
61.14.1 CSR memory map 2913
61.15 OTG_FS registers 2918
61.15.1 OTG control and status register (OTG_GOTGCTL) 2918
61.15.2 OTG interrupt register (OTG_GOTGINT) 2920
61.15.3 OTG AHB configuration register (OTG_GAHBCFG) 2921
61.15.4 OTG USB configuration register (OTG_GUSBCFG) 2922
61.15.5 OTG reset register (OTG_GRSTCTL) 2923
61.15.6 OTG core interrupt register [alternate] (OTG_GINTSTS) 2926
61.15.7 OTG core interrupt register [alternate] (OTG_GINTSTS) 2930
61.15.8 OTG interrupt mask register [alternate] (OTG_GINTMSK) 2934
61.15.9 OTG interrupt mask register [alternate] (OTG_GINTMSK) 2935
61.15.10 OTG receive status debug read [alternate] (OTG_GRXSTSR) 2937
61.15.11 OTG receive status debug read register [alternate] (OTG_GRXSTSR) 2938
61.15.12 OTG status read and pop registers [alternate] (OTG_GRXSTSP) . . 2939
61.15.13 OTG status read and pop registers [alternate] (OTG_GRXSTSP) . . 2940
61.15.14 OTG receive FIFO size register (OTG_GRXFSIZ) 2941
61.15.15 OTG host non-periodic transmit FIFO size register [alternate] (OTG_HNPTXFSIZ) 2942
61.15.16 Endpoint 0 Transmit FIFO size [alternate] (OTG_DIEPTXF0) 2942
61.15.17 OTG non-periodic transmit FIFO/queue status register (OTG_HNPTXSTS) 2943
61.15.18 OTG general core configuration register (OTG_GCCFG) 2944
61.15.19 OTG core ID register (OTG_CID) 2945
61.15.20 OTG core LPM configuration register (OTG_GLPMCFG) 2945
61.15.21 OTG host periodic transmit FIFO size register (OTG_HPTXFSIZ) 2950
61.15.22 OTG device IN endpoint transmit FIFO x size register (OTG_DIEPTXFx) 2950
61.15.23 Host-mode registers 2950
61.15.24 OTG host configuration register (OTG_HCFG) 2951
61.15.25 OTG host frame interval register (OTG_HFIR) 2951
61.15.26 OTG host frame number/frame time remaining register (OTG_HFNUM) 2952
61.15.27 OTG_Host periodic transmit FIFO/queue status register (OTG_HPTXSTS) 2953
61.15.28 OTG host all channels interrupt register (OTG_HAINT) 2954

61.15.29 OTG host all channels interrupt mask register (OTG_HAINTMSK) 2954
61.15.30 OTG host port control and status register (OTG_HPRT) 2955
61.15.31 OTG host channel x characteristics register (OTG_HCCHARx) 2957

1 Documentation conventions

1.1 General information

STM32H7Rx/7Sx devices have an Arm®(a) Cortex®-M7 with FPU core.

1.2 List of abbreviations for registers

The following abbreviations(b) are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.
read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.
OBKey	Option byte keys

a. Arm is a registered trademark of Arm Limited (or its subsidiaries) in the US and/or elsewhere.

b. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

1.3 Register reset value

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bits nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

1.5 Availability of peripherals

For availability of peripherals and their number across all devices, refer to the particular device datasheet.

1.6 Availability of security features

For security feature availability refer to the table below:

Table 1. Availability of security features

<table>
<tr><th>Security feature</th><th>STM32H7S3x8
STM32H7S7x8</th><th>STM32H7R3x8
STM32H7R7x8</th></tr>
<tr><td>Embedded flash memory (FLASH):
– Flash Secure-only area</td><td rowspan="6">Available</td><td rowspan="2">Available</td></tr>
<tr><td>Security memory management:
– Root secure services (RSS)</td></tr>
<tr><td>On-the-fly encryption / decryption</td><td rowspan="3">Not available</td></tr>
<tr><td>STiRoT</td></tr>
<tr><td>Cryptographic processor (CRYP and PKA)</td></tr>
<tr><td>Hash processor (HASH) with PKA verification always available</td><td>Available</td></tr>
</table>

2 Memory and bus architecture

2.1 System architecture

The STM32H7Rx/7Sx architecture relies on a Arm Cortex-M7 core optimized for execution by means of Cache, TCM, AXI, and an AHB bus matrix. This architecture also features a 64-bit AXI, an 32-bit multilayer AHB bus matrix, and bus bridges allow interconnection of bus masters with bus slaves, as shown in *Table 2: Bus-master-to-bus-slave interconnect*.

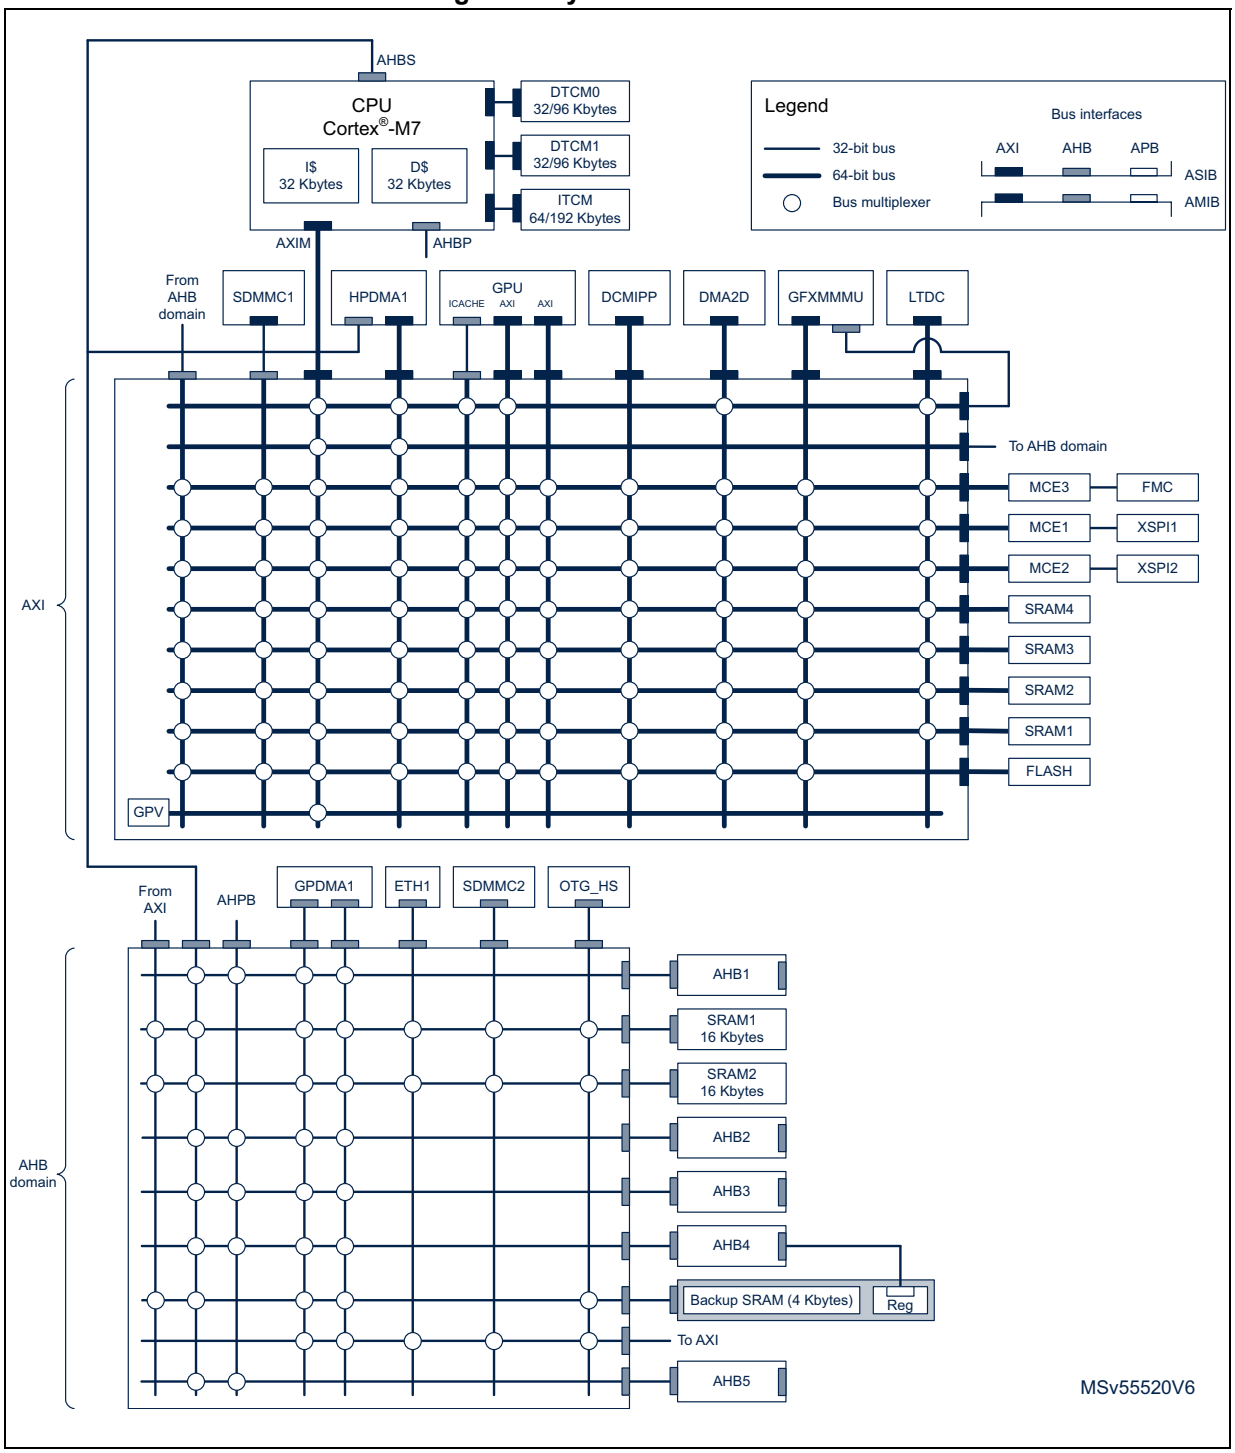

Table 2. Bus-master-to-bus-slave interconnect

1. **Bold** font type denotes 64-bit bus, plain type denotes 32-bit bus.
2. “X” = access possible, “-” = access not possible.
3. Every transfer can be done in 64 bits
4. Refer to *Table 102: Programmed HPDMA1 request* for the AHB/APB peripheral request.
5. Refer to *Table 94: Programmed GPDMA1 trigger*

The bus matrix provides access from a master to a slave, enabling concurrent access and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in the figure below.

Figure 1. System architecture

2.1.1 Bus matrices

AXI bus matrix

The multi AXI bus matrix ensures and arbitrates concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm with QoS capability.

Refer to *Section 2.2: AXI interconnect matrix (AXIM)* for more information on AXI interconnect.

AHB bus matrices

The AHB bus matrices ensure and arbitrate concurrent accesses from multiple masters to multiple slaves. This allows efficient simultaneous operation of high-speed peripherals.

The arbitration uses a round-robin algorithm.

2.1.2 Bus-to-bus bridges

To allow peripherals with different types of buses to communicate together, there is a number of bus-to-bus bridges in the system.

The AHB/APB bridges allow connecting peripherals on APB1, APB2, APB4, APB5 to AHB1, AHB2, AHB4 and AHB5, respectively. These AHB/APB bridges provide full synchronous interfacing, which allows the APB peripherals to operate with clocks independent of AHB that they connect to.

The AHB/APB bridges also allow APB1, APB2 and APB4 peripherals to connect to GPDMA1 peripheral buses, without transiting through the AHB BUS.

The AHB/APB bridges convert 8-bit / 16-bit APB data to 32-bit AHB data, by replicating it to the three upper bytes / the upper half-word of the 32-bit word.

The AXI bus matrix incorporates AHB/AXI bus bridge functionality on its slave bus interfaces. The AXI/AHB bus bridges on its master interfaces marked as 32-bit in *Figure 1: System architecture*are outside the matrix.

The Cortex-M7 CPU provides AHB/TCM-bus (ITCM and DTCM buses) translation from its AHBS slave AHB, allowing the HPDMA controller to access the ITCM and DTCM.

Note: When a 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.1.3 TCM-buses

The DTCM and ITCM (data and instruction tightly coupled RAMs) are connected through dedicated TCM buses directly to the Cortex-M7 core. The HPDMA controller can access the DTCM and ITCM through AHBS, a specific CPU slave AHB. The DTCM and ITCM are accessed by Cortex-M7 at CPU clock speed, with zero wait states.

2.1.4 CPU buses

Cortex-M7 AXIM bus

The Cortex-M7 CPU uses the 64-bit AXIM bus to access all memories (excluding ITCM, and DTCM)

The AXIM bus connects the CPU to the AXI bus matrix in the core domain.

Cortex-M7 ITCM bus

The Cortex-M7 CPU uses the 64-bit ITCM bus for fetching instructions from and accessing data in the ITCM.

Cortex-M7 DTCM bus

The Cortex-M7 CPU uses the 2x32-bit DTCM bus for accessing data in the DTCM. The 2x32-bit DTCM bus allows load/load and load/store instruction pairs to be dual-issued on the DTCM memory. It can also fetch instructions.

Cortex-M7 AHBS bus

The Cortex-M7 CPU uses the 32-bit AHBS slave bus to allow the HPDMA controller to access the ITCM and the DTCM.

Cortex-M7 AHBP bus

The Cortex-M7 CPU uses the 32-bit AHBP bus for accessing AHB1, AHB2, AHB3, AHB4, APB1, APB2 and APB4 peripherals via the AHB bus matrix.

2.1.5 Bus master peripherals

SDMMC1-bus

The SDMMC1 uses a 32-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and Flash memories, and external memories through the XSPIs controller and the FMC.

SDMMC2-bus

The SDMMC2 uses a 32-bit bus, connected to the AHB bus matrix. Through the system bus matrices, it can access the internal AXI SRAM, SRAM1, SRAM2, SRAM3 SRAM4, backup RAM, Flash memory, and external memories through the XSPIs controller and the FMC.

HPDMA-bus

The HPDMA controller has two bus masters: an AXI 64-bit bus, connected to the AXI bus matrix and an AHB 32-bit bus connected to the Cortex-M7 AHBS slave bus.

The HPDMA is optimized for DMA data transfers between memories since it supports linked list transfers that allow performing a chained list of transfers without the need for CPU intervention. Through the system bus matrices and the Cortex-M7 AHBS slave bus, the HPDMA can access all internal and external memories through the CTOSPIs controller and the FMC.

GPDMA-bus

The GPDMA controller has two 32-bit AHB bus masters connected to the AHB bus matrix.

The memory bus allows the GPDMA data transfers between memories. Through the system bus matrices, the memory bus can access all internal memories except ITCM and DTCM, and external memories through the XSPIs controller and the FMC. It also supports linked list transfers

The peripheral bus allows the GPDMA data transfers between two peripherals, between two memories or between a peripheral and a memory. Through the system bus matrices, the peripheral bus can access all internal memories except ITCM and DTCM, external memories through the XSPIs controller and the FMC, and all AHB and APB peripherals. A direct access to APB1 and APB2 is available, without passing through AHB1.

DMA2D-bus (Chrom-Art Accelerator)

The DMA2D graphics accelerator uses a 64-bit bus, connected to the AXI bus matrix. Through the system bus matrices, internal AXI SRAM, SRAM1, SRAM2, SRAM3, SRAM4 Flash memories and external memories through the XSPIs controller and the FMC.

LTDC-bus (LCD-TFT controller)

The LCD-TFT display controller, LTDC, uses a 64-bit bus, connected to the AXI bus matrix, through which it can access internal AXI SRAM and external memories through the XSPIs controller and the FMC.

Ethernet MAC-bus

The Ethernet MAC uses a 32-bit bus, connected to the AHB bus matrix. Through the system bus matrices, it can access all internal memories except backup RAM, ITCM, DTCM it can also access external memories, through the XSPIs controller and the FMC.

USB OTG-bus

The USBHS1 peripheral uses 32-bit buses, connected to the AHB bus matrix. Through the system bus matrices, it can access all internal memories except backup RAM, ITCM, DTCM and it access the external memories, through the XSPIs controller and the FMC.

2.1.6 GPU2D-bus

These buses connect the GPU2D master interfaces to the bus matrix. These buses are used to load/store data from/to the memory. These buses target the GFXMMU in addition to the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3 and SRAM4) and external memories through FMC, XSPIs. A 16-Kbyte data cache (ICACHE) is present on the GPU2D M0 bus in order to improve performances.

2.1.7 GFXMMU-bus

This bus connects the GFXMMU master interface to the bus matrix. This bus is used only by the GFXMMU to load/store data from/to the memory. This bus targets the data memories: internal Flash memory, internal SRAMs (SRAM1, SRAM2, SRAM3 and SRAM4) and external memories through FMC, XSPIs. The GFXMMU has also a slave bus connection to be accessed by graphical peripheral master buses.

2.1.8 Clocks to functional blocks

Upon reset, clocks to blocks such as peripherals and some memories are disabled (except for the SRAM, DTCM, ITCM and Flash memory). To operate a block with no clock upon reset, the software must first enable its clock through RCC_AHBxENR or RCC_APBxENR register, respectively.

2.2 AXI interconnect matrix (AXIM)

2.2.1 AXI introduction

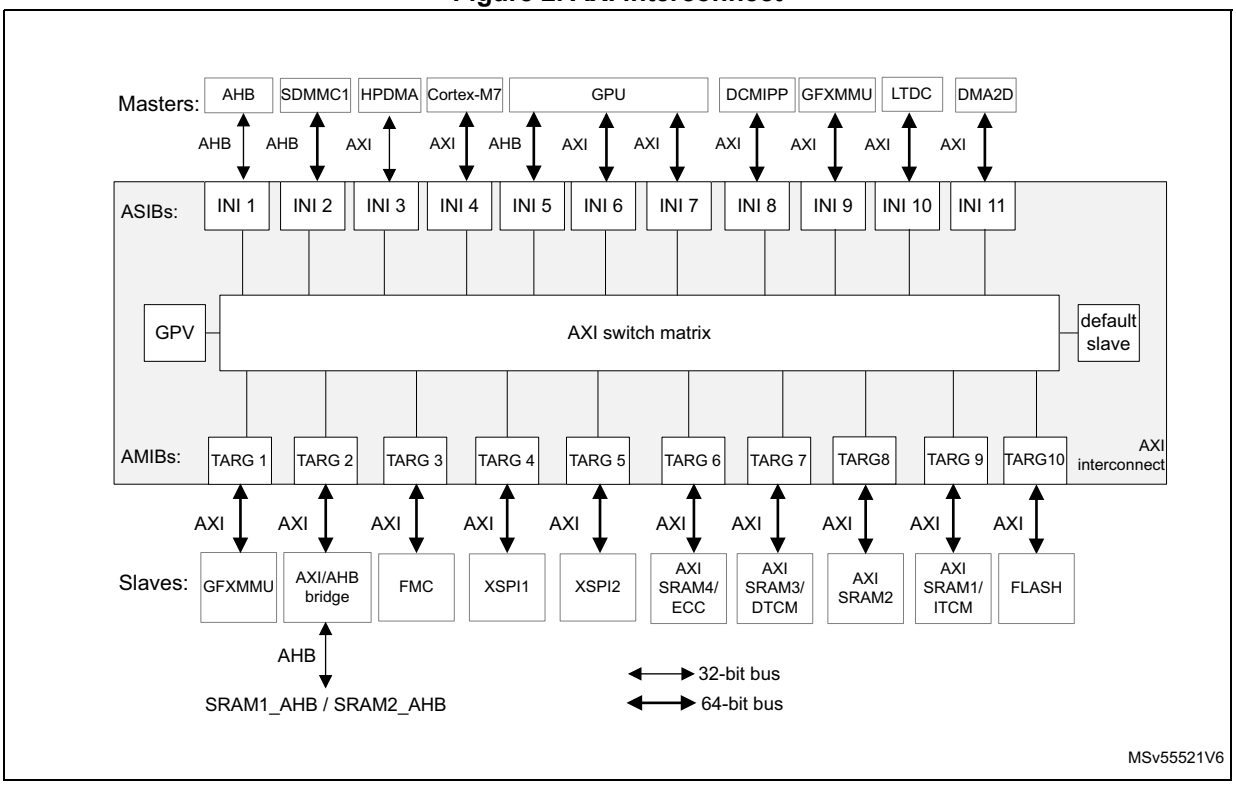
The AXI (advanced extensible interface) interconnect is based on the Arm® CoreLink™ NIC-400 Network Interconnect. The interconnect has eleven initiator ports, or ASIBs (AMBA slave interface blocks), and ten target ports, or AMIBs (AMBA master interface blocks). The ASIBs are connected to the AMIBs via an AXI switch matrix.

Each ASIB is a slave on an AXI bus or AHB (advanced high-performance bus). Similarly, each AMIB is a master on an AXI or AHB bus. Where an ASIB or AMIB is connected to an AHB, it converts between the AHB and the AXI protocol.

The AXI interconnect includes a GPV (global programmer view) which contains registers for configuring certain parameters, such as the QoS (quality of service) level at each ASIB.

Any accesses to unallocated address space are handled by the default slave, which generates the return signals. This ensures that such transactions complete and do not block the issuing master and ASIB.

2.2.2 AXI interconnect main features



- 64-bit AXI bus switch matrix with eleven ASIBs and ten AMIBs
- AHB/AXI bridge function built into the ASIBs
- concurrent connectivity of multiple ASIBs to multiple AMIBs
- programmable traffic priority management (QoS - quality of service)
- software-configurable via GPV

2.2.3 AXI interconnect functional description

Block diagram

The AXI interconnect is shown in *Figure 2*.

Figure 2. AXI interconnect

ASIB configuration

Table 3 summarizes the characteristics of the ASIBs.

Table 3. ASIB configuration

ASIB	Connected master	Protocol	Bus width	R/W issuing
INI 1	AHB from AHB peipherals	AHB-lite	32	1/1
INI 2	SDMMC1	AHB-lite	32	1/1
INI 3	HPDMA	AXI4	64	8/8
INI 4	Cortex-M7	AXI4	64	7/32
INI 5	GPU	AHB	64	1/1

AMIB configuration

Table 4 summarizes the characteristics of the AMIBs.

Table 4. AMIB configuration

AMIB	Connected slave	Protocol	Bus width	R/W/Total acceptance
TARG 1	GFXMMU	AXI4	64	2/2/4
TARG 2	AHB Sram	AXI4(1)	32	1/1/2
TARG 3	FMC	AXI4	64	1/1/2
TARG 4	XSPI1	AXI4	64	1/1/2
TARG 5	XSPI2	AXI4	64	1/1/2
TARG 6	AXI SRAM(2)	AXI4	64	2/2/4
TARG 7	AXI SRAM(3)	AXI4	64	2/2/4
TARG 8	AXI SRAM	AXI4	64	2/2/4
TARG 9	AXI SRAM(4)	AXI4	64	2/2/4
TARG 10	FLASH	AXI4	64	2/2/4

1. Conversion to AHB protocol is done via an AXI/AHB bridge sitting between AXI interconnect and the connected slave.
2. SRAM shared with the ECC (*Table 11: SRAM4 / ECC configurations*)
3. SRAM shared with the DTCM (*SRAM3 / DTCM configurations*)
4. SRAM shared with the ITCM (*SRAM1 / ITCM configurations*)

Quality of service (QoS)

The AXI switch matrix uses a priority-based arbitration when two ASIB simultaneously attempt to access the same AMIB. Each ASIB has programmable read channel and write channel priorities, known as QoS, from 0 to 15, such that the higher the value, the higher the priority. The read channel QoS value is programmed in the *AXI interconnect - INI x read QoS register (AXI_INIx_READ_QOS)*, and the write channel in the *AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS)*. The default QoS value for all channels is 0 (lowest priority).

If two coincident transactions arrive at the same AMIB, the higher priority transaction passes before the lower priority. If the two transactions have the same QoS value, then a least-recently-used (LRU) priority scheme is adopted.

The QoS values should be programmed according to the latency requirements for the application. Setting a higher priority for an ASIB ensures a lower latency for transactions initiated by the associated bus master. This can be useful for real-time-constrained tasks, such as graphics processing (LTDC, DMA2D). Assigning a high priority to masters that can make many and frequent accesses to the same slave (such as the Cortex-M7 CPU) can block access to that slave by other lower-priority masters.

Global programmer view (GPV)

The GPV contains configuration registers for the AXI interconnect. These registers are only accessible by the Cortex-M7 CPU.

2.2.4 AXI interconnect registers

AXI interconnect - peripheral ID4 register (AXI_PERIPH_ID_4)

Address offset: 0x1FD0

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WRITE_ISS_OVERRIDE**: Switch matrix write issuing override for target
- 0: Normal issuing capability
- 1: Set switch matrix write issuing capability to 1

Bit 0 **READ_ISS_OVERRIDE**: Switch matrix read issuing override for target
- 0: Normal issuing capability
- 1: Set switch matrix read issuing capability to 1

AXI interconnect - TARG x issuing functionality modification register (AXI_TARGx_FN_MOD)

Address offset: 0x1108+ 0x1000 * x, (x = 1 to 10)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WRITE_ISS_OVERRIDE**: Override AMIB write issuing capability
- 0: Normal issuing capability
- 1: Force issuing capability to 1

Bit 0 **READ_ISS_OVERRIDE**: Override AMIB read issuing capability
- 0: Normal issuing capability
- 1: Force issuing capability to 1

AXI interconnect - TARG x bus matrix functionality 2 register (AXI_TARG2_FN_MOD2)

Address offset: 0x3024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS_MERGE
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS_MERGE**: Disable packing of beats to match the output data width. Unaligned transactions are not realigned to the input data word boundary.

0: Normal operation

1: Disable packing

AXI interconnect - TARG x long burst functionality modification register (AXI_TARG2_FN_MOD_LB)

Address offset: 0x302C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FN_MOD_LB
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **FN_MOD_LB**: Controls burst breaking of long bursts

0: Long bursts can not be generated at the output of the AMIB

1: Long bursts can be generated at the output of the AMIB

AXI interconnect - INIx issuing functionality modification register (AXI_INIx_FN_MOD)

Address offset: 0x41108+ 0x10000 * x, (x = 1 to 11)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRITE_ISS_OVERRIDE	READ_ISS_OVERRIDE
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **WRITE_ISS_OVERRIDE**: Override ASIB write issuing capability
0: Normal issuing capability
1: Force issuing capability to 1

Bit 0 **READ_ISS_OVERRIDE**: Override ASIB read issuing capability
0: Normal issuing capability
1: Force issuing capability to 1

AXI interconnect - INI x write QoS register (AXI_INIx_WRITE_QOS)

Address offset: 0x41104 + 0x1000 * x, (x = 1 to 11)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

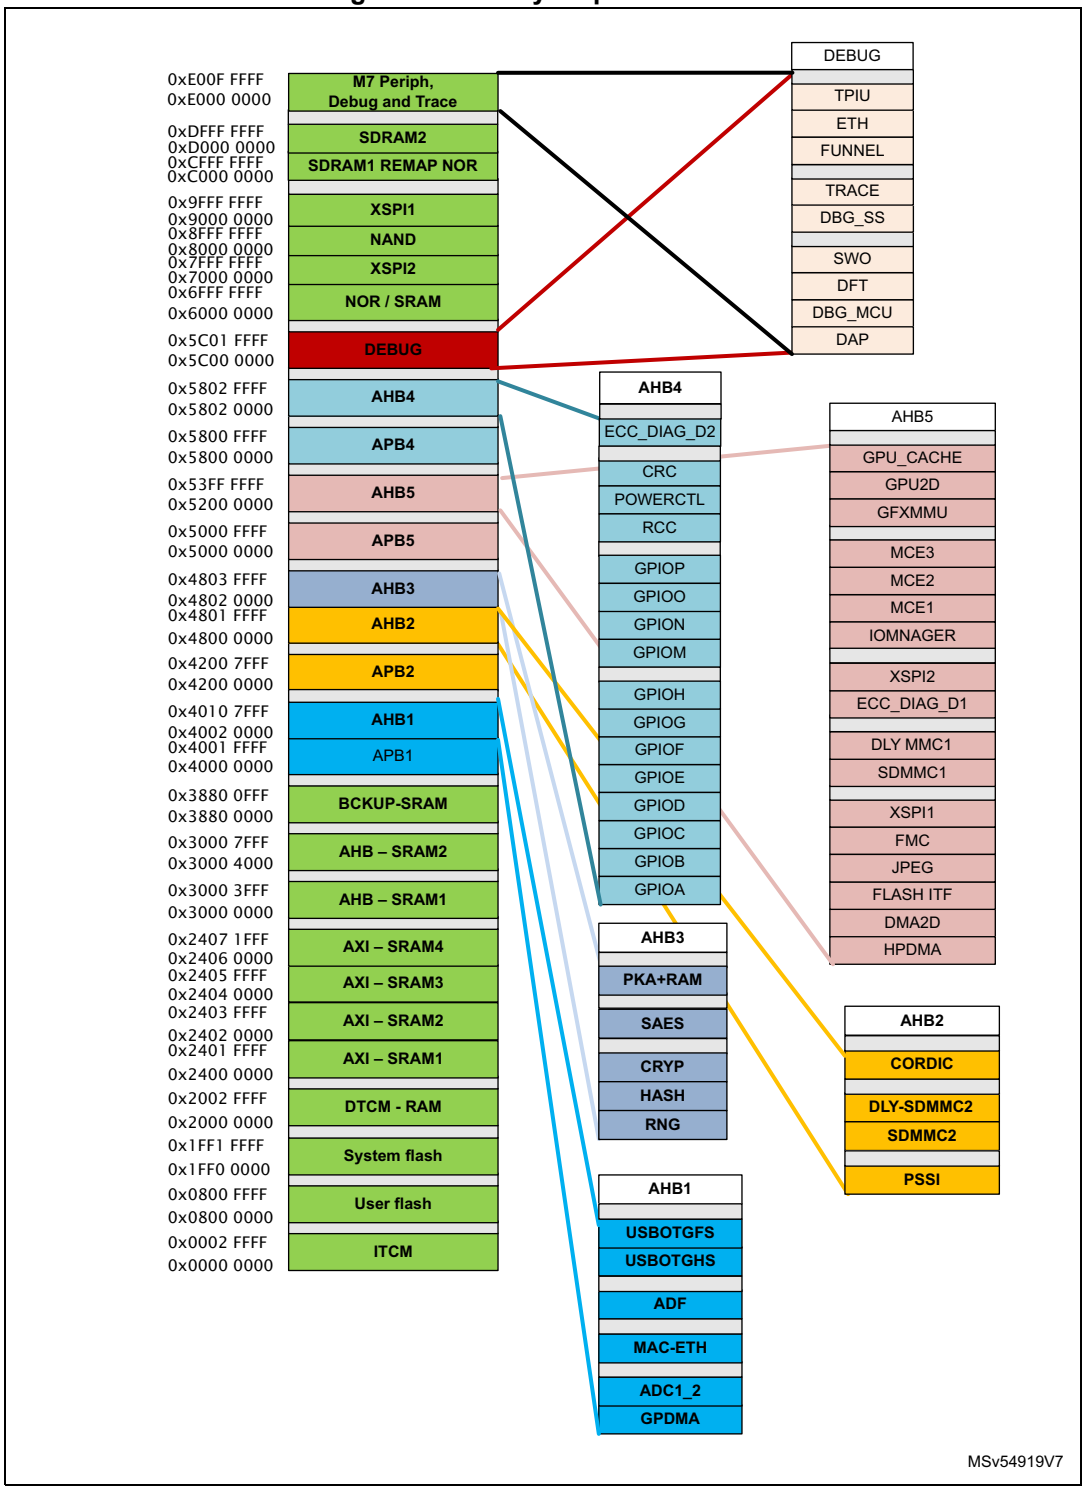
2.3 Memory organization



2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear 4-Gbyte address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 3. Memory map

All the memory map areas that are not allocated to on-chip memories and peripherals are considered “Reserved”. For the detailed mapping of available memory and register areas, refer to the following table.

The following tables gives, the default memory attribute and the boundary addresses of the peripherals available in the devices.

Table 6. Memory map and default device memory area attribute

Region	Boundary address	Arm® Cortex®-M7	Type	Attributes	Execute never
External Devices	0xD0000000 - 0xDFFFFFFF	Bank 2	Device	-	Yes
	0xC0000000 - 0xCFFFFFFF	FMC SDRAM Bank1 (or remap FMC NOR/PSRAM/SRAM 1/2 Bank1)			
	0xBFF00000 - 0xBFFFFFFF	GPV/AXIM			
	0xA0000000 - 0xBFF00000	Reserved			
External Memories	0x90000000 - 0x9FFFFFFF	XSPI1	Normal	Write-through cache attribute	No
	0x80000000 - 0x8FFFFFFF	FMC NAND Flash memory			
	0x70000000 - 0x7FFFFFFF	XSPI2		Write-back, write allocate cache attribute	
	0x60000000 - 0x6FFFFFFF	FMC NOR/PSRAM/SRAM 1 Bank1 (or remap of FMC SDRAM Bank1)			
Peripherals	0x40000000 - 0x5FFFFFFF	Peripherals. See *Table 7: Register boundary addresses*.	Device	-	Yes
RAM	0x38801000 - 0x3FFFFFFF	Reserved	Normal	Write-back, write allocate cache attribute	No
	0x38800000 - 0x38800FFF	Backup SRAM			
	0x38008000 - 0x387FFFFF	Reserved			
	0x30004000 - 0x30007FFF	SRAM2			
	0x30000000 - 0x30003FFF	SRAM1			
	0x24072000 - 0x2FFFFFFF	Reserved			
	0x24060000 - 0x24071FFF	AXI SRAM shared with ECC			
	0x24040000 - 0x2405FFFF	AXI SRAM shared with DTCM			
	0x24020000 - 0x2403FFFF	AXI SRAM			
	0x24000000 - 0x2401FFFF	AXI SRAM shared with ITCM			
	0x20030000 - 0x23FFFFFF	Reserved			
	0x20000000 - 0x2002FFFF	DTCM - RAM			

Table 6. Memory map and default device memory area attribute

Region	Boundary address	Arm® Cortex®-M7	Type	Attributes	Execute never
Code	0x1FF20000 - 0x1FFFFFFF	Reserved	Normal	Write-through cache attribute	No
	0x1FF00000 - 0x1FF1FFFF	System flash memory			
	0x90000000 - 0x1FEFFFFF	Reserved			
	0x08FFF800 - 0x08FFFFFF	Flash Read Only (ID, Trim, Stack ID)			
	0x08FFF400 - 0x08FFF7FF	Reserved			
	0x08FF0000 - 0x08FFF3FF	User OTP (Flash)			
	0x08010000 - 0x08FFEFFF	Reserved			
	0x08000000 - 0x0800FFFF	User flash memory bank 1			
	0x00010000 - 0x07FFFFFF	Reserved			
	0x00000000 - 0x0002FFFF	ITCM RAM			

Table 7. Register boundary addresses(1)

Boundary address	Peripheral	Bus	Registers
0x58028000 - 0x5BFFFFFF	Reserved	AHB4	Reserved
0x58027000 - 0x58027FFF	ECC_DIAG_D2		*RAMECC registers*
0x58025000 - 0x58026FFF	Reserved		Reserved
0x58024C00 - 0x58024FFF	CRC		*CRC registers*
0x58024800 - 0x58024BFF	PWR		*PWR registers*
0x58024400 - 0x580247FF	RCC		*RCC registers*
0x58024000 - 0x580243FF	Reserved		Reserved
0x58023C00 - 0x58023FFF	GPIOP		*GPIO registers*
0x58023800 - 0x58023BFF	GPIOO		
0x58023800 - 0x58023BFF	GPION		
0x58023000 - 0x580233FF	GPIOM		
0x58022000 - 0x58022FFF	Reserved		Reserved
0x58021C00 - 0x58021FFF	GPIOH		*GPIO registers*
0x58021800 - 0x58021BFF	GPIOG		
0x58021400 - 0x580217FF	GPIOF		
0x58021000 - 0x580213FF	GPIOE		
0x58020C00 - 0x58020FFF	GPIOD		
0x58020800 - 0x58020BFF	GPIOC		
0x58020400 - 0x580207FF	GPIOB		
0x58020000 - 0x580203FF	GPIOA		

Table 7. Register boundary addresses(1) (continued)

Boundary address	Peripheral	Bus	Registers
0x58006C00 - 0x5801FFFF	Reserved	APB4	Reserved
0x58006800 - 0x58006BFF	DTS		*DTS registers*
0x58004C00 - 0x580067FF	Reserved		Reserved
0x58004800 - 0x58004BFF	IWDG		*IWDG registers*
0x58004400 - 0x580047FF	TAMP		*TAMP registers*
0x58004000 - 0x580043FF	RTC		*RTC registers*
0x58003C00 - 0x58003FFF	VREFBUF		*VREFBUF registers*
0x58003400 - 0x58003BFF	Reserved		Reserved
0x58003000 - 0x580033FF	LPTIM5		*LPTIM registers*
0x58002C00 - 0x58002FFF	LPTIM4		
0x58002800 - 0x58002BFF	LPTIM3		
0x58002400 - 0x580027FF	LPTIM2

0x40001800 - 0x40001BFF	TIM12 (Light)		
0x40001400 - 0x400017FF	TIM7 (Basic)		*TIM6/TIM7 registers*

Table 7. Register boundary addresses(1) (continued)

Boundary address	Peripheral	Bus	Registers
0x40001000 - 0x400013FF	TIM6 (Basic)	APB1	*TIM6/TIM7 registers*
0x40000C00 - 0x40000FFF	TIM5 (32b)		*TIM2/TIM3/TIM4/TIM5 registers*
0x40000800 - 0x40000BFF	TIM4 (32b)		
0x40000400 - 0x400007FF	TIM3 (32b)		
0x40000000 - 0x400003FF	TIM2 (32b)		

1. Accessing a reserved area results in a bus error. Accessing undefined memory space in a peripheral returns zeros.

2.4 Embedded SRAM

The STM32H7Rx/7Sx devices include up to 456 Kbytes of AXI-SRAM mapped onto the AXI bus divided and shared as described in the following section.

- Up to 192 Kbytes of instruction TCM RAM *Table 9: SRAM1 / ITCM configurations*. This feature can be configured through the ITCM_AXI_SHARE[1:0] option byte in FLASH_OBW2SRP register as described in the *FLASH option byte word 2 status register (FLASH_OBW2SR)*
- Up to 192 Kbytes of data TCM RAM *Table 10: SRAM3 / DTCM configurations*. This feature can be configured through the DTCM_AXI_SHARE[1:0] option byte in described in the *FLASH option byte word 2 status register (FLASH_OBW2SR)*.
- Up to 72 Kbytes when ECC is disabled *Table 11: SRAM4 / ECC configurations*. This feature can be configured through the ECC_ON_SRAM option byte in FLASH_OBW2SRP register as described in the *FLASH option byte word 2 status register (FLASH_OBW2SR)*.
- 16 Kbyte AHB_SRAM1
- 16 Kbyte AHB_SRAM2

The system AHB SRAM can be accessed as bytes, half-words (16-bit units) or words (32-bit units), while the system AXI SRAM can be accessed as bytes, half-words, words or double-words (64-bit units). These memories can be addressed at maximum system clock frequency without wait state.

The AHB masters can read/write-access an SRAM section concurrently with the Ethernet MAC or the USB OTG HS peripheral accessing another SRAM section. For example, the Ethernet MAC accesses the SRAM2 while the CPU accesses the SRAM1, concurrently.

The TCM SRAMs are dedicated to the Cortex®-M7:

- DTCM-RAM on TCM interface is mapped at the address 0x2000 0000 and accessible by Cortex®-M7, and by HPDMA through AHBS slave bus of the Cortex®-M7 CPU. The DTCM-RAM can be used as read-write segment to host critical real-time data (such as stack and heap) for application running on Cortex®-M7 CPU.
- ITCM-RAM on TCM interface mapped at the address 0x0000 0000 and accessible by Cortex®-M7 and by HPDMA through AHBS slave bus of the Cortex®-M7 CPU. The ITCM-RAM can be used to host code for time-critical routines (such as interrupt handlers) that requires deterministic execution.

The backup RAM is mapped at the address 0x3880 0000 and is accessible by most of the system masters. With a battery connected to the V_{BAT} pin, the backup SRAM can be used to retain data during low-power mode (Standby and V_{BAT} mode).

These SRAMs are made of several blocks that are maintained but not usable in Stop mode (AXI SRAM) :

- AXI SRAM
  - SRAM1is splitted in fix allocation and shared part depending on the user option byte define in *FLASH option byte word 2 status register (FLASH_OBW2SR)*. 1x64-Kbyte fix allocation + 2x64 Kbytes shared with the ITCM.
  - SRAM2: 128-Kbytes not shared (no ECC).
  - SRAM3: 128-Kbytes shared by block of 64-Kbytes with DTCM0 and DTCM1. when shared the same amount is affected to each DTCM per 32-Kbytes each. The amount of memory allocated to each DTCM is define in *FLASH option byte word 2 status register (FLASH_OBW2SR)*.
  - SRAM4: 72-Kbyte (no ECC) comming from SRAM1 (24-Kbytes) and SRAM3 (48-Kbytes) when ECC is disabled *FLASH option byte word 2 status register (FLASH_OBW2SR)*
- backup SRAM
  - The backup SRAM (BKPSRAM) can be retained in all low-power modes and when V_{DD} is off in V_{BAT} mode. Refer to *Section 6.4.4: Backup domain* for more details. The backup SRAM is protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. They are also erased by hardware in case of a Backup domain reset. Refer to (link to *Section 50: Tamper and backup registers (TAMP)*) for more details.

The tables below summarize the different configuration supported by each internal SRAM:

Table 8. SRAMs structure

SRAM	STM32H7Rx/7Sx
SRAM1	From 0 to 128 Kbytes, shared with ITCM
SRAM2	128 Kbytes no ECC
SRAM3	From 0 up to 128 Kbytes, shared with DTCM0/1
SRAM4	From 0 to 72 Kbytes, shared with ECC
AHB SRAM1/2	16 Kbytes, AHB domain
BKPSRAM	4 Kbytes

Table 9. SRAM1 / ITCM configurations

Allocation	SRAM1 / ITCM split (Kbytes)		
SRAM1 allocation	0	64	128
ITCM allocation	192	128	64

Table 10. SRAM3 / DTCM configurations

Allocation	SRAM3 / DTCM split (Kbytes)		
SRAM3 allocation	0	64	128
DTCM0 allocation	96	64	32
DTCM1 allocation	96	64	32

Table 11. SRAM4 / ECC configurations

ECC	SRAM4 allocation (Kbytes)
ON	0
OFF	72

RAM shared between TCM and AXI RAM

128 Kbyte of RAM (SRAM1 for ITCM, SRAM3 for DTCM) can be used either as TCM or as AXI SRAM. This feature can be configured through the ITCM_AXI_SHARED[1:0] and DTCM_AXI_SHARED[1:0] option byte in FLASH_OBW2SRP register,in *Section 5: Embedded flash memory (FLASH)*, as described in *Table 12* and *Table 14*

Table 12. ITCM/AXI configuration

ITCM_AXI_ SHARED[1,0]	ITCM size (Kbyte)	ITCM memory mapping(1)	AXI size (Kbyte)	AXI SRAM1 memory mapping(2)
00/11	64	0x00000 0000 - 0x0000 FFFF	128	0x2400 0000 - 0x2401 FFFF
01	128	0x0000 0000 - 0x0001 FFFF	64	0x2401 0000 - 0x2401 FFFF
10	192	0x0000 0000 - 0x0002 FFFF	0	-

1. Access to an unmapped area gives a TCM error.
2. Access to an unmapped area gives a bus error.

Table 13. DTCM/AXI configuration

DTCM_AXI_ SHARED[1,0]	DTCM size (Kbyte)	DTCM memory mapping(1)	AXI size (Kbyte)	AXI SRAM3 memory mapping(2)
00/11	64	0x2000 0000 - 0x2000 FFFF	128	0x2404 0000 - 0x2405 FFFF
01	128	0x2000 0000 - 0x2001 FFFF	64	0x2404 0000 - 0x2404 FFFF
10	192	0x2000 0000 - 0x2002 FFFF	0	-

1. Access to an unmapped area gives a TCM error.
2. Access to an unmapped area gives a bus error.

RAM shared between ECC and AXI RAM

72 Kbyte of RAM (SRAM4) can be used either by ECC or as AXI SRAM. This feature can be configured through the ECC_ON_SRAM option byte in FLASH_OBW2SRP register as described in *Table 14*.

Table 14. ECC/AXI configuration

ECC_ON_SRAM	AXI size (Kbytes)	AXI SRAM4 memory mapping(1)
0	72	0x2406 0000 - 0x2407 1FFF
1	0	-

1. Access to an unmapped area gives a bus error.

Refer to *Section 5: Embedded flash memory (FLASH)* for a description of the ECC_ON_SRAM option byte.

2.5 Flash memory overview

The Flash memory interface manages accesses to the Flash memory. It implements the erase and program Flash memory operations and the read and write protection mechanisms.

The Flash memory is organized as follows:

- A main memory block divided into sectors.
- An information block:
  - System memory from which the device boots in System memory boot mode
  - Option bytes to configure read and write protection, BOR level, watchdog software/hardware and reset when the device is in Standby or Stop mode.

Refer to *Section 5: Embedded flash memory (FLASH)* for further details.

2.6 Boot configuration

In the STM32H7Rx/7Sx, two different boot areas can be selected through the BOOT0 pin as shown in the *Table 15*.

Table 15. Boot modes

Boot mode selection				Boot area
PRODUCT_STATE	NVSTATE	BOOT0	IROT_SELECT(1)	
Open	OPEN	0	-	Boot from the user flash memory at 0x0800 0000
		1		Boot from the bootloader
Provisioning	CLOSE	-		Boot from the RSS in system flash memory Then jump into the bootloader
Closed/Locked			Not 0xB4 or H7R	Boot from the RSS in system flash memory Then jump into the user flash memory at 0x0800 0000(2)
Closed/Locked			0xB4	Boot from the RSS in system flash memory Then jump into the ST iRoT in system flash memory

1. IROT_SELECT is relevant only on H7S.
2. MPU is enabled when executing OEM FW in user flash memory; depending on needed resources, OEM FW should update MPU configuration or disable MPU.

The values on the BOOT0 pin are latched on the 4th rising edge of SYSCLK after reset release. It is up to the user to set the BOOT0 pin after reset.

The BOOT0 pin is re-sampled when the device exits Standby mode. Consequently, the values must be kept in the required Boot mode configuration when the device is in Standby mode.

After startup delay, the selection of the boot area is done before releasing the processor reset.

Embedded bootloader

The embedded bootloader code is located in system memory. It is programmed by ST during production. It is used to reprogram the flash memory using one of the following serial interfaces:

- DFU: USB OTG FS (PM12/PM11) in device mode
- USART1: PA10/PA9
- USART2: PA3/PA2
- USART3: PD9/PD8
- UART4: PD0/PD1
- FDCAN2: PB5/PB1
- I2C1: PB8/PB7
- I2C2: PB10/PB11
- I2C3: PA8/PC9
- I3C1: PB8/PB7
- SPI1: PA4/PA5/PA6/PA7
- SPI2: PB15/PB14/PB13/PB12
- SPI3: PC12/PB4/PB3/PA15

For additional information, refer to *Section 8: System configuration, boot and security (SBS) on page 540*.

3 RAMECC monitoring (RAMECC)

3.1 Introduction

STM32H7Rx/7Sx devices feature a RAM ECC monitoring unit (RAMECC). This provides a means for application software to enable, verify the ECC status, and execute service routines when an error occurs.

3.2 RAMECC main features

The internal SRAM can be protected by ECC when enabled. The ECC mechanism is based on the SECDED algorithm. It supports single- and double-error detection, as well as single-error correction:

- 7 ECC bits are added per 32-bit word.
- 8 ECC bits are added per 64-bit word for ITCM-RAM.

RAM data word integrity is checked at each memory read access, or partial RAM word write operation. Two cycles are required to perform a partial RAM word write (read-modify-write).

The RAMECC monitoring unit includes the following features:

- RAM ECC monitoring per domain
- RAM failing address/data identification
- Error code correction (ECC)

When a half word is written to an internal SRAM (except DTCM and ITCM) and a reset occurs, this half word is not really written to the SRAM after reset. This due to the ECC behavior.

To ensures the data are effectively written to DTCM and ITCM internal memories, read back the programmed data.

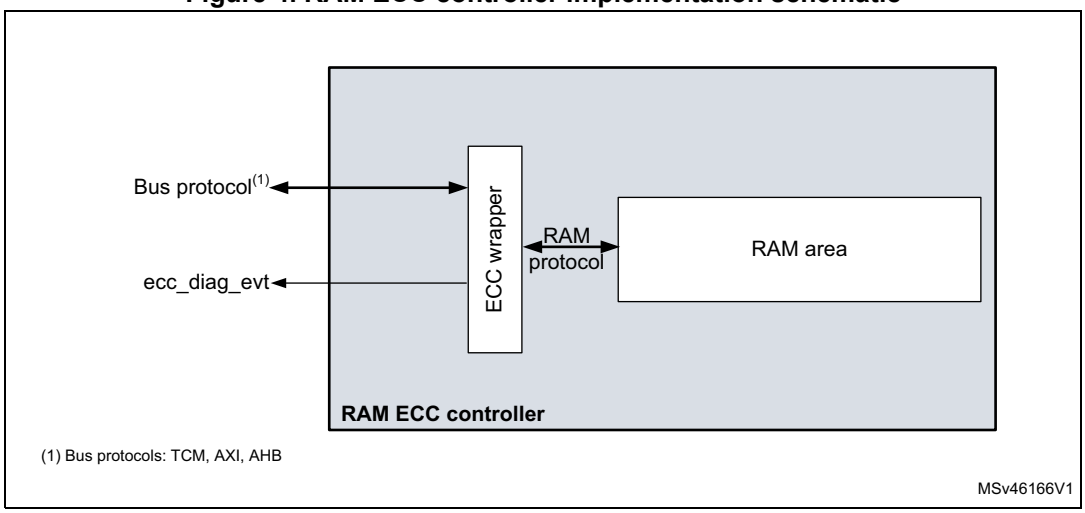
3.3 RAMECC functional description

The ECC is supported by SRAM1, SRAM3, BKPSRAM and TCM.The ECC is enabled / disabled by the user option byte ECC_ON_SRAM in *Section 5.9.34: FLASH option byte word 2 status register (FLASH_OBW2SR)*.

Seven ECC bits are added per 32-bit access, and nine for 64-bit access, allowing two bits for error detection, and one bit for error correction on memory read access.

As the ECC is calculated and checked for a 32/64-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is increased by 2 bus clock cycles.

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM. The SRAM is then released.



RAMECC block diagram

An ECC controller is associated to each RAM area. It performs the following functions:

- ECC encoding: ECC code computation and storage.
- ECC decoding: RAM data word loading and ECC code decoding to detect errors
- Error detection: single- and double-error detection
- Error correction: single-error correction.

The following figure describes the implementation of RAM ECC controllers.

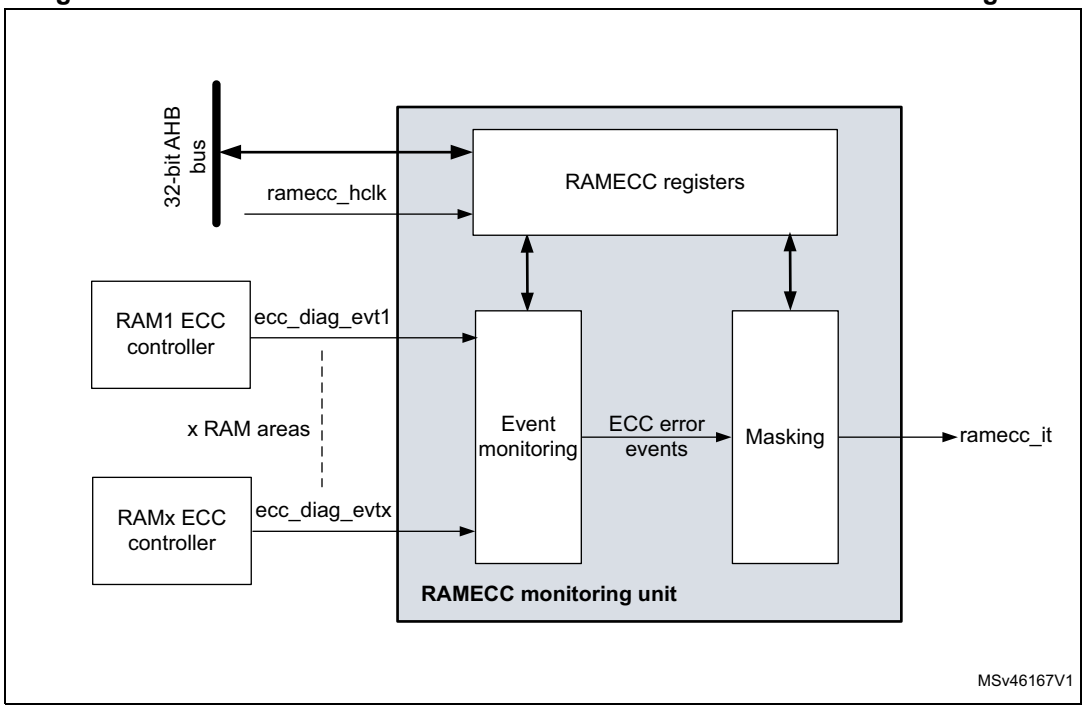


Figure 4. RAM ECC controller implementation schematic

A dedicated RAM ECC monitoring area is defined for each domain (see *Section 3.3.2: RAMECC monitor mapping*. The RAMECC allows the collection of ECC diagnostic events from each RAM ECC controller and provides a mean for the CPU to verify the ECC status.

Figure 5 shows the connection schematic between the RAM ECC controller and the RAMECC monitoring unit.

Figure 5. Connection between RAM ECC controller and RAMECC monitoring unit

3.3.1 RAMECC internal signals

Table 16 lists the internal signals that control the RAMECC unit.

Table 16. RAMECC internal input/output signals

Internal signal name	Signal type	Description
ramecc_hclk	Input	AHB clock
ecc_diag_evtx	Input	ECC diagnostic event generated by RAMx ECC controller x
ramecc_it	Output	Interrupt generated by the RAMECC monitoring unit when an ECC error is detected.

3.3.2 RAMECC monitor mapping

STM32H7Rx/7Sx devices features two RAMECC monitoring units The inputs from the ECC controllers are mapped as described in *Table 17*. The RAM ECC event monitoring status and configuration registers are described in *Section 3.6: RAMECC registers*.

Table 17. ECC controller mapping

RAMECC units(1)	Monitor number	SRAM ECC event monitoring status and configuration registers		Size in Kbytes	Address Offset
ECC_DIAG_D1 (AXI SRAM)	0	AXI SRAM1 ECC monitoring unit		See *Table 9: SRAM1 / ITCM configurations*	0x20
	1	ITCM-RAM ECC monitoring unit			0x40
	2	DTCM-RAM ECC monitoring unit	D0TCM	See *Table 10: SRAM3 / DTCM configurations*	0x60
	3		D1TCM		0x80
	4	AXI SRAM3 ECC monitoring unit			0xA0
ECC_DIAG_D2 (Backup/Vbat domain)	0	Reserved			0x20
	1	BKPRAM ECC monitoring unit		4	0x40

1. See *Table 7: Register boundary addresses*.

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDCF bits are set in the *RAMECC monitor x status register (RAMECC_MxSR)*. When a double error is detected, the DEDF bit are set in the *RAMECC monitor x status register (RAMECC_MxSR)*. An interrupt is generated if enabled by the GECCSEIE and GIE bits in the *RAMECC interrupt enable register (RAMECC_IER)*.

For single and double errors:

- An interrupt is generated if enabled by the GECCSEIE and GIE bit in the *RAMECC interrupt enable register (RAMECC_IER)*. Single errors cannot be detected when the SEDC bit is set.
- the context: failing address, data, ECC code are stored in the *RAMECC monitor x failing address register (RAMECC_MxFAR)*, *RAMECC monitor x failing data low register (RAMECC_MxFDRL)*, RAMECC monitor x failing data high register (RAMECC_MxFDRH) and *RAMECC monitor x failing ECC error code register (RAMECC_MxFECR)* if enabled by the ECCELEN bit in the *RAMECC monitor x configuration register (RAMECC_MxCR)*.

Caution: Double errors cannot be detected when the DEDF bit is set.

3.3.3 ECC fault injection test on SRAM1, SRAM3, and TCM

In order to test the ECC a mechanism, allow to test, 1 or 2 bits by word (for single or double error test respectively) and ECC alteration.

- ECCTEA[1:0] = 00 or 11: Normal mode, ECC and DATA memory access granted
- ECCTEA[1:0] = 01: ECC memory access mode granted, data memory access gated
- ECCTEA[1:0] = 10: ECC memory access mode gated, data memory access granted

example:

initialization

1. Set the normal mode: ECCTEA[1:0] = 00
2. Write 0xCAFEDECA, ECC = 0x19 (computed by ECC module)

data modification

3. bloc ECC memory access: ECCTEA[1:0] = 10
4. Grant data modification: Write 0xCAFEDECB (last bit flipped)
5. return to normal mode: ECCTEA[1:0] = 00
6. READ 0xCAFEDECB with ECC = 19 single error =’1’ (if enabled a flag is set and an interrupt to the NVIC is generated)

An ECC fault injection test triggers a system break events in TIM1/TIM15/TIM16/TIM17 if one of the following bits is set in the SBS_BKLOCKR register:

- ARAM1ECC_BL
- ARAM3ECC_BL
- ITCMECC_BL
- DTCMECC_BL

This implies that the test must be performed while the PWM outputs of the timers are in idle state.

3.3.4 Read access latency

To correctly read data from SRAMs, the number of wait states automatically set to one when ECC is enabled

3.4 RAMECC low-power modes

Table 18. Effect of low-power modes on RAMECC

Mode	Description
Sleep	No effect. RAMECC interrupts cause the device to exit the Sleep mode.
Stop	The content of RAMECC registers is kept. The ECC is functional and ECC error interrupt causes the device to exit from Stop.
Standby	The RAMECC peripheral is powered down and must be reinitialized after exiting Standby.

3.5 RAMECC interrupts

Table 19 lists the RAMECC interrupt requests.

Table 19. RAMECC interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit the Sleep/Stop mode	Exit the Standby modes
RAMECC	ECC single error detection and correction	SEDCF	GECCSEIE ECCSEIE	Write 0 in SEDCF	Yes	No
	ECC double error detection	DEDF	GECCDEIE GIE	Write 0 in DEDF	Yes	No

3.6 RAMECC registers

RAMECC registers can be accessed only in 32-bit (word) mode. Byte and half-word formats are not allowed.

In the registers described below, x refers to:

- SRAM1/2/3/4 when x = 1/2/3/4 respectively
- BKPSRAM when x = 5

3.6.1 RAMECC interrupt enable register (RAMECC_IER)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GECCDEBWIE	GECCDEIE	GECCSEIE	GIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **GECCDEBWIE**: Global ECC double error on byte write (BW) interrupt enable
When GECCDEBWIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a byte write operation to RAM (incomplete word write).
0: no interrupt generated when an ECC double detection error occurs on byte write
1: interrupt generated if an ECC double detection error occurs on byte write

Bit 2 **GECCDEIE**: Global ECC double error interrupt enable
When GECCDEIE bit is set to 1, an interrupt is generated when an ECC double detection error occurs during a read operation from RAM.
0: no interrupt generated when an ECC double detection error occurs
1: interrupt generated if an ECC double detection error occurs

Bit 1 **GECCSEIE**: Global ECC single error interrupt enable
When GECCSEIE bit is set to 1, an interrupt is generated when an ECC single error occurs during a read operation from RAM.
0: no interrupt generated when an ECC single error occurs
1: interrupt generated when an ECC single error occurs

Bit 0 **GIE**: Global interrupt enable
When GIE bit is set to 1, an interrupt is generated when an enabled global ECC error (GECCDEBWIE, GECCDEIE or GECCSEIE) occurs.
0: no interrupt generated when an ECC error occurs
1: interrupt generated when an ECC error occurs

3.6.2 RAMECC monitor x configuration register (RAMECC_MxCR)

Address offset: 0x00 + 0x20 * (x+1), (x = 0 to 4)

Reset value: 0x0000 0000

x is the ECC monitoring unit number

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCTEA[1:0]	
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCDEBWCEN	ECCDECEN	ECCSECEN	ECCELEN	ECCDEBWIE	ECCDEIE	ECCSEIE	Res.	Res.
							rw	rw	rw	rw	rw	rw	rw		

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **ECCTEA[1:0]:** ECC Test ECC access
00: inactive
01: write and read access blocked on data memory
10: write and read access blocked on ECC memory
11: inactive

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **ECCDEBWCEN:** ECC double error on byte write (BW) counter enable
When ECCDEBWCEN bit is set to 1, the occurrence counter is incremented when an ECC double detection error occurs during a byte write operation to RAM.
0: no counter increment when an ECC double detection error occurs on byte write
1: counter increment when an ECC double detection error occurs on byte write

Bit 7 **ECCDECEN**: ECC double error counter enable
When ECCDECEN bit is set to 1, the occurrence counter is incremented when an ECC double detection error occurs during a read operation from RAM.
0: no counter increment when an ECC double detection error occurs
1: counter increment when an ECC double detection error occurs

Bit 6 **ECCSECEN:** ECC single error counter enable
When ECCSECEN bit is set to 1, the occurrence counter is incremented when an ECC single error occurs during a read operation from RAM.
0: no counter increment when an ECC single error occurs
1: counter increment when an ECC single error occurs

Bit 5 **ECCELEN**: ECC error latching enable
When ECCELEN bit is set to 1, if an ECC error occurs (both for single error correction or double detection) during a read operation, the context (address, data and ECC code) that generated the error are latched to their respective registers.
0: no error context preserved when an ECC error occurs
1: error context preserved when an ECC error occurs

Bit 4 **ECCDEBWIE:** ECC double error on byte write (BW) interrupt enable
When ECCDEBWIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a byte write operation to RAM.
0: no interrupt generated when an ECC double detection error occurs on byte write
1: interrupt generated if an ECC double detection error occurs on byte write

Bit 3 **ECCDEIE:** ECC double error interrupt enable

When ECCDEIE bit is set to 1, monitor x generates an interrupt when an ECC double detection error occurs during a read operation from RAM.

0: no interrupt generated when an ECC double detection error occurs

1: interrupt generated if an ECC double detection error occurs

Bit 2 **ECCSEIE**: ECC single error interrupt enable

When ECCSEIE bit is set to 1, monitor x generates an interrupt when an ECC single error occurs during a read operation from RAM.

0: no interrupt generated when an ECC single error occurs

1: interrupt generated when an ECC single error occurs

Bits 1:0 Reserved, must be kept at reset value.

3.6.3 RAMECC monitor x status register (RAMECC_MxSR)

Address offset: 0x24 + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DEBWDF	DEDF	SEDCF
													rc_w0	rc_w0	rc_w0

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **DEBWDF:** ECC double error on byte write (BW) detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 1 **DEDF:** ECC double error detected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected
1: error detected

Bit 0 **SEDCF:** ECC single error detected and corrected flag
This bit is set by hardware. It is cleared by software by writing a 0
0: no error detected and corrected
1: error detected and corrected

3.6.4 RAMECC monitor x failing address register (RAMECC_MxFAR)

Address offset: 0x28 + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FADD[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FADD[31:0]:** ECC error failing address
When an ECC error occurs the FADD bitfield contains the address that generated the ECC error.

3.6.5 RAMECC monitor x failing data low register (RAMECC_MxFDRL)

Address offset: 0x2C + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FDATAL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FDATAL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FDATAL[31:0]:** Failing data low

When an ECC error occurs the FDATAL bitfield contains the LSB part of the data that generated the error. For 32-bit word SRAM, this bitfield contains the full memory word that generated the error.

3.6.6 RAMECC monitor x failing data high register (RAMECC_MxFDRH)

Address offset: 0x30 + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FDATAH[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FDATAH[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FDATAH[31:0]:** Failing data high (64-bit memory)

When an ECC error occurs the FDATAH bitfield contains the MSB part of the data that generated the error.

3.6.7 RAMECC monitor x failing ECC error code register (RAMECC_MxFECR)

Address offset: 0x34 + 0x20 * x, (x = 0 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FEC[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **FEC[31:0]:** Failing error code

When an ECC error occurs the FEC bitfield contains the ECC failing code that generated the error.

3.6.8 RAMECC register map

Table 20. RAMECC register map and reset values

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

4 System security

The STM32H7Rx/7Sx products are designed with a comprehensive set of security features.

This section explains the different security features available on STM32H7Rx/7Sx devices.

4.1 Key security features

- **Secure firmware installation (SFI)**: with device unique cryptographic key pair
  - leveraging the on-chip immutable bootloader that supports the download of image through USART, USB, I^2C, I^3C, SPI, FDCAN and JTAG
- **Boot entry**: the platform allows selection between native immutable root of trust, or proprietary boot entry (in user flash memory).
- **Security services**: The platform comes with native security services. The services are embedded in the system memory to manage root of trust services. Native root of trust services takes care of: platform security including secure boot, secure updates of next boot level (uROT: updatable root of trust), secure debug control (debug reopening, regression control). Security services can be personalized for each OEMs. OEM personalization is done thanks to provisioning tools.
- **Temporal isolation**: boot levels are isolated thanks to HDPL (hide protect level) monotonic counter.
- **Secure storage**, featuring:
  - three nonvolatile areas dedicated to secure storage. Areas are protected with HDPL.
  - Battery-powered volatile secure storage, automatically erased in case of tamper
  - Write-only key registers in the AES engines
  - Device 96-bit unique ID
  - Secure storage can rely to SAES engine to encrypt the stored data to benefit of DHUK properties. All data encrypted with the DHUK benefit of temporal isolations (HDPL), RHUK (Root Hardware Unique Key), EPOCH (regression counter) properties.

  a) Data are isolated: each data encrypted/decrypted relying to SAES+DHUK benefit of the variation of the DHUK for each different isolated area (HDPL0, HDPL1, HDPL2)

  b) RHUK: hardware secret nonvolatile unique per device keys (copy protection).

  c) EPOCH: counter incremented each time a regression is done (anti rollback).
- **General purpose cryptographic acceleration**:
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM and CCM chaining modes
  - Secure AES 256-bit security co-processor, supporting ECB, CBC, CTR, GCM and CCM chaining modes with side-channel counter-measures and mitigations
  - HASH processor, supporting SHA-1 checksums and SHA-2 secure hash (SHA2, SHA2-384, SHA2-512)
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified

- **3 MCEs**: for memory cypher engine of external memories
  - System bus in-line encryption and decryption
  - Crypto: Support block cyphering AES and Noekeon, and chaining modes and stream mode with AES.
  - Automatic key-erase in case of tamper
  - Optimization for octo-SPI/hexa-SPI/FMC data pre-fetching mechanism.
- **New flexible lifecycle scheme**:Allows product maintenance in-the-field (debug re-opening or regressions)
- **Active tamper and protection**: against temperature, voltage and frequency attacks
  - Up to eight active inputs, eight active output tamper pins, available in different power modes (refer to *Section 50.4: TAMP low-power modes*).

4.2 Secure install

The secure firmware install (SFI) is an immutable secure service embedded by STMicroelectronics in the devices. The SFI allows secure and counted installation of OEM firmware in untrusted production environment (such as OEM contract manufacturer).

The confidentiality of the installed images written in the internal flash memory is also protected using the AES.

The SFI native service leverages the following hardware security features:

- secure boot (see *Section 4.3*)
- temporal isolation using hide protection (see *Section 4.5.1*)
- secure execution (see *Section 4.6*)
- secure storage, with associated cryptographic engines (see *Section 4.7* and *Section 4.8*) and flash dedicated areas

Further information can be found in the application note *Overview secure firmware install (SFI)* (AN4992).

4.3 Secure boot

Secure boot is an immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk that invalid or malicious code runs on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.

The STM32H7Sx offers two options using IROT_SELECT option byte for the immutable code to be executed after a reset. The STiRoT takes advantage of the security services already embedded in the STM32. The other option allows OEMs to manage the secure boot path:

- Security services when STiRoT (ST immutable root of trust, code natively present in the system memory) is selected managing the secure boot of the next boot level. STiRoT takes care of the next level integrity, authenticity and updates using configuration done by OEMs. To do so, the H7Sxx STiRoT manages a boot sequence using several system resets to load the first application boot level from external memory to the SRAM, then launch a reset. The loaded image in SRAM is then verified by STiRoT, before the concerned level is launched. STiRoT can also manage the update of such firmware.
- Proprietary boot entry when the full chain is managed by the OEM (called OEM-iROT). The iROT is to be installed in user flash memory with proper security activation (WRP, HDP).

In the devices, the secure boot takes advantage of hardware security features such as:

- temporal isolation using hide protection levels (HDPL) (see *Section 4.5.1: Temporal isolation using secure hide protection (HDP)*)
- secure install and update (see *Section 4.2: Secure install* and *Section 4.4: Secure update*)
- per-domain secure storage, with associated cryptographic engines if available (see *Section 4.7: Secure storage* and *Section 4.8: Crypto engines*)

This section describes the features specifically designed for secure boot.

4.3.1 Unique boot entry

The IROT_SELECT option byte allows boot through the STiRoT or OEM-iROT (user flash memory). This selection is possible only for products embedding cryptographic acceleration (STM32H7Sx).

For more information on the boot mechanisms, see *Section 2.6: Boot configuration*.

4.3.2 Security services in system flash memory

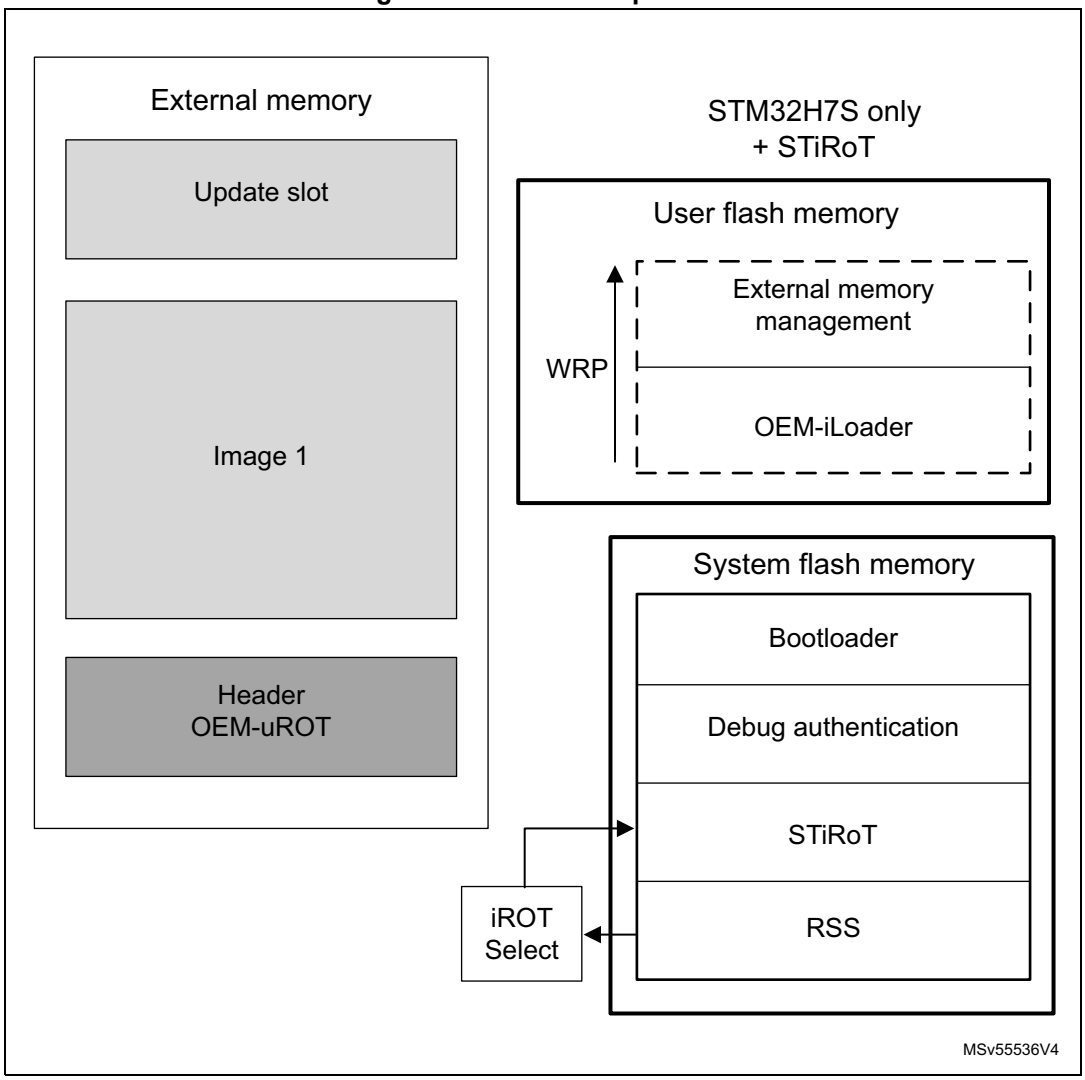
The security services located in the system flash memory, cover the root secure services (RSS), the STiRoT (immutable root of trust), and ST-DA (debug authentication).

The RSS (root secure service) allows the control of ST extensions loaded in SRAM (called RSS-e). One of the RSS-e manages the SFI (secure firmware Install). SFI allows secure and counted installation of OEM firmware in untrusted production environments (such as OEM contract manufacturer).

The STMicroelectronics immutable code also includes secure runtime services that can be called at runtime when a secure application sets the SBS_RSSCMDR register to a non-null value before triggering a system reset. This runtime feature is deactivated when the product state is different to “Provisioning”.

STM32H7Rx/7Sx products offer the following security services:

- ST-DA (debug authentication control): This allows control of the product life cycle for field return. It controls debug reopening or regression following OEM choices. It manages the debug authentication control feature, giving control of the debug re-opening and regressions of the product for after sales (field return) of the product.
- RSS and RSSe SFI: to handle secure provisioning and secure firmware installation in the user flash memory.



STM32H7Sxx products offer the following security services:

- STiRoT (immutable root of trust). This allows management of the boot of the system, ensuring the secure boot and secure update of the following stage. It handles the secure provisioning, secure boot, secure updates of the first updatable level of the platform. As the product is an “hybrid” between flashless and flash memory, the different boots from STiRoT are based on a multi-reset flow.

For this multi-reset flow, STiRoT secure boot or secure update sequence rely on:

- An OEM-iLoader that have to be installed in the user flash memory. OEM-iLoader is in charge of loading the first boot level from external memory to the SRAM. If OEM-iLoader detect an update (of the first boot level), it loads it to the SRAM. When an image is ready to be processed by STiRoT, a system reset is launched to let the STiRoT manage the proper action.
- OEM-iLoader relies on a library to access the external flash memory (external memory management).

Figure 6. Secure boot process

A typical secure boot flow is as follows:

Hypothesis: The IROT_SELECT has been set to STiRoT and the STiRoT has been provisioned. OEM-iLoader code has been installed and write protected in user flash memory. The first updatable boot level has been provisioned in the external memory.

Flow execution:

1. On the STiRoT initial execution, it verifies then launch the OEM-iLoader.
2. Then OEM-iLoader is able to read external memories:
   a) OEM-iLoader checks if an update image is present for the OEM-uROT. If so, it loads it to the SRAM then launch a reset, to let the STiRoT managing the secure controls before install.
   b) If no update image is present then OEM-iLoader loads OEM-uROT from external memory then launch a reset, to let the STiRoT managing the verification of the image before launching it.

4.4 Secure update

The secure update is the capacity of the product to update its firmware, allowing improvement of the product features, or fixing of vulnerabilities.

The product update is considered to be done in almost 2 parts:

- The iROT takes care of the next updatable level (uROT) hosted in external memory.
- The uROT must manage the overall application updates.

When STiRoT is selected, the secure update is executed in several steps. See the previous paragraph for more details.

When OEM-iROT is selected, it is hosted in the internal flash memory. It can be partially or fully immutable. It must manage the external memories, including the hardware setup, the secure boot, the secure update of the next updatable level (uROT).

The update process is performed in a secure way to prevent unauthorized updates and access to confidential on-device data.

4.5 Resource isolation using hide protect levels

In the STM32H7Rx/7Sx devices, the hardware and software resources used for boot can be isolated using the temporal isolation proposed with the HDPL (HiDe protect level) mechanism.

It is based on a monotonic counter, which by definition allows only incrementing of the levels. When the counter is incremented, the resources of the previous levels become hidden (code and data).

A typical usage of the HDPL, is to allocate the HDPL=1 to the iROT. Then the HDPL=2 to the uROT (including OEM-iLoader), then the application is executed in HDPL=3.

4.5.1 Temporal isolation using secure hide protection (HDP)

The embedded flash memory allows definition of an HDP area associated to an HDPL with an 8-Kbyte page granularity (defined through the option bytes). The code executed in this HDP area, with its related data and keys, can be hidden after boot until the next system reset.

The hide protection is related to HDPL=1 (hidden when HDPL becomes equal or greater than 2) when OEM-iROT is selected.

The hide protection is related to HDPL=2 (hidden when HDPL become equal or greater than 3) when STiRoT is selected.

Typically, the activation of an HDP area in user flash memory is related to HDPL1. This means that as soon as the HDPL becomes greater than or equal to 2. Then data read, write and instruction fetch (on the area defined by HDP_AREA_START and HDP_AREA_END in FLASH_HDP option bytes), are denied until the next device reset.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

4.6 Secure execution

Through a mix of special software and hardware features, the devices ensure their correct functional operation under abnormal situations. These can be caused by: programmer errors, software attacks through network access, or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

4.6.1 Memory protection unit (MPU)

The Cortex-M7 includes a memory protection unit (MPU) that can restrict read and write accesses to memory regions (including regions mapped to peripherals), based on one or more of the following parameters:

- Cortex-M7 operating mode (privileged, unprivileged)
- data/instruction fetch.

4.6.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (the system area is permanently write protected).

Any 8 Kbyte sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPS bit in the FLASH_WRPSR register.

The embedded flash memory write-protection user option bits can be modified when HDPL=0 or 1 in the SBS_HDPLSR register, using FLASH_WRPSRP.

Note: Bank erase aborts when it contains a write-protected area (WRP or HDP area).

4.6.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: V_{BAT}, V_{DDA}), temperature and clocking (LSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered automatically with V_{DD} or V_{BAT}

See *Section 50: Tamper and backup registers (TAMP)* for more details.

Tamper detection sources

The devices support eight active input/output pins, allowing four independent active-tamper meshes, or up to seven meshes if the same output pin is shared by several input pins (for a total of eight active-tamper I/Os).

The active pins are clocked by the LSE, and are functional in different system operating modes (Run, Sleep, Stop, or Standby), and in VBAT mode. Refer to *Section 50.4: TAMP low-power modes* for a list of tamper pins and their availability across power modes.

The detection time is programmable, and a digital filtering is available (tamper is triggered after two false comparison in four consecutive comparison samples).

Note: Timestamps are automatically generated when a tamper event occurs.

The internal tamper sources are listed in the table below.

Table 21. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
itamp1	0	Backup domain voltage continuous monitoring, functional in VBAT mode
itamp2	1	Temperature monitoring, functional in VBAT mode
itamp3	2	LSE monitoring(1), functional in VBAT mode
itamp4	3	HSE monitoring
itamp5	4	RTC calendar overflow (rtc_calovf)
itamp6	5	JTAG/SWD access
itamp7, 12, 13	6, 11, 12	Voltage monitoring (V_{CORE}, V_{REF+}), through ADC analog watchdog
itamp8	7	Monotonic counter overflow (generated internally)
itamp9	8	Fault generation for cryptographic peripherals (SAES, PKA, AES, RNG)
itamp11	10	IWDG timeout and potential tamper (IWDG reset when at least one enabled tamper flag is set)
itamp15	14	System fault detection

1. LSE missing or over frequency detection (> 2 MHz), Glitch filter (> 2 MHz).

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see the TAMPxMSK bits in the TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxPOM bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in AES, HASH and MCE (encrypted flash memory regions are read as zero)
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - CPU instruction cache memory
  - nonvolatile information used to derive the DHUK in SAES is zeroed
  - 4-Kbyte backup SRAM (depending on configuration bit), erased when V_{DD} is present
  - MCEs keys.

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in the TAMP_CR2 register. Access to device secrets is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present are only erased at the next V_{DD} power on.

Note: Device secret erase is also triggered by setting the BKERASE bit in the TAMP_CR2 register, or by performing a PRODUCT_STATE regression, as defined in Section 4.9.2.

Device secrets are not reset by system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxPOM bit in the TAMP_CR2 register (for external tamper pin), or TAMP_CR3 (for internal tamper).

In such situations, when the tamper flag is raised, access to the secrets below is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, backup SRAM: read-as-zero, write-ignored
- AES, SAES and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)
- MCEs: Keys

Once the application is notified by the tamper event, it analyzes the situation. There are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application just clears the flags to release secrets blocking (false tamper).

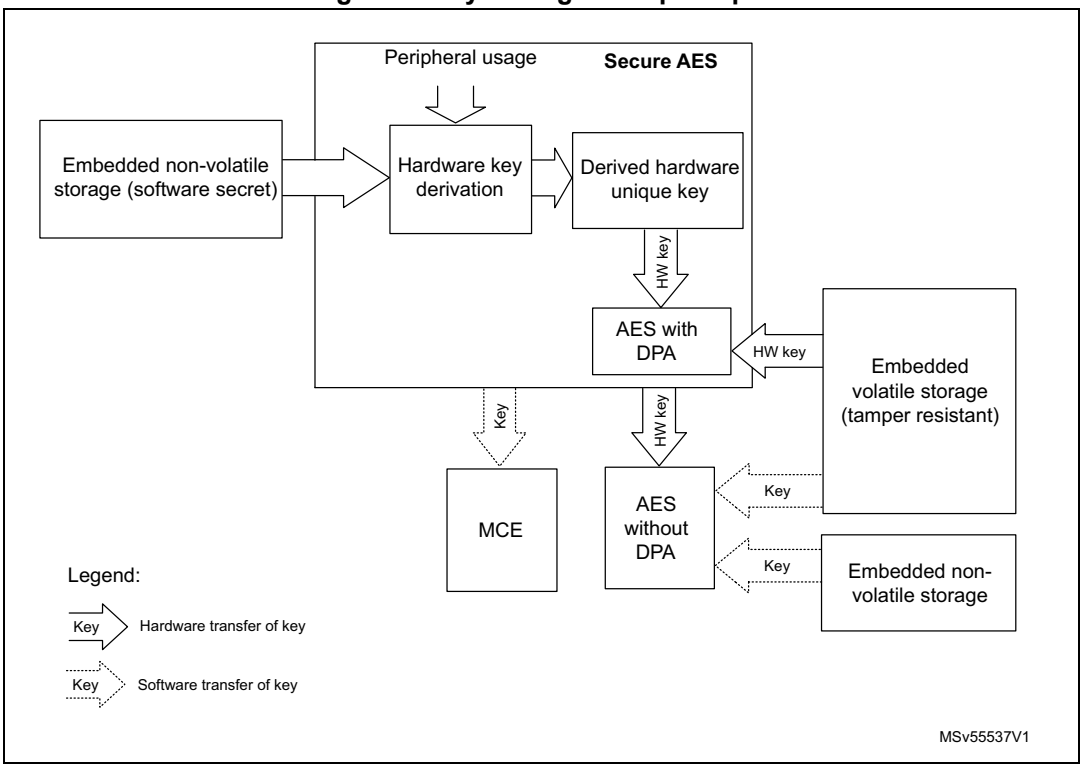
Note: If the tamper software fails to react to such a tamper flag, an IWDG reset automatically triggers the erase of secrets.

Tamper detection and low-power modes

The effect of low-power modes on tamper detection are summarized on the table below.

Table 22. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI Tamper events cause the device to exit the Standby mode.



4.7 Secure storage

A critical feature of any security system is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

Figure 7 shows how a key management-service application can use the AES engine, for example to compute external image decryption keys. Nonvolatile keys are stored in a dedicated flash memory area, including access control (see *Section 4.5.1*), while volatile key storage consists of the battery-powered, tamper-protected SRAM or registers-TAMP.

Figure 7 also shows keys that are manipulated by software (such as MCE keys), or keys that are managed only by hardware (such as DHUK). More information on those hardware keys can be found in *Section 4.7.1*.

Figure 7. Key management principle

Details of tamper protection are given in *Section 4.6.3*.

4.7.1 Hardware secret key management

As shown in the previous figure, the devices propose a better protection for application keys by using hardware secret keys. These AES keys can be made usable to the application, without exposing them in clear-text (unencrypted). Such keys also become immediately unusable in the case of tamper.

There are three different sources of hardware secret keys:

- DHUK: derived keys based on 256-bit nonvolatile device unique secret in flash memory. The flash memory provides a value provisioned during product manufacturing (called RHUK). The generation of a DHUK key takes into account the OBK-HDPLx (temporal isolation counter), the EPOCH (regression counter allowing anti-replay protection), and key use state (KMOD).
- BHK: 256-bit application key stored in tamper-resistant volatile storage in TAMP.
  This key is written at boot time, then read/write locked to application until next reset.
- XORK: result of a XOR of BHK and DHUK

These keys can be used in the following modes:

- as a normal key, loading in write-only key registers (software key mode)
- as an encryption/decryption key for another key, to be used in the DPA-resistant SAES (wrapped key mode)
- as an encryption/decryption key for another key, to be used in a faster AES engine (shared key mode).

4.7.2 Unique ID

The devices store a 96-bit ID that is unique to each device (see *Section 67.1: Unique device ID register (96 bits)*).

Application services can use this unique identity key to identify the product in the cloud network, or to make it difficult for counterfeit devices or clones to inject untrusted data into the network.

Alternatively, the 256-bit device unique key (DHUK) can be used (see *Section 4.7.1*).

4.8 Crypto engines

The devices implement state-of-the-art cryptographic algorithms featuring key sizes and computing protection as recommended by national security agencies. These agencies include: NIST for the U.S.A, BSI for Germany or ANSSI for France. The algorithms are used to support privacy, authentication, integrity, entropy and identity attestation.

The crypto engines embedded in STM32 reduce weaknesses in the implementation of critical cryptographic functions. They prevent, for example, the use of weak cryptographic algorithms and key sizes. They also enable shorter processing times and lower power consumption when performing cryptographic operations, by offloading those computations from Cortex-M7. This is especially true for asymmetric cryptography.

For product certification purposes, ST can provides certified device information on how these security functions are implemented and validated.

For more information on crypto engine processing times, refer to their respective sections in the reference manual.

4.8.1 Crypto engines features

The table below lists the accelerated cryptographic operations available in the devices. Two AES accelerators are available. One is side-channel attack protected (SAES), while the second is more performance oriented (CRYP).

Note: Additional operations can be added using firmware.

The PKA can accelerate asymmetric crypto operations (like key pair generation, ECC scalar multiplication, point on curve check). See Section 40: Public key accelerator (PKA) for more details.

Table 23. Accelerated cryptographic operations

Operations	Algo-rithm	Specification	Key lengths (in bit)	Modes
Get entropy	RNG	NIST SP800-90B(1)	N/A	Software and hardware(2) modes running in parallel
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR(3)
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D	128, 256	GCM, CCM
Cipher-based message authentication code		NIST SP800-38D	128, 256	GMAC

Table 23. Accelerated cryptographic operations (continued)

Operations	Algo-rithm	Specification	Key lengths (in bit)	Modes
Checksum	SHA-1	FIPS PUB 180-4	N/A	Digest 160-bit
Cryptographic hash	SHA-2		-	SHA-224, SHA-256 SHA2-384, SHA2-512
Keyed-hashing for message authentication	HMAC	FIPS PUB 198-1 IETF RFC 2104	Short, long (>64 bytes)	-
Encryption/decryption key-pair generation(4)	RSA	IETF RFC 8017 NIST SP800-56B	Up to 4160	RSAES-OAEP
Signature(4) with hashing Signature verification	RSA	IETF RFC 8017 FIPS PUB 186-4	Up to 4160	PKCS1-v1_5, PSS
	ECDSA	ANSI X9.62 IETF RFC 7027 FIPS PUB 186-4	Up to 640	Refer to *Table 390: Family of supported curves for ECC operations* for details
Key agreement	ECDH	ANSI X9.42		

1. Certifiable using STMicroelectronics reviewed documents.
2. Random numbers distribution to SAES and PKA using a dedicated hardware bus.
3. ECB and CBC chaining modes protected against side-channel and timing attacks in SAES (see *Section 4.8.2*).
4. Private key cryptography protected against side-channel and timing attacks.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

4.8.2 Secure AES co-processor (SAES)

The devices provide an on-chip hardware AES encryption and decryption engine, which implements countermeasures and mitigations against power and electromagnetic side-channel attacks.

Clocked by the AHB bus clock, the SAES offers very good performance for a DPA resistant hardware accelerator. The SAES engine supports 128-bit or 256-bit keys in electronic code book (ECB), cipher block chaining (CBC), (CTR), (GCM), (CCM), (GMAC) modes.

As shown in *Section 4.7*, the SAES can be used for extra-secure on-chip storage for sensitive information.

For more information, refer to *Section 36: Secure AES coprocessor (SAES)*.

4.8.3 Memory cipher engine (MCE)

Three MCEs propose on-the-fly encryption and decryption on external non volatile or volatile memories. Up to 4 regions can be defined on each MCE, with a granularity of 4 kbytes. Access filtering can be applied on different regions (priviledge, write).

When a tamper event is confirmed in TAMP, all MCE keys are erased.

4.9 Product life cycle

The product life cyle of the STM32H7Rx/7Sx is the result of combining the following settings:

- the flash interface state: FLASH_NVSRP -> NVSTATE = OPEN /CLOSE
- the option byte: FLASH_ROTSR->OEM_PRVD = iROT- provisioned or not
- the option byte: FLASH_ROTSR->DBG_AUTH = select the debug authentication control method, between locked, ECDSA (certificates), and password.

Figure 8. Product life-cycle security

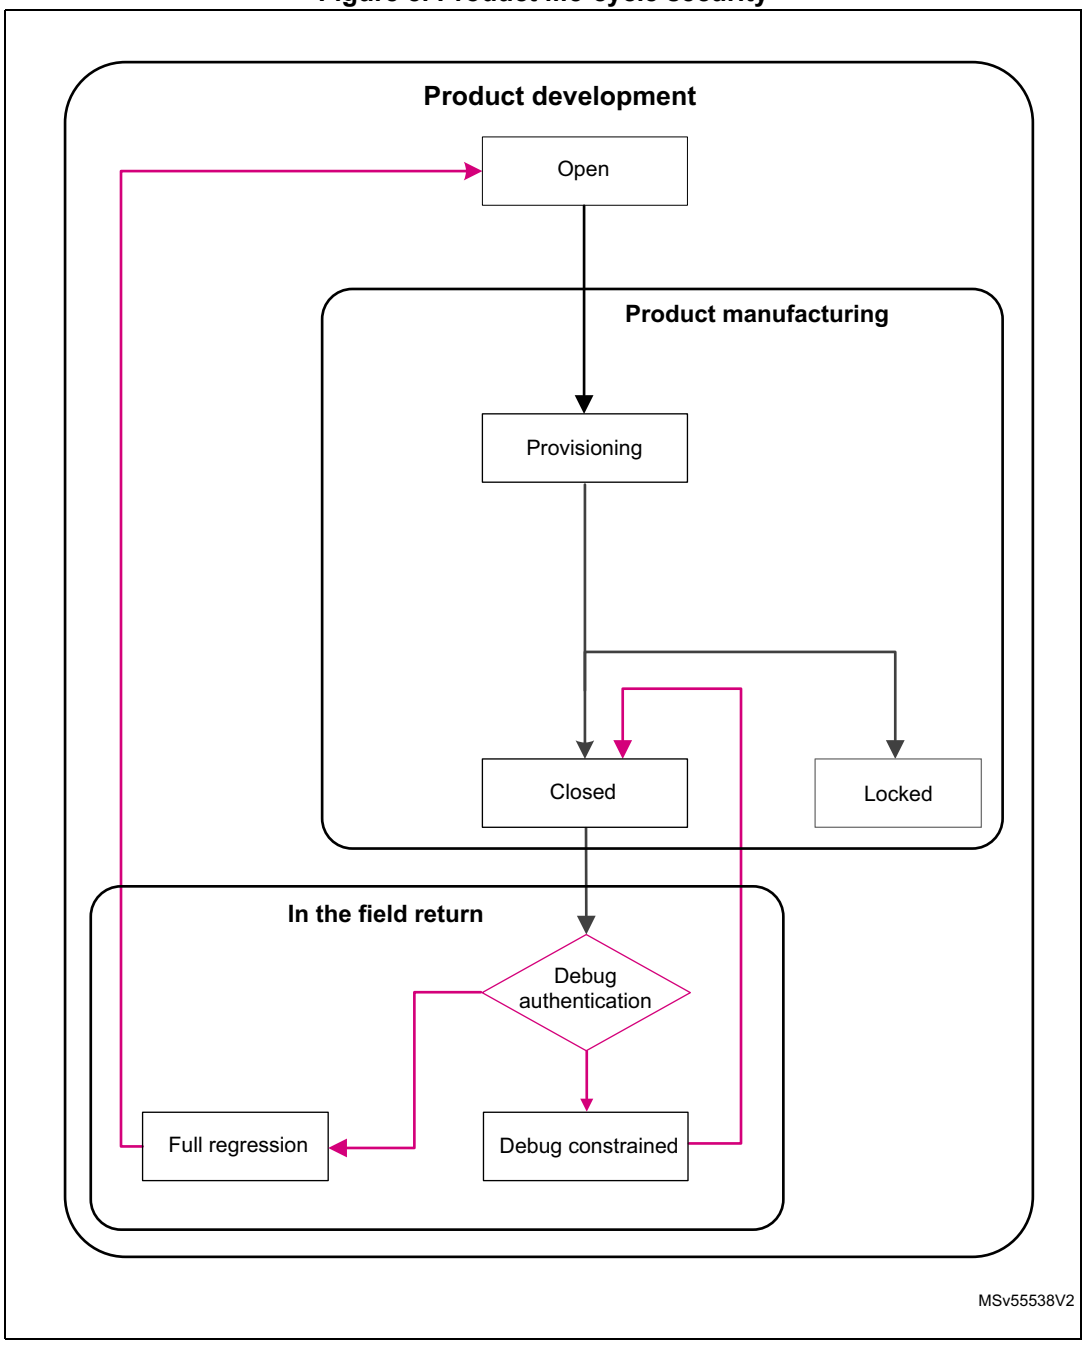


Table 24. Product life-cycle states

PRODUCT_STATE	Selecting PRODUCT_STATE	Description
Open	NVSTATE = OPEN	This state allows product development, as it provides the code debug. Using the boot pin allows the bootloader to be launched.
Provisioning	NVSTATE = CLOSE OEM_PROVD=!0xB4 and/or DBG_AUTH = Not set (!0xB4, !0x51,!0x8A)	This state allows product provisioning (partial or full). It allows launching of secure firmware Install, or bootloader to provision the product. Boot from SRAM is not permitted.
Closed	NVSTATE = CLOSE OEM_PROVD=0xB4 DBG_AUTH=0x51 or 0x8A	This state considers that the product configuration is finalized. It allows support of debug authentication for in-the-field repair (read the dedicated application note).
Locked	NVSTATE = CLOSE OEM_PROVD=0xB4 DBG_AUTH=0xB4	This state considers that the product configuration is finalized. The debug authentication is not permitted. The product is definitively in this state.

The features described below contribute to secure the device life-cycle.

4.9.1 Product configurations and security services

The product is provisioned with ST native security services. However, the product can be configured to leave full control of the boot chain to OEMs.

This is done by means of the unique boot entry (FLASH_ROTSRP: IROT_SELECT) option byte. This allows selection between the security services (STiRoT: ST immutable root of trust), or OEM boot implementation (OEM-iROT: OEM immutable root of trust) to be installed in the user part of the flash memory. The product boots on the STiRoT only when the IROT_SELECT is set to STiRoT and when the product state is Closed or Locked.

Security services are provisioned by ST in system flash memory (immutable). They provide the root of trust of the platform managing the verification, and update of the first updatable code (uROT).

STiRoT and OEM-iROT are only available on products embedding cryptographic acceleration (STM32H7Sx).

4.9.2 Recommended product settings

To ease the product maintenance (in-the-field), we recommend taking advantage of the called debug authentication control feature. This enables product maintenance by activating debug, and makes regression management possible, while considering the security of sensitive information.

This implies setting the product state to provisioning state then provision the DA-config and selecting the final product state (closed)

A dedicated application note is available to help when configuring the debug authentication control of the platform.

4.10 System memory

4.10.1 Introduction

System memory stores RSS (root secure services) firmware programmed by ST during production. The RSS provides runtime services to user firmware.

4.10.2 RSS user functions

The RSS provides runtime services thanks to RSS library, whose functions are exposed to user within the CMSIS device header file provided by the STM32CubeH7RS firmware package (see AN5935 "*Getting started with MCU hardware development for STM32H7R3/7S3 and STM32H7R7/7S7 product lines*" for more details).

RSS provides services through the RSSLIB library, dedicated to secure user firmware. Before calling RSSLIB functions, if MPU is enabled, the secure user firmware must:

- Define a MPU region to have read access on this location, starting from RSSLIB_SYS_FLASH_PFUNC_START (0x1FF1FD4C), up to RSSLIB_SYS_FLASH_PFUNC_END (0x1FF1FD78). These addresses are provided within the CMSIS device header file.
- Define a MPU region to allow execution of RSSLIB FW, starting from 0x1FF16800 up to 0x1FF17FFF.

Table 25. Macros for RSS services

C defined macro	Location in system memory
RSSLIB_PFUNC	0x1FF1FD4C
-	-

RSSLIB

The user firmware calls RSSLIB functions using RSSLIB_PFUNC C defined macro, which points to a location within non-secure system memory.

Table 26. RSS lib interface functions

Library	Callable function
RSSLIB_PFUNC	SetSecOB(1)
	GetRssStatus(1)
	SetProductState(1)
	DataProvisioning(1)
	JumpHDPLvl2
	JumpHDPLvl3
	GetProductState(1)

1. Functions used for OEM personalization done using provisioning tools.

SetSecOB

Prototype:

```
uint32_t SetSecOB(uint32_t ObAddr, uint32_t ObMask, uint32_t ObValue,
uint32_t ObPos)
```

User code function call example:

```
RSSLIB_PFUNC->SetSecOB((uint32_t) ObAddr, (uint32_t) ObMask, (uint32_t)
ObValue, (uint32_t) ObPos);
```

Arguments:

- ObAddr:
  - Input parameter, address of the secure OB to configure, must be one of:
    &(FLASH->WRPSRP)
    &(FLASH->HDPSRP)
    &(FLASH->ROTSRP)
- ObMask:
  - Input parameter, mask of the OB part to be updated (example 0x000000FF for updating WRP OB).
- ObValue:
  - Input parameter, OB value to be applied.
- ObPos:
  - Input parameter, OB bit shift to be applied on ObValue (ObValue<<ObPos must be aligned on ObMask).

The user calls SetSecOB to configure secure OB, the configuration is done by RSS after reset. This function is only available in provisioning product state.

On successful call, the function does not return and does not push LR onto the stack.

In case of failure (bad product state), SetSecOB returns 0xF5F5F5F5.

To retrieve OB change status (after RSS execution), need to call GetRssStatus function or read back the OB (for example read FLASH_WRPSR register).

GetRssStatus

Prototype:

```
uint32_t GetRssStatus(void)
```

User code function call example:

```
RSSLIB_PFUNC->GetRssStatus();
```

Arguments: None

The user calls GetRssStatus to get RSS execution status of previous RSSLIB function call that trigger a reset for execution by RSS (SetSecOB or DataProvisioning).

Returned values:

0xEAEAEAEA	Success
0xF5F5F5F5	Error
0xF5F5E0E0	Bad input address range
0xF5F50E0E	Bad size
0xF5F5E00E	Bad encryption value in DoEncryption
0xF5F50880	Hardware cryptography not available (H7R)
0xF5F50EE0	Encryption error
0xF5F50808	Programming error
0xF5F50008	Bad value in Destination

SetProductState

Prototype:

```
uint32_t SetProductState(uint32_t ProductState)
```

User code function call example:

```
RSSLIB_PFUNC->SetProductState((uint32_t) ProductState);
```

Arguments:

- ProductState:
  - Input parameter, STM32 product state to reach, must be one of:

    0x17: Provisioning product state, allowed when current product state is Open.

    0x72: Closed product state, allowed when current product state is Provisioning and Data provisioning has been made.
  - 0x5C: Locked product state, allowed when current product state is Provisioning.

User calls SetProductState to change STM32 product state, the configuration is done by RSS after reset.
On successful call, the function does not return and does not push LR onto the stack.

To retrieve new product state (after RSS execution), need to call **`GetProductState`** function.

In the case of failure (bad product state), SetProductState returns 0xF5F5F5F5.

DataProvisioning

Prototype:

```
uint32_t DataProvisioning(RSSLIB_DataProvisioningConf_t *pConfig)
```

User code function call example:

```
RSSLIB_PFUNC->DataProvisioning((RSSLIB_DataProvisioningConf_t*)pConfig));
```

Arguments:

pConfig: input parameter. **RSSLIB_DataProvisioningConf_t**

C structure definition is described below:

```
typedef struct
{
  uint32_t *pSource;
  uint32_t Destination;
  uint32_t Size;
  uint32_t DoEncryption;
  uint32_t Crc;
} RSSLIB_DataProvisioningConf_t;
```

Structure elements

pSource Provides the address of data to be provisioned. Must be within SRAM3 address range.

Destination Provides the destination information (where to provision the data).
0xDADAHHII:
– II provides OBKey starting index.
– HH provides OBKey HDPL.
– DADA provides Debug Authentication configuration, only relevant when OBKey HDPL0.

Size Provides the size of data to be provisioned (the number of bytes, must be a multiple of 32).

DoEncryption Notifies the DataProvisioning function if it must encrypt or not data within OBKeys.
DoEncrypt can be either 0xF5F5A0AAU or 0xCACA0AA0U (mandatory on STM32H7Rx)
– 0xF5F5A0AAU: notifies the DataProvisioning to encrypt data with relevant AHK before programming it within OBKeys. AHK is selected according to the **Destination** value.
– 0xCACA0AA0U: notifies DataProvisioning to program in clear data within OBKeys.

Crc CRC over full source data buffer, **pConfig->Destination** value, **pConfig->Size** value and finally **pConfig->DoEncryption** value.
CRC computation uses CRC-32 (Ethernet):
– CRC polynomial: 0x04C11DB7U
– Initial value: 0xFFFFFFFFU

Returned values

0xEAEAEAEAU	Success
0xF5F5F5F5U	Error: bad product state DataProvisioning only available in Open product state (encryption not supported) and Provisioning product state (encryption supported only on STM32H7Sx).
0xF5F5E0E0U	Error: bad input address range. **pConfig** or **pSource** are not in SRAM3
0xF5F50E0EU	Error: bad provisioning size – **Size** is not a multiple of 32 – OBKey starting index + **Size** does not fit within an OBKey section
0xF5F58080U	Error: computed CRC is not the expected one provided within **pConfig->CRC**
0xF5F5E00EU	Error: wrong **DoEncryption** parameter value
0xF5F50808U	Error: OBKeys programming error
0xF5F50008U	Error: bad Destination information – OBKey index not in the range 0 to 31 – OBKey HDPL not in the range 0 to 2 (representing HDPL0, HDPL1 and HDPL2) – On OBKey HDPL0, debug authentication not one of ECDSA, PASSWORD or LOCKED

DataProvisioning receives in input a data buffer and programs it within OBKeys. A CRC prevents any data and parameters tampering issue.

When requested through the **pConfig->DoEncryption** parameter, DataProvisioning encrypts data before programming them within OBKeys.

DataProvisioning uses AES CBC 128 bits with:

- IV: defined as (using C definition format)

  ```
  uint32_t IV = {0x8001D1CEU, 0xD1CED1CEU, 0xD1CE8001U, 0xCED1CED1U};
  ```

- Key: AHK corresponding to the targeted OBKeys HDPL that is randomly generated during the DA (HDPL0) provisioning that must be done first.

Note: Data encryption within OBkeys is supported only by STM32H7S devices.

JumpHDPLvl2

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply
  - The vector table format is the one used by the Cortex-M7 core
- MPUIndex:
  - Input parameter, MPU region index, (index 0 to 31 allowed). Caller function must define (but keep disabled) the corresponding MPU region before calling

JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl2 to close user Flash HDPL1 area by incrementing HDPL to 2, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl2 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex-M7 core.
- MPUIndex:
  - Input parameter, MPU region index, (index 0 to 31 allowed). Caller function must define but keep disabled the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table, whose function belongs to the MPU region.

User calls JumpHDPLvl3 to close user Flash HDPL1 and HDPL2 areas by incrementing HDPL up to 3, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as input parameter. Once the MPU region is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by the vector table. JumpHDPLvl3 does not set the new vector table.

On successful execution, the function does not return and does not push LR onto the stack.

In the case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

GetProductState

Prototype:

```
uint32_t GetProductState(void)
```

User code function call example:

```
RSSLIB_PFUNC->GetProductState();
```

Arguments: None

User calls GetProductState to get STM32 product state.

In case of failure (bad product configuration), GetProductState returns 0xF5F5F5F5 (Bad state).

On successful call, the function return one of the following product state:

- 0x39: Open product state.
- 0x17: Provisioning product state.
- 0x72: Closed product state.
- 0x5C: Locked product state.

5 Embedded flash memory (FLASH)

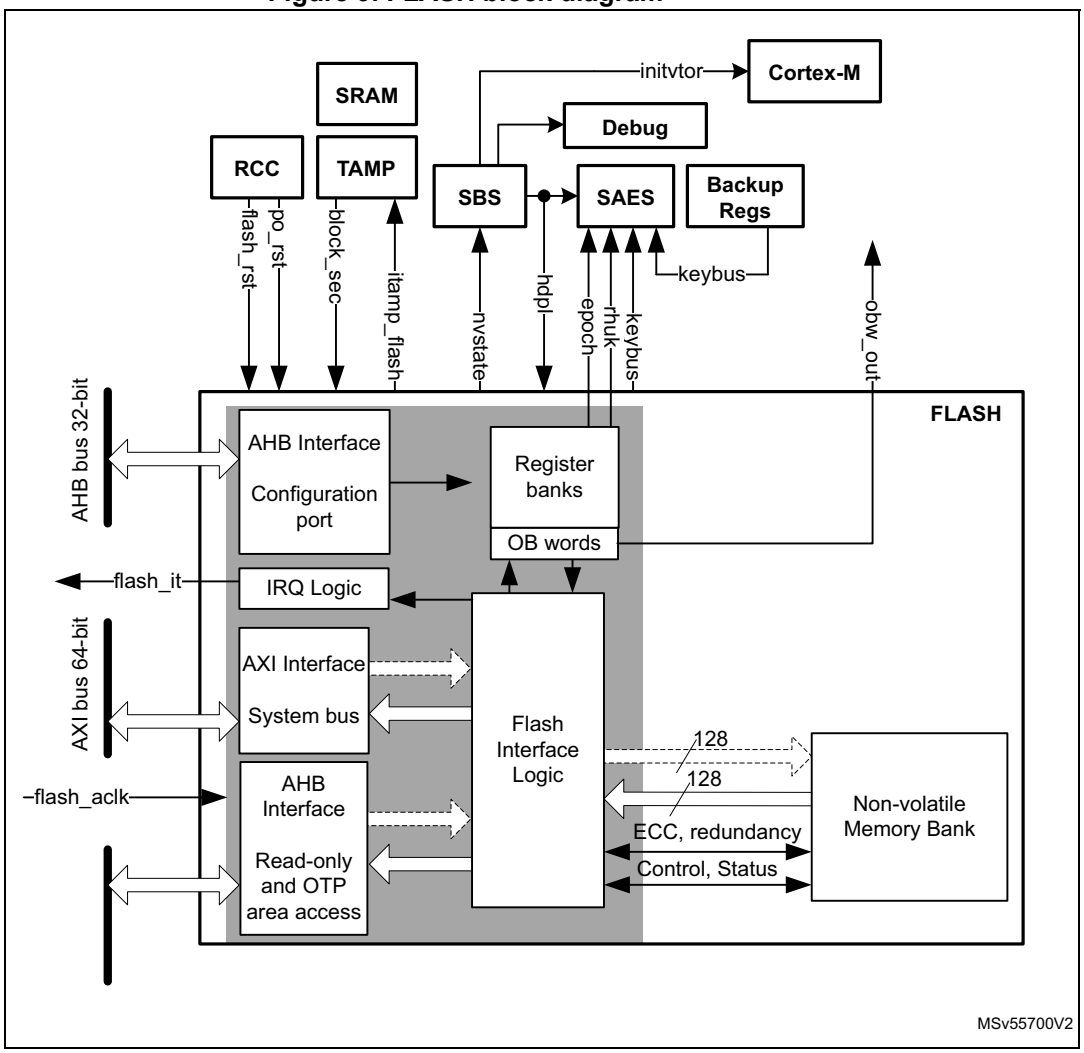
5.1 Introduction

The embedded flash memory (FLASH) manages the accesses to 196 Kbytes of embedded non-volatile memory (NVM) split into different functional areas such as the immutable root of trust, the STM32 secure firmware install (SFI) or the application's one-time-programmable information.

FLASH implements the read, program and erase operations, error corrections as well as various integrity and confidentiality protection mechanisms associated to those various functional areas.

The embedded flash memory manages the automatic loading of non-volatile user option bytes at power-on reset, and implements the dynamic update of those options. Those options includes non-volatile application keys that are protected by the device HDPL counter.

5.2 FLASH main features



- 64 Kbytes of non-volatile user flash memory
- Flash memory read operations supporting multiple length (64 bits, 32 bits, 16 bits or one byte)
- Flash memory programming by 128 bits (user area) and 16 bits (OTP area)
- 8 Kbytes sector erase, and bank erase (conditioned)
- Error Code Correction (ECC): one error detection/correction or two error detections per 128-bit flash word using 9 ECC bits
- Cyclic redundancy check (CRC) hardware module
- User configurable non-volatile option byte words
- Up to 1 Kbyte of protected non-volatile option byte keys, readable either by software or usable as a secret AES key through SAES peripheral (as AHK keys)
- Non-volatile security life cycle management of the device
  - Includes controlled security regression with RAM and flash automatic erase
- Temporal isolation enforcement based on application HDPL stored in SBS register
  - Securing one user flash area, and a set of option byte keys
  - Unique boot entry enforcement on a closed device
- 8 Kbytes sector write-protection (WRPS)
- 512 words of 16-bit of one-time programmable (OTP) reserved for user information
- 512-byte read-only area reserved to STMicroelectronics information
- Read command queue to streamline flash operations
- Support for ST immutable Root of Trust in system flash (STM32H7S only)
- Non-volatile 256-bit seed to compute derived root hardware keys (DHUK) in SAES peripheral
- Non-volatile key storage revocation counter (EPOCH)

5.3 FLASH functional description

5.3.1 FLASH block diagram

Figure 9 shows the embedded flash memory block diagram, with its interaction with the rest of the device.

Figure 9. FLASH block diagram

For more information on *RCC*, *SBS* (with its debug management) and *SAES*, refer to their dedicated chapters.

5.3.2 FLASH internal signals

Table 27 describes a list of the useful to know internal signals available at embedded flash memory level. These signals are not available on the microcontroller pads.

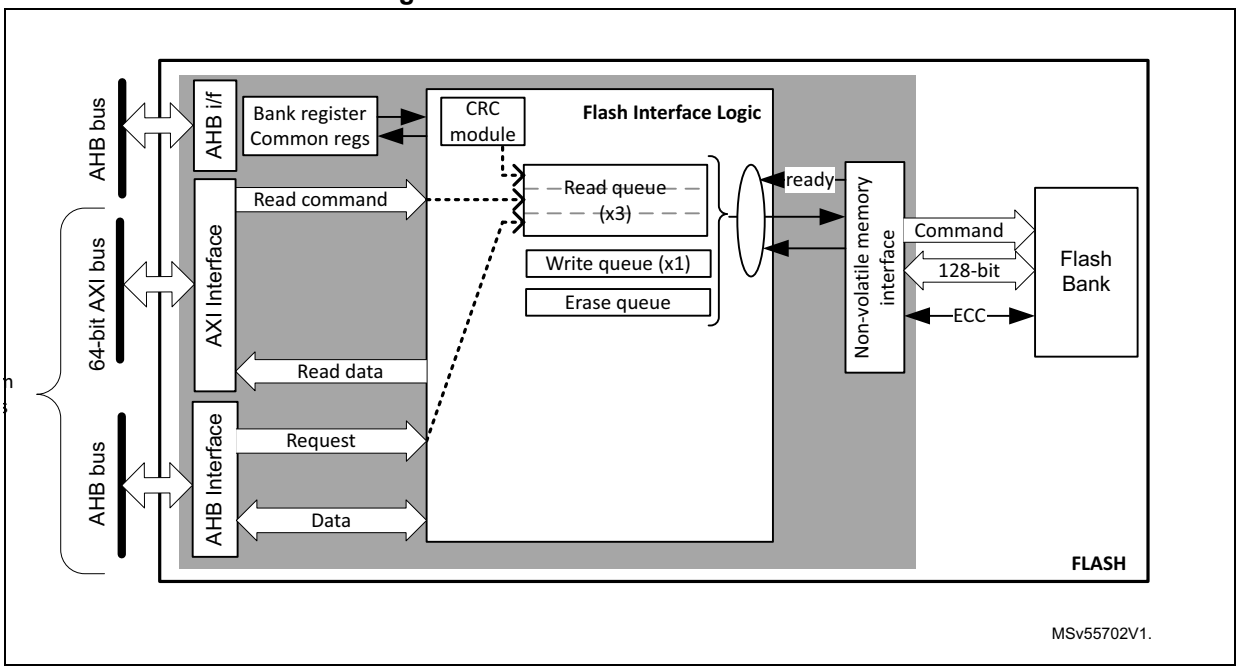
Table 27. FLASH internal input/output signals

Signal name	Signal type (1)	Description
po_rst	Input	Power on reset
flash_rst		Embedded flash reset
flash_aclk		AXI clock of system bus
flash_it	Output	Embedded flash memory interrupt request
keybus	Input/Output	Digital interface to transfer some option byte keys to SAES peripheral
rhuk	Output	256-bit hardware unique key to SAES peripheral
epoch	Output	24-bit revocation counter to SAES peripheral
hdpl[7:0]	Input	Hide protection level stored in SBS_HDPLSR register of SBS peripheral. Protected against physical attacks. Used by embedded flash memory.
nvstate[7:0]	Output	Non-volatile security state, used by SBS peripheral
block_sec	Input	Set by device to hide rhuk and all option byte keys stored in embedded flash (read as zero). When block_sec is cleared blocked keys becomes available again, depending on HDPL value.

1. Only digital signals

5.3.3 FLASH architecture and integration in the system

The embedded flash memory is a central resource for the whole microcontroller. It serves as an interface to a single non-volatile memory bank, and organizes the memory in a very specific way. The embedded flash memory also proposes a set of security features to protect the assets stored in the non-volatile memory at boot time, at run-time and during firmware and configuration upgrades.



The embedded flash memory offers three different interconnect interfaces:

- An AXI 64-bit slave port to access code/data
- An AHB 32-bit system slave port to access read-only and OTP area
- An AHB 32-bit configuration slave port to access register bank

Note: The application can simultaneously request a read and a write operation through the AXI slave port.

The embedded flash memory micro-architecture is shown in *Figure 10*.

Figure 10. Detailed FLASH architecture

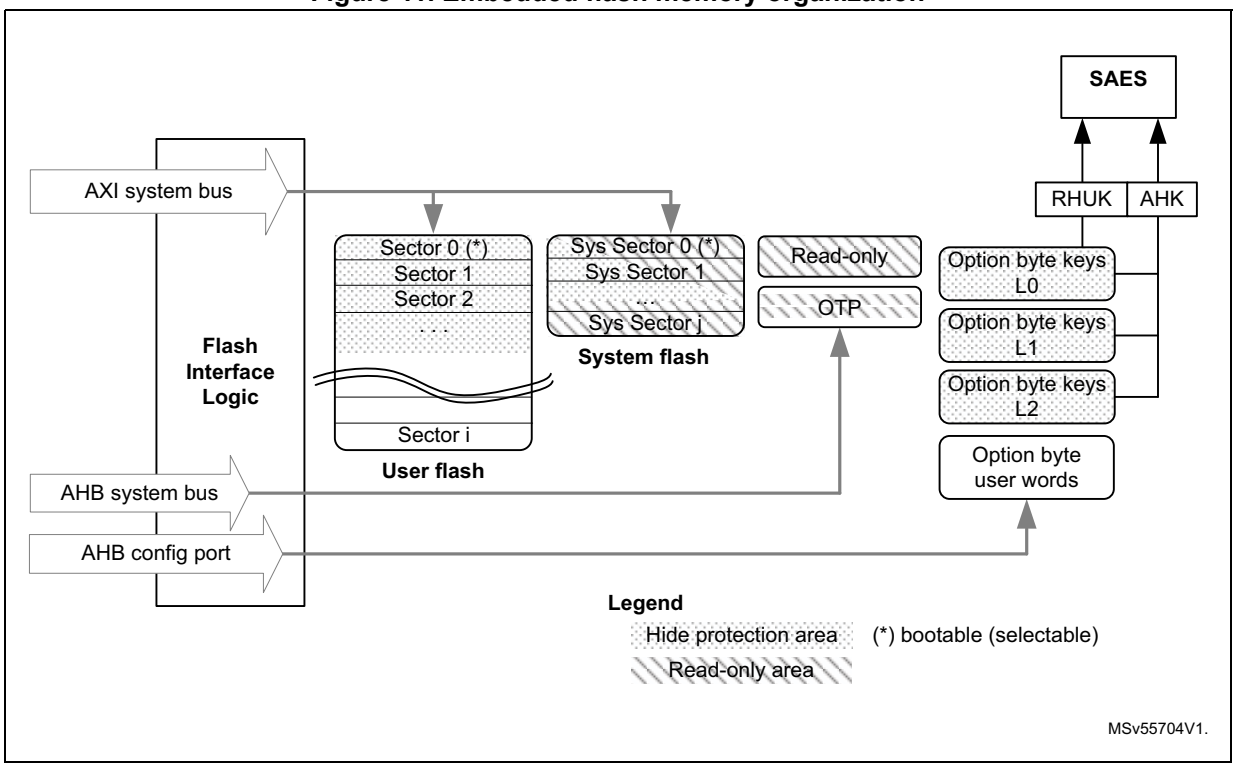
Behind the system interfaces, the embedded flash memory implements various command queues and buffers to perform flash read, write and erase operations with maximum efficiency.

By the addition of a read and write data buffer, the AXI slave port handles the following access types:

- Multiple length: 64 bits, 32 bits, 16 bits and 8 bits
- Single or burst accesses
- Write wrap burst must not cross 16-byte aligned address boundaries to target exactly one flash word

The AHB system slave port supports only 16-bit or 32-bit word accesses. For 8-bit accesses, an AHB bus error is generated and write accesses are ignored.

The AHB configuration slave port supports 8-bit, 16-bit and 32-bit word accesses.



The embedded flash memory is built in such a way that only one read or write operation can be executed at a time.

5.3.4 Flash memory architecture and usage

Flash memory architecture

Figure 11 shows the non-volatile memory organization in the embedded flash memory.

Figure 11. Embedded flash memory organization

The embedded flash non-volatile memory is composed of:

- A 64 Kbyte user memory block, organized as one bank divided in 8 sectors of 8 Kbytes each. This bank features flash-word rows of 128 bits + 9 bits of ECC per word. A user-defined address range benefits from a hide protection mechanism.
- A 128 Kbytes system memory block, organized as one bank divided in 16 sectors of 8 Kbytes each. The system flash memory features the same flash-word rows of 128 bits + 9 bits of ECC per word. A specific range, starting from the system boot sector, also benefit from a hide protection mechanism.
- A set of non-volatile user option byte words, loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.
- Three sets of non-volatile option byte keys, loaded at any time by the application software through the AHB configuration register interface. All the option byte keys benefit from a hide protection mechanism.
- A 1 Kbyte one-time-programmable (OTP) area that can be written only once by the application software.
- A 512-byte read-only area written by STMicroelectronics during SoC manufacturing.

Note: The system flash memory cannot be programmed nor erased by any application.

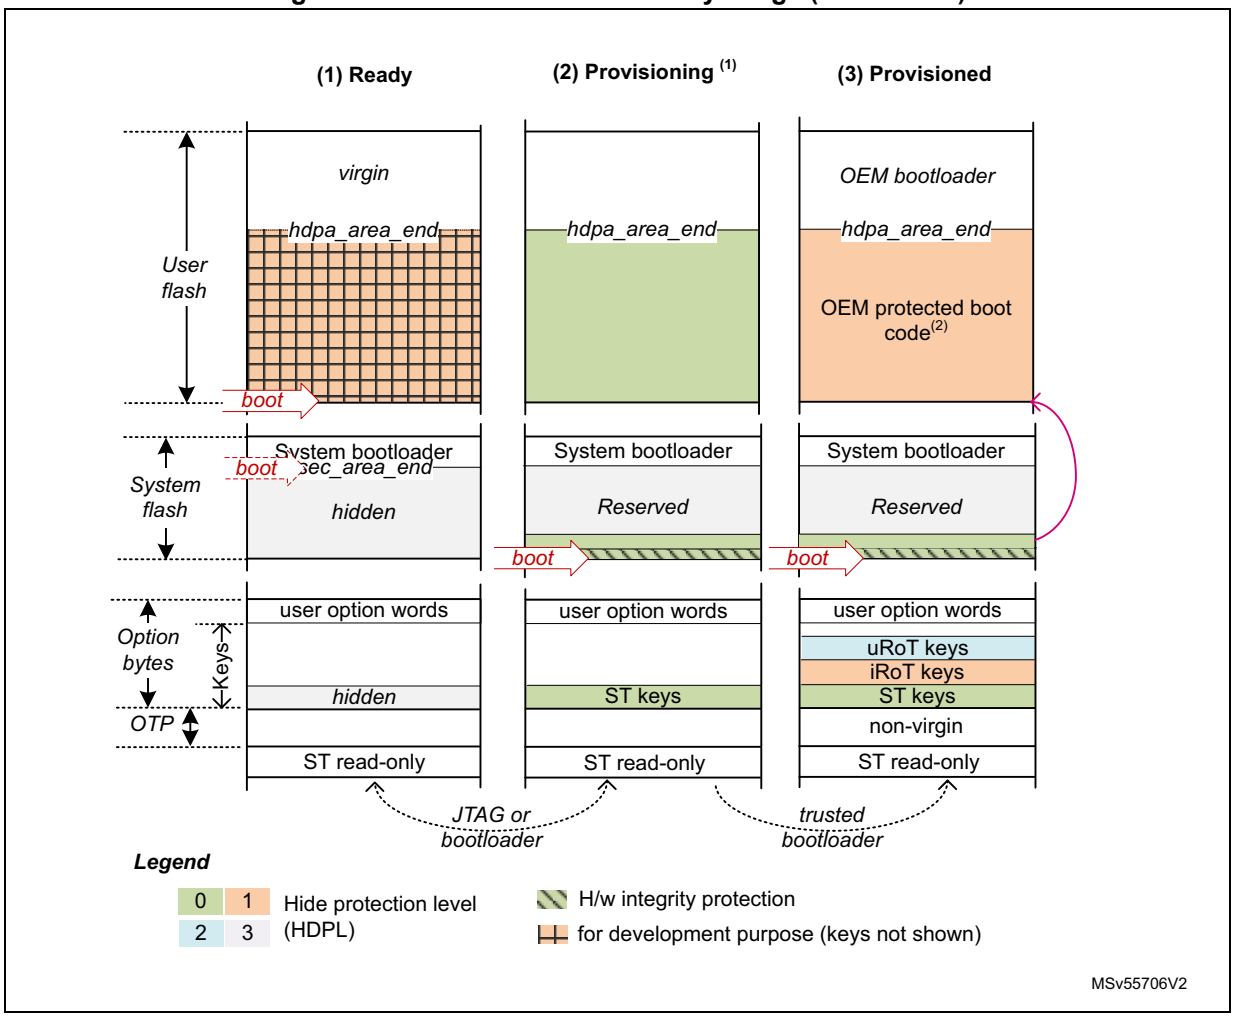
Since the OTP area has no specific protection, it must not be used to store confidential information.

The overall flash memory architecture and its corresponding access interface is summarized in *Table 28*.

Table 28. Flash memory organization

Flash memory area	Address range	Size (bytes)	Region name	Access interface	SSN(1)
User main memory	0x0800 0000-0x0800 1FFF	8 K	Sector 0	AXI port	0x0
	0x0800 2000-0x0800 3FFF	8 K	Sector 1		0x1
	...	...	...		...
	0x0800 E000-0x0800 FFFF	8 K	Sector 7		0x7
System memory	0x1FF0 0000-0x1FF0 1FFF	8 K	System sector 0	AXI port	N/A(2)
	...	...	...		
	0x1FF1 E000-0x1FF1 FFFF	8 K	System sector 15		
Special region	0x08FF F000-0x08FF F3FF	1 K	OTP area	AHB system port	N/A(2)
	0x08FF F800-0x08FF FFFF	512	Read-only area		
Option bytes	registers	-	User option bytes	Registers only	N/A

1. SSN contains the target sector number for an erase operation. See
2. Cannot be erased by application software



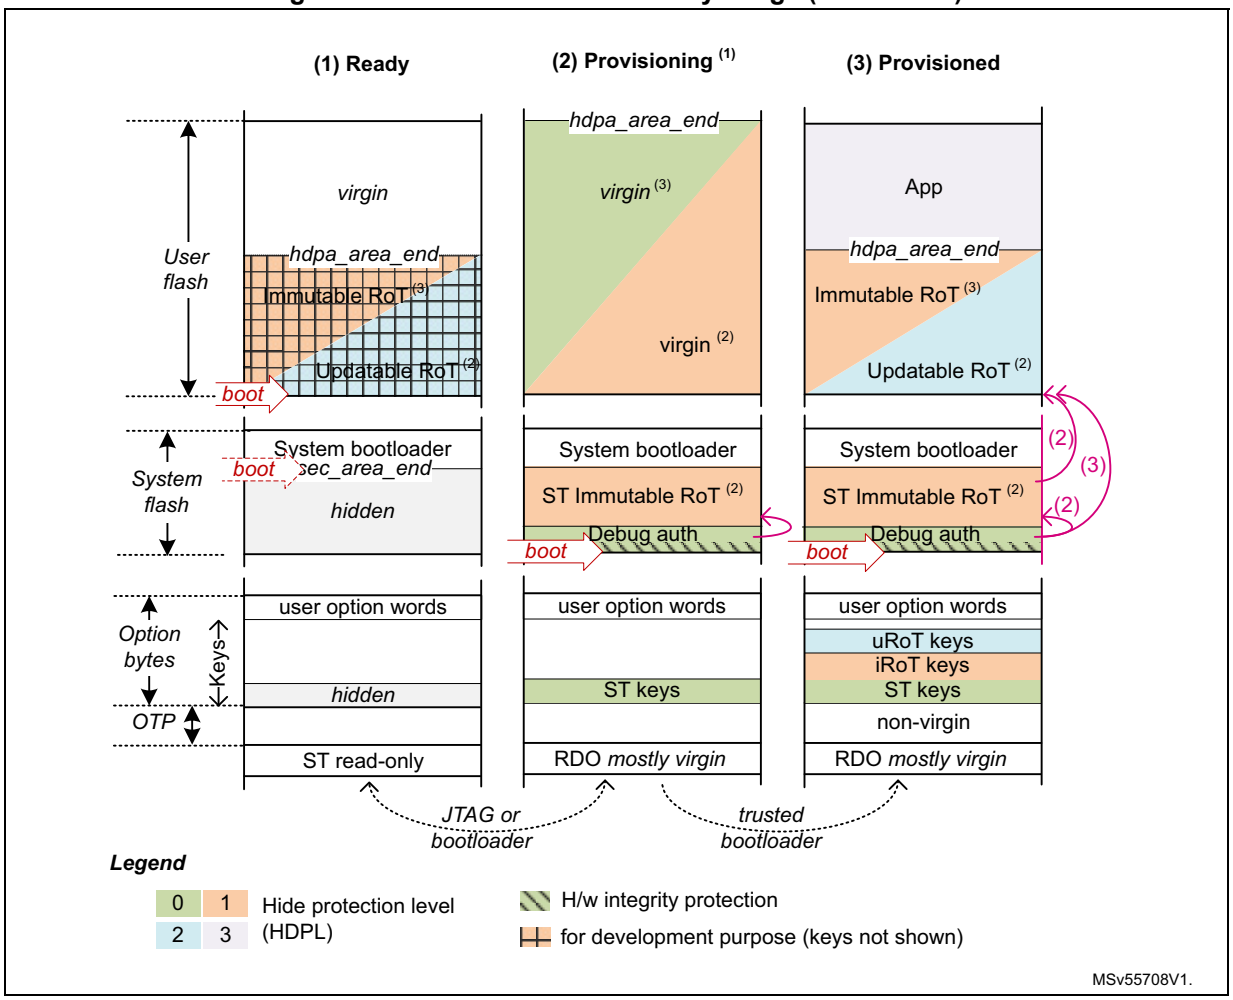
Partition usage

In the life of the product embedded flash memory stores different kinds of data. Data availability also vary according to the hide protection level (HDPL) selected by the application at any given time. See *Section 8: System configuration, boot and security (SBS)* for more details.

For STM32H7R devices the typical flash usages are described on *Figure 12* and below.

1. Device on a Nucleo board for s/w development, or in production warehouses.
2. Device is being provisioned with immutable root of trust firmware and root of trust keys on an untrusted OEM production line, using secure firmware install (SFI).
3. Device on the final personalization line of the customer, and as used in the final product.

Figure 12. Embedded flash memory usage (STM32H7R)

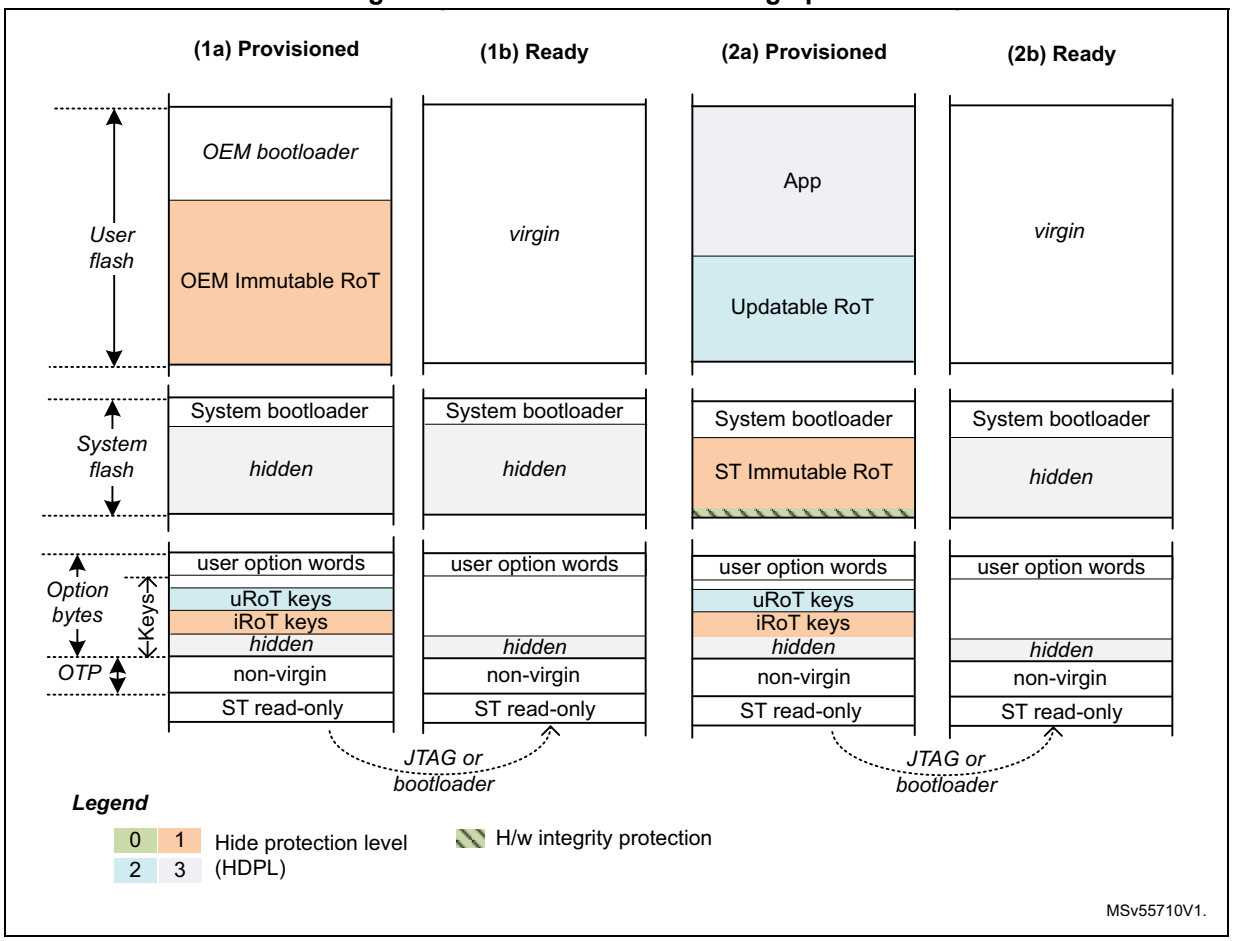


1. In this state OEM_PROVD option byte is not 0xB4
2. This boot code could be protected via the HDPL area refer to *Section 5.5.5: Hide protected user flash area*.

For STM32H7S devices the typical flash memory usage and options are described on *Figure 13* and below:

1. Device on a Nucleo board for software development, or in production warehouses.
2. Device is being provisioned with updatable root of trust firmware and root of trust keys on an untrusted OEM production line, using Secure Keys Provisioning (SKP) service. Alternatively, the device is being provisioned with immutable root of trust firmware and root of trust keys on an untrusted OEM production line, using secure firmware install (SFI).
3. Device on the final personalization line of the customer, and as used in the final product

Figure 13. Embedded flash memory usage (STM32H7S)



1. In this state OEM_PROVD option byte is not 0xB4
2. ST iRoT is selected through IROT_SELECT option byte
3. OEM iRoT is selected through IROT_SELECT option byte. When OEM iRoT executes ST iRoT is hidden.

Figure 14 shows how the embedded flash memory is used when an OEM returns a provisioned production device to an open state (for field return to ST) or to a closed state to build a product. Two decommissioning scenarios are proposed:

1. Device opening for devices with OEM iRoT
2. Device opening for devices with ST iRoT (STM32H7S only).

Note: In any device, if application knows the decommissioning key it can open the device using STM32 tools.

Figure 14. Flash decommissioning options

5.3.5 Flash hide protection schemes

Figure 11 gives an overview of the protection mechanism supported by the embedded flash memory:

- A user flash area can be defined as user HDP area, with an hardware defined access policy based on STM32 hide protection level (HDPL).
- A system flash starting from sector zero is defined as system HDP area, also with a hardware defined access policy based on STM32 hide protection level (HDPL).
- Three sets of option byte keys are each reserved to a specific hide protection level. Some of those keys can be reserved to be used exclusively by the side channel attacks protected SAES engine, as application hardware keys (AHK).

For more information on both HDP areas, refer to *Section 5.5.4: Hide protected system flash area* and *Section 5.5.5: Hide protected user flash area*. More details on option byte keys can be found in *Section 5.4.4: Option byte key management*.

5.3.6 Overview of FLASH operations

Read operations

The embedded flash memory can perform read operations on the whole non-volatile memory using various granularities: 64 bits, 32 bits, 16 bits or one byte. User and system flash memories are read through the AXI interface, while the option bytes are read through the register interface. Read-only and OTP special region are read through the system AHB interface.

To increase efficiency, the embedded flash memory implements the buffering of consecutive read requests.

For more details on read operations, refer to *Section 5.3.7: FLASH read operations*.

Program/erase operations

The embedded flash memory supports the following program and erase operations:

- Single flash word write (128-bit granularity for user flash memory, 16-bit granularity for OTP area), with the possibility for the application to force-write a user flash word with less than 128 bits in user flash memory
- Single sector erase
- Bank erase
- Option byte words update, option byte key write (if allowed)

Note: Program and erase operations are subject to the various protection that could be set on the embedded flash memory (see next).

For more details, refer to *Section 5.3.8: FLASH program operations* and *Section 5.3.9: FLASH erase operations*.

Protection mechanisms

The embedded flash memory supports different protection mechanisms:

- Configuration protection
- Write protection
- Temporal isolation enforcement of non-volatile secrets (code/data, keys), based on the hide protection level information stored in SBS_HDPLSR register.
- Life cycle management, based on flash root of trust option bytes
- OTP locking

For more details refer to *Section 5.5: FLASH protection mechanisms*.

Option byte loading

As part of the life cycle management, the embedded flash memory reliably loads the non-volatile option bytes stored in non-volatile memory after every power on reset, enforcing boot and security options to the whole device when the embedded flash memory becomes functional again. For more details refer to *Section 5.4: FLASH option bytes*.

5.3.7 FLASH read operations

Read operation overview

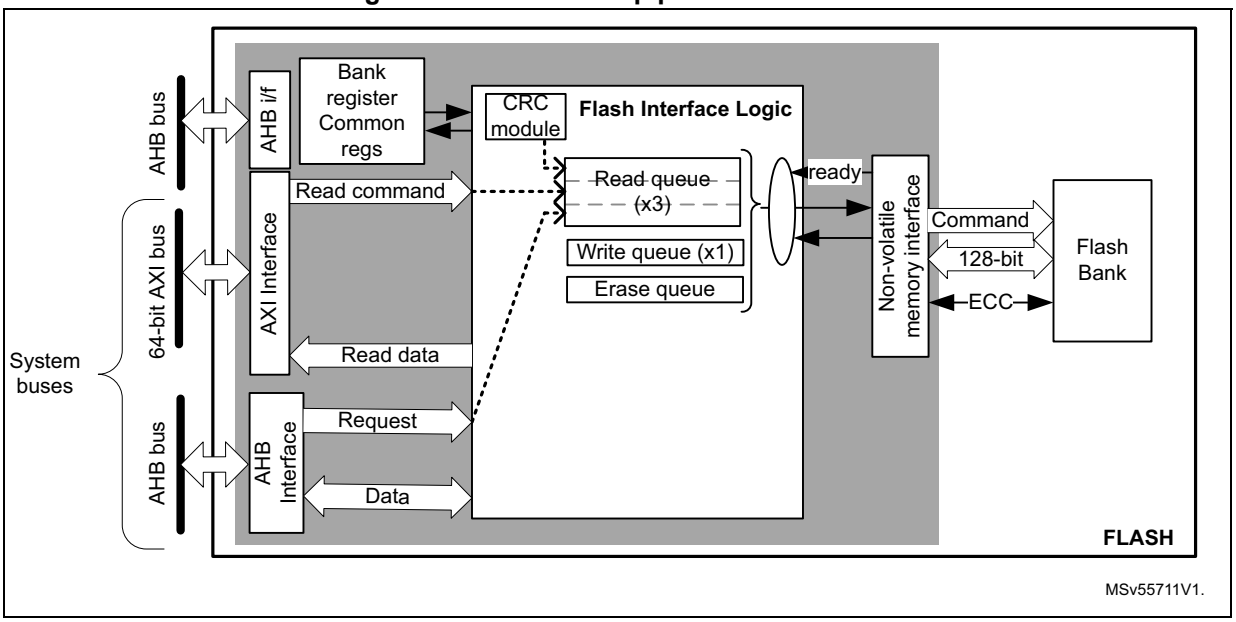
The embedded flash memory supports the execution of one read command while two are waiting in the read command queue. Multiple read access types are also supported as defined in *Section 5.3.3: FLASH architecture and integration in the system*.

The read commands is associated with a 128-bit read data buffer. These commands can be issued either by the AHB (OTP or read-only areas) or by the AXI interface (user flash or system flash memory).

Note: The embedded flash memory can perform single error correction and double error detection while read operations are being executed (see Section 5.3.10: Flash memory error protections).

The AXI interface read channel operates as follows:

- When the read command queue is full, any new AXI read request stalls the bus read channel interface and consequently the master that issued that request.
- If several consecutive read accesses request data that belong to the same flash data word (128 bits), the data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time a read access is granted. When a read access is rejected for security reasons (e.g. HDP protected word), the corresponding read error response is issued by the embedded flash memory and no read operation to flash memory is triggered.



The AHB system interface operates a follows:

- Until the AHB read request has been served, the embedded flash memory stalls the AHB bus and consequently the master that issued that request.

The Read pipeline architecture is summarized in *Figure 15*.

For more information on bus interfaces, refer to *Section 5.3.3: FLASH architecture and integration in the system*.

Figure 15. FLASH read pipeline architecture

Single read sequence

The recommended simple read sequence is the following:

1. For AXI interface: Freely perform read accesses to any AXI-mapped area. For AHB interface: perform either 16-bit or 32-bit read accesses to the AHB-mapped area (byte accesses generate a bus error).
2. The embedded flash memory effectively executes the read operation from the read command queue buffer as soon as the non-volatile memory is ready and the previously requested operations have been served.

Note: When reading an OTP data that has not been previously written, a double ECC error is reported and only 1's are returned (see Section 5.3.11 for details).

Adjusting read timing constraints

The embedded flash memory clock must be enabled and running before reading data from non-volatile memory.

To correctly read data from flash memory, the number of wait states (LATENCY) must be correctly programmed in the flash access control register (FLASH_ACR) according to the embedded flash memory AXI interface clock frequency (sys_ck) and the internal voltage range of the device (V_{core}).

Table 29 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency and its supply voltage ranges.

Table 29. FLASH recommended read wait states and programming delays

Wait states per flash word read (LATENCY)	Read latency (cycles per flash word)	Programming delay (WRHIGH FREQ)	AXI Interface clock frequency v.s. V_{CORE} range	
			VOS low range 1.15 V - 1.26 V	VOS high range 1.30 V - 1.40 V
0x0	1	00	[0MHz ; 36MHz]	[0MHz ; 40MHz]
0x1	2		[36MHz ; 72MHz]	[40MHz ; 80MHz]
0x2	3	01	[72MHz ; 108MHz]	[80MHz ; 120MHz]
0x3	4	01	[108MHz ; 144MHz]	[120MHz ; 160MHz]
0x4	5	10	[144MHz ; 180MHz]	[160MHz ; 200MHz]
0x5	6	10	[180MHz ; 216MHz]	[200MHz ; 240MHz]
0x6	7	11	N/A	[240MHz ; 280MHz]
0x7	8	11	N/A	[280 MHz; 320 MHz]

Adjusting the system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at VOS low.

When changing the AXI bus frequency, the application software must follow the below sequence in order to tune the number of wait states required to access the non-volatile memory.

To increase the embedded flash memory clock source frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 29*.
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AXI bus clock prescaler value are taken in account by reading back the embedded flash memory clock source status and/or the AXI bus prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the embedded flash memory clock source frequency:

1. Modify the embedded flash memory clock source and/or the AXI bus clock prescaler in the RCC_CFGR register of reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new AXI bus clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AXI interface prescaler value in the RCC_CFGR register of reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in FLASH_ACR register, as described in *Table 29*.
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Read errors

The embedded flash memory embeds an error correction mechanism, as described in *Section 5.3.10*.

Single error correction and double error detection are performed for each read operation. In both cases the embedded flash memory reports read errors as described in *Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF)*.

Read interrupts

See *Section 5.8: FLASH interrupts* for details.

5.3.8 FLASH program operations

Program operation overview

The virgin state of each non-volatile memory bitcell is 1. The embedded flash memory supports programming operations that can change any memory bitcell to 0. However these operations do not support the return of a bit to its virgin state. In this case an erase operation of the entire sector is required.

Program operation consists in issuing write commands. For write accesses issued by the AXI interface, since a 9-bit ECC code is associated to each 128-bit data flash word, the embedded flash memory must always perform write operations to non-volatile memory with a 128-bit word granularity.

Note: The application can decide to write as few as 8 bits to a 128-bit flash word. In this case, a force-write mechanism to the 128 bits + ECC is used (see FW bit of FLASH_CR register).

System flash memory cannot be written by the application software.

It is not recommended to overwrite a flash word that is not virgin. The result may lead to an inconsistent ECC code that is systematically reported by the embedded flash memory, as described in *Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF)*.

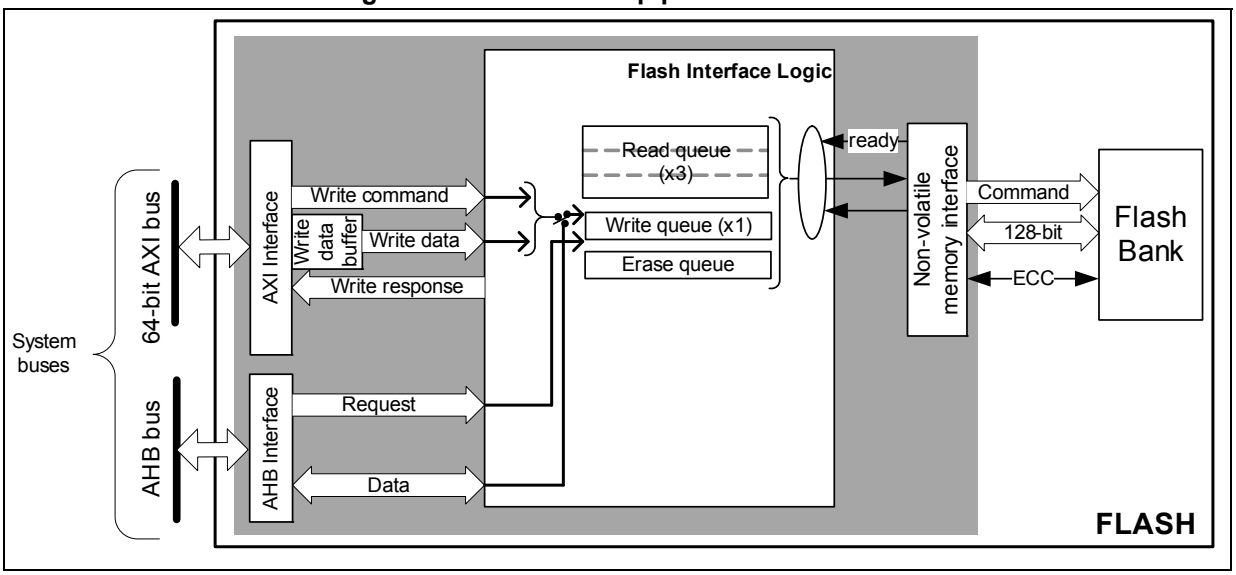
Write access requests issued by the AHB system interface are serialized with AXI commands and can only be used to program the memory OTP area. In this area, since a 6-bit ECC code is associated to each 16-bit data flash word, the embedded flash memory supports 16-bit or 32-bit write operations (8-bit write operations are not supported).

Note: The OTP area is typically write-protected on the final product, as described in Section 5.3.11: FLASH one-time programmable area.

Erase operations to the OTP area are not supported.

The AXI interface write channel operates as follows:

- A 128-bit write data buffer is associated with the AXI interface. It supports multiple write access types (64 bits, 32 bits, 16 bits and 8 bits).
- When the write queue is full, any new AXI write request stalls the bus write channel interface and consequently the master that issued that request.



The AHB system interface operates as follows:

- Write commands issued by the AHB system interface are associated with a 137-bit flash word buffer. Byte accesses are not supported.
- When the write queue is full, any new AHB request stalls the bus interface and consequently the master that issued that request.

The write pipeline architecture is described in *Figure 16*.

For more information on bus interfaces, refer to *Section 5.3.3: FLASH architecture and integration in the system*.

Figure 16. FLASH write pipeline architecture

Managing write protections

Before programming a user sector, the application software must check the protection of the targeted flash memory area.

The embedded flash memory checks the protection properties of the write transaction target at the output of the write queue buffer, just before the effective write operation to the non-volatile memory:

- If a write protection violation is detected, the write operation is canceled and write protection error (WRPERRF) is raised in FLASH_ISR register.
- If the write operation is valid, the 9-bit ECC code is concatenated to the 128 bits of data and the write to non-volatile memory is effectively executed.

Note: No write protection check is performed when the embedded flash memory accepts AXI write requests.

A similar mechanism exists for OTP areas with the following differences:

- If the write operation is valid, the 6-bit ECC code is concatenated to the 16 bits of data and the write to non-volatile memory is effectively executed.

The write protection flag does not need to be cleared before performing a new programming operation.

Monitoring ongoing write operations

The application software can use three status flags located in FLASH_SR in order to monitor ongoing write operations.

- **BUSY**: this bit indicates in real-time that an effective write, erase or option byte change operation is ongoing to the non-volatile memory. It is possible to know what type of

operation is being executed polling the bits IS_PROGRAM, IS_ERASE and IS_OPTCHANGE in the same register.

- **QW**: this bit indicates that a write, erase or option byte change operation is pending in the write queue or command queue buffer. It remains high until the write operation is complete. It supersedes the BUSY status bit.
- **WBNE**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, force-writes the operation using FW bit in FLASH_CR, or disables all write operations.

Enabling write operations

Before programming the user flash memory, the application software must make sure that PG bit is set in FLASH_CR. If it is not set an unlock sequence must be used once (see *Section 5.5.1: FLASH configuration protection*) and the PG bit must be set.

Before programming an option byte word or an option byte key, the application software must make sure that PG_OPT bit is set in FLASH_OPTCR. If it is not set an unlock sequence must be used once (see *Section 5.5.1: FLASH configuration protection*). For more information on option byte word (resp. option byte key) modification, refer to *Section 5.4.3* (or *Section 5.4.4* respectively).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset.

If needed, the application software can update the programming delay as described at the end of this section.

Single write sequence

The recommended single write sequence is the following:

1. Unlock the FLASH_CR register, as described in *Section 5.5.1: FLASH configuration protection* (only if register is not already unlocked).
2. Enable write operations by setting the PG bit in the FLASH_CR register.
3. Check the protection of the targeted memory area.
4. Write one flash-word corresponding to 16-byte data starting at 16-byte aligned address.
5. Check that QW has been raised and wait until it is cleared to 0.

If step 4 is executed incrementally (for example byte per byte), the write buffer can become partially filled. In this case the application software can decide to force-write what is stored in the write buffer by using FW bit in FLASH_CR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Note: Using a force-write operation prevents the application from updating later the missing bits with a value different from 1, which is likely to lead to a permanent ECC error.

Any write access requested while the PG bit is cleared to 0 is rejected. In this case, no error is generated on the bus, but the PGSERRF flag is raised.

Clearing the programming sequence error (PGSERRF) and inconsistency error (INCERRF) is mandatory before attempting a write operation (see Section 5.7: FLASH error management for details).

Adjusting programming timing constraints

Program operation timing constraints depend of the embedded flash memory clock frequency, which directly impacts the performance. If timing constraints are too tight, the non-volatile memory does not operate correctly, if they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to *Table 29* in *Section 5.3.7: FLASH read operations* for the recommended programming delay depending on the embedded flash memory clock frequency.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ parameter.

Caution: Modifying WRHIGHFREQ while programming/erasing the flash memory might corrupt the flash memory content.

Programming errors

When a program operation fails, an error can be reported as described in *Section 5.7: FLASH error management*.

Programming interrupts

See *Section 5.8: FLASH interrupts* for details.

5.3.9 FLASH erase operations

Erase operation overview

The embedded flash memory can perform erase operations (if allowed) on 8-Kbyte user sectors or on the whole user flash memory.

Note: System flash memory and read-only/OTP area cannot be erased by the application software.

The erase operation forces all non-volatile bit cells to high state, which corresponds to the virgin state. It clears existing data and corresponding ECC, allowing a new write operation to be performed. If the application software reads back a word that has been erased or not programmed, all the bits are read at 1. No ECC error is generated if the word is located in user flash memory, while a double ECC error is raised if the word is located in read-only or OTP area.

Erase operations are similar to read or program operations except that the commands are queued in a special buffer (a one-command deep erase queue).

Erase commands are issued through the AHB configuration interface. If the embedded flash memory receives simultaneously a write and an erase request, both operations are accepted but the write operation is executed first.

Erase and security

A user sector can be erased only if it does not contain hide protected or write-protected data (see *Section 5.5: FLASH protection mechanisms* for details). In other words, if the application software attempts to erase a user sector with at least one flash word that is protected, the sector erase operation is aborted and the WRPERRF flag is raised in the FLASH_ISR register, as described in *Section 5.7.2*.

The only method to erase HDP protected sectors is to perform a regression, triggering a NVSTATE change from CLOSE to OPEN. See *Section 5.5.3* for details.

Enabling erase operations

Before erasing a sector, the application software must make sure that FLASH_CR is unlocked. If it is not the case, an unlock sequence must be used (see *Section 5.5.1: FLASH configuration protection*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset.

Similar constraints apply to bank erase requests.

Flash sector erase sequence

To erase a 8-Kbyte user sector, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to *Section 5.7: FLASH error management* for details.
2. Unlock the FLASH_CR register, as described in *Section 5.5.1: FLASH configuration protection* (only if register is not already unlocked).
3. Set the SER bit and SSN bitfield in the corresponding FLASH_CR register. SER indicates a sector erase operation, while SSN contains the target sector number.
4. Set the START bit in the FLASH_CR register.
5. Wait for the QW bit to be cleared in the FLASH_SR register.

Note: If a bank erase is requested simultaneously to the sector erase (BER and SER bits set), the bank erase operation supersedes the sector erase operation.

Flash bank erase sequence

To erase all bank sectors except for those containing hide protected data, proceed as follows:

1. Check and clear (optional) all the error flags due to previous programming/erase operation. Refer to *Section 5.7: FLASH error management* for details.
2. Unlock the FLASH_CR register, as described in *Section 5.5.1: FLASH configuration protection* (only if register is not already unlocked).
3. Set the BER bit in the FLASH_CR register .
4. Set the START bit in the FLASH_CR register to start the bank erase operation. Then wait until the QW bit is cleared in FLASH_SR register.

Note: BER and START bits can be set together, so above steps 3 and 4 can be merged.

If a sector erase is requested simultaneously to the bank erase (SER bit set), the bank erase operation supersedes the sector erase operation.

5.3.10 Flash memory error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism. It is based on the SECDED algorithm in order to correct single errors and detects double errors.

Per 128-bit system and user flash word the embedded flash memory uses 9 ECC bits. During each read operation from a 128-bit flash word, FLASH retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the reference value. If they do not match, the corresponding ECC error is raised as described in *Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF)*. During each program operation, a 9-bit ECC code is associated to each 128-bit data flash word, and the resulting 137-bit flash word information is written in non-volatile memory.

For read-only and OTP areas, the embedded flash memory uses a stronger 6 ECC bits per 16-bit word. For option byte words and keys a double ECC scheme is used. For more information on read-only and OTP refer to *Section 5.3.11* and *Section 5.3.12*. For more information on option byte words and keys refer to *Section 5.4*.

Note: A double ECC error is generated for an OTP virgin word (i.e. a word with 22 bits at 1). When this OTP word is no more virgin, the ECC error disappears.

Cyclic redundancy codes (CRC)

The embedded flash memory implements a cyclic redundancy check (CRC) hardware module. This module checks the integrity of a given user flash memory area content.

The area processed by the CRC module can be defined either by sectors or by start/end addresses.

When enabled, the CRC hardware module performs multiple reads by chunks of 4, 16, 64 or 256 consecutive flash-word (i.e. chunks of 64, 256, 1024 or 4096 bytes). These consecutive read operations are pushed by the CRC module into the required read command queue together with other AXI read requests, thus avoiding to deny AXI read commands.

CRC computation uses CRC-32 (Ethernet) polynomial 0x4C11DB7:

$$X^{32}+ X^{26}+ X^{23}+ X^{22}+ X^{16}+ X^{12}+ X^{11}+ X^{10}+ X^{8}+ X^{7}+ X^{5}+ X^{4}+ X^{2}+ X + 1$$

The CRC operation is concurrent with the reading or writing of option byte user words, keys or OTP, because the same hardware is used for all those operations. To avoid corruption to the CRC computation the flash stalls above incoming requests when a CRC operation is on-going.

The sequence recommended to configure a CRC operation is the following:

1. Unlock FLASH_CR register, if not already unlocked.
2. Enable the CRC feature by setting the CRC_EN bit in FLASH_CR.
3. Program the desired data size in the CRC_BURST field of FLASH_CRCCR.
4. Define the user flash memory area on which the CRC has to be computed. Three solutions are possible:
   - Select all user flash sectors by setting the ALL_SECT bit in FLASH_CRCCR
   - Define the area start and end addresses by programing FLASH_CRCSADDR and FLASH_CRCEADDR, respectively,
   - Select the targeted sectors by setting the CRC_BY_SECT bit in FLASH_CRCCR. Also program consecutively the target sector numbers using the CRC_SECT field

of the FLASH_CRCCR register. Set ADD_SECT bit after each CRC_SECT programming.

5. When step 4 is completed start the CRC operation by setting the START_CRC bit in FLASH_CRCCR.
6. Wait until the CRC_BUSY flag is reset in FLASH_SR.
7. Retrieve the CRC result in FLASH_CRCDATAR.

Note: The application should avoid running a CRC on HDP user flash memory area when the hide protection level prevents access to it. Indeed, doing so may alter the expected CRC value. A special error flag defined in Section 5.7.8: CRC read error (CRCRDERRF) can be used to detect such a case.

CRC computation does not raise standard read error flags such as RDSERRF and DBECCERRF. Only CRCRDERRF is raised.

5.3.11 FLASH one-time programmable area

The embedded flash memory offers a 1024-byte memory area dedicated to application non-confidential one-time programmable data (OTP). It is composed of 512 words of 16 bits that cannot be erased, and can be written only once.

Note: The OTP area is virgin when the device is delivered by STMicroelectronics.

OTP data can be accessed through the AHB system port. They are organized as 16 blocks of 32 OTP words, as shown in *Table 30*. An entire OTP block can be protected (locked) from write accesses by setting the corresponding OTPL bit in the FLASH_OTPLSRP register, as shown. There is no special read protection mechanism on the OTP area.

*Note: The OTP block locking operation is **irreversible** and independent from the life cycle management described in Section 5.5.3.*

A block can be write-protected whether or not it has been programmed (even partially).

Table 30. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF F000	OTP001	OTP000	OTPL[0]
	0x08FF F004	OTP003	OTP002	
	...			
	0x08FF F03C	OTP031	OTP030	
Block 1	0x08FF F040	OTP033	OTP032	OTPL[1]
	0x08FF F044	OTP035	OTP034	
	...			
	0x08FF F07C	OTP063	OTP062	
Block 2	0x08FF F080	OTP065	OTP064	OTPL[2]
	0x08FF F084	OTP067	OTP066	
	...			
	0x08FF F0BC	OTP127	OTP126	

Table 30. Flash memory OTP organization (continued)

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
...				
Block 15	0x08FF F3C0	OTP481	OTP480	OTPL[15]
	0x08FF F3C4	OTP483	OTP482	
	...			
	0x08FF F3FC	OTP511	OTP510	

OTP error protection

OTP data are organized as 16 blocks of 32 OTP words, as shown on *Table 30*. Each 16-bit half-word is protected by 6 bits of ECC. Hence application must avoid overwriting a 16-bit half-word that has already been programmed, as it is leading to systematic ECC error. Similarly, do not write twice an 16-bit OTP word, as it could lead to systematic ECC error.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in *Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF)*.

When reading OTP data that has not been written by the application software (that is, virgin OTP), the ECC correction reports a double error detection (DBECCERRF), and all 1's are returned. It is therefore recommended that the application always writes the OTP data before trying to read it.

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check the protection status of the target OTP word (see *Table 30*). The corresponding OTPLi bit must be cleared in FLASH_OTPLSR register.
2. Unlock FLASH_CR if the register is not already unlocked, and then set PG_OTP bit in the FLASH_CR register.
3. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 30*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case the first 16-bit write operation starts immediately without waiting for the second one.
4. Check that the QW bit in FLASH_SR has been set and wait until it is cleared.
5. Read back the target OTP word to confirm the value
6. Optionally, lock the OTP block using OTPLi bit in FLASH_OTPLSRP in order to prevent further data changes. PG_OTP bit in the FLASH_CR register can also be cleared if needed.

Note: To avoid data corruption, it is important to complete the OTP write process (for example by reading back the OTP value), before starting a new option byte change.

No error sequence and no inconsistency error are generated during OTP write operations.

Writing OTP data at byte level is not supported and generates a bus error.

5.3.12 FLASH read-only area

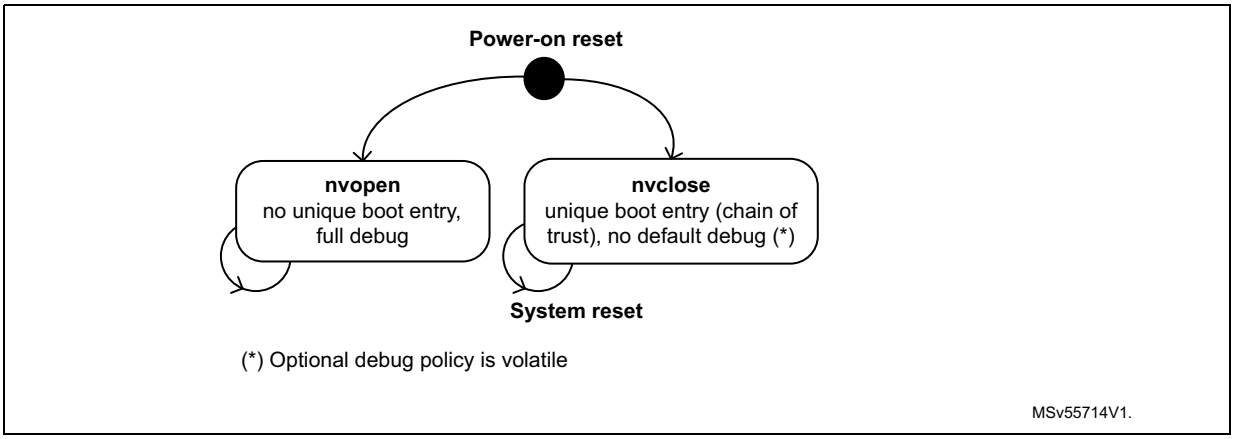
The embedded flash memory offers a 512-byte memory area dedicated to non-confidential and read-only information usable by application software.

Read-only area can be accessed through the AHB system port. It is organized as shown in *Table 31*. This information is provisioned by STMicroelectronics during the device manufacturing.

Table 31. Read-only public data organization

AHB address (read-only)	Read-only data name and usage
0x08FF F800	U_ID[31:0]
0x08FF F804	U_ID[63:32]
0x08FF F808	U_ID[95:64]
0x08FF F80C	Package code[15:0]
0x08FF F810 to 0x08FF F9FF	Reserved information

Read-only area error protection



Read-only area is protected by a robust ECC scheme. When reading a 32-bit word in this area with a single error corrected or a double error detected, the embedded flash memory reports the corresponding error, as described in *Section 5.7.6: Error correction code error (SNECCERRF/DBECCERRF)*.

5.3.13 FLASH reset and clocks

Reset management

Following a power-on reset embedded flash selects two security states, as shown on *Figure 17*. For more details on those states, refer to *Section 5.5.3*.

Figure 17. FLASH stateful initialization

Embedded flash memory stateful initialization is based on the overloading of option bytes default values by non-volatile values automatically loaded when the reset signal rises.

During this loading sequence, other parts of the device remains under reset and the embedded flash memory is not accessible from its interfaces.

The embedded flash memory can be reset at any time by the application through the RCC peripheral, with the following effects:

- All registers, except for option byte registers, are cleared, including read and write latencies. Option byte register list is found in *Section 5.4.5*.
- Most control registers are automatically protected against write operations, as described in *Section 5.5.1: FLASH configuration protection*.

It is important to note that the contents of the flash memory (except option bytes) are not guaranteed if a power-on-reset occurs during a flash memory write or erase operation. For option bytes a valid content is always guaranteed, as embedded flash uses the old option byte values when an option byte modification is interrupted by a reset. In this case a new option byte change request must be issued to modify those option bytes.

Clock management

The embedded flash memory uses the AXI interface clock. Depending on the device clock and internal supply voltage, specific read and write latency settings usually need to be set in the flash access control register (FLASH_ACR), as explained in *Section 5.3.7: FLASH read operations* and *Section 5.3.8: FLASH program operations*.

5.4 FLASH option bytes

5.4.1 About option bytes

The embedded flash memory includes a set of non-volatile option bytes that are either freely modified through configuration registers (option byte words), or are managed as non-volatile keys with a special temporal isolation protection mechanism.

This section explains:

- how option byte words and keys are loaded
- how application software can change option byte words, under which conditions
- how application software can program option byte keys
- what is the detailed list of option byte words, together with their default factory values (that is, before the first option byte change).

5.4.2 Option byte loading

When the device is first powered, the embedded flash memory automatically loads all the option byte words, and few selected option byte keys. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed.

When an ECC issue is detected during this option byte loading sequence OBLERRF flag is raised, as described in *Section 5.7.12*.

5.4.3 Option byte words modification

Changing option byte words

A option byte word change operation can modify the configuration and the protection settings saved in the non-volatile option byte area, if allowed.

The embedded flash memory features two sets of option byte words registers:

- The first register set contains the current values of the option bytes. Their names have the SR extension. All “SR” registers are read-only. Unless documented otherwise, their values are automatically loaded from the non-volatile memory after power-on reset, or after a successful option byte change operation.
- The second register set allows the modification of the option bytes. Their names ends with the SRP extension. All “SRP” registers can be accessed in read/write mode.

Note: When the OPTLOCK bit in FLASH_OPTCR register is set, writes to SRP registers are ignored.

When option byte word register “SRP” is written the embedded flash memory checks if at least one option byte needs to be programmed by comparing the current values in corresponding “SR” register. If a change is detected, if associated change conditions are met (see *Changing security option bytes*) and if PG_OPT bit is set in FLASH_OPTCR, the embedded flash memory launches the option byte modification in its non-volatile memory and update the “SR” register.

If one of the condition described in *Changing security option bytes* is not respected, the embedded flash memory sets the OPTERRF flag in the FLASH_OPTISR register and aborts the option byte change operation.

Unlocking the option byte modification

After reset, the OPTLOCK bit is set and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option byte words, setting PG_OPT bit. The FLASH_OPTCR unlock sequence is described in *Section 5.5.1*

Option byte modification sequence

To modify an option byte word, follow the sequence below:

1. Unlock FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Enable the write operations by setting the PG_OPT bit in FLASH_OPTCR.
3. Write the desired new option byte values in the corresponding option byte word register (FLASH_xSRP).
4. Wait until the QW bit is cleared in FLASH_SR register. Once cleared corresponding FLASH_xSR register has been updated, if security allows it (see next section).

Note: If a reset or a power-down occurs while the option byte words modification is ongoing, the original option byte value are kept. A new option byte modification sequence is required to program the new value.

Changing security option bytes

On top of OPTLOCK bit, there is a second level of protection for security-sensitive option byte words. Note that the option byte words defined in *Section 5.4.5* do not have any special protection.

Option byte words with specific protections are described hereafter.

- **Sector write protection (WRPS)**

  Those user options managing group of sector write protection can be changed using FLASH_WRPSRP register, if application is RSS or the immutable root of trust.

- **Non-volatile state (NVSTATE)**

  A detailed description of NVSTATE option bits is given in *Section 5.5.3*. The following rules must be respected to modify NVSTATE using FLASH_NVSRP register.

  – Writes to FLASH_NVSRP register are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

  – NVSTATE option change is triggered only after the RAM erase signal has confirmed that Backup RAM and PKA RAM have been successfully erased.

  – When NVSTATE=OPEN, option byte change to CLOSE is allowed. Writing any other value than 0x51 triggers an OPTERRF flag, without option change.

  – When NVSTATE=CLOSE, option byte change to OPEN is allowed, triggering a global erase explained in *Section 5.5.3*. Writing any other value than 0xB4 triggers an OPTERRF flag, without option change.

- **OEM provisioned (OEM_PROVD)**

  As defined in *Table 36: Boot level and HDP area protections (non STiRoT case)*, OEM_PROVD defines the protection of the HDP area. OEM_PROVD can only be changed by RSS in FLASH_ROTSRP.

- **iRoT selection (IROT_SELECT)**

  As defined in *Table 37: Boot level and HDP area protections (STiRoT case)*, *IROT_SELECT* defines where the immutable root of trust code is stored, for STM32H7S devices only. IROT_SELECT can only be changed when the device is opened by RSS in FLASH_ROTSRP.

- **Debug authentication method (DBG_AUTH)**

  DBG_AUTH defines the method used to open up the device debug. It has no hardware effect in embedded flash memory.

  DBG_AUTH can only be changed by RSS in FLASH_ROTSRP.

- **Secure storage counter (EPOCH)**

  This 24-bit non-volatile value is directly send by embedded flash to the SAES peripheral. As soon as this value changes all current keys encrypted with a derived hardware unique key (DHUK) are lost. For more details on the DHUK, refer to *SAES* chapter. EPOCH can only be changed by RSS.

- **Hide protection area size (HDP_AREA_START and HDP_AREA_END)**

  These user options configure the size of the user flash area that can be accessed while HDPL equals to the value defined in *Section 5.5.5*. Writes to FLASH_HDPSRP register are ignored if HDPL is different from 0 or 1 in the SBS_HDPLSR register.

Note: For all user option bytes in this section: default values are loaded when a double ECC error occurs. OBLERRF error flag is also raised.

Hide protection area end address in system flash is fixed by STMicroelectronics.

5.4.4 Option byte key management

Option byte key programming

Following sequence is required to program an option byte key in embedded flash memory:

1. Unlock FLASH_OPTCR register as described in *Section 5.5.1: FLASH configuration protection* (only if the register is not already unlocked).
2. Enable the write operation by setting the PG_OPT bit in FLASH_OPTCR, and make sure the KTEF and KVEF bits are cleared in FLASH_OPTISR.
3. Write the key value in the FLASH_OBKDRx registers. Key[31:0] goes in OBKDR0[31:0], Key[63:32] to OBKDR1[31:0], Key[95:64] to OBKDR2[31:0], Key[127:96] to OBKDR3[31:0], Key[159:128] to OBKDR4[31:0], Key[191:160] to OBKDR5[31:0], Key[223:192] to OBKDR6[31:0] and Key[255:224] to OBKDR7[31:0].
4. Fill the following information to FLASH_OBKCR:
   - OBKINDEX[4:0]: index of the key for this hide protection level
   - OBKSIZE[1:0]: size of the key (see bitfield description)
   - NEXTKL[1:0]: when HDPL=1 in SBS_HDPLSR register RoT application can set those bit to 01 to provision a key for the next HDPL level (2).
   - Set both KEYSTART and KEYPROG bits to start the programming sequence.
5. Read back the key to verify its value (recommended). See *Option byte key loading*.

Note: When HDPL value in SBS peripheral changes FLASH_OBKDR register is cleared to 0x0.

For a given hide protection level, if authorized the application writes to an OBKINDEX that has already being successfully used before the old key is overwritten with the new value.

Like for any option change, if an error occurs OPTERRF is set in FLASH_OPTISR. It must be cleared, like KTEF and KVEF, before initiating another option byte key programming (otherwise the setting of KEYSTART bit is ignored).

All key error flags (KVEF, KTEF) must be cleared before application reads or write an option byte key.

Note: Option byte key integrity could fail when a reset is issued while programing it. When this happens the previously written key is kept, and no key is returned if it was the first programming. The OBLERRF error flag is also raised.

Option byte key loading

If OBKINDEX[4:0] is or greater than or equal to 0x8, the following sequence is required to read an option byte key stored in embedded flash memory:

1. Fill the following information to FLASH_OBKCR:
   - OBKINDEX[4:0]: index of the key for this hide protection level. Size of the key is automatically recovered from the flash memory.
   - NEXTKL[1:0]: when HDPL=1 in SBS_HDPLSR register RoT application can set those bit to 01 to read a key provisioned for the next HDPL level (2).
   - Set KEYSTART bit with KEYPROG bit cleared to start the read sequence.
2. Wait until QW bit is cleared in FLASH_SR register.
3. Read the value of the key using FLASH_OBKDRx registers

If OBKINDEX[4:0] is less than 0x8, the following sequence is required to load to the SAES peripheral an option byte key stored in embedded flash.

1. In the SAES peripheral, set the correct KEYSIZE and write KEYSEL[2:0] =011 or 101 in the SAES_CR register.
2. Perform the same sequence as a normal option byte key read, with the exception of reading back the FLASH_OBKDRx registers. In this case, key data are automatically transfered from embedded flash memory to the SAES key registers, while the BUSY bit is set in the SAES_SR register.
3. Once the transfer is completed the BUSY bit is cleared and the KEYVALID bit is set in the SAES_SR register. If KEYVALID is not set when the BUSY bit is cleared, or if a key error flag (KEIF) is set in SAES, this means that an unexpected event occurred during the transfer. In this unlikely event the IPRST bit must be set then cleared in the SAES_CR register, then sequence can be restarted from Step 1 above.

During option byte key loading two errors can happen:

- Key valid error (see *Section 5.7.10*)
- Key transfer error (see *Section 5.7.11*)

All key error flags (KVEF, KTEF) must be cleared before application reads or writes an option byte key.

Note: When the HDPL value in the SBS peripheral changes, the FLASH_OBKDR register is cleared to 0x0.

5.4.5 Option byte user words overview

Table 32 lists all the user option bytes managed through the embedded flash memory registers, as well as their default values before the first option byte change (default factory value). They are configured by the end-user depending on the application requirements. Some option bytes might have been initialized by STMicroelectronics during manufacturing stage.

5.4.6 Description of user option byte word

The general-purpose option bytes that can be used by the application are listed below. They are accessed through the FLASH_OBWSRx registers.

- Watchdog management
  - IWDG_FZ_STOP: independent watchdog IWDG counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_FZ_SDBY: independent watchdog IWDG counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_HW: hardware (0) or software (1) IWDG watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written to or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STBY options, the IWDG can continue counting (1) or not (0) when the device is in Stop or Standby mode respectively. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - BOR_LEV: Brownout level option, indicating the supply level threshold that activates/releases the reset
  - NRST_STDBY: Independent watchdog generates a reset when entering Standby mode if cleared to 0
  - NRST_STOP: Independent watchdog generates a reset when entering Stop mode if cleared to 0.

Note: Whenever a Standby (respectively Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (respectively Stop) mode if NRST_STDBY (respectively NRST_STOP) is cleared to 0.

- Device options
  - VDDIO_HSLV: enables the configuration of pads below 2.5 V for VDDIO power rail if set to 1.
  - XSPI1_HSLV: enable I/O XSPIM_P1 high-speed option if set to 1.
  - XSPI2_HSLV: enable I/O XSPIM_P2 high-speed option if set to 1.

When STMicroelectronics delivers the device, the values programmed in the general-purpose option bytes are the following:

- Watchdog management
  - IWDG reset active in Standby and Stop modes (option value = 0x1)
  - IWDG not automatically enabled at power-on (option byte value = 0x1)
- Reset management:
  - BOR: brownout level option (reset level) equals 2.1 V (option byte value = 0x0). A reset is not generated when the device enters Standby or Stop low-power mode (option byte value = 0x1)
- The speed of the device I/Os are optimized when device voltage is low (VDDIO_HSLV=XSPI1_HSLV= XSPI2_HSLV= 0). Refer to *Section 10.3.16: High-speed low-voltage mode (HSLV)*.

Refer to *Section 5.9: FLASH registers* for details.

5.4.7 Description of security option bytes

The option bytes that are use by root of trust application to enhance security are listed below:

- NVSTATE[7:0]: Non-volatile state (see *Section 5.5.3* for details).
- IROT_SELECT[7:0]: Selection of ST iRoT (STM32H7S only).
- WRPS[7:0]: Write protection option of user flash sectors. It is active low. Refer to *Section 5.9.26* for details.
- OTPL[15:0]: Write protection option of OTP blocks. It is active high. Refer to *Section 5.3.11* for details.
- HDP_AREA: Hide protection user flash area definitions. Refer to *Section 5.5.5*.
  - HDP_AREA_START (respectively HDP_AREA_END) contains the first (respectively last) 256-byte block of the HDP area.

Usage of above options are summarized in *Table 33*.

Table 33. STM32H7Rx/7Sx device lifecycle table

Product state	NVSTATE	OEM_PROVD	DBG_AUTH	Description
Open	OPEN (0xB4)	x	x	Device delivered by ST. User flash memory usage is open, and debug access is enabled.
Provisioning	CLOSE (0x51)	Not 0xB4	Not set (0x00)	Device on the production line. User flash usage is restricted, and debug access is restricted.
Locked			Locked (0xB4)	Final product with root of trust and no debug. Transition to other state or policy change (including debug) is not permitted.
Closed(1)			ECDSA sign (0x51) Password (0x8A)	Final product, with root of trust and authenticated debug activated. Regression is possible.

1. A “closed” product with incorrect or non-defined debug certificate is equivalent to a “locked” product.

When STMicroelectronics delivers the device, the values programmed in the security option bytes are the following:

- OPEN device (NVSTATE value = 0xB4)
- iRoT selection (only on H7S part)
  - OEM iRoT (IROT_SELECT value = 0x6A)
  - ST iRoT (IROT_SELECT value = 0xB4)
- Swap is locked deactivated, with all user flash sector are allocated to bank A.
- HDP area protection disabled (start addresses higher than end addresses)
- Write protection disabled (all option byte bits set to 1)
- All OTP blocks are writable, as they are virgin (all option byte bits set to 0)

Refer to *Section 5.9: FLASH registers* for details.

5.5 FLASH protection mechanisms

Since sensitive information are stored in the flash memory, it is important to protect it against unwanted operations such as reading confidential areas, illegal programming of immutable sectors, or malicious flash memory erasing.

For this purpose FLASH implements the following protection mechanisms:

- Configuration protection
- User flash write protection
- Device non-volatile security life cycle and application temporal isolation management
- OTP locking

This section provides a detailed description of all these security mechanisms.

5.5.1 FLASH configuration protection

The embedded flash memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (e.g. software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

More specifically, write operations to embedded flash memory control registers (FLASH_CR and FLASH_OPTCR) are not allowed after reset.

The following sequence must be used to unlock FLASH_CR register:

1. Program KEY1 to 0x45670123 in FLASH_KEYR key register.
2. Program KEY2 to 0xCDEF89AB in FLASH_KEYR key register.
3. LOCK bit is now cleared and FLASH_CR is unlocked.

The following sequence must be used to unlock FLASH_OPTCR register:

1. Program OPTKEY1 to 0x08192A3B in FLASH_OPTKEYR option key register.
2. Program OPTKEY2 to 0x4C5D6E7F in FLASH_OPTKEYR option key register.
3. OPTLOCK bit is now cleared and FLASH_OPTCR register is unlocked.

Any wrong sequence locks up the corresponding register/bit until the next system reset, and generates a bus error.

The above registers can be locked again by software by setting the LOCK bit in the corresponding control register.

The FLASH_CR register remains locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register than FLASH_KEYR before FLASH_CR has been completely unlocked (KEY1 programmed but KEY2 not yet programmed)
- Writing less than 32 bits to KEY1 or KEY2.

Similarly the FLASH_OPTCR register remains locked and a bus error is generated when the following operations are executed:

- Programming a third key value
- Writing to a different register before FLASH_OPTCR has been completely unlocked (OPTKEY1 programmed but OPTKEY2 not yet programmed)
- Writing less than 32 bits to OPTKEY1 or OPTKEY2.

The embedded flash memory configuration registers protection is summarized in *Table 34*. Registers not present in this table are not protected by any key.

Table 34. Flash interface register protection summary

Register name	Unlocking register	HDP level(1)	Protected asset
FLASH_CR	FLASH_KEYR	Any	Flash write operations, erase commands
FLASH_IER	FLASH_CR		Interrupt generation masking sources
FLASH_CRCCR			Flash bank CRC operations
FLASH_OPTCR	FLASH_OPTKEYR		Option bytes changes
FLASH_OBKCR	FLASH_OPTCR	Any	Option byte key change
FLASH_NVSRP		0 or 1	Non-volatile state change
FLASH_ROTSRP		0	Root of trust parameter change
FLASH_HDPSRP		0 or 1	Hide protect area change
FLASH_EPOCHSRP		0	Epoch change
FLASH_OBWSRxP		Any	User option byte word x change
FLASH_WRPSRP			User flash write protection change
FLASH_OTPLSRP	FLASH_OPTCR(2)	Any	OTP write protection

1. Required HDP level in the device
2. Once set, the OTP Block Lock bits cannot be reset by the application.

5.5.2 Write protection

The purpose of embedded flash memory write protection is to prevent unwanted modifications to embedded non-volatile code and/or data.

Any 8 Kbyte sector can be independently write-protected or unprotected by clearing/setting the corresponding WRPS bit in the FLASH_WRPSR register.

A write-protected sector can neither be erased nor programmed. As a result, a full bank erase cannot be performed if one sector is write-protected, unless a NVSTATE transition to OPEN is triggered.

The embedded flash memory write-protection user option bits can be modified when HDPL=0 or 1 in SBS_HDPLSR register, using FLASH_WRPSRP.

Note: The HDP are in user flash is write and erase protected, while system flash cannot be erased by user application.

Write protection errors are documented in *Section 5.7: FLASH error management*.

5.5.3 Life cycle management

Introduction

Figure 18 shows how embedded flash manages the non-volatile security life cycle of the device.

Figure 18. Life cycle management scheme

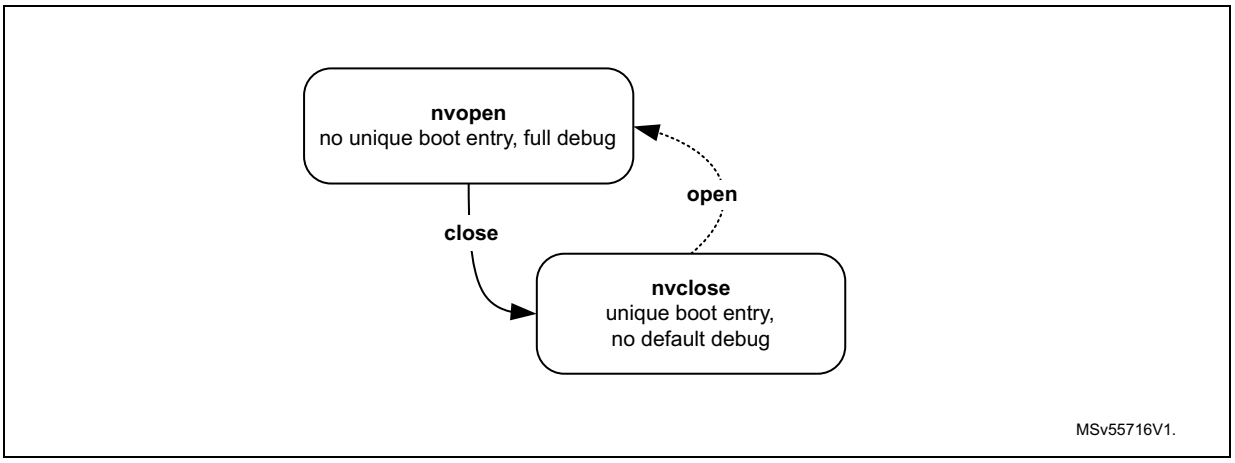

Table 35 details the non-volatile security lifecycle NVSTATE and its effects on the product.

Table 35. Flash security lifecycle definition

NVSTATE	Boot address(1)	Debug level	Regression to	Root HUK
OPEN	0x0800 0000 or Bootloader	Unconstrained (2)	n/a	0x0
CLOSE	0x1FF0 0000	Constrained (3)	OPEN	OB Key (ST)

1. Enforced outside flash.
2. Includes STMicroelectronics engineering test modes. Those are disabled in CLOSE state, by hardware.
3. User can attempt to unlock debug features, if allowed by DEBUG_AUTH option bits.

Flash opening

When requesting a change of NVSTATE to OPEN, writing 0xB4 to FLASH_NVSRP register, flash performs an automatic erase of the following information:

- The whole user flash (write protected or not)
- The write protection data in FLASH_WRPSR.
- The option byte register defining the hide protection area is reset to their default manufacturing values (disabled).
- The option byte keys, excluding hide protection level 0 keys
- Root of trust option byte registers: FLASH_ROTSR and FIXEDSR

Note: The FLASH_EPOCHSR setting is kept when opening the flash memory

NVSTATE option change is triggered only after the RAM erase signal has confirmed that Backup RAM and PKA RAM have been successfully erased.

The system flash memory and the read-only region are not affected by flash opening and remain unchanged.

Flash closing

Writing 0x51 to the FLASH_NVSRP register triggers a change of NVSTATE from OPEN to CLOSE, confirmed when NVSTATE=0x51 in FLASH_NVSR register.

5.5.4 Hide protected system flash area

System flash sectors included between 0x1FF0 0000 and SEC_AREA_END addresses can be used to store STMicroelectronics secure firmware install (SFI) code, or the STM32 immutable root of trust code and data, with the associated encrypted keys stored in option byte keys.

Embedded flash system area can only be accessed by Cortex M7 in read or execute. The hide protected area can only be accessed when NVSTATE is CLOSE and when hide protection level in SBS_HDPLSR is 0 or 1 for ST iRoT products (default), or just 0 for OEM iROT products.

In all other cases one of the following events is triggered:

- Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
- Read instruction transactions generate a bus error and the RDSERR error flag is raised.

Embedded flash system area is immutable, that is, it cannot be erased by any application code.

Note: When FLASH transition from CLOSE to OPEN state, embedded flash system area is kept.

5.5.5 Hide protected user flash area

Overview

User flash sectors included between HDP_AREA_START and HDP_AREA_END addresses are used to store the root of trust code and data, with the associated keys stored in embedded flash option byte keys.

Embedded flash hide protected (HDP) user area can only be accessed:

- by Cortex M7 in read, write or execute
- according to the conditions defined in following tables. *Table 36* concerns STM32H7R parts, or STM32H7S parts with IROT_SELECT different from 0xB4. STM32H7S parts with ST iRoT (IROT_SELECT=0xB4) are described in *Table 37*.

Table 36. Boot level and HDP area protections (non STiRoT case)

Product state	FLASH user options[1]		HDP level[2] to activate protection		Boot address (HDPL)	Comment
	NV STATE	OEM_ PROVD	HDP area in system flash	HDP area in user flash		
Open	OPEN	not 0xB4	>0	>1	User flash or bootloader (HDPL1)	RSS not visible
Provisioning	CLOSE			>0	RSS (HDPL0)	Firmware provisioning in user flash, and provisioning of related keys in OBKey area.
Closed or Locked		0xB4		>1		Firmware provisioned in user flash. All related OBKeys are also provisioned.

1. In FLASH_NVSR and FLASH_ROTSR registers
2. Level for which hide protection is activated.

Table 37. Boot level and HDP area protections (STiRoT case)

Product state	FLASH user options[1]		HDP level[2] to activate protection		Boot address (HDPL)	Comment
	NV STATE	OEM_ PROVD	HDP area in system flash	HDP area in user flash		
Open	OPEN	not 0xB4	>0	>2	User flash (HDPL2) or bootloader (HDPL1)	ST iRoT not visible
Provisioning	CLOSE		>1	>1	RSS (HDPL0)	OEM uRoT provisioning in user flash, and provisioning of related keys in OBKey area.
Closed or Locked		0xB4		>2		OEM uRoT provisioned in user flash. All related OBKeys are also provisioned.

1. In FLASH_NVSR and FLASH_ROTSR registers
2. Level for which hide protection is activated.

For more details on HDPL level following a reset, refer to *Section 8: System configuration, boot and security (SBS)*.

Note: IROT_SELECT is stored in the FLASH_ROTSR register.

Hide protection area in user flash programming

HDP user flash area is programmed in FLASH_HDPSRP by setting the HDP_AREA_START and HDP_AREA_END so that the END address is strictly higher than the START address.

HDP_AREA_START and HDP_AREA_END are defined with a granularity of 256 bytes. This means that the actual HDP user flash area size (in bytes) is defined by:

(HDP_AREA_END - HDP_AREA_START + 1) x 256

As an example, to set the HDP user flash area on the first 8 Kbytes (that is,from address 0x0800 0000 to address 0x0800 1FFF, both included), the embedded flash memory must be configured as follows:

HDP_AREA_START[15:0] = 0x0

HDP_AREA_END[15:0] = 0x001F

The HDP user flash area size defined above is equal to:

(HDP_AREA_END - HDP_AREA_START + 1) x 256 = 32 x 256 bytes = 8 Kbytes.

The minimum HDP user flash area that can be set is 32 flash words (or 512 bytes). The maximum area is the whole user flash memory bank, configured by setting HDP_AREA_START= HDP_AREA_END.

Note: It is recommended to align the HDP user area size with 8 Kbytes flash sector granularity to always be able to erase non-HDP code and data.

It is possible to disable HDP protections by setting HDP_AREA_END lower than HDP_AREA_START.

Hide protection area in user flash properties

- Embedded flash hide protected user area can only be accessed in the conditions described in *Overview*. In all other cases one of the following events is triggered:
  - Data read transactions return zero. Data write transactions are ignored. No bus error is generated but an error flag is raised (RDSERR for read, WRPERR for write).
  - Read instruction transactions generate a bus error and the RDSERR error flag is raised.
- HDP user flash area is erase-protected. As a result:
  - No erase operations to a sector located in this area are possible (including the sector containing the area end address), unless HDPL=0 or 1.
  - In HDPL=2 or 3 the only possibility to fully erase user flash bank is to perform a device opening sequence (see *Section 5.5.3*).
- Rules to change the HDP user flash area are detailed in *Changing option byte words* in *Section 5.4.3*.
- When FLASH transition from CLOSE to OPEN state, the whole user flash (hide protected or not) is automatically erased, with the HDP area disabled (see *Section 5.5.3*).

For more information on HDP user flash area errors, refer to *Section 5.7: FLASH error management*.

5.6 FLASH low-power modes

5.6.1 Introduction

Table 38 summarizes the behavior of the embedded flash memory in microcontroller low-power modes. The embedded flash memory belongs to the Core domain.

Table 38. Effect of low-power modes on the embedded flash memory

Power mode / System state	Core domain voltage range	Allowed if FLASH busy	FLASH power mode (in Core domain)
Run	VOS low / high	Yes	Run
Stop	SVOS low / high	No	Clock gated or Stopped
Standby	Off	No	Off

When the system state changes, or within a given system state, the embedded flash memory might be subjected to a different voltage supply range (VOS) depending on the application. The procedure to switch the embedded flash memory into various power modes (run, clock gated, stopped, off) is described below.

Note: For more information on microcontroller power states, refer to the Power control section (PWR).

5.6.2 Managing the FLASH domain switching to Stop or Standby

As explained in *Table 38*, if the embedded flash memory informs the reset and clock controller (RCC) that it is busy (that is, BUSY, QW, WBNE is set), the microcontroller cannot switch the Core domain to Stop or Standby mode.

Note: CRC_BUSY is not taken into account.

There are two ways to release the embedded flash memory:

- Reset the WBNE busy flag in the FLASH_SR register by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling-in the missing data, by activating the FW bit in the FLASH_CR register. This forces all missing data “high”.
  - Reset the PG bit in FLASH_CR register. This disables the write buffer and consequently leads to the loss of its content.
- Poll the QW busy bits in the FLASH_SR register until they are cleared. This indicates that all recorded write, erase and option change operations are complete.

The microcontroller can then switch the domain to Stop or Standby mode.

5.7 FLASH error management

5.7.1 Introduction

The embedded flash memory automatically reports when an error occurs during a read, program or erase operation. A wide range of errors are reported:

- *Write protection error (WRPERRF)*
- *Programming sequence error (PGSERRF)*
- *Strobe error (STRBERRF)*
- *Inconsistency error (INCERRF)*
- *Error correction code error (SNECCERRF/DBECCERRF)*
- *Read secure error (RDSERRF)*
- *CRC read error (CRCRDERRF)*
- *Option byte change error (OPTERRF)*
- *Key valid error (KVEF)*
- *Key transfer error (KTEF)*
- *Option byte loading error (OBLERRF)*

The application software can individually enable the interrupt for each error, as detailed in *Section 5.8: FLASH interrupts*.

Note: For some errors, the application software must clear the error flag before attempting a new operation.

Note: General purpose errors (e.g. INCERRF) are taken into account when queues are loaded. Temporal isolation and other protection errors (for example WRPERRF, RDSERRF) are taken into account at FSM level, in front of the flash bank interface controller.

5.7.2 Write protection error (WRPERRF)

When an illegal erase/program operation is attempted to the non-volatile memory, the embedded flash memory sets the write protection error flag WRPERRF in FLASH_ISR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- a sector belonging to a valid HDP user flash area (even partially), except if HDPL=0 or 1 in SBS_HDPLSR register.
- a sector write-locked with WRPS
- the read-only/OTP area

An program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- a protected user flash sector belonging to a valid HDP user flash area (see *Section 5.5.5*)
- a user sector write-locked with WRPS
- an OTP block, locked with OTPL
- a read-only section
- the system flash memory
- a reserved area

When the WRPERRF flag is raised, the operation is rejected and nothing is changed. If a write burst operation was ongoing, WRPERRF is raised each time a flash word write operation is processed by the embedded flash memory.

Note: The WRPERRF flag does not block any new erase/program operation.

Not clearing the WRPERRF flag does not generate a programming sequence error (see below).

WRPERRF flag is cleared by setting the corresponding bit in FLASH_ICR register.

If WRPERRIE bit in FLASH_IER register is set, an interrupt is generated when the WRPERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.3 Programming sequence error (PGSERRF)

When the programming sequence is incorrect, the embedded flash memory sets the programming sequence error flag PGSERRF in FLASH_ISR register.

More specifically, the PGSERRF flag is set if one of the conditions below is met:

- A write operation is requested but the program enable bit (PG or PG_OTP) has not been set in the FLASH_CR register prior to the request. This program enable bit must stay at 1 until write is added to operation queue (QW rises).
- The inconsistency error (INCERRF) has not been cleared before requesting a new write operation.

When THE PGSERRF flag is raised, the current program operation is aborted and nothing is changed in flash. The corresponding write data buffer is also flushed. If a write burst operation was ongoing, PGSERRF is raised at the end of the burst.

Note: When the PGSERRF flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. Hence it is recommended to generate interrupts on PGSERRF and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERRF flag also blocks any new program operation. This means that PGSERRF must be cleared before starting a new program operation.

The PGSERRF flag is cleared by setting the corresponding bit in the FLASH_ICR register.

If the PGSERRIE bit in FLASH_IER register is set, an interrupt is generated when the PGSERRF flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.4 Strobe error (STRBERRF)

When the application software writes several times to the same byte write buffer, the embedded flash memory sets the strobe error flag STRBERRF in the FLASH_ISR register.

When the STRBERRF flag is raised, the current program operation is not aborted and new byte data replaces the old data. The application can ignore the error, proceed with the current write operation and request new write operations. If a write burst was ongoing, STRBERRF is raised at the end of the burst.

The STRBERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the STRBERRIE bit in the FLASH_IER register is set, an interrupt is generated when the STRBERRF flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.5 Inconsistency error (INCERRF)

When a programming inconsistency is detected, the embedded flash memory sets the inconsistency error flag INCERRF in the FLASH_ISR register.

More specifically, the INCERRF flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One master starts a write operation, but before the buffer is full, another master starts a new write operation to the same address or to a different address.
- A wrap burst request issued by a master overlaps two or more 128-bit flash-word addresses, that is, wrap bursts must be done within 128-bit flash-word address boundaries.

Following the sequence below is recommended to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when the INCERRF flag is raised.
2. Stop all write requests to embedded flash memory.
3. Verify that the write operations that have been requested just before the INCERRF event have been successful by reading back the programmed values from the memory.
4. Clear the INCERRF bit in the FLASH_ICR register.
5. Restart the write operations where they have been interrupted.

Note: INCERRF flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERRF) is raised.

Any write triggering inconsistency error is discarded by embedded flash memory.

5.7.6 Error correction code error (SNECCERRF/DBECCERRF)

When a single error correction is detected during a read the embedded flash memory sets the single error correction flag SNECCERRF in the FLASH_ISR register.

When two ECC errors are detected during a read, the embedded flash memory sets the double error detection flag DBECCERRF in the FLASH_ISR register.

When the SNECCERRF flag is raised, the corrected read data are returned. Hence the application can ignore the error and request new read operations.

If a read burst operation was ongoing, the SNECCERRF or DBECCERRF flag is raised each time a new data is sent back to the requester through the corresponding system bus.

When the SNECCERRF (or DBECCERRF respectively) flag is raised, the address of the flash word that generated the error is saved in the FLASH_ECCSFAR (or FLASH_ECCDFAR respectively) register. This register is automatically cleared when the associated flag that generated the error is cleared.

Note: In the case of successive single correction (or double detection respectively) errors, only the address corresponding to the first error is stored in the *FLASH_ECCSFAR (or FLASH_ECCDFAR respectively) register.*

When the DBECCERRF flag is raised reading the user flash memory, a bus error is generated. In the case of successive double error detections, a bus error is generated each time a new data is sent back to the requester through the AXI interface.

Note: It is not mandatory to clear the *SNECCERRF or DBECCERRF flags before starting a new read operation.*

The SNECCERRF and DBECCERRF flags are cleared by setting corresponding bit in the FLASH_ICR register.

If the SNECCERRIE (or respectively DBECCERRIE) bit in the FLASH_ISR register is set, an interrupt is generated when the SNECCERRF (or respectively DBECCERRF) flag is raised. See *Section 5.8: FLASH interrupts* for details.

5.7.7 Read secure error (RDSERRF)

When an illegal read or execute operation is attempted to a hide protected area, the embedded flash memory sets the read secure the error flag RDSERRF in the FLASH_ISR register. For more information on illegal access definition, refer to *Section 5.5.4: Hide protected system flash area* and *Section 5.5.5: Hide protected user flash area*.

When the RDSERRF flag is raised, the current read operation is aborted and the application can request new read operations. If a read burst was ongoing, RDSERRF is raised each time a data is sent back to the requester through the AXI interface.

Note: The bus error is raised only if the illegal access is due to an instruction fetch.

RDSERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the RDSERRIE bit in the FLASH_IER register is set, an interrupt is generated when the RDSERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.8 CRC read error (CRCRDERRF)

After a CRC computation, the embedded flash memory sets the CRC read error flag CRCERR in the FLASH_ISR register when one or more address belonging to a protected area was read by the CRC module. A protected area corresponds to a valid HDP area in user flash, for which any read is currently illegal (see *Section 5.5.5* for details).

The CRCRDERRF flag is raised when the CRCEND bit is set (end of CRC calculation). In this case, it is likely that the CRC result is wrong since illegal read operations to protected areas return null values.

The CRCRDERRF flag is cleared by setting corresponding bit in the FLASH_ICR register.

If the CRCRDERRIE bit in the FLASH_IER register is set, an interrupt is generated when the CRCRDERRF flag is raised together with the CRCEND bit (see *Section 5.8: FLASH interrupts* for details).

5.7.9 Option byte change error (OPTERRF)

When the embedded flash memory finds an error during an option change operation, it aborts the operation and sets the option byte change the error flag OPTERRF in the FLASH_OPTISR register.

The OPTERRF flag is cleared by setting corresponding bit in the FLASH_OPTICR register.

If the OPTERRIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the OPTERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

It is mandatory to clear the OPTERRF flag before starting a new option byte change, or an option byte key programming.

5.7.10 Key valid error (KVEF)

KVEF error flag is set in the FLASH_OPTISR register in two cases:

- Embedded flash did not find an option byte key that corresponds to the given OBKINDEX[4:0] and the requested HDPL (optionally modified by NEXTKL[1:0]). It can happen for example when requested key has not being provisioned.
- A double error detection was found when loading the requested option byte key. In this case, if this key is provisioned again the error should disappear.

It is mandatory to clear the KVEF flag before doing any operation on option byte keys because when KVEF is set, writes to the START bit in the FLASH_OBKCR are ignored.

The KVEF flag is cleared by setting corresponding bit in FLASH_OPTICR register.

If the KVEIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the KVEF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.11 Key transfer error (KTEF)

The KTEF error flag is set in the FLASH_OPTISR register when embedded flash signals an error to the SAES peripheral. This happens when:

- the key size (128-bit or 256-bit) is not matching between embedded flash OBKSIZE[1:0] and KEYSIZE bit in SAES_CR register.
- an ECC dual error detection occurred while embedded flash loaded an option byte key for the SAES peripheral. In this case KVEF is also set.

It is mandatory to clear the KTEF flag before doing any operation on option byte keys. Because when KTEF is set write to the START bit in the FLASH_OBKCR is ignored.

The KTEF flag is cleared by setting corresponding bit in the FLASH_OPTICR register.

If the KTEIE bit in the FLASH_OPTCR register is set, an interrupt is generated when the KTEF flag is raised (see *Section 5.8: FLASH interrupts* for details).

While flash memory loads the option byte key to share with the SAES peripheral no other flash operation should be started until the key is transfered to the SAES. Otherwise the key transfer may fail (BUSY=KEYVALID=0 in the SAES_SR register) or the BUSY bit in the SAES_SR register stays at 1, until IPRST bit is used to clear it.

Note: When KTEF is cleared by the application the *error signal to SAES is cleared.*

5.7.12 Option byte loading error (OBLERRF)

When the embedded flash memory finds one of the following error during an option byte loading sequence (see *Section 5.4.2*) it sets the option byte change error flag OBLERRF in the FLASH_ISR register.

- ECC double error detection on one or more option byte (data or metadata)
- ECC double error detection on one or more option byte key (data or metadata)

In the case of an OBLERRF event the application should verify the correctness of the option byte information described in *Section 5.4*.

The OBLERRF flag is cleared by setting the corresponding bit in the FLASH_ICR register. If the OBLERRIE bit in the FLASH_IER register is set, an interrupt is generated when the OBLERRF flag is raised (see *Section 5.8: FLASH interrupts* for details).

5.7.13 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On the AXI system bus:
  - illegal instruction fetch to HDP protected area because of the lifecycle (e.g. protected system flash when NVSTATE=OPEN).
- On AHB configuration or system bus:
  - wrong key input to FLASH_KEYR or FLASH_OPTKEYR
  - 8-bit accesses to system AHB interface

5.8 FLASH interrupts

The embedded flash memory can generate a maskable interrupt to signal the following events:

- Read and write errors (see *Section 5.7: FLASH error management*)
  - Single ECC error correction during read operation
  - Double ECC error detection during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Option change error
  - Option byte keys error
- Security errors (see *Section 5.7: FLASH error management*)
  - Write protection error
  - Read security error
  - CRC computation on HDP area error
  - Option byte loading error
  - Key valid or key transfer errors
- Miscellaneous events (described below)
  - End of programming
  - CRC computation complete

These multiple sources are combined into a single interrupt signal, flash_it, which is the only interrupt signal from the embedded flash memory that drives the NVIC (nested vectored interrupt controller).

You can individually enable or disable embedded flash memory interrupt sources by changing the mask bits in the FLASH_IER register. Setting the appropriate mask bit enables the interrupt.

Note: Prior to writing, FLASH_IER register must be unlocked as explained in Section 5.5.1: FLASH configuration protection

Table 39 gives a summary of the available embedded flash memory interrupt features.

Note: Some flags need to be cleared before a new operation is triggered.

Table 39. Flash interrupt request

Interrupt event	Event flag	Enable control bit	Clear flag to resume operation	Bus error
End-of-program event	EOPF	EOPIE	N/A	N/A
CRC complete event	CRCENDF	CRCENDIE	N/A	N/A
Write protection error	WRPERRF	WRPERRIE	No	No
Programming sequence error	PGSERRF	PGSERRIE	**Yes**	No
Strobe error	STRBERRF	STRBERRIE	No	No
Inconsistency error	INCERRF	INCERRIE	**Yes**	No
ECC single error correction event	SNECCERRF	SNECCERRIE	No	No
ECC double error detection event	DBECCERRF	DBECCERRIE	No	**Yes**(1)
Read secure error	RDSERRF	RDSERRIE	No	No (data) **Yes** (fetch)
CRC error	CRCRDERRF	CRCRDERRIE	No	No
Option byte loading error	OBLERRF	OBLERRIE	No	No
Option byte change error	OPTERRF(2)	OPTERRIE	No	No
Key valid error	KVEF(2)	KVEIE	**Yes**	No
Key transfer error	KTEF(2)	KTEIE	**Yes**	No

1. AXI bus only
2. Set in FLASH_OPTISR register, cleared in FLASH_OPTICR register.

The status of the individual maskable interrupt sources described in *Table 39* (except for option byte error) can be read from the FLASH_ISR register. They can be cleared by setting the corresponding bit in the FLASH_ICR register.

No unlocking mechanism is required to clear an interrupt.

End-of-program event

Setting the end-of-operation interrupt enable bit (EOPIE) in the FLASH_IER register enables the generation of an interrupt at the end of an erase operation, a program operation or an option byte change. The EOPF bit in the FLASH_ISR register is also set when one of these events occurs.

Setting the EOPF bit in FLASH_ICR register clears the EOPF flag in the FLASH_ISR register.

CRC end of calculation event

Setting the CRC end-of-calculation interrupt enable bit (CRCENDIE) in the FLASH_IER register enables the generation of an interrupt at the end of a CRC operation. The CRCENDF bit in the FLASH_ISR register is also set when this event occurs.

Setting the CRCENDF bit in the FLASH_ICR register clears the CRCENDF flag in the FLASH_ISR register.

5.9 FLASH registers

5.9.1 FLASH access control register (FLASH_ACR)

Address offset: 0x000

Reset value: 0x0000 0013

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRHIGHFREQ [1:0]		LATENCY[3:0]			
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: Flash signal delay

These bits are used to control the delay between non-volatile memory signals during programming operations. Application software has to program them to the correct value depending on the embedded flash memory interface frequency. Refer to *Table 29* for details.

Note: Embedded flash does not verify that the configuration is correct.

Bits 3:0 **LATENCY[3:0]**: Read latency

These bits are used to control the number of wait states used during read operations on both non-volatile memory banks. The application software has to program them to the correct value depending on the embedded flash memory interface frequency and voltage conditions. Refer to *Table 29* for details.

0000: zero wait state used to read a word from non-volatile memory

0001: one wait state used to read a word from non-volatile memory

0010: two wait states used to read a word from non-volatile memory

...

0111: seven wait states used to read a word from non-volatile memory

1111: fifteen wait states used to read from non-volatile memory

Note: Embedded flash does not verify that the configuration is correct.

5.9.2 FLASH control key register (FLASH_KEYR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CUKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CUKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **CUKEY[31:0]**: Control unlock key

Following values must be written to FLASH_KEYR consecutively to unlock FLASH_CR register:
1st key = 0x4567 0123
2nd key = 0xCDEF 89AB
Reads to this register returns zero. If above sequence is wrong or performed twice, the FLASH_CR register is locked until the next system reset, and access to it generates a bus error.

5.9.3 FLASH control register (FLASH_CR)

Address offset: 0x010

Reset value: 0x0000 0001

When LOCK bit in this register is set writes to all other bits are ignored.

Write access to this register is controlled by FLASH_KEYR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALL_BANKS	Res.	Res.	Res.	Res.	Res.	Res.	CRC_EN	PG_OTP
							rw							rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SSN[2:0]			START	FW	BER	SER	PG	LOCK
							rw	rw	rw	rw	rw	rw	rw	rw	rs

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ALL_BANKS**: All banks select bit

When this bit is set the erase is done on all flash memory sectors.

ALL_BANKS is used only if a bank erase is required (BER=1). In all others operations, this control bit is ignored.

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **CRC_EN**: CRC enable

Setting this bit enables the CRC calculation. CRC_EN does not start CRC calculation but enables CRC configuration through FLASH_CRCCR register.
When CRC calculation is performed it can be disabled by clearing CRC_EN bit. Doing so sets CRCDATA to 0x0, clears CRC configuration and resets the content of FLASH_CRCDATAR register.

Bit 16 **PG_OTP**: Program Enable for OTP Area
Set this bit to enable write operations to OTP area.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:6 **SSN[2:0]**: Sector erase selection number
These bits are used to select the target sector for an erase operation (they are unused otherwise).
000: Sector 0
001: Sector 1
...
111: Sector 7

Bit 5 **START**: Erase start control bit
This bit is used to start a sector erase or a bank erase operation. The embedded flash memory resets START when the corresponding operation has been acknowledged. The user application cannot access any embedded flash memory register until the operation is acknowledged.

Bit 4 **FW**: Force write
This bit forces a write operation even if the write buffer is not full. In this case all bits not written are set by hardware. The embedded flash memory resets FW when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something other than 1, because this would likely to lead to a permanent ECC error.

Write forcing is effective only if the write buffer is not empty (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Bit 3 **BER**: Bank erase request
Setting this bit requests a bank erase operation (user flash memory only).
0: Bank erase is not requested
1: Bank erase is requested. Actual erase is started setting START bit in this register.
Write protection error is triggered when a bank erase is required and some sectors are protected.
BER has a higher priority than SER: if both are set, the embedded flash memory executes a bank erase.

Bit 2 **SER**: Sector erase request

Setting this bit requests a sector erase.

0: Sector erase not requested

1: Sector erase requested

Write protection error is triggered when a sector erase is required on at least one protected sector.

BER has a higher priority than SER: if both bits are set, the embedded flash memory executes a bank erase.

Bit 1 **PG**: Internal buffer control bit

Setting this bit enables internal buffer for write operations. This allows preparing program operations even if a sector or bank erase is ongoing. When PG is cleared, the internal buffer is disabled for write operations, and all the data stored in the buffer but not sent to the operation queue are lost.

0: Internal buffer disabled for write operations

1: Internal buffer enabled for write operations

Bit 0 **LOCK**: Configuration lock bit

When this bit is set write to all other bits in this register, and to FLASH_IER register, are ignored.

0: FLASH_CR and FLASH_IER registers are unlocked

1: Writes to FLASH_IER, and to other bits than LOCK in FLASH_CR, are ignored

Clearing this bit requires the correct write sequence to FLASH_KEYR register (see this register for details). If a wrong sequence is executed, or if the unlock sequence is performed twice, this bit remains locked until the next system reset.

During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.

5.9.4 FLASH status register (FLASH_SR)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IS_OPTCHANGE	IS_ERASE	IS_PROGRAM	CRC_BUSY	QW	WBNE	BUSY
									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **IS_OPTCHANGE**: Is an option change

This bit is set together with BUSY when an option change operation is ongoing. It is cleared when BUSY is cleared.

This flag can also raise with IS_PROGRAM or IS_ERASE, because a program or erase step is ongoing during option change.

Bit 5 **IS_ERASE**: Is an erase

This bit is set together with BUSY when an erase operation is ongoing. It is cleared when BUSY is cleared.

This flag can also raise with IS_OPTCHANGE, because an erase operation can happen during an option change.

Bit 4 **IS_PROGRAM**: Is a program

This bit is set together with BUSY when a program operation is ongoing. It is cleared when BUSY is cleared.

This flag can also raise with IS_OPTCHANGE, because an program operation can happen during an option change.

Bit 3 **CRC_BUSY**: CRC busy flag

This bit is set when a CRC calculation is ongoing. This bit cannot be forced to 0. The user must wait until the CRC calculation has completed or disable CRC computation using CRC_EN bit in FLASH_CR register.

0: No CRC calculation ongoing

1: CRC calculation ongoing

Bit 2 **QW**: Wait queue flag

This bit is set when a write, erase or option byte change operation is pending in the command queue buffer. It is not possible to know what type of programming operation is present in the queue.

This flag is reset by hardware when all write, erase or option byte change operations have been executed and thus removed from the waiting queue(s). This bit cannot be forced to 0. It is reset after a deterministic time if no other operations are requested.

0: No write, erase or option byte change operations waiting in the operation queues

1: At least one write, erase or option byte change operation is waiting in the operation queue

Bit 1 **WBNE**: Write buffer not empty flag

This bit is set when the embedded flash memory is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the event below:

- the application software forces the write operation using FW bit in FLASH_CR
- the embedded flash memory detects an error that involves data loss
- the application software has disabled write operations

This bit cannot be forced to 0. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: Write buffer empty or full

1: Write buffer waiting data to complete

Bit 0 **BUSY**: Busy flag

This bit is set when an effective write, erase or option byte change operation is ongoing. It is possible to know what type of operation is being executed reading the flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE.

BUSY cannot be cleared by application. It is automatically reset by hardware every time a step in a write, erase or option byte change operation completes. It is not recommended to do software polling on BUSY to know when one operation completed because, depending of operation, more pulses are possible for one only operation. For software polling it is therefore better to use QW flag or to check the EOPF flag.

0: No programming, erase or option byte change operation are being executed

1: Programming, erase or option byte change operation are being executed. See flags IS_PROGRAM, IS_ERASE and IS_OPTCHANGE for details.

5.9.5 FLASH interrupt enable register (FLASH_IER)

Address offset: 0x020

Reset value: 0x0000 0000

Writes to this register are ignored if LOCK bit is set in FLASH_CR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	CRCRDERRIE	CRCENDIE	DBECCERRIE	SNECCERRIE	RDSERRIE	Res.	Res.	INCERRIE	OBLERRIE	STRBERRIE	PGSERRIE	WRPERRIE	EOPIE
			rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRIE**: CRC read error interrupt enable bit
0: No interrupt is generated when CRCRDERRF bit is set in FLASH_ISR register
1: An interrupt is generated when CRCRDERRF bit is set in FLASH_ISR register

Bit 27 **CRCENDIE**: CRC end of calculation interrupt enable bit
0: No interrupt is generated when CRCEN bit is set in FLASH_ISR register
1: An interrupt is generated when CRCEN bit is set in FLASH_ISR register

Bit 26 **DBECCERRIE**: ECC double detection error interrupt enable bit
0: No interrupt is generated when DBECCERRF bit is set in FLASH_ISR register
1: An interrupt is generated when DBECCERRF bit is set in FLASH_ISR register

Bit 25 **SNECCERRIE**: ECC single correction error interrupt enable bit
0: No interrupt is generated when SNECCERRF bit is set in FLASH_ISR register
1: An interrupt is generated when SNECCERRF bit is set in FLASH_ISR register

Bit 24 **RDSERRIE**: Read security error interrupt enable bit
0: No interrupt is generated when RDSERRF bit is set in FLASH_ISR register
1: An interrupt is generated when RDSERRF bit is set in FLASH_ISR register

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRIE**: Inconsistency error interrupt enable bit
0: No interrupt is generated when INCERRF bit is set in FLASH_ISR register
1: An interrupt is generated when INCERRF bit is set in FLASH_ISR register

Bit 20 **OBLERRIE**: Option byte loading error interrupt enable bit
0: No interrupt is generated when OBLERRF bit is set in FLASH_ISR register
1: An interrupt is generated when OBLERRF bit is set in FLASH_ISR register

Bit 19 **STRBERRIE**: Strobe error interrupt enable bit
0: No interrupt is generated when STRBERRF bit is set in FLASH_ISR register
1: An interrupt is generated when STRBERRF bit is set in FLASH_ISR register

Bit 18 **PGSERRIE**: Programming sequence error interrupt enable bit
0: No interrupt is generated when PGSERRF bit is set in FLASH_ISR register
1: An interrupt is generated when PGSERRF bit is set in FLASH_ISR register

Bit 17 **WRPERRIE**: Write protection error interrupt enable bit
0: No interrupt is generated when WRPERRF bit is set in FLASH_ISR register
1: An interrupt is generated when WRPERRF bit is set in FLASH_ISR register

Bit 16 **EOPIE**: End-of-program interrupt control bit
0: No interrupt is generated when OEPF bit is set in FLASH_ISR register
1: An interrupt is generated when OEPF bit is set in FLASH_ISR register

Bits 15:0 Reserved, must be kept at reset value.

5.9.6 FLASH interrupt status register (FLASH_ISR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	CRCRDERRF	CRCENDF	DBECCERRF	SNECCERRF	RDSERRF	Res.	Res.	INCERRF	OBLERRF	STRBERRF	PGSERRF	WRPERRF	EOPF

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRF**: CRC read error flag
This bit is set when a word is found read protected during a CRC operation. An interrupt is generated if CRCRDIE is set. Setting CRCRDERRF bit in FLASH_ICR register clears this bit.
0: No protected area detected inside addresses read by CRC
1: At least one protected area has been detected inside address read by CRC. As a result CRC result is very likely incorrect.
This flag is valid only when CRCEND bit is set.

Bit 27 **CRCENDF**: CRC end flag
This bit is set when the CRC computation has completed. An interrupt is generated if CRCENDIE is set. It is not necessary to reset CRCEND before restarting CRC computation. Setting CRCENDF bit in FLASH_ICR register clears this bit.
0: CRC computation not complete
1: CRC computation complete

Bit 26 **DBECCERRF**: ECC double error flag
This bit is set when an ECC double detection error occurs during a read operation. An interrupt is generated if DBECCERRIE is set. Setting DBECCERRF bit in FLASH_ICR register clears this bit.
0: No ECC double detection error occurred
1: ECC double detection error occurred

Bit 25 **SNECCERRF**: ECC single error flag

This bit is set when an ECC single correction error occurs during a read operation. An interrupt is generated if SNECCERRIE is set. Setting SNECCERRF bit in FLASH_ICR register clears this bit.

0: No ECC single correction error occurred

1: ECC single correction error occurred

Bit 24 **RDSERRF**: Read security error flag

This bit is set when a read security error occurs (read access to hide protected area with incorrect hide protection level). An interrupt is generated if RDSERRIE is set. Setting RDSERRF bit in FLASH_ICR register clears this bit.

0: No security error occurred

1: A security error occurred

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRF:** Inconsistency error flag

This bit is set when a inconsistency error occurs. An interrupt is generated if INCERRIE is set. Setting INCERRF bit in the FLASH_ICR register clears this bit.

0: No inconsistency error occurred

1: A inconsistency error occurred

Bit 20 **OBLERRF:** Option byte loading error flag

This bit is set when an error is found during the option byte loading sequence. An interrupt is generated if OBLERRIE is set.

Setting OBLERRF bit in the FLASH_ICR register clears this bit.

0: No error found during option byte loading sequence

1: Some errors found during option byte loading sequence

Bit 19 **STRBERRF:** Strobe error flag

This bit is set when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set. Setting STRBERRF bit in FLASH_ICR register clears this bit.

0: No strobe error occurred

1: Astrobe error occurred

Bit 18 **PGSERRF:** Programming sequence error flag

This bit is set when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set. Setting PGSERRF bit in FLASH_ICR register clears this bit.

0: No sequence error occurred

1: Asequence error occurred

Bit 17 **WRPERRF**: Write protection error flag

This bit is set when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set. Setting WRPERRF bit in FLASH_ICR register clears this bit.

0: No write protection error occurred

1: A write protection error occurred

Bit 16 **EOPF**: End-of-program flag

This bit is set when a programming operation completes. An interrupt is generated if the EOPIE is set. It is not necessary to reset EOPF before starting a new operation. Setting EOPF bit in FLASH_ICR register clears this bit.

0: No programming operation completed

1: A programming operation completed

Bits 15:0 Reserved, must be kept at reset value.

5.9.7 FLASH interrupt clear register (FLASH_ICR)

Address offset: 0x028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **CRCRDERRF**: CRC error flag clear
Setting this bit clears CRCRDERRF flag in FLASH_ISR register.

Bit 27 **CRCENDF**: CRC end flag clear
Setting this bit clears CRCENDF flag in FLASH_ISR register.

Bit 26 **DBECCERRF**: ECC double error flag clear
Setting this bit clears DBECCERRF flag in FLASH_ISR register. If the SNECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCFAR register is reset to zero as well.

Bit 25 **SNECCERRF**: ECC single error flag clear
Setting this bit clears SNECCERRF flag in FLASH_ISR register. If the DBECCERRF flag of FLASH_ISR register is also cleared, FLASH_ECCFAR register is reset to zero as well.

Bit 24 **RDSERRF**: Read security error flag clear
Setting this bit clears RDSERRF flag in FLASH_ISR register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **INCERRF**: Inconsistency error flag clear
Setting this bit clears INCERRF flag in FLASH_ISR register.

Bit 20 **OBLERRF**: Option byte loading error flag clear
Setting this bit clears OBLERRF flag in FLASH_ISR register.

Bit 19 **STRBERRF**: Strobe error flag clear
Setting this bit clears STRBERRF flag in FLASH_ISR register.

Bit 18 **PGSERRF**: Programming sequence error flag clear
Setting this bit clears PGSERRF flag in FLASH_ISR register.

Bit 17 **WRPERRF**: Write protection error flag clear
Setting this bit clears WRPERRF flag in FLASH_ISR register.

Bit 16 **EOPF**: End-of-program flag clear
Setting this bit clears EOPF flag in FLASH_ISR register.

Bits 15:0 Reserved, must be kept at reset value.

5.9.8 FLASH CRC control register (FLASH_CRCCR)

Address offset: 0x030

Reset value: 0x001C 0000

Writes to this register are ignored if CRC_EN bit is cleared in FLASH_CR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				w	w	rw							rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ALL_SECT**: All sectors selection

When this bit is set all the sectors in user flash are added to list of sectors on which the CRC is to be calculated.

This bit is cleared when CRC computation starts.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **CRC_BURST[1:0]**: CRC burst size

CRC_BURST bits set the size of the bursts that are generated by the CRC calculation unit. A flash word is 128-bit.

00: every burst has a size of 4 flash words (64 Bytes)

01: every burst has a size of 16 flash words (256 Bytes)

10: every burst has a size of 64 flash words (1 Kbytes)

11: every burst has a size of 256 flash words (4 Kbytes)

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CLEAN_CRC**: CRC clear bit

Setting CLEAN_CRC to 1 clears the current CRC result stored in the FLASH_CRCDATAR register.

Bit 16 **START_CRC**: CRC start bit

START_CRC bit triggers a CRC calculation using the current configuration. No CRC calculation can launched when an option byte change operation is ongoing because all read accesses to embedded flash memory registers are put on hold until the option byte change operation has completed.

This bit is cleared when CRC computation starts.

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **CLEAN_SECT**: CRC sector list clear bit

When this bit is set the list of sectors on which the CRC is calculated is cleared.

Bit 10 **ADD_SECT**: CRC sector select bit

When this bit is set the sector whose number is written in CRC_SECT is added to the list of sectors on which the CRC is calculated.

Bit 9 **CRC_BY_SECT**: CRC sector mode select bit

When this bit is set the CRC calculation is performed at sector level, on the sectors present in the list of sectors. To add a sector to this list, use ADD_SECT and CRC_SECT bits. To clean the list, use CLEAN_SECT bit.

When CRC_BY_SECT is cleared the CRC calculation is performed on all addresses defined between start and end addresses defined in FLASH_CRCSADDR and FLASH_CRCEADDR registers.

Bits 8:3 Reserved, must be kept at reset value.

Bits 2:0 **CRC_SECT[2:0]**: CRC sector number

CRC_SECT is used to select one user flash sectors to be added to the list of sectors on which the CRC is calculated. The CRC can be computed either between two addresses (using registers FLASH_CRCSADDR and FLASH_CRCEADDR) or on a list of sectors using this register. If this latter option is selected, it is possible to add a sector to the list of sectors by programming the sector number in CRC_SECT and then setting ADD_SECT bit.

The list of sectors can be erased either by setting CLEAN_SECT bit or by disabling the CRC computation.

000: sector 0 for CRC

001: sector 1 for CRC

...

111: sector 7 for CRC

5.9.9 FLASH CRC start address register (FLASH_CRCSADDR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_START_ADDR[9:0]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 **CRC_START_ADDR[10:0]**: CRC start address

This register is used when CRC_BY_SECT is cleared. It must be programmed to the address of the first flash word to use for the CRC calculation, done burst by burst.

CRC computation starts at an address aligned to the burst size defined in CRC_BURST of FLASH_CRCCR register. Hence least significant bits [5:0] of the address are set by hardware to 0 (minimum burst size= 64 bytes).

The address is relative to the flash bank.

Bits 5:0 Reserved, must be kept at reset value.

5.9.10 FLASH CRC end address register (FLASH_CRCEADDR)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CRC_END_ADDR[9:0]										Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw						

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:6 **CRC_END_ADDR[10:0]**: CRC end address

This register is used when CRC_BY_SECT is cleared. It must be programmed to the address of the flash word starting the last burst of the CRC calculation. The burst size is defined in CRC_BURST of FLASH_CRCCR register.

The least significant bits [5:0] of the address are set by hardware to 0 (minimum burst size= 64 bytes). The address is relative to the flash bank.

Bits 5:0 Reserved, must be kept at reset value.

5.9.11 FLASH CRC data register (FLASH_CRCDATAR)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_DATA[31:16]

CRC_DATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **CRC_DATA[31:0]**: CRC result

This bitfield contains the result of the last CRC calculation. The value is valid only when CRC calculation completed (CRCENDF is set in FLASH_ISR register).

CRC_DATA is cleared when CRC_EN is cleared in FLASH_CR register (CRC disabled), or when CLEAN_CRC bit is set in FLASH_CRCCR register.

5.9.12 FLASH ECC single error fail address (FLASH_ECCSFADDR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SEC_FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **SEC_FADD[31:0]**: ECC single error correction fail address

When a single ECC error correction occurs during a read operation, the SEC_FADD bitfield contains the system bus address that generated the error.

This register is automatically cleared when SNECCERRF flag that generated the error is cleared.

Note that only the first address that generated an ECC single error correction error is saved in this register.

5.9.13 FLASH ECC double error fail address (FLASH_ECCDFADDR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DED_FADD[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DED_FADD[31:0]**: ECC double error detection fail address

When a double ECC detection occurs during a read operation, the DED_FADD bitfield contains the system bus address that generated the error.

This register is automatically cleared when the DBECCERRF flag that generated the error is cleared.

Note that only the first address that generated an ECC double error detection error is saved in this register.

5.9.14 FLASH options key register (FLASH_OPTKEYR)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OCUKEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OCUKEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **OCUKEY[31:0]**: Options configuration unlock key

Following values must be written to FLASH_OPTKEYR consecutively to unlock FLASH_OPTCR register:

1st key = 0x0819 2A3B

2nd key = 0x4C5D 6E7F

Reads to this register returns zero. If above sequence is performed twice locks up the corresponding register/bit until the next system reset, and generates a bus error.

5.9.15 FLASH options control register (FLASH_OPTCR)

Address offset: 0x104

Reset value: 0xX000 0001

When OPTLOCK bit in this register is set writes to all other bits are ignored.

Write access to this register is controlled by FLASH_OPTKEYR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	OPTERRIE	Res.	KTEIE	KVEIE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw		rw	rw											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PG_OPT	OPTLOCK
														rw	rs

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRIE**: Option byte change error interrupt enable bit

This bit controls if an interrupt has to be generated when an error occurs during an option byte change.

0: no interrupt is generated when an error occurs during an option byte change

1: an interrupt is generated when and error occurs during an option byte change.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **KTEIE**: Key transfer error interrupt enable bit

This bit controls if an interrupt has to be generated when KTEF is set in FLASH_OPTISR.

0: no interrupt is generated when a key transfer error occurs

1: an interrupt is generated when a key transfer error occurs

Bit 27 **KVEIE**: Key valid error interrupt enable bit
This bit controls if an interrupt has to be generated when KVEF is set in FLASH_OPTISR.
0: no interrupt is generated when a key valid error occurs
1: an interrupt is generated when a key valid error occurs

Bits 26:2 Reserved, must be kept at reset value.

Bit 1 **PG_OPT**: Program options
0: Update operations to user option bytes and option byte keys do not start
1: Write operation to user option bytes and option byte keys is enabled

Bit 0 **OPTLOCK**: Options lock
When this bit is set write to all other bits in this register, and write to OTP words, option bytes and option bytes keys control registers, are ignored.
0: OTP words, FLASH_OPTCR, FLASH_OBKCR and FLASH_xxSRP registers are unlocked
1: Writes to OTP words, FLASH_OBKCR, FLASH_xxSRP and to other bits than OPTLOCK in FLASH_OPTCR, are ignored
Clearing this bit requires the correct write sequence to FLASH_OPTKEYR register (see this register for details). If a wrong sequence is executed, or the unlock sequence is performed twice, this bit remains locked until next system reset.
During the write access to set LOCK bit from 0 to 1, it is possible to change the other bits of this register.

5.9.16 FLASH options interrupt status register (FLASH_OPTISR)

Address offset: 0x108

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	OPTERRF	Res.	KTEF	KVEF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	r		r	r											
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRF**: Option byte change error flag
When OPTERRF is set, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTERRIE bit of FLASH_OPTCR register is set. Setting OPTERRF of register FLASH_OPTICR clears this bit.
0: No option byte change errors occurred
1: One or more errors occurred during an option byte change operation.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **KTEF**: Key transfer error flag

This bit is set when embedded flash signals an error to the SAES peripheral. It happens when the key size (128-bit or 256-bit) is not matching between embedded flash OBKSIZE[1:0] and KEYSIZE bit in SAES_CR register. It also happen when an ECC dual error detection occurred while embedded flash loaded an option byte key for the SAES peripheral.

When KTEF is set write to START bit in FLASH_OBKCR is ignored.

An interrupt is generated when this flag is raised if the KTEIE bit of FLASH_OPTCR register is set. Setting KTEF bit of register FLASH_OPTICR clears this bit.

Bit 27 **KVEF**: Key valid error flag

This bit is set when loading an unknown or corrupted option byte key. More specifically:

– Embedded flash did not find an option byte key that corresponds to the given OBKINDEX[4:0] and the requested HDPL (optionally modified by NEXTKL[1:0]). It can happen for example when requested key has not being provisioned.

– A double error detection was found when loading the requested option byte key. In this case, if this key is provisioned again the error should disappear.

When KVEF is set write to START bit in FLASH_OBKCR is ignored.

An interrupt is generated when this flag is raised if the KVEIE bit of FLASH_OPTCR register is set. Setting KVEF bit of register FLASH_OPTICR clears this bit.

Bits 26:0 Reserved, must be kept at reset value.

5.9.17 FLASH options interrupt clear register (FLASH_OPTICR)

Address offset: 0x10C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **OPTERRF**: Option byte change error flag

Set this bit to clear OPTERRF flag in FLASH_OPTISR register.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **KTEF**: key transfer error flag

Set this bit to clear KTEF flag in FLASH_OPTISR register.

Bit 27 **KVEF**: key valid error flag

Set this bit to clear KVEF flag in FLASH_OPTISR register.

Bits 26:0 Reserved, must be kept at reset value.

5.9.18 FLASH option byte key control register (FLASH_OBKCR)

Address offset: 0x110

Reset value: 0x0000 0C00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **KEYSTART**: Key option start

This bit is used to start the option byte key operation defined by the PROG bit.

The embedded flash memory resets START when the corresponding operation has been acknowledged.

Bit 14 **KEYPROG**: Key program

This bit must be set to write option byte keys (keys are read otherwise).

0: Read key. Result of the operation is stored in FLASH_OBKDRx registers, if applicable.

1: Program key if PG_OPT is set in FLASH_OPTCR register, and KDREF flag is cleared in FLASH_OPTISR register. Correct key information must be stored in FLASH_OBKDRx register before setting PROG and START bits.

Bits 13:12 Reserved, must be kept at reset value.

Bits 11:10 **OBKSIZE[1:0]**: Option byte key size

Application must use this bitfield to specify how many bits must be used for the new key. Embedded flash ignores OBKSIZE during read of option keys because size is stored with the key.

00: Key size is 32 bits

01: Key size is 64 bits

10: Key size is 128 bits

11: Key size is 256 bits

Bits 9:8 **NEXTKL[1:0]**: Next key level

00: OBKINDEX represents the index of the option byte key stored for the hide protection level indicated in SBS_HDPLSR.

01: OBKINDEX represents the index of the option byte key stored for the hide protection level indicated in SBS_HDPLSR plus one (e.g. if HDPL=1 in SBS_HDPLR the key of level 2 is selected).

10 or 11: reserved

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **OBKINDEX[4:0]**: Option byte key index

This bitfield represents the index of the option byte key in a given hide protection level.

Reading keys with index lower that 8, the value is not be available in OBKDRx registers. It is instead sent directly to SAES peripheral. All others keys can be read using OBKDRx registers.

Up to 32 keys can be provisioned per hide protection level (0, 1 or 2), provided there is enough space left in the flash to store them.

5.9.19 FLASH option bytes key data register x (FLASH_OBKDRx)

Address offset: 0x118 + 0x4 * x (x=0 to 7)

Reset value: 0x0000 0000

Writes are ignored if KDREF is set in FLASH_OPTISR register.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OBKDATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OBKDATA[31:0]**: option byte key data, bits [31+x:0+x]
Data register used in conjunction with FLASH_OBKCR register.
Reading this register (read value once), or incrementing HDPL value in SBS peripheral automatically clears OBKDATA to 0x0. Writing this register prevents reading OBKDATA until option byte key programming sequence is completed.

5.9.20 FLASH non-volatile status register (FLASH_NVSR)

Address offset: 0x200

Reset value: 0x0000 XXXX

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NVSTATE[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **NVSTATE[7:0]**: Non-volatile state
0xB4: OPEN device
0x51: CLOSED device
Others: invalid configuration.

5.9.21 FLASH security status register programming (FLASH_NVSRP)

Address offset: 0x204

Reset value: 0x0000 XXXX (same as FLASH_NVSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR register.

Write are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NVSTATE[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **NVSTATE[7:0]**: Non-volatile state programming

Write to change corresponding bits in FLASH_NVSR register:

0xB4: OPEN

0x51: CLOSE

Actual option byte change from close to open is triggered only after memory clear hardware process is confirmed. When NVSTATE=0xB4 (resp. 0x51) writing any other value than 0x51 (resp. 0xB4) triggers an option byte change error (OPTERRF).

5.9.22 FLASH RoT status register (FLASH_ROTSR)

Address offset: 0x208

Reset value: 0x0000 XXXX

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IROT_SELECT[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	r	r	r	r	r	r								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_AUTH[7:0]								OEM_PROVD[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 **IROT_SELECT[7:0]**: iRoT selection
This option is ignored for STM32H7R device's (user firmware is always selected).
For STM32H7S devices there are two options:
0xB4: ST iRoT is selected at boot
0x6A (default): OEM iRoT is selected at boot.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **DBG_AUTH[7:0]**: Debug authentication method
0xB4: Locked device (no debug allowed)
0x51: Authentication method using ECDSA signature (NIST P256)
0x8A: Authentication method using password
Others: no authentication method selected (different to 0xB4, 0x51, 0x8A).

Bits 7:0 **OEM_PROVD[7:0]**: OEM provisioned device
0xB4: Device has been provisioned by the OEM
Others: device is not provisioned by the OEM.

5.9.23 FLASH RoT status register programming (FLASH_ROTSRP)

Address offset: 0x20C

Reset value: 0x0000 XXXX (same as FLASH_ROTSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Writes are ignored if HDPL is different from 0 in SBS_HDPLSR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IROT_SELECT[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_AUTH[7:0]								OEM_PROVD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **IROT_SELECT[7:0]**: iRoT selection
This option is ignored for STM32H7R devices.
Write to change corresponding bits in FLASH_ROTSR register.

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **DBG_AUTH[7:0]**: Debug authentication method programming
Write to change corresponding bits in FLASH_ROTSR register.

Bits 7:0 **OEM_PROVD[7:0]**: OEM provisioned device
Write to change corresponding bits in FLASH_ROTSR register..

5.9.24 FLASH OTP lock status register (FLASH_OTPLSR)

Address offset: 0x210

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OTPL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTPL[15:0]**: OTP lock n (n=0 to 15)
Block *n* corresponds to OTP 16-bit word 32 x *n* to 32 x *n* + 31.
OTPL[n] = 1 indicates that all OTP 16-bit words in OTP Block *n* are locked and can no longer be programmed.
OTPL[n] = 0 indicates that all OTP 16-bit words in OTP Block *n* are not locked and can still be modified.

5.9.25 FLASH OTP lock status register programming (FLASH_OTPLSRP)

Address offset: 0x214

Reset value: 0x0000 XXXX (same as for FLASH_OTPLSR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OTPL[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTPL[15:0]**: OTP lock n programming (n=0 to 15)
Write to change corresponding option byte bit in FLASH_OTPLSR.
OTPL bits can be only be set, not cleared.

5.9.26 FLASH write protection status register (FLASH_WRPSR)

Address offset: 0x218

Reset value: 0x0000 XXXX

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPS[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPS[7:0]**: Write protection for sector n (n=0 to 7)
This bit reflects the write protection status of user flash sector n
0: sector n is write protected
1: sector n is not write protected

5.9.27 FLASH write protection status register programming (FLASH_WRPSRP)

Address offset: 0x21C

Reset value: 0x0000 XXXX

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Writes are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

(The reset value is the same as for FLASH_WRPSR)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPS[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPS[7:0]**: Write protection for sector n programming (n=0 to 7)
Write to change corresponding bit in FLASH_WRPSR

5.9.28 FLASH hide protection status register (FLASH_HDPSR)

Address offset: 0x230

Reset value: 0x0XXX 0000

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP_AREA_END[8:0]								
							r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP_AREA_START[8:0]								
							r	r	r	r	r	r	r	r	r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **HDP_AREA_END[8:0]**: Hide protection user flash area end
This option sets the end address that contains the last 256-byte block of the hide protection (HDP) area in user flash area.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **HDP_AREA_START[8:0]**: Hide protection user flash area start
This option sets the start address that contains the first 256-byte block of the hide protection (HDP) area in user flash area.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.

5.9.29 FLASH hide protection status register programming (FLASH_HDPSRP)

Address offset: 0x234

Reset value: 0x0XXX 0000

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Write are ignored if HDPL is different from 0 or 1 in SBS_HDPLSR register.

(The reset value is the same as for FLASH_HDPSR.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP_AREA_END[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP_AREA_START[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **HDP_AREA_END[8:0]**: Hide protection user flash area end programming
Write to change corresponding option byte bits in FLASH_HDPSR.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.

Bits 15:9 Reserved, must be kept at reset value.

Bits 8:0 **HDP_AREA_START[8:0]**: Hide protection user flash area start programming
Write to change corresponding option byte bits in FLASH_HDPSR.
If HDP_AREA_END=HDP_AREA_START all the sectors are protected.
If HDP_AREA_END<HDP_AREA_START no sectors are protected.

5.9.30 FLASH epoch status register (FLASH_EPOCHSR)

Address offset: 0x250

Reset value: 0x0000 XXXX

This read-only register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPOCH[23:16]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EPOCH[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **EPOCH[23:0]**: Epoch

This value is distributed by hardware to the SAES peripheral.

5.9.31 FLASH RoT status register programming (FLASH_EPOCHSRP)

Address offset: 0x254

Reset value: 0x0000 XXXX

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

Writes are ignored if HDPL is different from 0 in SBS_HDPLSR register.

(The reset value is the same as for FLASH_EPOCHSR.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPOCH[23:16]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EPOCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **EPOCH[23:0]**: Epoch programming

Write to change corresponding bits in FLASH_EPOCHSR register.

5.9.32 FLASH option byte word 1 status register (FLASH_OBW1SR)

Address offset: 0x260

Reset value: 0xXXXX XXXX (see *Option byte user words organization*)

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	VDDIO_HSLV	PERSO_OK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IWDG_FZ_SDBY	IWDG_FZ_STOP	Res.
		r	r										r	r	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	XSPI2_HSLV	XSPI1_HSLV	NRST_STBY	NRST_STOP	Res.	IWDG_HW	BOR_LEV[1:0]		Res.	Res.
						r	r	r	r		r	r	r		

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: I/O High-Speed at Low-Voltage
This bit indicates that the product operates below 2.5 V.
0: Product working in the full voltage range, I/O speed optimization at low-voltage disabled
1: Product operating below 2.5 V, I/O speed optimization at low-voltage feature allowed

Bit 28 **PERSO_OK**: Personalization OK
This bit is set on STMicroelectronics production line.

Bits 27:19 Reserved, must be kept at reset value.

Bit 18 **IWDG_FZ_SDBY**: IWDG standby mode freeze
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode

Bit 17 **IWDG_FZ_STOP**: IWDG stop mode freeze
When set the independent watchdog IWDG is frozen in system Stop mode.
0: Independent watchdog frozen in Stop mode
1: Independent watchdog keep running in Stop mode

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **XSPI2_HSLV**: XSPIM_P2 High-Speed at Low-Voltage
0: I/O XSPIM_P2 High-Speed option disabled
1: I/O XSPIM_P2 High-Speed option enabled

Bit 8 **XSPI1_HSLV**: XSPIM_P1 High-Speed at Low-Voltage
0: I/O XSPIM_P1 High-Speed option disabled
1: I/O XSPIM_P1 High-Speed option enabled

Bit 7 **NRST_STBY**: Reset on standby mode
0: Independent WDG generates a reset if STANDBY mode is requested
1: Independent WDG does not generate a reset if STANDBY mode is requested

Bit 6 **NRST_STOP**: Reset on stop mode
0: Independent WDG generates a reset if STOP mode is requested
1: Independent WDG does not generate a reset if STOP mode is requested

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_HW**: Independent watchdog HW Control
1: IWDG watchdog is controlled by software
0: IWDG watchdog is controller by hardware

Bits 3:2 **BOR_LEV[1:0]**: Brownout level
These bits reflects the power level that generates a system reset.
00: BOR OFF, POR/PDR reset threshold level is applied
01: BOR Level 1, the threshold level is low (around 2.1 V)
10: BOR Level 2, the threshold level is medium (around 2.4 V)
11: BOR Level 3, the threshold level is high (around 2.7 V)

Bits 1:0 Reserved, must be kept at reset value.

5.9.33 FLASH option byte word 1 status register programming (FLASH_OBW1SRP)

Address offset: 0x264

Reset value: 0xXXXX XXXX (same as for FLASH_OBW1SR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw	rw	rw		rw	rw	rw		

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **VDDIO_HSLV**: I/O High-Speed at Low-Voltage programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 28:19 Reserved, must be kept at reset value.

Bit 18 **IWDG_FZ_SDBY**: IWDG standby mode freeze programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 17 **IWDG_FZ_STOP**: IWDG stop mode freeze
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 16:10 Reserved, must be kept at reset value.

Bit 9 **XSPI2_HSLV**: XSPIM_P2 High-Speed at Low-Voltage programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 8 **XSPI1_HSLV**: XSPIM_P1 High-Speed at Low-Voltage
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 7 **NRST_STBY**: Reset on standby mode programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 6 **NRST_STOP**: Reset on stop mode programming
Write to change corresponding bit in FLASH_OBW1SR register.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **IWDG_HW**: Independent watchdog HW Control
Write to change corresponding bit in FLASH_OBW1SR register.

Bits 3:2 **BOR_LEV[1:0]**: Brownout level
Write to change corresponding bits in FLASH_OBW1SR register.

Bits 1:0 Reserved, must be kept at reset value.

5.9.34 FLASH option byte word 2 status register (FLASH_OBW2SR)

Address offset: 0x268

Reset value: 0xXXXX XXXX (see *Option byte user words organization*)

This register reflects the current values of corresponding option bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	I2C_NI3C	ECC_ON_SRAM	Res.	DTCM_AXI_SHARE[2:0]			Res.	ITCM_AXI_SHARE[2:0]		
						r	r		r	r	r		r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **I2C_NI3C**: I2C Not I3C
0: I3C is selected
1: I2C is selected

Bit 8 **ECC_ON_SRAM**: ECC on SRAM

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DTCM_AXI_SHARE[2:0]**: DTCM SRAM configuration

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **ITCM_AXI_SHARE[2:0]**: ITCM SRAM configuration

5.9.35 FLASH option byte word 2 status register programming (FLASH_OBW2SRP)

Address offset: 0x26C

Reset value: 0xXXXX XXXX (same as for FLASH_OBW2SR)

Writes to this register are ignored if PG_OPT bit is cleared in FLASH_OPTCR register, or if BUSY and IS_OPTCHANGE bits are set in FLASH_SR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	I2C_NI3C	ECC_ON_SRAM	Res.	DTCM_AXI_SHARE[2:0]			Res.	ITCM_AXI_SHARE[2:0]		
						rw	rw		rw	rw	rw		rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **I2C_NI3C**: I2C Not I3C
Write to change corresponding bit in FLASH_OBW2SR register.

Bit 8 **ECC_ON_SRAM**: ECC on SRAM programming
Write to change corresponding bit in FLASH_OBW2SR register.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **DTCM_AXI_SHARE[2:0]**: DTCM AXI share programming
Write to change corresponding bits in the FLASH_OBW2SR register.
Bit 2 should be kept to 0:
– DTCM_AXI_SHARE = “000” or “011”: DTCM 64 Kbytes
– DTCM_AXI_SHARE = “001”: DTCM 128 Kbytes
– DTCM_AXI_SHARE = “010”: DTCM 192 Kbytes

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **ITCM_AXI_SHARE[2:0]**: ITCM AXI share programming
Write to change corresponding bits in FLASH_OBW2SR register.
Bit 2 should be kept to 0:
– ITCM_AXI_SHARE: = “000” or “011”: ITCM 64 Kbytes
– ITCM_AXI_SHARE = “001”: ITCM 128 Kbytes
– ITCM_AXI_SHARE = “010”: ITCM 192 Kbytes

5.9.36 FLASH register map

Table 40. FLASH register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

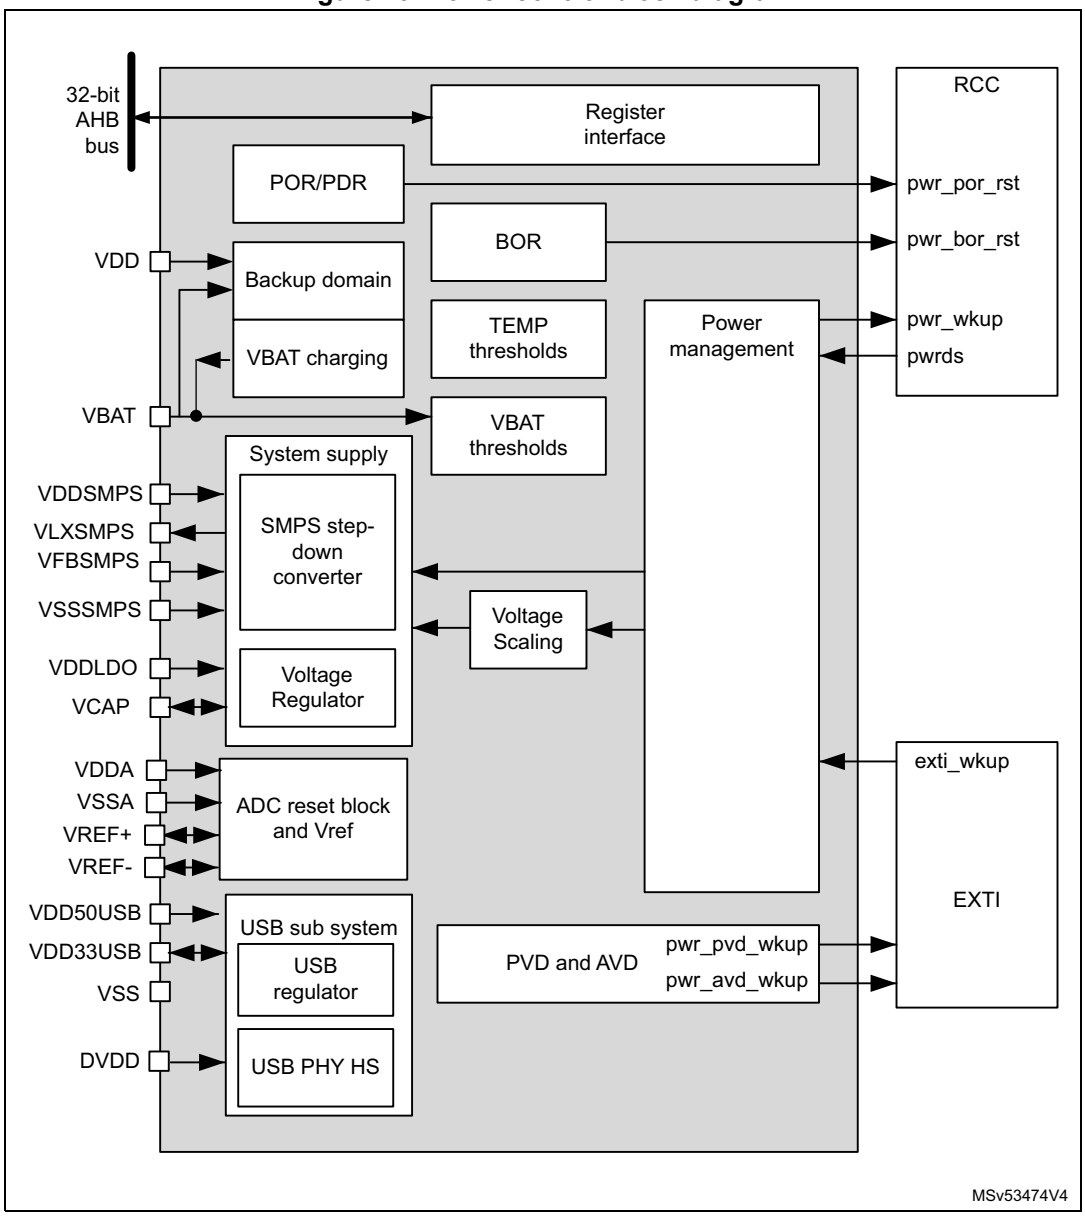
6 Power control (PWR)

6.1 Introduction

The power control section (PWR) provides an overview of the supply architecture for the different power domains and of the supply configuration controller.



It also describes the features of the power supply supervisors and explains how the V_{CORE} supply domain is configured depending on the operating modes, the selected performance (clock frequency) and the voltage scaling.

6.2 PWR main features

- Power supplies and supply domains
  - Core domains (V_{CORE} = V_{CAP})
  - V_{DD} domain
  - Backup domain (V_{SW}, V_{BKP})
  - Analog domain (V_{DDA})
- System supply voltage regulation
  - Switched-mode power supply power-efficient voltage down-converter (SMPS step-down converter)
  - Voltage regulator (LDO)
- Peripheral supply regulation
  - USB regulator
- Power supply supervision
  - POR/PDR monitor
  - BOR monitor
  - PVD monitor
  - AVD monitor
  - V_{BAT} thresholds
  - Temperature thresholds
- Power management
  - V_{BAT} battery charging
  - Operating modes
  - Voltage scaling control
  - Low-power modes

6.3 PWR block diagram

Figure 19. Power control block diagram

6.3.1 PWR pins and internal signals

Table 41 lists the PWR inputs and output signals connected to package pins or balls, while *Table 42* shows the internal PWR signals.

Table 41. PWR input/output signals connected to package pins or balls

Pin name	Signal type	Description
VDD	Supply input	Main I/O and V_{DD} domain supply input
VDDA	Supply input	External analog power supply for analog peripherals
VSSA	Supply	Analog peripherals ground
VREF+,VREF-	Supply input/output	External reference voltage for ADCs
VBAT	Supply input/output	Backup battery supply input
VDDSMPS	Supply input	Step-down converter supply input
VLXSMPS	Supply output	Step-down converter supply output
VFBSMPS	Supply input	Step-down converter feedback voltage sense
VSSSMPS	Supply input	Step-down converter ground
VDDLDO	Supply input	Voltage regulator supply input
VCAP	Supply Input/Outputs	Digital core domain supply
VDD50USB	Supply input	USB regulator supply input
VDD33USB	Supply Input/Outputs	USB regulator supply output or external USB supply input
DVDD	Supply	Digital supply for the USB HS PHY
VSS	Supply	Main ground
AHB	Input/output	AHB register interface
WKUPx	Input	Wake-up pins
SLEEP	Output	MCU in Sleep mode
STOP	Output	MCU in Stop modes
VDDXSPI1	Supply input	XSPI1 I/O
VDDXSPI2	Supply input	XSPI2 I/O

Table 42. PWR internal input/output signals

Signal name	Signal type	Description
AHB	Input/output	AHB register interface
pwr_pvd_wkup	Output	Programmable voltage detector output
pwr_avd_wkup	Output	Analog voltage detector output
pwr_por_rst	Output	Power-on reset
pwr_bor_rst	Output	Brownout reset
exti_wkup	Input	Wake-up request
pwr_wkup	Output	Bus matrix clock wake-up request

Each of the four wake-up events, WKUPx, can be generated from four pins or internal events

Table 43. table wake-up source selection

Port	Wake-up event
PA0	WKUP1
PA2	WKUP2
PC13	WKUP3
PC1	WKUP4

6.4 Power supplies

The device requires V_{DD} and V_{DDSMPS} power supplies as well as independent supplies for V_{DDLDO}, V_{DDA}, V_{DDUSB}, and V_{CAP}. It also provides regulated supplies for specific functions (step-down converter, voltage regulator, USB regulator).

- V_{DD}: external power supply for I/Os and system analog blocks such as reset, power management and oscillators
- $V_{DDxspi1}$,$V_{DDxspi2}$: external power supply for dedicated I/Os (Octo SPI and Hexa Deca SPI memories)
- V_{BAT}: optional external power supply for backup domain when V_{DD} is not present (V_{BAT} mode)

  This power supply must be connected to VDD when no battery is used.
- V_{DDSMPS}: external power supply for the SMPS step-down converter

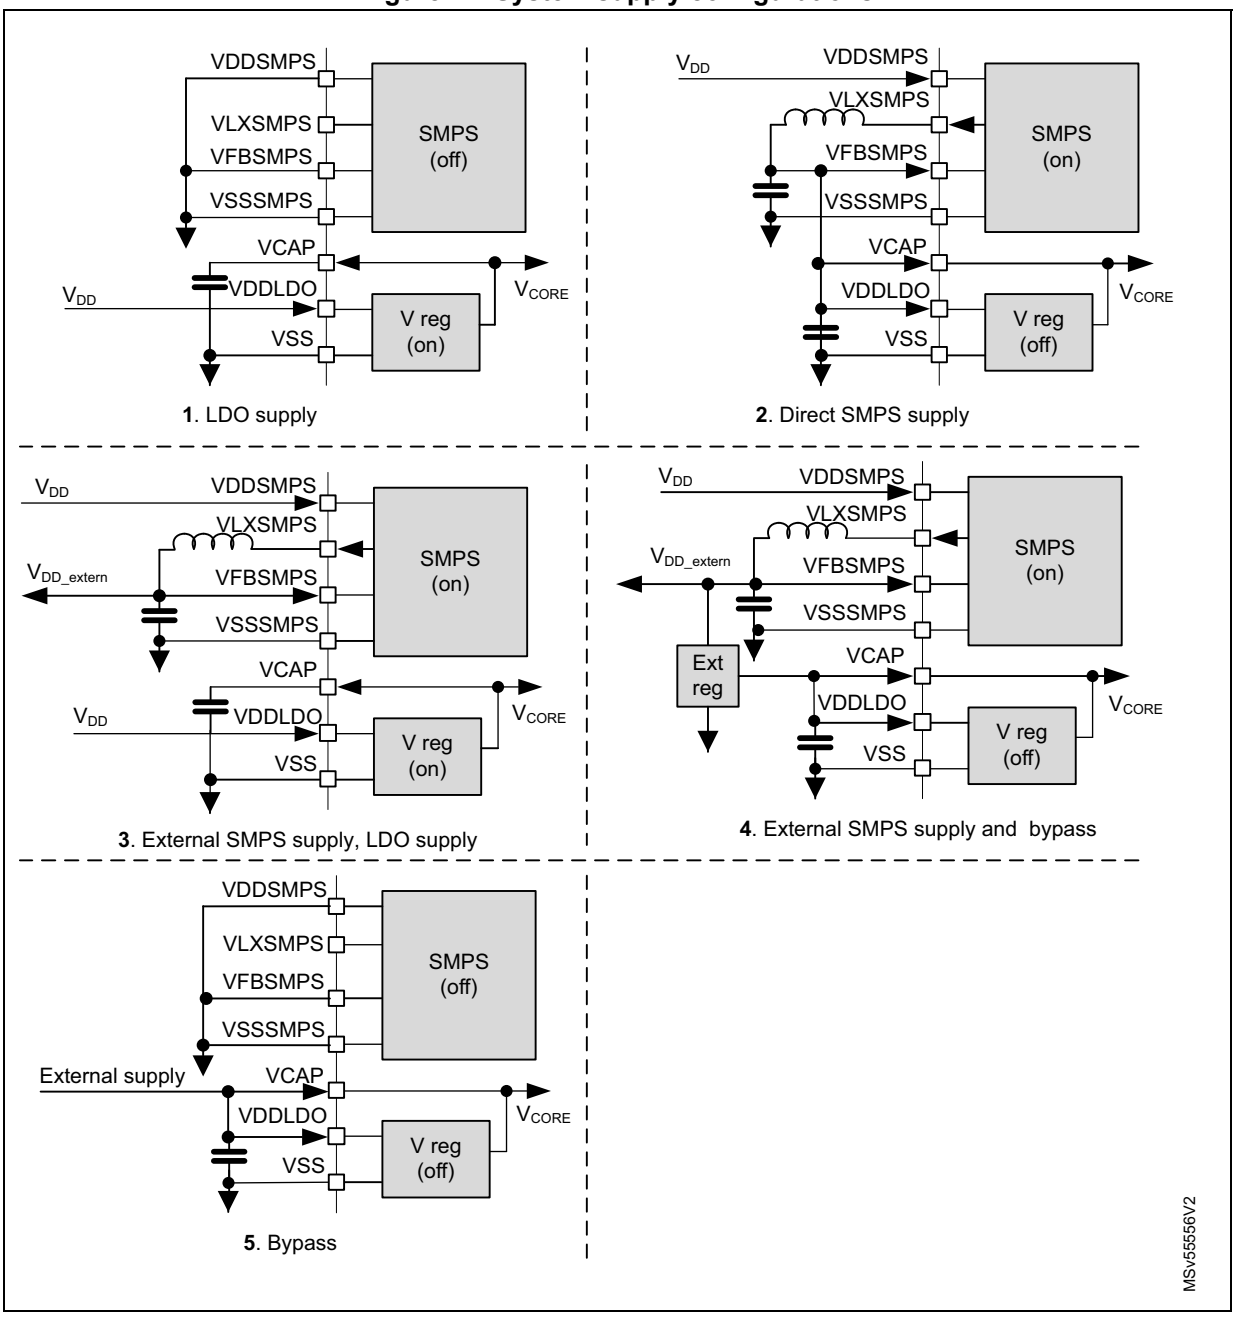
  VDDSMPS must be connected to VDD or tied to VSS when the SMPS is not used.
- V_{LXSMPS}: step-down converter supply output
- V_{FBSMPS}: step-down converter sense feedback
- V_{SSSMPS}: separate step-down converter ground
- V_{DDLDO}: external power supply for voltage regulator
- V_{CAP}: digital core domain supply

  This power supply is independent from all the other power supplies:
  - When the voltage regulator is enabled, V_{CORE} is delivered by the internal voltage regulator.
  - When the voltage regulator is disabled, V_{CORE} is delivered by an external power supply through VCAP pin, or by the SMPS step-down converter.
- V_{DDA}: external analog power supply for ADCs and voltage reference buffers

  This power supply is independent from all the other power supplies.
- V_{REF+}: external reference voltage for ADC.
  - When the voltage reference buffer is enabled, V_{REF+} and V_{REF-} are delivered by the internal voltage reference buffer.
  - When the voltage reference buffer is disabled, V_{REF+} is delivered by an independent external reference supply.
- V_{SSA}: separate analog and reference voltage ground.
- $V_{DD50USB}$: external power supply for USB regulator.
- $V_{DD33USB}$: USB regulator supply output for USB interface.
  - When the USB regulator is enabled, $V_{DD33USB}$ is delivered by the internal USB regulator.
  - When he USB regulator is disabled, $V_{DD33USB}$ is delivered by an independent external supply input.
- V_{SS}: common ground for all supplies except for step-down converter and analog peripherals.

Note: Depending on the operating power supply range, some peripherals might be used with limited features and performance. For more details, refer to section "General operating conditions" of the device datasheets.

Figure 20. Power supply overview[(a)]



a. Refer to application note AN5935 “Getting started hardware with STM32H7Rx/7Sx MCUs" for the possible power scheme and connected capacitors.

By configuring the SMPS step-down converter and LDO voltage regulator, the supply configurations shown in *Figure 21* are supported for the V_{CORE} core domain and an external supply. For the different configuration available per package refer to the product datasheet.

Note: The SMPS step-down converter is not available on all packages, and the Bypass mode is available only when the SMPS is available.

Figure 21. System supply configurations

The different supply configurations are controlled through the LDOEN, SDEN, SMPSEXTHP, SDHILEVEL and BYPASS bits in the *PWR control register 2 (PWR_CSR2)* register according to *Table 44*.

In the following table HP refers to High power, LP refers to Low Power and off refers to no supply.

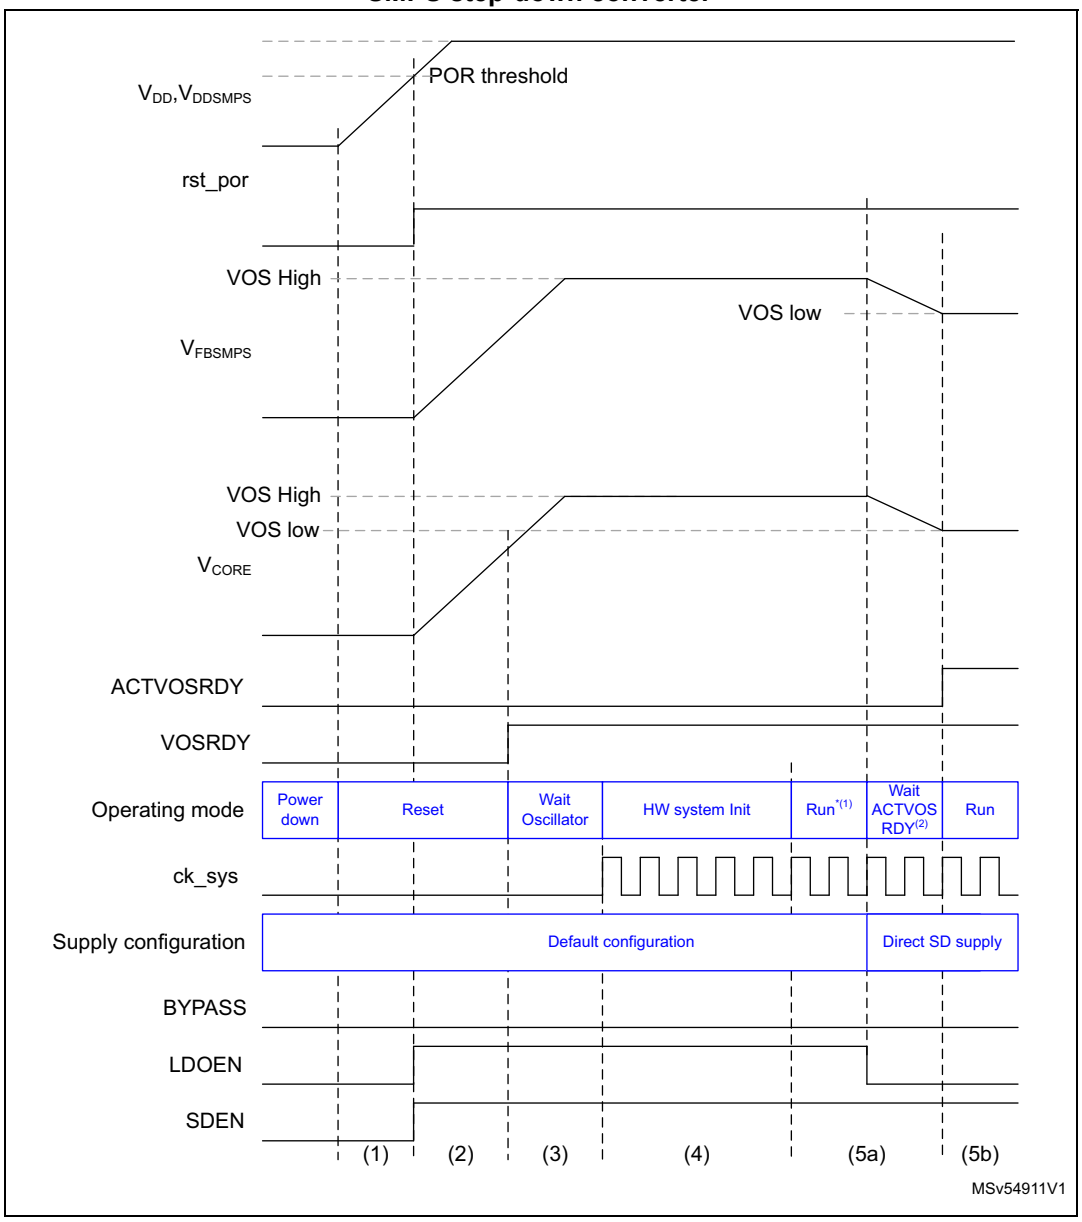
Table 44. Supply configuration control

ID	Supply configuration	SDHILEVEL	SMPSEXTHP	SDEN	LDOEN	BYPASS	Description
0	Startup configuration	0	0	1	1	0	– V_{CORE} power domains are supplied from the LDO according to VOS. – SMPS step-down converter enabled at 1.35 V, may be used to supply the LDO.
1	LDO supply	x	x	0	1	0	– V_{CORE} power domains are supplied from the LDO according to VOS. – LDO power mode (HP, LP, Off) follows the system low-power modes. – SMPS step-down converter disabled.
2	Direct SMPS step-down converter supply	X	0	1	0	0	– V_{CORE} power domains are supplied from SMPS step-down converter according to VOS. – LDO OFF. – SMPS step-down converter power mode (HP, LP, Off) follows system low-power modes. – SDHILEVEL is not taken into account, and is considered to be 0
3	SMPS step-down converter supplies External. LDO supplied by external VDD.	1	1	1	1	0	– V_{CORE} power domains are supplied from voltage regulator according to VOS – LDO power mode (HP, LP, Off) follows system low-power modes. – SMPS step-down converter enabled according to SDHILEVEL used to supply external circuits. – SMPS step-down converter forced ON in HP mode.
4	SMPS step-down converter supplies external and LDO Bypass	1	1	1	0	1	– V_{CORE} supplied from external source – SMPS step-down converter enabled according to SDHILEVEL used to supply external circuits and may supply the external source for V_{CORE}. – SMPS step-down converter forced ON in HP mode.
5	SMPS step-down converter disabled and LDO Bypass	x	x	0	0	1	– V_{CORE} supplied from external source – SMPS step-down converter disabled and LDO bypassed, voltage monitoring still active.

Table 44. Supply configuration control (continued)

ID	Supply configuration	SDHILEVEL	SMPSEXTHP	SDEN	LDOEN	BYPASS	Description
NA	Illegal	x	x	0	0	0	– Illegal combination, the default configuration is kept. (write data is ignored). – The cascade mode is prohibited and not detected.
		x	x	x	1	1	
		x	0	1	0	1	
		0	x	1	1	0	
		x	1	1	0	0	
		0	1	1	0	1	

6.4.1 System supply startup



The system startup sequence from power-on in different supply configurations is the following (see *Figure 22* and *Figure 23* for LDO supply and Direct SMPS supply, respectively):

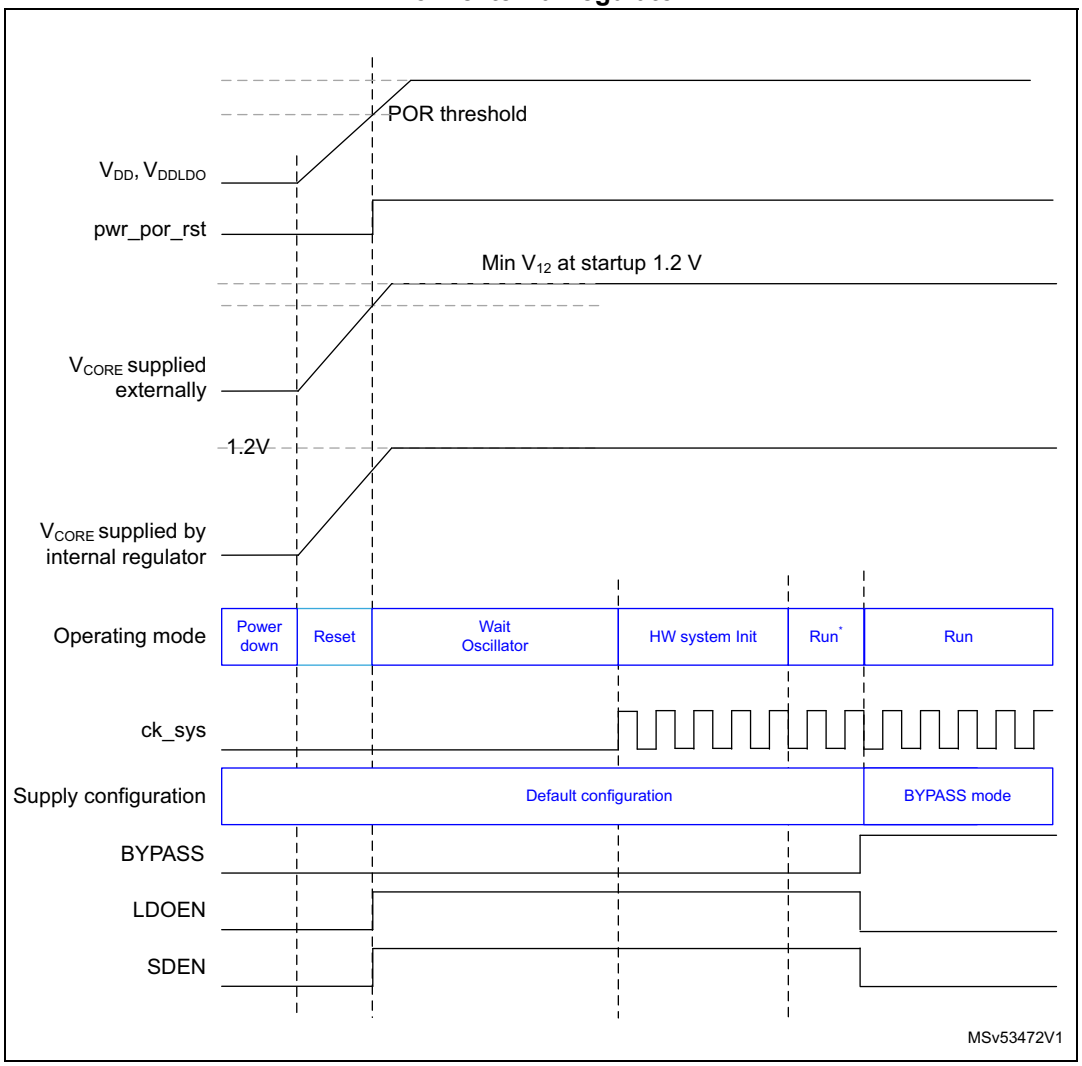
1. When the system is powered on, the POR monitors V_{DD} supply. Once V_{DD} is above the POR threshold level, the SMPS step-down converter and voltage regulator are enabled in the default supply configuration:
   The SMPS step-down converter output level is set at 1.35 V. The voltage regulator LDO output level is set at 1.19 V. Depending on the package and configuration the SMPS provides the voltage to internal power domain and/or LDO or external supply.
2. The system is kept in reset mode as long as V_{CORE} is not stable.
3. Once V_{CORE} is stable, the system is taken out of reset and the HSI oscillator is enabled.
4. Once the oscillator is stable, the system is initialized: Flash memory is ready, option bytes are loaded and the CPU starts in limited run mode (Run*).
5. The software must then initialize the system including supply configuration programming in *PWR control register 2 (PWR_CSR2)*. Once the supply configuration has been configured, the ACTVOSRDY bit in the *PWR control status register 1 (PWR_SR1)* must be checked to guarantee valid voltage levels:
   a) As long as ACTVOSRDY indicates that voltage levels are invalid, the system is in Run* mode and VOS must not be changed.
   b) Once ACTVOSRDY indicates that voltage levels are valid, the system is in normal Run mode, and VOS can be changed.

V_{CORE} directly supplied from the SMPS step-down converter

When V_{CORE} is directly supplied from the SMPS step-down converter, the V_{CORE} voltage first settles at V_{FBSMPS} default level (1.36 V). Due to a too high supply compared to the VOS level, the ACTVOSRDY bit in the *PWR control status register 1 (PWR_SR1)* indicates invalid voltage levels. V_{CORE} settles at VOS low and ACTVODSRDY indicates valid voltage levels only when the supply configuration has been programmed in *PWR control register 2 (PWR_CSR2)* (see *Figure 22*).

Figure 22. Device startup with V_{CORE} supplied directly from SMPS step-down converter

1. In Run* mode, write operations to RAM are not allowed.
2. VOS can be changed only when ACTVOSRDY is valid.



When exiting from Standby mode, the supply configuration is known by the system since the content of *PWR control register 2 (PWR_CSR2)* is retained. However the software must still wait for the ACTVOSRDY bit to be set in *PWR control status register 1 (PWR_SR1)* to indicate V_{CORE} voltage levels are valid, before performing changes to VOS.

V_{CORE} supplied in Bypass mode (LDO and SMPS OFF)

The devices that feature the SMPS can also be used in Bypass mode. When V_{CORE} is supplied in Bypass mode (LDO and SMPS OFF), the V_{CORE} voltage must first settles at a default level higher than 1.2 V. Due to the LDO default state after power-up (enabled by default), the external V_{CORE} voltage must remain higher than 1.2 V until the LDO is disabled by software.

When the LDO is disabled, the external V_{CORE} voltage can be adjusted according to the user application needs (refer to section *General operating conditions* of the datasheet for details on V_{CORE} level versus the maximum operating frequency).

Figure 23. Device startup with V_{CORE} supplied in Bypass mode from external regulator

6.4.2 Core domain

The V_{CORE} core domain supply can be provided by the SMPS step-down converter, LDO voltage regulator or by an external supply (V_{CAP}). V_{CORE} supplies all the digital circuitries except for the backup domain and the Standby circuitry. When a system reset occurs, the voltage regulator is enabled and supplies V_{CORE}. The SMPS step-down converter is also enabled to deliver 1.36 V. This allows the system to start up in any supply configurations (see *Figure 21*).

After a system reset, the software must configure the used supply configuration in *PWR control register 2 (PWR_CSR2)* register before changing VOS in the *PWR control status register 4 (PWR_CSR4)* or the RCC sys_ck frequency. The different system supply configurations are controlled as shown in *Table 44*.

Note: The SMPS step-down converter and the LDO are not available on all packages.

LDO voltage regulator

The embedded voltage regulator (LDO) requires external capacitors to be connected to VCAP pins.

The voltage regulator provides three different operating modes: High Power (HP), Low-power (LP) or Off. These modes are used depending on the system operating modes (Run, Stop and Standby).

- Run modes

  The LDO regulator is in Main mode and provides full power to the V_{CORE} domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS low and VOS high) that are configured through the VOS bit in the *PWR control status register 4 (PWR_CSR4)*. The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS low is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

  The voltage regulator supplies the V_{CORE} domain to retain the content of registers and internal memories, and must be set in LP mode.

  In LP mode the regulator mode is selected through the SVOS bit in the *PWR control register 1 (PWR_CR1)*. Due to a lower voltage level for SVOS low scaling, the Stop mode consumption can be further reduced.

- Standby mode

  The voltage regulator is OFF and the V_{CORE} domains are powered down. The content of the registers and memories is lost except for the Standby circuitry and the backup domain.

For more details, refer to the voltage regulator section in the datasheets.

SMPS step-down converter regulator

The SMPS step-down converter requires an external coil to be connected between the dedicated VLXSMPS pin and, via a capacitor, to VSS.

The SMPS step-down converter can be used in internal supply mode or external supply mode. The internal supply mode is used to directly supply the V_{CORE} domain, while the external supply mode is used to generate an intermediate supply level (V_{DD_extern} at 1.8 V) which can supply the voltage regulator and optionally an external circuitry.

The SMPS step-down converter works in three different power modes: High Power (HP), Low-power (LP) or Off.

When the SMPS step-down converter is used in internal supply mode, the converter operating modes depend on the system modes (Run, Stop, Standby) and are configured through the associated VOS and SVOS levels:

- Run mode

  The SMPS step-down converter operates in HP mode and provides full power to the V_{CORE} domain (core, memories and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS low and VOS high) that are configured through the VOS bit in the PWR control status register 4 (PWR_CSR4). The VOS voltage scaling allows optimizing the power consumption when the system is clocked below the maximum frequency. By default VOS low is selected after system reset. VOS can be changed on-the-fly to adapt to the required system performance.

- Stop mode

  The SMPS step-down converter supplies the V_{CORE} domain to retain the content of registers and internal memories, and must be set in LP mode. The voltage regulator mode is selected through the SVOS in the *PWR control register 1 (PWR_CR1)*. In LP mode only SVOS low and SVOS high scaling are allowed. Due to a lower voltage level for these scaling, the Stop mode consumption can be further reduced.

- Standby mode

  The SMPS step-down converter is OFF and the V_{CORE} domains are powered down. The content of the registers and memories are lost except for the Standby circuitry and the backup domain.

When the SMPS step-down converter supplies an external circuitry by generating an intermediate voltage level, the converter is forced ON and operates in HP mode. The intermediate voltage level is selected through SDHILEVEL bits in the *PWR control register 2 (PWR_CSR2)*. V_{DD_extern} is supplied at all times with full power whatever the system modes (Run, Stop, Standby).

Note: The SMPS step-down converter is not available on all packages, the SMPS supplies the voltage regulator and optionally an external circuitry.The LDO may not be used in some configuration,

6.4.3 PWR external supply

When V_{CORE} is supplied from an external source (Bypass mode), different operating modes can be used depending on the system operating modes (Run, Stop or Standby):

- In Run modes

  The external source supplies full power to the V_{CORE} domain (core, memories and digital peripherals). The external source output voltage is scalable through different voltage levels (VOS low and VOS high). The externally applied voltage level must be reflected in the VOS bit of PWR_CSR4 register. The RAMs must only be accessed for write operations when the external applied voltage level matches VOS settings.

- In Stop mode

  The external V_{CORE} supply should be maintain at the VOS level or at least over 0.95 V to ensure proper internal wake up.

- In Standby mode

  The wake mechanism should be monitored externally. Refer to the datasheet for the proper V_{CORE} ramp time.

6.4.4 Backup domain

To retain the content of the backup domain (RTC, backup registers and backup RAM) when V_{DD} is turned off, VBAT pin can be connected to an optional voltage which is supplied from a battery or from an another source.

The switching to V_{BAT} is controlled by the power-down reset embedded in the Reset block that monitors the V_{DD} supply.

Warning: **During $t_{RSTTEMPO}$ (temporization at V_{DD} startup) or after a PDR is detected, the power switch between V_{BAT} and V_{DD} remains connected to VBAT.**
During the startup phase, if V_{DD} is established in less than $t_{RSTTEMPO}$ (see the datasheet for the value of $t_{RSTTEMPO}$) and $V_{DD} > V_{BAT} + 0.6$ V, a current may be injected into V_{BAT} through an internal diode connected between V_{DD} and the power switch (V_{BAT}).
If the power supply/battery connected to the VBAT pin cannot support this current injection, it is strongly recommended to connect an external low-drop diode between this power supply and the VBAT pin.

When the V_{DD} supply is present, the backup domain is supplied from V_{DD}. This allows saving V_{BAT} power supply battery life time.

If no external battery is used in the application, it is recommended to connect VBAT externally to VDD, and add a a 100 nF external ceramic capacitor between VBAT and VSS.

When the V_{DD} supply is present and higher than the PDR threshold, the backup domain is supplied by V_{DD} and the following functions are available:

- PC14 and PC15 can be used either as GPIO or as LSE pins.
- PC13 can be used either as GPIO or as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see *Section 49.3.3: GPIOs controlled by the RTC and TAMP*).
- PB9/TAMP_IN2, PE1/TAMP_IN3 when configured by the RTC as tamper pins.

Note: Since the switch only sinks a limited amount of current, the use of PC13 and PC15 GPIOs is restricted: only one I/O can be used as an output at a time. These I/Os must not be used as current sources (for example to drive an LED). Refer to the DS

In V_{BAT} mode, when the V_{DD} supply is absent and a supply is present on V_{BAT}, the backup domain is supplied by V_{BAT} and the following functions are available:

- PC14 and PC15 can be used as LSE pins only.
- PC13 can be used as RTC_OUT1, RTC_TS, TAMP_IN1, TAMP_OUT2 pin assuming they have been configured by the RTC or the TAMPER registers (see *Section 49.3.3: GPIOs controlled by the RTC and TAMP*).
- PB9/TAMP_IN2, PE1/TAMP_IN3 when configured by the RTC as tamper pins.

Accessing the backup domain

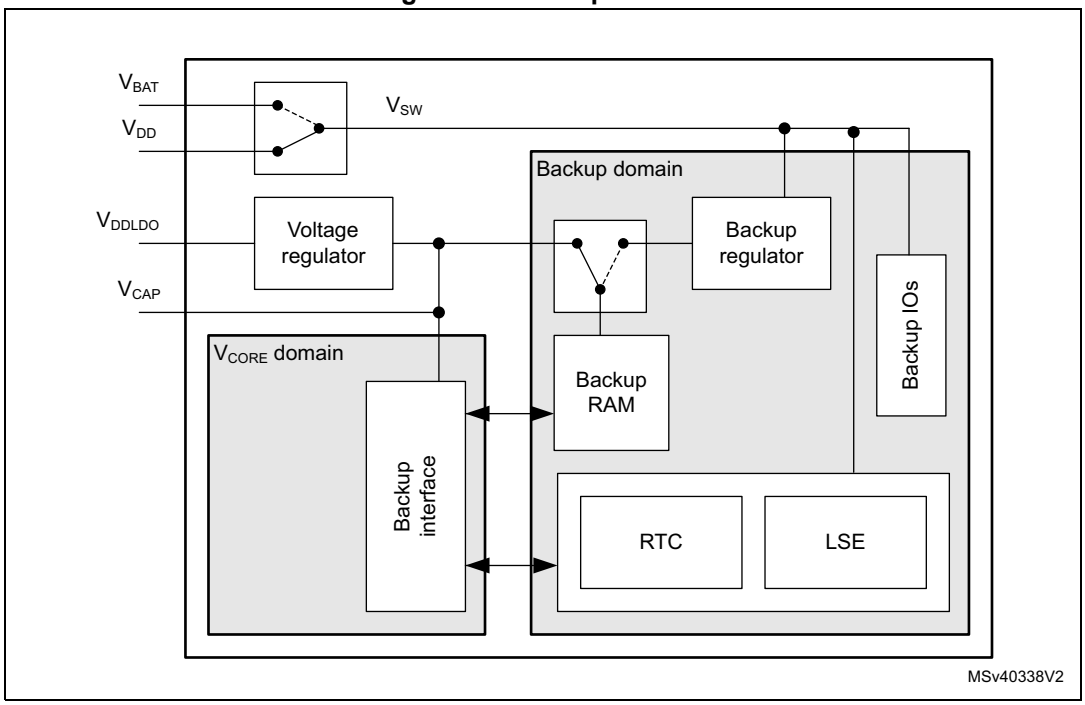
After reset, the backup domain (RTC registers and RTC backup registers) is protected against possible unwanted write accesses. To enable access to the backup domain, set the DBP bit in the *PWR control register 1 (PWR_CR1)*.

For more detail on RTC and backup RAM access, refer to *Section 7: Reset and clock control (RCC)*.

Backup RAM

The backup domain includes 4 Kbytes of backup RAM accessible in 32-bit, 16-bit or 8-bit data mode. The backup RAM is supplied from the backup regulator in the backup domain. When the backup regulator is enabled through BREN bit in the *PWR control status register 1 (PWR_CSR1)*, the backup RAM content is retained even in Standby and/or V_{BAT} mode (it can be considered as an internal EEPROM if V_{BAT} is always present.)

The backup regulator can be ON or OFF depending whether the application needs the backup RAM function in Standby or V_{BAT} modes.



After a tamper event, if the RTC flag is set, the backup RAM cannot be used until an erase is explicitly requested. When a tamper event is generated, reading the backup RAM returns 0x0, and any write different from 0 is not effective. The backup RAM can be erased:

- through the Flash memory interface when a regression from nvstate closed to nvstate open is requested. See also *Section 4: System security*.

  or

- by performing a simple dummy write with zero as data to any address of the backup RAM (this action resets the whole backup RAM when it is performed after a tamper event).

Figure 24. Backup domain

6.4.5 V_{BAT} battery charging

When V_{DD} is present, the external battery connected to VBAT can be charged through an internal resistance.

V_{BAT} charging can be performed either through a 5 kΩ resistor or through a 1.5 kΩ resistor, depending on the VBRS bit value in *PWR control register 2 (PWR_CSR2)*.

The battery charging is enabled by setting the VBE bit in the *PWR control register 2 (PWR_CSR2)*. It is automatically disabled in V_{BAT} mode.

6.4.6 Analog supply

Separate V_{DDA} analog supply

The analog supply domain is powered by dedicated V_{DDA} and V_{SSA} pads that allow the supply to be filtered and shielded from noise on the PCB, thus improving ADC conversion accuracy:

- The analog supply voltage input is available on a separate VDDA pin.
- An isolated supply ground connection is provided on VSSA pin.

Analog reference voltage V_{REF+}/V_{REF-}

To achieve better accuracy low-voltage signals, the ADC also has a separate reference voltage, available on $VREF_+$ pin. The user can connect a separate external reference voltage on VREF+.

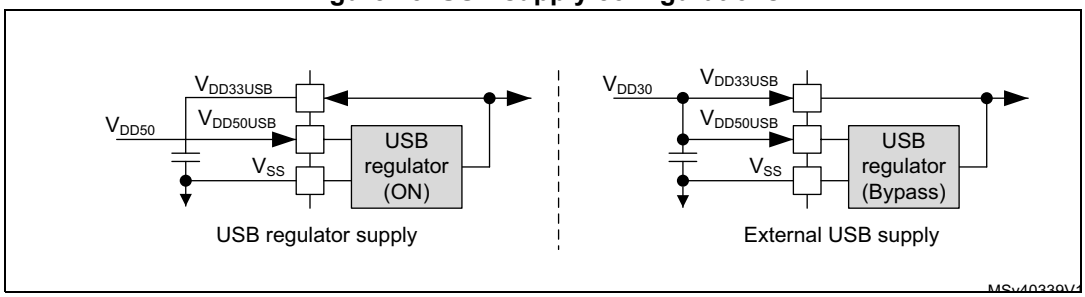
The VREF+ controls the highest voltage, represented by the full scale value, the lower voltage reference (V_{REF-}) being connected to VSSA.

When enabled by ENVR bit in the VREFBUF control and status register (see *Section 29: Voltage reference buffer (VREFBUF)*), V_{REF+} is provided from the internal voltage reference buffer. The internal voltage reference buffer can also deliver a reference voltage to external components through VREF+/VREF- pins.

When the internal voltage reference buffer is disabled by ENVR, V_{REF+} is delivered by an independent external reference supply voltage.

*Note: VREF+ and VREF- pins are not available on all packages (in this case they are connected internally respectively to VDDA and VSSA). **Do not** enable the internal voltage reference buffer when an external power supply is applied to the VREF+ pin.*

6.4.7 USB regulator



The USB transceivers are supplied from a dedicated $V_{DD33USB}$ supply that can be provided either by the integrated USB regulator, or by an external USB supply.

When enabled by USBREGEN bit in the *PWR control register 2 (PWR_CSR2)*, the $V_{DD33USB}$ is provided from the USB regulator, which is powered through the VDD50USB pin generally connect to the USB VBUS line. Before using $V_{DD33USB}$, check that it is available by monitoring USB33RDY bit in the *PWR control register 2 (PWR_CSR2)*. The $V_{DD33USB}$ supply level detector must be enabled through USB33DEN bit in the PWR_CSR2 register.

When the USB regulator is disabled through USBREGEN bit, VDD33USB can be provided from an external supply. In this case VDD33USB and VDD50USB must be connected together. The VDD33USB supply level detector must be enabled through USB33DEN bit in the PWR_CSR2 register before using the USB transceivers.

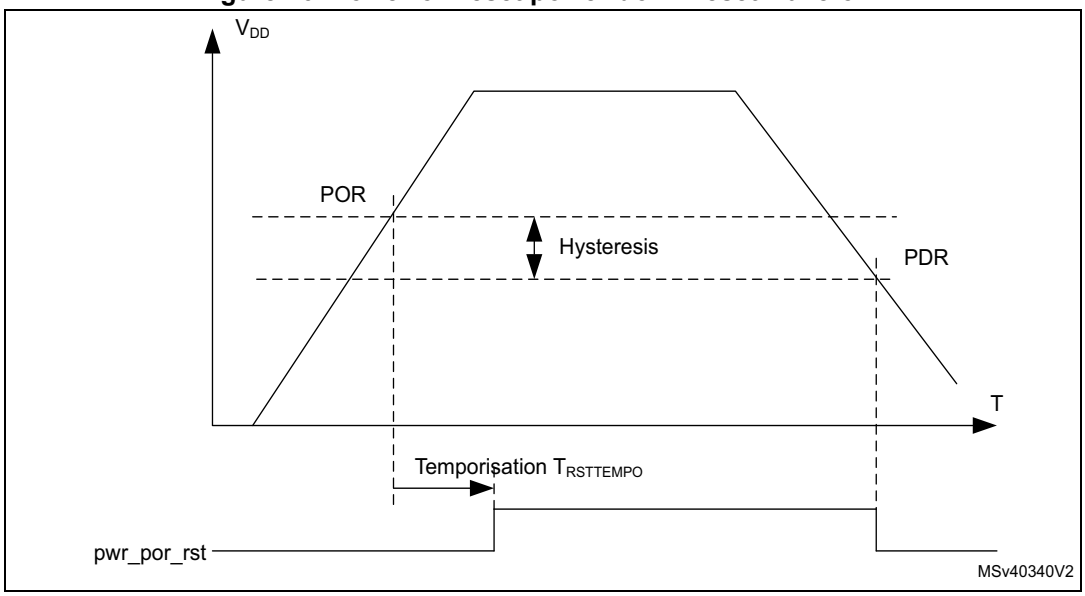
For more information on the USB regulator (see *Section 62: **USB on-the-go high-speed (OTG_HS)***).

Figure 25. USB supply configurations

6.5 Power supply supervision

Power supply level monitoring is available on the following supplies:

- V_{DD} (V_{DDSMPS}) can be monitored via POR/PDR (see *Section 6.5.1*), BOR (see *Section 6.5.2*) and PVD monitor (see *Section 6.5.3*)
- V_{DDA} can be monitored via AVD monitor (see *Section 6.5.4*)
- V_{BAT} can be monitored via VBAT threshold (see *Section 6.5.5*)
- V_{SW} can be monitored via rst_vsw, which keeps V_{SW} domain in Reset mode as long as the level is not OK.
- V_{BKP} can be monitored via a BRRDY bit in the *PWR control status register 1 (PWR_CSR1)*.
- V_{FBSMPS} can be monitored via a SDEXTRDY bit in the *PWR control register 2 (PWR_CSR2)*.
- $V_{DD33USB}$ can be monitored via the USB33RDY bit in the *PWR control register 2 (PWR_CSR2)*.



6.5.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in Reset mode when V_{DD} is below a specified V_{POR} threshold, without the need for an external reset circuit. Once the V_{DD} supply level is above the V_{POR} threshold, the system is taken out of reset (see *Figure 26*). For more details concerning the power-on/power-down reset threshold, refer to the electrical characteristics section of the datasheets.

By default the PDR is enabled.

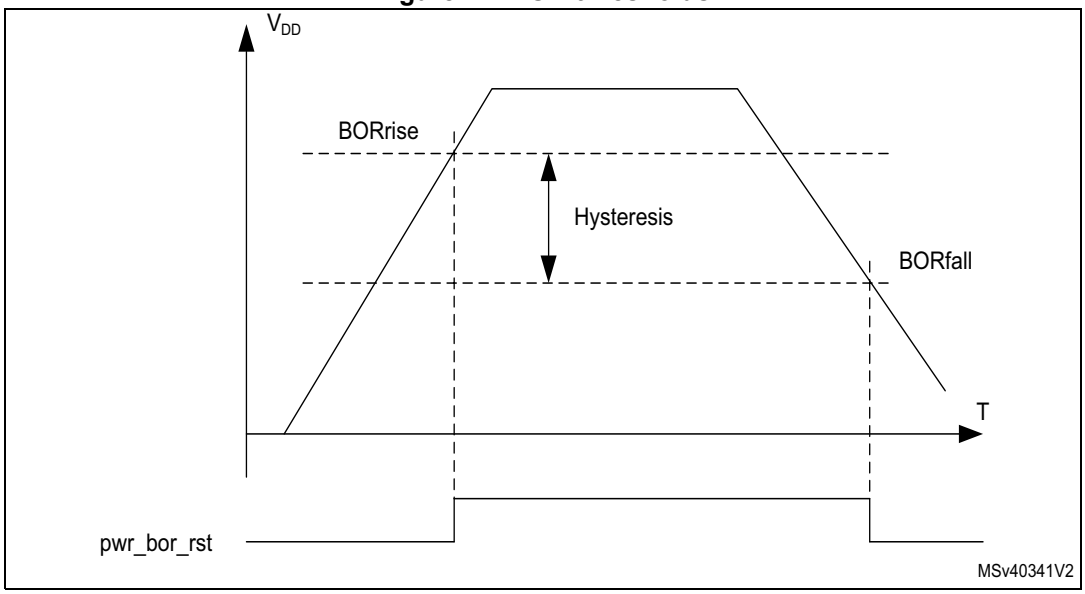
Figure 26. Power-on reset/power-down reset waveform

1. For thresholds and hysteresis values, refer to the datasheets.

6.5.2 Brownout reset (BOR)

During power-on, the Brownout reset (BOR) keeps the system under reset until the V_{DD} supply voltage reaches the specified V_{BOR} threshold.

The V_{BOR} threshold is configured through system option bytes. By default, BOR is OFF. The following programmable V_{BOR} thresholds can be selected:



- BOR OFF (V_{BOR0})
- BOR Level 1 (V_{BOR1})
- BOR Level 2 (V_{BOR2})
- BOR Level 3 (V_{BOR3})

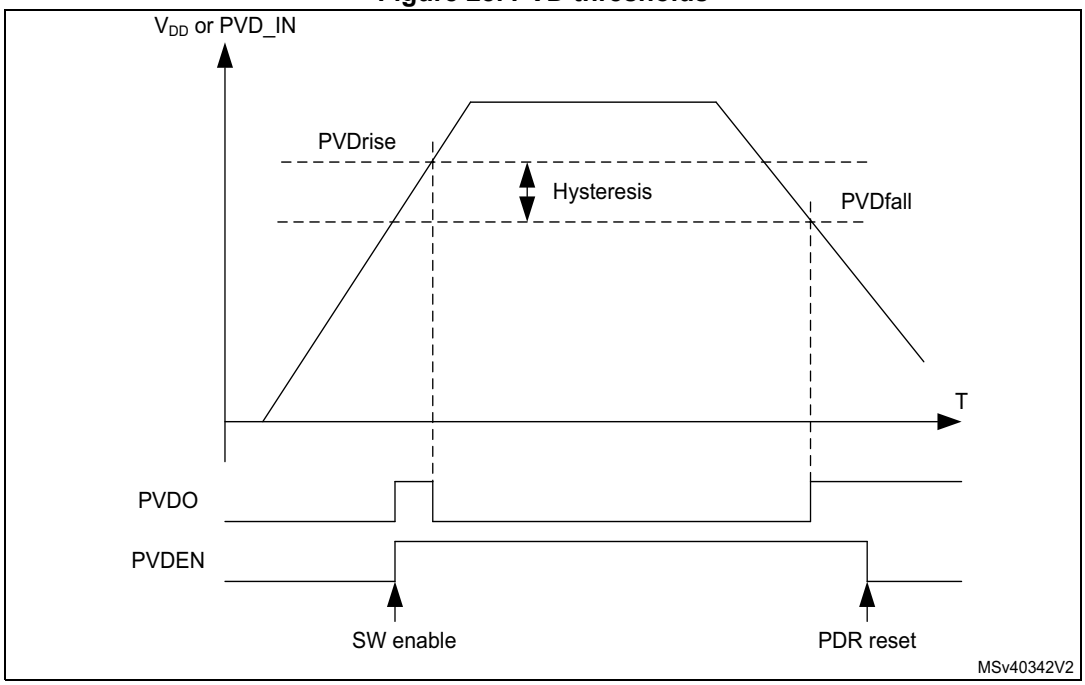
For more details on the brown-out reset thresholds, refer to the section “Electrical characteristics” of the product datasheets.

A system reset is generated when the BOR is enabled and V_{DD} supply voltage drops below the selected V_{BOR} threshold.

BOR can be disabled by programming the system option bytes. To disable the BOR function, V_{DD} must have been higher than V_{BOR0} to start the system option byte programming sequence. The power-down is then monitored by the PDR (see *Section 6.5.1*).

Figure 27. BOR thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.3 Programmable voltage detector (PVD)

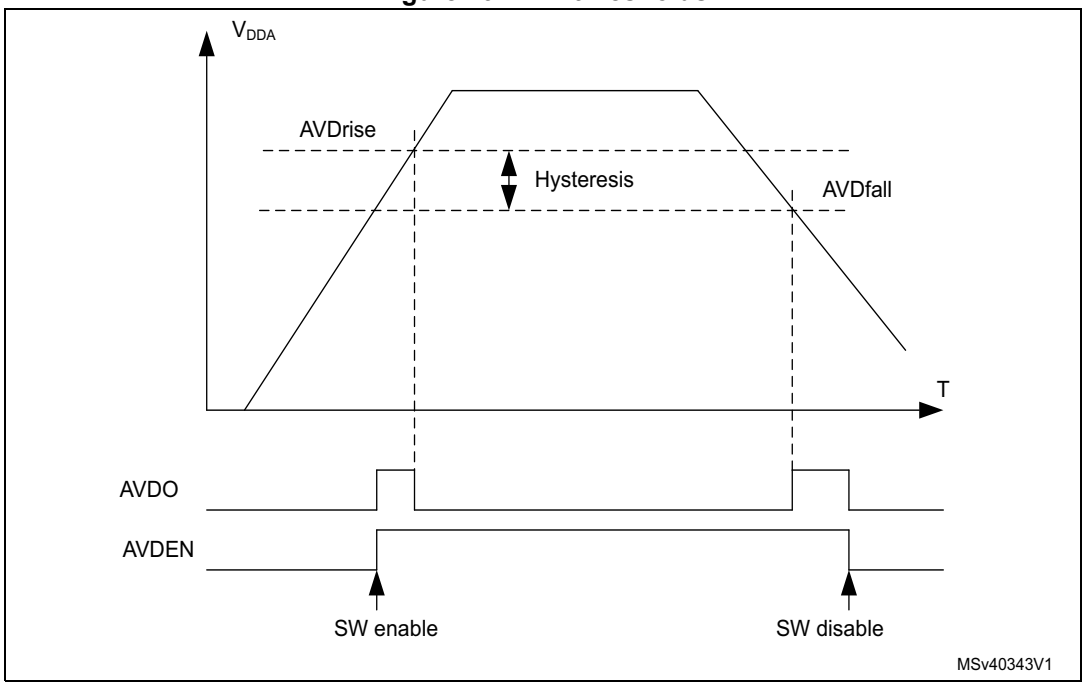
The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[2:0] bits in the *PWR control register 1 (PWR_CR1)*. The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case PVD_IN voltage is compared to the internal V_{REFINT} level.

The PVD is enabled by setting the PVDE bit in the *PWR control register 1 (PWR_CR1)*.

A PVDO flag is available in the *PWR control status register 1 (PWR_SR1)* to indicate if V_{DD} or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt, assuming it has been enabled through the EXTI registers. The PVDO output interrupt can be generated when V_{DD} or PVD_IN voltage drops below the PVD threshold and/or when V_{DD} or PVD_IN voltage rises above the PVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could perform emergency shutdown tasks.

Figure 28. PVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



6.5.4 Analog voltage detector (AVD)

The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS[1:0] bits in the *PWR control register 1 (PWR_CR1)*.

The AVD is enabled by setting the AVDEN bit in the *PWR control register 1 (PWR_CR1)*.

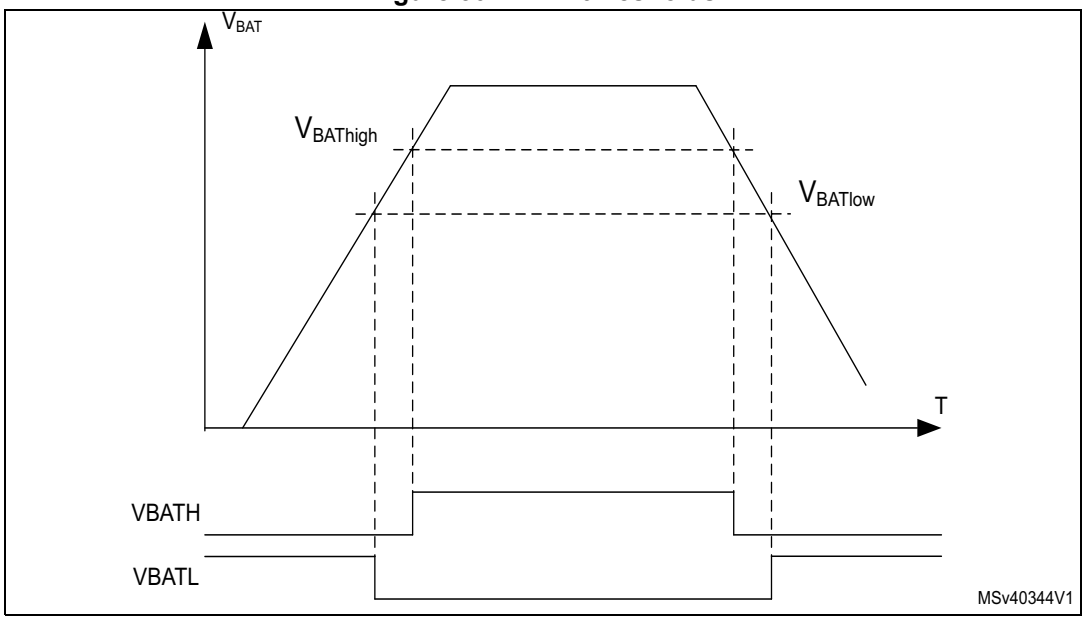
An AVDO flag is available in the *PWR control status register 1 (PWR_SR1)* to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers. The AVDO interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold depending on EXTI rising/falling edge configuration. As an example the service routine could indicate when the V_{DDA} supply drops below a minimum level.

Figure 29. AVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.

6.5.5 Battery voltage thresholds

The battery voltage supply monitors the backup domain V_{SW} level. Vsw is monitored by comparing it with two threshold levels: $V_{BAThigh}$ and V_{BATlow}. VBATH and VBATL flags in the *PWR control status register 1 (PWR_CSR1)*, indicate if V_{SW} is higher or lower than the threshold.



The V_{BAT} supply monitoring can be enabled/disabled via MONEN bit in the *PWR control status register 1 (PWR_CSR1)*. When it is enabled, the battery voltage thresholds increase power consumption. As an example the V_{SW} levels monitoring could be used to trigger a tamper event for an over or under voltage of the RTC power supply domain (available in VBAT mode).

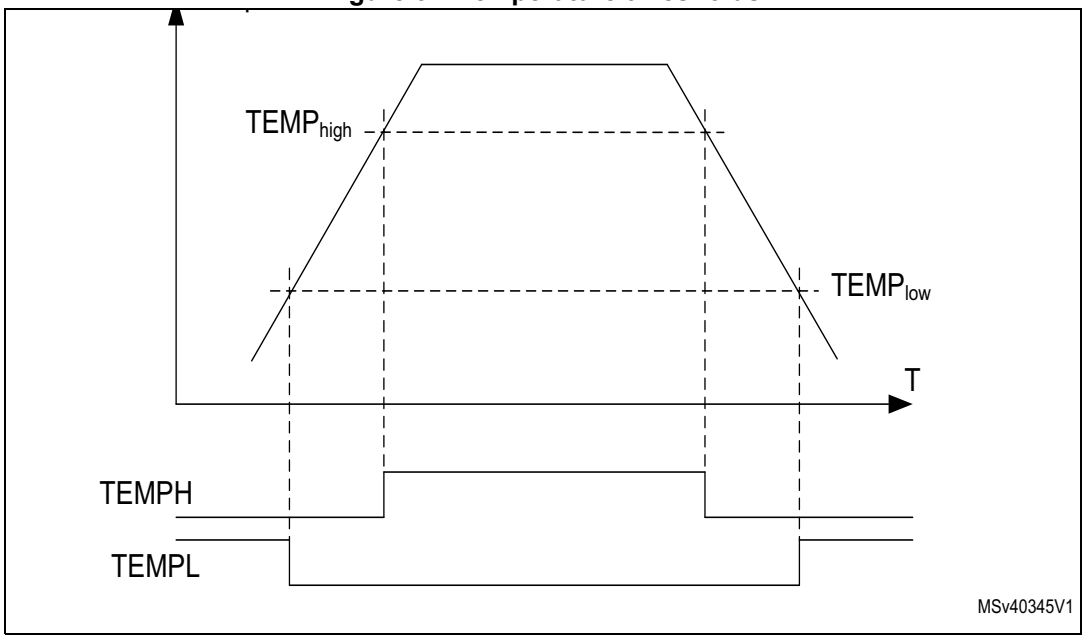
VBATH and VBATL are connected to RTC tamper signals (see *Section 49: Real-time clock (RTC)*).

Note: Battery voltage monitoring is only available when the backup regulator is enabled (BREN bit set in the PWR control status register 1 (PWR_CSR1)).

When the device does not operate in VBAT mode, the battery voltage monitoring checks V_{DD} level. When V_{DD} is available, V_{SW} is connected to V_{DD} through the internal power switch (see Section 6.4.4: Backup domain).

Figure 30. VBAT thresholds

1. For thresholds and hysteresis values, refer to the datasheets.



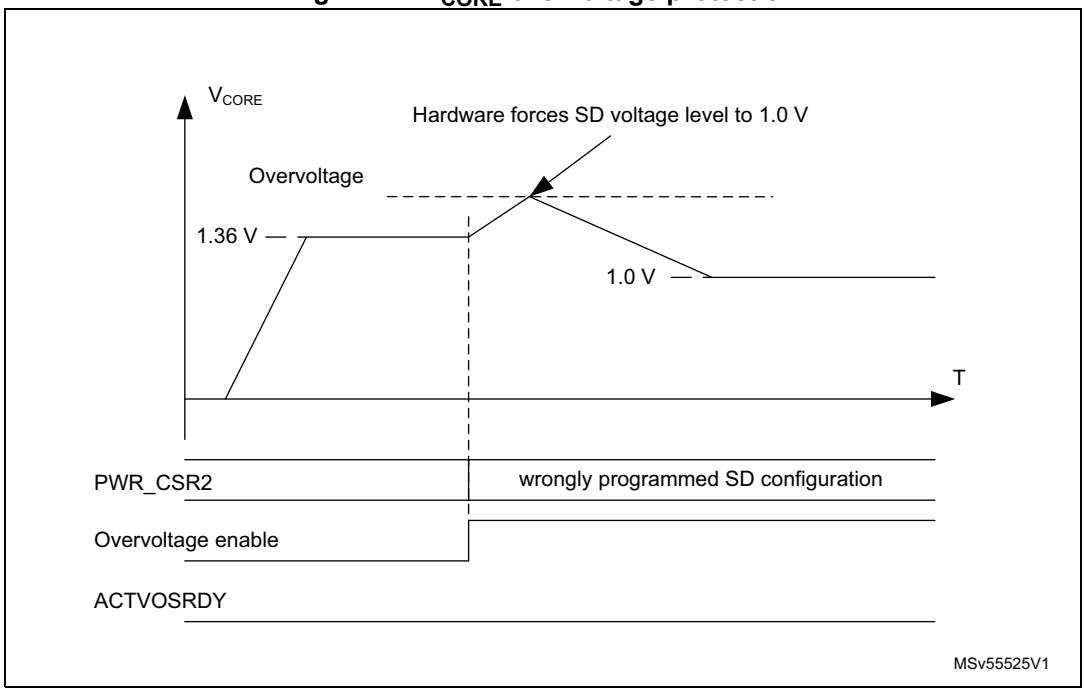
6.5.6 Temperature thresholds

The junction temperature can be monitored by comparing it with two threshold levels, $TEMP_{high}$ and $TEMP_{low}$. TEMPH and TEMPL flags, in the *PWR control status register 1 (PWR_CSR1)*, indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in the *PWR control status register 1 (PWR_CSR1)*. When enabled, the temperature thresholds increase power consumption. As an example the levels could be used to trigger a routine to perform temperature control tasks.

The temperature thresholds are available only when the backup regulator is enabled (BREN bit set in the PWR_CSR1 register).

TEMPH and TEMPL wake-up interrupts are available on the RTC tamper signals (see *Section 49: Real-time clock (RTC)*).

Figure 31. Temperature thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

6.5.7 V_{CORE} maximum voltage level detector

V_{CORE} is protected against too high voltages in the direct SMPS step-down converter supply configuration. V_{CORE} overvoltage protection is enabled at startup by hardware once the SMPS step-down converter configuration has been programmed into *PWR control register 2 (PWR_CSR2)*:

- V_{CORE} voltage level stays within range:
  - ACTVOSRDY bit in the *PWR control status register 1 (PWR_SR1)* indicate valid voltage levels.
  - The system operates normally and V_{CORE} overvoltage protection is disabled.
- V_{CORE} overvoltage (due to a wrongly programmed SMPS step-down converter configuration):
  - The hardware forces the SMPS step-down converter voltage level to 1.0 V.
  - The ACTVOSRDY goes on indicating invalid voltage levels. In this case the software must be corrected and re-loaded to program a correct SMPS step-down converter configuration that matches the application supply connections. The system must then be power cycled.

Figure 32. V_{CORE} overvoltage protection

6.6 Power management

The power management block controls the V_{CORE} supply in accordance with the system operation modes (see *Section 6.6.1*).

The device power domains can operate in one of the following operating modes:

- Run (power ON, clock ON)
- Sleep (power ON, core clock stopped, peripherals keep running)
- Stop (power ON, clock OFF)
- Standby (Power OFF, clock OFF).

The V_{CORE} supply level follows the system operating mode (Run, Stop, Standby).

The following voltage scaling features allow controlling the power with respect to the required system performance (see *Section 6.6.2: Voltage scaling*):

- To obtain a given system performance, the corresponding voltage scaling must be set in accordance with the system clock frequency. To do this, configure the VOS bits to the Run mode voltage scaling.
- To obtain the best trade-off between power consumption and exit-from-Stop mode latency, configure the SVOS bit to Stop mode voltage scaling.

6.6.1 Operating modes

Several system operating modes are available to tune the system according to the performance required, that is, when the CPU does not need to execute code and are waiting for an external event. It is up to the user to select the operating mode that gives the best compromise between low power consumption, short startup time and available wake-up sources.

The operating modes allow controlling the clock distribution to the different system blocks and powering them.

In Run mode, power consumption can be reduced by one of the following means:

- Lowering the system performance by slowing down the system clocks and reducing the V_{CORE} supply level through VOS voltage scaling bit.
- Gating the clocks to the APBx and AHBx peripherals when they are not used, through PERxEN bits.

Table 45. Operating mode summary

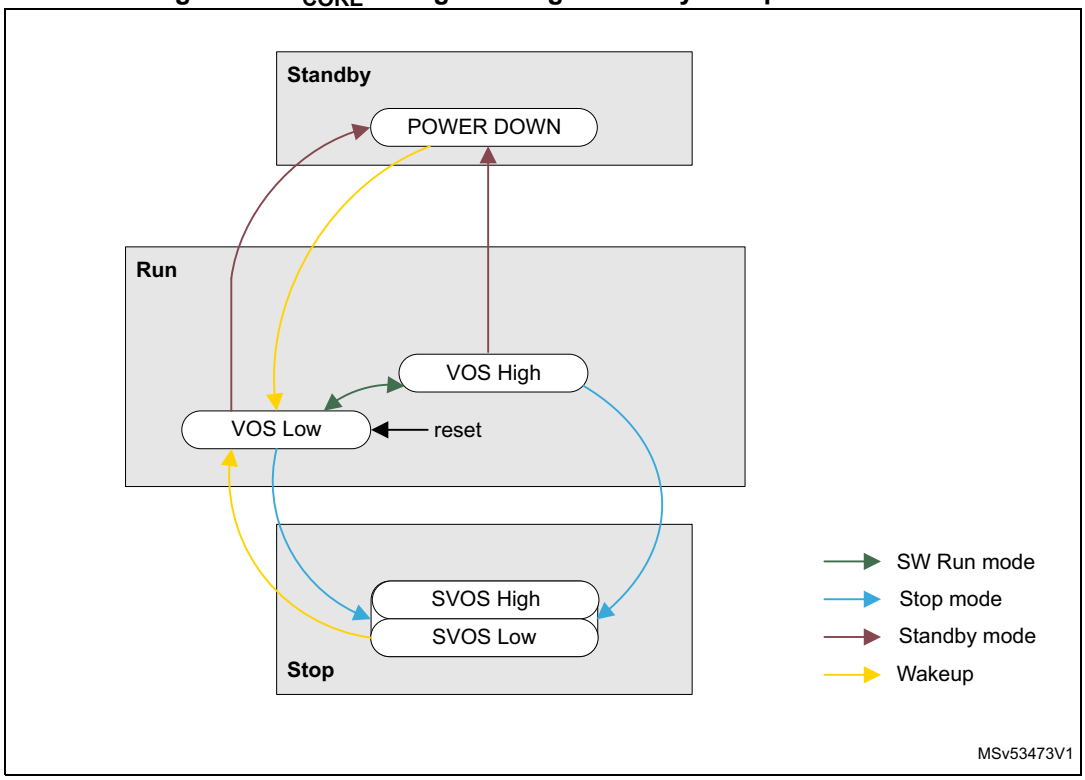
System	Entry	Wake-up	System oscillator	System clock	Peripheral clock	CPU clock	Voltage regulator
Run	-	-	ON	ON	ON	ON	ON (VOS)
Sleep	WFI or return from ISR or WFE	Any interrupt or event			ON/OFF(1)	OFF	
Stop	SLEEPDEEP bit + WFI or return from ISR or WFE or wake-up source cleared(2)	Any EXTI interrupt or event	ON/OFF(3)	OFF			ON (SVOS)
Standby	PDDS bit + SLEEPDEEP bit + WFI or return from ISR or WFE or wake-up source cleared(2)	WKUP pins rising or falling edge, RTC alarm (Alarm A or Alarm B), RTC wake-up event, RTC tamper events, RTC time stamp event, external reset in NRST pin, IWDG reset	OFF		OFF		OFF

1. The CPU subsystem peripherals that have a PERxLPEN bit operate accordingly.
2. When the CPU is in Stop the last EXTI wake-up source should be cleared by SW.
3. When the system oscillator HSI or CSI is used, the state is controlled by HSIKERON and CSIKERON, otherwise the system oscillator is OFF.

6.6.2 Voltage scaling

The V_{CORE} domain is supplied from a single voltage regulator supporting voltage scaling with the following features:

- Run mode voltage scaling
  - VOS low
  - VOS high
- Stop mode voltage scaling
  - SVOS low
  - SVOS high



For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS low). The voltage scaling can then be changed on-the-fly by software by programming the VOS bit in the *PWR control status register 4 (PWR_CSR4)* according to the required system performance. When exiting from Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS low value.

Before entering Stop mode, the software can preselect the SVOS level in *PWR control register 1 (PWR_CR1)*. The Stop mode voltage scaling for SVOS low and SVOS high also sets the voltage regulator in Low-power (LP) mode to further reduce power consumption.

In Standby mode the VCORE supply is switched off.

Figure 33. V_{CORE} voltage scaling versus system power modes

6.6.3 Power management examples

- *Figure 34* shows V_{CORE} voltage scaling behavior in Run mode.
- *Figure 35* shows V_{CORE} voltage scaling behavior in Stop mode.
- *Figure 36* shows V_{CORE} voltage regulator and voltage scaling behavior in Standby mode.

Example of V_{CORE} voltage scaling behavior in Run mode

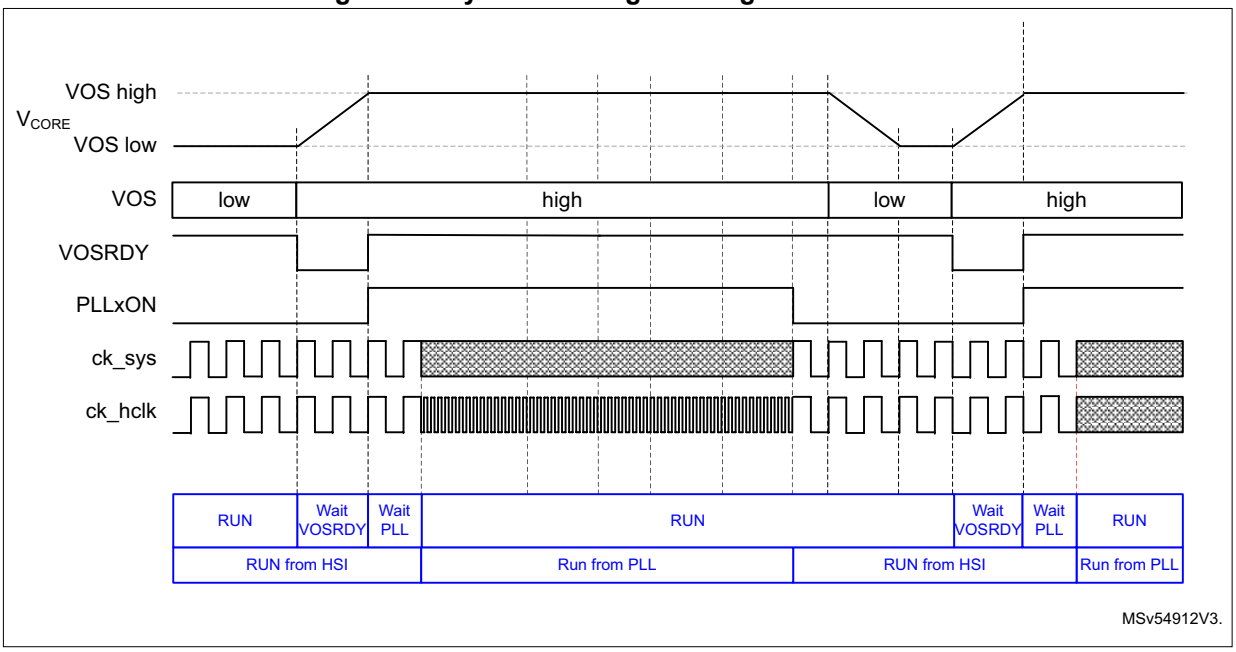


Figure 34 illustrates the following system operation sequence example:

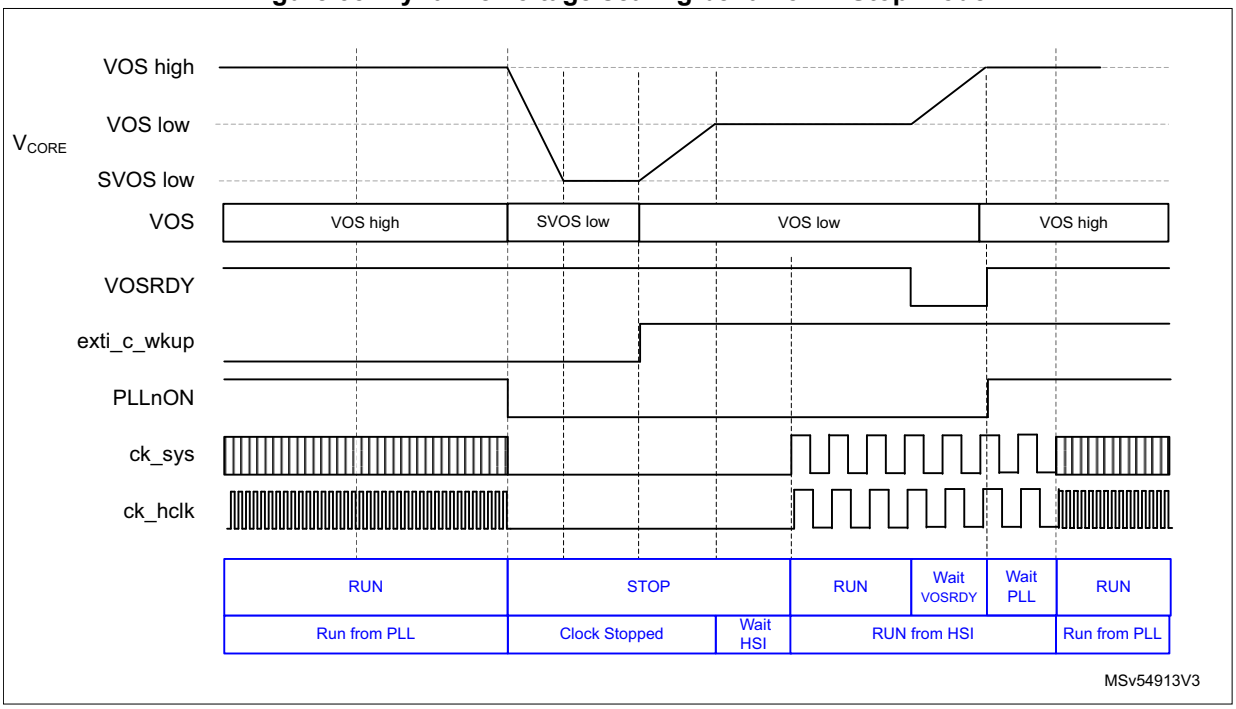
1. After reset, the system starts from HSI with VOS low.
2. The system performance is then increased to a high-speed clock from the PLL with voltage scaling VOS high. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The next step is to reduce the system performance to HSI clock with voltage scaling VOS low. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS low.

4. The system performance can then be increased to high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS high.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly. otherwise the system might be unreliable.

Figure 34. Dynamic voltage scaling in Run mode

1. The status of the register bits at each step is shown in blue.



Example of V_{CORE} voltage scaling behavior in Stop mode

Figure 35 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS high voltage scaling).
2. First the CPU subsystem deallocates all the peripheral, in a second step, the CPU subsystem enters Stop mode and the system enters Stop mode. The system clock is stopped and the hardware lowers the voltage scaling to the software preselected SVOS low.

3. The CPU subsystem is then woken up. The system exits from Stop mode and the CPU subsystem exits from Stop mode. The hardware always sets the voltage scaling to VOS low after exiting from Stop mode and waits for the requested supply level to be reached before enabling the HSI clock. Once the HSI clock is stable, the system clock is enabled and switch in run mode under HSI clock.
4. The system performance could then be increased. To do this:
   a) The software first sets the voltage scaling to VOS high.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, the clock frequency can be increased by enabling the PLL.
   c) Once the PLL is locked, the system clock can be switched.

Figure 35. Dynamic voltage scaling behavior in Stop mode

1. The status of the register bits at each step is shown in blue.

Example of V_{CORE} voltage regulator and voltage scaling behavior in Standby mode

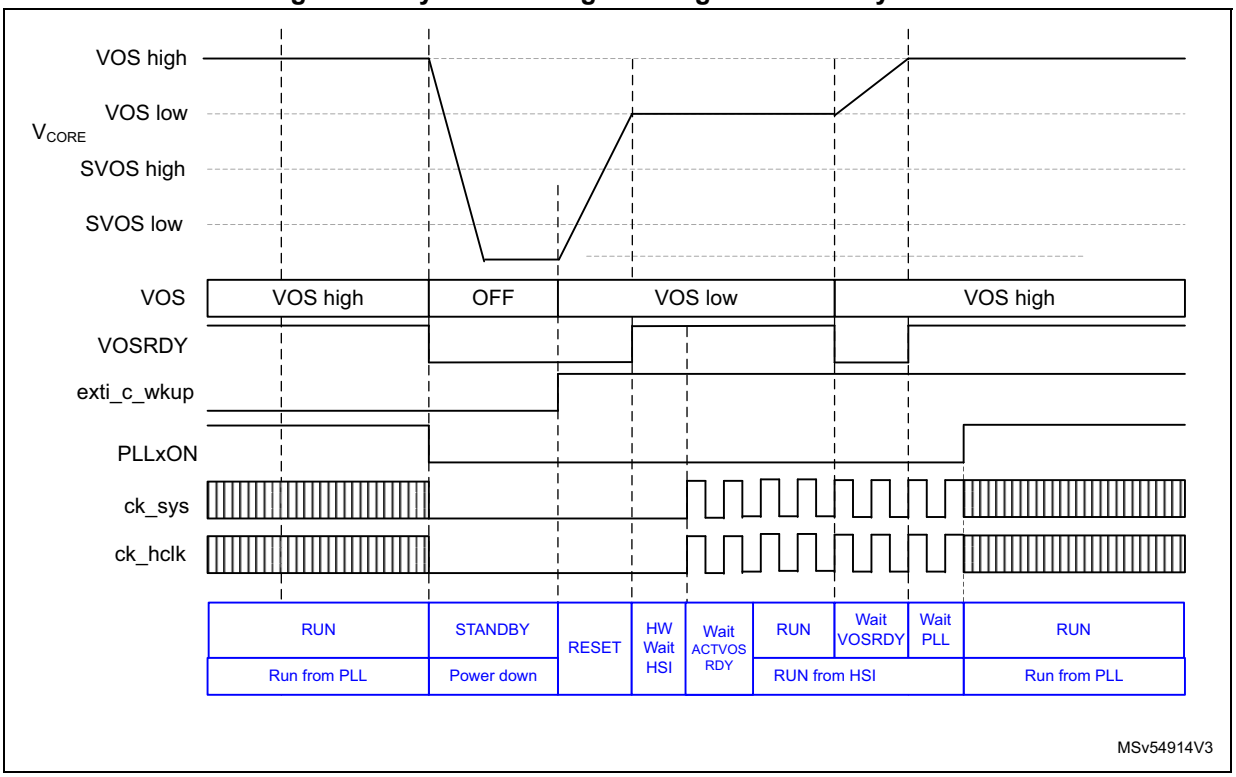


Figure 36 illustrates the following system operation sequence example:

1. The system is running from the PLL in high-performance mode (VOS high voltage scaling).
2. The CPU subsystem deallocates all the peripherals and the power is switched off. The system enter in standby mode.
3. The system is then woken up by a wake-up source. The system exits from Standby mode. The hardware sets the voltage scaling to the default VOS low and waits for the requested supply level to be reached before enabling the default HSI oscillator. Once

the HSI clock is stable, the system clock is enabled. The software must then check the ACTVOSRDY is valid before changing the system performance.

4. In a next step, increase the system performance. To do this:
   a) The software first increases the voltage scaling to VOS high
   b) Before enabling the PLL, it waits for the requested supply level to be reached by monitoring VOSRDY bit.
   c) Once the PLL is locked, the system clock can be switched.

Figure 36. Dynamic voltage scaling from Standby mode

1. The status of the register bits at each step is shown in blue.

6.7 Low-power modes

Several low-power modes are available to save power when the CPU does not need to execute code (i.e. when waiting for an external event). It is up to the user application to select the mode that gives the best compromise between low power consumption, short startup time and available wake-up sources:

- Slowing down system clocks (see *Section 7.5.6: System clock (**sys_ck**)*)
- Controlling individual peripheral clocks (see *Section 7.5.12: Peripheral clock gating control*)
- Low-power modes
  - Sleep (CPU clock stopped and still in RUN mode)
  - Stop (System clock stopped)
  - Standby (System powered down)

6.7.1 Slowing down system clocks

In Run mode, the speed of the system clock sys_ck can be reduced. For more details refer to *Section 7.5.6: System clock (**sys_ck**)*.

6.7.2 Controlling peripheral clocks

In Run mode, the HCLKx and PCLKx for individual peripherals can be stopped by configuring at any time PERxEN bit in RCC_xxxxENR to reduce power consumption.

To reduce power consumption in CSleep mode, the individual peripheral clocks can be disabled by configuring PERxLPEN bit in RCC_xxxxLPENR. For the peripherals still receiving a clock in Sleep mode, their clock can be slowed down before entering Sleep mode.

Example: for APB2 peripherals: the RCC registers is named: RCC_APB2ENR, this register contains SPI4EN, SAI1EN, and so on.

6.7.3 Entering low-power modes

CPU subsystem Sleep and Stop low-power modes are entered by the MCU when executing the WFI (Wait For Interrupt) or WFE (Wait for Event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M System Control register is set on Return from ISR.

The system can enter Stop or Standby low-power mode when all EXTI wake-up sources are cleared.

6.7.4 Exiting from low-power modes

The CPU subsystem exits from Sleep mode through any interrupt or event depending on how the low-power mode was entered:

- If the WFI instruction or Return from ISR was used to enter to low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the system.
- If the WFE instruction is used to enter to low-power mode, the CPU exits from low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  - An NVIC IRQ interrupt.

    When SEVONPEND = 0 in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

    When the MCU resumes from WFE, the peripheral interrupt pending bit and the NVIC peripheral IRQ channel pending bit in the NVIC interrupt clear pending register have to be cleared. Only NVIC interrupts with sufficient priority wakes up and interrupts the MCU.

    When SEVONPEND = 1 in the Cortex®-M7 System Control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when

enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) have to be cleared.

All NVIC interrupts wake-up the MCU, even the disabled ones.

Only enabled NVIC interrupts with sufficient priority wake-up and interrupt the MCU.

– An event

An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit as the pending bits corresponding to the event line is not set. It might be necessary to clear the interrupt flag in the peripheral.

The CPU subsystem exits from Stop modes by enabling an EXTI interrupt or event depending on how the low-power mode was entered (see above).

The CPU subsystem exits from Standby mode by enabling an EXTI interrupt or event. Program execution restarts from CPU local reset (such as a reset vector fetched from the system configuration boot and security block (SBS).

The CPU subsystem exits from Standby mode by enabling an external reset (NRST pin), an IWDG reset, a rising edge on one of the enabled WKUPx pins or a RTC event. Program execution restarts in the same way as after a system reset (such as boot pin sampling, option bytes loading or reset vector fetched).

6.7.5 Sleep mode

The Sleep mode applies only to the CPU subsystem. In Sleep mode, the CPU clock is stopped. The CPU subsystem peripheral clocks operate according to the values of PERxLPEN bits in RCC_xxxxENR.

Entering Sleep mode

The Sleep mode is entered according to *Section 6.7.3: Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M System Control register is cleared.

Refer to *Table 46* for details on how to enter to Sleep mode.

Exiting from Sleep mode

The Sleep mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 46* for more details on how to exit from Sleep mode.

Table 46. Sleep mode

Sleep mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 0 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared.
Mode exit	If WFI or return from ISR was used for entry: – Any Interrupt enabled in NVIC: Refer to *Table 142: NVIC* If WFE was used for entry and SEVONPEND = 0: – Any event: Refer to *Section 20.5.3: EXTI CPU wake-up procedure* If WFE was used for entry and SEVONPEND = 1: – Any Interrupt even when disabled in NVIC: refer to *Table 142: NVIC* or any event: refer to *Section 20.5.3: EXTI CPU wake-up procedure*
Wake-up latency	None

6.7.6 Stop mode

The Stop mode applies to the MCU. In Stop mode, the CPU clock is stopped. All CPU subsystem peripheral clocks are stopped too and.

In Stop mode, CPU subsystem peripherals having a kernel clock request can still request their kernel clock.

The Flash memory can enter low-power Stop mode when it is enabled through FLPS in PWR_CR1 register. This allows a trade-off between domain Stop restart time and low power consumption.

The HSI or CSI can remain enabled in system Stop mode (HSIKERON and CSIKERON set in RCC_CR register). After exiting Stop mode, the clock is quickly available as kernel clock

for peripherals. Other system oscillator sources are stopped in Stop mode and require a starting time after exiting Stop mode.

In Stop mode and SVOS high, peripherals using the LSI or LSE clock and peripherals having a kernel clock request are still able to operate.

In system Stop mode, the following features can be selected to remain active by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by writing to its key register or by hardware option. Once started it cannot be stopped except by a reset (see *Section 48.3* in *Section 48: Independent watchdog (IWDG)*.
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the *RCC Backup domain control register (RCC_BDCR)*.
- Internal RC oscillator (LSI RC)

  This is configured via the LSION bit in the *RCC clock control and status register (RCC_CSR)*.
- External 32.768 kHz oscillator (LSE OSC)

  This is configured via the LSEON bit in the *RCC Backup domain control register (RCC_BDCR)*.
- Peripherals capable of running on the LSI or LSE clock.
- Peripherals having a kernel clock request.
- Internal RC oscillators (HSI and CSI)

  This is configured via the HSIKERON and CSIKERON bits in the *RCC source control register (RCC_CR)*.
- The ADC can also consume power during Stop mode, unless they are disabled before entering this mode. To disable them, the ADON bit in the ADC_CR2 register must be written to 0.

The selected SVOS low levels add an additional startup delay when exiting from system Stop mode (see *Table 47*).

Table 47. Stop mode operation

SVOS	Stop mode Voltage regulator operation	Wake-up Latency
SVOS high	**LP**	Voltage regulator wake-up time from SVOS high LP mode to VOS low
SVOS low	**LP**	Voltage regulator wake-up time from SVOS low LP mode to VOS low

Entering Stop mode

The Stop mode is entered according to *Section 6.7.3: Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M System Control register is set.

If Flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the domain bus matrix is ongoing, the Stop mode entry is delayed until the domain bus matrix access is complete.

See *Table 48* below for details on how to enter to Stop mode.

Table 48. Stop mode

Stop mode	Description
Mode entry	WFI (Wait for Interrupt) or WFE (Wait for Event) while: – SLEEPDEEP = 1 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wake-up sources are cleared.
	On return from ISR while: – SLEEPDEEP = 1 and – SLEEPONEXIT = 1 (refer to the Cortex®-M System Control register.) – CPU NVIC interrupts and events cleared. – All CPU EXTI wake-up sources are cleared.
Mode exit	If WFI or return from ISR was used for entry: – EXTI Interrupt enabled in NVIC: refer to *Table 142: NVIC*, for peripheral which are not stopped or powered down. If WFE was used for entry and SEVONPEND = 0: – EXTI event: refer to *Section 20.5.3: EXTI CPU wake-up procedure*, for peripheral which are not stopped or powered down. If WFE was used for entry and SEVONPEND = 1: – EXTI Interrupt even when disabled in NVIC: refer to *Table 142: NVIC* or EXTI event: refer to *Section 20.5.3: EXTI CPU wake-up procedure*, for peripheral which are not stopped or powered down.
Wake-up latency	EXTI and RCC wake-up synchronization (see *Section 7.4.11: Power-on and wake-up sequences*)

To allow peripherals having a kernel clock request to operate in Stop mode, the system must use SVOS high.

Note: Use a DSB instruction to ensure that outstanding memory transactions complete before entering stop mode.

Exiting from Stop mode

The Stop mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

Refer to *Table 48: Stop mode* for more details on how to exit from Stop mode.

When exiting from Stop mode, the system clock, bus matrix clocks and voltage scaling are reset.

STOPF status flag in the *PWR CPU control register 3 (PWR_CSR3)* indicates that the system has exited from Stop mode.

I/O states in Stop mode

I/O pin configuration remain unchanged in Stop mode.

6.7.7 Standby mode

The Standby mode allows achieving the lowest power consumption. Like Stop mode, it is based on CPU subsystem Stop mode. However the V_{CORE} supply regulator is powered off.

When the system enters in Standby mode, the voltage regulator is disabled. The complete V_{CORE} domain is consequently powered off. The PLLs, HSI oscillator, CSI oscillator, HSI48 and the HSE oscillator are also switched off. SRAM and register contents are lost except for backup domain registers (RTC registers, RTC backup register and backup RAM), and Standby circuitry (see *Section 6.4.4: Backup domain*).

In system Standby mode, the following features can be selected by programming individual control bits:

- Independent watchdog (IWDG)

  The IWDG is started by programming its Key register or by hardware option. Once started, it cannot be stopped except by a reset (see *Section 48.3* in *Section 48: Independent watchdog (IWDG)*.
- Real-time clock (RTC)

  This is configured via the RTCEN bit in the backup domain control register (RCC_BDCR).
- Internal RC oscillator (LSI RC)

  This is configured by the LSION bit in the Control/status register (RCC_CSR).
- External 32.768 kHz oscillator (LSE OSC)

  This is configured by the LSEON bit in the backup domain control register (RCC_BDCR).

Entering Standby mode

The Standby mode is entered according to *Section 6.7.3: Entering low-power modes*, when the PDDS bits in the *PWR CPU control register 3 (PWR_CSR3)* is set to one.

If Flash memory programming is ongoing, the Standby mode entry is delayed until the memory access is finished.

Refer to *Table 50* for more details on how to enter to Standby mode.

Exiting from Standby mode

The Standby mode is exited according to *Section 6.7.4: Exiting from low-power modes*.

The system exits from Standby mode when an external Reset (NRST pin), an IWDG Reset, a WKUP pin event, a RTC alarm, a tamper event, or a time stamp event is detected. All registers are reset after waking up from Standby except for power control and status registers (*PWR control register 2 (PWR_CSR2)*, *PWR CPU control register 3 (PWR_CSR3)*), SBF bit in the *PWR CPU control register 3 (PWR_CSR3)*, *PWR wake-up flag register (PWR_WKUPFR)*, and *PWR wake-up enable and polarity register (PWR_WKUPEPR)*.

After waking up from Standby mode, the program execution restarts in the same way as after a system reset (boot option sampling, boot vector reset fetched, etc.). The SBF status flags in the *PWR CPU control register 3 (PWR_CSR3)* registers indicate from which mode the system has exited (refer to *Table 50*).

Table 49. Standby and Stop flags

SBF	STOPF	Description
0	1	System has been in Stop
1	0	System has been in Standby

Table 50. Standby mode

Standby mode	Description
Mode entry	– The CPU subsystem is in Stop mode, and there is no active EXTI wake-up source. – PDDS bit for select Standby. – All WKUPF bits in the Power Control/Status register (PWR_WKUPFR) are cleared.
Mode exit	– WKUP pins rising or falling edge, RTC alarm (Alarm A and Alarm B), RTC wake-up, tamper event, time stamp event, external reset in NRST pin, IWDG reset.
Wake-up latency	System reset phase (see *Section 7.4.2: The system and application resets (sys_rst and nreset)*)

I/O states in Standby mode

In Standby mode, all I/O pins are high impedance without pull, except for:

- Reset pad (still available)
- RTC_AF1 pin if configured for tamper, time stamp, RTC Alarm out, or RTC clock calibration out
- WKUP pins (if enabled). The WKUP pin pull configuration can be defined through WKUPPUPD register bits in the *PWR wake-up enable and polarity register (PWR_WKUPEPR)*
- I3C pin-pull configuration if enabled through the register PWR_APCR.

6.7.8 Monitoring low-power modes

The devices feature state monitoring pins to monitor the state transition to low-power mode (refer to *Table 51* for the list of pins and their description). The GPIO pin corresponding to each monitoring signal has to be programmed in alternate function mode.

This feature is not available in Standby mode since these I/O pins are switched to high impedance.

Table 51. Low-power modes monitoring pin overview

Power state monitoring pins	Description
PWR_CSLEEP (CSLEEP)	Sleeping CPU state
PWR_CSTOP (CDSLEEP)	Deepsleep CPU state

The values of the monitoring pins reflect the state of the CPU and domains. Refer to *Table 52* for the GPIO state depending on CPU and domain state.

Table 52. GPIO state according to CPU and domain state

CPU		CPU power state	Power mode
CSLEEP	CDSLEEP		
0	0	CPU in Run mode	Run mode
1	0	CPU in Sleep mode	
0	1	CPU in Run mode	
1	1	CPU in Deepsleep mode	Stop mode
-	-	-(1)	Standby mode

1. The CPU is powered off.

6.8 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

6.8.1 PWR control register 1 (PWR_CR1)

Address offset: 0x000

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALS[1:0]		AVDEN	AVDREADY	BOOSTE	Res.	FLPS	DBP	PLS[2:0]			PVDE	Res.	Res.	Res.	SVOS
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw				rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **ALS[1:0]**: Analog voltage detector level selection
These bits select the voltage threshold detected by the AVD.
00: AVD level 1
01: AVD level 2
10: AVD level 3
11: AVD level 4
Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bit 13 **AVDEN**: Peripheral voltage monitor on VDDA enable
0: Peripheral voltage monitor on VDDA disabled
1: Peripheral voltage monitor on VDDA enabled

Bit 12 **AVDREADY**: analog voltage ready
This bit is only used when the analog switch boost needs to be enabled (see BOOSTE bit). It must be set by software when the expected VDDA analog supply level is available. The correct analog supply level is indicated by the AVDO bit (PWR_CSR1 register) after setting the AVDEN bit and selecting the supply level to be monitored (ALS bits).
0: peripheral analog voltage VDDA not ready (default)
1: peripheral analog voltage VDDA ready

Bit 11 **BOOSTE**: analog switch VBoost control
This bit enables the booster to guarantee the analog switch AC performance when the VDD supply voltage is below 2.7 V (reduction of the total harmonic distortion to have the same switch performance over the full supply voltage range)
The VDD supply voltage can be monitored through the PVD and the PLS bits.
0: booster disabled (default)
1: booster enabled if analog voltage ready (AVD_READY = 1)

Bit 10 Reserved, must be kept at reset value.

Bit 9 **FLPS**: Flash low-power mode in Stop mode
This bit allows to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.
When it is set, the Flash memory enters low-power mode when device is in Stop mode.
0: Flash memory remains in normal mode when device enters Stop (quick restart time).
1: Flash memory enters low-power mode when device enters Stop mode (low-power consumption).

Bit 8 **DBP**: Disable backup domain write protection
In reset state, the RCC_BDCR register, the RTC registers (including the backup registers), BREN and MOEN bits in the PWR_CSR1 register, are protected against parasitic write access.
This bit must be set to enable write access to these registers.
0: Access to RTC, RTC backup registers and backup SRAM disabled
1: Access to RTC, RTC backup registers and backup SRAM enabled

Bits 7:5 **PLS[2:0]**: Programmable voltage detector level selection
These bits select the voltage threshold detected by the PVD.
000: PVD level 1
001: PVD level 2
010: PVD level 3
011: PVD level 4
100: PVD level 5
101: PVD level 6
110: PVD level 7
111: External voltage level on PVD_IN pin
111: External voltage level on PVD_IN pin, compared to internal VREFINT level.
Note: Refer to Section "Electrical characteristics" of the product datasheet for more details.

Bit 4 **PVDE**: Programmable voltage detector enable
0: Programmable voltage detector disabled.
1: Programmable voltage detector enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **SVOS**: System Stop mode voltage scaling selection.
0: SVOS low
1: SVOS high (default)

6.8.2 PWR control status register 1 (PWR_SR1)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	AVDO	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PVDO	Res.	Res.	ACTVOSRDY	ACTVOS
		r									r			r	r

Bits 31:14 Reserved, must be kept at reset value.

Bit 13 **AVDO**: Analog voltage detector output on VDDA
This bit is set and cleared by hardware. It is valid only if AVD on VDDA is enabled by the AVDEN bit.
0: VDDA is equal or higher than the AVD threshold selected with the ALS[1:0] bits.
1: VDDA is lower than the AVD threshold selected with the ALS[1:0] bits
Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the AVDEN bit is set

Bits 12:5 Reserved, must be kept at reset value.

Bit 4 **PVDO**: Programmable voltage detect output
This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.
0: VDD or PVD_IN voltage is equal or higher than the PVD threshold selected through the PLS[2:0] bits.
1: VDD or PVD_IN voltage is lower than the PVD threshold selected through the PLS[2:0] bits.
Note: Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **ACTVOSRDY**: Voltage levels ready bit for currently used ACTVOS and SDHILEVEL
This bit is set to 1 by hardware when the voltage regulator and the SMPS step-down converter are both disabled and Bypass mode is selected in PWR control register 2 (PWR_CSR2).
0: Voltage level invalid, above or below current ACTVOS and SDHILEVEL selected levels.
1: Voltage level valid, at current ACTVOS and SDHILEVEL selected levels.

Bit 0 **ACTVOS**: VOS currently applied for V_{CORE} voltage scaling selection.
These bit reflect the last VOS value applied to the PMU.
0: VOS low level
1: VOS high level

6.8.3 PWR control status register 1 (PWR_CSR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register is not reset by wake-up from Standby mode, RESET signal and V_{DD} POR. It is only reset by V_{SW} POR and VSWRST reset.

This register must not be accessed when VSWRST bit in the RCC_BDCR register resets the V_{SW} domain.

After reset, the PWR_CSR1 register is write-protected. Prior to modifying its content, the DBP bit in the PWR_CR1 register must be set to disable the write protection.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TEMPH	TEMPL	VBATH	VBATL	Res.	Res.	Res.	BRRDY
								r	r	r	r				r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.	Res.	Res.	BREN
											rw				rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: Temperature level monitoring versus high threshold
0: Temperature below high threshold level.
1: Temperature equal or above high threshold level.

Bit 22 **TEMPL**: Temperature level monitoring versus low threshold
0: Temperature above low threshold level.
1: Temperature equal or below low threshold level.

Bit 21 **VBATH**: V_{BAT} level monitoring versus high threshold
0: V_{BAT} level below high threshold level.
1: V_{BAT} level equal or above high threshold level.

Bit 20 **VBATL**: V_{BAT} level monitoring versus low threshold
0: V_{BAT} level above low threshold level.
1: V_{BAT} level equal or below low threshold level.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **BRRDY**: Backup regulator ready
This bit is set by hardware to indicate that the backup regulator is ready.
0: Backup regulator not ready.
1: Backup regulator ready.

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **MONEN:** V_{BAT} and temperature monitoring enable

When set, the V_{BAT} supply and temperature monitoring is enabled.

0: V_{BAT} and temperature monitoring disabled.

1: V_{BAT} and temperature monitoring enabled.

Note: V_{BAT} and temperature monitoring are only available when the backup regulator is enabled (BREN bit set to 1).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **BREN:** Backup regulator enable

When set, the backup regulator (used to maintain the backup RAM content in Standby and V_{BAT} modes) is enabled.

If BREN is reset, the backup regulator is switched off. The backup RAM can still be used in Run and Stop modes. However, its content is lost in Standby and V_{BAT} modes.

If BREN is set, the application must wait till the backup regulator ready flag (BRRDY) is set to indicate that the data written into the SRAMis maintained in Standby and V_{BAT} modes.

0: Backup regulator disabled.

1: Backup regulator enabled.

6.8.4 PWR control register 2 (PWR_CSR2)

Address offset: 0x00C

Reset value: 0x0000 0006

This register is reset only by a power-on reset (POR). It is not reset by a wake-up from Standby mode or RESET signal.

The lower byte of this register is written once after POR and must be written before entering low power mode, changing VOS level.

The lower byte of this register should be written as soon as possible after device start and the regulator state should be verified by reading ACTVOSRDY before entering the low power mode or changing VOS level.

No limitation applies to the upper bytes.

Programming data corresponding to an invalid combination of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS bits (see *Table 44: Supply configuration control* is ignored; data is not written because the written-once mechanism locks the register and any further write access is ignored.

The default supply configuration is kept, and the ACTVOSRDY bit in the PWR control status register 1 (PWR_SR1) continues to indicate invalid voltage levels. The system must be power cycled before writing a new value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	USBHSREGEN	USB33RDY	USBREGEN	USB33DEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SDEXTRDY

rw	rw	rw	rw	rw	rw	rw	rw				rwo	rwo	rwo	rwo	rwo

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **USBHSREGEN**: USB HS regulator enable.
0: USB HS PHY regulator disabled (default)
1: USB HS PHY regulator enabled

Note: This bit should only be set if USB HS is used

Bit 26 **USB33RDY**: USB supply ready.
0: USB33 supply not ready
1: USB33 supply ready.

Bit 25 **USBREGEN**: USB regulator enable.
0: USB regulator disabled
1: USB regulator enabled.

Bit 24 **USB33DEN**: VDD33USB voltage level detector enable
0: VDD33USB voltage level detector disabled
1: VDD33USB voltage level detector enabled.

Note: This bit should be set if USB HS, FS, or a GPIO on PMx is used

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **SDEXTRDY**: SMPS step-down converter external supply ready
This bit is set by hardware to indicate that the external supply from the SMPS step-down converter is ready.
0: External supply not ready.
1: External supply ready.

Bit 15 **EN_XSPIM2**: this bit allows the SW to enable the XSPI interface, when available. The XSPIM_P2 supply must be stable prior to setting this bit. It should also be set when FMC is used.
0: XSPIM2 interface is not enabled
1: XSPIM2 interface is enabled
CAUTION: Not respecting this condition could damage the device.

Bit 14 **EN_XSPIM1**: this bit allow the SW to enable the XSPI interface. The XSPIM_P1 supply must be stable prior to setting this bit.
0: XSPIM1 interface is not enabled
1: XSPIM1 interface is enabled
CAUTION not respecting this condition could damage the devic

Bits 13:12 **XSPICAP2[1:0]**: XSPI port 2 capacitor control bits
00: XSPI Capacitor OFF (default)
01: XSPI Capacitor set to 1/2
10: XSPI Capacitor set to 1/2
11: XSPI Capacitor set to full capacitance
see the product datasheet for more details

Bits 11:10 **XSPICAP1[1:0]**: XSPI port 1 capacitor control bits
00: XSPI Capacitor OFF (default)
01: XSPI Capacitor set to 1/2
10: XSPI Capacitor set to 1/2
11: XSPI Capacitor set to full capacitance
see the product datasheet for more details

Bit 9 **VBRS**: VBAT charging resistor selection
0: Charge VBAT through a 5 kΩ resistor.
1: Charge VBAT through a 1.5 kΩ resistor.

Bit 8 **VBE**: VBAT charging enable
0: VBAT battery charging disabled.
1: VBAT battery charging enabled.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SDHILEVEL**: SMPS step-down converter voltage output for external supply.
This bit is used when SMPSEXTHP is enabled. In this case SDHILEVEL has to be set to 1 to confirm the regulator settings.
0: Reset value
1: 1.8V

Bit 3 **SMPSEXTHP**: SMPS external power delivery selection
0: SMPS normal operating mode, no power delivery to external circuits
1: SMPS external operating mode, power delivery to external circuits

Note: Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS are described in Table 44.

Bit 2 **SDEN**: SMPS step-down converter enable
0: SMPS step-down converter disabled
1: SMPS step-down converter enabled. (Default)

Note: Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS are described in Table 44.

Bit 1 **LDOEN**: Low drop-out regulator enable
0: Low drop-out regulator disabled.
1: Low drop-out regulator enabled (default)

Note: Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS are described in Table 44.

Bit 0 **BYPASS**: Power management unit bypass
0: Power management unit normal operation.
1: Power management unit bypassed, voltage monitoring still active.

Note: Illegal combinations of SDHILEVEL, SMPSEXTHP, SDEN, LDOEN and BYPASS are described in Table 44.

6.8.5 PWR CPU control register 3 (PWR_CSR3)

This register allows controlling the CPU power.

Address offset: 0x010

Reset value: 0x0000 0000

After Standby Reset value: 0x0000 0200

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.	Res.	CSSF	PDDS
						r	r							rc_w1	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SBF**: System Standby flag
This bit is set by hardware and cleared only by a POR (Power-on Reset) or by setting the CPU CSSF bit"
0: System has not been in Standby mode
1: System has been in Standby mode

Bit 8 **STOPF**: STOP flag
This bit is set by hardware and cleared only by any reset or by setting the CPU CSSF bit.
0: System has not been in Stop mode
1: System has been in Stop mode

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CSSF**: Clear Standby and Stop flags (always read as 0)
This bit is cleared to 0 by hardware.
0: No effect.
1: flags (STOPF, SBF) are cleared.

Bit 0 **PDDS**: Power Down Deepsleep.
This bit allows CPU to define the Deepsleep mode
0: Stop mode when device enters Deepsleep.
1: Standby mode when device enters Deepsleep.

6.8.6 PWR control status register 4 (PWR_CSR4)

Address offset: 0x014

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOSRDY	VOS
														r	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **VOSRDY**: VOS Ready bit for V_{CORE} voltage scaling output selection.
When an internal regulator is used, this bit indicates that all the features allowed by the selected VOS can be used."
Note: When Bypass mode is selected in the PWR control register (PWR_CSR2), VOSRDY bit is set to 1 by hardware whatever the V_{CORE} level.
0: Not ready, voltage level below VOS selected level.
1: Ready, voltage level at or above VOS selected level.

Bit 0 **VOS**: Voltage scaling selection according to performance
These bits control the V_{CORE} voltage level and allow to obtains the best trade-off between power consumption and performance:
– When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
– When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.
0: VOS low level (default)
1: VOS high level
Note: Refer to Section “Electrical characteristics” of the product datasheet for more details.

6.8.7 PWR wake-up clear register (PWR_WKUPCR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPC4	WKUPC3	WKUPC2	WKUPC1
												rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **WKUPC4**:Clear wake-up pin flag for WKUP4
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF4 wake-up pin flag (bit is cleared to 0 by hardware)

Bit 2 **WKUPC3**:Clear wake-up pin flag for WKUP3
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF3 wake-up pin flag (bit is cleared to 0 by hardware)

Bit 1 **WKUPC2**:Clear wake-up pin flag for WKUP2
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF2 wake-up pin flag (bit is cleared to 0 by hardware)

Bit 0 **WKUPC1**:Clear wake-up pin flag for WKUP1
These bits are always read as 0.
0: No effect
1: Writing 1 clears the WKUPF1 wake-up pin flag (bit is cleared to 0 by hardware)

6.8.8 PWR wake-up flag register (PWR_WKUPFR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPF4	WKUPF3	WKUPF2	WKUPF1
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **WKUPF4**: Wake-up pin WKUP4 flag.
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC4 bit in the PWR wake-up clear register (PWR_WKUPCR).
0: No wake-up event occurred
1: A wake-up event was received from WKUP4 pin

Bit 2 **WKUPF3**: Wake-up pin WKUP3 flag.
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC3 bit in the PWR wake-up clear register (PWR_WKUPCR).
0: No wake-up event occurred
1: A wake-up event was received from WKUP3 pin

Bit 1 **WKUPF2**: Wake-up pin WKUP2 flag.
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC2 bit in the PWR wake-up clear register (PWR_WKUPCR).
0: No wake-up event occurred
1: A wake-up event was received from WKUP2 pin

Bit 0 **WKUPF1**: Wake-up pin WKUP1 flag.
This bit is set by hardware and cleared only by a Reset pin or by setting the WKUPC1 bit in the PWR wake-up clear register (PWR_WKUPCR).
0: No wake-up event occurred
1: A wake-up event was received from WKUP1 pin

6.8.9 PWR wake-up enable and polarity register (PWR_WKUPEPR)

Address offset: 0x028

Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WKUPPUPD4[1:0]		WKUPPUPD3[1:0]		WKUPPUPD2[1:0]		WKUPPUPD1[1:0]	
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	WKUP P4	WKUP P3	WKUP P2	WKUP P1	Res.	Res.	Res.	Res.	WKUP EN4	WKUP EN3	WKUP EN2	WKUP EN1
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **WKUPPUPDn[1:0]**: Wake-up pin pull configuration for WKUPn, (n = 4 to 1)
These bits define the I/O pad pull configuration used when WKUPENn = 1. The associated GPIO port pull configuration must be set to the same value or to 00.
The wake-up pin pull configuration is kept in Standby mode.
00: No pull-up
01: Pull-up
10: Pull-down
11: Reserved

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **WKUPP[4:1]**: Wake-up pin polarity bit for WKUPn, (n = 4, 3, 2, 1)
These bits define the polarity used for event detection on WKUPn external wake-up pin.
0: Detection on high level (rising edge)
1: Detection on low level (falling edge)

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **WKUPEN**[4:1]: Enable wake-up Pin WKUPn, (n = 4, 3, 2, 1)
Each bit is set and cleared by software.
0: An event on WKUPn pin does not wake the system up from Standby mode.
1: A rising or falling edge on WKUPn pin wakes the system up from Standby mode.
Note: An additional wake-up event is detected if WKUPn+1 pin is enabled (by setting the WKUPENn bit) when WKUPn pin level is already high when WKUPPn+1 selects rising edge, or low when WKUPPn selects falling edge.

6.8.10 PWR USB Type-C and Power Delivery register (PWR_UCPDR)

Address offset: 0x02C

Reset value: 0x0000 0002

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD_STBY	UCPD_DBDIS
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **UCPD_STBY**: UCPD Standby mode
When set, this bit is used to memorize the UCPD configuration in Standby mode.
This bit must be written to 1 just before entering Standby mode when using UCPD.
It must be written to 0 after exiting the Standby mode and before writing any UCPD registers.

Bit 0 **UCPD_DBDIS**: UCPD dead battery disable
After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all cases, either to stop this pull-down or to handover control to the UCPD (the UCPD must be initialized before doing the disable).
0: UCPD dead battery pull-down behavior enabled on UCPDx_CC1 and UCPDx_CC2 pins
1: UCPD dead battery pull-down behavior disabled on UCPDx_CC1 and UCPDx_CC2 pins

6.8.11 PWR apply pull configuration register (PWR_APCR)

Address offset: 0x030

Reset value: 0x0003 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
I3CPB9_PU	I3CPB8_PU	I3CPB7_PU	I3CPB6_PU	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PO5_PUPD	PN7_PUPD
rw	rw	rw	rw											rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APC
															rw

Bit 31 **I3CPB9_PU**: Port PB9 I3C pull-up bit
When I3C is used on PB9, when set, this bit activates the pull-up on I3C1_SDA (PB9) in standby mode.

Bit 30 **I3CPB8_PU**: Port PB8 I3C pull-up bit
When I3C is used on PB8, when set, this bit activates the pull-up on I3C1_SCL (PB8) in standby mode.

Bit 29 **I3CPB7_PU**: Port PB7 I3C pull-up bit
When I3C is used on PB7, when set, this bit activates the pull-up on I3C1_SDA (PB7) in standby mode.

Bit 28 **I3CPB6_PU**: Port PB6 I3C pull-up bit
When I3C is used on PB6, when set, this bit activates the pull-up on I3C1_SCL (PB6) in standby mode.

Bits 27:18 Reserved, must be kept at reset value.

Bit 17 **PO5_PUPD**: Port O bit 5 pull-up/down configuration
When this bit is set, a weak pull-up or pull
down resistor is applied on PO5 following inverse logic applied on PO4.
If the PUO4 bit in PWR_PUCRO register is set and APC bit is set the week pull-down is applied on PO5.
If the PDO4 bit in PWR_PDCRO register is set and APC bit is set the week pull-up is applied on PO5..

Bit 16 **PN7_PUPD**: Port N bit 7 pull-up/down configuration
When this bit is set, a weak pull-up or pull-
down resistor is applied on PN7 following inverse logic applied on PN6.
If the PUN6 bit in PWR_PUCRN register is set and APC bit is set the week pull-down is applied on PN7.
If the PDN6 bit in PWR_PDCRN register is set and APC bit is set the week pull-up is applied on PN7.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **APC**: Apply pull-up and pull-down configuration

When this bit is set, the I/O pull-up and pull-down configurations defined in PO5_PUPD, PN7_PUPD bits and PUCRx, PDCRx registers are applied in Standby mode even after wake-up until APC bit is reset to 0.

When this bit is cleared, the I/O pull-up or pull-down configurations defined in PO5_PUPD, PN7_PUPD bits and PUCRx and PDCRx registers are not applied in Standby mode and IO becomes Hi-Z.

6.8.12 PWR port N pull-up control register (PWR_PUCRN)

Address offset: 0x034

Reset value: 0x0000 0000 (POR and System Reset)

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	PUN12	Res.	Res.	Res.	Res.	Res.	PUN6	Res.	Res.	Res.	Res.	PUN1	Res.
			rw						rw					rw	

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **PUN12:** Port N pull-up bit 12
When set, each bit activates the pull-up on PN12 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD12 bit is also set.

Bits 11:7 Reserved, must be kept at reset value.

Bit 6 **PUN6**: Port N pull-up bit 6
When set activates the pull-up on PN6 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PDN6 bit is also set.

Bits 5:2 Reserved, must be kept at reset value.

Bit 1 **PUN1**: Port N pull-up bit 1
When set, each bit activates the pull-up on PN1 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding PD1 bit is also set.

Bit 0 Reserved, must be kept at reset value.

6.8.13 PWR port N pull-down control register (PWR_PDCRN)

Address offset: 0x038

Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rw				rw		rw				rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **PDN12**: Port N pull-down bit 12
When set activates the pull-down on PN12 when the APC bit is set in PWR_APCR.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **PDN8N11**: Port N - PN8 to PN11 pull-down activation
When set, four pull-down resistors are activated on PN8 to PN11 when the APC bit is set in PWR_APCR.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PDN6**: Port N pull-down bit 6
When set activates the pull-down on PN6 when the APC bit is set in PWR_APCR.

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **PDN2N5**: Port N PN2 to PN5 pull-down activation
When set, four pull-down resistors are activated on PN2 to PN5 when the APC bit is set in PWR_APCR.

Bit 1 **PDN1**: Port N pull-down bit 1
When set activates the pull-down on PN1 when the APC bit is set in PWR_APCR.

Bit 0 **PDN0**: Port N pull-down bit 0
When set activates the pull-down on PN0 when the APC bit is set in PWR_APCR.

6.8.14 PWR port O pull-up control register (PWR_PUCRO)

Address offset: 0x03C

Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw			rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **PUO4**: Port O pull-up bit 4
When set activates the pull-up on PO4 when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding bits PDO4 in PWR_PDCRO is also set.

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PUOn**: (n = 1 to 0) Port O pull-up bits
When set, each bit activates the pull-up on POy when the APC bit is set in PWR_APCR. The pull-up is not activated if the corresponding bits in PWR_PDCRO is also set.

6.8.15 PWR port O pull-down control register (PWR_PDCRO)

Address offset: 0x040

Reset value: 0x0000 0000

(Reset value after Standby: the value of the register is kept in Standby mode.)

			rw				rw				rw				rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **PDP12P15**: Port P12-P15 pull-down activation
When set, four pull-down resistors are activated on P8 to P11 when the APC bit is set in PWR_APCR.

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **PDP8P11**: Port P8-P11 pull-down activation
When set, four pull-down resistors are activated on P8 to P11 when the APC bit is set in PWR_APCR.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **PDP4P7**: Port P4-P7 pull-down activation
When set, four pull-down resitors are activated on P4 to P7 when the APC bit is set in PWR_APCR.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **PDP0P3**: Port P0-P3 pull-down activation
When set, four pull-down resistors are activated on P0 to P3 when the APC bit is set in PWR_APCR.

6.8.17 PWR register map

Table 53. Power control register map and reset values

Refer to *Section 2.3 on page 150* for the register boundary addresses.

7 Reset and clock control (RCC)

The RCC block manages the clock and reset generation for the whole microcontroller.

The operating modes to which this section refers are defined in *Section 6.6.1: Operating modes* of the PWR block.

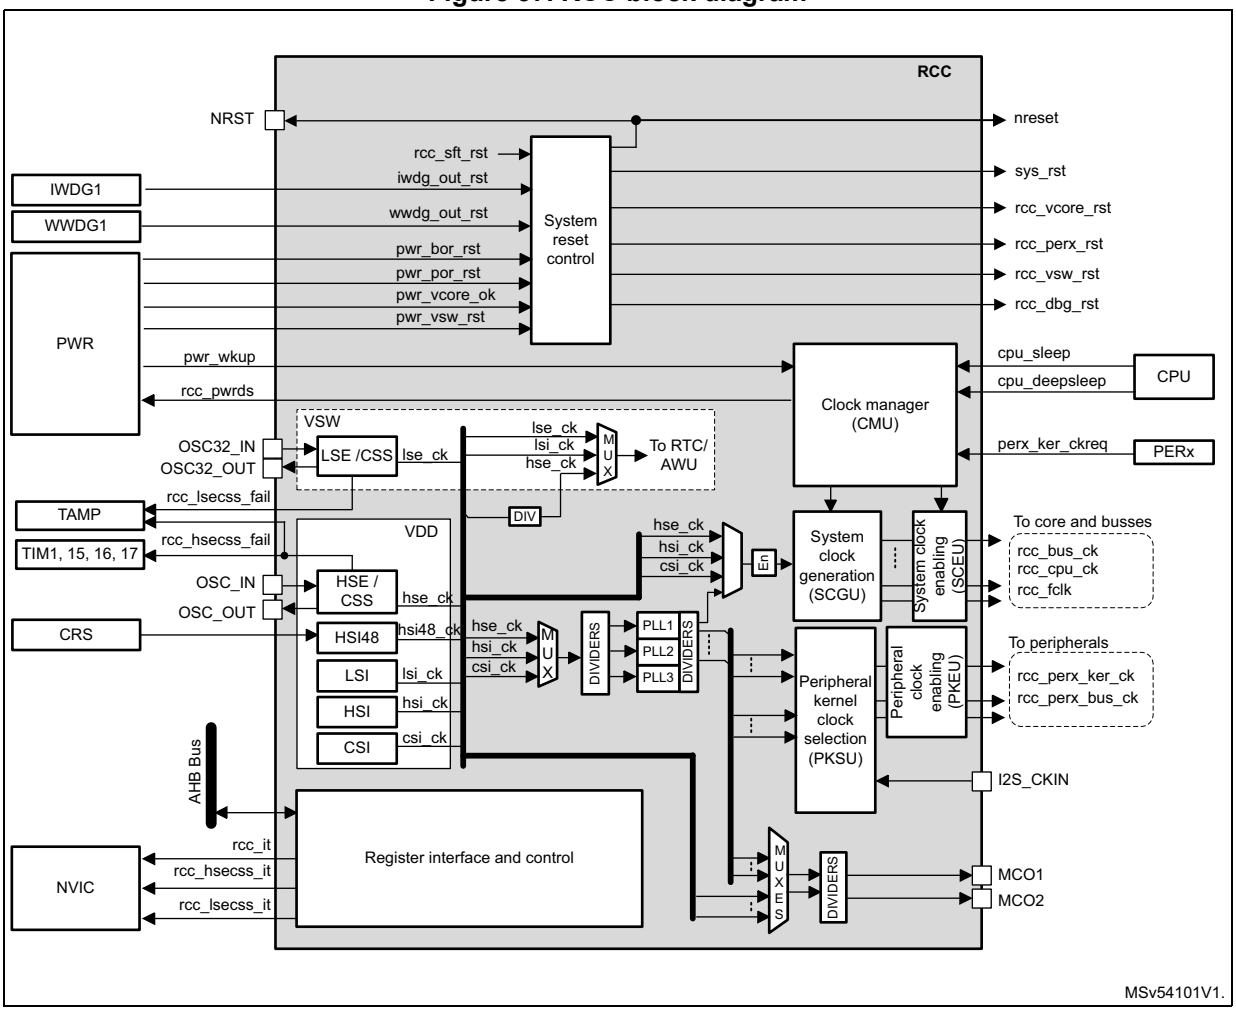
7.1 RCC main features

AHB-Lite bus interface

Reset block:

- Generation of local and system reset
- Bidirectional pin reset allowing to reset the microcontroller or external devices
- WWDG and IWDG reset supported
- Power-on (POR) and Brownout (BOR) resets initiated by the power control (PWR)

Clock generation block:



- Generation and dispatching of clocks for the complete device
- 3 separate PLLs using integer or fractional ratios
- Possibility of changing the PLL fractional ratios on-the-fly
- Smart clock gating to reduce power dissipation
- System clock protection
- 2 external oscillators:
  - High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 50 MHz frequency [a]
  - Low-speed external oscillator (LSE) for the 32 kHz crystals
- 4 internal oscillators
  - High-speed internal oscillator (HSI)
  - 48 MHz RC oscillator (HSI48)
  - Low-power internal oscillator (CSI)
  - Low-speed internal oscillator (LSI)
- Buffered clock outputs for external devices
- Generation of two types of interrupts lines:
  - Dedicated interrupt lines for clock security management
  - One general interrupt line for other events
- Clock generation handling in Stop and Standby mode

a. Note that when the USBHSPHY is used, the HSE frequency must be 16, 19.2, 20, 24, 26 or 32 MHz.

7.2 RCC block diagram

Figure 37 shows the RCC block diagram.

Figure 37. RCC block diagram

7.3 RCC pins and internal signals

Table 54 lists the RCC inputs and output signals connected to package pins or balls.

Table 54. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset, can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO1	O	Output clock 1 for external devices
MCO2	O	Output clock 2 for external devices
I2S_CKIN	I	External kernel clock input for digital audio interfaces: SPI/I2S, SAI, and ADF

The RCC exchanges a lot of internal signals with all components of the product, for that reason, *Table 55* only shows the most significant internal signals.

Table 55. RCC internal input/output signals

Signal name	Signal type	Description
rcc_it	O	General interrupt request line
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_lsecss_it	O	LSE clock security failure interrupt
rcc_hsecss_fail	O	Event indicating that a HSE clock security failure is detected. This signal is connected to TIMERS.
rcc_lsecss_fail	O	Event indicating that a LSE clock security failure is detected. This signal is connected to TAMP, EXTI and PWR
nreset	I/O	Application reset
sys_rst	I/O	System reset
iwdg_out_rst	I	Reset line driven by the IWDG, indicating that a timeout occurred
wwdg_out_rst	I	Reset line driven by the WWDG, indicating that a timeout occurred
pwr_bor_rst	I	Brownout reset generated by the PWR block
pwr_por_rst	I	Power-on reset generated by the PWR block
pwr_vsw_rst	I	Power-on reset of the VSW domain generated by the PWR block
rcc_perx_rst	O	Reset generated by the RCC for the peripherals
pwr_wkup	I	Wake-up domain request generated by the PWR and used to restore the domain clocks
rcc_pwd_req	O	Low-power request generated by the RCC and used to set the circuit into low-power mode

Table 55. RCC internal input/output signals (Continued)

Signal name	Signal type	Description
cpu_sleep	I	Signals generated by the CPU, indicating if the CPU is in CRun, Sleep or CStop
cpu_deepsleep	I	
perx_ker_ckreq	I	Signal generated by some peripherals in order to request the activation of their kernel clock
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC, for some peripherals
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals
rcc_bus_ck	O	Clocks for APB, AHB and AXI bridges generated by the RCC
rcc_cpu_ck	O	Clocks for the CPU, generated by the RCC
rcc_fclk	O	

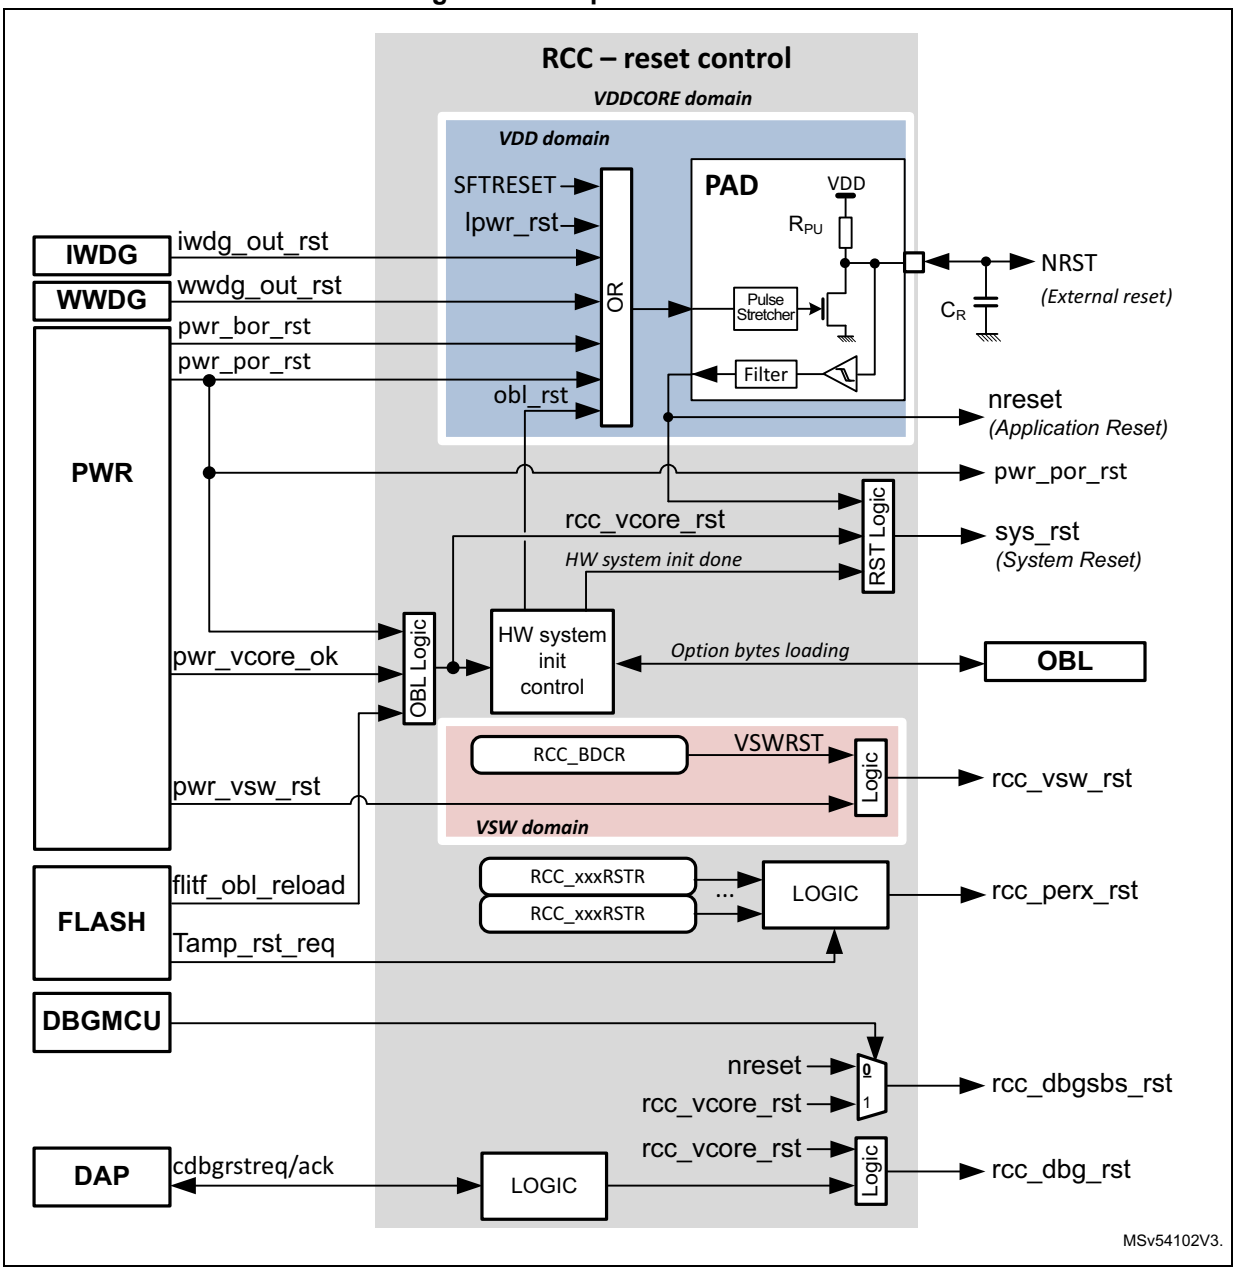
7.4 RCC reset block functional description

The RCC handles the reset generation for the complete product, using events coming from different sources:

- assertion of the NRST pin from an external device
- a failure on the supply voltage applied to VDD, VBAT
- an exit from Standby
- a watchdog timeout
- a software command

The reset scope depends on the source that generates the reset.

7.4.1 Reset from PWR block



The PWR block provides several reset signals to the RCC:

- The power-on/off reset signal (**pwr_por_rst**), which is asserted when the VDD supply is lower than the VPOR threshold.
- The brown-out reset signal (**pwr_bor_rst**), which is asserted when the VDD supply is lower than the VBOR threshold.
- The core reset signal (**pwr_vcore_ok**), which is asserted when the VDDCORE supply is not valid or available. Note that the VDDCORE voltage is switched off, when the product is in Standby. So when the system exits from Standby mode, the **pwr_vcore_ok** signal is asserted as long the VDDCORE voltage provided by the internal regulator is not valid. Note that when VDD supply is not valid, **pwr_vcore_ok** is asserted as well.
- The VSW domain reset signal (**pwr_vsw_rst**), which is asserted when the VSW supply is lower than the expected threshold.

*Note: The **rcc_vcore_rst** is generated from the **pwr_vcore_ok** signal, the main difference between these two signals is that **rcc_vcore_rst** remains asserted until the option byte loading operation is completed.*

Refer to *Table 56: Reset coverage summary* for details.

Figure 38. Simplified reset circuit

7.4.2 The system and application resets (sys_rst and nreset)

A system reset (**sys_rst)** resets most of the registers to their default values unless otherwise specified in the register description.

A system reset can be generated from one of the following sources:

- an assertion of the NRST pin (external reset)
- a reset from the power-on/off reset block (**pwr_por_rst**)
- a reset from the brownout reset block (**pwr_bor_rst**)
  Refer to *Section 6.5.2: Brownout reset (BOR)* for a detailed description of the BOR function.
- a reset from the independent watchdogs (**iwdg_out_rst**)
- an exit from Standby (**rcc_vcore_rst**).
- a reset from the window watchdogs depending on WWDG configuration (**wwdg_out_rst**)
- a software reset from the Cortex®-M7 core
  It is generated via the SYSRESETREQ signal issued by the Cortex®-M7 core. This signal is also named SFTRESET in this document.
- A reset from the low-power mode security reset, depending on option byte configuration (**lpwr_rst**).
- An option byte reload request from the flash interface (**obl_rst**)

The application reset (**nreset**) is similar to the system reset, but is it not asserted when the system exits from Standby.

Note: The SYSRESETREQ bit in Cortex®-M7 through the FPU application interrupt and reset control register, must be set to force a software reset on the device. Refer to the Cortex®-M7 with FPU technical reference manual for more details (see http://infocenter.arm.com).

7.4.3 The NRST reset

The NRST is active low. A pulse stretcher guarantees a minimum reset pulse duration of 20 µs (Refer to datasheet for details). In addition it is possible to extend the NRST assertion thanks to C_R capacitor. It is not recommended to let the NRST pin unconnected.

When it is not used, connect this pin to ground via a 10 to 100 nF capacitor (CR in *Figure 38*). As shown in *Figure 38*, a filter is also present in order to suppress spurs coming from NRST PAD.

7.4.4 Low-power mode security reset (lpwr_rst)

To prevent critical applications from mistakenly enter a low-power mode, two low-power mode security resets are available. When enabled through nRST_STOP and nRST_STANDBY option bytes, a system reset is generated if the following conditions are met:

- The CPU accidentally enters Stop mode.
  This type of reset is enabled by resetting nRST_STOP user option byte. In this case, whenever the Stop mode entry sequence is successfully executed, a system reset is generated.
- The system accidentally enter Standby mode.
  This type of reset is enabled by resetting nRST_STANDBY user option byte. In this

case, whenever a Standby mode entry sequence is successfully executed, a system reset is generated.
When the Standby mode is entered, a flag is also set in the power controller.

LPWRRSTF bit in the *RCC Reset status register (RCC_RSR)* indicates that a low-power mode security reset occurred (see line #7 in *Table 57*).

lpwr_rst is activated when a low-power mode security reset due to CPU occurred.

Refer to *Section 5.4: FLASH option bytes* for additional information.

Refer to *Section 6: Power control (PWR)* for additional information and *Table 45: Operating mode summary* for the overview of the existing power modes.

7.4.5 Backup domain reset

A backup domain reset (**pwr_vsw_rst**) is generated when one of the following events occurs:

- Software reset, triggered by setting the VSWRST bit in the *RCC Backup domain control register (RCC_BDCR)*. All RTC registers and the RCC_BDCR register are set to their reset values, with the exception of LSEDRV, which is not changed if LSEON=1. The BKPSRAM is not affected.
- When the VSW voltage is outside the operating range. All RTC registers and the RCC_BDCR register are set to their reset values. In this case the content of the BKPSRAM is no longer valid.

Refer to *Section 6.4.4: Backup domain* section of PWR block and to section “System security” for additional information.

7.4.6 Coresight debug reset

The coresight debug components can be reset in different ways:

- Over the DAP by setting to 1 the bit CDBGRSTREQ of the control/status register of the debug port. This action asserts the debug reset request signal cdbgrstreq connected to the RCC. Then the RCC activates the debug reset (**rcc_dbg_rst**), a handshake signal cdbgrstack is provided to the DAP request. The debug reset remains as long as the cdbgrstreq is to 1, refer to *Figure 38* for details.
- When VDDCORE power-on reset occurs (**rcc_vcore_rst**). This reset is activated after a power-on reset, or when the product exits from Standby.

Refer to Section 1.7.1: CoreSight Debug Reset for details.

7.4.7 Option bytes loading

As shown in *Figure 38*, the option bytes loading (OBL) sequence is triggered under the following conditions:

- After a power-on, or
- When the system exits from Standby
- When the flash interface requested a reload of option bytes

The system reset (**sys_rst**) can be released only when the option byte loading (OBL) is completed.

7.4.8 Peripheral resets

The application can individually reset any peripheral whenever requested. This can be done via the RCC_xxxxRSTR registers where “xxxx” is the name of the bus to which the peripheral is connected.

In order to reset a peripheral, the corresponding reset bit must be set to 1, and then set back to 0. There is no need to enable the peripheral clock in order to reset a peripheral.

Note also that the CRYP, SAES and HASH blocks can be reset in the case of a tamper event.

7.4.9 Reset coverage summary

Table 56: Reset coverage summary gives a detailed view of the reset coverage of the most important reset sources.

Note: When V_{DD} is not valid, V_{DDCORE} is also not valid.

Table 56. Reset coverage summary(1)

Functions that are reset		Main reset lines						
		pwr_por_rst (2)	rcc_vcore_rst	sys_rst	nreset (4)	rcc_dbg_rst	rcc_perx_rst	rcc_vsw_rst
VDD domain		x	-	-	-	-	-	-
MCU		x	x	x	-	-	-	-
WWDG		x	x	x	-	-	-	-
IWDG		x	-	-	x	-	-	-
AXI/AHB Interconnections.		x	x	x	-	-	-	-
Debug components, including DBGMCU Reset all the debug parts except the SWJ-DP function. The SWJ-DP is reset by the NJTRST or rcc_vcore_rst resets. The bit DCRT on DBGMCU_CR is reset with pwr_por_rst.		x	x	-	-	x	-	-
Hardware system init. It includes the reload of the option bytes.		x	x	-	-	-	-	-
RCC	*RCC Reset status register (RCC_RSR)*	x	-	-	-	-	-	-
	RCC clock control and status register (RCC_CSR)	x	-	-	-	-	-	-
	RCC Backup domain control register (RCC_BDCR)	-	-	-	-	-	-	x
	Other RCC registers	x	x	x	-	-	-	-
PWR	PWR_CSR1	-	-	-	-	-	-	x
	PWR_CSR2	x	-	-	-	-	-	-
	PWR_CSR3 Individual bits of this register do not have the same reset condition, refer to the PWR section for details.	x	x	x	-	-	-	-
	PWR_WKUPCR, PWR_WKUPFR, PWR_WKUPEPR	x	-	-	x	-	-	-
	Other registers	x	x	x	-	-	-	-
RTC		-	-	-	-	-	-	x
BKPSRAM After a reset of the VSW domain, the backup regulator of the BKPSRAM is disabled, this function is controlled via the PWR block, BREN bit. If the rcc_vsw_rst reset is due to a too low VSW voltage, the content of BKPSRAM is lost.		-	-	-	-	-	-	x
SBS	SBS_RSSCMDR	x	-	-	-	-	-	-
Other Peripherals		x	x	x	-	-	x	-

1. The ‘x’ means that the function is reset by the corresponding reset line, the ‘-’ means that the function isnot reset by the corresponding reset line.
2. The pwr_por_rst is asserted when the voltage applied to VDD is not valid.
When pwr_por_rst is asserted, the rcc_vcore_rst, NRST, the sys_rst and the nreset, are asserted as well.

3. The rcc_vcore_rst is asserted when the voltage applied to VDD is not valid, or when the system exits from Standby (because VDDCORE was switched off).
When rcc_vcore_rst is asserted, the sys_rst, and the pwr_dbg_rst are asserted as well.
4. When nreset is asserted, the sys_rst is also asserted.

7.4.10 Reset source identification

The CPU can identify the reset source by checking the reset flags in the RCC_RSR register.

The CPU can reset the flags by setting RMVF bit.

Table 57 shows how the status bits of the RCC_RSR register behave according to the situation that generated the reset. For example, when an IWDG timeout occurs (line #6), if the CPU is reading the RCC_RSR register during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 57. Reset source identification (RCC_RSR)(1)

#	Situations generating a reset	SBF (2)	LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	OBLRSTF
1	Power-on reset (**pwr_por_rst**)	0	0	0	0	0	1	1	1	0
2	Pin reset (NRST)	0	0	0	0	0	0	1	0	0
3	Brownout reset (**pwr_bor_rst**)	0	0	0	0	0	0	1	1	0
4	System reset generated by CPU (SFTRESET)	0	0	0	0	1	0	1	0	0
5	WWDG reset (**wwdg_out_rst**)	0	0	1	0	0	0	1	0	0
6	IWDG reset (**iwdg_out_rst**)	0	0	0	1	0	0	1	0	0
7	CPU erroneously enters Stop or Standby mode	0	1	0	0	0	0	1	0	0
8	The flash interface requested a reload of option bytes	0	0	0	0	0	0	1	0	1
9	The product exits from Standby	1	0	0	0	0	0	1	0	0

1. Grayed cells highlight the register bits that are set.
2. The SBF bit is located into the PWR_CSR3 register of the PWR block

7.4.11 Power-on and wake-up sequences

For detailed diagrams refer to *Section 6.4.1: System supply startup* in the PWR section.

The time interval between the event that exits the product from a low-power and the moment where the CPU is able to execute code, depends on the system state and on its configuration. *Figure 39* shows the most usual examples.

Power-on wake-up sequence

The power-on wake-up sequence shown in *Figure 39* gives the most significant phases of the power-on sequence. It is the longest sequence since the circuit was not powered. Note that this sequence remains unchanged, whatever V_{BAT} was present or not.

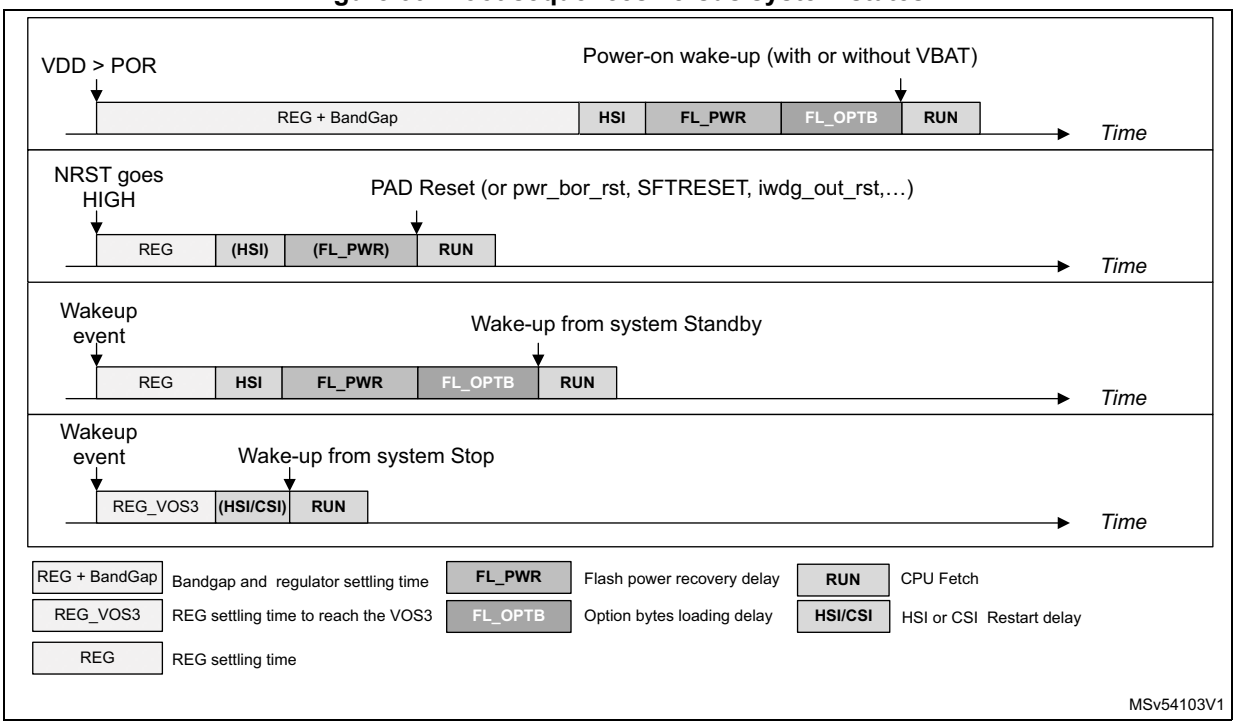
Boot from pin reset

When a pin reset occurs, V_{DD} is still present. As a result:

- The regulator settling time is faster since the reference voltage is already stable.
- The HSI restart delay may be needed if the HSI was not enabled when the NRST occurred, otherwise this restart delay phase is skipped.
- The Flash memory power recovery delay can also be skipped if the Flash memory was enabled when the NRST occurred.

Note: The boot sequence is similar for pwr_bor_rst, lpwr_rst, STFRESET, iwdg_out_rst and wwdg_out_rst.

Boot from system Standby



When waking up from system Standby, the reference voltage is stable since V_{DD} has not been removed. As a result, the regulator settling time is fast. Since V_{CORE} was not present, the restart delay for the HSI, the Flash memory power recovery and the option byte reloading cannot be skipped.

Restart from system Stop

When restarting from Stop, V_{DD} is still present. As a result, the sequence is mainly composed of two steps:

1. Regulator settling time to reach VOS low (default voltage).
2. HSI/CSI restart delay. This step can be skipped if HSIKERON or CSIKERON bit is set to 1 in the *RCC register map*.

Figure 39. Boot sequences versus system states

7.5 RCC clock block functional description

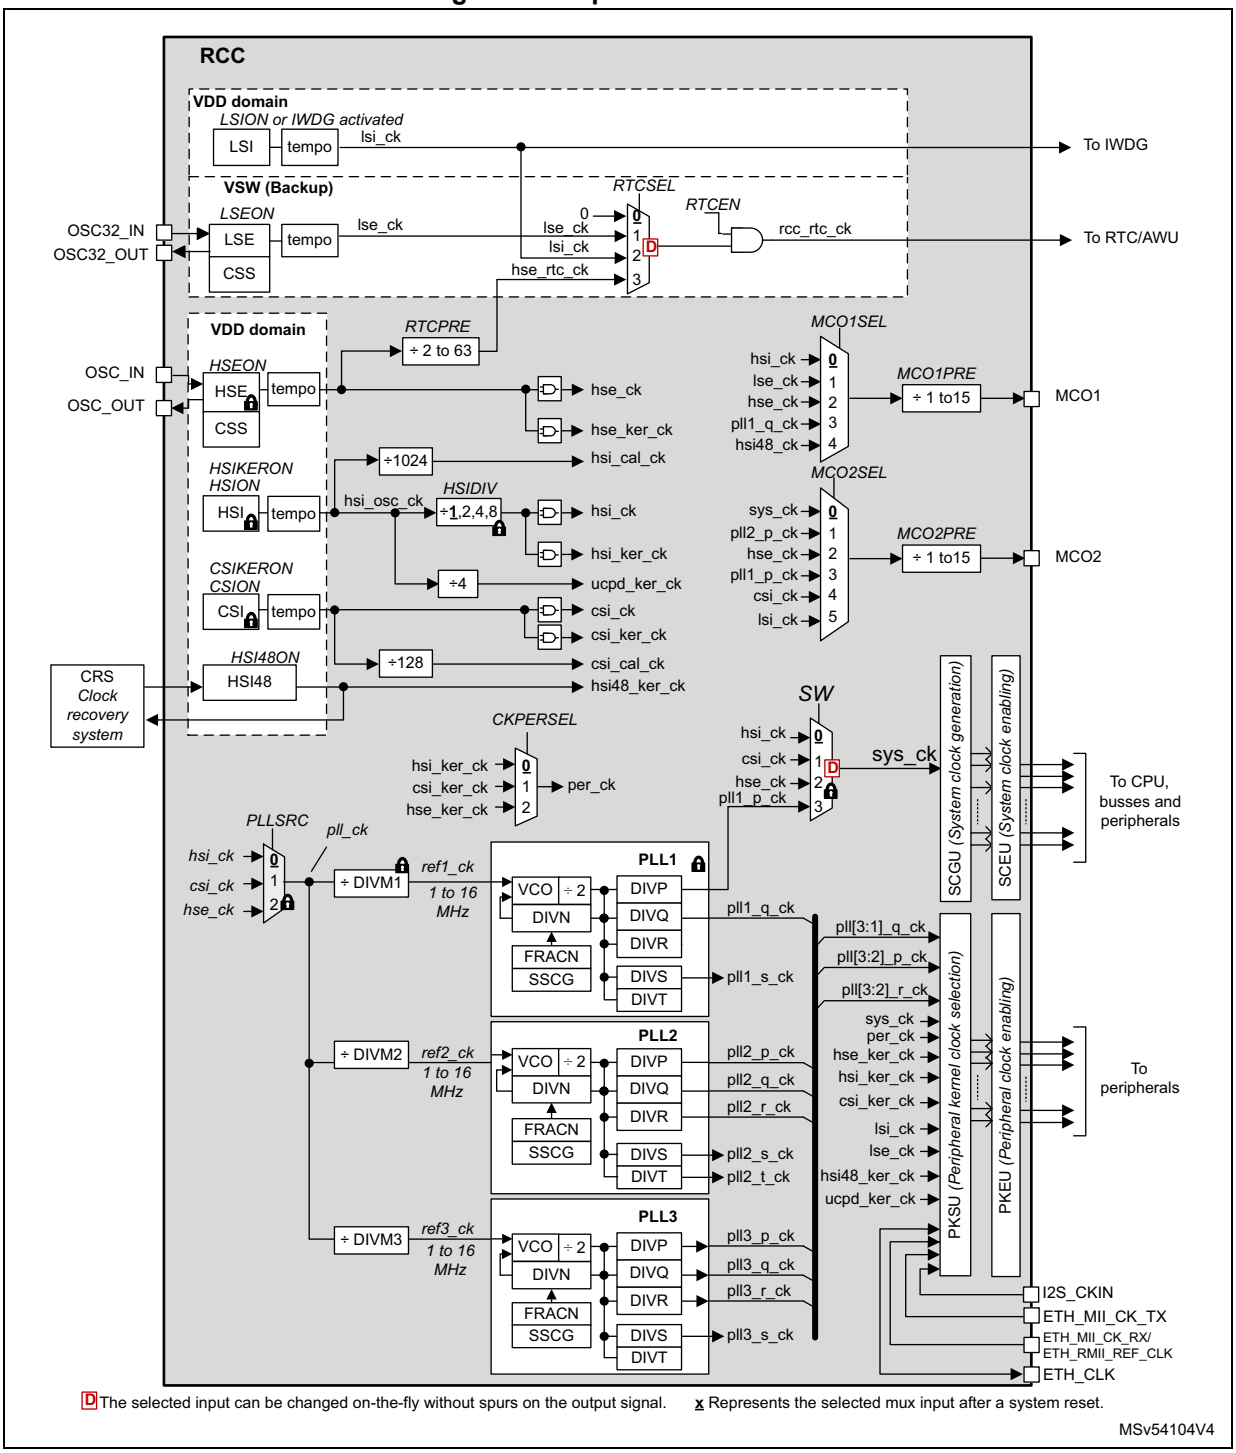
The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (high-speed external oscillator) clock: 4 to 50 MHz
- LSE (low-speed external oscillator) clock: 32 kHz
- LSI (low-speed internal oscillator) clock: ~ 32 kHz
- CSI (low-power internal oscillator) clock: ~4 MHz
- HSI48 (high-speed internal oscillator) clock: ~48 MHz

The RCC offers a high flexibility for the application to select the appropriate clock for CPU and peripherals, in particular for peripherals that require a specific clock such as SPI/I2S and SAI.

To optimize the power consumption, each clock source can be switched ON or OFF independently.

The RCC provides up to 3 PLLs; each of them can be configured in integer, with or without SSCG, or fractional mode.



As shown in the *Figure 40*, the RCC offers two clock outputs (MCO1 and MCO2), with a great flexibility on the clock selection and frequency adjustment.

The SCGU block (system clock generation unit) contains several prescalers used to configure the CPU and bus matrix clock frequencies.

The PKSU block (peripheral kernel clock selection unit) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PKEU (peripheral kernel clock enable unit) and SCEU (system clock enable unit) blocks perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.

Figure 40. Top-level clock tree

7.5.1 Clock naming convention

The RCC provides clocks to the complete circuit. To avoid misunderstanding, the following terms are used in this document:

- **Peripheral clocks**

  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clock are available:

  – bus interface clocks

  – kernel clocks

  A peripheral receives from the RCC a bus interface clock in order to access its registers, and thus control the peripheral operation. This clock is generally the AHB, APB or AXI clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (such as RNG, TIMx).

  Some peripherals also require a dedicated clock to handle the interface function. This clock is named kernel clock. As an example, peripherals such as SAI must generate specific and accurate master clock frequencies, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **CPU clock**

  The CPU clock is the clock provided to the CPU. It is derived from the system clock (**sys_ck**).

- **Bus matrix clocks**

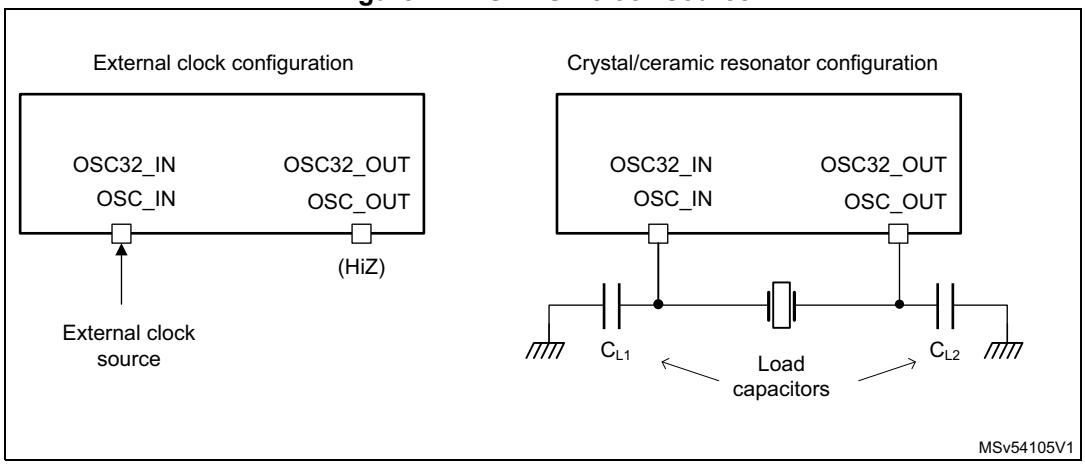
  The bus matrix clocks are the clocks provided to the different bridges (APB, AHB or AXI). These clocks are derived from the system clock (**sys_ck**).

7.5.2 Oscillators description

The table hereafter shows the oscillator states versus system modes, when the oscillators are enabled via registers. The term “available” means that the resource can be used if activated via registers.

Table 58. Oscillator states versus system modes

System modes	VDD domain					VSW domain
	HSE	HSI	HSI48	CSI	LSI	LSE
Exit from system reset	OFF	ON	OFF	OFF	Available	Available
Exit from system Stop	OFF	ON (1)	OFF	ON (2)	Available	Available
In Run/Sleep	Available	Available	Available	Available	Available	Available
In Stop	OFF	Available (3)	OFF	Available (4)	Available	Available
In Standby	OFF	OFF	OFF	OFF	Available	Available
In VBAT	OFF	OFF	OFF	OFF	OFF	Available



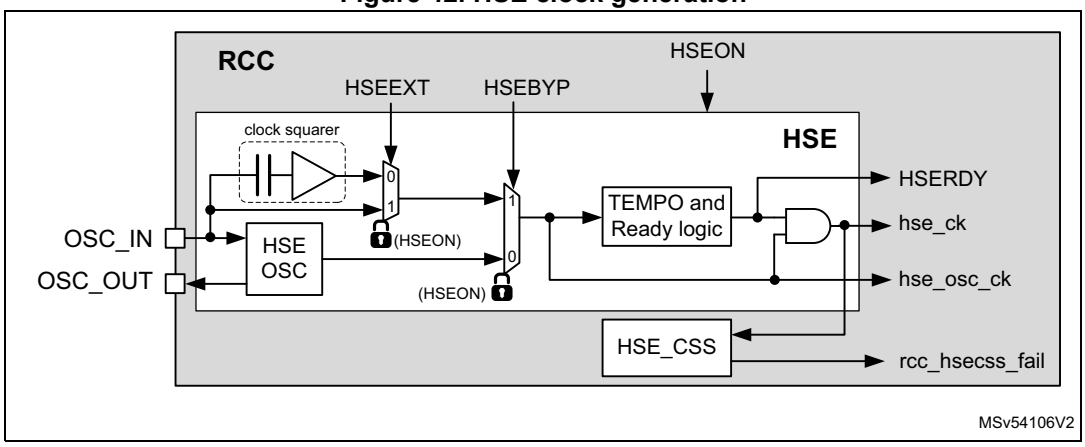
1. If STOPWUCK = 0 or STOPKERWUCK = 0
2. If STOPWUCK = 1 or STOPKERWUCK = 1
3. HSI can remain activated in Stop if HSIKERON = 1, or if a peripheral selecting HSI, generates a kernel clock request.
4. CSI can remain activated in Stop if CSIKERON = 1, or if the peripheral selecting CSI, generates a kernel clock request.

HSE oscillator

The HSE block allows the application to provide a very accurate high-speed clock for the product. The HSE can generate an internal clock from two possible sources:

- external clock source
- external crystal/ceramic resonator

Figure 41. HSE/LSE clock source



External clock source (HSE bypass)

In this mode the oscillator is not used, and an external clock source must be provided to OSC_IN pin. The external clock can be low swing (analog) or digital. The OSC_OUT pin must be left HI-Z (see *Figure 41*).

The external clock signal can be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude, is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected when HSEBYP = 1, and HSEON = 1. In case of an analog clock input (low swing) the HSEEXT must be set to 0, for a digital clock input, HSEEXT bits must be set to 1.

Figure 42. HSE clock generation

External crystal/ceramic resonator

A crystal/resonator can be connected as shown in *Figure 41*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is enabled by setting the HSEBYP bit to 0 and HSEON bit to 1.

HSE ready logic

The HSERDY flag indicates when a valid clock is available at HSE output (**hse_ck**). When the HSE is enabled (HSEON set to '1'), the HSERDY flag goes to '1' when 256 valid cycles of HSE have been detected. The **hse_ck** clock is not released until HSERDY goes to 1.

An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

HSE controls

The HSE can be switched ON and OFF through the HSEON bit.

The hardware does not allow modifying HSEON bit if one of the condition is met:

- The HSE is used directly (via SW switch) as system clock.
- The HSE is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via SW switch).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

The hardware does not allow changing the values of HSEBYP, and HSEEXT when HSEON = 1. Bits HSEBYP, HSEEXT and HSEON are located into the *RCC register map*.

The HSE is automatically disabled by hardware when the system enters Stop or Standby mode (See *Table 58: Oscillator states versus system modes*).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

Programming sequence

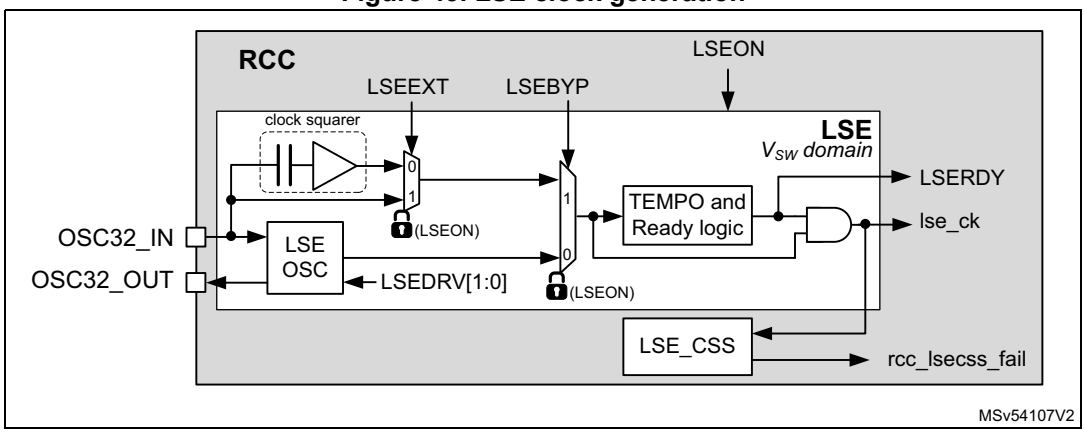
In order initialize the HSE, the application must follow the sequence hereafter:

- Make sure the HSE is not directly or indirectly used as system clock, if it is the case, use HSI or CSI as clock source for system clock.
- Make sure that XSPICKP and FMCCKP are set to 0
- Disable the HSE by writing to 0 the HSEON bit,
- Check that the HSE is disabled by waiting that the bit HSERDY is set to 0,
- If the oscillator mode is needed:
  - Select the oscillator mode by setting HSEBYP to 0,
- If an external clock is connected to OSC_IN:
  - Select the bypass mode by setting HSEBYP to 1,
  - If the input clock is a full-swing digital signal, set HSEEXT to 1
  - If the input clock is a low-swing signal, set HSEEXT to 0
- Enable again the HSE by writing the HSEON bit to 1,
- Wait for HSERDY = 1, then the HSE is ready for use.

LSE oscillator

The LSE block allows the application to provide a very accurate low-frequency clock for the product. The LSE can generate an internal clock from two possible sources:

- external user clock
- external crystal/ceramic resonator



External clock source (LSE bypass)

In this mode, the oscillator is not used, and an external clock source must be provided to OSC32_IN pin. The OSC32_OUT pin must be left HI-Z (see *Figure 41*).

The external clock signal can have a frequency up to 1 MHz and be digital or analog (square, sinus or triangle). An analog clock signal with a reduced amplitude, is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected by setting the LSEBYP and LSEON bits to 1. In case of an analog clock input (low swing) the LSEEXT must be set to 0, for a digital clock input, LSEEXT bits must be set to 1.

Figure 43. LSE clock generation

External crystal/ceramic resonator source (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It has the advantage to provide a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions. A crystal/resonator can be connected as shown in *Figure 41*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins in order to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is selected by setting LSEBYP bit to 0 and LSEON bit to 1.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to insure a stable oscillation.

The driving capability must be set before enabling the LSE oscillator.

Warning: It is not allowed to change the driving capability when the LSE is enabled. The LSE behavior is not guaranteed in that case.

LSE ready logic

The LSE offers a LSERDY flag which indicates whether the LSE clock is available or not. When the LSE is enabled (LSEON set to 1) the LSERDY flag goes to 1 when certain amount of valid cycles of LSE clock have been detected. The **lse_ck** clock is not released until LSERDY goes to 1.

When LSEBYP = 0, the RCC waits 4096 clocks cycles before activating the LSERDY flag, when LSEBYP = 1, the RCC waits 8 clocks cycles.

An interrupt, can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.

LSERDY bit is located into the *RCC Backup domain control register (RCC_BDCR)*.

LSE controls

The LSE control bits LSEBYP, LSEEXT, LSEDRV[1:0] and LSEON are located into the *RCC Backup domain control register (RCC_BDCR)*. This register is write-protected by DBP bit of PWR_CR1 register. In order to modify the RCC_BDCR register, the bit DBP must be set 1.

The LSE oscillator is switched ON and OFF using the LSEON bit.

The LSE remains enabled when the system enters Stop, Standby or VBAT mode (See *Table 58: Oscillator states versus system modes*).

The hardware does not allow changing the values of LSEBYP, and LSEEXT when LSEON = 1.

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for external components.

LSE Programming sequence

In order initialize the LSE, the application must follow the sequence hereafter:

- Set DBP bit of PWR_CR1 to 1 in order to allow write accesses to RCC_BDCR register.
- Disable the LSE by writing to 0 the LSEON bit,
- Check that the LSE is disabled by waiting that the bit LSERDY is set to 0,
- if the oscillator mode is needed:
  - Select the oscillator mode by setting LSEBYP to 0,
  - Configure LSEDRV[1:0],
- if an external clock is connected to OSC32_IN:
  - Select the bypass mode by setting LSEBYP to 1,
  - If the input clock is a full-swing digital signal, set LSEEXT to 1
  - If the input clock is a low-swing signal, set LSEEXT to 0
- Enable again the LSE by writing the LSEON bit to 1,
- Wait for LSERDY = 1, then the LSE is ready for use.
- If RCC_BDCR register no longer need to be changed, set DBP bit of PWR_CR1 to 0 in order to write-protect accesses.

If the RTC is used, the LSE bypass must not be configured in digital mode but in low swing analog mode (default value after reset).

HSI oscillator

The HSI block provides the default clock to the product.

The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider allows the application to select an HSI output frequency of 8, 16, 32 or 64 MHz. This predivider is controlled by the HSIDIV.

The HSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

HSI controls

The HSI can be switched ON and OFF using the HSION bit.

The hardware does not allow modifying HSION bit if one of the condition is met:

- The HSI is used directly (via software mux) as system clock.
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

Note that the HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case the hardware does not update the HSIDIV with the new value. However it is possible to change the HSIDIV if the HSI is used directly as system clock.

The HSIRDY flag indicates if the HSI is stable or not. At startup, the HSI output clock is not released until this bit is set by hardware.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *Section : CSS on HSE*).

The HSI can be disabled or not when the system enters Stop mode (See *Table 58: Oscillator states versus system modes*).

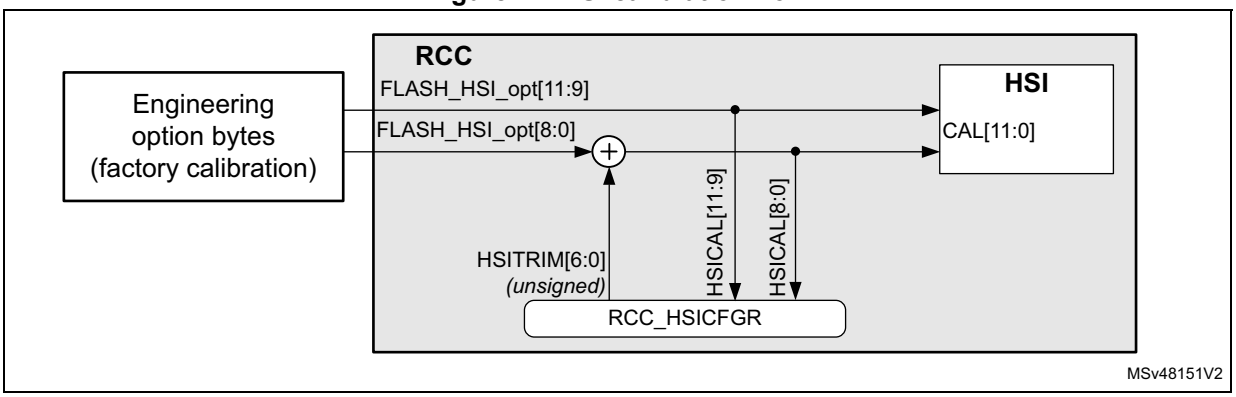
In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals, the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency accuracy.

HSION, HSIRDY and HSIDIV bits are located in the *RCC register map*.

HSI calibration



RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. That is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI} (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the HSICAL[11:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

Note: HSICAL[11:0] and HSITRIM[6:0] bits are located in the RCC HSI calibration register (RCC_HSICFGR).

Figure 44. HSI calibration flow

CSI oscillator

The CSI is a low-power RC oscillator that can be used directly as system clock, peripheral clock, or PLL input.

The CSI advantages are the following:

- low-cost clock source since no external crystal is required
- faster startup time than HSE (a few microseconds)
- very low-power consumption.

The CSI provides a clock frequency of about 4 MHz, while the HSI is able to provide a clock up to 64 MHz.

CSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

CSI controls

The CSI can be switched ON and OFF through the CSION bit. The CSIRDY flag indicates whether the CSI is stable or not. At startup, the CSI output clock is not released until this bit is set by hardware.

The hardware does not allow modifying CSION bit if one of the condition is met:

- The CSI is used directly (via software mux) as system clock.
- The CSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via software mux).
- The bit XSPICKP is set to 1.
- The bit FMCCKP is set to 1.

The CSI can be disabled or not when the system enters Stop mode (See *Table 58: Oscillator states versus system modes*).

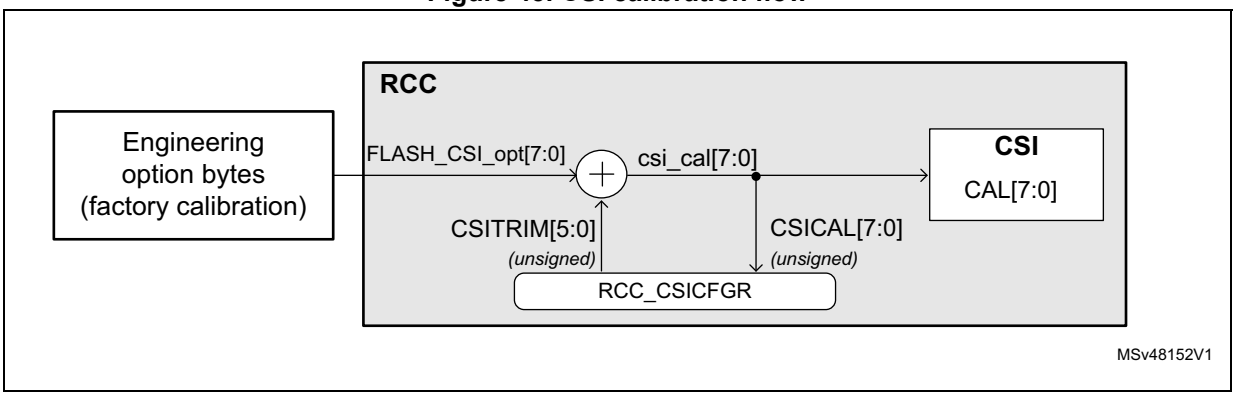
In addition, the CSI clock can be driven to the MCO2 output and used as clock source for other application components.

Even if the CSI settling time is faster than the HSI, care must be taken when the CSI is used as kernel clock for communication peripherals: the application must take into account the following parameters:

- the time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- the frequency precision.

Note: CSION and CSIRDY bits are located in the RCC register map.

CSI calibration



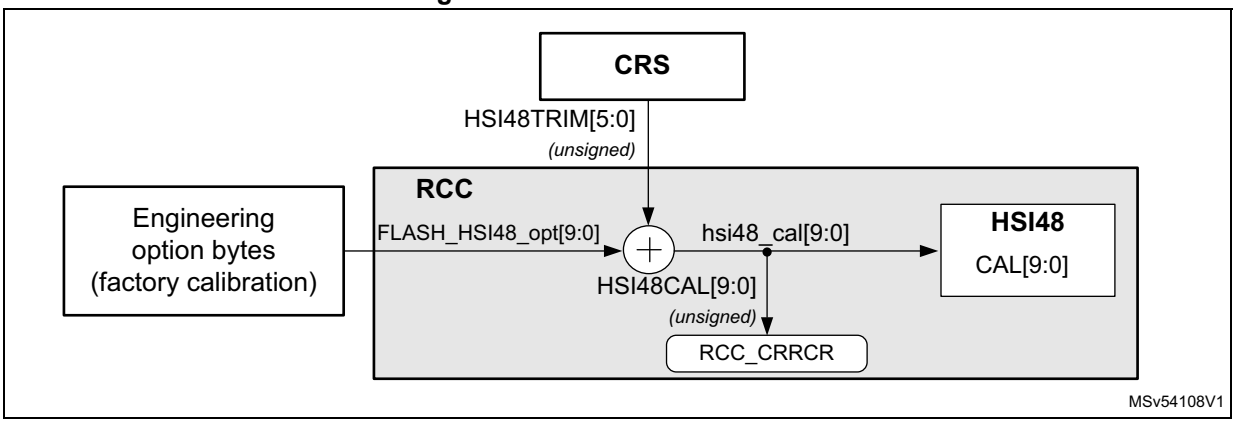
RC oscillator frequencies can vary from one chip to another due to manufacturing process variations, this is why each device is factory calibrated by STMicroelectronics to achieve accuracy of ACC_{CSI} (refer to the product datasheet for more information).

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded in the CSICAL[7:0] bits.

If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the CSI frequency using the CSITRIM[5:0] bits.

Note: Bits CSICAL[7:0] and CSITRIM[5:0] are located into the RCC CSI calibration register (RCC_CSICFGR)

Figure 45. CSI calibration flow



HSI48 oscillator

The HSI48 is an RC oscillator delivering a 48 MHz clock that can be used directly as kernel clock for some peripherals.

The HSI48 oscillator mainly aims at providing an accurate clock to the USB Full-Speed peripherals by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE or an external signal to automatically adjust the oscillator frequency on-the-fly, with a very small granularity. It is possible to read the calibration value provided to the HSI48 via *RCC clock recovery RC register (RCC_CRRCR)*. The HSI48TRIM value can be adjusted through the CRS block, for more details, refer to *Section 9: Clock recovery system (CRS)*.

Figure 46. HSI48 calibration flow

The HSI48 oscillator is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, this oscillator is free running and thus subject to manufacturing process variations. This is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI48} (refer to the product datasheet for more information).

The HSI48RDY flag indicates whether the HSI48 oscillator is stable or not. At startup, the HSI48 output clock is not released until this bit is set by hardware.

After a power-on reset, or at the exit of Standby mode, the factory calibration value is loaded into the HSI48.

The HSI48 can be switched ON and OFF using the HSI48ON bit.

The HSI48 clock can also be driven to the MCO1 multiplexer and used as clock source for other application components.

Note: HSI48ON and HSI48RDY bits are located in the RCC register map.

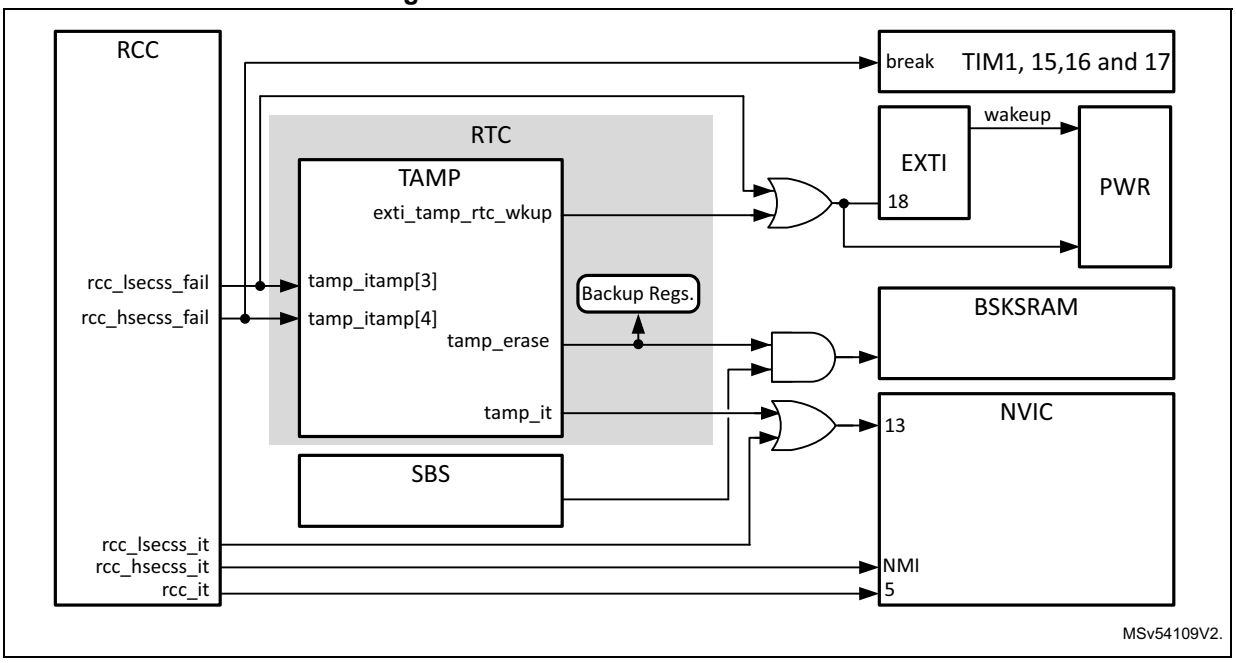
LSI oscillator

The LSI acts as a very-low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG) and auto-wake up unit (AWU). The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced ON and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode (See *Table 58: Oscillator states versus system modes*).

At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC clock source interrupt enable register (RCC_CIER)*.



In addition, the LSI clock can be driven to the MCO2 output and used as a clock source for other application components.

Note: Bits LSION and LSIRDY bits are located into the RCC clock control and status register (RCC_CSR).

7.5.3 Clock security system (CSS)

The RCC offers a clock security system for the HSE and LSE oscillators. The clock security systems are capable of detecting a failure on HSE and LSE oscillators. The figure hereafter shows how this function interact with other blocks.

Figure 47. LSE and HSE CSS function

CSS on HSE

The clock security system can be enabled by software via the HSECSSON bit. The HSECSSON bit can be enabled even when the HSEON is set to 0.

The CSS on HSE is activated when the HSE is enabled and ready, and the software sets the HSECSSON bit to 1. The CSS on HSE is no longer working when the HSE is disabled. For example, this function does not work when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software. The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode (see *Section 7.4.2: The system and application resets (sys_rst and nreset)*).

When the CSS on HSE is enabled, the following actions are done by the RCC if a failure is detected:

- The signal **rcc_hsecss_fail** is asserted.
- If the STOPWUCK = 0, the HSI clock is enabled and the SW switch automatically selects HSI as system clock.
- If the STOPWUCK = 1, the CSI clock is enabled and the SW switch automatically selects CSI as system clock.
- The HSE is then automatically disabled.
- If the HSE output was used as clock source for PLLs, the PLLs are also disabled.
- The XSPI[2:1]SEL switches go to recovery position.
- The FMCSEL switch goes to recovery position:
  - if PLL1 has been disabled and FMCSEL is in position 1.
  - if PLL2 has been disabled and FMCSEL is in position 2.

  See details on *Section : Clock distribution for SDMMCs, FMC, and XSPIs*.
- The clock failure event (**rcc_hsecss_fail**) is also sent to the break inputs of advanced-control timers (TIM1, TIM15, TIM16 and TIM17).
- A NMI interrupt is generated to inform the software about the failure (CSS interrupt: ***rcc_hsecss_it***), thus allowing the MCU to perform rescue operations. The CSS interrupt is asserted until the HSECSSF bit is cleared. The HSECSSF flag can be cleared by setting the HSECSSC bit in the *RCC clock source interrupt clear register (RCC_CICR)*.
- A tamper event can also be triggered, in order to clear content of the backup registers, and backup RAM.

CSS on LSE

A clock security system on the LSE oscillator can be enabled by software by programming the LSECSSON bit in the *RCC Backup domain control register (RCC_BDCR)*.

This bit is disabled by hardware if one of the following condition is met:

- After a V_{SW} hardware reset (**pwr_vsw_rst),**
- After a V_{SW} software reset via VSWRST bit

The software can also disable the clock security system after a LSE failure detection.

The CSS on LSE works in all modes (Run, Stop and Standby) including VBAT.

The LSECSS provides a re-arm feature, offering to the software the possibility to re-arm the LSECSS and re-enable the LSE clock when a failure has been detected. This feature allows the application to decide if the LSE is to be provided again to the RTC even if a failure occurred, or if another action must be performed. For example the application can decide to reset the V_{SW} domain only if a certain amount of consecutive LSE failures occurred, within a time window.

The LSECSS offers two flag signals:

- The LSECSSD, capable of retaining an LSE failures even in VBAT mode.
- The LSECSSF used to generate interrupt in case of LSE failure. This flag is not affected by a failure detected when the product is in VBAT mode

The sequence hereafter describes the LSE enabling sequence with the clock security system enabled.

- Follow the LSE enable procedure given is the section *LSE Programming sequence*, except the last step
- Select the LSE clock via RTCSEL[1:0]
- Set the LSECSSON bit to 1
- If RCC_BDCR register no longer needs to be changed, set DBP bit of PWR_CR1 to 0 in order to write-protect accesses.

Note: The LSECSSON bit must be enabled after the LSE is enabled (LSEON bit set by software) and ready (LSERDY set by hardware), and after the RTC clock has been selected through the RTCSEL bit.

If a failure is detected on the LSE, the hardware does the following:

- The LSE clock is no more delivered to the RTC.
- The values of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.
- A failure event is generated (**rcc_lsecss_fail**). This event allows the system to wake-up from Standby, but also to protect the backup registers and BKPSRAM via TAMP block. This event is also generated in VBAT mode.
- The interrupt flag LSECSSF is activated (except in VBAT mode) in order to generate an interrupt (**rcc_lsecss_it**).
- The LSECSSD flag is activated as well, retaining the first LSE failure even in VBAT.

In the software side, different actions can be taken according to the application requirements. Three different cases are described hereafter in order to illustrate the hardware behavior, they can also be combined. The application can also decide to handle LSE failure differently.

Case A:

The application no longer wants to use LSE when a failure is detected:

- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Disable the CSS function (this step is mandatory)
  - Clear the LSECSSF bit, if interrupt was enabled for this event
  - Set the LSECSSON bit to 0
  - Set the LSEON bit to 0, in order to disable the LSE
- Change the clock source for the RTC if needed:
  - Set the RTCEN bit to 0 to disable the RTC clock
  - Enable the new clock source for the RTC
  - Select the proper clock source via RTCSEL
  - Set the RTCEN bit to 1 to enable the RTC clock
- The application must perform specific actions consecutive to TAMPER events if enabled
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

Case B:

The application wants to re-initialize the V_{SW} domain:

- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Perform a VSW reset by setting VSWRST bit to 1, then back to 0 (it is in reality a pulse of one period of sys_ck)
- The application must perform specific actions consecutive to TAMPER events if enabled
- Re-initialize all components of the VSW domain.
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

Case C:

The application tries to re-use LSE when a failure is detected:

- If the number of failures in a given time window is higher than a given threshold then go to case A or B. Otherwise continue to next step.
- Unlock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 1
- Clear the LSECSSF bit if interrupt was enabled for this event.
- The application must perform specific actions consecutive to TAMPER events if enabled
- Set the LSECSSON bit to 0.
- Re-arm the LSECSS function by writing the LSECSSRA bit to 1, then back to 0.
- Wait for LSERDY set 1. The LSERDY flag must go to 1 after the oscillator settling time delay plus, 4096 periods of LSE clock. If this is not the case, it probably means that the LSE failure is permanent. It is not possible to set LSECSSON to 1, it is recommended to execute case A or B.
- Set the LSECSSON bit to 1.
- When LSECSSON is seen to 1, the LSE is enabled, and protected by LSECSS.
- Lock RCC_BDCR register by setting the DBP bit of PWR_CR1 to 0

All bits used in this sequences (except DBP) are located into *RCC Backup domain control register (RCC_BDCR)*.

7.5.4 Clock output generation (MCO1/MCO2)

Two microcontroller clock output pins MCO1 and MCO2, are available. A clock source can be selected for each output.The selected clock can be divided thanks to configurable prescaler (refer to *Figure 40* for additional information on signal selection).

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1SEL[2:0], MCO2PRE[3:0] and MCO2SEL[2:0] located in the *RCC clock configuration register (RCC_CFGR)*.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

The dividers MCO1PRE and MCO2PRE, provide a clock with a duty cycle of 50% for even divisions values. More generally the duty cycle is given by the following formula:

$$DC(\%) = \frac{\text{FLOOR}\left(\frac{\text{MCOxPRE}}{2}\right)}{\text{MCOxPRE}} \times 100$$

For MCOxPRE = 2 to 15.

Note that the MCO1 and MCO2 outputs are available in Run and Stop modes.

Caution: The clock provided to the MCOs outputs must not exceed the maximum PAD speed, refer to the product datasheet for information about the supported PAD speed.

The table hereafter show the signals available on each MCO output.

Table 59. Oscillator states versus system modes

MCO1SEL		MCO2SEL	
Pos.	**Clock source**	**Pos.**	**Clock source**
0	hsi_ck	0	sys_ck
1	lse_ck	1	pll2_p_ck
2	hse_ck	2	hse_ck
3	pll1_q_ck	3	pll1_p_ck
4	hsi48_ck	4	csi_ck
-	-	5	lsi_ck

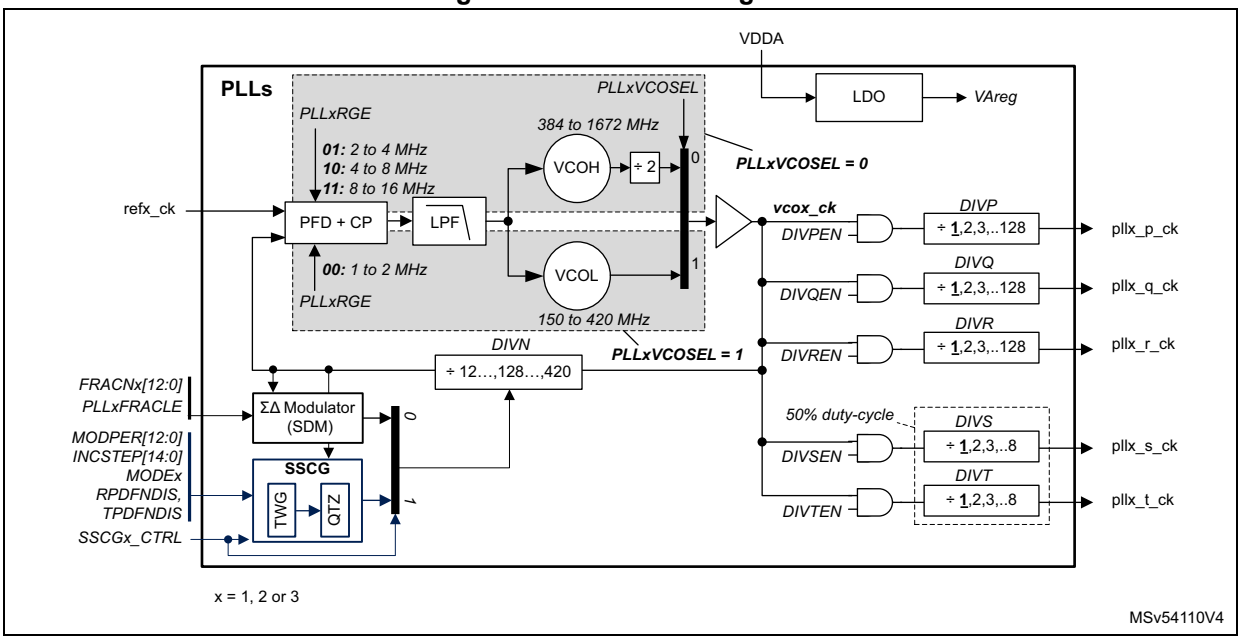
7.5.5 PLL description

The RCC features three PLLs:

- PLL1, generally used to provide clocks to the CPU, busses, and some peripherals
- PLL2, generally used to provide clocks to XSPI and SDMMC, and some peripherals
- PLL3, dedicated to the kernel clock generation for peripherals

The PLLs integrated into the RCC are completely independent. They offer the following features:

- A VCO supporting two modes:
  - a wide-range
  - a low-range used for instance in audio application cases
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- VCO frequency range:
  - 384 to 1672 MHz for the VCO in high-range mode (VCOH), before the divider.
  - 150 to 420 MHz for the VCO in low-range mode (VCOL)
- Capability to work either in integer with or without SSGC, or in fractional mode
- 13-bit sigma-delta modulator, allowing to fine-tune the VCO frequency by steps of 10 to 0.3 ppm
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs.
- PLLs offer up to 5 outputs with post-dividers.



For better flexibility, all PLLs offer two VCOs (VCOH and VCOL), the application can select the wanted VCO via PLLxVCOSEL bit.

The frequency of the reference clock provided to the PLLs (**refx_ck**) must range from 1 to 16 MHz. The DIVMx dividers of the *RCC PLLs clock source selection register (RCC_PLLCKSELR)* must be properly programmed in order to match this condition. In addition, the PLLxRGE[1:0] field of the *RCC PLLs configuration register (RCC_PLLCFGR)* must be set according to the reference input frequency to guarantee an optimal performance of the PLL.

The user application can then configure the proper VCO. VCOL must be chosen when the reference clock frequency is lower than 2 MHz.

To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.

Figure 48. PLL block diagram

The PLLs can be enabled by setting PLLxON to 1. The PLLxRDY bits indicate that the PLL is ready (means locked).

The DIVN loop divider must be programmed to achieve the expected frequency at VCO output. The VCO output range must be respected.

PLLs have a divider-by-2, at VCOH output, insuring that the clock provided to the post-dividers has a duty-cycle of 50%.

The frequency of the clocks provided by the PLLs can also be adjusted thanks to post-divider DIVP, DIVQ, DIVR, DIVS and DIVT. The post-divider values can be changed without disabling the PLLs, if their respective enable bits are set to 0.

The post-dividers provide clocks with 50% duty-cycle in the following conditions:

- When the post-dividers are dividing the clock by an even value.
- When VCOH is used and post-dividers are bypassed.
- When VCOH is selected and post-dividers DIVS and DIVT are used,

PLL programming recommendations

This section is providing a list of recommendations to follow in order to guarantee a good usage of the PLLs. Note that programming examples are given in Section 1.6.2: PLL programming.

- Before enabling the PLLs, the user must ensure that the reference frequency (**refx_ck**) provided to the PLL is stable and in the good range.
- When one or several PLL outputs are not used, the application must set the corresponding enable bit DIV[y]ENx and the divider value DIV[y]x to 0 (with x = 1, 2 or 3, and y = P, Q, R, S or T).
- In order to ensure the good behavior of the PLL, the bits PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN must be set to 0 before disabling the corresponding PLL. In the same way, the bits PLLxPEN, PLLxQEN, PLLxREN,

PLLxSEN and PLLxTEN can be set to 1 only if the corresponding bit PLLON is already set to 1 and the PLL is ready.

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

PLL protections

- The RCC hardware does not allow changing DIVMx, DIVN, PLLxRGE, PLLxVCOSEL when the corresponding PLLx is ON and it is also not possible to change PLLSRC when one of the PLL is ON.
- The RCC hardware does not allow changing of the post-dividers' DIVy when the corresponding PLLxyEN bit is set to 1 (with x = 1, 2 or 3, and y = P, Q, R, S or T).
- The hardware prevents writing PLL1ON or PLL1PEN to 0 if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to *Section 7.5.7: Clock protection*).

The PLLs are disabled by hardware when the system enters Stop or Standby mode

PLLs using HSE as reference clock are also disabled by hardware if an HSE failure is detected.

Note: The refx_ck clock is provided to the PLLx when the corresponding PLLON bit is set to 1.

The PLLs can work in 3 different modes:

- In integer mode
- In fractional mode
- In spread spectrum mode

Using the PLLs in integer mode

The PLL is working in integer mode when the sigma-delta modulator (SDM) is loaded with a 0, and the bit PLLxSSCGEN = 0.

In order to load 0 into the SDM, the user has to perform the following sequence:

– Write PLLxFRACLE of *RCC PLLs configuration register (RCC_PLLCFGR)* to 0
– Write FRACN[12:0] to 0,
– Write PLLxFRACLE to 1
– Wait at least 5 µs

The bits FRACN[12:0] are located in the RCC_PLLxFRACR registers.

The VCO frequency (F_{VCO}) and output frequencies expressions are given by the following table:

Table 60. VCO frequency and output frequency in integer mode

PLLxVCOSEL = 0	PLLxVCOSEL = 1
$F_{VCO} = 2 \times F_{ref_ck} \times (DIVN + 1)$	$F_{VCO} = F_{ref_ck} \times (DIVN + 1)$
$F_{pll_y_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}$ with y = P, Q, R, S or T	$F_{pll_y_ck} = \frac{F_{VCO}}{(DIVy + 1)}$ with y = P, Q, R, S or T

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

Using the PLLs in fractional mode

The fractional mode is activated when the value loaded into the SDM is different from 0, and the bit PLLxSSCGEN = 0.

The SDM value can be updated at anytime by the application by executing the following sequence:

- Write PLLxFRACLE bit to ‘0’
- Write into FRACN[12:0] the new fractional value,
- Write PLLxFRACLE to ‘1’.
  The new FRACN value is loaded into the SDM when PLLxFRACLE bit goes from 0 to 1.
- Wait at least 5 µs

The sigma delta modulator is designed in order to minimize the jitter impact while allowing very small frequency steps.

When the PLL is used in fractional mode, the DIVN divider must be initialized before enabling the PLL.
This feature can be used either to generate a specific frequency, with a good accuracy from any crystal value, or to perform a fine tuning of the frequency on-the-fly.

The VCO frequency (F_{VCO}) and output frequencies expressions are given by the following table:

Table 61. VCO frequency and output frequency in fractional mode

PLLxVCOSEL = 0	PLLxVCOSEL = 1
$F_{VCO} = 2 \times F_{ref_ck} \times \left(DIVN + 1 + \frac{FRACN}{2^{13}} \right)$	$F_{VCO} = F_{ref_ck} \times \left(DIVN + 1 + \frac{FRACN}{2^{13}} \right)$
$F_{pll_y_ck} = \frac{F_{VCO}}{2 \times (DIVy + 1)}$ with y = P, Q, R, S or T	$F_{pll_y_ck} = \frac{F_{VCO}}{(DIVy + 1)}$ with y = P, Q, R, S or T

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

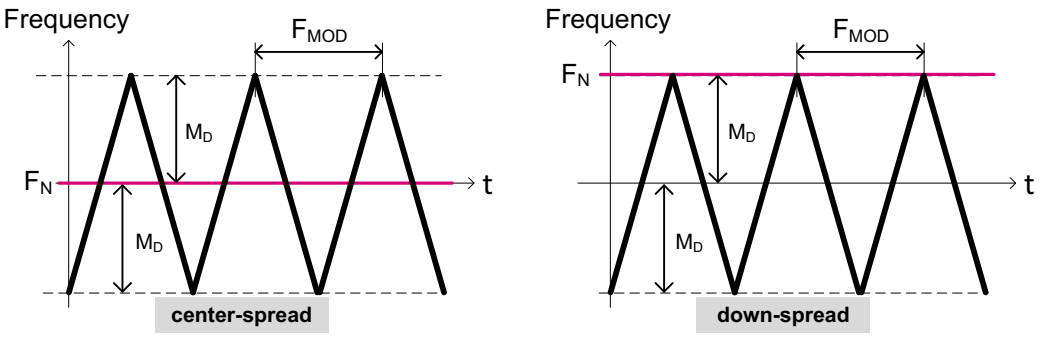
Using the PLLs in spread spectrum mode

The spread spectrum mode is activated when the SDM loaded with 0, and the bit PLLxSSCGEN = 1. This feature is available on all PLLs.

The VCOH must be selected when the spread spectrum mode is activated. VCOH is selected by setting PLLxVCOSEL to 0. PLLxVCOSEL are located into the *RCC clock configuration register (RCC_CFGR)*.

The spread spectrum technique consist of modulating the VCO frequency with a low-frequency signal (in our case a triangular signal), in order to spread the clock energy into a wider frequency band. As a consequence, the amount of emitted EMI peaks is reduced.

The parameters of the spread spectrum modulation are adjusted via the following fields:



- MODPER[12:0]: used to adjust the modulation frequency
- INCSTEP[14:0]: used to adjust the modulation depth (or modulation index)
- SPREADSEL: used to define if the modulation is centered around the VCO frequency (center-spread) or if it is lowered with respect to VCO frequency (down-spread).

The bits MODPER[12:0], INCSTEP[14:0] and SPREADSEL are located into the RCC_PLLxSSCGR registers with x=1, 2 or 3.

Figure 49 shows the signal modulating the nominal frequency (F_N), when SPREADSEL = 0 (center-spread) and SPREADSEL = 1 (down-spread). The nominal frequency is the frequency output by the PLL in integer mode, when no clock spreading is applied.

Setting the SPREADSEL bit to ‘1’ (down-spread) guarantees that the PLL output frequency does not exceed the programmed frequency value when the SSCG is enabled.

Figure 49. Spread-spectrum modulation

The peak modulation depth (in percentage) is given by the following formula:

$$M_D\ (\%) = \frac{MODPER \times INCSTEP \times 100 \times 5}{(2^{15} - 1) \times (DIVN + 1)}$$

Note that MODPER x INCSTEP must not exceed (2^{15}-1).

The modulation frequency (F_{mod}) is given by:

$$F_{mod} = \frac{F_{ck_ref}}{4 \times MODPER}$$

Note: Refer to the datasheet of the product for the recommended modulation frequency range

In order to use the spread spectrum feature, the user has to do the following:

- Program the PLL as explained into *Section : Using the PLLs in integer mode* in order to adjust the nominal frequency (F_N) according to the targeted by the application.
- Compute the MODPER value according to the wanted modulation frequency (F_{mod}):

$$MODPER = ROUND\left(\frac{F_{ck_ref}}{4 \times F_{mod}}\right)$$

- Compute the INCSTEP value according to the wanted modulation depth (M_D):

$$INCSTEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MODPER}\right)$$

  Check that MODPER x INCSTEP does not exceed (2^{15}-1).
- Then DIVP, Q, R, S or T can be adjusted, and the bit PLLxSSCGEN can be set to 1, and the PLL enabled.

The user can check F_{MIN},F_{MAX} and F_C as follow:

- If SSCG_MODE = ‘0’ (centered-spread)

  F_C is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_C \times (1 - M_D/100)$

  $F_{MAX} = F_C \times (1 + M_D/100)$

- If SSCG_MODE = ‘1’ (down-spread)

  F_{MAX} is given by the formula of the *Section : Using the PLLs in integer mode*

  $F_{MIN} = F_{MAX} \times (1 - 2 \times M_D/100)$

  $F_C = F_{MAX} \times (1 - M_D/100)$

Figure 50 shows the digital signal generated by Triangular Waveform Generator (TWG block), and the way of MODPER and INCSTEP are changing the triangular waveform.

Figure 50. Triangular waveform generator

Refer to section *Section 7.7.1: PLL programming procedure* for additional information.

7.5.6 System clock (sys_ck)

System clock selection

After a system reset, the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, it is not possible for the software to disable the selected source via the xxxON bits.

Of course, the system clock can be stopped by the hardware when the system enters Stop or Standby mode.

When the system is running, the user application can select the system clock (**sys_ck**) among the 4 following sources:

- HSE
- HSI
- CSI
- pll1_p_ck

This function is controlled by programming the *RCC clock configuration register (RCC_CFGR)*. A switch from one clock source to another occurs only if the target clock

source is ready (clock stable after startup delay or PLL locked). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The SWS status bits in the *RCC clock configuration register (RCC_CFGR)* indicate which clock is currently used as system clock. The other status bits in the RCC_CR register indicate which clock(s) is (are) ready.

System clock generation

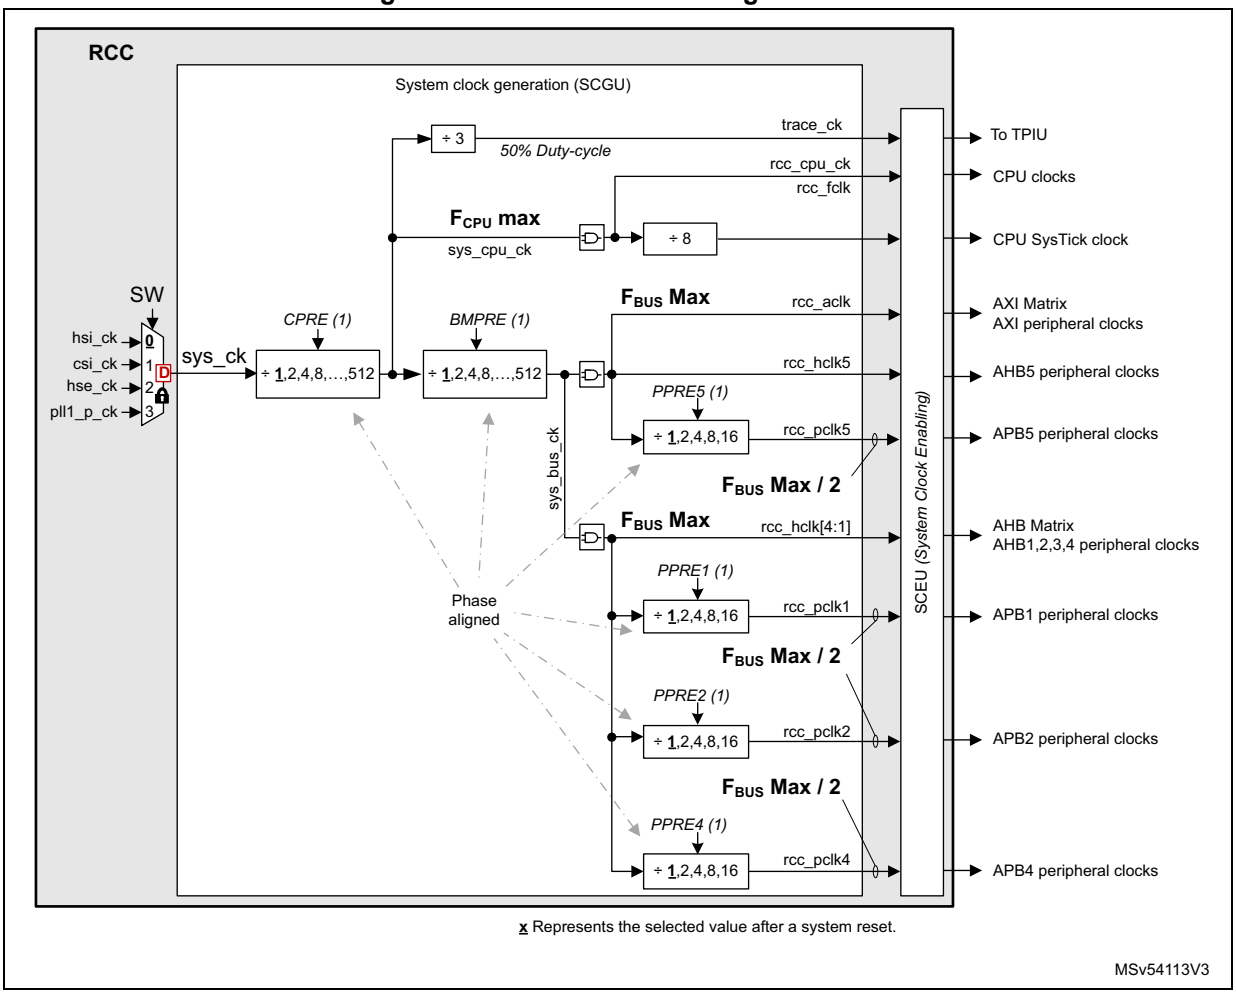


Figure 51 shows a simplified view of the clock distribution for the CPU and busses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simple solution to adapt the busses frequencies to the application needs, thus optimizing the power consumption.

The CPRE divider can be used to adjust the CPU clock. However this also impacts the clock frequency of all bus matrix. CPRE is controlled via RCC_CDCFGR register.

In the same way, BMPRE divider can be used to adjust the clock for the bus matrix (AHB and AXI), but this also impacts the clock frequency of APB busses. BMPRE is controlled via RCC_BMCFGR register.

Most of the prescalers are controlled via RCC_CDCFGR and RCC_SRDCFGR registers.

Figure 51. Core and bus clock generation

1. Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles.

Note that the application must respect the maximum allowed frequencies: F_{CPU} Max and F_{BUS} Max. F_{BUS} represents the maximum allowed frequency for the AHB and AXI busses. Refer to the product datasheet for maximum values.

Note as well that the trace clock (**trace_ck**) is generated from **sys_cpu_ck** clock, divided by 3. For additional information refer to *Section : Clock distribution for Debug and Trace*.

7.5.7 Clock protection

The RCC does not allow to disable the system clock (**sys_ck**). Several protections are implemented in order to prevent actions disabling accidentally the system clock.

In addition, protection bits are available in order to prevent accidental disabling of FMC and XSPI block activities.

The protections consist on ignoring the invalid write operations. It is recommended to read back registers having protection to insure that the clock configuration expected by the software is accepted by the RCC.

The table hereafter shows the protections handled by the RCC.

Table 62. Clock protection summary

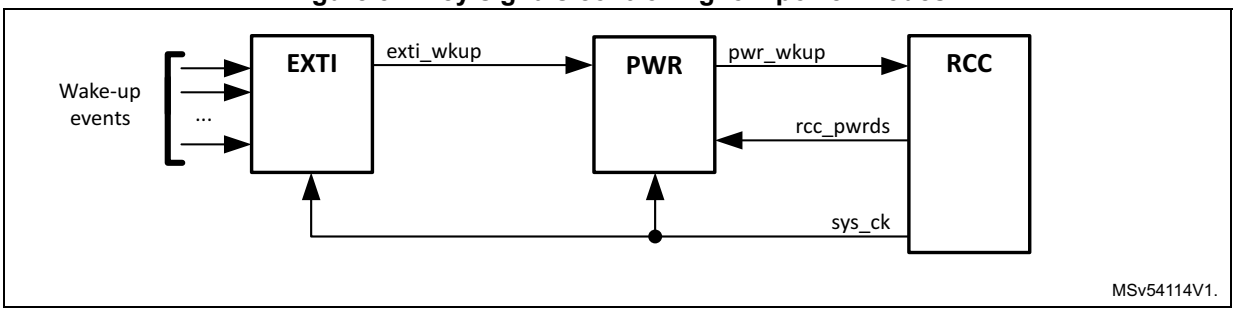
Protected fields	Conditions checked by the RCC
SW[2:0]	Changing SW value is allowed only if the targetted clock is enabled and ready.
PLLSRC[1:0]	Changing PLLSRC value is allowed if: - The targetted clock is enabled and ready, and, - All PLL disabled
HSEON, HSION or CSION	Changing these fields is allowed if: - The oscillator is not used directly or indirectly (via PLL1) as system clock, and - FMCCKP = XSPICKP = 0.
DIVMx[5:0], PLLxRGE[1:0], PLLxVCOSEL, DIVN[8:0]	Changing these fields is allowed only if the corresponding PLL is disabled (PLLxON=0)
DIVP[6:0], DIVQ[6:0], DIVR[6:0], DIVS[2:0], DIVT[2:0]	Changing these fields is allowed only if the corresponding DIVyEN bit is equal to 0 (y = P, Q, R, S or T)
PLL1ON	Changing this field is allowed if: - SW switch is not selecting the PLL1, and - FMCCKP = 0.
PLL1PEN	Disabling the DIVP output of PLL1 is allowed if the SW switch is not selecting PLL1
PLL2ON	Changing this field is allowed only if FMCCKP = XSPICKP = 0.
PLL2SEN, PLL2TEN, XSPI1EN XSPI2EN, XSPI1LPEN XSPI2LPEN, XSPI1RST XSPI2RST	Changing these fields is allowed only if XSPICKP = 0.
PLL1QEN, PLL2REN, FMCEN, FMCLPEN, FMCRST	Changing these fields is allowed only if FMCCKP = 0.
HSEBYP, HSEEXT	Changing these fields is allowed only if HSEON = 0.
LSEBYP, LSEEXT	Changing these fields is allowed only if LSEON = 0.

There is also clock protection mechanism in case of HSE failure, refer to *Section : CSS on HSE*.

7.5.8 Clock generation in Stop and Standby modes

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped and the following clock sources are disabled as well:

- CSI, HSI (depending on HSIKERON, and CSIKERON bits)
- HSE
- PLL1, PLL2 and PLL3
- HSI48



The content of the RCC registers is not altered except for PLL1ON, PLL2ON, PLL3ON HSEON and HSI48ON that are set to 0.

HSION and CSION bits are also affected depending on STOPWUCK and STOPKERWUCK bits (see *Table 63*).

When the CPU requested to go in Stop mode, the RCC first stop all the requested clocks, and inform the PWR that all clocks have been properly stopped. As shown in *Figure 52*, three main signals are used to control power transitions:

- The **rcc_pwrds** is used to indicate to the PWR that the RCC has stopped all the clocks, and thus the PWR can go to Stop or Standby.
- The **pwr_wkup** is used to indicate to the RCC to re-enable the clocks.
- The **exti_wkup** is used to indicate to the PWR that an event requests to exit the system from Stop mode.

Figure 52. Key signals controlling low-power modes

Exiting Stop mode

When the microcontroller exits system Stop mode via a wake-up event, the application can select which oscillator (HSI and/or CSI) is used to restart. The STOPWUCK bit selects the oscillator used as system clock. The STOPKERWUCK bit selects the oscillator used as kernel clock for peripherals. The STOPKERWUCK bit is useful if after a system Stop, a peripheral needs a kernel clock generated by an oscillator different from the one used for the system clock.

All these bits belong to the *RCC clock configuration register (RCC_CFGR)*.

Table 63 gives a detailed description of their behavior.

Table 63. STOPWUCK and STOPKERWUCK description

STOPWUCK	STOPKERWUCK	-	Activated oscillator when system exits Stop mode	Distributed clocks when system exits Stop mode	
				System clock	Kernel clock
0	0	→	HSI	HSI	HSI
	1	→	HSI and CSI		HSI and/or CSI
1	0	→		CSI	
	1	→	CSI		CSI

During Stop mode

There are two specific cases where the HSI or CSI can be enabled during system Stop mode:

- when a dedicated peripheral requests the kernel clock
  The peripheral receives the HSI or CSI according to the kernel clock source selected for this peripheral (via PERxSRC).
- when the HSIKERON or CSIKERON bits are set the HSI and CSI are kept running during Stop mode but the outputs are gated. The clock is then available immediately when the system exits Stop mode or when a peripheral requests the kernel clock (see *Table 64* for details).

HSIKERON and CSIKERON bits belong to *RCC register map*. *Table 64* gives a detailed description of their behavior.

Table 64. HSIKERON and CSIKERON behavior

HSIKERON (CSIKERON)	-	HSI (CSI) state during Stop mode	HSI (CSI) setting time
0	→	OFF	$t_{su(HSI)}$ ($t_{su(CSI)}$) (1)
1	→	Running and gated	Immediate

1. $t_{su(HSI)}$ and $t_{su(CSI)}$ are the startup times of the HSI and CSI oscillators (refer to the product datasheet for values of these parameters).

When the microcontroller exists Standby mode, the HSI is selected as system and kernel clock. The RCC registers are reset to their initial values except for the RCC_RSR and RCC_BDCR registers.

Note that the HSI and CSI outputs provide two clock paths (see *Figure 40*):

- one path for the system clock (**hsi_ck** or **csi_ck**)
- one path for the peripheral kernel clock (**hsi_ker_ck** or **csi_ker_ck**).

When a peripheral requests the kernel clock in system Stop mode, only the path providing the **hsi_ker_ck** or **csi_ker_ck** is activated.

Caution: The CPU does not get automatically the same clock frequencies when leaving Stop mode: it is up to the application to restore the previous clock settings if needed.

7.5.9 Peripheral clock distribution

Some peripherals are designed to work with two different clock domains that operate asynchronously:

- a clock domain synchronous with the register and bus interface (**ckg_bus_perx** clock)
- a clock domain generally synchronous with the peripheral (kernel clock)

The benefit of having peripherals supporting these two clock domains is that the user application has more freedom to choose optimized clock frequency for the CPU, bus matrix and for the kernel part of the peripheral.

As a consequence, the user application can change the bus frequency without reprogramming the peripherals. As an example an on-going transfer with UART is not disturbed if its APB clock is changed on-the-fly.

Table 65 shows the clocks the RCC delivers to the peripherals. Note as well that the clock named per_ck, is the output of a mux which allows the application to select:

- hsi_ker_ck, or
- csi_ker_ck, or
- hse_ker_ck

		hsi_ker_ck	3			
		csi_ker_ck	4			
		lse_ck	5			
	Bus	pclk1	-	-	F_{MAX} / 4	-
UCPD	Kernel	ucpd_ker_ck	-	-	25	A
	Bus	pclk1	-	-	F_{MAX} / 4	-
USBPHYC	Kernel	hse_ker_ck	**0**(4)	USBPHYCSEL	32	A
		hse_ker_ck / 2	1			
		pll3_q_ck	2			
VREFBUF	Bus	pclk4	-	-	F_{MAX} / 4	-
WWDG1	Bus	pclk1	-	-	F_{MAX} / 4	-

1. F_{MAX} value depends on the device reference and can be found on the datasheet of the product.
2. 'A' Means that the kernel clock is asynchronous with respect to bus interface clock.
3. 'S' Means that the kernel clock is synchronous with respect to bus interface clock.
4. Reset value
5. The RTC switch is in the VSW voltage domain

Figure 53 to *Figure 68* provide a more detailed description of kernel clock distribution. Refer to *Section 7.5.12: Peripheral clock gating control* for more details.

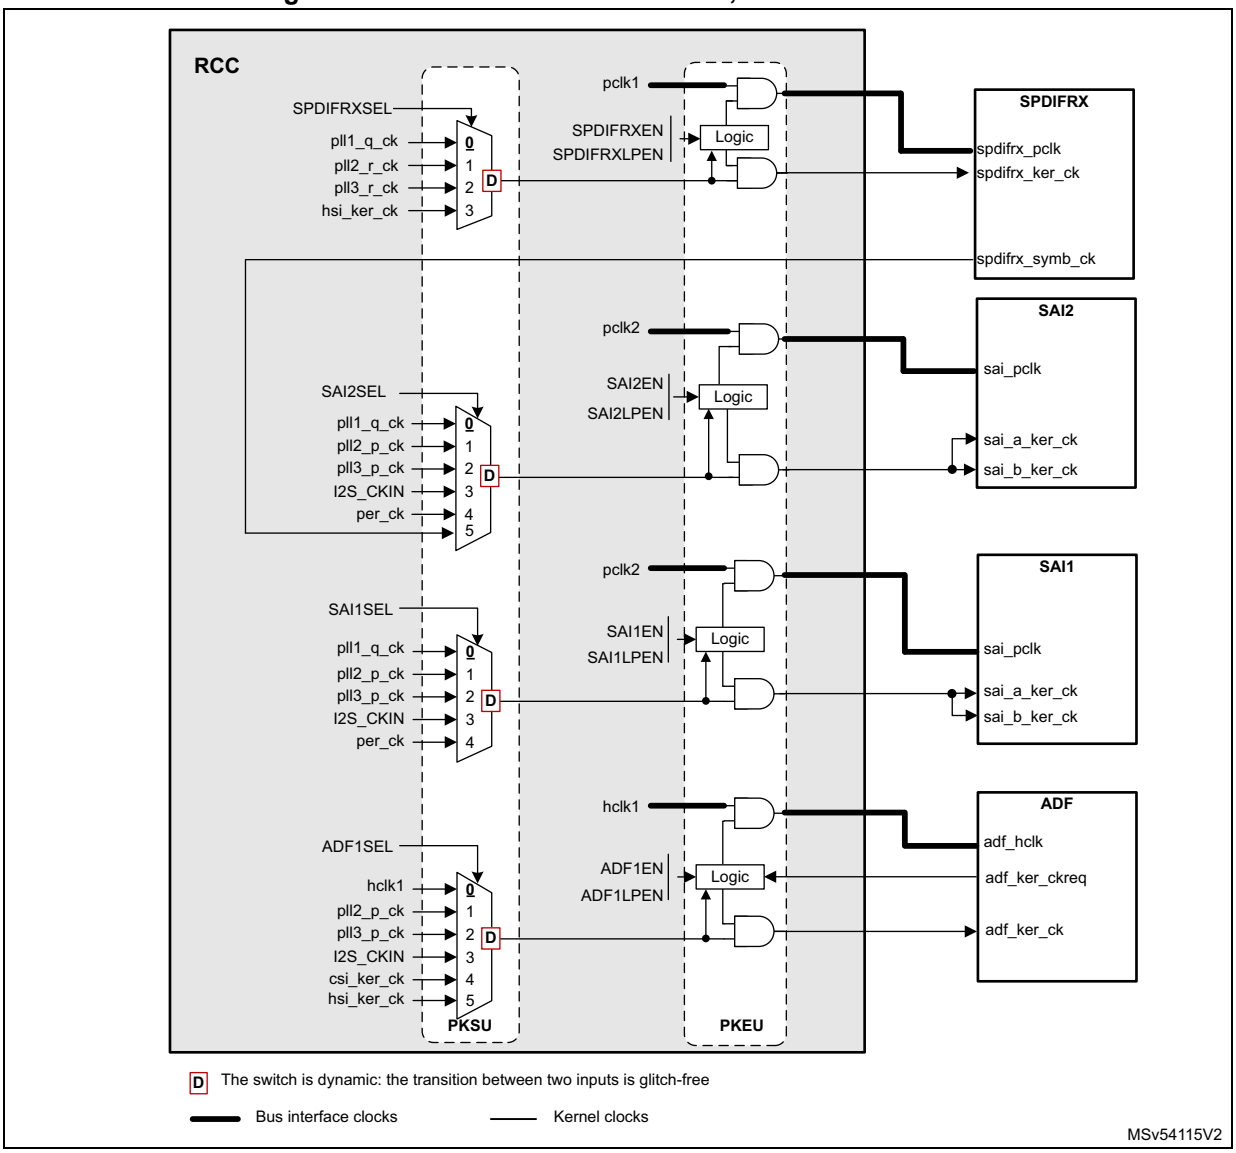
To reduce the amount of switches, some peripherals share the same kernel clock source. Nevertheless, all peripherals have their dedicated enable signal.

Clock distribution for ADF, SAIs, and SPDIFRX

The audio peripherals generally need specific accurate frequencies, except for SPDIFRX. As shown in *Figure 53* and *Figure 56*, the kernel clock of the SAIs or SPI(I2S)s can be generated by:

- PLL1 when the amount of active PLLs must be reduced (for SAIs and SPI/I2S1 to 3)
- APB2 peripheral clock (for SPI/I2S4 and 5)
- APB4 peripheral clock (for SPI/I2S6)
- PLL2 or 3 for optimal flexibility in frequency generation
- HSE, HSI or CSI for use-cases where the current consumption is critical
- I2S_CKIN when an external clock reference needs to be used

The SPDIFRX does not require a specific kernel clock frequency but only a frequency high enough to sample properly the incoming stream. Refer to the SPDIFRX description for more details.



The SPDIFRX also provides a symbol clock (spdifrx_symb_ck) which is 64 times faster than the received samples. The symbol clock is proposed as kernel clock for SAI2 in order to ease bridging from SPDIFRX to SAI2.

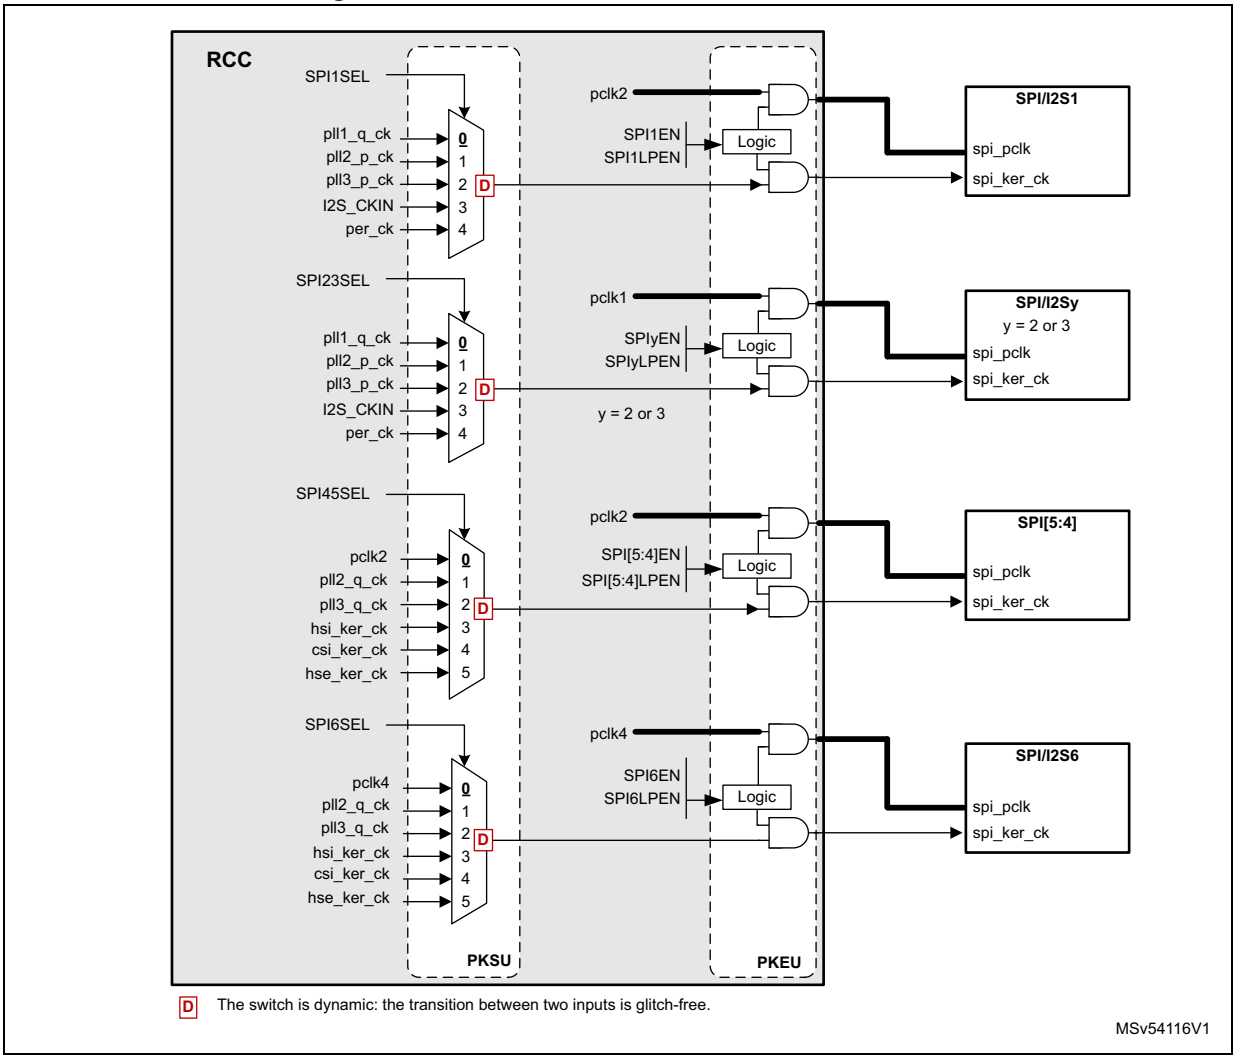
The audio blocks also have common kernel clocks in order to ease data exchange.

The ADF can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The ADF asserts the adf_ker_ckreq when the kernel clock is requested.

The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

Figure 53. Clock distribution for SAIs, ADF and SPDIFRX

1. **X** represents the selected mux input after a system reset.



Clock distribution for SPIs, SPI/I2Ss

SPI peripherals do not need an accurate kernel clock frequency but a clock fast enough for the serial interface. The SPI/I2S peripherals may request accurate kernel clock frequency when using the I2S function. For that purpose the source can be selected among the following ones:

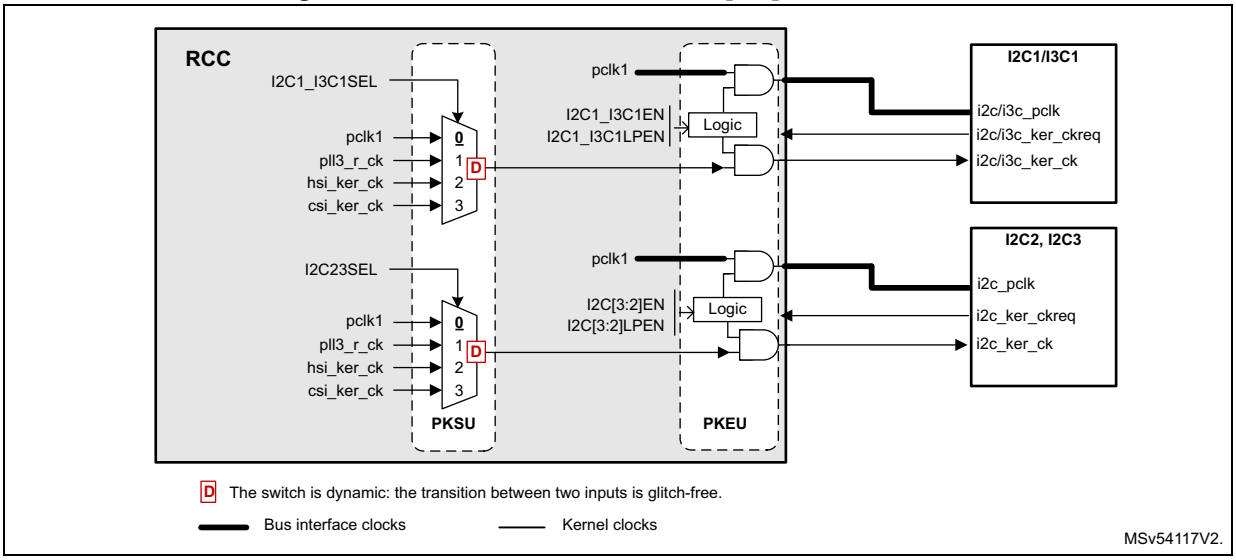
- The bus clock (for SPIs)
- PLL1 when the amount of active PLLs must be reduced
- PLL2 or PLL3 if better flexibility is required. As an example, this solution allows changing the frequency bus via PLL1 without affecting the speed of some serial interfaces.
- HSI or CSI or per_ck for low-power use-cases.

The SPI/I2S also have common kernel clocks with audio blocks in order to ease data exchange.

Figure 54. Clock distribution for SPIs and SPI/I2S

1. **X** represents the selected switch input after a system reset.

Clock distribution for I2C[3:2], and I2C1/I3C1



I2Cs and I3C1 peripherals do not need an accurate kernel clock frequency but a clock fast enough to handle properly the serial interface. The following kernel clock sources are proposed:

- The bus clock
- PLL3 in the case were the bus clock cannot be used
- HSI or CSI for low-power use-cases

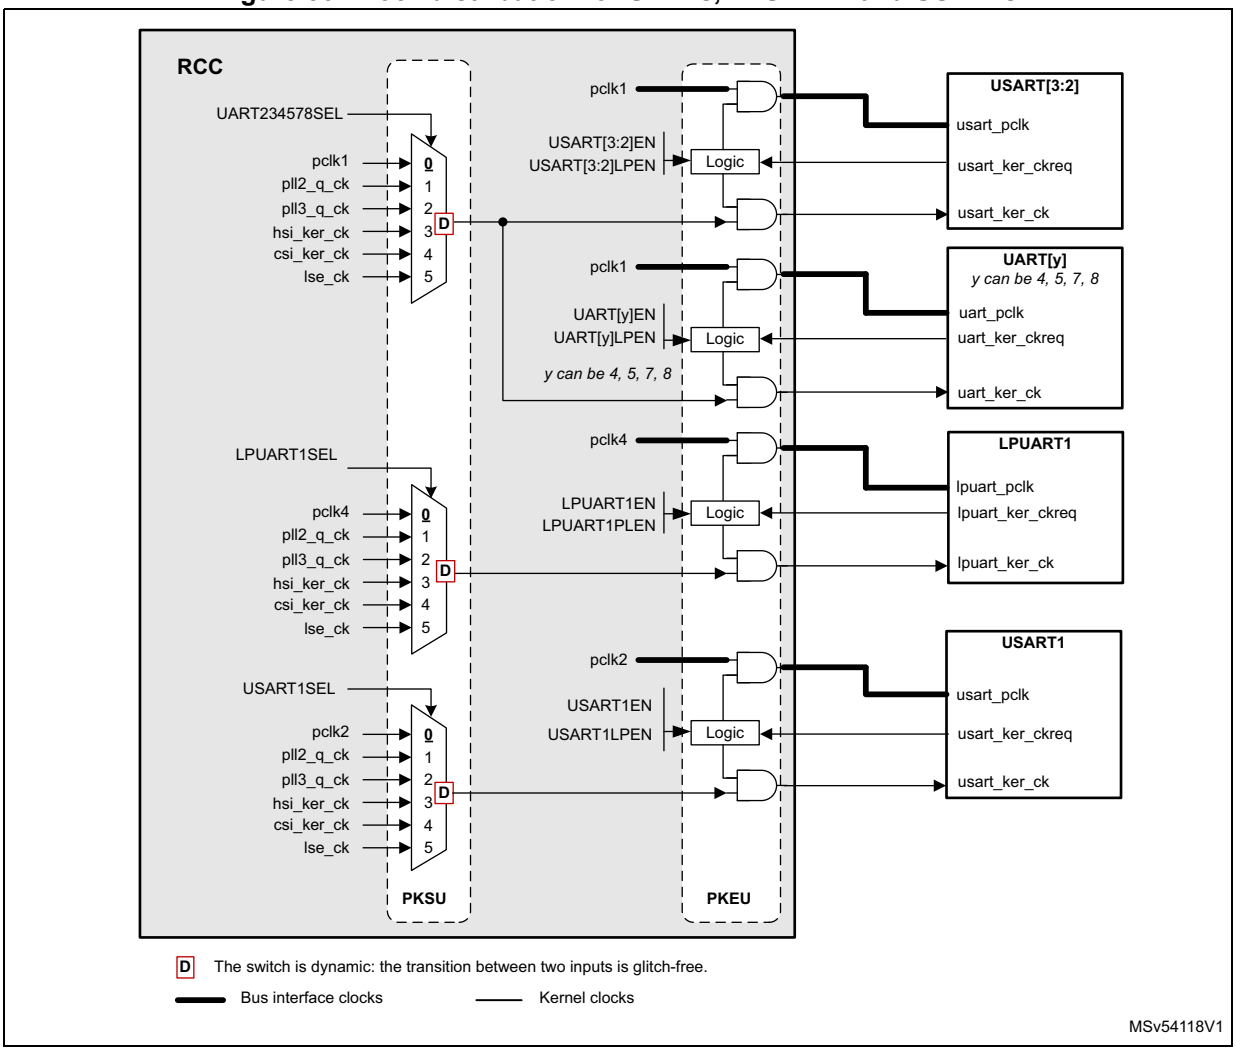
The I2Cs and I3C1 can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected **csi_ker_ck** or **hsi_ker_ck** as kernel clock sources. The I2Cs and I3C1 assert the **i2c_ker_ckreq** or **i3c_ker_ckreq** signals, when the kernel clock is requested.

The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

Figure 55. Clock distribution for I2C[3:2] and I2C1/I3C1

1. **X** represents the selected switch input after a system reset

Clock distribution for UARTs and USARTs



UARTs need kernel clock frequency allowing the adjustment of the baud rate with an acceptable accuracy (generally less than +/2%). For that purpose the source can be selected among the following ones:

- The bus clock
- PLL3 in the case were the bus clock cannot be used
- HSI, CSI or LSE for low-power use-cases

The UARTs can work even in Stop mode as long as the bus clock is not requested. Working in Stop mode is possible only if the application selected csi_ker_ck or hsi_ker_ck as kernel clock sources. The UARTs assert the **uartx_ker_ckreq** signal, when the kernel clock is requested. The kernel clock mechanism works only if the kernel clock source is provided by an RC oscillator (**hsi_ker_ck** or **csi_ker_ck**).

UARTs can also work in Stop mode using the LSE clock when high baud rates are not required.

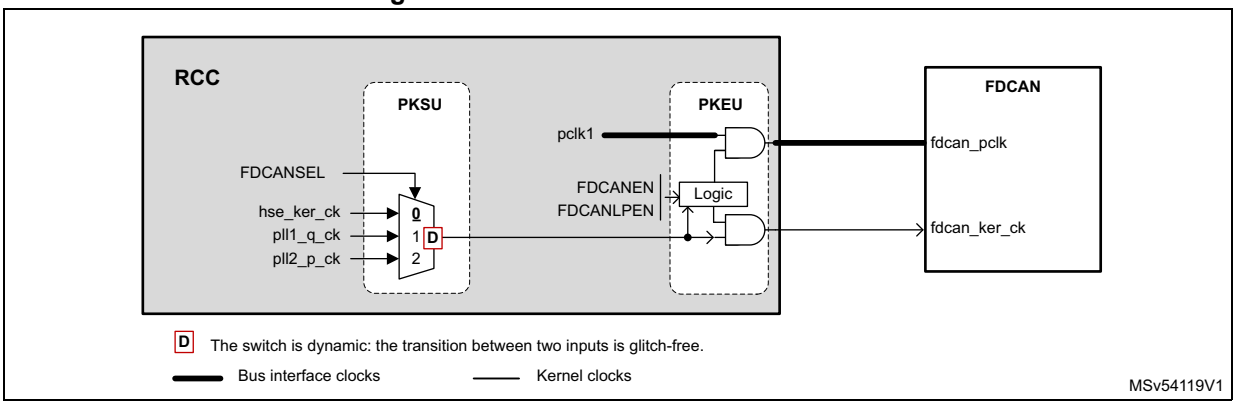


Figure 56. Clock distribution for UARTs, LPUART1 and USARTs

1. **X** represents the selected switch input after a system reset.

Clock distribution for FDCAN

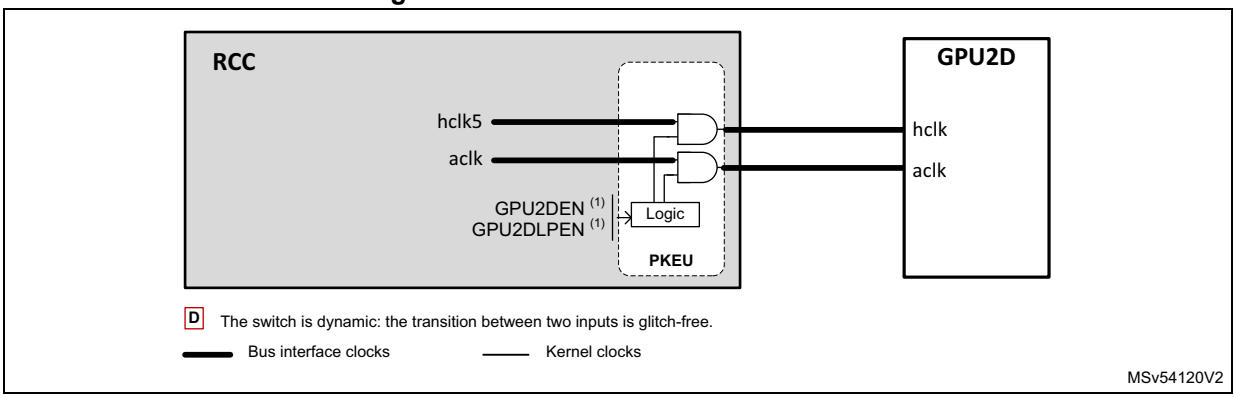

Figure 57. Clock distribution for FDCAN

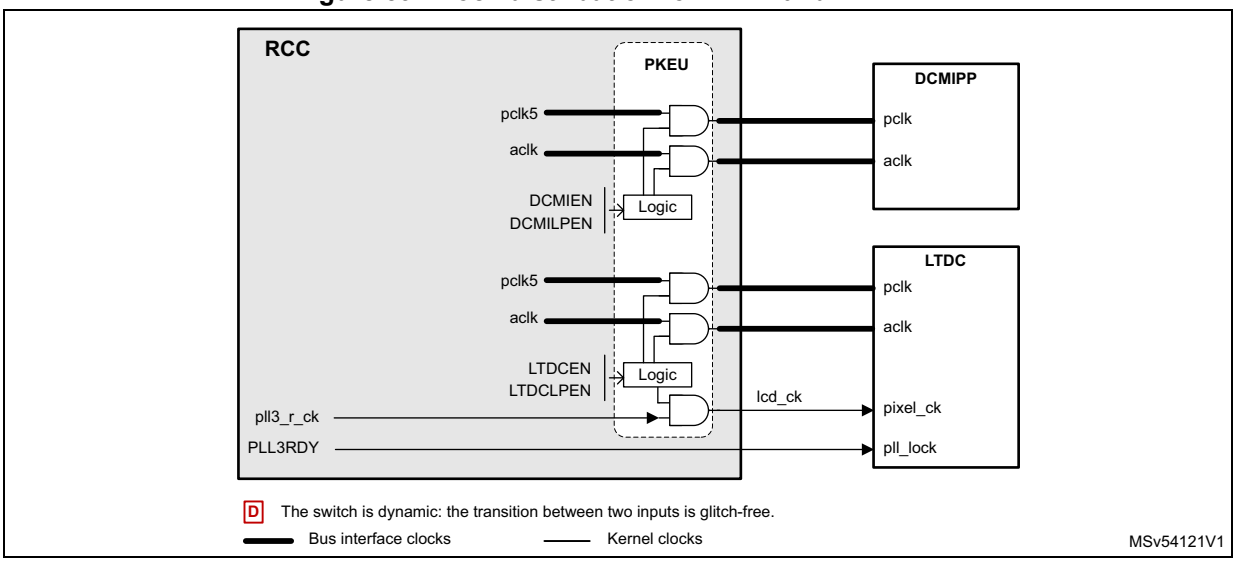
1. **X** represents the selected switch input after a system reset.

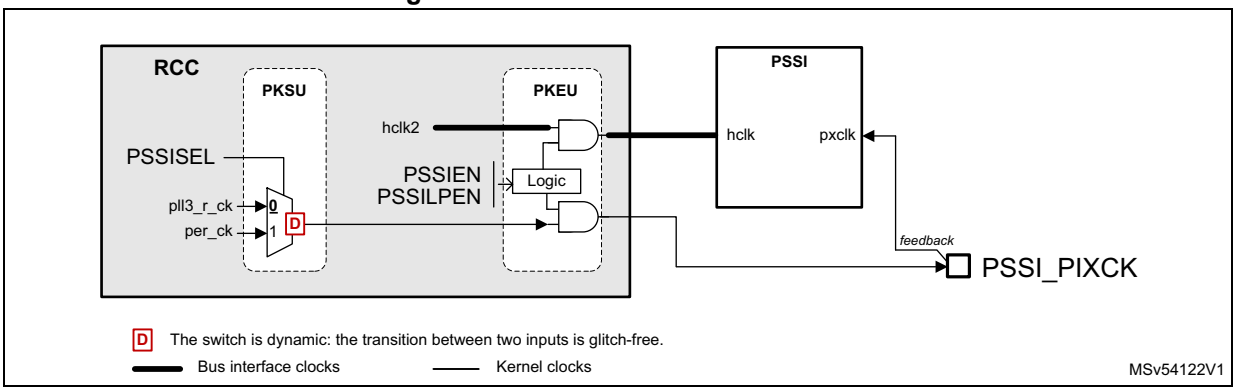


Clock distribution for graphic blocks (GPU2D, LTDC, DCMIPP and PSSI)

Figure 58. Clock distribution for GPU2D

1. **X** represents the selected switch input after a system reset.

Figure 59. Clock distribution for LTDC and DCMIPP



1. **X** represents the selected switch input after a system reset.

The PSSI receives an AHB clock and a kernel clock (pxclk).

The pxclk can be provided either by an external device via PSSI_PIXCK pad, or by the RCC. Note that the clock generated by the RCC is provided to pxclk input by the feedback path of the PSSI_PIXCK pad. The drive of the PSSI_PIXCK is controlled by the PSSI block.

Figure 60. Clock distribution for PSSI

1. **X** represents the selected switch input after a system reset.

Clock distribution for SDMMCs, FMC, and XSPIs

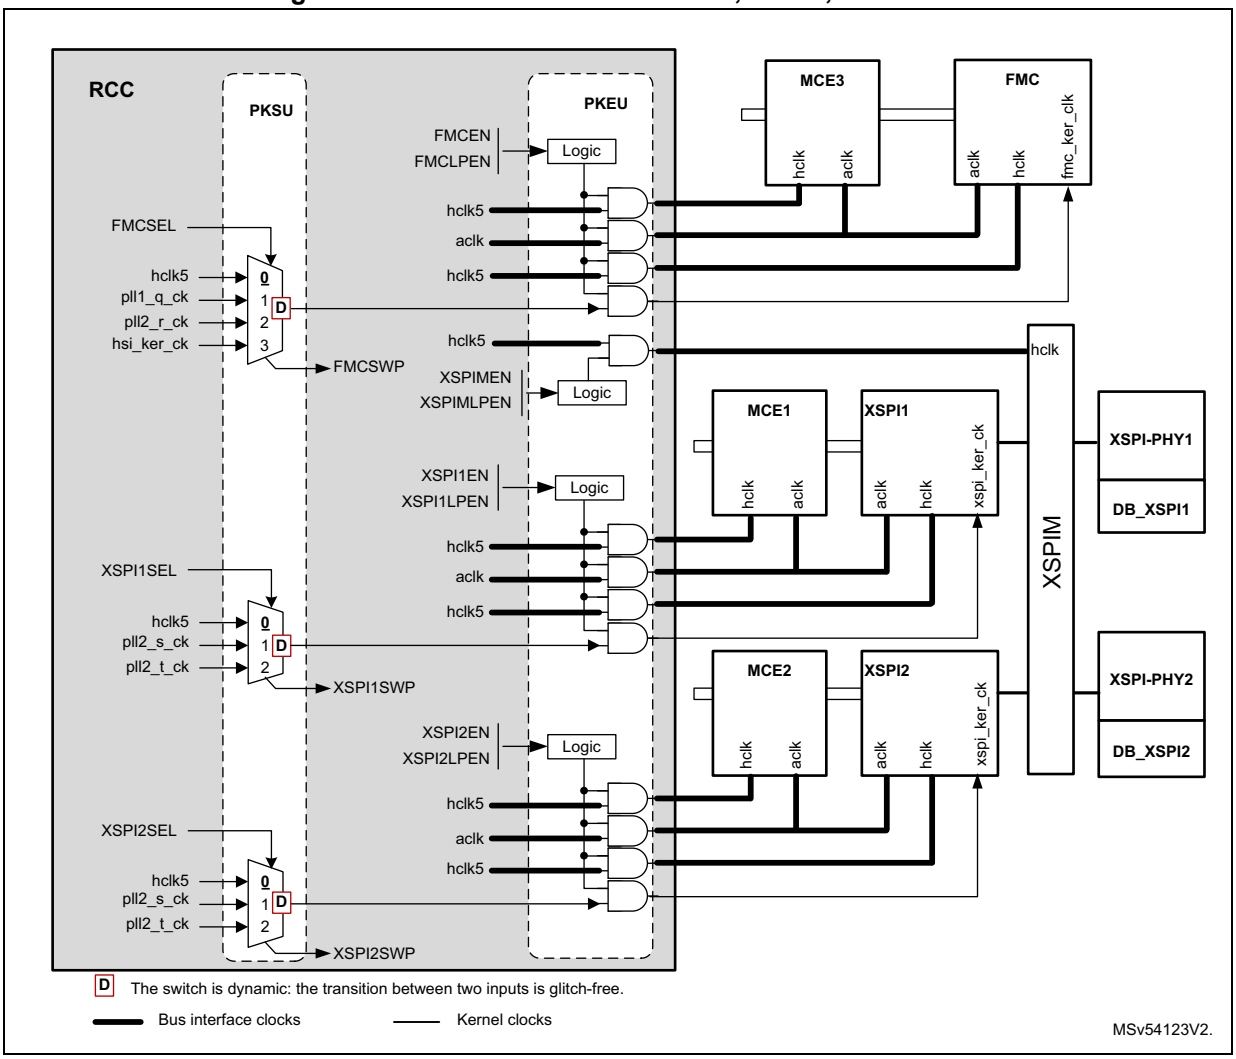
The FMC kernel clock can be chosen between 4 different sources, giving good flexibility.

For each XSPI, a clock switch allows the selection between 3 different sources, giving good flexibility. It is possible to enable independently each XSPI block.

The switches FMCSEL, XSPI[2:1]SEL, also embeds several protections:

- In case of HSE failure detected by the HSECSS function, the XSPI[2:1]SEL switches and the FMCSEL switch go to recovery position in order to provide a default clock.
- A protection bit: FMCCKP prevents the application to accidentally change the FMCSEL value. Refer to *Section 7.5.7: Clock protection* for details.
- A protection bit: XSPICKP prevents the application to accidentally change the XSPI[2:1]SEL values. Refer to *Section 7.5.7: Clock protection* for details.
- Status fields (FMCSWP, XSPI[2:1]SWP) located into *RCC clock protection register (RCC_CKPROTR)* allows the application to check the effective position of the switches.
- If one of the switch is selecting an input with an invalid clock, the switch outputs a recovery clock preventing a memory crash and allowing the application to log or correct the issue. The RCC provides **hclk5**/4 as recovery clock. In order to work fine, the

application must ensure that the recovery clock frequency is supported by the external device.



- For the XSPI[2:1]SEL switches:
  - Going to position 1 is allowed if PLL2ON = PLL2SEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2TEN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the recovery clock.
- For the FMCSEL switch:
  - Going to position 1 is allowed if PLL1ON = PLL1QEN = 1. If the application switches to position 1 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 2 is allowed if PLL2ON = PLL2REN = 1. If the application switches to position 2 when these conditions are not met, the switch generates the recovery clock.
  - Going to position 3 is allowed if HSION = 1. If the application switches to position 3 when this condition is not met, the switch generates the recovery clock.

How to handle properly XSPI switches:

- Switch on the wanted clock source,
- Ensure the clock source is ready, and conditions described above are met,
- Set XSPI1SEL to the wanted position,
- Enable the XSPI clock (XSPIxEN = 1),
- Read XSPISWP field from RCC_CKPROTR register,
- If the position given by XSPISWP is the same as the wanted, it means that the XSPIx kernel clock is as expected.
- If the position given by XSPISWP is 000, it means that there is no clock present at the selected input.

The XSPIs must provide a clock to the external memory, with a duty cycle distortion generally lower than 5%. In order to reach this requirement, the kernel clock provided to the XSPIs has a typical duty cycle of 50%. In addition, the XSPIs embed prescaler allowing clock division by even ratios.

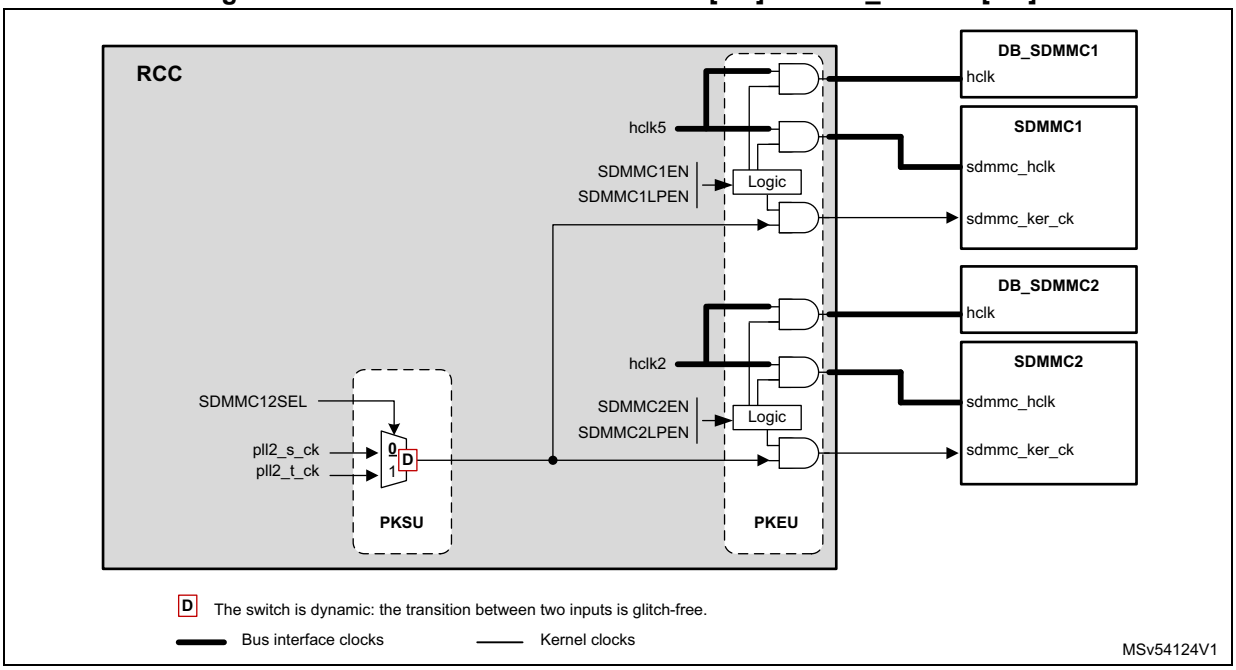
Figure 61. Clock distribution for FMC, XSPIs, and MCEs

1. **X** represents the selected switch input after a system reset.

The SDMMC1 and SDMMC2 share the same kernel clock. A clock switch allows the selection between 2 different sources. It is possible to enable independently each SDMMC block. Note that when one of the SDMMC is enabled via its SDMMC[2:1]EN bit, the associated delay block is enabled as well.

The application must take care about the duty-cycle of the kernel clock provided to the SDMMC blocks.

Table 66. SDMMC interface clock constraints



SDMMC mode	Mode name	Interface clock frequency	Duty cycle constraint
SDIO	SDR12	25 MHz or less	30 - 70%
	SDR25	50 MHz or less	30 - 70%
	DDR50	50 MHz or less	45 - 55%
	SDR50	100 MHz or less	30 - 70%

Table 66. SDMMC interface clock constraints

SDMMC mode	Mode name	Interface clock frequency	Duty cycle constraint
e.MMC	Backward compatible	26 MHz or less	30 - 70%
	High Speed SDR	52 MHz or less	30 - 70%
	High Speed DDR	52 MHz or less	45 - 55%

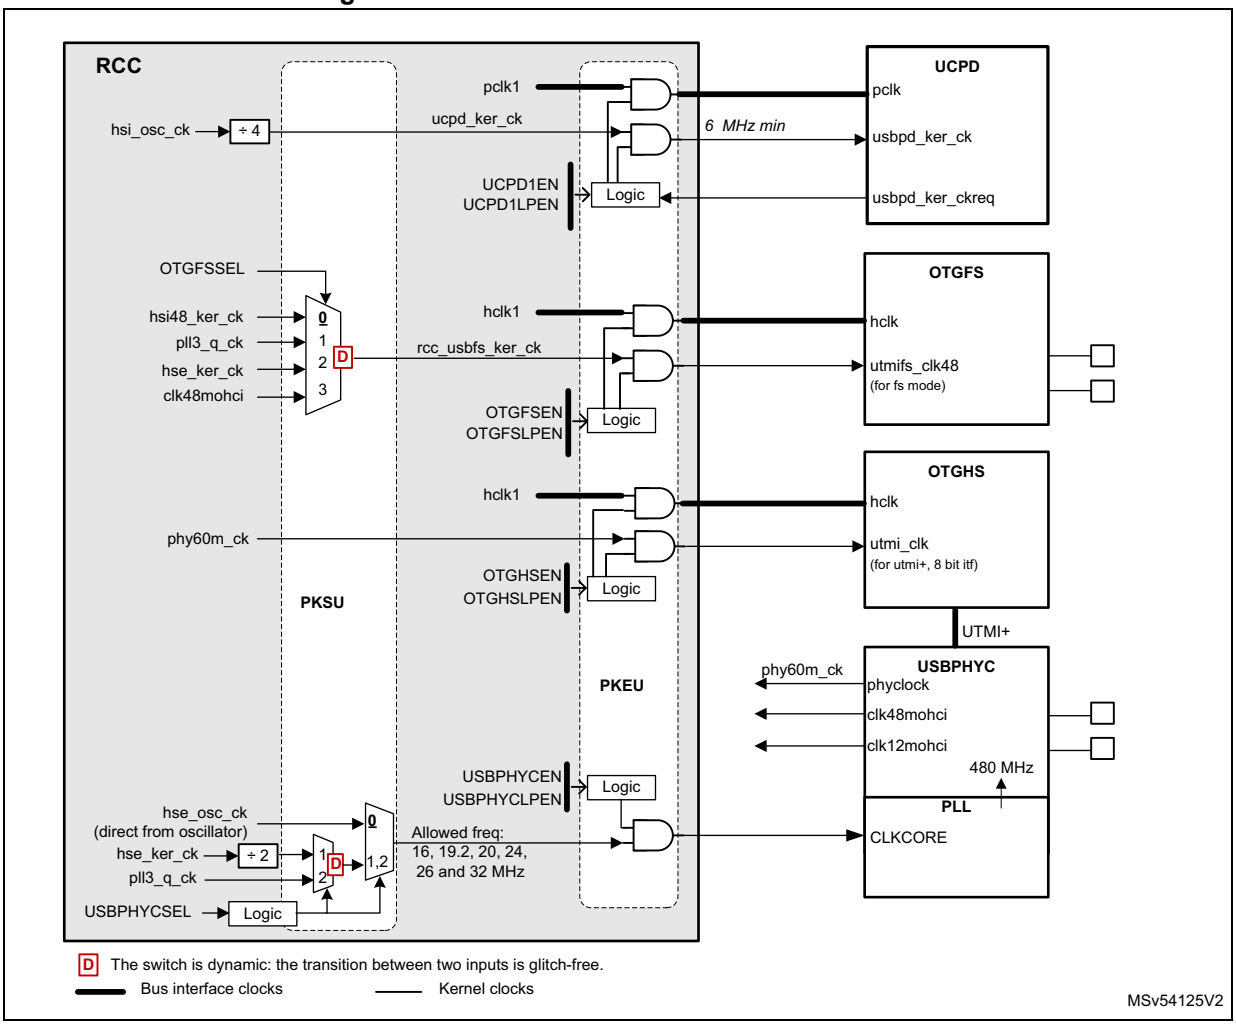
For example, if the SDMMC works in SDR50, then a kernel clock of 50 MHz, with a duty cycle better than 30-70% is enough. If the SDMMC works in DDR50, then it is recommended to provide a kernel clock of 100 MHz, and divide the frequency of the kernel clock by two, using the SDMMC divider in order to insure a duty-cycle very close to 50% for the SDMMC_CK.

Figure 62. Clock distribution for SDMMC[2:1] and DB_SDMMC[2:1]

1. **X** represents the selected switch input after a system reset.

Clock distribution for OTGFS, OTGHS and UCPD

Figure 63 shows the clock distribution for the USB blocks.



- The USB type-C power delivery block (UCPD), uses ucpd_ker_ck as kernel clock. The ucpd_ker_ck is directly generated from the HSI output divided by 4.
- The USBPHYC, embeds a PLL accepting a reference input frequency of 16, 19.2, 20, 24, 26 or 32 MHz. The reference clock can be selected among:
  - **hse_osc_ck**
  - **hse_ker_ck**/2 or
  - **pll3_q_ck**

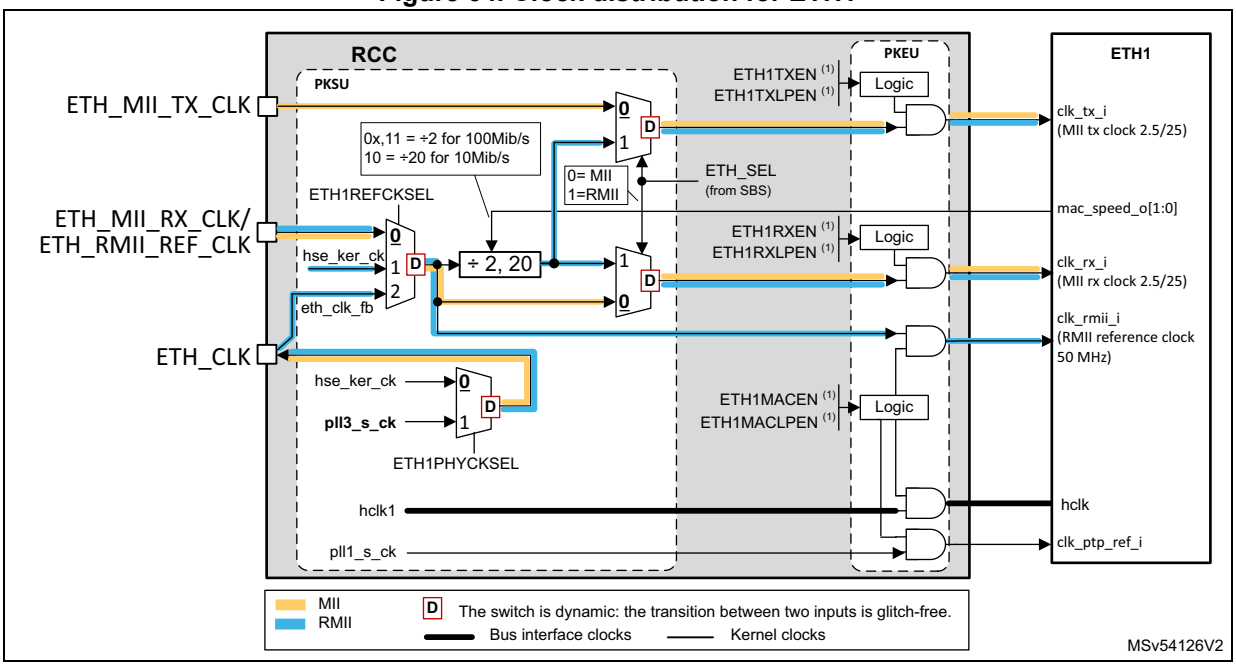
  The USBPHYC provides a 60 MHz clock to the OTGHS block, and a 48 MHz clock to the OTGFS block. The clock **hse_osc_ck** is the direct output of the HSE oscillator.
- The OTGHS receives the 60 MHz clock from the USBPHYC (phy60m_ck), when working in HS or FS mode.
- The OTGFS receives a 48 MHz clock. The application can select:
  - the clk48mohci (from USBPHYC)
  - the hsi48_ker_ck for crystal-less applications
  - hse_ker_ck or
  - pll3_q_ck

The selection of the reference clock for the USBPHYC is performed by a simple MUX. In order to change the clock source, the application must follow the sequence hereafter:

- Disable the USBPHYC clock by setting USBPHYCEN to 0
- Change the clock source selector (USBPHYCSEL) to the wanted value
- Enable the USBPHYC clock by setting USBPHYCEN to 1.

Figure 63. Clock distribution for USB and UCPD

1. **X** represents the selected switch input after a system reset.



Clock distribution for ETH1

The Ethernet clocks provided by the RCC are available on ETH_CLK pad. The application can select if the ETH_CLK is generated from the HSE kernel clock or from the **pll3_s_ck**.

The RCC also provides the bus clock and the reference clock for the PTP function.

Note that the bus and PTP clocks generation are controlled via ETH1MACEN and ETH1MACLPEN bits.

Figure 64. Clock distribution for ETH1

1. **X** represents the selected switch input after a system reset.

The signal ETH_SEL is provided by the SBS block and defines the interface type used:

In MII mode (orange path):

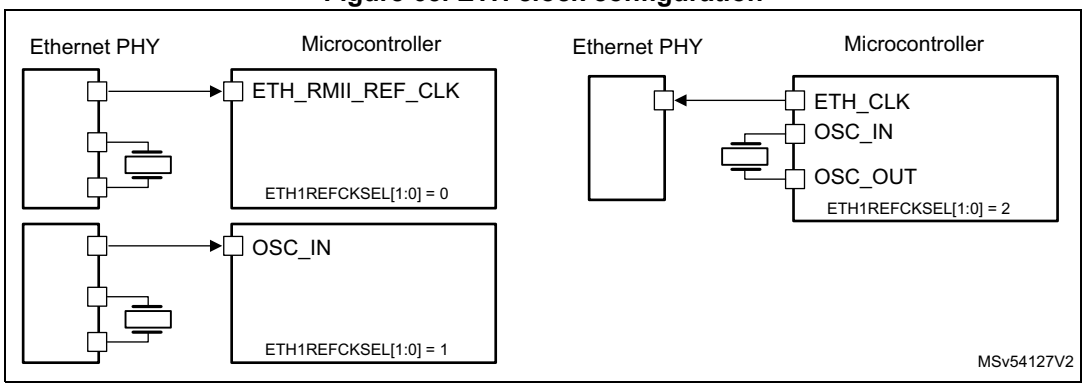
- The transmit clock is received from the external PHY via the pad ETH_MII_TX_CLK.
- The receive clock is received from the external PHY via the pad ETH_MII_RX_CLK.
- The clock frequency is 2.5 MHz for Ethernet at 10 Mbps or 25 MHz for Ethernet at 100 Mbps.

In RMII mode (blue path):

- The reference clock (50 MHz) can be selected between several sources:
  - The ETH_RMII_REF_CLK pad, if the reference clock is provided by the PHY
  - The hse_ker_ck in case the Ethernet PHY is providing a reference clock connected to OSC_IN
  - The ETH_CLK feedback clock (eth_clk_fb) if the RCC is providing the reference clock to the PHY. This selection is controlled via ETH1REFCKSEL[1:0].
- The ETH_SEL must be set to 1,
  - a clock must be provided to clk_rx_i and clk_tx_i inputs
  - The clock frequency at clk_rx_i and clk_tx_i inputs is 2.5 MHz (division by 20) for Ethernet at 10 Mbps, and 25 MHz (division by 2) for Ethernet at 100 Mbps.
  - The transmit and receive clock frequency can be adjusted dynamically to 2.5 or 25 MHz according to the signal mac_speed_o[0] provided by the ETH block.

Note that the ETH1REFCKSEL mux position cannot be changed when a clock is provided to the ETH1 block. In order to select the wanted mux position the following sequence must be respected:

- Set bits ETH1TXEN, ETH1RXEN and ETH1MACEN to 0,
- Set ETH1REFCKSEL to the wanted position,
- Set bits ETH1TXEN, ETH1RXEN and ETH1MACEN to 1



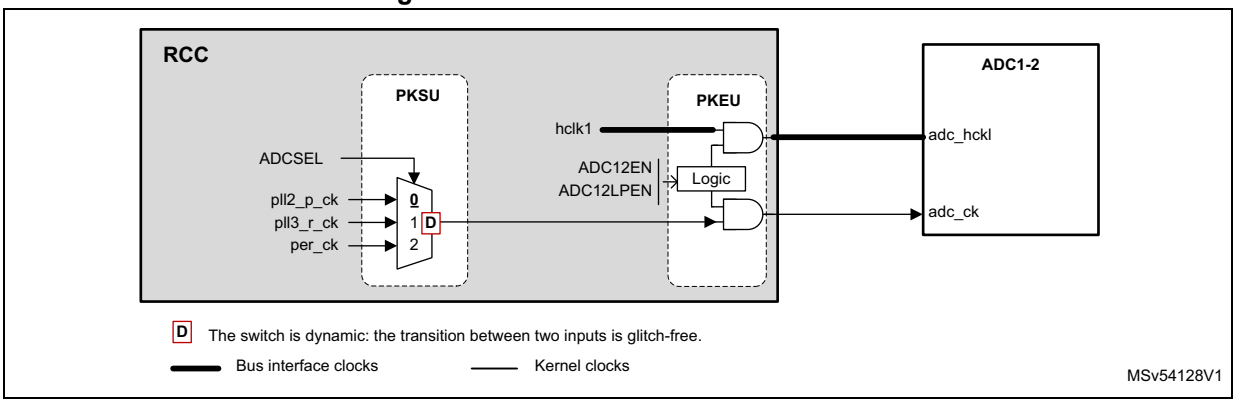
The RCC can generate a reference clock of 25 or 50 MHz to the external PHY, via ETH_CLK pad. The figure hereafter shows the possible clock configurations.

The ETH_CLK is generated only if:

- ETH1TXEN or ETH1RXEN are enabled, and
- the system is in Run or Sleep, and
- the clock source selected by ETH1PHYCKSEL is available.

The bits ETH1REFCKSEL[1:0] and ETH1PHYCKSEL are located into the *RCC AHB peripheral kernel clock selection register (RCC_CCIPR1)*.

Figure 65. ETH clock configuration



The ETH1 block provides information on the MAC speed (mac_speed_o[1:0]), which may change dynamically:

- mac_speed_o[1:0] = 0b10: for 10 Mbps
- mac_speed_o[1:0] = 0b11 or 0b0x: for 100 Mbps

Clock distribution for ADC1-2

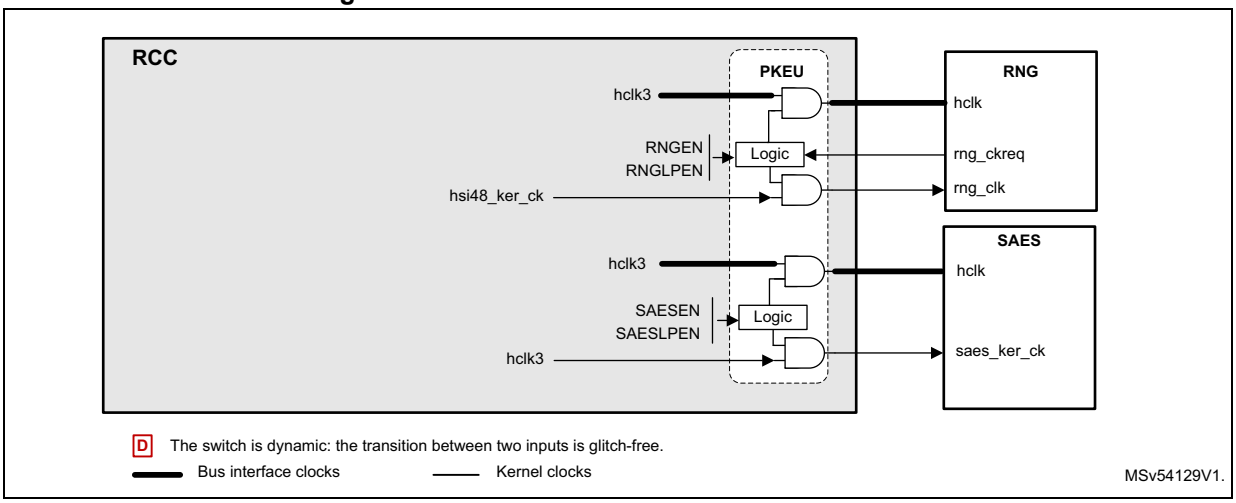


Figure 66. Clock distribution For ADCs

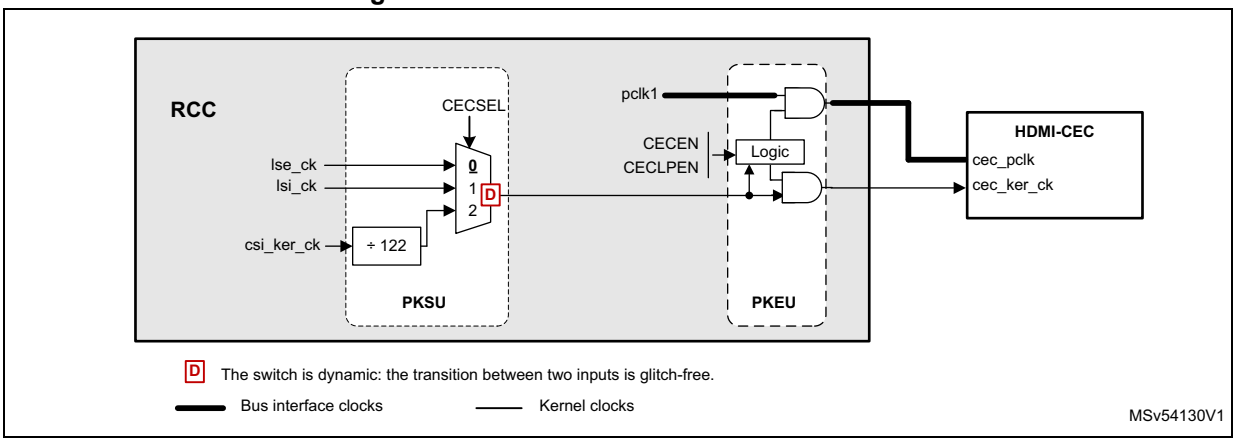
1. **X** represents the selected switch input after a system reset.

Clock distribution for SAES and RNG

Figure 67. Clock distribution for SAES and RNG



1. **X** represents the selected switch input after a system reset.

The RNG block is using the hsi48_ker_ck as kernel clock. The logic handling controlling the clock of the RNG is different from standard peripherals. When enabled, the RNG has to assert its kernel clock request, in order to get a kernel clock. For example, if the SAES needs the RNG resource, the RNG must also be enabled. Refer to *Section 7.5.12: Peripheral clock gating control* for details.

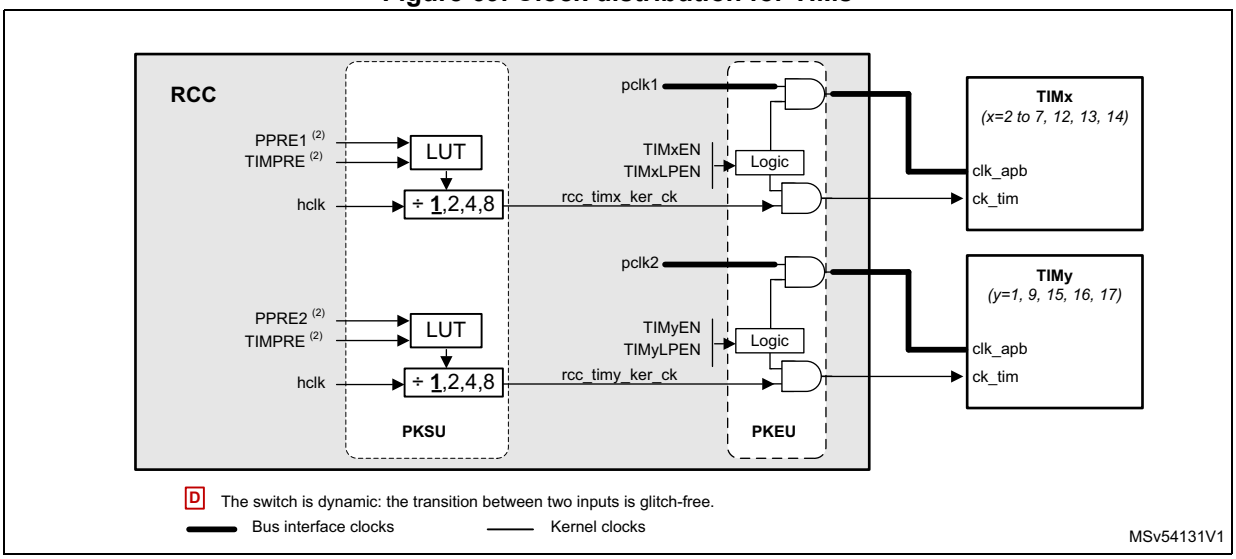
Clock distribution for HDMI-CEC

Figure 68. Clock distribution for HDMI-CEC

1. **X** represents the selected switch input after a system reset

Clock distribution for TIM and LPTIM

The TIMs timers are using kernel clocks (tim_ker_ck) phase aligned with the bus interface clock.



The working frequency of the timers clock depends on:

- The APB prescaler corresponding to the bus where the timer is connected,

and

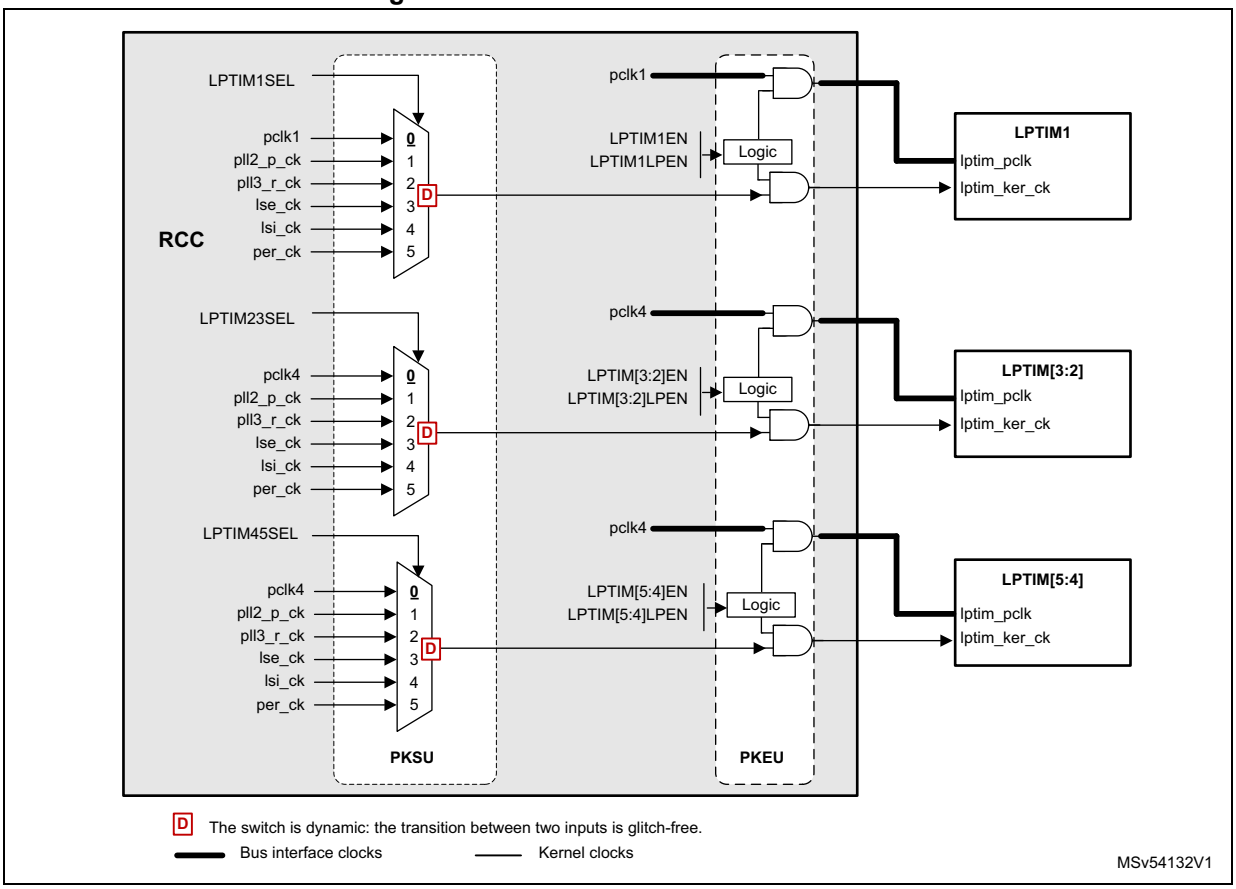
- The bit TIMPRE

Figure 69. Clock distribution for TIMs

1. **X** represents the selected switch input after a system reset
2. Can be changed on the fly

The *Table 67* shows how to select the timer clock frequency.

Table 67. Ratio between clock timer and pclk



PPRE1(1) PPRE2	TIMPRE (2)	-	$F_{rcc_timx_ker_ck}$ $F_{rcc_timy_ker_ck}$	F_{pclk1} F_{pclk2}	Comments
0xx	x	→	F_{hclk1}	F_{hclk1}	The timer clock is equal to the bus clock.
100	x	→	F_{hclk1}	F_{hclk1} / 2	The timer clock is twice as fast as the bus clock.
101	0	→	F_{hclk1} / 2	F_{hclk1} / 4	
110	0	→	F_{hclk1} / 4	F_{hclk1} / 8	
111	0	→	F_{hclk1} / 8	F_{hclk1} / 16	
101	1	→	F_{hclk1}	F_{hclk1} / 4	The timer clock is 4 times faster than the bus clock.
110	1	→	F_{hclk1} / 2	F_{hclk1} / 8	
111	1	→	F_{hclk1} / 4	F_{hclk1} / 16	

1. PPRE1 and PPRE2 are the prescaler for the APB1 and APB2 clocks.
2. TIMPRE belongs to *RCC clock configuration register (RCC_CFGR)*.

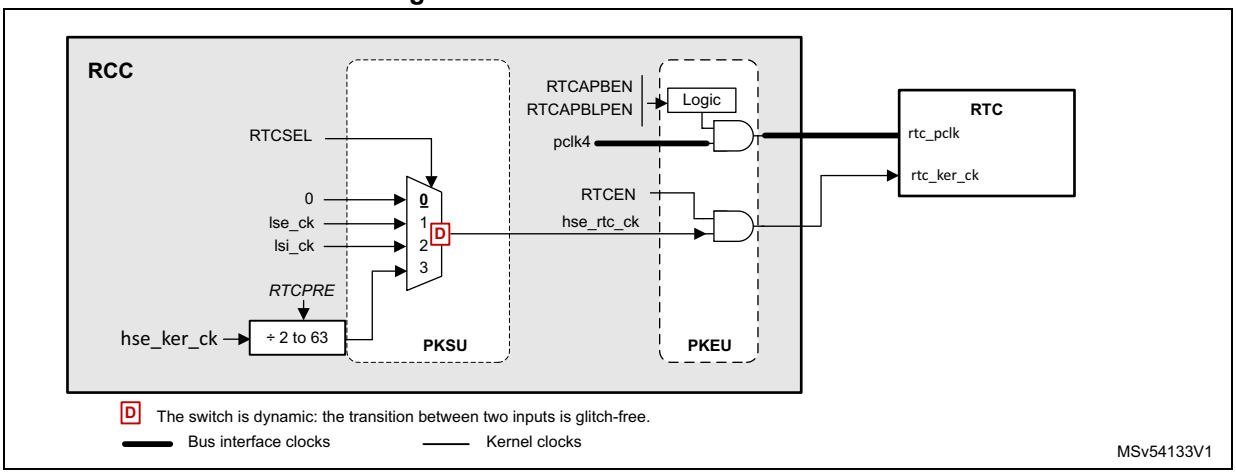
The LPTIMs timers have a kernel clocks fully asynchronous with respect to their bus interface clock. The kernel clock can be selected among up to 6 clock sources.

The LPTIMs also use lse_ck and lsi_ck as kernel clock, allowing them to work even when the system is in Stop mode.

Figure 70. Clock distribution for LPTIMs

1. **X** represents the selected switch input after a system reset

Clock distribution for RTC/AWU clock



The **rtc_ck** clock source can be one of the following:

- the **hse_rtc_ck** (**hse_ker_ck** divided by a programmable prescaler)
- the **lse_ck**
- the **lsi_ck** clock

The source clock is selected by programming the RTCSEL[1:0] bits in the *RCC Backup domain control register (RCC_BDCR)* and the RTCPRE[5:0] bits in the *RCC clock configuration register (RCC_CFGR)*.

This selection cannot be modified without resetting the Backup domain.

Figure 71. Clock distribution for RTC

1. **X** represents the selected switch input after a system reset

If the LSE is selected as RTC clock, the RTC works normally even if the backup or the V_{DD} supply disappears.

The LSE clock is in the Backup domain, whereas the other oscillators are not. As a consequence:

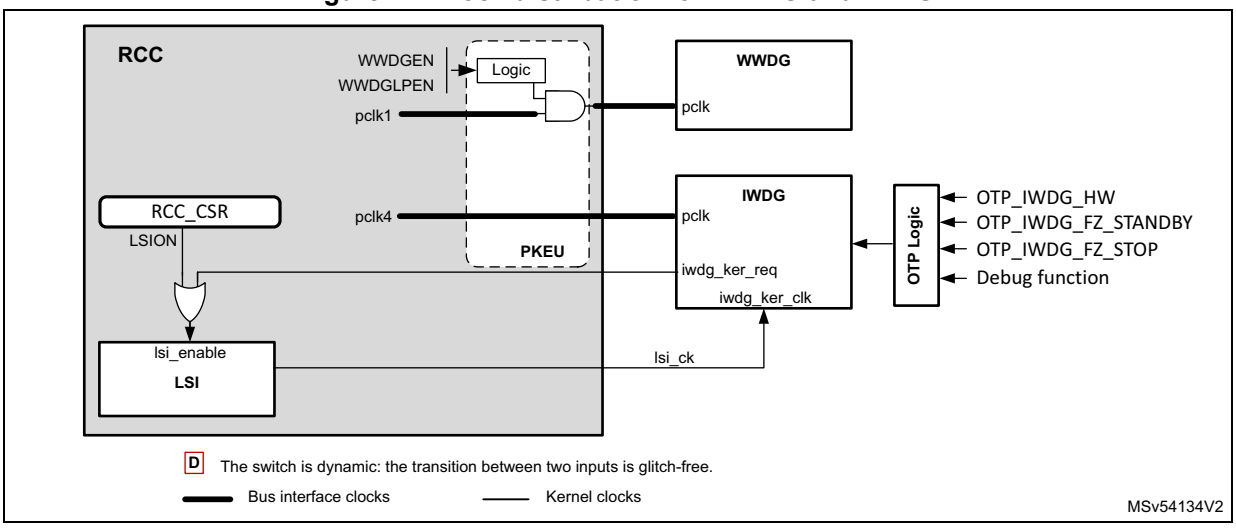
- If LSE is selected as RTC clock, the RTC continues working even if the V_{DD} supply is switched OFF, provided the V_{BAT} supply is maintained.
- If LSI is selected as the RTC clock, the AWU state is not guaranteed if the V_{DD} supply is powered off.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} supply is powered off or if the V_{CORE} supply is powered off. In addition the HSE is not available if the system goes to Stop.

The **rtc_ck** clock is enabled through RTCEN bit located in the *RCC Backup domain control register (RCC_BDCR)*.

The RTC bus interface clock (APB clock) is enabled through RTCAPBEN and RTCAPBLPEN bits located in RCC_APB4ENR/LPENR registers.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency ($F_{APB} < 7 \times F_{RTCLCK}$), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise a third read access must be performed.

Clock distribution for watchdog



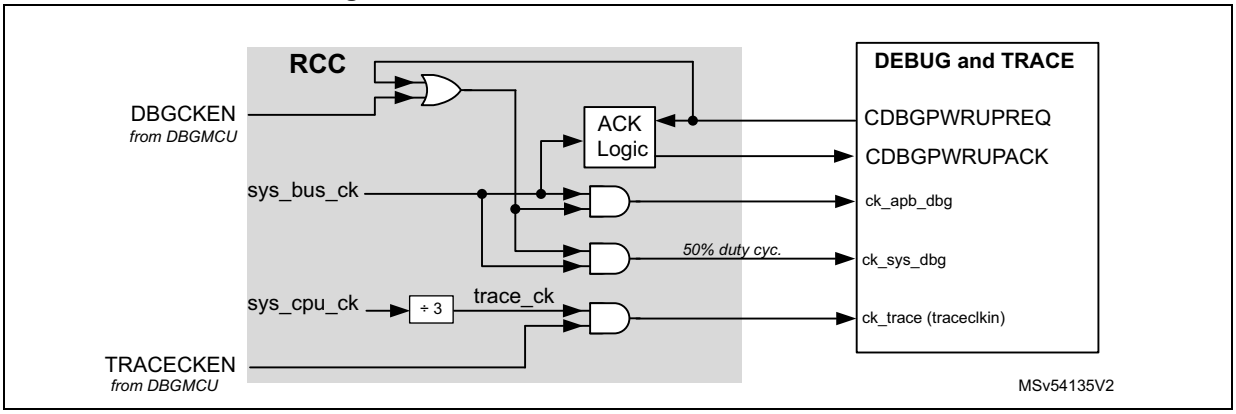
The RCC provides the clock for the two watchdog blocks available on the circuit. The independent watchdog (IWDG) is connected to the LSI. The window watchdog (WWDG) is connected to the APB clock.

If an independent watchdog is started by either hardware option or software access, the LSI is forced ON and cannot be disabled. After the LSI oscillator setup delay, the clock is provided to the IWDG.

The window watchdog clock (pclk1) can be enabled by setting the WWDGEN bit in RCC_APB1ENR register. The software cannot stop WWDG down-counting by setting WWDGEN bit to ‘0’.

The WWDG block is frozen when the MCU goes to Stop mode.

Figure 72. Clock distribution for WWDG and IWDG



1. **X** represents the selected switch input after a system reset

Clock distribution for Debug and Trace

The clock generation for the trace and debug is controlled by the DBGMCU block. The DBGCKEN bit allows the application to provide a clock to the debug components. It is also possible to enable this clock via the Debug Access Port.

The trace clock generation is controlled via TRACECKEN bit.

Figure 73. Clock distribution for DBG and trace

1. **X** represents the selected switch input after a system reset

Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx.

- Calibrating the HSI or CSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI or CSI. This requires to use the HSI or CSI as system clock source either directly or via PLL1. The number of system clock counts between

consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the high precision of LSE crystals (typically a few tens of ppm) we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

The basic concept consists in providing a relative measurement (e.g. HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio is, the more accurate the measurement is.

The HSI and CSI oscillators have dedicated user-accessible calibration bits for this purpose (see *RCC CSI calibration register (RCC_CSICFGR)*). When HSI or CSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultra-low-power LSI oscillator has a large manufacturing process deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC time base timeouts (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

7.5.10 General clock concept overview

The RCC handles the distribution of the CPU, bus interface and peripheral clocks for the system, according to the CPU operating mode (refer to *Section 7.5.1: Clock naming convention* for details on clock definitions).

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock. Prior to use a peripheral, the CPU must enable it (by setting PERxEN to 1), and define if this peripheral remains active in Sleep mode (by setting PERxLPEN to 1). This is called ‘allocation’ of a peripheral by the CPU (refer to *Section 7.5.11: Peripheral allocation* for more details).

The peripheral allocation is used:

- by the RCC to automatically control the clock gating according to the CPU modes, and
- by the PWR to control the supply voltages of VCORE.

Memory handling

The CPU can access all the memory areas available in the product:

- AXISRAM1, AXISRAM2, AXISRAM3, AXISRAM4, ITCM, DTCM1, DTCM2 and FLASH
- AHBSRAM1 and AHBSRAM2
- BKPRAM

The BKPRAM, AHBSRAM1 and AHBSRAM2 have dedicated enable bits in order to gate the bus interface clock. The CPU needs to enable them prior to use these memories.

Note: The memory interface clocks (Flash memory and RAM interfaces) can be stopped by software during Sleep mode (via SRAMyLPEN bits).

Refer to *Section 7.5.12: Peripheral clock gating control* and *Section 7.5.13: CPU and bus matrix clock gating control* sections for details on clock enabling.

7.5.11 Peripheral allocation

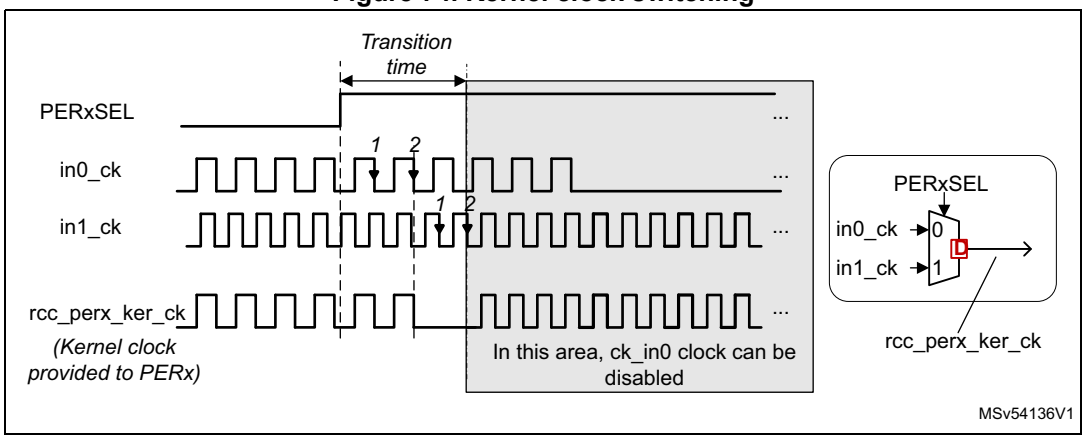
The CPU can allocate a peripheral and hence control its kernel and bus interface clock.

The CPU can allocate a peripheral by setting the dedicated PERxEN bit to 1.

The CPU can control the peripheral clocks gating when it is in Sleep mode via the PERxLPEN bits.

Refer to for additional information.

The peripheral allocation bits (PERxEN bits) are used by the hardware to provide the kernel and bus interface clocks to the peripherals. However they are also used to link peripherals to the CPU. In this way, the hardware is able to safely gate the peripheral clocks and bus matrix clocks according to CPU states.



Clock switches and gating

- Clock switching delays

  The input selected by the clock switches can be changed dynamically without generating spurs or timing violation. For example, if PERxSEL (In *Figure 74*) goes from 0 to 1, the switch first disables the clock output using the currently selected clock (in0_ck), and enables again the clock output using the new selected clock (in1_ck). The disable and enable commands are re-synchronized to their respective clocks. If one of the two clocks are not present, the sequence cannot be completed, and no clock is output. To recover from this situation, the user must either provide a valid clock to in1_ck input or set back PERxSEL to 0.

  During the transition from one input to another, the kernel clock provided to the peripheral is gated, in the worst case, during 2 or 3 clock cycles of the new selected clock. As shown in *Figure 74*, both input clocks must be present during transition time.

Figure 74. Kernel clock switching

- Clock enabling delays

  In the same way, the clock gating logic synchronizes the enable command (coming generally from a kernel clock request or PERxEN bits) with the selected clock, in order to avoid generation of spurs.

  – A maximum delay of two periods of the enabled clock may occur between the enable command and the first rising edge of the clock. The enable command can

be the rising edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request asserted by a peripheral.

– A maximum delay of 1.5 periods of the disabled clock may occur between the disable command and the last falling edge of the clock. The disable command can be the falling edge of the PERxEN bits of RCC_xxxxENR registers, or a kernel clock request released by a peripheral.

Note: Both the kernel and bus interface clocks are affected by this re-synchronization delay.

7.5.12 Peripheral clock gating control

As mentioned previously, each peripheral requires one or several bus interface clock, named **rcc_perx_bus_ck** (for peripheral 'x'). These clocks can be an APB, AHB or AXI clock, according to which bus or busses, the peripheral is connected.

The clocks used as bus interface for peripherals, can be **aclk**, **hclk[5:1]**, **pclk[5:4], or pclk[2:1],** depending on the bus connected to each peripheral.

Some peripherals also require dedicated clocks for their communication interface. These clocks are generally asynchronous with respect to the bus interface clock. They are named kernel clocks (**perx_ker_ck**). Both bus interface and kernel clocks can be gated according to several conditions detailed hereafter.

As shown in *Figure 75*, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits,

  PERxEN represents the peripheral enable (allocation) bit for the CPU. The CPU can write these bits to 1 via the RCC_xxxxENR registers.
- CPU state (**cpu_sleep** and **cpu_deepsleep** signals)
- Kernel clock request (**perx_ker_ckreq**) of the peripheral itself, when the feature is available

Refer to *Section 7.5.11: Peripheral allocation* for more details.

Figure 75. Peripheral kernel clock enable logic details

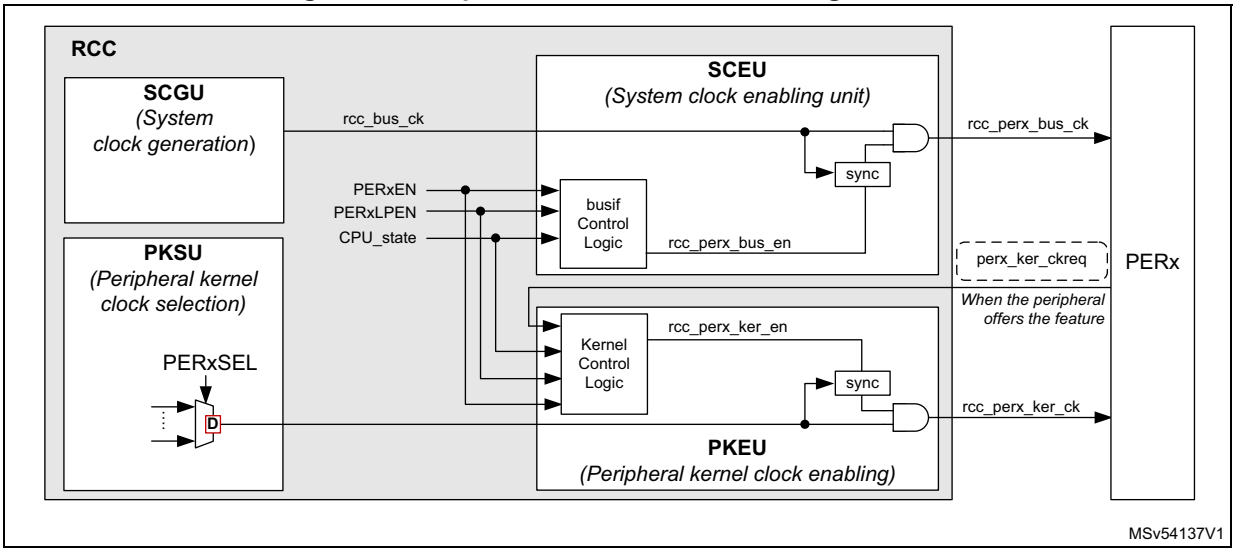


Table 68 gives a detailed description of the enabling logic of the peripheral clocks for peripherals located in the CPU domain and allocated by the CPU.

Table 68. Peripheral clock enabling

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq	CPU state	rcc_perx_ker_ck	rcc_perx_bus_ck	Comments
0	X	X	X	X	-	-	No clock provided to the peripheral, because PERxEN=0
1	X	X	X	Run	CK	CK	Kernel and bus interface clocks are provided to the peripheral, because the CPU is in Run, and PERxEN = 1.
1	0	X	X	Sleep	-	-	No clock provided to the peripheral, because the CPU is in Sleep and PERxLPEN = 0
1	1				CK	CK	Kernel and bus interface clocks are provided to the peripheral, because CPU is in Sleep, and PERxLPEN = 1
1	0	X	X	Stop	-	-	No clock provided to the peripheral because the PERxLPEN bit is set to 0.
1	1	no lsi_ck and no lse_ck and no hsi_ker_ck and no csi_ker_ck	X		-	-	No clock provided to the peripheral because CPU is in Stop and **lse_ck** or **lsi_ck** or **hsi_ker_ck** or **csi_ker_ck** are not selected as kernel clock.
1	1	lsi_ck or lse_ck	X		CK	-	Kernel clock is provided to the peripheral because: PERxEN = PERxLPEN = 1 and **lsi_ck** or **lse_ck** are selected and enabled. The bus interface clock is not provided as the CPU is in Stop.
1	1	hsi_ker_ck or csi_ker_ck	1		CK	-	Kernel clock is provided to the peripheral because: **req_ker_perx** = 1, and PERxEN = PERxLPEN = 1 and **hsi_ker_ck** or **csi_ker_ck** are selected and enabled. The bus interface clock is not provided as the CPU is in Stop.
1	1	hsi_ker_ck or csi_ker_ck	0		-	-	No clock provided to the peripheral because CPU is in Stop, and no kernel clock request pending

As a summary, we can state that the kernel clock is provided to the peripherals when the following conditions are met:

1. The CPU is in Run mode, and the peripheral is enabled.
2. The CPU is in Sleep mode and the peripheral is enabled with PERxLPEN = 1.
3. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1, the peripheral generates a kernel clock request and the selected clock is **hsi_ker_ck** or **csi_ker_ck**.
4. The CPU is in Stop mode, the peripheral is enabled with PERxLPEN = 1 and the kernel source clock of the peripheral is **lse_ck** or **lsi_ck**.

The bus interface clock is provided to the peripherals only when conditions 1 or 2 are met.

The RNG block is not clocked as other peripherals, the table hereafter shows the way RNG is clocked.

Table 69. RNG clock enabling

RNGEN	RNGLPEN	rng_ker_ckreq	CPU state	hsi48_ker_ck	rcc_rng_hclk3	Comments
0	X	X	X	-	-	No clock provided to the peripheral, because RNGEN=0
1	X	0	Run	-	CK	**hsi48_ker_ck** not provided because the kernel clock request is not asserted. hclk3 clock is provided
1	X	1		CK	CK	Both **hsi48_ker_ck** and hclk3 are provided because the kernel clock request is asserted, and RNGEN = 1.
1	0	X	Sleep	-	-	No clock provided, because the CPU is in Sleep and RNGLPEN = 0
1	1	0		-	CK	**hsi48_ker_ck** not provided because the kernel clock request is not asserted. hclk3 clock is provided
1	1	1		CK	CK	Both **hsi48_ker_ck** and hclk3 are provided because the kernel clock request is asserted, RNGEN = 1 and RNGLPEN = 1
1	X	X	Stop	-	-	No clock provided because the CPU is in Stop mode

7.5.13 CPU and bus matrix clock gating control

The clocks of the CPU, AHB and AXI bridges and APB busses are enabled according to the rules hereafter:

- The CPU clock (**rcc_cpu_ck**) is enabled when the CPU is in Run or Sleep mode.
- The AXI bridge clock is enabled when the CPU is in Run or Sleep mode.
- Each AXI master and slave has an independent clock gating activated by default, to further reduce the power consumption. When activated the clock is automatically enabled on bus transaction request. The *RCC AXI clocks gating disable register (RCC_CKGDISR)* allows he application to control this behavior.
- The AHB bus matrix clock is enabled if one of the following conditions is met:
  - The CPU is in Run mode
  - The CPU is in Sleep mode, and at least one peripheral connected to this bridge have both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode, and AHB1, AHB2, AHB3, AHB4 or AHB5 has its clock enabled
- The clocks of the bridges AHB1, 2, 3, 4, 5 are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - The CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.
  - The CPU is in Sleep mode and the APB bus connected to the AHB bridge has its clock enabled.
- The APB1, 2, 4, 5 clock busses are enabled when one of the following conditions is met:
  - The CPU is in Run mode.
  - When the CPU is in Sleep mode with at least one peripheral connected to this bus having both its PERxEN and PERxLPEN set to 1.

7.5.14 Low-power emulation modes

In order to ease the debugging of the circuit, the RCC is able to handle an emulation mode for Stop and Standby modes.

Sleep emulation mode

The Sleep emulation mode is controlled by the DBG_SLEEP bit of the DBGMCU_CR register. When the processor goes to Sleep with DBG_SLEEP = 1, then the processor clock, the clocks of all enabled peripherals, debug parts, and interconnect are maintained activated.

Stop emulation mode

The Stop emulation mode is controlled by the DBG_STOP bit of DBGMCU_CR register. When the processor goes to Stop with DBG_STOP = 1, then:

- The PWR and the RCC remains activated.
- The VDDCORE voltage is set to the minimum VOS value.
- The RCC selects HSI or CSI as system clock, depending on STOPWUCK bit.
- The processor clock is gated (rcc_cpu_ck, see *Figure 51*),
- The free-running clock is generated (rcc_fclk, see *Figure 51*), and all the debug parts remain clocked.
- All peripheral clocks are gated. Peripherals can still receive a kernel clock if they request it, and if the kernel clock source is an RC oscillator. They also receive the kernel clock if the kernel clock source is LSI or LSE.
- The interconnect clocks are gated.

When a wake-up event occurs:

- The VDDCORE voltage remains to the minimum VOS value.
- The peripheral waking up the system sends the interrupt to the NVIC via the EXTI.
- The CPU exits from STOP and the RCC provide the processor clock and interconnect clocks.

Standby emulation mode

The Standby emulation mode is controlled by the DBG_STANDBY bit of the DBGMCU_CR register.

When the system goes to Standby with DBG_STANDBY = '1', then:

- The VDDCORE voltage is not switched-off, but remains to the minimum VOS value.
- All the VDDCORE domain is under reset except the debug part.
- The debug part is clocked.
- Peripherals on VBat or VDD domains are not reset.

When the system exits from Standby, then:

- Option bytes are reloaded.
- The reset of the VDDCORE domain is released.
- The Standby flag is updated as well.

7.6 RCC interrupts

The RCC provides three interrupt lines:

- **rcc_it**: general interrupt line providing events when the PLLs are ready or when the oscillators are ready
- **rcc_hsecss_it**: interrupt line dedicated to the failure detection of the HSE CSS (clock security system)
- **rcc_lsecss_it**: interrupt line dedicated to the failure detection of the LSE CSS

The interrupt enable is controlled via *RCC clock source interrupt enable register (RCC_CIER)*, except for the HSE CSS failure. When the HSE CSS feature is enabled, it not possible to mask the interrupt generation.

The interrupt flags can be checked via *RCC clock source interrupt flag register (RCC_CIFR)*, and these flags can be cleared via *RCC clock source interrupt clear register (RCC_CICR)*.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Table 70 gives a summary of the interrupt sources and the way to control them.

Table 70. Interrupt sources and control

Interrupt source	Description	Interrupt enable	Action to clear interrupt	Interrupt line
LSIRDYF	LSI ready	LSIRDYIE	Set LSIRDYC to 1	rcc_it
LSERDYF	LSE ready	LSERDYIE	Set LSERDYC to 1	
HSIDRYF	HSI ready	HSIDRYIE	Set HSIRDYC to 1	
HSERDYF	HSE ready	HSERDYIE	Set HSERDYC to 1	
CSIRDYF	CSI ready	CSIRDYIE	Set CSIRDYC to 1	
HSI48RDYF	HSI48 ready	HSI48RDYIE	Set HSI48RDYC to 1	
PLL1RDYF	PLL1 ready	PLL1RDYIE	Set PLL1RDYC to 1	
PLL2RDYF	PLL2 ready	PLL2RDYIE	Set PLL2RDYC to 1	
PLL3RDYF	PLL3 ready	PLL3RDYIE	Set PLL3RDYC to 1	
LSECSSF	LSE CSS failure	LSECSSFIE (1)	Set LSECSSC to 1	rcc_lsecss_it
HSECSSF	HSE CSS failure	- (2)	Set HSECSSC to 1	rcc_hsecss_it

1. The security system feature must also be enabled (LSECSSON = 1), in order to generate interrupts.
2. It is not possible to mask this interrupt when the security system feature is enabled (HSECSSON = 1).

7.7 RCC Programming examples

7.7.1 PLL programming procedure

PLL initialization procedure

The recommended initialization sequence of the PLLs for the integer and fractional mode is given hereafter:

- The PLL is supposed to be disabled: PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN,PLLxTEN, PLLxON, and PLLxRDY set to ‘0’, if it is not the case, refer to *PLL disabling procedure*.
- Enable the wanted clock source (HSE, HSI, or CSI) and wait for the ready flag.
- Select the clock source via PLLSCR into *RCC PLLs clock source selection register (RCC_PLLCKSELR)*.
- Initialize the pre-dividers (DIVMx) in order to provide to the PLL, a valid reference clock. DIVMx are located into *RCC PLLs clock source selection register (RCC_PLLCKSELR)*.
- Configure the PLL:
  - In integer or clock spreading mode the application must ensure that a 0 is loaded into the SDM. This can be done as follows:
    - Set PLLxFRACLE to 0
    - Write FRACN to 0
    - Set PLLxFRACLE to 1
    - Write FRACN to 0
    - Wait at least 5 µs
  - In fractional mode, the application must load the SDM with the wanted value (FracInitValue) by executing a sequence similar to the integer mode, but with FRACN = FracInitValue.
  - Program the fields PLLxRGE, PLLxVCOSEL, SSCG_CTRL, DIVxN, DIVxP, DIVxQ, DIVxR, DIV2S and DIV2T.
  - If the clock spreading mode is used, program also the fields MODPER, INCSTEP, SPREADSEL, TPDFNDIS, RPDFNDIS, and set PLLxSSCGEN to 1.
  - If the clock spreading mode is not used, set PLLxSSCGEN to 0.
- Enable the PLL:
  - Set the corresponding PLLxON bit to 1, and wait for PLLxRDY bit set to 1,
  - If the PLL is in fractional mode, the FRACLE bit must not be set back to 0 as long as PLLxRDY = 0.
- When the PLLxRDY bit is equal to 1, the application can enable the wanted outputs by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN, PLLxTEN to 1.
- If the application intends to tune the PLL frequency on-the-fly (only possible in fractional mode), then:
  - Set PLLxFRACLE to ‘0’,
    When FRACLE = ‘0’, the sigma delta modulator is still operating with the current value,
  - Write the new value into FRACN[12:0] (FracValue(n)),
  - Set PLLxFRACLE to 1, in order to latch the content of FRACN[12:0] into the SDM.

– Wait at least 5 µs.

Note: When the PLLxRDY goes to 1, it means that the PLLx output frequency is within 2% of its target value.

Reprogramming post-dividers

When the PLLs are enabled, it is possible to change the values of a post-dividers (DIVP, DIVQ, DIVR, DIVS or DIVT) without disabling the corresponding PLLx, by performing the following sequence:

- Disable the wanted output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 0,
- Change the value of the corresponding post-divider (DIVP, DIVQ, DIVR, DIVS or DIVT),
- Re-enable this output by setting the bit PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN or PLLxTEN to 1.

PLL disabling procedure

The recommended disabling sequence is given hereafter:

- Disable all the post-dividers by setting PLLxPEN, PLLxQEN, PLLxREN, PLLxSEN and PLLxTEN bits of PLLx to 0,
- Disable the PLL: set PLLxON bit of PLLx to 0,
- Wait for PLLxRDY = 0.

Using the SSCG block

For example, if an application needs to generate with the PLL2, a clock signal having the following characteristics:

- A frequency at DIVS output (**FpII2_s_ck**) of 200 MHz Max,
- With a modulation depth of 0.5% peak (M_D),
- With a frequency modulation of 28 kHz (F_{MOD}).

The assumption is that the crystal oscillator is 8 MHz (F_{hse_ck}).

DIVM2 is programmed to 0 in order to provide a reference clock of 8 MHz to the PLL2 (F_{ref2_ck}). The VCOH must be selected when SSCG is used.

From a 8 MHz reference clock, it is possible to generate 200 MHz, by programming the PLL2 as follow: (DIVN+1) = 50, (Fvco = 800 MHz), (DIVS+1) = 4.

The application has to compute the following parameters:

Computing MODPER:

$$MODPER = ROUND\left(\frac{F_{ref_ck}}{4 \times F_{MOD}}\right) = ROUND\left(\frac{8 \times 10^6}{4 \times 28 \times 10^3}\right) = 71$$

Computing INCSTEP:

$$INCSTEP = ROUND\left(\frac{(2^{15} - 1) \times M_D \times (DIVN + 1)}{100 \times 5 \times MODPER}\right) = ROUND\left(\frac{32767 \times 0.5 \times (49 + 1)}{100 \times 5 \times 71}\right) = 23$$

Check that MODPER x INCSTEP is lower than (2^{15}-1)

In the example, MODPER x INCSTEP = 1633 ==> OK

Due to rounding operations, the modulation period and the modulation depth does not completely match the target. The real modulation depth is:

$$M_D\,(\%) = \frac{MODPER \times INCSTEP \times 100 \times 5}{(2^{15}-1)\times(DIVN+1)} = \frac{71 \times 23 \times 100 \times 5}{(2^{15}-1)\times(49+1)} = 0.498\ \%$$

And the modulation frequency (Fmod) is:

$$F_{mod} = \frac{F_{ck_ref}}{4 \times MODPER} = \frac{8 \times 10^6}{4 \times 71} = 28.2\ \text{kHz}$$

The down-spread modulation must be used (SPREADSEL = 1) to keep the maximum frequency to a value lower than 200 MHz.

7.7.2 Frequency configuration examples

This section gives various frequency settings for CPU and XSPI interfaces, combined with audio constraints. The case without audio constraints is not shown as it is obvious that PLL1 and PLL2 can provide the expected frequency. If audio applications are required, several options are offered to the user:

- Generate the kernel clock with PLL1, PLL2 or PLL3
- Use the external audio clock input (I2S_CKIN)
- Use oscillators

In this section, we explore the cases where PLL1 or PLL2 are used for audio.

Note as well that PLL2 is also used for XSPIs, if it is shared for audio application, it is not recommended to activate the SSCG.

The configurations listed in the tables hereafter are not exhaustive, many other setting are available. For example if the clock provided to the SAI must be shared with FDCAN, then the application would like to generate a clock around 100 MHz to insure good working conditions for FDCAN. These considerations are not taken into account in these tables.

Note also that in order to get the best clock quality at PLL output, F_{REF} must be as close as possible to 16 MHz. This is not always easy to do for PLLs in integer mode, but can be done easily when the PLLs are in fractional mode (as shown in the tables).

Table 71. Clock configuration examples with PLLs in integer mode

Configuration	HSE (MHz)	DIVM+1	F_{REF} (MHz) (1)	PLLxRGE	DIVN+1	FRACV	F_{VCO} (MHz) (2)	DIVP+1	DIVQ+1	DIVS/T+1	F_{CPU} (MHz)(3)	F_{XSPI} (MHz)(4)	F_{AUDIO} (MHz)(5)	F_{CPU} accuracy (%)	F_{XSPI} accuracy (%)	F_{AUDIO} accuracy (ppm)

		r	rw			rw	r	rw		r	rw	rw	r	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **PLL3RDY**: PLL3 clock ready flag
Set by hardware to indicate that the PLL3 is locked.
0: PLL3 unlocked (default after reset)
1: PLL3 locked

Bit 28 **PLL3ON**: PLL3 enable
Set and cleared by software to enable PLL3.
Cleared by hardware when entering Stop or Standby mode.
0: PLL3 OFF (default after reset)
1: PLL3 ON

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL2 is locked.
0: PLL2 unlocked (default after reset)
1: PLL2 locked

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if FMCCKP = 1, or XSPICKP = 1.
0: PLL2 OFF (default after reset)
1: PLL2 ON

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked (default after reset)
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable
Set and cleared by software to enable PLL1.
Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock (SW=3) or if FMCCKP = 1, or if XSPICKP = 1.
0: PLL1 OFF (default after reset)
1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSECSSON**: HSE clock security system enable
Set by software to enable clock security system on HSE.
This bit is “set only” (disabled by a system reset or when the system enters in Standby mode).
When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.
0: CSS on HSE OFF (clock detector OFF) (default after reset)
1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF if not).

Bit 19 **HSEEXT**: external high speed clock type in Bypass mode
Set and reset by software to select the external clock type (analog or digital).
The external clock must be enabled with the HSEON bit to be used by the device.
The HSEEXT bit can be written only if the HSE oscillator is disabled.
0: HSE in analog mode (default after reset)
1: HSE in digital mode

Bit 18 **HSEBYP**: HSE clock bypass
Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled with the HSEON bit to be used by the device.
The HSEBYP bit can be written only if the HSE oscillator is disabled.
0: HSE oscillator not bypassed (default after reset)
1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag
Set by hardware to indicate that the HSE oscillator is stable.
0: HSE clock is not ready (default after reset)
1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable
Set and cleared by software.
Cleared by hardware to stop the HSE when entering Stop or Standby mode.
This bit cannot be cleared if the HSE is used directly (via SW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.
0: HSE is OFF (default after reset)
1: HSE is ON

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **HSI48RDY**: HSI48 clock ready flag
Set by hardware to indicate that the HSI48 oscillator is stable.
0: HSI48 clock is not ready (default after reset)
1: HSI48 clock is ready

Bit 12 **HSI48ON**: HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.

0: HSI48 is OFF (default after reset)

1: HSI48 is ON

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CSIKERON**: CSI clock enable in Stop mode

Set and reset by software to force the CSI to ON, even in Stop mode, in order to be quickly available as kernel clock for some peripherals. This bit has no effect on the value of CSION.

0: no effect on CSI (default after reset)

1: CSI is forced to ON even in Stop mode

Bit 8 **CSIRDY**: CSI clock ready flag

Set by hardware to indicate that the CSI oscillator is stable. This bit is activated only if the RC is enabled by CSION (it is not activated if the CSI is enabled by CSIKERON or by a peripheral request).

0: CSI clock is not ready (default after reset)

1: CSI clock is ready

Bit 7 **CSION**: CSI clock enable

Set and reset by software to enable/disable CSI clock for system and/or peripheral.

Set by hardware to force the CSI to ON when the system leaves Stop mode, if STOPWUCK = 1 or STOPKERWUCK = 1.

This bit cannot be cleared if the CSI is used directly (via SW mux) as system clock, or if the CSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.

0: CSI is OFF (default after reset)

1: CSI is ON

Bit 6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag

Set and reset by hardware.

As a write operation to HSIDIV has not an immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV.

0: new division ratio not yet propagated to **hsi(_ker)_ck** (default after reset)

1: **hsi(_ker)_ck** clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed)

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider

Set and reset by software.

These bits allow selecting a division ratio in order to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set to 1). In that case, the new HSIDIV value is ignored.

00: division by 1, **hsi(_ker)_ck** = 64 MHz (default after reset)

01: division by 2, **hsi(_ker)_ck** = 32 MHz

10: division by 4, **hsi(_ker)_ck** = 16 MHz

11: division by 8, **hsi(_ker)_ck** = 8 MHz

Bit 2 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

Bit 1 **HSIKERON**: HSI clock enable in Stop mode

Set and reset by software to force the HSI to ON, even in Stop mode, in order to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION.

0: no effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

Bit 0 **HSION**: HSI clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product leaves Stop mode, if STOPWUCK = 0 or STOPKERWUCK = 0.

Set by hardware to force the HSI to ON when the product leaves Standby mode or in case of a failure of the HSE which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SW switch) as system clock, or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1) or if FMCCKP = 1, or if XSPICKP = 1.

0: HSI is OFF

1: HSI is ON (default after reset)

7.8.2 RCC clock protection register (RCC_CKPROTR)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FMCSWP[2:0]			Res.	XSPI2SWP[2:0]			Res.	XSPI1SWP[2:0]			Res.	Res.	FMCCKP	XSPICKP
	r	r	r		r	r	r		r	r	r			rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 **FMCSWP[2:0]**: FMC kernel clock switch position
Set by hardware.
This field can be used to verify the real position of FMC kernel switch selector.
000: The switch is in neutral mode and output clock is gated (default after reset)
001: The switch is selecting hclk5
010: The switch is selecting pll1_q_ck
011: The switch is selecting pll2_r_ck
100: The switch is selecting hsi_ker_ck
101: The switch is in recovery position (hclk5/4)

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **XSPI2SWP[2:0]**: XSPI2 kernel clock switch position
Set by hardware.
This field can be used to verify the real position of XSPI2 kernel switch selector.
000: The switch is in neutral mode and output clock is gated (default after reset)
001: The switch is selecting hclk5
010: The switch is selecting pll2_s_ck
011: The switch is selecting pll2_t_ck
100: The switch is in recovery position (hclk5/4)

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **XSPI1SWP[2:0]**: XSPI1 kernel clock switch position
Set by hardware.
This field can be used to verify the real position of XSPI1 kernel switch selector.
000: The switch is in neutral mode and output clock is gated (default after reset)
001: The switch is selecting hclk5
010: The switch is selecting pll2_s_ck
011: The switch is selecting pll2_t_ck
100: The switch is in recovery position (hclk5/4)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FMCCKP**: FMC clock protection
Set and cleared by software.
When set to 1, this bit prevents disabling accidentally the FMC. The following fields cannot be modified when this bit is set to 1:
PLL1ON, PLL2ON, PLL1QEN, PLL2REN, HSEON, HSION, CSION, FMCEN, FMCLPEN, FMCRST.
0: Clock protection is disabled (default after reset)
1: Clock protection is enabled

Bit 0 **XSPICKP**: XSPI clock protection
Set and cleared by software.
When set to 1, this bit prevents disabling accidentally the XSPIs. The following fields cannot be modified when this bit is set to 1:
PLL2ON, PLL2SEN, PLL2TEN, HSEON, HSION, CSION, XSPIxEN, XSPIxLPEN, XSPIxRST.
0: Clock protection is disabled (default after reset)
1: Clock protection is enabled

7.8.3 RCC HSI calibration register (RCC_HSICFGR)

Address offset: 0x004

Reset value: 0x4000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	HSITRIM[6:0]							Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSITRIM[6:0]**: HSI clock trimming
Set by software to adjust calibration.
HSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_HSI_opt) in order to form the calibration trimming value.
HSICAL = HSITRIM + FLASH_HSI_opt.
Note: The reset value of the field is 0x40.

Bits 23:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration
Set by hardware by option byte loading.
Adjusted by software through trimming bits HSITRIM.
This field represents the sum of engineering option byte calibration value and HSITRIM bits value.

7.8.4 RCC clock recovery RC register (RCC_CRRCR)

Address offset: 0x008

Reset value: 0x0000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	HSI48CAL[9:0]									
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration
Set by hardware by option byte loading.
Read-only.

7.8.5 RCC CSI calibration register (RCC_CSICFGR)

Address offset: 0x00C

Reset value: 0x2000 0XXX

Reset value depends on the flash option bytes setting.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	CSITRIM[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
		rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSICAL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **CSITRIM[5:0]**: CSI clock trimming
Set by software to adjust calibration.
CSITRIM field is added to the engineering option bytes loaded during reset phase (FLASH_CSI_opt) in order to form the calibration trimming value.
CSICAL = CSITRIM + FLASH_CSI_opt.
Note: The reset value of the field is 0x20.

Bits 23:8 Reserved, must be kept at reset value.

Bits 7:0 **CSICAL[7:0]**: CSI clock calibration
Set by hardware by option byte loading.
Adjusted by software through trimming bits CSITRIM.
This field represents the sum of engineering option byte calibration value and CSITRIM bits value.

7.8.6 RCC clock configuration register (RCC_CFGR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2SEL[2:0]			MCO2PRE[3:0]				MCO1SEL[2:0]			MCO1PRE[3:0]				Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMPRE	Res.	RTCPRE[5:0]						STOPKERWUCK	STOPWUCK	SWS[2:0]			SW[2:0]		
rw		rw	rw	rw	rw	rw	rw	rw	rw	r	r	r	rw	rw	rw

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: system clock selected (**sys_ck**) (default after reset)
001: PLL2 oscillator clock selected (**pll2_p_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_p_ck**)
100: CSI clock selected (**csi_ck**)
101: LSI clock selected (**lsi_ck**)
others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1

Set and cleared by software. Clock source selection may generate glitches on MCO1.
It is highly recommended to configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: HSI clock selected (**hsi_ck**) (default after reset)
001: LSE oscillator clock selected (**lse_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_q_ck**)
100: HSI48 clock selected (**hsi48_ck**)
others: reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler

Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. It is highly recommended to change this prescaler only after reset, before enabling the external oscillators and the PLLs.

0000: prescaler disabled (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 17:16 Reserved, must be kept at reset value.

Bit 15 **TIMPRE**: timers clocks prescaler selection

This bit is set and reset by software to control the clock frequency of all the timers connected to APB1 and APB2 domains.

0: The timers kernel clock is equal to **rcc_hclk1** if CDPPREx is corresponding to division by 1 or 2, else it is equal to 2 x $\mathbf{F_{rcc_pclkx_d2}}$ (default after reset)
1: The timers kernel clock is equal to **rcc_hclk1** if CDPPREx is corresponding to division by 1, 2 or 4, else it is equal to 4 x $\mathbf{F_{rcc_pclkx_d2}}$
Refer to *Table 67: Ratio between clock timer and pclk* for more details.

Bit 14 Reserved, must be kept at reset value.

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock

Set and cleared by software to divide the HSE to generate a clock for RTC.
Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000: no clock (default after reset)
000001: no clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
...
111110: HSE/62
111111: HSE/63

Bit 7 **STOPKERWUCK**: kernel clock selection after a wake up from system Stop

Set and reset by software to select the kernel wake-up clock from system Stop.

0: HSI selected as wake up clock from system Stop (default after reset)
1: CSI selected as wake up clock from system Stop
See *Section 1.: Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles.* for details.

Bit 6 **STOPWUCK**: system clock selection after a wake up from system Stop

Set and reset by software to select the system wake-up clock from system Stop.

The selected clock is also used as emergency clock for the clock security system (CSS) on HSE.

0: HSI selected as wake up clock from system Stop (default after reset)

1: CSI selected as wake up clock from system Stop

See *Section 1.: Dividers values can be changed on-the-fly. All dividers provide have 50% duty-cycles.* for details.

Caution: STOPWUCK must not be modified when CSS is enabled (by HSECSSON bit) and the system clock is HSE (SWS = 10) or a switch on HSE is requested (SW =10).

Bits 5:3 **SWS[2:0]**: system clock switch status

Set and reset by hardware to indicate which clock source is used as system clock.

000: HSI used as system clock (**hsi_ck**) (default after reset)

001: CSI used as system clock (**csi_ck**)

010: HSE used as system clock (**hse_ck**)

011: PLL1 used as system clock (**pll1_p_ck**)

others: reserved

Bits 2:0 **SW[2:0]**: system clock switch

Set and reset by software to select system clock source (**sys_ck**).

Set by hardware in order to force the selection of the HSI or CSI (depending on STOPWUCK selection) when leaving a system Stop mode or in case of failure of the HSE when used directly or indirectly as system clock.

000: HSI selected as system clock (**hsi_ck**) (default after reset)

001: CSI selected as system clock (**csi_ck**)

010: HSE selected as system clock (**hse_ck**)

011: PLL1 selected as system clock (**pll1_p_ck**)

others: reserved

7.8.7 RCC CPU domain clock configuration register (RCC_CDCFGR)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CPRE[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **CPRE[3:0]**: CPU domain core prescaler

Set and reset by software to control the CPU clock division factor.

Changing this division ratio has an impact on the frequency of the CPU clock and all bus matrix clocks.

After changing this prescaler value, it takes up to 16 periods of the slowest APB clock before the new division ratio is taken into account. The application can check if the new division factor is taken into account by reading back this register.

0xxx: **sys_ck** not divided (default after reset)
1000: **sys_ck** divided by 2
1001: **sys_ck** divided by 4
1010: **sys_ck** divided by 8
1011: **sys_ck** divided by 16
1100: **sys_ck** divided by 64
1101: **sys_ck** divided by 128
1110: **sys_ck** divided by 256
1111: **sys_ck** divided by 512

Caution: Care must be taken when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change and before lowering the V_{CORE} voltage, this register must be read in order to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application must program a correct value in BMPRE to make sure that the system frequency does not exceed the maximum frequency.

7.8.8 RCC AHB clock configuration register (RCC_BMCFGR)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BMPRE[3:0]			
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:0 **BMPRE[3:0]**: Bus matrix clock prescaler

Set and reset by software to control the division factor of **rcc_hclk[5:1]** and **rcc_aclk**. This group of clocks is also named **sys_bus_ck**. Changing this division ratio has an impact on the frequency of all bus matrix clocks.

0xxx: **sys_bus_ck= sys_cpu_ck** (default after reset)
1000: **sys_bus_ck** = **sys_cpu_ck** / 2
1001: **sys_bus_ck= sys_cpu_ck** / 4
1010: **sys_bus_ck** = **sys_cpu_ck** / 8
1011: **sys_bus_ck** = **sys_cpu_ck** / 16
1100: **sys_bus_ck** = **sys_cpu_ck** / 64
1101: **sys_bus_ck** = **sys_cpu_ck** / 128
1110: **sys_bus_ck** = **sys_cpu_ck** / 256
1111: **sys_bus_ck** = **sys_cpu_ck** / 512

*Note: The clocks are divided by the new prescaler factor from 1 to 16 periods of the slowest APB clock among **rcc_pclk1,2,4,5** after BMPRE update.*

*Note: Note also that frequency of **rcc_hclk[5:1]** = **rcc_aclk** = **sys_bus_ck**.*

7.8.9 RCC APB clocks configuration register (RCC_APBCFGR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	PPRE5[2:0]			Res.	PPRE4[2:0]			Res.	PPRE2[2:0]			Res.	PPRE1[2:0]		
	rw	rw	rw		rw	rw	rw		rw	rw	rw		rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE5[2:0]**: CPU domain APB5 prescaler

Set and reset by software to control the division factor of **rcc_pclk5**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE5 write.
0xx: **rcc_pclk5** = **sys_bus_ck** (default after reset)
100: **rcc_pclk5** = **sys_bus_ck** / 2
101: **rcc_pclk5** = **sys_bus_ck** / 4
110: **rcc_pclk5** = **sys_bus_ck** / 8
111: **rcc_pclk5** = **sys_bus_ck** / 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE4[2:0]**: CPU domain APB4 prescaler

Set and reset by software to control the division factor of **rcc_pclk4**.
The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE4 write.
0xx: **rcc_pclk4** = **sys_bus_ck** (default after reset)
100: **rcc_pclk4** = **sys_bus_ck** / 2
101: **rcc_pclk4** = **sys_bus_ck** / 4
110: **rcc_pclk4** = **sys_bus_ck** / 8
111: **rcc_pclk4** = **sys_bus_ck** / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE2[2:0]**: CPU domain APB2 prescaler

Set and reset by software to control the division factor of **rcc_pclk2**.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE2 write.

0xx: **rcc_pclk2** = **sys_bus_ck** (default after reset)

100: **rcc_pclk2** = **sys_bus_ck** / 2

101: **rcc_pclk2** = **sys_bus_ck** / 4

110: **rcc_pclk2** = **sys_bus_ck** / 8

111: **rcc_pclk2** = **sys_bus_ck** / 16

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **PPRE1[2:0]**: CPU domain APB1 prescaler

Set and reset by software to control the division factor of **rcc_pclk1**.

The clock is divided by the new prescaler factor from 1 to 16 cycles of **sys_bus_ck** after PPRE1 write.

0xx: **rcc_pclk1** = **sys_bus_ck** (default after reset)

100: **rcc_pclk1** = **sys_bus_ck** / 2

101: **rcc_pclk1** = **sys_bus_ck** / 4

110: **rcc_pclk1** = **sys_bus_ck** / 8

111: **rcc_pclk1** = **sys_bus_ck** / 16

7.8.10 RCC PLLs clock source selection register (RCC_PLLCKSELR)

Address offset: 0x028

Reset value: 0x0202 0200

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	DIVM3[5:0]						Res.	Res.	DIVM2[5:4]

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:20 **DIVM3[5:0]:** prescaler for PLL3

Set and cleared by software to configure the prescaler of the PLL3.
The hardware does not allow any modification of this prescaler when PLL3 is enabled (PLL3ON = 1).
In order to save power when PLL3 is not used, the value of DIVM3 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:12 **DIVM2[5:0]**: prescaler for PLL2

Set and cleared by software to configure the prescaler of the PLL2.
The hardware does not allow any modification of this prescaler when PLL2 is enabled (PLL2ON = 1).
In order to save power when PLL2 is not used, the value of DIVM2 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:4 **DIVM1[5:0]**: prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this prescaler when PLL1 is enabled (PLL1ON = 1).
In order to save power when PLL1 is not used, the value of DIVM1 must be set to 0.
000000: prescaler disabled
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32 (default after reset)
...
111111: division by 63

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **PLLSRC[1:0]:** DIVMx and PLLs clock source selection

Set and reset by software to select the PLL clock source.
These bits can be written only when all PLLs are disabled.
In order to save power, when no PLL is used, PLLSRC must be set to ‘11’.
00: HSI selected as PLL clock (**hsi_ck**) (default after reset)
01: CSI selected as PLL clock (**csi_ck**)
10: HSE selected as PLL clock (**hse_ck**)
11: no clock send to DIVMx divider and PLLs

7.8.11 RCC PLLs configuration register (RCC_PLLCFGR)

Address offset: 0x02C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw			rw		rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **PLL3SEN**: PLL3 DIVS divider output enable
Set and reset by software to enable the **pll3_s_ck** output of the PLL3.
To save power, PLL3SEN must be set to 0 when the **pll3_s_ck** is not used.
0: **pll3_s_ck** output disabled (default after reset)
1: **pll3_s_ck** output enabled

Bit 29 **PLL3REN**: PLL3 DIVR divider output enable
Set and reset by software to enable the **pll3_r_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll3_r_ck** output disabled (default after reset)
1: **pll3_r_ck** output enabled

Bit 28 **PLL3QEN**: PLL3 DIVQ divider output enable
Set and reset by software to enable the **pll3_q_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll3_q_ck** output disabled (default after reset)
1: **pll3_q_ck** output enabled

Bit 27 **PLL3PEN**: PLL3 DIVP divider output enable
Set and reset by software to enable the **pll3_p_ck** output of the PLL3.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll3_p_ck** output disabled (default after reset)
1: **pll3_p_ck** output enabled

Bits 26:25 **PLL3RGE[1:0]**: PLL3 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL3.
These bits must be written before enabling the PLL3.
00: PLL3 input (**ref3_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (**ref3_ck**) clock range frequency between 2 and 4 MHz
10: PLL3 input (**ref3_ck**) clock range frequency between 4 and 8 MHz
11: PLL3 input (**ref3_ck**) clock range frequency between 8 and 16 MHz

Bit 24 **PLL3SSCGEN**: PLL3 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL3, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 23 **PLL3VCOSEL**: PLL3 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL3.
This bit must be written before enabling the PLL3. It allows the application to select the VCO range:
– VCOH: working from 384to 1672 MHz (F_{ref2_ck} must be between 2 and 16 MHz)
– VCOL: working from 150 to 420 MHz (F_{ref2_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 22 **PLL3FRACEN**: PLL3 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL3FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 419* for additional information.
PLL3FRACEN must remain at 0 for at least 5 µs

Bit 21 Reserved, must be kept at reset value.

Bit 20 **PLL2TEN**: PLL2 DIVT divider output enable
Set and reset by software to enable the **pll2_t_ck** output of the PLL2.
To save power, PLL2TEN must be set to 0 when the **pll2_t_ck** is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: **pll2_t_ck** output disabled (default after reset)
1: **pll2_t_ck** output enabled

Bit 19 **PLL2SEN**: PLL2 DIVS divider output enable
Set and reset by software to enable the **pll2_s_ck** output of the PLL2.
To save power, PLL2SEN must be set to 0 when the **pll2_s_ck** is not used.
The hardware prevents writing this bit if XSPICKP = 1.
0: **pll2_s_ck** output disabled (default after reset)
1: **pll2_s_ck** output enabled

Bit 18 **PLL2REN**: PLL2 DIVR divider output enable
Set and reset by software to enable the **pll2_r_ck** output of the PLL2.
The hardware prevents writing this bit if FMCCKP = 1.
To save power, PLL3REN and DIVR bits must be set to 0 when the **pll3_r_ck** is not used.
0: **pll2_r_ck** output disabled (default after reset)
1: **pll2_r_ck** output enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable
Set and reset by software to enable the **pll2_q_ck** output of the PLL2.
To save power, PLL3QEN and DIVQ bits must be set to 0 when the **pll2_q_ck** is not used.
0: **pll2_q_ck** output disabled (default after reset)
1: **pll2_q_ck** output enabled

Bit 16 **PLL2PEN**: PLL2 DIVP divider output enable
Set and reset by software to enable the **pll2_p_ck** output of the PLL2.
To save power, PLL2PEN and DIVP bits must be set to 0 when the **pll2_p_ck** is not used.
0: **pll2_p_ck** output disabled (default after reset)
1: **pll2_p_ck** output enabled

Bits 15:14 **PLL2RGE[1:0]**: PLL2 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL2.
These bits must be written before enabling the PLL2.
00: PLL3 input (**ref2_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL3 input (**ref2_ck**) clock range frequency between 2 and 4 MHz
10: PLL3 input (**ref2_ck**) clock range frequency between 4 and 8 MHz
11: PLL3 input (**ref2_ck**) clock range frequency between 8 and 16 MHz

Bit 13 **PLL2SSCGEN**: PLL2 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL2, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 12 **PLL2VCOSEL**: PLL2 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL2.
This bit must be written before enabling the PLL2. It allows the application to select the VCO range:
– VCOH: working from 384to 1672 MHz (F_{ref2_ck} must be between 2 and 16 MHz)
– VCOL: working from 150 to 420 MHz (F_{ref2_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 11 **PLL2FRACLEN**: PLL2 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL2FRACLEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 419* for additional information.
PLL2FRACLEN must remain at 0 for at least 5 µs.

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PLL1SEN**: PLL1 DIVS divider output enable
Set and reset by software to enable the **pll1_s_ck** output of the PLL1.
To save power, PLL1SEN must be set to 0 when the **pll1_s_ck** is not used.
0: **pll1_s_ck** output disabled (default after reset)
1: **pll1_s_ck** output enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **PLL1QEN**: PLL1 DIVQ divider output enable
Set and reset by software to enable the **pll1_q_ck** output of the PLL1.
The hardware prevents writing this bit if FMCCKP = 1.
In order to save power, when the **pll1_q_ck** output of the PLL1 is not used, the **pll1_q_ck** must be disabled.
0: **pll1_q_ck** output disabled (default after reset)
1: **pll1_q_ck** output enabled

Bit 5 **PLL1PEN**: PLL1 DIVP divider output enable
Set and reset by software to enable the **pll1_p_ck** output of the PLL1.
The hardware prevents writing this bit to 0, if the PLL1 output is used as the system clock (SW=3).
In order to save power, when the **pll1_p_ck** output of the PLL1 is not used, the **pll1_p_ck** must be disabled.
0: **pll1_p_ck** output disabled (default after reset)
1: **pll1_p_ck** output enabled

Bits 4:3 **PLL1RGE[1:0]**: PLL1 input frequency range
Set and reset by software to select the proper reference frequency range used for PLL1.
This bit must be written before enabling the PLL1.
00: PLL1 input (**ref1_ck**) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL1 input (**ref1_ck**) clock range frequency between 2 and 4 MHz
10: PLL1 input (**ref1_ck**) clock range frequency between 4 and 8 MHz
11: PLL1 input (**ref1_ck**) clock range frequency between 8 and 16 MHz

Bit 2 **PLL1SSCGEN**: PLL1 SSCG enable
Set and reset by software to enable the Spread Spectrum Clock Generator of PLL1, in order to reduce the amount of EMI peaks.
0: SSCG disabled (default after reset)
1: SSCG enabled

Bit 1 **PLL1VCOSEL**: PLL1 VCO selection
Set and reset by software to select the proper VCO frequency range used for PLL1.
This bit must be written before enabling the PLL1. It allows the application to select the VCO range:
– VCOH: working from 384 to 1672 MHz (F_{ref1_ck} must be between 2 and 16 MHz)
– VCOL: working from 150 to 420 MHz (F_{ref1_ck} must be between 1 and 2 MHz)
0: VCOH selected (default after reset)
1: VCOL selected

Bit 0 **PLL1FRACEN**: PLL1 fractional latch enable
Set and reset by software to latch the content of FRACN into the sigma-delta modulator.
In order to latch the FRACN value into the sigma-delta modulator, PLL1FRACEN must be set to 0, then set to 1. The transition 0 to 1 transfers the content of FRACN into the modulator.
Refer to *PLL initialization procedure on page 419* for additional information.
PLL1FRACEN must remain at 0 for at least 5 µs.

7.8.12 RCC PLL1 dividers configuration register 1 (RCC_PLL1DIVR1)

Address offset: 0x030

Reset value: 0x0101 0280

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DIVP[6:0]							DIVN[8:0]								
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ[6:0]**: PLL1 DIVQ division factor

Set and reset by software to control the frequency of the **pll1_q_ck** clock.
These bits can be written only when the PLL1QEN = 0.
0000000: **pll1_q_ck** = **vco1_ck**
0000001: **pll1_q_ck** = **vco1_ck** / 2 (default after reset)
0000010: **pll1_q_ck** = **vco1_ck** / 3
0000011: **pll1_q_ck** = **vco1_ck** / 4
...
1111111: **pll1_q_ck** = **vco1_ck** / 128

Bits 15:9 **DIVP[6:0]**: PLL1 DIVP division factor

Set and reset by software to control the frequency of the **pll1_p_ck** clock.
These bits can be written only when the PLL1PEN = 0.
0000000: **pll1_p_ck** = **vco1_ck**
0000001: **pll1_p_ck** = **vco1_ck** / 2 (default after reset)
0000010: not allowed
0000011: **pll1_p_ck** = **vco1_ck** / 4
...
1111111: **pll1_p_ck** = **vco1_ck** / 128

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL1 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL1ON = PLL1RDY = 0).
.....: not used
0x006: wrong configuration
0x007: DIVN = 8
...
0x080: DIVN = 129 (default after reset)
...
0x1A3: DIVN = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 128 to 544MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x DIVN, when fractional value 0 has been loaded into FRACN, with:

- DIVN between 8 and 420
- The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

7.8.13 RCC PLL1 dividers configuration register 2 (RCC_PLL1DIVR2)

Address offset: 0x0C0

Reset value: 0x0000 0101

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIVS[2:0]		
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bits 2:0 **DIVS[2:0]**: PLL1 DIVS division factor

Set and reset by software to control the frequency of the **pll1_s_ck** clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:

– With VCOL, if (DIVS+1) is even,
– With VCOH, for all DIVS values

These bits can be written only when the PLL1SEN = 0.
000: **pll1_s_ck** = **vco1_ck**
001: **pll1_s_ck** = **vco1_ck** / 2 (default after reset)
010: **pll1_s_ck** = **vco1_ck** / 3
011: **pll1_s_ck** = **vco1_ck** / 4
100: **pll1_s_ck** = **vco1_ck** / 5
101: **pll1_s_ck** = **vco1_ck** / 6
110: **pll1_s_ck** = **vco1_ck** / 7
111: **pll1_s_ck** = **vco1_ck** / 8

7.8.14 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN[12:0]**: fractional part of the multiplication factor for PLL1 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 192 to 836 MHz if PLL1VCOSEL = 0
- 150 to 420 MHz if PLL1VCOSEL = 1

VCO output frequency = F_{ref1_ck} x $\left(DIVN + (FRACN / 2^{13})\right)$, with

- DIVN between 8 and 420
- FRACN can be between 0 and 2^{13}- 1
- The input frequency F_{ref1_ck} must be between 1 and 16 MHz.

To change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL1FRACEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL1FRACEN to 1
- Wait at least 5 µs.

Bits 2:0 Reserved, must be kept at reset value.

7.8.15 RCC PLL1 Spread Spectrum Clock Generator register (RCC_PLL1SSCGR)

Address offset: 0x0CC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:16 **INCSTEP[14:0]**: Modulation Depth Adjustment for PLL1

Set and reset by software to adjust the modulation depth of the clock spreading generator.

Bit 15 **SPREADSEL**: Spread spectrum clock generator mode for PLL1

Set and reset by software to select the clock spreading mode.

0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 14 **RPDFNDIS**: Dithering RPDF noise control for PLL1

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a rectangular probability density function.

0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bit 13 **TPDFNDIS**: Dithering TPDF noise control for PLL1

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a triangular probability density function.

0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bits 12:0 **MODPER[12:0]**: Modulation Period Adjustment for PLL1

Set and reset by software to adjust the modulation period of the clock spreading generator.

7.8.16 RCC PLL2 dividers configuration register 1 (RCC_PLL2DIVR1)

Address offset: 0x038

Reset value: 0x0101 0280

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **DIVR[6:0]**: PLL2 DIVR division factor

Set and reset by software to control the frequency of the **pll2_r_ck** clock.
These bits can be written only when the PLL2REN = 0.
0000000: **pll2_r_ck** = **vco2_ck**
0000001: **pll2_r_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_r_ck** = **vco2_ck** / 3
0000011: **pll2_r_ck** = **vco2_ck** / 4
...
1111111: **pll2_r_ck** = **vco2_ck** / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ[6:0]**: PLL2 DIVQ division factor

Set and reset by software to control the frequency of the **pll2_q_ck** clock.
These bits can be written only when the PLL2QEN = 0.
0000000: **pll2_q_ck** = **vco2_ck**
0000001: **pll2_q_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_q_ck** = **vco2_ck** / 3
0000011: **pll2_q_ck** = **vco2_ck** / 4
...
1111111: **pll2_q_ck** = **vco2_ck** / 128

Bits 15:9 **DIVP[6:0]**: PLL2 DIVP division factor

Set and reset by software to control the frequency of the **pll2_p_ck** clock.
These bits can be written only when the PLL2PEN = 0.
0000000: **pll2_p_ck** = **vco2_ck**
0000001: **pll2_p_ck** = **vco2_ck** / 2 (default after reset)
0000010: **pll2_p_ck** = **vco2_ck** / 3
0000011: **pll2_p_ck** = **vco2_ck** / 4
...
1111111: **pll2_p_ck** = **vco2_ck** / 128

Bits 8:0 **DIVN[8:0]**: multiplication factor for PLL2 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL2ON = PLL2RDY = 0).
.....: not used
0x006: wrong configuration
0x007: DIVN = 8
...
0x080: DIVN = 129 (default after reset)
...
0x1A3: DIVN = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 192 to 836 MHz if PLL2VCOSEL = 0
- 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = F_{ref2_ck} x DIVN, when fractional value 0 has been loaded into FRACN, with

- DIVN between 8 and 420
- The input frequency F_{ref2_ck} must be between 1 and 16MHz.

7.8.17 RCC PLL2 dividers configuration register 2 (RCC_PLL2DIVR2)

Address offset: 0x0C4

Reset value: 0x0000 0101

					rw	rw	rw						rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:8 **DIVT[2:0]**: PLL2 DIVT division factor

Set and reset by software to control the frequency of the **pll2_t_ck** clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:

- With VCOL, if (DIVT+1) is even,
- With VCOH, for all DIVT values

These bits can be written only when the PLL2TEN = 0.
000: **pll2_t_ck** = **vco2_ck**
001: **pll2_t_ck** = **vco2_ck** / 2 (default after reset)
010: **pll2_t_ck** = **vco2_ck** / 3
011: **pll2_t_ck** = **vco2_ck** / 4
100: **pll2_t_ck** = **vco2_ck** / 5
101: **pll2_t_ck** = **vco2_ck** / 6
110: **pll2_t_ck** = **vco2_ck** / 7
111: **pll2_t_ck** = **vco2_ck** / 8

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **DIVS[2:0]**: PLL2 DIVS division factor

Set and reset by software to control the frequency of the **pll2_s_ck** clock.
This post-divider performs divisions with 50% duty-cycle.
The duty-cycle of 50% is guaranteed only in the following conditions:

- With VCOL, if (DIVS+1) is even,
- With VCOH, for all DIVS values

These bits can be written only when the PLL2SEN = 0.
000: **pll2_s_ck** = **vco2_ck**
001: **pll2_s_ck** = **vco2_ck** / 2 (default after reset)
010: **pll2_s_ck** = **vco2_ck** / 3

FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **FRACN[12:0]**: fractional part of the multiplication factor for PLL2 VCO

Set and reset by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 192 to 836 MHz if PLL2VCOSEL = 0
- 150 to 420 MHz if PLL2VCOSEL = 1

VCO output frequency = F_{ref2_ck} x $\left(DIVN + (FRACN / 2^{13})\right)$, with

- DIVN between 8 and 420
- FRACN can be between 0 and 2^{13} - 1
- The input frequency F_{ref2_ck} must be between 1 and 16 MHz.

In order to change the FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

- Set the bit PLL2FRACLEN to 0.
- Write the new fractional value into FRACN.
- Set the bit PLL2FRACLEN to 1
- Wait at least 5 µs.

Bits 2:0 Reserved, must be kept at reset value.

7.8.19 RCC PLL2 Spread Spectrum Clock Generator register (RCC_PLL2SSCGR)

Address offset: 0x0D0

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:16 **INCSTEP[14:0]**: Modulation Depth Adjustment for PLL2

Set and reset by software to adjust the modulation depth of the clock spreading generator.

Bit 15 **SPREADSEL**: Spread spectrum clock generator mode for PLL2

Set and reset by software to select the clock spreading mode.

0: Center-spread modulation selected (default after reset)
1: Down-spread modulation selected

Bit 14 **RPDFNDIS**: Dithering RPDF noise control for PLL2

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a rectangular probability density function.

0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bit 13 **TPDFNDIS**: Dithering TPDF noise control for PLL2

Set and reset by software.

This bit is used to enable or disable the injection of a dithering noise into the SSCG modulator. This dithering noise is generated using a triangular probability density function.

0: Dithering noise injection enabled (default after reset)
1: Dithering noise injection disabled

Bits 12:0 **MODPER[12:0]**: Modulation Period Adjustment for PLL2

Set and reset by software to adjust the modulation period of the clock spreading generator.

7.8.20 RCC PLL3 dividers configuration register 1 (RCC_PLL3DIVR1)

Address offset: 0x040

Reset value: 0x0101 0280

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **DIVQ[6:0]**: PLL3 DIVQ division factor

Set and reset by software to control the frequency of the **pll3_q_ck** clock.
These bits can be written only when the PLL3QEN = 0.
0000000: **pll3_q_ck** = **vco3_ck**
0000001: **pll3_q_ck** = **vco3_ck** / 2 (default after reset)
0000010: **pll3_q_ck** = **vco3_ck** / 3
0000011: **pll3_q_ck** = **vco3_ck** / 4
...
1111111: **pll3_q_ck** = **vco3_ck** / 128

Bits 15:9 **DIVP[6:0]**: PLL3 DIVP division factor

Set and reset by software to control the frequency of the **pll3_p_ck** clock.
These bits can be written only when the PLL3PEN = 0.
0000000: **pll3_p_ck** = **vco3_ck**
0000001: **pll3_p_ck** = **vco3_ck** / 2 (default after reset)
0000010: **pll3_p_ck** = **vco3_ck** / 3
0000011: **pll3_p_ck** = **vco3_ck** / 4
...
1111111: pll3_p_ck = **vco3_ck** / 128

Bits 8:0 **DIVN[8:0]**: Multiplication factor for PLL3 VCO

Set and reset by software to control the multiplication factor of the VCO.
These bits can be written only when the PLL is disabled (PLL3ON = PLL3RDY = 0).
.....: not used
0x006: wrong configuration
0x007: DIVN = 8
...
0x080: DIVN = 129 (default after reset)
...
0x1A3: DIVN = 420
Others: wrong configurations

Caution: The software must set correctly these bits to insure that the VCO output frequency is between its valid frequency range, that is:

- 192 to 836 MHz if PLL3VCOSEL = 0
- 150 to 420 MHz if PLL3VCOSEL = 1

VCO output frequency = F_{ref3_ck} x DIVN, when fractional value 0 has been loaded into FRACN, with:

- DIVN between 8 and 420
- The input frequency F_{ref3_ck} must be between 1 and 16MHz

7.8.21 RCC PLL3 dividers configuration register 2 (RCC_PLL3DIVR2)

Set and reset by software.
00: **lse_ck** selected as kernel clock (default after reset)
01: **lsi_ck** selected as kernel clock
10: **csi_ker_ck** divided by 122 selected as kernel clock
11: reserved, the kernel clock is disabled

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:24 **SPDIFRXSEL[1:0]**: SPDIFRX kernel clock source selection
00: **pll1_q_ck** selected as SPDIFRX kernel clock (default after reset)
01: **pll2_r_ck** selected as SPDIFRX kernel clock
10: **pll3_r_ck** selected as SPDIFRX kernel clock
11: **hsi_ker_ck** selected as SPDIFRX kernel clock

Bits 23:22 **FDCANSEL[1:0]**: FDCAN kernel clock source selection
00: **hse_ker_ck** selected as FDCAN kernel clock (default after reset)
01: **pll1_q_ck** selected as FDCAN kernel clock
10: **pll2_p_ck** selected as FDCAN kernel clock
11: reserved, the kernel clock is disabled

Bits 21:19 Reserved, must be kept at reset value.

Bits 18:16 **LPTIM1SEL[2:0]**: LPTIM1 kernel clock source selection
Set and reset by software.
000: **pclk1** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **I2C1_I3C1SEL[1:0]**: I2C1 or I3C1 kernel clock source selection
Set and reset by software.
00: **pclk1** selected as kernel peripheral clock (default after reset)
01: **pll3_r_ck** selected as kernel peripheral clock
10: **hsi_ker_ck** selected as kernel peripheral clock
11: **csi_ker_ck** selected as kernel peripheral clock

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **I2C23SEL[1:0]**: I2C2, I2C3 kernel clock source selection
Set and reset by software.
00: **pclk1** selected as kernel clock (default after reset)
01: **pll3_r_ck** selected as kernel clock
10: **hsi_ker_ck** selected as kernel clock
11: **csi_ker_ck** selected as kernel clock

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI23SEL[2:0]**: SPI/I2S2 and SPI/I2S3 kernel clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 412* for additional information.

000: **pll1_q_ck** selected as kernel clock (default after reset)
001: **pll2_p_ck** selected as kernel clock
010: **pll3_p_ck** selected as kernel clock
011: I2S_CKIN selected as kernel clock
100: **per_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **UART234578SEL[2:0]**: USART2,3, UART4,5,7,8 (APB1) kernel clock source selection
Set and reset by software.
000: **pclk1** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

7.8.26 RCC APB2 peripherals kernel clock selection register (RCC_CCIPR3)

Address offset: 0x054

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SAI2SEL[2:0]			Res.	SAI1SEL[2:0]

					rw	rw	rw		rw	rw	rw		rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **SAI2SEL[2:0]**: SAI2 kernel clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not possible to switch to another clock. Refer to *Clock switches and gating on page 412* for additional information.

000: **pll1_q_ck** selected as SAI2 kernel clock (default after reset)
001: **pll2_p_ck** selected as SAI2 kernel clock
010: **pll3_p_ck** selected as SAI2 kernel clock
011: I2S_CKIN selected as SAI2 kernel clock
100: **per_ck** selected as SAI2 kernel clock
101: **spdifrx_symb_ck** selected as SAI2 kernel clock
others: reserved, the kernel clock is disabled

*Note: I2S_CKIN is an external clock taken from a pin. **spdifrx_symb_ck** is the symbol clock generated by the spdifrx (see Figure 53).*

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **SAI1SEL[2:0]**: SAI1 kernel clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not possible to switch to another clock. Refer to *Clock switches and gating on page 412* for additional information.

000: **pll1_q_ck** selected as SAI1 kernel clock (default after reset)
001: **pll2_p_ck** selected as SAI1 kernel clock
010: **pll3_p_ck** selected as SAI1 kernel clock
011: I2S_CKIN selected as SAI1 kernel clock
100: **per_ck** selected as SAI1 kernel clock
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SPI1SEL[2:0]**: SPI/I2S1 kernel clock source selection
Set and reset by software.

Caution: If the selected clock is the external clock and this clock is stopped, it is not be possible to switch to another clock. Refer to *Clock switches and gating on page 412* for additional information.

000: **pll1_q_ck** selected as SPI/I2S1 and 7 kernel clock (default after reset)
001: **pll2_p_ck** selected as SPI/I2S1 and 7 kernel clock
010: **pll3_p_ck** selected as SPI/I2S1 and 7 kernel clock
011: I2S_CKIN selected as SPI/I2S1 and 7 kernel clock
100: **per_ck** selected as SPI/I2S1,and 7 kernel clock
others: reserved, the kernel clock is disabled

Note: I2S_CKIN is an external clock taken from a pin.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI45SEL[2:0]**: SPI4 and 5 kernel clock source selection
Set and reset by software.
000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** is selected as kernel clock
010: **pll3_q_ck** is selected as kernel clock
011: **hsi_ker_ck** is selected as kernel clock
100: **csi_ker_ck** is selected as kernel clock
101: **hse_ker_ck** is selected as kernel clock
others: reserved, the kernel clock is disabled

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **USART1SEL[2:0]**: USART1 kernel clock source selection
Set and reset by software.
000: **pclk2** selected as kernel clock (default after reset)
001: **pll2_q_ck** selected as kernel clock
010: **pll3_q_ck** selected as kernel clock
011: **hsi_ker_ck** selected as kernel clock
100: **csi_ker_ck** selected as kernel clock
101: **lse_ck** selected as kernel clock
others: reserved, the kernel clock is disabled

7.8.27 RCC APB4,5 peripherals kernel clock selection register (RCC_CCIPR4)

Address offset: 0x058

Reset value: 0x0000 0000

Changing the clock source on-the-fly is allowed and does not generate any timing violation. However the user must make sure that both the previous and the new clock sources are present during the switching, and during the whole transition time. Refer to *Clock switches and gating*.

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:12 **LPTIM45SEL[2:0]**: LPTIM4, and LPTIM5 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LPTIM23SEL[2:0]**: LPTIM2 and LPTIM3 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_p_ck** selected as kernel peripheral clock
010: **pll3_r_ck** selected as kernel peripheral clock
011: **lse_ck** selected as kernel peripheral clock
100: **lsi_ck** selected as kernel peripheral clock
101: **per_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **SPI6SEL[2:0]**: SPI/I2S6 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_q_ck** selected as kernel peripheral clock
010: **pll3_q_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **csi_ker_ck** selected as kernel peripheral clock
101: **hse_ker_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LPUART1SEL[2:0]**: LPUART1 kernel clock source selection
Set and reset by software.
000: **pclk4** selected as kernel peripheral clock (default after reset)
001: **pll2_q_ck** selected as kernel peripheral clock
010: **pll3_q_ck** selected as kernel peripheral clock
011: **hsi_ker_ck** selected as kernel peripheral clock
100: **csi_ker_ck** selected as kernel peripheral clock
101: **lse_ck** selected as kernel peripheral clock
others: reserved, the kernel clock is disabled

7.8.28 RCC clock source interrupt enable register (RCC_CIER)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSIE**: LSE clock security system interrupt enable
Set and reset by software to enable/disable interrupt caused by the clock security system (CSS) on external 32 kHz oscillator.
0: LSE CSS interrupt disabled (default after reset)
1: LSE CSS interrupt enabled

Bit 8 **PLL3RDYIE**: PLL3 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL3 lock.
0: PLL3 lock interrupt disabled (default after reset)
1: PLL3 lock interrupt enabled

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL2 lock.
0: PLL2 lock interrupt disabled (default after reset)
1: PLL2 lock interrupt enabled

Bit 6 **PLL1RDYIE**: PLL1 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by PLL1 lock.
0: PLL1 lock interrupt disabled (default after reset)
1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE**: HSI48 ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI48 oscillator stabilization.
0: HSI48 ready interrupt disabled (default after reset)
1: HSI48 ready interrupt enabled

Bit 4 **CSIRDYIE**: CSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the CSI oscillator stabilization.
0: CSI ready interrupt disabled (default after reset)
1: CSI ready interrupt enabled

Bit 3 **HSERDYIE**: HSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSE oscillator stabilization.
0: HSE ready interrupt disabled (default after reset)
1: HSE ready interrupt enabled

Bit 2 **HSIRDYIE**: HSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the HSI oscillator stabilization.
0: HSI ready interrupt disabled (default after reset)
1: HSI ready interrupt enabled

Bit 1 **LSERDYIE**: LSE ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSE oscillator stabilization.
0: LSE ready interrupt disabled (default after reset)
1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable
Set and reset by software to enable/disable interrupt caused by the LSI oscillator stabilization.
0: LSI ready interrupt disabled (default after reset)
1: LSI ready interrupt enabled

7.8.29 RCC clock source interrupt flag register (RCC_CIFR)

Address offset: 0x64

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSF	LSECSSF	PLL3RDYF	PLL2RDYF	PLL1RDYF	HSI48RDYF	CSIRDYF	HSERDYF	HSIRDYF	LSERDYF	LSIRDYF
					r	r	r	r	r	r	r	r	r	r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Reset by software by writing HSECSSC bit.
Set by hardware in case of HSE clock failure.
0: no clock security interrupt caused by HSE clock failure (default after reset)
1: clock security interrupt caused by HSE clock failure

Bit 9 **LSECSSF**: LSE clock security system interrupt flag
Reset by software by writing LSECSSC bit.
Set by hardware when a failure is detected on the external 32 kHz oscillator and LSECSSIE is set.
0: no failure detected on the external 32 kHz oscillator (default after reset)
1: failure detected on the external 32 kHz oscillator

Bit 8 **PLL3RDYF**: PLL3 ready interrupt flag
Reset by software by writing PLL3RDYC bit.
Set by hardware when the PLL3 locks and PLL3RDYIE is set.
0: no clock ready interrupt caused by PLL3 lock (default after reset)
1: clock ready interrupt caused by PLL3 lock

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Reset by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: no clock ready interrupt caused by PLL2 lock (default after reset)
1: clock ready interrupt caused by PLL2 lock

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Reset by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: no clock ready interrupt caused by PLL1 lock (default after reset)
1: clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Reset by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: no clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: clock ready interrupt caused by the HSI48 oscillator

Bit 4 **CSIRDYF**: CSI ready interrupt flag
Reset by software by writing CSIRDYC bit.
Set by hardware when the CSI clock becomes stable and CSIRDYIE is set.
0: no clock ready interrupt caused by the CSI (default after reset)
1: clock ready interrupt caused by the CSI

Bit 3 **HSERDYF**: HSE ready interrupt flag
Reset by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: no clock ready interrupt caused by the HSE (default after reset)
1: clock ready interrupt caused by the HSE

Bit 2 **HSIRDYF**: HSI ready interrupt flag
Reset by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: no clock ready interrupt caused by the HSI (default after reset)
1: clock ready interrupt caused by the HSI

Bit 1 **LSERDYF**: LSE ready interrupt flag
Reset by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: no clock ready interrupt caused by the LSE (default after reset)
1: clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Reset by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: no clock ready interrupt caused by the LSI (default after reset)
1: clock ready interrupt caused by the LSI

7.8.30 RCC clock source interrupt clear register (RCC_CICR)

Address offset: 0x68

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	HSECSSC	LSECSSC	PLL3RDYC	PLL2RDYC	PLL1RDYC	HSI48RDYC	CSIRDYC	HSERDYC	HSIRDYC	LSERDYC	LSIRDYC
					rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF.
Reset by hardware when clear done.
0: HSECSSF no effect (default after reset)
1: HSECSSF cleared

Bit 9 **LSECSSC**: LSE clock security system interrupt clear
Set by software to clear LSECSSF.
Reset by hardware when clear done.
0: LSECSSF no effect (default after reset)
1: LSECSSF cleared

Bit 8 **PLL3RDYC**: PLL3 ready interrupt clear
Set by software to clear PLL3RDYF.
Reset by hardware when clear done.
0: PLL3RDYF no effect (default after reset)
1: PLL3RDYF cleared

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Set by software to clear PLL2RDYF.
Reset by hardware when clear done.
0: PLL2RDYF no effect (default after reset)
1: PLL2RDYF cleared

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Set by software to clear PLL1RDYF.
Reset by hardware when clear done.
0: PLL1RDYF no effect (default after reset)
1: PLL1RDYF cleared

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Set by software to clear HSI48RDYF.
Reset by hardware when clear done.
0: HSI48RDYF no effect (default after reset)
1: HSI48RDYF cleared

Bit 4 **CSIRDYC**: CSI ready interrupt clear
Set by software to clear CSIRDYF.
Reset by hardware when clear done.
0: CSIRDYF no effect (default after reset)
1: CSIRDYF cleared

Bit 3 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF.
Reset by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 2 **HSIRDYC**: HSI ready interrupt clear
Set by software to clear HSIRDYF.
Reset by hardware when clear done.
0: HSIRDYF no effect (default after reset)
1: HSIRDYF cleared

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF.
Reset by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF.
Reset by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared

7.8.31 RCC Backup domain control register (RCC_BDCR)

Address offset: 0x070

Reset value: 0x0000 0010

Reset by Backup domain reset.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

After a system reset, the RCC_BDCR register is write-protected. To modify this register, the DBP bit in the *PWR control register 1 (PWR_CR1)* must be set to 1. RCC_BDCR bits are only reset after a Backup domain reset (see *Section 7.4.5: Backup domain reset*). Any other internal or external reset does not have any effect on these bits.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VSWRST
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	LSECSSRA	Res.	Res.	RTCSEL[1:0]		LSEEXT	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw			rw			rwo	rwo	rw	r	rs	rw	rw	rw	r	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **VSWRST:** VSwitch domain software reset
Set and reset by software.
To generate a VSW reset, it is recommended to write this bit to 1, then back to 0.
0: reset not activated (default after Backup domain reset)
1: generates a reset pulse, resetting the entire VSW domain.

Bit 15 **RTCEN**: RTC clock enable
Set and reset by software.
0: **rtc_ck** disabled (default after Backup domain reset)
1: **rtc_ck** enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LSECSSRA**: Re-Arm the LSECSS function
Set by software.
After a LSE failure detection, the software application can re-enable the LSECSS by writing this bit to 1. Reading this bit returns the written value. Prior to set this bit to 1, LSECSSON must be set to 0. Refer to *Section : CSS on LSE* for details.
0: Writing 0 has no effect (default after Backup domain reset)
1: Writing 1 generates a re-arm pulse for the LSECSS function

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection

Set by software to select the clock source for the RTC. These bits can be written only one time (except in case of failure detection on LSE). These bits must be written before LSECSSON is enabled. The VSWRST bit can be used to reset them, then it can be written one time again.

If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).

00: no clock (default after Backup domain reset)

01: LSE selected as RTC clock

10: LSI selected as RTC clock

11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 **LSEEXT**: low-speed external clock type in Bypass mode

Set and reset by software to select the external clock type (analog or digital).

The external clock must be enabled with the LSEON bit, to be used by the device.

The LSEEXT bit can be written only if the LSE oscillator is disabled.

0: LSE in analog mode (default after Backup domain reset)

1: LSE in digital mode (do not use if RTC is active).

Bit 6 **LSECSSD**: LSE clock security system failure detection

Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator.

0: no failure detected on 32 kHz oscillator (default after Backup domain reset)

1: failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable

Set by software to enable the clock security system on 32 kHz oscillator.

LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.

Once enabled, this bit can only be disabled,

- After a LSE failure detection (LSECSSD = 1). In that case the software **must** disable LSECSSON.
- After a back-up domain reset

0: CSS on 32 kHz oscillator OFF (default after Backup domain reset)

1: CSS on 32 kHz oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability

Set by software to select the driving capability of the LSE oscillator.

00: lowest drive

01: medium-low drive

10: medium-high drive (default after backup domain if LSEON=0)

11: highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass
Set and reset by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = 1)
0: LSE oscillator not bypassed (default after Backup domain reset)
1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready
Set and reset by hardware to indicate when the LSE is stable. This bit needs 6 cycles of **lse_ck** clock to fall down after LSEON has been set to 0.
0: LSE oscillator not ready (default after Backup domain reset)
1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled
Set and reset by software.
0: LSE oscillator OFF (default after Backup domain reset)
1: LSE oscillator ON

7.8.32 RCC clock control and status register (RCC_CSR)

Address offset: 0x074

Reset value: 0x0000 0000

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access

Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LSIRDY	LSION
														r	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LSIRDY**: LSI oscillator ready
Set and reset by hardware to indicate when the low-speed internal RC oscillator is stable.
This bit needs 3 cycles of **lsi_ck** clock to fall down after LSION has been set to 0.
This bit can be set even when LSION is not enabled if there is a request for LSI clock by the clock security system on LSE or by the low-speed watchdog or by the RTC.
0: LSI clock is not ready (default after reset)
1: LSI clock is ready

Bit 0 **LSION**: LSI oscillator enable
Set and reset by software.
0: LSI is OFF (default after reset)
1: LSI is ON

7.8.33 RCC AHB1 peripheral reset register (RCC_AHB1RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw										rw	rw				

Bit 31 **ADF1RST**: ADF block reset
Set and reset by software.
0: does not reset ADF block (default after reset)
1: resets ADF block

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSRST**: OTGFS block reset
Set and reset by software.
0: does not reset OTGFS block (default after reset)
1: resets OTGFS block

Bit 26 **USBPHYCRST**: USBPHYC block reset
Set and reset by software.
0: does not reset USBPHYC block (default after reset)
1: resets USBPHYC block

Bit 25 **OTGHSRST**: OTGHS block reset
Set and reset by software.
0: does not reset OTGHS block (default after reset)
1: resets OTGHS block

Bits 24:16 Reserved, must be kept at reset value.

Bit 15 **ETH1RST**: ETH1 block reset
Set and reset by software.
0: does not reset ETH1 block (default after reset)
1: resets ETH1 block

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12RST**: ADC1 and 2 blocks reset
Set and reset by software.
0: does not reset ADC1 and 2 blocks (default after reset)
1: resets ADC1 and 2 blocks

Bit 4 **GPDMA1RST**: GPDMA1 blocks reset
Set and reset by software.
0: does not reset GPDMA1 block (default after reset)
1: resets GPDMA1 block

Bits 3:0 Reserved, must be kept at reset value.

7.8.34 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw					rw								rw	

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **CORDICRST**: CORDIC reset
Set and reset by software.
0: does not reset CORDIC block (default after reset)
1: resets CORDIC block

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2RST**: SDMMC2 and SDMMC2 delay blocks reset
Set and reset by software.
0: does not reset SDMMC2 and SDMMC2 delay blocks (default after reset)
1: resets SDMMC2 and SDMMC2 delay blocks

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **PSSIRST**: PSSI block reset
Set and reset by software.
0: does not reset PSSI block (default after reset)
1: resets PSSI block

Bit 0 Reserved, must be kept at reset value.

7.8.35 RCC AHB3 peripheral reset register (RCC_AHB3RSTR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PKARST	Res.	SAESRST	Res.	CRYPRST	HASHRST	RNGRST
									rw		rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PKARST**: PKA block reset
Set and reset by software.
0: does not reset PKA block (default after reset)
1: resets PKA block

Bit 5 Reserved, must be kept at reset value.

Bit 4 **SAESRST**: SAES block reset
Set and reset by software.
0: does not reset SAES block (default after reset)
1: resets SAES block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPRST**: CRYP block reset
Set and reset by software.
0: does not reset CRYP block (default after reset)
1: resets CRYP block

Bit 1 **HASHRST**: HASH block reset
Set and reset by software.
0: does not reset HASH block (default after reset)
1: resets HASH block

Bit 0 **RNGRST**: random number generator block reset
Set and reset by software.
0: does not reset RNG block (default after reset)
1: resets RNG block

7.8.36 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x088

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **CRCRST**: CRC block reset
Set and reset by software.
0: does not reset the CRC block (default after reset)
1: resets the CRC block

Bits 18:16 Reserved, must be kept at reset value.

Bit 15 **GPIOPRST**: GPIOP block reset
Set and reset by software.
0: does not reset the GPIOP block (default after reset)
1: resets the GPIOP block

Bit 14 **GPIOORST**: GPIOO block reset
Set and reset by software.
0: does not reset the GPIOO block (default after reset)
1: resets the GPIOO block

Bit 13 **GPIONRST**: GPION block reset
Set and reset by software.
0: does not reset the GPION block (default after reset)
1: resets the GPION block

Bit 12 **GPIOMRST**: GPIOM block reset
Set and reset by software.
0: does not reset the GPIOM block (default after reset)
1: resets the GPIOM block

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHRST**: GPIOH block reset
Set and reset by software.
0: does not reset the GPIOH block (default after reset)
1: resets the GPIOH block

Bit 6 **GPIOGRST**: GPIOG block reset
Set and reset by software.
0: does not reset the GPIOG block (default after reset)
1: resets the GPIOG block

Bit 5 **GPIOFRST**: GPIOF block reset
Set and reset by software.
0: does not reset the GPIOF block (default after reset)
1: resets the GPIOF block

Bit 4 **GPIOERST**: GPIOE block reset
Set and reset by software.
0: does not reset the GPIOE block (default after reset)
1: resets the GPIOE block

Bit 3 **GPIODRST**: GPIOD block reset
Set and reset by software.
0: does not reset the GPIOD block (default after reset)
1: resets the GPIOD block

Bit 2 **GPIOCRST**: GPIOC block reset
Set and reset by software.
0: does not reset the GPIOC block (default after reset)
1: resets the GPIOC block

Bit 1 **GPIOBRST**: GPIOB block reset
Set and reset by software.
0: does not reset the GPIOB block (default after reset)
1: resets the GPIOB block

Bit 0 **GPIOARST**: GPIOA block reset
Set and reset by software.
0: does not reset the GPIOA block (default after reset)
1: resets the GPIOA block

7.8.37 RCC AHB5 peripheral reset register (RCC_AHB5RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GPU2DRST	GFXMMURST	Res.	Res.	Res.
											rw	rw

	rw		rw				rw			rw	rw	rw		rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **GPU2DRST**: GPU2D block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 19 **GFXMMURST**: GFXMMU block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bits 18:15 Reserved, must be kept at reset value.

Bit 14 **XSPIMRST**: XSPIM reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 13 Reserved, must be kept at reset value.

Bit 12 **XSPI2RST**: XSPI2 and MCE2 blocks reset
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: reset is released (default after reset)
1: reset is asserted

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1RST**: SDMMC1 and DB_SDMMC1 blocks reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1RST**: XSPI1 and MCE1 blocks reset
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: reset is released (default after reset)
1: reset is asserted

Bit 4 **FMCRST**: FMC and MCE3 blocks reset
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: reset is released (default after reset)
1: reset is asserted

Bit 3 **JPEGRST**: JPEG block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DRST**: DMA2D block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

Bit 0 **HPDMA1RST**: HPDMA1 block reset
Set and reset by software.
0: reset is released (default after reset)
1: reset is asserted

7.8.38 RCC APB1 peripheral reset register 1 (RCC_APB1RSTR1)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UART8RST**: UART8 block reset
Set and reset by software.
0: does not reset the UART8 block (default after reset)
1: resets the UART8 block

Bit 30 **UART7RST**: UART7 block reset
Set and reset by software.
0: does not reset the UART7 block (default after reset)
1: resets the UART7 block

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **CECRST**: HDMI-CEC block reset
Set and reset by software.
0: does not reset the HDMI-CEC block (default after reset)
1: resets the HDMI-CEC block

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3RST**: I2C3 block reset
Set and reset by software.
0: does not reset the I2C3 block (default after reset)
1: resets the I2C3 block

Bit 22 **I2C2RST**: I2C2 block reset
Set and reset by software.
0: does not reset the I2C2 block (default after reset)
1: resets the I2C2 block

Bit 21 **I2C1_I3C1RST**: I2C1/I3C1 block reset
Set and reset by software.
0: does not reset the I2C1/I3C1 block (default after reset)
1: resets the I2C1/I3C1 block

Bit 20 **UART5RST**: UART5 block reset
Set and reset by software.
0: does not reset the UART5 block (default after reset)
1: resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and reset by software.
0: does not reset the UART4 block (default after reset)
1: resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and reset by software.
0: does not reset the USART3 block (default after reset)
1: resets the USART3 block

Bit 17 **USART2RST**: USART2 block reset
Set and reset by software.
0: does not reset the USART2 block (default after reset)
1: resets the USART2 block

Bit 16 **SPDIFRXRST**: SPDIFRX block reset
Set and reset by software.
0: does not reset the SPDIFRX block (default after reset)
1: resets the SPDIFRX block

Bit 15 **SPI3RST**: SPI2S3 block reset
Set and reset by software.
0: does not reset the SPI2S3 block (default after reset)
1: resets the SPI2S3 block

Bit 14 **SPI2RST**: SPI2S2 block reset
Set and reset by software.
0: does not reset the SPI2S2 block (default after reset)
1: resets the SPI2S2 block

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1RST**: LPTIM1 block reset
Set and reset by software.
0: does not reset the LPTIM1 block (default after reset)
1: resets the LPTIM1 block

Bit 8 **TIM14RST**: TIM14 block reset
Set and reset by software.
0: does not reset the TIM14 block (default after reset)
1: resets the TIM14 block

Bit 7 **TIM13RST**: TIM13 block reset
Set and reset by software.
0: does not reset the TIM13 block (default after reset)
1: resets the TIM13 block

Bit 6 **TIM12RST**: TIM12 block reset
Set and reset by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 5 **TIM7RST**: TIM7 block reset
Set and reset by software.
0: does not reset the TIM7 block (default after reset)
1: resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and reset by software.
0: does not reset the TIM6 block (default after reset)
1: resets the TIM6 block

Bit 3 **TIM5RST**: TIM5 block reset
Set and reset by software.
0: does not reset the TIM5 block (default after reset)
1: resets the TIM5 block

Bit 2 **TIM4RST**: TIM4 block reset
Set and reset by software.
0: does not reset the TIM4 block (default after reset)
1: resets the TIM4 block

Bit 1 **TIM3RST**: TIM3 block reset
Set and reset by software.
0: does not reset the TIM3 block (default after reset)
1: resets the TIM3 block

Bit 0 **TIM2RST**: TIM2 block reset
Set and reset by software.
0: does not reset the TIM2 block (default after reset)
1: resets the TIM2 block

7.8.39 RCC APB1 peripheral reset register 2 (RCC_APB1RSTR2)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1RST**: UCPD block reset
Set and reset by software.
0: does not reset the UCPD block (default after reset)
1: resets the UCPD block

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANRST**: FDCAN block reset
Set and reset by software.
0: does not reset the FDCAN block (default after reset)
1: resets the FDCAN block

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSRST**: MDIOS block reset
Set and reset by software.
0: does not reset the MDIOS block (default after reset)
1: resets the MDIOS block

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CRSRST**: clock recovery system reset
Set and reset by software.
0: does not reset CRS (default after reset)
1: resets CRS

Bit 0 Reserved, must be kept at reset value.

7.8.40 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x098

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **SAI2RST**: SAI2 block reset
Set and reset by software.
0: does not reset the SAI2 (default after reset)
1: resets the SAI2

Bit 22 **SAI1RST**: SAI1 block reset
Set and reset by software.
0: does not reset the SAI1 (default after reset)
1: resets the SAI1

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5RST**: SPI5 block reset
Set and reset by software.
0: does not reset the SPI5 block (default after reset)
1: resets the SPI5 block

Bit 19 **TIM9RST**: TIM9 block reset
Set and reset by software.
0: does not reset the TIM9 block (default after reset)
1: resets the TIM9 block

Bit 18 **TIM17RST**: TIM17 block reset
Set and reset by software.
0: does not reset the TIM17 block (default after reset)
1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
Set and reset by software.
0: does not reset the TIM16 block (default after reset)
1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
Set and reset by software.
0: does not reset the TIM15 block (default after reset)
1: resets the TIM15 block

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4RST**: SPI4 block reset
Set and reset by software.
0: does not reset the SPI4 block (default after reset)
1: resets the SPI4 block

Bit 12 **SPI1RST**: SPI2S1 block reset
Set and reset by software.
0: does not reset the SPI2S1 block (default after reset)
1: resets the SPI2S1 block

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **USART1RST**: USART1 block reset
Set and reset by software.
0: does not reset the USART1 block (default after reset)
1: resets the USART1 block

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TIM1RST**: TIM1 block reset
Set and reset by software.
0: does not reset the TIM1 block (default after reset)
1: resets the TIM1 block

7.8.41 RCC APB4 peripheral reset register (RCC_APB4RSTR)

Address offset: 0x09C

Reset value: 0x0000 0000

rw			rw	rw	rw	rw				rw		rw		rw	

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DTSRST**: DTS block reset
Set and reset by software.
0: does not reset the DTS block (default after reset)
1: resets the DTS block

Bits 25:16 Reserved, must be kept at reset value.

Bit 15 **VREFRST**: VREF block reset
Set and reset by software.
0: does not reset the VREF block (default after reset)
1: resets the VREF block

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5RST**: LPTIM5 block reset
Set and reset by software.
0: does not reset the LPTIM5 block (default after reset)
1: resets the LPTIM5 block

Bit 11 **LPTIM4RST**: LPTIM4 block reset
Set and reset by software.
0: does not reset the LPTIM4 block (default after reset)
1: resets the LPTIM4 block

Bit 10 **LPTIM3RST**: LPTIM3 block reset
Set and reset by software.
0: does not reset the LPTIM3 block (default after reset)
1: resets the LPTIM3 block

Bit 9 **LPTIM2RST**: LPTIM2 block reset
Set and reset by software.
0: does not reset the LPTIM2 block (default after reset)
1: resets the LPTIM2 block

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6RST**: SPI/I2S6 block reset
Set and reset by software.
0: does not reset the SPI/I2S6 block (default after reset)
1: resets the SPI/I2S6 block

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1RST**: LPUART1 block reset
Set and reset by software.
0: does not reset the LPUART1 block (default after reset)
1: resets the LPUART1 block

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSRST**: SBS block reset
Set and reset by software.
0: does not reset the SBS block (default after reset)
1: resets the SBS block

Bit 0 Reserved, must be kept at reset value.

7.8.42 RCC APB5 peripheral reset register (RCC_APB5RSTR)

Address offset: 0x08C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GFXTIMRST	Res.	DCMIPPRST	LTDCRST	Res.
											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **GFXTIMRST**: GFXTIM block reset
Set and reset by software.
0: does not reset the GFXTIM block (default after reset)
1: resets the GFXTIM block

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPRST**: DCMIPP block reset
Set and reset by software.
0: does not reset the DCMIPP block (default after reset)
1: resets the DCMIPP block

Bit 1 **LTDCRST**: LTDC block reset
Set and reset by software.
0: does not reset the LTDC block (default after reset)
1: resets the LTDC block

Bit 0 Reserved, must be kept at reset value.

7.8.43 RCC AXI clocks gating disable register (RCC_CKGDISR)

Address offset: 0x0B0

Reset value: 0x8000 0000

The dynamic power consumption can be optimized by enabling the functional clock gating.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **JTAGCKG**: JTAG automatic clock gating disabling
This bit is set and reset by software.
0: The clock gating is enabled. The clock is disabled except if a JTAG connection has been detected
1: The clock gating is disabled. The clock is always enabled. (default after reset)

Bit 30 **EXTICKG**: EXTI clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock is enabled after an event detection and stopped again when the event flag is cleared. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bits 29:22 Reserved, must be kept at reset value.

Bit 21 **FLASHCKG**: AXI slave Flash interface (FLIFT) clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the FLASH is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 20 **AXISRAM1CKG**: AXI slave SRAM1 / error code correction (ECC) clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 19 **AXISRAM2CKG**: AXI slave SRAM2 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM2 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 18 **AXISRAM3CKG**: AXI matrix slave SRAM3 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM3 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 17 **AXISRAM4CKG**: AXI matrix slave SRAM4 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the SRAM4 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 16 **XSPI2CKG**: AXI slave XSPI2 and MCE2 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the XSPI2 and MCE2 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 15 **XSPI1CKG**: AXI slave XSPI1 and MCE1 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the XSPI1 and MCE1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 14 **FMCCKG**: AXI slave FMC and MCE3 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the FMC and MCE3 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 13 **AHBSCKG**: AXI slave AHB clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The AXI matrix slave AHB clock is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 12 **GFXMMUMCKG**: AXI master GFXMMU clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the GFXMMU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 11 **LTDCCKG**: AXI master LTDC clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the LTDC is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 10 **GFXMMUSCKG**: AXI matrix slave GFXMMU clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI slave port connected to the GFXMMU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 9 **DMA2DCKG**: AXI master DMA2D clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the DMA2D is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 8 **DCMIPPCKG**: AXI master DCMIPP clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the DCMIPP is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 7 **GPU2DCLCKG**: AXI master cache GPU2D clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D I-Cache is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 6 **GPU2DS1CKG**: AXI master 1 GPU2D clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D port 1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 5 **GPU2DS0CKG**: AXI master 0 GPU2D clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the GPU2D port 0 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 4 **CPUCKG**: AXI master CPU clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the CPU is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled.

Bit 3 **HPDMA1CKG**: AXI master HPDMA1 clock gating disable
This bit is set and reset by software.
0: The clock gating is enabled. The clock of the AXI master port connected to the HPDMA1 is enabled on bus transaction request. (default after reset)
1: The clock gating is disabled. The clock is always enabled

Bit 2 **SDMMC1CKG**: AXI master SDMMC1 clock gating disable

This bit is set and reset by software.

0: The clock gating is enabled. The clock of the AXI master port connected to SDMMC1 is enabled on bus transaction request. (default after reset)

1: The clock gating is disabled. The clock is always enabled.

Bit 1 **AHBMCKG**: AXI master AHB clock gating disable

This bit is set and reset by software.

0: The clock gating is enabled. The clock of the AXI master port connected to the AHB interconnect is enabled on bus transaction request. (default after reset)

1: The clock gating is disabled. The clock is always enabled.

Bit 0 **AXICKG**: AXI interconnect matrix clock gating disable

This bit is set and reset by software.

0: The clock gating is enabled. The AXI interconnect matrix clock is enabled on bus transaction request. (default after reset)

1: The clock gating is disabled. The clock is always enabled

7.8.44 RCC Reset status register (RCC_RSR)

Address offset: 0x130

Reset value: 0x00E0 0000

Reset by power-on reset only.

Access: 0 ≤ wait state ≤ 7, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	LPWRRSTF	Res.	WWDGRSTF	Res.	IWDGRSTF	Res.	SFTRSTF	PORRSTF	PINRSTF	BORRSTF	Res.	Res.	Res.	OBLRSTF	RMVF
	r		r		r		r	r	r	r				r	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **LPWRRSTF**: reset due to illegal Stop or Standby flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the CPU goes erroneously in Stop or Standby mode,
0: no illegal reset occurred (default after power-on reset)
1: illegal Stop or Standby reset occurred

Bit 29 Reserved, must be kept at reset value.

Bit 28 **WWDGRSTF**: window watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: no window watchdog reset occurred from WWDG (default after power-on reset)
1: window watchdog reset occurred from WWDG

Bit 27 Reserved, must be kept at reset value.

Bit 26 **IWDGRSTF**: independent watchdog reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when an independent watchdog reset occurs.
0: no independent watchdog reset occurred (default after power-on reset)
1: independent watchdog reset occurred

Bit 25 Reserved, must be kept at reset value.

Bit 24 **SFTRSTF**: system reset from CPU reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of AIRCR register of the core M7.
0: no CPU software reset occurred (default after power-on reset)
1: a system reset has been generated by the CPU

Bit 23 **PORRSTF**: POR/PDR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a POR/PDR reset occurs.
0: no POR/PDR reset occurred
1: POR/PDR reset occurred (default after power-on reset)

Bit 22 **PINRSTF**: pin reset flag (NRST) (1)
Reset by software by writing the RMVF bit.
Set by hardware when a reset from pin occurs.
0: no reset from pin occurred
1: reset from pin occurred (default after power-on reset)

Bit 21 **BORRSTF**: BOR reset flag (1)
Reset by software by writing the RMVF bit.
Set by hardware when a BOR reset occurs (**pwr_bor_rst**).
0: no BOR reset occurred
1: BOR reset occurred (default after power-on reset)

Bits 20:18 Reserved, must be kept at reset value.

Bit 17 **OBLRSTF**: Option byte loading reset flag (1)
Reset by software by the RMVF bit.
Set by hardware when a reset from the option byte loading occurs.
0: No reset from option byte loading occurred
1: Reset from option byte loading occurred

Bit 16 **RMVF**: remove reset flag
Set and reset by software to reset the value of the reset flags.
0: reset of the reset flags not activated (default after power-on reset)
1: resets the value of the reset flags

Bits 15:0 Reserved, must be kept at reset value.

1. Refer to *Table 57: Reset source identification (RCC_RSR)* for details on flag behavior.

7.8.45 RCC AHB1 clock enable register (RCC_AHB1ENR)

Address offset: 0x138

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADF1EN	Res.	Res.	Res.	OTGFSEN	USBPHYCEN	OTGHSEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ETH1RXEN	ETH1TXEN
rw				rw	rw	rw								rw	rw

rw										rw	rw				

Bit 31 **ADF1EN**: ADF clocks enable
Set and reset by software.
0: ADF clocks disabled (default after reset)
1: ADF clocks enabled

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSEN**: OTGFS peripheral clocks enable
Set and reset by software.
0: OTGFS peripheral clocks disabled (default after reset)
1: OTGFS peripheral clocks enabled

Bit 26 **USBPHYCEN**: USBPHYC clocks enable
Set and reset by software.
0: USBPHYC clocks disabled (default after reset)
1: USBPHYC clocks enabled

Bit 25 **OTGHSEN**: OTGHS clocks enable
Set and reset by software.
0: OTGHS clocks disabled (default after reset)
1: OTGHS clocks enabled

Bits 24:18 Reserved, must be kept at reset value.

Bit 17 **ETH1RXEN**: ETH1 reception clock enable
Set and reset by software.
0: ETH1 reception clock disabled (default after reset)
1: ETH1 reception clock enabled

Bit 16 **ETH1TXEN**: ETH1 transmission clock enable
Set and reset by software.
0: ETH1 transmission clock disabled (default after reset)
1: ETH1 transmission clock enabled

Bit 15 **ETH1MACEN**: ETH1 MAC peripheral clock enable
Set and reset by software.
0: ETH1 MAC peripheral clock disabled (default after reset)
1: ETH1 MAC peripheral clock enabled

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12EN**: ADC1 and 2 peripheral clocks enable
Set and reset by software.
0: ADC1 and 2 peripheral clocks disabled (default after reset)
1: ADC1 and 2 peripheral clocks enabled
The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to ADCx_CK input, and the **hclk1** bus interface clock.

Bit 4 **GPDMA1EN**: GPDMA1 clock enable
Set and reset by software.
0: GPDMA1 clock disabled (default after reset)
1: GPDMA1 clock enabled

Bits 3:0 Reserved, must be kept at reset value.

7.8.46 RCC AHB2 clock enable register (RCC_AHB2ENR)

Address offset: 0x13C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SRAM2EN	SRAM1EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
	rw	rw

Res.	CORDICEN	Res.	Res.	Res.	Res.	SDMMC2EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PSSIEN	Res.
	rw					rw								rw	

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SRAM2EN**: SRAM2 clock enable
Set and reset by software.
0: SRAM2 clock disabled (default after reset)
1: SRAM2 clock enabled

Bit 29 **SRAM1EN**: SRAM1 clock enable
Set and reset by software.
0: SRAM1 clock disabled (default after reset)
1: SRAM1 clock enabled

Bits 28:15 Reserved, must be kept at reset value.

Bit 14 **CORDICEN**: CORDIC clock enable
Set and reset by software.
0: CORDIC clock disabled (default after reset)
1: CORDIC clock enabled

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2EN**: SDMMC2 and SDMMC2 delay clock enable
Set and reset by software.
0: SDMMC2 and SDMMC2 delay clock disabled (default after reset)
1: SDMMC2 and SDMMC2 delay clock enabled

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **PSSIEN**: PSSI peripheral clocks enable
Set and reset by software.
0: PSSI peripheral clocks disabled (default after reset)
1: PSSI peripheral clocks enabled:

Bit 0 Reserved, must be kept at reset value.

7.8.47 RCC AHB3 clock enable register (RCC_AHB3ENR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PKAEN	Res.	SAESEN	Res.	CRYPEN	HASHEN	RNGEN
									rw		rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PKAEN**: PKA peripheral clock enable
Set and reset by software.
0: PKA peripheral clock disabled (default after reset)
1: PKA peripheral clock enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4 **SAESEN**: SAES peripheral clock enable
Set and reset by software.
This bit controls the enable of the clock delivered to the SAES.
0: The SAES peripheral clocks are disabled (default after reset)
1: The SAES peripheral clocks are enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPEN**: CRYP peripheral clock enable
Set and reset by software.
0: CRYP peripheral clock disabled (default after reset)
1: CRYP peripheral clock enabled

Bit 1 **HASHEN**: HASH peripheral clock enable
Set and reset by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled

Bit 0 **RNGEN**: RNG peripheral clocks enable
Set and reset by software.
0: RNG peripheral clocks disabled (default after reset)
1: RNG peripheral clocks enabled.

7.8.48 RCC AHB4 clock enable register (RCC_AHB4ENR)

Address offset: 0x140

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	BKPRAMEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CRCEN	Res.	Res.	Res.

rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMEN**: Backup RAM clock enable
Set and reset by software.
0: Backup RAM clock disabled (default after reset)
1: Backup RAM clock enabled

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **CRCEN**: CRC clock enable
Set and reset by software.
0: CRC clock disabled (default after reset)
1: CRC clock enabled

Bits 18:16 Reserved, must be kept at reset value.

Bit 15 **GPIOPEN**: GPIOP peripheral clock enable
Set and reset by software.
0: GPIOP peripheral clock disabled (default after reset)
1: GPIOP peripheral clock enabled

Bit 14 **GPIOOEN**: GPIOO peripheral clock enable
Set and reset by software.
0: GPIOO peripheral clock disabled (default after reset)
1: GPIOO peripheral clock enabled

Bit 13 **GPIONEN**: GPION peripheral clock enable
Set and reset by software.
0: GPION peripheral clock disabled (default after reset)
1: GPION peripheral clock enabled

Bit 12 **GPIOMEN**: GPIOM peripheral clock enable
Set and reset by software.
0: GPIOM peripheral clock disabled (default after reset)
1: GPIOM peripheral clock enabled

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHEN**: GPIOH peripheral clock enable
Set and reset by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled

Bit 6 **GPIOGEN**: GPIOG peripheral clock enable
Set and reset by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled

Bit 5 **GPIOFEN**: GPIOF peripheral clock enable
Set and reset by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled

Bit 4 **GPIOEEN**: GPIOE peripheral clock enable
Set and reset by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 3 **GPIODEN**: GPIOD peripheral clock enable
Set and reset by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 2 **GPIOCEN**: GPIOC peripheral clock enable
Set and reset by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 1 **GPIOBEN**: GPIOB peripheral clock enable
Set and reset by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 0 **GPIOAEN**: GPIOA peripheral clock enable
Set and reset by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

7.8.49 RCC AHB5 clock enable register (RCC_AHB5ENR)

Address offset: 0x134

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw		rw				rw			rw	rw	rw		rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **GPU2DEN**: GPU2D peripheral clock enable
Set and reset by software.
0: GPU2D peripheral clock disabled (default after reset)
1: GPU2D peripheral clock enabled

Bit 19 **GFXMMUEN**: GFXMMU peripheral clock enable
Set and reset by software.
0: GFXMMU peripheral clock disabled (default after reset)
1: GFXMMU peripheral clock enabled

Bits 18:15 Reserved, must be kept at reset value.

Bit 14 **XSPIMEN**: XSPIM peripheral clock enable
Set and reset by software.
0: XSPIM peripheral clock disabled (default after reset)
1: XSPIM peripheral clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **XSPI2EN**: XSPI2 and MCE2 peripheral clocks enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI2 and MCE2 peripheral clocks disabled (default after reset)
1: XSPI2 and MCE2 peripheral clocks enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1EN**: SDMMC1 and DB_SDMMC1 peripheral clocks enable
Set and reset by software.
0: SDMMC1 and DB_SDMMC1 peripheral clocks disabled (default after reset)
1: SDMMC1 and DB_SDMMC1 peripheral clocks enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1EN**: XSPI1 and MCE1 peripheral clocks enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI1 and MCE1 peripheral clocks disabled (default after reset)
1: XSPI1 and MCE1 peripheral clocks enabled

Bit 4 **FMCEN**: FMC and MCE3 peripheral clocks enable
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: FMC and MCE3 peripheral clocks disabled (default after reset)
1: FMC and MCE3 peripheral clocks enabled
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the **hclk5** bus interface clock.

Bit 3 **JPEGEN**: JPEG peripheral clock enable
Set and reset by software.
0: JPEG peripheral clock disabled (default after reset)
1: JPEG peripheral clock enabled

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DMA2DEN**: DMA2D peripheral clock enable
Set and reset by software.
0: DMA2D peripheral clock disabled (default after reset)
1: DMA2D peripheral clock enabled

Bit 0 **HPDMA1EN**: HPDMA1 peripheral clock enable
Set and reset by software.
0: HPDMA1 peripheral clock disabled (default after reset)
1: HPDMA1 peripheral clock enabled

7.8.50 RCC APB1 clock enable register 1 (RCC_APB1ENR1)

Address offset: 0x148

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **UART8EN**: UART8 peripheral clocks enable
Set and reset by software.
0: UART8 peripheral clocks disabled (default after reset)
1: UART8 peripheral clocks enabled

Bit 30 **UART7EN**: UART7 peripheral clocks enable
Set and reset by software.
0: UART7 peripheral clocks disabled (default after reset)
1: UART7 peripheral clocks enabled

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **CECEN**: HDMI-CEC peripheral clock enable
Set and reset by software.
0: HDMI-CEC peripheral clock disabled (default after reset)
1: HDMI-CEC peripheral clock enabled

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3EN**: I2C3 peripheral clocks enable
Set and reset by software.
0: I2C3 peripheral clocks disabled (default after reset)
1: I2C3 peripheral clocks enabled

Bit 22 **I2C2EN**: I2C2 peripheral clocks enable
Set and reset by software.
0: I2C2 peripheral clocks disabled (default after reset)
1: I2C2 peripheral clocks enabled

Bit 21 **I2C1_I3C1EN**: I2C1/I3C1 peripheral clocks enable
Set and reset by software.
0: I2C1/I3C1 peripheral clocks disabled (default after reset)
1: I2C1/I3C1 peripheral clocks enabled

Bit 20 **UART5EN**: UART5 peripheral clocks enable
Set and reset by software.
0: UART5 peripheral clocks disabled (default after reset)
1: UART5 peripheral clocks enabled

Bit 19 **UART4EN**: UART4 peripheral clocks enable
Set and reset by software.
0: UART4 peripheral clocks disabled (default after reset)
1: UART4 peripheral clocks enabled
The peripheral clocks of the UART4 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 18 **USART3EN**: USART3 peripheral clocks enable
Set and reset by software.
0: USART3 peripheral clocks disabled (default after reset)
1: USART3 peripheral clocks enabled
The peripheral clocks of the USART3 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 17 **USART2EN**: USART2peripheral clocks enable
Set and reset by software.
0: USART2 peripheral clocks disabled (default after reset)
1: USART2 peripheral clocks enabled
The peripheral clocks of the USART2 are the kernel clock selected by USART234578SEL and provided to UCLK input, and the **rcc_pclk1** bus interface clock.

Bit 16 **SPDIFRXEN**: SPDIFRX peripheral clocks enable
Set and reset by software.
0: SPDIFRX peripheral clocks disabled (default after reset)
1: SPDIFRX peripheral clocks enabled
The peripheral clocks of the SPDIFRX are the kernel clock selected by SPDIFRXSEL and provided to SPDIFRX_CLK input, and the **rcc_pclk1** bus interface clock.

Bit 15 **SPI3EN**: SPI3 peripheral clocks enable
Set and reset by software.
0: SPI3 peripheral clocks disabled (default after reset)
1: SPI3 peripheral clocks enabled
The peripheral clocks of the SPI3 are the kernel clock selected by I2S123SRC and provided to **com_clk** input, and the **rcc_pclk1** bus interface clock.

Bit 14 **SPI2EN**: SPI2 peripheral clocks enable
Set and reset by software.
0: SPI2 peripheral clocks disabled (default after reset)
1: SPI2 peripheral clocks enabled
The peripheral clocks of the SPI2 are the kernel clock selected by I2S123SRC and provided to **com_clk** input, and the **rcc_pclk1** bus interface clock.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGEN**: WWDG clock enable
Set by software, and reset by hardware when a system reset occurs.
0: WWDG peripheral clock disable (default after reset)
1: WWDG peripheral clock enabled

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1EN**: LPTIM1 peripheral clocks enable
Set and reset by software.
0: LPTIM1 peripheral clocks disabled (default after reset)
1: LPTIM1 peripheral clocks enabled
The peripheral clocks of the LPTIM1 are the kernel clock selected by LPTIM1SEL and provided to **clk_lpt** input, and the **rcc_pclk1** bus interface clock.

Bit 8 **TIM14EN**: TIM14 peripheral clock enable
Set and reset by software.
0: TIM14 peripheral clock disabled (default after reset)
1: TIM14 peripheral clock enabled

Bit 7 **TIM13EN**: TIM13 peripheral clock enable
Set and reset by software.
0: TIM13 peripheral clock disabled (default after reset)
1: TIM13 peripheral clock enabled

Bit 6 **TIM12EN**: TIM12 peripheral clock enable
Set and reset by software.
0: TIM12 peripheral clock disabled (default after reset)
1: TIM12 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 peripheral clock enable
Set and reset by software.
0: TIM7 peripheral clock disabled (default after reset)
1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 peripheral clock enable
Set and reset by software.
0: TIM6 peripheral clock disabled (default after reset)
1: TIM6 peripheral clock enabled

Bit 3 **TIM5EN**: TIM5 peripheral clock enable
Set and reset by software.
0: TIM5 peripheral clock disabled (default after reset)
1: TIM5 peripheral clock enabled

Bit 2 **TIM4EN**: TIM4 peripheral clock enable
Set and reset by software.
0: TIM4 peripheral clock disable (default after reset)
1: TIM4 peripheral clock enabled

Bit 1 **TIM3EN**: TIM3 peripheral clock enable
Set and reset by software.
0: TIM3 peripheral clock disabled (default after reset)
1: TIM3 peripheral clock enabled

Bit 0 **TIM2EN**: TIM2 peripheral clock enable
Set and reset by software.
0: TIM2 peripheral clock disabled (default after reset)
1: TIM2 peripheral clock enabled

7.8.51 RCC APB1 clock enable register 2 (RCC_APB1ENR2)

Address offset: 0x14C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1EN**: UCPD peripheral clock enable
Set and reset by software.
0: UCPD peripheral clock disabled (default after reset)
1: UCPD peripheral clock enabled

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANEN**: FDCAN peripheral clock enable
Set and reset by software.
0: FDCAN peripheral clock disabled (default after reset)
1: FDCAN peripheral clock enabled

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSEN**: MDIOS peripheral clock enable
Set and reset by software.
0: MDIOS peripheral clock disabled (default after reset)
1: MDIOS peripheral clock enabled

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CRSEN**: clock recovery system peripheral clock enable
Set and reset by software.
0: CRS peripheral clock disabled (default after reset)
1: CRS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

7.8.52 RCC APB2 clock enable register (RCC_APB2ENR)

Address offset: 0x150

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SAI2EN	SAI1EN	Res.	SPI5EN	TIM9EN	TIM17EN	TIM16EN	TIM15EN

		rw	rw								rw				rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **SAI2EN**: SAI2 peripheral clocks enable
Set and reset by software.
0: SAI2 peripheral clocks disabled (default after reset)
1: SAI2 peripheral clocks enabled:
The peripheral clocks of the SAI2 are the kernel clock selected by SAI2SEL, and the **pclk2** bus interface clock.

Bit 22 **SAI1EN**: SAI1 peripheral clocks enable
Set and reset by software.
0: SAI1 peripheral clocks disabled (default after reset)
1: SAI1 peripheral clocks enabled:
The peripheral clocks of the SAI1 are the kernel clock selected by SAI1SEL, and the **pclk2** bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5EN**: SPI5 peripheral clocks enable
Set and reset by software.
0: SPI5 peripheral clocks disabled (default after reset)
1: SPI5 peripheral clocks enabled:
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL, and the **pclk2** bus interface clock.

Bit 19 **TIM9EN**: TIM9 peripheral clock enable
Set and reset by software.
0: TIM9 peripheral clock disabled (default after reset)
1: TIM9 peripheral clock enabled

Bit 18 **TIM17EN**: TIM17 peripheral clock enable
Set and reset by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 peripheral clock enable
Set and reset by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 peripheral clock enable
Set and reset by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4EN**: SPI4 Peripheral Clocks Enable
Set and reset by software.
0: SPI4 peripheral clocks disabled (default after reset)
1: SPI4 peripheral clocks enabled:
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL, and the **pclk2** bus interface clock.

Bit 12 **SPI1EN**: SPI2S1 Peripheral Clocks Enable
Set and reset by software.
0: SPI2S1 peripheral clocks disabled (default after reset)
1: SPI2S1 peripheral clocks enabled:
The peripheral clocks of the SPI2S1 are: the kernel clock selected by SPI1SEL, and the **pclk2** bus interface clock.

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **USART1EN**: USART1 peripheral clocks enable
Set and reset by software.
0: USART1 peripheral clocks disabled (default after reset)
1: USART1 peripheral clocks enabled:
The peripheral clocks of the USART1 are the kernel clock selected by USART1SEL, and the **pclk2** bus interface clock.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TIM1EN**: TIM1 peripheral clock enable
Set and reset by software.
0: TIM1 peripheral clock disabled (default after reset)
1: TIM1 peripheral clock enabled

7.8.53 RCC APB4 clock enable register (RCC_APB4ENR)

Address offset: 0x154

Reset value: 0x0001 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw			rw	rw	rw	rw				rw		rw		rw	

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DTSEN**: Temperature Sensor peripheral clock enable
Set and reset by software.
0: DTS peripheral clock disabled (default after reset)
1: DTS peripheral clock enabled

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBEN**: RTC APB clock enable
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled
1: The register clock interface of the RTC (APB) is enabled (default after reset)

Bit 15 **VREFEN**: VREF peripheral clock enable
Set and reset by software.
0: VREF peripheral clock disabled (default after reset)
1: VREF peripheral clock enabled

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5EN**: LPTIM5 peripheral clocks enable
Set and reset by software.
0: LPTIM5 peripheral clocks disabled (default after reset)
1: LPTIM5 peripheral clocks enabled
The LPTIM5 kernel clock can be selected by LPTIM45SEL.

Bit 11 **LPTIM4EN**: LPTIM4 peripheral clocks enable
Set and reset by software.
0: LPTIM4 peripheral clocks disabled (default after reset)
1: LPTIM4 peripheral clocks enabled
The LPTIM4 kernel clock can be selected by LPTIM45SEL.

Bit 10 **LPTIM3EN**: LPTIM3 peripheral clocks enable
Set and reset by software.
0: LPTIM3 peripheral clocks disabled (default after reset)
1: LPTIM3 peripheral clocks enabled
The LPTIM3 kernel clock can be selected by LPTIM23SEL.

Bit 9 **LPTIM2EN**: LPTIM2 peripheral clocks enable
Set and reset by software.
0: LPTIM2 peripheral clocks disabled (default after reset)
1: LPTIM2 peripheral clocks enabled
The LPTIM2 kernel clock can be selected by LPTIM23SEL.

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6EN**: SPI/I2S6 peripheral clocks enable
Set and reset by software.
0: SPI/I2S6 peripheral clocks disabled (default after reset)
1: SPI/I2S6 peripheral clocks enabled
The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to **com_clk** input, and the **pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1EN**: LPUART1 peripheral clocks enable
Set and reset by software.
0: LPUART1 peripheral clocks disabled (default after reset)
1: LPUART1 peripheral clocks enabled
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to UCLK input, and the **pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSEN**: SBS peripheral clock enable
Set and reset by software.
0: SBS peripheral clock disabled (default after reset)
1: SBS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

7.8.54 RCC APB5 clock enable register (RCC_APB5ENR)

Address offset: 0x144

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	GFXTIMEN	Res.	DCMIPPEN	LTDCEN	Res.
											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **GFXTIMEN**: GFXTIM peripheral clock enable
Set and reset by software.
0: GFXTIM peripheral clock disabled (default after reset)
1: GFXTIM peripheral clock provided

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPEN**: DCMIPP peripheral clock enable
Set and reset by software.
0: DCMIPP peripheral clock disabled (default after reset)
1: DCMIPP peripheral clock provided

Bit 1 **LTDCEN**: LTDC peripheral clock enable
Provides the pixel clock (**ltdc_clk**) to the LTDC block.
Set and reset by software.
0: LTDC peripheral clock disabled (default after reset)
1: LTDC peripheral clock provided to the LTDC block

Bit 0 Reserved, must be kept at reset value.

7.8.55 RCC AHB5 low-power clock enable register (RCC_AHB5LPENR)

Address offset: 0x15C

Reset value: 0xF018 513F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw		rw				rw			rw	rw	rw	rw	rw	rw

Bit 31 **AXISRAMLPEN**:
AXISRAM[4:1] low-power peripheral clock enable
Set and reset by software.
0: AXISRAM[4:1] interface peripheral clock disabled in low-power mode
1: AXISRAM[4:1] interface peripheral clock enabled in low-power mode (default after reset)

Bit 30 **ITCMLPEN**: ITCM low-power peripheral clock enable
Set and reset by software.
0: ITCM interface peripheral clock disabled in low-power mode
1: ITCM interface peripheral clock enabled in low-power mode (default after reset)

Bit 29 **DTCM2LPEN**: DTCM2 low-power peripheral clock enable
Set and reset by software.
0: DTCM2 interface peripheral clock disabled in low-power mode
1: DTCM2 interface peripheral clock enabled in low-power mode (default after reset)

Bit 28 **DTCM1LPEN**: DTCM1 low-power peripheral clock enable
Set and reset by software.
0: DTCM1 interface peripheral clock disabled in low-power mode
1: DTCM1 interface peripheral clock enabled in low-power mode (default after reset)

Bits 27:21 Reserved, must be kept at reset value.

Bit 20 **GPU2DLPEN**: GPU2D low-power peripheral clock enable
Set and reset by software.
0: GPU2D interface clock peripheral disabled in low-power mode
1: GPU2D interface clock peripheral enabled in low-power mode (default after reset)

Bit 19 **GFXMMULPEN**: GFXMMU low-power peripheral clock enable
Set and reset by software.
0: GFXMMU interface peripheral clock disabled in low-power mode
1: GFXMMU interface peripheral clock enabled in low-power mode (default after reset)

Bits 18:15 Reserved, must be kept at reset value.

Bit 14 **XSPIMLPEN**: XSPIM low-power peripheral clock enable
Set and reset by software.
0: XSPIM interface peripheral clock disabled in low-power mode
1: XSPIM interface peripheral clock enabled in low-power mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **XSPI2LPEN:** XSPI2 and MCE2 low-power peripheral clock enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI2 and MCE2 peripheral clock disabled in low-power mode
1: XSPI2 and MCE2 peripheral clock enabled in low-power mode (default after reset)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **SDMMC1LPEN**: SDMMC1 and SDMMC1 delay low-power peripheral clock enable
Set and reset by software.
0: SDMMC1 and SDMMC1 delay peripheral clock disabled in low-power mode
1: SDMMC1 and SDMMC1 delay peripheral clock enabled in low-power mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI1LPEN**: XSPI1 and MCE1 low-power peripheral clock enable
Set and reset by software.
The hardware prevents writing this bit if XSPICKP = 1.
0: XSPI1 and MCE1 peripheral clock disabled in low-power mode
1: XSPI1 and MCE1 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **FMCLPEN**: FMC and MCE3 peripheral clocks enable in low-power mode
Set and reset by software.
The hardware prevents writing this bit if FMCCKP = 1.
0: FMC and MCE3 peripheral clocks disabled in low-power mode
1: FMC and MCE3 peripheral clocks enabled in low-power mode (default after reset):
The peripheral clocks of the FMC are the kernel clock selected by FMCSEL, and the **hclk5** bus interface clock.

Bit 3 **JPEGLPEN**: JPEG clock enable in low-power mode
Set and reset by software.
0: JPEG peripheral clock disabled in low-power mode
1: JPEG peripheral clock enabled in low-power mode (default after reset)

Bit 2 **FLASHLPEN**: FLASH low-power peripheral clock enable
Set and reset by software.
0: FLASH peripheral clock disabled in low-power mode
1: FLASH peripheral clock enabled in low-power mode (default after reset)

Bit 1 **DMA2DLPEN**: DMA2D low-power peripheral clock enable
Set and reset by software.
0: DMA2D peripheral clock disabled in low-power mode
1: DMA2D peripheral clock enabled in low-power mode (default after reset)

Bit 0 **HPDMA1LPEN**: HPDMA1 low-power peripheral clock enable
Set and reset by software.
0: HPDMA1 peripheral clock disabled in low-power mode
1: HPDMA1 peripheral clock enabled in low-power mode (default after reset)

7.8.56 RCC AHB1 low-power clock enable register (RCC_AHB1LPENR)

Address offset: 0x160

Reset value: 0x8E03 8030

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw										rw	rw				

Bit 31 **ADF1LPEN**: ADF clock enable in low-power mode
Set and reset by software.
0: ADF peripheral clock disabled in low-power mode
1: ADF peripheral clock enabled in low-power mode (default after reset)

Bits 30:28 Reserved, must be kept at reset value.

Bit 27 **OTGFSLPEN**: OTGFS clock enable in low-power mode
Set and reset by software.
0: OTGFS peripheral clock disabled in low-power mode
1: OTGFS peripheral clock enabled in low-power mode (default after reset)

Bit 26 **USBPHYCLPEN**: USBPHYC peripheral clock enable in low-power mode
Set and reset by software.
0: USBPHYC peripheral clock disabled in low-power mode
1: USBPHYC peripheral clock enabled in low-power mode (default after reset)

Bit 25 **OTGHSLPEN**: OTGHS peripheral clock enable in low-power mode
Set and reset by software.
0: OTGHS peripheral clock disabled in low-power mode
1: OTGHS peripheral clock enabled in low-power mode (default after reset)

Bit 24 **UCPDCTRL**: USBPHYC common block power-down control
Set and reset by software.
0: In SUSPEND, PHY state machine, bias and USBPHYC PLL remain powered (default after reset).
1: In SUSPEND, PHY state machine, bias and USBPHYC PLL are powered down.

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **ETH1RXLPEN**: ETH1 reception peripheral clock enable in low-power mode
Set and reset by software.
0: ETH1 reception peripheral clock disabled in low-power mode
1: ETH1 reception peripheral clock enabled in low-power mode (default after reset)

Bit 16 **ETH1TXLPEN**: ETH1 transmission peripheral clock enable in low-power mode
Set and reset by software.
0: ETH1 transmission peripheral clock disabled in low-power mode
1: ETH1 transmission peripheral clock enabled in low-power mode (default after reset)

Bit 15 **ETH1MACLPEN**: ETH1 MAC peripheral clock enable in low-power mode
Set and reset by software.
0: ETH1 MAC peripheral clock disabled in low-power mode
1: ETH1 MAC peripheral clock enabled in low-power mode (default after reset)

Bits 14:6 Reserved, must be kept at reset value.

Bit 5 **ADC12LPEN**: ADC1 and 2 peripheral clocks enable in low-power mode
Set and reset by software.
0: ADC1 and 2 peripheral clocks disabled in low-power mode
1: ADC1 and 2 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the ADC1 and 2 are the kernel clock selected by ADCSEL and provided to ADCx_CK input, and the **rcc_hclk1** bus interface clock.

Bit 4 **GPDMA1LPEN**: GPDMA1 clock enable in low-power mode
Set and reset by software.
0: GPDMA1 clock disabled in low-power mode
1: GPDMA1 clock enabled in low-power mode (default after reset)

Bits 3:0 Reserved, must be kept at reset value.

7.8.57 RCC AHB2 low-power clock enable register (RCC_AHB2LPENR)

Address offset: 0x164

Reset value: 0x6000 4202

	rw					rw								rw	

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SRAM2LPEN**: SRAM2 clock enable in low-power mode
Set and reset by software.
0: SRAM2 clock disabled in low-power mode
1: SRAM2 clock enabled in low-power mode (default after reset)

Bit 29 **SRAM1LPEN**: SRAM1 clock enable in low-power mode
Set and reset by software.
0: SRAM1 clock disabled in low-power mode
1: SRAM1 clock enabled in low-power mode (default after reset)

Bits 28:15 Reserved, must be kept at reset value.

Bit 14 **CORDICLPEN**: CORDIC clock enable in low-power mode
Set and reset by software.
0: CORDIC clock disabled in low-power mode
1: CORDIC clock enabled in low-power mode (default after reset)

Bits 13:10 Reserved, must be kept at reset value.

Bit 9 **SDMMC2LPEN**: SDMMC2 and SDMMC2 delay clock enable in low-power mode
Set and reset by software.
0: SDMMC2 and SDMMC2 delay clock disabled in low-power mode
1: SDMMC2 and SDMMC2 delay clock enabled in low-power mode (default after reset)

Bits 8:2 Reserved, must be kept at reset value.

Bit 1 **PSSILPEN**: PSSI peripheral clock enable in low-power mode
Set and reset by software.
0: PSSI peripheral clock disabled in low-power mode
1: PSSI peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.8.58 RCC AHB3 low-power clock enable register (RCC_AHB3LPENR)

Address offset: 0x16C

Reset value: 0x0000 0057

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

									rw		rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **PKALPEN**: PKA peripheral clock enable in low-power mode
Set and reset by software.
0: PKA peripheral clock disabled in low-power mode
1: PKA peripheral clock enabled in low-power mode (default after reset)

Bit 5 Reserved, must be kept at reset value.

Bit 4 **SAESLPEN**: SAES peripheral clock enable in low-power mode
Set and reset by software.
0: SAES peripheral clock disabled in low-power mode
1: SAES peripheral clock enabled in low-power mode (default after reset)

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CRYPLPEN**: CRYP peripheral clock enable in low-power mode
Set and reset by software.
0: CRYP peripheral clock disabled in low-power mode
1: CRYP peripheral clock enabled in low-power mode (default after reset)

Bit 1 **HASHLPEN**: HASH peripheral clock enable in low-power mode
Set and reset by software.
0: HASH peripheral clock disabled in low-power mode
1: HASH peripheral clock enabled in low-power mode (default after reset)

Bit 0 **RNGLPEN**: RNG peripheral clock enable in low-power mode
Set and reset by software.
0: RNG peripheral clocks disabled in low-power mode
1: RNG peripheral clock enabled in low-power mode (default after reset)

7.8.59 RCC AHB4 low-power clock enable register (RCC_AHB4LPENR)

Address offset: 0x168

Reset value: 0x1008 F0FF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **BKPRAMLPEN**: Backup RAM clock enable in low-power mode
Set and reset by software.
0: Backup RAM clock disabled in low-power mode
1: Backup RAM clock enabled in low-power mode (default after reset)

Bits 27:20 Reserved, must be kept at reset value.

Bit 19 **CRCLPEN**: CRC clock enable in low-power mode
Set and reset by software.
0: CRC clock disabled in low-power mode
1: CRC clock enabled in low-power mode (default after reset)

Bits 18:16 Reserved, must be kept at reset value.

Bit 15 **GPIOPLPEN**: GPIOP peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOP peripheral clock disabled in low-power mode
1: GPIOP peripheral clock enabled in low-power mode (default after reset)

Bit 14 **GPIOOLPEN**: GPIOO peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOO peripheral clock disabled in low-power mode
1: GPIOO peripheral clock enabled in low-power mode (default after reset)

Bit 13 **GPIONLPEN**: GPION peripheral clock enable in low-power mode
Set and reset by software.
0: GPION peripheral clock disabled in low-power mode
1: GPION peripheral clock enabled in low-power mode (default after reset)

Bit 12 **GPIOMLPEN**: GPIOM peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOM peripheral clock disabled in low-power mode
1: GPIOM peripheral clock enabled in low-power mode (default after reset)

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **GPIOHLPEN**: GPIOH peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOH peripheral clock disabled in low-power mode
1: GPIOH peripheral clock enabled in low-power mode (default after reset)

Bit 6 **GPIOGLPEN**: GPIOG peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOG peripheral clock disabled in low-power mode
1: GPIOG peripheral clock enabled in low-power mode (default after reset)

Bit 5 **GPIOFLPEN**: GPIOF peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOF peripheral clock disabled in low-power mode
1: GPIOF peripheral clock enabled in low-power mode (default after reset)

Bit 4 **GPIOELPEN**: GPIOE peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOE peripheral clock disabled in low-power mode
1: GPIOE peripheral clock enabled in low-power mode (default after reset)

Bit 3 **GPIODLPEN**: GPIOD peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOD peripheral clock disabled in low-power mode
1: GPIOD peripheral clock enabled in low-power mode (default after reset)

Bit 2 **GPIOCLPEN**: GPIOC peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOC peripheral clock disabled in low-power mode
1: GPIOC peripheral clock enabled in low-power mode (default after reset)

Bit 1 **GPIOBLPEN**: GPIOB peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOB peripheral clock disabled in low-power mode
1: GPIOB peripheral clock enabled in low-power mode (default after reset)

Bit 0 **GPIOALPEN**: GPIOA peripheral clock enable in low-power mode
Set and reset by software.
0: GPIOA peripheral clock disabled in low-power mode
1: GPIOA peripheral clock enabled in low-power mode (default after reset)

7.8.60 RCC APB1 low-power clock enable register 1 (RCC_APB1LPENR1)

Address offset: 0x170

Reset value: 0xC8FF CBFF

Bit 31 **UART8LPEN**: UART8 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART8 peripheral clocks disabled in low-power mode
1: UART8 peripheral clocks enabled in low-power mode (default after reset)

Bit 30 **UART7LPEN**: UART7 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART7 peripheral clocks disabled in low-power mode
1: UART7 peripheral clocks enabled in low-power mode (default after reset)

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **CECLPEN**: HDMI-CEC peripheral clocks enable in low-power mode
Set and reset by software.
0: HDMI-CEC peripheral clocks disabled in low-power mode
1: HDMI-CEC peripheral clocks enabled in low-power mode (default after reset)

Bits 26:24 Reserved, must be kept at reset value.

Bit 23 **I2C3LPEN**: I2C3 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C3 peripheral clocks disabled in low-power mode
1: I2C3 peripheral clocks enabled in low-power mode (default after reset):

Bit 22 **I2C2LPEN**: I2C2 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C2 peripheral clocks disabled in low-power mode
1: I2C2 peripheral clocks enabled in low-power mode (default after reset):.

Bit 21 **I2C1_I3C1LPEN**: I2C1/I3C1 peripheral clocks enable in low-power mode
Set and reset by software.
0: I2C1/I3C1 peripheral clocks disabled in low-power mode
1: I2C1/I3C1 peripheral clocks enabled in low-power mode (default after reset):

Bit 20 **UART5LPEN**: UART5 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART5 peripheral clocks disabled in low-power mode
1: UART5 peripheral clocks enabled in low-power mode (default after reset)

Bit 19 **UART4LPEN**: UART4 peripheral clocks enable in low-power mode
Set and reset by software.
0: UART4 peripheral clocks disabled in low-power mode
1: UART4 peripheral clocks enabled in low-power mode (default after reset)

Bit 18 **USART3LPEN**: USART3 peripheral clocks enable in low-power mode
Set and reset by software.
0: USART3 peripheral clocks disabled in low-power mode
1: USART3 peripheral clocks enabled in low-power mode (default after reset):

Bit 17 **USART2LPEN**: USART2 peripheral clocks enable in low-power mode
Set and reset by software.
0: USART2 peripheral clocks disabled in low-power mode
1: USART2 peripheral clocks enabled in low-power mode (default after reset).

Bit 16 **SPDIFRXLPEN**: SPDIFRX peripheral clocks enable in low-power mode
Set and reset by software.
0: SPDIFRX peripheral clocks disabled in low-power mode
1: SPDIFRX peripheral clocks enabled in low-power mode (default after reset).

Bit 15 **SPI3LPEN**: SPI3 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI3 peripheral clocks disabled in low-power mode
1: SPI3 peripheral clocks enabled in low-power mode (default after reset).

Bit 14 **SPI2LPEN**: SPI2 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI2 peripheral clocks disabled in low-power mode
1: SPI2 peripheral clocks enabled in low-power mode (default after reset).

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **WWDGLPEN**: WWDG clock enable in low-power mode
Set and reset by software.
0: WWDG clock disable in low-power mode
1: WWDG clock enabled in low-power mode (default after reset)

Bit 10 Reserved, must be kept at reset value.

Bit 9 **LPTIM1LPEN**: LPTIM1 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM1 peripheral clocks disabled in low-power mode
1: LPTIM1 peripheral clocks enabled in low-power mode (default after reset).

Bit 8 **TIM14LPEN**: TIM14 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM14 peripheral clock disabled in low-power mode
1: TIM14 peripheral clock enabled in low-power mode (default after reset)

Bit 7 **TIM13LPEN**: TIM13 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM13 peripheral clock disabled in low-power mode
1: TIM13 peripheral clock enabled in low-power mode (default after reset)

Bit 6 **TIM12LPEN**: TIM12 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM12 peripheral clock disabled in low-power mode
1: TIM12 peripheral clock enabled in low-power mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM7 peripheral clock disabled in low-power mode
1: TIM7 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM6 peripheral clock disabled in low-power mode
1: TIM6 peripheral clock enabled in low-power mode (default after reset)

Bit 3 **TIM5LPEN**: TIM5 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM5 peripheral clock disabled in low-power mode
1: TIM5 peripheral clock enabled in low-power mode (default after reset)

Bit 2 **TIM4LPEN**: TIM4 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM4 peripheral clock disabled in low-power mode
1: TIM4 peripheral clock enabled in low-power mode (default after reset)

Bit 1 **TIM3LPEN**: TIM3 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM3 peripheral clock disabled in low-power mode
1: TIM3 peripheral clock enabled in low-power mode (default after reset)

Bit 0 **TIM2LPEN**: TIM2 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM2 peripheral clock disabled in low-power mode
1: TIM2 peripheral clock enabled in low-power mode (default after reset)

7.8.61 RCC APB1 low-power clock enable register 2 (RCC_APB1LPENR2)

Address offset: 0x174

Reset value: 0x0800 0122

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw			rw				rw	

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **UCPD1LPEN**: UCPD peripheral clock enable in low-power mode
Set and reset by software.
0: UCPD peripheral clock disabled in low-power mode
1: UCPD peripheral clock enabled in low-power mode (default after reset)

Bits 26:9 Reserved, must be kept at reset value.

Bit 8 **FDCANLPEN**: FDCAN peripheral clock enable in low-power mode
Set and reset by software.
0: FDCAN peripheral clock disabled in low-power mode
1: FDCAN peripheral clock enabled in low-power mode (default after reset)

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **MDIOSLPEN**: MDIOS peripheral clock enable in low-power mode
Set and reset by software.
0: MDIOS peripheral clock disabled in low-power mode
1: MDIOS peripheral clock enabled in low-power mode (default after reset)

Bits 4:2 Reserved, must be kept at reset value.

Bit 1 **CRSLPEN**: clock recovery system peripheral clock enable in low-power mode
Set and reset by software.
0: CRS peripheral clock disabled in low-power mode
1: CRS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.8.62 RCC APB2 low-power clock enable register (RCC_APB2LPENR)

Address offset: 0x178

Reset value: 0x00DF 3011

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw								rw				rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **SAI2LPEN**: SAI2 peripheral clocks enable in low-power mode
Set and reset by software.
0: SAI2 peripheral clocks disabled in low-power mode
1: SAI2 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SAI2 are: the kernel clock selected by SAI2SEL and provided to SAI_CK_A and SAI_CK_B inputs, and the **pclk2** bus interface clock.

Bit 22 **SAI1LPEN**: SAI1 peripheral clocks enable in low-power mode
Set and reset by software.
0: SAI1 peripheral clocks disabled in low-power mode
1: SAI1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SAI1 are: the kernel clock selected by SAI1SEL and provided to SAI_CK_A and SAI_CK_B inputs, and the **pclk2** bus interface clock.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **SPI5LPEN**: SPI5 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI5 peripheral clocks disabled in low-power mode
1: SPI5 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI5 are the kernel clock selected by SPI45SEL and provided to **com_clk** input, and the **pclk2** bus interface clock.

Bit 19 **TIM9LPEN**: TIM9 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM9 peripheral clock disabled in low-power mode
1: TIM9 peripheral clock enabled in low-power mode (default after reset)

Bit 18 **TIM17LPEN**: TIM17 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM17 peripheral clock disabled in low-power mode
1: TIM17 peripheral clock enabled in low-power mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM16 peripheral clock disabled in low-power mode
1: TIM16 peripheral clock enabled in low-power mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM15 peripheral clock disabled in low-power mode
1: TIM15 peripheral clock enabled in low-power mode (default after reset)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **SPI4LPEN**: SPI4 peripheral clock enable in low-power mode
Set and reset by software.
0: SPI4 peripheral clocks disabled in low-power mode
1: SPI4 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI4 are: the kernel clock selected by SPI45SEL and provided to **com_clk** input, and the **pclk2** bus interface clock.

Bit 12 **SPI1LPEN**: SPI2S1 peripheral clock enable in low-power mode
Set and reset by software.
0: SPI2S1 peripheral clocks disabled in low-power mode
1: SPI2S1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI2S1 are: the kernel clock selected by I2S1SEL and provided to **spi_ker_ck** input, and the **pclk2** bus interface clock.

Bits 11:5 Reserved, must be kept at reset value.

Bit 4 **USART1LPEN**: USART1 peripheral clock enable in low-power mode
Set and reset by software.
0: USART1 peripheral clocks disabled in low-power mode
1: USART1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the USART1 are the kernel clock selected by USART169SEL and provided to UCLK inputs, and the **pclk2** bus interface clock.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TIM1LPEN**: TIM1 peripheral clock enable in low-power mode
Set and reset by software.
0: TIM1 peripheral clock disabled in low-power mode
1: TIM1 peripheral clock enabled in low-power mode (default after reset)

7.8.63 RCC APB4 low-power clock enable register (RCC_APB4LPENR)

Address offset: 0x17C

Reset value: 0x0401 9E2A

rw			rw	rw	rw	rw				rw		rw		rw	

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **DTSLPEN**: temperature sensor peripheral clock enable in low-power mode
Set and reset by software.
0: DTS peripheral clock disabled in low-power mode
1: DTS peripheral clock enabled in low-power mode (default after reset)

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCAPBLPEN**: RTC APB clock enable in low-power mode
Set and reset by software.
0: The register clock interface of the RTC (APB) is disabled in low-power mode
1: The register clock interface of the RTC (APB) is enabled in low-power mode (default after reset)

Bit 15 **VREFLPEN**: VREF peripheral clock enable in low-power mode
Set and reset by software.
0: VREF peripheral clock disabled in low-power mode
1: VREF peripheral clock enabled in low-power mode (default after reset)

Bits 14:13 Reserved, must be kept at reset value.

Bit 12 **LPTIM5LPEN**: LPTIM5 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM5 peripheral clocks disabled in low-power mode
1: LPTIM5 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM5 are the kernel clock selected by LPTIM45SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 11 **LPTIM4LPEN**: LPTIM4 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM4 peripheral clocks disabled in low-power mode
1: LPTIM4 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM4 are the kernel clock selected by LPTIM45SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 10 **LPTIM3LPEN**: LPTIM3 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM3 peripheral clocks disabled in low-power mode
1: LPTIM3 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM3 are the kernel clock selected by LPTIM23SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bit 9 **LPTIM2LPEN**: LPTIM2 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPTIM2 peripheral clocks disabled in low-power mode
1: LPTIM2 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPTIM2 are the kernel clock selected by LPTIM23SEL and provided to **clk_lpt** input, and the **pclk4** bus interface clock.

Bits 8:6 Reserved, must be kept at reset value.

Bit 5 **SPI6LPEN**: SPI/I2S6 peripheral clocks enable in low-power mode
Set and reset by software.
0: SPI/I2S6 peripheral clocks disabled in low-power mode
1: SPI/I2S6 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the SPI/I2S6 are the kernel clock selected by SPI6SEL and provided to **com_ck** input, and the **rcc_pclk4** bus interface clock.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **LPUART1LPEN**: LPUART1 peripheral clocks enable in low-power mode
Set and reset by software.
0: LPUART1 peripheral clocks disabled in low-power mode
1: LPUART1 peripheral clocks enabled in low-power mode (default after reset)
The peripheral clocks of the LPUART1 are the kernel clock selected by LPUART1SEL and provided to UCLK input, and the **rcc_pclk4** bus interface clock.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **SBSLPEN**: SBS peripheral clock enable in low-power mode
Set and reset by software.
0: SBS peripheral clock disabled in low-power mode
1: SBS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.8.64 RCC APB5 low-power clock enable register (RCC_APB5LPENR)

Address offset: 0x180

Reset value: 0x0000 0016

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw		rw	rw	

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **GFXTIMLPEN**: GFXTIM peripheral clock enable in low-power mode
Set and reset by software.
0: GFXTIM peripheral clock disabled in low-power mode
1: GFXTIM peripheral clock enabled in low-power mode (default after reset)

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCMIPPLPEN**: DCMIPP peripheral clock enable in low-power mode
Set and reset by software.
0: DCMIPP peripheral clock disabled in low-power mode
1: DCMIPP peripheral clock enabled in low-power mode (default after reset)

Bit 1 **LTDCLPEN**: LTDC peripheral clock enable in low-power mode
Set and reset by software.
0: LTDC peripheral clock disabled in low-power mode
1: LTDC peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

7.9 RCC register map

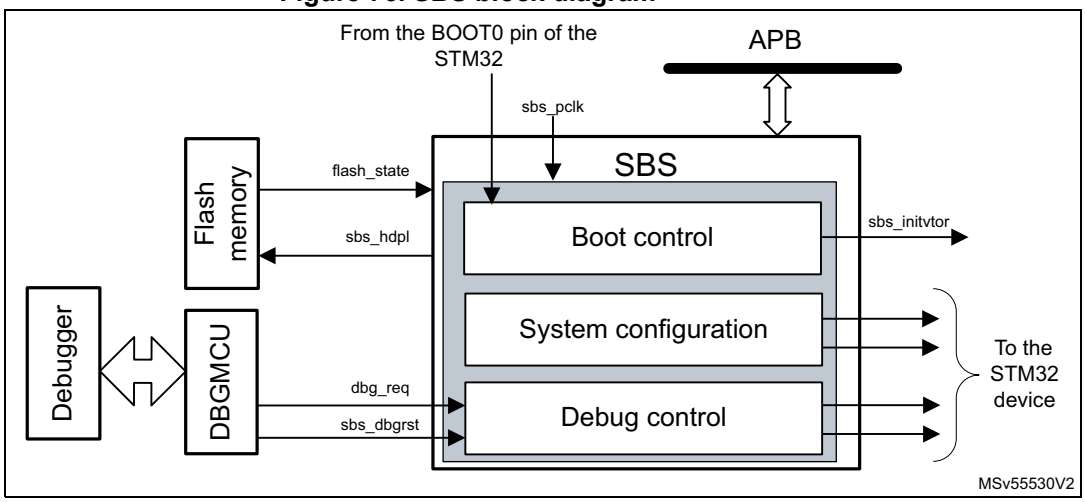
Refer to *Section 2.3 on page 150* for the register boundary addresses.

8 System configuration, boot and security (SBS)

8.1 SBS introduction

The STM32H7Rx/7Sx devices feature a set of configuration registers located in the SBS. On top of various device configurations, this SBS peripheral controls key boot and security features, including debug.



8.2 SBS main features

- Boot control
  - Upon system reset, configure the Cortex-M7 boot address and the hide protection level (HDPL) depending on the device life cycle (open or close).
- Debug control
  - Control the opening of the device debug interface, ensuring the sequencing of events that guarantee the device security
- System configuration
  - Analog switch configuration management
  - I^2C Fast-mode Plus configuration
  - Selection of the Ethernet PHY interface
  - I/O compensation cell management
  - Selection of source input to the EXTI inputs used for external interrupt/event detection
  - Configuration for Cortex-M7 FPU interrupts
  - Enable/disable the divider by 32 on ADC12 clock
  - Optional one wait-state added to all AXI RAMs when ECC = 0
- Security status
  - BKPRAM and PKA SRAM erase
- RSSCMD[15:0] in SBS_RSSCMDR for applications to pass on a command to the RSS (root secure services) executed at the next reset

8.3 SBS functional description

8.3.1 SBS block diagram

Figure 76. SBS block diagram

8.3.2 SBS internal signals

The tables below detail the SBS pins and internal signals.

Table 74. SBS input/output pins

Pin name	Type	Description
BOOT	Input	Boot from flash memory or bootloader.

Table 75. SBS internal input/output signals

Signal name	Type	Description
sbs_pclk	Input	APB bus clock
sbs_dbgrst		Debug configuration reset from DBGMCU
flash_state		Non-volatile security status input from Flash memory
sbs_hdpl	Output	Hide protection level information
sbs_initvtor		Vector address for Cortex-M7. See *Section 8.3.5* for more details.
dbg_req	Input	External host request to launch the debug authentication protocol. See *Section 8.3.6* for more details.

8.3.3 SBS reset and clocks

The SBS configuration port is clocked by the APB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.

8.3.4 SBS hide protection management

The HDPL is a monotonic counter incremented during the boot stages. It is reset to its default value only following a power-on reset or a system reset. This default value (0 or 1) depends on the device lifecycle, as defined in *Table 76: SBS boot control*.

The device uses HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HDPL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

Note: The use of HDPL in the embedded Flash memory is detailed in Section 5: Embedded flash memory (FLASH).

The HDPL can take a 0 to 3 value. When reaching the value 3, HDPL keeps this value until reset. The current HDPL value is readable in HDPL bitfield in SBS_HDPLSR register.

Incrementing HDPL

The application must write 0x6A to INCR_HDPL bitfield in SBS_HDPLCR register to increment the HDPL by one.

After such increment, and before doing any subsequent action, the application must check if the HDPL has effectively been incremented, by reading SBS_HDPLSR.

8.3.5 SBS boot control

The figure below and *Table 76* shows how the SBS uses multiple information to define the Cortex-M7 boot address (INITVTOR) and the HDPL before the CPU reset is released.

Figure 77. SBS boot control

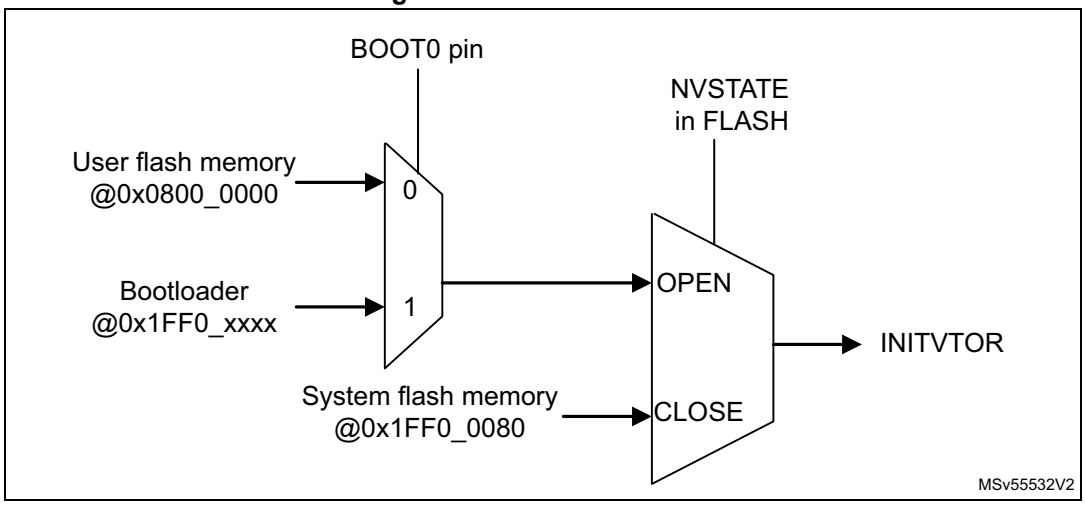


Table 76. SBS boot control

SBS input		SBS output			
NVSTATE (from FLASH)	**BOOT pin**	**Boot address**	**INITVTOR(1) (to Cortex-M7)**	**Immutable RoT selection(2)**	**HDPL value in SBS_HDPLSR**
OPEN	0	User Flash memory	0x0800 0000	OEM	1
				ST	2
	1	Bootloader(3)	Defined by ST	Any	1
CLOSE	x	System Flash memory (ST RSS)			0

1. Readable in SBS_BOOTSR register.
2. ST iRoT is not available on STM32H7Rx/7Sx devices.
3. Located in the system memory, it is used to reprogram the Flash memory by using USART, I2C, SPI, FDCAN or USB_OTG in device mode through the DFU (device firmware upgrade) (TBC)

The BOOT value coming from the external pin is latched upon reset release. This pin is in input mode during the complete reset phase, and then switches automatically in analog mode after reset is released.

The NVSTATE value comes from the Flash memory interface, following an automatic option-byte load sequence (see *Section 5: Embedded flash memory (FLASH)* for details).

8.3.6 SBS debug management

Device debug is allowed or not depending on the lifecycle of the device:

- For open devices (NVSTATE = OPEN), the debug is always allowed.
- For close devices (NVSTATE = CLOSE), the debug is disabled at boot but can be reopened during the boot after an authenticated debug sequence.

When debug is forbidden, mailbox access port, CM7 access port, and CPU debug interface are locked. In this situation, the debugger cannot access the CPU and no effective debug can be done. Refer to *Section 66: Debug infrastructure* for more details.

Authenticated debug sequence

1. External host requests to launch the debug authentication protocol, via the DBGMCU access port mailbox. The rest of the device is kept under reset.
2. SBS selects the ST RSS boot address and requests the CPU to be released from reset
3. CPU running RSS library executes the debug authentication library in system Flash memory. If the device is closed, the access port mailbox is closed until RSS acknowledges the authentication sequence start request.
4. As soon as a debug certificate is accepted by the device, RSS programs the opening of the Cortex-M7 access port by writing to AP_UNLOCK bitfield in SBS_DBGCR register. RSS also programs the opening of the CPU debug interface by writing to DBG_UNLOCK bitfield in SBS_DBGCR register.
5. Above re-openings are effective only when the HDPL in SBS_HDPLSR register has a value equal or superior to the value programmed in DBG_AUTH_HDPL in SBS_DBGCR register. If DBG_AUTH_HDPL bitfield is kept at 0x0, the debug never opens (forbidden value).

Note: The debug authentication library in system Flash memory is only available when HDPL = 0 in SBS_HDPLSR. Only this code can perform the above steps 3 and 4.

At any time, the application via DBGMCU can reset the debug configuration in SBS_DBGCR register. See dedicated sections for details (TBC).

Debug locking

To ensure the debug configuration is not modified by an unauthorized code, any application can lock it by writing to DBGCFG_LOCK bitfield in SBS_DBGLOCKR register. Once the debug configuration is locked, the application can unlock it using DBGMCU (TBC).

8.3.7 SBS voltage booster for I/O analog switches

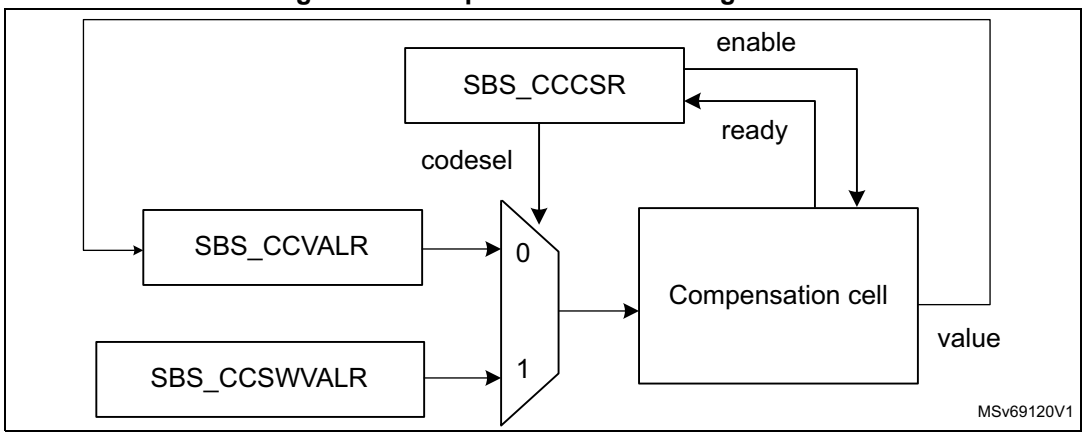
By setting BOOSTEN in SBS_PMCR, the application reduces the total harmonic distortion (THD) of the I/O analog switches when the supply voltage is below 2.7 V, to guarantee the same performance as with the full voltage range.

To avoid current consumption due to booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for the analog switches, by setting BOOSTVDDSEL in SBS_PMCR.

In this case, BOOSTEN must be cleared to avoid unexpected power consumption.

Table 77. Analog switches recommended configuration

V_{DDA}	V_{DD}	BOOSTEN	BOOSTVDDSEL	Analog switch supply voltage
≤ 2.7 V	≤ 2.7 V	1	0	Booster
	> 2.7 V	0	1	V_{DD}
> 2.7V		0	0	V_{DDA}



8.3.8 SBS I/O compensation cell management

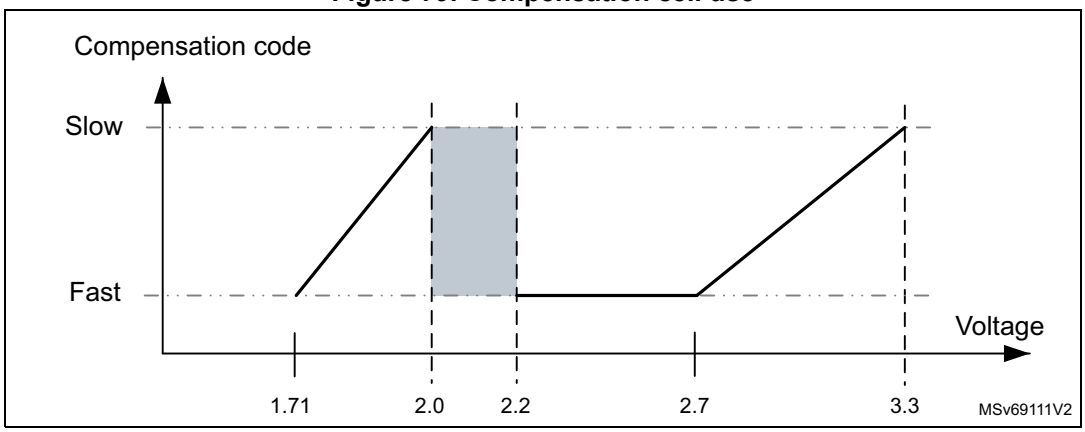
The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS), that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the t_{fall} and t_{rise} time), in order to reduce the I/O noise on power supply.

The CSI is used by the compensation cells and must be enabled before enabling the compensation cells

As shown in *Figure 78*, the compensation cell is split into two blocks: one block to provide an optimal code for the current PVT, and one block to drive the block controlled by the software.

Figure 78. Compensation cell management

The compensation cell value can be read when the READY flag is set in SBS_CCCSR. With CODESEL in SBS_CCCSR, the application can select the value to apply between two options: the code from the cell or the code from SBS_CCSWVALR.



Three compensation cells are embedded in STM32H7Rx/7Sx devices:

- one for the I/Os supplied by V_{DD} or V_{DDA} (see *Section 8.3.7*)
- one for the dedicated I/Os of the XSPI1
- one for the dedicated I/Os of the XSPI2

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os.

Note: The compensation cell can be used only when 2.7 V ≤ V_{DDIOx} ≤ 3.6 V or 1.71 V ≤ V_{DDIOx} ≤ 2 V (see the figure below).

Figure 79. Compensation cell use

8.3.9 SBS registers access control

Some SBS registers can be accessed only if HDPL = 0 in SBS_HDPLSR (hence only accessible by the ST RSS code).

Some bitfields in SBS are security critical, reset in non-secure state (coded as 0xB4) or in secure state (any other values). For bitfields reset in non-secure state, when the secure state is selected writing any value but 0xB4, the bitfield is no more writable until a reset occurs.

As a general rule, it is recommended to write 0xC3 to select a secure state and read back 0x6A to acknowledge the write is effective.

Protected fields are the following:

- INCR_HDPL
- DBGCFG_LOCK

8.3.10 SBS error management

The SBS does not manage errors.

8.4 SBS interrupts

The SBS does not support interrupts.

8.5 SBS registers

8.5.1 SBS boot status register (SBS_BOOTSR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INITVTOR[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INITVTOR[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **INITVTOR[31:0]**: initial vector for Cortex-M7

This register includes the physical boot address used by the Cortex-M7 after reset

8.5.2 SBS hide protection control register (SBS_HDPLCR)

Address offset: 0x010

Reset value: 0x0000 00B4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **INCR_HDPL[7:0]**: increment HDPL

Write 0x6A to increment device HDPL by one.

After a write, the register value reverts to its default value (0xB4).

8.5.3 SBS hide protection status register (SBS_HDPLSR)

Address offset: 0x014

Reset value: 0x0000 00XX (see *Section 8.3.5*)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]**: hide protection level

This bitfield returns the current HDPL of the device.

0xB4: HDPL0, corresponding to ST-RSS (default when device is CLOSE)

0x51: HDPL1

0x8A: HDPL2

0x6F and other codes: HDPL3, corresponding to non-boot application.

Note: The device state (open/close) is defined in FLASH_NVSTATER register of the embedded Flash memory.

8.5.4 SBS debug control register (SBS_DBGCR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBG_AUTH_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_UNLOCK[7:0]								AP_UNLOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **DBG_AUTH_HDPL[7:0]**: authenticated debug hide protection level

Writing to this bitfield defines at which HDPL the authenticated debug opens.

0x51: HDPL1

0x8A: HDPL2

0x6F: HDPL3

Note: Writing any other values is ignored. Reading any other value means the authenticated debug always fails.

Bits 15:8 **DBG_UNLOCK[7:0]**: debug unlock

Write 0xB4 to this bitfield to open the debug when HDPL in SBS_HDPLSR equals to DBG_AUTH_HDPL in this register.

Bits 7:0 **AP_UNLOCK[7:0]**: access port unlock

Write 0xB4 to this bitfield to open the device access port.

8.5.5 SBS debug lock register (SBS_DBGLOCKR)

Address offset: 0x024

Reset value: 0x0000 00B4

This register is reset when sbs_dbgrst is asserted.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBGCFG_LOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DBGCFG_LOCK[7:0]**: debug configuration lock

Reading this bitfield returns 0x6A if the bitfield value is different from 0xB4.

0xB4: Writes to SBS_DBGCR allowed (default)

Other: Writes to SBS_DBGCR ignored

Note: 0xC3 is the recommended value to lock the debug configuration using this bitfield.

8.5.6 SBS RSS command register (SBS_RSSCMDR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSSCMD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RSSCMD[15:0]**: RSS command

The application can use this bitfield to pass on a command to the RSS, executed at the next reset.

8.5.7 SBS product mode and configuration register (SBS_PMCR)

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	AXISRAM_WS	Res.	Res.	Res.	Res.	ETH_PHYSEL[2:0]			Res.	Res.	Res.	Res.	Res.
			rw					rw	rw	rw					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	BOOSTVDDSEL	BOOSTEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **AXISRAM_WS**: AXISRAM wait state

Set this bit to add one wait state to all AXISRAMs when ECC = 0. When ECC = 1 there is one wait state by default.

0: No wait state added when accessing any AXISRAM with ECC = 0

1: One wait state added when accessing any AXISRAM with ECC = 0. In this case, refer to the datasheet for maximum frequency.

Bits 27:24 Reserved, must be kept at reset value.

Bits 23:21 **ETH_PHYSEL[2:0]**: Ethernet PHY interface selection

000: GMII or MII

100: RMII

Other: reserved

Bits 20:10 Reserved, must be kept at reset value.

Bit 9 **BOOSTVDDSEL**: booster V_{DD} selection

This bit selects the analog switch supply voltage, between V_{DD}, V_{DDA} and booster.
To avoid current consumption due to booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for analog switches. In this case, the BOOSTEN bit must be cleared to avoid unwanted power consumption.
When both $V_{DD\ and}$ V_{DDA} are below 2.7 V, the booster is still needed to obtain full AC performances from the I/O analog switches.
0: V_{DDA} selected as analog switch booster voltage supply (when BOOSTEN bit is cleared)
1: V_{DD} selected as analog switch booster voltage supply

Bit 8 **BOOSTEN**: booster enable

Set this bit to reduce the THD of the analog switches when the supply voltage is below 2.7 V. guaranteeing the same performance as with the full voltage range. To avoid current consumption due to booster activation when V_{DDA} < 2.7 V and V_{DD} > 2.7 V, V_{DD} can be selected as supply voltage for analog switches by setting BOOSTVDDSEL bit in SBS_PMCR. In this case, the BOOSTEN bit must be cleared to avoid unwanted power consumption.
0: Booster disabled
1: Booster enabled

Bits 7:0 Reserved, must be kept at reset value.

8.5.8 SBS FPU interrupt mask register (SBS_FPUIMR)

Address offset: 0x104

Reset value: 0x0000 001F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: FPU interrupt enable

Set and cleared by software to enable the Cortex-M7 FPU interrupts
xxxxx1: Invalid operation interrupt enabled (xxxxx0 to disable)
xxxx1x: Divide-by-zero interrupt enabled (xxxx0x to disable)
xxx1xx: Underflow interrupt enabled (xxx0xx to disable)
xx1xxx: Overflow interrupt enabled (xx0xxx to disable)
x1xxxx: Input denormal interrupt enabled (x0xxxx to disable)
1xxxxx: Inexact interrupt enabled (0xxxxx to disable), disabled by default

8.5.9 SBS memory erase status register (SBS_MESR)

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MEF
															r

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **MEF**: memory erase flag

This bit is set by hardware when BKPRAM and PKA SRAM erase is ongoing after a power-on reset or one tamper event (see *Section 50: Tamper and backup registers (TAMP)* for details). This bit is set when the erase is done.

0: Automatic erase of BKPRAM and PKA RAM memories ongoing

1: Automatic erase of BKPRAM and PKA RAM memories done

8.5.10 SBS I/O compensation cell control and status register (SBS_CCCSR)

Address offset: 0x110

Reset value: 0x0000 0000

For more details on this register, refer to *Section 8.3.7* and *Section 8.3.8*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	XSPI2_IOHSLV	XSPI1_IOHSLV	IOHSLV

Res.	Res.	Res.	Res.	Res.	XSPI2_COMP_RDY	XSPI1_COMP_RDY	COMP_RDY	Res.	Res.	XSPI2_COMP_CODESEL	XSPI2_COMP_EN	XSPI1_COMP_CODESEL	XSPI1_COMP_EN	COMP_CODESEL	COMP_EN
					r	r	r			r	r	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bit 18 **XSPI2_IOHSLV**: XSPIM_P2 I/O high speed at low voltage

When this bit is set, the speed of the XSPIM_P2 I/Os is optimized when the device voltage is low.

This bit is active only if XSPI2_HSLV user option bit is set in FLASH. This bit must be used only if the device supply voltage is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V may be destructive.

0: No XSPIM_P2 I/O speed optimization when device voltage is low

1: XSPIM_P2 I/O speed optimized when device voltage is low, if XSPI2_HSLV user option is set (no effect otherwise)

Bit 17 **XSPI1_IOHSLV**: XSPIM_P1 I/O high speed at low voltage

When this bit is set, the speed of the XSPIM_P1 I/Os is optimized when the device voltage is low.

This bit is active only if XSPI1_HSLV user option bit is set in FLASH. This bit must be used only if the device supply voltage is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V may be destructive.

0: No XSPIM_P1 I/O speed optimization when device voltage is low

1: XSPIM_P1 I/O speed optimized when device voltage is low, if XSPI1_HSLV user option is set (no effect otherwise)

Bit 16 **IOHSLV**: I/O high speed at low voltage

When this bit is set, the speed of the I/Os is optimized when the device voltage is low.

This bit is active only if VDDIO_HSLV user option bit is set in FLASH. It must be used only if the device supply voltage is below 2.7 V. Setting this bit when V_{DD} is higher than 2.7 V may be destructive.

0: No I/O speed optimization when device voltage is low

1: I/O speed optimized when device voltage is low, if VDDIO_HSLV user option is set (no effect otherwise)

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **XSPI2_COMP_RDY**: XSPIM_P2 compensation cell ready

This bit provides the status of the XSPIM_P2 compensation cell.

0: XSPIM_P2 I/O compensation cell not ready

1: XSPIM_P2 I/O compensation cell ready. The code value provided by the cell can be used

Note: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (XSPI2_COMP_RDY) is not set if the CSI clock is not enabled.

Bit 9 **XSPI1_COMP_RDY**: XSPIM_P1 compensation cell ready

This bit provides the status of the XSPIM_P1 compensation cell.

0: XSPIM_P1 I/O compensation cell not ready

1: XSPIM_P1 I/O compensation cell ready. The code value provided by the cell can be used

Note: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (XSPI1_COMP_RDY) is not set if the CSI clock is not enabled.

Bit 8 **COMP_RDY**: Compensation cell ready

This bit provides the status of the compensation cell.

0: I/O compensation cell not ready

1: I/O compensation cell ready. The code value provided by the cell can be used.

Note: The CSI clock is required for the compensation cell to work properly. The compensation cell ready bit (COMP_RDY) is not set if the CSI clock is not enabled.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **XSPI2_COMP_CODESEL**: XSPIM_P2 compensation cell code selection
This bit selects the code to be applied for the XSPIM_P2 I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 4 **XSPI2_COMP_EN**: XSPIM_P2 compensation cell enable
Set this bit to enable the XSPIM_P2 compensation cell.
0: XSPIM_P2 compensation cell disabled
1: XSPIM_P2 compensation cell enabled

Bit 3 **XSPI1_COMP_CODESEL**: XSPIM_P1 compensation cell code selection
This bit selects the code to be applied for the XSPIM_P1 I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 2 **XSPI1_COMP_EN**: XSPIM_P1 compensation cell enable
Set this bit to enable the XSPIM_P1 compensation cell.
0: XSPIM_P1 compensation cell disabled
1: XSPIM_P1 compensation cell enabled

Bit 1 **COMP_CODESEL**: Compensation cell code selection
This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from the SBS software value register (SBS_CCSWVALR)

Bit 0 **COMP_EN**: Compensation cell enable
Set this bit to enable the compensation cell.
0: Compensation cell disabled
1: Compensation cell enabled

8.5.11 SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114

Reset value: 0x0000 0088

Reset: system reset

For more details on this register, refer to *Section 8.3.8*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	XSPI2_PSRC[3:0]				XSPI2_NSRC[3:0]

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **XSPI2_PSRC[3:0]**: XSPIM_P2 PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the PMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 19:16 **XSPI2_NSRC[3:0]**: XSPIM_P2 NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the NMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 15:12 **XSPI1_PSRC[3:0]**: XSPIM_P1 PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the PMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 11:8 **XSPI1_NSRC[3:0]**: XSPIM_P1 NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the NMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 7:4 **PSRC[3:0]**: PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.

Bits 3:0 **NSRC[3:0]**: NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 0 in SBS_CCCSR register.

8.5.12 SBS compensation cell for I/Os software value register (SBS_CCSWVALR)

Address offset: 0x118

Reset value: 0x0000 0088

For more details on this register, refer to *Section 8.3.8*.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:20 **XSPI2_SW_PSRC[3:0]**: XSPIM_P2 software PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the PMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 19:16 **XSPI2_SW_NSRC[3:0]**: XSPIM_P2 software NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P2 to compensate the NMOS transistors slew rate in the functional range if XSPI2_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 15:12 **XSPI1_SW_PSRC[3:0]**: XSPIM_P1 software PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the PMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 11:8 **XSPI1_SW_NSRC[3:0]**: XSPIM_P1 software NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew -ate compensation value computed by the cell. It is interpreted by XSPIM_P1 to compensate the NMOS transistors slew rate in the functional range if XSPI1_COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 7:4 **SW_PSRC[3:0]**: Software PMOS transistors slew-rate compensation

This bitfield returns the PMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the PMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.

Bits 3:0 **SW_NSRC[3:0]**: Software NMOS transistors slew-rate compensation

This bitfield returns the NMOS transistors slew-rate compensation value computed by the cell. It is interpreted to compensate the NMOS transistors slew rate in the functional range if COMP_CODESEL = 1 in SBS_CCCSR register.

8.5.13 SBS break lockup register (SBS_BKLOCKR)

Address offset: 0x120

Reset value: 0x0000 0088

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARAM1ECC_BL	Res.	ARAM3ECC_BL	Res.	Res.	Res.	Res.	Res.
								rs		rs					

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	ITCMECC_BL	DTCMECC_BL	Res.	Res.	Res.	Res.	Res.	BKRAMECC_BL	CM7LCKUP_BL	Res.	Res.	FLASHECC_BL	PVD_BL	Res.	Res.
	rs	rs						rs	rs			rs	rs		

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **ARAM1ECC_BL**: AXISRAM1 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM1 ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: AXISRAM1 ECC double error detection flag disconnected from TIM1/5/16/17 break inputs

1: AXISRAM1 ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 22 Reserved, must be kept at reset value.

Bit 21 **ARAM3ECC_BL**: AXISRAM3 ECC error break lock

Set this bit to enable and lock the connection between AXISRAM3 ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set this bit is cleared only by a system reset.

0: AXISRAM3 ECC double error detection flag disconnected from TIM1/15/16/17 break inputs

1: AXISRAM3 ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bits 20:15 Reserved, must be kept at reset value.

Bit 14 **ITCMECC_BL**: ITCM ECC error break lock

Set this bit to enable and lock the connection between ITCM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: ITCM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs

1: ITCM ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 13 **DTCMECC_BL**: DTCM ECC error break lock

Set this bit to enable and lock the connection between DTCM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: DTCM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs

1: DTCM ECC double error detection flag connected to TIM1/15/16/17 break inputs

Note: The DTCM0 and DTCM1 are Or'ed to give DTCMECC

Bits 12:8 Reserved, must be kept at reset value.

Bit 7 **BKRAMECC_BL**: Backup RAM ECC error break lock

Set this bit to enable and lock the connection between backup RAM ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: Backup RAM ECC double error detection flag disconnected from TIM1/15/16/17 break inputs.

1: Backup RAM ECC double error detection flag connected to TIM1/15/16/17 break inputs.

Bit 6 **CM7LCKUP_BL**: Cortex-M7 lockup break lock

Set this bit to enable and lock the connection between the Cortex-M7 lockup (HardFault) output and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: Cortex-M7 lockup output disconnected from TIM1/15/16/17 break inputs

1: Cortex-M7 lockup output connected to TIM1/15/16/17 break inputs

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **FLASHECC_BL**: Flash ECC error break lock

Set this bit to enable and lock the connection between embedded flash memory ECC double error detection flag and break inputs of TIM1/15/16/17 peripherals.

Once set, this bit is cleared only by a system reset.

0: FLASH ECC double error detection flag disconnected from TIM1/15/16/17 break inputs

1: FLASH ECC double error detection flag connected to TIM1/15/16/17 break inputs

Bit 2 **PVD_BL**: PVD break lock

This bit is set by SW and cleared only by a system reset. it can be used to enable and lock the connection to TIM1/8/15/16/17Break input as well as the PVDE and PLS[2:0] bitfields in the PWR_CR1 register.

Once set, this bit is cleared only by a system reset.

0: PVD interrupt disconnected from TIM1/8/15/16/17 break inputs. PVDE and PLS[2:0] bitfields can be programmed by the application.

1: PVD output connected to TIM1/8/15/16/17 break input. PVDE and PLS[2:0] bits are read only.

Bits 1:0 Reserved, must be kept at reset value.

8.5.14 SBS external interrupt configuration register x (SBS_EXTICRx)

Address offset: 0x130 + 0x4 * (x-1) (x = 1 to 4)

Reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

9 Clock recovery system (CRS)

9.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

9.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 9.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

9.3 CRS implementation

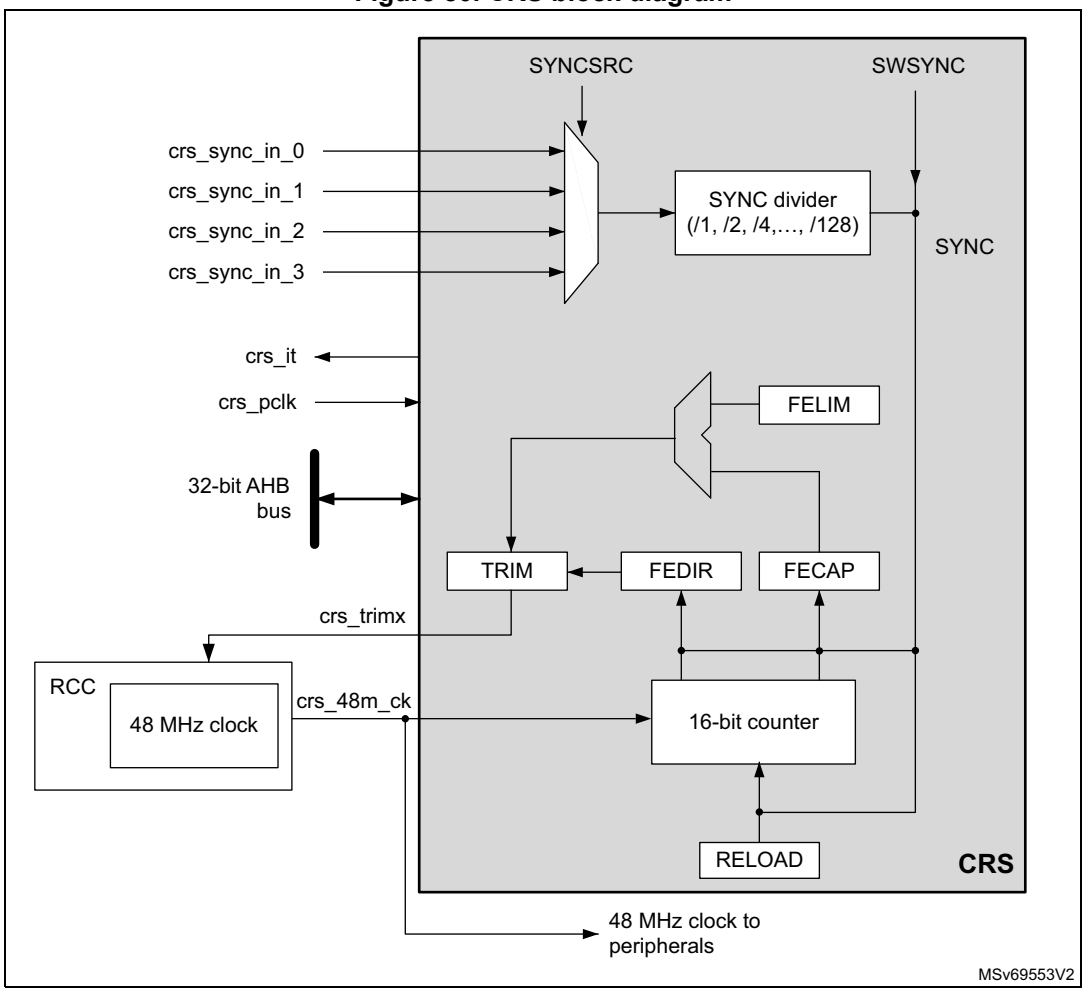

Table 79. CRS features

Feature	CRS
TRIM width	6 bits

9.4 CRS functional description

9.4.1 CRS block diagram

Figure 80. CRS block diagram

9.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 80. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSI48 48 MHz clock
crs_trim[0:5]	Digital output	HSI48 oscillator smooth trimming value

Table 80. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 81. CRS interconnection

Internal signal name	Description
crs_sync_in_0	GPIO selected as SYNC signal source
crs_sync_in_1	LSE selected as SYNC signal source
crs_sync_in_2	OTG_FS_SOF (SOF from OTG_FS) selected as SYNC signal source (default)
crs_sync_in_3	OTG_HS_SOF (SOF from OTG_HS) selected as SYNC signal source (default)

9.4.3 Synchronization input

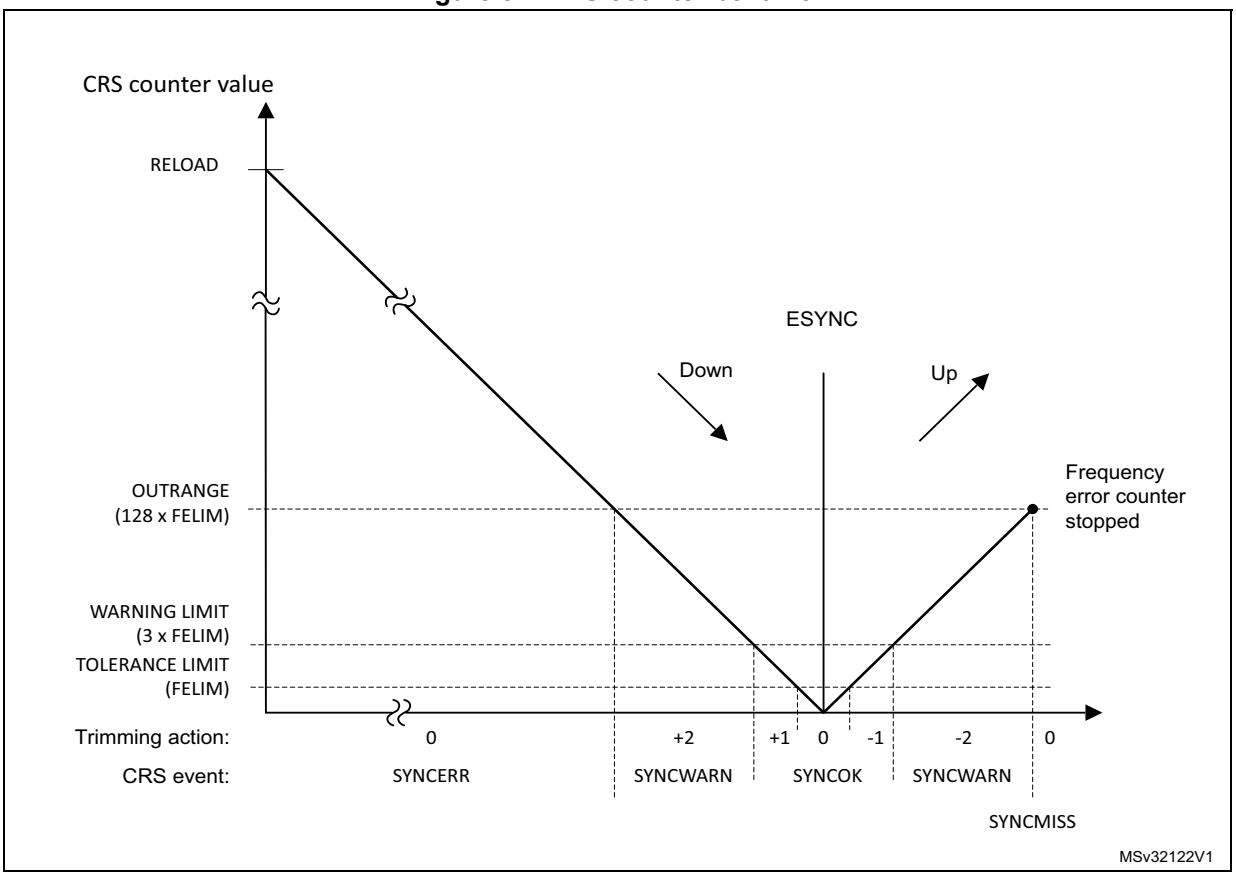
The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 9.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.



9.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR

(frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 81. CRS counter behavior

9.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode

- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated
  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

9.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode

requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

9.5 CRS in low-power modes

Table 82. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.
Shutdown	The peripheral is powered down and must be reinitialized after exiting Shutdown mode.

9.6 CRS interrupts

Table 83. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

9.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

9.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 2000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
		rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value is 32, corresponding to the middle of the trimming interval. The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 9.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

9.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.

0: SYNC active on rising edge (default)

1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 9.4.2: CRS internal signals*).

00: crs_sync_in_0 selected as SYNC signal source

01: crs_sync_in_1 selected as SYNC signal source

10: crs_sync_in_2 selected as SYNC signal source

11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.

000: SYNC not divided (default)

001: SYNC divided by 2

010: SYNC divided by 4

011: SYNC divided by 8

100: SYNC divided by 16

101: SYNC divided by 32

110: SYNC divided by 64

111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 9.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 9.4.4* for more details about counter behavior.

9.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 9.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

9.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

9.7.5 CRS register map

Table 84. CRS register map and reset values

Offset	Register name / Reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3* for the register boundary addresses.

10 General-purpose I/Os (GPIO)

10.1 Introduction

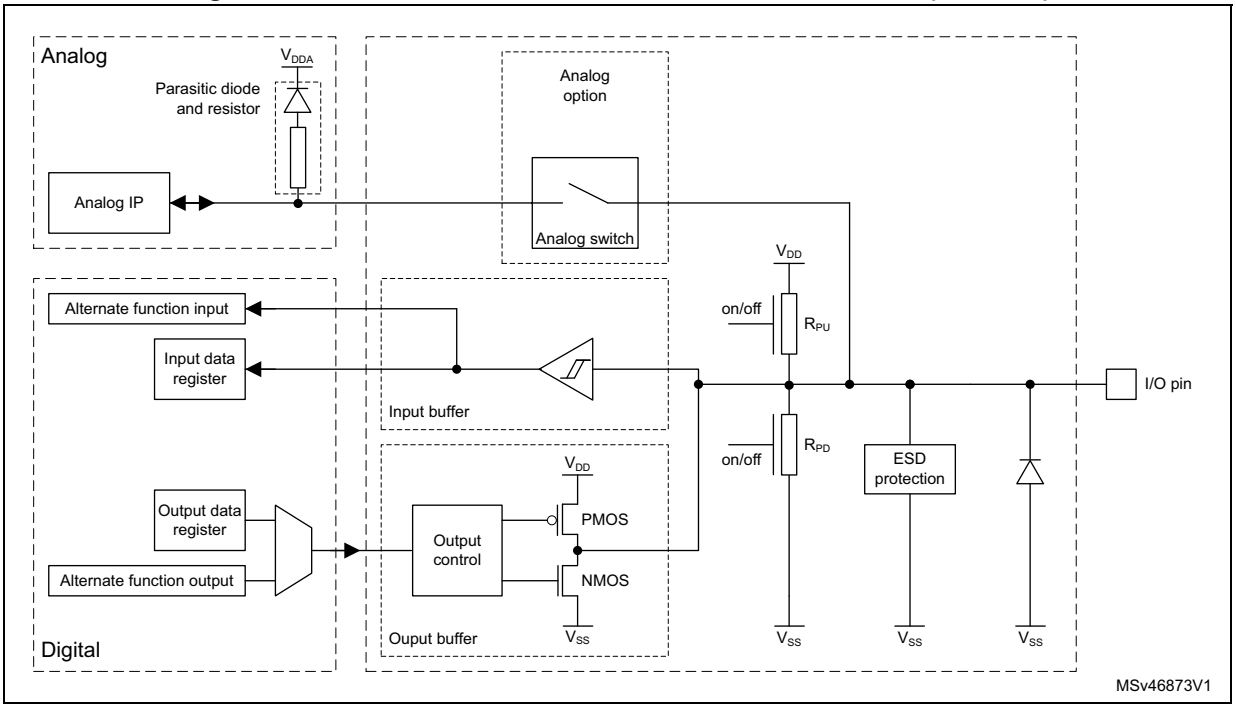
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16 bits reset register (GPIOx_BRR) and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL).

10.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bitwise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions

10.3 GPIO functional description



Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

The figure below shows the basic structure of a three-volt or five-volt tolerant GPIO (TT or FT). The *Table 85* gives the possible port bit configurations.

Figure 82. Structure of three-volt or five-volt tolerant GPIO (TT or FT)

Note: On a TT GPIO, the analog switch is not present and replaced by a direct connection. The analog bloc parasitic circuitry does not allow five-volt tolerance.

Table 85. Port bit configuration(1)

MODE(i) [1:0]	OTYPE(i)	OSPEED(i) [1:0]	PUPD(i) [1:0]		I/O configuration

00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Input/output	Analog
	x	x	x	0	1	Reserved	
	x	x	x	1	0		
	x	x	x	1	1		

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

10.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, high level is HI-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, that can be activated or not depending on the value in the GPIOx_PUPDR register.

10.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages. The I/O pins on Port P and port O do not have alternate functions as these are dedicated for xSPI interface.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input or analog in the GPIOx_MODER register.
- **Peripheral alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
- **Additional functions:**
  - For all ADCs, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC registers.
  - For the additional functions like RTC, WKUPx and oscillators, configure the required function in the related RTC, PWR and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

10.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

10.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (*GPIO port input data register (GPIOx_IDR) (x = A to G, M to P)* and *GPIO port output data register (GPIOx_ODR) (x = A to G, M to P)*).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data input through the I/O are stored into the input data register (GPIOx_IDR), a read-only register.

10.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

10.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can only be performed using a word (32-bit long) access to the GPIOx_LCKR register due to the fact that GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

10.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

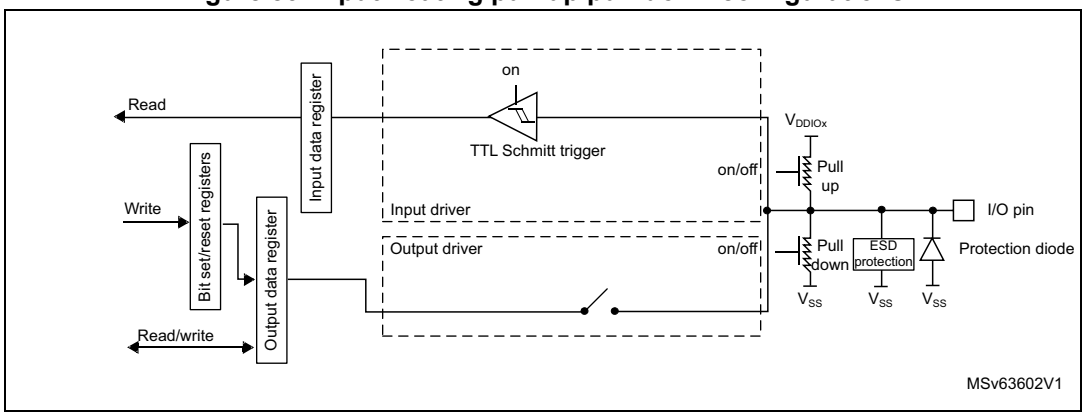
This means that a number of possible peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can

thus select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

10.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output or alternate function mode (the port must not be configured in analog mode). Refer to *Section 20: Extended interrupt and event controller (EXTI)*.



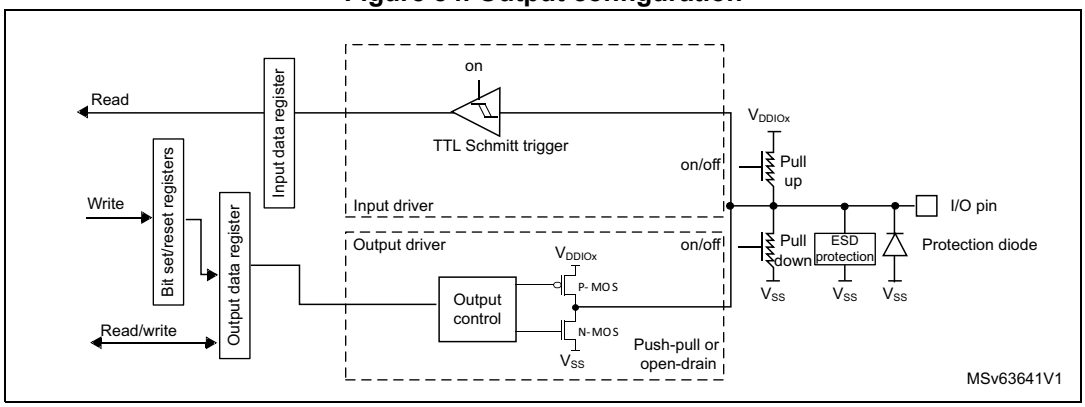
10.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

The figure below shows the input configuration of the I/O port bit.

Figure 83. Input floating/pull-up/pull-down configurations



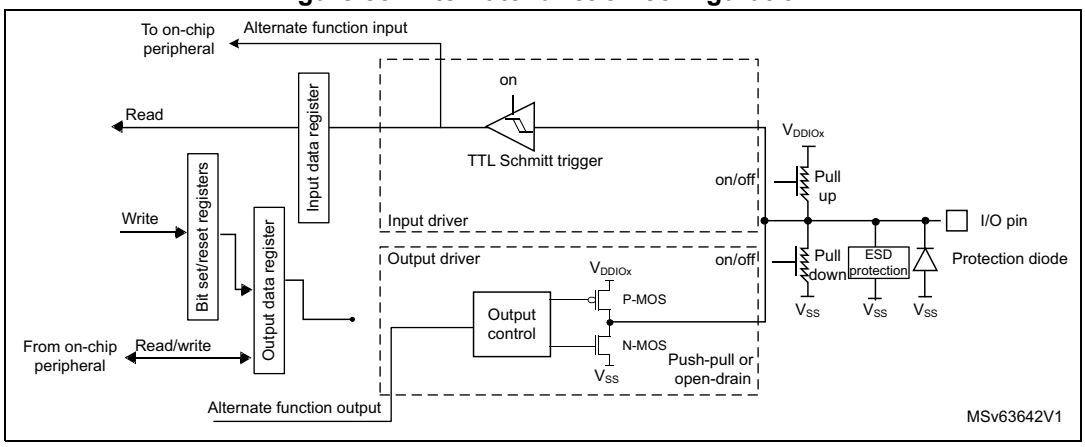
10.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in Hi-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

The figure below shows the output configuration of the I/O port bit.

Figure 84. Output configuration



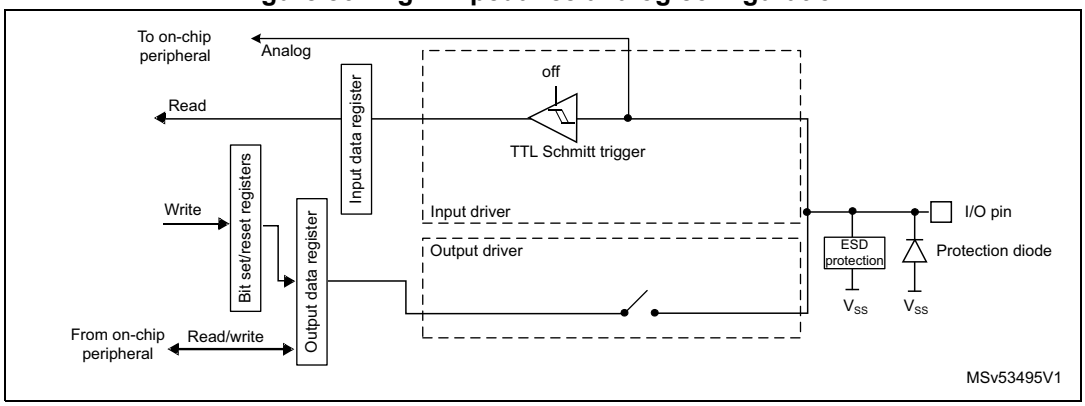
10.3.11 Alternate function configuration

When the I/O port is programmed as alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

The figure below shows the alternate function configuration of the I/O port bit.

Figure 85. Alternate function configuration



10.3.12 Analog configuration

When the I/O port is programmed as analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up and pull-down resistors are disabled by hardware.
- Read access to the input data register gets the value 0.

The figure below shows the high-impedance, analog-input configuration of the I/O port bits.

Figure 86. High-impedance analog configuration

10.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

10.3.14 Using the GPIO pins in the RTC supply domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 49.3: RTC functional description*

10.3.15 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or non-secure).

10.3.16 High-speed low-voltage mode (HSLV)

The I/Os can increase their maximum speed at low voltage by configuring them in HSLV mode. The I/O HSLV bit controls whether the I/O output speed is optimized to operate at 3.3 V (default setting) or at 1.8 V (HSLV = 1). The CSI must be enabled in order to configure the I/Os in HSLV mode.

Procedure to set the HSLV mode for the XSPIx interface:

1. Set the user option byte for the targeted interface (XSPI1_HSLV, XSPI2_HSLV) in the *FLASH option byte word 1 status register (FLASH_OBW1SR)*.
2. Enable the target interface EN_XSPIM1, EN_XSPIM2 in the *PWR control register 2 (PWR_CSR2)*.
3. Activate the HSLV on the targeted i/f (XSPI1_IOHSLV, XSPI2_IOHSLV) in the *SBS I/O compensation cell control and status register (SBS_CCCSR)*.

Procedure to set the HSLV mode for the FMC interface:

1. Set the user option byte for the GPIO and the shared XSPI interface (VDDIO_HSLV, XSPI2_HSLV) in the *FLASH option byte word 1 status register (FLASH_OBW1SR)*
2. Enable the target interface EN_XSPIM2 in the *PWR control register 2 (PWR_CSR2)*.
3. Activate the HSLV on the targeted i/f (IOHSLV, XSPI2_IOHSLV) in the *SBS I/O compensation cell control and status register (SBS_CCCSR)*.

Caution: The I/O HSLV configuration bit must not be set if the I/O supply (V_{DD}) is above 2.7 V. Setting it while the voltage is higher than 2.7 V can damage the device.

There is no hardware protection associated to this feature so it is recommended to use it only as a static configuration for fixed I/O supply.

Caution: The GPIOs are all programed with the same HSLV setting, except those from dedicated power rail (OCTO, HEXA and USB):

- XSPIM2 rail: PN[0:12]
- XSPIM1 rail: PO[0:5], PP[0:15]
- USB no software compensation setting

GPIOs that are shared with the USB are limited in terms of frequency, to hundreds of kHz for UCPD-based GPIOs, and up to 1 MHz for USBHS and USBFS-based GPIOs. Refer to the datsheet for the exact values. In order to be used the IO supply must be above 2.7 V for the USBHS/FS.

Note: When using an FMC with HSLV both the XSPIM2 and GPIO must be set to HSLV and on the same supply, still respecting the HSLV I/O supply limitation.

10.3.17 I/O compensation cell

The I/O commutation slew rate (tfall / trise) can be adapted by software depending on process, voltage and temperature conditions, in order to reduce the I/O noise on the power supply.

10.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half word or byte mode.

10.4.1 GPIO port mode register (GPIOx_MODER) (x=A to H, M to P)

Address offset: 0x00

Reset value: 0xABFF FFFF (port A)

Reset value: 0xFFFF FEBF (port B)

Reset value: 0xFFFF FFFF (ports C...H and M...P)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MODE15[1:0]		MODE14[1:0]		MODE13[1:0]		MODE12[1:0]		MODE11[1:0]		MODE10[1:0]		MODE9[1:0]		MODE8[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MODE7[1:0]		MODE6[1:0]		MODE5[1:0]		MODE4[1:0]		MODE3[1:0]		MODE2[1:0]		MODE1[1:0]		MODE0[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MODEy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O mode.

00: Input mode

01: General purpose output mode

10: Alternate function mode

11: Analog mode (reset state)

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.2 GPIO port output type register (GPIOx_OTYPER) (x = A to G, M to P)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to G, M to P)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications and the power supply and load conditions for each speed.

The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to G, M to P)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.5 GPIO port input data register (GPIOx_IDR) (x = A to G, M to P)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.6 GPIO port output data register (GPIOx_ODR) (x = A to G, M to P)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to G) (x = M to P).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to G, M to P)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BR15	BR14	BR13	BR12	BR11	BR10	BR9	BR8	BR7	BR6	BR5	BR4	BR3	BR2	BR1	BR0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BS15	BS14	BS13	BS12	BS11	BS10	BS9	BS8	BS7	BS6	BS5	BS4	BS3	BS2	BS1	BS0
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to G, M to P)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each lock bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

10.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to G, M to P)

Address offset: 0x20

Reset value: 0x0000 0000

11 Peripheral interconnect

11.1 Introduction

Several peripherals have direct connections between them. This allows autonomous communication and or synchronization between peripherals, saving CPU resources, thus power supply consumption.

In addition, these hardware connections remove software latency and allow design of predictable system.

Depending on peripherals, these interconnections can operate in various power modes: Run, Sleep or Stop modes.

11.2 Connection summary

1. Letters in the table correspond to the type of connection described in *Section 11.2: Connection summary*
2. The "-" symbol in a gray cell means no interconnect.

11.3 Interconnection details

11.3.1 Master to slave interconnection for timers

From timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM9/TIM12/TIM13/TIM14/TIM15/TIM16/TIM17) to timer (TIM1/TIM2/TIM3/TIM4/TIM5/TIM9/TIM12/TIM13/TIM14/TIM15/TIM16/TIM17)

Purpose

Some of the TIMx timers are linked together internally for timer synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop or clock the counter of another timer configured in slave mode.

Timer synchronization

The synchronization modes are detailed in:

- *Section 41.3.30: Timer synchronization* for advanced-control timers TIM1
- *Section 42.4.23: Timer synchronization* for general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Section 44.4.20: Timer synchronization (TIM9/TIM12 only)* for the general-purpose timer (Lite no DT) TIM9/TIM12
- *Section 45.4.26: Timer synchronization (TIM15 only)* for the general-purpose timer (Lite) TIM15

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1) following a configurable timer event. It can be also from signals tim16_oc1 and tim17_oc1 in case of TIM16/TIM17. The input (to slave) is on signals TIMx_ITR0/ITR1/ITR2/ITR3.

The possible master/slave connections are given in:

- *Table 408: Internal trigger connection* for advanced-control timers TIM1
- *Table 431: TIMx internal trigger connection* for the general-purpose timers TIM2/TIM3/TIM4/TIM5
- *Table 452: TIMx internal trigger connection* for general-purpose timers TIM9/TIM12
- *Table 464: TIMx internal trigger connection* for general-purpose timers TIM15

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 420: Effect of low-power modes on TIM1*
- *Table 445: Effect of low-power modes on TIM6/TIM7*
- *Table 438: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 454: Effect of low-power modes on TIM9/TIM12/TIM13/TIM14*
- *Table 470: Effect of low-power modes on TIM15/TIM16/TIM17*

11.3.2 Triggers to ADCs

From EXTI, timers (TIM1/TIM2/TIM3/TIM4/TIM6/TIM9/TIM12/TIM15) and LP timers (LPTIM1/ LPTIM2/LPTIM3) to ADC1

Purpose

A conversion, or a sequence of conversions, can be triggered either by software or by an external event (such as timer capture or input pins). For ADC1, if the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events can trigger a conversion with the selected polarity. More details in:

- *Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- *ADC configuration register (ADC_CFGR)*
- *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/TIM3/TIM4), basic timer (TIM6), advanced-control timers (TIM1) and general-purpose timer (TIM9/TIM12/TIM15) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1/ LPTIM2/LPTIM3) can be used to generate the ADC triggering event through the LPTIM channels (TIMx synchronization described in *Section 41.3.30: Timer synchronization* for TIM1) in addition to the EXTI on channels 11 and 15.

Triggering signals

For ADC1, the input triggering signals and the description of the interconnection between ADC1, and timers, are given in:

- *Table 229: ADC interconnection*
- *Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*
- *Section 27.4.25: Timing diagrams example (single/continuous modes, hardware/software triggers)*

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active in Run and Sleep mode only. The effects of low-power modes are given in:

- *Table 420: Effect of low-power modes on TIM1*
- *Table 438: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 454: Effect of low-power modes on TIM9/TIM12/TIM13/TIM14*
- *Table 476: STM32H7Rx/7Sx LPTIM features*

11.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC2 to TIM1

Purpose

The internal analog watchdog output signals coming from ADC1, are connected to on-chip timers. ADC1can provide trigger event through analog watchdog signals to advanced-control timers (TIM1) in order to reset, start, stop or clock the counter.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 41.3.6: External trigger input*
- *Table 409: Interconnect to the tim_etr input multiplexer* for the internal ADC1 sources connected to TIM1 (tim_etr) input multiplexer
- *Table 228: ADC internal input/output signals* for the ADC_AWDx

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger).

Active power mode

ADC1 are active in Run and Sleep modes.

11.3.4 Triggers on ADF1

From EXTI to ADF1

Purpose

EXTI (EXTI15) can be used to generate a triggering event on ADF1 module and start an A/C conversion.

A description is given in:

- *Section 27.4.2: ADC pins and internal signals*
- *Section 30.4.9: Start-up sequence examples*

Triggering signals

The adf_trgi trigger input is the triggering input signal. The ADF trigger inputs connections are detailed in:

- *Table 257: ADF trigger connections*

Active power mode

This interconnection remains active down to Stop (SVOS high) for ADF1, assuming the trigger source remains active.

11.3.5 Internal input and clock sources to timers

From HSE, LSE, HSI CSI and MCO to TIM (TIM9, TIM12), LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5) and RTC

Purpose

A timer input or timer counter can receive different clock sources and can be used to calibrate internal oscillator on a reference clock for example.

Internal clocks (CSI, HSI) and microcontroller output clock (MCO) can be used as input to timers:

- HSI and CSI are assigned to general purpose timers TIM12 as external inputs signals. This allows the calibration. HSI/CSI can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) Inputs assignment and clock selection description are detailed in:
  - *Section 44.4.5: Clock selection* for TIM12
  - External clock mode1: *Table 442: TIM internal input/output signals* for TIM12, tim_ti1_in2 (HSI) and tim_ti1_in3(CSI)
- Microcontroller output clock (MCO) is connected as external input to general-purpose timers TIM9. This allows the calibration or clock measurement. When the low-speed external (LSE) oscillator is used, no additional hardware connections are required. This feature is given in *Table 450: Interconnect to the tim_ti1 input multiplexer*
- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in *Table 485: LPTIM1 input capture 2 connections*
- HSI/1024 CSI/128 can be selected as input capture 2 to LPTIM2 as described in *Table 486: LPTIM2 input capture 2 connections*.

Triggering signals

lptim_ic2_mux1 LPTIM input capture selection can be set in the LPTIM configuration register 2 (LPTIM_CFGR2). For timers, the internal clock signal can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in).

Active power mode

This feature is available under Run and Sleep modes.

11.3.6 Triggers to low-power timers

From EXTI, TAMP and RTC alarm to LP timers (LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5)

Purpose

LPTIM1/LPTIM2/LPTIM3/LPTIM4/LPTIM5 counters may be started either by software or after the detection of an active edge on one of the eight trigger inputs.

GPIO can also be selected as LPTIM input capture selection or LPTIM input selection, according to the LPTIM configuration register 2 (LPTIM_CFGR2).

Triggering signals

This trigger feature is described in *Table 46.4.7: Trigger multiplexer* and the following sections. The input selection is described in *Table 481: LPTIM1/2/3/4/5 external trigger connections*.

Active power mode

This interconnection remains active down to Stop mode.

11.3.7 RTC wake-up as inputs to timers

From RTC to timers (TIM16)

Purpose

RTC wake-up interrupt can be used as input to general-purpose timers (TIM16) channel 1.

Triggering signals

RTC wake-up signal is connected to tim_ti1_in3 signal as described in *Table 450: Interconnect to the tim_ti1 input multiplexer* for TIM15.

Active power mode

This interconnection is active down to Stop. Timers are not active but the count is performed at wake-up.

11.3.8 USB OTG SOF as trigger to timers

From USB OTG SOF to TIM2

Purpose

USB OTG SOF (start-of-frame) can generate a trigger to the general-purpose timer TIM2/TIM5. The USB connection to TIM2/TIM5 are described in *Table 431: TIMx internal trigger connection*.

Triggering signals

The tim_itr13 internal signal is generated by OTG HS SOF, the tim_itr14 internal signal is generated by OTG FS SOF.

Active power mode

This interconnection is active in Run and Sleep modes.

11.3.9 System errors as break signals to timers

The following system-level errors can trigger a timer break event: Cortex-M7 lockup, PVD low threshold, CSS, double ECC errors in AXISRAM1, AXISRAM3, ITCM, DTCM, backup RAM and flash memory.

The purpose of the break event is to disable the timer outputs to protect the power transistors they control.

System errors apply in RUN and Sleep modes.

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 420: Effect of low-power modes on TIM1*
- *Table 470: Effect of low-power modes on TIM15/TIM16/TIM17*

11.3.10 Triggers to GPDMA/HPDMA

From EXTI, RTC (wake-up), timers (TIM1/TIM2/TIM3/TIM4/TIM5/TIM6/TIM7/TIM9/TIM12/TIM15), LP timers (LPTIM1/LPTIM3/LPTIM4/LPTIM5), HP/GPDMA1 transfer complete (gpdma1_chx_tcf/lhdma1_chx_tcf), SPI6, LPUART,

Purpose

A HP/GPDMA trigger can be assigned to a HP/GPDMA channel x. A programmed HP/GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 12.3.6: GPDMA triggers* and *Section 13.3.6: HPDMA triggers*
- *Section 12.4.12: GPDMA triggered transfer* and *Section 13.4.12: HPDMA triggered transfer*
- *Section 12.8.9: GPDMA channel x transfer register 2 (GPDMA_CxTR2)* and *Section 13.8.9: HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0].
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

GPDMA trigger mapping is specified in *Table 94: Programmed GPDMA1 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

HPDMA trigger mapping is specified in *Table 106: Programmed HPDMA1 trigger*, according to HPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

Assuming sources are active down to Stop modes, this interconnection remains functional in Stop.

Refer to:

- *Section 12.6: GPDMA in low-power modes*
- *Section 13.6: HPDMA in low-power modes*

11.3.11 Internal analog signals to analog peripherals

From internal analog source to ADC (ADC1)

Purpose

The internal reference voltage (VREFINT), the internal temperature sensor (V_{SENSE}) monitoring channel are connected to ADC (ADC1) input channels. In addition, the internal

digital core voltage (VCORE) and VBAT are connected to input channels. This is according to:

- *Section 27.4.32: Temperature sensor*
- *Section 27.4.33: VBAT supply monitoring*
- *Section 27.4.34: Monitoring the internal voltage reference*
- *Section 27.4.35: Monitoring the supply voltage*

Active power mode

These interconnections remain in Stop modes if the selected peripheral is kept active. Refer to *Section 27.5: ADC in low-power modes*

11.3.12 ADC data filtering by the ADF1

From ADC1 to ADF1

Purpose

The ADF1 allows the connection of up to two ADCs to the filter path. For each filter, the DATSRC[1:0] field in the ADF digital filter configuration register x (ADF_DFLTxCICR) is used to select either data from the ADCs in:

- *Section 27.4.4: ADC connectivity*
- *Table 229: ADC interconnection*
  - mdf_adcitf1_dat[15:0] to adc_da
- *Table 268: Effect of low-power modes on ADF*

Active power mode

This feature remains available down to Sleep mode.

11.3.13 Internal tamper sources

From internal peripherals, clocks or monitoring to tamper.

Purpose

In order to detect any abnormal activity or tentative to corrupt the device, tampers are introduced and alert the system of such undesired event. Different actions can be taken in consequences.

List of tamper sources can be found in *Table 21: Internal tampers in TAMP*

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

11.3.14 Output from tamper to RTC

From TAMP to RTC

Purpose

The RTC can timestamp a tamper event in order to retrieve history in time of such detection. The RTC can also control GPIOs and set a signal based on tamp or alarm status outside the MCU.

Refer to *Section 49.3.3: GPIOs controlled by the RTC and TAMP* for more details.

Active power mode

This interconnection remain active in all power modes.

11.3.15 Encryption keys to AES/SAES

From TAMP backup registers, system Flash memory to and in between SAES and AES

Purpose

The encryption mechanism requires an hardware key that must be stored in a protected non-volatile memory. Different approaches are implemented in order to load them in a non-readable way. Tamper backup registers or system Flash can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to *Section 36.4.14: SAES operation with wrapped keys* for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to *Section 36.4.15: SAES operation with shared keys* for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.

12 General purpose direct memory access controller (GPDMA)

12.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

12.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 12.3.1*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 12.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

12.3 GPDMA implementation

12.3.1 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 88. GPDMA1 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	2	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and AHB SRAM.
x = 12 to 15	4	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers, between a demanding AHB peripheral and AHB SRAM, or for transfers from/to AXI SRAM or external AXI memories.

12.3.2 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 89. GPDMA1 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1 in Sleep mode

12.3.3 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[6:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

Table 90. Programmed GPDMA1 request

12.3.4 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 91. Programmed GPDMA1 request as a block request

GPDMA block requests
lptim1_ue_dma
lptim2_ue_dma
lptim3_ue_dma

12.3.5 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 92. GPDMA1 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0 and x = 15

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the GPDMA has transferred the whole block (see *Section 12.4.14* for more details).

Table 93. Programmed GPDMA1 request with peripheral early termination

Programmed GPDMA channel x request with peripheral early termination
i3c1_rx_dma

12.3.6 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

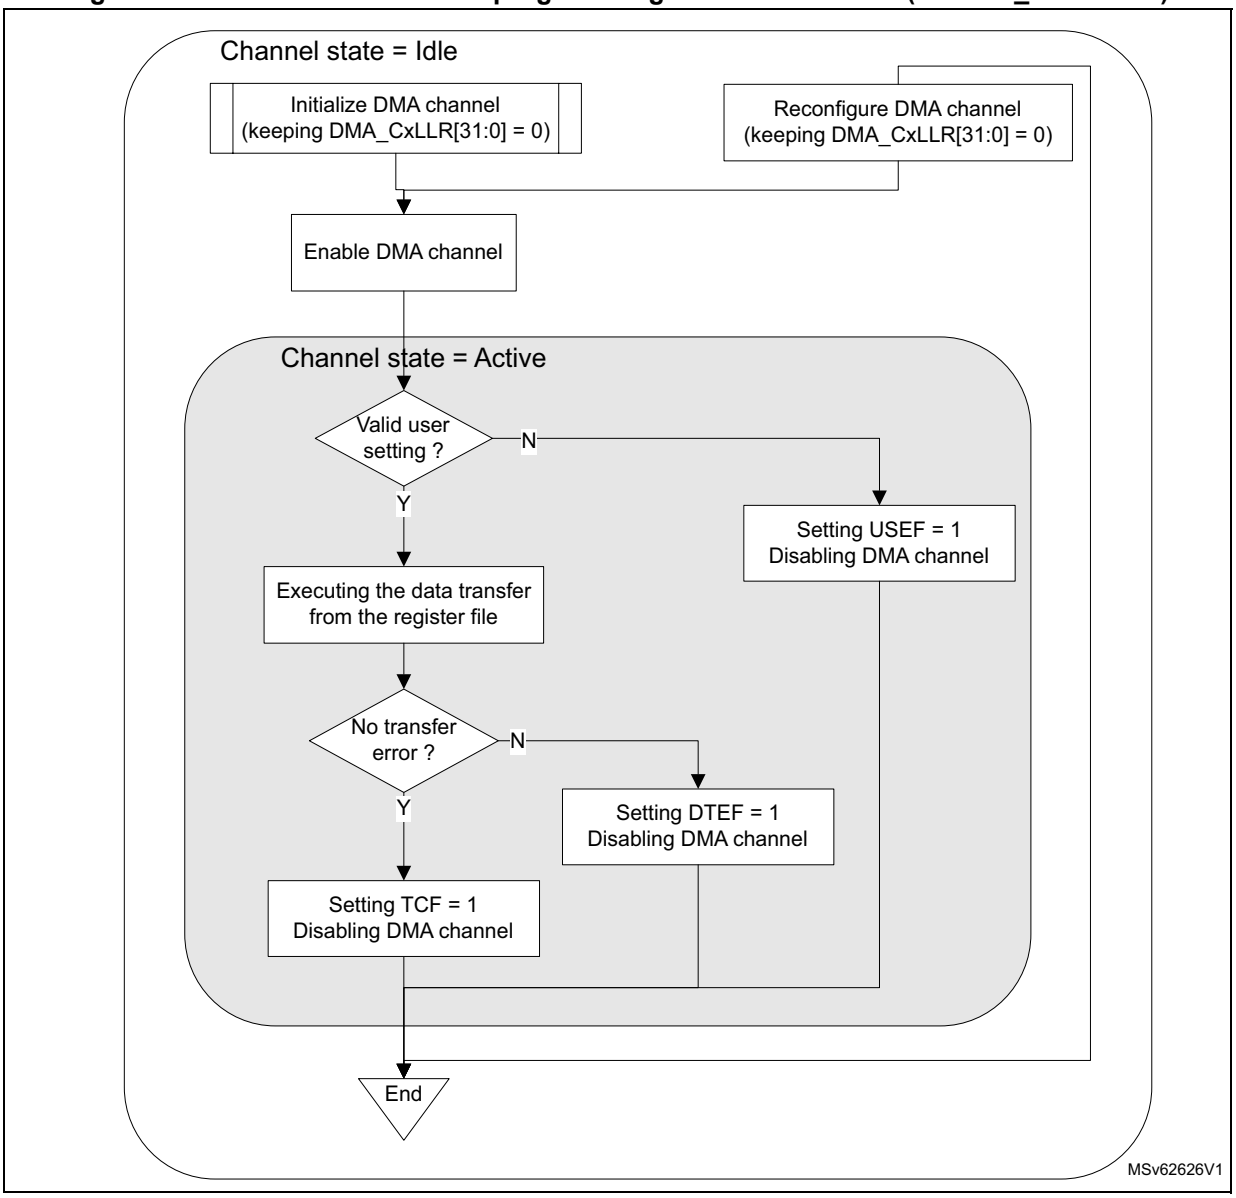
12.4 GPDMA functional description

12.4.1 GPDMA block diagram

Figure 87. GPDMA block diagram



12.4.2 GPDMA channel state and direct programming without any linked-list

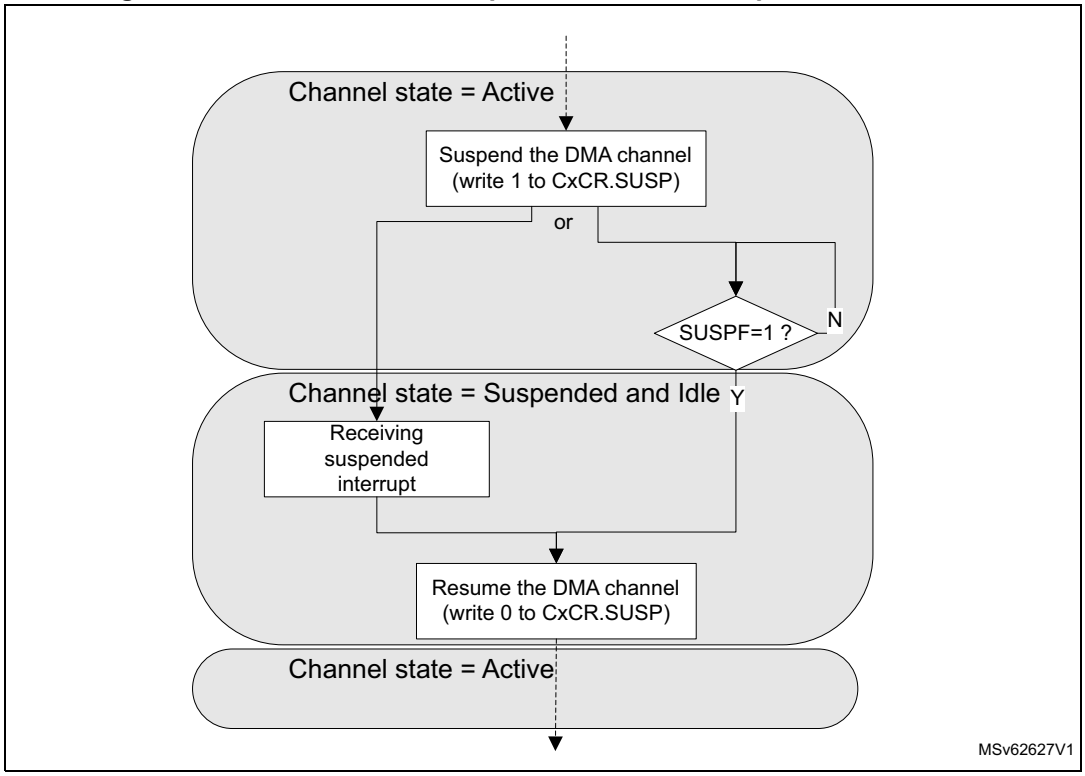
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 88 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 88. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

12.4.3 GPDMA channel suspend and resume



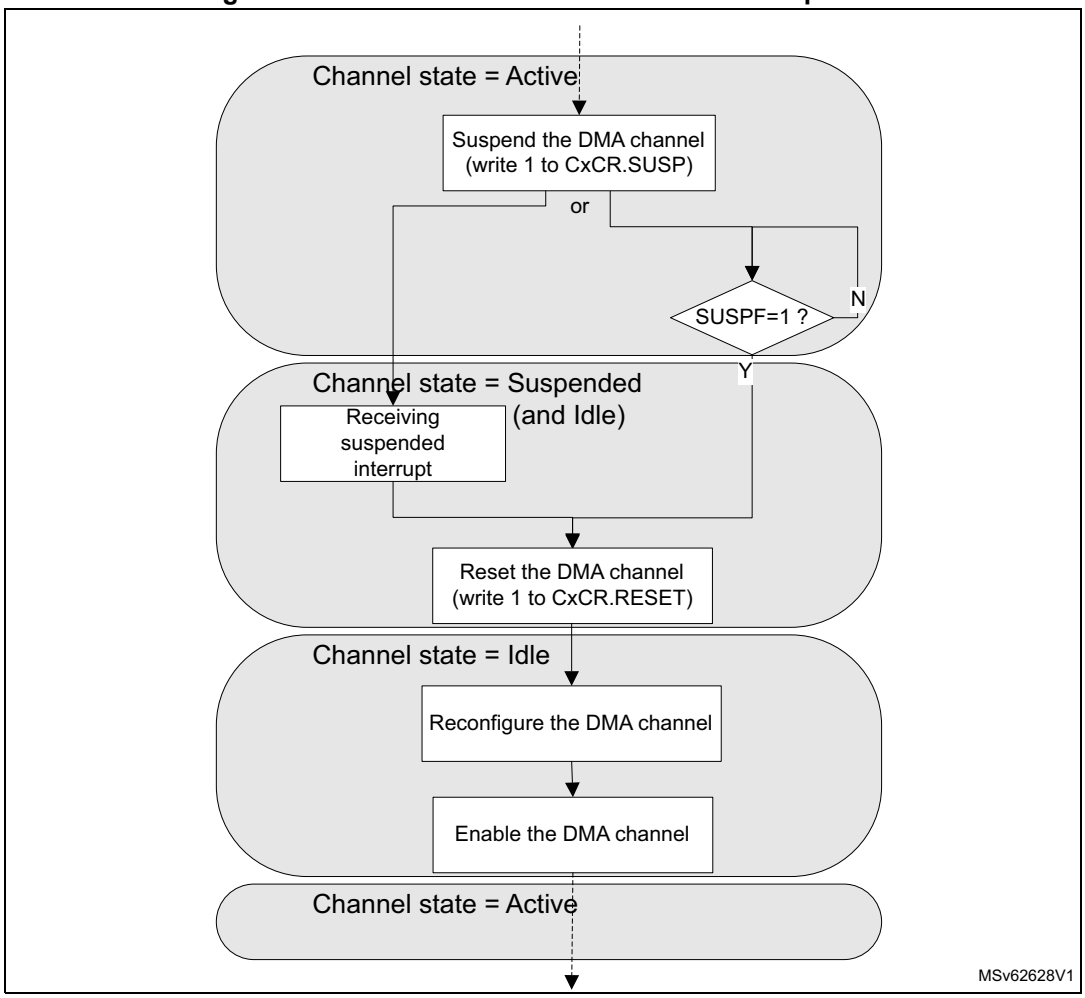
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 89. GPDMA channel suspend and resume sequence



Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

12.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 90. GPDMA channel abort and restart sequence

12.4.5 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the UT1, UT2, UB1, USA, UDA and ULL bits, plus UB2 and UT3, in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3 or GPDMA_CxBR2) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the

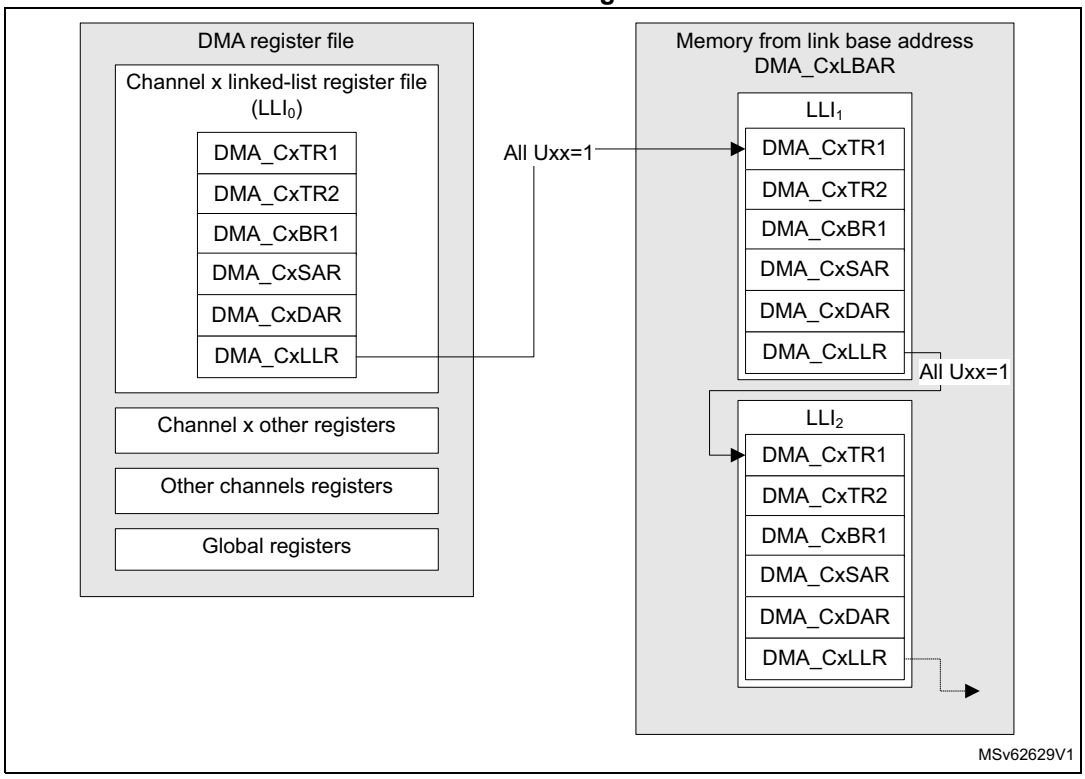
GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 11) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 91*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 12 to 15), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2 (see *Figure 92*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 91. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



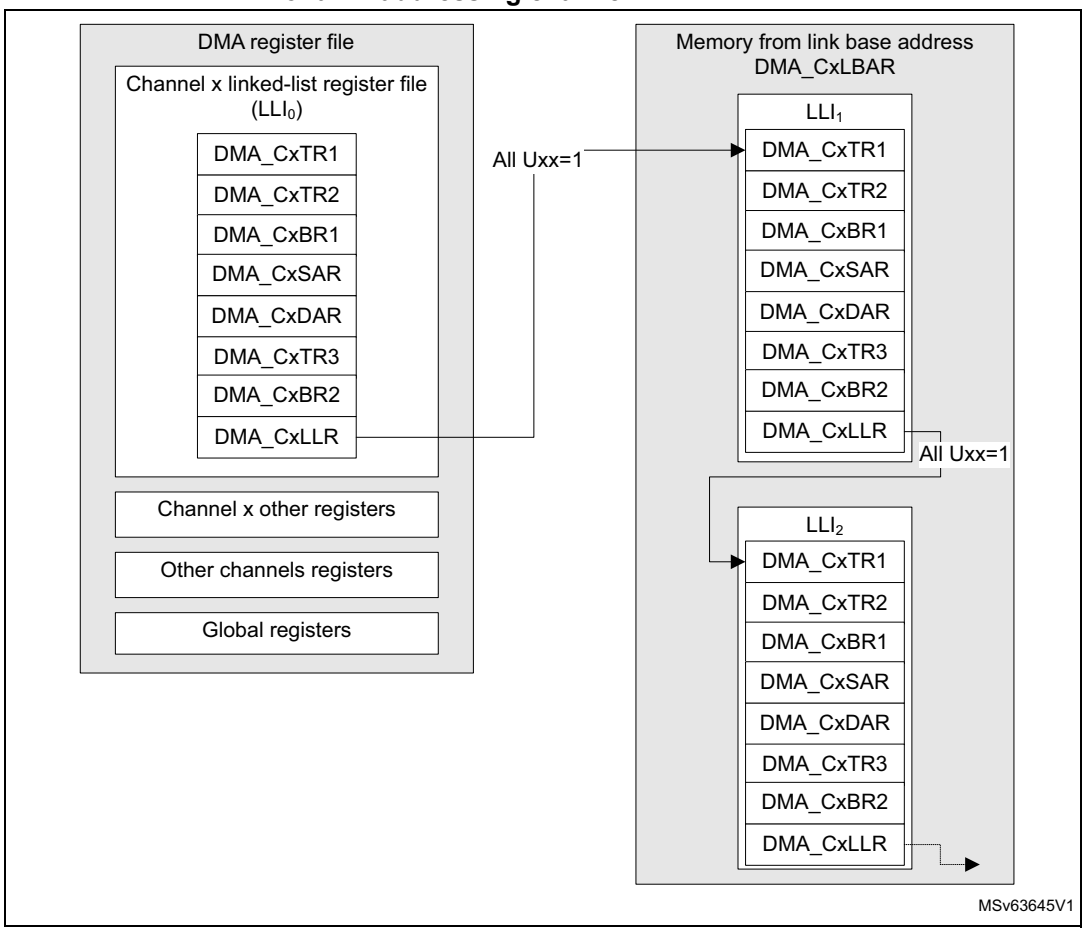


Figure 92. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

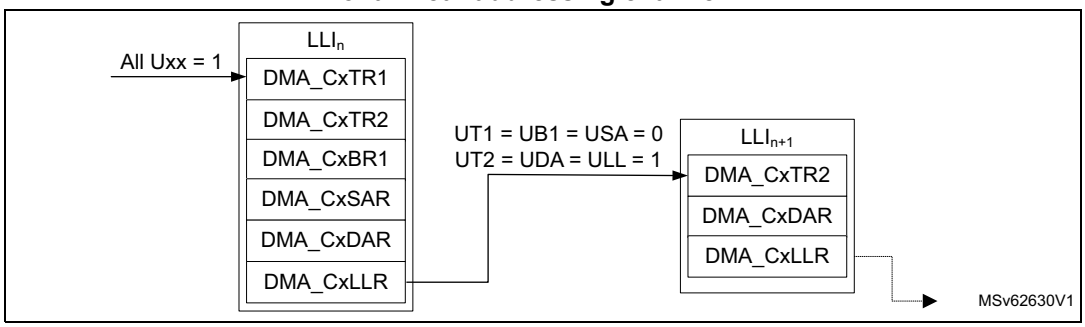
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 93*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 94*.

Figure 93. GPDMA dynamic linked-list data structure of a linear addressing channel x



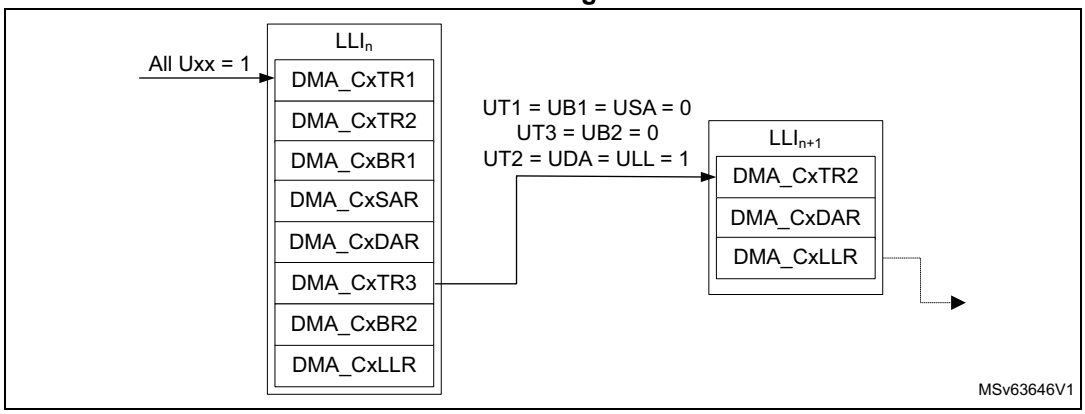


Figure 94. GPDMA dynamic linked-list data structure of a 2D addressing channel x

The user must program GPDMA_CxLLR for each LLI_n to be 32-bit aligned and not to exceed the 64-Kbyte addressable space pointed by GPDMA_CxLBAR.

12.4.6 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

12.4.7 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

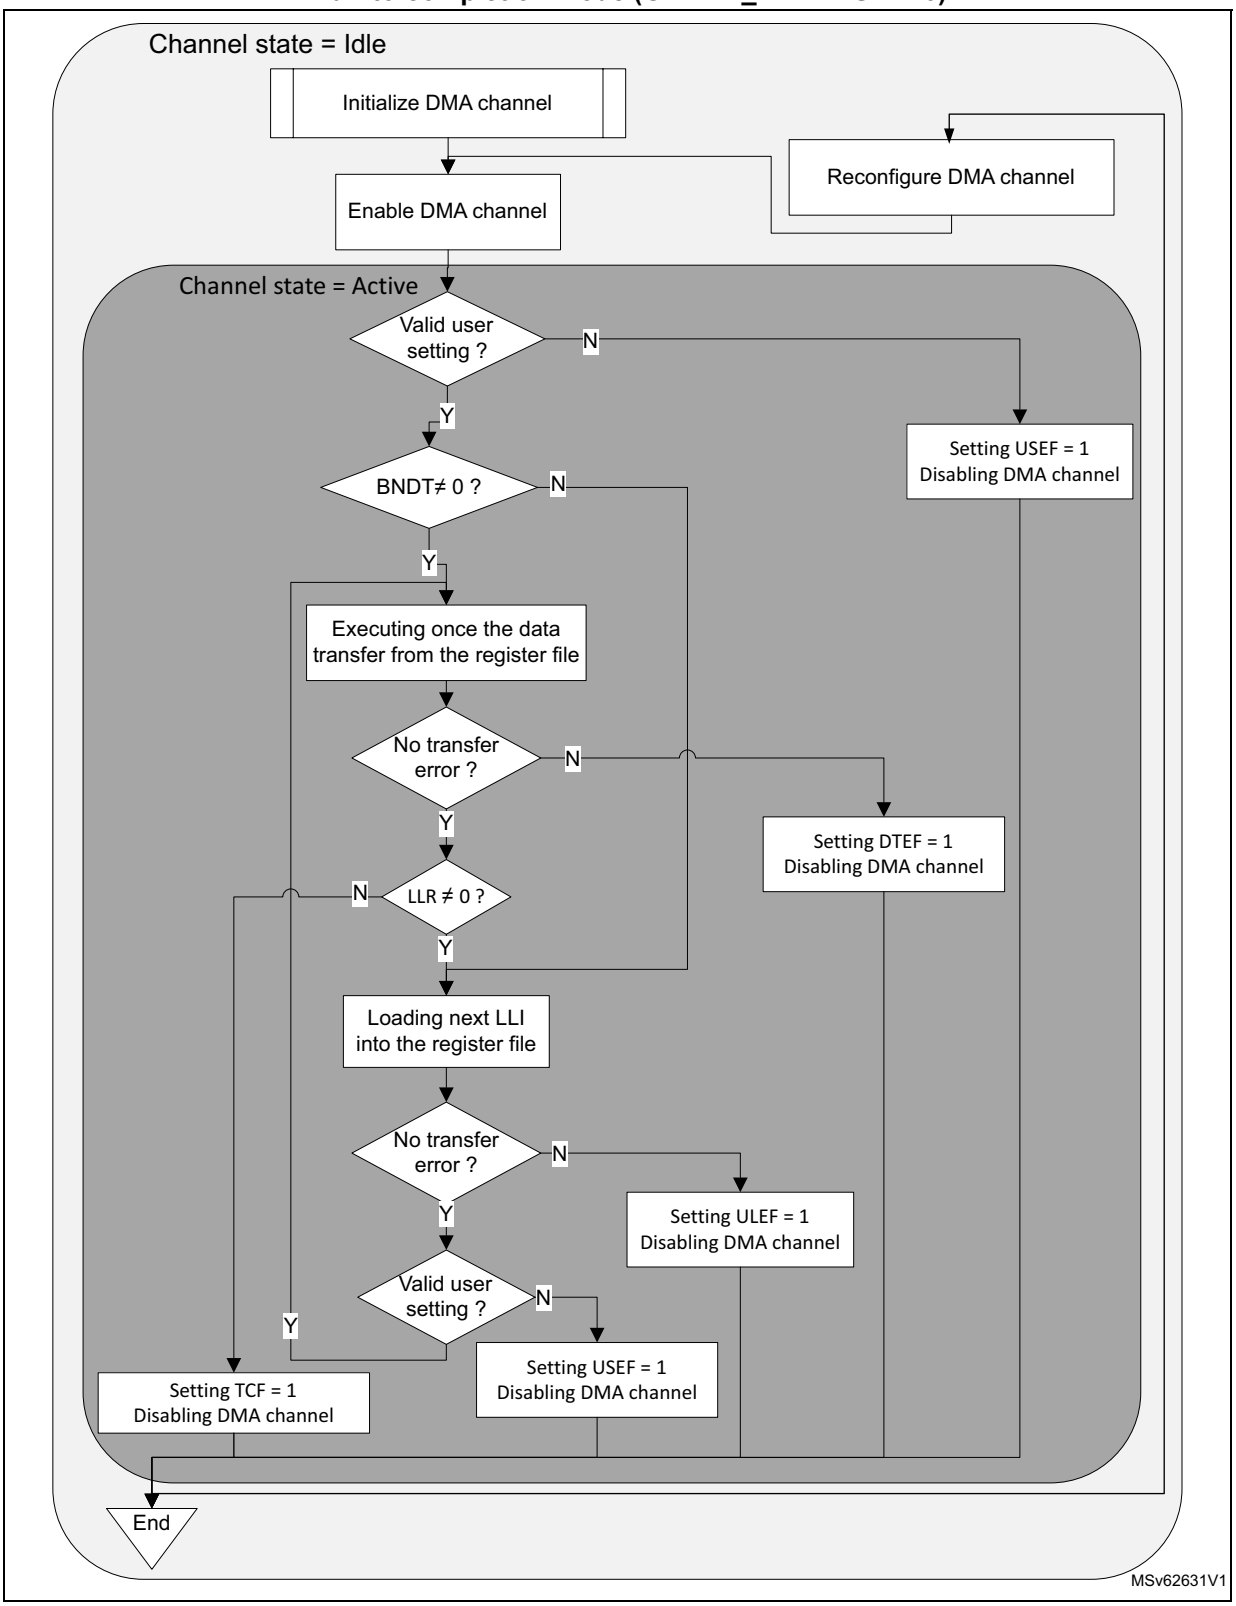
GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 12.4.14* for more details).



In the typical run-to-completion mode, the allocation of a GPDMA channel, including its fine programming, is done once during the GPDMA initialization. In order to have a reserved data communication link and GPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

Figure 95 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

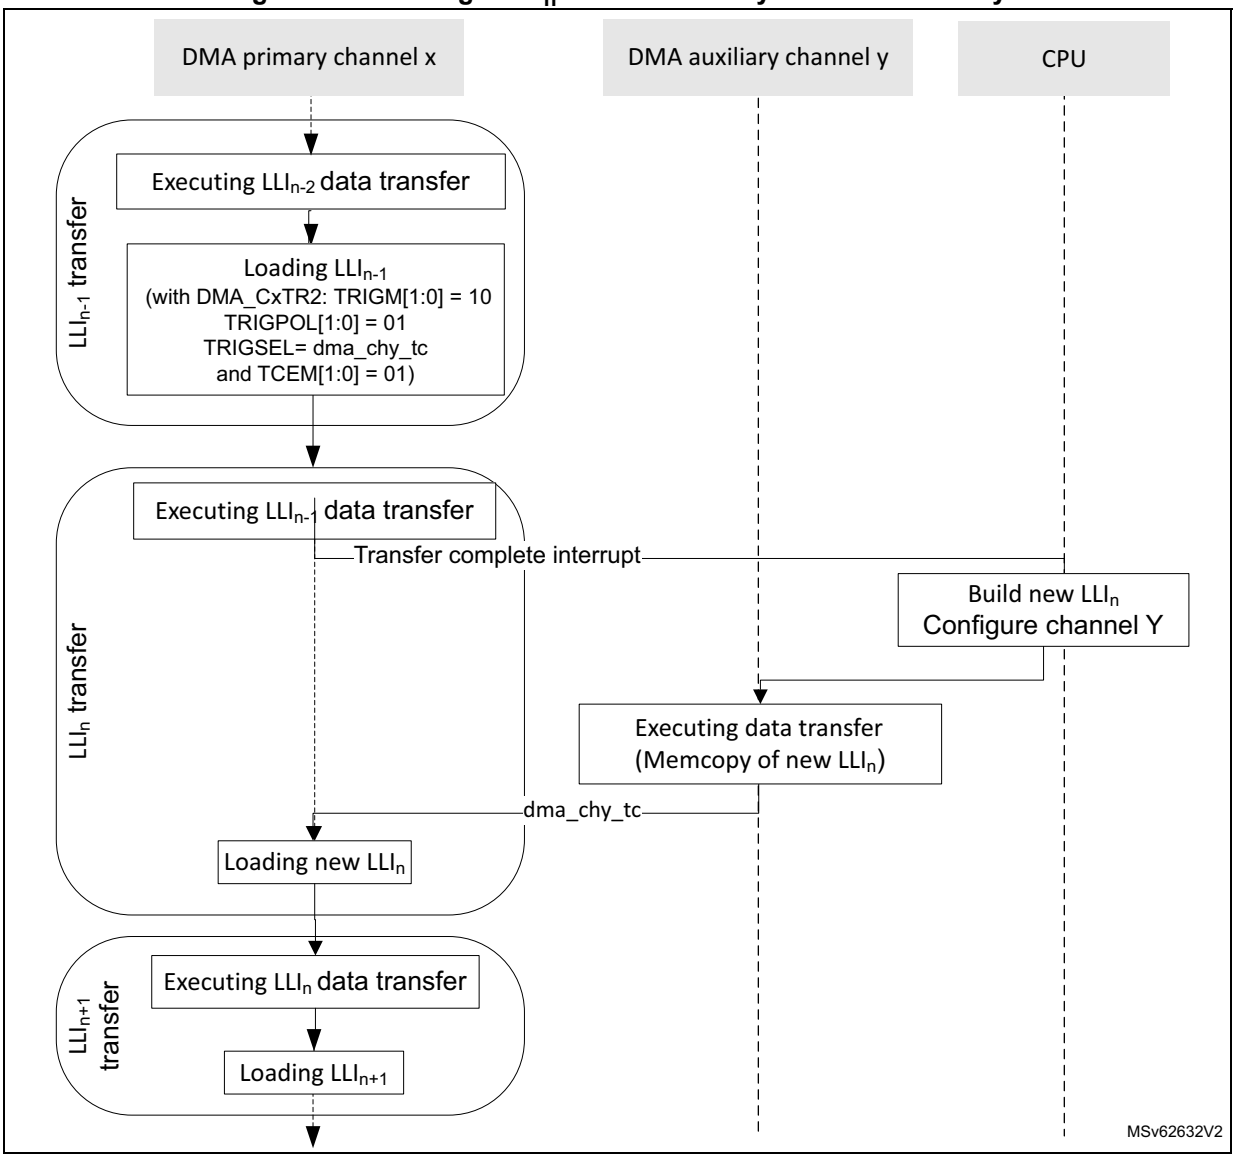
Note: Figure 95 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 95, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).

Figure 95. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 12.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 96 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 96. Inserting a LLI_n with an auxiliary GPDMA channel y

12.4.8 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

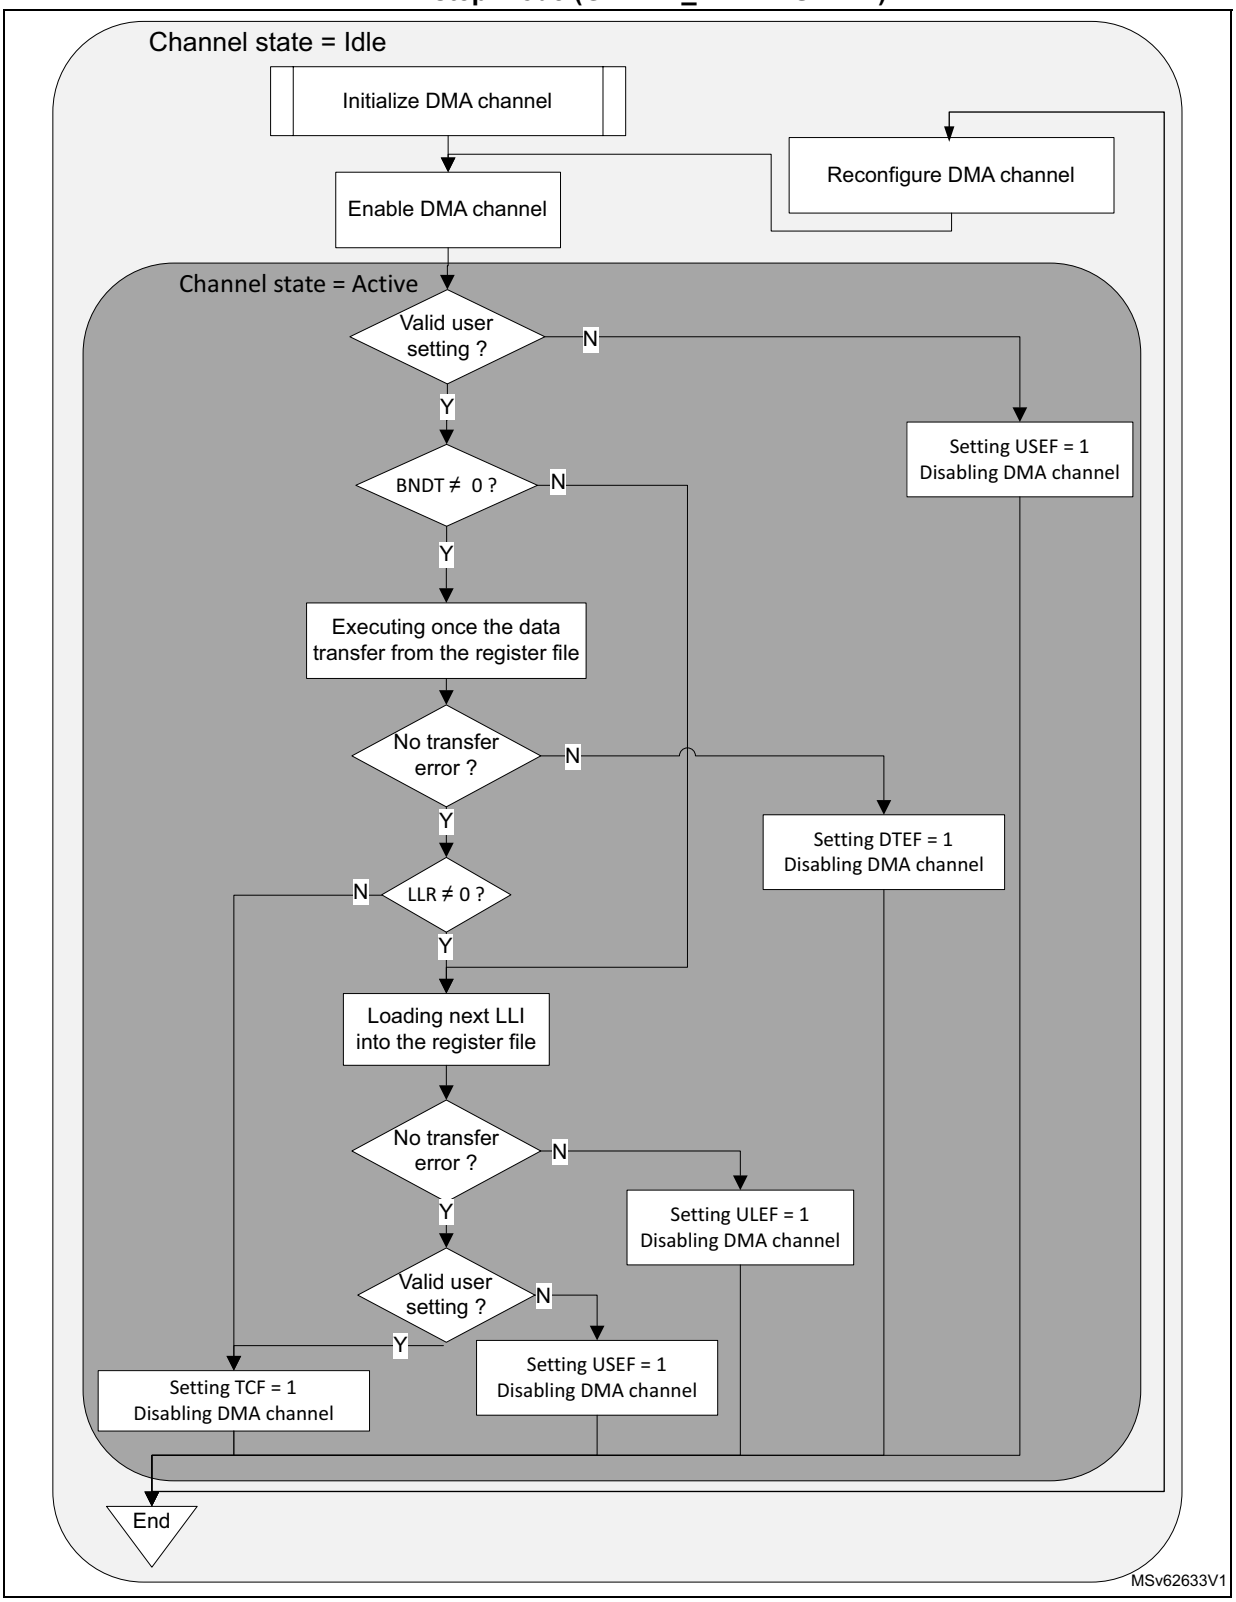
A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 12 to 15), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated by the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 12.4.14* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 97 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 97 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 97, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).

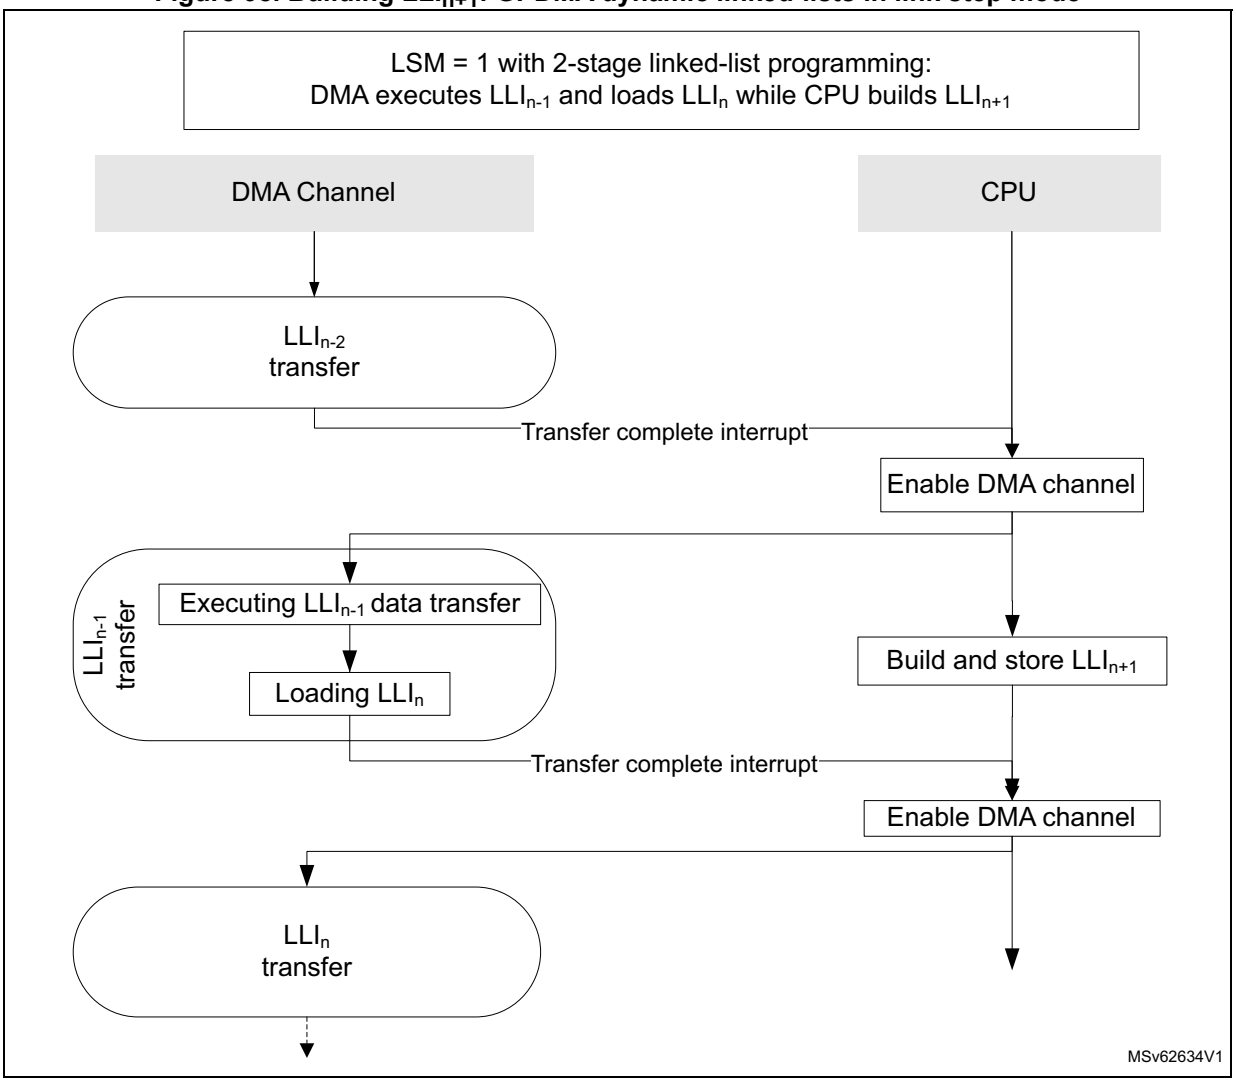


Figure 97. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 98*.

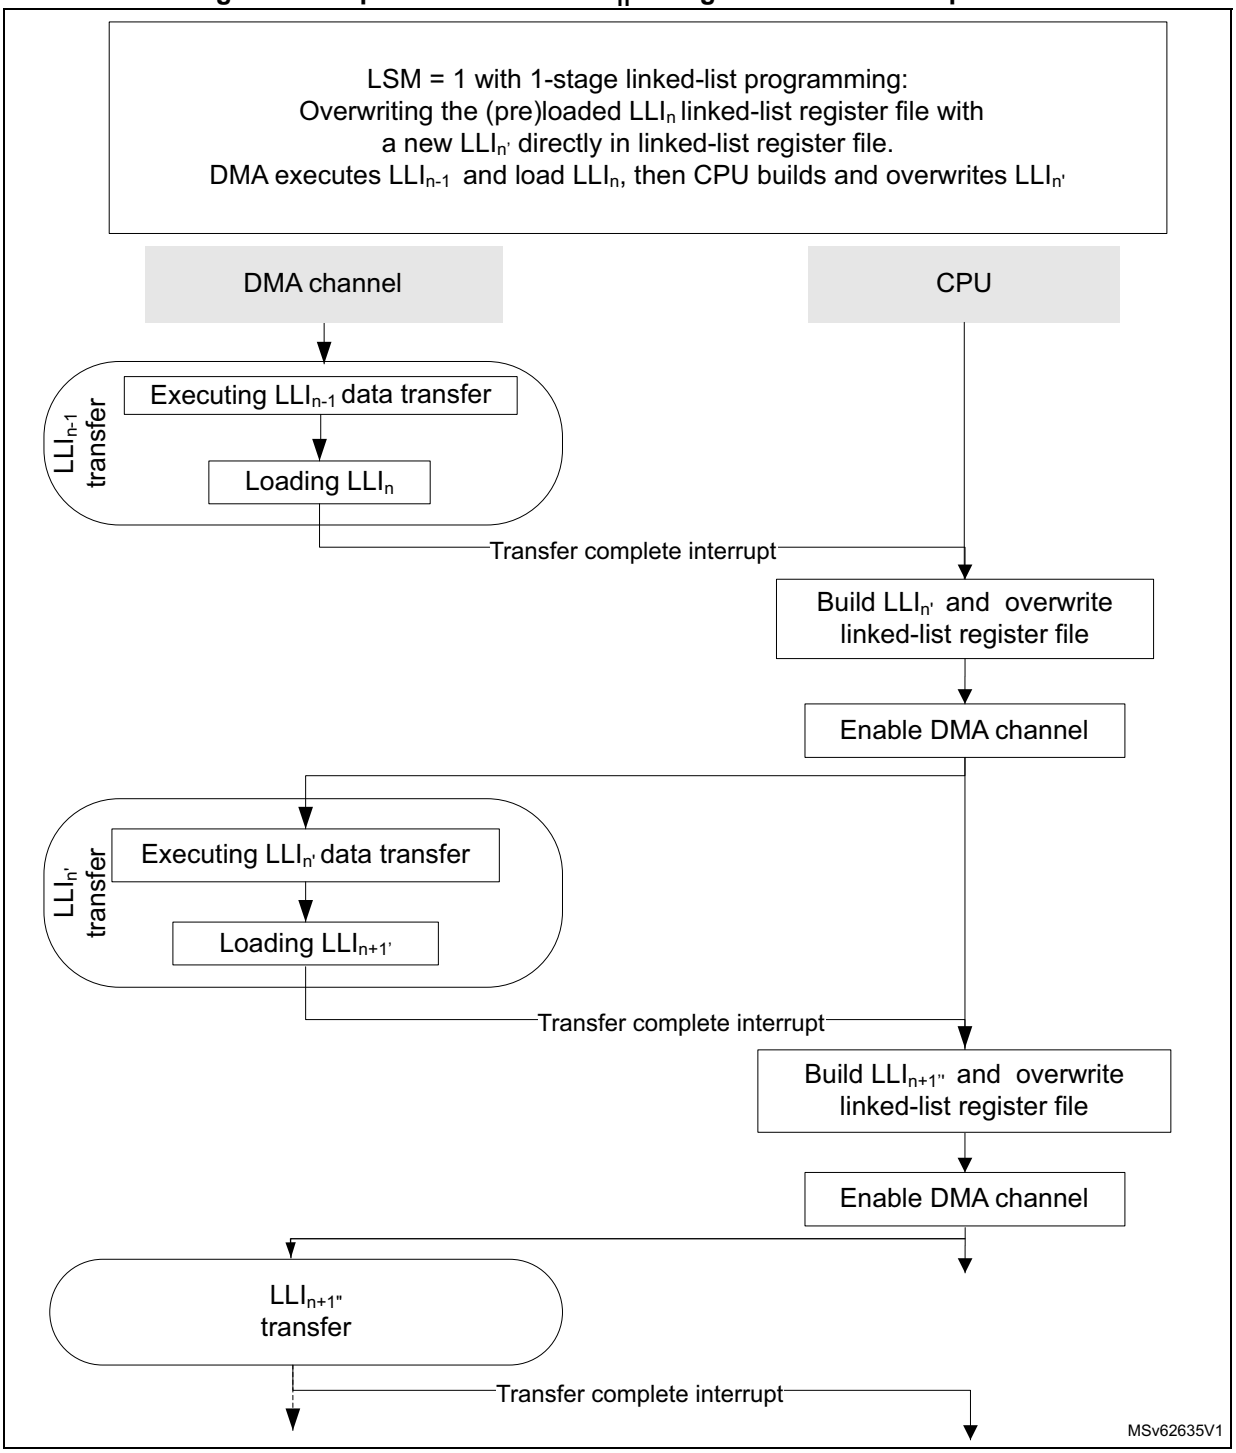

Figure 98. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 99*.

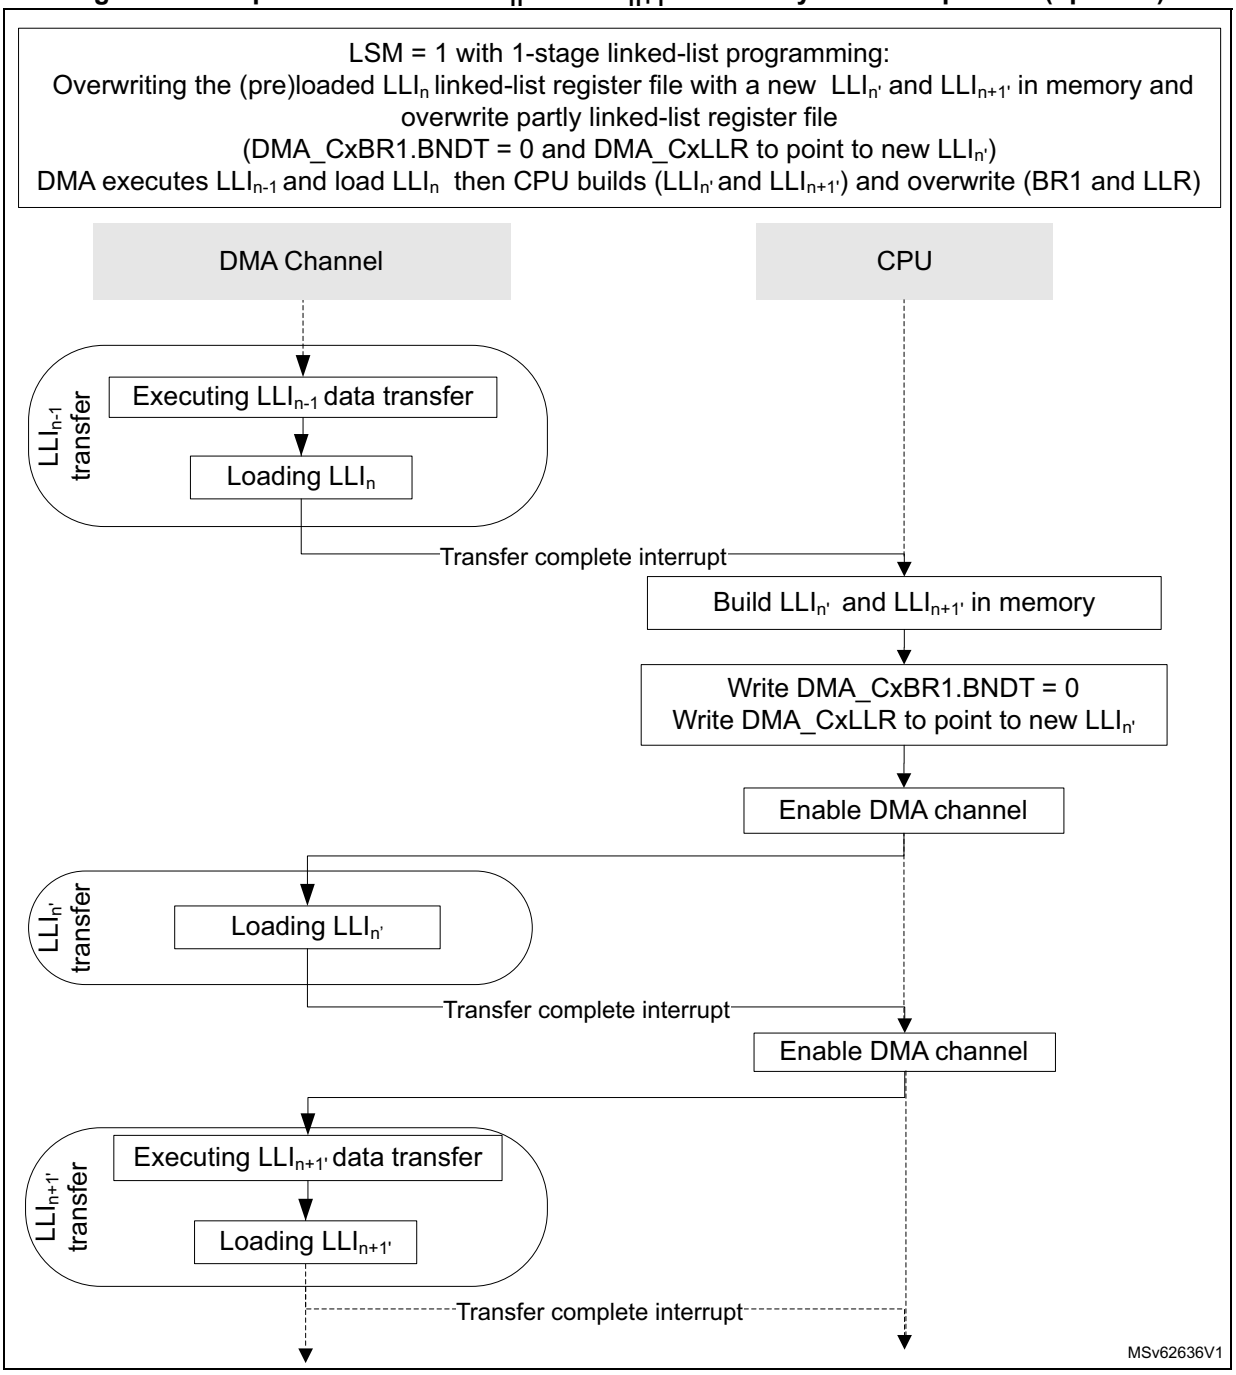

Figure 99. Replace with a new $LLI_{n'}$ in register file in link step mode

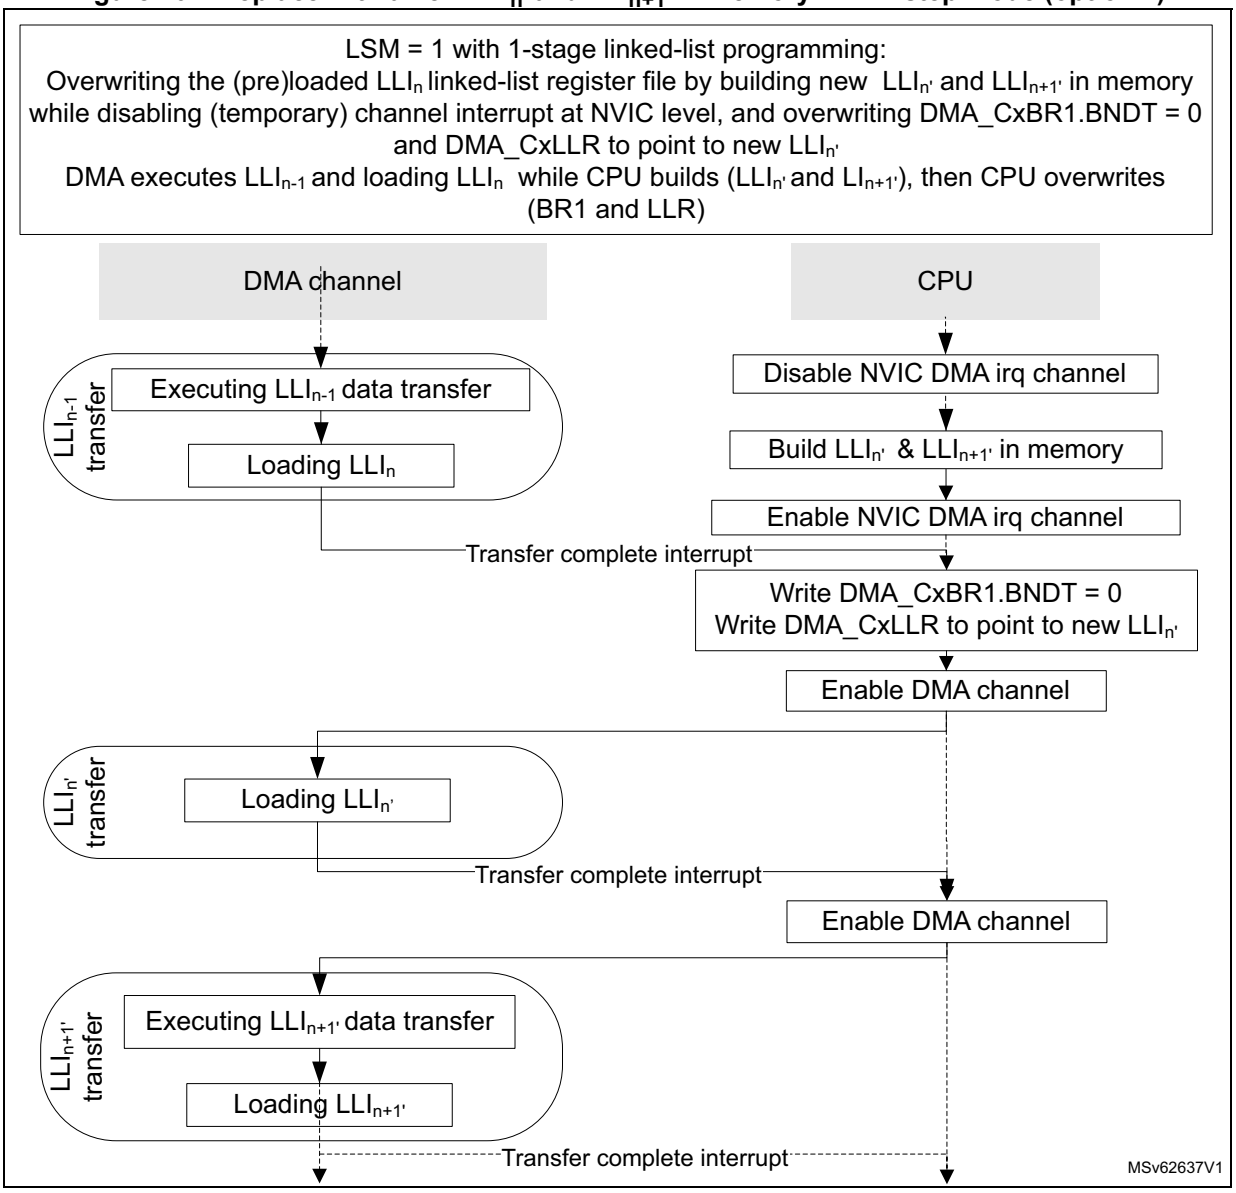
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 100*.

Figure 100. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 101*.

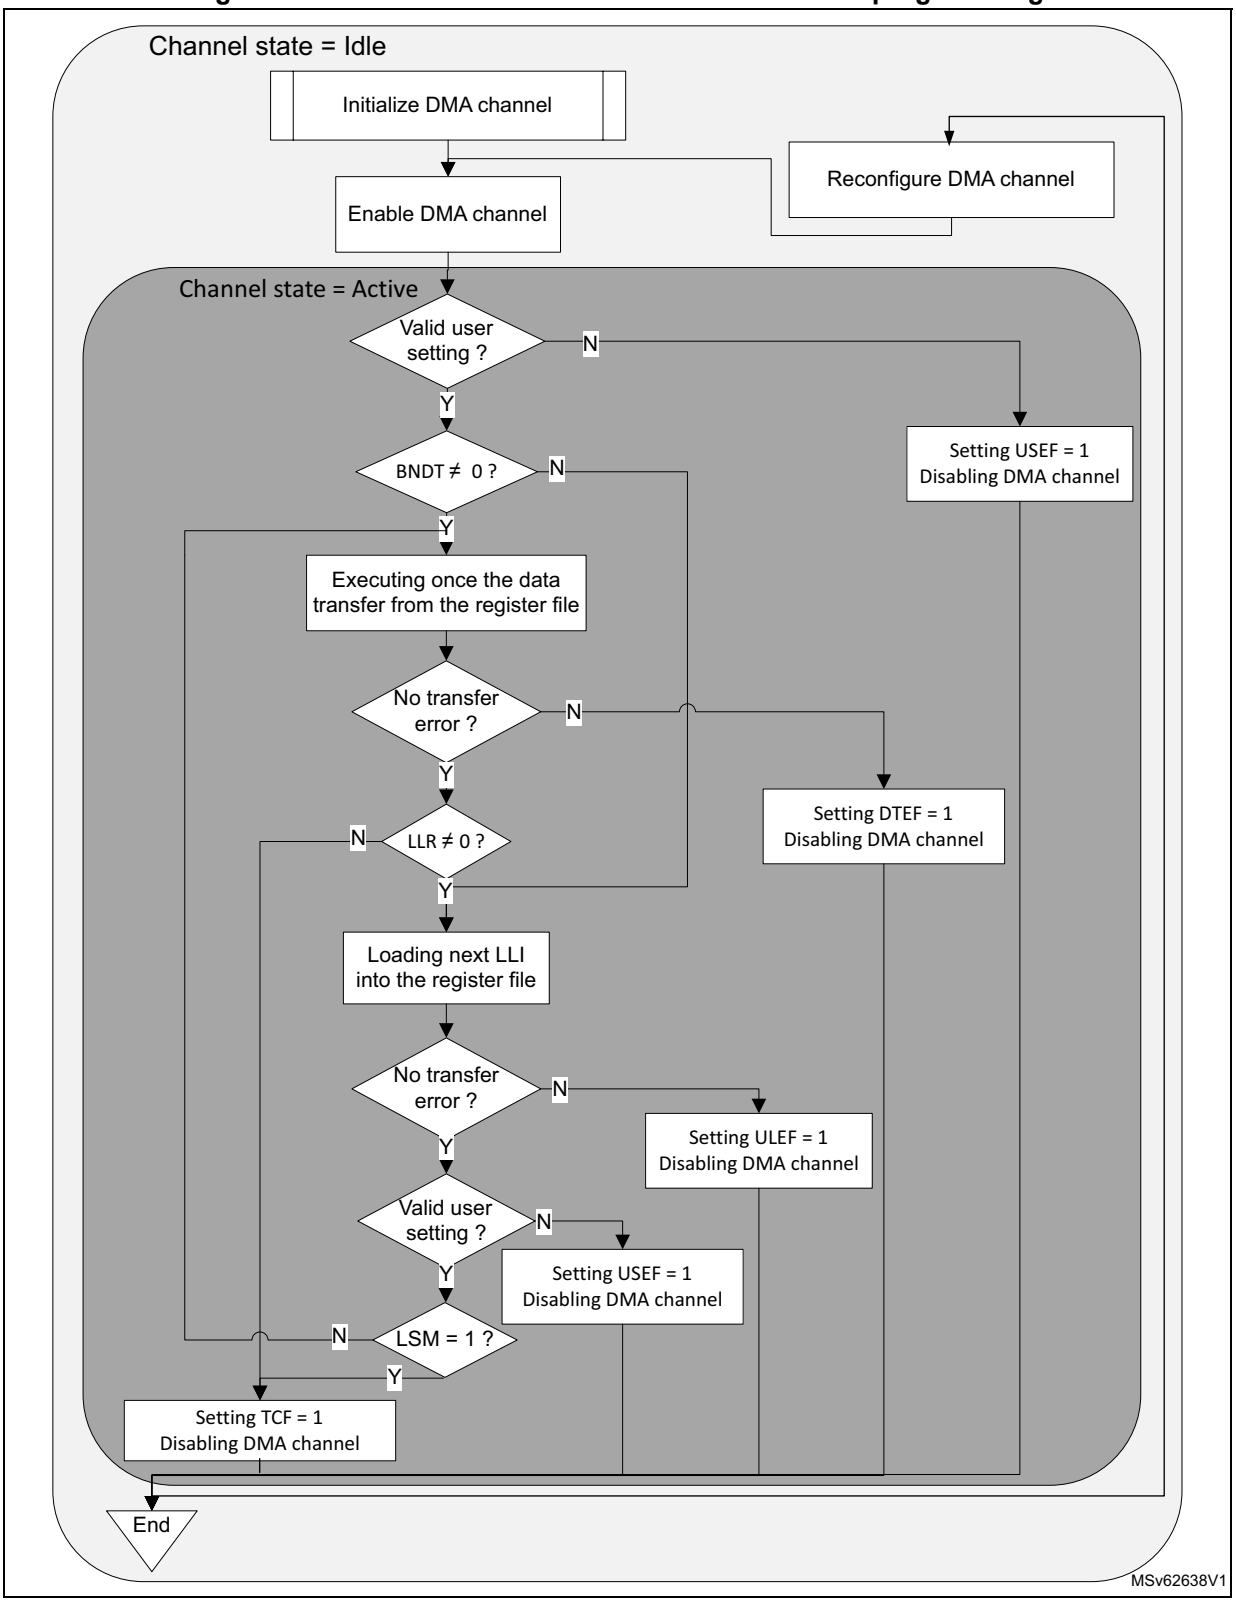
Figure 101. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

12.4.9 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before that this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 12.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 102 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 102 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 102, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 12.3.5).

Figure 102. GPDMA channel execution and linked-list programming

12.4.10 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 12.3.1* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

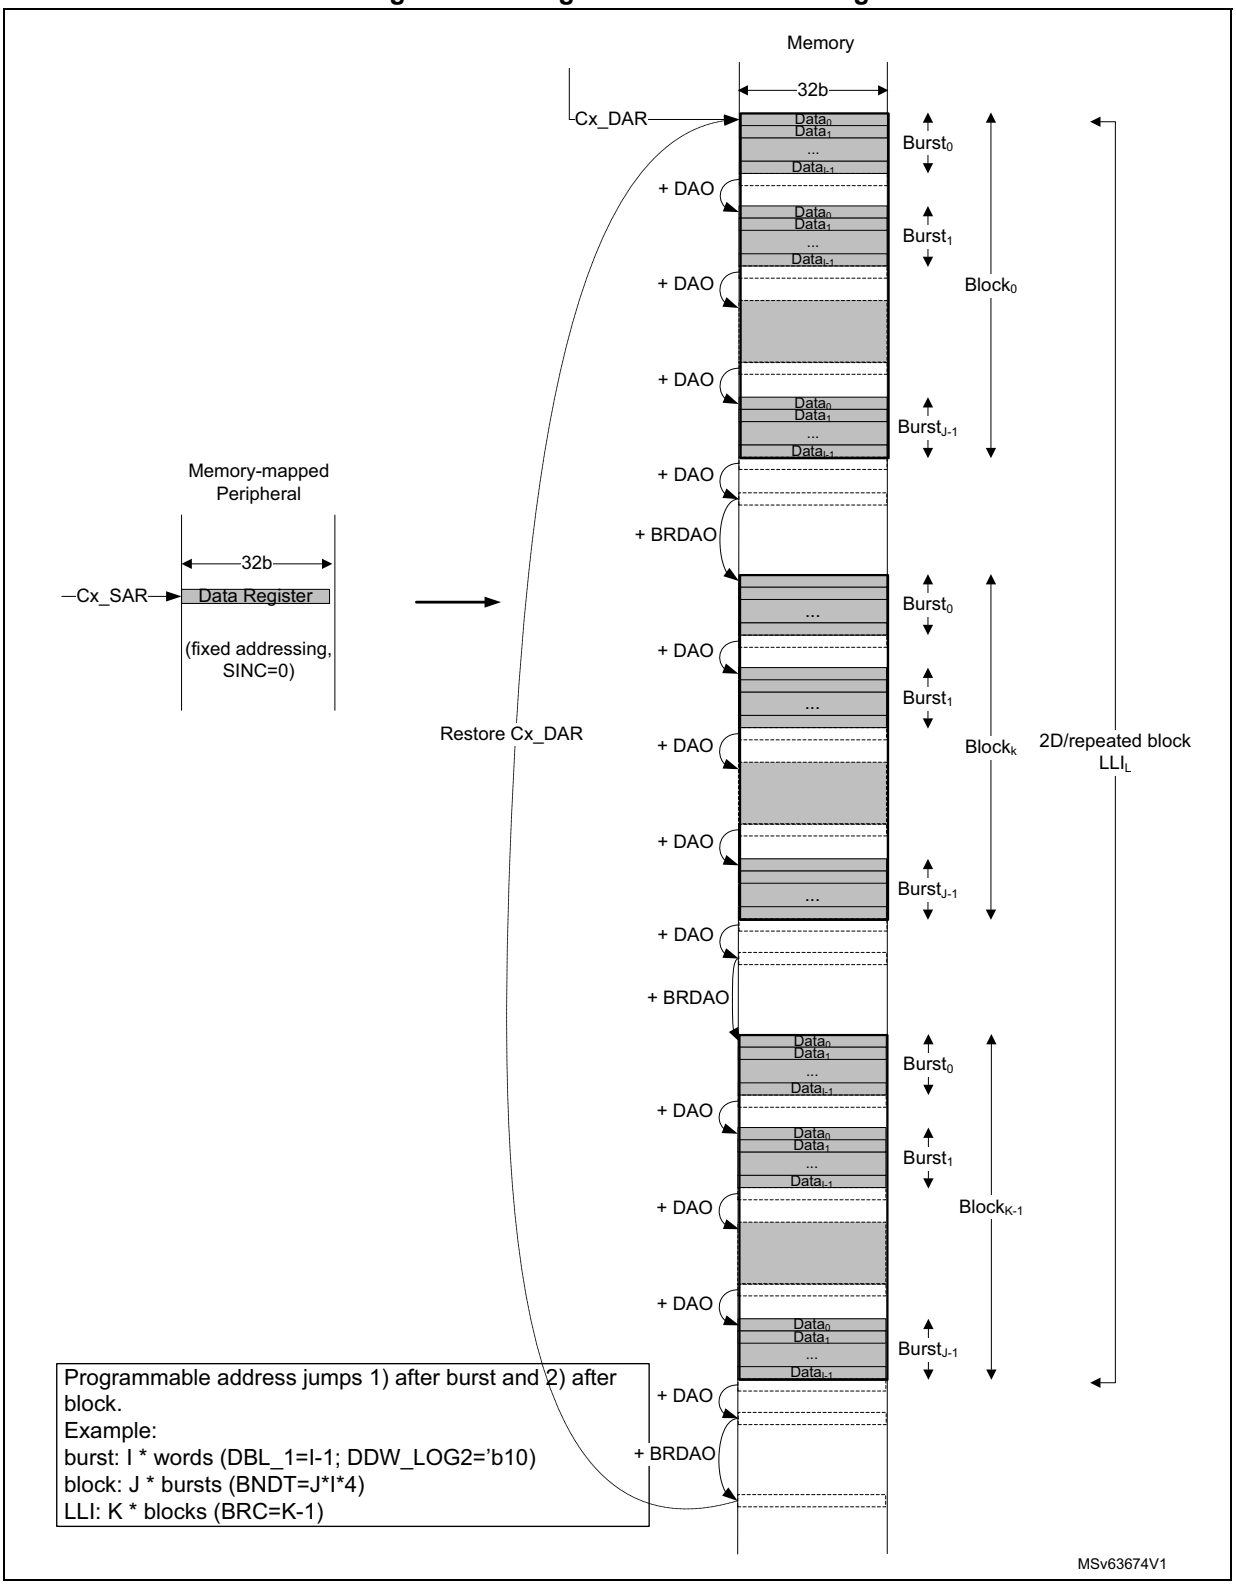
The table below lists the main characteristics of a GPDMA burst.

Table 95. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



GPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 103* with a 2D destination buffer.

Figure 103. Programmed 2D addressing

GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half of the FIFO size of the channel x, in bytes (see *Section 12.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 96*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 96. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

12.4.11 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[6:0] field (see *Section 12.3.3*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[6:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

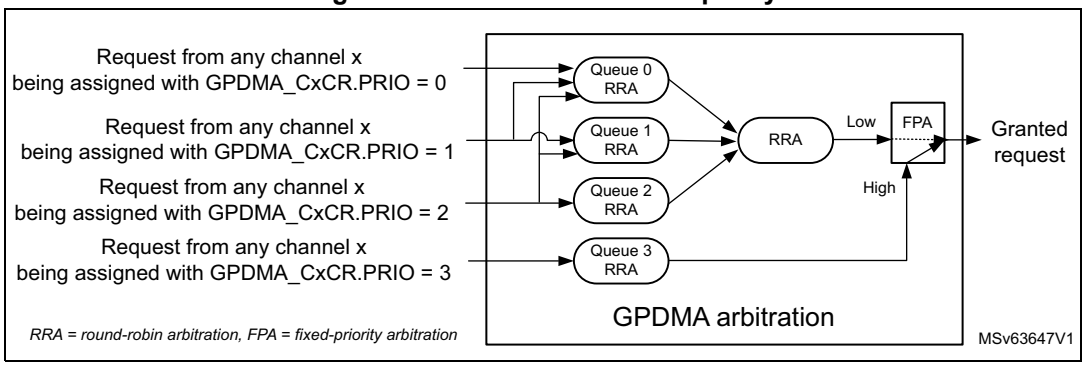
An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 104*, is defined by:



- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 104. GPDMA arbitration policy

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

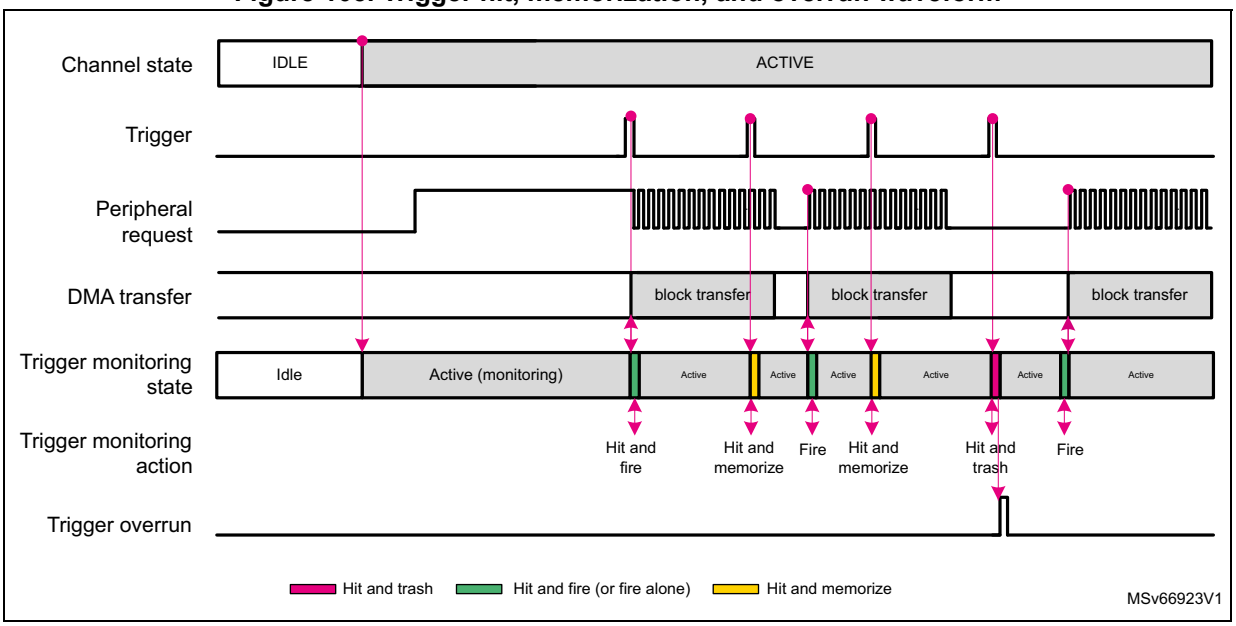
12.4.12 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 12.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 12 to 15), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

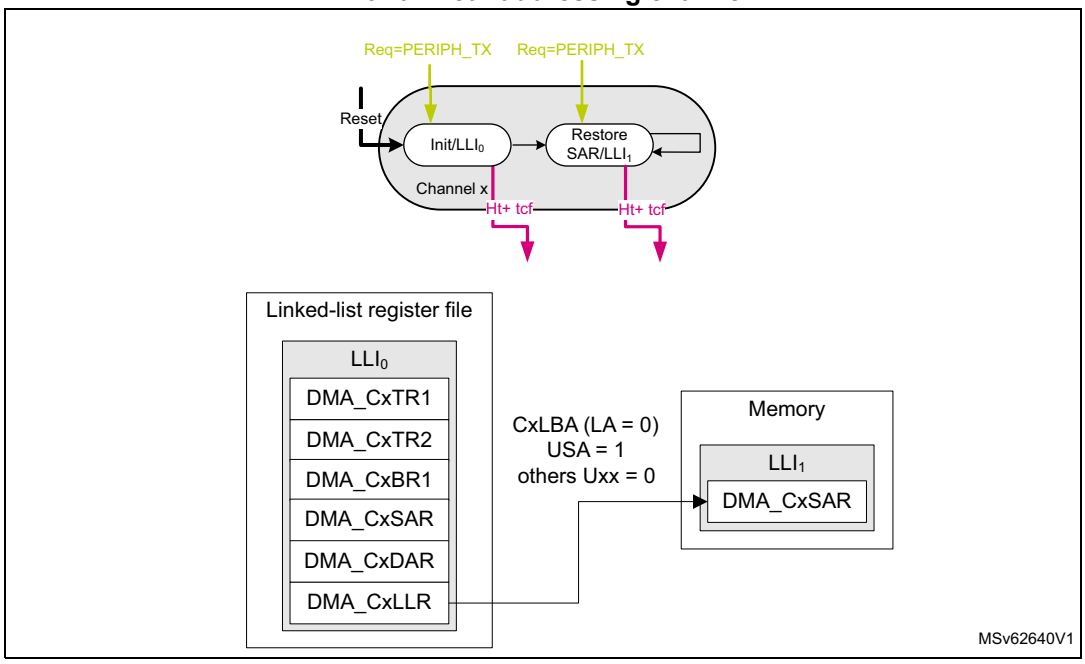
Figure 105 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 105. Trigger hit, memorization, and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

12.4.13 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel



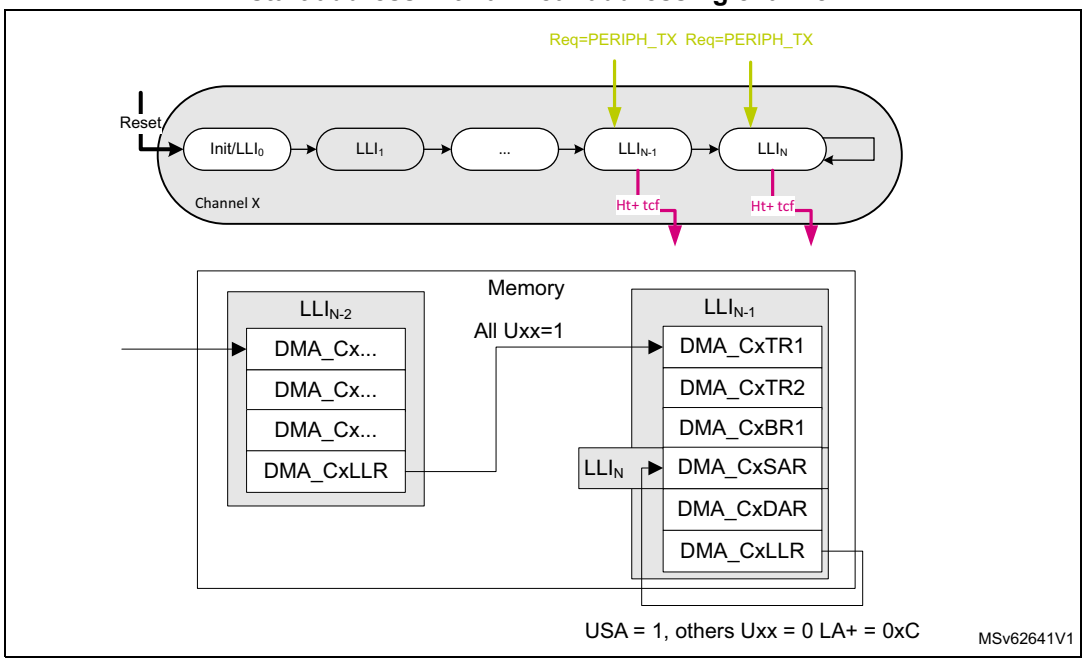
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 106 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 106. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 107 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 107. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

12.4.14 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 12.3.5*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

12.4.15 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

12.4.16 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).

- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).
- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR1.BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 12 to 15): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])

- for channel x (x = 12 to 15): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
- a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x (x = 12 to 15): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x (x = 12 to 15): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width (GPDMA_CxTR1.SDW_LOG2[1:0] = 11)
- a programmed double-word destination data width (GPDMA_CxTR1.DDW_LOG2[1:0] = 11)
- a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

12.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

12.6 GPDMA in low-power modes

Table 97. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 12.3.2* to know if any Stop mode is supported.

12.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 98. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half transfer event is an half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 12.4.16*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

12.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

12.8.1 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: privileged state of channel x (x = 15 to 0)

0: unprivileged

1: privileged

12.8.2 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any GPDMA channel/resource (to lock the setting of GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCK15	LOCK14	LOCK13	LOCK12	LOCK11	LOCK10	LOCK9	LOCK8	LOCK7	LOCK6	LOCK5	LOCK4	LOCK3	LOCK2	LOCK1	LOCK0
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: lock the configuration of GPDMA_PRIVCFGR.PRIVx, until a global GPDMA reset (x = 15 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: privilege configuration of the channel x is writable.

1: privilege configuration of the channel x is not writable.

12.8.3 GPDMA masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bit fields returning zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: masked interrupt status of channel x (x = 15 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

12.8.4 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LBA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

12.8.5 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

	w	w	w	w	w	w	w								

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

12.8.6 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or non-privileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOF	SUSPF	USEF	ULEF	DTEF	HTF	TCF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IDLEF
	r	r	r	r	r	r	r								r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see GPDMA_CxTR1.DDW_LOG2[1:0], in units of bytes, half-words, or words).

Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half transfer flag
0: no half transfer event
1: a half transfer event occurred
A half transfer event is either a half block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

12.8.7 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	Res.	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw						rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 89*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset
This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).
The reset is effective when the channel is in steady state, meaning one of the following:
- active channel in suspended state (GPDMA_CxSR.SUSPF = 1 and GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).
After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 90*).
0: no channel reset
1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

12.8.8 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see GPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word
If the source data width is shorter than a word, this bit is ignored.
If the source data width is a word:
0:no byte-based exchange within the unaligned half-word of each source word
1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode
If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.
Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.
Condition: PAM_1
00: source data is transferred as right aligned, padded with 0s up to the destination data width
01: source data is transferred as right aligned, sign extended up to the destination data width
10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer
Condition: PAM_2
00: source data is transferred as right aligned, left-truncated down to the destination data width
01: source data is transferred as left-aligned, right-truncated down to the destination data width
10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63
The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst
0: fixed burst
1: contiguously incremented burst
The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: A source block size must be a multiple of the source data width (GPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

12.8.9 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	Res.	REQSEL[6:0]						
rw	rw		rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: channel x (x = 0 to 11), same as 00, channel x (x =12 to 15), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x =12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 12.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 12 to 15), for each block if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 11), same as 00; channel x (x = 12 to 15), at 2D/repeated block level. The first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 12.3.1 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 12.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 12.3.3*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[6:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[6:0] is ignored.

Bits 8:7 Reserved, must be kept at reset value.

Bits 6:0 **REQSEL[6:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 12.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[6:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

12.8.10 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

12.8.11 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or non-privileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is

automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI

- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.

– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated by the LLI in the memory.

- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.

- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).

- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (GPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

12.8.12 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

12.8.13 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

12.8.14 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]

Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

12.8.15 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

12.8.16 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0: no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

12.8.17 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).
Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

13 High-performance direct memory access controller (HPDMA)

13.1 HPDMA introduction

The high-performance direct memory access (HPDMA) controller is a bus master and system peripheral.

The HPDMA is used to perform programmable data transfers between memory-mapped peripherals, and/or memories via linked-lists, upon the control of an off-loaded CPU.

13.2 HPDMA main features

- Single bidirectional AXI master and single bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 16 concurrent HPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 13.3.1*)
  - Intra-channel HPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel HPDMA transfers chaining via programmable HPDMA input triggers connection to HPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level
  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at block level, between successive burst transfers

  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 13.3.1*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Selection of programmable HPDMA request and trigger
  - Generation of programmable HPDMA half-transfer and transfer-complete event
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the HPDMA linked-list control registers
  - Channel abort and restart
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- Privileged/unprivileged support:
  - Support for privileged and unprivileged HPDMA transfers, independently at channel level
  - Privileged-aware AHB slave port

13.3 HPDMA implementation

13.3.1 HPDMA channels

A given HPDMA channel x is implemented with the following features and intended use.

To make the best use of the HPDMA performance, the following table lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested HPDMA transfer.

Table 100. Implementation of HPDMA1 channels

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 11	3	0	Channel x (x = 0 to 11) is implemented with: – a FIFO of 16 bytes, 4 words, 2 double-words – fixed/contiguously incremented addressing These channels can be used for HPDMA transfers between an APB or AHB peripheral, an AHB/AXI SRAM, or CPU TCM.
x = 12 to 15	5	1	Channel x (x = 12 to 15) is implemented with: – a FIFO of 64 bytes, 8 double-words – 2D addressing These channels can be also used for HPDMA transfers, including AXI external memories.

13.3.2 HPDMA in low-power modes

The HPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 101. HPDMA1 in low-power modes

Feature	Low-power modes
Wake-up	HPDMA1 in Sleep mode

13.3.3 HPDMA requests

An HPDMA request from a peripheral can be assigned to a HPDMA channel x, via REQSEL[4:0] in HPDMA_CxTR2, provided that SWREQ = 0.

The HPDMA requests mapping is specified in the table below.

Table 102. Programmed HPDMA1 request

HPDMA_CxTR2.REQSEL[4:0]	Selected HPDMA request
0	jpeg_rx_dma
1	jpeg_tx_dma
2	xspi1_rx_dma
3	xspi2_rx_dma
4	spi3_rx_dma
5	spi3_tx_dma
6	spi4_rx_dma
7	spi4_tx_dma
8	adc1_dma
9	adc2_dma
10	adf1_flt0_dma

15	uart7_rx_dma
16	uart7_tx_dma
17	lptim2_ic1_dma
18	lptim2_ic2_dma
19	lptim2_ue_dma

13.3.4 HPDMA block requests

Some HPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in HPDMA_CxTR2 must be set for a correct HPDMA execution of the requested peripheral transfer at the hardware level.

Table 103. Programmed HPDMA1 request as a block request

HPDMA block requests
lptim2_ue_dma

13.3.5 HPDMA channels with peripheral early termination

An HPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 104. HPDMA1 channel with peripheral early termination

HPDMA channel x with peripheral early termination
x = 15

This HPDMA support is activated when the channel x is programmed with HPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before that the HPDMA has transferred the whole block (see *Section 13.4.14* for more details).

Table 105. Programmed HPDMA request with peripheral early termination

Programmed HPDMA channel x request with peripheral early termination
jpeg_tx_dma

13.3.6 HPDMA triggers

An HPDMA trigger can be assigned to an HPDMA channel x, via TRIGSEL[5:0] in HPDMA_CXTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

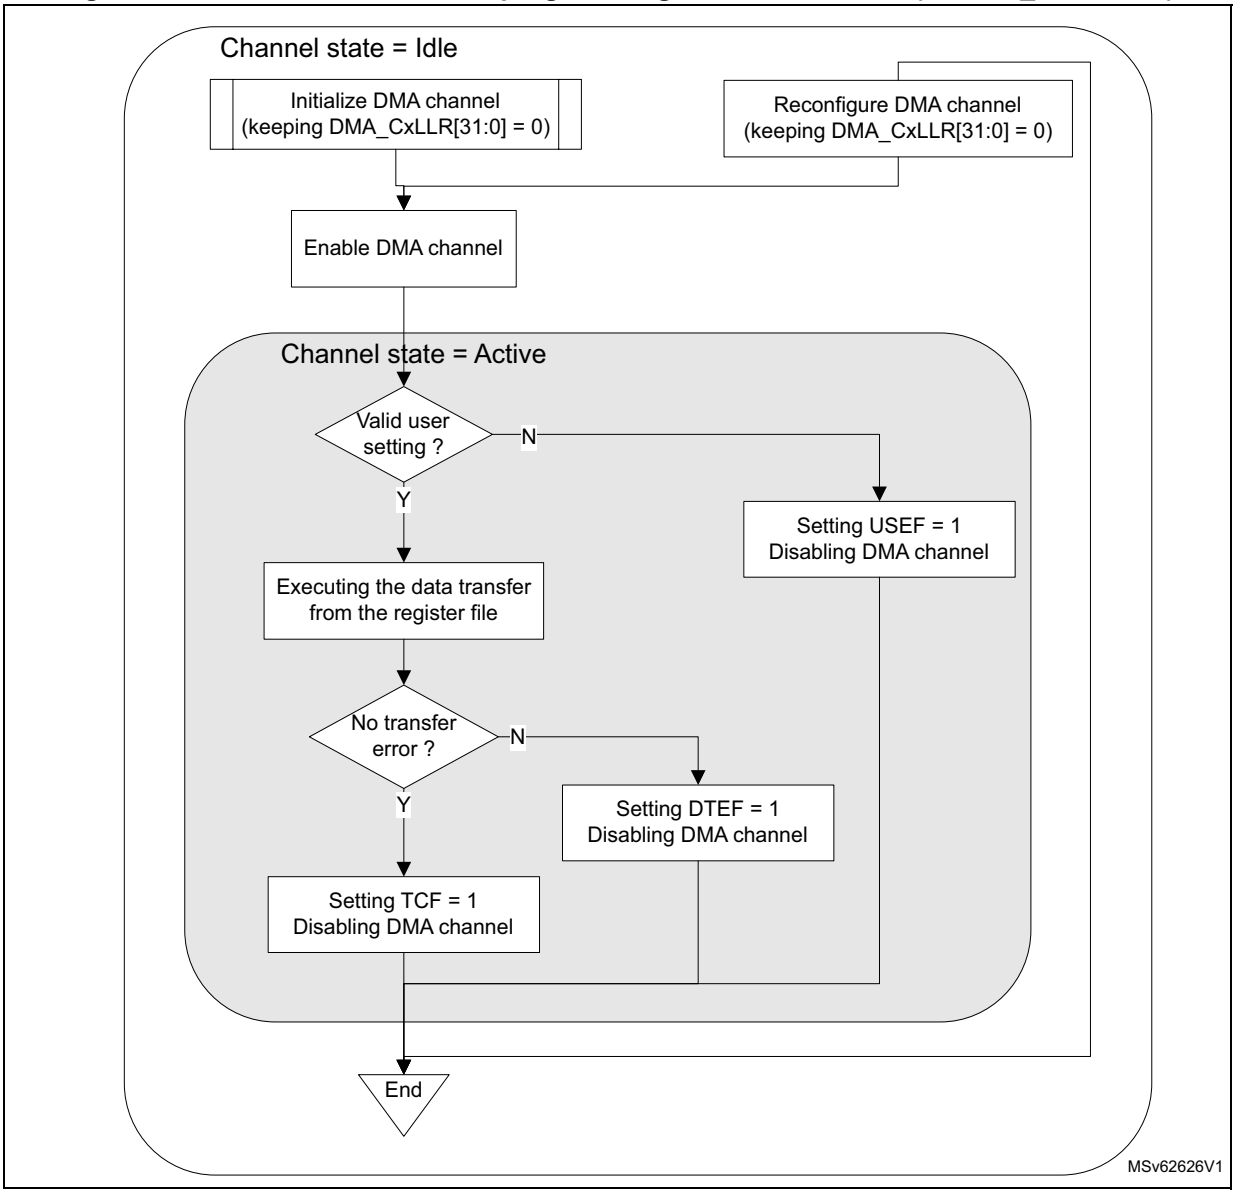
13.4 HPDMA functional description

13.4.1 HPDMA block diagram

Figure 108. HPDMA block diagram



13.4.2 HPDMA channel state and direct programming without any linked-list

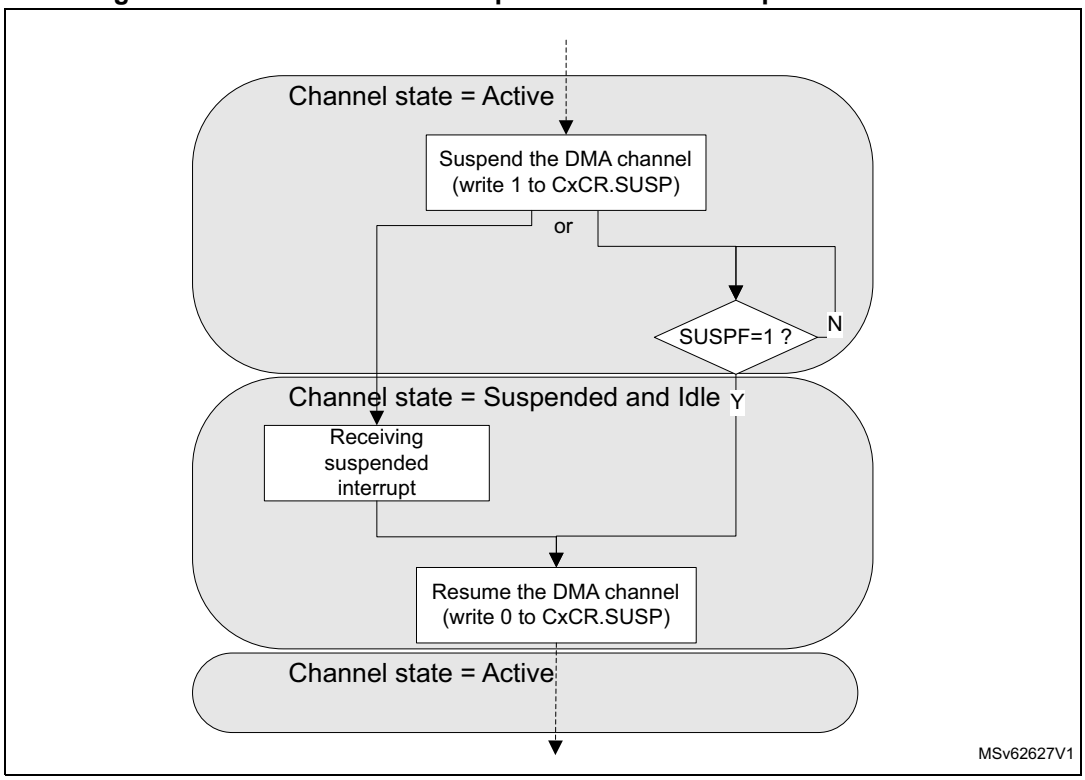
After an HPDMA reset, an HPDMA channel x is in idle state. When the software writes 1 into the HPDMA_CxCR.EN enable control bit, the channel takes into account the value of the different channel configuration registers (HPDMA_CxXXX), switches to the active/non-idle state, and starts to execute the corresponding requested data transfers.

After enabling/starting an HPDMA channel transfer by writing 1 into HPDMA_CxCR.EN, an HPDMA channel interrupt on a complete transfer notifies the software that the HPDMA channel is back in idle state (EN is then deasserted by hardware), and that the channel is ready to be reconfigured then enabled again.

The figure below illustrates this HPDMA direct programming without any linked-list (HPDMA_CxLLR = 0).

Figure 109. HPDMA channel direct programming without linked-list (HPDMA_CxLLR = 0)

13.4.3 HPDMA channel suspend and resume



The software can suspend on its own a channel still active, with the following sequence:

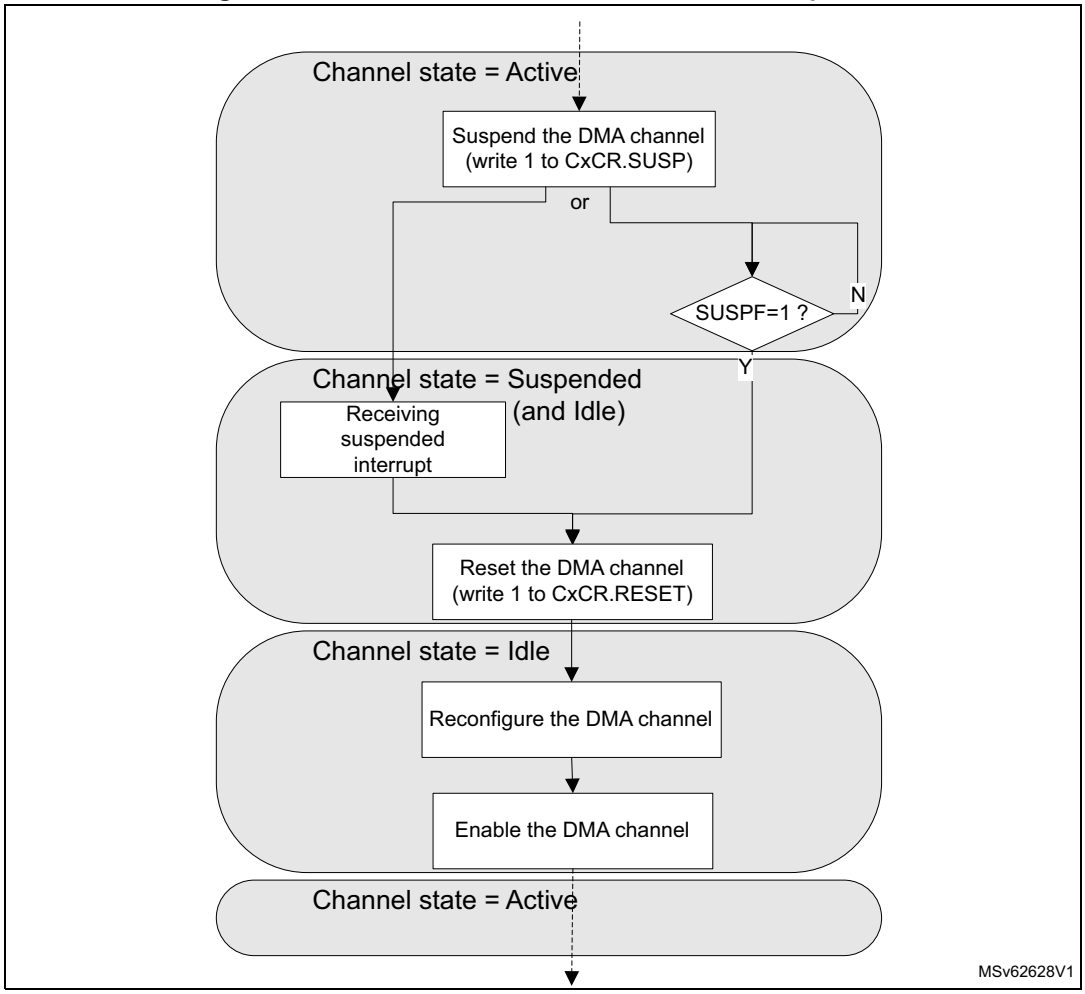
1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or bitfield that is hardware modifiable.

Note: An ongoing HPDMA transfer can be a data transfer (a source/destination burst transfer,) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to HPDMACxCR.SUSP.

Figure 110. HPDMA channel suspend and resume sequence

Note: A suspend and resume sequence does not impact the HPDMA_*CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.*



13.4.4 HPDMA channel abort and restart

Alternatively, like for aborting a continuous HPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the HPDMA_CxCR.SUSP bit.
2. The software polls suspended flag HPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to HPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing HPDMA transfer over its master port.
3. The software resets the channel by writing 1 to HPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the HPDMA_CxCR.EN bit, and the reset of the HPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram hardware-modified HPDMA_CxBR1, HPDMA_CxSAR, and HPDMA_CxDAR.

5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the HPDMA_CxCR.EN bit.

Figure 111. HPDMA channel abort and restart sequence

13.4.5 HPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

For a channel x, the base address in memory of the data structure of a next LLI_{n+1} is the sum of the following:

- the link base address of the channel x (in HPDMA_CxLBAR)
- the link address offset LA[15:2] bitfield in HPDMA_CxLLR, that is the updated result from the data structure of the previous LLIn of the channel x

The data structure for each LLI can be specific.

A linked-list data structure is addressed following the value of UT1, UT2, UB1, USA, UDA, and ULL bits, plus UB2 and UT3 when present, in HPDMA_CxLLR.

In linked-list mode, each HPDMA linked-list register (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR or HPDMA_CxLLR,

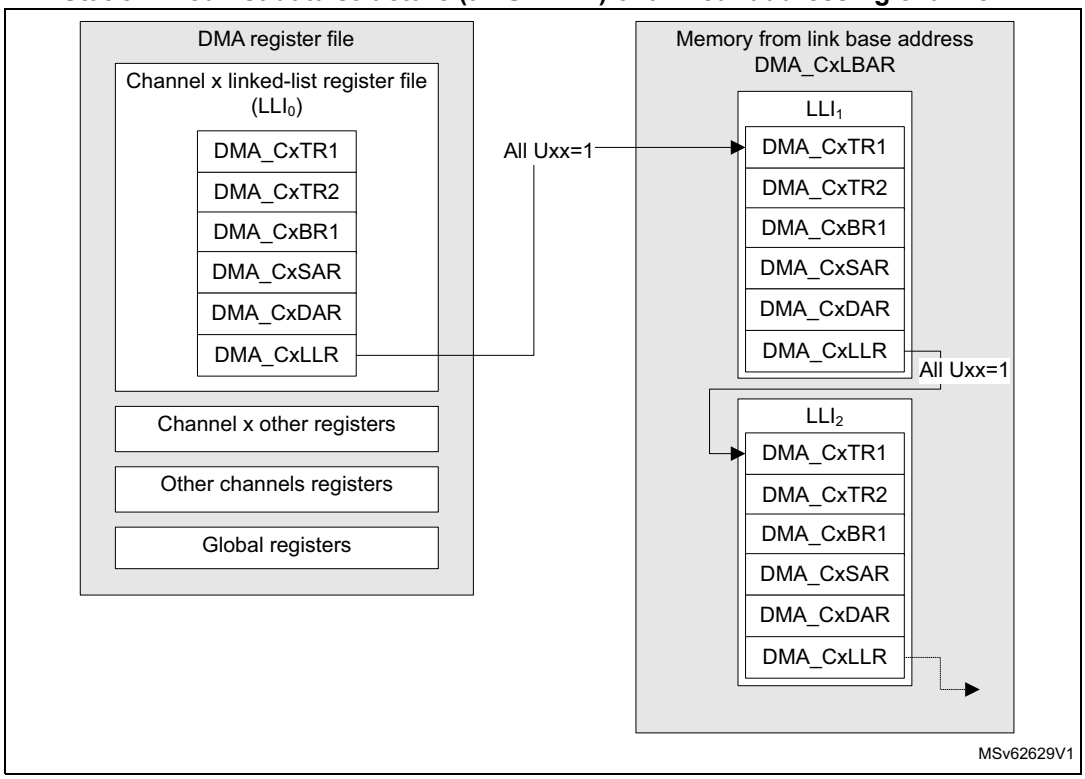
plus HPDMA_CxTR3 or HPDMA_CxBR2 when present) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of HPDMA_CxLLR that was conditionally updated from the linked-list data structure of the previous LLI.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present) in HPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x, x = 0 to 11, six contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR (see *Figure 112*) and including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory
- channel x, x = 12 to 15, eight contiguous 32-bit locations, including HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 (see *Figure 113*), including the first linked-list register file (LLI_0), and the next LLIs (LLI_1, LLI_2,...) in the memory

Figure 112. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



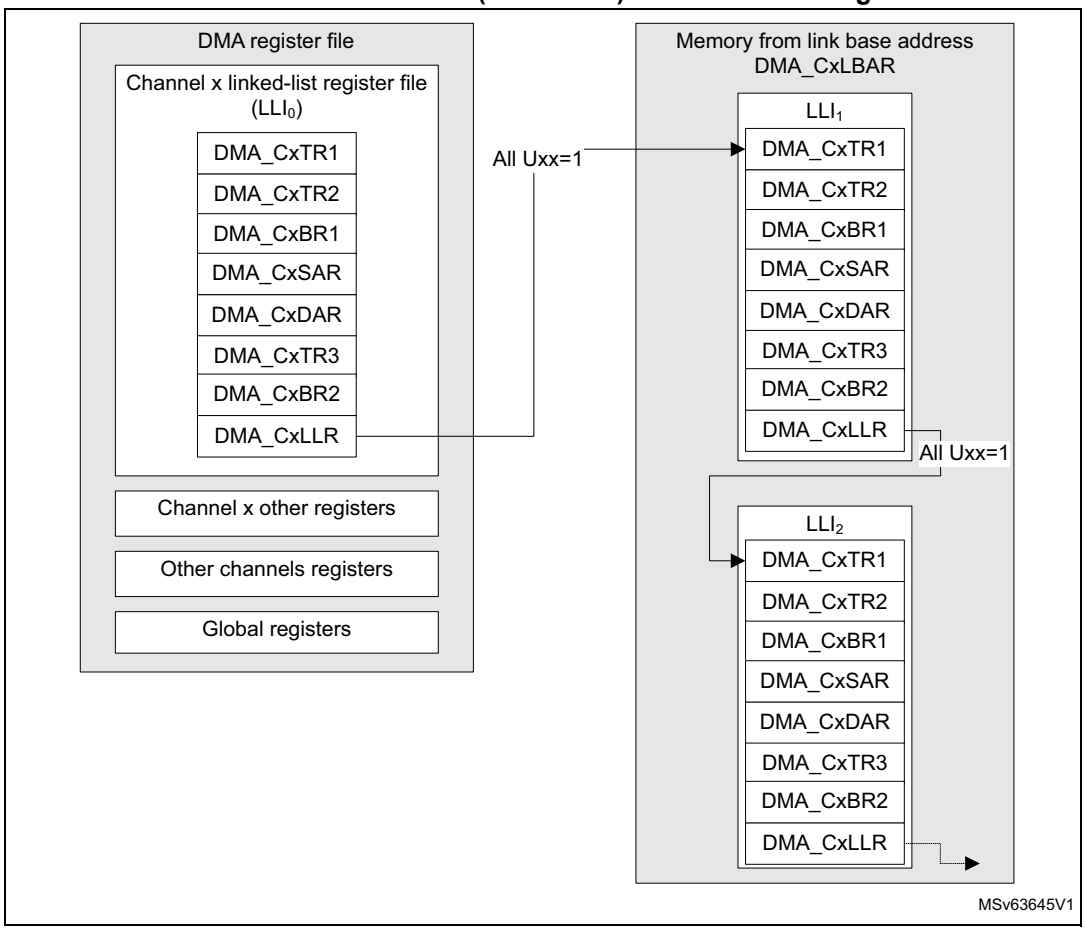


Figure 113. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

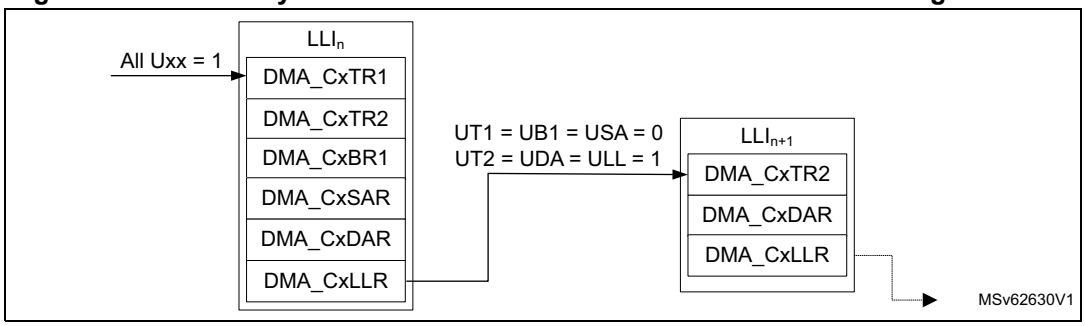
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of HPDMA_CxLLR points to the updated value of HPDMA_CxTR2, instead of HPDMA_CxTR1 which is not to be modified (see *Figure 114*).

Example: if UT1 = UB1 = USA = 0, and if UT3 = UB2 = 0 when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for HPDMA_CxTR1, nor HPDMA_CxBR1, nor HPDMA_CxSAR, nor HPDMA_CxTR3, nor HPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for HPDMA_CxTR2, HPDMA_CxDAR, and HPDMA_CxLLR, as shown in *Figure 115*.

Figure 114. HPDMA dynamic linked-list data structure of linear addressing channel x



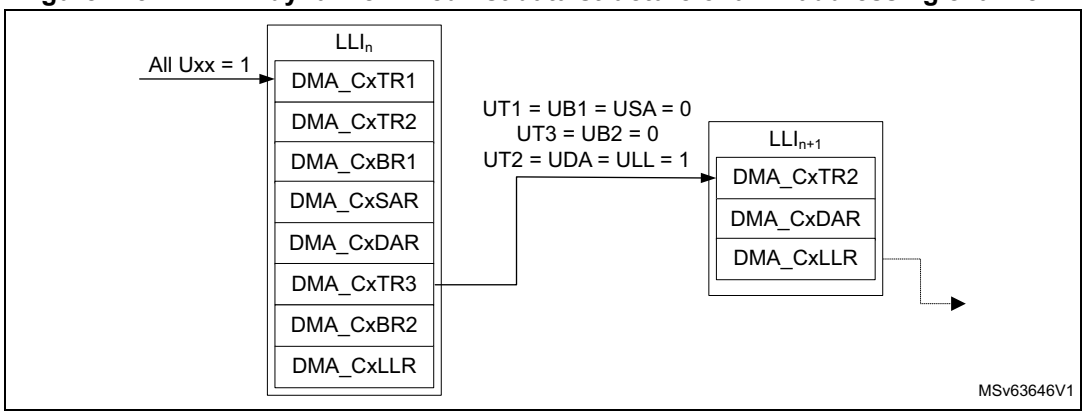


Figure 115. HPDMA dynamic linked-list data structure of a 2D addressing channel x

The user must program HPDMA_CxLLR for each LLI_n to be 32-bit aligned, and not to exceed the 64-Kbyte addressable space pointed by HPDMA_CxLBAR.

13.4.6 Linked-list item transfer execution

An LLI_n transfer is the sequence of:

1. a data transfer: the HPDMA executes the data transfer as described by the HPDMA internal register file (this data transfer can be void/null for LLI_0).
2. a conditional link transfer: the HPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the HPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer, as defined by the internal register file (LLI_0), can be null (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxTR2.PFREQ = 0), provided that UB1 is set in HPDMA_CxLLR (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended HPDMA use, an HPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, HPDMA_CxCR.LSM = 0), or can be programmed for a single execution of a LLI (link step mode, HPDMA_CxCR.LSM = 1), as described in the next sections.

13.4.7 HPDMA channel state and linked-list programming in run-to-completion mode

When HPDMA_CxCR.LSM = 0 (in full-list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), an HPDMA channel x is initially programmed, started by writing 1 to HPDMA_CxCR.EN, and after completed at channel level.
The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present
  - the last LLI_N described by the linked-list data structure in memory, as defined by HPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when HPDMA_CxLLR[31:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if BRC[10:0] is present and HPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

HPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion, and means the following:

- The 16 low significant bits HPDMA_CxLLR.LA[15:0] of the next link address are null.
- All bits HPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA, and ULL, plus UB2 and UT3 when present).

The channel may never be completed when HPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI, in one of the following:
  - HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value.
  - HPDMA_CxLLR.ULL = 0
- If LLI_N points to a previous LLI

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 13.4.14* for more details).

In the typical run-to-completion mode, the allocation of an HPDMA channel, including its fine programming, is done once during the HPDMA initialization. In order to have a reserved data communication link and HPDMA service during run-time, for continuously repeated transfers (from/to a peripheral respectively to/from memory or for memory-to-memory transfers). This reserved data communication link can consist of a channel, or the channel can be shared and a repeated transfer consists of a sequence of LLIs.

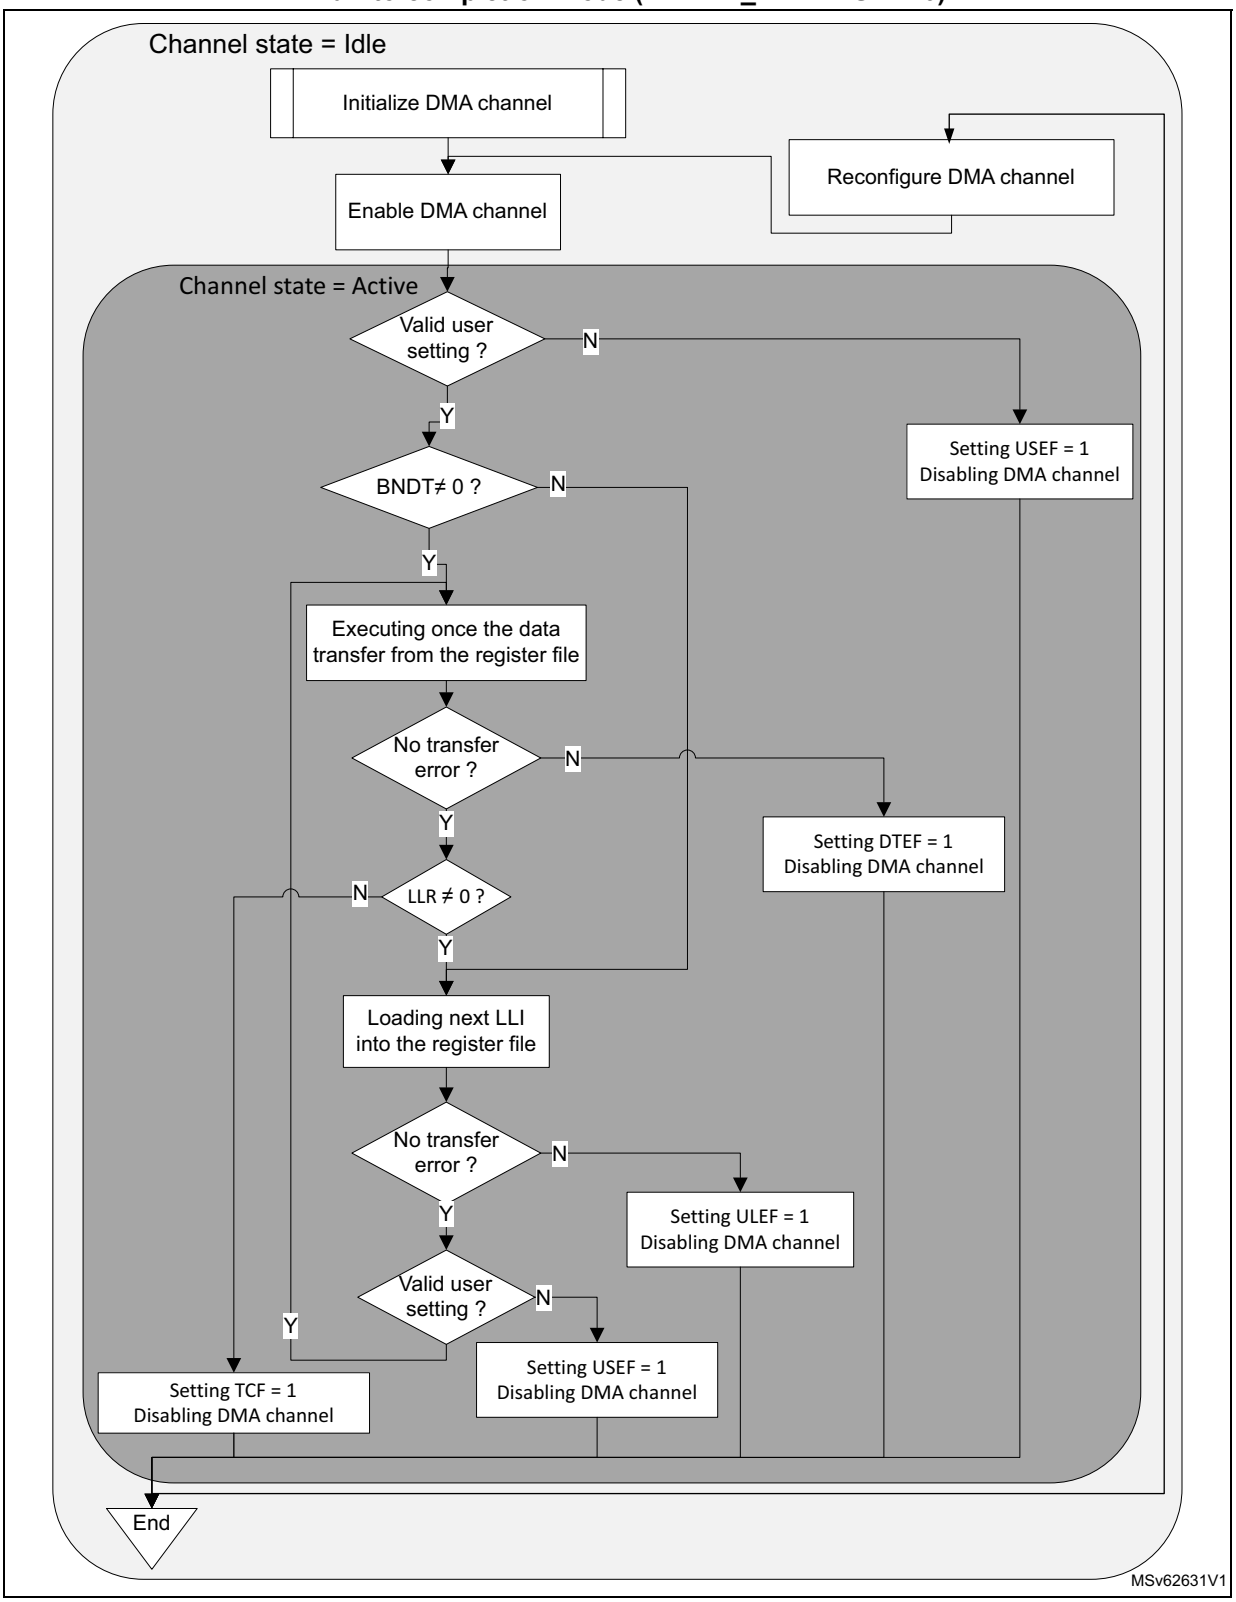

Figure 116 depicts the HPDMA channel execution and its registers programming in run-to-completion mode.

Note: Figure 116 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel

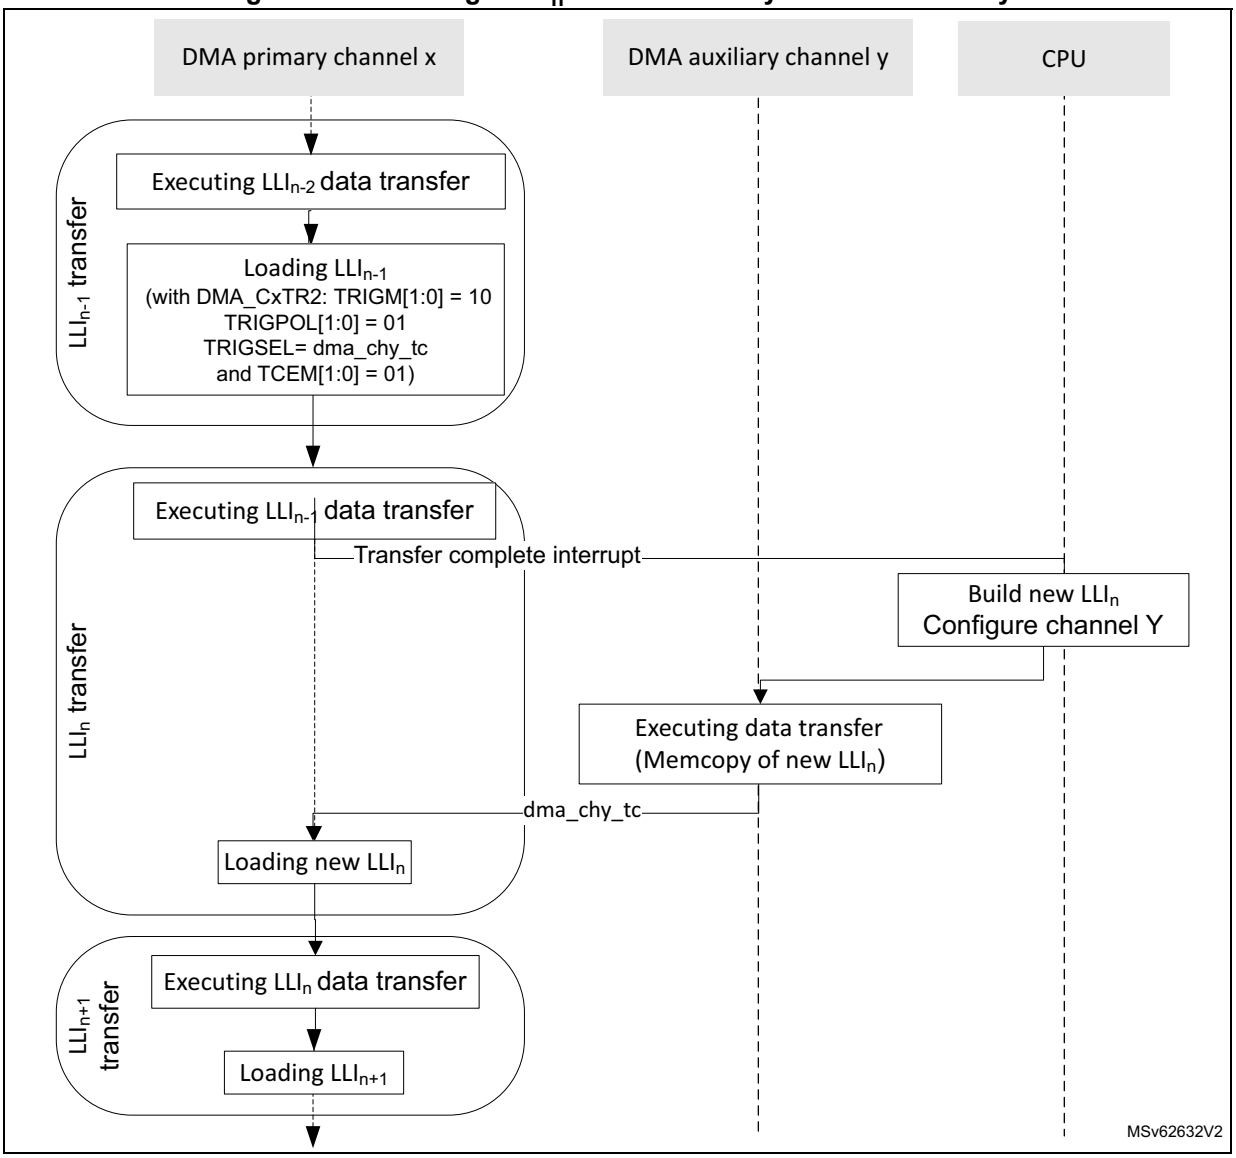
completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 116, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 13.3.5).

Figure 116. HPDMA channel execution and linked-list programming in run-to-completion mode (HPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following bitfields of HPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 13.3.6* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory, and to generate a transfer complete event hpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 117 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with an LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 117. Inserting a LLI_n with an auxiliary HPDMA channel y

13.4.8 HPDMA channel state and linked-list programming in link step mode

When HPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

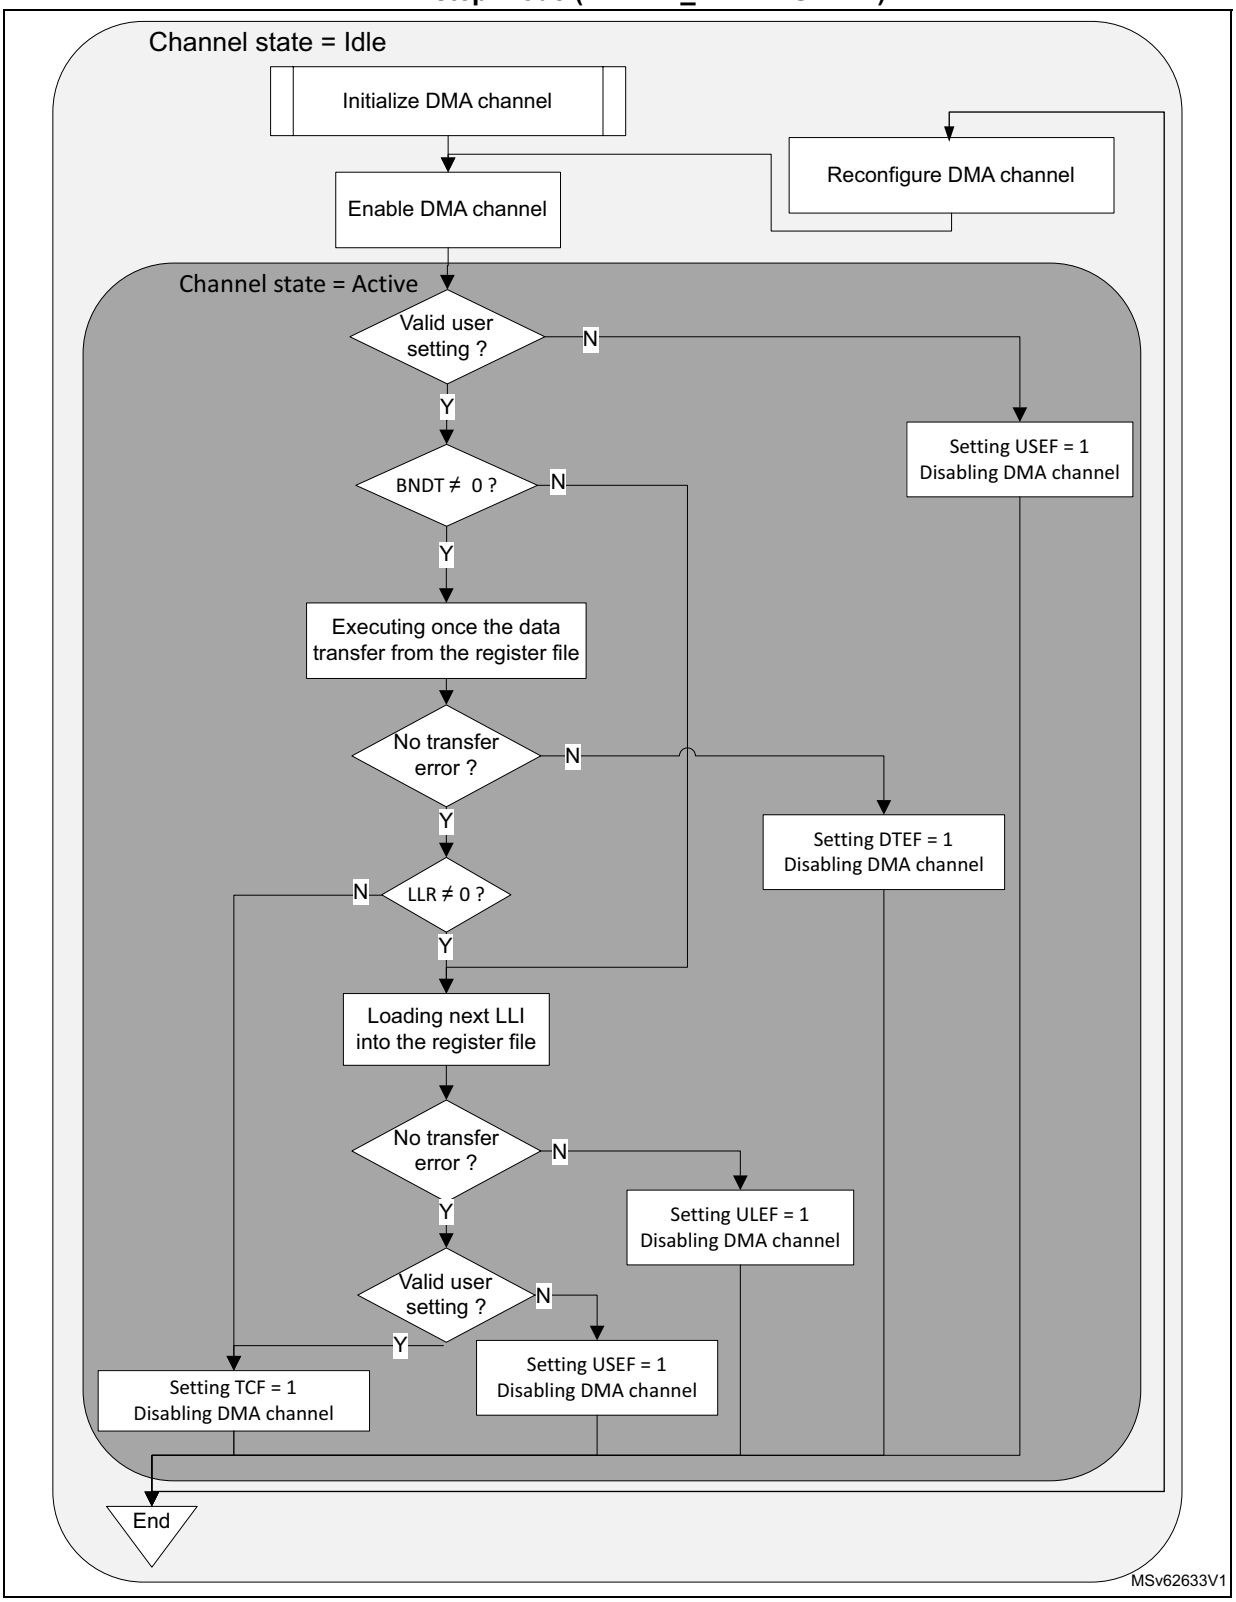
An HPDMA channel transfer can be programmed at an LLI level, started by writing 1 into HPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with the following:
  - HPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - HPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]), for channel x = 12 to 15, the number of blocks at a 2D/repeated block level (BRC[10:0]+1), and the incrementing/decrementing mode for address offsets.

  - HPDMA_CxTR2 defines the input control (request, trigger), and the output control (transfer-complete event) of the transfer.
  - HPDMA_CxSAR and HPDMA_CxDAR define the source/destination transfer start address.
  - HPDMA_CxTR3 (for channel x = 12 to 15) defines the source/destination additional address offset between burst transfers.
  - HPDMA_CxBR2 (for channel x = 12 to 15) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - HPDMA_CxLLR defines the data structure, and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when HPDMA_CxBR1.BRC[10:0] = 0 if BRC[10:0] is present, and HPDMA_CxBR1.BNDT[15:0] = 0)
  - after the (conditional) update of the HPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If an LLI is recursive (pointing to itself as a next LLI, either HPDMA_CxLLR.ULL = 1 and HPDMA_CxLLR.LA[15:2] is updated by the same value, or HPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer can be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 13.4.14* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of HPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 118 depicts the HPDMA channel execution mode, and its programming in link step mode.

Note: Figure 118 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 118, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 13.3.5).

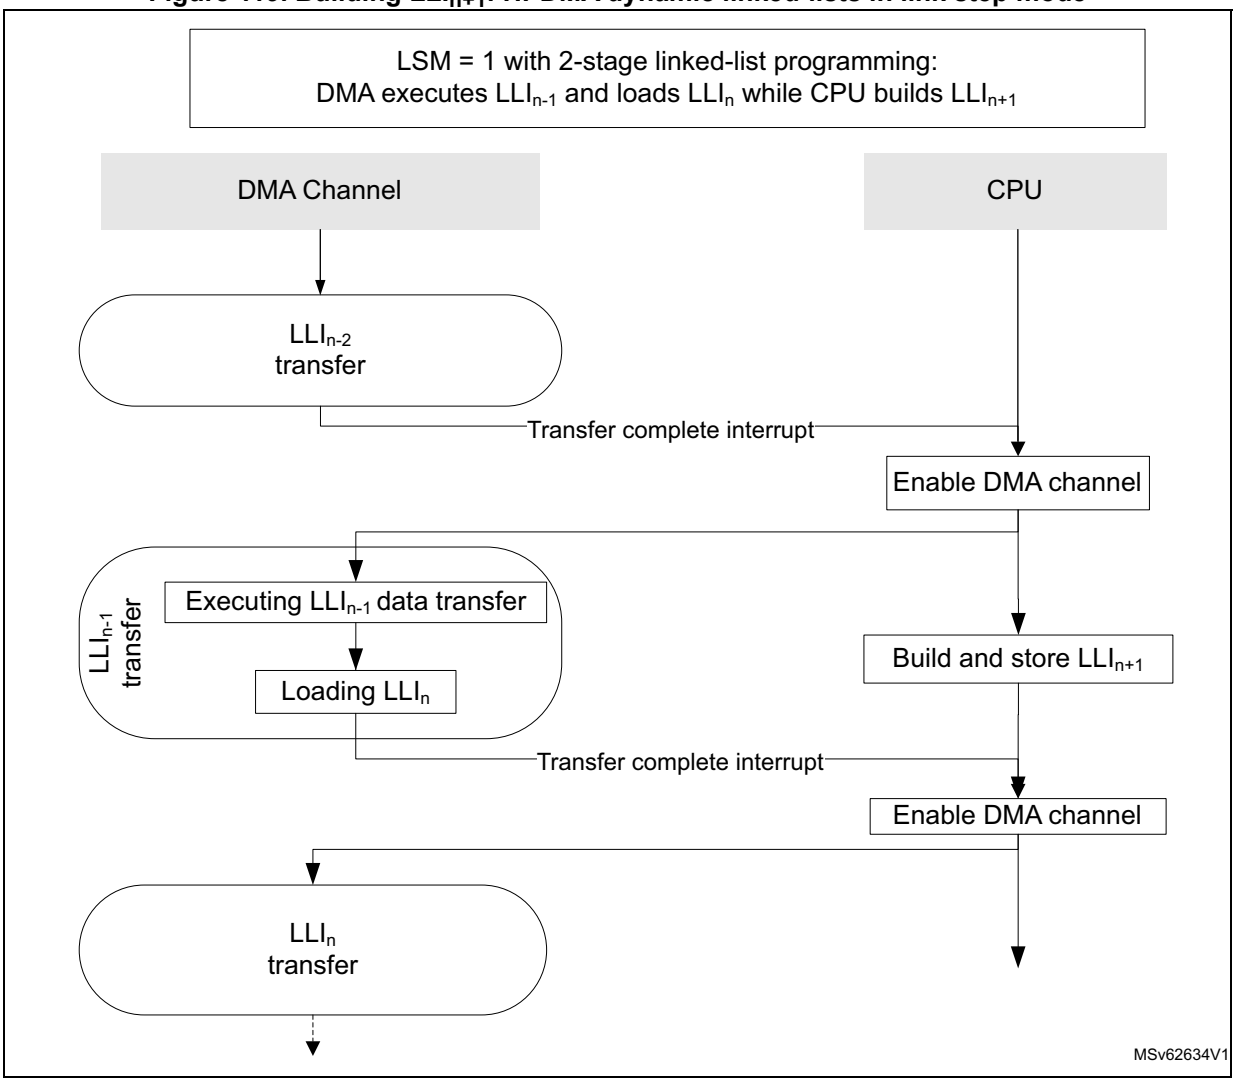


Figure 118. HPDMA channel execution and linked-list programming in link step mode (HPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after the HPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in the figure below.

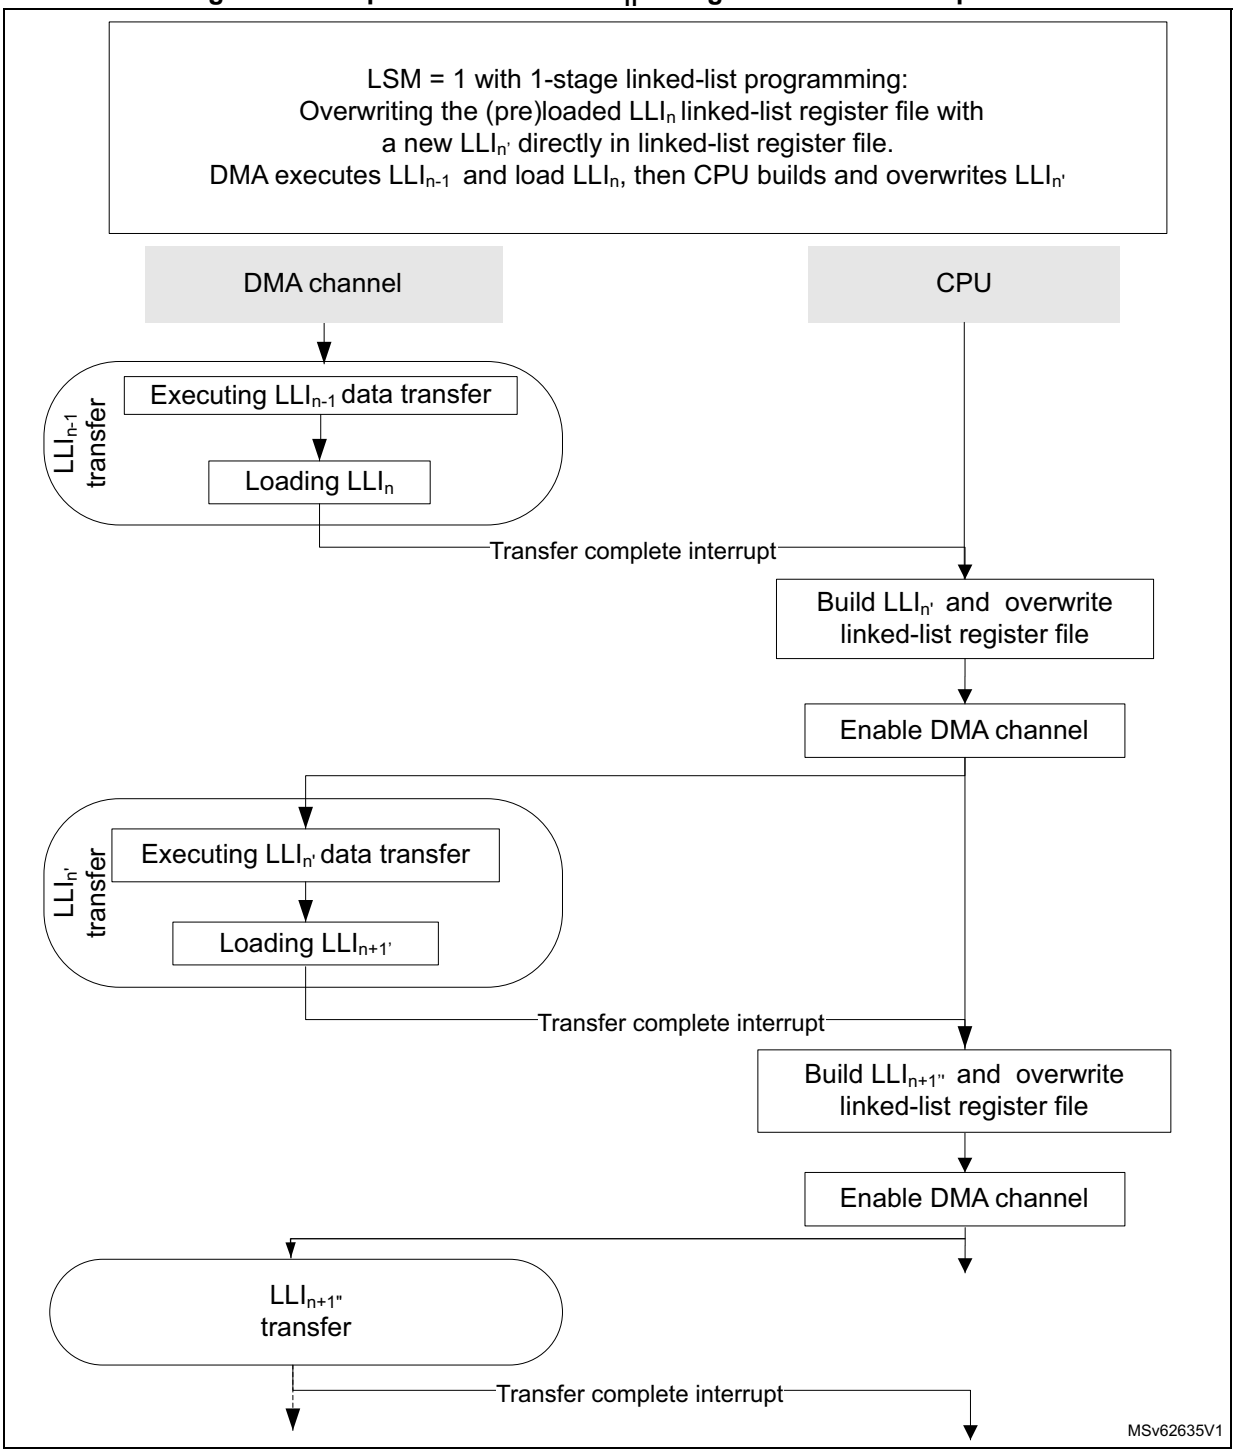

Figure 119. Building LLI_{n+1}: HPDMA dynamic linked-lists in link step mode

Run-time replacing an LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after the HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 120*.

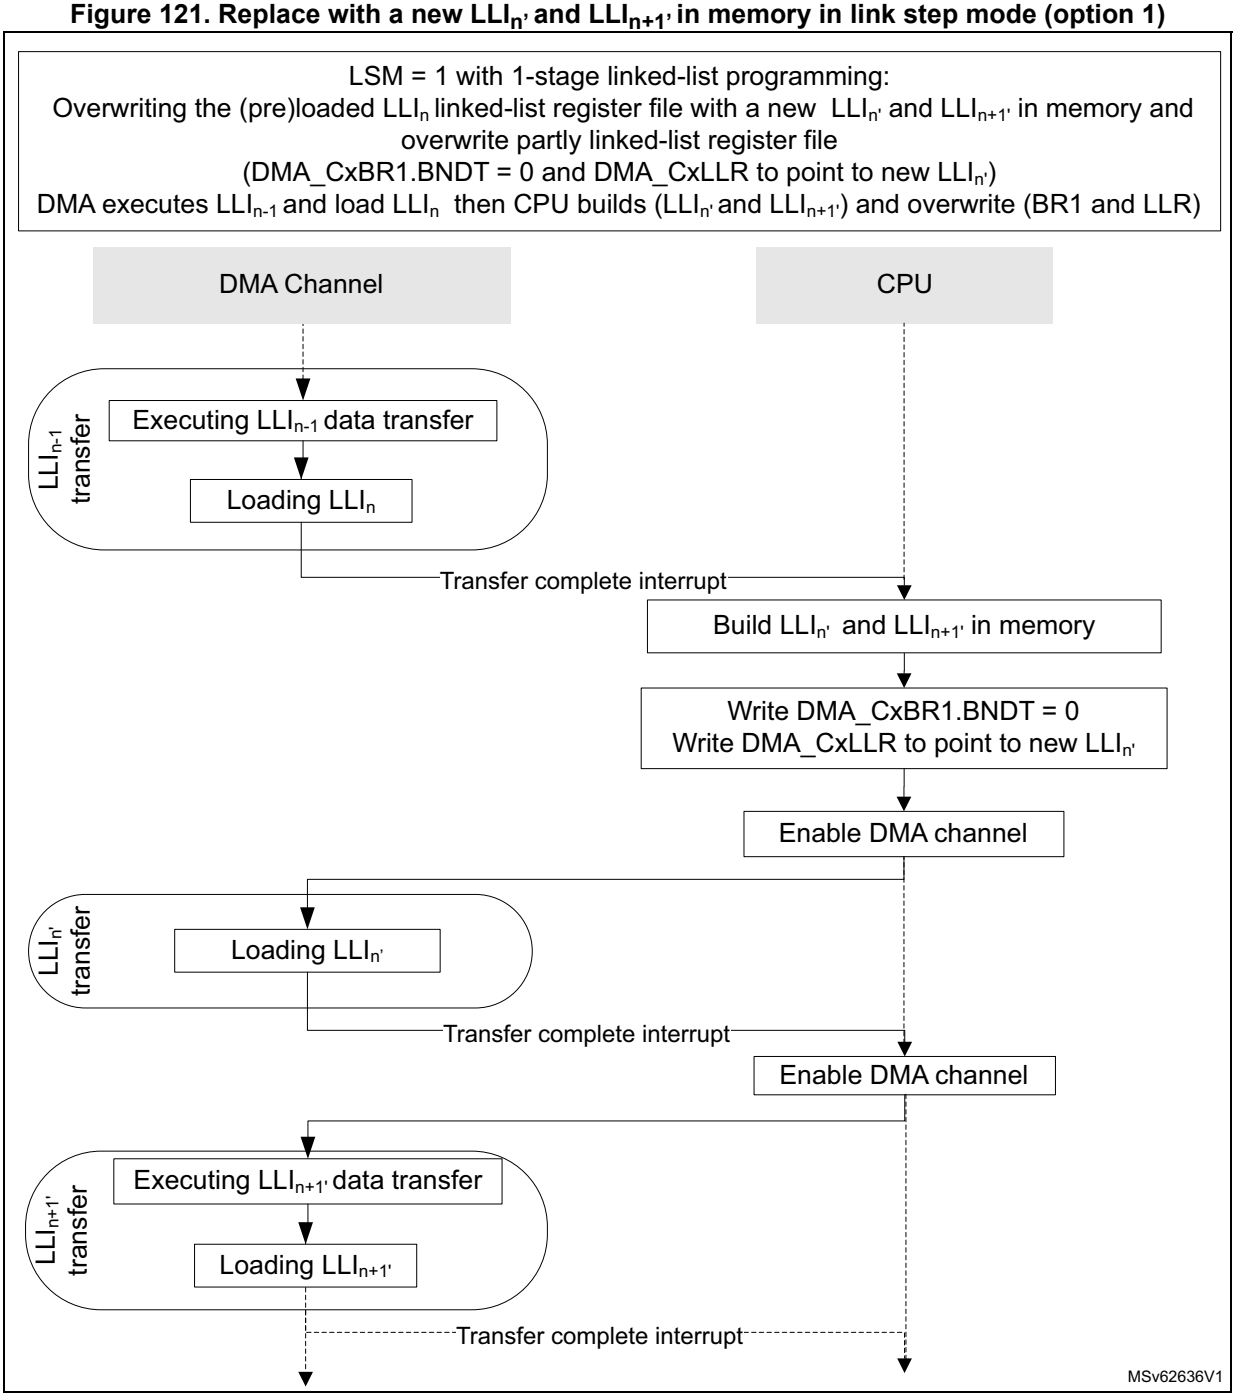

Figure 120. Replace with a new $LLI_{n'}$ in register file in link step mode

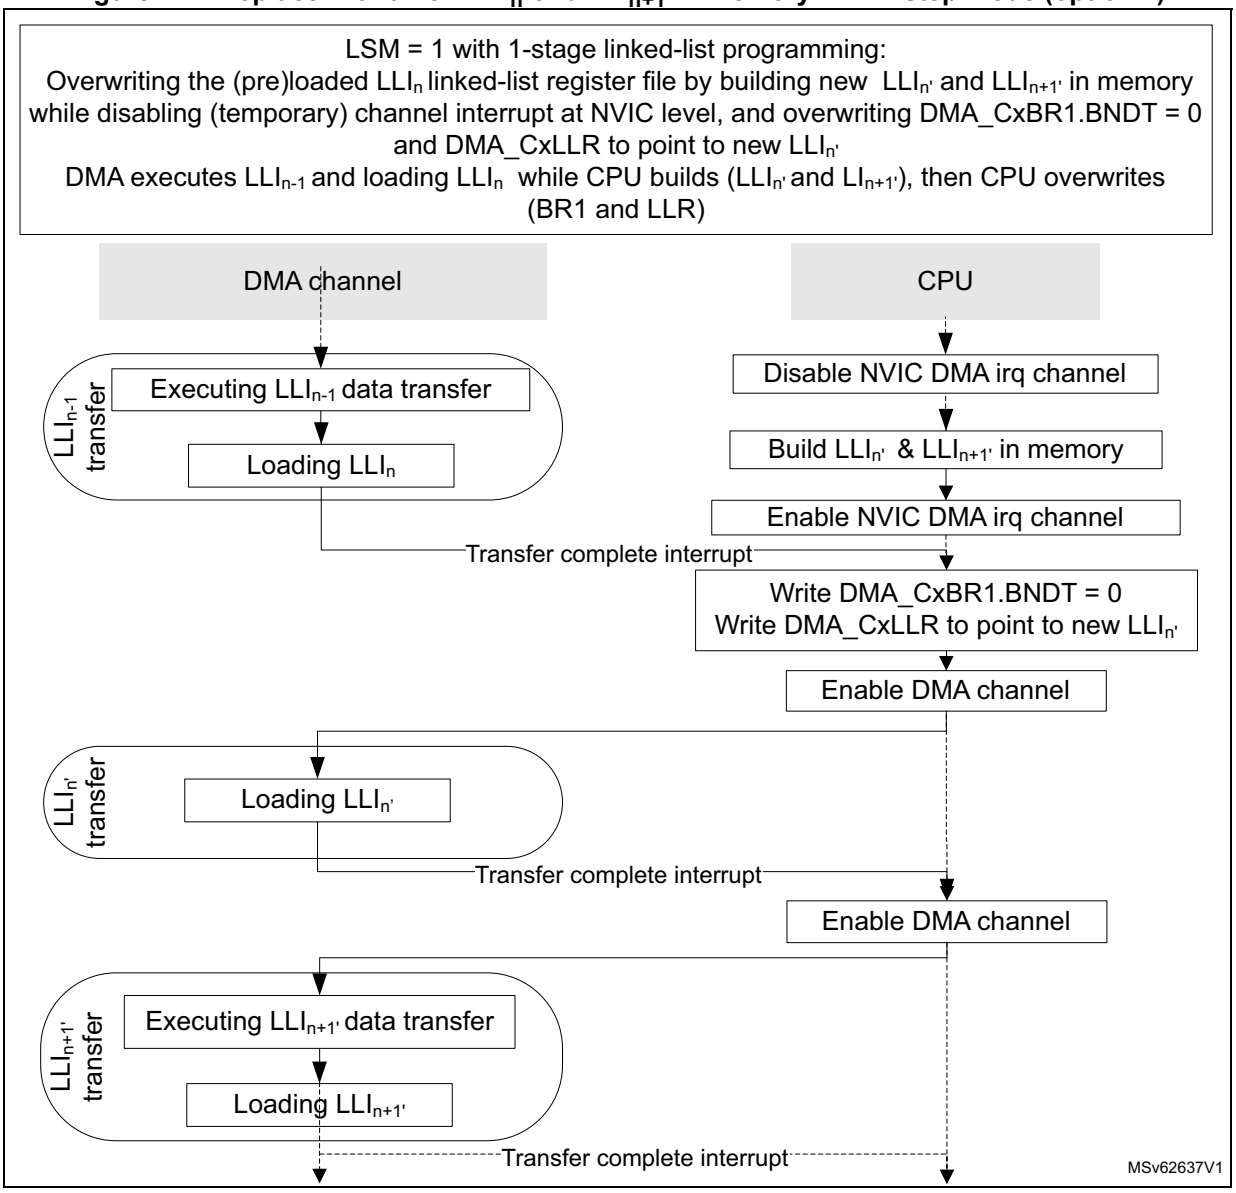
Run-time replacing an LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after HPDMA executed the transfer from the LLI_{n-1}, and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (HPDMA_CxBR1.BNDT[15:0] to be null, and HPDMA_CxLLR to point to new LLI_n) as shown in *Figure 121*.

Figure 121. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile the HPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite HPDMA_CxBR1.BNDT[15:0] to be null and HPDMA_CxLLR to point to new $LLI_{n'}$, as shown in the figure below.

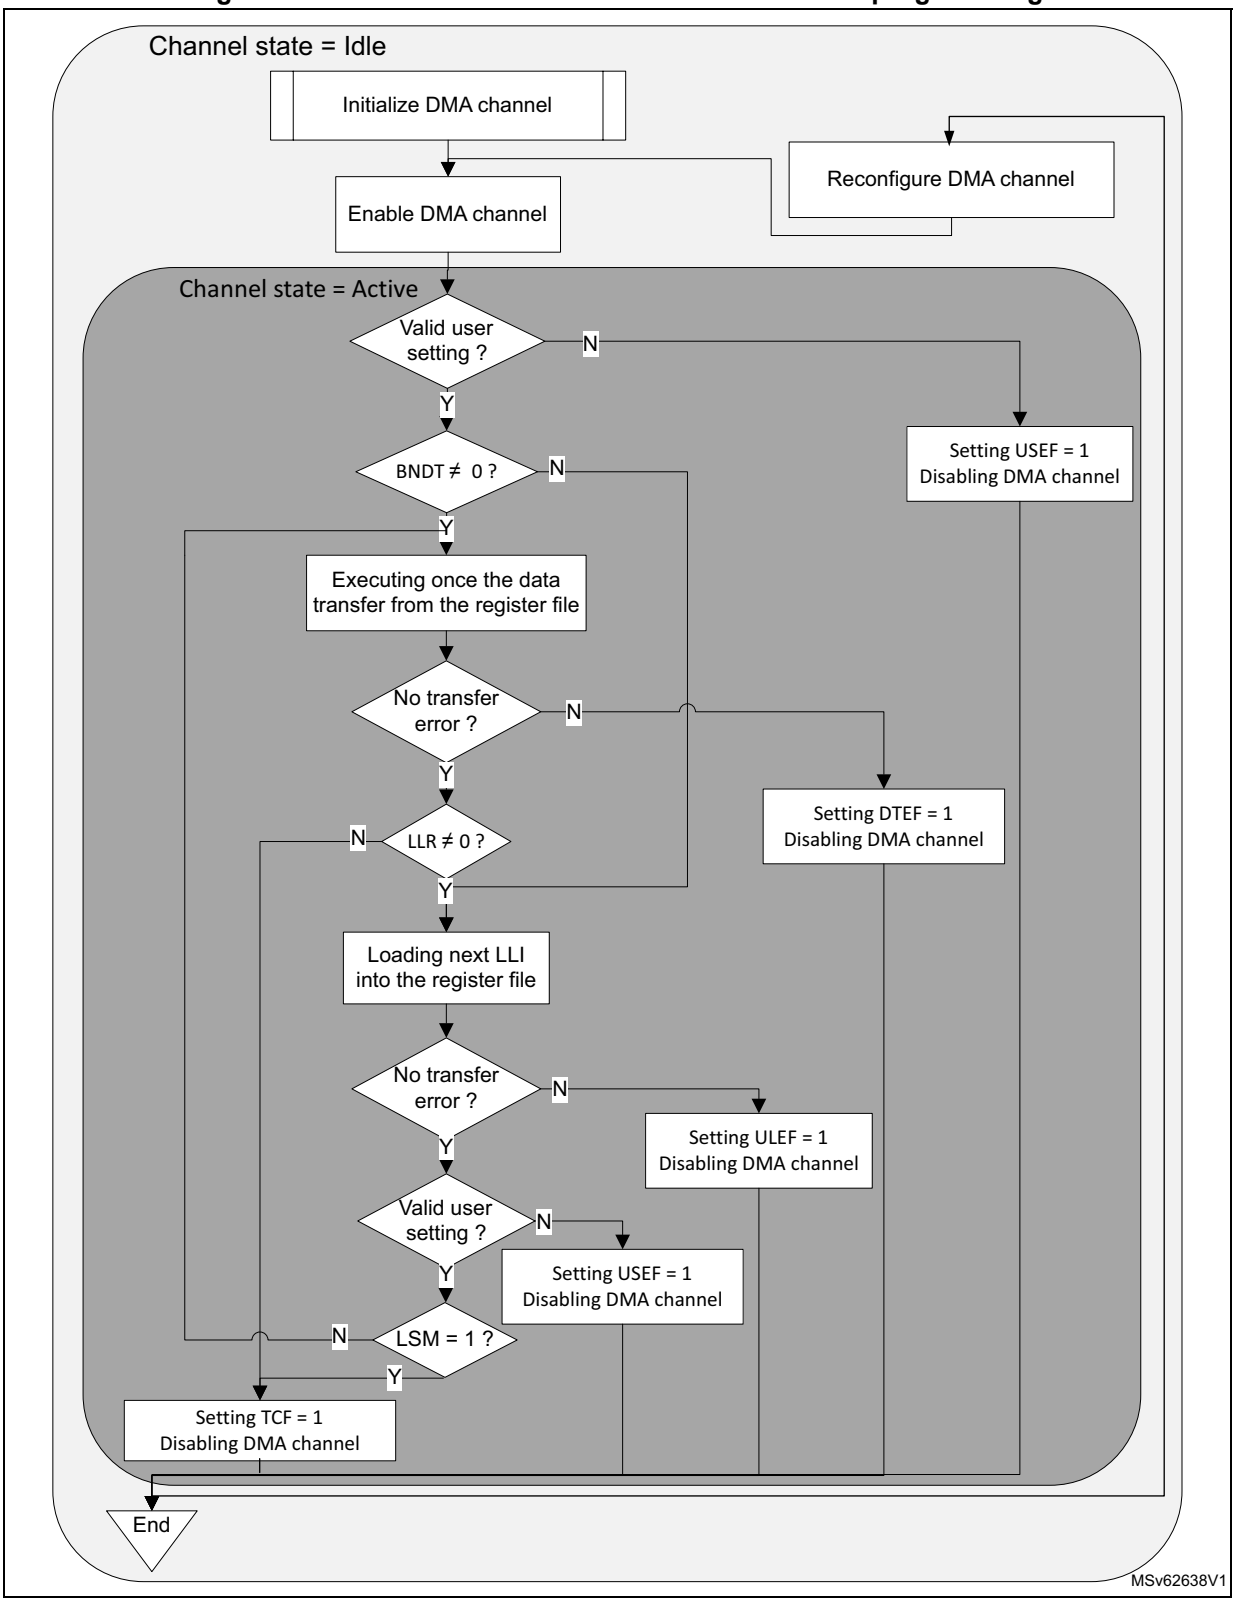
Figure 122. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

13.4.9 HPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (HPDMA_CxCR.EN = 0), and update the execution mode (HPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the HPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the HPDMA channel
- abort and reconfigure the channel with an LSM update (see *Section 13.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 123 shows the overall and unified HPDMA linked-list programming, whatever is the execution mode.

Note: Figure 123 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in HPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 123, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes BNDT ≠ 0 and PFREQ = 1 if the peripheral requests a data transfer with early termination (see Section 13.3.5).

Figure 123. HPDMA channel execution and linked-list programming

13.4.10 HPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 13.3.1* for more details).

HPDMA burst

A programmed transfer at the lowest level is an HPDMA burst.

An HPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in HPDMA_CxTR1.

The addressing mode after each data (named beat) of an HPDMA burst is defined by SINC and DINC in HPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of an HPDMA source/destination burst (defined by HPDMA_CxSAR and HPDMA_CxDAR) must be aligned with the respective data width.

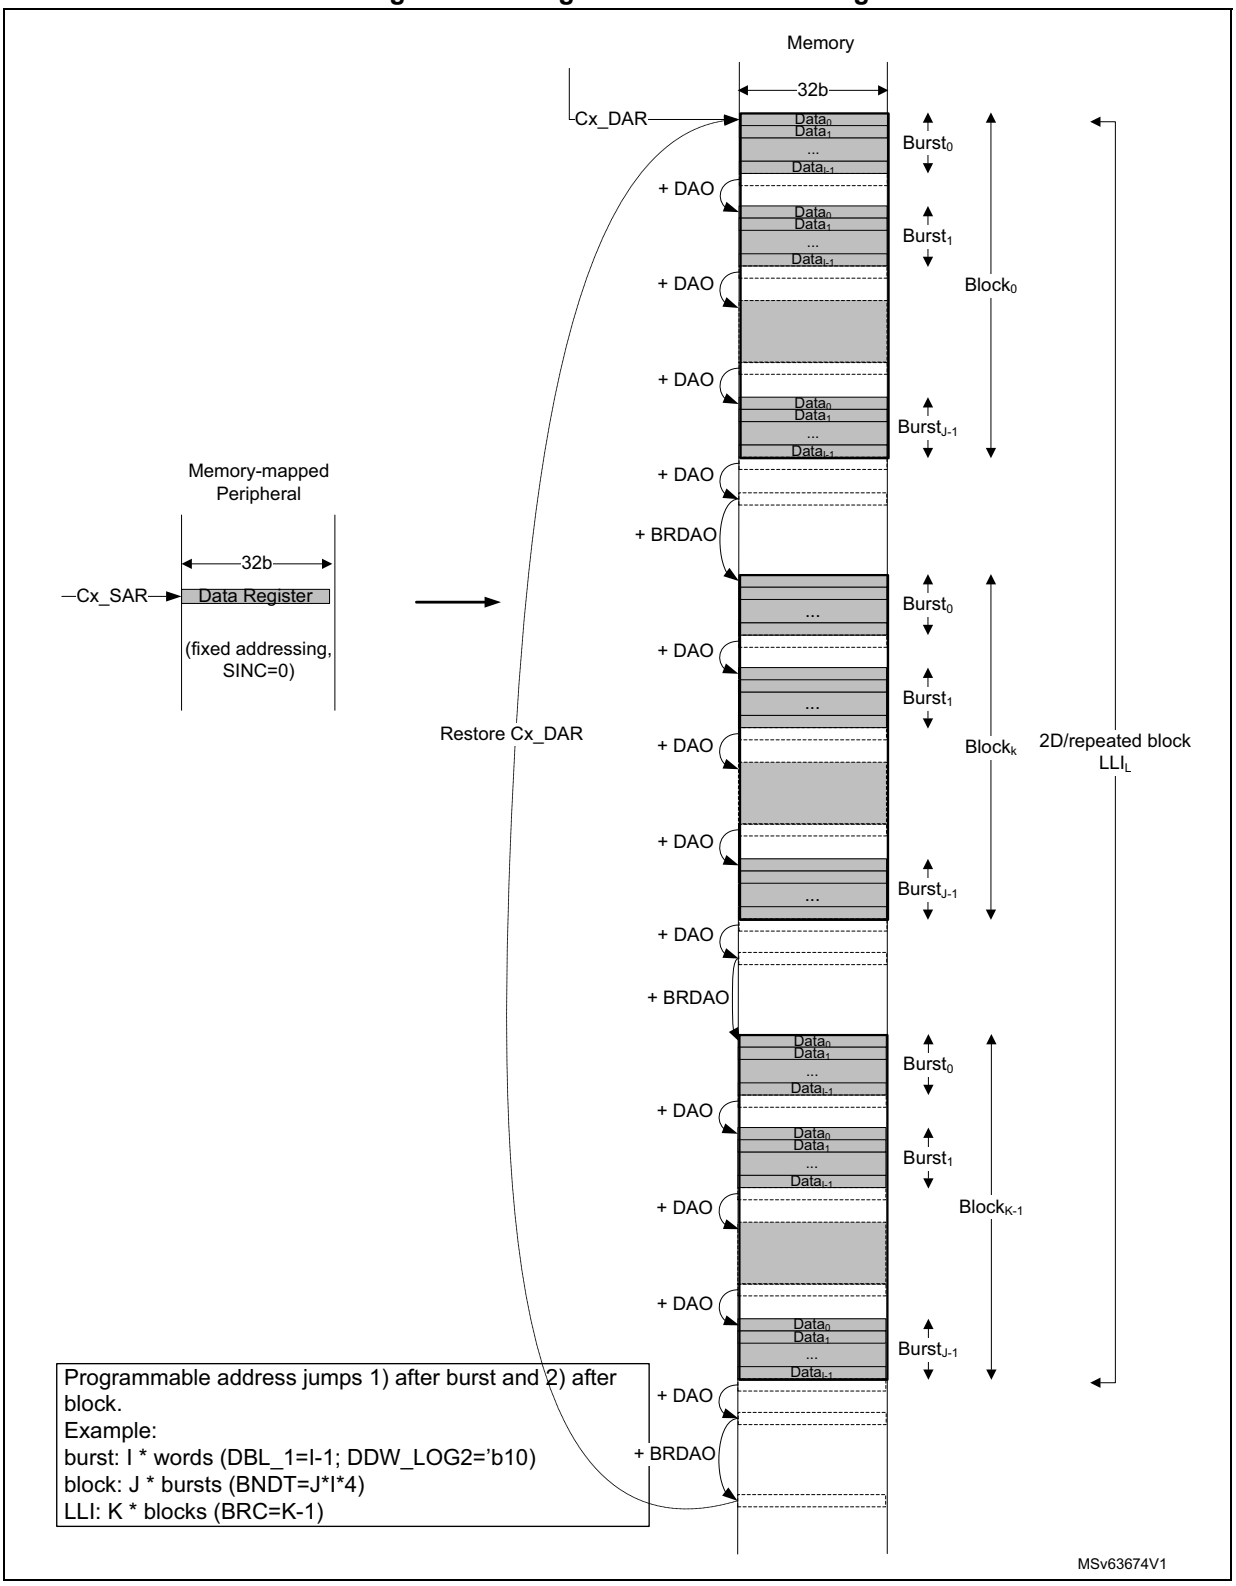
The table below lists the main characteristics of an HPDMA burst.

Table 107. Programmed HPDMA source/destination burst

SAP/DAP (allocated port)	SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/ beats)	Next data/ beat address	Next burst address	Burst address alignment
0: AXI 1: AHB	00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
	01	2						2
	10	4						4
0: AXI	11	8						8
0: AXI 1: AHB	00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
	01	2				+ 2	+ 2 * (n + 1)	2
	10	4				+ 4	+ 4 * (n + 1)	4
0: AXI	11	8				+ 8	+ 8 * (n + 1)	8
0: AHB	11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by HPDMA_CxSAR or HPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



HPDMA burst with 2D addressing (channel x = 12 to 15)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by HPDMA_CxTR2.SAO[12:0]/DAO[12:0] and HPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by HPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and HPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 124* with a 2D destination buffer.

Figure 124. Programmed 2D addressing

HPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by HPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by HPDMA_CxTR1.DAP

HPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the channel x FIFO size, in bytes (see *Section 13.3.1* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (HPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

HPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

HPDMA burst versus source block size, 1- or 4-Kbyte address boundary and FIFO size

The programmed source/destination HPDMA burst is implemented with an AHB/AXI burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination HPDMA burst is implemented with a series of singles or bursts of a lower size, each transfer being of a size that is lower or equal than half of the FIFO size, without any user constraint.
- if the source block size (HPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (HPDMA_CxTR1.SDW_LOG2[1:0]), the HPDMA modifies and shortens bursts into

singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1- or 4-Kbyte address boundary on, respectively, an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, or if the source/destination burst on an AXI transfer is both with fixed addressing and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol, without any user constraint.

In any case, the HPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in HPDMA_CxSR) is compared to and updated with the effective transfer size, and the HPDMA re-arbitrates between each AHB/AXI single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the HPDMA read transfers related to the update of the linked-list parameters from the memory to the internal HPDMA registers, are scheduled over the link allocated port, as programmed by HPDMA_CxCR.LAP.

HPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension, and left/right alignment

The data handling is controlled by HPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word, word, or double-word, as per SDW_LOG2[1:0] and DDW_LOG2[1:0] (see *Table 108*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if the source data width is a word or a double-word (for AXI source bus, SAP = 0), the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data-width conversion by packing, unpacking, padding, or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.

3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.
   - If DWX = 1and if the destination data width is a double-word and the destination bus is AXI (DAP = 0), the two aligned words are exchanged within aligned (post PAM[1:0]) double-words).

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding, and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 108. Programmed data handling

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.
3. RA= right aligned. LA = left aligned. RT = right truncated. LT = left truncated.
4. 0P= zero-bit padding up to the destination data width. SE = sign bit extended up to the destination data width.
5. if DDW_LOG2[1:0] = 11 and if DAP = 0 (destination allocated port is AXI). Else if DDW_LOG2[1:0] = 11 and DAP = 1 (AHB), a user setting error (USEF) is reported.
6. if SDW_LOG2[1:0] = 11 and if SAP = 0 (source allocated source port is AXI). Else if SDW_LOG2[1:0] = 11 and SAP = 1 (AHB), a user setting error (USEF) is reported.

13.4.11 HPDMA transfer request and arbitration

HPDMA transfer request

As defined by HPDMA_CxTR2, a programmed HPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the HPDMA hardware peripheral request is driven by REQSEL[4:0] (see *Section 13.3.4*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in HPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control register update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign the same input hardware peripheral HPDMA request via HPDMA_CxTR.REQSEL[4:0] to two different channels, if at a given time this request is asserted by the peripheral, and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

HPDMA transfer request for arbitration

A ready FIFO-based HPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (HPDMA_CxTR1.SAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

A ready FIFO-based HPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (HPDMA_CxTR1.DAP) is arbitrated based on the channel priority (HPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested HPDMA transfers to the same master port.

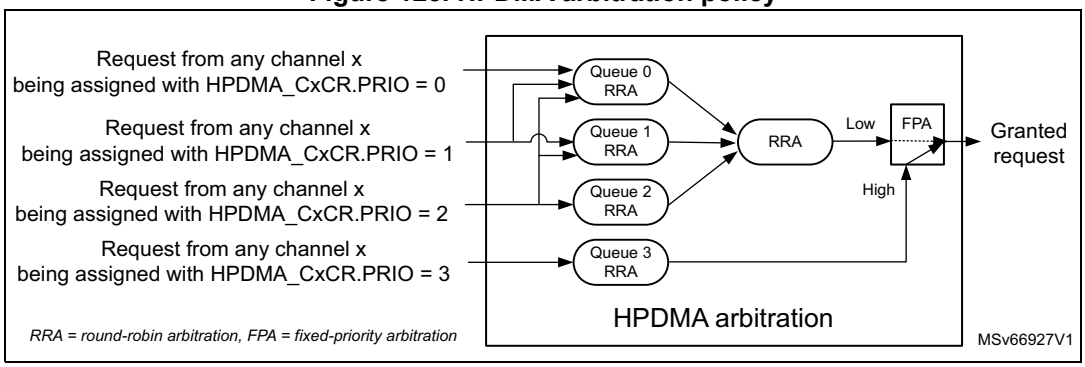
An arbitrated HPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in the memory to one of the linked-list registers (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, HPDMA_CxTR3, HPDMA_CxBR2 or HPDMA_CxLLR). Each 32-bit read from the memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (HPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (HPDMA_CxTR2.SWREQ = 1), or with a hardware request (HPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (HPDMA_CxTR2.SWREQ = 0 and HPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request

to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

HPDMA arbitration



The HPDMA arbitration is directed from the 4-grade assigned channel priority (HPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 125*, is defined by:

- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1 or 2) for non time-sensitive channels with priority 0, 1 or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.
  - Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
  - Any queue 0, 1 or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
  - Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1 and queue 2.

Figure 125. HPDMA arbitration policy

HPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- equal maximum bandwidth between requests with same priority
- reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive HPDMA requests: req0 and req1. There are the following programming possibilities:
  - If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).

    $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).

    $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$

    $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  - If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).

    $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$

    $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$

  The above computed bandwidth calculation is based on a theoretical input request, always active for any HPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one HPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.
- **Example 2**: application where the user distributes a same non-null N number of HPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is

    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is

    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is

    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is

    $B_{n, P0} = 1/N * 1/9 * (1 - B_{Q3})$

    $B_{n, P1} = 1/N * 5/18 * (1 - B_{Q3})$

    $B_{n, P2} = 1/N * 11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for J > 0 (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ (K>0 in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 (K > 0)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 (K = 0)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the HPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

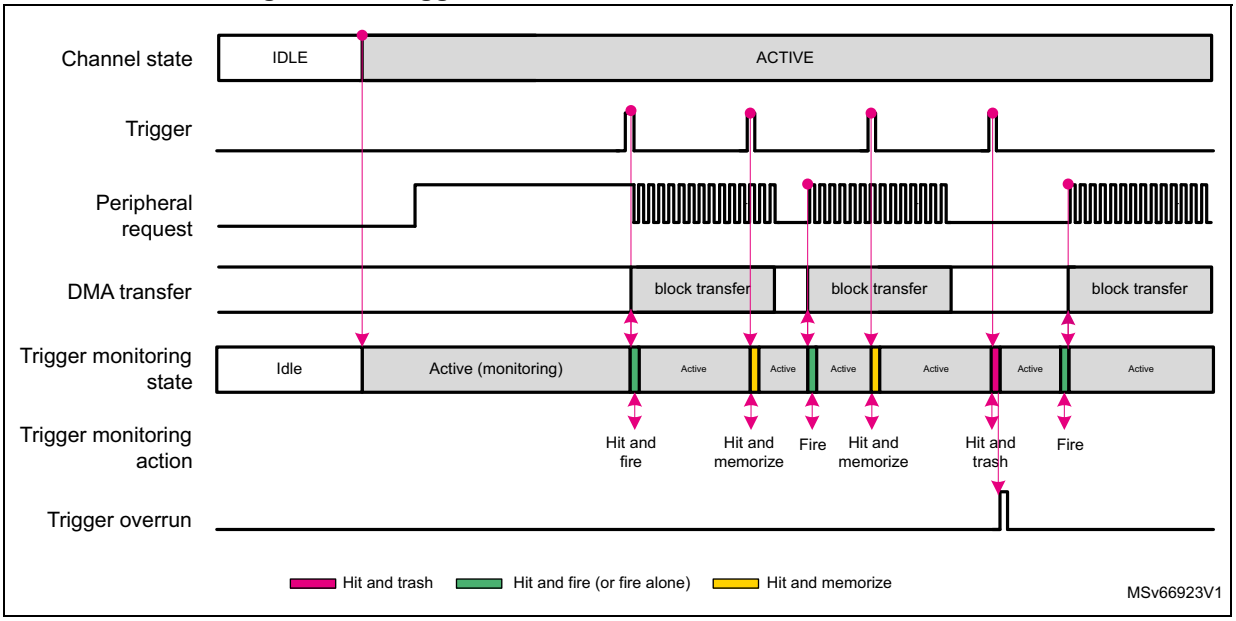
13.4.12 HPDMA triggered transfer

A programmed HPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by HPDMA_CxTR2.TRIGPOL[1:0] and HPDMA_CxTR2.TRIGSEL[5:0] (see *Section 13.3.6* for the trigger selection).

The triggered transfer, as defined by the trigger mode in HPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block (for channel x = 12 to 15), or each programmed burst read/write. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details).

Trigger hit memorization and trigger overrun flag generation

The HPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

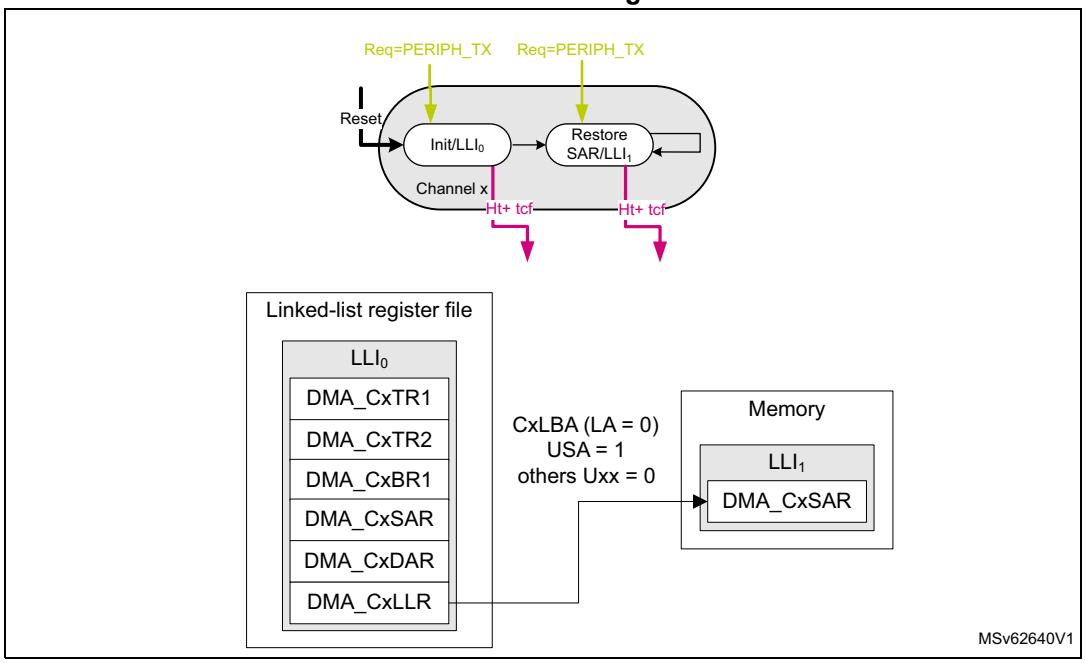
Caution: After a first new trigger, hit_{n+1} is memorized. If another trigger hit_{n+2} is detected, and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

The figure below illustrates the trigger hit, memorization, and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 126. Trigger hit, memorization and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

13.4.13 HPDMA circular buffering with linked-list programming



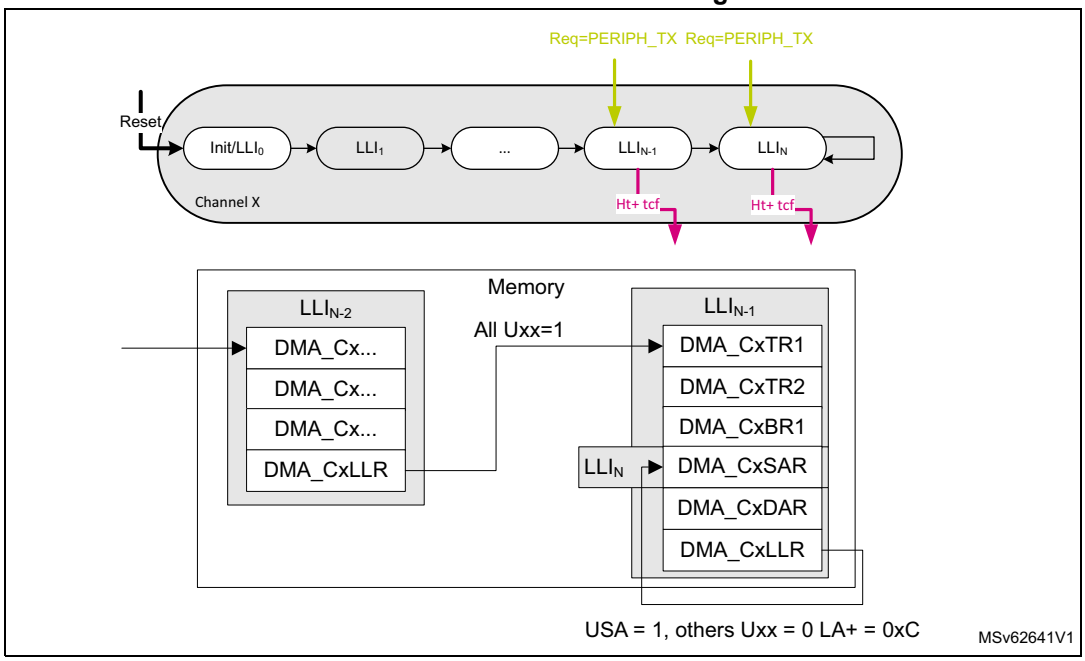
HPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel

For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete-transfer event/interrupt generation (HPDMA_CxCR.HTIE = 1 and HPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel.
A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address for the memory-to-peripheral transfer (respectively the peripheral-to-memory).
The HPDMA automatically reloads the initially programmed HPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore HPDMA_CxBR1.

The figure below illustrates this programming with a linear addressing HPDMA channel and a source circular buffer.

Figure 127. HPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, a single LLI can be used with HPDMA_CxBR1.BRC[10:0] = 1. The user can program a negative memory block address offset with HDMA_CxBR2 and HDMA_CxBR1, in order to jump back to the memory source or destination start address.

If the circular buffering must be executed after some other transfers over the shared HPDMA channel x, the before-last LLI_{N-1} in the memory is needed to configure the first block transfer. The last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory).

The figure below illustrates this programming with a linear addressing shared HPDMA channel, and a source circular buffer.

Figure 128. Shared HPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

13.4.14 HPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate an HPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 13.3.5*).

If the related HPDMA channel x is also programmed in peripheral flow-control mode (HPDMA_CxTR2.PFREQ = 1):

- The HPDMA block transfer starts as follows:
  - If HPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the HPDMA hardware.
  - If HPDMA_CxBR1.BNDT[15:0] = 0, the HPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The HPDMA block transfer is completed as soon as the first occurrence of any of the following condition occurs:
  - when HPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on HPDMA_CxTR2. Then the software can read the current number of transferred bytes from the source (HPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (HPDMA_CxSAR[31:0] or HPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with an hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- HPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

13.4.15 HPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via HPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a bitfield of this channel is forced to return 0, except for HPDMA_PRIVCFGR that is readable by an unprivileged agent.
- An unprivileged write access to a bitfield of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB/AXI master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the HPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the HPDMA_CxCR.LAP allocated master port.

The HPDMA generates a privileged bus that reflects HPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each HPDMA channel x.

13.4.16 HPDMA error management

The HPDMA can manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as an AHB/AXI single or a burst) to the source or the destination

- The source or destination target reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware). The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1) and the data error (HPDMA_CxSR.DTEF = 1).
- After an HPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After an HPDMA data transfer error, the user must issue a channel reset (set HPDMA_CxCR.RESET) to reset the hardware HPDMA channel data path and the FIFO content, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a HPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB/AXI error.
- The programmed channel transfer is stopped (HPDMA_CxCR.EN cleared by the HPDMA hardware), the channel status register reports an idle state HPDMA_CxSR.IDLEF = 1), and the link error (HPDMA_CxSR.ULEF = 1).
- After an HPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (HPDMA_CxLBAR and HPDMA_CxLLR), including the protection attributes.
- After an HPDMA link error, the user must explicitly write the linked-list register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR, plus HPDMA_CxTR3 and HPDMA_CxBR2 when present), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of an HPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (HPDMA_CxCR.EN forced and cleared by the HPDMA hardware), preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (HPDMA_CxSR.IDLEF = 1), and a user setting error (HPDMA_CxSR.USEF = 1).
- After an HPDMA user setting error, the user must perform a debug session, taking care of the HPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxLLR.UB1 = 0)
  - a programmed non-null source block size being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - when in packing/unpacking mode (if PAM[1] = 1), a programmed non-null source block size being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR1.BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed unaligned source start address being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxSAR[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x =12 to 15, a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxTR3.SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x =12 to 15, a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (HPDMA_CxBR2.BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxDAR[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])

- for channel x =12 to 15, a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxTR3.DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
- for channel x =12 to 15, a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (HPDMA_CxBR2.BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0])
- a programmed double-word source data width and a programmed AHB source allocated port (HPDMA_CxTR1.SDW_LOG2[1:0] = 11 and HPDMA_CxTR1.SAP = 1)
- a programmed double-word destination data width and a programmed AHB destination allocated port (HPDMA_CxTR1.DDW_LOG2[1:0] = 11 and HPDMA_CxTR1.DAP = 1)
- a programmed linked-list item LLI_{n+1} with a null data transfer (HPDMA_CxLLR.UB1 = 1 and HPDMA_CxBR1. BNDT = 0)

13.5 HPDMA in debug mode

When the device enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, HPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, HPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

13.6 HPDMA in low-power modes

Table 109. Effect of low-power modes on HPDMA

Mode	Description
Sleep	No effect. HPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of HPDMA registers is kept when entering Stop mode.
Standby	The HPDMA is powered down, and must be reinitialized after exiting Standby mode.

1. Refer to *Section 13.3.2* to know which Stop mode is supported.

13.7 HPDMA interrupts

There is one HPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 110. HPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
HPDMA_CHx	Transfer complete	HPDMA_CxCR.TCIE	HPDMA_CxSR.TCF	Writes 1 to HPDMA_CxFCR.TCF
	Half transfer	HPDMA_CxCR.HTIE	HPDMA_CxSR.HTF	Writes 1 to HPDMA_CxFCR.HTF
	Data transfer error	HPDMA_CxCR.DTEIE	HPDMA_CxSR.DTEF	Writes 1 to HPDMA_CxFCR.DTEF
	Update link error	HPDMA_CxCR.ULEIE	HPDMA_CxSR.ULEF	Writes 1 to HPDMA_CxFCR.ULEF
	User setting error	HPDMA_CxCR.USEIE	HPDMA_CxSR.USEF	Writes 1 to HPDMA_CxFCR.USEF
	Suspended	HPDMA_CxCR.SUSPIE	HPDMA_CxSR.SUSPF	Writes 1 to HPDMA_CxFCR.SUSPF
	Trigger overrun	HPDMA_CxCR.TOFIE	HPDMA_CxSR.TOF	Writes 1 to HPDMA_CxFCR.TOF

An HPDMA channel x event can be:

- a transfer complete
- an half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal hpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (HPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (HPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into HPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by HPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer-complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].
- A half-transfer event is an half-block transfer, or a half 2D/repeated block transfer, depending on the transfer complete event mode HPDMA_CxTR2.TCEM[1:0].

An half-block transfer occurs when half of the source block size bytes (rounded-up integer of HPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

An half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (HPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *HPDMA channel x transfer register 2 (HPDMA_CxTR2)* for more details.

Note: The interrupt mode must be used (not the polling mode) to be notified on an half transfer when the write data transaction has been completed over the AXI destination allocated port (written at the destination memory-mapped address), and not just before when has been issued, at HPDMA level, this AXI burst transaction.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of an HPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of an HPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the HPDMA channel programming versus the USEF root causes list (see *Section 13.4.16*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

13.8 HPDMA registers

The HPDMA registers must be accessed with an aligned 32-bit word data access.

13.8.1 HPDMA privileged configuration register (HPDMA_PRIVCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a HPDMA channel (HPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PRIVx**: Privileged state of channel x (x = 15 to 0)
0: Unprivileged
1: Privileged

13.8.2 HPDMA configuration lock register (HPDMA_RCFGLOCKR)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be written by a software agent with privileged attributes in order to individually lock, for example at boot time, the privileged attributes of any HPDMA channel/resource (to lock the setting of HPDMA_PRIVCFGR for any channel x at, for example at boot time).

A read access may be privileged or unprivileged.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LOCKx**: Lock of the configuration of HPDMA_PRIVCFGR.PRIVx until a global HPDMA reset (x = 15 to 0)
This bit is cleared after reset and, once set, it cannot be reset until a global HPDMA reset.
0: privilege configuration of the channel x is writable.
1: privilege configuration of the channel x is not writable.

13.8.3 HPDMA masked interrupt status register (HPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This is a read register.

This register contains the masked interrupt status bit MISx for each channel x. It is a logical OR of all the HPDMA_CxSR flags, each source flag being enabled by the corresponding HPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when writing 1 to the corresponding HPDMA_CxFCR flag clear bit.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel HPDMA_PRIVCFGR.PRIVx. A privileged software can read the full interrupt status. An unprivileged software is restricted to read the status of unprivileged channels, other privileged bitfields returning zero.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISx**: Masked interrupt status of channel x (x = 15 to 0)
0: No interrupt occurred on channel x.
1: An interrupt occurred on channel x.

13.8.4 HPDMA channel x linked-list base address register (HPDMA_CxLBAR)

Address offset: 0x050 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x HPDMA_PRIVCFGR.PRIVx.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the HPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit HPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: Linked-list base address of HPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

13.8.5 HPDMA channel x flag clear register (HPDMA_CxFCR)

Address offset: 0x05C+ 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This is a write register privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag clear
0: No effect
1: Corresponding TOF flag cleared

Bit 13 **SUSPF**: Completed suspension flag clear
0: No effect
1: Corresponding SUSPF flag cleared

Bit 12 **USEF**: User setting error flag clear
0: No effect
1: Corresponding USEF flag cleared

Bit 11 **ULEF**: Update link transfer error flag clear
0: No effect
1: Corresponding ULEF flag cleared

Bit 10 **DTEF**: Data transfer error flag clear
0: No effect
1: Corresponding DTEF flag cleared

Bit 9 **HTF**: Half transfer flag clear
0: No effect
1: Corresponding HTF flag cleared

Bit 8 **TCF**: Transfer complete flag clear
0: No effect
1: Corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

13.8.6 HPDMA channel x status register (HPDMA_CxSR)

Address offset: 0x060 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is privileged or unprivileged, depending on the privileged state of the channel (HPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[8:0]								
							r	r	r	r	r	r	r	r	r

	r	r	r	r	r	r	r								r

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **FIFOL[8:0]**: Monitored FIFO level

Number of available write beats in the FIFO, in units of the programmed destination data width (see *Section 13.8.8: HPDMA channel x transfer register 1 (HPDMA_CxTR1)* DDW_LOG2[1:0], in units of bytes, half-words, words or double-words).

Note: After having suspended an active transfer, the user may need to read FIFOL[8:0], additionally to HPDMA_CxBR1.BDNT[15:0] and HPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (HPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: Trigger overrun flag

0: No trigger overrun event

1: A trigger overrun event occurred.

Bit 13 **SUSPF**: Completed suspension flag

0: No completed suspension event

1: A completed suspension event occurred.

Bit 12 **USEF**: User setting error flag

0: No user setting error event

1: A user setting error event occurred.

Bit 11 **ULEF**: Update link transfer error flag

0: No update link transfer error event

1: A master bus error event occurred while updating a linked-list register from memory.

Bit 10 **DTEF**: Data transfer error flag

0: No data transfer error event

1: A master bus error event occurred on a data transfer.

Bit 9 **HTF**: Half transfer flag

0: No half transfer event

1: An half transfer event occurred.

An half transfer event is either an half block transfer or an half 2D/repeated block transfer, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).

An half block transfer occurs when half of the bytes of the source block size (rounded up integer of HPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.

An half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (HPDMA_CxBR1.BRC[10:0]+1)/2)) has been transferred to the destination.

Bit 8 **TCF**: Transfer complete flag

0: No transfer complete event

1: A transfer complete event occurred.

A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (HPDMA_CxTR2.TCEM[1:0]).

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **IDLEF**: Idle flag

0: Channel not in idle state

1: Channel in idle state

This idle flag is deasserted by hardware when the channel is enabled (HPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).

This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

13.8.7 HPDMA channel x control register (HPDMA_CxCR)

Address offset: 0x064 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x (HPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** Priority level of the channel x HPDMA transfer versus others
00: Low priority, low weight
01: Low priority, mid weight
10: Low priority, high weight
11: High priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: lLnked-list allocated port
This bit is used to allocate the master port for the update of the HPDMA linked-list registers from the memory.
0: Port 0 (AXI) allocated
1: Port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: Channel executed for the full linked-list and completed at the end of the last LLI (HPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0 if present). Then HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0 if present.
1: Channel executed once for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until HPDMA_CxBR1.BNDT[15:0] = 0 and HPDMA_CxBR1.BRC[10:0] = 0, if present. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by HPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: Trigger overrun interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 13 **SUSPIE**: cCmpleted suspension interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 12 **USEIE**: User setting error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 11 **ULEIE**: Update link transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 10 **DTEIE**: Data transfer error interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 9 **HTIE**: Half transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bit 8 **TCIE**: Transfer complete interrupt enable
0: Interrupt disabled
1: Interrupt enabled

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **SUSP:** Suspend

Writing 1 to RESET in this register causes the hardware to deassert this SUSP bit, whatever is written into this SUSP. Else:

Software must write 1 in order to suspend an active channel (a channel with an ongoing HPDMA transfer over its master ports).

The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 110*.

0: Write: resume channel, read: channel not suspended

1: Write: suspend channel, read: channel suspended

Bit 1 **RESET:** Reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP and EN bits (whatever is written receptively in bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (HPDMA_CxSR.SUSPF = 1 and HPDMA_CxSR.IDLEF = HPDMA_CxCR.EN = 1)
- channel in disabled state (HPDMA_CxSR.IDLEF = 1 and HPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (HPDMA_CxBR1, HPDMA_CxSAR and HPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 111*).

0: No channel reset

1: Channel reset

Bit 0 **EN:** Enable

Writing 1 to RESET in this register causes the hardware to deassert this EN bit, whatever is written into this bit 0. Else:

This bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: Write: ignored, read: channel disabled

1: Write: enable channel, read: channel enabled

13.8.8 HPDMA channel x transfer register 1 (HPDMA_CxTR1)

Address offset: 0x090 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of the channel x in HPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	DAP	Res.	DWX	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DAP**: Destination allocated port

This bit is used to allocate the master port for the destination transfer

0: Port 0 (AXI) allocated

1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DWX**: Destination word exchange

If the destination data size is not a double-word, this bit is ignored.

If the destination data size is a double-word and if destination bus is AXI (DAP = 0):

0: No word-based exchanged within double-word

1: The two consecutive (post PAM) words are exchanged in each destination double-word.

Bit 27 **DHX**: Destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word or double-word and if destination bus is AXI (DAP = 0):

0: No half-word-based exchanged within word

1: The two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: Destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0: No byte-based exchange within half-word

1: The two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: Destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB/AXI protocol.

If the burst length exceeds 16 on an AHB transfer, or if the burst on an AXI transfer is both with fixed addressing (DINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into bursts of lower length, to be compliant with the AHB or AXI protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: Destination incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The destination address, pointed by HPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: Binary logarithm of the destination data width of a burst, in bytes

00: Byte

01: Half-word (2 bytes)

10: Word (4 bytes)

11: If DAP = 0 (AXI), double-word (8 bytes)

if DAP = 1, user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address HPDMA_CxDAR[2:0] and if present address offset HPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

When configured in packing mode (PAM[1] = 1 and destination data width different from source data width), a source block size must be a multiple of the destination data width (see HPDMA_CxBR1.BNDT[2:0] versus DDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **SAP**: Source allocated port

This bit is used to allocate the master port for the source transfer

0: Port 0 (AXI) allocated

1: Port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: Source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word or a double-word, and if source bus is AXI (SAP = 0):

0: No byte-based exchange within the unaligned half-word of each source word

1: The two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: Padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: Source data is transferred as right aligned, padded with 0s up to the destination data width

01: Source data is transferred as right aligned, sign extended up to the destination data width

10-11: Successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: Source data is transferred as right aligned, left-truncated down to the destination data width

01: Source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: Source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: Source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1- or 4-Kbyte address boundary on respectively an AHB or an AXI transfer, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If the burst length exceeds 16 on a AHB transfer, or if the burst on a AXI transfer is both with fixed addressing (SINC = 0) and with a burst length which exceeds 16, the HPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with HPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: Source incrementing burst

0: Fixed burst

1: Contiguously incremented burst

The source address, pointed by HPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: Binary logarithm of the source data width of a burst in bytes
00: Byte
01: Half-word (2 bytes)
10: Word (4 bytes)
11: If SAP = 0 (AXI), double-word (8 bytes)
if SAP = 1, user setting error reported and no transfer issued

Note: A source block size must be a multiple of the source data width (HPDMA_CxBR1.BNDT[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and no transfer is issued.

A source burst transfer must have an aligned address with its data width (start address HPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

A burst with a double-word data width must be allocated to the AXI master port, else a user setting error is reported and none transfer is issued.

13.8.9 HPDMA channel x transfer register 2 (HPDMA_CxTR2)

Address offset: 0x094 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory, if HPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	Res.	Res.	Res.	REQSEL[4:0]				
rw	rw		rw	rw	rw	rw					rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: Transfer complete event mode

These bits define the transfer granularity for the transfer complete and half transfer complete events generation.

00: At block level (when HPDMA_CxBR1.BNDT[15:0] = 0): The complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

01: Channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level (when HPDMA_CxBR1.BRC[10:0] = 0 and HPDMA_CxBR1.BNDT[15:0] = 0), the complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half transfer event is generated.

10: At LLI level: The complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half transfer event is generated at the half of the LLI data transfer (the LLI data transfer being a block transfer or a 2D/repeated block transfer for channel x = 12 to 15), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with HPDMA_CxBR1.BNDT[15:0] = 0), then the half transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: At channel level: The complete transfer event is generated at the end of the last LLI transfer. The half transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address HPDMA_CxLLR.LA[15:2] to zero and clears all the HPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2 if present). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: Trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: No trigger (masked trigger event)

01: Trigger on the rising edge

10: Trigger on the falling edge

11: Same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: Trigger event input selection

These bits select the trigger event input of the HPDMA transfer (as per *Section 13.3.6*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: Trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (HPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, an HPDMA transfer is conditioned by at least one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x = 12 to 15, for each block if a 2D/repeated block is configured with HPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x = 0 to 11, same as 00; channel x = 12 to 15, at 2D/repeated block level, the first burst read of a 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. The LLI data transfer (if any) is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger.

– If the peripheral is programmed as a source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is programmed as a destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and the first trigger hit.

The HPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10).

The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled.

Transferring a next LLI_{n+1} that updates the HPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (HPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (HPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1/4-Kbyte boundary address crossing maximum burst length versus AHB/AXI protocol): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 13.3.5 for the list of the implemented channels with this feature.

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in HPDMA control mode. The HPDMA is programmed with HPDMA_CxCBR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The HPDMA block transfer can be early completed by the peripheral itself (see *Section 13.3.5* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (HPDMA_CxBR1.BRC[10:0] must be set to 0 if present)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, HPDMA_CxTR1.PAM[1] must be set to 0).

- HPDMA_CxBR1.BNDT[15:0] must be set as a multiple of the source (peripheral) burst size.

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: The selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 13.3.4*).

Bit 10 **DREQ**: Destination hardware request

This bit is ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: Selected hardware request driven by a source peripheral (request signal taken into account by the HPDMA transfer scheduler over the source/read port)

1: Selected hardware request driven by a destination peripheral (request signal taken into account by the HPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (HPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: Software request

This bit is internally taken into account when HPDMA_CxCR.EN is asserted.

0: No software request. The selected hardware request REQSEL[4:0] is taken into account.

1: Software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[4:0] is ignored.

Bits 8:5 Reserved, must be kept at reset value.

Bits 4:0 **REQSEL[4:0]**: Hardware request selection

These bits are ignored if channel x is activated (HPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 13.3.3*.

Caution: The user must not assign a same input hardware request (same REQSEL[4:0] value) to different active HPDMA channels (HPDMA_CxCR.EN = 1 and HPDMA_CxTR2.SWREQ = 0 for these channels). The HPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

13.8.10 HPDMA channel x block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfield BNDT[15:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If HPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.
- if HPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this bitfield is internally restored to the programmed value.
- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] = 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).
- if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (HPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

13.8.11 HPDMA channel x alternate block register 1 (HPDMA_CxBR1)

Address offset: 0x098 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has de-asserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer:

- if HPDMA_CxLLR.UB1 = 1, this register is automatically updated by the HPDMA from the next LLI in memory.
- If HPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0].
- If all the update bits HPDMA_CxLLR.Uxx are null and if HPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the bitfields BNDT[15:0] and BRC[10:0] after each execution of this final LLI
- If HPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: At the end of a block transfer, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxBR2.BRDAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a block transfer, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRDAO from the current HPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), HPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the HPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: At the end of a block transfer, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxBR2.BRSAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a block transfer, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxBR2.BRSAO from the current HPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), HPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the HPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by adding the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the HPDMA_CxDAR register is updated by subtracting the programmed offset HPDMA_CxTR3.DAO to the current HPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by adding the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the HPDMA_CxSAR register is updated by subtracting the programmed offset HPDMA_CxTR3.SAO to the current HPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This bitfield contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this bitfield becomes read-only. After decrements, this bitfield indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If HPDMA_CxLLR.UB1 = 1, all HPDMA_CxBR1 bitfields are updated by the next LLI in the memory.

– If HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.

– if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).

– if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: Block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this bitfield becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred.

BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if HPDMA_CxLLR.UB1 = 1, this bitfield is updated by the LLI in the memory.

- if HPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this bitfield is internally restored to the programmed value.

- if all HPDMA_CxLLR.Uxx = 0 and if HPDMA_CxLLR.LA[15:0] ≠ 0, this bitfield is internally restored to the programmed value (infinite/continuous last LLI).

- if HPDMA_CxLLR = 0, this bitfield is kept as zero following the last LLI data transfer.

Note: A non-null source block size must be a multiple of the source data width (BNDT[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

When configured in packing mode (HPDMA_CxTR1.PAM[1] = 1 and destination data width different from source data width), a non-null source block size must be a multiple of the destination data width (BNDT[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.

13.8.12 HPDMA channel x source address register (HPDMA_CxSAR)

Address offset: 0x09C + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: Source address

This bitfield is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (HPDMA_CxTR1.SINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.SBL_1[5:0] and HPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by HPDMA_CxBR1.SDEC and HPDMA_CxTR3.SAO[12:0]

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 12 to 15). additional block repeat source incremented/decremented offset value as programmed by HPDMA_CxBR1.BRSDEC and HPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

13.8.13 HPDMA channel x destination address register (HPDMA_CxDAR)

Address offset: 0x0A0 + 0x80 * x (x = 0 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by HPDMA from the memory if HPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This bitfield is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (HPDMA_CxTR1.DINC), this bitfield is kept fixed or incremented by the data width (HPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (HPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by HPDMA_CxTR1.DBL_1[5:0] and HPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by HPDMA_CxBR1.DDEC and HPDMA_CxTR3.DAO[12:0]

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 12 to 15), the additional block repeat destination incremented/decremented offset value as programmed by HPDMA_CxBR1.BRDDEC and HPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the HPDMA from the memory, provided the LLI is set with HPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

13.8.14 HPDMA channel x transfer register 3 (HPDMA_CxTR3)

Address offset: 0x0A4 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: Destination address offset increment

The destination address, pointed by HPDMA_CxDAR, is incremented or decremented (depending on HPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: Source address offset increment

The source address, pointed by HPDMA_CxSAR, is incremented or decremented (depending on HPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (HPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional HPDMA_CxTR3.SAO[12:0] is not applied.

13.8.15 HPDMA channel x block register 2 (HPDMA_CxBR2)

Address offset: 0x0A8 + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRDDEC) the current destination address (HPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus HPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this bitfield is used to update (by addition or subtraction depending on HPDMA_CxBR1.BRSDEC) the current source address (HPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus HPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued.
BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if HPDMA_CxTR2.PFREQ = 1).

13.8.16 HPDMA channel x linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 0 to 11)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory

This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory

This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory

This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory

This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0: No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR, and HPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

13.8.17 HPDMA channel x alternate linked-list address register (HPDMA_CxLLR)

Address offset: 0x0CC + 0x80 * x (x = 12 to 15)

Reset value: 0x0000 0000

This register is privileged or unprivileged, depending on the privileged state of channel x (HPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when HPDMA_CxCR.EN = 0.

This register is read-only when HPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted HPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI, or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the HPDMA from the memory if HPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update HPDMA_CxTR1 from memory
This bit controls the update of HPDMA_CxTR1 from the memory during the link transfer.
0: No HPDMA_CxTR1 update
1: HPDMA_CxTR1 update

Bit 30 **UT2**: Update HPDMA_CxTR2 from memory
This bit controls the update of HPDMA_CxTR2 from the memory during the link transfer.
0: No HPDMA_CxTR2 update
1: HPDMA_CxTR2 update

Bit 29 **UB1**: Update HPDMA_CxBR1 from memory
This bit controls the update of HPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if HPDMA_CxLLR ≠ 0, the linked-list is not completed.
HPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: No HPDMA_CxBR1 update from memory (HPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: HPDMA_CxBR1 update

Bit 28 **USA**: Update HPDMA_CxSAR from memory
This bit controls the update of HPDMA_CxSAR from the memory during the link transfer.
0: No HPDMA_CxSAR update
1: HPDMA_CxSAR update

Bit 27 **UDA**: Update HPDMA_CxDAR register from memory
This bit is used to control the update of HPDMA_CxDAR from the memory during the link transfer.
0:No HPDMA_CxDAR update
1: HPDMA_CxDAR update

Bit 26 **UT3**: Update HPDMA_CxTR3 from memory
This bit controls the update of HPDMA_CxTR3 from the memory during the link transfer.
0: No HPDMA_CxTR3 update
1: HPDMA_CxTR3 update

Bit 25 **UB2**: Update HPDMA_CxBR2 from memory
This bit controls the update of HPDMA_CxBR2 from the memory during the link transfer.
0: No HPDMA_CxBR2 update
1: HPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update HPDMA_CxLLR register from memory
This bit is used to control the update of HPDMA_CxLLR from the memory during the link transfer.
0: No HPDMA_CxLLR update
1: HPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: Pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL= 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list HPDMA register file.
Else, this bitfield is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list HPDMA internal register file (HPDMA_CxTR1, HPDMA_CxTR2, HPDMA_CxBR1, HPDMA_CxSAR, HPDMA_CxDAR and HPDMA_CxLLR).

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

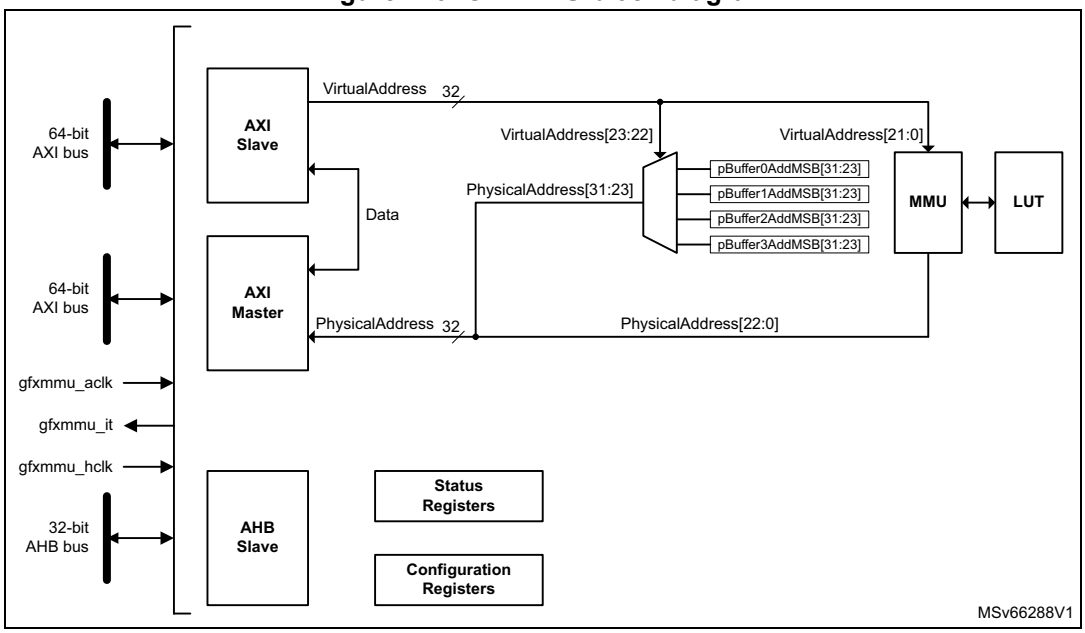
Refer to *Section 2.3* for the register boundary addresses.

14 Chrom-GRC (GFXMMU)

14.1 Introduction

The Chrom-GRC (GFXMMU) is a graphical oriented memory management unit aimed to optimize memory usage according to the display shape.

14.2 GFXMMU main features



- Fully programmable display shape to physically store only the visible pixel
- Up to 4 virtual buffers
- Each virtual buffer have 3072 or 4096 bytes per line and 1024 lines
- Each virtual buffer can be physically mapped to any system memory
- Packing and unpacking operation to store 32-bit pixel data into 24-bit packed
- Interrupt in case of buffer overflow (1 per buffer)
- Interrupt in case of memory transfer error

14.3 GFXMMU functional and architectural description

The GFXMMU is responsible of address resolution to convert the virtual buffer address into the physical buffer address.

14.3.1 GFXMMU block diagram

Figure 129. GFXMMU block diagram

14.3.2 GFXMMU internal signals

Table 112. GFXMMU internal input/output signals

Internal signal name	Signal type	Description
gfxmmu_aclk	input	GFXMMU AXI clock
gfxmmu_hclk	Input	GFXMMU AHB clock
gfxmmu_it	Output	GFXMMU global interrupt

14.3.3 Virtual memory

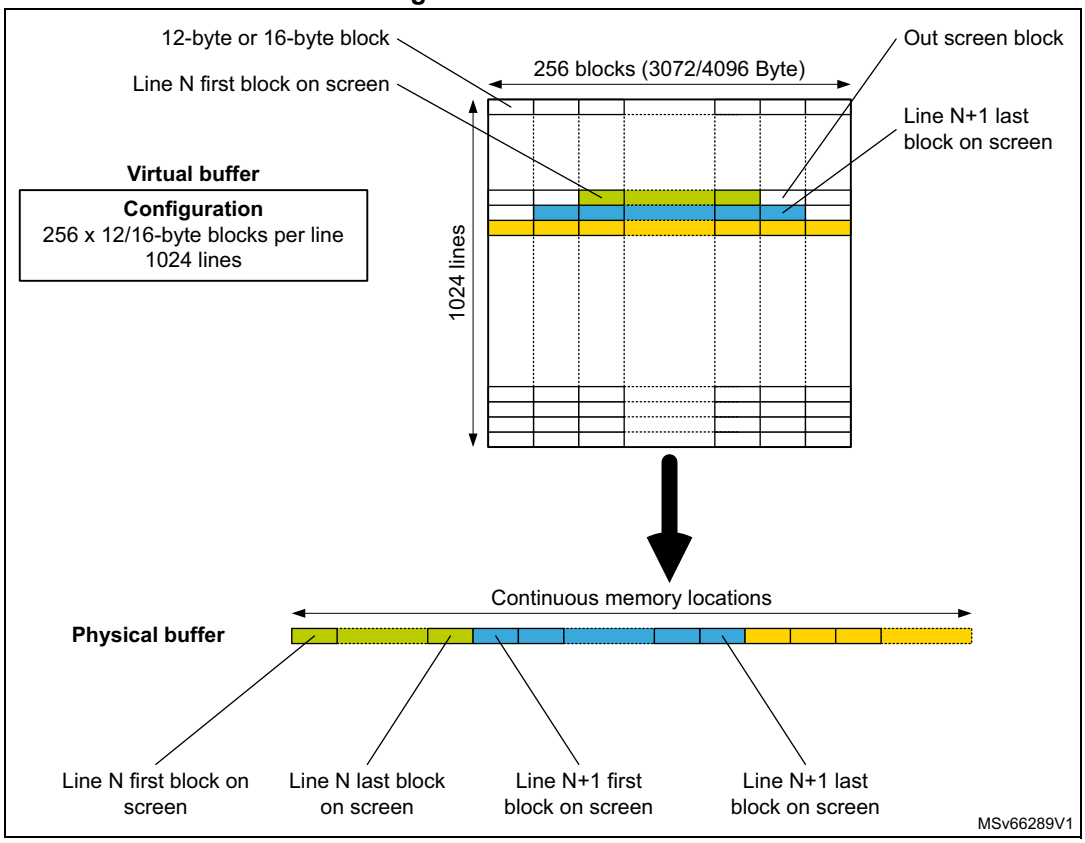
The GFXMMU provides a virtual memory space seen by the system masters. This virtual memory space is divided into four virtual buffers.

Virtual buffer

A virtual buffer is seen by any system master as a continuous memory space representing a virtual frame buffer of 1024 lines.

Each line is divided into 256 12-byte or 16-byte blocks depending on the BS bit of the GFXMMU configuration register (GFXMMU_CR).

When the address translation is enabled setting the address translation enable (ATE) bit of the graphic MMU configuration register (GFXMMU_CR), each line can be configured individually to be mapped onto a physical memory.



Depending on the display shape and size, only the necessary blocks are mapped to a physical memory location. This mapping is done programming the LUT entry for each line:

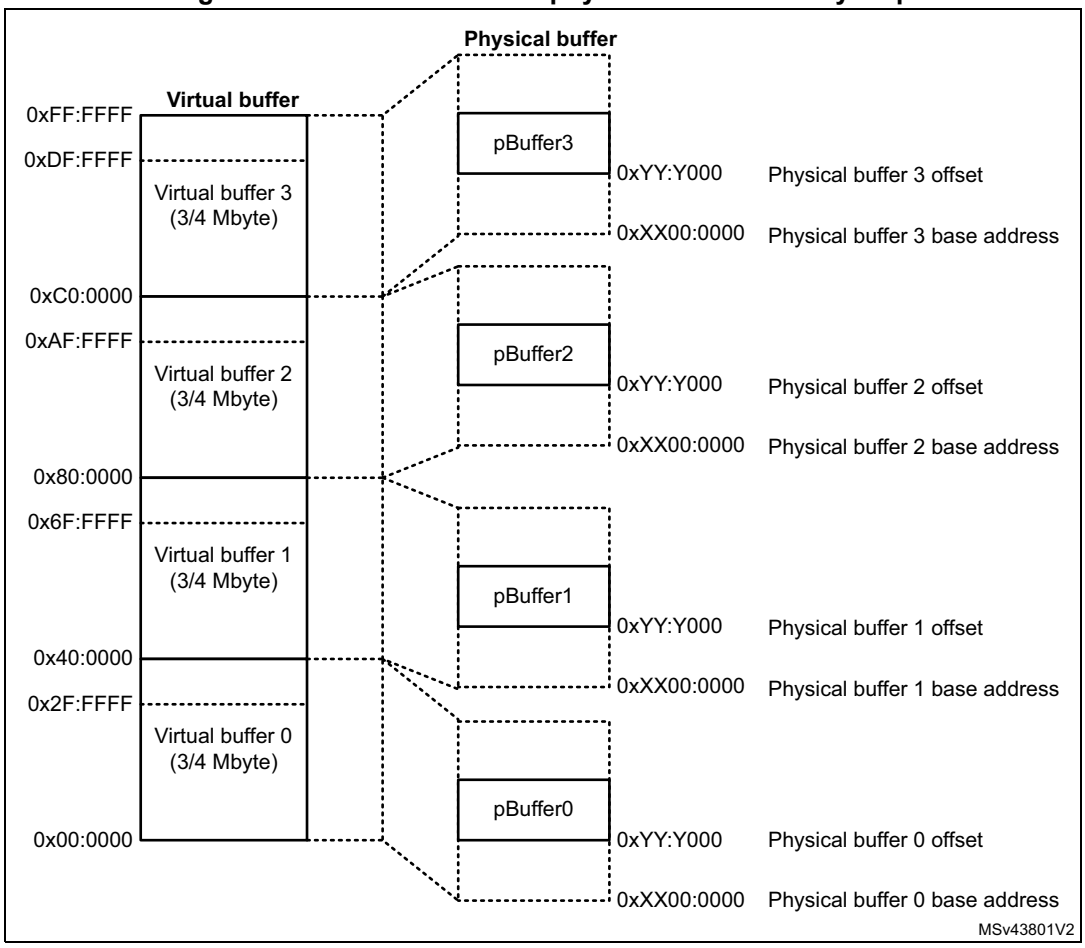
- The enable of the line
- The number of the first “visible” block
- The number of the last “visible” block
- The address offset of the line within the physical buffer

The “visible” blocks can be arranged in the physical buffer in a continuous way programming the address offset of each line.

The LUT is common to all the buffers i.e. all the buffers have the same “shape”.

Figure 130. Virtual buffer

Virtual buffer overview



For a frame buffer coded in 32 bpp or 16 bpp, the virtual buffer can be configured to have 12-byte or 16-byte blocks. This results in a virtual frame buffer of 768 x 1024 or 1024 x 1024 pixels for 32 bpp and 1536 x 1024 or 2048 x 1024 for 16 bpp.

For a frame buffer coded in 24 bpp, the virtual buffer must be configured to have 12-byte blocks to have an integer number of pixel per lines. This results in a virtual frame buffer of 1024 x 1024 pixels for 24 bpp.

Each buffer can be physically mapped anywhere in the physical memory thanks to:

- The physical buffer base address (PBBA) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR). It configures the physical location of the 8-Mbyte area where the buffer is mapped.
- The physical buffer location respective to the physical buffer base address is defined by the physical buffer offset (PBO) field of the GFXMMU buffer x configuration register (GFXMMU_BxCR).

Figure 131. Virtual buffer and physical buffer memory map

The buffer can not overflow the 8-Mbyte boundary of the zone defined by its base address. In case of overflow, the buffer x overflow flag (BxOF) of the GFXMMU status register (GFXMMU_SR) is set and an interrupt is generated if the buffer x overflow interrupt enable (BxOIE) bit of the GFXMMU configuration register (GFXMMU_CR) is set.

Virtual buffer application use case

As the physical locations are independently configurable, the four virtual buffers can be physically mapped to non continuous locations. This would allow for example to have the four buffers mapped on to four different SDRAM banks and avoid extra precharge cycles accessing the SDRAM.

As a consequence, one buffer must be used by the CPU/Graphic accelerator for frame buffer calculation while an other one must be used by the LTDC.

The two remaining buffers can be used as a graphical library requiring extra drawing buffers.

14.3.4 Packing and unpacking

When addressing 24bpp frame buffers, the virtual buffer must be configured in 12-byte block mode to have an integer number of pixel per block.

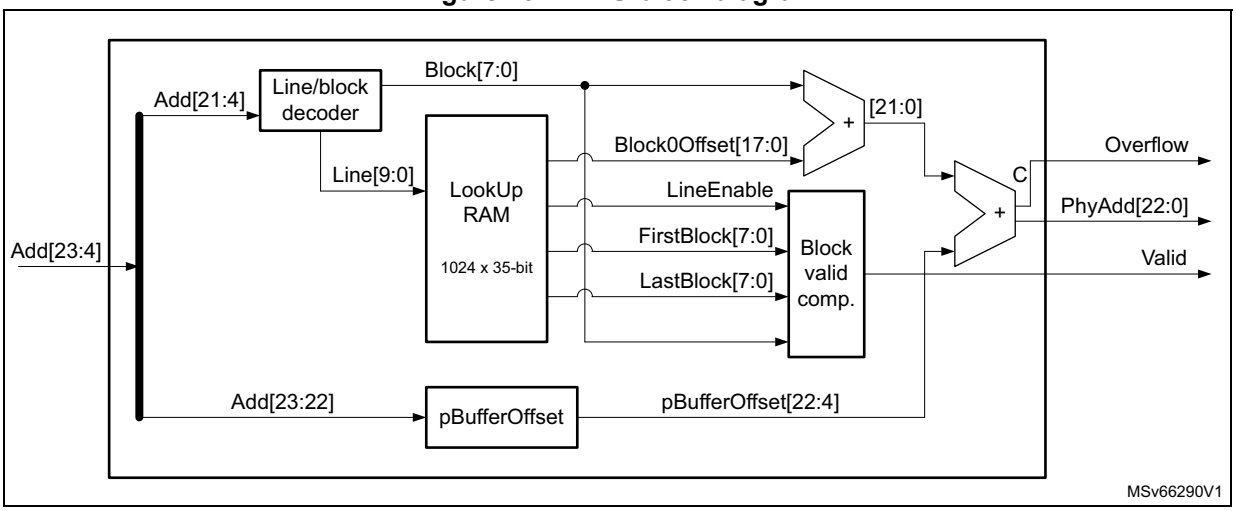
Nevertheless, it is possible to access these 24-bit data as if they where unpacked in a 32-bit word.

The packing mode is enabled, per buffer setting the buffer x packing enable (BxPE) bit of the graphic MMU configuration register (GFXMMU_CR).

When the packing mode is enabled and the 12-byte mode is selected, the access to the buffer are done as in 16-byte mode, but either the most significant byte or the less significant byte is ignored to transform each 32-bit word into a 24-bit word.

The ignored byte is selected with the buffer x packing mode (BxPM) bit of the graphic MMU configuration register (GFXMMU_CR).

During write operation MSB or LSB is ignored. During read operation, the ignored MSB or LSB is replaced by the 8-bit default value programmed in the default alpha (DA) field of the graphic MMU default alpha register (GFXMMU_DAR)



The buffer x packing enable (BxPE) bit has no effect when the graphic MMU is configured in 16-byte block.

14.3.5 MMU architecture

The MMU block is responsible of the address resolution. It receives the 24-bit address and returns the physical 23-bit address and a valid signals to indicate the address is physically mapped or not. The MMU also checks overflow of a area boundary.

The MMU LUT is implemented as a 1024 x 35-bit RAM

Figure 132. MMU block diagram

Line block decoder

The line block decoder is generating the block number and the line number according the address.

Look up RAM

The look up RAM is a 1024 x 35-bit RAM with the following fields:

- 1-bit line enable
- 8-bit first valid block
- 8-bit last valid block
- 18-bit for line offset

As the RAM is bigger than a word, each entry is split into two words on the memory map. The write access are done in two steps:

1. Write the first word with enable/first valid block/last valid block in the GFXMMU_LUTxL memory location (internally buffered).
2. Write the second word with line offset in the GFXMMU_LUTxH memory location (effective write into the memory together with the internally buffered value).

A write in the LUT can happen any time but it can lead to inconsistencies if a master is using the MMU at the same time. As the CPU has the priority during LUT programming, this may slow down MMU calculation.

There is no restriction during read operations, but this may slow down CPU as the MMU has the priority on LUT accesses.

Block validation/comparator

This block is checking if the block is valid.

A block is considered as valid (physically mapped) when:

- Line is enable.
- The block number is greater or equal to the first valid block.
- The block number is lower or equal to the last valid block.

When the block is valid, the physical address generated is considered as correct.

If the result of the MMU evaluation is not valid, the write operations are ignored, and read operations return the default 32-bit value stored in the default value (DV) field of the GFXMMU default value register (GFXMMU_DVR).

Block offset address calculation within the buffer

The block number is added to the line offset to get the offset of the block within the physical buffer.

As a consequence, the line offset stored in the LUT is given by the following formula:

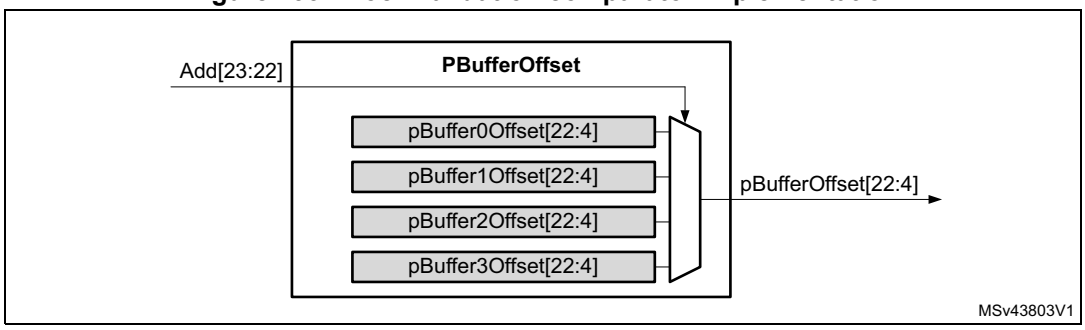
$$\text{Line offset} = [(\text{Number of visible blocks already used}) - (1^{st} \text{ visible block})]$$

with:

- The maximum value for the line offset is when all the block of all the line are used. As the consequence the line offset for the last line can be maximum:
  1023 x 256 = 0x3:FF00
- The minimum value for the line offset is when the last block of the first line is the first valid block: -255 = - 0xFF i.e 0x3:FF01

As the consequence the full range of the line offset entry of the LUT is used.

Carry is not taken into account as this stage to be able to perform negative offset calculations (values from 0x3:FF01 to 0x3:FFFF)



As the block offset is within a 4-Mbyte buffer, the address generated is 22-bit wide.

Block offset address calculation

Once the offset of the block within the buffer as been calculated, this value is added to the offset of the block respective to the physical buffer base address.

The offset of the blocks are defined in registers as shown in *Figure 133*:

Figure 133. Block validation/comparator implementation

The resulting address and the buffer offset address must be on 23-bit.

The carry is taken into account to trigger address overflow. The carry is propagated to the GFXMMU status register (GFXMMU_SR) to set the buffer x overflow flag (BxOF).

Example of calculation

Consider the following configuration for virtual buffer 0:

- 16-byte block mode
- First visible block of line 0: block 7
- Number of visible block in line 0: 10
- First visible block of line 1: block 6
- Number of visible block in line 1: 12
- Address of the physical buffer: 0xC020:0000

The configuration must be:

- The base address of the physical buffer 0: 0xC000:0000
- The offset of buffer 0: 0x20:0000
- First visible block of line 0: block 7
- Last visible block of line 0: block 16
- Block 0 offset of line 0: (0 - 7) = -0x7 = 0x3:FFF9
- First visible block of line 1: block 6
- Last visible block of line 1: block 17
- Block 0 offset of line 1: (10 - 6) = (0xA - 0x6) = 0x4

As a consequence:

- the physical address of block 7 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 without carry) x 0x10 = 0xC020:0000

- the physical address of block 16 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 without carry) x 0x10 = 0xC020:0090

- the physical address of block 6 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x6 without carry) x 0x10 = 0xC020:00A0

- the physical address of block 17 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x11 without carry) x 0x10 = 0xC020:0150

For the same example in 12-byte mode, the user has the same configuration regarding the offsets by the addresses are different in the physical buffer:

- the physical address of block 7 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x7 without carry) x 0x0C = 0xC020:0000

- the physical address of block 16 of line 0 is:

0xC000:0000 + 0x20:0000 + (0x3:FFF9 + 0x10 without carry) x 0x0C = 0xC020:006C

- the physical address of block 6 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x6 without carry) x 0x0C = 0xC020:0078

- the physical address of block 17 of line 1 is:

0xC000:0000 + 0x20:0000 + (0x4 + 0x11 without carry) x 0x0C = 0xC020:00FC

14.4 GFXMMU interrupts

An interrupt can be produced on the following events:

- Buffer 0 overflow
- Buffer 1 overflow
- Buffer 2 overflow
- Buffer 3 overflow
- AXI master error

Separate interrupt enable bits are available for flexibility.

Table 113. GFXMMU interrupt requests

Interrupt event	Event flag	Enable control bit
Buffer 0 overflow	B0OF	B0OIE
Buffer 1 overflow	B1OF	B1OIE
Buffer 2 overflow	B2OF	B2OIE
Buffer 3 overflow	B3OF	B3OIE
AXI master error	AMEF	AMEIE

14.5 GFXMMU registers

14.5.1 GFXMMU configuration register (GFXMMU_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

rw									rw		rw	rw	rw	rw	rw

Bit 31 **B3PM**: Buffer 3 packing mode

This bit selects the byte to be removed during packing operations on buffer 3

0: MSB is removed

1: LSB is removed

Bit 30 **B3PE**: Buffer 3 packing enable

This bit enables the packing on buffer 3.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 29 **B2PM**: Buffer 2 packing mode

This bit selects the byte to be removed during packing operations on buffer 2

0: MSB is removed

1: LSB is removed

Bit 28 **B2PE**: Buffer 2 packing enable

This bit enables the packing on buffer 2.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 27 **B1PM**: Buffer 1 packing mode

This bit selects the byte to be removed during packing operations on buffer 1

0: MSB is removed

1: LSB is removed

Bit 26 **B1PE**: Buffer 1 packing enable

This bit enables the packing on buffer 1.

The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.

0: Packing is disabled

1: Packing is enable

Bit 25 **B0PM**: Buffer 0 packing mode

This bit selects the byte to be removed during packing operations on buffer 0

0: MSB is removed

1: LSB is removed

Bit 24 **B0PE**: Buffer 0 packing enable
This bit enables the packing on buffer 0.
The packing is functional only if the block size is configured in 12-byte mode. In 16-byte mode, this bit is ignored.
0: Packing is disabled
1: Packing is enable

Bits 23:16 Reserved, must be kept at reset value.

Bit 15 **ATE**: Address translation enable
This bit enables the address translation based on the values programmed in the LUT.
0: Address translation is disable
1: Address translation is enable

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **BS**: Block size
This bit defines the size of the blocks
0: 16-byte blocks
1: 12-byte blocks

Bit 5 Reserved, must be kept at reset value.

Bit 4 **AMEIE**: AXI master error interrupt enable
This bit enables the AXI master error interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 3 **B3OIE**: Buffer 3 overflow interrupt enable
This bit enables the buffer 3 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 2 **B2OIE**: Buffer 2 overflow interrupt enable
This bit enables the buffer 2 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 1 **B1OIE**: Buffer 1 overflow interrupt enable
This bit enables the buffer 1 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

Bit 0 **B0OIE**: Buffer 0 overflow interrupt enable
This bit enables the buffer 0 overflow interrupt.
0: Interrupt disable
1: Interrupt enabled

14.5.2 GFXMMU status register (GFXMMU_SR)

Address offset: 0x0004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	AMEF	B3OF	B2OF	B1OF	B0OF
											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **AMEF**: AXI master error flag
This bit is set when an AXI error happens during a transaction. It is cleared by writing 1 to CAMEF.

Bit 3 **B3OF**: Buffer 3 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 3. It is cleared by writing 1 to CB3OF.

Bit 2 **B2OF**: Buffer 2 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 2. It is cleared by writing 1 to CB2OF.

Bit 1 **B1OF**: Buffer 1 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 1. It is cleared by writing 1 to CB1OF.

Bit 0 **B0OF**: Buffer 0 overflow flag
This bit is set when an overflow occurs during the offset calculation of the buffer 0. It is cleared by writing 1 to CB0OF.

14.5.3 GFXMMU flag clear register (GFXMMU_FCR)

Address offset: 0x0008

Reset value: 0x0000 0000

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CAMEF**: Clear AXI master error flag
Writing 1 clears the AXI master error flag in the GFXMMU_SR register.

Bit 3 **CB3OF**: Clear buffer 3 overflow flag
Writing 1 clears the buffer 3 overflow flag in the GFXMMU_SR register.

Bit 2 **CB2OF**: Clear buffer 2 overflow flag
Writing 1 clears the buffer 2 overflow flag in the GFXMMU_SR register.

Bit 1 **CB1OF**: Clear buffer 1 overflow flag
Writing 1 clears the buffer 1 overflow flag in the GFXMMU_SR register.

Bit 0 **CB0OF**: Clear buffer 0 overflow flag
Writing 1 clears the buffer 0 overflow flag in the GFXMMU_SR register.

14.5.4 GFXMMU default value register (GFXMMU_DVR)

Address offset: 0x0010

Reset value: 0x0000 0000

Refer to *Section 2.3* for the register boundary addresses.

15 Chrom-ART Accelerator controller (DMA2D)

15.1 DMA2D introduction

The Chrom-ART Accelerator (DMA2D) is a specialized DMA dedicated to image manipulation. It can perform the following operations:

- Filling a part or the whole of a destination image with a specific color
- Copying a part or the whole of a source image into a part or the whole of a destination image
- Copying a part or the whole of a source image into a part or the whole of a destination image with a pixel format conversion
- Blending a part and/or two complete source images with different pixel format and copy the result into a part or the whole of a destination image with a different color format

All the classical color coding schemes are supported from 4-bit up to 32-bit per pixel with indexed or direct color mode, including block based YCbCr to handle JPEG decoder output. The DMA2D has its own dedicated memories for CLUTs (color look-up tables).

15.2 DMA2D main features

The main DMA2D features are:

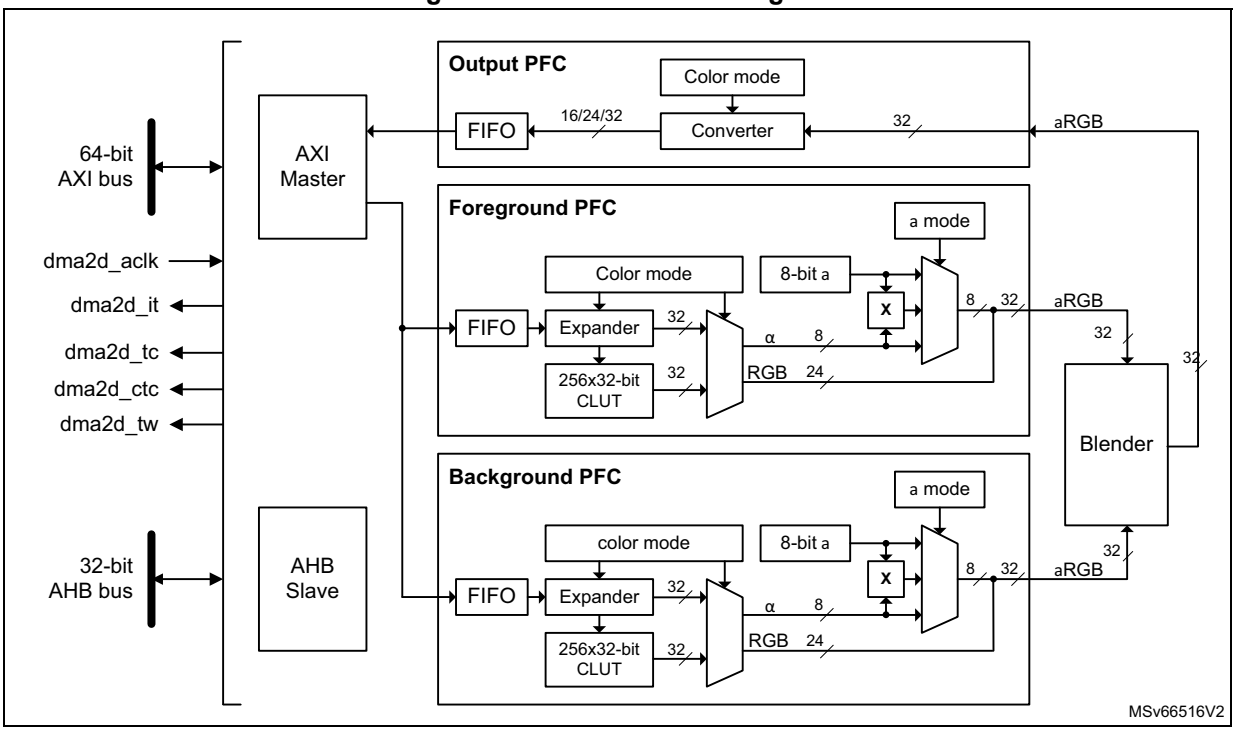
- Single AXI master bus architecture
- AHB slave programming interface supporting 8-,16-,32-bit accesses (except for CLUT accesses which are 32-bit)
- User-programmable working area size
- User-programmable offset for sources and destination areas expressed in pixels or bytes
- User-programmable sources and destination addresses on the whole memory space
- Up to two sources with blending operation
- Alpha value that can be modified (source value, fixed value, or modulated value)
- User programmable source and destination color format
- Up to 12 color formats supported from 4-bit up to 32-bit per pixel with indirect or direct color coding
- Block based (8x8) YCbCr support with 4:4:4, 4:2:2 and 4:2:0 chroma sub-sampling factors
- 2 internal memories for CLUT storage in indirect color mode
- Automatic CLUT loading or CLUT programming via the CPU
- User programmable CLUT size
- Internal timer to control AXI bandwidth
- 6 operating modes: register-to-memory, memory-to-memory, memory-to-memory with pixel format conversion, memory-to-memory with pixel format conversion and blending, memory-to memory with pixel format conversion, blending and fixed color foreground, and memory-to memory with pixel format conversion, blending and fixed color background.
- Area filling with a fixed color

- Copy from an area to another
- Copy with pixel format conversion between source and destination images
- Copy from two sources with independent color format and blending
- Output buffer byte swapping to support refresh of displays through parallel interface
- Abort and suspend of DMA2D operations
- Watermark interrupt on a user programmable destination line
- Interrupt generation on bus error or access conflict
- Interrupt generation on process completion

15.3 DMA2D functional description

15.3.1 General description

The DMA2D controller performs direct memory transfer. As an AXI master, it can take the control of the AXI bus matrix to initiate AXI transactions.



The DMA2D can operate in the following modes:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with pixel format conversion
- Memory-to-memory with pixel format conversion and blending
- Memory-to-memory with pixel format conversion, blending and fixed color foreground
- Memory-to-memory with pixel format conversion, blending and fixed color background

The AHB slave port is used to program the DMA2D controller.

The block diagram of the DMA2D is shown in *Figure 134*.

Figure 134. DMA2D block diagram

15.3.2 DMA2D internal signals

The internal signals of the DMA2D are given in the table below:

Table 115. DMA2D internal signals

Names	Signal type	Description
dma2d_aclk	Input	DMA2D AXI clock
dma2d_it	Output	DMA2D global interrupt request
dma2d_ctc	Output	DMA2D CLUT transfer complete trigger
dma2d_tc	Output	DMA2D transfer complete trigger
dma2d_tw	Output	DMA2D transfer watermark trigger

Table 116. DMA2D trigger interconnections

Trigger name	Direction	Trigger source/destination
dma2d_ctc	Output	hpdma_trigsel[4]
dma2d_tc	Output	hpdma_trigsel[5]
dma2d_tw	Output	hpdma_trigsel[6]

15.3.3 DMA2D control

The DMA2D controller is configured through DMA2D_CR. The user application can perform the following operations:

- Select the operating mode.
- Enable/disable the DMA2D interrupt.
- Start/suspend/abort ongoing data transfers.

15.3.4 DMA2D foreground and background FIFOs

The DMA2D foreground (FG) FG FIFO and background (BG) FIFO fetch the input data to be copied and/or processed.

The FIFOs fetch the pixels according to the color format defined in their respective pixel format converter (PFC).

They are programmed through the following control registers:

- DMA2D foreground memory address register (DMA2D_FGMAR)
- DMA2D foreground offset register (DMA2D_FGOR)
- DMA2D background memory address register (DMA2D_BGMAR)
- DMA2D background offset register (DMA2D_BGBOR)
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR)

When the DMA2D operates in register-to-memory mode, none of the FIFOs is activated.

When the DMA2D operates in memory-to-memory mode (no pixel format conversion nor blending operation), only the FG FIFO is activated, and acts as a buffer.

When the DMA2D operates in memory-to-memory operation with pixel format conversion (no blending operation), the BG FIFO is not activated.

15.3.5 DMA2D foreground and background PFC

DMA2D foreground pixel format converter (PFC) and background pixel format converter perform the pixel format conversion to generate a 32-bit per pixel value. The PFC can also modify the alpha channel.

The first PFC stage converts the color format. The original color format of the foreground and background pixels are configured through CM[3:0] in DMA2D_FGPFCCR and DMA2D_BGPFCCR, respectively.

The supported input formats are given in the table below.

Table 117. Supported color mode in input

CM[3:0]	Color mode
0000	ARGB8888
0001	RGB888
0010	RGB565
0011	ARGB1555
0100	ARGB4444
0101	L8

Table 117. Supported color mode in input (continued)

CM[3:0]	Color mode
0110	AL44
0111	AL88
1000	L4
1001	A8
1010	A4
1011	YCbCr (only for foreground)

The color format are coded as follows:

- Alpha value field: transparency
  0xFF value corresponds to an opaque pixel and 0x00 to a transparent one.
- R field for Red
- G field for Green
- B field for Blue
- L field: luminance
  This field is the index to a CLUT to retrieve the three/four RGB/ARGB components.

If the original format was direct color mode (ARGB/RGB), the extension to 8-bit per channel is performed by copying the MSBs into the LSBs. This ensures a perfect linearity of the conversion.

If the original format does not include an alpha channel, the alpha value is automatically set to 0xFF (opaque).

If the original format is indirect color mode (L/AL), a CLUT is required, and each pixel format converter is associated with a 256 entry 32-bit CLUT.

For the specific alpha mode A4 and A8, no color information is stored nor indexed. The color to be used for the image generation is fixed and defined in DMA2D_FGCOLR for foreground pixels, and in DMA2D_BGCOLR for background pixels.

The order of the fields in the system memory is defined in the table below.

Table 118. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]
L8	L_3[7:0]	L_2[7:0]	L_1[7:0]	L_0[7:0]
AL44	A_3[3:0]L_3[3:0]	A_2[3:0]L_2[3:0]	A_1[3:0]L_1[3:0]	A_0[3:0]L_0[3:0]

Table 118. Data order in memory (continued)

AL88	A_1[7:0]	L_1[7:0]	A_0[7:0]	L_0[7:0]
L4	L_7[3:0]L_6[3:0]	L_5[3:0]L_4[3:0]	L_3[3:0]L_2[3:0]	L_1[3:0]L_0[3:0]
A8	A_3[7:0]	A_2[7:0]	A_1[7:0]	A_0[7:0]
A4	A_7[3:0]A_6[3:0]	A_5[3:0]A_4[3:0]	A_3[3:0]A_2[3:0]	A_1[3:0]A_0[3:0]

The 24-bit RGB888 aligned on 32-bit is supported through the ARGB8888 mode.

Once the 32-bit value is generated, the alpha channel can be modified according to AM[1:0] in DMA2D_FGPFCCR or DMA2D_BGPFCCR, as shown in *Table 119*.

One of the following happens for the alpha channel:

- It is kept as it is (no modification).
- It is replaced by ALPHA[7:0] value i nDMA2D_FGPFCCR/DMA2D_BGPFCCR.
- It is replaced by the original alpha value multiplied by ALPHA[7:0] in DMA2D_FGPFCCR/DMA2D_BGPFCCR divided by 255.

Table 119. Alpha mode configuration

AM[1:0]	Alpha mode
00	No modification
01	Replaced by value in DMA2D_xxPFCCR
10	Replaced by original value multiplied by the value in DMA2D_xxPFCCR / 255
11	Reserved

Note: To support the alternate format, the incoming alpha value can be inverted setting AI in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the Alpha value stored in the DMA2D_FGPFCCR or DMA2D_BGPFCCR, and in the CLUT.

The R and B fields can also be swapped setting RBS in DMA2D_FGPFCCR or DMA2D_BGPFCCR. This applies also to the RGB order used in the CLUT, and in DMA2D_FGCOLR or DMA2D_BGCOLR.

15.3.6 DMA2D foreground and background CLUT interface

The CLUT interface manages the CLUT memory access and the automatic loading of the CLUT.

Three kinds of accesses are possible:

- CLUT read by the PFC during pixel format conversion operation
- CLUT accessed through the AHB slave port when the CPU is reading or writing data into the CLUT
- CLUT written through the AXI master port when an automatic loading of the CLUT is performed

The CLUT memory loading can be done in two different ways:

- Automatic loading

  The following sequence must be followed to load the CLUT:

a) Program the CLUT address into DMA2D_FGCMAR (foreground CLUT) or DMA2D_BGCMAR (background CLUT).

b) Program the CLUT size with CS[7:0] field in DMA2D_FGPFCCR (foreground CLUT), or DMA2D_BGPFCCR (background CLUT).

c) Set START in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) to start the transfer. During this automatic loading process, the CLUT is not accessible by the CPU. If a conflict occurs, a CLUT access error interrupt is raised assuming CAEIE = 1 in DMA2D_CR.

- Manual loading

  The application has to program the CLUT manually through the DMA2D AHB slave port to which the local CLUT memory is mapped.The foreground CLUT (FGCLUT) is located at address offset 0x0400 and the background CLUT (BGCLUT) at address offset 0x0800.

The CLUT format can be 24 or 32 bits. It is configured through CCM in DMA2D_FGPFCCR (foreground CLUT) or DMA2D_BGPFCCR (background CLUT) as shown in table below.

Table 120. Supported CLUT color mode

CCM	CLUT color mode
0	32-bit ARGB8888
1	24-bit RGB888

The way the CLUT data are organized in the system memory is specified in the table below.

Table 121. CLUT data order in memory

CLUT Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]

15.3.7 DMA2D blender

The DMA2D blender blends the source pixels by pair to compute the resulting pixel.

The blending is performed according to the following equation:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division is rounded to the nearest lower integer

No configuration register is required by the blender. The blender use depends on the DMA2D operating mode defined by MODE[2:0] in DMA2D_CR.

15.3.8 DMA2D output PFC

The output PFC performs the pixel format conversion from 32 bits to the output format defined by CM[2:0] in DMA2D_OPFCCR.

Supported output formats are given in the table below

Table 122. Supported color mode in output

CM[2:0]	Color mode
000	ARGB8888
001	RGB888
010	RGB565
011	ARGB1555
100	ARGB4444

Note: To support the alternate format, the calculated alpha value can be inverted setting AI bit in DMA2D_OPFCCR. This applies also to the Alpha value used in DMA2D_OCOLR.

The R and B fields can also be swapped setting RBS in DMA2D_OPFCCR. This applies also to the RGB order used in DMA2D_OCOLR.

15.3.9 DMA2D output FIFO

The output FIFO programs the pixels according to the color format defined in the output PFC.

The destination area is defined through the following registers:

- DMA2D output memory address register (DMA2D_OMAR)
- DMA2D output offset register (DMA2D_OOR**)**
- DMA2D number of lines register (number of lines and pixel per lines) (DMA2D_NLR**)**

If the DMA2D operates in register-to-memory mode, the configured output rectangle is filled by the color specified in DMA2D_OCOLR which contains a fixed 32-, 24-, or 16-bit value. The format is selected by CM[2:0] in DMA2D_OPFCCR.

The data are stored into the memory in the order defined in the table below.

Table 123. Data order in memory

Color mode	@ + 3	@ + 2	@ + 1	@ + 0
ARGB8888	A_0[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]
ARGB1555	A_1[0]R_1[4:0]G_1[4:3]	G_1[2:0]B_1[4:0]	A_0[0]R_0[4:0]G_0[4:3]	G_0[2:0]B_0[4:0]
ARGB4444	A_1[3:0]R_1[3:0]	G_1[3:0]B_1[3:0]	A_0[3:0]R_0[3:0]	G_0[3:0]B_0[3:0]

The RGB888 aligned on 32 bits is supported through the ARGB8888 mode.

15.3.10 DMA2D output FIFO byte reordering

The output FIFO bytes can be reordered to support display frame buffer update through a parallel interface (F(S)MC) directly from the DMA2D.

The reordering of bytes can be done using:

- RBS bit to swap red and blue component
- SB bit to swap byte two by two in the output FIFO

When the byte swapping is activated (SB = 1 in DMA2D_OPFCR), the number of pixel per line (PL field in DMA2D_NLR) must be even, and the output memory address (MA field in DMA2D_OMAR) must be even. The output line offset computed in bytes (resulting from LOM field in DMA2D_CR and LO field in DMA2D_OOR values) must also be even. If not a configuration error is detected.

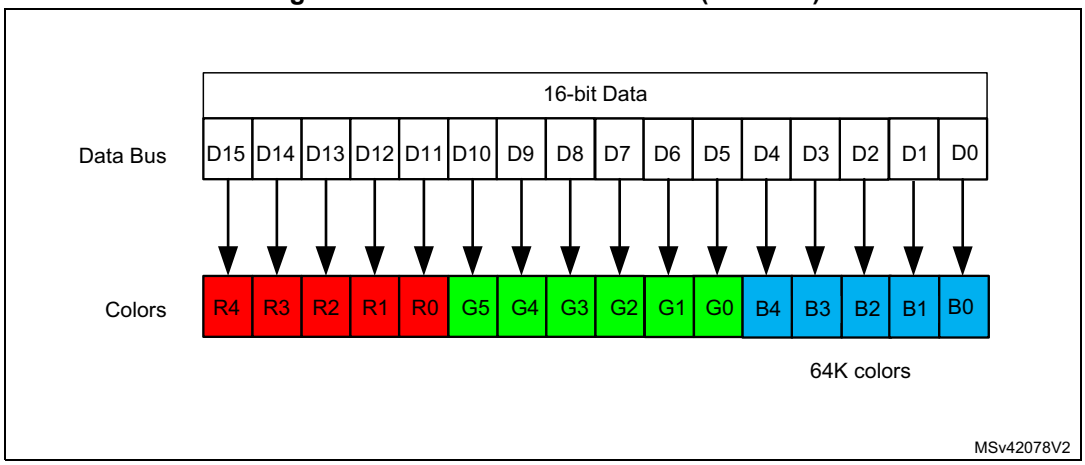


Table 124. Standard data order in memory

Color Mode	@ + 3	@ + 2	@ + 1	@ + 0
RGB888	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
RGB565	R_1[4:0]G_1[5:3]	G_1[2:0]B_1[4:0]	R_0[4:0]G_0[5:3]	G_0[2:0]B_0[4:0]

16-bit mode (RGB565)

This mode is supported without byte reordering by the DMA2D.

Figure 135. Intel 8080 16-bit mode (RGB565)

18/24-bit mode (RGB888)

This mode needs data reordering:

1. The red and the blue have to be swapped (setting the RBS bit).
2. MSB and the LSB bytes of an half-word must be swapped (setting SB bit).

Figure 136. Intel 8080 18/24-bit mode (RGB888)

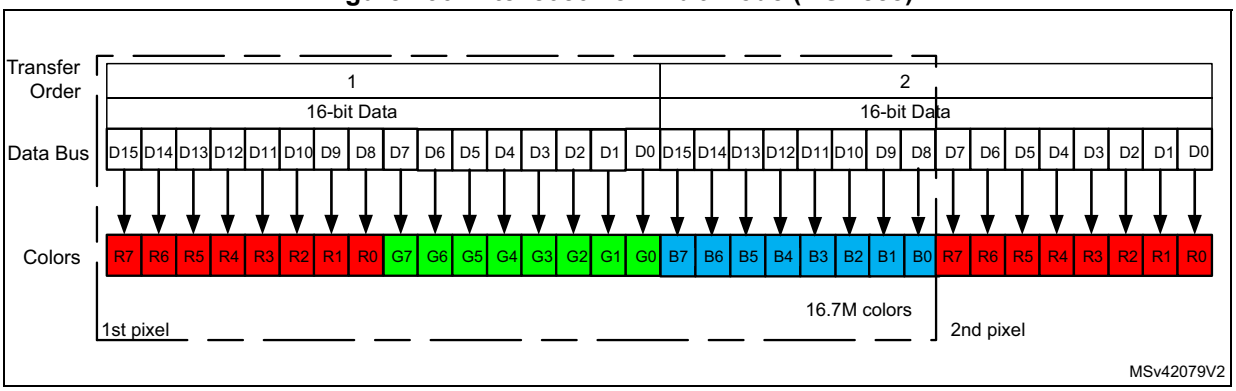

Table 125. Output FIFO byte reordering steps

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Original data ordering	B_1[7:0]	R_0[7:0]	G_0[7:0]	B_0[7:0]
	G_2[7:0]	B_2[7:0]	R_1[7:0]	G_1[7:0]
	R_3[7:0]	G_3[7:0]	B_3[7:0]	R_2[7:0]
Setting the RBS bit				
Data ordering after Red and Blue swap (RBS set)	R_1[7:0]	B_0[7:0]	G_0[7:0]	R_0[7:0]
	G_2[7:0]	R_2[7:0]	B_1[7:0]	G_1[7:0]
	B_3[7:0]	G_3[7:0]	R_3[7:0]	B_2[7:0]
Setting the SB bit				

Table 125. Output FIFO byte reordering steps (continued)

Steps	@ + 3	@ + 2	@ + 1	@ + 0
Data ordering after byte swapping (SB set)	B_0[7:0]	R_1[7:0]	R_0[7:0]	G_0[7:0]
	R_2[7:0]	G_2[7:0]	G_1[7:0]	B_1[7:0]
	G_3[7:0]	B_3[7:0]	B_2[7:0]	R_3[7:0]

15.3.11 DMA2D AXI master port timer

An 8-bit timer is embedded into the AXI master port to provide an optional limitation of the bandwidth on the crossbar. This timer is clocked by the AXI clock and counts a dead time between two consecutive accesses. This limits the bandwidth usage.

The timer enabling and dead time value are configured through DMA2D_AMPTCR.

15.3.12 DMA2D transactions

DMA2D transactions consist of a sequence of a given number of data transfers. Number of data and width can be programmed by software.

Each DMA2D data transfer is composed of up to four steps:

1. Data loading from the memory location pointed by DMA2D_FGMAR and pixel format conversion as defined in DMA2D_FGCR
2. Data loading from a memory location pointed by DMA2D_BGMAR and pixel format conversion as defined in DMA2D_BGCR
3. Blending of all retrieved pixels according to the alpha channels resulting of PFC operation on alpha values
4. Pixel format conversion of resulting pixels according to DMA2D_OCR and programming of data to the memory location addressed through DMA2D_OMAR

15.3.13 DMA2D configuration

Both source and destination data transfers can target peripherals and memories in the whole 4-Gbyte memory area, at addresses ranging between 0x0000 0000 and 0xFFFF FFFF.

The DMA2D can operate in any of the following modes selected through MODE[2:0] in DMA2D_CR:

- Register-to-memory
- Memory-to-memory
- Memory-to-memory with PFC
- Memory-to-memory with PFC and blending
- Memory-to-memory with PFC, blending and fixed FG color
- Memory-to-memory with PFC, blending and fixed BG color

Register-to-memory

The register-to-memory mode is used to fill a user defined area with a predefined color. The color format is set in DMA2D_OPFCCR.

The DMA2D does not perform any data fetching from any source. It just writes the color defined in DMA2D_OCOLR to the area located at the address pointed by DMA2D_OMAR and defined in DMA2D_NLR and DMA2D_OOR.

Memory-to-memory

In memory-to-memory mode, the DMA2D does not perform any graphical data transformation. The foreground input FIFO acts as a buffer, and data are transferred from the source memory location defined in DMA2D_FGMAR, to the destination memory location pointed by DMA2D_OMAR.

The color mode programmed by CM[3:0] in DMA2D_FGPFCCR defines the number of bits per pixel for both input and output.

The size of the area to be transferred is defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Memory-to-memory with PFC

In this mode, the DMA2D performs a pixel format conversion of the source data, and stores them in the destination memory location.

The size of the areas to be transferred are defined by DMA2D_NLR and DMA2D_FGOR for the source, and by DMA2D_NLR and DMA2D_OOR for the destination.

Data are fetched from the location defined in DMA2D_FGMAR, and processed by the foreground PFC. The original pixel format is configured through DMA2D_FGPFCCR.

If the original pixel format is direct-color mode, the color channels are all expanded to 8 bits.

If the pixel format is indirect color mode, the associated CLUT has to be loaded into the CLUT memory.

The CLUT loading can be done automatically by following the sequence below:

1. Set the CLUT address into DMA2D_FGCMAR.
2. Set the CLUT size with CS[7:0] in DMA2D_FGPFCCR.
3. Set the CLUT format (24 or 32 bits) with CCM in DMA2D_FGPFCCR.
4. Start the CLUT loading by setting START in DMA2D_FGPFCCR.

Once the CLUT loading is complete, CTCIF flag in DMA2D_IFR is raised, and an interrupt is generated if CTCIE is set in DMA2D_CR. The automatic CLUT loading process cannot work in parallel with classical DMA2D transfers.

The CLUT can also be filled by the CPU or by any other master through the AHB port. The access to the CLUT is not possible when a DMA2D transfer is ongoing, and uses the CLUT (indirect color format).

In parallel to the color conversion process, the alpha value can be added or changed depending on the value programmed in DMA2D_FGPFCCR. If the original image does not have an alpha channel, a default alpha value of 0xFF is automatically added to obtain a fully opaque pixel.

The alpha value is modified as follows according to AM[1:0] in DMA2D_FGPFCCR:

- It is unchanged.
- It is replaced by ALPHA[7:0] value in DMA2D_FGPFCCR.
- It is replaced by the original value multiplied by ALPHA[7:0] value in DMA2D_FGPFCCR divided by 255.

The resulting 32-bit data are encoded by the output PFC into the format specified by CM[2:0] in DMA2D_OPFCCR. The output pixel format cannot be the indirect mode since no CLUT generation process is supported.

Processed data are written into destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC and blending

In this mode, two sources are fetched in the foreground and background FIFOs from the memory locations defined by DMA2D_FGMAR and DMA2D_BGMAR respectively.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory.

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended according to the equation below:

$$\text{with } \alpha_{Mult} = \frac{\alpha_{FG} \cdot \alpha_{BG}}{255}$$

$$\alpha_{OUT} = \alpha_{FG} + \alpha_{BG} - \alpha_{Mult}$$

$$C_{OUT} = \frac{C_{FG}.\alpha_{FG} + C_{BG}.\alpha_{BG} - C_{BG}.\alpha_{Mult}}{\alpha_{OUT}} \quad \text{with C = R or G or B}$$

Division are rounded to the nearest lower integer

The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format, and data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color FG

In this mode, only one source is fetched in the background FIFO from the memory location defined by DMA2D_BGMAR.

The value of the foreground color is given by DMA2D_FGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_FGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by its respective PFC, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Memory-to-memory with PFC, blending and fixed color BG

In this mode, only open source is fetched in the foreground FIFO from the memory location defined by DMA2D_FGMAR.

The value of the background color is given by DMA2D_BGCOLR, and the alpha value is set to 0xFF (opaque).

The alpha value can be replaced or modified according to AM[1:0] and ALPHA[7:0] in DMA2D_BGPFCCR.

The two pixel format converters have to be configured as described in memory-to-memory mode. Their configurations can be different as each pixel format converter is independent and has its own CLUT memory

Once each pixel has been converted into 32 bits by their respective PFCs, all pixels are blended together. The resulting 32-bit pixel value is encoded by the output PFC according to the specified output format. Data are written into the destination memory location pointed by DMA2D_OMAR.

Configuration error detection

The DMA2D checks that the configuration is correct before any transfer. The configuration error interrupt flag is set by hardware when a wrong configuration is detected when a new transfer/automatic loading starts. An interrupt is then generated if CEIE = 1 in DMA2D_CR.

The wrong configurations that can be detected are listed below:

- Foreground CLUT automatic loading: MA bits in DMA2D_FGCMAR are not aligned with CCM in DMA2D_FGPFCCR.
- Background CLUT automatic loading: MA bits in DMA2D_BGCMAR are not aligned with CCM in DMA2D_BGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): MA bits in DMA2D_FGMAR are not aligned with CM in DMA2D_FGPFCCR.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): CM bits in DMA2D_FGPFCCR are invalid.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): PL bits in DMA2D_NLR are odd while CM is DMA2D_FGPFCCR is A4 or L4.
- Memory transfer (except in register-to-memory and memory-to-memory with blending and fixed color FG): LO bits in DMA2D_FGOR are odd while CM in DMA2D_FGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (only in blending mode, except in memory-to-memory with blending and fixed color FG): MA bits in DMA2D_BGMAR are not aligned with the CM in DMA2D_BGPFCCR
- Memory transfer (only in blending and blending with fixed color FG): CM bits in DMA2D_BGPFCCR are invalid.
- Memory transfer (only in blending and blending with fixed color FG mode): PL bits in DMA2D_NLR odd while CM inDMA2D_BGPFCCR is A4 or L4.
- Memory transfer (only in blending and blending with fixed color FG): LO bits in DMA2D_BGOR are odd while CM inDMA2D_BGPFCCR is A4 or L4, and LOM in DMA2D_CR is pixel mode.
- Memory transfer (except in memory-to-memory): MA bits in DMA2D_OMAR are not aligned with CM in DMA2D_OPFCCR.
- Memory transfer (except in memory-to-memory): CM bits in DMA2D_OPFCCR are invalid.

- Memory transfer with byte swapping: PL bits in DMA2D_NLR are odd, or MA bits in DMA2D_OMAR are odd, or LO in bytes (resulting from LOM in DMA2D_CR and LO in DMA2D_OOR) are odd while SB = 1 in DMA2D_OPFCCR.
- Memory transfer: NL bits in DMA2D_NLR are all zeros.
- Memory transfer: PL bits in DMA2D_NLR are all zeros.
- Memory transfer: MODE bits in DMA2D_CR are invalid.
- YCbCr format: when a CLUT loading starts setting START in DMA2D_FGPFCCR
- YCbCr format: when memory-to-memory mode is selected
- YCbCr format: when YCbCR4:4:4 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 8 pixels
- YCbCr format: when YCbCr4:2:2 or YCbCr4:2:0 is selected, and the sum of number of pixel (PL) and line offset LO is not a multiple of 16 pixels

15.3.14 YCbCr support

The DMA2D foreground plane can support 8x8 block-based YCbCr as output by the JPEG decoder with different chroma subsampling factors.

The memory organization follows the standard JFIF rules:

- Each of the three color components must be coded on 8-bit.
- Each component must be arranged by blocks of 8x8 (64 bytes) called MCU.

Depending of the chroma subsampling factor, the MCU must be arranged in the memory as described in the table below.

Table 126. MCU order in memory

Sub-sampling	@	@ + 64	@ + 128	@+192	@+256	@ + 320
4:4:4	Y_1	Cb_1	Cr_1	Y_2	Cb_2	Cr_2
4:2:2	Y_1	Y_2	Cb_{12}	Cr_{12}	Y_3	Y_4
4:2:0	Y_1	Y_2	Y_3	Y_4	Cb_{1234}	Cr_{1234}

The chroma subsampling factor is configured through CSS in DMA2D_FGPFCCR.

Once the DMA2D has started with the foreground configured in YCbCr color mode, the first two chroma MCUs are loaded in the foreground CLUT. Once the chroma MCUs are loaded, the DMA2D performs the loading of the Y MCU as for a classical color mode.

15.3.15 DMA2D transfer control (start, suspend, abort, and completion)

Once the DMA2D is configured, the transfer can be launched by setting START in DMA2D_CR. Once the transfer is completed, START is automatically reset, and TCIF flag is raised in DMA2D_ISR. An interrupt can be generated if TCIE is set in DMA2D_CR.

The user application can suspend the DMA2D at any time by setting SUSP in DMA2D_CR. The transaction can be aborted by setting ABORT i nDMA2D_CR, or can be restarted by resetting SUSP in DMA2D_CR.

The user application can abort at any time an ongoing transaction by setting ABORT in DMA2D_CR. In this case, the TCIF flag is not raised.

Automatic CLUT transfers can also be aborted or suspended by using their own START bits in DMA2D_FGPFCCR and DMA2D_BGPFCCR.

15.3.16 Watermark

A watermark can be programmed to generate an interrupt when the last pixel of a given line has been written to the destination memory area.

The line number is defined in LW[15:0] in DMA2D_LWR.

When the last pixel of this line has been transferred, TWIF flag is raised in DMA2D_ISR, and an interrupt is generated if TWIE is set in DMA2D_CR.

15.3.17 Error management

Two kind of errors can be triggered:

- AXI master port errors signaled by TEIF flag in DMA2D_ISR
- Conflicts caused by CLUT access (CPU trying to access the CLUT while a CLUT loading or a DMA2D transfer is ongoing) signaled by CAEIF flag in DMA2D_ISR

Both flags are associated to their own interrupt enable flag in DMA2D_CR to generate an interrupt if need be (TEIE and CAEIE).

15.3.18 AXI dead time

To limit the AXI bandwidth use, a dead time between two consecutive AXI accesses can be programmed. This feature can be enabled by setting EN in DMA2D_AMTCR.

The dead-time value is stored in DT[7:0] in DMA2D_AMTCR. This value represents the guaranteed minimum number of cycles between two consecutive transactions on AXI bus.

The update of the dead-time value while the DMA2D is running is taken into account for the next AXI transfer.

15.4 DMA2D interrupts

An interrupt can be generated on the following events:

- Configuration error
- CLUT transfer complete
- CLUT access error
- Transfer watermark reached
- Transfer complete
- Transfer error

Separate interrupt enable bits are available for flexibility.

Table 127. DMA2D interrupt requests

Interrupt event	Event flag	Enable control bit
Configuration error	CEIF	CEIE
CLUT transfer complete	CTCIF	CTCIE

Table 127. DMA2D interrupt requests (continued)

Interrupt event	Event flag	Enable control bit
CLUT access error	CAEIF	CAEIE
Transfer watermark	TWF	TWIE
Transfer complete	TCIF	TCIE
Transfer error	TEIF	TEIE

15.5 DMA2D registers

15.5.1 DMA2D control register (DMA2D_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **MODE[2:0]**: DMA2D mode
This bit is set and cleared by software. It cannot be modified while a transfer is ongoing.
000: Memory-to-memory (FG fetch only)
001: Memory-to-memory with PFC (FG fetch only with FG PFC active)
010: Memory-to-memory with blending (FG and BG fetch with PFC and blending)
011: Register-to-memory (no FG nor BG, only output stage active)
100: Memory-to-memory with blending and fixed color FG (BG fetch only with FG and BG PFC active)
101: Memory-to-memory with blending and fixed color BG (FG fetch only with FG and BG PFC active)
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CEIE**: Configuration error (CE) interrupt enable
This bit is set and cleared by software.
0: CE interrupt disabled
1: CE interrupt enabled

Bit 12 **CTCIE**: CLUT transfer complete (CTC) interrupt enable
This bit is set and cleared by software.
0: CTC interrupt disabled
1: CTC interrupt enabled

Bit 11 **CAEIE**: CLUT access error (CAE) interrupt enable
This bit is set and cleared by software.
0: CAE interrupt disabled
1: CAE interrupt enabled

Bit 10 **TWIE**: Transfer watermark (TW) interrupt enable
This bit is set and cleared by software.
0: TW interrupt disabled
1: TW interrupt enabled

Bit 9 **TCIE**: Transfer complete (TC) interrupt enable
This bit is set and cleared by software.
0: TC interrupt disabled
1: TC interrupt enabled

Bit 8 **TEIE**: Transfer error (TE) interrupt enable
This bit is set and cleared by software.
0: TE interrupt disabled
1: TE interrupt enabled

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LOM**: Line offset mode
This bit configures how the line offset is expressed (pixels or bytes) for the foreground, background and output.
This bit is set and cleared by software. It can not be modified while a transfer is ongoing.
0: Line offsets expressed in pixels
1: Line offsets expressed in bytes

Bits 5:3 Reserved, must be kept at reset value.

Bit 2 **ABORT**: Abort
This bit can be used to abort the current transfer. This bit is set by software, and is automatically reset by hardware when START = 0.
0: No transfer abort requested
1: Transfer abort requested

Bit 1 **SUSP**: Suspend
This bit can be used to suspend the current transfer. This bit is set and reset by software. It is automatically reset by hardware when START = 0.
0: Transfer not suspended
1: Transfer suspended

Bit 0 **START**: Start
This bit can be used to launch the DMA2D according to parameters loaded in the various configuration registers. This bit is automatically reset by the following events:
- at the end of the transfer
- when the data transfer is aborted by the user by setting ABORT in this register
- when a data transfer error occurs
- when the data transfer has not started due to a configuration error, or another transfer operation already ongoing (automatic CLUT loading)

15.5.2 DMA2D interrupt status register (DMA2D_ISR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CEIF	CTCIF	CAEIF	TWIF	TCIF	TEIF
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CEIF**: Configuration error interrupt flag
This bit is set when START is set in DMA2D_CR, DMA2DFGPFCCR or DMA2D_BGPFCCR, and a wrong configuration has been programmed.

Bit 4 **CTCIF**: CLUT transfer complete interrupt flag
This bit is set when the CLUT copy from a system memory area to the internal DMA2D memory is complete.

Bit 3 **CAEIF**: CLUT access error interrupt flag
This bit is set when the CPU accesses the CLUT while the CLUT is being automatically copied from a system memory to the internal DMA2D.

Bit 2 **TWIF**: Transfer watermark interrupt flag
This bit is set when the last pixel of the watermarked line has been transferred.

Bit 1 **TCIF**: Transfer complete interrupt flag
This bit is set when a DMA2D transfer operation is complete (data transfer only).

Bit 0 **TEIF**: Transfer error interrupt flag
This bit is set when an error occurs during a DMA transfer (data transfer or automatic CLUT loading).

15.5.3 DMA2D interrupt flag clear register (DMA2D_IFCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

										rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:6 Reserved, must be kept at reset value.

Bit 5 **CCEIF**: Clear configuration error interrupt flag
Programming this bit to 1 clears the CEIF flag in DMA2D_ISR.

Bit 4 **CCTCIF**: Clear CLUT transfer complete interrupt flag
Programming this bit to 1 clears the CTCIF flag in DMA2D_ISR.

Bit 3 **CAECIF**: Clear CLUT access error interrupt flag
Programming this bit to 1 clears the CAEIF flag in DMA2D_ISR.

Bit 2 **CTWIF**: Clear transfer watermark interrupt flag
Programming this bit to 1 clears the TWIF flag in DMA2D_ISR.

Bit 1 **CTCIF**: Clear transfer complete interrupt flag
Programming this bit to 1 clears the TCIF flag in DMA2D_ISR.

Bit 0 **CTEIF**: Clear transfer error interrupt flag
Programming this bit to 1 clears the TEIF flag in DMA2D_ISR.

15.5.4 DMA2D foreground memory address register (DMA2D_FGMAR)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the foreground image
The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned, and a 4-bit per pixel format must be 8-bit aligned.

15.5.5 DMA2D foreground offset register (DMA2D_FGOR)

Address offset: 0x010

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the foreground image, expressed:

– in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.

– in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

15.5.6 DMA2D background memory address register (DMA2D_BGMAR)

Address offset: 0x014

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address, address of the data used for the background image

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned, a 16-bit per pixel format must be 16-bit aligned and a 4-bit per pixel format must be 8-bit aligned.

15.5.7 DMA2D background offset register (DMA2D_BGOR)

Address offset: 0x018

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the background image, expressed:

– in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.

– in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

If the image format is 4-bit per pixel, the line offset must be even.

15.5.8 DMA2D foreground PFC control register (DMA2D_FGPFCCR)

Address offset: 0x01C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								Res.	Res.	RBS	AI	CSS[1:0]		AM[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value

These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied by the original alpha value, according to the alpha mode selected through AM[1:0] in this register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap

This bit allows to swap Red and Blue to support BGR or ABGR color formats.

0: Regular mode (RGB or ARGB)

1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha inverted

This bit inverts the alpha value.

0: Regular alpha

1: Inverted alpha

Bits 19:18 **CSS[1:0]**: Chroma subsampling

These bits define the chroma subsampling mode for YCbCr color mode.

00: 4:4:4 (no chroma subsampling)

01: 4:2:2

10: 4:2:0

Others: Reserved

Bits 17:16 **AM[1:0]**: Alpha mode
These bits select the alpha channel value to be used for the foreground image.
00: No modification of the foreground image alpha channel value
01: Replace original foreground image alpha channel value by ALPHA[7: 0]
10: Replace original foreground image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the foreground image.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit can be set to start the automatic loading of the CLUT. It is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already ongoing (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
This bit defines the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits defines the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555
0100: ARGB4444
0101: L8
0110: AL44
0111: AL88
1000: L4
1001: A8
1010: A4
1011: YCbCr
Others: Reserved

15.5.9 DMA2D foreground color register (DMA2D_FGCOLR)

Address offset: 0x020

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RED[7:0]

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the foreground image
Used also for fixed color FG in memory-to-memory mode with blending and fixed color FG (BG fetch only with FG and BG PFC active).

15.5.10 DMA2D background PFC control register (DMA2D_BGPFCCR)

Address offset: 0x024

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CS[7:0]								Res.	Res.	START	CCM	CM[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw			rc_w1	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha value
These bits define a fixed alpha channel value which can replace the original alpha value, or be multiplied with the original alpha value according to the alpha mode selected with AM[1:0].

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap
This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted
This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:18 Reserved, must be kept at reset value.

Bits 17:16 **AM[1:0]**: Alpha mode
These bits define which alpha channel value to be used for the background image.
00: No modification of the foreground image alpha channel value
01: Replace original background image alpha channel value by ALPHA[7: 0]
10: Replace original background image alpha channel value by ALPHA[7:0] multiplied with original alpha channel value
Others: Reserved

Bits 15:8 **CS[7:0]**: CLUT size
These bits define the size of the CLUT used for the BG.
The number of CLUT entries is equal to CS[7:0] + 1.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **START**: Start
This bit is set to start the automatic loading of the CLUT. This bit is automatically reset:
- at the end of the transfer
- when the transfer is aborted by the user by setting ABORT bit in DMA2D_CR
- when a transfer error occurs
- when the transfer has not started due to a configuration error or another transfer operation already on going (data transfer or automatic background CLUT transfer)

Bit 4 **CCM**: CLUT color mode
These bits define the color format of the CLUT.
0: ARGB8888
1: RGB888

Bits 3:0 **CM[3:0]**: Color mode
These bits define the color format of the foreground image.
0000: ARGB8888
0001: RGB888
0010: RGB565
0011: ARGB1555

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **RED[7:0]**: Red value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 15:8 **GREEN[7:0]**: Green value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

Bits 7:0 **BLUE[7:0]**: Blue value for the A4 or A8 mode of the background
Used also for fixed color BG in memory-to-memory mode with blending and fixed color BG (FG fetch only with FG and BG PFC active).

15.5.12 DMA2D foreground CLUT memory address register (DMA2D_FGCMAR)

Address offset: 0x02C

Reset value: 0x0000 0000

This register can only be written when data transfers are disabled. Once the data transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address
Address of the data used for the CLUT address dedicated to the foreground image.
If the foreground CLUT format is 32-bit, the address must be 32-bit aligned.

15.5.13 DMA2D background CLUT memory address register (DMA2D_BGCMAR)

Address offset: 0x030

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the CLUT address dedicated to the background image. If the background CLUT format is 32-bit, the address must be 32-bit aligned.

15.5.14 DMA2D output PFC control register (DMA2D_OPFCCR)

Address offset: 0x034

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw						rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **RBS**: Red/Blue swap

This bit allows to swap Red and Blue to support BGR or ABGR color formats.
0: Regular mode (RGB or ARGB)
1: Swap mode (BGR or ABGR)

Bit 20 **AI**: Alpha Inverted

This bit inverts the alpha value.
0: Regular alpha
1: Inverted alpha

Bits 19:9 Reserved, must be kept at reset value.

Bit 8 **SB**: Swap bytes
When this bit is set, the bytes in the output FIFO are swapped two by two. The number of pixels per line (PL) must be even, and the output memory address (OMAR) must be even.
0: Bytes in regular order in the output FIFO
1: Bytes swapped two by two in the output FIFO

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **CM[2:0]**: Color mode
These bits define the color format of the output image.
000: ARGB8888
001: RGB888
010: RGB565
011: ARGB1555
100: ARGB4444
Others: Reserved

15.5.15 DMA2D output color register (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB8888 or RGB888 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALPHA[7:0]								RED[7:0]

GREEN[7:0]								BLUE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ALPHA[7:0]**: Alpha channel value of the output color in ARGB8888 mode (otherwise reserved)

Bits 23:16 **RED[7:0]**: Red value of the output image in ARGB8888 or RGB888 mode

Bits 15:8 **GREEN[7:0]**: Green value of the output image in ARGB8888 or RGB888

Bits 7:0 **BLUE[7:0]**: Blue value of the output image in ARGB8888 or RGB888

15.5.16 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

RGB565 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

A	RED[4:0]					GREEN[4:0]					BLUE[4:0]				
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **A**: Alpha channel value of the output color in ARGB1555 mode

Bits 14:10 **RED[4:0]**: Red value of the output image in ARGB1555 mode

Bits 9:5 **GREEN[4:0]**: Green value of the output image in ARGB1555 mode

Bits 4:0 **BLUE[4:0]**: Blue value of the output image in ARGB1555 mode

15.5.18 DMA2D output color register [alternate] (DMA2D_OCOLR)

Address offset: 0x038

Reset value: 0x0000 0000

The same register is used to show the color values, with different formats depending on the color mode.

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

ARGB4444 color mode

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALPHA[3:0]				RED[3:0]				GREEN[3:0]				BLUE[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **ALPHA[3:0]**: Alpha channel of the output color value in ARGB4444

Bits 11:8 **RED[3:0]**: Red value of the output image in ARGB4444 mode

Bits 7:4 **GREEN[3:0]**: Green value of the output image in ARGB4444 mode

Bits 3:0 **BLUE[3:0]**: Blue value of the output image in ARGB4444 mode

15.5.19 DMA2D output memory address register (DMA2D_OMAR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MA[31:0]**: Memory address

Address of the data used for the output FIFO.

The address alignment must match the image format selected: a 32-bit per pixel format must be 32-bit aligned and a 16-bit per pixel format must be 16-bit aligned.

15.5.20 DMA2D output offset register (DMA2D_OOR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

LO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LO[15:0]**: Line offset

This field gives the line offset used for the output, expressed:

- in pixels when LOM = 0 in DMA2D_CR. Only LO[13:0] bits are considered, LO[15:14] bits are ignored.
- in bytes when LOM = 1

This value is used for the address generation. It is added at the end of each line to determine the starting address of the next line.

15.5.21 DMA2D number of line register (DMA2D_NLR)

Address offset: 0x044

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	PL[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:16 **PL[13:0]**: Pixel per lines per lines of the area to be transferred

If any of the input image format is 4-bit per pixel, pixel per lines must be even.

Bits 15:0 **NL[15:0]**: Number of lines of the area to be transferred.

15.5.22 DMA2D line watermark register (DMA2D_LWR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can only be written when transfers are disabled. Once the CLUT transfer started, this register is read-only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LW[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LW[15:0]**: Line watermark for interrupt generation

An interrupt is raised when the last pixel of the watermarked line has been transferred.

15.5.23 DMA2D AXI master timer configuration register (DMA2D_AMTCR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DT[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN
rw	rw	rw	rw	rw	rw	rw	rw								rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **DT[7:0]**: Dead time

Dead time value in the AXI clock cycle inserted between two consecutive accesses on the AXI master port. These bits represent the minimum guaranteed number of cycles between two consecutive AXI accesses.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **EN**: Dead-time functionality enable

15.5.24 DMA2D foreground CLUT (DMA2D_FGCLUTx)

Address offset: 0x400 + 0x4 * x, (x = 0 to 255)

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

16 Neo-Chrom graphic processor (GPU2D)

16.1 GPU2D introduction

GPU2D is a dedicated graphics processing unit accelerating numerous 2.5D graphics applications such as graphical user interface (GUI), menu display or animations.

The GPU2D peripheral works together with an optimized software stack designed for state of the art graphic rendering.

16.2 GPU2D main features

Main features

- Multithreaded fragment (pixel) processing core with a VLIW (very long instruction word) instruction set
- Fixed-point functional units
- Command-list-based DMAs to minimize CPU overhead
- Two 64-bit AXI master interfaces for texture and frame buffer access
- Dedicated 64-bit AXI master interface for command list
- 32-bit AHB slave interface for register bank access
- Up to four general-purpose flags for system-level synchronization
- Texture decompression unit with TSC™4 and TSC™6/TSC™6a support

2D drawing features

- Pixel/line drawing
- Filled rectangles
- Triangles, quadrilateral drawing
- Anti-aliasing 8xMSAA (multisample anti-aliasing)

Image transformations

- 3D perspective correct projections
- Texture mapping with bilinear filtering or point sampling

Blit support

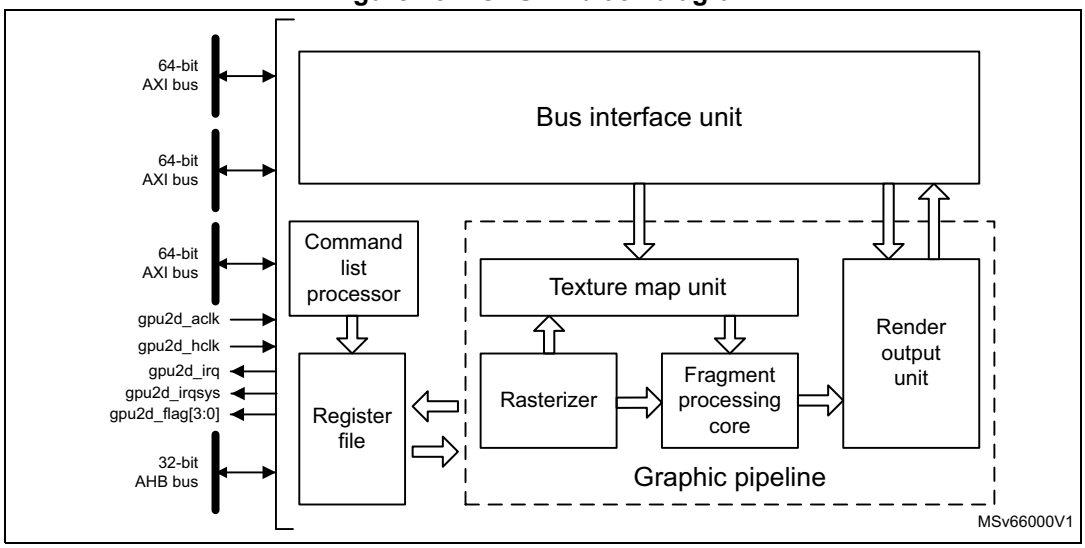
- Rotation, mirroring, stretching (independently on x and y axis)
- Source and/or destination color keying
- Pixel format conversions

Text rendering support

- A1, A2, A4, and A8 bitmap anti-aliased
- Subsampled anti-aliased

Color formats

- ABGR8888, ARGB8888, BGRA8888, RGBA8888
- xBGR8888, xRGB8888, BGRx8888, RGBx8888, RGB888, BGR888
- BGR565, RGB565
- RGB322, BGR322
- TSC4, TSC6, TSC6A
- L1, L2, L4, L8 (grayscale)
- A1, A2, A4, A8



Full alpha blending with hardware blender

- Programmable blending modes
- Source/destination color keying

16.3 GPU2D general description

16.3.1 GPU2D block diagram

Figure 137. GPU2D block diagram

16.3.2 GPU2D pins and internal signals

The internal signals of the GPU2D peripheral are given in the following table.

Table 129. GPU2D internal input/output signals

Internal signal name	Signal type	Description
gpu2d_aclk	Input	GPU2D AXI clock
gpu2d_hclk	Input	GPU2D AHB clock
gpu2d_irq	Output	GPU2D interrupt request

Table 129. GPU2D internal input/output signals (continued)

Internal signal name	Signal type	Description
gpu2d_irqsys	Output	GPU2D system interrupt request
gpu2d_flag[3:0]	Output	GPU2D general purpose flags

Table 130. GPU2D trigger connections

Trigger name	Direction	Trigger source/destination
gpu2d_flag[0]	Output	hpdma_trigsel[13]
gpu2d_flag[1]	Output	hpdma_trigsel[14]
gpu2d_flag[2]	Output	hpdma_trigsel[15]
gpu2d_flag[3]	Output	hpdma_trigsel[16]

17 Texture cache (ICACHE)

17.1 ICACHE introduction

The texture cache (ICACHE) is introduced on the AXI read-only texture port of the GPU to improve performance when reading texture data from internal and external memories.

The texture cache is an assembly of ICACHE (a peripheral with AHB ports) and an AXI-to-AHB bus bridge plugged on ICACHE AHB slave port, providing an AXI interface on the texture cache slave port.

The following sections only describe the AHB ICACHE peripheral itself.

Some specific features like hit-under-miss, and critical-word-first refill policy, allow close to zero-wait-state performance in most use cases.

17.2 ICACHE main features

The main features of ICACHE are listed below:

- Bus interface
  - One 64-bit AHB slave port, the read port (input from GPU texture read interface)
  - One 64-bit AHB master port: master1 port (output to texture bus of main AXI/AHB bus matrix)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, **w**, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls
- Performance counters

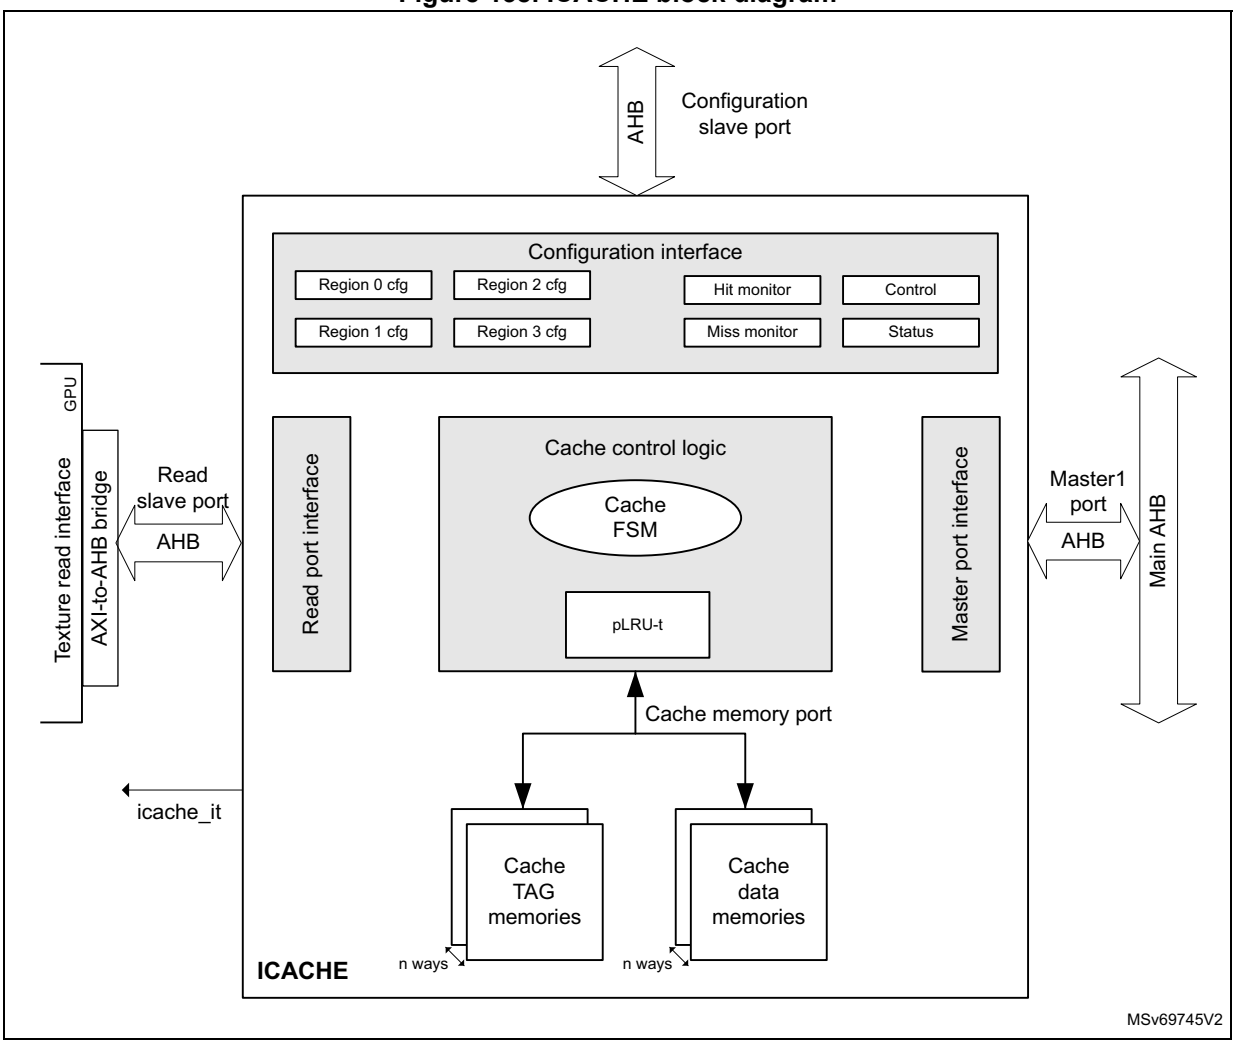
  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error and optionally to raise an interrupt
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, noninterruptible

17.3 ICACHE implementation

Table 131. ICACHE features

Feature	ICACHE
Number of ways	4
Cache size	16 Kbytes
Cache line width	32 bytes
Number of regions to remap	0
Data size of AHB slave interface	64 bits
Data size of AHB fast master1 interface	64 bits
Data size of AHB slow master2 interface	0

17.4 ICACHE functional description



The purpose of the texture cache is to cache GPU read accesses to texture data. As such, the ICACHE only manages cacheable read transactions and does not manage cacheable write transactions.

The noncacheable transactions (both read and write ones) bypass the ICACHE.

For the error management purpose, in case a write cacheable transaction is presented (this only happens in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

17.4.1 ICACHE block diagram

Figure 138. ICACHE block diagram

17.4.2 ICACHE reset and clocks

The ICACHE is clocked on the texture AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (=0).

Note: When disabled, the ICACHE is bypassed: slave input requests are forwarded to the master port.

17.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags that indicate which data are contained in the cache data memories
- validity bits

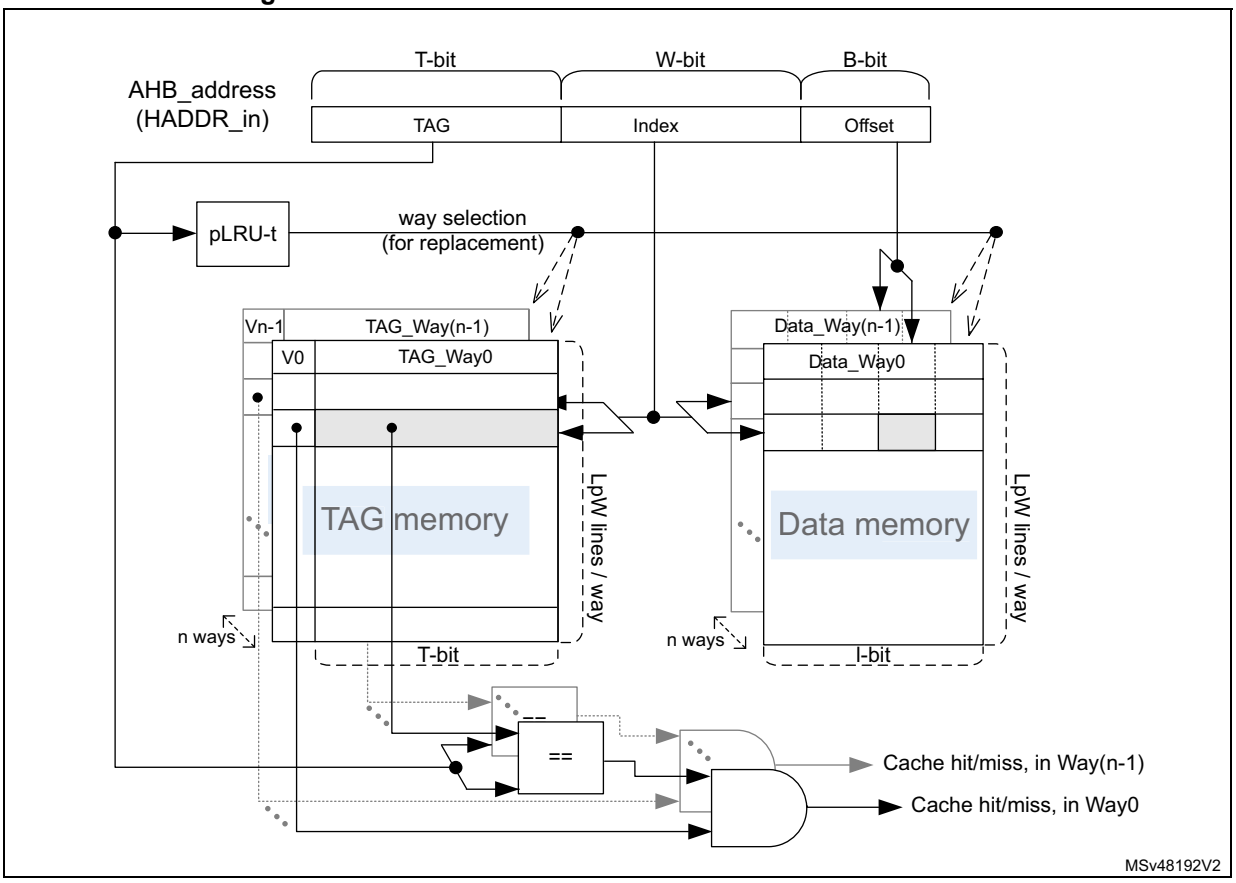
There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 132* for B and W definitions):



- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. *Figure 139* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

Table 132. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 139. ICACHE TAG and data memories functional view

17.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 133. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = log2(L) bit	4-bit
Address way index size	W = log2(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 17.4.7*): only one way (the unique one) is possible for any data refill.

17.4.5 ICACHE enable

To activate the ICACHE, the EN bit must be set to 1 in ICACHE_CR.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave port to the master port in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate procedure before enabling the ICACHE. This procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The ICACHE is by default disabled at boot.

17.4.6 Cacheable and noncacheable traffic

The ICACHE is placed on the GPU texture bus, and thus caches all internal and external memory regions (ranging from address 0x0000 0000 to 0x3FFF FFFF, respectively 0x6000 0000 to 0x9FFF FFFF, of the memory map).

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 134*. This AHB attribute depends on the GPU setting for the addressed region.

Table 134. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Noncacheable

In the case of a noncacheable access (either a noncacheable read or a noncacheable write), the ICACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in *Section 17.4.7*.

17.4.7 Cacheable accesses

When the ICACHE receives a cacheable transaction from the GPU, the ICACHE checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy ensures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port.
- The address is not present in TAG memory, but belongs to the refill burst from the main memory currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as the data is available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If ever the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

17.4.8 ICACHE maintenance

The software can invalidate the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

17.4.9 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 17.4.7*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

17.4.10 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

17.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by reading textures from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with lower performance profile (in terms of hit ratio) and stringent power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 139*). The power consumption is reduced by accessing, for each request, only the necessary cut of TAG and data memories. The cache effect still improves memory access performance, even if for most texture accesses, it is less efficient than with an n-way set associative cache mode.

17.6 ICACHE error management and interrupts

If an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 135. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as address decoding issues) from the master1 port back to the slave read port.

17.7 ICACHE registers

17.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISSMRST	HITMRST	MISSMEN	HITMEN

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WAYSEL	CACHEINV	EN
													rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable
0: cache miss monitor switched off. Stopping the monitor does not reset it.
1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable
0: cache hit monitor switched off. Stopping the monitor does not reset it.
1: cache hit monitor enabled

Bits 15:3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection
This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).
0: direct mapped cache (1-way cache)
1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation
Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

17.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

17.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERRIE	BSYENDIE	Res.
													rw	rw	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error

Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)

0: interrupt disabled on error

1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end

Set by software to enable an interrupt generation at the end of a cache invalidate operation.

0: interrupt disabled on busy end

1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

17.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CERRF	CBSYENDF	Res.
													w	w	

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **CERRF**: clear cache error flag

Set by software.

0: no effect

1: clears ERRF flag in ICACHE_SR

Bit 1 **CBSYENDF**: clear busy end flag

Set by software.

0: no effect

1: clears BSYENDF flag in ICACHE_SR.

Bit 0 Reserved, must be kept at reset value.

17.7.5 ICACHE hit monitor register (ICACHE_HMONR)

Address offset: 0x010

Reset value: 0x0000 0000

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

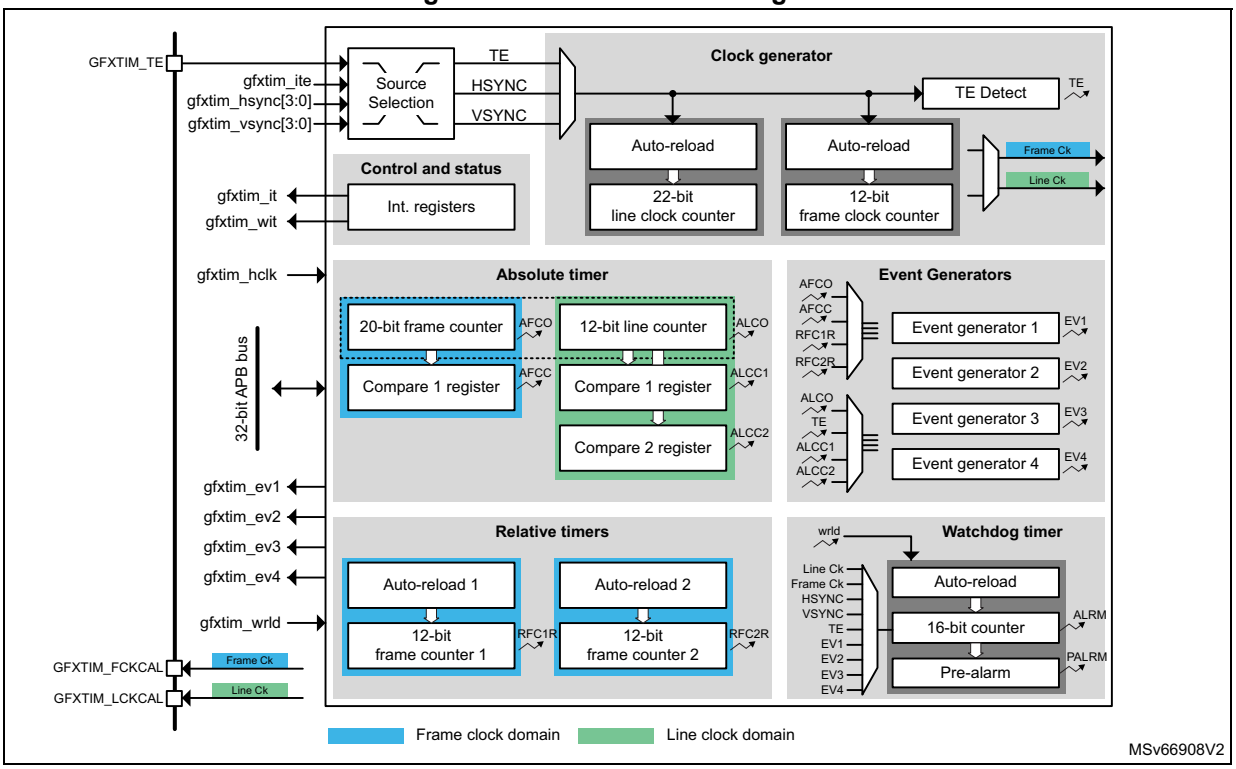
18 Graphic timer (GFXTIM)

18.1 Introduction

The graphic timer (GFXTIM) is a graphic oriented timer allowing smart management of graphical events for frame or line counting.

18.2 GFXTIM main features

- Integrated frame and line clock generation
- One absolute frame counter with one compare channel
- Two auto-reload relative frame counters
- One line timer with two compare channels
- External tearing-effect line management and synchronization
- Four programmable event generators with external trigger generation
- One watchdog counter



18.3 GFXTIM functional description

18.3.1 Block diagram

The graphic timer is split into six functional blocks

- Clock generator
- Absolute timers
- Relative timers
- Tearing-effect detection
- Event generators
- Watchdog timer

Figure 140. GFXTIM block diagram

18.3.2 GFXTIM pins and internal signals

Table 137. GFXTIM input/output pins

Pin name	Signal type	Description
GFXTIM_TE	Input	Tearing effect
GFXTIM_FCKCAL	Output	Frame clock calibration output
GFXTIM_LCKCAL	Output	Line clock calibration output

Table 138. GFXTIM internal signals

Signal name	Signal type	Description
gfxtim_hclk	Digital input	Kernel and register interface clock
gfxtim_it	Digital output	Global interrupt
gfxtim_wit	Digital output	Watchdog global interrupt
gfxtim_ev1	Digital output	Graphic timer event 1
gfxtim_ev2	Digital output	Graphic timer event 2
gfxtim_ev3	Digital output	Graphic timer event 3
gfxtim_ev4	Digital output	Graphic timer event 4
gfxtim_wrld	Digital input	Watchdog reload
gfxtim_ite	Digital input	Internal tearing effect

Table 138. GFXTIM internal signals (continued)

Signal name	Signal type	Description
gfxtim_hsync[3:0]	Digital input	Horizontal synchronization
gfxtim_vsync[3:0]	Digital input	Vertical synchronization

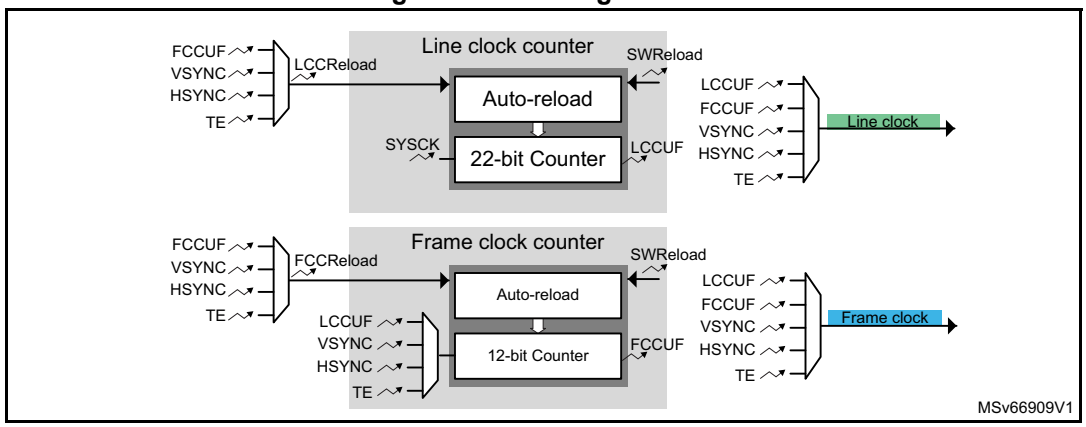
The table below shows how GFXTIM triggers are connected.

Table 139. GFXTIM trigger interconnections

Trigger name	Direction	Trigger source/destination
gfxtim_ev1	Output	hpdma_trigsel[20]
gfxtim_ev2	Output	hpdma_trigsel[19]
gfxtim_ev3	Output	hpdma_trigsel[18]
gfxtim_ev4	Output	hpdma_trigsel[17]
gfxtim_wrld	Input	reserved
gfxtim_ite	Input	reserved
gfxtim_hsync[0]	Input	LCD_HSYNC
gfxtim_hsync[1]	Input	dcmipp_p0_hsync_evt
gfxtim_hsync[2]	Input	reserved
gfxtim_hsync[3]	Input	reserved
gfxtim_vsync[0]	Input	LCD_VSYNC
gfxtim_vsync[1]	Input	dcmipp_p0_vsync_evt
gfxtim_vsync[2]	Input	reserved
gfxtim_vsync[3]	Input	reserved

18.3.3 Clock generator

Two clocks are generated internally to fed the absolute and relative timers:



- the frame clock: clocking frame counters
- the line clock: clocking line counters

Internal counter for time base generation

The GFXTIM embeds a two-clock generation counter:

- a 22-bit auto-reload down-counter on the system clock
- a 12-bit auto-reload down-counter on selectable internal or external event

Figure 141. Clock generator

Line clock counter

The line clock counter is a 22-bit auto-reload down-counter on the system clock.

The line clock counter is enabled selecting its clock source with LCCCS (line clock counter clock source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded automatically when one of the following event occurs:

- frame clock counter underflows
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with LCCHRS (line clock counter hardware reload source) in GFXTIM_CGCR (clock generator control register).

The line clock counter can be reloaded by software, setting LCCFR (line clock counter force reload) in GFXTIM_CGCR (clock generator control register).

The reload value is programmed in GFXTIM_LCCRR (line clock counter reload register).

Frame clock counter

The frame clock counter if an 12-bit auto-reload down-counter clocked by either, TE, HYSNC, VSYNC or a line clock counter underflow.

The frame clock counter is enabled selecting its clock source with FCCCS in GFXTIM_CGCR.

The frame clock counter can be reloaded automatically when one of the following event occurs:

- line clock counter underflow
- VSYNC edge (with control of polarity)
- HSYNC edge (with control of polarity)
- TE edge (with control of polarity)

The hardware reload function and source can be selected with FCCHRS in GFXTIM_CGCR.

The frame clock counter can be reloaded by software, setting FCCFR in GFXTIM_CGCR.

The reload value is programmed in GFXTIM_FCCRR.

Clock generation

The line clock source can be one of the following:

- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

The frame clock source can be one of the following:

- underflow flag of the internal 22-bit down-counter
- underflow flag of the internal 12-bit down-counter
- HSYNC, VSYNC or TE pin (with control of polarity)

Clock calibration output

For calibration/debug purpose, the frame clock and line clock can be output on a specific I/O.

The frame clock calibration output is enabled by setting FCCOE (frame clock calibration output enable) in GFXTIM_CR (configuration register).

The line clock calibration output is enabled by setting LCCOE in GFXTIM_CR.

Synchronization and tearing-effect sources

The GFXTIM can be connected to peripherals providing HSYNC and/or VSYNC synchronization signals, like the LCD-TFT controller or the camera interface.

The source of HSYNC and/or VSYNC is selected through SYNCS (synchronization source) in GFXTIM_CR.

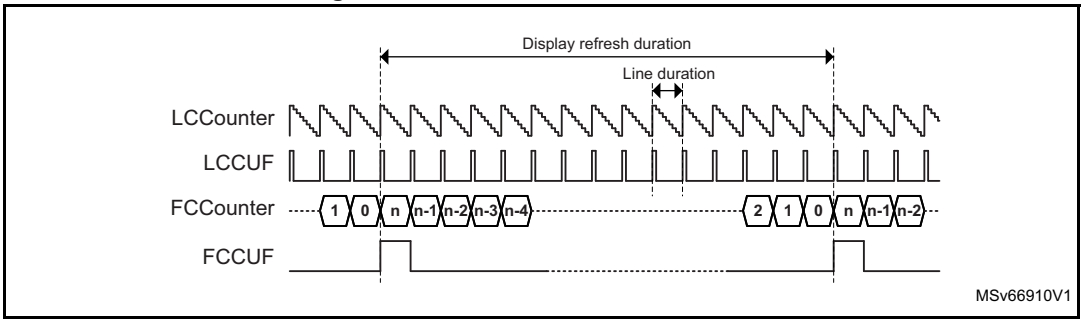
The tearing-effect source can be an external pin or can be provided by the MIPI® DSI Host on system embedding this interface. To extend the orthogonality versus the synchronization signals, the tearing-effect source can be also the selected HSYNC or VSYNC input.

The tearing-effect source can be selected with TES (TE source) in GFXTIM_CR.

18.3.4 Example of clock generator configuration

The clock generator can have several configuration to work:

- in standalone (without any external synchronization)
- with external HSYNC and VSYNC
- with external HSYNC only
- with external VSYNC only
- with external CSYNC (TE) only



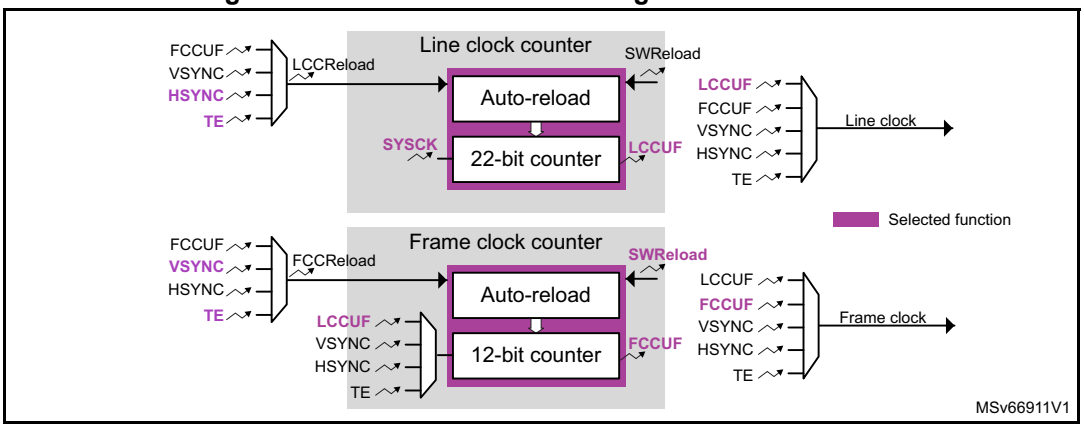
The synchronization signals, HSYNC, VSYNC and TE, are symmetrical in the implementation and can be exchanged if needed.

The set of examples detailed below are given for reference, but other combinations can be programmed int the clock generator.

Standalone

In standalone configuration, the clock generator provides to the GFXTIM, the frame clock and the line clock without any external signals.

Figure 142. Waveforms in standalone



The LCCUF (line-clock counter underflow) event acts as line clock and the FCCUF (frame-clock counter underflow) acts as frame clock.

The clock generator can be synchronized by one of the following ways:

- by software reload, setting the FCCFR in GFXTIM_CGCR.
- by hardware reload on an external VSYNC (or TE)

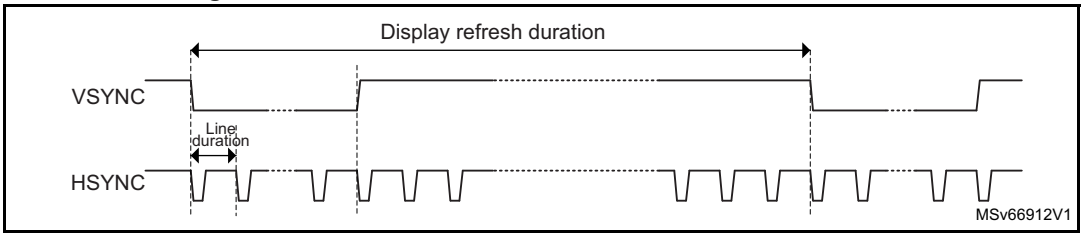


Figure 143. Active counters and signals in standalone

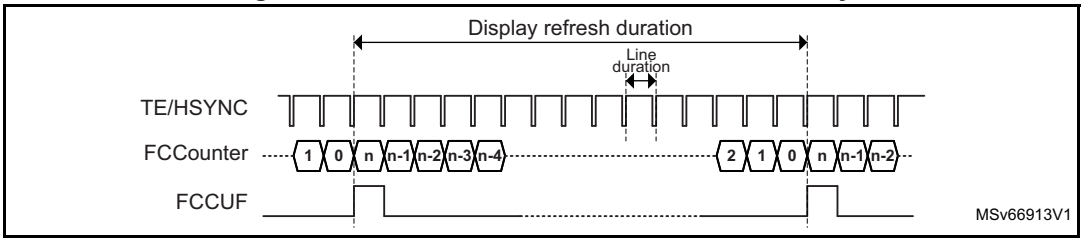
External HSYNC and VSYNC

When using external HSYNC and VSYNC, the counters are not used for the line and frame clock generation. The clock generator copy directly HSYNC to the line clock and VSYNC to the frame clock.

Figure 144. Waveforms with external HSYNC and VSYNC

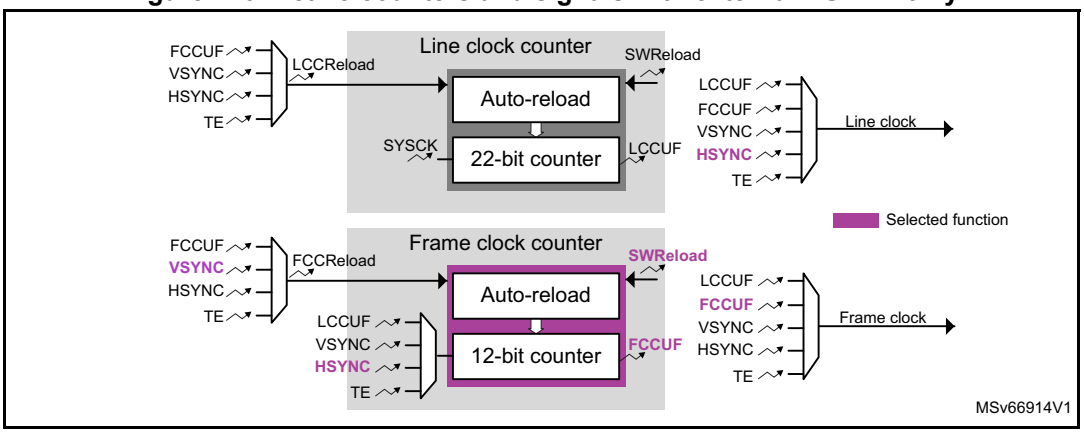


HSYNC acts as line clock and VSYNC acts as frame clock.

External HSYNC only

With external HSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on HSYNC.

Figure 145. Waveforms with external HSYNC only



HSYNC acts as line clock and FCCUF acts as frame clock.

The clock generator can be synchronized by one of the following ways:

- by software reload, setting FCCFR in GFXTIM_CGCR
- by hardware reload on an external VSYNC (or TE)

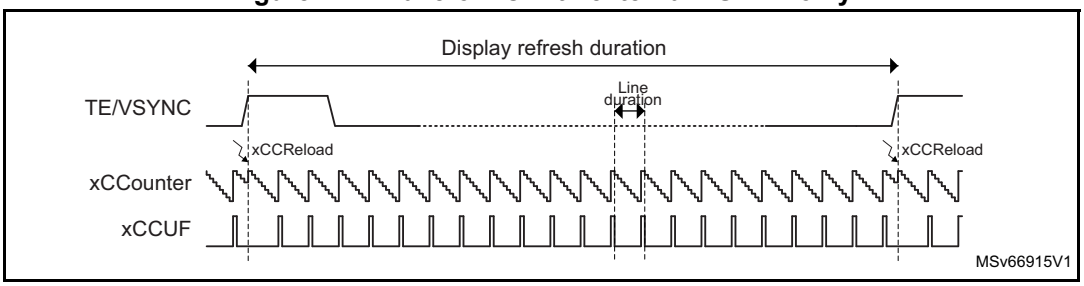


Figure 146. Active counters and signals with external HSYNC only

External VSYNC only

With external VSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on VSYNC.

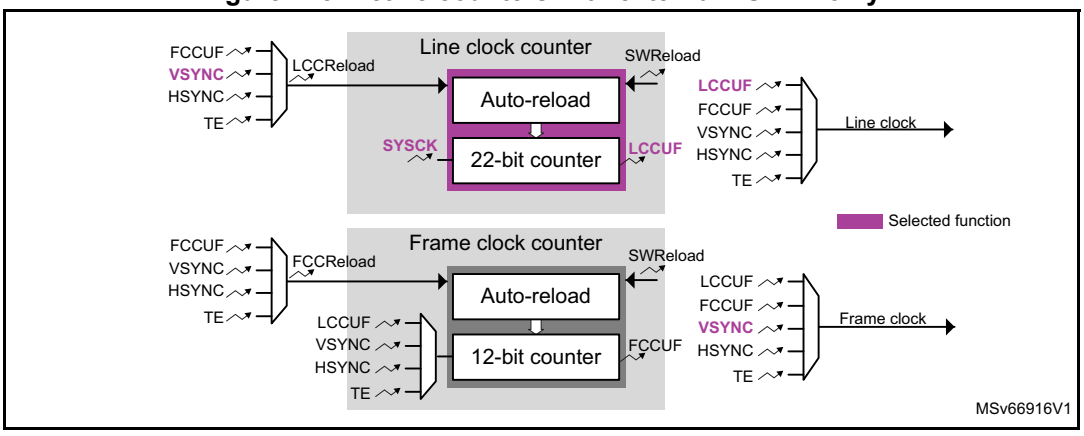

Figure 147. Waveforms with external VSYNC only

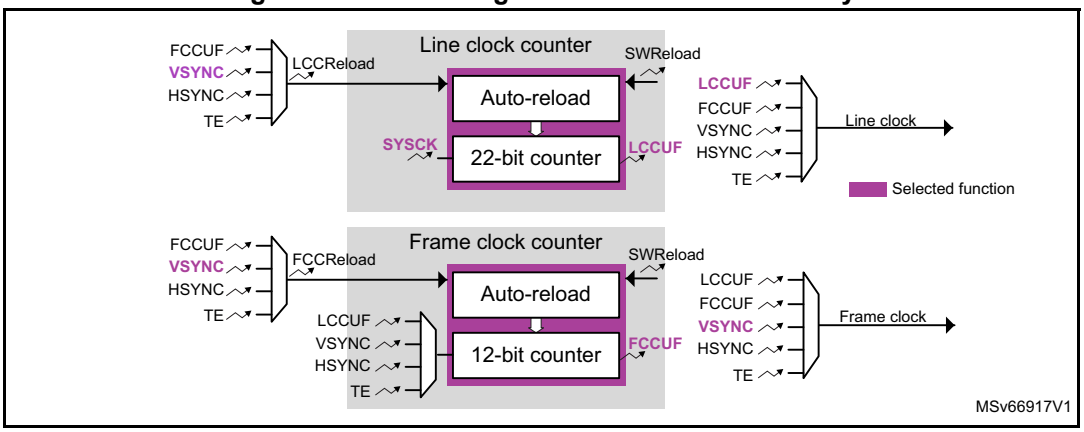
LCCUF (line clock counter underflow) acts as line clock and VSYNC acts as frame clock.



The line clock counter generating the line clock is reloaded on VSYNC event.

Figure 148. Active counters with external VSYNC only

The line clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as line clock.

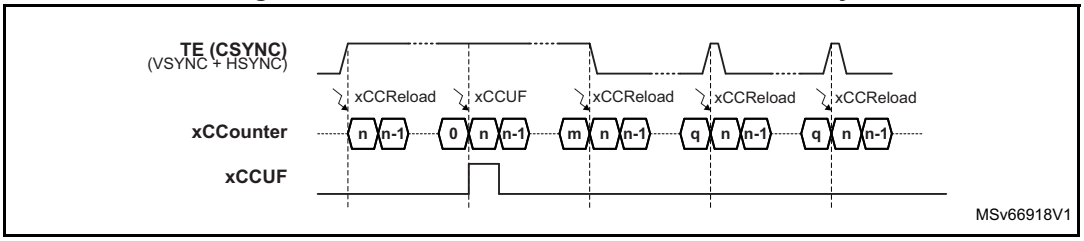


Figure 149. Prescaling when external VSYNC only

External CSYNC only

With external CSYNC only, the clock generator provides to the GFXTIM, the frame clock and the line clock based only on CSYNC (in the following figures, CSYNC is input on TE).

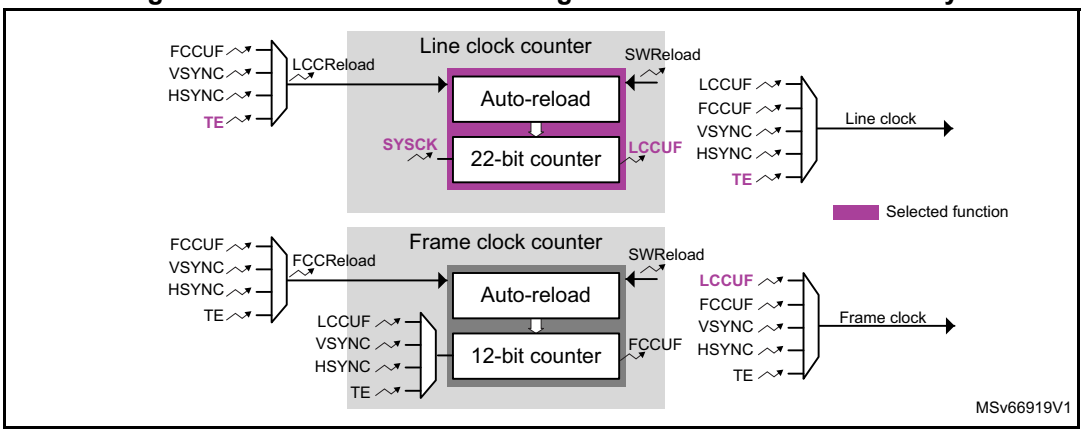

Figure 150. Waveforms with external CSYNC only

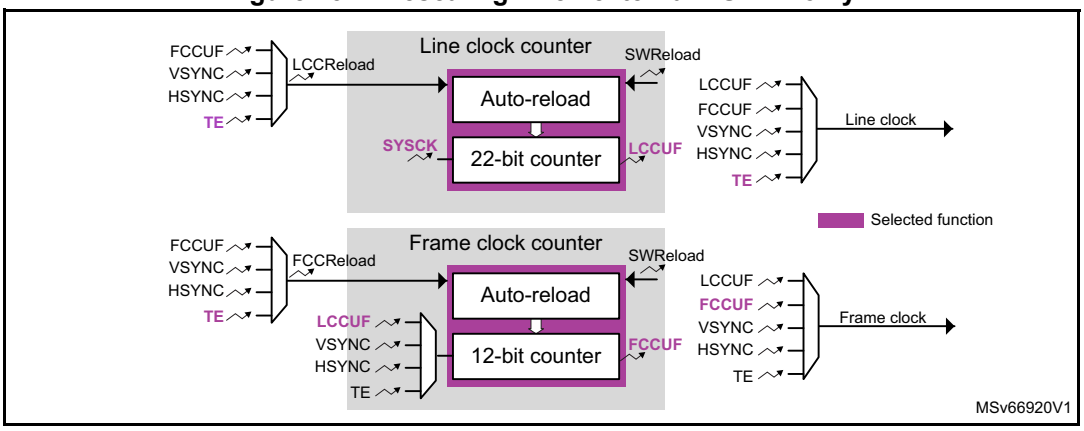
The CSYNC (on TE pin in this example) acts as line clock and LCCUF acts as frame clock.



The line clock counter generating the frame clock is reloaded on CSYNC event.

Figure 151. Active counters and signals with external CSYNC only

The line-clock counter can also act as a prescaler for the frame clock counter to have a wider range of counting. FCCUF acts as frame clock.

Figure 152. Prescaling when external CSYNC only

18.3.5 Absolute timers

Absolute time

The absolute time 32-bit value can be read directly in GFXTIM_ATR (absolute time register) to provide a global time and to generate absolute time accurate event to synchronize the graphical software.

The absolute time is generated by the combination of:

- the absolute frame counter
- the absolute line counter

Absolute frame counter

The absolute frame counter is a 20-bit free running up-counter with a software controlled reset.

It can be enabled by writing 1 in AFCEN (absolute-frame counter enable) of GFXTIM_TCR (timers configuration register).

The counter is incremented at each rising edge of the frame clock and is reset by setting FAFCR (force absolute-frame counter reset) in GFXTIM_TCR.

In case of overflow of the absolute frame counter, AFCOF (overflow flag) is set in GFXTIM_ISR (interrupt status register), and an interrupt is generated if AFCOIE (overflow interrupt enable) is set in (interrupt enable register).

A 20-bit compare register can generate an absolute-frame counter compare event when the counter value matches the compare value. When a compare event occurs, AFCC1F (compare 1 flag) is set in GFXTIM_ISR, and an interrupt is generated if AFCC1IE (compare 1 interrupt enable) is set in GFXTIM_IER.

The absolute frame counter can be disabled by writing 1 in AFCDIS (counter disable) of GFXTIM_TDR (timers disable register).

The status (enabled/disabled) can be monitored through AFCS (counter status) in GFXTIM_TSR (timers status register).

Absolute line counter

The absolute line counter is 12-bit free running-up counter with an hardware controlled reset.

It can be enabled by writing 1 in ALCEN of GFXTIM_TCR.

The counter is incremented at each rising edge of the line clock an is reset at each rising edge of the frame clock or setting FALCR in GFXTIM_TCR).

In case of overflow of the absolute line counter, ALCOF is set in GFXTIM_ISR, and an interrupt is generated if ALCOIE is set in GFXTIM_IER.

Two 12-bit compare registers can generate an absolute line counter compare events when the counter value matches the compare value. When a compare event occurs, ALCC1F or ALCC2F is set in GFXTIM_ISR, and an interrupt is generated if ALCC1IE or ALCC2IE is set in GFXTIM_IER.

The absolute line counter can be disabled writing 1 in ALCDIS of GFXTIM_TDR.

The status (enabled/disabled) can be monitored through ALCS in GFXTIM_TSR.

18.3.6 Relative timers

The relative timers can generate periodic events to synchronize the graphical tasks at frame level.

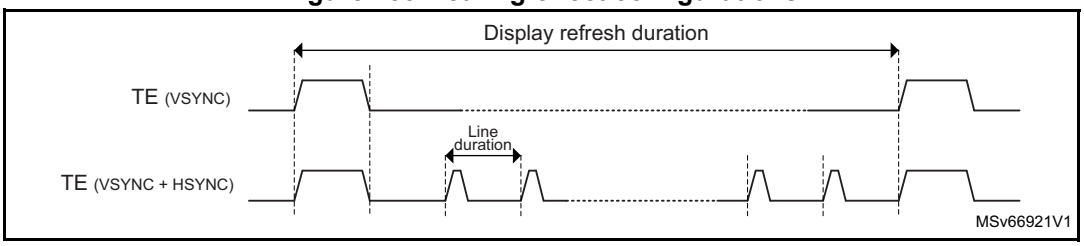
The relative frame counters are 12-bit down-counting auto-reload timers that are decremented at each rising edge of the frame clock. The counter is started by writing 1 in RFCxEN (relative frame counter x enable) of GFXTIM_TCR. The starting value is automatically loaded from GFXTIM_RFCxRR (relative frame counter x reload register).

The current relative frame counter value can be read directly in GFXTIM_RFCxR.

Once the counter reaches zero, it is automatically reloaded with the value of GFXTIM_RFCxRR. RFCxRF (reload flag) is set in GFXTIM_ISR is set, and an interrupt is generated if RFCxRIE (interrupt enable) is set in GFXTIM_IER.

Once the reload operation occurs, the timer can be disabled automatically or continue counting if RFCxCM (continuous mode) is set in GFXTIM_TCR.

The status (enabled/disabled) can be monitored through RFCxS in GFXTIM_TSR.



The counter can be reloaded on the fly by setting FRFCRx in GFXTIM_TCR. This force reload neither stop the timer (even if RFCxCM = 0 in GFXTIM_TCR), nor set RFCxRF (reload flag) in GFXTIM_ISR.

The relative frame counter can be disabled by setting RFCxDIS (disable) in GFXTIM_TDR.

18.3.7 Tearing-effect detection

A tearing-effect line can work in one of the two configurations shown in the figure below.

Figure 153. Tearing-effect configurations

A tearing-effect event can be generated on rising or falling edge depending on TEPOL (tearing-effect polarity) in GFXTIM_CR.

When a tearing-effect event is detected, TEF (tearing-event flag) is set in GFXTIM_ISR, and an interrupt is generated if TEIE (interrupt enable) is set in GFXTIM_IER.

18.3.8 Event generator

The event generator can combine timer events into complex events. Up to four combined events can be generated.

The events can be used for:

- interrupt generation
- watchdog clocking
- external trigger generation

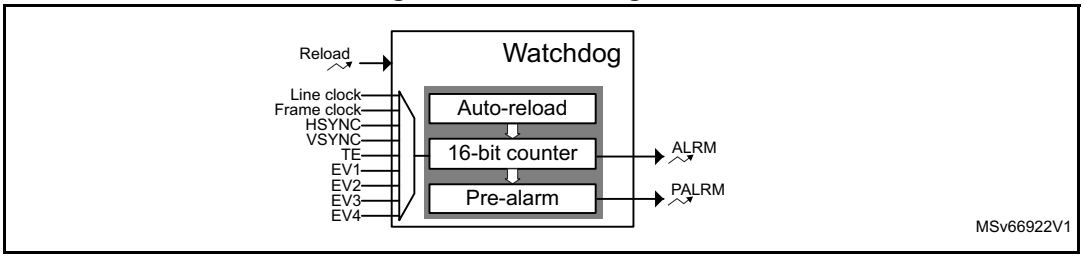
A complex event is a combination between a frame event and a line event.

Once a frame event occurs, the GFXTIM waits for the line event to occur before generating the complex event.

The frame event is selected by the corresponding FESx (frame event selection x) in GFXTIM_EVSR (events selection y register). The line event is selected by the corresponding LESx in GFXTIM_EVSR.

The complex event generation is enabled by setting the corresponding EVxEN (event x enable) in GFXTIM_EVCR (event control register).

It is recommended to disable the event generation prior to any event configuration to avoid spurious complex event generation



When a complex event occurs, the corresponding EVxF (event x flag) is set in GFXTIM_ISR, and an interrupt is generated if EVxIE (event x interrupt enable) is set in GFXTIM_IER.

Each of the events can be connected to another peripherals (such as DMA) to generate hardware triggers.

18.3.9 Watchdog timer

The watchdog timer is a 16-bit auto-reload down-counter with a programmable clock source.

Figure 154. Watchdog timer

Clock source

The watchdog clock source can be selected through WDGCS (clock source) in GTXTIM_WDGTCR (watchdog timer configuration register), between one of the following:

- line clock
- frame clock
- HSYNC
- VSYNC
- TE
- event 1
- event 2
- event 3
- event 4

Startup

The watchdog is started by setting WDGEN in GFXTIM_WDGTCR and stops automatically when reaching 0.

On start, the watchdog counter is automatically loaded with the auto-reload value programmed in GFXTIM_WDGRR (watchdog reload register).

The current watchdog value can be read through GFXTIM_WDGCR.

Auto-reload

The auto-reload can be forced in one of the following ways:

- by software, setting FWDGR (force watchdog reload) in GTXTIM_WDGTCR (watchdog timer configuration register)
- by hardware through an external trigger (gfxtim_wrld signal)

  The polarity of the trigger is configured by WDGHRC (watchdog hardware reload configuration) in GFXTIM_WDGTCR.

Event and interrupt generation

The watchdog can generate two events:

- an alarm when the watchdog down-counter reaches 0

  The watchdog counter is automatically stopped, and WDGAF (alarm flag) is set in GFXTIM_ISR. An interrupt is generated if WDGAIE (alarm interrupt enable) is set in GFXTIM_IER.
- a pre-alarm when the watchdog counter matches the pre-alarm register value in GFXTIM_WDGPAR (watchdog pre-alarm register)

  WDGPF (pre-alarm flag) is set in GFXTIM_ISR, and an interrupt is generated if WDGPIE (pre-alarm interrupt enable) is set in GFXTIM_IER.

18.4 GFXTIM interrupts

An interrupt can be produced on the following events:

- absolute frame counter compare event
- absolute frame counter overflow
- absolute line counter compare events
- absolute line counter overflow
- relative frame counter reload events
- external tearing effect
- combined events
- watchdog alarm event
- watchdog pre-alarm event

Separate interrupt enable bits are available for flexibility.

Table 140. Graphic timer interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
GFXTIM	Absolute frame counter overflow	AFCOF	AFCOIE	write 1 in CAFCOF
	Absolute frame counter compare 1	AFCC1F	AFCC1IE	write 1 in CAFCC1F
	Absolute line counter overflow	ALCOF	ALCOIE	write 1 in CALCOF
	Absolute line counter compare 1	ALCC1F	ALCC1IE	write 1 in CALCC1F
	Absolute line counter compare 2	ALCC2F	ALCC2IE	write 1 in CALCC2F
	Relative frame counter 1 reload	RFC1RF	RFC1RIE	write 1 in CRFC1RF
	Relative frame counter 2 reload	RFC2RF	RFC2RIE	write 1 in CRFC2RF
	External tearing effect	TEF	TEIE	write 1 in CTEF
	Event 1	EV1F	EV1IE	write 1 in CEV1F
	Event 2	EV2F	EV2IE	write 1 in CEV2F
	Event 3	EV3F	EV3IE	write 1 in CEV3F
	Event 4	EV4F	EV4IE	write 1 in CEV4F

Table 140. Graphic timer interrupt requests (continued)

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
GFXTIMW	Watchdog alarm	WDGAF	WDGAIE	write 1 in CWDGAF
	Watchdog pre-alarm	WDGPF	WDGPIE	write 1 in CWDGPF

18.5 GFXTIM registers

18.5.1 GFXTIM configuration register (GFXTIM_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCCOE	FCCOE

Res.	Res.	Res.	Res.	Res.	Res.	SYNCS[1:0]		Res.	Res.	Res.	TEPOL	Res.	Res.	TES[1:0]	
						rw	rw				rw			rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **LCCOE**: Line-clock calibration output enable
This bit enables the line-clock output.
0: Line-clock output disabled
1: Line-clock output enabled

Bit 16 **FCCOE**: Frame-clock calibration output enable
This bit enables the frame-clock output.
0: Frame-clock output disabled
1: Frame-clock output enabled

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **SYNCS[1:0]**: Synchronization source
This bitfield selects the synchronization signals (HSYNC and VSYNC) sources.
00: gfxtim_hsync[0] and gfxtim_vsync[0] selected
01: gfxtim_hsync[1] and gfxtim_vsync[1] selected
10: gfxtim_hsync[2] and gfxtim_vsync[2] selected
11: gfxtim_hsync[3] and gfxtim_vsync[3] selected

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TEPOL**: Tearing--effect polarity
This bit selects the tearing-effect polarity.
0: Tearing effect active on rising edge
1: Tearing effect active on falling edge

Bits 3:2 Reserved, must be kept at reset value.

Bits 1:0 **TES[1:0]**: Tearing source
This bitfield selects the tearing-effect source.
00: TE input pad selected
01: gfxtim_ite selected
10: HSYNC input selected by SYNCS[1:0]
11: VSYNC input selected by SYNCS[1:0]

18.5.2 GFXTIM clock generator configuration register (GFXTIM_CGCR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	FCCHRS[2:0]			Res.	Res.	Res.	FCCFR	Res.	FCCCS[2:0]			Res.	FCS[2:0]

	rw	rw	rw				w				rw		rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **FCCHRS[2:0]**: Frame clock counter hardware reload source
This bitfield configures the hardware reload source for the frame clock counter.
000: No hardware reload
001: Line- -clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **FCCFR**: Frame clock counter force reload
This bit forces frame clock counter reload
0: No effect
1: Frame clock counter reload forced

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **FCCCS[2:0]**: Frame clock counter clock source
This bitfield configures the clock source for the frame clock counter.
000: Frame clock counter disabled
001: Line clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **FCS[2:0]**: Frame clock source
This bitfield configures the frame clock source.
000: Line clock counter underflow
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **LCCHRS[2:0]**: Line clock counter hardware reload source
This bitfield configures the hardware reload source for the line clock counter.
000: No hardware reload
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **LCCFR**: Line clock counter force reload
This bit forces line clock counter reload.
0: No effect
1: Line clock counter reload forced

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **LCCCS**: Line clock counter clock source
This bit configures the clock source for the line clock counter.
0: Line clock counter disabled
1: System clock selected

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LCS[2:0]**: Line clock source
This bitfield configures the line clock source.
000: Line clock counter underflow
001: Frame clock counter underflow
010: HSYNC rising edge
011: HSYNC falling edge
100: VSYNC rising edge
101: VSYNC falling edge
110: TE rising edge
111: TE falling edge

18.5.3 GFXTIM timers configuration register (GFXTIM_TCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FALCR	ALCEN	Res.	Res.	FAFCR	AFCEN
										w	w			w	w

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **FRFC2R**: Force relative frame counter 2 reload
This bit forces the reload of the relative frame counter 2.
0: No effect
1: Relative frame counter 2 reload forced

Bit 21 **RFC2CM**: Relative frame counter 2 continuous mode
This bit enables the continuous mode of the relative frame counter 2.
0: Relative frame counter 2 is one shot.
1: Relative frame counter 2 is in continuous mode.

Bit 20 **RFC2EN**: Relative frame counter 2 enable
This bit enables the relative frame counter 2.
0: No effect
1: Relative frame counter 2 enabled

Bit 19 Reserved, must be kept at reset value.

Bit 18 **FRFC1R**: Force relative frame counter 1 reload
This bit forces the reload of the relative frame counter 1.
0: No effect
1: Relative frame counter 1 reload forced

Bit 17 **RFC1CM**: Relative frame counter 1 continuous mode
This bit enables the continuous mode of the relative frame counter 1.
0: Relative frame counter 1 is one shot.
1: Relative frame counter 1 is in continuous mode.

Bit 16 **RFC1EN**: Relative frame counter 1 enable
This bit enables the relative frame counter 1.
0: No effect
1: Relative frame counter enabled

Bits 15:6 Reserved, must be kept at reset value.

Bit 5 **FALCR**: Force absolute line counter reset
This bit forces the reset of the absolute line counter.
0: No effect
1: Absolute line counter reset forced

Bit 4 **ALCEN**: Absolute line counter enable
This bit enables the absolute line counter.
0: No effect
1: Absolute line counter enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FAFCR**: Force absolute frame counter reset
This bit forces the reset of the absolute frame counter.
0: No effect
1: Absolute frame counter reset forced

Bit 0 **AFCEN**: Absolute frame counter enable
This bit enables the absolute frame counter.
0: No effect
1: Absolute frame counter enabled

18.5.4 GFXTIM timers disable register (GFXTIM_TDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALCDIS	Res.	Res.	Res.	AFCDIS
											w				w

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **RFC2DIS**: Relative frame counter 2 disable
This bit disables the relative frame counter 2.
0: No effect
1: Relative frame counter 2 disabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RFC1DIS**: Relative frame counter 1 disable
This bit disables the relative frame counter 1.
0: No effect
1: Relative frame counter 1 disabled

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **ALCDIS**: Absolute line counter disable
This bit disables the absolute line counter.
0: No effect
1: Absolute line counter disabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **AFCDIS**: Absolute frame counter disable
This bit disables the absolute frame counter.
0: No effect
1: Absolute frame counter disabled

18.5.5 GFXTIM events control register (GFXTIM_EVCR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **EV4EN**: Event 4 enable
This bit enables the complex event 4 generation.
0: Event 4 generation disabled
1: Event 4 generation enabled

Bit 2 **EV3EN**: Event 3 enable
This bit enables the complex event 3 generation.
0: Event 3 generation disabled
1: Event 3 generation enabled

Bit 1 **EV2EN**: Event 2 enable
This bit enables the complex event 2 generation.
0: Event 2 generation disabled
1: Event 2 generation enabled

Bit 0 **EV1EN**: Event 1 enable
This bit enables the complex event 1 generation.
0: Event 1 generation disabled
1: Event 1 generation enabled

18.5.6 GFXTIM events selection register (GFXTIM_EVSR)

Address offset: 0x014

Reset value: 0x0000 0000

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **FES4[2:0]**: Frame-event selection 4
This bitfield defines the frame-event selection for complex event 4 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **LES4[2:0]**: Line-event selection 4
This bitfield defines the line-event selection for complex event 4 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **FES3[2:0]**: Frame-event selection 3
This bitfield defines the frame-event selection for complex event 3 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **LES3[2:0]**: Line-event selection 3
This bitfield defines the line-event selection for complex event 3 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **FES2[2:0]**: Frame-event selection 2
This bitfield defines the frame-event selection for complex event 2 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **LES2[2:0]**: Line-event selection 2
This bitfield defines the line-event selection for complex event 2 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **FES1[2:0]**: Frame-event selection 1
This bitfield defines the frame-event selection for complex event 1 generation.
000: No frame event
001: Absolute frame counter overflow
010: Absolute frame counter compare
100: Relative frame counter 1 reload
101: Relative frame counter 2 reload
Others: Reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **LES1[2:0]**: Line-event selection 1
This bitfield defines the line-event selection for complex event 1 generation.
000: No line event
001: Absolute line counter overflow
010: Tearing effect
100: Absolute line counter 1 compare
101: Absolute line counter 2 compare
Others: Reserved

18.5.7 GFXTIM watchdog timer configuration register (GFXTIM_WDGTCR)

Address offset: 0x020

Reset value: 0x0000 0000

Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WDGHRC[1:0]**: Watchdog hardware reload configuration
This bitfield configures the watchdog hardware reload.
00: Watchdog hardware reload disabled
01: Watchdog reloaded a rising edge of gfxtim_wrld
10: Watchdog reloaded a falling edge of gfxtim_wrld
11: Reserved

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WDGS**: Watchdog status
This bit returns the status of the graphic watchdog.
0: Graphic watchdog disabled
1: Graphic watchdog enabled

Bit 1 **WDGDIS**: Watchdog disable
This bit disables the graphic watchdog.
0: No effect
1: Graphic watchdog disabled

Bit 0 **WDGEN**: Watchdog enable
This bit enables the graphic watchdog.
0: No effect
1: Graphic watchdog enabled

18.5.8 GFXTIM interrupt status register (GFXTIM_ISR)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		r	r			r	r				r		r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WDGPF**: Watchdog pre-alarm flag
This bit indicates that a graphic watchdog pre-alarm occurred.
0: No graphic watchdog pre-alarm occurred.
1: A graphic watchdog pre-alarm occurred.

Bit 24 **WDGAF**: Watchdog alarm flag
This bit indicates that a graphic watchdog alarm occurred.
0: No graphic watchdog alarm occurred.
1: A graphic watchdog alarm occurred.

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **EV4F**: Event 4 flag
This bit indicates a complex event 4 occurred.
0: No complex event 4 occurred.
1: A complex event 4 occurred.

Bit 18 **EV3F**: Event 3 flag
This bit indicates a complex event 3 occurred.
0: No complex event 3 occurred.
1: A complex event 3 occurred.

Bit 17 **EV2F**: Event 2 flag
This bit indicates a complex event 2 occurred.
0: No complex event 2 occurred.
1: A complex event 2 occurred.

Bit 16 **EV1F**: Event 1 flag
This bit indicates a complex event 1 occurred.
0: No complex event 1 occurred.
1: Complex event 1 occurred.

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **RFC2RF**: Relative frame counter 2 reload flag
This bit indicates relative frame counter 2 has been reloaded.
0: No reload occurred on relative frame counter 2.
1: A reload on relative frame counter 2 occurred.

Bit 12 **RFC1RF**: Relative frame counter 1 reload flag
This bit indicates relative frame counter 1 has been reloaded.
0: No reload occurred on relative frame counter 1.
1: A reload on relative frame counter 1 occurred.

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2F**: Absolute line counter compare 2 flag
This bit indicates match on compare 2 of the absolute line counter.
0: No match occurred on compare 2 of the absolute line counter.
1: A match on compare 2 of the absolute line counter occurred.

Bit 8 **ALCC1F**: Absolute line counter compare 1 flag
This bit indicates match on compare 1 of the absolute line counter.
0: No match occurred on compare 1 of the absolute line counter.
1: A match on compare 1 of the absolute line counter occurred.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1F**: Absolute frame counter compare 1 flag
This bit indicates match on compare 1 of the absolute frame counter.
0: No match occurred on compare 1 of the absolute frame counter.
1: A match on compare 1 of the absolute frame counter occurred.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEF**: Tearing-effect flag
This bit indicates a tearing effect event occurred.
0: No tearing effect occurred.
1: A tearing effect occurred.

Bit 1 **ALCOF**: Absolute line counter overflow flag
This bit indicates an overflow occurred on the absolute line counter.
0: No overflow occurred on the absolute line counter.
1: A overflow on the absolute line counter occurred.

Bit 0 **AFCOF**: absolute frame counter overflow flag
This bit indicates an overflow occurred on the absolute frame counter.
0: No overflow occurred on the absolute frame counter.
1: An overflow on the absolute frame counter occurred.

18.5.9 GFXTIM interrupt clear register (GFXTIM_ICR)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	CWDGPF	CWDGAF	Res.	Res.	Res.	Res.	CEV4F	CEV3F	CEV2F	CEV1F

		w	w			w	w				w		w	w	w

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CWDGPF**: Clear watchdog pre-alarm flag
This bit clears WDGPF in GXFXTIM_ISR.
0: No effect
1: WDGPF cleared

Bit 24 **CWDGAF**: Clear watchdog alarm flag
This bit clears WDGAF in GXFXTIM_ISR.
0: No effect
1: WDGAF cleared

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **CEV4F**: Clear event 4 flag
This bit clears EV4F in GXFXTIM_ISR.
0: No effect
1: EV4F cleared

Bit 18 **CEV3F**: Clear event 3 flag
This bit clears EV3F in GXFXTIM_ISR.
0: No effect
1: EV3F cleared

Bit 17 **CEV2F**: Clear event 2 flag
This bit clears EV2F in GXFXTIM_ISR.
0: No effect
1: EV2F cleared

Bit 16 **CEV1F**: Clear event 1 flag
This bit EV1F in GXFXTIM_ISR.
0: No effect
1: EV1F cleared

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **CRFC2RF**: Clear relative frame counter 2 reload flag
This bit clears RFC2RF in GXFXTIM_ISR.
0: No effect
1: RFC2RF cleared

Bit 12 **CRFC1RF**: Clear relative frame counter 1 reload flag
This bit clears RFC1RF in GXTIM_ISR.
0: No effect
1: RFC1RF cleared

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **CALCC2F**: Clear absolute line counter compare 2 flag
This bit clears ALCC2F in GXTIM_ISR.
0: No effect
1: ALCC2F cleared

Bit 8 **CALCC1F**: Clear absolute line counter compare 1 flag
This bit clears ALCC1F in GXTIM_ISR.
0: No effect
1: ALCC1F cleared

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CAFCC1F**: Clear absolute frame counter compare 1 flag
This bit clears AFCC1F in GXTIM_ISR.
0: No effect
1: AFCC1F cleared

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CTEF**: Clear tearing-effect flag
This bit clears TEF in GXTIM_ISR.
0: No effect
1: TEF cleared

Bit 1 **CALCOF**: Clear absolute line counter overflow flag
This bit clears ALCOF in GXTIM_ISR.
0: No effect
1: ALCOF cleared

Bit 0 **CAFCOF**: Clear absolute frame counter overflow flag
This bit clears AFCOF in GXTIM_ISR.
0: No effect
1: AFCOF cleared

18.5.10 GFXTIM interrupt enable register (GFXTIM_IER)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	WDGPIE	WDGAIE	Res.	Res.	Res.	Res.	EV4IE	EV3IE	EV2IE	EV1IE
						rw	rw					rw	rw	rw	rw

Res.	Res.	RFC2RIE	RFC1RIE	Res.	Res.	ALCC2IE	ALCC1IE	Res.	Res.	Res.	AFCC1IE	Res.	TEIE	ALCOIE	AFCOIE
		rw	rw			rw	rw				rw		rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **WDGPIE**: Watchdog pre-alarm interrupt enable
This bit enables the watchdog pre-alarm interrupt generation.
0: Watchdog pre-alarm interrupt disabled
1: Watchdog pre-alarm interrupt enabled

Bit 24 **WDGAIE**: Watchdog alarm interrupt enable
This bit enables the watchdog alarm interrupt generation.
0: Watchdog alarm interrupt disabled
1: Watchdog alarm interrupt enabled

Bits 23:20 Reserved, must be kept at reset value.

Bit 19 **EV4IE**: Event 4 interrupt enable
This bit enables the complex event 4 interrupt generation.
0: Event 4 interrupt disabled
1: Event 4 interrupt enabled

Bit 18 **EV3IE**: Event 3 interrupt enable
This bit enables the complex event 3 interrupt generation.
0: Event 3 interrupt disabled
1: Event 3 interrupt enabled

Bit 17 **EV2IE**: Event 2 interrupt enable
This bit enables the complex event 2 interrupt generation.
0: Event 2 interrupt disabled
1: Event 2 interrupt enabled

Bit 16 **EV1IE**: Event 1 interrupt enable
This bit enables the complex event 1 interrupt generation.
0: Event 1 interrupt disabled
1: Event 1 interrupt enabled

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **RFC2RIE**: Relative frame counter 2 reload interrupt enable
This bit enables the relative frame counter 2 reload interrupt generation.
0: Relative frame counter 2 reload interrupt disabled
1: Relative frame counter 2 reload interrupt enabled

Bit 12 **RFC1RIE**: Relative frame counter 1 reload interrupt enable
This bit enables the relative frame counter 1 reload interrupt generation.
0: Relative frame counter 1 reload interrupt disabled
1: Relative frame counter 1 reload interrupt enabled

Bits 11:10 Reserved, must be kept at reset value.

Bit 9 **ALCC2IE**: Absolute line counter compare 2 interrupt enable
This bit enables the absolute line counter compare 2 interrupt generation.
0: Absolute line counter compare 2 interrupt disabled
1: Absolute line counter compare 2 interrupt enabled

Bit 8 **ALCC1IE**: Absolute line counter compare 1 interrupt enable
This bit enables the absolute line counter compare 1 interrupt generation.
0: Absolute line counter compare 1 interrupt disabled
1: Absolute line counter compare 1 interrupt enabled

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **AFCC1IE**: Absolute frame counter compare 1 interrupt enable
This bit enables the absolute frame counter compare interrupt generation.
0: Absolute frame counter compare 1 interrupt disabled
1: Absolute frame counter compare 1 interrupt enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TEIE**: Tearing-effect interrupt enable
This bit enables the Tearing Effect interrupt generation.
0: Tearing-effect interrupt disabled
1: Tearing-effect interrupt enabled

Bit 1 **ALCOIE**: Absolute line counter overflow interrupt enable
This bit enables the absolute line counter overflow interrupt generation.
0: Absolute line counter overflow interrupt disabled
1: Absolute line counter overflow interrupt enabled

Bit 0 **AFCOIE**: Absolute frame counter overflow interrupt enable
This bit enables the absolute frame counter overflow interrupt generation.
0: Absolute frame counter overflow interrupt disabled
1: Absolute frame counter overflow interrupt enabled

18.5.11 GFXTIM timers status register (GFXTIM_TSR)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALCS	Res.	Res.	Res.	AFCS
											r				r

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **RFC2S**: Relative frame counter 2 status
This bit returns the status of the relative frame counter 2.
0: Relative frame counter 2 disabled
1: Relative frame counter 2 enabled

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **RFC1S**: Relative frame counter 1 status
This bit returns the status of the relative frame counter 1.
0: Relative frame counter 1 disabled
1: Relative frame counter 1 enabled

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **ALCS**: Absolute line counter status
This bit returns the status of the absolute line counter.
0: Absolute line counter disabled
1: Absolute line counter enabled

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **AFCS**: Absolute frame counter status
This bit returns the status of the absolute frame counter.
0: Absolute frame counter disabled
1: Absolute frame counter enabled

18.5.12 GFXTIM line clock counter reload register (GFXTIM_LCCRR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RELOAD[21:16]					
										rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **RELOAD[21:0]**: Reload value
Reload value of the line clock counter.

18.5.13 GFXTIM frame clock counter reload register (GFXTIM_FCCRR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	RELOAD[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:0 **RELOAD[11:0]**: Reload value
Reload value of the frame clock counter.

18.5.14 GFXTIM absolute time register (GFXTIM_ATR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FRAME[19:4]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

FRAME[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **FRAME[19:0]**: Frame number
Current value of the absolute frame counter.
Note: This bitfield can only be written when the absolute frame counter is disabled.

18.5.16 GFXTIM absolute line counter register (GFXTIM_ALCR)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Refer to *Section 2.3* for the register boundary addresses.

19 Nested vectored interrupt controller (NVIC)

19.1 NVIC features

The NVIC includes the following features:

- up to 140 maskable interrupt channels for STM32H7xxx (not including the 10 interrupt lines of Cortex®-M7 with FPU
- 16 programmable priority levels (4 bits of interrupt priority are used)
- low-latency exception and interrupt handling
- power management control
- implementation of system control registers

The NVIC and the processor core interface are closely coupled, which enables low latency interrupt processing and efficient processing of late-arriving interrupts.

All interrupts, including the core exceptions, are managed by the NVIC.

For more information on exceptions and NVIC programming, refer to PM0253 programming manual for Cortex®-M7.

19.1.1 SysTick calibration value register

The SysTick calibration value (SYST_CALIB) is fixed to 0x3E8. It provides a reference timebase of 1 ms based when the SysTick clock frequency is 1 MHz. To match the 1 ms timebase whatever the application frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- If the SysTick clock source is the 100 MHz CPU clock (HCLK):

$$\text{reload value} = (F_{HCLK} \times \text{SYST_CALIB}) - 1$$

- If the SysTick clock source is an external clock:

$$\text{reload value} = ((F_{HCLK} / 8) \times \text{SYST_CALIB}) - 1$$

  where F_{HCLK} refers to the AHB frequency expressed in MHz.

For example, to achieve a timebase of 1 ms when the SysTick clock source is the 100 MHz HCLK:

$$\text{reload value} = (100 \times \text{SYST_CALIB}) - 1 = 0\text{x}1869\text{F}$$

19.1.2 Interrupt and exception vectors

The exception vectors connected to the NVIC are the following: reset, NMI, HardFault, MemManage, Bus Fault, UsageFault, SVCall, DebugMonitor, PendSV, SysTick.

Table 142. NVIC(1)

NVIC position	Priority	Type of priority	Acronym	Description	Address offset
-	-	-		Reserved	0x0000 0000
-	-3	fixed	Reset	Reset	0x0000 0004
-	-2	fixed	NMI	Non maskable interrupt. The RCC Clock Security System (HSE CSS) is linked to the NMI vector.	0x0000 0008
-	-1	fixed	HardFault	All class of fault	0x0000 000C
-	0	fixed	MemManage	Memory management	0x0000 0010
-	1	settable	BusFault	Pre-fetch fault, memory access fault	0x0000 0014

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.

20 Extended interrupt and event controller (EXTI)

The extended interrupt and event controller (EXTI) manages wake-up through configurable and direct event inputs. It provides wake-up requests to the power control, and generates interrupt requests to the CPU NVIC and events to the CPU event input.

The EXTI wake-up requests allow the system to be woken up from Stop mode, and the CPU to be woken up from CStop mode.

Both the interrupt request and event request generation can also be used in Run modes.

20.1 EXTI main features

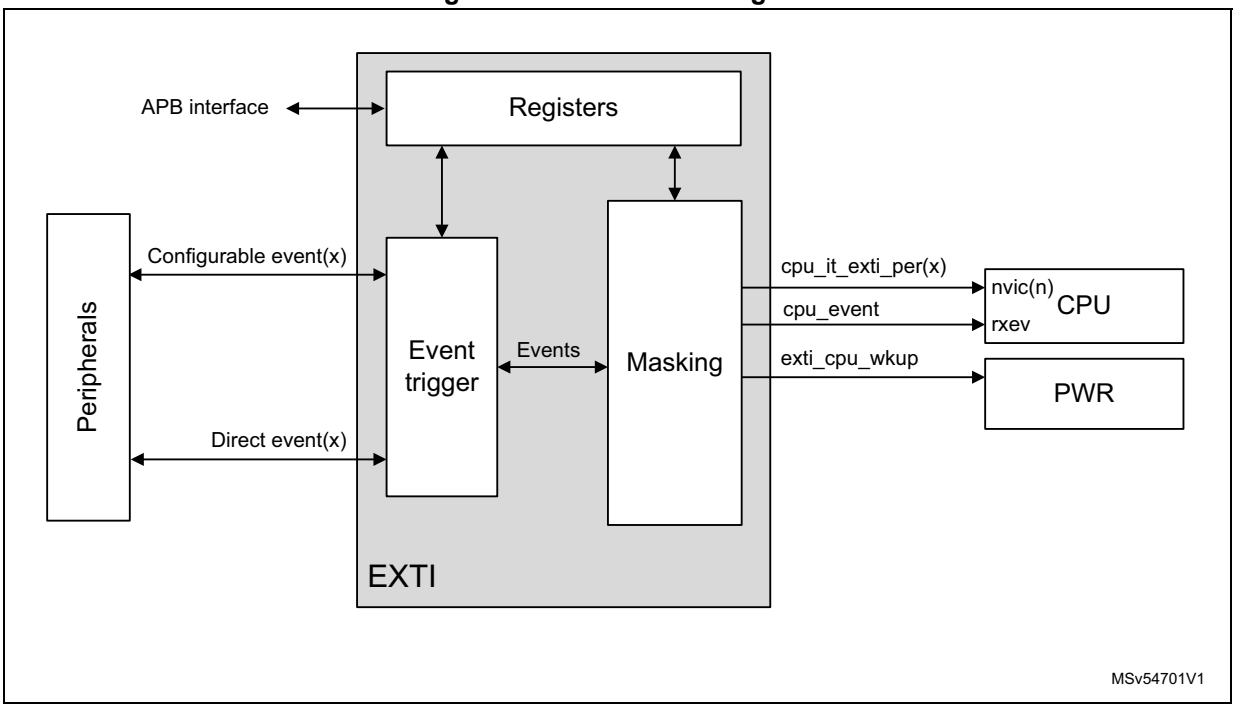
The EXTI main features are as follows:

- All event inputs allow the CPU to wake up and to generate a CPU interrupt and/or CPU event

The asynchronous event inputs are classified in 2 groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse) that feature:
  - Selectable active trigger edge
  - Interrupt pending status register bit
  - Individual interrupt and event generation mask
  - SW trigger possibility
- Direct events (interrupt and wake-up sources from other peripherals, requiring to be cleared in the peripheral) that feature:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status is provided by the peripheral generating the event)
  - Individual interrupt and event generation mask
  - No SW trigger possibility.

20.2 EXTI block diagram



As shown in *Figure 155*, the EXTI consists of a register block accessed via an APB interface, an event input Trigger block, and a masking block.

The register block contains all EXTI registers.

The event input trigger block provides event input edge triggering logic.

The masking block provides the event input distribution to the different wake-up, interrupt and event outputs, and their masking.

Figure 155. EXTI block diagram

20.2.1 EXTI connections between peripherals and CPU

The peripherals able to generate wake-up events when the system is in Stop mode or the CPU is in CStop mode are connected to an EXTI configurable event input or direct event input:

- Peripheral signals that generate a pulse are connected to an EXTI configurable event input. For these events the EXTI provides a CPU status pending bit that has to be cleared.
- Peripheral interrupt and wake-up sources that have to be cleared in the peripheral are connected to an EXTI direct event input. There is no CPU status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral.

The CPU interrupts are connected to their respective CPU NVIC, and, similarly, the CPU event is connected to the CPU rxev input.

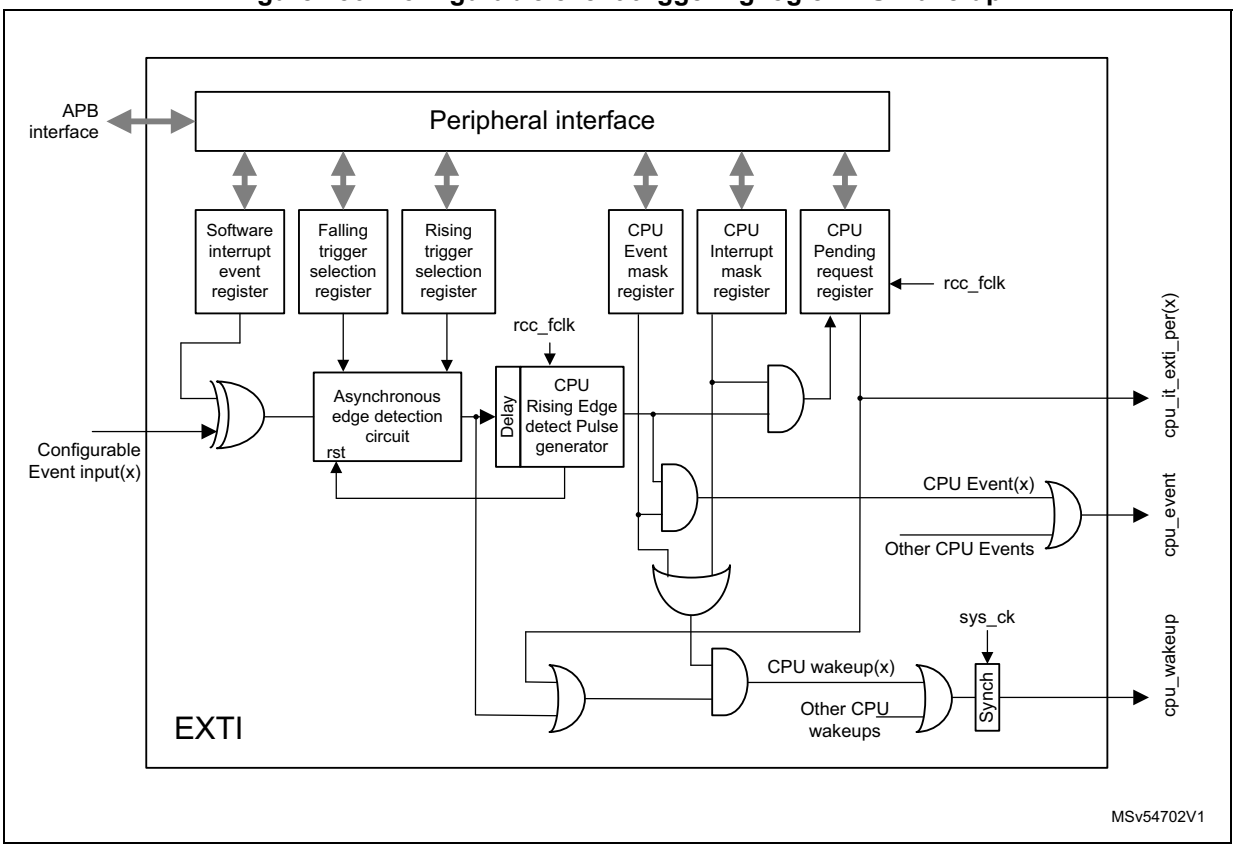
The EXTI wake-up signals are connected to the PWR block, and are used to wake up the CPU.

20.3 EXTI functional description

Depending on the EXTI event input type and wake-up target(s), different logic implementations are used. The applicable features are controlled from register bits:

- Active trigger edge enable, by *EXTI rising trigger selection register (EXTI_RTSR1)*, *EXTI rising trigger selection register (EXTI_RTSR2)*, *EXTI interrupt mask register (EXTI_IMR1)*, and *EXTI falling trigger selection register (EXTI_FTSR1)*, *EXTI falling trigger selection register (EXTI_FTSR2)*, *EXTI interrupt mask register (EXTI_IMR1)*
- Software trigger, by *EXTI software interrupt event register (EXTI_SWIER1)*, *EXTI software interrupt event register (EXTI_SWIER2)*, *EXTI interrupt mask register (EXTI_IMR1)*
- CPU interrupt enable, by *EXTI interrupt mask register (EXTI_IMR1)*, *EXTI interrupt mask register (EXTI_IMR2)*, *EXTI interrupt mask register (EXTI_IMR3)*
- CPU event enable, by *EXTI event mask register (EXTI_EMR1)*, *EXTI interrupt mask register (EXTI_IMR2)*, *EXTI event mask register (EXTI_EMR3)*

Table 143. EXTI event input configurations and register control(1)



Event input type	Wake-up target(s)	Logic implementation	EXTI_RTSR	EXTI_FTSR	EXTI_SWIER	EXTI_IMR	EXTI_EMR
Configurable	CPU	Configurable event input, CPU wake-up logic	X	X	X	X	X
Direct	CPU	Direct event input, CPU wake-up logic	-	-	-	X	X

1. X indicates that functionality is available.

20.3.1 EXTI configurable event input - CPU wake-up

Figure 20.3.2 is a detailed representation of the logic associated with configurable event inputs which always wake up the CPU.

Figure 156. Configurable event triggering logic CPU wake-up

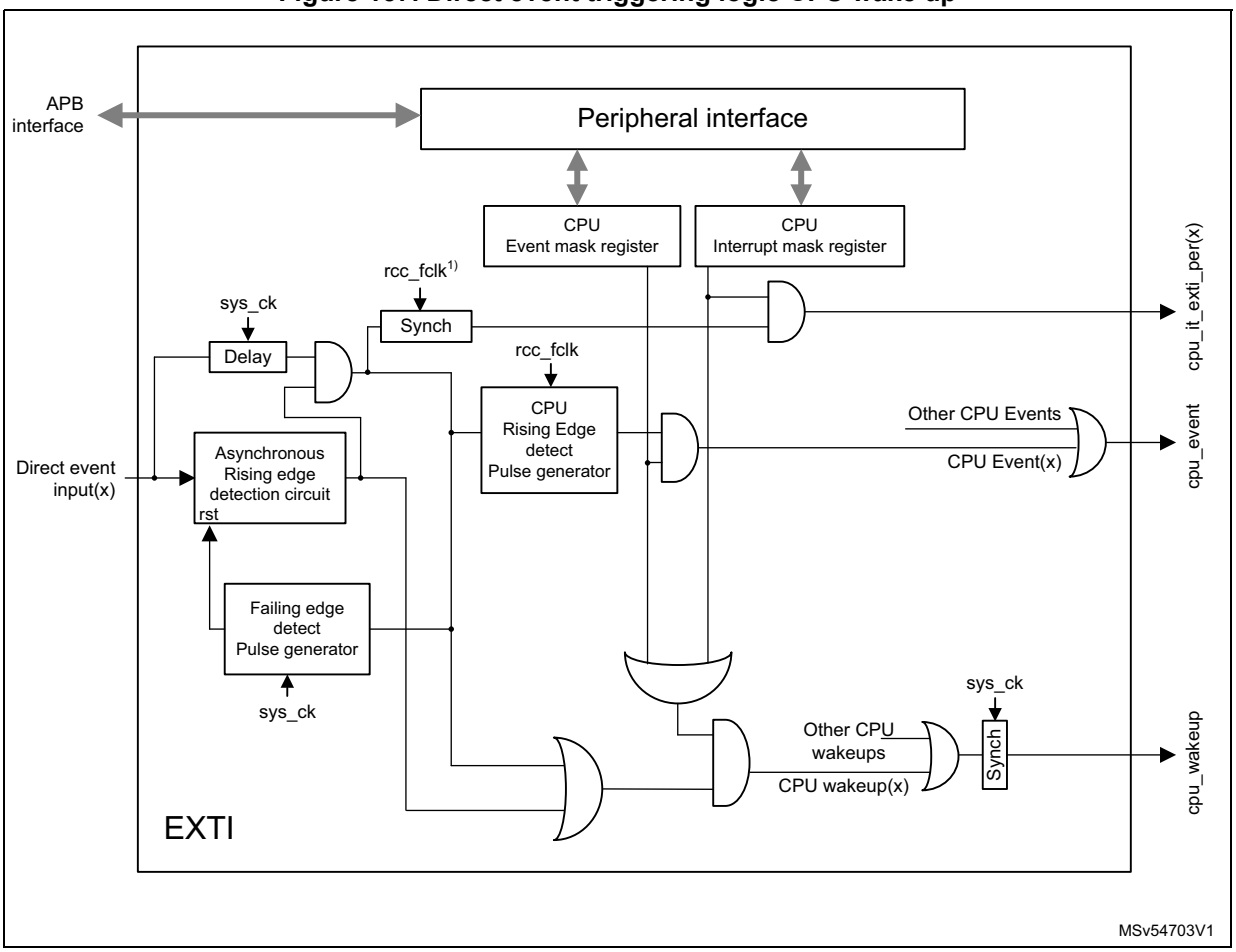
The software interrupt event register allows the system to trigger configurable events by software, writing the *EXTI software interrupt event register (EXTI_SWIER1)*, the *EXTI software interrupt event register (EXTI_SWIER2)*, or the *EXTI interrupt mask register (EXTI_IMR1)* register bit.

The rising edge *EXTI rising trigger selection register (EXTI_RTSR1)*, *EXTI rising trigger selection register (EXTI_RTSR2)*, *EXTI interrupt mask register (EXTI_IMR1)*, and falling edge *EXTI falling trigger selection register (EXTI_FTSR1)*, *EXTI falling trigger selection register (EXTI_FTSR2)*, *EXTI interrupt mask register (EXTI_IMR1)* selection registers allow the system to enable and select the configurable event active trigger edge or both edges.

The devices feature dedicated interrupt mask registers, namely *EXTI interrupt mask register (EXTI_IMR1)* and *EXTI interrupt mask register (EXTI_IMR2)*, *EXTI interrupt mask register (EXTI_IMR3)*, and *EXTI pending register (EXTI_PR1)*, *EXTI pending register (EXTI_PR2)*, for configurable event pending request registers. The CPU pending register is only set for an unmasked CPU interrupt. Each event provides a individual CPU interrupt to the CPU NVIC. The configurable event interrupts need to be acknowledged by software in the EXTI_PR register.

The devices feature dedicated event mask registers, i.e. *EXTI event mask register (EXTI_EMR1)*, *EXTI interrupt mask register (EXTI_IMR2)*, and *EXTI event mask register (EXTI_EMR3)*. The enabled event then generates an event on the CPU. All events for a CPU are OR-ed together into a single CPU event signal. The CPU pending register (EXTI_PR) is not set for an unmasked CPU event.

When a CPU interrupt or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the CPU clock is woken up before the asynchronous edge detection circuit is reset.



Note: A detected configurable event, enabled by the CPU, is only cleared when the CPU wakes up.

20.3.2 EXTI direct event input - CPU wake up

Figure 157 is a detailed representation of the logic associated with direct event inputs waking up the CPU.

Direct events only provide CPU interrupt enable and CPU event enable functionality.

Figure 157. Direct event triggering logic CPU wake up

1. The CPU interrupt for asynchronous direct event inputs (peripheral wake-up signals) is synchronized with the CPU clock. The synchronous direct event inputs (peripheral interrupt signals), after the asynchronous edge detection, are directly sent to the CPU interrupt without resynchronization.

20.4 EXTI event input mapping

For the sixteen GPIO event inputs the associated IOPORT pin has to be selected in the SBS register SBS_EXTICRn. The same pin from each IOPORT maps to the corresponding EXTI event input.

The wake-up capabilities of each event input are detailed in *Table 144*. An event input can wake up the CPU.

The EXTI event inputs with a connection to the CPU NVIC are indicated in the *Connection to NVIC* column. For the EXTI events not having a connection to the NVIC, the peripheral interrupt is directly connected to the NVIC in parallel with the connection to the EXTI.

All EXTI event inputs are OR-ed together and connected to the CPU event input (rxev).

Table 144. EXTI event input mapping

Event input	Source	Event input type	Connection to NVIC

1. PVD and AVD signals are OR-ed together on the same EXTI event input.
2. RTC Tamper, RTC timestamp and LSE_CSS are OR-ed together on the same EXTI event input.
3. lpi_intr_o OR pmt_intr_o

20.5 EXTI functional behavior

The direct event inputs are enabled in the respective peripheral generating the event. The configurable events are enabled by enabling at least one of the trigger edges.

An event only wakes up the CPU when the event-associated CPU interrupt is unmasked and/or the CPU event is unmasked.

Table 145. Masking functionality

CPU		Configurable event inputs PRx bits of EXTI_PR	CPU		
Interrupt enable MRx bits of EXTI_IMR	Event enable MRx bits of EXTI_EMR		Interrupt	Event	Wake-up
0	0	No	Masked	Masked	Masked
0	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes
1	1	Status latched	Yes	Yes	Yes

For configurable event inputs, when the enabled edge(s) occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending PRx bit in EXTI_PR is set and the CPU interrupt signal is activated. EXTI_PR PRx pending bit must be cleared by software writing it to ‘1’. This clears the CPU interrupt.

For direct event inputs, when enabled in the associated peripheral, an event request is generated on the rising edge only. There is no corresponding CPU pending bit. When the associated CPU interrupt is unmasked the corresponding CPU interrupt signal is activated.

The CPU event has to be unmasked to generate an event. When the enabled edge(s) occur on the event input a CPU event pulse is generated. There is no CPU event pending bit.

Both a CPU interrupt and a CPU event may be enabled on the same event input. They both trigger the same event input condition(s).

For the configurable event inputs an event input request can be generated by software when writing a ‘1’ in the software interrupt/event register EXTI_SWIER.

20.5.1 EXTI CPU interrupt procedure

- Unmask the event input interrupt by setting the corresponding mask bits in the EXTI_IMR register.
- For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- Enable the associated interrupt source in the CPU NVIC or use the SEVONPEND, so that an interrupt coming from the CPU interrupt signal is detectable by the CPU after a WFI/WFE instruction.
  - For configurable event inputs the associated EXTI pending bit needs to be cleared.

20.5.2 EXTI CPU event procedure

- Unmask the event input by setting the corresponding mask bits of the EXTI_EMR register.
- For configurable event inputs, enable the event input by setting either one or both the corresponding trigger edge enable bits in EXTI_RTSR and EXTI_FTSR registers.
- The CPU event signal is detected by the CPU after a WFE instruction.
  - For configurable event inputs there is no EXTI pending bit to clear.

20.5.3 EXTI CPU wake-up procedure

- Unmask the event input by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers. The CPU wake-up is generated at the same time as the unmasked CPU interrupt and/or CPU event.
- For configurable event inputs, enable the event input by setting either one or both of the corresponding trigger edge enable bits in the EXTI_RTSR and EXTI_FTSR registers.
- Direct events automatically generate a CPU wake-up.

20.5.4 EXTI software interrupt/event trigger procedure

Any of the configurable event inputs can be triggered from the software interrupt/event register (the associated CPU interrupt and/or CPU event must be enabled by their respective procedure).

- Enable the event input by setting at least one of the corresponding edge trigger bits in the EXTI_RTSR and/or EXTI_FTSR registers.
- Unmask the software interrupt/event trigger by setting at least one of the corresponding mask bits in the EXTI_IMR and/or EXTI_EMR registers.
- Trigger the software interrupt/event by writing “1” to the corresponding bit in the EXTI_SWIER register.
- The event input may be disabled by clearing the EXTI_RTSR and EXTI_FTSR register bits.

Note: An edge on the configurable event input also triggers an interrupt/event.

20.6 EXTI registers

The registers can only be accessed with a 32-bit (word). A byte or half-word cannot be read or written.

20.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **RT[21:0]:** Rising trigger event configuration bit of configurable event input x.(1)

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

20.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **FT[21:0]:** Falling trigger event configuration bit of configurable event input x.(1)

0: Falling trigger disabled (for event and interrupt) for input line

1: Falling trigger enabled (for event and interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

20.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW 21	SW 20	SW 19	SW 18	SW 17	SW 16
										rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SW 15	SW 14	SW 13	SW 12	SW 11	SW 10	SW9	SW8	SW7	SW6	SW5	SW4	SW3	SW2	SW1	SW0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **SWx:** Software interrupt on event x (x = 21 to 0).
This bitfield alway returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

20.6.4 EXTI rising trigger selection register (EXTI_RTSR2)

Address offset: 0x20

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	RT46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT34	Res.	Res.
	rw												rw		

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **RT54:** Rising trigger event configuration bit of configurable event input x+32.(1)
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **RT51:** Rising trigger event configuration bit of configurable event input x+32.(1)
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 18 Reserved, must be kept at reset value.

Bit 17 **RT49:** Rising trigger event configuration bit of configurable event input x+32.(1)
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **RT46:** Rising trigger event configuration bit of configurable event input x+32.(1)
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **RT34:** Rising trigger event configuration bit of configurable event input x+32.(1)
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 1:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

20.6.5 EXTI falling trigger selection register (EXTI_FTSR2)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT54	Res.	Res.	FT51	Res.	FT49	Res.
									rw			rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	FT46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT34	Res.	Res.
	rw												rw		

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **FT54:** Falling trigger event configuration bit of configurable event input x+32.(1)
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **FT51:** Falling trigger event configuration bit of configurable event input x+32.(1)
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

Bit 18 Reserved, must be kept at reset value.

Bit 17 **FT49:** Falling trigger event configuration bit of configurable event input x+32.(1)
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **FT46:** Falling trigger event configuration bit of configurable event input x+32.(1)
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **FT34:** Falling trigger event configuration bit of configurable event input x+32.(1)
0: Falling trigger disabled (for event and interrupt) for input line
1: Falling trigger enabled (for event and interrupt) for input line

Bits 1:0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

20.6.6 EXTI software interrupt event register (EXTI_SWIER2)

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW 54	Res.	Res.	SW 51	Res.	SW 49	Res.
									rw			rw		rw	

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	SW 46	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW 34	Res.	Res.
	rw												rw		

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **SW54:** Software interrupt on event x+32
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **SW51:** Software interrupt on event x+32
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **SW49:** Software interrupt on event x+32
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **SW46:** Software interrupt on event x+32
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **SW34:** Software interrupt on event x+32
Always returns 0 when read.
0: Writing 0 has no effect.
1: Writing a 1 to this bit triggers an event on line x. This bit is auto cleared by HW.

Bits 1:0 Reserved, must be kept at reset value.

20.6.7 EXTI interrupt mask register (EXTI_IMR1)

Address offset: 0x80

Reset value: 0xFFC0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IM31	IM30	IM29	IM28	IM27	IM26	IM25	IM24	IM23	IM22	IM21	IM20	IM19	IM18	IM17	IM16
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IM15	IM14	IM13	IM12	IM11	IM10	IM9	IM8	IM7	IM6	IM5	IM4	IM3	IM2	IM1	IM0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 **IM[31:22]:** CPU interrupt mask on direct event input x(1)
0: Interrupt request from line x is masked
1: Interrupt request from line x is unmasked

Bits 21:0 **IM[21:0]:** CPU interrupt mask on configurable event input x (2)
0: Interrupt request from line x is masked
1: Interrupt request from line x is unmasked

1. The reset value for direct event inputs is set to ‘1’ in order to enable the interrupt by default.
2. The reset value for configurable event inputs is set to ‘0’ in order to disable the interrupt by default.

20.6.8 EXTI event mask register (EXTI_EMR1)

Address offset: 0x84

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PR54:** Configurable event inputs x+32 Pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **PR51:** Configurable event inputs x+32 Pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PR49:** Configurable event inputs x+32 Pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **PR46:** Configurable event inputs x+32 Pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 13:3 Reserved, must be kept at reset value.

Bit 2 **PR34:** Configurable event inputs x+32 Pending bit
0: No trigger request occurred
1: selected trigger request occurred
This bit is set when the selected edge event arrives on the external interrupt line. This bit is cleared by writing a 1 into the bit or by changing the sensitivity of the edge detector.

Bits 1:0 Reserved, must be kept at reset value.

20.6.13 EXTI interrupt mask register (EXTI_IMR3)

Address offset: 0xA0

Reset value: 0x0F8B FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

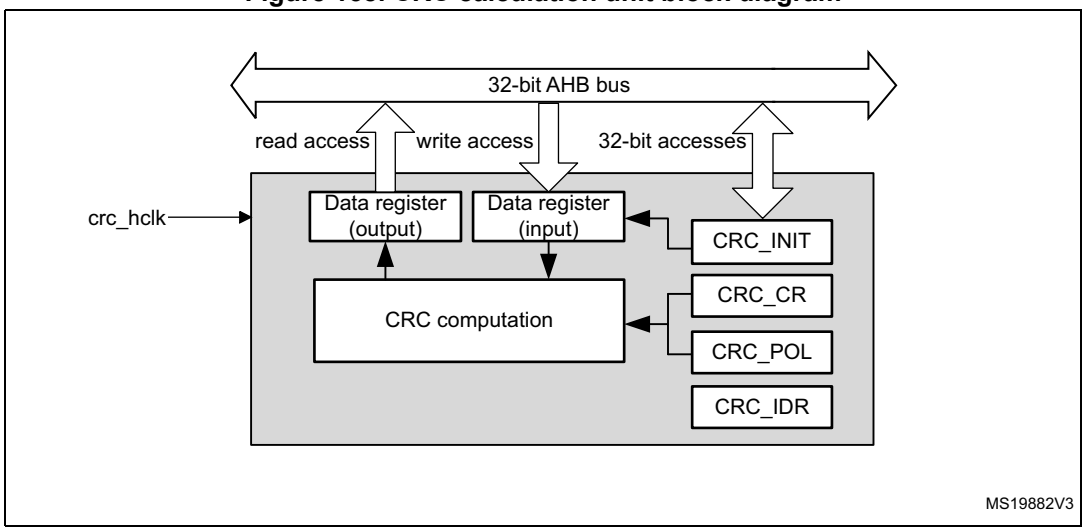
Refer to *Section 2.3 on page 150* for the register boundary addresses.

21 Cyclic redundancy check calculation unit (CRC)

21.1 Introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.



21.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility option on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

21.3 CRC functional description

21.3.1 CRC block diagram

Figure 158. CRC calculation unit block diagram

21.3.2 CRC internal signals

Table 147. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

21.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register.

For example, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte
- 0xD458B23C with bit-reversal done by half-word
- 0xB23CD458 with bit-reversal done on the full word

The output data can also be reversed by setting the REV_OUT bit in the CRC_CR register.

The operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC calculation. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7, 8, 16 or 32 bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

21.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes. For the other registers only 32-bit accesses are allowed.

21.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

21.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

21.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REV_OUT	REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
								rw	rw	rw	rw	rw			rs

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **REV_OUT**: Reverse output data

This bit controls the reversal of the bit order of the output data.

0: Bit order not affected

1: Bit-reversed output format

Bits 6:5 **REV_IN[1:0]**: Reverse input data

This bitfield controls the reversal of the bit order of the input data

00: Bit order not affected

01: Bit reversal done by byte

10: Bit reversal done by half-word

11: Bit reversal done by word

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware

21.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

21.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

21.4.6 CRC register map

Table 148. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

22 CORDIC coprocessor (CORDIC)

22.1 CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

22.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atan2, atanh, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

22.3 CORDIC functional description

22.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

22.3.2 CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register.

Table 149 lists the functions supported by the CORDIC coprocessor.

Table 149. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	$\tan^{-1} x$	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	$\tanh^{-1} x$	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2), and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, and cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 22.3.4*) can be applied to extend the range beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 150. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · cos θ	[-1, 1]

Table 150. Cosine parameters (continued)

Parameter	Description	Range
RES2	m · sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 151. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m · sin θ	[-1, 1]
RES2	m · cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 152. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 152. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 153. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 154. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \tan^{-1} x$, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, $x = \tan \theta$. If $|x| > 1$, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is $\tan \theta = 128$, which corresponds to an angle $\theta = 89.55$ degrees. For $|x| > 128$, a software method must be used to find $\tan^{-1} x$.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle $\theta = \tan^{-1} x$. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 155. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 156. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value $x \cdot 0.5$ is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 157. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \text{atanh } x$	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the -0.806 to +0.806 range are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

$x \cdot 0.5$ is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 158. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < 1-2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 159 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 159. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \le x < 1$	$0.0535 \le ARG1 < 0.5$
2	$1 \le x < 3$	$0.25 \le ARG1 < 0.75$
3	$3 \le x < 7$	$0.375 \le ARG1 < 0.875$
4	$7 \le x \le 9.35$	$0.4375 \le ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 160. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 161 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 161. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	$0.027 \leq ARG1 < 0.75$
1	$0.75 \leq x < 1.75$	$0.375 \leq ARG1 < 0.875$
2	$1.75 \leq x \leq 2.341$	$0.4375 \leq ARG1 \leq 0.585$

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

22.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

22.3.4 Scaling factor

Several of the functions listed in *Section 22.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is

required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

22.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 159*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 160*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 161*).

Figure 159. CORDIC convergence for trigonometric functions

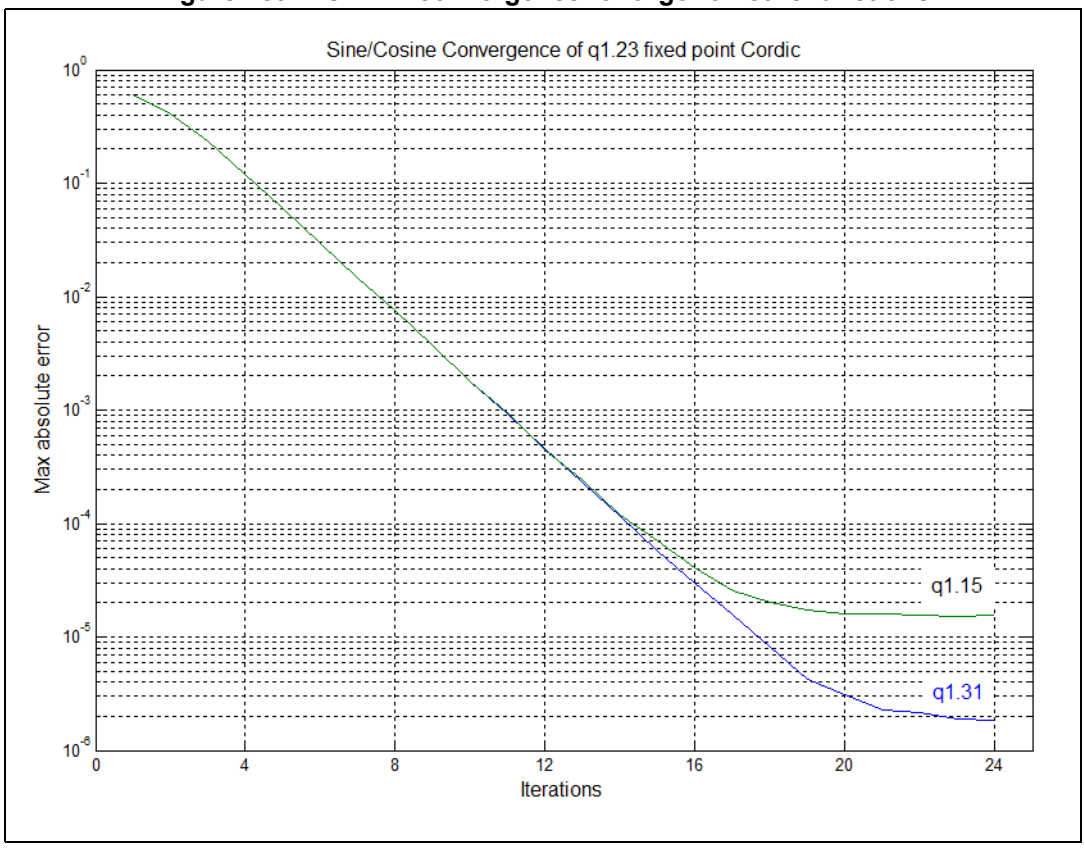

Figure 160. CORDIC convergence for hyperbolic functions

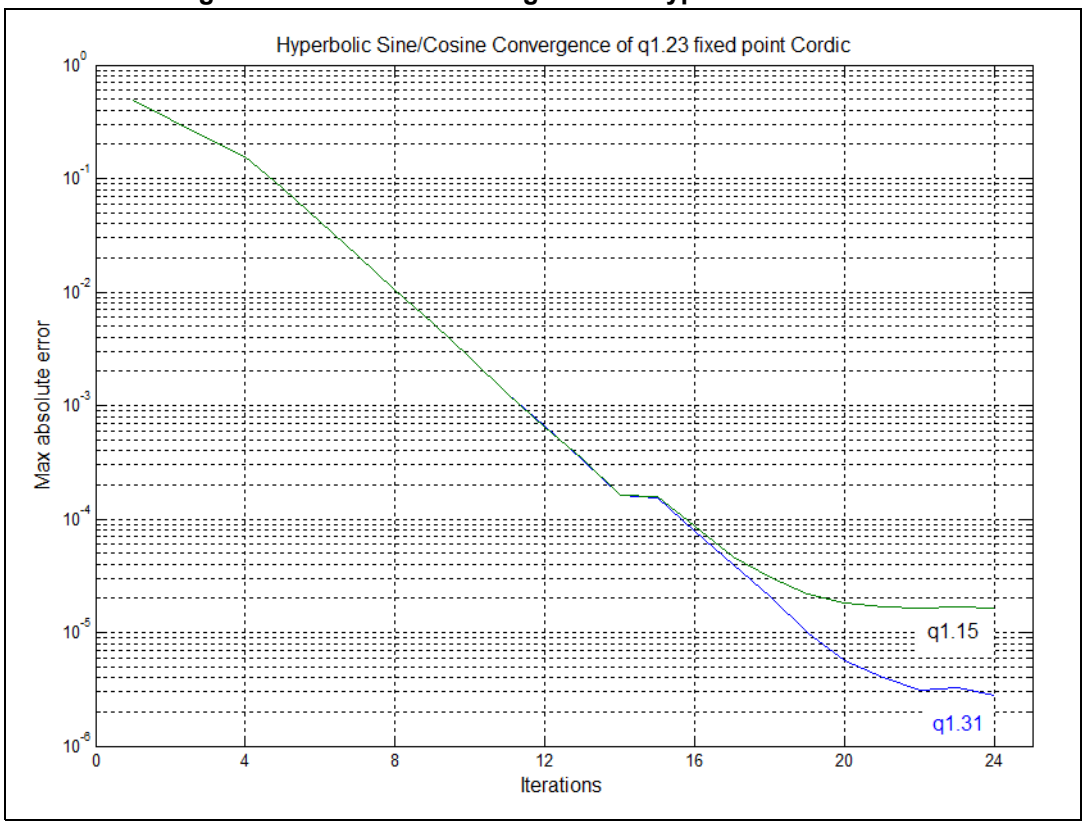

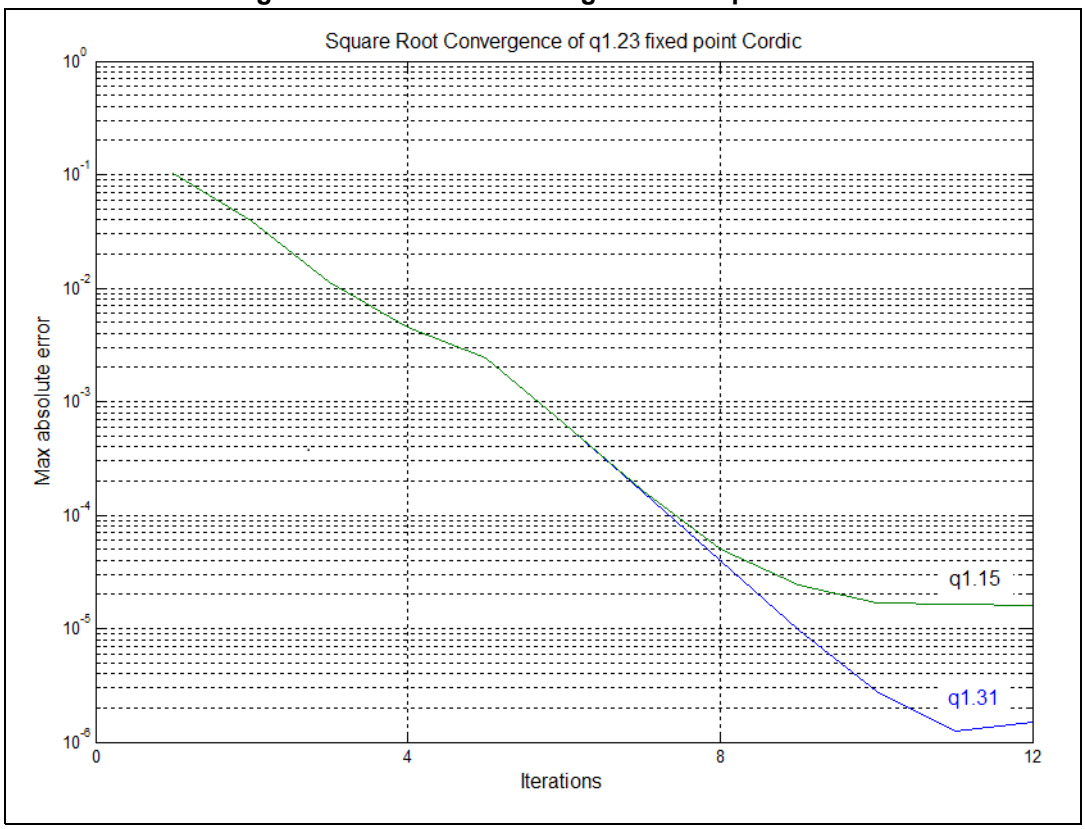

Figure 161. CORDIC convergence for square root

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 162*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

Table 162. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 162. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

22.3.6 Zero-overhead mode

The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait-states until the calculation is completed, before returning the result. It is then possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be reprogrammed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous ones have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be a calculation in progress, or waiting for the results to be read, and an operation pending. Any further access to CORDIC_WDATA while an operation is pending cancels it and overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

22.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice, depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. The processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (for example, if low latency interrupts must be serviced).

22.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

22.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

22.4 CORDIC registers

The CORDIC registers can be accessed only in 32-bit word format

22.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	N ARGS	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register

0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.

1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.

Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register

0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.

1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.

Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel

0: Disabled. No DMA write requests are generated.

1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel

0: Disabled. No DMA read requests are generated.

1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.

0: Disabled. No interrupt requests are generated.

1: Enabled. An interrupt request is generated whenever the RRDY flag is set.

This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor

The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 22.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)

0: reserved

1 to 15: (Number of iterations)/4

To determine the number of iterations needed for a given accuracy refer to *Table 162*.

Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square root
10 to 15: Reserved

22.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 22.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

22.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

22.4.4 CORDIC register map

Table 163. CORDIC register map and reset value

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0x00	CORDIC_CSR	RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARGSIZE	RESSIZE	NARGS	NRES	DMAWEN	DMAREN	IEN	Res.	Res.	Res.	Res.	SCALE [2:0]				PRECISION [3:0]				FUNC [3:0]			
	Reset value	0									0	0	0	0	0	0	0					0	0	0	0	0	1	0	1	0	0	0	0

	Reset value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Refer to *Section 2.3* for the register boundary addresses.

23 Flexible memory controller (FMC)

The flexible memory controller (FMC) includes three memory controllers:

- The NOR/PSRAM memory controller
- The NAND memory controller
- The Synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) controller

23.1 FMC main features

The FMC functional block makes the interface with: synchronous and asynchronous static memories, SDRAM memories, and NAND flash memory. Its main purposes are:

- to translate AXI transactions into the appropriate external device protocol
- to meet the access time requirements of the external memory devices

All external memories share the addresses, data and control signals with the controller. Each external device is accessed by means of a unique Chip Select. The FMC performs only one access at a time to an external device.

The main features of the FMC are the following:

- Interface with static-memory mapped devices including:
  - Static random access memory (SRAM)
  - NOR flash memory/OneNAND flash memory
  - PSRAM (4 memory banks)
  - NAND flash memory with ECC hardware to check up to 8 Kbytes of data
- Interface with synchronous DRAM (SDRAM/Mobile LPSDR SDRAM) memories
- Burst mode support for faster access to synchronous devices such as NOR flash memory, PSRAM and SDRAM)
- Programmable continuous clock output for asynchronous and synchronous accesses
- 8-,16- or 32-bit wide data bus
- Independent Chip Select control for each memory bank
- Independent configuration for each memory bank
- Write enable and byte lane select outputs for use with PSRAM, SRAM and SDRAM devices
- External asynchronous wait control
- Write FIFO with 16 x32-bit depth

  The Write FIFO is common to all memory controllers and consists of:
  - a Write Data FIFO which stores the data to be written to the memory
  - a Write Address FIFO which stores the address (up to 28 bits) plus the data size (up to 2 bits). When operating in Burst mode, only the start address is stored except when crossing a page boundary (for PSRAM and SDRAM). In this case, the burst is broken into two FIFO entries.
- Cacheable Read FIFO with 6 x64-bit depth (6 x14-bit address tag) for SDRAM controller.

At startup the FMC pins must be configured by the user application. The FMC I/O pins which are not used by the application can be used for other purposes.

The FMC registers that define the external device type and associated characteristics are set at boot time and do not change until the next reset or power-up. However, only a few bits can be changed on-the-fly:

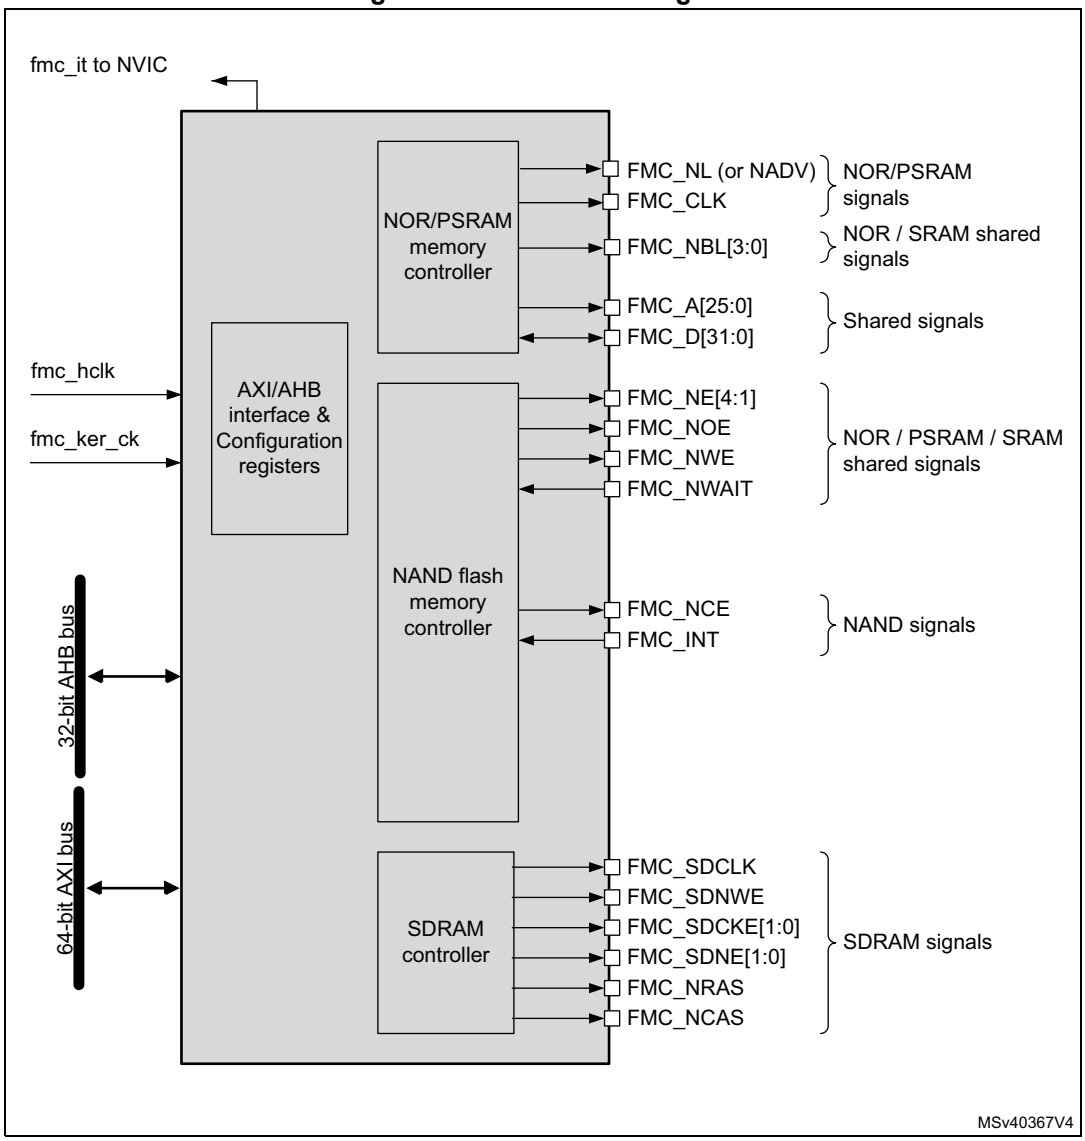
- ECCEN and PBKEN bits in the FMC_PCR register
- IFS, IRS and ILS bits in the FMC_SR register
- MODE[2:0], CTB1/CTB2, NRFS and MRD bits in the FMC_SDCMR register
- REIE and CRE bits in the FMC_SDRTR register.

Follow the below sequence to modify parameters while the FMC is enabled:

1. First disable the FMC to prevent further accesses to any memory controller while the register is modified.
2. Update all required configurations.
3. Enable the FMC again.

When the SDRAM controller is used, if the SDCLK Clock ratio or refresh rate has to be modified after initialization phase, the following procedure must be followed.

1. Put the SDRAM device in Self-refresh mode.
2. Disable the FMC by resetting the FMCEN bit in the FMC_BCR1 register.
3. Update the required parameters.
4. Enable the FMC once all parameters have been updated.
5. Then, send the Clock Configuration Enable command to exit Self-fresh mode.



23.2 FMC block diagram

The FMC consists of the following main blocks:

- The NOR flash/PSRAM/SRAM controller
- The NAND controller
- The SDRAM controller
- The AXI interface
- The AHB interface (including the FMC configuration registers)

The block diagram is shown in the figure below.

Figure 162. FMC block diagram

23.3 FMC internal signals

Table 164 gives the list of FMC internal signals. FMC pins (or external signals) are described in *Section 23.7.1: External memory interface signals*.

Table 164. FMC pins

Names	Signal type	Description
fmc_it	Digital output	FMC interrupt
fmc_ker_ck	Digital input	FMC kernel clock
fmc_hclk	Digital input	FMC interface clock

23.4 AHB interface

The AHB slave interface allows internal CPUs to configure the FMC registers.

The AHB clock (fmc_hclk) is the reference clock for the FMC register accesses.

23.5 AXI interface

The AXI slave interface allows internal CPUs and other bus master peripherals to access the external memories.

AXI transactions are translated into the external device protocol. As the AXI data bus is 64-bit wide, the AXI transactions might be split into several consecutive 32-, 16- or 8-bit accesses according to data size accesses. The FMC Chip Select (FMC_NEx) does not toggle between consecutive accesses except in case of accesses in mode D when the Extended mode is enabled.

The FMC generates an AXI slave error when one of the following conditions is met:

- Reading or writing to an FMC bank (Bank 1 to 4) which is not enabled.
- Reading or writing to the NOR flash bank while the FACCEN bit is reset in the FMC_BCRx register.
- Writing to a write protected SDRAM bank (WP bit set in the FMC_SDCRx register).
- Violation of the SDRAM address range (access to reserved address range)
- Attempting to read/write access from/to SDRAM bank when it is not yet initialized

The FMC generates an AXI decoder error when ADDR[31:28] address bits are not supported by the FMC bank base address following the BMAP[1:0] bits configuration.

The kernel clock for the FMC is the asynchronous fmc_ker_ck clock (refer to *Section Reset and Clock control (RCC)* for fmc_ker_ck clock source selection).

23.5.1 Supported memories and transactions

General transaction rules

The requested AXI transaction data size can be 8-, 16-, 32- or 64-bit wide whereas the accessed external device has a fixed data width. The best performance is always achieved with aligned AXI transactions whose size matches the external device data width.

When AXI transaction data size is different from the device data width, the result depends on the following factors:

- AXI transaction data size is greater than the device data width:
  - Read/Write transactions: the FMC splits the AXI transaction into smaller consecutive accesses matching the external device data width.
- AXI transaction data size is smaller than the external device data width and the device supports byte selection (SRAM, PSRAM, SDRAM):
  - Write transactions, the FMC manages the transaction using the byte lane signals.
  - Read transactions, the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.
- AXI transaction data size is smaller than the external device data width and the device does not support byte selection (NOR and NAND flash memories):
  - Write transactions: the FMC writes some irrelevant bytes which may corrupt the external device
  - Read transactions: the FMC returns all bytes according to the external device data width. The useless bytes are discarded by the system.

Caution: Address alignment

- Read transactions with unaligned addresses (such as half-word starting at an odd address) are not supported by the FMC.
- Write transactions with unaligned addresses

  Their support depends on byte selection availability on the external device:
  - If the device does not support byte selection (NOR and NAND flash memories), narrow write transactions and/or unaligned write transaction are not supported since the FMC would write irrelevant bytes and corrupt the external device.

Wrap support for NOR flash/PSRAM and SDRAM

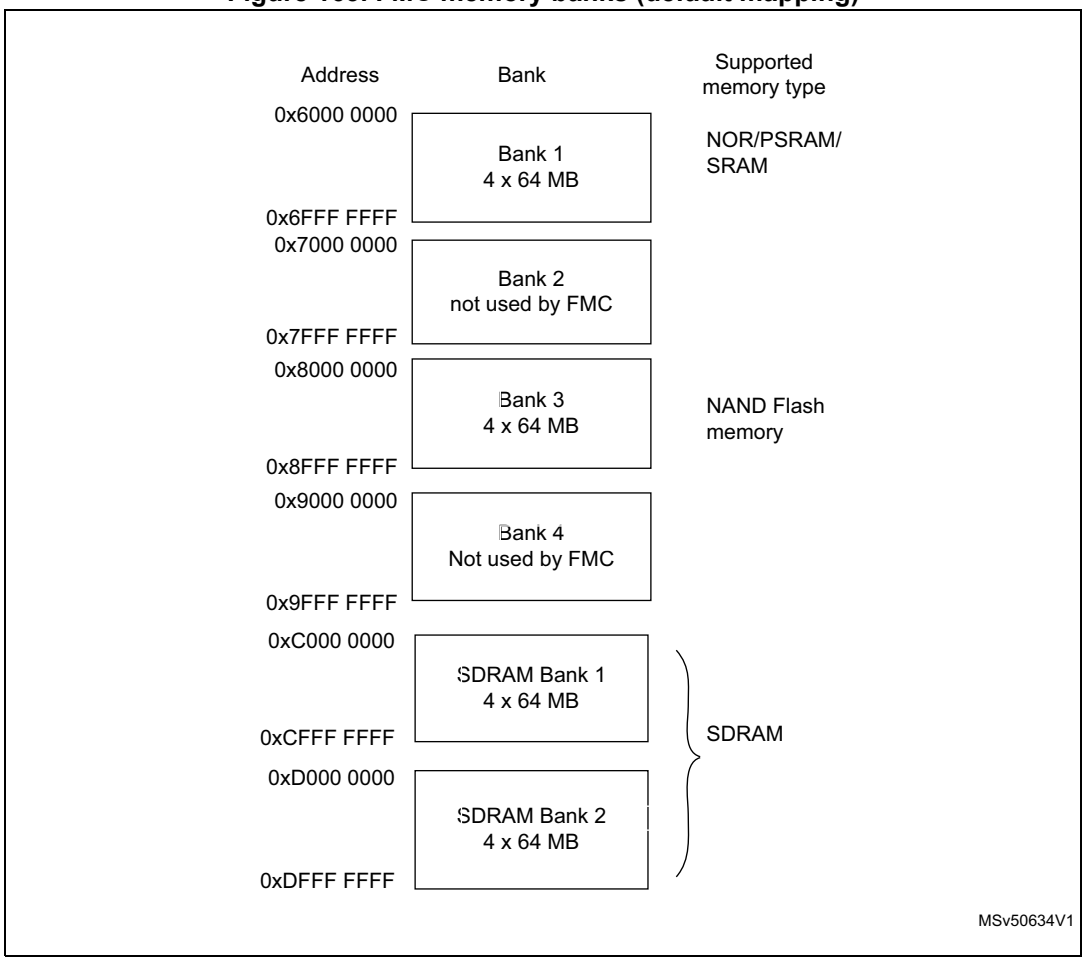
The synchronous memories must be configured in Linear burst mode of undefined length as not all masters can issue wrap transactions.

If a master generates a wrap transaction:

- The read is split into two linear burst transactions.
- The write is split into two linear burst transactions if the write FIFO is enabled and into several linear burst transactions if the write FIFO is disabled.

Configuration registers

The FMC can be configured through a set of registers. Refer to *Section 23.7.6*, for a detailed description of the NOR flash/PSRAM controller registers. Refer to *Section 23.8.7*, for a detailed description of the NAND flash registers and to *Section 23.9.5* for a detailed description of the SDRAM controller registers.



23.6 External device address mapping

From the FMC point of view, the external memory is divided into fixed-size banks of 256 Mbytes each (see *Figure 163*):

- Bank 1 is used to address up to 4 NOR flash memory or PSRAM devices. This bank is split into 4 NOR/PSRAM subbanks with 4 dedicated Chip Selects, as follows:
  - Bank 1 - NOR/PSRAM 1
  - Bank 1 - NOR/PSRAM 2
  - Bank 1 - NOR/PSRAM 3
  - Bank 1 - NOR/PSRAM 4
- Bank 2 and Bank 4 are not used by the FMC.
- Bank 3 is used to address NAND flash memory devices.The MPU memory attribute for this space must be reconfigured by software to Device.
- Bank 5 and 6 are used to address SDRAM devices (1 device per bank).

For each bank the type of memory to be used can be configured by the user application through the Configuration register.

Figure 163. FMC memory banks (default mapping)

The FMC bank mapping can be modified through the BMAP[1:0] bits in the FMC_BCR1 register. *Table 165* shows the configuration to swap the NOR/PSRAM bank with SDRAM banks.

Table 165. FMC bank mapping options

Start -End address	BMAP[1:0]=00 (Default mapping)	BMAP[1:0]=01 NOR/PSRAM and SDRAM banks swapped
0x6000 0000 - 0x6FFF FFFF	NOR/PSRAM bank	SDRAM bank1
0x7000 0000 - 0x7FFF FFFF	Not used by FMC	
0x8000 0000 - 0x8FFF FFFF	NAND bank	NAND bank
0x9000 0000 - 0x9FFF FFFF	Not used by FMC	
0xC000 0000 - 0xCFFF FFFF	SDRAM bank1	NOR/PSRAM bank
0xD000 0000 - 0xDFFF FFFF	SDRAM bank2	SDRAM bank2

23.6.1 NOR/PSRAM address mapping

ADDR[27:26] bits are used to select one of the four memory banks as shown in *Table 166*.

Table 166. NOR/PSRAM bank selection

ADDR[27:26](1)	Selected bank
00	Bank 1 - NOR/PSRAM 1
01	Bank 1 - NOR/PSRAM 2
10	Bank 1 - NOR/PSRAM 3
11	Bank 1 - NOR/PSRAM 4

1. ADDR are internal address lines that are translated to external memory.

The ADDR[25:0] bits contain the external memory address. Since ADDR is a byte address whereas the memory is addressed at word level, the address actually issued to the memory varies according to the memory data width, as shown in the following table.

Table 167. NOR/PSRAM External memory address

Memory width(1)	Data address issued to the memory	Maximum memory capacity (bits)
8-bit	ADDR[25:0]	64 Mbytes x 8 = 512 Mbit
16-bit	ADDR[25:1] >> 1	64 Mbytes/2 x 16 = 512 Mbit
32-bit	ADDR[25:2] >> 2	64 Mbytes/4 x 32 = 512 Mbit

1. In case of a 16-bit external memory width, the FMC internally uses ADDR[25:1] to generate the address for external memory FMC_A[24:0]. In case of a 32-bit memory width, the FMC internally uses ADDR[25:2] to generate the external address.
Whatever the external memory width, FMC_A[0] should be connected to external memory address A[0].

23.6.2 NAND flash memory address mapping

The NAND bank is divided into memory areas as indicated in *Table 168*.

Table 168. NAND memory mapping and timing registers

Start address	End address	FMC bank	Memory space	Timing register
0x8800 0000	0x8BFF FFFF	Bank 3 - NAND flash	Attribute	FMC_PATT (0x8C)
0x8000 0000	0x83FF FFFF		Common	FMC_PMEM (0x88)

For NAND flash memory, the common and attribute memory spaces are subdivided into three sections (see in *Table 169* below) located in the lower 256 Kbytes:

- Data section (first 64 Kbytes in the common/attribute memory space)
- Command section (second 64 Kbytes in the common / attribute memory space)
- Address section (next 128 Kbytes in the common / attribute memory space)

Table 169. NAND bank selection

Section name	ADDR[17:16]	Address range
Address section	1X	0x020000-0x03FFFF
Command section	01	0x010000-0x01FFFF
Data section	00	0x000000-0x0FFFF

The application software uses the 3 sections to access the NAND flash memory:

- **To send a command to NAND flash memory**, the software must write the command value to any memory location in the command section.
- **To specify the NAND flash address that must be read or written**, the software must write the address value to any memory location in the address section. Since an address can be 4 or 5 bytes long (depending on the actual memory size), several consecutive write operations to the address section are required to specify the full address.
- **To read or write data,** the software reads or writes the data from/to any memory location in the data section.

Since the NAND flash memory automatically increments addresses, there is no need to increment the address of the data section to access consecutive memory locations.

23.6.3 SDRAM address mapping

Two SDRAM banks are available as indicated in *Table 170*.

Table 170. SDRAM bank selection

Selected bank	Control register	Timing register
SDRAM Bank1	FMC_SDCR1	FMC_SDTR1
SDRAM Bank2	FMC_SDCR2	FMC_SDTR2

Table 171 shows SDRAM mapping for a 13-bit row and an 11-bit column configuration.

Table 171. SDRAM address mapping

Memory width(1)	Internal bank	Row address	Column address(2)	Maximum memory capacity (Mbytes)
8-bit	ADDR[25:24]	ADDR[23:11]	ADDR[10:0]	64 Mbytes: 4 x 8K x 2K
16-bit	ADDR[26:25]	ADDR[24:12]	ADDR[11:1]	128 Mbytes: 4 x 8K x 2K x 2
32-bit	ADDR[27:26]	ADDR[25:13]	ADDR[12:2]	256 Mbytes: 4 x 8K x 2K x 4

1. When interfacing with a 16-bit memory, the FMC internally uses the ADDR[11:1] internal address lines to generate the external address. When interfacing with a 32-bit memory, the FMC internally uses ADDR[12:2] lines to generate the external address. Whatever the memory width, FMC_A[0] has to be connected to the external memory address A[0].
2. The AutoPrecharge is not supported. FMC_A[10] must be connected to the external memory address A[10] but it is always driven low.

The ADDR[27:0] bits are translated into an external SDRAM address depending on the SDRAM controller configuration:

- Data size:8, 16 or 32 bits
- Row size:11, 12 or 13 bits
- Column size: 8, 9, 10 or 11 bits
- Number of internal banks: two or four internal banks

The following tables show the SDRAM address mapping versus the SDRAM controller configuration.

Table 172. SDRAM address mapping with 8-bit data bus width(1)(2)

Row size configuration	ADDR(Internal Address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.							Bank [1:0]	Row[10:0]												Column[7:0]							
	Res.								Bank [1:0]	Row[10:0]											Column[8:0]							
	Res.									Bank [1:0]	Row[10:0]										Column[9:0]							
	Res.										Bank [1:0]	Row[10:0]									Column[10:0]							

Table 172. SDRAM address mapping with 8-bit data bus width(1)(2) (continued)

Row size configuration	ADDR(Internal Address Lines)																											
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
12-bit row size configuration	Res.						Bank [1:0]		Row[11:0]										Column[7:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[8:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[9:0]									
	Res.						Bank [1:0]		Row[11:0]										Column[10:0]									
13-bit row size configuration	Res.						Bank [1:0]		Row[12:0]										Column[7:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[8:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[9:0]									
	Res.						Bank [1:0]		Row[12:0]										Column[10:0]									

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to ‘0’.
2. Access to Reserved (Res.) address range generates an AXI slave error.

Table 173. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	ADDR(address Lines)																											
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.						Bank [1:0]		Row[10:0]										Column[7:0]									BM0 (3)
	Res.						Bank [1:0]		Row[10:0]										Column[8:0]									BM0
	Res.						Bank [1:0]		Row[10:0]										Column[9:0]									BM0
	Res.						Bank [1:0]		Row[10:0]										Column[10:0]									BM0
12-bit row size configuration	Res.						Bank [1:0]		Row[11:0]										Column[7:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[8:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[9:0]									BM0
	Res.						Bank [1:0]		Row[11:0]										Column[10:0]									BM0

Table 173. SDRAM address mapping with 16-bit data bus width(1)(2)

Row size Configuration	ADDR(address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
13-bit row size configuration	Res.				Bank [1:0]		Row[12:0]													Column[7:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[8:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[9:0]								BM0
	Res.				Bank [1:0]		Row[12:0]													Column[10:0]								BM0

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI Slave error.
3. BM0: is the byte mask for 16-bit access.

Table 174. SDRAM address mapping with 32-bit data bus width(1)(2)

Row size configuration	ADDR(address Lines)																										
	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
11-bit row size configuration	Res.					Bank [1:0]		Row[10:0]											Column[7:0]								BM[1:0](3)	
	Res.					Bank [1:0]		Row[10:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[10:0]											Column[9:0]								BM[1:0	
	Res.					Bank [1:0]		Row[10:0]											Column[10:0]								BM[1:0	
12-bit row size configuration	Res.					Bank [1:0]		Row[11:0]											Column[7:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[9:0]								BM[1:0	
	Res.					Bank [1:0]		Row[11:0]											Column[10:0]								BM[1:0	
13-bit row size configuration	Res.					Bank [1:0]		Row[12:0]											Column[7:0]								BM[1:0	
	Res.					Bank [1:0]		Row[12:0]											Column[8:0]								BM[1:0	
	Res.					Bank [1:0]		Row[12:0]											Column[9:0]								BM[1:0	
	Bank [1:0]					Row[12:0]													Column[10:0]								BM[1:0	

1. BANK[1:0] are the Bank Address BA[1:0]. When only 2 internal banks are used, BA1 must always be set to '0'.
2. Access to Reserved space (Res.) generates an AXI slave error.
3. BM[1:0]: is the byte mask for 32-bit access.

23.7 NOR flash/PSRAM controller

The FMC generates the appropriate signal timings to drive the following types of memories:

- Asynchronous SRAM and ROM
  - 8 bits
  - 16 bits
  - 32 bits
- PSRAM (Cellular RAM)
  - Asynchronous mode
  - Burst mode for synchronous accesses with configurable option to split burst access when crossing boundary page for CRAM 1.5.
  - Multiplexed or non-multiplexed
- NOR flash memory
  - Asynchronous mode
  - Burst mode for synchronous accesses
  - Multiplexed or non-multiplexed

The FMC outputs a unique Chip Select signal, NE[4:1], per bank. All the other signals (addresses, data and control) are shared.

The FMC supports a wide range of devices through a programmable timings among which:

- Programmable wait states (up to 15)
- Programmable bus turnaround cycles (up to 15)
- Programmable output enable and write enable delays (up to 15)
- Independent read and write timings and protocol to support the widest variety of memories and timings
- Programmable continuous clock (FMC_CLK) output.

The FMC output Clock (FMC_CLK) is a sub-multiple of the fmc_ker_ck clock. It can be delivered to the selected external device either during synchronous accesses only or during asynchronous and synchronous accesses depending on the CCKEN bit configuration in the FMC_BCR1 register:

- If the CCLKEN bit is reset, the FMC generates the clock (FMC_CLK) only during synchronous accesses (Read/write transactions).
- If the CCLKEN bit is set, the FMC generates a continuous clock during asynchronous and synchronous accesses. To generate the FMC_CLK continuous clock, Bank 1 must be configured in Synchronous mode (see *Section 23.7.6: NOR/PSRAM controller registers*). Since the same clock is used for all synchronous memories, when a continuous output clock is generated and synchronous accesses are performed, the AXI data size has to be the same as the memory data width (MWID) otherwise the FMC_CLK frequency is changed depending on AXI data transaction (refer to *Section 23.7.5: Synchronous transactions* for FMC_CLK divider ratio formula).

The size of each bank is fixed and equal to 64 Mbytes. Each bank is configured through dedicated registers (see *Section 23.7.6: NOR/PSRAM controller registers*).

The programmable memory parameters include access times (see *Table 175*) and support for wait management (for PSRAM and NOR flash memory accessed in Burst mode).

Table 175. Programmable NOR/PSRAM access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Address setup	Duration of the address setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	0	15
Address hold	Duration of the address hold phase	Asynchronous, muxed I/Os	FMC clock cycle (fmc_ker_ck)	1	15
Data setup	Duration of the data setup phase	Asynchronous	FMC clock cycle (fmc_ker_ck)	1	256
Bust turn	Duration of the bus turnaround phase	Asynchronous and synchronous read	FMC clock cycle (fmc_ker_ck)	0	15
Clock divide ratio	Number of FMC clock cycles (fmc_ker_ck) to build one memory clock cycle (CLK)	Synchronous	FMC clock cycle (fmc_ker_ck)	2	16
Data latency	Number of clock cycles to issue to the memory before the first data of the burst	Synchronous	Memory clock cycle (fmc_ker_ck)	2	17

23.7.1 External memory interface signals

Table 176, *Table 177* and *Table 178* list the signals that are typically used to interface with NOR flash memory, SRAM and PSRAM.

Note: The prefix “N” identifies the signals which are active low.

NOR flash memory, non-multiplexed I/Os

Table 176. Non-multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Bidirectional data bus
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits (26 address lines).

NOR flash memory, 16-bit multiplexed I/Os

Table 177. 16-bit multiplexed I/O NOR flash memory

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)
NE[x]	O	Chip Select, x = 1..4
NOE	O	Output enable
NWE	O	Write enable
NL(=NADV)	O	Latch enable (this signal is called address valid, NADV, by some NOR flash devices)
NWAIT	I	NOR flash wait input signal to the FMC

The maximum capacity is 512 Mbits.

PSRAM/SRAM, non-multiplexed I/Os

Table 178. Non-multiplexed I/Os PSRAM/SRAM

FMC pin name	I/O	Function
CLK	O	Clock (only for PSRAM synchronous access)
A[25:0]	O	Address bus
D[31:0]	I/O	Data bidirectional bus
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid only for PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[3:0]	O	Byte lane output. Byte 0 to Byte 3 control (Upper and lower byte enable)

The maximum capacity is 512 Mbits.

PSRAM, 16-bit multiplexed I/Os

Table 179. 16-Bit multiplexed I/O PSRAM

FMC pin name	I/O	Function
CLK	O	Clock (for synchronous access)
A[25:16]	O	Address bus
AD[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus (the 16-bit address A[15:0] and data D[15:0] are multiplexed on the databus)

Table 179. 16-Bit multiplexed I/O PSRAM (continued)

FMC pin name	I/O	Function
NE[x]	O	Chip Select, x = 1..4 (called NCE by PSRAM (Cellular RAM i.e. CRAM))
NOE	O	Output enable
NWE	O	Write enable
NL(= NADV)	O	Address valid PSRAM input (memory signal name: NADV)
NWAIT	I	PSRAM wait input signal to the FMC
NBL[1:0]	O	Byte lane output. Byte 0 and Byte 1 control (upper and lower byte enable)

The maximum capacity is 512 Mbits (26 address lines).

23.7.2 Supported memories and transactions

Table 180 below shows an example of the supported devices, access modes and transactions when the memory data bus is 16-bit wide for NOR flash memory, PSRAM and SRAM. The transactions not allowed (or not supported) by the FMC are shown in gray in this example.

Table 180. NOR flash/PSRAM: Example of supported memories and transactions(1)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NOR flash (muxed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	N	
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	

Table 180. NOR flash/PSRAM: Example of supported memories and transactions(1) (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
PSRAM (multiplexed I/Os and non-multiplexed I/Os)	Asynchronous	R	8	16	Y	
	Asynchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	16	16	Y	
	Asynchronous	W	16	16	Y	
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses
	Asynchronous page	R	-	16	N	Mode is not supported
	Synchronous	R	8	16	N	
	Synchronous	R	16	16	Y	
	Synchronous	R	32/64	16	Y	
	Synchronous	W	8	16	Y	Use of byte lanes NBL[1:0]
	Synchronous	W	16/32/64	16	Y	
SRAM and ROM	Asynchronous	R	8/16	16	Y	
	Asynchronous	W	8/16	16	Y	Use of byte lanes NBL[1:0]
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses Use of byte lanes NBL[1:0]
	Asynchronous	R	64	16	Y	Split into 4 FMC accesses
	Asynchronous	W	64	16	Y	Split into 4 FMC accesses Use of byte lanes NBL[1:0]

1. NBL[1:0] are also driven by AXI write strobes.

23.7.3 General timing rules

Signal synchronization is performed as follows:

- All controller output signals change on the rising edge of the fmc_ker_ck clock.
- In Synchronous read and write modes, all output signals change on the rising edge of fmc_ker_ck clock. Whatever the CLKDIV value, all outputs change as follows:
  - NOEL/NWEL/ NEL/NADVL/ NADVH /NBLL/ Address valid outputs change on the falling edge of FMC_CLK clock.
  - NOEH/ NWEH / NEH/ NOEH/NBLH/ Address invalid outputs change on the rising edge of FMC_CLK clock.

23.7.4 NOR flash/PSRAM controller asynchronous transactions

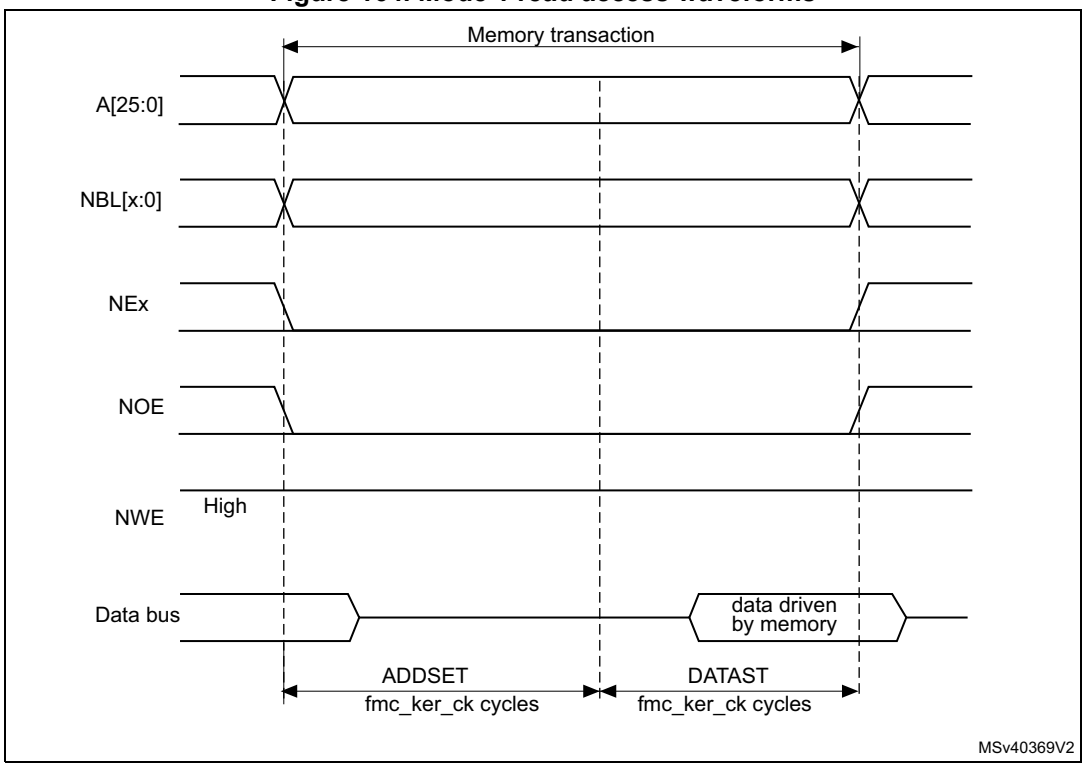
Asynchronous transactions on static memories (NOR flash memory, PSRAM, SRAM) are performed as follows:

- Signals are synchronized by the internal clock. This clock is not issued to the memory.
- The FMC always samples the data before deasserting the Chip Select signal. This guarantees that the memory data hold timing constraint is met (minimum Chip Enable high to data transition is usually 0 ns)
- If the Extended mode is enabled (EXTMOD bit is set in the FMC_BCRx register), up to four extended modes (A, B, C and D) are available. It is possible to mix A, B, C and D modes for read and write operations. For example, read operation can be performed in mode A and write in mode B.
- If the Extended mode is disabled (EXTMOD bit is reset in the FMC_BCRx register), the FMC can operate in Mode1 or Mode2 as follows:
  - Mode 1 is the default mode when SRAM/PSRAM memory type is selected (MTYP = 0x0 or 0x01 in the FMC_BCRx register)
  - Mode 2 is the default mode when NOR memory type is selected (MTYP = 0x10 in the FMC_BCRx register).

Mode 1 - SRAM/PSRAM (CRAM)

The next figures show the read and write transactions for the supported modes followed by the required configuration of FMC_BCRx, and FMC_BTRx/FMC_BWTRx registers.

Figure 164. Mode 1 read access waveforms



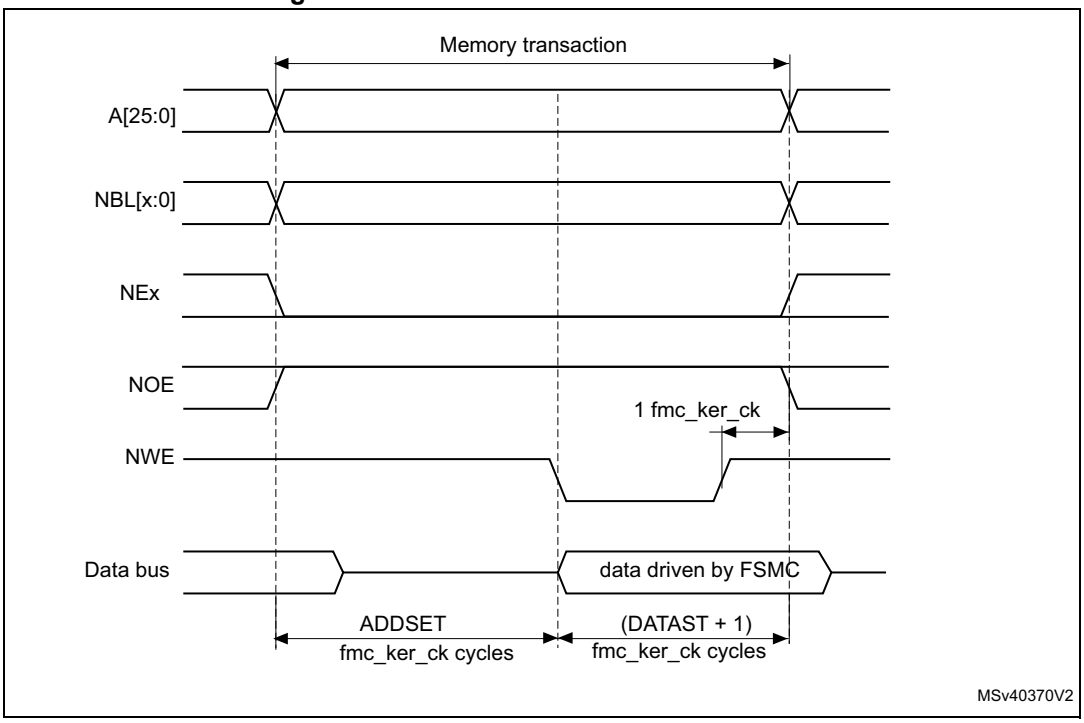


Figure 165. Mode 1 write access waveforms

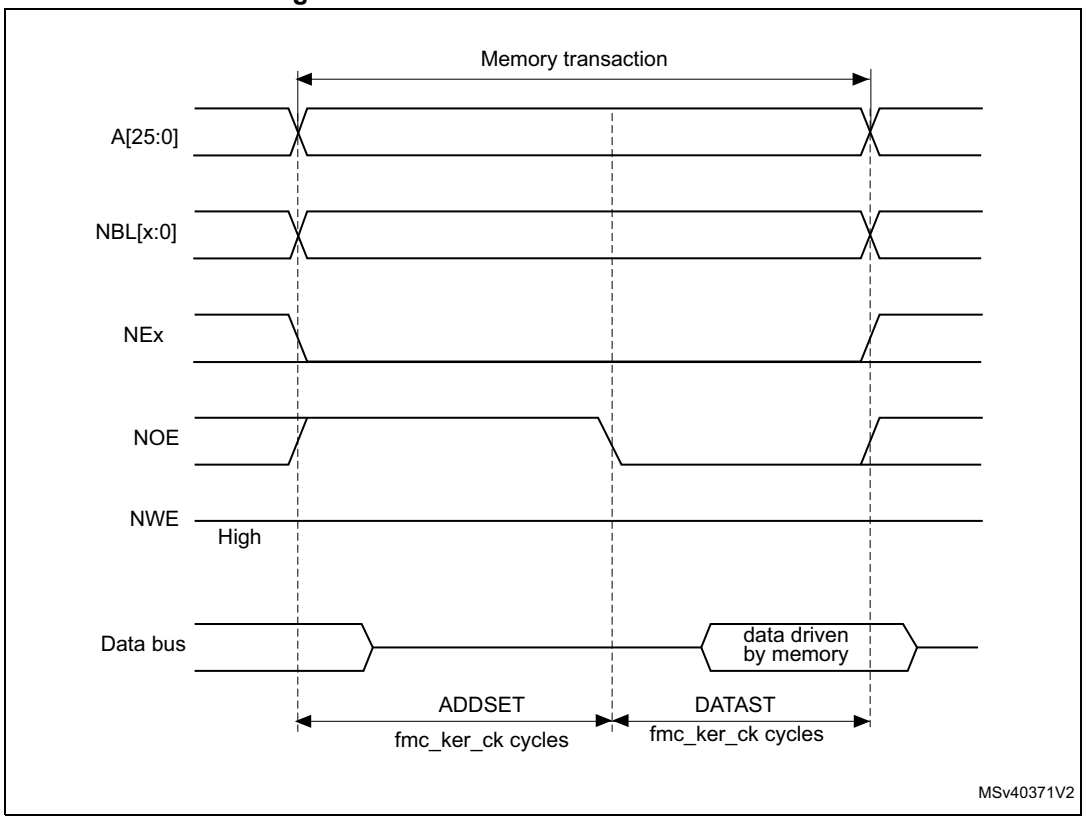
The fmc_ker_ck cycle at the end of the write transaction helps guarantee the address and data hold time after the NWE rising edge. Due to the presence of this fmc_ker_ck cycle, the DATAST value must be greater than zero (DATAST > 0).

Table 181. FMC_BCRx bitfields (mode 1)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:26	Reserved	0x000
25:24	BMAP	As needed
23:22	Reserved	0x000
21	WFDIS	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x0
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed
11	WAITCFG	Don’t care
10	Reserved	0x0

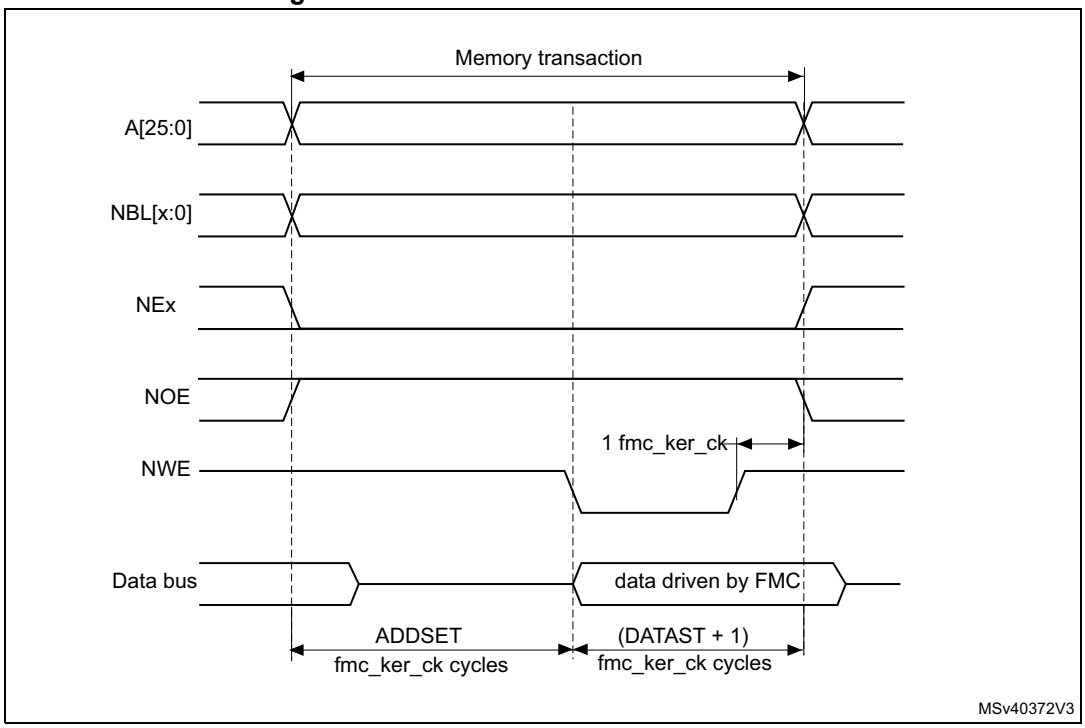
Table 181. FMC_BCRx bitfields (mode 1) (continued)



Bit number	Bit name	Value to set
9	WAITPOL	Meaningful only if bit 15 is 1
8	BURSTEN	0x0
7	Reserved	0x1
6	FACCEN	Don’t care
5:4	MWID	As needed
3:2	MTYP	As needed, exclude 0x2 (NOR flash memory)
1	MUXE	0x0
0	MBKEN	0x1

Table 182. FMC_BTRx bitfields (mode 1)

Bit number	Bit name	Value to set
31:30	Reserved	0x0
29:28	ACCMOD	Don’t care
27:24	DATLAT	Don’t care
23:20	CLKDIV	Don’t care
19:16	BUSTURN	Time between NEx high to NEx low (BUSTURN fmc_ker_ck)
15:8	DATAST	Duration of the second access phase (DATAST+1 fmc_ker_ck cycles for write accesses, DATAST fmc_ker_ck cycles for read accesses).
7:4	ADDHLD	Don’t care
3:0	ADDSET	Duration of the first access phase (ADDSET fmc_ker_ck cycles). Minimum value for ADDSET is 0.



Mode A - SRAM/PSRAM (CRAM) OE toggling

Figure 166. Mode A read access waveforms

1. NBL[3:0] are driven low during the read access

Figure 167. Mode A write access waveforms

The differences compared with Mode1 are the toggling of NOE and the independent read and write timings.

Table 183. FMC_BCRx bitfields (mode A)

Bit number	Bit name	Value to set
31	FMCEN	0x1
30:26	Reserved	0x000
25:24	BMAP	As needed
23:22	Reserved	0x000
21	WFDIS	As needed
20	CCLKEN	As needed
19	CBURSTRW	0x0 (no effect in Asynchronous mode)
18:16	CPSIZE	0x0 (no effect in Asynchronous mode)
15	ASYNCWAIT	Set to 1 if the memory supports this feature. Otherwise keep at 0.
14	EXTMOD	0x1
13	WAITEN	0x0 (no effect in Asynchronous mode)
12	WREN	As needed

WAIT management in asynchronous accesses

If the asynchronous memory asserts the WAIT signal to indicate that it is not yet ready to accept or to provide data, the ASYNCWAIT bit has to be set in FMC_BCRx register.

If the WAIT signal is active (high or low depending on the WAITPOL bit), the second access phase (Data setup phase), programmed by the DATAST bits, is extended until WAIT becomes inactive. Unlike the data setup phase, the first access phases (Address setup and Address hold phases), programmed by the ADDSET and ADDHLD bits, are not WAIT sensitive and so they are not prolonged.

The data setup phase must be programmed so that WAIT can be detected 4 fmc_ker_ck cycles before the end of the memory transaction. The following cases must be considered:

1. The memory asserts the WAIT signal aligned to NOE/NWE which toggles:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + \text{max_wait_assertion_time}$$

2. The memory asserts the WAIT signal aligned to NEx (or NOE/NWE not toggling):

   if

$$\text{max_wait_assertion_time} > \text{address_phase} + \text{hold_phase}$$

   then:

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck}) + (\text{max_wait_assertion_time} - \text{address_phase} - \text{hold_phase})$$

   otherwise

$$\text{DATAST} \geq (4 \times \text{fmc_ker_ck})$$

   where max_wait_assertion_time is the maximum time taken by the memory to assert the WAIT signal once NEx/NOE/NWE is low.

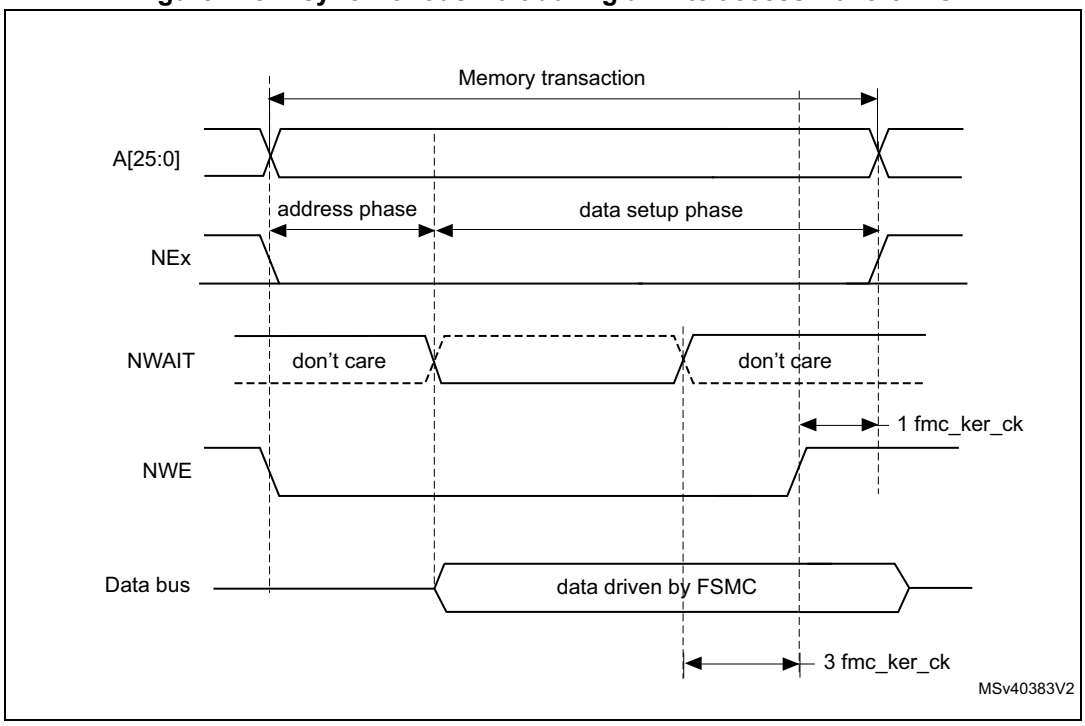

Figure 177 and *Figure 178* show the number of fmc_ker_ck clock cycles that are added to the memory access phase after WAIT is released by the asynchronous memory (independently of the above cases).

Figure 177. Asynchronous wait during a read access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

Figure 178. Asynchronous wait during a write access waveforms

1. NWAIT polarity depends on WAITPOL bit setting in FMC_BCRx register.

23.7.5 Synchronous transactions

The memory clock, FMC_CLK, is a sub-multiple of fmc_ker_ck. It depends on the value of CLKDIV and the MWID/ AXI data size, following the formula given below:

$$\text{FMC_CLK divider ratio} = \max(\text{CLKDIV} + 1, \text{MWID}(\text{AXI data size}))$$

If MWID is 16 or 8-bit, the FMC_CLK divider ratio is always defined by the programmed CLKDIV value.

If MWID is 32-bit, the FMC_CLK divider ratio depends also on AXI data size.

Example:

- If CLKDIV=1, MWID = 32 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/4.
- If CLKDIV=1, MWID = 16 bits, AXI data size=8 bits, FMC_CLK=fmc_ker_ck/2.

NOR flash memories specify a minimum time from NADV assertion to FMC_CLK high. To meet this constraint, the FMC does not issue the clock to the memory during the first internal clock cycle of the synchronous access (before NADV assertion). This guarantees that the rising edge of the memory clock occurs in the middle of the NADV low pulse.

For some PSRAM memories which must be configured to Synchronous mode, during the BCR register writing, the memory attribute space must be configured to device or strongly-ordered. Once PSRAM BCR register is configured, the memory attribute of PSRAM address space can be programmed to cacheable.

Data latency versus NOR memory latency

The data latency is the number of cycles to wait before sampling the data. The DATLAT value must be consistent with the latency value specified in the NOR flash configuration register. The FMC does not include the clock cycle when NADV is low in the data latency count.

Caution: Some NOR flash memories include the NADV Low cycle in the data latency count, so that the exact relation between the NOR flash latency and the FMC DATLAT parameter can be either:

- NOR flash latency = (DATLAT + 2) FMC_CLK clock cycles
- or NOR flash latency = (DATLAT + 3) FMC_CLK clock cycles

Some recent memories assert NWAIT during the latency phase. In such cases DATLAT can be set to its minimum value. As a result, the FMC samples the data and waits long enough to evaluate if the data are valid. Thus the FMC detects when the memory exits latency and real data are processed.

Other memories do not assert NWAIT during latency. In this case the latency must be set correctly for both the FMC and the memory, otherwise invalid data are mistaken for good data, or valid data are lost in the initial phase of the memory access.

Single-burst transfer

When the selected bank is configured in Burst mode for synchronous accesses, if for example a single-burst transaction is requested on 16-bit memories, the FMC performs a burst transaction of length 1 (if the AXI transfer is 16 bits), or length 2 (if the AXI transfer is 32 bits) and deassert the Chip Select signal when the last data is strobed.

Such transfers are not the most efficient in terms of cycles compared to asynchronous read operations. Nevertheless, a random asynchronous access would first require to re-program the memory access mode, which would altogether last longer.

Cross boundary page for Cellular RAM 1.5

Cellular RAM 1.5 does not allow burst access to cross the page boundary. The FMC allows to split automatically the burst access when the memory page size is reached by configuring the CPSIZE bits in the FMC_BCR1 register following the memory page size.

Wait management

For synchronous NOR flash memories, NWAIT is evaluated after the programmed latency period, which corresponds to (DATLAT+2) FMC_CLK clock cycles.

If NWAIT is active (low level when WAITPOL = 0, high level when WAITPOL = 1), wait states are inserted until NWAIT is inactive (high level when WAITPOL = 0, low level when WAITPOL = 1).

When NWAIT is inactive, the data is considered valid either immediately (bit WAITCFG = 1) or on the next clock edge (bit WAITCFG = 0).

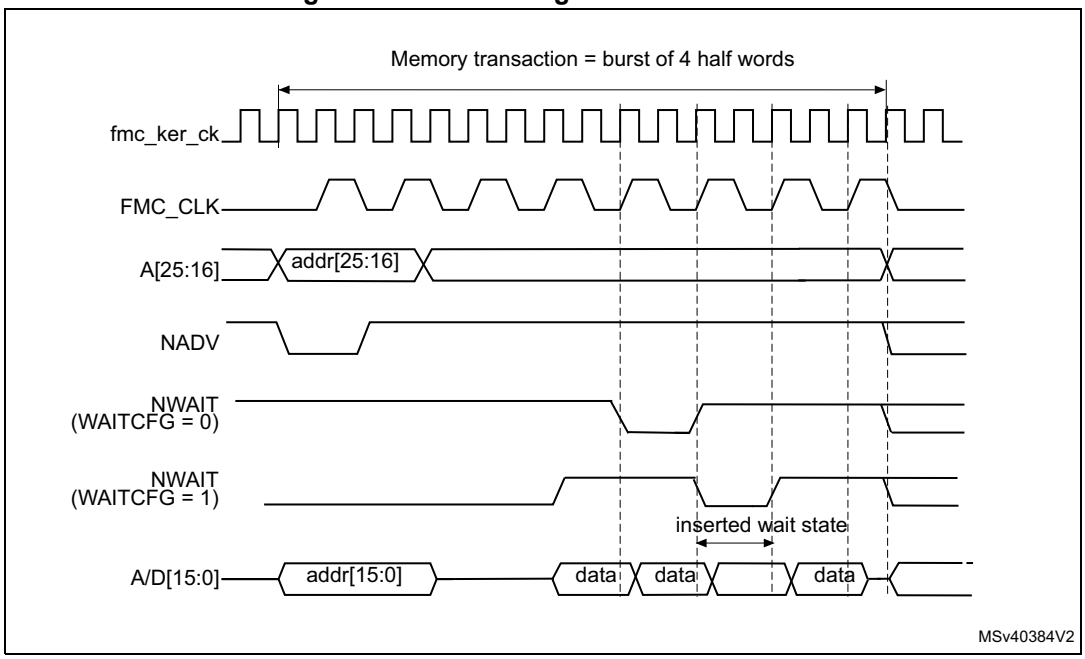
During wait-state insertion via the NWAIT signal, the controller continues to send clock pulses to the memory, keeping the Chip Select and output enable signals valid. It does not consider the data as valid.

In Burst mode, there are two timing configurations for the NOR flash NWAIT signal:

- The flash memory asserts the NWAIT signal one data cycle before the wait state (default after reset).
- The flash memory asserts the NWAIT signal during the wait state

The FMC supports both NOR flash wait state configurations, for each Chip Select, thanks to the WAITCFG bit in the FMC_BCRx registers (x = 0..3).

Figure 179. Wait configuration waveforms



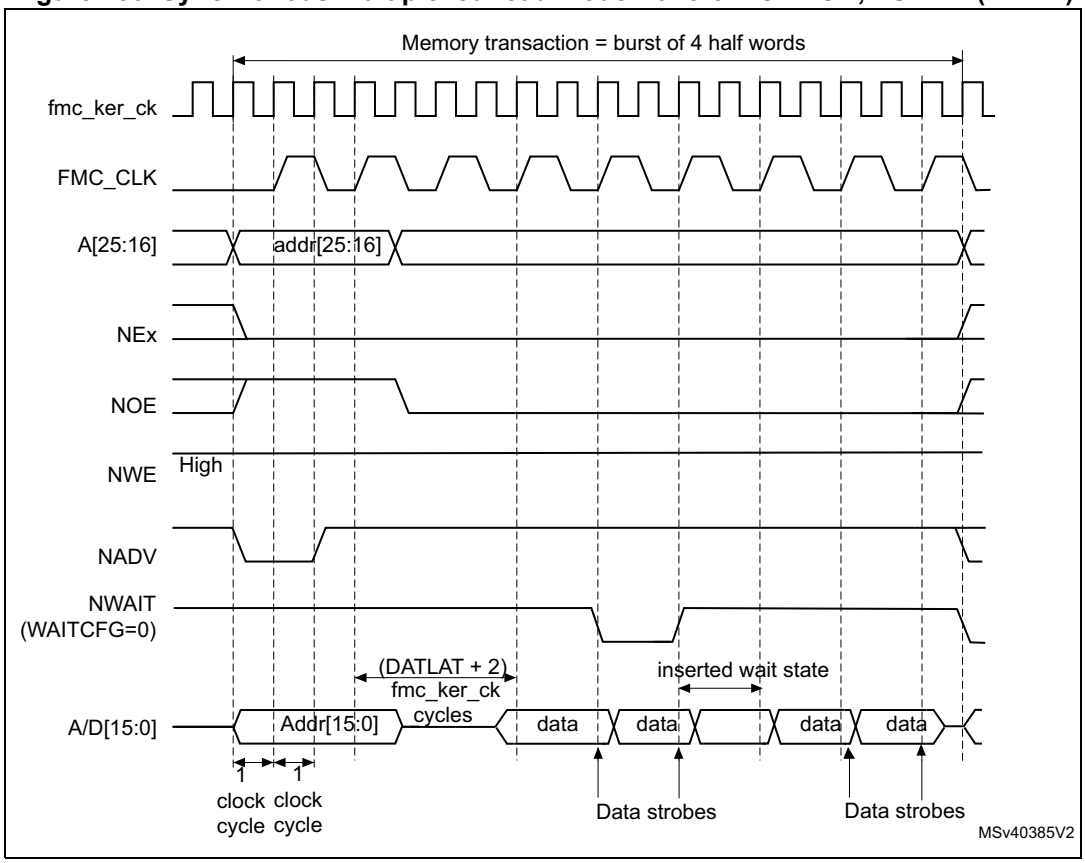


Figure 180. Synchronous multiplexed read mode waveforms - NOR, PSRAM (CRAM)

1. Byte lane outputs (NBL are not shown; for NOR access, they are held high, and, for PSRAM (CRAM) access, they are held low.

Bit 31 **FMCEN:** FMC Enable

This bit enables/disables the FMC.

0: Disable the FMC

1: Enable the FMC

Note: The FMCEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **BMAP[1:0]:** FMC bank mapping

These bits allow different remap or swap of the FMC NOR/PSRAM and SDRAM banks (refer to *Table 165*).

00: Default mapping (refer to *Figure 163* and *Table 165*).

01: NOR/PSRAM bank and SDRAM bank 1 are swapped.

10: Reserved

11: Reserved.

Note: The BMAP bits of the FMC_BCR2..4 registers are don't care. It is only enabled through the FMC_BCR1 register.

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **WFDIS:** Write FIFO Disable

This bit disables the Write FIFO used by the FMC.

0: Write FIFO enabled (Default after reset)

1: Write FIFO disabled

Note: The WFDIS bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register.

Bit 20 **CCLKEN:** Continuous Clock Enable

This bit enables the FMC_CLK clock output to external memory devices.

0: The FMC_CLK is only generated during the synchronous memory access (read/write transaction). The FMC_CLK clock ratio is specified by the programmed CLKDIV value in the FMC_BCRx register (default after reset).

1: The FMC_CLK is generated continuously during asynchronous and synchronous access. The FMC_CLK clock is activated when the CCLKEN is set.

Note: The CCLKEN bit of the FMC_BCR2..4 registers is don't care. It is only enabled through the FMC_BCR1 register. Bank 1 must be configured in Synchronous mode to generate the FMC_CLK continuous clock.

If CCLKEN bit is set, the FMC_CLK clock ratio is specified by CLKDIV value in the FMC_BTR1 register. CLKDIV in FMC_BWTR1 is don't care.

If the Synchronous mode is used and CCLKEN bit is set, the synchronous memories connected to other banks than Bank 1 are clocked by the same clock (the CLKDIV value in the FMC_BTR2..4 and FMC_BWTR2..4 registers for other banks has no effect.)

Bit 19 **CBURSTRW:** Write burst enable

For PSRAM (CRAM) operating in Burst mode, the bit enables synchronous accesses during write operations. The enable bit for synchronous read accesses is the BURSTEN bit in the FMC_BCRx register.

0: Write operations are always performed in Asynchronous mode

1: Write operations are performed in Synchronous mode.

Bits 18:16 **CPSIZE[2:0]**: CRAM Page Size

These are used for Cellular RAM 1.5 which does not allow burst access to cross the address boundaries between pages. When these bits are configured, the FMC splits automatically the burst access when the memory page size is reached (refer to memory datasheet for page size).

000: No burst split when crossing page boundary (default after reset).

001: 128 bytes

010: 256 bytes

100: 1024 bytes

Other configuration: reserved.

Bit 15 **ASYNCWAIT**: Wait signal during asynchronous transfers

This bit enables/disables the FMC to use the wait signal even during an asynchronous protocol.

0: NWAIT signal is not taken in to account when running an asynchronous protocol (default after reset)

1: NWAIT signal is taken in to account when running an asynchronous protocol

Bit 14 **EXTMOD**: Extended mode enable.

This bit enables the FMC to program the write timings for asynchronous accesses inside the FMC_BWTR register, thus resulting in different timings for read and write operations.

0: values inside FMC_BWTR register are not taken into account (default after reset)

1: values inside FMC_BWTR register are taken into account

Note: When the Extended mode is disabled, the FMC can operate in Mode1 or Mode2 as follows:

- *Mode 1 is the default mode when the SRAM/PSRAM memory type is selected (MTYP =0x0 or 0x01)*
- *Mode 2 is the default mode when the NOR memory type is selected (MTYP = 0x10).*

Bit 13 **WAITEN**: Wait enable bit

This bit enables/disables wait-state insertion via the NWAIT signal when accessing the memory in Synchronous mode.

0: NWAIT signal is disabled (its level not taken into account, no wait state inserted after the programmed flash latency period)

1: NWAIT signal is enabled (its level is taken into account after the programmed latency period to insert wait states if asserted) (default after reset)

Bit 12 **WREN**: Write enable bit

This bit indicates whether write operations are enabled/disabled in the bank by the FMC:

0: Write operations are disabled in the bank by the FMC, an AXI slave error is reported

1: Write operations are enabled for the bank by the FMC (default after reset).

Bit 11 **WAITCFG**: Wait timing configuration

The NWAIT signal indicates whether the data from the memory are valid or if a wait state must be inserted when accessing the memory in Synchronous mode. This configuration bit determines if NWAIT is asserted by the memory one clock cycle before the wait state or during the wait state:

0: NWAIT signal is active one data cycle before wait state (default after reset)

1: NWAIT signal is active during wait state (not used for PSRAM).

Bit 10 Reserved, must be kept at reset value.

Bit 9 **WAITPOL**: Wait signal polarity bit

This bit defines the polarity of the wait signal from memory used for either in Synchronous or Asynchronous mode:

0: NWAIT active low (default after reset)

1: NWAIT active high.

Bit 8 **BURSTEN**: Burst enable bit

This bit enables/disables synchronous accesses during read operations. It is valid only for synchronous memories operating in Burst mode:

0: Burst mode disabled (default after reset). Read accesses are performed in Asynchronous mode

1: Burst mode enable. Read accesses are performed in Synchronous mode.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **FACCEN**: Flash access enable

This bit enables NOR flash memory access operations.

0: Corresponding NOR flash memory access is disabled

1: Corresponding NOR flash memory access is enabled (default after reset)

Bits 5:4 **MWID[1:0]:** Memory data bus width

Defines the external memory device width, valid for all type of memories.

00: 8 bits

01: 16 bits (default after reset)

10: 32 bits

11: reserved

Bits 3:2 **MTYP[1:0]:** Memory type

These bits define the type of external memory attached to the corresponding memory bank:
00: SRAM (default after reset for Bank 2...4)
01: PSRAM (CRAM)
10: NOR flash/OneNAND flash (default after reset for Bank 1)
11: reserved

Bit 1 **MUXEN:** Address/data multiplexing enable bit

When this bit is set, the address and data values are multiplexed on the data bus, valid only with NOR and PSRAM memories:
0: Address/Data non-multiplexed
1: Address/Data multiplexed on databus (default after reset)

Bit 0 **MBKEN:** Memory bank enable bit

This bit enables the memory bank. After reset Bank1 is enabled, all others are disabled. Accessing a disabled bank causes an ERROR on AXI bus.
0: Corresponding memory bank is disabled
1: Corresponding memory bank is enabled

SRAM/NOR-flash chip-select timing registers for bank x (FMC_BTRx)

Address offset: 0x04 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank, used for SRAMs, PSRAM and NOR flash memories.If the EXTMOD bit is set in the FMC_BCRx register, then this register is partitioned for write and read access, that is, 2 registers are available: one to configure read accesses (this register) and one to configure write accesses (FMC_BWTRx registers).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		DATLAT[3:0]				CLKDIV[3:0]				BUSTURN[3:0]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode

These bits specify the Asynchronous access modes as shown in the timing diagrams. They are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:24 **DATLAT[3:0]:** (see note below bit descriptions): Data latency for synchronous memory

For synchronous access with read/write Burst mode enabled (BURSTEN / CBURSTRW bits set), these bits define the number of memory clock cycles (+2) to issue to the memory before reading/writing the first data:

This timing parameter is not expressed in fmc_ker_ck periods, but in FMC_CLK periods.

For asynchronous access, this value is don't care.

0000: Data latency of 2 FMC_CLK clock cycles for first burst access

1111: Data latency of 17 FMC_CLK clock cycles for first burst access (default value after reset)

Bits 23:20 **CLKDIV[3:0]:** Clock divide ratio (for FMC_CLK signal)

These bits define the period of FMC_CLK clock output signal, expressed in number of fmc_ker_ck cycles:

0000: FMC_CLK period = 1 x fmc_ker_ck period

0001: FMC_CLK period = 2 × fmc_ker_ck periods

0010: FMC_CLK period = 3 × fmc_ker_ck periods

1111: FMC_CLK period = 16 × fmc_ker_ck periods (default value after reset)

In asynchronous NOR flash, SRAM or PSRAM accesses, this value is don’t care.

Note: Refer to Section 23.7.5: Synchronous transactions for FMC_CLK divider ratio formula)

Bits 19:16 **BUSTURN[3:0]:** Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write-to-read (and read-to-write) transaction. This delay allows to match the minimum time between consecutive transactions (t_{EHEL} from NEx high to NEx low) and the maximum time needed by the memory to free the data bus after a read access (t_{EHQZ}). The programmed bus turnaround delay is inserted between an asynchronous read (muxed or mode D) or write transaction and any other asynchronous /synchronous read or write to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different except for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed

as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 1 FMC clock cycle between:
  - –Two consecutive asynchronous read transfers to the same static memory bank except for muxed and D modes.
  - –An asynchronous read to an asynchronous or synchronous write to any static bank or dynamic bank except for muxed and D modes.
  - –An asynchronous (modes 1, 2, A, B or C) read and a read from another static bank.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) access and an asynchronous write or read transfer to or from static memory bank (the bank can be the same or different for the case of read.
  - –Two consecutive synchronous reads (burst or single) followed by any synchronous/asynchronous read or write from/to another static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) access and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 x fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration

These bits are written by software to define the duration of the data phase (refer to *Figure 164* to *Figure 176*), used in asynchronous accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

For each memory type and access mode data-phase duration, refer to the respective figure (*Figure 164* to *Figure 176*).

Example: Mode1, write access, DATAST = 1: Data-phase duration = DATAST+1 = 1 x fmc_ker_ck clock cycles.

Note: In synchronous accesses, this value is don't care.

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 164* to *Figure 176*), used in mode D or multiplexed accesses:
0000: Reserved
0001: ADDHLD phase duration =1 × fmc_ker_ck clock cycle
0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle
...
1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address-hold phase duration, refer to the respective figure (*Figure 164* to *Figure 176*).

Note: In synchronous accesses, this value is not used, the address hold phase is always 1 memory clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration

These bits are written by software to define the duration of the *address setup* phase (refer to *Figure 164* to *Figure 176*), used in SRAMs, ROMs and asynchronous NOR flash:
0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle
...
1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)
For each access mode address setup phase duration, refer to the respective figure (refer to *Figure 164* to *Figure 176*).

Note: In synchronous accesses, this value is don't care.
In Muxed mode or mode D, the minimum value for ADDSET is 1.
In mode 1 and PSRAM memory, the minimum value for ADDSET is 1.

Note: PSRAMs (CRAMs) have a variable latency due to internal refresh. Therefore these memories issue the NWAIT signal during the whole latency phase to extend the latency as needed.
On PSRAMs (CRAMs) the filled DATLAT must be set to 0, so that the FMC exits its latency phase soon and starts sampling NWAIT from memory, then starts to read or write when the memory is ready.
This method can be used also with the latest generation of synchronous flash memories that issue the NWAIT signal, unlike older flash memories (check the datasheet of the specific flash memory being used).

SRAM/NOR-flash write timing registers for bank x (FMC_BWTRx)

Address offset: 0x104 + 0x8 * (x - 1), (x = 1 to 4)

Reset value: 0x0FFF FFFF

This register contains the control information of each memory bank. It is used for SRAMs, PSRAMs and NOR flash memories. When the EXTMOD bit is set in the FMC_BCRx register, then this register is active for write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	ACCMOD[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BUSTURN[3:0]			
		rw	rw									rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAST[7:0]								ADDHLD[3:0]				ADDSET[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **ACCMOD[1:0]:** Access mode.

These bits specify the asynchronous access modes as shown in the next timing diagrams.These bits are taken into account only when the EXTMOD bit in the FMC_BCRx register is 1.

00: access mode A

01: access mode B

10: access mode C

11: access mode D

Bits 27:20 Reserved, must be kept at reset value.

Bits 19:16 **BUSTURN[3:0]**: Bus turnaround phase duration

These bits are written by software to add a delay at the end of a write transaction to match the minimum time between consecutive transactions (t_{EHEL} from ENx high to ENx low):

(BUSTRUN + 1) fmc_ker_ck period ≥ $t_{EHELmin}$.

The programmed bus turnaround delay is inserted between an asynchronous write transfer and any other asynchronous /synchronous read or write transfer to or from a static bank. The bank can be the same or different in case of read, in case of write the bank can be different expect for muxed or mode D.

In some cases, whatever the programmed BUSTURN values, the bus turnaround delay is fixed as follows:

- The bus turnaround delay is not inserted between two consecutive asynchronous write transfers to the same static memory bank except for muxed and D modes.
- There is a bus turnaround delay of 2 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to the same bank.
  - –A synchronous write (burst or single) transfer and an asynchronous write or read transfer to or from static memory bank.
- There is a bus turnaround delay of 3 FMC clock cycle between:
  - –Two consecutive synchronous writes (burst or single) to different static bank.
  - –A synchronous write (burst or single) transfer and a synchronous read from the same or a different bank.

0000: BUSTURN phase duration = 0 fmc_ker_ck clock cycle added

...

1111: BUSTURN phase duration = 15 fmc_ker_ck clock cycles added (default value after reset)

Bits 15:8 **DATAST[7:0]:** Data-phase duration.

These bits are written by software to define the duration of the data phase (refer to *Figure 164* to *Figure 176*), used in asynchronous SRAM, PSRAM and NOR flash memory accesses:

0000 0000: Reserved

0000 0001: DATAST phase duration = 1 × fmc_ker_ck clock cycles

0000 0010: DATAST phase duration = 2 × fmc_ker_ck clock cycles

...

1111 1111: DATAST phase duration = 255 × fmc_ker_ck clock cycles (default value after reset)

Bits 7:4 **ADDHLD[3:0]:** Address-hold phase duration.

These bits are written by software to define the duration of the *address hold* phase (refer to *Figure 164* to *Figure 176*), used in asynchronous multiplexed accesses:

0000: Reserved

0001: ADDHLD phase duration = 1 × fmc_ker_ck clock cycle

0010: ADDHLD phase duration = 2 × fmc_ker_ck clock cycle

...

1111: ADDHLD phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous NOR flash accesses, this value is not used, the address hold phase is always 1 flash clock period duration.

Bits 3:0 **ADDSET[3:0]:** Address setup phase duration.

These bits are written by software to define the duration of the *address setup* phase in fmc_ker_ck cycles (refer to *Figure 164* to *Figure 176*), used in asynchronous accesses:

0000: ADDSET phase duration = 0 × fmc_ker_ck clock cycle

...

1111: ADDSET phase duration = 15 × fmc_ker_ck clock cycles (default value after reset)

Note: In synchronous accesses, this value is not used, the address setup phase is always 1 flash clock period duration. In muxed mode, the minimum ADDSET value is 1.

23.8 NAND flash controller

The FMC generates the appropriate signal timings to drive 8- and 16-bit NAND flash memories.

The NAND bank is configured through dedicated registers (*Section 23.8.7*). The programmable memory parameters include access timings (shown in *Table 201*) and ECC configuration.

Table 201. Programmable NAND flash access parameters

Parameter	Function	Access mode	Unit	Min.	Max.
Memory setup time	Number of clock cycles (fmc_ker_ck) required to set up the address before the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	255
Memory wait	Minimum duration (in fmc_ker_ck clock cycles) of the command assertion	Read/Write	AHB clock cycle (fmc_ker_ck)	2	255
Memory hold	Number of clock cycles (fmc_ker_ck) during which the address must be held (as well as the data if a write access is performed) after the command deassertion	Read/Write	AHB clock cycle (fmc_ker_ck)	1	254
Memory databus high-Z	Number of clock cycles (fmc_ker_ck) during which the data bus is kept in high-Z state after a write access has started	Write	AHB clock cycle (fmc_ker_ck)	0	254

23.8.1 External memory interface signals

The following tables list the signals that are typically used to interface NAND flash memories.

Note: The prefix “N” identifies the signals which are active low.

8-bit NAND flash memory

Table 202. 8-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[7:0]	I/O	8-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

16-bit NAND flash memory

Table 203. 16-bit NAND flash memory

FMC pin name	I/O	Function
A[17]	O	NAND flash address latch enable (ALE) signal
A[16]	O	NAND flash command latch enable (CLE) signal
D[15:0]	I/O	16-bit multiplexed, bidirectional address/data bus
NCE	O	Chip Select
NOE(= NRE)	O	Output enable (memory signal name: read enable, NRE)
NWE	O	Write enable
NWAIT/INT	I	NAND flash ready/busy input signal to the FMC

Note: Theoretically, there is no capacity limitation as the FMC can manage as many address cycles as needed.

23.8.2 NAND flash supported memories and transactions

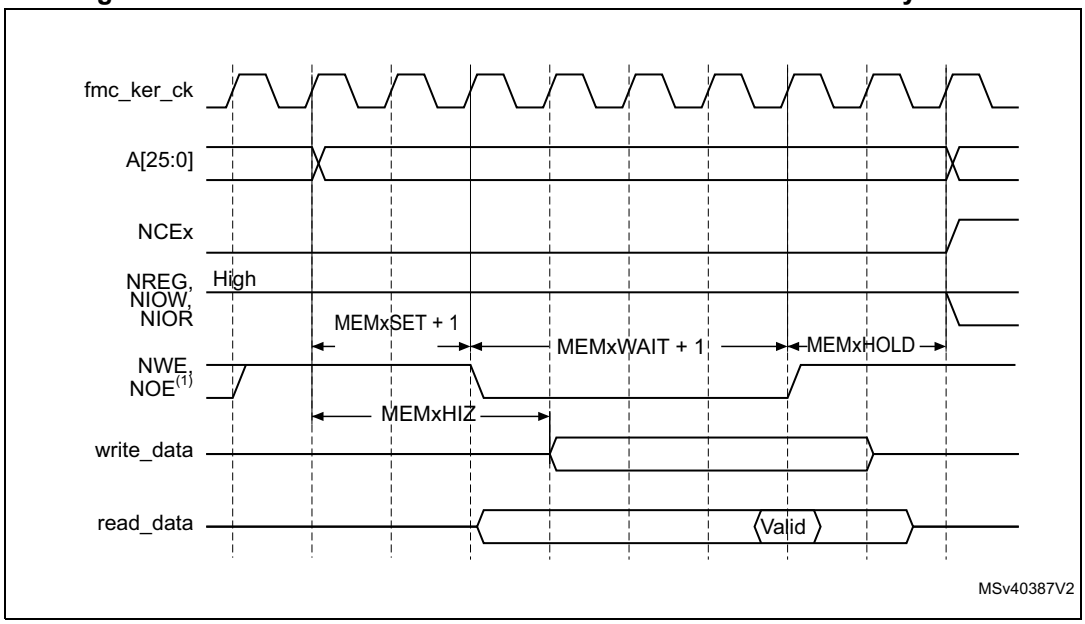
Table 204 shows the supported devices, access modes and transactions. Transactions not allowed (or not supported) by the NAND flash controller are shown in gray.

Table 204. Supported memories and transactions

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 8-bit	Asynchronous	R	8	8	Y	-
	Asynchronous	W	8	8	Y	-
	Asynchronous	R	16	8	Y	Split into 2 FMC accesses
	Asynchronous	W	16	8	Y	Split into 2 FMC accesses
	Asynchronous	R	32	8	Y	Split into 4 FMC accesses
	Asynchronous	W	32	8	Y	Split into 4 FMC accesses
	Asynchronous	R	32	8	Y	Split into 8 FMC accesses
	Asynchronous	W	32	8	Y	Split into 8 FMC accesses

Table 204. Supported memories and transactions (continued)

Device	Mode	R/W	AXI data size	Memory data size	Allowed/ not allowed	Comments
NAND 16-bit	Asynchronous	R	8	16	Y	-
	Asynchronous	W	8	16	N	-
	Asynchronous	R	16	16	Y	-
	Asynchronous	W	16	16	Y	-
	Asynchronous	R	32	16	Y	Split into 2 FMC accesses
	Asynchronous	W	32	16	Y	Split into 2 FMC accesses
	Asynchronous	R	32	16	Y	Split into 4 FMC accesses
	Asynchronous	W	32	16	Y	Split into 4 FMC accesses



23.8.3 Timing diagrams for NAND flash memories

The NAND flash memory bank is managed through a set of registers:

- Control register: FMC_PCR
- Interrupt status register: FMC_SR
- ECC register: FMC_ECCR
- Timing register for Common memory space: FMC_PMEM
- Timing register for Attribute memory space: FMC_PATT

Each timing configuration register contains three parameters used to define the number of fmc_ker_ck cycles for the three phases of any NAND flash access, plus one parameter that defines the timing to start driving the data bus when a write access is performed. *Figure 182* shows the timing parameter definitions for common memory accesses, knowing that Attribute memory space access timings are similar.

Figure 182. NAND flash controller waveforms for common memory access

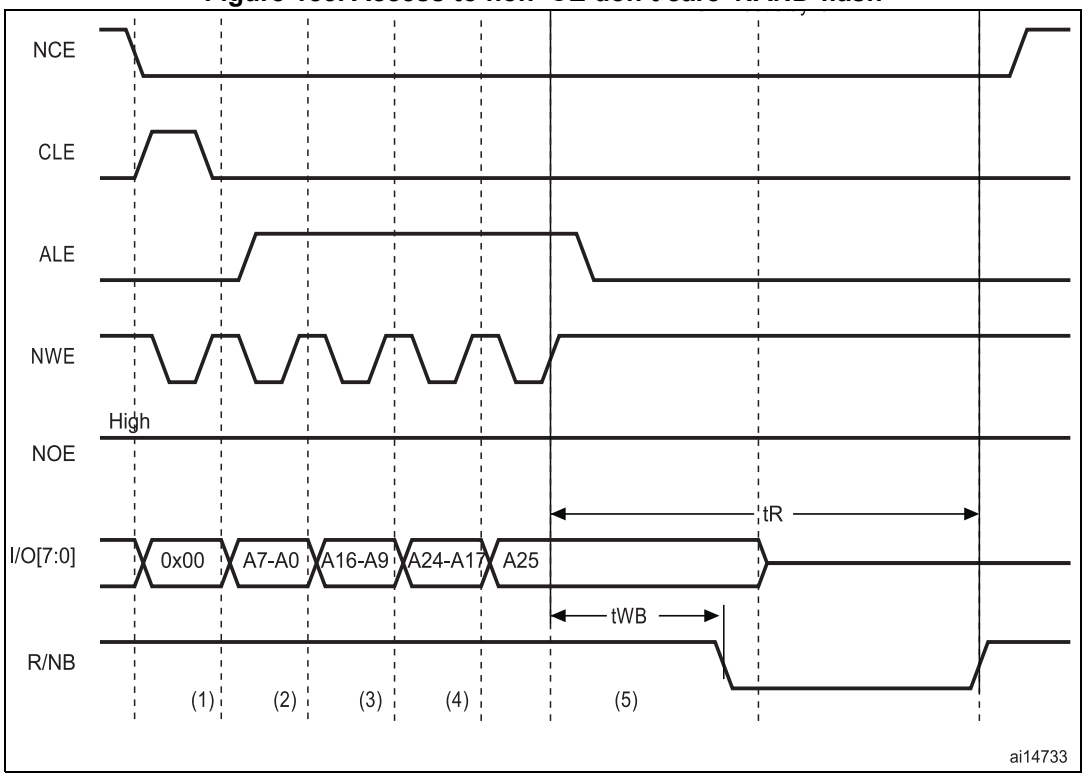
1. NOE remains high (inactive) during write accesses. NWE remains high (inactive) during read accesses.
2. For write accesses, the hold phase delay is (MEMHOLD) fmc_ker_ck cycles and for read access is (MEMHOLD + 1) fmc_ker_ck cycles.

23.8.4 NAND flash operations

The command latch enable (CLE) and address latch enable (ALE) signals of the NAND flash memory device are driven by address signals from the FMC. This means that to send a command or an address to the NAND flash memory, the CPU has to perform a write to a specific address in its memory space.

A typical page read operation from the NAND flash device requires the following steps:

1. Program and enable the corresponding memory bank by configuring the FMC_PCR and FMC_PMEM (and for some devices, FMC_PATT, see *Section 23.8.5: NAND flash prewait feature*) registers according to the characteristics of the NAND flash memory (PWID bits for the data bus width of the NAND flash memory, PWAITEN = 0 or 1 as needed, see *Section 23.6.2: NAND flash memory address mapping* for timing configuration).
2. The CPU performs a byte write to the common memory space, with data byte equal to one flash command byte (for example 0x00 for Samsung NAND flash devices). The LE input of the NAND flash memory is active during the write strobe (low pulse on NWE), thus the written byte is interpreted as a command by the NAND flash memory. Once the command is latched by the memory device, it does not need to be written again for the following page read operations.
3. The CPU can send the start address (STARTAD) for a read operation by writing four bytes (or three for smaller capacity devices), STARTAD[7:0], STARTAD[16:9], STARTAD[24:17] and finally STARTAD[25] (for 64 Mb x 8 bit NAND flash memories) in the common memory or attribute space. The ALE input of the NAND flash device is active during the write strobe (low pulse on NWE), thus the written bytes are interpreted as the start address for read operations. Using the attribute memory space makes it possible to use a different timing configuration of the FMC, which can be used



to implement the prewait functionality needed by some NAND flash memories (see details in *Section 23.8.5: NAND flash prewait feature*).

4. The controller waits for the NAND flash memory to be ready (R/NB signal high), before starting a new access to the same or another memory bank. While waiting, the controller holds the NCE signal active (low).
5. The CPU can then perform byte read operations from the common memory space to read the NAND flash page (data field + Spare field) byte by byte.
6. The next NAND flash page can be read without any CPU command or address write operation. This can be done in three different ways:
   - by simply performing the operation described in step 5
   - a new random address can be accessed by restarting the operation at step 3
   - a new command can be sent to the NAND flash device by restarting at step 2

23.8.5 NAND flash prewait feature

Some NAND flash devices require that, after writing the last part of the address, the controller waits for the R/NB signal to go low. (see *Figure 183*).

Figure 183. Access to non 'CE don't care' NAND-flash

1. CPU wrote byte 0x00 at address 0x7001 0000.
2. CPU wrote byte A7~A0 at address 0x7002 0000.
3. CPU wrote byte A16~A9 at address 0x7002 0000.
4. CPU wrote byte A24~A17 at address 0x7002 0000.
5. CPU wrote byte A25 at address 0x8802 0000: FMC performs a write access using FMC_PATT2 timing definition, where ATTHOLD ≥ 7 (providing that (7+1) × fmc_ker_ck = 112 ns > t_{WB} max). This guarantees that NCE remains low until R/NB goes low and high again (only requested for NAND flash memories where NCE is not don't care).

When this function is required, it can be performed by programming the MEMHOLD value to meet the t_{WB} timing. However, any CPU read access to NAND flash memory has a hold delay of (MEMHOLD + 1) fmc_ker_ck cycles, and any CPU write access has a hold delay of (MEMHOLD) fmc_ker_ck cycles that is inserted between the rising edge of the NWE signal and the next access.

To cope with this timing constraint, the attribute memory space can be used by programming its timing register with an ATTHOLD value that meets the t_{WB} timing, and by keeping the MEMHOLD value at its minimum value. The CPU must then use the common memory space for all NAND flash read and write accesses, except when writing the last address byte to the NAND flash device, where the CPU must write to the attribute memory space.

23.8.6 Computation of the error correction code (ECC) in NAND flash memory

The FMC includes an error correction code computation hardware block. It reduces the host CPU workload when processing the ECC by software.The ECC block is associated with NAND bank.

The ECC algorithm implemented in the FMC can perform 1-bit error correction and 2-bit error detection per 256, 512, 1 024, 2 048, 4 096 or 8 192 bytes read or written from/to the NAND flash memory. It is based on the Hamming coding algorithm and consists in calculating the row and column parity.

The ECC modules monitor the NAND flash data bus and read/write signals (NCE and NWE) each time the NAND flash memory bank is active.

The ECC operates as follows:

- When accessing NAND flash bank, the data present on the D[15:0] bus is latched and used for ECC computation.
- When accessing any other address in NAND flash memory, the ECC logic is idle, and does not perform any operation. As a result, write operations to define commands or addresses to the NAND flash memory are not taken into account for ECC computation.

Once the desired number of bytes has been read/written from/to the NAND flash memory by the host CPU, the FMC_ECCR registers must be read to retrieve the computed value. Once read, they should be cleared by resetting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to one in the FMC_PCR registers.

Execute below the sequence to perform an ECC computation:

1. Enable the ECCEN bit in the FMC_PCR register.
2. Write data to the NAND flash memory page. While the NAND page is written, the ECC block computes the ECC value.
3. Wait until the ECC code is ready (FIFO empty).
4. Read the ECC value available in the FMC_ECCR register and store it in a variable.
5. Clear the ECCEN bit and then enable it in the FMC_PCR register before reading back the written data from the NAND page. While the NAND page is read, the ECC block computes the ECC value.
6. Read the new ECC value available in the FMC_ECCR register.
7. If the two ECC values are the same, no correction is required, otherwise there is an ECC error and the software correction routine returns information on whether the error can be corrected or not.

23.8.7 NAND flash controller registers

NAND flash control registers (FMC_PCR)

Address offset: 0x80

Reset value: 0x0000 0018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:17 **ECCPS[2:0]:** ECC page size.
These bits define the page size for the extended ECC:
000: 256 bytes
001: 512 bytes
010: 1024 bytes
011: 2048 bytes
100: 4096 bytes
101: 8192 bytes

Bits 16:13 **TAR[3:0]:** ALE to RE delay.
These bits set time from ALE low to RE low in number of fmc_ker_ck clock cycles.
Time is: t_ar = (TAR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the FMC clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 12:9 **TCLR[3:0]:** CLE to RE delay.
These bits set time from CLE low to RE low in number of fmc_ker_ck clock cycles. The time is give by the following formula:
t_clr = (TCLR + SET + 2) × $t_{fmc_ker_ck}$ where $t_{fmc_ker_ck}$ is the fmc_ker_ck clock period
0000: 1 x fmc_ker_ck cycle (default)
1111: 16 x fmc_ker_ck cycles
Note: Set is MEMSET or ATTSET according to the addressed space.

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **ECCEN:** ECC computation logic enable bit
0: ECC logic is disabled and reset (default after reset),
1: ECC logic is enabled.

Bits 5:4 **PWID[1:0]:** Data bus width.
These bits define the external memory device width.
00: 8 bits
01: 16 bits (default after reset).
10: reserved.
11: reserved.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **PBKEN:** NAND flash memory bank enable bit.

This bit enables the memory bank. Accessing a disabled memory bank causes an ERROR on AXI bus

0: Corresponding memory bank is disabled (default after reset)

1: Corresponding memory bank is enabled

Bit 1 **PWAITEN:** Wait feature enable bit.

This bit enables the Wait feature for the NAND flash memory bank:

0: disabled

1: enabled

Bit 0 Reserved, must be kept at reset value.

FIFO status and interrupt register (FMC_SR)

Address offset: 0x84

Reset value: 0x0000 0040

This register contains information about the FIFO status and interrupt. The FMC features a FIFO that is used when writing to memories to transfer up to 16 words of data.

This is used to quickly write to the FIFO and free the AXI bus for transactions to peripherals other than the FMC, while the FMC is draining its FIFO into the memory. One of these register bits indicates the status of the FIFO, for ECC purposes.

The ECC is calculated while the data are written to the memory. To read the correct ECC, the software must consequently wait until the FIFO is empty.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **FEMPT:** FIFO empty.

Read-only bit that provides the status of the FIFO

0: FIFO not empty

1: FIFO empty

Bit 5 **IFEN:** Interrupt falling edge detection enable bit

0: Interrupt falling edge detection request disabled

1: Interrupt falling edge detection request enabled

Bit 4 **ILEN:** Interrupt high-level detection enable bit

0: Interrupt high-level detection request disabled

1: Interrupt high-level detection request enabled

Bit 3 **IREN:** Interrupt rising edge detection enable bit

0: Interrupt rising edge detection request disabled

1: Interrupt rising edge detection request enabled

Bit 2 **IFS:** Interrupt falling edge status
The flag is set by hardware and reset by software.
0: No interrupt falling edge occurred
1: Interrupt falling edge occurred
Note: If this bit is written by software to 1 it is set.

Bit 1 **ILS:** Interrupt high-level status
The flag is set by hardware and reset by software.
0: No Interrupt high-level occurred
1: Interrupt high-level occurred

Bit 0 **IRS:** Interrupt rising edge status
The flag is set by hardware and reset by software.
0: No interrupt rising edge occurred
1: Interrupt rising edge occurred
Note: If this bit is written by software to 1 it is set.

Common memory space timing register (FMC_PMEM)

Address offset: 0x88

Reset value: 0xFCFC FCFC

The FMC_PMEM read/write register contains the timing information for NAND flash memory bank. This information is used to access either the common memory space of the NAND flash for command, address write access and data read/write access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

MEMWAIT[7:0]								MEMSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **MEMHIZ[7:0]:** Common memory x data bus Hi-Z time
These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept Hi-Z after the start of a NAND flash write access to common memory space. This is only valid for write transactions:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **MEMHOLD[7:0]:** Common memory hold time
These bits define the number of fmc_ker_ck clock cycles for write accesses and fmc_ker_ck+1 clock cycles for read accesses during which the address is held (and data for write accesses) after the command is deasserted (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: reserved.
0000 0001: 1 fmc_ker_ck cycle for write access / 3 fmc_ker_ck cycle for read access
1111 1110: 254 fmc_ker_ck cycles for write access / 257 fmc_ker_ck cycles for read access
1111 1111: reserved.

Bits 15:8 **MEMWAIT[7:0]:** Common memory wait time

These bits define the minimum number of fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to common memory space. The duration of command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:
0000 0000: reserved
0000 0001: x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)
1111 1111: reserved.

Bits 7:0 **MEMSET[7:0]:** Common memory x setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up the address before the command assertion (NWE, NOE), for NAND flash read or write access to common memory space:
0000 0000: fmc_ker_ck cycles
1111 1110: 255 x fmc_ker_ck cycles
1111 1111: reserved

Attribute memory space timing registers (FMC_PATT)

Address offset: 0x8C

Reset value: 0xFCFC FCFC

The FMC_PATT read/write register contains the timing information for NAND flash memory bank. It is used for 8-bit accesses to the attribute memory space of the NAND flash for the last address write access if the timing must differ from that of previous accesses (for Ready/Busy management, refer to *Section 23.8.5: NAND flash prewait feature*).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ATTHIZ[7:0]								ATTHOLD[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ATTWAIT[7:0]								ATTSET[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **ATTHIZ[7:0]:** Attribute memory data bus Hi-Z time

These bits define the number of fmc_ker_ck clock cycles during which the data bus is kept in Hi-Z after the start of a NAND flash write access to attribute memory space on socket. Only valid for writ transaction:
0000 0000: 0 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 23:16 **ATTHOLD[7:0]:** Attribute memory hold time

These bits define the number of fmc_ker_ck clock cycles during which the address is held (and data for write access) after the command deassertion (NWE, NOE), for NAND flash read or write access to attribute memory space:
0000 0000: reserved
0000 0001: 1 x fmc_ker_ck cycle
1111 1110: 254 x fmc_ker_ck cycles
1111 1111: reserved.

Bits 15:8 **ATTWAIT[7:0]:** Attribute memory wait time

These bits define the minimum number of x fmc_ker_ck (+1) clock cycles to assert the command (NWE, NOE), for NAND flash read or write access to attribute memory space. The duration for command assertion is extended if the wait signal (NWAIT) is active (low) at the end of the programmed value of fmc_ker_ck:

0000 0000: reserved

0000 0001: 2 x fmc_ker_ck cycles (+ wait cycle introduced by deassertion of NWAIT)

1111 1110: 255 x fmc_ker_ck cycles (+ wait cycle introduced by deasserting NWAIT)

1111 1111: reserved.

Bits 7:0 **ATTSET[7:0]:** Attribute memory setup time

These bits define the number of fmc_ker_ck (+1) clock cycles to set up address before the command assertion (NWE, NOE), for NAND flash read or write access to attribute memory space:

0000 0000: 1 x fmc_ker_ck cycle

1111 1110: 255 x fmc_ker_ck cycles

1111 1111: reserved.

ECC result registers (FMC_ECCR)

Address offset: 0x94

Reset value: 0x0000 0000

This register contain the current error correction code value computed by the ECC computation modules of the FMC NAND controller. When the CPU reads/writes the data from a NAND flash memory page at the correct address (refer to *Section 23.8.6: Computation of the error correction code (ECC) in NAND flash memory*), the data read/written from/to the NAND flash memory are processed automatically by the ECC computation module. When X bytes have been read (according to the ECCPS field in the FMC_PCR registers), the CPU must read the computed ECC value from the FMC_ECC registers. It then verifies if these computed parity data are the same as the parity value recorded in the spare area, to determine whether a page is valid, and, to correct it otherwise. The FMC_ECCR register should be cleared after being read by setting the ECCEN bit to ‘0’. To compute a new data block, the ECCEN bit must be set to ’1’.

23.9 SDRAM controller

23.9.1 SDRAM controller main features

The main features of the SDRAM controller are the following:

- Two SDRAM banks with independent configuration
- 8-bit, 16-bit, 32-bit data bus width
- 13-bits Address Row, 11-bits Address Column, 4 internal banks: 4x16Mx32bit (256 MB), 4x16Mx16bit (128 MB), 4x16Mx8bit (64 MB)
- Word, half-word, byte access
- SDRAM clock can be fmc_ker_ck/2 or fmc_ker_ck/3
- Automatic row and bank boundary management
- Multibank ping-pong access
- Programmable timing parameters
- Automatic Refresh operation with programmable Refresh rate
- Self-refresh mode
- Power-down mode
- SDRAM power-up initialization by software
- CAS latency of 1,2,3
- Cacheable Read FIFO with depth of 6 lines x32-bit (6 x14-bit address tag)

23.9.2 SDRAM External memory interface signals

At startup, the SDRAM I/O pins used to interface the FMC SDRAM controller with the external SDRAM devices must configured by the user application. The SDRAM controller I/O pins which are not used by the application, can be used for other purposes.

Table 206. SDRAM signals

SDRAM signal	I/O type	Description	Alternate function
SDCLK	O	SDRAM clock	-
SDCKE[1:0]	O	SDCKE0: SDRAM Bank 1 Clock Enable SDCKE1: SDRAM Bank 2 Clock Enable	-
SDNE[1:0]	O	SDNE0: SDRAM Bank 1 Chip Enable SDNE1: SDRAM Bank 2 Chip Enable	-
A[12:0]	O	Address	FMC_A[12:0]
D[31:0]	I/O	Bidirectional data bus	FMC_D[31:0]

SDNWE	O	Write Enable	-
NBL[3:0]	O	Output Byte Mask for write accesses (memory signal name: DQM[3:0]	FMC_NBL[3:0]

23.9.3 SDRAM controller functional description

All SDRAM controller outputs (signals, address and data) change on the falling edge of the memory clock (FMC_SDCLK).

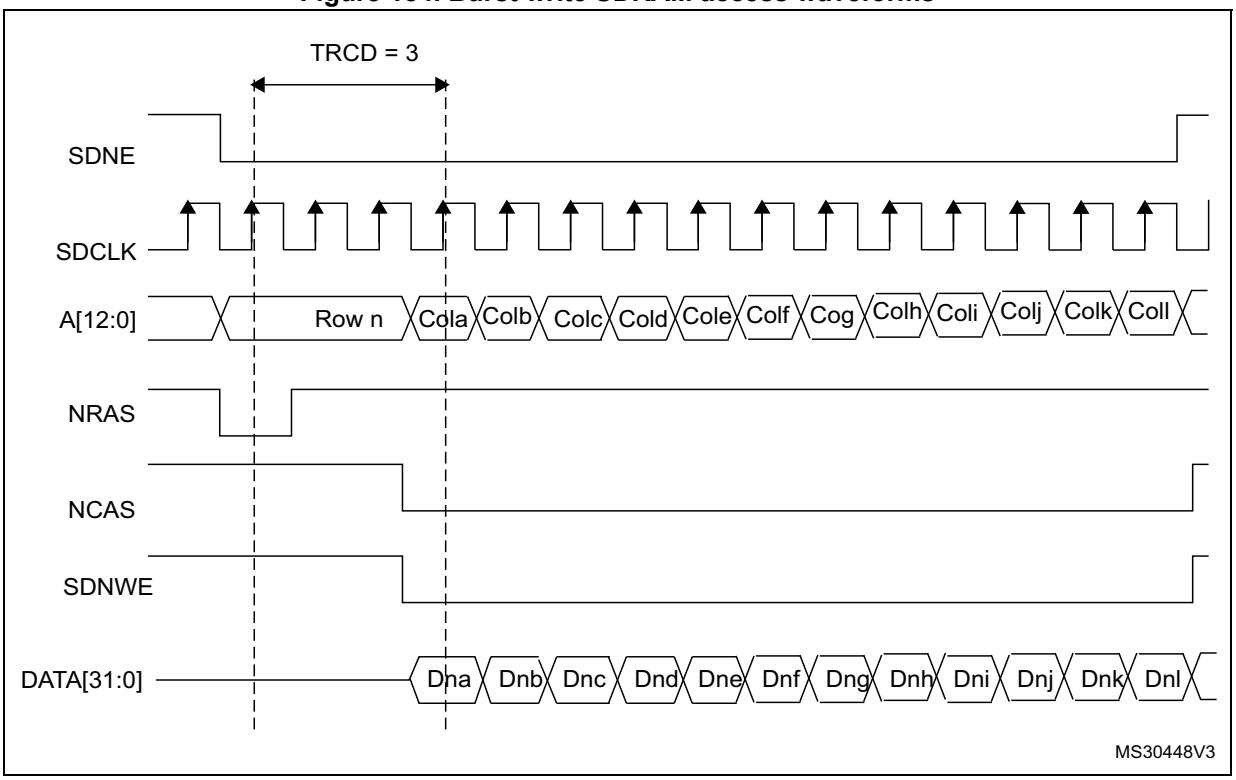
SDRAM initialization

The initialization sequence is managed by software. If the two banks are used, the initialization sequence must be generated simultaneously to Bank 1and Bank 2 by setting the Target Bank bits CTB1 and CTB2 in the FMC_SDCMR register:

1. Program the memory device features into the FMC_SDCRx register. The SDRAM clock frequency, RBURST and RPIPE must be programmed in the FMC_SDCR1 register.
2. Program the memory device timing into the FMC_SDTRx register. The TRP and TRC timings must be programmed in the FMC_SDTR1 register.
3. Set MODE bits to ‘001’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to start delivering the clock to the memory (SDCKE is driven high).
4. Wait during the prescribed delay period. Typical delay is around 100 µs (refer to the SDRAM datasheet for the required delay after power-up).
5. Set MODE bits to ‘010’ and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Precharge All” command.
6. Set MODE bits to ‘011’, and configure the Target Bank bits (CTB1 and/or CTB2) as well as the number of consecutive Auto-refresh commands (NRFS) in the FMC_SDCMR register. Refer to the SDRAM datasheet for the number of Auto-refresh commands that should be issued. Typical number is 8.
7. Configure the MRD field, set the MODE bits to ‘100’, and configure the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register to issue a “Load Mode Register” command and program the SDRAM device. In particular the Burst Length (BL) has to be set to ‘1’) and the CAS latency has to be selected. If the Mode Register is not the same for both SDRAM banks, this step has to be repeated twice, once for each bank and the Target Bank bits set accordingly. For mobile SDRAM devices, the MRD field is also used to configure the extended mode register while issuing the Load Mode Register”
8. Program the refresh rate in the FMC_SDRTR register

   The refresh rate corresponds to the delay between refresh cycles. Its value must be adapted to SDRAM devices.

At this stage the SDRAM device is ready to accept commands. If a system reset occurs during an ongoing SDRAM access, the data bus might still be driven by the SDRAM device. Therefor the SDRAM device must be first reinitialized after reset before issuing any new access by the NOR flash/PSRAM/SRAM or NAND flash controller.



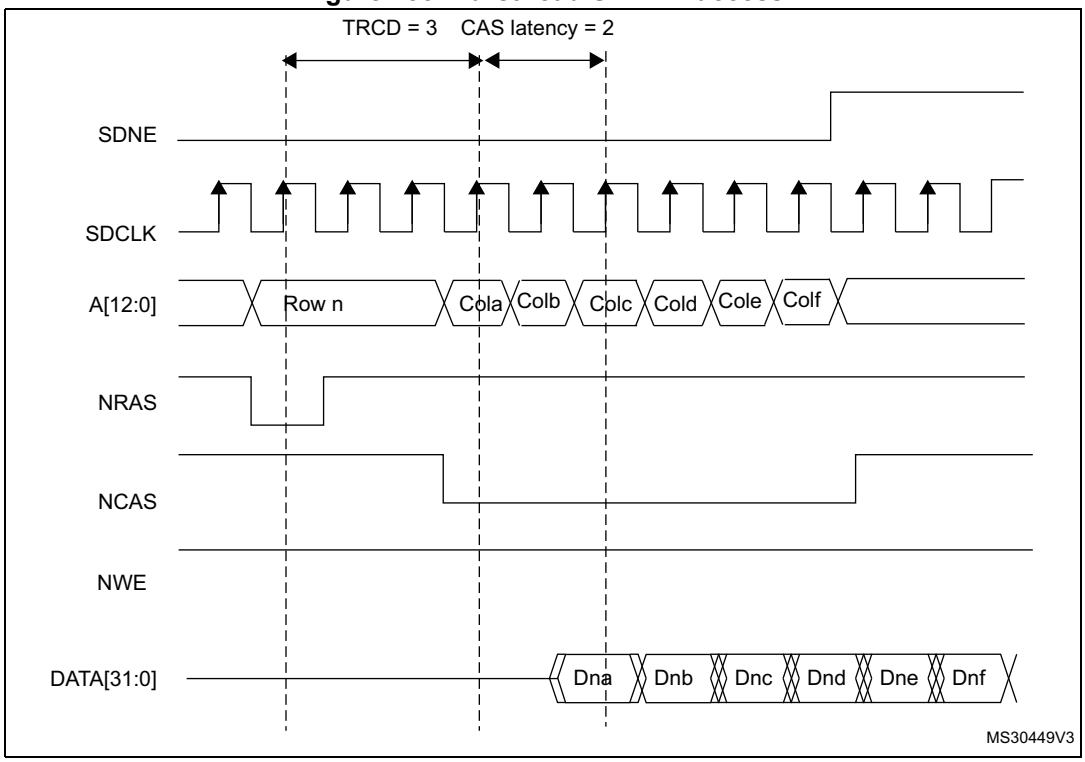
Note: If two SDRAM devices are connected to the FMC, all the accesses performed at the same time to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for SDRAM Bank 1 (TMRD andTRAS timings) in the FMC_SDTR1 register.

SDRAM controller write cycle

The SDRAM controller accepts single and burst write requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row for each bank to be able to perform consecutive write accesses to different banks (Multibank ping-pong access).

Before performing any write access, the SDRAM bank write protection must be disabled by clearing the WP bit in the FMC_SDCRx register.

Figure 184. Burst write SDRAM access waveforms



The SDRAM controller always checks the next access.

- If the next access is in the same row or in another active row, the write operation is carried out,
- if the next access targets another row (not active), the SDRAM controller generates a precharge command, activates the new row and initiates a write command.

SDRAM controller read cycle

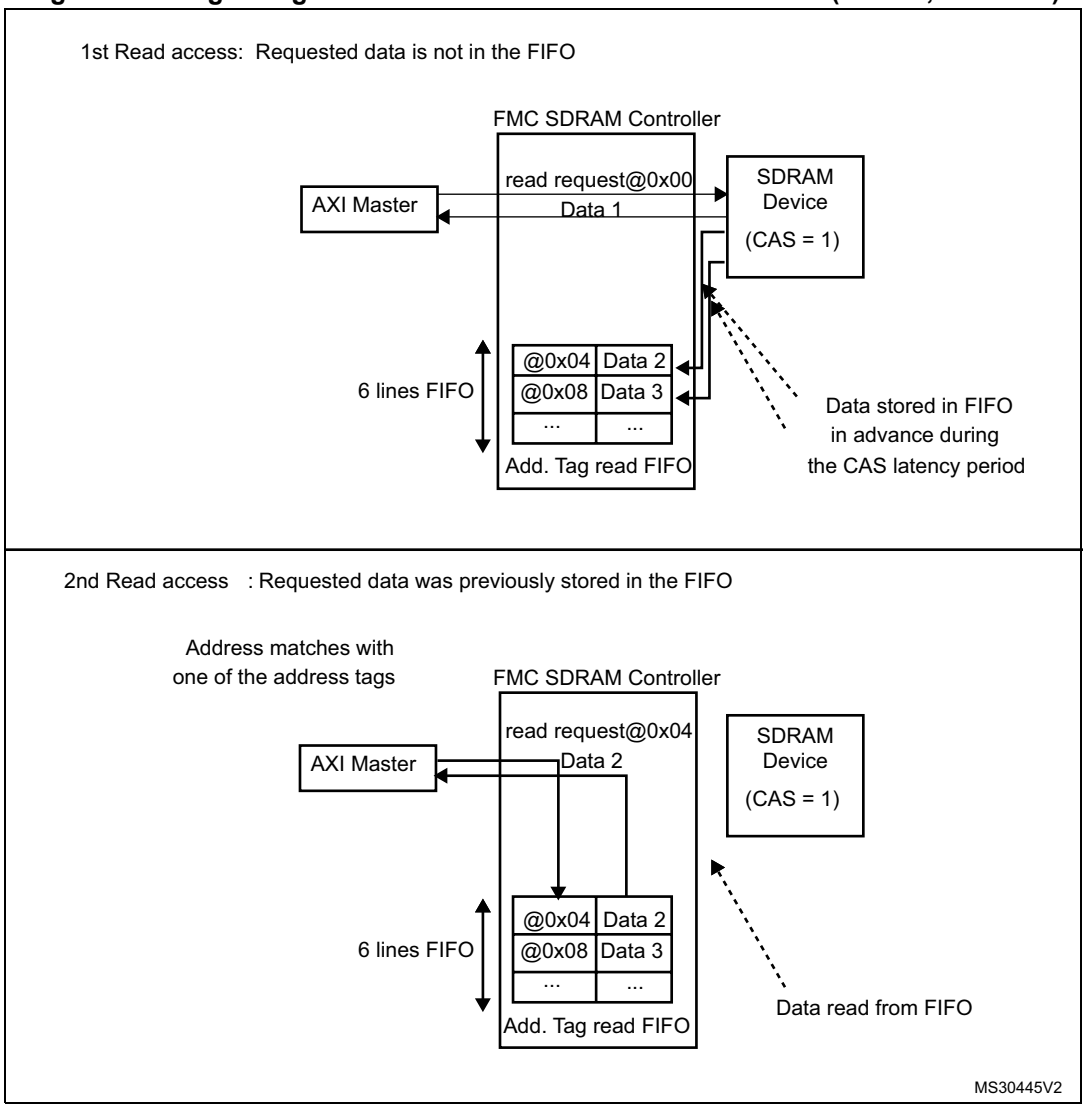
The SDRAM controller accepts single and burst read requests and translates them into single memory accesses. In both cases, the SDRAM controller keeps track of the active row in each bank to be able to perform consecutive read accesses in different banks (Multibank ping-pong access).

Figure 185. Burst read SDRAM access

The FMC SDRAM controller features a Cacheable read FIFO (6 lines x 32 bits). It is used to store data read in advance during the CAS latency period (up to 3 memory clock cycles, programmed FMC_SDCRx) and during the RPIPE delay when set to 2xfmc_ker_ck clock cycles as configured in FMC_SDCR1) following this formula: CAS Latency + 1 + (RPIPE DIV2). The RBURST bit must be set in the FMC_SDCR1 register to anticipate the next read access.

Examples:

- CAS=3, RPIPE= 2xfmc_ker_ck. In this case, 5 data (not committed) are stored in the FIFO (4 data during CAS latency and 1 data during RPIPE delay)
- CAS=3, RPIPE= 1xfmc_ker_ck. In this case, 4 data (not committed) are stored in the FIFO (4 data during CAS latency)



The read FIFO features a 14-bit address tag to each line to identify its content: 11 bits for the column address, 2 bits to select the internal bank and the active row, and 1 bit to select the SDRAM device

When the end of the row is reached in advance during an burst read transaction, the data read in advance (not committed) are not stored in the read FIFO. For single read access, data are correctly stored in the FIFO.

Each time a read request occurs, the SDRAM controller checks:

- If the address matches one of the address tags, data are directly read from the FIFO and the corresponding address tag/ line content is cleared and the remaining data in the FIFO are compacted to avoid empty lines.
- Otherwise, a new read command is issued to the memory and the FIFO is updated with new data. If the FIFO is full, the older data are lost.

Figure 186. Logic diagram of Read access with RBURST bit set (CAS=2, RPIPE=0)

During a write access or a Precharge command, the read FIFO is flushed and ready to be filled with new data.

After the first read request, if the current access was not performed to a row boundary, the SDRAM controller anticipates the next read access during the CAS latency period and the RPIPE delay (if configured). This is done by incrementing the memory address. The following condition must be met:

- RBURST control bit should be set to ‘1’ in the FMC_SDCR1 register.

The address management depends on the next AXI request:

- Next request is sequential (Burst access)

  In this case, the SDRAM controller increments the address.
- Next request is not sequential
  - If the new read request targets the same row or another active row, the new address is passed to the memory and the master is stalled for the CAS latency period, waiting for the new data from memory.
  - If the new read request does not target an active row, the SDRAM controller generates a Precharge command, activates the new row, and initiates a read command.

If the RBURST is reset, the read FIFO is not used.

Row and bank boundary management

When a read or write access crosses a row boundary, if the next read or write access is sequential and the current access was performed to a row boundary, the SDRAM controller executes the following operations:

1. Precharge of the active row,
2. Activation of the new row
3. Start of a read/write command.

At a row boundary, the automatic activation of the next row is supported for all columns and data bus width configurations.

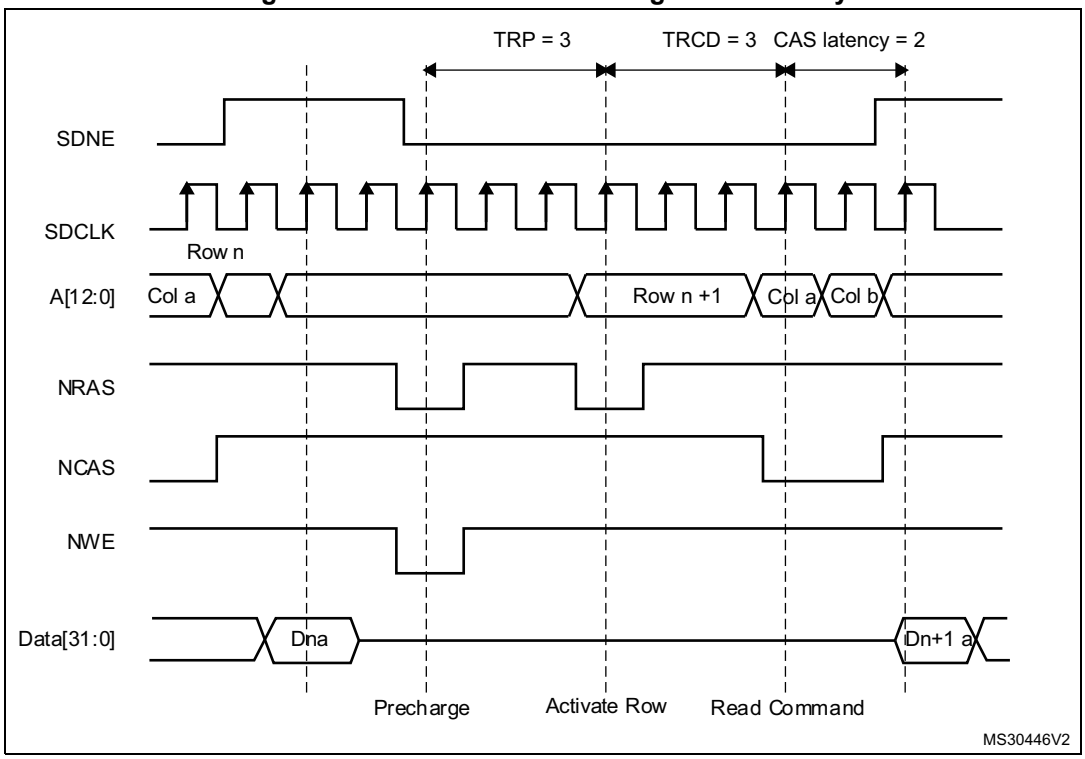
If necessary, the SDRAM controller inserts additional clock cycles between the following commands:

- Between Precharge and Active commands to match TRP parameter (only if the next access is in a different row in the same bank),
- Between Active and Read commands to match the TRCD parameter.

These parameters are defined into the FMC_SDTRx register.

Refer to *Figure 184* and *Figure 185* for read and burst write access crossing a row boundary.

Figure 187. Read access crossing row boundary



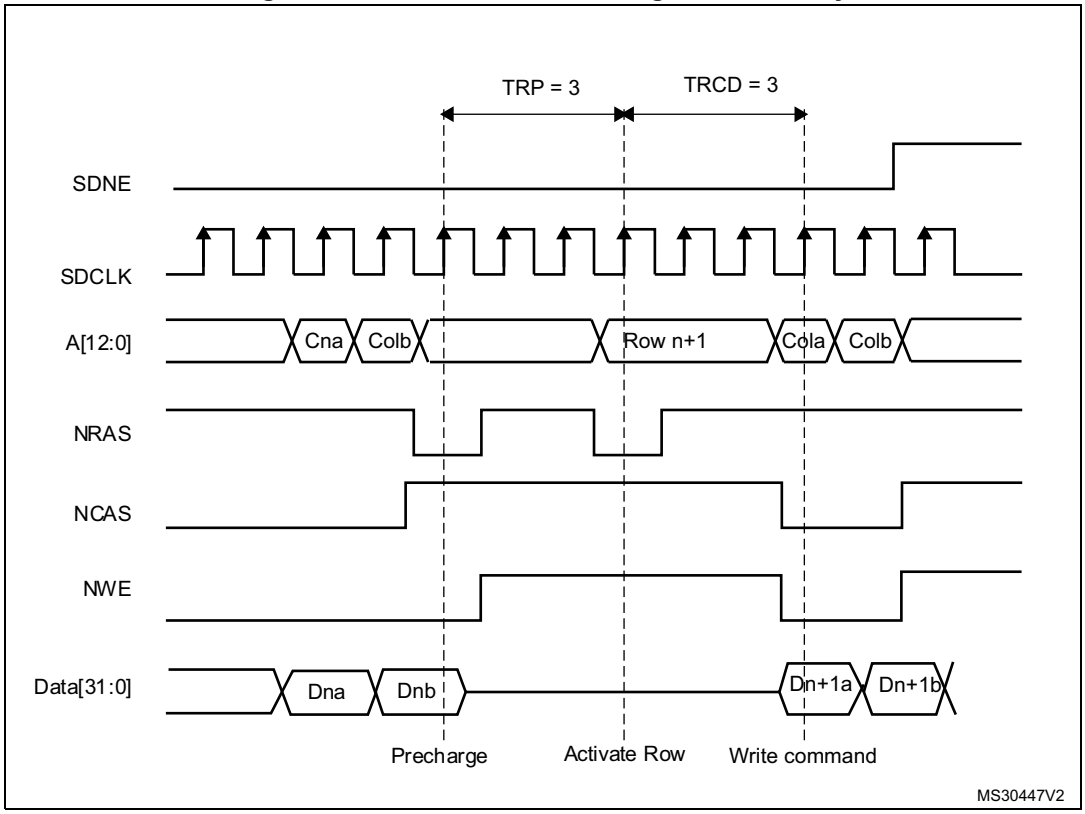


Figure 188. Write access crossing row boundary

If the next access is sequential and the current access crosses a bank boundary, the SDRAM controller activates the first row in the next bank and initiates a new read/write command. Two cases are possible:

- If the current bank is not the last one, the active row in the new bank must be precharged.At a bank boundary, the automatic activation of the next row is supported for all rows/columns and data bus width configuration.
- If the current bank is the last one, the automatic activation of the next row is supported only when addressing 13-bit rows, 11-bit columns, 4 internal banks and 32-bit data bus SDRAM devices. Otherwise, the SDRAM address range is violated and an AXI slave error is generated.
- In case of 13-bit row address, 11-bit column address, 4 internal banks and bus width 32-bit SDRAM memories, at boundary bank, the SDRAM controller continues to read/write from the second SDRAM device (assuming it has been initialized):
  a) The SDRAM controller activates the first row (after precharging the active row, if there is already an active row in the first internal bank, and initiates a new read/write command.
  b) If the first row is already activated, the SDRAM controller just initiates a read/write command.

SDRAM controller refresh cycle

The Auto-refresh command is used to refresh the SDRAM device content. The SDRAM controller periodically issues auto-refresh commands. An internal counter is loaded with the COUNT value in the register FMC_SDRTR. This value defines the number of memory clock cycles between the refresh cycles (refresh rate). When this counter reaches zero, an internal pulse is generated.

If a memory access is ongoing, the auto-refresh request is delayed. However, if the memory access and the auto-refresh requests are generated simultaneously, the auto-refresh request takes precedence.

If the memory access occurs during an auto-refresh operation, the request is buffered and processed when the auto-refresh is complete.

If a new auto-refresh request occurs while the previous one was not served, the RE (Refresh Error) bit is set in the Status register. An Interrupt is generated if it has been enabled (REIE = ‘1’).

If SDRAM lines are not in idle state (not all row are closed), the SDRAM controller generates a PALL (Precharge ALL) command before the auto-refresh.

If the Auto-refresh command is generated by the FMC_SDCMR Command Mode register (Mode bits = ‘011’), a PALL command (Mode bits =’ 010’) must be issued first.

23.9.4 Low-power modes

Two low-power modes are available:

- Self-refresh mode

  The auto-refresh cycles are performed by the SDRAM device itself to retain data without external clocking.
- Power-down mode

  The auto-refresh cycles are performed by the SDRAM controller.

Self-refresh mode

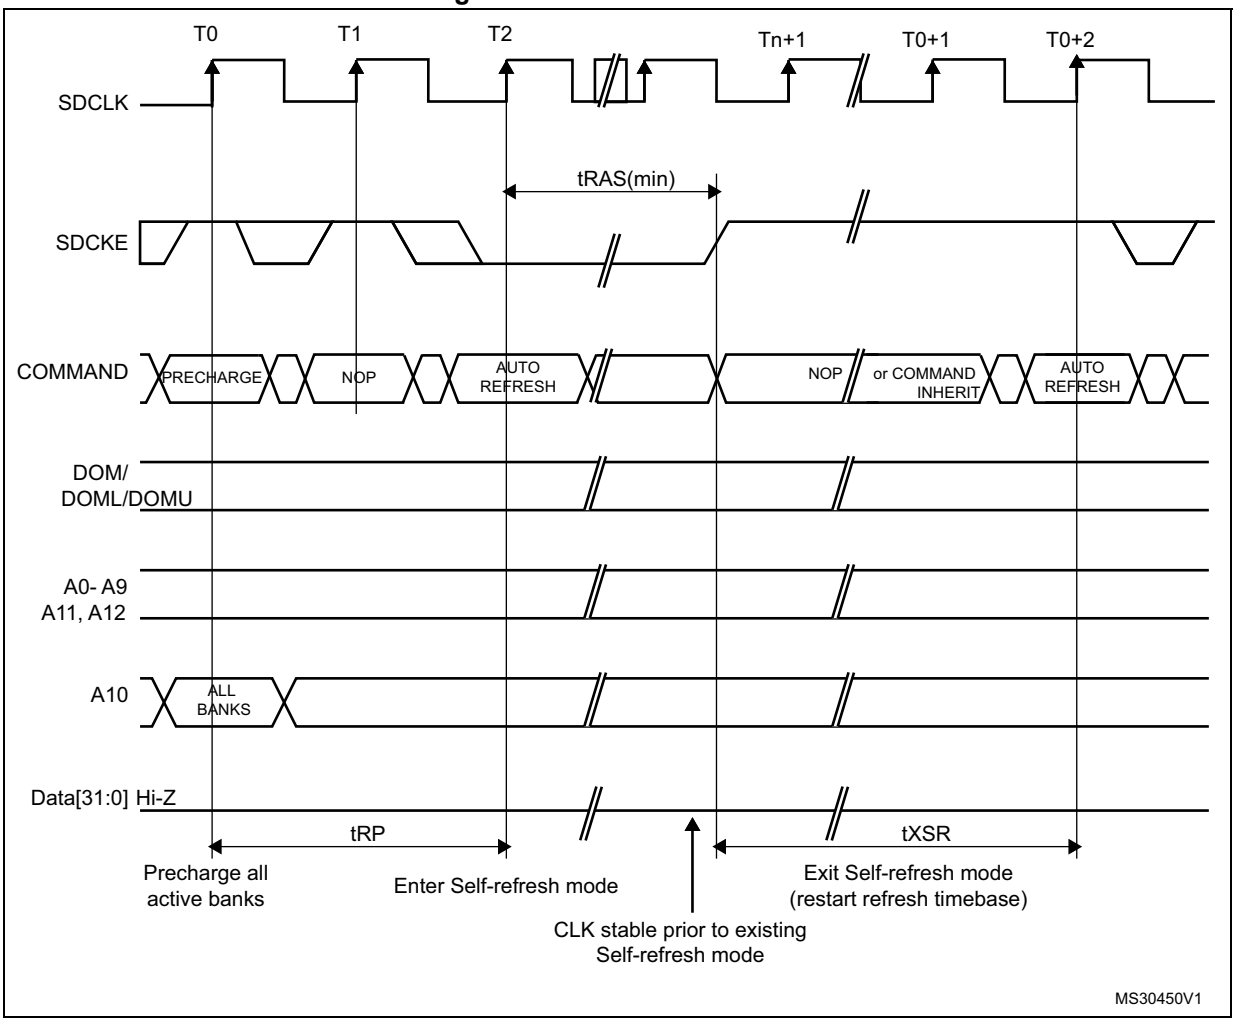
This mode is selected by setting the MODE bits to ‘101’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

The SDRAM clock stops running after a TRAS delay and the internal refresh timer stops counting only if one of the following conditions is met:

- A Self-refresh command is issued to both devices
- One of the devices is not activated (SDRAM bank is not initialized).

Before entering Self-Refresh mode, the SDRAM controller automatically issues a PALL command.

If the Write data FIFO is not empty, all data are sent to the memory before activating the Self-refresh mode and the BUSY status flag remains set.



In Self-refresh mode, all SDRAM device inputs become don’t care except for SDCKE which remains low.

The SDRAM device must remain in Self-refresh mode for a minimum period of time of TRAS and can remain in Self-refresh mode for an indefinite period beyond that. To guarantee this minimum period, the BUSY status flag remains high after the Self-refresh activation during a TRAS delay.

As soon as an SDRAM device is selected, the SDRAM controller generates a sequence of commands to exit from Self-refresh mode. After the memory access, the selected device remains in Normal mode.

To exit from Self-refresh, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

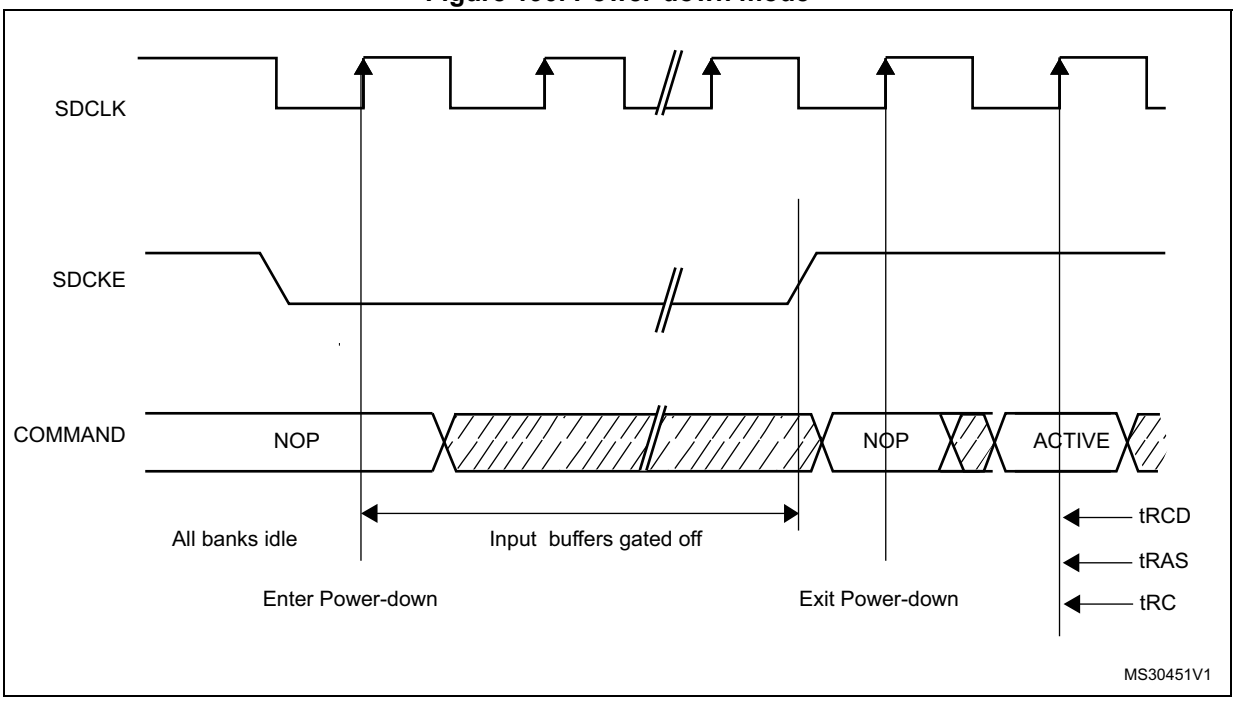


Figure 189. Self-refresh mode

Power-down mode

This mode is selected by setting the MODE bits to ‘110’ and by configuring the Target Bank bits (CTB1 and/or CTB2) in the FMC_SDCMR register.

Figure 190. Power-down mode

If the Write data FIFO is not empty, all data are sent to the memory before activating the Power-down mode.

As soon as an SDRAM device is selected, the SDRAM controller exits from the Power-down mode. After the memory access, the selected SDRAM device remains in Normal mode.

During Power-down mode, all SDRAM device input and output buffers are deactivated except for the SDCKE which remains low.

The SDRAM device cannot remain in Power-down mode longer than the refresh period and cannot perform the Auto-refresh cycles by itself. Therefore, the SDRAM controller carries out the refresh operation by executing the operations below:

1. Exit from Power-down mode and drive the SDCKE high
2. Generate the PALL command only if a row was active during Power-down mode
3. Generate the auto-refresh command
4. Drive SDCKE low again to return to Power-down mode.

To exit from Power-down mode, the MODE bits must be set to ‘000’ (Normal mode) and the Target Bank bits (CTB1 and/or CTB2) must be configured in the FMC_SDCMR register.

23.9.5 SDRAM controller registers

SDRAM Control registers for SDRAM memory bank x (FMC_SDCRx)

Address offset: 0x140+ 0x4* (x - 1), (x = 1 to 2)

Reset value: 0x0000 02D0

This register contains the control parameters for each SDRAM memory bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RPIPE[1:0]		RBURST	SDCLK[1:0]		WP	CAS[1:0]		NB	MWID[1:0]		NR[1:0]		NC[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:15 Reserved, must be kept at reset value.

Bits 14:13 **RPIPE[1:0]:** Read pipe

These bits define the delay, in fmc_ker_ck clock cycles, for reading data after CAS latency.
00: No fmc_ker_ck clock cycle delay
01: One fmc_ker_ck clock cycle delay
10: Two fmc_ker_ck clock cycle delay
11: reserved.

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 12 **RBURST:** Burst read

This bit enables Burst read mode. The SDRAM controller anticipates the next read commands during the CAS latency and stores data in the Read FIFO.
0: single read requests are not managed as bursts
1: single read requests are always managed as bursts

Note: The corresponding bit in the FMC_SDCR2 register is read only.

Bits 11:10 **SDCLK[1:0]:** SDRAM clock configuration

These bits define the SDRAM clock period for both SDRAM banks and allow disabling the clock before changing the frequency. In this case the SDRAM must be re-initialized.
00: SDCLK clock disabled
01: Reserved
10: SDCLK period = 2 x fmc_ker_ck periods
11: SDCLK period = 3 x fmc_ker_ck periods

Note: The corresponding bits in the FMC_SDCR2 register is read only.

Bit 9 **WP:** Write protection

This bit enables Write mode access to the SDRAM bank.
0: Write accesses allowed
1: Write accesses ignored

Bits 8:7 **CAS[1:0]:** CAS Latency
This bits sets the SDRAM CAS latency in number of memory clock cycles
00: reserved.
01: 1 cycle
10: 2 cycles
11: 3 cycles

Bit 6 **NB:** Number of internal banks
This bit sets the number of internal banks.
0: Two internal Banks
1: Four internal Banks

Bits 5:4 **MWID[1:0]:** Memory data bus width.
These bits define the memory device width.
00: 8 bits
01: 16 bits
10: 32 bits
11: reserved.

Bits 3:2 **NR[1:0]:** Number of row address bits
These bits define the number of bits of a row address.
00: 11 bit
01: 12 bits
10: 13 bits
11: reserved.

Bits 1:0 **NC[1:0]:** Number of column address bits
These bits define the number of bits of a column address.
00: 8 bits
01: 9 bits
10: 10 bits
11: 11 bits.

Note: Before modifying the RBURST or RPIPE settings or disabling the SDCLK clock, the user must first send a PALL command to make sure ongoing operations are complete.

SDRAM Timing registers for SDRAM memory bank x (FMC_SDTRx)

Address offset: 0x148 + 0x4 * (x - 1), (x = 1 to 2)

Reset value: 0x0FFF FFFF

This register contains the timing parameters of each SDRAM bank

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	TRCD[3:0]				TRP[3:0]				TWR[3:0]			
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRC[3:0]				TRAS[3:0]				TXSR[3:0]				TMRD[3:0]			
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TRCD[3:0]:** Row to column delay

These bits define the delay between the Activate command and a Read/Write command in number of memory clock cycles.
0000: 1 cycle.
0001: 2 cycles
....
1111: 16 cycles

Bits 23:20 **TRP[3:0]:** Row precharge delay

These bits define the delay between a Precharge command and another command in number of memory clock cycles. The TRP timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP must be programmed with the timing of the slowest device.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 19:16 **TWR[3:0]:** Recovery delay

These bits define the delay between a Write and a Precharge command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: TWR must be programmed to match the write recovery time (t_{WR}) defined in the SDRAM datasheet, and to guarantee that:

TWR ≥ TRAS - TRCD and TWR ≥ TRC - TRCD - TRP

Example: TRAS= 4 cycles, TRCD= 2 cycles. So, TWR ≥ 2 cycles. TWR must be programmed to 0x1.

If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TWR timing corresponding to the slowest SDRAM device.
If only one SDRAM device is used, the TWR timing must be kept at reset value (0xF) for the not used bank.

Bits 15:12 **TRC[3:0]:** Row cycle delay

These bits define the delay between the Refresh command and the Activate command, as well as the delay between two consecutive Refresh commands. It is expressed in number of memory clock cycles. The TRC timing is only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRC must be programmed with the timings of the slowest device.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: TRC must match the TRC and TRFC (Auto Refresh period) timings defined in the SDRAM device datasheet.

Note: The corresponding bits in the FMC_SDTR2 register are don't care.

Bits 11:8 **TRAS[3:0]:** Self refresh time

These bits define the minimum Self-refresh period in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Bits 7:4 **TXSR[3:0]:** Exit Self-refresh delay

These bits define the delay from releasing the Self-refresh command to issuing the Activate command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: If two SDRAM devices are used, the FMC_SDTR1 and FMC_SDTR2 must be programmed with the same TXSR timing corresponding to the slowest SDRAM device.

Bits 3:0 **TMRD[3:0]:** Load Mode Register to Active

These bits define the delay between a Load Mode Register command and an Active or Refresh command in number of memory clock cycles.
0000: 1 cycle
0001: 2 cycles
....
1111: 16 cycles

Note: If two SDRAM devices are connected, all the accesses performed simultaneously to both devices by the Command Mode register (Load Mode Register command) are issued using the timing parameters configured for Bank 1 (TMRD and TRAS timings) in the FMC_SDTR1 register.

The TRP and TRC timings are only configured in the FMC_SDTR1 register. If two SDRAM devices are used, the TRP and TRC timings must be programmed with the timings of the slowest device.

SDRAM Command mode register (FMC_SDCMR)

Address offset: 0x150

Reset value: 0x0000 0000

This register contains the command issued when the SDRAM device is accessed. This register is used to initialize the SDRAM device, and to activate the Self-refresh and the Power-down modes. As soon as the MODE field is written, the command is issued only to one or to both SDRAM banks according to CTB1 and CTB2 command bits. This register is the same for both SDRAM banks.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MRD[13:7]						
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MRD[6:0]							NRFS[3:0]				CTB1	CTB2	MODE[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w	w	w	w	w

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:9 **MRD[13:0]:** Mode Register definition

This 14-bit field defines the SDRAM Mode Register content. The Mode Register is programmed using the Load Mode Register command. The MRD[13:0] bits are also used to program the extended mode register for mobile SDRAM.

Bits 8:5 **NRFS[3:0]:** Number of Auto-refresh

These bits define the number of consecutive Auto-refresh commands issued when MODE = '011'.
0000: 1 Auto-refresh cycle
0001: 2 Auto-refresh cycles
....
1110: 15 Auto-refresh cycles
1111: 16 Auto-refresh cycles

Bit 4 **CTB1:** Command Target Bank 1

This bit indicates whether the command is issued to SDRAM Bank 1 or not.
0: Command not issued to SDRAM Bank 1
1: Command issued to SDRAM Bank 1

Bit 3 **CTB2:** Command Target Bank 2

This bit indicates whether the command is issued to SDRAM Bank 2 or not.
0: Command not issued to SDRAM Bank 2
1: Command issued to SDRAM Bank 2

Bits 2:0 **MODE[2:0]:** Command mode

These bits define the command issued to the SDRAM device.
000: Normal Mode
001: Clock Configuration Enable
010: PALL ("All Bank Precharge") command
011: Auto-refresh command
100: Load Mode Register
101: Self-refresh command
110: Power-down command
111: Reserved

Note: When a command is issued, at least one Command Target Bank bit (CTB1 or CTB2) must be set otherwise the command is ignored.

Note: If two SDRAM banks are used, the Auto-refresh and PALL command must be issued simultaneously to the two devices with CTB1 and CTB2 bits set otherwise the command is ignored.

Note: If only one SDRAM bank is used and a command is issued with it's associated CTB bit set, the other CTB bit of the unused bank must be kept to 0.

SDRAM refresh timer register (FMC_SDRTR)

Address offset: 0x154

Reset value: 0x0000 0000

This register sets the refresh rate in number of SDCLK clock cycles between the refresh cycles by configuring the Refresh Timer Count value.

$$\text{Refresh rate} = (\text{COUNT} + 1) \times \text{SDRAM clock frequency}$$

$$\text{COUNT} = (\text{SDRAM refresh period} / \text{Number of rows}) - 20$$

Below an example of refresh rate calculation:

$$\text{Refresh rate} = 64\ \text{ms} / (8196\text{rows}) = 7.81\mu\text{s}$$

where 64 ms is the SDRAM refresh period.

$$7.81\mu\text{s} \times 60\text{MHz} = 468.6$$

The refresh rate must be increased by 20 SDRAM clock cycles (as in the above example) to obtain a safe margin if an internal refresh request occurs when a read request has been accepted. It corresponds to a COUNT value of '0000111000000' (448).

This 13-bit field is loaded into a timer which is decremented using the SDRAM clock. This timer generates a refresh pulse when zero is reached. The COUNT value must be set at least to 41 SDRAM clock cycles.

As soon as the FMC_SDRTR register is programmed, the timer starts counting. If the value programmed in the register is '0', no refresh is carried out. This register must not be reprogrammed after the initialization procedure to avoid modifying the refresh rate.

Each time a refresh pulse is generated, this 13-bit COUNT field is reloaded into the counter.

If a memory access is in progress, the Auto-refresh request is delayed. However, if the memory access and Auto-refresh requests are generated simultaneously, the Auto-refresh takes precedence. If the memory access occurs during a refresh operation, the request is buffered to be processed when the refresh is complete.

This register is common to SDRAM bank 1 and bank 2.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	REIE	COUNT[12:0]													CRE
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	w

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **REIE:** RES Interrupt Enable
0: Interrupt is disabled
1: An Interrupt is generated if RE = 1

Bits 13:1 **COUNT[12:0]:** Refresh Timer Count
This 13-bit field defines the refresh rate of the SDRAM device. It is expressed in number of memory clock cycles. It must be set at least to 58 SDRAM clock cycles (0x34).
Refresh rate = (COUNT + 1) x SDRAM frequency clock
COUNT = (SDRAM refresh period / Number of rows) - 20

Bit 0 **CRE:** Clear Refresh error flag
This bit is used to clear the Refresh Error Flag (RE) in the Status Register.
0: no effect
1: Refresh Error flag is cleared

Note: The programmed COUNT value must not be equal to the sum of the following timings: TWR+TRP+TRC+TRCD+4 memory clock cycles .

SDRAM Status register (FMC_SDSR)

Address offset: 0x158

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

											r	r	r	r	r

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:3 **MODES2[1:0]:** Status Mode for Bank 2
These bits define the Status Mode of SDRAM Bank 2.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bits 2:1 **MODES1[1:0]:** Status Mode for Bank 1
These bits define the Status Mode of SDRAM Bank 1.
00: Normal Mode
01: Self-refresh mode
10: Power-down mode

Bit 0 **RE:** Refresh error flag
0: No refresh error has been detected
1: A refresh error has been detected
An interrupt is generated if REIE = 1 and RE = 1

23.9.6 FMC register map

The following table summarizes the FMC registers.

Table 207. FMC register map

Offset	Register name reset value	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 150* for the register boundary addresses.

24 Extended-SPI interface (XSPI)

24.1 Introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocols with associated frame formats:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

24.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- Support for single, dual, quad, and octal communication
- Dual-memory configuration, where 8 bits can be sent/received simultaneously by accessing two quad or two octal memories in parallel
- XSPI mode accessing a single 16-bit memory
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- AXI interface with transaction acceptance limited to one: the interface accepts the next transfer on AXI bus only once the previous is completed on memory side.
- Dual chip select support (NCS1 and NCS2)

24.3 XSPI implementation

Table 208. XSPI implementation

Feature	XSPI1/2

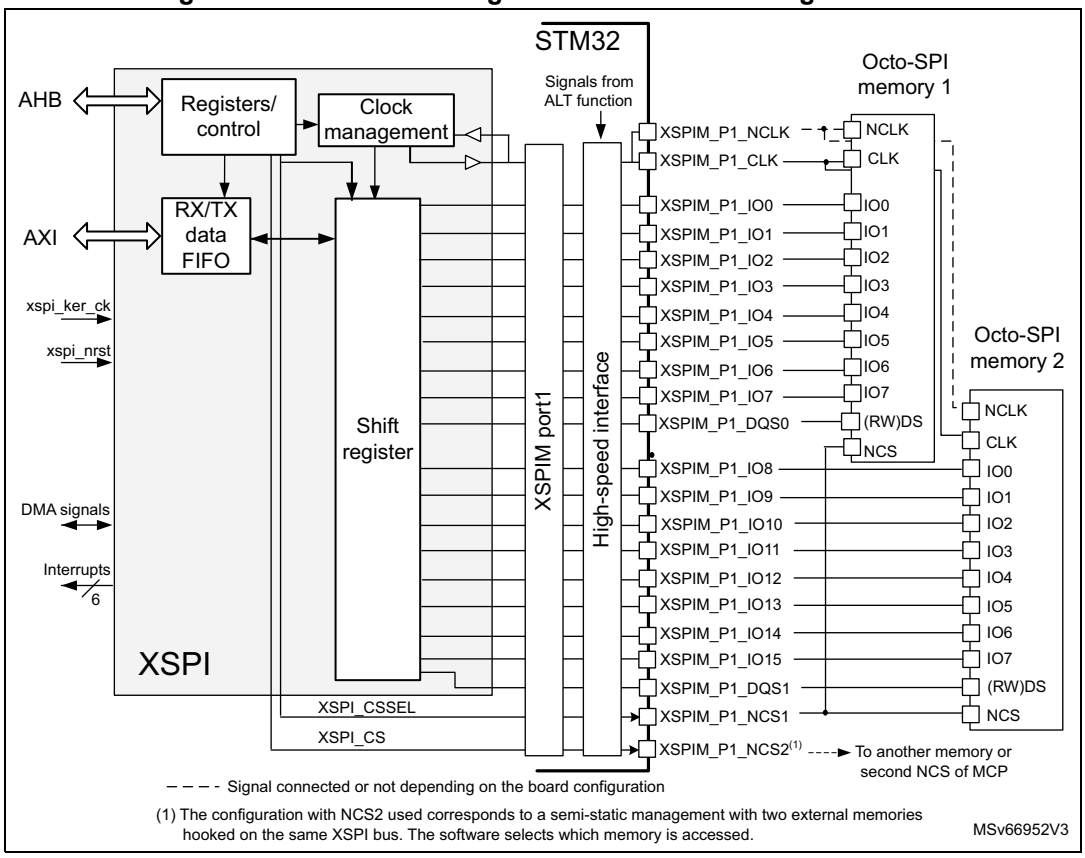
24.4 XSPI functional description

24.4.1 XSPI block diagram

The block diagrams provided below correspond to a single XSPI connected to the I/O ports.



In case several XSPIs are connected to the I/O ports through the XSPIM I/O manager, refer to *Section 25: XSPI I/O manager (XSPIM)* for more details.

Figure 191. XSPI block diagram for 16-bit configuration(1)

1. The configuration depends on the package (see the datasheet for more details).

Figure 192. XSPI block diagram for dual-octal configuration(1)

1. The configuration depends on the package (see the datasheet for more details).

Figure 193. XSPI block diagram for octal configuration

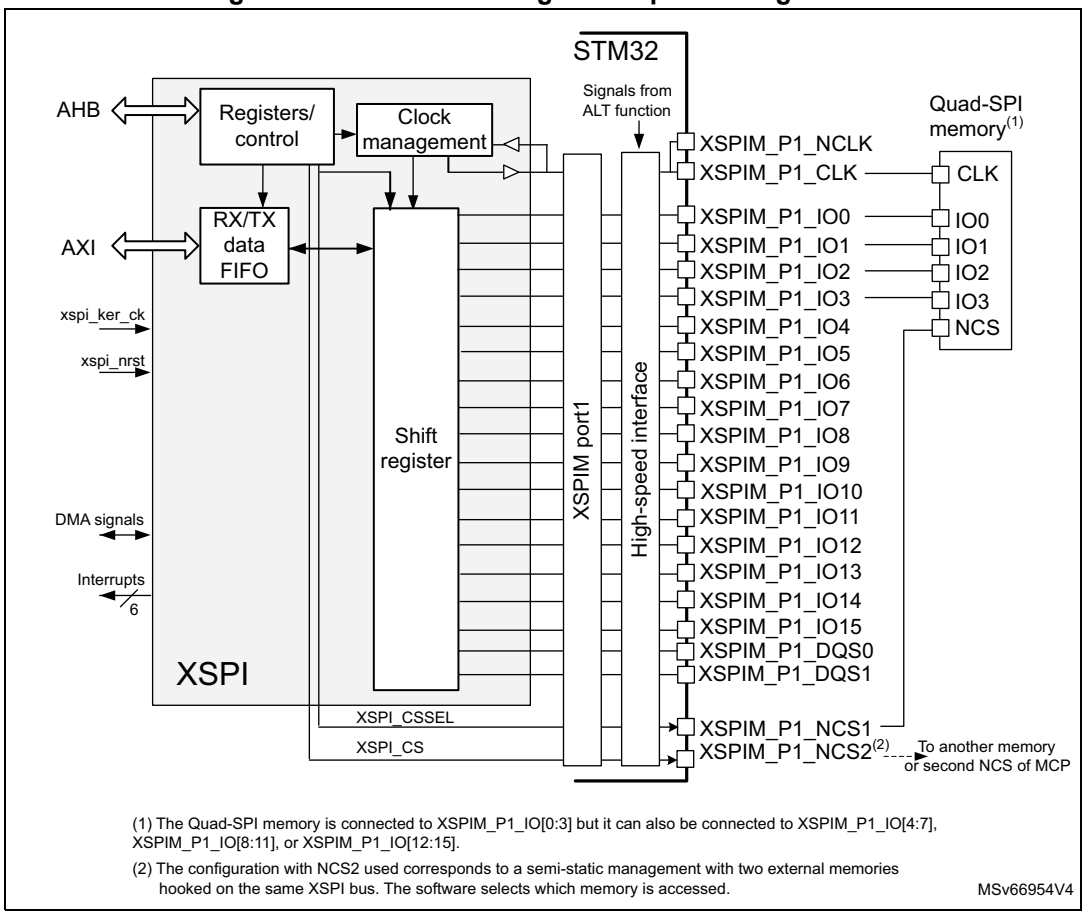

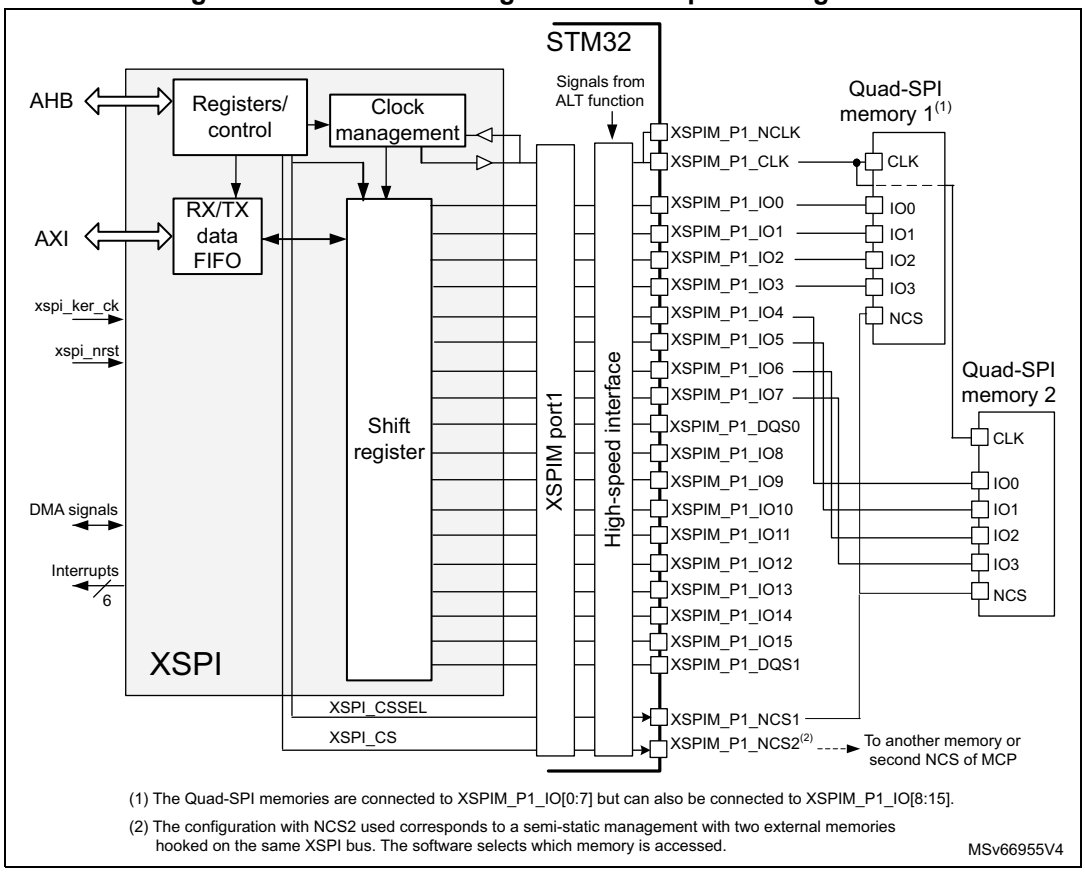

Figure 195. XSPI block diagram for dual-quad configuration

24.4.2 XSPI pins and internal signals

Table 209. XSPI input/output pins(1)

Pin name	Type	Description
XSPIM_Px_NCLK	Output	XSPI inverted clock to support 1.8 V HyperBus protocol.
XSPIM_Px_CLK	Output	XSPI clock
XSPIM_Px_IOn (n = 0 to 15)	Input/output	XSPI data pins
XSPIM_Px_NCS1,2	Output	Chip select for the memory
XSPIM_Px_DQS0,1	Input/output	Data strobe/write mask signal from/to the memory

1. x = 1 to 2.

Caution: Use the same configuration (output speed, HSLV) for all XSPI input/output pins to avoid any data corruption.

Table 210. XSPI internal signals

Signal name	Type	Description
xspi_hclk	Input	XSPI AHB clock
xspi_aclk	Input	XSPI AXI clock

Table 210. XSPI internal signals

Signal name	Type	Description
xspi_ker_ck	Input	XSPI kernel clock
xspi_dma	N/A	DMA request signal
xspi_it	Output	Global interrupt line (see *Table 214* for the multiple sources of interrupt)

24.4.3 Clock constraints

The XSPI AXI clock (xspi_aclk) has to be greater or equal than the XSPI kernel clock (xspi_ker_ck).

24.4.4 XSPI interface to memory modes

The XSPI supports the following protocols:

- regular-command protocol
- HyperBus protocol

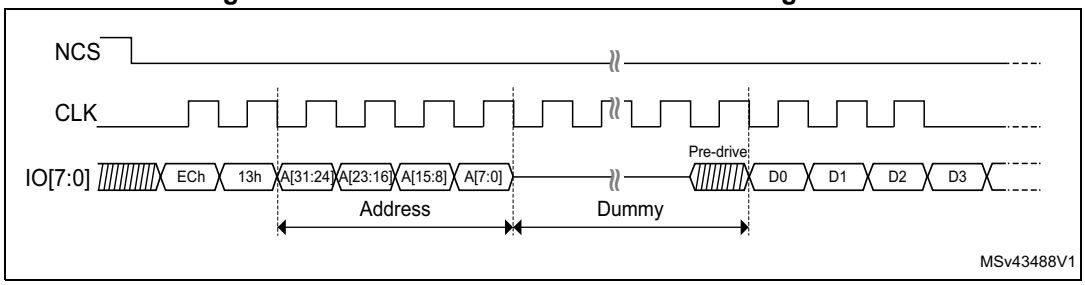
The XSPI uses from 6 to 21 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time).
- CLK: communication clock
- NCLK: inverted clock used only in the 1.8 V HyperBus protocol
- DQS0, DQS1: data strobe used only in regular-command protocol
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus used as possible remap for quad-SPI mode
- IO[15:8]:
  - data bus MSB used in dual-quad, dual-octal and 16-bit configurations
  - data bus used as possible remap for octal-SPI mode
  - IO[15:12] and IO[11:8] can also be used as possible remap for quad-SPI mode

24.4.5 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:

- instruction phase
- address phase
- alternate-byte phase
- dummy-cycle phase
- data phase



Only the data phase uses 16 bits. Instruction, address, and alternate phases use only the eight LSB of the bus as for octal configuration.

Any of these phases can be configured to be skipped, but single-phase commands supported are only those with instruction phase.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operation are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 196. SDR read command in 16-bit configuration

1. Data (such as D0, D1, D2) are sent in 16-bit configuration mode over IO[15:0]. Only the command and address are sent over IO[7:0] as for octal mode.

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured in ISIZE[1:0] of XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR (double-transfer rate) mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

When in memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured in ADSIZE[1:0] of XSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified in ADDRESS[31:0] of XSPI_AR. In memory-mapped mode, the address is given directly via the AXI (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ADMODE[2:0] of XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

Warning: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value.So the software needs to multiply the address by two when accessing the memory registers.

Alternate-byte phase

In the alternate-bytes phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured in ABSIZE[1:0] of XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode, or in 16-bit SPI mode)

This can be configured using ABMODE[2:0] of XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR of XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-bytes phase is skipped and the command sequence proceeds directly to the next phase, if any.

Only a single nibble may need to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011), and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0], while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified in DCYC[4:0] of XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, quad-, octal-, or 16-bit SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR. In indirect-read mode, the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AXI to the Cortex core or to a DMA.

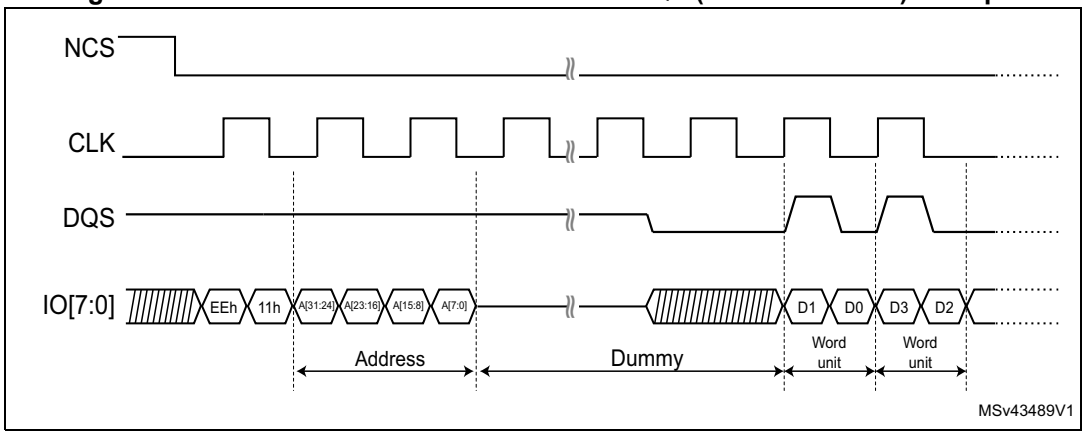
The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)
- 16 bits at a time (over IO0 to IO15 in 16-bit SPI mode)

This can be configured using DMODE[2:0] of XSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR of XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.



In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE of XSPI_CCR.

Figure 197. DTR read in octal-SPI mode with DQS (Macronix mode) example

24.4.6 XSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-bit mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0 (to deactivate the “write protect” function).
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO15 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 010, IO0/IO1 are always high-impedance.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO15 are in output mode and forced to 0.

In the dummy phase when DMODE[2:0] = 011, IO0 to IO3 are all high-impedance.

Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 100, IO[0:7] are all high-impedance.

XSPI mode

In XSPI mode, the 16 bits are sent/received simultaneously over the IO[0:15] signals during the data phase.

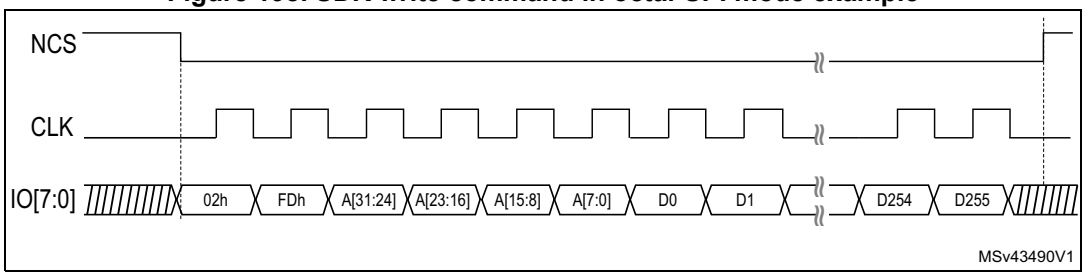
The following phases must be configured separately to use the XSPI mode:

1. Set to 100 the IMODE, ADMODE, and ABMODE fields (in XSPI_CCR and XSPI_WCCR).
2. Set to 101 the DMODE fields (in XSPI_CCR and XSPI_WCCR).

In each phase that is configured in XSPI mode, IO[0:15] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase when DMODE[2:0] = 101, IO[0:15] are all high-impedance.

IO[8:15] are used only in XSPI mode. If none of the phases are configured to use this mode, then the pins corresponding to IO[8:15] can be used for other functions, even while the XSPI is active.



Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

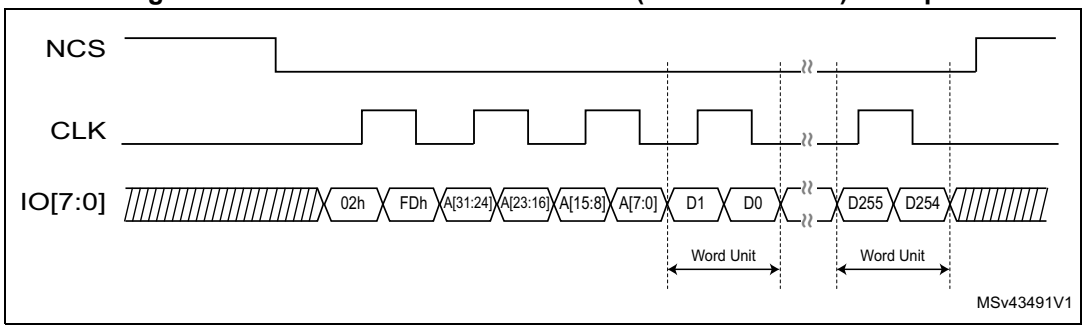
In SDR mode, when the XSPI drives the IO0/SO and IO1 to IO15 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

Figure 198. SDR write command in octal-SPI mode example

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.



In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.

In DTR mode, when the XSPI drives the IO0 to IO15 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

Figure 199. DTR write in octal-SPI mode (Macronix mode) example

Dual-quad configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either SDR or DTR mode.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The forth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Dual-octal configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: when DMODE = 100, two external octal-SPI devices (device A and device B) are used in order to receive 32 bits in DTR mode every cycle, effectively doubling the throughput as well as the capacity.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO7 signals.

The dual-octal configuration can be used in DTR mode exclusively in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-octal DTR mode, twice as many bytes must be read compared to the same read in regular DTR mode: if each device gives twice eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 4 bytes. The LSB is the LSB of device A, and the third byte is the LSB of device B.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-octal DTR mode. In such case, the order of retrieved status bits is as follows:

- first byte: LSB of device A
- second byte: second byte of device A
- third byte: LSB of device B
- fourth byte: second byte of device B

In indirect mode using DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and bit 1 of the DL[31:0] bitfield in XSPI_DLR are stuck at 0 when DMODE[2:0] = 101.

In dual-octal configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycles phases. In other words, each device always receives the same instruction and the same address.

Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

Note: The variable latency is not supported in dual-octal configuration.

XSPI mode

When DMODE[2:0] = 0b101 in XSPI_CCR, the XSPI is in single 16-bit-memory configuration: when DMODE[2:0] = 0b101 with DMM value ignored in that case. A single external XSPI device is used in order to send/receive 16 bits (or 32 bits in DTR mode) every cycle, effectively doubling the throughput.

The device provides/receives two separate DQS signals: DQS0 for the eight LSBs and DQS1 for the eight MSBs.

The XSPI mode can be used in conjunction with the single-SPI, dual-SPI, quad-SPI and octal-SPI modes, as well as with either the SDR or the DTR mode.

The device size, as specified in DEVSIZE[4:0] of XSPI_DCR1, must reflect the total external device capacity.

In SDR mode, a number of bytes multiple of two must always be accessed in XSPI mode. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 0 when DMODE = 101.

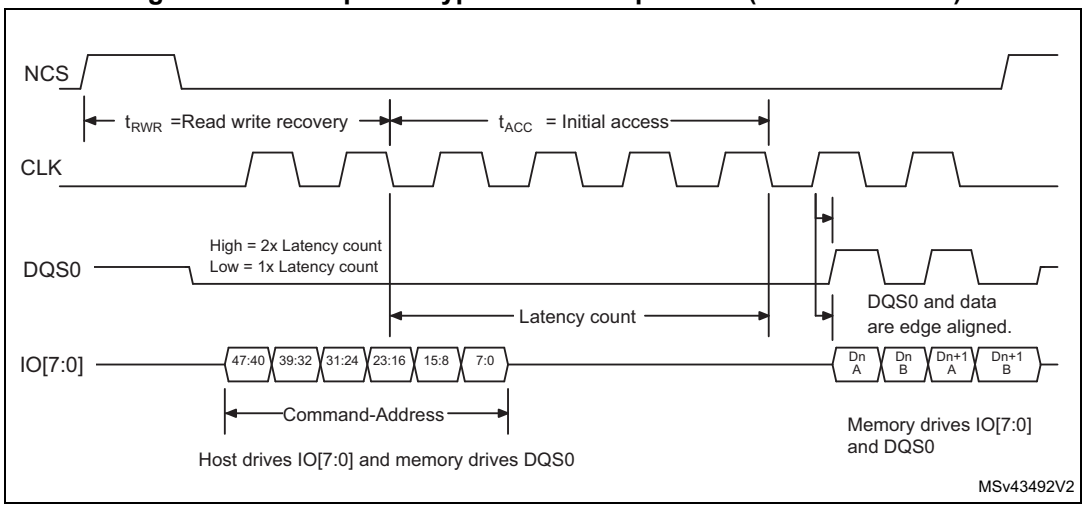
In DTR mode, a number of bytes multiple of four must always be accessed in XSPI mode. For this reason, bit 0 and 1 of DL[31:0] in XSPI_DLR are stuck at 0 when DMODE = 101.

24.4.7 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins in 8-bit data mode, or 19 to 20 pins in 16-bit data mode depending on the operating voltage:

- IO[7:0] as bidirectional data bus for 8-bit data mode and IO[15:0] as bidirectional data bus for 16-bit data mode
- DQS for read and write data strobe and latency insertion
- NCS
- CLK
- NCLK for 1.8 V operations (to support this mode, the device must be powered with 1.8 V)



The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- command/address phase
- data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 200. Example of HyperBus read operation (8-bit data mode)

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 211. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write
46	Address space	Indicates if the transaction accesses the memory or the register space
45	Burst type	Indicates if the burst is linear or wrapped
44-16	Row and upper column address	Selects the row and the upper column addresses
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page

The address space is configured through the memory type MTYP[2:0] of XSPI_DCR1.

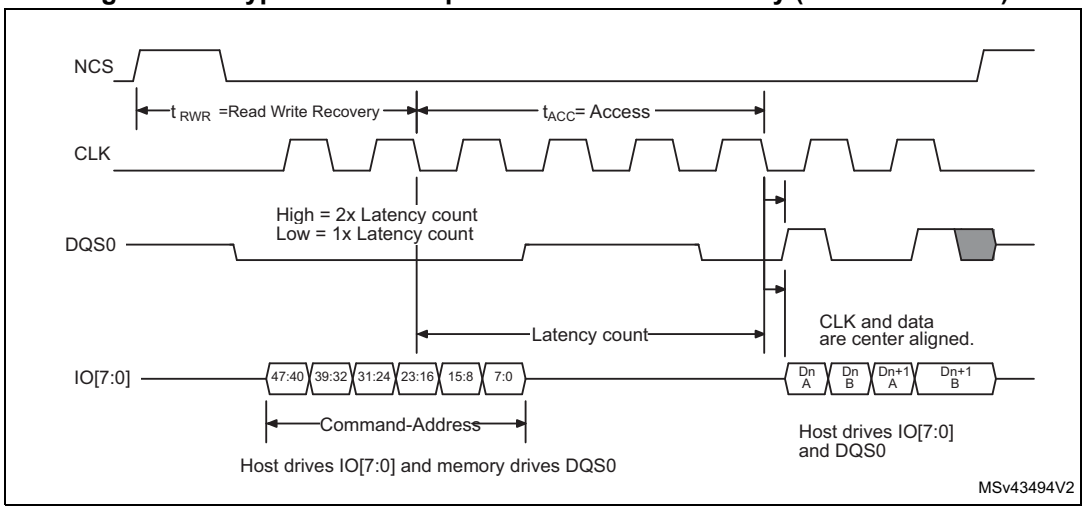
The total size of the device must be considered through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Warning: Some memory specifications consider that each address corresponds to a 16-bit value. The XSPI considers that each address corresponds to an 8-bit value. So, the software needs to multiple the address by two when accessing the memory registers.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- t_{ACC}: access time for the device (defined in TACC[7:0] of XSPI_HLCR) according to the memory latency



During the read operation, the DQS0/1 is used by the device, in two ways (see *Figure 200*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS0/1 is used:

- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

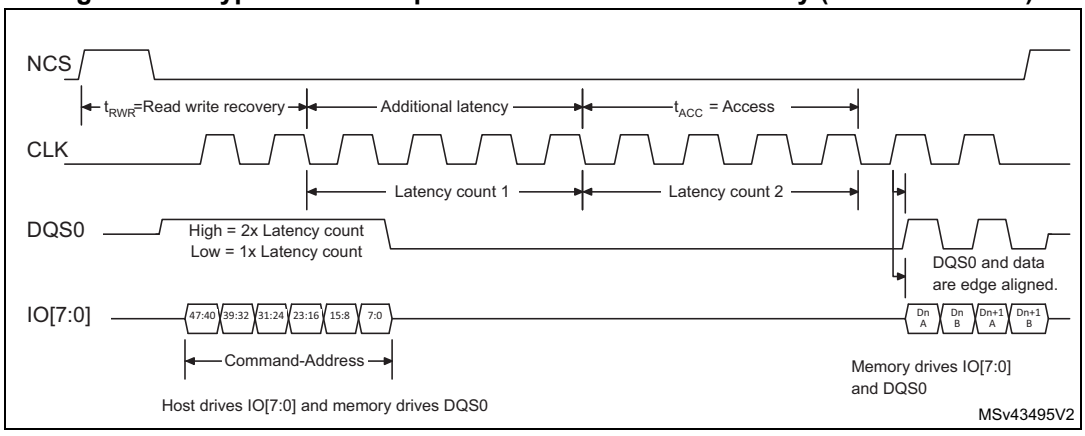
Figure 201. HyperBus write operation with initial latency (8-bit data mode)

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS0/1 must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the XSPI to meet the device request.

Figure 202. HyperBus read operation with additional latency (8-bit data mode)



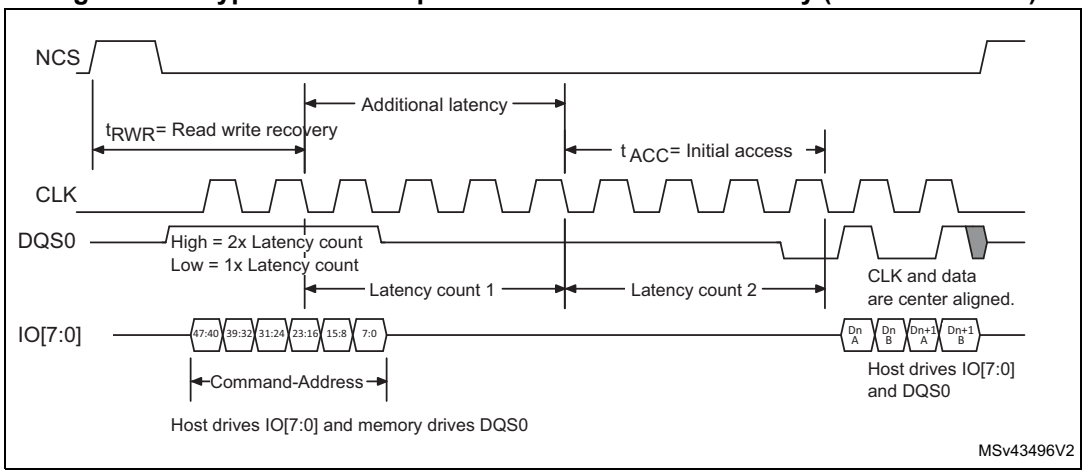


Figure 203. HyperBus write operation with additional latency (8-bit data mode)

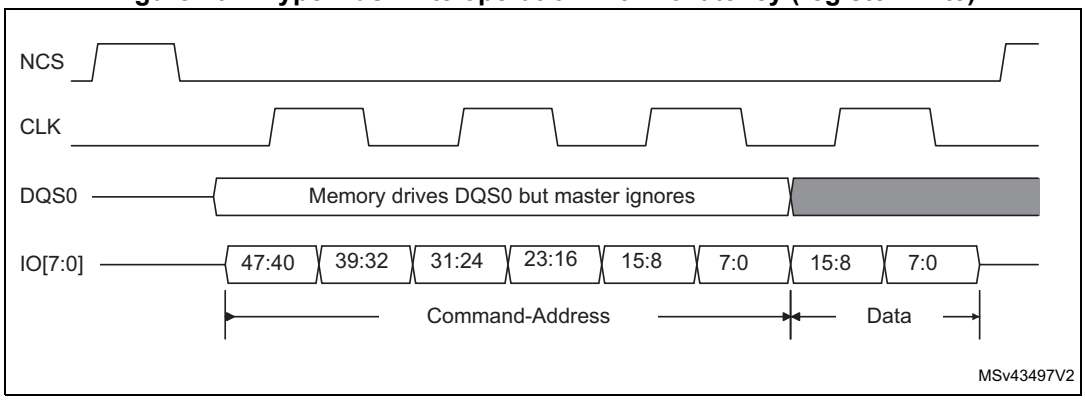
Fixed latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.



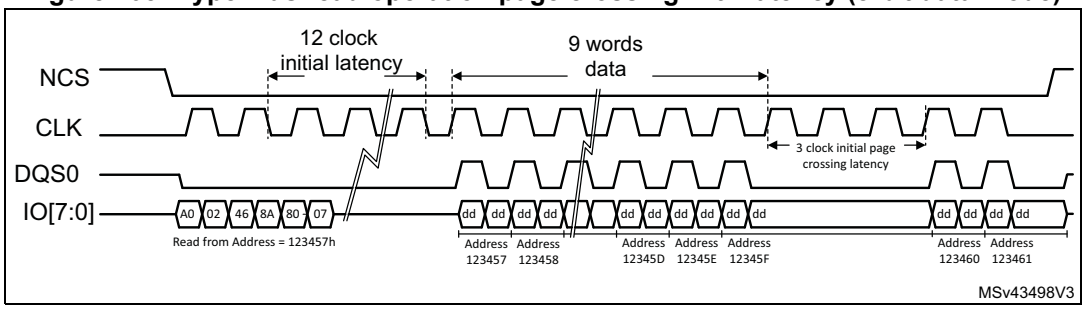
The latency can be forced to 2 x t_{ACC} by setting LM of XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI and an additional latency is always added leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.

Figure 204. HyperBus write operation with no latency (register write)

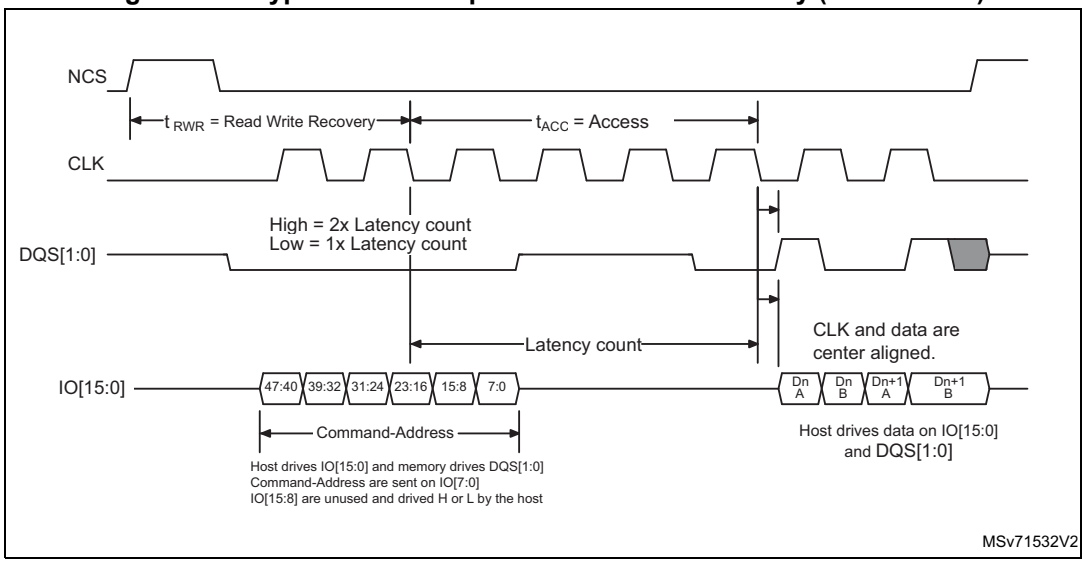


Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 205. HyperBus read operation page crossing with latency (8-bit data mode)



16-bit data transfer using HyperBus

In HyperBus protocol, the XSPI supports a dual-octal configuration (16-bit data transfers) when DMM = 1 in XSPI_CR: one octal HyperBus memory is connected to IO0-IO7 and another is connected to IO8-IO15. These memories share all signals except DQS that are dedicated.

For 16-bit data transfers, DMODE[2:0] must be to equal to 101. Any other value in DMODE[2:0] correspond to 8-bit data transfer (quad-, dual-, and single-bit data transfer do not exist in HyperBus protocol). Command-address phase is always using 8 bits in HyperBus protocol (from IO8-IO15). Only the data is on 16-bit for write or read operations accessing the memory space (from IO0-IO15) as shown for instance in *Figure 206*. For the memory register accesses, the data is on 8-bit (from IO0 to IO7, IO8 to IO15 being not used but driven by the controller) as shown in *Figure 204*.

The behavior of the interface at protocol-level is exactly the same as for HyperBus octal configuration, as described above, except that the variable latency is not supported in dual-octal HyperBus configuration. LM in XSPI_HLCR must be set.

Figure 206. HyperBus write operation with initial latency (16-bit mode)

24.4.8 Specific features

The XSPI supports some specific features, such as:

- wrap support
- NCS boundary and refresh
- communication regulation

Wrap support

The XSPI supports an hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 8 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated registers XSPI_WPxxx must be programmed according to the wrapped-read access characteristics. The dedicated XSPI_WPxxx registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with is configured in CSBOUND[4:0] of XSPI_DCR3 and it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. As a consequence, the NCS is released each time that the LSB address is equal to 0xF, and each time that a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed in REFRESH[31:0] of XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

Communication regulation

The communication regulation feature is useful in case two or more XSPIs share access to the same I/O port through an I/O manager. This feature limits the maximum length of a transaction to the value programmed in MAXTRAN[7:0] of XSPI_DCR3.

If the number of clock cycles of XSPI1 for example reach the MAXTRAN + 1 value, and if the second interface connected to the I/O manager requests an access, the NCS is released, and a new transaction is issued. If the second interface connected to the I/O manager does not request an access, the transaction is not stopped, and the NCS is not released.

If MAXTRAN[7:0] = 0, no limitation occurs.

The MAXTRAN[7:0] value must be greater than the minimal transaction size in terms of number of cycles including the command, address, alternate, and dummy phases.

Note: The communication regulation feature cannot be used in write mode for the flash memory devices that require extra command to reenable the write operation after the NCS is active again.

If NCS boundary, refresh and communication regulation are enabled at the same time, the NCS is released on the first condition met.

Restarting after an interrupted transfer

When a read or write operation is interrupted by a timeout, the XSPI interface, as soon as possible after getting back the port ownership, re-issues the initial command sequence together with the address following the last address actually accessed before interruption. The transfer initially set goes on and ends seamlessly.

24.4.9 XSPI operating modes introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

24.4.10 XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and the data is transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, TCF bit is set in XSPI_SR and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data needs to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data needs to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR

- if data needs to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01)
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00)
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01)

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode pass through a 32-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in the XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to the XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

In indirect-read mode, when the FIFO becomes full, the XSPI temporarily stops reading bytes from the external device to avoid an overrun.

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

24.4.11 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value.

The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point, and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must be configured in fixed latency.

24.4.12 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AXI error is given. The effect of this error depends on the AXI master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation, it either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without an access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

24.4.13 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

24.4.14 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

24.4.15 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

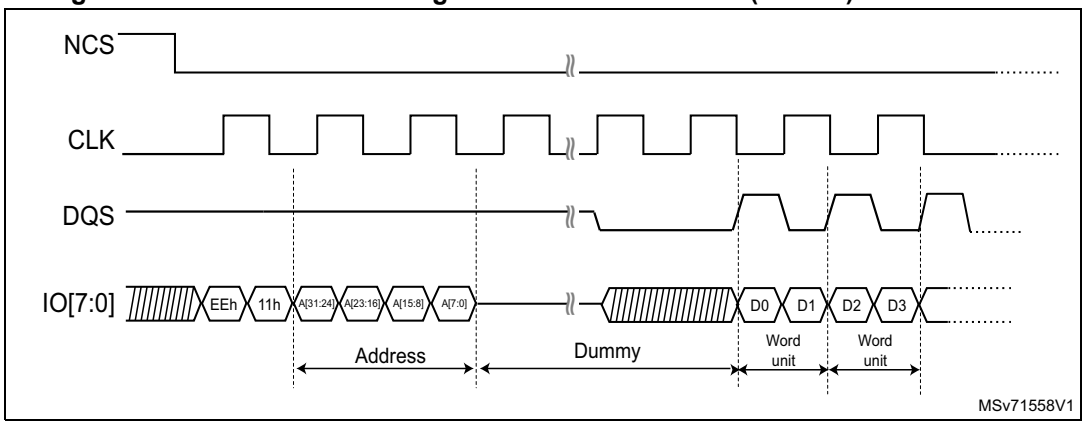
If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the NCS high between the two commands, at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles (up to 64) for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the Latency mode must be configured in XSPI_HLCR.



Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:

- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 207. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 197: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 212: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock when reading data from the memory.

Figure 208. OctaRAM read operation with reverse data ordering D1/D0

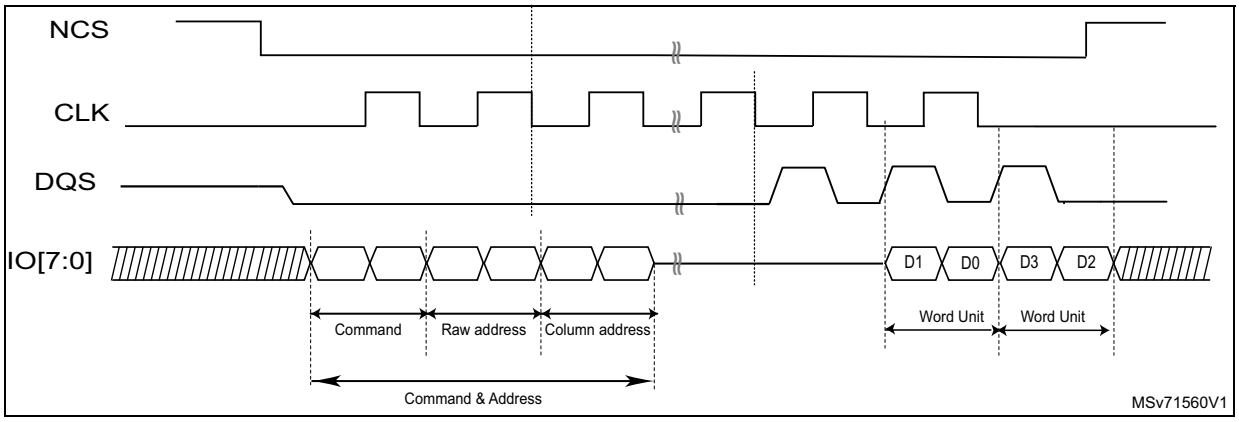


Table 212. OctaRAM command address bit assignment (based on 64 Mb[1] OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0[2]

1. Example of 64 Mb OctaRAM address assignment:
Row Address [RA12:RA0]: 8K. Column address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.
- The software must configure MTYP[2:0] = 110 when the memory targeted comes from APmemory and DMODE[2:0] = 101 to fit with the memory provider requirements concerning the address formating.
- Standard mode. It is the mode to use whenever the targeted memory is not corresponding to any others configurations described in this section. MTYP[2:0] = 010 for this standard mode.

24.4.16 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected and data can be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.

5. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as XSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and the data is retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in XSPI_DLR, it is ignored, and only 4 bytes are read.The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.
3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

Memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AXI master accesses the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All the configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 have no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

Memory-mapped write operations are not supported without write strobe.

XSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

XSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

24.4.17 XSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AXI master is accessing the memory mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

24.4.18 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).

- in indirect mode, if the address plus the data length exceed the device size. TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AXI slave error in the following situations:

- The memory-mapped mode is disabled and an AXI read or write request occurs.
- Read or write address exceeds the size of the external memory.
- Abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to *Section 24.4.20: XSPI BUSY and ABORT*.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in hyperbus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means AXI Bus transfer size (ARSIZE) is different from 8 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and 16-bit mode is set.

24.4.19 XSPI high-speed interface and calibration

To reach higher frequencies, a dedicated high-speed interface is inserted between the XSPI (or the I/O manager in case the product embeds one), and the I/O pads.

The following is valid for all data bus sizes 1, 2, 4, 8 or 16 bits.

The high-speed interface block embeds resynchronization registers that are clocked by a delayed clock created from a DLL (delay locked loop) also located in the high-speed interface. The high-speed interface features are controlled by registers located in the XSPI.

The purpose of resynchronization is primary to shift data or data strobe by one quarter of controller bus clock period, with a correct timing accuracy. DLL must be calibrated versus this clock period.

The calibration process is automatically enabled when one of the three conditions below is met:

- The XSPI exits reset state.
- A value is written in PRESCALER[7:0] of XSPI_DCR2.
- A value is written in XSPI_CCR.

The calibration process starts when the two following conditions are **both** met:

- The calibration has been enabled by one of the three conditions above.
- An action that sets BUSY = 1 is performed. For example the first transfer to memory after calibration is enabled. When the calibration is completed, BUSY returns to 0.

In case a periodic recalibration is needed (for example to take in account possible variations in temperature or power supply on a long duration), this recalibration must be triggered by writing periodically in PRESCALER[7:0] of XSPI_DCR2, while BUSY = 0.

Once the calibration is completed, the value of the SPI bus clock period, expressed in number of unitary delay, is available to user in COARSE[5:0] and FINE[6:0] of XSPI_CALFCR.

After auto-calibration, XSPI_CALSOR and XSPI_CALSIR are automatically loaded with the same value that corresponds to the delay for a quarter cycle.

The automatic calibration is not executed if at least one of both registers XSPI_CALSOR/XSPI_CALSIR is written between the last write operation on XSPI_DCR2 or XSPI_CCR and the next transfer start. In such case, the calibration values must be set by the software code into XSPI_CALSOR and XSPI_CALSIR registers. It may improve the flash programming time without relaunching the automatic calibration processing between two programming pages.

When the memory is not supporting DQS (DQSE = 0), the automatic calibration is not used in reception. The DLL Master is used instead for delaying the feedback clock (XSPI_CALMR). This delay needs to be adjusted by the application itself, using a software sequence that determines which delay is optimal to guarantee the correct read operations.

When the clock is divided in DTR transmission mode, the quarter cycle delays on DQS/data are not inserted by the DLLs themselves, but by internal flops design scheme. In SDR transmission mode, the DLLs are not used and this, whatever the clock prescaler value.

In case of DTR mode and prescaler bypassed (PRESCALER[7:0] = 0), the kernel clock provided to interface must have a 50 % duty-cycle.

When using the high-speed-interface, the system clock (AXI clock) must be at least as fast as the SPI clock.

24.4.20 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

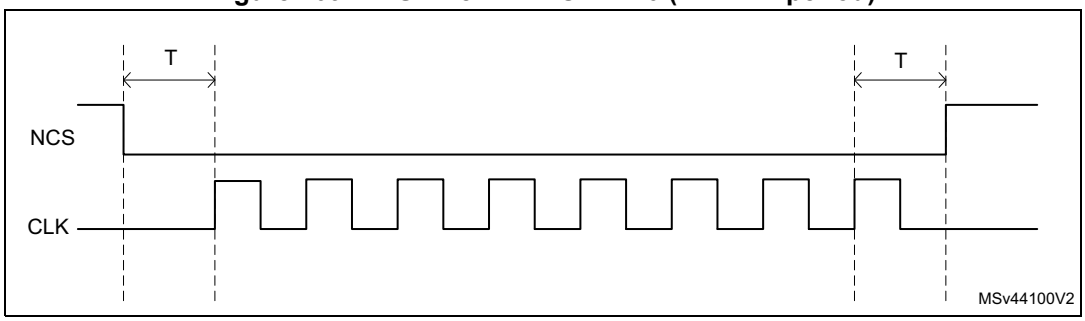
Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the XSPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

24.4.21 XSPI reconfiguration or deactivation

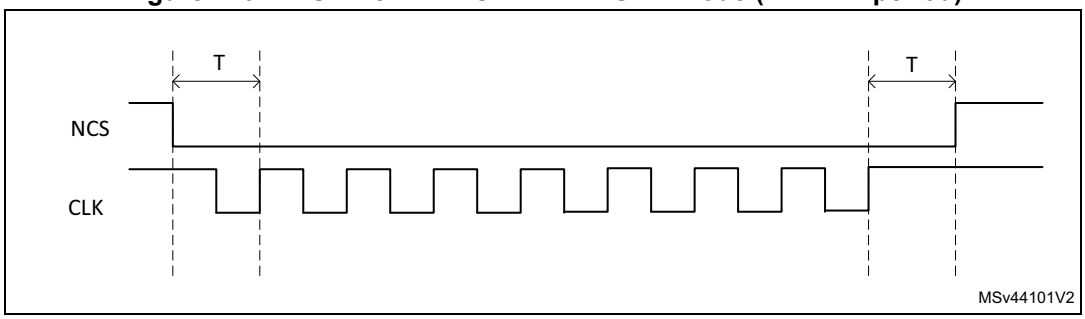
Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:



- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier then an abort.

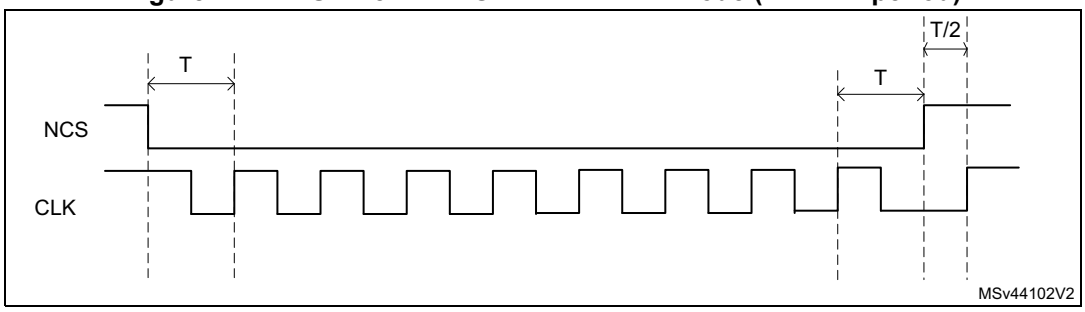
24.4.22 NCS behavior

By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.



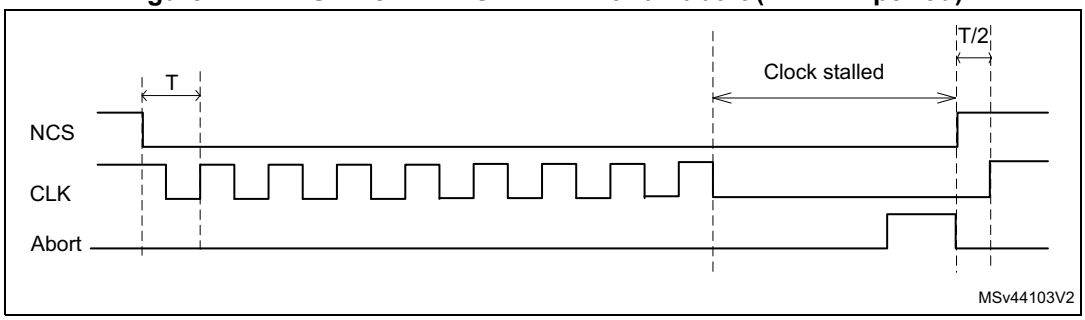
When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 209. NCS when CKMODE = 0 (T = CLK period)



When CKMODE = 1 (clock mode 3: CLK goes high when no operation is in progress) and when in SDR mode, NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 210. NCS when CKMODE = 1 in SDR mode (T = CLK period)

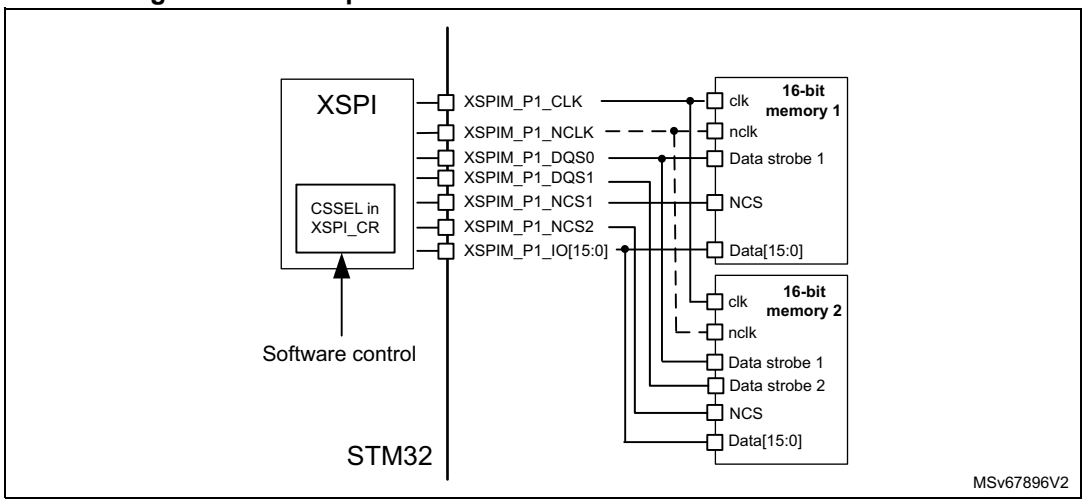


When the CKMODE = 1 (clock mode 3) and DDTR = 1 (data DTR mode), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final active rising CLK edge (see the figure below). Because the DTR operations must finish with a falling edge, the CLK is low when NCS rises, and CLK rises back up one half of a CLK cycle afterwards.

Figure 211. NCS when CKMODE = 1 in DTR mode (T = CLK period)

When the FIFO stays full during a read operation, or if the FIFO stays empty during a write operation, the operation stalls and CLK stays low until the software services the FIFO. If an abort occurs when an operation is stalled, NCS rises just after the abort is requested and then CLK rises one half of a CLK cycle later (see the figure below).

Figure 212. NCS when CKMODE =1 with an abort (T = CLK period)



In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1. The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.

24.4.23 Software control of two external memories

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus.
From a memory-map point of view, these two memories are located in the same address range.

Figure 213. Example of software control of two external memories

24.5 Address alignment and data number

The following table summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 213. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6), or 16-bit memory in SDR mode without WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
16-bit or dual-octal memory in DTR mode without WDM	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM write	Aligned	Slave error	N × 4	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
HyperBus	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

Table 213. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
16-bit data bus memory or dual-octal memory with WDM	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write(8)				
	MM write				
16-bit HyperBus	IND read 32-bit	Aligned	ADDR[1:0] is assumed to be 00.(4)	N × 4	DLR[1:0] is assumed to be 11.(5)
	MM read	None	None	None	None
	IND write(9)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.
8. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode or modulo 2 in SDR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.
9. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 4 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

24.6 XSPI interrupts

An interrupt can be produced on the following events:

- timeout
- status match
- FIFO threshold
- transfer complete
- transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 214. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE

Table 214. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

24.7 XSPI registers

24.7.1 XSPI control register (XSPI_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MSEL[1:0]		FMODE[1:0]		Res.	Res.	Res.	CSSEL	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
rw	rw	rw	rw				rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					Res.	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw		rw			rw	rw	rw	rw

Bits 31:30 **MSEL[1:0]**: Flash select

These bits select the memory to be addressed in single-, dual-, quad-, or octal-SPI mode in single-memory configuration (when DMM = 0).

- when in quad-SPI mode:

00: Data exchanged over IO[3:0]

01: Data exchanged over IO[7:4]

10: Data exchanged over IO[11:8]

11: Data exchanged over IO[15:12]

- when in octal-SPI mode or dual-quad configuration:

0x: Data exchanged over IO[7:0]

1x: Data exchanged over IO[15:8]

These bits are ignored when in dual-octal configuration (data on 8 bits and DMM = 1) or 16-bit configuration (data exchanged over IO[15:0]).

Note: Bit 30 is mirrored in bit 7. This bitfield can be modified only when BUSY = 0.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the XSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **CSSEL**: chip select selection
This bit indicates if the XSPI must activate NCS1 or NCS2.
0: NCS1 active
1: NCS2 active
Note: This bit can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.
Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.
1: Automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status match interrupt enable
This bit enables the status match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.

00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.

00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.

...

11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.

Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity.

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via XSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. It is automatically reset once the abort is completed. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the XSPI.

0: XSPI disabled

1: XSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation. In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

24.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	Res.	DEVSIZE[4:0]				
					rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes. In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect read/write modes must be used.

110: APmemory mode. If DMODE = 101, there is a special hardware operation on address word from the bit 10 and above to fit the provider requirement (shift operation on the left from the address bit 10, keeping this last at 0).

Others: Reserved

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.
0x0: NCS stays high for at least 1 cycle between external device commands.
0x1: NCS stays high for at least 2 cycles between external device commands.
...
0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.
0: CLK is not free running.
1: CLK is free running (always provided).

Note: Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0/mode 3

This bit indicates the level taken by the CLK between commands (when NCS = 1).
0: CLK must stay low while NCS is high (chip-select released), referred to as clock mode 0.
1: CLK must stay high while NCS is high (chip-select released), referred to as clock mode 3.

24.7.3 XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories, which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in XSPI_WPIR.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Others: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50%. The clock signal remains low one cycle longer than it stays high.

Writing this bitfield automatically starts a new calibration of high-speed interface DLL at the start of next transfer, except in case XSPI_CALSOR or XSPI_CALSIR have been written in the meantime. BUSY stays high during the whole calibration execution.

24.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MAXTRAN[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of three is recommended.

The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Others: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **MAXTRAN[7:0]**: Maximum transfer

This bitfield enables the communication regulation feature.
The NCS is released every MAXTRAN+1 clock cycles when the other XSPI request the access to the bus.
0: Maximum communication disabled
Others: Maximum communication is set to (MAXTRAN + 1) bytes.

24.7.5 XSPI device configuration register 4 (XSPI_DCR4)

Address offset: 0x014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual-, or quad-SPI mode, because the byte transmission must be completed.
0: Refresh disabled
Others: Maximum communication length is set to REFRESH + 1 clock cycles.

24.7.6 XSPI status register (XSPI_SR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO.FLEVEL = 0 when the FIFO is empty, and 32 when it is full. In automatic-status polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).
It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.
It is cleared automatically as soon as the threshold condition is no longer true.
In automatic status-polling mode this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode.
It is cleared by writing 1 to CTEF.

24.7.7 XSPI flag clear register (XSPI_FCR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag

Writing 1 clears the TOF flag in the XSPI_SR register.

Bit 3 **CSMF**: Clear status match flag

Writing 1 clears the SMF flag in the XSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag

Writing 1 clears the TCF flag in the XSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag

Writing 1 clears the TEF flag in the XSPI_SR register.

24.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value + 1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect when in memory-mapped mode.

24.7.9 XSPI address register (XSPI_AR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADDRESS[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In HyperBus protocol, this bitfield must be even as this protocol is 16-bit word oriented. In dual-memory configuration, AR[0] is forced to 0.

Caution: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiply the address by two when accessing the memory registers.

24.7.10 XSPI data register (XSPI_DR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

24.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

24.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match

Value to be compared with the masked status register to get a match

24.7.13 XSPI polling interval register (XSPI_PIR)

Address offset: 0x090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval

Number of CLK cycles between a read during the automatic status-polling phases

24.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for the data phase

1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101: Data on 16 lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size

This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate

This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode

This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

24.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift

By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bits 29:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles

This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

24.7.17 XSPI alternate bytes register (XSPI_ABR)

Address offset: 0x120

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address.

24.7.18 XSPI low-power timeout register (XSPI_LPTR)

Address offset: 0x130

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

24.7.19 XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable

This bit enables the data strobe management.

0: DQS disabled

1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate

This bit sets the DTR mode for the data phase.

0: DTR mode disabled for the data phase

1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode

This bitfield defines the data phase mode of operation.

000: No data

001: Data on a single line

010: Data on two lines

011: Data on four lines

100: Data on eight lines

101: Data on 16 lines

Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size

This bitfield defines the alternate-byte size.

00: 8-bit alternate bytes

01: 16-bit alternate bytes

10: 24-bit alternate bytes

11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

24.7.20 XSPI wrap timing configuration register (XSPI_WPTCR)

Address offset: 0x148

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1).

Bits 29:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.21 XSPI wrap instruction register (XSPI_WPIR)

Address offset: 0x150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

24.7.22 XSPI wrap alternate byte register (XSPI_WPABR)

Address offset: 0x160

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

24.7.23 XSPI write communication configuration register (XSPI_WCCR)

Address offset: 0x180

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	DQSE	Res.	DDTR	DMODE[2:0]			Res.	Res.	ABSIZE[1:0]		ABDTR	ABMODE[2:0]		
		rw		rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for the data phase
1: DTR mode enabled for the data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
101: Data on 16 lines
Others: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size:
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate-byte double-transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Others: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Others: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines the instruction size:
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Others: Reserved

24.7.24 XSPI write timing configuration register (XSPI_WTCR)

Address offset: 0x188

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency. In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.25 XSPI write instruction register (XSPI_WIR)

Address offset: 0x190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

24.7.26 XSPI write alternate byte register (XSPI_WABR)

Address offset: 0x1A0

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes
Optional data to be sent to the external SPI device right after the address

24.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR)

Address offset: 0x200

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRWR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TACC[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	WZL	LM
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device Read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.

0: Latency on write accesses

1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.

0: Variable initial latency

1: Fixed latency

Note: This bit must be set when using the dual-octal HyperBus configuration.

24.7.28 XSPI full-cycle calibration configuration (XSPI_CALFCR)

Address offset: 0x210

Reset value: 0x0000 0000

This read-only register gives the calibration code needed by the DLL master so that its delay is equivalent to a full memory-clock cycle. The value of this register is updated every time that auto-calibration finishes.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CALMAX	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
r											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									r	r	r	r	r	r	r

Bit 31 **CALMAX:** Max value
This bit gets set when the memory-clock period is outside the range of DLL master, in which case XSPI_CALFCR and XSPI_CALSR are updated with the values for the maximum delay.

Bits 30:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

24.7.29 XSPI DLL master calibration configuration (XSPI_CALMR)

Address offset: 0x218

Reset value: 0x0000 0000

The DLL Master is used for delaying the feedback clock when reading without DQS. The delay of the master DLL is determined by the value in this register.

This register can always be read by software and can be modified only when BUSY = 0.

This register never gets updated automatically by hardware.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology (see the datasheet).

24.7.30 XSPI DLL slave output calibration configuration (XSPI_CALSOR)

Address offset: 0x220

Reset value: 0x0000 0000

The DLL output slave is used to delay the output data in DDR mode for write operations. The delay of the output slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSIR as well).

This register can always be read by software and can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]				
											rw	rw	rw	rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FINE[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **COARSE[4:0]**: Coarse calibration
The delay unitary value for this bitfield depends on product technology.

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **FINE[6:0]**: Fine calibration
The delay unitary value for this bitfield depends on product technology.

24.7.31 XSPI DLL slave input calibration configuration (XSPI_CALSIR)

Address offset: 0x228

Reset value: 0x0000 0000

The DLL input slave is used to delay the DQS input for sampling the data when DQS is enabled for read operations. The delay of the input slave DLL is determined by the value in this register.

This register is updated automatically by hardware at the end of calibration (at the same moment that XSPI_CALFCR is updated).

If this register is written after the last write to XSPI_DCR2 or XSPI_CCR, then auto-calibration is not executed on the next transfer (auto-calibration is not performed for XSPI_CALSOR as well).

This register can always be read by software and can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COARSE[4:0]

25 XSPI I/O manager (XSPIM)

25.1 Introduction

The XSPI I/O manager is a low-level interface, enabling an efficient XSPI pin assignment with a full I/O matrix (before alternate function map), and multiplex of single/dual/quad/octal/16-bit SPI interfaces over the same bus.

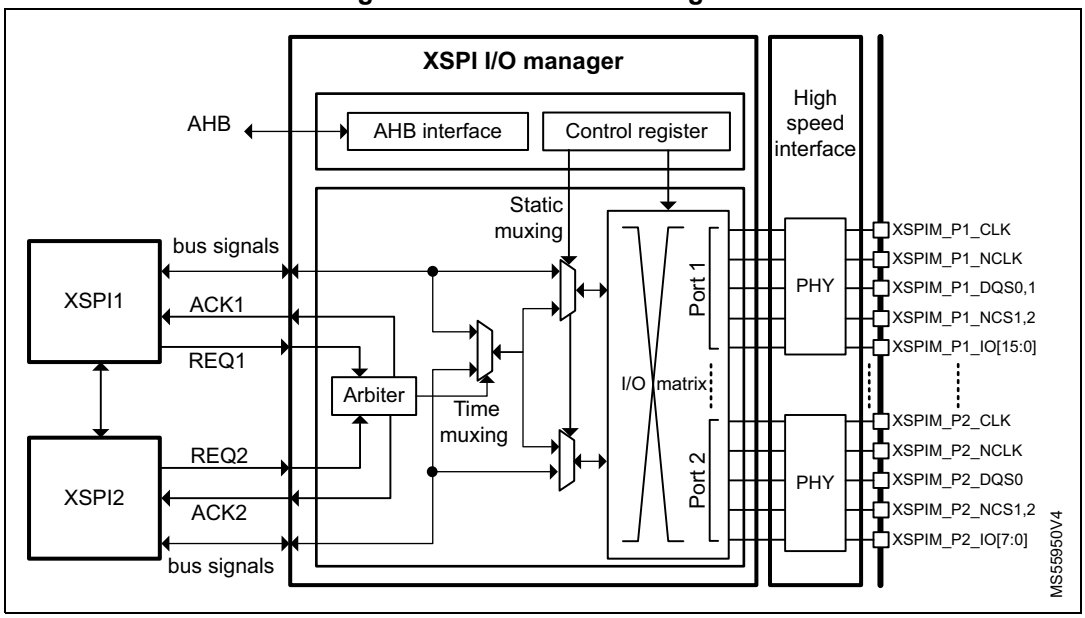
25.2 XSPIM main features

- Supports up to two single/dual/quad/octal/16-bit SPI interfaces
- Supports up to two ports for pin assignment
- Supports high-speed interfaces

25.3 XSPIM implementation

Table 216 describes the XSPIM implementation.

Table 216. XSPIM implementation



XSPI feature	Available on the devices
Supports up to two single/dual/quad interfaces	X
Fully I/O multiplexing capability	X
Supports time-multiplexed mode	X
Supports high-speed interface	X
Chip select selection if XSPI provides dual chip select	X
Supports 16-bit data interface and dual-octal mode	X

25.4 XSPIM functional description

25.4.1 XSPIM block diagram

The block diagram of the XSPI I/O manager is shown in *Figure 214*.

Figure 214. XSPIM block diagram

25.4.2 XSPIM input/output pins

Table 217. XSPIM input/output pins

Pin name(1)	Signal type	Description
XSPIM_Px_NCLK	Output	XSPI inverted clock to support 1.8 V HyperBus protocol
XSPIM_Px_CLK		XSPI clock
XSPIM_Px_IOn (n = 0 to 15)	Input/output	XSPI data pins
XSPIM_Px_NCS1,2	Output	Chip select for the memory
XSPIM_Px_DQS0,1	Input/output	Data strobe/write mask signals from/to the memory

1. x = 1 to 2.

25.4.3 XSPIM matrix

The XSPI I/O manager matrix allows the user to set a premapping of functions:

- XSPI1 mapped to Port 1, with XSPI2 mapped to Port 2 (direct mode)
- XSPI1 mapped to Port 2, with XSPI2 mapped to Port 1 (swapped mode)
- XSPI1 and XSPI2 both mapped to Port 1, with arbitration (multiplexed mode)
- XSPI1 and XSPI2 both mapped to Port 2, with arbitration (multiplexed mode)

Note: There is no possibility to use mixed combinations of signals (like NCS of XSPI1 with data of XSPI2).

When several I/O pins have the same configuration and are enabled at the same time, the result can be unpredictable.

In the default out-of-reset configuration, all the XSPI1 and XSPI2 signals are mapped, respectively, on Port 1 and on Port 2.

The configuration can be changed only when all XSPIs are disabled.

25.4.4 XSPIM multiplexed mode

When this mode is set, the XSPIs are time-multiplexed over the same bus. They get the ownership of the bus (in turn) through a request/acknowledge protocol with REQ/ACK signals.

The time-multiplexing is enabled by setting the MUXEN bit in the configuration register XSPIM_CR.

The fairness counter (MAXTRAN) of each XSPI can be used to manage the maximum duration for which a given XSPI takes the bus: this feature ensures the maximum bus access latency for the other XSPI(s). When one XSPI releases the bus, a round-robin arbitration phase occurs: when another XSPI requests the bus, it gets it.

When the multiplexed mode is enabled, either the fairness counter or the refresh timeout counter of both XSPI interfaces must be activated.

Each XSPI delivers one NCS signal together with a CSSEL control signal. The CSSEL signal selects which of the two outputs (NCS1, NCS2) is active. In multiplexed modes the active CCSEL signal is the one of the XSPI owning the bus. The default value of XSPI_CR.CSSEL is 0 for XSPI1 and 1 for XSPI2. Only XSPIn_IOs, XSPIn_DQS and XSPIn_CLK / XSPIn_NCLK are multiplexed.

When the multiplexed mode is used, only clock mode 0 is supported on the XSPIs.

Due to arbitration and bus sharing, the auto polling interval time of the XSPI, when used, can be increased.

Minimum switching duration

The minimum number of cycles needed to switch from an XSPI to another can be configured. This guarantees a latency between the falling edge of the REQ signal of the active XSPI (the active one releases the bus), and the rising edge of the ACK signal to the requesting XSPI (the bus is granted to the requesting one).

The duration is defined by the REQ2ACK_TIME field in the XSPIM_CR register.

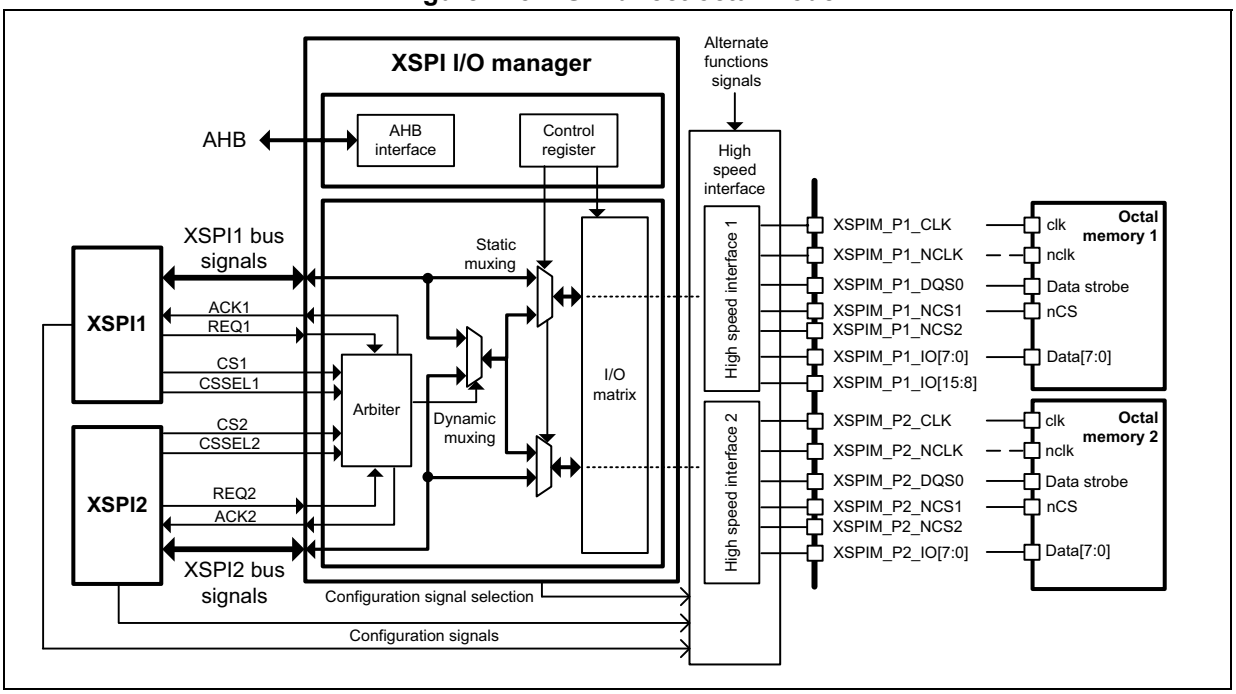
25.5 Use cases description

The following table summarizes the use cases corresponding to IO manager modes.

Table 218. Use cases

IO manager mode	MUXEN	Mode	Reference
Direct	0	0	*Section 25.5.1* *Section 25.5.2*
Swapped	0	1	*Section 25.5.4*
Multiplexed to Port1	1	0	*Section 25.5.5*
Multiplexed to Port2	1	1	*Section 25.5.6*
Two XSPIs drive one external memory	1	0 or 1, depending upon the port connected to the memory	*Section 25.5.7*
One XSPI drives two external memories	0	0 with CS selection command from XSPI1 or 2.	*Section 25.5.8*

25.5.1 XSPIs direct octal mode



This is the baseline mode: each XSPI independently drives the corresponding port and high-speed interface. There is no multiplexing.

The configuration selection signal selects the signals used for each high speed interface. These signals come from the XSPI_CR and XSPI_CALxxx register outputs.

Alternate function signals can be routed on NCS2 pins (they are not used for the XSPI bus), nclk clocks are requested in case of 1.8 V HyperBus memory type.

This mode is selected by default through bits XSPIM_CR[1:0].

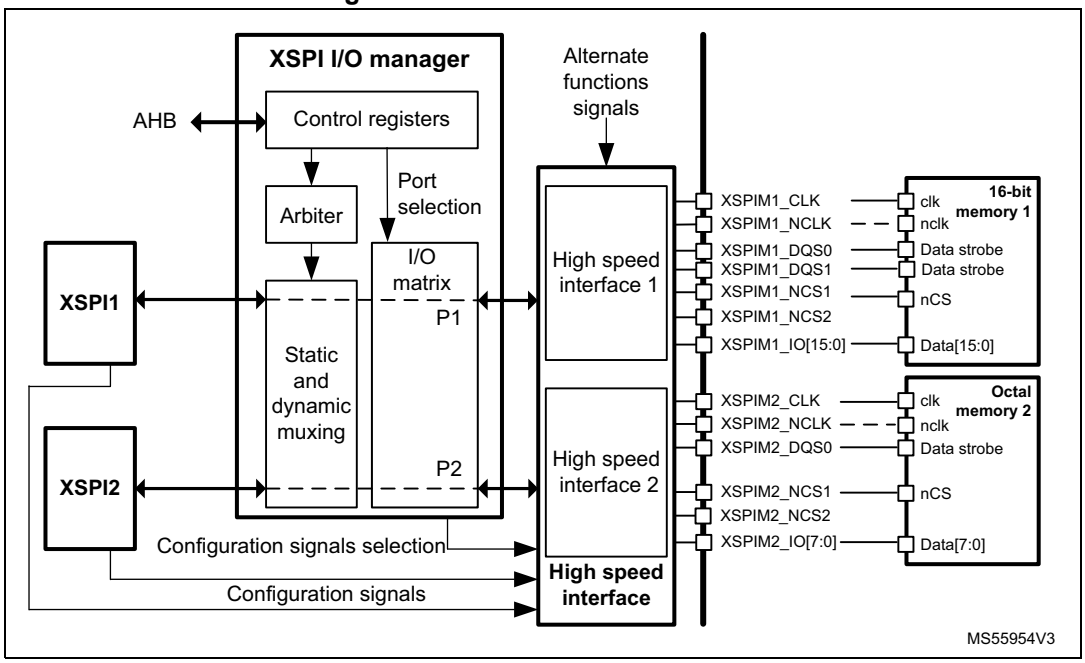


Figure 215. XSPI direct octal mode

25.5.2 XSPI direct 16-bit mode

This is the baseline mode, completely similar to XSPI octal direct mode, where each XSPI directly drives the corresponding port (XSPI1 connected to Port 1, XSPI2 connected to Port 2). Two DQS (1 per byte) are needed for each 16-bit port, when available.

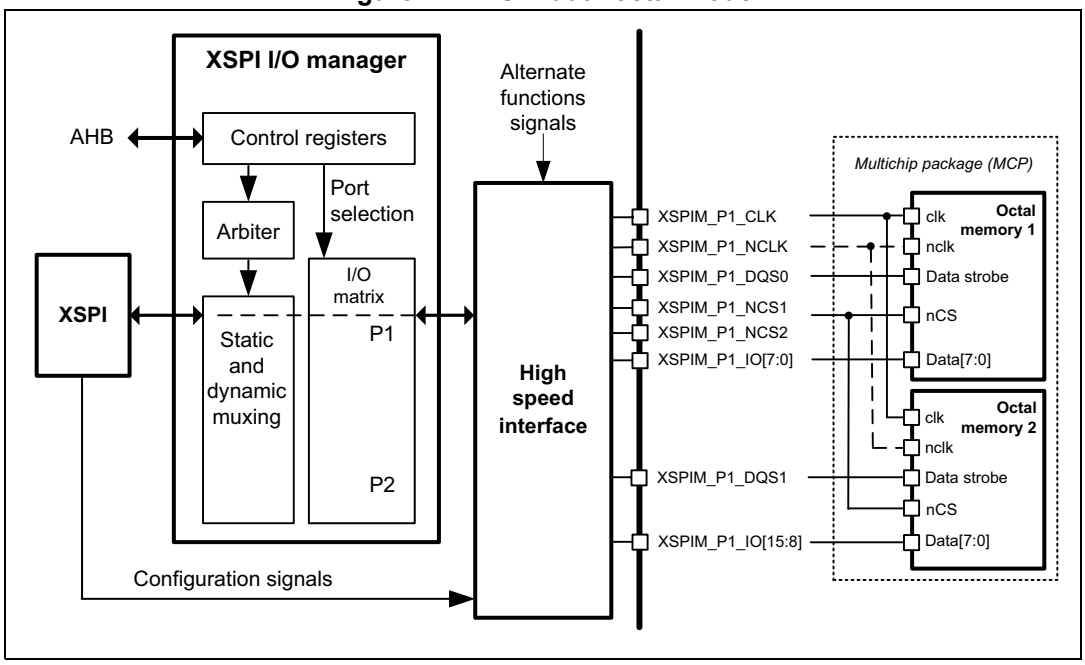

Figure 216. XSPI direct 16-bit mode

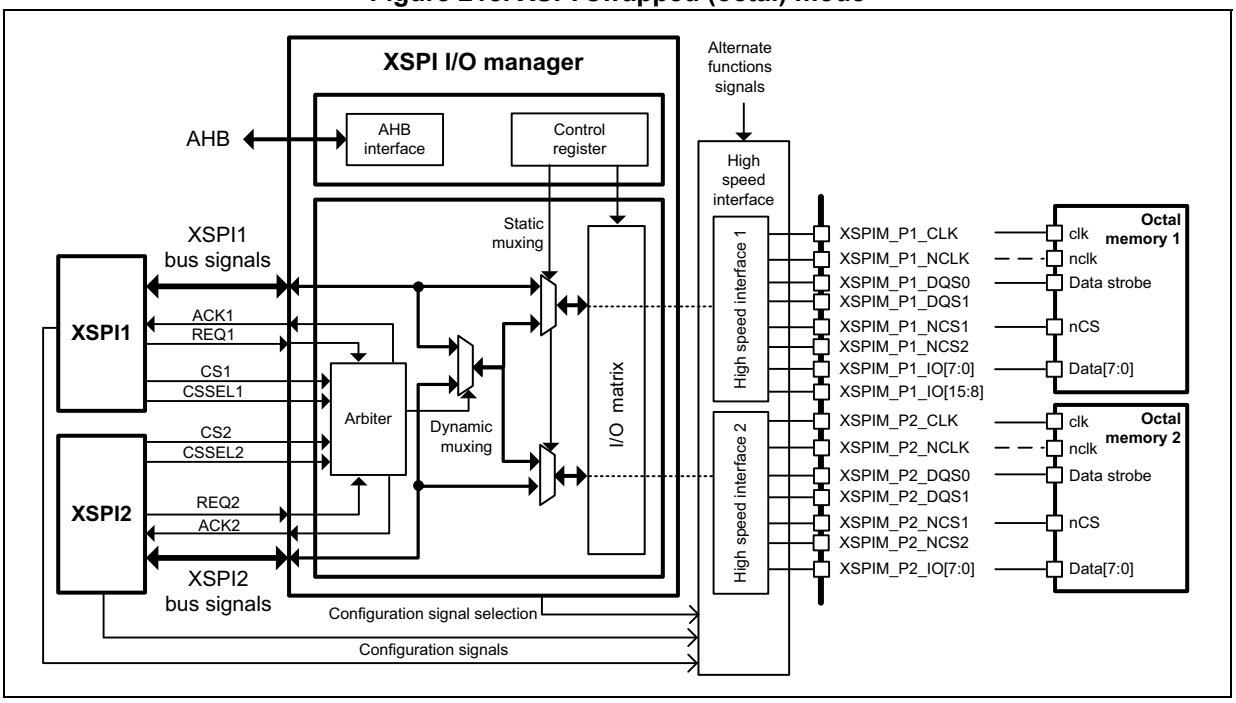
25.5.3 XSPI dual-octal mode

This mode is equivalent to XSPI direct mode, but, for simplicity, only one XSPI interface is represented. Two external octal memories are accessed in parallel, similarly to the dual-quad mode implemented with octal interfaces.

Figure 217. XSPI dual-octal mode



25.5.4 XSPI swapped mode

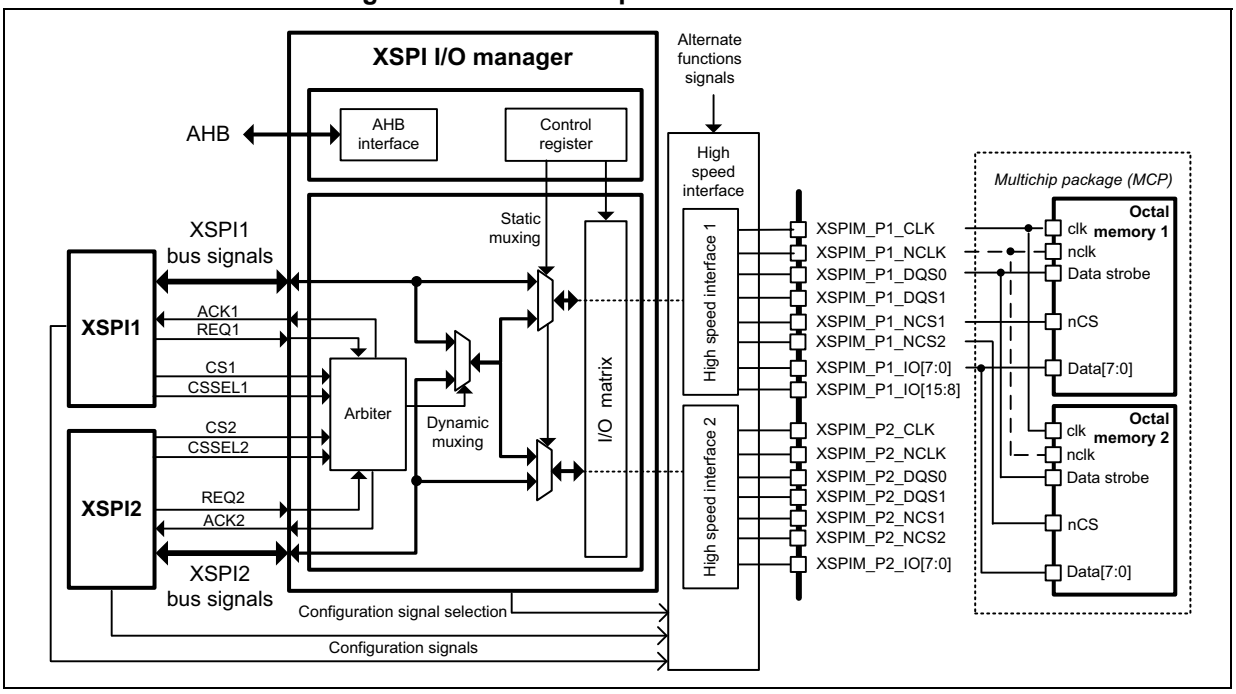
This mode is similar to XSPI direct mode, but the ports are swapped, to help I/O mapping. The mode is selected by bits XSPIM_CR[1:0].

If XSPIM.CR[0] or XSPIM.CR[1] is toggled in application, XSPI DCR2 or XSPI.CCR must be written, so that the calibration of the high speed interface is launched according to the new XSPI using it.

Note: In swapped mode, the XSPI2 can be configured in 16-bit mode, and the XSPI1 can be configured in octal mode, to connect an external 16-bit memory on Port 1, and to connect in a concurrent way an octal external memory connected to Port 2 of the I/O manager.

Figure 218. XSPI swapped (octal) mode

25.5.5 Two XSPIs multiplexed mode to Port 1 accessing two external memories



If only one output port is used to access two memories, alternate function signals can be routed to pins corresponding to the other port. This mode is selected by bits XSPIM_CR[1:0].

The arbiter in the IO manager selects XSPI1 or XSPI2 to own the octal-SPI bus according to the existing transfer requests and status of the two MAXTRAN fairness counters.

The external memories can be on separate chips, or embedded in a single multichip package. In this case, each memory requests a dedicated Chip select, selected according to the CSSEL control of the XSPI currently owning the bus.

The configuration signals of the high speed interface toggle when the corresponding XSPI is selected, because the timing characteristics of the two memories can be different.

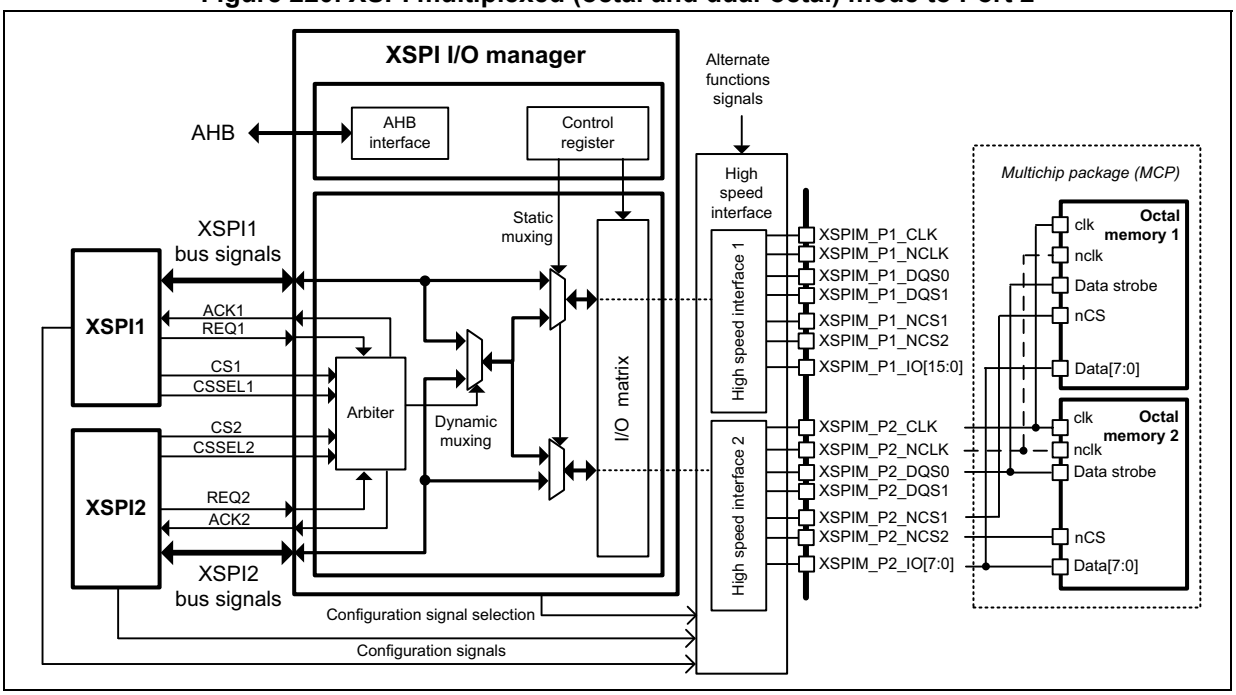


Figure 219. XSPI multiplexed mode to Port 1

25.5.6 Two XSPIs multiplexed mode to Port 2 accessing two external memories

This is similar to XSPI multiplexed mode to Port 1, but the target is Port 2. This mode is selected by bits XSPIM_CR[2:1].

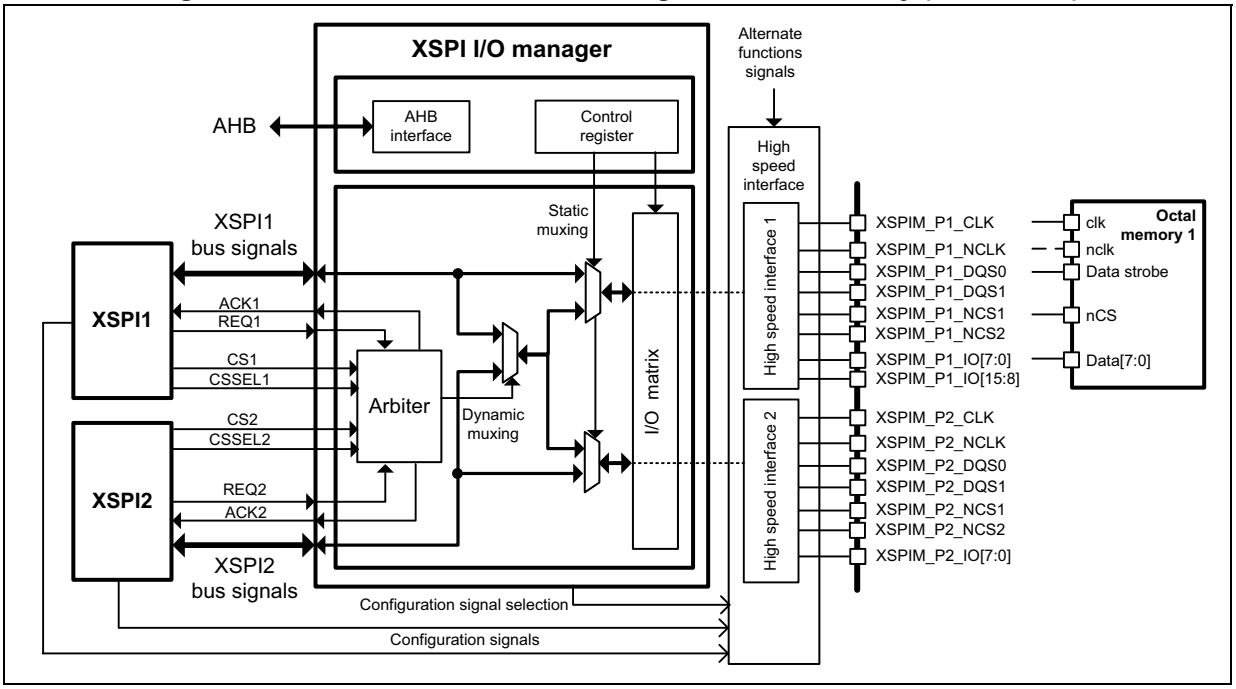

Figure 220. XSPI multiplexed (octal and dual-octal) mode to Port 2

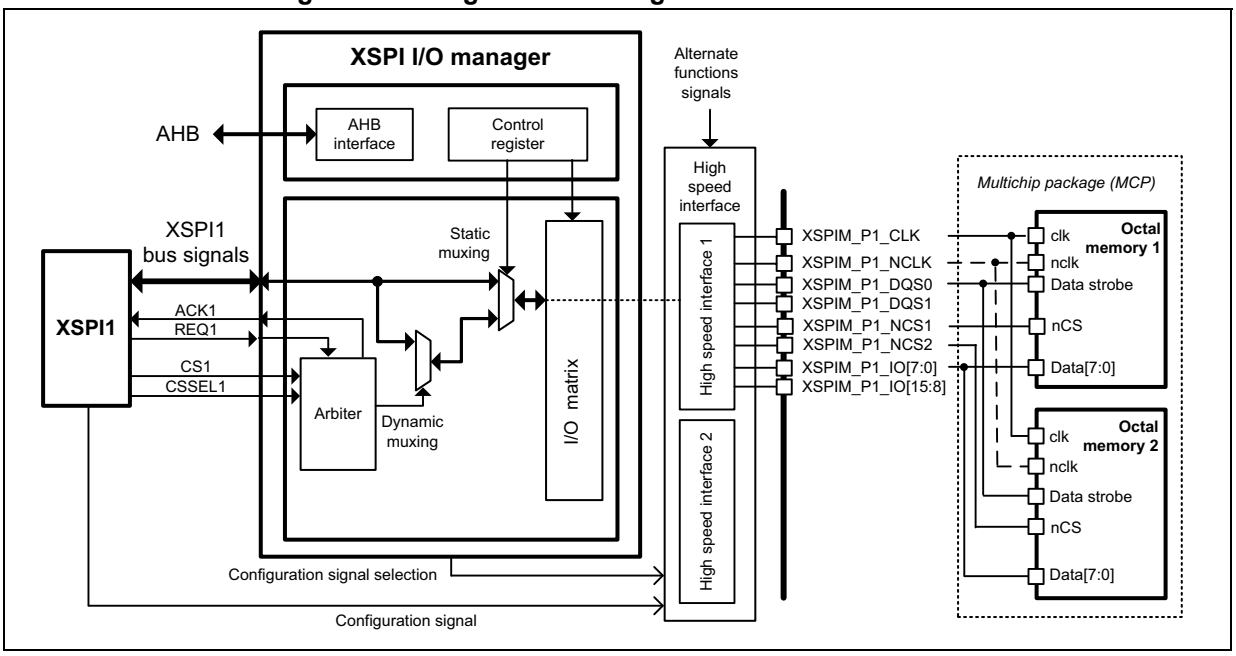
25.5.7 XSPI1 and XSPI2 drive a single external memory

This is similar to XSPIs multiplexed mode to Port 1, but in this case only one external memory is present. Both CSSEL controls must target the same NCS (NCS1 in *Figure 221*).

Figure 221. XSPI1 and XSPI2 drive a single external memory (octal mode)



This use case is valid even when Port 2 is used instead of Port 1, and also possible with XSPI1 and XSPI2 interfacing a 16-bit memory (connecting XSPIM_P1_DQS1 to the memory).

25.5.8 A single XSPI drives two external memories

This is a subset of direct mode and corresponds to semi-dynamic switching. There are two target memories, but the arbiter is not used. The software must set the XSPI1 chip selector (bit 24 of the XSPI_CR register) each time the target memory changes.

The baseline use case boots on flash (memory1) and then switches to SRAM (memory2) for the rest of the application.

Figure 222. Single XSPI driving two external memories

This use case is valid even when Port 2 is used instead of Port 1, and also with XSPI3 interfacing two 16-bit memories (connecting XSPIM_P1_DQS1 to the memory).

25.6 XSPIM registers

25.6.1 XSPIM control register (XSPIM_CR)

Address offset: 0x0000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	REQ2ACK_TIME[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSSEL_OVR_O2	CSSEL_OVR_O1	CSSEL_OVR_EN	Res.	Res.	MODE	MUXEN
									rw	rw	rw			rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REQ2ACK_TIME[7:0]**: REQ to ACK time
In Multiplexed mode (MUXEN = 1), this field defines the time between two transactions.
The value is the number of XSPI clock cycles - 1

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **CSSEL_OVR_O2**: Chip select selector override setting for XSPI2
0: the chip select signal from XSPI2 is sent to NCS1
1: the chip select signal from XSPI2 is sent to NCS2

Bit 5 **CSSEL_OVR_O1**: Chip select selector override setting for XSPI1
0: the chip select signal from XSPI1 is sent to NCS1
1: the chip select signal from XSPI1 is sent to NCS2

Bit 4 **CSSEL_OVR_EN**: Chip select selector override enable
0: override not enabled
1: CSSEL_OVR_O1 and CSSEL_OVR_O2 bit values overwrite the CSSEL signal values coming from XSPI1 and XSPI2

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **MODE**: XSPI multiplexing mode
0: if MUXEN = 0 direct mode, if MUXEN = 1 arbitration mode to output Port 1
1: if MUXEN = 0 swapped mode, if MUXEN = 1 arbitration mode to output Port 2

Bit 0 **MUXEN**: Multiplexed mode enable
This bit enables the multiplexing of the two XSPIs.
0: No multiplexing, hence no arbitration
1: XSPI1 and XSPI2 are multiplexed over the same bus

25.6.2 XSPIM register map

Table 219. XSPIM register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value									0	0	0	0	0	0	0	0										0	0	0			0	0

Refer to *Section 2.3 on page 150* for the register boundary addresses.

26 Delay block (DLYB)

26.1 Introduction

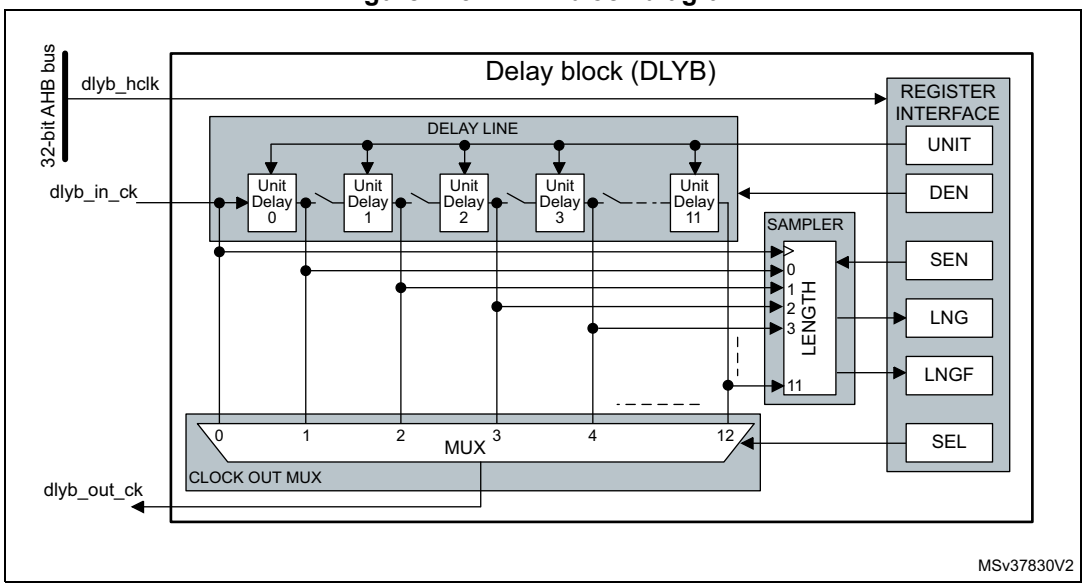
The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an SDMMC interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

26.2 DLYB main features

The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.



26.3 DLYB functional description

26.3.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 223. DLYB block diagram

26.3.2 DLYB pins and internal signals

Table 220 lists the DLYB internal signals.

Table 220. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

Table 221. DLYB interconnection

Signal name	Source/destination	
	SDMMC1	SDMMC2
dlyb_in_ck	sdmmc_io_in_ck	
dlyb_out_ck	sdmmc_fb_ck	

26.3.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 222. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don’t care	Don’t care	Don’t care	Don’t care	Enabled (= Input clock)

Table 222. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

26.3.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

26.3.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

SDMMC use case:

The delay block is used in conjunction with SDMMC interface variable delay. For correct sampling point tuning the delay value must cover a whole SDMMC_CK clock period. After having tuned the delay line length the individual delays are used in the sampling point tuning to find the optimal sampling point.

26.4 DLYB registers

All registers can be accessed in word, half-word and byte access.

26.4.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

26.4.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.

These bits can only be written when SEN = 1.

Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.

These bits can only be written when SEN = 1.

Output clock phase = input clock + SEL[3:0] x unit delay

27 Analog-to-digital converters (ADC1/2)

27.1 Introduction

This section describes the implementation of up to 2 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).

Each ADC consists of a 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 19 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned 16-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

27.2 ADC main features

- High-performance features
  - Up to 2 ADCs which can operate in dual mode:
    ADC1 is connected to 17 external channels and to 2 internal channels
    ADC2 is connected to 17 external channels and to 2 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Manage single-ended or differential inputs
  - AHB slave bus interface to allow fast data handling
  - Self-calibration
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Data can be routed to ADF interface for post processing
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (auto-delayed mode)
- Oversampler
  - 16-bit data register
  - Oversampling ratio adjustable from 2 to 256x
  - Programmable data shift up to 8 bits
- Data preconditioning
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC):

    Up to 6 fast channels from GPIO pads

    Up to 11 slow channels from GPIO pads
  - 1 channel for the internal temperature sensor (V_{SENSE})
  - 1 channel for the internal reference voltage (V_{REFINT})
  - 1 channel for monitoring the external VBAT power supply pin
  - 1 channel for monitoring the internal V_{DDCORE} supply
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timers events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC
  - Watchdog can perform filtering to ignore out-of-range data
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 224 shows the block diagram of one ADC.

27.4 ADC functional description

27.4.1 ADC block diagram

Figure 224 shows the ADC block diagram and *Table 227* gives the ADC pin description.

Figure 224. ADC block diagram

27.4.2 ADC pins and internal signals

Table 227. ADC input/output pins

Pin name	Signal type	Description
VDDA	Input, analog supply	Analog power supply and positive reference voltage for the ADC
VSSA	Input, analog supply ground	Ground for analog power supply, equal to V_{SS}.
VREF+	Input, analog reference positive	The higher/positive reference voltage for the ADC.
VREF−	Input, analog reference negative	The lower/negative reference voltage for the ADC. V_{REF-} is internally connected to V_{SSA}
ADC1/2_INNi/INPi	Negative/positive external analog input signals	19 negative/positive external analog input channels (refer to *Section 27.4.4: ADC connectivity* for details)

Table 228. ADC internal input/output signals

Internal signal name	Signal type	Description
$V_{INP}i$	Positive analog input channels	Positive internal analog input channels connected either to ADC1/2_INP*i* external channels or to internal channels.
$V_{INN}i$	Negative analog input channels	Negative internal analog input channels connected either to ADC1/2_INN*i* external channels or to internal channels
adc_ext_trgi	Inputs	ADC external trigger inputs for regular conversions.These inputs are shared between the ADC master and the ADC slave.
adc_jext_trgi	Inputs	ADC external trigger inputs for the injected conversions. These inputs are shared between the ADC master and the ADC slave.
adc_awdx	Output	Internal analog watchdog output signal connected to on-chip timers. (x = Analog watchdog number 1,2,3)
adc_ker_ck_input	Input	ADC kernel clock
adc_hclk	Input	ADC peripheral clock
adc_it	Output	ADC interrupt
adc_dma	Output	ADC DMA request
adc_dat[15:0]	Output	ADC data outputs

Table 229. ADC interconnection

Signal name	Source/destination
ADC1 V_{INP}[16]	V_{SENSE} (internal temperature sensor output voltage).
ADC1 V_{INP}[17]	V_{REFINT} (output voltage from internal reference voltage).
ADC2 V_{INP}[16]	V_{BAT}/4 (VBAT pin input voltage divided by 4).
ADC2 V_{INP}[17]	V_{DDCORE} (internal digital core voltage).

27.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC clock is independent from the AHB bus clock.

The ADC input clock can be selected between two different clock sources (see *Figure 225: ADC clock scheme*):

1. The ADC clock can be a specific clock source (adc_ker_ck_input), independent and asynchronous with the AHB clock.

   Refer to section *Reset and clock control (RCC)* for more information on how to generate the ADC dedicated clock. To select this scheme, CKMODE[1:0] bits of ADC_CCR register must be set to 00.

2. The ADC clock can be derived from the AHB clock interface divided by a programmable factor of 1, 2 or 4. To select this scheme, CKMODE[1:0] bits of ADC_CCR must be different from 00. The programmable divider factor can be configured through to CKMODE[1:0] bits of ADC_CCR.

   The prescaling factor of 1 (CKMODE[1:0] = 01) can be used only if the AHB prescaler is set to 1 (HPRE[3:0] = 0xxx in the RCC_CFGR register).

Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected. The ADC clock can eventually be divided by the following ratio: 1, 2, 4, 6, 8, 12, 16, 32, 64, 128, 256, using the prescaler configured with bits PRESC[3:0] in the ADC_CCR register.

Option **2** has the advantage of bypassing the clock domain resynchronizations. This can be useful when the ADC is triggered by a timer and if the application requires that the ADC is precisely triggered without any uncertainty (otherwise, an uncertainty of the trigger instant is added by the resynchronizations between the two clock domains).

The clock is configured through CKMODE[1:0] bits must be compliant with the operating frequency specified in the device datasheet.

Figure 225. ADC clock scheme

Clock ratio constraint between ADC clock and AHB clock

There are generally no constraints to be respected for the ratio between the ADC clock and the AHB clock except if some injected channels are programmed. In this case, it is mandatory to respect the following ratio:

- $F_{adc_hclk} \geq F_{ADC} / 4$ if the resolution of all channels are 12-bit or 10-bit
- $F_{adc_hclk} \geq F_{ADC} / 3$ if there are some channels with resolutions equal to 8-bit (and none with lower resolutions)
- $F_{adc_hclk} \geq F_{ADC} / 2$ if there are some channels with resolutions equal to 6-bit

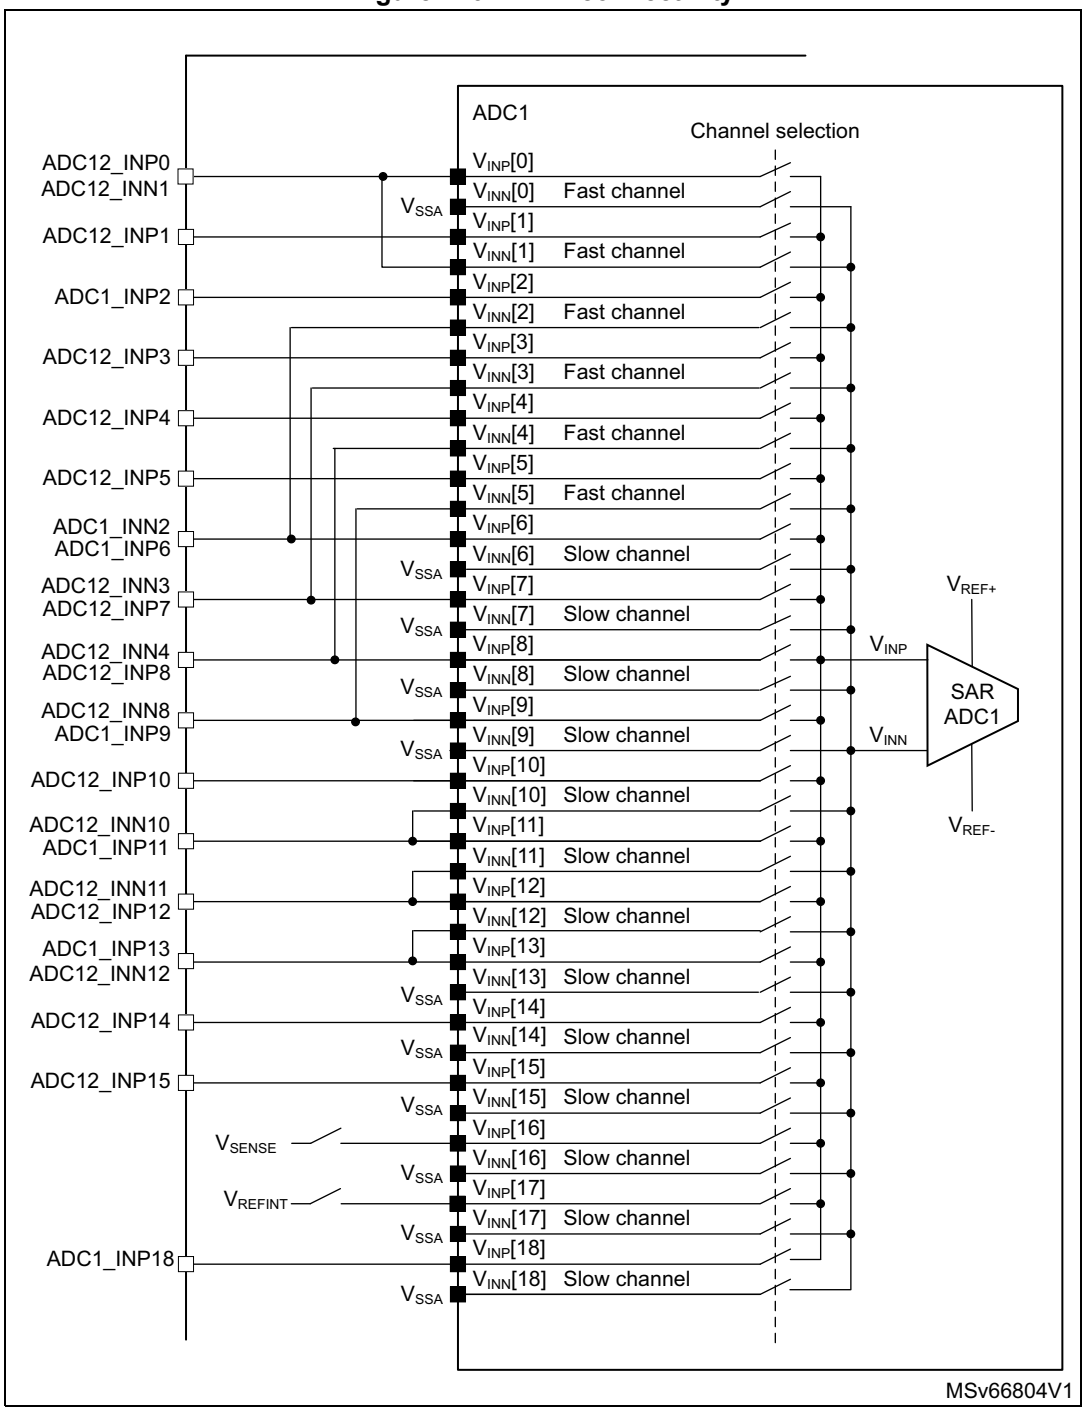
Constraints between ADC clocks

When several ADC interfaces are used simultaneously, it is mandatory to use the same clock source from the RCC block without prescaler ratio for all ADC interfaces.

27.4.4 ADC connectivity

ADC inputs are connected to the external channels as well as internal sources as described below.

Figure 226. ADC1 connectivity



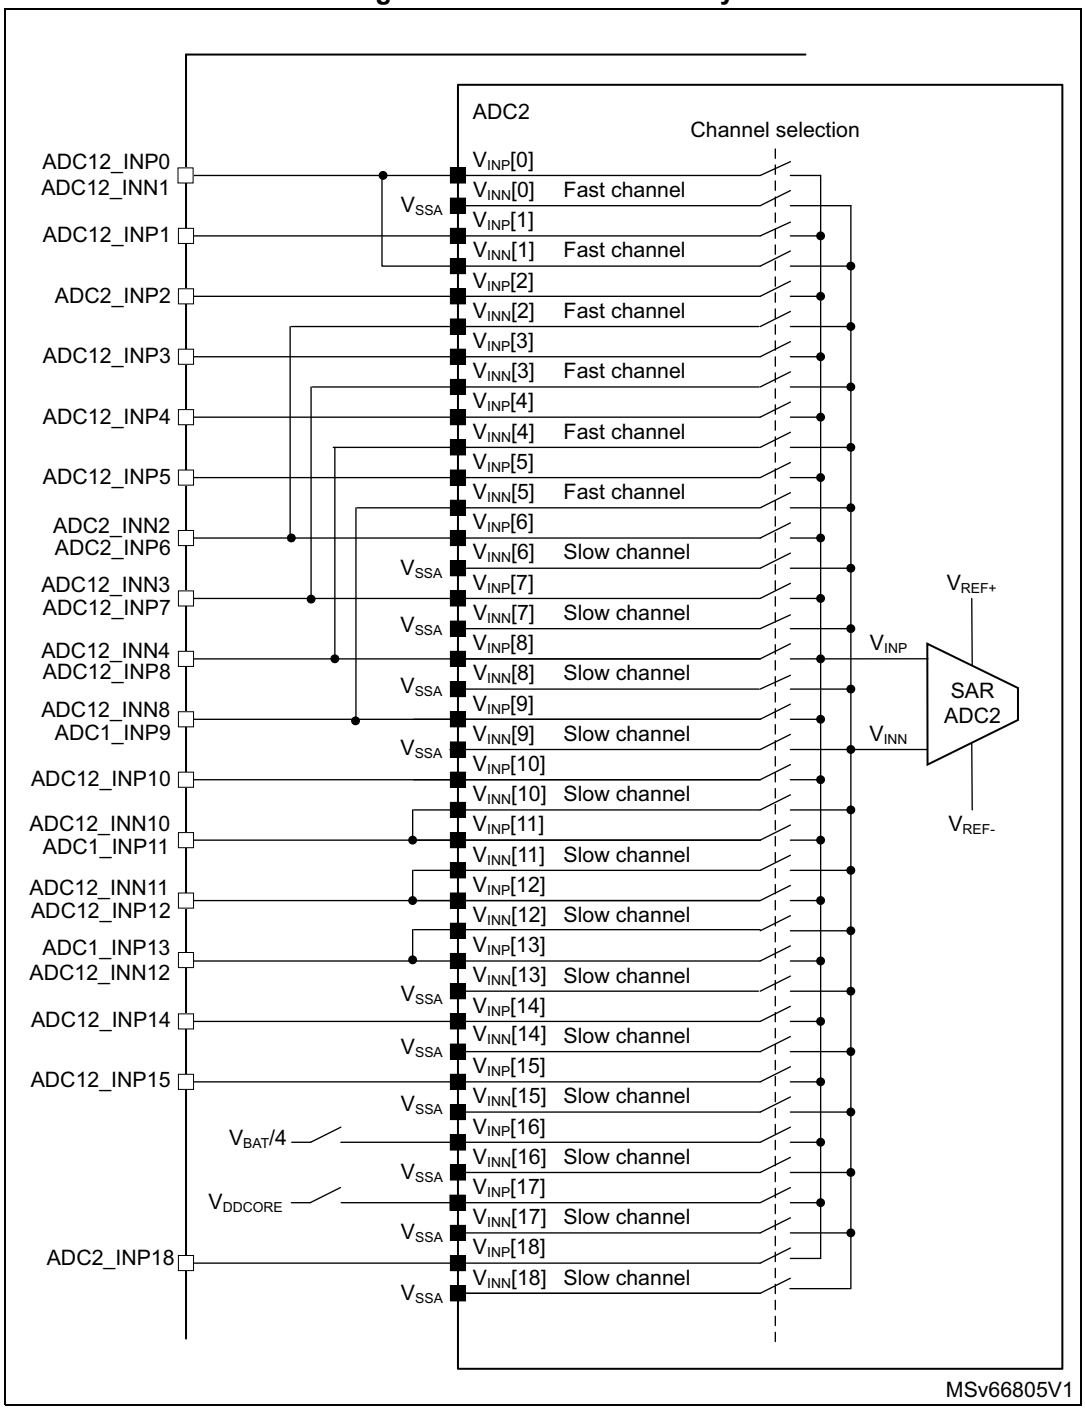


Figure 227. ADC2 connectivity

27.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word (32-bit) accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and never generates AHB errors.

27.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in Deep-power-down mode where its supply is internally switched off to reduce the leakage currents (the reset state of bit DEEPPWD is 1 in the ADC_CR register).

To start ADC operations, it is first needed to exit Deep-power-down mode by setting bit DEEPPWD = 0.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the bit ADVREGEN = 1 into ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software.

For the startup time of the ADC voltage regulator, refer to device datasheet for $T_{ADCVREG_STUP}$ parameter.

When ADC operations are complete, the ADC can be disabled (ADEN = 0). It is possible to save power by also disabling the ADC voltage regulator. This is done by writing bit ADVREGEN = 0.

Then, to save more power by reducing the leakage currents, it is also possible to re-enter in ADC Deep-power-down mode by setting bit DEEPPWD = 1 into ADC_CR register. This is particularly interesting before entering Stop mode.

Note: Writing DEEPPWD = 1 automatically disables the ADC voltage regulator and bit ADVREGEN is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN = 0), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or re-apply the calibration factor which was previously saved (refer to *Section 27.4.8: Calibration (ADCAL, ADCALDIF, ADC_CALFACT)*).

27.4.7 Single-ended and differential input channels

Channels can be configured to be either single-ended input or differential input by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be written while the ADC is disabled (ADEN = 0). Note that the DIFSEL[i] bits corresponding to single-ended channels are always programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and V_{REF-} (negative input).

In differential input mode, the analog voltage to be converted for channel “i” is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

The output data for the differential mode is an unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC_Full_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When ADC is configured as differential mode, both inputs should be biased at (V_{REF+}) /2 voltage.

The input signals are supposed to be differential (common mode voltage should be fixed).

Internal channels (such as V_{REFINT} and V_{SENSE}) are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to *Section 27.4.4: ADC connectivity*.

Caution: When configuring the channel “i” in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-ended mode or in differential mode and must never be configured to be converted. Some channels are shared between ADC1/ADC2: this can make the channel on the other ADC unusable. Only exception is interleaved mode for ADC master and the slave.

27.4.8 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure which drives all the calibration sequence including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor which is 7-bit wide and which is applied internally to the ADC until the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

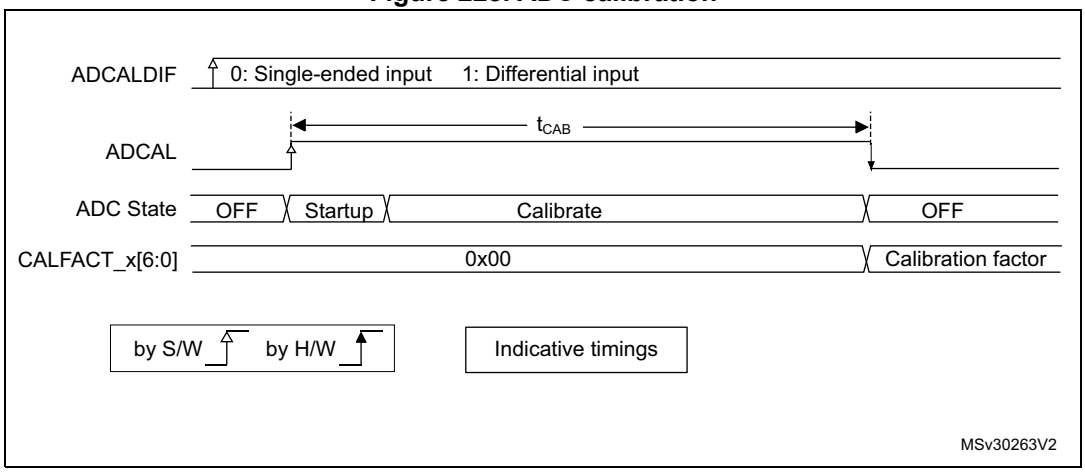
The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Write ADCALDIF = 0 before launching a calibration which is applied for single-ended input conversions.
- Write ADCALDIF = 1 before launching a calibration which is applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). ADCAL bit stays at 1 during all the

calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of ADC_CALFACT register (depending on single-ended or differential input calibration)

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before re-enabling the ADC.



The internal analog calibration is lost each time the power of the ADC is removed (example, when the product enters in Standby or V_{BAT} mode). In this case, to avoid spending time recalibrating the ADC, it is possible to re-write the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when V_{REF+} voltage changed more than 10%.

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by setting ADCALDIF = 0 (single-ended input) or ADCALDIF = 1 (differential input).
4. Set ADCAL = 1.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from ADC_CALFACT register.

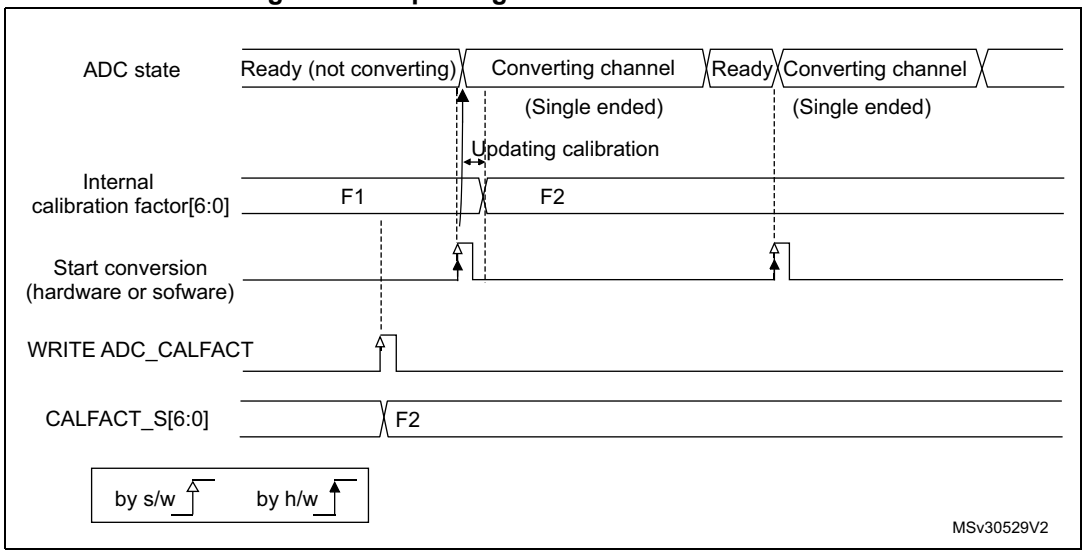


Figure 228. ADC calibration

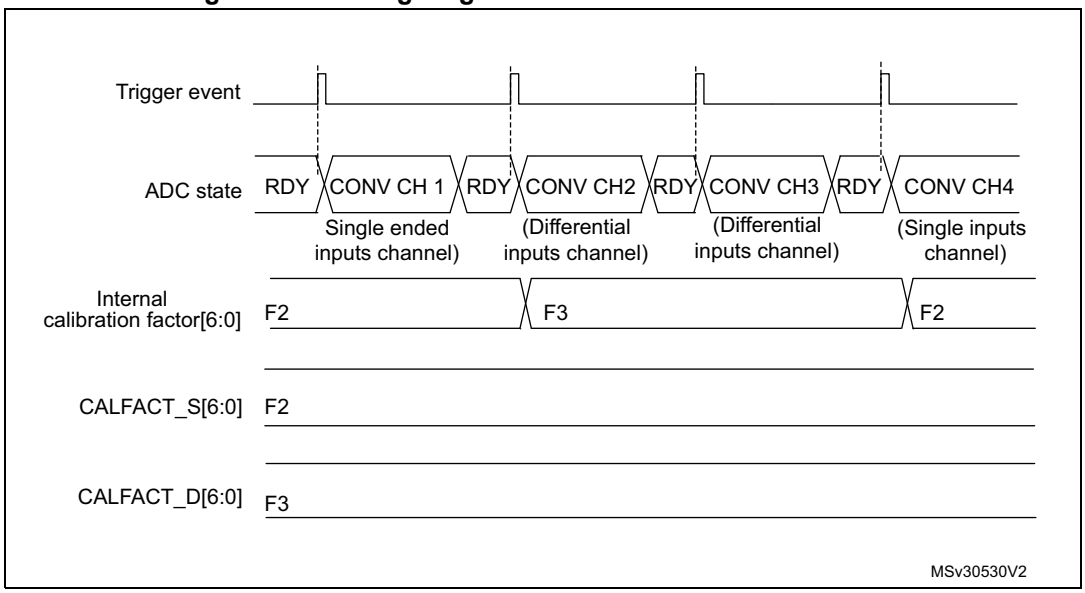
Software procedure to reinject a calibration factor into the ADC

1. Ensure ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Figure 229. Updating the ADC calibration factor



Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential inputs channel (and vice-versa), the calibration is automatically injected into the analog ADC.

Figure 230. Mixing single-ended and differential channels

27.4.9 ADC on-off control (ADEN, ADDIS, ADRDY)

First of all, follow the procedure explained in *Section 27.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

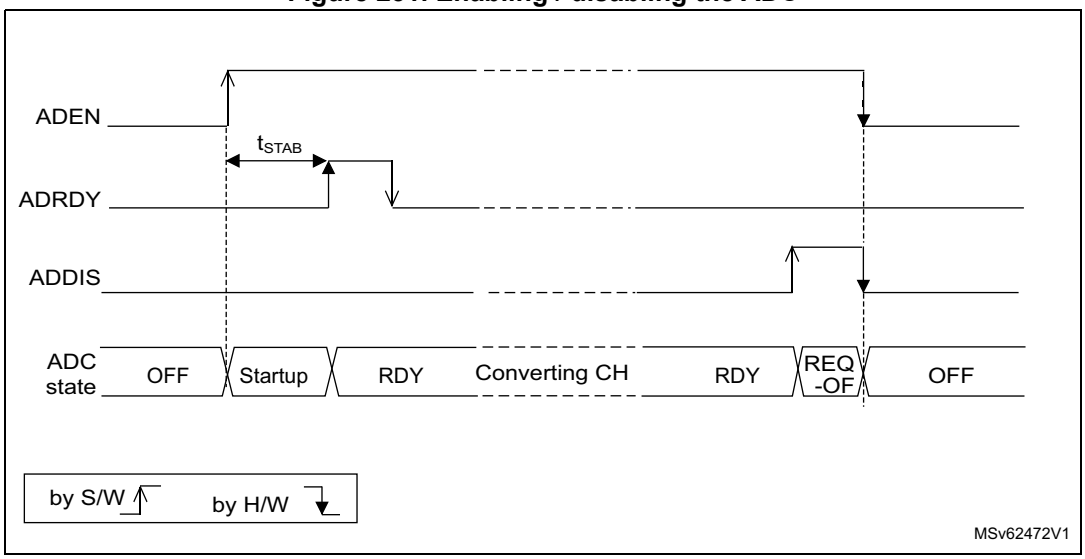
Once DEEPPWD = 0 and ADVREGEN = 1, the ADC can be enabled and the ADC needs a stabilization time of t_{STAB} before it starts converting accurately, as shown in *Figure 231*. Two control bits enable or disable the ADC:

- ADEN = 1 enables the ADC. The flag ADRDY is set once the ADC is ready for operation.
- ADDIS = 1 disables the ADC. ADEN and ADDIS are then automatically cleared by hardware as soon as the analog ADC is effectively disabled.

Regular conversion can then start either by setting ADSTART = 1 (refer to *Section 27.4.18: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)*) or when an external trigger event occurs, if triggers are enabled.

Injected conversions start by setting JADSTART = 1 or when an external injected trigger event occurs, if injected triggers are enabled.

Software procedure to enable the ADC



1. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’.
2. Set ADEN = 1.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done using the associated interrupt (setting ADRDYIE = 1).
4. Clear the ADRDY bit in the ADC_ISR register by writing ‘1’ (optional).

Caution: ADEN bit cannot be set when ADCAL is set and during four ADC clock cycles after the ADCAL bit is cleared by hardware (end of the calibration).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop any regular and injected conversion ongoing by setting ADSTP = 1 and JADSTP = 1 and then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS = 1.
3. If required by the application, wait until ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 231. Enabling / disabling the ADC

27.4.10 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC Section), the DIFSEL[i] control bits in the ADC_DIFSEL register and the control bits ADCAL and ADEN in the ADC_CR register, only if the ADC is disabled (ADEN must be equal to 0).

The software is then allowed to write the control bits ADSTART, JADSTART and ADDIS of the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

For all the other control bits of the ADC_CFGR, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no regular conversion ongoing (ADSTART must be equal to 0).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if the ADC is enabled (ADEN = 1) and if there is no injected conversion ongoing (JADSTART must be equal to 0).
- ADC_TRy registers can be modified when an analog-to-digital conversion is ongoing (refer to *Section 27.4.29: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)* for details).

The software is allowed to write the ADSTP or JADSTP control bits of the ADC_CR register only if the ADC is enabled, possibly converting, and if there is no pending request to disable the ADC (ADSTART or JADSTART must be equal to 1 and ADDIS to 0).

The software can write the register ADC_JSQR at any time, when the ADC is enabled (ADEN = 1). Refer to *Section 27.7.16: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: There is no hardware protection to prevent these forbidden write accesses and ADC behavior may become in an unknown state. To recover from this situation, the ADC must be disabled (clear ADEN = 0 as well as all the bits of ADC_CR register).

27.4.11 Channel selection (SQRx, JSQRx)

The ADC features up to 19 multiplexed channels per ADC, out of which:

- Up to 17 analog inputs coming from GPIO pads (ADC_INP/INN[i]) depending on the products, not all of them are available on GPIO pads.
- Up to 4 internal channels (refer to *Section 27.4.4: ADC connectivity* for details)

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming bits VREFEN, VBATEN or TSEN in the ADC_CCR registers.

Refer to *Table ADC interconnection* in *Section 27.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to external ADC pins or internal signals.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADC1/2_INP/INN3, ADC1/2_INP/INN8, ADC1/2_INP/INN2, ADC1/2_INN/INP2, ADC1/2_INP/INN0, ADC1/2_INP/INN2, ADC1/2_INP/INN2, ADC1/2_INP/INN15.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The total number of conversions in the regular group must be written in the L[3:0] bits in the ADC_SQR1 register.
- An **injected group** is composed of up to 4 conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the L[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while regular conversions can occur. For this, the ADC regular conversions must be first stopped by writing ADSTP = 1 (refer to *Section 27.4.17: Stopping an ongoing conversion (ADSTP, JADSTP)*).

The software is allowed to modify on-the-fly the ADC_JSQR register when JADSTART is set to 1 (injected conversions ongoing) only when the context queue is enabled (JQDIS = 0 in ADC_CFGR register). Refer to *Section 27.4.21: Queue of context for injected conversions*

27.4.12 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be enough for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time which is programmable using the SMP[2:0] bits in the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 6.5 ADC clock cycles
- SMP = 010: 12.5 ADC clock cycles
- SMP = 011: 24.5 ADC clock cycles
- SMP = 100: 47.5 ADC clock cycles
- SMP = 101: 92.5 ADC clock cycles
- SMP = 110: 247.5 ADC clock cycles
- SMP = 111: 640.5 ADC clock cycles

The total conversion time is calculated as follows:

T_{CONV} = Sampling time + 12.5 ADC clock cycles

Example:

With $F_{adc_ker_ck}$ = 30 MHz and a sampling time of 2.5 ADC clock cycles:

T_{CONV} = (2.5 + 12.5) ADC clock cycles = 15 ADC clock cycles = 500 ns

The ADC notifies the end of the sampling phase by setting the status bit EOSMP (only for regular conversion).

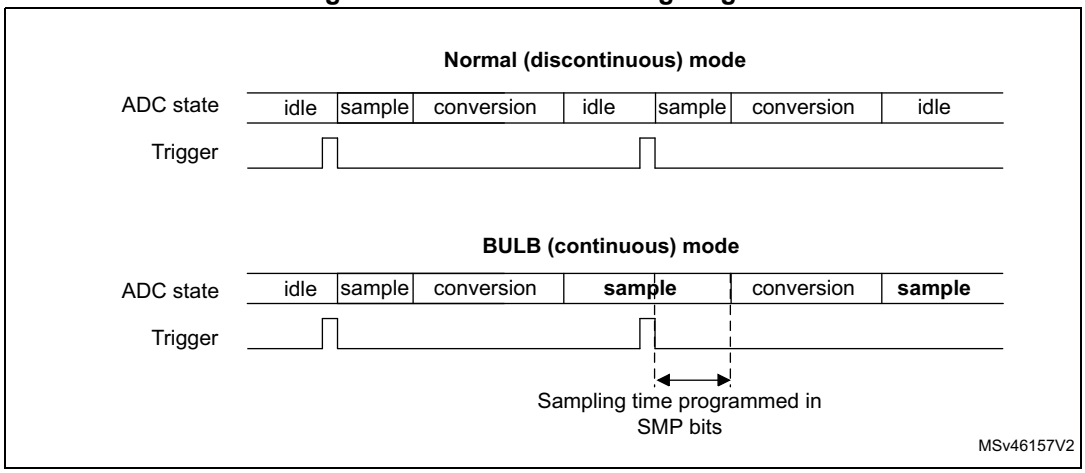
Note: Depending on the ADC conversion mode, the real sampling time can vary compared to the SMP value programmed above, while the equivalent total conversion time (T_{CONV}) does not change:

- *For the first conversion in scan or continuous mode and all the conversions in discontinuous mode, the real sampling time is 0.5 clock cycle less compared to the value configured above.*
- *For the second and subsequent conversions in scan or continuous mode, 0.5 cycle is added to the configured sampling time. This additional 0.5 clock cycle overlaps with the previous conversion cycle.*

Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum sampling time as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode



When the BULB bit is set in ADC register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPR1 register. The very first ADC conversion, after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

The bulb mode is neither compatible with the continuous conversion mode nor with the injected channel conversion.

When the BULB bit is set, it is not allowed to set SMPTRIG bit in ADC_CFGR2.

Figure 232. Bulb mode timing diagram

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed though SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected, each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

When a software trigger is selected, the software trigger is not the ADSTART bit in ADC_CR but the SWTRIG bit. SWTRIG bit has to be set to start the sampling period, and the SWTRIG bit has to be cleared to end the sampling period and start the conversion.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is neither compatible with the continuous conversion mode, nor with the injected channel conversion.

When SMPTRIG bit is set, it is not allowed to set BULB bit.

I/O analog switch voltage booster

The resistance of the I/O analog switches increases when the V_{DDA} voltage is too low. The sampling time must consequently be adapted accordingly (refer to the device datasheet for the corresponding electrical characteristics). This resistance can be minimized at low V_{DDA}

by enabling an internal voltage booster through BOOSTE bit or by selecting a V_{DD} booster voltage (if V_{DD} > 2.7 V) through the ADV_READY bit of the PWR_PMCR register.

SMPPLUS control bit

The SMPPLUS bit can be used to change the sampling time from 2.5 ADC clock cycles to 3.5 ADC clock cycles.

27.4.13 Single conversion mode (CONT = 0)

In single conversion mode, the ADC performs once all the conversions of the channels. This mode is started with the CONT bit at 0 by either:

- Setting the ADSTART bit in the ADC_CR register (for a regular channel)
- Setting the JADSTART bit in the ADC_CR register (for an injected channel)
- External hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of regular conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 16-bit ADC_JDRy registers
- The JEOC (end of injected conversion) flag is set
- An interrupt is generated if the JEOCIE bit is set

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set
- An interrupt is generated if the JEOSIE bit is set

Then the ADC stops until a new external regular or injected trigger occurs or until bit ADSTART or JADSTART is set again.

Note: To convert a single channel, program a sequence with a length of 1.

27.4.14 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts each conversions of the sequence. This mode is started with the CONT bit at 1 either by external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 16-bit ADC_DR register
- The EOC (end of conversion) flag is set
- An interrupt is generated if the EOCIE bit is set

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set
- An interrupt is generated if the EOSIE bit is set

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled: it is forbidden to set both DISCEN = 1 and CONT = 1.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit), refer to Auto-injection mode section).

27.4.15 Starting conversions (ADSTART, JADSTART)

Software starts ADC regular conversions by setting ADSTART = 1.

When ADSTART is set, the conversion starts:

- Immediately: if EXTEN = 0x0 (software trigger)
- At the next active edge of the selected regular hardware trigger: if EXTEN is not equal to 0x0

Software starts ADC injected conversions by setting JADSTART = 1.

When JADSTART is set, the conversion starts:

- Immediately, if JEXTEN = 0x0 (software trigger)
- At the next active edge of the selected injected hardware trigger: if JEXTEN is not equal to 0x0

Note: In auto-injection mode (JAUTO = 1), use ADSTART bit to start the regular conversions followed by the auto-injected conversions (JADSTART must be kept cleared).

ADSTART and JADSTART also provide information on whether any ADC operation is currently ongoing. It is possible to re-configure the ADC while ADSTART = 0 and JADSTART = 0 are both true, indicating that the ADC is idle.

ADSTART is cleared by hardware:

- In single mode with software regular trigger (CONT = 0, EXTSEL = 0x0)
  - At any end of regular conversion sequence (EOS assertion) or at any end of subgroup processing if DISCEN = 1
- In all cases (CONT = x, EXTSEL = x)
  - After execution of the ADSTP procedure asserted by the software.

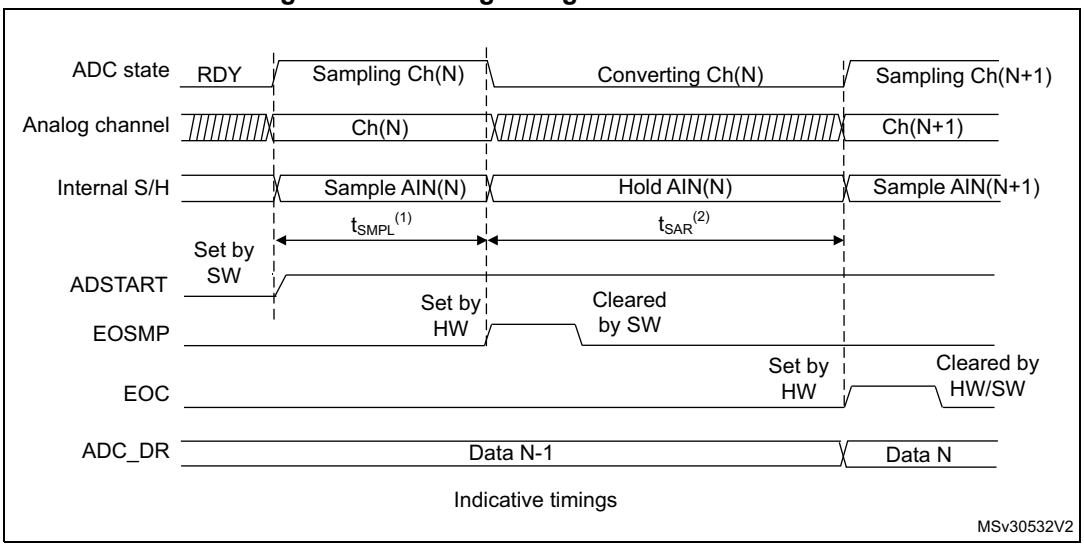
Note: In continuous mode (CONT = 1), ADSTART is not cleared by hardware with the assertion of EOS because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTSEL # 0x00), ADSTART is not cleared by hardware with the assertion of EOS to help the software which does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

JADSTART is cleared by hardware:

- In single mode with software injected trigger (JEXTSEL = 0x0)
  - At any end of injected conversion sequence (JEOS assertion) or at any end of subgroup processing if JDISCEN = 1
- in all cases (JEXTSEL = x)
  - After execution of the JADSTP procedure asserted by the software.

Note: When the software trigger is selected, ADSTART bit should not be set if the EOC flag is still high.



27.4.16 ADC timing

The elapsed time between the start of a conversion and the end of conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [2.5\ _{|min} + 12.5\ _{|12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 83.33\ ns\ _{|min} + 416.67\ ns\ _{|12bit} = 500.0\ ns$ (for $F_{ADC_CLK} = 30$ MHz)

Figure 233. Analog-to-digital conversion time

1. T_{SMPL} depends on SMP[2:0].
2. T_{SAR} depends on RES[2:0].

27.4.17 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop regular conversions ongoing by setting ADSTP = 1 and injected conversions ongoing by setting JADSTP = 1.

Stopping conversions resets the ongoing ADC operation. Then the ADC can be reconfigured (ex: changing the channel selection or the trigger) ready for a new operation.

Note that it is possible to stop injected conversions while regular conversions are still operating and vice-versa. This allows, for instance, re-configuration of the injected conversion sequence and triggers while regular conversions are still operating (and vice-versa).

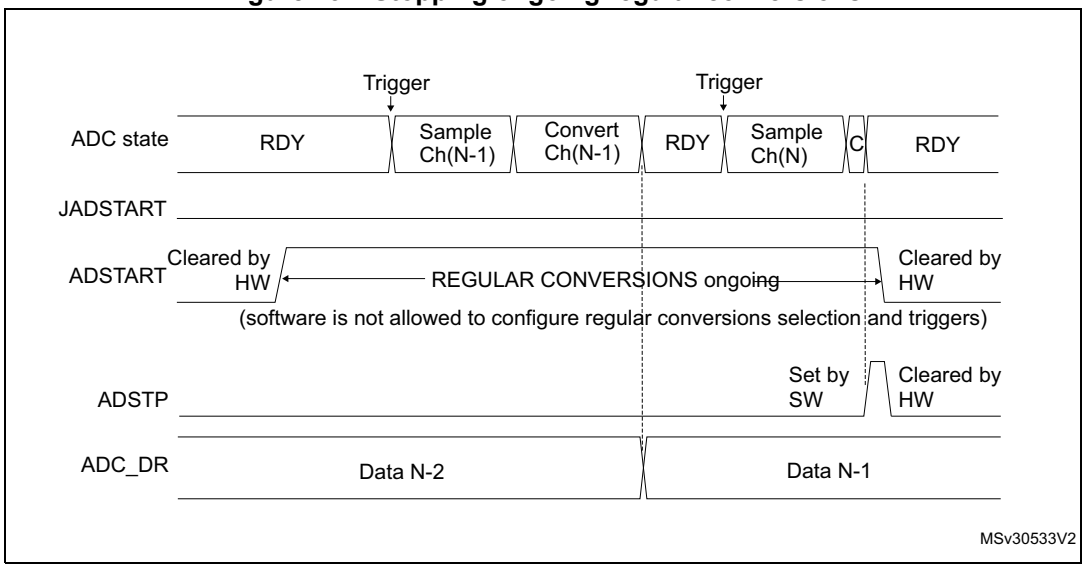
When the ADSTP bit is set by software, any ongoing regular conversion is aborted with partial result discarded (ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC would restart a new sequence).

Once this procedure is complete, bits ADSTP/ADSTART (in case of regular conversion), or JADSTP/JADSTART (in case of injected conversion) are cleared by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In auto-injection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 234. Stopping ongoing regular conversions



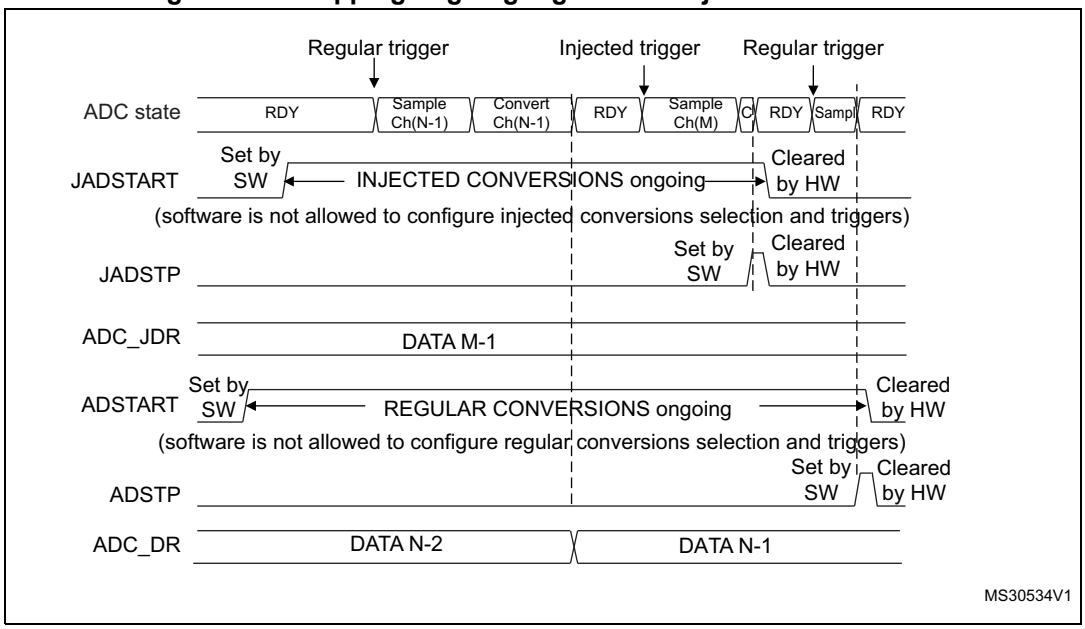


Figure 235. Stopping ongoing regular and injected conversions

27.4.18 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN,JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (such as timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

When the Injected Queue is enabled (bit JQDIS = 0), injected software triggers are not possible.

The regular trigger selection is effective once software has set bit ADSTART = 1 and the injected trigger selection is effective once software has set bit JADSTART = 1.

Any hardware triggers which occur while a conversion is ongoing are ignored.

- If bit ADSTART = 0, any regular hardware triggers which occur are ignored.
- If bit JADSTART = 0, any injected hardware triggers which occur are ignored.

Table 230 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

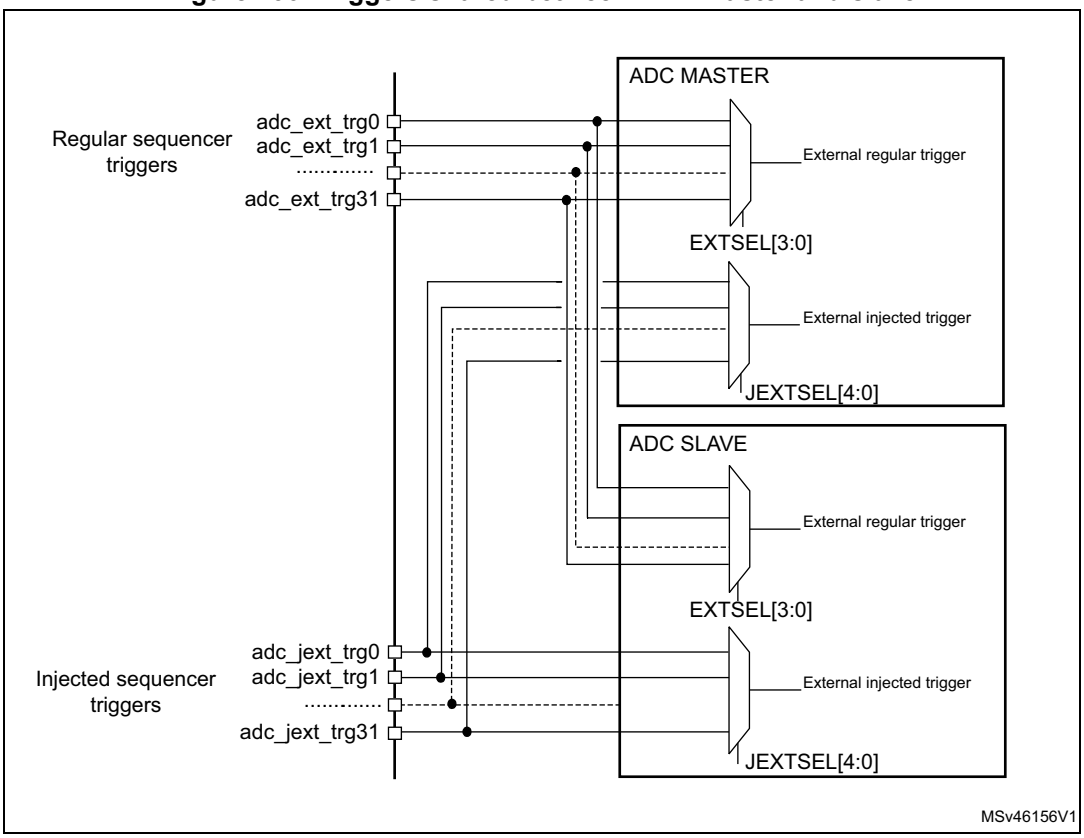
Table 230. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

Table 231. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	– If JQDIS = 1 (Queue disabled): Hardware trigger detection disabled, software trigger detection enabled – If JQDIS = 0 (Queue enabled), Hardware and software trigger detection disabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges



Note: The polarity of the injected trigger can be anticipated and changed on-the-fly when the queue is enabled (JQDIS = 0). Refer to Section 27.4.21: Queue of context for injected conversions.

The EXTSEL and JEXTSEL control bits select which out of 32 possible events can trigger conversion for the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Note: The regular trigger selection cannot be changed on-the-fly. The injected trigger selection can be anticipated and changed on-the-fly. Refer to Section 27.4.21: Queue of context for injected conversions on page 1106.

Figure 236. Triggers shared between ADC master and slave

Refer to Table ADC interconnection in *Section 27.4.2: ADC pins and internal signals* for the list of all the external triggers that can be used for regular conversion.

27.4.19 Injected channel management

Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR register must be cleared.

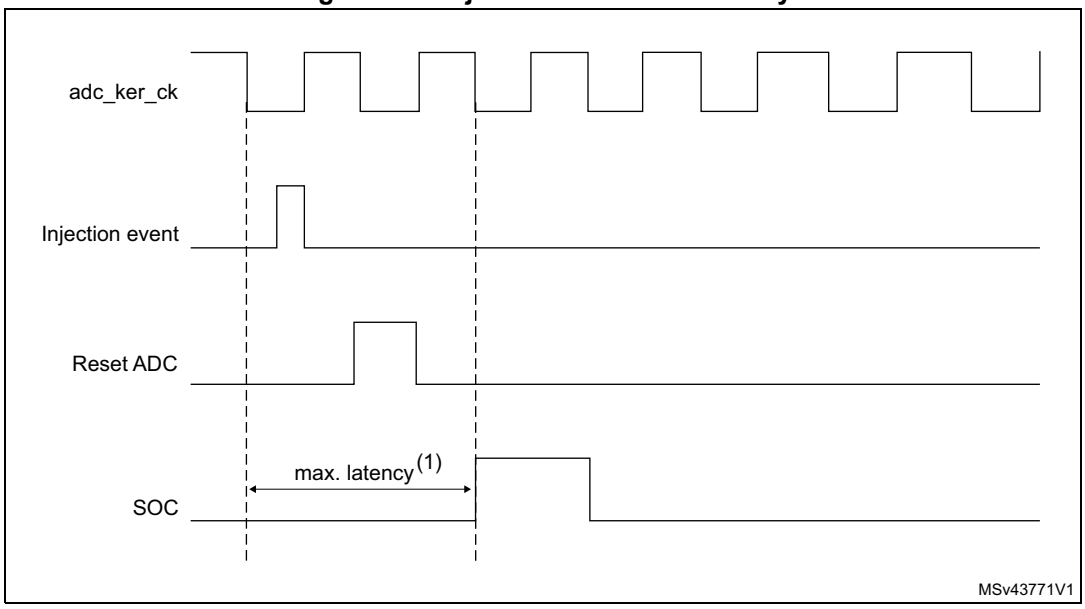
1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 237* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence. For instance, if the sequence length is 30 ADC clock cycles (that is two conversions with a sampling time of 2.5 clock periods), the minimum interval between triggers must be 31 ADC clock cycles.

Auto-injection mode

If the JAUTO bit in the ADC_CFGR register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).



In this mode, external trigger on injected channels must be disabled.

If the CONT bit is also set in addition to the JAUTO bit, regular channels followed by injected channels are continuously converted.

Note: It is not possible to use both the auto-injected and discontinuous modes simultaneously.

When the DMA is used for exporting regular sequencer's data in JAUTO mode, it is necessary to program it in circular mode (CIRC bit set in DMA_CCRx register). If the CIRC bit is reset (single-shot mode), the JAUTO sequence is stopped upon DMA Transfer Complete event.

Figure 237. Injected conversion latency

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

27.4.20 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN bit in the ADC_CFGR register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the L[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11
  - 1st trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - 2nd trigger: channels converted are 6, 7, 8 (an EOC event is generated at each conversion).
  - 3rd trigger: channels converted are 9, 10, 11 (an EOC event is generated at each conversion) and an EOS event is generated after the conversion of channel 11.
  - 4th trigger: channels converted are 1, 2, 3 (an EOC event is generated at each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - 1st trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the 4th trigger reconverts the channels 1, 2 and 3 in the 1st subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels where ‘n’ is fixed to 1.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JL[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - 1st trigger: channel 1 converted (a JEOC event is generated)
  - 2nd trigger: channel 2 converted (a JEOC event is generated)
  - 3rd trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all microcontrollers.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the 4th trigger reconverts the 1st injected channel 1.

It is not possible to use both auto-injected mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

27.4.21 Queue of context for injected conversions

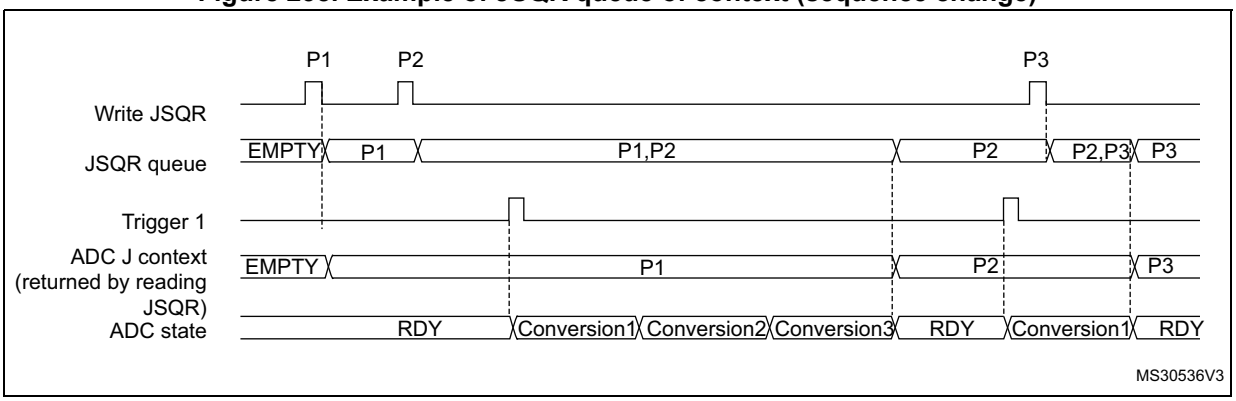
A queue of context is implemented to anticipate up to 2 contexts for the next injected sequence of conversions. JQDIS bit of ADC_CFGR register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled.

This context consists of:

- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JL[1:0] in ADC_JSQR register)

All the parameters of the context are defined into a single register ADC_JSQR and this register implements a queue of 2 buffers, allowing the bufferization of up to 2 sets of parameters:

- The JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written into the JSQR register is stored into the Queue of context.
- At the beginning, the Queue is empty and the first write access into the JSQR register immediately changes the context and the ADC is ready to receive injected triggers.
- Once an injected sequence is complete, the Queue is consumed and the context changes according to the next JSQR parameters stored in the Queue. This new context is applied for the next injected sequence of conversions.
- A Queue overflow occurs when writing into register JSQR while the Queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two possible behaviors are possible when the Queue becomes empty, depending on the value of the control bit JQM of register ADC_CFGR:
  - If JQM = 0, the Queue is empty just after enabling the ADC, but then it can never be empty during run operations: the Queue always maintains the last active context and any further valid start of injected sequence is served according to the last active context.
  - If JQM = 1, the Queue can be empty after the end of an injected sequence or if the Queue is flushed. When this occurs, there is no more context in the queue and hardware triggers are disabled. Therefore, any further hardware injected triggers are ignored until the software re-writes a new injected context into JSQR register.
- Reading JSQR register returns the current JSQR context which is active at that moment. When the JSQR context is empty, JSQR is read as 0x0000.
- The Queue is flushed when stopping injected conversions by setting JADSTP = 1 or when disabling the ADC by setting ADDIS = 1:
  - If JQM = 0, the Queue is maintained with the last active context.
  - If JQM = 1, the Queue becomes empty and triggers are ignored.



Note: When configured in discontinuous mode (bit JDISCEN = 1), only the last trigger of the injected sequence changes the context and consumes the Queue.The 1st trigger only consumes the queue but others are still valid triggers as shown by the discontinuous mode example below (length = 3 for both contexts):

- *1st trigger, discontinuous. Sequence 1: context 1 consumed, 1st conversion carried out*
- *2nd trigger, disc. Sequence 1: 2nd conversion.*
- *3rd trigger, discontinuous. Sequence 1: 3rd conversion.*
- *4th trigger, discontinuous. Sequence 2: context 2 consumed, 1st conversion carried out.*
- *5th trigger, discontinuous. Sequence 2: 2nd conversion.*
- *6th trigger, discontinuous. Sequence 2: 3rd conversion.*

Behavior when changing the trigger or sequence context

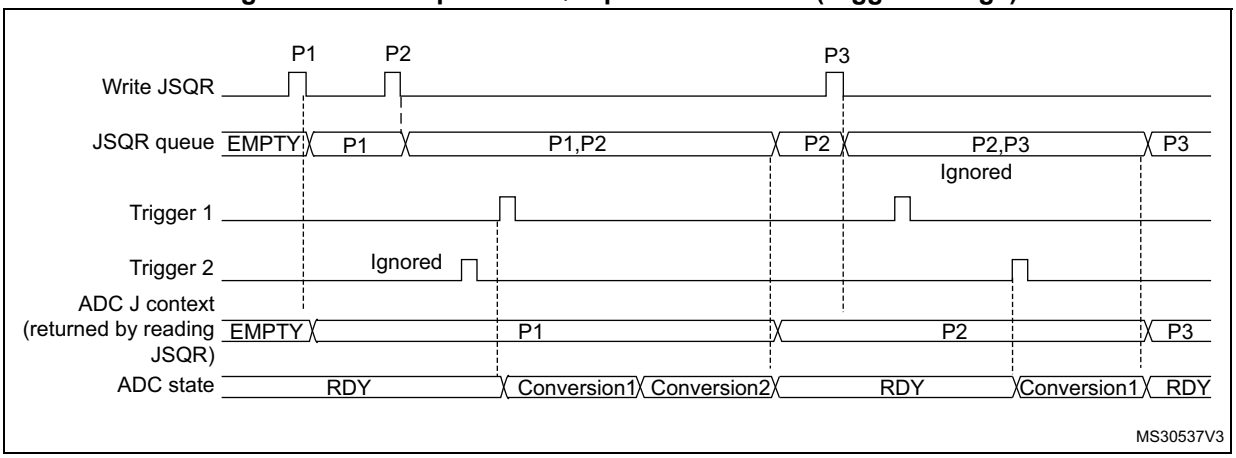


Figure 238 and *Figure 239* show the behavior of the context Queue when changing the sequence or the triggers.

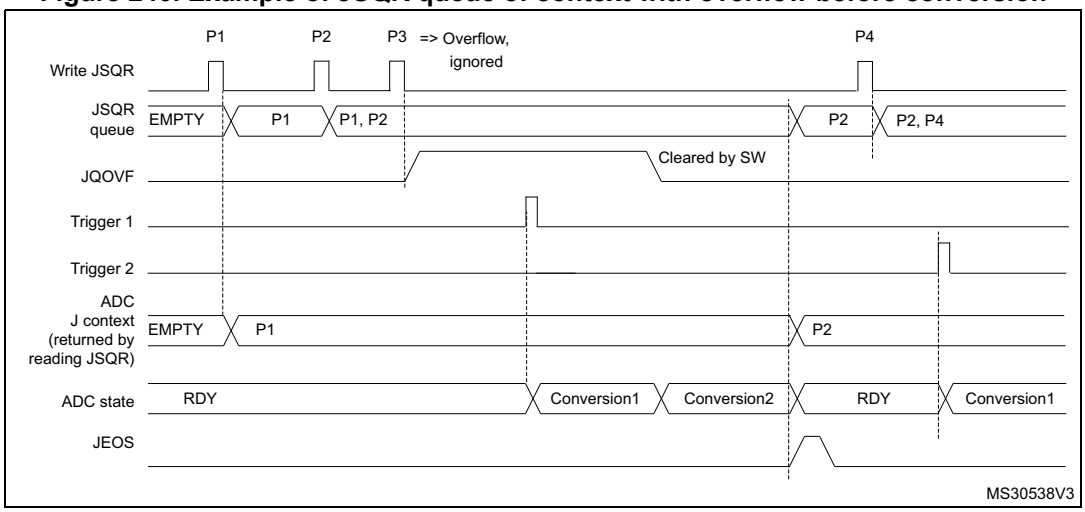
Figure 238. Example of JSQR queue of context (sequence change)

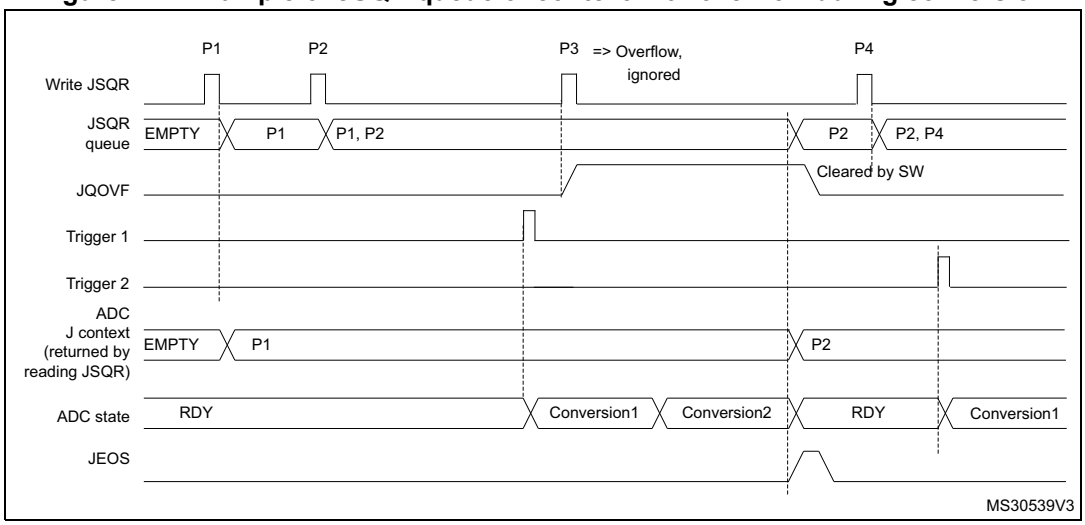
1. Parameters:
   P1: sequence of 3 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 4 conversions, hardware trigger 1

Figure 239. Example of JSQR queue of context (trigger change)



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs



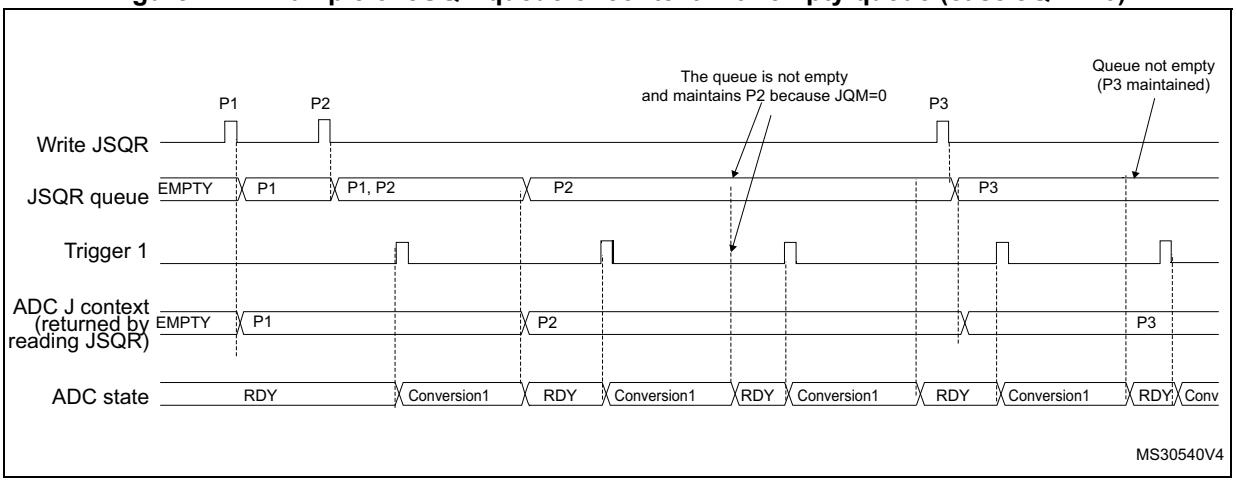
The *Figure 240* and *Figure 241* show the behavior of the context Queue if an overflow occurs before or during a conversion.

Figure 240. Example of JSQR queue of context with overflow before conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

Figure 241. Example of JSQR queue of context with overflow during conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1



It is recommended to manage the queue overflows as described below:

- After each P context write into JSQR register, flag JQOVF shows if the write has been ignored or not (an interrupt can be generated).
- Avoid Queue overflows by writing the third context (P3) only once the flag JEOS of the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 242 and *Figure 243* show the behavior of the context Queue when the Queue becomes empty in both cases JQM = 0 or 1.

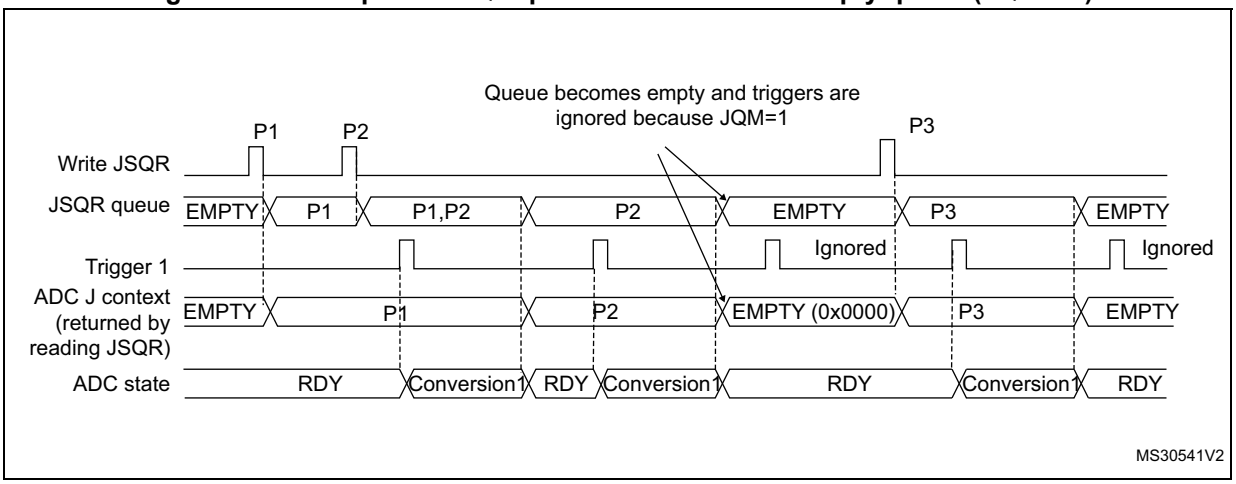


Figure 242. Example of JSQR queue of context with empty queue (case JQM = 0)

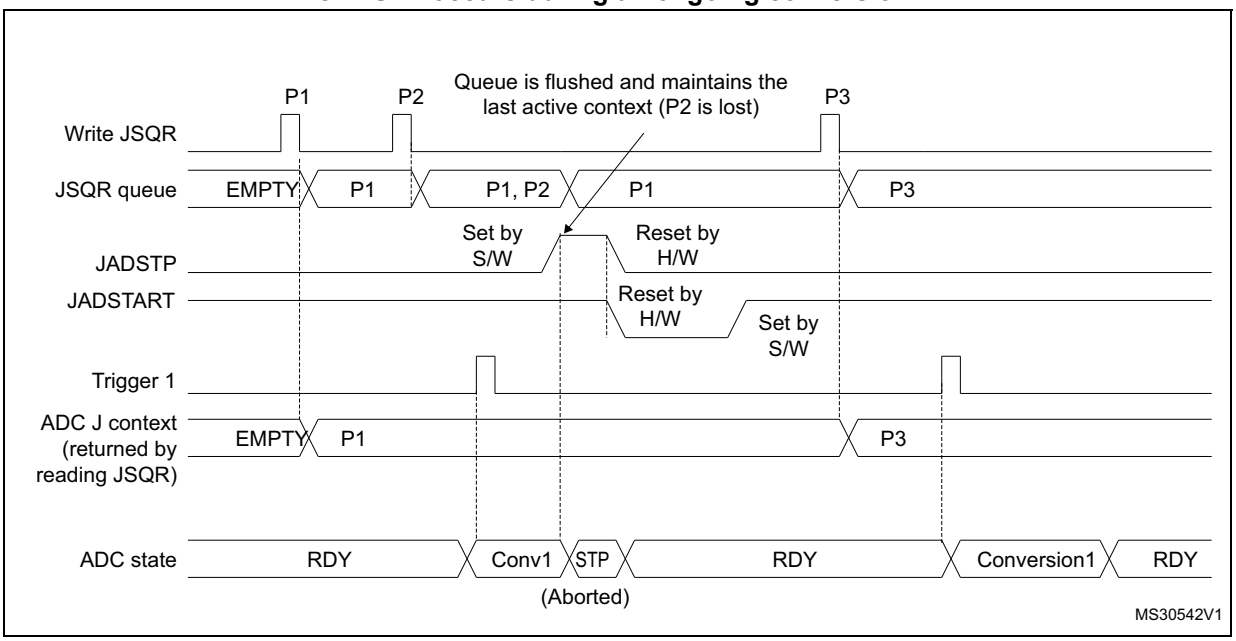
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

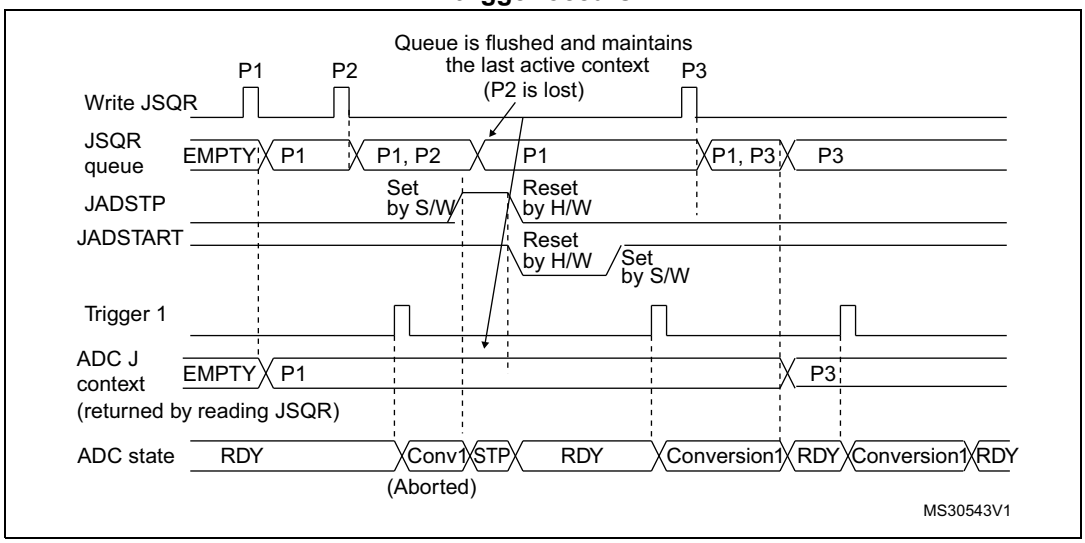
Note: When writing P3, the context changes immediately. However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately.

Figure 243. Example of JSQR queue of context with empty queue (JQM = 1)



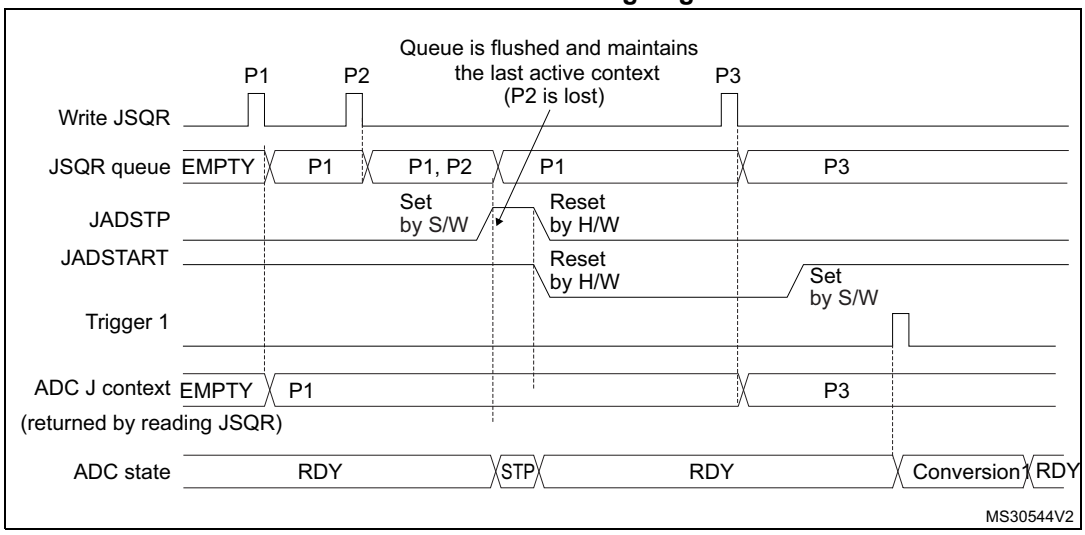
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Flushing the queue of context



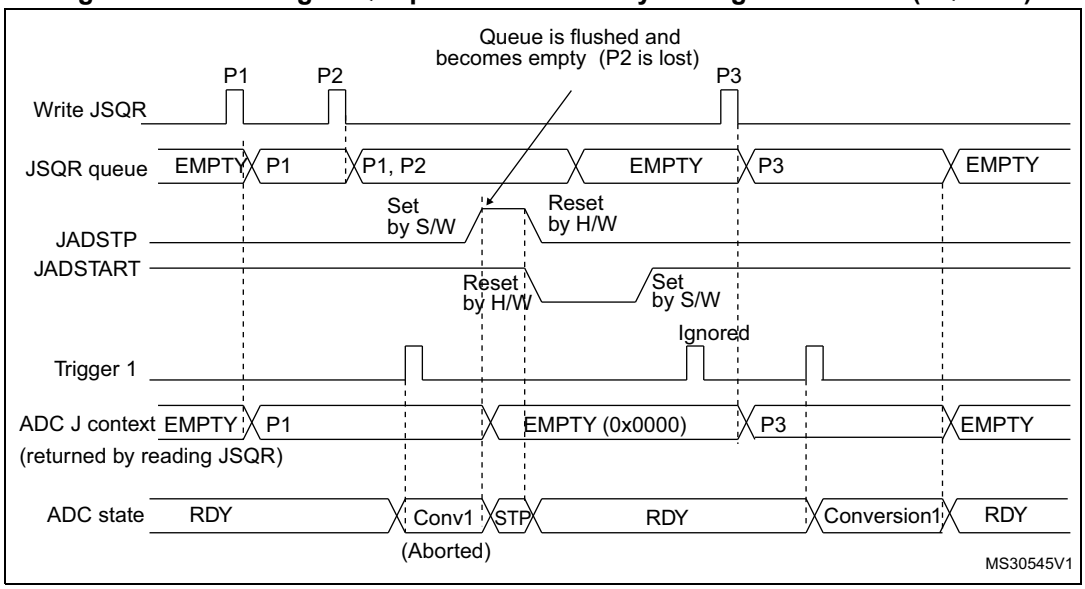
The figures below show the behavior of the context Queue in various situations when the queue is flushed.

Figure 244. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.



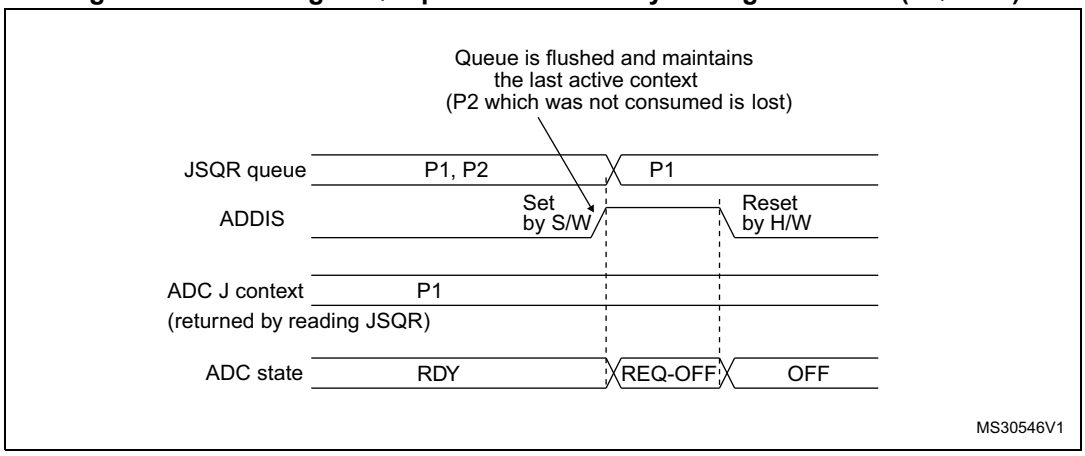
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 245. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs



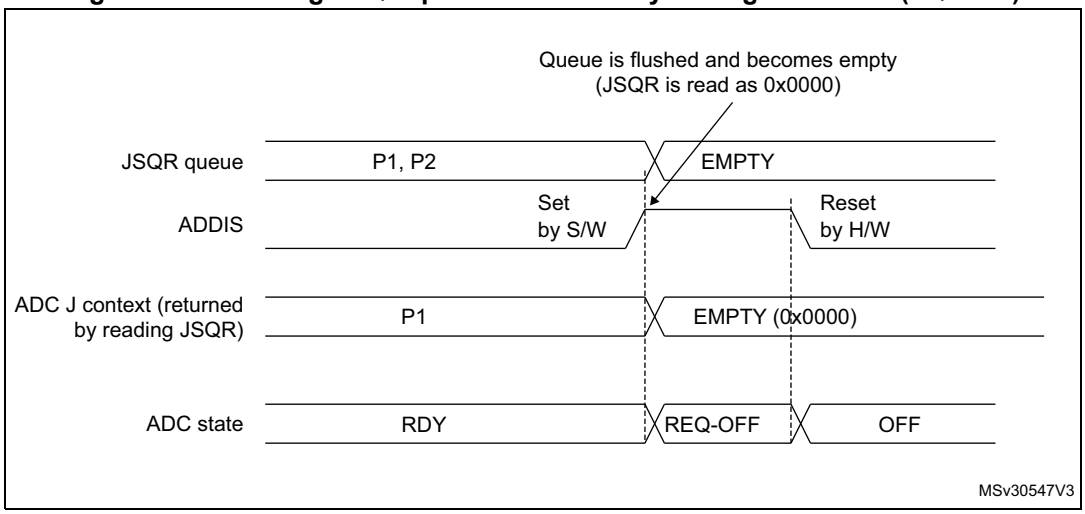
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 246. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 247. Flushing JSQR queue of context by setting JADSTP = 1 (JQM = 1)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 248. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 0)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 249. Flushing JSQR queue of context by setting ADDIS = 1 (JQM = 1)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Starting the ADC with an empty queue

The following procedure must be followed to start ADC operation with an empty queue, in case the first context is not known at the time the ADC is initialized. This procedure is only applicable when JQM bit is reset:

5. Write a dummy JSQR with JEXTEN not equal to 0 (otherwise triggering a software conversion)
6. Set JADSTART
7. Set JADSTP
8. Wait until JADSTART is reset
9. Set JADSTART.

Disabling the queue

It is possible to disable the queue by setting bit JQDIS = 1 into the ADC_CFGR register.

27.4.22 Programmable resolution (RES) - fast conversion mode

It is possible to perform faster conversion by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the control bits RES[1:0]. *Figure 254*, *Figure 255*, *Figure 256* and *Figure 257* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 232*.

Table 232. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at F_{ADC} = 30 MHz	T_{CONV} (ADC clock cycles) (with Sampling Time = 2.5 ADC clock cycles)	T_{CONV} (ns) at F_{ADC} = 30 MHz
12	12.5 ADC clock cycles	416.67 ns	15 ADC clock cycles	500.0 ns
10	10.5 ADC clock cycles	350.0 ns	13 ADC clock cycles	433.33 ns
8	8.5 ADC clock cycles	203.33 ns	11 ADC clock cycles	366.67 ns
6	6.5 ADC clock cycles	216.67 ns	9 ADC clock cycles	300.0 ns

27.4.23 End of conversion, end of sampling phase (EOC, JEOC, EOSMP)

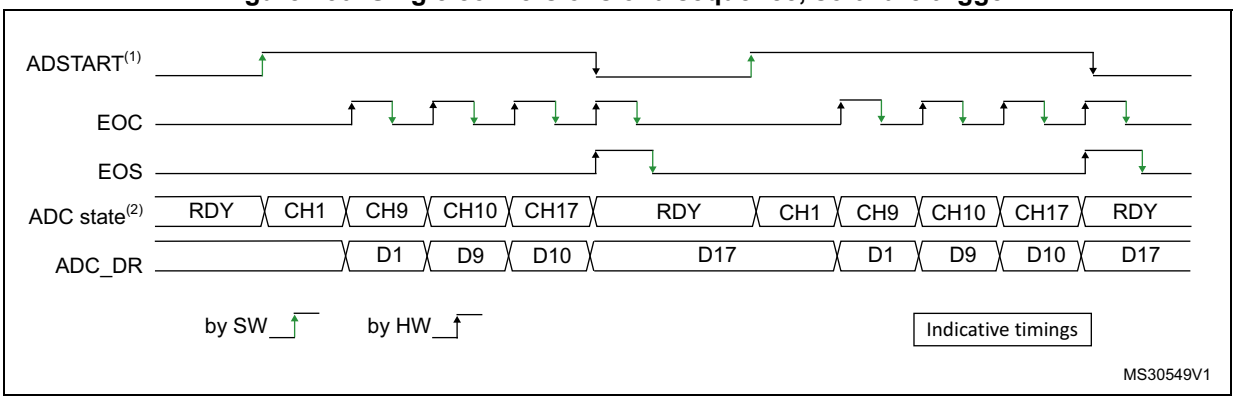
The ADC notifies the application for each end of regular conversion (EOC) event and each injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if bit EOCIE is set. EOC flag is cleared by the software either by writing 1 to it or by reading ADC_DR.

The ADC sets the JEOC flag as soon as a new injected conversion data is available in one of the ADC_JDRy register. An interrupt can be generated if bit JEOCIE is set. JEOC flag is cleared by the software either by writing 1 to it or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of Sampling phase by setting the status bit EOSMP (for regular conversions only). EOSMP flag is cleared by software by writing 1 to it. An interrupt can be generated if bit EOSMPIE is set.

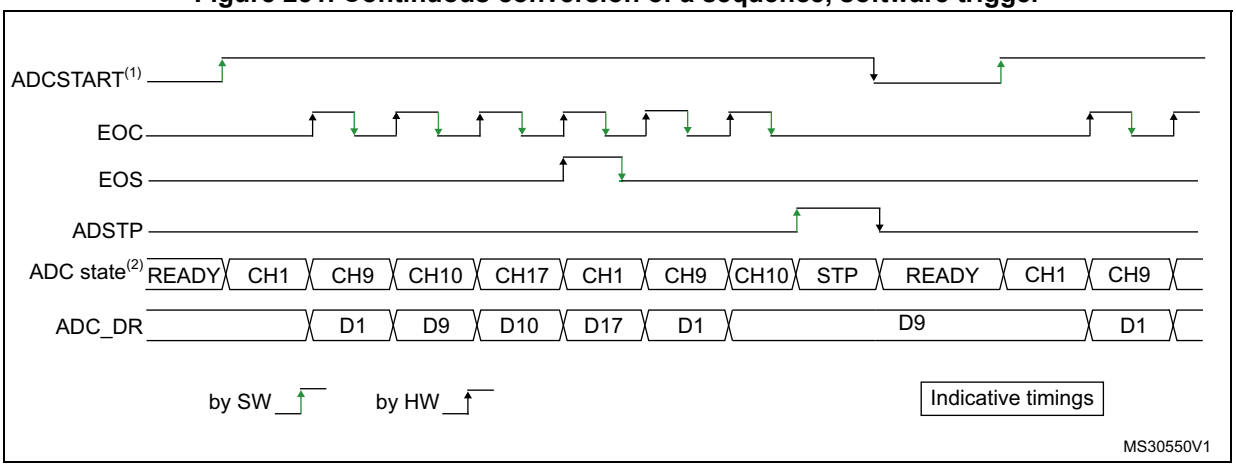
27.4.24 End of conversion sequence (EOS, JEOS)



The ADC notifies the application for each end of regular sequence (EOS) and for each end of injected sequence (JEOS) event.

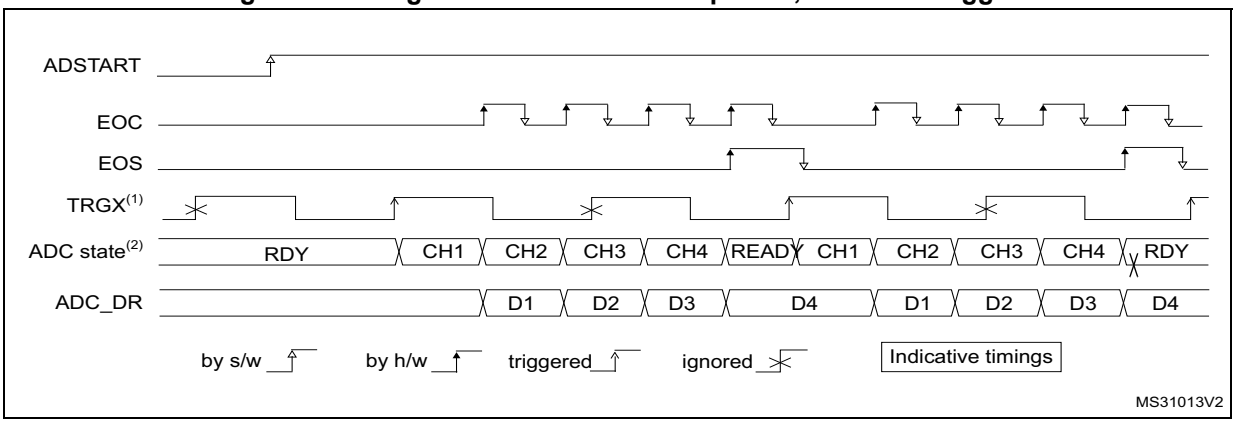
The ADC sets the EOS flag as soon as the last data of the regular conversion sequence is available in the ADC_DR register. An interrupt can be generated if bit EOSIE is set. EOS flag is cleared by the software either by writing 1 to it.

The ADC sets the JEOS flag as soon as the last data of the injected conversion sequence is complete. An interrupt can be generated if bit JEOSIE is set. JEOS flag is cleared by the software either by writing 1 to it.



27.4.25 Timing diagrams example (single/continuous modes, hardware/software triggers)

Figure 250. Single conversions of a sequence, software trigger



1. EXTEN = 0x0, CONT = 0
2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

2. Channels selected = 1,9, 10, 17; AUTDLY = 0.

Figure 252. Single conversions of a sequence, hardware trigger

1. TRGx (over-frequency) is selected as trigger source, EXTEN = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

Figure 253. Continuous conversions of a sequence, hardware trigger

1. TRGx is selected as trigger source, EXTEN = 10, CONT = 1
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

27.4.26 Data management

Data register, data alignment and offset (ADC_DR, OFFSET, OFFSET_CH, ALIGN)

Data and alignment

At the end of each regular conversion channel (when EOC event occurs), the result of the converted data is stored into the ADC_DR data register which is 16 bits wide.

At the end of each injected conversion channel (when JEOC event occurs), the result of the converted data is stored into the corresponding ADC_JDRy data register which is 16 bits wide.

The ALIGN bit in the ADC_CFGR register selects the alignment of the data stored after conversion. Data can be right- or left-aligned as shown in *Figure 254*, *Figure 255*, *Figure 256* and *Figure 257*.

Special case: when left-aligned, the data are aligned on a half-word basis except when the resolution is set to 6-bit. In that case, the data are aligned on a byte basis as shown in *Figure 256* and *Figure 257*.

Note: Left-alignment is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the ALIGN bit value is ignored and the ADC only provides right-aligned data.

Offset

An offset y (y = 1,2,3,4) can be applied to a channel by setting the bit OFFSET_EN = 1 into ADC_OFRy register. The channel to which the offset is to be applied is programmed into the bits OFFSET_CH[4:0] of ADC_OFRy register. In this case, the converted value is decreased by the user-defined offset written in the bits OFFSET[11:0]. The result may be a negative value so the read data is signed and the SEXT bit represents the extended sign value.

Note: Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Table 235 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Table 233. Offset computation versus data resolution

Resolution (bits RES[1:0])	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed 12-bit data	-
01: 10-bit	DATA[11:2],00	OFFSET[11:0]	Signed 10-bit data	The user must configure OFFSET[1:0] to “00”

Table 233. Offset computation versus data resolution (continued)

Resolution (bits RES[1:0])	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
10: 8-bit	DATA[11:4],0000	OFFSET[11:0]	Signed 8-bit data	The user must configure OFFSET[3:0] to “0000”
11: 6-bit	DATA[11:6],000000	OFFSET[11:0]	Signed 6-bit data	The user must configure OFFSET[5:0] to “000000”

When reading data from ADC_DR (regular channel) or from ADC_JDRy (injected channel, y = 1,2,3,4) corresponding to the channel “i”:

- If one of the offsets is enabled (bit OFFSET_EN = 1) for the corresponding channel, the read data is signed.
- If none of the four offsets is enabled for this channel, the read data is not signed.

Figure 254, *Figure 255*, *Figure 256* and *Figure 257* show alignments for signed and unsigned data.

Figure 254. Right alignment (offset disabled, unsigned value)

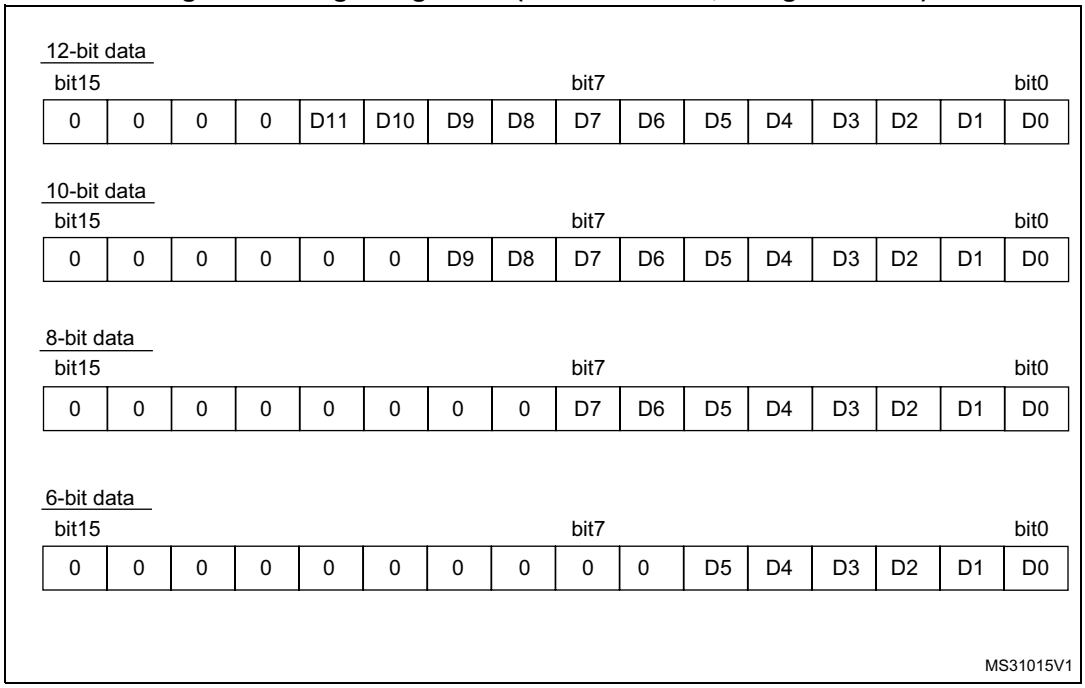

Figure 255. Right alignment (offset enabled, signed value)

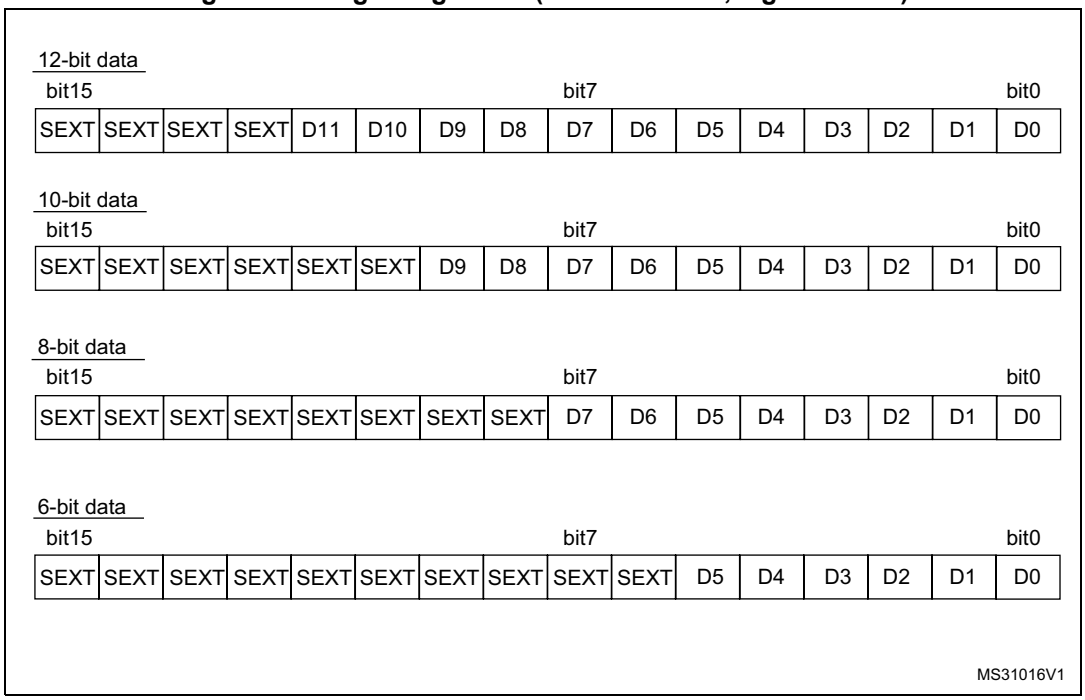

Figure 256. Left alignment (offset disabled, unsigned value)

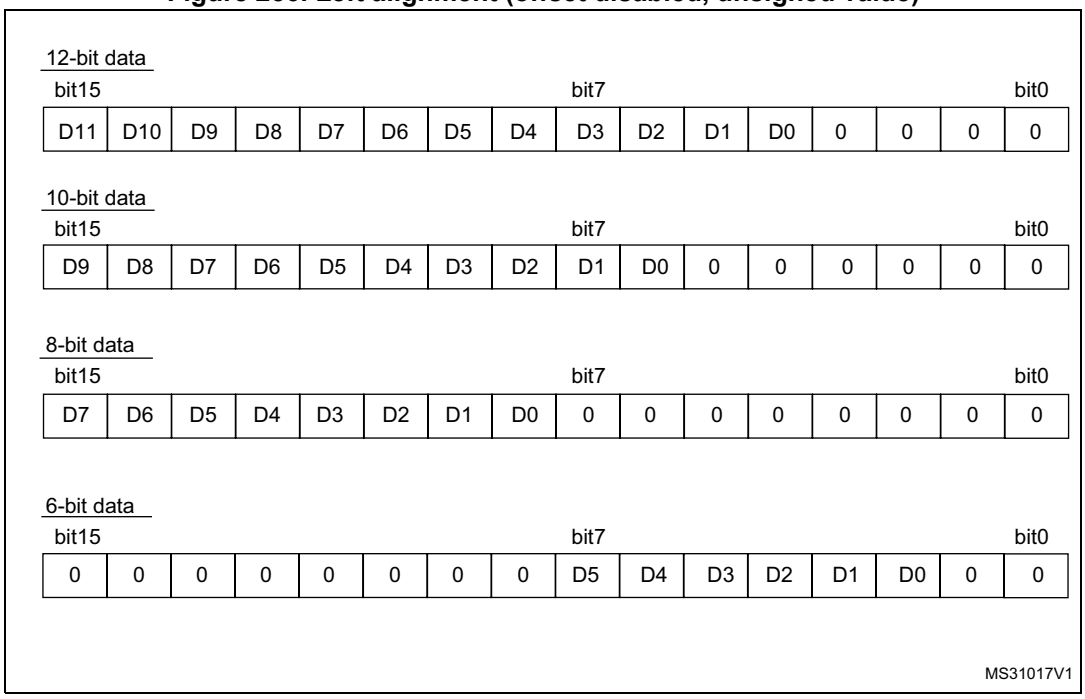

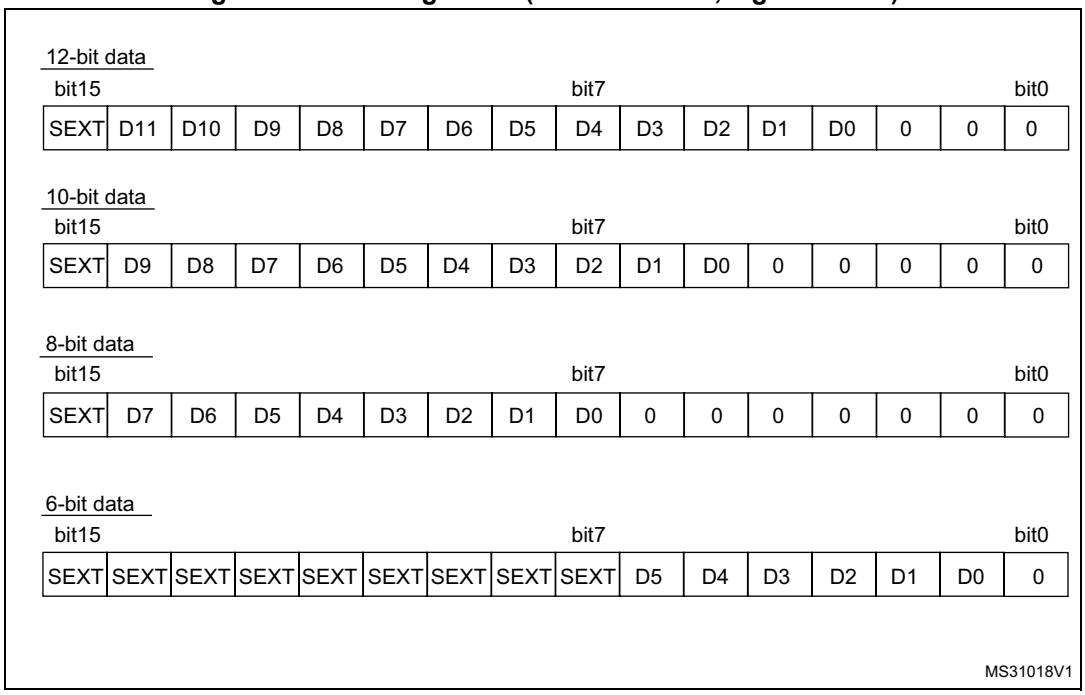

Figure 257. Left alignment (offset enabled, signed value)

Offset compensation

When SATEN bit is set in ADC_OFRy register during offset operation, data are unsigned. All the offset data saturate at 0x000 (in 12-bit mode). When OFFSETPOS bit is set, the offset direction is positive and the data saturate at 0xFFF (in 12-bit mode). In 8-bit mode, data saturate at 0x00 and 0xFF, respectively.

The analog watchdog comparison is performed before the offset compensation.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) notifies when the regular converted data has not been read (by the CPU or the DMA) before ADC_DR FIFO (three stages) is overflowed.

The OVR flag is set when a new conversion completes while ADC_CR register FIFO was full. An interrupt is generated if OVRIE bit is set to 1.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP to 1. Since ADC_DR FIFO features three stages, up to three data are stored in the FIFO.

OVR flag is cleared by software by writing 1 to it.

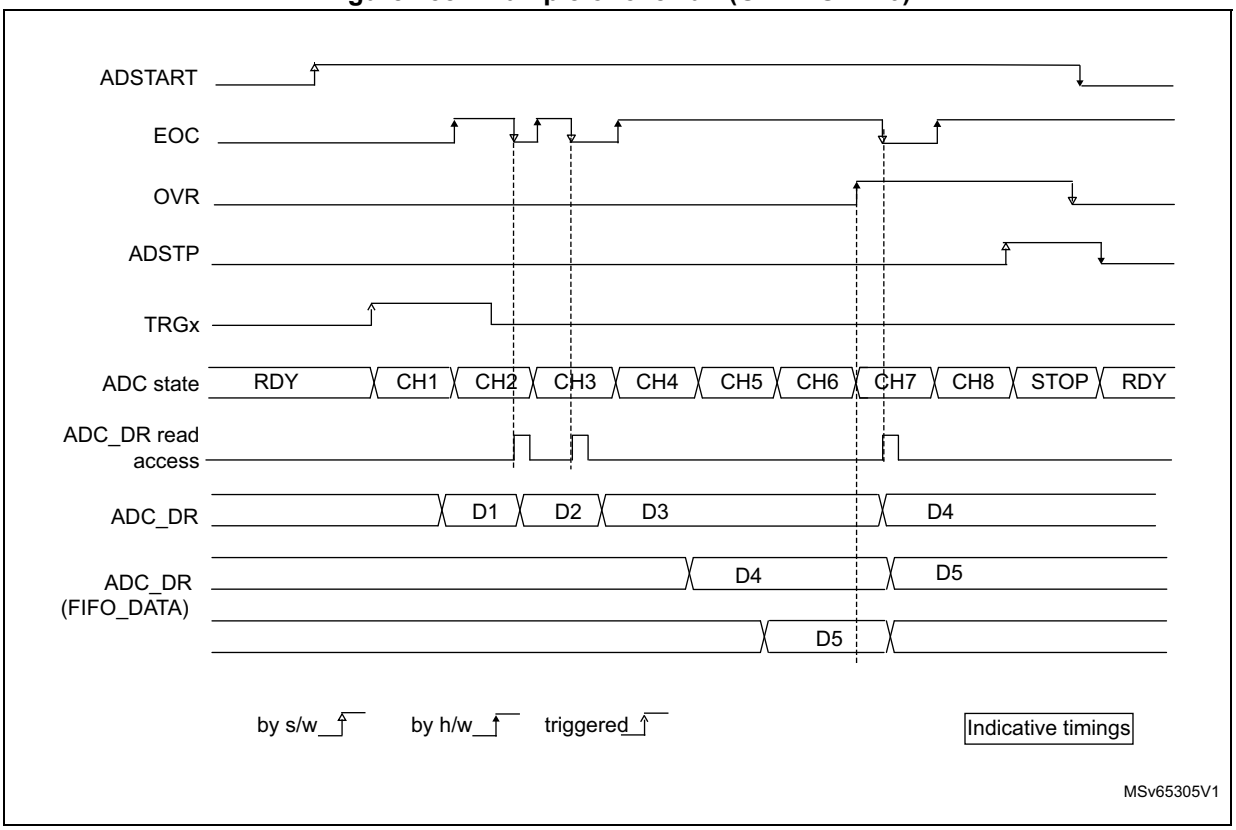
It is possible to configure if data is preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0: The overrun event preserves the data register from being overwritten: the old data is maintained up to ADC_DR FIFO depth (three stages) and the new conversion is discarded and lost. In this mode, ADC_DR FIFO is disabled. If the FIFO is full, any further conversion is performed but the resulting data is also discarded. EOC

is cleared by reading ADC_DR register. However, the FIFO can still contain previously converted data.

- OVRMOD = 1: The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversions is performed normally and the ADC_DR register always contains the latest converted data.

Figure 258. Example of overrun (OVRMOD = 0)



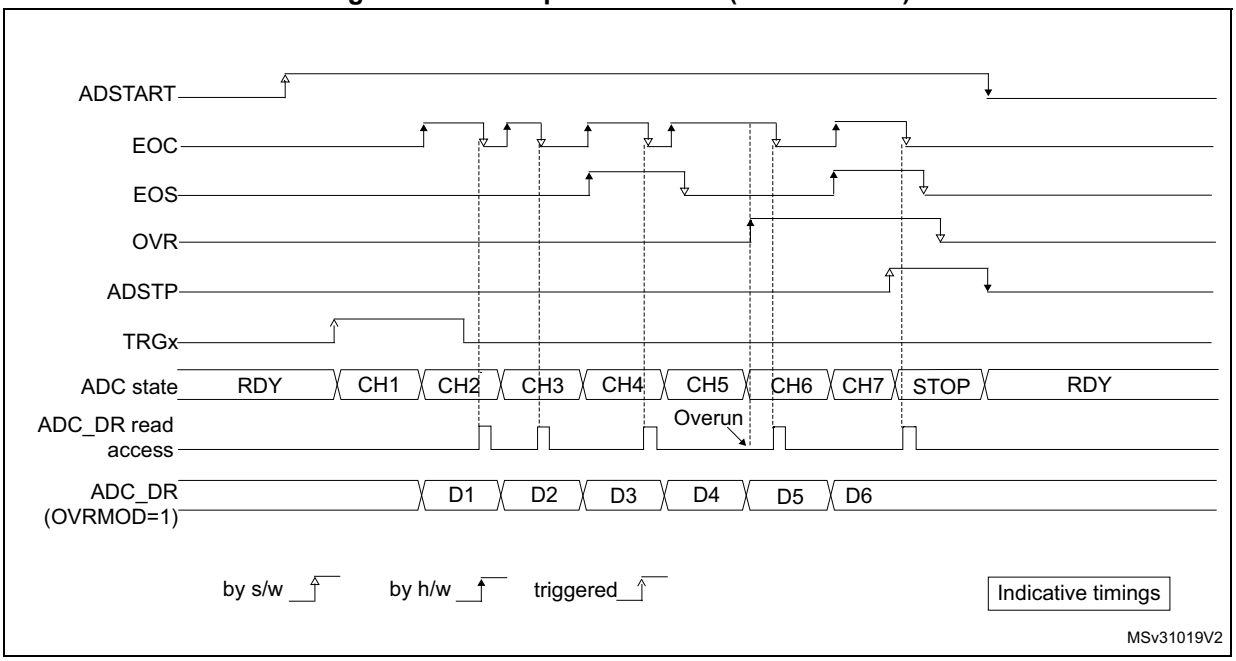


Figure 259. Example of overrun (OVRMOD = 1)

Note: There is no overrun detection on the injected channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as an error.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and OVR flag should be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

Since converted channel values are stored into a unique data register, it is useful to use DMA for conversion of more than one channel. This avoids the loss of the data already stored in the ADC_DR register.

When the DMA mode is enabled (DMAEN bit set to 1 in the ADC_CFGR register in single ADC mode or MDMA different from 0b00 in dual ADC mode), a DMA request is generated after each conversion of a channel. This allows the transfer of the converted data from the ADC_DR register to the destination location selected by the software.

Despite this, if an overrun occurs (OVR = 1) because the DMA could not serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA. Which means that all the data transferred to the RAM can be considered as valid.

Depending on the configuration of OVRMOD bit, the data is either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*).

The DMA transfer requests are blocked until the software clears the OVR bit.

Two different DMA modes are proposed depending on the application use and are configured with bit DMACFG of the ADC_CFGR register in single ADC mode, or with bit DMACFG of the ADC_CCR register in dual ADC mode:

- DMA one shot mode (DMACFG = 0).
  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMACFG = 1)
  This mode is suitable when programming the DMA in circular mode.

DMA one shot mode (DMACFG = 0)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (when a transfer complete interrupt occurs - refer to DMA section) even if a conversion has been started again.

When the DMA transfer is complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- Any ongoing conversion is aborted with partial result discarded.
- No new DMA request is issued to the DMA controller. This avoids generating an overrun error if there are still conversions which are started.
- Scan sequence is stopped and reset.
- The DMA is stopped.

DMA circular mode (DMACFG = 1)

In this mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register, even if the DMA has reached the last DMA transfer. This allows configuring the DMA in circular mode to handle a continuous analog input data stream.

27.4.27 Managing conversions using the ADF

The ADC conversion results can be transferred directly to the audio digital filter (ADF).

In this case, the ADFCFG bit must be set to 1 and DMAEN bit must be cleared to 0.

The ADC transfers all the 16 bits of the regular data register to the ADF and resets the EOC flag once the transfer is complete.

The data format must be 16-bit signed:

ADC_DR[15:12] = sign extended

ADC_DR[11] = sign

ADC_DR[11:0] = data

To obtain 16-bit signed format in 12-bit ADC mode, the software needs to configure the OFFSET[11:0] to 0x800 after having set OFFSET_EN to 1.

Only right aligned data format is available for the ADF interface (see *Figure 255: Right alignment (offset enabled, signed value)*).

27.4.28 Dynamic low-power features

Auto-delayed conversion mode (AUTDLY)

The ADC implements an auto-delayed conversion mode controlled by the AUTDLY configuration bit. Auto-delayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there would be risk of encountering an ADC overrun.

When AUTDLY = 1, a new conversion can start only if all the previous data of the same group has been treated:

- For a regular conversion: once the ADC_DR register has been read or if the EOC bit has been cleared (see *Figure 260*).
- For an injected conversion: when the JEOS bit has been cleared (see *Figure 261*).

This is a way to automatically adapt the speed of the ADC to the speed of the system which reads the data.

The delay is inserted after each regular conversion (whatever DISCEN = 0 or 1) and after each sequence of injected conversions (whatever JDISCEN = 0 or 1).

Note: There is no delay inserted between each conversions of the injected sequence, except after the last one.

During a conversion, a hardware trigger event (for the same group of conversions) occurring during this delay is ignored.

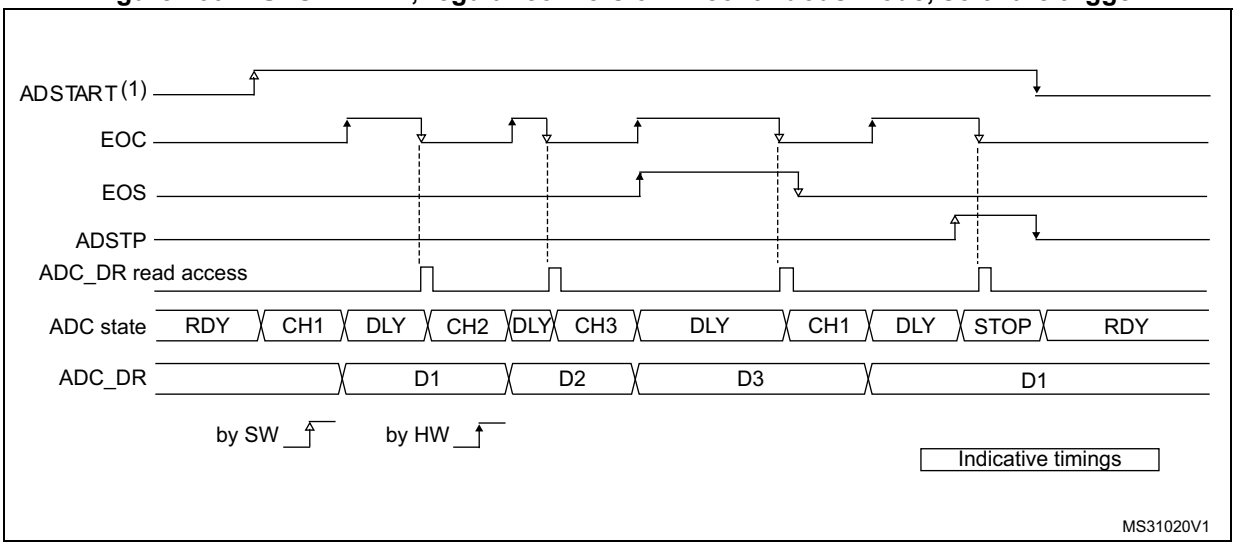
Note: This is not true for software triggers where it remains possible during this delay to set the bits ADSTART or JADSTART to restart a conversion: it is up to the software to read the data before launching a new conversion.

No delay is inserted between conversions of different groups (a regular conversion followed by an injected conversion or conversely):

- If an injected trigger occurs during the automatic delay of a regular conversion, the injected conversion starts immediately (see *Figure 261*).
- Once the injected sequence is complete, the ADC waits for the delay (if not ended) of the previous regular conversion before launching a new regular conversion (see *Figure 263*).

The behavior is slightly different in auto-injected mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 264*).

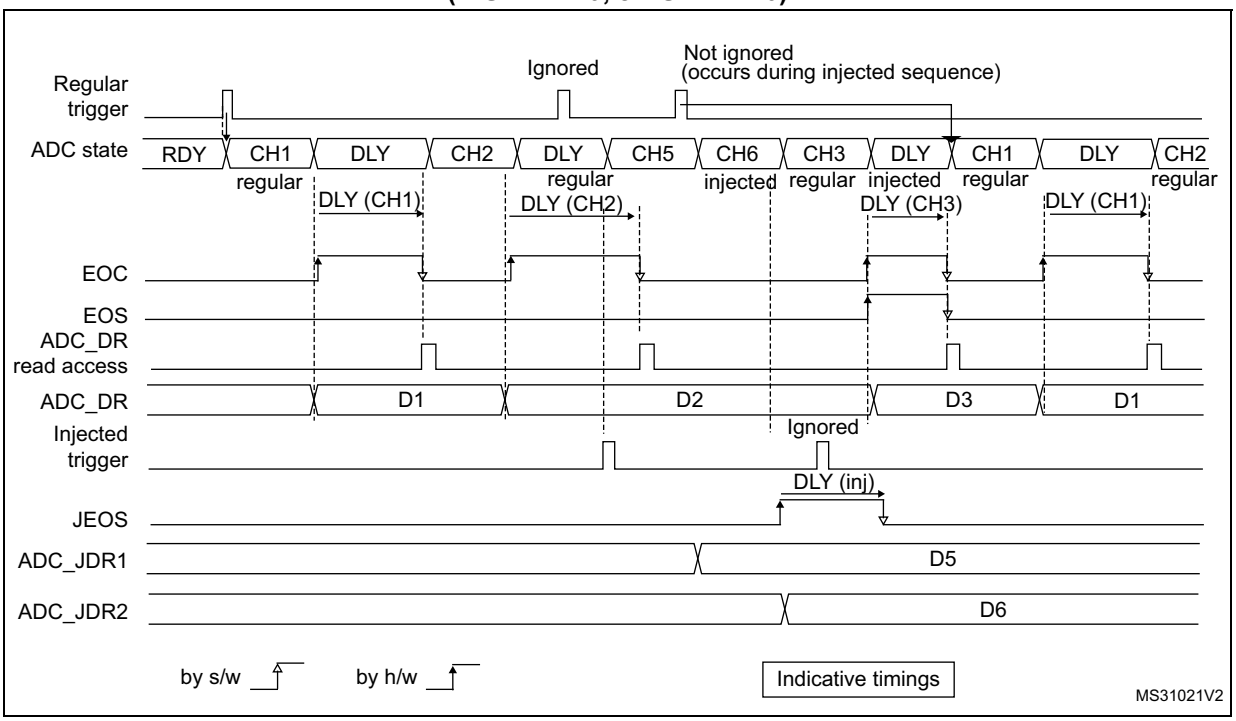
To stop a conversion in continuous auto-injection mode combined with autodelay mode (JAUTO = 1, CONT = 1 and AUTDLY = 1), follow the following procedure:



1. Wait until JEOS = 1 (no more conversions are restarted)
2. Clear JEOS,
3. Set ADSTP = 1
4. Read the regular data.

If this procedure is not respected, a new regular sequence can restart if JEOS is cleared after ADSTP has been set.

In AUTDLY mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.



In AUTDLY mode, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.

27.4.29 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWD2CH, AWD3CH, AWD_HTx, AWD_LTx, AWDx)

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 265. Analog watchdog guarded area

AWDx flag and interrupt

An interrupt can be enabled for each of the 3 analog watchdogs by setting AWDxIE in the ADC_IER register (x = 1,2,3).

AWDx (x = 1,2,3) flag is cleared by software by writing 1 to it.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN bit in the ADC_CFGR register. This watchdog monitors whether either one selected channel or all enabled channels(1) remain within a configured voltage range (window).

Table 234 shows how the ADC_CFGR registers should be configured to enable the analog watchdog on one or more channels.

Table 234. Analog watchdog channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog status bit is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed in bits HT1[11:0] and LT1[11:0] of the ADC_TR1 register for the analog watchdog 1. When converting data with a resolution of less than 12 bits (according to bits RES[1:0]), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data (left aligned) before the offset compensation stage.

Table 235 describes how the comparison is performed for all the possible resolutions for analog watchdog 1.

Table 235. Analog watchdog 1 comparison

Resolution(bit RES[1:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned	Thresholds	
00: 12-bit	DATA[11:0]	LT1[11:0] and HT1[11:0]	-
01: 10-bit	DATA[11:2],00	LT1[11:0] and HT1[11:0]	User must configure LT1[1:0] and HT1[1:0] to 00
10: 8-bit	DATA[11:4],0000	LT1[11:0] and HT1[11:0]	User must configure LT1[3:0] and HT1[3:0] to 0000
11: 6-bit	DATA[11:6],000000	LT1[11:0] and HT1[11:0]	User must configure LT1[5:0] and HT1[5:0] to 000000

Analog watchdog filter for watchdog 1

When an ADC is configured with only one input channel (selecting several channels in scan mode not allowed), a valid ADC conversion data interval can be configured through the ADC_TR1 register:

- When converted data belong to the interval defined in ADC_TR1, a DMA request is generated.
- Otherwise, no DMA request is issued. RDATA register is updated at each conversion. If data are out-of-range a number of times higher than the value specified in AWDFILT bit of ADC_TR1, the AWDx flag is set an the corresponding interrupt is issued.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDxCH[18:0] (x = 2,3).

The corresponding watchdog is enabled when any bit of AWDxCH[18:0] (x = 2,3) is set.

They are limited to a resolution of 8 bits and only the 8 MSBs of the thresholds can be programmed into HTx[7:0] and LTx[7:0]. *Table 236* describes how the comparison is performed for all the possible resolutions.

Table 236. Analog watchdog 2 and 3 comparison

Resolution (bits RES[1:0])	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned	Thresholds	
00: 12-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	DATA[3:0] are not relevant for the comparison
01: 10-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	DATA[3:2] are not relevant for the comparison
10: 8-bit	DATA[11:4]	LTx[7:0] and HTx[7:0]	-
11: 6-bit	DATA[11:6],00	LTx[7:0] and HTx[7:0]	User must configure LTx[1:0] and HTx[1:0] to 00

ADCy_AWDx_OUT signal output generation

Each analog watchdog is associated to an internal hardware signal ADCy_AWDx_OUT (y = ADC number, x = watchdog number) which is directly connected to the ETR input (external trigger) of some on-chip timers. Refer to the on-chip timers section to understand how to select the ADCy_AWDx_OUT signal as ETR.

ADCy_AWDx_OUT is activated when the associated analog watchdog is enabled:

- ADCy_AWDx_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADCy_AWDx_OUT is reset after the end of the next guarded conversion which is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADCy_AWDx_OUT is also reset when disabling the ADC (when setting ADDIS = 1). Note that stopping regular or injected conversions (setting ADSTP = 1 or JADSTP = 1) has no influence on the generation of ADCy_AWDx_OUT.

Note: AWDx flag is set by hardware and reset by software: AWDx flag has no influence on the generation of ADCy_AWDx_OUT (ex: ADCy_AWDx_OUT can toggle while AWDx flag remains at 1 if the software did not clear the flag).

Figure 266. ADCy_AWDx_OUT signal generation (on all regular channels)

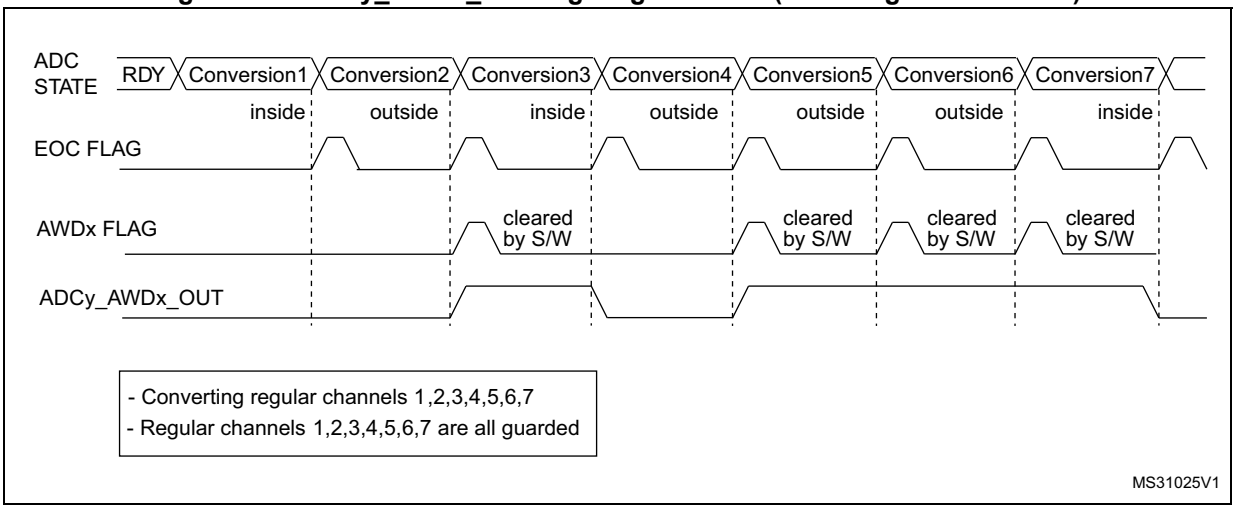

Figure 267. ADCy_AWDx_OUT signal generation (AWDx flag not cleared by software)

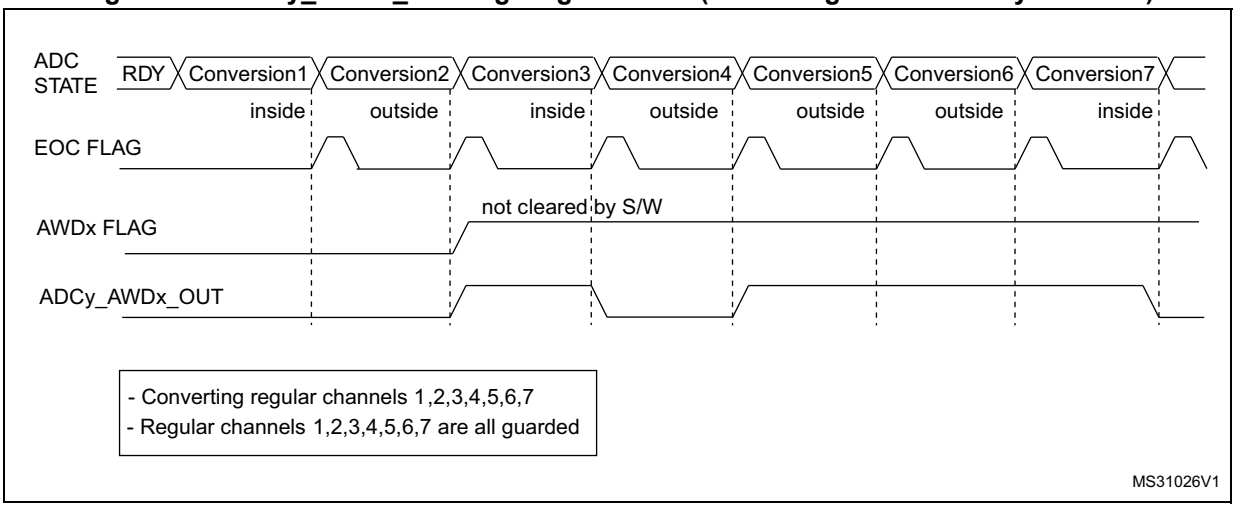

Figure 268. ADCy_AWDx_OUT signal generation (on a single regular channel)

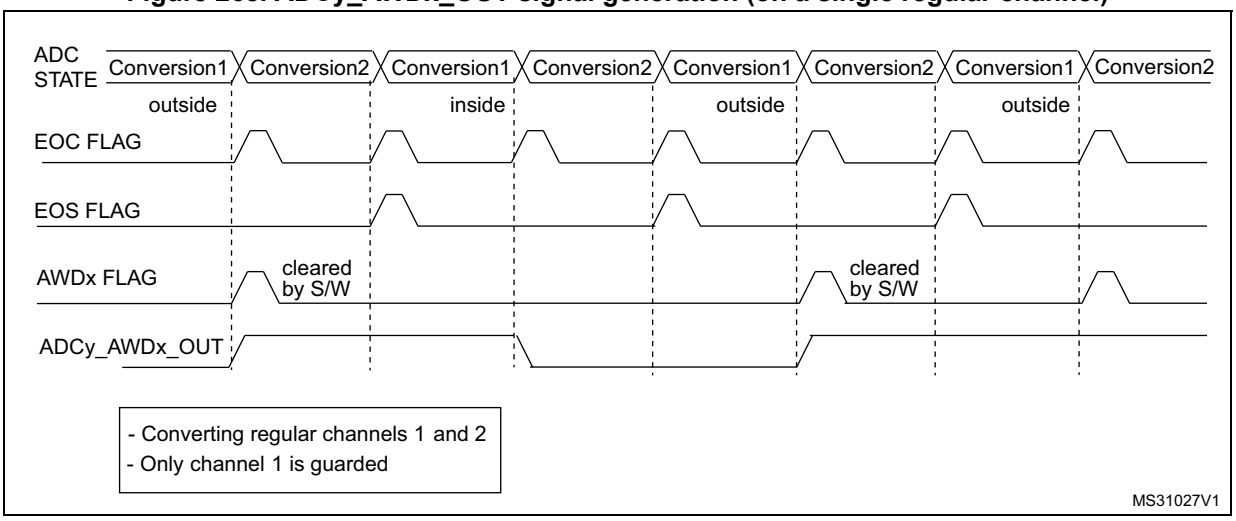

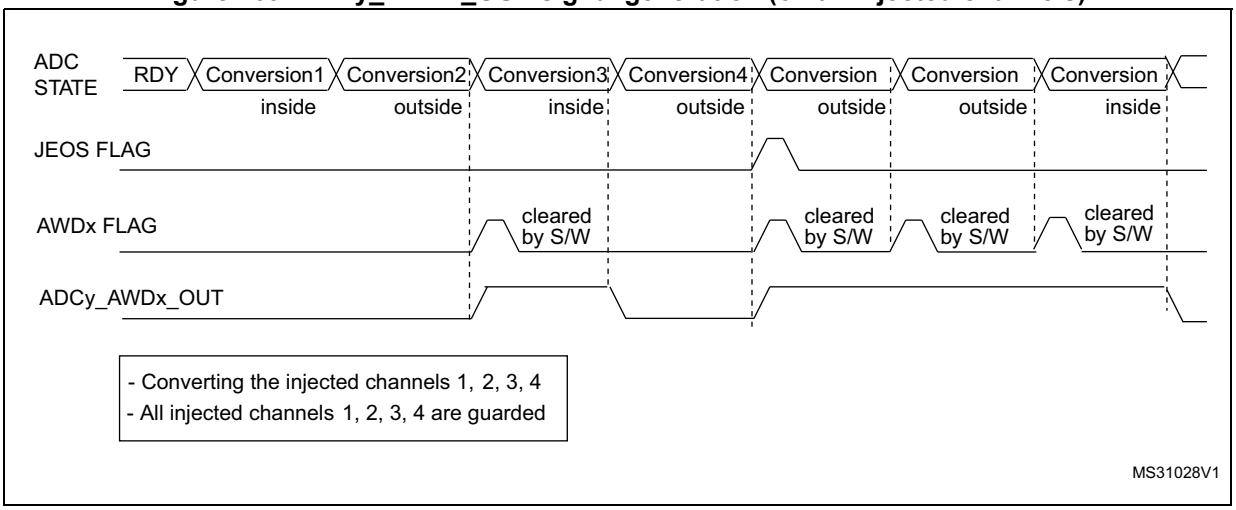

Figure 269. ADCy_AWDx_OUT signal generation (on all injected channels)

Analog watchdog threshold control

LTx[11:0] and HTx[11:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTx[11:0] and HTx[11:0] are updated during the ADC conversion of the ADC guarded channel, the watchdog function is masked for this conversion. This masking is removed at the next start of conversion, resulting in a analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new interval, no interrupt and AWDx_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion which started after the threshold update. If AWD_xOUT is already asserted, programming the new thresholds does not deassert the AWDx_OUT signal.

To update both LTx[11:0] and HTx[11:0] during an ADC conversion, a unique write access to the ADC_TRx register be performed.

Analog watchdog with offset compensation

When the offset compensation is enabled, the analog watchdog compares the threshold before the data compensation.

27.4.30 Oversampler

The oversampling unit performs data pre-processing to offload the CPU. It is able to handle multiple conversions and average them into a single data with increased data width, up to 16-bit.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It allows to perform by hardware the following functions: averaging, data rate reduction, SNR improvement, basic filtering.

The oversampling ratio N is defined using the OVFS[2:0] bits in the ADC_CFGR2 register, and can range from 2x to 256x. The division coefficient M consists of a right bit shift up to 8 bits, and is defined using the OVSS[3:0] bits in the ADC_CFGR2 register.

The summation unit can yield a result up to 20 bits (256x 12-bit results), which is first shifted right. It is then truncated to the 16 least significant bits, rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred into the ADC_DR data register.

Note: If the intermediary result after the shifting exceeds 16-bit, the result is truncated as is, without saturation.

Figure 270. 20-bit to 16-bit result truncation

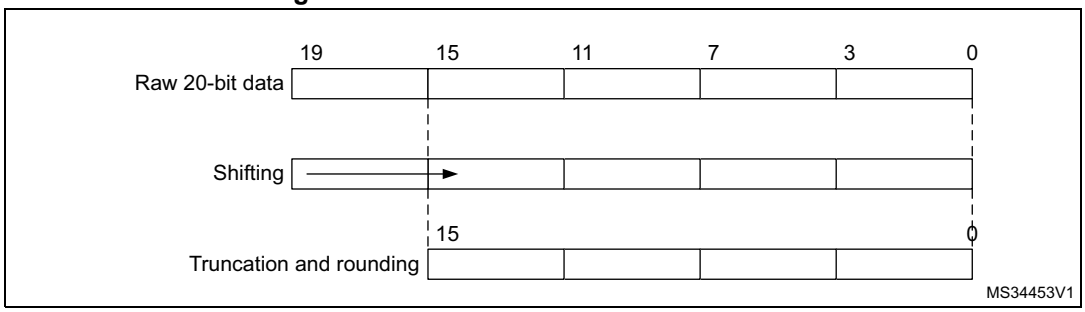

Figure 271 gives a numerical example of the processing, from a raw 20-bit accumulated data to the final 16-bit result.

Figure 271. Numerical example with 5-bit shift and rounding

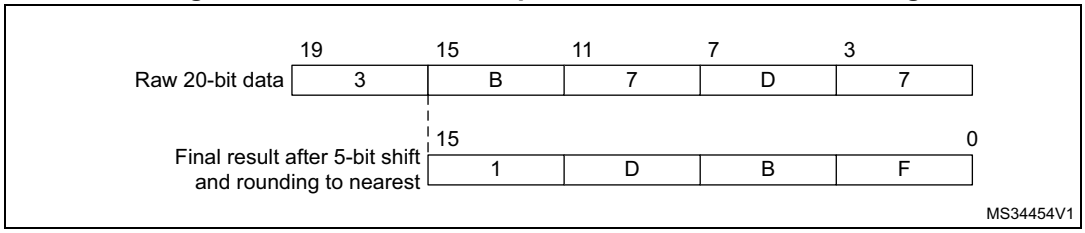

Table 237 gives the data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 237. Maximum output results versus N and M (gray cells indicate truncation)

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS = 0111	8-bit shift OVSS = 1000
2x	0x1FFE	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040	0x020
4x	0x3FFC	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040
8x	0x7FF8	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080
16x	0xFFF0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100
32x	0x1FFE0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200
64x	0x3FFC0	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400
128x	0x7FF80	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800
256x	0xFFF00	0xFF00	0xFF80	0xFFC0	0xFFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF

There are no changes for conversion timings in oversampled mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N

conversions, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follow:

- The end of the sampling phase (EOSMP) is set after each sampling phase
- The end of conversion (EOC) occurs once every N conversions, when the oversampled result is available
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after N x sequence length conversions total)

ADC operating modes supported when oversampling (single ADC mode)

In oversampling mode, most of the ADC operating modes are maintained:

- Single or continuous conversion modes
- ADC conversions start either by software or with triggers
- ADC stop during a conversion (abort)
- Data read via CPU or DMA with overrun detection
- Low-power modes (AUTDLY)
- Programmable resolution: in this case, the reduced conversion values (as per RES[1:0] bits in ADC_CFGR register) are accumulated, truncated, rounded and shifted in the same way as 12-bit conversions are

Note: The alignment mode is not available when working with oversampled data. The ALIGN bit in ADC_CFGR is ignored and the data are always provided right-aligned.

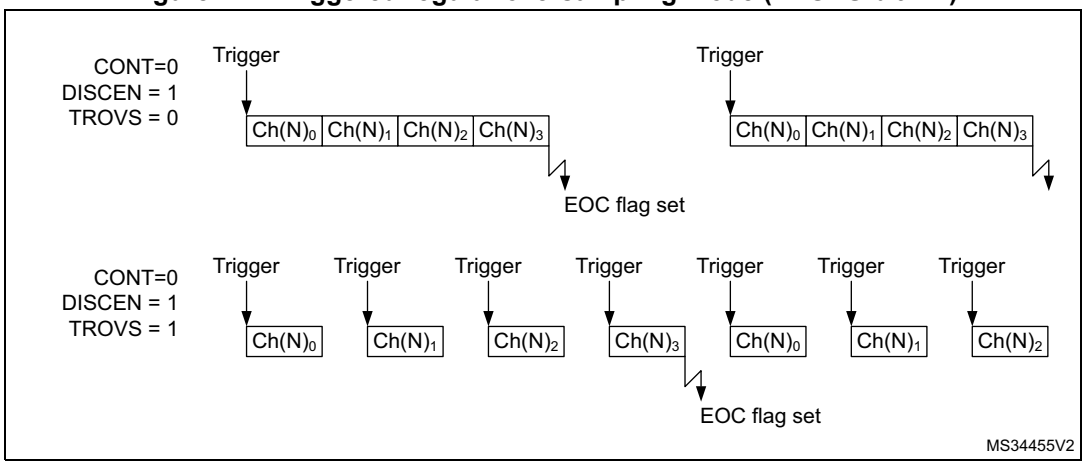
Offset correction is not supported in oversampling mode. When ROVSE and/or JOVSE bit is set, the value of the OFFSET_EN bit in ADC_OFRy register is ignored (considered as reset).

Analog watchdog

The analog watchdog functionality is maintained, with the following difference:

- The RES[1:0] bits are ignored, the comparison is always done by using the full 12-bit values HT1[11:0] and LT1[11:0] for AWD1, and the 8-MSB value of HT2/HT3[7:0] and LT2/LT3[7:0] for AWD2 and AWD3.
- The comparison is done on the most significant 12-bit of the 16-bit oversampled results ADC_DR[15:4] for AWD1, and ADC_DR[15:8] for AWD2 and ADW3

Note: Care must be taken when using high shifting values, this reduces the comparison range. For instance, if the oversampled result is shifted by 4 bits, thus yielding a 12-bit data right-aligned, the effective analog watchdog comparison can only be performed on 8 bits. The comparison is done between ADC_DR[11:4] and HTx[7:0] / LTx[7:0] (AWD1/2/3), with HT1[11:8] and LT1[11:8] kept reset (AWD1 only).



Triggered mode

The averager can also be used for basic filtering purpose. Although not a very powerful filter (slow roll-off and limited stop band attenuation), it can be used as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched mode power supply). For this purpose, a specific discontinuous mode can be enabled with TROVS bit in ADC_CFGR2, to be able to have an oversampling frequency defined by a user and independent from the conversion time itself.

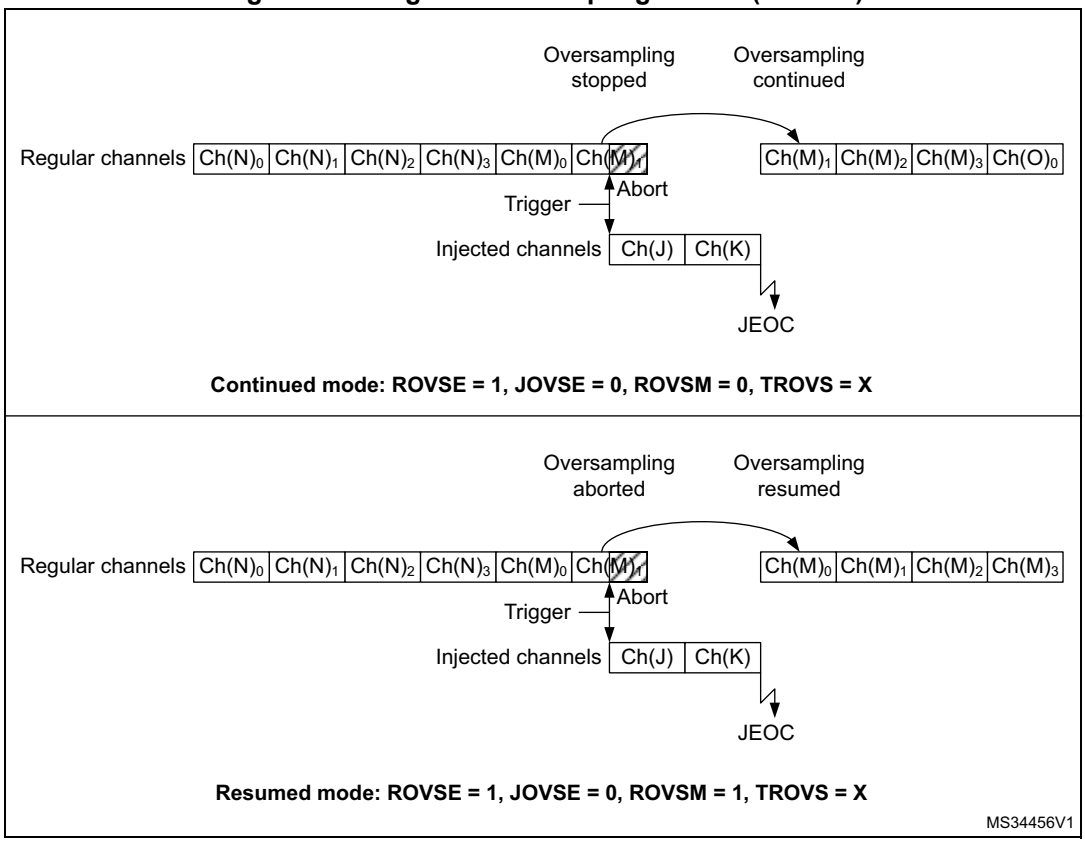
The *Figure 272* below shows how conversions are started in response to triggers during discontinuous mode.

If the TROVS bit is set, the content of the DISCEN bit is ignored and considered as 1.

Figure 272. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management when oversampling

In oversampling mode, it is possible to have differentiated behavior for injected and regular sequencers. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously (this is related to a unique accumulation unit).



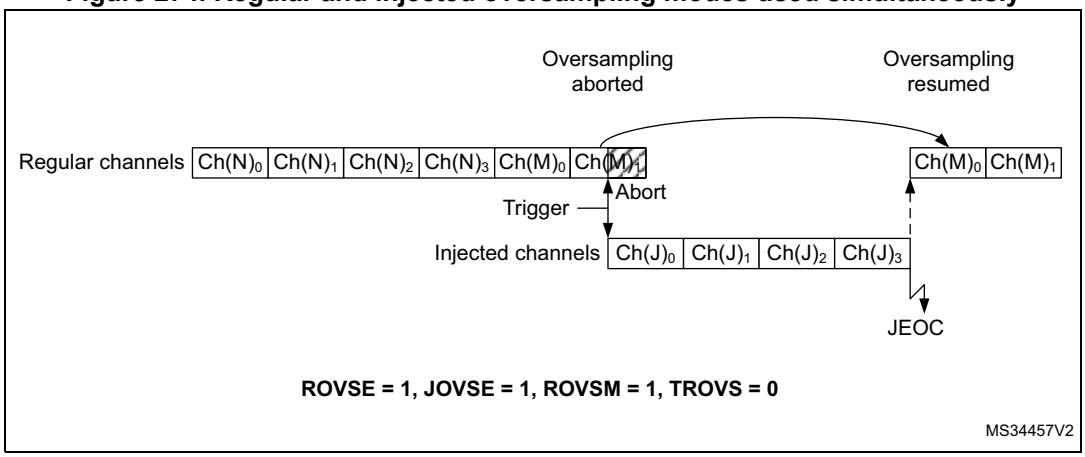
Oversampling regular channels only

The regular oversampling mode bit ROVSM defines how the regular oversampling sequence is resumed if it is interrupted by injected conversion:

- In continued mode, the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be completed between triggers);
- In resumed mode, the accumulation restarts from 0 (previous conversions results are ignored). This mode allows to guarantee that all data used for oversampling were converted back-to-back within a single timeslot. Care must be taken to have a injection trigger period above the oversampling period length. If this condition is not respected, the oversampling cannot be completed and the regular sequencer is blocked.

The *Figure 273* gives examples for a 4x oversampling ratio.

Figure 273. Regular oversampling modes (4x ratio)



Oversampling Injected channels only

The Injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and Injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling mode is forced to resumed mode (ROVSM bit ignored), as represented on *Figure 274* below.

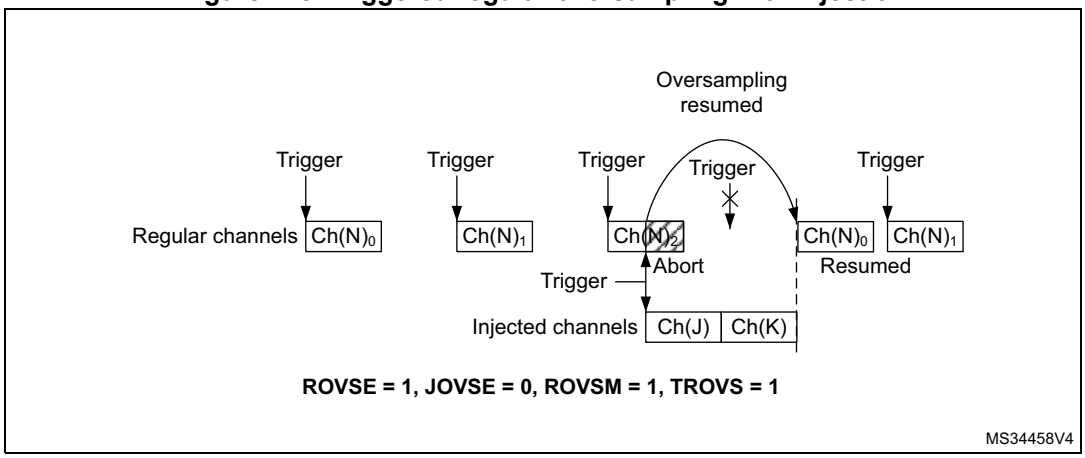


Figure 274. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected mode oversampling mode must be disabled, and the ROVSM bit is ignored (resumed mode is forced). The JOVSE bit must be reset. The behavior is represented on *Figure 275* below.

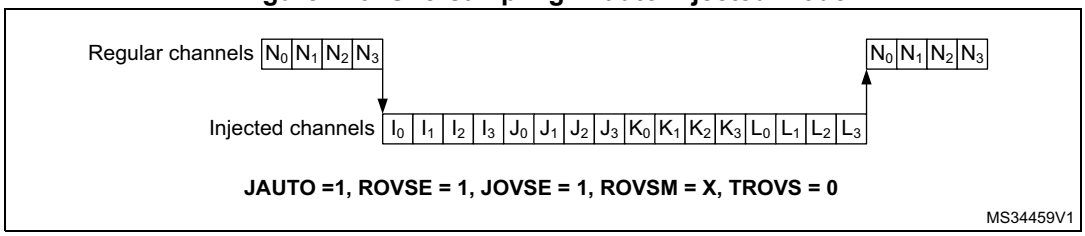

Figure 275. Triggered regular oversampling with injection

Auto-injected mode

It is possible to oversample auto-injected sequences and have all conversions results stored in registers to save a DMA resource. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1, other combinations are not supported. The ROVSM bit is ignored in auto-injected mode. The *Figure 276* below shows how the conversions are sequenced.

Figure 276. Oversampling in auto-injected mode

It is possible to have also the triggered mode enabled, using the TROVS bit. In this case, the ADC must be configured as following: JAUTO = 1, DISCEN = 0, JDISCEN = 0, ROVSE = 1, JOVSE = 1 and TROVSE = 1.

Dual ADC modes supported when oversampling

It is possible to have oversampling enabled when working in dual ADC configuration, for the injected simultaneous mode and regular simultaneous mode. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (ROVSE = 1 or JOVSE = 1).

Combined modes summary

The *Table 238* below summarizes all combinations, including modes not supported.

Table 238. Oversampler operating modes summary

Regular Oversampling ROVSE	Injected Oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered Regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

27.4.31 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 277*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADCx master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADC_CCR register.

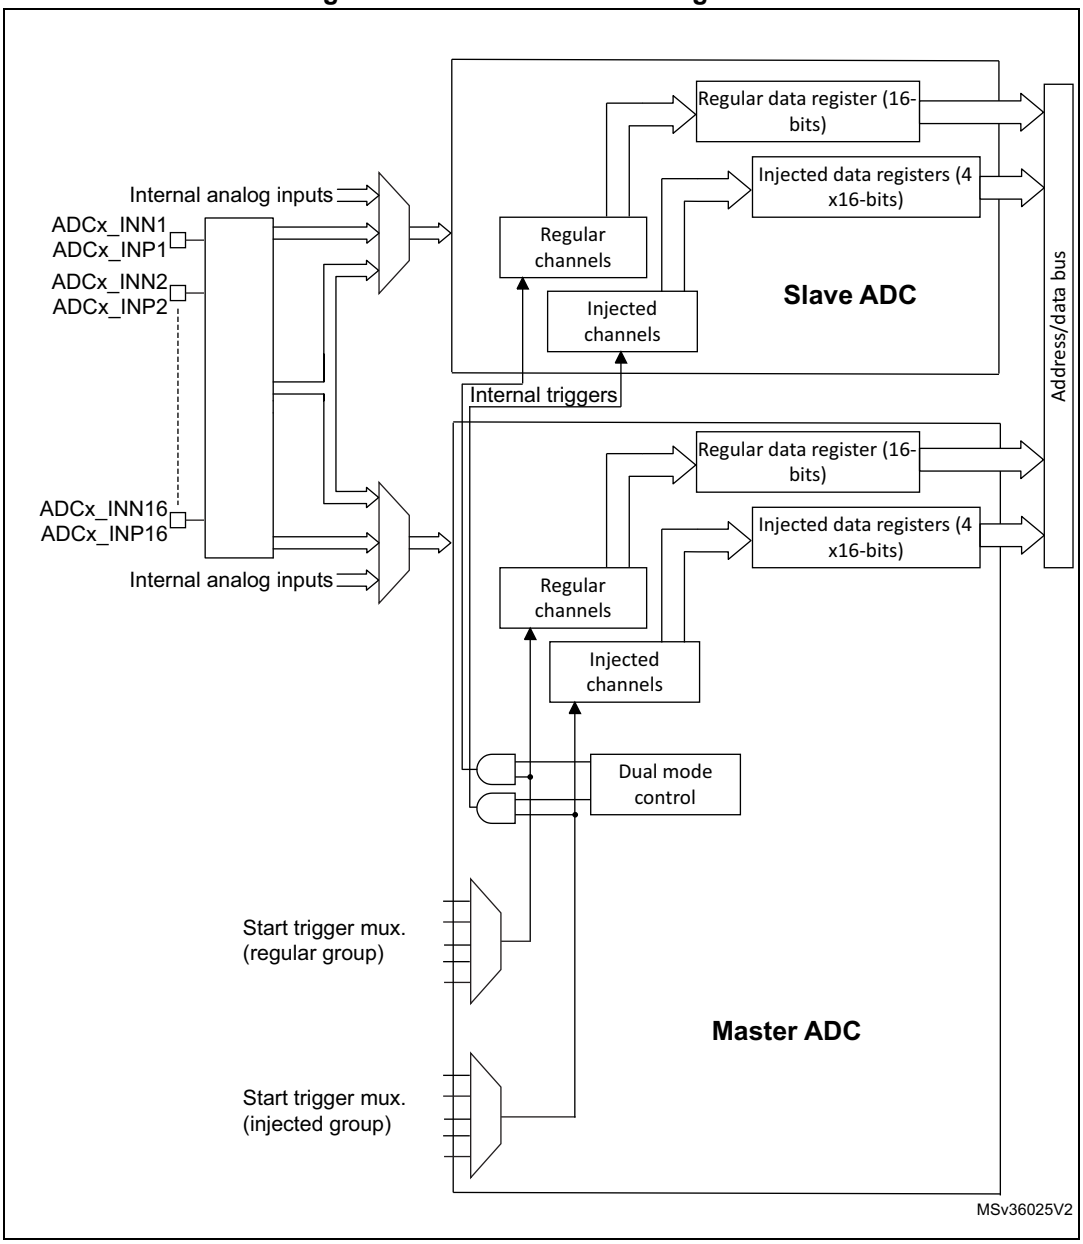
Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

In dual ADC mode (when bits DUAL[4:0] in ADC_CCR register are not equal to zero), the bits CONT, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JQM, JAUTO of the ADC_CFGR register are shared between the master and slave ADC: the bits in the slave ADC are always equal to the corresponding bits of the master ADC.



To start a conversion in dual mode, the user must program the bits EXTEN, EXTSEL, JEXTEN, JEXTSEL of the master ADC only, to configure a software or hardware trigger, and a regular or injected trigger. (the bits EXTEN[1:0] and JEXTEN[1:0] of the slave ADC are don’t care).

In regular simultaneous or interleaved modes: once the user sets bit ADSTART or bit ADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit ADSTART or bit ADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In injected simultaneous or alternate trigger modes: once the user sets bit JADSTART or bit JADSTP of the master ADC, the corresponding bit of the slave ADC is also automatically set. However, bit JADSTART or bit JADSTP of the slave ADC is not necessary cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADC_CDR). The status bits can be also read in parallel by reading the dual-mode status register (ADC_CSR).

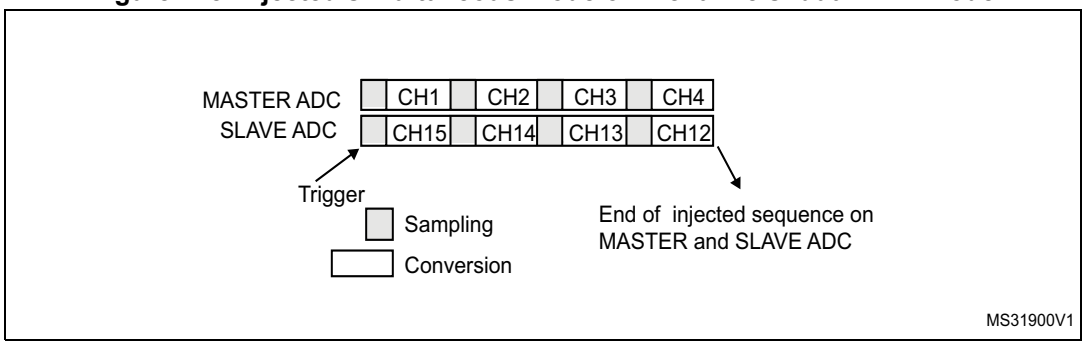
Figure 277. Dual ADC block diagram(1)

1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode

This mode is selected by programming bits DUAL[4:0] = 00101

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).



Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

- At the end of injected sequence of conversion event (JEOS) on the master ADC, the converted data is stored into the master ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- At the end of injected sequence of conversion event (JEOS) on the slave ADC, the converted data is stored into the slave ADC_JDRy registers and a JEOS interrupt is generated (if enabled)
- If the duration of the master injected sequence is equal to the duration of the slave injected one (like in *Figure 278*), it is possible for the software to enable only one of the two JEOS interrupt (ex: master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 278. Injected simultaneous mode on 4 channels: dual ADC mode

If JDISCEN = 1, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the

ongoing regular sequence and the associated delay phases are ignored.
There is the same behavior for regular sequences occurring on the slave ADC.

Regular simultaneous mode with independent injected

This mode is selected by programming bits DUAL[4:0] = 00110.

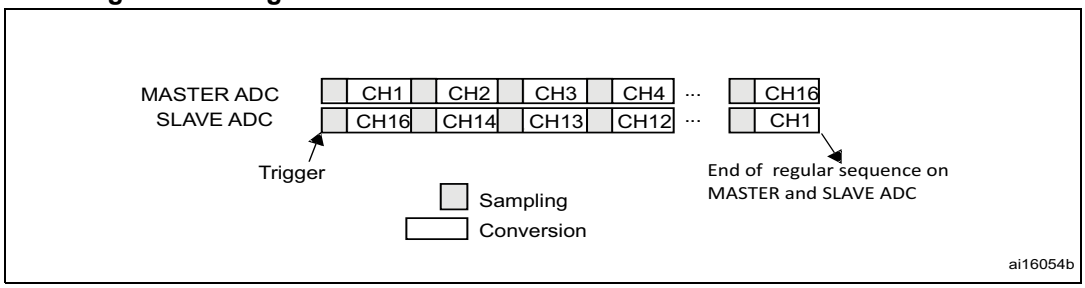
This mode is performed on a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on master or on the slave) aborts the current simultaneous conversions, which are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, one must convert sequences with the same length or ensure that the interval between triggers is longer than the longer conversion time of the 2 sequences. Otherwise, the ADC with the shortest sequence may restart while the ADC with the longest sequence is completing the previous conversions.

Software is notified by interrupts when it can read the data:



- At the end of each conversion event (EOC) on the master ADC, a master EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the master ADC.
- At the end of each conversion event (EOC) on the slave ADC, a slave EOC interrupt is generated (if EOCIE is enabled) and software can read the ADC_DR of the slave ADC.
- If the duration of the master regular sequence is equal to the duration of the slave one (like in *Figure 279*), it is possible for the software to enable only one of the two EOC interrupt (ex: master EOC) and read both converted data from the Common Data register (ADC_CDR).

It is also possible to read the regular data using the DMA. Two methods are possible:

- Using two DMA channels (one for the master and one for the slave). In this case bits MDMA[1:0] must be kept cleared.
  - Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  - Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Using MDMA mode, which leaves one DMA channel free for other uses:
  - Configure MDMA[1:0] = 0b10 or 0b11 (depending on resolution).
  - A single DMA channel is used (the one of the master). Configure the DMA master ADC channel to read the common ADC register (ADC_CDR)
  - A single DMA request is generated each time both master and slave EOC events have occurred. At that time, the slave ADC converted data is available in the upper half-word of the ADC_CDR 32-bit register and the master ADC converted data is available in the lower half-word of ADC_CDR register.
  - Both EOC flags are cleared when the DMA reads the ADC_CDR register.

Note: In MDMA mode (MDMA[1:0] = 0b10 or 0b11), the user must program the same number of conversions in the master's sequence as in the slave's sequence. Otherwise, the remaining conversions does not generate a DMA request.

Figure 279. Regular simultaneous mode on 16 channels: dual ADC mode

If DISCEN = 1 then each “n” simultaneous conversions of the regular sequence require a regular trigger event to occur (“n” is defined by DISCNUM).

This mode can be combined with AUTDLY mode:
