Reference manual

STM32G56x/55x/54x/53x Arm®-based 32-bit MCUs

Introduction

This reference manual targets application developers. It provides complete information on how to use the STM32G56x/55x/54x/53x microcontrollers memory and peripherals.

For ordering information, mechanical and electrical device characteristics, refer to the corresponding datasheets.

For information on the Arm® Cortex®-M33 core, refer to the corresponding Arm® Technical Reference Manual available on http://infocenter.arm.com.

STM32G56x/55x/54x/53x microcontrollers include ST state-of-the-art patented technology.

Contents

1 Documentation conventions 111

1.1 General information 111

1.2 List of abbreviations for registers 111

1.3 Register reset value 112

1.4 Glossary 112

1.5 Availability of peripherals 112

2 Memory and bus architecture 113

2.1 System architecture 113

2.1.1 Fast C-bus 115

2.1.2 Slow C-bus 115

2.1.3 S-bus 115

2.1.4 DCACHE S-bus 116

2.1.5 GPDMA1 and GPDMA2 buses 116

2.1.6 BusMatrix 116

2.1.7 AHB/APB bridges 116

2.2 TrustZone security architecture 116

2.2.1 Default TrustZone security state 117

2.2.2 TrustZone peripheral classification 118

2.3 Memory organization 122

2.3.1 Introduction 122

2.3.2 Memory map and register boundary addresses 123

2.3.3 Embedded SRAM 129

2.3.4 Flash memory overview 130

2.3.5 Boot modes 130

3 System security 131

3.1 Key security features 131

3.2 Secure install 132

3.3 Secure boot 133

3.3.1 Unique boot entry 133

3.3.2 Immutable root of trust in system flash memory 134

3.3.3 Temporal isolation levels 134

3.4 Secure update . . . 134
3.4.1 Live update . . . 135
3.5 Resource isolation using TrustZone . . . 135
3.5.1 TrustZone security architecture . . . 136
3.5.2 Armv8-M security extension of Cortex-M33 . . . 136
3.5.3 Memory and peripheral allocation using IDAU/SAU . . . 136
3.5.4 Memory and peripheral allocation using GTZC . . . 138
3.5.5 Managing security in TrustZone-aware peripherals . . . 142
3.5.6 Activating TrustZone security . . . 148
3.5.7 Deactivating TrustZone security . . . 149
3.5.8 Resource isolation using Cortex privileged mode . . . 149
3.6 Secure execution . . . 153
3.6.1 Memory protection unit (MPU) . . . 153
3.6.2 Embedded flash memory write protection . . . 154
3.6.3 Tamper detection and response . . . 154
3.7 Secure storage . . . 156
3.8 Product life cycle . . . 157
3.8.1 Life-cycle management . . . 159
3.8.2 Recommended product settings . . . 162
3.8.3 Software intellectual property protection . . . 162
3.8.4 Software intellectual property protection with OTFDEC . . . 162
3.8.5 Other software intellectual property protections . . . 164

5 Global TrustZone® controller (GTZC) . . . 168
5.1 GTZC introduction . . . 168
5.2 GTZC main features . . . 168
5.3 GTZC implementation . . . 170
5.4 GTZC functional description . . . 172
5.4.1 GTZC block diagram . . . 172
5.4.2 Illegal access definition . . . 173
5.4.3 TrustZone security controller (TZSC) . . . 173
5.4.4 Memory protection controller - block based (MPCBB) . . . 175
5.4.5 TrustZone illegal access controller (TZIC) . . . 175
5.4.6 Power-on/reset state . . . 175

5.5 GTZC interrupts 176
5.6 GTZC1 TZSC registers 176
5.6.1 GTZC1 TZSC control register (GTZC1_TZSC_CR) 176
5.6.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1) 177
5.6.3 GTZC1 TZSC secure configuration register 2 (GTZC1_TZSC_SECCFGR2) 180
5.6.4 GTZC1 TZSC secure configuration register 3 (GTZC1_TZSC_SECCFGR3) 182
5.6.5 GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1) 185
5.6.6 GTZC1 TZSC privilege configuration register 2 (GTZC1_TZSC_PRIVCFGR2) 188
5.6.7 GTZC1 TZSC privilege configuration register 3 (GTZC1_TZSC_PRIVCFGR3) 190
5.6.8 GTZC1 TZSC memory x subregion z watermark configuration register (GTZC1_TZSC_MPCWM1zCFGR) (z = A to B) 193
5.6.9 GTZC1 TZSC subregion A watermark register (GTZC1_TZSC_MPCWM1AR) 194
5.6.10 GTZC1 TZSC subregion B watermark register (GTZC1_TZSC_MPCWM1BR) 195
5.6.11 GTZC1 TZSC register map 195
5.7 GTZC1 TZIC registers 197
5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1) 197
5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2) 199
5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3) 202
5.7.4 GTZC1 TZIC interrupt enable register 4 (GTZC1_TZIC_IER4) 204
5.7.5 GTZC1 TZIC status register 1 (GTZC1_TZIC_SR1) 206
5.7.6 GTZC1 TZIC status register 2 (GTZC1_TZIC_SR2) 210
5.7.7 GTZC1 TZIC status register 3 (GTZC1_TZIC_SR3) 212
5.7.8 GTZC1 TZIC status register 4 (GTZC1_TZIC_SR4) 215
5.7.9 GTZC1 TZIC flag clear register 1 (GTZC1_TZIC_FCR1) 217
5.7.10 GTZC1 TZIC flag clear register 2 (GTZC1_TZIC_FCR2) 219
5.7.11 GTZC1 TZIC flag clear register 3 (GTZC1_TZIC_FCR3) 221
5.7.12 GTZC1 TZIC flag clear register 4 (GTZC1_TZIC_FCR4) 224
5.7.13 GTZC1 TZIC register map 226
5.8 GTZC1 MPCBBz registers (z = 1 to 3) 228
5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3) 228

5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1 (GTZC1_MPCBBz_CFGLOCK1) (z = 1 to 3) . . . 229
5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3) . . . 229
5.8.4 GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3) . . . 230
5.8.5 GTZC1 MPCBBz register map (z = 1 to 3) . . . 230

6 RAMs configuration controller (RAMCFG) . . . 231
6.1 Introduction . . . 231
6.2 RAMCFG main features . . . 231
6.3 RAMCFG functional description . . . 231
6.3.1 Internal SRAMs features . . . 231
6.3.2 Error code correction (SRAM1, SRAM2, SRAM3) . . . 232
6.3.3 Write protection . . . 233
6.3.4 Software erase . . . 233
6.4 RAMCFG low-power modes . . . 233
6.5 RAMCFG interrupts . . . 234
6.6 RAMCFG registers . . . 234
6.6.1 RAMCFG memory x control register (RAMCFG_MxCR) . . . 234
6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER) . . . 235
6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR) . . . 235
6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR) . . . 236
6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR) . . . 236
6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR) . . . 237
6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_MxWPR1) . . . 237
6.6.8 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2) . . . 238
6.6.9 RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR) . . . 238
6.6.10 RAMCFG memory x erase key register (RAMCFG_MxERKEYR) . . . 239
6.6.11 RAMCFG register map . . . 239

7 Embedded flash memory (FLASH) . . . 242
7.1 Introduction . . . 242
7.2 FLASH main features . . . 242

7.3 FLASH functional description 243
7.3.1 FLASH block diagram 243
7.3.2 FLASH signals 244
7.3.3 Flash memory architecture and usage 245
7.3.4 FLASH read operations 247
7.3.5 FLASH program operations 249
7.3.6 FLASH erase operations 252
7.3.7 PUF operations 256
7.3.8 FLASH parallel operations 258
7.3.9 FLASH error protections 258
7.3.10 OTP and RO memory access 258
7.3.11 Flash high-cycle data 261
7.3.12 Flash bank swapping 265
7.3.13 FLASH reset and clocks 270
7.4 FLASH option bytes 272
7.4.1 About option bytes 272
7.4.2 Option byte loading 272
7.4.3 Option-byte modification 272
7.4.4 Option-byte overview 274
7.4.5 Description of user and system option bytes 275
7.4.6 Description of data protection option bytes 276
7.4.7 Description of boot address option bytes 277
7.4.8 Specific rules for modifying option bytes 277
7.5 Option-byte key management 280
7.5.1 OBK loading 280
7.5.2 OBK access per HDPL level 280
7.5.3 OBK programming sequence 280
7.5.4 OBK programming finite state machine 283
7.5.5 OBK swap page 283
7.5.6 OBK alternate page erase 286
7.6 FLASH security and protections 286
7.6.1 TrustZone® security protection 287
7.6.2 Hide protection (HDP) 289
7.6.3 Block-based secure flash memory area protection 291
7.6.4 Block-based privileged flash memory area protection 292
7.6.5 Flash memory register privileged and unprivileged modes 293
7.6.6 Flash memory bank attributes in case of bank swap 294

7.6.7 Flash memory configuration protection 295
7.6.8 Write protection 296
7.6.9 Flash high-cycle data protections 296
7.6.10 Life cycle management 298
7.6.11 Product state transitions 299
7.6.12 OBK protection 301
7.6.13 One-time-programmable and read-only memory protections 302
7.7 System memory 303
7.7.1 Introduction 303
7.7.2 RSS user functions 303
7.8 FLASH low-power modes 310
7.9 FLASH error management 311
7.9.1 Introduction 311
7.9.2 Nonsecure write protection error (WRPERR) 312
7.9.3 Secure write protection error (WRPERR) 312
7.9.4 Nonsecure programming sequence error (PGSERR) 313
7.9.5 Secure programming sequence error (PGSERR) 315
7.9.6 Nonsecure strobe error (STRBERR) 316
7.9.7 Secure strobe error (STRBERR) 316
7.9.8 Nonsecure inconsistency error (INCERR) 316
7.9.9 Secure inconsistency error (INCERR) 317
7.9.10 Error correction code error (ECCC, ECCD) 318
7.9.11 Illegal access (ILAFM/ILAP) 319
7.9.12 Option-byte change error (OPTCHANGEERR) 319
7.9.13 Miscellaneous HardFault errors 320
7.9.14 OBK error cases (OBKERR, OBKWERR) 320
7.10 FLASH interrupts 321
7.11 FLASH registers 323
7.11.1 FLASH access control register (FLASH_ACR) 323
7.11.2 FLASH nonsecure key register (FLASH_KEYR) 324
7.11.3 FLASH secure key register (FLASH_SKEYR) 324
7.11.4 FLASH option key register (FLASH_OPTKEYR) 325
7.11.5 FLASH nonsecure OBK key register (FLASH_OBKKEYR) 325
7.11.6 FLASH secure OBK key register (FLASH_SOBKKEYR) 326
7.11.7 FLASH operation status register (FLASH_OPSR) 326
7.11.8 FLASH option control register (FLASH_OPTCR) 327

7.11.9 FLASH nonsecure status register (FLASH_SR) 328
7.11.10 FLASH secure status register (FLASH_SSR) 330
7.11.11 FLASH nonsecure control register (FLASH_CR) 332
7.11.12 FLASH secure control register (FLASH_SCR) 335
7.11.13 FLASH nonsecure clear control register (FLASH_CCR) 338
7.11.14 FLASH secure clear control register (FLASH_SCCR) 339
7.11.15 FLASH privilege configuration register (FLASH_PRIVCFGR) 340
7.11.16 FLASH nonsecure OBK configuration register (FLASH_OBKCFGR) 340
7.11.17 FLASH secure OBK configuration register (FLASH_SOBKCFGR) 342
7.11.18 FLASH HDP extension register (FLASH_HDPEXTR) 343
7.11.19 FLASH option status register (FLASH_OPTSR_CUR) 343
7.11.20 FLASH option status register (FLASH_OPTSR_PRG) 345
7.11.21 FLASH nonsecure EPOCH register (FLASH_EPOCHR_CUR) 346
7.11.22 FLASH nonsecure EPOCH register (FLASH_EPOCHR_PRG) 347
7.11.23 FLASH secure EPOCH register (FLASH_SEPOCHR_CUR) 347
7.11.24 FLASH secure EPOCH register (FLASH_SEPOCHR_PRG) 348
7.11.25 FLASH option status register 2 (FLASH_OPTSR2_CUR) 348
7.11.26 FLASH option status register 2 (FLASH_OPTSR2_PRG) 349
7.11.27 FLASH option status register 3 (FLASH_OPTSR3_CUR) 350
7.11.28 FLASH option status register 3 (FLASH_OPTSR3_PRG) 351
7.11.29 FLASH nonsecure boot register (FLASH_BOOTR_CUR) 352
7.11.30 FLASH nonsecure boot register (FLASH_BOOTR_PRG) 352
7.11.31 FLASH secure boot register (FLASH_SBOOTR_CUR) 353
7.11.32 FLASH secure boot register (FLASH_SBOOTR_PRG) 354
7.11.33 FLASH nonsecure OTP block lock (FLASH_OTPBLR_CUR) 354
7.11.34 FLASH nonsecure OTP block lock (FLASH_OTPBLR_PRG) 355
7.11.35 FLASH bootloader interface selection (FLASH_BL_COM_CFG_CUR) 356
7.11.36 FLASH bootloader interface selection (FLASH_BL_COM_CFG_PRG) 357
7.11.37 FLASH secure block based registers for Bank1 (FLASH_SECBB1R) 358
7.11.38 FLASH privilege block based registers for Bank1 (FLASH_PRIVBB1R) 358
7.11.39 FLASH security watermark for Bank1 (FLASH_SECWM1R_CUR) . . 359
7.11.40 FLASH security watermark for Bank1 (FLASH_SECWM1R_PRG) . . 359

7.11.41 FLASH write page group protection for Bank1 (FLASH_WRP1R_CUR) . . . 360
7.11.42 FLASH write page group protection for Bank1 (FLASH_WRP1R_PRG) . . . 361
7.11.43 FLASH data page configuration Bank1 (FLASH_EDATA1R_CUR) . . . 361
7.11.44 FLASH data page configuration Bank1 (FLASH_EDATA1R_PRG) . . . 362
7.11.45 FLASH HDP Bank1 configuration (FLASH_HDP1R_CUR) . . . 363
7.11.46 FLASH HDP Bank1 configuration (FLASH_HDP1R_PRG) . . . 363
7.11.47 FLASH ECC correction register (FLASH_ECCCORR) . . . 364
7.11.48 FLASH ECC detection register (FLASH_ECCDETR) . . . 365
7.11.49 FLASH ECC data (FLASH_ECCDR) . . . 366
7.11.50 FLASH secure block-based registers for Bank2 (FLASH_SECBB2R) . . . 366
7.11.51 FLASH privilege block-based registers for Bank2 (FLASH_PRIVBB2R) . . . 367
7.11.52 FLASH security watermark for Bank2 (FLASH_SECWM2R_CUR) . . 367
7.11.53 FLASH security watermark for Bank2 (FLASH_SECWM2R_PRG) . . 368
7.11.54 FLASH write page group protection for Bank2 (FLASH_WRP2R_CUR) . . . 368
7.11.55 FLASH write page group protection for Bank2 (FLASH_WRP2R_PRG) . . . 369
7.11.56 FLASH data page configuration Bank2 (FLASH_EDATA2R_CUR) . . . 370
7.11.57 FLASH data page configuration Bank2 (FLASH_EDATA2R_PRG) . . . 371
7.11.58 FLASH HDP Bank2 configuration (FLASH_HDP2R_CUR) . . . 371
7.11.59 FLASH HDP Bank2 configuration (FLASH_HDP2R_PRG) . . . 372
7.12 FLASH register map and reset values . . . 373

8 Instruction cache (ICACHE) . . . 378

8.1 ICACHE introduction . . . 378
8.2 ICACHE main features . . . 378
8.3 ICACHE implementation . . . 379
8.4 ICACHE functional description . . . 380
8.4.1 ICACHE block diagram . . . 380
8.4.2 ICACHE reset and clocks . . . 381
8.4.3 ICACHE TAG memory . . . 381
8.4.4 Direct-mapped ICACHE (1-way cache) . . . 382
8.4.5 ICACHE enable . . . 383
8.4.6 Cacheable and noncacheable traffic . . . 384

8.4.7 Address remapping . . . 385
8.4.8 Cacheable accesses . . . 387
8.4.9 Dual-master cache . . . 388
8.4.10 ICACHE security . . . 388
8.4.11 ICACHE maintenance . . . 388
8.4.12 ICACHE ECC support . . . 388
8.4.13 ICACHE performance monitoring . . . 390
8.4.14 ICACHE boot . . . 390
8.5 ICACHE low-power modes . . . 390
8.6 ICACHE error management and interrupts . . . 391
8.7 ICACHE registers . . . 392
8.7.1 ICACHE control register (ICACHE_CR) . . . 392
8.7.2 ICACHE status register (ICACHE_SR) . . . 393
8.7.3 ICACHE interrupt enable register (ICACHE_IER) . . . 394
8.7.4 ICACHE flag clear register (ICACHE_FCR) . . . 394
8.7.5 ICACHE hit monitor register (ICACHE_HMONR) . . . 395
8.7.6 ICACHE miss monitor register (ICACHE_MMONR) . . . 395
8.7.7 ICACHE region x configuration register (ICACHE_CRRx) . . . 396
8.7.8 ICACHE register map . . . 397

9 Data cache (DCACHE) . . . 398
9.1 DCACHE introduction . . . 398
9.2 DCACHE main features . . . 398
9.3 DCACHE implementation . . . 399
9.4 DCACHE functional description . . . 399
9.4.1 DCACHE block diagram . . . 400
9.4.2 DCACHE reset and clocks . . . 400
9.4.3 DCACHE TAG memory . . . 400
9.4.4 DCACHE enable . . . 402
9.4.5 Cacheable and noncacheable traffic . . . 402
9.4.6 Cacheable accesses . . . 403
9.4.7 DCACHE security . . . 405
9.4.8 DCACHE maintenance . . . 405
9.4.9 DCACHE ECC support . . . 407
9.4.10 DCACHE performance monitoring . . . 410
9.4.11 DCACHE boot . . . 411

9.5 DCACHE low-power modes 411
9.6 DCACHE error management and interrupts 411
9.7 DCACHE registers 412
9.7.1 DCACHE control register (DCACHE_CR) 412
9.7.2 DCACHE status register (DCACHE_SR) 414
9.7.3 DCACHE interrupt enable register (DCACHE_IER) 415
9.7.4 DCACHE flag clear register (DCACHE_FCR) 416
9.7.5 DCACHE read-hit monitor register (DCACHE_RHMONR) 417
9.7.6 DCACHE read-miss monitor register (DCACHE_RMMONR) 417
9.7.7 DCACHE write-hit monitor register (DCACHE_WHMONR) 417
9.7.8 DCACHE write-miss monitor register (DCACHE_WMMONR) 418
9.7.9 DCACHE command range start address register (DCACHE_CMDRSADDRR) 418
9.7.10 DCACHE command range end address register (DCACHE_CMDREADDRR) 418
9.7.11 DCACHE register map 419

10 Power control (PWR) 420
10.1 Introduction 420
10.2 PWR main features 420
10.3 PWR pins and internal signals 421
10.4 PWR power supplies and supply domains 422
10.4.1 External power supplies 424
10.4.2 Internal and external regulators 424
10.4.3 Power-up and power-down power sequences 426
10.4.4 Independent analog peripherals supply 427
10.4.5 USB transceivers supply 428
10.4.6 RTC domain 428
10.5 PWR system supply voltage regulation 428
10.5.1 SMPS and LDO embedded regulators 428
10.5.2 V_{CORE} supply versus reset, voltage scaling, and low-power modes . . 429
10.5.3 Embedded voltage regulator operating modes 429
10.5.4 Regulator bypass operating modes 429
10.6 PWR power supply and temperature supervision 430
10.6.1 Power-on reset (POR)/power-down reset (PDR) 430
10.6.2 Programmable voltage detector (PVD) 431
10.6.3 Analog voltage detector (AVD) 431

10.6.4 VDD voltage monitoring 432
10.6.5 Temperature monitoring 433
10.7 PWR management 434
10.7.1 Voltage scaling 434
10.7.2 Power management examples 435
10.8 Power modes 436
10.8.1 Slowing down system clocks 439
10.8.2 Peripheral clock gating 440
10.8.3 Low-power modes 440
10.8.4 Sleep mode 441
10.8.5 Stop mode 442
10.8.6 Standby mode 444
10.8.7 Power modes output pins 447
10.9 PWR security and privileged protection 448
10.9.1 PWR security protection 448
10.9.2 PWR privileged protection 449
10.10 PWR interrupts 450
10.11 PWR registers 451
10.11.1 PWR low power mode control register (PWR_LPMCR) 451
10.11.2 PWR status register (PWR_PMSR) 452
10.11.3 PWR voltage scaling control register (PWR_VOSCR) 453
10.11.4 PWR voltage scaling status register (PWR_VOSSR) 453
10.11.5 PWR tamper monitoring control register (PWR_TMCR) 454
10.11.6 PWR RTC domain control register (PWR_RTCCR) 455
10.11.7 PWR tamper monitoring status register (PWR_TMSR) 455
10.11.8 PWR USB Type-C® power delivery register (PWR_UCPDR) 456
10.11.9 PWR supply configuration control register (PWR_SCCR) 456
10.11.10 PWR voltage monitor control register (PWR_VMCR) 457
10.11.11 PWR USB supply control register (PWR_USBSCR) 458
10.11.12 PWR voltage monitor status register (PWR_VMSR) 459
10.11.13 PWR wake-up status clear register (PWR_WUSCR) 459
10.11.14 PWR wake-up status register (PWR_WUSR) 460
10.11.15 PWR wake-up configuration register (PWR_WUCR) 460

15 Peripherals interconnect matrix 713

15.1 Interconnect matrix introduction 713
15.2 Connection summary 713
15.3 Interconnection details 718
15.3.1 Master to slave interconnection for timers 718
15.3.2 Triggers to ADCs 718
15.3.3 ADC analog watchdogs as triggers to timers 719
15.3.4 From comparators to timers (TIMx, HRTIM, LPTIM) 720
15.3.5 Triggers to DAC 721
15.3.6 Clock sources to timers 722
15.3.7 Triggers to low-power timers 723
15.3.8 RTC wake-up as inputs to timers 723
15.3.9 System errors as break signals to timers and HRTIM 723
15.3.10 From timers to comparators 724
15.3.11 Triggers to GPDMA1/2 724
15.3.12 Internal analog signals to ADCs 725
15.3.13 Internal analog signals to COMPs 725
15.3.14 Internal analog signals to OPAMPs 725
15.3.15 Clock source for the DAC sample and hold mode 726
15.3.16 Internal tamper sources 726
15.3.17 Output from tamper to RTC 726
15.3.18 PLAY inputs/outputs from/to internal peripherals 726
15.3.19 Encryption keys to AES/SAES 727
15.3.20 From USB to timers 727
15.3.21 CRS clock sources 727
15.3.22 Internal sources for EXTI lines 728

15.3.23 Internal signals to POSENC 728

16 General purpose direct memory access controller (GPDMA) 729

16.1 GPDMA introduction 729

16.2 GPDMA main features 729

16.3 GPDMA implementation 730

16.3.1 GPDMA instances 730

16.3.2 GPDMA channels 730

16.3.3 GPDMA in low-power modes 731

16.3.4 GPDMA requests 731

16.3.5 GPDMA block requests 736

16.3.6 GPDMA channels with peripheral early termination 736

16.3.7 GPDMA triggers 737

16.4 GPDMA functional description 739

16.4.1 GPDMA block diagram 739

16.4.2 GPDMA channel state and direct programming without any linked-list 739

16.4.3 GPDMA channel suspend and resume 740

16.4.4 GPDMA channel abort and restart 741

16.4.5 GPDMA channel terminate and drain FIFO 742

16.4.6 GPDMA linked-list data structure 743

16.4.7 Linked-list item transfer execution 747

16.4.8 GPDMA channel state and linked-list programming in run-to-completion mode 747

16.4.9 GPDMA channel state and linked-list programming in link step mode 751

16.4.10 GPDMA channel state and linked-list programming 758

16.4.11 GPDMA FIFO-based transfers 760

16.4.12 GPDMA transfer request and arbitration 767

16.4.13 GPDMA triggered transfer 771

16.4.14 GPDMA circular buffering with linked-list programming 772

16.4.15 GPDMA transfer in peripheral flow-control mode 774

16.4.16 GPDMA byte-based padding at the block level 775

16.4.17 GPDMA secure/nonsecure channel 776

16.4.18 GPDMA privileged/unprivileged channel 777

16.4.19 GPDMA error management 778

16.5 GPDMA in debug mode 779

16.6 GPDMA in low-power modes 779
16.7 GPDMA interrupts 780

19.6.14 EXTI privilege configuration register 2 (EXTI_PRIVCFGR2) 923
19.6.15 EXTI external interrupt selection register (EXTI_EXTICR1) 924
19.6.16 EXTI external interrupt selection register (EXTI_EXTICR2) 926
19.6.17 EXTI external interrupt selection register (EXTI_EXTICR3) 928
19.6.18 EXTI external interrupt selection register (EXTI_EXTICR4) 929
19.6.19 EXTI lock register (EXTI_LOCKR) 931
19.6.20 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1) 932
19.6.21 EXTI CPU wake-up with event mask register (EXTI_EMR1) 932
19.6.22 EXTI CPU wake-up with interrupt mask register 2 (EXTI_IMR2) 933
19.6.23 EXTI CPU wake-up with event mask register 2 (EXTI_EMR2) 934
19.6.24 EXTI register map 936

20 Cyclic redundancy check calculation unit (CRC) 938

20.1 CRC introduction 938
20.2 CRC main features 938
20.3 CRC functional description 939
20.3.1 CRC block diagram 939
20.3.2 CRC internal signals 939
20.3.3 CRC operation 939
20.4 CRC registers 941
20.4.1 CRC data register (CRC_DR) 941
20.4.2 CRC independent data register (CRC_IDR) 941
20.4.3 CRC control register (CRC_CR) 942
20.4.4 CRC initial value (CRC_INIT) 943
20.4.5 CRC polynomial (CRC_POL) 943
20.4.6 CRC register map 944

21 CORDIC coprocessor (CORDIC) 945
21.1 CORDIC introduction 945
21.2 CORDIC main features 945
21.3 CORDIC functional description 945
21.3.1 General description 945
21.3.2 CORDIC functions 945
21.3.3 Fixed point representation 952
21.3.4 Scaling factor 952
21.3.5 Precision 953
21.3.6 Zero-overhead mode 956
21.3.7 Polling mode 957
21.3.8 Interrupt mode 958
21.3.9 DMA mode 958
21.4 CORDIC registers 959
21.4.1 CORDIC control/status register (CORDIC_CSR) 959
21.4.2 CORDIC argument register (CORDIC_WDATA) 961
21.4.3 CORDIC result register (CORDIC_RDATA) 962
21.4.4 CORDIC register map 962

22 Filter math accelerator (FMAC) 963
22.1 FMAC introduction 963
22.2 FMAC main features 963
22.3 FMAC functional description 964
22.3.1 General description 964
22.3.2 Local memory and buffers 965
22.3.3 Input buffers 965
22.3.4 Output buffer 968
22.3.5 Initialization functions 970
22.3.6 Filter functions 971
22.3.7 Fixed point representation 975
22.3.8 Implementing FIR filters with the FMAC 975
22.3.9 Implementing IIR filters with the FMAC 977
22.3.10 Examples of filter initialization 979
22.3.11 Examples of filter operation 980
22.3.12 Filter design tips 982
22.4 FMAC registers 983

22.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG) 983
22.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG) 983
22.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG) 984
22.4.4 FMAC parameter register (FMAC_PARAM) 985
22.4.5 FMAC control register (FMAC_CR) 986
22.4.6 FMAC status register (FMAC_SR) 987
22.4.7 FMAC write data register (FMAC_WDATA) 988
22.4.8 FMAC read data register (FMAC_RDATA) 989
22.4.9 FMAC register map 989

23 Programmable logic array (PLAY) 991

23.1 PLAY introduction 991
23.2 PLAY main features 991
23.3 PLAY functional description 992
23.3.1 PLAY block diagram 992
23.3.2 PLAY pins and internal signals 992
23.3.3 PLAY reset and clocks 998
23.3.4 Input selection 999
23.3.5 Input filtering and edge detection 999
23.3.6 Software programmable inputs 1002
23.3.7 Logic elements 1002
23.3.8 Input interconnect 1006
23.3.9 Output interconnect 1011
23.3.10 Flags 1012
23.3.11 Miscellaneous status bits 1013
23.4 PLAY in low-power modes 1013
23.5 PLAY interrupts 1013
23.6 PLAY registers 1014
23.6.1 PLAY configuration control register (PLAY_CFGCR) 1015
23.6.2 PLAY security attributes configuration register (PLAY_SECCFGR) . 1015
23.6.3 PLAY privilege attributes configuration register (PLAY_PRIVCFGR) 1016
23.6.4 PLAY filter x configuration register (PLAY_FILTxCFG) 1017
23.6.5 PLAY logic element x configuration register 1 (PLAY_LExCFG1) . . . 1018
23.6.6 PLAY logic element x configuration register 2 (PLAY_LExCFG2) . . . 1018
23.6.7 PLAY output x configuration register (PLAY_OUTxCFG) 1019
23.6.8 PLAY software input status register (PLAY_SWIN) 1020

23.6.9 PLAY software input set register (PLAY_SWINSET) 1020
23.6.10 PLAY software input clear register (PLAY_SWINCLR) 1021
23.6.11 PLAY output status register (PLAY_OSR) 1022
23.6.12 PLAY flag status register (PLAY_FLSTAT) 1022
23.6.13 PLAY flag set register (PLAY_FLSET) 1023
23.6.14 PLAY flag clear register (PLAY_FLCLR) 1024
23.6.15 PLAY flag interrupt enable register (PLAY_FLIER) 1024
23.6.16 PLAY flag control register (PLAY_FLCTL) 1025
23.6.17 PLAY miscellaneous status register (PLAY_MSR) 1026
23.6.18 PLAY interrupt status register (PLAY_ISR) 1026
23.6.19 PLAY interrupt clear register (PLAY_ICR) 1027
23.6.20 PLAY interrupt enable register (PLAY_IER) 1028
23.7 PLAY register map 1028

24 Extended-SPI interface (XSPI) 1031
24.1 XSPI introduction 1031
24.2 XSPI main features 1031
24.3 XSPI implementation 1032
24.4 XSPI functional description 1033
24.4.1 XSPI block diagram 1033
24.4.2 XSPI pins and internal signals 1034
24.4.3 XSPI interface to memory modes 1035
24.4.4 XSPI regular-command protocol 1035
24.4.5 XSPI regular-command protocol signal interface 1038
24.4.6 HyperBus protocol 1042
24.4.7 Specific features 1045
24.4.8 XSPI operating mode introduction 1046
24.4.9 XSPI indirect mode 1046
24.4.10 XSPI automatic status-polling mode 1048
24.4.11 XSPI memory-mapped mode 1049
24.4.12 XSPI configuration introduction 1050
24.4.13 XSPI system configuration 1050
24.4.14 XSPI device configuration 1051
24.4.15 XSPI regular-command mode configuration 1054
24.4.16 XSPI HyperBus protocol configuration 1056
24.4.17 XSPI error management 1057
24.4.18 XSPI BUSY and ABORT 1057

24.4.19 XSPI reconfiguration or deactivation 1058
24.4.20 NCS behavior 1058
24.4.21 Software control of two external memories 1058
24.4.22 Hardware-controlled extended memory support 1059
24.5 Address alignment and data number 1060
24.6 XSPI interrupts 1061
24.7 XSPI registers 1062
24.7.1 XSPI control register (XSPI_CR) 1062
24.7.2 XSPI device configuration register 1 (XSPI_DCR1) 1065
24.7.3 XSPI device configuration register 2 (XSPI_DCR2) 1067
24.7.4 XSPI device configuration register 3 (XSPI_DCR3) 1068
24.7.5 XSPI device configuration register 4 (XSPI_DCR4) 1068
24.7.6 XSPI status register (XSPI_SR) 1069
24.7.7 XSPI flag clear register (XSPI_FCR) 1070
24.7.8 XSPI data length register (XSPI_DLR) 1070
24.7.9 XSPI address register (XSPI_AR) 1071
24.7.10 XSPI data register (XSPI_DR) 1072
24.7.11 XSPI polling status mask register (XSPI_PSMKR) 1072
24.7.12 XSPI polling status match register (XSPI_PSMAR) 1073
24.7.13 XSPI polling interval register (XSPI_PIR) 1073
24.7.14 XSPI communication configuration register (XSPI_CCR) 1073
24.7.15 XSPI timing configuration register (XSPI_TCR) 1075
24.7.16 XSPI instruction register (XSPI_IR) 1076
24.7.17 XSPI alternate bytes register (XSPI_ABR) 1076
24.7.18 XSPI low-power timeout register (XSPI_LPTR) 1077
24.7.19 XSPI wrap communication configuration register (XSPI_WPCCR) 1077
24.7.20 XSPI wrap timing configuration register (XSPI_WPTCR) 1079
24.7.21 XSPI wrap instruction register (XSPI_WPIR) 1080
24.7.22 XSPI wrap alternate bytes register (XSPI_WPABR) 1080
24.7.23 XSPI write communication configuration register (XSPI_WCCR) 1081
24.7.24 XSPI write timing configuration register (XSPI_WTCR) 1083
24.7.25 XSPI write instruction register (XSPI_WIR) 1083
24.7.26 XSPI write alternate bytes register (XSPI_WABR) 1084
24.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR) 1084
24.7.28 XSPI register map 1085

25 Delay block (DLYB) 1088
25.1 DLYB introduction 1088
25.2 DLYB main features 1088
25.3 DLYB implementation 1088
25.4 DLYB functional description 1088
25.4.1 DLYB diagram 1088
25.4.2 DLYB pins and internal signals 1089
25.4.3 General description 1089
25.4.4 Delay line length configuration procedure 1090
25.4.5 Output clock phase configuration procedure 1091
25.5 DLYB registers 1092
25.5.1 DLYB control register (DLYB_CR) 1092
25.5.2 DLYB configuration register (DLYB_CFGR) 1092
25.5.3 DLYB register map 1093

26 Analog-to-digital converters (ADC) 1094
26.1 ADC introduction 1094
26.2 ADC main features 1094
26.3 ADC implementation 1096
26.4 ADC functional description 1097
26.4.1 ADC block diagram 1097
26.4.2 ADC pins and internal signals 1098
26.4.3 ADC clocks 1103
26.4.4 ADC connectivity 1105
26.4.5 Slave AHB interface 1108
26.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN) 1108
26.4.7 Single-ended and differential input channels 1108
26.4.8 Pseudodifferential mode 1109
26.4.9 Calibration (ADCAL, ADCALDIF, ADC_CALFACT) 1109
26.4.10 ADC on-off control (ADEN, ADDIS, ADRDY) 1112
26.4.11 Constraints when writing the ADC control bits 1113
26.4.12 Channel selection (ADC_SQRy, ADC_JSQR) 1114
26.4.13 Channel preselection register (ADC_PCSEL) 1115
26.4.14 Channel-wise programmable sampling time (SMPR1, SMPR2) 1115
26.4.15 Single conversion mode 1117

26.4.16 Continuous conversion mode (CONT = 1) 1118
26.4.17 Discontinuous mode (DISCEN, DISCNUM, JDISCEN) 1118
26.4.18 Starting conversions (ADSTART, JADSTART) 1120
26.4.19 Timing 1121
26.4.20 Stopping an ongoing conversion (ADSTP, JADSTP) 1122
26.4.21 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN) 1123
26.4.22 Injected channel management 1125
26.4.23 Queue of context for injected conversions 1126
26.4.24 Programmable resolution (RES) - fast conversion mode 1134
26.4.25 End of conversion and end of sampling phase (EOC, JEOC, EOSMP) 1135
26.4.26 End of conversion sequence (EOS, JEOS) 1135
26.4.27 Timing diagram examples (single/continuous modes, hardware/software triggers) 1136
26.4.28 Data management 1138
26.4.29 Dynamic low-power features 1146
26.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT) 1150
26.4.31 Oversampler 1155
26.4.32 Parallel injected oversampling mode 1161
26.4.33 Dual ADC modes 1163
26.4.34 Temperature sensor 1178
26.4.35 Monitoring the internal voltage reference 1180
26.4.36 Monitoring the OPAMP output voltage 1182
26.4.37 Monitoring the supply voltage 1182
26.5 ADC interrupts 1182
26.6 ADC registers (for each ADC) 1183
26.6.1 ADC interrupt and status register (ADC_ISR) 1183
26.6.2 ADC interrupt enable register (ADC_IER) 1186
26.6.3 ADC control register (ADC_CR) 1188
26.6.4 ADC configuration register (ADC_CFGR1) 1191
26.6.5 ADC configuration register 2 (ADC_CFGR2) 1194
26.6.6 ADC sample time register 1 (ADC_SMPR1) 1197
26.6.7 ADC sample time register 2 (ADC_SMPR2) 1198
26.6.8 ADC channel preselection register (ADC_PCSEL) 1198
26.6.9 ADC regular sequence register 1 (ADC_SQR1) 1199

26.6.10 ADC regular sequence register 2 (ADC_SQR2) 1200
26.6.11 ADC regular sequence register 3 (ADC_SQR3) 1201
26.6.12 ADC regular sequence register 4 (ADC_SQR4) 1202
26.6.13 ADC regular data register (ADC_DR) 1203
26.6.14 ADC injected sequence register (ADC_JSQR) 1203
26.6.15 ADC offset y configuration register (ADC_OFCFGRy) 1205
26.6.16 ADC offset y register (ADC_OFRy) 1206
26.6.17 ADC gain compensation register (ADC_GCOMP) 1206
26.6.18 ADC analog watchdog y source channel register (ADC_AWDySR) . 1207
26.6.19 ADC injected channel y data register (ADC_JDRy) 1208
26.6.20 ADC configuration register 3 (ADC_CFGR3) 1208
26.6.21 ADC injected oversampling counter register 1 (ADC_JOVSCR1) . . . 1210
26.6.22 ADC injected oversampling counter register 2 (ADC_JOVSCR2) . . . 1211
26.6.23 ADC analog watchdog 2 configuration register (ADC_AWD2CR) . . . 1212
26.6.24 ADC analog watchdog 3 configuration register (ADC_AWD3CR) . . . 1212
26.6.25 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR) 1213
26.6.26 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR) 1213
26.6.27 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR) 1214
26.6.28 ADC analog watchdog 2 higher threshold register (ADC_AWD2HTR) 1214
26.6.29 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR) 1215
26.6.30 ADC analog watchdog 3 higher threshold register (ADC_AWD3HTR) 1215
26.6.31 ADC differential mode selection register (ADC_DIFSEL) 1216
26.6.32 ADC calibration factors (ADC_CALFACT) 1216
26.6.33 ADC option register (ADC_OR) 1218
26.7 ADC common registers 1219
26.7.1 ADC common status register (ADCC_CSR) 1219
26.7.2 ADC common control register (ADCC_CCR) 1221
26.7.3 ADC common regular data register for dual mode (ADCC_CDR) 1222
26.7.4 ADC common regular data register for dual mode (ADCC_CDR2) 1223
26.8 ADC register map 1223

27 Digital temperature sensor (DTS) 1228
27.1 DTS introduction 1228

27.2 DTS main features 1228
27.3 DTS functional description 1229
27.3.1 DTS block diagram 1229
27.3.2 DTS internal signals 1229
27.3.3 DTS block operation 1230
27.3.4 Operating modes 1230
27.3.5 Calibration 1230
27.3.6 Prescaler 1230
27.3.7 Temperature measurement principles 1231
27.3.8 Sampling time 1232
27.3.9 Quick measurement mode 1232
27.3.10 Trigger input 1233
27.3.11 On-off control and ready flag 1233
27.3.12 Temperature measurement sequence 1234
27.4 DTS low-power modes 1235
27.5 DTS interrupts 1235
27.5.1 Temperature window comparator 1235
27.5.2 Synchronous interrupt 1235
27.5.3 Asynchronous wake-up 1235
27.6 DTS registers 1236
27.6.1 Temperature sensor configuration register 1 (DTS_CFGR1) 1236
27.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1) 1237
27.6.3 Temperature sensor ramp value register (DTS_RAMPVALR) 1238
27.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1) 1238
27.6.5 Temperature sensor data register (DTS_DR) 1239
27.6.6 Temperature sensor status register (DTS_SR) 1239
27.6.7 Temperature sensor interrupt enable register (DTS_ITENR) 1240
27.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR) 1242
27.6.9 Temperature sensor option register (DTS_OR) 1242
27.6.10 DTS register map 1243

28 Digital-to-analog converter (DAC) 1245
28.1 DAC introduction 1245
28.2 DAC main features 1245
28.3 DAC implementation 1246
28.4 DAC functional description 1247

28.4.1 DAC block diagram . . . 1247
28.4.2 DAC pins and internal signals . . . 1247
28.4.3 DAC channel enable . . . 1251
28.4.4 DAC data format . . . 1251
28.4.5 DAC conversion . . . 1252
28.4.6 DAC output voltage . . . 1253
28.4.7 DAC trigger selection . . . 1253
28.4.8 DMA requests . . . 1254
28.4.9 Noise generation . . . 1254
28.4.10 Triangle-wave generation . . . 1256
28.4.11 DAC sawtooth wave generation . . . 1257
28.4.12 DAC extended sawtooth wave generation . . . 1258
28.4.13 DAC channel modes . . . 1261
28.4.14 DAC channel buffer calibration . . . 1265
28.4.15 DAC channel conversion modes . . . 1266
28.5 DAC in low-power modes . . . 1267
28.6 DAC interrupts . . . 1268
28.7 DAC registers . . . 1268
28.7.1 DAC control register (DAC_CR) . . . 1268
28.7.2 DAC software trigger register (DAC_SWTRGR) . . . 1270
28.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1) . . . 1270
28.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1) . . . 1271
28.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1) . . . 1271
28.7.6 DAC channel1 data output register (DAC_DOR1) . . . 1272
28.7.7 DAC status register (DAC_SR) . . . 1272
28.7.8 DAC calibration control register (DAC_CCR) . . . 1273
28.7.9 DAC mode control register (DAC_MCR) . . . 1273
28.7.10 DAC channel1 sample and hold sample time register (DAC_SHSR1) . . . 1274
28.7.11 DAC sample and hold time register (DAC_SHHR) . . . 1275
28.7.12 DAC sample and hold refresh time register (DAC_SHRR) . . . 1275
28.7.13 DAC channel1 sawtooth register (DAC_STR1) . . . 1276
28.7.14 DAC sawtooth mode register (DAC_STMODR) . . . 1276
28.7.15 DAC extended sawtooth reset control register (DAC_STEXTRST) . 1277

28.7.16 DAC extended sawtooth minimum and maximum value register (DAC_STEXTMM1) . . . 1277
28.7.17 DAC option register (DAC_OR) . . . 1278
28.7.18 DAC register map . . . 1278

29 Voltage reference buffer (VREFBUF) . . . 1281
29.1 VREFBUF introduction . . . 1281
29.2 VREFBUF implementation . . . 1281
29.3 VREFBUF functional description . . . 1281
29.4 VREFBUF trimming . . . 1282
29.5 VREFBUF registers . . . 1283
29.5.1 VREFBUF control and status register (VREFBUF_CSR) . . . 1283
29.5.2 VREFBUF calibration control register (VREFBUF_CCR) . . . 1284
29.5.3 VREFBUF register map . . . 1285

30 Comparator (COMP) . . . 1286
30.1 COMP introduction . . . 1286
30.2 COMP main features . . . 1286
30.3 COMP functional description . . . 1287
30.3.1 COMP simplified block diagram . . . 1287
30.3.2 COMP pins and internal signals . . . 1287
30.3.3 COMP reset and clocks . . . 1289
30.3.4 Comparator LOCK mechanism . . . 1289
30.3.5 Window comparator . . . 1289
30.3.6 Hysteresis . . . 1290
30.3.7 Deglitcher feature . . . 1291
30.3.8 Digital signal filter . . . 1291
30.3.9 Comparator output blanking function . . . 1292
30.3.10 COMP startup stabilization time . . . 1292
30.4 COMP low-power modes . . . 1293
30.5 COMP interrupts . . . 1293
30.6 COMP registers . . . 1293
30.6.1 Comparator x configuration register (COMPx_CSR) . . . 1293
30.6.2 Comparator x filter configuration register (COMPx_FLTR) . . . 1295
30.6.3 COMPx register map . . . 1296

31 Operational amplifier (OPAMP) 1297

31.1 Introduction 1297

31.2 OPAMP main features 1297

31.3 OPAMP implementation 1297

31.4 OPAMP functional description 1299

31.4.1 OPAMP block diagram 1299

31.4.2 OPAMP pins and internal signals 1300

31.4.3 OPAMP reset and clocks 1301

31.4.4 OPAMP output redirection to an internal ADC/COMP channel 1302

31.4.5 OPAMP initial configuration 1302

31.4.6 OPAMP operational amplifier speed 1302

31.4.7 OPAMP enable 1302

31.4.8 OPAMP operating modes 1302

31.4.9 OPAMP programmable gain 1309

31.4.10 OPAMP operational amplifier offset compensation 1310

31.4.11 OPAMP calibration 1310

31.4.12 Timer-controlled operation 1312

31.5 OPAMP in low-power modes 1313

31.6 OPAMP registers 1314

31.6.1 OPAMP control/status register (OPAMP_CSR) 1314

31.6.2 OPAMP timer-controlled mode register (OPAMP_TCMR) 1317

31.6.3 OPAMP register map 1320

32 Coupling and chaining bridge (CCB) 1321

32.1 CCB introduction 1321

32.2 CCB main features 1321

32.3 CCB implementation 1322

32.4 CCB functional description 1322

32.4.1 CCB block diagram 1322

32.4.2 CCB internal signals 1323

32.4.3 CCB reset and clocks 1323

32.4.4 CCB coupling and chaining 1323

32.4.5 CCB error management 1326

32.5 CCB coupling and chaining operations 1326

32.5.1 Preliminary steps before any protected operation 1328

32.5.2 ECDSA signature 1329

32.5.3 ECC scalar multiplication 1336
32.5.4 RSA modular exponentiation 1339
32.6 CCB interrupts 1341
32.7 CCB registers 1342
32.7.1 CCB control register (CCB_CR) 1342
32.7.2 CCB status register (CCB_SR) 1343
32.7.3 CCB reference tag register (CCB_REFTAGRx) 1345
32.7.4 CCB register map 1346

33 True random number generator (RNG) 1347
33.1 RNG introduction 1347
33.2 RNG main features 1347
33.3 RNG functional description 1348
33.3.1 RNG block diagram 1348
33.3.2 RNG internal signals 1348
33.3.3 Random number generation 1349
33.3.4 RNG initialization 1351
33.3.5 RNG operation 1352
33.3.6 RNG clocking 1354
33.3.7 Error management 1354
33.3.8 RNG low-power use 1356
33.4 RNG interrupts 1356
33.5 RNG processing time 1357
33.6 RNG entropy source validation 1357
33.6.1 Introduction 1357
33.6.2 Validation conditions 1357
33.7 RNG registers 1359
33.7.1 RNG control register (RNG_CR) 1359
33.7.2 RNG status register (RNG_SR) 1361
33.7.3 RNG data register (RNG_DR) 1362
33.7.4 RNG noise source control register (RNG_NSCR) 1363
33.7.5 RNG health test control register x (RNG_HTCRx) 1363
33.7.6 RNG health test status register 0 (RNG_HTSR0) 1364
33.7.7 RNG health test status register 1 (RNG_HTSR1) 1364
33.7.8 RNG noise source mask register (RNG_NSMR) 1365
33.7.9 RNG register map 1366

34 AES hardware accelerator (AES) 1367
34.1 AES introduction 1367
34.2 AES main features 1367
34.3 AES implementation 1368
34.4 AES functional description 1368
34.4.1 AES block diagram 1368
34.4.2 AES internal signals 1369
34.4.3 AES reset and clocks 1369
34.4.4 AES symmetric cipher implementation 1369
34.4.5 AES encryption or decryption typical usage 1370
34.4.6 AES authenticated encryption, decryption, and cipher-based message authentication 1373
34.4.7 AES ciphertext stealing and data padding 1373
34.4.8 AES suspend and resume operations 1374
34.4.9 AES basic chaining modes (ECB, CBC) 1374
34.4.10 AES counter (CTR) mode 1378
34.4.11 AES Galois/counter mode (GCM) 1380
34.4.12 AES Galois message authentication code (GMAC) 1385
34.4.13 AES counter with CBC-MAC (CCM) 1386
34.4.14 AES key sharing with secure AES co-processor 1391
34.4.15 AES data registers and data swapping 1392
34.4.16 AES key registers 1394
34.4.17 AES initialization vector registers 1394
34.4.18 AES error management 1395
34.5 AES interrupts 1396
34.6 AES DMA requests 1396
34.7 AES processing latency 1397
34.8 AES registers 1399
34.8.1 AES control register (AES_CR) 1399
34.8.2 AES status register (AES_SR) 1401
34.8.3 AES data input register (AES_DINR) 1402
34.8.4 AES data output register (AES_DOUTR) 1403
34.8.5 AES key register 0 (AES_KEYR0) 1403
34.8.6 AES key register 1 (AES_KEYR1) 1404
34.8.7 AES key register 2 (AES_KEYR2) 1404
34.8.8 AES key register 3 (AES_KEYR3) 1404

34.8.9 AES initialization vector register 0 (AES_IVR0) 1405
34.8.10 AES initialization vector register 1 (AES_IVR1) 1405
34.8.11 AES initialization vector register 2 (AES_IVR2) 1405
34.8.12 AES initialization vector register 3 (AES_IVR3) 1406
34.8.13 AES key register 4 (AES_KEYR4) 1406
34.8.14 AES key register 5 (AES_KEYR5) 1406
34.8.15 AES key register 6 (AES_KEYR6) 1407
34.8.16 AES key register 7 (AES_KEYR7) 1407
34.8.17 AES suspend registers (AES_SUSPRx) 1407
34.8.18 AES interrupt enable register (AES_IER) 1408
34.8.19 AES interrupt status register (AES_ISR) 1409
34.8.20 AES interrupt clear register (AES_ICR) 1410
34.8.21 AES register map 1410

35 Secure AES coprocessor (SAES) 1413

35.1 SAES introduction 1413
35.2 SAES main features 1413
35.3 SAES implementation 1414
35.4 SAES functional description 1414
35.4.1 SAES block diagram 1414
35.4.2 SAES internal signals 1415
35.4.3 SAES reset and clocks 1416
35.4.4 SAES symmetric cipher implementation 1416
35.4.5 SAES encryption or decryption typical usage 1417
35.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication 1419
35.4.7 SAES ciphertext stealing and data padding 1420
35.4.8 SAES suspend and resume operations 1420
35.4.9 SAES basic chaining modes (ECB, CBC) 1421
35.4.10 SAES counter (CTR) mode 1425
35.4.11 SAES Galois/counter mode (GCM) 1427
35.4.12 SAES Galois message authentication code (GMAC) 1431
35.4.13 SAES counter with CBC-MAC (CCM) 1433
35.4.14 SAES operation with wrapped keys 1438
35.4.15 SAES operation with shared keys 1442
35.4.16 SAES data registers and data swapping 1443
35.4.17 SAES key registers 1446

35.4.18 SAES initialization vector registers . . . 1447
35.4.19 SAES error management . . . 1448
35.5 SAES interrupts . . . 1450
35.6 SAES DMA requests . . . 1450
35.7 SAES processing latency . . . 1451
35.8 SAES registers . . . 1453
35.8.1 SAES control register (SAES_CR) . . . 1453
35.8.2 SAES status register (SAES_SR) . . . 1456
35.8.3 SAES data input register (SAES_DINR) . . . 1457
35.8.4 SAES data output register (SAES_DOUTR) . . . 1458
35.8.5 SAES key register 0 (SAES_KEYR0) . . . 1458
35.8.6 SAES key register 1 (SAES_KEYR1) . . . 1459
35.8.7 SAES key register 2 (SAES_KEYR2) . . . 1459
35.8.8 SAES key register 3 (SAES_KEYR3) . . . 1459
35.8.9 SAES initialization vector register 0 (SAES_IVR0) . . . 1460
35.8.10 SAES initialization vector register 1 (SAES_IVR1) . . . 1460
35.8.11 SAES initialization vector register 2 (SAES_IVR2) . . . 1460
35.8.12 SAES initialization vector register 3 (SAES_IVR3) . . . 1461
35.8.13 SAES key register 4 (SAES_KEYR4) . . . 1461
35.8.14 SAES key register 5 (SAES_KEYR5) . . . 1461
35.8.15 SAES key register 6 (SAES_KEYR6) . . . 1462
35.8.16 SAES key register 7 (SAES_KEYR7) . . . 1462
35.8.17 SAES suspend registers (SAES_SUSPRx) . . . 1462
35.8.18 SAES interrupt enable register (SAES_IER) . . . 1463
35.8.19 SAES interrupt status register (SAES_ISR) . . . 1464
35.8.20 SAES interrupt clear register (SAES_ICR) . . . 1465
35.8.21 SAES register map . . . 1466

36 Hash processor (HASH) . . . 1468
36.1 HASH introduction . . . 1468
36.2 HASH main features . . . 1468
36.3 HASH implementation . . . 1469
36.4 HASH functional description . . . 1469
36.4.1 HASH block diagram . . . 1469
36.4.2 HASH internal signals . . . 1469
36.4.3 About secure hash algorithms . . . 1470

36.4.4 Message data feeding 1470
36.4.5 Message digest computing 1471
36.4.6 Message padding 1473
36.4.7 HMAC operation 1475
36.4.8 HASH suspend/resume operations 1476
36.4.9 HASH DMA interface 1478
36.4.10 HASH error management 1479
36.4.11 HASH processing time 1479
36.5 HASH interrupts 1480
36.6 HASH registers 1480
36.6.1 HASH control register (HASH_CR) 1480
36.6.2 HASH data input register (HASH_DIN) 1482
36.6.3 HASH start register (HASH_STR) 1483
36.6.4 HASH digest registers 1484
36.6.5 HASH interrupt enable register (HASH_IMR) 1486
36.6.6 HASH status register (HASH_SR) 1486
36.6.7 HASH context swap registers 1487
36.6.8 HASH register map 1488

37 Public key accelerator (PKA) 1490
37.1 PKA introduction 1490
37.2 PKA main features 1490
37.3 PKA functional description 1491
37.3.1 PKA block diagram 1491
37.3.2 PKA internal signals 1491
37.3.3 PKA reset and clocks 1491
37.3.4 PKA public key acceleration 1491
37.3.5 Typical applications for PKA 1493
37.3.6 PKA procedure to perform an operation 1495
37.3.7 PKA error management 1496
37.4 PKA operating modes 1497
37.4.1 Introduction 1497
37.4.2 Montgomery parameter computation 1498
37.4.3 Modular addition 1498
37.4.4 Modular subtraction 1499
37.4.5 Modular and Montgomery multiplication 1499

37.4.6 Modular exponentiation 1500
37.4.7 Modular inversion 1501
37.4.8 Modular reduction 1502
37.4.9 Arithmetic addition 1502
37.4.10 Arithmetic subtraction 1503
37.4.11 Arithmetic multiplication 1503
37.4.12 Arithmetic comparison 1503
37.4.13 RSA CRT exponentiation 1504
37.4.14 Point on elliptic curve Fp check 1505
37.4.15 ECC Fp scalar multiplication 1505
37.4.16 ECDSA sign 1506
37.4.17 ECDSA verification 1508
37.4.18 ECC complete addition 1509
37.4.19 ECC double base ladder 1509
37.4.20 ECC projective to affine 1510
37.5 Example of configurations and processing times 1511
37.5.1 Supported elliptic curves 1511
37.5.2 Computation times 1513
37.6 PKA interrupts 1515
37.7 PKA registers 1516
37.7.1 PKA control register (PKA_CR) 1516
37.7.2 PKA status register (PKA_SR) 1518
37.7.3 PKA clear flag register (PKA_CLRFR) 1519
37.7.4 PKA RAM 1519
37.7.5 PKA register map 1520

38 Public key secure accelerator (PKA) 1521
38.1 PKA introduction 1521
38.2 PKA main features 1521
38.3 PKA functional description 1522
38.3.1 PKA block diagram 1522
38.3.2 PKA internal signals 1522
38.3.3 PKA reset and clocks 1523
38.3.4 PKA public key acceleration 1523
38.3.5 Typical applications for PKA 1525
38.3.6 PKA procedure to perform an operation 1527

38.3.7 Private keys protection using CCB 1528
38.3.8 PKA error management 1532
38.4 PKA operating modes 1532
38.4.1 Introduction 1532
38.4.2 Montgomery parameter computation 1534
38.4.3 Modular addition 1534
38.4.4 Modular subtraction 1535
38.4.5 Modular and Montgomery multiplication 1535
38.4.6 Modular exponentiation 1536
38.4.7 Modular inversion 1538
38.4.8 Modular reduction 1538
38.4.9 Arithmetic addition 1539
38.4.10 Arithmetic subtraction 1539
38.4.11 Arithmetic multiplication 1540
38.4.12 Arithmetic comparison 1540
38.4.13 RSA CRT exponentiation 1540
38.4.14 Point on elliptic curve Fp check 1541
38.4.15 ECC Fp scalar multiplication 1542
38.4.16 ECDSA sign 1543
38.4.17 ECDSA verification 1545
38.4.18 ECC complete addition 1546
38.4.19 ECC double base ladder 1546
38.4.20 ECC projective to affine 1547
38.5 Example of configurations and processing times 1548
38.5.1 Supported elliptic curves 1548
38.5.2 Computation times 1550
38.6 PKA interrupts 1552
38.7 PKA registers 1553
38.7.1 PKA control register (PKA_CR) 1553
38.7.2 PKA status register (PKA_SR) 1555
38.7.3 PKA clear flag register (PKA_CLRFR) 1557
38.7.4 PKA RAM 1558
38.7.5 PKA register map 1559

39 On-the-fly decryption engine (OTFDEC) 1560

39.1 OTFDEC introduction 1560

39.2 OTFDEC main features 1560
39.3 OTFDEC functional description 1561
39.3.1 OTFDEC block diagram 1561
39.3.2 OTFDEC internal signals 1561
39.3.3 OTFDEC on-the-fly decryption 1562
39.3.4 OTFDEC usage of AES in counter mode decryption 1563
39.3.5 Flow control management 1564
39.3.6 OTFDEC error management 1564
39.4 OTFDEC interrupts 1565
39.5 OTFDEC application information 1565
39.5.1 OTFDEC initialization process 1565
39.5.2 OTFDEC and power management 1567
39.5.3 Encrypting for OTFDEC 1567
39.5.4 OTFDEC key CRC source code 1568
39.6 OTFDEC registers 1569
39.6.1 OTFDEC control register (OTFDEC_CR) 1569
39.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR) 1570
39.6.3 OTFDEC region x configuration register (OTFDEC_RxCFGR) 1570
39.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR) 1572
39.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR) . 1572
39.6.6 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0) 1573
39.6.7 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1) 1574
39.6.8 OTFDEC region x key register 0 (OTFDEC_RxKEYR0) 1574
39.6.9 OTFDEC region x key register 1 (OTFDEC_RxKEYR1) 1575
39.6.10 OTFDEC region x key register 2 (OTFDEC_RxKEYR2) 1575
39.6.11 OTFDEC region x key register 3 (OTFDEC_RxKEYR3) 1576
39.6.12 OTFDEC interrupt status register (OTFDEC_ISR) 1576
39.6.13 OTFDEC interrupt clear register (OTFDEC_ICR) 1577
39.6.14 OTFDEC interrupt enable register (OTFDEC_IER) 1578
39.6.15 OTFDEC register map 1579

40 High-resolution timer (HRTIM) 1583
40.1 Introduction 1583
40.2 Main features 1584
40.3 Functional description 1585

40.3.1 General description . . . 1585
40.3.2 HRTIM pins and internal signals . . . 1587
40.3.3 Clocks . . . 1593
40.3.4 Timer A..F timing units . . . 1597
40.3.5 Master timer . . . 1628
40.3.6 Up-down counting mode . . . 1630
40.3.7 Set/reset events priorities and narrow pulses management . . . 1637
40.3.8 External events global conditioning . . . 1640
40.3.9 External event filtering in timing units . . . 1645
40.3.10 Delayed protection . . . 1653
40.3.11 Register preload and update management . . . 1659
40.3.12 PWM mode with “greater than” comparison . . . 1663
40.3.13 Events propagation within or across multiple timers . . . 1664
40.3.14 Output management . . . 1669
40.3.15 Burst mode controller . . . 1671
40.3.16 Chopper . . . 1679
40.3.17 Fault protection . . . 1680
40.3.18 Auxiliary outputs . . . 1685
40.3.19 Synchronizing the HRTIM with other timers or HRTIM instances . . . 1688
40.3.20 ADC triggers . . . 1691
40.3.21 DAC triggers . . . 1695
40.3.22 Interrupts . . . 1699
40.3.23 DMA . . . 1701
40.3.24 HRTIM initialization . . . 1705
40.3.25 Debug . . . 1706
40.4 Application use cases . . . 1707
40.4.1 Buck converter . . . 1707
40.4.2 Buck converter with synchronous rectification . . . 1708
40.4.3 Multiphase converters . . . 1709
40.4.4 Transition mode power factor correction . . . 1711
40.5 HRTIM registers . . . 1713
40.5.1 HRTIM master timer control register (HRTIM_MCR) . . . 1713
40.5.2 HRTIM master timer interrupt status register (HRTIM_MISR) . . . 1716
40.5.3 HRTIM master timer interrupt clear register (HRTIM_MICR) . . . 1717
40.5.4 HRTIM master timer DMA interrupt enable register (HRTIM_MDIER) . . . 1718
40.5.5 HRTIM master timer counter register (HRTIM_MCNTR) . . . 1720

40.5.6 HRTIM master timer period register (HRTIM_MPER) 1720
40.5.7 HRTIM master timer repetition register (HRTIM_MREP) 1721
40.5.8 HRTIM master timer compare 1 register (HRTIM_MCMP1R) 1721
40.5.9 HRTIM master timer compare 2 register (HRTIM_MCMP2R) 1722
40.5.10 HRTIM master timer compare 3 register (HRTIM_MCMP3R) 1722
40.5.11 HRTIM master timer compare 4 register (HRTIM_MCMP4R) 1723
40.5.12 HRTIM timer x control register (HRTIM_TIMxCR) (x = A to F) 1724
40.5.13 HRTIM timer x interrupt status register (HRTIM_TIMxISR) (x = A to F) 1728
40.5.14 HRTIM timer x interrupt clear register (HRTIM_TIMxICR) (x = A to F) 1730
40.5.15 HRTIM timer x DMA interrupt enable register (HRTIM_TIMxDIER) (x = A to F) 1732
40.5.16 HRTIM timer x counter register (HRTIM_CNTxR) (x = A to F) 1735
40.5.17 HRTIM timer x period register (HRTIM_PERxR) (x = A to F) 1735
40.5.18 HRTIM timer x repetition register (HRTIM_REPxR) (x = A to F) 1737
40.5.19 HRTIM timer x compare 1 register (HRTIM_CMP1xR) (x = A to F) . . 1737
40.5.20 HRTIM timer x compare 1 compound register (HRTIM_CMP1CxR) (x = A to F) 1739
40.5.21 HRTIM timer x compare 2 register (HRTIM_CMP2xR) (x = A to F) . . 1739
40.5.22 HRTIM timer x compare 3 register (HRTIM_CMP3xR) (x = A to F) . . 1741
40.5.23 HRTIM timer x compare 4 register (HRTIM_CMP4xR) (x = A to F) . . 1742
40.5.24 HRTIM timer x capture 1 register (HRTIM_CPT1xR) (x = A to F) . . . 1743
40.5.25 HRTIM timer x capture 2 register (HRTIM_CPT2xR) (x = A to F) 1744
40.5.26 HRTIM timer x deadtime register (HRTIM_DTxR) (x = A to F) 1745
40.5.27 HRTIM timer x output 1 set register (HRTIM_SETx1R) (x = A to F) . 1747
40.5.28 HRTIM timer x output 1 reset register (HRTIM_RSTx1R) (x = A to F) 1750
40.5.29 HRTIM timer x output 2 set register (HRTIM_SETx2R) (x = A to F) . 1752
40.5.30 HRTIM timer x output 2 reset register (HRTIM_RSTx2R) (x = A to F) 1755
40.5.31 HRTIM timer x external event filtering register 1 (HRTIM_EEFxR1) (x = A to F) 1758
40.5.32 HRTIM timer x external event filtering register 2 (HRTIM_EEFxR2) (x = A to F) 1761
40.5.33 HRTIM timer A reset register (HRTIM_RSTAR) 1762
40.5.34 HRTIM timer B reset register (HRTIM_RSTBR) 1764
40.5.35 HRTIM timer C reset register (HRTIM_RSTCR) 1766
40.5.36 HRTIM timer D reset register (HRTIM_RSTDR) 1768
40.5.37 HRTIM timer E reset register (HRTIM_RSTER) 1770

40.5.38 HRTIM timer F reset register (HRTIM_RSTFR) 1772
40.5.39 HRTIM timer x chopper register (HRTIM_CHPxR) (x = A to F) 1774
40.5.40 HRTIM timer A capture 1 control register (HRTIM_CPT1ACR) 1775
40.5.41 HRTIM timer B capture 1 control register (HRTIM_CPT1BCR) 1777
40.5.42 HRTIM timer C capture 1 control register (HRTIM_CPT1CCR) 1779
40.5.43 HRTIM timer D capture 1 control register (HRTIM_CPT1DCR) 1781
40.5.44 HRTIM timer E capture 1 control register (HRTIM_CPT1ECR) 1783
40.5.45 HRTIM timer F capture 1 control register (HRTIM_CPT1FCR) 1785
40.5.46 HRTIM timer A capture 2 control register (HRTIM_CPT2ACR) 1787
40.5.47 HRTIM timer B capture 2 control register (HRTIM_CPT2BCR) 1789
40.5.48 HRTIM timer C capture 2 control register (HRTIM_CPT2CCR) 1791
40.5.49 HRTIM timer D capture 2 control register (HRTIM_CPT2DCR) 1793
40.5.50 HRTIM timer E capture 2 control register (HRTIM_CPT2ECR) 1795
40.5.51 HRTIM timer F capture 2 control register (HRTIM_CPT2FCR) 1797
40.5.52 HRTIM timer x output register (HRTIM_OUTxR) (x = A to F) 1799
40.5.53 HRTIM timer x fault register (HRTIM_FLTxR) (x = A to F) 1802
40.5.54 HRTIM timer x control register 2 (HRTIM_TIMxCR2) (x = A to F) . . . 1804
40.5.55 HRTIM timer x external event filtering register 3 (HRTIM_TIMxEEFR3) (x = A to F) 1808
40.5.56 HRTIM timer x external event selection register (HRTIM_EESELxR) (x = A to F) 1810
40.5.57 HRTIM timer x crossbar override trigger register (HRTIM_COTRGxR) (x = A to F) 1813
40.5.58 HRTIM timer x crossbar override forcing event register (HRTIM_COFExR) (x = A to F) 1816
40.5.59 HRTIM timer x crossbar override delayed fault event register (HRTIM_CODExR) (x = A to F) 1819
40.5.60 HRTIM control register 1 (HRTIM_CR1) 1820
40.5.61 HRTIM control register 2 (HRTIM_CR2) 1822
40.5.62 HRTIM interrupt status register (HRTIM_ISR) 1824
40.5.63 HRTIM interrupt clear register (HRTIM_ICR) 1825
40.5.64 HRTIM interrupt enable register (HRTIM_IER) 1826
40.5.65 HRTIM output enable register (HRTIM_OENR) 1827
40.5.66 HRTIM output disable register (HRTIM_ODISR) 1828
40.5.67 HRTIM output disable status register (HRTIM_ODSR) 1829
40.5.68 HRTIM burst mode control register (HRTIM_BMCR) 1830
40.5.69 HRTIM burst mode trigger register (HRTIM_BMTRGR) 1832
40.5.70 HRTIM burst mode compare register (HRTIM_BMCMPR) 1834

40.5.71 HRTIM burst mode period register (HRTIM_BMPER) 1834
40.5.72 HRTIM timer external event control register 1 (HRTIM_EECR1) . . . 1835
40.5.73 HRTIM timer external event control register 2 (HRTIM_EECR2) . . . 1837
40.5.74 HRTIM timer external event control register 3 (HRTIM_EECR3) . . . 1838
40.5.75 HRTIM ADC trigger 1 register (HRTIM_ADC1R) 1839
40.5.76 HRTIM ADC trigger 2 register (HRTIM_ADC2R) 1842
40.5.77 HRTIM ADC trigger 3 register (HRTIM_ADC3R) 1844
40.5.78 HRTIM ADC trigger 4 register (HRTIM_ADC4R) 1846
40.5.79 HRTIM DLL control register (HRTIM_DLLCR) 1848
40.5.80 HRTIM fault input register 1 (HRTIM_FLTINR1) 1849
40.5.81 HRTIM fault input register 2 (HRTIM_FLTINR2) 1851
40.5.82 HRTIM burst DMA master timer update register (HRTIM_BDMUPR) 1853
40.5.83 HRTIM burst DMA timer x update register (HRTIM_BDTxUPR) (x = A to F) 1854
40.5.84 HRTIM burst DMA data register (HRTIM_BDMADR) 1856
40.5.85 HRTIM ADC extended trigger register (HRTIM_ADCER) 1857
40.5.86 HRTIM ADC trigger update register (HRTIM_ADCUR) 1860
40.5.87 HRTIM ADC post scaler register 1 (HRTIM_ADCPS1) 1861
40.5.88 HRTIM ADC post scaler register 2 (HRTIM_ADCPS2) 1862
40.5.89 HRTIM fault input register 3 (HRTIM_FLTINR3) 1863
40.5.90 HRTIM fault input register 4 (HRTIM_FLTINR4) 1865
40.5.91 HRTIM fault input register 5 (HRTIM_FLTINR5) 1867
40.5.92 HRTIM timer external event control register 4 (HRTIM_EECR4) . . . 1869
40.5.93 HRTIM timer external event control register 5 (HRTIM_EECR5) . . . 1871
40.5.94 HRTIM timer external event control register 6 (HRTIM_EECR6) . . . 1873
40.5.95 HRTIM timer external event control register 7 (HRTIM_EECR7) . . . 1874
40.5.96 HRTIM control register 3 (HRTIM_CR3) 1876
40.5.97 HRTIM option register (HRTIM_OR) 1876
40.5.98 HRTIM register map 1878

41 Advanced-control timers (TIM1/TIM8/TIM20) 1889

41.1 TIM1/TIM8/TIM20 introduction 1889
41.2 TIM1/TIM8/TIM20 main features 1889
41.3 TIM1/TIM8/TIM20 functional description 1890
41.3.1 Block diagram 1890
41.3.2 TIM1/TIM8/TIM20 pins and internal signals 1891
41.3.3 Time-base unit 1897

41.3.4 Counter modes 1900
41.3.5 Repetition counter 1912
41.3.6 External trigger input 1913
41.3.7 Clock selection 1914
41.3.8 Capture/compare channels 1918
41.3.9 Input capture mode 1921
41.3.10 PWM input mode 1922
41.3.11 Forced output mode 1923
41.3.12 Output compare mode 1923
41.3.13 PWM mode 1924
41.3.14 Asymmetric PWM mode 1933
41.3.15 Combined PWM mode 1936
41.3.16 Combined 3-phase PWM mode 1939
41.3.17 Complementary outputs and dead-time insertion 1940
41.3.18 Clock dividers for dead-time generators and digital filters 1943
41.3.19 Using the break function 1943
41.3.20 Delayed break 1949
41.3.21 Bidirectional break inputs 1951
41.3.22 Output idle state override 1953
41.3.23 Clearing the tim_ocxref signal on an external event 1954
41.3.24 6-step PWM generation 1957
41.3.25 One-pulse mode 1958
41.3.26 Retriggerable One-pulse mode 1960
41.3.27 Pulse on compare mode 1961
41.3.28 Encoder interface mode 1963
41.3.29 Encoder with built-in debouncer 1980
41.3.30 Direction bit output 1982
41.3.31 Clock drift measurement 1982
41.3.32 UIF bit remapping 1983
41.3.33 Timer input XOR function 1983
41.3.34 Interfacing with Hall sensors 1985
41.3.35 Timer synchronization 1986
41.3.36 ADC triggers 1991
41.3.37 ADC synchronization 1991
41.3.38 DMA burst mode 1992
41.3.39 TIM1/TIM8/TIM20 DMA requests 1993
41.3.40 Debug mode 1994

41.4 TIM1/TIM8/TIM20 low-power modes 1994
41.5 TIM1/TIM8/TIM20 interrupts 1994
41.6 TIM1/TIM8/TIM20 registers 1996
41.6.1 TIM control register 1 (TIM_CR1) 1996
41.6.2 TIM control register 2 (TIM_CR2) 1998
41.6.3 TIM slave mode control register (TIM_SMCR) 2003
41.6.4 TIM DMA/interrupt enable register (TIM_DIER) 2007
41.6.5 TIM status register (TIM_SR) 2008
41.6.6 TIM event generation register (TIM_EGR) 2012
41.6.7 TIM capture/compare mode register 1 (TIM_CCMR1) 2013
41.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2015
41.6.9 TIM capture/compare mode register 2 (TIM_CCMR2) 2019
41.6.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2) . . . 2021
41.6.11 TIM capture/compare enable register (TIM_CCER) 2024
41.6.12 TIM counter (TIM_CNT) 2028
41.6.13 TIM prescaler (TIM_PSC) 2028
41.6.14 TIM autoreload register (TIM_ARR) 2029
41.6.15 TIM repetition counter register (TIM_RCR) 2029
41.6.16 TIM capture/compare register 1 (TIM_CCR1) 2030
41.6.17 TIM capture/compare register 2 (TIM_CCR2) 2030
41.6.18 TIM capture/compare register 3 (TIM_CCR3) 2031
41.6.19 TIM capture/compare register 4 (TIM_CCR4) 2032
41.6.20 TIM break and dead-time register (TIM_BDTR) 2033
41.6.21 TIM capture/compare register 5 (TIM_CCR5) 2037
41.6.22 TIM capture/compare register 6 (TIM_CCR6) 2039
41.6.23 TIM capture/compare mode register 3 (TIM_CCMR3) 2040
41.6.24 TIM timer deadtime register 2 (TIM_DTR2) 2043
41.6.25 TIM timer encoder control register (TIM_ECR) 2044
41.6.26 TIM timer input selection register (TIM_TISEL) 2045
41.6.27 TIM alternate function option register 1 (TIM_AF1) 2046
41.6.28 TIM alternate function register 2 (TIM_AF2) 2051
41.6.29 TIM capture/compare register 7 (TIM_CCR7) 2055
41.6.30 TIM capture/compare mode register 4 (TIM_CCMR4) 2056
41.6.31 TIM multilevel protection register 1 (TIM_MPR1) 2058
41.6.32 TIM multilevel protection register 2 (TIM_MPR2) 2060
41.6.33 TIM output override register (TIM_OOR) 2062
41.6.34 TIM DMA control register (TIM_DCR) 2063

41.6.35 TIM DMA address for full transfer (TIM_DMAR) 2065
41.6.36 TIM1/TIM8/TIM20 register map 2065

42 General-purpose timers (TIM2/TIM3/TIM4/TIM5) 2069

42.1 TIM2/TIM3/TIM4/TIM5 introduction 2069
42.2 TIM2/TIM3/TIM4/TIM5 main features 2069
42.3 TIM2/TIM3/TIM4/TIM5 implementation 2070

45.4.3 Time-base unit 2294
45.4.4 Counter modes 2296
45.4.5 Repetition counter 2308
45.4.6 Clock selection 2310
45.4.7 Capture/compare channels 2312
45.4.8 Input capture mode 2314
45.4.9 PWM input mode (only for TIM15) 2315
45.4.10 Forced output mode 2316
45.4.11 Output compare mode 2317
45.4.12 PWM mode 2318
45.4.13 Asymmetric PWM mode (TIM15 only) 2325
45.4.14 Combined PWM mode (TIM15 only) 2326
45.4.15 Complementary outputs and dead-time insertion 2327
45.4.16 Clock dividers for dead-time generators and digital filters 2330
45.4.17 Using the break function 2330
45.4.18 Delayed break 2335
45.4.19 Bidirectional break input 2337

45.4.20 Output idle state override . . . 2339
45.4.21 Clearing the tim_ocxref signal on an external event . . . 2339
45.4.22 6-step PWM generation . . . 2341
45.4.23 One-pulse mode . . . 2343
45.4.24 Retriggerable one pulse mode (TIM15 only) . . . 2344
45.4.25 Encoder interface mode . . . 2345
45.4.26 Encoder with built-in debouncer (TIM15 only) . . . 2352
45.4.27 Clock drift measurement . . . 2353
45.4.28 UIF bit remapping . . . 2354
45.4.29 Timer input XOR function (TIM15 only) . . . 2354
45.4.30 External trigger synchronization (TIM15 only) . . . 2356
45.4.31 Slave mode – combined reset + trigger mode (TIM15 only) . . . 2359
45.4.32 Slave mode – combined reset + gated mode (TIM15 only) . . . 2359
45.4.33 Timer synchronization (TIM15 only) . . . 2360
45.4.34 Using timer output as trigger for other timers (TIM16/TIM17 only) . . 2360
45.4.35 ADC triggers (TIM15 only) . . . 2360
45.4.36 ADC synchronization (TIM15 only) . . . 2361
45.4.37 DMA burst mode . . . 2361
45.4.38 TIM15/TIM16/TIM17 DMA requests . . . 2362
45.4.39 Debug mode . . . 2363
45.5 TIM15/TIM16/TIM17 low-power modes . . . 2363
45.6 TIM15/TIM16/TIM17 interrupts . . . 2363
45.7 TIM15 registers . . . 2365
45.7.1 TIM control register 1 (TIM_CR1) . . . 2365
45.7.2 TIM control register 2 (TIM_CR2) . . . 2367
45.7.3 TIM slave mode control register (TIM_SMCR) . . . 2370
45.7.4 TIM DMA/interrupt enable register (TIM_DIER) . . . 2373
45.7.5 TIM status register (TIM_SR) . . . 2374
45.7.6 TIM event generation register (TIM_EGR) . . . 2376
45.7.7 TIM capture/compare mode register 1 (TIM_CCMR1) . . . 2377
45.7.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2379
45.7.9 TIM capture/compare enable register (TIM_CCER) . . . 2382
45.7.10 TIM counter (TIM_CNT) . . . 2385
45.7.11 TIM prescaler (TIM_PSC) . . . 2385
45.7.12 TIM autoreload register (TIM_ARR) . . . 2385
45.7.13 TIM repetition counter register (TIM_RCR) . . . 2386
45.7.14 TIM capture/compare register 1 (TIM_CCR1) . . . 2386

45.7.15 TIM capture/compare register 2 (TIM_CCR2) 2388
45.7.16 TIM break and dead-time register (TIM_BDTR) 2388
45.7.17 TIM timer deadtime register 2 (TIM_DTR2) 2391
45.7.18 TIM input selection register (TIM_TISEL) 2392
45.7.19 TIM alternate function register 1 (TIM_AF1) 2393
45.7.20 TIM alternate function register 2 (TIM_AF2) 2397
45.7.21 TIM multilevel protection register 1 (TIM_MPR1) 2398
45.7.22 TIM multilevel protection register 2 (TIM_MPR2) 2398
45.7.23 TIM output override register (TIM_OOR) 2399
45.7.24 TIM DMA control register (TIM_DCR) 2400
45.7.25 TIM DMA address for full transfer (TIM_DMAR) 2401
45.7.26 TIM15 register map 2402
45.8 TIM16/TIM17 registers 2405
45.8.1 TIM control register 1 (TIM_CR1) 2405
45.8.2 TIM control register 2 (TIM_CR2) 2407
45.8.3 TIM DMA/interrupt enable register (TIM_DIER) 2408
45.8.4 TIM status register (TIM_SR) 2409
45.8.5 TIM event generation register (TIM_EGR) 2410
45.8.6 TIM capture/compare mode register 1 (TIM_CCMR1) 2411
45.8.7 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1) . . . 2412
45.8.8 TIM capture/compare enable register (TIM_CCER) 2414
45.8.9 TIM counter (TIM_CNT) 2417
45.8.10 TIM prescaler (TIM_PSC) 2417
45.8.11 TIM autoreload register (TIM_ARR) 2418
45.8.12 TIM repetition counter register (TIM_RCR) 2418
45.8.13 TIM capture/compare register 1 (TIM_CCR1) 2419
45.8.14 TIM break and dead-time register (TIM_BDTR) 2420
45.8.15 TIM timer deadtime register 2 (TIM_DTR2) 2423
45.8.16 TIM input selection register (TIM_TISEL) 2424
45.8.17 TIM alternate function register 1 (TIM_AF1) 2424
45.8.18 TIM alternate function register 2 (TIM_AF2) 2428
45.8.19 TIM multilevel protection register 1 (TIM_MPR1) 2429
45.8.20 TIM multilevel protection register 2 (TIM_MPR2) 2430
45.8.21 TIM output override register (TIM_OOR) 2430
45.8.22 TIM DMA control register (TIM_DCR) 2431
45.8.23 TIM DMA address for full transfer (TIM_DMAR) 2432
45.8.24 TIM16/TIM17 register map 2433

46 Low-power timer (LPTIM) 2436
46.1 LPTIM introduction 2436
46.2 LPTIM main features 2436
46.3 LPTIM implementation 2436
46.4 LPTIM functional description 2438
46.4.1 LPTIM block diagram 2438
46.4.2 LPTIM pins and internal signals 2438
46.4.3 LPTIM input and trigger mapping 2439
46.4.4 LPTIM reset and clocks 2441
46.4.5 Glitch filter 2441
46.4.6 Prescaler 2442
46.4.7 Trigger multiplexer 2442
46.4.8 Operating mode 2443
46.4.9 Timeout function 2445
46.4.10 Waveform generation 2445
46.4.11 Register update 2446
46.4.12 Counter mode 2447
46.4.13 Timer enable 2447
46.4.14 Timer counter reset 2448
46.4.15 Encoder mode 2448
46.4.16 Repetition counter 2450
46.4.17 Capture/compare channels 2451
46.4.18 Input capture mode 2452
46.4.19 PWM mode 2454
46.4.20 DMA requests 2456
46.4.21 Debug mode 2457
46.5 LPTIM low-power modes 2457
46.6 LPTIM interrupts 2457
46.7 LPTIM registers 2458
46.7.1 LPTIM1 interrupt and status register [alternate] (LPTIM1_ISR) 2459
46.7.2 LPTIM1 interrupt and status register [alternate] (LPTIM1_ISR) 2461
46.7.3 LPTIM1 interrupt clear register [alternate] (LPTIM1_ICR) 2463
46.7.4 LPTIM1 interrupt clear register [alternate] (LPTIM1_ICR) 2464
46.7.5 LPTIM1 interrupt enable register [alternate] (LPTIM1_DIER) 2466
46.7.6 LPTIM1 interrupt enable register [alternate] (LPTIM1_DIER) 2467
46.7.7 LPTIM configuration register (LPTIM_CFGR) 2469

46.7.8 LPTIM control register (LPTIM_CR) 2471
46.7.9 LPTIM compare register 1 (LPTIM_CCR1) 2472
46.7.10 LPTIM autoreload register (LPTIM_ARR) 2473
46.7.11 LPTIM counter register (LPTIM_CNT) 2473
46.7.12 LPTIM configuration register 2 (LPTIM_CFGR2) 2474
46.7.13 LPTIM repetition register (LPTIM_RCR) 2475
46.7.14 LPTIM capture/compare mode register 1 (LPTIM_CCMR1) 2476
46.7.15 LPTIM compare register 2 (LPTIM_CCR2) 2478
46.7.16 LPTIM register map 2479

47 Independent watchdog (IWDG) 2481

47.1 IWDG introduction 2481
47.2 IWDG main features 2481
47.3 IWDG implementation 2481
47.4 IWDG functional description 2482
47.4.1 IWDG block diagram 2482
47.4.2 IWDG internal signals 2483
47.4.3 Software and hardware watchdog modes 2483
47.4.4 Window option 2484
47.4.5 Debug 2487
47.4.6 Register access protection 2487
47.5 IWDG low power modes 2488
47.6 IWDG interrupts 2488
47.7 IWDG registers 2490
47.7.1 IWDG key register (IWDG_KR) 2491
47.7.2 IWDG prescaler register (IWDG_PR) 2491
47.7.3 IWDG reload register (IWDG_RLR) 2492
47.7.4 IWDG status register (IWDG_SR) 2492
47.7.5 IWDG window register (IWDG_WINR) 2494
47.7.6 IWDG early wake-up interrupt register (IWDG_EWCR) 2494
47.7.7 IWDG interrupt clear register (IWDG_ICR) 2495
47.7.8 IWDG register map 2496

48 System window watchdog (WWDG) 2497

48.1 WWDG introduction 2497
48.2 WWDG main features 2497

48.3 WWDG implementation 2497
48.4 WWDG functional description 2498
48.4.1 WWDG block diagram 2498
48.4.2 WWDG internal signals 2498
48.4.3 Enabling the watchdog 2499
48.4.4 Controlling the down-counter 2499
48.4.5 How to program the watchdog timeout 2499
48.4.6 Debug mode 2500
48.5 WWDG interrupts 2501
48.6 WWDG registers 2501
48.6.1 WWDG control register (WWDG_CR) 2501
48.6.2 WWDG configuration register (WWDG_CFR) 2502
48.6.3 WWDG status register (WWDG_SR) 2503
48.6.4 WWDG register map 2503

49 Real-time clock (RTC) 2504
49.1 RTC introduction 2504
49.2 RTC main features 2504
49.3 RTC functional description 2504
49.3.1 RTC block diagram 2504
49.3.2 RTC pins and internal signals 2506
49.3.3 GPIOs controlled by the RTC 2507
49.3.4 RTC registers write protection 2507
49.3.5 RTC secure protection modes 2507
49.3.6 RTC privilege protection modes 2509
49.3.7 Clock and prescalers 2510
49.3.8 Real-time clock and calendar 2511
49.3.9 Calendar ultra-low power mode 2512
49.3.10 Programmable alarms 2512
49.3.11 Periodic auto-wake-up 2512
49.3.12 RTC initialization and configuration 2513
49.3.13 Reading the calendar 2516
49.3.14 Resetting the RTC 2517
49.3.15 RTC synchronization 2517
49.3.16 RTC reference clock detection 2518
49.3.17 RTC smooth digital calibration 2519

49.3.18 Timestamp function 2521
49.3.19 Calibration clock output 2522
49.3.20 Tamper and alarm output 2522
49.4 RTC low-power modes 2523
49.5 RTC interrupts 2523
49.6 RTC registers 2525
49.6.1 RTC time register (RTC_TR) 2525
49.6.2 RTC date register (RTC_DR) 2526
49.6.3 RTC subsecond register (RTC_SSR) 2527
49.6.4 RTC initialization control and status register (RTC_ICSR) 2528
49.6.5 RTC prescaler register (RTC_PRER) 2530
49.6.6 RTC wake-up timer register (RTC_WUTR) 2531
49.6.7 RTC control register (RTC_CR) 2532
49.6.8 RTC privilege mode control register (RTC_PRIVCFGR) 2536
49.6.9 RTC secure configuration register (RTC_SECCFGR) 2537
49.6.10 RTC write protection register (RTC_WPR) 2538
49.6.11 RTC calibration register (RTC_CALR) 2539
49.6.12 RTC shift control register (RTC_SHIFTR) 2540
49.6.13 RTC timestamp time register (RTC_TSTR) 2541
49.6.14 RTC timestamp date register (RTC_TSDR) 2542
49.6.15 RTC timestamp subsecond register (RTC_TSSSR) 2543
49.6.16 RTC alarm A register (RTC_ALRMAR) 2543
49.6.17 RTC alarm A subsecond register (RTC_ALRMASSR) 2545
49.6.18 RTC alarm B register (RTC_ALRMBR) 2546
49.6.19 RTC alarm B subsecond register (RTC_ALRMBSSR) 2547
49.6.20 RTC status register (RTC_SR) 2548
49.6.21 RTC nonsecure masked interrupt status register (RTC_MISR) 2549
49.6.22 RTC secure masked interrupt status register (RTC_SMISR) 2550
49.6.23 RTC status clear register (RTC_SCR) 2551
49.6.24 RTC timestamp on tamper control register (RTC_TAMPTSCR) 2552
49.6.25 RTC timestamp status register (RTC_TSIDR) 2553
49.6.26 RTC alarm A binary mode register (RTC_ALRABINR) 2554
49.6.27 RTC alarm B binary mode register (RTC_ALRBBINR) 2554
49.6.28 RTC register map 2555

50 Tamper and backup registers (TAMP) 2558

50.1 TAMP introduction 2558

50.2 TAMP main features . . . 2558
50.3 TAMP functional description . . . 2559
50.3.1 TAMP block diagram . . . 2559
50.3.2 TAMP pins and internal signals . . . 2560
50.3.3 GPIOs controlled by the RTC and TAMP . . . 2563
50.3.4 TAMP register write protection . . . 2565
50.3.5 TAMP secure protection modes . . . 2565
50.3.6 Backup register protection zones . . . 2566
50.3.7 TAMP privilege protection modes . . . 2566
50.3.8 Boot hardware key (BHK) . . . 2567
50.3.9 Tamper detection . . . 2567
50.3.10 TAMP backup registers and other device secret erase . . . 2568
50.3.11 Tamper detection configuration and initialization . . . 2570
50.4 TAMP low-power modes . . . 2576
50.5 TAMP interrupts . . . 2577
50.6 TAMP registers . . . 2577
50.6.1 TAMP control register 1 (TAMP_CR1) . . . 2577
50.6.2 TAMP control register 2 (TAMP_CR2) . . . 2579
50.6.3 TAMP control register 3 (TAMP_CR3) . . . 2581
50.6.4 TAMP filter control register (TAMP_FLTCR) . . . 2582
50.6.5 TAMP active tamper control register 1 (TAMP_ATCR1) . . . 2583
50.6.6 TAMP active tamper seed register (TAMP_ATSEEDR) . . . 2585
50.6.7 TAMP active tamper output register (TAMP_ATOR) . . . 2585
50.6.8 TAMP active tamper control register 2 (TAMP_ATCR2) . . . 2586
50.6.9 TAMP secure configuration register (TAMP_SECCFGR) . . . 2587
50.6.10 TAMP privilege configuration register (TAMP_PRIVCFGR) . . . 2588
50.6.11 TAMP interrupt enable register (TAMP_IER) . . . 2589
50.6.12 TAMP status register (TAMP_SR) . . . 2591
50.6.13 TAMP nonsecure masked interrupt status register (TAMP_MISR) . . . 2593
50.6.14 TAMP secure masked interrupt status register (TAMP_SMISR) . . . 2595
50.6.15 TAMP status clear register (TAMP_SCR) . . . 2596
50.6.16 TAMP monotonic counter 1 register (TAMP_COUNT1R) . . . 2598
50.6.17 TAMP option register (TAMP_OR) . . . 2598
50.6.18 TAMP resources protection configuration register (TAMP_RPCFGR) 2599
50.6.19 TAMP backup x register (TAMP_BKPxR) . . . 2601
50.6.20 TAMP register map . . . 2602

51 Inter-integrated circuit interface (I2C) 2604

51.1 I2C introduction 2604

51.2 I2C main features 2604

51.3 I2C implementation 2605

51.4 I2C functional description 2605

51.4.1 I2C block diagram 2606

51.4.2 I2C pins and internal signals 2606

51.4.3 I2C clock requirements 2607

51.4.4 I2C mode selection 2607

51.4.5 I2C initialization 2608

51.4.6 I2C reset 2612

51.4.7 I2C data transfer 2613

51.4.8 I2C target mode 2615

51.4.9 I2C controller mode 2624

51.4.10 I2C_TIMINGR register configuration examples 2635

51.4.11 SMBus specific features 2637

51.4.12 SMBus initialization 2639

51.4.13 SMBus I2C_TIMEOUTR register configuration examples 2641

51.4.14 SMBus target mode 2642

51.4.15 SMBus controller mode 2645

51.4.16 Wake-up from Stop mode on address match 2648

51.4.17 Error conditions 2649

51.5 I2C in low-power modes 2651

51.6 I2C interrupts 2651

51.7 I2C DMA requests 2652

51.7.1 Transmission using DMA 2652

51.7.2 Reception using DMA 2652

51.8 I2C debug modes 2652

51.9 I2C registers 2653

51.9.1 I2C control register 1 (I2C_CR1) 2653

51.9.2 I2C control register 2 (I2C_CR2) 2656

51.9.3 I2C own address 1 register (I2C_OAR1) 2658

51.9.4 I2C own address 2 register (I2C_OAR2) 2658

51.9.5 I2C timing register (I2C_TIMINGR) 2659

51.9.6 I2C timeout register (I2C_TIMEOUTR) 2660

51.9.7 I2C interrupt and status register (I2C_ISR) 2661

51.9.8 I2C interrupt clear register (I2C_ICR) 2664
51.9.9 I2C PEC register (I2C_PECR) 2665
51.9.10 I2C receive data register (I2C_RXDR) 2665
51.9.11 I2C transmit data register (I2C_TXDR) 2666
51.9.12 I2C register map 2667

52 Improved inter-integrated circuit (I3C) 2668

52.1 I3C introduction 2668
52.2 I3C main features 2668
52.2.1 I3C MIPI® support 2670
52.2.2 I3C without clock stretching by the target 2671
52.3 I3C implementation 2673
52.3.1 I3C instantiation 2673
52.3.2 I3C wake-up from low-power mode(s) 2673
52.3.3 I3C FIFOs 2673
52.3.4 I3C triggers 2673
52.3.5 I3C interrupt(s) 2673
52.4 I3C block diagram 2674
52.5 I3C pins and internal signals 2674
52.6 I3C reset and clocks 2675
52.6.1 I3C reset 2675
52.6.2 I3C clocks and requirements 2675
52.7 I3C peripheral state and programming 2677
52.7.1 I3C peripheral state 2677
52.7.2 I3C controller state and programming sequence 2678
52.7.3 I3C target state and programming sequence 2683
52.8 I3C registers and programming 2687
52.8.1 I3C register set, as controller/target 2687
52.8.2 I3C registers and fields use versus peripheral state, as controller . . 2688
52.8.3 I3C registers and fields usage versus peripheral state, as target . . . 2691
52.9 I3C bus transfers and programming 2693
52.9.1 I3C command set (CCCs), as controller/target 2693
52.9.2 I3C broadcast/direct CCC transfer (except ENTDAA, RSTACT), as controller 2697
52.9.3 I3C broadcast ENTDAA CCC transfer, as controller 2699
52.9.4 I3C broadcast/direct RSTACT CCC transfer, as controller 2699

52.9.5 I3C broadcast/direct CCC transfer (except ENTDAA, DEFTGTS, DEFGRPA), as target 2701
52.9.6 I3C broadcast ENTDAA CCC transfer, as target 2703
52.9.7 I3C broadcast DEFTGTS CCC transfer, as target 2704
52.9.8 I3C broadcast DEFGRPA CCC transfer, as target 2705
52.9.9 I3C direct GETSTATUS CCC response, as target 2706
52.9.10 I3C private read/write transfer, as controller 2707
52.9.11 I3C private read/write transfer, as target 2708
52.9.12 Legacy I2C read/write transfer, as controller 2709
52.9.13 I3C IBI transfer, as controller/target 2710
52.9.14 I3C hot-join request transfer, as controller/target 2712
52.9.15 I3C controller-role request transfer, as controller/target 2713
52.10 I3C FIFOs management, as controller 2714
52.10.1 C-FIFO management, as controller 2714
52.10.2 TX-FIFO management, as controller 2715
52.10.3 RX-FIFO management, as controller 2718
52.10.4 S-FIFO management, as controller 2720
52.11 I3C FIFOs management, as target 2722
52.11.1 RX-FIFO management, as target 2722
52.11.2 TX-FIFO management, as target 2723
52.12 I3C error management 2726
52.12.1 Controller error management 2726
52.12.2 Target error management 2728
52.13 I3C wake-up from low-power mode(s) 2729
52.13.1 Wake-up from Stop 2729
52.14 I3C in low-power modes 2732
52.15 I3C interrupts 2733
52.16 I3C registers 2733
52.16.1 I3C message control register (I3C_CR) 2733
52.16.2 I3C message control register [alternate] (I3C_CR) 2735
52.16.3 I3C configuration register (I3C_CFGR) 2737
52.16.4 I3C receive data byte register (I3C_RDR) 2742
52.16.5 I3C receive data word register (I3C_RDWR) 2743
52.16.6 I3C transmit data byte register (I3C_TDR) 2744
52.16.7 I3C transmit data word register (I3C_TDWR) 2745
52.16.8 I3C IBI payload data register (I3C_IBIDR) 2746

52.16.9 I3C target transmit configuration register (I3C_TGTTDR) 2747
52.16.10 I3C status register (I3C_SR) 2748
52.16.11 I3C status error register (I3C_SER) 2749
52.16.12 I3C received message register (I3C_RMR) 2751
52.16.13 I3C event register (I3C_EVR) 2752
52.16.14 I3C interrupt enable register (I3C_IER) 2756
52.16.15 I3C clear event register (I3C_CEVR) 2758
52.16.16 I3C masked interrupt status register (I3C_MISR) 2760

1 Documentation conventions

1.1 General information

The STM32G56x/55x/54x/53x series devices have an Arm® Cortex®-M33 core with Arm® TrustZone® technology.

arm

Note: Arm and Cortex are registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere.

Arm and TrustZone are registered trademarks of Arm Limited (or its subsidiaries or affiliates) in the US and/or elsewhere.

The Arm word and logo are trademarks of Arm Limited (or its subsidiaries) in the US and/or elsewhere. All rights reserved.

1.2 List of abbreviations for registers

The following abbreviations[a] are used in register descriptions:

read/write (rw)	Software can read and write to this bit.
read-only (r)	Software can only read this bit.
write-only (w)	Software can only write to this bit. Reading this bit returns the reset value.
read/clear write0 (rc_w0)	Software can read as well as clear this bit by writing 0. Writing 1 has no effect on the bit value.
read/clear write1 (rc_w1)	Software can read as well as clear this bit by writing 1. Writing 0 has no effect on the bit value.
read/clear write (rc_w)	Software can read as well as clear this bit by writing to the register. The value written to this bit is not important.
read/clear by read (rc_r)	Software can read this bit. Reading this bit automatically clears it to 0. Writing this bit has no effect on the bit value.
read/set by read (rs_r)	Software can read this bit. Reading this bit automatically sets it to 1. Writing this bit has no effect on the bit value.
read/set (rs)	Software can read as well as set this bit. Writing 0 has no effect on the bit value.
read/write once (rwo)	Software can only write once to this bit and can also read it at any time. Only a reset can return the bit to its reset value.
toggle (t)	The software can toggle this bit by writing 1. Writing 0 has no effect.

a. This is an exhaustive list of all abbreviations applicable to STMicroelectronics microcontrollers, some of them may not be used in the current document.

read-only write trigger (rt_w1)	Software can read this bit. Writing 1 triggers an event but has no effect on the bit value.
Reserved (Res.)	Reserved bit, must be kept at reset value.

1.3 Register reset value

Bits (binary notation) or bit nibbles (hexadecimal notation) of which the reset value is undefined are marked as X.

Bits (binary notation) or bit nibbles (hexadecimal notation) of which the reset value is unmodified are marked as U.

1.4 Glossary

This section gives a brief definition of acronyms and abbreviations used in this document:

- **Word**: data of 32-bit length.
- **Half-word**: data of 16-bit length.
- **Byte**: data of 8-bit length.
- **AHB**: advanced high-performance bus.

1.5 Availability of peripherals

For detailed availability of peripherals and their number across all sales types (depending on product line and package), refer to the device datasheet.

2 Memory and bus architecture

2.1 System architecture

The architecture relies on a Arm Cortex-M33 core, optimized for execution, as a result of an instruction cache having a direct access to the embedded flash memory.

This architecture also features a 32-bit multilayer AHB bus matrix that interconnects:

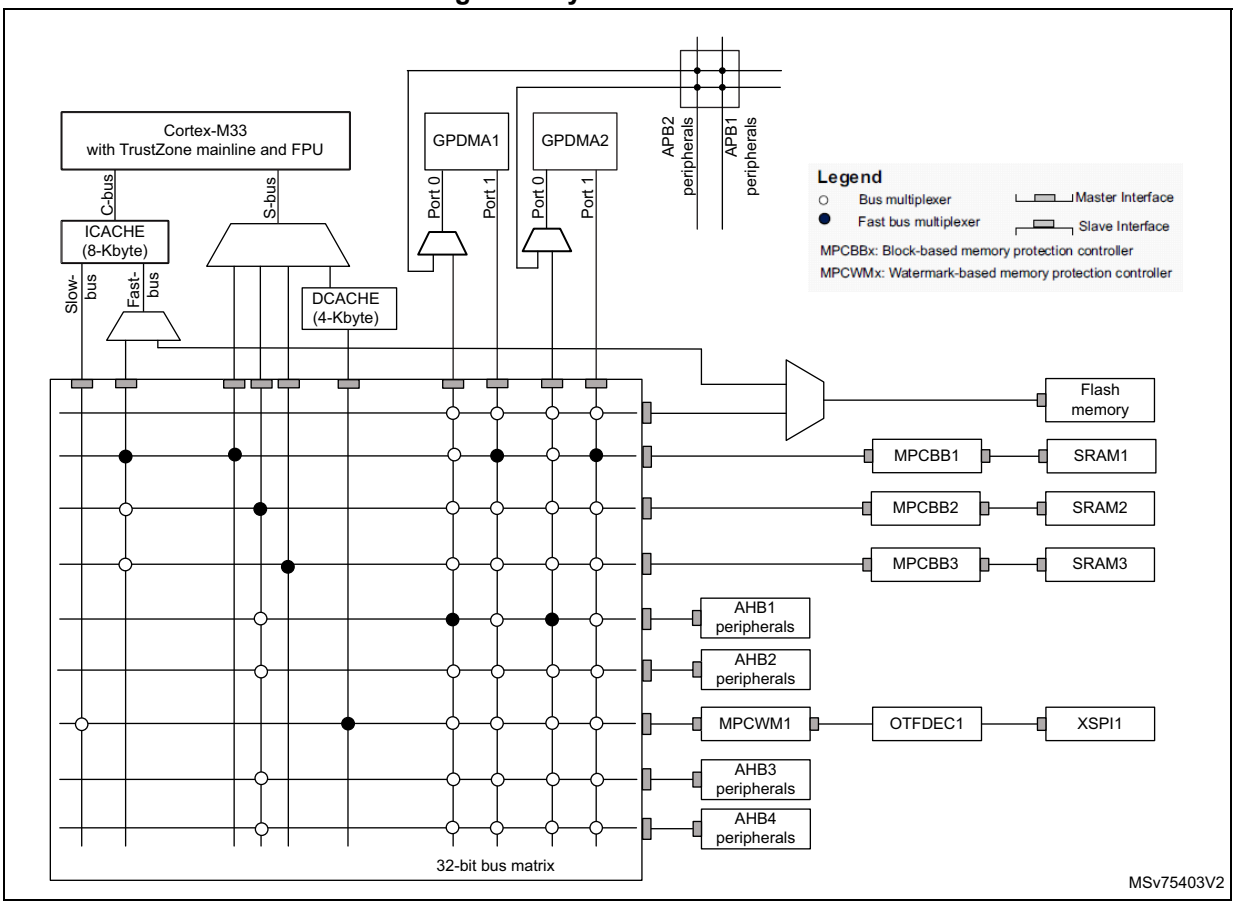
- Up to 10 masters
  - Fast C-bus, connecting Cortex-M33 with TrustZone mainline and FPU core C-bus to the internal SRAMs through the instruction cache
  - Slow C-bus, connecting Cortex-M33 with TrustZone mainline and FPU core C-bus to the external memories through the instruction cache
  - Cortex-M33 with TrustZone mainline and FPU core S-bus (three masters connected to three internal SRAMs without latency)
  - Cortex-M33 with TrustZone mainline and FPU core S-bus connected to the external memories through the data cache
  - GPDMA1 (general purpose DMA featuring two master ports)
  - GPDMA2 (general purpose DMA featuring two master ports)
- Up to 9 slaves
  - Internal flash memory
  - Internal SRAM1
  - Internal SRAM2
  - Internal SRAM3
  - AHB1 peripherals including AHB to APB bridges and APB peripherals (connected to APB1 and APB2)
  - AHB2 peripherals
  - XSPI
  - AHB3 peripherals, including AHB to APB bridge and APB peripherals (connected to APB3)
  - AHB4 peripherals

This architecture also features a 32-bit multilayer AHB bus matrix with the interconnections detailed in *Table 1* and *Table 2*.

Table 1. Implementation of masters

Master	Comments	STM32G55x/56x	STM32G53x/54x
Cortex-M33 Fast C-bus	Connecting Cortex-M33 (with Arm TrustZone mainline and FPU) to the internal SRAMs and flash memory through ICACHE	X	X
Cortex-M33 Slow C-bus	Connecting Cortex-M33 (with Arm TrustZone mainline and FPU) to the external memories through ICACHE	X	X
Cortex-M33 S-bus	Connecting the Cortex-M33 (with Arm TrustZone mainline and FPU) to internal SRAMs without latency	3 masters	2 masters
	Connecting Cortex-M33 (with Arm TrustZone mainline and FPU) to the external memories through DCACHE	X	-

Table 1. Implementation of masters (continued)



Master	Comments	STM32G55x/56x	STM32G53x/54x
GPDMA1	-	2 masters	
GPDMA2	-	2 masters	

Table 2. Implementation of slaves

Slave	Comments	STM32G55x/56x	STM32G53x/54x
Flash memory	-	X	X
SRAM1	-	X	X
SRAM2	-	X	X
SRAM3	-	X	-
AHB1	Peripherals including AHB to APB bridge, and APB peripherals (connected to APB1 and APB2)	X	X
AHB2	Peripherals	X	X
XSPI1	-	X	-
AHB3	Including AHB to APB bridge, and APB peripherals (connected to APB3)	X	X
AHB4	Peripherals	X	X

The bus matrix provides access from a master to a slave, enabling concurrent accesses and efficient operation even when several high-speed peripherals work simultaneously. This architecture is shown in *Figure 1*.

Figure 1. System architecture

2.1.1 Fast C-bus

This bus connects the C-bus of the Cortex-M33 core to the internal flash memory and to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the internal memories mapped in code region. This bus targets the internal flash memory and the internal SRAMs (SRAM1, SRAM2, and SRAM3).

SRAM1, SRAM2, and SRAM3 are accessible on this bus with a continuous mapping.

Code execution from SRAM1 code area is always without wait states due to fast bus multiplexer from C-bus to SRAM1. Code execution from SRAM2 or SRAM3 adds 1 wait state per one 32-bit access due to connection through standard bus multiplexer.

2.1.2 Slow C-bus

This bus connects the C-bus of the Cortex-M33 core to the BusMatrix via the instruction cache. This bus is used for instruction fetch and data access to the external memories mapped in code region. This bus targets the external memories (XSPI).

2.1.3 S-bus

This bus connects the system bus of the Cortex-M33 core to the BusMatrix. This bus is used by the core to access data located in a peripheral or SRAM area. This bus targets the

internal SRAMs (SRAM1, SRAM2, and SRAM3), the AHB1 peripherals including the APB1, APB2, AHB2, AHB3, and AHB4 peripherals.

SRAM1, SRAM2, and SRAM3 are accessible on this bus with a continuous mapping.

Code execution is possible also through S-bus but with a penalty that 1 wait state is added per one access.

Note: The Bus Matrix has a zero latency when accessing data from SRAM1, SRAM2, and SRAM3. Code execution through S-bus always add 1 wait state per one access.

2.1.4 DCACHE S-bus

This bus connects the system bus of the Cortex-M33 core to the BusMatrix via the data cache. This bus is used for instruction fetch and data access to the external memories mapped in data region. This bus targets the external memories (XSPI).

Note: Fetching instructions through this bus is less efficient than fetching instructions through the slow C-bus.

2.1.5 GPDMA1 and GPDMA2 buses

These buses connect the four AHB master interfaces of the GPDMA1 and GPDMA2 to the BusMatrix. These buses target the internal flash memory, the internal SRAMs (SRAM1, SRAM2, and SRAM3), the AHB1 peripherals including the APB1 and APB2 peripherals, the AHB2 peripherals, the AHB3 peripherals, AHB4 peripherals and the external memories through XSPI.

2.1.6 BusMatrix

The BusMatrix manages the access arbitration between masters. The arbitration uses a round-robin algorithm. This BusMatrix features a fast bus multiplexer used to connect each master to a given slave without latency (see *Figure 1: System architecture*). For the same master, other slaves undergo a latency of at least one cycle at each new access (connection through standard bus multiplexer).

2.1.7 AHB/APB bridges

The three AHB/APB bridges provide full synchronous connections between the AHB and the APB buses, allowing flexible selection of the peripheral frequency.

Refer to *Section 2.3.2: Memory map and register boundary addresses* for the address mapping of the peripherals connected to these bridges.

After each device reset, all peripheral clocks are disabled (except for the internal SRAMs and flash memory interfaces). Before using a peripheral, its clock must be enabled in the RCC_AHBxENR and RCC_APBxENR registers.

Note: When an 8- or 16-bit access is performed on an APB register, the access is transformed into a 32-bit access: the bridge duplicates the 8- or 16-bit data to feed the 32-bit vector.

2.2 TrustZone security architecture

The security architecture is based on Arm TrustZone with the Armv8-M mainline extension.

The TrustZone security is activated by the TZEN option bit in the FLASH_OPTR register.

When the TrustZone is enabled, the SAU (security-attribution unit) and IDAU (implementation-defined-attribution unit) defines the access permissions based on secure and nonsecure states.

- SAU: Up to eight SAU configurable regions are available for security attribution.
- IDAU: provides a first memory partition as nonsecure or nonsecure callable attributes. The IDAU memory map partition is not configurable, it is fixed by hardware implementation (refer to *Figure 2: Memory map based on IDAU mapping (STM32G55x/56x devices)*). It is then combined with the results from the SAU security attribution, and the higher security state is selected.

Based on IDAU security attribution, the flash memory, system SRAMs and peripheral memory spaces are aliased twice for secure and nonsecure states. However, the external memory space is not aliased.

2.2.1 Default TrustZone security state

When the TrustZone security is activated by the TZEN option bit in the FLASH_OPTR, the default system security state is detailed below:

- CPU:
  - Cortex-M33 is in secure state after reset. The boot address must be at a secure address.
- Memory map:
  - SAU is fully secure after reset. Consequently, all memory map is fully secure. Up to eight SAU configurable regions are available for security attribution.
- Flash memory:
  - The flash memory security area is defined by watermark user options.
  - Block-based security attributions are nonsecure after reset.
- SRAMs:
  - All SRAMs are secure after reset. MPCBBx (block-based memory protection controller) are secure.
- External memories:
  - XSPI banks are secure after reset. MPCWMx (watermark-based memory protection controller) are secure.
- Peripherals (see *Table 3: Securable peripherals by TZSC* and *Table 4: TrustZone-aware peripherals for a list of securable and TrustZone-aware peripherals)*
  - Securable peripherals are nonsecure after reset.
  - TrustZone-aware peripherals are nonsecure after reset. Their secure configuration registers are secure.
- All GPIOs are secure after reset.
- Interrupts:
  - NVIC: All interrupts are secure after reset. NVIC is banked for secure and Nonsecure state.
  - TZIC: All illegal access interrupts are disabled after reset (see *GTZC TrustZone system architecture*).

2.2.2 TrustZone peripheral classification

When the TrustZone security is active, a peripheral can be either securable or TrustZone-aware type as follows:

- Securable: peripheral protected by an AHB/APB firewall gate that is controlled from TZSC controller to define security properties
- TrustZone-aware: peripheral connected directly to AHB or APB bus and implementing a specific TrustZone behavior such as a subset of registers being secure.

Refer to *GTZC TrustZone system architecture* for more details.

The following tables list the securable and TrustZone-aware peripherals within the system.

2.3 Memory organization

2.3.1 Introduction

Program memory, data memory, registers and I/O ports are organized within the same linear address space.

The bytes are coded in memory in Little Endian format. The lowest numbered byte in a word is considered the word's least significant byte and the highest numbered byte the most significant.

2.3.2 Memory map and register boundary addresses

Figure 2. Memory map based on IDAU mapping (STM32G55x/56x devices)

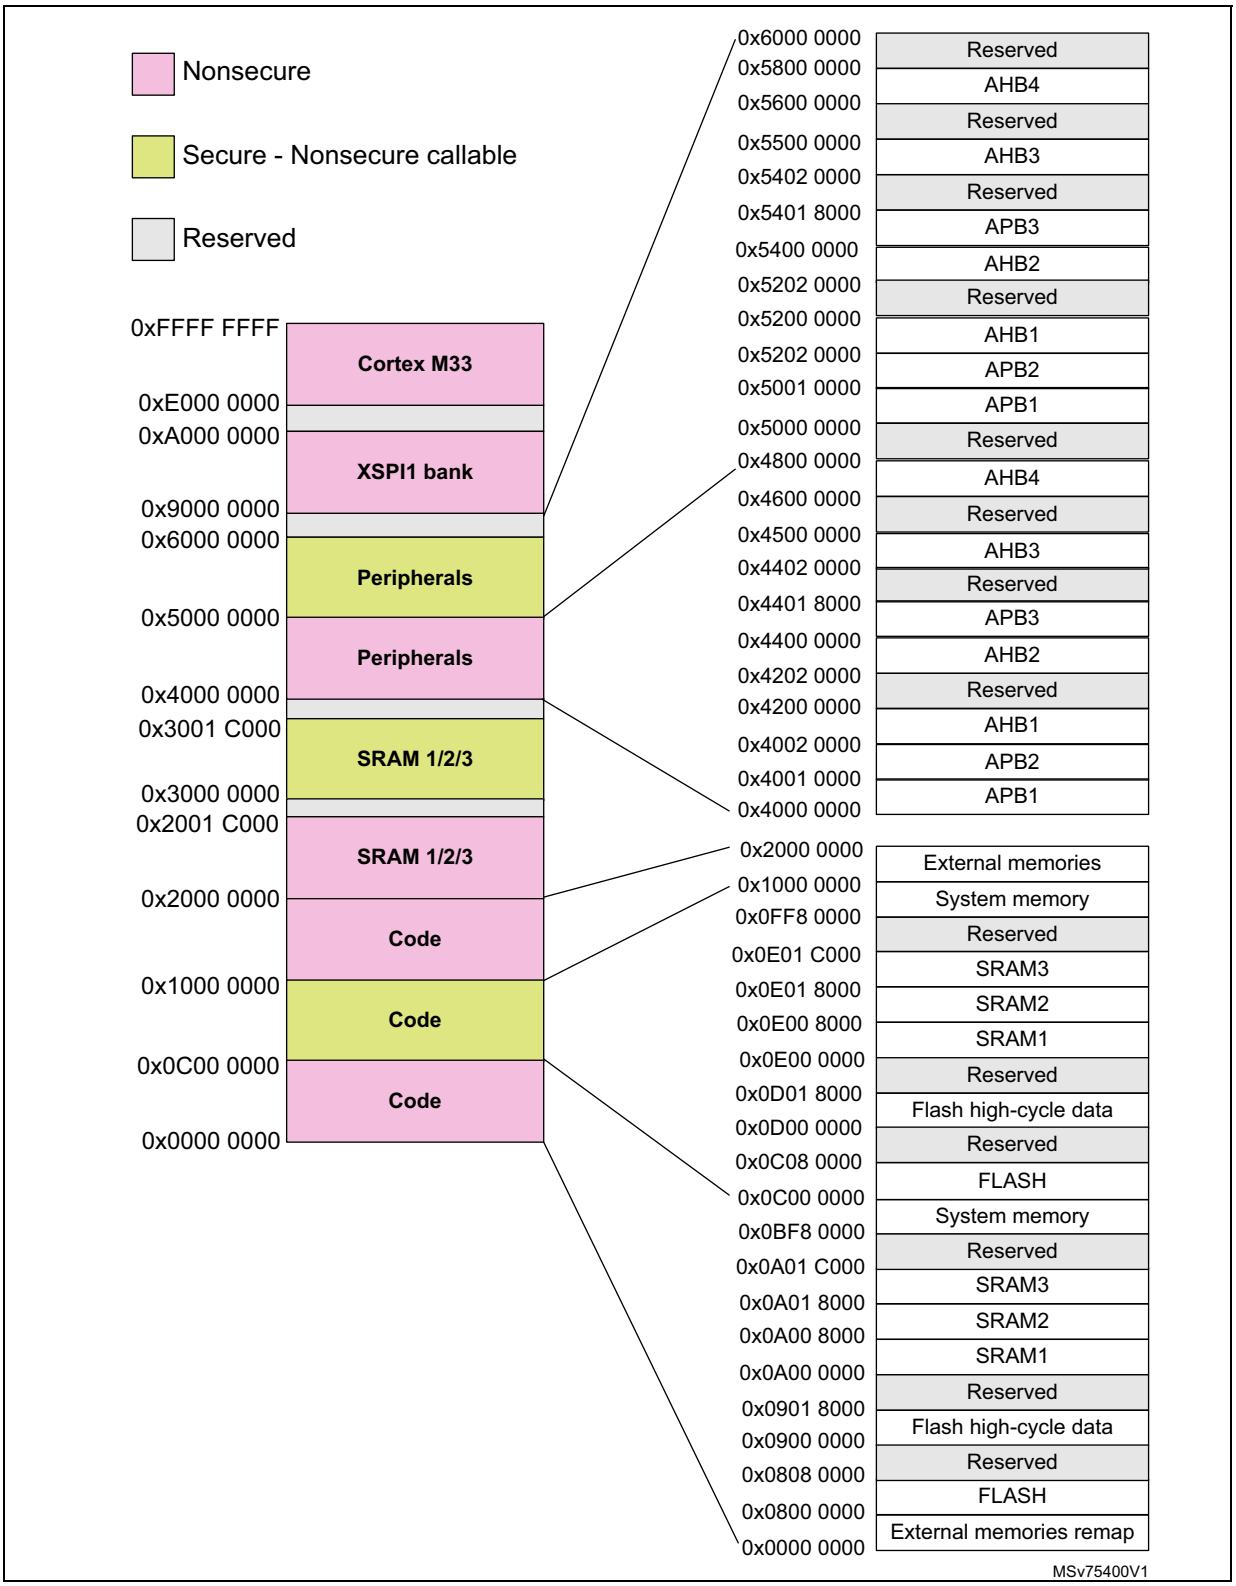

Figure 3. Memory map based on IDAU mapping (STM32G53x/54x devices)

2.3.3 Embedded SRAM

STM32G55x/56x devices feature up to 112-Kbyte SRAMs:

- 32-Kbyte SRAM1
- 64-Kbyte SRAM2
- 16-Kbyte SRAM3

STM32G53x/54x devices feature up to 60-Kbyte SRAMs:

- 20-Kbyte SRAM1
- 40-Kbyte SRAM2

These SRAMs can be accessed as bytes, half-words (16 bits), or full words (32 bits). These memories can be addressed both by CPU and DMAs.

The CPU can access the SRAM1, SRAM2, and SRAM3 through the system bus or through the C-bus depending on the selected address.

When the TrustZone® security is enabled, all SRAMs are secure after reset. The SRAM can be programmed as nonsecure with a block granularity. For more details, refer to *Section 5: Global TrustZone® controller (GTZC)*.

SRAM features are detailed in *Section 6.3.1: Internal SRAMs features*.

2.3.4 Flash memory overview

The flash memory is composed of two distinct physical areas:

- The main flash memory block that contains the application program and user data (dual bank).
- The information block that is composed of the following parts:
  - Option bytes for hardware and memory protection user configuration
  - System memory that contains ST proprietary code
  - OTP (one-time programmable) area

The flash interface implements instruction access and data access based on the AHB protocol. It also implements the logic necessary to carry out the flash memory operations (program/erase) controlled through the flash registers plus security access control features. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.

2.3.5 Boot modes

At startup, the core jumps to the boot address configured through the BOOT0 pin, the BOOT_ADDR option bytes, the TZEN option bit, debug request, and the product state.

If BOOT_ADDR is not yet configured, dedicated libraries (programmed during ST production), can be used for secure boot. They are located in system flash memory:

- ST libraries in system flash memory assist the application software boot with special features such as secure boot and secure firmware install (SFI-RSS).
- ST iROT (immutable root of trust) secure software in user flash memory is used for secure firmware update and provisioning (SFU).

If a debugger is attached to the product, the entry point is a debug authentication policy, which is used to unlock the device when attached to a debugger. A digital signature must be provided to perform a regression to product state, where debug is allowed.

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. Refer to the application note STM32 microcontroller system memory boot mode (AN2606).

3 System security

The devices are designed with a comprehensive set of security features, some of them based on the standard Arm® TrustZone® technology.

This section introduces the purpose these features serve in fulfilling security functions. Describing how the security functions are addressed is essential in evaluating IoT devices against security standards and regulations such as CRA. They also significantly reduce the cost and complexity of software development for OEM and third-party developers by facilitating the reuse, improving the interoperability, and minimizing the API fragmentation.

This section lists the different security functions and how to achieve them using features available on the devices.

3.1 Key security features

Product security is built on secure HW features:

- Secure isolation and privilege mode based on Armv8-M architecture of the Cortex-M33 core, extended to securable I/O, memories, and peripherals.
- Temporal isolation separates boot levels using HDPL (hide protect level) monotonic counter.
- Life cycle scheme based on PRODUCT_STATE transitions
  - Debug Authentication allows product maintenance in-the-field (debug reopening or regression)

  - Allows protected firmware distribution in up to three steps: immutable root of trust, secure (TZ-Closed), and nonsecure application (Closed/Locked)
- Cryptographic acceleration
  - AES 256-bit engine, supporting ECB, CBC, CTR, GCM, and CCM chaining modes
  - Secure AES 256-bit security coprocessor, supporting ECB, CBC, CTR, GCM, and CCM chaining modes with side-channel counter measures and mitigations
  - HASH processor supporting SHA-1 checksum, SHA-2 secure hash (224, 256, 384 and 512) and six Keccak-based functions (SHA3-224, SHA3-256, SHA3-384, SHA3-512, SHAKE128, and SHAKE256)
  - Public key accelerator (PKA) for RSA/DH (up to 4096 bits) and ECC (up to 640 bits), implementing side-channel counter measures and mitigations when manipulating secrets
  - True random number generator (RNG), NIST SP800-90B pre-certified
- On-the-fly decryption of encrypted image stored on external flash memory
  - Low or zero latency with standard NOR flash memories
  - Can be used to encrypt the image using the device unique secret keys
  - Automatic key-erase in case of tamper
  - Supported on STM32G56x
- Active tamper signals and protection against temperature, voltage, and frequency attacks
  - Up to two active inputs, two active output tamper pins, available in different power modes
- Identifiers preventing replay and cloning, such as UID, EPOCH and PUF (HUK).

Following root security services (RSS) are provided by the code in the product system memory, only fully supported on STM32G56x and partially on STM32G54x:

- RSSSF guarantees Secure firmware installation (SFI) with device unique cryptographic key pair
- RSSiSB is the entry point for secure boot controlling integrity of a user flash code. It is typically used with STiRoT.
- RSSREG providing minimum services to serve Debug Authentication, allowing control for PRODUCT_STATE regression.

Following secure firmware is proposed for installation in user flash memory:

- STiRoT for Secure Boot and Secure Update extending STiSB.
- STDA for Debug Authentication control extension.
- STiReg provides services involving certificate management.
- STuRoT as an updatable root of trust extension.

3.2 Secure install

*T*he secure firmware install (SFI) is a STMicroelectronics secure service authenticated and decrypted by the immutable RSS code stored in the device. The SFI allows secure and counted installation of OEM firmware in an untrusted production environment (such as OEM contract manufacturer).
The confidentiality of the installed images written in the internal flash memory or encrypted in an external flash memory, is also protected, using the AES.

The SFI native service is an immutable Root Secure Service (RSS) implemented in the system flash area of the nonvolatile memory. Leveraging the on-chip immutable bootloader supports the image download through USART, USB, SPI, FDCAN, I2C, and JTAG.
SFI is supported by STM32G56x and not implemented on STM32G54x/53x/52x because it relies on secure HW cryptography (refer to *Section 35: Secure AES coprocessor (SAES)*).
Further information can be found in AN4992 *"Overview secure firmware install (SFI)"*.

3.3 Secure boot

Secure boot relies on immutable code that is always executed after a system reset. As a root of trust, this code checks the device static protections and activates available device runtime protections, reducing the risk of invalid or malicious code running on the platform. As root of trust, the secure boot also checks the integrity and authenticity of the next level firmware before executing it.
The product always boots from CPU1 for all configurations.
On STM32G56x/54x devices, there are two options using BOOT_UBE (refer to *Section 14.3.6: SBS boot control*) to execute code after a reset:

- Booting through security services RSSiSB when selected. RSSiSB controls integrity of a user flash code. The user flash code can be a ST-iROT (provided by ST) or an OEM code.
- Booting directly in user flash when the OEM manages the full chain (OEM-iROT). This is the default configuration.

On STM32G55x/53x devices, the secure boot must be implemented in user flash. Secure boot starting point in user flash is fixed using a combination of configurable boot address and BOOT_LOCK option, that becomes immutable (refer to *Section 7.4.7: Description of boot address option bytes*).
The secure boot typically initializes the secure storage and installs on-the-fly decryption keys in the OTFDEC (STM32G56x), to be able to use encrypted firmware stored in an external flash memory.
The secure boot shall take advantage of hardware security features:

- Unique boot entry
- Resource isolation using TrustZone (refer to *Section 5: Global TrustZone® controller (GTZC)*)
- Boot modes (refer to *Section 4: Boot modes*)
- SBS boot control (HDPL) (refer to *Section 14.3.6: SBS boot control*)
- HDPL storage (refer to *Section 7.6.2: Hide protection (HDP)*)

3.3.1 Unique boot entry

Using the unique boot entry (BOOT_UBE), it is possible to select the boot entry point between security services in system flash (RSSiSB) and proprietary boot entry (OEMiROT) located in user flash memory. This selection is possible only for products embedding cryptographic acceleration when TrustZone is enabled (TZEN = 0xB4).
When TrustZone is enabled and SBOOT_LOCK secure option bit is cleared, the application selects a boot entry point located either in the system flash memory (refer to *Section 3.3.2*), or in the secure user flash memory, at the address defined by SBOOTADD option bytes.
When TrustZone is enabled and SBOOT_LOCK secure option bit is set, the device unique

boot entry is the unmodifiable secure address defined by SBOOTADD option bytes. The application cannot modify these option bytes when SBOOT_LOCK is set.
When TrustZone is disabled (TZEN = 0xC3) and BOOT_LOCK option bit is cleared, the application selects a boot entry point located in the nonsecure user flash memory, at the address defined by BOOTADD option bytes.
When TrustZone is disabled and BOOT_LOCK option bit is set, the device unique boot entry is the unmodifiable nonsecure address defined by BOOTADD option bytes. The application cannot modify these option bytes when BOOT_LOCK is set.

Note: SBOOT_LOCK and BOOT_LOCK can be changed only when PRODUCT_STATE = Open, Provisioning, or Regression.

BOOT_UBE is not applicable on products not supporting hardware crypto accelerators.

For more information on the boot mechanisms, refer to *Section 4: Boot modes*.

3.3.2 Immutable root of trust in system flash memory

The immutable root-of-trust code (RSSFS) stored in the system flash memory is first used to load and verify extensions (ST extensions: RSS-e-XXX). One typical extension is the RSS-e-SFI that allows SFI for secure and counted installation of OEM firmware in untrusted production environments (such as an OEM contract manufacturer).
The immutable code also includes secure runtime services that can be called at runtime, when a secure application sets the SBS_RSSCMDR register to a non-null value, before triggering a system reset. This runtime feature is deactivated when the BOOT_LOCK secure option bit is set or when the PRODUCT_STATE is different from Open.

3.3.3 Temporal isolation levels

The hardware and software resources used during boot can be isolated. This is called temporal isolation, based on a monotonic counter, with respect to the incrementation of the levels. When the counter is incremented, the resources (code and data) of the previous levels are hidden.

This increases security because it is impossible to execute the boot process partially from within the application, and thus compromise security.

For more details refer to (*Section 14.3.6: SBS boot control*).

System flash functions JumpHDPLvlx are available in RSSLib to securely facilitate the HDPL increment.

3.4 Secure update

The secure firmware update is a secure service that runs after a secure boot. Its actual functions depend on the availability of the TrustZone features, and on the firmware stored in the device.

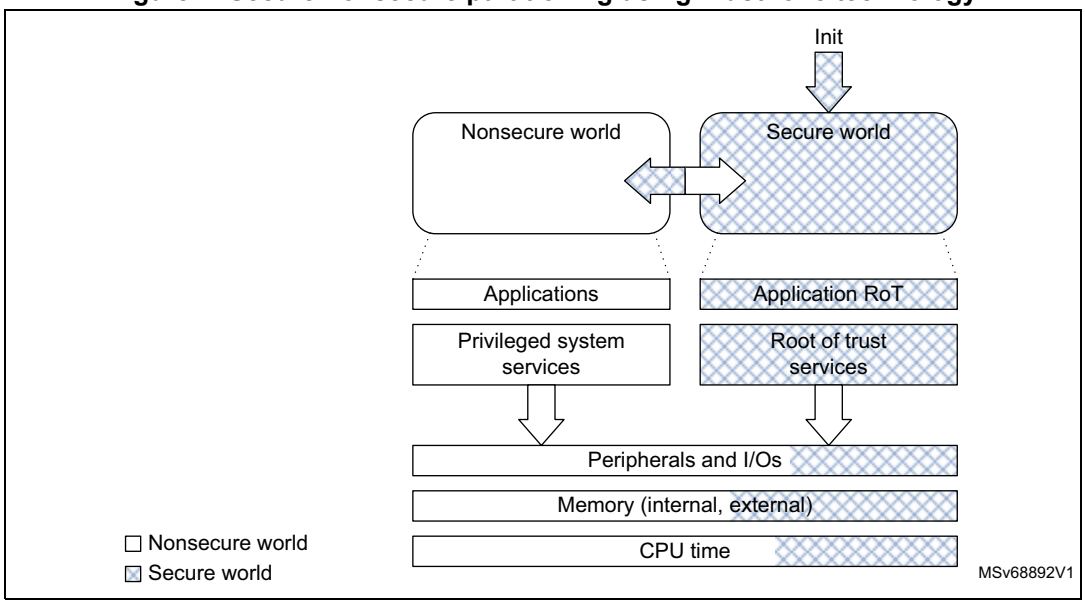
Cortex-M is commonly used to run trusted boot and a trusted OS to create a Trusted Execution Environment (TEE). The trusted boot and TEE application, supported by the STM32 ecosystem, allow the update of the microcontroller built-in program with new firmware versions, adding new features and correcting potential issues. The update process is performed in a secure way, to prevent unauthorized updates and access to confidential on-device data.

A firmware update can be done either on a single firmware image including both secure and nonsecure parts, or on the secure (respectively nonsecure) part of the firmware image, independently.

In the devices, the secure update application leverages the same hardware security as the firmware install described in *Section 3.2*.

3.4.1 Live update

STM32G5 series includes an option to minimize the downtime during transition from one code version to another. In dual bank device, a new code is loaded to the other bank, while the present version is still fully functional. Refer to *Section 3.4.1: Live update*.



There are two ways to swap the user flash banks and switch to the new content. Either the device reboot with new bank mapping, or the banks are swapped live during execution of a small portion of code that must be left unmodified. Refer to *Section 7.3.12: Flash bank swapping*.

Security of swap operations must be guaranteed by execution protection and authentication of the code image. If the security conditions are not met, or the swapping is not desirable, it can be securely disabled, both temporarily and permanently.

3.5 Resource isolation using TrustZone

The hardware and software resources can be partitioned so that they exist in the secure or in the nonsecure world, as shown in the figure below.

Figure 4. Secure/nonsecure partitioning using TrustZone technology

Note: The initial partitioning of the platform is under the responsibility of the secure firmware executed after device reset.

Thanks to this resource isolation technology, the secure world can be used to protect critical code against intentional or unintentional tampering from the more exposed code running in the nonsecure world.

Note: The secure code is typically small and rarely modified, while the nonsecure code is more exposed, and prone to firmware updates.

3.5.1 TrustZone security architecture

The Armv8-M TrustZone technology is a comprehensive hardware architecture that proposes to developers a comprehensive, holistic protection across the entire processor and system. The device TrustZone hardware features include:

- The Armv8-M mainline security extension of Cortex-M33, enabling a new processor secure state, with its associated secure interrupts
- The dynamic allocation of memory and peripherals to TrustZone using eight security attribution unit (SAU) regions of Cortex-M33
- Global TrustZone framework (GTZC) extending the TrustZone protection against transactions coming from masters in the system different from Cortex-M33
- TrustZone-aware embedded flash memory and peripherals

Note: The TZEN option bit in the FLASH_OPTSR2_PRG register activates TrustZone security.

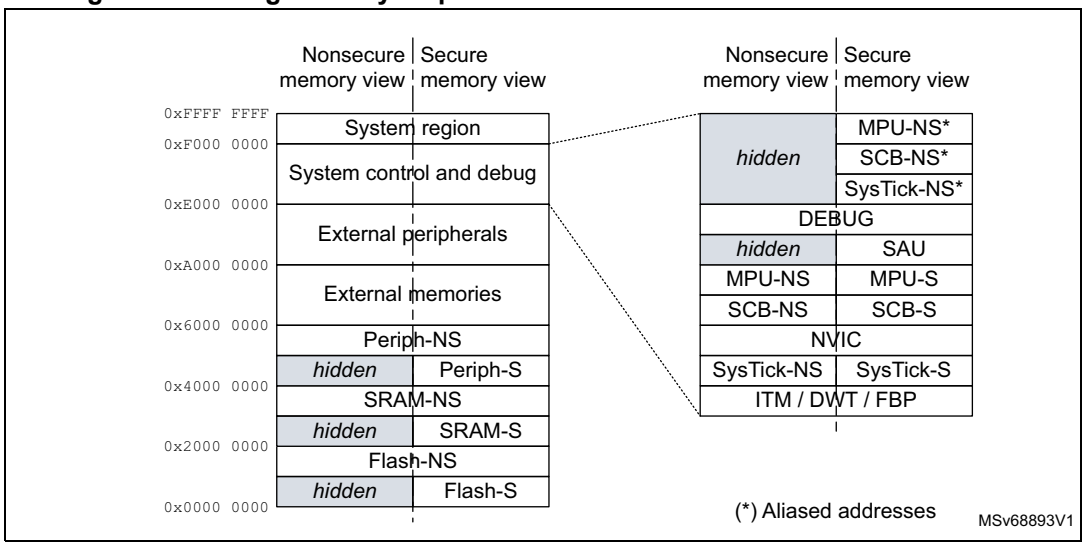
3.5.2 Armv8-M security extension of Cortex-M33

The Arm security extension of the Cortex-M33 is an evolution, not a revolution. It uses the programmer model from earlier Cortex-M subfamilies like Cortex-M4. Indeed, Armv8-M is architecturally similar to Armv7-M, using the same 32-bit architecture, the same memory mapped resources protected with an MPU. Armv8-M also uses the nested vector interrupt controller (NVIC).

The implementation on STM32G5 devices is composed of the following features:

- A new processor state, with almost no additional code/cycle overhead (as opposed to Armv8-A TrustZone) that uses a dedicated exception routine to trigger a secure/nonsecure world change
- Two memory map views of a shared 4-Gbyte address space
- A low interrupt latency for both secure and nonsecure domains, and a new interrupt configuration for security grouping and priority setting
- Separated exception vector tables for the secure and nonsecure exceptions
- Micro-coded context preservation
- Banking of specific registers across secure/nonsecure states, including stack pointers with stack-limit checkers
- Banking of the following Cortex-M33 programmable components (two separate units for secure and nonsecure):
  - SysTick timer
  - MPU configuration registers (12 MPU regions in secure, eight in nonsecure)
  - Some of the system control block (SCB) registers
- New system exception (SecureFault) for handling of security violations
- Configurable debug support, as defined in *Section 3.8.3*

For more information, refer to the Cortex-M33 programming manual (PM0264).



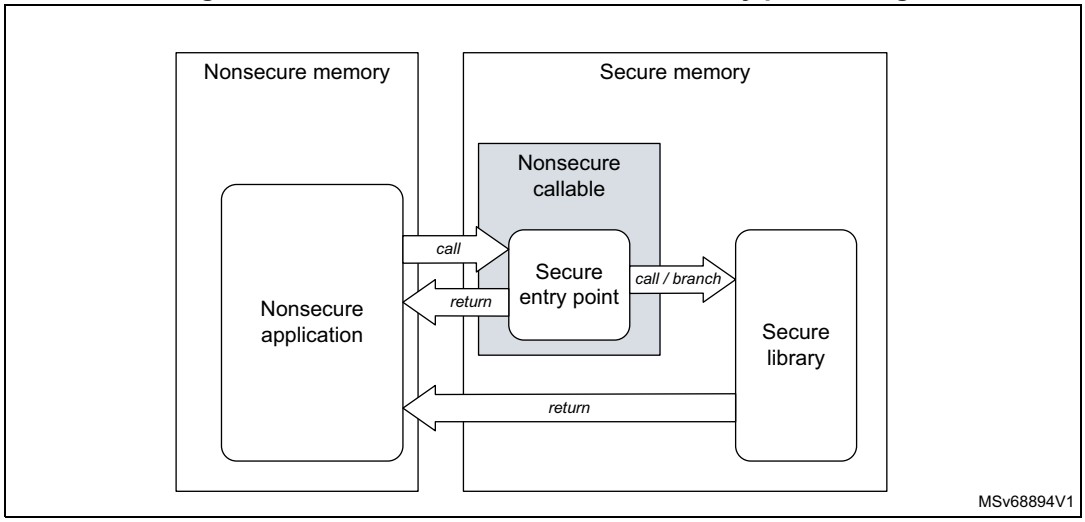
3.5.3 Memory and peripheral allocation using IDAU/SAU

Security attributes

As illustrated in *Figure 5*, the Armv8-M nonsecure memory view is similar to Armv7-M (found in Cortex-M4), with the difference that the secure memory is hidden. The secure memory view shows the flash memory, SRAM and peripherals that are accessible only while the Cortex processor executes in Secure state.

Note: Figure 5 shows the 32-bit address space after SAU configuration, as viewed by the secure code.

Figure 5. Sharing memory map between CPU in secure and nonsecure state



The Cortex processor state (and the associated rights) depends upon the security attribute assigned to the memory region where it is executed:

- A processor in a nonsecure/secure state executes only from nonsecure (NS)/secure (S) program memory.
- When running in secure state, the processor can access data from both S and NS memories. When running in nonsecure state, the CPU is limited to nonsecure memories.

To manage transitions to the secure world, developers must create nonsecure callable (NSC) regions containing valid entry points to the secure libraries. The first instruction in

these entry points must be the new secure gate (SG) instruction, used by the nonsecure code to call a secure function (see the figure below).

Figure 6. Secure world transition and memory partitioning

Programming security attributes

In Cortex-M33, the static implementation defined attribution unit (IDAU) works with the programmable security attribution unit (SAU) to assign a specific security attribute (S, NS, or NSC) to a specific address, as shown in the table below.

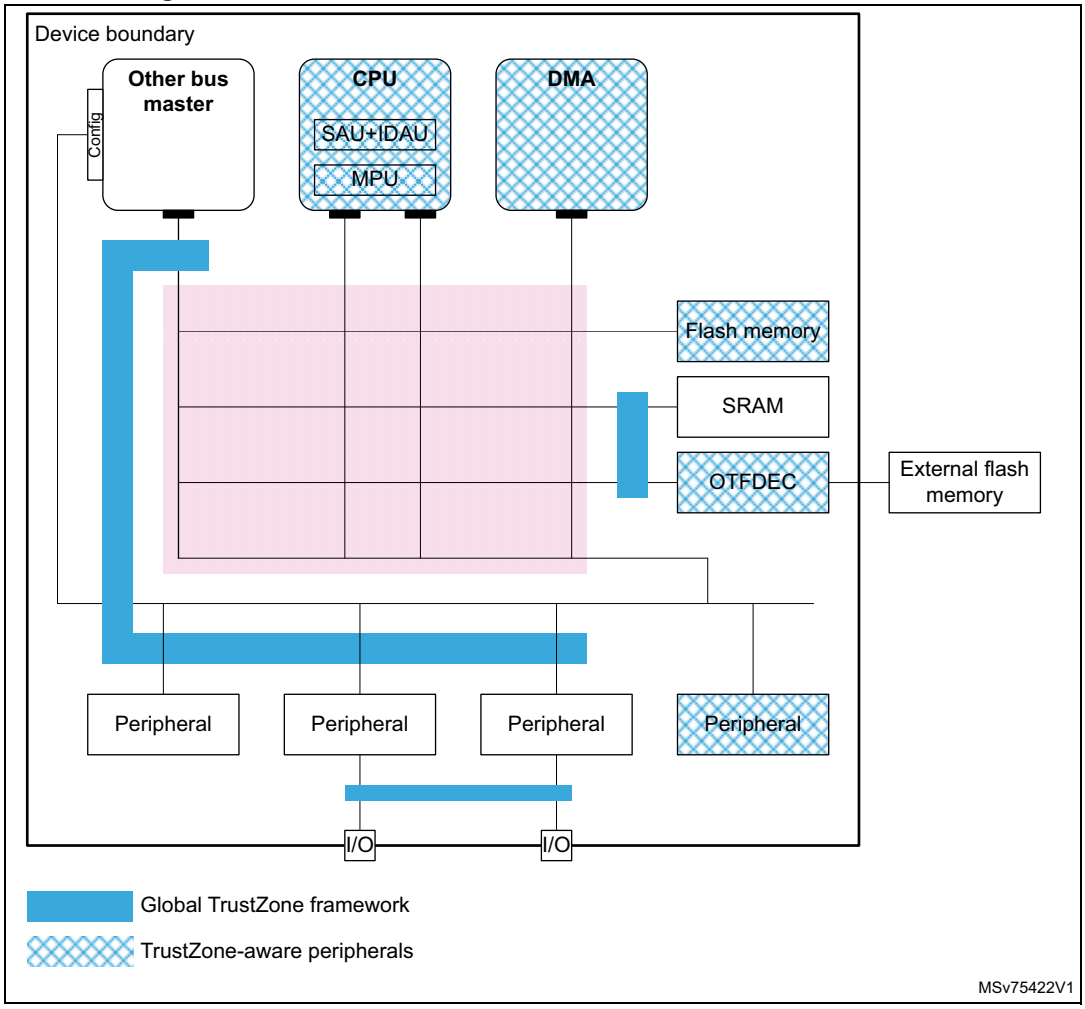
Table 6. Configuring security attributes with IDAU and SAU

IDAU security attribution	SAU security attribution(1)	Final security attribution
Nonsecure	Secure	Secure
	Secure-NSC	Secure-NSC
	Nonsecure	Nonsecure
Secure-NSC	Secure	Secure
	Nonsecure	Secure-NSC

1. Defined regions are aligned to 32-byte boundaries.

The Cortex-M33 can configure the SAU only in the secure-privilege state. When the TrustZone is enabled, the SAU defaults all addresses as secure (S). A secure boot application can then program the SAU to create NSC or NS regions, as shown in *Table 6*.

Note: The SAU/IDAU settings are applicable only to the Cortex-M33*. The other masters, like DMA, are not affected by these policies.*



3.5.4 Memory and peripheral allocation using GTZC

Global TrustZone framework architecture

On top of the Armv8-M TrustZone security extension in Cortex-M33, the devices embed complementary security features that reinforce, in a flexible way, the isolation between secure and nonsecure worlds. Unlike the SAU/IDAU, the GTZC can protect legacy

memories and peripherals against nonsecure transactions coming from other masters than the Cortex-M33.

Figure 7. Global TrustZone framework and TrustZone awareness

Securing peripherals with TZSC

When the TrustZone security is active, a peripheral is either securable through the GTZC, or is natively TrustZone-aware, as shown in *Figure 7*:

- A securable peripheral or memory is protected by an AHB/APB firewall gate, controlled by the TrustZone security controller (TZSC).
- A TrustZone-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific TrustZone behavior, such as a subset of secure registers or a secure memory area.

TrustZone-aware AHB masters like Cortex-M33 or DMAs, drive a secure signal in the AHB interconnect, according to their security mode, independently to the GTZC.

Securing memories with TZSC and MPCBB

The TZSC block in GTZC provides the capability to manage the security and privilege for all securable external memories, programming the MPCWM resources as defined in the table below.

Table 7. MPCWMx resources for STM32G55x/56x

Memory	MPC resource	Type of filtering	Number of regions	Default security	On-the-fly decryption(1)
XSPI1	MPCWM1	Nonsecure, privileged, or unprivileged region (watermarks)	2	Secure privileged(2)	Yes

1. Using the OTFDEC.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.

The MPCBB resources in GTZC provide the capability to configure the security and privilege of embedded SRAM blocks, as defined in the tables below.

Table 8. MPCBBx resources for STM32G53x/54x

Memory	MPC resource	Type of filtering	Memory size	Block size	Number of super-blocks	Default security
SRAM1	GTZC1_MPCBB1	Block-based, managing security and privilege	20 KB	512(1) bytes	2	Secure privileged(2)
SRAM2	GTZC1_MPCBB2		40 KB		3	

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.

Table 9. MPCBBx resources for STM32G55x/56x

Memory	MPC resource	Type of filtering	Memory size	Block size	Number of super-blocks	Default security
SRAM1	GTZC1_MPCBB1	Block-based, managing security and privilege	32 KB	512(1) bytes	4	Secure privileged (2)
SRAM2	GTZC1_MPCBB2		64 KB		8	
SRAM3	GTZC1_MPCBB3		16 KB		2	

1. Blocks are grouped in super-blocks of 32 consecutive blocks, to manage the configuration locking.
2. Assuming TrustZone is activated on the device, nonsecure unprivileged otherwise.

Applying GTZC configurations

The TZSC and MPCBB blocks can be used in one of the following ways:

- Statically programmed during the secure boot, locked and not changed afterwards
- Dynamically reprogrammed using a specific application code or real-time kernel

When the dynamic option is selected and the configuration is not locked:

- MPCBB secure blocks or MPCWM nonsecure region size can be changed by a secure software. This software must be privileged for MPCWM, can be unprivileged if the particular block is not privileged-only.
- The secure (respectively privilege) state of each peripheral can be changed writing to GTZC_TZSC_SECCFRGx (respectively GTZC_TZSC_PRIVCFGRx) registers.

Securing peripherals with TZSC

The TZSC block in GTZC provides the capability to manage the security and the privilege for all securable peripherals.

Note: When the TrustZone is deactivated, the resource isolation hardware GTZC can still be used to isolate peripherals to privileged code only.

When the TrustZone is activated, peripherals are set as nonsecure and unprivileged after reset.

TrustZone-aware peripherals

The devices include the following TrustZone-aware peripherals:

- GPIOA to GPIOH
- GTZCx_MPCBB, GTZCx_TZIC and GTZCx_TZSC (GTZC blocks)
- OTFDEC1, writable only in secure if TZEN is enabled
- EXTI
- Flash memory
- RCC and PWR
- GPDMA1 and GPDMA2
- SBS registers
- RTC and TAMP
- MCU debug unit DBGMCU
- PLAY1

TrustZone illegal access controller (TZIC)

The TZIC block in GTZC gathers all illegal access events originated from sources either protected by GTZC or TrustZone-aware, generating one global secure interrupt towards the NVIC.

TZIC is available only when the system is TrustZone enabled (TZEN = 0xB4). All accesses to TZIC registers must be secured.

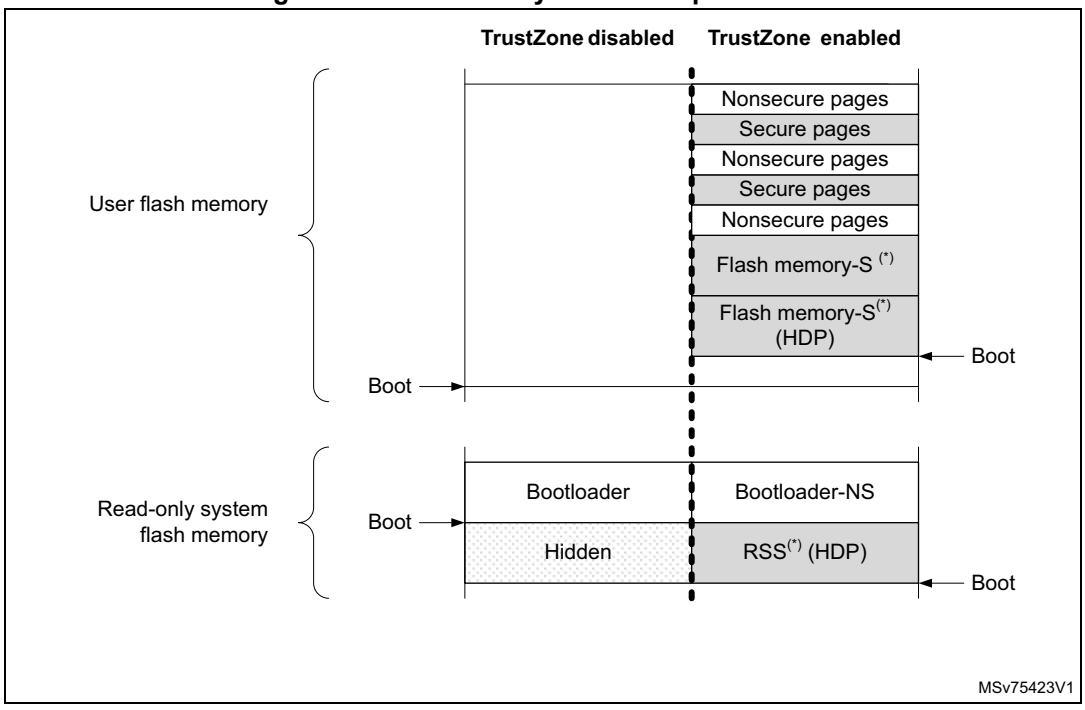
For each illegal event source, a status flag and a clear bit exist. Each illegal event can be masked, not generating an interrupt toward the NVIC.

Note: By default, all events are masked.

3.5.5 Managing security in TrustZone-aware peripherals

This section gives more details on how the security is implemented in the TrustZone-aware peripherals listed in the previous section.

Embedded flash memory



When the TrustZone security is enabled through option bytes (TZEN = 0xB4), the whole memory is secure after reset. The following protections, shown in *Figure 8*, are available to the application:

- nonvolatile user secure areas, defined with nonvolatile secure user option bytes
  - watermark-based secure only area (x2)
  - secure hide protection (HDP) area, stickily hidden after boot (x2)
- volatile user secure pages, defined with volatile secure registers (lost after reset)
  - Any page set as nonsecure (example: outside watermark-based secure only area), can be set as secure on-the-fly using the block-based configuration registers.

Note: All areas are aligned on the page granularity of the flash memory, which can be configured as secure while it is tagged as nonsecure in Cortex-M33 IDAU/SAU. In this case, nonsecure accesses by the CPU to the flash memory are denied.

Erase or program operations can be available to secure/nonsecure code only for secure/ nonsecure pages or memory. A flash memory is considered secure if at least one page is secure.

Figure 8. Flash memory TrustZone protections

As shown above, when TrustZone is enabled (TZEN = 0xB4), the application code can use the HDP area that is part of the flash memory watermark-based secure area. Indeed, when

the application changes the HDPL level, data read, write, and instruction fetch on this HDP area is denied until the next system reset.

For example, the software code in the secure flash memory HDP area can be executed only once, with any further access to this area denied until the next system reset. Additionally, any flash memory page belonging to an active HDP area cannot be erased anymore.

When the TrustZone is disabled (TZEN = 0xC3), the volatile/non-volatile secure area features are deactivated and all secure registers are RAZ/WI.

See *Section 7: Embedded flash memory (FLASH)* for more details.

On-the-fly encryption/decryption (OTFDEC)

When the TrustZone security is enabled (TZEN = 0xB4), the OTFDEC can be initialized only by secure applications. Each of the four encrypted regions, once the configuration is confirmed, can be write-locked until the next power-on-reset.

Note: This resource is only supported by STM32G56x, not implemented on STM32G53x/54x/55x.

Any application (secure or nonsecure) can verify the initialization context of each OTFDEC region (including CRC of the keys), by reading the peripheral registers.

Key registers in each OTFDEC are write-only.

Direct memory access controllers (GPDMAx)

When a DMA channel x is defined as secure (SECx = 1 in GPDMA_SECCFGR), the source and destination transfers can be independently set as secure or nonsecure by a secure application using SSEC and DSEC bits in GPDMA_CxTR1. The table below summarizes these security options available in each DMA channel.

Table 10. DMA channel use (security)(1)

Destination type	Secure DMA channel x (SECx = 1)		Nonsecure DMA channel y (SECy = 0)	
	Secure source	Nonsecure source	Secure source	Nonsecure source
Secure destination	OK	OK(2)	Transfer blocked	
Nonsecure destination	OK(3)	OK(4)	Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return 0s. An illegal access event to TZIC is automatically triggered by the memory/peripheral used as source or destination.
2. If the source is a memory, the transfer is possible only if SSEC = 0, otherwise the transfer is blocked.
3. If the destination is a memory, the transfer is possible only if DSEC = 0, otherwise the transfer is blocked.
4. If the transfer is memory-to-memory, it is possible only if SSEC = 0 and DSEC = 0, otherwise it is blocked.

When a channel is configured as secure:

- Registers allocated to this channel (excluding GPDMA_SECCFGR, GPDMA_PRIVCFGR and GPDMA_RCFGLOCKR) are read as 0. Writes are ignored for nonsecure accesses. A secure illegal access event may also be triggered towards the TZIC peripheral.
  - Writes to GPDMA_SECCFGR and GPDMA_RCFGLOCKR must be secure. For each bit in GPDMA_PRIVCFGR, write must be secure if the corresponding bit in GPDMA_SECCFGR is set.
- In linked-list mode, the loading of the next linked-list data structure from memory is performed with secure transfers.

- When switching to a nonsecure state, the secure application must abort the channel or wait until the secure channel is completed before doing the switch.

Note: DMA secure channels are not available when TrustZone is deactivated. When a channel is configured as nonsecure, in linked-list mode, the loading of the next linked-list data structure from memory is performed with nonsecure transfers.

See *Section 16: General purpose direct memory access controller (GPDMA)* for more details.

Power control (PWR)

When the TrustZone security is enabled (TZEN = 0xB4), the selected PWR registers can be secured through PWR_SECCFGR, protecting the following PWR features:

- Low power mode setup
- Wake-up (WKUP) pins definition
- Voltage detection and monitoring
- RTC domain control

Other PWR configuration bits become secure:

- When the system clock selection is secure in the RCC: the voltage scaling (VOS) becomes secure.
- When a GPIO is configured as secure: its corresponding bit for pull-up/pull-down configuration in Standby mode becomes secure.
- When the USB Type-C/USB power delivery interface (UCPD) is configured as secure in TZSC: PWR_UCPDR register becomes secure.

See *Section 10: Power control (PWR)* for details.

Secure clock and reset (RCC)

When the TrustZone security is enabled (TZEN = 0xB4) and security is enabled in the RCC, the bits controlling the peripheral clocks and resets become TrustZone-aware:

- If the peripheral is securable and programmed as secure in the TZSC, the peripheral clock and reset bits become secure.
- If the peripheral is TrustZone-aware, the peripheral clock and reset bits become secure when at least one function is configured as secure inside the peripheral.

Additionally, the following configurations can be made secure-only using RCC_SECCFGR:

- External clock (such as HSE or LSE), internal oscillator (such as HSI or LSI)
- Main PLL and AHB prescaler
- System clock source selection
- MCO clock output
- Reset flag
- Automatic internal oscillator waking up configuration

See *Section 11: Reset and clock control (RCC)* for details.

Real-time clock (RTC)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured RTC register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the RTC illegal access event is enabled in the TZIC.

After a RTC domain power-on reset, all RTC registers can be read or written in both secure and nonsecure modes. The secure boot code can then change the security setup, making registers Alarm A, Alarm B, wakeup timer, and timestamp secure or not, using RTC_SECCFGR.

When the SEC bit is set in secure-only RTC_SECCFGR:

- Writing the RTC registers is possible only in secure mode.
- Reading RTC_SECCFGR, RTC_PRIVCFGR, RTC_MISR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER, and RTC_CALR is always possible in secure and nonsecure modes. All the other RTC registers can be read only in secure mode.

When SEC is cleared in secure-only RTC_SECCFGR, it is still possible to restrict access in secure mode to some RTC registers by setting dedicated control bits: INITSEC, CALSEC, TSSEC, WUTSEC, ALRASEC, and ALRBSEC.

Note: The RTC security configuration is not affected by a system reset.

See*Section 49: Real-time clock (RTC)* for more details.

Tamper and backup registers (TAMP)

Like all TrustZone-aware peripherals, a nonsecure read/write access to a secured TAMP register is RAZ/WI. It also generates an illegal access event that triggers a secure illegal access interrupt if the TAMP illegal access event is enabled in the TZIC.

After a RTC domain power-on reset, all TAMP registers can be read or written in both secure and nonsecure modes. The secure boot code can change this security setup, making some registers secure or not as needed, using TAMP_SECCFGR register.

When TAMPSEC is set in TAMP_SECCFGR:

- Writing the TAMP registers is possible only in secure mode. Backup registers have their own write protection (see below).
- Reading the TAMP registers (exception TAMP_SECCFGR, TAMP_PRIVCFGR, and TAMP_MISR) returns 0 if the access is nonsecure. Backup registers have their own read protection (see below).

The application can also:

- make TAMP_COUNTR register read and write secure-only by setting the CNT1SEC bit in TAMP_SECCFGR secure register
- increase security in backup registers for two of the three protection zones configured using BKPRWSEC[7:0] and BKPWSEC[7:0] bitfields in TAMP_SECCFGR:
  - protection zone 1 is read nonsecure, write nonsecure
  - protection zone 2 is read nonsecure, write secure
  - protection zone 3 is read secure, write secure

Note: The TAMP security configuration is not affected by a system reset.

See *Section 50: Tamper and backup registers (TAMP)* for more details.

General-purpose I/Os (GPIO)

When the TrustZone security is enabled (TZEN = 0xB4), each I/O pin of the GPIO ports can be individually configured as secure through the GPIOx_SECCFGR registers. Only a secure application can write to GPIOx_SECCFGR registers. After boot, each I/O pin is set as secure.

When an I/O pin is configured as secure, its corresponding configuration bits for alternate function (AF), mode selection (MODE), and I/O data are RAZ/WI in case of nonsecure access.

When a digital alternate function is used (input/output mode) to protect data transiting from/to the I/O managed by a secure peripheral, the devices add a secure alternate function gate on the path between the peripheral and its allocated I/Os:

- if the peripheral is secure, the I/O pin must also be secure to allow input/output of data
- if the peripheral is not secure, the connection is allowed regardless of the I/O pin state.

The TrustZone-aware logic around GPIO ports, used as alternate functions, is summarized in the table below.

Table 11. Secure alternate function between peripherals and allocated I/Os

Security configuration		Alternate function logic		Comment
Peripheral	**Allocated I/O pin**	**Input**	**Output**	
Secure	Secure	I/O data	Peripheral data	-
Nonsecure				Out of reset configuration
Secure	Nonsecure	0	0	-
Nonsecure		I/O data	Peripheral data	

When an analog function with an analog switch is used, the connection to the peripherals listed in the table below is blocked by hardware when the peripheral is nonsecure and the I/O is secure.

Table 12. Nonsecure peripheral functions that cannot be connected to secure I/Os

Peripheral	Analog function(1)	Input	Output
ADC12	ADC12_INy (y = 1 to 17)	X	-

1. Used to find the I/O corresponding to the signal/function on the package (refer to the product datasheet).

Finally, regarding GPIO and security, *Table 13* summarizes the list of I/Os without any hardware protection linked to TrustZone. The listed signals (input and/or outputs) are not blocked when the I/O is set as secure, and the associated peripheral is nonsecure.

For example, when a secure application sets PA4 as secure to be used as LPTIM2_CH1, if the DAC is nonsecure, it can be programmed to output data to PA4, potentially causing malfunction to the secure application.

Similarly, when a secure application sets PA0 as secure to be used as UART4_TX, if TAMP is nonsecure, it can be programmed to capture the USART input traffic through the TAMP_IN signal.

It is important that, for each case described in *Table 13*, the secure application decides if a potential effect on data integrity or confidentiality is critical or not. For example, if the USART situation described above is not acceptable (data transiting on secure USART is confidential), then the secure application must configure the TAMP as secure even if not used by the secure application.

Table 13. Nonsecure peripheral functions that can be connected to secure I/Os

Peripheral	Signal[1]	Input	Output	How to set the peripheral or function as secure
DAC	DAC1_OUTx (x = 1, 2)	-	X	Set DAC1SEC in GTZC1_TZSC_SECCFGR1.
UCPD	UCPD1_CCx (x = 1, 2)	X	X	Set UCPD1SEC in GTZC1_TZSC_ SECCFGR1.
	UCPD1_DBx (x = 1, 2)	X	-	
TAMP	TAMP_INx (x = 1 to 8)	X	-	Set TAMPSEC in TAMP_SECCFGR
	TAMP_OUTx (x = 1 to 8)	-	X	
RTC	RTC_OUTx (x = 1, 2)	-	X	Set SEC in RTC_SECCFGR.
	RTC_TS	X	-	Set TSSEC in RTC_SECCFGR.
PWR	WKUPx (x = 1 to 8)	X	-	Set WUPxSEC in PWR_SECCFGR.
RCC	LSCO	-	X	Set LSESEC in RCC_SECCFGR.
EXTI	EXTIx (x= 0 to 58)	X	-	Set SECx bit in EXTI_SECCFGR.

1. To find the I/O corresponding to the signal/function on the package, refer to the product datasheet.

Refer to *Section 13: General-purpose I/Os (GPIO)* for more details.

Extended interrupts and event controller (EXTI)

When the TrustZone security is enabled, the EXTI is able to protect event register bits from being modified by nonsecure accesses. The protection can individually be activated per input event via the register bits in EXTI_SECCFGRx. When an input event is configured as secure, only a secure application can change the configuration (including security), change the masking or clear the status of this input event.

The security configuration in EXTI_SECCFGR1 and EXTI_SECCFGR2 can be globally locked after reset in EXTI_LOCKR.

See *Section 19: Extended interrupts and event controller (EXTI)* for more details.

System configuration, boot, and security (SBS)

Like all TrustZone-aware peripherals, when the TrustZone security is enabled, a nonsecure read/write access to a secured SBS register is RAZ/WI. Such access also generates an illegal access event that triggers a secure illegal access interrupt if the SBS illegal access event is not masked in the TZIC.

See *Section 14: System configuration, boot, and security (SBS)* for more details.

Microcontroller debug unit (DBGMCU)

The MCU debug component (DBGMCU) helps the debugger, providing support for:

- low-power modes behavior during debug
- peripheral freeze during debug, applicable to I2Cs, IWDG, WWDG, timers, low-power timers, and GPDMA channels

The DBGCMU is a TrustZone-aware peripheral, managing accesses to its control registers as described in the table below.

Table 14. TrustZone-aware DBGMCU nonsecure accesses management

Debug profile	Peripheral status(1)	DBG_xx_STOP control bits	
		Write access	Read access
Nonsecure invasive (SPIDEN = 0)	NS	Yes (S(2) or NS)	Yes (S or NS)
	S	None (S or NS)	
Secure invasive (SPIDEN =1)	NS	Yes (S or NS)	
	S	Yes (S only)	

1. As reported by the GTZC, the TrustZone-aware peripheral or the DMA channel.
2. Secure access from debugger is converted to nonsecure access in the device.

Refer to *Section 60: Debug support (DBG)* for more details.

3.5.6 Activating TrustZone security

The TrustZone is deactivated by default in all devices. It can be activated by setting the TZEN option bit in FLASH_OPTSR2_PRG when PRODUCT_STATE is Open. Once TZEN has changed from disabled to enabled (0xC3 to 0xB4), the default security state, after reset, is always the following:

- CPU subsystem
  - Cortex-M33 exits reset in secure state, hence the boot address must point toward a secure memory area.
  - All interrupt sources are secure (in NVIC).
  - The memory mapped viewed by the CPU through IDAU/SAU is fully secure.
- Embedded flash memory
  - Flash memory nonvolatile secure areas (with their HDP zone), are defined with nonvolatile registers FLASH_SECWMxR (x = 1, 2). Default secure option bytes setup is all user flash secure, without HDP area defined.
  - Volatile block-based security attributions of the flash memory are nonsecure.
- Embedded SRAMs
  - All SRAMs are secure, as defined in GTZC/MPCBB. The secure boot code can change this security setup, making blocks secure or not.
- External memories
  - All memory devices connected to XSPI1 are secure. The secure-boot code can change this security setup, making components secure or not.
- All GPIOs are secure.
- All GPDMA channels are nonsecure.
- Backup registers are nonsecure.
- Peripherals and GTZC:
  - Securable peripherals are nonsecure and unprivileged.
  - TrustZone-aware peripherals are nonsecure, with their secure configuration registers being secure.

– All illegal access interrupts in GTZC/TZIC are disabled.

3.5.7 Deactivating TrustZone security

Once TrustZone is activated, it can only be deactivated during a PRODUCT_STATE regression to Open.

Note: Such PRODUCT_STATE regression triggers the erasing of embedded memories (SRAM2, flash), and the reset of all peripherals, including the OTFDEC and all crypto engines.

After the TrustZone deactivation, the following features are no longer available:

- The nonvolatile secure area of the embedded flash memory is deactivated, including the HDP area.
- Only the NVIC manages nonsecure interrupts.
- All secure registers in TrustZone-aware peripherals are RAZ/WI.

3.5.8 Resource isolation using Cortex privileged mode

In parallel to the TrustZone isolation described in *Section 3.5*, the hardware and software resources can be partitioned so that they are restricted to software running in Cortex privileged mode.

Thanks to this hardware isolation technology, available even if TrustZone is disabled, critical code or data can be protected against intentional or unintentional tampering from the more exposed unprivileged code.

Memory and peripheral privileged allocation using MPU

The Cortex-M33 MPU divides the unified memory into eight regions in nonsecure and twelve in TrustZone, each aligned to a multiple of 32 bytes. Each memory region can be programmed to generate faults when accessed inappropriately by unprivileged software.

Memory and peripheral privileged allocation using GTZC

For the Cortex-M33 master, to complement the coarse isolation provided by the MPU, the GTZC reinforces, in a flexible way, the isolation between privileged and unprivileged tasks, for peripherals and selected memories.

- Securing peripherals with TZSC (privileged-only)

  In the devices, a peripheral is either securable privileged-only through GTZC, or is natively privileged-aware:

  – A securable privileged-only peripheral or memory is protected by an AHB/APB firewall gate controlled by the TZSC.

  – A privileged-aware peripheral or memory is connected directly to AHB or APB interconnect, implementing a specific behavior (for example, a subset of registers Privilege-aware masters like GPDMA1 and GPDMA2, drive privileged signal in the

AHB interconnect according to their internal privileged mode, independently to the GTZC.

- Securing memories with TZSC and MPCBB (privileged-only)

  The TZSC logic in GTZC provides the capability to manage the privilege level for all securable external memories, programming the MPCWM resources.

  Similarly, the TZSC logic in GTZC provides the capability to configure the privilege level of embedded SRAM blocks, programming the MPCBB resources.

- Error management (privileged-only)
  - Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal unprivileged read and write accesses.
  - The addressed resource follows a silent-fail behavior, returning all-0 data for read and ignoring any write.
  - When an illegal unprivileged access occurs, no bus error is generated, except when this is an instruction fetch, accessing a privileged memory or a peripheral register.

Managing security in privileged-aware peripherals

TrustZone-aware peripherals also implement privileged-only access mode. The privileged protection is valid even if TrustZone is disabled (TZEN = 0xC3):

- Embedded flash memory

  By default, all registers can be read or programmed in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in FLASH_PRIVCFGR, reading and writing the secure registers is possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When nonsecure privileged bit NSPRIV is set in FLASH_PRIVCFGR, reading and writing the flash memory nonsecure registers is possible only in privileged mode.

  Regarding privileged protection, the devices offer the following features:
  - The system flash memory can be accessed in both privileged and unprivileged modes.
  - Each watermark-based secure area, including its secure HDP area, is accessible in secure-privileged and secure-unprivileged mode, if applicable.
  - Each 8-Kbyte page of the embedded flash memory can be programmed on-the-fly as privileged only, using the block-based privileged configuration registers FLASH_PRIV1BBRx and FLASH_PRIV2BBRx. An unprivileged page is accessible by privileged or unprivileged access.

Note: Switching a page from privileged to unprivileged does not erase its content.

When applicable, an erase or program operation is always available to privileged code, and is available to unprivileged code only for unprivileged pages or unprivileged memory.

- On-the-fly encryption/decryption (OTFDEC)

  When privileged bit PRIV is set in OTFDEC_PRIVCFGR, only a privileged application can initialize the OTFDEC.

Note: OTFDEC_PRIVCFGR can be read by both privileged and unprivileged code.

- Direct memory access controllers (GPDMAx)

  When a DMA channel x is defined as privileged (PRIVx = 1 in GPDMA_PRIVCFGR), special rules (see the table below) apply when accessing privileged/unprivileged source or destination.

Table 15. DMA channel use (privilege)

Destination	Privileged DMA channel x (PRIVx = 1)		Unprivileged DMA channel y (PRIVy = 0)	
	Privileged source	Unprivileged source	Privileged source	Unprivileged source
Privileged	OK		Transfer blocked(1)	
Unprivileged			Transfer blocked	OK

1. When a transfer is blocked, the transfer completes but the corresponding writes are ignored, and reads return 0s.

- Power control (PWR)

  By default, after a power-on or a system reset, all PWR registers except PWR_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in PWR_PRIVCFGR, reading and writing the PWR securable registers are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When nonsecure privileged bit NSPRIV is set in PWR_PRIVCFGR, reading and writing the PWR nonsecure registers are possible only in privileged mode.

  See *Section 10: Power control (PWR)* for details.

- Secure clock and reset (RCC)

  By default, after a power-on or a system reset, all RCC registers except RCC_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When secure privileged bit SPRIV is set in RCC_PRIVCFGR, reading and writing the RCC securable bits are possible only in privileged mode. Write access to this bit is ignored if TrustZone is disabled (TZEN = 0xC3).

  When nonsecure privileged bit NSPRIV is set in RCC_PRIVCFGR, reading and writing the RCC nonsecure bits are possible only in privileged mode.

  See *Section 11: Reset and clock control (RCC)* for details.

- Real time clock (RTC)

  By default after any RTC domain reset, all RTC registers except RTC_PRIVCFGR, can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only RTC_PRIVCFGR:

  – Writing the RTC registers is possible only in privileged mode.

  – Reading the RTC_SECCFGR, RTC_PRIVCFGR, RTC_TR, RTC_DR, RTC_SSR, RTC_PRER and RTC_CALR is always possible in privileged and unprivileged modes.

  All the other RTC registers can be read only in privileged mode.

  When PRIV bit is cleared in privileged-only RTC_PRIVCFGR register, it is still possible to restrict access to privileged mode to some RTC registers by setting dedicated control bits: INITPRIV, CALPRIV, TSPRIV, WUTPRIV, ALRAPRV, or ALRBPRIV.

  See *Section 49: Real-time clock (RTC)* for details.

- Tamper and backup registers (TAMP)

  By default after any RTC domain reset, all TAMP registers except TAMP_PRIVCFGR can be read or written in both privileged and unprivileged modes.

  When PRIV bit is set in privileged-only TAMP_PRIVCFGR:

  – Writing the TAMP registers is possible only in privileged mode, except for the backup registers and the monotonic counters that have their own protection setting.

  – Reading the TAMP_SECCFGR or TAMP_PRIVCFGR is always possible in privilege and unprivileged modes. All the other TAMP registers can be read only in

privilege mode, except for the backup registers and the monotonic counters that have their own protection setting.

The application can also:

– make TAMP_COUNT1R register read and write privileged-only by setting the CNTPRIV bit in TAMP_PRIVCFGR

– increase security for two of the three protection zones in backup registers, using BKPRWPRIV and BKPWPRIV bits in TAMP_PRIVCFGR:

– Make protection zone 1 read privileged, write privileged.

– Make protection zone 2 read privileged or unprivileged, write privileged.

– Protection zone 3 is always read and write privileged or unprivileged.

- General-purpose I/Os (GPIO)

  All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

- Extended interrupts and event controller (EXTI)

  The EXTI peripheral is able to protect event register bits from being modified by unprivileged accesses. The protection is individually activated per input event via the register bits in the privileged-only EXTI_PRIVCFGRx registers. When an input event is configured as privileged, only a privileged application can change the configuration (including security if applicable), change the masking or clear the status of this input event.

  The security configuration in EXTI_PRIVCFGR1 and EXTI_PRIVCFGR2 can be globally locked after reset in EXTI_LOCKR.

  See *Section 19: Extended interrupts and event controller (EXTI)* for more details.

- System configuration boot and security (SBS)

  All SBS registers can be read and written in both privileged and unprivileged modes, except:

  – FPUSEC bit in SBS_SECCFGR registers (privileged only)

  – SBS registers for CPU configuration: SBS_CSLCKR, SBS_FPUIMR, SBS_CNSLCKR, SBS_EPOCHSELCR, SBS_ECCNMIR, SBS_ECCNMIR, SBS_SWAPLOCKR and SBS_FBMODER

  See *Section 14: System configuration, boot, and security (SBS)* for more details.

3.6 Secure execution

Through a mix of special software and hardware features, the devices ensure the correct operation of their functions against abnormal situations caused by programmer errors, software attacks through network access or local attempt for tampering code execution.

This section describes the hardware features specifically designed for secure execution.

3.6.1 Memory protection unit (MPU)

The Cortex-M33 includes a memory protection unit (MPU) that can restrict the read and write accesses to Each memory region (including those mapped to peripherals), based on one or more of the following parameters

- Cortex-M33 operating mode (privileged, unprivileged)
- data/instruction fetch

The memory map and the programming of the nonsecure and secure MPU split memory into regions (up to eight for the nonsecure, and up to twelve for the secure). Secure MPU is only available when TrustZone is activated.

3.6.2 Embedded flash memory write protection

The embedded flash memory write protection (WRP) prevents illegal or unwanted write/erase to special sections of the embedded flash memory user area (system area is permanently write protected).

Write protected area is defined through the option bytes.

Write protected areas can be modified using option bytes only until PRODUCT_STATE = Provisioned.

Note: Bank erase is not possible when it contains a write-protected area (WRP or HDP area).

3.6.3 Tamper detection and response

Principle

The devices include active protection of critical security assets against temperature, voltage and frequency attacks, with the following features:

- erasure of device secrets upon tamper detection
- improved guarantee of safe execution for the CPU and its associated security peripherals, including:
  - out-of-range voltage (example: V_{DD}, V_{CORE}, V_{REF+}), temperature and clocking (LSE, HSE) detection
  - security watchdog IWDG clocked by the internal oscillator LSI
  - possible selection of internal oscillator HSI as system clock
- power supply protection
  - RTC/TAMP domain powered with V_{DD}

See *Section 50: Tamper and backup registers (TAMP)* for more details.

Tamper detection sources

The devices support four active input/output pins, allowing two independent active-tamper meshes, or up to two meshes if the same output pin is shared by several input pins (for a total of two active-tamper I/Os).

The active pins are clocked by the LSE, and are functional in different system operating modes (Run, Sleep, Stop, or Standby). Refer to TAMP pins functionality over modes for list of tamper pins and their availability across power modes

Detection time is programmable, and a digital filtering is available (tamper triggered after two false comparisons in four consecutive comparison samples).

Note: Timestamps can be generated when a tamper event occurs.

The internal tamper sources are listed in the table below.

Table 16. Internal tampers in TAMP

Tamper input	NOER bit number in TAMP_CR3	Tamper source
itamp1	0	V_{DD} domain voltage continuous monitoring, functional in Standby mode
itamp2	1	Temperature monitoring, functional in Standby mode
itamp3	2	LSE monitoring(1), functional in Standby mode
itamp4	3	HSE monitoring
itamp5	4	RTC calendar overflow (rtc_calovf)
itamp6	5	JTAG/SWD access
itamp7, 12, 13, 14	6, 11, 12, 15	Voltage monitoring (V_{CORE}, V_{REF+}), through ADC analog watchdog
itamp8	7	Monotonic counter overflow (generated internally)
itamp9	8	Fault generation for cryptographic peripherals (SAES, PKA, AES, RNG)
itamp11	10	IWDG timeout and potential tamper (IWDG reset when at least one enabled tamper flag is set)
itamp15	14	System fault detection

1. LSE missing or over frequency detection (> 2 MHz), Glitch filter (> 2 MHz).

Response to tampers

Each source of tamper in the device can be configured to trigger the following events:

- Generate an interrupt, capable of waking up the device from Stop and Standby modes (see TAMPxMSK bits in TAMP_CR2 register).
- Generate a hardware trigger for the low-power timers.
- Erase device secrets if the corresponding TAMPxPOM bit is cleared in TAMP_CR2 (for tamper pins) or TAMP_CR3 (for internal tamper). These erasable secrets are:
  - symmetric keys stored in backup registers (x32), in AES, HASH, and OTFDEC (encrypted flash memory regions are read as 0)
  - asymmetric keys stored in PKA SRAM, erased when V_{DD} is present
  - other secrets stored in SRAM2 and CPU instruction cache memory (SRAM2 erased when V_{DD} is present)
  - nonvolatile information used to derive the DHUK in SAES is 0-ed until complete SRAM2 erase

Read/write accesses by software to all these secrets can be blocked, by setting the BKBLOCK bit in TAMP_CR2. The device secrets access is possible only when BKBLOCK is cleared, and no tamper flag is set for any enabled tamper source.

If V_{DD} is not present, the secrets that are erased when V_{DD} is present are erased only at the next V_{DD} power on.

Note: Device secret erase is also triggered by setting the BKERASE bit in TAMP_CR2, or by performing a PRODUCT_STATE regression as defined in Section 3.8.1.

Device secrets are not reset by a system reset or when the device wakes up from Standby mode.

Software filtering mechanism

Each tamper source can be configured not to launch an immediate erase, by setting the corresponding TAMPxPOM bit in TAMP_CR2 (for external tamper pin) or TAMP_CR3 (for internal tamper).

In such situation, when the tamper flag is raised, access to below secrets is blocked until all tamper flags are cleared:

- DHUK in SAES: fixed to a dummy value
- Backup registers, SRAM2: read as 0, write-ignored
- AES, SAES, and HASH peripherals: automatically reset by RCC
- PKA peripheral: reset, with memory use blocked (meaning PKA not usable)

Once the application, notified by the tamper event, analyzes the situation, there are two possible cases:

- The application launches secrets erase with a software command (confirmed tamper).
- The application clears the flags to release secrets blocking (false tamper).

Note: If the tamper software fails to react to such a tamper flag, an IWDG reset triggers an automatic erasing of secrets.

Tamper detection and low-power modes

The effect of low-power modes on a tamper detection are summarized in the table below.

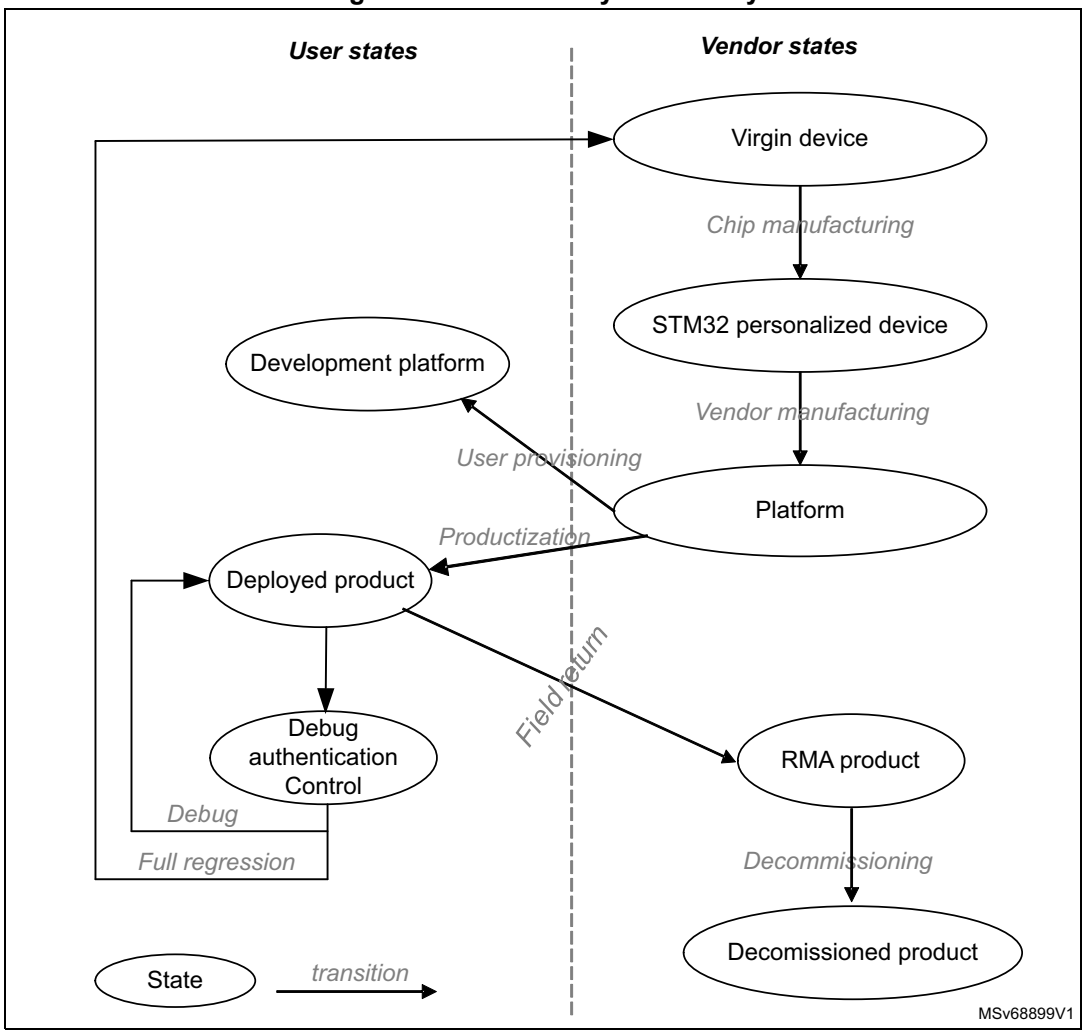
Table 17. Effect of low-power modes on TAMP

Mode	Description
Sleep	No effect on tamper detection features. TAMP interrupts cause the device to exit the Sleep mode.
Stop	No effect on tamper detection features, except for level detection with filtering and active tamper modes that remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Stop mode.
Standby	No effect on tamper detection features, except for level detection with filtering and active tamper modes which remain active only when the clock source is LSE or LSI. Tamper events cause the device to exit the Standby mode.

3.7 Secure storage

A critical feature of security systems is how long-term keys are stored, protected, and provisioned. Such keys are typically used for loading a boot image, or handling of critical user data.

- nonvolatile areas dedicated to secure storage, access controlled based on HDPL, TrustZone with one 8 kilo-bytes area (*Section 7.5: Option-byte key management*)
- Write-only key registers in the AES engines (*Section 34: AES hardware accelerator (AES)*)
- Secure storage on STM32G56x can rely on the SAES engine to encrypt/decrypt the stored data, to benefit of DHUK properties (*Section 34: AES hardware accelerator*



(AES), *Section 14: System configuration, boot, and security (SBS)*). DHUK offers several security properties to protect data:

- Temporal Isolation: data encrypted/decrypted relying on SAES+DHUK benefit of the variation of the DHUK for each different isolated area with HDPL0, HDPL1, HDPL2, HDPL3 (*Section 60: Debug support (DBG)*)
- Runtime Isolation: data encrypted/decrypted relying on SAES+DHUK benefit of the variation of DHUK for each compartment (CID) combined with TrustZone (HNONSEC). (*Section 5: Global TrustZone® controller (GTZC)*)
- DHUK (based on RHUK, which is also based on PUF (Physically Unclonable Function): hardware secret nonvolatile, unique per device keys (allowing anticloning)
- EPOCH counters: 3 counters to increment during regression (allows protection data against rollback)
- Coupling and chaining bridge (CCB) provide secure handling of stored asymmetric keys (*Section 32: Coupling and chaining bridge (CCB)*)

3.8 Product life cycle

A typical IoT device life cycle is summarized in *Figure 9*. For each step, the devices propose secure life cycle management mechanisms embedded in the hardware.

Figure 9. Device life-cycle security

Additional details on the various phases and associated transitions, found either at the vendor or end-user premises, are summarized in the table below.

Table 18. Main product life-cycle transitions

Transitions	Description
Device manufacturing	ST creates new STM32 devices, always checking for manufacturing defects. During this process, the device is provisioned with ROM firmware, and a public ID. STM32G56x provisioning also includes a secure firmware install (SFI) unique key pair, not implemented on STM32G55x/54x/53x.
Vendor manufacturing	One (or more) vendor is responsible for the platform assembly, initialization, and provisioning before delivery to the end user. This end user can use the final product (“productization” transition) or he/she can use the platform for software development (“user provisioning” transition).
Productization	The end user gets a product ready for use. All security functions of the platform are enabled, the debugging/testing features are restricted/disabled, and unique boot entry to immutable code is enforced.

Table 18. Main product life-cycle transitions (continued)

Transitions	Description
User provisioning	Platform vendor prepares an individual platform for development, not to be connected to a production cloud network.
Field return	The product is returned for analysis to field return centers. Analysis is possible by opening it partially, or by launching a partial or a full regression. Such accesses require provisioning, including certificates provided by the vendor. STMicroelectronics does not perform analysis on defective parts in closed or locked states.

The features described hereafter contribute to secure the device life cycle.

3.8.1 Life-cycle management

The product life cycle allows to control access to different assets (code and data) of the product, including during development, manufacturing, and after sales.

It allows to provision the product with different distribution models taking care on the code and data provisioned.

Table 19. Typical product life-cycle phases

PRODUCT_STATE + DebugState		Debug (default configuration)	Comments
Open	Device open	Secure(1) and nonsecure	Allows to develop the product, as it provides the debug of the code. Boot address must target a secure area when TrustZone is enabled. Using the boot pin allows to launch the bootloader. Using boot pin and BOOT_UBE allows to launch user flash code through ST-iROT.
Provisioning	Debug partially opened (only nonsecure)	HDPL3 + nonsecure only	Allows to manage the provisioning of the product (partial or full). It allows to launch secure firmware Install, or bootloader to provision the product. Boot address must target a secure area when TrustZone is enabled. Boot on SRAM is not permitted.
iROT-Provisioned	Debug partially opened (only nonsecure)	HDPL3 + nonsecure only	Assumes that immutable root of trust is installed, including its configuration (code, option bytes, secure storage). Boot address must target a secure area when TrustZone is enabled. Boot on SRAM is not permitted.
TZ-Closed	Debug partially opened (only nonsecure)	HDPL3 + nonsecure only	Assumes that the Secure OS is installed in TrustZone (this state exist only if TZEN = 0xB4). Debug is opened for nonsecure applications
Closed	Debug closed	No debug + debug authentication control	Assumes the product configuration as finalized. It allows to support debug authentication for in-the-field repair (read the dedicated application note).
Locked	Debug locked	None	Assumes the product configuration as finalized. The debug authentication is not permitted. The product is definitively in this state.

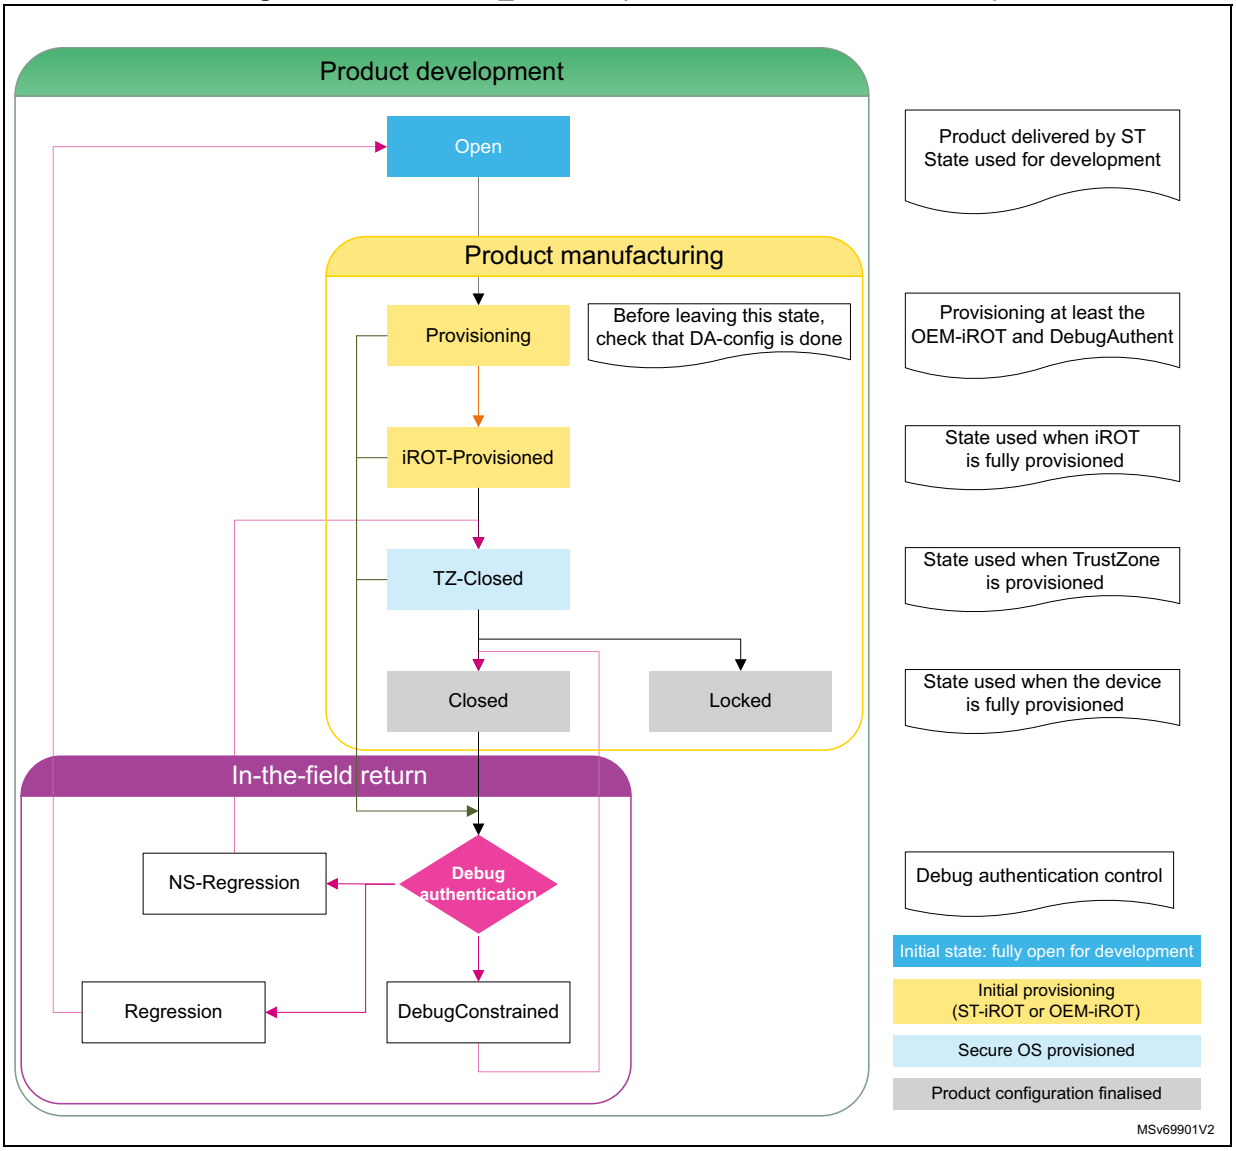


Table 19. Typical product life-cycle phases (continued)

PRODUCT_STATE + DebugState		Debug (default configuration)	Comments
NS-Regression	Debug closed	No debug	This is a temporary (but nonvolatile) state to manage the partial regression to the TZ-Closed, removing all nonsecure code and data including in secure storage.
Regression	Debug closed	No debug	This is a temporary state (but nonvolatile) to manage the full regression to Open state, removing all user flash code and data including in secure storage (HDPL1 to HDPL3).
Debug Constrained	Debug opened following debug authentication permissions	Depends upon permissions	This is a temporary state (until power-on-reset) to manage debug based on the permissions acquired by the debug authentication protocol.

1. Debug is not available when executing RSS code.

The supported transitions, summarized in the figure below, can be requested (when available) through the debug interface or via the system bootloader.

Figure 10. PRODUCT_STATEs (full TrustZone activated view)

The full view of the life cycle includes the debug authentication part, to help product maintenance to manage field returns (in-the-field centers). The debug authentication control is ensured thanks to a protocol based on Arm PSA ADAC specification. It allows controlling that the host has a trusted certificate with permissions. Permissions definition allows a lot of flexibility, in our default model we consider: Full or Partial regression, or to open the debug for nonsecure.

When TrustZone is disabled, the state TZ-Closed cannot be set. For details on the debug authentication feature, refer to the corresponding application note.

The protocol includes a “DISCOVER” command allowing to get basic informations of the target: manufacturer, product name, device identifier, protocol version supported and crypto scheme for authentication (this help selecting between certificates and password).

3.8.2 Recommended product settings

To ease the product maintenance (in-the-field), we recommend to take benefit of the feature called debug authentication control. This enables the maintenance of product activating the debug and makes possible to manage regressions while considering the security of the sensible information.

This implies the following actions:

- set the PRODUCT_STATE in Closed state when the product has been configured
- When debug authentication control is based on certificates, **provision the OEM-PublicKey and the SOC-Mask**. Setting the SOC-Mask to propose only the nonsecure-debug and partial and full regression guarantee to be compliant with the Arm PSA security model.
- When debug authentication control is based on password, only the HASH of the password must be provisioned.

A dedicated application note is available to help configuring the platform, the host tools and to generate certificates.

3.8.3 Software intellectual property protection

As described in *Section 7.6.11: Product state transitions,* the hardware PRODUCT_STATE mechanism controls the accesses to secrets provisioned in the device. The protection of these secrets are defined in the table below.

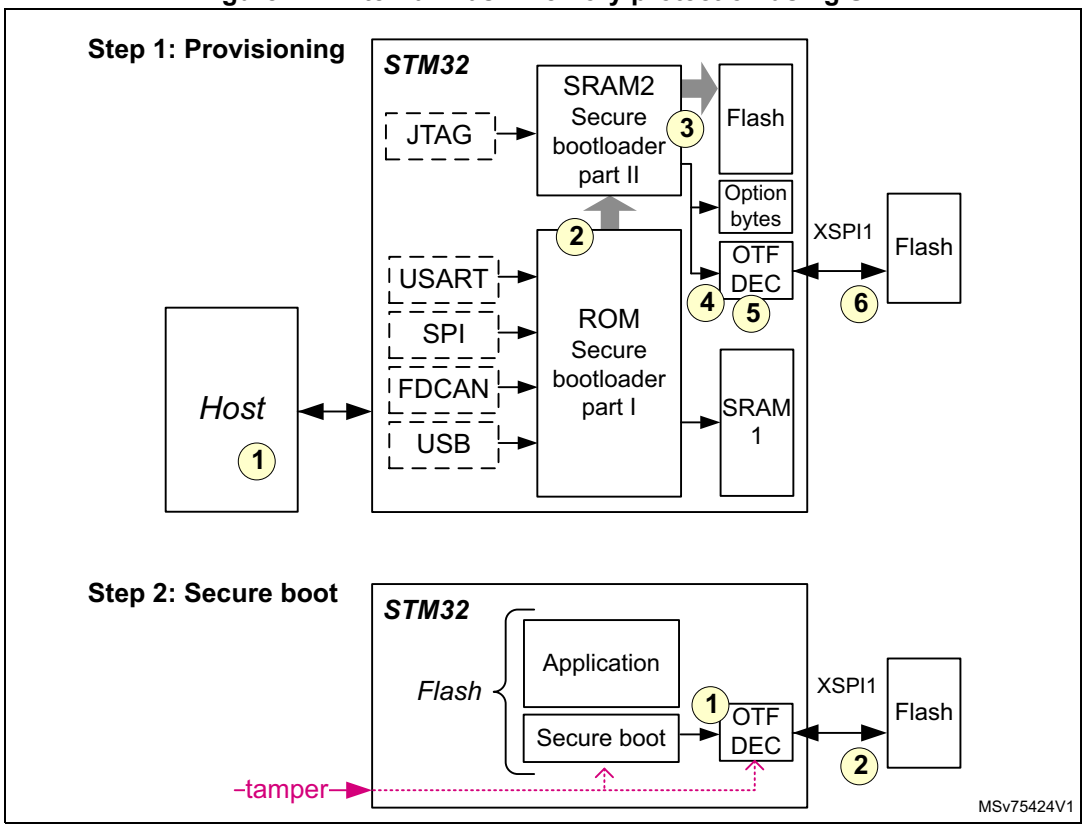
Table 20. Software intellectual property protection with PRODUCT_STAT

PRODUCT_STATE protection level		Secret protection
Open	Device open	No special protections.
Provisioning	Debug partially opened (only nonsecure)	All areas protected with HDPL1 cannot be dumped, debugged or traced. The iROT can setup a higher level of protection.
iROT-Provisioned	Debug partially opened (only nonsecure)	All areas protected with HDPL1 cannot be dumped, debugged or traced. The iROT can setup a higher level of protection.
TZ-Closed	Debug partially opened (only nonsecure)	All peripherals and memories mapped as secure during secure boot cannot be dumped, debugged or traced
Closed	No debug	No debug possible except through debug authentication.
Locked	No debug	All data and code stored in the device or encrypted in external flash memory cannot be dumped clear-text, debugged or traced.

3.8.4 Software intellectual property protection with OTFDEC

The feature described in this section is supported by STM32G56x, not implemented on STM32G55x/54x/53x.

As described in *Section 39: On-the-fly decryption engine (OTFDEC),* the OTFDEC associated with the XSPI1 is able to decrypt on the fly, the encrypted images stored in external SPI flash memories.



Thanks to this feature, the devices allow the installation of intellectual properties in one of the following ways:

- Over the air, with the image already encrypted with a key provisioned in the device
- Through a provisioning host located in a trusted or a non-trusted environment/facility

Figure 11 illustrates this last case, with the provisioning, in a non-trusted environment, of software intellectual properties both in the embedded flash memory and in an external SPI flash memory (encrypted).

Note: Since the OTFDEC uses the AES in counter mode (CTR) to achieve the lowest possible latency, each time the content of one encrypted region is changed, the corresponding cryptographic context (key or initialization vector) must be changed. This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash memory.

Figure 11. External Flash memory protection using SFI

Provisioning

Assuming the device is virgin, the first step is to provision both flash memories, as detailed below:

1. The user creates a SFI image, composed of:
   - encrypted internal firmware and data (including external flash memory drivers)
   - encrypted external firmware and data AES key (up to 4)

  - encrypted external firmware and data image

2. The secure bootloader stored in the system memory, loads the second part of the secure bootloader in SRAM2, through the supported communication ports (USART, SPI, FDCAN, USB, and JTAG). This second part runs in the secure SRAM2 and is responsible for executing the SFI process, applying the SFI protocol thanks to the commands received through the above mentioned supported communication ports.
3. The internal flash memory is programmed with decrypted option bytes, internal firmware and data, and external firmware and data AES keys. Alternatively, device unique external firmware AES keys can be used instead of such global keys.
4. The OTFDEC is properly initialized with encrypted region information, including the corresponding external firmware and data AES key.
5. Running the SFI process, chunks of encrypted external firmware and data image are decrypted in the device, then re-encrypted in the OTFDEC.
6. After a chunk OTFDEC re-encryption, the user external flash memory programmer is responsible for programming the last encrypted chunks to the external SPI flash memories through the XSPI1.

Secure boot

After provisioning, each time the device initializes on a trusted firmware, the following actions are required:

1. Secure-boot firmware executes, programming the external firmware and data AES keys to the OTFDEC write-only key registers, along with the other needed information.
2. The application reads or executes the encrypted external firmware and data through the XSPI1 in memory mapped mode, unless a tamper event is detected. In this case, all OTFDEC keys are erased and encrypted regions are read as 0 until the OTFDEC is properly initialized.

For more information on SFI solutions for the devices, refer to the AN4992 “*STM32 MCUs secure firmware install (SFI) overview”.*

3.8.5 Other software intellectual property protections

The device additional protections to software intellectual property are:

- Invasive attacks such as physical tampering or perturbation are countered by detection then decommissioning of the device before the detected attack succeeds (refer to *Section 50: Tamper and backup registers (TAMP)*).
- Noninvasive attacks, such as side channel attacks, are countered by not leaking secret information via side channels (such as timing, power, and EM radiations) on STM32G56x(refer to *Section 35: Secure AES coprocessor (SAES)* and *Section 32: Coupling and chaining bridge (CCB)*).

4 Boot modes

At startup, a BOOT0 pin and BOOTADD/SBOOTADD option bytes are used to select the boot memory address that includes:

- Boot from any address in user flash memory
- Boot from system memory
  - Bootloader
  - ST immutable root of trust (ST-iROT)
  - Root security service (RSS)
  - Debug authentication library (RSS-DA)

Note: RSS resources are supported by STM32G55x/56x, not implemented on STM32G53x/54x.

Note: ST-iROT resources are supported by STM32G56x, not implemented on STM32G53x/54x/55x.

Embedded bootloader

The embedded bootloader is located in the system memory, programmed by ST during production. It is used to reprogram the flash memory by using USART, SPI, FDCAN, I2C, or USB through the DFU (device firmware upgrade) protocol.

Refer to the application note *STM32 microcontroller system memory boot mode (*AN2606).

Embedded root security services (RSS)

The embedded RSS are located in the secure information block, programmed by ST during production.

Refer to the application note *Overview secure firmware install (SFI) (*AN4992).

Embedded immutable root of trust (ST-iROT)

The embedded ST-iROT in the system memory, is programmed by ST during production. ST-iROT is the immutable root of trust managing the secure boot and secure install of the first updatable level to execute in a boot sequence.

Embedded debug authentication (ST-DA)

The embedded ST-DA in the system memory, is programmed by ST during production. ST-DA is the library that manages the debug authentication protocol by allowing to securely reopen the debug or to launch regressions on secured products in the field.

The tables below provide the detail of the boot mode products when the TrustZone is, respectively, disabled (TZEN = 0xC3) and enabled (TZEN = 0xB4).

Table 21. Boot mode when TrustZone is disabled (TZEN = 0xC3)

PRODUCT_STATE	BOOT0 pin	BOOT_UBE FLASH_OPTSR [29:22]	Boot address option-byte selection	Boot area	ST programmed default value
Open	0	NA	BOOTADD	Boot address defined by user option byte BOOTADD(1)	Flash: 0x0800 0000
	1	NA	NA	Bootloader	Bootloader
Provisioning	x	NA	NA	RSS(1)	RSS
Provisioned, Closed, Locked	x	NA	BOOTADD	Boot address defined by user option byte BOOTADD	Flash: 0x0800 0000

1. Jump to Bootloader can be enforced alternatively by using RSSCMD in SBS.

Table 22. Boot mode when TrustZone is enabled (TZEN = 0xB4) for STM32G53x/54x/55x

PRODUCT_STATE	BOOT0 pin	BOOT_UBE FLASH_OPTSR [29:22]	Boot address option-byte selection	Boot area	ST programmed default value
Open	0	NA	SBOOTADD	Boot address defined by user option byte SBOOTADD	Flash: 0x0C00 0000
	1	NA	NA	Bootloader	Bootloader
Provisioned, Provisioning, TZ_Closed, Closed, Locked	x	NA	SBOOTADD	Boot address defined by user option byte SBOOTADD	Flash: 0x0C00 0000

Table 23. Boot mode when TrustZone is enabled (TZEN = 0xB4) for STM32G56x

PRODUCT_STATE	BOOT0 pin	BOOT_UBE FLASH_OPTSR [29:22]	Boot address option-byte selection	Boot area	ST programmed default value
Open	0	x	SBOOTADD	Boot address defined by user option byte SBOOTADD	Flash: 0x0C00 0000
-	1	0xB4	NA	Bootloader	Bootloader
-	1	0xC3	NA	ST-iROT	ST-iROT
Provisioning	x	NA	NA	RSS	RSS

Table 23. Boot mode when TrustZone is enabled (TZEN = 0xB4) for STM32G56x (continued)

PRODUCT_STATE	BOOT0 pin	BOOT_UBE FLASH_OPTSR [29:22]	Boot address option-byte selection	Boot area	ST programmed default value
Provisioned, TZ_Closed, Closed, Locked	x	0xC3	ST-iROT	ST-iROT	ST-iROT
		0xB4	SBOOTADD	Boot address defined by user option byte SBOOTADD	Flash: 0x0C00 0000

When TrustZone is enabled (TZEN = 0xB4), the boot space must be in secure area. SBOOTADD option bytes are used to select the boot secure memory address. A unique boot entry option can be selected by setting the SBOOT_LOCK option bit.

5 Global TrustZone® controller (GTZC)

5.1 GTZC introduction

The global TrustZone controller (GTZC) block that contains the following subblocks:

- **TZSC**: TrustZone security controller

  Defines the secure/privileged state of slave peripherals, and controls the subregion area size and properties for the watermark memory peripheral controller (MPCWM). The TZSC informs some peripherals (such as RCC or GPIOs) about the secure status of each securable peripheral, by sharing with RCC and I/O logic.
- **MPCBB**: memory protection controller - block based

  Configures the internal RAM in a TrustZone-system product having segmented SRAM (pages of 512 bytes) with programmable-security and privileged attributes.
- **TZIC**: TrustZone illegal access controller

  Gathers all illegal access events in the system, and generates secure interrupts towards NVIC.

These subblocks are used to configure TrustZone system security in a product having bus agents with programmable-security and privileged attributes such as:

- On-chip RAM with programmable secure and/or privileged blocks (pages)
- AHB and APB peripherals with programmable security and/or privileged access
- Off-chip memories with secure and/or privileged areas

5.2 GTZC main features

- Three independent 32-bit AHB interfaces for TZSC, TZIC, and MPCBB
- TZIC accessible only with secure transactions
- Secure and nonsecure access supported for privileged and unprivileged parts of TZSC and MPCBB
- Set of registers to define product security settings:
  - Secure/privileged blocks for internal SRAMs
  - Secure/privileged regions for external memories
  - Secure/privileged access mode for securable peripherals
  - Secure/privileged access mode for securable masters

GTZC TrustZone system architecture

The Armv8-M supports security per TrustZone-M model with isolation between:

- A secure world, where usually security sensitive applications are run and critical resources are located
- A nonsecure or public world (such as the usual non secure operating system and user space)

The TrustZone architecture is extended beyond AHB and Armv8-M with:

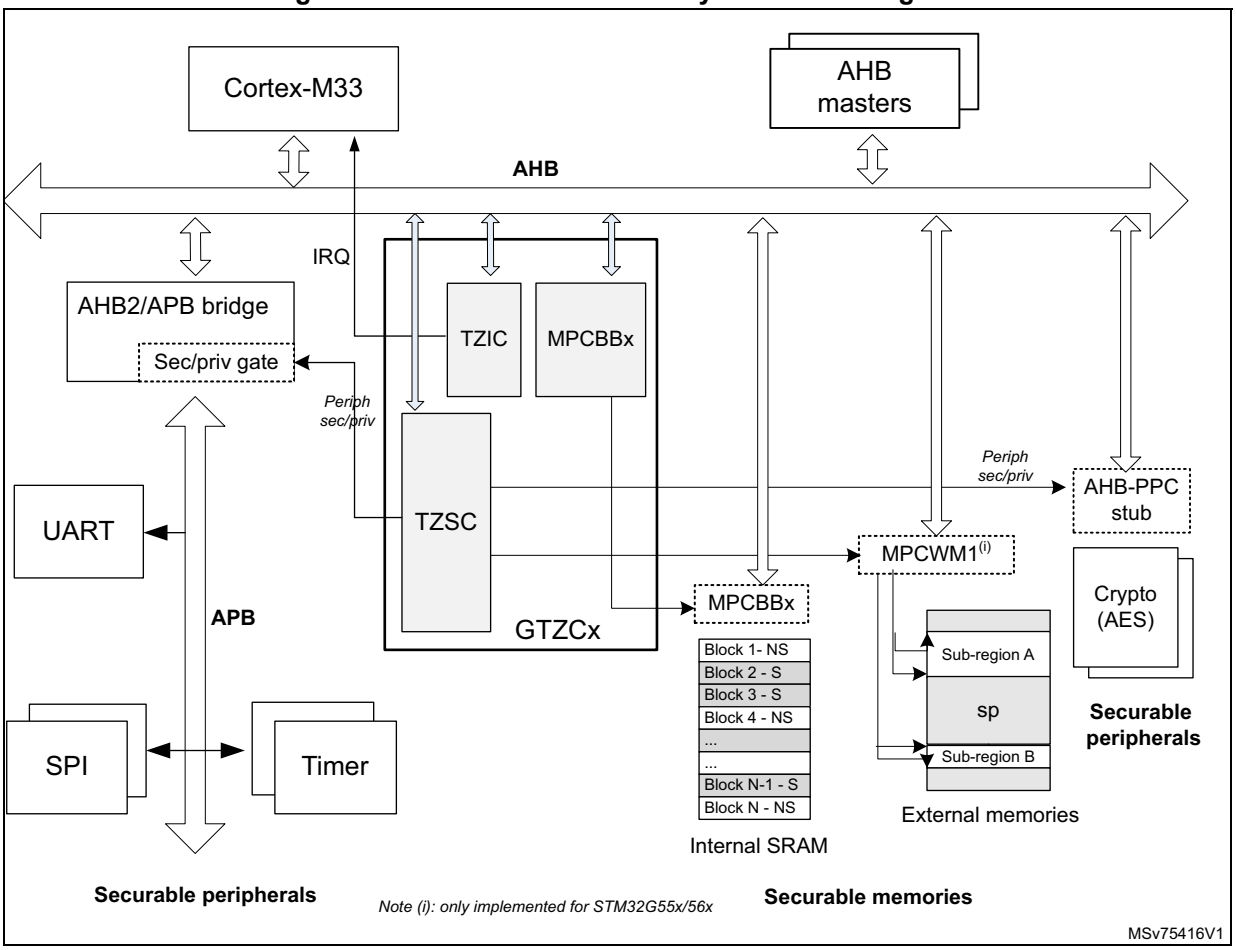
- AHB/APB bridge used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards APB agents

- PPC (peripheral protection controller) used as secure gate to block or propagate secure/nonsecure and privileged/unprivileged transaction towards AHB agents
- TrustZone block-based MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards internal SRAMs
- TrustZone watermark MPC firewalls used as secure gate to filter secure/non secure, privileged/unprivileged access towards external memories

AHB and APB peripherals can be categorized as:

- **privileged**: peripherals protected by AHB/APB firewall stub that is controlled from TZSC to define privilege properties
- **secure**: peripherals always protected by an AHB/APB firewall stub. These peripherals are always secure (such as TZIC)
- **securable**: peripherals protected by an AHB/APB firewall stub that is controlled from TZSC to define security properties (optional)
- **nonsecure and unprivileged:** peripherals connected directly to AHB/APB interconnect without any secure gate
- **TrustZone-aware**: peripherals connected directly to the AHB or APB bus and implementing a specific TrustZone behavior (such as a subset of registers being secure). TrustZone-aware AHB masters always drive HNONSEC signal according to their security mode (such as Armv8-M core or DMA)

AHB securable masters can be configured in the TZSC to be secure/nonsecure and/or privileged/unprivileged.



Application information

The TZSC, MPCBB, and TZIC can be used in one of the following ways:

- Programmed only during secure boot, locked and not changed afterwards
- Dynamically re-programmed when using specific application code or secure kernel (microvisor). When not locked, MPC secure blocks or region size can be changed by secure software executing from the secure FLASH region or secure SRAM. The same applies to the GTZC1_TZSC_SECCFGRx/PRIVCFGRx registers that define secure/privileged state of each peripheral.

The Armv8-M security architecture with secure, securable, and TrustZone-aware peripherals is shown in *Figure 12*.

Figure 12. GTZC in Armv8-M subsystem block diagram

5.3 GTZC implementation

The STM32G56x/55x/54x/53x devices embed one instance of GTZC.

Table 24. GTZC features

GTZC subblocks	GTZC1
GTZC1_TZSC	X
GTZC1_TZIC	X
GTZC1_MPCBBx subblock on STM32G53x/54x devices	MPCBB1/2
GTZC1_MPCBBx subblock on STM32G55x/56x devices	MPCBB1/2/3

The table below shows the address offset of GTZC subblocks versus GTZC base address (refer to *Section 2.3: Memory organization* for GTZC1 base address).

Table 25. GTZC1 subblock address offset

GTZC1 subblock	Address offset
GTZC1_TZSC	0x0
GTZC1_TZIC	0x400
GTZC1_MPCBB1	0x800
GTZC1_MPCBB2	0xC00
GTZC1_MPCBB3	0x1000

The table below describes the characteristics of the available MPCWM.

Table 26. MPCWM resource assignment

GTZC	MPC	Target memory interface	Number of sec/nonsec and priv/unpriv regions	Watermark granularity (bytes)	STM32G53x/54x	STM32G55x/56x
GTZC1	MPCWM1	XSPI1	2	128 K	-	X

The table below describes the characteristics of the available MPCBB.

Table 27. MPCBB resource assignment for STM32G53x/54x

GTZC	MPC	Resource	Memory size (Kbytes)	Block size (bytes)	Number of blocks	Number of super-blocks
GTZC1	MPCBB1	SRAM1	20	512	40	2
	MPCBB2	SRAM2	40		80	3

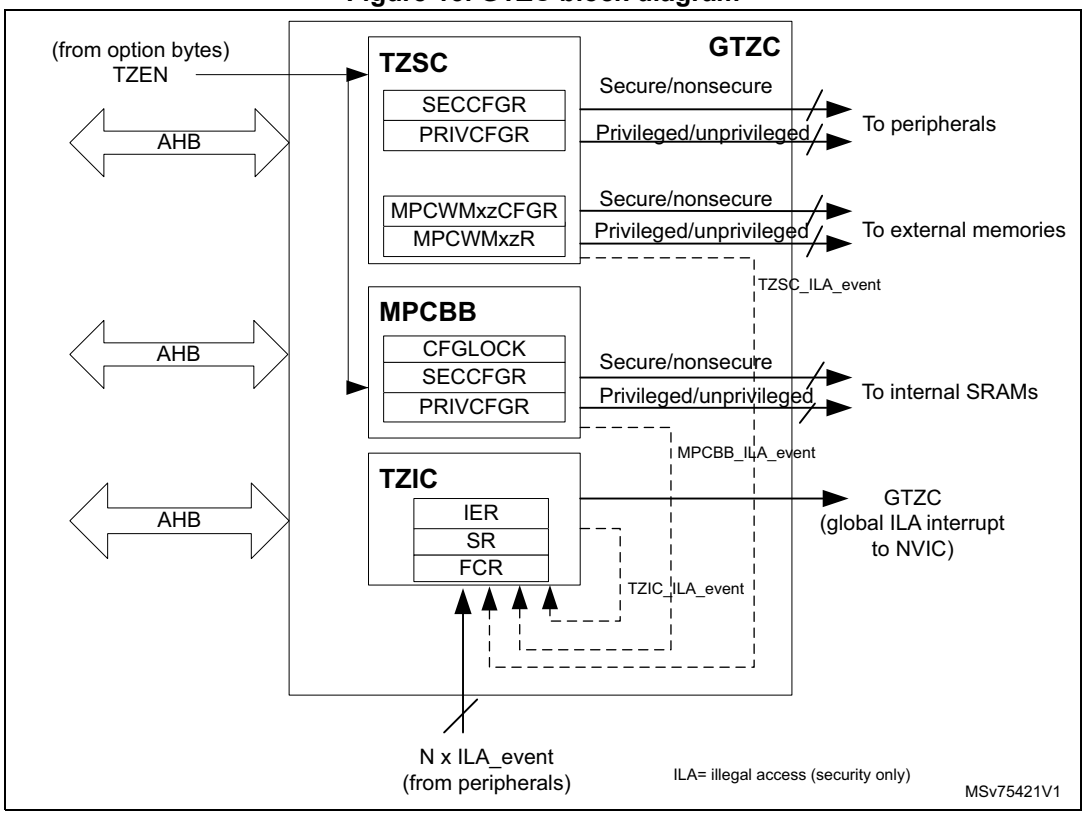
Table 28. MPCBB resource assignment for STM32G55x/56x

GTZC	MPC	Resource	Memory size (Kbytes)	Block size (bytes)	Number of blocks	Number of super-blocks
GTZC1	MPCBB1	SRAM1	32	512	64	4
	MPCBB2	SRAM2	64		128	8
	MPCBB3	SRAM3	16		32	2

5.4 GTZC functional description

5.4.1 GTZC block diagram

Figure 13 describes the combined feature of TZSC, MPCBB, and TZIC. Each subblock is controlled by its own AHB configuration port.



The TZSC defines which peripheral is secure and/or privileged. The privileged configuration bit of a peripheral can be modified by a secure privileged transaction when the peripheral is configured as secure. Otherwise, a privileged transaction (nonsecure) is sufficient.

On the opposite, the secure configuration bit of a peripheral can be modified only with a secure privileged transaction if the peripheral is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The secure configuration bit of a given RAM block can be modified only with a secure privileged transaction if the same block is configured as privileged. Otherwise, a secure transaction (unprivileged) is sufficient.

The TZIC gathers illegal events generated within the system when an illegal access is detected. TZIC can then generate a secure interrupt towards the CPU if needed.

Figure 13. GTZC block diagram

5.4.2 Illegal access definition

Three different types of illegal access exist:

- Illegal nonsecure access

  Any nonsecure transaction trying to write a secure resource is considered as illegal, hence the addressed resource generates an illegal access interrupt for illegal write access and a bus error for illegal fetch access. There are some exceptions on secure and privileged configuration registers: the latter ones authorize non secure read access to secure registers (see GTZC1_TZSC_SECCFGRx/GTZC1_TZSC_PRIVCFGRx).

- Illegal secure access

  Any secure transaction trying to access nonsecure block in internal block-based SRAM or watermarked memory is considered as illegal.

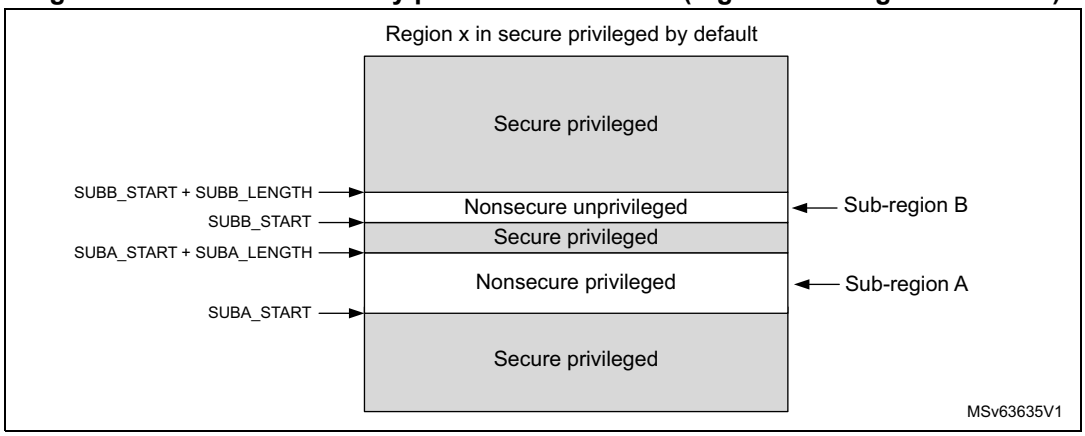
  A correct TZIC setting allows the capture of the associated event and then generates the GTZC_IRQn interrupt to the NVIC. This applies for read, write, and execute access.

  Concerning the MPCBB controller, there is an option to ignore secure data read/write access on nonsecure SRAM blocks, by setting the SRWILADIS bit in the GTZC1_MPCBBz_CR register. Secure read and write data transactions are then allowed on nonsecure SRAM blocks, while secure execution access remains not allowed.

  Any secure execute transaction trying to access a nonsecure peripheral register is considered as illegal and generates a bus error.

- Illegal unprivileged access

  Any unprivileged transaction trying to access a privileged resource is considered as illegal. There is no illegal access event generated for illegal read and write accesses. The addressed resource follows a silent-fail behavior, returning all 0 data for read and ignoring any write. No bus error is generated. A bus error is generated when an unprivileged execute transaction tries to access a privileged memory.



5.4.3 TrustZone security controller (TZSC)

The TZSC is composed of a configurable set of registers, providing the following features:

- Control of secure and privileged state for all peripherals, done through:
  - GTZC1_TZSC_SECCFGRx registers to control AHB/APB firewall stubs for the securable peripherals
  - GTZC1_TZSC_PRIVCFGRx registers to control AHB/APB firewall stubs for the privileged peripherals
- For STM32G55x/56x watermark XSPI memory protection controller, two independent regions can be defined and the following fields are used to program:
  - the start of the first protected subregion on the external memory: SUBA_START[10:0]
  - the length of the first protected subregion on the external memory: SUBA_LENGTH[11:0]
  - the start of the second protected subregion on the external memory: SUBB_START[10:0]
  - the length of the second protected subregion on the external memory: SUBB_LENGTH[11:0]

A control register for each subregion can be used to enable/disable the watermark memory protection controller, and to define the right attributes of each subregion.

Figure 14. Watermark memory protection controller (region x/subregions A and B)

In *Figure 14*, region x represents the external memory. Secure and privileged attributes of subregions A and B are independently configurable. When no subregions are defined or enabled on the region x, the default attribute of the region x is set as secure-privileged.

The following tables describe the secure/privileged properties of the common area of subregions A and B, when an overlap exists.

Table 29. Secure properties of subregions A and B

Subregion A	Subregion B	Properties of overlapped region A and B
nonsecure	nonsecure	nonsecure
nonsecure	Secure	nonsecure
Secure	nonsecure	nonsecure
Secure	Secure	Secure

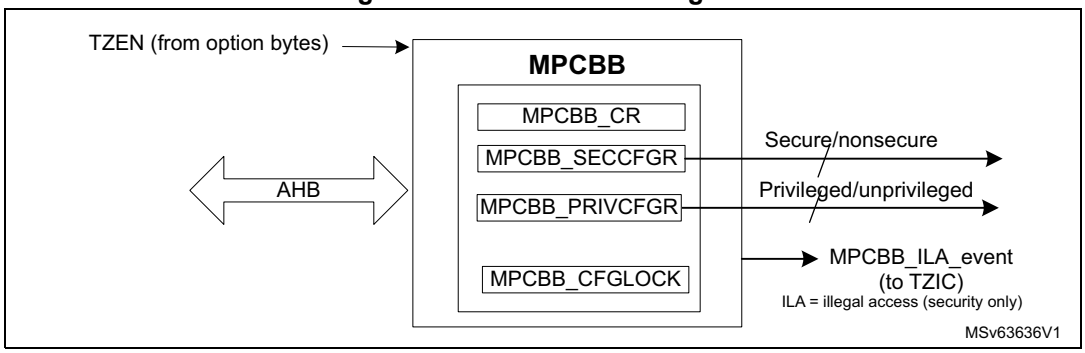


Table 30. Privileged properties of subregions A and B

Subregion A	Subregion B	Properties of overlapped region A and B
Unprivileged	Unprivileged	Unprivileged
Unprivileged	Privileged	Unprivileged
Privileged	Unprivileged	Unprivileged
Privileged	Privileged	Privileged

5.4.4 Memory protection controller - block based (MPCBB)

The MPCBB is composed of a configurable set of registers allowing to define security and privileged policy for internal SRAMs. The security and privileged policy can be individually configured per each 512-byte block.

Figure 15. MPCBB block diagram

To set up the MPCBB, the following actions are needed (for example at boot time):

- Secure firmware must define which memory blocks are secure by setting the correct bits in GTZC1_MPCBBz_SECCFGRx.
- Privileged firmware must define which memory blocks are privileged by setting the correct bits in GTZC1_MPCBBz_PRIVCFGRx.

An MPCBB super-block is made of 32 consecutive blocks. For each super-block, secure application can lock all related security/privileged bits using the correct bits in GTZC1_MPCBBz_CFGLOCK. This lock remains active until the next system reset.

*Note: The block size is 512 bytes. The super-block size is 512 * 32 = 16 Kbytes.*

5.4.5 TrustZone illegal access controller (TZIC)

The TZIC concentrates all illegal access source events. It is used only when the system is TrustZone enabled (TZEN = 0xB4).

TZIC allows to trace (flag) the event that triggered the secure illegal access interrupt. Register masks (GTZC1_TZIC_IERx) are available to filter unwanted event. On unmasked illegal event, TZIC generates the GTZC_IRQn interrupt to the NVIC.

For each illegal event source, a status flag and a clear bit exist (respectively within GTZC1_TZIC_SRx and GTZC1_TZIC_FCRx). The reset value of mask registers (GTZC1_TZIC_IERx) is such that all events are masked.

5.4.6 Power-on/reset state

The power-on and reset state of the TZSC clear to 0 all bits of GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx, meaning that all securable peripherals are respectively set to nonsecure and unprivileged.

For internal SRAMx (x = 1 to 3), all GTZC1_MPCBBz_SECCFGRx and GTZC1_MPCBBz_PRIVCFGRx are set:

- to 0xFFFF FFFF, making these internal memories block secure and privileged by default when TrustZone security is enabled at system level (TZEN = 0xB4).
- to 0x0000 0000, making these internal memories block nonsecure and unprivileged by default when TrustZone security is disabled at system level (TZEN = 0xC3)

For STM32G55x/56x external memory, GTZC1_TZSC_MPCWM1zR registers are set:

- to 0x0000 0000, making these memories secure and privileged by default when TrustZone security is enabled at system level (TZEN = 0xB4).
- to 0x0800 0000, making these memories nonsecure and non-privileged by default when TrustZone security is disabled at system level (TZEN = 0xC3)

Secure boot code can then program the security settings, making components secure or not as needed.

5.5 GTZC interrupts

TZIC is a secure peripheral, thus it systematically generates an illegal access event when accessed by a nonsecure access. The MPCBB and TZSC are TrustZone-aware peripherals, meaning that secure and nonsecure registers coexist within the peripheral.

Table 31. GTZC interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
GTZC	Illegal access	All flags in GTZC1_TZIC_SRx	All bits in GTZC1_TZIC_IERx	Write 1 in the bit GTZC1_TZIC_FCRx	Yes	Yes	No

5.6 GTZC1 TZSC registers

All registers are accessed only by words (32-bit).

5.6.1 GTZC1 TZSC control register (GTZC1_TZSC_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LCK**: lock the configuration of GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx until next reset

This bit is cleared by default, and once set, it cannot be reset until system reset.

0: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx not locked

1: configuration of all GTZC1_TZSC_SECCFGRx and GTZC1_TZSC_PRIVCFGRx locked

5.6.2 GTZC1 TZSC secure configuration register 1 (GTZC1_TZSC_SECCFGR1)

Address offset: 0x010

Reset value: 0x0000 0000

Write-secure access only.

This register can be written only by secure privileged transaction when the corresponding GTZC1_TZSC_PRIVCFGR signal is set to 1. If a given PRIV bit is not set, the equivalent SEC bit can be written by secure unprivileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.5 GTZC1 TZSC privilege configuration register 1 (GTZC1_TZSC_PRIVCFGR1)

Address offset: 0x020

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when the corresponding GTZC1_TZSC_SECCFGR signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by nonsecure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.6 GTZC1 TZSC privilege configuration register 2 (GTZC1_TZSC_PRIVCFGR2)

Address offset: 0x024

Reset value: 0x0000 0000

Write-privileged access only.

This register can be read or written only by secure privileged transaction when the corresponding GTZC1_TZSC_SECCFGR signal is set to1. If a given SEC bit is not set, the equivalent PRIV bit can be read/written by nonsecure privileged transaction.

Read accesses are authorized for any type of transactions, secure or not, privileged or not.

5.6.8 GTZC1 TZSC memory x subregion z watermark configuration register (GTZC1_TZSC_MPCWM1zCFGR) (z = A to B)

Address offset: Block A: 0x40

Address offset: Block B: 0x48

Reset value: 0x0000 0000

Secure privilege access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	PRIV	SEC	Res.	Res.	Res.	Res.	Res.	Res.	SRLOCK	SREN
						rw	rw							rs	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **PRIV**: Privileged subregion z of base region
This bit is taken into account only if SREN is set.
0: Privileged and unprivileged accesses are granted in subregion z.
1: Only privileged accesses are granted in subregion z.

Bit 8 **SEC**: Secure subregion z of base region
This bit is taken into account only if SREN is set.
0: Only nonsecure data accesses are granted to subregion z.
1: Only secure data accesses are granted to subregion z.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **SRLOCK**: subregion z lock
This bit, once set, can be cleared only by a system reset.
0: GTZC1_TZSC_MPCWM1CFGR, GTZC1_TZSC_MPCWM1AR and GTZC1_TZSC_MPCWM1BR can be written.
1: Writes to GTZC1_TZSC_MPCWM1CFGR, GTZC1_TZSC_MPCWM1AR and GTZC1_TZSC_MPCWM1BR are ignored.

Bit 0 **SREN**: subregion z enable

0: subregion z is disabled. Access control of base region applies to any access between this subregion start- and end-addresses.

1: subregion z is enabled. Access control defined in GTZC1_TZSC_MPCWM1_CFGR applies to any access between this subregion start- and end-addresses, defined in GTZC1_TZSC_MPCWM1AR and GTZC1_TZSC_MPCWM1BR.

Note: Watermark controlled external memories start fully nonsecure/unprivileged at reset when TZEN = 0xC3. When TZEN = 0xB4, they start fully secure/fully privileged (inverted reset-value).

5.6.9 GTZC1 TZSC subregion A watermark register (GTZC1_TZSC_MPCWM1AR)

Address offset: 0x44

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0800 0000 when TZEN = 0xC3.

Secure privilege access only.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically.

When an overlap of subregion A and B exists, secure/privileged attributes of both subregions apply on the common section (see *Section 5.4.3*)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	SUBA_LENGTH[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SUBA_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBA_LENGTH[11:0]**: Length of subregion A in base region

This field defines the length of the subregion A, to be multiplied by the granularity defined in *Table 26*.

When SUBA_START + SUBA_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBA_LENGTH is applied automatically. If SUBA_LENGTH = 0, subregion A is disabled (SREN bit in GTZC1_TZSC_MPCMW1ACFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBA_START[10:0]**: Start of subregion A in base region

This field defines the address offset of the subregion A, to be multiplied by the granularity defined in *Table 26*, versus the start of the region.

Watermark controlled external memories start fully nonsecure at reset when TZEN = 0xC3. When TZEN = 0xB4, they start fully secure (inverted reset value).

5.6.10 GTZC1 TZSC subregion B watermark register (GTZC1_TZSC_MPCWM1BR)

Address offset: 0x4C

Reset value: 0x0000 0000

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0800 0000 when TZEN = 0xC3.

Secure privilege access only.

When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.

When an overlap of subregion A and B exists, secure/privileged attributes of both subregions apply on the common section (see *Section 5.4.3*)

Res.	Res.	Res.	Res.	Res.	SUBB_START[10:0]										
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **SUBB_LENGTH[11:0]**: Length of subregion B in base region

This field defines the length of the subregion B, to be multiplied by the granularity defined in *Table 26*.

When SUBB_START + SUBB_LENGTH is higher than the maximum size allowed for the memory, a saturation of SUBB_LENGTH is applied automatically.

If SUBB_LENGTH = 0, the subregion B is disabled (SREN bit in GTZC1_TZSC_MPCMW1BCFGR is cleared).

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:0 **SUBB_START[10:0]**: Start of subregion B in base region

This field defines the address offset of the subregion B, to be multiplied by the granularity defined in *Table 26*, versus the start of the region x.

Watermark controlled external memories start fully nonsecure at reset when TZEN = 0xC3. When TZEN = 0xB4, they start fully secure (inverted reset value).

Refer to *Table 25: GTZC1 subblock address offset*.

5.7 GTZC1 TZIC registers

All registers are accessed only by words (32-bit).

5.7.1 GTZC1 TZIC interrupt enable register 1 (GTZC1_TZIC_IER1)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **DTSIE**: illegal access interrupt enable for DTS
0: interrupt disabled
1: interrupt enabled

Bit 29 Reserved, must be kept at reset value.

Bit 28 **TIM11IE**: illegal access interrupt enable for TIM11
0: interrupt disabled
1: interrupt enabled

Bit 27 **TIM10IE**: illegal access interrupt enable for TIM10
0: interrupt disabled
1: interrupt enabled

Bit 26 **TIM9IE**: illegal access interrupt enable for TIM9
0: interrupt disabled
1: interrupt enabled

Bit 25 **DAC2IE**: illegal access interrupt enable for DAC2
0: interrupt disabled
1: interrupt enabled

Bit 24 **DAC1IE**: illegal access interrupt enable for DAC1
0: interrupt disabled
1: interrupt enabled

Bit 23 Reserved, must be kept at reset value.

Bit 22 Reserved, must be kept at reset value.

Bit 21 **UART6IE**: illegal access interrupt enable for UART6
0: interrupt disabled
1: interrupt enabled

Bit 20 **CRSIE**: illegal access interrupt enable for CRS
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 19 **I3C1IE**: illegal access interrupt enable for I3C1
0: interrupt disabled
1: interrupt enabled

Bit 18 **I2C2IE**: illegal access interrupt enable for I2C2
0: interrupt disabled
1: interrupt enabled

Bit 17 **I2C1IE**: illegal access interrupt enable for I2C1
0: interrupt disabled
1: interrupt enabled

Bit 16 **UART5IE**: illegal access interrupt enable for UART5
0: interrupt disabled
1: interrupt enabled

Bit 15 **UART4IE**: illegal access interrupt enable for UART4
0: interrupt disabled
1: interrupt enabled

Bit 14 **USART3IE**: illegal access interrupt enable for USART3
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 13 **USART2IE**: illegal access interrupt enable for USART2
0: interrupt disabled
1: interrupt enabled

Bit 12 **SPI3IE**: illegal access interrupt enable for SPI3
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 11 **SPI2IE**: illegal access interrupt enable for SPI2
0: interrupt disabled
1: interrupt enabled

Bit 10 **IWDGIE**: illegal access interrupt enable for IWDG
0: interrupt disabled
1: interrupt enabled

Bit 9 **WWDGIE**: illegal access interrupt enable for WWDG
0: interrupt disabled
1: interrupt enabled

Bit 8 **TIM14IE**: illegal access interrupt enable for TIM14
0: interrupt disabled
1: interrupt enabled

Bit 7 **TIM13IE**: illegal access interrupt enable for TIM13
0: interrupt disabled
1: interrupt enabled

Bit 6 **TIM12IE**: illegal access interrupt enable for TIM12
0: interrupt disabled
1: interrupt enabled

Bit 5 **TIM7IE**: illegal access interrupt enable for TIM7
0: interrupt disabled
1: interrupt enabled

Bit 4 **TIM6IE**: illegal access interrupt enable for TIM6
0: interrupt disabled
1: interrupt enabled

Bit 3 **TIM5IE**: illegal access interrupt enable for TIM5
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 2 **TIM4IE**: illegal access interrupt enable for TIM4
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 1 **TIM3IE**: illegal access interrupt enable for TIM3
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 0 **TIM2IE**: illegal access interrupt enable for TIM2
0: interrupt disabled
1: interrupt enabled

5.7.2 GTZC1 TZIC interrupt enable register 2 (GTZC1_TZIC_IER2)

Address offset: 0x004

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 18 **HRTIM1IE**: illegal access interrupt enable for HRTIM1
0: interrupt disabled
1: interrupt enabled

Bits 17:15 Reserved, must be kept at reset value.

Bit 14 **TIM17IE**: illegal access interrupt enable for TIM17
0: interrupt disabled
1: interrupt enabled

Bit 13 **TIM16IE**: illegal access interrupt enable for TIM16
0: interrupt disabled
1: interrupt enabled

Bit 12 **TIM15IE**: illegal access interrupt enable for TIM15
0: interrupt disabled
1: interrupt enabled

Bit 11 **USART1IE**: illegal access interrupt enable for USART1
0: interrupt disabled
1: interrupt enabled

Bit 10 **TIM8IE**: illegal access interrupt enable for TIM8
0: interrupt disabled
1: interrupt enabled

Bit 9 **SPI1IE**: illegal access interrupt enable for SPI1
0: interrupt disabled
1: interrupt enabled

Bit 8 **TIM1IE**: illegal access interrupt enable for TIM1
0: interrupt disabled
1: interrupt enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **UCPD1IE**: illegal access interrupt enable for UCPD1
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 2 **FDCAN3IE**: illegal access interrupt enable for FDCAN3
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 1 **FDCAN2IE**: illegal access interrupt enable for FDCAN2
0: interrupt disabled
1: interrupt enabled
Note: depending on device

Bit 0 **FDCAN1IE**: illegal access interrupt enable for FDCAN1 and FDCAN message RAM
0: interrupt disabled
1: interrupt enabled

5.7.3 GTZC1 TZIC interrupt enable register 3 (GTZC1_TZIC_IER3)

Address offset: 0x008

Reset value: 0x0000 0000

Secure privileged access only.

This register is used to enable interrupt of illegal access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1: status flag cleared

Bit 5 Reserved, must be kept at reset value.

Bit 4 **OTFDEC1CF:** clear the illegal access flag for OTFDEC1
0: no action
1: status flag cleared
Note: depending on device

Bit 3 **FLASH_REGCF:** clear the illegal access flag for FLASH memory
0: no action
1: status flag cleared

Bit 2 **FLASHCF:** clear the illegal access flag for FLASH registers
0: no action
1: status flag cleared

Bit 1 **GPDMA2CF:** clear the illegal access flag for GPDMA2
0: no action
1: status flag cleared

Bit 0 **GPDMA1CF:** clear the illegal access flag for GPDMA1
0: no action
1: status flag cleared

5.7.13 GTZC1 TZIC register map

Table 33. GTZC1 TZIC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Table 25: GTZC1 subblock address offset*.

5.8 GTZC1 MPCBBz registers (z = 1 to 3)

All registers are accessed only by words (32-bit).

5.8.1 GTZC1 SRAMz MPCBB control register (GTZC1_MPCBBz_CR) (z = 1 to 3)

Address offset: 0x000

Reset value: 0x0000 0000

Secure privileged access only.

															rs

Bit 31 **SRWILADIS**: secure read/write illegal access disable

This bit disables the detection of an illegal access when a secure read/write transaction access a nonsecure blocks of the block-based SRAM (secure fetch on nonsecure block is always considered illegal).

0: enabled, secure read/write access not allowed on nonsecure SRAM block

1: disabled, secure read/write access allowed on nonsecure SRAM block

Bit 30 **INVSECSTATE**: SRAMx clocks security state

This bit is used to define the internal SRAMs clocks control in RCC as secure or not.

0: SRAMs clocks are secure if a secure area exists in the MPCBB. It is non secure if there is no secure area.

1: SRAMs clocks are nonsecure even if a secure area exists in the MPCBB, and secure even if no secure block is set in the MPCBB.

Bits 29:1 Reserved, must be kept at reset value.

Bit 0 **GLOCK**: lock the control register of the MPCBB until next reset

This bit is cleared by default, and once set, it cannot be reset until system reset.

0: control register not locked

1: control register locked

5.8.2 GTZC1 SRAMz MPCBB configuration lock register 1 (GTZC1_MPCBBz_CFGLOCK1) (z = 1 to 3)

Address offset: 0x010

Reset value: 0x0000 0000

Secure privileged access only.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **SPLCKy**: Security/privilege configuration lock for super-block (y = 31 to 0)
This bit is set by software and can be cleared only by system reset.
0: GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy can be written.
1: Writes to GTZC1_MPCBBz_SECCFGRy and GTZC1_MPCBBz_PRIVCFGRy are ignored

5.8.3 GTZC1 SRAMz MPCBB security configuration for super-block x register (GTZC1_MPCBBz_SECCFGRx) (z = 1 to 3)

Address offset: 0x100 + 0x4 * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0000 0000 when TZEN = 0xC3.

Write access to this register is secure only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SECy**: Security configuration for block y (y = 31 to 0)
0: nonsecure access only to block y, belonging to super-block x. Secure access is also allowed if the SRWILADIS bit is set in GTZC1_MPCBBz_CR.
1: Secure access only to block y, belonging to super-block x.
Unprivileged write to this bit is ignored if PRIVy bit is set in GTZC1_MPCBBz_PRIVCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCK.

5.8.4 GTZC1 SRAMz MPCBB privileged configuration for super-block x register (GTZC1_MPCBBz_PRIVCFGRx) (z = 1 to 3)

Address offset: 0x200 + 0x4 * x, (x = 0 to 31)

Reset value: 0xFFFF FFFF

The given reset value is valid when TZEN = 0xB4. The reset value is 0x0000 0000 when TZEN = 0xC3. Write access to this register is privileged only. Any read is allowed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIVy**: Privileged configuration for block y, belonging to super-block x (y = 31 to 0).
0: Privileged and unprivileged access to block y, belonging to super-block x
1: Only privileged access to block y, belonging to super-block x
nonsecure write to this bit is ignored if SECy bit is set in GTZC1_MPCBBz_SECCFGRx.
Writes are ignored if SPLCKx bit is set in GTZC1_MPCBBz_CFGLOCK.

5.8.5 GTZC1 MPCBBz register map (z = 1 to 3)

Refer to *Table 25: GTZC1 subblock address offset*.

6 RAMs configuration controller (RAMCFG)

6.1 Introduction

The RAMCFG configures the features of the internal SRAMs (SRAM1, SRAM2 and SRAM3).

Note: SRAM3 resource is supported by STM32G55x/56x, not implemented on STM32G53x/54x

6.2 RAMCFG main features

The internal SRAM supports some of the features listed hereafter, configured in RAMCFG:

- Error code correction (ECC):
  - Single error detection and correction with interrupt generation
  - Double error detection with interrupt or NMI generation
  - Status with failing address
- Write protection (1-Kbyte granularity)
- SRAM software erase

6.3 RAMCFG functional description

6.3.1 Internal SRAMs features

Five SRAMs are embedded in the devices, each with specific features:

- SRAM1, SRAM2, SRAM3 are the main SRAMs, made of several blocks that can be powered down in Stop mode to reduce consumption.
- Block partitioning for STM32G53x/54x:
  - SRAM1: 16-Kbyte + 4-Kbyte blocks (total 20Kbytes)
  - SRAM2: Two 16-Kbyte blocks + 8-Kbyte (total 40Kbytes)
- Block partitioning for STM32G55x/56x:
  - SRAM1: one 32-Kbyte block
  - SRAM2: 16-Kbyte + 48-Kbyte blocks (total 64Kbytes)
  - SRAM3: one 16-Kbyte block
- SRAM2 is erased when a system reset occurs if the SRAM2_RST option bit is selected in the flash memory user option bytes. SRAM1 and SRAM3 are erased when a system reset occurs if the SRAM13_RST option bit is selected in the flash memory user option bytes. Refer to *Section 7: Embedded flash memory (FLASH)* for more details.
- SRAM1 and SRAM2 are protected by the tamper detection circuit, and are erased by hardware in case of tamper detection. Refer to *Section 50: Tamper and backup registers (TAMP)* for more details.
- The RAMCFG embeds the registers related to the internal SRAMs ECC, write protection and software erase.

Table 35 summarizes the features supported by each internal SRAM.

Table 35. Internal SRAMs features

SRAM feature	SRAM1	SRAM2	SRAM3
Size for STM32G53x/54x (Kbytes)	20	40	-
Size for STM32G55x/56x (Kbytes)	32	64	16
Optional retention in Standby mode	-	-	-
Erased with tamp.er detection and backup domain reset	X	X	-
Optionally erased with system reset	X	X	X
Software erase	X	X	X
ECC	X	X	X
Write protection	X	X	-

6.3.2 Error code correction (SRAM1, SRAM2, SRAM3)

The ECC is supported by SRAM1, SRAM2 and SRAM3 when enabled with the SRAM1_ECC, SRAM2_ECC, SRAM3_ECC user option bits. Refer to*Section 7: Embedded flash memory (FLASH)* for more details.

Seven ECC bits are added per 32 bits of SRAM, allowing two bits error detection and one bit error correction on memory read access.

As the ECC is calculated and checked for a 32-bit word, the byte and half-word write accesses are managed by the SRAM interface by first reading the whole word, then write the word again with the new byte/half-word value. ECC double errors are also detected during these byte or half-word AHB write accesses (read/modify/write done by interface). The byte or half-word write access latency is two AHB clock cycles.

Caution: In case of a byte or half-word write on SRAM with ECC, the read/modify/write operation is done in a buffer. The buffer content is written into the SRAM two AHB clock cycles after the SRAM AHB is released (when SRAM is no more accessed).

Single and double ECC errors

When a single error is detected, it is automatically corrected and the SEDC/CSEDC bits are set, respectively, in RAMCFG_MxISR/RAMCFG_MxICR. An interrupt is generated if enabled by the SEIE bit in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxSEAR if the ALE bit is set in RAMCFG_MxCR.

Caution: Single errors cannot be detected when the SEDC bit is set.

When a double error is detected, the DED and CDED bits are set in RAMCFG_MxISR and RAMCFG_MxICR respectively. An interrupt or NMI is generated if enabled by the DEIE or ECCNMI bit in RAMCFG_MxIER. The failing address is stored in RAMCFG_MxDEAR if the ALE bit is set in RAMCFG_MxCR.

Caution: Double errors cannot be detected when the DED bit is set.

When ECC is enabled by user option bits, the ECCE bit is automatically set after system reset in related RAMCFG_MxCR.

The ECC can be deactivated by executing the following software sequence:

1. Write 0xAE in RAMCFG_MxECCKEYR.
2. Write 0x75 in RAMCFG_MxECCKEYR.
3. Write 0 in RAMCFG_MxCR.

6.3.3 Write protection

The SRAM1 and SRAM2 is made of 1-Kbyte pages, each of them can be write-protected by setting its corresponding PyWP bit (0<y<max. page number) in RAMCFG_MxWPR1 and RAMCFG_MxWPR2 (x = 1, 2).

6.3.4 Software erase

SRAM erase can be requested by executing this software sequence:

1. Write 0xCA in RAMCFG_MxERKEYR.
2. Write 0x53 in RAMCFG_MxERKEYR.
3. Write 1 in RAMCFG_MxCR.

SRAMBUSY flag is set in the related SRAM interrupt status register as long as the erase is ongoing.

The total duration of each SRAM erase is N AHB clock cycles, where N is the size of the SRAM in 32-bit words.

If the SRAM is read or written while an erase is ongoing, accesses on the AHB bus are RAZ/WI until the end of the operation.

6.4 RAMCFG low-power modes

Table 36. Effect of low-power modes on RAMCFG

Mode	Description
Sleep	No effect. RAMCFG interrupts cause the device to exit the Sleep mode
Stop	The content of RAMCFG registers is kept
Standby	The RAMCFG is powered down and must be reinitialized after exiting Standby mode.

6.5 RAMCFG interrupts

Table 37. RAMCFG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit(s)	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby modes
RAMCFG	ECC single error detection and correction	SEDC	SEIE	Write 1 in CSEDC	Yes	No	No
	ECC double error detection	DED	DEIE = 1 and ECCNMI = 0	Write 1 in CDED	Yes	No	No
NMI	ECC double error detection	DED	ECCNMI	Write 1 in CDED	Yes	No	No

6.6 RAMCFG registers

In the registers described below, x refers to:

- SRAM1/2/3 when x = 1/2/3, respectively for STM32G55x/56x
- SRAM1/2 when x = 1/2, respectively for STM32G53x/54x

6.6.1 RAMCFG memory x control register (RAMCFG_MxCR)

Address offset: 0x00 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 000X

ECCE reset value depends on ECC enable user option bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMER	Res.	Res.	Res.	ALE	Res.	Res.	Res.	ECCE
							rs				rw				rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMER**: SRAM erase

This bit can be set by software only after writing the unlock sequence in the ERASEKEY field of the RAMCFG_MxERKEYR register. Setting this bit starts the SRAM erase. This bit is automatically cleared by hardware at the end of the erase operation.

0: No erase operation on going

1: Erase operation on going

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ALE**: Address latch enable

0: Failing address not stored in the SRAMx ECC single/double error address registers

1: Failing address stored in the SRAMx ECC single/double error address registers

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **ECCE**: ECC enable.
This bit reset value is defined by the user option bit configuration. When set, it can be cleared by software only after writing the unlock sequence in the RAMCFG_MxECCKEYR register.
0: ECC disabled
1: ECC enabled

6.6.2 RAMCFG memory x interrupt enable register (RAMCFG_MxIER)

Address offset: 0x004 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCNMI	Res.	DEIE	SEIE
												rs		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ECCNMI**: Double error NMI
This bit is set by software and cleared only by a global RAMCFG reset.
0: NMI not generated in case of ECC double error
1: NMI generated in case of ECC double error
Note: if ECCNMI is set, the RAMCFG maskable interrupt is not generated whatever DEIE bit value.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **DEIE**: ECC double error interrupt enable
0: Double error interrupt disabled
1: Double error interrupt enabled

Bit 0 **SEIE**: ECC single error interrupt enable
0: Single error interrupt disabled
1: Single error interrupt enabled

6.6.3 RAMCFG memory interrupt status register (RAMCFG_MxISR)

Address offset: 0x008 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	SRAMBUSY	Res.	Res.	Res.	Res.	Res.	Res.	DED	SEDC
							r							r	r

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **SRAMBUSY**: SRAM busy with erase operation

0: No erase operation on going

1: Erase operation on going

Note: Depending on the SRAM, the erase operation can be performed due to software request, system reset if the option bit is enabled, tamper detection or readout protection regression. Refer to Table 35.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DED**: ECC double error detected

0: No double error

1: Double error detected

Bit 0 **SEDC**: ECC single error detected and corrected

0: No single error

1: Single error detected and corrected

6.6.4 RAMCFG memory x ECC single error address register (RAMCFG_MxSEAR)

Address offset: 0x00C + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ESEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **ESEA[31:0]**: ECC single error address

When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC single error.

6.6.5 RAMCFG memory x ECC double error address register (RAMCFG_MxDEAR)

Address offset: 0x010 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EDEA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **EDEA[31:0]**: ECC double error address

When the ALE bit is set in the RAMCFG_MxCR register, this field is updated with the address corresponding to the ECC double error.

6.6.6 RAMCFG memory x interrupt clear register x (RAMCFG_MxICR)

Address offset: 0x014 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CDED	CSEDC
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **CDED**: Clear ECC double error detected

Writing 1 to this flag clears the DED bit in the RAMCFG_MxISR register. Reading this flag returns the DED value.

Bit 0 **CSEDC**: Clear ECC single error detected and corrected

Writing 1 to this flag clears the SEDC bit in the RAMCFG_MxISR register. Reading this flag returns the SEDC value.

6.6.7 RAMCFG memory 2 write protection register 1 (RAMCFG_MxWPR1)

Address offset: 0x018 + 0x040 * (x - 1), (x = 1 to 2)

Reset value: 0x0000 0000

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 31 to 0)

These bits are set by software and cleared only by a global RAMCFG reset.

0: Write protection of SRAMx 1-Kbyte page y is disabled.

1: Write protection of SRAMx 1-Kbyte page y is enabled.

6.6.8 RAMCFG memory 2 write protection register 2 (RAMCFG_M2WPR2)

Address offset: 0x05C

Reset value: 0x0000 0000

Bits 31:0 **PyWP**: SRAM2 1-Kbyte page y write protection (y = 63 to 32)
These bits are set by software and cleared only by a global RAMCFG reset.
0: Write protection of SRAM2 1-Kbyte page y is disabled.
1: Write protection of SRAM2 1-Kbyte page y is enabled.

6.6.9 RAMCFG memory x ECC key register (RAMCFG_MxECCKEYR)

Address offset: 0x024 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ECCKEY[7:0]**: ECC write protection key
The following steps are required to unlock the write protection of the ECCE bit in the RAMCFG_MxCR register.
1) Write 0xAE into ECCKEY[7:0].
2) Write 0x75 into ECCKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

6.6.10 RAMCFG memory x erase key register (RAMCFG_MxERKEYR)

Address offset: 0x028 + 0x040 * (x - 1), (x = 1 to 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ERASEKEY[7:0]							
								w	w	w	w	w	w	w	w

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **ERASEKEY[7:0]**: Erase write protection key

The following steps are required to unlock the write protection of the SRAMER bit in the RAMCFG_MxCR register.

1) Write 0xCA into ERASEKEY[7:0].

2) Write 0x53 into ERASEKEY[7:0].

Note: Writing a wrong key reactivates the write protection.

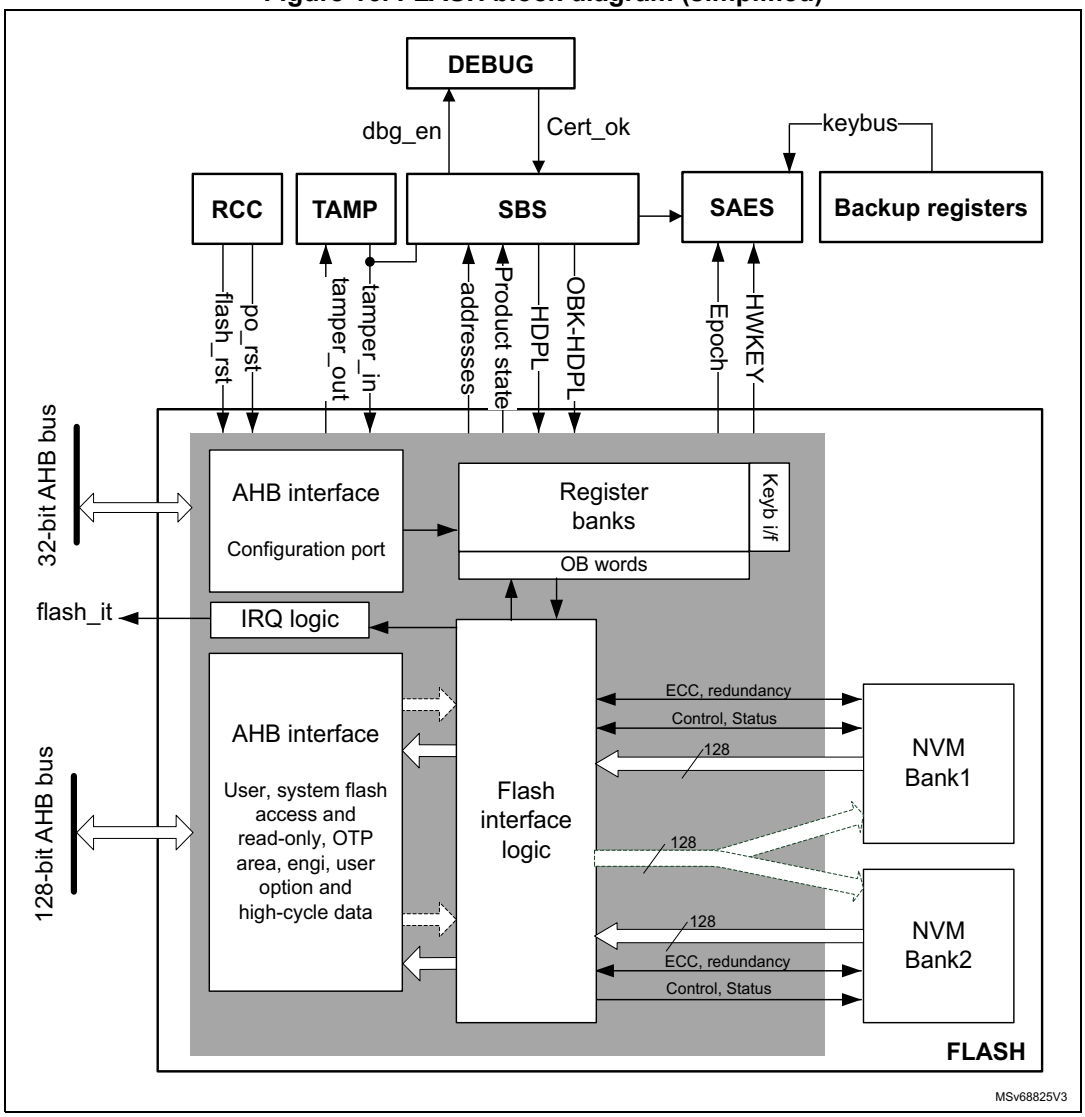
7 Embedded flash memory (FLASH)

7.1 Introduction

The embedded flash memory (FLASH) manages the access of any master device to the embedded nonvolatile memory. It implements the read, program, and erase operations, error corrections, as well as various integrity and confidentiality protection mechanisms.

FLASH manages the automatic loading of nonvolatile user option bytes at power-on reset and implements the dynamic update of these options. It also features a high-cycle data area, a one-time-programmable (OTP) area, a secure key storage area (OBKeys), and a read-only area configured by STMicroelectronics during manufacturing.

7.2 FLASH main features



- Up to 512 Kbytes of nonvolatile memory, divided into two equally sized banks (256 Kbytes for STM32G53x/54x and 512 Kbytes for STM32G55x/56x devices)
- Flash memory read operations supporting multiple lengths: 128 bits, 64 bits, 32 bits, 16 bits, or one byte
- Flash memory programming by 128 (user area, OBKeys) and by 16 bits (OTP and flash high-cycle data area)
- 8-Kbyte page erase, bank erase, and dual-bank mass erase
- Dual-bank organization supporting:
  - Simultaneous operations: read-while-write (program and erase) is supported, including flash high-cycle data area. The two banks share the same interface, hence write and erase cannot be performed in parallel (write-while-write is not supported).
  - Bank swapping: the address mapping of the user memory of each bank can be swapped, along with the corresponding registers. Security flags remain valid for the physical bank, so the data are not revealed by swapping to a bank with lower security configuration.
- Error code correction (ECC): one-error detection/correction, or two-error detection per 128-bit flash word using nine ECC bits on the code flash area, on 6-bit words with six ECC bits within the configurable flash high-cycle data area
- User-configurable nonvolatile option bytes
- Flash memory enhanced protections, activated by option bytes
  - Different product states for protecting memory content from debug access
  - Page group write-protection (WRPG), protecting up to 32 groups of four pages (32 Kbytes) per bank
  - Two secure-only areas (one per user flash bank): when enabled, these areas are accessible only if the microcontroller operates in secure access mode
  - HDP protection, providing temporal isolation for startup code
- 2-Kbyte one-time programmable (OTP) area
- Read-only area configured by STMicroelectronics
- Prefetch reads the next sequential instruction from flash memory
- Up to 48 Kbytes per bank (up to 24 Kbytes per bank for STM32G53x/54x and up to 48 Kbytes per bank for STM32G55x/56x devices) supporting high-cycling capability (100 kcycles), to be used for data (EEPROM emulation)

7.3 FLASH functional description

7.3.1 FLASH block diagram

Figure 16 shows the embedded flash memory block diagram.

Figure 16. FLASH block diagram (simplified)

7.3.2 FLASH signals

The flash memory has two AHB connections, namely the flash AHB register interface and the main AHB interface.

Flash AHB register interface

- The data size is 32 bits.
- Except for some registers (FLASH_KEYR/SKEYR, FLASH_OBKKEYR/FLASH_SOBKKEYR, and FLASH_OPTKEYR that only can be written by 32 bits), it is possible to read and write all registers by 8, 16, and 32 bits.
- When the unlock sequence for control and option registers is wrong, a bus error is raised, otherwise no read or write errors are generated on the bus.

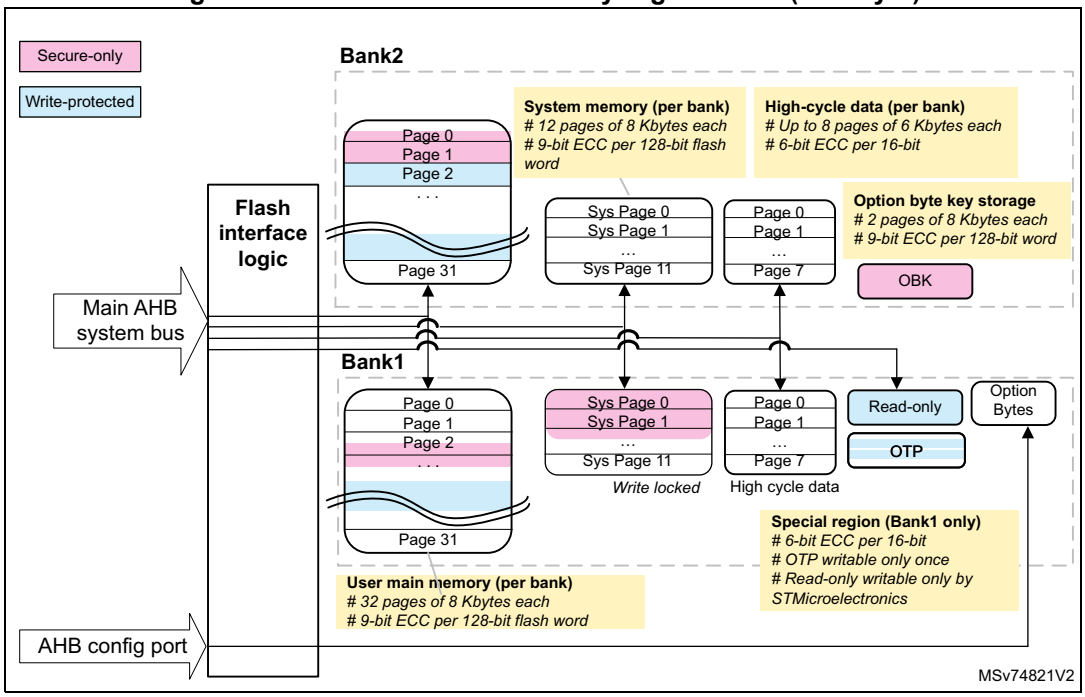
Main AHB interface

The AHB data bus size is 128 bits. This interface is used to handle three different targets:

- Code placed in the user and system memory
- Secure keys placed in OBKey pages
- OTP, read-only, and flash memory high-cycle data area

The main AHB interface is implemented as follows:

- User and system memory, OBKeys storage:
  - Supports multiple lengths: 128-, 64-, 32-, 16-, and 8-bit data width.
  - There is a read buffer of 128 bits for each bank where the last data read is stored. If data are available in the read buffer, no read access is given to the flash memory. The buffer is flushed when write access, OTP access, OBK swap, OBK alternate page erase, high-cycle data area access, user option change request, or erase operation occur.
  - There is a prefetch of the same size as the read buffer.
  - A 9-bit ECC complements each 128-bit data flash memory word.
- OTP, read-only, and flash high-cycle data
  - Two dedicated data buffers of 137 bits are used to manage 16-bit data with a 6-bit ECC.
  - Reading the same address twice triggers two instances of flash read operations.
  - During a read operation, two additional wait states are included in the memory wait states to parse the data buffer.
  - Every instance of writing data triggers a write operation in the flash memory.
  - A 6-bit ECC complements each 16-bit data word.



By default, the full AHB memory range is cacheable. For regions where caching is not practical (OTP, RO, data area), MPU must be used to disable local cacheability.

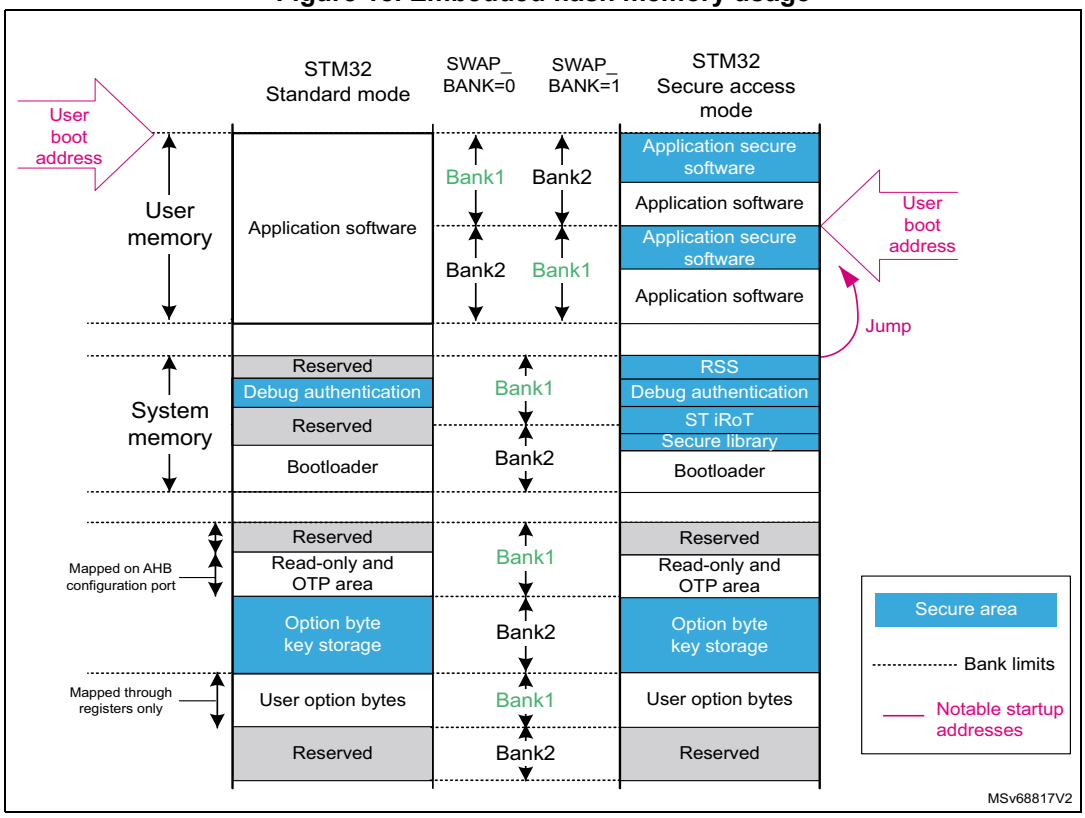
7.3.3 Flash memory architecture and usage

Flash memory architecture

Figure 17 shows the organization supported by the embedded flash memory.

Figure 17. Embedded flash memory organization (512kbyte)

The embedded nonvolatile flash memory is composed of:



- A main memory block, organized in two equal banks. Each bank is divided in pages of 8 Kbytes, and features flash-word rows of 128 bits + 9 bits of ECC per word.
- A system memory block of 192 Kbytes, divided into two 96-Kbyte banks. Each bank is divided in 8-Kbyte pages. The system flash memory is ECC-protected (9-bit ECC per 128-bit word).
- A set of nonvolatile option bytes, loaded at reset by the embedded flash memory and accessible by the application software only through the AHB configuration register interface.
- A 2-Kbyte one-time-programmable (OTP) area that can be written only once by the application software.
- A 2-Kbyte read-only area. It contains a unique device ID and product information.
- Two memory pages (2 x 8 Kbytes) of secure key storage, OBKeys.
- Up to 16 pages of user flash memory with a high cycling capability (100 K cycles) for data, (four pages per bank for STM32G53x/54x and eight pages per bank for STM32G55x/56x devices).

The overall flash memory architecture and its corresponding access interface are summarized in *Table 72*.

Partition usage

Figure 18 shows how the embedded flash memory is used by STMicroelectronics and by the application software.

Figure 18. Embedded flash memory usage

The user and system memories are used differently, according to the product state and other option byte settings:

- The user memory contains the application code and data, while the system memory is used with root secure services (RSS), the debug authentication code, and the STM32 bootloader. When a reset occurs, the core jumps to the boot address configured through the BOOT pin, the BOOTADD/SBOOTADD option bytes, and the product state.
- The unique boot entry (BOOT_UBE) is set to either STiRoT, located in the system flash memory, or iRoT in the user flash memory. This feature is available only on cryptography-enabled devices.
- The secure service library in the system flash memory is available in secure mode.
- If the debugger is attached to the product, the entry point is the debug authentication policy, used to unlock the device via the SBS when attached to the debugger. A digital signature is required to perform a regression to the product state, where debug is allowed.
- If BOOTADD/SBOOTADD is not yet configured, dedicated libraries can be used for the secure boot. They are located in the system flash memory:
  - ST libraries in the system flash memory assist the application software boot with special features, such as the secure boot and secure firmware installation (SFI-RSS).

– STiRoT (ST immutable Root of trust) secure software in the user flash memory is used for the secure firmware update and provisioning (SFU).

Note: For more information on the option byte setup for boot, refer to Section 7.4.7.

7.3.4 FLASH read operations

Read operation overview

Read access to the main and system flash memories operates as follows:

- A 128-bit read data buffer is associated with each bank, storing the last data read. If several consecutive read access operations request data belonging to the same flash data word (128 bits), data are read directly from the current data read buffer, without triggering additional flash read operations. This mechanism occurs each time read access is granted. When read access is rejected for security reasons, the corresponding read error response is issued by the embedded flash memory and no read operation of the flash memory is triggered.
- The buffer is invalidated by write access, OBK swap, user option change request, read access to 16-bit flash word area or any erase operation.

Read access to the OTP, RO, and flash high-cycle data operates as follows:

1. A flash data word of 137 bits is read and stored in a temporary buffer.
2. The interface parses the 137-bit data word and selects the 16- or 32-bit data requested.
3. While parsing the 137-bit data word, two wait states are added, and the AHB bus is stalled.
4. If the application reads an OTP data or flash high-cycle data not previously written, **a double ECC error** is reported and **only a word full of set bits is returned** (see *Section 7.3.10* for details). The read data (in 16 bits) is stored in the FLASH_ECCDR register.
5. Reading the same address twice triggers two read operations in the flash memory.
6. For 8-bit access instances, an AHB bus error is generated.

Note: The embedded flash memory can perform single-error correction and double-error detection while read operations are in execution (see Section 7.3.9).

Instruction prefetch

The Cortex®-M33 processor fetches instructions and literal pools (constants/data) over the C-bus and through the instruction cache, if enabled. The prefetch block aims at increasing the efficiency of C-bus access operations when the instruction cache is enabled, by reducing the cache refill latency.

Prefetch is efficient in case of sequential code. Prefetch in the flash memory allows the next sequential instruction line to be read from the memory, while the current instruction line is being filled in the instruction cache and executed by the CPU.

Prefetch is enabled by setting the PRFTEN bit in the FLASH access control register (FLASH_ACR). The PRFTEN must be set only if at least one wait state is needed to access the flash memory.

Adjusting read timing constraints

The embedded clock must be enabled and running before reading data from a nonvolatile memory.

To read data from the memory correctly, the number of wait states (LATENCY) must be correctly programmed in the access control register (FLASH_ACR), according to the main AHB interface clock frequency and the internal voltage range of the device (V_{core}).

Table 39 shows the correspondence between the number of wait states (LATENCY), the programming delay parameter (WRHIGHFREQ), the embedded flash memory clock frequency, and the supply voltage range.

Table 39. Recommended number of wait states and programming delay

Number of wait states (LATENCY)	Programming delay (WRHIGHFREQ)	Interface clock frequency vs. V_{CORE} range(1)		
		VOS2 range 1.05 to 1.15 V	VOS1 range 1.15 to 1.26 V	VOS0 range 1.30 to 1.40 V
0 WS (1 FLASH clock cycle)	00	0 to 30 MHz	0 to 34 MHz	0 to 42 MHz
1 WS (2 FLASH clock cycles)		30 to 60 MHz	34 to 68 MHz	42 to 84 MHz
2 WS (3 FLASH clock cycles)	01	60 to 90 MHz	68 to 102 MHz	84 to 126 MHz
3 WS (4 FLASH clock cycles)		90 to 120 MHz	102 to 137 MHz	126 to 168 MHz
4 WS (5 FLASH clock cycles)	10	120 to 150 MHz	137 to 171 MHz	168 to 210 MHz
5 WS (6 FLASH clock cycles)		150 to 170 MHz	171 to 205 MHz	210 to 252 MHz
6 WS (7 FLASH clock cycles)	11	N/A	205 to 240 MHz	252 to 280 MHz

1. Voltage range from 1.26 to 1.30 V is not supported.

Adjusting system frequency

After power-on, the embedded flash memory is clocked by the 64 MHz high-speed internal oscillator (HSI), with a voltage range set at a scaled value of VOS2: a conservative two wait-state latency is specified in the FLASH_ACR register (see *Table 39*).

When changing the bus frequency, the application software must follow the sequence described below, to tune the number of wait states required to access the memory.

To increase the CPU frequency:

1. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 39.*
2. Check that the new number of wait states is taken into account by reading back the FLASH_ACR register.
3. Modify the embedded flash memory clock source and/or the clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
4. Check that the new embedded flash memory clock source and/or the new AHB clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).

To decrease the CPU frequency:

1. Modify the embedded flash memory clock source and/or the clock prescaler in the RCC_CFGR register of the reset and clock controller (RCC).
2. Check that the embedded flash memory new clock source and/or the new clock prescaler value are taken into account by reading back the embedded flash memory clock source status and/or the AHB interface prescaler value in the RCC_CFGR register of the reset and clock controller (RCC).
3. If necessary, program the LATENCY and WRHIGHFREQ bits to the right value in the FLASH_ACR register, as described in *Table 39.*
4. Check that the new number of wait states has been taken into account by reading back the FLASH_ACR register.

Error code correction (ECC)

The memory embeds an error correction mechanism. Single-error correction and double-error detection are performed for each read operation. For more details, refer to *Section 7.3.9*.

Read errors

When the ECC mechanism is unable to correct the read operation, the memory reports read errors, as described in *Section 7.9.10: Error correction code error (ECCC, ECCD)*.

Read interrupts

See *Section 7.10: FLASH interrupts* for details.

7.3.5 FLASH program operations

Program operation overview

Program operation consists of issuing write commands. The memory supports the execution of only one write command at a time. Write-while-write is not supported. Nothing prevents overwriting a non-virgin flash word, but it is not recommended as this may lead to invalid data and inconsistent ECC code.

User flash, OBK storage and system flash memories pages

For the user and system flash memories, a 9-bit ECC complements each 128-bit data flash word. In this case, the embedded flash memory must always perform write operations to nonvolatile memory with a 128-bit word granularity. Once the write buffer is full (128 bits), the Busy flag is set, and a programming operation is triggered.

There is a write buffer common to Bank1 and 2, which supports multiple write-access types (128, 64, 32, 16, or 8 bits). The application can decide to write from 8 bits to 128 words. In this case, a force-write mechanism to the 128 bits + ECC is used (refer to the FW bit of the FLASH_CR/FLASH_SCR register).

When the write request is issued to the memory, any new write request stalls the main AHB bus. Moreover, while a write operation is ongoing, any new read request for the same bank stalls the main AHB bus.

OTP, RO, flash high-cycle data

When the target memory is OTP, RO or flash high-cycle data pages, a 6-bit ECC code complements each 16-bit data flash word. The embedded flash memory supports 16- or 32-bit write operations (8-bit write operations are not supported).For 8-bit operations, write access requests are ignored. There is no write data buffer and each write access request triggers a write operation in the flash memory.

Note: The OTP area is typically write-protected on the final product, as described in Section 7.3.10.

The write protection check is performed at the reception of the write request (during the address phase).Write protection is not checked at the output of the write buffer anymore. If a write protection violation is detected, the write operation is canceled, and a write protection error (WRPERR) is raised in the FLASH_SR/FLASH_SSR register.

Note: For write protections of the main flash memory, ICP, and OTP see Section 7.6: FLASH security and protections.

Monitoring ongoing write operations

The application software can use a status flag located in FLASH_SR/FLASH_SSR to monitor ongoing write operations. Since only one operation is possible at a time, this flag indicates if any operation (write, erase, option change) is ongoing, whatever the bank.

- **BSY**: indicates that an effective write, erase, option byte change, OBK swap, OBK alt page erase, or PUF operation is ongoing in the nonvolatile memory. This flag is not dedicated to a specific bank. It is set when an operation is starting on the memory, whatever the bank. An operation is triggered by:
  - An erase (FLASH_CR/SCR.STRT)
  - A write (FLASH_CR/SCR.PG + AHB write)
  - An option modification (FLASH_OPTCR.OPTSTRT)
  - PUF_LAUNCH
  - OBKeys page swap and OBKeys page erase (FLASH_OBKCFGR/SOBKCFGR.SWAP_SECT_REQ and FLASH_OBKCFGR/SOBKCFGR.ALT_SECT_ERASE)

They are cleared when the current operation ends, or in case of an error.

- **WBNE**: this bit indicates that the embedded flash memory is waiting for new data to complete the 128-bit write buffer. In this state the write buffer is not empty. It is reset as soon as the application software fills the write buffer, forces the write operations by using the FW bit in FLASH_CR/SCR, or an error is detected. When WBNE is high, it is not possible to launch an erase operation, an option modification, an OBK swap, or an OBK alternate page erase operation on the flash memory.
- **DBNE**: this bit indicates that the data buffer for parsing 16-bit data is not empty:
  - 16-bit data write access is received, and the data buffer is being filled. It is set at the reception of a valid write access, and reset as soon as the write request preparation has been processed.

Note: If the memory is busy at the reception of the AHB write request, the CPU execution is stalled.

Enabling write operations

Before programming the user flash memory in Bank1 or in Bank2, the application software must ensure that the PG bit is set to 1 in FLASH_CR/SCR. If not, an unlock sequence must be used (see *Section 7.6.7: Flash memory configuration protection*), and the PG bit must be set.

When an option byte or an option byte key must be modified, or a mass erase must be started, the application software must ensure that FLASH_OPTCR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 7.6.7: Flash memory configuration protection*).

A separate mechanism with similar use exists for FLASH_OBKCFGR/SOBKCFGR. The control register must be unlocked prior to the start of any OBKeys storage modification. Writing the correct sequence to the FLASH_OBKKEYR unlocks FLASH_OBKCFGR. FLASH_SOBKKEYR is linked to FLASH_SOBKCFGR, as described in the *Section 7.6.7: Flash memory configuration protection*.

Note: The application software must not unlock an already unlocked register, otherwise this register remains locked until the next system reset.

If needed, the application software can update the programming delay, as described in *Adjusting programming timing constraints*.

Writing to the FLASH control register FLASH_CR/SCR and FLASH_OPTCR

The FLASH_CR/SCR, FLASH_OPTCR and FLASH_OBKCFGR/SOBKCFGR registers are not accessible in write mode when the BSY bit is set. Any attempt to write these registers while the BSY bit is set causes the AHB bus to stall until the BSY bit is cleared.

Single-write sequence

The recommended single-write sequence is the following:

1. Make sure a protection mechanism does not prevent programming.
2. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR/SSR register and CDBNE bits in the FLASH_SR/SSR register. Check that the write buffer is empty by checking the WBNE bit in the FLASH_SR/SSR register.
3. Check and clear all the error flags due to a previous programming/erase operation.
4. Unlock the FLASH_CR/SCR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
5. Enable write operations by setting the PG bit in the FLASH_CR/SCR register
6. Write one flash word at the aligned address.

Note: The WBNE flag indicates if the 128-bit write buffer is waiting for new data.

Note: No erase request, options change request, PUF, or OBK operation is allowed between the first write and the completion of the write operation.

7. Wait for the BSY bit to be cleared in the corresponding FLASH_SR/SSR register.
8. Clear the PG bit in theFLASH_CR/SCR register if there are no more programming requests.

If step 6 is executed incrementally (for example, byte per byte), the write buffer can become partially filled. In this case, the application software can decide to force-write what is stored in the write buffer by using the FW bit in the FLASH_CR/SCR register. In this particular

case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Note: Using a force-write operation prevents the application from, at a later stage, updating the missing bits with a value different from 1. This can lead to unexpected or inconsistent data, or ECC.

Adjusting programming timing constraints

Program operation timing constraints depend on the memory clock frequency, which impacts performance directly. If timing constraints are too tight, the nonvolatile memory does not operate correctly. If they are too lax, the programming speed is not optimal.

The user must therefore trim the optimal programming delay through the WRHIGHFREQ parameter in the FLASH_ACR register. Refer to *Table 39: Recommended number of wait states and programming delay* for the recommended programming delay, depending on the memory clock frequency.

The FLASH_ACR configuration register is common to both banks.

The application software must check that no program/erase operation is ongoing before modifying WRHIGHFREQ.

Caution: Modifying WRHIGHFREQ while programming/erasing the memory can corrupt its content.

Programming errors

When a program operation fails, an error is reported, as described in *Section 7.9: FLASH error management*.

Programming interrupts

See *Section 7.10: FLASH interrupts* for details.

7.3.6 FLASH erase operations

Erase operation overview

The memory can perform erase operations on 8-Kbyte user pages, on one user flash memory bank, or on two user flash memory banks (for example mass erase). For more details on the user flash memory, ICP, user options, and OTP erase protection, see *Section 7.6: FLASH security and protections*.

Erase commands are issued through the AHB configuration interface. The memory supports one operation at a time, if it receives simultaneously a write and an erase request an error flag is raised, and both operations are canceled. See *Section 7.9: FLASH error management* for details.

After successful completion of erase, all the bytes in the erased flash pages are set to the flash default 0xFF value.

Erase and WRP

If the application software attempts to erase a write-protected user page, the page erase operation is aborted, and the WRPERR flag is raised in the FLASH_SR/SSR register, as described in *Section 7.9.2: Nonsecure write protection error (WRPERR)*.

Flash busy

The busy signal is described in *Section : Monitoring ongoing write operations*.

Writing to the FLASH control register FLASH_CR/SCR and FLASH_OPTCR

Refer to *Section : Writing to the FLASH control register FLASH_CR/SCR and FLASH_OPTCR*.

Enabling erase operations

Before erasing a page, the application software must make sure that FLASH_CR/SCR is unlocked. If this is not the case, an unlock sequence must be used (see *Section 7.6.7: Flash memory configuration protection*).

Note: The application software must not unlock a register that is already unlocked, otherwise this register remains locked until next system reset. This can be used to deliberately lock out a register from further access.

Similar constraints apply to bank erase requests.

Standard flash page erase sequence

To erase an 8- or 6-Kbyte data user page without security protections, proceed as follows:

1. Make sure a protection mechanism does not prevent page erase (WRP, secure flag, HDP).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SR register, and that the write buffer is empty by checking the WBNE bit in the FLASH_SR register.
3. Check and clear all nonsecure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_CR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
5. Set the BKSEL bit, the PER bit, and the PNB bitfield in the FLASH_CR register. BKSEL indicates in which physical bank the page must be erased, then PER indicates a page erase operation, while PNB contains the target page number. In case of a data page, use the number of the corresponding regular page. Refer to *Figure 19* to *Figure 24* for orientation.
6. Set the STRT bit in the FLASH_CR register.
7. Wait for the BSY bit to be cleared in the FLASH_SR register.
8. The STRT bit is automatically cleared at the end of the page erase, or in case of an error.
9. Clear PER in the FLASH_CR register if there are no more page erase requests to be issued.

Note: If another erase flag is requested simultaneously to the page erase, a PGSERR error is generated.

Secure flash memory page erase sequence

To erase an 8- or 6-Kbyte data secure configured user page, proceed as follows:

1. Make sure write protection or an HDP mechanism does not prevent page erase.
2. Ensure that no flash memory operation is ongoing (by checking the BSY and DBNE bits in the FLASH_SSR register), and that the write buffer is empty (by checking the WBNE bit in the FLASH_SSR register).
3. Check and clear all secure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_SCR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
5. Set the BKSEL bit, the PER bit, and the PNB bitfield in the FLASH_SCR register. BKSEL indicates in which physical bank the page must be erased, then PER indicates a page erase operation, while PNB contains the target secure page number. In case of a data page, use the number of the corresponding regular page. Refer to *Figure 19* to *Figure 24* for orientation.
6. Set the STRT bit in the FLASH_SCR register.
7. Wait for the BSY bit to be cleared in the FLASH_SSR register.
8. The STRT bit is automatically cleared at the end of the page erase or in case of an error.
9. Clear PER in the FLASH_SCR register if there are no more secure page erase requests to be issued.

Note: If another erase flag is requested simultaneously to the page erase, a PGSERR error is generated.

Standard flash memory bank erase sequence

To erase a bank where no page is configured as secure:

1. Make sure a protection mechanism does not prevent page erase.
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SR register and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all nonsecure error flags due to previous programming/erase operation. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_CR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
5. Set the BKSEL bit and the BER bit in the FLASH_CR register to the targeted physical bank (swap setting is ignored).
6. Set the STRT bit in the FLASH_CR register to start the bank erase operation. Then wait until the BSY bit is cleared in the FLASH_SR register.
7. The STRT bit is automatically cleared at the end of the erase sequence or in case of an error.
8. Clear BER in the FLASH_CR register if there is no other bank erase request to be issued.

Secure flash memory bank erase sequence

To erase a bank where all pages are configured with a secure flag:

1. Make sure a protection mechanism does not prevent page erase (for mass erase HDP is also considered, it cannot be fully executed from HDPL=2,3 if HDP is defined).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SSR register, and that the write buffer is empty by checking the WBNE bit in the same register.
3. Check and clear all the secure error flags due to previous programming/erase operation. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_SCR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
5. Set the BKSEL bit and the BER bit in the FLASH_SCR register to the targeted physical bank (swap setting is ignored).
6. Set the STRT bit in the FLASH_SCR register to start the bank erase operation. Then wait until the BSY bit is cleared in the FLASH_SSR register.
7. STRT bit is automatically cleared at the end of erase sequence or in case of an error.
8. Clear BER in the FLASH_SCR register if there is no other bank erase request to be issued.

Flash mass erase sequence

To erase all pages of both banks, using nonsecure access, all pages must be configured as nonsecure. The application software can set the MER bit to 1 in the FLASH_CR register, as described below:

1. Make sure no protection mechanisms prevent mass erase (*Section 7.6.7: Flash memory configuration protection*).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SR register.
3. Check and clear all nonsecure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_CR register as described in *Section 7.6.7: Flash memory configuration protection* (only if the registers are not already unlocked).
5. Set the MER bit to 1 in FLASH_CR register.
6. Set the STRT bit in the FLASH_CR register. Then wait until the BSY bit is cleared in the FLASH_SR register.
7. The STRT bit is cleared automatically at the end of the erase sequence, or in case of an error.
8. Clear MER in the FLASH_CR register.

Secure flash memory mass erase sequence

To erase all pages of both banks simultaneously, using secure access, all pages must be configured as secure. The application software can set the MER bit to 1 in the FLASH_SCR register, as described below:

1. Make sure no protection mechanisms prevent mass erase (*Section 7.6.7: Flash memory configuration protection*).
2. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SSR register, and that the write buffer is empty by checking the WBNE bit in the FLASH_SSR register.
3. Check and clear all secure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
4. Unlock the FLASH_SCR register as described in *Section 7.6.7: Flash memory configuration protection* (only if the registers are not already unlocked).
5. Set the MER bit to 1 in FLASH_SCR register.
6. Set the STRT bit in the FLASH_SCR register. Then wait until the BSY bit is cleared in the FLASH_SSR register.
7. The STRT bit is cleared automatically at the end of the erase sequence, or in case of an error.
8. Clear MER in the FLASH_SCR register.

Note: Mass and bank erase also erase high-cycle data pages aliased from the erased bank.

7.3.7 PUF operations

PUF serves as HUK for secure storage using SAES. The PUF value is based on hardware technology that requires a special initialization procedure.

PUF initialization is performed by PUF_Launch and subsequent cryptographic test. The test is needed to establish that the PUF retrieved from the HW remains the same across the device operating envelope (voltage, temperature, for example).

During the product manufacturing a PUF_REF_Value is stored in the flash read-only area (refer to *Section 61: Device electronic signature*).

This value is the result of a cryptographic operation as the PUF value is never accessible. To verify the PUF, the application must reproduce the exact same cryptographic operation and retrieve the same value. This verification is not needed in PRODUCT_STATE = Open, where actual PUF value is also not used.

Verification process consists of following steps:

1. PUF_Launch: Initialize the HW IP (if PRODUCT_STATE = Open, jump to end)
2. In nonsecure code, with HDPL1 (SBS_NEXTHDPLCR), EPOCH forced to zero (SBS_EPOCHSELCR), ... SAES engine set with ECB mode, 256-bit DHUK selected use SAES to encrypt ClearPufRef value.
3. Compare the result with PUF_REF_Value stored in the read-only area.
4. If different, return to step 1.

The process is implemented in the Cube package under SAES example folder.

The plaintext input value for SAES is the following:

uint8_t ClearPufRef[32] = {

0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU,

0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU,

0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U,

0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U, 0xCEU, 0xD1U,

};

Not following the procedure may cause problems using SAES based secure storage because it leads to inconsistency in cryptographic key value.

Note: PUF operations last for several milliseconds and use flash memory controller write services. These are not usable until the operation finishes.

PUF verification with TrustZone disabled

To launch a PUF verification, proceed as follows:

1. Check that no flash memory operation is ongoing by checking the NSBSY and NSDBNE bits in the FLASH_SR register, and that the write buffer is empty by checking the NSWBNE bit in the FLASH_SR register.
2. Check and clear all nonsecure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
3. Unlock the FLASH_CR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
4. Write NS_PUF_LAUNCH in FLASH_CR.
5. Wait for the NSBSY bit to be cleared in the FLASH_SR register.
6. The NS_PUF_LAUNCH bit is automatically reset by the hardware at the end of the operation. If NS_PUF_READY is set in FLASH_SR, the PUF is usable until the next power-off/standby.

PUF verification with TrustZone enabled

To launch a PUF verification, proceed as follows:

1. Check that no flash memory operation is ongoing by checking the SECBSY and SECDBNE bits in the FLASH_SSR register, and that the write buffer is empty by checking the SECWBNE bit in the FLASH_SSR register.
2. Check and clear all nonsecure error flags due to previous programming/erase operations. Refer to *Section 7.9: FLASH error management* for details.
3. Unlock the FLASH_SCR register, as described in *Section 7.6.7: Flash memory configuration protection* (only if this register is not already unlocked).
4. Write SEC_PUF_LAUNCH in FLASH_SCR.
5. Wait for the SECBSY bit to be cleared in the FLASH_SSR register.
6. The SEC_PUF_LAUNCH bit is automatically reset by hardware at the end of the operation.
7. If SEC_PUF_READY is set in FLASH_SSR, the PUF is usable until the next power-off/standby.

7.3.8 FLASH parallel operations

The flash memory is divided in two independent banks. The embedded flash memory interface supports a read operation in one bank, while an erase or write (RWW: read-while-write) operation is executed simultaneously in the other bank. It does not support write-while-write, nor read-while-read. The same is valid for the high-cycle data area, system flash libraries, option bytes (located on Bank1), and OBK (located on Bank2).

In all cases, the sequences described in *Section 7.3.4*, *Section 7.3.5* and *Section 7.3.6* apply.

7.3.9 FLASH error protections

Error correction codes (ECC)

The embedded flash memory supports an error correction code (ECC) mechanism, based on the SECDED algorithm, to correct single errors and detect double errors.

This mechanism uses nine ECC bits per 128-bit flash word, and applies to the user and system memories. For read-only, OTP, and flash high-cycle data, six ECC bits per 16-bit word are used. A double ECC error is generated for an OTP or flash high-cycle data virgin word (for example, an OTP word with all 22 bits at 1). When this OTP or flash high-cycle data word is no longer virgin, the ECC error disappears.

More specifically, during each read operation from a 128-bit flash word, the embedded flash memory retrieves the 9-bit ECC information, computes the ECC of the flash word, and compares the result with the reference value. If these do not match, the corresponding ECC error is raised, as described in *Section 7.9.10: Error correction code error (ECCC, ECCD)*.

During each programming operation, a 9-bit ECC code complements each 128-bit data flash word, and the resulting 137-bit flash word information is written in the nonvolatile memory.

A similar mechanism applies to read-only and OTP areas, but with 6-bit ECC for 16-bit data.

7.3.10 OTP and RO memory access

The OTP and RO memories are accessed through the main AHB interface. The OTP memory is accessible at addresses 0x08FF F000 to 0x08FF F7FF, and the read-only section is accessible from 0x08FF F800 to 0x08FF FFFF.

FLASH one-time programmable area

The embedded flash memory offers a 2048-byte memory area dedicated to application non-confidential, one-time-programmable (OTP) data. This area is composed of 1024 words of 16 bits (plus 6 bits of ECC). It cannot be erased and can be written only once. The OTP area can be accessed through the main AHB interface from the address range 0x08FF F000 to 0x08FF F7FE.

OTP data can be programmed by the application software in 16-bit chunks. Overwriting an already programmed 16-bit half word is not supported.

Note: The OTP area is empty when the device is delivered by STMicroelectronics.

When reading OTP data with a single error corrected or a double error detected, the embedded flash memory reports read errors, as described in *Section 7.9.10: Error correction code error (ECCC, ECCD)*.

OTP write protection

OTP data are organized as 32 blocks of 32 OTP words, as shown in *Table 40*. An entire OTP block can be protected (locked) from write access by setting the LOCKBLi bit (i = 0 to 31) corresponding to each OTP block in the FLASH_OTPBLR register. A block can be write-protected, whether it has been programmed (even partially) or not.

The OTP block locking operation is irreversible, regardless of the product life state.

Note: The OTP area can be accessed only in read mode.

Table 40. Flash memory OTP organization

OTP block	AHB address	AHB word		Lock bit
		[31:16]	[15:0]	
Block 0	0x08FF F000	OTP001	OTP000	LOCKBL0
	0x08FF F004	OTP003	OTP002	
	...			
	0x08FF F03C	OTP031	OTP030	
Block 1	0x08FF F040	OTP033	OTP032	LOCKBL1
	0x08FF F044	OTP035	OTP034	
	...			
	0x08FF F07C	OTP063	OTP062	
Block 2	0x08FF F080	OTP065	OTP064	LOCKBL2
	0x08FF F084	OTP067	OTP066	
	...			
	0x08FF F0BC	OTP95	OTP94	
...				
Block 31	0x08FF F7C0	OTP993	OTP992	LOCKBL31
	0x08FF F7C4	OTP995	OTP994	
	...			
	0x08FF F7FC	OTP1023	OTP1022	

OTP write sequence

Follow the sequence below to write an OTP word:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR register and that the data buffer is empty by checking the DBNE bit in the FLASH_SR register.
2. Check and clear all error flags due to previous programming/erase operations.
3. Set the PG bit in the FLASH_CR register.
4. Check the protection status of the target OTP word (see *Table 40*). The corresponding LOCKBLi bit must not be set to 1.
5. Write two OTP words (32 bits) corresponding to the 4-byte aligned address shown in *Table 40*. Alternatively, the application software can program separately the 16-bit MSB or 16-bit LSB. In this case, the first 16-bit write operation starts immediately without waiting for the second one.
6. Wait for the BSY bit to be cleared in the FLASH_SR register.
7. Clear the PG bit in FLASH_CR register if there are no further programming requests in the bank.
8. Optionally, lock the OTP block using LOCKBLi to prevent further data changes.

Note: Do not write a 16-bit OTP word twice, as it generates an error.

Writing OTP data at byte level is not supported, and generates a bus error.

To avoid data corruption, it is important to complete the OTP write process (for example, by reading back the OTP value), before starting an option change.

Flash read-only area

The embedded flash memory offers a 2-Kbyte area to store read-only data. This area can be accessed through the AHB main port, and is protected by a robust ECC scheme, as detailed in *Section 7.3.9*.

The read-only information (programmed by STMicroelectronics) that can be used by the application software is detailed in *Table 41*.

Table 41. Read-only public data organization

Read-only data name	Address	Comment
Unique device ID	0x08FF F800	U_ID[31:0]
	0x08FF F804	U_ID[63:32]
	0x08FF F808	U_ID[96:64]
Flash memory size/ package	0x08FF F80C	Flash memory size[15:0]/Package code[15:0]
Trim data	0x08FF F810 to 0x08FF F81B	Sensor and voltage reference trimming values
PUF_REF_Value	0x08FF F81C to 0x08FF F83B	Reference value used for PUF initialization
Trim data	0x08FF F83C - 0x08FF F84B	USBPD trim data
Reserved	0x08FF F84C to 0x08FF FFFF	Reserved information, except for values described elsewhere in user documentation

7.3.11 Flash high-cycle data

The embedded flash memory offers up to 96 Kbytes (maximum) memory area with high-cycling capability (100 kcycles) to store data and emulate EEPROM (up to 48 Kbytes for STM32G53x/54x and up to 96 Kbytes per bank for STM32G55x/56x devices). It can be accessed through the AHB system port from address 0x0900_0000 to 0x0901_7FFF (see *Figure 19*). It is mapped in the 8 (or 4) last pages of Bank1 and 2. This area is protected by a robust
6-bit ECC, which allows a read and write granularity of 16 bits at the expense of having the page size shrunk to 6 Kbytes.

A threshold per bank (EDATA(1/2)_STRT) is programmable to determine the beginning of the data flash area. By default, the entire memory is used for code.

For example, if 48 Kbytes of data are needed in Bank1, in FLASH_EDATA1R set EN to 1, and STRT to 7. If no data are needed in Bank2, reset FLASH_EDATA2R.EN to 0. In this case the data are accessible from address 0x0900_0000 to address 0x0900_BFFF for Bank1.

For greater efficiency, it is always recommended to use pages on the other bank for flash high-cycle data, so that the application benefits from the RWW capability of the dual-bank arrangement.

When banks are swapped (FB_MODE setting in SBS): the flash high-cycle data in Bank 2 are accessible from 0x0900_000 to 0x0900_BFFF, and the data in Bank 1 are accessible from 0x0900_C000 to 0x0901_7FFF.

A bus error is generated on:

- An attempt to access an address between 0x0900_0000 to 0x0901_7FFF and this address is not valid, not enabled, or STRT incorrect).
- An attempt to fetch instructions from the pages occupied by the flash high-cycle data area.

Erasing the data area page is possible by normal erase request for corresponding user flash page (24-31).

Protections and security of high-cycle area are detailed in *Section 7.6.9: Flash high-cycle data protections*.

Figure 19. Flash high-cycle data memory map on STM32G55xB/56xB devices (128 Kbytes)

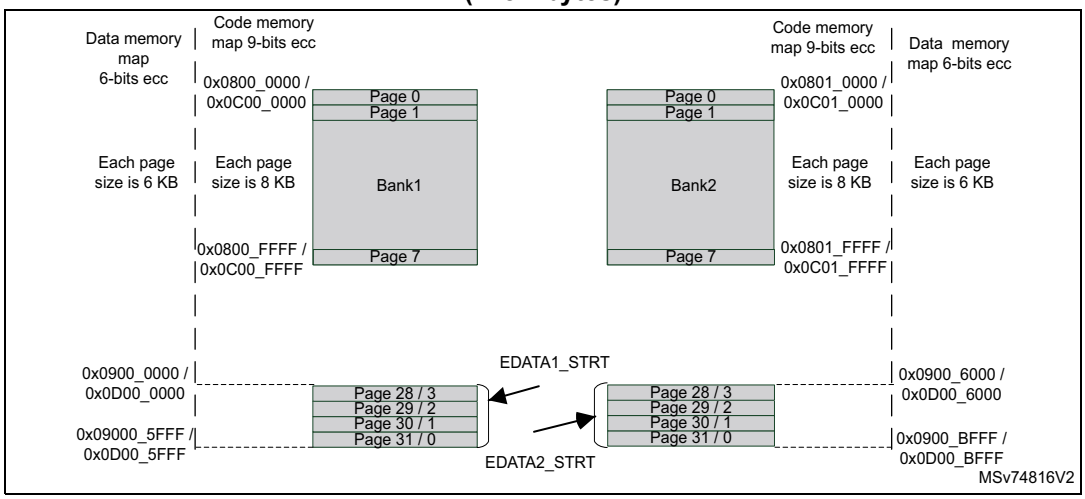


Figure 20. Flash high-cycle data memory map on STM32G55xC/56xC devices (256 Kbytes)

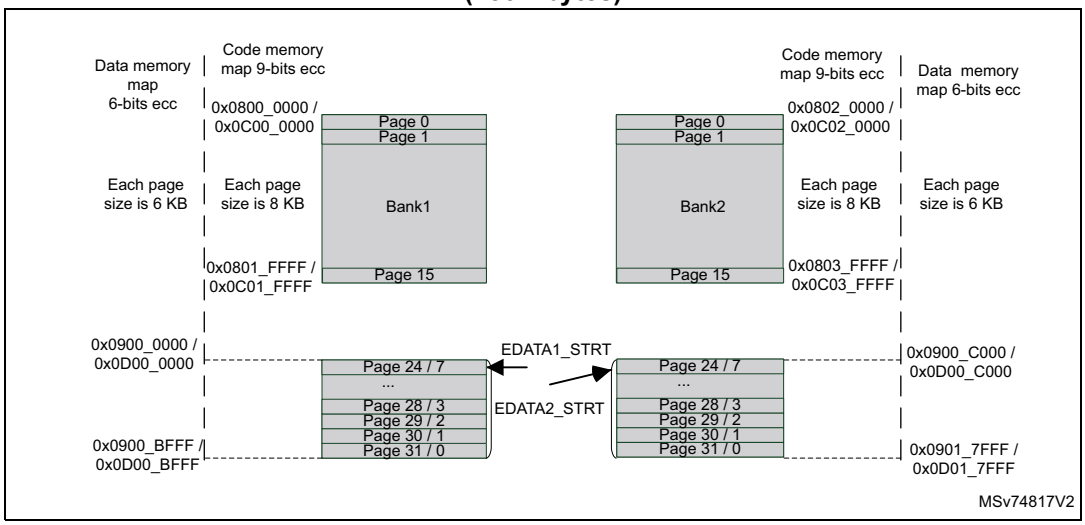

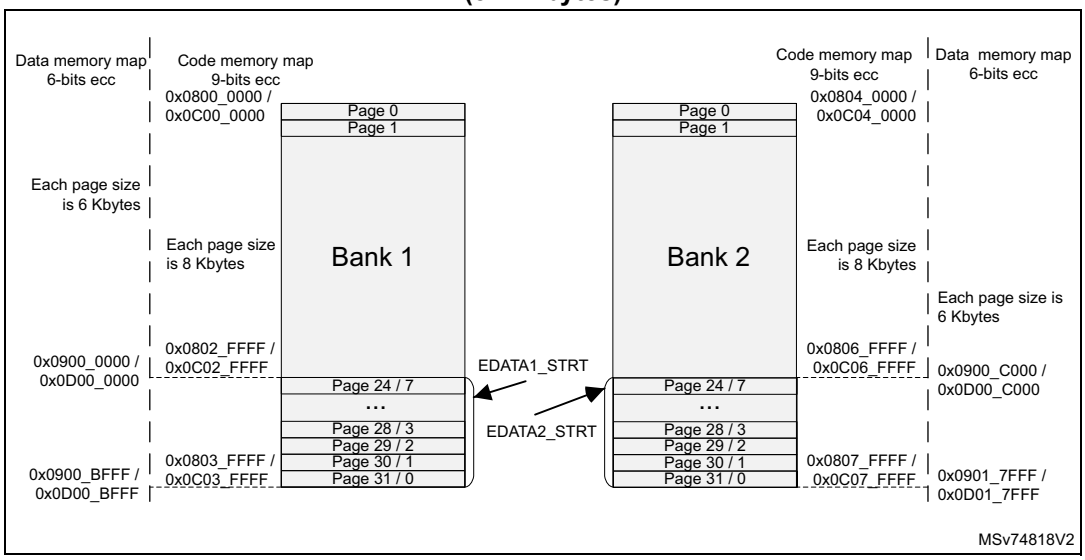

Figure 21. Flash high-cycle data memory map on STM32G55xE/56xE devices (512 Kbytes)

Note: When the flash high-cycle data area on Bank1 is enabled, the code memory map is not continuous to the following flash segment using 512 Kbytes of user flash memory on STM32G55xE/56xE.

Figure 22. Flash high-cycle data memory map on STM32G53x8/54x8 devices (64 Kbytes)

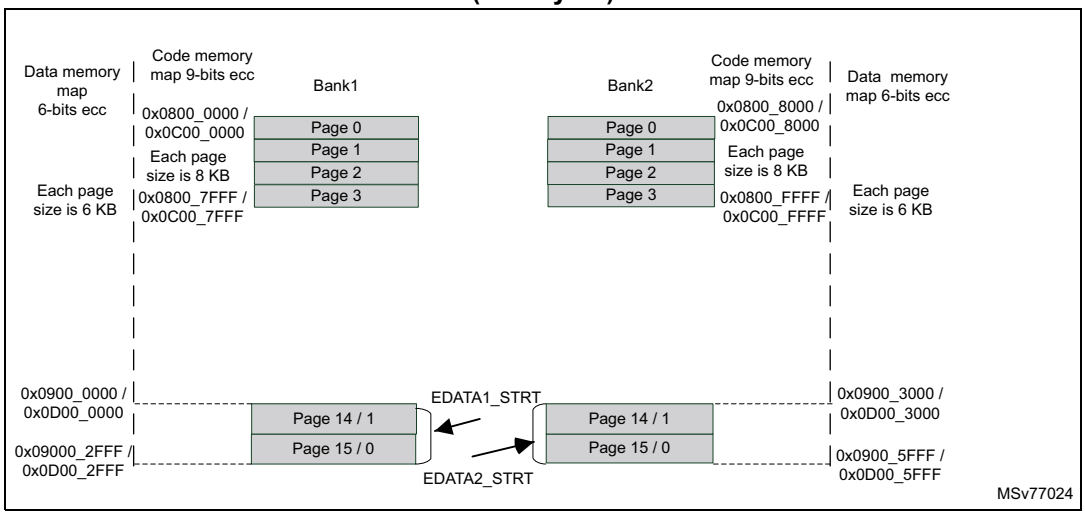

Figure 23. Flash high-cycle data memory map on STM32G53xB/54xB devices (128 Kbytes)

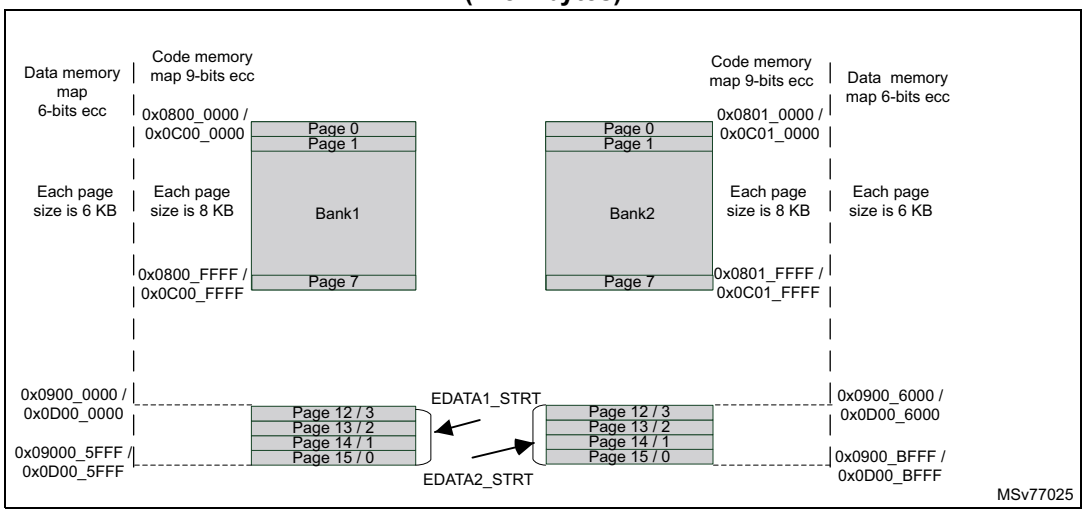

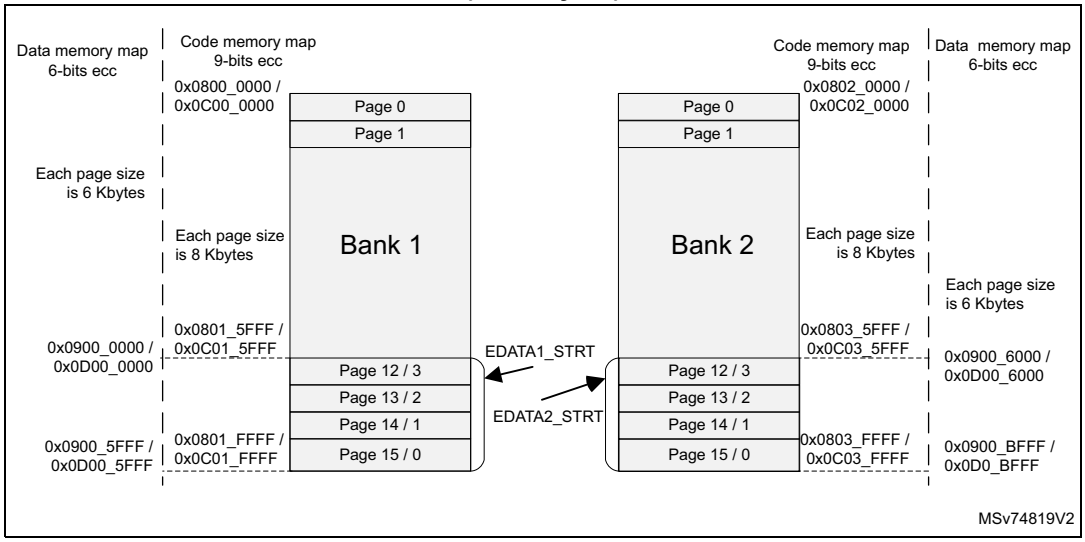

Figure 24. Flash high-cycle data memory map on STM32G53xC/54xC devices (256 Kbytes)

Note: When flash high-cycle data area on Bank1 is enabled, the code memory map is not continuous on STM32G53x/54x.

7.3.12 Flash bank swapping

Bank1 and Bank2 can be swapped for the user flash memory. This feature can be used for a firmware upgrade to switch the device to the new firmware. Bank swapping uses a user option byte flag controlled by the SWAP_BANK byte of the FLASH_OPTSR3 register and mapping controls available in the SBS. As explained in *Section 14.3.9: SBS flash banks control*, the SBS value of FB_MODE is also the definitive indicator of the currently used bank mapping.

Bank-specific settings for data area and security attributes follow the original bank and its contents. Control bit BKSEL always refers to the physical bank, not the mapping indicated by the FB_MODE setting.
The FB_MODE setting is loaded from the SWAP_BANK option only after a system reset or POR.

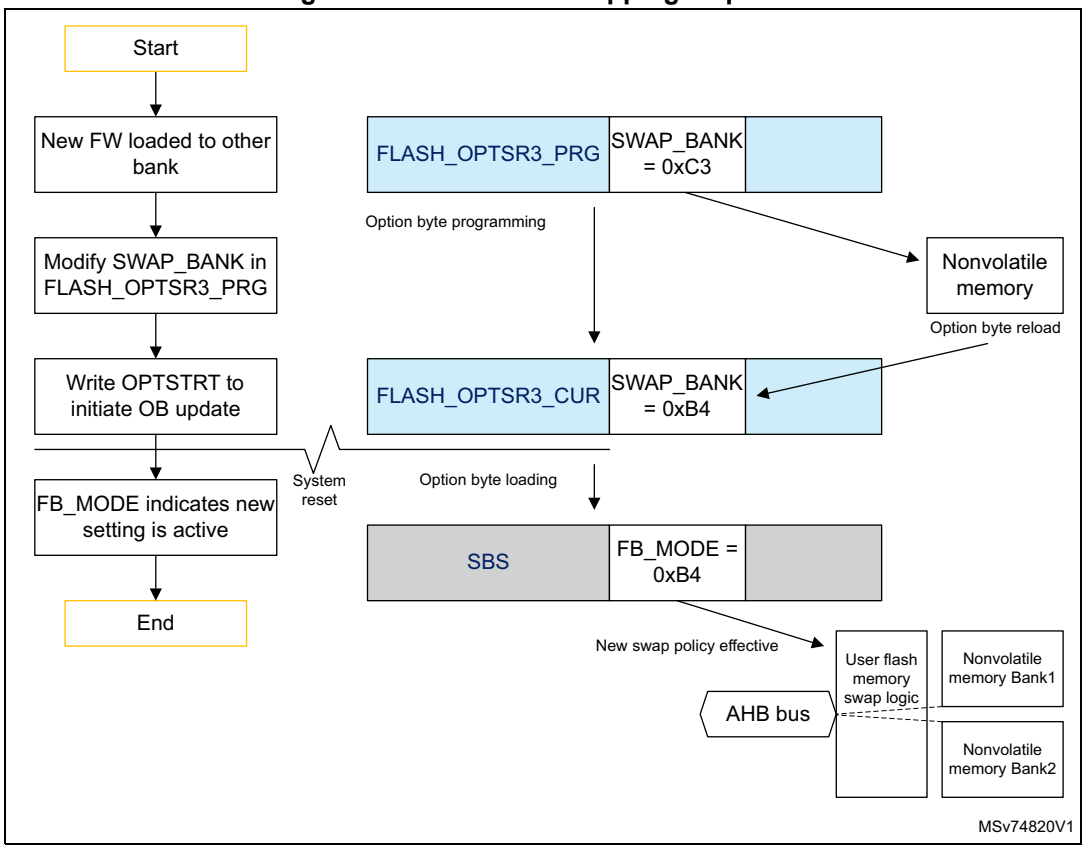
Bank swap with intermediate reset

To change the SWAP_BANK setting, follow the sequence below:



1. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SR/SSR register, and that the write buffer is empty by checking the WBNE bit in the FLASH_SR/SSR register.
2. Clear all error flags due to any previous operations.
3. Unlock the OPTLOCK bit, if not already unlocked.
4. Set the new desired SWAP_BANK value in the FLASH_OPTSR3_PRG register.
5. Start the option byte change sequence by setting the OPTSTRT bit in the FLASH_OPTCR register.
6. Once the option byte change has been completed, FLASH_OPTSR3_CUR contains the expected SWAP_BANK value, but FB_MODE has not yet been modified and the bank swapping is not yet effective.
7. Force a system reset or a POR. When the reset rises up, the bank swapping is effective and the new firmware shall be executed.

Note: The SWAP_BANK bit in FLASH_OPTSR3_CUR is read-only, and cannot be modified by the application software.

The SWAP_BANK option bit in FLASH_OPTSR3_PRG can be modified during any product state, provided the SWAP_LOCK protection value, controlled by the SBS, is 0xC3 (not engaged).

Figure 25 gives an overview of the bank swapping sequence.

Figure 25. Flash bank swapping sequence

On-the-fly bank swap

When not locked, the FB_MODE setting can be changed at any moment during runtime, resulting in an immediate remapping of the flash memory banks. This mechanism is useful for the implementation of on-the-fly field-upgrades with minimum down time. In case of security concerns, this bit can be locked out from modification (see details in the SBS chapter).

When the FB_MODE value is changed during runtime, the CPU fetches the next instruction from the other bank. To prevent a crash, essentially both banks need to contain the exact same code in the code segment performing the swap, interrupts should be disabled, no other flash access must be ongoing, and the new code needs to be able to successfully unroll the stack created by the old code.

This exact same code performing the swap is called unmodifiable code. The execution may continue to execute the updated code after the successful swap.

The recommended sequence of unmodifiable code is:

1. Disable interrupts
2. Disable and flush cache
3. Modify the interrupt vector table offset (if needed)
4. Swap the bank
5. Restore cache configuration
6. Enable interrupts

It's important to know that in the case of a reset, the boot bank is selected according to the SWAP_BANK setting. It's recommended to modify the setting to follow the latest functional code.

7.3.13 FLASH reset and clocks

Reset management

The embedded flash memory can be reset by a core domain reset, driven by the reset and clock control (RCC). The main effects of this reset are the following:

- All registers, except for option byte registers, are cleared, including read and write latencies. If the bank swapping option is changed, it is applied.
- Most control registers are automatically protected against write operations. To disable the protection, new unlock sequences must be used as described in *Section 7.6.7: Flash memory configuration protection*.

The memory can be reset by a power-on core domain reset, driven by the reset and clock control (RCC). When the reset falls, all option byte registers are reset. When the reset rises up, the option bytes are loaded, potentially applying new features. During this loading sequence, the device remains under reset, and the memory is not accessible.

The reset signal can have a critical impact on the memory: the content is not guaranteed if a device reset occurs during a write or erase operation.

Reset occurring during flash operation

If a reset occurs during a flash operation (programing, erase, or option change), the content of the memory is not guaranteed. It is mandatory for integrity to restart the operation. The status register FLASH_OPSR gives information about operations interrupted by a reset.

FLASH_OPSR.CODE_OP gives the opcode of the operation. *Table 46* indicates how to use FLASH_OPSR, and which operation is required.

Table 46. Recommended reactions to FLASH_OPSR contents

CODE_OP	Operation interrupted	OTP_OP	SYSF_OP	BK_OP	DATA_OP	Flash area	ADDR_OP min	ADDR_OP max	Recommended action
0x000	No operation ongoing while reset	0	0	0	0	-[1]	-	-	No extra action
0x001	Write operation	0	0	0/1	0	User flash	0x0000	0xFFFF	Erase page and rewrite
		0	1	0/1	0	System flash	0x0000	0x0FFF	
		1	0	0	0	OTP	0x0600	0x07FF	
		1	0	1	0	OBKeys[2]	0x0000	0x03FF	
		0	0	0/1	1	Data area[3]	0xF000	0xFFFF	
0x010	OBK alternate page erase	0	0	1	0	OBKeys	0	0	Relaunch the alternate page erase
0x011	page erase[4]	0	0	0/1	0	User flash	0x0000	0xFFFF	Relaunch page erase
		0	1	0/1	0	System flash	0x0000	0x0FFF	
0x100	Bank erase	0	0	0/1	0	User flash	-	-	Relaunch bank erase
0x101	Mass erase	0	0	0	0		-	-	Relaunch mass erase
0x110	Option change	0	0	0	0	User configuration	-	-	New attempt on option change
0x111	OBK swap page	0	0	1	0	OBKeys	-	-	Erase alternate page, reprogram new OBKeys and relaunch swap

1. Dash represents “does not matter”.
2. Depends on current OBK page.
3. Depends on EDATA setting in the OB.
4. Addresses indicated are aligned to page start, data area pages are erased by erase request to corresponding user flash memory page.

Clock management

The memory uses the microcontroller system clock (sys_ck), here the AHB interface clock.

7.4 FLASH option bytes

7.4.1 About option bytes

The memory includes a set of nonvolatile option bytes. They are loaded at power-on reset and can be read and modified only through configuration registers. This section documents:

- When option bytes are loaded.
- How application software can modify them.
- Their detailed list, together with their initial values (before the first option byte change, user default configuration).

7.4.2 Option byte loading

There are multiple ways of loading the option bytes:

- **Power-on wakeup**

  When the device is powered on, the embedded flash memory automatically loads all the option bytes. During the option byte loading sequence, the device remains under reset and the embedded flash memory cannot be accessed.

- **Wakeup from system standby**

  When the core power domain, which contains the embedded flash memory, is switched from Standby mode to Run mode, the embedded flash memory behaves as during a power-on sequence.

Note: During loading time the device is not under reset, unlike during a power-on sequence.

- **Dedicated option byte reloading by the application**

  When the user application successfully modifies the option byte content through the memory registers, the nonvolatile option bytes are programmed and the memory automatically reloads all option bytes to update the option registers.

Note: The option-byte read sequence is protected by error correction code. In case of error, the option bytes are loaded with default values (see Section 7.4.3: Option-byte modification), different from the initial values (user default configuration), and more restrictive.

7.4.3 Option-byte modification

Changing user option bytes

A user option-byte change operation can be used to modify the configuration and the protection settings saved in the nonvolatile option byte area of memory Bank1. It's important to account for a stall in execution from Bank1, when the option bytes are being modified.

Several rules are enforced when attempting to change a user option byte. These are summarized in *Section 7.4.8*. Failing to stick to those rules usually results in errors, as described in *Section 7.9.12*.

The embedded flash memory features two sets of option byte registers:

- The first register set contains the current values of the option bytes. Their names have the _CUR extension. All these registers are read-only. Their values are automatically loaded from the nonvolatile memory after power-on reset, wakeup from system standby or after an option byte change operation.

- The second register set allows the modification of the option bytes. Their names contain the _PRG extension. All “_PRG” registers can be accessed in read/write mode.

When the OPTLOCK bit in the FLASH_OPTCR register is set, modifying the FLASH_XXX_PRG registers is not possible.

When the OPTSTRT bit is set to 1, the memory checks the programming sequence (PGSERR) and the conditions described in *Section 7.4.8* (OPTCHANGEERR). If no error has been detected (PGSERR/OPTCHANGEERR), the flash memory launches the option byte modification and updates the option byte registers with _CUR extension.

If one of the condition described in *Section 7.4.8*, *Section 7.9.12* or *Section 7.9.5*, alternatively *Section 7.9.4* is not respected, the memory aborts the option byte change operation. In this case, the FLASH_XXX_PRG registers are not overwritten by the current option value. The user application can check what was wrong in their configuration.

Unlocking the option-byte modification

After reset, the OPTLOCK bit is set to 1 and the FLASH_OPTCR is locked. As a result, the application software must unlock the option configuration register before attempting to change the option bytes. The FLASH_OPTCR unlock sequence is described in *Section 7.6.7: Flash memory configuration protection*.

Option-byte modification sequence

To modify user option bytes, follow the sequence below:

1. Check that no flash memory operation is ongoing by checking the BSY bit in the FLASH_SR/SSR register, and that the write buffer is empty by checking the WBNE bit in the FLASH_SR/SSR register.
2. Check that the data buffer is empty (DBNE = 0) in the FLASH_SR/SSR register.
3. Clear all error flags due to a previous operation.
4. Unlock the FLASH_OPTCR register as described in *Section 7.6.7: Flash memory configuration protection*, unless the register is already unlocked.
5. Write the desired new option byte values in the corresponding option registers (FLASH_XXX_PRG).
6. Set the option byte start change OPTSTRT bit to 1 in the FLASH_OPTCR register.
7. Wait until BSY bit is cleared in the FLASH_SR/SSR register.
8. The OPTSTRT bit is cleared automatically at the end of the sequence (or in case of an error).
9. Reset the device. This step is always recommended, and even mandatory when one of the following option bytes is impacted:
   a) BOOTADDR
   b) SBOOTADD
   c) TZEN
   d) BOOT_UBE

Note: If a reset or power-down occurs while the option byte modification is ongoing, the original option byte value is kept. A new option byte modification sequence is required to program it.

7.4.4 Option-byte overview

Table 47 lists all user option bytes managed through the memory registers, as well as initial values before the first option byte change (production values configuration).

Table 47. Option-byte organization

7.4.5 Description of user and system option bytes

The general-purpose option bytes that can be used by the application are listed below:

- Watchdog management
  - IWDG_STOP: independent watchdog IWDG counter active in Stop mode if 1 (stop counting or freeze if 0)
  - IWDG_STDBY: independent watchdog IWDG counter active in Standby mode if 1 (stop counting or freeze if 0)
  - IWDG_SW: hardware (0) or software (1) IWDG watchdog control selection

Note: If the hardware watchdog "control selection" feature is enabled (set to 0), the watchdog is automatically enabled at power-on, thus generating a reset unless the watchdog key register is written into or the down-counter is reloaded before the end-of-count is reached.

Depending on the configuration of IWDG_STOP and IWDG_STDBY options, the IWDG can continue counting (1) or not (0) when the device is, respectively, in Stop or Standby mode. When the IWDG is kept running during Stop or Standby mode, it can wake up the device from these modes.

- Reset management
  - NRST_STDBY generates a reset when entering Standby mode if cleared to 0.
  - NRST_STOP generates a reset when entering Stop mode if cleared to 0.

Note: Whenever a Standby (Stop) mode entry sequence is successfully executed, the device is reset instead of entering Standby (Stop) mode if NRST_STDBY (NRST_STOP) is cleared to 0.

- Bootloader configuration
  - After OBL, if the STMicroelectronics bootloader is activated, it reads the contents of BL_COM_CFG and only attempts to establish communication on selected interfaces. This setting allows using the bootloader safely in applications where it would otherwise cause trouble by reconfiguring some GPIOs.

At delivery, the values programmed in the user option bytes are the following:

- Watchdog management
  - IWDG (also known as WDGLS_CD) active in Standby and Stop modes: 0x1
  - IWDG (also known as WDGLS_CD) not automatically enabled at power-on: 0x1
- All bootloader interfaces enabled

Refer to *Section 7.11: FLASH registers* for details.

7.4.6 Description of data protection option bytes

The option bytes that can be used to enhance data protection are listed below:

- PRODUCT_STATE[7:0]: a product life cycle state (see *Section 7.6.11: Product state transitions* for details).
- WRPGn1/2: write protection option of the corresponding group of four consecutive pages in Bank1 (respectively Bank2). It is active low. Refer to *Section 7.6.8: Write protection* for details.
  - Bit N: Group embedding pages 4 x N to 4 x N + 3
  - Number of bits configurable depends on the total user flash size
- SECWMx: TrustZone® secure-only watermark area definition (refer to *Section 7.6.1: TrustZone® security protection* for details).
  - STRT (respectively END) contains the first (respectively last) page of the secure access only zone in Bankx.
  - The number of configurable bits depends on the total user flash memory size.
- TZEN: this nonvolatile option can be used to deactivate the secure access mode, as described in *Section 7.6: FLASH security and protections*. For security reasons, the TZEN is stored with redundancy on eight bits. While the TZEN OB value is set

immediately after programming, to actually disable the isolation, a reset is required to set the TZ_STATE in SBS.

When TZEN is changed, the secure watermark settings and secure boot address may be reset to default to prevent a deadlock in case the previous values were incorrect.

- HDPx: secure hide protection - HDPL exclusive area control in the user flash memory.
  - The number of configurable bits depends on the total user flash memory size.

The factory-programmed values of the data protection option bytes are the following:

- Flash bank erase operations do not impact watermarked secure data areas.
- Secure watermark area protections are disabled (the start addresses is higher than the end addresses).
- Write protection is disabled (all option byte bits set to 1).
- TrustZone® secure access mode is enabled (TZEN option byte value = 0xB4).

Refer to *Section 7.11: FLASH registers* for details.

7.4.7 Description of boot address option bytes

The option bytes that can be used to configure the appropriate boot address for an application are listed below:

- PRODUCT_STATE
- BOOT_UBE: available only on cryptography-enabled devices.
  Selects either STiRoT or the user flash memory as the default boot address. Also used by RSS(SFI) to choose either the bootloader or STiRoT as the next stage.
- BOOTADD: selects the default boot address when TZ is disabled.
- SBOOTADD: selects the default boot address when TZ is enabled.
- BOOT_LOCK/SBOOT_LOCK: protects the boot configuration from further modification attempts.
- SWAP_LOCKOUT: reset value for the SWAP_LOCK setting in the SBS. If engaged, bank swapping is disabled.
- SWAP_BANK: bank swapping option, set to 1 to swap user flash banks after boot. If SWAP_LOCK is active in the SBS, the value in SWAP_BANK is locked out from modification until reset.

When STMicroelectronics delivers the device, the PRODUCT_STATE is Open, BOOT_LOCK/SBOOT_LOCK is not set (0xC3) and the BOOT_UBE is set to the user flash memory (0xB4). Addresses are SBOOTADD = 0x0C00 0000, BOOTADD = 0x0800 0000.

Refer to *Section 7.11: FLASH registers* for details.

7.4.8 Specific rules for modifying option bytes

On top of OPTLOCK bit and register access rules, other protective means for selected security-sensitive option byte fields are in place.

Multiple option bytes can be modified simultaneously, but if they rely on each other for protection, both states are checked. For example, when trying to modify PRODUCT_STATE and TZEN simultaneously, the resulting state must be coherent with the rules. With a few exceptions, listed in this section, failing to uphold the rules results in raising the OPTCHANGEERR flag (*Section 7.9.12* for additional details).

Table 48. Specific OB modifying rules

Option byte	HDPL	TZ secure	Value	Product state
PRODUCT_STATE	1(1)	Some values only when TZ is enabled	Set of possible transitions	Set of possible transitions (*Table 39*)
HDP	1(2)	(3)	-	Refer to *Table 49*
TZEN	-	-	-	Regression, Open, or Provisioning
EPOCH (secure)	0	-	PRG > CUR	Regression
EPOCH	-	-	PRG > CUR	NS-Regression, Regression
SECWM	-	Secure mode only	-	Refer to *Table 49*
BOOT_UBE	-	-	-	Open or Provisioning, SBOOT_LOCK
SBOOTADD	-	Secure mode only(2)	-	
BOOTADD	-	-	-	Open or Provisioning, BOOT_LOCK disabled
BL_COM_CFG	-	-	-	Open or Provisioning, both BOOT_LOCK/SBOOT_LOCK disabled
LOCKBL	-	-	One way switch	-
SWAP_LOCKOUT	-	-	-	Open or Provisioning
SWAP_BANK	-	-	Fixed if SWAP_LOCK is set	-
SBOOT_LOCK	-	Secure mode only	-	Open, Regression, or Provisioning to unlock
BOOT_LOCK	-	-	-	

1. Most transitions are possible regardless of HDPL, only a few require specific HDPL, see text below.
2. No OPTCHANGEERR raised in violation of this.
3. Dash means there is no limitation from this side.

Even in the closed PRODUCT_STATE progression, some OBs can still be modified, if all the other constraints are satisfied. An overview is presented in *Table 49*.

Table 49. OB modifiable in closed product

PRODUCT_STATE	Modifiable OBs
TZ-Closed	SWAP_BANK, LOCKBL, PRODUCT_STATE, SECWM, HDP
Closed	SWAP_BANK, LOCKBL, PRODUCT_STATE
Locked	SWAP_BANK, LOCKBL

Specific rules must be respected to update the following OB:

- **PRODUCT_STATE**

  PRODUCT_STATE transitions follow a state machine with two types of transition. Locking down the product is allowed without restriction. Opening the product is possible only when using a debug interface and following a digital signature

verification. The regression to a less secure state results in the erasure of the protected content. More details are given in *Section 7.6.11: Product state transitions*.

Summary: Selected changes are only possible in HDPL1. Some states are accessible only when TZEN is enabled.

- **HDP**

  Can only be modified in HDPL1. Must not be set to overlap with the flash high-cycle data area.

- **TrustZone® access mode (TZEN)**

  Can only be changed in Open, Regression, and Provisioning.

- **SEPOCH and EPOCH**

  The value programmed must be greater than current value.The increment is done in specific product states: Regression and NS-Regression.

- **Secure watermark area (SECWM1/2 STRT and END)**

  Can be changed only in secure mode (TZ_state = 0xB4). Automatically reset to default value when TZEN is enabled. Must not be set to overlap with flash high-cycle data area.

- **BOOT_UBE**

  Available only on cryptography enabled devices.
  Can only be changed in product states open for debug, like Open, and also in Provisioning. BOOT_LOCK must be disabled to change.

- **SBOOTADD**

  Can only be changed in Open and Provisioning. Locked by SBOOT_LOCK. Automatically reset to default value when TZEN is enabled.

- **BOOTADD**

  Can only be changed in Open and Provisioning. Locked by BOOT_LOCK.

- **LOCKBL**

  Can only be changed freely in one direction. A permanent irreversible switch.

- **SWAP_BANK**

  Not modifiable when SWAP_LOCK is 0xB4 (set) in the SBS.

- **SWAP_LOCKOUT**

  Can only be changed in Open and Provisioning. If engaged, modification of SWAP_BANK and FB_MODE is locked out (not possible) and the controls remain in default state.

- **SBOOT_LOCK**

  Can only be changed freely in locking direction. Unlock is possible in Open, Provisioning, and Regression.

- **BOOT_LOCK**

  Can only be changed freely in locking direction. Unlock is possible in Open, Provisioning, and Regression.

Note: For all user option bytes above, the default values are loaded and Tamper is signaled when a double ECC error occurs during OBL.

7.5 Option-byte key management

This section describes the key storage tied with the SAES and OBK-HDPL value set by the SBS (refer to *Section 14.3.8: SBS hardware secure storage control*). The OBKs are stored in 128 bits and protected by a 9-bit ECC (SECDED). They are written alternatively in two pages.

7.5.1 OBK loading

OBKs are memory-mapped and accessible through the main AHB bus (C-Bus), starting from the address 0x0FFD 0000. A 9-bit ECC complements each 128-bit data flash word.

Note: Read access is allowed in the current and alternate page, except for the last address of the current and alternate page. In case of a read access, no error is reported but the read data is always 0x0 (see Section 7.6.12: OBK protection).

7.5.2 OBK access per HDPL level

Table 50 describes the option-byte key areas. The key storage is not dedicated to a particular key, and the usage is defined by the application.

An option-byte key can be accessed only if the OBK-HDPL (set in SBS) matches the HDPL associated with the storage offset, as indicated below (refer to *Section 14.3.8: SBS hardware secure storage control*). If this is not the case, an OBKERR error is raised.

Table 50. Option-byte key area

OBK-HDPL	Address offset start	Address offset end	Comment
-	0x0000	0x00FF	Reserved
1	0x0100	0x08FF	OEM iRoT keys
2	0x0900	0x0FFF	uRoT, OS, or secure application
3	0x1000	0x17FF	HDPL 3 secure keys
3	0x1800	0x1FEF	HDPL 3 nonsecure keys

7.5.3 OBK programming sequence

The sequence to write OBK is the same as a write operation to the main flash memory, except that the “alternate page” (ALT_SECT) bit must be set to write in the alternate OBK page. The ALT_SECT bit is checked each time a write access request is received. If it does not match the one stored in the write buffer, an error is raised.

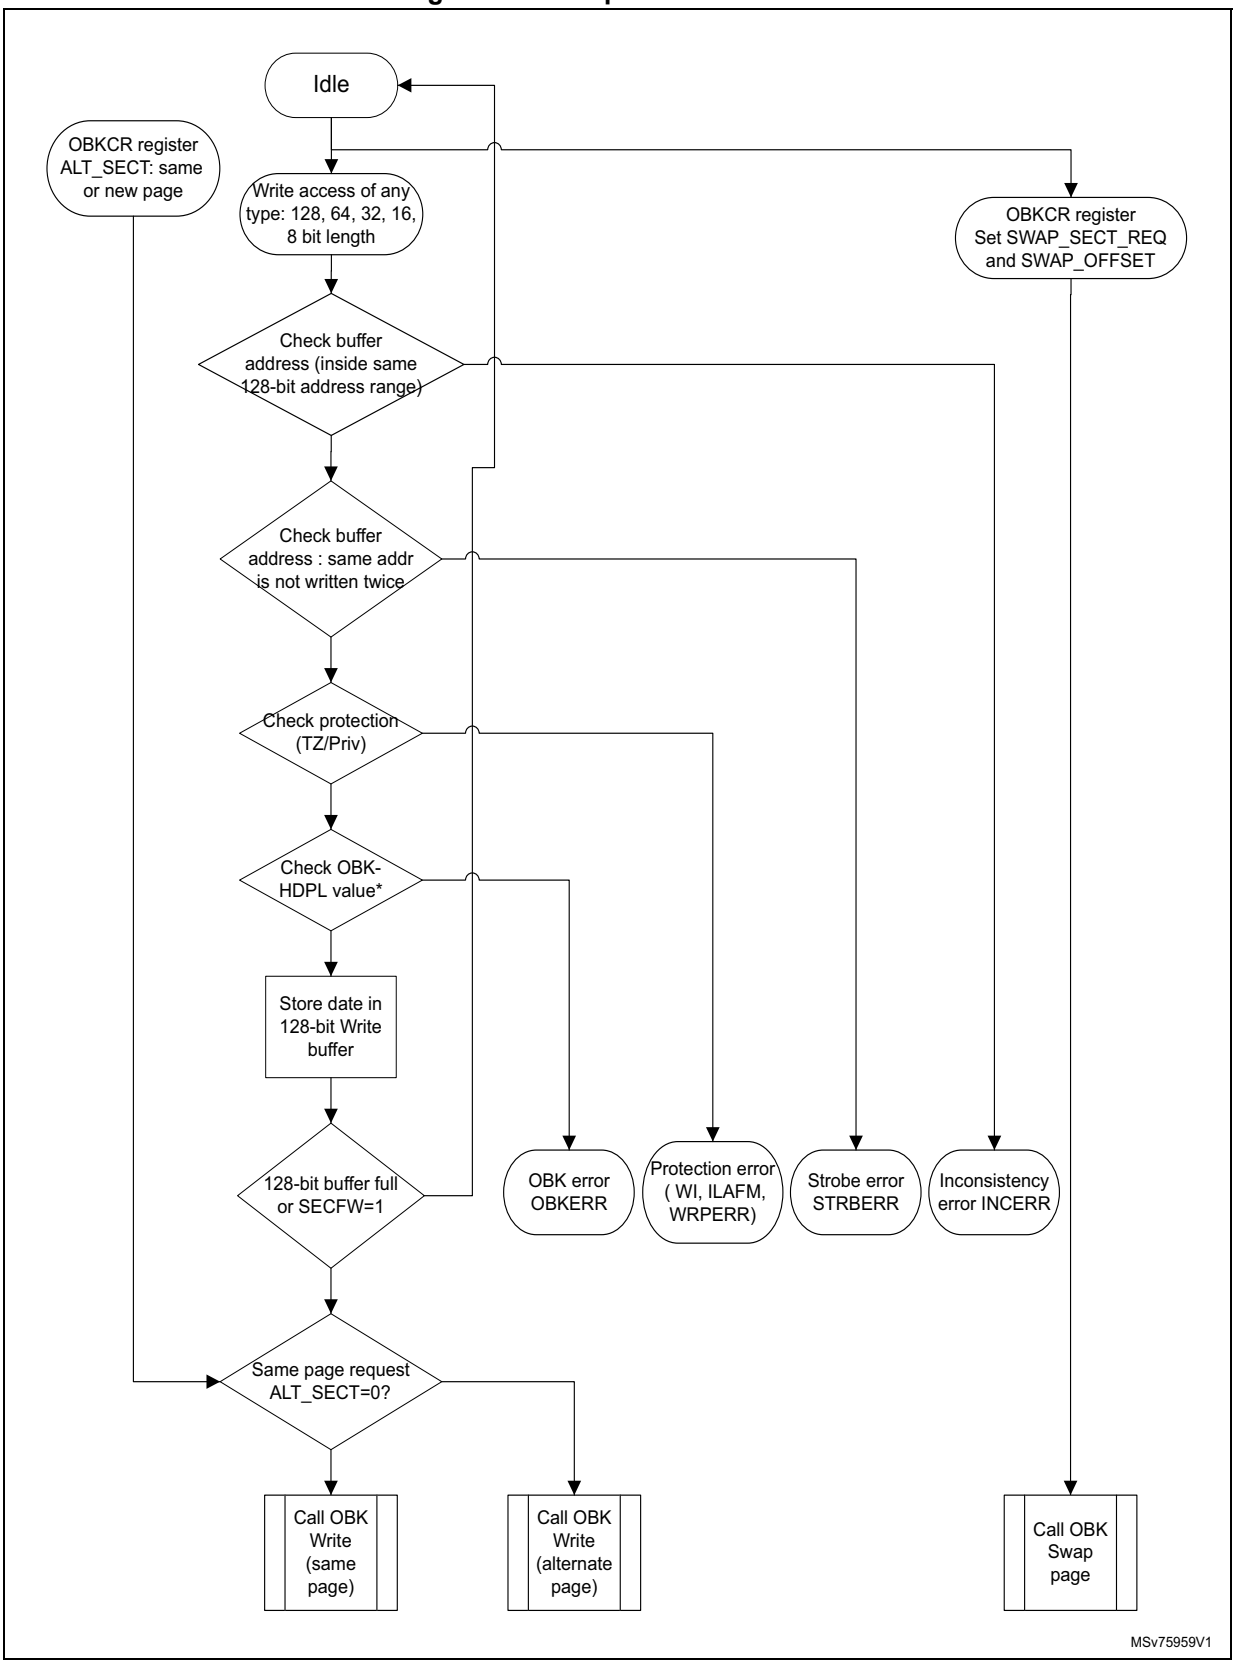
Note: Before writing in the alternate OBK page, the user must ensure that the entire key space (128, 256, or 512 bits) is free by reading the alternate OBK page.

If the alternate page is not free, erase the page using the ALT_SECT_ERASE command.

Secure programming method

Using the secure register if TrustZone® is active (TZ_STATE = 0xB4):

1. Program the ALT_SECT bit.
2. Make sure protection mechanism does not prevent programming (TZ, PRIV and OBK-HDPL).
3. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SSR register.
4. Check and clear all secure error flags due to previous operation.
5. Unlock the FLASH_SCR register only if this register is not already unlocked, as described in *Section 7.6.7: Flash memory configuration protection*.
6. Enable write operations by setting the SECPG bit in the FLASH_SCR register.
7. Write one flash-word corresponding to 16-byte data starting at a 16-byte aligned address.



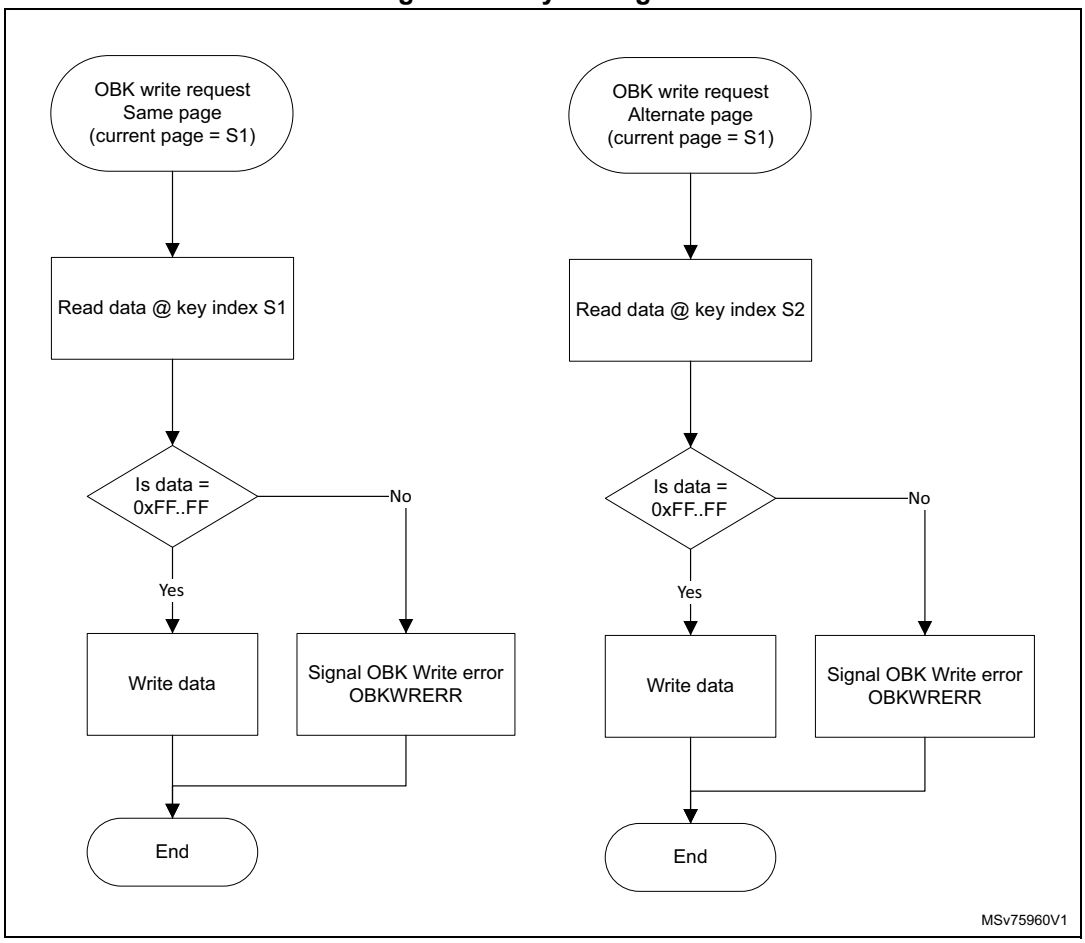
Note: The WBNE flag indicates if the 128-bit write buffer is waiting for new data.

Note: No erase request, options change request, OBK swap page, or OBK alternate page erase is allowed between the first write and the completion of a flash write operation.

8. Wait for the BSY bit to be cleared in the corresponding FLASH_SSR register.
9. Clear the PG bit in the FLASH_SCR register if there is no further programming requests in the bank.

If step 7 is executed incrementally (byte per byte), the write buffer can become partially filled. In this case, the application software can decide to force-write what is stored in the write buffer by using the FW bit in the FLASH_SCR register. In this particular case, the unwritten bits are automatically set to 1. If no bit in the write buffer is cleared to 0, the FW bit has no effect.

Figure 26. OBK protection checks



7.5.4 OBK programming finite state machine

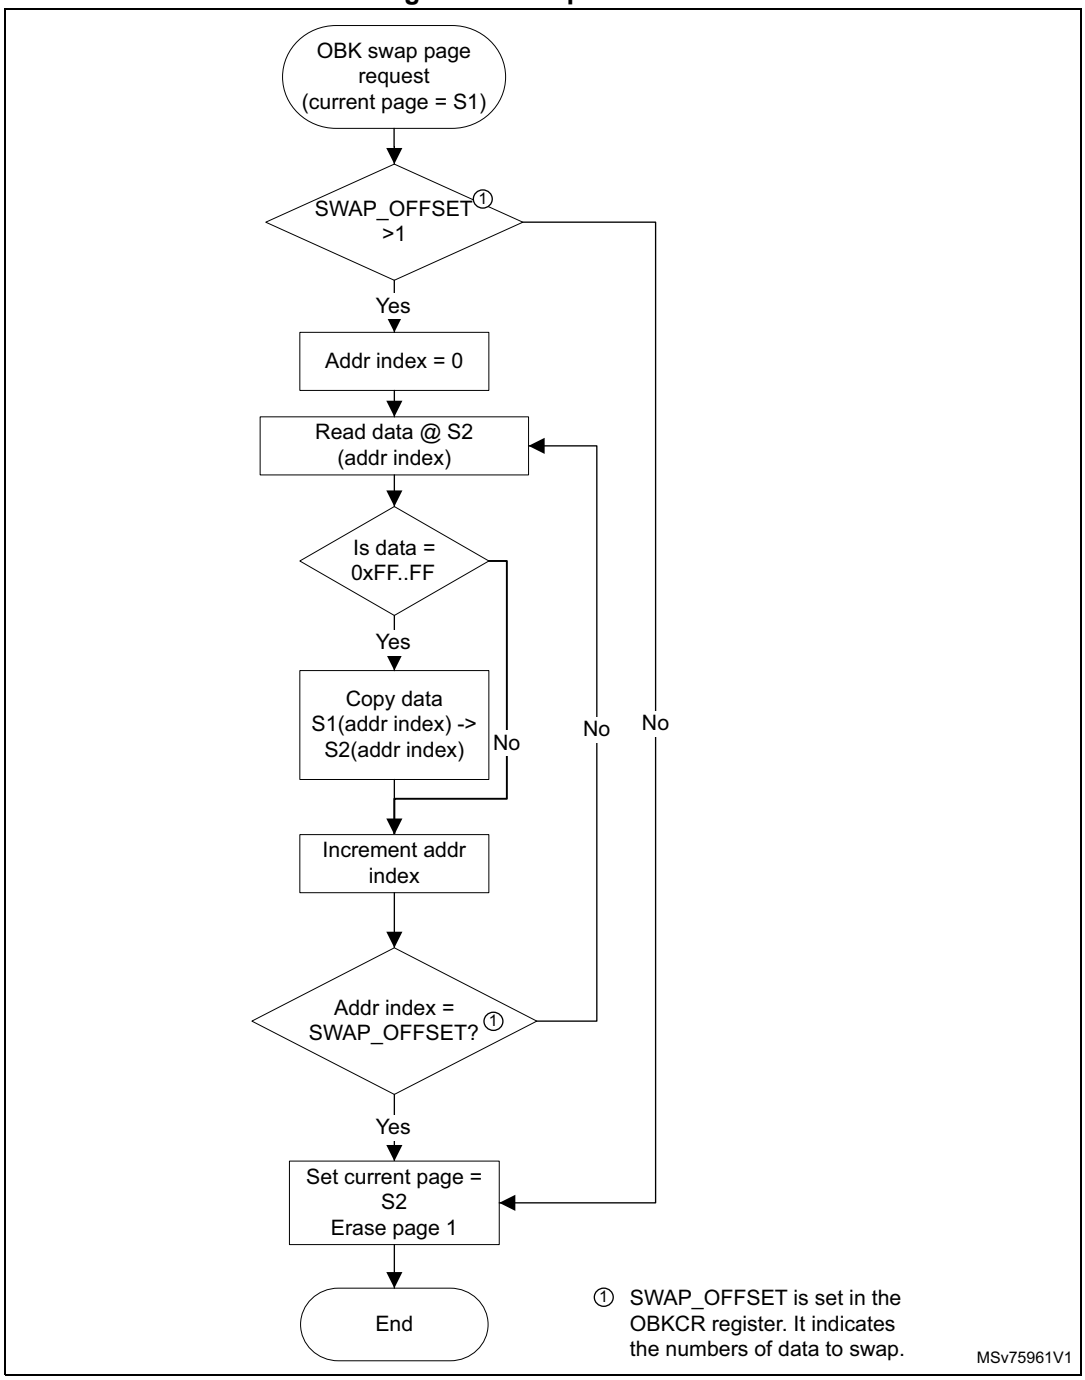
When the OBK write buffer is filled, the OBK programing is launched automatically either in the current OBK page or in the alternate OBK page, depending on the ALT_SECT bit.

If the address is not virgin, the OBKWRERR is raised.

Figure 27. Key writing flow

7.5.5 OBK swap page

The user can request a swap of the option byte keys by setting the bit SWAP_SECT_REQ in the FLASH_OBKCFGR/SOBKCFGR register. The number of keys swapped are defined by the SWAP_OFFSET value in the FLASH_OBKCFGR/SOBKCFGR register.



The swap is limited by the OBK-HDPL value and only the following SWAP_OFFSET values are permitted:

- OBK_HDPL1_OFFSET = 144
- OBK_HDPL2_OFFSET = 256
- OBK_HDPL3SEC_OFFSET = 384
- OBK_HDPL3NS_OFFSET = 511

The programming sequence is the following:

1. Check that no flash memory operation is ongoing by checking the BSY and DBNE bit in the FLASH_S/NSSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_S/NSSR register.
2. Check and clear all secure/nonsecure error flags due to previous operations.
3. Unlock the OBKCFGR/SOBKCFGR register if not unlocked already by using FLASH_OBKKEYR/SOBKKEYR.
4. Define the numbers of keys to be swapped with the SWAP_OFFSET field in FLASH_OBKCFGR/SOBKCFGR. SWAP_OFFSET must be equal to or greater than OBK_HDPL<N-1>_OFFSET.
5. Set the SWAP_SECT_REQ bit in the FLASH_OBKCFGR/SOBKCFGR register.
6. Wait for the BSY bit to be cleared. In case of an error, the OBKERR flag is raised.
7. SWAP_SECT_REQ is cleared automatically at the end of the operation or in case of an error.

Figure 28. Swap workflow

While the OBK swap operation is ongoing, the BSY flag is set and no other operation (write, erase, user option change) can be launched simultaneously.

7.5.6 OBK alternate page erase

The user can request the erasure of the alternate OBK page by setting the ALT_SECT_ERASE bit in the FLASH_OBKCFGR/SOBKCFGR register.

The programming sequence must be:

1. Check that no flash memory operation is ongoing by checking the BSY and DBNE bits in the FLASH_SR/SSR register and that the write buffer is empty by checking the WBNE bit in the FLASH_SR/SSR register.
2. Check and clear all secure/nonsecure error flags due to previous operations.
3. Set the ALT_SECT_ERASE bit in the FLASH_OBKCFGR/SOBKCFGR register.
4. Wait for the BSY bit to be cleared.
5. ALT_SECT_ERASE is cleared automatically at the end of the operation or in case of an error.

7.6 FLASH security and protections

To protect sensitive information from unwanted operations (such as reading confidential areas, illegal programming of immutable pages, or malicious flash memory erasing), the FLASH implements the following protection mechanisms:

- TrustZone®-backed watermark and block security protection
- Temporal isolation protection (HDP)
- Configuration protection
- User flash write protection
- Device nonvolatile security life cycle and application boot state management
- OTP locking

The microcontroller can have TrustZone® active (TZ_STATE = 0xB4) or inactive (TZ_STATE = 0xC3).

When TrustZone® is enabled, the flash memory can be accessed in four basic modes:

- nonsecure and unprivileged
- nonsecure and privileged
- secure and privileged
- secure and unprivileged

When TrustZone® is disabled, only two modes are possible:

- nonsecure and unprivileged
- nonsecure and privileged

The flash memory interface evaluates the access restrictions in the following order:

1. TrustZone® security
2. Write protection (for write access)
3. HDP
4. Privilege

7.6.1 TrustZone® security protection

The global TrustZone® system security is activated by default, using the setting TZEN in the FLASH_OPTSR2_PRG register. However, the actual state of TZ is determined by the SBS and the setting of TZ_STATE (refer to *Section 14.3.6: SBS boot control*).

When TrustZone® is active (TZ_STATE = 0xB4), the following additional security features are available:

- Secure watermark-based user options bytes defining secure areas.
- Secure or nonsecure block-based areas can be configured on the fly after reset. This is a volatile secure area.
- Additional product states associated (TZ-Closed, NS-Regression) provide protection of the secure domain against external access (debug or bootloader).
- Erase or program operations can be performed in secure or nonsecure mode with an associated configuration bit. When TrustZone® is disabled (TZ_STATE = 0xC3), the features above are deactivated and all secure registers are RAZ/WI.
- The nonsecure access address space starts at 0x0800 0000 and the secure address space for the same physical memory starts at 0x1800 0000. The mapping is identical, but the address determines whether the TZ isolation allows or denies the memory access.

Active TrustZone® security

When TrustZone® is activated (TZ_STATE = 0xB4), the secure BOOTADD and the secure watermark areas are set to a secure default value. Default settings are also used in case of a corrupted configuration. In this default state, the user flash memory is secure as shown in the table below.

Table 51. Default secure watermark

Secure watermark in case of configuration error	Security attribute
STRT = 0 END = 0x1F	All flash memory is secure

Illegal access generation

Nonsecure access to a secure flash memory area is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the FLASHIE illegal access interrupt is enabled in the TZIC_IER2 register.

Nonsecure access to a secure flash register generates an illegal access event. An illegal access interrupt is generated if the FLASH_REGIE illegal access interrupt is enabled in the TZIC_IER2 register.

Table 52. Flash memory TZ protection summary

TZ protection (TZ_STATE = 0xB4)		Main flash	
		Nonsecure page	**Secure page**
Secure	Fetch	BUS ERROR	OK
	Read	RAZ, ILAFM	
	Write	WI, WRPERR, ILAFM	If not WRP: OK else: WI, WRPERR
	Erase		
Nonsecure	Fetch	OK	BUS ERROR
	Read		RAZ, ILAFM
	Write	If not WRP: OK else: WI, WRPERR	WI, WRPERR, ILAFM
	Erase		

Table 53. TZ protection and bank or mass erase summary

TZ protection (TZ_STATE = 0xB4)	**Main flash**		
	Nonsecure flash	**Secure flash**	**Mix of secure and nonsecure**
MES	WI, WRPERR, ILAFM	OK	WI, WRPERR, ILAFM
MENS	OK	WI, WRPERR, ILAFM	WI, WRPERR, ILAFM

Deactivated TrustZone® security

Reversing the TZ setting in OB (TZEN) is possible when the product state is Open or Provisioning. Deactivating TZEN from other states requires full regression (Regression state).

When TrustZone® is deactivated (TZ_STATE = 0xC3) after option bytes loading, the following security features are deactivated:

- Watermark-based secure area (refer to *Watermark-based secure flash area protection*)
- Block-based secure area (refer to *Section 7.6.3: Block-based secure flash memory area protection*)
- Secure interrupts (refer to *Section 7.9.11: Illegal access (ILAFM/ILAP)*)
- All secure registers are RAZ/WI.

Watermark-based secure flash area protection

When TrustZone® security is active (TZ_STATE = 0xB4), a part of the flash memory can be protected from nonsecure read and write access operations. Up to two different nonvolatile secure areas can be defined by option bytes and can be read or written by a secure access operation only: one area per bank can be selected with a page granularity.

The secure areas are defined by a start page offset and end page offset using the respective STRT and END option bytes. These offsets are defined in the secure watermark registers address registers *FLASH security watermark for Bank1 (FLASH_SECWM1R_CUR)*, *FLASH security watermark for Bank2 (FLASH_SECWM2R_CUR)* and modified by corresponding FLASH_XXX_PRG registers.

The STRT and END option bytes can only be modified by secure firmware.

Table 54. Secure watermark-based area

Secure watermark option bytes values (x = 1,2)	Secure watermark protection area
STRT > END	No secure area
STRT = END	One page defined by STRT is secure watermark-based protected
STRT < END	The area between STRT and END is secure watermark-based protected

Caution: Switching a memory area from secure to nonsecure does not erase its content. The user secure software must perform the needed operation to erase the secure area before switching an area to nonsecure whenever needed. It is also recommended to flush the instruction cache.

7.6.2 Hide protection (HDP)

The HDP area is independent of the flash watermark-based secure area. One nonvolatile secure hide protection (HDP) area per bank can be defined with a page granularity. Access to the hide protection area can be denied by progressing the HDPL level in the SBS.

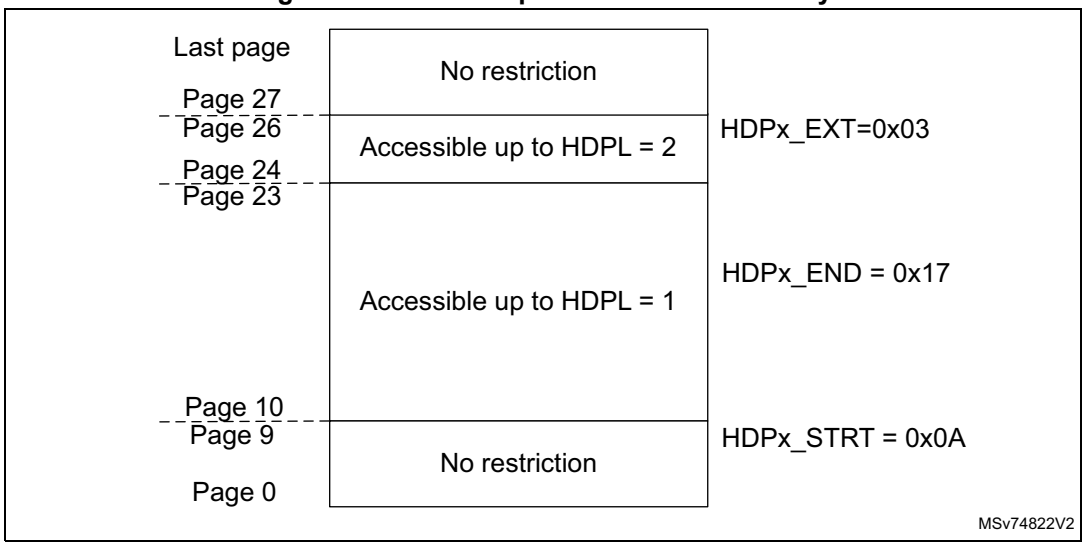
When the HDPL = 1, no user flash memory is protected by the HDP. With HDPL ≥ 2 the user-OB-defined HDP area in each bank is closed. No read, write, fetch, or erase operation is allowed in the HDP area.

The HDP area can be extended. The extension setting is only a register value, not stored in OB. With HDPL = 3, the HDP area remains activated and the extension is added. If extension is added while the base user-OB-defined area is inactive, the extension covers one more page, because the END page is also protected.

The HDPL level can only be cleared by a system reset; there is no means to deactivate the HDP area.

The protected HDP area is defined by setting its size using start and end pages in a similar way as the secure watermark.

The size of the inaccessible area can be extended using register FLASH_HDPEXTR values HDPx_EXT. The value HDPx_EXT is a number of pages added to the HDP area (past the END page). The volatile HDPx_EXT value in the register can be increased but not decremented.



In case of STRT > END, the extension covers the (HDPx_EXT + 1) size area between pages marked by END and END + HDPx_EXT.

By default (from production), END is set to 0 and STRT is set to 1. This means that the HDP area in the user flash memory is size zero and extends from the flash memory start address (first page).

For example, to protect area by HDP from the address 0x0801 4000 (included) to the address 0x0802 FFFF (included):

- For physical Bank1, the FLASH_HDP1R must be programmed with:
  - STRT = 0x0A
  - END = 0x17

Figure 29. HDP example in user flash memory

- Once the HDPL is incremented to 2, the marked area becomes inaccessible. The HDPL = 2 code then sets the extension size to 3. Extension becomes inaccessible after HDPL is incremented to 3.
- Alternatively, in HDPL3 if:
  - END = 0, START = 1, HDPx_EXT = 1 page 0 and page 1 are HDP-protected.
  - END = 2, START = 7, HDPx_EXT = 3, pages 2 to 5 are HDP-protected (rather unusual example).
- If the two banks are swapped, the protection defined for physical Bank1 remains on the physical Bank1, unaffected by the swap. Separate protection applies to physical Bank2 and FLASH_HDP2R must also be programmed with:
  - STRT = 0x0A
  - END = 0x17

Note: For more details on the bank swapping mechanism, refer to Section 7.6.6: Flash memory bank attributes in case of bank swap.

Table 55. Secure hide protection

HDPx watermark option-byte values (x = 1, 2)		Hide protection area
HDPL ≤ 1	-	No inaccessible HDP area in user flash memory
HDPL = 2	END < STRT	No inaccessible HDP area in user flash memory
	END = STRT	Exactly one page is protected by HDP.
	END > STRT	The area between STRT and END is HDP protected.

Table 55. Secure hide protection (continued)

HDPx watermark option-byte values (x = 1, 2)		Hide protection area
HDPL = 3	END < STRT and HDPx_EXT = 0	No inaccessible HDP area in user flash memory
	END ≥ STRT or HDPx_EXT > 0	The area between min(STRT, END) and (END + HDPx_EXT) is HDP-protected.

Table 56. HDP protections summary

HDP protection	User flash			
	Access to OB HDP area		Access to EXT HDP area	
	HDPL 2 or 3	HDPL1	HDPL3	HDPL1or HDPL 2
Fetch	BUS ERROR	OK	BUS ERROR	OK
Read	RAZ		RAZ	
Write	WI, WRPERR	If not WRP: OK else: WI, WRPERR	WI, WRPERR	If not WRP: OK else: WI, WRPERR
Erase (mass erase)				

7.6.3 Block-based secure flash memory area protection

Any page can be programmed on-the-fly as secure or nonsecure using the block-based configuration registers. FLASH_SECBB1/FLASH_SECBB2 registers are used to configure the security attribute for pages in Bank1/Bank2 respectively.

When the page security attribute bit SECy[i] is set, the security attribute is the same as the secure watermark-based area. The secure page is accessible only by a secure access operation.

If the SECy[i] bit is set or reset for a page already included in a secure watermark-based area, the page keeps the watermark-based protection security attributes.

To modify a block-based page security attribute, it is recommended to:

- Check that no flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute SECy[i].

Caution: Switching a page from secure to nonsecure does not erase the content of the associated page. User secure software must perform the needed operations before switching to the nonsecure attribute:

- Erase page content.
- Invalidate the instruction cache.

Note: For SECy[i] access control, refer to Table 57.

Execution protection for the S-Bus (AHB register bus) is done in AHB decoder, not in the flash memory interface itself.

Table 57. Secure configuration block-based registers access conditions

Access			Corresponding page privileged status	Page setting in SECBBxR
Fetch	Secure/ nonsecure	Privileged/ unprivileged	-	BUS ERROR
Read			-	OK
Write	Secure	Privileged	-	OK
		Unprivileged	0	OK
			1	WI
	Nonsecure	Privileged/ unprivileged	-	WI, ILAP

7.6.4 Block-based privileged flash memory area protection

Any page can be programmed on the fly as privileged or unprivileged using the block-based configuration registers. The FLASH_PRIVBB1 and FLASH_PRIVBB2 registers are used to configure the privilege attribute for pages in Bank1/Bank2 respectively.

When the page privilege attribute PRIVy[i] bit is set, the page is accessible only for privileged access. An unprivileged page is accessible by privileged or unprivileged access.

To modify a block-based privilege attribution, it is recommended to:

- Check that no flash operation is ongoing on the related page.
- Add an ISB instruction after modifying the page security attribute PRIVy[i].

Caution: Switching a page from privileged to unprivileged does not erase the content of the associated page.

Table 58. Privilege protection summary

Access (TZ not relevant)		Main flash	
		Unprivileged page	Privileged page
Privileged	Fetch	OK	
	Read		
	Write		
	Erase		
Unprivileged	Fetch	OK	RAZ
	Read		
	Write		WI, WRPERR
	Erase		

Table 59. Privilege and mass or bank erase

Access (TZ state not relevant)	Main flash		
	Unprivileged FLASH	Privileged FLASH	Mix unprivileged and privileged FLASH
MEP	OK		
MENP	OK	WI, WRPERR	

Note: For PRIVy[i] access control, refer to Table 60 and Table 61.

Table 60. Privilege configuration register access conditions (TZ enabled)

Access			Corresponding page secure status(1)	Page setting access in PRIVBByR
Fetch	Privileged/ unprivileged	Secure/ nonsecure	-	BUS ERROR
Read			-	OK (all pages)
Write	Privileged	Secure	-	OK (all pages)
		Nonsecure	NS	OK (only the page corresponding to the bit)
			S	WI (only the page corresponding to the bit)
	Unprivileged	Secure/ nonsecure	-	WI

1. Either watermark or block-based.

Table 61. Privilege configuration register access conditions (TZ disabled)

Access		Page setting access in PRIVBByR
Fetch	Privileged/ unprivileged	BUS ERROR
Read		OK
Write	Privileged	OK
	Unprivileged	WI

7.6.5 Flash memory register privileged and unprivileged modes

The flash registers can be read and written by privileged and unprivileged access, depending on the SPRIV and PRIV bits in *FLASH privilege configuration register (FLASH_PRIVCFGR)*:

- When the SPRIV/PRIV bit is reset, all secure/nonsecure) flash registers can be read and written by both privileged or unprivileged access.
- When the SPRIV/PRIV bit is set, all secure/nonsecure flash registers can be read and written by privileged access only. Unprivileged access to a privileged register is RAZ/WI.

The registers related to key storage (FLASH_OBKCFGR, FLASH_SOBKCFGR, FLASH_OBKKEYR, FLASH_SOBKEYR) are exceptions to this rule and can only be accessed in privileged mode, regardless of other settings.

The table below summarizes flash registers access control.

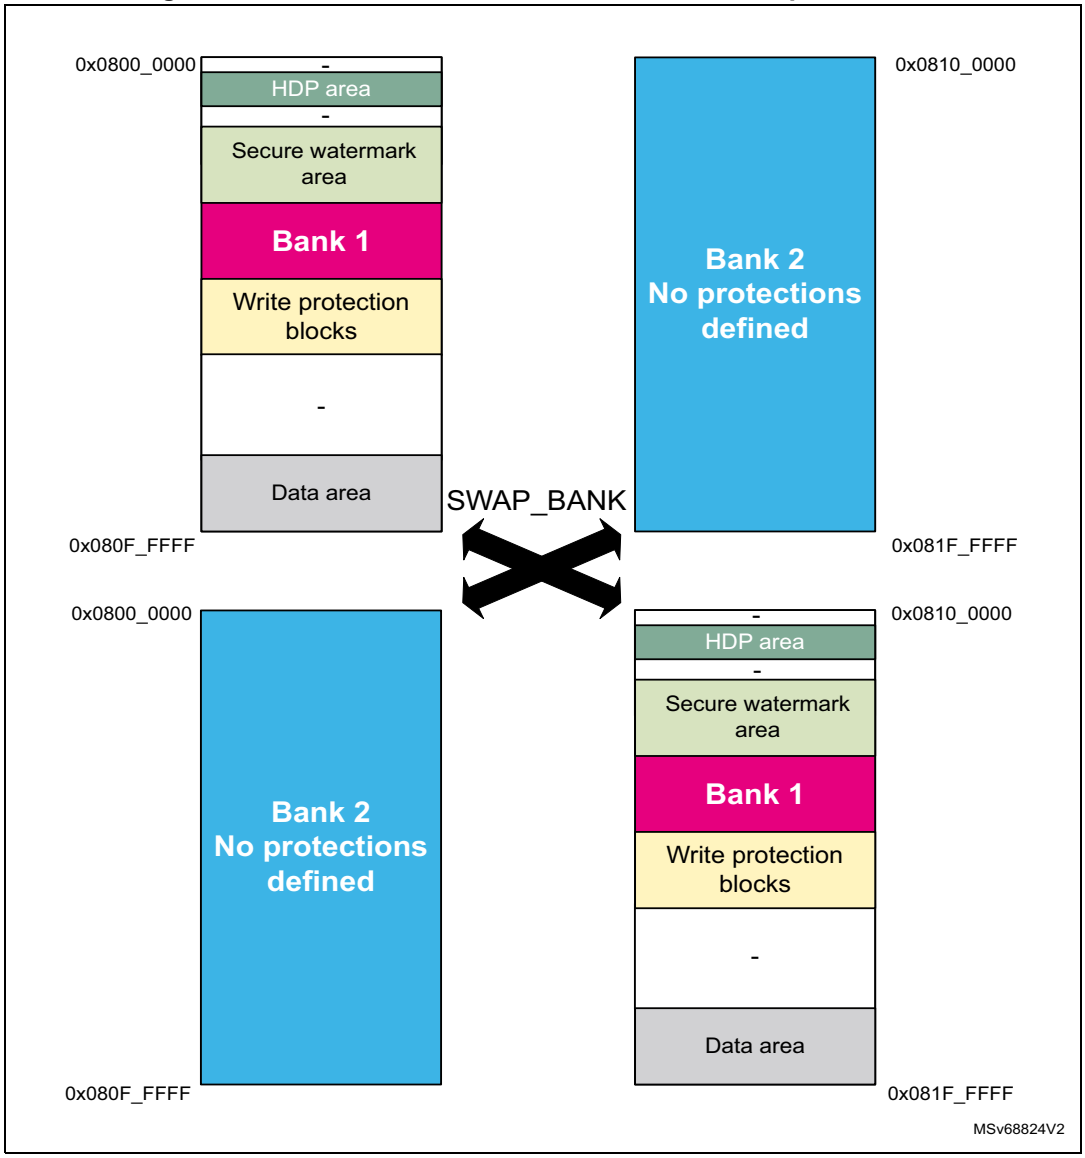
Table 62. Flash register accesses(1)

Access			Nonsecure register		Secure register	
			PRIV = 1	PRIV = 0	SPRIV = 1	SPRIV = 0
X	Secure/ nonsecure	Privileged/ unprivileged	Bus error			
R/W	Secure	Privileged	OK			
R/W		Unprivileged	RAZ, WI	OK	RAZ, WI	OK
R/W	Nonsecure	Privileged	OK		RAZ, WI, ILAP	
R/W		Unprivileged	RAZ, WI	OK		

1. Some registers are privilege only and not configurable.

7.6.6 Flash memory bank attributes in case of bank swap

The FB_MODE setting in SBS modifies the address of each bank in the memory map. When not active, flash Bank1 is mapped at the lower address range. FB_MODE reset value is controlled by the SWAP_BANK option byte, controlled in FLASH_OPTSR3. When FB_MODE is set, flash Bank1 is mapped at the higher address range. Flash bank attributes follow their bank contents so there is no need to modify their setting registers when swapping banks:



- Flash secure watermark x FLASH_SECWMx
- Flash write protection page group FLASH_WRPG (refer to *Section 7.6.8: Write protection*)
- Hide protection in FLASH_HDPx registers
- Flash secure block based bank x register FLASH_SECBBxR
- Flash privilege block based bank x register FLASH_PRIVBBxR
- The data area configuration FLASH_EDATAx

The SWAP_BANK is rendered immutable by setting SWAP_LOCKOUT in the user OB. This sets the reset value for SWAP_LOCK in the SBS that locks the SWAP_BANK option.

Note: The BK_ECC bit in the FLASH ECC detection register (FLASH_ECCDETR) and FLASH ECC correction register (FLASH_ECCCORR), BKSEL bit in FLASH nonsecure control register (FLASH_CR) and BKSEL bit in FLASH secure control register (FLASH_SCR) always refers to Bank1 (respectively Bank2) when it is low (respectively high), regardless of the SWAP_BANK value.

Figure 30 below shows how security attributes and protections behave in case of bank swap.

Figure 30. Protection attributes in case of bank swap illustration

7.6.7 Flash memory configuration protection

The memory uses hardware mechanisms to protect the following assets against unwanted or spurious modifications (such as software bugs):

- Option bytes change
- Write operations
- Erase commands
- Interrupt masking

The memory configuration registers protection is summarized in *Table 63*. Registers not present in this table are not protected by a key.

Table 63. Flash interface register protection summary

Register name	Unlocking register	Protected asset
FLASH_CR	FLASH_KEYR	Write/erase control
FLASH_SCR	FLASH_SKEYR	Secure write/erase control
FLASH_OPTCR + all _PRG registers	FLASH_OPTKEYR	Flash bank option byte words change
FLASH_OBKCFGR	FLASH_OBKKEYR	Flash OBKey storage manipulation
FLASH_SOBKCFGR	FLASH_SOBKKEYR	

7.6.8 Write protection

The purpose of write protection is to prevent unwanted modifications to code and/or data.

Any flash group of four consecutive 8-Kbyte pages can be independently write-protected or unprotected by clearing/setting the corresponding WRPGn1/2 bit in the FLASH_WRPG1/2 register (see *FLASH write page group protection for Bank1 (FLASH_WRP1R_CUR)* and *FLASH write page group protection for Bank2 (FLASH_WRP2R_CUR)*).

A write-protected group of pages cannot be erased nor programmed. As a result, a bank erase cannot be performed if one group of pages is write-protected, unless an PRODUCT_STATE transition to OPEN is triggered (erasing the entire user flash memory).

Note: Write protection errors are documented in Section 7.9: FLASH error management.

7.6.9 Flash high-cycle data protections

The embedded flash memory can be configured to have up to 96-Kbyte memory area with high-cycling capability (100 kcycles) to store data and emulate EEPROM (see *Section 7.3.11*).

Option-byte controlled security features for user flash memory prevent pages from being used as high-cycle data area. No OPTCHANGEERR is raised in case of setting conflict, it only makes the pages unusable. Details are listed in *Table 64*.

Volatile settings using FLASH_SECBBxR and FLASH_PRIVBBxR can be applied. In this case the security setting of user flash page 63 applies to flash high-cycle data page 0 and so on, as indicated in *Figure 19*, *Figure 24*, and *Figure 25*.

Volatile settings of HDP extension that extends into pages of data area causes the data area to be inaccessible.

Table 64. High-cycle area protection summary: access to data area address range

<table>
<tr><th colspan="2" rowspan="3">TZ protection (when TZ_STATE = 0xB4)(1)</th><th colspan="6">Data page enabled</th><th rowspan="3">Data page not enabled</th></tr>

7.6.10 Life cycle management

Nonvolatile or debug states are determined by the product state set by user option bytes. Debug possibility and the possibility to change selected security settings are related to it. While the state is stored in the OB, it is the SBS that controls the debug policy.

OBK storage access conditions are unaffected by the PRODUCT_STATE, but keys can be evicted in regression transitions.

HDP works equally regardless of the debug state. Even in debug the HDP area is hidden when HDPL increments.

The following states are defined:

Table 67. Product states, debug states, and debug policy

PRODUCT_STATE	Code in OB	Description
Open	0xED	User flash open (TZ secure and nonsecure open). External access (debug) N and NS enabled (~RDP0).
Provisioning	0x17	Provisioning - immutable root of trust is being installed. Open if TZEN = 0xC3.
iRoT-Provisioned	0x2E	The immutable root of trust is installed (~RDP 0.5).
TZ-Closed	0xC6	State for debugging the NS application. Debug is restrained to nonsecure areas.
Closed	0x72	State for running a secure application. Debug disabled, regression is possible.
Locked	0x5C	Transition to other state, policy change or debug not permitted(1).
Regression	0x9A	The temporary state initiated by the debug authentication system in transition to Open.
NS-Regression	0xA3	The temporary state initiated by the debug authentication system in transition to TZ-Closed.

1. The same situation is Closed state with incorrect or undefined debug certificates.

1. No debug protection

Read, program, and erase operations into the main flash memory area are possible. Least restriction on the option bytes.

2. Nonsecure debug only

All read and write operations (if no write protection is set) from/to the nonsecure flash memory are possible. Debug access to the secure area is prohibited. Debug access to the nonsecure area remains possible.

The following rules are enforced:

- User mode: code executing in user mode (boot flash) can access the main flash memory and option bytes with all operations (read, erase, program).
- Nonsecure debug mode: the secure flash memory areas are inaccessible; the nonsecure flash memory areas remain accessible for debug purposes.

- Boot RAM mode: boot from SRAM is not possible.
- Transition to Open state is possible with the consequence of a flash memory mass erase and key slot revocation, depending on the debug unlock policy (see below).

3. Full protection

All debug features are disabled and the following rules enforced:

- User mode: code executing in user mode (boot flash) can access the main flash memory and selected option bytes with all operations (read, erase, program).
- Boot RAM mode: boot from SRAM is not possible.
- Transition to TZ-Closed or Open state is possible with the consequence of a flash memory mass erase and key slot revocation, depending on the debug unlock policy (see below).

7.6.11 Product state transitions

Progressing to a more closed state is the normal product life cycle, that does not require security measures. Transitioning to an open state is a regression, controlled by the debug authentication control. If the debug unlock policy is set to “locked”, no regression is accepted. The locked state can be reinforced by invalidating the debug authentication certificates.

All transitions not listed in this chapter are invalid.

There is no restriction on reading the current product state.

Transitions in progress direction

The transition from Open to any of the closed states is a matter of correct product configuration and provisioning. The transitions must be done in the correct order.

The normal progressing order is:

- Open, Provisioning, or iRoT-Provisioned
- Provisioning to iRoT-Provisioned
- iRoT-Provisioned to Closed, Locked, or Closed
- Closed to Locked or Closed

The transition is managed either by software running on the device, or directly, using a debug interface. Transitions from Closed are only possible by software running on the device. By software it is assumed that transitions are triggered by the bootloader, or root-of-trust services, but generally any software running on the device can do a progression transition.

Transition to Open state

This transition is a full regression. The starting state can be any except Open and Locked. The debug tools are used to authenticate debug regression access rights with the debug authentication library, running on the device in HDPL1 (refer to *Section 14.3.7: SBS debug control*). After verifying the credentials, it puts the device in the intermediate Regression state. From this state, the device regresses securely to Open.

The transition has the following consequences:

- Epoch secure counter incremented
- Key slots revocation
- Product state updated
- User options updated (security settings reset, TZEN reset)
- Flash memory mass erase

Transition from closed to TZ-Closed debug state

This transition opens the device to authorize the debugging of the nonsecure application software without compromising the security of the RoT functions.

The starting state is Closed. The debug tools are used to authenticate debug regression access rights with the debug authentication library, running on the device in the HDPL1 (refer to *Section 14.3.7: SBS debug control*). After verifying the credentials, it puts the device into intermediate state NS-Regression. From this state, the device regresses securely in Closed.

The transition has the following consequences:

- Epoch nonsecure counter incremented
- Nonsecure slot revocation
- Product state updated
- Flash memory pages that are not covered by the secure watermark are erased

Table 68. PRODUCT_STATE transitions

From	To[1]							
	Open	Provisioning	iRoT-Provisioned	TZ-Closed[2]	Closed	Locked	Regression	NS-Regression[2]
Open	-	OK	OK	X	X	X	X	X
Provisioning	X	-	OK	OK	OK	OK	OK (HDPL1)	X
iRoT-Provisioned	X	X	-	OK	OK	OK	OK (HDPL1)	X
TZ-Closed	X	X	X	-	OK	OK	OK (HDPL1)	X
Closed	X	X	X	X	-	X	OK (HDPL1)	OK (HDPL1)
Locked	X	X	X	X	X	-	X	X
Regression	OK	X	X	X	X	X	-	X
NS-Regression	X	X	X	OK	X	X	X	-

1. X = transitions not permitted (OPTCHANGEERR raised), - = no change, OK = valid transitions.
2. To transition into this state, both current and programmed value of TZEN must be enabled (TZEN = 0xB4), otherwise the change is ignored with OPTCHANGEERR.

In *Table 68*, X indicates transitions that are not permitted, a dash indicates no change, and OK indicates valid transitions. Some transitions are possible only in one specific HDPL, provided in parenthesis. Attempts at an illegal transition result in OPTCHANGEERR.

An incorrect PRODUCT_STATE is interpreted as Locked.

7.6.12 OBK protection

At the receipt of an OBK access (read/write/execute), secure and privileged attributes are first checked, followed by OBK-HDPL. The OBK-HDPL value must exactly match the HDPL assigned to the key location, otherwise the OBKERROR flag is raised. The flash memory interface response is described in *Table 69*.

Table 69. TZ OBK protection summary

TZ protection (when TZ_STATE = 0xB4)	OBK access		
	No tamper		Tamper
	HDPL1/2/3	OBK selector	
XS	BUS ERROR	BUS ERROR	RAZ, WI
RS	OK if privileged, otherwise RAZ	RAZ

XNS	BUS ERROR	BUS ERROR	
RNS	RAZ, ILAFM	RAZ, ILAFM	
WNS	WI, WRPERR, ILAFM	WI, WRPERR, ILAFM	
Erase	NA	NA	NA

Table 70. OBK protection summary with TZ disabled

TZ protection (when TZ_STATE = 0xC3)	OBK access		
	No tamper		Tamper
	HDPL1/2/3	OBK selector	
XNS	BUS ERROR	BUS ERROR	RAZ, WI
RNS	OK if privilege, otherwise RAZ	RAZ	
WNS	OK if privilege, otherwise WI, WRPERR	WI if privilege, otherwise WI, WRPERR	
Erase	NA	NA	NA

Note: Cacheable access is managed at system level and not in the flash memory interface. The MPU must be configured to disable cache where it is not desirable.

In case of a tamper, all keys are read as 0x00.

There are also rules for accessing the OBKFGCR and OBKKEYR registers.

Table 71. Access conditions to secure control register

-	S/NS	P/NP	TZ state	SOBKCFGR and SOBKKEYR access
X	-	-	-	Bus error
R/W	S	P	Active	OK
R/W	S	NP	Active	RAZ, WI
R/W	NS	P	Active	RAZ, WI, ILAP
R/W	NS	NP	Active	RAZ, WI, ILAP
R/W	-	-	Deactivated	RAZ, WI

Table 72. Access conditions to nonsecure control register

	S/NS	P/NP	TZ state	OBKCFGR and OBKKEYR access
X	-	-	-	Bus error
R/W	-	-	Active	RAZ, WI
R/W	-	P	Deactivated	OK
R/W	-	NP	Deactivated	RAZ, WI

7.6.13 One-time-programmable and read-only memory protections

Sections of OTP/RO in the flash memory are described in detail in *Section 7.3.10*. There is no protection provided by the flash memory interface other than the dedicated write protection.

No write is possible to the RO area. *OTP write protection* describes a method of locking out the OTP area.

The access conditions are summarized in *Table 73*.

Table 73. OTP/RO access constraints

-	8 Kbytes page dedicated to RO/OTP			
	0x08FF_E000 - E7FF	**0x08FF_E800 - EFFF Reserved**	**0x08FF_F000 - F7FF OTP**	**0x08FF_F800 - FFFF RO**
XS	BUS ERROR	BUS ERROR		
RS		RAZ, ILAC		
WS		WI, WRPERR, ILAFM		
XNS	BUS ERROR	BUS ERROR		
RNS		If correct size(1) RAZ, else BUS ERROR	If correct size OK, else BUS ERROR	
WNS		If correct size WI, else BUS ERROR	BUS ERROR if incorrect size. WRPERR if block is protected by LOCKBL, else OK.	If correct size WI, else BUS ERROR
Erase	WI			

1. Word size is 16 bits. 32-bit access is possible. Any other access attempts lead to bus error.

7.7 System memory

7.7.1 Introduction

System memory stores RSS (root secure services) firmware programmed by STMicroelectronics during production. RSS provides runtime services to user firmware.

When TrustZone® is enabled (user sets the TZEN bitfield to 0xB4), RSS provides secure services to the secure user firmware only. When TrustZone® is disabled (user sets the TZEN bitfield to 0xC3), RSS provides nonsecure services to the user firmware.

7.7.2 RSS user functions

The RSS provides runtime services using the RSS library, whose functions are exposed to the user within the CMSIS device header file, provided by the STM32Cube firmware package.

RSS provides services through two different libraries, RSSLIB and NSSLIB, dedicated to secure user firmware when the system is configured, respectively, with TrustZone® enabled (TZEN bitfield set to 0xB4) and TrustZone® disabled (TZEN bitfield set to 0xC3).

Table 74. Macros for RSS services

TrustZone	C defined macro	Location in flash memory
Enabled	RSSLIB_PFUNC	0x0BFADB68
Disabled	NSSLIB_PFUNC	0x0BFADB6C

RSSLIB

The secure and nonsecure firmware can call RSSLIB functions:

- Secure firmware can call secure callable functions and nonsecure callable functions.
- Nonsecure firmware can only call nonsecure callable functions.

The user firmware calls the RSSLIB functions using RSSLIB_PFUNC C-defined macro, which points to a location within the nonsecure system memory. Before calling the RSSLIB functions, the secure user firmware must:

- Define a nonsecure region above this location within SAU of the Cortex®-M33 processor, starting from RSSLIB_SYS_FLASH_NS_PFUNC_START (0x0BFADB68) up to RSSLIB_SYS_FLASH_NS_PFUNC_END (0x0BFADB84).
- Define a nonsecure calleable region above the RSSLIB-NSC location within SAU of the Cortex®-M33 processor, starting from RSSLIB_NSC_BASE (0x0FF9E040) up to RSSLIB_NSC_END (0x0FF9E13F).
- Ensure that the RSSLIB is executable. The RSSLIB is located in the secure system flash address RSSLIB_BASE (0x0FF9E040) with a size of RSSLIB_SIZE (0x3FC0). These addresses and size are provided within the CMSIS device header file.

The user can configure the SAU regions either by using the CMSIS system partition header file, or by implementing their own code for SAU setup. The CMSIS system partition header file is part of the STM32Cube firmware package.

Table 75. RSS lib interface functions

Library	Function	Attributes
RSSLIB_PFUNC	JumpHDPLvl2	Secure callable function
	JumpHDPLvl3	
	JumpHDPLvl3NS	
	RSSLIB_DataProvisioning	Nonsecure callable function

RSSLIB_DataProvisioning

Secure attribute: nonsecure callable function.

Prototype:

```
uint32_t RSSLIB_DataProvisioning_(RSSLIB_DataProvisioningConf_t *pConfig)
```

Arguments:

`pConfig`: input parameter. **`RSSLIB_DataProvisioningConf_t`**

The C structure definition is described below:

```
typedef struct
{
  uint32_t *pSource;
  uint32_t *pDestination;
  uint32_t Size;
  uint32_t DoEncryption;
  uint32_t Crc;
} RSSLIB_DataProvisioningConf_t;
```

Structure elements

`pSource` Provides the address of the data to be provisioned. Must be within the SRAM1 address range (nonsecure aliases).

`pDestination` Provides the address where to store the data to be provisioned. Must be within the OBKeys address range. To be aligned on 16 bytes.

`Size` Provides the size of the data to be provisioned (the number of bytes, must be a multiple of 16).

`DoEncryption` Notifies RSSLIB_DataProvisioning function if it must encrypt or not the data within OBKeys.

DoEncrypt can be either 0xF5F5A0AAU or 0xCACA0AA0U

– 0xF5F5A0AAU: notifies RSSLIB_DataProvisioning to encrypt data with relevant DHUK before programming it within OBKeys. DHUK is selected according to **`pDestination`** value. This value is allowed only on STM32G55x/56x devices.
– 0xCACA0AA0U: notifies RSSLIB_DataProvisioning to program in clear data within OBKeys.

`Crc` CRC over full source data buffer, **`pConfig->pDestination`** value, **`pConfig->Size`** value and finally **`pConfig->DoEncryption`** value.

CRC computation uses CRC-32 (Ethernet):

– CRC polynomial: 0x04C11DB7U
– Initial value: 0xFFFFFFFFU

Returned values

0xEAEAEAEAU	Success
0xF5F5F5F5U	Error: – **`pConfig`** or **`pSource`** are not in SRAM1
0xF5F5E0E0U	Error: – **`pDestination`** is not aligned on 16 bytes – **`pDestination + Size`** does not fit within an OBKey section
0xF5F50E0EU	Error: **`Size`** is not a multiple of 16
0xF5F58080U	Error: computed CRC is not the expected one provided within **`pConfig->CRC`**
0xF5F58008U	Error: cannot program data within OBKeys destination section
0xF5F5E00EU	Error: wrong **`DoEncryption`** parameter value
0xF5F50880U	Error: encryption requested, butw platform does not support it
0xF5F50EE0U	Error: encryption error
0xF5F50808U.	Error: OBKeys programming error

RSSLIB_DataProvisioning receives in input a data buffer and programs it within OBKeys. A CRC prevents any data and parameter tampering issues.

The destination address (**`pDestination`**) added to the size (**`Size`**) of the data to be provisioned must not cross the OBKeys section boundaries, listed below.

OBKeys Level1	Start address: 0x0FFD0100UL
	End address: 0x0FFD08FFUL
OBKeys Level2	Start address: 0x0FFD0900UL
	End address: 0x0FFD0FFFUL
OBKeys Level3 secure	Start address: 0x0FFD1000UL
	End address: 0x0FFD17FFUL
OBKeys Level3 nonsecure	Start address: 0x0FFD1800UL
	End address: 0x0FFD1FEFUL

When requested through the **`pConfig->DoEncryption`** parameter, RSSLIB_DataProvisioning encrypts the data before programming them within OBKeys.

RSSLIB_DataProvisioning uses AES CBC 128 bits with:

- IV: defined as (using C definition format)

  `uint32_t IV = {0x8001D1CEU, 0xD1CED1CEU, 0xD1CE8001U, 0xCED1CED1U};`
- Key: DHUK corresponding to the targeted OBKeys section defined by **`pConfig->pDestination`** parameter.

Note: Data encryption within the OBK is only supported on devices with a hardware cryptographic accelerator.

Note: This function uses the following peripherals:

- CRC, RNG, SAES, HASH, PKA, CCB: reset, use and reset
- SBS, FLASH, GTZC: use

JumpHDPLvl2

Secure attribute: Secure callable function.

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 processor.
- MPUIndex:
  - Input parameter, MPU region index. The caller function must define (but keep disabled) the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

The user calls JumpHDPLvl2 to close the user flash memory HDPL1 area by incrementing HDPL to 2, then jump to the reset handler embedded within the vector table, whose address is passed as an input parameter.

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as an input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl2 does not set the new vector table. To ensure the correct interrupts handling during this service, the user must choose one of the following options:

- option 1: the user disables the interrupts before calling JumpHDPLvl2 and restores the interrupts once in HDPL2 after setting the new vector table
- option 2: the user ensures the vector tables are always accessible (i.e. vector tables are located outside the HDPL areas)

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), RSSLIB_Sec_JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Secure attribute: secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 processor.
- MPUIndex:
  - Input parameter, MPU region index. Caller function must define but keep disabled the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table, whose function belongs to the MPU region.

User calls JumpHDPLvl3 to close the user flash memory HDPL1 and HDPL2 areas by incrementing HDPL up to 3, then jump to the reset handler embedded within the vector table, whose address is passed as input parameter.

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as an input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by the vector

table. JumpHDPLvl3 does not set the new vector table. To ensure the correct interrupts handling during this service, the user must choose one of the following options:

- option 1: the user disables the interrupts before calling JumpHDPLvl3 and restore the interrupts once in HDPL3 after setting the new vector table
- option 2: the user ensures the vector tables are always accessible (i.e. vector tables are located outside the HDPL areas)

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

JumpHDPLvl3NS

Secure attribute: secure callable function.

Prototype:

```
uint32_t JumpHDPLvl3NS(uint32_t VectorTableAddr)
```

User code function call example:

```
RSSLIB_PFUNC->S.JumpHDPLvl3NS((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 processor.

User calls JumpHDPLvl3NS to close the user flash memory HDPL1 and HDPL2 areas by incrementing HDPL up to 3, to move from secure to nonsecure domain, then jump to the nonsecure reset handler embedded within the vector table, whose address is passed as an input parameter.

After closing HDPL1/2, JumpHDPLvl3 jumps to the nonsecure reset handler function supported by the vector table. JumpHDPLvl3NS sets the new nonsecure vector table and the new nonsecure SP to the address provided by the passed vector table. To ensure the correct interrupts handling during this service, the user must choose one of the following options:

- option 1: the user disables the interrupts before calling JumpHDPLvl3NS, configure NVIC to allow selected nonsecure IRQ and restore the interrupts once in HDPL3NS
- option 2: the user ensures the vector tables are always accessible (i.e. vector tables are located outside the HDPL areas)

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3NS returns 0xF5F5F5F5.

NSSLIB

The user firmware calls only the NSSLIB function when TrustZone is disabled (TZEN bitfield is set to 0xC3).

The user firmware calls NSSLIB functions using NSSLIB_PFUNC C defined macro, which points to a location within system memory. The user firmware must:

- Ensure that the NSSLIB is executable. The NSSLIB is located in nonsecure system flash address NSSLIB_BASE (0x0FFA2150) with a size of NSSLIB_SIZE (0xAB0).

These address and size are provided within the CMSIS device header file.

Table 76. NSS lib interface functions

Library	Function	Attributes
NSSLIB_PFUNC	JumpHDPLvl2	Nonsecure function
	JumpHDPLvl3	

JumpHDPLvl2

Prototype:

```
uint32_t JumpHDPLvl2(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
NSSLIB_PFUNC->JumpHDPLvl2((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 processor.
- MPUIndex:
  - Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl2. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl2 to close the user flash memory HDPL1 area by incrementing HDPL to 2, and to jump to the reset handler embedded within the vector table which address is passed as an input parameter

After closing HDPL1, JumpHDPLvl2 enables the MPU region provided as input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table and jumps to the reset handler function supported by the vector table too. JumpHDPLvl2 does not set the new vector table. To ensure the correct interrupts handling during this service, the user must choose one of the following options:

- option 1: the user disables the interrupts before calling JumpHDPLvl2 and restore the interrupts once in HDPL2 after setting the new vector table
- option 2: the user ensures the vector tables are always accessible (i.e. vector tables are located outside the HDPL areas)

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), RSSLIB_Sec_JumpHDPLvl2 returns 0xF5F5F5F5.

JumpHDPLvl3

Prototype:

```
uint32_t JumpHDPLvl3(uint32_t VectorTableAddr, uint32_t MPUIndex)
```

User code function call example:

```
NSSLIB_PFUNC->JumpHDPLvl3((uint32_t)NextVectorTableAddr, 1U );
```

Arguments:

- VectorTableAddr:
  - Input parameter, address of the next vector table to apply.
  - The vector table format is the one used by the Cortex®-M33 processor.
- MPUIndex:
  - Input parameter, MPU region index. Caller function shall define but keep disable the corresponding MPU region before calling JumpHDPLvl3. The function enables the MPU region before jumping to the reset handler of the vector table. The vector table reset handler function belongs to the MPU region.

User calls JumpHDPLvl3 to close the user flash memory HDPL1 and HDPL2 areas by incrementing HDPL up to 3, and then jump to the reset handler embedded within the vector table, whose address is passed as an input parameter.

After closing HDPL1/2, JumpHDPLvl3 enables the MPU region provided as an input parameter. Once the MPU is enabled, the function sets the SP to the address provided by the passed vector table, and jumps to the reset handler function supported by it. JumpHDPLvl3 does not set the new vector table. To ensure the correct interrupts handling during this service, the user must choose one of the following options:

- option 1: the user disables the interrupts before calling JumpHDPLvl3 and restore the interrupts once in HDPL3 after setting the new vector table
- option 2: the user ensures the vector tables are always accessible (i.e. vector tables are located outside the HDPL areas)

On successful execution, the function does not return and does not push LR onto the stack.

In case of failure (bad input parameter value), JumpHDPLvl3 returns 0xF5F5F5F5.

7.8 FLASH low-power modes

Table 77 summarizes the memory behavior in STM32 low-power modes. The embedded flash memory belongs to the core domain.

Table 77. Effect of low-power modes on the embedded flash memory

Power mode	Core domain voltage range	Allowed if FLASH busy	FLASH power mode
Run	VOS0/1/2	Yes	Run
Stop1 (clock stopped)	SVOS3	No	Clock gated
Standby	Off	No	Off

When the system state changes or within a given system state, the memory can operate with a different voltage supply range (VOS), according to the application. The procedure to switch the memory into power modes (run, clock-gated, stopped, off) is described hereafter.

Note: For more information on the microcontroller power states, refer to Section 10: Power control (PWR).

Managing the FLASH domain switching to Stop or Standby

As explained in *Table 77*, if the memory informs the reset and clock controller (RCC) that it is busy (BSY, DBNE, WBNE is set), the microcontroller cannot switch the core domain to Stop or Standby mode.

There are two ways to release the memory:

- Reset the WBNE busy flag in the FLASH_SR/SSR register by any of the following actions:
  - Complete the write buffer with missing data.
  - Force the write operation without filling the missing data by activating the FW bit in the FLASH_CR/SCR register. This forces all missing data to “high”.
- Poll BSY busy bits in FLASH_SR/SSR register until they are cleared. This indicates that all recorded write, erase, and option change operations are complete.

The microcontroller can then switch the domain to Stop or Standby mode.

7.9 FLASH error management

7.9.1 Introduction

The memory automatically reports when an error occurs during a read, program, or erase operation. A wide range of errors are reported:

- *Nonsecure write protection error (WRPERR)*
- *Secure write protection error (WRPERR)*
- *Nonsecure programming sequence error (PGSERR)*
- *Secure programming sequence error (PGSERR)*
- *Secure strobe error (STRBERR)*
- *Error correction code error (ECCC, ECCD)*
- *Illegal access (ILAFM/ILAP)*
- *Option-byte change error (OPTCHANGEERR)*
- OBK nonsecure general error (OBKERR)
- OBK secure general error (OBKERR)
- OBK nonsecure write error (OBKWERR)
- OBK secure write error (OBKWERR)

The application software can individually enable the interrupt for each error, as detailed in *Section 7.10: FLASH interrupts*.

The flash memory interface uses different interrupt lines to trigger the event. There are two direct lines to NVIC, one for secure interrupts, another for nonsecure. The third line leads to TZIC, for the ILAFM interrupt.

Note: For all errors, the application software must clear the error flag before attempting a new modify operation.

Since there is just one write buffer and only one operation allowed at a time, the write control bits and status bits are shared by both banks:

- Write control bits (PG, FW, EOPIE, WRPERRIE, PGSERRIE, STRBERRIE, INCERRIE, and all related clear bits) control Bank1 and Bank2 simultaneously.
- Write status flags report (WBNE, DBNE, EOP, WRPERR, PGSERR, STRBERR, INCERR, BSY) errors for Bank1 and Bank2 simultaneously.

7.9.2 Nonsecure write protection error (WRPERR)

When an illegal, nonsecure erase/program operation is attempted in the nonvolatile memory, the flash memory interface sets the write protection error flag WRPERR in the FLASH_SR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A page that is write-protected with WRPGn
- An HDP area while the HDPL has made it inaccessible
- Secure (TZ) state not matching the erased memory attribute
- Attempt to erase a privilege page within unprivileged mode

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- System flash memory
- A user page that is write-protected with WRPGn
- An OTP block, locked with LOCKBL
- A read-only section
- A reserved area
- Secure area
- Privileged area from within the unprivileged mode
- OBK access conditions check error

When the WRPERR flag is raised, the operation is rejected and nothing is changed in the corresponding bank. If this error is detected, the write buffer is invalidated.

Note: The WRPERR flag must be cleared before any erase/program operation.

The WRPERR flag is cleared by setting the WRPERR bit to 1 in the FLASH_CCR register.

If the WRPERRIE bit in the FLASH_CR register is set to 1, an interrupt is generated when the WRPERR flag is raised (see *Section 7.10* for details).

7.9.3 Secure write protection error (WRPERR)

When an illegal secure erase/program operation is attempted in the nonvolatile memory, the flash memory interface sets the write protection error flag WRPERR in the FLASH_SSR register.

An erase operation is rejected and flagged as illegal if it targets one of the following memory areas:

- A page that is write-protected with WRPGn
- An HDP area while the HDPL has made it inaccessible
- Secure (TZ) state not matching the erased memory attribute
- Attempt to erase a privileged page within unprivileged mode

A program operation is ignored and flagged as illegal if it targets one of the following memory areas:

- System flash memory
- A user page that is write-protected with WRPGn
- An OTP block, locked with LOCKBL
- A read-only section
- A reserved area
- Nonsecure area
- Privileged area from within unprivileged mode
- OBK access condition check error

When the WRPERR flag is raised, the operation is rejected and nothing is changed in the corresponding bank.

If this error is detected the write buffer is invalidated.

Note: The WRPERR flag must be cleared before any erase/program operation.

The WRPERR flag is cleared by setting WRPERR bit to 1 in FLASH_SCCR register.

If the WRPERRIE bit in the FLASH_SCR register is set to 1, an interrupt is generated when the WRPERR flag is raised (see *Section 7.10* for details).

7.9.4 Nonsecure programming sequence error (PGSERR)

When the nonsecure programming sequence is incorrect, the flash memory interface sets the programming sequence error flag PGSERR in the FLASH_SR register.

More specifically, the PGSERR flag is set when one of the conditions below is met:

- An error like INCERR, WRPERR, PGSERR, STRBERR, OPTCHANGEERR, OBKERR, or OBKWERR has not been cleared before requesting a new write or erase operation, OBK operation, or options change.
- For erase, PGSERR is set if:
  - Missing erase operation (FLASH_CR): STRT = 1 with (MER = 0, PER = 0 and BER = 0)
  - Page and bank erase requested at the same time (NSSTRT and more than one of MER, PER and BER)
  - PG set during erase operation (it ensures that no erase req and write req happen at the same time): (STRT = 1) with (PG = 1)
  - Erase operation is started while write buffer is waiting for next data: (STRT = 1) with WBNE = 1.
  - STRT = 1 set by secure access.
  - Erase operation is started while DBNE = 1.

- For programming, PGSERR is set if:
  - Missing write flag: a write operation is requested but the program enable bit PG has not been set in FLASH_CR register prior to the request.
  - Write operation to flash high-cycle data is requested but PG = 0.
  - AHB write request is received and (PER = 1, BER = 1 or MER = 1)
  - 16 bit data access requested while WBNE = 1
- For options change, PGSERR is set if:
  - Option change is started while write buffer is waiting for next data: OPTSTRT = 1 with WBNE = 1
  - OPTSTRT set with nonsecure DBNE = 1.
- For option byte key storage access, PGSERR is set if:
  - Error flags from previous operation not cleared
  - ALT_SECT_ERASE and SWAP_SECT_REQ in FLASH_OBKCFGR are set at the same time
  - SWAP_OFFSET value is wrong: when SWAP_SECT_REQ is set to 1, the SWAP_OFFSET should be equal or greater than OBK_HDPL< N - 1 > _SWAP_OFFSET
  - ALT_SECT_ERASE or OBK_SWAP set while DBNE = 1
  - OBK-HDPL is incorrect and nonsecure OBK_SWAP is requested
  - If OBKSWAP or OBK alternate erase is started while write buffer is waiting for new data (WBNE = 1)
- For PUF operation, the NSPGSERR is set if:
  - NS_PUF_LAUNCH is set and FLASH_SR flags are not cleare.
  - NS_PUF_LAUNCH is set with NSPG = 1
  - NS_PUF_LAUNCH is set with NSSTRT = 1
  - NS_PUF_LAUNCH is set with NSWBNE = 1
  - NS_PUF_LAUNCH is set with NSDBNE = 1

When the PGSERR flag is raised as a consequence of a failed write attempt (flash programming), the current program operation is aborted and nothing is changed in the corresponding bank. The write data buffer is also invalidated.

Note: When the PGSERR flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above-mentioned protection mechanism. It is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation was successful by reading back the value in the flash memory.

The PGSERR flag also blocks any new program operation. This means that PGSERR must be cleared before starting a new program operation.

The PGSERR flag is cleared by PGSERR bit to 1 in FLASH_CCR register.

If the PGSERRIE bit in the FLASH_CR register is set to 1, an interrupt is generated when PGSERR flag is raised. See *Section 7.10* for details.

7.9.5 Secure programming sequence error (PGSERR)

When the secure programming sequence is incorrect, the flash interface sets the programming sequence error flag PGSERR in the FLASH_SSR register.

More specifically, the PGSERR flag is set when one of the conditions below is met:

- An error like INCERR, WRPERR, PGSERR, STRBERR, OBKERR, or OBKWERR has not been cleared before requesting a new write or erase operation, OBK operation or options change.
- For erase, PGSERR is set if:
  - Missing erase operation (FLASH_SCR): STRT = 1 with (PER = 0 and BER = 0, MER = 0)
  - Page and bank erase requested at the same time (SECSTRT and more than one of MER, PER, and BER)
  - PG set during erase operation (it ensures that no erase request and write request happen at the same time): (STRT = 1) with (PG = 1)
  - Erase operation is started while write buffer is waiting for next data: (STRT = 1) with WBNE = 1.
  - Operation started while secure DBNE = 1.
- For programming, PGSERR is set if:
  - Missing write flag: a write operation is requested but the program enable bit PG has not been set in FLASH_SCR register prior to the request
  - Write operation to flash high-cycle data is requested but PG = 0
  - AHB write request is received and (PER = 1, SBER = 1, or MER = 1)
  - 16-bit data access requested while WBNE = 1
- For options change, PGSERR is set if:
  - Option change is started while write buffer is waiting for next data: OPTSTRT = 1 with WBNE = 1
  - OPTSTRT set with secure DBNE = 1
- For options byte key storage access, SECPGSERR is set if:
  - Error flags from previous operation not cleared
  - ALT_SECT_ERASE and SWAP_SECT_REQ are set at the same time
  - SWAP_OFFSET value is wrong: when SWAP_SECT_REQ = 1, SWAP_OFFSET must be equal or greater than OBK_HDPL<N-1>_SWAP_OFFSET.
  - SWAP_SECT_REQ or OBK_SWAP set while DBNE = 1
  - OBK-HDPL is incorrect and secure OBK_SWAP is requested
  - If OBKSWAP or OBK alternate erase is started while write buffer is waiting for new data (WBNE = 1)
- For PUF operation, the SECPGSERR is set if:
  - SEC_PUF_LAUNCH is set and FLASH_SSR flags are not cleared
  - SEC_PUF_LAUNCH is set with SECPG = 1
  - SEC_PUF_LAUNCH is set with SECSTRT = 1
  - SEC_PUF_LAUNCH is set with SECWBNE = 1
  - SEC_PUF_LAUNCH is set with SECDBNE = 1

When the PGSERR flag is raised as a consequence of a failed write attempt (flash programming), the current program operation is aborted and nothing is changed in the corresponding bank. The write data buffer is also invalidated.

Note: When the PGSERR flag is raised, there is a risk that the last write operation performed by the application has been lost because of the above protection mechanism. It is recommended to generate interrupts on PGSERR and verify in the interrupt handler if the last write operation has been successful by reading back the value in the flash memory.

The PGSERR flag also blocks any new program operation. This means that PGSERR must be cleared before starting a new program operation.

The PGSERR flag is cleared by setting SECPGSERR bit to 1 in FLASH_SCCR register.

If the PGSERRIE bit in the FLASH_SCR register is set to 1, an interrupt is generated when the PGSERR flag is raised. See *Section 7.10* for details.

7.9.6 Nonsecure strobe error (STRBERR)

When the nonsecure application software writes several times to the same byte in the write buffer, the flash memory interface sets the strobe error flag STRBERR (FLASH_SR) whatever the target bank of the write access.

When the STRBERR flag is raised, the current program operation is aborted and the write buffer is invalidated.

The STRBERR flag is cleared by setting STRBERR bit to 1 in FLASH_CCR register.

If the STRBERRIE bit in the FLASH_CR register is set to 1, an interrupt is generated when the STRBERR flag is raised. See *Section 7.10* for details.

7.9.7 Secure strobe error (STRBERR)

When the secure application software writes several times to the same byte in the write buffer, the memory sets the strobe error flag STRBERR (FLASH_SSR) whatever the target bank of the write access.

When the STRBERR flag is raised, the current program operation is aborted and the write buffer is invalidated.

The STRBERR flag is cleared by setting the STRBERR bit to 1 in the FLASH_SCCR register.

If the STRBERRIE bit in the FLASH_SCR register is set to 1, an interrupt is generated when the STRBERR flag is raised. See *Section 7.10* for details.

7.9.8 Nonsecure inconsistency error (INCERR)

When a programming inconsistency in a nonsecure access operation is detected, the flash memory interface sets the inconsistency error flag INCERR in the FLASH_SR register.

More specifically, the INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One AHB master starts a write operation, but before the buffer is full, another master starts a new write operation at the same address or at a different address.
  - ALT_SECT in FLASH_OBKCFGR changed while filling the write buffer.

Note: The INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow this sequence to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when the INCERR flag is raised.
2. Stop all write requests to the memory.
3. Clear the INCERR bit.
4. Restart the write operations from where they have been interrupted.

The INCERR flag is cleared by setting the INCERR bit to 1 in the FLASH_CCR register.

If the INCERRIE bit in the FLASH_CR register is set to 1, an interrupt is generated when INCERR flag is raised (see *Section 7.10* for details).

7.9.9 Secure inconsistency error (INCERR)

When a programming inconsistency is detected, the flash interface sets the inconsistency error flag INCERR in register FLASH_SSR.

More specifically, the INCERR flag is set when one of the following conditions is met:

- A write operation is attempted before completion of the previous write operation, for example:
  - The application software starts a write operation to fill the 128-bit write buffer, but sends a new write burst request to a different flash memory address before the buffer is full.
  - One AHB master starts a write operation, but before the buffer is full, another master starts a new write operation at the same address or at a different address.

Note: The INCERR flag must be cleared before starting a new write operation, otherwise a sequence error (PGSERR) is raised.

It is recommended to follow the sequence below to avoid losing data when an inconsistency error occurs:

1. Execute a handler routine when the INCERR flag is raised.
2. Stop all write requests to the flash memory.
3. Clear the INCERR bit.
4. Restart the write operations from where they have been interrupted.

The INCERR flag is cleared by setting the INCERR bit to 1 in the FLASH_SCCR register.

If the INCERRIE bit in the FLASH_SCR register is set to 1, an interrupt is generated when the INCERR flag is raised (see *Section 7.10* for details).

7.9.10 Error correction code error (ECCC, ECCD)

When a single-error correction is detected during a read, the flash memory interface sets the single-error correction flag ECCC in the FLASH_ECCCORR register.

When two ECC errors are detected during a read, the flash memory interface sets the double error detection flag ECCD in the FLASH_ECCDETR register.

When the ECCC flag is raised, the corrected read data are returned. The application can ignore the error and request new read operations. When the ECCD the flag is raised, an NMI is generated, which can be masked in SBS registers (*SBS ECC NMI mask register (SBS_ECCNMIR)*) for data access (OTP, data area, RO data). Software must invalidate the instruction cache (CACHEINV = 1) in the NMI interrupt service routine when the ECCD flag is set.

When the ECCC or ECCD flag is raised, the address of the flash word that generated the error is saved in the FLASH_ECCCORR (FLASH_ECCDETR) register. If the address corresponds to a read-only area or to an OTP area or flash high-cycle data, the OTP_ECC bit is also set to 1 in the FLASH_ECCCORRR (FLASH_ECCDETR) register. This register is automatically cleared when the associated flag that generated the error is reset.

A BK_ECC flag indicates in which flash bank the error occurred.

A SYSF_ECC flag indicates an error detected in the system flash area.

Table 78. Locating ECC failure

OTP_ECC	SYSF_ECC	BK_ECC	EDATA_ECC	OBK_ECC	Flash area	ADDR_ECC min	ADDR_ECC max
0	0	0/1	0	0	User flash	0x0000	0xFFFF
0	1	0/1	0	0	System flash	0x0000	0x0FFF
1	0	0	0	0	OTP	0x0600	0x07FF
0	0	1	0	1	OBKeys	0x0000	0x03FF
0	0	0/1	1	0	Data area page 7	0xX200	0xX3FF
0	0	0/1	1	0	Data area page 6	0xX400	0xX5FF
0	0	0/1	1	0	Data area page 5	0xX600	0xX7FF
0	0	0/1	1	0	Data area page 4	0xX800	0xX9FF
0	0	0/1	1	0	Data area page 3	0xXA00	0xXBFF
0	0	0/1	1	0	Data area page 2	0xXC00	0xXDFF
0	0	0/1	1	0	Data area page 1	0xX000	0xX1FF
0	0	0/1	1	0	Data area page 0	0xXE00	0xXFFF

Note: In case of successive single correction or double detection errors, only the address corresponding to the first error is stored in the FLASH_ECCCORR (FLASH_ECCDETR) *register.*

It is mandatory to clear the ECCC or ECCD flags before starting a new read operation.

As the ECC interface is shared by the two banks, if the same error is registered simultaneously, a physical Bank1 error is registered. Both errors are registered if one bank reports ECCD and the other bank ECCC.

ECCC (respectively ECCD) flag is cleared by setting to 1 the ECCC bit (respectively ECCD bit) in the FLASH_ECCCORR (FLASH_ECCDETR) register.

If the ECCC bit in the FLASH_ECCCORR register is set to 1, an interrupt is generated when the ECCC flag is raised. Only NMI is generated for the ECCD. See *Section 7.10* for details.

7.9.11 Illegal access (ILAFM/ILAP)

Illegal access is a signal to the TZIC, triggering a secure interrupt in there. It is complementary to the other interrupts and only generated when the TZ is enabled (TZ_STATE = 0xB4).

It can be masked only on GTZC level.

ILAFM is generated when rules on the secure flash memory access are violated:

- Attempt to access a secure memory location in nonsecure mode.
- Attempt to access a nonsecure memory location in secure mode.

ILAP is generated on:

- Attempt to access a secure register in nonsecure mode.

If ILAFM is detected during write, the write buffer is invalidated.

Note: ILAFM and ILAP has no flag within the flash memory controller to clear to resume operation. It is dealt within the TZIC.

7.9.12 Option-byte change error (OPTCHANGEERR)

When the flash memory interface finds an error during an option change operation, it aborts the operation and sets the option byte change error flag OPTCHANGEERR in the FLASH_SR register.

The error is raised after the OPTSTRT bit set if:

- TZEN is not set and transition to TZ-Closed or NS-Regression state is requested. Also any other forbidden PRODUCT_STATE transition (*Table 68*).
- SWAP_BANK is locked out by SWAP_LOCK.
- OB modification is attempted in wrong HDPL (selected PRODUCT_STATE transitions)
- Attempt to modify OB with invalid value:
  - New EPOCH value not greater than current
  - Value not recognized by the specification (enumerated magic numbers only)
- Attempt to modify OB in product state where it is not allowed (usually a state open for debug is required for change).

Note: Exceptions and details provided in the OB description (see Section 7.4.8 and Table 48).

The OPTCHANGEERR flag is cleared by setting the OPTCHANGEERR bit to 1 in the FLASH_CCR register.

If the OPTCHANGEERRIE bit in the FLASH_CR register is set to 1, an interrupt is generated when the OPTCHANGEERR flag is raised (see *Section 7.10* for details).

It is mandatory to clear the OPTCHANGEERR flag before starting a new operation (option change, erase, or write).

7.9.13 Miscellaneous HardFault errors

The following events generate a bus error on the corresponding bus interface:

- On the main AHB system bus for access targeting code and data with 9 bits ECC.
  - Fetching from the secure user flash memory in nonsecure mode.
  - Fetching from the nonsecure user flash memory in secure mode.
  - Access to an invalid address (including data addresses forbidden for code use).
  - Fetching from the HDP area with incorrect HDPL value.
  - Fetching from a privilege area in unprivileged mode.
- On the AHB configuration or system bus for accesses targeting OTP/RO (all addresses using 6 bits ECC):
  - wrong key input to FLASH_KEYR/SKEYR or FLASH_OPTKEYR.
  - 8-bit access to system AHB interface.
  - Wrong unlock sequence on a register.

7.9.14 OBK error cases (OBKERR, OBKWERR)

Four error types can be detected while filling the OBK write buffer: STRBERR, INCERR, WRPERR, or OBKERR. The OBKERR is specific to the OBK access and cannot be raised by access to any other flash memory asset.

Note: For STRBERR, INCERR, and WRPERR, nonsecure or secure flags are used depending on the AHB access type (secure or nonsecure). If a nonsecure access request is received, the nonsecure error flags are used. If a secure access request is received, the secure error flags are used.

For OBKERR and OBKWERR, nonsecure or secure flags are used depending on the value of the secure state. If the SOC is in secure state (TZ_STATE active), the secure error flags (OBKERR and OBKWERR) are used. Otherwise the nonsecure error flags (OBKERR and OBKWERR) are used.

OBKERR is raised when the OBK-HDPL (input signal from SBS) does not match the HDPL associated with the key during read or write access, and the TZ and PRIV attributes are correct (See *Section 7.4.2: Option byte loading* for more details).

If OBKERR is raised during write access, the write buffer is flushed. If OBKERR is raised on read access, the write buffer remains intact. In both cases, the flag must be cleared to enable write or erase access to the flash memory.

OBKWERR is detected after filling the write buffer and raised if:

- The address is not virgin during a write access.
- The OBK selector in the alternate page is not virgin during a swap operation.

If OBKWERR is raised, the write buffer is flushed. The flag must be cleared to enable write or erase access to the flash memory.

7.10 FLASH interrupts

The flash memory interface can generate a maskable interrupt to signal the following events on a given bank:

- Read and write errors (see *Section 7.9: FLASH error management*):
  - Single ECC error correction during read operation
  - Write inconsistency error
  - Bad programming sequence
  - Strobe error during write operations
  - Option change operation error
- Security errors (see *Section 7.9: FLASH error management*):
  - Write protection error
  - Illegal access error - signal to TZIC
- Miscellaneous events (described below):
  - End of programming

An NMI is raised on double ECC error detection during a read operation.

Two interrupt lines gather all error sources, one for errors in nonsecure access and another for errors that happen in secure access.

The user can enable or disable the flash interface interrupt sources individually by changing the mask bits in the FLASH_CR/SCR, FLASH_ECCCORR, and FLASH_ECCDETR register. Setting the appropriate mask bit to 1 enables the interrupt.

Note: Prior to writing, the FLASH_CR/SCR register must be unlocked, as explained in Section 7.6.7: Flash memory configuration protection.

Table 79 gives a summary of the available flash memory interface interrupt features. As mentioned in the table below, some flags need to be cleared before triggering a new operation.

Table 79. Flash interrupt request

Interrupt event Event flag	Error flag label in register	Enable control bit	Clear flag to resume operation
End of operation event	EOP	EOPIE	N/A
Write protection error	WRPERR	WRPERRIE	Yes
Programming sequence error	PGSERR	PGSERRIE	Yes
Strobe error	STRBERR	STRBERRIE	Yes
OBK write error	OBKWERR	OBKWERRIE	Yes
OBK general error	OBKERR	OBKERRIE	Yes
Inconsistency error	INCERR	INCERRIE	Yes
Illegal access error	ILAFM	TZEN	No

Table 79. Flash interrupt request (continued)

Interrupt event Event flag	Error flag label in register	Enable control bit	Clear flag to resume operation
Option byte error	OPTCHANGEERR	-	Yes
ECC single error correction event	ECCC	ECCCIE	No
ECC double error detection event(1)	ECCD	Disabled	No

1. NMI.

The status of the individual maskable interrupt sources described in *Table 79* (except for option byte error and ECC) can be read from the FLASH_SR/SSR register. They can be cleared by setting to 1 the adequate bit in the FLASH_CCR/SCCR register.

Note: No unlocking mechanism is required to clear an interrupt.

End of operation event

Setting the end of operation interrupt enable bit (EOPIE) in the FLASH_CR/SCR register enables the generation of an interrupt at the end of an erase operation, a program operation, a PUF operation, or an option byte change.

When managing the OBKey storage area, the EOP is also associated with the OBK swap operation and the alternate area erase operation. The EOP bit in the FLASH_SR/SSR register is also set when one of these events occurs.

Setting the EOP bit in the FLASH_CCR/SCCR register clears the EOP flag.

7.11 FLASH registers

Each register has an assigned offset address and reset value. In case of registers representing option byte value, the reset value is determined by the OBL process. In case of success, the reset value is loaded from OB. In case of OBL failure, a highly restrictive default value is set.

7.11.1 FLASH access control register (FLASH_ACR)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

For more details, refer to *Section 7.3.4* and *Section 7.3.5*.

Address offset: 0x000

Reset value: 0x0000 0012

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ACR_SEC_EN
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRFTEN	Res.	Res.	WRHIGHFREQ[1:0]		LATENCY[3:0]			
							rw			rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **ACR_SEC_EN**: This bit restricts the contents of the FLASH_ACR from nonsecure write access.
0: all nonsecure access to FLASH_ACR permitted.
1: nonsecure write access to FLASH_ACR results in illegal access error. The register is read only for nonsecure code.
Note: This bit is only considered when TrustZone is enabled..

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **PRFTEN**: Prefetch enable. When bit value is modified, user must read back ACR register to be sure PRFTEN has been taken into account.
Bits used to control the prefetch.
0: prefetch disabled.
1: prefetch enabled when latency is at least one wait state.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **WRHIGHFREQ[1:0]**: Flash signal delay
These bits are used to control the delay between nonvolatile memory signals during programming operations. Application software has to program them to the correct value depending on the memory interface frequency. Please refer to *Table 39* for details.
Note: No check is performed to verify that the configuration is correct.
Two WRHIGHFREQ values can be selected for some frequencies.

Bits 3:0 **LATENCY[3:0]**: Read latency

These bits are used to control the number of wait states used during read operations on both nonvolatile memory banks. The application software has to program them to the correct value depending on the memory interface frequency and voltage conditions.

0000: zero wait states used to read a word from nonvolatile memory

0001: one wait state used to read a word from nonvolatile memory

0010: two wait states used to read a word from nonvolatile memory

...

0111: seven wait states used to read a word from nonvolatile memory

1111: 15 wait states used to read a word from nonvolatile memory

Note: No check is performed by hardware to verify that the configuration is correct.

7.11.2 FLASH nonsecure key register (FLASH_KEYR)

This register is nonsecure. It can written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_KEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_CR register and allow programming/erasing it. A wrong sequence locks the FLASH_CR register until next system reset.

First key = 0x4567 0123

Second key = 0xCDEF 89AB

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]

KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Non-volatile memory nonsecure configuration access unlock key

7.11.3 FLASH secure key register (FLASH_SKEYR)

This register is secure. It can be written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_SKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_SCR register and allow programming/erasing it. A wrong sequence locks the FLASH_SCR register until next system reset.

First key = 0x4567 0123

Second key = 0xCDEF 89AB

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Non-volatile memory secure configuration access unlock key

7.11.4 FLASH option key register (FLASH_OPTKEYR)

This register is nonsecure. It can be written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

FLASH_OPTKEYR is a write-only register. The following values must be programmed consecutively to unlock FLASH_OPTCR register. A wrong sequence locks FLASH_OPTCR register until next system reset.

First key = 0x0819 2A3B

Second key = 0x4C5D 6E7F

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: FLASH option bytes control access unlock key

7.11.5 FLASH nonsecure OBK key register (FLASH_OBKKEYR)

This is a write-only register. The following values must be programmed consecutively to unlock FLASH_OBKCFGR register. A wrong sequence locks FLASH_OBKCFGR register until next system reset.

First key = 0x192A 083B

Second key = 0x6E7F 4C5D

This register is nonsecure. This register can be written only by privileged access.

Address offset: 0x0010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: FLASH nonsecure option bytes keys control access unlock key

7.11.6 FLASH secure OBK key register (FLASH_SOBKKEYR)

This is a write-only register. The following values must be programmed consecutively to unlock FLASH_SOBKCFGR register. A wrong sequence locks FLASH_SOBKCFGR register until next system reset.

First key = 0x192A 083B

Second key = 0x6E7F 4C5D

This register is secure. This register can only be written by privileged access.

Address offset: 0x0014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: FLASH secure option bytes keys control access unlock key

7.11.7 FLASH operation status register (FLASH_OPSR)

This register is nonsecure. This register can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x0018

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ADDR_OP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 **CODE_OP[2:0]**: Flash memory operation code
000: No flash operation on going during previous reset
001: Single write operation interrupted
010: OBK alternate page erase
011: Page erase operation interrupted
100: Bank erase operation interrupted
101: Mass erase operation interrupted
110: Option change operation interrupted
111: OBK swap page request

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **OTP_OP**: OTP operation interrupted
Indicates that reset interrupted an ongoing operation in OTP area (or OBKeys area).

Bit 23 **SYSF_OP**: Operation in system flash memory interrupted
Indicates that reset interrupted an ongoing operation in system flash.

Bit 22 **BK_OP**: Interrupted operation bank
It indicates which bank was concerned by operation.

Bit 21 **DATA_OP**: Flash high-cycle data area operation interrupted
It indicates if flash high-cycle data area is concerned by operation.

Bit 20 Reserved, must be kept at reset value.

Bits 19:0 **ADDR_OP[19:0]**: Interrupted operation address

7.11.8 FLASH option control register (FLASH_OPTCR)

This register is nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no FLASH memory operations are ongoing. The FLASH_OPTCR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it while the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x01C

Reset value: 0xX000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPTSTRT	OPTLOCK
														rw	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **OPTSTRT**: Option byte start change option configuration bit

OPTSTRT triggers an option byte change operation. The user can set OPTSTRT only when the OPTLOCK bit is cleared to 0. It is set only by Software and cleared when the option byte change is completed or an error occurs (PGSERR or OPTCHANGEERR). It is reseted at the same time as BSY bit.

The user application cannot modify any FLASH_XXX_PRG flash interface register until the option change operation has been completed.

Before setting this bit, the user has to write the required values in the FLASH_XXX_PRG registers. The FLASH_XXX_PRG registers are locked until the option byte change operation has been executed in nonvolatile memory.

Bit 0 **OPTLOCK**: FLASH_OPTCR lock option configuration bit

The OPTLOCK bit locks the FLASH_OPTCR register as well as all _PRG registers. The correct write sequence to FLASH_OPTKEYR register unlocks this bit. If a wrong sequence is executed, or the unlock sequence to FLASH_OPTKEYR is performed twice, this bit remains locked until next system reset.

It is possible to set OPTLOCK by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When OPTLOCK changes from 0 to 1, the others bits of FLASH_OPTCR register do not change.

0: FLASH_OPTCR register unlocked

1: FLASH_OPTCR register locked.

7.11.9 FLASH nonsecure status register (FLASH_SR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x020

Reset value: 0x0000 000X

												r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERR**: Option byte change error flag

OPTCHANGEERR flag indicates that an error occurred during an option byte change operation. When OPTCHANGEERR is set to 1, the option byte change operation did not successfully complete. An interrupt is generated when this flag is raised if the OPTCHANGEERRIE bit of FLASH_CR register is set to 1.

Use FLASH_CCR to clear OPTCHANGEERR.

0: no option byte change errors occurred

1: one or more errors occurred during an option byte change operation.

Note: The OPTSTRT bit in FLASH_OPTCR cannot be set while OPTCHANGEERR is set.

Bit 22 **OBKWERR**: OBK write error flag

OBKWERR flag is raised when the address is not virgin on a write access to the OBK storage. Alternatively also when the OBK selector in the alternate page is not virgin during a swap operation.

0: no OBK write error occurred

1: an OBK write error occurred

Bit 21 **OBKERR**: OBK general error flag

OBKERR flag is raised when the OBK-HDPL signal from the SBS does not match the HDPL value associated with the key slot during access to the key location. Alternatively also when the ALT_SECT is unexpectedly changed while the write buffer is being filled.

0: no OBK general error occurred

1: an OBK general error occurred

Bit 20 **INCERR:** inconsistency error flag

NSINCERR flag is raised when a inconsistency error occurs. An interrupt is generated if INCERRIE is set to 1.

Use FLASH_CCR to clear INCERR.

0: no inconsistency error occurs

1: a inconsistency error occurs

Bit 19 **STRBERR:** strobe error flag

STRBERR flag is raised when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set to 1. Use FLASH_CCR to clear STRBERR.

0: no strobe error occurred

1: a strobe error occurred

Bit 18 **PGSERR:** programming sequence error flag

PGSERR flag is raised when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set to 1. Use FLASH_CCR to clear PGSERR.

0: no sequence error occurred

1: a sequence error occurred

Bit 17 **WRPERR**: write protection error flag

WRPERR flag is raised when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set to 1. Use FLASH_CCR to clear WRPERR.

0: no write protection error occurred

1: a write protection error occurred

Bit 16 **EOP**: end of operation flag

EOP flag is set when a operation (program/erase) completes. An interrupt is generated if the EOPIE is set to 1. It is not necessary to reset EOP before starting a new operation. EOP bit is cleared in FLASH_CCR register.

0: no operation completed

1: a operation completed

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **DBNE**: data buffer not empty flag

DBNE flag is set when the flash interface is processing 6-bits ECC data in dedicated buffer. This bit cannot be set to 0 by software. The hardware resets it once the buffer is free.

0: data buffer not used

1: data buffer used, wait

Bit 2 **PUF_STATE**: PUF readiness

PUF_STATE flag is set when a PUF operation is completed successfully and PUF is ready for use. The value is not reset by regular reset, only after power up or standby.

0: PUF is not ready. Retry PUF_LAUNCH

1: PUF is ready for use

Bit 1 **WBNE**: write buffer not empty flag

WBNE flag is set when the flash interface is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the events below:

- the application software forces the write operation using FW bit in FLASH_CR
- the memory detects an error that involves data loss

This bit cannot be reset by software writing 0 directly. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer empty or full

1: write buffer waiting data to complete

Bit 0 **BSY**: busy flag

BSY flag indicates that a flash memory is busy by an operation (write, erase, option byte change, OBK, and PUF operations). It is set at the beginning of a flash memory operation and cleared when the operation finishes, or an error occurs.

0: no programming, erase or option byte change operation being executed

1: programming, erase or option byte change operation being executed

7.11.10 FLASH secure status register (FLASH_SSR)

This register is secure. It can be read only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x024

Reset value: 0x0000 000X

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBNE	PUF_STATE	WBNE	BSY
												r	r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **OBKWERR**: OBK write error flag

OBKWERR flag is raised when the address is not virgin on a write access to the OBK storage. Alternatively also when the OBK selector in the alternate page is not virgin during a swap operation.

0: no OBK write error occurred

1: an OBK write error occurred

Bit 21 **OBKERR**: OBK general error flag

OBKERR flag is raised when the OBK-HDPL signal from the SBS does not match the HDPL value associated with the key slot during access to the key location. Alternatively also when the ALT_SECT is unexpectedly changed while the write buffer is being filled.

0: no OBK general error occurred

1: an OBK general error occurred

Bit 20 **INCERR:** inconsistency error flag

INCERR flag is raised when a inconsistency error occurs. An interrupt is generated if INCERRIE is set to 1. Use FLASH_SCCR to clear INCERR.

0: no inconsistency error occurred

1: a inconsistency error occurred

Bit 19 **STRBERR:** strobe error flag

STRBERR flag is raised when a strobe error occurs (when the master attempts to write several times the same byte in the write buffer). An interrupt is generated if the STRBERRIE bit is set to 1. Use FLASH_SCCR to clear STRBERR.

0: no strobe error occurred

1: a strobe error occurred

Bit 18 **PGSERR:** programming sequence error flag

PGSERR flag is raised when a sequence error occurs. An interrupt is generated if the PGSERRIE bit is set to 1. Use FLASH_SCCR to clear PGSERR.

0: no sequence error occurred

1: a sequence error occurred

Bit 17 **WRPERR**: write protection error flag

WRPERR flag is raised when a protection error occurs during a program operation. An interrupt is also generated if the WRPERRIE is set to 1. Use FLASH_SCCR to clear WRPERR.

0: no write protection error occurred

1: a write protection error occurred

Bit 16 **EOP**: end of operation flag

EOP flag is set when a operation (program/erase) completes. An interrupt is generated if the EOPIE is set to. It is not necessary to reset EOP before starting a new operation. EOP bit is cleared in FLASH_SCCR register.

0: no operation completed

1: a operation completed

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **DBNE**: data buffer not empty flag

DBNE flag is set when the memory interface is processing 6-bits ECC data in dedicated buffer. This bit cannot be set to 0 by software. The hardware resets it once the buffer is free.

0: data buffer not used

1: data buffer used, wait

Bit 2 **PUF_STATE**: PUF readiness

PUF_STATE flag is set when a PUF operation is completed successfully and PUF is ready for use. The value is not reset by regular reset, only after power up or standby.

0: PUF is not ready. Retry PUF_LAUNCH

1: PUF is ready for use.

Bit 1 **WBNE**: write buffer not empty flag

WBNE flag is set when the flash interface is waiting for new data to complete the write buffer. In this state, the write buffer is not empty. WBNE is reset by hardware each time the write buffer is complete or the write buffer is emptied following one of the events below:

- the application software forces the write operation using FW bit in FLASH_SCR
- the flash interface detects an error that involves data loss

This bit cannot be reset by writing 0 directly by software. To reset it, clear the write buffer by performing any of the above listed actions, or send the missing data.

0: write buffer empty or full

1: write buffer waiting data to complete

Bit 0 **BSY**: busy flag

BSY flag indicates that a FLASH memory is busy (write, erase, option byte change, OBK operations, PUF operation). It is set at the beginning of a flash memory operation and cleared when the operation finishes or an error occurs.

0: no programming, erase or option byte change operation being executed

1: programming, erase or option byte change operation being executed

7.11.11 FLASH nonsecure control register (FLASH_CR)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no memory operations are ongoing. The FLASH_CR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x028

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BKSEL	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPTCHANGEERRIE	OBKWERRIE	OBKERRIE	INCERRIE	STRBERRIE	PGSERRIE	WRPERRIE	EOPIE

MER	Res.	PUF_LAUNCH	Res.	Res.	PNB[4:0]					STRT	FW	BER	PER	PG	LOCK
rw		rw			rw	rw	rw	rw	rw	rs	rw	rw	rw	rw	rs

Bit 31 **BKSEL**: Bank selector bit

Can only be programmed when LOCK is cleared to 0. The bit selects physical bank, SWAP_BANK setting is ignored.

0: Bank1 is selected for Bank erase / page erase / interrupt enable

1: Bank2 is selected for BER / PER

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERRIE**: Option byte change error interrupt enable bit

This bit controls if an interrupt must be generated when an error occurs during an option byte change. It can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated when an error occurs during an option byte change

1: an interrupt is generated when and error occurs during an option byte change.

Bit 22 **OBKWERRIE**: OBK write error interrupt enable bit

OBKWERRIE enables generation of interrupt in case of OBK specific write error. This bit can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated on OBK write error

1: an interrupt is generated on OBK write error

Bit 21 **OBKERRIE**: OBK general error interrupt enable bit

OBKERRIE enables generating an interrupt in case of OBK specific access error. This bit can be programmed only when LOCK bit is cleared to 0.

0: no interrupt is generated on OBK general access error

1: an interrupt is generated on OBK general access error

Bit 20 **INCERRIE**: inconsistency error interrupt enable bit

When INCERRIE bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation. INCERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a inconsistency error occurs

1: interrupt generated when a inconsistency error occurs.

Bit 19 **STRBERRIE**: strobe error interrupt enable bit

When STRBERRIE bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation. STRBERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a strobe error occurs

1: interrupt generated when strobe error occurs.

Bit 18 **PGSERRIE**: programming sequence error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation. PGSERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a sequence error occurs

1: interrupt generated when sequence error occurs

Bit 17 **WRPERRIE**: write protection error interrupt enable bit

When this bit is set to 1, an interrupt is generated when a protection error occurs during a program operation. WRPERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a protection error occurs

1: interrupt generated when a protection error occurs

Bit 16 **EOPIE**: end of operation interrupt control bit

Setting EOPIE bit to 1 enables the generation of an interrupt at the end of a program or erase operation. EOPIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated at the end of operation.

1: interrupt enabled when at the end of operation

Bit 15 **MER**: Mass erase request

Setting MER bit to 1 requests a mass erase operation (user flash memory only). MER can be programmed only when LOCK is cleared to 0.

If BER or PER are both set, a PGSERR is raised.

0: mass erase not requested

1: mass erase requested

Note: An error is triggered when a mass erase is required and some pages are protected.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **PUF_LAUNCH**: PUF preparation start control bit

PUF_LAUNCH bit is used to launch a PUF operation. PUF_LAUNCH can be set only when LOCK is cleared to 0. The setting is only valid when TZstate = 0xC3 and HDPL is 0 or 1, ignored otherwise.

PUF_LAUNCH is reset at the end of the operation or when an error occurs. It cannot be reset by software.

Bits 12:11 Reserved, must be kept at reset value.

Bits 10:6 **PNB[4:0]**: page erase selection number

These bits are used to select the target page for an erase operation (they are unused otherwise). They can be programmed only when LOCK is cleared to 0.

0x00: Page 0 selected

0x01: Page 1 selected

..

0x1F: Page 31 selected

Note: For products with lower page count consider the extra PNB bits reserved.

Bit 5 **STRT**: erase start control bit

STRT bit is used to start a page erase or a bank erase operation. STRT can be programmed only when LOCK is cleared to 0.

STRT is reset at the end of the operation or when an error occurs. It cannot be reseted by software.

Bit 4 **FW:** write forcing control bit

FW forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW can be programmed only when LOCK is cleared to 0.

The memory resets FW when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it leads to permanent ECC error.

Write forcing is effective only if the write buffer is not empty and was filled by nonsecure access (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Since there is just one write buffer, FW can force a write in Bank1 or Bank2.

Bit 3 **BER**: erase request

Setting BER bit to 1 requests a bank erase operation (user flash memory only). BER can be programmed only when LOCK is cleared to 0.

If MER and PER are also set, a PGSERR is raised.

0: bank erase not requested

1: bank erase requested

Note: Write protection error is triggered when a bank erase is required and some pages are protected.

Bit 2 **PER**: page erase request

Setting PER bit to 1 requests a page erase. PER can be programmed only when LOCK is cleared to 0.

If MER and PER are also set, a PGSERR is raised.

0: page erase not requested

1: page erase requested

Bit 1 **PG**: programming control bit
PG can be programmed only when LOCK is cleared to 0.
PG allows programming in Bank1 and Bank2.
0: programming disabled
1: programming enabled

Bit 0 **LOCK**: configuration lock bit
This bit locks the FLASH_CR register. The correct write sequence to FLASH_KEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_KEYR is performed twice, this bit remains locked until the next system reset.
LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_CR register do not change.
0: FLASH_CR register unlocked
1: FLASH_CR register locked

7.11.12 FLASH secure control register (FLASH_SCR)

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Access: No wait state when no memory operations are ongoing. The FLASH_SCR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x02C

Reset value: 0x0000 0001

rw		rw			rw	rw	rw	rw	rw	rs	rw	rw	rw	rw	rs

Bit 31 **BKSEL**: bank selector bit
Can only be programmed when LOCK is cleared to 0. The bit selects physical bank, SWAP_BANK setting is ignored.
0: Bank1 is selected for Bank erase / page erase / interrupt enable
1: Bank2 is selected for BER / PER

Bit 30 Reserved, must be kept at reset value.

Bit 29 **INV**: Flash memory security state invert.
This bit inverts the flash memory security state.

Bits 28:23 Reserved, must be kept at reset value.

Bit 22 **OBKWERRIE**: OBK write error interrupt enable bit

OBKWERRIE enables generation of interrupt in case of OBK specific write error. OBKWERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt is generated on OBK write error

1: an interrupt is generated on OBK write error

Bit 21 **OBKERRIE**: OBK general error interrupt enable bit

OBKERRIE enables generating an interrupt in case of OBK specific access error. OBKERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt is generated on OBK general access error

1: an interrupt is generated on OBK general access error

Bit 20 **INCERRIE**: inconsistency error interrupt enable bit

When INCERRIE bit is set to 1, an interrupt is generated when an inconsistency error occurs during a write operation. INCERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a inconsistency error occurs

1: interrupt generated when a inconsistency error occurs.

Bit 19 **STRBERRIE**: strobe error interrupt enable bit

When STRBERRIE bit is set to 1, an interrupt is generated when a strobe error occurs (the master programs several times the same byte in the write buffer) during a write operation. STRBERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a strobe error occurs

1: interrupt generated when strobe error occurs.

Bit 18 **PGSERRIE**: programming sequence error interrupt enable bit

When PGSERRIE bit is set to 1, an interrupt is generated when a sequence error occurs during a program operation. PGSERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a sequence error occurs

1: interrupt generated when sequence error occurs

Bit 17 **WRPERRIE**: write protection error interrupt enable bit

When WRPERRIE bit is set to 1, an interrupt is generated when a protection error occurs during a program operation. WRPERRIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated when a protection error occurs

1: interrupt generated when a protection error occurs

Bit 16 **EOPIE**: end of operation interrupt control bit

Setting EOPIE bit to 1 enables the generation of an interrupt at the end of a program/erase operation. EOPIE can be programmed only when LOCK is cleared to 0.

0: no interrupt generated at the end of operation.

1: interrupt enabled when at the end of operation

Bit 15 **MER**: mass erase request

Setting MER bit to 1 requests a mass erase operation (user flash memory only). MER can be programmed only when LOCK is cleared to 0.

If BER or PER are also set, a PGSERR is raised.

0: mass erase not requested

1: mass erase requested

Note: An error is triggered when a mass erase is required and some pages are protected.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **PUF_LAUNCH**: PUF preparation start control bit

PUF_LAUNCH bit is used to launch a PUF operation. PUF_LAUNCH can be set only when LOCK is cleared to 0 and HDPL is 0 or 1.

PUF_LAUNCH is reseted at the end of the operation or when an error occurs. It cannot be reset by software.

Bits 12:11 Reserved, must be kept at reset value.

Bits 10:6 **PNB[4:0]**: page erase selection number

These bits are used to select the target page for an erase operation (they are unused otherwise). They can be programmed only when LOCK is cleared to 0.

0x00: Page 0 selected

0x01: Page 1 selected

..

0x1F: Page 31 selected

Note: For products with lower page count consider the extra PNB bits reserved.

Bit 5 **STRT**: erase start control bit

STRT bit is used to start a page erase or a bank erase operation. STRT can be programmed only when LOCK is cleared to 0.

STRT is reseted at the end of the operation or when an error occurs. It cannot be reset by software.

Bit 4 **FW:** write forcing control bit

FW forces a write operation even if the write buffer is not full. In this case all bits not written are set to 1 by hardware. FW can be programmed only when LOCK is cleared to 0.

The memory resets FW when the corresponding operation has been acknowledged.

Note: Using a force-write operation prevents the application from updating later the missing bits with something else than 1, because it is likely that it leads to permanent ECC error.

Write forcing is effective only if the write buffer is not empty and was filled by secure access (in particular, FW does not start several write operations when the force-write operations are performed consecutively).

Since there is just one write buffer, FW can force a write in Bank1 or Bank2.

Bit 3 **BER**: erase request

Setting BER bit to 1 requests a bank erase operation (user flash memory only). BER can be programmed only when LOCK is cleared to 0.

If MER and PER are also set, a PGSERR is raised.

0: bank erase not requested

1: bank erase requested

Note: Write protection error is triggered when a bank erase is required and some pages are protected.

Bit 2 **PER**: page erase request

Setting PER bit to 1 requests a page erase. PER can be programmed only when LOCK is cleared to 0.

If BER and MER are also set, a PGSERR is raised.

0: page erase not requested

1: page erase requested

Bit 1 **PG**: programming control bit

PG can be programmed only when LOCK is cleared to 0.

PG allows programming in Bank1 and Bank2.

0: programming disabled

1: programming enabled

Bit 0 **LOCK**: configuration lock bit

This bit locks the FLASH_SCR register. The correct write sequence to FLASH_SKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence to FLASH_SKEYR is performed twice, this bit remains locked until the next system reset.

LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_SCR register do not change.

0: FLASH_SCR register unlocked

1: FLASH_SCR register locked

7.11.13 FLASH nonsecure clear control register (FLASH_CCR)

This register is nonsecure. It can be written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x030

Reset value: 0x0000 0000

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **OPTCHANGEERR:** Clear the flag corresponding flag in FLASH_SR by writing this bit.

Bit 22 **OBKWERR**: OBKWERR flag clear bit.

Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_SR register.

Bit 21 **OBKERR**: OBKERR flag clear bit.

Setting this bit to 1 resets to 0 OBKERR flag in FLASH_SR register.

Bit 20 **INCERR**: INCERR flag clear bit

Setting this bit to 1 resets to 0 INCERR flag in FLASH_SR register.

Bit 19 **STRBERR**: STRBERR flag clear bit

Setting this bit to 1 resets to 0 STRBERR flag in FLASH_SR register.

Bit 18 **PGSERR**: PGSERR flag clear bit
Setting this bit to 1 resets to 0 PGSERR flag in FLASH_SR register.

Bit 17 **WRPERR**: WRPERR flag clear bit
Setting this bit to 1 resets to 0 WRPERR flag in FLASH_SR register.

Bit 16 **EOP**: EOP flag clear bit
Setting this bit to 1 resets to 0 EOP flag in FLASH_SR register.

Bits 15:0 Reserved, must be kept at reset value.

7.11.14 FLASH secure clear control register (FLASH_SCCR)

This register is secure. It can be written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x034

Reset value: 0x0000 0000

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **OBKWERR**: OBKWERR flag clear bit
Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_SSR register.

Bit 21 **OBKERR**: OBKWERR flag clear bit
Setting this bit to 1 resets to 0 OBKWERR flag in FLASH_SSR register.

Bit 20 **INCERR**: INCERR flag clear bit
Setting this bit to 1 resets to 0 INCERR flag in FLASH_SSR register.

Bit 19 **STRBERR**: STRBERR flag clear bit
Setting this bit to 1 resets to 0 STRBERR flag in FLASH_SSR register.

Bit 18 **PGSERR**: PGSERR flag clear bit
Setting this bit to 1 resets to 0 PGSERR flag in FLASH_SSR register.

Bit 17 **WRPERR**: WRPERR flag clear bit
Setting this bit to 1 resets to 0 WRPERR flag in FLASH_SSR register.

Bit 16 **EOP**: EOP flag clear bit
Setting this bit to 1 resets to 0 EOP flag in FLASH_SSR register.

Bits 15:0 Reserved, must be kept at reset value.

7.11.15 FLASH privilege configuration register (FLASH_PRIVCFGR)

Address offset: 0x03C

Reset value: 0x0000 0000

This register can be read by both privileged and unprivileged access. PRIV is a nonsecure bit. SPRIV is a secure bit. It can be written only by privileged mode.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **PRIV**: privilege attribute for non secure registers
- 0: access to non secure registers is always granted
- 1: access to non secure registers is denied in case of unprivileged access.

Bit 0 **SPRIV**: privilege attribute for secure registers
- 0: access to secure registers is always granted
- 1: access to secure registers is denied in case of unprivileged access.

7.11.16 FLASH nonsecure OBK configuration register (FLASH_OBKCFGR)

Register is only available when TZ_STATE = 0xC3. This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can only be accessed by privilege code.

The FLASH_OBKCFGR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x040

Reset value: 0x01FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP_OFFSET[8:0]								
							rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALT_SECT_ERASE	ALT_SECT	SWAP_SECT_REQ	LOCK
												rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **SWAP_OFFSET[8:0]**: key index (offset /16 bytes) pointing for next swap.
0x00: means that no OBK is copied from current to alternate OBK page during SWAP operation.
0x01 means that only the first OBK data (128 bits) are copied from current to alternate OBK page
0x02 means that the two first OBK data are copied …
…
0x1FF: means that all OBK data (511) are copied

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **ALT_SECT_ERASE**: alternate page erase bit
0: do not touch OBK page
1: erase the alternate OBK page
When ALT_SECT bit is set, use this bit to generate an erase command for the OBK alternate page. It is set only by Software and cleared when the OBK swap operation is completed or an error occurs (PGSERR). It is reseted at the same time as BUSY bit.

Bit 2 **ALT_SECT**: alternate page bit
0: current OBK page is mapped to OBK address range for access
1: alternate OBK page is mapped to OBK address range for access
This bit must not change while filling the write buffer, otherwise an error (OBKERR) is generated

Bit 1 **SWAP_SECT_REQ**: OBK swap page request bit
0: no swap requested
1: launch the page swap
When set, all the OBKs not updated in the alternate page are copied from current page to alternate one.
The SWAP_OFFSET value must have a minimum value for the swap to be launched. Minimum value is 16 for OBK-HDPL = 1, 144 for OBK-HDPL = 2 and 256 for OBK-HDPL = 3.

Bit 0 **LOCK**: OBKCFGR lock option configuration bit
This bit locks the register. The correct write sequence to FLASH_OBKKEYR register unlocks it. If a wrong sequence is executed, or if the unlock sequence is performed twice, this bit remains locked until the next system reset. LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_CR register do not change.
0: FLASH_OBKCFGR register unlocked
1: FLASH_OBKCFGR register locked

7.11.17 FLASH secure OBK configuration register (FLASH_SOBKCFGR)

This register can be accessed only in secure privileged mode. The FLASH_SOBKCFGR register is not accessible in write mode when the BSY bit is set. Any attempt to write to it with the BSY bit set causes the AHB bus to stall until the BSY bit is cleared.

Address offset: 0x044

Reset value: 0x01FF 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

												rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bits 24:16 **SWAP_OFFSET[8:0]**: key index (offset /16 bits) pointing for next swap.
0x0: no OBK is copied from current to alternate OBK page during SWAP operation.
0x1: only the first OBK data (128 bits) are copied from current to alternate OBK page
0x2: the two first OBK data are copied …
…
0x1FF: that the 511 first OBK data are copied

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **ALT_SECT_ERASE**: alternate page erase bit
0: do not touch OBK page
1: erase the alternate OBK page
When ALT_SECT bit is set, use this bit to generate an erase command for the OBK alternate page. It is set only by Software and cleared when the OBK swap operation is completed or an error occurs (PGSERR). It is reset at the same time as the BUSY bit.

Bit 2 **ALT_SECT**: alternate page bit
0: current OBK page is mapped to OBK address range for access
1: alternate OBK page is mapped to OBK address range for access
This bit must not change while filling the write buffer, otherwise an error is generated

Bit 1 **SWAP_SECT_REQ**: OBK swap page request bit
0: no swap requested
1: launch the page swap
When set, all the OBKs not updated in the alternate page are copied from current page to alternate one.
The SWAP_OFFSET value must have a minimum value for the swap to be launched.
Minimum value is 16 for OBK-HDPL = 1, 144 for OBK-HDPL = 2 and 256 for OBK-HDPL = 3.

Bit 0 **LOCK**: OBKCFGR lock option configuration bit

This bit locks the register. The correct write sequence to FLASH_SOBKKEYR register unlocks this bit. If a wrong sequence is executed, or if the unlock sequence is performed twice, this bit remains locked until the next system reset. LOCK can be set by programming it to 1. When set to 1, a new unlock sequence is mandatory to unlock it. When LOCK changes from 0 to 1, the other bits of FLASH_CR register do not change.

0: FLASH_OBKCFGR register unlocked
1: FLASH_OBKCFGR register locked

7.11.18 FLASH HDP extension register (FLASH_HDPEXTR)

All bits in this register are nonsecure. It can be read and written by both secure and nonsecure access. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

The register can only be modified in HDPL<=2.

The values in this register cannot be decremented. Attempt to write a lower value that current is ignored.

Address offset: 0x048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDP1_EXT[4:0]				
											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **HDP2_EXT[4:0]**: HDP area extension in 8 Kbytes pages in Bank2. Extension is added after the END page (included).

Note: For products with lower page count consider the extra bits 20 or 19 reserved.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **HDP1_EXT[4:0]**: HDP area extension in 8 Kbytes pages in Bank1. Extension is added after the END page (included).

Note: For products with lower page count consider the extra bits 4 or 3 reserved.

7.11.19 FLASH option status register (FLASH_OPTSR_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x2D30 EDD8

Default value: 0x2D30 5CD8 (value in case of double ECC issue during OBL)

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x050

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	BOOT_UBE[7:0]								IWDG_ STDBY	IWDG_ STOP	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r		r	r			

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:22 **BOOT_UBE[7:0]:** Available only on cryptography enabled devices.
Unique boot entry control, selects either ST or OEM iRoT for secure boot.
0xC3: ST-iRoT (system flash) selected
0xB4: OEM-iRoT (user flash) selected. In Open PRODUCT_STATE this value selects bootloader. Default value.

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option status bit
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog 1 frozen in Standby mode
1: Independent watchdog 1 keep running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option status bit
When set the independent watchdog IWDG is in system Stop mode.
0: Independent watchdog 1 frozen in system Stop mode
1: Independent watchdog 1 keep running in system Stop mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:8 **PRODUCT_STATE[7:0]**: Life state code (based on Hamming 8,4). See in *Section 7.6.11: Product state transitions*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option status bit
0: a reset is generated when entering Standby mode on core domain
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option status bit
0: a reset is generated when entering Stop mode on core domain
1: no reset generated when entering Stop mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option status bit
0: WWDG watchdog is controlled by hardware
1: WWDG watchdog is controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option status bit
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bits 2:0 Reserved, must be kept at reset value.

7.11.20 FLASH option status register (FLASH_OPTSR_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Address offset: 0x054

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRODUCT_STATE[7:0]								NRST_STDBY	NRST_STOP	Res.	WWDG_SW	IWDG_SW	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw			

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:22 **BOOT_UBE[7:0]:** Available only on cryptography enabled devices.
Unique boot entry control, selects either ST or OEM iRoT for secure boot.
0xC3: ST-iRoT (system flash) selected
0xB4: OEM-iRoT (user flash) selected.
In Open PRODUCT_STATE this value selects bootloader. Default value.

Bit 21 **IWDG_STDBY**: IWDG Standby mode freeze option status bit
When set the independent watchdog IWDG is frozen in system Standby mode.
0: Independent watchdog frozen in Standby mode
1: Independent watchdog keep running in Standby mode.

Bit 20 **IWDG_STOP**: IWDG Stop mode freeze option status bit
When set the independent watchdog IWDG is in system Stop mode.
0: Independent watchdog frozen in system Stop mode
1: Independent watchdog keep running in system Stop mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:8 **PRODUCT_STATE[7:0]**: Life state code (based on Hamming 8,4). See in *Section 7.6.11: Product state transitions*.

Bit 7 **NRST_STDBY**: Core domain Standby entry reset option configuration bit
0: a reset is generated when entering Standby mode on core domain
1: no reset generated when entering Standby mode on core domain.

Bit 6 **NRST_STOP**: Core domain Stop entry reset option configuration bit
0: a reset is generated when entering Stop mode on core domain
1: no reset generated when entering Stop mode on core domain.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **WWDG_SW**: WWDG control mode option configuration bit
0: WWDG watchdog is controlled by hardware
1: WWDG watchdog is controlled by software

Bit 3 **IWDG_SW**: IWDG control mode option configuration bit
0: IWDG watchdog is controlled by hardware
1: IWDG watchdog is controlled by software

Bits 2:0 Reserved, must be kept at reset value.

7.11.21 FLASH nonsecure EPOCH register (FLASH_EPOCHR_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x0000 0001

Default value: 0x00FF FFFF (value in case of double ECC issue during OBL)

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x060

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EPOCH[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:0 **EPOCH[23:0]:** Non-volatile nonsecure EPOCH counter

7.11.22 FLASH nonsecure EPOCH register (FLASH_EPOCHR_PRG)

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

HDPL0 level is necessary to modify this register contents.

This register is used to program values in corresponding option bits.

Address offset: 0x064

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

								r	r	r	r	r	r		

Bits 31:24 **TZEN[7:0]**: TrustZone enable configuration bits
This bit enables the device is in TrustZone mode during an option byte change.
0xC3: TrustZone disabled
0xB4: TrustZone enabled.

Bits 23:8 Reserved, must be kept at reset value.

Bit 7 **SRAM3_ECC**: SRAM3 ECC detection and correction disable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled
Note that SRAM3_ECC is not available on the STM32G53x/54x devices.

Bit 6 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 5 **SRAM1_ECC**: SRAM1 ECC detection and correction disable
0: SRAM1 ECC check enabled
1: SRAM1 ECC check disabled

Bit 4 **SRAM3_RST**: SRAM3 erase upon system reset
0: SRAM3 erased when a system reset occurs
1: SRAM3 not erased when a system reset occurs
Note that SRAM3_RST is not available on the STM32G53x/54x devices.

Bit 3 **SRAM2_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs.

Bit 2 **SRAM1_RST**: SRAM1 erase upon system reset
0: SRAM1 erased when a system reset occurs
1: SRAM1 not erased when a system reset occurs

Bits 1:0 Reserved, must be kept at reset value.

7.11.26 FLASH option status register 2 (FLASH_OPTSR2_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Address offset: 0x074

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

Bits 31:24 **TZEN[7:0]**: TrustZone enable configuration bits
This bit enables the device is in TrustZone mode during an option byte change.
0xC3: TrustZone disabled
0xB4: TrustZone enabled

Bits 23:8 Reserved, must be kept at reset value.

Bit 7 **SRAM3_ECC**: SRAM3 ECC detection and correction disable
0: SRAM3 ECC check enabled
1: SRAM3 ECC check disabled
Note that SRAM3_ECC is not available on STM32G53x/54x devices.

Bit 6 **SRAM2_ECC**: SRAM2 ECC detection and correction disable
0: SRAM2 ECC check enabled
1: SRAM2 ECC check disabled

Bit 5 **SRAM1_ECC**: SRAM1 ECC detection and correction disable
0: SRAM1 ECC check enabled
1: SRAM1 ECC check disabled

Bit 4 **SRAM3_RST**: SRAM3 erase upon system reset
0: SRAM3 erased when a system reset occurs
1: SRAM3 not erased when a system reset occurs
Note that SRAM3_RST is not available on STM32G53x/54x devices.

Bit 3 **SRAM2_RST**: SRAM2 erase when system reset
0: SRAM2 erased when a system reset occurs
1: SRAM2 not erased when a system reset occurs.

Bit 2 **SRAM1_RST**: SRAM1 erase upon system reset
0: SRAM1 erased when a system reset occurs
1: SRAM1 not erased when a system reset occurs

Bits 1:0 Reserved, must be kept at reset value.

7.11.27 FLASH option status register 3 (FLASH_OPTSR3_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x00C3 C300

Default value: 0x00B4 C300 (value in case of double ECC issue during OBL)

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x078

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SWAP_BANK[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r	r	r	r	r	r	r	r								

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **SWAP_LOCKOUT**: Configuration option specifies if the mapping of bank address space can be altered
0xC3: Swapping permitted
0xB4: Swapping disabled by configuration.
May only be modified in Open and Provisioning state

Bits 15:8 **SWAP_BANK**: Configuration option specifies the mapping of bank address space after reset
0xC3: Default mapping, Bank1 starts first
0xB4: Altered mapping, Bank2 starts first

Bits 7:0 Reserved, must be kept at reset value.

7.11.28 FLASH option status register 3 (FLASH_OPTSR3_PRG)

This register is secure when TrustZone® is active (RAZ, WI in nonsecure access) and nonsecure when TrustZone® is disabled. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits. Values after reset reflects the current values of the corresponding option bits.

Address offset: 0x07C

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP_LOCKOUT[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWAP_BANK[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **SWAP_LOCKOUT**: Configuration option specifies if the mapping of bank address space can be altered
0xC3: Swapping permitted
0xB4: Swapping disabled by configuration.
May only be modified in Open and Provisioning state

Bits 15:8 **SWAP_BANK**: Configuration option specifies the mapping of bank address space after reset
0xC3: Default mapping, Bank1 starts first
0xB4: Altered mapping, Bank2 starts first

Bits 7:0 Reserved, must be kept at reset value.

7.11.29 FLASH nonsecure boot register (FLASH_BOOTR_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x0800 00C3

Default value: 0xFFFF FFB4 (value in case of double ECC issue during OBL)

This register reflects the current values of the corresponding option bits.

Address offset: 0x080

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOTADD[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTADD[7:0]								BOOT_LOCK[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:8 **BOOTADD[23:0]**: Non secure unique boot entry address
These bits reflect the Non secure UBE address

Bits 7:0 **BOOT_LOCK[7:0]:** Field locking the value of BOOTADD.
0xC3: BOOTADD can still be modified following their individual rules.
0xB4: BOOTADD is frozen.

7.11.30 FLASH nonsecure boot register (FLASH_BOOTR_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x084

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BOOTADD[23:8]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BOOTADD[7:0]								BOOT_LOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **BOOTADD[23:0]**: Non secure unique boot entry address
These bits allow configuring the Non secure BOOT address

Bits 7:0 **BOOT_LOCK[7:0]:** Field locking the BOOTADD setting.
0xC3: BOOTADD can still be modified following their individual rules.
0xB4: BOOTADD is frozen.

7.11.31 FLASH secure boot register (FLASH_SBOOTR_CUR)

This register is secure. It can be read only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x0C00 00C3

Default value: 0xFFFF FFB4 (value in case of double ECC issue during OBL)

This register reflects the current values of the corresponding option bits.

Address offset: 0x088

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SBOOTADD[23:8]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SBOOTADD[7:0]								SBOOT_LOCK[7:0]							
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:8 **SBOOTADD[23:0]**: Unique boot entry secure address
These bits reflect the Secure UBE address

Bits 7:0 **SBOOT_LOCK[7:0]:** Field locking the values of UBE and SBOOTADD settings.
0xC3: BOOT_UBE and SBOOTADD can still be modified following their individual rules.
0xB4: BOOT_UBE and SBOOTADD are frozen.

7.11.32 FLASH secure boot register (FLASH_SBOOTR_PRG)

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x08C

Reset value: 0xXXXX XXXX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SBOOTADD[23:8]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SBOOTADD[7:0]								SBOOT_LOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 **SBOOTADD[23:0]**: Secure unique boot entry address.
These bits allow configuring the secure UBE address.

Bits 7:0 **SBOOT_LOCK[7:0]:** A field locking the values of UBE and SBOOTADD setting.
0xC3: BOOT_UBE and SBOOTADD can still be modified following their individual rules.
0xB4: BOOT_UBE and SBOOTADD are frozen.

7.11.33 FLASH nonsecure OTP block lock (FLASH_OTPBLR_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x0000 0000

Default value: 0xFFFF FFFF (value in case of double ECC issue during OBL)

This register reflects the current values of the corresponding option bits.

Address offset: 0x090

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCKBL[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **LOCKBL[31:0]**: OTP block lock

Block *i* corresponds to OTP 16-bit word 32*i to 32**i* + 31.
LOCKBLi = 1 indicates that all OTP 16-bit words in OTP Block *i* are locked and attempt to program them results in WRPERR.
LOCKBLi = 0 indicates that all OTP 16-bit words in OTP Block *i* are not locked.
When one block is locked, it's not possible to remove the write protection.
Even if not locked, it is not possible to erase OTP words, only program virgin ones.

7.11.34 FLASH nonsecure OTP block lock (FLASH_OTPBLR_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x094

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCKBL[31:16]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LOCKBL[15:0]															
rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:0 **LOCKBL[31:0]**: OTP block lock

Block *i* corresponds to OTP 16-bit word 32*i to 32**i* + 31.
LOCKBLi = 1 indicates that all OTP 16-bit words in OTP Block *i* are locked and attempt to program them results in WRPERR.
LOCKBLi = 0 indicates that all OTP 16-bit words in OTP Block *i* are not locked.
When one block is locked, it is not possible to remove the write protection.
LOCKBL bits can be set if the corresponding bit in FLASH_OTPBLR_CUR is cleared.

7.11.35 FLASH bootloader interface selection (FLASH_BL_COM_CFG_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0xFFFF FFFF

Default value: 0xFFFF FFFF (value in case of double ECC issue during OBL)

This register reflects the current values of the corresponding option bits.

Address offset: 0x098

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BL_COM_CFG[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BL_COM_CFG[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **BL_COM_CFG[31:0]**: Bootloader interface selection/configuration

This register is used to configure the set of interfaces on which the ST bootloader is active.
BL_COM_CFG[0] = 0 USART2 interface disabled for ST embedded bootloader.
BL_COM_CFG[0] = 1 USART2 interface enabled for ST embedded bootloader.
BL_COM_CFG[1] = 0 USART4 interface disabled for ST embedded bootloader.
BL_COM_CFG[1] = 1 USART4 interface enabled for ST embedded bootloader.
BL_COM_CFG[2] = 0 USART5 interface disabled for ST embedded bootloader.
BL_COM_CFG[2] = 1 USART5 interface enabled for ST embedded bootloader.
BL_COM_CFG[4] = 1 I2C2 interface disabled for ST embedded bootloader.
BL_COM_CFG[4] = 0 I2C2 interface enabled for ST embedded bootloader.
BL_COM_CFG[5] = 0 I2C3 interface disabled for ST embedded bootloader.
BL_COM_CFG[5] = 1 I2C3 interface enabled for ST embedded bootloader.
BL_COM_CFG[8] = 0 SPI1 interface disabled for ST embedded bootloader.
BL_COM_CFG[8] = 1 SPI1 interface enabled for ST embedded bootloader.
BL_COM_CFG[9] = 0 SPI2 interface disabled for ST embedded bootloader.
BL_COM_CFG[9] = 1 SPI2 interface enabled for ST embedded bootloader.
BL_COM_CFG[16] = 0 FDCAN1 interface disabled for ST embedded bootloader.
BL_COM_CFG[16] = 1 FDCAN1 interface enabled for ST embedded bootloader.
BL_COM_CFG[20] = 0 USB interface disabled for ST embedded bootloader.
BL_COM_CFG[20] = 1 USB interface enabled for ST embedded bootloader.
If the interface is enabled then it is used by the ST bootlader, corresponding GPIOs are used by ST bootloader.
If the interface is disabled then it is not used by the ST bootloader, corresponding GPIOs remain in default state.
For more information of bootloader interfaces and assigned GPIOs see the bootloader documentation (AN2606).

7.11.36 FLASH bootloader interface selection (FLASH_BL_COM_CFG_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x09C

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BL_COM_CFG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BL_COM_CFG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **BL_COM_CFG[31:0]**: Bootloader interface selection/configuration

This register is used to configure the set of interfaces on which the ST bootloader is active.
BL_COM_CFG[0] = 0 USART2 interface disabled for ST embedded bootloader.
BL_COM_CFG[0] = 1 USART2 interface enabled for ST embedded bootloader.
BL_COM_CFG[1] = 0 USART4 interface disabled for ST embedded bootloader.
BL_COM_CFG[1] = 1 USART4 interface enabled for ST embedded bootloader.
BL_COM_CFG[2] = 0 USART5 interface disabled for ST embedded bootloader.
BL_COM_CFG[2] = 1 USART5 interface enabled for ST embedded bootloader.
BL_COM_CFG[4] = 1 I2C2 interface disabled for ST embedded bootloader.
BL_COM_CFG[4] = 0 I2C2 interface enabled for ST embedded bootloader.
BL_COM_CFG[5] = 0 I2C3 interface disabled for ST embedded bootloader.
BL_COM_CFG[5] = 1 I2C3 interface enabled for ST embedded bootloader.
BL_COM_CFG[8] = 0 SPI1 interface disabled for ST embedded bootloader.
BL_COM_CFG[8] = 1 SPI1 interface enabled for ST embedded bootloader.
BL_COM_CFG[9] = 0 SPI2 interface disabled for ST embedded bootloader.
BL_COM_CFG[9] = 1 SPI2 interface enabled for ST embedded bootloader.
BL_COM_CFG[16] = 0 FDCAN1 interface disabled for ST embedded bootloader.
BL_COM_CFG[16] = 1 FDCAN1 interface enabled for ST embedded bootloader.
BL_COM_CFG[20] = 0 USB interface disabled for ST embedded bootloader.
BL_COM_CFG[20] = 1 USB interface enabled for ST embedded bootloader.
If the interface is enabled then it is used by the ST bootlader, corresponding GPIOs are used by ST bootloader.
If the interface is disabled then it is not used by the ST bootloader, corresponding GPIOs remain in default state.
For more information of bootloader interfaces and assigned GPIOs see the bootloader documentation (AN2606).

7.11.37 FLASH secure block based registers for Bank1 (FLASH_SECBB1R)

These registers are secure. They can be read and written only by secure access. A nonsecure read/write access is RAZ/WI.

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SEC1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SEC1[31:0]**: Secure/nonsecure 8 Kbytes flash Bank1 page attributes (y= 0 to 31)
0: page (y) in Bank1 is non secure.
1: page (y) in Bank1 is secure.
Note: For products with lower page count consider the extra upper bits reserved.

7.11.38 FLASH privilege block based registers for Bank1 (FLASH_PRIVBB1R)

These registers is privileged. They can be read and written only by a privileged access. These registers can be protected against nonsecure write access.

Address offset: 0x0C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
PRIV1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIV1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIV1[31:0]**: Privileged/unprivileged 8-Kbyte flash Bank1 page attribute (y = 0 to 31)
0: page (y) in Bank1 is unprivileged.
1: page (y) in Bank1 is privileged.
Note: For products with lower page count consider the extra upper bits reserved.

7.11.39 FLASH security watermark for Bank1 (FLASH_SECWM1R_CUR)

This read-only register is nonsecure, it can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x001F 0000

Default value: 0x001F 0000

It reflects the current values of the corresponding option bits.

Address offset: 0x0E0

Reset value: 0x00XX 00XX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	END[4:0]				
											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRT[4:0]				
											r	r	r	r	r

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **END[4:0]**: Bank1 security WM area 1 end page
Note: For products with lower page count consider the bits 20 or 19 reserved.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **STRT[4:0]**: Bank1 security WM area 1 start page
Note: For products with lower page count consider the bits 4 or 3 reserved.

7.11.40 FLASH security watermark for Bank1 (FLASH_SECWM1R_PRG)

This register is secure. It can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. This register can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register. This register is used to program values in the corresponding option bits.

Address offset: 0x0E4

Reset value: 0x00XX 00XX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRT[4:0]				
											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **END[4:0]**: Bank1 security WM area 1 end page
Note: For products with lower page count consider the bits 20 or 19 reserved.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **STRT[4:0]**: Bank1 security WM area 1 start page
Note: For products with lower page count consider the bits 4 or 3 reserved.

7.11.41 FLASH write page group protection for Bank1 (FLASH_WRP1R_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses, and can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0xFFFF FFFF

Default value: 0x0000 0000

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x0E8

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPG1[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPG1[7:0]**: Bank1 page group protection option status byte
Each FLASH_WRP1R_CUR bit reflects the write protection status of the corresponding group of four consecutive pages in Bank1 (0: the group is write-protected; 1: the group is not write-protected)
Bit 0: Group embedding pages 0 to 3
Bit 1: Group embedding pages 4 to 7
Bit N: Group embedding pages 4 x N to 4 x N + 3
Bit 7: Group embedding pages 31 to 28
Note: For products with lower page count consider the extra bits reserved.

7.11.42 FLASH write page group protection for Bank1 (FLASH_WRP1R_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x0EC

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPG1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPG1[7:0]**: Bank1 page group protection option status byte

Setting WRPG1 bits to 0 write protects the corresponding group of four consecutive pages in Bank1 (0: the group is write-protected; 1: the group is not write-protected)

Bit 0: Group embedding pages 0 to 3

Bit 1: Group embedding pages 4 to 7

Bit N: Group embedding pages 4 x N to 4 x N + 3

Bit 7: Group embedding pages 31 to 28

Note: For products with lower page count consider the bits representing unsupported pages reserved.

7.11.43 FLASH data page configuration Bank1 (FLASH_EDATA1R_CUR)

This register is nonsecure, can be read by both secure and nonsecure accesses. The register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x0000 0000

Default value: 0x0000 0000

This read-only register reflects the current values of the corresponding options bits.

Address offset: 0x0F0

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	STRT[2:0]		
r													r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EN:** Bank1 flash high-cycle data enable
0: No flash high-cycle data area
1: Flash high-cycle data is used

Bits 14:3 Reserved, must be kept at reset value.

Bits 2:0 **STRT[2:0]:**
STRT contains the start pages of the flash high-cycle data area in Bank1 There is no hardware effect to those bits. They shall be managed by ST tools in Flasher.
000: The last page of the Bank1 is reserved for flash high-cycle data
001: The two last pages of the Bank1 are reserved for flash high-cycle data
010: The three last pages of the Bank1 are reserved for flash high-cycle data
...
111: The eight last pages of the Bank1 are reserved for flash high-cycle data
Note: For products with lower EDATA page count consider the bit 2 reserved.

7.11.44 FLASH data page configuration Bank1 (FLASH_EDATA1R_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding options bits.

Address offset: 0xF4

Reset value: 0xXXXX XXXX

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **EN:** Bank1 flash high-cycle data enable
0: No flash high-cycle data area
1: Flash high-cycle data is used

Bits 14:3 Reserved, must be kept at reset value.

Bits 2:0 **STRT[2:0]:**
STRT contains the start pages of the flash high-cycle data area in Bank1 There is no hardware effect to those bits. They shall be managed by ST tools in Flasher.
000: The last page of the Bank1 is reserved for flash high-cycle data
001: The two last pages of the Bank1 are reserved for flash high-cycle data
010: The three last pages of the Bank1 are reserved for flash high-cycle data
...
111: The eight last pages of the Bank1 are reserved for flash high-cycle data
Note: For products with lower EDATA page count consider the bit 2 reserved.

7.11.45 FLASH HDP Bank1 configuration (FLASH_HDP1R_CUR)

This register is nonsecure. It can be read by both secure and nonsecure accesses, and can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register. This register is initially loaded with the values of the corresponding option bits.

Production value: 0x0000 0001

Default value: 0x001F 0000

Address offset: 0x0F8

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

											rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **END[4:0]:** HDPL barrier end set in number of 8-Kbyte pages
Note: For products with lower page count consider the bit 20 or 19 reserved.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **STRT[4:0]:** HDPL barrier start set in number of 8-Kbyte pages
Note: For products with lower page count consider the bit 4 or 3 reserved.

7.11.47 FLASH ECC correction register (FLASH_ECCCORR)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses, and it can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ECCC	Res.	Res.	Res.	Res.	ECCCIE	OTP_ECC	SYSF_ECC	BK_ECC	EDATA_ECC	OBK_ECC	Res.	Res.	Res.	Res.
	rw					rw	r	r	r	r	r				

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 Reserved, must be kept at reset value.

Bit 30 **ECCC:** ECC correction set by hardware when single ECC error has been detected and corrected.
Cleared by writing 1.

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **ECCCIE**: ECC single correction error interrupt enable bit
When ECCCIE bit is set to 1, an interrupt is generated when an ECC single correction error occurs during a read operation.
0: no interrupt generated when an ECC single correction error occurs
1: nonsecure interrupt generated when an ECC single correction error occurs

Bit 24 **OTP_ECC**: OTP ECC error bit
This bit is set to 1 when one single ECC correction occurred during the last successful read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC fail for corrected ECC error in system flash memory
It indicates if system flash memory is concerned by ECC error.

Bit 22 **BK_ECC**: ECC fail bank for corrected ECC error
It indicates which bank is concerned by ECC error

Bit 21 **EDATA_ECC**: ECC fail for corrected ECC error in flash high-cycle data area
It indicates if flash high-cycle data area is concerned by ECC error.

Bit 20 **OBK_ECC**: Single ECC error corrected in flash OB Keys storage area. It indicates the OBK storage concerned by ECC error.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address

When an ECC error occurs (for single correction) during a read operation, the ADDR_ECC contains the address that generated the error. It is reset when the flag error is reset.

The flash interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an ECC error is saved.

The address in ADDR_ECC is relative to the flash memory area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

7.11.48 FLASH ECC detection register (FLASH_ECCDETR)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x104

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ECCD	Res.	Res.	Res.	Res.	Res.	Res.	OTP_ECC	SYSF_ECC	BK_ECC	EDATA_ECC	OBK_ECC	Res.	Res.	Res.	Res.
rw							r	r	r	r	r				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bit 31 **ECCD:** ECC detection

Set by hardware when two ECC error has been detected.

When this bit is set, a NMI is generated.

Cleared by writing 1. Needs to be cleared in order to detect subsequent double ECC errors.

Bits 30:25 Reserved, must be kept at reset value.

Bit 24 **OTP_ECC**: OTP ECC error bit

This bit is set to 1 when double ECC detection occurred during the last read operation from the read-only/ OTP area. The address of the ECC error is available in ADDR_ECC bitfield.

Bit 23 **SYSF_ECC**: ECC fail for double ECC error in system flash memory

It indicates if system flash memory is concerned by ECC error.

Bit 22 **BK_ECC**: ECC fail bank for double ECC error

It indicates which bank is concerned by ECC error

Bit 21 **EDATA_ECC**: ECC fail double ECC error in flash high-cycle data area

It indicates if flash high-cycle data area is concerned by ECC error.

Bit 20 **OBK_ECC**: ECC fail double ECC error in flash OB Keys storage area. It indicates the OBK storage concerned by ECC error.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:0 **ADDR_ECC[15:0]**: ECC error address

When an ECC error occurs (double detection) during a read operation, the ADDR_ECC contains the address that generated the error. It is reset when the flag error is reset.
The flash interface programs the address in this register only when no ECC error flags are set. This means that only the first address that generated an double ECC error is saved.
The address in ADDR_ECC is relative to the flash memory area where the error occurred (user flash memory, system flash memory, data area, read-only/OTP area).

7.11.49 FLASH ECC data (FLASH_ECCDR)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses, and it can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x108

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DATA_ECC[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **DATA_ECC[15:0]**: ECC error data

When an double detection ECC error occurs on special areas with 6-bit ECC on 16-bit data (data area, read-only/OTP area), the failing data is read to this register.
By checking if it is possible to determine whether the failure was on a real data, or due to access to uninitialized memory.

7.11.50 FLASH secure block-based registers for Bank2 (FLASH_SECBB2R)

These registers are secure. They can be read and written only by secure access. A nonsecure read/write access is RAZ/WI. The registers can be protected against unprivileged access when SPRIV = 1 in the FLASH_PRIVCFGR register.

Address offset: 0x1A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

SEC2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SEC2[31:0]**: Secure/nonsecure flash Bank2 page attribute (y = 0 to 31)
0: page (y) in Bank2 is non secure
1: page (y) in Bank2 is secure
Note: For products with lower page count consider the extra upper bits reserved.

7.11.51 FLASH privilege block-based registers for Bank2 (FLASH_PRIVBB2R)

These registers are privileged. They can be read and written only by a privileged access. The registers can be protected against nonsecure write access by watermark.

Address offset: 0x1C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PRIV2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PRIV2[31:0]:** Privileged / non-privileged 8-Kbyte flash Bank2 page attribute (y = 0 to 31)
0: page (y) in Bank2 is unprivileged
1: page (y) in Bank2 is privileged
Note: For products with lower page count consider the extra upper bits reserved

7.11.52 FLASH security watermark for Bank2 (FLASH_SECWM2R_CUR)

This register is nonsecure. This register can be protected against unprivileged access when NSPRIpageV = 1 in the FLASH_PRIVCFGR register.

Production value: 0x001F 0000

Default value: 0x001F 0000

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x1E0

Reset value: 0x00XX 00XX

(Register bits 0 to 31 are loaded with values from the flash memory at OBL)

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **END[4:0]**: Bank2 security WM end page
Note: For products with lower page count consider the bit 20 or 19 reserved.

Bits 15:5 Reserved, must be kept at reset value.

Bits 4:0 **STRT[4:0]**: Bank2 security WM area start page
Note: For products with lower page count consider the bit 4 or 3 reserved.

7.11.54 FLASH write page group protection for Bank2 (FLASH_WRP2R_CUR)

This register is nonsecure, can be read by both secure and nonsecure accesses, and protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

Production value: 0xFFFF FFFF

Default value: 0x0000 0000

This read-only register reflects the current values of the corresponding option bits.

Address offset: 0x1E8

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRPG2[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **WRPG2[7:0]**: Bank2 page group protection option status byte

Each bit reflects the write protection status of the corresponding group of four consecutive pages in Bank2 (0: group is write-protected; 1: group is not write-protected)

Bit 0: Group embedding pages 0 to 3

Bit 1: Group embedding pages 4 to 7

Bit N: Group embedding pages 4 x N to 4 x N + 3

Bit 7: Group embedding pages 28 to 31

Note: For products with lower page count consider the extra upper bits reserved.

7.11.55 FLASH write page group protection for Bank2 (FLASH_WRP2R_PRG)

This register is nonsecure. It can be read and written by both secure and nonsecure accesses. This register can be protected against unprivileged access when PRIV = 1 in the FLASH_PRIVCFGR register.

This register is used to program values in the corresponding option bits.

Address offset: 0x1EC

Reset value: 0xXXXX XXXX

Refer to *Section 2.3* for the register boundary addresses.

8 Instruction cache (ICACHE)

8.1 ICACHE introduction

The instruction cache (ICACHE) is implemented on the C-AHB code bus of the Cortex®-M33 processor to improve performance when fetching instructions and data from internal and external memories.

Some specific features, like dual master ports, hit-under-miss, and critical-word-first refill policy, result in close to zero-wait-state performance in most use cases.

8.2 ICACHE main features

The main features of ICACHE are listed below:

- Bus interface
  - One 32-bit AHB slave port, the execution port (input from Cortex®-M33 C-AHB code interface)
  - Two AHB master ports: master1 and master2 ports, with outputs to Fast and Slow buses of main AHB bus matrix, respectively(master2 port is available only on STM32G55x/56x devices)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for ICACHE registers access)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Dual master(only on STM32G55x/56x devices) access: feature used to decouple the traffic according to targeted memory. For example, the ICACHE assigns fast traffic (addressing flash memories and SRAMs) to the AHB master1 port, and slow traffic (addressing external memories) to the AHB master2 port, thus preventing processor stalls on line refills from external memories. This allows ISR (interrupt service routine) fetching on internal flash memory to take place in parallel with a cache line refill from external memories.
  - Minimal impact on interrupt latency, thanks to dual master
  - Optimal cache line refill thanks to WRAPw bursts of the size of the cache line (32-bit word size, **w**, aligned on cache line size)
  - n-way set-associative default configuration with possibility to configure as 1-way, means direct mapped cache, for applications needing very-low-power consumption profile
- Memory address remap
  - Possibility to remap input address falling into up to four memory regions (used to remap aliased code in external memories to the code region, for execution from the C-AHB code interface)
- Replacement and refill
  - pLRU-t (pseudo-least-recently-used, based on binary tree) replacement policy, algorithm with best complexity/performance balance
  - Critical-word-first refill policy, minimizing processor stalls

  - Possibility to configure burst type of AHB memory transaction for remapped regions: INCRw or WRAPw (size w aligned on cache line size)
- ECC hardware support: single-bit and double-bit error detection (DED)
- Performance counters

  The ICACHE implements two performance counters:
  - Hit monitor counter (32-bit)
  - Miss monitor counter (16-bit)
- Error management
  - Possibility to detect an unexpected cacheable write access, to flag an error, and optionally, to raise an interrupt
- TrustZone® security support
- Maintenance operation
  - Cache invalidate: full cache invalidation, fast command, noninterruptible

8.3 ICACHE implementation

Table 81. ICACHE features for STM32G55x/56x

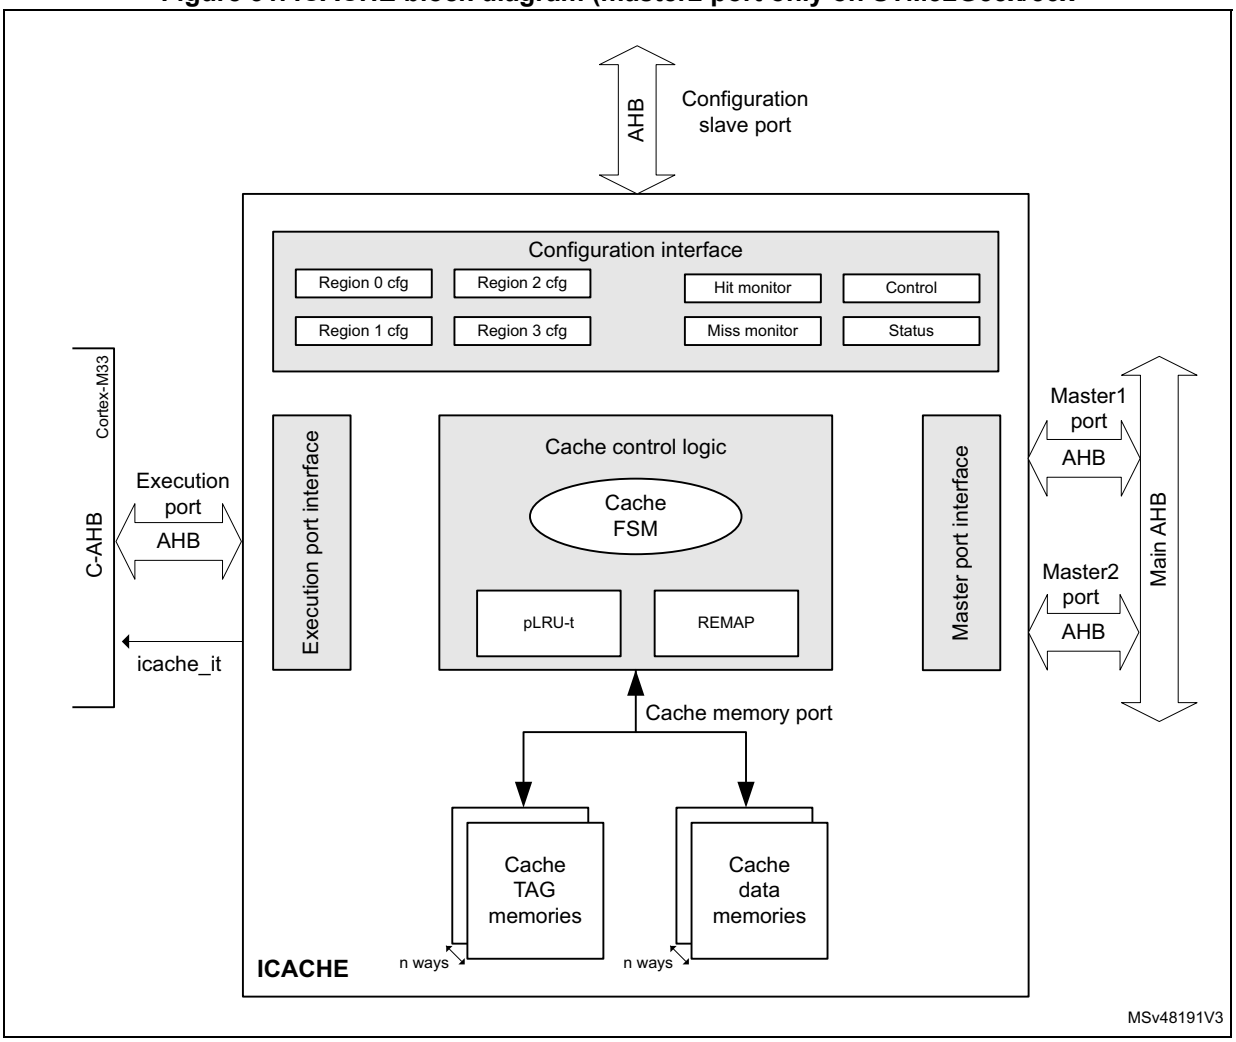
Data size of AHB slow master2 interface	-
ECC support	Yes

8.4 ICACHE functional description

The purpose of this block is to cache instruction fetches or instruction memories loads, coming from the processor. As such, the ICACHE manages only cacheable read transactions, and does not manage cacheable write transactions.



The noncacheable transactions (both read and write) bypass the ICACHE.

For the error management purpose, if a write cacheable transaction is presented (this happens only in case of bad software programming), the ICACHE sets an error flag and, if enabled, raises an interrupt to the processor.

The ICACHE also implements the hardware support for ECC, with a single-bit and double-bit error detection (DED; see *Section 8.4.12: ICACHE ECC support* for more details on ECC feature).

8.4.1 ICACHE block diagram

Figure 31. ICACHE block diagram (master2 port only on STM32G55x/56x

8.4.2 ICACHE reset and clocks

The ICACHE is clocked on the Cortex®-M33 C-AHB bus clock.

When the ICACHE reset signal is released, a cache invalidate procedure is automatically launched, making the ICACHE busy (ICACHE_SR = 0x0000 0001).

When this procedure is finished:

- the ICACHE is invalidated: “cold cache”, with all cache line valid bits = 0 and also all TAG addresses, ECC bit-fields and data reset to 0 (ICACHE must be filled up)
- ICACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- the ICACHE is disabled: the EN bit in ICACHE_CR holds its reset state (= 0).

Note: When disabled, the ICACHE is bypassed, except the remapping mechanism that is still functional: slave input requests (remapped or not) are forwarded to the master port(s).

8.4.3 ICACHE TAG memory

The ICACHE TAG memory contains:

- address tags indicating which data are contained in the cache data memories
- validity bits

There is one valid bit per cache line (per way).

The valid bit is set when a cache line is refilled (after a miss).

Valid bits and also TAG addresses, ECC bit-fields and data are reset in any of the below cases:

- after the ICACHE reset is released
- when the cache is disabled, by setting EN = 0 in ICACHE_CR (by software)
- when executing an ICACHE invalidate command, by setting CACHEINV = 1 in ICACHE_CR (by software)

When a cacheable transaction is received at the execution input port, its AHB address (HADDR_in) is split into the following fields (see *Table 83* for B and W definitions):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select inside a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to the TAG memory address to check if the requested data is already available (meaning valid) inside the ICACHE.

The following table gives a summary of the ICACHE main parameters for TAG memory dimensioning. *Figure 32* shows the functional view of TAG and data memories, for an n-way set associative ICACHE.

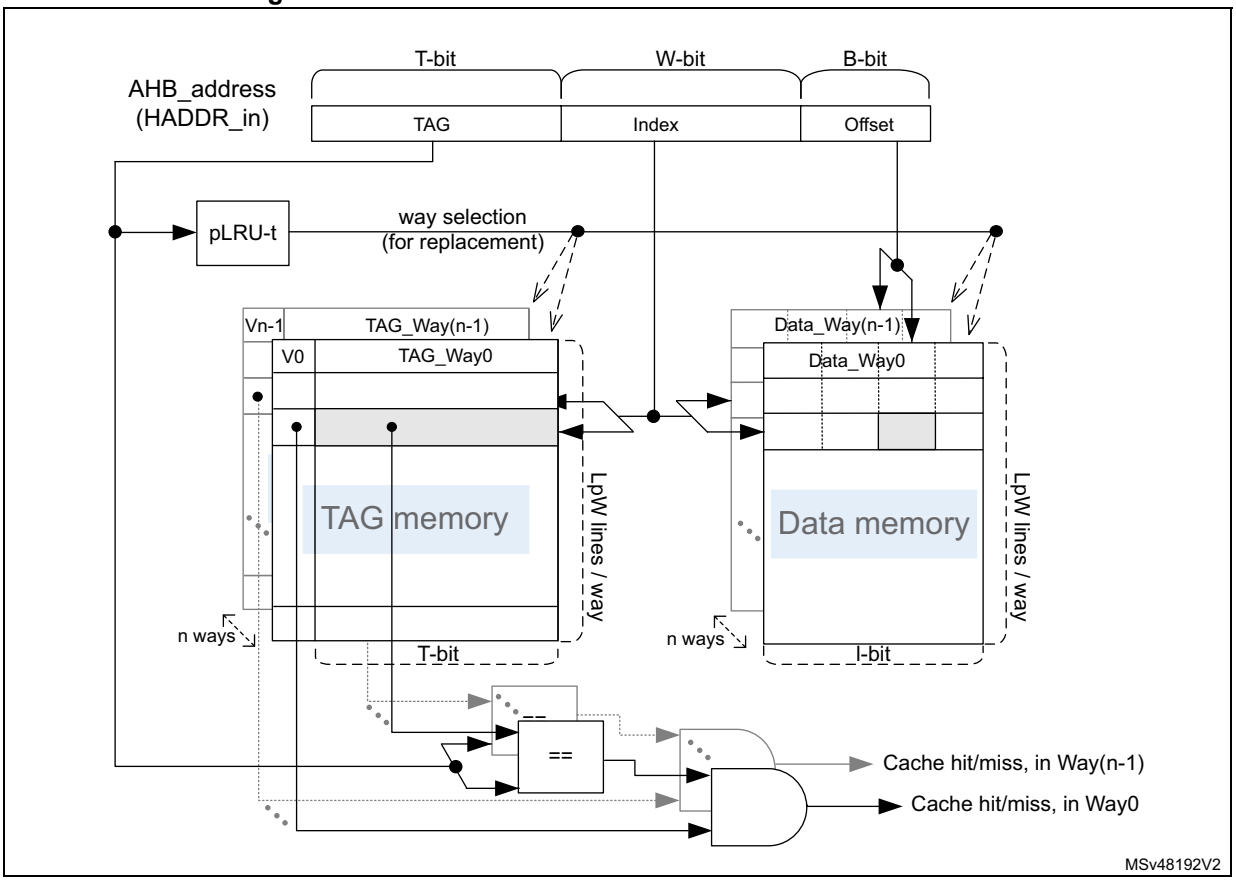


Table 83. TAG memory dimensioning parameters for n-way set associative operating mode (default)

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit

Table 83. TAG memory dimensioning parameters for n-way set associative operating mode (default) (continued)

Parameter	Value	Example
Number of cache lines	LpW = s / (n x L) lines / way	256 lines / way
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	8-bit
TAG address size	T = (32 - W - B) bit	20-bit

Figure 32. ICACHE TAG and data memories functional view

8.4.4 Direct-mapped ICACHE (1-way cache)

The default configuration (at reset) is an n-way set associative cache (WAYSEL = 1 in ICACHE_CR), but the user can configure the ICACHE as direct mapped by writing WAYSEL = 0 (only possible when the cache is disabled, EN = 0 in ICACHE_CR).

The following table gives a summary of ICACHE main parameters for TAG memory when the direct-mapped cache operating mode is selected.

Table 84. TAG memory dimensioning parameters for direct-mapped cache mode

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	8 Kbytes = 8192 bytes
Cache number of ways	1	1
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines	LpW = s / L lines	512 lines
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	9-bit
TAG address size	T = (32 - W - B) bit	19-bit

All cache operations (such as read, refill, remapping, invalidation) remain the same in the direct-mapped configuration. The only difference is the absence of a replacement algorithm in case of line eviction (as explained in *Section 8.4.8*): only one way (the unique one) is possible for any data refill.

8.4.5 ICACHE enable

To activate the ICACHE, the EN bit in ICACHE_CR must be set to 1.

When the ICACHE is disabled, it is bypassed and all transactions are copied from the slave to the master ports in the same clock cycle.

It is recommended to initialize or modify the main memory content (region to be later cached) with the ICACHE disabled, and to enable the ICACHE only when this region remains unchanged (an enabled ICACHE detects cacheable write transactions as errors).

To ensure performance determinism, it is recommended to wait for the end of a potential cache invalidate (and initialize) procedure before enabling the ICACHE. This procedure occurs when the hardware reset signal is released, when CACHEINV is set, or when EN is cleared in ICACHE_CR. During the procedure, BUSYF is set in ICACHE_SR, and once finished, BUSYF is cleared and BSYENDF is set in the same register (raising the ICACHE interrupt if enabled on such a busy end condition).

The software must test BUSYF and/or BSYENDF values before enabling the ICACHE. Else, if the ICACHE is enabled before the end of an invalidate procedure, any cache access (while BUSYF = 1) is treated as noncacheable, and its performance depends on the main memory access time.

The address remapping is performed, whether the ICACHE is enabled or not, if the input transaction address falls into the memory regions defined and enabled in ICACHE_CRRx (see *Figure 33*).

The ICACHE is, by default, disabled at boot.

8.4.6 Cacheable and noncacheable traffic

The ICACHE is developed for the Cortex®-M33 core. It is placed on the C-AHB bus, and thus caches the code memory region, ranging from address 0x0000 0000 to 0x1FFF FFFF of the memory map.

To make other memory regions cacheable, the ICACHE supports a memory region remapping feature, used to define up to four external memory regions, whose addresses have an alias in the code region. Addressing these memory regions through their code alias address allows the memory request to be routed to the C-AHB bus, and to be managed by the ICACHE.

Any external memory space physically mapped at an address in the range [0x6000 0000:0xAFFF FFFF] can be aliased with an address in the range [0x0000 0000:0x07FF FFFF] or [0x1000 0000:0x1FFF FFFF].

For a given memory request in the code region, the ICACHE implements the address remapping functionality first. If aliased, it is the remapped address, which is then cached, and, if needed, provided to the master port to address the main AHB bus matrix. The destination physical address does not need further manipulation on the AHB bus.

The remapping functionality is available also for noncacheable traffic, and when the cache is disabled.

Additional details on address remapping are provided in *Section 8.4.7*.

An incoming memory request to the ICACHE is defined as cacheable according to its AHB transaction memory lookup attribute, as shown in *Table 85*. This AHB attribute depends on the MPU (memory protection unit) programming for the addressed region.

Table 85. ICACHE cacheability for AHB transaction

AHB lookup attribute	Cacheability
1	Cacheable
0	Noncacheable

In the case of a noncacheable access (read or write), the ICACHE is bypassed. The AHB transaction is propagated unchanged to the master output port, except the transaction address, which may be modified due to the address remapping feature (see *Section 8.4.7*).

The bypass, and eventual remap logic, does not increase the latency of the access to the targeted memory.

In the case of a cacheable access, the ICACHE behaves as explained in *Section 8.4.8*.

Cacheable memory regions are defined and programmed by the user in the MPU responsible for the generation of the AHB attribute signals (HPROT[6:0]) for any transaction addressing a given region.

Table 86 summarizes programmable configurations of various memories.

Table 86. Memory configurations

Memory	Cacheable (MPU programming)	Remapped in the ICACHE (ICACHE_CRRx programming)
Flash	Yes or no	Not required
SRAM	Not recommended	Not required
External memories	Yes	Required
	No	Required if the user wants code in external memories fetched on C-AHB bus (else on S-AHB bus)

8.4.7 Address remapping

The ICACHE allows an alias address to be defined in the code region for up to four external memory regions.

The address remapping is applied on the code alias address, transforming it into the destination external physical address.

The remapping operation is fully software configurable by programming ICACHE_CRRx (x = 0 to 3, number of remapped regions). This programming can be done only when the ICACHE is disabled.

Each region x can be individually enabled with REN in ICACHE_CRRx. Once enabled, the remap operation occurs even if the ICACHE is disabled, or if the transaction is noncacheable.

Remap regions can have different size: each can be programmed in RSIZE of its ICACHE_CRRx. The size of each region is a power of two multiple of range granularity (2 Mbytes), with a minimum of 2 Mbytes, and a maximum of 128 Mbytes.

The address remapping mechanism is based on the matching of an incoming AHB address (HADDR_in) with a given code subregion base-address, and the modification of this address into its (remapped) physical address, as follows:

- HADDR_in belongs to region x if HADDR_in[31:RI] = 000:BASEADDR[28:RI], where:
  - 000:BASEADDR is the code subregion base-address programmed in BASEADDR of ICACHE_CRRx.
  - RI defines the number of significant bits to consider. RI = $\log_2$ (region size) with a minimum value of 21 (for a 2-Mbyte region) and a maximum value of 27 (for a 128-Mbyte region).
- If the region x is enabled, the master port output AHB address (HADDR_out) is composed by concatenating the two below parts:
  - REMAPADDR[31:RI] field of ICACHE_CRRx as MSBs
  - HADDR_in[RI-1:0] as LSBs

Figure 33 describes the matching and the output address generation.

Figure 33. ICACHE remapping address mechanism

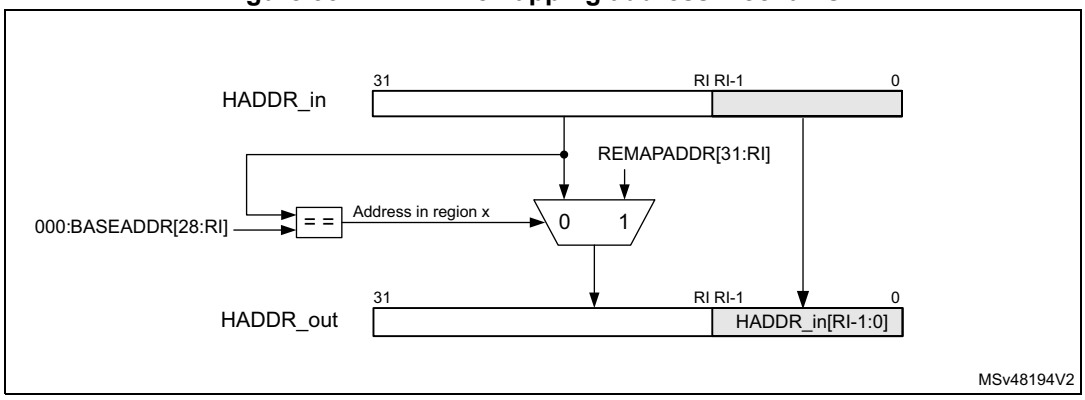

Table 87 summarizes all possible configurations of BASEADDR and REMAPADDR sizes (number of significant MSBs) in ICACHE_CRRx, depending upon RSIZE.

Table 87. ICACHE remap region size, base address, and remap address

Region size (Mbytes)	Base address size (MSBs)	Remap address (MSBs)
2	8	11
4	7	10
8	6	9
16	5	8
32	4	7
64	3	6
128	2	5

Care must be taken while programming BASEADDR and REMAPADDR in ICACHE_CRRx: if the programmed value is bigger than expected (number of MSBs, see *Table 87*), the unneeded extra LSBs are ignored.

Typical remapping example: a 128-Mbyte external RAM region physically located in the external address range [0x9000 0000:0x97FF FFFF], remapped in the code section range [0x1800 0000:0x1FFF FFFF]:

- REMAPADDR[31:21] = 0x480
- BASEADDR[28:21] = 0xC0
- HADDR_in[31:27] is compared to 000:BASEADDR[28:27], while HADDR_in and BASEADDR[26:21] are ignored.

If the comparison matches:

- HADDR_out[31:27] gets REMAPADDR[31:27] (in place of HADDR_in[31:27])
- HADDR_out[26:0] gets HADDR_in[26:0]

The software can program the kind of AHB burst generated by the ICACHE master ports on the bus matrix (for cache line refill), by setting HBURST in ICACHE_CRRx with:

- WRAP for remapped external memories accessed through interfaces that can support WRAP burst mode, providing the benefit of the critical-word-first feature performance:
  - WRAP burst size = cache line size
  - WRAP burst start address = word address of the first data requested by the core
- INCR: INCR burst mode for external memories accessed through the interfaces that do not support WRAP burst mode (losing the benefit of critical-word-first feature):
  - INCR burst size = cache line size
  - INCR burst start address = address aligned on the boundary of the cache line containing the requested word.

Note: Coherency is needed when programming the SAU (secure attribution unit) and the MPU (memory protection unit) attributes for both the external regions and their aliased code subregions.

8.4.8 Cacheable accesses

When the ICACHE receives a cacheable transaction from the Cortex®-M33, it checks if the address requested is present in its TAG memory, and if the corresponding cache line is valid.

There are then three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache hit**, the data is read from the cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first policy ensures minimum wait cycles for the processor, since read data can be provided while the cache still performs a cache line refill (associated latency is the latency of fetching one word from the main memory).

  The burst generated on the ICACHE master bus is WRAPw (w being the cache line width, in words) if no address remap occurs. If an address remap occurs, the kind of burst depends upon the HBURST programmed in corresponding ICACHE_CRRx.

  The AHB transaction attributes are also propagated to the main AHB bus matrix on the master port selected for the line refill.
- The address is not present in TAG memory, but belongs to the refill burst from the main memory currently ongoing: **cache hit** (hit-under-miss feature).

  This happens during cache-line refill. The ICACHE can provide the requested data as soon as data are available at its master interface, thus avoiding a miss (fetching data from the main memory).

In the case of cache refill (due to cache miss), the ICACHE selects which cache line is written with the refill data:

- In direct map (1-way) mode, only one line can be used to store the refill data: the line pointed by the index of the input address.
- In n-way set associative mode, one line among n can be used (the line pointed by the address index, in each of the n ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be invalidated first. This is true whatever the direct map or n-way set associative cache mode.

8.4.9 Dual-master cache

The ICACHE implements a dual-port AHB master on the main AHB bus matrix: master1 and master2 ports(master2 port is available only on STM32G55x/56x devices). This is used to split the traffic going to different destination memories.

The nonremapped traffic goes systematically to master1 port. The remapped traffic can be routed on the master2 port by programming MSTSEL in ICACHE_CRRx (on a region basis).

The code can typically be fetched as follows:

- internal flash memory and internal SRAM on master1 port (Fast bus)
- external flash memory/RAM on master2 port (Slow bus)

For systems not implementing external memories, the traffic to the internal flash memory can be decoupled from the traffic to the internal SRAM (when remapped by the ICACHE). This feature is used to prevent further processor stalls on misses.

Alongside with hit-under-miss, this dual-master feature allows the processor to have an alternative path in case of fetching from different memories.

8.4.10 ICACHE security

The ICACHE implements an Armv8-M TrustZone.

ICACHE configuration registers are protected at system level.

8.4.11 ICACHE maintenance

The software can invalidate (and initialize) the whole content of the ICACHE by programming CACHEINV in the ICACHE_CR register.

When CACHEINV = 1, the ICACHE control logic sets the BUSYF flag in ICACHE_SR and launches the invalidate cache operation, resetting each TAG valid bit to 0 (one valid bit per cache line). Each TAG addresses, ECC bit-fields and data are also reset to 0 during cache invalidation to prevent unknown values and potential ECC errors detection at the next cache line read access. CACHEINV is automatically cleared.

Once the invalidate operation is finished (all valid bits and also TAG addresses, ECC bit-fields and data reset to 0), the ICACHE automatically clears BUSYF, and sets BSYENDF in the ICACHE_SR register.

If enabled on this flag condition (BSYENDIE = 1 in ICACHE_IER), the ICACHE interrupt is raised. Then, the (empty) cache is available again.

8.4.12 ICACHE ECC support

An error correction code (ECC) hardware is implemented in the ICACHE to detect errors when a cache line is read.

This ICACHE ECC hardware enables the detection of single-bit and double-bit errors, and is then called DED ECC.

The ECC feature is implemented by the addition (in TAG memory) of an extra ECC bitfield to each ICACHE cache line, in order to provide some redundancy in the TAG + data memories content.

The ECC bitfield size depends on the cache line size (TAG and data).

When the ECC function is enabled (by setting ECCEN = 1 in ICACHE_CR), the ECC bitfield:

- is encoded by the ECC encoder, based on both the TAG (including address and valid bits) and the data to write in a given cache line (when the ICACHE is refilled from the main memory, on cache miss occurrence)
- is written along with the cache line TAG
- is read along with the TAG of any cache line (when the cache line TAG is accessed to check if its address matches or not with the address of the incoming ICACHE fetch request)
- is decoded along with the read cache line (TAG and data), in order to detect if one or two bits are erroneous in this TAG and/or data.

If no ECC error is detected, the ICACHE processes the request as usual (hit or miss).

If the ECC decoder detects a single-bit or a double-bit error on a given cache line (read for the TAG comparison process), the ICACHE:

- considers the cache access as a miss (even if the TAG read matches the address of the incoming request, because this TAG may contain errors).
- invalidates (and resets) the erroneous cache line (this can be considered as an indirect correction of the cache content)
- processes this miss as a usual miss, by refilling a cache line from the main memory and then providing a safe data to the fetch requester.
- reports the single-bit or double-bit error detection to allow the system to measure some ICACHE memories corruption (soft error) and/or aging (see *Section 8.6: ICACHE error management and interrupts* for more details on the related error flags).

As the TAG (and data) are read, in parallel, in all the ICACHE ways, an ECC decoder is implemented for each way.

Table 88 summarizes the behavior of the ICACHE when the ECC feature is enabled.

Table 88. ICACHE read requests management (when ECC is enabled)

ECC error detected on cache line (TAG address/valid bits or data)	Decision and operation	ECC error reporting
No ECC error	Hit or Miss	No
Single-bit ECC error	Miss (erroneous cache line invalidated)	ECC single-bit error flag
Double-bit ECC error		ECC double-bit error flag

When the ECC function is disabled (by setting ECCEN = 0 in ICACHE_CR), the ECC bitfield is neither encoded in the cache lines (not written), nor decoded on the cache lines read, and the ICACHE behaves as if the ECC feature is not implemented (including the ECC single-bit error and double-bit error flags remain clear).

8.4.13 ICACHE performance monitoring

The ICACHE provides the following monitors for performance analysis:

- The 32-bit hit monitor counts the cacheable AHB-transactions on the slave cache port that hits the ICACHE content.

  It also takes into account all accesses whose address is present in the TAG memory or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 8.4.8*).
- The 16-bit miss monitor counts the cacheable AHB-transactions on the slave cache port that misses the ICACHE content.

  It also takes into account all accesses whose address is not present neither in the TAG memory nor in the refill buffer.

Upon reaching their maximum values, these monitors do not wrap over.

Hit and miss monitors can be enabled and reset by software allowing the analysis of specific pieces of code.

The software can perform the following tasks:

- Enable/stop the hit monitor through HITMEN in ICACHE_CR.
- Reset the hit monitor by setting HITMRST in ICACHE_CR.
- Enable/stop the miss monitor through MISSMEN in ICACHE_CR.
- Reset the miss monitor by setting MISSMRST in ICACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

8.4.14 ICACHE boot

The ICACHE is disabled (EN = 0 in ICACHE_CR) at boot.

The code remapping at boot is not needed for a Cortex®-M33 as it implements the VTOR (vector tables) that allows a boot start address definition different than 0x0.

Once the boot is finished, the ICACHE can be enabled (software setting EN = 1 in CACHE_CR).

8.5 ICACHE low-power modes

At device level, using the ICACHE reduces the power consumption by fetching instructions from the internal ICACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even higher if the cached main memories are external.

Applications with lower performance profile (in terms of hit ratio) and stringent power consumption constraints may benefit from the lower power consumption of an ICACHE configured as direct mapped. This single-way cache configuration is obtained by programming WAYSEL = 0 in ICACHE_CR (see *Figure 32*). The power consumption is reduced by accessing, for each request, only the necessary cut of TAG and data memories. The cache effect still improves fetch performance, even if for most code execution, it is less efficient than with an n-way set associative cache mode.

8.6 ICACHE error management and interrupts

If an unsupported cacheable write request is detected (functional error), the ICACHE generates an error by setting the ERRF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in ICACHE_IER).

When the ECC function is enabled (by setting ECCEN = 1 in ICACHE_CR), two ECC error flags can be set in ICACHE_SR:

- the ECC single-bit error flag, SERRF
- the ECC double-bit error flag, DERRF

and an interrupt is then generated if the corresponding interrupt enable bit is set (SERRIE = 1, respectively DERRIE = 1, in ICACHE_IER).

The other possible interrupt generation is at the end of a cache invalidation operation. When the cache-busy state is finished, the ICACHE sets the BSYENDF flag in ICACHE_SR. An interrupt is generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in ICACHE_IER).

All ICACHE interrupt sources raise the same and unique interrupt signal, icache_it, and then use the same interrupt vector.

Table 89. ICACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
ICACHE	Functional error	ERRF in ICACHE_SR	ERRIE in ICACHE_IER	Set CERRF to 1 in ICACHE_FCR
	ECC single-bit error	SERRF in ICACHE_SR	SERRIE in ICACHE_IER	Set CSERRF to 1 in ICACHE_FCR
	ECC double-bit error	DERRF in ICACHE_SR	DERRIE in ICACHE_IER	Set CDERRF to 1 in ICACHE_FCR
	End of busy state (invalidate finished)	BSYENDF in ICACHE_SR	BSYENDIE in ICACHE_IER	Set CBSYENDF to 1 in ICACHE_FCR

The ICACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from the master1 or master2 port back to the execution port.

8.7 ICACHE registers

8.7.1 ICACHE control register (ICACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MISSMRST	HITMRST	MISSMEN	HITMEN
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCEN	Res.	WAYSEL	CACHEINV	EN
											rw		rw	w	rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **MISSMRST**: miss monitor reset

0: release the cache miss monitor reset (needed to enable the counting)

1: reset cache miss monitor

Bit 18 **HITMRST**: hit monitor reset

0: release the cache miss monitor reset (needed to enable the counting)

1: reset cache hit monitor

Bit 17 **MISSMEN**: miss monitor enable

0: cache miss monitor switched off. Stopping the monitor does not reset it.

1: cache miss monitor enabled

Bit 16 **HITMEN**: hit monitor enable

0: cache hit monitor switched off. Stopping the monitor does not reset it.

1: cache hit monitor enabled

Bits 15:5 Reserved, must be kept at reset value.

Bit 4 **ECCEN**: ECC enable

ECCEN can be modified (by software) only when the cache is disabled (EN = 0).

0: ECC encoder and decoder disabled

1: ECC encoder and decoder enabled

Bit 3 Reserved, must be kept at reset value.

Bit 2 **WAYSEL**: cache associativity mode selection

This bit allows user to choose ICACHE set-associativity. It can be written by software only when cache is disabled (EN = 0).

0: direct mapped cache (1-way cache)

1: n-way set associative cache (reset value)

Bit 1 **CACHEINV**: cache invalidation

Set by software and cleared by hardware when the BUSYF flag is set (during cache maintenance operation). Writing 0 has no effect.

0: no effect

1: invalidate entire cache (all cache lines valid bit and TAG/ECC/data = 0)

Bit 0 **EN**: enable
0: cache disabled
1: cache enabled

8.7.2 ICACHE status register (ICACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	DERRF	SERRF	Res.	Res.	Res.	Res.	Res.	ERRF	BSYENDF	BUSYF
						rw	rw						r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **DERRF**: ECC double-bit error flag
DERRF can be set to 1 by software for debug purpose; writing 0 has no effect (clearing through CDERRF in ICACHE_FCR)
0: no ECC double-bit error detected
1: an ECC double-bit error was detected

Bit 8 **SERRF**: ECC single-bit error flag
SERRF can be set to 1 by software for debug purpose; writing 0 has no effect (clearing through CSERRF in ICACHE_FCR)
0: no ECC single-bit error detected
1: an ECC single-bit error was detected

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **ERRF**: cache error flag
0: no error
1: an error occurred during the operation (cacheable write)

Bit 1 **BSYENDF**: busy end flag
0: cache busy
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF**: busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

8.7.3 ICACHE interrupt enable register (ICACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						rw	rw						rw	rw	

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **DERRIE**: interrupt enable on ECC double-bit error detection
Set by software to enable an interrupt generation in case of ECC double-bit error detection
0: interrupt disabled on ECC double-bit error detection
1: interrupt enabled on ECC double-bit error detection

Bit 8 **SERRIE**: interrupt enable on ECC single-bit error detection
Set by software to enable an interrupt generation in case of ECC single-bit error detection
0: interrupt disabled on ECC single-bit error detection
1: interrupt enabled on ECC single-bit error detection

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **ERRIE**: interrupt enable on cache error
Set by software to enable an interrupt generation in case of cache functional error (cacheable write access)
0: interrupt disabled on error
1: interrupt enabled on error

Bit 1 **BSYENDIE**: interrupt enable on busy end
Set by software to enable an interrupt generation at the end of a cache invalidate operation.
0: interrupt disabled on busy end
1: interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

8.7.4 ICACHE flag clear register (ICACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MISSMON[15:0]**: cache miss monitor counter

8.7.7 ICACHE region x configuration register (ICACHE_CRRx)

Address offset: 0x020 + 0x4 * x, (x = 0 to 3)

Reset value: 0x0000 0200

Define an alias address in the code region for other regions, making them cacheable.

BASEDADDR and REMAPADDR fields are write locked (read only) when EN = 1 in ICACHE_CR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	MSTSEL	Res.	REMAPADDR[31:21]										
rw			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

REN	Res.	Res.	Res.	RSIZE[2:0]			Res.	BASEADDR[28:21]							
rw				rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **HBURST**: output burst type for region x
0: WRAP
1: INCR

Bits 30:29 Reserved, must be kept at reset value.

Bit 28 **MSTSEL**: AHB cache master selection for region x
0: no action (master1 selected by default)
1: master2 selected
Note: MSTSEL is not available on the STM32G53x/54x devices.

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **REMAPADDR[31:21]**: remapped address for region x
This field replaces the alias address defined by BASEADDR field.
The only useful bits are [31:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

Bit 15 **REN**: enable for region x
0: disabled
1: enabled

Bits 14:12 Reserved, must be kept at reset value.

Bits 11:9 **RSIZE[2:0]**: size for region x
000: reserved
001: 2 Mbytes
010: 4 Mbytes
011: 8 Mbytes
100: 16 Mbytes
101: 32 Mbytes
110: 64 Mbytes
111: 128 Mbytes

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **BASEADDR[28:21]**: base address for region x
This alias address is replaced by REMAPADDR field.
The only useful bits are [28:RI], where 21 ≤ RI ≤ 27 is the number of bits of RSIZE (see *Section 8.4.7*). If the programmed value has more LSBs, the useless bits are ignored.

8.7.8 ICACHE register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

9 Data cache (DCACHE)

9.1 DCACHE introduction

The data cache (DCACHE) is introduced, only for STM32G55x/56x products, on S-AHB system bus of the Cortex®-M33 processor to improve the performance of data traffic to/from external memories.

Some specific features, like hit-under-miss and critical-word-first refill policy, optimize performance on external memories data accesses.

9.2 DCACHE main features

The main features of DCACHE are described below:

- Bus interface
  - One 32-bit AHB slave port, the system port (input from Cortex®-M33 S-AHB system interface)
  - One 32-bit AHB master port (output to main AHB bus matrix)
  - One 32-bit AHB slave port for control (input from AHB peripherals interconnect, for access to DCACHE registers)
- Cache access
  - 0 wait-state on hits
  - Hit-under-miss capability: ability to serve processor requests (access to cached data) during an ongoing line refill due to a previous cache miss
  - Optimized cache line refill thanks to WRAP bursts of the size of the cache line (such as WRAP4 for 128-bit cache line)
  - 2-way set-associative
  - Supports both write-back and write-through policies (selectable with AHB bufferable attribute)
  - Read and write-back always allocate
  - Write-through always non-allocate (write-around)
  - Supports byte, half-word, and word writes
- Replacement and refill
  - pLRU-t replacement policy (pseudo-least-recently-used, based on binary tree), algorithm with best complexity/performance balance
  - Critical-word-first refill policy for read transactions, minimizing processor stalls
  - Possibility to configure burst type of all AHB memory transactions: INCRw or WRAPw (size w aligned on cache line size)
- ECC hardware support: single-bit error correction, double-bit error detection (SEC-DED)
- Performance counters

  The DCACHE implements four performance counters:
  - Two hit-monitor counters (32-bit): number of read hits, number of write hits
  - Two miss-monitor counters (16-bit): number of read misses, number of write misses

- Error management
  - Possibility to detect error for master port request initiated by DCACHE itself (a cache line written back into main memory, because of an eviction or a clean operation), to flag this error, and optionally to raise an interrupt
- TrustZone security support
- Maintenance operations
  - Cache invalidate: full cache invalidation, fast command, non-interruptible
  - Cache invalidate range: invalidates cache lines whose address belongs to defined range, background task, interruptible
  - Cache clean range: cleans cache lines (if dirty bit = 1, write back line, then clear dirty bit) whose address belongs to defined range, background task, interruptible
  - Cache clean and invalidate range: cleans and invalidates cache lines (if dirty bit = 1, write back line, then invalidate it) whose address belongs to defined range, background task, interruptible

9.3 DCACHE implementation

The DCACHE1 is placed on Cortex®-M33 S-AHB bus, and caches only the external RAM memory region (OCTOSPI), in the address range [0x6000 0000:0x9FFF FFFF] of the memory map.

Indeed, by placing a bus matrix demultiplexing node in front of the DCACHE1, S-AHB bus memory requests addressing SRAM region or peripherals region (respectively in ranges [0x2000 0000:0x3FFF FFFF] and [0x4000 0000:0x5FFF FFFF]) are routed directly to the main AHB bus matrix, and the DCACHE1 is bypassed.

Table 91. DCACHE features

Features	DCACHE1
Number of ways	2
Cache size	4 Kbytes
Cache line width	16 bytes
Data size of AHB Master interface	32 bits
ECC support	Yes

9.4 DCACHE functional description

The purpose of the data cache is to cache external memory data loads and stores, coming from the processor. These accesses include the instruction fetches that may occur at an external memory address. The DCACHE manages both read and write transactions.

The DCACHE also implements the hardware support for ECC, with a single-bit error correction and a double-bit error detection (SEC-DED; see *Section 9.4.9* for more details).

9.4.1 DCACHE block diagram

9.4.2 DCACHE reset and clocks

The DCACHE is clocked on the Cortex®-M33 S-AHB bus clock.

When the DCACHE reset signal is released, a cache invalidate procedure is automatically launched, making the DCACHE busy (DCACHE_SR = 0x0000 0001).

When this procedure is finished:

- The DCACHE is invalidated: cold cache, with all cache line valid, dirty, and privilege bits = 0 and also all TAG addresses, ECC bit-fields and data reset to 0 (DCACHE must be filled up)
- DCACHE_SR = 0x0000 0002 (reflecting the cache is no longer busy)
- The DCACHE is disabled: the EN bit in DCACHE_CR holds its reset state (= 0).

Note: When disabled, the DCACHE is bypassed: slave input requests are just forwarded to the master port.

9.4.3 DCACHE TAG memory

The DCACHE TAG memory contains:

- address tags that indicate which data are contained in the cache data memories
- validity bits
- dirty bits
- privilege bits

There is one valid bit, one dirty bit, and one privilege bit per cache line (per way).

The valid bit enables/disables access to the data cache line: if the line is not valid, the data access (read or write) is performed in the main memory.

The valid bit is set when the cache line is written (refilled by either a read miss or a write-back miss).

Valid bits and also TAG addresses, ECC bit-fields and data are reset in any of the below cases:

- after the DCACHE reset is released
- when the cache is disabled, by setting EN = 0 in DCACHE_CR (by software)
- when executing one of the DCACHE invalidate commands, setting by software CACHEINV = 0, or CACHECMD = 0b010 or 0b011 in DCACHE_CR (see *Section 9.4.8*).

The dirty bit indicates that the cache line has up-to-date values with respect to the main memory content (the cache has last right value, the main memory is not up to date).

The dirty bit is set when the cache line is written by a slave port write transaction (only in case of an access with write-back attribute).

Dirty bits are reset in any of the below cases:

- after the DCACHE reset is released
- when a line refill is performed on a read miss (on a write-back miss, the refilled cache line is modified by the written data, and dirty bit = 1)
- when the cache invalidation is performed
- when executing one of the DCACHE clean operations (cache line written back to the main memory), setting by software CACHECMD = 0b001 or 0b011 in DCACHE_CR (see *Section 9.4.8*).

The privilege bit indicates if the data is managed by a privileged entity. It is assigned according to the value of AHB privileged attribute at the input slave port, for the first access to this line (it is written only during the line refill, on read miss or write-back miss).

The privilege bit holds the same polarity as the privileged attribute: 1 for privileged access, 0 for unprivileged access.

Privilege bits are reset when the cache is invalidated, and after the DCACHE reset is released.

When a cacheable transaction is received at input slave port, its AHB address (HADDR_in) is split into the following fields (see the table below for B and W values):

- HADDR_in[B-1:0]: address byte offset, indicates which byte to select within a cache line.
- HADDR_in[B+W-1:B]: address way index, indicates which cache line to select inside each way.
- HADDR_in[31:B+W]: tag address, to be compared to TAG memory address to check if the requested data is already available (meaning valid) within the DCACHE

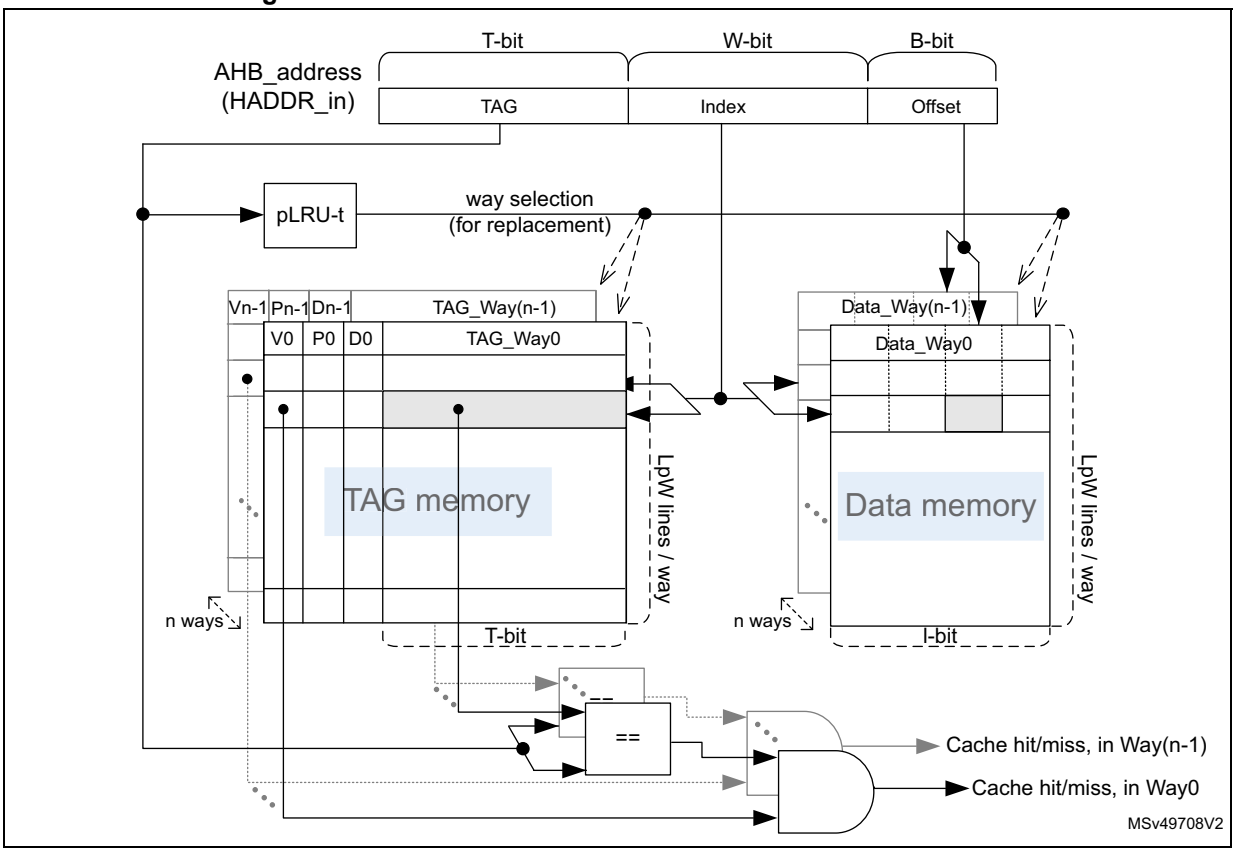

Table 92 gives DCACHE main parameters for TAG memory dimensioning.

Figure 34 shows the functional view of TAG and data memories, for an n-way set associative DCACHE.

Table 92. TAG memory dimensioning parameters

Parameter	Value	Example
Cache size	S Kbytes = s bytes (s = 1024 x S)	4 Kbytes = 4096 bytes
Cache number of ways	n	2
Cache line size	L-byte = l-bit (l = 8 x L)	16-byte = 128-bit
Number of cache lines (per way)	LpW = s / (n x L) lines/way	128 lines/way
Address byte offset size	B = $\log_2$(L) bit	4-bit
Address way index size	W = $\log_2$(LpW) bit	7-bit
TAG address size	T = (32 - W - B) bit	21-bit

Figure 34. DCACHE TAG and data memories functional view

9.4.4 DCACHE enable

To activate the DCACHE functioning, the EN bit must be set in DCACHE_CR control register.

When DCACHE is disabled, it is bypassed and all transactions are copied from slave port to master port in the same clock cycle, and no comparison is performed with TAG address.

DCACHE is by default disabled at boot.

9.4.5 Cacheable and noncacheable traffic

DCACHE is developed for a Cortex®-M33 core and caches the memory regions addressed by the AHB bus connected to it.

In addition, the AHB bus traffic to the memory regions can be cacheable or noncacheable. An incoming memory request to DCACHE is defined as cacheable according to its AHB transaction memory lookup attribute.

In case of write transaction, the DCACHE write policy is defined as write-through or write-back according to its AHB transaction memory bufferable attribute (see *Table 93*).

These AHB attributes depend on the memory protection unit (MPU) programming for the addressed region.

Table 93. DCACHE cacheability for AHB transaction

AHB lookup attribute	AHB bufferable attribute	Cacheability
0	x	Read and write: non cacheable
1	0	Read: cacheable Write: (cacheable) write-through
1	1	Read: cacheable Write: (cacheable) write-back

In case of noncacheable access, the DCACHE is bypassed, meaning that the AHB transaction is propagated unchanged to the master output port.

The bypass does not increase the latency of the access to the targeted memory.

In case of cacheable access, the DCACHE behaves as explained in *Section 9.4.6*.

Cacheable memory regions are defined and programmed by the user in the MPU, responsible for the generation of the AHB attribute signals for any transaction addressing a given region.

9.4.6 Cacheable accesses

When the DCACHE receives a cacheable transaction from Cortex®-M33 on its slave port, the DCACHE checks if the address requested is present in its TAG memory and if the corresponding cache line is valid.

For **read** transaction, there are three alternatives:

- The address is present inside the TAG memory, the cache line is valid: **cache read hit**, the data is read from cache and provided to the processor in the same cycle.
- The address is not present in the TAG memory: **cache read miss**, the data is read from the main memory and provided to the processor, and a cache line refill is performed.

  The critical-word-first refill policy insures minimum wait cycles for the processor, since read data can be provided while cache is still performing cache line refill (associated latency is the latency of fetching one word from main memory).

  The kind of burst generated on the DCACHE master bus depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words).

  The AHB transaction attributes are also propagated from the slave input (missing) request to the master output refill request.
- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache read hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can provide the requested read data as soon as the data is available at its master interface, thus avoiding a miss (with data fetch from main memory).

For **write-back** transaction (write transaction, with write-back bufferable attribute), there are three alternatives as well:

- The address is present inside the TAG memory, cache line is valid: **cache write-back hit**, the data is written in cache.
- The address is not present in the TAG memory (or the cache line is not valid): **cache write-back miss**.

  First, a line allocation is performed by reading the entire cache line data from main memory. The kind of burst generated on the DCACHE master bus for this line refill depends on HBURST bit in DCACHE_CR: either INCRw or WRAPw (w being the cache line width, in words), and the AHB transaction attributes are propagated from the slave port initial request.

  Once the refilled line is written in the DCACHE, the initial data provided on the slave port is written in this DCACHE line (it overwrites the data part of the cache line that was refilled just before).
- The address is not present in the TAG memory but belongs to the refill burst from main memory that is currently ongoing: **cache write-back hit** as well (hit-under-miss feature).

  Whatever the line refill is due to a read or write (missing) transaction, the DCACHE can write incoming data directly inside the refilled line, thus avoiding a miss (with refill from main memory).

For **write-through** transaction (write transaction, with write-through bufferable attribute), only two alternatives exist:

- The address is present inside the TAG memory, cache line is valid: **cache write-through hit**, the data is written both in cache and in main memory (through master port).
- The address is not present in the TAG memory (or the cache line is not valid): **cache write-through miss**, the data incoming at slave port is written only in main memory (unlike the write-back miss, there is no line allocation and data written in cache).

In case of cache refill (due to cache miss), the DCACHE selects which cache line is written with the refill data: as a 2-way set associative cache, one line among two can be used (line pointed by the address index, in each of the two ways). The way selection is based on a pLRU-t replacement algorithm that points, for each index, on the way candidate for the next refill.

If the cache line where the refill data must be written is already valid, the targeted cache line must be evicted first:

- If the dirty tag of this line equals 0 (clean data), the line is simply invalidated.
- If it equals 1 (dirty data), the line must be written back in the main memory.

  The DCACHE generates a burst write transaction on its master port, with burst type set to INCRw (w being the cache line width, in words), and with AHB memory transaction attribute signals set as below:
  - data (not instruction)
  - privileged = TAG privilege bit
  - write-back (even if it does not care)
  - normal memory
  - cacheable
  - allocate (even if it does not care)

– nonshareable

These AHB attributes cannot be propagated from the slave port (as it is the case for all other transactions emitted by the DCACHE) because the evicting transaction has no relation with the initial missing transaction. Setting of the AHB attributes is fixed, except for the privileged bit that is copied from the TAG privilege bit of the evicted line.

9.4.7 DCACHE security

The DCACHE implements an Armv8-M TrustZone.

DCACHE configuration registers are protected at system level.

9.4.8 DCACHE maintenance

The DCACHE features several maintenance operations that the software can programmed in DCACHE_CR control register:

- **Full invalidate**: invalidates (and initializes) the whole cache, non interruptible task.

  The software can invalidate the whole DCACHE content by programming CACHEINV in DCACHE_CR.

  When CACHEINV = 1, the DCACHE control logic sets BUSYF flag in DCACHE_SR status register, and performs the operation of cache invalidation, resetting each TAG valid bit to 0 (one valid bit per cache line). Each dirty and privilege bits and TAG addresses, ECC bit-fields and data are also reset to 0 during cache invalidation to prevent unknown values and potential ECC errors detection at next cache line validation. CACHEINV is automatically cleared.

  Once the full invalidate operation is finished, the DCACHE automatically clears BUSYF flag, and sets BSYENDF in DCACHE_SR.

  If enabled on this flag condition (BSYENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised. Then, the (empty) cache is available again.

  This full invalidate operation is not interruptible, meaning that the cache does not treat any cacheable request while BUSYF = 1. However, non-cacheable traffic is treated (since the request address is not compared to TAG ones), the DCACHE being bypassed in the same clock cycle (same behavior as when the DCACHE is disabled).

- **Invalidate range**: invalidates (and initializes) a certain range of addresses in the cache, background task (interruptible).

  The software can invalidate a given data region in the DCACHE by programming STARTCMD = 1 and CACHECMD = 0b010 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), the

corresponding cache line is invalidated (line TAG bits cleared, valid bit = dirty bit = privilege bit = TAG address = ECC = data = 0).

When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the invalidate range operation. STARTCMD is also automatically cleared.

Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

During this invalidate range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the invalidation process. The TAG memory is accessed for invalidate range operation only if not already accessed by an external cache request. This implies that invalidate range execution is usually not performed in one go, but can be interrupted.

- **Clean range**: cleans a certain range of addresses in the cache, background task (interruptible).

  Cleaning a cache line means making sure that the main memory content is up-to-date with the data, which may have been modified in the cache. The clean operation consists in performing the write-back in the main memory of the cache lines that are tagged as “dirty” (the ones with TAG dirty bit set).

  The software can clean a given data region in DCACHE by programming STARTCMD = 1, and CACHECMD = 0b001 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  The DCACHE control logic then parses the whole TAG memory. If the read line address (TAG address + line index) falls in the programmed address range (DCACHE_CMDRSADDRR ≤ Line Addr ≤ DCACHE_CMDREADDRR), and the corresponding line is dirty, this line is cleaned, meaning the whole cache line is written-back in the memory through the DCACHE master port, and its TAG dirty bit is cleared, and then its ECC bit-field is updated.

  When STARTCMD is set, the DCACHE control logic sets BUSYCMDF in DCACHE_SR and launches the clean range operation. STARTCMD is also automatically cleared.

  Once the operation is finished (all TAG memory parsed), the DCACHE automatically clears BUSYCMDF and sets CMDENDF in DCACHE_SR.

  If enabled on this flag condition (CMDENDIE = 1 in DCACHE_IER), the DCACHE interrupt is raised.

  During this clean range operation, the DCACHE is interruptible, meaning it can accept new incoming requests that take higher priority than the cleaning process. The TAG memory is accessed for clean range operation only if not already accessed by an external cache request. This implies that clean range execution is usually not performed in one go, but can be interrupted.

  It is under the software responsibility that no bus initiator attempts to change the content of the region being cleaned until clean range is completed. For that, the software can take advantage of BUSYCMDF flag in DCACHE_SR, and can poll this flag to prevent any spurious access to the area being cleaned.

Alternatively it can also rely on the command end flag (CMDENDF) or on the DCACHE interrupt to detect the end of the clean range execution.

- **Clean and invalidate range**: cleans and invalidates (and initializes) a certain range of addresses in the cache, background task (interruptible).

  This operation cleans the “dirty” cache lines that belong to the operation address range (the same as the clean range operation), and also invalidates all the (valid) cache lines that belong to this address range (whether they are dirty or not).

  The software can launch this clean and invalidate range operation, by programming STARTCMD = 1, and CACHECMD = 0b011 in DCACHE_CR, after the address range was programmed into DCACHE_CMDRSADDRR (range start address) and DCACHE_CMDREADDRR (range end address).

  This sets and clears the same flags, and potentially the same interrupt as invalidate range or clean range operations.

9.4.9 DCACHE ECC support

An Error Correction Code (ECC) hardware is implemented in the DCACHE in order to detect and correct errors when a cache line is read.

This DCACHE ECC hardware enables the detection and the correction of single-bit errors and the detection of double-bit errors, and is then called SEC-DED ECC.

The ECC feature is implemented by the addition (in TAG memory) of an extra ECC bit-field to each DCACHE cache line, in order to provide some redundancy in the TAG + data memories content.

The ECC bit-field size depends on the cache line size (TAG and data).

When the ECC function is enabled (by setting ECCEN = 1 in DCACHE_CR), the ECC bit-field:

- is encoded by the ECC encoder, based on both the TAG (including address and valid bits) and the data to write in a given cache line (when the DCACHE is refilled from the main memory, on cache miss occurrence; or on cache line read-modify-write operation, on a write access that hits)
- is written along with the cache line TAG
- is read along with the TAG of any cache line (when the cache line TAG is accessed to check if its address matches or not with the address of the incoming DCACHE read or write request or the address range of a maintenance range operation).
- is decoded along with the read cache line (TAG and data), to detect if one or two bits are erroneous in this TAG and/or data
  - if the ECC decoder detects a single-bit error, it corrects the erroneous bit (on the fly, by swapping its value between 0 and 1), either in the TAG bit-field (and then it is the corrected TAG which is compared to the address of the incoming request), or in the data bit-field (in order to provide a corrected data, in case of cache hit).

    On a DCACHE read access, the cache line detected with a single-bit error is neither corrected in the cache itself, nor invalidated, and can imply another ECC error detection (and correction) when read on further DCACHE read or write requests.

    On a DCACHE hitting write access, the cache line detected with a single-bit error is not invalidated, and is corrected, when the TAG, the data and the corresponding

ECC bit-field are written back in the cache line (read and correct/modify/write correctly the cache line).

When a cache line refill occurs (because of a cache miss), it may imply a cache line eviction. The cache line candidate for the replacement is read first, to know if it is valid and dirty, or not. If a single-bit error is detected during this read operation, the cache line is corrected (potentially its valid or dirty bit is corrected), and the single-bit error detection is reported. If the valid and dirty bits of the cache line (potentially corrected) are set, its data (potentially corrected as well) is written back to the main memory. If the dirty bit or the valid bit is clear, no further action occurs with the cache line read value (it is simply dropped).

On a DCACHE maintenance range operation (clean and/or invalidate an address range), all cache lines are read to check if their TAG address matches the maintenance address range. If a single-bit error is detected, the TAG or the data is corrected and the maintenance operation is processed correctly (cache line invalidated and/or dirty cache line evicted adequately).

Even if the TAG or the data is corrected on the fly, and then the read or write access, or the eviction or the maintenance operation is safe, the single-bit error detection is reported, to allow the system to measure some DCACHE memories corruption (soft error) and/or aging (see *Section 9.6: DCACHE error management and interrupts* for more details on the related error flags).

– if the ECC decoder detects a double-bit error, it is not able to correct the TAG and/or the data read, and is then unable to decide safely if the request hits or misses (since the TAG may contain errors).

  On read or write-back access to the DCACHE, when such a double-bit error is detected on a cache line in a given cache way, and all other cache lines miss (in the other ways), the read or write operation is aborted, and the DCACHE responds to the incoming request with a bus error.

  For read request, this prevents, in case of a hit (potentially false), the risk of returning a corrupted (and uncorrectable) data from cache; or, in case of a miss (potentially false), the risk of returning and refilling the cache with a data from the main memory which is not necessarily up-to-date (if the first copy of it is marked as dirty in the DCACHE and not yet evicted/written-back in main memory).

  For write-back request, this prevents, in case of a hit (potentially false), the risk of corrupting a cache line (by either writing to a wrong cache line, or by modifying and writing in the cache line a data that were erroneously read); or, in case of a write-back miss (potentially false), the risk of refilling the cache with a data from the main memory which is not necessarily up-to-date.

  On write-through access to the DCACHE, when such a double-bit error is detected on a cache line in a given cache way, and all other cache lines miss (in the other ways), the DCACHE considers the write-through cache access as a miss: the data is written only in the main memory, and is not written into the cache. Compared to a usual (error-less) write-through miss, the only difference is the setting of the ECC double-bit error flag.

On a cache line replacement, the cache line is read first, potentially to perform an eviction (in case this cache line is both valid and dirty), before it is replaced. If a double-bit error is detected on the cache line read, the potential eviction is aborted (the valid and dirty bits may be erroneous, and/or the data written-back to the main memory would be potentially erroneous as well) and the cache line is lost (since replaced/over-written by the new TAG and data from main memory).

On a DCACHE maintenance range operation (clean and/or invalidate an address range), all cache lines are read to check if their TAG address matches the maintenance address range. If a double-bit error is detected on a given cache line read, the maintenance operation is not performed on this cache line, since the double-bit error can affect its valid, dirty or address TAG. This erroneous cache line is not invalidated and/or not copied back to the main memory; and the maintenance operation continues on the other cache lines.

In both cases above, as the potentially needed eviction of a dirty data is not performed, some data may be lost (dirty data were only in cache) and/or the main memory may be not up-to-date, as it was intended.

The cache line detected with a double-bit error is not automatically invalidated in the DCACHE, nor necessarily over-written by a refill operation: then, as long as it remains in the DCACHE, this erroneous cache line may imply another ECC double-bit error detection, when it is read on further DCACHE accesses.

In all cases above, the double-bit error detection is reported (see *Section 9.6: DCACHE error management and interrupts*), in order the system to react and potentially to reset the complete DCACHE content (by disabling the DCACHE, or by launching a full invalidate maintenance operation), considering that some data may be lost and/or the main memory may not be up-to-date. At least this is the only safe way to invalidate such erroneous cache lines (with a double-bit error).

As the TAG (and data) are read, in parallel, in all the ways of the DCACHE, an ECC decoder is implemented for each way of the DCACHE.

Table 94 summarizes the behavior of the DCACHE when the ECC feature is enabled.

Table 94. DCACHE accesses management (when ECC is enabled)

Access type	ECC error detected on cache line (TAG address/valid/dirty bits or data)	Decision and operation	ECC error reporting
Read/ Write-back/ Write-through	No ECC error	Hit or Miss	No
	Single-bit ECC error	Hit or Miss (error corrected on the fly)	ECC single-bit error flag
Read/ Write-back	Double-bit ECC error (and all other ways miss)	Bus error (erroneous cache line still in cache; no data read / data to write in cache lost)	ECC double-bit error flag
Write-through		Miss (erroneous cache line still in cache; main memory up-to-date)	ECC double-bit error flag

Table 94. DCACHE accesses management (when ECC is enabled) (continued)

Access type	ECC error detected on cache line (TAG address/valid/dirty bits or data)	Decision and operation	ECC error reporting
Eviction (replacement)	No ECC error	Eviction	No
	Single-bit ECC error	Eviction (data corrected on the fly)	ECC single-bit error flag
	Double-bit ECC error	Eviction aborted (dirty data lost)	ECC double-bit error flag
Clean and/or invalidate range maintenance operation	No ECC error	Maintenance operation	No
	Single-bit ECC error	Maintenance operation (error corrected on the fly)	ECC single-bit error flag
	Double-bit ECC error	Operation aborted only on the erroneous cache line (erroneous cache line still in cache and/or main memory not up-to-date)	ECC double-bit error flag

When the ECC function is disabled (by setting ECCEN = 0 in DCACHE_CR), the ECC bit-field is neither encoded in the cache lines (not written), nor decoded on the cache lines read, and the DCACHE behaves as if the ECC feature is not implemented (including the ECC single-bit error and double-bit error flags remain clear).

9.4.10 DCACHE performance monitoring

The DCACHE provides the following monitors for performance analysis:

- The two 32-bit read-hit and write-hit monitors count the AHB transactions at the DCACHE input (slave port) that do not generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is present in the TAG memory, or in the refill buffer (due to a previous miss, and whose data is coming, or is soon to come, from the cache master port) (see *Section 9.4.6*).
- The two 16-bit read-miss and write-miss monitors count the AHB transactions at the DCACHE input (slave port) that generate a transaction on the DCACHE output (master port).

  These monitors also take into account all accesses whose address is not present neither in the TAG memory, nor in the refill buffer.

Upon reaching their maximum values, the monitors do not wrap over.

The software can perform the following tasks:

- Enable/stop the read (write) hit monitor, through R(W)HITMEN in DCACHE_CR.
- Reset the read (write) hit monitor, by setting R(W)HITMRST in DCACHE_CR.
- Enable/stop the read (write) miss monitor, through R(W)MISSMEN in DCACHE_CR.
- Reset the read (write) miss monitor, by setting R(W)MISSMRST in DCACHE_CR.

To reduce power consumption, these monitors are disabled (stopped) by default.

9.4.11 DCACHE boot

The DCACHE is disabled (EN = 0 in DCACHE_CR) at boot.

Once the boot is finished, the DCACHE can be enabled (software setting EN = 1 in DCACHE_CR).

9.5 DCACHE low-power modes

At product level, the DCACHE reduces the power consumption by loading/storing data from/to the internal DCACHE most of the time, rather than from the bigger and then more power consuming main memories. This reduction is even much higher, since the cached main memories are external.

9.6 DCACHE error management and interrupts

A transaction initiated on the DCACHE master port may return an error (a write attempt into a read-only memory, for instance). If the master port request was propagated from a slave port request, the error is propagated back to the slave port. If ever the master port request is initiated by the DCACHE itself (a cache line is written back into the main memory because of an eviction or a clean operation), the DCACHE receives this functional error and flags it internally by setting the ERRF flag in DCACHE_SR.

In such a case, an interrupt is generated if the corresponding interrupt enable bit is set (ERRIE = 1 in DCACHE_IER).

When the ECC function is enabled (by setting ECCEN = 1 in DCACHE_CR), two ECC error flags can be set in DCACHE_SR:

- the ECC single-bit error flag, SERRF.
- the ECC double-bit error flag, DERRF.

and an interrupt is then generated if the corresponding interrupt enable bit is set (SERRIE = 1, respectively DERRIE = 1, in DCACHE_IER).

The detection of an ECC double-bit error also drives a related DCACHE double-bit error signal, in order to potentially launch a timer break (the double-bit error signal level is a copy of the DERRF flag value).

Another case of potential interrupt generation is at the end of a full invalidate operation: when the cache busy state is finished, the DCACHE sets BSYENDF flag in DCACHE_SR.

An interrupt is then generated if the corresponding interrupt enable bit is set (BSYENDIE = 1 in DCACHE_IER).

Last case is at the end of invalidate and/or clean range operations: when the command busy state is finished, the DCACHE sets CMDENDF flag in DCACHE_SR.

An interrupt is also generated if the corresponding interrupt enable bit is set (CMDENDIE = 1 in DCACHE_IER).

All DCACHE interrupt sources raise the same and unique interrupt signal, dcache_it, and then use the same interrupt vector.

Table 95. DCACHE interrupts

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method
DCACHE	Functional error	ERRF in DCACHE_SR	ERRIE in DCACHE_IER	Set CERRF to 1 in DCACHE_FCR
	ECC single-bit error	SERRF in DCACHE_SR	SERRIE in DCACHE_IER	Set CSERRF to 1 in DCACHE_FCR
	ECC double-bit error	DERRF in DCACHE_SR	DERRIE in DCACHE_IER	Set CDERRF to 1 in DCACHE_FCR
	End of busy state (full invalidate finished)	BSYENDF in DCACHE_SR	BSYENDIE in DCACHE_IER	Set CBSYENDF to 1 in DCACHE_FCR
	End of cache operations (address range based)	CMDENDF in DCACHE_SR	CMDENDIE in DCACHE_IER	Set CCMDENDF to 1 in DCACHE_FCR

The DCACHE also propagates all AHB bus errors (such as security issues, address decoding issues) from master port back to the S-AHB slave port.

9.7 DCACHE registers

9.7.1 DCACHE control register (DCACHE_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HBURST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WMISSMRST	WHITMRST	WMISSMEN	WHITMEN	RMISSMRST	RHITMRST	RMISSMEN	RHITMEN
rw								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	STARTCMD	CACHECMD[2:0]			Res.	Res.	Res.	ECCEN	Res.	Res.	CACHEINV	EN
				w	rw	rw	rw				rw			w	rw

Bit 31 **HBURST:** output burst type for cache master port read accesses
Can be set by software, only when EN = 0.
Master port write accesses are always done in INCR burst type.
0: WRAP
1: INCR

Bits 30:24 Reserved, must be kept at reset value.

Bit 23 **WMISSMRST:** write-miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache write-miss monitor

Bit 22 **WHITMRST:** write-hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache write-hit monitor

Bit 21 **WMISSMEN:** write-miss monitor enable
0: cache write-miss monitor switched off. Stopping the monitor does not reset it.
1: cache write-miss monitor enabled

Bit 20 **WHITMEN:** write-hit monitor enable
0: cache write-hit monitor switched off. Stopping the monitor does not reset it.
1: cache write-hit monitor enabled

Bit 19 **RMISSMRST:** read-miss monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache read-miss monitor

Bit 18 **RHITMRST:** read-hit monitor reset
0: release the cache miss monitor reset (needed to enable the counting)
1: reset cache read-hit monitor

Bit 17 **RMISSMEN:** read-miss monitor enable
0: cache read-miss monitor switched off. Stopping the monitor does not reset it.
1: cache read-miss monitor enabled

Bit 16 **RHITMEN:** read-hit monitor enable
0: cache read-hit monitor switched off. Stopping the monitor does not reset it.
1: cache read-hit monitor enabled

Bits 15:12 Reserved, must be kept at reset value.

Bit 11 **STARTCMD:** starts maintenance command (maintenance operation defined in CACHECMD).
Can be set by software, only when EN = 1, BUSYCMDF = 0, BUSYF = 0 and CACHECMD = 0b001, 0b010 or 0b011.
Cleared by hardware when the BUSYCMDF flag is set (during cache maintenance operation). Writing 0 has no effect.
0: command operation (cache maintenance) finished
1: start maintenance command (cache maintenance)

Bits 10:8 **CACHECMD[2:0]:** cache command maintenance operation (cleans and/or invalidates an address range)
Can be set and cleared by software, only when no maintenance command is ongoing (BUSYCMDF = 0).
000: no operation
001: clean range
010: invalidate range
011: clean and invalidate range
others: reserved

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **ECCEN**: ECC enable
ECCEN can be modified (by software) only when the cache is disabled (EN = 0).
0: ECC encoder and decoder disabled
1: ECC encoder and decoder enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **CACHEINV:** full cache invalidation
Can be set by software, only when EN = 1.
Cleared by hardware when the BUSYF flag is set (during full cache invalidation operation).
Writing 0 has no effect.
0: no effect
1: invalidate entire cache (all cache lines valid bit and TAG/ECC/data = 0)

Bit 0 **EN:** enable
0: cache disabled
1: cache enabled

9.7.2 DCACHE status register (DCACHE_SR)

Address offset: 0x004

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	DERRF	SERRF	Res.	Res.	Res.	CMDENDF	BUSYCMDF	ERRF	BSYENDF	BUSYF
						rw	rw				r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **DERRF**: ECC double-bit error flag
DERRF can be set to 1 by software for debug purpose; writing 0 has no effect (clearing through CDERRF in DCACHE_FCR)
0: no ECC double-bit error detected
1: an ECC double-bit error was detected

Bit 8 **SERRF**: ECC single-bit error flag
SERRF can be set to 1 by software for debug purpose; writing 0 has no effect (clearing through CSERRF in DCACHE_FCR)
0: no ECC single-bit error detected
1: an ECC single-bit error was detected

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDF:** command end flag
Cleared by writing DCACHE_FCR.CCMDENDF = 1.
0: cache busy or in idle
1: CACHECMD command finished

Bit 3 **BUSYCMDF:** command busy flag
0: cache not busy on a CACHECMD command
1: cache busy on a CACHECMD command (clean and/or invalidate an address range)

Bit 2 **ERRF:** cache error flag
Cleared by writing DCACHE_FCR.CERRF = 1.
0: no error
1: an error occurred during the operation (eviction or clean operation write-back error).

Bit 1 **BSYENDF:** full invalidate busy end flag
Cleared by writing DCACHE_FCR.CBSYENDF = 1.
0: cache busy or in idle
1: full invalidate CACHEINV operation finished

Bit 0 **BUSYF:** full invalidate busy flag
0: cache not busy on a CACHEINV operation
1: cache executing a full invalidate CACHEINV operation

9.7.3 DCACHE interrupt enable register (DCACHE_IER)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	DERRIE	SERRIE	Res.	Res.	Res.	CMDENDIE	Res.	ERRIE	BSYENDIE	Res.
						rw	rw				rw		rw	rw	

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **DERRIE**: interrupt enable on ECC double-bit error detection
Set by software to enable an interrupt generation in case of ECC double-bit error detection
0: interrupt disabled on ECC double-bit error detection
1: interrupt enabled on ECC double-bit error detection

Bit 8 **SERRIE**: interrupt enable on ECC single-bit error detection
Set by software to enable an interrupt generation in case of ECC single-bit error detection
0: interrupt disabled on ECC single-bit error detection
1: interrupt enabled on ECC single-bit error detection

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CMDENDIE**: interrupt enable on command end
Set by software to enable an interrupt generation at the end of a cache command (clean and/or invalidate an address range)
0: interrupt disabled on command end
1: interrupt enabled on command end

Bit 3 Reserved, must be kept at reset value.

Bit 2 **ERRIE:** interrupt enable on cache error
Set by software to enable an interrupt generation in case of cache functional error (eviction or clean operation write-back error)
0: interrupt disabled on error
1: interrupt enabled on error

Bit 1 **BSYENDIE:** interrupt enable on busy end
Set by SW to enable an interrupt generation at the end of a cache full invalidate operation.
0: Interrupt disabled on busy end
1: Interrupt enabled on busy end

Bit 0 Reserved, must be kept at reset value.

9.7.4 DCACHE flag clear register (DCACHE_FCR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	CDERRF	CSERRF	Res.	Res.	Res.	CCMDENDF	Res.	CERRF	CBSYENDF	Res.
						w	w				w		w	w	

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **CDERRF**: clear ECC double-bit error flag
Set by software.
0: no effect
1: clears DERRF flag in DCACHE_SR

Bit 8 **CSERRF**: clear ECC single-bit error flag
Set by software.
0: no effect
1: clears SERRF flag in DCACHE_SR

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **CCMDENDF:** clear command end flag
Set by software.
0: no effect
1: clears CMDENDF flag in DCACHE_SR

Bit 3 Reserved, must be kept at reset value.

Bit 2 **CERRF:** clear cache error flag
Set by software.
0: no effect
1: clears ERRF flag in DCACHE_SR

Bit 1 **CBSYENDF:** clear full invalidate busy end flag
Set by software.
0: no effect
1: clears BSYENDF flag in DCACHE_SR

Bit 0 Reserved, must be kept at reset value.

9.7.5 DCACHE read-hit monitor register (DCACHE_RHMONR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RHITMON[31:16]

10 Power control (PWR)

10.1 Introduction

The power controller manages the device power supplies and power modes transitions.

10.2 PWR main features

The power controller (PWR) main features are:

- Power supplies and supply domains
  - Core domain (V_{CORE})
  - V_{DD} domain
  - RTC domain
  - Analog domain (V_{DDA})
  - Supply for the SMPS power stage (available on SMPS packages)
  - V_{DD} for USB transceiver
- System supply voltage regulation
  - SMPS step-down converter
  - Linear voltage regulator (LDO)
  - V_{CORE} provided from an external supply (bypass)
- Power supply supervision
  - POR/PDR monitoring
  - PVD monitoring
  - AVD monitoring
  - Out of functional range temperature monitoring
  - Maximum V_{DD} voltage monitoring
- Power management
  - Operating modes
  - Voltage scaling control
  - Low-power modes
- TrustZone® security and privileged protection

10.3 PWR pins and internal signals

Table 97. PWR input/output pins

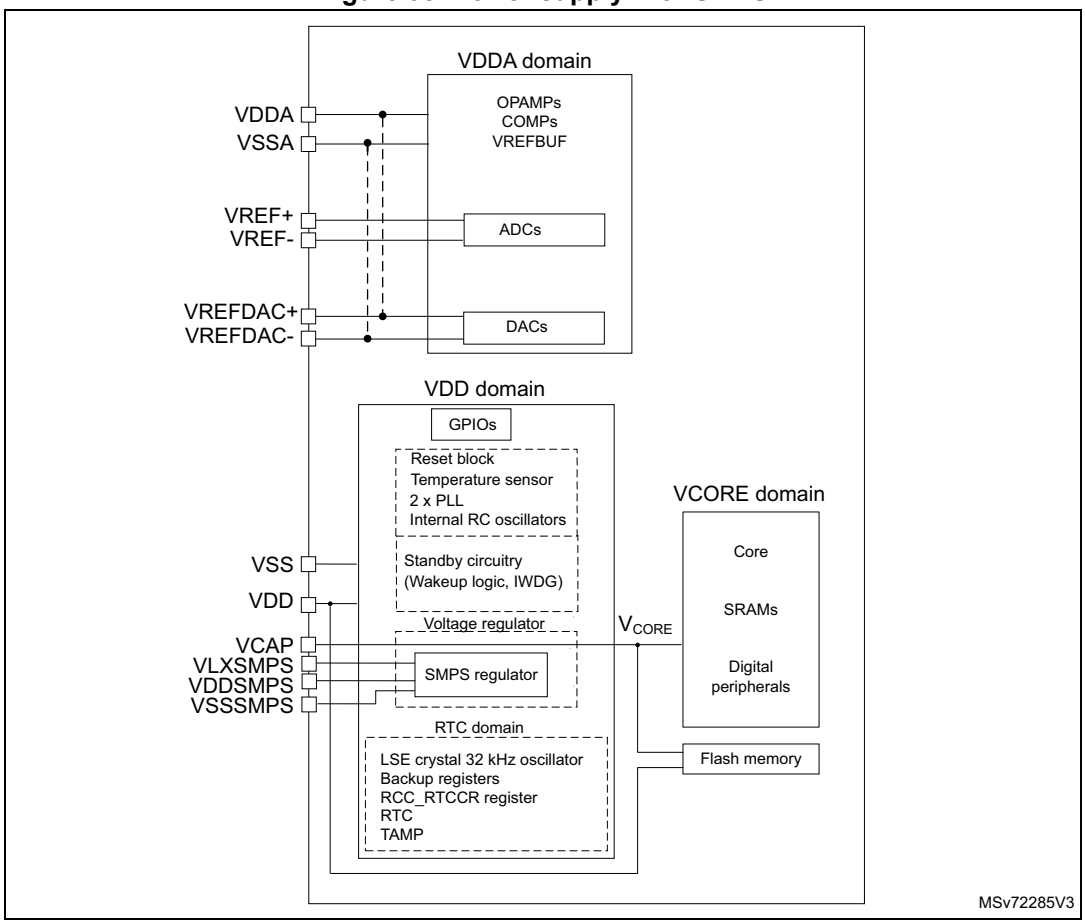
Pin name	Signal type	Description
VDD	Supply	Main supply
GND	Supply	Main ground
VDDA	Supply	Analog peripherals supply
VSSA	Supply	Analog peripherals ground
VCAP	Supply	Logic supply (V_{CORE})
VDDSMPS	Supply	SMPS supply
VSSSMPS	Supply	SMPS ground
VLXSMPS	Supply	SMPS output
VREF+	Supply	ADC high reference voltage
VREF-	Supply	ADC low reference voltage
VREFDAC+	Supply	DAC high reference voltage
VREFDAC-	Supply	DAC low reference voltage
WKUPx (x = 1, 2, 4 to 8)	Input	Wake-up pins
CSLEEP	Output	MCU in Sleep mode
CSTOP	Output	CPU in Stop modes

Table 98. PWR internal input/output signals

Internal signal name	Signal type	Description
WKUPx (x = 1, 2, 4 to 8)	Input	Wake-up event source

10.4 PWR power supplies and supply domains

Figure 35. Power supply with SMPS



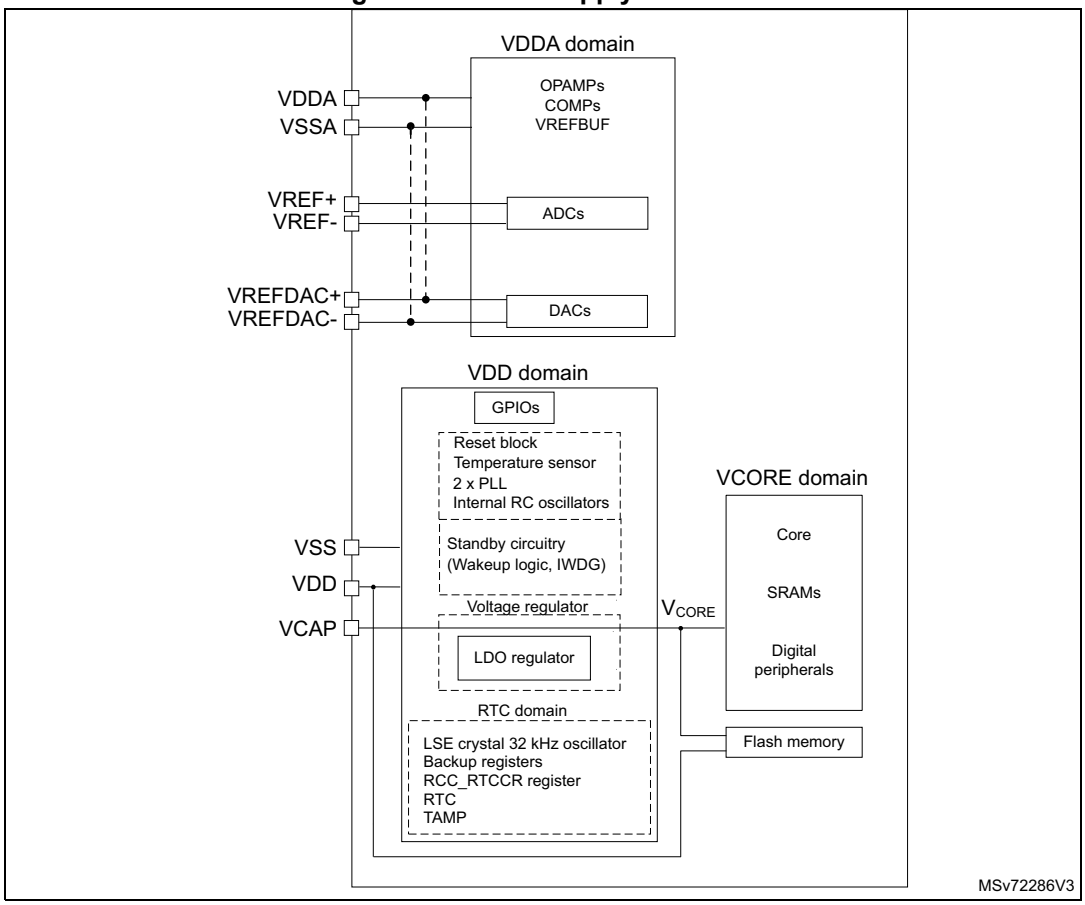


Figure 36. Power supply with LDO

10.4.1 External power supplies

The devices require a 2.7 V to 3.6 V V_{DD} operating voltage supply. Several independent supplies can be provided for specific peripherals:

- V_{DD} = 2.7 V to 3.6 V

  V_{DD} is the external power supply for the I/Os, the internal regulator, and the system analog such as reset, power management, and internal clocks. It is provided externally through the VDD pins.

  V_{DD} is the power supply for RTC, LSE, external clock 32 kHz oscillator, and backup registers.

- V_{DDA} = 2.7 V to 3.6 V

  V_{DDA}/V_{SSA} is the external analog power supply for ADCs, DACs, COMPs, OPAMPs, and VREFBUF. The V_{DDA} voltage level is independent from the V_{DD} voltage and must preferably be connected to VDD when these peripherals are not used.

  If VDDA/VSSA pins are not available on the package, then these pins are double bonded to VDD/VSS.

- V_{DDSMPS} = 2.7 V to 3.6 V

  V_{DDSMPS}/V_{SSSMPS} is the external power supply for the SMPS step-down converter. It is provided externally through VDDSMPS supply pin and must be connected to the same supply as VDD.

- V_{LXSMPS} is the switched SMPS step-down converter output. The SMPS power supply pins are available only on packages with SMPS step-down converter option.

- V_{REF+}/V_{REF-}

  V_{REF+}/V_{REF-} is the input reference voltage for ADCs. It is also the output of the internal voltage reference buffer when enabled (VREFBUF).

  VREF+ can be grounded when ADCs are not active.

  VREF+ and VREF-pins are not available on all packages. When not available, they are bonded to VDDA and VSSA, respectively.

  When the VREF+ is double-bonded to VDDA in a package, the internal voltage reference buffer is not available and must be kept disabled.

  V_{REF-} must always be equal to V_{SSA}.

- $V_{REFDAC+}/V_{REFDAC-}$

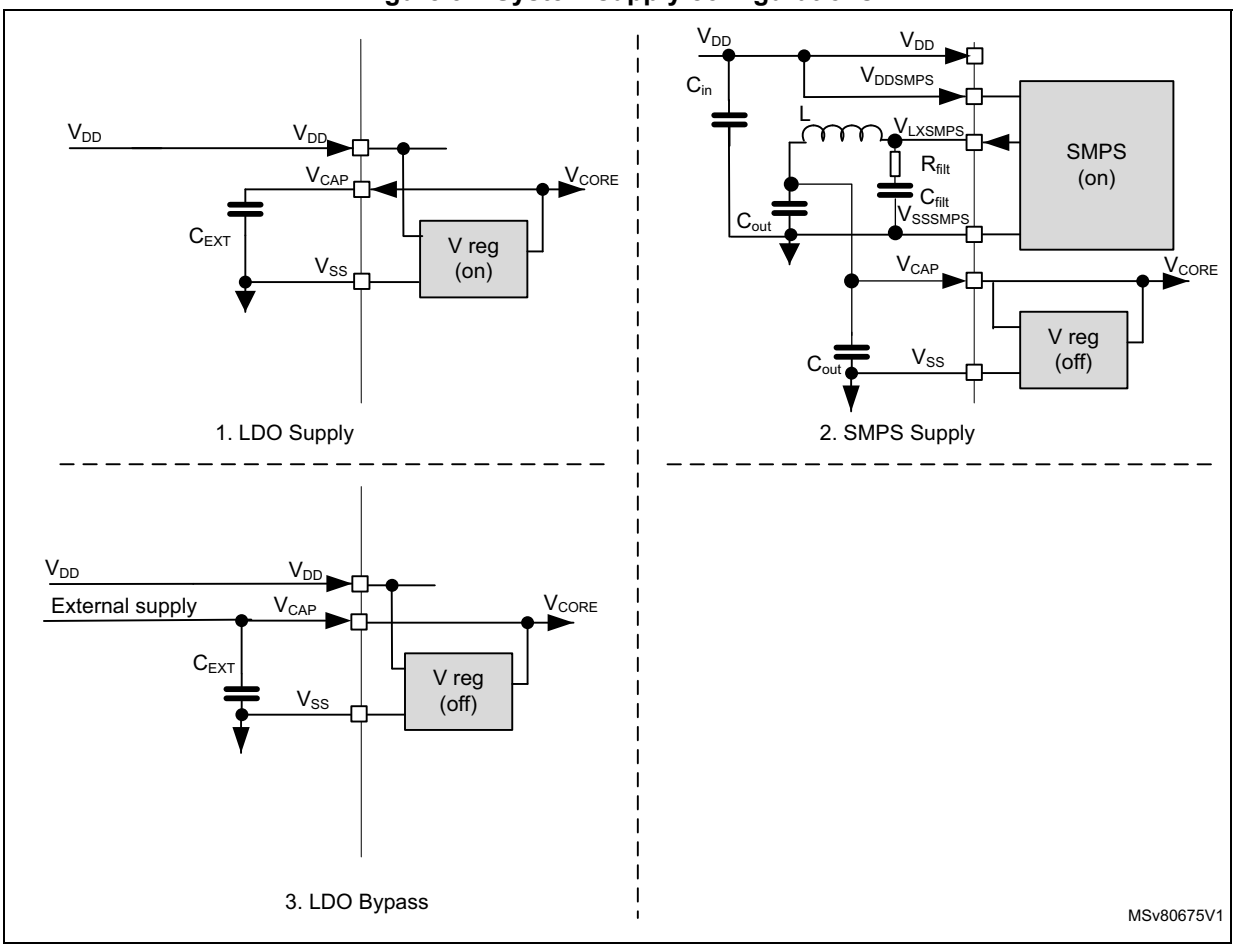
  $V_{REFDAC+}/V_{REFDAC-}$is the input reference voltage for DACs.

  VREFDAC+ can be grounded when DACs are not active.

  VREFDAC+ and VREFDAC- pins are not available on all packages. When not available, they are bonded to VDDA and VSSA, respectively.

  $V_{REFDAC-}$ must always be equal to V_{SSA}.

10.4.2 Internal and external regulators



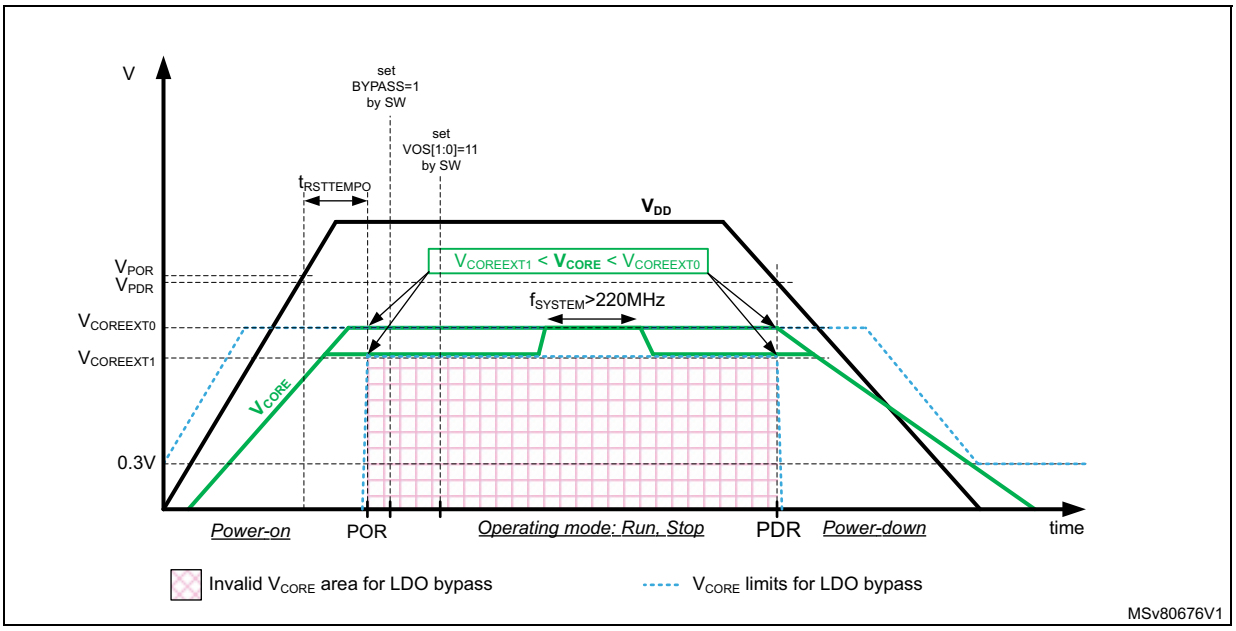
Depending upon the package, the devices embed an LDO and/or an SMPS regulator, to provide the V_{CORE} supply for digital peripherals, SRAM1, SRAM2, SRAM3, and embedded flash memory. The SMPS generates this voltage on VCAP pins, with an external capacitor of 10 µF (typical) on each VCAP pin. The SMPS requires an external coil. The LDO generates this voltage on VCAP pins connected to external capacitors of 2.2 µF each (typical). If only one VCAP pin is present on the package, the sum of the capacity is used for this one VCAP pin (4.7 uF for LDO devices). The SMPS requires an external capacitor 220 pF in

series with a resistor of 18 Ω between VLXSMPS and VSSSMPS pins. For LDO devices, it is not necessary to connect all VCAP pins together (it is optional). For SMPS devices, all VCAP pins must be connected together with low impedance path.

Both regulators can provide three different voltages (voltage scaling), and can operate in Stop mode.

Depending on the package configuration (SMPS or LDO), the regulator is selected by hardware. SMPS and LDO regulator are exclusively selected. The supply configurations shown in *Figure 37* are supported for the VCORE domain supply.

Figure 37. System supply configurations



Startup with V_{CORE} provided from an external supply (bypass)

In addition to LDO or SMPS regulators that provide the V_{CORE} supply, the devices support LDO bypass mode on all non-SMPS packages. In bypass mode, the V_{CORE} supply is provided from the external power supply to VCAP pins. In this configuration, the device is started in standard LDO mode but the external power supply must provide V_{CORE} voltage to VCAP pins at a level always higher than the output from the internal LDO regulator. The default V_{CORE} startup range is VOS2, therefore the external voltage during startup must be at higher $V_{COREEXT1}$ or $V_{COREEXT0}$ levels (refer to the datasheet values). The external V_{CORE} supply voltage must reach this correct level while V_{DD} reaches the V_{POR} threshold

level + $t_{RSTTEMPO}$ temporization time. V_{CORE} voltage must be always lower than V_{DD} voltage (it is recommended to put a Schottky diode between VCAP and VDD pins to avoid current injection from V_{CORE} to V_{DD}). The firmware must then disable the internal LDO regulator by setting the BYPASS bit in the PWR_SCCR register, and continue to supply V_{CORE} only from the external power supply. The external power supply level must follow V_{CORE} voltage requirements for the selected operation frequency ranges: $V_{COREEXT1}$ (for f_{HCLK} < 220 MHz, T_{jmax} = 140°C) or $V_{COREEXT0}$ (for f_{HCLK} < 280 MHz, T_{jmax} = 105°C. VOS[1:0] bits (in PWR_VOSCR register) must be set to VOS0 range (VOS[1:0] = 3) after setting BYPASS = 1 and before increasing the system frequency above 150 MHz. This VOS0 setting must be used for any operating conditions in bypass mode. Standby mode must not be used in bypass mode. The lowest supported power mode in bypass mode is Stop mode.

Figure 38. Startup sequence if V_{CORE} provided from external supply (LDO bypass)

In LDO bypass mode (BYPASS = 1), the states of ACTVOS[1:0], ACTVOSRDY and VOSRDY bits do not reflect the V_{CORE} voltage range. ACTVOS[1:0], ACTVOSRDY and VOSRDY bit states are valid only if the internal LDO or SMPS regulator is active (BYPASS = 0). The SRAMLS bit reflects the SRAM timing setting in all LDO, SMPS, and Bypass modes (see *Section 10.11.4: PWR voltage scaling status register (PWR_VOSSR)*).

10.4.3 Power-up and power-down power sequences

During power-up and power-down phases, the following power sequence requirements must be respected:

- When V_{DD} is below 1 V, other power supplies (V_{DDA}, V_{REF+}, $V_{REFDAC+}$) must remain below V_{DD} + 300 mV.
- When V_{DD} is above 1 V, all power supplies are independent (but V_{REF+} and $V_{REFDAC+}$ must be below V_{DDA} + 300 mV).

During the power-down phase, V_{DD} can temporarily become lower than other supplies only if the energy provided to the MCU remains below 1 mJ. This allows external decoupling

capacitors to be discharged with different time constants during the power-down transient phase.

10.4.4 Independent analog peripherals supply

To improve analog peripheral conversion accuracy (ADC, DAC, OPAMP, COMP, VREFBUF) and to extend the supply flexibility, the analog peripherals have an independent power supply that can be separately filtered and shielded from noise on the PCB:

- The voltage supply input of the analog peripherals is available on a separate VDDA pin.
- An isolated supply ground connection is provided on the VSSA pin.

The V_{DDA} supply voltage can be different from V_{DD}. The presence of V_{DDA} must be checked before enabling any of the analog peripherals supplied by V_{DDA} (ADC, DAC, OPAMP, COMP, VREFBUF).

Power supply level monitoring is available on VDDA via AVDO bit in the PWR_VMSR register.

When a single supply is used, V_{DDA} can be externally connected to V_{DD} through the external filtering circuit to ensure a noise-free V_{DDA} reference voltage.

ADC reference voltage

To ensure a better ADC accuracy, the user can connect to VREF+, a separate reference voltage lower than V_{DDA}. V_{REF+} is the highest voltage represented by the full-scale value for an analog input (ADC).

V_{REF+} can be provided either by an external reference or by an internal buffered voltage reference (VREFBUF). The internal voltage reference (VREFBUF) can output a configurable voltage, namely 1.8 V, 2.048 V, 2.5 V, and 2.9 V. VREFBUF provides the voltage to external components through VREF+ pin. Refer to the device datasheet and to *Section 29: Voltage reference buffer (VREFBUF)* for further information.

VREF+/VREF- pins must be always correctly decoupled by external capacitors. The recommended value for these capacitors is a 1 µF capacitor in parallel with a 100 nF capacitor. The capacitors must be placed very close to VREF+ and VREF- pins. Correct decoupling of VREF+/VREF- pins has a significant impact on ADC performance. It is recommended to use low ESR capacitors and minimize parasitic inductance from capacitors to VREF+/VREF- pins (by placing capacitors immediately to VREF+/VREF- pins with no vias in the path).

Note: The VREF- pin is not available on all packages (internally connected to VSS).

Do not enable the internal voltage reference buffer when an external power supply is applied to the VREF+ pin.

DAC reference voltage

To ensure a better DAC accuracy, the user can connect to VREFDAC+/VREFDAC- a separate reference voltage lower than V_{DDA}. $V_{REFDAC+}$ is the highest voltage represented by the full-scale value for an analog output signal from a DAC.

$V_{REFDAC+}$ can be provided only by an external reference (or by the external connection of VREFDAC+/VREFDAC- pins to VREF+/VREF- pins).

VREFDAC+/VREFDAC- pins must be always correctly decoupled by external capacitors. The recommended value for these capacitors is a 1 µF capacitor in parallel with a 100 nF

capacitor. The capacitors must be placed very close to VREFDAC+ and VREFDAC- pins. Correct decoupling of VREFDAC+/VREFDAC- pins has a significant impact on DAC performance. It is recommended to use low ESR capacitors and minimize parasitic inductance from capacitors to VREFDAC+/VREFDAC- pins (by placing capacitors immediately to VREFDAC+/VREFDAC- pins with no vias in path).

Note: The VREFDAC+ and VREFDAC- pins are not available on all packages (internally connected, respectively, to VDDA and VSSA).

10.4.5 USB transceivers supply

The USB transceivers are supplied from VDD/VSS pins. For correct USB operation, V_{DD} must range from 3.0 to 3.6 V.

To use the USB peripheral, the USB33SV bit of the PWR_USBSCR register must be set. It is used to validate the V_{DD} supply for electrical and logical isolation purposes.

10.4.6 RTC domain

The RTC domain is powered from the V_{DD} supply. It contains the RTC unit, the backup registers, the TAMP peripheral, the LSE oscillator (PC14/PC15 pins, and PC13 pin), allowing those blocks to operate even in Standby mode (when the V_{CORE} supply domain is switched off). The RTC domain is not reset by system reset.

When the RTC domain operates in Stop or Standby mode, the following pins are available:

- PC13, PC14 and PC15, which can be configured by RTC or LSE (refer to *Section 49.3: RTC functional description*)
- PC13, PA0, and PA1 when they are configured by TAMP peripheral as tamper pins.

RTC domain access

After a system reset, the RTC domain (RCC RTC domain control register RCC_RTCCR, RTC registers, TAMP registers and backup registers) is protected against possible unwanted write accesses. To enable accesses to the RTC domain, set the DRTCP bit in PWR_RTCCR.

10.5 PWR system supply voltage regulation

10.5.1 SMPS and LDO embedded regulators

The devices embed two internal regulators, exclusively enabled by hardware on power-on reset, depending upon package configuration. To supply the V_{CORE} from an external source, it is possible to disable the regulator by setting the BYPASS bit in the PWR_SCCR register.

The BYPASS bit is written once after power-on reset. Written-once mechanism locks the register and any further write access is ignored. The system must be power cycled before writing a new value.

When V_{CORE} is supplied from an external source, refer to *Section : Startup with VCORE provided from an external supply (bypass)*.

Both regulators can provide three different voltages (voltage scaling) and can operate in Stop mode.

10.5.2 V_{CORE} supply versus reset, voltage scaling, and low-power modes

After reset, the V_{CORE} is in the VOS2 range.

When exiting the Stop or Standby mode, the voltage range is the VOS2.

10.5.3 Embedded voltage regulator operating modes

There are three different power modes: Run, Stop, and Standby modes.

Run mode

The voltage regulator provides full power to the V_{CORE} domain (core, memories, and digital peripherals). The regulator output voltage can be scaled by software to different voltage levels (VOS0, VOS1, and VOS2) that are configured through the VOS bits in the PWR voltage scaling control register (PWR_VOSCR).

The VOS voltage scaling allows optimization of the power consumption when the system is clocked below the maximum frequency. By default, VOS2 is selected after system reset.

VOSx bits can be changed on-the-fly to adapt to the required system performance.

Stop mode

The voltage regulator supplies the V_{CORE} domain to retain the content of registers and internal memories. The regulator mode is automatically set to the Stop mode range to reduce power consumption (lower voltage level than VOS2).

Standby mode

The regulator is OFF and the V_{CORE} domain is powered down. The content of the registers and memories is lost except for the Standby circuitry and the RTC domain.

The Standby mode must not be used if V_{CORE} is provided from an external supply (bypass).

10.5.4 Regulator bypass operating modes

This mode is available only for packages without an SMPS regulator option.

The external power supply provides the voltage for V_{CORE}. The internal LDO regulator must be disabled by software (by setting the BYPASS bit of the PWR_SCCR register).

Two different power modes can be used: Run and Stop. Refer to section *Startup with VCORE provided from an external supply (bypass)*.

Run mode

The external voltage regulator provides full power to the V_{CORE} domain (core, memories, and digital peripherals).

After the power-on reset, the external regulator must provide a voltage at given range: $V_{COREEXT1}$ (for f_{HCLK} < 220 MHz, T_{jmax} = 140°C) or $V_{COREEXT0}$ (for f_{HCLK} < 280 MHz, T_{jmax} = 105°C).

VOS[1:0] bits (in PWR_VOSCR register) must be set to VOS0 range (VOS[1:0] = 3) after setting BYPASS = 1 and before increasing the system frequency above 150 MHz. This VOS0 setting must be used for any operating conditions in bypass mode.

Refer to *Startup with VCORE provided from an external supply (bypass)*for the requirements on external regulator value, startup/shutdown timings, and level changing sequence.

Stop mode

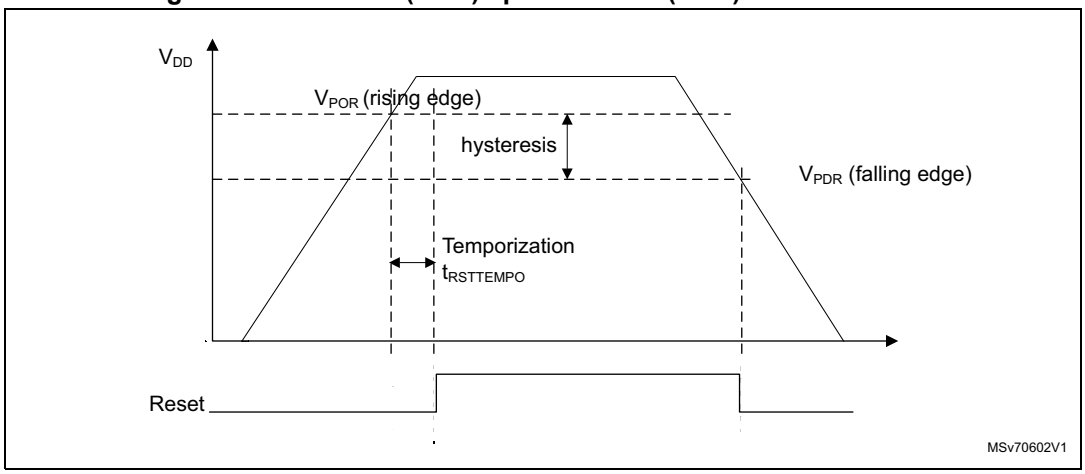
The external voltage regulator supplies the V_{CORE} domain to retain the content of registers and internal memories. The voltage supplied by the external regulator must be within the range $V_{COREEXT1}$ or $V_{COREEXT2}$.

Standby mode

The Standby mode must not be used if V_{CORE} is provided from an external supply.

10.6 PWR power supply and temperature supervision

Power supply level monitoring is available on the following supplies:



- V_{DD} via POR/PDR (see *Section 10.6.1: Power-on reset (POR)/power-down reset (PDR)*), PVD monitoring (see *Section 10.6.2: Programmable voltage detector (PVD)*), and V_{DD} high threshold monitoring (see *Section 10.6.4: VDD voltage monitoring*)
- V_{DDA} via AVD monitoring (see *Section 10.6.3: Analog voltage detector (AVD)*)
- Temperature monitoring (see *Section 10.6.5: Temperature monitoring*)
- Maximum V_{DD} voltage monitoring (see *Section 10.6.4: VDD voltage monitoring*)

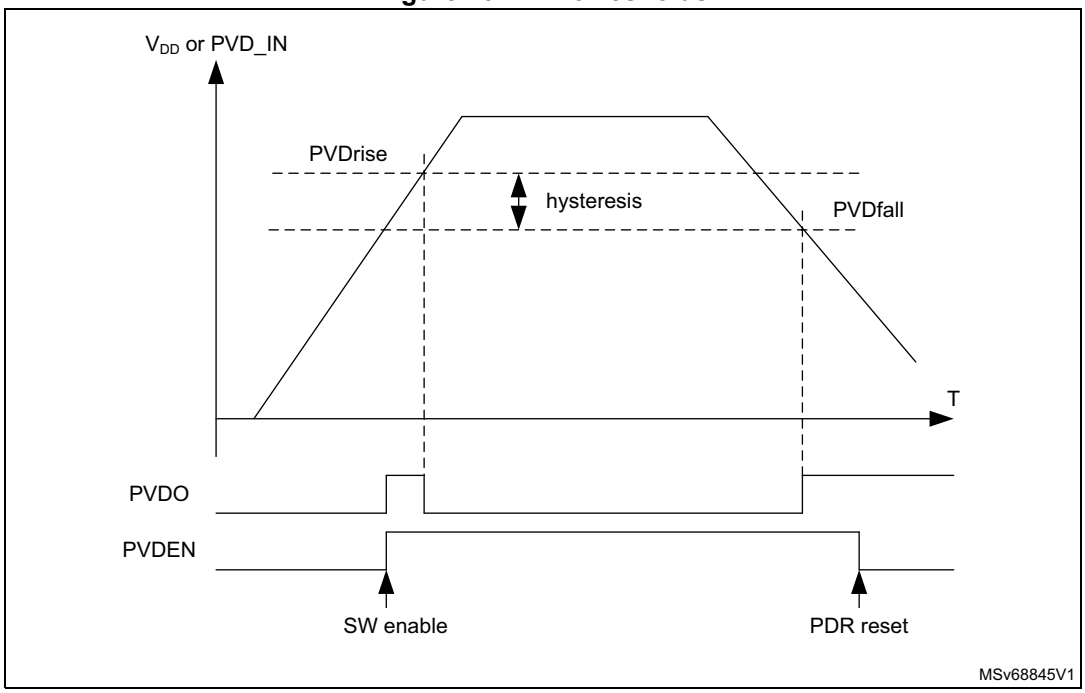
10.6.1 Power-on reset (POR)/power-down reset (PDR)

The system has an integrated POR/PDR circuitry that ensures proper startup operation.

The system remains in reset mode when V_{DD} is below a specified V_{POR} threshold, without the need for an external reset circuit. Once the supply level is above the V_{POR} threshold, the system is taken out of reset (see *Figure 39*). For more details concerning the reset thresholds, refer to the electrical characteristics section of the datasheets.

Figure 39. Power-on (POR) / power-down (PDR) reset waveform

1. For thresholds and hysteresis values, refer to the datasheets.



10.6.2 Programmable voltage detector (PVD)

The PVD can be used to monitor the V_{DD} power supply by comparing it to a threshold selected by the PLS[1:0] bits in the *PWR voltage monitor control register (PWR_VMCR)*. The PVD can also be used to monitor a voltage level on the PVD_IN pin. In this case, PVD_IN voltage is compared to the internal VREFINT level.

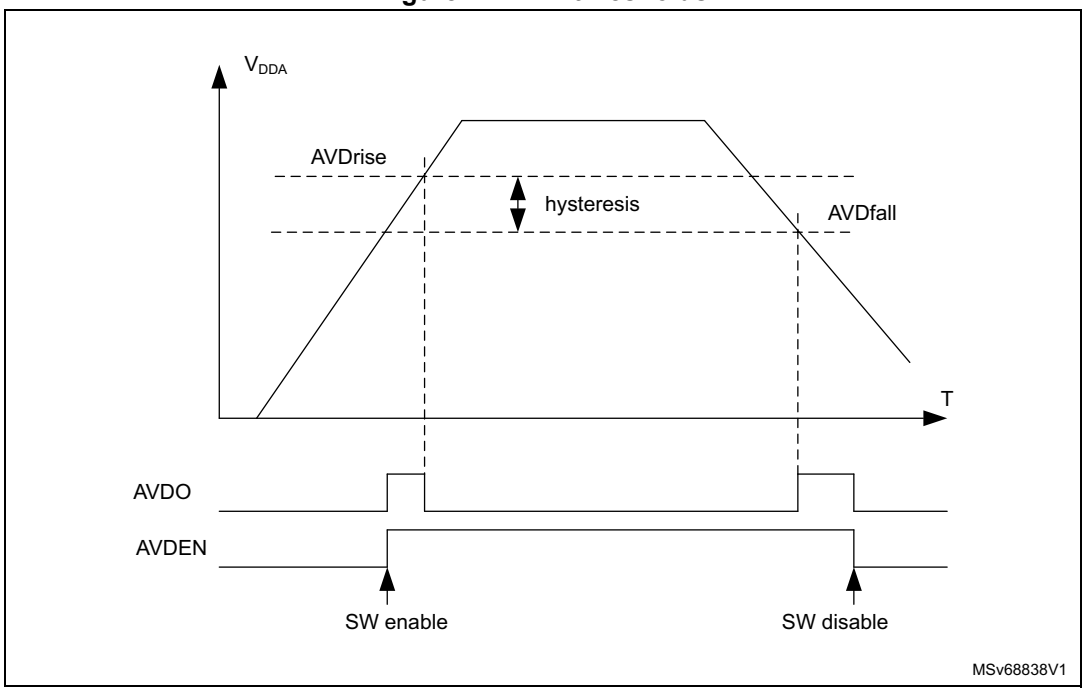
The PVD is enabled by setting the PVDE bit in *PWR voltage monitor control register (PWR_VMCR)*.

A PVDO flag is available in the *PWR voltage monitor status register (PWR_VMSR)* to indicate if the V_{DD} or PVD_IN voltage is higher or lower than the PVD threshold. This event is internally connected to the EXTI and can generate an interrupt (PWR_PVD_AVD), provided it has been enabled through the EXTI registers. The rising/falling edge sensitivity of the EXTI line must be configured according to PVD output behavior. As an example, if the EXTI line is configured to rising edge sensitivity, the interrupt is generated when V_{DD} or PVD_IN voltage drops below the PVD threshold. The service routine can then start an emergency shutdown.

Figure 40. PVD thresholds

1. For thresholds and hysteresis values, refer to the datasheets.

10.6.3 Analog voltage detector (AVD)



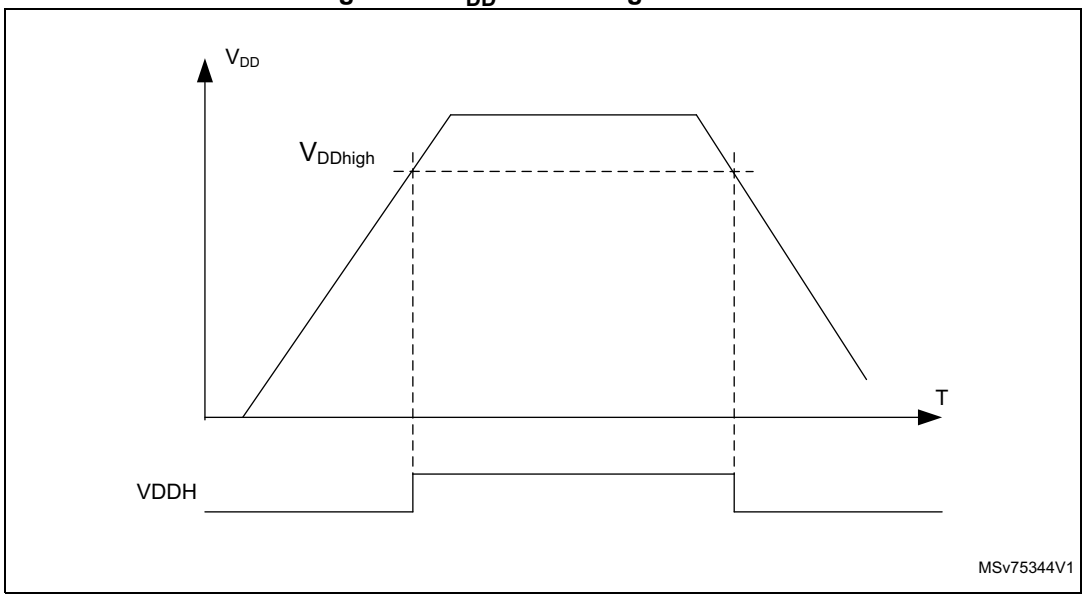
The AVD can be used to monitor the V_{DDA} supply by comparing it to a threshold selected by the ALS bit of the *PWR voltage monitor control register (PWR_VMCR)*.

The AVD is enabled by setting the AVDEN bit in *PWR voltage monitor control register (PWR_VMCR)*.

An AVDO flag is available in the *PWR voltage monitor status register (PWR_VMSR)* to indicate whether V_{DDA} is higher or lower than the AVD threshold. This event is internally connected to the EXTI and can generate an interrupt if enabled through the EXTI registers.

The PWR_PVD_AVD interrupt can be generated when V_{DDA} drops below the AVD threshold and/or when V_{DDA} rises above the AVD threshold, depending on EXTI rising/falling edge configuration. As an example, the service routine can indicate when the V_{DDA} supply drops below a minimum level.

Figure 41. AVD thresholds



1. For thresholds and hysteresis values, refer to the datasheets.

10.6.4 V_{DD} voltage monitoring

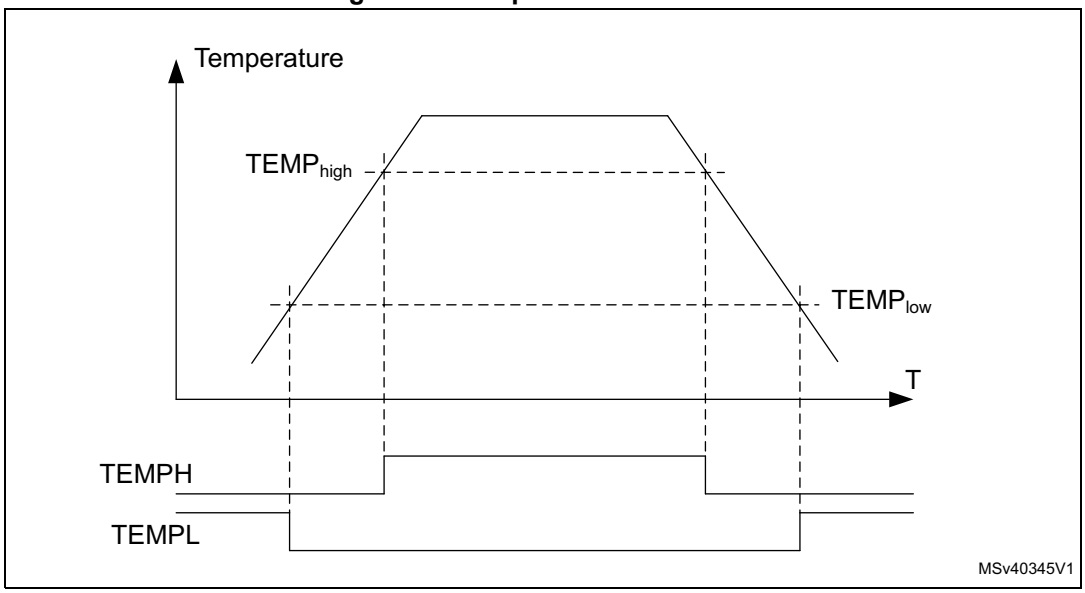
The V_{DD} supply voltage can be monitored by comparing it with the high threshold level V_{DDhigh}. The V_{DD} supply monitoring can be enabled/disabled via MONEN bit in *PWR tamper monitoring control register (PWR_TMCR)*. The VDDH flag of the *PWR tamper monitoring status register (PWR_TMSR)* indicates whether the device V_{DD} voltage is higher or lower than the V_{DDhigh} threshold.

If the V_{DD} voltage monitoring internal tamper is enabled in the TAMP peripheral (ITAMP1E = 1 in the TAMP_CR1 register), a tamper event is generated when the V_{DD} voltage is above the functional range.

Figure 42. V_{DD} monitoring threshold

1. For threshold and hysteresis values, refer to the datasheets.

10.6.5 Temperature monitoring



A dedicated temperature sensor cell is embedded in the power control. The junction temperature can be monitored by comparing it with two threshold levels, $TEMP_{high}$ and $TEMP_{low}$. The TEMPH and TEMPL flags of the *PWR tamper monitoring status register (PWR_TMSR)*, which indicate whether the device temperature is higher or lower than the threshold. The temperature monitoring can be enabled/disabled via MONEN bit in *PWR tamper monitoring control register (PWR_TMCR)*.

When enabled, the temperature thresholds increase power consumption. As an example the levels may be used to trigger a routine to perform temperature control tasks.

If the temperature monitoring internal tamper is enabled in the TAMP peripheral (ITAMP2E = 1 in the TAMP_CR1 register), a tamper event is generated when the temperature is above or below the functional range.

TEMPH and TEMPL wake-up interrupts are available on the tamper signals (see *Section 50: Tamper and backup registers (TAMP)*).

Figure 43. Temperature thresholds

1. For thresholds and hysteresis values, refer to the datasheets.

10.7 PWR management

10.7.1 Voltage scaling

The voltage regulator supporting voltage scaling with the following features:

- Run mode voltage scaling
  - VOS0: range 0
  - VOS1: range 1
  - VOS2: range 2
- Stop mode voltage scaling

For more details on voltage scaling values, refer to the product datasheets.

After reset, the system starts on the lowest Run mode voltage scaling (VOS2). The voltage scaling can be changed on-the-fly by software by programming VOS bits of the PWR_VOSCR register, according to the required system performance. When exiting from the Stop mode or Standby mode, the Run mode voltage scaling is reset to the default VOS2 value.

Specific voltage scaling is used in Stop mode to decrease power consumption.

10.7.2 Power management examples

Figure 44. Dynamic voltage scaling in Run mode

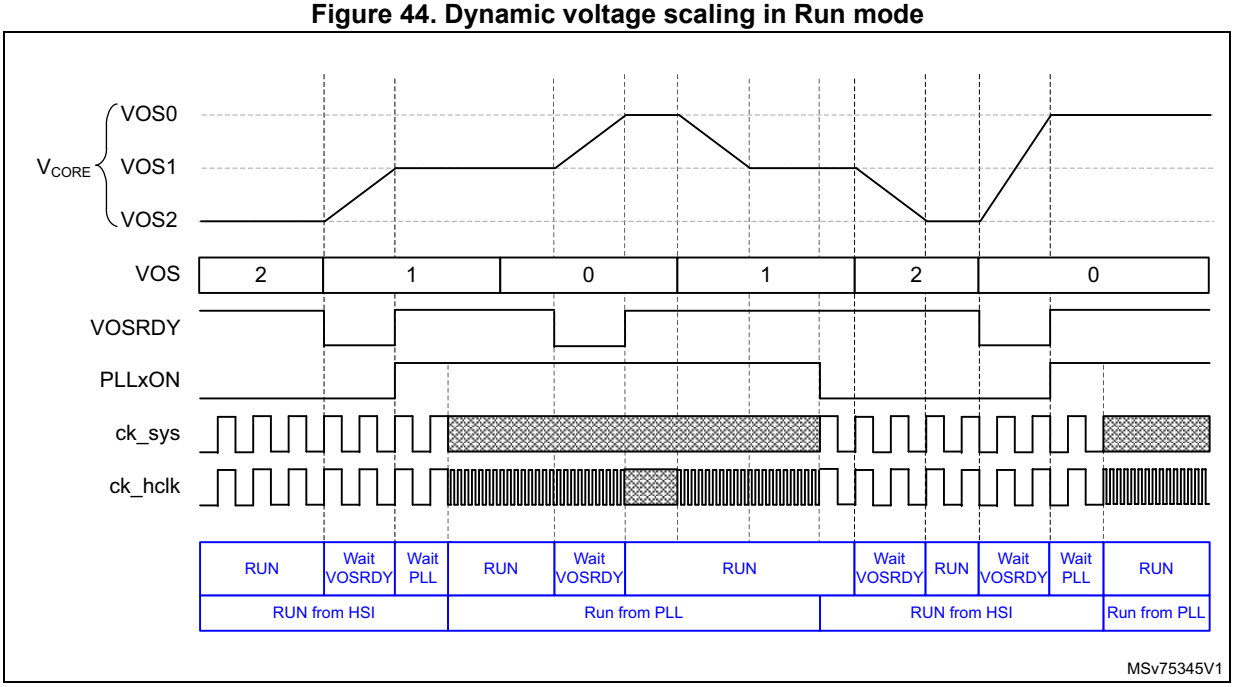


Figure 44 illustrates the following system operation sequence example:

1. After reset, the system starts from HSI with VOS2.
2. The system performance is increased to a medium-speed clock from the PLL with voltage scaling VOS1. To do this:
   a) Program the voltage scaling to VOS1.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.
3. The system performance is increased to a high-speed clock from the PLL with voltage scaling VOS0. To do this:
   a) Program the voltage scaling to VOS0.
   b) Once the VCORE supply has reached the required level indicated by VOSRDY, increase the clock frequency.
4. The system performance is reduced to a medium-speed clock with voltage scaling VOS1. To do this:
   a) First decrease the system frequency.
   b) Then decrease the voltage scaling to VOS1.
5. The next step is to reduce the system performance to the HSI clock with voltage scaling VOS2. To do this:
   a) Switch the clock to HSI.
   b) Disable the PLL.
   c) Decrease the voltage scaling to VOS2.

6. The system performance can then be increased to a high-speed clock from the PLL. To do this:
   a) Program the voltage scaling to VOS0.
   b) Once the V_{CORE} supply has reached the required level indicated by VOSRDY, increase the clock frequency by enabling the PLL.
   c) Once the PLL is locked, switch the system clock.

When the system performance (clock frequency) is changed, VOS must be set accordingly, otherwise the system can be unreliable.

10.8 Power modes

By default, the microcontroller is in Run mode after a system or a power reset. Several low-power modes are available to reduce consumption when there is no need to keep the CPU running, for example when waiting for an external event. The user can select the mode that gives the best compromise between low-power consumption, short startup time, and wake-up sources.

The device features the following low-power modes:

- Sleep mode

  CPU clock off, peripherals such as NVIC and SysTick can run and wake up the CPU when an interrupt or an event occurs. Refer to *Section 10.8.4: Sleep mode*.

- Stop mode

  Achieves the lowest power consumption, while retaining the content of SRAM and registers. All clocks in the core domain are stopped. The PLL, the HSE crystal oscillators, HSI (except if HSIKERON is set), and HSI48 are disabled. The LSE or LSI is still running.

  The RTC can remain active (Stop mode with RTC, Stop mode without RTC).

  The system clock when exiting from Stop mode is set to HSI.

  SRAMs pages can be individually powered-down to further reduce power consumption.

  Refer to *Section 10.8.5: Stop mode*.

- Standby mode

  This mode achieves the lowest power consumption. The internal regulator is switched off so that the core domain is powered off. The PLL, the HSI RC, HSI48, and the HSE crystal oscillators are also switched off.

  The RTC can remain active (Standby mode with RTC, Standby mode without RTC).

  The state of the I/O (except I/Os used by standby mode) during Standby mode can be retained.

  After entering Standby mode, SRAMs and register contents are lost except for registers in the RTC domain and Standby circuitry.

  The device exits Standby mode when an external reset (NRST pin), an IWDG reset, WKUP pin event (configurable rising or falling edge), an RTC event occurs (alarm, periodic wake-up, timestamp), or a tamper detection. The tamper detection can be raised either due to external pins or due to an internal failure detection.

  The system clock after wake-up is HSI at 64 MHz.

  Refer to *Section 10.8.6: Standby mode*.

Table 99 shows the power modes overview.

Table 99. Low-power mode summary

Mode name	Entry	Wake-up source(1)	Wake-up system clock	Effect on clocks	Voltage regulators
Sleep (Sleep-now or Sleep-on-exit)	WFI or Return from ISR	Any interrupt	Same as before entering Sleep mode	– CPU clock OFF – No effect on other clocks or analog clock sources	VOS2, VOS1, or VOS0
	WFE	Wake-up event			
Stop	LPMS = 0 + SLEEPDEEP bit + WFI or Return from ISR or WFE	– Any EXTI line (configured in the EXTI registers)	HSI with the frequency before entering Stop mode, up to 64 MHz	– All clocks OFF except LSI and LSE – HSI can be enabled temporarily when requested by peripherals	Regulator in Stop mode range
Standby	LPMS = 1 + SLEEPDEEP bit + WFI or Return from ISR or WFE	WKUP pin edge, RTC event, IWDG reset, external reset in NRST pin	HSI clock at 64 MHz	All clocks OFF except LSI and LSE	OFF

1. Refer to *Table 100*.

FLASH	Y	Y	-	-	-	-
SBS	O	O	-	-	-	-

1. Y = yes (enabled). O = optional (disabled by default, can be enabled by software). - = not available.
2. The memory can be configured in low-power mode.
3. The SRAM clock can be gated on or off independently. By default, the clock is enabled in Run and Sleep modes.
4. The SRAMs can be powered on or off independently. By default, they are not in power-off mode during Stop.
5. Wake-up with internal tamper.
6. I/Os can be configured with internal pull-up, pull-down or floating in Standby mode.
7. WKUPx pins are capable of wake-up from Standby mode.

In addition, the power consumption in Run mode can be reduced by slowing down the system clocks, configuring voltage scaling to lower power ranges, and by gating the clocks to the APB and AHB peripherals when they are not used.

Debug mode

By default, the debug connection is lost if the application puts the MCU in Stop or Standby mode while the debug features are used. This is because the Cortex®-M33 core is no longer clocked.

However, by setting some configuration bits in the DBGMCU control registers, the software can be debugged even when using the low-power modes extensively. For more details, refer to *Section 60.2.5: Debug and low-power modes*.

10.8.1 Slowing down system clocks

In Run mode, the speed of the system clocks (SYSCLK, HCLK, PCLK) can be reduced by programming the prescaler registers. These prescalers can also be used to slow down the peripherals before entering the Sleep mode.

For more details, refer to *Section 11: Reset and clock control (RCC)*.

10.8.2 Peripheral clock gating

In Run mode, the HCLK, and PCLK for individual peripherals and memories can be stopped at any time to reduce the power consumption.

In addition, to further reduce the power consumption, the peripheral clocks can be automatically disabled during Sleep mode.

The peripheral clock gating is controlled by the RCC_AHBxENR and RCC_APBxENR registers.

Disabling the peripheral clocks in Sleep mode is performed automatically by resetting the corresponding bit in the RCC_AHBxLPENR and RCC_APBxLPENR registers.

10.8.3 Low-power modes

Entering low-power modes

The MCU enters in low-power modes by executing the WFI (wait for interrupt), or WFE (wait for event) instructions, or when the SLEEPONEXIT bit in the Cortex®-M33 system control register is set on return from ISR.

Entering into a low-power mode through WFI or WFE is executed only if no interrupt is pending or no event is pending.

Exiting from low-power modes

The MCU exits the Sleep or Stop mode according to how the low-power mode was entered:

- If the WFI instruction or return from ISR was used to enter the low-power mode, any peripheral interrupt acknowledged by the NVIC can wake up the device.
- If the WFE instruction is used to enter the low-power mode, the MCU exits the low-power mode as soon as an event occurs. The wake-up event can be generated either by:
  - An NVIC IRQ interrupt:

    When SEVONPEND = 0 in the Cortex®-M33 system control register, the interrupt must be enabled in the peripheral control register and in the NVIC.

    When the MCU resumes from WFE, the peripheral interrupt pending bit, and the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared. Only NVIC interrupts with sufficient priority can wake up and interrupt the MCU.

    When SEVONPEND = 1 in the Cortex®-M33 system control register, the interrupt must be enabled in the peripheral control register and optionally in the NVIC. When the MCU resumes from WFE, the peripheral interrupt pending bit and, when enabled, the NVIC peripheral IRQ channel pending bit (in the NVIC interrupt clear pending register) must be cleared.

    All NVIC interrupts wake up the MCU, even the disabled ones.
  - An event:

    An EXTI line must be configured in event mode. When the CPU resumes from WFE, it is not necessary to clear the EXTI peripheral interrupt pending bit or the NVIC IRQ channel pending bit, as the pending bits corresponding to the event line are not set. It may be necessary to clear the interrupt flag in the peripheral.

The MCU exits Standby mode through an external reset (NRST pin), an IWDG reset, a

rising edge on one of the enabled WKUPx pins or a RTC/TAMP event (see *Figure 801: RTC block diagram*).

After waking up from Standby mode, the program execution restarts in the same way as after a reset (boot pin sampling, option bytes loading, reset vector is fetched).

10.8.4 Sleep mode

I/O states in Sleep mode

In Sleep mode, all I/O pins keep the same state as in Run mode.

Entering Sleep mode

The MCU enters the Sleep mode as described in *Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M33 system control register is clear (see the table below for details on how to enter the Sleep mode).

Exiting from Sleep mode

The MCU exits the Sleep mode as described in *Exiting from low-power modes* (see the table below for details on how to exit the Sleep mode).

Table 101. Sleep mode

Sleep mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP = 0 – No interrupt (for WFI) or event (for WFE) pending Refer to the Cortex-M33 system control register.
	On return from ISR while: – SLEEPDEEP = 0 and – SLEEPONEXIT = 1 – No interrupt pending Refer to the Cortex-M33 system control register.
Mode exit	If WFI or Return from ISR was used for entry Interrupt (see *Table 173: STM32G56x/55x/54x/53x vector table*) If WFE was used for entry and SEVONPEND = 0: Wake-up event (see *Section 19.3: EXTI functional description*) If WFE was used for entry and SEVONPEND = 1: Interrupt even when disabled in NVIC (see *Table 173: STM32G56x/55x/54x/53x vector table*) or wake-up event (see *Section 19.3: EXTI functional description*)
Wake-up latency	None

10.8.5 Stop mode

The Stop mode is based on the Cortex®-M33 deep-sleep mode combined with the peripheral clock gating. The voltage regulator is configured in Stop mode voltage range. In Stop mode, all clocks in the core domain are stopped. The PLL, HSI, HSI48, and HSE oscillators are disabled.

It is possible to keep the HSI clock enabled during Stop mode, to be quickly available as kernel clock for peripherals.

All SRAMs and register contents are preserved, but the SRAMs can be totally or partially switched off to further reduce consumption. The user can select which memory is discarded during Stop mode by means of xxSO bits in PWR_LPMCR registers.

Table 102. Memory power-down block selection for STM32G53x/54x devices

Selection bit	Power-down block in Stop mode
SRAM1PDS	AHB SRAM1 block from 0 to 16 Kbytes
SRAM2PDS1	AHB SRAM2 block from 0 to 16 Kbytes
SRAM2PDS2	AHB SRAM2 block from 16 to 32 Kbytes

Table 103. Memory power-down block selection for STM32G55x/56x devices

Selection bit	Power-down block in Stop mode
SRAM1PD	AHB SRAM1
SRAM2PDS1	AHB SRAM2 block from 0 to 16 Kbytes
SRAM2PDS2	AHB SRAM2 block from 16 to 64 Kbytes
SRAM3PDS	AHB SRAM3

I/O states in Stop mode

In the Stop mode, all I/O pins keep the same state as in the Run mode.

Entering Stop mode

The MCU enters the Stop mode as described in *Entering low-power modes* , when the SLEEPDEEP bit in the Cortex®-M33 system control register is set (see *Table 104* for details on how to enter the Stop mode).

If the flash memory programming is ongoing, the Stop mode entry is delayed until the memory access is finished.

If an access to the APB domain is ongoing, the Stop mode entry is delayed until the APB access is finished.

In Stop mode, the following features can be selected by programming the individual control bits:

- The independent watchdog (IWDG) is started by writing to its key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 47.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in the *RCC RTC domain control register (RCC_RTCCR)*
- The internal RC oscillator LSI clock is configured by the LSION bit in *RCC RTC domain control register (RCC_RTCCR)*.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in *RCC RTC domain control register (RCC_RTCCR)*.

The AVD and the PVD can be used in Stop mode. If they are not needed, they must be disabled by software to save their power consumptions.

The ADCx, DACx, OPAMPs, COMPx, the temperature sensor, and the VREFBUF can consume power during the Stop mode, unless they are disabled before entering this mode.

Exiting from Stop mode

The MCU exits Stop mode by enabling an EXTI interrupt or event depending on how the low-power mode was entered. Some peripherals are able to wake up the system (refer to *Table 176: EXTI line connections*) from Stop mode.

When exiting Stop mode by issuing an interrupt or a wake-up event, the HSI oscillator is selected as the system clock.

The MCU exits Stop mode by invoking an EXTI interrupt or event depending on how the low-power mode was entered.

When exiting the Stop mode, the MCU is in Run mode, VOS2.

Table 104. Stop mode

Stop mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 000 in PWR_CR1
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 0 in PWR_LPMCR
	Note: To enter Stop mode, all EXTI line pending bits (in the EXTI rising edge pending register 2 (EXTI_RPR2)), and the peripheral flags generating wake-up interrupts must be cleared. Otherwise, the Stop mode entry procedure is ignored and the program execution continues.

Table 104. Stop mode (continued)

Stop mode	Description
Mode exit	If WFI or Return from ISR was used for entry: - any EXTI line configured in interrupt mode (the corresponding EXTI interrupt vector must be enabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 173: STM32G56x/55x/54x/53x vector table*). If WFE was used for entry and SEVONPEND = 0: - any EXTI line configured in event mode (see *Section 19.3: EXTI functional description*). If WFE was used for entry and SEVONPEND = 1: - any EXTI line configured in interrupt mode (even if the corresponding EXTI interrupt vector is disabled in the NVIC). The interrupt source can be external interrupts or peripherals with wake-up capability (see *Table 173: STM32G56x/55x/54x/53x vector table*). - any EXTI line is configured in event mode (see *Section 19.3: EXTI functional description*)
Wake-up latency	Refer to the datasheet.

10.8.6 Standby mode

The lowest power mode is the Standby mode. It is based on the Cortex®-M33 deep-sleep mode, with the voltage regulators disabled. The PLL, HSI, HSI48, and HSE oscillators are also switched off.

The SRAMs and register contents are lost except for registers in the RTC domain and Standby circuitry (see *Figure 45*).

The POR is always available in Standby mode.

I/O states in Standby mode

In Standby, the I/Os are by default in floating state. If the IORETEN bit in the PWR_IORETR register is set, the I/Os pull or output state is retained during Standby mode. I/O retention mode is enabled for all I/Os except those supporting the standby functionality and JTAG I/Os (PA13, PA14, PA15, and PB4). When entering into Standby mode, the state of the I/O is sampled, and pull-up or pull-down resistor are set to maintain the I/O output during Standby mode.

If the JTAGIORETEN bit in the PWR_IORETR register is set, the I/Os pull or output state is retained during Standby mode. I/O retention mode is enabled for PA13, PA14, PA15, and PB4 (default JTAG pull-up/pull-down after wake-up is not enabled).

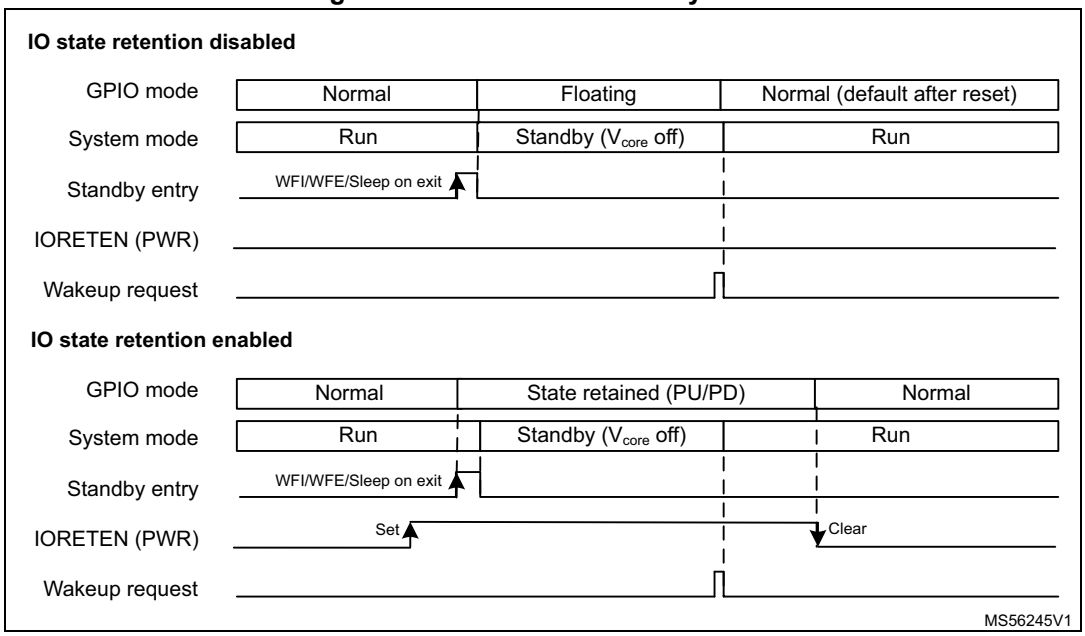

Table 105. I/O retention with pull-up and pull-down

IORETEN/JTAGIORETEN	I/O GPIO configuration before entering Standby	I/O configuration in Standby
0	Any	High-Z

Table 105. I/O retention with pull-up and pull-down (continued)

IORETEN/JTAGIORETEN	I/O GPIO configuration before entering Standby	I/O configuration in Standby
1	Input, no pulls	High-Z
	Input or output with pull-up	Pull-up
	Input or output with pull-down	Pull-down
	Output, no pull driving high level	Pull-up
	Output, no pull driving low level	Pull-down

Figure 45. I/O states in Standby mode

After wake-up from Standby mode, as long as IORETEN (or JTAGIORETEN for JTAG I/Os) is set, the retained stated (pull-up/pull-down) remains applied.

Before Standby, the GPIO pin state can be identified with GPIO_IDR register (when both GPIO port clock and input buffer are enabled).

The application releases the I/O state (clear the retained Pull-up/Pull-down) by clearing the IORETEN (or JTAGIORETEN for JTAG IOs) bit. The GPIOs should be configured before releasing the retained state to control continuously I/O level. It is recommended to clear the IORETEN (or JTAGIORETEN for JTAG IOs) bit just after the required GPIOs are configured (GPIOs which should control continuously I/O level) to avoid pull-up / pull-down conflict set by Standby mode (latched in V_{DD} domain) and set by Run mode.The RTC outputs on PC13 are functional in Standby mode. PC14 and PC15 used for LSE are also functional. Up to seven wake-up (WKUPx, x = 1, 2, 4 to 8) and four tamper pins (two input and two output pins) are available.

Entering Standby mode

The MCU enters the Standby mode as described in *Entering low-power modes*, when the SLEEPDEEP bit in the Cortex®-M33 system control register is set (see *Table 106* for details

on how to enter Standby mode).

In Standby mode, the following features can be selected by programming individual control bits:

- The independent watchdog (IWDG) is started by writing to its Key register or by hardware option. Once started, it can be stopped only by a reset (see *Section 47.4: IWDG functional description*).
- The real-time clock (RTC) is configured by the RTCEN bit in *RCC RTC domain control register (RCC_RTCCR))*.
- The internal RC oscillator LSI clock is configured by the LSION bit in *RCC RTC domain control register (RCC_RTCCR)*.
- The external 32.768 kHz oscillator (LSE) is configured by the LSEON bit in *RCC RTC domain control register (RCC_RTCCR)*.
- The I/Os retention is configured by the IIORETEN/JTAGIORETEN bits in the PWR_IORETR register.

Exiting from Standby mode

The MCU exits the Standby mode as described in *Exiting from low-power modes*. The SBF status flag in the *PWR status register (PWR_PMSR)* indicates that the MCU was in Standby mode. All registers are reset after wake-up from Standby except for *PWR tamper monitoring control register (PWR_TMCR)* and *PWR I/O retention register (PWR_IORETR)* *(see Table 106* for more details on how to exit Standby mode).

When exiting Standby mode, I/Os output state that were retained during Standby through IORETEN bit, keep this configuration upon exiting Standby mode until the IORETEN bit in PWR_IORETR register is cleared. Once IORETEN is cleared, the I/Os are configured to their reset values, or to the pull-up/pull-down state according to the GPIOx_PUPDR registers.

For I/Os, with a pull-up or pull-down predefined after reset (some JTAG/SWD I/Os), in case those pull-up or pull-down are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Also in case the GPIOx_PUPDR values programed after exiting from Standby are different from the retained values during Standby, both a pull-down and pull-up are applied until IORETEN is cleared, releasing the retained value.

Table 106. Standby mode

Standby mode	Description
Mode entry	WFI (wait for interrupt) or WFE (wait for event) while: – SLEEPDEEP bit is set in Cortex-M33 system control register – No interrupt (for WFI) or event (for WFE) pending – LPMS = 1 in PWR_LPMCR – WUFx bits cleared in PWR_WUSR
	On Return from ISR while: – SLEEPDEEP bit is set in Cortex-M33 system control register – SLEEPONEXIT = 1 – No interrupt pending – LPMS = 1 in PWR_LPMCR – WUFx bits cleared in PWR_WUSR – RTC/TAMP flags corresponding to the chosen wake-up source, cleared
Mode exit	WKUPx pin edge, RTC event, external Reset in NRST pin, IWDG Reset, POR reset
Wake-up latency	Reset phase

10.8.7 Power modes output pins

To help the debug, three signals are available as device pins alternate functions:

- **CSLEEP**

  When set, CSLEEP indicates that the system is in Sleep mode: WFI or WFE has been executed.

  When cleared, CSLEEP indicates that the system is in Run mode.

- **CSTOP**

  When set, CSTOP indicates that the system is in CStop mode, meaning that the following conditions are fulfilled:

  – WFI or WFE has been executed with CPU SLEEPDEEP = 1.

  – No AHB/APB clock is running.

  When cleared, CSTOP indicates that the system is not in CStop mode: AHB/APB clocks are running.

The table below explains the MCU power mode depending on these signals states.

Table 107. Power modes output states versus MCU power modes

CSLEEP	CSTOP	MCU power modes(1)
0	0	Run mode
1	0	Sleep mode or Stop mode, with AHB/APB clocks running
1	1	Stop mode

1. CSLEEP and CSTOP are generated in the core domain, consequently they are not driven in Standby mode.

10.9 PWR security and privileged protection

10.9.1 PWR security protection

When the TrustZone® security is activated by the TZEN option byte in the flash memory option byte configuration register, some PWR register fields can be secured against nonsecure accesses.

The PWR TrustZone® security allows the following features to be secured through the PWR_SECCFGR register:

- Low-power mode
- Wake-up (WKUP) pins
- Voltage detection and monitoring
- I/Os retention configuration

Other PWR configuration bits are secure when:

- The system clock selection is secure in RCC: the voltage scaling (VOS) configuration is secure.
- The UCPD is secure in the GTZC: the PWR_UCPDR register is secure.

Table 108 gives a summary of the PWR secured bits following the security configuration bit in PWR_SECCFGR.

A nonsecure access to a secure-protected register bit is denied:

- The secured bits are not written (WI) with a nonsecure write access.
- The secured bits are read as 0 (RAZ) with a nonsecure read access.

A nonsecure write access to PWR_SECCFGR is WI and generates an illegal access event and an interrupt if enabled in the GTZC. It can be read with a nonsecure read access.

When the TrustZone® security is disabled (TZEN = 0xC3), PWR_SECCFGR is RAZ/WI and all other registers are nonsecure.

Table 108. PWR security configuration summary

Secure configuration register	Security configuration bit	Register name	Secured bits	Nonsecure access on secure bits
PWR_SECCFGR	Not applicable(1)	PWR_SECCFGR	All bits	Read OK. WI and illegal access event
PWR_SECCFGR	At least one bit is set	PWR_PRIVCFGR	SPRIV	Read OK. WI
PWR_SECCFGR	LPMSEC	PWR_LPMCR	All bits	WI
PWR_SECCFGR	VUSBSEC	PWR_USBSCR	All bits	WI
PWR_SECCFGR	RTMSEC	PWR_TMCR	All bits	WI
		PWR_RTCCR	All bits	WI
PWR_SECCFGR	RETSEC	PWR_IORETR	All bits	WI

Table 108. PWR security configuration summary (continued)

Secure configuration register	Security configuration bit	Register name	Secured bits	Nonsecure access on secure bits
PWR_SECCFGR	WUPxSEC (x = 1, 2, 4 to 8)	PWR_WUCR	WUPENx	RAZ/WI
			WUPPx	RAZ/WI
			WUPPUPD	RAZ/WI
		PWR_WUSCR	CWUFx	WI
GTZC1_TZSC_SECCFGR2	UCPD1SEC	PWR_UCPDR	All bits	RAZ/WI
RCC_SECCFGR	SYSCLKSEC	PWR_VOSCR	VOS[1:0]	RAZ/WI
PWR_SECCFGR	SCMSEC	PWR_SCCR	All bits	WI
	SCMSEC	PWR_VMCR	All bits	WI

1. PWR_SECCFGR is always secure.

10.9.2 PWR privileged protection

By default, after a reset, all registers can be read or written with both privileged and unprivileged accesses, except PWR_PRIVCFGR, which can be written only with privileged access. PWR_PRIVCFGR can be read by secure and nonsecure, privileged, and unprivileged accesses.

The SPRIV bit in PWR_PRIVCFGR can be written only with secure privileged access. This bit configures the privileged access of all PWR secure functions (defined by PWR_SECCFGR, GTZC, RCC, or GPIO, as shown in *Table 108*).

When the SPRIV bit is set in PWR_PRIVCFGR:

- The PWR secure bits can be written only with privileged access, including PWR_SECCFGR.
- The PWR secure bits can be read only with privileged access except PWR_SECCFGR and PWR_PRIVCFGR that can be read by privileged or unprivileged access.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as 0 and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit of PWR_PRIVCFGR can be written only with privileged access, secure, or nonsecure. It configures the privileged access of all PWR securable functions configured as nonsecure (defined by PWR_SECCFGR, GTZC, RCC, or GPIO, see *Table 108*).

When the NSPRIV bit is set in PWR_PRIVCFGR:

- The PWR securable bits configured as nonsecure can be written only with privileged access.
- The PWR securable bits configured as nonsecure can be read only with privileged access except PWR_PRIVCFGR, which can be read by privileged or unprivileged accesses.
- The VOSRDY and BOOSTRDY bits in PWR_VOSR, PWR_SR, PWR_VMSR, PWR_TMSR and PWR_WUSR can be read with privileged or unprivileged accesses.
- An unprivileged access to a privileged PWR bit or register is discarded: the bits are read as 0, and the write to these bits is ignored (RAZ/WI).

10.10 PWR interrupts

Table 109 gives a summary of the interrupt sources and the way to control them.

Table 109. PWR interrupt requests

Interrupt vector	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep, Stop modes	Exit Standby mode
PWR_PVD_AVD output	Programmable voltage detector through EXTI line 16 (PVD) and EXTI line 53 (AVD)	PVDO/ AVDO	EXTI line 16 enabled (PVD) and EXTI line 53 enabled (AVD)	Set EXTI PIF16 (PVD), or set EXTI PIF53 (AVD)	Yes	No

10.11 PWR registers

The PWR registers can be accessed in word, half-word and byte format, unless otherwise specified.

10.11.1 PWR low power mode control register (PWR_LPMCR)

This register is protected against nonsecure accesses when LPMSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when LPMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when LPMSEC = 0 and NSPRIV = 1.

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	FLPS	Res.	CSSF	Res.	Res.	Res.	Res.	Res.	Res.	LPMS
						rw		rw							rw

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **SRAM1PDS**: AHB SRAM1 power-down in Stop mode

0: AHB RAM1 content is kept in Stop mode.

1: AHB RAM1 content is lost in Stop mode.

Note: For page definition, refer to c and Table 103: Memory power-down block selection for STM32G55x/56x devices.

Bit 25 **SRAM2PDS2**: AHB SRAM2 page 2 power-down in Stop mode.

0: AHB RAM2 page 2 content is kept in Stop mode.

1: AHB RAM2 page 2 content is lost in Stop mode.

Note: For page definition, refer to Table 102: Memory power-down block selection for STM32G53x/54x devices and Table 103: Memory power-down block selection for STM32G55x/56x devices.

Bit 24 **SRAM2PDS1**: AHB SRAM2 page 1 power-down in Stop mode.

0: AHB RAM2 page 1 content is kept in Stop mode.

1: AHB RAM2 page 1 content is lost in Stop mode.

Note: For page definition, refer to Table 102: Memory power-down block selection for STM32G53x/54x devices and Table 103: Memory power-down block selection for STM32G55x/56x devices.

Bit 23 **SRAM3PDS**: AHB SRAM3 power-down in Stop mode.

0: AHB RAM3 content is kept in Stop mode.

1: AHB RAM3 content is lost in Stop mode.

Note: For page definition, refer to Table 102: Memory power-down block selection for STM32G53x/54x devices and Table 103: Memory power-down block selection for STM32G55x/56x devices.

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FLPS**: flash memory low-power mode in Stop mode

This bit is used to obtain the best trade-off between low-power consumption and restart time when exiting from Stop mode.

When it is set, the flash memory enters low-power mode when the system is in Stop mode.

0: flash memory remains in normal mode when the system enters Stop mode (quick restart time).

1: flash memory enters low-power mode when the system enters Stop mode (low-power consumption).

Bit 8 Reserved, must be kept at reset value.

Bit 7 **CSSF**: clear Standby and Stop flags (always read as 0)

This bit is cleared to 0 by hardware.

0: no effect

1: STOPF and SBF flags cleared

Bits 6:1 Reserved, must be kept at reset value.

Bit 0 **LPMS**: low-power mode selection

This bit defines the Deepsleep mode.

0: keeps Stop mode when entering DeepSleep.

1: allows Standby mode when entering DeepSleep.

10.11.2 PWR status register (PWR_PMSR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SBF	STOPF	Res.	Res.	Res.	Res.	Res.
									r	r					

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SBF**: System standby flag

This bit is set by hardware and cleared only by a POR or by setting the CSSF bit.

0: system has not been in Standby mode.

1: system has been in Standby mode.

Bit 5 **STOPF**: Stop flag

This bit is set by hardware and cleared only by any reset or by setting the CSSF bit.

0: system has not been in Stop mode.

1: system has been in Stop mode.

Bits 4:0 Reserved, must be kept at reset value.

10.11.3 PWR voltage scaling control register (PWR_VOSCR)

Some register fields are protected against nonsecure accesses, depending on the RCC_SECCFGR register. These fields can be protected against unprivileged accesses, depending on PWR_PRIVCFGR register configuration.

Address offset: 0x010

Reset value: 0x0000 0010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOS[1:0]		Res.	Res.	Res.	Res.
										rw	rw				

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:4 **VOS[1:0]**: voltage scaling selection according to performance

These bits control the V_{CORE} voltage level and allow to obtain the best trade-off between power consumption and performance:

- In bypass mode, these bits must be set to VOS[1:0] = 11 (range 0) before increasing the system frequency above 150 MHz.
- When increasing the performance, the voltage scaling must be changed before increasing the system frequency.
- When decreasing performance, the system frequency must first be decreased before changing the voltage scaling.

00: Reserved (no effect)

01: range 2 (VOS2, default): Low-power range

10: range 1: Medium-performance range

11: range 0: High-performance range

Bits 3:0 Reserved, must be kept at reset value.

10.11.4 PWR voltage scaling status register (PWR_VOSSR)

Address offset: 0x014

Reset value: 0x0000 6009

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ACTVOS[1:0]		ACTVOSRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VOSRDY	Res.	Res.	SRAMLS
r	r	r										r			r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **ACTVOS[1:0]**: Current voltage scaling range

This field provides the voltage scaling range value currently applied to V_{CORE}.

00: Reserved

01: VOS2 (lowest power)

10: VOS1

11: VOS0 (highest frequency)

Note: The ACTVOS[1:0] state is not valid in LDO bypass mode (BYPASS = 1). In LDO bypass mode, V_{CORE} is provided from external power supply. The ACTVOS[1:0] state is then always equal to the default VOS2 scale.

Bit 13 **ACTVOSRDY**: Current VOS voltage level ready

0: V_{CORE} is above or below the current voltage scaling provided by ACTVOS[1:0]

1: V_{CORE} is equal to the current voltage scaling provided by ACTVOS[1:0]

Note: The ACTVOSRDY state is not valid in LDO bypass mode (BYPASS = 1). In LDO bypass mode, the ACTVOSRDY state is always set.

Bits 12:4 Reserved, must be kept at reset value.

Bit 3 **VOSRDY**: Ready bit for V_{CORE} voltage scaling output selection

0: Not ready, voltage level below VOS selected level

1: Ready, voltage level at or above VOS selected level

The VOSRDY flag must be used only when switching from low to high-voltage scale (like switching from VOS2 to VOS0).

Note: The VOSRDY state is not valid in LDO bypass mode (BYPASS = 1). In LDO bypass mode, the VOSRDY state is always set.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **SRAMLS**: SRAM memories operation at low speed

0: SRAMs operating at high speed (VOS1 or VOS0 voltage scaling)

1: SRAMs operating at low speed (VOS2 voltage scaling)

10.11.5 PWR tamper monitoring control register (PWR_TMCR)

This register is protected against nonsecure accesses when RTMSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when RTMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when RTMSEC = 0 and NSPRIV = 1.

This register is not reset by wake-up from Standby mode, and by a RESET signal. It is reset only by a POR or an RTC domain reset (RTCDRST bit of the RCC_RTCCR register).

Address offset: 0x020

RTC domain reset value: 0x0000 0000

System reset value: 0x0000 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MONEN	Res.
														rw	

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **MONEN**: V_{DD} voltage and temperature monitoring enable
0: V_{DD} voltage and temperature monitoring disabled
1: V_{DD} voltage and temperature monitoring enabled

Bit 0 Reserved, must be kept at reset value.

10.11.6 PWR RTC domain control register (PWR_RTCCR)

This register is protected against nonsecure accesses when RTMSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when RTMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when RTMSEC = 0 and NSPRIV = 1.

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DRTCP
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **DRTCP**: Disable RTC domain write protection
In reset state, all the registers in the RTC domain are protected against parasitic write accesses. This bit must be set to enable write access to these registers.
0: Write access to RTC domain disabled
1: Write access to RTC domain enabled

10.11.7 PWR tamper monitoring status register (PWR_TMSR)

This register is not reset by wake-up from Standby mode, or by a RESET signal. It is reset only by a POR or an RTC domain reset (RTCDRST bit of the RCC_RTCCR register).

Address offset: 0x028

RTC domain reset value: 0x0000 0000

System reset value: 0x00X0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TEMPH**: temperature level monitoring versus high threshold
0: temperature below high threshold level
1: temperature equal or above high threshold level

Bit 22 **TEMPL**: temperature level monitoring versus low threshold
0: temperature above low threshold level
1: temperature equal or below low threshold level

Bit 21 **VDDH**: V_{DD} level monitoring versus high threshold
0: V_{DD} level below high threshold level
1: V_{DD} level equal or above high threshold level

Bits 20:0 Reserved, must be kept at reset value.

10.11.8 PWR USB Type-C® power delivery register (PWR_UCPDR)

This register is protected against nonsecure accesses when UCPD1SEC = 1 in the TZSC_SECCFGR register, and against unprivileged accesses when UCPD1SEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when UCPD1SEC = 0 and NSPRIV = 1.

Note: This register is not available on STM32G53x/54x devices.

Address offset: 0x02C

Reset value: 0x0000 0000

Not affected by exit Standby mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UCPD_STBY	UCPD_DBDIS
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **UCPD_STBY**: USB Type-c and Power delivery Standby mode
When set, this bit is used to memorize the UCPD configuration in Standby mode. This bit must be written to 1 just before entering Standby mode when using UCPD, and it must be written to 0 after exiting the standby mode and before writing any UCPD register.

Bit 0 **UCPD_DBDIS**: USB Type-C and power delivery dead battery disable
After exiting reset, the USB Type-C “dead battery” behavior is enabled, which may have a pull-down effect on CC1 and CC2 pins. It is recommended to disable it in all case, either to stop this pull-down or to hand over control to the UCPD (which should therefore be initialized before doing the disable).
0: Enable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins.
1: Disable USB Type-C dead battery pull-down behavior on UCPDx_CC1 and UCPDx_CC2 pins.

10.11.9 PWR supply configuration control register (PWR_SCCR)

This register is protected against nonsecure accesses when SCMSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when SCMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when SCMSEC = 0 and NSPRIV = 1.

Address offset: 0x030

Power-on reset value: 0x0000 0X00

System reset value: 0x0000 0X0X

The reset value of this register changes according to the package. Bits 9 and 8 indicate the power configuration. Their values are exclusive.

Reset by POR only, not reset by wake-up from Standby mode and RESET pad. The BYPASS bit of this register is written once after POR. Written-once mechanism locks the register and any further write access is ignored. The system must be power cycled before writing a new value.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	SMPS EN	LDO EN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	BYPASS
						r	r								rwo

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **SMPSEN**: SMPS enable
The value is set by hardware when the package uses the SMPS regulator.

Bit 8 **LDOEN**: LDO enable
The value is set by hardware when the package uses the LDO regulator.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **BYPASS**: power management unit bypass
0: Power management unit normal operation. Use the internal regulator.
1: Power management unit bypassed. Use the external power (voltage monitoring still active)

10.11.10 PWR voltage monitor control register (PWR_VMCR)

This register is protected against nonsecure accesses when SCMSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when SCMSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when SCMSEC = 0 and NSPRIV = 1.

The PVDE and PLS bits are protected by a lock mechanism. The lock control is in the SBS module controlled b.y PVDL bit in SBS_CFGR2 register. By default, the PVDE, and PLS are unlocked.

Address offset: 0x034

Reset value: 0x0000 0000

						rw	rw						rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **ALS**: analog voltage detector (AVD) level selection
These bits select the analog voltage detector (AVD) thresholds.
0: AVD level0
1: AVD level1

Bit 8 **AVDEN**: peripheral voltage monitor on V_{DDA} enable
0: peripheral voltage monitor on V_{DDA} disabled
1: peripheral voltage monitor on V_{DDA} enabled

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:1 **PLS[1:0]**: programmable voltage detector (PVD) level selection
These bits select the programmable voltage detector (PVD) thresholds.
00: PVD level0
01: PVD level1
10: Reserved
11: PVD_IN pin

Bit 0 **PVDE**: PVD enable
0: PVD disabled
1: PVD enabled

10.11.11 PWR USB supply control register (PWR_USBSCR)

This register is protected against nonsecure accesses when VUSBSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when VUSBSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when VUSBSEC = 0 and NSPRIV = 1.

Note: This register is not available on STM32G53x/54x devices.

Address offset: 0x038

Reset value: 0x0000 0000

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **USB33SV:** USB supply valid
This bit is used to validate the V_{DD} supply for electrical and logical isolation purpose. Setting this bit is mandatory to use the USB peripheral.
0: V_{DD} is not valid for USB usage
1: V_{DD} is valid for USB usage

Bits 24:0 Reserved, must be kept at reset value.

10.11.12 PWR voltage monitor status register (PWR_VMSR)

Address offset: 0x03C

Reset value: 0x00X0 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **PVDO**: programmable voltage detector output

This bit is set and cleared by hardware. It is valid only if the PVD has been enabled by the PVDE bit.

0: V_{DD} is equal or higher than the PVD threshold selected through the PLS[1:0] bits.

1: V_{DD} is lower than the PVD threshold selected through the PLS[1:0] bits.

Note: Since the PVD is disabled in Standby mode, this bit is equal to 0 after Standby or reset until the PVDE bit is set.

Bits 21:20 Reserved, must be kept at reset value.

Bit 19 **AVDO**: analog voltage detector output on V_{DDA}

This bit is set and cleared by hardware. It is valid only if AVD on VDDA is enabled by the AVDEN bit.

0: V_{DDA} is equal or higher than the AVD threshold selected with the ALS bit.

1: V_{DDA} is lower than the AVD threshold selected with the ALS bit.

Note: Since the AVD is disabled in Standby mode, this bit is equal to 0 after standby or reset until the AVDEN bit is set.

Bits 18:0 Reserved, must be kept at reset value.

10.11.13 PWR wake-up status clear register (PWR_WUSCR)

Each register bit CWUFx (x = 1, 2, 4 to 8) is protected against nonsecure accesses when WUPxSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC 0 and NSPRIV = 1.

Address offset: 0x040

Reset value: 0x0000 0000

								w	w	w	w	w		w	w

Bits 31:8, 2 Reserved, must be kept at reset value.

Bits 7:3, 1:0 **CWUFx**: clear wake-up pin flag for WUFx (x = 8 to 4, 2 to 1)
These bits are always read as 0.
0: no effect
1: writing 1 clears the WUFx wake-up pin flag (bit is cleared to 0 by hardware).
Note: CWUF8 is not available on the STM32G53x/54x devices.

10.11.14 PWR wake-up status register (PWR_WUSR)

Address offset: 0x044

Reset value: 0x0000 0000

								r	r	r	r	r		r	r

Bits 31:8, 2 Reserved, must be kept at reset value.

Bits 7:3, 1:0 **WUFx**: wake-up pin WUFx flag (x = 8 to 4, 2 to 1)
This bit is set by hardware and cleared only by a RESET pin or by setting the CWUFx bit in PWR_WUSCR register.
0: no wake-up event occurred.
1: wake-up event received from WUFx pin.
Note: WUF8 is not available on the STM32G53x/54x devices.

10.11.15 PWR wake-up configuration register (PWR_WUCR)

Each WUPPUPDx (x = 1, 2, 4 to 8), WUPPx (x = 1, 2, 4 to 8), and WUPENx (x = 1, 2, 4 to 8) bit is protected against nonsecure accesses when WUPxSEC = 1 (x = 1, 2, 4 to 8) in the PWR_SECCFGR register. Each WUPENx bit is protected against unprivileged accesses when WUPxSEC = 1 in PWR_SECCFGR and SPRIV = 1 in PWR_PRIVCFGR, or when WUPxSEC = 0 and NSPRIV = 1.

Address offset: 0x048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bits 21:20, 10, 2 Reserved, must be kept at reset value.

Bits 31:22, 19:16 **WUPPUPDx[1:0]**: wake-up pin pull configuration for WKUPx (x = 8 to 4, 2 to 1)

These bits define the I/O pad pull configuration used when WUPENx = 1. The associated GPIO port pull configuration must be set to the same value or to 00. The wake-up pin pull configuration is kept in Standby mode.

00: no pull-up

01: pull-up

10: pull-down

11: reserved

Note: WUPPUPD8 is not available on the STM32G53x/54x devices.

Bits 15:11, 9:8 **WUPPx**: wake-up pin polarity bit for WUPx (x = 8 to 4, 2 to 1)

These bits define the polarity used for event detection on WUPx external wake-up pin.

0: detection on high level (rising edge)

1: detection on low level (falling edge)

Note: WUPP8 is not available on the STM32G53x/54x devices.

Bits 7:3, 1:0 **WUPENx**: enable wake-up pin WUPx (x = 8 to 4, 2 to 1)

These bits are set and cleared by software.

0: an event on WUPx pin does not wake-up the system from Standby mode.

1: a rising or falling edge on WUPx pin wakes up the system from Standby mode.

Note: An additional wake-up event is detected if WUPx pin is enabled (by setting the WUPENx bit) when WUPx pin level is already high when WUPPx selects rising edge, or low when WUPPx selects falling edge.

WUPEN8 is not available on the STM32G53x/54x devices.

10.11.16 PWR I/O retention register (PWR_IORETR)

This register is protected against nonsecure accesses when RETSEC = 1 in the PWR_SECCFGR register, and against unprivileged accesses when RETBSEC = 1 and SPRIV = 1 in the PWR_PRIVCFGR register, or when RETSEC = 0 and NSPRIV = 1.

Address offset: 0x050

Power-on reset value: 0x0000 0000

System reset value: 0x000X 000X

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IORETEN
															rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **JTAGIORETEN**: JTAG IOs retention enable

0: PA13, PA14, PA15, and PB4 IO Retention mode disabled.

1: PA13, PA14, PA15, and PB4 Retention mode enabled.

The I/O pull or output level is sampled when entering Standby mode. Pull-up or pull-down are applied to the IO during the Standby mode, according to the I/O pull or sampled level.

Note: The IO state is not retained if the DBG_STANDBY bit is set in DBGMCU_CR register.

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **IORETEN**: IO retention enable

0: IOs (except JTAG I/Os) Retention mode disabled.

1: IOs (except JTAG I/Os) Retention mode enabled for all IOs except those that are functional in Standby mode.

The I/O pull or output level is sampled when entering Standby mode. Pull-up or pull-down are applied to the IO during the Standby mode, according to the I/O pull or sampled level.

Note: The IO state is not retained if the DBG_STANDBY bit is set in DBGMCU_CR register.

10.11.17 PWR security configuration register (PWR_SECCFGR)

This register can be written only when the accesses is secure. It can be read by secure or nonsecure accesses. The register is write-protected against unprivileged write accesses when SPRIV = 1 in the PWR_PRIVCFGR.

Address offset: 0x100

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw				rw	rw	rw	rw	rw		rw	rw

Bits 31:16, 10:8, 2 Reserved, must be kept at reset value.

Bit 15 **VUSBSEC**: voltage USB secure protection

0: PWR_USBSCR can be read and written with secure or nonsecure accesses.

1: PWR_USBSCR can be read and written only with secure accesses.

Bit 14 **RTMSEC**: RTC domain and tamper monitoring secure protection

0: PWR_TMCR and PWR_RTCCR can be read and written with secure or nonsecure accesses.

1: PWR_TMCR and PWR_RTCCR can be read and written only with secure accesses.

Bit 13 **SCMSEC**: supply configuration and monitoring secure protection.

0: PWR_SCCR and PWR_VMCR can be read and written with secure or nonsecure accesses.

1: PWR_SCCR and PWR_VMCR can be read and written only with secure accesses.

Bit 12 **LPMSEC**: low-power modes secure protection

0: PWR_LPMCR can be read and written with secure or nonsecure accesses.

1: PWR_LPMCR can be read and written only with secure accesses.

Bit 11 **RETSEC**: retention secure protection

0: PWR_IORETR can be read and written with secure or nonsecure accesses.

1: PWR_IORETR can be read and written only with secure accesses.

Bits 10:8 Reserved, must be kept at reset value.

Bits 7:3, 1:0 **WUPxSEC**: WUPx secure protection (x = 8 to 4, 2 to 1)

0: The bits related to the WKUPx wake-up pin in PWR_WUSCR and PWR_WUCR can be read and written with secure or nonsecure accesses.

1: The bits related to the WKUPx wake-up pin in PWR_WUSCR and PWR_WUCR can be read and written only with secure accesses.

Note: WUP8SEC is not available on the STM32G53x/54x devices.

10.11.18 PWR privilege configuration register (PWR_PRIVCFGR)

This register can be written only when the access is privileged. It can be read by privileged or unprivileged accesses.

Address offset: 0x104

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: PWR nonsecure functions privilege configuration

Set and reset by software. This bit can be written only by privileged accesses, secure or nonsecure.

0: Read and write to PWR nonsecure functions can be done by privileged or unprivileged accesses.

1: Read and write to PWR nonsecure functions can be done by privileged accesses only.

Bit 0 **SPRIV**: PWR secure functions privilege configuration

Set and reset by software. This bit can be written only by a secure privileged accesses.

0: Read and write to PWR secure functions can be done by privileged or unprivileged accesses.

1: Read and write to PWR secure functions can be done by privileged accesses only.

1. This bit is not available on the STM32G53x/54x devices.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

11 Reset and clock control (RCC)

This section describes the RCC implementation on STM32G53x/54x and STM32G55x/56x devices. Refer to the datasheet for implementation details.

11.1 RCC introduction

The RCC block manages the clock and reset generation for the whole microcontroller.

The operating modes to which this section refers are defined in *Section 10.8: Power modes*.

11.2 RCC main features

- AHB-lite bus interface
- Reset block:
  - Generation of local and system reset
  - Bidirectional pin reset allowing the reset of the microcontroller and external devices
  - WWDG and IWDG reset supported
  - Power-on (POR) resets initiated by the power control (PWR)
- Clock generation block:
  - Generation and dispatching of clocks for the whole microcontroller
  - Up to two PLLs[a] using integer or fractional ratios:
    Update of PLL fractional ratios on-the-fly
    Each PLL outputs three clocks
  - Smart clock gating to reduce power consumption
  - Two external oscillators:
    High-speed external oscillator (HSE) supporting a wide range of crystals from 4 to 50 MHz frequency
    Low-speed external oscillator (LSE) for the 32.768 kHz crystals
  - Several internal oscillators:
    HSI oscillator delivering up to 64 MHz clock
    HSI48 oscillator delivering a 48 MHz clock[b]
    LSI oscillator delivering a 32 kHz very-low power clock
  - Buffered clock outputs (MCO1/2)
  - Generation of three interrupts lines:
    Two general interrupt lines for ready and unlock events
    One dedicated interrupt lines for LSE and HSE clock security events

a. PLL2 is not available on STM32G53x/54x devices. Refer to the device datasheet for the number of PLL instances.

b. HSI48 is not available on STM32G53x/54x devices. Refer to the device datasheet for the number of PLL instances.

  - Clock generation handling in Stop and Standby modes
- TrustZone®:
  - Restricted access to RCC resources according to security and privilege attributes

11.3 RCC functional description overview

11.3.1 RCC block diagram

shows the RCC block diagram.

Figure 46. RCC block diagram

1. PLL2 and HSI48 are not available on STM32G53x/54x devices. Refer to the device datasheet for more details.

11.3.2 RCC pins and internal signals

lists the RCC inputs and output signals connected to package pins or balls.

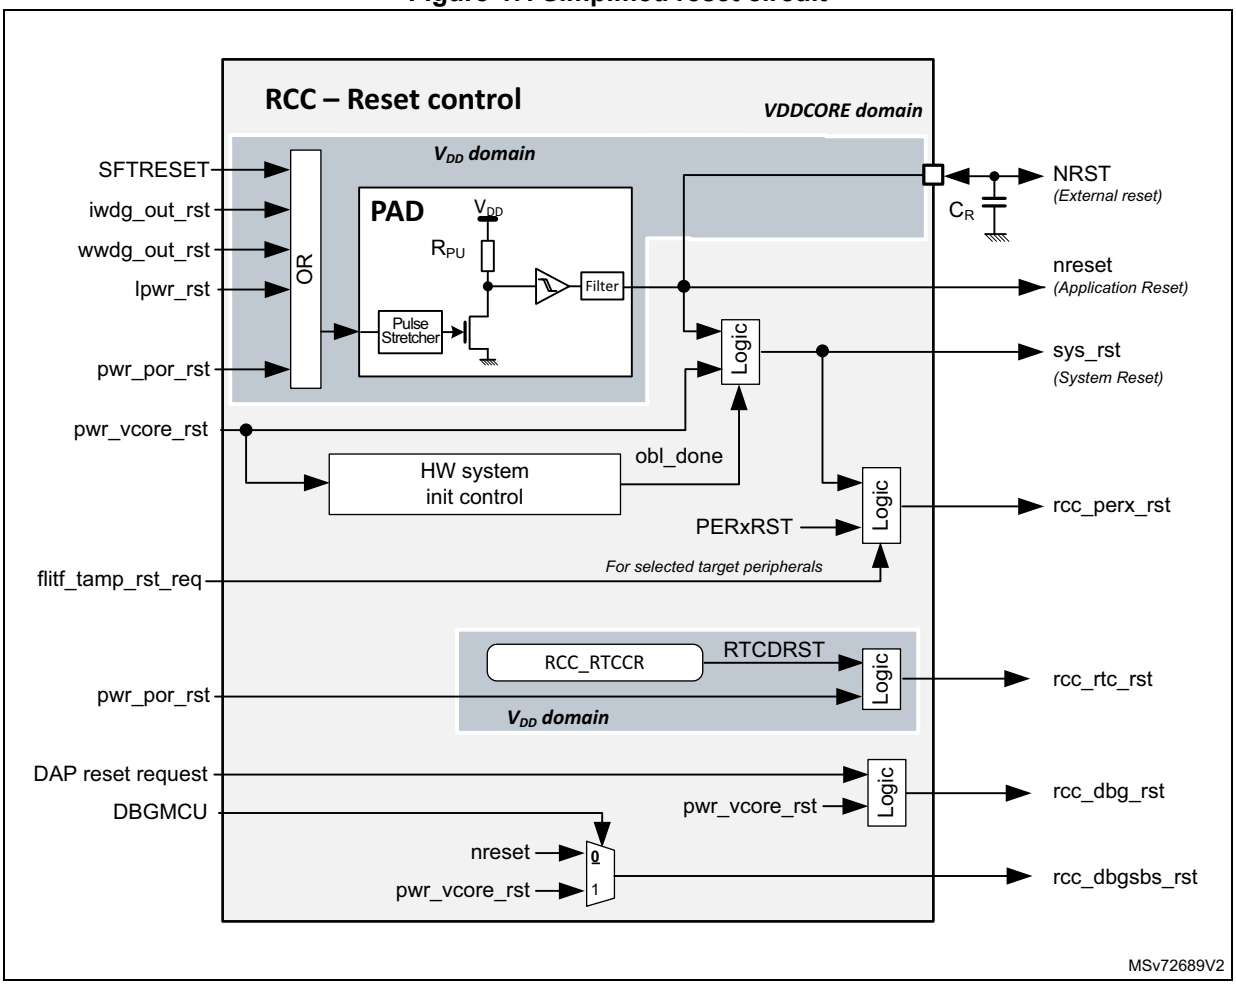
Table 111. RCC input/output signals connected to package pins or balls

Signal name	Signal type	Description
NRST	I/O	System reset. It can be used to provide reset to external devices
OSC32_IN	I	32 kHz oscillator input
OSC32_OUT	O	32 kHz oscillator output
OSC_IN	I	System oscillator input
OSC_OUT	O	System oscillator output
MCO1	O	Output clock for external devices
MCO2	O	Output clock for external devices
AUDIOCLK	I	External kernel clock input for SPI blocks

Table 112. RCC internal input/output signals

New signal name	Signal type	Description
rcc_it	O	General interrupt request line
rcc_s_it	O	General secure interrupt request line
rcc_hsecss_it	O	HSE clock security failure interrupt
rcc_hsecss_fail	O	Event indicating that a HSE clock security failure is detected
rcc_lsecss_fail	O	Event indicating that a LSE clock security failure is detected
nreset	I/O	Application reset
sys_rst	I/O	System reset
iwdg_out_rst	I	Reset line driven by the IWDG, indicating that a timeout occurred
wwdg_out_rst	I	Reset line driven by the WWDG, indicating that a timeout occurred
pwr_por_rst	I	Power-on reset generated by the PWR block
rcc_perx_rst	O	Reset generated by the RCC for the peripherals
pwr_wkup	I	Wakeup domain request generated by the PWR and used to restore the domain clocks
rcc_pwd_req	O	Low-power request generated by the RCC and used to set the device into low-power mode
cpu_sleep	I	Signals generated by the CPU, indicating if the CPU is in CRun, Sleep or CStop
cpu_deepsleep	I	
perx_ker_ckreq	I	Signal generated by some peripherals in order to request the activation of their kernel clock

Table 112. RCC internal input/output signals (continued)



New signal name	Signal type	Description
rcc_perx_ker_ck	O	Kernel clock signals generated by the RCC, for some peripherals
rcc_perx_bus_ck	O	Bus interface clock signals generated by the RCC for peripherals
rcc_bus_ck	O	Clocks for APB, AHB and AXI bridges generated by the RCC
rcc_cpu_ck	O	Clocks for the CPU, generated by the RCC
rcc_fclk	O	

11.4 RCC reset functional description

The RCC handles several types of resets:

- Reset from/to external devices (NRST)
- Application reset (nreset)
- System reset (sys_rst)
- RTC domain reset (rcc_rtc_rst)
- Debug domain reset (rcc_dbg_rst)
- Dedicated peripheral resets (rcc_perx_rst)

Figure 47. Simplified reset circuit

11.4.1 Reset from/to external devices (NRST pin)

The RCC offers a bidirectional NRST pad, which can be asserted either by internal reset sources or by external components.

A pulse stretcher guarantees a minimum reset pulse duration of 20 µs (refer to the device datasheet for details). In addition, the NRST assertion can be extended thanks to the C_R capacitor. A filter is also present to suppress spurs coming from the NRST pad.

The NRST is active low and can be activated by one of the following sources:

- An external component connected to NRST
- The **pwr_por_rst** signal from the PWR block

  The power-on/off reset signal (pwr_por_rst) is asserted by the PWR when the V_{DD} supply is lower than the V_{POR} threshold. The V_{POR} threshold is defined to reset the product when the supply voltage is no longer safe. Refer to *Section 10: Power control (PWR)* for details.
- An independent watchdog reset (**iwdg_out_rst**)
- A window watchdog reset (**wwdg_out_rst**)
- A software reset from the CPU core

  The CPU can generate a system reset via the SYSRESETREQ bit (also named SFTRESET) issued by the Cortex®-M33 core. The SYSRESETREQ bit of the Cortex®-M33 core is controlled via the AIRCR register. Refer to the Arm® technical reference manual for more details (see http://infocenter.arm.com).
- A reset from the low-power mode security reset, depending on option byte configuration (**lpwr_rst**). Refer to *Section 11.4.7: Low-power mode security reset (lpwr_rst)*.

Note: When the NRST pad is not used, it is recommended to connect this pin to the ground via a 10 to 100 nF capacitor (C_R in Figure 46).

Refer to *Table 113: Reset coverage summary* for details.

11.4.2 Application and system resets

The application reset (**nreset**) is activated only when the NRST pad is asserted.

A system reset (**sys_rst**) resets most of the registers to their default values unless otherwise specified in the register description.

A system reset is activated when:

- NRST pad is asserted (that is, **nreset**),
- Exiting from Standby (**pwr_vcore_rst**)

  The core reset signal (**pwr_vcore_rst**) is asserted when the V_{DDCORE} or V_{DD} supply is not valid. As V_{DDCORE} is switched OFF when the product is in Standby, **pwr_vcore_rst** is also asserted in Standby. The registers outside the V_{DDCORE} domain (RTC, WKUP, IWDG, and GPIO pull-up/pull-down configuration during Standby and Standby mode exit) are not impacted.

11.4.3 RTC domain reset

The RTC domain contains a group of peripherals powered by V_{DD}. The RCC offers the possibility to perform a dedicated reset to the peripherals located in this domain. This domain contains the RTC, the TAMP, as well as the LSE and its logic.

There are two ways to generate an RTC domain reset:

- By a software reset

  The software reset is triggered by setting the RTCDRST bit of *RCC RTC domain control register (RCC_RTCCR)*. Write access to this bit must be enabled via the DRTCP bit located into the PWR block.
- By asserting the **pwr_por_rst** reset signal. This signal is asserted when the V_{DD} supply is lower than the minimum allowed V_{DD} value.

11.4.4 CoreSight™ debug reset

There are two ways to reset the CoreSight™ debug components:

- Over the DAP by setting the bit CDBGRSTREQ of the control/status register of the debug port.

  This action asserts the debug reset request signal cdbgrstreq connected to the RCC. Then the RCC activates the debug reset (**rcc_dbg_rst**), a handshake signal cdbgrstack is provided to the DAP request. The debug reset remains as long as the cdbgrstreq is set (refer to *Figure 47* for details).
- When a V_{DDCORE} power-on reset occurs (**rcc_vcore_rst**)

  This reset is activated after a power-on reset, or when the product exits from Standby.

11.4.5 Option bytes loading

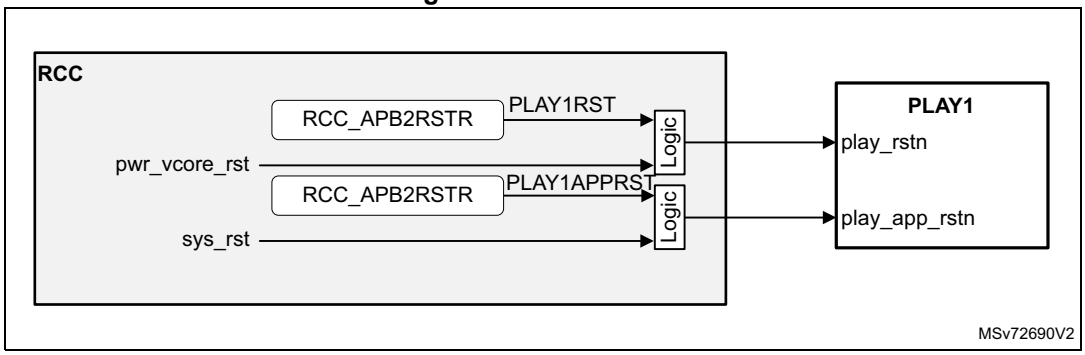
As shown in *Figure 47*, the option byte loading (OBL) sequence is triggered under the following conditions:

- After a power-on, or
- When the system exits from Standby

The system reset (**sys_rst**) can be released only when the option byte loading (OBL) is complete.

11.4.6 Peripherals reset

The application can reset individually most of the peripherals whenever it is requested. Most of the time, this is done via the PERxRST bitfields.



To reset a peripheral, the corresponding reset bit must be set, and then clears. There is no need to enable the peripheral clocks for resetting a peripheral.

Also note that the CRYP, SAES, and HASH blocks can be reset in case of a tamper event.

Specific case of PLAY1 reset[a]

The PLAY1APPRST bit resets the PLAY1 but not the PLAY1 configuration. When the reset is released, the PLAY1 restarts. The PLAY1RST bit resets the complete PLAY1 block including its configuration.

Figure 48. PLAY1 reset

11.4.7 Low-power mode security reset (lpwr_rst)

To avoid that critical applications mistakenly enter a low-power mode, the following low-power mode security resets are available. If enabled in option bytes, an NRST reset is generated when any of the following conditions occurs:

- Standby mode entry: this type of reset is enabled by resetting the nRST_STDBY bit in user option bytes. In this case, whenever a Standby mode entry sequence is successfully executed, the device is reset instead of entering Standby mode.
- Stop mode entry: this type of reset is enabled by resetting the nRST_STOP bit in user option bytes. In this case, whenever a Stop mode entry sequence is successfully executed, the device is reset instead of entering Stop mode.

For further information on the user option bytes, refer to *Section 7.4.1: About option bytes*.

a. PLAY1 is not available on the STM32G53x/54x devices. Refer to the device datasheet for details.

11.4.8 Reset coverage summary

Table 113 gives a detailed view of the reset coverage for the most important reset sources.

Note: When V_{DD} is not valid, V_{DDCORE} is not valid as well.

Table 113. Reset coverage summary (1)

Reseted functions		Main reset lines						
		pwr_por_rst (2)	pwr_vcore_rst (3)	sys_rst	nreset (4)	rcc_dbg_rst	rcc_perx_rst	rcc_rtc_rst
CPU		-	-	x	-	-	-	-
WWDG		-	-	x	-	-	-	-
IWDG		-	-	-	x	-	-	-
AHB/APB Interconnections		-	-	x	-	-	-	-
Debug components, including DBGMCU Reset all the debug parts except the SWJ-DP function. The SWJ-DP is reset by the NJTRST or **pwr_vcore_rst** resets.		-	-	-	-	x	-	-
Hardware system initialization. It includes the reload of the option bytes.		x	x	-	-	-	-	-
RCC	HSE, HSI related registers	-	-	x	-	-	-	-
	LSI oscillator and related registers	x	-	-	x	-	-	-
	RCC_RTCCR, RTCSEL of RCC_RTCCFGR, RTCEN of RCC_RTCCFGR	-	-	-	-	-	-	x
	Other RCC registers	-	-	x	-	-	-	-
PWR	PWR_TMCR, PWR_TMSR	x	-	-	-	-	-	x
	PWR_SCCR	x	-	-	-	-	-	-
	PWR_WUSR	x	-	-	x	-	-	-
	Other registers	-	-	x	-	-	-	-
GPIO	Pull-up/pull-down configuration during Standby and Standby mode exit	-	-	x	-	-	x	-
LSE		x	-	-	-	-	-	x
RTC	Including backup registers	x	-	-	-	-	-	x
PLAY1 (5)		-	x	x	-	-	x	-
Kernel clock switches		-	-	x	-	-	-	-
Other Peripherals		-	-	x	-	-	x	-

1. The ‘x’ means that the function is reset by the corresponding reset line, the ‘-’ means that the function is not reset by the corresponding reset line.
2. The **pwr_por_rst** is asserted when the voltage applied to V_{DD} is not valid.
When **pwr_por_rst** is asserted, the **pwr_vcore_rst**, the **rcc_rtc_rst**, NRST, the **sys_rst**, and the **nreset**, are asserted as well.
3. The **pwr_vcore_rst** is asserted when the voltage applied to V_{DD} is not valid, or when the system exits from Standby (because VDDCORE was switched OFF).
When **pwr_vcore_rst** is asserted, the **sys_rst**, and the **pwr_dbg_rst** are asserted as well.
4. When **nreset** is asserted, the **sys_rst** is asserted as well.
5. PLAY1 is not available on the STM32G53x/54x devices.

11.4.9 Reset source identification

The application can identify the reset source by checking the reset flags of the *RCC reset status register (RCC_RSR)*.

The software can reset the flags by setting the RMVF bit.

Table 114 shows how the status bits of the *RCC reset status register (RCC_RSR)* behave according to the situation that generated the reset. For example, when an IWDG timeout occurs, if the CPU is reading the *RCC reset status register (RCC_RSR)* during the boot phase, both PINRSTF and IWDGRSTF bits are set, indicating that the IWDG also generated a pin reset.

Table 114. Reset source identification (RCC_RSR)(1)

	Reset	LPWRRSTF	WWDGRSTF	IWDGRSTF	SFTRSTF	PORRSTF	PINRSTF
1	Power-on reset	0	0	0	0	1	1
2	Pin/pad reset	0	0	0	0	0	1
3	System reset generated by CPU	0	0	0	1	0	1
4	WWDG reset	0	1	0	0	0	1
5	IWDG reset	0	0	1	0	0	1
6	Illegal stop entry reset	1	0	0	0	0	1

1. Gray cells highlight the register bits that are set.

11.5 RCC clock functional description

The RCC provides a wide choice of clock generators:

- HSI (high-speed internal oscillator) clock: ~ 8, 16, 32 or 64 MHz
- HSE (high-speed external oscillator) clock: 4 to 50 MHz
- LSE (low-speed external oscillator) clock: 32.768 kHz
- LSI (low-speed internal oscillator) clock: ~ 32 kHz
- HSI48 (high-speed internal oscillator) clock: ~48 MHz(a)

The RCC offers a high flexibility for the application to select the appropriate clock for CPU and peripherals.

To optimize the power consumption, each clock source can be switched ON and OFF independently.

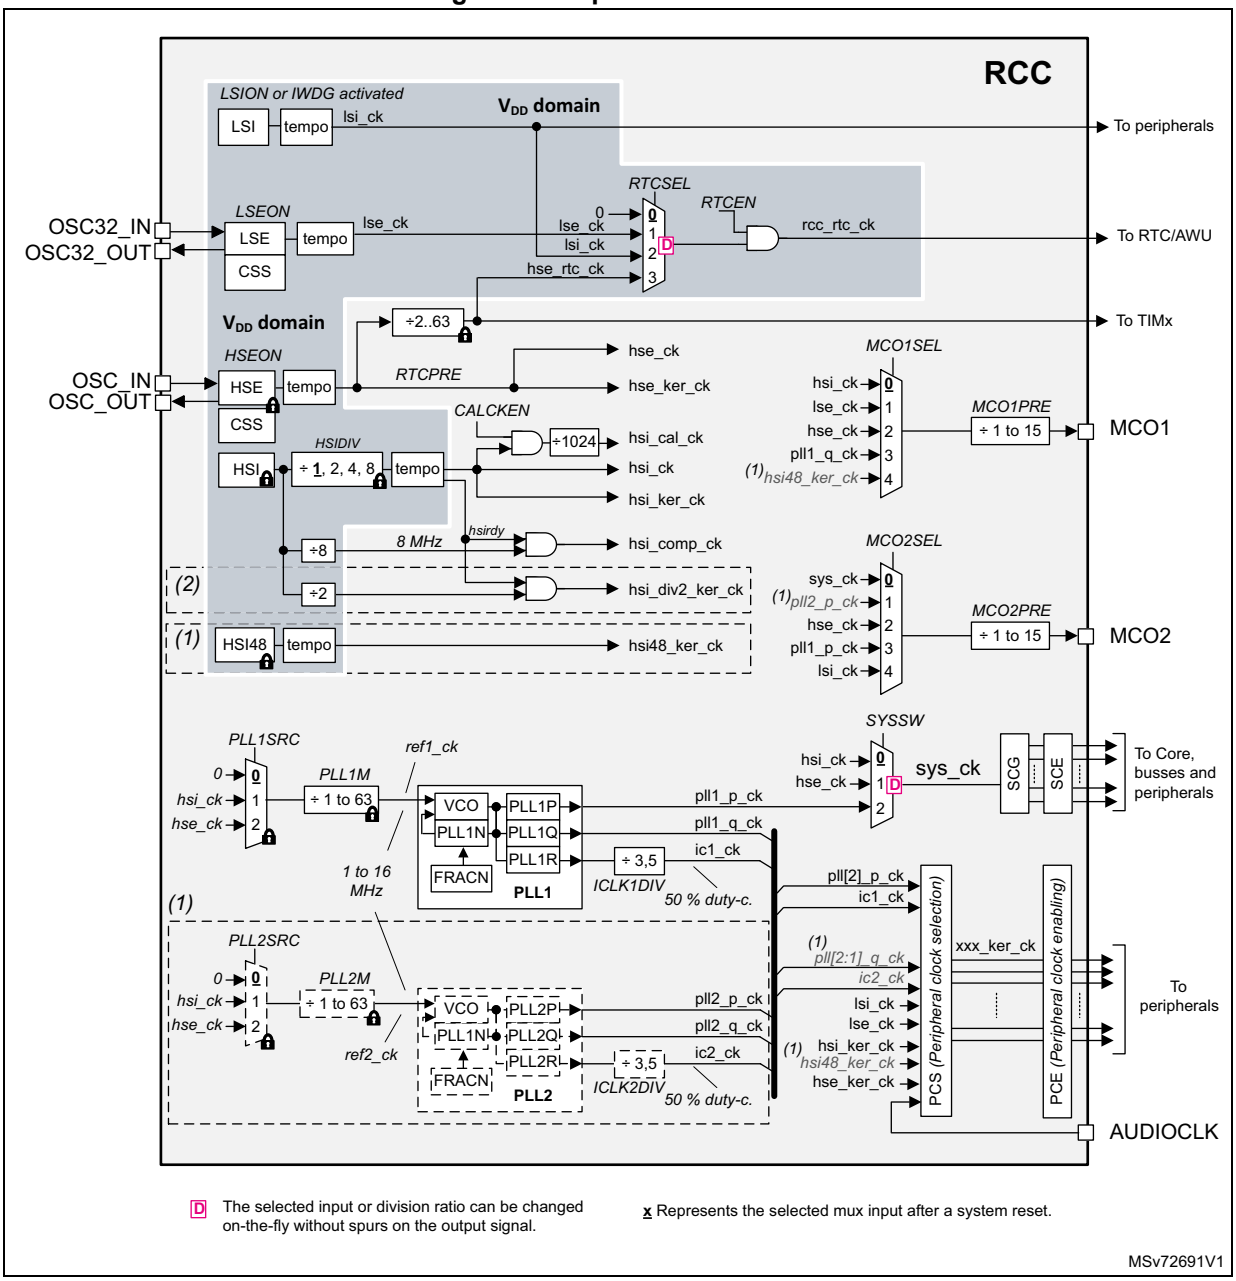
The RCC provides up to two PLLs, each of them can be configured in integer or fractional mode.[a]

As shown below, the RCC offers two clock outputs (MCO1 and MCO2), with a great flexibility in the clock selection and frequency adjustment.

The SCG block (system clock generation) includes several prescalers used to configure the CPU and bus matrix clock frequencies.

The PCS block (peripheral clock selection) provides several dynamic switches allowing a large choice of kernel clock distribution to peripherals.

The PCE and SCE blocks (peripheral or system clock enable) perform the peripheral kernel clock gating, and the bus interface/cores/bus matrix clock gating, respectively.



Three different clock sources can be used to drive the system clock (SYSCLK):

- HSI
- HSE
- PLL1

The HSI is used as system clock source after startup from reset, and configured at 64 MHz.

a. PLL2 and HSI48 are not available on the STM32G53x/54x devices. Refer to the device datasheet for availability.

Figure 49. Top-level clock tree

1. The PLL2 and HSI48 are not available on the STM32G53x/54x devices. Refer to the device datasheet for availability.
2. The hsi_div2_ker_ck is not implemented on STM32G55x/56x.

11.5.1 Clock naming convention

The RCC provides the clocks to the whole device. The following terms are used in this document:

- **Peripheral clocks**

  The peripheral clocks are the clocks provided by the RCC to the peripherals. Two kinds of clocks are available:

  – Bus interface clocks

  – Kernel clocks

  A peripheral receives a bus interface clock from the RCC, to access its registers and thus control the peripheral operation. This clock is generally the AHB or APB clock depending on which bus the peripheral is connected to. Some peripherals only need a bus interface clock (such as RNG or TIMx).

  Some peripherals also require a dedicated clock to handle the interface function. These clocks are generally asynchronous with respect to the bus interface clock. They are named kernel clocks (rcc_perx_ker_ck). As an example, peripherals such as SPI in I2S mode must generate specific and accurate synchronization signals, which require dedicated kernel clock frequencies. Another advantage of decoupling the bus interface clock from the specific interface needs, is that the bus clock can be changed without reprogramming the peripheral.

- **System clock**

  The system clock (**sys_ck**) is the root clock for the CPU clock (**cpu_ck**), the bus matrix clock (**bus_ck**), and the peripheral system.

- **Bus matrix clocks**

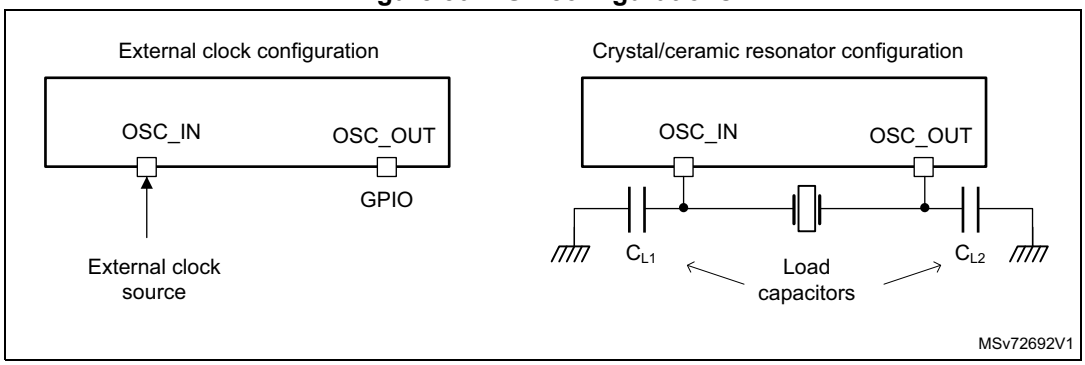
  Bus matrix clocks are the clocks provided to the different bridges (APB or AHB). These clocks are derived from the main bus matrix clock (**bus_ck**).

11.5.2 Oscillators state summary

Table 115 shows the oscillator states versus system modes, when the oscillators are enabled via registers. The term “available” means that the resource can be used if enabled via registers.

Table 115. Oscillator states versus system modes

Situations	VDD domain				RTC domain
	HSE	HSI	HSI48 (1)	LSI	LSE
After a power-on reset (pwr_por_rst)	OFF	ON	OFF	OFF	OFF
After a system reset (sys_rst)	OFF	ON	OFF	Available	Available
After a system Stop	OFF	ON	OFF	Available	Available
In Run/Sleep	Available	Available	Available	Available	Available
In Stop	OFF	Available (2)	OFF	Available	Available
In Standby	OFF	OFF	OFF	Available	Available
After a RTCDRST reset	Available	Available	Available	OFF	OFF



1. The HSI48 is not available on the STM32G53x/54x devices. Refer to the device datasheet for availability.
2. The HSI can remain activated in Stop mode if HSIKERON = 1, or if a peripheral selecting the HSI generates a kernel clock request.

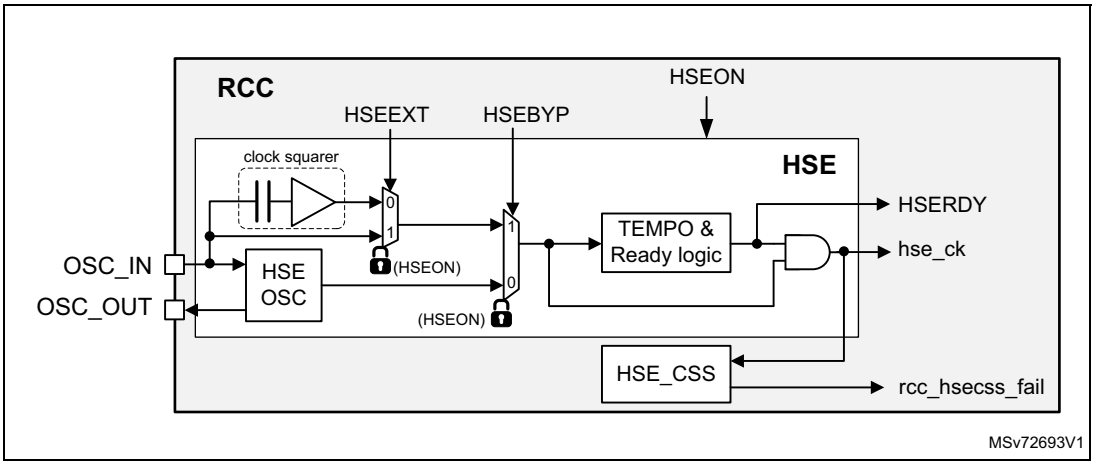
11.5.3 HSE oscillator

The HSE block enables the application to provide a very accurate high-speed clock for the product. The HSE can generate an internal clock from two possible sources:

- External clock source
- External crystal/ceramic resonator

Figure 50. HSE configurations

External clock source (HSE bypass)



In this mode, the oscillator is not used and an external clock source must be provided to the OSC_IN pin. The external clock can be low swing (analog) or digital. The OSC_OUT pin can be used as GPIO (see *Figure 50*).

The external clock signal can be digital or analog (square, sinus, or triangle). An analog clock signal with a reduced amplitude is supported thanks to an internal clock squarer. The input signal must have a duty cycle close to 50%. Refer to the datasheet for additional information.

This mode is selected when both the HSEBYP and HSEON bits are set. In case of an analog clock input (low swing), the HSEEXT must be cleared. For a digital clock input, the HSEEXT bits must be set.

The HSEEXT, HSEBYP, and HSEON bits are located in the *RCC clock control register (RCC_CR)*.

Figure 51. HSE clock generation

External crystal/ceramic resonator

A crystal/resonator can be connected as shown in *Figure 50*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is enabled by clearing the HSEBYP bit and setting the HSEON bit.

HSE ready logic

The HSERDY flag indicates when a valid clock is available on the HSE output (**hse_ck**). When the HSE is enabled (HSEON set), the HSERDY flag is set when 256 valid cycles of HSE have been detected. The **hse_ck** clock remains gated until HSERDY is set.

An interrupt can be generated if enabled in the *RCC interrupt enable register (RCC_IER)*.

HSE controls

The HSE can be switched ON and OFF through the HSEON bit.

The hardware does not allow clearing the HSEON bit if one of the following conditions is met:

- The HSE is used directly (via the SYSSW switch) as system clock.
- The HSE is selected as the reference clock for PLL1, with PLL1 enabled and selected to provide the system clock.

The hardware does not allow changing the values of HSEBYP and HSEEXT when HSEON is set.

The HSE is automatically disabled by hardware when the system enters is system Stop or Standby mode (see *Table 115: Oscillator states versus system modes*).

In addition, the HSE clock can be driven to the MCO1 and MCO2 outputs and used as clock source for other application components.

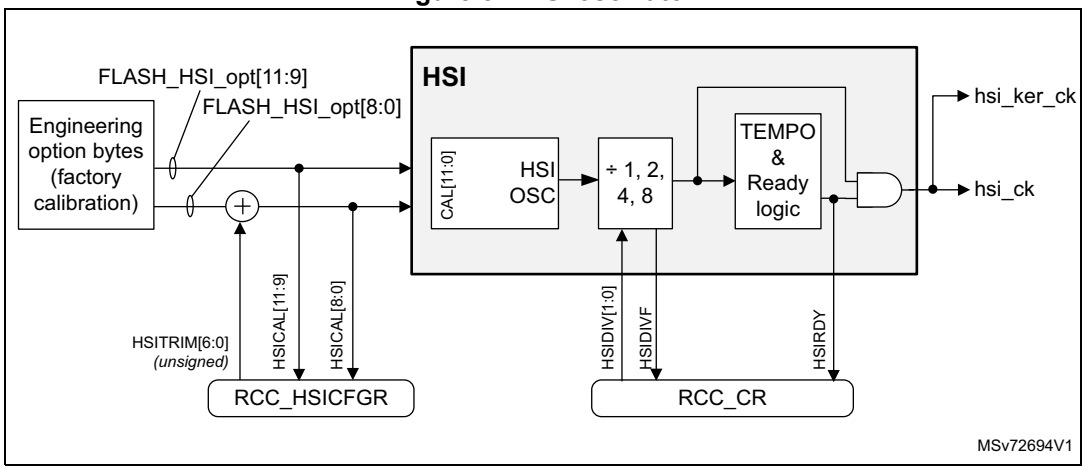
Programming sequence

To initialize the HSE, the application must follow the sequence below:

1. Make sure that the HSE is not directly or indirectly used as system clock. If it is the case, use the HSI as clock source for the system clock.
2. Disable the HSE by clearing the HSEON bit.
3. Check that the HSE is disabled by waiting until the bit HSERDY is cleared.
4. If the oscillator mode is needed, select the oscillator mode by clearing HSEBYP.
5. If an external clock is connected to OSC_IN:
   - Select the bypass mode by setting HSEBYP.
   - If the input clock is a full-swing digital signal, set HSEEXT.
   - If the input clock is a low-swing signal, clear HSEEXT.
6. Enable again the HSE by setting the HSEON bit.
7. Wait until HSERDY is set. The HSE is then ready for use.

11.5.4 HSI oscillator

The HSI block provides the default clock to the product.



The HSI is a high-speed internal RC oscillator that can be used directly as system clock, peripheral clock, or as PLL input. A predivider enables the application to select an HSI output frequency of 8, 16, 32 or 64 MHz.

The HSI advantages are the following:

- Low-cost clock source, as no external crystal is required
- Faster startup time than HSE (a few microseconds)

The HSI frequency, even with frequency calibration, is less accurate than an external crystal oscillator or ceramic resonator.

Figure 52. HSI oscillator

HSI controls

The HSI can be switched ON and OFF using the HSION bit.

The hardware does not allow clearing the HSION bit if one of the following conditions is met:

- The HSI is used directly (via the SYSSW switch) as system clock.
- The HSI is selected as reference clock for PLL1, with PLL1 enabled and selected to provide the system clock (via the SYSSW switch).

In addition, the HSIDIV cannot be changed if the HSI is selected as reference clock for a PLL. In that case, the hardware does not update the HSIDIV with the new value. However, it is possible to change the HSIDIV on-the-fly if the HSI is not used as PLL reference clock. The HSIDIVF flag indicates when the new division ratio is applied.

The HSIRDY flag indicates when a valid clock is available at HSI output. When the HSI is enabled (HSION set), the HSIRDY flag is set when 16 valid cycles provided by HSIDIV have been detected. The HSIDIV output remains gated until HSIRDY is set.

The HSI clock can also be used as a backup source (auxiliary clock) if the HSE fails (refer to *Section : Clock security system on HSE*).

The HSI can be disabled or not when the system enters system Stop mode. It is not available in system Standby (see *Table 115: Oscillator states versus system modes*). When exiting Standby mode, the user trim is lost.

In addition, the HSI clock can be driven to the MCO1 output and used as clock source for other application components.

Care must be taken when the HSI is used as kernel clock for communication peripherals. In this case, the application must consider the following parameters:

- The time interval between the moment where the peripheral generates a kernel clock request and the moment where the clock is really available,
- The frequency accuracy.

HSION, HSIRDY, HSIDIVF, and HSIDIV[1:0] bits are located in the *RCC clock control register (RCC_CR)*.

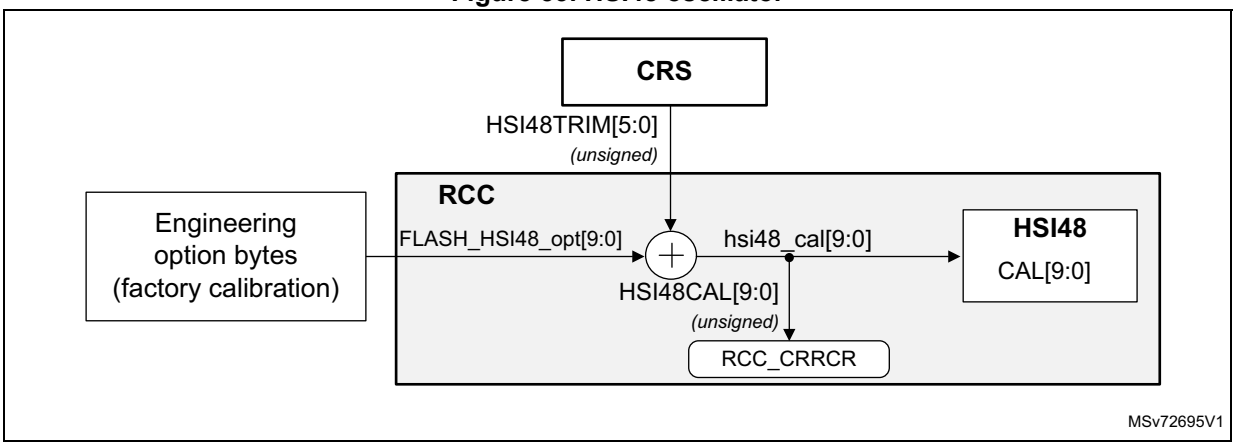
HSI calibration

RC oscillator frequencies can vary from one chip to another due to manufacturing process variations. This is why each device is factory calibrated by STMicroelectronics to achieve an accuracy of ACC_{HSI} (refer to the product datasheet for more information).

After a power-on reset, the factory calibration value is loaded into the HSICAL[11:0] bits. If the application is subject to voltage or temperature variations, this may affect the RC oscillator frequency. The user application can trim the HSI frequency using the HSITRIM[6:0] bits.

Note: HSICAL[11:0] and HSITRIM[6:0] are located in the RCC HSI calibration register (RCC_HSICFGR).

11.5.5 HSI48 oscillator



The HSI48 block is not available on the STM32G53x/54x devices. Refer to the device datasheet for availability.

The HSI48 clock signal is generated from an internal 48 MHz RC oscillator, and can be used directly for the USB and the random number generator (RNG).

The internal 48 MHz RC oscillator is mainly dedicated to provide a high-precision clock to the USB peripheral by means of a special clock recovery system (CRS) circuitry. The CRS can use the USB SOF signal, the LSE, or an external signal to adjust automatically and quickly the oscillator frequency on-the-fly, with a very small granularity. The calibration value provided to the HSI48 can be read via the *RCC clock recovery RC register (RCC_CRRCR)*

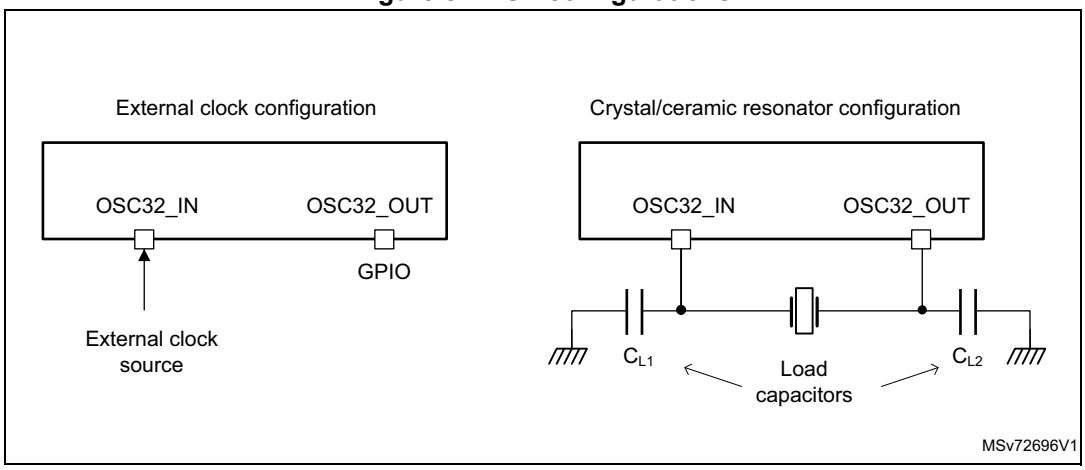
The HSI48TRIM value can be adjusted through the CRS block, for more details, refer to *Section 12: Clock recovery system (CRS)*.

Figure 53. HSI48 oscillator

The HSI48 is disabled as soon as the system enters Stop or Standby mode. When the CRS is not used, the HSI48 oscillator runs on its default frequency, which is subject to manufacturing process variations.

The HSI48RDY flag in the *RCC clock control register (RCC_CR)* indicates whether the HSI48 RC oscillator is stable or not. At startup, the HSI48 RC oscillator output clock is not released until this bit is set by hardware.

The HSI48 can be switched ON and OFF using the HSI48ON bit of the *RCC clock control register (RCC_CR)*.



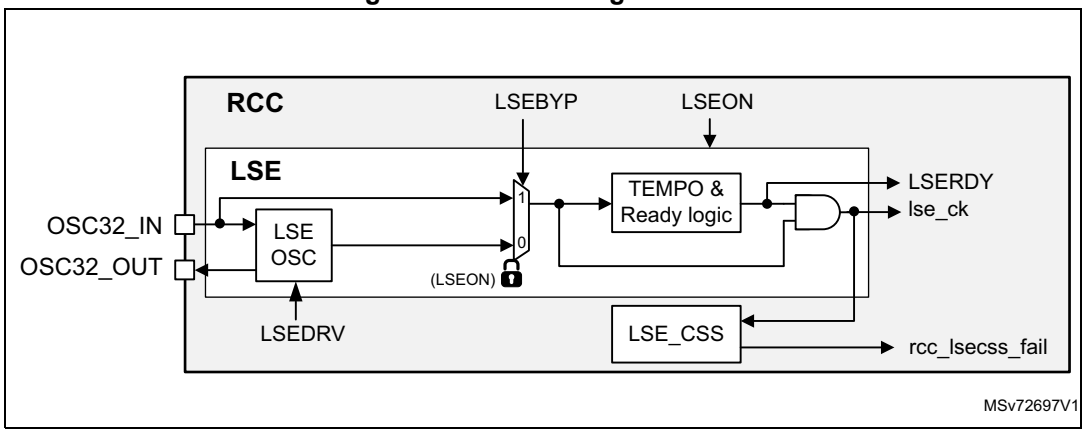
In addition, the HSI48 clock can be driven to the MCO1 output and used as clock source for other application components.

11.5.6 LSE oscillator

The LSE block enables the application to provide a very accurate low-frequency clock for the product. The LSE can generate an internal clock from two possible sources:

- External user clock
- External crystal/ceramic resonator

Figure 54. LSE configurations



External clock source (LSE bypass)

In this mode, an external clock source must be provided to the OSC32_IN pin. The input clock can have a frequency of up to 1 MHz, and must be a digital signal. A duty cycle close to 50% is recommended.

This external clock is provided to the OSC32_IN pin while the OSC32_OUT pin can be used as GPIO.

The external clock mode is selected by setting the LSEBYP and LSEON bits.

Figure 55. LSE clock generation

External crystal/ceramic resonator (LSE crystal)

The LSE clock is generated from a 32.768 kHz crystal or ceramic resonator. It provides a low-power highly accurate clock source to the real-time clock (RTC) for clock/calendar or other timing functions. A crystal/resonator can be connected as shown in *Figure 54*: the crystal/resonator and the load capacitors must be placed as close as possible to the oscillator pins to minimize output distortion and startup stabilization time. The loading capacitance values must be adjusted according to the selected crystal or ceramic resonator. Refer to the electrical characteristics section of the datasheet for more details.

The oscillator mode is selected by clearing the LSEBYP bit and setting the LSEON bit.

The LSE also offers a programmable driving capability (LSEDRV[1:0]) that can be used to modulate the amplifier driving capability. This driving capability is chosen according to the external crystal/ceramic component requirement to ensure a stable oscillation. The driving capability must be set before enabling the LSE oscillator.

Warning: It is not allowed to change the driving capability when the LSE is enabled, otherwise the LSE behavior is not guaranteed.

LSE ready logic

The LSE offers an LSERDY flag (see *RCC RTC domain control register (RCC_RTCCR)*), which indicates whether the LSE clock is available or not. When the LSE is enabled (LSEON set), the LSERDY flag is set when a certain number of valid cycles of LSE clock have been detected. The **lse_ck** clock is not released until LSERDY is set.

When LSEBYP = 0, the RCC waits for 4096 clock cycles before activating the LSERDY flag.

When LSEBYP = 1, the RCC waits for one clock cycle.

An interrupt can be generated if enabled in the *RCC interrupt enable register (RCC_IER)*.

LSE controls

The LSE control bits LSEBYP, LSEDRV[1:0], and LSEON are located in the *RCC RTC domain control register (RCC_RTCCR)*. This register is write-protected via the DRTCP bit of the PWR_RTCCR register. To modify the *RCC RTC domain control register (RCC_RTCCR)*, the bit DRTCP must be set.

The LSE oscillator is switched ON and OFF using the LSEON bit. The hardware does not allow changing the LSEBYP values when LSEON is set.

The LSE remains enabled when the system enters Stop or Standby (see *Table 115: Oscillator states versus system modes*).

In addition, the LSE clock can be driven to the MCO1 output and used as clock source for external components.

LSE programming sequence

To initialize the LSE, the application must follow the sequence below:

1. Set the DRTCP bit of the PWR_RTCCR to allow write access to the *RCC RTC domain control register (RCC_RTCCR)*.
2. Disable the LSE by clearing the LSEON bit.
3. Check that the LSE is disabled by waiting until the LSERDY bit is cleared.
4. If the oscillator mode is needed:
   a) Select the oscillator mode by clearing LSEBYP.
   b) If needed, configure LSEDRV[1:0].
5. If an external clock is connected to OSC32_IN, select the bypass mode by setting LSEBYP.
6. Enable again the LSE by setting the LSEON bit.
7. Wait until LSERDY is set. The LSE is then ready for use.
8. If no other protected bits need to be changed, clear the DRTCP bit to write-protect the *RCC RTC domain control register (RCC_RTCCR)*.

11.5.7 LSI oscillator

The LSI acts as a low-power clock source that can be kept running when the system is in Stop or Standby mode for the independent watchdog (IWDG), RTC, and auto-wake-up unit (AWU).

The clock frequency is around 32 kHz. For more details, refer to the electrical characteristics section of the device datasheet.

The LSI can be switched ON and OFF using the LSION bit. The LSIRDY flag indicates whether the LSI oscillator is stable or not. If an independent watchdog is started either by hardware or software, the LSI is forced on and cannot be disabled.

The LSI remains enabled when the system enters Stop or Standby mode.

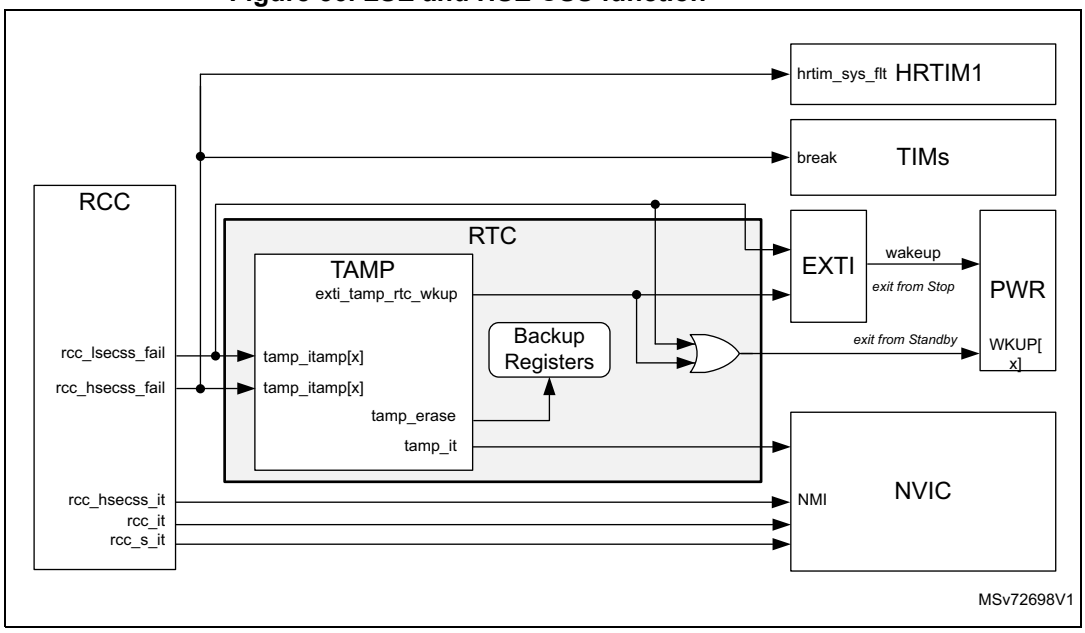
At LSI startup, the clock is not provided until the hardware sets the LSIRDY bit. An interrupt can be generated if enabled in the *RCC interrupt enable register (RCC_IER)*.

In addition, the LSI clock can be driven to the MCO2 output, and used as a clock source for other application components.

Note: The LSION and LSIRDY bits are located in the RCC RTC domain control register (RCC_RTCCR).

11.5.8 Clock security system (CSS)

The RCC offers a clock security system for the HSE and LSE oscillators. The clock security systems can detect a failure on HSE and LSE oscillators. *Figure 56* shows how this function interacts with other blocks.



The rcc_lsecss_fail signal is used for several purposes:

- As an input to the TAMP block to generate a tamper event
- As an input of the EXTI, to wake up the system from Stop in case of LSE failure
- As an input to the PWR, to exit the system from Standby in case of LSE failure.

rcc_lsecss_fail is released when LSECSSD is cleared.

The rcc_hsecss_fail signal is routed to some TIMs and to HRTIM1 as break input signal.

Figure 56. LSE and HSE CSS function

Clock security system on HSE

The clock security system on HSE detects when a failure is occurs on the HSE. The clock security system on HSE can be enabled by software via the HSECSSON bit, even when the HSEON is cleared.

The CSS on HSE is activated when the HSE is enabled and ready, and the software sets the HSECSSON bit. As a consequence, the CSS on HSE is not active when the HSE is disabled. For example, this function is not active when the system is in Stop mode.

It is not possible to clear directly the HSECSSON bit by software. The HSECSSON bit is cleared by hardware when a system reset occurs or when the system enters Standby mode.

When the CSS on HSE is enabled, the following actions are performed by the RCC if a failure is detected:

1. The signal **rcc_hsecss_fail** is asserted.
2. The HSI clock is enabled (HSION set) and the SYSSW switch automatically selects HSI as system clock.
3. The HSE is then automatically disabled (HSEON is cleared).
4. If the HSE output was used as clock source for PLLs, the PLLs are also disabled.
5. The clock failure event (**rcc_hsecss_fail**) is also sent to the break inputs of advanced-control timers and the hrtim_sys_flt input of high-resolution timer (HRTIM1).
6. An NMI interrupt is generated to inform the software about the failure (CSS interrupt: ***rcc_hsecss_it***), thus allowing the MCU to perform rescue operations. The CSS interrupt is asserted until the HSECSSF bit is cleared. The HSECSSF flag can be cleared by setting the HSECSSC bit in the *RCC interrupt flag register (RCC_IFR)*.

A tamper event can also be triggered to clear the content of the backup registers.

Clock security system on LSE

The clock security system on LSE detects when a failure is occurs on the LSE.The clock security system on the LSE oscillator can be enabled by programming the LSECSSON bit in the *RCC RTC domain control register (RCC_RTCCR)*.

This bit is disabled by hardware if one of the following conditions is met:

- After a power-on hardware reset (**pwr_por_rst)**
- After an RTC domain software reset via RTCDRST bit

The software can also disable the clock security system after an LSE failure detection.

The CSS on LSE works in Run, Stop, and Standby.

The LSECSS offers two flag signals:

- The LSECSSD, capable of retaining an LSE failure even in Standby mode.
- The LSECSSF, used to generate an interrupt in case of LSE failure.

The sequence below describes the LSE enabling sequence with the clock security system enabled:

1. Follow the LSE enable procedure given is the section *Section : LSE programming sequence*, except for the last step.
2. Select the LSE clock via RTCSEL[1:0].
3. Set the LSECSSON bit.
4. If no other protected bits need to be changed, clear the DRTCP bit to write-protect the *RCC RTC domain control register (RCC_RTCCR)*.

Note: Set the LSECSSON bit only after the LSE is enabled and ready, and after the RTC clock has been selected through the RTCSEL bits.

If a failure is detected on the LSE, the hardware performs the following actions:

1. The LSE clock is no more delivered to the RTC.
2. LSERDY is cleared, but the values of RTCSEL, LSECSSON and LSEON bits are not changed by the hardware.
3. A failure event is generated (**rcc_lsecss_fail**). This event enables the system to wake up from Stop or Standby, but also protects the backup registers via the TAMP block.
4. The interrupt flag LSECSSF is set to generate an interrupt (**rcc_lsecss_it**).
5. The LSECSSD flag is also set, retaining the first LSE failure even if it occurred in Standby.

On the software side, different actions can be taken according to the application requirements:

- If the application no longer intends to use LSE when a failure has been detected:
  a) Unlock the *RCC RTC domain control register (RCC_RTCCR)* by setting the DRTCP bit of PWR_RTCCR.
  b) Clear the LSECSSF bit, if an interrupt was enabled for this event.
  c) Disable the LSE by clearing the LSEON bit.
  d) If needed, change the clock source for the RTC:
  – Clear the RTCEN bit to disable the RTC clock.
  – Enable the new clock source for the RTC.
  – Select the proper clock source via RTCSEL.
  – Set the RTCEN bit to enable the RTC clock.
  e) Clear the LSECSSON bit.
  f) The application must perform specific actions consecutive to TAMPER events if enabled.
  g) If no other protected bits need to be changed, clear the bit DRTCP to write-protect the *RCC RTC domain control register (RCC_RTCCR)*.
- If the application wants to reinitialize the RTC domain:
  a) Unlock the *RCC RTC domain control register (RCC_RTCCR)* by setting the DRTCP bit of the PWR_RTCCR.
  b) Perform an RTC domain reset by setting the RTCDRST bit, then clear it.
  c) The application must perform specific actions consecutive to TAMPER events if enabled.
  d) Reinitialize all components of the RTC domain.
  e) If no other protected bits need to be changed, clear the DRTCP bit to write-protect *RCC RTC domain control register (RCC_RTCCR)*.

- If the application wants to reuse the LSE when a failure has been detected:
  a) Unlock the *RCC RTC domain control register (RCC_RTCCR)* by setting the DRTCP bit of the PWR_RTCCR.
  b) Clear the LSECSSF bit if an interrupt was enabled for this event.
  c) The application must perform specific actions consecutive to TAMPER events if enabled.
  d) Clear the LSECSSON bit. This action also clears the LSECSSD flag.
  e) Set LSECSSON again.
  f) Wait until LSERDY is set. The LSERDY flag is set after the oscillator settling time delay plus 4096 LSE clock periods. If it is not the case, it probably means that th LSE failure is permanent.

Refer to the device datasheet for CSS on LSE electrical characteristics.

11.5.9 Clock output generation (MCO1, MCO2)

Two microcontroller clock output pins (MCO1 and MCO2) are available. A clock source can be selected for each output. The selected clock can be divided thanks to a configurable prescaler.

MCO1 and MCO2 outputs are controlled via MCO1PRE[3:0], MCO1[2:0], MCO2PRE[3:0], and MCO2[2:0], located in the *RCC clock configuration register1 (RCC_CFGR1)*.

The GPIO port corresponding to each MCO pin must be programmed in alternate function mode.

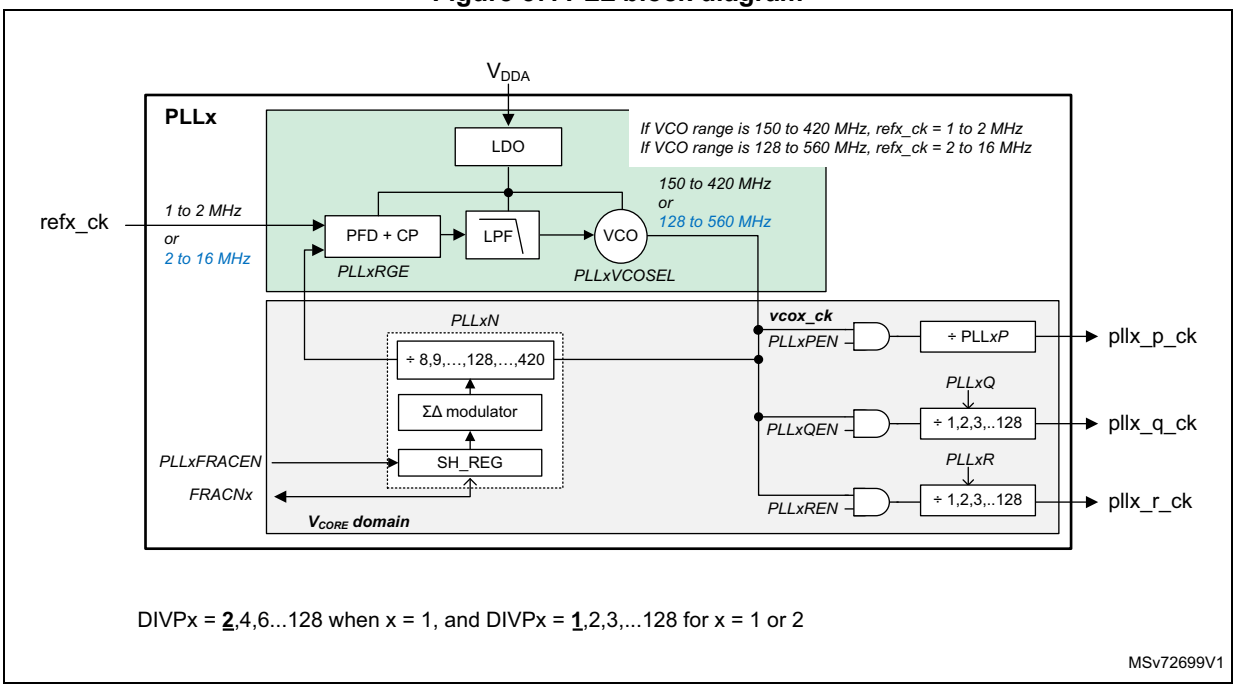
The dividers MCO1PRE and MCO2PRE provide a clock with a duty cycle of 50% for even division values. More generally the duty cycle is given by the following formula:

$$DC(\%) = \frac{\text{FLOOR}\left(\frac{\text{MCOxPRE}}{2}\right)}{\text{MCOxPRE}} \times 100$$

Where MCOxPRE = 2 to 15.

The clock provided to the MCOs outputs must not exceed the maximum pin speed (refer to the device datasheet for information on the supported speed).

MCO1 and MCO2 outputs are available in Stop mode, but not in Standby mode.



11.5.10 PLL description

The STM32G56x/55x/54x/53x devices feature up to two PLLs, PLL1 and PLL2. PLL2 is only available on STM32G55x/56x (refer to the device datasheet for details).

The PLLs integrated into the RCC are completely independent. They offer the following features:

- A VCO supporting two modes:
  - A wide-range mode (128 to 560 MHz)
  - A low-range used mode (150 to 420 MHz)
- Input frequency range:
  - 2 to 16 MHz for the VCO in wide-range mode
  - 1 to 2 MHz for the VCO in low-range mode
- Capability to work either in integer or fractional mode
- 13-bit sigma-delta modulator.
- The sigma-delta modulator can be updated on-the-fly without generating frequency overshoots on PLLs outputs
- Each PLL offers three outputs with postdividers

Figure 57. PLL block diagram

The PLLs are controlled via the RCC_PLLxDIVR, RCC_PLLxFRACR, RCC_PLLCFGR, and RCC_CR registers.

The frequency of the reference clock provided to the PLLs (**refx_ck**) must range from 1 to 16 MHz. The PLLxM dividers of the RCC_PLLxCFGR register must be properly programmed to match this condition. In addition, the PLLxRGE[1:0] bitfield of the RCC_PLLxCFGR registers must be set according to the reference input frequency, to optimize performance.

The user application can then configure the VCO. The smaller range must be chosen when the reference clock frequency is lower than 2 MHz. To reduce the power consumption, it is recommended to configure the VCO output to the smaller range.

DIVNx loop divider must be programmed to achieve the expected frequency at VCO output. In addition, the VCO output range must be respected.

The PLLs operate in integer mode when the value of the SH_REG bit of the FRACNx shadow register is cleared. The SH_REG bit is updated with the FRACNx value when the PLLxFRACEN bit goes from 0 to 1. The sigma-delta modulator is designed to minimize the jitter impact, while allowing very small frequency steps.

The PLLs can be enabled by setting PLLxON. The PLLxRDY bits indicate that the PLL is ready (locked).

*Note: Before enabling the PLLs, make sure that the reference frequency (**refx_ck**) is stable, since PLLxM cannot be changed when PLLx is ON, neither can PLLSRC when one of the PLLs is ON.*

The hardware prevents clearing PLL1ON if the PLL1 is currently used to deliver the system clock. There are other hardware protections on the clock generators (refer to HSE oscillator, HSI oscillator, and HSI48 oscillator).

The following PLL parameters cannot be changed once the PLL is enabled: DIVNx, PLLxRGE, PLLxVCOSEL, PLLxP (DIVP), PLLxQ (DIVQ), and PLLxR (DIVR).

For optimal behavior of the PLL when one of the postdividers (DIVP, DIVQ, or DIVR) is not used, the application must clear the enable bit (DIVyEN) as well as the corresponding postdivider bits (DIVP, DIVQ, or DIVR).

If the above rules are not respected, the PLL output frequency is not guaranteed.

PLLs frequency limits

The next table shows the most important frequency limits the application must respect when programming the PLLs.

Table 116. PLLs frequency limits

Blocks	Functional signals	Frequency range(1)			Applicable voltage scaling	Comments
		Min	Max	Unit		
PLL1, PLL2(2)	pllx_p_ck	-	F_{MAX}	MHz	All VOS	PLLxP output
	pllx_q_ck	-	F_{MAX}		All VOS	PLLxQ output
	pllx_r_ck	-	500		Only VOS0	PLLxR output, connected to ICLKxDIV
		-	400		All VOS	
	vcox_ck	128	560		All VOS	PLLxVCOSEL = 0 and PLLxRGE = 1, 2 or 3
	refx_ck	2	16		All VOS	
	vcox_ck	150	420		All VOS	PLLxVCOSEL = 1 and PLLxRGE = 0
	refx_ck	1	2		All VOS	

1. F_{MAX} value represents the maximum frequency at which the CPU can run. This value depends on the STM32G56x/55x/54x/53x device and can be found on the device datasheet.
2. The PLL2 is not available on the STM32G53x/54x devices. Refer to the device datasheet for availability.

Output frequency computation

When the PLL is configured in integer mode (SH_REG = 0), the VCO frequency (F_{VCO}) is given by the following formulas:

$$F_{VCO} = F_{REF_CK} \times DIVN$$

$$F_{PLL_y_CK} = (F_{VCO} / (DIVy + 1)) \text{ with y = P, Q, or R}$$

When the PLL is configured in fractional mode (SH_REG different from 0), the DIVN divider must be initialized before enabling the PLLs. However, it is possible to change the value of FRACNx on-the-fly without disturbing the PLL output.This feature can be used either to generate a specific frequency from any crystal value with a good accuracy, or to fine-tune the frequency on-the-fly.

For each PLL, the VCO frequency is given by the following formula:

$$F_{VCO} = F_{ref_ck} \times \left(DIVN + \frac{FRACN}{2^{(13)}} \right)$$

Note: For PLL1, DIVP can only take odd values.

The PLLs are disabled by hardware when:

- The system enters Stop or Standby mode.
- An HSE failure occurs when HSE or PLL (clocked by HSE) are used as system clock.

Recommended PLL initialization sequence

The PLLx are supposed to be disabled at the start of the initialization sequence:

1. Enable the oscillator used as PLL clock source, and wait for oscillator ready state.
2. Select the clock source via PLLxSRC[1:0].
3. Select the predivider ratio via PLLxM[5:0].
4. Configure the PLLx:
   a) Select the correct input frequency range via PLLxRGE[1:0] and the VCO range via PLLxVCOSEL.
   b) Set the VCO frequency via PLLxN[8:0].
   c) If PLLx is used in integer mode:
      Set PLLxFRACEN.
      Clear PLLxFRACN[12:0].
      Clear PLLxFRACEN.
   d) If PLLx is used in fractional mode:
      Set the fractional multiplication ratio into PLLxFRACN[12:0].
      Set PLLxFRACEN.
   e) Select the division ratio for each PLL output: PLLxP[6:0], PLLxQ[6:0], and PLLxR[6:0].
   f) Enable DIVP, DIVQ, and DIVR if used (PLLxPEN, PLLxQEN, PLLxREN).
5. Enable the PLLx by setting PLLxON.

6. Wait until PLLxRDY = 1. If the PLLx is in fractional mode, the PLLxFRACEN bit must not be cleared again as long as PLLxRDY = 0.
7. If ICLK1 or ICLK2 must be enabled, just enable the corresponding PLLxREN.
8. PLLx is ready to use.

Note: When the PLLxRDY is set, the difference between the PLLx output frequency and the target value is lower than ±2%.

Updating the fractional value

The fractional part of the PLLx can be updated at any time by following the sequence below:

1. Clear PLLxFRACEN.

   When PLLxFRACEN = 0, the sigma-delta modulator still operates with the current PLLxFRACN[12:0] value. The application must wait for three clock periods of refx_ck (PLLxFRACEN bit propagation delay).
2. Write a new fractional value to PLLxFRACN[12:0].
3. Set PLLxFRACEN to take into account the new PLLxFRACN value. The new value is taken into account after three clock periods of refx_ck (PLLxFRACEN bit propagation delay).

Note: The disabling of ICLK1 and ICLK2 can be simply done by clearing PLL1REN or PLL2REN.

Changing the division ratio of ICLK1 or ICLK2 can be done on-the-fly, without disabling ICLK1 or ICLK2.

11.5.11 Intermediate clock generation (ICLKx)

The STM32G55x/56x devices offer two PLLs, while the STM32G53x/54x feature only one. As a consequence, the former feature both ICLK1 and ICLK2, while the latter only features ICLK1 (refer to the device datasheet for availability).

The DIVR outputs of PLL1 and PLL2 are directly connected to intermediate clock dividers.

Each intermediate clock divider allows division by 3 and by 5, to improve the duty cycle and match the needs of some peripherals.

Changing the division ratio can be done on-the-fly, without disabling the ICLKx. The disabling of ICLK1 and ICLK2 can be simply done by clearing PLL1REN or PLL2REN.

ICLK1DIV and ICLK2DIV are located in the *RCC PLL clock source selection register (RCC_PLL1CFGR)* and *RCC PLL clock source selection register (RCC_PLL2CFGR)*, respectively.

Note that the duty cycle at ICLKx output depends on the duty cycle of the input clock. *Table 117* gives some value examples.

Table 117. Resulting duty cycle examples

Duty cycle of the input clock	Division ratio	Duty cycle of the ICLKx output clock
33 %	3	44.3 %
	5	46.6 %
40 %	3	46.7 %
	5	48.0 %

Table 117. Resulting duty cycle examples (continued)

Duty cycle of the input clock	Division ratio	Duty cycle of the ICLKx output clock
45 %	3	48.3 %
	5	49.0 %

Note: If DIVR selects even division factors, the duty cycle at ICLKx output is 50%.

11.5.12 System clock (sys_ck)

System clock selection

When the system is running, the user application can select the system clock (**sys_ck**) among the following sources:

- HSI
- HSE
- pll1_p_ck

After a system reset (or after exiting Standby mode), the HSI is selected as system clock and all PLLs are switched OFF. When a clock source is used for the system clock, the software cannot disable the selected source via the xxxON bits.

The system clock can be stopped by the hardware when the system enters Stop or Standby mode.

The system switch function is controlled by programming the SYSSW[1:0]. A switch from one clock source to another occurs only if the targeted clock source is enabled and ready (clock stable after startup delay or PLL ready). If a clock source that is not yet ready is selected, the switch occurs when the clock source is ready.

The status bits SYSSWS[1:0] of the *RCC clock configuration register1 (RCC_CFGR1)* indicate which clock is currently used as a system clock.

System clock generation

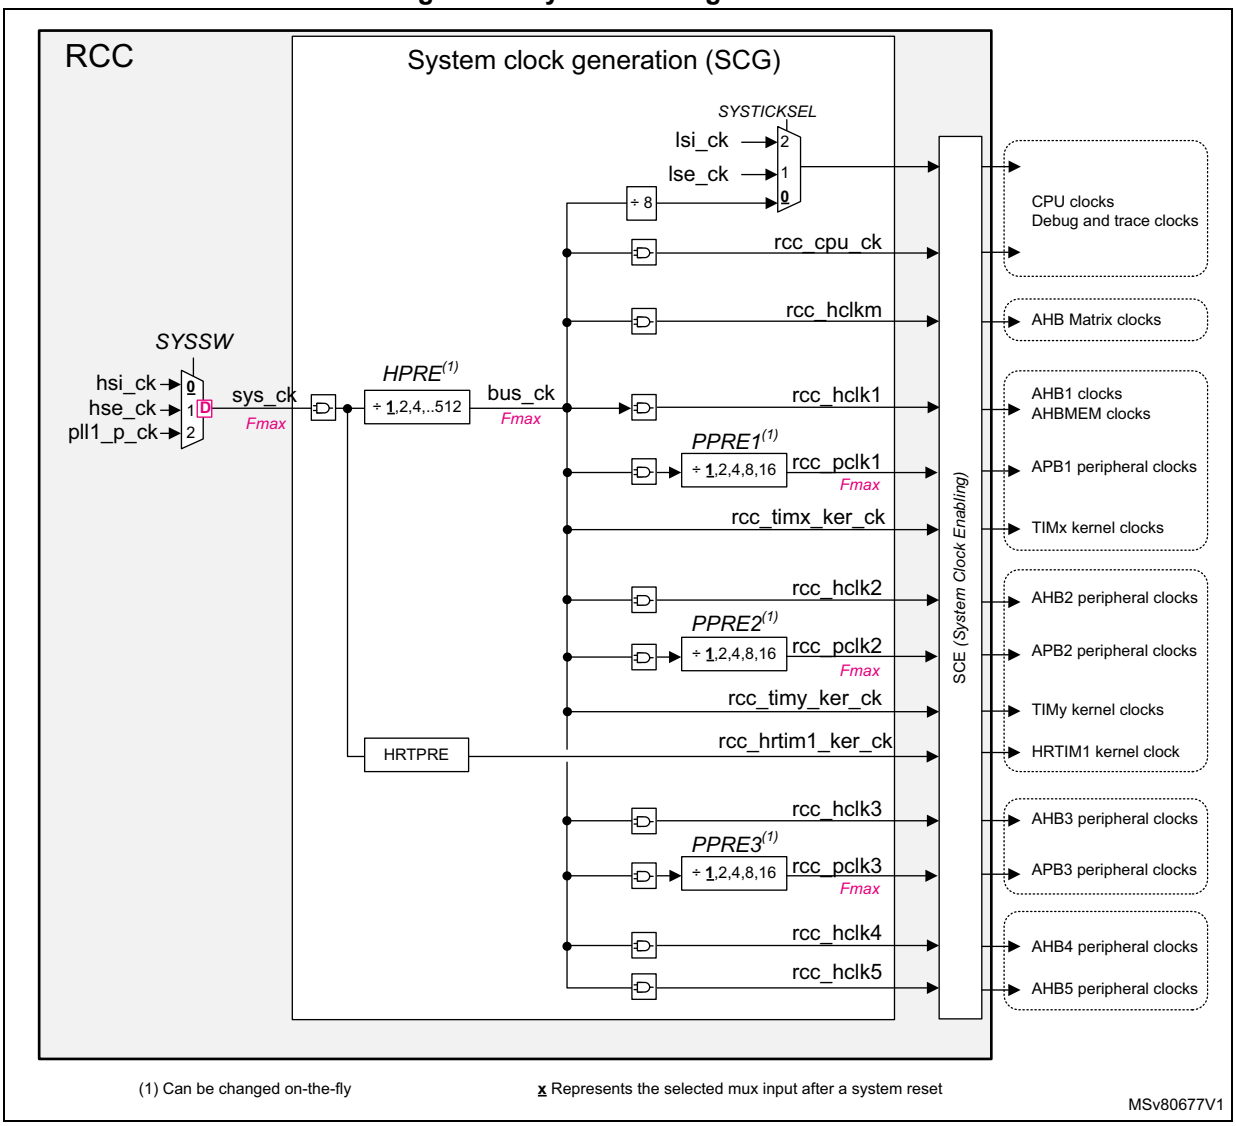


Figure 58 shows a simplified view of the clock distribution for the CPUs and buses. All the dividers shown in the block diagram can be changed on-the-fly without generating timing violations. This feature is a very simple solution to adapt the bus frequencies to the application needs, thus optimizing the power consumption.

When the system clock (sys_ck) is provided by the PLL1, it is possible to change dynamically the core frequency by simply updating the DIVP division ratio. Even divisions are preferred. Odd divisions can be used with care: if F_{MAX} is the maximum allowed frequency for the CPU, the high and low level of the CPU clock must not be shorter than $1 / (2 \times F_{MAX})$. Refer to *Section 11.5.10: PLL description* for details.

Changing the DIVP value of PLL1, impacts the CPUs clock frequency but also the clock frequency of all bus matrices.

The CPUs and all AHB matrices are working at the same frequency. PPREx dividers allow to adapt independently the frequency of APB buses.

Figure 58. System clock generation

1. Divider values can be changed on-the-fly. All clocks are phase-aligned.

Note: The application must respect the maximum allowed frequency F_{MAX}. Refer to the product datasheet for maximum values.

*The trace clock (**trace_ck**) is generated from the **cpu_ck** clock. For additional information, refer to Section : Clock distribution for debug and trace.*

11.5.13 Handling clock generators in Stop and Standby modes

Entering Stop mode

When the whole system enters Stop mode, all the clocks (system and kernel clocks) are stopped, as well as the following clock sources:

- HSI
- HSE
- PLL1 and PLL2 if present (refer to the device datasheet for availability)
- HSI48 if present (refer to the device datasheet for availability).

The content of the RCC registers is not altered except for PLLxON, HSEON, and HSI48ON, which are cleared.

If a flash memory programming operation is ongoing, Stop or Standby mode entry is delayed until the flash memory interface access is finished.

If an access to the APB domain is ongoing, Stop or Standby mode entry is delayed until the APB access is finished.

During Stop mode

There are two specific cases where the HSI can be enabled during in Stop mode:

- When a dedicated peripheral requests the kernel clock, the peripheral receives the HSI according to the kernel clock source selected for this peripheral.
- When the HSIKERON bit of the *RCC clock control register (RCC_CR)* is set, the HSI is kept running, but the output is gated. The clock is then available immediately when the system exits Stop mode, or when a peripheral requests the kernel clock (see *Table 118* for details).

Table 118. HSIKERON behavior

HSIKERON	HSI state during Stop mode	HSI state setting time
0	OFF	$t_{su(HSI)}$(1)
1	Running and gated	Immediate

1. $t_{su(HSI)}$ is the startup time of the HSI oscillator (refer to the device datasheet for the value of this parameter).

Caution: HSIKERON must be set only when the HSION is set.

Exiting Stop mode

When the system exits Stop mode via a wake-up event, the device restarts with the HSI oscillator.

Exiting Standby mode

When the system exits Standby mode, the HSI is restarted and selected as system and kernel clock.

The RCC registers are reset to their initial values except for the *RCC reset status register (RCC_RSR)* and *RCC RTC domain control register (RCC_RTCCR)*.

Note: The HSI output provides two clock paths:

- *One path for the system clock (hsi_ck)*
- *One path for the peripheral kernel clock (hsi_ker_ck).*

When a peripheral requests the kernel clock in system Stop mode, only the path providing the hsi_ker_ck is activated.

11.5.14 Peripheral clock distribution

The RCC handles the distribution of the CPU, interconnect, bus interface, and peripheral clocks for the whole device, according to the CPU operating mode.

The clocks used as bus interface for peripherals can be hclkx or pclkx, depending on the bus connected to each peripheral. Some peripherals also request additional clocks (named kernel clocks) to handle specific functions.

The peripheral clock bus interfaces and kernel clocks can be asynchronous or synchronous.

Having separate kernel and peripheral bus clocks enables the user application to change the bus frequency without disturbing the service provided by the peripheral.

For each peripheral, the application can control the activation/deactivation of its kernel and bus interface clock via the RCC block.

Prior to using a peripheral, the application must enable its clocks (by setting PERxEN), and define if this peripheral remains active in low-power mode (by setting PERxLPEN). PERxEN and PERxLPEN bits are located in the RCC_AHBxENR, RCC_APBxENR, RCC_AHBxLPENR and RCC_APBxLPENR registers (PERx is the peripheral name).

When the peripheral clocks are not active, read or write accesses to the peripheral registers are not supported.

When an enable bit is set or when a kernel clock request is asserted, the clock is active after two kernel clock cycles. The peripheral bus interface clock is also affected by this synchronization mechanism.

Caution: Just after enabling the clock for a peripheral, the software must wait for these two clock cycles before accessing the peripheral registers.

Figure 59 shows typical peripheral clock distribution. The PCC (peripheral clock control) block provides a synchronization mechanism (not shown in the figure) that offers a glitch-free clock enabling or disabling.

In addition, the clock switch controlled by PERxSEL and the kernel clock request are not always present (see *Table 119*). This clock switch is glich-free and can be changed on-the-fly. These clock switches and their control are reset by sys_rst unless otherwise specified.

Figure 59. Typical peripheral clock distribution

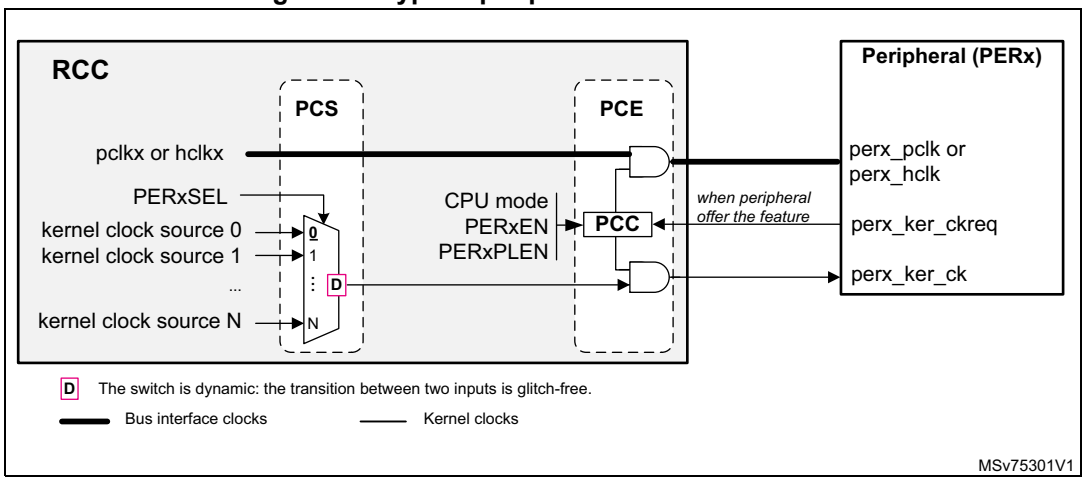

Table 119 shows the peripheral clocks that the RCC can deliver to most of the peripherals. For each peripheral, *Table 119* shows the possible kernel clock sources, the name of the kernel clock selector, the bus clock source, and the maximum allowed frequency.

The gray cells indicate the signals or peripherals that are not present on all STM32G56x/55x/54x/53x devices. Refer to the device datasheet to find out which blocks are present in the product you are using.

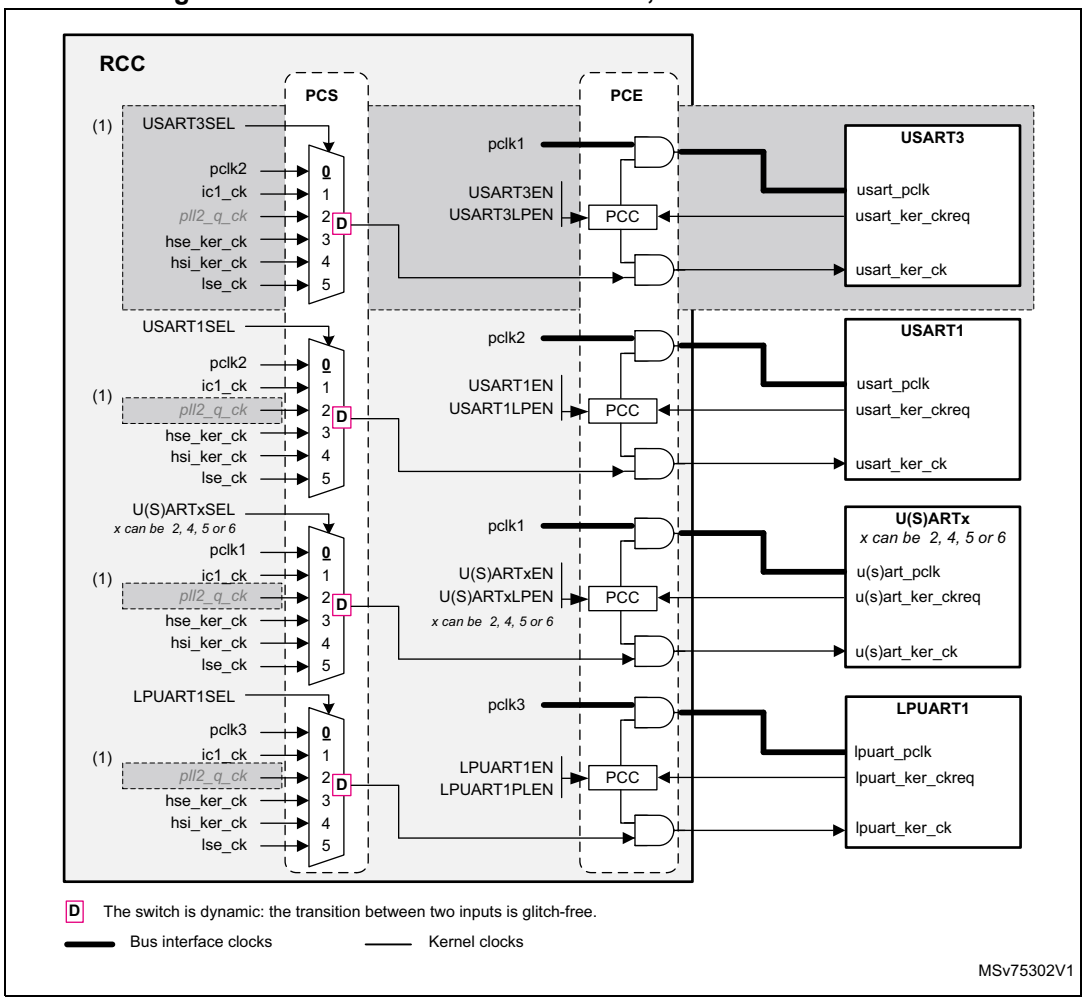
1. F_{MAX} value represents the maximum frequency at which the CPU can run. This value depends on the STM32G56x/55x/54x/53x device and can be found on the device datasheet.
2. 'A' means that the kernel clock is asynchronous with respect to bus interface clock.
‘S’ means that the kernel clock is synchronous with respect to bus interface clock.
3. This signal is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
4. These peripherals are not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
5. On STM32G56x/55x/54x/53x devices where the HSI48 is not available, hsi_ker_ck / 2 is provided instead. Refer to the device datasheet for availability.

Clock distribution for UART, USART, and LPUART

The UART and USART kernel clock sources are selected thanks to UARTxSEL[2:0] and USARTxSEL[2:0] in the *RCC kernel clock configuration register (RCC_CCIPR1)*.



The UARTs, USARTs, and LPUART provide kernel clock request signals handled by the RCC allowing those blocks to get kernel clock even when the device is in Stop mode. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

This mechanism works if the selected kernel clock source is hsi_ker_ck (automatically turned on, on peripheral request). If lse_ck is selected as kernel clock source, it is always provided to the peripheral if the LSE is enabled.

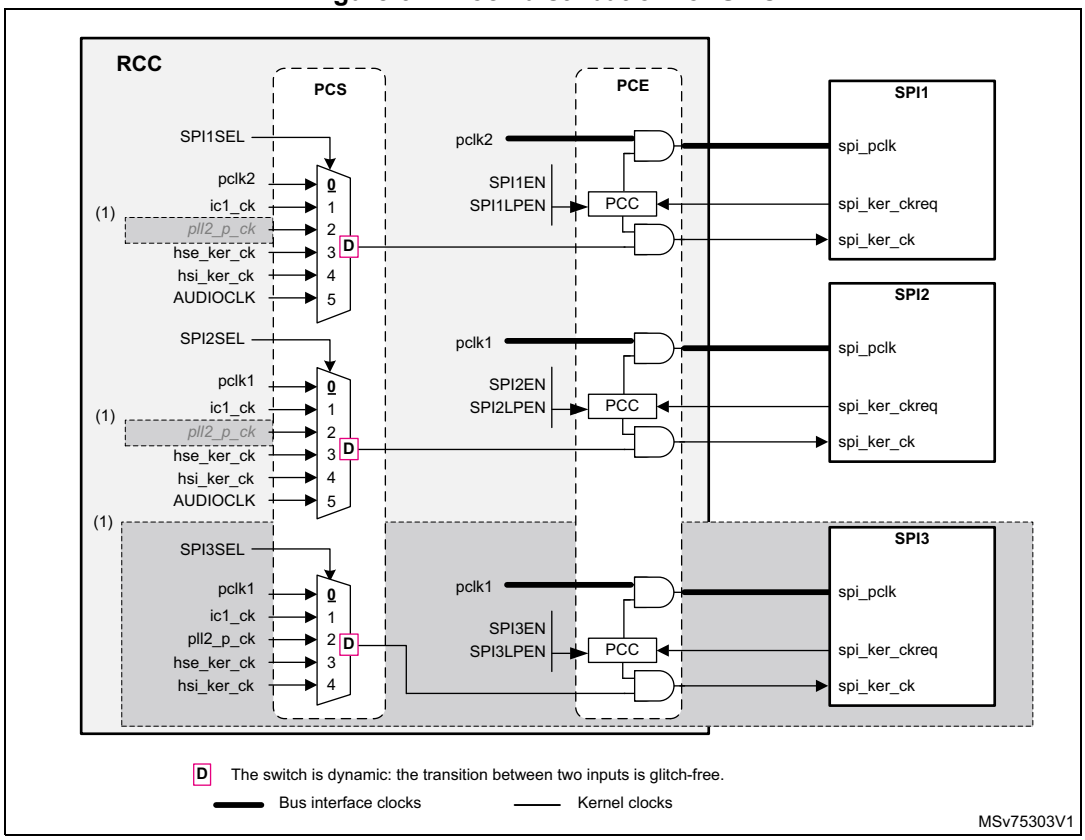
If UARTs, USARTs or LPUART1 is set to secure via TZSC, the corresponding bitfields xxxSEL, xxxEN, xxxLPEN, and xxxRST can only be changed by secure access. In addition if SPRIV is set, only secure privileged access can modify these bitfields.

If UARTs, USARTs or LPUART1 is set to nonsecure via TZSC, the corresponding bitfields xxxSEL, xxxEN, xxxLPEN, and xxxRST can be changed by secure or nonsecure access. In addition, if NSPRIV is set, only nonsecure or secure privileged access can modify these bitfields.

Figure 60. Clock distribution for UARTs, USARTs and LPUART

1. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

All peripheral clocks of the cryptographic subsystem must be disabled before issuing a software reset to any CCB/PKA/RNG/AES/SAES/HASH peripheral of this subsystem.



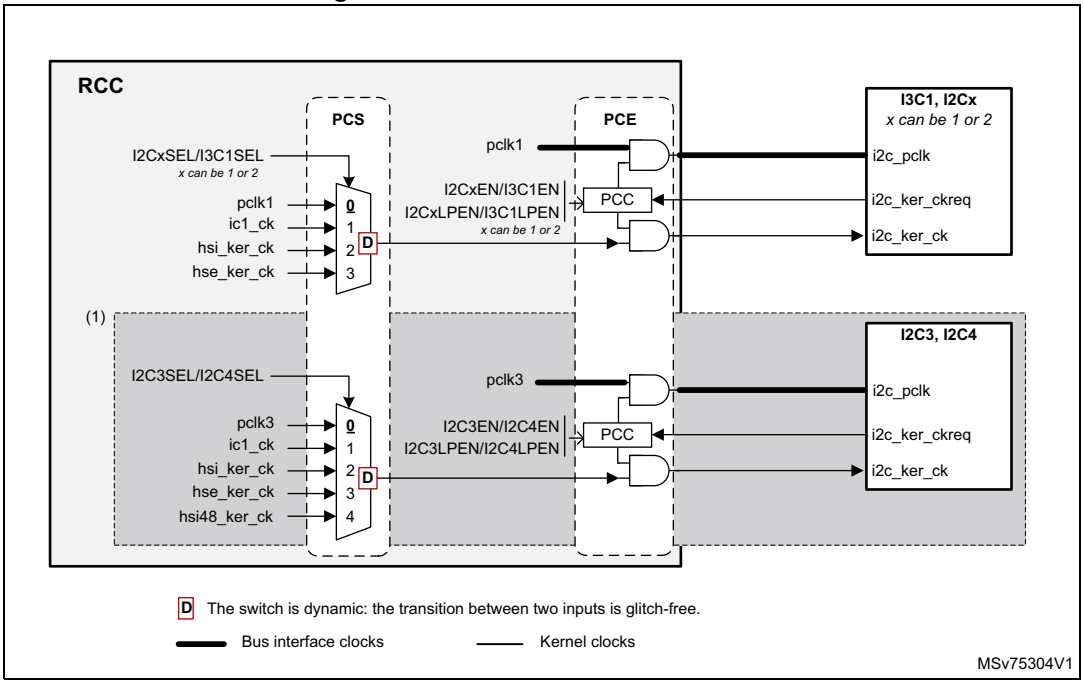
For any CCB/PKA/RNG/AES/SAES/HASH peripheral of this subsystem, the software must ensure that peripheral is not busy (by polling on the BUSY bit flag of the related CCB/PKA/RNG/AES/SAES/HASH peripheral) before disabling the peripheral clock.

Clock distribution for SPIs

The SPI kernel clock sources are selected through SPIxSEL[2:0] in the *RCC kernel clock configuration register (RCC_CCIPR3)*. SPI with I2S feature also supports audio applications. For audio use-cases, the application can select the RC oscillator source hsi_ker_ck for the power-critical applications that do not request an accurate clock, or use hse_ker_ck, PLL outputs or AUDIOCLK when accurate frequency is needed.

The SPIs provide kernel clock request signals allowing these blocks to get kernel clock even when the device is in Stop mode. This mechanism works if the selected kernel clock source is hsi_ker_ck. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

Figure 61. Clock distribution for SPIs



1. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Clock distribution for I2C and I3C

The I2Cs and I3C1 kernel clock sources are selected through I2CxSEL[2:0] and I3C1SEL[2:0], respectively. These bitfields belong to the *RCC kernel clock configuration register (RCC_CCIPR4)*.

The I2Cs and I3C1 provide a kernel clock request signals handled by the RCC allowing those blocks to get kernel clock even when the device is in Stop mode. This mechanism works if the selected kernel clock source is hsi_ker_ck. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

Figure 62. Clock distribution for I2Cs

1. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Clock distribution for TIMs, HRTIM1 and LPTIM1

The timers (TIMs) use kernel clocks (rcc_tim_ker_ck) that are phase-aligned with the bus interface clock. The TIMs can work at a frequency higher than their bus interface clock, depending on the division factors configured through PPREx. For example if PPRE1 performs a division by 4, then TIM2 kernel clock is set to F_{HCLK}, and the bus interface clock to F_{HCLK} / 4.

The HRTIM1 has a different mechanism allowing it to work at a higher rate than the CPU. As for the TIMs, the kernel clock (rcc_hrtim_ker_ck) must be phase-aligned with the bus interface clock.

The kernel clock frequency depends on:

- The APB2 prescaler (PPRE2), and
- The CPU prescaler HPRE

A logic, named LUT in the drawing below, limits the ratio between the kernel clock frequency and the bus interface clock to ×32.

As shown in *Table 120*, if PPRE2 performs a division by 4 and HPRE a division by 2, then the HRTIM1 kernel clock frequency is eight times faster than the bus interface clock.

Table 120. HRTIM1 clock multiplication ratio (1)

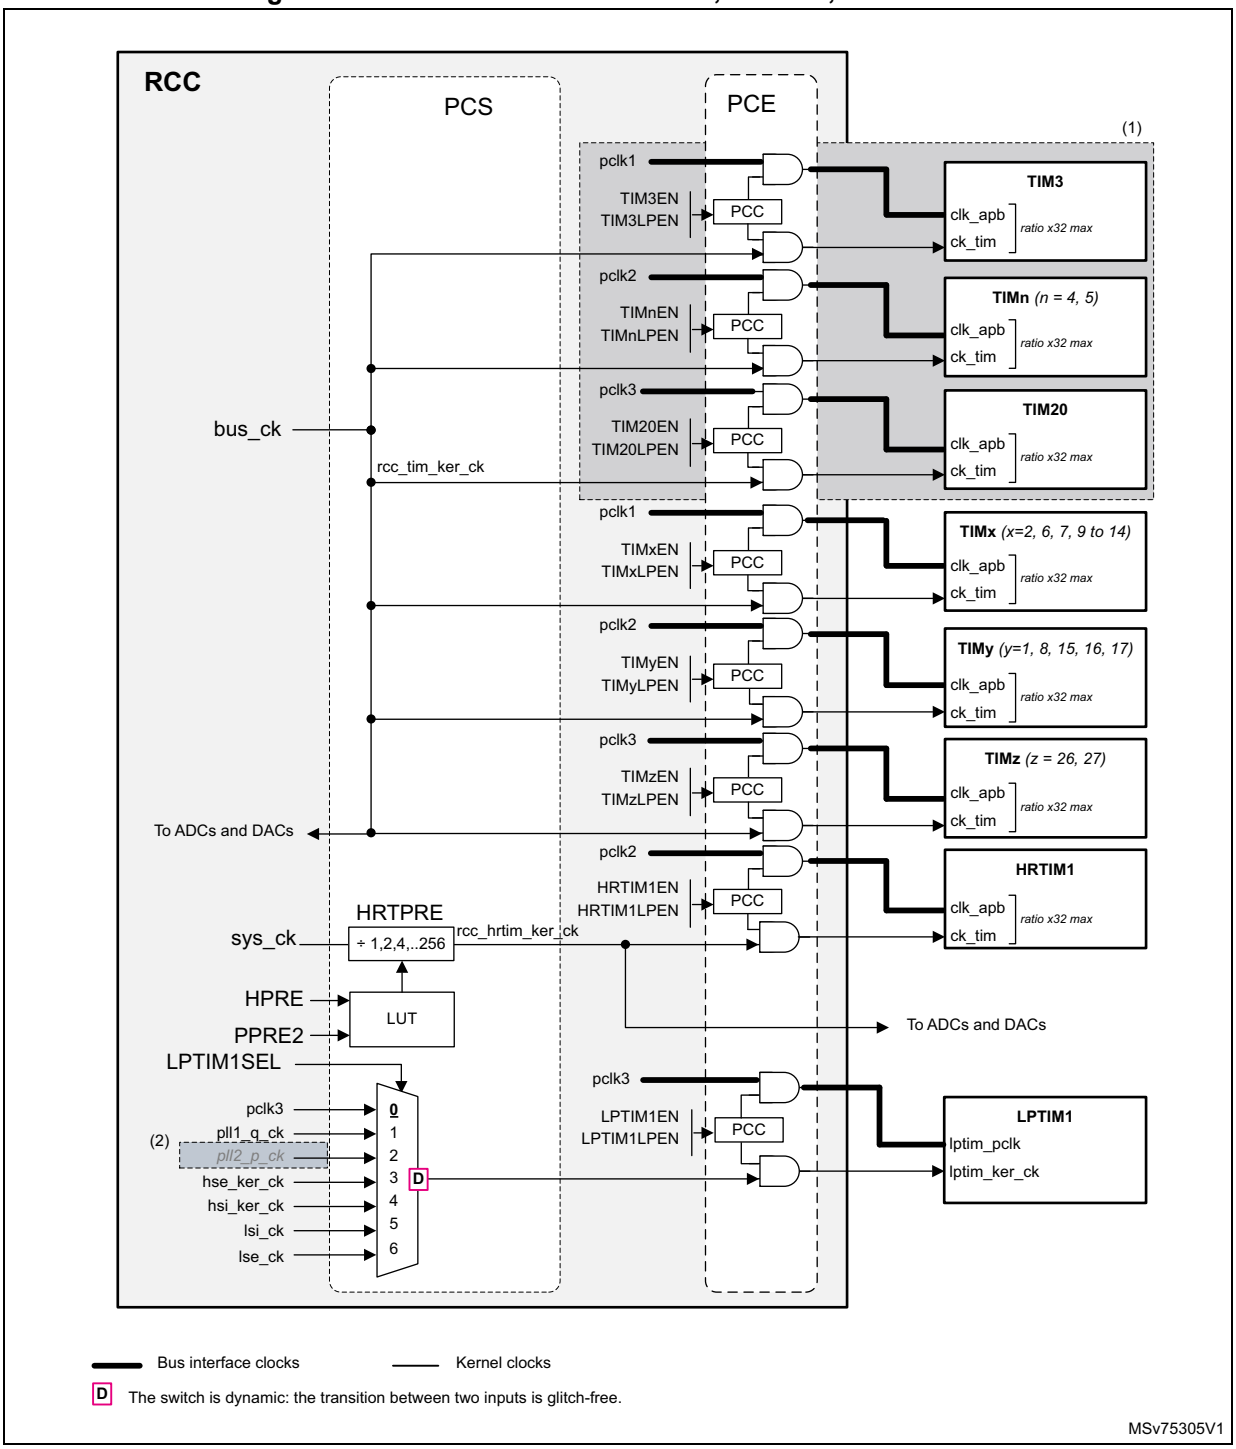
<table>
<tr><th colspan="2" rowspan="2">HRTIM clock multiplication ratio</th><th colspan="5">PPRE2 division ratio</th></tr>
<tr><th>1</th><th>2</th><th>4</th><th>8</th><th>16</th></tr>
<tr><td rowspan="9">HPRE division ratio</td><td>1</td><td>× 1</td><td>× 2</td><td>× 4</td><td>× 8</td><td>× 16</td></tr>
<tr><td>2</td><td>× 2</td><td>× 4</td><td>× 8</td><td>× 16</td><td rowspan="5">× 32</td></tr>
<tr><td>4</td><td>× 4</td><td>× 8</td><td>× 16</td><td rowspan="4">× 32</td></tr>
<tr><td>8</td><td>× 8</td><td>× 16</td><td rowspan="4">× 32</td></tr>
<tr><td>16</td><td>× 16</td><td rowspan="4">× 32</td></tr>
<tr><td>64</td><td rowspan="4">× 32</td></tr>
<tr><td>128</td></tr>
<tr><td>256</td></tr>
<tr><td>512</td></tr>
</table>

1. The multiplication ratio is the ratio between the HRTIM kernel clock and the bus interface clock F_{ck_tim} / F_{clk_apb}.

The LPTIM1 can have a kernel clock fully asynchronous from the bus interface clock. A clock switch controlled by LPTIM1SEL[2:0] allows the application to select a wide variety of kernel clock sources.

TIMs and HRTIM1 cannot work in Stop mode because the system clock is no longer present in this mode (see *Table 121*).

Table 121. Clock gating rules for TIMs and HRTIM1



TIMxEN (HRTIMxEN)	TIMxLPEN (HRTIMxLPEN)	CPU Modes	-	Kernel clock (ck_tim)	Bus clock (clk_apb)	Comments
0	X	X	→	-	-	No clock provided
1	X	Run	→	CK	CK	Clock provided
1	0	Sleep	→	-	-	No clock provided
1	1		→	CK	CK	Clocks provided
X	X	Stop	→	-	-	No clock provided

The LPTIM1 can work in Stop mode if the selected kernel clock is either:

- lse_ck, and the LSE is enabled, or
- lsi_ck, and the LSI is enabled, or
- hsi_ker_ck, and the HSI is enabled

Refer to *Section : Generic clock gating rules* for details on clock gating rules.

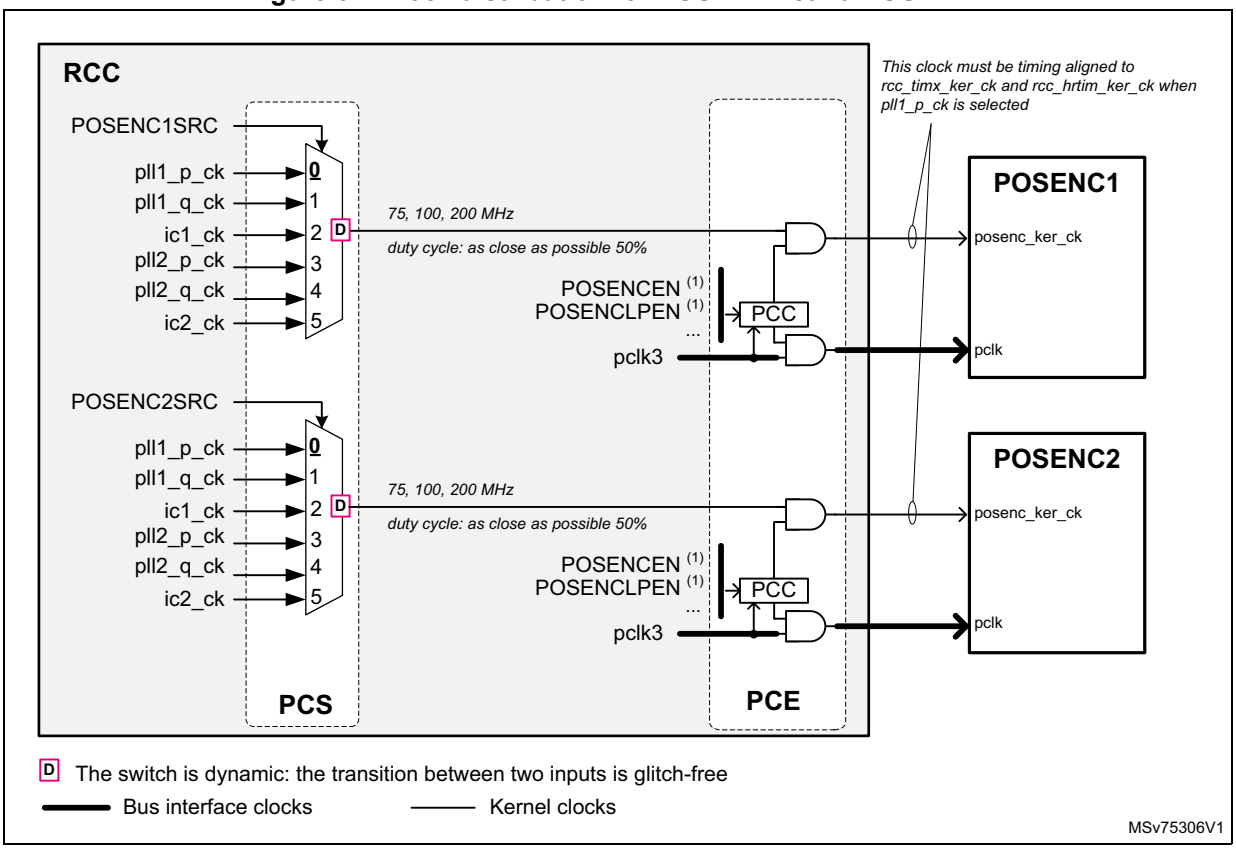
Figure 63. Clock distribution for TIMs, HRTIM1, and LPTIM1

1. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. This signal is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
3. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Clock distribution for POSENC1 and POSENC2

These blocks are not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

The POSENC1 and POSENC2 kernel clock sources are selected through POSEN1SEL[2:0] and POSENC2SEL[2:0], respectively. These bitfields belong to the *RCC kernel clock configuration register (RCC_CCIPR5)*.



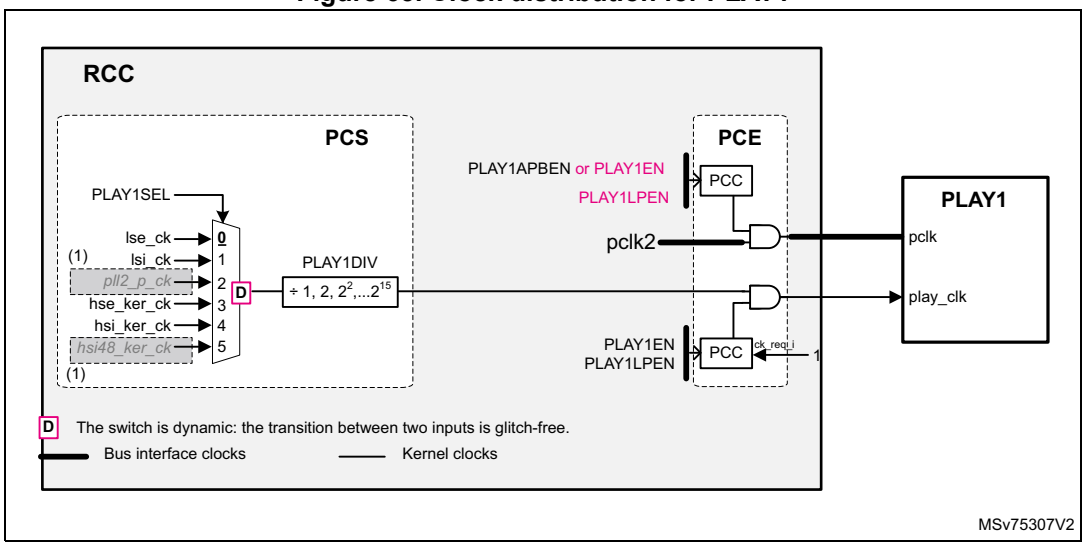
There is no kernel clock request mechanism for POSENC blocks, so they cannot work when the device is in Stop mode. Refer to *Section : Generic clock gating rules* for details.

The POSENC blocks support Endat3 and Hyperface DSL interfaces. Only one interface can be active at a given time. *Table 122* gives the allowed clock frequencies and constraints for each interface.

Table 122. POSENC1 and POSENC2 clock constraints

Protocol	posenc_ker_ck frequencies (MHz)	Duty cycle (%)	Accuracy (ppm)	Other constraints
Endat 3	100 or 200	50	100	APB clock higher than 48 MHz and lower than posenc_ker_ck
Hiperface DSL	75	50	100	

Figure 64. Clock distribution for POSENC1 sand POSENC2



1. PCC stands for peripheral clock control, PCC blocks also receives security and CPU mode signals. They are not shown to simplify the drawing.

Clock distribution for PLAY1

The PLAY1 is a dual-clock domain: it requires a bus clock interface and a kernel clock. The bus clock is required to configure the PLAY1 but also in functional mode.

The PLAY1 kernel clock sources are selected through the PLAY1SEL[2:0]. In addition, a prescaler is available to adjust the kernel clock rate. The prescaler value is adjusted via PLAY1DIV[3:0]. Both PLAY1DIV[3:0] and PLAY1SEL[2:0] are located in the *RCC kernel clock configuration register (RCC_CCIPR3)*.

Figure 65. Clock distribution for PLAY1

1. This signal is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

In Run mode, the bus clock (pclk2) is provided to the PLAY1 if the PLAY1APBEN or the PLAY1EN bit is set. In addition, the bus clock is also provided in Sleep mode if PLAY1LPEN is set. In Stop mode, this clock is not provided.

In Run mode, the kernel clock is provided to the PLAY1 if PLAY1EN is set. In addition, the kernel clock is also provided in Sleep mode if PLAY1LPEN is set. In Stop mode, this clock is also provided if the selected kernel clock is hsi_ker_ck, lse_ck, or lsi_ck.

If the hsi_ker_ck clock is selected, the RCC automatically switches the HSI oscillator ON (see *Table 123* and *Table 124*).

Table 123. Clock gating rules for PLAY1 bus clock

PLAY1APBEN or PLAY1EN	PLAY1LPEN	CPU Modes	-	PLAY1 bus clock	Comments
0	X	X	→	-	No clock provided
1	X	Run	→	CK	Clocks provided

Table 123. Clock gating rules for PLAY1 bus clock (continued)

PLAY1APBEN or PLAY1EN	PLAY1LPEN	CPU Modes	-	PLAY1 bus clock	Comments
1	0	Sleep	→	-	No clock provided
1	1		→	CK	Clocks provided
X	X	Stop	→	-	No clock provided

Table 124. Clock gating rules for PLAY1 kernel clock

PLAY1EN	PLAY1LPEN	PLAY1SEL	CPU Modes	-	PLAY1 kernel clock	Comments
0	X	X	X	→	-	No kernel clock provided
1	X	X	Run	→	CK	Kernel clocks provided
1	0	X	Sleep	→	-	No kernel clock provided
1	1	X		→	CK	Kernel clocks provided
1	0	X	Stop	→	-	No kernel clock provided
1	1	Other clock selected		→	-	No kernel clock provided
1	1	lsi_ck or lse_ck or hsi_ker_ck		→	CK	Kernel clocks provided

Clock distribution for ADC and DAC

The kernel clock source of all ADCs is selected through ADCSEL[2:0], and can be divided directly in the RCC by the ADCDIV[3:0]. ADCSEL[2:0] and ADCDIV[3:0] are located in the *RCC kernel clock configuration register (RCC_CCIPR5)*.

For each DAC, the kernel clock source can be selected through DACxSEL[2:0] in the *RCC kernel clock configuration register (RCC_CCIPR2)*. Some DACs also offer an additional low-power clock (LSI or LSE) to operate in sample and hold mode, available in Stop mode. This clock is selected via the DACxSHSEL bits of the *RCC kernel clock configuration register (RCC_CCIPR2)*.

There is no kernel clock request mechanism for DAC and ADC blocks. The ADCs cannot work when the device is in Stop mode. Similarly, most of the DACs cannot work when the device is in Stop mode except the hold function clocked by LSE or LSI for DACs receiving these clocks.

Refer to *Section : Generic clock gating rules* for details on clock gating rules.

To optimize analog-to-digital conversion, it is strongly recommended to adjust the kernel clock frequency of the ADCs by adjusting ADCDIV, instead of changing the default values of the prescalers located into each ADC block. It guarantees that all ADCs sample data without disturbing each other. The divider ADCDIV provides a 50% duty cycle clock signal. In order to change the division value the application must perform the following sequence:

1. Disable all ADCs by clearing ADC12EN and ADC3EN.
2. Change the ADCDIV[3:0] division factor.
3. Enable the ADCs by setting ADC12EN and/or ADC3EN.

If the application requires that the ADCs are precisely triggered by a TIMx timer without any uncertainty (fixed trigger latency); ADCSEL must select rcc_tim_ker_ck as clock source (position 0).

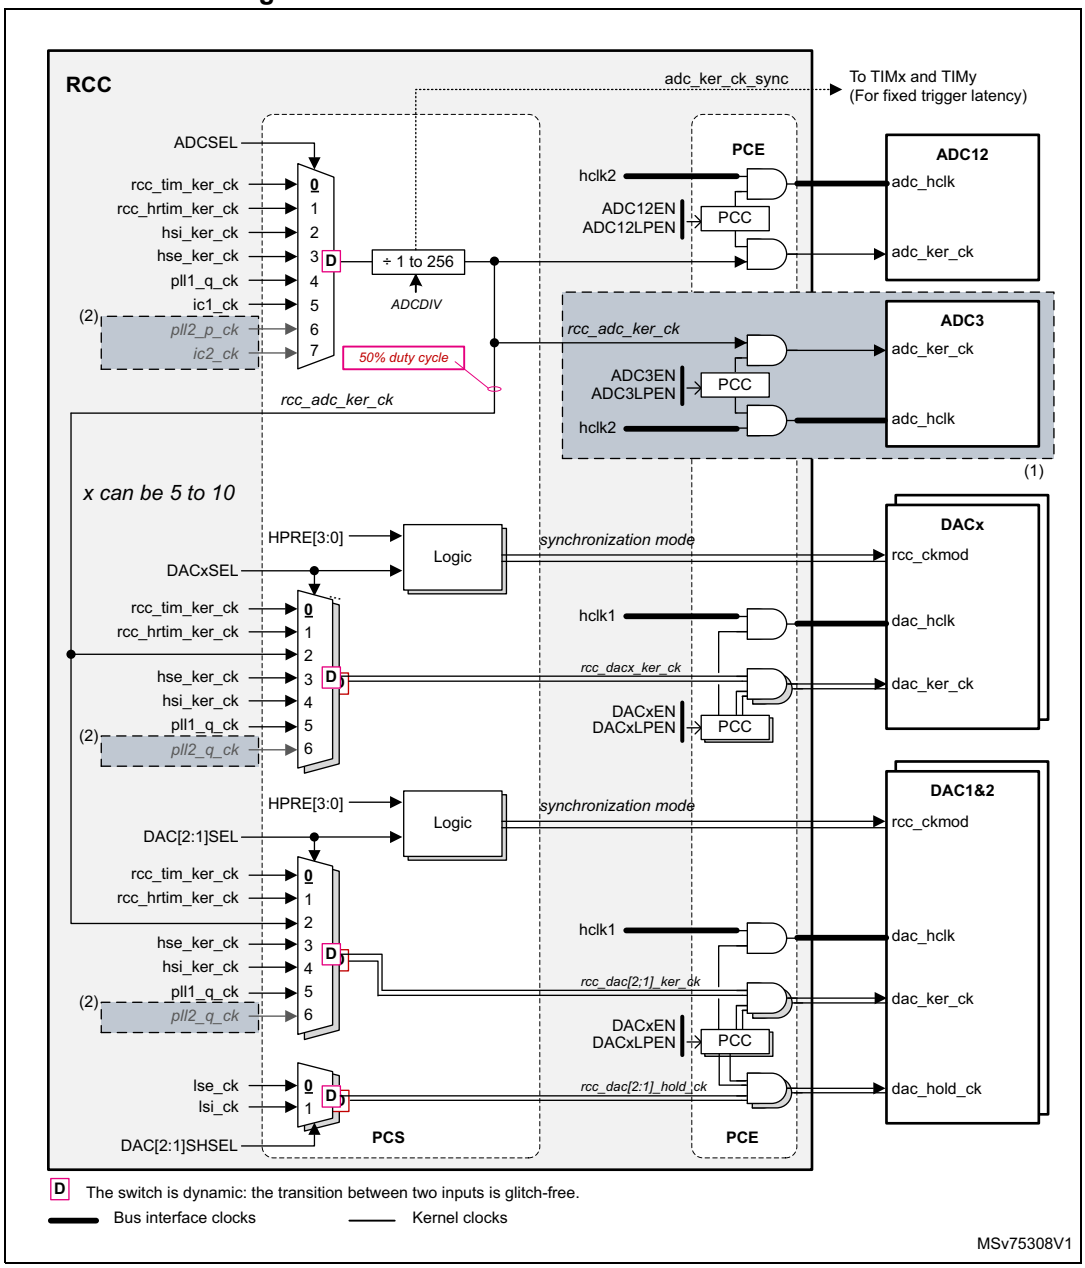
Note: To solve trigger uncertainty, the ADCDIV[3:0] divider delivers a synchronization signal to the timers.

If the application requires that the DACs are precisely triggered by a TIMx timer without any uncertainty (fixed trigger latency), DACxSEL and HPRE must be programmed as follows:

- Clear DACxSEL (HPRE value is don’t care), or
- Set both DACxSEL and HPRE.

In all other configurations, there might be a small trigger uncertainty due to clock resynchronization.

If DACxSEL is set, and HPRE has to be changed, it is strongly recommended to first disable the corresponding DAC (via DACxEN bits), then change the HPRE value, and enable again the DAC.



If the kernel clock source of the DACx has to be changed, the following sequence must be respected by the application:

1. Disable the DACx clocks by clearing DACxEN.
2. Program DACxSEL to the desired value.
3. Enable the DACx clocks by setting DACxEN.

Note: If ADCs or DACs are triggered by timers, and the ADC or DAC clock sources are asynchronous with respect to timer clocks, there is an uncertainty of the trigger instant due to the resynchronization between the two clock domains.

If ADC12 or ADC3 is set to secure via TZSC, the common bitfields ADCSEL[2:0] and ADCDIV[3:0] can only be changed by secure accesses. In addition if SPRIV is set, only secure privileged access can modify these bitfields.

Figure 66. Clock distribution for ADCs and DACs

1. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. This signal is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
3. PCC stands for peripheral clock control, PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Clock distribution for cryptographic blocks

The configuration of cryptographic blocks depends on the STM32G56x/55x/54x/53x device. Some devices feature a CCB subsystem including RNG, PKA, SAES, AES, HASH, others offer only a subset including RNG, PKA, AES, and HASH, while some others do not have cryptographic blocks (refer to the device datasheet for availability).

Configuration with CCB subsystem (STM32G55x/56x devices)

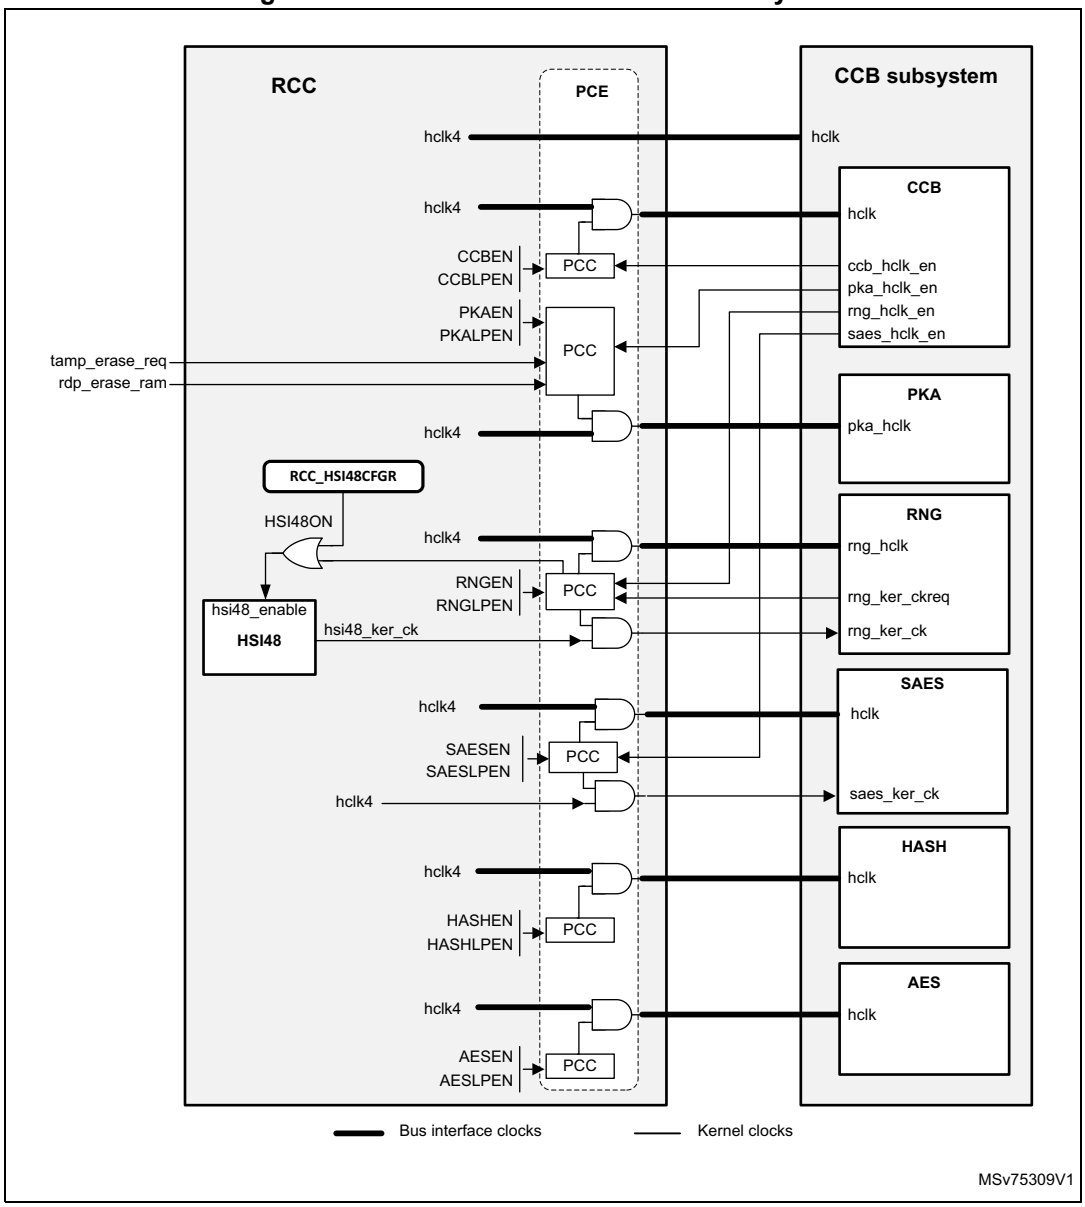
The CCB block shares the same clock as the AHB bus clock. The CCB automatically requests the RCC to enable clocks of the RNG, SAES, and PKA, using dedicated clock request signals.

The PKA receives a clock when the tamp_erase_req or rdp_erase_ram becomes active, whatever the values of PKAEN and PKALPEN (see *Table 125* for details).

Table 125. PKA clock gating rules

PKAEN	PKALPEN	tamp_erase_req	rdp_erase_ram	CPU state	-	pka_hclk
0	X	0	0	CRun or CSleep	→	-
X	X	1	X			CK
X	X	X	1			CK
1	X	0	0	CRun		CK
	0			CSleep		-
	1					CK
X	X	X	X	CStop		-

The RNG block uses the hsi48_ker_ck as kernel clock. When the CCB activates the rng_hclk_en, the RCC provides to the RNG the kernel clock and bus clock even if the RNGEN bit is cleared. If the HSI48 oscillator is disabled, the RCC automatically enables it, waits until the clock is ready, and provides it to the RNG.



The logic that controls the clock of the RNG is different from standard peripherals. When enabled, the RNG has to assert its kernel clock request to get a kernel clock. For example, if the SAES needs the RNG resource, the RNG must also be enabled (see *Table 126*).

Table 126. RNG clock gating rules with CCB

RNGEN	RNGLPEN	rng_ker_ckreq	rng_ck_en	CPU state	-	rng_ker_ck	rng_hclk
0	X	X	0	CRun or CSleep	→	-	-
X	X	X	1			CK	CK
1	X	0	0	CRun		-	CK
1	X	1	0			CK	CK
1	0	X	0	CSleep		-	-
1	1	0	0			-	CK
1	1	1	0			CK	CK
1	X	X	X	CStop		-	-

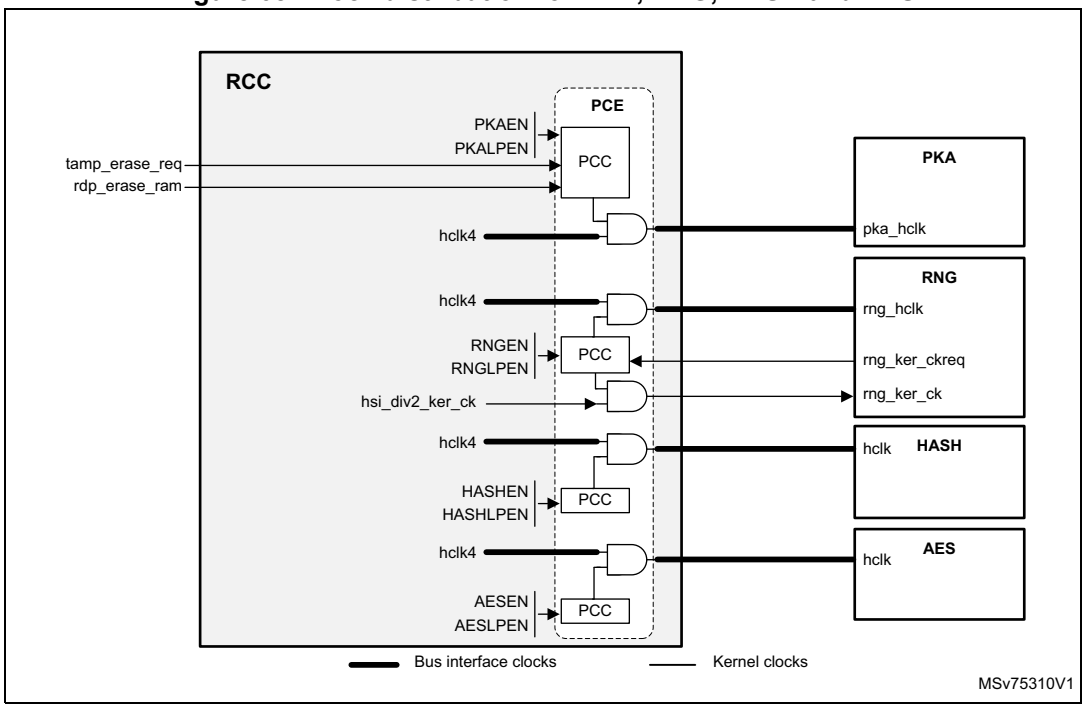
Note: The RNG kernel clock is the hsi48_ker_ck.

Figure 67. Clock distribution for CCB subsystem

1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.
2. All peripheral clocks of the cryptographic subsystem must be disabled before issuing a software reset to any CCB/PKA/RNG/AES/SAES/HASH peripheral of this subsystem. For any CCB/PKA/RNG/AES/SAES/HASH peripheral of this subsystem, the software must ensure that the peripheral is not busy (by polling on the BUSY bit flag of the related CCB/PKA/RNG/AES/SAES/HASH peripheral) before disabling the peripheral clock.

Configuration with AES, RNG, PKA, and HASH (STM32G53x/54x devices)

The PKA receives a clock when the tamp_erase_req or rdp_erase_ram becomes active, whatever the values of PKAEN and PKALPEN (see *Table 125: PKA clock gating rules* for details).



The RNG block uses the hsi_div2_ker_ck as kernel clock. The logic controlling the clock of the RNG is different from standard peripherals. When enabled, the RNG has to assert its kernel clock request to get a kernel clock. If the HSI oscillator is disabled, the RCC automatically enables it, waits until the clock is ready, and provides it to the RNG (see *Table 127*).

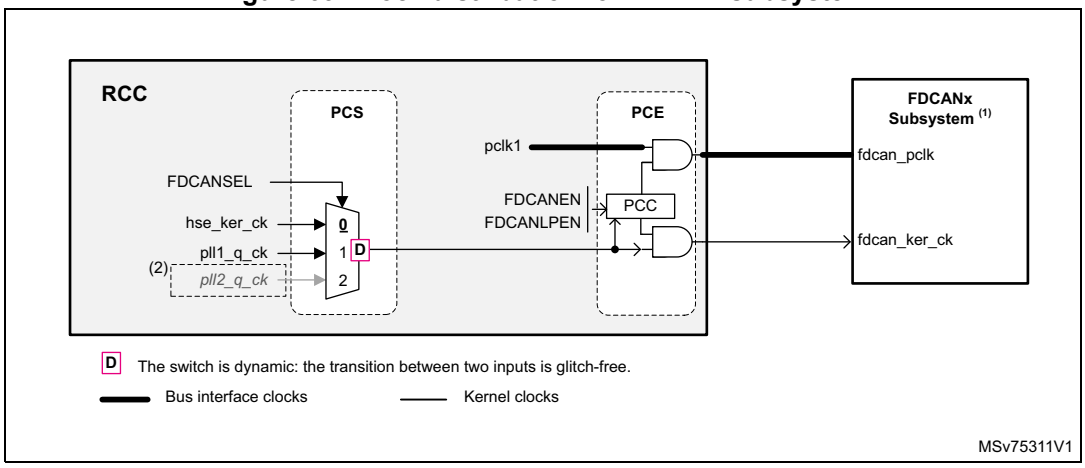
Table 127. RNG clock gating rules without CCB

RNGEN	RNGLPEN	rng_ker_ckreq	CPU state	-	rng_ker_ck	rng_hclk
0	X	X	CRun or CSleep	→	-	-
1	X	0	CRun		-	CK
1	X	1			CK	CK
1	0	X	CSleep		-	-
1	1	0			-	CK
1	1	1			CK	CK
1	X	X	CStop		-	-

Note: The RNG kernel clock is the hsi_div2_ker_ck.

Figure 68. Clock distribution for PKA, RNG, HASH and AES

1. PCC stands for peripheral clock control. PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.



Clock distribution for FDCAN subsystem

STM32G56x/55x/54x/53x FDCAN subsystem embeds one or three FDCAN instances, and all sharing the same bus clock and the same kernel clock. The FDCAN kernel clock is selected by the FDCANSEL[1:0] bitfield located into *RCC kernel clock configuration register (RCC_CCIPR5)*.

There is no kernel clock request mechanism for FDCAN blocks, so they cannot work when the device is in Stop mode. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

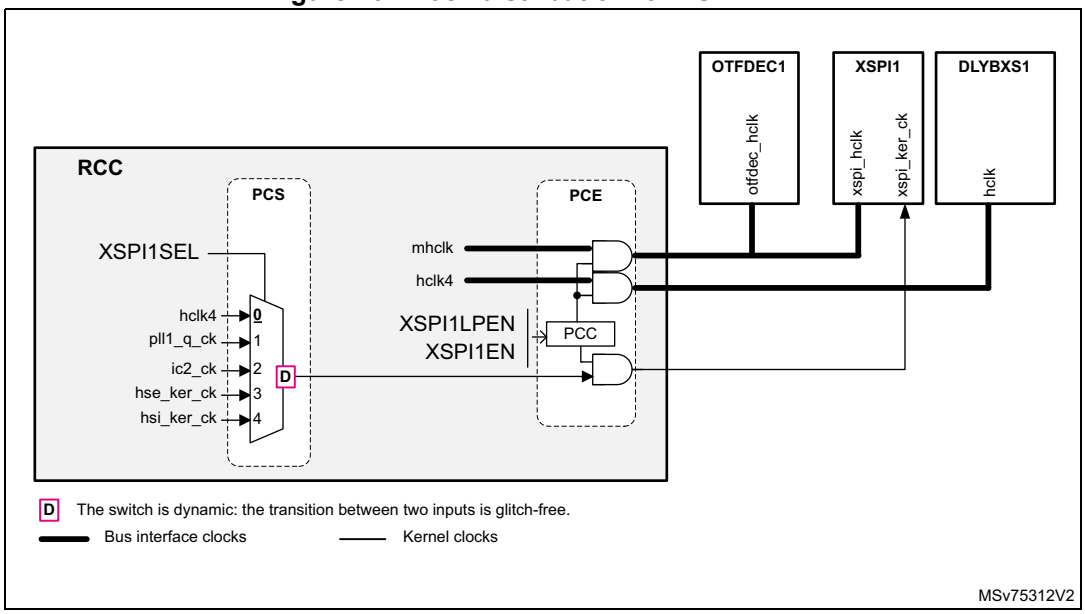
If one of the FDCAN instances (FDCAN1, FDCAN2 or FDCAN3) is configured to be secure via TZSC, the FDCANSEL[1:0], FDCANRST, FDCANEN, and FDCANLPEN bitfields can only be changed by secure access. In addition, if SPRIV is set, only secure privileged access can modify these bitfields.

Figure 69. Clock distribution for FDCAN subsystem

1. The STM32G53x/54x devices feature only one FDCAN instance, while others have three instances. Refer to the device datasheet for availability.
2. This signal is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
3. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Note: The frequency of the FDCAN bus clock (fdcan_pclk) must be higher than the kernel clock frequency (fdcan_ker_ck).

Clock distribution for XSPI1



This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

The XSPI1 kernel clock sources are selected through XSPI1SEL[2:0] in the *RCC kernel clock configuration register (RCC_CCIPR4)*.

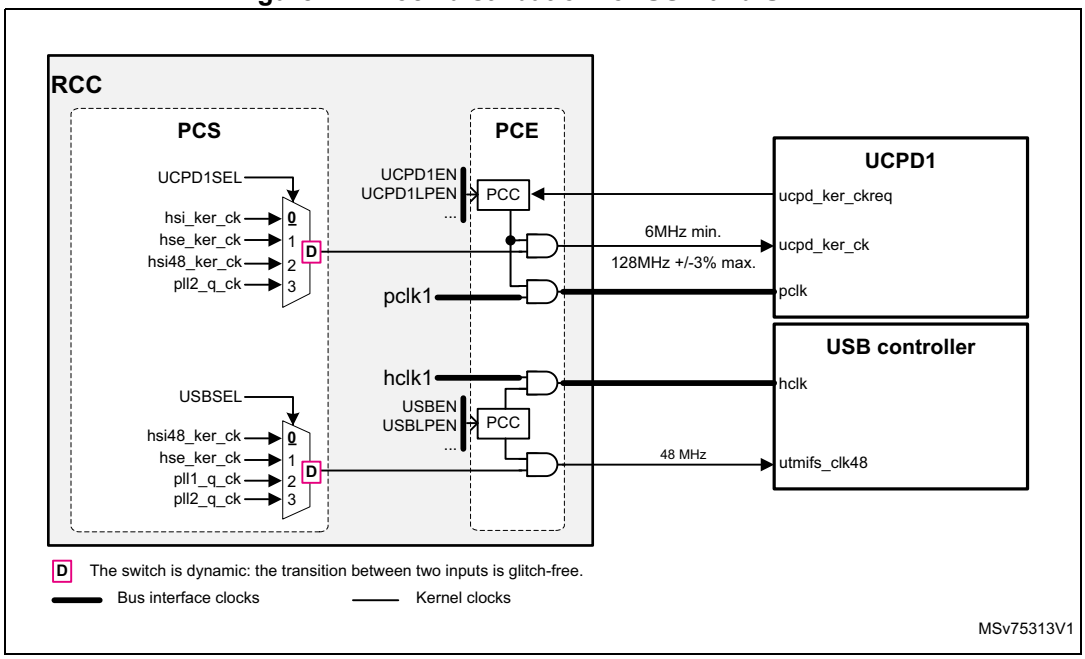
There is no kernel clock request mechanism for XSPI1, so they cannot work when the device is in Stop mode. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

The kernel clock must be lower or equal to the bus clock.

Figure 70. Clock distribution for XSPI1 (1) (2)

1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.
2. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

Clock distribution for USB and UCPD1



This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

USB and UCPD1 kernel clocks are selected through USBSEL[1:0] and UCPD1SEL[1:0], respectively. These bitfields are located in the *RCC kernel clock configuration register (RCC_CCIPR4)*.

The UCPD1 kernel clock must not be lower than 6 MHz, and must not exceed 100 MHz, with a precision of ± 3%.

The UCPD1 provides a kernel clock request signal allowing this block to get kernel clock even when the device is in Stop mode. This mechanism works if the selected kernel clock source is hsi_ker_ck. Refer to *Table 128: Clock gating rules for generic peripherals* for details on clock gating rules.

Figure 71. Clock distribution for USB and UCPD1

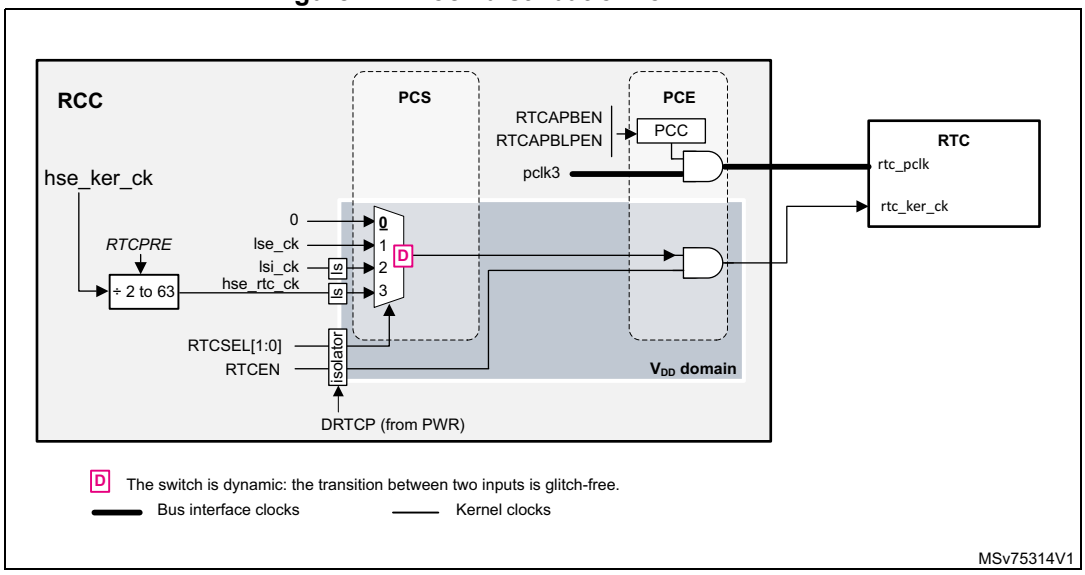
1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.
2. This block is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

Clock distribution for RTC/TAMP

The kernel clock source, used by the RTC and TAMP blocks, can be one of the following:

- The hse_rtc_ck (hse_ker_ck divided by a programmable prescaler)
- The lse_ck
- The lsi_ck clock

The source clock is selected by programming the RTCSEL[1:0] bits of the *RCC RTC domain control register (RCC_RTCCR)* and the RTCPRE[5:0] bits of the *RCC clock configuration register1 (RCC_CFGR1)*.



Note that the content of RTCEN and RTCSEL[1:0] is propagated to the V_{DD} domain only when DRTCP is set.

RTCSEL[1:0] can be written only once after an RTC domain reset, or after a failure detection on LSE. RTCSEL[1:0] must not be modified if LSECSSON is cleared.

The system must always be configured so as to provide a bus clock frequency (pclk3) greater than or equal to the clock frequency provided to rtc_ker_ck.

The TAMP does not require any kernel clock if only the backup registers are used, with tampers in edge detection mode. All other tamper detection modes require a kernel clock (refer to *Section 50: Tamper and backup registers (TAMP)*).

Figure 72. Clock distribution for RTC/TAMP

1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

Note: The hse_rtc_ck clock is also connected to timers for applications requesting a check of HSE frequency before using it as system clock. See Section 11.5.15: Clock frequency measurement using TIMx.

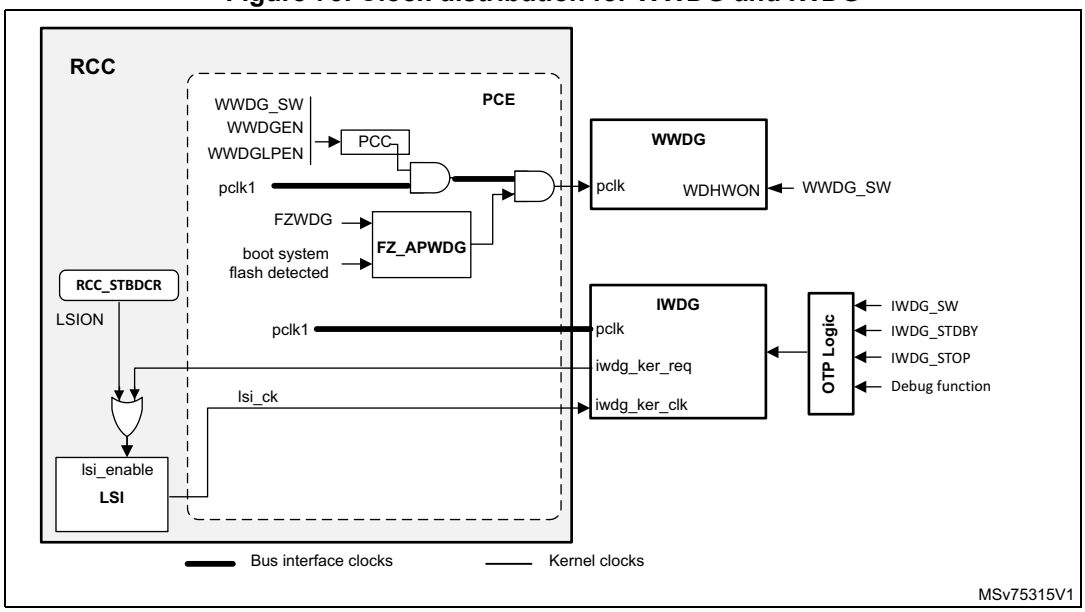
The LSE clock belongs to the RTC domain.

- If LSI or LSE is selected as the RTC and TAMP clock, the RTC state is not guaranteed if the V_{DD} supply is powered off:
  - The TAMP block can remain functional if used in a mode that does not need any kernel clock.
  - The RTC works in Stop and Standby modes.
- If the HSE clock is used as RTC clock, the RTC state is not guaranteed if the V_{DD} or V_{CORE} supplies are powered off:
  - The TAMP block can remain functional if used in a mode that does not need any kernel clock.
  - The RTC does not work in Stop and Standby modes.

When the RTC and TAMP clock is LSE or LSI, the RTC remains clocked and functional under system reset.

The RTC bus interface clock (APB clock) is enabled through the RTCAPBEN and RTCAPBLPEN bits of the *RCC APB3 peripheral clock enable register (RCC_APB3ENR)* and *RCC APB3 peripheral low-power clock enable register (RCC_APB3LPENR)*, respectively.

Note: To read the RTC calendar register when the APB clock frequency is less than seven times the RTC clock frequency (FAPB < 7 × FRTCLCK), the software must read the calendar time and date registers twice. The data are correct if the second read access to RTC_TR gives the same result than the first one. Otherwise, a third read access must be performed.



Clock distribution for WWDG and IWDG

The RCC provides the clock for all the watchdog blocks available in the device. The independent watchdog IWDG uses the clock generated by LSI as kernel clock, while the window watchdog WWDG uses the APB clock as kernel clock.

The IWDG can be started by using the IWDG_SW option byte or by software. When started, the LSI is forced ON and cannot be disabled. After the LSI oscillator startup delay, the clock is provided to the IWDG.

The WWDG can be started by using the WWDG_SW option byte or by software. When started by option byte, the APB clock is forced ON, as well as the WWDGEN and WWDGLPEN. Whatever the way the WWDG is started, the software cannot stop it by clearing the WWDGEN bit.

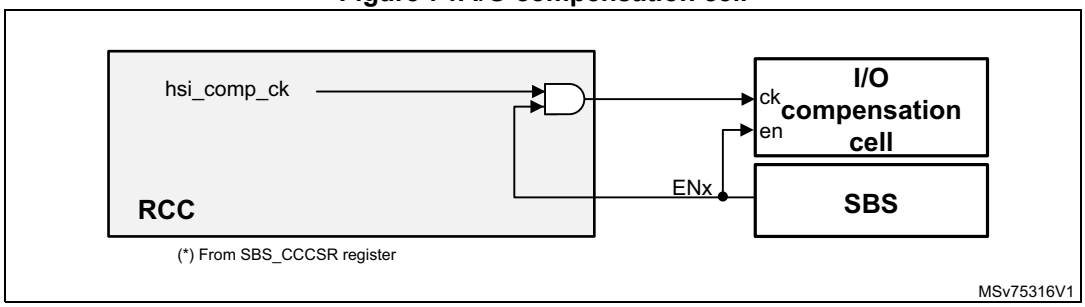
Figure 73. Clock distribution for WWDG and IWDG

1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

The WWDG is frozen in the following cases:

- When the MCU goes to Stop mode.
- If the WWDG is not started by option bytes, clearing the WWDGLPEN bit freezes the WWDG when the MCU goes to Sleep.
- After a system reset, if the product reboots from system flash memory, the WWDG is frozen during the execution of the system flash code.

The FZ_APWDG logic blocks are used to freeze and unfreeze the watchdog clock according to the boot sequence.



Clock distribution for the I/O compensation cell

The I/O compensation cell is used to calibrate the I/O slew rate. For that purpose, the RCC provides the hsi_comp_ck clock to the I/O compensation cell block.

When the compensation mechanism needs to be activated, the clock must be provided to the I/O compensation cell block, meaning that the application has to set the HSION bit.

When HSION is set, the hsi_comp_ck remains gated until HSIRDY is set, to avoid propagating spurs.

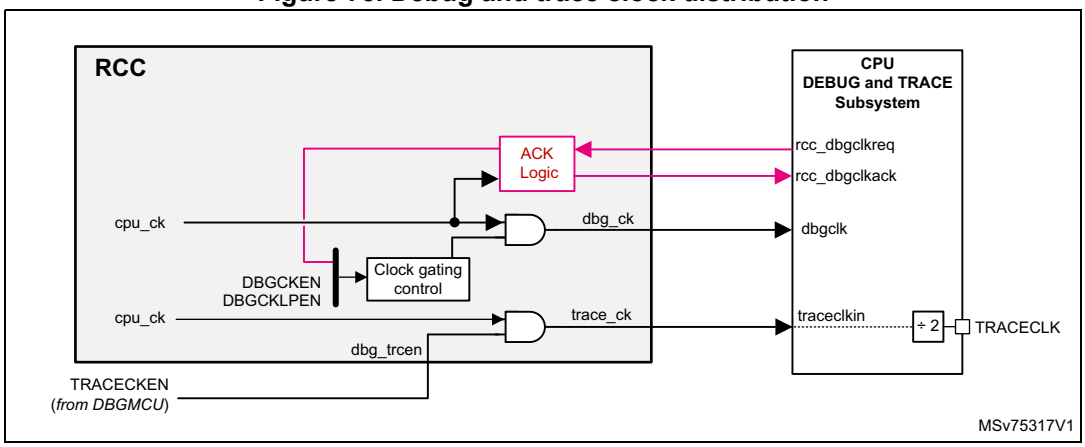
Figure 74. I/O compensation cell

1. PCC stands for peripheral clock control (see *Section 11.5.16: Peripheral clock gating* for details). PCC blocks also receive security and CPU mode signals. They are not shown to simplify the drawing.

The hsi_comp_ck clock is not provided to the I/O compensation cell if the ENx of the SBS_CCCSR register is cleared.

The hsi_comp_ck clock is automatically gated when the system goes to Stop, provided the HSIKERON bit is cleared. Setting the HSIKERON bit allows to maintain the hsi_comp_ck clock enabled even in system Stop.

In system Standby mode, the hsi_comp_ck clock is disabled.



Clock distribution for debug and trace

The clock generation for the debug components is controlled either by the RCC or by the CPU debug and trace subsystem. The clock generation for the trace is controlled via the DBGMCU block.

- The DBGCKEN bit allows the application to provide a clock to the debug components, when the CPU is in Run mode.
- The DBGCKLPEN bit allows the application to provide a clock to the debug components, when the CPU is in Sleep or Stop mode.
- It is also possible to enable the dbg_ck clock via the debug access port using a request/acknowledge handshake.

DBGCKEN and DBGCKLPEN are located in the *RCC AHB3 peripheral clock enable register (RCC_AHB3ENR)* and *RCC AHB3 peripheral low-power clock enable register (RCC_AHB3LPENR)*.

Figure 75. Debug and trace clock distribution

11.5.15 Clock frequency measurement using TIMx

Most of the clock source generator frequencies can be measured by means of the input capture of TIMx:

- Calibrating the HSI with the HSE:

  The RCC provides a dedicated signal hsi_cal_ck to perform the calibration of the HSI oscillator. The hsi_cal_ck represents the HSI oscillator output divided by 1024.

  The signal hsi_cal_ck is connected to at least one timer input capture. Check which timer is connected to hsi_cal_ck in your product.

  For this calibration, it is expected to have the HSE used as the interconnect clock source via PLL1. The number of ck_tim clock periods between consecutive edges of the hsi_cal_ck signal provides a measurement of the HSI clock period. tim_ck is the timer kernel clock.

  The calibration accuracy depends on the frequency ratio between the timer kernel clock (tim_ck) and the hsi_cal_ck clock. The greater the ratio, the more accurate the measurement. The frequency of the hsi_cal_ck can range between ~7 kHz and ~63 kHz. For a timer kernel clock of 50 MHz, the HSI calibration accuracy is about 0.13% (worst case).

  The HSI oscillator has dedicated user-accessible calibration bits to tune the oscillator frequency (see *RCC HSI calibration register (RCC_HSICFGR)*). When the HSI is used via PLLs, the PLL output frequency can also be fine-tuned by adjusting the fractional divider instead of changing HSITRIM[6:0].

- Calibrating the HSI with the LSE:

  The primary purpose of having the LSE connected to a TIMx input capture is to be able to accurately measure the HSI. This requires to use the HSI as system clock source either directly or via PLL1. The number of system clock counts between consecutive edges of the LSE signal gives a measurement of the internal clock period. Taking advantage of the precision of LSE crystals, we can determine the internal clock frequency with the same resolution, and trim the source to compensate for manufacturing-process and/or temperature- and voltage-related frequency deviations.

  The basic concept consists in providing a relative measurement (HSI/LSE ratio). The precision is therefore tightly linked to the ratio between the two clock sources. The greater the ratio, the more accurate the measurement.

  For this purpose, the HSI oscillator has dedicated user-accessible calibration bits (see *RCC HSI calibration register (RCC_HSICFGR)*). When the HSI is used via the PLLx, the system clock can also be fine-tuned by using the fractional divider of the PLLs.

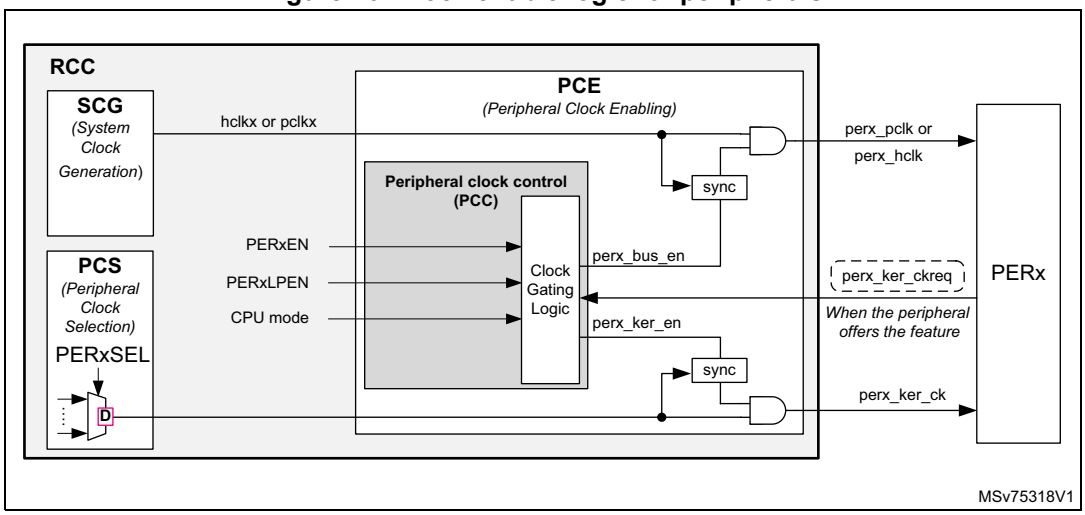
- Calibrating the LSI with the HSI:

  The LSI frequency can also be measured: this is useful for applications that do not have a crystal. The ultralow-power LSI oscillator has a large manufacturing process deviation. The LSI clock frequency can be measured using the more precise HSI clock source. Using this measurement, a more accurate RTC timebase timeout (when LSI is used as the RTC clock source) and/or an IWDG timeout with an acceptable accuracy can be obtained.

Crystal frequency estimation

The hse_rtc_ck clock (HSE divided by a programmable prescaler) is also connected to a timer to have a rough indication of the external crystal frequency. This can be useful, for instance, to ensure compliance with the IEC 60730/IEC 61335 standards, which require to be able to determine harmonic or subharmonic frequencies (-50/+100% deviations).

To use this feature after a power-on reset, the application must do the following:



1. Keep HSI as system clock.
2. Program the RTCPRE[5:0] bitfield of the *RCC clock configuration register1 (RCC_CFGR1)* to 0x3F to select the 63 division factor.
3. Program the timer receiving the hse_rtc_ck on one of its input channels, to count the number of HSI periods within a period of hse_rtc_ck.
4. Check that the hse_rtc_ck period value is roughly the one expected.
5. The HSE can then be used as system clock.

11.5.16 Peripheral clock gating

As shown in *Figure 76*, enabling the kernel and bus interface clocks of each peripheral depends on several input signals:

- PERxEN and PERxLPEN bits.
- The CPU mode.
- The kernel clock request (perx_ker_ckreq) of the peripheral itself, when this feature is available.

Figure 76. Clock enable logic for peripherals

Generic clock gating rules

Table 128: Clock gating rules for generic peripherals shows the clock gating rules applying to most of the peripherals:

- UARTs, USARTs, LPUART1
- SPI/I2Ss
- I2Cs, I3Cs
- POSENCs (when available in the product)
- ADCs, DACs
- FDCAN
- XSPI1, USB, UCPD1 (when available in the product)

Table 128. Clock gating rules for generic peripherals

PERxEN	PERxLPEN	PERxSEL	perx_ker_ckreq [1]	CPU Modes	-	perx_ker_ck	perx_pclk or perx_hclk	Comments
0	X	X	X	X	→	-	-	No clock provided to the peripheral, because PERxEN = 0
1	X	X	X	Run	→	CK	CK	Clocks provided: the System is in Run, and PERxEN = 1
1	0	X	X	Sleep	→	-	-	No clock provided: the System is in Sleep, and PERxLPEN = 0
1	1	X	X		→	CK	CK	Clocks provided: the System is in Sleep and PERxEN = PERxLPEN = 1
1	0	X	X	Stop	→	-	-	No clock provided: the PERxLPEN bit is cleared.
1	1	no RC oscillator selected	X		→	-	-	No clock provided: the System is in Stop and **lse_ck** or RC oscillators are not selected.
1	1	lsi_ck or lse_ck	X		→	CK	-	Kernel clock provided: PERxEN = PERxLPEN = 1 and **lsi_ck** or **lse_ck** are selected. Bus interface clock not provided: the System is in Stop. It is up to the application to enable the LSE or LSI if requested.
1	1	HSI oscillator selected	1		→	CK	-	Kernel clock provided: clock request = 1 and PERxEN = PERxLPEN = 1 and an RC oscillator is selected. If the oscillators are OFF, the RCC enable them when a kernel clock request occurs. Bus interface clock not provided: the System is in Stop.
1	1		0		→	-	-	No clock provided: the System is in Stop, and no kernel clock request pending

1. This signal is not provided by all peripherals. For peripherals not handling the kernel clock request, it must be considered set to 0 unless otherwise specified.

As a summary, the kernel clock is provided to the peripherals when the following conditions are met:

1. The CPU is in Run mode, and the peripheral is enabled.
2. The CPU is in Sleep mode and the peripheral is enabled with PERxLPEN = 1.
3. The CPU is in Stop mode. The peripheral is enabled with PERxLPEN = 1. The peripheral generates a kernel clock request, and the selected clock is hsi_ker_ck.
4. The CPU is in Stop mode. The peripheral is enabled with PERxLPEN = 1 and the kernel source clock of the peripheral is lse_ck or lsi_ck.

The bus interface clock is provided to the peripherals only when conditions 1 or 2 are met.

Clock gating rules for other peripherals

- For TIMs and HRTIM1, see *Section : Clock distribution for TIMs, HRTIM1 and LPTIM1*.
- For PLAY1, see *Section : Clock distribution for PLAY1*.
- For cryptographic blocks, see *Section : Clock distribution for cryptographic blocks*.

11.5.17 Bus and CPU clocks

AHB and APB peripheral clocks, including the DMA clock, can be disabled by software via the xxxDIS bits located in the *RCC CPU domain clock configuration register 2 (RCC_CFGR2)*.

In Sleep mode, the CPU clock is stopped. The memory interface clocks (flash memory, caches, and all SRAM interfaces) can be stopped by software during Sleep mode.

The AHB to APB bridge clocks are disabled by hardware during Sleep mode when all the clocks of the peripherals connected to them are disabled.

In Stop mode, all the clocks in the core domain are stopped and the PLLs, HSI, HSI48 and HSE oscillators are disabled. However, the HSI can be switched ON to allow some peripherals to generate a wake-up interrupt. The LSI and LSE remain active in Stop mode.

In Standby mode, all the clocks in the core domain are stopped and the PLLs, HSI, HSI48 and HSE oscillators are disabled.

The CPU deep-sleep mode can be overridden for debugging by setting the DBG_STOP or DBG_STANDBY bit in the DBGMCU_CR register.

11.6 RCC security and privilege functional description

11.6.1 TrustZone® security protection modes

When the TrustZone® security is activated by the TZEN option byte in the flash memory option byte configuration register, the RCC is able to secure the RCC configuration and status bits from being modified by nonsecure accesses.

This is configured through the *RCC secure configuration register (RCC_SECCFGR)* to prevent nonsecure accesses to read or modify the following features:

- HSE, HSE-CSS, HSI, LSI, LSE, LSE-CSS, HSI48 configuration and status bits
- PLL1, PLL2, AHB, and APB prescalers configuration and status bits
- System clock (SYSCLK) and ICLK source clock selection and status bits
- MCO clock output configuration
- Remove reset flag RMVF configuration

If SPRIV is set in the *RCC privilege configuration register (RCC_PRIVCFGR)*, the RCC_SECCFGR register can be written only by secure and privileged accesses. If SPRIV is cleared, RCC_SECCFGR can be written only by secure accesses, privileged or unprivileged.

RCC_SECCFGR can be read by secure, nonsecure, privileged, and unprivileged accesses.

When a peripheral is configured as secure, its related clock, reset, clock source selection, and clock enable during low-power modes control bits, are also secure in the RCC_AHBxENR, RCC_APBxENR, RCC_CCIPRx and *RCC RTC domain control register (RCC_RTCCR)* registers.

A peripheral is secure when:

- For peripherals securable by TZSC (see *Section 5.4.3: TrustZone security controller (TZSC)*), the SEC security bit corresponding to this peripheral is set in the GTZC TZSC secure configuration registers.
- For TrustZone®-aware peripherals, a security feature of this peripheral is enabled through its dedicated bits.

Table 129 summarizes the RCC secured bits following the security configuration bit in the RCC_SECCFGR register.

When one security configuration bit is set, some configuration and status bits are secured. The RCC registers may contain secure and nonsecure bits:

- Secure bits: read and write operations are only allowed by secure accesses. Nonsecure read returns 0 and write accesses are ignored. No illegal access event is generated.
- Nonsecure bits: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.
- A nonsecure write access to RCC_SECCFGR is ignored and generates an illegal access event. An illegal access interrupt is generated if the RCC illegal access interrupt is enabled in the GTZC TZIC registers. RCC_SECCFGR can be read by secure or nonsecure accesses.

When the TrustZone® security is disabled (TZEN = 0xC3), all registers are nonsecure. RCC_SECCFGR write accesses are ignored.

Table 129. RCC security configuration summary

Configuration bit in RCC_SECCFGR	Secured bits	Corresponding register
HSISEC	HSION, HSIKERON, HSIRDY	RCC_CR

1. PLL2 is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
2. TRIM field of the HSI48 is located in CRS peripheral. Be sure to secure it using CRSSEC bit in GTZC1 TZSC secure configuration register 1.
3. HSI48 is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

11.6.2 Privileged protection modes

By default, after reset, all RCC registers can be read or written by both privileged and unprivileged accesses, except the registers that can be written with privileged accesses only. *RCC privilege configuration register (RCC_PRIVCFGR)* can be read by secure and nonsecure, privileged, and unprivileged accesses.

The SPRIV bit in RCC_PRIVCFGR can be written with secure privileged accesses only. This bit configures the privileged access of all RCC secure functions (as defined by *RCC secure configuration register (RCC_SECCFGR)*, by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone®-aware peripherals).

When the SPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC secure bits is possible only with privileged accesses, including RCC_SECCFGR.
- The RCC secure bits can be read only with privileged accesses except RCC_SECCFGR and RCC_PRIVCFGR that can be read by privileged or unprivileged accesses.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and the write to these bits is ignored (RAZ/WI).

The NSPRIV bit in RCC_PRIVCFGR can be written with privileged accesses only, secure or nonsecure. This bit configures the privileged access of all RCC nonsecure functions (as defined by RCC_SECCFGR, or by the GTZC for securable peripherals, or by the peripheral itself in case of TrustZone®-aware peripherals).

When the NSPRIV bit is set in RCC_PRIVCFGR:

- Writing the RCC nonsecure bits is possible only with privileged accesses.
- The RCC nonsecure bits can be read only with privileged accesses except RCC_PRIVCFGR that can be read by privileged or unprivileged accesses.
- An unprivileged access to a privileged RCC bit or register is discarded: the bits are read as zero and any write to these bits is ignored (RAZ/WI).

11.6.3 Clock protection

The RCC does not allow to disable the system clock (**sys_ck**). Several protections are implemented to prevent actions accidentally disabling the system clock.

In addition, PLLs and oscillators are also protected to avoid wrong programming sequences.

The protections consist in ignoring the invalid write operations except for SYSSW. Read back the protected registers to ensure that the clock configuration expected by the software is accepted by the RCC.

Table 130 shows the protections handled by the RCC.

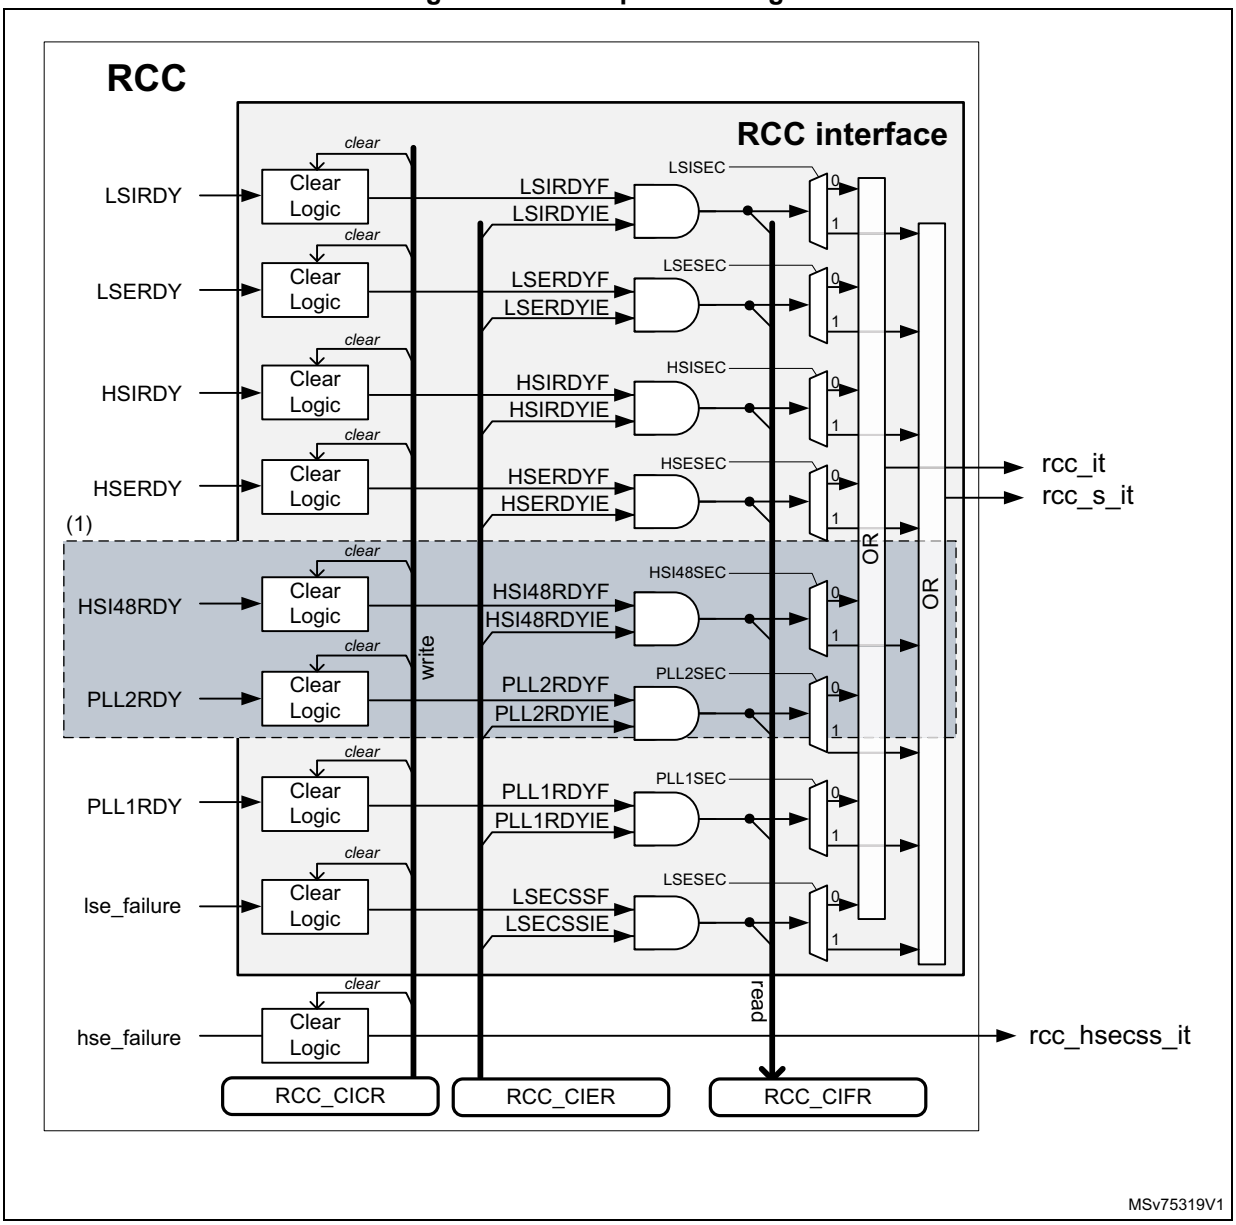
Table 130. Clock protection summary

Protected fields	Conditions checked by the RCC
SYSSW[2:0]	The RCC prevents accidental disabling of the system clock. If SYSSW position is changed to an input having no clock available, the SYSSW remains in its original position. When the clock on the new selected position is activated and ready the SYSSW switched to the new position. It is not possible to disable the clock currently used by the SYSSW. The SYSSWS[1:0] status flag enables the application to check the selected input.
PLLxSRC[1:0]	Changing PLLxSRC value is allowed if: – The targeted clock is enabled and ready, and, – PLLx is disabled
HSEON or HSION	Changing these bits is allowed if the oscillator is not used directly or indirectly (via PLL1) as system clock
PLLxM[5:0], PLLxRGE[1:0], PLLxVCOSEL, PLLxN[8:0], PLLxP[6:0], PLLxQ[6:0], PLLxR[6:0]	Changing these fields is allowed only if the corresponding PLLx is disabled (PLLxON = 0).
PLL1ON	Changing this bit is allowed if SYSSW switch is not selecting the PLL1
PLL1PEN	Changing this bit is allowed if SYSSW switch is not selecting the PLL1
HSEBYP, HSEEXT	Changing these fields is allowed only if HSEON = 0.
LSEBYP	Changing these fields is allowed only if LSEON = 0.

A clock protection mechanism also exists in case of HSE failure (refer to *Section : Clock security system on HSE*).

11.7 RCC interrupts

The RCC provides several interrupt lines:



- rcc_it: general nonsecure interrupt line
- rcc_s_it: general secure interrupt line
- rcc_hsecss_it: interrupt line dedicated to the failure detection of the HSE CSS (clock security system). This line is connected to the NMI of the NVIC. The security level of this interrupt is defined by the BFHFNMINS bit of the AIRCR register, and must be aligned with the HSE security level.

The interrupt enable bits are controlled via the *RCC interrupt enable register (RCC_IER)*, except for the HSE CSS failure. When the HSE CSS feature is enabled, the generated interrupt cannot be masked.

The interrupt flags can be checked via the *RCC interrupt flag register (RCC_IFR)*. These flags can be cleared via *RCC Interrupt clear register (RCC_ICR)*.

Note: The interrupt flags are not relevant if the corresponding interrupt enable bit is not set.

Figure 77. Interrupt block diagram

1. These signals are not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

Table 131 summarizes the interrupt sources and the way to control them.

Table 131. Interrupt sources and control

Interrupt vector	Interrupt event flag	Description	Enable control bits	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby modes
RCC	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 0	Set LSIRDYC	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 0	Set LSERDYC	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 0	Set HSIRDYC	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 0	Set HSERDYC	Yes	No
	LSECSSF	LSE CSS failure	LSECSSIE and LSESEC = 0	Set LSECSSC	Yes	Yes
	HSI48RDYF	HSI48 ready	HSI48RDYIE and HSI48SEC = 0	Set HSI48RDYC	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 0	Set PLL1RDYC	Yes	No
	PLL2RDYF	PLL2 ready	PLL2RDYIE and PLL2SEC = 0	Set PLL2RDYC	Yes	No
RCC_S (1)	LSIRDYF	LSI ready	LSIRDYIE and LSISEC = 1	Set LSIRDYC	Yes	No
	LSERDYF	LSE ready	LSERDYIE and LSESEC = 1	Set LSERDYC	Yes	No
	HSIDRYF	HSI ready	HSIDRYIE and HSISEC = 1	Set HSIRDYC	Yes	No
	HSERDYF	HSE ready	HSERDYIE and HSESEC = 1	Set HSERDYC	Yes	No
	LSECSSF	LSE CSS failure	LSECSSIE and LSESEC = 1	Set LSECSSC	Yes	Yes
	HSI48RDYF (2)	HSI48 ready	HSI48RDYIE and HSI48SEC = 1	Set HSI48RDYC	Yes	No
	PLL1RDYF	PLL1 ready	PLL1RDYIE and PLL1SEC = 1	Set PLL1RDYC	Yes	No
	PLL2RDYF (3)	PLL2 ready	PLL2RDYIE and PLL2SEC = 1	Set PLL2RDYC	Yes	No
TAMP	ITAMP3F(4)	LSE CSS failure	LSECSSON and ITAMP3E(4) and ITAMP3IE(4)	Set CITAMP3F(4)	Yes	Yes
NMI	HSECSSF	HSE CSS failure	(5)	Set HSECSSC	Yes	No

1. The RCC secure interrupt vector is used only when TrustZone® is enabled.
2. HSI48 is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.
3. PLL2 is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

4. The LSE CSS failure event (LSECSSD) is connected to TAMP internal tamper 3. To get the interrupt associated to this event, the internal tamper 3 must be enabled, and the internal tamper 3 interrupt must be enabled. Refer to *Section 50: Tamper and backup registers (TAMP)* for details on the ITAMP3F, ITAMP3E, ITAMP3IE, and CITAMP3F bits.
5. This interrupt cannot be masked when the security system feature is enabled (HSECSSON = 1).

11.8 RCC registers

11.8.1 RCC clock control register (RCC_CR)

Address offset: 0x000

Reset value: 0x0000 0023

Reset by a system reset.

This register contains the main clock control and status bits.

This register can be accessed in secure or nonsecure mode, depending on the HSISEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

		r	rw							r	rw	rw	rw	r	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **PLL2RDY**: PLL2 clock ready flag
Set by hardware to indicate that the PLL is locked.
0: PLL2 unlocked
1: PLL2 locked
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 26 **PLL2ON**: PLL2 enable
Set and cleared by software to enable PLL2.
Cleared by hardware when entering Stop or Standby mode.
0: PLL2 OFF (default after reset)
1: PLL2 ON
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 25 **PLL1RDY**: PLL1 clock ready flag
Set by hardware to indicate that the PLL1 is locked.
0: PLL1 unlocked (default after reset)
1: PLL1 locked

Bit 24 **PLL1ON**: PLL1 enable

Set and cleared by software to enable PLL1.

Cleared by hardware when entering Stop or Standby mode. Note that the hardware prevents clearing this bit if the PLL1 output is used as the system clock.

0: PLL1 OFF (default after reset)

1: PLL1 ON

Bits 23:21 Reserved, must be kept at reset value.

Bit 20 **HSEEXT**: External high-speed clock type in bypass mode

Set and cleared by software to select the external clock type (analog or digital).

The external clock must be enabled through the HSEON bit to be used by the device. The HSEEXT bit can be written only if the HSE oscillator is disabled.

0: HSE in analog mode (default after reset)

1: HSE in digital mode

Bit 19 **HSECSSON**: HSE clock security system enable

Set by software to enable clock security system on HSE.

This bit is “set only” (disabled by a system reset or when the system enters Standby mode). When HSECSSON is set, the clock detector is enabled by hardware when the HSE is ready and disabled by hardware if an oscillator failure is detected.

0: CSS on HSE OFF (clock detector OFF) (default after reset)

1: CSS on HSE ON (clock detector ON if the HSE oscillator is stable, OFF otherwise).

Bit 18 **HSEBYP**: HSE clock bypass

Set and cleared by software to bypass the oscillator with an external clock. The external clock must be enabled through the HSEON bit to be used by the device.

The HSEBYP bit can be written only if the HSE oscillator is disabled.

0: HSE oscillator not bypassed (default after reset)

1: HSE oscillator bypassed with an external clock

Bit 17 **HSERDY**: HSE clock ready flag

Set by hardware to indicate that the HSE oscillator is stable.

0: HSE clock is not ready (default after reset)

1: HSE clock is ready

Bit 16 **HSEON**: HSE clock enable

Set and cleared by software.

Cleared by hardware to stop the HSE when entering Stop or Standby mode.

This bit cannot be cleared if the HSE is used directly (via SYSSW mux) as system clock, or if the HSE is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set).

0: HSE is OFF (default after reset)

1: HSE is ON

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **HSI48RDY**: HSI48 clock ready flag

Set by hardware to indicate that the HSI48 oscillator is stable.

0: HSI48 clock is not ready (default after reset)

1: HSI48 clock is ready

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 12 **HSI48ON**: HSI48 clock enable

Set by software and cleared by software or by the hardware when the system enters to Stop or Standby mode.

0: HSI48 is OFF (default after reset)

1: HSI48 is ON

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 11:6 Reserved, must be kept at reset value.

Bit 5 **HSIDIVF**: HSI divider flag

Set and cleared by hardware.

As a write operation to HSIDIV has no immediate effect on the frequency, this flag indicates the current status of the HSI divider. HSIDIVF goes immediately to 0 when HSIDIV value is changed, and is set back to 1 when the output frequency matches the value programmed into HSIDIV[1:0].

0: new division ratio not yet propagated to hsi_ck, hsi_ker_ck (default after reset)

1: hsi_ck, hsi_ker_ck clock frequency reflects the new HSIDIV value (default register value when the clock setting is completed).

Bits 4:3 **HSIDIV[1:0]**: HSI clock divider

Set and cleared by software.

These bits select the division ratio to configure the wanted HSI clock frequency. The HSIDIV cannot be changed if the HSI is selected as reference clock for at least one enabled PLL (PLLxON bit set). In that case, the new HSIDIV value is ignored.

00: division by 1, hsi_ck, hsi_ker_ck = 64 MHz (default after reset)

01: division by 2, hsi_ck, hsi_ker_ck = 32 MHz

10: division by 4, hsi_ck, hsi_ker_ck = 16 MHz

11: division by 8, hsi_ck, hsi_ker_ck = 8 MHz

Bit 2 **HSIKERON**: HSI clock enable in Stop mode

Set and cleared by software to force the HSI to ON, even in Stop mode, to be quickly available as kernel clock for peripherals. This bit has no effect on the value of HSION. It is recommended to set this bit to 1 only when HSION is set to 1.

0: no effect on HSI (default after reset)

1: HSI is forced to ON even in Stop mode

Bit 1 **HSIRDY**: HSI clock ready flag

Set by hardware to indicate that the HSI oscillator is stable.

0: HSI clock is not ready (default after reset)

1: HSI clock is ready

Bit 0 **HSION**: HSI clock enable

Set and cleared by software.

Set by hardware to force the HSI to ON when the product exits Stop or Standby mode or in case of a HSE failure which is used as the system clock source.

This bit cannot be cleared if the HSI is used directly (via SYSSW mux) as system clock, or if the HSI is selected as reference clock for PLL1 with PLL1 enabled (PLL1ON bit set to 1).

0: HSI is OFF

1: HSI is ON (default after reset)

11.8.2 RCC HSI calibration register (RCC_HSICFGR)

Address offset: 0x010

Reset value: 0x0040 0XXX

The reset value of HSICAL depends on the settings of the flash memory option bytes. HSITRIM[6:0] is reset by a system reset.

This register is used to trim the HSI clock frequency.

This register can be accessed in secure or nonsecure mode, depending on the HSISEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HSITRIM[6:0]

Res.	Res.	Res.	Res.	HSICAL[11:0]											
				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **HSITRIM[6:0]**: HSI clock trimming

Set by software to adjust the calibration.

HSITRIM[6:0] bitfield is added to the engineering option bytes loaded during the reset phase (FLASH_HSI_OPT) to form the calibration trimming value.

HSICAL = HSITRIM[6:0] + FLASH_HSI_OPT.

After a change of HSITRIM[6:0], it takes one system clock cycle before the new HSITRIM[6:0] value is updated

Note: The reset value of the bitfield is 0x40.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **HSICAL[11:0]**: HSI clock calibration

Set by hardware by option byte loading during system reset nreset. Adjusted by software through the trimming bits HSITRIM[6:0].

This bitfield represents the sum of engineering option byte calibration and HSITRIM[6:0] values.

11.8.3 RCC clock recovery RC register (RCC_CRRCR) [a]

Address offset: 0x014

Reset value: 0x0000 0XXX

The reset value depends on the flash option bytes setting

This register shows the calibration value of HSI48.

This register can be accessed in secure or nonsecure mode, depending on the HSI48SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **HSI48CAL[9:0]**: Internal RC 48 MHz clock calibration
Set by hardware by option-byte loading during system reset NRESET. Read-only.

a. This register is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

11.8.4 RCC clock configuration register1 (RCC_CFGR1)

Address offset: 0x01C

Reset value: 0x0000 0000

Reset by system reset

Access: word, half-word, and byte access. One or two wait states are inserted only if the access occurs during the clock source switch.

This register contains the clock configuration bits.

This register can be accessed in secure or nonsecure mode, depending on the setting of the *RCC secure configuration register (RCC_SECCFGR)*, and the RTC security signals. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MCO2SEL[2:0]			MCO2PRE[3:0]				MCO1SEL[2:0]			MCO1PRE[3:0]				Res.	Res.

		rw	rw	rw	rw	rw	rw				r	r		rw	rw

Bits 31:29 **MCO2SEL[2:0]**: microcontroller clock output 2

Set and cleared by software. Clock source selection may generate glitches on MCO2. Configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: system clock selected (**sys_ck**) (default after reset)
001: PLL2 oscillator clock selected (**pll2_p_ck**) (1)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_p_ck**)
100: LSI clock selected (**lsi_ck**)
Others: reserved

Bits 28:25 **MCO2PRE[3:0]**: MCO2 prescaler

Set and cleared by software to configure the prescaler of the MCO2. Modification of this prescaler may generate glitches on MCO2. Change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled, no clock output on MCO2 (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 24:22 **MCO1SEL[2:0]**: Microcontroller clock output 1
Set and cleared by software. Clock source selection may generate glitches on MCO1. Configure these bits only after reset, before enabling the external oscillators and the PLLs.
000: HSI clock selected (**hsi_ck**) (default after reset)
001: LSE oscillator clock selected (**lse_ck**)
010: HSE clock selected (**hse_ck**)
011: PLL1 clock selected (**pll1_q_ck**)
100: HSI48 clock selected (**hsi48_ker_ck**)
Others: reserved

Bits 21:18 **MCO1PRE[3:0]**: MCO1 prescaler
Set and cleared by software to configure the prescaler of the MCO1. Modification of this prescaler may generate glitches on MCO1. Change this prescaler only after reset, before enabling the external oscillators and the PLLs.
0000: prescaler disabled, no clock output on MCO1 (default after reset)
0001: division by 1 (bypass)
0010: division by 2
0011: division by 3
0100: division by 4
...
1111: division by 15

Bits 17:14 Reserved, must be kept at reset value.

Bits 13:8 **RTCPRE[5:0]**: HSE division factor for RTC clock
Set and cleared by software to divide the HSE to generate a clock for RTC.

Caution: The software must set these bits correctly to ensure that the clock supplied to the RTC is lower than 1 MHz. These bits must be configured if needed before selecting the RTC clock source.

000000: no clock (default after reset)
000001: no clock
000010: HSE/2
000011: HSE/3
000100: HSE/4
...
111110: HSE/62
111111: HSE/63

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:3 **SYSSWS[1:0]**: system clock switch status
Set and cleared by hardware to indicate which clock source is used as system clock.
00: HSI used as system clock (**hsi_ck**) (default after reset).
01: HSE used as system clock (**hse_ck**)
10: PLL1 used as system clock (**pll1_p_ck**)
Others: reserved

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SYSSW[1:0]**: system clock and trace clock switch

Set and cleared by software to select system clock and trace clock sources (**sys_ck**).

Set by hardware to:

- Force the selection of the HSI when leaving a system Stop mode
- Force the selection of the HSI in case of failure of the HSE when used directly or indirectly as system clock

00: HSI selected as system clock (**hsi_ck**) (default after reset)

01: HSE selected as system clock (**hse_ck**)

10: PLL1 selected as system clock (**pll1_p_ck**)

Others: reserved

1. This source is not available on STM32G53x/54x devices. When the source is not available, the corresponding input must not be selected. Refer to the device datasheet for availability

11.8.5 RCC CPU domain clock configuration register 2 (RCC_CFGR2)

Address offset: 0x020

Reset value: 0x0000 0000

Reset by system reset

One of two wait states are inserted only if the access occurs during the clock source switch. From 0 to 15 wait states are inserted if the access occurs when an update of the APB or AHB prescalers values is ongoing.

This register contains the clock configuration bits for the APB and AHB buses.

This register can be accessed in secure or nonsecure mode, depending on the PRESCSEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw		rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **APB3DIS**: APB3 clock disable value

Set and cleared by software.

This bit can be set to further reduce power consumption, when none of the APB3 peripherals are used and when their clocks are disabled in the *RCC APB3 peripheral clock enable register (RCC_APB3ENR)*. When this bit is set, all the APB3 peripheral clocks are OFF.

0: APB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB3 clock disabled

Bit 21 **APB2DIS**: APB2 clock disable value

This bit can be set to further reduce power consumption, when none of the APB2 peripherals are used and when their clocks are disabled in the *RCC APB2 peripheral clock enable register (RCC_APB2ENR)*. When this bit is

set, all the APB2 peripheral clocks are off.

0: APB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB2 clock disabled

Bit 20 **APB1DIS**: APB1 clock disable value

This bit can be set to further reduce power consumption, when none of the APB1 peripherals (except IWDG) are used and when their clocks are disabled in *RCC APB1 peripheral clock enable register (RCC_APB1LENR)* and *RCC APB1 peripheral clock enable register (RCC_APB1HENR)*. When this bit is set, all the APB1 peripheral clocks are off, except for IWDG.

0: APB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: APB1 clock disabled

Bit 19 **AHB4DIS**: AHB4 clock disable

This bit can be set to further reduce power consumption, when none of the AHB4 peripherals are used, and when their clocks are disabled in the *RCC AHB4 peripheral clock enable register (RCC_AHB4ENR)*. When this bit is set, all the AHB4 peripheral clocks from RCC_AHB4ENR are OFF.

0: AHB4 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB4 clock disabled

Bit 18 **AHB3DIS**: AHB3 clock disable

This bit can be set to further reduce power consumption, when none of the AHB3 peripherals are used and when their clocks are disabled in the *RCC AHB3 peripheral clock enable register (RCC_AHB3ENR)*. When this bit is set, all the AHB3 peripheral clocks from RCC_AHB3ENR are OFF.

0: AHB3 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB3 clock disabled

Bit 17 **AHB2DIS**: AHB2 clock disable

This bit can be set to further reduce power consumption, when none of the AHB2 peripherals are used and when their clocks are disabled in the *RCC AHB2 peripheral clock enable register (RCC_AHB2ENR)*. When this bit is set, all the AHB2 peripheral clocks are OFF, except for SRAM2 (and SRAM3 if available in the product).

0: AHB2 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB2 clock disabled

Bit 16 **AHB1DIS**: AHB1 clock disable

This bit can be set to further reduce power consumption, when none of the AHB1 peripherals are used and when their clocks are disabled in the *RCC AHB1 peripheral clock enable register (RCC_AHB1ENR)*. When this bit is set, all the AHB1 peripheral clocks are OFF, except for FLASH, ICACHE, DCACHE and SRAM1.

0: AHB1 clock enabled, distributed to peripherals according to their dedicated clock enable control bits

1: AHB1 clock disabled

Note: DCACHE is not always present. Refer to the device datasheet for availability.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **PPRE3[2:0]**: APB low-speed prescaler (APB3)
Set and cleared by software to control the APB low-speed clock division factor.
The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE3 write.
0xx: rcc_pclk3 = rcc_hclk1
100: rcc_pclk3 = rcc_hclk1 / 2
101: rcc_pclk3 = rcc_hclk1 / 4
110: rcc_pclk3 = rcc_hclk1 / 8
111: rcc_pclk3 = rcc_hclk1 / 16

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **PPRE2[2:0]**: APB high-speed prescaler (APB2)
Set and cleared by software to control APB high-speed clocks division factor.
The clocks are divided with the new prescaler factor from 1 to 16 APB cycles after PPRE2 write.
0xx: rcc_pclk2 = rcc_hclk1
100: rcc_pclk2 = rcc_hclk1 / 2
101: rcc_pclk2 = rcc_hclk1 / 4
110: rcc_pclk2 = rcc_hclk1 / 8
111: rcc_pclk2 = rcc_hclk1 / 16

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **PPRE1[2:0]**: APB low-speed prescaler (APB1)
Set and cleared by software to control the division factor of rcc_pclk1.
The clock is divided by the new prescaler factor from 1 to 16 cycles of rcc_hclk after PPRE write.
0xx: rcc_pclk1 = rcc_hclk1 (default after reset)
100: rcc_pclk1 = rcc_hclk1 / 2
101: rcc_pclk1 = rcc_hclk1 / 4
110: rcc_pclk1 = rcc_hclk1 / 8
111: rcc_pclk1 = rcc_hclk1 / 16

Bits 3:0 **HPRE[3:0]**: AHB prescaler
Set and cleared by software to control the division factor of rcc_hclk. Changing this division ratio has an impact on the frequency of all bus matrix clocks
0xxx: rcc_hclk = sys_ck (default after reset)
1000: rcc_hclk = sys_ck / 2
1001: rcc_hclk = sys_ck / 4
1010: rcc_hclk = sys_ck / 8
1011: rcc_hclk = sys_ck / 16
1100: rcc_hclk = sys_ck / 64
1101: rcc_hclk = sys_ck / 128
1110: rcc_hclk = sys_ck / 256
1111: rcc_hclk = sys_ck / 512

Caution: Be careful when using the voltage scaling. Due to the propagation delay of the new division factor, after a prescaler factor change, and before lowering the V_{CORE} voltage, this register must be read to check that the new prescaler value has been taken into account.

Depending on the clock source frequency and the voltage range, the software application must program a correct value in HPRE to make sure that the system frequency does not exceed the maximum frequency.

11.8.6 RCC PLL clock source selection register (RCC_PLL1CFGR)

Address offset: 0x028

Reset value: 0x0000 0000

Access: No wait state, word, half-word, and byte access

This register can be accessed in secure or nonsecure mode, depending on th PLL1SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ICLK1DIV**: Intermediate clock 1 division

Set and cleared by software to select the intermediate clock (ic1_ck) division ratio. There is no need to disable ICLK1 to change the division ratio.

0: Intermediate clock 1 division ratio is 5 (default after reset)

1: Intermediate clock 1 division ratio is 3

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **PLL1REN**: PLL1 DIVR and ICLK1 divider output enable

Set and cleared by software to enable the pll1_r_ck and ic1_ck outputs.

To save power, PLL1REN and PLL1R[6:0] bits must be cleared when the ic1_ck is not used.

0: pll1_r_ck and ic1_ck outputs disabled (default after reset)

1: pll1_r_ck and ic1_ck outputs enabled

Bit 17 **PLL1QEN**: PLL1 DIVQ divider output enable

Set and cleared by software to enable the pll1_q_ck output of the PLL1.

To save power, when the pll1_q_ck output of the PLL1 is not used, the pll1_q_ck must be disabled.

0: pll1_q_ck output disabled (default after reset)

1: pll1_q_ck output enabled

Bit 16 **PLL1PEN**: PLL1 DIVP divider output enable

Set and cleared by software to enable the pll1_p_ck output of the PLL1. The hardware prevents clearing this bit if the PLL1 output is used as the system clock.

To save power, when the pll1_p_ck output of the PLL1 is not used, the pll1_p_ck must be disabled.

0: pll1_p_ck output disabled (default after reset)

1: pll1_p_ck output enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **PLL1M[5:0]**: Prescaler for PLL1

Set and cleared by software to configure the prescaler of the PLL1.
The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
To save power when PLL1 is not used, the value of PLL1M must be cleared.
000000: prescaler disabled (default after reset)
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32
...
111111: division by 63

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PLL1VCOSEL**: PLL1 VCO selection

Set and cleared by software to select the proper VCO frequency range used for PLL1. The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
0: wide VCO range: 128 to 560 MHz (default after reset)
1: medium VCO range: 150 to 420 MHz

Bit 4 **PLL1FRACEN**: PLL1 fractional latch enable

Set and cleared by software to latch the content of PLL1FRACN into the sigma-delta modulator.
To latch the PLL1FRACN value into the sigma-delta modulator, PLL1FRACEN must be cleared, then set. The transition 0 to 1 transfers the content of PLL1FRACN into the modulator.

Bits 3:2 **PLL1RGE[1:0]**: PLL1 input frequency range

Set and cleared by software to select the proper reference frequency range used for PLL1. The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
00: PLL1 input (ref1_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL1 input (ref1_ck) clock range frequency between 2 and 4 MHz
10: PLL1 input (ref1_ck) clock range frequency between 4 and 8 MHz
11: PLL1 input (ref1_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL1SRC[1:0]**: PLL1M and PLLs clock source selection

Set and cleared by software to select the PLL clock source. The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
To save power, when no PLL is used, the value of PLL1SRC must be set to 0b00.
00: no clock sent to PLL1M divider and PLL1 (default after reset).
01: HSI selected as PLL clock (hsi_ck)
10: HSE selected as PLL clock (hse_ck)
11: no clock sent to PLL1M divider and PLL1

11.8.7 RCC PLL clock source selection register (RCC_PLL2CFGR) [a]

Address offset: 0x02C

Reset value: 0x0000 0000

Access: no wait state, word, half-word, and byte access.

This register can be accessed in secure or nonsecure mode, depending on the PLL2SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **ICLK2DIV**: Intermediate clock 2 division

Set and cleared by software to select the intermediate clock (ic2_ck) division ratio. There is no need to disable ICLK2 to change the division ratio.

0: Intermediate clock 2 division ratio is 5 (default after reset)

1: Intermediate clock 2 division ratio is 3

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **PLL2REN**: PLL2 DIVR and ICLK2 divider output enable

Set and cleared by software to enable the pll2_r_ck and ic2_ck outputs.

To save power, PLL2REN and PLL2R[6:0] bits must be cleared when the ic2_ck is not used.

0: pll2_r_ck and ic2_ck output disabled (default after reset)

1: pll2_r_ck and ic2_ck outputs enabled

Bit 17 **PLL2QEN**: PLL2 DIVQ divider output enable

Set and cleared by software to enable the pll2_q_ck output of the PLL2.

To save power, when the pll2_q_ck output of the PLL2 is not used, the pll2_q_ck must be disabled.

0: pll2_q_ck output disabled (default after reset)

1: pll2_q_ck output enabled

a. This register is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

Bit 16 **PLL2PEN**: PLL2 DIVP divider output enable
Set and cleared by software to enable the pll2_p_ck output of the PLL2.
To save power, when the pll2_p_ck output of the PLL2 is not used, the pll2_p_ck must be disabled.
0: pll2_p_ck output disabled (default after reset)
1: pll2_p_ck output enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **PLL2M[5:0]**: prescaler for PLL2
Set and cleared by software to configure the prescaler of the PLL2.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
To save power when PLL2 is not used, the value of PLL2M must be cleared.
000000: prescaler disabled (default after reset)
000001: division by 1 (bypass)
000010: division by 2
000011: division by 3
...
100000: division by 32
...
111111: division by 63

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **PLL2VCOSEL**: PLL2 VCO selection
Set and cleared by software to select the proper VCO frequency range used for PLL2.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
0: wide VCO range: 128 to 560 MHz (default after reset)
1: medium VCO range: 150 to 420 MHz

Bit 4 **PLL2FRACEN**: PLL2 fractional latch enable
Set and cleared by software to latch the content of PLL2FRACN into the sigma-delta modulator. In order to latch the PLL2FRACN value into the sigma-delta modulator, PLL2FRACEN must be cleared, then set. The transition 0 to 1 transfers the content of PLL2FRACN into the modulator.

Bits 3:2 **PLL2RGE[1:0]**: PLL2 input frequency range
Set and cleared by software to select the proper reference frequency range used for PLL2.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
00: PLL2 input (ref2_ck) clock range frequency between 1 and 2 MHz (default after reset)
01: PLL2 input (ref2_ck) clock range frequency between 2 and 4 MHz
10: PLL2 input (ref2_ck) clock range frequency between 4 and 8 MHz
11: PLL2 input (ref2_ck) clock range frequency between 8 and 16 MHz

Bits 1:0 **PLL2SRC[1:0]**: PLL2 clock source selection
Set and cleared by software to select the PLL clock source.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
To save power, when no PLL is used, the value of PLL2SRC must be set to 0b00.
00: no clock send to PLL2M divider and PLL2 (default after reset)
01: HSI selected as PLL2 clock (hsi_ck)
10: HSE selected as PLL2 clock (hse_ck)
11: no clock send to PLL2M divider and PLL2

11.8.8 RCC PLL1 divider register (RCC_PLL1DIVR)

Address offset: 0x034

Reset value: 0x0101 0280

Access: no wait state, word, half-word, and byte access.

This register can be accessed in secure or nonsecure mode, depending on the PLL1SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	PLL1R[6:0]							Res.	PLL1Q[6:0]						
	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw

PLL1P[6:0]								PLL1N[8:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **PLL1R[6:0]**: PLL1 DIVR division factor

Set and cleared by software to control the frequency of the pll1_r_ck clock.
The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
0000000: pll1_r_ck = vco1_ck / 1
0000001: pll1_r_ck = vco1_ck / 2 (default after reset)
0000010: pll1_r_ck = vco1_ck / 3
0000011: pll1_r_ck = vco1_ck / 4
...
1111111: pll1_r_ck = vco1_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PLL1Q[6:0]**: PLL1 DIVQ division factor

Set and cleared by software to control the frequency of the pll1_q_ck clock.
The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
0000000: pll1_q_ck = vco1_ck
0000001: pll1_q_ck = vco1_ck / 2 (default after reset)
0000010: pll1_q_ck = vco1_ck / 3
0000011: pll1_q_ck = vco1_ck / 4
...
1111111: pll1_q_ck = vco1_ck / 128

Bits 15:9 **PLL1P[6:0]**: PLL1 DIVP division factor

Set and cleared by software to control the frequency of the pll1_p_ck clock.
The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
Note that odd division factors are not allowed.
0000000: Not allowed
0000001: pll1_p_ck = vco1_ck / 2 (default after reset)
0000010: Not allowed
0000011: pll1_p_ck = vco1_ck / 4
...
1111111: pll1_p_ck = vco1_ck / 128

Bits 8:0 **PLL1N[8:0]**: Multiplication factor for PLL1VCO

Set and cleared by software to control the multiplication factor of the VCO.
The hardware does not allow any modification of this bitfield when PLL1 is enabled (PLL1ON = 1 or PLL1RDY = 1).
0x003: PLL1N = 4
0x004: PLL1N = 5
0x005: PLL1N = 6
...
0x080: PLL1N = 129 (default after reset)
...
0x1FF: PLL1N = 512
Others: reserved

Caution: The software must set correctly these bits to insure that the VCO output frequency is in the valid frequency range, that is:
128 to 560 MHz if PLL1VCOSEL = 0
150 to 420 MHz if PLL1VCOSEL = 1
VCO output frequency = F_{ref1_ck} x PLL1N, with PLL1N between 4 and 512

11.8.9 RCC PLL1 fractional divider register (RCC_PLL1FRACR)

Address offset: 0x038

Reset value: 0x0000 0000

Access: no wait state, word, and half-word access.

This register can be accessed in secure or nonsecure mode, depending on the PLL1SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

PLL1FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL1FRACN[12:0]**: Fractional part of the multiplication factor for PLL1 VCO

Set and cleared by software to control the fractional part of the multiplication factor of the VCO.

These bits can be written at any time, allowing dynamic fine-tuning of the PLL1 VCO.

VCO output frequency = F_{ref1_ck} × (PLL1N + (PLL1FRACN / 2^{13})), with

- PLL1N between 4 and 512
- PLL1FRACN between 0 and 2^{13} - 1

To change the PLL1FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

1. Clear the bit PLL1FRACEN.
2. Write the new fractional value into PLL1FRACN.
3. Set the bit PLL1FRACEN.

Bits 2:0 Reserved, must be kept at reset value.

11.8.10 RCC PLL2 divider register (RCC_PLL2DIVR) [a]

Address offset: 0x03C

Reset value: 0x0101 0280

Access: no wait state, word, half-word, and byte access.

This register can be accessed in secure or nonsecure mode, depending on the PLL2SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **PLL2R[6:0]**: PLL2 DIVR division factor

Set and cleared by software to control the frequency of the pll2_r_ck clock.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
0000000: pll2_r_ck = vco2_ck
0000001: pll2_r_ck = vco2_ck / 2 (default after reset)
0000010: pll2_r_ck = vco2_ck / 3
0000011: pll2_r_ck = vco2_ck / 4
...
1111111: pll2_r_ck = vco2_ck / 128

Bit 23 Reserved, must be kept at reset value.

Bits 22:16 **PLL2Q[6:0]**: PLL2 DIVQ division factor

Set and cleared by software to control the frequency of the pll2_q_ck clock.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
0000000: pll2_q_ck = vco2_ck
0000001: pll2_q_ck = vco2_ck / 2 (default after reset)
0000010: pll2_q_ck = vco2_ck / 3
0000011: pll2_q_ck = vco2_ck / 4
...
1111111: pll2_q_ck = vco2_ck / 128

a. This register is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

Bits 15:9 **PLL2P[6:0]**: PLL2 DIVP division factor

Set and cleared by software to control the frequency of the pll2_p_ck clock.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
0000000: pll2_p_ck = vco2_ck
0000001: pll2_p_ck = vco2_ck / 2 (default after reset)
0000010: pll2_p_ck = vco2_ck / 3
0000011: pll2_p_ck = vco2_ck / 4
...
1111111: pll2_p_ck = vco2_ck / 128

Bits 8:0 **PLL2N[8:0]**: Multiplication factor for PLL2VCO

Set and cleared by software to control the multiplication factor of the VCO.
The hardware does not allow any modification of this bitfield when PLL2 is enabled (PLL2ON = 1 or PLL2RDY = 1).
0x003: PLL2N = 4
0x004: PLL2N = 5
0x005: PLL2N = 6
...
0x080: PLL2N = 129 (default after reset)
...
0x1FF: PLL2N = 512
Others: reserved

Caution: The software must set correctly these bits to ensure that the VCO output frequency is in the valid frequency range, that is:
128 to 560 MHz if PLL2VCOSEL = 0
150 to 420 MHz if PLL2VCOSEL = 1
VCO output frequency = F_{ref2_ck} x PLL2N, with PLL2N between 4 and 512

11.8.11 RCC PLL2 fractional divider register (RCC_PLL2FRACR) [a]

Address offset: 0x040

Reset value: 0x0000 0000

Access: no wait state; word and half-word access.

This register can be accessed in secure or nonsecure mode, depending on the PLL2SEC bit of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

PLL2FRACN[12:0]													Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw			

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:3 **PLL2FRACN[12:0]:** fractional part of the multiplication factor for PLL2 VCO

Set and cleared by software to control the fractional part of the multiplication factor of the VCO. These bits can be written at any time, allowing dynamic fine-tuning of the PLL2 VCO.

VCO output frequency = F_{ref2_ck} x (PLL2N + (PLL2FRACN / 2^{13})), with

- PLL2N between 4 and 512
- PLL2FRACN between 0 and 2^{13} - 1

To change the PLL2FRACN value on-the-fly even if the PLL is enabled, the application must proceed as follows:

1. Clear the bit PLL2FRACEN.
2. Write the new fractional value into PLL2FRACN.
3. Set the bit PLL2FRACEN.

Bits 2:0 Reserved, must be kept at reset value.

a. This register is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

11.8.12 RCC interrupt enable register (RCC_IER)

Address offset: 0x050

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security bits of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

						rw		rw	rw	rw	rw	rw		rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **LSECSSIE**: LSE clock security system interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the clock security system (CSS) on the LSE oscillator.

0: LSE CSS interrupt disabled (default after reset)

1: LSE CSS interrupt enabled

Bit 8 Reserved, must be kept at reset value.

Bit 7 **PLL2RDYIE**: PLL2 ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the PLL2 lock.

0: PLL2 lock interrupt disabled (default after reset)

1: PLL2 lock interrupt enabled

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **PLL1RDYIE**: PLL1 ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the PLL1 lock.

0: PLL1 lock interrupt disabled (default after reset)

1: PLL1 lock interrupt enabled

Bit 5 **HSI48RDYIE: HSI48 ready interrupt enable**

Set and cleared by software to enable/disable the interrupt caused by the HSI48 oscillator stabilization.

0: HSI48 ready interrupt disabled (default after reset)

1: HSI48 ready interrupt enabled

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **HSERDYIE**: HSE ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the HSE oscillator stabilization.

0: HSE ready interrupt disabled (default after reset)

1: HSE ready interrupt enabled

Bit 3 **HSIRDYIE**: HSI ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the HSI oscillator stabilization.

0: HSI ready interrupt disabled (default after reset)

1: HSI ready interrupt enabled

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LSERDYIE**: LSE ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the LSE oscillator stabilization.

0: LSE ready interrupt disabled (default after reset)

1: LSE ready interrupt enabled

Bit 0 **LSIRDYIE**: LSI ready interrupt enable

Set and cleared by software to enable/disable the interrupt caused by the LSI oscillator stabilization.

0: LSI ready interrupt disabled (default after reset)

1: LSI ready interrupt enabled

11.8.13 RCC interrupt flag register (RCC_IFR)

Address offset: 0x054

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security bits of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

					r	r		r	r	r	r	r		r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSF**: HSE clock security system interrupt flag
Cleared by software by writing HSECSSC bit.
Set by hardware in case of HSE clock failure.
0: no clock security interrupt caused by HSE clock failure (default after reset)
1: clock security interrupt caused by HSE clock failure

Bit 9 **LSECSSF**: LSE clock security system interrupt flag
Cleared by software by writing LSECSSC bit.
Set by hardware in case of LSE clock failure if LSECSSIE is set.
0: no clock security interrupt caused by HSE clock failure (default after reset)
1: clock security interrupt caused by HSE clock failure

Bit 8 Reserved, must be kept at reset value.

Bit 7 **PLL2RDYF**: PLL2 ready interrupt flag
Cleared by software by writing PLL2RDYC bit.
Set by hardware when the PLL2 locks and PLL2RDYIE is set.
0: no clock ready interrupt caused by PLL2 lock (default after reset)
1: clock ready interrupt caused by PLL2 lock

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **PLL1RDYF**: PLL1 ready interrupt flag
Cleared by software by writing PLL1RDYC bit.
Set by hardware when the PLL1 locks and PLL1RDYIE is set.
0: no clock ready interrupt caused by PLL1 lock (default after reset)
1: clock ready interrupt caused by PLL1 lock

Bit 5 **HSI48RDYF**: HSI48 ready interrupt flag
Cleared by software by writing HSI48RDYC bit.
Set by hardware when the HSI48 clock becomes stable and HSI48RDYIE is set.
0: no clock ready interrupt caused by the HSI48 oscillator (default after reset)
1: clock ready interrupt caused by the HSI48 oscillator
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **HSERDYF**: HSE ready interrupt flag
Cleared by software by writing HSERDYC bit.
Set by hardware when the HSE clock becomes stable and HSERDYIE is set.
0: no clock ready interrupt caused by the HSE (default after reset)
1: clock ready interrupt caused by the HSE

Bit 3 **HSIRDYF**: HSI ready interrupt flag
Cleared by software by writing HSIRDYC bit.
Set by hardware when the HSI clock becomes stable and HSIRDYIE is set.
0: no clock ready interrupt caused by the HSI (default after reset)
1: clock ready interrupt caused by the HSI

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LSERDYF**: LSE ready interrupt flag
Cleared by software by writing LSERDYC bit.
Set by hardware when the LSE clock becomes stable and LSERDYIE is set.
0: no clock ready interrupt caused by the LSE (default after reset)
1: clock ready interrupt caused by the LSE

Bit 0 **LSIRDYF**: LSI ready interrupt flag
Cleared by software by writing LSIRDYC bit.
Set by hardware when the LSI clock becomes stable and LSIRDYIE is set.
0: no clock ready interrupt caused by the LSI (default after reset)
1: clock ready interrupt caused by the LSI

11.8.14 RCC Interrupt clear register (RCC_ICR)

Address offset: 0x058

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security bits of the *RCC secure configuration register (RCC_SECCFGR)*. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **HSECSSC**: HSE clock security system interrupt clear
Set by software to clear HSECSSF.
Cleared by hardware when clear done.
0: HSECSSF no effect (default after reset)
1: HSECSSF cleared

Bit 9 **LSECSSC**: LSE clock security system interrupt clear
Set by software to clear LSECSSF.
Cleared by hardware when clear done.
0: LSECSSF no effect (default after reset)
1: LSECSSF cleared

Bit 8 Reserved, must be kept at reset value.

Bit 7 **PLL2RDYC**: PLL2 ready interrupt clear
Set by software to clear PLL2RDYF.
Cleared by hardware when clear done.
0: PLL2RDYF no effect (default after reset)
1: PLL2RDYF cleared

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **PLL1RDYC**: PLL1 ready interrupt clear
Set by software to clear PLL1RDYF.
Cleared by hardware when clear done.
0: PLL1RDYF no effect (default after reset)
1: PLL1RDYF cleared

Bit 5 **HSI48RDYC**: HSI48 ready interrupt clear
Set by software to clear HSI48RDYF.
Cleared by hardware when clear done.
0: HSI48RDYF no effect (default after reset)
1: HSI48RDYF cleared
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **HSERDYC**: HSE ready interrupt clear
Set by software to clear HSERDYF.
Cleared by hardware when clear done.
0: HSERDYF no effect (default after reset)
1: HSERDYF cleared

Bit 3 **HSIRDYC**: HSI ready interrupt clear
Set by software to clear HSIRDYF.
Cleared by hardware when clear done.
0: HSIRDYF no effect (default after reset)
1: HSIRDYF cleared

Bit 2 Reserved, must be kept at reset value.

Bit 1 **LSERDYC**: LSE ready interrupt clear
Set by software to clear LSERDYF.
Cleared by hardware when clear done.
0: LSERDYF no effect (default after reset)
1: LSERDYF cleared

Bit 0 **LSIRDYC**: LSI ready interrupt clear
Set by software to clear LSIRDYF.
Cleared by hardware when clear done.
0: LSIRDYF no effect (default after reset)
1: LSIRDYF cleared

11.8.15 RCC AHB1 reset register (RCC_AHB1RSTR)

Address offset: 0x060

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGRST**: RAMCFG block reset
Set and cleared by software.
0: does not reset RAMCFG block (default after reset)
1: resets RAMCFG block

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMAC1RST**: FMAC1 block reset
Set and cleared by software.
0: does not reset FMAC1 block (default after reset)
1: resets FMAC1 block

Bit 14 **CORDIC1RST**: CORDIC1 block reset
Set and cleared by software.
0: does not reset CORDIC1 block (default after reset)
1: resets CORDIC1 block

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCRST**: CRC block reset Set and cleared by software.
0: does not reset CRC block (default after reset)
1: resets CRC block

Bits 11:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2RST**: GPDMA2 block reset
Set and cleared by software.
0: does not reset GPDMA2 block (default after reset)
1: resets GPDMA2 block

Bit 0 **GPDMA1RST**: GPDMA1 block reset
Set and cleared by software.
0: does not reset GPDMA1 block (default after reset)
1: resets GPDMA1 block

11.8.16 RCC AHB2 peripheral reset register (RCC_AHB2RSTR)

Address offset: 0x064

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

rw						rw	rw	rw	rw	rw	rw			rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADC3RST**: ADC3 blocks reset
Set and cleared by software.
0: does not reset ADC3 blocks (default after reset)
1: resets ADC3 blocks

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **ADC12RST**: ADC1 and 2 blocks reset
Set and cleared by software.
0: does not reset ADC1 and 2 blocks (default after reset)
1: resets ADC1 and 2 blocks

Bit 15 **FMAC2RST**: FMAC2 block reset
Set and cleared by software.
0: does not reset FMAC2 block (default after reset)
1: resets FMAC2 block

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DAC10RST**: DAC10 block reset
Set and cleared by software.
0: does not reset DAC10 block (default after reset)
1: resets DAC10 block

Bit 8 **DAC9RST**: DAC9 block reset
Set and cleared by software.
0: does not reset DAC9 block (default after reset)
1: resets DAC9 block

Bit 7 **DAC8RST**: DAC8 block reset
Set and cleared by software.
0: does not reset DAC8 block (default after reset)
1: resets DAC8 block

Bit 6 **DAC7RST**: DAC7 block reset
Set and cleared by software.
0: does not reset DAC7 block (default after reset)
1: resets DAC7 block

Bit 5 **DAC6RST**: DAC6 block reset
Set and cleared by software.
0: does not reset DAC6 block (default after reset)
1: resets DAC6 block

Bit 4 **DAC5RST**: DAC5 block reset
Set and cleared by software.
0: does not reset DAC5 block (default after reset)
1: resets DAC5 block

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **DAC2RST**: DAC2 block reset
Set and cleared by software.
0: does not reset DAC2 block (default after reset)
1: resets DAC2 block

Bit 0 **DAC1RST**: DAC1 block reset
Set and cleared by software.
0: does not reset DAC1 block (default after reset)
1: resets DAC1 block

11.8.17 RCC AHB4 peripheral reset register (RCC_AHB4RSTR)

Address offset: 0x06C

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	XSPI1RST	Res.	Res.	Res.	GPIOHRST
											rw				rw

rw	rw	rw	rw	rw	rw	rw		rw		rw	rw	rw	rw	rw	rw

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **XSPI1RST**: XSPI1 block reset
Set and cleared by software.
0: does not reset XSPI1 block (default after reset)
1: resets XSPI1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **GPIOHRST**: GPIOH block reset
Set and cleared by software.
0: does not reset the GPIOH block (default after reset)
1: resets the GPIOH block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **GPIOGRST**: GPIOG block reset
Set and cleared by software.
0: does not reset the GPIOG block (default after reset)
1: resets the GPIOG block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **GPIOFRST**: GPIOF block reset
Set and cleared by software.
0: does not reset the GPIOF block (default after reset)
1: resets the GPIOF block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 13 **GPIOERST**: GPIOE block reset
Set and cleared by software.
0: does not reset the GPIOE block (default after reset)
1: resets the GPIOE block

Bit 12 **GPIODRST**: GPIOD block reset
Set and cleared by software.
0: does not reset the GPIOD block (default after reset)
1: resets the GPIOD block

Bit 11 **GPIOCRST**: GPIOC block reset
Set and cleared by software.
0: does not reset the GPIOC block (default after reset)
1: resets the GPIOC block

Bit 10 **GPIOBRST**: GPIOB block reset
Set and cleared by software.
0: does not reset the GPIOB block (default after reset)
1: resets the GPIOB block

Bit 9 **GPIOARST**: GPIOA block reset
Set and cleared by software.
0: does not reset the GPIOA block (default after reset)
1: resets the GPIOA block

Bit 8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1RST**: OTFDEC1 block reset
Set and cleared by software.
0: does not reset OTFDEC1 block (default after reset)
1: resets OTFDEC1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CCBRST**: CCB block reset
Set and cleared by software.
0: does not reset CCB block (default after reset)
1: resets CCB block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **SAESRST**: SAES block reset
Set and cleared by software.
0: does not reset SAES block (default after reset)
1: resets SAES block
Note: This bit is not available on STM32G53x/54x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 3 **PKARST**: PKA block reset
Set and cleared by software.
0: does not reset PKA block (default after reset)
1: resets PKA block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 2 **RNGRST**: RNG block reset
Set and cleared by software.
0: does not reset RNG block (default after reset)
1: resets RNG block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 **HASHRST**: HASH block reset
Set and cleared by software.
0: does not reset HASH block (default after reset)
1: resets HASH block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **AESRST**: AES block reset
Set and cleared by software.
0: does not reset AES block (default after reset)
1: resets AES block
Note: This bit is not available on STM32G53x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

11.8.18 RCC APB1 peripheral low reset register (RCC_APB1LRSTR)

Address offset: 0x074

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw			rw	rw	rw	rw	rw	rw	rw	rw			rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **UART6RST**: UART6 block reset
Set and cleared by software.
0: does not reset the UART6 block (default after reset)
1: resets the UART6 block

Bit 24 **CRSRST**: CRS block reset
Set and cleared by software.
0: does not reset the CRS block (default after reset)
1: resets the CRS block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 23 **I3C1RST**: I3C1 block reset
Set and cleared by software.
0: does not reset the I3C1 block (default after reset)
1: resets the I3C1 block

Bit 22 **I2C2RST**: I2C2 block reset
Set and cleared by software.
0: does not reset the I2C2 block (default after reset)
1: resets the I2C2 block

Bit 21 **I2C1RST**: I2C1 block reset
Set and cleared by software.
0: does not reset the I2C1 block (default after reset)
1: resets the I2C1 block

Bit 20 **UART5RST**: UART5 block reset
Set and cleared by software.
0: does not reset the UART5 block (default after reset)
1: resets the UART5 block

Bit 19 **UART4RST**: UART4 block reset
Set and cleared by software.
0: does not reset the UART4 block (default after reset)
1: resets the UART4 block

Bit 18 **USART3RST**: USART3 block reset
Set and cleared by software.
0: does not reset the USART3 block (default after reset)
1: resets the USART3 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **USART2RST**: USART2 block reset
Set and cleared by software.
0: does not reset the USART2 block (default after reset)
1: resets the USART2 block

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3RST**: SPI3 block reset
Set and cleared by software.
0: does not reset the SPI3 block (default after reset)
1: resets the SPI3 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **SPI2RST**: SPI2 block reset
Set and cleared by software.
0: does not reset the SPI2 block (default after reset)
1: resets the SPI2 block

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **TIM14RST**: TIM14 block reset
Set and cleared by software.
0: does not reset the TIM14 block (default after reset)
1: resets the TIM14 block

Bit 10 **TIM13RST**: TIM13 block reset
Set and cleared by software.
0: does not reset the TIM13 block (default after reset)
1: resets the TIM13 block

Bit 9 **TIM12RST**: TIM12 block reset
Set and cleared by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 8 **TIM11RST**: TIM12 block reset
Set and cleared by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 7 **TIM10RST**: TIM12 block reset
Set and cleared by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 6 **TIM9RST**: TIM12 block reset
Set and cleared by software.
0: does not reset the TIM12 block (default after reset)
1: resets the TIM12 block

Bit 5 **TIM7RST**: TIM7 block reset
Set and cleared by software.
0: does not reset the TIM7 block (default after reset)
1: resets the TIM7 block

Bit 4 **TIM6RST**: TIM6 block reset
Set and cleared by software.
0: does not reset the TIM6 block (default after reset)
1: resets the TIM6 block

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM3RST**: TIM3 block reset
Set and cleared by software.
0: does not reset the TIM3 block (default after reset)
1: resets the TIM3 block

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **TIM2RST**: TIM2 block reset
Set and cleared by software.
0: does not reset the TIM2 block (default after reset)
1: resets the TIM2 block

11.8.19 RCC APB1 peripheral high reset register (RCC_APB1HRSTR)

Address offset: 0x078

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1RST**: UCPD1 block reset
Set and cleared by software.
0: does not reset the UCPD1 block (default after reset)
1: resets the UCPD1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANRST**: FDCAN1, FDCAN2 and FDCAN3 block reset
Set and cleared by software.
0: does not reset the FDCAN1, FDCAN2 and FDCAN3 blocks (default after reset)
1: resets the FDCAN1, FDCAN2 and FDCAN3 blocks
Note: This bit is not available on STM32G53x/54x devices. When the bit is not available the corresponding input must not be selected. Refer to the device datasheet for availability.
Some STM32G56x/55x/54x/53x devices only have one FDCAN instance. Refer to the device datasheet for availability.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **DTSRST**: DTS block reset
Set and cleared by software.
0: does not reset the DTS block (default after reset)
1: resets the DTS block

Bits 2:0 Reserved, must be kept at reset value.

11.8.20 RCC APB2 peripheral reset register (RCC_APB2RSTR)

Address offset: 0x07C

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TIM5RST**: TIM5 block reset
Set and cleared by software.
0: does not reset the TIM5 block (default after reset)
1: resets the TIM5 block

Bit 29 **TIM4RST**: TIM4 block reset
Set and cleared by software.
0: does not reset the TIM4 block (default after reset)
1: resets the TIM4 block

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **USBRST**: USB block reset
Set and cleared by software.
0: does not reset the USB block (default after reset)
1: resets the USB block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **TIM17RST**: TIM17 block reset
Set and cleared by software.
0: does not reset the TIM17 block (default after reset)
1: resets the TIM17 block

Bit 17 **TIM16RST**: TIM16 block reset
Set and cleared by software.
0: does not reset the TIM16 block (default after reset)
1: resets the TIM16 block

Bit 16 **TIM15RST**: TIM15 block reset
Set and cleared by software.
0: does not reset the TIM15 block (default after reset)
1: resets the TIM15 block

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1RST**: USART1 block reset
Set and cleared by software.
0: does not reset the USART1 block (default after reset)
1: resets the USART1 block

Bit 13 **TIM8RST**: TIM8 block reset
Set and cleared by software.
0: does not reset the TIM8 block (default after reset)
1: resets the TIM8 block

Bit 12 **SPI1RST**: SPI1 block reset
Set and cleared by software.
0: does not reset the SPI1 block (default after reset)
1: resets the SPI1 block

Bit 11 **TIM1RST**: TIM1 block reset
Set and cleared by software.
0: does not reset the TIM1 block (default after reset)
1: resets the TIM1 block

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **PLAY1APPRST**: PLAY1 application block reset
Set and cleared by software. This bit reset the PLAY1 but not its configuration. When the reset is released the PLAY1 restarts.
0: does not reset PLAY1 block (default after reset)
1: resets PLAY1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 2 **PLAY1RST**: PLAY1 global block reset
Set and cleared by software. This bit resets the PLAY1 block including its configuration.
0: does not reset PLAY1 block (default after reset)
1: resets PLAY1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **HRTIM1RST**: HRTIM1 block reset
Set and cleared by software.
0: does not reset the HRTIM1 block (default after reset)
1: resets the HRTIM1 block

11.8.21 RCC APB3 peripheral reset register (RCC_APB3RSTR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 **COMP8RST**: COMP8 block reset
Set and cleared by software.
0: does not reset the COMP8 block (default after reset)
1: resets the COMP8 block

Bit 30 **COMP7RST**: COMP7 block reset
Set and cleared by software.
0: does not reset the COMP7 block (default after reset)
1: resets the COMP7 block

Bit 29 **COMP6RST**: COMP6 block reset
Set and cleared by software.
0: does not reset the COMP6 block (default after reset)
1: resets the COMP6 block

Bit 28 **COMP5RST**: COMP5 block reset
Set and cleared by software.
0: does not reset the COMP5 block (default after reset)
1: resets the COMP5 block

Bit 27 **COMP4RST**: COMP4 block reset
Set and cleared by software.
0: does not reset the COMP4 block (default after reset)
1: resets the COMP4 block

Bit 26 **COMP3RST**: COMP3 block reset
Set and cleared by software.
0: does not reset the COMP3 block (default after reset)
1: resets the COMP3 block

Bit 25 **COMP2RST**: COMP2 block reset
Set and cleared by software.
0: does not reset the COMP2 block (default after reset)
1: resets the COMP2 block

Bit 24 **COMP1RST**: COMP1 block reset
Set and cleared by software.
0: does not reset the COMP1 block (default after reset)
1: resets the COMP1 block

Bit 23 Reserved, must be kept at reset value.

Bit 22 **VREFRST**: VREFBUF block reset
Set and cleared by software.
0: does not reset the VREFBUF block (default after reset)
1: resets the VREFBUF block

Bits 21:19 Reserved, must be kept at reset value.

Bit 18 **OPAMP3RST**: OPAMP3 block reset
Set and cleared by software.
0: does not reset the OPAMP3 block (default after reset)
1: resets the OPAMP3 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **OPAMP2RST**: OPAMP2 block reset
Set and cleared by software.
0: does not reset the OPAMP2 block (default after reset)
1: resets the OPAMP2 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **OPAMP1RST**: OPAMP1 block reset
Set and cleared by software.
0: does not reset the OPAMP1 block (default after reset)
1: resets the OPAMP1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **POSENC2RST**: POSENC2 block reset
Set and cleared by software.
0: does not reset the POSENC2 block (default after reset)
1: resets the POSENC2 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **POSENC1RST**: POSENC1 block reset
Set and cleared by software.
0: does not reset the POSENC1 block (default after reset)
1: resets the POSENC1 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1RST**: LPTIM1 block reset
Set and cleared by software.
0: does not reset the LPTIM1 block (default after reset)
1: resets the LPTIM1 block

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4RST**: I2C4 block reset
Set and cleared by software.
0: does not reset the I2C4 block (default after reset)
1: resets the I2C4 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 7 **I2C3RST**: I2C3 block reset
Set and cleared by software.
0: does not reset the I2C3 block (default after reset)
1: resets the I2C3 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **LPUART1RST**: LPUART1 block reset
Set and cleared by software.
0: does not reset the LPUART1 block (default after reset)
1: resets the LPUART1 block

Bit 5 Reserved, must be kept at reset value.

Bit 4 **TIM27RST**: TIM27 block reset
Set and cleared by software.
0: does not reset the TIM27 block (default after reset)
1: resets the TIM27 block

Bit 3 **TIM26RST**: TIM26 block reset
Set and cleared by software.
0: does not reset the TIM26 block (default after reset)
1: resets the TIM26 block

Bit 2 **TIM20RST**: TIM20 block reset
Set and cleared by software.
0: does not reset the TIM20 block (default after reset)
1: resets the TIM20 block
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 1:0 Reserved, must be kept at reset value.

11.8.22 RCC AHB1 peripheral clock enable register (RCC_AHB1ENR)

Address offset: 0x088

Reset value: 0xCC00 0100

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 **SRAM1EN**:SRAM1 clock enable
Set and cleared by software.
0: SRAM1 clock disabled
1: SRAM1 clock enabled (default after reset)

Bit 30 **DCACHEEN**: DCACHE clock enable
Set and cleared by software
0: DCACHE peripheral clock disabled
1: DCACHE peripheral clock enabled (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **SRAM3EN**:SRAM3 clock enable
Set and cleared by software.
0: SRAM3 clock disabled
1: SRAM3 clock enabled (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 26 **SRAM2EN**:SRAM2 clock enable
Set and cleared by software.
0: SRAM2 clock disabled
1: SRAM2 clock enabled (default after reset)

Bit 25 Reserved, must be kept at reset value.

Bit 24 **TZSC1EN**: TZSC1 clock enable
Set and cleared by software
0: TZSC1 peripheral clock disabled (default after reset)
1: TZSC1 peripheral clock enabled

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGEN**: RAMCFG clock enable
Set and cleared by software.
0: RAMCFG peripheral clock disabled (default after reset)
1: RAMCFG peripheral clock enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMAC1EN**: FMAC1 clock enable
Set and cleared by software.
0: FMAC1 peripheral clock disabled (default after reset)
1: FMAC1 peripheral clock enabled

Bit 14 **CORDIC1EN**: CORDIC1 clock enable
Set and cleared by software.
0: CORDIC1 peripheral clock disabled (default after reset)
1: CORDIC1 peripheral clock enable

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCEN**: CRC clock enable
Set and cleared by software.
0: CRC peripheral clock disabled (default after reset)
1: CRC peripheral clock enabled

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHEN**: Flash memory interface clock enable
Set and cleared by software.
0: Flash memory interface clock disabled
1: Flash memory interface clock enabled (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2EN**: GPDMA2 clock enable
Set and cleared by software.
0: GPDMA2 peripheral clock disabled (default after reset)
1: GPDMA2 peripheral clock enabled

Bit 0 **GPDMA1EN**: GPDMA1 clock enable
Set and cleared by software.
0: GPDMA1 peripheral clock disabled (default after reset)
1: GPDMA1 peripheral clock enabled

11.8.23 RCC AHB2 peripheral clock enable register (RCC_AHB2ENR)

Address offset: 0x08C

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **ADC3EN**: ADC3 peripheral clocks enable
Set and cleared by software.
0: ADC3 peripheral clocks disabled (default after reset)
1: ADC3 peripheral clocks enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **ADC12EN**: ADC1 and ADC2 peripheral clocks enable
Set and cleared by software.
0: ADC1 and ADC2 peripheral clocks disabled (default after reset)
1: ADC1 and ADC2 peripheral clocks enabled

Bit 15 **FMAC2EN**: FMAC2 clock enable
Set and cleared by software.
0: FMAC2 peripheral clock disabled (default after reset)
1: FMAC2 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DAC10EN**: DAC10 clock enable
Set and cleared by software.
0: DAC10 peripheral clock disabled (default after reset)
1: DAC10 peripheral clock enabled

Bit 8 **DAC9EN**: DAC9 clock enable
Set and cleared by software.
0: DAC9 peripheral clock disabled (default after reset)
1: DAC9 peripheral clock enabled

Bit 7 **DAC8EN**: DAC8 clock enable
Set and cleared by software.
0: DAC8 peripheral clock disabled (default after reset)
1: DAC8 peripheral clock enabled

Bit 6 **DAC7EN**: DAC7 clock enable
Set and cleared by software.
0: DAC7 peripheral clock disabled (default after reset)
1: DAC7 peripheral clock enabled

Bit 5 **DAC6EN**: DAC6 clock enable
Set and cleared by software.
0: DAC6 peripheral clock disabled (default after reset)
1: DAC6 peripheral clock enabled

Bit 4 **DAC5EN**: DAC5 clock enable
Set and cleared by software.
0: DAC5 peripheral clock disabled (default after reset)
1: DAC5 peripheral clock enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **DAC2EN**: DAC2 clock enable
Set and cleared by software.
0: DAC2 peripheral clock disabled (default after reset)
1: DAC2 peripheral clock enabled

Bit 0 **DAC1EN**: DAC1 clock enable
Set and cleared by software.
0: DAC1 peripheral clock disabled (default after reset)
1: DAC1 peripheral clock enabled

11.8.24 RCC AHB3 peripheral clock enable register (RCC_AHB3ENR)

Address offset: 0x090

Reset value: 0x0000 0000

This register has no security or privilege protection.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **XSPI1EN**: XSPI1 clock enable
Set and cleared by software.
0: XSPI1 peripheral clock disabled (default after reset)
1: XSPI1 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **GPIOHEN**: GPIOH clock enable
Set and cleared by software.
0: GPIOH peripheral clock disabled (default after reset)
1: GPIOH peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **GPIOGEN**: GPIOG clock enable
Set and cleared by software.
0: GPIOG peripheral clock disabled (default after reset)
1: GPIOG peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **GPIOFEN**: GPIOF clock enable
Set and cleared by software.
0: GPIOF peripheral clock disabled (default after reset)
1: GPIOF peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 13 **GPIOEEN**: GPIOE clock enable
Set and cleared by software.
0: GPIOE peripheral clock disabled (default after reset)
1: GPIOE peripheral clock enabled

Bit 12 **GPIODEN**: GPIOD clock enable
Set and cleared by software.
0: GPIOD peripheral clock disabled (default after reset)
1: GPIOD peripheral clock enabled

Bit 11 **GPIOCEN**: GPIOC clock enable
Set and cleared by software.
0: GPIOC peripheral clock disabled (default after reset)
1: GPIOC peripheral clock enabled

Bit 10 **GPIOBEN**: GPIOB clock enable
Set and cleared by software.
0: GPIOB peripheral clock disabled (default after reset)
1: GPIOB peripheral clock enabled

Bit 9 **GPIOAEN**: GPIOA clock enable
Set and cleared by software.
0: GPIOA peripheral clock disabled (default after reset)
1: GPIOA peripheral clock enabled

Bit 8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1EN**: OTFDEC1 clock enable
Set and cleared by software.
0: OTFDEC1 peripheral clock disabled (default after reset)
1: OTFDEC1 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CCBEN**: CCB clock enable
Set and cleared by software.
0: CCB peripheral clock disabled (default after reset)
1: CCB peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **SAESEN**: SAES clock enable
Set and cleared by software.
0: SAES peripheral clock disabled (default after reset)
1: SAES peripheral clock enabled
Note: This bit is not available on STM32G53x/54x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 3 **PKAEN**: PKA clock enable
Set and cleared by software.
0: PKA peripheral clock disabled (default after reset)
1: PKA peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 2 **RNGEN**: RNG clock enable
Set and cleared by software.
0: RNG peripheral clock disabled (default after reset)
1: RNG peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 **HASHEN**: HASH clock enable
Set and cleared by software.
0: HASH peripheral clock disabled (default after reset)
1: HASH peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **AESEN**: AES clock enable
Set and cleared by software.
0: AES peripheral clock disabled (default after reset)
1: AES peripheral clock enabled
Note: This bit is not available on STM32G53x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

11.8.26 RCC APB1 peripheral clock enable register (RCC_APB1LENR)

Address offset: 0x09C

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **UART6EN**: UART6 clock enable
Set and cleared by software.
0: UART6 peripheral clock disabled (default after reset)
1: UART6 peripheral clock enabled

Bit 24 **CRSEN**: CRS clock enable
Set and cleared by software.
0: CRS peripheral clock disabled (default after reset)
1: CRS peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 23 **I3C1EN**: I3C1 clock enable
Set and cleared by software.
0: I3C1 peripheral clock disabled (default after reset)
1: I3C1 peripheral clock enabled

Bit 22 **I2C2EN**: I2C2 clock enable
Set and cleared by software.
0: I2C2 peripheral clock disabled (default after reset)
1: I2C2 peripheral clock enabled

Bit 21 **I2C1EN**: I2C1 clock enable
Set and cleared by software.
0: I2C1 peripheral clock disabled (default after reset)
1: I2C1 peripheral clock enabled

Bit 20 **UART5EN**: UART5 clock enable
Set and cleared by software.
0: UART5 peripheral clock disabled (default after reset)
1: UART5 peripheral clock enabled

Bit 19 **UART4EN**: UART4 clock enable
Set and cleared by software.
0: UART4 peripheral clock disabled (default after reset)
1: UART4 peripheral clock enabled

Bit 18 **USART3EN**: USART3 clock enable
Set and cleared by software.
0: USART3 peripheral clock disabled (default after reset)
1: USART3 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **USART2EN**: USART2 clock enable
Set and cleared by software.
0: USART2 peripheral clock disabled (default after reset)
1: USART2 peripheral clock enabled

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3EN**: SPI3 clock enable
Set and cleared by software.
0: SPI3 peripheral clock disabled (default after reset)
1: SPI3 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **SPI2EN**: SPI2 clock enable
Set and cleared by software.
0: SPI2 peripheral clock disabled (default after reset)
1: SPI2 peripheral clock enabled

Bit 13 Reserved, must be kept at reset value.

Bit 12 **WWDGEN**: WWDG clock enable
This bit is set by software to enable the window watchdog clock. It is reset by hardware system reset. This bit can also be set by hardware if the WWDG_SW option bit is reset.
0: WWDG peripheral clock disabled (default after reset)
1: WWDG peripheral clock enabled

Bit 11 **TIM14EN**: TIM14 clock enable
Set and cleared by software.
0: TIM14 peripheral clock disabled (default after reset)
1: TIM14 peripheral clock enabled

Bit 10 **TIM13EN**: TIM13 clock enable
Set and cleared by software.
0: TIM13 peripheral clock disabled (default after reset)
1: TIM13 peripheral clock enabled

Bit 9 **TIM12EN**: TIM12 clock enable
Set and cleared by software.
0: TIM12 peripheral clock disabled (default after reset)
1: TIM12 peripheral clock enabled

Bit 8 **TIM11EN**: TIM11 clock enable
Set and cleared by software.
0: TIM11 peripheral clock disabled (default after reset)
1: TIM11 peripheral clock enabled

Bit 7 **TIM10EN**: TIM10 clock enable
Set and cleared by software.
0: TIM10 peripheral clock disabled (default after reset)
1: TIM10 peripheral clock enabled

Bit 6 **TIM9EN**: TIM9 clock enable
Set and cleared by software.
0: TIM9 peripheral clock disabled (default after reset)
1: TIM9 peripheral clock enabled

Bit 5 **TIM7EN**: TIM7 clock enable
Set and cleared by software.
0: TIM7 peripheral clock disabled (default after reset)
1: TIM7 peripheral clock enabled

Bit 4 **TIM6EN**: TIM6 clock enable
Set and cleared by software.
0: TIM6 peripheral clock disabled (default after reset)
1: TIM6 peripheral clock enabled

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM3EN**: TIM3 clock enable
Set and cleared by software.
0: TIM3 peripheral clock disabled (default after reset)
1: TIM3 peripheral clock enabled

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **TIM2EN**: TIM2 clock enable
Set and cleared by software.
0: TIM2 peripheral clock disabled (default after reset)
1: TIM2 peripheral clock enabled

11.8.27 RCC APB1 peripheral clock enable register (RCC_APB1HENR)

Address offset: 0x0A0

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1EN**: UCPD1 clock enable
Set and cleared by software.
0: UCPD1 peripheral clock disabled (default after reset)
1: UCPD1 peripheral clock enabled

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANEN**: FDCAN1, FDCAN2 and FDCAN3 peripheral clock enable
Set and cleared by software.
0: FDCAN1, FDCAN2 and FDCAN3 peripheral clock disabled (default after reset)
1: FDCAN1, FDCAN2 and FDCAN3 peripheral clock enabled

Note: Some STM32G56x/55x/54x/53x devices only have one FDCAN instance. Refer to the device datasheet for availability.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **DTSEN**: DTS clock enable
Set and cleared by software.
0: DTS peripheral clock disabled (default after reset)
1: DTS peripheral clock enabled

Bits 2:0 Reserved, must be kept at reset value.

11.8.28 RCC APB2 peripheral clock enable register (RCC_APB2ENR)

Address offset: 0x0A4

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TIM5EN**: TIM5 clock enable
Set and cleared by software.
0: TIM5 peripheral clock disabled (default after reset)
1: TIM5 peripheral clock enabled

Bit 29 **TIM4EN**: TIM4 clock enable
Set and cleared by software.
0: TIM4 peripheral clock disabled (default after reset)
1: TIM4 peripheral clock enabled

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **USBEN**: USB clock enable
Set and cleared by software.
0: USB peripheral clock disabled (default after reset)
1: USB peripheral clock enabled

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **TIM17EN**: TIM17 clock enable
Set and cleared by software.
0: TIM17 peripheral clock disabled (default after reset)
1: TIM17 peripheral clock enabled

Bit 17 **TIM16EN**: TIM16 clock enable
Set and cleared by software.
0: TIM16 peripheral clock disabled (default after reset)
1: TIM16 peripheral clock enabled

Bit 16 **TIM15EN**: TIM15 clock enable
Set and cleared by software.
0: TIM15 peripheral clock disabled (default after reset)
1: TIM15 peripheral clock enabled

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1EN**: USART1 clock enable
Set and cleared by software.
0: USART1 peripheral clock disabled (default after reset)
1: USART1 peripheral clock enabled

Bit 13 **TIM8EN**: TIM8 clock enable
Set and cleared by software.
0: TIM8 peripheral clock disabled (default after reset)
1: TIM8 peripheral clock enabled

Bit 12 **SPI1EN**: SPI1 clock enable
Set and cleared by software.
0: SPI1 peripheral clock disabled (default after reset)
1: SPI1 peripheral clock enabled

Bit 11 **TIM1EN**: TIM1 clock enable
Set and cleared by software.
0: TIM1 peripheral clock disabled (default after reset)
1: TIM1 peripheral clock enabled

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **PLAY1EN**: PLAY1 clock enable
Set and cleared by software.
0: PLAY1 peripheral clock disabled (default after reset)
1: PLAY1 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 2 **PLAY1APBEN**: PLAY1 APB clock enable
Set and cleared by software.
0: PLAY1 APB clock disabled (default after reset)
1: PLAY1 APB clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **HRTIM1EN**: HRTIM1 clock enable
Set and cleared by software.
0: HRTIM1 peripheral clock disabled (default after reset)
1: HRTIM1 peripheral clock enabled

11.8.29 RCC APB3 peripheral clock enable register (RCC_APB3ENR)

Address offset: 0x0A8

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 **COMP8EN**: COMP8 clock enable
Set and cleared by software.
0: COMP8 clock disabled (default after reset)
1: COMP8 clock enabled

Bit 30 **COMP7EN**: COMP7 clock enable
Set and cleared by software.
0: COMP7 clock disabled (default after reset)
1: COMP7 clock enabled

Bit 29 **COMP6EN**: COMP6 clock enable
Set and cleared by software.
0: COMP6 clock disabled (default after reset)
1: COMP6 clock enabled

Bit 28 **COMP5EN**: COMP5 clock enable
Set and cleared by software.
0: COMP5 clock disabled (default after reset)
1: COMP5 clock enabled

Bit 27 **COMP4EN**: COMP4 clock enable
Set and cleared by software.
0: COMP4 clock disabled (default after reset)
1: COMP4 clock enabled

Bit 26 **COMP3EN**: COMP3 clock enable
Set and cleared by software.
0: COMP3 clock disabled (default after reset)
1: COMP3 clock enabled

Bit 25 **COMP2EN**: COMP2 clock enable
Set and cleared by software.
0: COMP2 clock disabled (default after reset)
1: COMP2 clock enabled

Bit 24 **COMP1EN**: COMP1 clock enable
Set and cleared by software.
0: COMP1 clock disabled (default after reset)
1: COMP1 clock enabled

Bit 23 **RTCAPBEN**: RTC APB interface clock enable
Set and cleared by software.
0: RTC APB interface clock disabled (default after reset)
1: RTC APB interface clock enabled

Bit 22 **VREFEN**: VREFBUF clock enable
Set and cleared by software.
0: VREFBUF peripheral clock disabled (default after reset)
1: VREFBUF peripheral clock enabled

Bits 21:19 Reserved, must be kept at reset value.

Bit 18 **OPAMP3EN**: OPAMP3 clock enable
Set and cleared by software.
0: OPAMP3 clock disabled (default after reset)
1: OPAMP3 clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **OPAMP2EN**: OPAMP2 clock enable
Set and cleared by software.
0: OPAMP2 clock disabled (default after reset)
1: OPAMP2 clock enabled
This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **OPAMP1EN**: OPAMP1 clock enable
Set and cleared by software.
0: OPAMP1 clock disabled (default after reset)
1: OPAMP1 clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **POSENC2EN**: POSENC2 clock enable
Set and cleared by software.
0: POSENC2 clock disabled (default after reset)
1: POSENC2 clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **POSENC1EN**: POSENC1 clock enable
Set and cleared by software.
0: POSENC1 clock disabled (default after reset)
1: POSENC1 clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1EN**: LPTIM1 clock enable
Set and cleared by software.
0: LPTIM1 peripheral clock disabled (default after reset)
1: LPTIM1 peripheral clock enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4EN**: I2C4 clock enable
Set and cleared by software.
0: I2C4 peripheral clock disabled (default after reset)
1: I2C4 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 7 **I2C3EN**: I2C3 clock enable
Set and cleared by software.
0: I2C3 peripheral clock disabled (default after reset)
1: I2C3 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **LPUART1EN**: LPUART1 clock enable
Set and cleared by software.
0: LPUART1 peripheral clock disabled (default after reset)
1: LPUART1 peripheral clock enabled

Bit 5 Reserved, must be kept at reset value.

Bit 4 **TIM27EN**: TIM27 clock enable
Set and cleared by software.
0: TIM27 peripheral clock disabled (default after reset)
1: TIM27 peripheral clock enabled

Bit 3 **TIM26EN**: TIM26 clock enable
Set and cleared by software.
0: TIM26 peripheral clock disabled (default after reset)
1: TIM26 peripheral clock enabled

Bit 2 **TIM20EN**: TIM20 clock enable
Set and cleared by software.
0: TIM20 peripheral clock disabled (default after reset)
1: TIM20 peripheral clock enabled
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 **SBSEN**: SBS clock enable
Set and cleared by software.
0: SBS peripheral clock disabled (default after reset)
1: SBS peripheral clock enabled

Bit 0 Reserved, must be kept at reset value.

11.8.30 RCC AHB1 peripheral low-power clock enable register (RCC_AHB1LPENR)

Address offset: 0x0B0

Reset value: 0xED02 D103

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Set and cleared by software
0: SRAM1 clock disabled in low-power mode
1: SRAM1 clock enabled in low-power mode (default after reset)

Bit 30 **DCACHELPEN**: DCACHE clock enable in low-power mode
Set and cleared by software
0: DCACHE peripheral clock disabled in low-power mode
1: DCACHE peripheral clock enabled in low-power mode (default after reset)

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 29 **ICACHELPEN**: ICACHE clock enable in low-power mode
Set and cleared by software
0: ICACHE peripheral clock disabled in low-power mode
1: ICACHE peripheral clock enabled in low-power mode (default after reset)

Bit 28 Reserved, must be kept at reset value.

Bit 27 **SRAM3LPEN**: SRAM3 clock enable in low-power mode
Set and cleared by software
0: SRAM3 peripheral clock disabled in low-power mode
1: SRAM3 peripheral clock enabled in low-power mode (default after reset)

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 26 **SRAM2LPEN**: SRAM2 clock enable in low-power mode
Set and cleared by software
0: SRAM2 peripheral clock disabled in low-power mode
1: SRAM2 peripheral clock enabled in low-power mode (default after reset)

Bit 25 Reserved, must be kept at reset value.

Bit 24 **TZSC1LPEN**: TZSC1 clock enable in low-power mode
Set and cleared by software
0: TZSC1 peripheral clock disabled in low-power mode
1: TZSC1 peripheral clock enabled in low-power mode (default after reset)

Bits 23:18 Reserved, must be kept at reset value.

Bit 17 **RAMCFGLPEN**: RAMCFG clock enable in low-power mode
Set and cleared by software.
0: RAMCFG peripheral clock disabled in low-power mode
1: RAMCFG peripheral clock enabled in low-power mode (default after reset)

Bit 16 Reserved, must be kept at reset value.

Bit 15 **FMAC1LPEN**: FMAC1 clock enable in low-power mode
Set and cleared by software.
0: FMAC1 peripheral clock disabled in low-power mode
1: FMAC1 peripheral clock enabled in low-power mode (default after reset)

Bit 14 **CORDIC1LPEN**: CORDIC1 clock enable in low-power mode
Set and cleared by software.
0: CORDIC1 peripheral clock disabled in low-power mode
1: CORDIC1 peripheral clock enabled in low-power mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CRCLPEN**: CRC clock enable in low-power mode
Set and cleared by software.
0: CRC peripheral clock disabled in low-power mode
1: CRC peripheral clock enabled in low-power mode (default after reset)

Bits 11:9 Reserved, must be kept at reset value.

Bit 8 **FLASHLPEN**: Flash memory interface clock enable in low-power mode
Set and cleared by software.
0: Flash memory interface clock disabled in low-power mode
1: Flash memory interface clock enabled in low-power mode (default after reset)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **GPDMA2LPEN**: GPDMA2 clock enable in low-power mode
Set and cleared by software.
0: GPDMA2 peripheral clock disabled in low-power mode
1: GPDMA2 peripheral clock enabled in low-power mode (default after reset)

Bit 0 **GPDMA1LPEN**: GPDMA1 clock enable in low-power mode
Set and cleared by software.
0: GPDMA1 peripheral clock disabled in low-power mode
1: GPDMA1 peripheral clock enabled in low-power mode (default after reset)

11.8.31 RCC AHB2 peripheral low-power clock enable register (RCC_AHB2LPENR)

Address offset: 0x0B4

Reset value: 0x0003 83F3

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 17 **ADC3LPEN**: ADC3 peripheral clock enable in low-power mode
Set and cleared by software.
0: ADC3 peripheral clocks disabled in low-power mode
1: ADC3 peripheral clocks enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **ADC12LPEN**: ADC1 and 2 peripheral clock enable in low-power mode
Set and cleared by software.
0: ADC1 and 2 peripheral clock disabled in low-power mode
1: ADC1 and 2 peripheral clock enabled in low-power mode (default after reset)

Bit 15 **FMAC2LPEN**: FMAC2 clock enable in low-power mode
Set and cleared by software.
0: FMAC2 peripheral clock disabled in low-power mode
1: FMAC2 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DAC10LPEN**: DAC10 clock enable in low-power mode
Set and cleared by software.
0: DAC10 peripheral clock disabled in low-power mode
1: DAC10 peripheral clock enabled in low-power mode (default after reset)

Bit 8 **DAC9LPEN**: DAC9 clock enable in low-power mode
Set and cleared by software.
0: DAC9 peripheral clock disabled in low-power mode
1: DAC9 peripheral clock enabled in low-power mode (default after reset)

Bit 7 **DAC8LPEN**: DAC8 clock enable in low-power mode
Set and cleared by software.
0: DAC8 peripheral clock disabled in low-power mode
1: DAC8 peripheral clock enabled in low-power mode (default after reset)

Bit 6 **DAC7LPEN**: DAC7 clock enable in low-power mode
Set and cleared by software.
0: DAC7 peripheral clock disabled in low-power mode
1: DAC7 peripheral clock enabled in low-power mode (default after reset)

Bit 5 **DAC6LPEN**: DAC6 clock enable in low-power mode
Set and cleared by software.
0: DAC6 peripheral clock disabled in low-power mode
1: DAC6 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **DAC5LPEN**: DAC5 clock enable in low-power mode
Set and cleared by software.
0: DAC5 peripheral clock disabled in low-power mode
1: DAC5 peripheral clock enabled in low-power mode (default after reset)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **DAC2LPEN**: DAC2 clock enable in low-power mode
Set and cleared by software.
0: DAC2 peripheral clock disabled in low-power mode
1: DAC2 peripheral clock enabled in low-power mode (default after reset)

Bit 0 **DAC1LPEN**: DAC1 clock enable in low-power mode
Set and cleared by software.
0: DAC1 peripheral clock disabled in low-power mode
1: DAC1 peripheral clock enabled in low-power mode (default after reset)

11.8.32 RCC AHB3 peripheral low-power clock enable register (RCC_AHB3LPENR)

Address offset: 0x0B8

Reset value: 0x0020 0000

This register has no security or privilege protection.

Bits 31:21 Reserved, must be kept at reset value.

Bit 20 **XSPI1LPEN**: XSPI1 clock enable in low-power mode
Set and cleared by software.
0: XSPI1 peripheral clock disabled in low-power mode
1: XSPI1 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 19:17 Reserved, must be kept at reset value.

Bit 16 **GPIOHLPEN**: GPIOH clock enable in low-power mode
Set and cleared by software.
0: GPIOH peripheral clock disabled in low-power mode
1: GPIOH peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **GPIOGLPEN**: GPIOG clock enable in low-power mode
Set and cleared by software.
0: GPIOG peripheral clock disabled in low-power mode
1: GPIOG peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **GPIOFLPEN**: GPIOF clock enable in low-power mode
Set and cleared by software.
0: GPIOF peripheral clock disabled in low-power mode
1: GPIOF peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 13 **GPIOELPEN**: GPIOE clock enable in low-power mode
Set and cleared by software.
0: GPIOE peripheral clock disabled in low-power mode
1: GPIOE peripheral clock enabled in low-power mode (default after reset)

Bit 12 **GPIODLPEN**: GPIOD clock enable in low-power mode
Set and cleared by software.
0: GPIOD peripheral clock disabled in low-power mode
1: GPIOD peripheral clock enabled in low-power mode (default after reset)

Bit 11 **GPIOCLPEN**: GPIOC clock enable in low-power mode
Set and cleared by software.
0: GPIOC peripheral clock disabled in low-power mode
1: GPIOC peripheral clock enabled in low-power mode (default after reset)

Bit 10 **GPIOBLPEN**: GPIOB clock enable in low-power mode
Set and cleared by software.
0: GPIOB peripheral clock disabled in low-power mode
1: GPIOB peripheral clock enabled in low-power mode (default after reset)

Bit 9 **GPIOALPEN**: GPIOA clock enable in low-power mode
Set and cleared by software.
0: GPIOA peripheral clock disabled in low-power mode
1: GPIOA peripheral clock enabled in low-power mode (default after reset)

Bit 8 Reserved, must be kept at reset value.

Bit 7 **OTFDEC1LPEN**: OTFDEC1 clock enable in low-power mode
Set and cleared by software.
0: OTFDEC1 peripheral clock disabled in low-power mode
1: OTFDEC1 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CCBLPEN**: CCB clock enable in low-power mode
Set and cleared by software.
0: CCB peripheral clock disabled in low-power mode
1: CCB peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 4 **SAESLPEN**: SAES clock enable in low-power mode
Set and cleared by software.
0: SAES peripheral clock disabled in low-power mode
1: SAES peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 3 **PKALPEN**: PKA clock enable in low-power mode
Set and cleared by software.
0: PKA peripheral clock disabled in low-power mode
1: PKA peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 2 **RNGLPEN**: RNG clock enable in low-power mode
Set and cleared by software.
0: RNG peripheral clock disabled in low-power mode
1: RNG peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 **HASHLPEN**: HASH clock enable in low-power mode
Set and cleared by software.
0: HASH peripheral clock disabled in low-power mode
1: HASH peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **AESLPEN**: AES clock enable in low-power mode
Set and cleared by software.
0: AES peripheral clock disabled in low-power mode
1: AES peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/55x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

11.8.34 RCC APB1 peripheral low-power clock enable register (RCC_APB1LLPENR)

Address offset: 0x0C4

Reset value: 0x03FE DFF3

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **UART6LPEN**: UART6 clock enable in low-power mode
Set and cleared by software.
0: UART6 peripheral clock disabled in low-power mode
1: UART6 peripheral clock enabled in low-power mode (default after reset)

Bit 24 **CRSLPEN**: CRS clock enable in low-power mode
Set and cleared by software.
0: CRS peripheral clock disabled in low-power mode
1: CRS peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 23 **I3C1LPEN**: I3C1 clock enable in low-power mode
Set and cleared by software.
0: I3C1 peripheral clock disabled in low-power mode
1: I3C1 peripheral clock enabled in low-power mode (default after reset)

Bit 22 **I2C2LPEN**: I2C2 clock enable in low-power mode
Set and cleared by software.
0: I2C2 peripheral clock disabled in low-power mode
1: I2C2 peripheral clock enabled in low-power mode (default after reset)

Bit 21 **I2C1LPEN**: I2C1 clock enable in low-power mode
Set and cleared by software.
0: I2C1 peripheral clock disabled in low-power mode
1: I2C1 peripheral clock enabled in low-power mode (default after reset)

Bit 20 **UART5LPEN**: UART5 clock enable in low-power mode
Set and cleared by software.
0: UART5 peripheral clock disabled in low-power mode
1: UART5 peripheral clock enabled in low-power mode (default after reset)

Bit 19 **UART4LPEN**: UART4 clock enable in low-power mode
Set and cleared by software.
0: UART4 peripheral clock disabled in low-power mode
1: UART4 peripheral clock enabled in low-power mode (default after reset)

Bit 18 **USART3LPEN**: USART3 clock enable in low-power mode
Set and cleared by software.
0: USART3 peripheral clock disabled in low-power mode
1: USART3 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **USART2LPEN**: USART2 clock enable in low-power mode
Set and cleared by software.
0: USART2 peripheral clock disabled in low-power mode
1: USART2 peripheral clock enabled in low-power mode (default after reset)

Bit 16 Reserved, must be kept at reset value.

Bit 15 **SPI3LPEN**: SPI3 clock enable in low-power mode
Set and cleared by software.
0: SPI3 peripheral clock disabled in low-power mode
1: SPI3 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **SPI2LPEN**: SPI2 clock enable in low-power mode
Set and cleared by software.
0: SPI2 peripheral clock disabled in low-power mode
1: SPI2 peripheral clock enabled in low-power mode (default after reset)

Bit 13 Reserved, must be kept at reset value.

Bit 12 **WWDGLPEN**: WWDG clock enable in low-power mode
Set and cleared by software. It is forced to one by hardware when the hardware WWDG option is activated.
0: WWDG peripheral clock disabled in low-power mode
1: WWDG peripheral clock enabled in low-power mode (default after reset)

Bit 11 **TIM14LPEN**: TIM14 clock enable in low-power mode
Set and cleared by software.
0: TIM14 peripheral clock disabled in low-power mode
1: TIM14 peripheral clock enabled in low-power mode (default after reset)

Bit 10 **TIM13LPEN**: TIM13 clock enable in low-power mode
Set and cleared by software.
0: TIM13 peripheral clock disabled in low-power mode
1: TIM13 peripheral clock enabled in low-power mode (default after reset)

Bit 9 **TIM12LPEN**: TIM12 clock enable in low-power mode
Set and cleared by software.
0: TIM12 peripheral clock disabled in low-power mode
1: TIM12 peripheral clock enabled in low-power mode (default after reset)

Bit 8 **TIM11LPEN**: TIM11 clock enable in low-power mode
Set and cleared by software.
0: TIM11 peripheral clock disabled in low-power mode
1: TIM11 peripheral clock enabled in low-power mode (default after reset)

Bit 7 **TIM10LPEN**: TIM10 clock enable in low-power mode
Set and cleared by software.
0: TIM10 peripheral clock disabled in low-power mode
1: TIM10 peripheral clock enabled in low-power mode (default after reset)

Bit 6 **TIM9LPEN**: TIM9 clock enable in low-power mode
Set and cleared by software.
0: TIM9 peripheral clock disabled in low-power mode
1: TIM9 peripheral clock enabled in low-power mode (default after reset)

Bit 5 **TIM7LPEN**: TIM7 clock enable in low-power mode
Set and cleared by software.
0: TIM7 peripheral clock disabled in low-power mode
1: TIM7 peripheral clock enabled in low-power mode (default after reset)

Bit 4 **TIM6LPEN**: TIM6 clock enable in low-power mode
Set and cleared by software.
0: TIM6 peripheral clock disabled in low-power mode
1: TIM6 peripheral clock enabled in low-power mode (default after reset)

Bits 3:2 Reserved, must be kept at reset value.

Bit 1 **TIM3LPEN**: TIM3 clock enable in low-power mode
Set and cleared by software.
0: TIM3 peripheral clock disabled in low-power mode
1: TIM3 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 0 **TIM2LPEN**: TIM2 clock enable in low-power mode
Set and cleared by software.
0: TIM2 peripheral clock disabled in low-power mode
1: TIM2 peripheral clock enabled in low-power mode (default after reset)

11.8.35 RCC APB1 peripheral low-power clock enable register (RCC_APB1HLPENR)

Address offset: 0x0C8

Reset value: 0x4080 0208

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **UCPD1LPEN**: UCPD1 clock enable in low-power mode
Set and cleared by software.
0: UCPD1 peripheral clock disabled in low-power mode
1: UCPD1 peripheral clock enabled in low-power mode (default after reset)

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 22:10 Reserved, must be kept at reset value.

Bit 9 **FDCANLPEN**: FDCAN1, FDCAN2 and FDCAN3 peripheral clock enable in low-power mode
Set and cleared by software.
0: FDCAN1, FDCAN2 and FDCAN3 peripheral clock disabled in low-power mode
1: FDCAN1, FDCAN2 and FDCAN3 peripheral clock enabled in low-power mode (default after reset)

Note: Some STM32G56x/55x/54x/53x devices only have one FDCAN instance. Refer to the device datasheet for availability.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **DTSLPEN**: DTS clock enable in low-power mode
Set and cleared by software.
0: DTS peripheral clock disabled in low-power mode
1: DTS peripheral clock enabled in low-power mode (default after reset)

Bits 2:0 Reserved, must be kept at reset value.

11.8.36 RCC APB2 peripheral low-power clock enable register (RCC_APB2LPENR)

Address offset: 0x0CC

Reset value: 0x6107 7809

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **TIM5LPEN**: TIM5 clock enable in low-power mode
Set and cleared by software.
0: TIM5 peripheral clock disabled in low-power mode
1: TIM5 peripheral clock enabled in low-power mode (default after reset)

Bit 29 **TIM4LPEN**: TIM4 clock enable in low-power mode
Set and cleared by software.
0: TIM4 peripheral clock disabled in low-power mode
1: TIM4 peripheral clock enabled in low-power mode (default after reset)

Bits 28:25 Reserved, must be kept at reset value.

Bit 24 **USBLPEN**: USB clock enable in low-power mode
Set and cleared by software.
0: USB peripheral clock disabled in low-power mode
1: USB peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 23:19 Reserved, must be kept at reset value.

Bit 18 **TIM17LPEN**: TIM17 clock enable in low-power mode
Set and cleared by software.
0: TIM17 peripheral clock disabled in low-power mode
1: TIM17 peripheral clock enabled in low-power mode (default after reset)

Bit 17 **TIM16LPEN**: TIM16 clock enable in low-power mode
Set and cleared by software.
0: TIM16 peripheral clock disabled in low-power mode
1: TIM16 peripheral clock enabled in low-power mode (default after reset)

Bit 16 **TIM15LPEN**: TIM15 clock enable in low-power mode
Set and cleared by software.
0: TIM15 peripheral clock disabled in low-power mode
1: TIM15 peripheral clock enabled in low-power mode (default after reset)

Bit 15 Reserved, must be kept at reset value.

Bit 14 **USART1LPEN**: USART1 clock enable in low-power mode
Set and cleared by software.
0: USART1 peripheral clock disabled in low-power mode
1: USART1 peripheral clock enabled in low-power mode (default after reset)

Bit 13 **TIM8LPEN**: TIM8 clock enable in low-power mode
Set and cleared by software.
0: TIM8 peripheral clock disabled in low-power mode
1: TIM8 peripheral clock enabled in low-power mode (default after reset)

Bit 12 **SPI1LPEN**: SPI1 clock enable in low-power mode
Set and cleared by software.
0: SPI1 peripheral clock disabled in low-power mode
1: SPI1 peripheral clock enabled in low-power mode (default after reset)

Bit 11 **TIM1LPEN**: TIM1 clock enable in low-power mode
Set and cleared by software.
0: TIM1 peripheral clock disabled in low-power mode
1: TIM1 peripheral clock enabled in low-power mode (default after reset)

Bits 10:4 Reserved, must be kept at reset value.

Bit 3 **PLAY1LPEN**: PLAY1 clock enable in low-power mode
Set and cleared by software.
0: PLAY1 peripheral clock disabled in low-power mode
1: PLAY1 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **HRTIM1LPEN**: HRTIM1 clock enable in low-power mode
Set and cleared by software.
0: HRTIM1 peripheral clock disabled in low-power mode
1: HRTIM1 peripheral clock enabled in low-power mode (default after reset)

11.8.37 RCC APB3 peripheral low-power clock enable register (RCC_APB3LPENR)

Address offset: 0x0D0

Reset value: 0xFFC7 C9DE

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Set and cleared by software.
0: COMP8 peripheral clock disabled in low-power mode
1: COMP8 peripheral clock enabled in low-power mode (default after reset)

Bit 30 **COMP7LPEN**: COMP7 clock enable in low-power mode
Set and cleared by software.
0: COMP7 peripheral clock disabled in low-power mode
1: COMP7 peripheral clock enabled in low-power mode (default after reset)

Bit 29 **COMP6LPEN**: COMP6 clock enable in low-power mode
Set and cleared by software.
0: COMP6 peripheral clock disabled in low-power mode
1: COMP6 peripheral clock enabled in low-power mode (default after reset)

Bit 28 **COMP5LPEN**: COMP5 clock enable in low-power mode
Set and cleared by software.
0: COMP5 peripheral clock disabled in low-power mode
1: COMP5 peripheral clock enabled in low-power mode (default after reset)

Bit 27 **COMP4LPEN**: COMP4 clock enable in low-power mode
Set and cleared by software.
0: COMP4 peripheral clock disabled in low-power mode
1: COMP4 peripheral clock enabled in low-power mode (default after reset)

Bit 26 **COMP3LPEN**: COMP3 clock enable in low-power mode
Set and cleared by software.
0: COMP3 peripheral clock disabled in low-power mode
1: COMP3 peripheral clock enabled in low-power mode (default after reset)

Bit 25 **COMP2LPEN**: COMP2 clock enable in low-power mode
Set and cleared by software.
0: COMP2 peripheral clock disabled in low-power mode
1: COMP2 peripheral clock enabled in low-power mode (default after reset)

Bit 24 **COMP1LPEN**: COMP1 clock enable in low-power mode
Set and cleared by software.
0: COMP1 peripheral clock disabled in low-power mode
1: COMP1 peripheral clock enabled in low-power mode (default after reset)

Bit 23 **RTCAPBLPEN**: RTC APB interface clock enable in low-power mode
Set and cleared by software.
0: RTC APB interface clock disabled in low-power mode
1: RTC APB interface clock enabled in low-power mode (default after reset)

Bit 22 **VREFLPEN**: VREFBUF clock enable in low-power mode
Set and cleared by software.
0: VREFBUF peripheral clock disabled in low-power mode
1: VREFBUF peripheral clock enabled in low-power mode (default after reset)

Bits 21:19 Reserved, must be kept at reset value.

Bit 18 **OPAMP3LPEN**: OPAMP3 clock enable in low-power mode
Set and cleared by software.
0: OPAMP3 peripheral clock disabled in low-power mode
1: OPAMP3 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 17 **OPAMP2LPEN**: OPAMP2 clock enable in low-power mode
Set and cleared by software.
0: OPAMP2 peripheral clock disabled in low-power mode
1: OPAMP2 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 16 **OPAMP1LPEN**: OPAMP1 clock enable in low-power mode
Set and cleared by software.
0: OPAMP1 peripheral clock disabled in low-power mode
1: OPAMP1 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 15 **POSENC2LPEN**: POSENC2 clock enable in low-power mode
Set and cleared by software.
0: POSENC2 peripheral clock disabled in low-power mode
1: POSENC2 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 14 **POSENC1LPEN**: POSENC1 clock enable in low-power mode
Set and cleared by software.
0: POSENC1 peripheral clock disabled in low-power mode
1: POSENC1 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 13:12 Reserved, must be kept at reset value.

Bit 11 **LPTIM1LPEN**: LPTIM1 clock enable in low-power mode
Set and cleared by software.
0: LPTIM1 peripheral clock disabled in low-power mode
1: LPTIM1 peripheral clock enabled in low-power mode (default after reset)

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **I2C4LPEN**: I2C4 clock enable in low-power mode
Set and cleared by software.
0: I2C4 peripheral clock disabled in low-power mode
1: I2C4 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 7 **I2C3LPEN**: I2C3 clock enable in low-power mode
Set and cleared by software.
0: I2C3 peripheral clock disabled in low-power mode
1: I2C3 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 6 **LPUART1LPEN**: LPUART1 clock enable in low-power mode
Set and cleared by software.
0: LPUART1 peripheral clock disabled in low-power mode
1: LPUART1 peripheral clock enabled in low-power mode (default after reset)

Bit 5 Reserved, must be kept at reset value.

Bit 4 **TIM27LPEN**: TIM27 clock enable in low-power mode
Set and cleared by software.
0: TIM27 peripheral clock disabled in low-power mode
1: TIM27 peripheral clock enabled in low-power mode (default after reset)

Bit 3 **TIM26LPEN**: TIM26 clock enable in low-power mode
Set and cleared by software.
0: TIM26 peripheral clock disabled in low-power mode
1: TIM26 peripheral clock enabled in low-power mode (default after reset)

Bit 2 **TIM20LPEN**: TIM20 clock enable in low-power mode
Set and cleared by software.
0: TIM20 peripheral clock disabled in low-power mode
1: TIM20 peripheral clock enabled in low-power mode (default after reset)
Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 1 **SBSLPEN**: SBS clock enable in low-power mode
Set and cleared by software.
0: SBS peripheral clock disabled in low-power mode
1: SBS peripheral clock enabled in low-power mode (default after reset)

Bit 0 Reserved, must be kept at reset value.

11.8.38 RCC kernel clock configuration register (RCC_CCIPR1)

Address offset: 0x0D8

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bit 31 Reserved, must be kept at reset value.

Bits 30:28 **DAC10SEL[2:0]**: DAC10 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **DAC9SEL[2:0]**: DAC9 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 23 Reserved, must be kept at reset value.

Bits 22:20 **DAC8SEL[2:0]**: DAC8 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **DAC7SEL[2:0]**: DAC7 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **DAC6SEL[2:0]**: DAC6 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **DAC5SEL[2:0]**: DAC5 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 7 **DAC2SHSEL**: DAC2 sample and hold clock
Set and cleared by software.
0: lse_ck selected as kernel clock (default after reset)
1: lsi_ck selected as kernel clock

Bits 6:4 **DAC2SEL[2:0]**: DAC2 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

Bit 3 **DAC1SHSEL**: DAC1 sample and hold clock
Set and cleared by software.
0: lse_ck selected as kernel clock (default after reset)
1: lsi_ck selected as kernel clock

Bits 2:0 **DAC1SEL[2:0]**: DAC1 kernel clock source selection
Set and cleared by software.
000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)
001: rcc_hrtim_ker_ck selected as kernel clock
010: rcc_adc_ker_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: pll1_q_ck selected as kernel clock
110: pll2_q_ck selected as kernel clock (1)
111: reserved, the kernel clock is disabled

1. This source is not available on STM32G53x/54x devices. When the source is not available, the corresponding input must not be selected. Refer to the device datasheet for availability

11.8.40 RCC kernel clock configuration register (RCC_CCIPR3)

Address offset: 0x0E0

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:28 **SYSTICKSEL[1:0]**: SYSTICK clock source selection

Set and cleared by software.

00: rcc_hclk/8 selected as clock source (default after reset)

01: lsi_ck selected as clock source

10: lse_ck selected as clock source

11: reserved, the kernel clock is disabled

*Note: rcc_hclk frequency must be four times higher than lsi_ck/lse_ck, that is, period (LSI/LSE) / 4 * period (HCLK).*

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **LPTIM1SEL[2:0]**: LPTIM1 kernel clock source selection

Set and cleared by software.

000: rcc_pclk3 selected as kernel clock (default after reset)

001: pll1_q_ck selected as kernel clock

010: pll2_p_ck selected as kernel clock (1)

011: hse_ker_ck selected as kernel clock

100: hsi_ker_ck selected as kernel clock

101: lsi_ck selected as kernel clock

110: lse_ck selected as kernel clock

111: reserved, the kernel clock is disabled

Bits 23:20 **PLAY1DIV[3:0]**: PLAY1 kernel clock divider
Set and cleared by software
0000: Selected kernel is not divided (default after reset)
0001: Selected kernel clock is divided by 2
0010: Selected kernel clock is divided by 4

111: reserved, the kernel clock is disabled

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:8 **USBSEL[1:0]**: USB kernel clock source selection
Set and cleared by software.
00: hsi48_ker_ck selected as kernel clock (default after reset)
01: hse_ker_ck selected as kernel clock
10: pll1_q_ck selected as kernel clock
11: pll2_q_ck selected as kernel clock

Note: This bitfield is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **UCPD1SEL[1:0]**: UCPD1 clock source selection
Set and cleared by software.
00: hsi_ker_ck selected as kernel clock (default after reset)
01: hse_ker_ck selected as kernel clock
10: hsi48_ker_ck selected as kernel clock
11: pll2_q_ck selected as kernel clock

Note: This bitfield is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **XSPI1SEL[2:0]**: XSPI1 kernel clock source selection
Set and cleared by software.
000: rcc_hclk4 selected as kernel clock (default after reset)
001: pll1_q_ck selected as kernel clock
010: ic2_ck selected as kernel clock
011: hse_ker_ck selected as kernel clock
100: hsi_ker_ck selected as kernel clock
101: reserved, the kernel clock is disabled
110: reserved, the kernel clock is disabled
111: reserved, the kernel clock is disabled

Note: This bitfield is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

11.8.42 RCC kernel clock configuration register (RCC_CCIPR5)

Address offset: 0x0E8

Reset value: 0x0000 0000

This register can be accessed in secure or nonsecure mode, depending on the security level of each peripheral. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **POSENC2SEL[2:0]**: POSENC2 kernel clock source selection
Set and cleared by software.
000: pll1_p_ck selected as kernel clock (default after reset)
001: pll1_q_ck selected as kernel clock
010: ic1_ck selected as kernel clock
011: pll2_p_ck selected as kernel clock
100: pll2_q_ck selected as kernel clock
101: ic2_ck selected as kernel clock
110: reserved, the kernel clock is disabled
111: reserved, the kernel clock is disabled

Note: This bitfield is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **POSENC1SEL[2:0]**: POSENC1 kernel clock source selection
Set and cleared by software.
000: pll1_p_ck selected as kernel clock (default after reset)
001: pll1_q_ck selected as kernel clock
010: ic1_ck selected as kernel clock
011: pll2_p_ck selected as kernel clock
100: pll2_q_ck selected as kernel clock
101: ic2_ck selected as kernel clock
110: reserved, the kernel clock is disabled
111: reserved, the kernel clock is disabled

Note: This bitfield is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **FDCANSEL[1:0]**: FDCAN1, FDCAN2, and FDCAN3 kernel clock source selection
Set and cleared by software.
00: hse_ker_ck selected as kernel clock (default after reset)
01: pll1_q_ck selected as kernel clock
10: pll2_q_ck selected as kernel clock (1)
11: reserved, the kernel clock is disabled

Note: Some STM32G56x/55x/54x/53x devices only have one FDCAN instance. Refer to the device datasheet for availability.

Bits 11:8 Reserved, must be kept at reset value.

Bits 7:4 **ADCDIV[3:0]**: ADC clock prescaler
Set and cleared by software.
This bitfields selects the divider value on the ADC kernel clock.
0000: ADC kernel clock not divided (default after reset)
0001: ADC kernel clock divided by 2
0010: ADC kernel clock divided by 4
0011: ADC kernel clock divided by 6
0100: ADC kernel clock divided by 8
0101: ADC kernel clock divided by 10
0110: ADC kernel clock divided by 12
0111: ADC kernel clock divided by 16
1000: ADC kernel clock divided by 32
1001: ADC kernel clock divided by 64
1010: ADC kernel clock divided by 128
1011: ADC kernel clock divided by 256
others: reserved

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **ADCSEL[2:0]**: ADC12 and ADC3 kernel clock source selection

Set and cleared by software.

000: bus_ck (same as rcc_tim_ker_ck) selected as kernel clock (default after reset)

001: rcc_hrtim_ker_ck selected as kernel clock

010: hsi_ker_ck selected as kernel clock

011: hse_ker_ck selected as kernel clock

100: pll1_q_ck selected as kernel clock

101: ic1_ck selected as kernel clock

110: pll2_p_ck selected as kernel clock (1)

111: ic2_ck selected as kernel clock (1)

Note: ADC3 is not available on STM32G53x/54x devices. Refer to the device datasheet for availability.

1. This source is not available on STM32G53x/54x devices. When the source is not available, the corresponding input must not be selected. Refer to the device datasheet for availability.

11.8.43 RCC RTC domain control register (RCC_RTCCR)

Address offset: 0x0F0

Reset value: 0x0000 0000

Reset by RTC domain reset.

Access time: between 0 and 3 wait states, size can be word, half-word half-word, and byte access. Wait states are inserted in case of successive accesses to this register.

Note: After a system reset, this register is write-protected by DRTCP (except LSION and RTCEN bits). To modify these bits, the DRTCP bit of the PWR_RTCCR *must be set. All bits are reset only after an RTC domain reset (see Section 11.4.3).*

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	LSIRDY	LSION	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RTCDRST
				r	rw										rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RTCEN	Res.	Res.	Res.	Res.	Res.	RTCSEL[1:0]		Res.	LSECSSD	LSECSSON	LSEDRV[1:0]		LSEBYP	LSERDY	LSEON
rw						rwo	rwo		r	rw	rw	rw	rw	r	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **LSIRDY**: LSI oscillator ready

Set and cleared by hardware to indicate when the LSI oscillator is stable. After the LSION bit is cleared, LSIRDY goes low after three internal low-speed oscillator clock cycles.

This bit is set when the LSI is used by IWDG or RTC, even if LSION = 0.

0: LSI oscillator not ready (default after power-on reset)

1: LSI oscillator ready

Bit 26 **LSION**: LSI oscillator enable
Set and cleared by software.
0: LSI oscillator off (default after power-on reset)
1: LSI oscillator on

Bits 25:17 Reserved, must be kept at reset value.

Bit 16 **RTCDRST**: RTC domain software reset
Set and cleared by software.
0: reset not activated (default after RTC domain reset)
1: resets the entire RTC domain

Bit 15 **RTCEN**: RTC clock enable
Set and cleared by software.
0: rtc_ck disabled (default after RTC domain reset)
1: rtc_ck enabled

Bits 14:10 Reserved, must be kept at reset value.

Bits 9:8 **RTCSEL[1:0]**:RTC clock source selection
Set by software to select the clock source for the RTC.
These bits can be written only once, or when LSECSSD = 0.
The RTCDRST bit can be used to reset them.
If HSE is selected as RTC clock, this clock is lost when the system is in Stop mode or in case of a pin reset (NRST).
00: no clock (default after RTC domain reset)
01: LSE selected as RTC clock
10: LSI selected as RTC clock
11: HSE divided by RTCPRE value selected as RTC clock

Bit 7 Reserved, must be kept at reset value.

Bit 6 **LSECSSD**: LSE clock security system failure detection
Set by hardware to indicate when a failure has been detected by the clock security system on the external 32 kHz oscillator. This bit is reset when LSECSSON is cleared.
0: no failure detected on 32 kHz oscillator (default after V_{DD} domain reset)
1: failure detected on 32 kHz oscillator

Bit 5 **LSECSSON**: LSE clock security system enable
Set by software to enable the clock security system on LSE oscillator.
LSECSSON must be enabled after LSE is enabled (LSEON enabled) and ready (LSERDY set by hardware) and after RTCSEL is selected.
0: CSS on LSE oscillator OFF (default after V_{DD} domain reset)
1: CSS on LSE oscillator ON

Bits 4:3 **LSEDRV[1:0]**: LSE oscillator driving capability
Set by software to select the driving capability of the LSE oscillator.
This field can be written only if LSE oscillator is disabled (LSEON = 0). The user must also wait for LSERDY = 0.
0x: medium-low drive (default after V_{DD} domain reset)
10: medium-high drive
11: highest drive

Bit 2 **LSEBYP**: LSE oscillator bypass

Set and cleared by software to bypass oscillator in debug mode. This bit must not be written when the LSE is enabled (by LSEON) or ready (LSERDY = 1)

0: LSE oscillator not bypassed (default after V_{DD} domain reset)

1: LSE oscillator bypassed

Bit 1 **LSERDY**: LSE oscillator ready

Set and cleared by hardware to indicate when the LSE is stable.

This bit needs six cycles of lse_ck clock to fall down after LSEON has been cleared.

0: LSE oscillator not ready (default after V_{DD} domain reset)

1: LSE oscillator ready

Bit 0 **LSEON**: LSE oscillator enabled

Set and cleared by software.

0: LSE oscillator OFF (default after VDD domain reset)

1: LSE oscillator ON

11.8.44 RCC reset status register (RCC_RSR)

Address offset: 0x0F4

Reset value: 0x0C00 0000

Reset by power-on reset only.

Access: between 0 half-word, and 3 wait states, word, half-word and byte access. Wait states are inserted in case of successive accesses to this register.

RMVF bit can be accessed in secure or nonsecure mode, depending on RMVSEC bit. The privileged access depends on the values of the SPRIV and NSPRIV bits of the *RCC privilege configuration register (RCC_PRIVCFGR)*.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bit 31 **LPWRRSTF**: Low-power reset flag

Set by hardware when a reset occurs due to Stop or Standby mode entry, whereas the corresponding nRST_STOP, nRST_STBY option bit is cleared.
Cleared by writing to the RMVF bit.
0: No illegal low-power mode reset occurred
1: Illegal low-power mode reset occurred

Bit 30 **WWDGRSTF**: window watchdog reset flag

Cleared by software by writing the RMVF bit.
Set by hardware when a window watchdog reset occurs.
0: no window watchdog reset occurred from WWDG (default after power-on reset)
1: window watchdog reset occurred from WWDG

Bit 29 **IWDGRSTF**: independent watchdog reset flag

Cleared by software by writing the RMVF bit.
Set by hardware when an independent watchdog reset occurs.
0: no independent watchdog reset occurred (default after power-on reset)
1: independent watchdog reset occurred

Bit 28 **SFTRSTF**: system reset from CPU reset flag

Cleared by software by writing the RMVF bit.
Set by hardware when the system reset is due to CPU.The CPU can generate a system reset by writing SYSRESETREQ bit of the AIRCR register of the Cortex® M33.
0: no CPU software reset occurred (default after power-on reset)
1: a system reset has been generated by the CPU

Bit 27 **PORRSTF**: POR reset flag

Cleared by software by writing the RMVF bit.
Set by hardware when a POR reset occurs (pwr_por_rst).
0: no POR reset occurred
1: POR reset occurred (default after power-on reset)

Bit 26 **PINRSTF**: pin reset flag (NRST)
Cleared by software by writing the RMVF bit.
Set by hardware when a reset from pin occurs.
0: no reset from pin occurred
1: reset from pin occurred (default after power-on reset)

Bits 25:24 Reserved, must be kept at reset value.

Bit 23 **RMVF**: remove reset flag
Set by software and reset by hardware.
0: reset of the reset flags not activated (default after power-on reset)
1: resets the value of the reset flags

Bits 22:0 Reserved, must be kept at reset value.

11.8.45 RCC secure configuration register (RCC_SECCFGR)

Address offset: 0x110

Reset value: 0x0000 0000

Access: no wait state; word, half-word half-word, and byte access

When the system is secure (TZEN = 0xB4), this register can be written only by a secure privileged access if SPRIV = 1, and by a secure privileged or unprivileged access if SPRIV = 0. A nonsecure write access generates an illegal access event and data is not written. This register can be read by secure or nonsecure, privilege or unprivileged access. When the system is not secure (TZEN = 0xC3), this register is read as 0 and the register write is ignored.

			rw	rw			rw	rw	rw	rw	rw	rw		rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **RMVFSEC**: Remove reset flag security
Set and cleared by software.
0: nonsecure
1: secure

Bit 11 **HSI48SEC**: HSI48 clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **PLL2SEC**: PLL2 clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

Note: This bit is not available on STM32G53x/54x devices. If not present, it must be kept to its reset value. Refer to the device datasheet for availability.

Bit 7 **PLL1SEC**: PLL1 clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

Bit 6 **PRESCSEC**: AHBx/APBx prescaler configuration bits security
Set and cleared by software.
0: nonsecure
1: secure

Bit 5 **SYSCLKSEC**: SYSCLK clock selection, clock output on MCO configuration security
Set and cleared by software.
0: nonsecure
1: secure

Bit 4 **LSESEC**: LSE clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

Bit 3 **LSISEC**: LSI clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HSESEC**: HSE clock configuration bits, status bits and HSE_CSS security
Set and cleared by software.
0: nonsecure
1: secure

Bit 0 **HSISEC**: HSI clock configuration and status bits security
Set and cleared by software.
0: nonsecure
1: secure

11.8.46 RCC privilege configuration register (RCC_PRIVCFGR)

Address offset: 0x114

Reset value: 0x0000 0000

Access: no wait state; word, half-word and byte access

This register can be written only by a privileged access. It can be read by privileged or unprivileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NSPRIV	SPRIV
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **NSPRIV**: RCC nonsecure functions privilege configuration

Set and cleared by software. This bit can be written only by privileged access, secure or nonsecure.

0: Read and write to RCC nonsecure functions can be done by privileged or unprivileged access.

1: Read and write to RCC nonsecure functions can be done by privileged access only

Bit 0 **SPRIV**: RCC secure functions privilege configuration

Set and cleared by software. This bit can be written only by a secure privileged access.

0: Read and write to RCC secure functions can be done by privileged or unprivileged access.

1: Read and write to RCC secure functions can be done by privileged access only

12 Clock recovery system (CRS)

This section applies only to STM32G55x/56x devices.

12.1 CRS introduction

The clock recovery system (CRS) is an advanced digital controller acting on the internal fine-granularity trimmable RC oscillator HSI48. The CRS provides powerful means to evaluate the oscillator output frequency, based on comparison with a selectable synchronization signal. The CRS can perform automatic trimming adjustments based on the measured frequency error value, while keeping the possibility of a manual trimming.

The CRS is ideally suited to provide a precise clock to the USB peripheral. In this case, the synchronization signal can be derived from the start-of-frame (SOF) packet signalization on the USB bus, sent by a USB host at 1 ms intervals.

The synchronization signal can also be derived from alternative synchronization or generated by the user software.

12.2 CRS main features

- Selectable synchronization source with programmable prescaler and polarity (see *Section 12.4.2: CRS internal signals*)
- Possibility to generate synchronization pulses by software
- Automatic oscillator trimming capability with no need of CPU action
- Manual control option for faster startup convergence
- 16-bit frequency error counter with automatic error value capture and reload
- Programmable limit for automatic frequency error value evaluation and status reporting
- Maskable interrupts/events:
  - Expected synchronization (ESYNC)
  - Synchronization OK (SYNCOK)
  - Synchronization warning (SYNCWARN)
  - Synchronization or trimming error (ERR)

12.3 CRS implementation

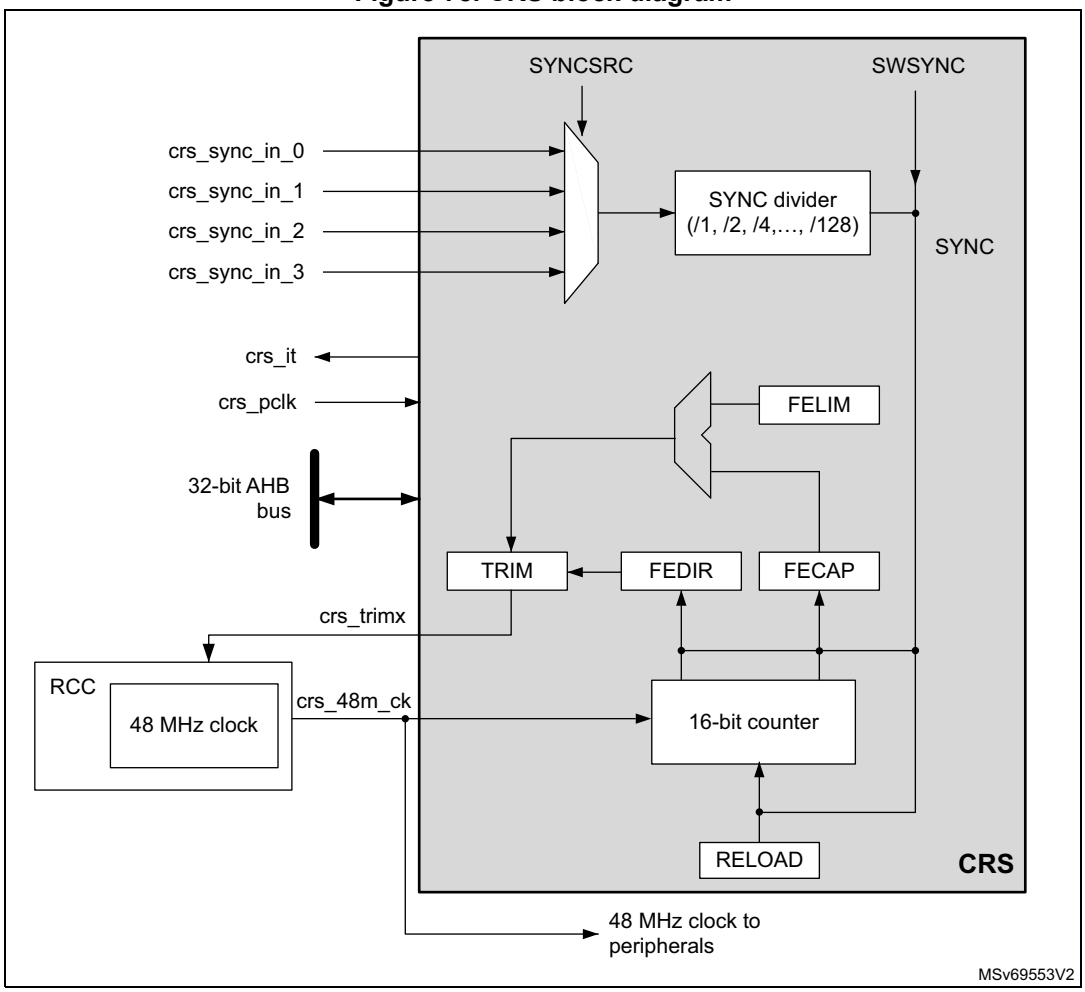

Table 133. CRS features

Feature	CRS

12.4 CRS functional description

12.4.1 CRS block diagram

Figure 78. CRS block diagram

12.4.2 CRS internal signals

Below the list of CRS internal signals.

Table 134. CRS internal input/output signals

Internal signal name	Signal type	Description
crs_it	Digital output	CRS interrupt
crs_pclk	Digital input	AHB bus clock
crs_48m_ck	Digital input	HSI48 48 MHz clock
crs_trim[0:5]	Digital output	HSI48 oscillator smooth trimming value

Table 134. CRS internal input/output signals (continued)

Internal signal name	Signal type	Description
crs_sync_in_0	Digital input	SYNC signal source
crs_sync_in_1		
crs_sync_in_2		
crs_sync_in_3		

Table 135. CRS interconnection

Internal signal name	Description
crs_sync_in_0	GPIO selected as SYNC signal source
crs_sync_in_1	LSE selected as SYNC signal source
crs_sync_in_2	USB SOF selected as SYNC signal source (default)
crs_sync_in_3	Reserved

12.4.3 Synchronization input

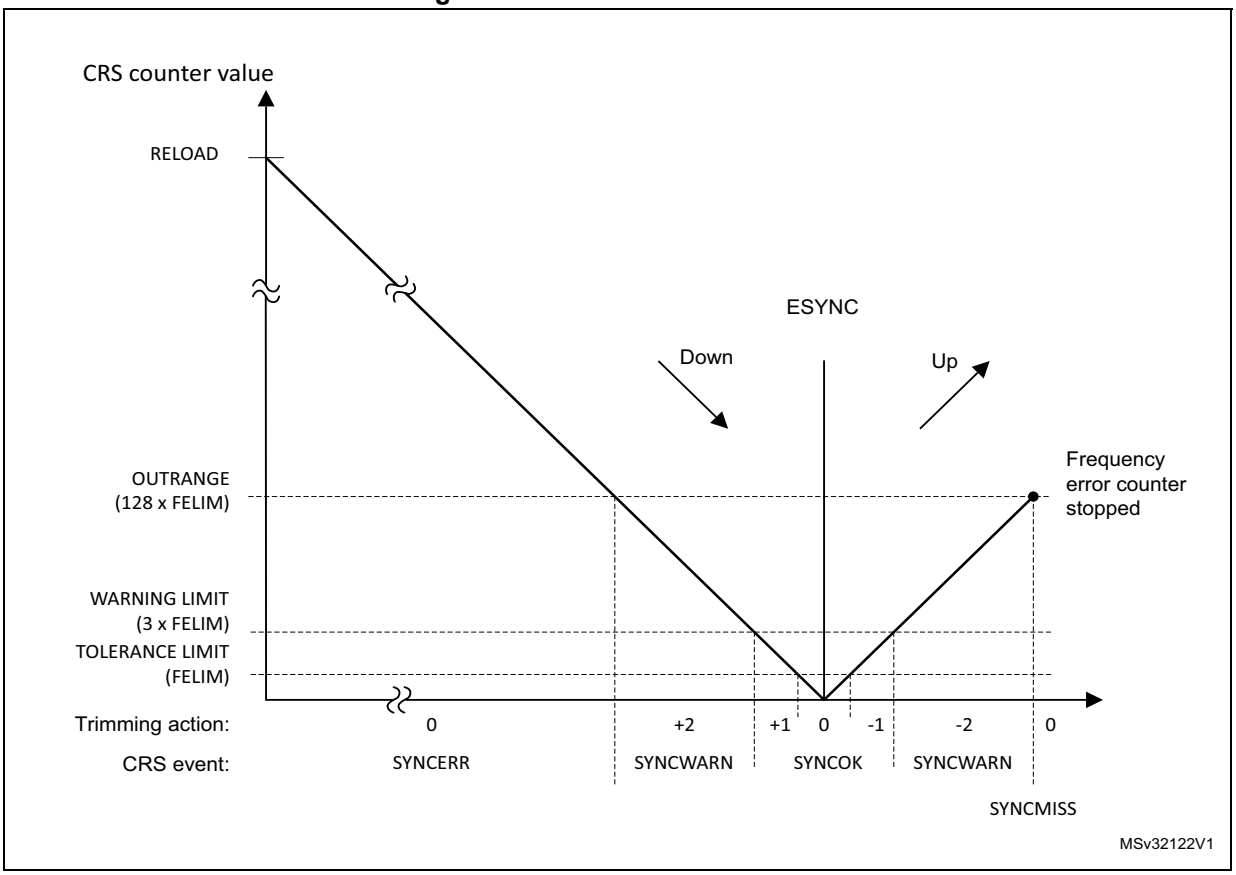
The CRS synchronization source (crs_sync_in_x) can be selected through SYNCSRC[1:0] bitfield of CRS_CFGR register (refer to *Section 12.4.2: CRS internal signals* for the possible sources). For a better robustness of the crs_sync_in_x input, a simple digital filter (2 out of 3 majority votes, sampled by the 48 MHz clock) is implemented to filter out glitches. In addition, the source signal has a configurable polarity (selected through SYNCPOL bit of CRS_CFGR). The signal can then be divided by a programmable binary prescaler to obtain a synchronization signal in a suitable frequency range (usually around 1 kHz).

For more information on the CRS synchronization source configuration, refer to CRS_CFGR register.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.

For more information on the CRS synchronization source configuration, refer to *CRS configuration register (CRS_CFGR)*.

It is also possible to generate a synchronization event by software, by setting the SWSYNC bit in the CRS_CR register.



12.4.4 Frequency error measurement

The frequency error counter is a 16-bit down/up counter, reloaded with the RELOAD value on each SYNC event. It starts counting down until it reaches the zero value, where the ESYNC (expected synchronization) event is generated. Then it starts counting up to the OUTRANGE limit, where it eventually stops (if no SYNC event is received), and generates a SYNCMISS event. The OUTRANGE limit is defined as the frequency error limit (FELIM field of the CRS_CFGR register) multiplied by 128.

When the SYNC event is detected, the actual value of the frequency error counter and its counting direction are stored in the FECAP (frequency error capture) field and in the FEDIR (frequency error direction) bit of the CRS_ISR register. When the SYNC event is detected during the down-counting phase (before reaching the zero value), it means that the actual

frequency is lower than the target (the TRIM value must be incremented). When it is detected during the up-counting phase, it means that the actual frequency is higher (the TRIM value must be decremented).

Figure 79. CRS counter behavior

12.4.5 Frequency error evaluation and automatic trimming

The measured frequency error is evaluated by comparing its value with a set of limits:

- TOLERANCE LIMIT, given directly in the FELIM field of the CRS_CFGR register
- WARNING LIMIT, defined as 3 × FELIM value
- OUTRANGE (error limit), defined as 128 × FELIM value

The result of this comparison is used to generate the status indication and also to control the automatic trimming, which is enabled by setting the AUTOTRIMEN bit in the CRS_CR register:

- When the frequency error is below the tolerance limit, it means that the actual trimming value in the TRIM field is the optimal one, hence no trimming action is needed.
  - SYNCOK status indicated
  - TRIM value not changed in AUTOTRIM mode
- When the frequency error is below the warning limit but above or equal to the tolerance limit, it means that some trimming action is necessary but that adjustment by one trimming step is enough to reach the optimal TRIM value.
  - SYNCOK status indicated

  - TRIM value adjusted by one trimming step in AUTOTRIM mode
- When the frequency error is above or equal to the warning limit but below the error limit, a stronger trimming action is necessary, and there is a risk that the optimal TRIM value is not reached for the next period.
  - SYNCWARN status indicated
  - TRIM value adjusted by two trimming steps in AUTOTRIM mode
- When the frequency error is above or equal to the error limit, the frequency is out of the trimming range. This can also happen when the SYNC input is not clean, or when some SYNC pulse is missing (for example when one USB SOF is corrupted).
  - SYNCERR or SYNCMISS status indicated
  - TRIM value not changed in AUTOTRIM mode

Note: If the actual value of the TRIM field is close to its limits and the automatic trimming can force it to overflow or underflow, the TRIM value is set to the limit, and the TRIMOVF status is indicated.

In AUTOTRIM mode (AUTOTRIMEN bit set in the CRS_CR register), the TRIM field of CRS_CR is adjusted by hardware and is read-only.

12.4.6 CRS initialization and configuration

RELOAD value

The RELOAD value must be selected according to the ratio between the target frequency and the frequency of the synchronization source after prescaling. This value is decreased by 1, to reach the expected synchronization on the zero value. The formula is the following:

$$RELOAD = (f_{TARGET} / f_{SYNC}) - 1$$

The reset value of the RELOAD field corresponds to a target frequency of 48 MHz and a synchronization signal frequency of 1 kHz (SOF signal from USB).

FELIM value

The selection of the FELIM value is closely coupled with the HSI48 oscillator characteristics and its typical trimming step size. The optimal value corresponds to half of the trimming step size, expressed as a number of oscillator clock ticks. The following formula can be used:

$$FELIM = (f_{TARGET} / f_{SYNC}) * STEP[\%] / 100\% / 2$$

The result must be always rounded up to the nearest integer value to obtain the best trimming response. If frequent trimming actions are not needed in the application, the hysteresis can be increased by slightly increasing the FELIM value.

The reset value of the FELIM field corresponds to $(f_{TARGET} / f_{SYNC}) = 48000$, and to a typical trimming step size of 0.14%.

Note: The trimming step size depends upon the product, check the datasheet for accurate setting.

Caution: There is no hardware protection from a wrong configuration of the RELOAD and FELIM fields, this can lead to an erratic trimming response. The expected operational mode requires proper setup of the RELOAD value (according to the synchronization source frequency), which is also greater than 128 * FELIM value (OUTRANGE limit).

12.5 CRS in low-power modes

Table 136. Effect of low-power modes on CRS

Mode	Description
Sleep	No effect. CRS interrupts cause the device to exit the Sleep mode.
Stop	CRS registers are frozen. The CRS stops operating until the Stop mode is exited and the HSI48 oscillator is restarted.
Standby	The peripheral is powered down and must be reinitialized after exiting Standby mode.
Shutdown	The peripheral is powered down and must be reinitialized after exiting Shutdown mode.

12.6 CRS interrupts

Table 137. Interrupt control bits

Interrupt event	Event flag	Enable control bit	Clear flag bit
Expected synchronization	ESYNCF	ESYNCIE	ESYNCC
Synchronization OK	SYNCOKF	SYNCOKIE	SYNCOKC
Synchronization warning	SYNCWARNF	SYNCWARNIE	SYNCWARNC
Synchronization or trimming error (TRIMOVF, SYNCMISS, SYNCERR)	ERRF	ERRIE	ERRC

12.7 CRS registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed only by words (32-bit).

12.7.1 CRS control register (CRS_CR)

Address offset: 0x00

Reset value: 0x0000 2000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	TRIM[5:0]						SW SYNC	AUTO TRIMEN	CEN	Res.	ESYNC IE	ERR IE	SYNC WARNIE	SYNC OKIE
		rw	rw	rw	rw	rw	rw	rt_w1	rw	rw		rw	rw	rw	rw

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **TRIM[5:0]**: HSI48 oscillator smooth trimming

These bits provide a user-programmable trimming value to the HSI48 oscillator. They can be programmed to adjust to variations in voltage and temperature that influence the oscillator frequency.

The default value of the HSI48 oscillator smooth trimming is 32, for a complete TRIM range of 64 steps.

The trimming step is specified in the product datasheet. A higher TRIM value corresponds to a higher output frequency.

When the AUTOTRIMEN bit is set, this field is controlled by hardware and is read-only.

Bit 7 **SWSYNC**: Generate software SYNC event

This bit is set by software in order to generate a software SYNC event. It is automatically cleared by hardware.

0: No action

1: A software SYNC event is generated.

Bit 6 **AUTOTRIMEN**: Automatic trimming enable

This bit enables the automatic hardware adjustment of TRIM bits according to the measured frequency error between two SYNC events. If this bit is set, the TRIM bits are read-only. The TRIM value can be adjusted by hardware by one or two steps at a time, depending on the measured frequency error value. Refer to *Section 12.4.5* for more details.

0: Automatic trimming disabled, TRIM bits can be adjusted by the user.

1: Automatic trimming enabled, TRIM bits are read-only and under hardware control.

Bit 5 **CEN**: Frequency error counter enable

This bit enables the oscillator clock for the frequency error counter.

0: Frequency error counter disabled

1: Frequency error counter enabled

When this bit is set, the CRS_CFGR register is write-protected and cannot be modified.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **ESYNCIE**: Expected SYNC interrupt enable

0: Expected SYNC (ESYNCF) interrupt disabled

1: Expected SYNC (ESYNCF) interrupt enabled

Bit 2 **ERRIE**: Synchronization or trimming error interrupt enable

0: Synchronization or trimming error (ERRF) interrupt disabled

1: Synchronization or trimming error (ERRF) interrupt enabled

Bit 1 **SYNCWARNIE**: SYNC warning interrupt enable

0: SYNC warning (SYNCWARNF) interrupt disabled

1: SYNC warning (SYNCWARNF) interrupt enabled

Bit 0 **SYNCOKIE**: SYNC event OK interrupt enable

0: SYNC event OK (SYNCOKF) interrupt disabled

1: SYNC event OK (SYNCOKF) interrupt enabled

12.7.2 CRS configuration register (CRS_CFGR)

This register can be written only when the frequency error counter is disabled (the CEN bit is cleared in CRS_CR). When the counter is enabled, this register is write-protected.

Address offset: 0x04

Reset value: 0x2022 BB7F

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SYNCPOL	Res.	SYNCSRC[1:0]		Res.	SYNCDIV[2:0]			FELIM[7:0]							
rw		rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RELOAD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **SYNCPOL**: SYNC polarity selection

This bit is set and cleared by software to select the input polarity for the SYNC signal source.

0: SYNC active on rising edge (default)

1: SYNC active on falling edge

Bit 30 Reserved, must be kept at reset value.

Bits 29:28 **SYNCSRC[1:0]**: SYNC signal source selection

These bits are set and cleared by software to select the SYNC signal source (see *Section 12.4.2: CRS internal signals*).

00: crs_sync_in_0 selected as SYNC signal source

01: crs_sync_in_1 selected as SYNC signal source

10: crs_sync_in_2 selected as SYNC signal source

11: crs_sync_in_3 selected as SYNC signal source

Note: When using USB LPM (link power management) and the device is in Sleep mode, the periodic USB SOF is not generated by the host. No SYNC signal is therefore provided to the CRS to calibrate the 48 MHz clock on the run. To guarantee the required clock precision after waking up from Sleep mode, the LSE clock or the SYNC pin must be used as SYNC signal.

Bit 27 Reserved, must be kept at reset value.

Bits 26:24 **SYNCDIV[2:0]**: SYNC divider

These bits are set and cleared by software to control the division factor of the SYNC signal.

000: SYNC not divided (default)

001: SYNC divided by 2

010: SYNC divided by 4

011: SYNC divided by 8

100: SYNC divided by 16

101: SYNC divided by 32

110: SYNC divided by 64

111: SYNC divided by 128

Bits 23:16 **FELIM[7:0]**: Frequency error limit

FELIM contains the value to be used to evaluate the captured frequency error value latched in the FECAP[15:0] bits of the CRS_ISR register. Refer to *Section 12.4.5* for more details about FECAP evaluation.

Bits 15:0 **RELOAD[15:0]**: Counter reload value

RELOAD is the value to be loaded in the frequency error counter with each SYNC event. Refer to *Section 12.4.4* for more details about counter behavior.

12.7.3 CRS interrupt and status register (CRS_ISR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FECAP[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FEDIR	Res.	Res.	Res.	Res.	TRIM OVF	SYNC MISS	SYNC ERR	Res.	Res.	Res.	Res.	ESYNCF	ERRF	SYNC WARNF	SYNC OKF
r					r	r	r					r	r	r	r

Bits 31:16 **FECAP[15:0]**: Frequency error capture

FECAP is the frequency error counter value latched in the time of the last SYNC event. Refer to *Section 12.4.5* for more details about FECAP usage.

Bit 15 **FEDIR**: Frequency error direction

FEDIR is the counting direction of the frequency error counter latched in the time of the last SYNC event. It shows whether the actual frequency is below or above the target.

0: Up-counting direction, the actual frequency is above the target

1: Down-counting direction, the actual frequency is below the target

Bits 14:11 Reserved, must be kept at reset value.

Bit 10 **TRIMOVF**: Trimming overflow or underflow

This flag is set by hardware when the automatic trimming tries to over- or under-flow the TRIM value. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No trimming error signaled

1: Trimming error signaled

Bit 9 **SYNCMISS**: SYNC missed

This flag is set by hardware when the frequency error counter reaches value FELIM * 128 and no SYNC is detected, meaning either that a SYNC pulse was missed, or the frequency error is too big (internal frequency too high) to be compensated by adjusting the TRIM value, hence some other action must be taken. At this point, the frequency error counter is stopped (waiting for a next SYNC), and an interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC missed error signaled

1: SYNC missed error signaled

Bit 8 **SYNCERR**: SYNC error

This flag is set by hardware when the SYNC pulse arrives before the ESYNC event and the measured frequency error is greater than or equal to FELIM * 128. This means that the frequency error is too big (internal frequency too low) to be compensated by adjusting the TRIM value, and that some other action has to be taken. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software by setting the ERRC bit in the CRS_ICR register.

0: No SYNC error signaled

1: SYNC error signaled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCF**: Expected SYNC flag

This flag is set by hardware when the frequency error counter reached a zero value. An interrupt is generated if the ESYNCIE bit is set in the CRS_CR register. It is cleared by software by setting the ESYNCC bit in the CRS_ICR register.

0: No expected SYNC signaled

1: Expected SYNC signaled

Bit 2 **ERRF**: Error flag

This flag is set by hardware in case of any synchronization or trimming error. It is the logical OR of the TRIMOVF, SYNCMISS and SYNCERR bits. An interrupt is generated if the ERRIE bit is set in the CRS_CR register. It is cleared by software in reaction to setting the ERRC bit in the CRS_ICR register, which clears the TRIMOVF, SYNCMISS and SYNCERR bits.

0: No synchronization or trimming error signaled

1: Synchronization or trimming error signaled

Bit 1 **SYNCWARNF**: SYNC warning flag

This flag is set by hardware when the measured frequency error is greater than or equal to FELIM * 3, but smaller than FELIM * 128. This means that to compensate the frequency error, the TRIM value must be adjusted by two steps or more. An interrupt is generated if the SYNCWARNIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCWARNC bit in the CRS_ICR register.

0: No SYNC warning signaled

1: SYNC warning signaled

Bit 0 **SYNCOKF**: SYNC event OK flag

This flag is set by hardware when the measured frequency error is smaller than FELIM * 3. This means that either no adjustment of the TRIM value is needed or that an adjustment by one trimming step is enough to compensate the frequency error. An interrupt is generated if the SYNCOKIE bit is set in the CRS_CR register. It is cleared by software by setting the SYNCOKC bit in the CRS_ICR register.

0: No SYNC event OK signaled

1: SYNC event OK signaled

12.7.4 CRS interrupt flag clear register (CRS_ICR)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ESYNCC	ERRC	SYNC WARNC	SYNC OKC
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **ESYNCC**: Expected SYNC clear flag
Writing 1 to this bit clears the ESYNCF flag in the CRS_ISR register.

Bit 2 **ERRC**: Error clear flag
Writing 1 to this bit clears TRIMOVF, SYNCMISS, and SYNCERR bits and consequently also the ERRF flag in the CRS_ISR register.

Bit 1 **SYNCWARNC**: SYNC warning clear flag
Writing 1 to this bit clears the SYNCWARNF flag in the CRS_ISR register.

Bit 0 **SYNCOKC**: SYNC event OK clear flag
Writing 1 to this bit clears the SYNCOKF flag in the CRS_ISR register.

12.7.5 CRS register map

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

13 General-purpose I/Os (GPIO)

13.1 Introduction

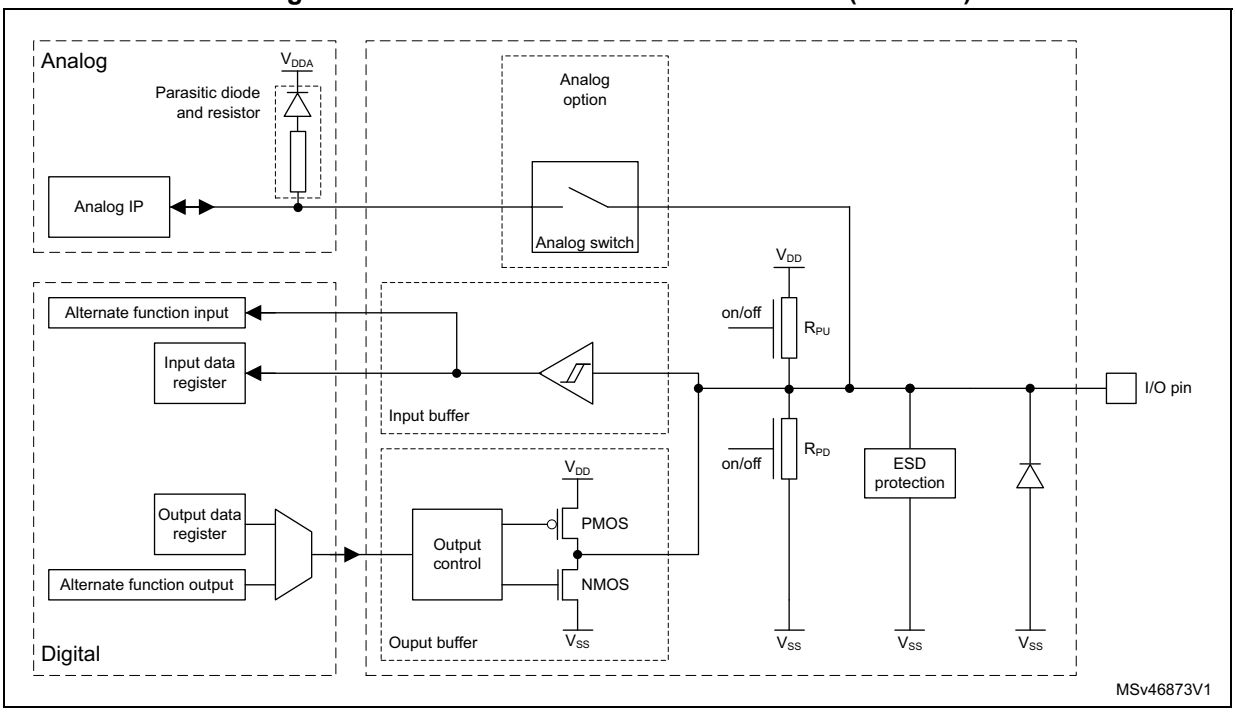
Each general-purpose I/O port has four 32-bit configuration registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR and GPIOx_PUPDR), two 32-bit data registers (GPIOx_IDR and GPIOx_ODR), a 16-bit reset register (GPIOx_BRR), and a 32-bit set/reset register (GPIOx_BSRR).

In addition, all GPIOs have a 32-bit locking register (GPIOx_LCKR), two 32-bit alternate function selection registers (GPIOx_AFRH and GPIOx_AFRL), a secure configuration register (GPIOx_SECCFGR).

13.2 GPIO main features

- Output states: push-pull or open drain + pull-up/down
- Output data from output data register (GPIOx_ODR) or peripheral (alternate function output)
- Speed selection for each I/O
- Input states: floating, pull-up/down, analog
- Input data to input data register (GPIOx_IDR) or peripheral (alternate function input)
- Bit set and reset register (GPIOx_ BSRR) for bit-wise write access to GPIOx_ODR
- Lock mechanism (GPIOx_LCKR) provided to freeze the I/O port configurations
- Analog function
- Alternate function selection registers
- Fast toggle capable of changing every two clock cycles
- Highly flexible pin multiplexing allows the use of I/O pins as GPIOs or as one of several peripheral functions
- TrustZone® security support
- I/Os state retention during Standby mode

13.3 GPIO functional description



Subject to the specific hardware characteristics of each I/O port listed in the datasheet, each port bit of the general-purpose I/O (GPIO) ports can be individually configured by software in several modes:

- Input floating
- Input pull-up
- Input-pull-down
- Analog
- Output open-drain with pull-up or pull-down capability
- Output push-pull with pull-up or pull-down capability
- Alternate function push-pull with pull-up or pull-down capability
- Alternate function open-drain with pull-up or pull-down capability

Each I/O port bit is freely programmable, however the I/O port registers must be accessed as 32-bit words, half-words, or bytes. The GPIOx_BSRR and GPIOx_BRR registers allow atomic read/modify accesses to any of the GPIOx_ODR registers. In this way, there is no risk of an IRQ occurring between the read and the modify access.

Figure 80 shows the basic structure of a 3- or 5-V tolerant GPIO (TT or FT). *Table 139* gives the possible port bit configurations.

Figure 80. Structure of 3- or 5-V tolerant GPIO (TT or FT)

Note: On a TT GPIO, the analog switch is not present, it is replaced by a direct connection.

Caution: When the analog switch is enabled, it connects analog blocks, which does not allow five-volt tolerance.

Table 139. Port bit configuration(1)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]	PUPD(i)[1:0]		I/O configuration	
01	0	SPEED[1:0]	0	0	GP output	PP

	0		1	0	GP output	PP + PD
	0		1	1	Reserved	
	1		0	0	GP output	OD
	1		0	1	GP output	OD + PU
	1		1	0	GP output	OD + PD
	1		1	1	Reserved (GP output OD)	

Table 139. Port bit configuration[1] (continued)

MODE(i)[1:0]	OTYPE(i)	OSPEED(i)[1:0]		PUPD(i)[1:0]		I/O configuration	
10	0	SPEED[1:0]		0	0	AF	PP
	0			0	1	AF	PP + PU
	0			1	0	AF	PP + PD
	0			1	1	Reserved	
	1			0	0	AF	OD
	1			0	1	AF	OD + PU
	1			1	0	AF	OD + PD
	1			1	1	Reserved	
00	x	x	x	0	0	Input	Floating
	x	x	x	0	1	Input	PU
	x	x	x	1	0	Input	PD
	x	x	x	1	1	Reserved (input floating)	
11	x	x	x	0	0	Analog I/O	Floating
	x	x	x	0	1	Reserved	
	x	x	x	1	0	Analog I/O	PD
	x	x	x	1	1	Reserved	

1. GP = general-purpose, PP = push-pull, PU = pull-up, PD = pull-down, OD = open-drain, AF = alternate function.

13.3.1 General-purpose I/O (GPIO)

During and just after reset, the alternate functions are not active and most of the I/O ports are configured in analog mode.

The debug pins are in AF pull-up/pull-down after reset:

- PA15: JTDI in pull-up
- PA14: JTCK/SWCLK in pull-down
- PA13: JTMS/SWDIO in pull-up
- PB4: NJTRST in pull-up
- PB3: JTDO/TRACESWO in floating state no pull-up/pull-down

BOOT0 is in input mode during the reset until at least the end of the option byte loading phase (see *Section 13.3.17*).

When the pin is configured as output, the value written to the output data register (GPIOx_ODR) is output on the I/O pin. It is possible to use the output driver in push-pull mode or open-drain mode (only the low level is driven, the high level is high-Z).

The input data register (GPIOx_IDR) captures the data present on the I/O pin at every AHB clock cycle.

All GPIO pins have weak internal pull-up and pull-down resistors, which can be activated or not, depending upon the value in the GPIOx_PUPDR register.

13.3.2 I/O pin alternate function multiplexer and mapping

The device I/O pins are connected to on-board peripherals/modules through a multiplexer that allows only one peripheral alternate function (AF) connected to an I/O pin at a time. In this way, there is no conflict between peripherals available on the same I/O pin.

Each I/O pin has a multiplexer with up to 16 alternate function inputs (AF0 to AF15) that can be configured through the GPIOx_AFRL (for pin 0 to 7) and GPIOx_AFRH (for pin 8 to 15) registers:

- After reset, the multiplexer selection is alternate function 0 (AF0). The I/Os are configured in alternate function mode through GPIOx_MODER register.
- The specific alternate function assignments for each pin are detailed in the device datasheet.

In addition to this flexible I/O multiplexing architecture, each peripheral has alternate functions mapped onto different I/O pins to optimize the number of peripherals available in smaller packages.

To use an I/O in a given configuration, the user must proceed as follows:

- **Debug function**: after each device reset these pins are assigned as alternate function pins immediately usable by the debugger host.
- **GPIO**: configure the desired I/O as output, input, or analog in the GPIOx_MODER register.
- **Alternate function**:
  - Connect the I/O to the desired AFx in one of the GPIOx_AFRL or GPIOx_AFRH register.
  - Select the type, pull-up/pull-down, and output speed via the GPIOx_OTYPER, GPIOx_PUPDR and GPIOx_OSPEEDR registers respectively.
  - Configure the desired I/O as an alternate function in the GPIOx_MODER register.
  - The Cortex-M33 output EVENTOUT signal can be output as alternate function on I/O. An event can be signaled through the configured pin after executing SEV instruction.
- **Additional functions:**
  - For the ADC and DAC, configure the desired I/O in analog mode in the GPIOx_MODER register and configure the required function in the ADC and DAC registers.
  - For the additional functions like RTC, WKUPx, and oscillators, configure the required function in the related RTC, PWR, and RCC registers. These functions have priority over the configuration in the standard GPIO registers.

Refer to the “Alternate function mapping” table in the device datasheet for the detailed mapping of the alternate function I/O pins.

13.3.3 I/O port control registers

Each of the GPIO ports has four 32-bit memory-mapped control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR) to configure up to 16 I/Os. The GPIOx_MODER register is used to select the I/O mode (input, output, AF, analog). The GPIOx_OTYPER and GPIOx_OSPEEDR registers are used to select the output type (push-pull or open-drain) and speed. The GPIOx_PUPDR register is used to select the pull-up/pull-down whatever the I/O direction.

13.3.4 I/O port data registers

Each GPIO has two 16-bit memory-mapped data registers: input and output data registers (*GPIO port input data register (GPIOx_IDR) (x = A to H)* and *GPIO port output data register (GPIOx_ODR) (x = A to H)*).

GPIOx_ODR stores the data to be output, it is read/write accessible. The data entered through the I/Os are stored into the input data register (GPIOx_IDR), a read-only register.

13.3.5 I/O data bitwise handling

The bit set reset register (GPIOx_BSRR) is a 32-bit register that allows the application to set and reset each individual bit in the output data register (GPIOx_ODR). The bit set reset register has twice the size of GPIOx_ODR.

To each bit in GPIOx_ODR, correspond two control bits in GPIOx_BSRR: BS(i) and BR(i). When written to 1, BS(i) sets the corresponding ODR(i) bit. When written to 1, BR(i) resets the ODR(i) corresponding bit.

Writing any bit to 0 in GPIOx_BSRR does not have any effect on the corresponding bit in GPIOx_ODR. If there is an attempt to both set and reset a bit in GPIOx_BSRR, the set action takes priority.

Using the GPIOx_BSRR register to change the values of individual bits in GPIOx_ODR is a “one-shot” effect that does not lock the GPIOx_ODR bits. The GPIOx_ODR bits can always be accessed directly. The GPIOx_BSRR register provides a way of performing atomic bitwise handling.

There is no need for the software to disable interrupts when programming the GPIOx_ODR at bit level: one or more bits can be modified in a single atomic AHB write access.

13.3.6 GPIO locking mechanism

The GPIO control registers can be frozen by applying a specific write sequence to the GPIOx_LCKR register. The frozen registers are GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL, GPIOx_AFRH.

To write the GPIOx_LCKR register, a specific write/read sequence must be applied. When the right LOCK sequence is applied to the bit 16 in this register, the value of LCKR[15:0] is used to lock the configuration of the I/Os (during the write sequence the LCKR[15:0] value must be the same). When the LOCK sequence is applied to a port bit, the value of the port bit can no longer be modified until the next MCU reset or peripheral reset. Each GPIOx_LCKR bit freezes the corresponding bit in the control registers (GPIOx_MODER, GPIOx_OTYPER, GPIOx_OSPEEDR, GPIOx_PUPDR, GPIOx_AFRL and GPIOx_AFRH.

The LOCK sequence can be performed only using a word (32-bit long) access to the GPIOx_LCKR register, because GPIOx_LCKR bit 16 must be set at the same time as the [15:0] bits.

13.3.7 I/O alternate function input/output

Two registers are provided to select one of the alternate function inputs/outputs available for each I/O. With these registers, the user can connect an alternate function to some other pin as required by the application.

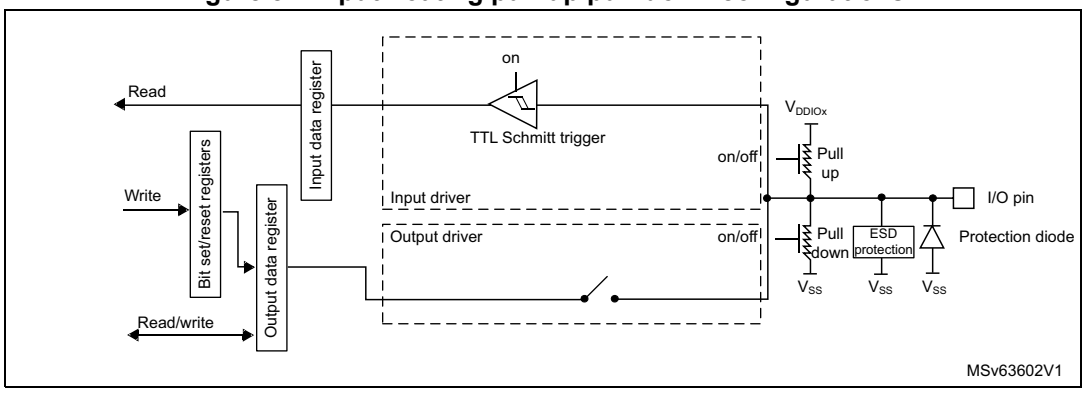
This means that some peripheral functions are multiplexed on each GPIO using the GPIOx_AFRL and GPIOx_AFRH alternate function registers. The application can thus

select any one of the possible functions for each I/O. The AF selection signal being common to the alternate function input and alternate function output, a single channel is selected for the alternate function input/output of a given I/O.

To know which functions are multiplexed on each GPIO pin, refer to the device datasheet.

13.3.8 External interrupt/wake-up lines

All ports have external interrupt capability. To use external interrupt lines, the port can be configured in input, output, or alternate function mode (the port must not be configured in analog mode). Refer to *Section 19: Extended interrupts and event controller (EXTI)*.



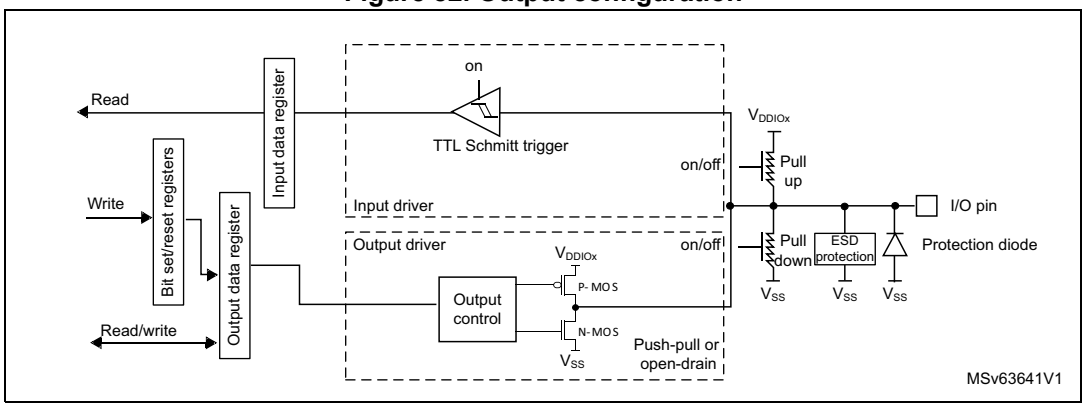
13.3.9 Input configuration

When the I/O port is programmed as input:

- The output buffer is disabled.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register provides the I/O state.

Figure 81 shows the input configuration of the I/O port bit.

Figure 81. Input floating/pull-up/pull-down configurations



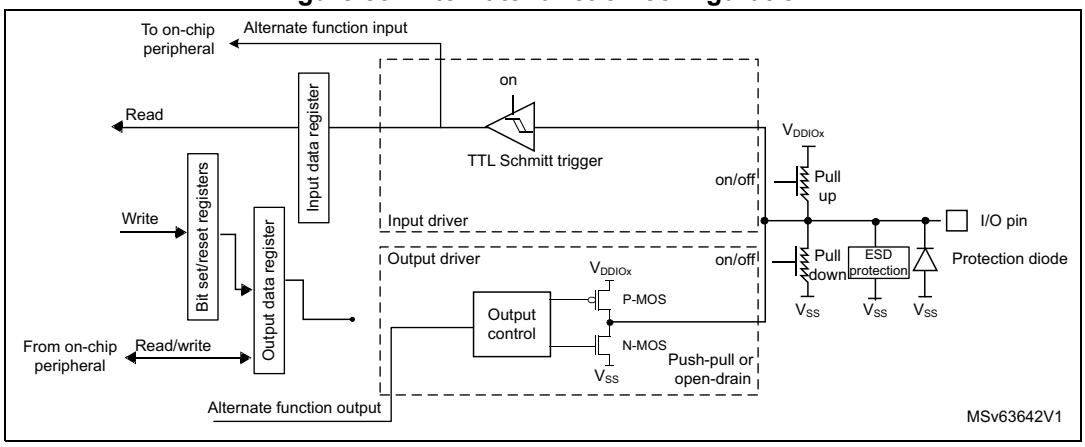
13.3.10 Output configuration

When the I/O port is programmed as output:

- The output buffer is enabled:
  - Open-drain mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register leaves the port in high-Z (the P-MOS is never activated).
  - Push-pull mode: a 0 in the output register activates the N-MOS whereas a 1 in the output register activates the P-MOS.
- The Schmitt trigger input is activated.
- The pull-up and pull-down resistors are activated depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.
- A read access to the output data register gets the last written value.

Figure 82 shows the output configuration of the I/O port bit.

Figure 82. Output configuration



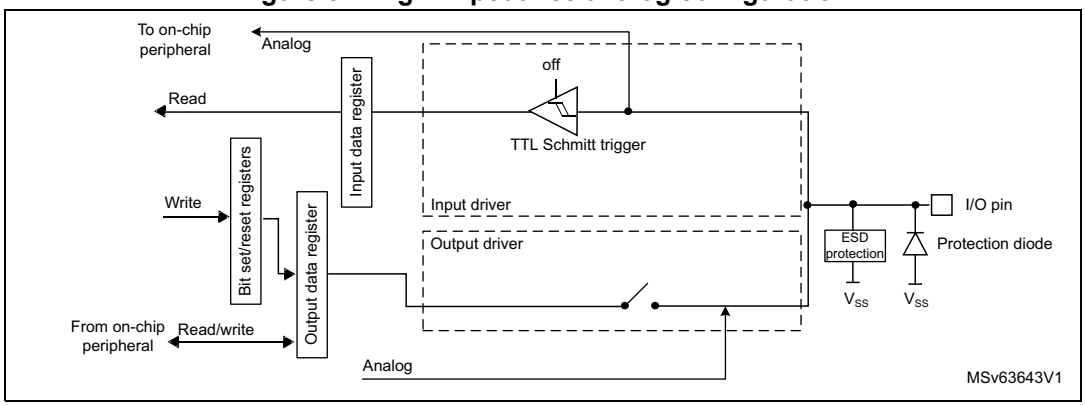
13.3.11 Alternate function configuration

When the I/O port is programmed as an alternate function:

- The output buffer can be configured in open-drain or push-pull mode.
- The output buffer is driven by the signals coming from the peripheral (transmitter enable and data).
- The Schmitt trigger input is activated.
- The weak pull-up and pull-down resistors are activated or not depending on the value in the GPIOx_PUPDR register.
- The data present on the I/O pin are sampled into the input data register every AHB clock cycle.
- A read access to the input data register gets the I/O state.

Figure 83 shows the alternate function configuration of the I/O port bit.

Figure 83. Alternate function configuration



13.3.12 Analog configuration

When the I/O port is programmed as an analog configuration:

- The output buffer is disabled.
- The Schmitt trigger input is deactivated, providing zero consumption for every analog value of the I/O pin. The output of the Schmitt trigger is forced to a constant value (0).
- The weak pull-up is disabled by hardware. The weak pull-down is configurable.
- Read access to the input data register gets the value 0.

Figure 84 shows the high-Z, analog-input configuration of the I/O port bits.

Figure 84. High-impedance analog configuration

13.3.13 Using the HSE or LSE oscillator pins as GPIOs

When the HSE or LSE oscillator is switched off (default state after reset), the related oscillator pins can be used as normal GPIOs.

When the HSE or LSE oscillator is switched on (by setting the HSEON or LSEON bit in the RCC_CSR register), the oscillator takes control of its associated pins and the GPIO configuration of these pins has no effect.

When the oscillator is configured in a user external clock mode, only the pin is reserved for clock input, and the OSC_OUT or OSC32_OUT pin can still be used as normal GPIO.

OSC32_IN and OSC32_OUT pins have limited driving capability and speed (see device datasheet for the data).

13.3.14 Using the GPIO pins in the RTC domain

The PC13/PC14/PC15 GPIO functionality is lost when the core supply domain is powered off (when the device enters Standby mode). In this case, if their GPIO configuration is not bypassed by the RTC configuration, these pins are set in an analog input mode.

For details about I/O control by the RTC, refer to *Section 49.3: RTC functional description*.

13.3.15 Privileged and unprivileged modes

All GPIO registers can be read and written by privileged and unprivileged accesses, whatever the security state (secure or nonsecure).

13.3.16 SMBUS 3.3 compliant mode for I2C pins

Some I/Os have the capability to be compliant with SMBUS 3.3 version. See device datasheet pinout table for a list of GPIOs that support SMBUS 3.3 compliant mode. To enable SMBUS 3.3 compliant mode on those pins, the pin must be configured in AF mode for the I2Cx peripheral and the corresponding I2CxSMB3EN bit must be set (in SBS_PMCR register).

13.3.17 I/Os state retention during standby mode

In the Standby mode, the I/Os are by default in floating state.

If the IORETEN or JTAGIORETEN bit in the PWR_IORETR register is set, the I/Os state is sampled during standby entry. The state of I/Os is applied to the pin via pull-up and pull-down resistors. The pull-up and pull-down resistors remains applied after Standby wake-up until the IORETEN/JTAGIORETEN bit in the PWR_IORETR register is cleared by the software.

13.3.18 TrustZone security

The TrustZone security is activated by the TZEN option byte in the FLASH option byte register. When the TrustZone is active (TZEN = 0xB4), each I/O pin of the GPIO port can be individually configured as secure through the GPIOx_SECCFGR register.

When the selected I/O pin is configured as secure, its corresponding configuration bits for alternate function, mode selection, I/O data are secure against a nonsecure access. In case of nonsecure access, these bits are RAZ/WI.

The I/Os with peripheral functions are also conditioned by the peripheral security configuration (see *Section 5: Global TrustZone® controller (GTZC)* for more details):

- For peripherals for which the I/O pin selection is done through alternate functions registers: if the peripheral is configured as secure, it cannot be connected to a nonsecure I/O pin. If this is not respected, the input data to the secure peripheral is

forced to 0 (I/O input pin value is ignored) and the output pin value is forced to 0, thus avoiding any secure information leak through nonsecure I/Os.

- For I/Os with analog switches, directly controlled by peripherals (such as ADC for instance): If the I/O is secure, the I/O analog switch cannot be controlled by a nonsecure peripheral. If this is not respected, the switch remains open. This prevents the redirection of secure data to a nonsecure peripheral or I/O through the analog path. Refer to *Section 3: System security* for more details.
- Some of the paths between I/Os “additional functions” and peripherals are not blocked if the I/O is secure and the peripheral is nonsecure. Therefore, it is recommended to configure those peripherals as secure even when not used by the application. Refer to *Section 3: System security* for the list of concerned peripherals. When the path has a security control, it follows the same rule as I/O selection through alternate functions.

Refer to the device pins definition table in the datasheet for more information about peripherals alternate functions and additional functions mapping.

After reset, all GPIO ports are secure.

The table below gives a summary of the I/O port-secured bits following the security configuration bit in the GPIO_SECCFGR register. When the I/O bit port is configured as secure:

- Secured bits: read and write operations are only allowed by a secure access. Non secure-read or write accesses on secured bits are RAZ/WI. There is no illegal access event generated.
- Nonsecure bits: no restriction. Read and write operations are allowed by both secure and nonsecure accesses.

When the TrustZone security is disabled (TZEN = 0xC3 in FLASH_OPTSR2 register), all registers bits are nonsecure. The GPIOx_SECCFGR register is WI and its content has no effect.

Table 140. GPIO secured bits

Secure configuration bit	Secured bit	Register name	Nonsecure access on secure bits
SECy = 1 in GPIOx_SECCFGR(1)	MODEy[1:0]	GPIOx_MODER	RAZ/WI

1. x = A to H

13.3.19 I/O compensation cell

The I/O commutation slew rate (tfall / trise) can be adapted by software depending on process, voltage and temperature conditions, to reduce the I/O noise on the power supply. Refer to *Section 14: System configuration, boot, and security (SBS)* for more details.

13.4 GPIO registers

This section gives a detailed description of the GPIO registers.

The peripheral registers can be written in word, half-word, or byte mode.

13.4.1 GPIO port mode register (GPIOx_MODER) (x = A to H)

Address offset:0x00

Reset value: 0xABFF FFFF (for port A)

Reset value: 0xFFFC FEBF (for port B)

Reset value: 0xFFFF FFFF (for port C) (0xFFC3 FFFF for STM32G53x/54x devices)

Reset value: 0xFFFF FFFF (for port D) (0x03FF 0000 for STM32G53x/54x devices)

Reset value: 0xFFFF FFF0 (for port E) (0xFC00 0030 for STM32G53x/54x devices)

Reset value: 0xFFFF C3F3 (for port F) (0x003C 0330 for STM32G53x/54x devices)

Reset value: 0x3FFC 0FF0 (for port G) (0x0000 00F0 for STM32G53x/54x devices)

Reset value: 0x0000 0C0F (for port H) (0x0000 0000F for STM32G53x/54x devices)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **OTy:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output type.

0: Output push-pull (reset state)

1: Output open-drain

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.3 GPIO port output speed register (GPIOx_OSPEEDR) (x = A to H)

Address offset: 0x08

Reset value: 0x0C00 0000 (for port A)

Reset value: 0x0000 00C0 (for port B)

Reset value: 0x0000 0000 (for the other ports)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **OSPEEDy[1:0]**: Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O output speed.

00: Low speed

01: Medium speed

10: High speed

11: Very-high speed

Note: Refer to the device datasheet for the frequency specifications, the power supply, and the load conditions for each speed.

The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.4 GPIO port pull-up/pull-down register (GPIOx_PUPDR) (x = A to H)

Address offset: 0x0C

Reset value: 0x6400 0000 (for port A)

Reset value: 0x0000 0100 (for port B)

Reset value: 0x0000 0000 (for the other ports)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **PUPDy[1:0]:** Port x configuration I/O pin y (y = 15 to 0)

These bits are written by software to configure the I/O pull-up or pull-down

00: No pull-up, pull-down

01: Pull-up

10: Pull-down

11: Reserved

Note: The bitfield is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.5 GPIO port input data register (GPIOx_IDR) (x = A to H)

Address offset: 0x10

Reset value: 0x0000 XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **IDy:** Port x input data I/O pin y (y = 15 to 0)

These bits are read-only. They contain the input value of the corresponding I/O port.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.6 GPIO port output data register (GPIOx_ODR) (x = A to H)

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **ODy:** Port output data I/O pin y (y = 15 to 0)

These bits can be read and written by software.

Note: For atomic bit set/reset, the OD bits can be individually set and/or reset by writing to the GPIOx_BSRR or GPIOx_BRR registers (x = A to H).

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.7 GPIO port bit set/reset register (GPIOx_BSRR) (x = A to H)

Address offset: 0x18

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 **BRy:** Port x reset I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Resets the corresponding ODy bit

Note: If both BSy and BRy are set, BSy has priority.

The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

Bits 15:0 **BSy:** Port x set I/O pin y (y = 15 to 0)

These bits are write-only. A read to these bits returns the value 0x0000.

0: No action on the corresponding ODy bit

1: Sets the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.8 GPIO port configuration lock register (GPIOx_LCKR) (x = A to H)

This register is used to lock the configuration of the port bits when a correct write sequence is applied to bit 16 (LCKK). The value of bits [15:0] is used to lock the configuration of the GPIO. During the write sequence, the value of LCKR[15:0] must not change. When the LOCK sequence has been applied on a port bit, the value of this port bit can no longer be modified until the next MCU reset or peripheral reset.

Note: A specific write sequence is used to write to the GPIOx_LCKR register. Only word access (32-bit long) is allowed during this locking sequence.

Each bit freezes a specific configuration register (control and alternate function registers).

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LCKK
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
LCK15	LCK14	LCK13	LCK12	LCK11	LCK10	LCK9	LCK8	LCK7	LCK6	LCK5	LCK4	LCK3	LCK2	LCK1	LCK0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **LCKK:** Lock key

This bit can be read any time. It can only be modified using the lock key write sequence.

0: Port configuration lock key not active

1: Port configuration lock key active. The GPIOx_LCKR register is locked until the next MCU reset or peripheral reset.

- LOCK key write sequence:

WR LCKR[16] = 1 + LCKR[15:0]

WR LCKR[16] = 0 + LCKR[15:0]

WR LCKR[16] = 1 + LCKR[15:0]

- LOCK key read

RD LCKR[16] = 1 (this read operation is optional but it confirms that the lock is active)

Note: During the LOCK key write sequence, the value of LCK[15:0] must not change.

Any error in the lock sequence aborts the LOCK.

After the first LOCK sequence on any bit of the port, any read access on the LCKK bit returns 1 until the next MCU reset or peripheral reset.

Bits 15:0 **LCKy:** Port x lock I/O pin y (y = 15 to 0)

These bits are read/write but can only be written when the LCKK bit is 0

0: Port configuration not locked

1: Port configuration locked

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.9 GPIO alternate function low register (GPIOx_AFRL) (x = A to H)

Address offset: 0x20

Reset value: 0x0000 0000

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BRy:** Port x reset IO pin y (y = 15 to 0)
These bits are write-only. A read to these bits returns the value 0x0000.
0: No action on the corresponding ODy bit
1: Reset the corresponding ODy bit

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.12 GPIO secure configuration register (GPIOx_SECCFGR) (x = A to H)

When the system is secure (TZEN = 0xB4), this register provides write access security and can be written only by a secure access. It is used to configure a selected I/O as secure. A nonsecure write access to this register is discarded.

When the system is not secure (TZEN = 0xC3), this register is WI and its content has no effect.

Address offset: 0x30

Reset value: 0x0000 FFFF (for port A)

Reset value: 0x0000 FEFF (for port B)

Reset value: 0x0000 FFFF (for port C) (0x0000 F9FF for STM32G53x/54x devices)

Reset value: 0x0000 FFFF (for port D) (0x0000 1F00 for STM32G53x/54x devices)

Reset value: 0x0000 FFFC (for port E) (0x0000 E004 for STM32G53x/54x devices)

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **SECy**: I/O pin of Port x secure bit enable y (y = 15 to 0)

These bits are written by software to enable or disable the I/O port pin security.

0: The I/O pin is nonsecure

1: The I/O pin is secure. Refer to *Table 140* for all corresponding secured bits.

Note: The bit is reserved and must be kept to reset value when the corresponding I/O is not available on the selected package.

13.4.13 GPIO register map

Table 141. GPIO register map and reset values

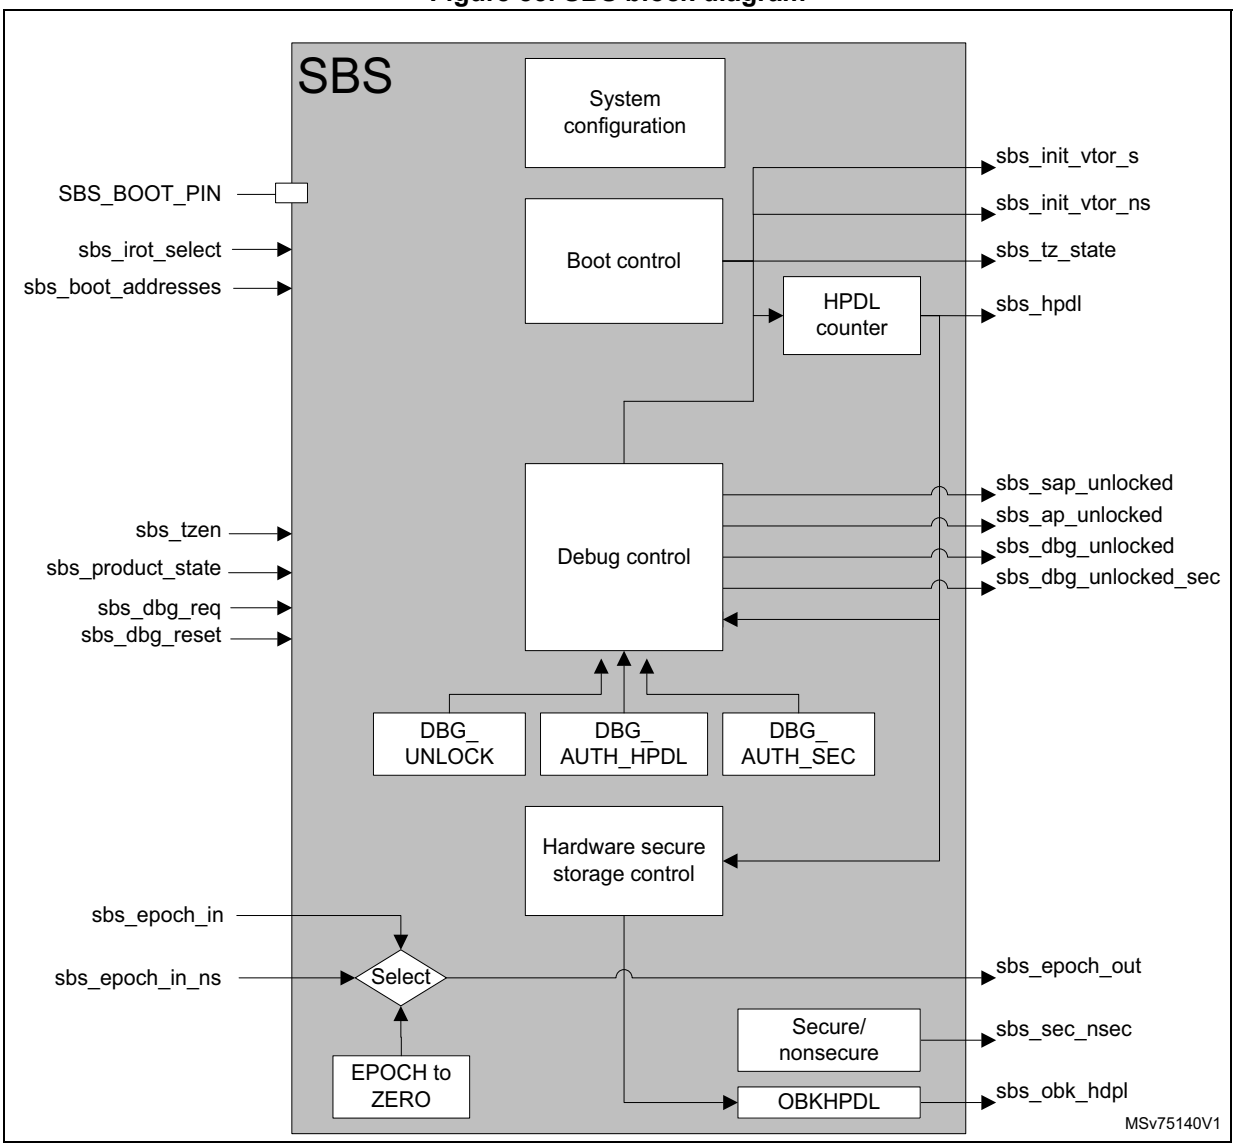
14 System configuration, boot, and security (SBS)

14.1 SBS introduction

The STM32G56x/55x/54x/53x devices feature a set of configuration registers located in the SBS. On top of various device configurations, this peripheral controls key boot and security features, including debug control and secure storage control.

14.2 SBS main features

- System configuration
  - Manage safety feature
  - Enable/disable the FMP (Fast-mode Plus) high-drive capability of some I/Os
  - Manage the I/O compensation cell
  - Configure register security access
- Boot control
  - Upon system reset, configure the Cortex-M33 boot address and the temporal isolation level depending on the current configuration such as PRODUCT_STATE (sbs_product_state), BOOT_UBE (sbs_irot_select), or TZEN (sbs_tzen).
  - Manage the temporal isolation feature implemented thanks to the hide protect level (HDPL) monotonic counter
- Debug control
  - Control the opening of the device debug interface, ensuring the sequencing of events that guarantee the device security
- Hardware secure storage control
  - Control the secure storage selections: OBK-HDPL selection (selects the area of secure storage of the flash memory and selects the corresponding DHUK in SAES), EPOCH selection



14.3 SBS functional description

14.3.1 SBS block diagram

Figure 85 shows the SBS block diagram, including the four main functions:

- System configuration
- Boot control
- Debug control
- Hardware secure storage control

Figure 85. SBS block diagram

14.3.2 SBS signals

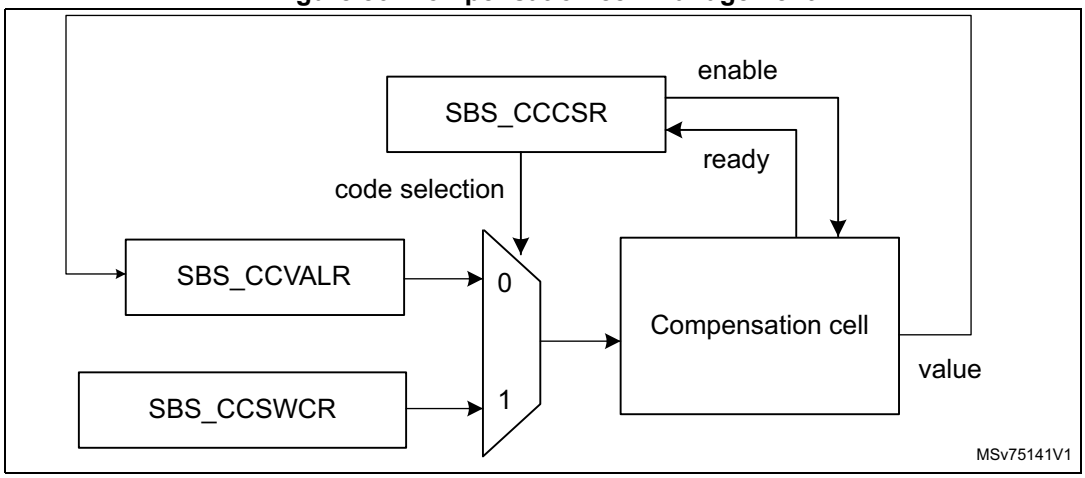
Table 142 details the user relevant internal signals that interface the SBS.

Table 142. SBS internal input/output signals

Signal name	Type	Description
BOOT0	Input	Select booting on user flash memory or bootloader when TrustZone is disabled (TZEN = 0xC3), or on RSS when TrustZone is enabled (TZEN = 0xB4).
sbs_irot_select		Signal based on BOOT_UBE option byte to select the iROT between STiRoT and user flash memory (OEMiRoT).
sbs_tzen		Signal based on TZEN option byte to activate/deactivate the TrustZone
sbs_boot_addresses		List of addresses defined by the flash memory: – BOOTADD: nonsecure boot address – SBOOTADD: secure boot address
sbs_product_state		Signal based on PRODUCT_STATE option byte to activate the different security mechanisms depending on the product use. Expected values are described in *Section 7: Embedded flash memory (FLASH)*.
sbs_dbg_req		Launch the debug authentication protocol when booting.
sbs_init_vtor_s	Output	Vector address for Cortex-M33 secure entry point.
sbs_init_vtor_ns		Vector address for Cortex-M33 nonsecure entry point.
sbs_tz_state		Inform the Cortex-M33 on the secure state of the core.
sbs_hdpl		HDPL (temporal isolation level, ID of the boot level, used to isolate boot levels) This signal reflects a monotonic counter that can be incremented from 0 to 3, and that is reset to 0 only on software reset or POR.
sbs_ap_unlocked		Control the Cortex-M33 access port.
sbs_sap_unlocked		Control the AHB access port.
sbs_dbg_unlocked		Unlock the debug (when set to 1) for the Cortex-M33 nonsecure part.
sbs_dbg_unlocked_sec		Unlock the debug (when set to 1) for the Cortex-M33 secure part.
sbs_dbg_reset	Input	Control the reset of the debug authentication configuration to be done with a system reset or a power-on reset. The configuration is done through the DBGMCU using the DCRT bitfield of DBGMCU_CR register.
sbs_obk_hdpl	Output	Select secure storage domain (OBK-HDPL) for current HDPL, or greater ones to allow provisioning.
sbs_epoch_out		EPOCH counters (NS_EPOCH and SEC_EPOCH, inputs from flash memory) are used to manage the REPLAY protection.
sbs_sec_nsec		Reflect secure/nonsecure selection for the secure storage.

14.3.3 SBS reset and clocks

The SBS configuration port is clocked by the AHB bus clock. There is a general reset and a debug configuration reset controlled in DBGMCU.



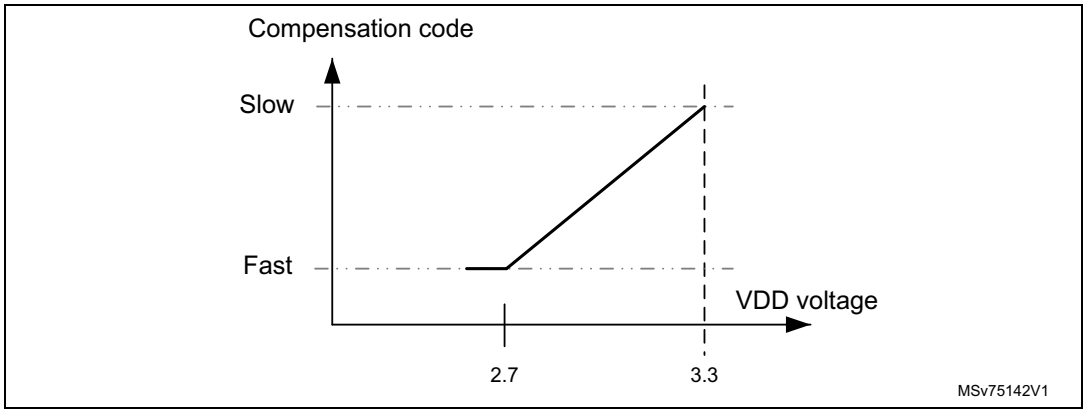
14.3.4 SBS system configuration

SBS I/O compensation cell management

The I/O compensation cell generates an 8-bit value for the I/O buffer (4 bits for N-MOS and 4 bits for P-MOS) that depends on PVT operating conditions (process, voltage, temperature). These bits are used to control the output impedance in the I/O buffer, and the slew rate of the I/O commutation (the t_{fall} and t_{rise} time) in order to reduce the I/O noise on power supply.

As shown in *Figure 86*, the compensation cell is split in two blocks: one block to provide an optimal code for the current PVT, and one block to drive the block controlled by the software.

Figure 86. Compensation cell management



The compensation cell value can be read when the READY flag is set in SBS_CCCSR. With CS1 in SBS_CCCSR, the application can select the value to apply between two options: the code from the cell or the code from SBS_CCSWCR.

One compensation cell is embedded in STM32G56x/55x/54x/53x and dedicated to the I/Os supplied by the V_{DD} power rail.

By default, the compensation cells are disabled, and a fixed code is applied to all the I/Os.

Figure 87. Compensation cell use

SBS TrustZone security and privilege

- SBS TrustZone security

  When the TrustZone security is activated, the SBS is able to protect secure registers from being modified by nonsecure accesses.

  The TrustZone security is activated by the TZEN option byte in FLASH_OPTSR2_PRG.

  A nonsecure read/write access to a secured register is RAZ/WI and generates an illegal access event. An illegal access interrupt is generated if the SBS illegal access event is enabled in the GTZC.

- Privileged/unprivileged mode

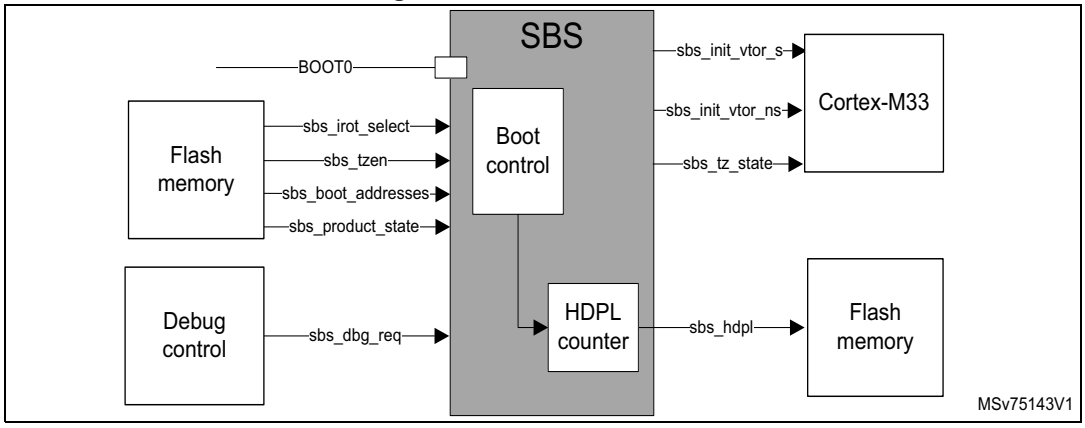
  The SBS registers can be read and written by privileged and unprivileged accesses except the SBS registers for CPU configuration:

  – SBS_CSLCKR, SBS_FPUIMR, SBS_CNSLCKR, SBS_EPOCHSELCR, SBS_ECCNMIR, SBS_ECCNMIR, SBS_SWAPLOCKR and SBS_FBMODER

  – FPUSEC in SBS_SECCFGR

  An unprivileged access to a privileged register is RAZ/WI.

14.3.5 SBS SMBUS 3.3 control



The SBS can be used to control the I/Os which are compliant with SMBUS revision 3.3 specification. SMBUS 3.3 compliant mode on specific pins (see device datasheet pinout table) is controlled by corresponding I2CxSMB3EN bit (in SBS_PMCR register).

14.3.6 SBS boot control

The SBS can be used to control the boot entry points considering the product settings. The main boot control actions are listed below:

- Run product with or without TrustZone enabled.
- Select between STiRoT or OEMiRoT.
- Boot when launching a debug authentication sequence.
- Select boot between the bootloader or the user flash memory boot.
- Initialize the HDPL boot value.

Figure 88. SBS boot control

The boot configurations are selected considering the product settings:

- BOOT0: to select booting on user flash memory or RSS (root secure services)
- BOOT_UBE option byte to select the iRoT between STiRoT and OEMiRoT
- TZEN option byte to activate/deactivate the TrustZone
- sbs_boot_addresses: list of addresses defined by the flash memory:
  - BOOTADD: nonsecure boot address
  - SBOOTADD: secure boot address
- PRODUCT_STATE: option byte to activate the different security mechanisms depending on the product use. Expected values are described in *Section 7: Embedded flash memory (FLASH)*.
- sbs_dbg_req: used to launch the debug authentication protocol when booting.

The boot control logic sets the following data:

- sbs_init_vtor_s: vector address for Cortex-M33 secure entry point
- sbs_init_vtor_ns: vector address for Cortex-M33 nonsecure entry point
- sbs_tz_state (secure/nonsecure): informs the Cortex-M33 on the secure state of the core.
- HDPL

SBS HDPL (temporal isolation level) management

The HDPL is a monotonic counter incremented during the boot stages. The HDPL is reset to its default value only after a power-on or a system reset. This default value (0 or 1) depends on the device life cycle, as defined in boot logic.

The devices use HDPL information to automatically isolate code and its associated secrets (like keys) during the boot process. Incrementing HPDL ensures that private code and data for one boot stage cannot be directly accessible from later boot stages.

The HDPL is used by the user flash memory. See *Section 7: Embedded flash memory (FLASH)* for more details. The HDPL can take values from 0 to 3. When reaching 3, HDPL keeps this value until reset. The current HDPL value is readable in HDPL bitfield in SBS_HDPLSR.

To increment the HDPL by one, the application must write 0x6A to INCR_HDPL in SBS_HDPLCR. After such increment, and before doing any subsequent action, the user must check that the HDPL has effectively been incremented by reading SBS_HDPLSR.

Table 143. HDPL encoded values

HDPL	Code
0	0xB4

14.3.7 SBS debug control

The SBS debug control is used to manage debug opening, taking care on the product context (PRODUCT_STATE, TZEN, HDPL) on register settings, or through a debug authentication control.

When the debug is forbidden, the mailbox access port, Cortex-M33 access port, and CPU debug interface are locked. In this situation, the debugger cannot access the CPU and no effective debug can be done. Refer to the*Section 60: Debug support (DBG)* for more details.

Authenticated debug sequence

1. The external host requests to launch the debug authentication protocol via the DBGMCU access port mailbox. The rest of the device is kept under reset.
2. SBS selects the STMicroelectronics RSS-DA (debug authentication library) boot address, and requests the CPU to be released from reset.
3. The CPU running RSS-DA library executes the debug authentication protocol in the system flash memory. If the device is closed, the access port mailbox is closed until RSS-DA acknowledges the authentication sequence start request.
4. There are two authentication methods:
   – Certificate: As soon as the device fully verifies a debug certificate chain:

     If the certificate concerns a debug permission, then the STRSS-DA programs the debug opening of the Arm® Cortex-M33. Note that in case the TrustZone is

disabled (TZEN = 0xC3), the nonsecure only debug opening and secure/nonsecure debug opening have the same effect.

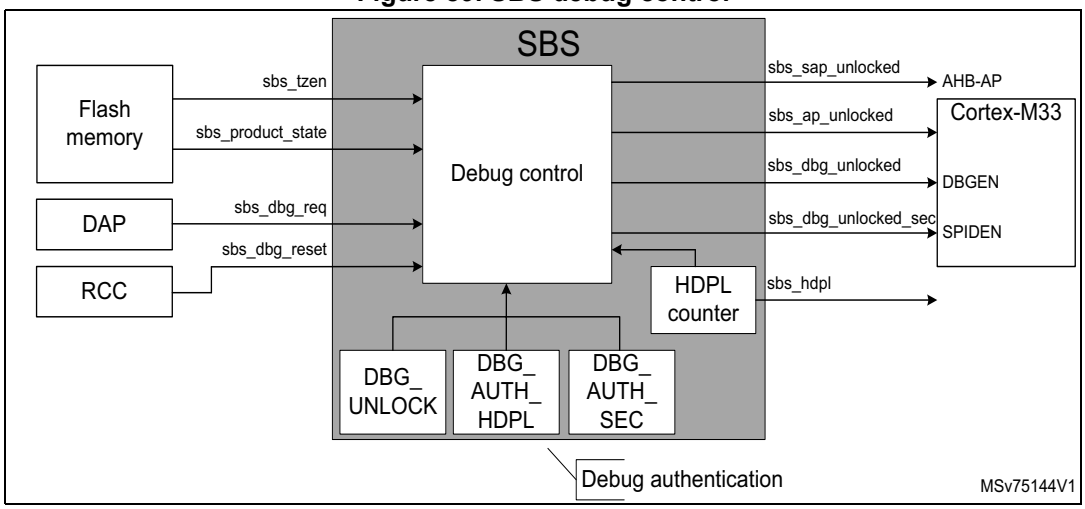
Alternatively, the certificate can authorize partial or full regression that allows debugging on a regressed part.

– Password: This method only allows the full regression of the product to be controlled.

5. Above reopenings are effective only when HDPL in SBS_HDPLSR has a value equal or superior to the value programmed in DBG_AUTH_HDPL in SBS_DBGCR. In case of authentication failure, the user is informed through the host interface.

*Note: The debug authentication library in system flash memory is available only when HDPL = 0 or 1 in SBS_*HDPL*SR. Only this library can perform the steps 3 and 4 described above.*

Debug reset



The debug opening can have the configuration to be reset by system or power-on reset, depending on a DBGMCU register field.

Debug locking

The debug configuration can be locked thanks to DBGCFG_LOCK in SBS_DBGLOCKR. SBS_DBGCR and SBS_DBGCR2 is then no longer writable.

When DBGCFG_LOCK is set to 1, it can be reset only by system or power-on reset. The configuration is done through the DBGMCU using the DCRT field of DBGMCU_CR.

Figure 89. SBS debug control

Inputs used to control the debug opening:

- sbs_dbg_req: input signal that a host requests to launch the debug authentication protocol. When this signal is set, the boot address is set to launch the debug authentication library.
- sbs_tzen: inform on the selected platform configuration related to TrustZone activation. When TZEN value is set to 0 (0xC3), the platform does not support TrustZone and the

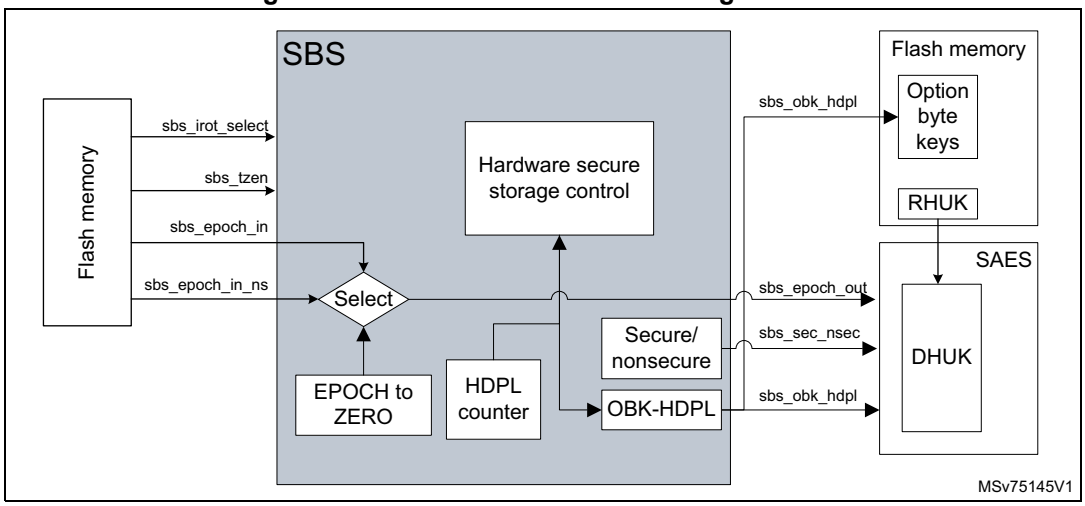
simplified life cycle is proposed. See *Section 7: Embedded flash memory (FLASH)* for more details.

- sbs_product_state: provide the current PRODUCT_STATE (from flash memory). See *Section 7: Embedded flash memory (FLASH)* for more details.
- sbs_dbg_reset: reset information coming from the RCC, and reset SBS_DBGCR and SBS_CBGCR2 if these registers are configured to be reset.

Configuration

- DBG_UNLOCK in SBS_DBGCR: debug unlock when DBG_AUTH_HDPL is reached.
- AP_UNLOCK in SBS_DBGCR: access port unlock
- SEC_AP_UNLOCK in SBS_DBGCR: Arm® Cortex®-M33 (AHB_AP) secure access port unlock
- DBG_AUTH_HDPL in SBS_DBGCR: authenticated debug temporal isolation level. Define the HDPL value from which the debug can be opened. Value can only be from 1 to 3.
- DBG_AUTH_SEC in SBS_DBGCR: specify if the debug reopening is for nonsecure only or for both (secure and nonsecure).
- DBGC_LOCK in SBS_DBGLOCKR: lock the current debug configuration (released only by a reset).

Outputs



- sbs_sap_unlocked: signal controlling the AHB access port
  - 1: 0xB4
  - 0: all other codes
- sbs_ap_unlocked: signal controlling the Cortex-M33 access port
  - 1: 0xB4
  - 0: all other codes
- sbs_dbg_unlocked: unlock the debug (when set to 1) for the Cortex-M33 nonsecure.
  - 1: 0xB4
  - 0: all other codes
- sbs_dbg_unlocked_sec: unlock the debug (when set to 1) for the Cortex-M33 secure.
  - 1: 0xB4
  - 0: all other codes

14.3.8 SBS hardware secure storage control

This feature ensures the isolation of keys and data related to RoT (root-of-trust) when re-opening the debug (when product in the field).

This includes a dedicated area called OB-Keys in the flash memory (see *Section 7: Embedded flash memory (FLASH)* for more details), and the key derivation (DHUK) mechanism protecting data using a hardware key different for the identified domains.

Figure 90. SBS hardware secure storage control

- sbs_obk_hdpl: select secure storage context for current HDPL, or greater ones (to allow provisioning). This signal is set thanks to the SBS_NEXTHDPLCR register. This information is used by the flash memory to select the right area, and by the SAES when processing the derived key to generate a key derived related to HDPL context.
- sbs_epoch_out: EPOCH counters are used to manage the REPLAY protection. These counters are incremented when regressions are done. Injecting the EPOCH in the DHUK (in the SAES) ensures that all information encrypted with the DHUK cannot be replayed after a regression.
- sbs_sec_nsec: apply a different protection DHUK for secure and nonsecure assets.

All keys encrypted using the SAES/DHUK inherit of the RHUK property: unique per device.

All data encrypted thanks to the SAES using the DHUK are specific to a combination of [sbs_obk_hdpl + sbs_epoch_out + sbs_sec_nsec].

Inputs used to control the hardware secure storage control

sbs_epoch_in and sbs_epoch_in_ns: 24-bit values coming from the flash memory and representing regression counters respectively for secure and nonsecure.

Configuration

- NEXTHDPL in SBS_NEXTHDPLCR: access to next HDPL secure storage areas.
- EPOCH_SEL in SBS_EPOCHSELCR: select the EPOCH source related to the secure storage under control (SEC_EPOCH, NS_EPOCH, or FORCED_To_Zero).

Table 145. OBK-HDPL logic

HDPL[7:0] in SBS_HDPLSR	NEXTHDPL[1:0]			
	0x0	0x1	0x2	0x3
0 (0xB4)	0xB4	0x51	0x8A	0x6F
1 (0x51)	0x51	0x8A	0x6F	
2 (0x8A)	0x8A	0x6F		
3 (0x6F)	0x6F			
Others				

14.3.9 SBS flash banks control

Two registers control the flash bank swapping operation as shown in *Table 146*:

- FB_MODE value indicates the hardware physical address of flash banks.
- SWAP_LOCK value, when asserted, prevents any CPU access from modifying the bank mapping.

Table 146. Bank swap control

SWAP_LOCK	FB_MODE	Bank1 address	Bank2 address	FB_MODE change allowed	SWAP_LOCK change allowed
0xC3	0xC3	0x0800_0000	0x0804_00000	0xB4	0xB4
0xC3	0xB4	0x0804_0000	0x0800_0000	0xC3	
0xB4	0xC3	0x0800_0000	0x0804_0000	no change allowed	
0xBA	0xB4	0x0804_0000	0x0800_0000		

Both FB_MODE and SWAP_LOCK access permissions are restricted to secure state if TrustZone is enabled (TZEN = 0xB4), and always restricted to privileged mode whatever the TrustZone is enabled or disabled. Any illegal access is reported in TZIC.

Hardware initialization

- FB_MODE inherits after reset from the value of the SWAP_BANK option byte.
- SWAP_LOCK inherits after reset from the value of the SWAP_LOCKOUT option byte.

14.4 SBS interrupts

SBS does not support interrupts.

14.5 SBS registers

14.5.1 SBS temporal isolation control register (SBS_HDPLCR)

Address offset: 0x010

Reset value: 0x0000 00B4

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	INCR_HDPL[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **INCR_HDPL[7:0]**: increment HDPL value
0xB4: no increment
0x6A: recommended value to increment HDPL level by one
Others: all other values allow a HDPL level increment.

14.5.2 SBS temporal isolation status register (SBS_HDPLSR)

Address offset: 0x014

Reset value: 0xXXXX XXXX

The reset value depends on boot case: booting with HDPL0 for ST code, or HDPL1 for all other cases. See *Table 144* for more details.

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	HDPL[7:0]							
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **HDPL[7:0]**: temporal isolation level
This bitfield returns the current temporal isolation level.
0xB4: HDPL0, RSS
0x51: HDPL1, iRoT
0x8A: HDPL2, uRoT
0x6F: HDPL3, application (secure/nonsecure)

14.5.3 SBS next HDPL control register (SBS_NEXTHDPLCR)

Address offset: 0x018

Reset value: 0x0000 0000

Reset: system reset

Register security: no restriction

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NEXTHDPL[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **NEXTHDPL[1:0]**: index to point to a higher HDPL than the current one

Index to add to the current HDPL to point (through OBK-HDPL) to the next secure storage areas (OBK-HDPL = HDPL + NEXTHDPL). See *Table 145* for more details.

14.5.4 SBS debug control register (SBS_DBGCR)

Address offset: 0x020

Reset value: 0x0000 0000

Reset: debug reset (system reset or power-on reset)

Register security: HDPL0/1, RAZ/WI otherwise

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DBG_AUTH_SEC[7:0]								DBG_AUTH_HDPL[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DBG_UNLOCK[7:0]								AP_UNLOCK[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 **DBG_AUTH_SEC[7:0]**: control debug opening secure/nonsecure

Write 0xB4 to this bitfield to open debug for secure and nonsecure.
Writing any other values only open nonsecure.

Bits 23:16 **DBG_AUTH_HDPL[7:0]**: authenticated debug temporal isolation level

Writing to this bitfield defines at which HDPL the authenticated debug opens.
0x51: HDPL1
0x8A: HDPL2
0x6F: HDPL3

Note: Writing any other values is ignored. Reading any other value means the debug never opens.

Bits 15:8 **DBG_UNLOCK[7:0]**: debug unlock when DBG_AUTH_HDPL is reached

Write 0xB4 to this bitfield to open the debug when HDPL in SBS_HDPLSR equals to DBG_AUTH_HDPL in this register.

Bits 7:0 **AP_UNLOCK[7:0]**: access port unlock
Write 0xB4 to this bitfield to open the device access port.

14.5.5 SBS debug lock register (SBS_DBGLOCKR)

Address offset: 0x024

Reset value: 0x0000 00B4

Reset: debug reset (system reset or power-on reset)

Register security: HDPL0/1, RAZ/WI otherwise

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBGCFG_LOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **DBGCFG_LOCK[7:0]**: debug configuration lock
Reading this bitfield returns 0x6A if the bitfield value is different from 0xB4.
0xC3 is the recommended value to lock the debug configuration using this bitfield.
0xB4: Writes to SBS_DBGCR and SBS_DBGCR2 allowed (default)
Others: Writes to SBS_DBGCR and SBS_DBGCR2 ignored

14.5.6 SBS debug control register 2 (SBS_DBGCR2)

Address offset: 0x028

Reset value: 0x0000 0000

Reset: debug reset (system reset or power-on reset)

Register security: HDPL0/1, RAZ/WI otherwise

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC_AP_UNLOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SEC_AP_UNLOCK[7:0]**: Secure AHB access port unlock.
Write 0xB4 to this bitfield to open the secure AHB access port.

14.5.7 SBS RSS command register (SBS_RSSCMDR)

Address offset: 0x034

Reset value: 0x0000 0000

Reset: power-on reset

Register security: always secure (RAZ/WI if nonsecure)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RSSCMD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RSSCMD[15:0]**: RSS command

The application can use this bitfield to pass on a command to the RSS, executed at the next reset.

When RSSCMD ≠ 0 and PRODUCT_STATE is in Open, then the system always boots on RSS whatever is the boot pin value.

14.5.8 SBS EPOCH selection control register (SBS_EPOCHSELCR)

Address offset: 0x0A0

Reset value: 0x0000 0000

Reset: system reset

Register security: Secure when TZ_STATE = 1 (RAZ, WI in nonsecure access). Nonsecure protection when TZ_STATE = 0. This register is protected by privileged whatever is TZ_STATE, RAZ/WI if non privileged access.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EPOCH_SEL[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **EPOCH_SEL[1:0]**: select EPOCH value to be sent to the SAES

00: NS_EPOCH (nonsecure) counter input selected

01: SEC_EPOCH counter input selected

1x: EPOCH forced to zero

14.5.9 SBS security mode configuration control register (SBS_SECCFGR)

Address offset: 0x0C0

Reset value: 0x0000 0000

Reset: system reset

Register security: always secure. RAZ/WI if nonsecure transaction and TZ_STATE = 1. RAZ/WI if TZ_STATE = 0.

This register is programmed by secure software if the user wants functions configurable through system registers to be secure or not.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPUSEC	Res.	CLASSBSEC	SBSSEC
												rw		rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **FPUSEC**: FPU security enable
0: SBS_FPUIMR register accessible through secure or nonsecure transaction
1: SBS_FPUIMR register accessible only through secure transaction
Note: This bit can be written only through privilege transaction.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CLASSBSEC**: ClassB security enable
0: SBS_CFGR2 register accessible through secure or nonsecure transaction
1: SBS_CFGR2 register accessible only through secure transaction

Bit 0 **SBSSEC**: SBS clock control, memory-erase status register and compensation cell register security enable
0: SBS_MESR, SBS_CCCSR, SBS_CCVALR, SBS_CCSWCR registers accessible through secure or nonsecure transaction
1: SBS_MESR, SBS_CCCSR, SBS_CCVALR, SBS_CCSWCR registers accessible only through secure transaction

14.5.10 SBS product mode and configuration register (SBS_PMCR)

Address offset: 0x100

Reset value: 0x0000 0000

Reset: system reset

Register security:

- When TrustZone is activated (TZEN = 0xB4):
  - depending on I/O PBx_SEC_EN secure input for PBx_FMP configuration bits
- When TrustZone is disabled (TZEN = 0xC3), there is no access restriction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PB9_FMP	Res.	PB7_FMP	PB6_FMP
												rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	I2C4SMB3EN	I2C3SMB3EN	Res.	I2C1SMB3EN
												rw	rw		rw

Bits 31:20 Reserved, must be kept at reset value.

Bit 19 **PB9_FMP**: Fast-mode Plus driving capability activation on PB9

This bit can be read and written only with secure access if PB9 is secure in GPIOB. This bit enables the Fm+ driving mode for PB9 when PB9 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB9 pin operates in standard mode.

1: Fm+ mode is enabled on PB9 pin and the speed control is bypassed.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PB7_FMP**: Fast-mode Plus driving capability activation on PB7

This bit can be read and written only with secure access if PB7 is secure in GPIOB. This bit enables the Fm+ driving mode for PB7 when PB7 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB7 pin operates in standard mode.

1: Fm+ mode is enabled on PB7 pin and the speed control is bypassed.

Bit 16 **PB6_FMP**: Fast-mode Plus driving capability activation on PB6

This bit can be read and written only with secure access if PB6 is secure in GPIOB. This bit enables the Fm+ driving mode for PB6 when PB6 is not used by I2C peripheral. This can be used to drive a LED for instance.

0: PB6 pin operates in standard mode.

1: Fm+ mode is enabled on PB6 pin and the speed control is bypassed.

Bits 15:4 Reserved, must be kept at reset value.

Bit 3 **I2C4SMB3EN**: SMBUS 3.0 on I2C4 enable

0: SMBUS 3.3 on I2C4 disable

1: SMBUS 3.3 on I2C4 enable

Note: Depending on device

Bit 2 **I2C3SMB3EN**: SMBUS 3.3 on I2C3 enable
0: SMBUS 3.3 on I2C3 disable
1: SMBUS 3.3 on I2C3 enable
Note: Depending on device

Bit 1 Reserved, must be kept at reset value.

Bit 0 **I2C1SMB3EN**: SMBUS 3.3 on I2C1 enable
0: SMBUS 3.3 on I2C1 disable
1: SMBUS 3.3 on I2C1 enable

14.5.11 SBS FPU interrupt mask register (SBS_FPUIMR)

Address offset: 0x104

Reset value: 0x0000 001F

Reset: system reset

Register security: depends on FPUSEC in SBS_SECCFGR

This register is accessible only through privilege transaction.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPU_IE[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **FPU_IE[5:0]**: FPU interrupt enable
Set and cleared by software to enable the Cortex-M33 FPU interrupts
FPU_IE[5]: inexact interrupt enable (interrupt disabled at reset)
FPU_IE[4]: input abnormal interrupt enable
FPU_IE[3]: overflow interrupt enable
FPU_IE[2]: underflow interrupt enable
FPU_IE[1]: divide-by-zero interrupt enable
FPU_IE[0]: invalid operation interrupt enable

14.5.12 SBS memory erase status register (SBS_MESR)

Address offset: 0x108

Reset value: 0x0000 000X (bit 0 is not affected by system reset)

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPMEE
															rc_w1
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MCLR
															rc_w1

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **IPMEE**: ICACHE erase status
This bit is set by hardware when ICACHE and PKA RAM erase is completed after potential and confirmed tamper detection or a product state regression. Refer to *Section 50: Tamper and backup registers (TAMP)* for more details.
This bit is cleared by software by writing 1 to it.
0: ICACHE and PKA RAM erase on going
1: ICACHE and PKA RAM erase done

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **MCLR**: device memories erase status
This bit is set by hardware when SRAM1, SRAM2, SRAM3, ICACHE, DCACHE and PKA RAM erase is completed after power-on reset or tamper detection or product state regression. Refer to *Section 50: Tamper and backup registers (TAMP)*.
This bit is not reset by system reset and is cleared by software by writing 1 to it.
0: memory erase on going if not yet cleared by software
1: Memory erase done

14.5.13 SBS compensation cell for I/Os control and status register (SBS_CCCSR)

Address offset: 0x110

Reset value: 0x0000 0000

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	RDY1	Res.	Res.	Res.	Res.	Res.	Res.	CS1	EN1
							r							rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **RDY1**: VDD compensation cell ready flag
This bit provides the status of the compensation cell.
0: VDD compensation cell not ready
1: VDD compensation cell ready (code value provided by the cell can be used)

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **CS1**: code selection for VDD power rail (reset value set to 1)
This bit selects the code to be applied for the I/O compensation cell.
0: Code from the cell (available in the SBS_CCVALR)
1: Code from SBS_CCSWCR

Bit 0 **EN**1: enable compensation cell for VDD power rail
This bit enables the I/O compensation cell.
0: I/O compensation cell disabled
1: I/O compensation cell enabled

14.5.14 SBS compensation cell for I/Os value register (SBS_CCVALR)

Address offset: 0x114

Reset value: 0x0000 0088

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	APSRC1[3:0]				ANSRC1[3:0]			
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **APSRC1[3:0]**: compensation value for the PMOS transistor

This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

Bits 3:0 **ANSRC1[3:0]**: compensation value for the NMOS transistor

This value is provided by the cell and must be interpreted by the processor to compensate the slew rate in the functional range.

14.5.15 SBS compensation cell for I/Os software code register (SBS_CCSWCR)

Address offset: 0x118

Reset value: 0x0000 0078

Reset: system reset

Register security: depends on SBSSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SW_APSRC1[3:0]				SW_ANSRC1[3:0]			
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:4 **SW_APSRC1[3:0]**: PMOS compensation code for the VDD power rails

This bitfield is written by software to define an I/O compensation cell code for PMOS transistors of the VDD power rail. This code is applied to the I/O when CS1 is set in SBS_CCCSR.

Bits 3:0 **SW_ANSRC1[3:0]**: NMOS compensation code for VDD power rails

This bitfield is written by software to define an I/O compensation cell code for NMOS transistors of the VDD power rail. This code is applied to the I/O when CS1 is set in SBS_CCCSR.

14.5.16 SBS Class B register (SBS_CFGR2)

Address offset: 0x120

Reset value: 0x0000 0000

Reset: system reset

Register security: depends on CLASSBSEC in SBS_SECCFGR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCECCL	ECCL	PVDL	SEL	CLL
											rs	rw	rs	rs	rs

Bits 31:5 Reserved, must be kept at reset value.

Bit 4 **DCECCL**: Arm® Cortex®-M33 D-CACHE ECC lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the Arm® Cortex®-M33 D-CACHE double ECC error with break input of TIM1/8/15/16/17.

0: Arm® Cortex®-M33 D-CACHE double ECC error flag disconnected to timer break inputs

1: Arm® Cortex®-M33 D-CACHE double ECC error flag connected to timer break inputs

Bit 3 **ECCL**: ECC lock

This bit is set and cleared by software. It can be used to enable and lock the flash memory double ECC error with break input of TIM1/8/15/16/17.

0: double ECC error flag disconnected to timer break inputs

1: double ECC error flag connected to timer break inputs

Bit 2 **PVDL**: PVD lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the PVD connection with TIM1/8/15/16/17 break inputs.

0: PVD interrupt disconnected from timer break inputs. PVDE and PLS[2:0] in the PWR registers are read/write

1: PVD interrupt is connected to timer break inputs. PVDE and PLS[2:0] in the PWR registers are read only

Bit 1 **SEL**: SRAM ECC error lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the SRAM double ECC error signal with break input of TIM1/8/15/16/17.

0: SRAM double ECC error flag disconnected from timer break inputs

1: SRAM double ECC error flag connected to timer break inputs

Bit 0 **CLL**: core lockup lock

This bit is set by software and cleared only by a system reset. It can be used to enable and lock the lockup (HardFault) output of Cortex-M33 with TIM1/8/15/16/17 break inputs.

0: lockup output disconnected from timer break inputs

1: lockup output connected to timer break inputs

14.5.17 SBS CPU nonsecure lock register (SBS_CNSLCKR)

Address offset: 0x144

Reset value: 0x0000 0000

Reset: system reset

Register security: This register can be read and written by privileged access only. Unprivileged access is RAZ/WI.

This register is used to lock the configuration of nonsecure MPU and VTOR_NS registers of the Cortex-M33.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKNSMPU	LOCKNSVTOR
														rs	rs

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **LOCKNSMPU**: nonsecure MPU register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to nonsecure MPU_CTRL_NS, MPU_RNR_NS and MPU_RBAR_NS registers.

0: nonsecure MPU registers write enabled

1: nonsecure MPU registers write disabled

Bit 0 **LOCKNSVTOR**: VTOR_NS register lock

This bit is set by software and cleared only by a system reset.

0: VTOR_NS register write enabled

1: VTOR_NS register write disabled

14.5.18 SBS CPU secure lock register (SBS_CSLCKR)

Address offset: 0x148

Reset value: 0x0000 0000

Reset: system reset

Register security: This register can be written only when the access is secure/privilege.

A nonsecure read/write access is RAZ/WI and generates an illegal access event. When the system is not secure (TZ_STATE = 0), this register is RAZ/WI.

This register is used to lock the configuration of PRIS and BFHFNMINS in the AIRCR, SAU, secure MPU and VTOR_S registers of the Cortex-M33.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCKSAU	LOCKSMPU	LOCKSVTAIRCR
													rs	rs	rs

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **LOCKSAU**: SAU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers.

0: SAU registers write enabled

1: SAU registers write disabled

Bit 1 **LOCKSMPU**: secure MPU registers lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to secure MPU_CTRL, MPU_RNR and MPU_RBAR registers.

0: Secure MPU registers writes enabled

1: Secure MPU registers writes disabled

Bit 0 **LOCKSVTAIRCR**: VTOR_S and AIRCR register lock

This bit is set by software and cleared only by a system reset. When set, this bit disables write access to VTOR_S register, PRIS and BFHFNMINS bits in the AIRCR register.

0: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write enabled

1: VTOR_S register PRIS and BFHFNMINS bits in the AIRCR register write disabled

14.5.19 SBS ECC NMI mask register (SBS_ECCNMIR)

Address offset: 0x14C

Reset value: 0x0000 0000

Reset: system reset

Register security: secure access only when TZ_STATE = 1 (RAZ/WI in nonsecure access). No security protection if TZ_STATE = 0.

This register is accessible only through privilege transaction.

This register sets up the expected behavior on NMI regarding double ECC errors from the flash memory.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ECCNMI_MASK_EN
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ECCNMI_MASK_EN**: NMI behavior setup when a double ECC error occurs on FLASH data part

0: NMI generated if a double ECC error in the FLASH data part

1: NMI not generated if a double ECC error in the FLASH data part

14.5.20 SBS debug control register 2 (SBS_SWAPLOCKR)

Address offset: 0x170

Reset value: 0x0000 00B4

Reset: debug reset (system reset or power-on reset)

Register security:

- Secure access only when TZ_STATE = 1 (RAZ/WI in nonsecure access). No security protection if TZ_STATE = 0.
- This register is accessible only through privilege transaction.
- Write ignored if SBS_SWAPLOCKR.SWAP_LOCK = 0xB4.

This register is used to prevent specific configurations on memory remap.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWAP_LOCK[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SWAP_LOCK[7:0]**: Flash bank swap operation lock

0xC3: Flash bank swap operation allowed, FB_MODE and SWAP_BANK option byte can be modified
0xB4: Flash bank swap operation not allowed, FB_MODE and SWAP_BANK option byte access blocked

14.5.21 SBS debug control register 2 (SBS_FBMODER)

Address offset: 0x174

Reset value: 0x0000 00C3

Reset: debug reset (system reset or power-on reset)

Register security:

- Secure access only when TZ_STATE = 1 (RAZ/WI in nonsecure access). No security protection if TZ_STATE = 0.
- This register is accessible only through privilege transaction.
- Write ignored if SBS_SWAPLOCKR.SWAP_LOCK = 0xB4.

This register is used for specific configurations on memory remap.

Refer to *Section 2.3* for the register boundary addresses.

15 Peripherals interconnect matrix

15.1 Interconnect matrix introduction

Several peripherals have direct connections between them, enabling autonomous communication and/or synchronization: this approach saves CPU resources and power supply consumption. In addition, these hardware connections remove software latency and help the design of a predictable system.

Depending on peripherals, these interconnections can operate in Run, Sleep, and Stop modes.

15.2 Connection summary

1. Numbers in this table are links to corresponding subsections of *Section 15.3*.
2. "-" means no interconnect.
3. Refer to the product datasheet for the availability of peripherals. If the peripheral is not present, consider the associated interconnection as unavailable.

15.3 Interconnection details

15.3.1 Master to slave interconnection for timers

From timer (TIM1/2/3/4/5/6/7/8/9/10/11/12/13/14/15/16/17/20/26/27 and HRTIM1) to timer (TIM1/2/3/4/5/6/7/8/9/10/11/12/13/14/15/16/17/20/26/27 and HRTIM1).

Purpose

Some timers are linked together internally for synchronization or chaining.

When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

A description of the feature is provided in *Section 42.4.27: Timer synchronization*.

The synchronization modes are detailed in:

- *Section 41* for advanced-control timers TIM1/8/20
- *Section 42* for general-purpose timers TIM2/3/4/5
- *Section 44* for the general-purpose timers TIM9/TIM10/TIM11/TIM12/TIM13/TIM14
- *Section 45* for the general-purpose timer TIM15/TIM16/TIM17
- *Table 411: External events mapping and associated features* for HRTIM1
- *Table 412: Update enable inputs and sources* for HRTIM1
- *Table 413: Burst mode clock sources* for HRTIM1
- *Table 414: Burst mode trigger source* for HRTIM1
- *Table 415: Internal synchronization source* for HRTIM1

Triggering signals

The output (from master) is on signal TIMx_TRGO (and TIMx_TRGO2 for TIM1/8/20) following a configurable timer event. It can be also from signals timx_oc1 in case of TIM10/11/13/14/16/17. The input (to slave) is on signals timx_itry.

The possible master/slave connections are given in:

- *Table 451* for advanced-control timers TIM1/8/20
- *Table 477* for general-purpose timers TIM2/3/4/5
- *Table 503* for the general-purpose timers TIM9/TIM10/TIM11/TIM12/TIM13/TIM14
- *Table 515* for the general-purpose timer TIM15/TIM16/TIM17

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 471: Effect of low-power modes on TIM1/TIM8/TIM20*
- *Table 492: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 508: Effect of low-power modes on TIM9/TIM10/TIM11/TIM12/TIM13/TIM14*
- *Table 529: Effect of low-power modes on TIM15/TIM16/TIM17*

15.3.2 Triggers to ADCs

From EXTI, timers (TIM1/2/3/4/6/7/8/9/12/15/16/17/20/26/27) and LPTIM1 and HRTIM1 to ADC1/ADC2/ADC3.

Purpose

A conversion (or a sequence of conversions) can be triggered either by software or by an external event (such as timer capture or input pins). For ADC1/ADC2/ADC3, if the EXTEN[1:0] (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, external events can trigger a conversion with the selected polarity.

More details in:

- *Table 226: ADC1/2/3 interconnection*
- EXTEN[1:0] defined in *ADC configuration register (ADC_CFGR1)*
- JEXTEN[1:0] defined in *ADC injected sequence register (ADC_JSQR)*

General-purpose timers (TIM2/3/4/5), basic timer (TIM6), advanced-control timers (TIM1/8/20), and general-purpose timer (TIM9/12/15/16/17) can be used to generate the ADC triggering event through the timer outputs tim_oc and tim_trgo.

Low-power timers (LPTIM1) can be used to generate the ADC triggering event through the LPTIM channels, in addition to the EXTI on channels 11 and 15 (for ADC1/2) and EXTI on channels 6 and 7 (for ADC3).

HRTIM timer can be used to generate the ADC triggering event through the HRTIM output trigger signals.

Triggering signals

For ADC1/ADC2/ADC3, the input triggering signals and the description of the interconnection between ADC1/ADC2/ADC3 and timers are given in:

- adc_ext_trg: *Table 226: ADC1/2/3 interconnection*
- adc_jext_trg: *Table 226: ADC1/2/3 interconnection*
- *Section 26.4.21: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*

Active power mode

This interconnection is active in Run and Sleep modes for all ADCs. The timers are active only in Run and Sleep modes. The effects of low-power modes are given in:

- *Table 471: Effect of low-power modes on TIM1/TIM8/TIM20*
- *Table 492: Effect of low-power modes on TIM2/TIM3/TIM4/TIM5*
- *Table 529: Effect of low-power modes on TIM15/TIM16/TIM17*
- *Table 499: Effect of low-power modes on TIM6/TIM7/TIM26/TIM27*
- *Table 508: Effect of low-power modes on TIM9/TIM10/TIM11/TIM12/TIM13/TIM14*
- *Table 535: STM32G56x/55x/54x/53x LPTIM features*
- *Table 546: Effect of low-power modes on the LPTIM*

15.3.3 ADC analog watchdogs as triggers to timers

From ADC1/ADC2/ADC3 to TIM1/8/20, TIM2/3/4 and HRTIM1.

Purpose

The internal analog watchdog output signals coming from ADC1/ADC2/ADC3 are connected to on-chip timers and HRTIM. ADC1/ADC2/ADC3 can provide trigger events through analog watchdog signals to advanced-control timers (TIM1/8/20) and general-

purpose timers (TIM2/TIM3/TIM4) to reset, start, stop, or clock the counter. ADC1/ADC2/ADC3 can provide trigger events through analog watchdog signals to HRTIM1 external event signals for various functions in HRTIM.

Settings description of the ADC analog watchdog and timer trigger, are provided in:

- *Section 41.3.6: External trigger input* for TIM1/8/20
- *Section 42.4.5: External trigger input* for TIM2/3/4
- *Table 457: Interconnect to the tim_etr input multiplexer* for TIM1/8/20
- *Table 483: Interconnect to the tim_etr input multiplexer* for TIM2/3/4
- *Section 15.3.12: Internal analog signals to ADCs* for the ADC1/ADC2/ADC3/ADC_AWDy_OUT signal output generation
- *Table 411: External events mapping and associated features* for HRTIM1

Triggering signals

The output (from ADC) is on signals ADCn_AWDx_OUT, with n being the ADC instance and x = 1, 2, 3 (three watchdogs per ADC). The input (to timer) is on signal TIMx_ETR (external trigger). The input (to HRTIM) is on signal hrtim_eevy (external event).

Active power mode

ADC1/ADC2/ADC3 are active in Run and Sleep modes.

15.3.4 From comparators to timers (TIMx, HRTIM, LPTIM)

From COMP (COMP1 to 8) to timer (TIM1/2/3/4/5/8/910/11/12/13/14/15/16/17/20 and LPTIM1).

Purpose

The comparators (COMP1..8) output can be used as timers (TIM1/2/3/4/5/8/910/11/12/13/14/15/16/17/20, LPTIM1) input (tim_ti_in, tim_itr, tim_etr, tim_ocref_clr, tim_brk_cmp, tim_brk2_cmp) for various purposes (triggers, clearing, break input). The comparators (COMP1..8) output can be used as HRTIM (HRTIM1) external event input or fault input (hrtim_eev, hrtim_eev).

Triggering signals

Comparators outputs selection to timers and HRTIM inputs is provided in:

- *Table 478: Interconnect to the tim_ti1 input multiplexer* for TIM2/TIM3/TIM4/TIM5
- *Table 479: Interconnect to the tim_ti2 input multiplexer* for TIM2/TIM3/TIM4/TIM5
- *Table 483: Interconnect to the tim_etr input multiplexer* for TIM2/TIM3/TIM4/TIM5
- *Table 484: Interconnect to the tim_ocref_clr input multiplexer* for TIM2/TIM3/TIM4/TIM5
- *Table 516: Interconnect to the tim_ti1 input multiplexer* for TIM15/TIM16/TIM17
- *Table 519: Timer break interconnect* for TIM15/TIM16/TIM17
- *Table 521: Interconnect to the ocref_clr input multiplexer* for TIM15/TIM16/TIM17
- *Table 504: Interconnect to the tim_ti1 input multiplexer* for TIM9/TIM10/TIM11/TIM12/TIM13/TIM14
- *Table 452: Interconnect to the tim_ti1 input multiplexer* for TIM1/TIM8/TIM20
- *Table 457: Interconnect to the tim_etr input multiplexer* for TIM1/TIM8/TIM20
- *Table 458: Interconnect to the tim_brk_cmp multiplexer* for TIM1/TIM8/TIM20
- *Table 306: Timer break2 interconnect* for TIM1/TIM8/TIM20
- *Table 460: Interconnect to tim_ocref_clr multiplexer* for TIM1/TIM8/TIM20
- *Section 46.4.3: LPTIM input and trigger mapping* for LPTIM1
- *Table 411: External events mapping and associated features* for HRTIM1
- *Table 416: Fault inputs* for HRTIM1

Active power mode

Interconnect to timers is active in Run and Sleep modes.

Comparators and LPTIM1 are active in Run, Sleep, and Stop modes.

- *Table 546: Effect of low-power modes on the LPTIM*
- *Table 264: Comparator behavior in low-power modes*

15.3.5 Triggers to DAC

From timer (TIM1/2/3/4/5/6/7/8/9/15/20/26/27), HRTIM, low-power timers (LPTIM1), and EXTI to DAC.

Purpose

General-purpose timers (TIM2/3/4/5/8/9/15), basic timers (TIM6/7/26/27), advanced-control timers (TIM1/8/20), LP timers (LPTIM1) outputs channels (lptim1_ch1), HRTIM1, and EXTI can be used as triggering event to start a DAC conversion.

Triggering signals

The output (from timer) on the TIMx_TRGO signal from LPTIM1 and from HRTIM1 timers are directly connected to corresponding DAC inputs.

The selection of input triggers on DAC is provided in:

- *Table 250: DAC interconnection*
- *Section 28.4.7: DAC trigger selection*
- *Table 418: HRTIM DAC triggers connections*

Active power mode

This interconnect is active in Run and Sleep modes.

15.3.6 Clock sources to timers

From HSE, LSE, LSI, HSI, and MCO to timers (TIM2/9/12/15/16/17) and LP timers (LPTIM1).

Purpose

A timer input or counter can receive different clock sources, and can be used, for example, to calibrate the internal oscillator on a reference clock.

External clocks (HSE, LSE), internal clocks (LSI, HSI), and microcontroller output clock (MCO1, MCO2) can be used as input to timers:

- LSE is assigned to general purpose timer TIM2 as external inputs signals. LSE can be selected as counter clock provided by an external clock source in mode1 (tim_ti1_in) and mode2 (external trigger input tim_etr_in). Inputs assignment and clock selection description are detailed in:
  - *Section 42.4.6: Clock selection* for TIM2
  - External clock mode1: *Table 504: Interconnect to the tim_ti1 input multiplexer* for TIM9/12, tim_ti1_in4 (HSI)
  - External clock mode2: *Table 483: Interconnect to the tim_etr input multiplexer* for TIM2, tim_etr22 (LSE)
- LSE, LSI, and HSE are assigned to general purpose timers TIM15/16/17 as external inputs signals. LSE/HSE can be selected as counter clock provided by an external clock source in mode1 (tim_ti1 or tim_ti2 signals). Inputs assignment and clock selection description are detailed in:
  - *Section 45.4.6: Clock selection* for TIM15/16/17. External clock mode1: external input pin (tim_ti1 or tim_ti2, if available)
  - *Table 516: Interconnect to the tim_ti1 input multiplexer* for TIM15/16/17, tim_ti1_in2, tim_ti1_in3, tim_ti1_in4, tim_ti1_in10
- Microcontroller output clock (MCO): MCO1 is connected as external input to general-purpose timer TIM15/17, MCO2 is connected as external input to general-purpose timer TIM15.
  - *Table 516: Interconnect to the tim_ti1 input multiplexer* for TIM15/16/17
- LSI and LSE can be selected as input capture 2 to LPTIM1 as described in *Table 540: LPTIM1 input 2 connections*.
- hsi_cal_ck (HSI/1024) can be selected as input capture 1 to LPTIM1 as described in *Table 539: LPTIM1 input 1 connections*.

Active power mode

This feature is available under Run and Sleep modes.

15.3.7 Triggers to low-power timers

From EXTI, TAMP, and RTC alarm to LP timers (LPTIM1).

Purpose

LPTIM1 counters can be started either by software, or after the detection of an active edge on one of the eight trigger inputs (see *Section 46.4.7: Trigger multiplexer*).

Triggering signals

This trigger feature is described in *Section 46.4.7: Trigger multiplexer* and the following sections. The input selection is described in *Table 538: LPTIM1 external trigger connections*.

Active power mode

This interconnection is active in Run, Sleep, and Stop modes.

15.3.8 RTC wake-up as inputs to timers

From RTC to timer (TIM16).

Purpose

RTC wake-up interrupt can be used as input to general-purpose timer (TIM16) channel 1.

Triggering signals

RTC wake-up signal is connected to tim_ti1_in4 signal as described in *Table 516: Interconnect to the tim_ti1 input multiplexer* for TIM16.

Active power mode

This interconnection is active down to Stop mode. Timers are not active but the count is performed at wake-up.

15.3.9 System errors as break signals to timers and HRTIM

From system errors to timers (TIM1/8/15/16/17/20).

Purpose

CSS, CPU lockup, SRAM1/2 ECC double errors, DCACHE ECC double-error detection, FLASH ECC double-error detection, and PVD can generate system errors in the form of timer break toward timers (TIM1/8/15/16/17/20) and HRTIM system fault input.

The purpose of the break function is to protect power switches driven by PWM signals generated by the timers.

Triggering signals

The possible sources of break are described in:

- *Section 41.3.19: Using the break function* for TIM1/8/20
- *Section 45.4.17: Using the break function* for TIM15/16/17
- *Table 308: System break interconnect* for TIM1/8/20

- *Table 520: System break interconnect* for TIM15/16/17
- *Table 410: HRTIM inputs/outputs summary* for HRTIM

Active power mode

Timers are optionally active in Run and Sleep modes. The effects of low-power modes on TIMx are given in:

- *Table 471: Effect of low-power modes on TIM1/TIM8/TIM20*
- *Table 529: Effect of low-power modes on TIM15/TIM16/TIM17*
- *Table 410: HRTIM inputs/outputs summary* for HRTIM

15.3.10 From timers to comparators

From timer (TIM1/2/3/4/8/9/12/15/20) to comparator (COMP1 to 8).

Purpose

Timers (TIM1/2/3/4/8/9/12/15/20) can generate blanking window for comparators (COMP1 to 8).

Triggering signals

The timers outputs (tim_oc) selection to comparator blanking signal (comp_blk) is provided in:

- *Table 263: COMPx blanking source assignment (COMP1 to COMP8)*

Active power mode

This interconnect is active in Run and Sleep modes.

15.3.11 Triggers to GPDMA1/2

From EXTI, RTC (alarm/wake-up), TAMP, timers (TIM2/5/6/7/9/12/15), LP timers (LPTIM1), GPDMA transfer complete (gpdma1_chx_tc, gpdma2_chx_tcf) to GPDMA1/2.

Purpose

A GPDMA trigger can be assigned to GPDMA channel x. A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event. The trigger mode can also be programmed to condition the LLI link transfer. More details are given in the sections below:

- *Section 16.3.7: GPDMA triggers*
- *Section 16.4.13: GPDMA triggered transfer*
- *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details on:
  - Trigger selection TRIGSEL[5:0] field
  - Trigger mode (LLI) defined by TRIGM[1:0]
  - Trigger polarity as defined by TRIGPOL[1:0]

Triggering signals

GPDMA trigger mapping is specified in *Table 155: Programmed GPDMA1/2 trigger*, according to GPDMA_CxTR2.TRIGSEL[5:0].

Active power mode

This interconnection remains functional in Sleep mode.

Refer to:

- *Section 16.6: GPDMA in low-power modes*

15.3.12 Internal analog signals to ADCs

From internal analog source to ADC (ADC1/2/3).

Purpose

The internal reference voltage (V_{REFINT}), the internal temperature sensor (V_{SENSE}), the internal digital core voltage (V_{DDCORE}), and the OPAMPs internal outputs (opamp1_int, opamp2_int, opamp3_int) are connected to ADC (ADC1/2/3) input channels.

This is according to:

- *Table 226: ADC1/2/3 interconnection*
- *Section 26.4.12: Channel selection (ADC_SQRy, ADC_JSQR)*

Active power mode

This interconnect is active in Run and Sleep modes.

15.3.13 Internal analog signals to COMPs

From internal analog sources to COMP (COMP1 to 8).

Purpose

The internal reference voltage (1/4 V_{REFINT}, 1/2 V_{REFINT}, 3/4 V_{REFINT}, V_{REFINT}), the DAC outputs (DAC1/2/5/6/7/8/9/10) are connected to the COMP (COMP1 to 8) input channels.

- *Table 262: COMPx_INM inverting input assignment (COMP1 to COMP8)*

The internal OPAMP (OPAMP1/2/3) are connected to the COMP (COMP1 to 8) input channels.

- *Table 261: COMPx_INP non-inverting input assignment (COMP1 to COMP8)*

Active power mode

This feature remains available in Run, Sleep, and Stop modes.

15.3.14 Internal analog signals to OPAMPs

From internal analog sources to OPAMP (OPAMP1/3).

Purpose

The DAC outputs (DAC5/6) are connected to the OPAMP (OPAMP1/3) input channels.

- *Table 267: OPAMP pin and signal assignment per instance*

Active power mode

This feature remains available in Run, Sleep, and Stop modes.

15.3.15 Clock source for the DAC sample and hold mode

From LSI/LSE to DACs.

Purpose

DACs can run in Stop mode. The sample and hold block and its associated registers use the LSI or LSE clock source (dac_hold_ck) in Stop mode.

Table 249: DAC internal input/output signals: dac_hold_ck

Active power mode

This feature remains available in Run, Sleep, and Stop modes.

15.3.16 Internal tamper sources

From internal peripherals, clocks, or monitoring, to tamper.

Purpose

To detect any abnormal activity or tentative to corrupt the device, embedded tampers alert the system of undesired events. Different actions can be taken as consequence.

The list of tamper sources can be found in *Table 570: TAMP interconnection*.

Active power mode

This interconnection is active in all power modes if the tamper source is activated.

15.3.17 Output from tamper to RTC

From TAMP to RTC.

Purpose

The RTC can timestamp a tamper event to retrieve history of the detection. The RTC can also control GPIOs, and set a signal based on tamp or alarm status outside the MCU.

Refer to section *Section 49.3.18: Timestamp function* and *Section 49.6.24: RTC timestamp on tamper control register (RTC_TAMPTSCR)* for more details.

Active power mode

This interconnection remains active in all power modes.

15.3.18 PLAY inputs/outputs from/to internal peripherals

PLAY1 inputs and outputs connection to on-chip peripherals.

Purpose

PLAY1 peripheral can implement additional function as response from many inputs from internal peripherals and the control of peripherals by providing output to peripherals.

Input/output signals selection into/from PLAY1 are provided in:

- *Table 202: PLAY1 logic array input n signal selection*
- *Table 203: PLAY1 output connections*

Active power mode

This feature remains available in Run, Sleep, and Stop modes.

15.3.19 Encryption keys to AES/SAES

From TAMP backup registers, system flash memory to and in between SAES and AES.

Purpose

The encryption mechanism requires a hardware key that must be stored in a protected nonvolatile memory. Different approaches are implemented to load them in a non-readable way. Tamper backup registers or system flash memory can be used to store respectively BHK or RHUK, and to implement a dedicated bus to pass it to the SAES.

Refer to *Section 35.4.14: SAES operation with wrapped keys* for more details.

The AES encryption mechanism (faster than the SAES) can benefit from the sharing key of the SAES. Refer to *Section 35.4.15: SAES operation with shared keys* for more details.

Active power mode

AES and SAES are operating under Run and Sleep modes.

15.3.20 From USB to timers

From USB_SOF signal to TIM2/3/4/5/9.

Purpose

The USB signal usb_sof can be used as trigger for timers.

Triggering signals

Description of the USB source for timer trigger, are provided in:

- *Table 483: Interconnect to the tim_etr input multiplexer* for TIM2/3/4/5
- *Table 504: Interconnect to the tim_ti1 input multiplexer* for TIM9.

Active power mode

This feature is available under Run and Sleep modes.

15.3.21 CRS clock sources

From various clock signals to clock recovery system (CRS).

Purpose

Precise clock signal can be used as synchronization clock for clock recovery system (CRS).

Triggering signals

Description of the clock sources for CRS are provided in:

- *Table 135: CRS interconnection*

Active power mode

This feature is available under Run and Sleep modes.

15.3.22 Internal sources for EXTI lines

From various peripherals outputs to EXTI lines.

Purpose

Some peripherals able to generate wake-up or interrupt events for the input to EXTI lines.

Triggering signals

Description of the EXTI lines are provided in:

- *Table 176: EXTI line connections*

Active power mode

This feature is available under Run, Sleep and Stop modes.

15.3.23 Internal signals to POSENC

Purpose

Synchronization signal from timers (TIM1/8/20) to POSENC1/2 strobe interface to synchronize position reading.

Triggering signals

Description of the POSENC strobe signals are provided in:

- *Section 57.3.7: POSENC strobe interface*

Active power mode

This feature is available under Run and Sleep modes.

16 General purpose direct memory access controller (GPDMA)

This section applies only to STM32G55x/56x devices.

16.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

16.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half-transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 8 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 16.3.2*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level and byte-based padding

  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 16.3.2*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half-transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
  - Channel terminate with FIFO draining
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

16.3 GPDMA implementation

16.3.1 GPDMA instances

There are two instances of the GPDMA in the devices, named as GPDMA1 and GPDMA2.

Each GPDMA instance has the same channel-based implementation and is connected to the same requests and triggers, as detailed in the following sub-sections.

16.3.2 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 149. GPDMA1/2 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 3	2	0	Channel x (x = 0 to 3) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM.
x = 4 to 5	4	0	Channel x (x = 4 to 5) is implemented with: – a FIFO of 32 bytes, 8 words – fixed/contiguously incremented addressing These channels may be used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.
x = 6 to 7	4	1	Channel x (x = 6 to 7) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

16.3.3 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 150. GPDMA1/2 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1/2 in Sleep mode

16.3.4 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[7:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

16.3.5 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 152. Programmed GPDMA1/2 request as a block request

GPDMA block requests

16.3.6 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 153. GPDMA1/2 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before the GPDMA has transferred the whole block (see *Section 16.4.15* for more details).

Table 154. Programmed GPDMA1/2 request with peripheral early termination

16.3.7 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

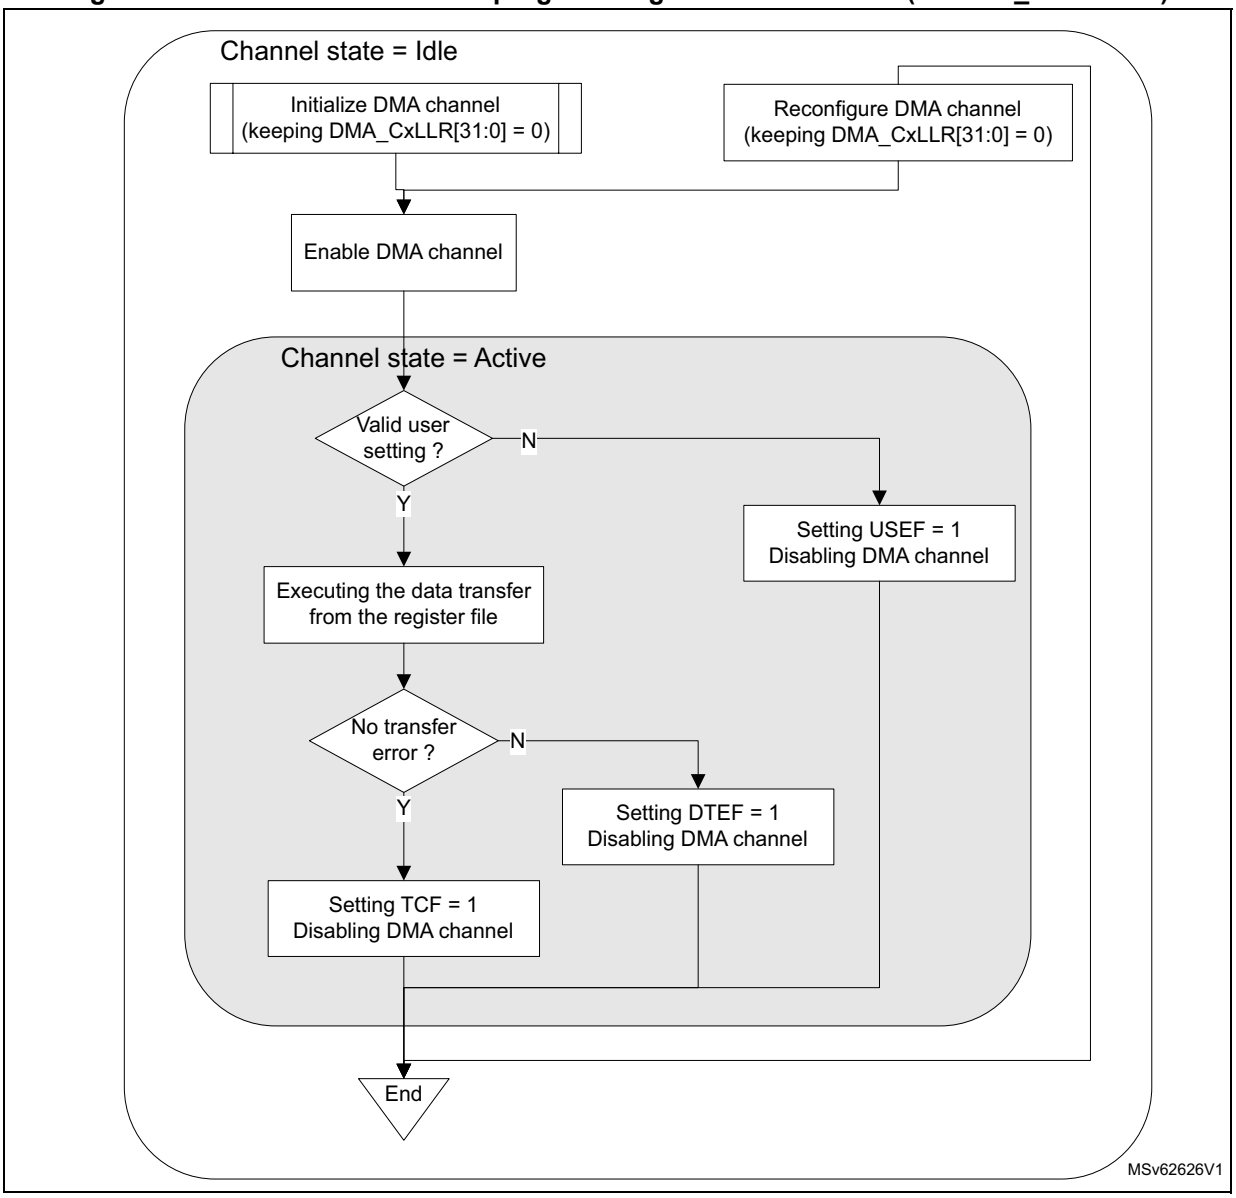
16.4 GPDMA functional description

16.4.1 GPDMA block diagram

Figure 91. GPDMA block diagram



16.4.2 GPDMA channel state and direct programming without any linked-list

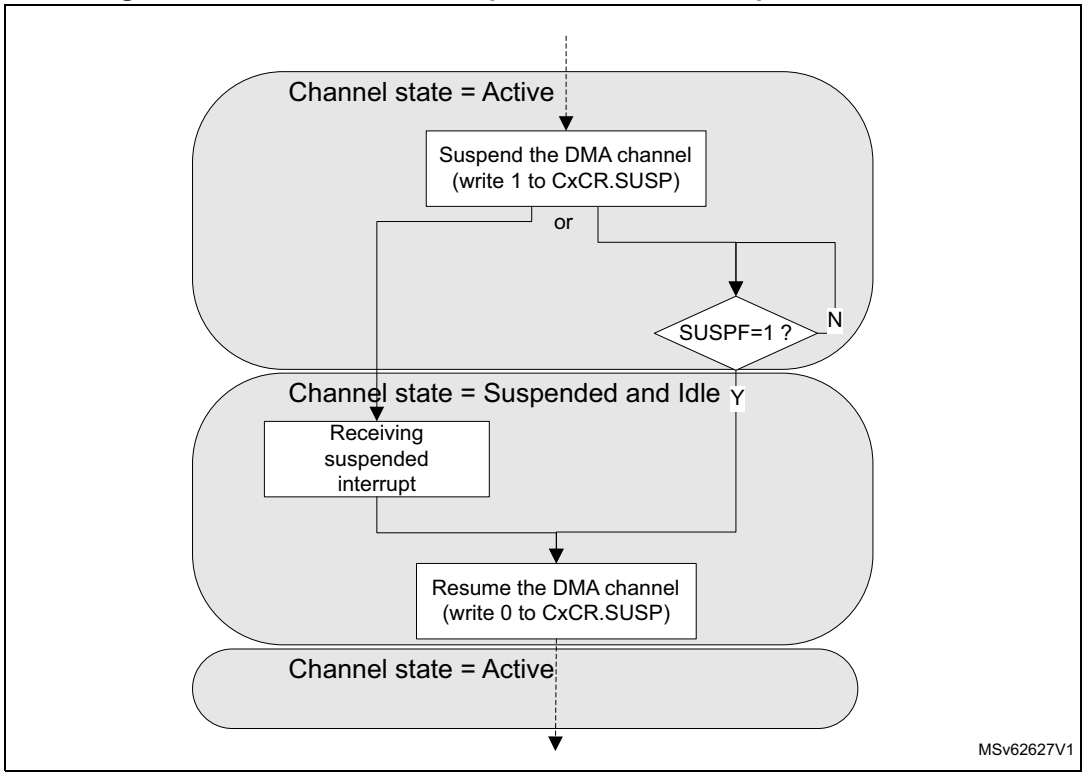
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 92 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 92. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

16.4.3 GPDMA channel suspend and resume



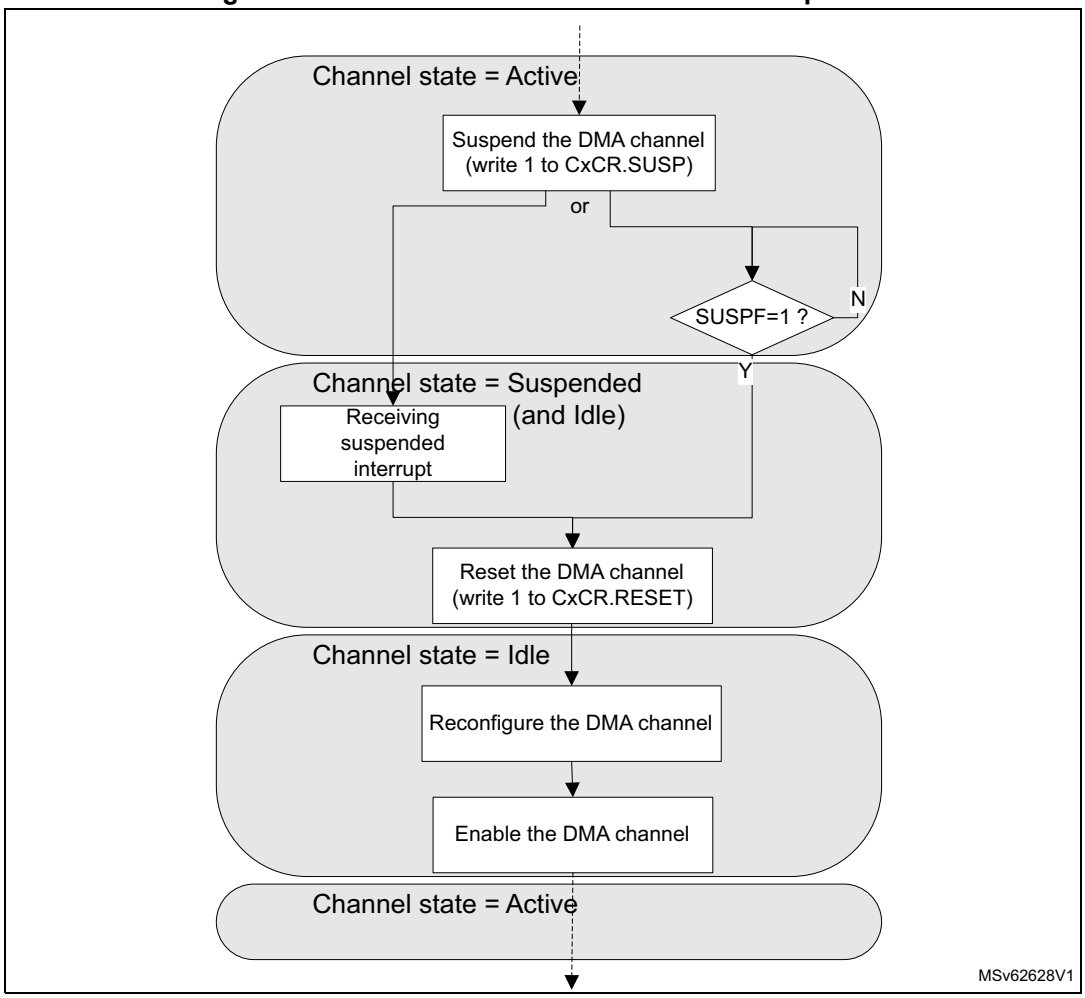
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 93. GPDMA channel suspend and resume sequence



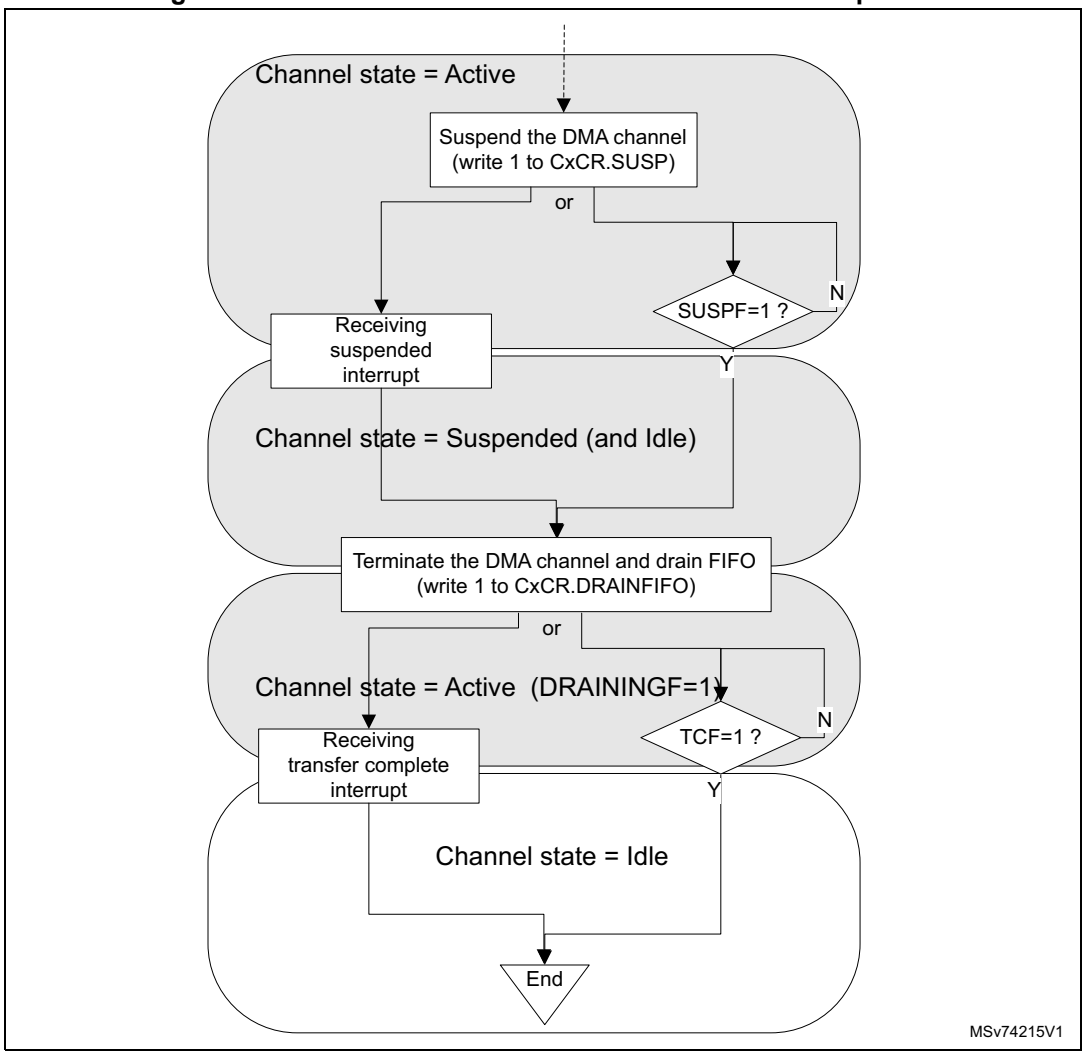
Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

16.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 94. GPDMA channel abort and restart sequence



16.4.5 GPDMA channel terminate and drain FIFO

Alternatively, for terminating a continuous GPDMA transfer with a circular buffering or a double buffering, and having popped out any residual byte(s) in the channel FIFO and writing them to the destination, the software can terminate an active channel and drain the channel FIFO with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software orders to drain the channel FIFO by writing 1 to GPDMA_CxCR.DRAINFIFO.
4. The software polls transfer complete flag GPDMA_CxSR.TCF until TCF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.TCIE. Wait for the channel to be effectively with a drained FIFO means wait for completion of any residual write burst from the FIFO to the destination. Then the channel is disabled by hardware and in IDLE state.

Figure 95. GPDMA channel terminate and drain FIFO sequence

Note: If the softwares writes the GPDMA_CxCR register in a single shot with concurrently SUSP = 1, DRAINFIFO = 1, and RESET = 0, then the sequence for terminating and draining the FIFO also occurs.

GPDMA_CxTR2.DREQ = 1 and GPDMA_CxCR.DRAINFIFO = 1 is not supported, only peripheral-to-memory and memory-to-memory transfers are supported to be terminated with drained FIFO.

16.4.6 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the following UT1, UT2, UB1, USA, UDA, UT3 and UB2 if present, and ULL bits in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3 and GPDMA_CxBR2 if present, and GPDMA_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

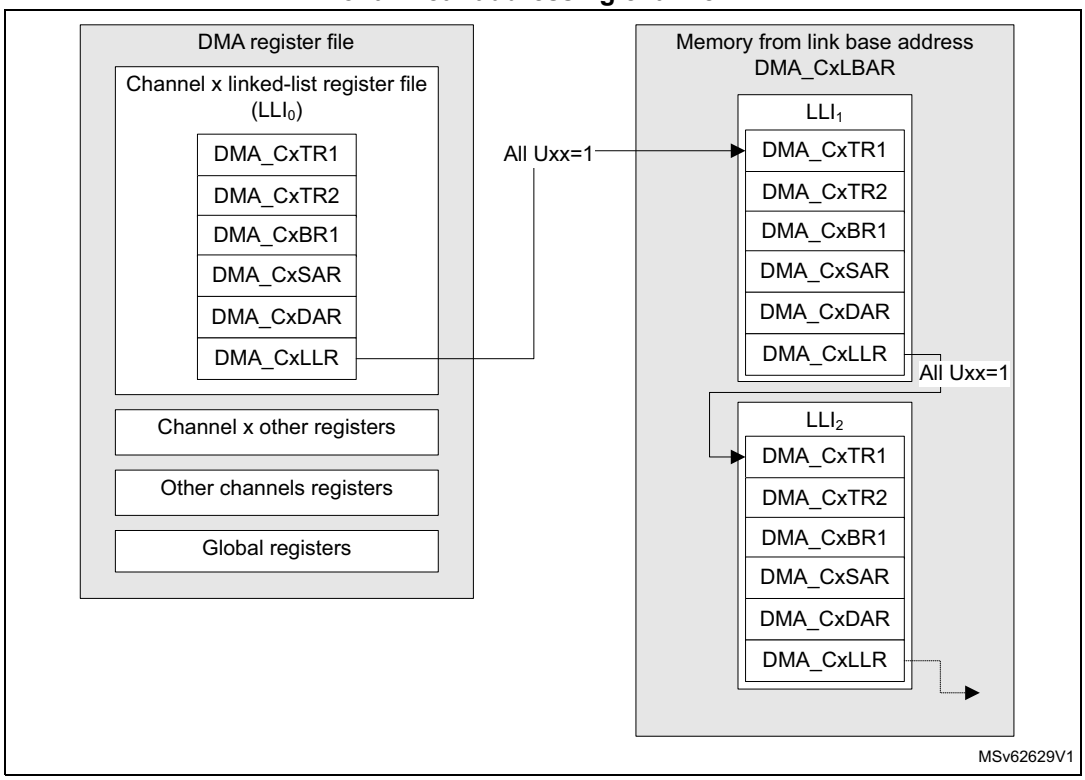
Caution: The user must program the pointer to the next linked-list data structure (GPDMA_CxLLR[15:0]) not to exceed the 64-Kbyte addressable space defined by the link base address register (GPDMA_CxLBAR). The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, plus UB2 and UT3 if present, and ULL) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 5) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 96*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 6 to 7), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3, GPDMA_CxBR2 and GPDMA_CxLLR, (see *Figure 97*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 96. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



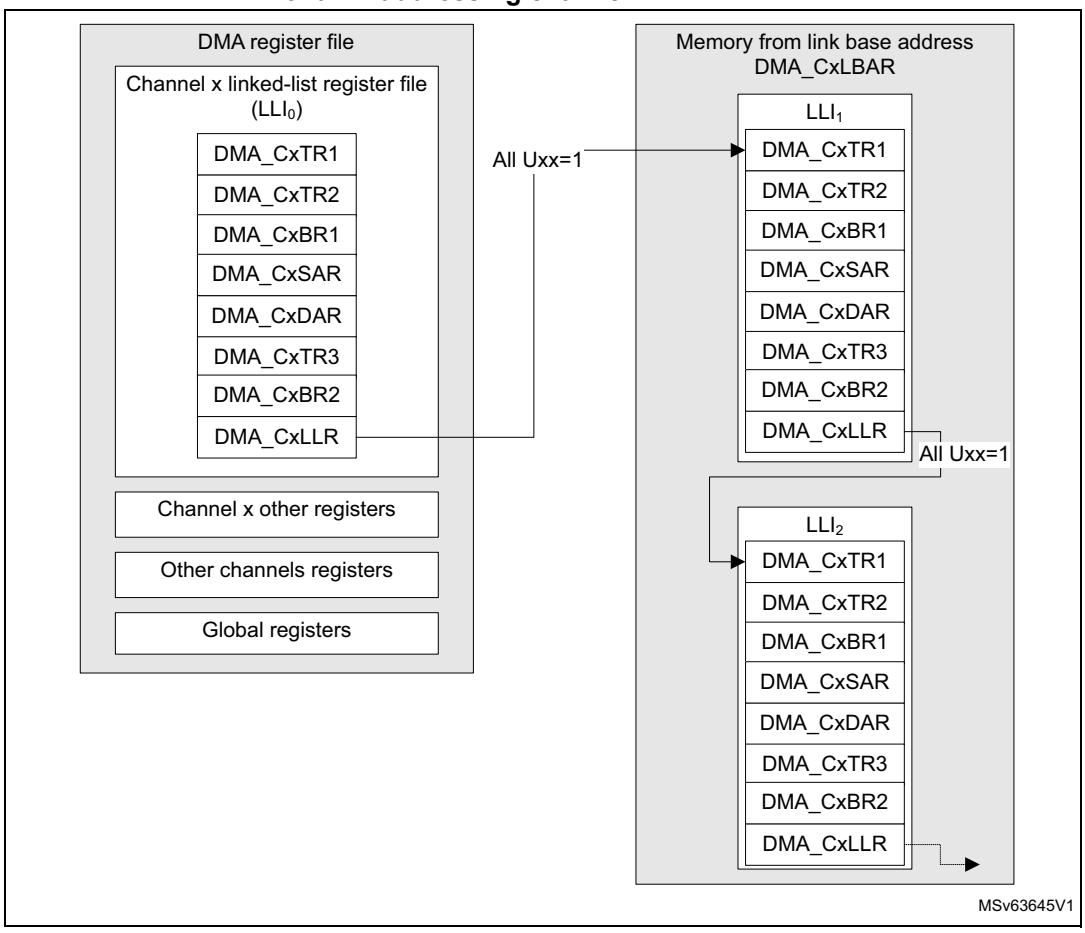


Figure 97. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

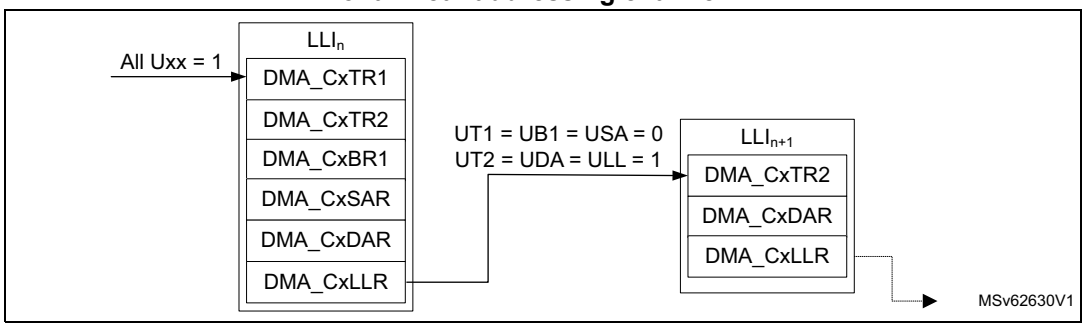
Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 98*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 99*.

Figure 98. GPDMA dynamic linked-list data structure of a linear addressing channel x



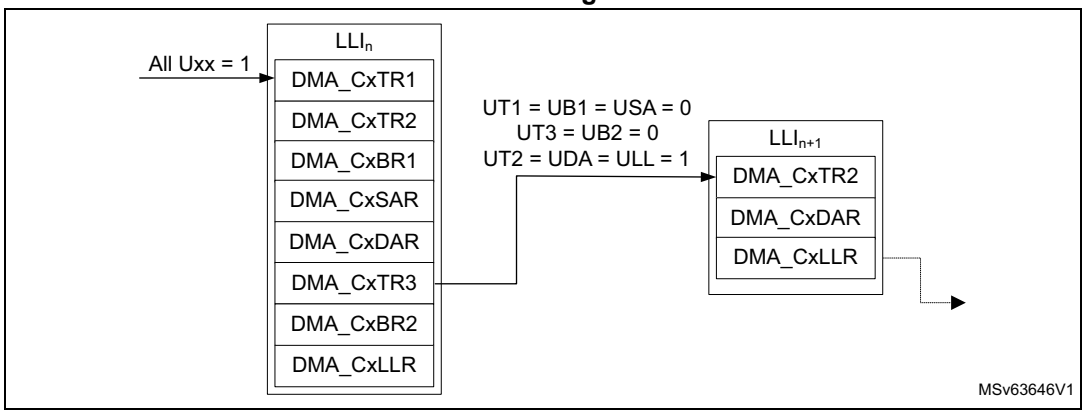


Figure 99. GPDMA dynamic linked-list data structure of a 2D addressing channel x

16.4.7 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

16.4.8 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started

by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

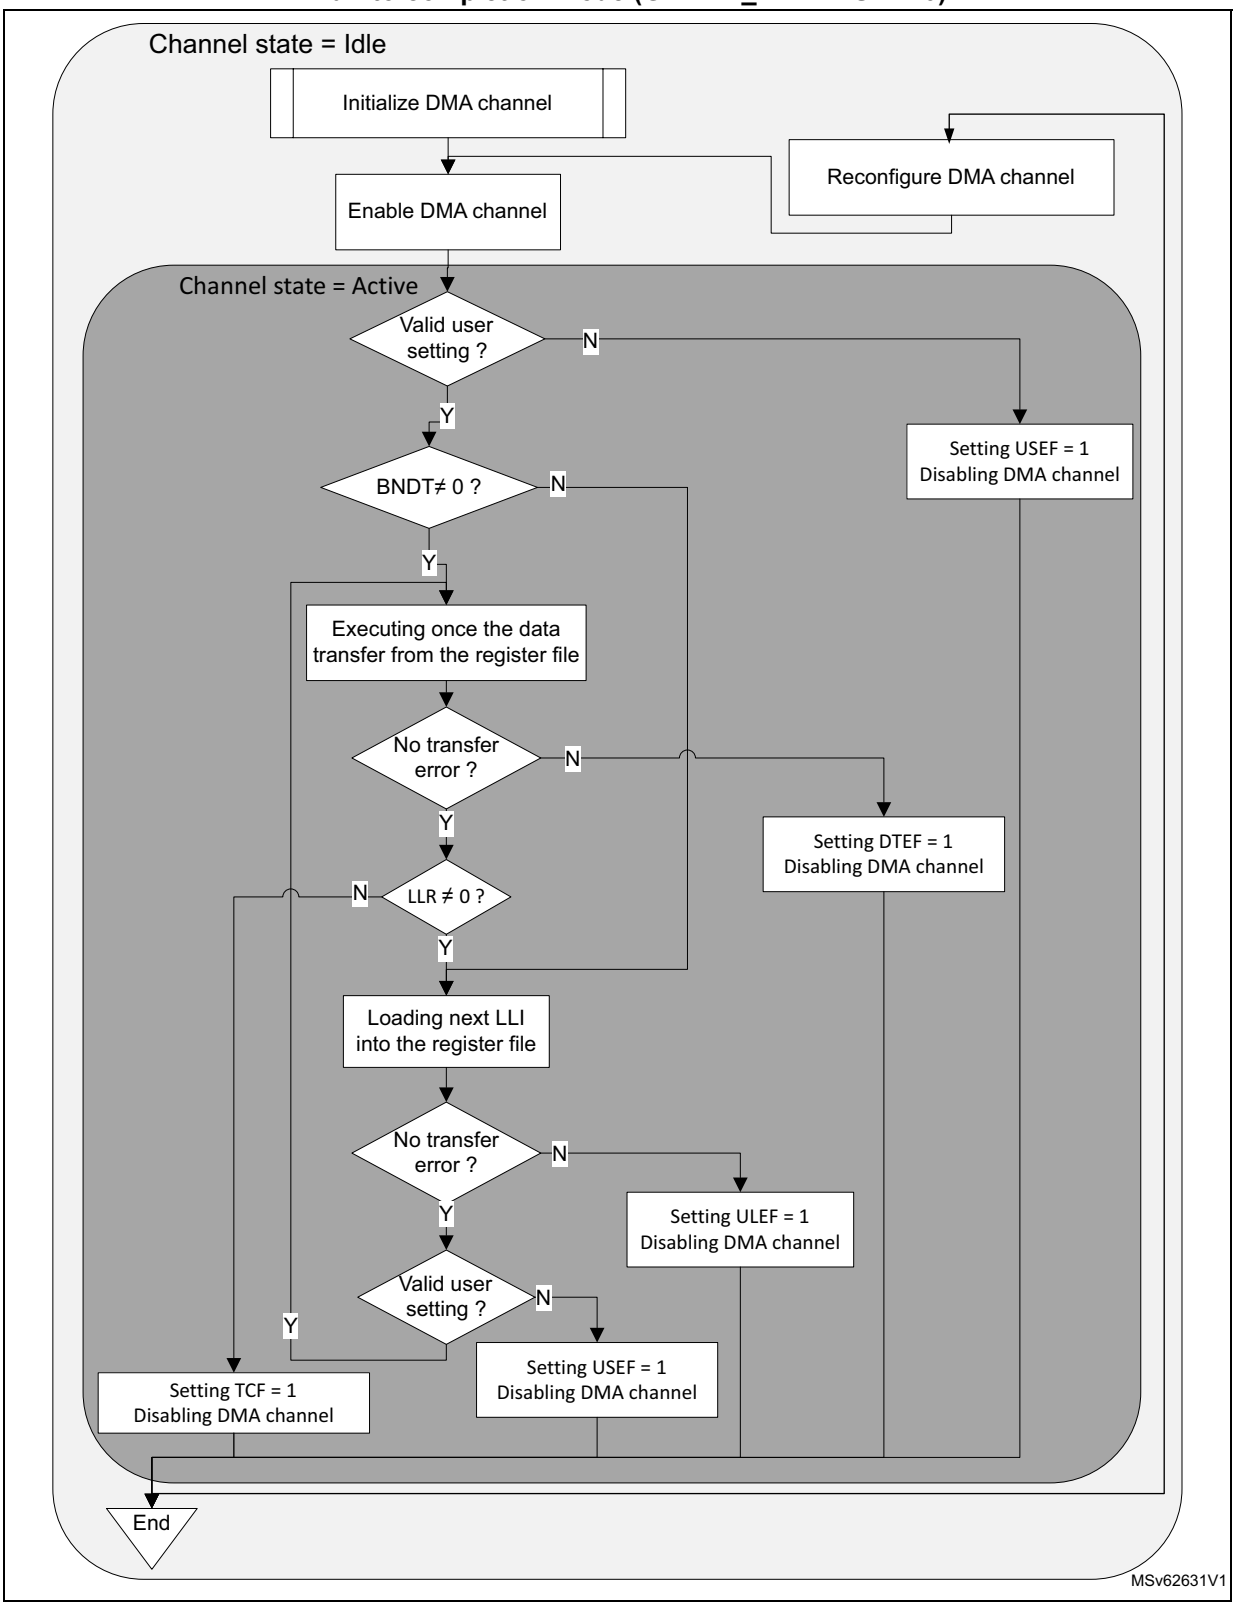
GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 16.4.15* for more details).



In typical run-to-completion mode, allocation of an GPDMA channel, including detailed programming, occurs once during GPDMA initialization. This process reserves a data communication link and GPDMA service during run-time for repeated transfers, such as transfers from a peripheral to memory, from memory to a peripheral, or memory-to-memory transfers. The reserved data communication link may consist of a dedicated channel, or the channel may be shared. A repeated transfer consists of a sequence of linked list items (LLIs).

Figure 100 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

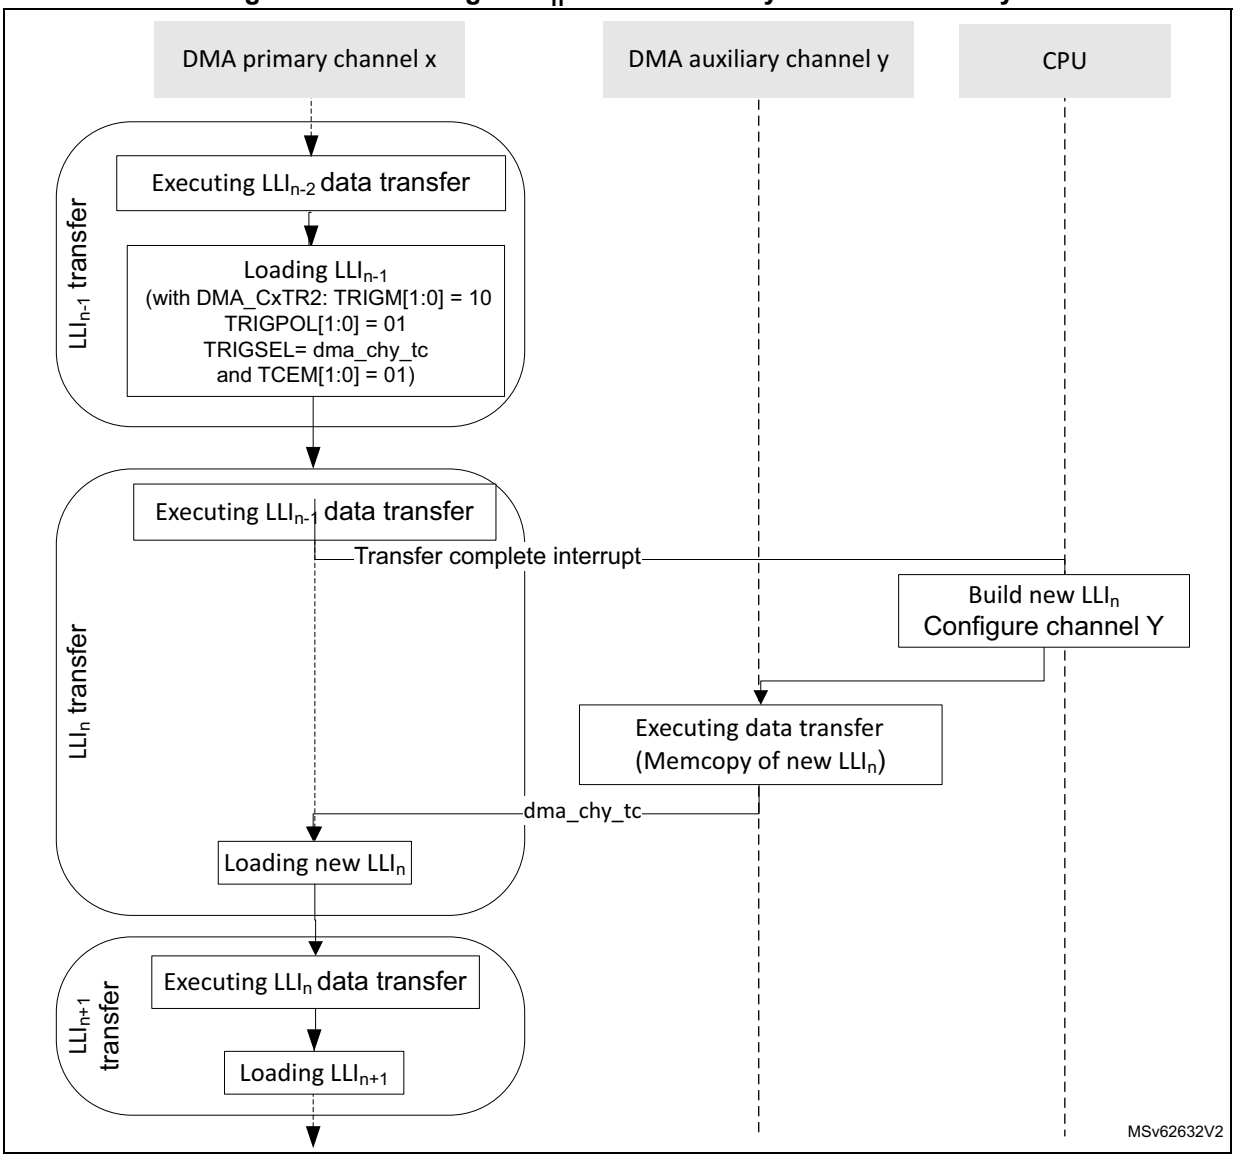
Note: Figure 100 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 100, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

Figure 100. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 16.3.7* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 101 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 101. Inserting a LLI_n with an auxiliary GPDMA channel y

16.4.9 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

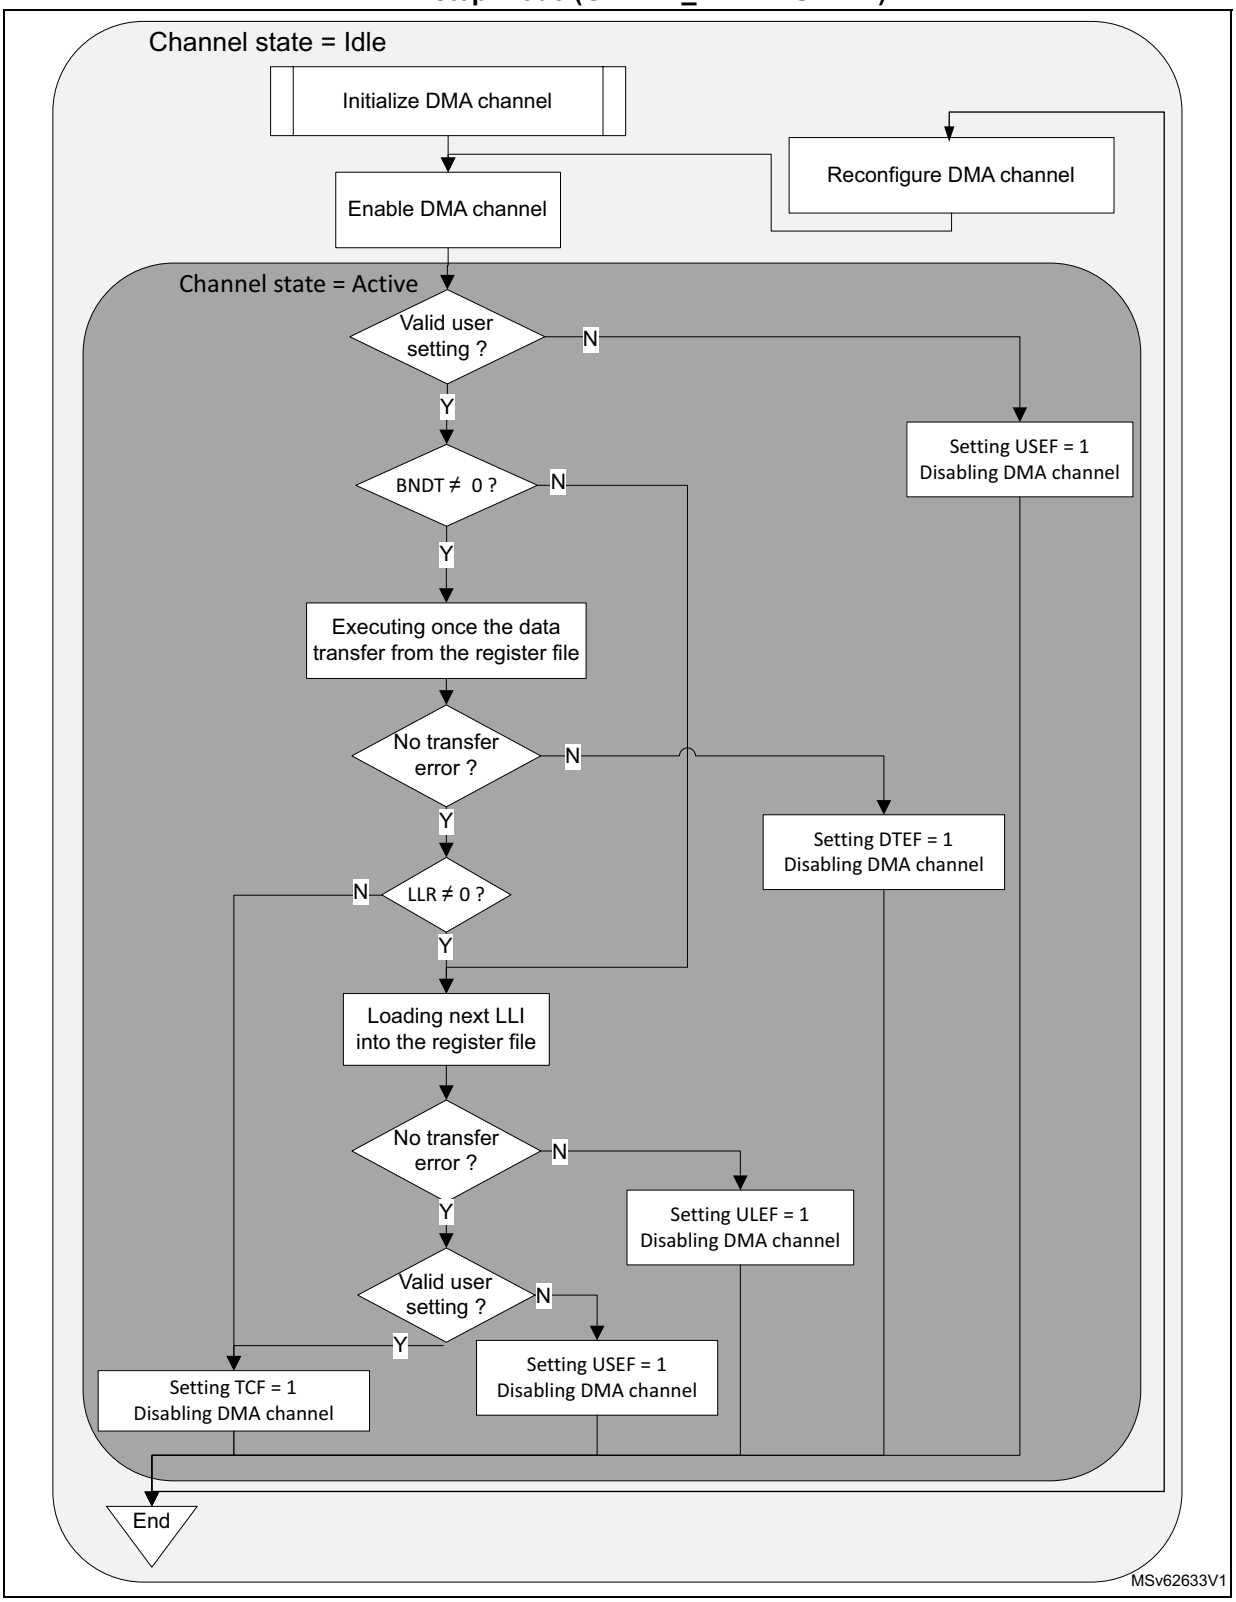
A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 6 to 7), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 6 to 7) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 6 to 7) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 16.4.15* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 102 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 102 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 102, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

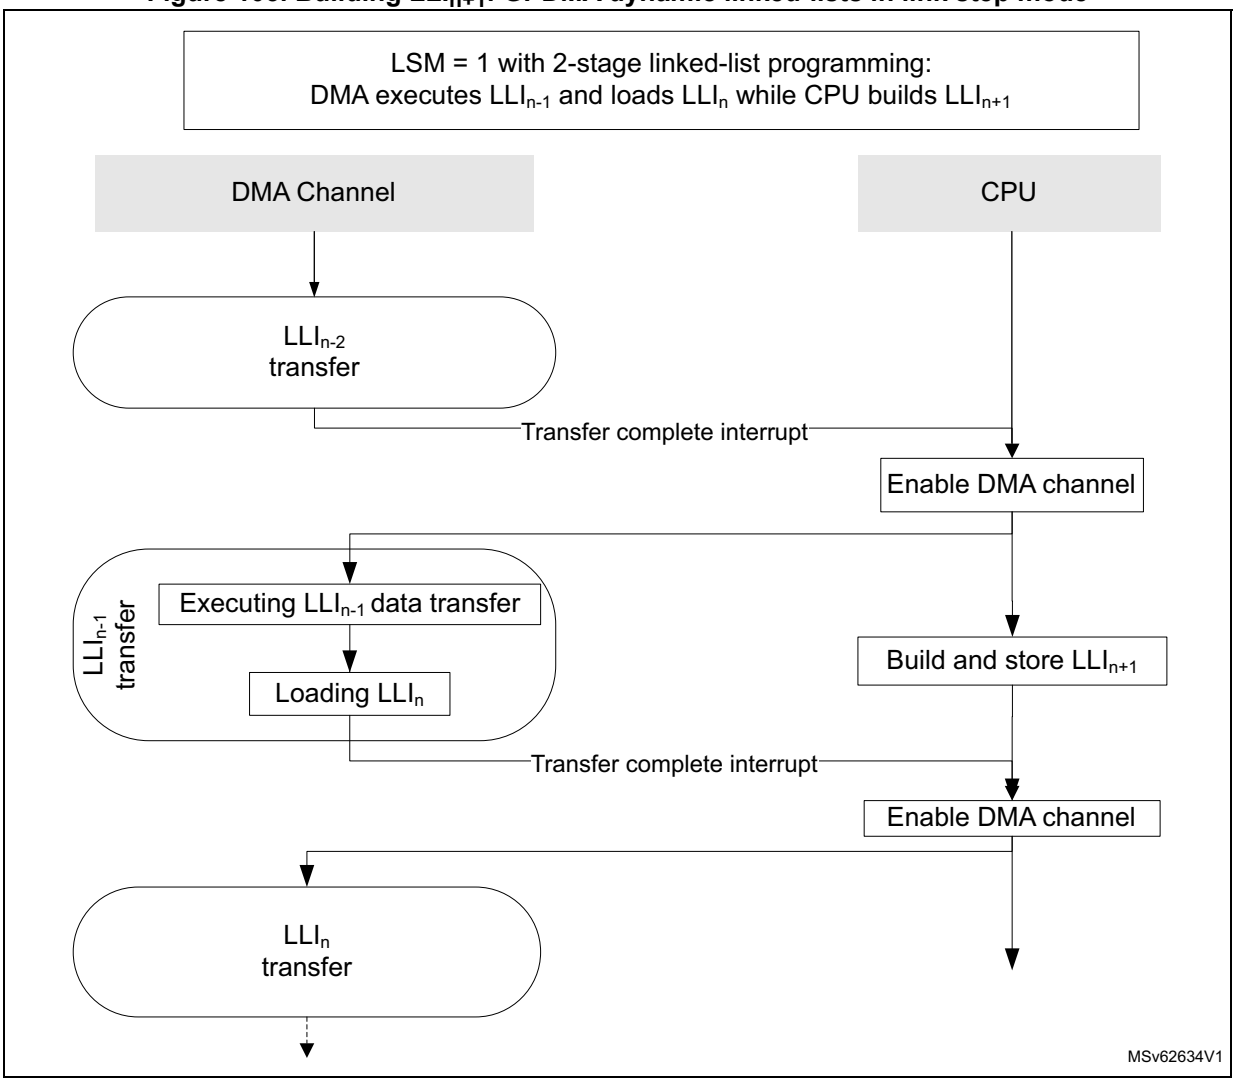


Figure 102. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 103*.

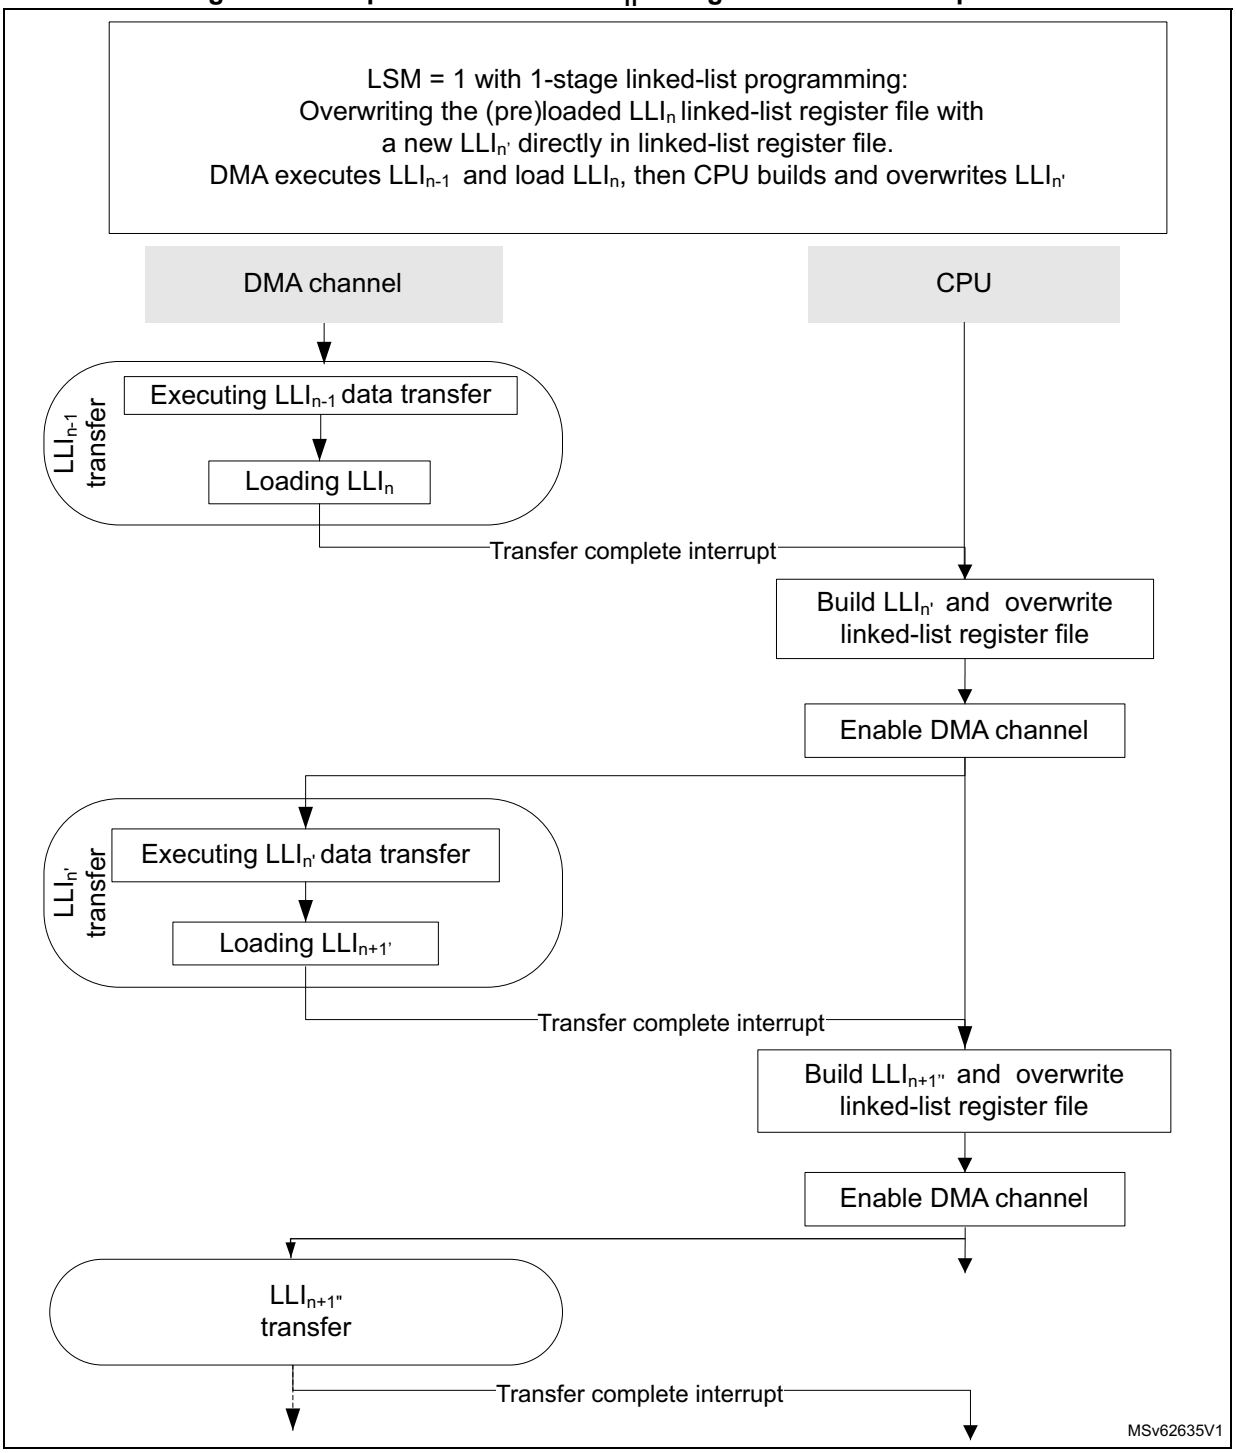

Figure 103. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 104*.

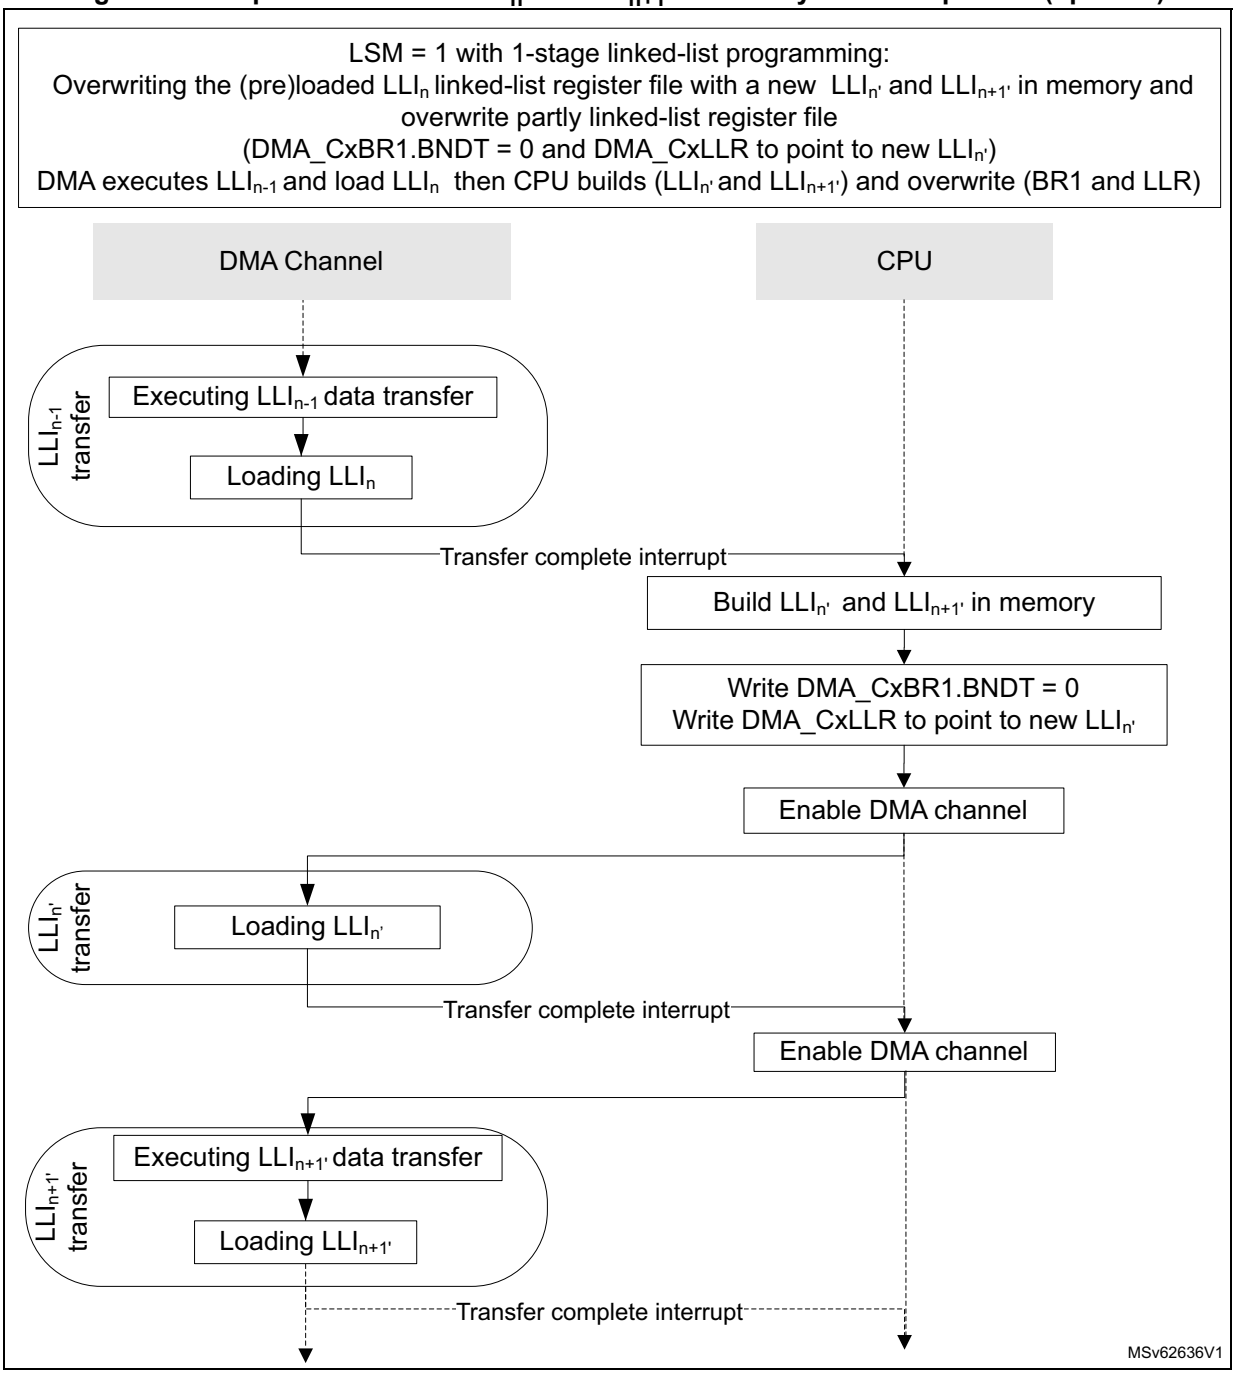

Figure 104. Replace with a new $LLI_{n'}$ in register file in link step mode

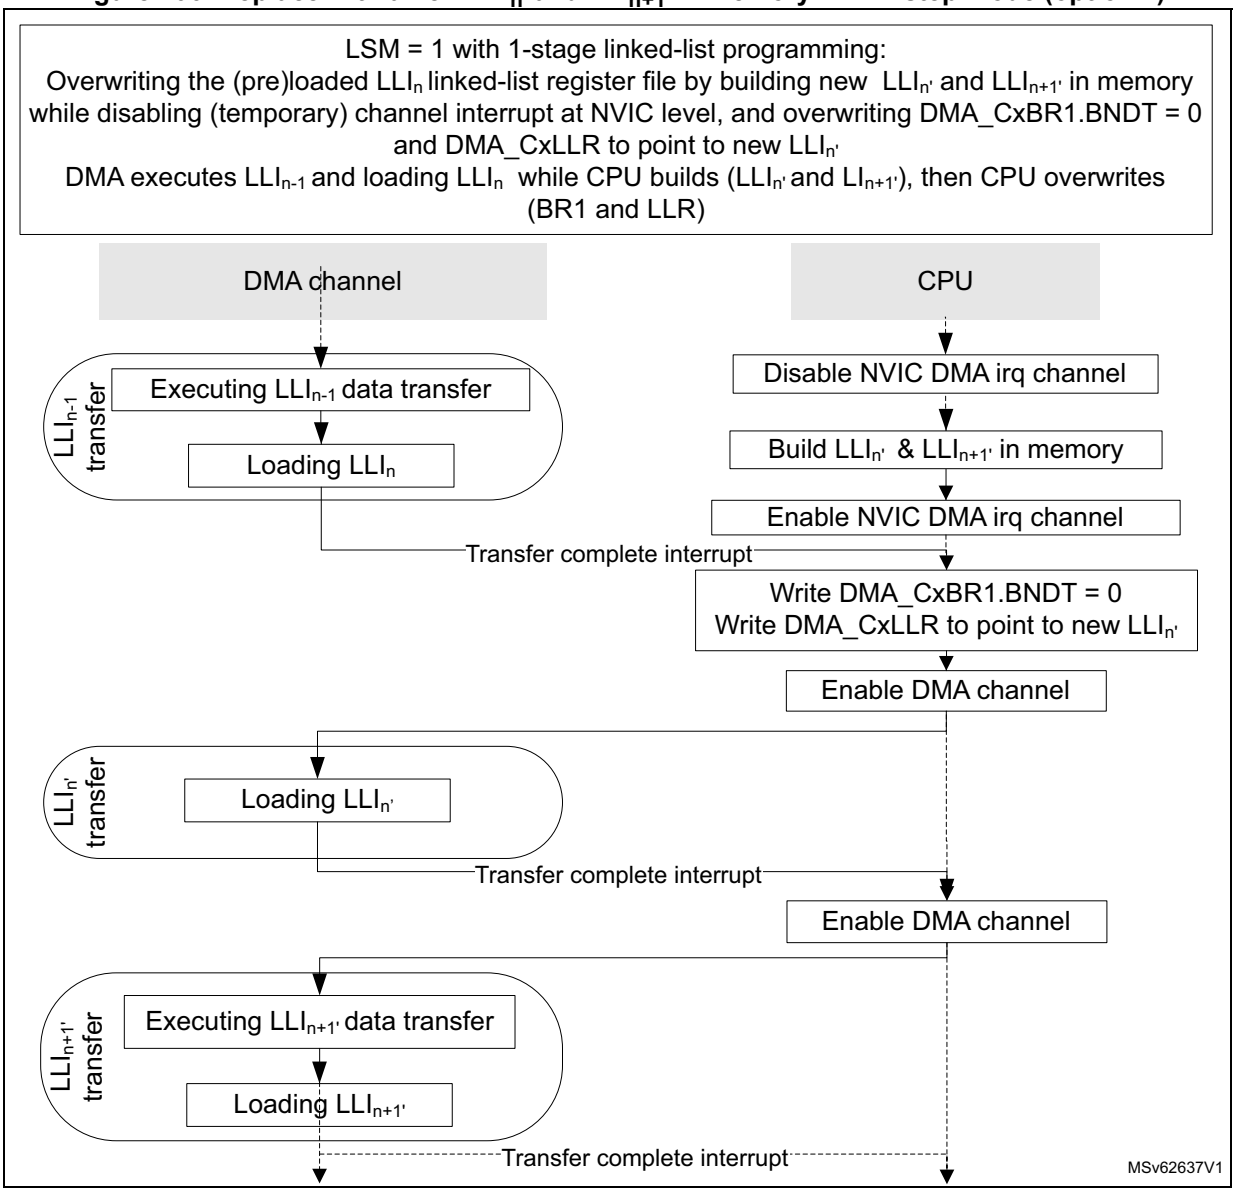
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 105*.

Figure 105. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 106*.

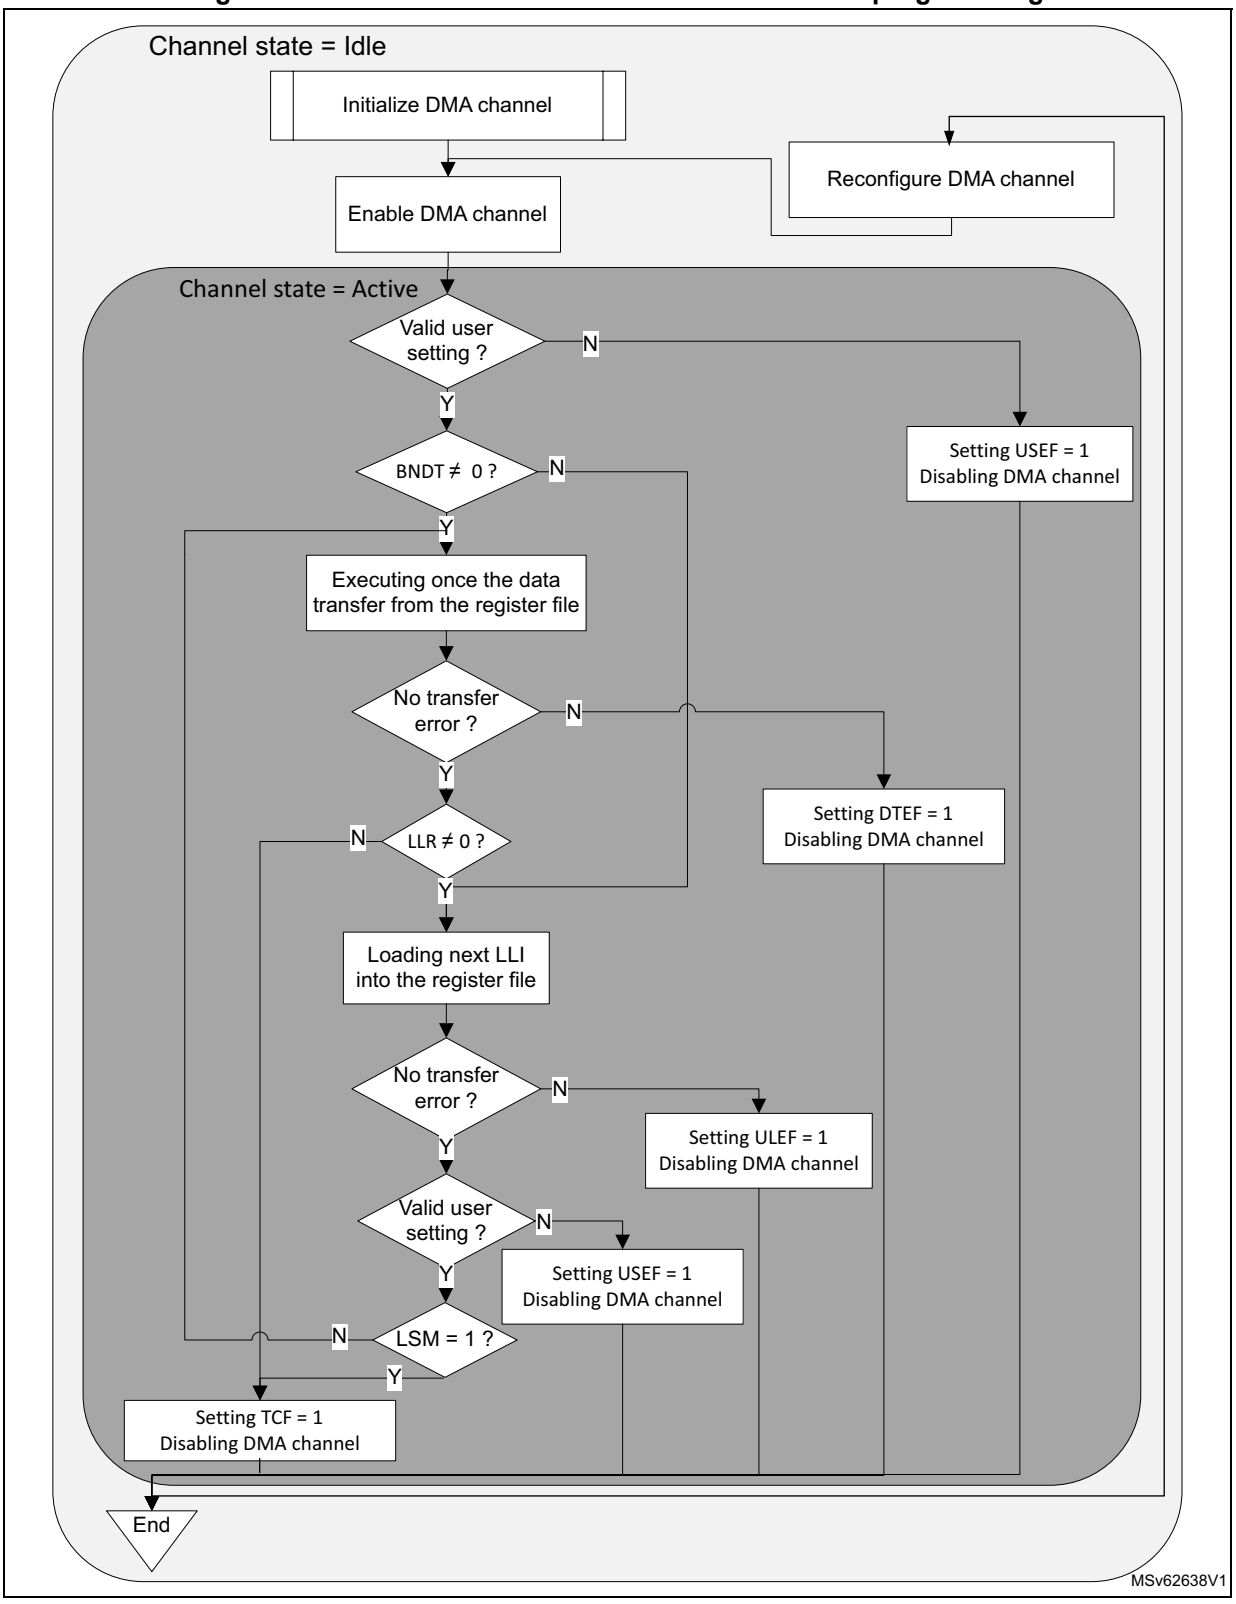
Figure 106. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

16.4.10 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 16.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 107 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 107 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 107, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 16.3.6).

Figure 107. GPDMA channel execution and linked-list programming

16.4.11 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 16.3.2* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

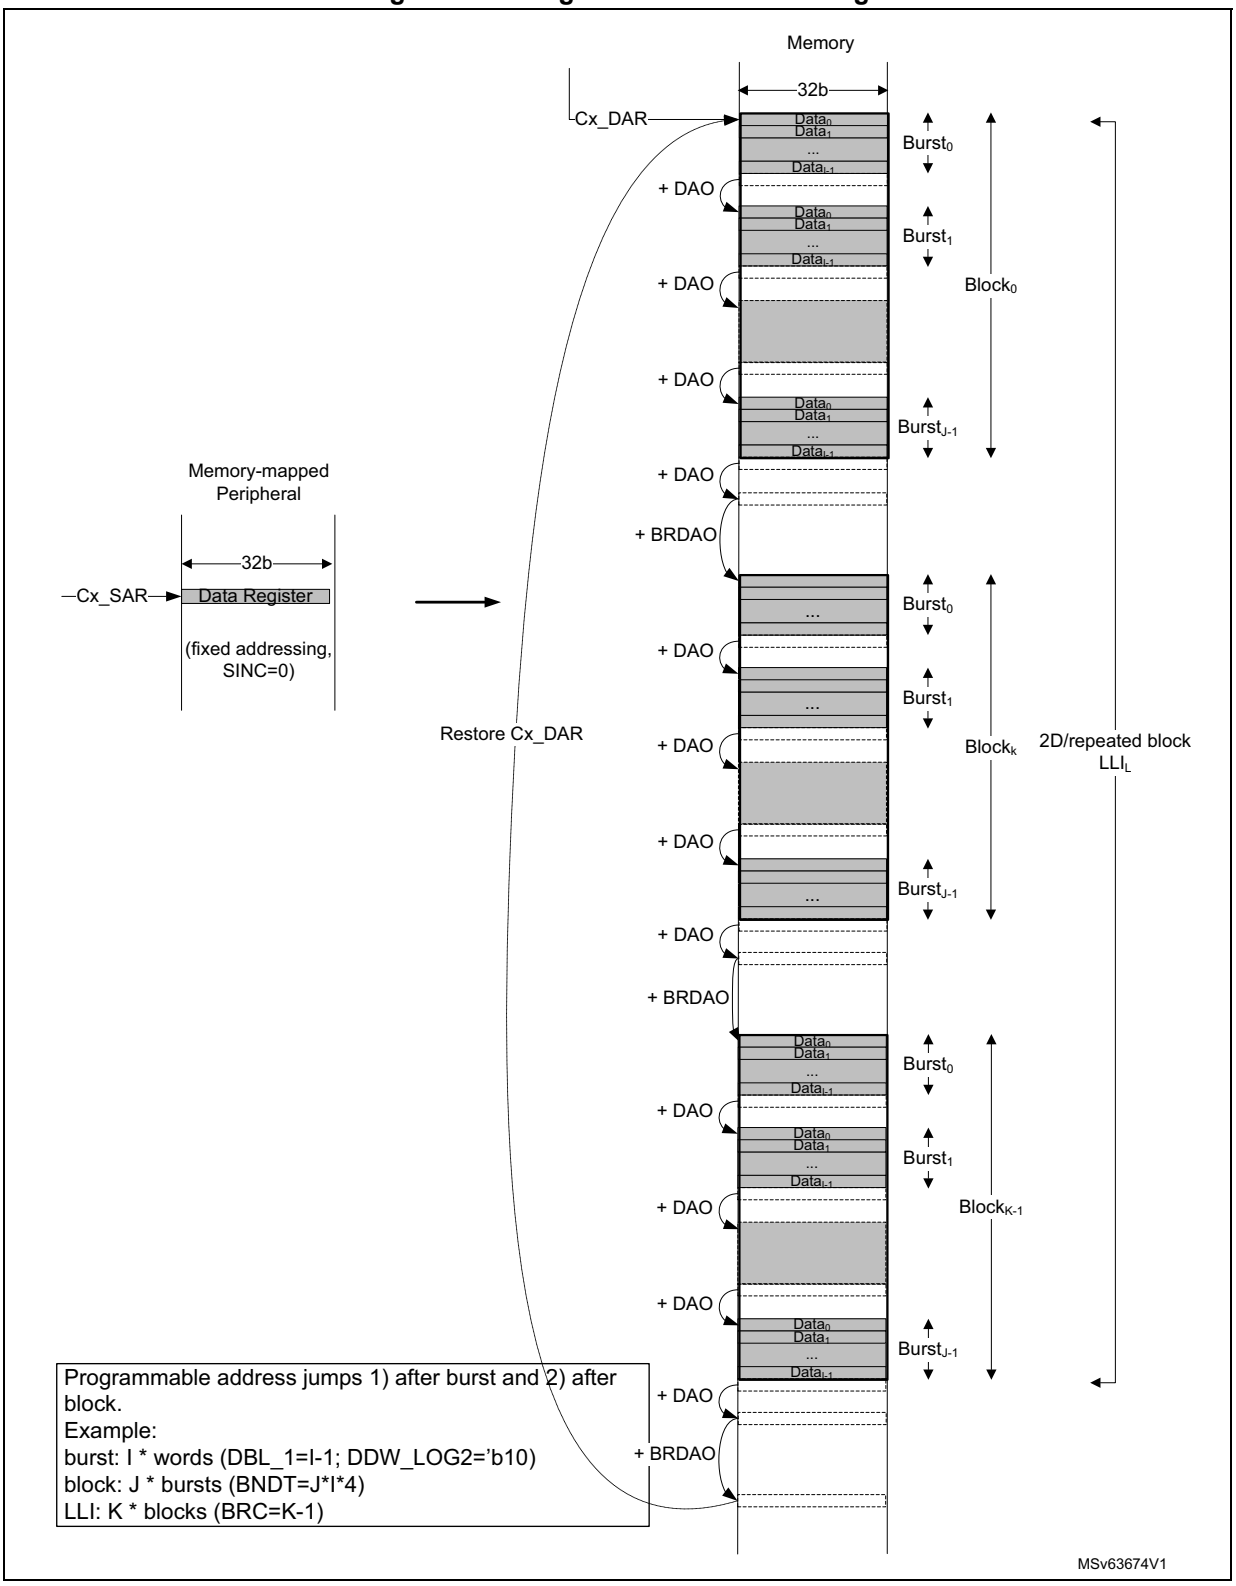
The table below lists the main characteristics of a GPDMA burst.

Table 156. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



GPDMA burst with 2D addressing (channel x = 6 to 7)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 108* with a 2D destination buffer.

Figure 108. Programmed 2D addressing

GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half the FIFO size of channel x, in bytes (see *Section 16.3.2* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size. Each transfer is of a size that is lower than or equal to half of the FIFO size, without any user constraint.
- If the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 157*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 157. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

16.4.12 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[7:0] field (see *Section 16.3.4*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

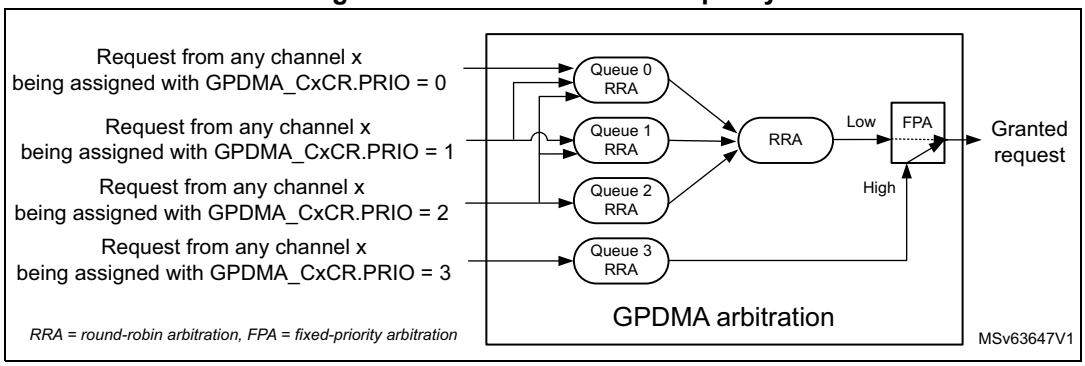
An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 109*, is defined by:



- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 109. GPDMA arbitration policy

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

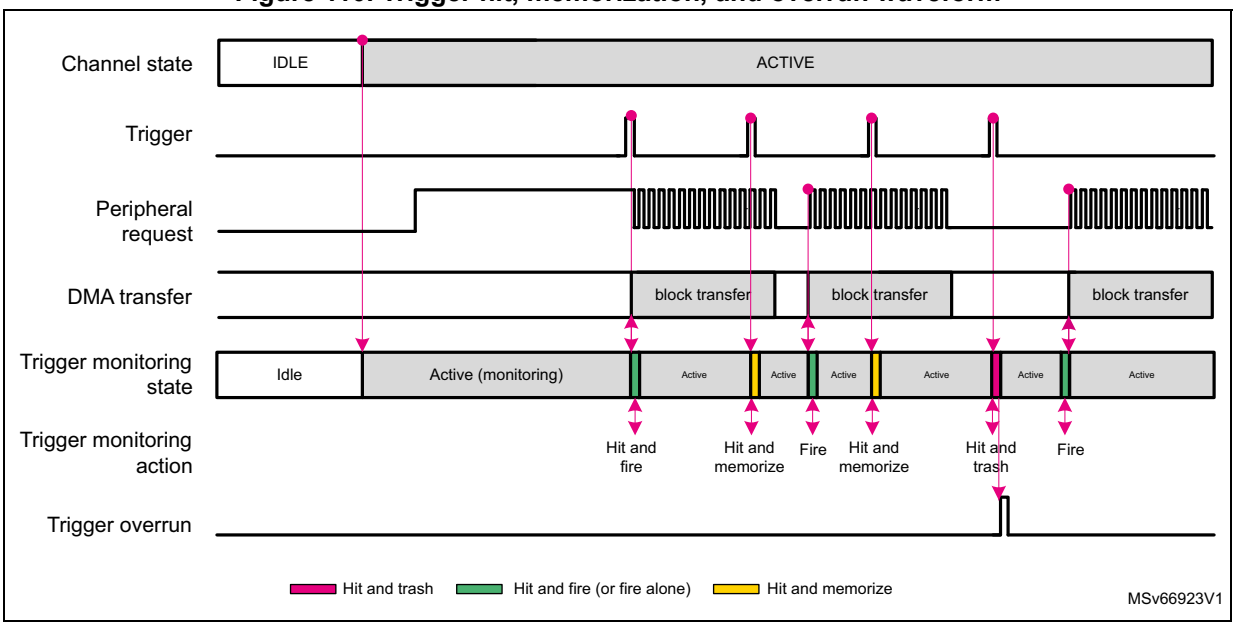
16.4.13 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 16.3.7* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 6 to 7), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

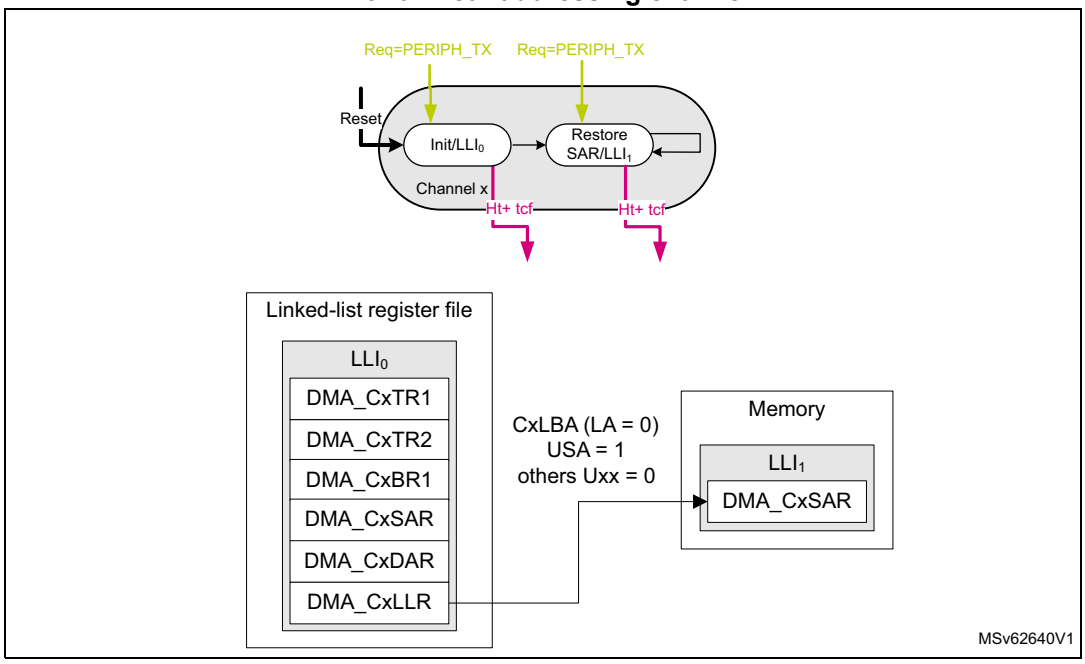
Figure 110 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 110. Trigger hit, memorization, and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

16.4.14 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel



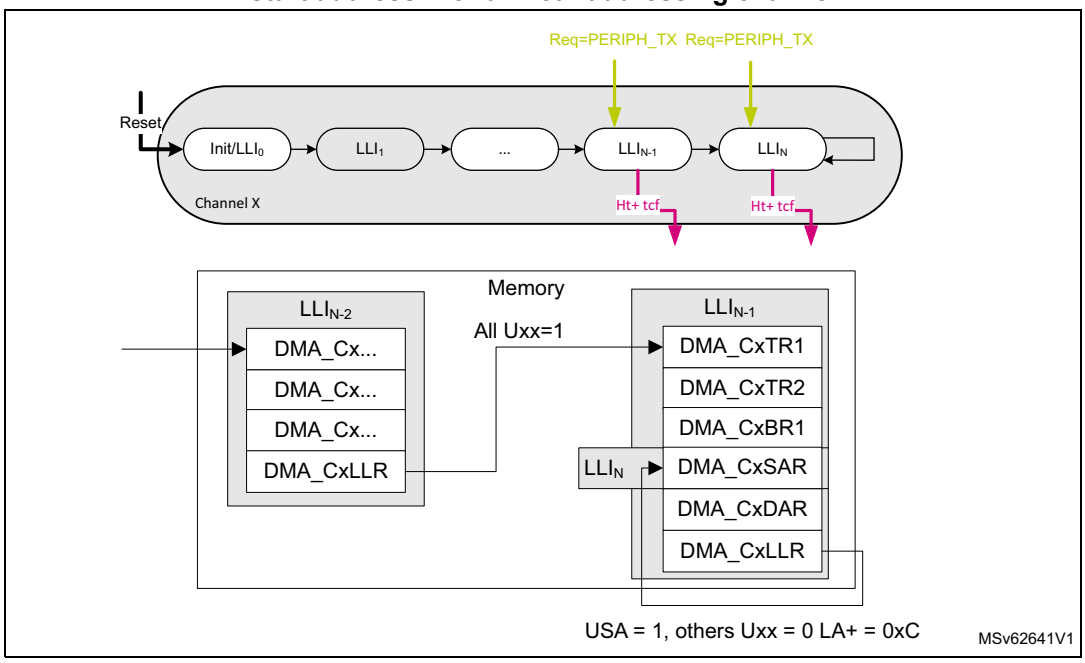
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 111 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 111. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 112 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 112. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

16.4.15 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 16.3.6*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

16.4.16 GPDMA byte-based padding at the block level

For a given channel x, a LLI_n data transfer consists of a block transfer and is defined by the source block size GPDMA_CxBR1.BNDT[15:0], the size of the block of data to be transfered from the source, in bytes.

During a peripheral-to-memory transfer, a peripheral may be streaming and receiving a given number of bytes (for example, via an I2C, UART/USART/LPUART, ADC, DAC) or half-words, and this block size may not be a multiple of a word or a double-word. It is important to allow the user to program any number of bytes for the GPDMA source block size independently from the source data width and the destination data width, in order to use efficiently the bandwidth of the 32-bit AHB system bus and/or the 64-bit AXI system bus when accessing and writing into memory (embedded SRAM, NVM or external memory). This enables to decrease the bus bandwidth for the memory transfers by a ratio of up to 4 in AHB and up to 8 in AXI. More generally, having the source block size independent from the source data width and the destination data width can be useful also with memory-to-peripheral transfers, and with memory-to-memory transfers (AHB from/to AXI).

A FIFO-based channel is able to perform byte-based padding on the last write(s) up to the fully transferred source block size. Then channel FIFO is empty. Data handling is performed on zero bytes in the same way as on regular data bytes from the source, as explained in *GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment*.

There is byte-based padding at the block level:

1. If source data width is less than the destination data width, and if FIFO queuing and data packing is configured (PAM[1:0] = 1x):

- Padding with zero bytes. For example, if BNDT= 5, 8-bit reads, 32-bit writes:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 000B_4, $B_3B_2B_1B_0$
  - if DBX = 0, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> 0$B_4$00, $B_1B_0B_3B_2$
  - if DBX = 1, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 00$B_4$0, $B_2B_3B_0B_1$
  - if DBX = 1, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> $B_4$000, $B_0B_1B_2B_3$

2. If source data width > destination data width, and if FIFO queuing and data unpacking is configured (PAM[1:0] = 1x):

- Padding with zero bytes.
- On the last read, only the number of LSB(s) up to the block size are written to the FIFO. The last written data to the destination is padded with zero bytes up to the destination data width. For example, if BNDT= 5, 32-bit reads, 16-bit writes:
  - if DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 0B_4, B_3B_2, B_1B_0
  - if DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$, -> $B_4$0, B_2B_3, B_0B_1

3. If source data width = destination data width (and BNDT[15:0] is not a multiple of that value):

- Padding with zero bytes. For example, if BNDT= 6, 32-bit reads, 32-bit writes are configured
  - if SBX = 0, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_5B_4$, $B_3B_2B_1B_0$
  - if SBX = 0, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_5B_400, $B_1B_0B_3B_2$
  - if SBX = 0, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_4B_5$, $B_2B_3B_0B_1$
  - if SBX = 0, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4B_500, $B_0B_1B_2B_3$
  - if SBX = 1, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $000B_4$, $B_3B_1B_2B_0$
  - if SBX = 1, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_400$, $B_2B_0B_3B_1$
  - if SBX = 1, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_40$, $B_1B_3B_0B_2$
  - if SBX = 1, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4000, $B_0B_2B_1B_3$

4. If source data width < destination data width, and if destination data is configured as right-aligned and, either configured with zero padding bytes (PAM[1:0] = 00), or configured with sign extension (PAM[1:0] = 01):

- Padding with zero bytes if PAM[1:0] = 00. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 00:
  - if DBX =0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $000B_4$, $000B_3$, $000B_2$, $000B_1$, $000B_0$
- Padding with sign extension if PAM[1:0] = 01. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 01:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $SSSB_4$, $SSSB_3$, $SSSB_2$, $SSSB_1$, $SSSB_0$

5. If source data width > destination data width, and if destination data is configured as right-aligned (PAM[1:0] = 00), or left-aligned (PAM[1:0] = 01):

- Padding with zero bytes. For example, BNDT = 5, 32-bit reads, 16-bit writes:
  - if SBX = 0, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_1B_0
  - if SBX = 0, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_1
  - if SBX = 0, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_2
  - if SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_2B_3
  - if SBX = 1, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_2B_0
  - If SBX = 1, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_2
  - If SBX = 1, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_1
  - If SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_1B_3

16.4.17 GPDMA secure/nonsecure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR, GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

16.4.18 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR, GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the

privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

16.4.19 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).

- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 6 to 7): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

16.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

16.6 GPDMA in low-power modes

Table 158. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 16.3.3* to know if any Stop mode is supported.

16.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 159. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half-transfer event is a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 16.4.19*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

16.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

16.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **SECx**: secure state of channel x (x = 7 to 0)
0: Nonsecure
1: Secure

16.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **PRIVx**: privileged state of channel x (x = 7 to 0)
0: unprivileged
1: privileged

16.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock, for example at boot time, the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR, GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

Note: If TZEN = 0, this register cannot be written.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK7	LOCK6	LOCK5	LOCK4	LOCK3	LOCK2	LOCK1	LOCK0
								rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx, GPDMA_PRIVCFGR.PRIVx until a global GPDMA reset (x = 7 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

16.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MISx**: masked interrupt status of channel x (x = 7 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

16.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MIS7	MIS6	MIS5	MIS4	MIS3	MIS2	MIS1	MIS0
								r	r	r	r	r	r	r	r

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MISx**: masked interrupt status of the secure channel x (x = 7 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

16.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

16.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

	w	w	w	w	w	w	w								

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half-transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

16.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOF	SUSPF	USEF	ULEF	DTEF	HTF	TCF	Res.	Res.	Res.	Res.	Res.	Res.	DRAINING F	IDLEF
	r	r	r	r	r	r	r							r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level (in bytes)
Number of available bytes in the FIFO.
Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half-transfer flag
0: no half-transfer event
1: a half-transfer event occurred
A half-transfer event is either a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half-block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DRAININGF**: FIFO draining flag
0: No received order to drain the FIFO or channel FIFO draining completed
1: Ongoing channel FIFO draining and channel termination
This flag is asserted after that the order to drain the FIFO is received, and meanwhile that the channel is enabled and draining the FIFO and before the channel is terminated with a drained FIFO.
This flag is deasserted by hardware when the enabled channel has been ordered to be terminated with FIFO draining, and the hardware effectively terminates.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

16.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	DRAIN FIFO	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw					w	rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half-transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DRAINFIFO:** empty FIFO
This bit is write only. Writing 0 has no impact.
Writing 1 to RESET in this register causes the hardware to deassert this DRAINFIFO bit, whatever is written into this DRAINFIFO. Else:
Software must write 1 in order to drain the channel FIFO on a suspended channel.
If the software concurrently writes 1 to DRAINFIFO and 1 to SUSP and 0 to reset, the hardware suspends the channel and drains the FIFO by popping out the residual FIFO bytes to the destination (see the programming sequence in *Figure 95*).
0: Write: no action
1: Write: drain FIFO after having suspended the channel

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 93*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP, DRAINFIFO and EN bits (whatever is written receptively in bit 3 and bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (GPDMA_CxSR.SUSPF = 1, GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1 and GPDMA_CxSR.DRAININGF = 0)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 94*).

0: no channel reset

1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

16.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or unprivileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes
00: byte
01: half-word (2 bytes)
10: word (4 bytes)
11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source
If GPDMA_SECCFGR.SECx = 1 and the access is secure:
0: GPDMA transfer nonsecure
1: GPDMA transfer secure
This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.
When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: source allocated port
This bit is used to allocate the master port for the source transfer
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word
If the source data width is shorter than a word, this bit is ignored.
If the source data width is a word:
0:no byte-based exchange within the unaligned half-word of each source word
1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst

0: fixed burst

1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

16.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x. This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TCEM[1:0]		Res.	Res.	Res.	Res.	TRIGPOL[1:0]		Res.	Res.	TRIGSEL[5:0]					
rw	rw					rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half-transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

01: channel x (x = 0 to 5), same as 00, channel x (x = 6 to 7), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half-transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x = 6 to 7), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half-transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half-transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 16.3.7*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 6 to 7): same, each block also if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 5): same as 00; channel x (x = 6 to 7): at 2D/repeated block level: the first burst read of the 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. LLI data transfer is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger:

– If the peripheral is the source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is the destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and one trigger hit.

As shown in *Figure 110: Trigger hit, memorization, and overrun waveform*, the GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10). The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled. After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 16.3.2 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 16.3.6* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 16.3.4*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[7:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1(software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 16.3.4*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

16.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

16.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

16.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 6 to 7). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

16.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 6 to 7), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

16.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	DAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

16.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

16.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory

This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.

0: no GPDMA_CxDAR update

1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory

This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.

0: no GPDMA_CxLLR update

1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register GPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

16.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 6 to 7)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.

0: no GPDMA_CxTR1 update

1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.

0: no GPDMA_CxTR2 update

1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.

0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)

1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.

0: no GPDMA_CxSAR update

1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory
This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.
0:no GPDMA_CxDAR update
1: GPDMA_CxDAR update

Bit 26 **UT3**: Update GPDMA_CxTR3 from memory
This bit controls the update of GPDMA_CxTR3 from the memory during the link transfer.
0: no GPDMA_CxTR3 update
1: GPDMA_CxTR3 update

Bit 25 **UB2**: Update GPDMA_CxBR2 from memory
This bit controls the update of GPDMA_CxBR2 from the memory during the link transfer.
0: no GPDMA_CxBR2 update
1: GPDMA_CxBR2 update

Bits 24:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory
This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.
0: no GPDMA_CxLLR update
1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure
If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.
Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register GPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

17 General purpose direct memory access controller (GPDMA)

This section applies only to STM32G53x/54x devices.

17.1 GPDMA introduction

The general purpose direct memory access (GPDMA) controller is a bus master and system peripheral.

The GPDMA is used to perform programmable data transfers between memory-mapped peripherals and/or memories via linked-lists, upon the control of an off-loaded CPU.

17.2 GPDMA main features

- Dual bidirectional AHB master
- Memory-mapped data transfers from a source to a destination:
  - Peripheral-to-memory
  - Memory-to-peripheral
  - Memory-to-memory
  - Peripheral-to-peripheral

  Transfer arbitration based on a 4-grade programmed priority at channel level:
  - One high-priority traffic class, for time-sensitive channels (queue 3)
  - Three low-priority traffic classes, with a weighted round-robin allocation for non time-sensitive channels (queues 0, 1, 2)
- Per channel event generation, on any of the following events: transfer complete, half-transfer complete, data transfer error, user setting error, link transfer error, completed suspension, and trigger overrun
- Per channel interrupt generation, with separately programmed interrupt enable per event
- 6 concurrent GPDMA channels:
  - Per channel FIFO for queuing source and destination transfers (see *Section 17.3.2*)
  - Intra-channel GPDMA transfers chaining via programmable linked-list into memory, supporting two execution modes: run-to-completion and link step mode
  - Intra-channel and inter-channel GPDMA transfers chaining via programmable GPDMA input triggers connection to GPDMA task completion events
- Per linked-list item within a channel:
  - Separately programmed source and destination transfers
  - Programmable data handling between source and destination: byte-based reordering, packing or unpacking, padding or truncation, sign extension and left/right realignment
  - Programmable number of data bytes to be transferred from the source, defining the block level and byte-based padding

  - Linear source and destination addressing: either fixed or contiguously incremented addressing, programmed at a block level, between successive burst transfers
  - 2D source and destination addressing: programmable signed address offsets between successive burst transfers (non-contiguous addressing within a block, combined with programmable signed address offsets between successive blocks, at a second 2D/repeated block level, for a reduced set of channels (see *Section 17.3.2*)
  - Support for scatter-gather (multi-buffer transfers), data interleaving and deinterleaving via 2D addressing
  - Programmable GPDMA request and trigger selection
  - Programmable GPDMA half-transfer and transfer complete events generation
  - Pointer to the next linked-list item and its data structure in memory, with automatic update of the GPDMA linked-list control registers
  - Channel abort and restart
  - Channel terminate with FIFO draining
- Debug:
  - Channel suspend and resume support
  - Channel status reporting, including FIFO level, and event flags
- TrustZone support:
  - Support for secure and nonsecure GPDMA transfers, independently at a first channel level, and independently at a source/destination and link sublevels
  - Secure and nonsecure interrupts reporting, resulting from any of the respectively secure and nonsecure channels
  - TrustZone-aware AHB slave port, protecting any GPDMA secure resource (register, register field) from a nonsecure access
- Privileged/unprivileged support:
  - Support for privileged and unprivileged GPDMA transfers, independently at a channel level
  - Privileged-aware AHB slave port

17.3 GPDMA implementation

17.3.1 GPDMA instances

There are two instances of the GPDMA in the devices, named as GPDMA1 and GPDMA2.

Each GPDMA instance has the same channel-based implementation and is connected to the same requests and triggers, as detailed in the following sub-sections.

17.3.2 GPDMA channels

A given GPDMA channel x is implemented with the following features and intended usage. To make the best use of the GPDMA performances, the table below lists some general recommendations, allowing the user to select and allocate a channel, given its implemented FIFO size and the requested GPDMA transfer.

Table 161. GPDMA1/2 channel implementation

Channel x	Hardware parameters		Features
	dma_fifo_size[x]	dma_addressing[x]	
x = 0 to 3	2	0	Channel x (x = 0 to 3) is implemented with: – a FIFO of 8 bytes, 2 words – fixed/contiguously incremented addressing These channels must be typically allocated for GPDMA transfers between an APB or AHB peripheral and SRAM.
x = 4 to 5	4	1	Channel x (x = 4 to 5) is implemented with: – a FIFO of 32 bytes, 8 words – 2D addressing These channels may be also used for GPDMA transfers between a demanding AHB peripheral and SRAM, or for transfers from/to external memories.

17.3.3 GPDMA in low-power modes

The GPDMA wake-up feature is implemented in the device low-power modes as per the table below.

Table 162. GPDMA1/2 wake-up in low-power modes

Feature	Low-power modes
Wake-up	GPDMA1/2 in Sleep mode

17.3.4 GPDMA requests

A GPDMA request from a peripheral can be assigned to a GPDMA channel x, via REQSEL[7:0] in GPDMA_CxTR2, provided that SWREQ = 0.

The GPDMA requests mapping is specified in the table below.

17.3.5 GPDMA block requests

Some GPDMA requests must be programmed as a block request, and not as a burst request. Then BREQ in GPDMA_CxTR2 must be set for a correct GPDMA execution of the requested peripheral transfer at the hardware level.

Table 164. Programmed GPDMA1/2 request as a block request

GPDMA block requests
lptim1_ue_dma

17.3.6 GPDMA channels with peripheral early termination

A GPDMA channel, if implemented with this feature, can support the early termination of the data transfer from the peripheral which does also support this feature.

Table 165. GPDMA1/2 channel with peripheral early termination

GPDMA channel x with peripheral early termination
x = 0

This GPDMA support is activated when the channel x is programmed with GPDMA_CxTR2.PFREQ = 1. Then, the peripheral itself can initiate and request a data transfer completion, before the GPDMA has transferred the whole block (see *Section 17.4.15* for more details).

Table 166. Programmed GPDMA1/2 request with peripheral early termination

Programmed GPDMA channel x request with peripheral early termination
i3c1_rx_dma

17.3.7 GPDMA triggers

A GPDMA trigger can be assigned to a GPDMA channel x, via TRIGSEL[5:0] in GPDMA_CxTR2, provided that TRIGPOL[1:0] defines a rising or a falling edge of the selected trigger (TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).

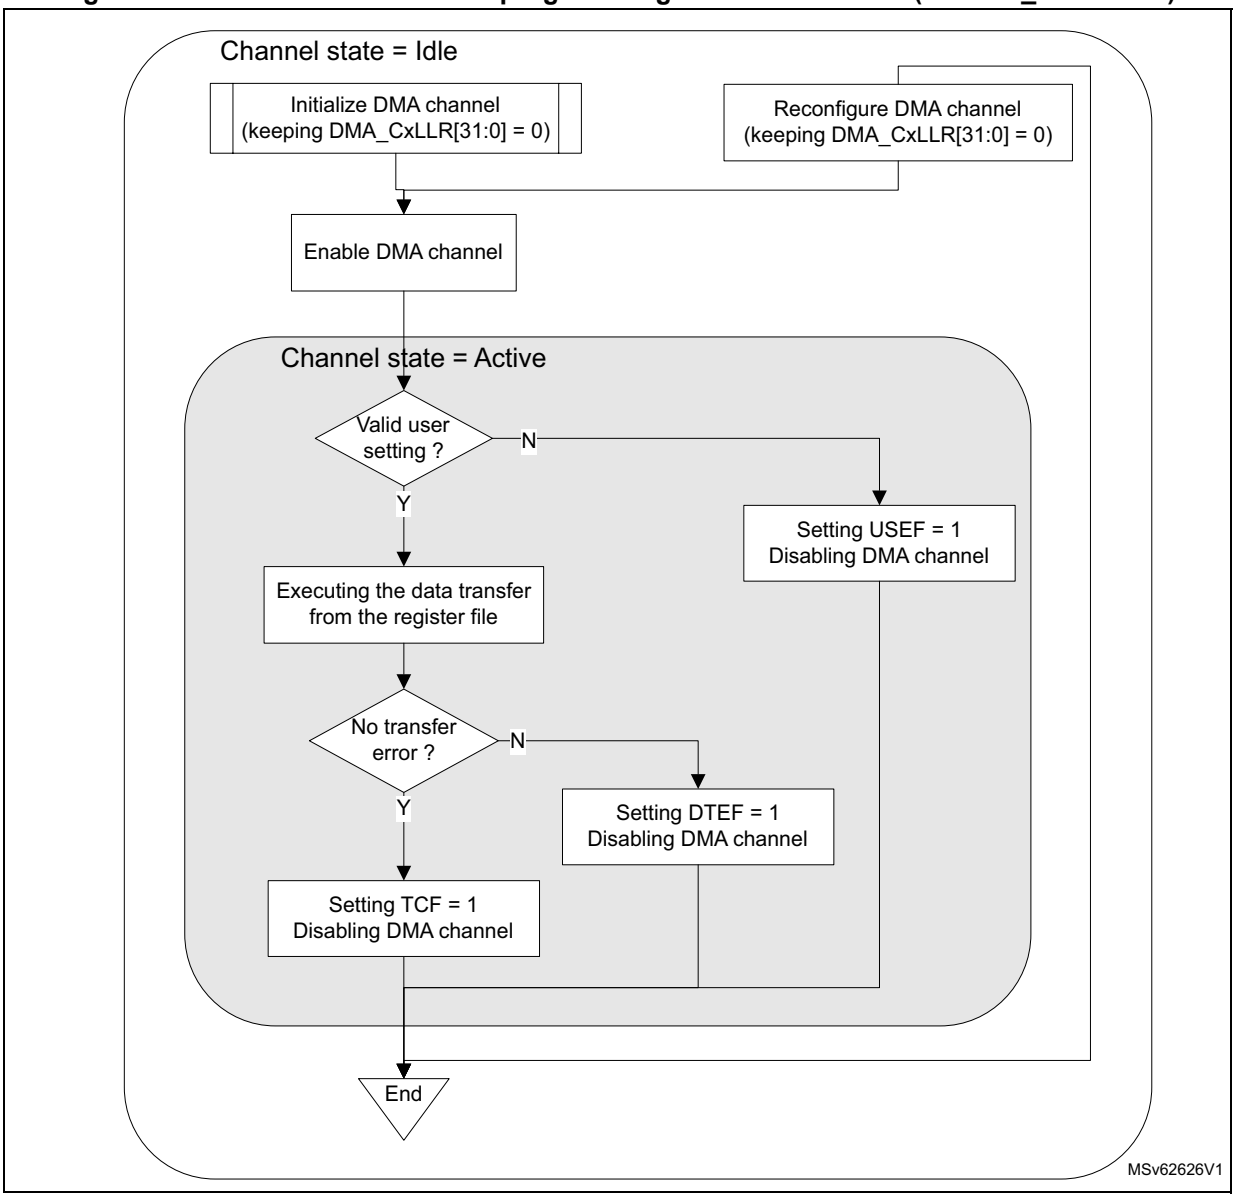
17.4 GPDMA functional description

17.4.1 GPDMA block diagram

Figure 113. GPDMA block diagram



17.4.2 GPDMA channel state and direct programming without any linked-list

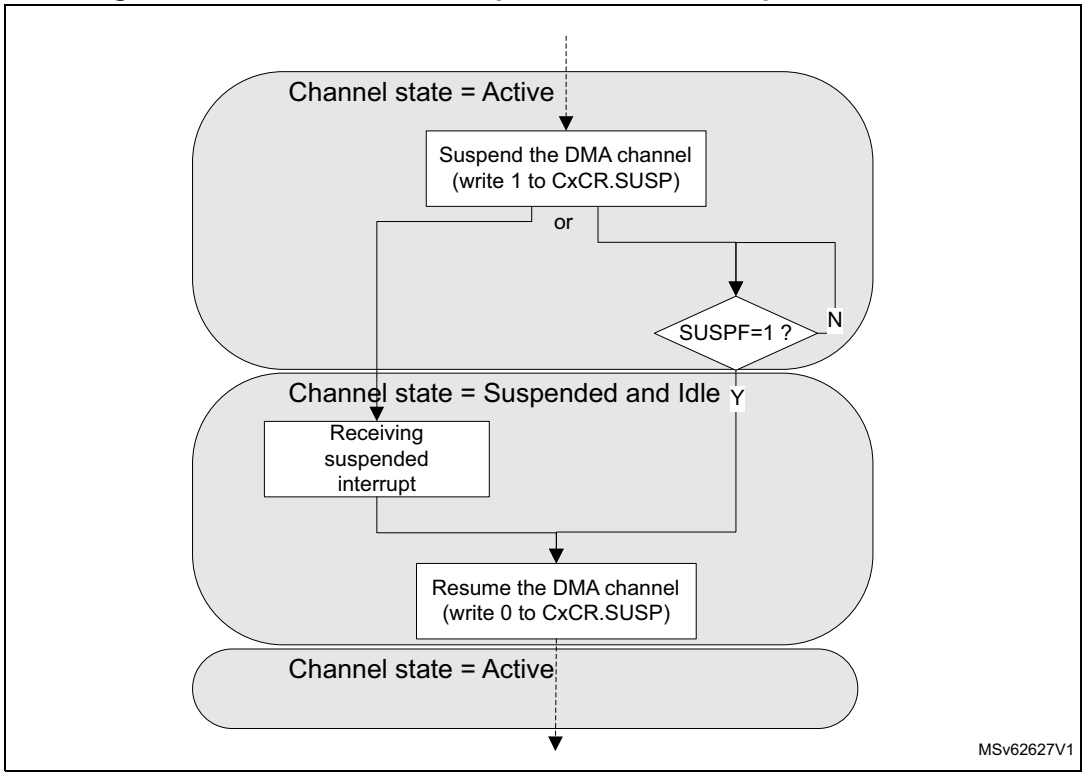
After a GPDMA reset, a GPDMA channel x is in idle state. When the software writes 1 in GPDMA_CxCR.EN, the channel takes into account the value of the different channel configuration registers (GPDMA_CxXXX), switches to the active/non-idle state and starts to execute the corresponding requested data transfers.

After enabling/starting a GPDMA channel transfer by writing 1 in GPDMA_CxCR.EN, a GPDMA channel interrupt on a complete transfer notifies the software that the GPDMA channel is back in idle state (EN is then deasserted by hardware) and that the channel is ready to be reconfigured then enabled again.

Figure 114 illustrates this GPDMA direct programming without any linked-list (GPDMA_CxLLR = 0).

Figure 114. GPDMA channel direct programming without linked-list (GPDMA_CxLLR = 0)

17.4.3 GPDMA channel suspend and resume



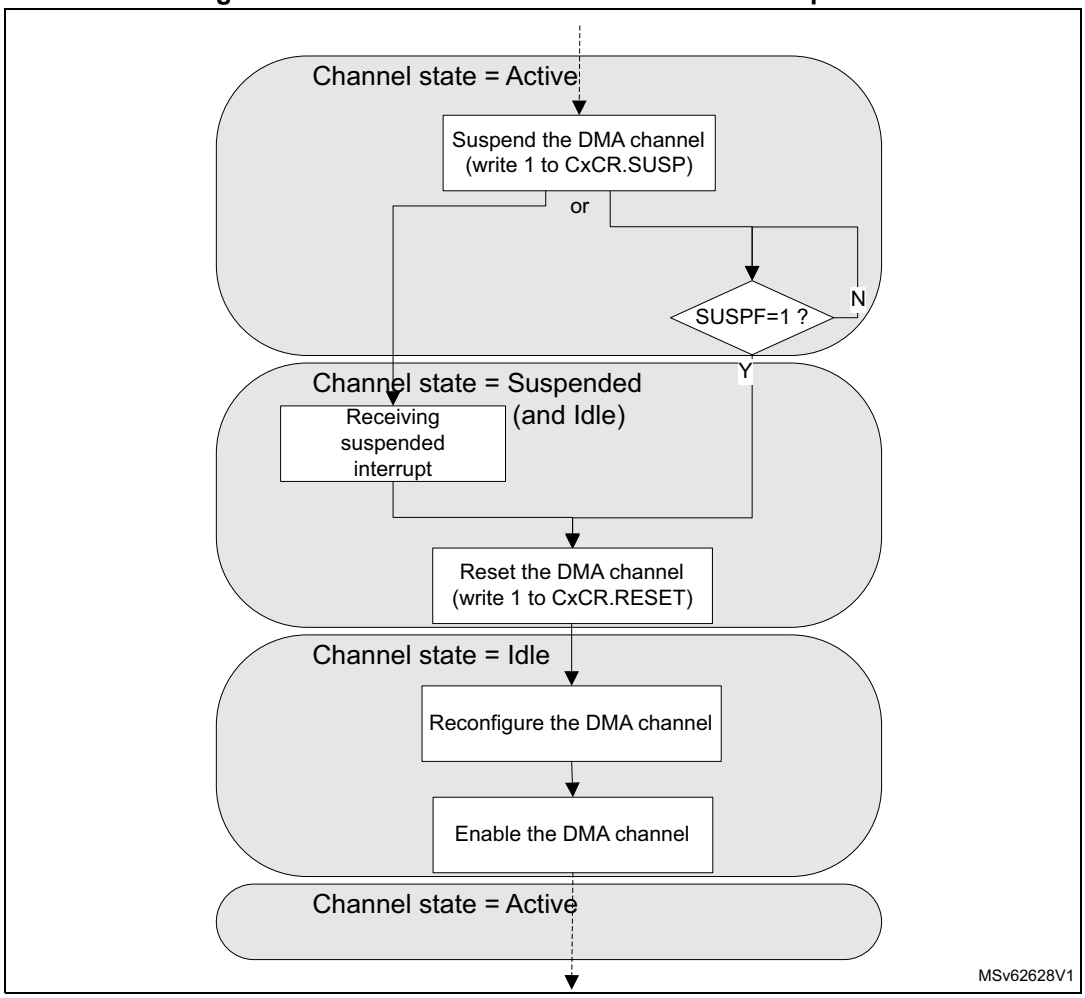
The software can suspend on its own a channel still active, with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls the suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master ports. Then the software can observe, in a steady state, any read register or register field that is hardware modifiable.

Note: An ongoing GPDMA transfer can be a data transfer (a source/destination burst transfer) or a link transfer for the internal update of the linked-list register file from the next linked-list item.

3. The software safely resumes the suspended channel by writing 0 to GPDMA_CxCR.SUSP.

Figure 115. GPDMA channel suspend and resume sequence



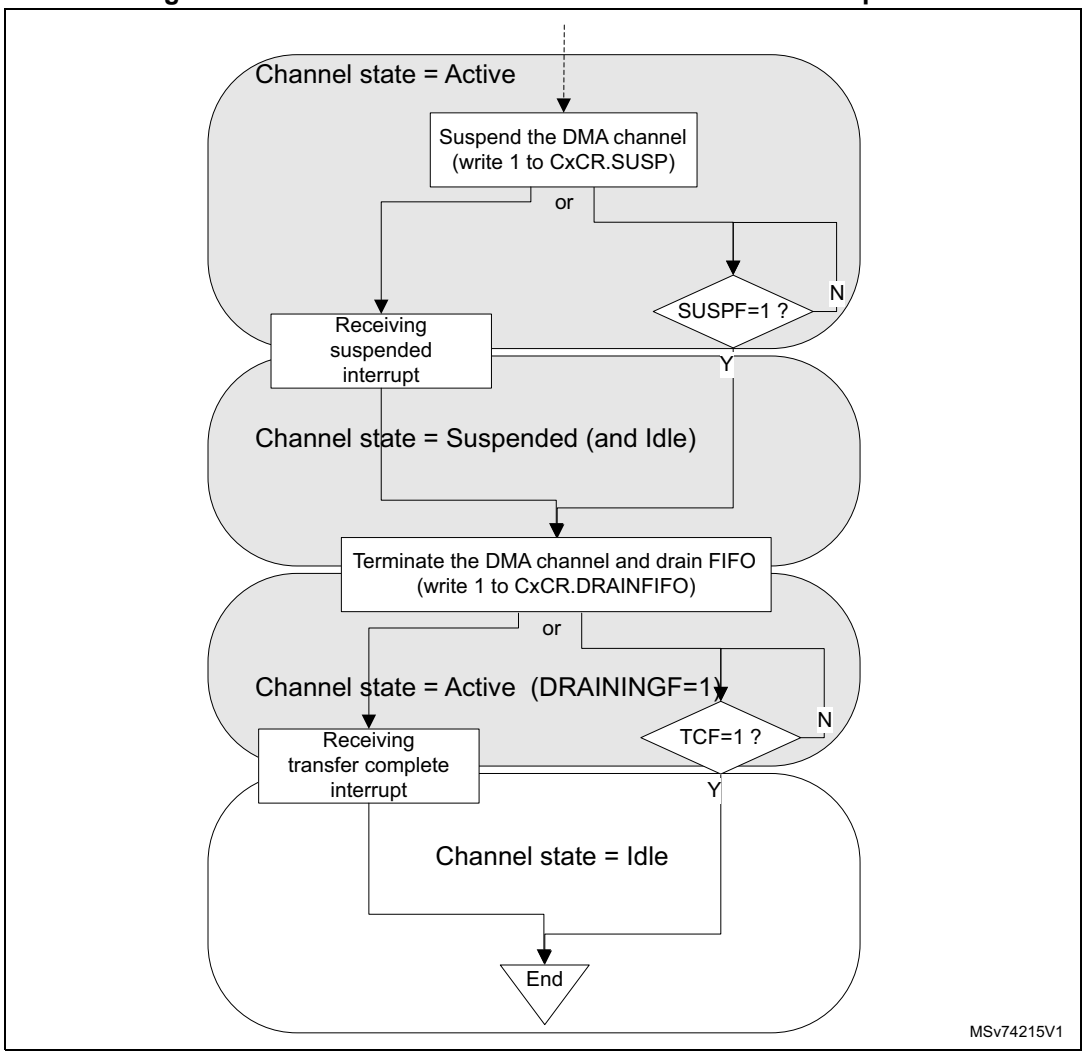
Note: A suspend and resume sequence does not impact the GPDMA_CxCR.EN bit. Suspending a channel (transfer) does not suspend a started trigger detection.

17.4.4 GPDMA channel abort and restart

Alternatively, like for aborting a continuous GPDMA transfer with a circular buffering or a double buffering, the software can abort, on its own, a still active channel with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software resets the channel by writing 1 to GPDMA_CxCR.RESET. This causes the reset of the FIFO, the reset of the channel internal state, the reset of the GPDMA_CxCR.EN bit, and the reset of the GPDMA_CxCR.SUSP bit.
4. The software safely reconfigures the channel. The software must reprogram the hardware-modified GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR registers.
5. In order to restart the aborted then reprogrammed channel, the software enables it again by writing 1 to the GPDMA_CxCR.EN bit.

Figure 116. GPDMA channel abort and restart sequence



17.4.5 GPDMA channel terminate and drain FIFO

Alternatively, for terminating a continuous GPDMA transfer with a circular buffering or a double buffering, and having popped out any residual byte(s) in the channel FIFO and writing them to the destination, the software can terminate an active channel and drain the channel FIFO with the following sequence:

1. The software writes 1 into the GPDMA_CxCR.SUSP bit.
2. The software polls suspended flag GPDMA_CxSR.SUSPF until SUSPF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.SUSPIE. Wait for the channel to be effectively in suspended state means wait for the completion of any ongoing GPDMA transfer over its master port.
3. The software orders to drain the channel FIFO by writing 1 to GPDMA_CxCR.DRAINFIFO.
4. The software polls transfer complete flag GPDMA_CxSR.TCF until TCF = 1, or waits for an interrupt previously enabled by writing 1 to GPDMA_CxCR.TCIE. Wait for the channel to be effectively with a drained FIFO means wait for completion of any residual write burst from the FIFO to the destination. Then the channel is disabled by hardware and in IDLE state.

Figure 117. GPDMA channel terminate and drain FIFO sequence

Note: If the softwares writes the GPDMA_CxCR register in a single shot with concurrently SUSP = 1, DRAINFIFO = 1, and RESET = 0, then the sequence for terminating and draining the FIFO also occurs.

GPDMA_CxTR2.DREQ = 1 and GPDMA_CxCR.DRAINFIFO = 1 is not supported, only peripheral-to-memory and memory-to-memory transfers are supported to be terminated with drained FIFO.

17.4.6 GPDMA linked-list data structure

Alternatively to the direct programming mode, a channel can be programmed by a list of transfers, known as a list of linked-list items (LLI). Each LLI is defined by its data structure.

The base address in memory of the data structure of a next LLI_{n+1} of a channel x is the sum of the following:

- the link base address of the channel x (in GPDMA_CxLBAR)
- the link address offset (LA[15:2] field in GPDMA_CxLLR). The linked-list register GPDMA_CxLLR is the updated result from the data structure of the previous LLIn of the channel x.

The data structure for each LLI may be specific.

A linked-list data structure is addressed following the value of the following UT1, UT2, UB1, USA, UDA, UT3 and UB2 if present, and ULL bits in GPDMA_CxLLR.

In linked-list mode, each GPDMA linked-list register (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3 and GPDMA_CxBR2 if present, and GPDMA_CxLLR) is conditionally and automatically updated from the next linked-list data structure in the memory, following the current value of the GPDMA_CxLLR register that was conditionally updated from the linked-list data structure of the previous LLI.

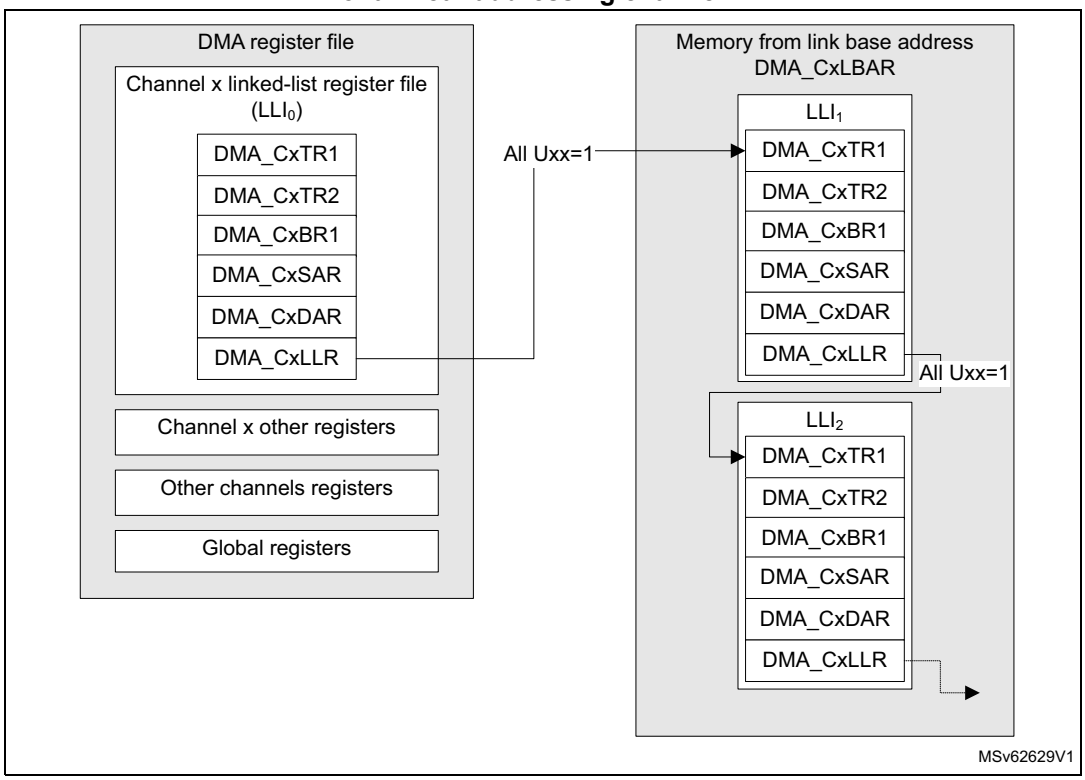
Caution: The user must program the pointer to the next linked-list data structure (GPDMA_CxLLR[15:0]) not to exceed the 64-Kbyte addressable space defined by the link base address register (GPDMA_CxLBAR). The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Static linked-list data structure

For example, when the update bits (UT1, UT2, UB1, USA, UDA, plus UB2 and UT3 if present, and ULL) in GPDMA_CxLLR are all asserted, the linked-list data structure in the memory is maximal with:

- channel x (x = 0 to 3) contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR (see *Figure 118*) and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory
- channel x (x = 4 to 5), contiguous 32-bit locations, including GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, GPDMA_CxTR3, GPDMA_CxBR2 and GPDMA_CxLLR, (see *Figure 119*), and including the first linked-list register file (LLI_0) and the next LLIs (such as LLI_1, LLI_2) in the memory

Figure 118. Static linked-list data structure (all Uxx = 1) of a linear addressing channel x



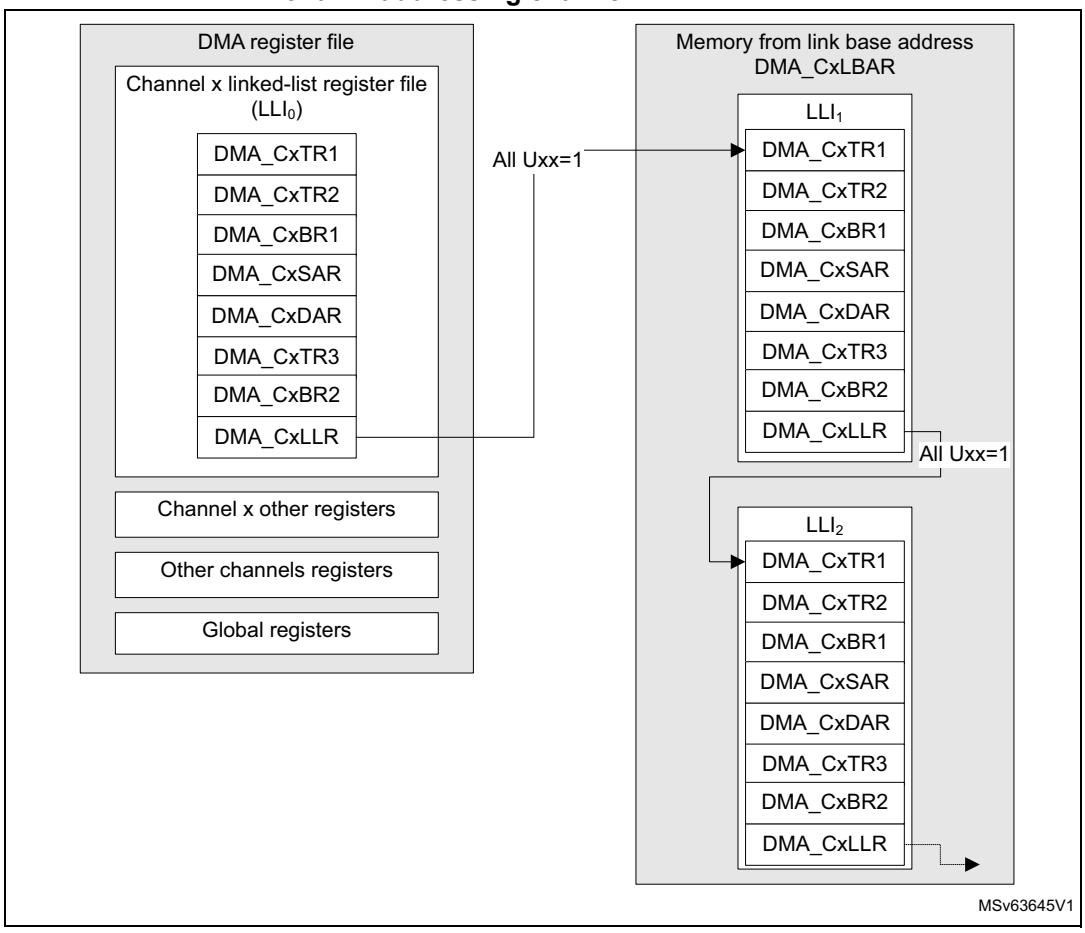


Figure 119. Static linked-list data structure (all Uxx = 1) of a 2D addressing channel x

Dynamic linked-list data structure

Alternatively, the memory organization for the full list of LLIs can be compacted with specific data structure for each LLI.

If UT1 = 0 and UT2 = 1, the link address offset of the register GPDMA_CxLLR is pointing to the updated value of the GPDMA_CxTR2 instead of the GPDMA_CxTR1 which is not to be modified (see *Figure 120*).

Example: if UT1 = UB1 = USA = 0 and if UT3 = UB2 = 0, when channel x is with 2D addressing, and if UT2 = UDA = ULL = 1, the next LLI does not contain an (updated) value for GPDMA_CxTR1, nor GPDMA_CxBR1, nor GPDMA_CxSAR, nor GPDMA_CxTR3, nor GPDMA_CxBR2 when channel x is with 2D addressing. The next LLI contains an updated value for GPDMA_CxTR2, GPDMA_CxDAR, and GPDMA_CxLLR, as shown in *Figure 121*.

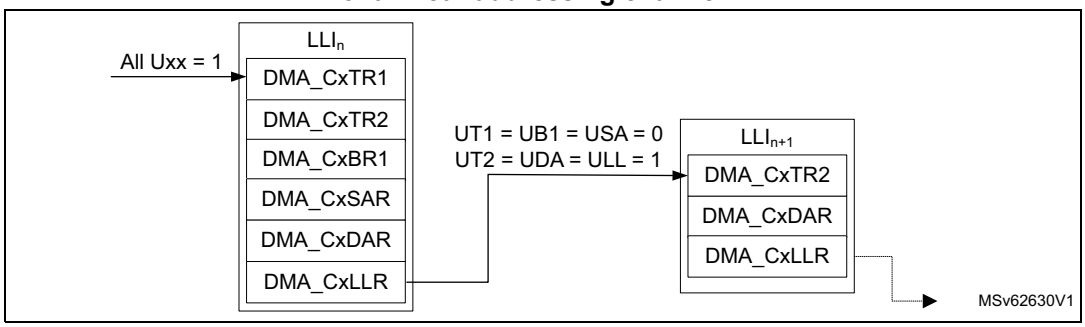

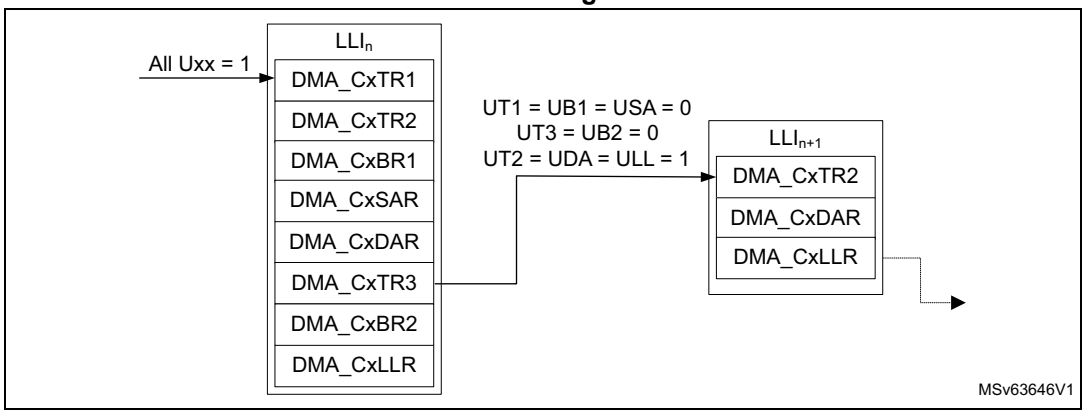

Figure 121. GPDMA dynamic linked-list data structure of a 2D addressing channel x

17.4.7 Linked-list item transfer execution

A LLI_n transfer is the sequence of:

1. a data transfer: GPDMA executes the data transfer as described by the GPDMA internal register file (this data transfer can be void/null for LLI_0)
2. a conditional link transfer: GPDMA automatically and conditionally updates its internal register file by the data structure of the next LLI_{n+1}, as defined by the GPDMA_CxLLR value of the LLI_n.

Note: The initial data transfer as defined by the internal register file (LLI_0) can be null (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxTR2.PFREQ = 0) provided that the conditional update bit UB1 in GPDMA_CxLLR is set (meaning there is a non-null data transfer described by the next LLI_1 in the memory to be executed).

Depending on the intended GPDMA usage, a GPDMA channel x can be executed as described by the full linked-list (run-to-completion mode, GPDMA_CxCR.LSM = 0) or a GPDMA channel x can be programmed for a single execution of a LLI (link step mode, GPDMA_CxCR.LSM = 1), as described in the next sections.

17.4.8 GPDMA channel state and linked-list programming in run-to-completion mode

When GPDMA_CxCR.LSM = 0 (in full list execution mode, execution of the full sequence of LLIs, named run-to-completion mode), a GPDMA channel x is initially programmed, started

by writing 1 to GPDMA_CxCR.EN, and after completed at channel level. The channel transfer is:

- configured with at least the following:
  - the first LLI_0, internal linked-list register file: GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2
  - the last LLI_N, described by the linked-list data structure in memory, as defined by the GPDMA_CxLLR reflecting the before last LLI_{N-1}
- completed when GPDMA_CxLLR[31:0] = 0, GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0, at the end of the last LLI_{N-1} transfer

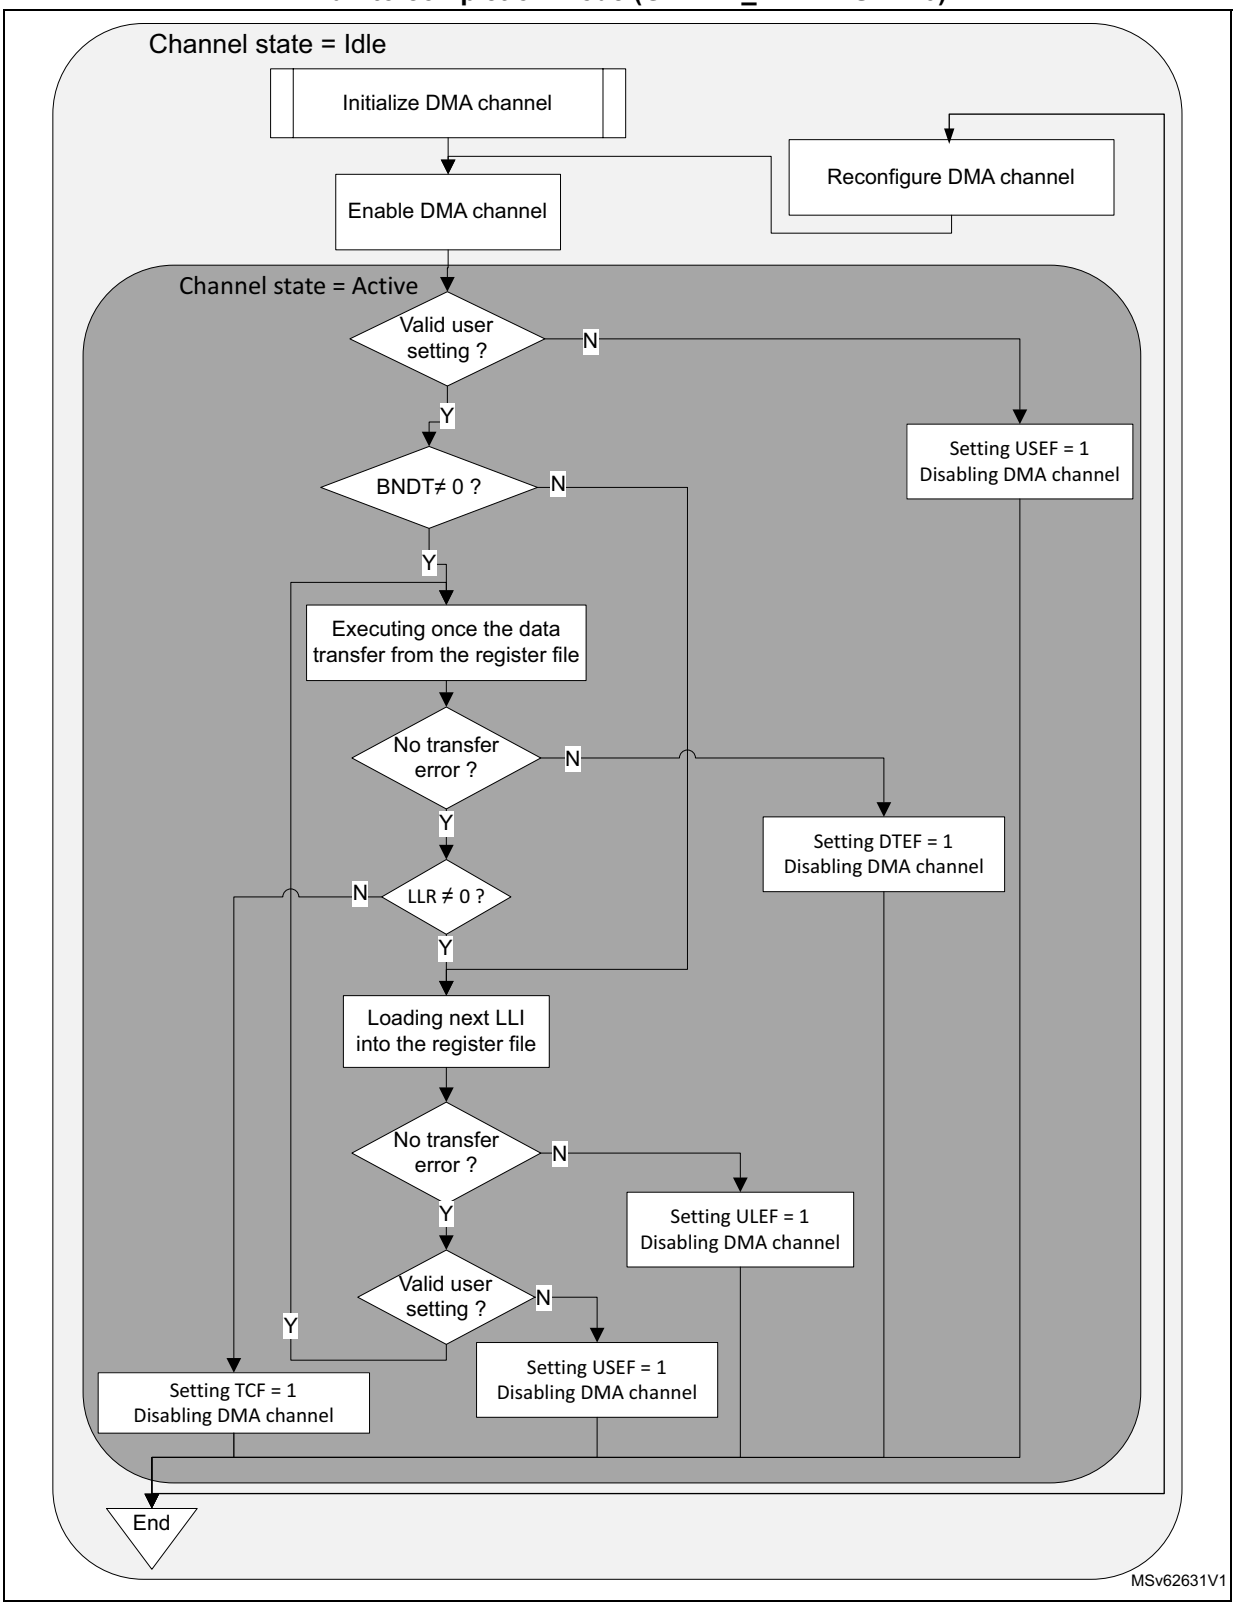
GPDMA_CxLLR[31:0] = 0 is the condition of a linked-list based channel completion and means the following:

- The 16 low significant bits GPDMA_CxLLR.LA[15:0] of the next link address are null.
- All the update bits GPDMA_CxLLR.Uxx are null (UT1, UT2, UB1, USA, UDA and ULL, plus UB2 and UT3).

The channel may never be completed when GPDMA_CxLLR.LSM = 0:

- If the last LLI_N is recursive, pointing to itself as a next LLI:
  - either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value
  - or GPDMA_CxLLR.ULL = 0
- If LLI_N is pointing to a previous LLI

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0 (if present). Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 17.4.15* for more details).



In typical run-to-completion mode, allocation of an GPDMA channel, including detailed programming, occurs once during GPDMA initialization. This process reserves a data communication link and GPDMA service during run-time for repeated transfers, such as transfers from a peripheral to memory, from memory to a peripheral, or memory-to-memory transfers. The reserved data communication link may consist of a dedicated channel, or the channel may be shared. A repeated transfer consists of a sequence of linked list items (LLIs).

Figure 122 depicts the GPDMA channel execution and its registers programming in run-to-completion mode.

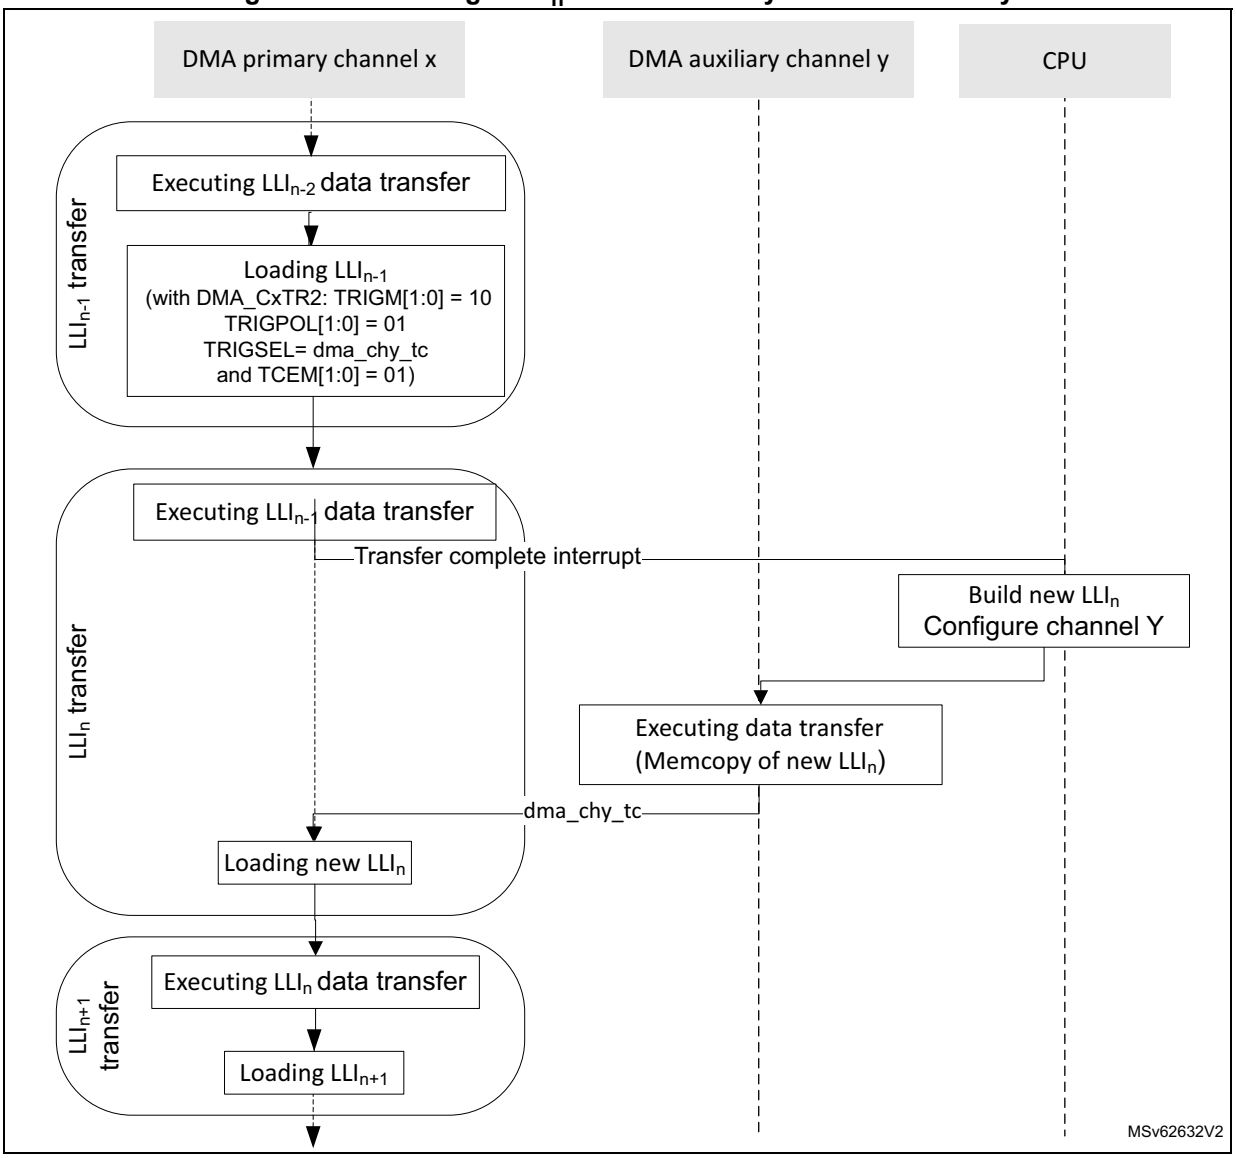
Note: Figure 122 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at channel completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion, the hardware always set TCEF = 1 and disables the channel.

In Figure 122, BNDT ≠ 0 is the typical condition for starting the first data transfer in this figure. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 17.3.6).

Figure 122. GPDMA channel execution and linked-list programming in run-to-completion mode (GPDMA_CxCR.LSM = 0)

Run-time inserting a LLI_n via an auxiliary channel, in run-to-completion mode

The start of the link transfer of the LLI_{n-1} (start of the LLI_n loading) can be conditioned by the occurrence of a trigger, when programming the following fields of the GPDMA_CxTR2 in the data structure of the LLI_{n-1}:



- TRIGM[1:0] = 10 (link transfer triggering mode)
- TRIGPOL[1:0] = 01 or 10 (rising or falling edge)
- TRIGSEL[5:0] (see *Section 17.3.7* for the trigger selection details)

Another auxiliary channel y can be used to store the channel x LLI_n in the memory and to generate a transfer complete event gpdma_chy_tc. By selecting this event as the input trigger of the link transfer of the LLI_{n-1} of the channel x, the software can pause the primary channel x after its LLI_{n-1} data transfer, until it is indeed written the LLI_n.

Figure 123 depicts such a dynamic elaboration of a linked-list of a primary channel x, via another auxiliary channel y.

Caution: This use case is restricted to an application with a LLI_{n-1} data transfer that does not need a trigger. The triggering mode of this LLI_{n-1} is used to load the next LLI_n.

Figure 123. Inserting a LLI_n with an auxiliary GPDMA channel y

17.4.9 GPDMA channel state and linked-list programming in link step mode

When GPDMA_CxCR.LSM = 1 (in link step execution mode, single execution of one LLI), a channel transfer is executed and completed after each single execution of a LLI, including its (conditional) data transfer and its (conditional) link transfer.

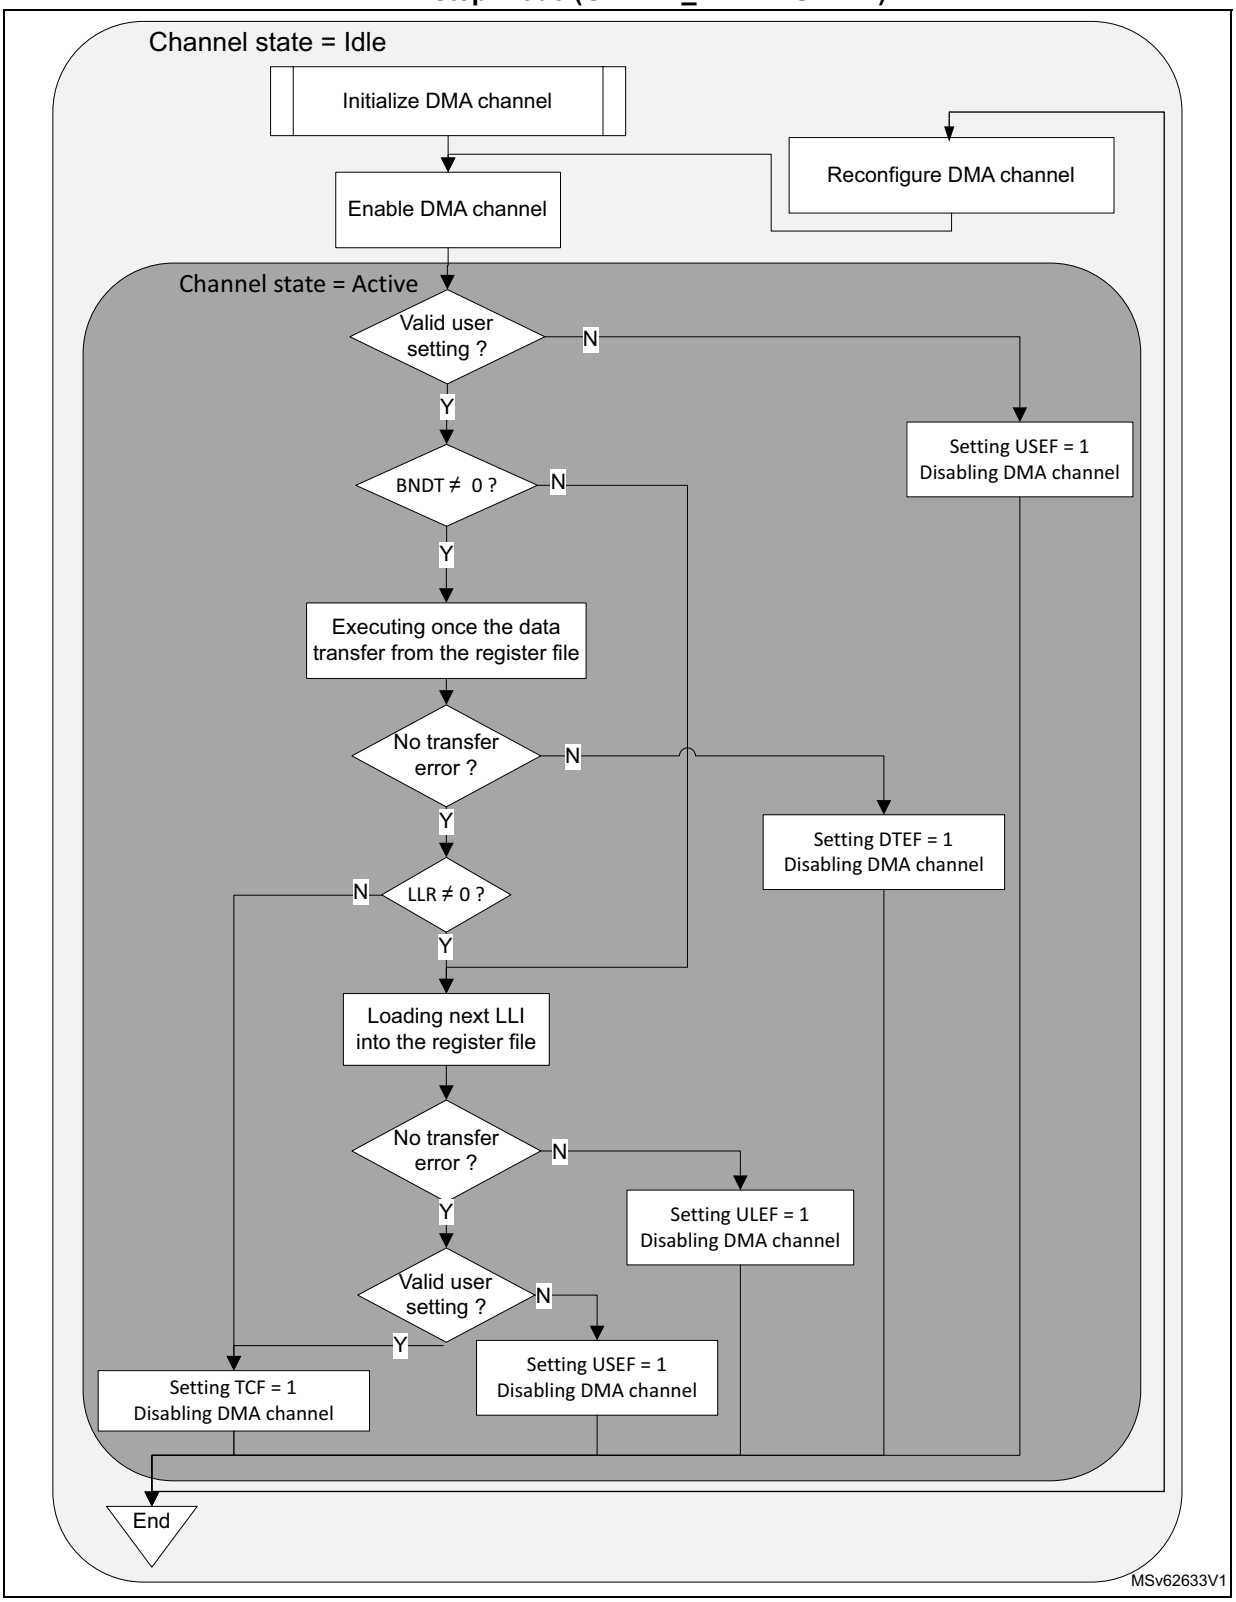
A GPDMA channel transfer can be programmed at LLI level, started by writing 1 into GPDMA_CxCR.EN, and after completed at LLI level:

- The current LLI_n transfer is described with:
  - GPDMA_CxTR1 defines the source/destination elementary single/burst transfers.
  - GPDMA_CxBR1 defines the number of bytes at a block level (BNDT[15:0]) and, for channel x (x = 4 to 5), the number of blocks at a 2D/repeated block level (BRC[10:0]+1) and the incrementing/decrementing mode for address offsets.

  - GPDMA_CxTR2 defines the input control (request, trigger) and the output control (transfer complete event) of the transfer.
  - GPDMA_CxSAR/GPDMA_CxDAR define the source/destination transfer start address.
  - GPDMA_CxTR3 for channel x (x = 4 to 5) defines the source/destination additional address offset between burst transfers.
  - GPDMA_CxBR2 for channel x (x = 4 to 5) defines the source/destination additional address offset between blocks at a 2D/repeated block level.
  - GPDMA_CxLLR defines the data structure and the address offset of the next LLI_{n+1} in the memory.
- The current LLI_n transfer is completed after the single execution of the current LLI_n:
  - after the (conditional) data transfer completion (when GPDMA_CxBR1.BRC[10:0] = 0, and GPDMA_CxBR1.BNDT[15:0] = 0
  - after the (conditional) update of the GPDMA link register file from the data structure of the next LLI_{n+1} in memory

Note: If a LLI is recursive (pointing to itself as a next LLI, either GPDMA_CxLLR.ULL = 1 and GPDMA_CxLLR.LA[15:2] is updated with the same value, or GPDMA_CxLLR.ULL = 0), a channel in link step mode is completed after each repeated single execution of this LLI.

In the regular data transfer completion at a block level, GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Alternatively, a block transfer may be early completed by a peripheral (such as an I3C in Rx mode), and then BNDT[15:0] is not null (see *Section 17.4.15* for more details).



The link step mode can be used to elaborate dynamically LLIs in memory during run-time. The software can be facilitated by using a static data structure for any LLI_n (all update bits of GPDMA_CxLLR have a static value, LLI_n.LLR.LA = LLI_{n-1}.LLR.LA + constant).

Figure 124 depicts the GPDMA channel execution mode, and its programming in link step mode.

Note: Figure 124 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 124, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 17.3.6).

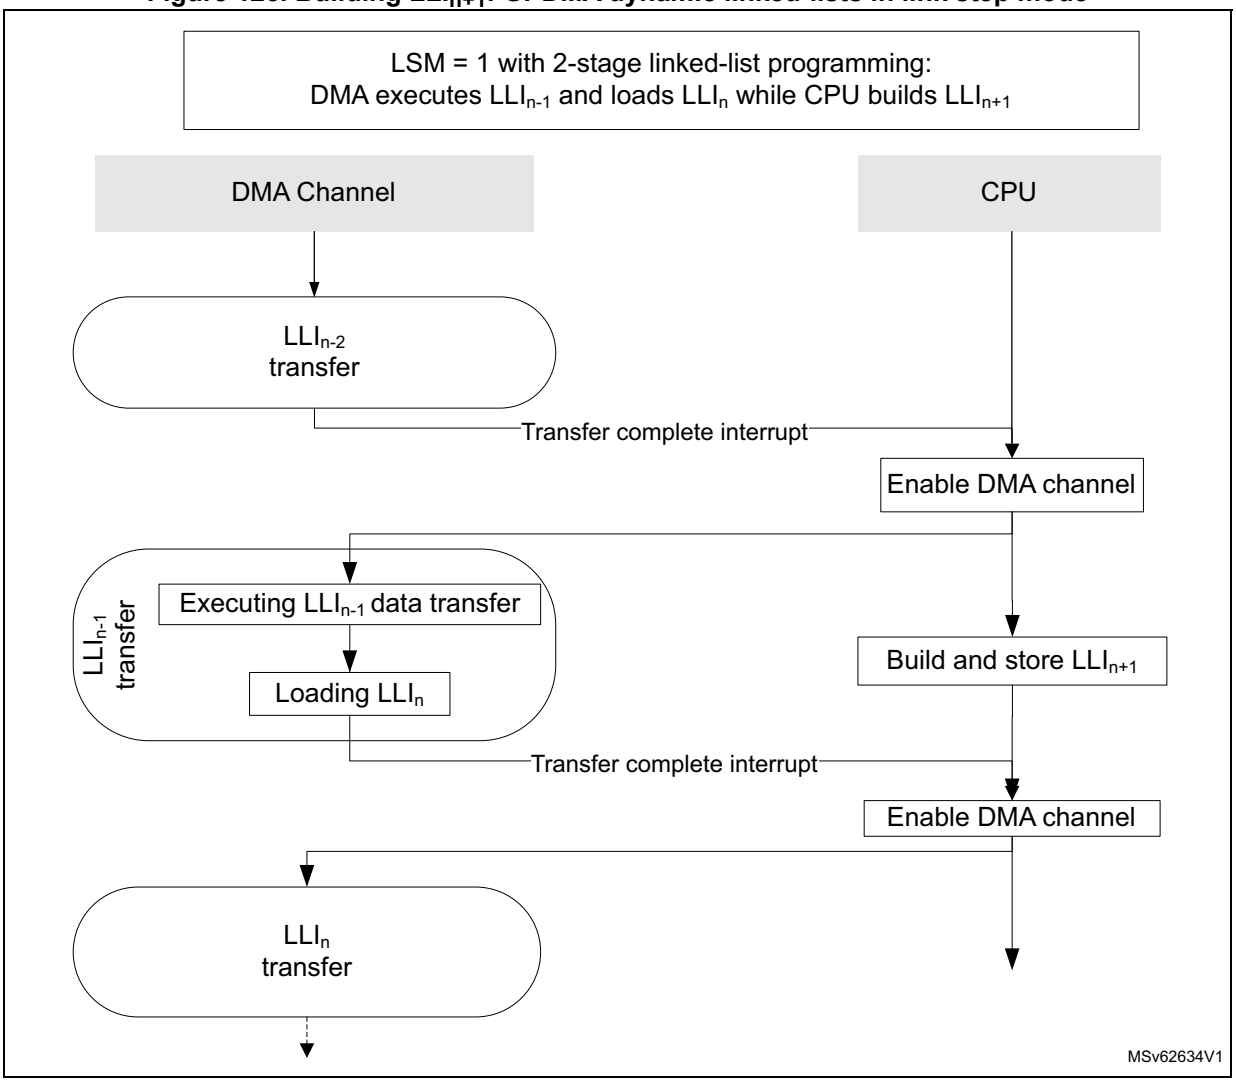


Figure 124. GPDMA channel execution and linked-list programming in link step mode (GPDMA_CxCR.LSM = 1)

Run-time adding a LLI_{n+1} in link step mode

During run-time, the software can defer the elaboration of the LLI_{n+1} (and next LLIs), until/after GPDMA executed the transfer from the LLI_{n-1} and loaded the LLI_n from the memory, as shown in *Figure 125*.

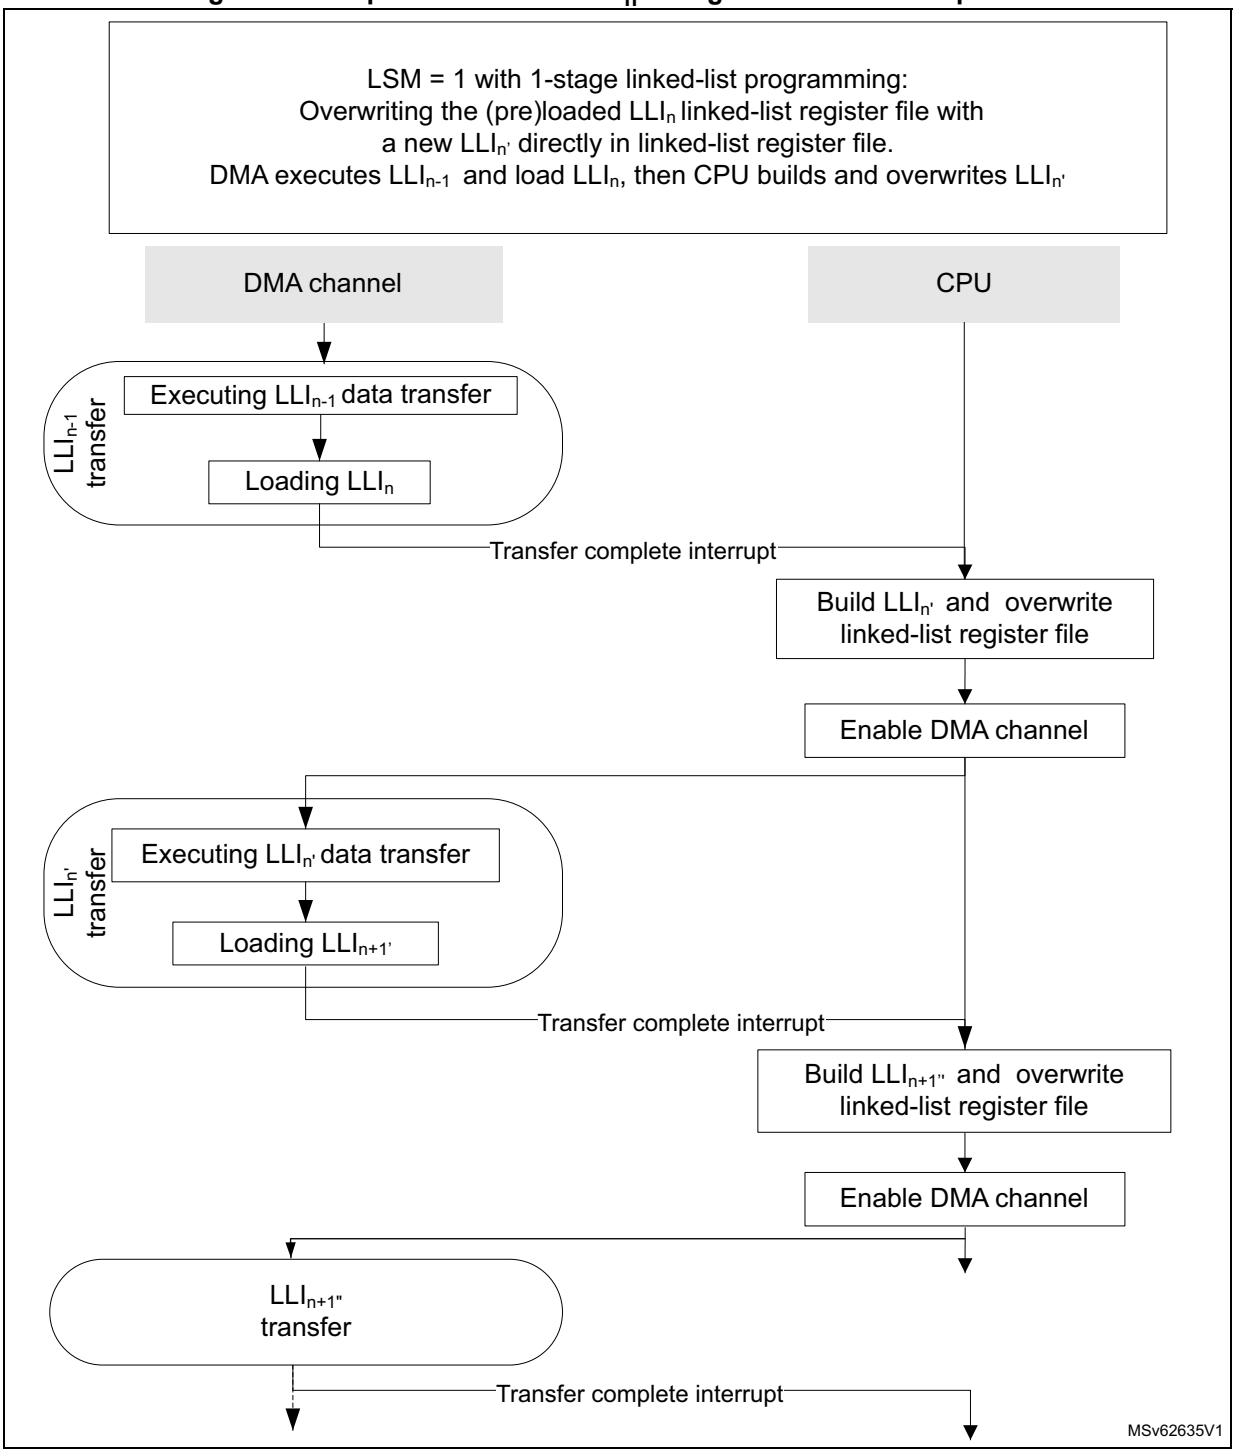

Figure 125. Building LLI_{n+1}: GPDMA dynamic linked-lists in link step mode

Run-time replacing a LLI_n with a new LLI_n', in link step mode (in linked-list register file)

In this link step mode, during run-time, the software can build and insert a new LLI_n', after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory by overwriting directly the linked-list register file with the new LLI_n', as shown in *Figure 126*.

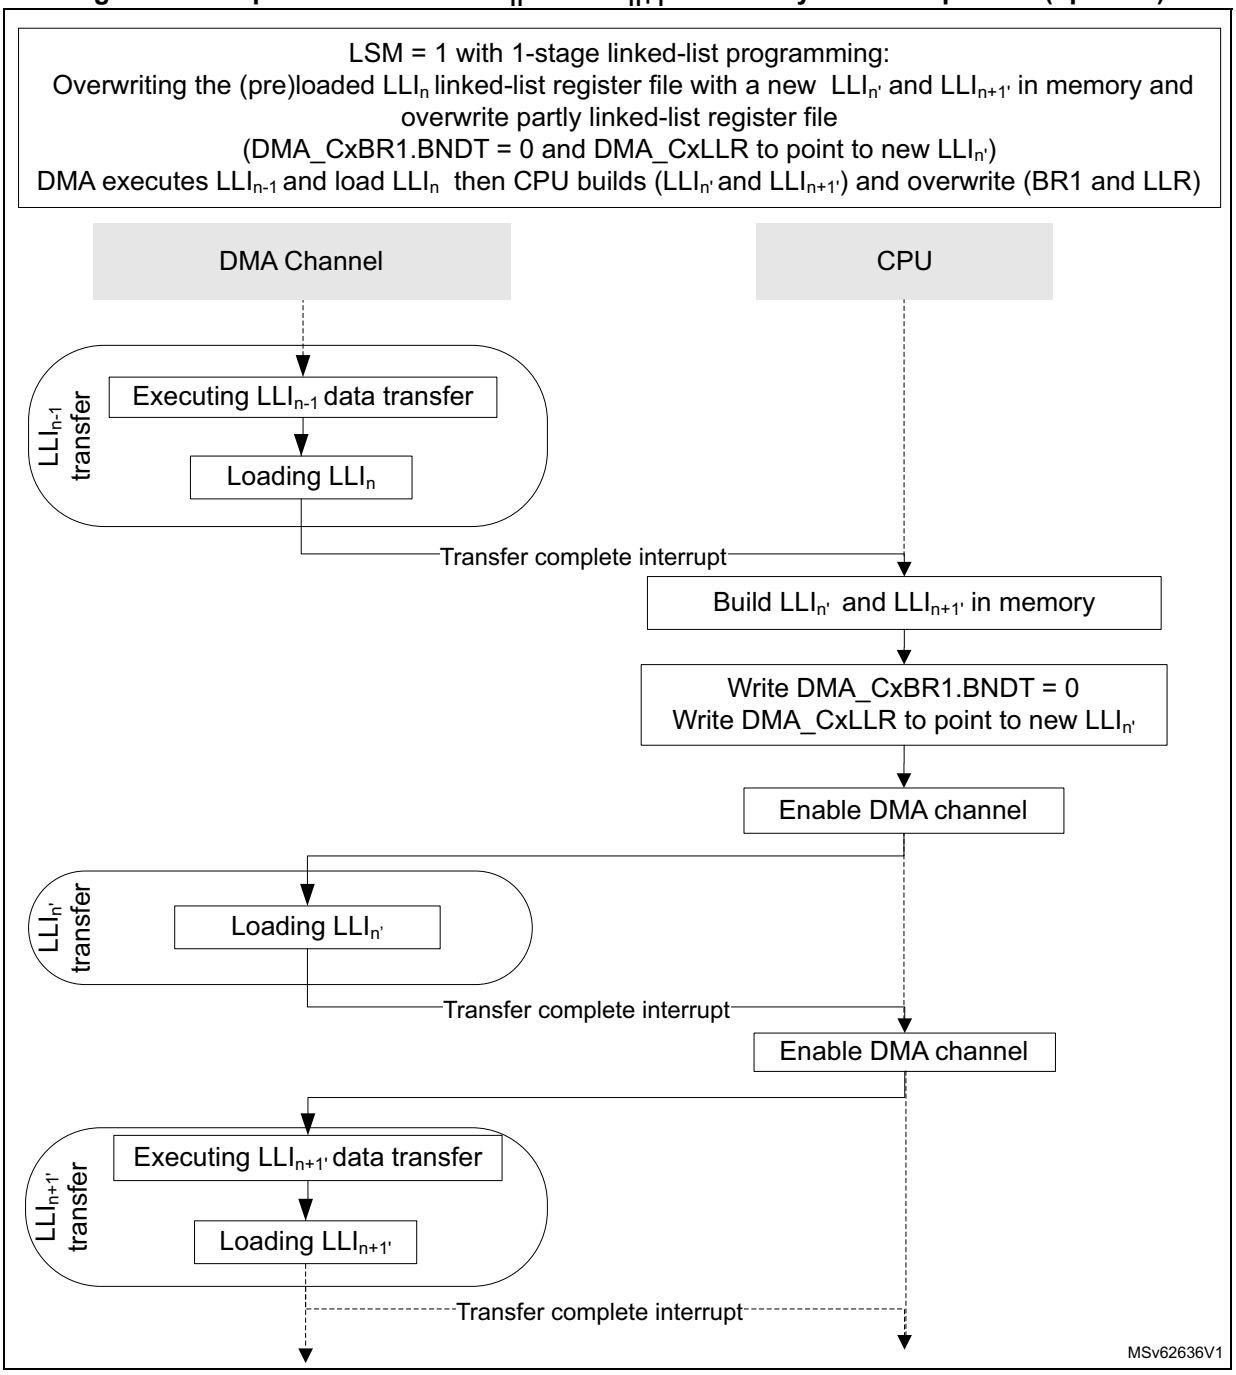

Figure 126. Replace with a new $LLI_{n'}$ in register file in link step mode

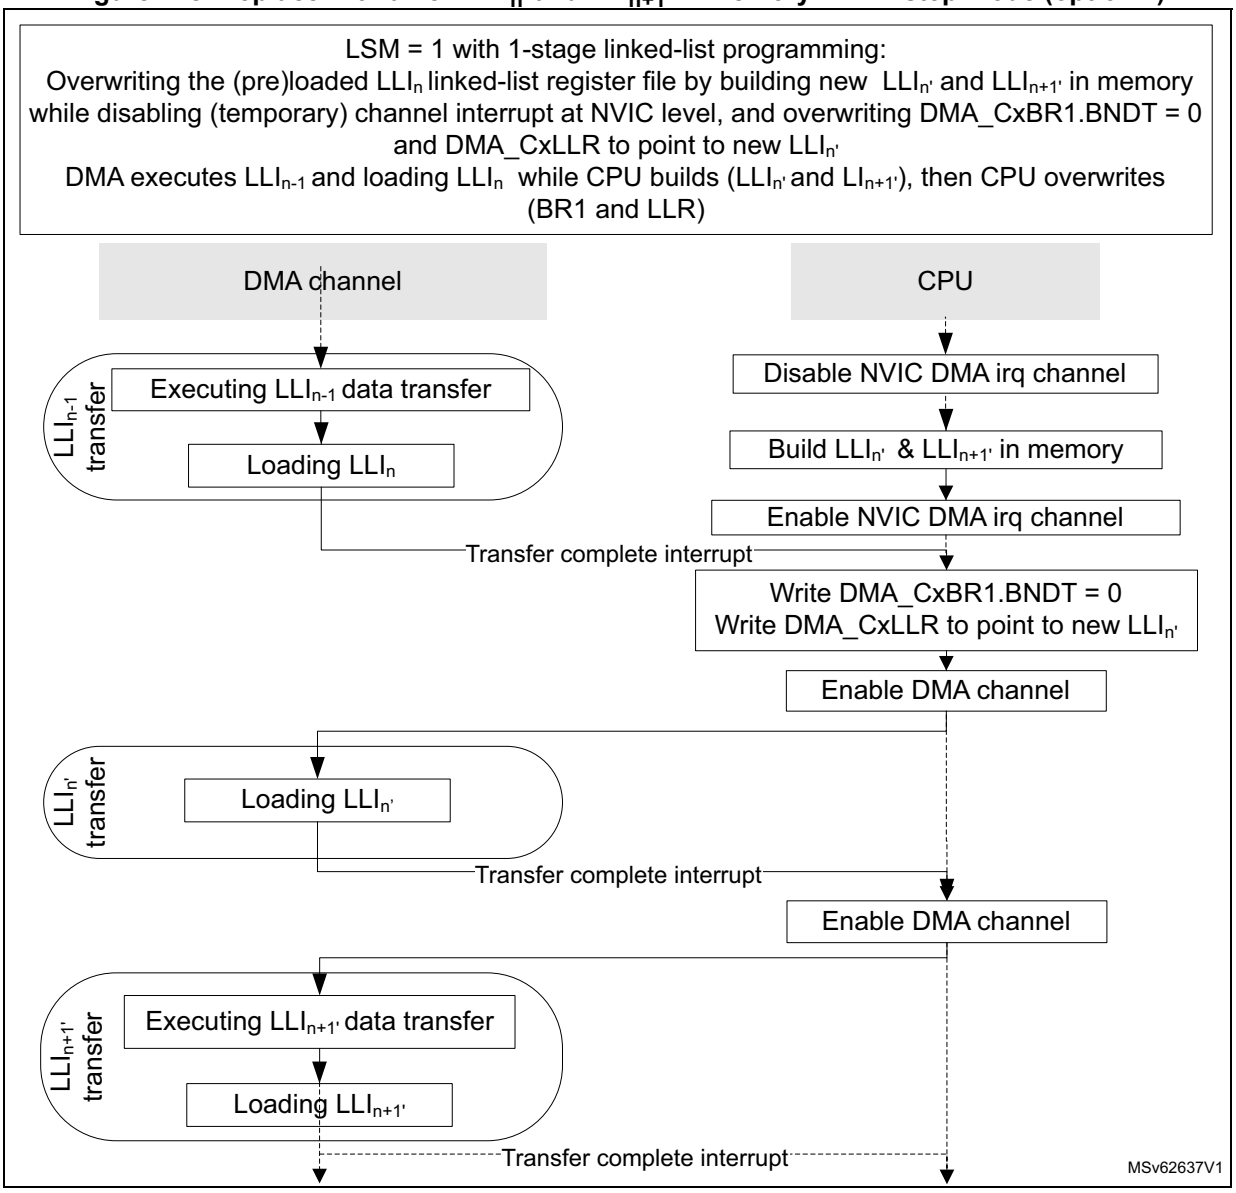
Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode (in the memory)

The software can build and insert a new $LLI_{n'}$ and $LLI_{n+1'}$ in the memory, after GPDMA executed the transfer from the LLI_{n-1} and loaded a formerly elaborated LLI_n from the memory, by overwriting partly the linked-list register file (GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n')}$ as shown in *Figure 127*.

Figure 127. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 1)



Run-time replacing a LLI_n with a new $LLI_{n'}$ in link step mode

Other software implementations exist. Meanwhile GPDMA executes the transfer from the LLI_{n-1} and loads a formerly elaborated LLI_n from the memory (or even earlier), the software can do the following:

1. Disable the NVIC for not being interrupted by the interrupt handling.
2. Build a new $LLI_{n'}$ and a new $LLI_{n+1'}$.
3. Enable again the NVIC for the channel interrupt (transfer complete) notification.

The software in the interrupt handler for LLI_{n-1} is then restricted to overwrite GPDMA_CxBR1.BNDT[15:0] to be null and GPDMA_CxLLR to point to new $LLI_{n'}$, as shown in *Figure 128*.

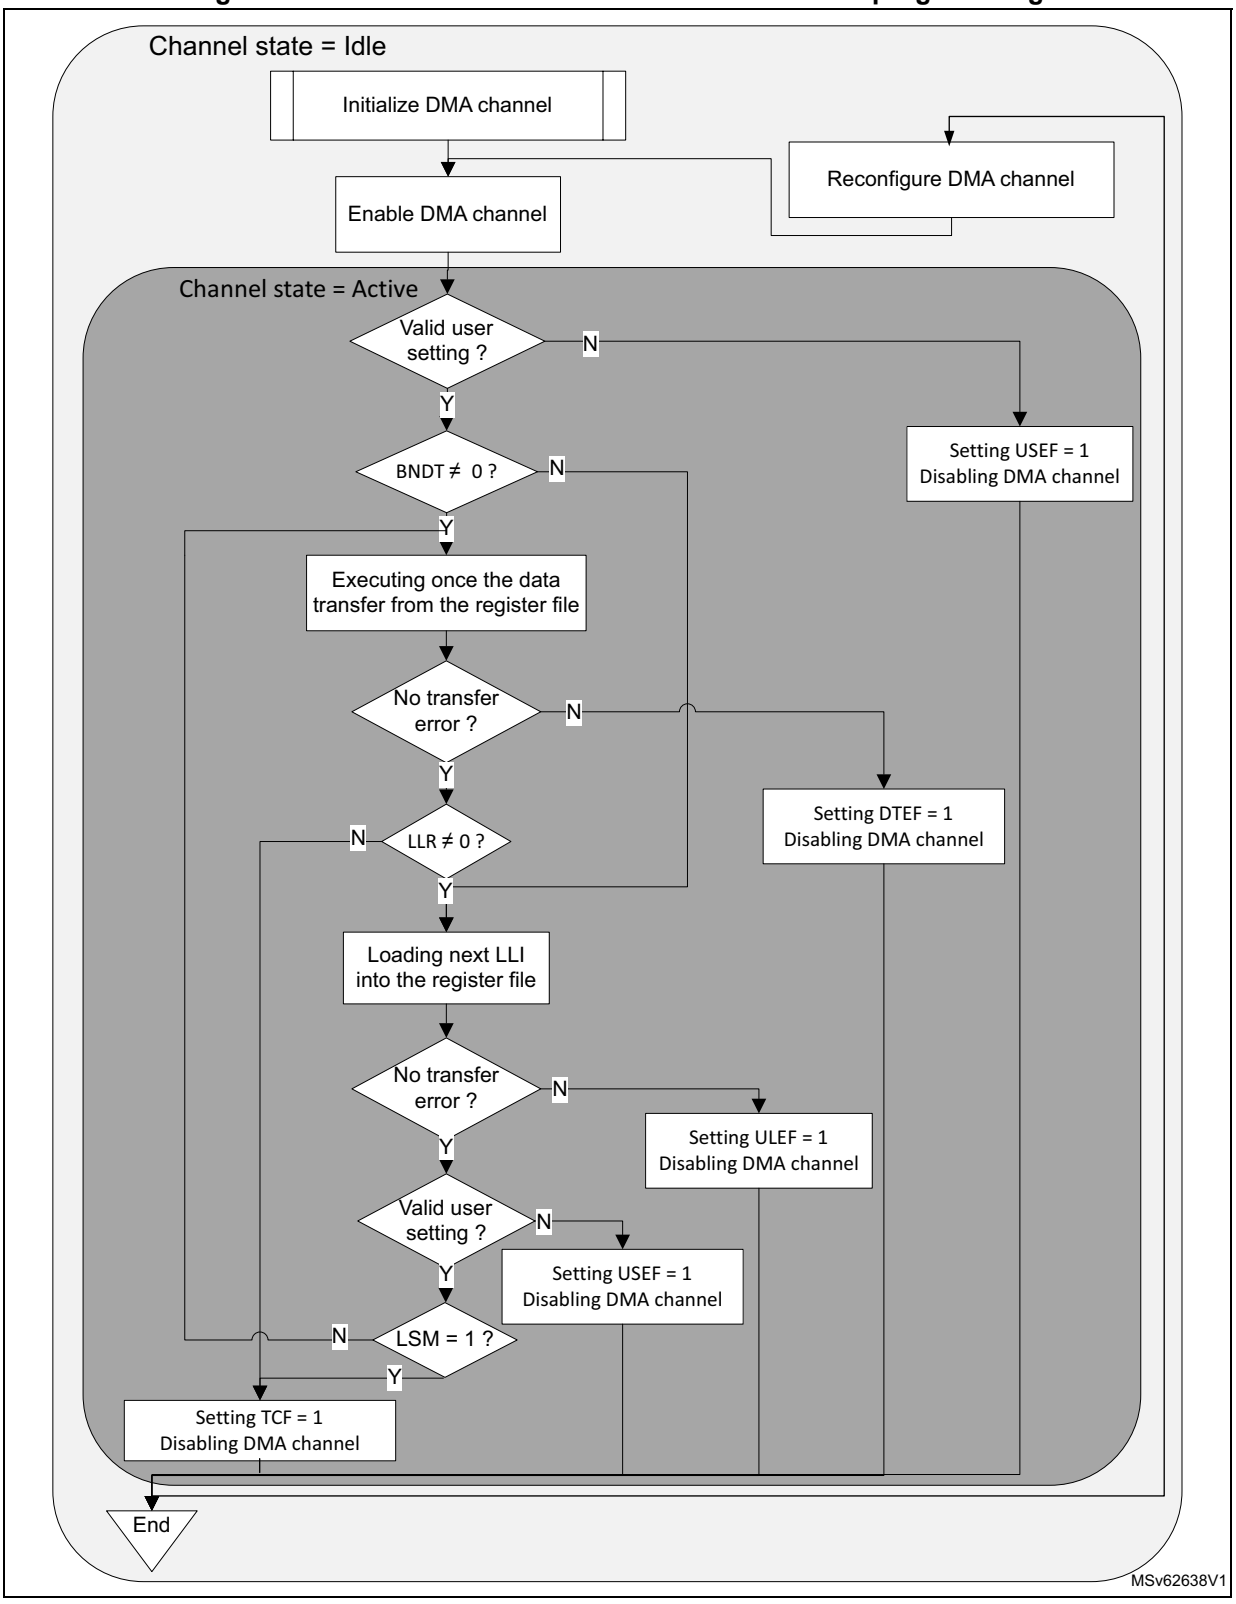
Figure 128. Replace with a new $LLI_{n'}$ and $LLI_{n+1'}$ in memory in link step mode (option 2)

17.4.10 GPDMA channel state and linked-list programming

The software can reconfigure a channel when the channel is disabled (GPDMA_CxCR.EN = 0) and update the execution mode (GPDMA_CxCR.LSM) to change from/to run-to-completion mode to/from link step mode.

In any execution mode, the software can:

- reprogram LLI_{n+1} in the memory to finally complete the channel by this LLI_{n+1} (clear the GPDMA_CxLLR of this LLI_{n+1}), before this LLI_{n+1} is loaded/used by the GPDMA channel
- abort and reconfigure the channel with a LSM update (see *Section 17.4.4*.)



In link step mode, the software can clear LSM after each a single execution of any LLI, during LLI_{n-1}.

Figure 129 shows the overall and unified GPDMA linked-list programming, whatever is the execution mode.

Note: Figure 129 is not intended to illustrate how often a TCEF can be raised, depending on the programmed value of TCEM[1:0] in GPDMA_CxTR2. It can be raised at (each) block completion, at (each) 2D block completion, at (each) LLI completion, or only at the last LLI data transfer completion. In run-to-completion mode, whatever is the value of TCEM[1:0], at the channel completion the hardware always set TCEF = 1 and disables the channel. In link step mode, the channel is disabled after each single execution of a LLI, and depending on the value of TCEM[1:0] a TCEF is raised or not.

In Figure 129, BNDT ≠ 0 is the typical condition for starting the first data transfer. This condition becomes (BNDT ≠ 0 and PFREQ = 1) if the peripheral requests a data transfer with early termination (see Section 17.3.6).

Figure 129. GPDMA channel execution and linked-list programming

17.4.11 GPDMA FIFO-based transfers

There is a single transfer operation mode: the FIFO mode. There are FIFO-based transfers. Any channel x is implemented with a dedicated FIFO whose size is defined by dma_fifo_size[x] (see *Section 17.3.2* for more details).

GPDMA burst

A programmed transfer at the lowest level is a GPDMA burst.

A GPDMA burst is a burst of data received from the source, or a burst of data sent to the destination. A source (and destination) burst is programmed with a burst length by the field SBL_1[5:0] (respectively DBL_1[5:0]), and with a data width defined by the field SDW_LOG2[1:0] (respectively DDW_LOG2[1:0]) in the GPDMA_CxTR1 register.

The addressing mode after each data (named beat) of a GPDMA burst is defined by SINC and DINC in GPDMA_CxTR1, for source and destination respectively: either a fixed addressing or an incremented addressing with contiguous data.

The start and next addresses of a GPDMA source/destination burst (defined by GPDMA_CxSAR and GPDMA_CxDAR) must be aligned with the respective data width.

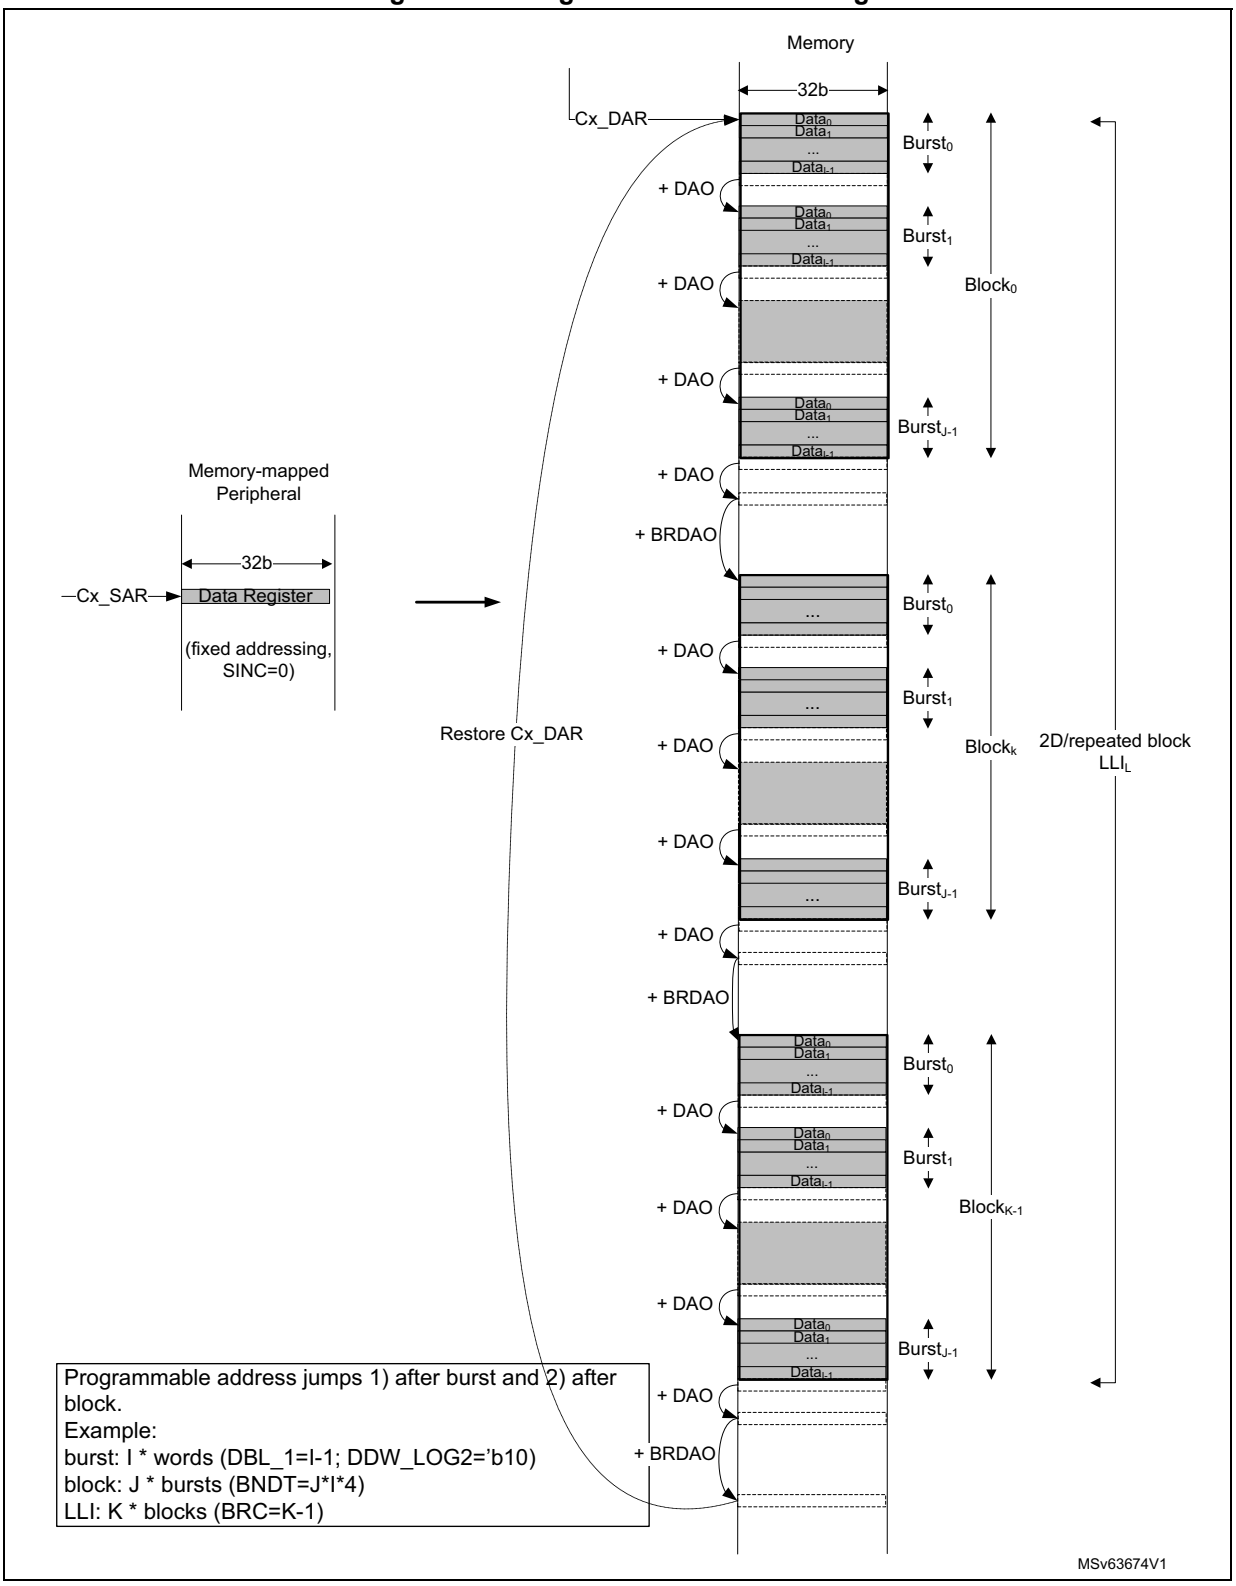
The table below lists the main characteristics of a GPDMA burst.

Table 168. Programmed GPDMA source/destination burst

SDW_LOG2[1:0] DDW_LOG2[1:0]	Data width (bytes)	SINC/DINC	SBL_1[5:0] DBL_1[5:0]	Burst length (data/beats)	Next data/ beat address	Next burst address	Burst address alignment
00	1	0 (fixed)	n = 0 to 63(1)	n+1	+ 0	+ 0	1
01	2						2
10	4						4
00	1	1 (contiguously incremented)			+ 1	+ (n + 1)	1
01	2				+ 2	+ 2 * (n + 1)	2
10	4				+ 4	+ 4 * (n + 1)	4
11	forbidden user setting, causing USEF generation and none burst to be issued.						

1. When S/DBL_1[5:0] = 0, burst is of length 1. Then burst can be also named as single.

The next burst address in the above table is the next source/destination default address pointed by GPDMA_CxSAR or GPDMA_CxDAR, once the programmed source/destination burst is completed. This default value refers to the fixed/contiguously incremented address.



GPDMA burst with 2D addressing (channel x = 4 to 5)

When the channel has additional 2D addressing feature, this default value refers to the value without taking into account the two programmed incremented or decremented offsets. These two additional offsets (with a null default value) are applied:

- after each completed source/destination burst, as defined respectively by GPDMA_CxTR2.SAO[12:0]/DAO[12:0] and GPDMA_CxBR1.SDEC/DDEC
- after each completed block, as defined respectively by GPDMA_CxBR2.BRSAO[15:0]/BRDAO[15:0] and GPDMA_CxBR1.BRSDEC/BRDDEC)

Then, a 2D/repeated block can be addressed with a first programmed address jump after each completed burst, and with a second programmed address jump after each block, as depicted by *Figure 130* with a 2D destination buffer.

Figure 130. Programmed 2D addressing

GPDMA FIFO-based burst

In FIFO-mode, a transfer generally consists of two pipelined and separated burst transfers:

- one burst from the source to the FIFO over the allocated source master port, as defined by GPDMA_CxTR1.SAP
- one burst from the FIFO to the destination over the allocated destination master port, as defined by GPDMA_CxTR1.DAP

GPDMA source burst

The requested source burst transfer to the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to get one new burst from the source):

when FIFO level ≤ $2^{dma_fifo_size[x]}$ - (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- $2^{dma_fifo_size[x]}$ is the half the FIFO size of channel x, in bytes (see *Section 17.3.2* for the implementation details and dma_fifo_size[x] value).
- (SBL_1[5:0]+1) * $2^{SDW_LOG2[1:0]}$ is the size of the programmed source burst transfer, in bytes.

Based on the channel priority (GPDMA_CxCR.PRIO[1:0]), this ready FIFO-based source transfer is internally arbitrated versus the other requested and active channels.

GPDMA destination burst

The requested destination burst transfer from the FIFO can be scheduled as early as possible over the allocated port, depending on the current FIFO level versus the programmed burst size (when the FIFO is ready to push one new burst to the destination):

when FIFO level ≥ (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$

where:

- FIFO level is the current filling level of the FIFO, in bytes.
- (DBL_1[5:0]+1) * $2^{DDW_LOG2[1:0]}$ is the size of the programmed destination burst transfer, in bytes.

Based on the channel priority, this ready FIFO-based destination transfer is internally arbitrated versus the other requested and active channels.

GPDMA burst vs source block size, 1-Kbyte address boundary and FIFO size

The programmed source/destination GPDMA burst is implemented with an AHB burst as is, unless one of the following conditions is met:

- When half of the FIFO size of the channel x is lower than the programmed source/destination burst size, the programmed source/destination GPDMA burst is implemented with a series of singles or bursts of a lower size. Each transfer is of a size that is lower than or equal to half of the FIFO size, without any user constraint.
- If the source block size (GPDMA_CxBR1.BNDT[15:0]) is not a multiple of the source burst size but is a multiple of the data width of the source burst (GPDMA_CxTR1.SDW_LOG2[1:0]), the GPDMA modifies and shortens bursts into singles or bursts of lower length, in order to transfer exactly the source block size, without any user constraint.

- if the source/destination burst transfer have crossed the 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.
- If the source/destination burst length exceeds 16 on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol, without any user constraint.

In any case, the GPDMA keeps ensuring source/destination data (and address) integrity without any user constraint. The current FIFO level (software readable in GPDMA_CxSR) is compared to and updated with the effective transfer size, and the GPDMA re-arbitrates between each AHB single or burst transfer, possibly modified.

Based on the channel priority, each single or burst of a lower burst size versus the programmed burst, is internally arbitrated versus the other requested and active channels.

Note: In linked-list mode, the GPDMA read transfers related to the update of the linked-list parameters from the memory to the internal GPDMA registers, are scheduled over the link allocated port, as programmed by GPDMA_CxCR.LAP.

GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment

The data handling is controlled by GPDMA_CxTR1. The source/destination data width of the programmed burst is byte, half-word or word, as per the SDW_LOG2[1:0] and DDW_LOG2[1:0] fields (see *Table 169*).

The user can configure the data handling between transferred data from the source and transfer to the destination. More specifically, programmed data handling is orderly performed with:

1. Byte-based source reordering
   - If SBX = 1 and if source data width is a word, the two bytes of the unaligned half-word at the middle of each source data word are exchanged.
2. Data width conversion by packing, unpacking, padding or truncation, if destination data width is different than the source data width, depending on PAM[1:0]:
   - If destination data width > source data width, the post SBX source data is either right-aligned and padded with 0 s, or sign extended up to the destination data width, or is FIFO queued and packed up to the destination data width.
   - If destination data width < source data width, the post SBX data is either right-aligned and left-truncated down to the destination data width, or is FIFO queued and unpacked and streamed down to the destination data width.
3. Byte-based destination re-ordering:
   - If DBX = 1 and if the destination data width is not a byte, the two bytes are exchanged within the aligned post PAM[1:0] half-words.
   - If DHX = 1 and if the destination data width is neither a byte nor a half-word, the two aligned half-words are exchanged within the aligned post PAM[1:0] words.

Note: Left-alignment with 0s-padding can be achieved by programming both a right-alignment with a 0s-padding and a destination byte-based re-ordering.

The table below lists the possible data handling from the source to the destination.

Table 169. Programmed data handling

SDW_LOG2 [1:0]	Source data	Source data stream(1)	SBX	DDW_LOG2 [1:0]	Destination data	PAM[1:0](2)	DBX	DHX	Destination data stream(1)

1. Data stream is timely ordered starting from the byte with the lowest index (B_0).
2. RA= right aligned, LA = left aligned, RT = right truncated, LT = left truncated, 0P = zero bit padding up to the destination data width, SE = sign bit extended up to the destination data width.

17.4.12 GPDMA transfer request and arbitration

GPDMA transfer request

As defined by GPDMA_CxTR2, a programmed GPDMA data transfer is requested with one of the following:

- a software request if the control bit SWREQ = 1: This is used typically by the CPU for a data transfer from a memory-mapped address to another memory mapped address (memory-to-memory, GPIO to/from memory)
- an input hardware request coming from a peripheral if SWREQ = 0: The selection of the GPDMA hardware peripheral request is driven by the REQSEL[7:0] field (see *Section 17.3.4*). The selected hardware request can be one of the following:
  - an hardware request from a peripheral configured in GPDMA mode (for a transfer from/to the peripheral data register respectively to/from the memory)
  - an hardware request from a peripheral for its control registers update from the memory
  - an hardware request from a peripheral for a read of its status registers transferred to the memory

Caution: The user must not assign a same input hardware peripheral GPDMA request via GPDMA_CxTR.REQSEL[7:0] to two different channels, if at a given time this request is asserted by the peripheral and each channel is ready to execute this requested data transfer. There is no user setting error reporting.

GPDMA transfer request for arbitration

A ready FIFO-based GPDMA source single/burst transfer (from the source address to the FIFO) to be scheduled over the allocated master port (GPDMA_CxTR1.SAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

A ready FIFO-based GPDMA destination single/burst transfer (from the FIFO to the destination address) to be scheduled over the allocated master port (GPDMA_CxTR1.DAP) is arbitrated based on the channel priority (GPDMA_CxCR.PRIO[1:0]) versus the other simultaneous requested GPDMA transfers to the same master port.

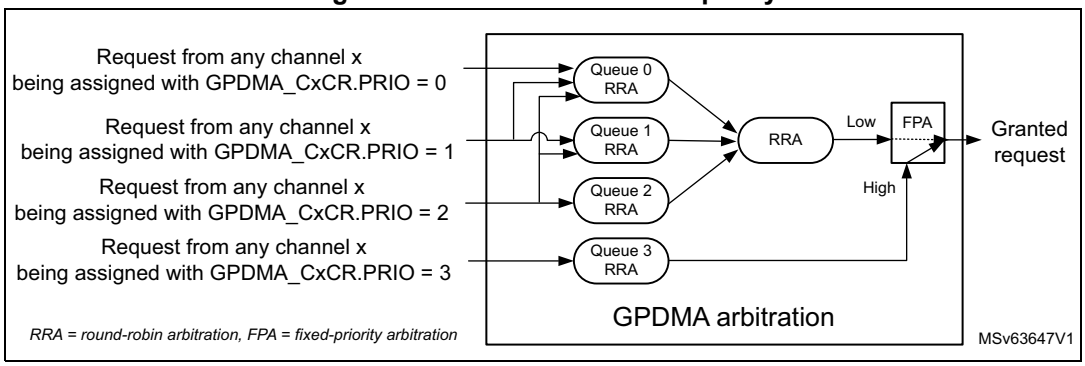
An arbitrated GPDMA requested link transfer consists of one 32-bit read from the linked-list data structure in memory to one of the linked-list registers (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR or GPDMA_CxLLR, plus GPDMA_CxTR3, GPDMA_CxBR2). Each 32-bit read from memory is arbitrated with the same channel priority as for data transfers, in order to be scheduled over the allocated master port (GPDMA_CxCR.LAP).

Whatever the requested data transfer is programmed with a software request for a memory-to- memory transfer (GPDMA_CxTR2.SWREQ = 1), or with a hardware request (GPDMA_CxTR2.SWREQ = 0) for a memory-to-peripheral transfer or a peripheral-to-memory transfer and whatever is the hardware request type, re-arbitration occurs after each granted single/burst transfer.

When an hardware request is programmed from a destination peripheral (GPDMA_CxTR2.SWREQ = 0 and GPDMA_CxTR2.DREQ = 1), the first memory read of a (possibly 2D/repeated) block (the first ready FIFO-based source burst request), is gated by the occurrence of the corresponding and selected hardware request. This first read request to memory is not taken into account earlier by the arbiter (not as soon as the block transfer is enabled and executable).

GPDMA arbitration

The GPDMA arbitration is directed from the 4-grade assigned channel priority (GPDMA_CxCR.PRIO[1:0]). The arbitration policy, as illustrated in *Figure 131*, is defined by:



- one high-priority traffic class (queue 3), dedicated to the assigned channels with priority 3, for time-sensitive channels

  This traffic class is granted via a fixed-priority arbitration against any other low-priority traffic class. Within this class, requested single/burst transfers are round-robin arbitrated.
- three low-priority traffic classes (queues 0, 1, or 2) for non time-sensitive channels with priority 0, 1, or 2

  Each requested single/burst transfer within this class is round-robin arbitrated, with a weight that is monotonically driven from the programmed priority:
  - Requests with priority 0 are allocated to the queue 0.
  - Requests with priority 1 are allocated and replicated to the queue 0 and queue 1.

– Requests with priority 2 are allocated and replicated to the queue 0, queue 1, and queue 2.
– Any queue 0, 1, or 2 equally grants any of its active input requests in a round-robin manner, provided there are simultaneous requests.
– Additionally, there is a second stage for the low-traffic with a round-robin arbiter that fairly alternates between simultaneous selected requests from queue 0, queue 1, and queue 2.

Figure 131. GPDMA arbitration policy

GPDMA arbitration and bandwidth

With this arbitration policy, the following is guaranteed:

- Equal maximum bandwidth between requests with same priority
- Reserved bandwidth (noted as B_{Q3}) to the time-sensitive requests (with priority 3)
- Residual weighted bandwidth between different low-priority requests (priority 0 versus priority 1 versus priority 2).

The two following examples highlight that the weighted round-robin arbitration is driven by the programmed priorities:

- **Example 1**: basic application with two non time-sensitive GPDMA requests: req0 and req1. There are the following programming possibilities:
  – If they are assigned with same priority, the allocated bandwidth by the arbiter to req0 (B_{req0}) is **equal** to the allocated bandwidth to req1(B_{req1}).
  $B_{req0} = B_{req1} = 1/2 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 1, the allocated bandwidth to req0 (B_{P0}) is **3 times less** than the allocated bandwidth to req1 (B_{P1}).
  $B_{req0} = B_{P0} = 1/2 * 1/2 * (1 - B_{Q3}) = 1/4 * (1 - B_{Q3})$
  $B_{req1} = B_{P1} = (1/2 + 1) * 1/2 * (1 - B_{Q3}) = 3/4 * (1 - B_{Q3})$
  – If req0 is assigned to priority 0 and req1 to priority 2, the allocated bandwidth to req0 (B_{P0}) is **5 times less** than the allocated bandwidth to req1 (B_{P2}).
  $B_{req0} = B_{P0} = 1/2 * 1/3 * (1 - B_{Q3}) = 1/6 * (1 - B_{Q3})$
  $B_{req1} = B_{P2} = (1/2 + 1 + 1) * 1/3 * (1 - B_{Q3}) = 5/6 * (1 - B_{Q3})$
  The above computed bandwidth calculation is based on a theoretical input request, always active for any GPDMA clock cycle. This computed bandwidth from the arbiter must be weighted by the frequency of the request given by the application, that cannot be always active and may be quite much variable from one GPDMA client (example I2C at 400 kHz) to another one (PWM at 1 kHz) than the above x3 and x5 ratios.

- **Example 2**: application where the user distributes a same non-null N number of GPDMA requests to every non time-sensitive priority 0, 1 and 2. The bandwidth calculation is then the following:
  - The allocated bandwidth to the set of requests of priority 0 (B_{P0}) is
    $B_{P0} = 1/3 * 1/3 * (1 - B_{Q3}) = 1/9 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 1(B_{P1}) is
    $B_{P1} = (1/3 + 1/2) * 1/3 * (1 - B_{Q3}) = 5/18 * (1 - B_{Q3})$
  - The allocated bandwidth to the set of requests of priority 2(B_{P2}) is
    $B_{P2} = (1/3 + 1/2 + 1) * 1/3 * (1 - B_{Q3}) = 11/18 * (1 - B_{Q3})$
  - The allocated bandwidth to any request n ($B_{n)}$ among the N requests of that priority Pi (i = 0 to 2) is $B_n = 1/N * B_{Pi}$
  - The allocated bandwidth to any request n of priority 0i ($B_{n, Pi}$) is
    $B_{n, P0} = 1/N *1/9 * (1 - B_{Q3})$
    $B_{n, P1} = 1/N *5/18 * (1 - B_{Q3})$
    $B_{n, P2} = 1/N *11/18 * (1 - B_{Q3})$

  In this example, when the master port bus bandwidth is not totally consumed by the time-sensitive queue 3, the residual bandwidth is such that 2.5 times less bandwidth is allocated to any request of priority 0 versus priority 1, and 5.5 times less bandwidth is allocated to any request of priority 0 versus priority 2.

More generally, assume that the following requests are present:

- I requests (I ≥ 0) assigned to priority 0
  If I > 0, these requests are noted from i = 0 to I-1.
- J requests (J ≥ 0) assigned to priority 1
  If J > 0, these requests are noted from j = 0 to J-1.
- K requests (K > 0) assigned to priority 2
  These requests are noted from k = 0 to K-1
- L requests (L ≥ 0) assigned to priority 3
  If L > 0, these requests are noted from l = 0 to L-1.

As B_{Q3} is the reserved bandwidth to time-sensitive requests, the bandwidth for each request L with priority 3 is:

- $B_l = B_{Q3} / L$ for L > 0 (else: $B_l = 0$)

The bandwidth for each non-time sensitive queue is:

- $B_{Q0} = 1/3 * (1 - B_{Q3})$
- $B_{Q1} = 1/3 * (1 - B_{Q3})$
- $B_{Q2} = 1/3 * (1 - B_{Q3})$

The bandwidth for the set of requests with priority 0 is:

- $B_{P0} = I / (I + J + K) * B_{Q0}$

The bandwidth for each request i with priority 0 is:

- $B_i = B_{P0} / I$ for L > 0 (else $B_{P0} = 0$)

The bandwidth for the set of requests with priority 1 and routed to queue 0 is:

- $B_{P1,Q0} = J / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 1 and routed to queue 1 is:

- $B_{P1,Q1} = J / (J + K) * B_{Q1}$

The total bandwidth for the set of requests with priority 1 is:

- $B_{P1} = B_{P1,Q0} + B_{P1,Q1}$

The bandwidth for each request j with priority 1 is:

- $B_j = B_{P1} / J$ for $J > 0$ (else $B_j = 0$)

The bandwidth for the set of requests with priority 2 and routed to queue 0 is:

- $B_{P2,Q0} = K / (I + J + K) * B_{Q0}$

The bandwidth for the set of requests with priority 2 and routed to queue 1 is:

- $B_{P2,Q1} = K / (J + K) * B_{Q1}$

The bandwidth for the set of requests with priority 2 and routed to queue 2 is:

- $B_{P2,Q2} = B_{Q2}$

The total bandwidth for the set of requests with priority 2 is:

- $B_{P2} = B_{P2,Q0} + B_{P2,Q1} + B_{P2,Q2}$

The bandwidth for each request k with priority 2 is:

- $B_k = B_{P2} / K$ ($K>0$ in the general case)

Thus finally the maximum allocated residual bandwidths for any i, j, k non-time sensitive request are:

- in the general case (when there is at least one request k with a priority 2 ($K > 0$)):
  - $B_i = 1/I * 1/3 * I/(I + J + K) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/3 *[J/(I + J + K) + J/(J + K)] * (1 - B_{Q3})$
  - $B_k = 1/K * 1/3 *[K/(I + J + K) + K/(J + K) + 1] * (1 - B_{Q3})$
- in the specific case (when there is no request k with a priority 2 ($K = 0$)):
  - $B_i = 1/I * 1/2 * I/(I + J) * (1 - B_{Q3})$
  - $B_j = 1/J * 1/2 *[J/(I + J) + 1] * (1 - B_{Q3})$

Consequently, the GPDMA arbiter can be used as a programmable weighted bandwidth limiter, for each queue and more generally for each request/channel. The different weights are monotonically resulting from the programmed channel priorities.

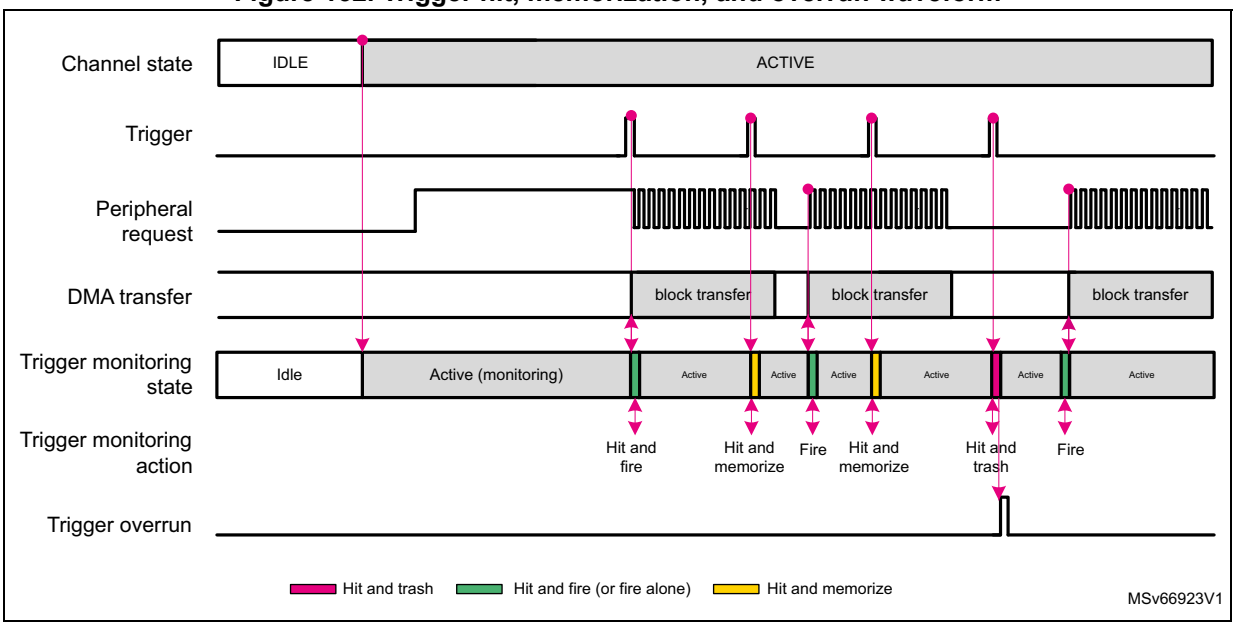
17.4.13 GPDMA triggered transfer

A programmed GPDMA transfer can be triggered by a rising/falling edge of a selected input trigger event, as defined by GPDMA_CxTR2.TRIGPOL[1:0] and GPDMA_CxTR2.TRIGSEL[5:0] (see *Section 17.3.7* for the trigger selection).

The triggered transfer, as defined by the trigger mode in GPDMA_CxTR2.TRIGM[1:0], can be at LLI data transfer level, to condition the first burst read of a block, the first burst read of a 2D/repeated block for channel x (x = 4 to 5), or each programmed single read. The trigger mode can also be programmed to condition the LLI link transfer (see TRIGM[1:0] in GPDMA_CxTR2 for more details).

Trigger hit memorization and trigger overrun flag generation

The GPDMA monitoring of a trigger for a channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (respectively TRIGPOL[1:0] = 01 or TRIGPOL[1:0] = 10).



The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer. If a new trigger is detected, this hit is internally memorized to grant the next transfer, as long as the defined rising/falling edge and TRIGSEL[5:0] are not modified, and the channel is enabled.

Transferring a next $LLI_{n+1,}$ that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the possible memorized hit of the formerly defined LLI_n trigger.

Caution: After a first new trigger hit_{n+1} is memorized, if another trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1) and an interrupt is generated if enabled (if GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

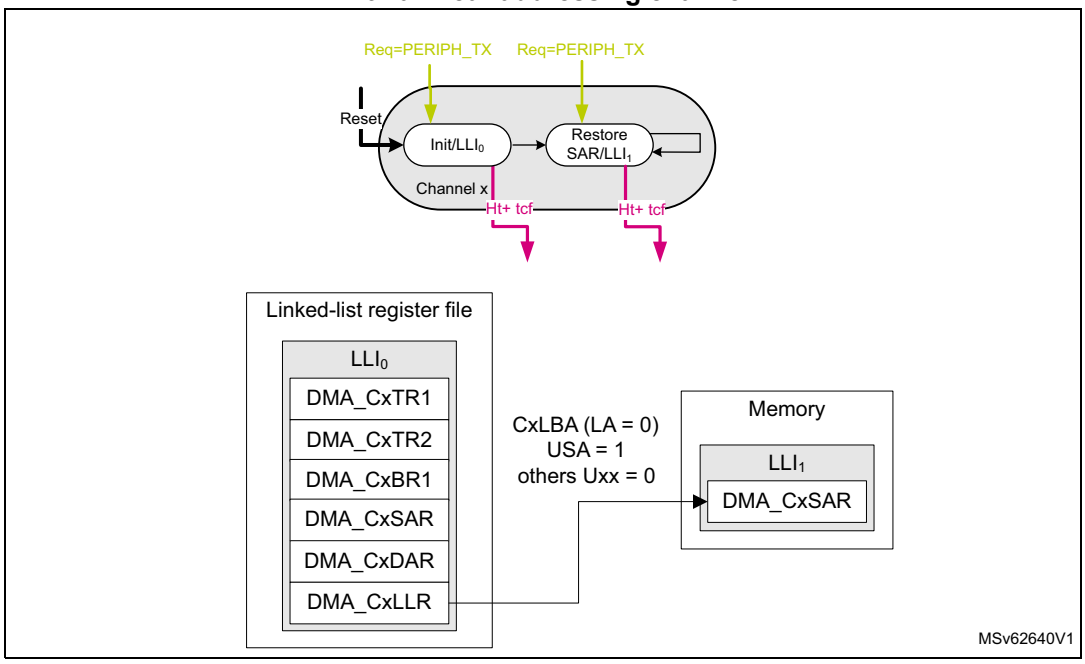
Figure 132 illustrates the trigger hit, memorization and overrun in the configuration example with a block-level trigger mode and a rising edge trigger polarity.

Figure 132. Trigger hit, memorization, and overrun waveform

Note: The user can assign the same input trigger event to different channels. This can be used to trigger different channels on a broadcast trigger event.

17.4.14 GPDMA circular buffering with linked-list programming

GPDMA circular buffering for memory-to-peripheral and peripheral-to-memory transfers, with a linear addressing channel



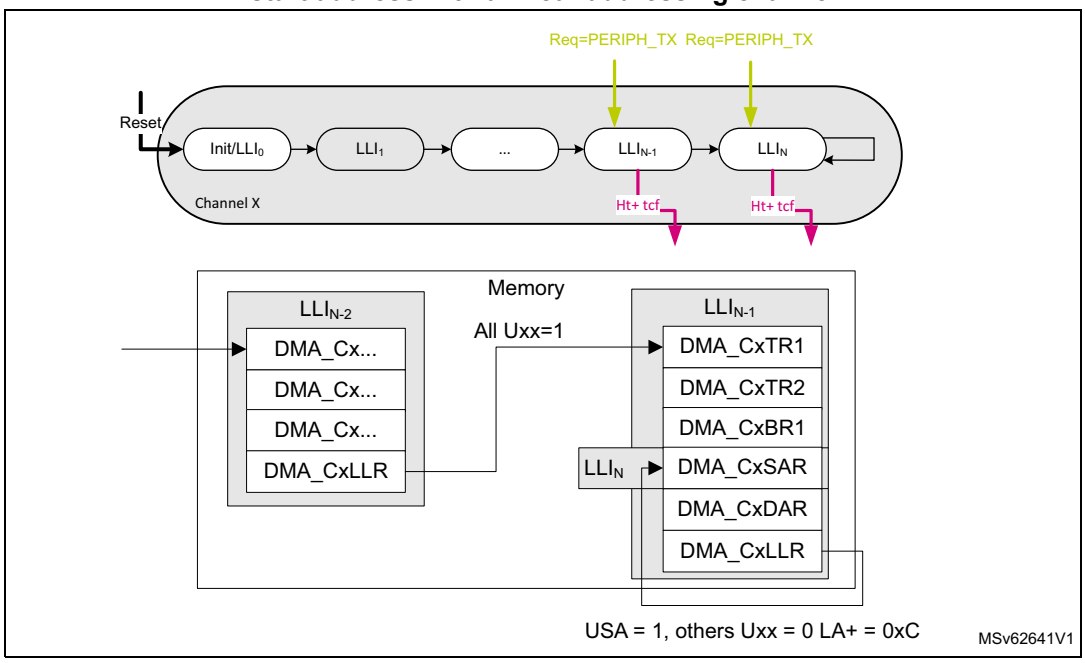
For a circular buffering, with a continuous memory-to-peripheral (or peripheral-to-memory) transfer, the software must set up a channel with half-transfer and complete transfer

events/interrupts generation (GPDMA_CxCR.HTIE = 1 and GPDMA_CxCR.TCIE = 1), in order to enable a concurrent buffer software processing.

LLI_0 is configured for the first block transfer with the linear addressing channel. A continuously-executed LLI_1 is needed to restore the memory source (or destination) start address, for the memory-to-peripheral transfer (respectively the peripheral-to-memory transfer). GPDMA automatically reloads the initially programmed GPDMA_CxBR1.BNDT[15:0] when a block transfer is completed, and there is no need to restore GPDMA_CxBR1.

Figure 133 illustrates this programming with a linear addressing GPDMA channel and a source circular buffer.

Figure 133. GPDMA circular buffer programming: update of the memory start address with a linear addressing channel



Note: With a 2D addressing channel, the user may use a single LLI with GPDMA_CxBR1.BRC[10:0] = 1, and program a negative memory block address offset with GDMA_CxBR2 and GDMA_CxBR1, in order to jump back to the memory source or the destination start address.

If circular buffering must be executed after some other transfers over the shared GPDMA channel x, the before-last LLI_{N-1} in memory is needed to configure the first block transfer. And the last LLI_N restores the memory source (or destination) start address in memory-to-peripheral transfer (respectively in peripheral-to-memory transfer).

Figure 134 illustrates this programming with a linear addressing shared GPDMA channel, and a source circular buffer.

Figure 134. Shared GPDMA channel with circular buffering: update of the memory start address with a linear addressing channel

17.4.15 GPDMA transfer in peripheral flow-control mode

A peripheral with the peripheral flow-control mode feature can decide to early terminate a GPDMA block transfer, provided that the allocated channel is implemented with this feature (see *Section 17.3.6*).

If the related GPDMA channel x is also programmed in peripheral flow-control mode (GPDMA_CxTR2.PFREQ = 1):

- The GPDMA block transfer starts as follows:
  - If GPDMA_CxBR1.BNDT[15:0] ≠ 0, the programmed value is internally taken into account by the GPDMA hardware.
  - If GPDMA_CxBR1.BNDT[15:0] = 0, the GPDMA hardware internally considers a 64-Kbyte value for the maximum source block size to be transferred.
- The GPDMA block transfer is completed as soon as the first occurrence of one of the following condition occurs:
  - when GPDMA_CxBR1.BNDT[15:0] = 0
  - when the peripheral early terminates the block. The complete transfer event is generated if programmed, depending on GPDMA_CxTR2 (see *GPDMA channel x transfer register 2 (GPDMA_CxTR2)*). Then the software can read the current number of transferred bytes from the source (GPDMA_CxBR1.BNDT[15:0]), and/or read the current source or destination address of the buffer in memory (GPDMA_CxSAR[31:0] or GPDMA_CxDAR[31:0]).

In peripheral flow-control mode:

- a destination peripheral with a hardware requested transfer is not supported: memory-to-peripheral transfer is not supported.
- Data packing from a source peripheral is not supported.
- 2D/repeated block is not supported.
- GPDMA_CxBR1.BNDT[15:0] must be programmed as a multiple of the source (peripheral) burst size.

17.4.16 GPDMA byte-based padding at the block level

For a given channel x, a LLI_n data transfer consists of a block transfer and is defined by the source block size GPDMA_CxBR1.BNDT[15:0], the size of the block of data to be transfered from the source, in bytes.

During a peripheral-to-memory transfer, a peripheral may be streaming and receiving a given number of bytes (for example, via an I2C, UART/USART/LPUART, ADC, DAC) or half-words, and this block size may not be a multiple of a word or a double-word. It is important to allow the user to program any number of bytes for the GPDMA source block size independently from the source data width and the destination data width, in order to use efficiently the bandwidth of the 32-bit AHB system bus and/or the 64-bit AXI system bus when accessing and writing into memory (embedded SRAM, NVM or external memory). This enables to decrease the bus bandwidth for the memory transfers by a ratio of up to 4 in AHB and up to 8 in AXI. More generally, having the source block size independent from the source data width and the destination data width can be useful also with memory-to-peripheral transfers, and with memory-to-memory transfers (AHB from/to AXI).

A FIFO-based channel is able to perform byte-based padding on the last write(s) up to the fully transferred source block size. Then channel FIFO is empty. Data handling is performed on zero bytes in the same way as on regular data bytes from the source, as explained in *GPDMA data handling: byte-based reordering, packing/unpacking, padding/truncation, sign extension and left/right alignment*.

There is byte-based padding at the block level:

1. If source data width is less than the destination data width, and if FIFO queuing and data packing is configured (PAM[1:0] = 1x):

- Padding with zero bytes. For example, if BNDT= 5, 8-bit reads, 32-bit writes:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 000B_4, $B_3B_2B_1B_0$
  - if DBX = 0, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> 0$B_4$00, $B_1B_0B_3B_2$
  - if DBX = 1, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> 00$B_4$0, $B_2B_3B_0B_1$
  - if DBX = 1, DHX = 1: B_4,B_3,B_2,B_1,B_0 -> $B_4$000, $B_0B_1B_2B_3$

2. If source data width > destination data width, and if FIFO queuing and data unpacking is configured (PAM[1:0] = 1x):

- Padding with zero bytes.
- On the last read, only the number of LSB(s) up to the block size are written to the FIFO. The last written data to the destination is padded with zero bytes up to the destination data width. For example, if BNDT= 5, 32-bit reads, 16-bit writes:
  - if DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 0B_4, B_3B_2, B_1B_0
  - if DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$, -> $B_4$0, B_2B_3, B_0B_1

3. If source data width = destination data width (and BNDT[15:0] is not a multiple of that value):

- Padding with zero bytes. For example, if BNDT= 6, 32-bit reads, 32-bit writes are configured
  - if SBX = 0, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_5B_4$, $B_3B_2B_1B_0$
  - if SBX = 0, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_5B_400, $B_1B_0B_3B_2$
  - if SBX = 0, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_4B_5$, $B_2B_3B_0B_1$
  - if SBX = 0, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4B_500, $B_0B_1B_2B_3$
  - if SBX = 1, DBX = 0, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $000B_4$, $B_3B_1B_2B_0$
  - if SBX = 1, DBX = 0, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_400$, $B_2B_0B_3B_1$
  - if SBX = 1, DBX = 1, DHX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $00B_40$, $B_1B_3B_0B_2$
  - if SBX = 1, DBX = 1, DHX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_4000, $B_0B_2B_1B_3$

4. If source data width < destination data width, and if destination data is configured as right-aligned and, either configured with zero padding bytes (PAM[1:0] = 00), or configured with sign extension (PAM[1:0] = 01):

- Padding with zero bytes if PAM[1:0] = 00. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 00:
  - if DBX =0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $000B_4$, $000B_3$, $000B_2$, $000B_1$, $000B_0$
- Padding with sign extension if PAM[1:0] = 01. For example, BNDT = 5, 8-bit reads, 32-bit writes, PAM[1:0] = 01:
  - if DBX = 0, DHX = 0: B_4,B_3,B_2,B_1,B_0 -> $SSSB_4$, $SSSB_3$, $SSSB_2$, $SSSB_1$, $SSSB_0$

5. If source data width > destination data width, and if destination data is configured as right-aligned (PAM[1:0] = 00), or left-aligned (PAM[1:0] = 01):

- Padding with zero bytes. For example, BNDT = 5, 32-bit reads, 16-bit writes:
  - if SBX = 0, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_1B_0
  - if SBX = 0, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_1
  - if SBX = 0, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_2
  - if SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_2B_3
  - if SBX = 1, PAM[1:0] = 00, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> $0B_4$, B_2B_0
  - If SBX = 1, PAM[1:0] = 00, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> B_40, B_0B_2
  - If SBX = 1, PAM[1:0] = 01, DBX = 0: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_3B_1
  - If SBX = 0, PAM[1:0] = 01, DBX = 1: $B_7B_6B_5B_4$, $B_3B_2B_1B_0$ -> 00, B_1B_3

17.4.17 GPDMA secure/nonsecure channel

The GPDMA controller is compliant with the TrustZone hardware architecture at channel level, partitioning all its resources so that they exist in one of the secure and nonsecure worlds at any given time.

Any channel x is a secure or a nonsecure hardware resource, as configured by GPDMA_SECCFGR.SECx.

When a channel x is configured in secure state by a secure and privileged agent, the following access control rules are applied:

- A nonsecure read access to a register field of this channel is forced to return 0, except for GPDMA_SECCFGR, GPDMA_PRIVCFGR, GPDMA_RCFGLOCKR that are readable by a nonsecure agent.
- A nonsecure write access to a register field of this channel has no impact.

When a channel x is configured in secure state, a secure agent can configure separately as secure or nonsecure the GPDMA data transfer from the source (GPDMA_CxTR1.SSEC) and the GPDMA data transfer to the destination (GPDMA_CxTR1.DSEC).

When a channel x is configured in secure state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with secure transfers via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a secure bus that reflects GPDMA_SECCFGR, to keep the other peripherals informed of the secure/nonsecure state of each GPDMA channel x.

The GPDMA also generates a security illegal access pulse signal on an illegal nonsecure access to a secure GPDMA register. This signal is routed to the TrustZone interrupt controller.

When the secure software must switch a channel from a secure state to a nonsecure state, the secure software must abort the channel or wait until the secure channel is completed before switching. This is needed to dynamically re-allocate a channel to a next nonsecure transfer as a nonsecure software is not allowed to do so and must have GPDMA_CxCR.EN = 0 before the nonsecure software can reprogram the GPDMA_CxCR for a next transfer. The secure software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

17.4.18 GPDMA privileged/unprivileged channel

Any channel x is a privileged or unprivileged hardware resource, as configured by a privileged agent via GPDMA_PRIVCFGR.PRIVx.

When a channel x is configured in a privileged state by a privileged agent, the following access control rules are applied:

- An unprivileged read access to a register field of this channel is forced to return 0, except for GPDMA_PRIVCFGR, GPDMA_SECCFGR, GPDMA_RCFGLOCKR that are readable by an unprivileged agent.
- An unprivileged write access to a register field of this channel has no impact.

When a channel is configured in a privileged (or unprivileged) state, the source and destination data transfers are privileged (respectively unprivileged) transfers over the AHB master port.

When a channel is configured in a privileged (or unprivileged) state and in linked-list mode, the loading of the next linked-list data structure from the GPDMA memory into its register file, is automatically performed with privileged (respectively unprivileged) transfers, via the GPDMA_CxCR.LAP allocated master port.

The GPDMA generates a privileged bus that reflects GPDMA_PRIVCFGR, to keep the other peripherals informed of the privileged/unprivileged state of each GPDMA channel x.

When the privileged software must switch a channel from a privileged state to an unprivileged state, the privileged software must abort the channel or wait until that the

privileged channel is completed before switching. This is needed to dynamically re-allocate a channel to a next unprivileged transfer as an unprivileged software is not allowed to do so, and must have GPDMA_CxCR.EN = 0 before the unprivileged software can reprogram the GPDMA_CxCR for a next transfer. The privileged software may reset not only the channel x (GPDMA_CxCR.RESET = 1) but also the full channel x register file to its reset value.

17.4.19 GPDMA error management

The GPDMA is able to manage and report to the user a transfer error, as follows, depending on the root cause.

Data transfer error

On a bus access (as a AHB single or a burst) to the source or the destination:

- The source or destination target reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware). The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the data error (GPDMA_CxSR.DTEF = 1).
- After a GPDMA data transfer error, the user must perform a debug session, taking care of the product-defined memory mapping of the source and destination, including the protection attributes.
- After a GPDMA data transfer error, the user must issue a channel reset (set GPDMA_CxCR.RESET) to reset the hardware GPDMA channel data path and the content of the FIFO, before the user enables again the same channel for a next transfer.

Link transfer error

On a tentative update of a GPDMA channel register from the programmed LLI in the memory:

- The linked-list memory reports an AHB error.
- The programmed channel transfer is stopped (GPDMA_CxCR.EN cleared by the GPDMA hardware), the channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and the link error (GPDMA_CxSR.ULEF = 1).
- After a GPDMA link error, the user must perform a debug session, taking care of the product-defined memory mapping of the linked-list data structure (GPDMA_CxLBAR and GPDMA_CxLLR), including the protection attributes.
- After a GPDMA link error, the user must explicitly write the linked-list register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR and GPDMA_CxLLR, plus GPDMA_CxTR3 and GPDMA_CxBR2), before the user enables again the same channel for a next transfer.

User setting error

On a tentative execution of a GPDMA transfer with an unauthorized user setting:

- The programmed channel transfer is disabled (GPDMA_CxCR.EN forced and cleared by the GPDMA hardware) preventing the next unauthorized programmed data transfer from being executed. The channel status register reports an idle state (GPDMA_CxSR.IDLEF = 1) and a user setting error (GPDMA_CxSR.USEF = 1).

- After a GPDMA user setting error, the user must perform a debug session, taking care of the GPDMA channel programming. A user setting error can be caused by one of the following:
  - a programmed null source block size without a programmed update of this value from the next LLI_1 (GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxLLR.UB1 = 0)
  - a programmed unaligned source start address, being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxSAR[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 4 to 5): a programmed unaligned source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxTR3.SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - for channel x (x = 4 to 5): a programmed unaligned block repeated source address offset being not a multiple of the programmed data width of a source burst transfer (GPDMA_CxBR2.BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0])
  - a programmed unaligned destination start address, being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxDAR[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 4 to 5): a programmed unaligned destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxTR3.DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - for channel x (x = 4 to 5): a programmed unaligned block repeated destination address offset being not a multiple of the programmed data width of a destination burst transfer (GPDMA_CxBR2.BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0])
  - a programmed linked-list item LLI_{n+1} with a null data transfer (GPDMA_CxLLR.UB1 = 1 and GPDMA_CxBR1. BNDT = 0)

17.5 GPDMA in debug mode

When the microcontroller enters debug mode (core halted), any channel x can be individually either continued (default) or suspended, depending on the programmable control bit in the DBGMCU module.

Note: In debug mode, GPDMA_CxSR.SUSPF is not altered by a suspension from the programmable control bit in the DBGMCU module. In this case, GPDMA_CxSR.IDLEF can be checked to know the completion status of the channel suspension.

17.6 GPDMA in low-power modes

Table 170. Effect of low-power modes on GPDMA

Mode	Description
Sleep	No effect. GPDMA interrupts cause the device to exit Sleep mode.
Stop(1)	The content of the GPDMA registers is kept when entering Stop mode.
Standby	The GPDMA is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 17.3.3* to know if any Stop mode is supported.

17.7 GPDMA interrupts

There is one GPDMA interrupt line for each channel, and separately for each CPU (if several ones in the devices).

Table 171. GPDMA interrupt requests

Interrupt acronym	Interrupt event	Interrupt enable	Event flag	Event clear method
GPDMA_CHx	Transfer complete	GPDMA_CxCR.TCIE	GPDMA_CxSR.TCF	Write 1 to GPDMA_CxFCR.TCF
	Half transfer	GPDMA_CxCR.HTIE	GPDMA_CxSR.HTF	Write 1 to GPDMA_CxFCR.HTF
	Data transfer error	GPDMA_CxCR.DTEIE	GPDMA_CxSR.DTEF	Write 1 to GPDMA_CxFCR.DTEF
	Update link error	GPDMA_CxCR.ULEIE	GPDMA_CxSR.ULEF	Write 1 to GPDMA_CxFCR.ULEF
	User setting error	GPDMA_CxCR.USEIE	GPDMA_CxSR.USEF	Write 1 to GPDMA_CxFCR.USEF
	Suspended	GPDMA_CxCR.SUSPIE	GPDMA_CxSR.SUSPF	Write 1 to GPDMA_CxFCR.SUSPF
	Trigger overrun	GPDMA_CxCR.TOFIE	GPDMA_CxSR.TOF	Write 1 to GPDMA_CxFCR.TOF

A GPDMA channel x event may be:

- a transfer complete
- a half-transfer complete
- a transfer error, due to either:
  - a data transfer error
  - an update link error
  - a user setting error completed suspension
- a trigger overrun

Note: When a channel x transfer complete event occurs, the output signal gpdma_chx_tc is generated as a high pulse of one clock cycle.

An interrupt is generated following any xx event, provided that both:

- the corresponding interrupt event xx is enabled (GPDMA_CxCR.xxIE = 1)
- the corresponding event flag is cleared (GPDMA_CxSR.xxF = 0). This means that, after a previous same xx event occurrence, a software agent must have written 1 into the corresponding xx flag clear control bit (write 1 into GPDMA_CxFCR.xxF).

TCF (transfer complete) and HTF (half transfer) events generation is controlled by GPDMA_CxTR2.TCEM[1:0] as follows:

- A transfer complete event is a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

- A half-transfer event is a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode GPDMA_CxTR2.TCEM[1:0].

  A half-block transfer occurs when half of the source block size bytes (rounded-up integer of GPDMA_CxBR1.BNDT[15:0] / 2) is transferred to the destination.

  A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded-up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2) is transferred to the destination.

See *GPDMA channel x transfer register 2 (GPDMA_CxTR2)* for more details.

A transfer error rises in one of the following situations:

- during a single/burst data transfer from the source or to the destination (DTEF)
- during an update of a GPDMA channel register from the programmed LLI in memory (ULEF)
- during a tentative execution of a GPDMA channel with an unauthorized setting (USEF)

  The user must perform a debug session to correct the GPDMA channel programming versus the USEF root causes list (see *Section 17.4.19*).

A trigger overrun is described in *Trigger hit memorization and trigger overrun flag generation*.

17.8 GPDMA registers

The GPDMA registers must be accessed with an aligned 32-bit word data access.

17.8.1 GPDMA secure configuration register (GPDMA_SECCFGR)

Address offset: 0x00

Reset value: 0x0000 0000

A write access to this register must be secure and privileged. A read access is secure or nonsecure, privileged or unprivileged.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (when GPDMA_CxCR.EN = 0), to securely allocate individually any channel x to the secure or nonsecure world.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC5	SEC4	SEC3	SEC2	SEC1	SEC0
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **SECx**: secure state of channel x (x = 5 to 0)
0: Nonsecure
1: Secure

17.8.2 GPDMA privileged configuration register (GPDMA_PRIVCFGR)

Address offset: 0x04

Reset value: 0x0000 0000

A write access to this register must be privileged. A read access can be privileged or unprivileged, secure or nonsecure.

This register can mix secure and nonsecure information. If a channel x is configured as secure (GPDMA_SECCFGR.SECx = 1), the PRIVx bit can be written only by a secure (and privileged) agent.

A write access is ignored at bit level if the corresponding channel x is locked (GPDMA_RCFGLOCKR.LOCKx = 1).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN =1.

This register must be programmed at a bit level, at the initialization/closure of a GPDMA channel (GPDMA_CxCR.EN = 0), to individually allocate any channel x to the privileged or unprivileged world.

										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **PRIVx**: privileged state of channel x (x = 5 to 0)
0: unprivileged
1: privileged

17.8.3 GPDMA configuration lock register (GPDMA_RCFGLOCKR)

Address offset: 0x08

Reset value: 0x0000 0000

This register can be written by a software agent with secure privileged attributes in order to individually lock, for example at boot time, the secure privileged attributes of any GPDMA

channel/resource (to lock the setting of GPDMA_CxSECCFGR, GPDMA_CxPRIVCFGR for any channel x, for example at boot time).

A read access may be privileged or unprivileged, secure or nonsecure.

Note: If TZEN = 0, this register cannot be written.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK5	LOCK4	LOCK3	LOCK2	LOCK1	LOCK0
										rs	rs	rs	rs	rs	rs

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **LOCKx**: lock the configuration of GPDMA_SECCFGR.SECx, GPDMA_PRIVCFGR.PRIVx until a global GPDMA reset (x = 5 to 0)

This bit is cleared after reset and, once set, it cannot be reset until a global GPDMA reset.

0: secure privilege configuration of the channel x is writable.

1: secure privilege configuration of the channel x is not writable.

17.8.4 GPDMA nonsecure masked interrupt status register (GPDMA_MISR)

Address offset: 0x0C

Reset value: 0x0000 0000

This register is a read register.

This is a nonsecure register, containing the masked interrupt status bit MISx for each nonsecure channel x (channel x configured with GPDMA_SECCFGR.SECx = 0). It is a logical OR of all the flags of GPDMA_CxSR, each source flag being enabled by the corresponding interrupt enable bit of GPDMA_CxCR.

Every bit is deasserted by hardware when writing 1 to the corresponding flag clear bit in GPDMA_CxFCR.

If a channel x is in secure state (GPDMA_SECCFGR.SECx = 1), a read access to the masked interrupt status bit MISx of this channel x returns zero.

This register may mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full nonsecure interrupt status. An unprivileged software is restricted to read the status of unprivileged (and nonsecure) channels, other privileged bit fields returning zero.

										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **MISx**: masked interrupt status of channel x (x = 5 to 0)
0: no interrupt occurred on channel x
1: an interrupt occurred on channel x

17.8.5 GPDMA secure masked interrupt status register (GPDMA_SMISR)

Address offset: 0x10

Reset value: 0x0000 0000

This is a secure read register, containing the masked interrupt status bit MISx for each secure channel x (GPDMA_SECCFGR.SECx = 1). It is a logical OR of all the GPDMA_CxSR flags, each source flag being enabled by the corresponding GPDMA_CxCR interrupt enable bit.

Every bit is deasserted by hardware when securely writing 1 to the corresponding GPDMA_CxFCR flag clear bit.

This register does not contain any information about a nonsecure channel.

This register can mix privileged and unprivileged information, depending on the privileged state of each channel GPDMA_PRIVCFGR.PRIVx. A privileged software can read the full secure interrupt status. An unprivileged software is restricted to read the status of unprivileged and secure channels, other privileged bit fields returning zero.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MIS5	MIS4	MIS3	MIS2	MIS1	MIS0
										r	r	r	r	r	r

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **MISx**: masked interrupt status of the secure channel x (x = 5 to 0)
0: no interrupt occurred on the secure channel x
1: an interrupt occurred on the secure channel x

17.8.6 GPDMA channel x linked-list base address register (GPDMA_CxLBAR)

Address offset: 0x50 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register must be written by a privileged software. It is either privileged readable or not, depending on the privileged state of the channel x GPDMA_PRIVCFGR.PRIVx.

This register is either secure or nonsecure depending on the secure state of the channel x (GPDMA_SECCFGR.SECx).

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This channel-based register is the linked-list base address of the memory region, for a given channel x, from which the LLIs describing the programmed sequence of the GPDMA transfers, are conditionally and automatically updated.

This 64-Kbyte aligned channel x linked-list base address is offset by the 16-bit GPDMA_CxLLR register that defines the word-aligned address offset for each LLI.

Bits 31:16 **LBA[31:16]**: linked-list base address of GPDMA channel x

Bits 15:0 Reserved, must be kept at reset value.

17.8.7 GPDMA channel x flag clear register (GPDMA_CxFCR)

Address offset: 0x5C+ 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This is a write register, secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

Bits 31:15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag clear
0: no effect
1: corresponding TOF flag cleared

Bit 13 **SUSPF**: completed suspension flag clear
0: no effect
1: corresponding SUSPF flag cleared

Bit 12 **USEF**: user setting error flag clear
0: no effect
1: corresponding USEF flag cleared

Bit 11 **ULEF**: update link transfer error flag clear
0: no effect
1: corresponding ULEF flag cleared

Bit 10 **DTEF**: data transfer error flag clear
0: no effect
1: corresponding DTEF flag cleared

Bit 9 **HTF**: half-transfer flag clear
0: no effect
1: corresponding HTF flag cleared

Bit 8 **TCF**: transfer complete flag clear
0: no effect
1: corresponding TCF flag cleared

Bits 7:0 Reserved, must be kept at reset value.

17.8.8 GPDMA channel x status register (GPDMA_CxSR)

Address offset: 0x60 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0001

This is a read register, reporting the channel status.

This register is secure or nonsecure, depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel (GPDMA_PRIVCFGR.PRIVx).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FIFOL[7:0]							
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	TOF	SUSPF	USEF	ULEF	DTEF	HTF	TCF	Res.	Res.	Res.	Res.	Res.	Res.	DRAINING F	IDLEF
	r	r	r	r	r	r	r							r	r

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **FIFOL[7:0]**: monitored FIFO level (in bytes)
Number of available bytes in the FIFO.
Note: After having suspended an active transfer, the user may need to read FIFOL[7:0], additionally to GPDMA_CxBR1.BDNT[15:0] and GPDMA_CxBR1.BRC[10:0], to know how many data have been transferred to the destination. Before reading, the user may wait for the transfer to be suspended (GPDMA_CxSR.SUSPF = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOF**: trigger overrun flag
0: no trigger overrun event
1: a trigger overrun event occurred

Bit 13 **SUSPF**: completed suspension flag
0: no completed suspension event
1: a completed suspension event occurred

Bit 12 **USEF**: user setting error flag
0: no user setting error event
1: a user setting error event occurred

Bit 11 **ULEF**: update link transfer error flag
0: no update link transfer error event
1: a master bus error event occurred while updating a linked-list register from memory

Bit 10 **DTEF**: data transfer error flag
0: no data transfer error event
1: a master bus error event occurred on a data transfer

Bit 9 **HTF**: half-transfer flag
0: no half-transfer event
1: a half-transfer event occurred
A half-transfer event is either a half-block transfer or a half 2D/repeated block transfer, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).
A half-block transfer occurs when half of the bytes of the source block size (rounded up integer of GPDMA_CxBR1.BNDT[15:0]/2) has been transferred to the destination.
A half 2D/repeated block transfer occurs when half of the repeated blocks (rounded up integer of (GPDMA_CxBR1.BRC[10:0] + 1) / 2)) has been transferred to the destination.

Bit 8 **TCF**: transfer complete flag
0: no transfer complete event
1: a transfer complete event occurred
A transfer complete event is either a block transfer complete, a 2D/repeated block transfer complete, or a LLI transfer complete including the upload of the next LLI if any, or the full linked-list completion, depending on the transfer complete event mode (GPDMA_CxTR2.TCEM[1:0]).

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **DRAININGF**: FIFO draining flag
0: No received order to drain the FIFO or channel FIFO draining completed
1: Ongoing channel FIFO draining and channel termination
This flag is asserted after that the order to drain the FIFO is received, and meanwhile that the channel is enabled and draining the FIFO and before the channel is terminated with a drained FIFO.
This flag is deasserted by hardware when the enabled channel has been ordered to be terminated with FIFO draining, and the hardware effectively terminates.

Bit 0 **IDLEF**: idle flag
0: channel not in idle state
1: channel in idle state
This idle flag is deasserted by hardware when the channel is enabled (GPDMA_CxCR.EN = 1) with a valid channel configuration (no USEF to be immediately reported).
This idle flag is asserted after hard reset or by hardware when the channel is back in idle state (in suspended or disabled state).

17.8.9 GPDMA channel x control register (GPDMA_CxCR)

Address offset: 0x64 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of the channel x (GPDMA_PRIVCFGR.PRIVx).

This register is used to control a channel (activate, suspend, abort or disable it).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIO[1:0]		Res.	Res.	Res.	Res.	LAP	LSM
								rw	rw					rw	rw

Res.	TOIE	SUSPIE	USEIE	ULEIE	DTEIE	HTIE	TCIE	Res.	Res.	Res.	Res.	DRAIN FIFO	SUSP	RESET	EN
	rw	rw	rw	rw	rw	rw	rw					w	rw	w	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:22 **PRIO[1:0]:** priority level of the channel x GPDMA transfer versus others
00: low priority, low weight
01: low priority, mid weight
10: low priority, high weight
11: high priority
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 21:18 Reserved, must be kept at reset value.

Bit 17 **LAP**: linked-list allocated port
This bit is used to allocate the master port for the update of the GPDMA linked-list registers from the memory.
0: port 0 (AHB) allocated
1: port 1 (AHB) allocated
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 16 **LSM**: Link step mode
0: channel executed for the full linked-list and completed at the end of the last LLI (GPDMA_CxLLR = 0). The 16 low-significant bits of the link address are null (LA[15:0] = 0) and all the update bits are null (UT1 = UB1 = UT2 = USA = UDA = ULL = 0 and UT3 = UB2 = 0). Then GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0.
1: channel executed **once** for the current LLI
First the (possible 1D/repeated) block transfer is executed as defined by the current internal register file until GPDMA_CxBR1.BNDT[15:0] = 0 and GPDMA_CxBR1.BRC[10:0] = 0. Secondly the next linked-list data structure is conditionally uploaded from memory as defined by GPDMA_CxLLR. Then channel execution is completed.
Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TOIE**: trigger overrun interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 13 **SUSPIE**: completed suspension interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 12 **USEIE**: user setting error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 11 **ULEIE**: update link transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 10 **DTEIE**: data transfer error interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 9 **HTIE**: half-transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bit 8 **TCIE**: transfer complete interrupt enable
0: interrupt disabled
1: interrupt enabled

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DRAINFIFO:** empty FIFO
This bit is write only. Writing 0 has no impact.
Writing 1 to RESET in this register causes the hardware to deassert this DRAINFIFO bit, whatever is written into this DRAINFIFO. Else:
Software must write 1 in order to drain the channel FIFO on a suspended channel.
If the software concurrently writes 1 to DRAINFIFO and 1 to SUSP and 0 to reset, the hardware suspends the channel and drains the FIFO by popping out the residual FIFO bytes to the destination (see the programming sequence in *Figure 117*).
0: Write: no action
1: Write: drain FIFO after having suspended the channel

Bit 2 **SUSP:** suspend
Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 2. Else:
Software must write 1 in order to suspend an active channel (channel with an ongoing GPDMA transfer over its master ports).
The software must write 0 in order to resume a suspended channel, following the programming sequence detailed in *Figure 115*.
0: write: resume channel, read: channel not suspended
1: write: suspend channel, read: channel suspended.

Bit 1 **RESET:** reset

This bit is write only. Writing 0 has no impact. Writing 1 implies the reset of the following: the FIFO, the channel internal state, SUSP, DRAINFIFO and EN bits (whatever is written receptively in bit 3 and bit 2 and bit 0).

The reset is effective when the channel is in steady state, meaning one of the following:

- active channel in suspended state (GPDMA_CxSR.SUSPF = 1, GPDMA_CxSR.IDLEF = GPDMA_CxCR.EN = 1 and GPDMA_CxSR.DRAININGF = 0)
- channel in disabled state (GPDMA_CxSR.IDLEF = 1 and GPDMA_CxCR.EN = 0).

After writing a RESET, to continue using this channel, the user must explicitly reconfigure the channel including the hardware-modified configuration registers (GPDMA_CxBR1, GPDMA_CxSAR, and GPDMA_CxDAR) before enabling again the channel (see the programming sequence in *Figure 116*).

0: no channel reset

1: channel reset

Bit 0 **EN:** enable

Writing 1 into the field RESET (bit 1) causes the hardware to de-assert this bit, whatever is written into this bit 0. Else:

this bit is deasserted by hardware when there is a transfer error (master bus error or user setting error) or when there is a channel transfer complete (channel ready to be configured, for example if LSM = 1 at the end of a single execution of the LLI).

Else, this bit can be asserted by software.

Writing 0 into this EN bit is ignored.

0: write: ignored, read: channel disabled

1: write: enable channel, read: channel enabled

17.8.10 GPDMA channel x transfer register 1 (GPDMA_CxTR1)

Address offset: 0x90 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx) except for secure DSEC and SSEC, privileged or unprivileged, depending on the privileged state of the channel x in GPDMA_PRIVCFGR.PRIVx.

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed. Then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UT1 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DSEC	DAP	Res.	Res.	DHX	DBX	DBL_1[5:0]						DINC	Res.	DDW_LOG2[1:0]	
rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SSEC	SAP	SBX	PAM[1:0]		Res.	SBL_1[5:0]						SINC	Res.	SDW_LOG2[1:0]	
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw		rw	rw

Bit 31 **DSEC**: security attribute of the GPDMA transfer to the destination

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this DSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer to the destination is nonsecure.

Bit 30 **DAP**: destination allocated port

This bit is used to allocate the master port for the destination transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bits 29:28 Reserved, must be kept at reset value.

Bit 27 **DHX**: destination half-word exchange

If the destination data size is shorter than a word, this bit is ignored.

If the destination data size is a word:

0: no halfword-based exchanged within word

1: the two consecutive (post PAM) half-words are exchanged in each destination word.

Bit 26 **DBX**: destination byte exchange

If the destination data size is a byte, this bit is ignored.

If the destination data size is not a byte:

0:no byte-based exchange within half-word

1: the two consecutive (post PAM) bytes are exchanged in each destination half-word.

Bits 25:20 **DBL_1[5:0]**: destination burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If DBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width DDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 19 **DINC**: destination incrementing burst

0: fixed burst

1: contiguously incremented burst

The destination address, pointed by GPDMA_CxDAR, is kept constant after a burst beat/single transfer, or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 18 Reserved, must be kept at reset value.

Bits 17:16 **DDW_LOG2[1:0]**: binary logarithm of the destination data width of a burst, in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

Note: A destination burst transfer must have an aligned address with its data width (start address GPDMA_CxDAR[2:0] and if present address offset GPDMA_CxTR3.DAO[2:0], versus DDW_LOG2[1:0]). Otherwise a user setting error is reported and no transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and none transfer is issued.

Bit 15 **SSEC**: security attribute of the GPDMA transfer from the source

If GPDMA_SECCFGR.SECx = 1 and the access is secure:

0: GPDMA transfer nonsecure

1: GPDMA transfer secure

This is a secure register bit. This bit can only be read by a secure software. This bit must be written by a secure software when GPDMA_SECCFGR.SECx = 1. A secure write is ignored when GPDMA_SECCFGR.SECx = 0.

When GPDMA_SECCFGR.SECx is deasserted, this SSEC bit is also deasserted by hardware (on a secure reconfiguration of the channel as nonsecure), and the GPDMA transfer from the source is nonsecure.

Bit 14 **SAP**: source allocated port

This bit is used to allocate the master port for the source transfer

0: port 0 (AHB) allocated

1: port 1 (AHB) allocated

Note: This bit must be written when EN = 0. This bit is read-only when EN = 1.

Bit 13 **SBX**: source byte exchange within the unaligned half-word of each source word

If the source data width is shorter than a word, this bit is ignored.

If the source data width is a word:

0:no byte-based exchange within the unaligned half-word of each source word

1: the two consecutive bytes within the unaligned half-word of each source word are exchanged.

Bits 12:11 **PAM[1:0]**: padding/alignment mode

If DDW_LOG2[1:0] = SDW_LOG2[1:0]: if the data width of a burst destination transfer is equal to the data width of a burst source transfer, these bits are ignored.

Else, in the following enumerated values, the condition PAM_1 is when destination data width is higher than source data width, and the condition PAM_2 is when source data width is higher than destination data width.

Condition: PAM_1

00: source data is transferred as right aligned, padded with 0s up to the destination data width

01: source data is transferred as right aligned, sign extended up to the destination data width

10-11: successive source data are FIFO queued and packed at the destination data width, in a left (LSB) to right (MSB) order (named little endian), before a destination transfer

Condition: PAM_2

00: source data is transferred as right aligned, left-truncated down to the destination data width

01: source data is transferred as left-aligned, right-truncated down to the destination data width

10-11: source data is FIFO queued and unpacked at the destination data width, to be transferred in a left (LSB) to right (MSB) order (named little endian) to the destination

Note: If the transfer from the source peripheral is configured with peripheral flow-control mode (SWREQ = 0 and PFREQ = 1 and DREQ = 0), and if the destination data width > the source data width, packing is not supported.

Bit 10 Reserved, must be kept at reset value.

Bits 9:4 **SBL_1[5:0]**: source burst length minus 1, between 0 and 63

The burst length unit is one data named beat within a burst. If SBL_1[5:0] = 0, the burst can be named as single. Each data/beat has a width defined by the destination data width SDW_LOG2[1:0].

Note: If a burst transfer crossed a 1-Kbyte address boundary on a AHB transfer, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the AHB protocol.

If a burst transfer is of length greater than the FIFO size of the channel x, the GPDMA modifies and shortens the programmed burst into singles or bursts of lower length, to be compliant with the FIFO size. Transfer performance is lower, with GPDMA re-arbitration between effective and lower singles/bursts, but the data integrity is guaranteed.

Bit 3 **SINC**: source incrementing burst

0: fixed burst

1: contiguously incremented burst

The source address, pointed by GPDMA_CxSAR, is kept constant after a burst beat/single transfer or is incremented by the offset value corresponding to a contiguous data after a burst beat/single transfer.

Bit 2 Reserved, must be kept at reset value.

Bits 1:0 **SDW_LOG2[1:0]**: binary logarithm of the source data width of a burst in bytes

00: byte

01: half-word (2 bytes)

10: word (4 bytes)

11: user setting error reported and no transfer issued

A source burst transfer must have an aligned address with its data width (start address GPDMA_CxSAR[2:0] versus SDW_LOG2[1:0]). Otherwise, a user setting error is reported and none transfer is issued.

Setting a 8-byte data width causes a user setting error to be reported and no transfer is issued.

17.8.11 GPDMA channel x transfer register 2 (GPDMA_CxTR2)

Address offset: 0x94 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x. This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (the hardware deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory, if GPDMA_CxLLR.UT2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TRIGM[1:0]		Res.	PFREQ	BREQ	DREQ	SWREQ	Res.	REQSEL[7:0]							
rw	rw		rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **TCEM[1:0]**: transfer complete event mode

These bits define the transfer granularity for the transfer complete and half-transfer complete events generation.

00: at block level (when GPDMA_CxBR1.BNDT[15:0] = 0): the complete (and the half) transfer event is generated at the (respectively half of the) end of a block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

01: channel x (x = 0 to 3), same as 00, channel x (x = 4 to 5), at 2D/repeated block level (when GPDMA_CxBR1.BRC[10:0] = 0 and GPDMA_CxBR1.BNDT[15:0] = 0). The complete (and the half) transfer event is generated at the end (respectively half of the end) of the 2D/repeated block.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then neither the complete transfer event nor the half-transfer event is generated.

10: at LLI level: the complete transfer event is generated at the end of the LLI transfer, including the update of the LLI if any. The half-transfer event is generated at the half of the LLI data transfer The LLI data transfer is a block transfer or a 2D/repeated block transfer for channel x (x = 4 to 5), if any data transfer.

Note: If the initial LLI_0 data transfer is null/void (directly programmed by the internal register file with GPDMA_CxBR1.BNDT[15:0] = 0), then the half-transfer event is not generated, and the transfer complete event is generated when is completed the loading of the LLI_1.

11: at channel level: the complete transfer event is generated at the end of the last LLI transfer. The half-transfer event is generated at the half of the data transfer of the last LLI. The last LLI updates the link address GPDMA_CxLLR.LA[15:2] to zero and clears all the GPDMA_CxLLR update bits (UT1, UT2, UB1, USA, UDA and ULL, plus UT3 and UB2). If the channel transfer is continuous/infinite, no event is generated.

Bits 29:26 Reserved, must be kept at reset value.

Bits 25:24 **TRIGPOL[1:0]**: trigger event polarity

These bits define the polarity of the selected trigger event input defined by TRIGSEL[5:0].

00: no trigger (masked trigger event)

01: trigger on the rising edge

10: trigger on the falling edge

11: same as 00

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:16 **TRIGSEL[5:0]**: trigger event input selection

These bits select the trigger event input of the GPDMA transfer (as per *Section 17.3.7*), with an active trigger event if TRIGPOL[1:0] ≠ 00.

Bits 15:14 **TRIGM[1:0]**: trigger mode

These bits define the transfer granularity for its conditioning by the trigger.

If the channel x is enabled (GPDMA_CxCR.EN asserted) with TRIGPOL[1:0] = 00 or 11, these TRIGM[1:0] bits are ignored.

Else, a GPDMA transfer is conditioned by one trigger hit:

00: at block level: the first burst read of each block transfer is conditioned by one hit trigger (channel x (x = 4 to 5): same, each block also if a 2D/repeated block is configured with GPDMA_CxBR1.BRC[10:0] ≠ 0).

01: channel x (x = 0 to 3): same as 00; channel x (x = 4 to 5): at 2D/repeated block level: the first burst read of the 2D/repeated block transfer is conditioned by one hit trigger.

10: at link level: a LLI link transfer is conditioned by one hit trigger. LLI data transfer is not conditioned.

11: at programmed burst level: If SWREQ = 1, each programmed burst read is conditioned by one hit trigger. If SWREQ = 0, each programmed burst that is requested by the selected peripheral, is conditioned by one hit trigger:

– If the peripheral is the source (DREQ = 0) of the LLI data transfer, each programmed burst read is conditioned.

– If the peripheral is the destination (DREQ = 1) of the LLI data transfer, each programmed burst write is conditioned. The first memory burst read of a (possibly 2D/repeated) block, also named as the first ready FIFO-based source burst, is gated by the occurrence of both the hardware request and one trigger hit.

As shown in *Figure 132: Trigger hit, memorization, and overrun waveform*, the GPDMA monitoring of a trigger for channel x is started when the channel is enabled/loaded with a new active trigger configuration: rising or falling edge on a selected trigger (TRIGPOL[1:0] = 01 or respectively TRIGPOL[1:0] = 10). The monitoring of this trigger is kept active during the triggered and uncompleted (data or link) transfer; and if a new trigger is detected then, this hit is internally memorized to grant the next transfer, as long as the defined rising or falling edge is not modified, and the TRIGSEL[5:0] is not modified, and the channel is enabled. After a first new trigger hit_{n+1} is memorized, if another second trigger hit_{n+2} is detected and if the hit_n triggered transfer is still not completed, hit_{n+2} is lost and not memorized. A trigger overrun flag is reported (GPDMA_CxSR.TOF = 1), and an interrupt is generated if enabled (GPDMA_CxCR.TOIE = 1). The channel is not automatically disabled by hardware due to a trigger overrun.

Transferring a next LLI_{n+1} that updates the GPDMA_CxTR2 with a new value for any of TRIGSEL[5:0] or TRIGPOL[1:0], resets the monitoring, trashing the memorized hit of the formerly defined LLI_n trigger.

Note: When the source block size is not a multiple of the source burst size and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, if TRIGM[1:0] = 11 and (SWREQ = 1 or (SWREQ = 0 and DREQ = 0)), the shortened burst transfer (by singles or/and by bursts of lower length) is conditioned once by the trigger.

When the programmed destination burst is internally shortened by singles or/and by bursts of lower length (versus FIFO size, versus block size, 1-Kbyte boundary address crossing): if the trigger is conditioning the programmed destination burst (if TRIGM[1:0] = 11 and SWREQ = 0 and DREQ = 1), this shortened destination burst transfer is conditioned once by the trigger.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **PFREQ**: Hardware request in peripheral flow control mode

Important: If a given channel x is not implemented with this feature, this bit is reserved and PFREQ is not present (see Section 17.3.2 for the list of the implemented channels with this feature).

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in GPDMA control mode. The GPDMA is programmed with GPDMA_CxTR1.BNDT[15:0] and this is internally used by the hardware for the block transfer completion.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol in peripheral control mode. The GPDMA block transfer can be early completed by the peripheral itself (see *Section 17.3.6* for more details).

Note: In peripheral flow control mode, there are the following restrictions:

- no 2D/repeated block support (GPDMA_CxBR1.BRC[10:0] must be set to 0)

- the peripheral must be set as the source of the transfer (DREQ = 0).

- data packing to a wider destination width is not supported (if destination width > source data width, GPDMA_CxTR1.PAM[1] must be set to 0).

Bit 11 **BREQ**: Block hardware request

If the channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer), this bit is ignored. Else:

0: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a burst level.

1: the selected hardware request is driven by a peripheral with a hardware request/acknowledge protocol at a block level (see *Section 17.3.4*).

Bit 10 **DREQ**: destination hardware request

This bit is ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1 (software request for a memory-to-memory transfer). Else:

0: selected hardware request driven by a source peripheral (request signal taken into account by the GPDMA transfer scheduler over the source/read port)

1: selected hardware request driven by a destination peripheral (request signal taken into account by the GPDMA transfer scheduler over the destination/write port)

Note: If the channel x is activated (GPDMA_CxCR.EN is asserted) with SWREQ = 0 and PFREQ = 1 (peripheral hardware request with peripheral flow-control mode), any software assertion to this DREQ bit is ignored: in peripheral flow-control mode, only a peripheral-to-memory transfer is supported.

Bit 9 **SWREQ**: software request

This bit is internally taken into account when GPDMA_CxCR.EN is asserted.

0: no software request. The selected hardware request REQSEL[7:0] is taken into account.

1: software request for a memory-to-memory transfer. The default selected hardware request as per REQSEL[7:0] is ignored.

Bit 8 Reserved, must be kept at reset value.

Bits 7:0 **REQSEL[7:0]**: GPDMA hardware request selection

These bits are ignored if channel x is activated (GPDMA_CxCR.EN asserted) with SWREQ = 1(software request for a memory-to-memory transfer). Else, the selected hardware request is internally taken into account as per *Section 17.3.4*.

Caution: The user must not assign a same input hardware request (same REQSEL[7:0] value) to different active GPDMA channels (GPDMA_CxCR.EN = 1 and GPDMA_CxTR2.SWREQ = 0 for these channels). GPDMA is not intended to hardware support the case of simultaneous enabled channels incorrectly configured with a same hardware peripheral request signal, and there is no user setting error reporting.

17.8.12 GPDMA channel x block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the field BNDT[15:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for BNDT[15:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, this register and BNDT[15:0] are kept as null, channel x is completed.

BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one non null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] = 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

17.8.13 GPDMA channel x alternate block register 1 (GPDMA_CxBR1)

Address offset: 0x98 + 0x80 * x (x = 4 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when channel x is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, or LLI or full linked-list.

In linked-list mode, during the link transfer:

- if GPDMA_CxLLR.UB1 = 1, this register is automatically updated by the GPDMA from the next LLI in memory.
- If GPDMA_CxLLR.UB1 = 0 and if there is at least one linked-list register to be updated from the next LLI in memory, this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0].
- If all the update bits GPDMA_CxLLR.Uxx are null and if GPDMA_CxLLR.LA[15:0] ≠ 0, the current LLI is the last one and is continuously executed: this register is automatically and internally restored with the programmed value for the fields BNDT[15:0] and BRC[10:0] after each execution of this final LLI
- If GPDMA_CxLLR = 0, BNDT[15:0] and BRC[10:0] are kept as null, channel x is completed.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDDEC	BRSDEC	DDEC	SDEC	Res.	BRC[10:0]										
rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BNDT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BRDDEC**: Block repeat destination address decrement

0: at the end of a block transfer, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxBR2.BRDAO to the current GPDMA_CxDAR value (current destination address)

1: at the end of a block transfer, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRDAO from the current GPDMA_CxDAR value (current destination address)

Note: On top of this increment/decrement (depending on BRDDEC), GPDMA_CxDAR is in the same time also updated by the increment/decrement (depending on DDEC) of the GPDMA_CxTR3.DAO value, as it is usually done at the end of each programmed burst transfer.

Bit 30 **BRSDEC**: Block repeat source address decrement

0: at the end of a block transfer, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxBR2.BRSAO to the current GPDMA_CxSAR value (current source address)

1: at the end of a block transfer, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxBR2.BRSAO from the current GPDMA_CxSAR value (current source address)

Note: On top of this increment/decrement (depending on BRSDEC), GPDMA_CxSAR is in the same time also updated by the increment/decrement (depending on SDEC) of the GPDMA_CxTR3.SAO value, as it is done after any programmed burst transfer.

Bit 29 **DDEC**: destination address decrement

0: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by adding the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

1: At the end of a programmed burst transfer to the destination, the GPDMA_CxDAR register is updated by subtracting the programmed offset GPDMA_CxTR3.DAO to the current GPDMA_CxDAR value (current destination address)

Bit 28 **SDEC**: source address decrement

0: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by adding the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

1: At the end of a programmed burst transfer from the source, the GPDMA_CxSAR register is updated by subtracting the programmed offset GPDMA_CxTR3.SAO to the current GPDMA_CxSAR value (current source address)

Bit 27 Reserved, must be kept at reset value.

Bits 26:16 **BRC[10:0]**: Block repeat counter

This field contains the number of repetitions of the current block (0 to 2047).

When the channel is enabled, this field becomes read-only. After decrements, this field indicates the remaining number of blocks, excluding the current one. This counter is hardware decremented for each completed block transfer.

Once the last block transfer is completed (BRC[10:0] = BNDT[15:0] = 0):

– If GPDMA_CxLLR.UB1 = 1, all GPDMA_CxBR1 fields are updated by the next LLI in the memory.
– If GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
– if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
– if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI and data transfer.

Bits 15:0 **BNDT[15:0]**: block number of data bytes to transfer from the source

Block size transferred from the source. When the channel is enabled, this field becomes read-only and is decremented, indicating the remaining number of data items in the current source block to be transferred. BNDT[15:0] is programmed in number of bytes, maximum source block size is 64 Kbytes -1.

Once the last data transfer is completed (BNDT[15:0] = 0):

- if GPDMA_CxLLR.UB1 = 1, this field is updated with the LLI in the memory.
- if GPDMA_CxLLR.UB1 = 0 and if there is at least one not null Uxx update bit, this field is internally restored to the programmed value.
- if all GPDMA_CxLLR.Uxx = 0 and if GPDMA_CxLLR.LA[15:0] ≠ 0, this field is internally restored to the programmed value (infinite/continuous last LLI).
- if GPDMA_CxLLR = 0, this field is kept as zero following the last LLI data transfer.

17.8.14 GPDMA channel x source address register (GPDMA_CxSAR)

Address offset: 0x9C + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the source start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer from the source.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.USA = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SA[31:0]**: source address

This field is the pointer to the address from which the next data is read.

During the channel activity, depending on the source addressing mode (GPDMA_CxTR1.SINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.SDW_LOG2[1:0]) after each burst source data, reflecting the next address from which data is read.

During the channel activity, this address is updated after each completed source burst, consequently to:

– the programmed source burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.SINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.SBL_1[5:0] and GPDMA_CxTR1.SDW_LOG2[1:0]

– the additional source incremented/decremented offset value as programmed by GPDMA_CxBR1.SDEC and GPDMA_CxTR3.SAO[12:0].

– once/if completed source block transfer, for a channel x with 2D addressing capability (x = 4 to 5). additional block repeat source incremented/decremented offset value as programmed by GPDMA_CxBR1.BRSDEC and GPDMA_CxBR2.BRSAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.USA = 1.

Note: A source address must be aligned with the programmed data width of a source burst (SA[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

When the source block size is not a multiple of the source burst size and is a multiple of the source data width, the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

17.8.15 GPDMA channel x destination address register (GPDMA_CxDAR)

Address offset: 0xA0 + 0x80 * x (x = 0 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the destination start address of a transfer.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1, and continuously updated by hardware, in order to reflect the address of the next burst transfer to the destination.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by GPDMA from the memory if GPDMA_CxLLR.UDA = 1.

DA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DA[31:0]**: destination address

This field is the pointer to the address from which the next data is written.

During the channel activity, depending on the destination addressing mode (GPDMA_CxTR1.DINC), this field is kept fixed or incremented by the data width (GPDMA_CxTR1.DDW_LOG2[1:0]) after each burst destination data, reflecting the next address from which data is written.

During the channel activity, this address is updated after each completed destination burst, consequently to:

– the programmed destination burst; either in fixed addressing mode or in contiguous-data incremented mode. If contiguously incremented (GPDMA_CxTR1.DINC = 1), then the additional address offset value is the programmed burst size, as defined by GPDMA_CxTR1.DBL_1[5:0] and GPDMA_CxTR1.DDW_LOG2[1:0]

– the additional destination incremented/decremented offset value as programmed by GPDMA_CxBR1.DDEC and GPDMA_CxTR3.DAO[12:0].

– once/if completed destination block transfer, for a channel x with 2D addressing capability (x = 4 to 5), the additional block repeat destination incremented/decremented offset value as programmed by GPDMA_CxBR1.BRDDEC and GPDMA_CxBR2.BRDAO[15:0]

In linked-list mode, after a LLI data transfer is completed, this register is automatically updated by the GPDMA from the memory, provided the LLI is set with GPDMA_CxLLR.UDA = 1.

Note: A destination address must be aligned with the programmed data width of a destination burst (DA[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

17.8.16 GPDMA channel x transfer register 3 (GPDMA_CxTR3)

Address offset: 0xA4 + 0x80 * x (x = 4 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UT3 = 1.

Res.	Res.	Res.	SAO[12:0]												
			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:16 **DAO[12:0]**: destination address offset increment

The destination address, pointed by GPDMA_CxDAR, is incremented or decremented (depending on GPDMA_CxBR1.DDEC) by this offset DAO[12:0] for each programmed destination burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.DINC = 1).

Note: A destination address offset must be aligned with the programmed data width of a destination burst (DAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else, a user setting error is reported and no transfer is issued.

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:0 **SAO[12:0]**: source address offset increment

The source address, pointed by GPDMA_CxSAR, is incremented or decremented (depending on GPDMA_CxBR1.SDEC) by this offset SAO[12:0] for each programmed source burst. This offset is not including and is added to the programmed burst size when the completed burst is addressed in incremented mode (GPDMA_CxTR1.SINC = 1).

Note: A source address offset must be aligned with the programmed data width of a source burst (SAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and none transfer is issued.

When the source block size is not a multiple of the destination burst size, and is a multiple of the source data width, then the last programmed source burst is not completed and is internally shorten to match the block size. In this case, the additional GPDMA_CxTR3.SAO[12:0] is not applied.

17.8.17 GPDMA channel x block register 2 (GPDMA_CxBR2)

Address offset: 0xA8 + 0x80 * x (x = 4 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register controls the transfer of a channel x at a 2D/repeated block level.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block, 2D/repeated block, LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.UB2 = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRDAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

BRSAO[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **BRDAO[15:0]**: Block repeated destination address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRDDEC) the current destination address (GPDMA_CxDAR) at the end of a block transfer.

Note: A block repeated destination address offset must be aligned with the programmed data width of a destination burst (BRDAO[2:0] versus GPDMA_CxTR1.DDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRDAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

Bits 15:0 **BRSAO[15:0]**: Block repeated source address offset

For a channel with 2D addressing capability, this field is used to update (by addition or subtraction depending on GPDMA_CxBR1.BRSDEC) the current source address (GPDMA_CxSAR) at the end of a block transfer.

Note: A block repeated source address offset must be aligned with the programmed data width of a source burst (BRSAO[2:0] versus GPDMA_CxTR1.SDW_LOG2[1:0]). Else a user setting error is reported and no transfer is issued. BRSAO[15:0] must be set to 0 in peripheral flow-control mode (if GPDMA_CxTR2.PFREQ = 1).

17.8.18 GPDMA channel x linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 0 to 3)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Bit 31 **UT1**: Update GPDMA_CxTR1 from memory

This bit controls the update of GPDMA_CxTR1 from the memory during the link transfer.
0: no GPDMA_CxTR1 update
1: GPDMA_CxTR1 update

Bit 30 **UT2**: Update GPDMA_CxTR2 from memory

This bit controls the update of GPDMA_CxTR2 from the memory during the link transfer.
0: no GPDMA_CxTR2 update
1: GPDMA_CxTR2 update

Bit 29 **UB1**: Update GPDMA_CxBR1 from memory

This bit controls the update of GPDMA_CxBR1 from the memory during the link transfer.
If UB1 = 0 and if GPDMA_CxLLR ≠ 0, the linked-list is not completed.
GPDMA_CxBR1.BNDT[15:0] is then restored to the programmed value after data transfer is completed and before the link transfer.
0: no GPDMA_CxBR1 update from memory (GPDMA_CxBR1.BNDT[15:0] restored if any link transfer)
1: GPDMA_CxBR1 update

Bit 28 **USA**: update GPDMA_CxSAR from memory

This bit controls the update of GPDMA_CxSAR from the memory during the link transfer.
0: no GPDMA_CxSAR update
1: GPDMA_CxSAR update

Bit 27 **UDA**: Update GPDMA_CxDAR register from memory

This bit is used to control the update of GPDMA_CxDAR from the memory during the link transfer.

0: no GPDMA_CxDAR update

1: GPDMA_CxDAR update

Bits 26:17 Reserved, must be kept at reset value.

Bit 16 **ULL**: Update GPDMA_CxLLR register from memory

This bit is used to control the update of GPDMA_CxLLR from the memory during the link transfer.

0: no GPDMA_CxLLR update

1: GPDMA_CxLLR update

Bits 15:2 **LA[15:2]**: pointer (16-bit low-significant address) to the next linked-list data structure

If UT1 = UT2 = UB1 = USA = UDA = ULL = 0 and if LA[15:2] = 0, the current LLI is the last one. The channel transfer is completed without any update of the linked-list GPDMA register file.

Else, this field is the pointer to the memory address offset from which the next linked-list data structure is automatically fetched from, once the data transfer is completed, in order to conditionally update the linked-list GPDMA internal register file (GPDMA_CxTR1, GPDMA_CxTR2, GPDMA_CxBR1, GPDMA_CxSAR, GPDMA_CxDAR, and GPDMA_CxLLR).

Caution: The user must program this pointer not to exceed the 64-Kbyte addressable space defined by the link base address register GPDMA_CxLBAR. The complete linked-list data structure must be included in the 64-Kbyte addressable space.

Note: The user must program the pointer to be 32-bit aligned. The two low-significant bits are write ignored.

Bits 1:0 Reserved, must be kept at reset value.

17.8.19 GPDMA channel x alternate linked-list address register (GPDMA_CxLLR)

Address offset: 0xCC + 0x80 * x (x = 4 to 5)

Reset value: 0x0000 0000

This register is secure or nonsecure depending on the secure state of channel x (GPDMA_SECCFGR.SECx), and privileged or unprivileged, depending on the privileged state of channel x (GPDMA_PRIVCFGR.PRIVx).

This register configures the data structure of the next LLI in the memory and its address pointer. A channel transfer is completed when this register is null.

This register must be written when GPDMA_CxCR.EN = 0.

This register is read-only when GPDMA_CxCR.EN = 1.

This register must be written when the channel is completed (then the hardware has deasserted GPDMA_CxCR.EN). A channel transfer can be completed and programmed at different levels: block or LLI or full linked-list.

In linked-list mode, during the link transfer, this register is automatically updated by the GPDMA from the memory if GPDMA_CxLLR.ULL = 1.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

18 Nested vectored interrupt controller (NVIC)

18.1 NVIC main features

- 148 maskable interrupt channels (not including the 16 Cortex-M33 with FPU interrupt lines)
- 16 programmable priority levels (four bits of interrupt priority used)
- Low-latency exception and interrupt handling
- Power management control
- Implementation of system control registers

The NVIC and the processor core interface are closely coupled, enabling low-latency interrupt processing and efficient processing of late-arriving interrupts.

The NVIC registers are banked across secure and nonsecure states.

All interrupts. Including the core exceptions, are managed by the NVIC.

18.2 SysTick calibration value register

The Cortex-M33 with TrustZone mainline security extension embeds two SysTick timers.

When TrustZone is activated, the following SysTick timers are available:

- SysTick, secure instance
- SysTick, nonsecure instance

When TrustZone is disabled, only one SysTick timer is available.

The SysTick timer calibration value (STCALIB) is 0x3E8. It gives a reference time base of 1 ms based on a SysTick clock frequency of 1 MHz. To match the 1 ms time base for an application running at a given frequency, the SysTick reload value must be programmed as follows in the SYST_RVR register:

- When SysTick clock source is CPU clock HCLK reload value = (HCLK x STCALIB) - 1
- When SysTick clock source is external clock (HCLK/8) reload value = ((HCLK / 8) x STCALIB) - 1

The HCLK refers to the AHB frequency value in MHz.

Example: SysTick clock source is CPU clock HCLK of 100 MHz, to match a time base of 1 ms: SysTick reload value = (100 x STCALIB) - 1 = 0x1869F.

18.3 Interrupt and exception vectors

For the actual availability of some peripherals, refer to the datasheet. If not present, consider them as reserved.

1. When different signals are connected to the same NVIC interrupt line, they are OR-ed.
2. Refer to the Programming Manual of Cortex-M33 for more information about priority.
3. Security attribute configuration can be configured as secure or nonsecure.
4. NMI and BusFault can be configured to target secure or nonsecure state using BFHFNMINS, bit13 in Cortex-M33 AIRCR register.

   For more information, refer to Arm® Technical Reference Manuals.
5. SecureFault always targets secure state.
6. DebugMonitor exception can target secure or nonsecure state depending on debug authentication signals status DBGEN/NIDEN/SPIDEN/SPNIDEN. For more information, refer to Arm® Technical Reference Manuals.

19 Extended interrupts and event controller (EXTI)

The extended interrupts and event controller (EXTI) manages the individual CPU and system wake-up through configurable and direct event inputs. It provides wake-up requests to the power control and generates an interrupt request to the CPU NVIC and events to the CPU event input. For the CPU, an additional event generation block (EVG) is needed to generate the CPU event signal.

The EXTI wake-up requests allow the system to be woken up from Stop modes.

The interrupt request and event request generation can be used also in Run modes.

The EXTI also includes the EXTI mux IO port selection.

19.1 EXTI main features

The EXTI main features are the following:

- 59 input events supported.
- All event inputs allow the possibility to wake up the system.
- Events that do not have an associated wake-up flag in the peripheral, have a flag in the EXTI and generate an interrupt to the CPU from the EXTI.
- Events can be used to generate a CPU wake-up event.

The asynchronous event inputs are classified in two groups:

- Configurable events (signals from I/Os or peripherals able to generate a pulse), with the following features
  - Selectable active trigger edge
  - Interrupt pending status register bits independent for the rising and falling edge
  - Individual interrupt and event generation mask, used for conditioning the CPU wake-up, interrupt and event generation
  - Software trigger possibility
  - Secure events: The access to control and configuration bits of secure input events can be made secure and or privilege.
  - EXTI IO port selection
- Direct events (interrupt and wake-up sources from peripherals having an associated flag which requires to be cleared in the peripheral), with the following features:
  - Fixed rising edge active trigger
  - No interrupt pending status register bit in the EXTI (the interrupt pending status flag is provided by the peripheral generating the event)
  - Individual interrupt generation mask, used to condition the CPU wake-up generation
  - No software trigger possibility

19.2 EXTI block diagram

The EXTI consists of a register block accessed via an AHB interface, the event input trigger block, the masking block and EXTI mux as shown in *Figure 135*.

The register block contains all the EXTI registers.

The event input trigger block provides event input edge trigger logic.

The masking block provides the event input distribution to the different wake-up, interrupt and event outputs, and their masking.

The EXTI mux provides the IO port selection on to the EXTI event signal.

Figure 135. EXTI block diagram

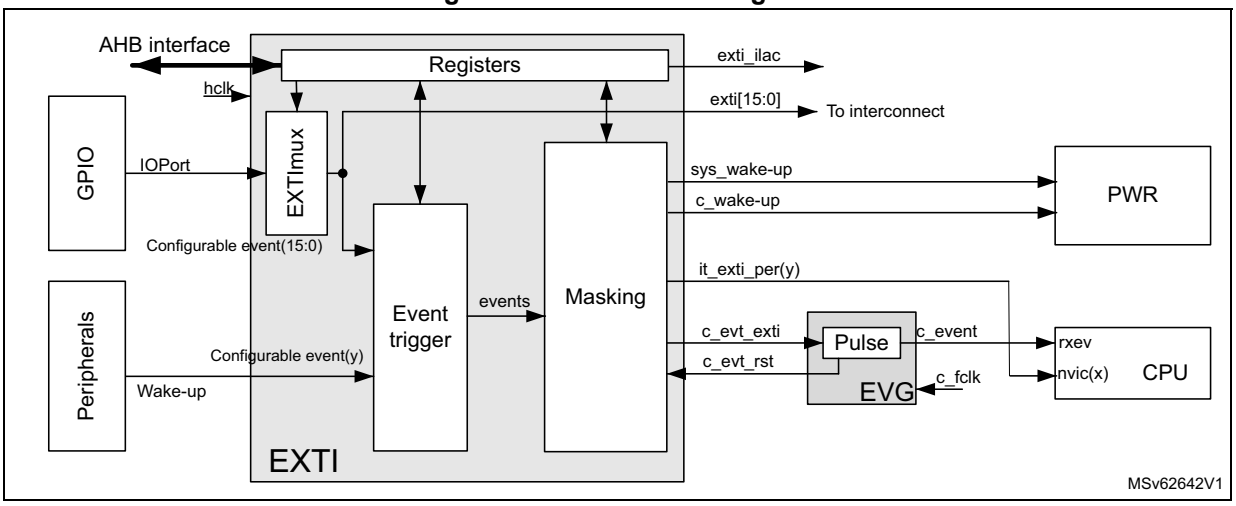

Table 174. EXTI signals

Pin name	I/O	Description
AHB interface	I/O	EXTI register bus interface. When one event is configured to enable security, the AHB interface supports secure accesses.
hclk	I	AHB bus clock and EXTI system clock
Configurable event(y)	I	Asynchronous wake-up events from peripherals without an associated interrupt and flag
Direct event(x)	I	Synchronous and asynchronous wake-up events from peripherals with an associated interrupt and flag
exti_ilac	O	Illegal access event
IOPort(n)	I	GPIOs block IO ports[15:0]
exti[15:0]	O	EXTI GPIO output port to trigger other peripherals
it_exti_per (y)	O	Interrupts to the CPU associated with configurable event (y)
c_evt_exti	O	High-level sensitive event output for CPU, synchronous to hclk
c_evt_rst	I	Asynchronous reset input to clear c_evt_exti
sys_wakeup	O	Asynchronous system wake-up request to PWR for ck_sys and hclk
c_wakeup	O	Wake-up request to PWR for CPU, synchronous to hclk

Table 175. EVG signals

Pin name	I/O	Description
c_fclk	I	CPU free running clock
c_evt_in	I	High-level sensitive events input from EXTI, asynchronous to CPU clock
c_event	O	Event pulse, synchronous to CPU clock
c_evt_rst	O	Event reset signal, synchronous to CPU clock

19.2.1 EXTI connections between peripherals and CPU

Some peripherals able to generate wake-up or interrupt events when the system is in Stop mode are connected to the EXTI.

- Peripheral wake-up signals that generate a pulse or do not have an interrupt status bits in the peripheral are connected to an EXTI configurable event input. For these events, the EXTI provides a status pending bit to be cleared. It is the EXTI interrupt, associated with the status bit, that interrupts the CPU.
- Peripheral interrupt and wake-up signals with a status bit in the peripheral to be cleared are connected to an EXTI direct event input. There is no status pending bit within the EXTI. The interrupt or wake-up is cleared by the CPU in the peripheral. It is the peripheral interrupt that interrupts the CPU directly.
- All GPIO ports input to the EXTI multiplexer allow the selection of a port pin to wake up the system via a configurable event.

The EXTI configurable event interrupts are connected to the NVIC.

The dedicated EXTI/EVG CPU event is connected to the CPU rxev input.

The EXTI CPU wake-up signals are connected to the PWR and are used to wake up the system and the CPU subsystem bus clocks.

19.2.2 EXTI interrupt/event mapping

The EXTI lines are connected as shown in the table below.

Table 176. EXTI line connections

EXTI line	Line source	Line type

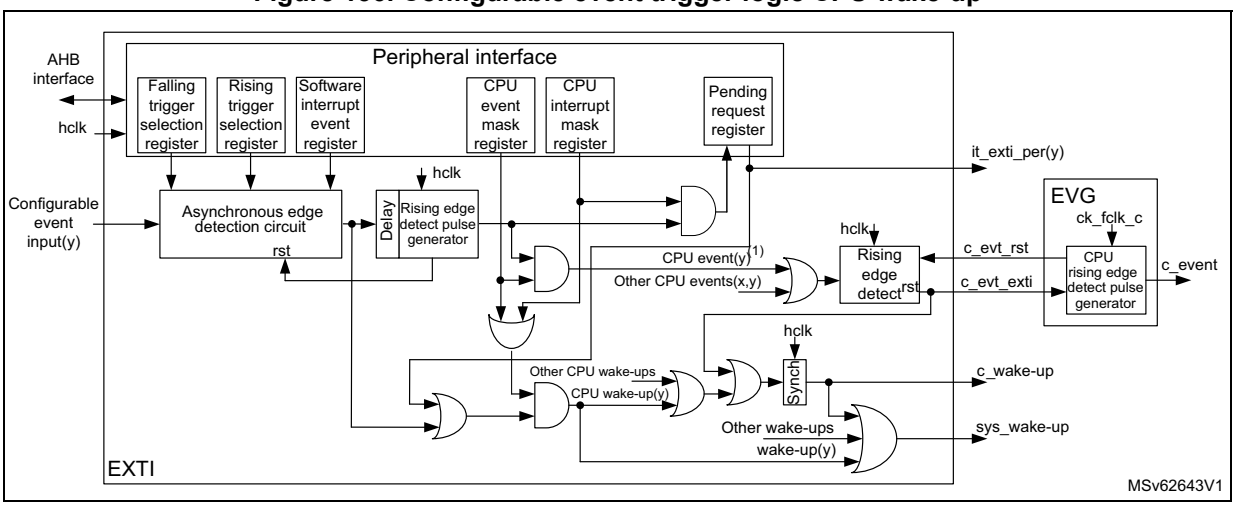
1. EXTI lines 23, 27, 42, 47, 48, 51, 52 (and corresponding control bits in registers) are available only on STM32G55x/56x devices.

19.3 EXTI functional description



The events features are controlled from register bits as follows:

- Active trigger edge enable
  - by rising edge selection in *EXTI rising trigger selection register (EXTI_RTSR1)* and *EXTI rising trigger selection register 2 (EXTI_RTSR2)*
  - by falling edge selection in *EXTI falling trigger selection register (EXTI_FTSR1)* and *EXTI falling trigger selection register 2 (EXTI_FTSR2)*
- Software trigger in the *EXTI software interrupt event register (EXTI_SWIER1)* and *EXTI software interrupt event register 2 (EXTI_SWIER2)*
- Interrupt pending flag in
  - *EXTI rising edge pending register (EXTI_RPR1)* and *EXTI rising edge pending register 2 (EXTI_RPR2)*
  - *EXTI falling edge pending register (EXTI_FPR1)* and *EXTI falling edge pending register 2 (EXTI_FPR2)*
- CPU wake-up and interrupt enable in *EXTI CPU wake-up with interrupt mask register (EXTI_IMR1)* and *EXTI CPU wake-up with interrupt mask register 2 (EXTI_IMR2)*
- CPU wake-up and event enable in *EXTI CPU wake-up with event mask register (EXTI_EMR1)* and *EXTI CPU wake-up with event mask register 2 (EXTI_EMR2)*

19.3.1 EXTI configurable event input wake-up

The figure below details the logic associated with configurable event inputs that wake up the CPU subsystem bus clocks, and generate an EXTI pending flag and interrupt to the CPU, and/or a CPU wake-up event.

Figure 136. Configurable event trigger logic CPU wake-up

1. Only for the input events that support CPU rxev generation c_event.

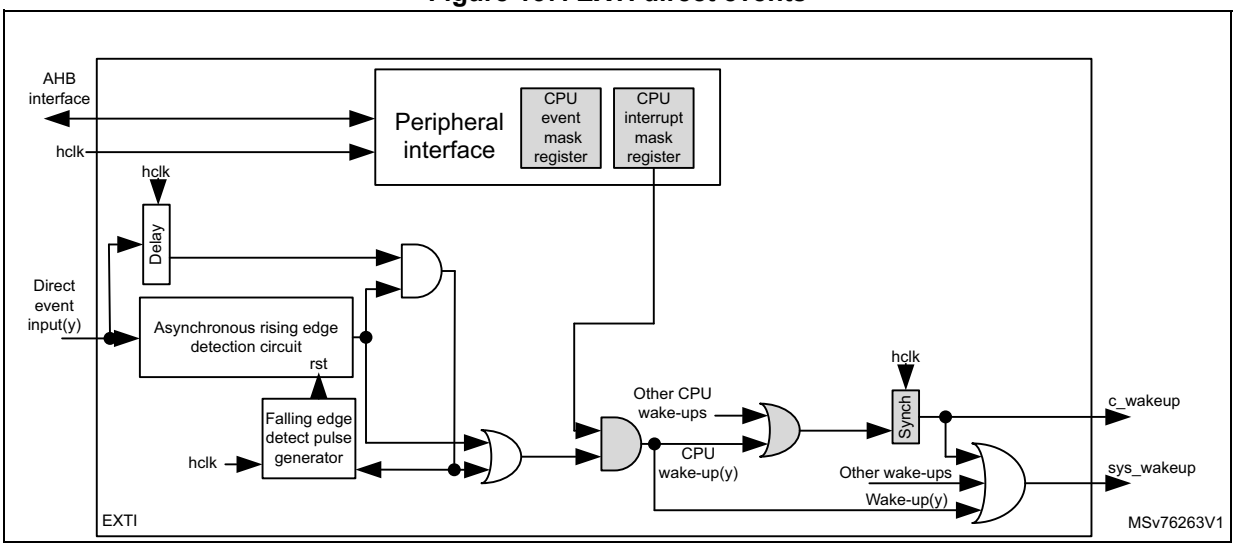
The software interrupt event register allows configurable events to be triggered by software, writing the corresponding register bit, whatever the edge selection setting.

The configurable event active trigger edge (or both edges) is selected and enabled in the rising/falling edge selection registers.

The CPU has its dedicated wake-up (interrupt) mask register and a dedicated event mask registers. When the event is enabled, it is generated to the CPU. All events for the CPU are ORed together into a single CPU event signal. The event pending registers (EXTI_RPR and EXTI_FPR) are not set for an unmasked CPU event.

The configurable events have unique interrupt pending request registers. The pending register is only set for an unmasked interrupt. Each configurable event provides a common interrupt to the CPU. The configurable event interrupts must be acknowledged by software in the EXTI_RPR and/or EXTI_FPR registers.

When a CPU wake-up (interrupt) or CPU event is enabled, the asynchronous edge detection circuit is reset by the clocked delay and rising edge detect pulse generator. This guarantees that the EXTI hclk clock is woken up before the asynchronous edge detection circuit is reset.



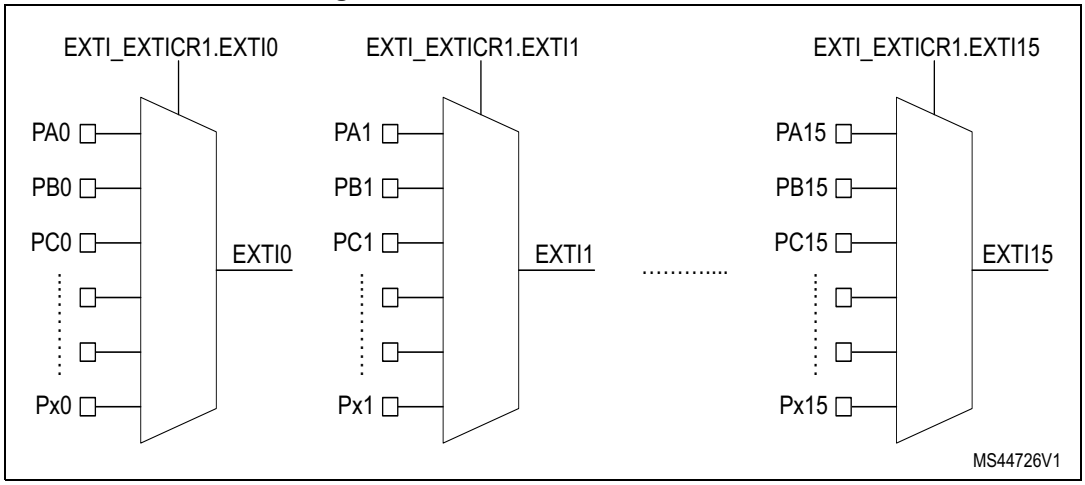
Note: A detected configurable event interrupt pending request can be cleared by the CPU with the correct access permission. The system is not able to enter low-power modes as long as an interrupt pending request is active.

19.3.2 EXTI direct event input wake-up

The direct events do not have an associated EXTI interrupt. The EXTI only wakes up the system and CPU subsystem clocks. The peripheral synchronous interrupt, associated with the direct wake-up event, wakes up the CPU.

The EXTI direct event is able to wake up the CPU.

Figure 137. EXTI direct events



19.3.3 EXTI mux selection

The EXTI mux allows the selection of GPIOs as interrupts and wake-up. GPIOs are connected via 16 EXTI mux lines to the first 16 EXTI events as configurable event. The

selection of GPIO port as EXTI mux output is controlled in the *EXTI external interrupt selection register (EXTI_EXTICR1)*.

Figure 138. EXTI mux GPIO selection

The EXTI mux outputs are available as output signals from the EXTI to trigger other peripherals, whatever the masking in EXTI_IMR and EXTI_EMR registers.

19.4 EXTI functional behavior

The configurable events are enabled by enabling at least one of the trigger edges.

Once an event input is enabled, the CPU wake-up generation is conditioned by the CPU interrupt mask and CPU event mask.

Table 177. Masking functionality

CPU interrupt enable (in EXTI_IMR.IMn)	CPU event enable (in EXTI_EMR.EMn)	Configurable event inputs (in EXTI_RPR.RPIFn and EXTI_FPR.FPIFn)	Exti(n) interrupt(1)	CPU event	CPU wake-up
0	0	No	Masked	Masked	Masked
	1	No	Masked	Yes	Yes
1	0	Status latched	Yes	Masked	Yes(2)
	1	Status latched	Yes	Yes	Yes

1. The single exti(n) interrupt goes to the CPU. If no interrupt is required for CPU(m), the exti(n) interrupt must be masked in the CPU NVIC.
2. Only if CPU interrupt is enabled in EXTI_IMR.IMn.

For configurable event inputs, when the enabled edges occur on the event input, an event request is generated. When the associated CPU interrupt is unmasked, the corresponding pending bits EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn is/are set: the CPU subsystem is woken up and the CPU interrupt signal is activated. The EXTI_RPR.RPIFn and/or EXTI_FPR.FPIFn pending bits must be cleared by software writing them to 1. This action clears the CPU interrupt.

For the configurable event inputs, an event request can be generated by software when writing a 1 in the software interrupt/event register EXTI_SWIER, allowing the generation of a rising edge on the event. The rising edge event pending bit is set in EXTI_RPR, whatever the setting in EXTI_RTSR.

19.5 EXTI event protection

The EXTI is able to protect event register bits from being modified by nonsecure and unprivileged accesses. The protection is individually activated per input event via the register bits in EXTI_SECCFGR and EXTI_PRIVCFGR. At EXTI level, the protection consists in preventing the following unauthorized write access:

- Change the settings of the secure and/or privileged configurable events.
- Change the masking of the secure and/or privileged input events.
- Clear pending status of the secure and/or privileged input events.

Table 178. Register protection overview

Register name	Access type	Protection(1)(2)
EXTI_RTSR	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_FTSR	RW	
EXTI_SWIER	RW	
EXTI_RPR	RW	
EXTI_FPR	RW	
EXTI_SECCFGR	RW	Always secure. Privilege can be bit-wise enabled in EXTI_PRIVCFGR.
EXTI_PRIVCFGR	RW	Always privilege. Security can be bit-wise enabled in EXTI_SECCFGR.
EXTI_EXTICRn	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_LOCKR	RW	Always secure
EXTI_IM	RW	Security and privilege can be bit-wise enabled in EXTI_SECCFGR and EXTI_PRIVCFGR.
EXTI_EMR	RW	

1. Security is enabled with the individual input event (EXTI_SECCFGR register).
2. Privilege is enabled with the individual Input event (EXTI_PRIVCFGR register).

19.5.1 EXTI security protection

When security is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a secure access. A nonsecure write access is discarded and a read returns 0.

When input events are nonsecure, the security is disabled. The associated input event configuration and control bits can be modified and read by a secure access and nonsecure access.

The security configuration in registers EXTI_SECCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

19.5.2 EXTI privilege protection

When privilege is enabled for an input event, the associated input event configuration and control bits can only be modified and read by a privileged access. An unprivileged write access is discarded and a read returns 0.

When input events are unprivileged, the privilege is disabled. The associated input event configuration and control bits can be modified and read by a privileged access and unprivileged access.

The privileged configuration in registers EXTI_PRIVCFGR can be globally locked after reset by EXTI_LOCKR.LOCK.

19.6 EXTI registers

Table 179. EXTI register map sections

Address offset	Description
0x000 - 0x01C	General configurable event [31:0] configuration
0x020 - 0x03C	General configurable event [58:32] configuration
0x060 - 0x06C	EXTI IO port mux selection
0x070	EXTI protection lock configuration
0x080 - 0x0BC	CPU input event configuration

All registers can be accessed with word (32-bit), half-word (16-bit), and byte (8-bit) access.

19.6.1 EXTI rising trigger selection register (EXTI_RTSR1)

Address offset: 0x000

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT16
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RT15	RT14	RT13	RT12	RT11	RT10	RT9	RT8	RT7	RT6	RT5	RT4	RT3	RT2	RT1	RT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.

0: Rising trigger disabled (for event and interrupt) for input line

1: Rising trigger enabled (for event and interrupt) for input line

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

19.6.2 EXTI falling trigger selection register (EXTI_FTSR1)

Address offset: 0x004

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT16
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FT15	FT14	FT13	FT12	FT11	FT10	FT9	FT8	FT7	FT6	FT5	FT4	FT3	FT2	FT1	FT0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FTx:** Falling trigger event configuration bit of configurable event input x [(1)] (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Nonsecure write to this FTx is discarded, nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.

0: Falling trigger disabled (for event and Interrupt) for input line

1: Falling trigger enabled (for event and Interrupt) for input line.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

19.6.3 EXTI software interrupt event register (EXTI_SWIER1)

Address offset: 0x008

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI16
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SWI15	SWI14	SWI13	SWI12	SWI11	SWI10	SWI9	SWI8	SWI7	SWI6	SWI5	SWI4	SWI3	SWI2	SWI1	SWI0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **SWIx:** Software interrupt on event x (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Nonsecure write to this SWI x is discarded, nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.

A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.

0: Writing 0 has no effect.

1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

19.6.4 EXTI rising edge pending register (EXTI_RPR1)

Address offset: 0x00C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF16
															rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RPIF15	RPIF14	RPIF13	RPIF12	RPIF11	RPIF10	RPIF9	RPIF8	RPIF7	RPIF6	RPIF5	RPIF4	RPIF3	RPIF2	RPIF1	RPIF0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **RPIFx:** configurable event inputs x rising edge pending bit (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Nonsecure write to this RPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

19.6.5 EXTI falling edge pending register (EXTI_FPR1)

Address offset: 0x010

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF16
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FPIF15	FPIF14	FPIF13	FPIF12	FPIF11	FPIF10	FPIF9	FPIF8	FPIF7	FPIF6	FPIF5	FPIF4	FPIF3	FPIF2	FPIF1	FPIF0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **FPIFx:** configurable event inputs x falling edge pending bit (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Nonsecure write to this FPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

19.6.6 EXTI security configuration register (EXTI_SECCFGR1)

Address offset: 0x014

Reset value: 0x0000 0000

This register provides write access security, a nonsecure write access is ignored and causes the generation of an illegal access event. A nonsecure read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SEC30	SEC29	SEC28	SEC27	SEC26	SEC25	SEC24	SEC23	SEC22	SEC21	SEC20	SEC19	SEC18	SEC17	SEC16
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC15	SEC14	SEC13	SEC12	SEC11	SEC10	SEC9	SEC8	SEC7	SEC6	SEC5	SEC4	SEC3	SEC2	SEC1	SEC0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 **SECx:** Security enable on event input x (x = 30 to 0)

When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

19.6.7 EXTI privilege configuration register (EXTI_PRIVCFGR1)

Address offset: 0x018

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	PRIV30	PRIV29	PRIV28	PRIV27	PRIV26	PRIV25	PRIV24	PRIV23	PRIV22	PRIV21	PRIV20	PRIV19	PRIV18	PRIV17	PRIV16
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIV15	PRIV14	PRIV13	PRIV12	PRIV11	PRIV10	PRIV9	PRIV8	PRIV7	PRIV6	PRIV5	PRIV4	PRIV3	PRIV2	PRIV1	PRIV0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 **PRIVx:** Security enable on event input x (x = 30 to 0)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. nonsecure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

19.6.8 EXTI rising trigger selection register 2 (EXTI_RTSR2)

Address offset: 0x020

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	RT57	RT56	RT55	RT54	RT53	Res.	RT51	RT50	Res.	Res.
						rw	rw	rw	rw	rw		rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RT36	RT35	RT34	RT33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 57 to 53)
When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **RTx:** Rising trigger event configuration bit of configurable event input x[(1)] (x = 51 to 50)
When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **RTx:** Rising trigger event configuration bit of configurable event input x[1] (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, RTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RTx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RTx can only be accessed with privileged access. Unprivileged write to this bit x is discarded, unprivileged read returns 0.
0: Rising trigger disabled (for event and interrupt) for input line
1: Rising trigger enabled (for event and interrupt) for input line

Bit 0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a rising edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

19.6.9 EXTI falling trigger selection register 2 (EXTI_FTSR2)

Address offset: 0x024

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FT57	FT56	FT55	FT54	FT53	Res.	FT51	FT50	Res.	Res.
						rw	rw	rw	rw	rw		rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FT36	FT35	FT34	FT33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **FTx:** Falling trigger event configuration bit of configurable event input x[1] (x = 57 to 53)
When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Nonsecure write to this FTx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **FTx:** Falling trigger event configuration bit of configurable event input x[1] (x = 51 to 50)
When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Nonsecure write to this FTx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **FTx:** Falling trigger event configuration bit of configurable event input x[1] (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, FTx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FTx can only be accessed with secure access. Nonsecure write to this FTx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FTx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FTx can only be accessed with privileged access. Unprivileged write to this FTx is discarded, unprivileged read returns 0.
0: Falling trigger disabled (for event and Interrupt) for input line
1: Falling trigger enabled (for event and Interrupt) for input line.

Bit 0 Reserved, must be kept at reset value.

1. The configurable event inputs are edge triggered, no glitch must be generated on these inputs.
If a falling edge on the configurable event input occurs during writing of the register, the associated pending bit is not set.
Rising and falling edge triggers can be set for the same configurable event input. In this case, both edges generate a trigger.

19.6.10 EXTI software interrupt event register 2 (EXTI_SWIER2)

Address offset: 0x028

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	SWI57	SWI56	SWI55	SWI54	SWI53	Res.	SWI51	SWI50	Res.	Res.
						rw	rw	rw	rw	rw		rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWI36	SWI35	SWI34	SWI33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **SWIx:** Software interrupt on event x (x = 57 to 53)
When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Nonsecure write to this SWI x is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.
A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.
0: Writing 0 has no effect.
1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **SWIx:** Software interrupt on event x (x = 51 to 50)
When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Nonsecure write to this SWI x is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.
A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.
0: Writing 0 has no effect.
1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **SWIx:** Software interrupt on event x (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, SWIx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, SWIx can only be accessed with secure access. Nonsecure write to this SWI x is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, SWIx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SWIx can only be accessed with privileged access. Unprivileged write to this SWIx is discarded, unprivileged read returns 0.
A software interrupt is generated independent from the setting in EXTI_RTSR and EXTI_FTSR. It always returns 0 when read.
0: Writing 0 has no effect.
1: Writing 1 triggers a rising edge event on event x. This bit is auto cleared by hardware.

Bit 0 Reserved, must be kept at reset value.

19.6.11 EXTI rising edge pending register 2 (EXTI_RPR2)

Address offset: 0x02C

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	RPIF57	RPIF56	RPIF55	RPIF54	RPIF53	Res.	RPIF51	RPIF50	Res.	Res.
						rw	rw	rw	rw	rw		rw	rw		
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RPIF36	RPIF35	RPIF34	RPIF33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **RPIFx:** configurable event inputs x rising edge pending bit (x = 57 to 53)

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Nonsecure write to this RPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **RPIFx:** configurable event inputs x rising edge pending bit (x = 51 to 50)

When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Nonsecure write to this RPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **RPIFx:** configurable event inputs x rising edge pending bit (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, RPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, RPIFx can only be accessed with secure access. Nonsecure write to this RPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, RPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, RPIFx can only be accessed with privileged access. Unprivileged write to this RPIFx is discarded, unprivileged read returns 0.
0: No rising edge trigger request occurred
1: Rising edge trigger request occurred
This bit is set when the rising edge event or an EXTI_SWIER software trigger arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 0 **Reserved, must be kept at reset value.**

19.6.12 EXTI falling edge pending register 2 (EXTI_FPR2)

Address offset: 0x030

Reset value: 0x0000 0000

Contains only register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FPIF57	FPIF56	FPIF55	FPIF54	FPIF53	Res.	FPIF51	FPIF50	Res.	Res.
						rw	rw	rw	rw	rw		rw	rw		

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FPIF36	FPIF35	FPIF34	FPIF33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **FPIFx:** configurable event inputs x falling edge pending bit (x = 57 to 53)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Nonsecure write to this FPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **FPIFx:** configurable event inputs x falling edge pending bit (x = 51 to 50)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Nonsecure write to this FPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **FPIFx:** configurable event inputs x falling edge pending bit (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, FPIFx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, FPIFx can only be accessed with secure access. Nonsecure write to this FPIFx is discarded, nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, FPIFx can be accessed with unprivileged and privileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, FPIFx can only be accessed with privileged access. Unprivileged write to this FPIFx is discarded, unprivileged read returns 0.
0: No falling edge trigger request occurred
1: Falling edge trigger request occurred
This bit is set when the falling edge event arrives on the configurable event line. This bit is cleared by writing 1 to it.

Bit 0 Reserved, must be kept at reset value.

19.6.13 EXTI security configuration register 2 (EXTI_SECCFGR2)

Address offset: 0x034

Reset value: 0x0000 0000

This register provides write access security, a nonsecure write access is ignored and causes the generation of an illegal access event. A nonsecure read returns the register data.

Contains only register bits for privilege capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	SEC58	SEC57	SEC56	SEC55	SEC54	SEC53	SEC52	SEC51	SEC50	Res.	SEC48
					rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SEC47	Res.	Res.	Res.	Res.	SEC42	SEC41	SEC40	Res.	SEC38	SEC37	SEC36	SEC35	SEC34	SEC33	Res.
rw					rw	rw	rw		rw	rw	rw	rw	rw	rw	

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:18 **SECx:** Security enable on event input x (x = 58 to 50)
When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

Bit 17 Reserved, must be kept at reset value.

Bits 16:15 **SECx:** Security enable on event input x (x = 48 to 47)
When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **SECx:** Security enable on event input x (x = 42 to 40)
When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

Bit 7 Reserved, must be kept at reset value.

Bits 6:1 **SECx:** Security enable on event input x (x = 38 to 33)
When EXTI_PRIVCFGR.PRIVx is disabled, SECx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, SECx can only be written with privileged access. Unprivileged write to this SECx is discarded.
0: Event security disabled (nonsecure)
1: Event security enabled (secure)

Bit 0 Reserved, must be kept at reset value.

19.6.14 EXTI privilege configuration register 2 (EXTI_PRIVCFGR2)

Address offset: 0x038

Reset value: 0x0000 0000

This register provides privileged write access protection. An unprivileged read returns the register data.

Contains only register bits for security capable input events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PRIV58	PRIV57	PRIV56	PRIV55	PRIV54	PRIV53	PRIV52	PRIV51	PRIV50	Res.	PRIV48
					rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PRIV47	Res.	Res.	Res.	Res.	PRIV42	PRIV41	PRIV40	Res.	PRIV38	PRIV37	PRIV36	PRIV35	PRIV34	PRIV33	Res.
rw					rw	rw	rw		rw	rw	rw	rw	rw	rw	

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:18 **PRIVx:** Security enable on event input x (x = 58 to 50)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Nonsecure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

Bit 17 Reserved, must be kept at reset value.

Bits 16:15 **PRIVx:** Security enable on event input x (x = 48 to 47)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Nonsecure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **PRIVx:** Security enable on event input x (x = 42 to 40)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Nonsecure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

Bit 7 Reserved, must be kept at reset value.

Bits 6:1 **PRIVx:** Security enable on event input x (x = 38 to 33)
When EXTI_SECCFGR.SECx is disabled, PRIVx can be accessed with secure and nonsecure access.
When EXTI_SECCFGR.SECx is enabled, PRIVx can only be written with secure access. Nonsecure write to this PRIVx is discarded.
0: Event privilege disabled (unprivileged)
1: Event privilege enabled (privileged)

Bit 0 Reserved, must be kept at reset value.

19.6.15 EXTI external interrupt selection register (EXTI_EXTICR1)

Address offset: 0x060

(EXTI mux 0, 1, 2, 3)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
EXTI3[7:0]								EXTI2[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 7:0 **EXTI12[7:0]:** EXTI12 GPIO port selection

These bits are written by software to select the source input for EXTI12 external interrupt.
When EXTI_SECCFGR1.SEC12 is disabled, EXTI12 can be accessed with nonsecure and secure access.
When EXTI_SECCFGR1.SEC12 is enabled, EXTI12 can only be accessed with secure access. Nonsecure write is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR1.PRIV12 is disabled, EXTI12 can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR1.PRIV12 is enabled, EXTI12 can only be accessed with privileged access. Unprivileged write to this bit is discarded.

19.6.19 EXTI lock register (EXTI_LOCKR)

Address offset: 0x070

Reset value: 0x0000 0000

This register provides write access security: a nonsecure write access is ignored, a read access returns zero data, and both generate an illegal access event.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LOCK
															rs

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **LOCK**: Global security and privilege configuration registers (EXTI_SECCFGR and EXTI_PRIVCFGR) lock
This bit is written once after reset.
0: Security and privilege configuration open, can be modified.
1: Security and privilege configuration locked, can no longer be modified.

19.6.20 EXTI CPU wake-up with interrupt mask register (EXTI_IMR1)

Address offset: 0x080

Reset value: 0x7FFE 0000

Contains register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	IM30	IM29	IM28	IM27	IM26	IM25	IM24	IM23	IM22	IM21	IM20	IM19	IM18	IM17	IM16
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:0 **IMx:** CPU wake-up with interrupt mask on event input x [1] (x = 30 to 0)
When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Nonsecure write to this bit is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with interrupt request from input event x is masked.
1: Wake-up with interrupt request from input event x is unmasked.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

19.6.21 EXTI CPU wake-up with event mask register (EXTI_EMR1)

Address offset: 0x084

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bits 16:0 **EMx:** CPU wake-up with event generation mask on event input x (x = 16 to 0)

When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wake-up with event generation from Line x is masked.

1: Wake-up with event generation from Line x is unmasked.

19.6.22 EXTI CPU wake-up with interrupt mask register 2 (EXTI_IMR2)

Address offset: 0x090

Reset value: 0x0411 8760

Contains register bits for configurable events.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	IM58	IM57	IM56	IM55	IM54	IM53	IM52	IM51	IM50	Res.	IM48
					rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

rw					rw	rw	rw		rw	rw	rw	rw	rw	rw	

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:18 **IMx:** CPU wake-up with interrupt mask on event input x[(1)] (x = 58 to 50)

When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.

When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Nonsecure write to this bit is discarded and nonsecure read returns 0.

When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.

When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.

0: Wake-up with interrupt request from input event x is masked.

1: Wake-up with interrupt request from input event x is unmasked.

Bit 17 Reserved, must be kept at reset value.

Bits 16:15 **IMx:** CPU wake-up with interrupt mask on event input x[1] (x = 48 to 47)
When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Nonsecure write to this bit is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with interrupt request from input event x is masked.
1: Wake-up with interrupt request from input event x is unmasked.

Bits 14:11 Reserved, must be kept at reset value.

Bits 10:8 **IMx:** CPU wake-up with interrupt mask on event input x[1] (x = 42 to 40)
When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Nonsecure write to this bit is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with interrupt request from input event x is masked.
1: Wake-up with interrupt request from input event x is unmasked.

Bit 7 Reserved, must be kept at reset value.

Bits 6:1 **IMx:** CPU wake-up with interrupt mask on event input x[1] (x = 38 to 33)
When EXTI_SECCFGR.SECx is disabled, IMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, IMx can only be accessed with secure access. Nonsecure write to this bit is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, IMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, IMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with interrupt request from input event x is masked.
1: Wake-up with interrupt request from input event x is unmasked.

Bit 0 Reserved, must be kept at reset value.

1. The reset value for configurable event inputs is set to 0 in order to disable the interrupt by default.

19.6.23 EXTI CPU wake-up with event mask register 2 (EXTI_EMR2)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	EM36	EM35	EM34	EM33	Res.
											rw	rw	rw	rw	

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:21 **EMx:** CPU wake-up with event generation mask on event input x (x = 57 to 53)
When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with event generation from Line x is masked.
1: Wake-up with event generation from Line x is unmasked.

Bit 20 Reserved, must be kept at reset value.

Bits 19:18 **EMx:** CPU wake-up with event generation mask on event input x (x = 51 to 50)
When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with event generation from Line x is masked.
1: Wake-up with event generation from Line x is unmasked.

Bits 17:5 Reserved, must be kept at reset value.

Bits 4:1 **EMx:** CPU wake-up with event generation mask on event input x (x = 36 to 33)
When EXTI_SECCFGR.SECx is disabled, EMx can be accessed with nonsecure and secure access.
When EXTI_SECCFGR.SECx is enabled, EMx can only be accessed with secure access. Nonsecure write to this bit x is discarded and nonsecure read returns 0.
When EXTI_PRIVCFGR.PRIVx is disabled, EMx can be accessed with privileged and unprivileged access.
When EXTI_PRIVCFGR.PRIVx is enabled, EMx can only be accessed with privileged access. Unprivileged write to this bit is discarded.
0: Wake-up with event generation from Line x is masked.
1: Wake-up with event generation from Line x is unmasked.

Bit 0 Reserved, must be kept at reset value.

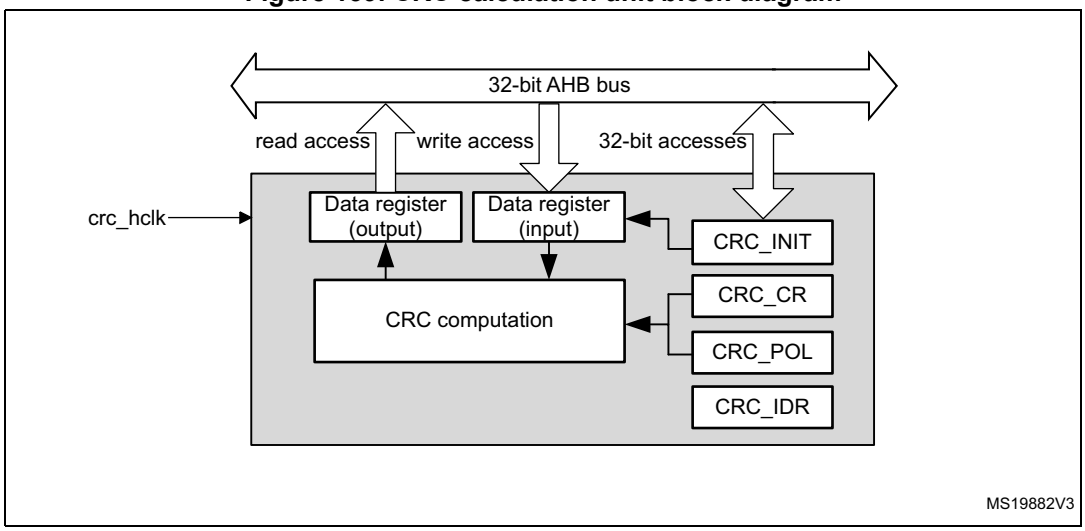
20 Cyclic redundancy check calculation unit (CRC)

20.1 CRC introduction

The CRC (cyclic redundancy check) calculation unit is used to get a CRC code from 8-, 16- or 32-bit data word and a generator polynomial.

Among other applications, CRC-based techniques are used to verify data transmission or storage integrity. In the scope of the functional safety standards, they offer a means of verifying the flash memory integrity. The CRC calculation unit helps compute a signature of the software during runtime, to be compared with a reference signature generated at link time and stored at a given memory location.



20.2 CRC main features

- Uses CRC-32 (Ethernet) polynomial: 0x4C11DB7
  $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$
- Alternatively, uses fully programmable polynomial with programmable size (7, 8, 16, 32 bits)
- Handles 8-,16-, 32-bit data size
- Programmable CRC initial value
- Single input/output 32-bit data register
- Input buffer to avoid bus stall during calculation
- CRC computation done in 4 AHB clock cycles (HCLK) for the 32-bit data size
- General-purpose 8-bit register (can be used for temporary storage)
- Reversibility options on I/O data
- Accessed through AHB slave peripheral by 32-bit words only, with the exception of CRC_DR register that can be accessed by words, right-aligned half-words and right-aligned bytes

20.3 CRC functional description

20.3.1 CRC block diagram

Figure 139. CRC calculation unit block diagram

20.3.2 CRC internal signals

Table 181. CRC internal input/output signals

Signal name	Signal type	Description
crc_hclk	Digital input	AHB clock

20.3.3 CRC operation

The CRC calculation unit has a single 32-bit read/write data register (CRC_DR). It is used to input new data (write access), and holds the result of the previous CRC calculation (read access).

Each write operation to the data register creates a combination of the previous CRC value (stored in CRC_DR) and the new one. CRC computation is done on the whole 32-bit data word or byte by byte depending on the format of the data being written.

The CRC_DR register can be accessed by word, right-aligned half-word and right-aligned byte. When the RTYPE_IN bit is set in CRC_CR, non-word accesses to CRC_DR register are ignored. For the other registers only 32-bit accesses are allowed.

The duration of the computation depends on input data width:

- 4 AHB clock cycles for 32 bits
- 2 AHB clock cycles for 16 bits
- 1 AHB clock cycles for 8 bits

An input buffer allows a second data to be immediately written without waiting for any wait-states due to the previous CRC calculation.

The data size can be dynamically adjusted to minimize the number of write accesses for a given number of bytes. For instance, a CRC for 5 bytes can be computed with a word write followed by a byte write.

The input data can be reversed to manage the various endianness schemes. The reversing operation can be performed on 8 bits, 16 bits and 32 bits depending on the REV_IN[1:0] bits in the CRC_CR register. If RTYPE_IN bit is set in this register, the input reversing operation can be performed with a byte or half-word granularity, but not with single bit granularity.

For example, with RTYPE_IN cleared, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x58D43CB2 with bit-reversal done by byte (REV_IN[1:0] = 01)
- 0xD458B23C with bit-reversal done by half-word (REV_IN[1:0] = 10)
- 0xB23CD458 with bit-reversal done on the full word (REV_IN[1:0] = 11)

With RTYPE_IN set, 0x1A2B3C4D input data are used for CRC calculation as:

- 0x3C4D1A2B with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x4D3C2B1A with byte-reversal done by word (REV_IN[1:0] = 10)

The output data can also be reversed by setting the REV_OUT[1:0] bits in the CRC_CR register. If RTYPE_OUT is set in this register, the output reversing operation is performed with a byte or half-word granularity, but not with single bit granularity.

With RTYPE_OUT cleared, the operation is done at bit level. For example, 0x11223344 output data are converted to 0x22CC4488.

With RTYPE_OUT set, 0x11223344 output data are converted as:

- 0x33441122 with half-word reversal done by word (REV_IN[1:0] = 01)
- 0x44332211 with byte-reversal done by word (REV_IN[1:0] = 10)

The CRC calculator can be initialized to a programmable value using the RESET control bit in the CRC_CR register (the default value is 0xFFFFFFFF).

The initial CRC value can be programmed with the CRC_INIT register. The CRC_DR register is automatically initialized upon CRC_INIT register write access.

The CRC_IDR register can be used to hold a temporary value related to CRC 7-, 8-, 16-, and 32-bit calculations. It is not affected by the RESET bit in the CRC_CR register.

Polynomial programmability

The polynomial coefficients are fully programmable through the CRC_POL register, and the polynomial size can be configured to be 7-, 8-, 16-, or 32-bits by programming the POLYSIZE[1:0] bits in the CRC_CR register. Even polynomials are not supported.

Note: The type of an even polynomial is $X+X^2+..+X^n$, while the type of an odd polynomial is $1+X+X^2+..+X^n$.

If the CRC data is less than 32-bit, its value can be read from the least significant bits of the CRC_DR register.

To obtain a reliable CRC calculation, the change on-fly of the polynomial value or size can not be performed during a CRC calculation. As a result, if a CRC calculation is ongoing, the application must either reset it or perform a CRC_DR read before changing the polynomial.

The default polynomial value is the CRC-32 (Ethernet) polynomial: 0x4C11DB7.

20.4 CRC registers

The CRC_DR register can be accessed by words, right-aligned half-words and right-aligned bytes when RTYPE bit is cleared in CRC_CR. When RTYPE is set, only word accesses are allowed. For the other registers only 32-bit accesses are allowed.

20.4.1 CRC data register (CRC_DR)

Address offset: 0x00

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DR[31:0]:** Data register bits

This register is used to write new data to the CRC calculator.

It holds the previous CRC calculation result when it is read.

If the data size is less than 32 bits, the least significant bits are used to write/read the correct value.

20.4.2 CRC independent data register (CRC_IDR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IDR[31:0]**: General-purpose 32-bit data register bits

These bits can be used as a temporary storage location for four bytes.

This register is not affected by CRC resets generated by the RESET bit in the CRC_CR register

20.4.3 CRC control register (CRC_CR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	RTYPE_OUT	RTYPE_IN	REV_OUT[1:0]		REV_IN[1:0]		POLYSIZE[1:0]		Res.	Res.	RESET
					rw	rw	rw	rw	rw	rw	rw	rw			rs

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **RTYPE_OUT**: Reverse type output
This bit controls the reversal granularity of the output data.
0: Bit level output
1: Byte or half-word level output

Bit 9 **RTYPE_IN**: Reverse type input
This bit controls the reversal granularity of the input data.
0: Bit level input
1: Byte or half-word level input

Bits 8:7 **REV_OUT[1:0]**: Reverse output data
This bitfield controls the reversal of the bit order of the output data.
00: Bit order not affected (RTYPE_OUT = 0 or 1)
01: Bit-reversed output format (RTYPE_OUT = 0) or half-word reversal done by word (RTYPE_OUT = 1)
10: Bit order not affected (RTYPE_OUT = 0) or byte reversal done by word (RTYPE_OUT = 1)
11: Bit order not affected (RTYPE_OUT = 0 or 1)

Bits 6:5 **REV_IN[1:0]**: Reverse input data
This bitfield controls the reversal of the bit order of the input data
00: Bit order not affected (RTYPE_IN = 0 or 1)
01: Bit reversal done by byte (RTYPE_IN = 0) or half-word reversal done by word (RTYPE_IN = 1)
10: Bit reversal done by half-word (RTYPE_IN = 0) or byte reversal done by word (RTYPE_IN = 1)
11: Bit reversal done by word (RTYPE_IN = 0) or bit order is not affected (RTYPE_IN = 1)

Bits 4:3 **POLYSIZE[1:0]**: Polynomial size

These bits control the size of the polynomial.

00: 32 bit polynomial

01: 16 bit polynomial

10: 8 bit polynomial

11: 7 bit polynomial

Bits 2:1 Reserved, must be kept at reset value.

Bit 0 **RESET**: RESET bit

This bit is set by software to reset the CRC calculation unit and set the data register to the value stored in the CRC_INIT register. This bit can only be set, it is automatically cleared by hardware.

20.4.4 CRC initial value (CRC_INIT)

Address offset: 0x10

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CRC_INIT[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CRC_INIT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CRC_INIT[31:0]**: Programmable initial CRC value

This register is used to write the CRC initial value.

20.4.5 CRC polynomial (CRC_POL)

Address offset: 0x14

Reset value: 0x04C1 1DB7

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
POL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
POL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **POL[31:0]**: Programmable polynomial

This register is used to write the coefficients of the polynomial to be used for CRC calculation.

If the polynomial size is less than 32 bits, the least significant bits have to be used to program the correct value.

20.4.6 CRC register map

Table 182. CRC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

21 CORDIC coprocessor (CORDIC)

21.1 CORDIC introduction

The CORDIC coprocessor provides hardware acceleration of mathematical functions (mainly trigonometric ones) commonly used in motor control, metering, signal processing, and many other applications.

It speeds up the calculation of these functions compared to a software implementation, making possible the use of a lower operating frequency, or freeing up processor cycles to perform other tasks.

21.2 CORDIC main features

- 24-bit CORDIC rotation engine
- Circular and Hyperbolic modes
- Rotation and Vectoring modes
- Functions: sine, cosine, sinh, cosh, atan, atanh, phase, modulus, square root, natural logarithm
- Programmable precision
- Low latency AHB slave interface
- Results can be read as soon as ready, without polling or interrupt
- DMA read and write channels
- Multiple register read/write by DMA

21.3 CORDIC functional description

21.3.1 General description

The CORDIC is a cost-efficient successive approximation algorithm for evaluating trigonometric and hyperbolic functions.

In trigonometric (circular) mode, the sine and cosine of an angle θ are determined by rotating the unit vector [1, 0] through decreasing angles until the cumulative sum of the rotation angles equals the input angle θ. The x and y cartesian components of the rotated vector then correspond, respectively, to the cosine and sine of θ. Inversely, the angle of a vector [x, y] corresponding to arctangent (y / x), is determined by rotating [x, y] through successively decreasing angles to obtain the unit vector [1, 0]. The cumulative sum of the rotation angles gives the angle of the original vector.

The CORDIC algorithm can also be used for calculating hyperbolic functions (sinh, cosh, atanh), by replacing the successive circular rotations by steps along a hyperbole.

Other functions can be derived from the basic functions described above.

21.3.2 CORDIC functions

The first step when using the coprocessor is to select the required function, by programming the FUNC field of the CORDIC_CR register.

Table 183 lists the functions supported by the CORDIC coprocessor.

Table 183. CORDIC functions

Function	Primary argument (ARG1)	Secondary argument (ARG2)	Primary result (RES1)	Secondary result (RES2)
Cosine	angle θ	modulus m	$m \cdot \cos\theta$	$m \cdot \sin\theta$
Sine	angle θ	modulus m	$m \cdot \sin\theta$	$m \cdot \cos\theta$
Phase	x	y	atan2(y,x)	$\sqrt{x^2+y^2}$
Modulus	x	y	$\sqrt{x^2+y^2}$	atan2(y,x)
Arctangent	x	none	atan x	none
Hyperbolic cosine	x	none	cosh x	sinh x
Hyperbolic sine	x	none	sinh x	cosh x
Hyperbolic arctangent	x	none	atanh x	none
Natural logarithm	x	none	ln x	none
Square root	x	none	$\sqrt{x}$	none

Several functions take two input arguments (ARG1 and ARG2), and some generate two results (RES1 and RES2) simultaneously. This is a side-effect of the algorithm and means that only one operation is needed to obtain two values. This is the case, for example, when performing polar-to-rectangular conversion: sin θ also generates cos θ, and cos θ also generates sin θ. Similarly for rectangular-to-polar conversion (phase(x,y), modulus(x,y)) and for hyperbolic functions (cosh θ, sinh θ).

Note: The exponential function, exp x, can be obtained as the sum of sinh x and cosh x. Furthermore, base N logarithms, $\log_N x$, can be derived by multiplying ln x by a constant K, where K = 1/ln N.

For certain functions (atan, log, sqrt) a scaling factor (see *Section 21.3.4*) can be applied to extend the range beyond the maximum [-1, 1] supported by the q1.31 fixed point format. The scaling factor must be set to 0 for all other circular functions, and to 1 for hyperbolic functions.

Cosine

Table 184. Cosine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • cos θ	[-1, 1]

Table 184. Cosine parameters (continued)

Parameter	Description	Range
RES2	m • sin θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the cosine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the cosine of the angle, multiplied by the modulus.

The secondary result, RES2, is the sine of the angle, multiplied by the modulus.

Sine

Table 185. Sine parameters

Parameter	Description	Range
ARG1	Angle θ in radians, divided by π	[-1, 1]
ARG2	Modulus m	[0, 1]
RES1	m • sin θ	[-1, 1]
RES2	m • cos θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the sine of an angle in the range -π to π. It can also be used to perform polar to rectangular conversion.

The primary argument is the angle θ in radians. It must be divided by π before programming ARG1.

The secondary argument is the modulus m. If m is greater than 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the sine of the angle, multiplied by the modulus.

The secondary result, RES2, is the cosine of the angle, multiplied by the modulus.

Phase

Table 186. Phase parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Phase angle θ in radians, divided by π	[-1, 1]

Table 186. Phase parameters (continued)

Parameter	Description	Range
RES2	Modulus m	[0, 1]
SCALE	Not applicable	0

This function calculates the phase angle in the range -π to π of a vector **v** = [x y] (also known as atan2(y,x). It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the phase angle θ of the vector **v**. RES1 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

The secondary result, RES2, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES2 is saturated to 1.

Modulus

Table 187. Modulus parameters

Parameter	Description	Range
ARG1	x coordinate	[-1, 1]
ARG2	y coordinate	[-1, 1]
RES1	Modulus m	[0, 1]
RES2	Phase angle θ	[-1, 1]
SCALE	Not applicable	0

This function calculates the magnitude, or modulus, of a vector **v** = [x y]. It can also be used to perform rectangular to polar conversion.

The primary argument is the x coordinate, that is, the magnitude of the vector in the direction of the x axis. If |x| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG1.

The secondary argument is the y coordinate, that is, the magnitude of the vector in the direction of the y axis. If |y| > 1, a scaling must be applied in software to adapt it to the q1.31 range of ARG2.

The primary result, RES1, is the modulus, given by: $|v| = \sqrt{x^2 + y^2}$. If |**v**| > 1 the result in RES1 is saturated to 1.

The secondary result, RES2, is the phase angle θ of the vector **v**. RES2 must be multiplied by π to obtain the angle in radians. Note that values close to π may sometimes wrap to -π due to the circular nature of the phase angle.

Arctangent

Table 188. Arctangent parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-1, 1]
ARG2	Not applicable	-
RES1	2^{-n} • atan x, in radians, divided by p	[-1, 1]
RES2	Not applicable	-
SCALE	n	[0 7]

This function calculates the arctangent, or inverse tangent, of the input argument x.

The primary argument, ARG1, is the input value, x = tan θ. If |x| > 1, a scaling factor of 2^{-n} must be applied in software such that $-1 < x \cdot 2^{-n} < 1$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the scale factor n must be programmed in the SCALE parameter.

Note that the maximum input value allowed is tan θ = 128, which corresponds to an angle θ = 89.55 degrees. For |x| > 128, a software method must be used to find atan x.

The secondary argument, ARG2, is unused.

The primary result, RES1, is the angle θ = atan x. RES1 must be multiplied by $2^n \cdot \pi$ to obtain the angle in radians.

The secondary result, RES2, is unused.

Hyperbolic cosine

Table 189. Hyperbolic cosine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \cosh x$	[0.5 0.846]
RES2	$2^{-n} \cdot \sinh x$	[-0.683 0.683]
SCALE	n	1

This function calculates the hyperbolic cosine of a hyperbolic angle x. It can also be used to calculate the exponential functions $e^x = \cosh x + \sinh x$, and $e^{-x} = \cosh x - \sinh x$.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. Since the minimum value of cosh x is 1, which is beyond the range of the q1.31 format, a scaling factor of 2^{-n} must be applied in software. The factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic cosine, cosh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic sine, sinh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic sine

Table 190. Hyperbolic sine parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[-0.559, 0.559]
ARG2	Not applicable	-
RES1	$2^{-n} \cdot \sinh x$	[-0.683, 0.683]
RES2	$2^{-n} \cdot \cosh x$	[0.5, 0.846]
SCALE	n	1

This function calculates the hyperbolic sine of a hyperbolic angle x. It can also be used to calculate the exponential functions e^x = cosh x + sinh x, and e^{-x} = cosh x- sinh x.

The primary argument is the hyperbolic angle x. Only values of x in the range -1.118 to +1.118 are supported. For all input values, a scaling factor of 2^{-n} must be applied in software, where n = 1. The scaled value x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result, RES1, is the hyperbolic sine, sinh x. RES1 must be multiplied by 2 to obtain the correct result.

The secondary result, RES2, is the hyperbolic cosine, cosh x. RES2 must be multiplied by 2 to obtain the correct result.

Hyperbolic arctangent

Table 191. Hyperbolic arctangent parameters

Parameter	Description	Range
ARG1	$x \bullet 2^{-n}$	[-0.403 0.403]
ARG2	Not applicable	-
RES1	$2^{-n} \bullet$atanh x	[-0.559 0.559]
RES2	Not applicable	-
SCALE	n	1

This function calculates the hyperbolic arctangent of the input argument x.

The primary argument is the input value x. Only values of x in the -0.806 to +0.806 range are supported. The value x must be scaled by a factor 2^{-n}, where n = 1. The scaled value

x • 0.5 is programmed in ARG1 and the factor n = 1 must be programmed in the SCALE parameter.

The secondary argument is not used.

The primary result is the hyperbolic arctangent, atanh x. RES1 must be multiplied by 2 to obtain the correct value.

The secondary result is not used.

Natural logarithm

Table 192. Natural logarithm parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.054 0.875]
ARG2	Not applicable	-
RES1	$2^{-(n+1)}.\ln x$	[-0.279 0.137]
RES2	Not applicable	-
SCALE	n	[1 4]

This function calculates the natural logarithm of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.107 to 9.35 are supported. The value x must be scaled by a factor 2^{-n}, such that $x < 2^{-n} < 1\text{-}2^{-n}$. The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 193 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 193. Natural log scaling factors and corresponding ranges

n	x range	ARG1 range
1	$0.107 \le x < 1$	$0.0535 \le ARG1 < 0.5$
2	$1 \le x < 3$	$0.25 \le ARG1 < 0.75$
3	$3 \le x < 7$	$0.375 \le ARG1 < 0.875$
4	$7 \le x \le 9.35$	$0.4375 \le ARG1 < 0.584$

The secondary argument is not used.

The primary result is the natural logarithm, ln x. RES1 must be multiplied by $2^{(n+1)}$ to obtain the correct value.

The secondary result is not used.

Square root

Table 194. Square root parameters

Parameter	Description	Range
ARG1	$x \cdot 2^{-n}$	[0.027 0.875]
ARG2	Not applicable	-
RES1	$2^{-n}\sqrt{x}$	[0.04 1]
RES2	Not applicable	-
SCALE	n	[0 2]

This function calculates the square root of the input argument x.

The primary argument is the input value x. Only values of x in the range 0.027 to 2.34 are supported. The value x must be scaled by a factor 2^{-n}, such that $x \cdot 2^{-n} < (1 - 2^{(-n-2)})$.

The scaled value $x \cdot 2^{-n}$ is programmed in ARG1 and the factor n must be programmed in the SCALE parameter.

Table 195 lists the valid scaling factors, n, and the corresponding ranges of x and ARG1.

Table 195. Square root scaling factors and corresponding ranges

n	x range	ARG1 range
0	$0.027 \leq x < 0.75$	$0.027 \leq ARG1 < 0.75$
1	$0.75 \leq x < 1.75$	$0.375 \leq ARG1 < 0.875$
2	$1.75 \leq x \leq 2.341$	$0.4375 \leq ARG1 \leq 0.585$

The secondary argument is not used.

The primary result is the square root of x. RES1 must be multiplied by 2^n to obtain the correct value.

The secondary result is not used.

21.3.3 Fixed point representation

The CORDIC operates in fixed point signed integer format. Input and output values can be either q1.31 or q1.15.

In q1.31 format, numbers are represented by one sign bit and 31 fractional bits (binary decimal places). The numeric range is therefore -1 (0x80000000) to $1 - 2^{-31}$ (0x7FFFFFFF).

In q1.15 format, the numeric range is 1 (0x8000) to $1 - 2^{-15}$ (0x7FFF). This format has the advantage that two input arguments can be packed into a single 32-bit write, and two results can be fetched in one 32-bit read.

21.3.4 Scaling factor

Several of the functions listed in *Section 21.3.2* specify a scaling factor, SCALE. This allows the function input range to be extended to cover the full range of values supported by the CORDIC, without saturating the input, output, or internal registers. If the scaling factor is

required, it must be calculated by software and programmed into the SCALE field of the CORDIC_CSR register. The input arguments must be scaled accordingly before programming the scaled values in the CORDIC_WDATA register. The scaling must also be undone on the results read from the CORDIC_RDATA register.

Note: The scaling factor entails a loss of precision due to truncation of the scaled value.

21.3.5 Precision

The precision of the result is dependent on the number of CORDIC iterations. The algorithm converges at a constant rate of one binary digit per iteration for trigonometric functions (sine, cosine, phase, modulus), see *Figure 140*.

For hyperbolic functions (hyperbolic sine, hyperbolic cosine, natural logarithm), the convergence rate is less constant due to the peculiarities of the CORDIC algorithm (see *Figure 141*). The square root function converges at roughly twice the speed of the hyperbolic functions (see *Figure 142*).

Figure 140. CORDIC convergence for trigonometric functions

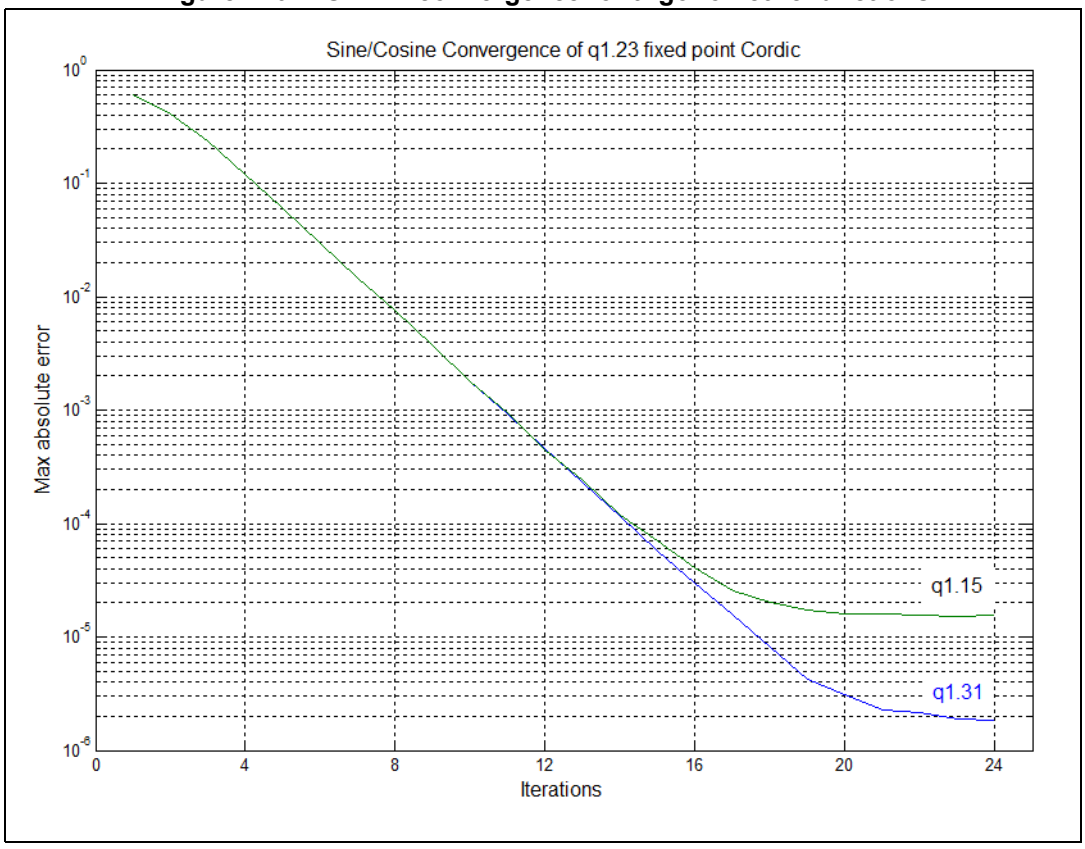

Figure 141. CORDIC convergence for hyperbolic functions

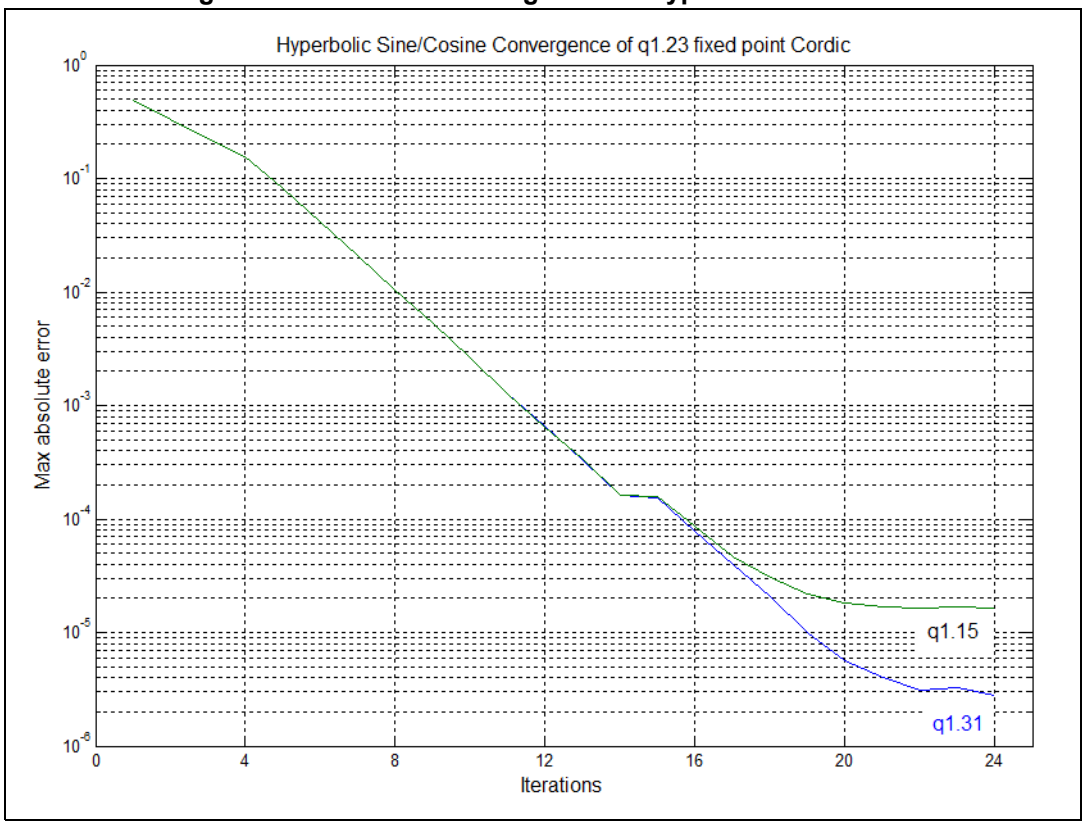

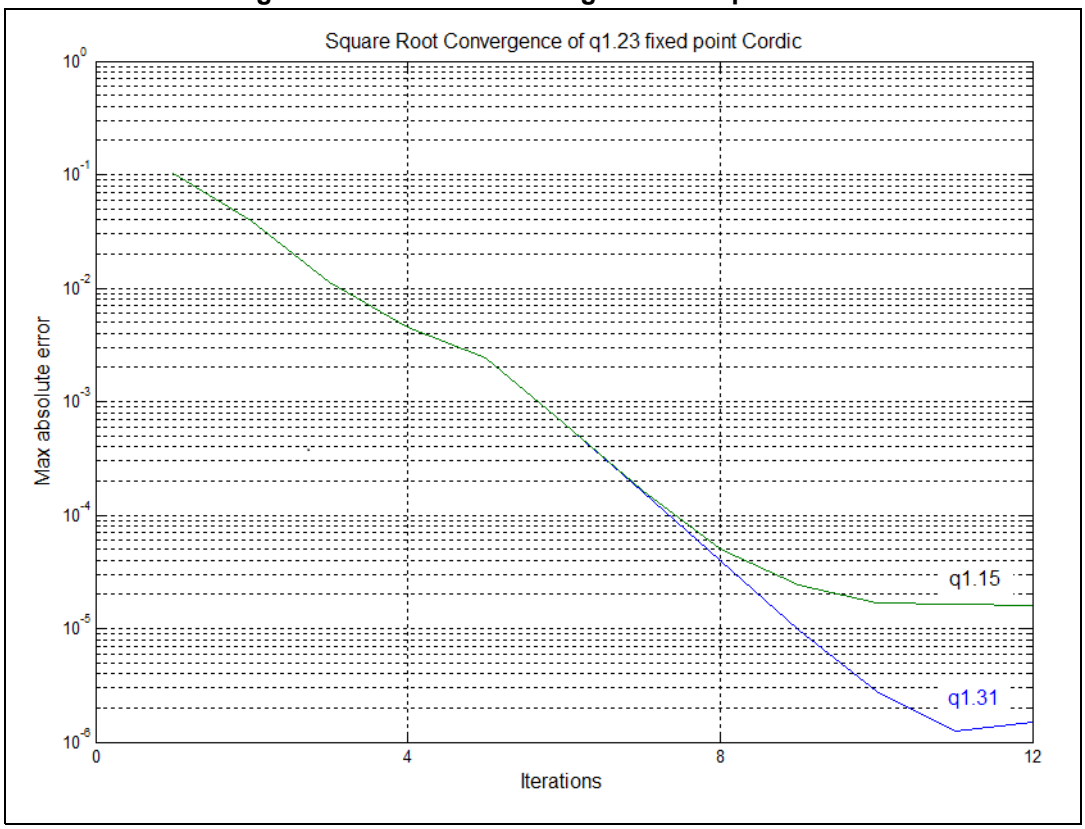

Figure 142. CORDIC convergence for square root

Note: The convergence rate decreases as the quantization error starts to become significant.

The CORDIC can perform four iterations per clock cycle. For each function, the maximum error remaining after every four iterations is shown in *Table 196*, together with the number of clock cycles required to reach that precision. From this table, the desired number of cycles can be determined and programmed in the PRECISION field of the CORDIC_CR register. The coprocessor stops as soon as the programmed number of iterations is completed, and the result can be read immediately.

Table 196. Precision vs. number of iterations

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sin, Cos, Phase(2), Mod, Atan(4)	4	1	2^{-3}	2^{-3}
	8	2	2^{-7}	2^{-7}
	12	3	2^{-11}	2^{-11}
	16	4	2^{-15}	2^{-15}
	20	5	2^{-18}	2^{-16}
	24	6	2^{-19}	2^{-16}

Table 196. Precision vs. number of iterations (continued)

Function	Number of iterations	Number of cycles	Max residual error(1)	
			q1.31 format	q1.15 format
Sinh, Cosh, Atanh, Ln(3)	4	1	2^{-2}	2^{-2}
	8	2	2^{-6}	2^{-6}
	12	3	2^{-10}	2^{-10}
	16	4	2^{-13}	2^{-13}
	20	5	2^{-17}	2^{-15}
	24	6	2^{-18}	2^{-15}
Sqrt(4)	4	1	2^{-7}	2^{-7}
	8	2	2^{-14}	2^{-14}
	12	3	2^{-19}	2^{-15}

1. Max residual error is the maximum error remaining after the given number of iterations, compared to the identical calculation performed in double precision floating point. An additional rounding error may be incurred, of up to 2^{-16} for q15 format or 2^{-20} for q31 format.
2. For modulus > 0.5. The achievable precision reduces proportionally to the magnitude of the modulus, as quantization error becomes significant.
3. SCALE = 1. If a higher scaling factor is used, the achievable precision is reduced proportionally.
4. SCALE = 0. If a higher scaling factor is used, the achievable precision is reduced proportionally.

21.3.6 Zero-overhead mode

The fastest way to use the coprocessor is to preprogram the CORDIC_CSR register with the function to be performed (FUNC), the desired number of clock cycles (PRECISION), the size of the input and output values (ARGSIZE, RESSIZE), the number of input arguments (NARGS) and/or results (NRES), and the scaling factor (SCALE), if applicable.

The calculation is triggered by writing the input arguments to the CORDIC_WDATA register. As soon as the correct number of input arguments has been written (and any ongoing calculation has finished), a new calculation is launched using these input arguments and the current CORDIC_CSR settings. There is no need to reprogram the CORDIC_CSR register if there is no change.

If a dual 32-bit input argument is needed (ARGSIZE = 0, NARGS = 1), the primary input argument (ARG1) must be written first, followed by the secondary argument (ARG2). If the secondary argument remains unchanged for a series of calculations, the second write can be avoided, by reprogramming the number of arguments to one (NARGS = 0), once the first calculation has started. The secondary argument retains its programmed value as long as the function is not changed.

Note: ARG2 is set to +1 (0x7FFFFFFF) after a reset.

If two 16-bit arguments are used (ARGSIZE = 1) they must be packed into a 32-bit word, with ARG1 in the least significant half-word and ARG2 in the most significant half-word. The packed 32-bit word is then written to the CORDIC_WDATA register. Only one write is needed in this case (NARGS = 0).

For functions taking only one input argument, ARG1, it is recommended to set NARGS = 0. If NARGS = 1, a second write to CORDIC_WDATA must be performed to trigger the calculation. The ARG2 data in this case is not used.

Once the calculation starts, any attempt to read the CORDIC_RDATA register inserts bus wait-states until the calculation is completed, before returning the result. It is then possible for the software to write the input and immediately read the result without polling to see if it is valid. Alternatively, the processor can wait for the appropriate number of clock cycles before reading the result. This time can be used to program the CORDIC_CSR register for the next calculation, and prepare the next input data, if needed. The CORDIC_CSR register can be reprogrammed while a calculation is in progress, without affecting the result of the ongoing calculation. In the same way, the CORDIC_WDATA register can be updated with the next argument(s) once the previous ones have been taken into account. The next arguments and settings remain pending until the previous calculation has completed.

When a calculation is finished, the result(s) can be read from the CORDIC_RDATA register. If two 32-bit results are expected (NRES = 1, RESSIZE = 0), the primary result (RES1) is read out first, followed by the secondary result (RES2). If only one 32-bit result is expected (NRES = 0, RESSIZE = 0), then RES1 is output on the first read.

If 16-bit results are expected (RESSIZE = 1), a single read to CORDIC_RDATA fetches both results packed into a 32-bit word. RES1 is in the lower half-word, and RES2 in the upper half-word. In this case, it is recommended to program NRES = 0. IF NRES = 1, a second read of CORDIC_RDATA must be performed to free up the CORDIC for the next operation. The data from this second read must be discarded.

The next calculation starts when the expected number of results has been read, provided the expected number of arguments has been written. This means that at any time, there can be a calculation in progress, or waiting for the results to be read, and an operation pending. Any further access to CORDIC_WDATA while an operation is pending cancels it and overwrites the data.

The following sequence summarizes the use of the CORDIC_IP in zero-overhead mode:

1. Program the CORDIC_CSR register with the appropriate settings
2. Program the argument(s) for the first calculation in the CORDIC_WDATA register. This launches the first calculation.
3. If needed, update the CORDIC_CSR register settings for the next calculation.
4. Program the argument(s) for the next calculation in the CORDIC_WDATA register.
5. Read the result(s) from the CORDIC_RDATA register. This triggers the next calculation.
6. Go to step *3*.

21.3.7 Polling mode

When a new result is available in the CORDIC_RDATA register, the RRDY flag is set in the CORDIC_CSR register. The flag can be polled by reading the register. It is reset by reading the CORDIC_RDATA register (once or twice, depending on the NRES field of the CORDIC_CSR register).

Polling the RRDY flag takes slightly longer than reading the CORDIC_RDATA register directly, since the result is not read as soon as it is available. The processor and bus interface are not stalled while reading the CORDIC_CSR register, so this mode may be of interest if stalling the processor is not acceptable (for example, if low latency interrupts must be serviced).

21.3.8 Interrupt mode

By setting the interrupt enable (IE) bit in the CORDIC_CSR register, an interrupt is generated whenever the RRDY flag is set. The interrupt is cleared when the flag is reset.

This mode allows the result of the calculation to be read under interrupt service routine, and hence given a priority relative to other tasks. However, it is slower than directly reading the result, or polling the flag, due to the interrupt handling delays.

21.3.9 DMA mode

If the DMA write enable (DMAWEN) bit is set in the CORDIC_CSR register, and no operation is pending, a DMA write channel request is generated. The DMA controller can transfer a primary input argument (ARG1) from memory into the CORDIC_WDATA register. Writing into the register deasserts the DMA request. If NARGS = 1 in the CORDIC_CSR register, a second DMA write channel request is generated to transfer the secondary input argument (ARG2) into the CORDIC_WDATA register. When all input arguments have been written, and any ongoing calculation has been completed (by reading the results), a new calculation is started and another DMA write channel request is generated.

If the DMA read enable (DMAREN) bit is set in the CORDIC_CSR register, the RRDY flag going active generates a DMA read channel request. The DMA controller can then transfer the primary result (RES1) from the CORDIC_RDATA register to memory. Reading the register deasserts the DMA request. If NRES = 1 in the CORDIC_CSR register, a second DMA request is generated to read out the secondary result (RES2). When all results have been read, the RRDY flag is deasserted.

The DMA read and write channels can be enabled separately. If both channels are enabled, the CORDIC can autonomously perform repeated calculations on a buffer of data without processor intervention. This allows the processor to perform other tasks. The DMA controller is operating in memory-to-peripheral mode for the write channel, and peripheral-to-memory mode for the read channel. The sequence is started by the processor setting the DMAWEN flag, the DMA read and write requests are generated as fast as the CORDIC can process the data.

In some cases, the input data may be stored in memory, and the output is transferred at regular intervals to another peripheral, such as a digital-to-analog converter. In this case, the destination peripheral generates a DMA request each time it needs a new data. The DMA controller can directly fetch the next sample from the CORDIC_RDATA register (in this case the DMA controller is operating in memory-to-peripheral mode, even though the source is a peripheral register). The act of reading the result allows the CORDIC to start a new calculation, which in turn generates a DMA write channel request, and the DMA controller transfers the next input value to the CORDIC_WDATA register. The DMA write channel is enabled (DMAWEN = 1), but the read channel must not be enabled.

In a similar way, data coming from another peripheral, such as an ADC, can be transferred directly to the CORDIC_WDATA register (in peripheral-to-memory mode). The DMA write channel must not be enabled. The CORDIC processes the input data and generates a DMA read request when complete, if DMAREN = 1. The DMA controller then transfers the result from CORDIC_RDATA register to memory (peripheral-to-memory mode).

Note: No DMA request is generated to program the CORDIC_CSR register. DMA mode is therefore useful only when repeatedly performing the same function with the same settings. The scale factor cannot be changed during a series of DMA transfers.

Note: Each DMA request must be acknowledged, as a result of the DMA performing an access to the CORDIC_WDATA or CORDIC_RDATA register. If an extraneous access to the relevant register occurs before this, the acknowledge is asserted prematurely, and may block the DMA channel. Therefore, when the DMA read channel is enabled, CPU access to the CORDIC_RDATA register must be avoided. Similarly, the processor must avoid accessing the CORDIC_WDATA register when the DMA write channel is enabled.

21.4 CORDIC registers

The CORDIC registers can be accessed only in 32-bit word format

21.4.1 CORDIC control/status register (CORDIC_CSR)

Address offset: 0x00

Reset value: 0x0000 0050

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RRDY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARG SIZE	RES SIZE	N ARGS	NRES	DMA WEN	DMA REN	IEN
r									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SCALE[2:0]			PRECISION[3:0]				FUNC[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **RRDY**: Result ready flag

0: No new data in output register

1: CORDIC_RDATA register contains new data.

This bit is set by hardware when a CORDIC operation completes. It is reset by hardware when the CORDIC_RDATA register is read (NRES+1) times.

When this bit is set, if the IEN bit is also set, the CORDIC interrupt is asserted. If the DMAREN bit is set, a DMA read channel request is generated. While this bit is set, no new calculation is started.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **ARGSIZE**: Width of input data

0: 32-bit

1: 16-bit

ARGSIZE selects the number of bits used to represent input data.

If 32-bit data is selected, the CORDIC_WDATA register expects arguments in q1.31 format.

If 16-bit data is selected, the CORDIC_WDATA register expects arguments in q1.15 format. The primary argument (ARG1) is written to the least significant half-word, and the secondary argument (ARG2) to the most significant half-word.

Bit 21 **RESSIZE**: Width of output data

0: 32-bit

1: 16-bit

RESSIZE selects the number of bits used to represent output data.

If 32-bit data is selected, the CORDIC_RDATA register contains results in q1.31 format.

If 16-bit data is selected, the least significant half-word of CORDIC_RDATA contains the primary result (RES1) in q1.15 format, and the most significant half-word contains the secondary result (RES2), also in q1.15 format.

Bit 20 **NARGS**: Number of arguments expected by the CORDIC_WDATA register
0: Only one 32-bit write (or two 16-bit values if ARGSIZE = 1) is needed for the next calculation.
1: Two 32-bit values must be written to the CORDIC_WDATA register to trigger the next calculation.
Reads return the current state of the bit.

Bit 19 **NRES**: Number of results in the CORDIC_RDATA register
0: Only one 32-bit value (or two 16-bit values if RESSIZE = 1) is transferred to the CORDIC_RDATA register on completion of the next calculation. One read from CORDIC_RDATA resets the RRDY flag.
1: Two 32-bit values are transferred to the CORDIC_RDATA register on completion of the next calculation. Two reads from CORDIC_RDATA are necessary to reset the RRDY flag.
Reads return the current state of the bit.

Bit 18 **DMAWEN**: Enable DMA write channel
0: Disabled. No DMA write requests are generated.
1: Enabled. Requests are generated on the DMA write channel whenever no operation is pending
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 17 **DMAREN**: Enable DMA read channel
0: Disabled. No DMA read requests are generated.
1: Enabled. Requests are generated on the DMA read channel whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 16 **IEN**: Enable interrupt.
0: Disabled. No interrupt requests are generated.
1: Enabled. An interrupt request is generated whenever the RRDY flag is set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bits 15:11 Reserved, must be kept at reset value.

Bits 10:8 **SCALE[2:0]**: Scaling factor
The value of this field indicates the scaling factor applied to the arguments and/or results. A value n implies that the arguments have been multiplied by a factor 2^{-n}, and/or the results need to be multiplied by 2^{n}. Refer to *Section 21.3.2* for the applicability of the scaling factor for each function and the appropriate range.

Bits 7:4 **PRECISION[3:0]**: Precision required (number of iterations)
0: reserved
1 to 15: (Number of iterations)/4
To determine the number of iterations needed for a given accuracy refer to *Table 196*.
Note that for most functions, the recommended range for this field is 3 to 6.

Bits 3:0 **FUNC[3:0]**: Function

0: Cosine
1: Sine
2: Phase
3: Modulus
4: Arctangent
5: Hyperbolic cosine
6: Hyperbolic sine
7: Arctanh
8: Natural logarithm
9: Square root
10 to 15: Reserved

21.4.2 CORDIC argument register (CORDIC_WDATA)

Address offset: 0x04

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARG[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARG[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **ARG[31:0]**: Function input arguments

This register is programmed with the input arguments for the function selected in the CORDIC_CSR register FUNC field.

If 32-bit format is selected (CORDIC_CSR.ARGSIZE = 0) and two input arguments are required (CORDIC_CSR.NARGS = 1), two successive writes are required to this register. The first writes the primary argument (ARG1), the second writes the secondary argument (ARG2).

If 32-bit format is selected and only one input argument is required (NARGS = 0), only one write is required to this register, containing the primary argument (ARG1).

If 16-bit format is selected (CORDIC_CSR.ARGSIZE = 1), one write to this register contains both arguments. The primary argument (ARG1) is in the lower half, ARG[15:0], and the secondary argument (ARG2) is in the upper half, ARG[31:16]. In this case, NARGS must be set to 0.

Refer to *Section 21.3.2* for the arguments required by each function, and their permitted range.

When the required number of arguments has been written, the CORDIC evaluates the function designated by CORDIC_CSR.FUNC using the supplied input arguments, provided any previous calculation has completed. If a calculation is ongoing, the ARG1 and ARG 2 values are held pending until the calculation is completed and the results read. During this time, a write to the register cancels the pending operation and overwrite the argument data.

21.4.3 CORDIC result register (CORDIC_RDATA)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RES[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RES[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RES[31:0]**: Function result

If 32-bit format is selected (CORDIC_CSR.RESSIZE = 0) and two output values are expected (CORDIC_CSR.NRES = 1), this register must be read twice when the RRDY flag is set. The first read fetches the primary result (RES1). The second read fetches the secondary result (RES2) and resets RRDY.

If 32-bit format is selected and only one output value is expected (NRES = 0), only one read of this register is required to fetch the primary result (RES1) and reset the RRDY flag.

If 16-bit format is selected (CORDIC_CSR.RESSIZE = 1), this register contains the primary result (RES1) in the lower half, RES[15:0], and the secondary result (RES2) in the upper half, RES[31:16]. In this case, NRES must be set to 0, and only one read performed.

A read from this register resets the RRDY flag in the CORDIC_CSR register.

21.4.4 CORDIC register map

Table 197. CORDIC register map and reset value

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

22 Filter math accelerator (FMAC)

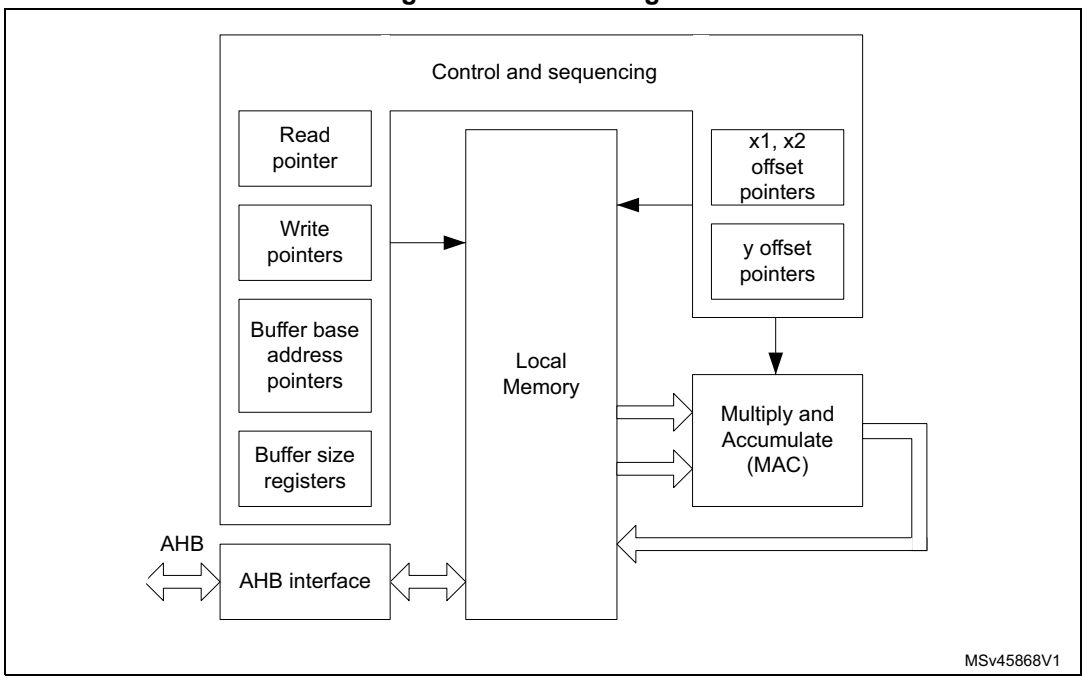
22.1 FMAC introduction

The filter math accelerator unit performs arithmetic operations on vectors. It comprises a multiplier/accumulator (MAC) unit, together with address generation logic which allows it to index vector elements held in local memory.

The unit includes support for circular buffers on input and output, which allows digital filters to be implemented. Both finite and infinite impulse response filters can be realized.

The unit allows frequent or lengthy filtering operations to be offloaded from the CPU, freeing up the processor for other tasks. In many cases it can accelerate such calculations compared to a software implementation, resulting in a speed-up of time critical tasks.

22.2 FMAC main features



- 16 x 16-bit multiplier
- 24 + 2-bit accumulator with addition and subtraction
- 16-bit input and output data
- 256 x 16-bit local memory
- Up to three areas can be defined in memory for data buffers (two input, one output), defined by programmable base address pointers and associated size registers
- Input and output buffers can be circular
- Filter functions: FIR, IIR (direct form 1)
- Vector functions: Dot product, convolution, correlation
- AHB slave interface
- DMA read and write data channels

22.3 FMAC functional description

22.3.1 General description

The FMAC is shown in *Figure 143*.

Figure 143. Block diagram

The unit is built around a fixed point multiplier and accumulator (MAC). The MAC can take two 16-bit input signed values from memory, multiply them together and add them to the contents of the accumulator. The address of the input values in memory is determined using a set of pointers. These pointers can be loaded, incremented, decremented or reset by the internal hardware. The pointer and MAC operations are controlled by a built-in sequencer in order to execute the requested operation.

To calculate a dot product, the two input vectors are loaded into the local memory by the processor or DMA controller, and the requested operation is selected and started. Each pair of input vector elements is fetched from memory, multiplied together and accumulated. When all the vector elements have been processed, the contents of the accumulator are stored in the local memory, from where they can be read out by the processor or DMA.

The finite impulse response (FIR) filter operation (also known as convolution) consists in repeatedly calculating the dot product of the coefficient vector and a vector of input samples, the latter being shifted by one sample delay, with the least recent sample being discarded and a new sample added, at each repetition.

The infinite impulse response (IIR) filter operation is the convolution of the feedback coefficients with the previous output samples, added to the result of the FIR convolution.

A more detailed description of the filter operations is given in *Section 22.3.6: Filter functions*.

22.3.2 Local memory and buffers

The unit contains a 256 x 16-bit read/write memory which is used for local storage:

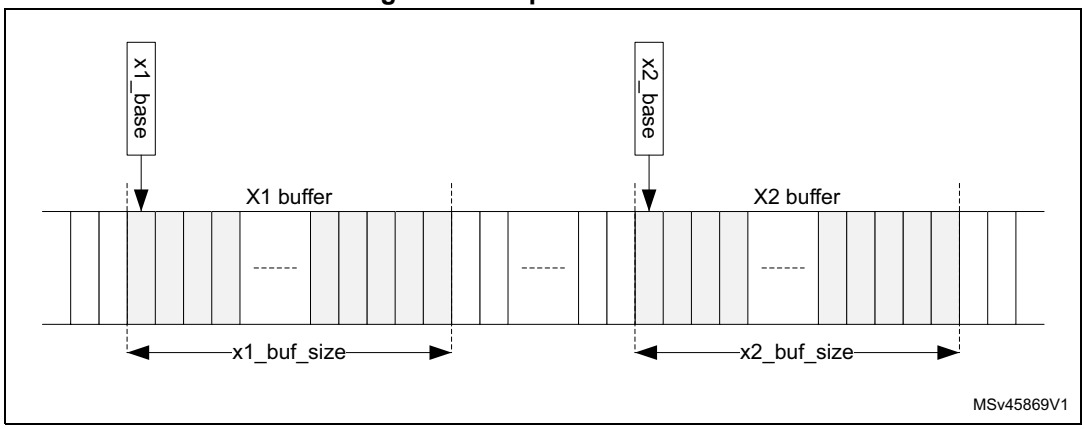
- Input values (the elements of the input vectors) are stored in two buffers, X1 and X2.
- Output values (the results of the operations) are stored in another buffer, Y.
- The locations and sizes of the buffers are designated as follows:
  - x1_base: the base address of the X1 buffer
  - x2_base: the base address of the X2 buffer
  - y_base: the base address of the Y buffer
  - x1_buf_size: the number of 16-bit addresses allocated to the X1 buffer
  - x2_buf_size: the number of 16-bit addresses allocated to the X2 buffer
  - y_buf_size: the number of 16-bit addresses allocated to the Y buffer.

These parameters are programmed in the corresponding registers when configuring the unit.

The CPU (or DMA controller) can initialize the contents of each buffer using the Initialization functions (*Section 22.3.5: Initialization functions*) and writing to the write data register. The data is transferred to the location within the target buffer indicated by a write pointer. After each new write, the write pointer is incremented. When the write pointer reaches the end of the allocated buffer space, it wraps back to the base address. This feature is used to load the elements of a vector prior to an operation, or to initialize a filter and load filter coefficients.

Buffer configuration

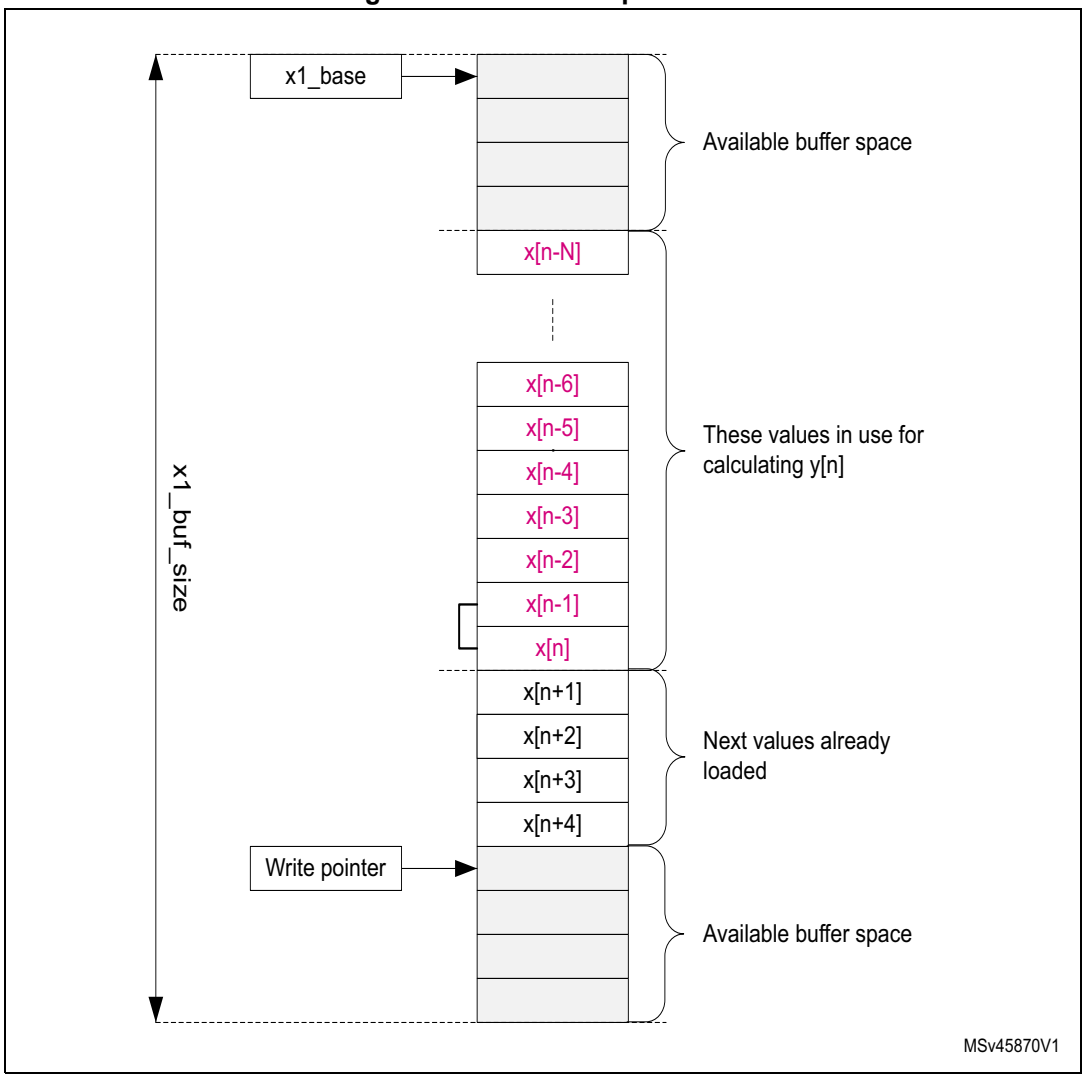
The buffer sizes and base address offsets must be configured in the X1, X2 and Y buffer configuration registers. For each function, the required buffer size is specified in the function description in *Section 22.3.6: Filter functions*. The base addresses can be chosen anywhere in internal memory, provided that all buffers fit within the internal memory address range (0x00 to 0xFF), that is, base address + buffer size must be less than 256.



There is no constraint on the size and location of the buffers (they can overlap or even coincide exactly). For filter functions it is recommended not to overlap buffers as this can lead to erroneous behavior.

When circular buffer operation is required, an optional “headroom”, d, can be added to the buffer size. Furthermore, a watermark level can be set, to regulate the CPU or DMA activity. The value of d and the watermark level must be chosen according to the application performance requirements. For maximum throughput, the input buffer must never go empty, so d must be somewhat greater than the watermark level, allowing for any interrupt or DMA latency. On the other hand, if the input data can not be provided as fast as the unit can process them, the buffer can be allowed to empty waiting for the next data to be written, so d can be equal to the watermark level (to ensure that no overflow occurs on the input).

22.3.3 Input buffers



The X1 and X2 buffers are used to store data for input to the MAC. Each multiplication takes a value from the X1 buffer and a value from the X2 buffer and multiplies them together. A pointer in the control unit generates the read address offset (relative to the buffer base address) for each value. The pointers are managed by hardware according to the current function.

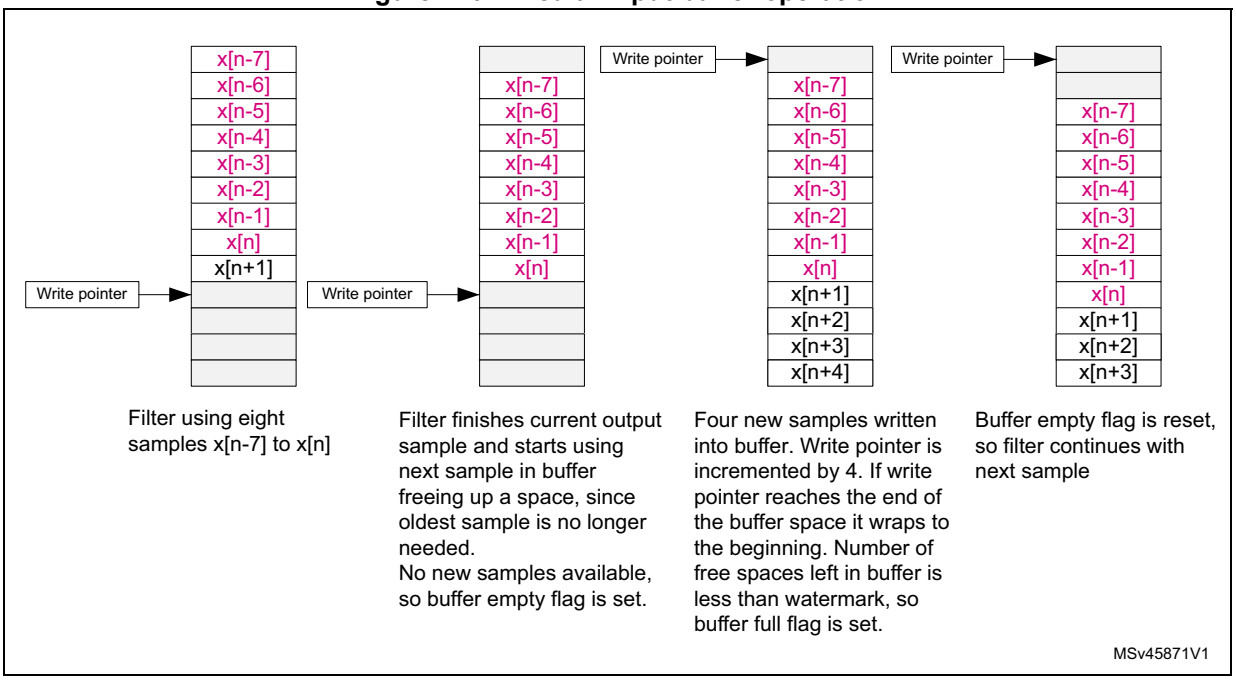
Figure 144. Input buffer areas

The X1 buffer can be used as a circular buffer, in which case new data are continually transferred into the input buffer whenever space is available. Pre-loading this buffer is optional for digital filters, since if no input samples have been written in the buffer when the operation is started, it is flagged as empty, which triggers the CPU or DMA to load new samples until there are enough to begin operation. Pre-loading is nevertheless useful in the case of a vector operation, that is, the input data is already available in system memory and circular operation is not required.

Figure 145. Circular input buffer

The X2 buffer can only be used in vector mode (that is not circular), and needs to be pre-loaded, except if the contents of the buffer do not change from one operation to the next. For filter functions, the X2 buffer is used to store the filter coefficients.

When operating as a circular buffer, the space allocated to the buffer (x1_buf_size) must generally be bigger than the number of elements in use for the current calculation, so that there are always new values available in the buffer. *Figure 145* illustrates the layout of the buffer for a filter operation. While calculating an output sample y[n], the unit uses a set of N+1 input samples, x[n-N] to x[n]. When this is finished, the unit starts the calculation of y[n+1], using the set of input samples x[n-N+1] to x[n+1]. The least-recent input sample, x[n-N], drops out of the input set, and a new sample, x[n+1], is added to it.



The processor, or DMA controller, must ensure that the new sample x[n+1] is available in the buffer space when required. If not, the buffer is flagged as empty, which stalls the execution of the unit until a new sample is added. No underflow condition is signaled on the X1 buffer.

Note: If the flow of samples is controlled by a timer or other peripheral such as an ADC, the buffer regularly goes empty, since the filter processes each new sample faster than the source can provide it. This is an essential feature of filter operation.

If the number of free spaces in the buffer is less than the watermark threshold programmed in the FULL_WM bitfield of the FMAC_X1BUFCFG register, the buffer is flagged as full. As long as the full flag is not set, interrupts are generated, if enabled, to request more data for the buffer. The watermark allows several data to be transferred under one interrupt, without danger of overflow. Nevertheless, if an overflow does occur, the OVFL error flag is set and the write data is ignored. The write pointer is not incremented in the event of an overflow.

The operation of the X1 buffer during a filtering operation is illustrated in *Figure 146*. This example shows an 8-tap FIR filter with a watermark set to four.

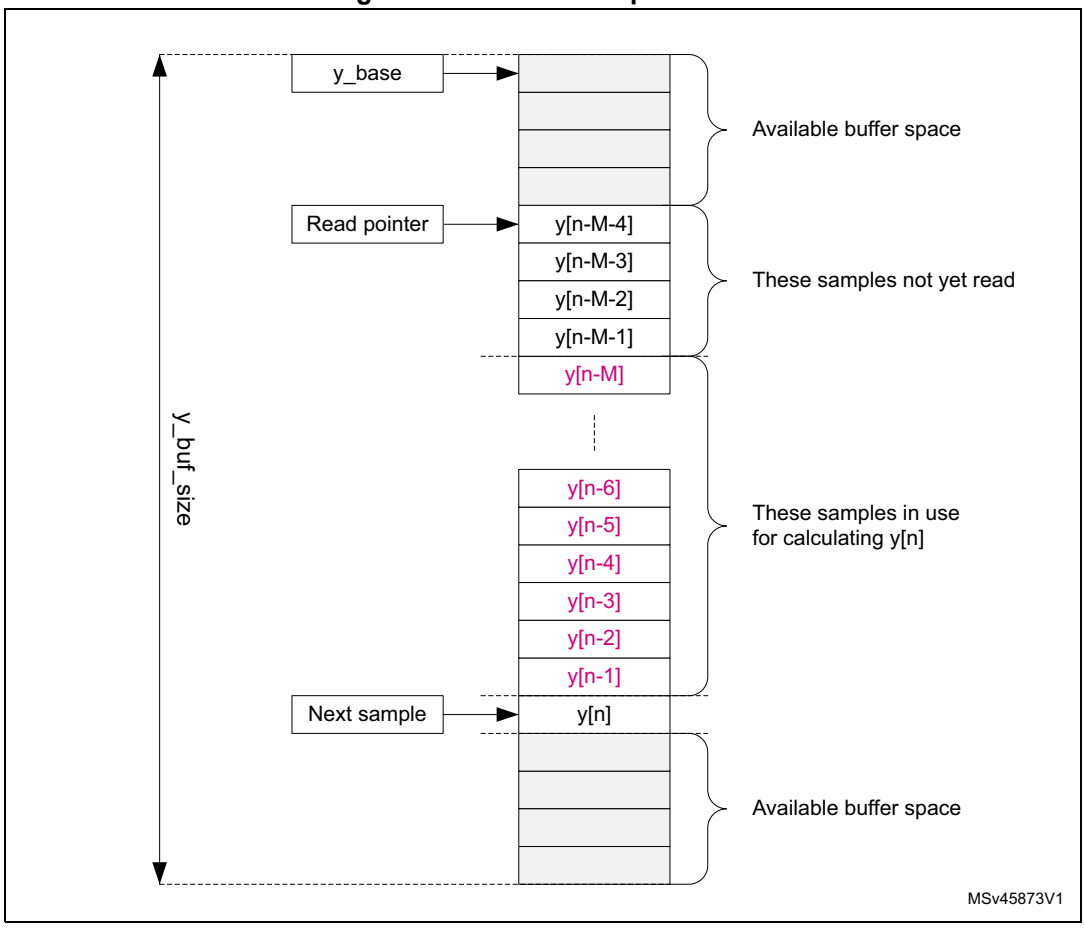


Figure 146. Circular input buffer operation

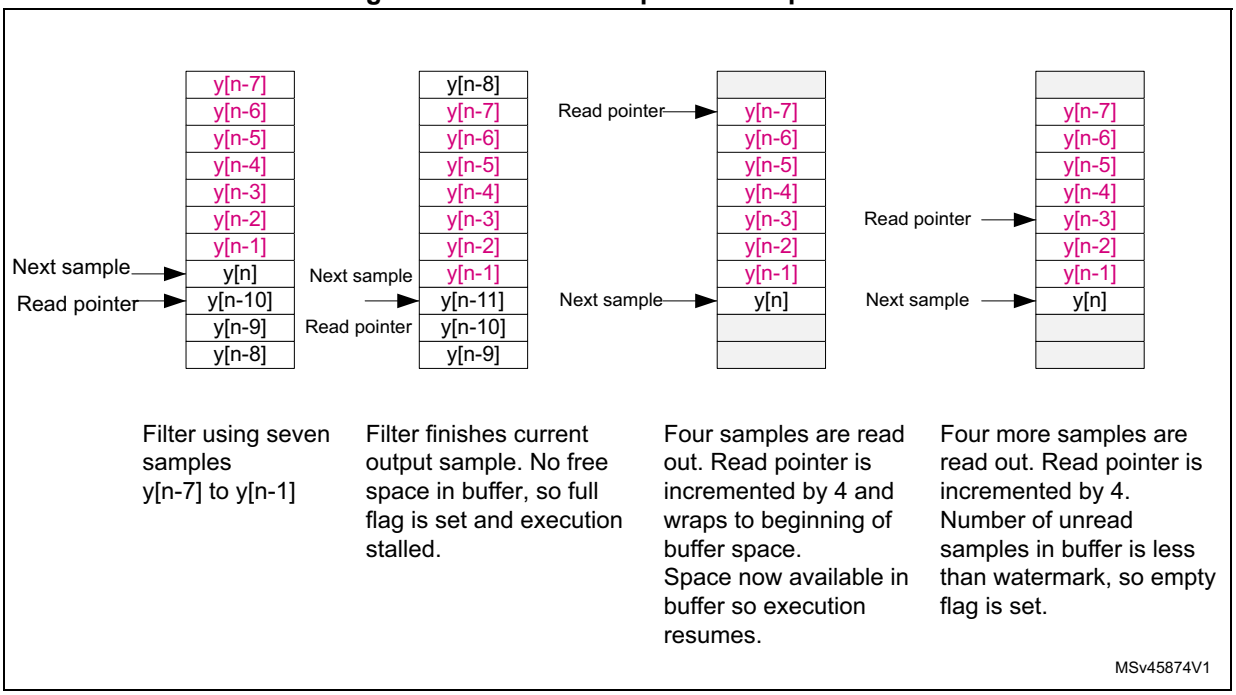
22.3.4 Output buffer

The Y (output) buffer is used to store the output of an accumulation. Each new output value is stored in the buffer until it is read by the processor or DMA controller. Each time a read access is made to the read data register, the read data is fetched from the address indicated by the read pointer. This pointer is incremented after each read, and wraps back to the base address when it reaches the end of the allocated Y buffer space.

Figure 147. Circular output buffer



The Y buffer can also operate as a circular buffer. If the address for the next output value is the same as that indicated by the read pointer (an unread sample), then the buffer is flagged as full and execution stalled until the sample is read.

In the case of IIR filters, the Y buffer is used to store the set of M previous output samples, y[n-M] to y[n-1], used for calculating the next output sample y[n]. Each time a new sample is added to the set, the least recent sample y[n-M] drops out.

If the number of unread data in the buffer is less than the watermark threshold programmed in the EMPTY_WM bitfield of the FMAC_YBUFCFG register, the buffer is flagged as empty. As long as the empty flag is not set, interrupts or DMA requests are generated, if enabled, to request reads from the buffer. The watermark allows several data to be transferred under one interrupt, without danger of underflow. Nevertheless, if an underflow does occur, the UNFL error flag is set. In this case, the read pointer is not incremented and the read operation returns the content of the memory at the read pointer address.

The operation of the Y buffer in circular mode is illustrated in *Figure 148*. This example shows a 7-tap IIR filter with a watermark set to four.

Figure 148. Circular output buffer operation

22.3.5 Initialization functions

The following functions initialize the FMAC unit. They are triggered by writing the appropriate value in the FUNC bitfield of the FMAC_PARAM register, with the START bit set. The P and Q bitfields must also contain the appropriate parameter values for each function as detailed below. The R bitfield is not used. When the function completes, the START bit is automatically reset by hardware.

During initialization, it is recommended that the DMA requests and interrupts be disabled. The transfer of data into the FMAC memory can be done by software or by memory-to-memory DMA transfers, since no flow control is required.

Load X1 buffer

This function pre-loads the X1 buffer with N values, starting from the address in X1_BASE. Successive writes to the FMAC_WDATA register load the write data into the X1 buffer and increment the write address. The write pointer points to the address X1_BASE + N when the function completes.

The function can be used to pre-load the buffer with the elements of a vector, or to initialize the input storage elements of a filter.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X1 buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

Load X2 buffer

This function pre-loads the X2 buffer with N + M values, starting from the address in X2_BASE. Successive writes to the FMAC_WDATA register load the write data into the X2 buffer and increment the write address.

The function can be used to pre-load the buffer with the elements of a vector, or the coefficients of a filter. In the case of an IIR, the N feed-forward and M feed-back coefficients are concatenated and loaded together into the X2 buffer. The total number of coefficients is equal to N + M. For an FIR, there are no feedback coefficients, so M = 0.

Parameters

- The parameter P contains the number of values, N, to be loaded into the X2 buffer starting from address X2_BASE.
- The parameter Q contains the number of values, M, to be loaded into the X2 buffer starting from address X2_BASE + N.
- The parameter R is not used.

The function completes when N + M writes have been performed to the FMAC_WDATA register.

Load Y buffer

This function pre-loads the Y buffer with N values, starting from the address in Y_BASE. Successive writes to the FMAC_WDATA register load the write data into the Y buffer and increment the write address. The read pointer points to the address Y_BASE + N when the function completes.

The function can be used to pre-load the feedback storage elements of an IIR filter.

Parameters

- The parameter P contains the number of values to be loaded into the Y buffer.
- The parameters Q and R are not used.

The function completes when N writes have been performed to the FMAC_WDATA register.

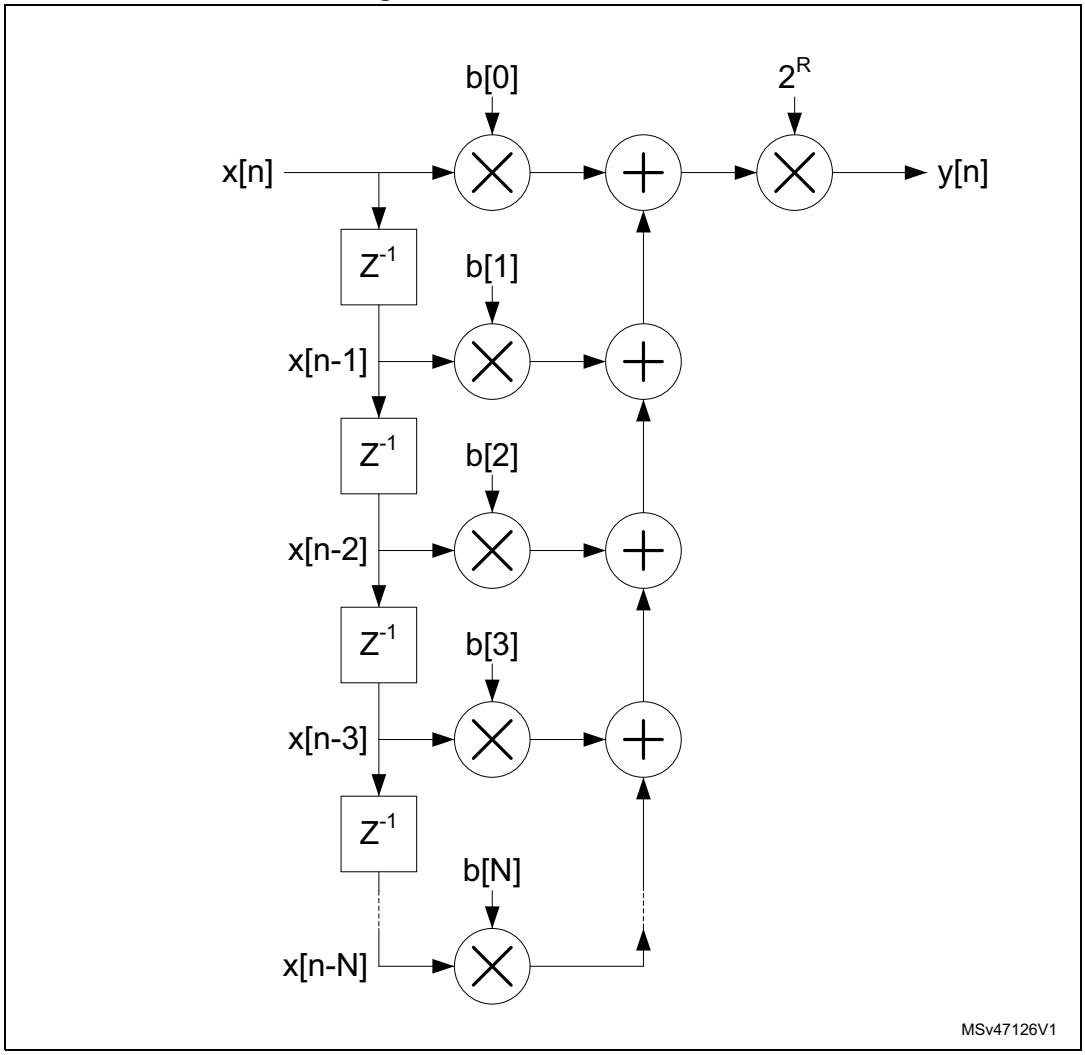
22.3.6 Filter functions

The following filter functions are supported by the FMAC unit. These functions are triggered by writing the corresponding value in the FUNC bitfield of the FMAC_PARAM register with the START bit set. The P, Q and R bitfields must also contain the appropriate parameter values for each function as detailed below. The filter functions continue to run until the START bit is reset by software.

Convolution (FIR filter)

Y = **B***__X__

$$y_n = 2^R \cdot \sum_{k=0}^{N} b_k x_{n-k}$$



This function performs a convolution of a vector **B** of length N+1 and a vector **X** of indefinite length. The elements of **Y** for incrementing values of n are calculated as the dot product,

$y_n = \underline{\mathbf{B}}.\underline{\mathbf{X}}_{\mathbf{n}}$, where $\underline{\mathbf{X}}_{\mathbf{n}} = [x_{n-N},...,x_n]$ is composed of the N+1 elements of **X** at indexes n - N to n.

This function corresponds to a finite impulse response (FIR) filter, where vector **B** contains the filter coefficients and vector **X** the sampled data.

The structure of the filter (direct form) is shown in *Figure 149*.

Figure 149. FIR filter structure

Note that the cross correlation vector can be calculated by reversing the order of the coefficient vector **B**.

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1 + d.
- X2 buffer contains the elements of vector **B**. It is a fixed buffer of length N + 1.

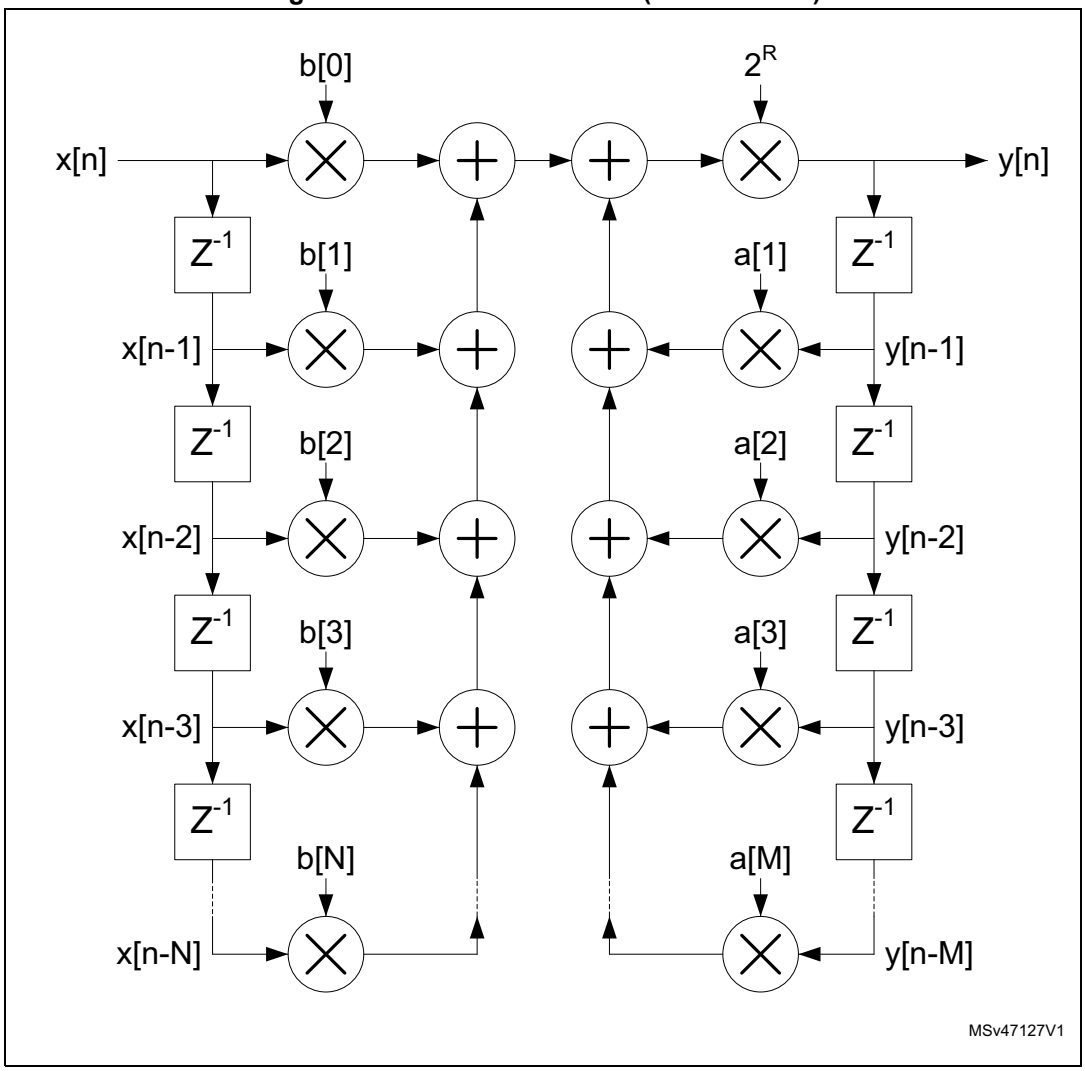
Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length d.

Parameters:

- The parameter P contains the length, N+1, of the coefficient vector **B** in the range [2:127].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7]
- The parameter Q is not used.

The function completes when the START bit in the FMAC_PARAM register is reset by software.



IIR filter

Y = B*X+A*Y'

$$y_n = 2^R \cdot \left(\sum_{k=0}^{N} b_k x_{n-k} + \sum_{k=1}^{M} a_k y_{n-k} \right)$$

This function implements an infinite impulse response (IIR) filter. The filter output vector **Y** is the convolution of a coefficient vector **B** of length N+1 and a vector **X** of indefinite length, plus the convolution of the delayed output vector **Y'** with a second coefficient vector **A**, of length M. The elements of **Y** for incrementing values of n are calculated as y_n = **B**.$\mathbf{X_n}$ + **A**.$\mathbf{Y_{n-1}}$, where $\mathbf{X_n}$ = $[x_{n-N},...,x_n]$ comprises the N+1 elements of **X** at indexes n - N to n, while $\mathbf{Y_{n-1}}$ = $[y_{n-M},...,y_{n-1}]$ comprises the M elements of **Y** at indexes n - M to n - 1. The structure of the filter (direct form 1) is shown in *Figure 150*.

Figure 150. IIR filter structure (direct form 1)

Input:

- X1 buffer contains the elements of vector **X**. It is a circular buffer of length N + 1+ d.
- X2 buffer contains the elements of coefficient vectors **B** and **A** concatenated (b_0, b_1, b_2..., b_N, a_1, a_2, ..., a_M). It is a fixed buffer of length M+N+1.

Output:

- Y buffer contains the output values, y_n. It is a circular buffer of length M + d.

Parameters

- The parameter P contains the length, N + 1, of the coefficient vector **B** in the range [2:64].
- The parameter Q contains the length, M, of the coefficient vector **A** in the range [1:63].
- The parameter R contains the gain to be applied to the accumulator output. The value output to the Y buffer is multiplied by 2^R, where R is in the range [0:7].

The function completes when the START bit in the FMAC_PARAM register is reset by software.

22.3.7 Fixed point representation

The FMAC operates in fixed point signed integer format. Input and output values are q1.15.

In q1.15 format, numbers are represented by one sign bit and 15 fractional bits (binary decimal places). The numeric range is therefore -1 (0x8000) to 1 - 2^{-15} (0x7FFF).

The accumulator has 26 bits, of which 22 are fractional and 4 are integer/sign (q4.22). This allows it to support partial accumulation sums in the range -8 (0x2000000) to +7.99999976 (0x1FFFFFF). A programmable gain from 0dB to 42dB in steps of 6dB can be applied at the output of the accumulator.

Note that the content of the accumulator is not saturated if the numeric range is exceeded. Partial sums whose value is greater than +7.99999976 or less than -8, wrap but this is harmless provided subsequent accumulations undo the wrapping. Nevertheless, the SAT flag in the FMAC_SR register is set if wrapping occurs, and generates an interrupt if the SATIEN bit is set in the FMAC_CR register. This helps in debugging the filter.

The data output by the accumulator can optionally be saturated, after application of the programmable gain, by setting the CLIPEN bit in the FMAC_CR register. If this bit is set, then any value which exceeds the numeric range of the q1.15 output, is set to 1 - 2^{-15} or -1, according to the sign. If clipping is not enabled, the unused accumulator bits after applying the gain is simply truncated.

22.3.8 Implementing FIR filters with the FMAC

The FMAC supports FIR filters of length N, where N is the number of taps or coefficients. The minimum local memory requirement for a FIR filter of length N is 2N + 1:

- N coefficients
- N input samples
- 1 output sample

Since the local memory size is 256, the maximum value for N is 127.

If maximum throughput is required, it may be necessary to allocate a small amount of extra space, d1 and d2, to the input and output sample buffers respectively, to ensure that the filter never stalls waiting for a new input sample, or waiting for the output sample to be read. In this case, the local memory requirement is 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N;
- Y_BUF_SIZE = d2 (or 1 if no extra space is required)

The buffer base addresses can be allocated anywhere, but the X2 buffer must not overlap with the others, or else the coefficients are overwritten. An example configuration is:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = 2N + d1

However, if the memory space is limited, the X1 and Y buffer areas can be overlapped, such that each output sample takes the place of the oldest input sample, which is no longer required:

- X2_BASE = 0;
- X1_BASE = N;
- Y_BASE = N

In this case, Y_BUF_SIZE = X1_BUF_SIZE = N + d1, so that the buffers remain in sync.

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

The filter coefficients **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. There is no point in pre-loading the Y buffer, since for the FIR filter there is no feedback path.

After configuring and initializing the buffers, the FMAC_CR register must be programmed according to the method used for writing and reading data to and from the FMAC memory.

Three methods are supported:

- Polling: No DMA request or Interrupt request is generated. Software must check that the X1_FULL flag is low before writing to WDATA, or that the Y_EMPTY flag is low before reading from RDATA.
- Interrupt: The interrupt request is asserted while the X1_FULL flag is low, for writes, or when the Y_EMPTY flag is low, for reads.
- DMA: DMA requests are asserted on the DMA write channel while the X1_FULL flag is low, and on the read channel while the Y_EMPTY flag is low.

Different methods can be used for read and for write. However it is not recommended to use both interrupts and DMA requests for the same operation[(a)]. The valid combinations are listed in *Table 198*.

Table 198. Valid combinations for read and write methods

WIEN	RIEN	DMAWEN	DMAREN	Write	Read
0	0	0	0	Polling	Polling
0	1	0	0	Polling	Interrupt
1	0	0	0	Interrupt	Polling
1	1	0	0	Interrupt	Interrupt
0	0	0	1	Polling	DMA
0	0	1	0	DMA	Polling
0	0	1	1	DMA	DMA
0	1	1	0	DMA	Interrupt
1	0	0	1	Interrupt	DMA

a. If both interrupts and DMA requests are enabled then only DMA must perform the transfer.

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 8 (FIR filter);
- P = N (number of coefficients);
- Q = “Don’t care”;
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.

The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples).

When 2^{EMPTY_WM} output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high.

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

22.3.9 Implementing IIR filters with the FMAC

The FMAC supports IIR filters of length N, where N is the number of feed-forward taps or coefficients. The number of feedback coefficients, M, can be any value from 1 to N-1. Only direct form 1 implementations can be realized, so filters designed for other forms need to be converted.

The minimum memory requirement for an IIR filter with N feed-forward coefficients and M feed-back coefficients is 2N + 2M:

- N + M coefficients
- N input samples
- M output samples

If M = N-1, then the maximum filter length that can be implemented is N = 64.

As for the FIR, for maximum throughput, a small amount of additional space, d1 and d2, is allowed in the input and output buffer size respectively, making the total memory requirement 2M + 2N + d1 + d2.

The buffers must be configured as follows:

- X1_BUF_SIZE = N + d1;
- X2_BUF_SIZE = N + M;
- Y_BUF_SIZE = M + d2;

The buffer base addresses can be allocated anywhere, but must not overlap. An example configuration is given below:

- X2_BASE = 0;
- X1_BASE = N + M;
- Y_BASE = 2N + M + d1;

Note: The FULL_WM bitfield of X1 buffer configuration register must be programmed with a value less than or equal to $log_2(d1)$, otherwise the buffer is flagged full before N input samples have been written, and no more samples are requested. Similarly, the EMPTY_WM bitfield of the Y buffer configuration register must be less than or equal to $log_2(d2)$.

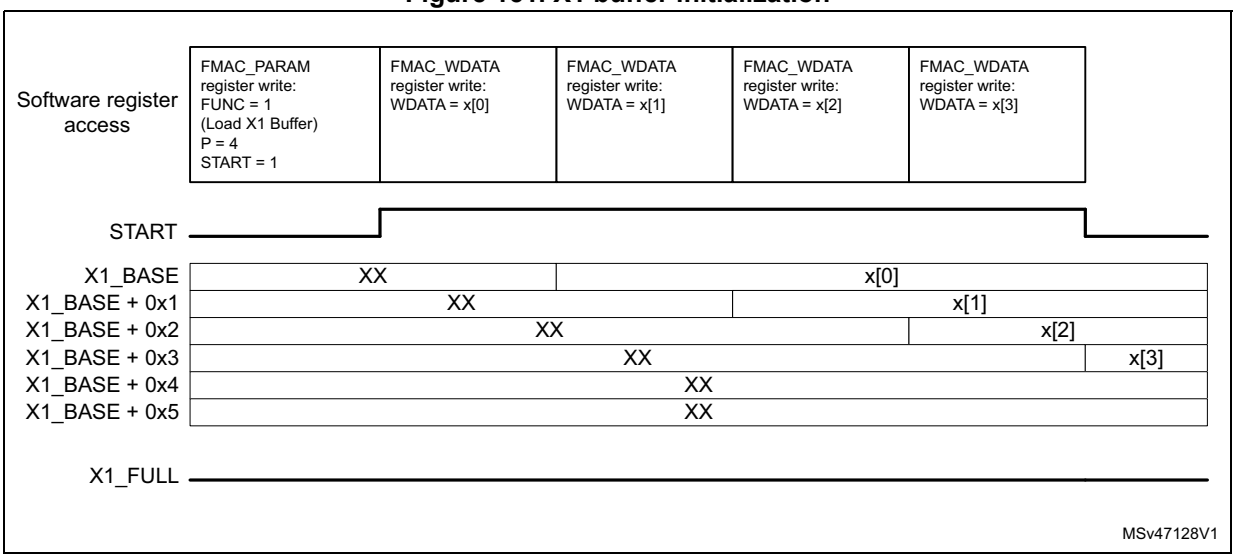
The filter coefficients (N feed-forward followed by M feedback) **must** be pre-loaded into the X2 buffer, using the Load X2 Buffer function. The X1 buffer can optionally be pre-loaded with any number of samples up to a maximum of N. The Y buffer can optionally be pre-loaded with any number of values up to a maximum of M. This has the effect of initializing the feedback delay line.

After configuring the buffers, the FMAC_CR register must be programmed in the same way as for the FIR filter (see *Section 22.3.8: Implementing FIR filters with the FMAC*).

The filter is started by writing to the FMAC_PARAM register with the following bitfield values:

- FUNC = 9 (IIR filter);
- P = N (number of feed-forward coefficients);
- Q = M (number of feed-back coefficients);
- R = Gain;
- START = 1;

If less than N + d - 2^{FULL_WM} values have been pre-loaded in the X1 buffer, the X1FULL flag remains low. If the WIEN bit is set in the FMAC_CR register, then the interrupt request is asserted immediately to request the processor to write 2^{FULL_WM} additional samples into the buffer, via the FMAC_WDATA register. It remains asserted until the X1FULL flag goes high in the FMAC_SR register. The interrupt service routine must check the X1FULL flag after every 2^{FULL_WM} writes to the FMAC_WDATA register, and repeat the transfer until the flag goes high. Similarly, if the DMAWEN bit is set in the FMAC_CR register, DMA write channel requests are generated until the X1FULL flag goes high.



The filter calculates the first output sample when at least N samples have been written into the X1 buffer (including any pre-loaded samples). The first sample is calculated using the first N samples in the X1 buffer, and the first M samples in the Y buffer (whether or not they are preloaded. The first output sample is written into the Y buffer at Y_BASE + M.

When 2^{EMPTY_WM} new output samples have been written into the Y buffer, the YEMPTY flag in the FMAC_SR register goes low. If the RIEN bit is set in the FMAC_CR register, the interrupt request is asserted to request the processor to read 2^{EMPTY_WM} samples from the buffer, via the FMAC_RDATA register. It remains asserted until the YEMPTY flag goes high. The interrupt service routine must check the YEMPTY flag after every 2^{EMPTY_WM} reads from the FMAC_RDATA register, and repeat the transfer until the flag goes high. If the DMAREN bit is set in the FMAC_CR, DMA read channel requests are generated until the YEMPTY flag goes high

The filter continues to operate in this fashion until it is stopped by the software resetting the START bit.

22.3.10 Examples of filter initialization

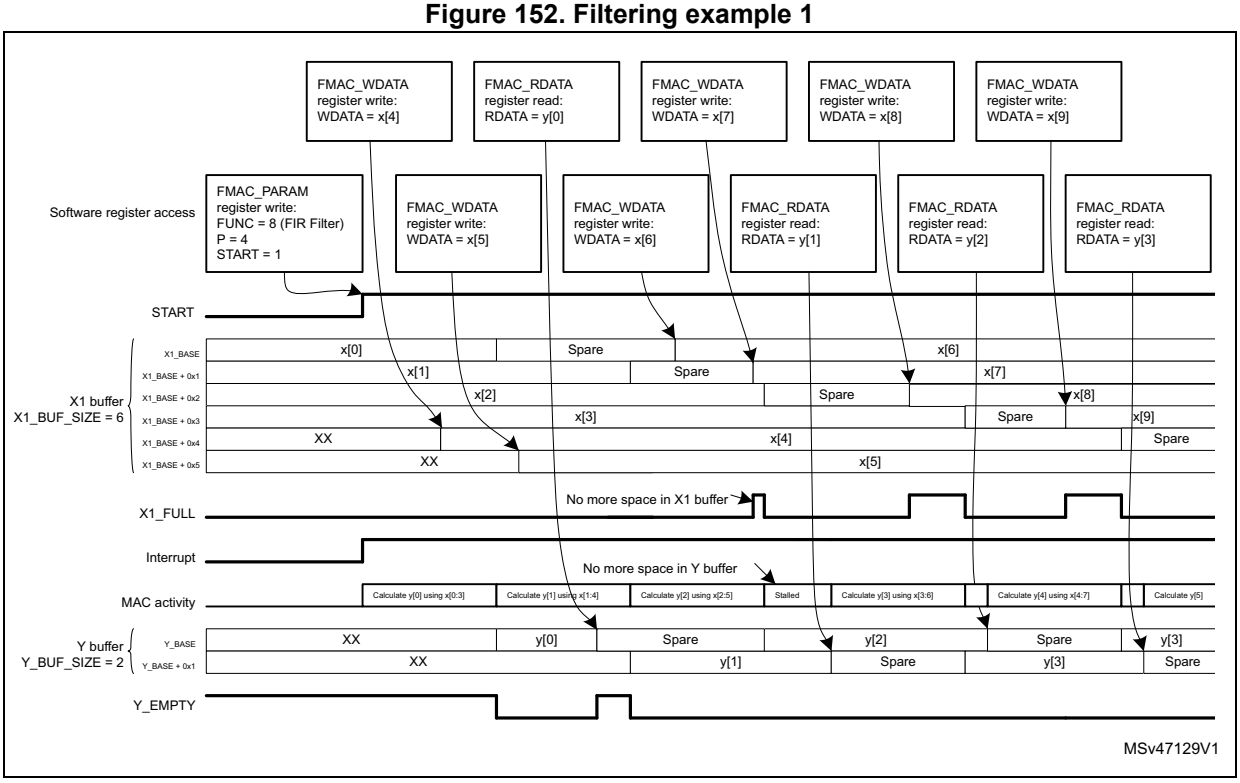


Figure 151. X1 buffer initialization

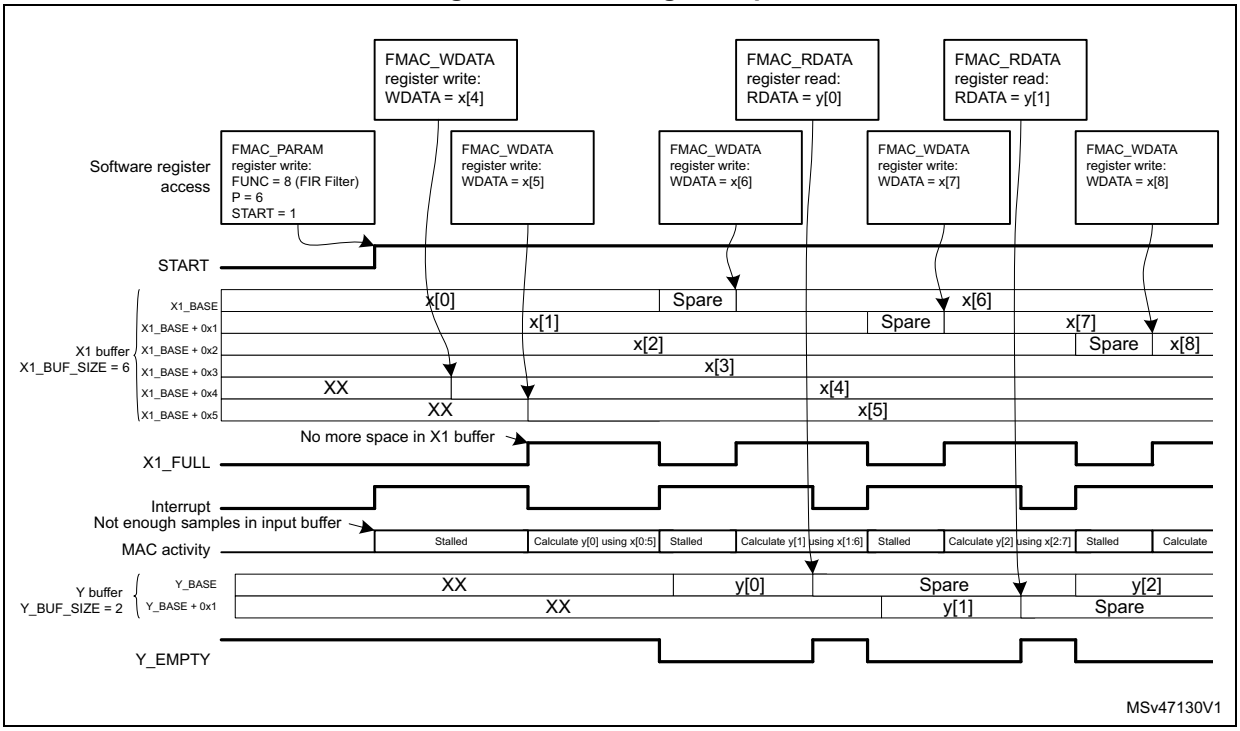
The example in *Figure 151* illustrates an X1 buffer pre-load with four samples (P = 4). The buffer size is six (X1_BUF_SIZE = 6). The initialization is launched by programming the FMAC_PARAM register with the START bit set. The four samples are then written to FMAC_WDATA, and transferred into local memory from X1_BASE onwards. The START bit resets after the fourth sample has been written. At this point, the X1 buffer contains the four samples, in order of writing, and the write pointer (next empty space) is at X1_BASE + 0x4.

22.3.11 Examples of filter operation

Figure 152. Filtering example 1

The example in *Figure 152* illustrates the beginning of a filter operation. The filter has four taps (P=4). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 151*. So the filter starts calculating the first output sample, y[0], immediately after the START bit is set. Since the X1FULL flag is not set (due to two uninitialized spaces in the X1 buffer), the interrupt is asserted straight away, to request new data. The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer.



In the mean time, the FMAC finishes calculating the first output sample, y[0], and writes it into the Y buffer, causing the Y_EMPTY flag to go low. At the same time, the x[0] sample is discarded, as it is no longer required, freeing up its location in memory (at X1_BASE). The FMAC can immediately start work on the second output sample, y[1], since all the required input samples x[1:5] are present in the X1 buffer.

Since the Y_EMPTY flag is low, the interrupt remains active after the processor finishes writing x[5]. The processor reads y[0] from the FMAC_RDATA register, freeing up its location in the Y buffer. There are now no samples in the output buffer since y[1] is still being calculated, so the Y_EMPTY flag goes high. Nevertheless, the interrupt remains active, because there is still free space in the X1 buffer, which the processor next fills with x[6], and so on.

Note: In this example, the processor can fill the input buffer more quickly than the FMAC can process them, so the X1_full flag regularly goes active. However, it struggles to read the Y buffer fast enough, so the FMAC stalls regularly waiting for space to be freed up in the Y buffer. This means the filter is not executing at maximum throughput. The reason is that the

filter length is small and the processor relatively slow, in this example. So increasing the Y buffer size does not help.

Figure 153. Filtering example 2

The example in *Figure 153* illustrates the beginning of the same filter operation, but this time the filter has six taps (P=6). The X1 buffer size is six and the Y buffer size is two. The FULL_WM and EMPTY_WM bitfields are both set to 0. Prior to starting the filter, the X1 buffer has been pre-loaded with four samples, x[0:3] as in *Figure 151*. Because there are not enough samples in the input buffer, the X1FULL flag is not set, so the interrupt is asserted straight away, to request new data. The FMAC is stalled.

The processor writes two new samples, x[4] and x[5], to the FMAC_WDATA register, which are transferred to the empty locations in the X1 buffer. As soon as there are six unused samples in the X1 buffer, the X1_FULL flag goes active (since the buffer size is six), causing the interrupt to go inactive. The FMAC starts calculating the first output sample, y[0]. Since this requires all six input samples, there are no free spaces in the X1 buffer and so the X1_FULL flag remains active. Only when the FMAC finishes calculating y[0] and writes it into the Y buffer, can x[0] be discarded, freeing up a space in the X1 buffer, and deasserting X1_FULL. At the same time, the Y_EMPTY flag goes inactive. Both these flag states cause the interrupt to be asserted, requesting the processor to write a new input sample, first of all, and then read the output sample just calculated. The FMAC remains stalled until a new input sample is written.

In this example, the processor has to wait for the FMAC to finish calculating the current output sample, before it can write a new input sample, and therefore the X1 buffer regularly goes empty, stalling the FMAC. This can be avoided by allowing some extra space in the input buffer.

22.3.12 Filter design tips

The FMAC architecture imposes some constraints detailed below, on the design of digital filters.

1. Implementation of direct form 2, or transposed forms, is not efficient. Filters which have been designed for such forms must be converted to direct form 1.
2. Cascaded filters must either be combined into a single stage, or implemented as separate filters. In the latter case, multiple sets of filter coefficients can be pre-loaded into the memory, one set per stage, and only the X2_BASE address changed to select which set is used. The most efficient method of implementing a multi-stage filter is to pre-load a large X1 buffer with input samples, run the IIR filter function on it using the first stage coefficients, and store the output samples back in memory. Then change the X2_BASE pointer to point to the 2nd stage coefficients, and reload the input buffer with the output of the first stage (with a gain if required), before running the IIR function again. The procedure is repeated for all stages. Once the final stage samples have been transferred back into system memory, the input buffer can be loaded with the next set of input samples, and a new round of calculations started. Note that the N sample input buffer of each stage must be pre-loaded first of all with the N-1 last inputs from the previous round, plus one new sample, in order to keep continuity between each round. Similarly, the output buffer of each stage must be loaded with the last M samples from the previous round, for the same reason.
3. The use of direct form 1 for IIR designs can lead to large positive or negative partial sums in the accumulator, if for example a large step occurs on the input, or some of the filter coefficients' absolute values are >1. Since the accumulator is limited to 26 bits, the biggest value that it can handle without wrapping (changing sign) is 0x1FFFFFF positive or 0x2000000 negative. This corresponds to 3.99999988 and -4 respectively in q3.23 fixed point format. Wrapping does not represent a problem provided the wrapping is "undone" before the end of the accumulation. However this is not always the case when a filter is starting up and can lead to unexpected results. Consider pre-loading the output buffer with suitable values to avoid this.
4. The IIR filter has feed-forward (numerator) coefficients $[b_0, b_1, ..., b_{N-1}]$, and feed-back (denominator) coefficients $[1, a_1, ..., a_M]$. Many IIR filters require some of the denominator coefficients to have an absolute value greater than 1 to achieve a steep roll-off in the frequency response. Given that the coefficients are coded in fixed point q1.15 format, this is not possible. Nevertheless, by scaling the denominator coefficients by a factor 2^{-R}, such that $2^{-R}.[1, a_1, ..., a_M]$ are all less than 1, such filters can be implemented. However an inverse gain of 2^R must be applied at the output of the accumulator to compensate the scaling. This has an adverse effect on the signal-to-noise ratio.

22.4 FMAC registers

22.4.1 FMAC X1 buffer configuration register (FMAC_X1BUFCFG)

Address offset: 0x00

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FULL_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X1_BUF_SIZE[7:0]								X1_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FULL_WM[1:0]**: Watermark for buffer full flag

Defines the threshold for setting the X1 buffer full flag when operating in circular mode. The flag is set if the number of free spaces in the buffer is less than 2^{FULL_WM}.

0: Threshold = 1

1: Threshold = 2

2: Threshold = 4

3: Threshold = 8

Setting a threshold greater than 1 allows several data to be transferred into the buffer under one interrupt.

Threshold must be set to 1 if DMA write requests are enabled (DMAWEN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **X1_BUF_SIZE[7:0]**: Allocated size of X1 buffer in 16-bit words

The minimum buffer size is the number of feed-forward taps in the filter (+ the watermark threshold - 1).

Bits 7:0 **X1_BASE[7:0]**: Base address of X1 buffer

22.4.2 FMAC X2 buffer configuration register (FMAC_X2BUFCFG)

Address offset: 0x04

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
X2_BUF_SIZE[7:0]								X2_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:8 **X2_BUF_SIZE[7:0]**: Size of X2 buffer in 16-bit words
This bitfield can not be modified when a function is ongoing (START = 1).

Bits 7:0 **X2_BASE[7:0]**: Base address of X2 buffer
The X2 buffer base address can be modified while START=1, for example to change coefficient values. The filter must be stalled when doing this, since changing the coefficients while a calculation is ongoing affects the result.

22.4.3 FMAC Y buffer configuration register (FMAC_YBUFCFG)

Address offset: 0x08

Reset value: 0x0000 0000

Access: word access

This register can only be modified if START = 0 in the FMAC_PARAM register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	EMPTY_WM[1:0]		Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
						rw	rw								

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Y_BUF_SIZE[7:0]								Y_BASE[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **EMPTY_WM[1:0]**: Watermark for buffer empty flag
Defines the threshold for setting the Y buffer empty flag when operating in circular mode. The flag is set if the number of unread values in the buffer is less than 2^{EMPTY_WM}.
0: Threshold = 1
1: Threshold = 2
2: Threshold = 4
3: Threshold = 8
Setting a threshold greater than 1 allows several data to be transferred from the buffer under one interrupt.
Threshold must be set to 1 if DMA read requests are enabled (DMAREN = 1 in FMAC_CR register).

Bits 23:16 Reserved, must be kept at reset value.

Bits 15:8 **Y_BUF_SIZE[7:0]**: Size of Y buffer in 16-bit words
For FIR filters, the minimum buffer size is 1 (+ the watermark threshold). For IIR filters the minimum buffer size is the number of feedback taps (+ the watermark threshold).

Bits 7:0 **Y_BASE[7:0]**: Base address of Y buffer

22.4.4 FMAC parameter register (FMAC_PARAM)

Address offset: 0x0C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
START	FUNC[6:0]							R[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Q[7:0]								P[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **START**: Enable execution
0: Stop execution
1: Start execution
Setting this bit triggers the execution of the function selected in the FUNC bitfield. Resetting it by software stops any ongoing function. For initialization functions, this bit is reset by hardware.

Bits 30:24 **FUNC[6:0]**: Function
0: Reserved
1: Load X1 buffer
2: Load X2 buffer
3: Load Y buffer
4 to 7: Reserved
8: Convolution (FIR filter)
9: IIR filter (direct form 1)
10 to 127: Reserved
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 23:16 **R[7:0]**: Input parameter R.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 15:8 **Q[7:0]**: Input parameter Q.
The value of this parameter is dependent on the function.
This bitfield can not be modified when a function is ongoing (START = 1)

Bits 7:0 **P[7:0]**: Input parameter P.
The value of this parameter is dependent on the function
This bitfield can not be modified when a function is ongoing (START = 1)

22.4.5 FMAC control register (FMAC_CR)

Address offset: 0x10

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RESET
															rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CLIP EN	Res.	Res.	Res.	Res.	Res.	DMA WEN	DMA REN	Res.	Res.	Res.	SAT IEN	UNFL IEN	OVFL IEN	WIEN	RIEN
rw						rw	rw				rw	rw	rw	rw	rw

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **RESET**: Reset FMAC unit

This resets the write and read pointers, the internal control logic, the FMAC_SR register and the FMAC_PARAM register, including the START bit if active. Other register settings are not affected. This bit is reset by hardware.

0: Reset inactive

1: Reset active

Bit 15 **CLIPEN**: Enable clipping

0: Clipping disabled. Values at the output of the accumulator which exceed the q1.15 range, wrap.

1: Clipping enabled. Values at the output of the accumulator which exceed the q1.15 range are saturated to the maximum positive or negative value (+1 or -1) according to the sign.

Bits 14:10 Reserved, must be kept at reset value.

Bit 9 **DMAWEN**: Enable DMA write channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the X1 buffer is not full.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bit 8 **DMAREN**: Enable DMA read channel requests

0: Disable. No DMA requests are generated

1: Enable. DMA requests are generated while the Y buffer is not empty.

This bit can only be modified when START= 0 in the FMAC_PARAM register. A read returns the current state of the bit.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **SATIEN**: Enable saturation error interrupts

0: Disabled. No interrupts are generated upon saturation detection.

1: Enabled. An interrupt request is generated if the SAT flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 3 **UNFLIEN**: Enable underflow error interrupts

0: Disabled. No interrupts are generated upon underflow detection.

1: Enabled. An interrupt request is generated if the UNFL flag is set

This bit is set and cleared by software. A read returns the current state of the bit.

Bit 2 **OVFLIEN**: Enable overflow error interrupts
0: Disabled. No interrupts are generated upon overflow detection.
1: Enabled. An interrupt request is generated if the OVFL flag is set
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 1 **WIEN**: Enable write interrupt
0: Disabled. No write interrupt requests are generated.
1: Enabled. An interrupt request is generated while the X1 buffer FULL flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

Bit 0 **RIEN**: Enable read interrupt
0: Disabled. No read interrupt requests are generated.
1: Enabled. An interrupt request is generated while the Y buffer EMPTY flag is not set.
This bit is set and cleared by software. A read returns the current state of the bit.

22.4.6 FMAC status register (FMAC_SR)

Address offset: 0x14

Reset value: 0x0000 0001

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	SAT	UNFL	OVFL	Res.	Res.	Res.	Res.	Res.	Res.	X1 FULL	Y EMPTY
					r	r	r							r	r

Bits 31:11 Reserved, must be kept at reset value.

Bit 10 **SAT**: Saturation error flag
Saturation occurs when the result of an accumulation exceeds the numeric range of the accumulator.
0: No saturation detected
1: Saturation detected. If the SATIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 9 **UNFL**: Underflow error flag
An underflow occurs when a read is made from FMAC_RDATA when no valid data is available in the Y buffer.
0: No underflow detected
1: Underflow detected. If the UNFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bit 8 **OVFL**: Overflow error flag
An overflow occurs when a write is made to FMAC_WDATA when no free space is available in the X1 buffer.
0: No overflow detected
1: Overflow detected. If the OVFLIEN bit is set, an interrupt is generated.
This flag is cleared by a reset of the unit.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **X1FULL**: X1 buffer full flag

The buffer is flagged as full if the number of available spaces is less than the FULL_WM threshold. The number of available spaces is the difference between the write pointer and the least recent sample currently in use.

0: X1 buffer not full. If the WIEN bit is set, the interrupt request is asserted until the flag is set. If DMAWEN is set, DMA write channel requests are generated until the flag is set.

1: X1 buffer full.

This flag is set and cleared by hardware, or by a reset.

Note: after the last available space in the X1 buffer is filled there is a delay of 3 clock cycles before the X1FULL flag goes high. To avoid any risk of overflow it is recommended to insert a software delay after writing to the X1 buffer before reading the FMAC_SR. Alternatively, a FULL_WM threshold of 2 can be used.

Bit 0 **YEMPTY**: Y buffer empty flag

The buffer is flagged as empty if the number of unread data is less than the EMPTY_WM threshold. The number of unread data is the difference between the read pointer and the current output destination address.

0: Y buffer not empty. If the RIEN bit is set, the interrupt request is asserted until the flag is set. If DMAREN is set, DMA read channel requests are generated until the flag is set.

1: Y buffer empty.

This flag is set and cleared by hardware, or by a reset.

Note: after the last sample is read from the Y buffer there is a delay of 3 clock cycles before the YEMPTY flag goes high. To avoid any risk of underflow it is recommended to insert a software delay after reading from the Y buffer before reading the FMAC_SR. Alternatively, an EMPTY_WM threshold of 2 can be used.

22.4.7 FMAC write data register (FMAC_WDATA)

Address offset: 0x18

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
WDATA[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **WDATA[15:0]**: Write data

When a write access to this register occurs, the write data are transferred to the address offset indicated by the write pointer. The pointer address is automatically incremented after each write access.

22.4.8 FMAC read data register (FMAC_RDATA)

Address offset: 0x1C

Reset value: 0x0000 0000

Access: word access

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **RDATA[15:0]**: Read data

When a read access to this register occurs, the read data are the contents of the Y output buffer at the address offset indicated by the READ pointer. The pointer address is automatically incremented after each read access.

22.4.9 FMAC register map

Table 199.FMAC register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

23 Programmable logic array (PLAY)

This section is applied only to STM32G55x/56x devices.

23.1 PLAY introduction

The programmable logic array allows the user to create custom logic and state machines without the need for external programmable logic devices, such as FPGAs. The PLAY provides a number of programmable logic elements, in the form of look-up tables (LUTs), each of which have four inputs and one output. The output can be programmed to be any logical function of the four inputs. More complex functions can be created by cascading logic elements.

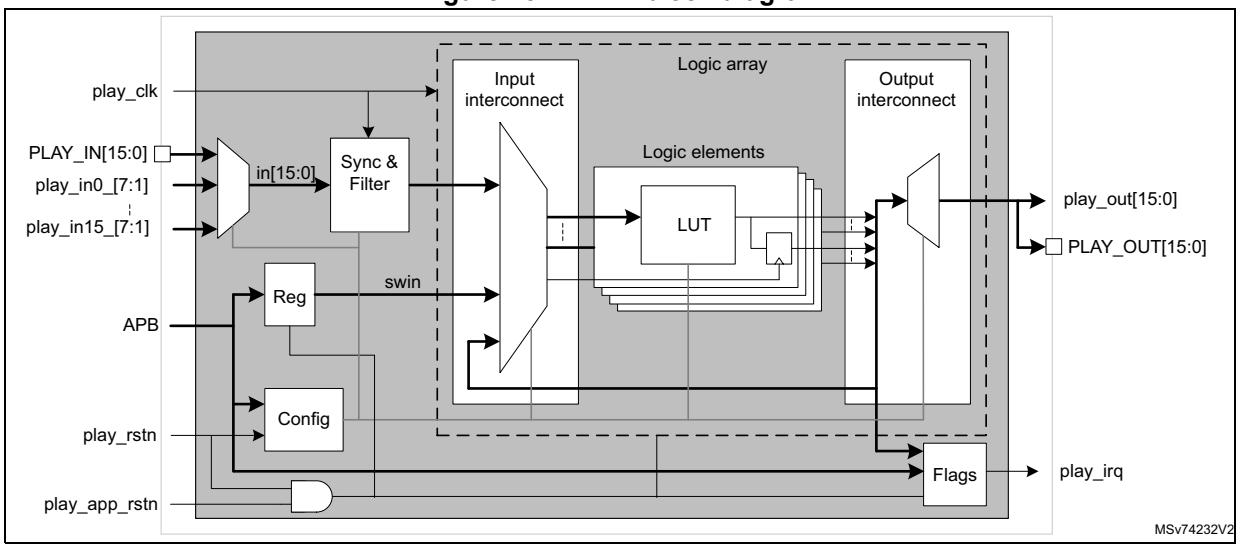
Inputs to and outputs from the logic array can be selected from a choice of external I/Os, internal signals or software programmable register bits. External inputs can be synchronized to the internal clock and filtered to remove short pulses, or connected directly to the logic array if purely combinatorial or asynchronous functions are required.

Each logic element output can be registered using the internal clock, or another signal. Registered outputs can be fed back to the logic array inputs to create finite state machines. Transitions on the outputs can set flags, which can generate interrupts to the processor. The state of the flags can be read and reset by software. The raw states of the logic element outputs can also be read by software or by an external debugger. This provides visibility of the logic array state to simplify debugging of the programmed logic functions.

The array is configured via memory-mapped registers. Configuration is simple and intuitive. Configuration registers are protected against accidental programming by a lock bit. The configuration is maintained in case of a warm system reset.

23.2 PLAY main features

- Glitch-free programmable logic elements each comprising a 4-input look-up table and a register
- Configurable input and output interconnects
- Optional synchronization of inputs, with programmable glitch filters and edge detection/pulse extension feature.
- Software programmable inputs
- Flags with interrupt capability for communication with software
- Simple register-based configuration interface, protected by software lock



23.3 PLAY functional description

- a logic array, including
  - 16 logic elements
  - an input interconnect
  - an output interconnect
- a synchronization and filter unit
- a configuration unit
- a flag and interrupt unit
- an APB bus slave interface

These are shown in *Figure 154*.

23.3.1 PLAY block diagram

Figure 154. PLAY block diagram

23.3.2 PLAY pins and internal signals

Table 200. PLAY pins

Pin name	Pin type	Description
PLAY_IN[15:0]	Digital inputs	External inputs to the PLAY
PLAY_OUT[15:0]	Digital outputs	External outputs from the PLAY

Table 201. PLAY internal signals

Signal name	Signal type	Description
play_in[15:0]_[7:1]	Digital inputs	PLAY internal inputs
play_out[15:0]	Digital outputs	PLAY internal outputs
play_clk	Clock input	PLAY clock from RCC

Table 201. PLAY internal signals (continued)

Signal name	Signal type	Description
pclk	Clock input	APB bus clock
play_irq	Interrupt request	Global interrupt
play_rstn	Reset input	Global reset (includes config)
play_app_rstn	Reset input	Application reset (excludes config)
play_priv0, play_priv1	Digital outputs	Privilege attribute indicators

Table 202 lists the signals connected to the PLAY1 inputs. Up to 16 inputs can be selected for connection to the logic array, one from each row. See *Section 23.3.4: Input selection* for details.

23.3.3 PLAY reset and clocks

The PLAY has two reset inputs:

- play_rstn: connected to the power reset
- play_app_rstn: connected to the system reset

The PLAY configuration registers are reset by:

- play_rstn

All other registers, including the PLAY logic element output registers, are reset by:

- play_rstn
- play_app_rstn

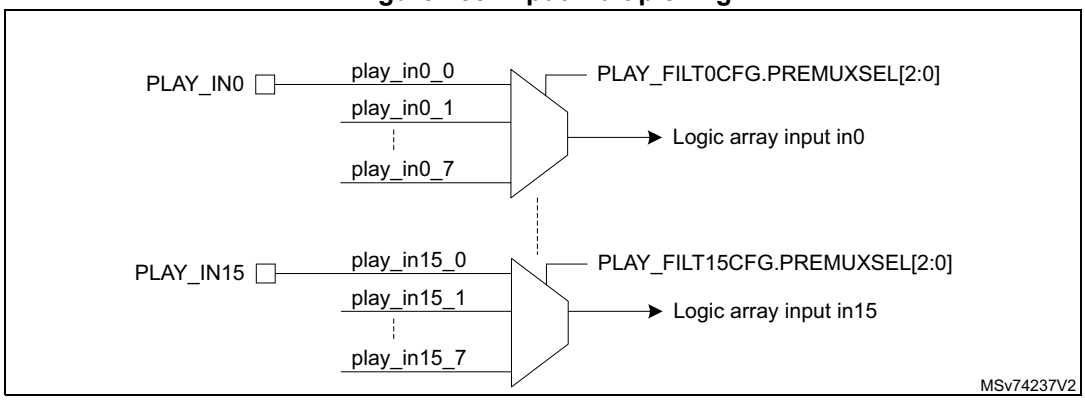
The PLAY configuration and control registers are clocked by:

- pclk (APB bus clock)

The synchronisation and filters are clocked by:

- play_clk

The PLAY logic element output registers are clocked by:



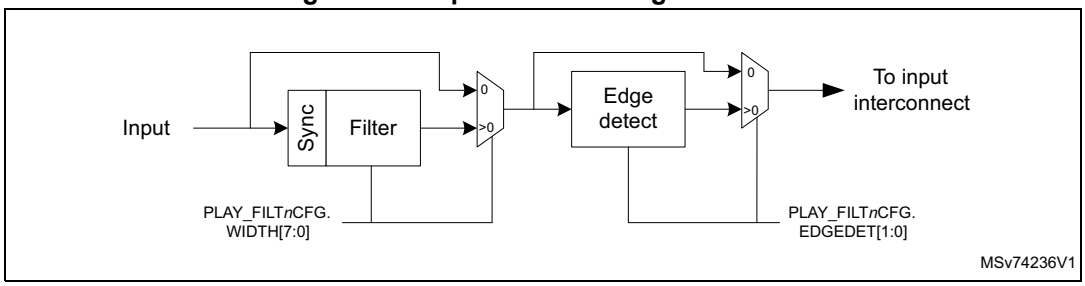
- play_clk, optionally conditioned by any of the PLAY inputs or logic element registered outputs

23.3.4 Input selection

There are 16 inputs to the logic array, in0 to in15, which can be connected to external I/Os or internal signals coming from other functional units.

Each logic array input can connect to one of eight signals. A pre-multiplexer selects which signal is connected to an input. The pre-multiplexer for logic array input *n* is configured by the PLAY_FILT*n*CFG.PREMUXSEL[2:0] register field (see *Figure 155*). Only one signal can be chosen per input.

Figure 155. Input multiplexing

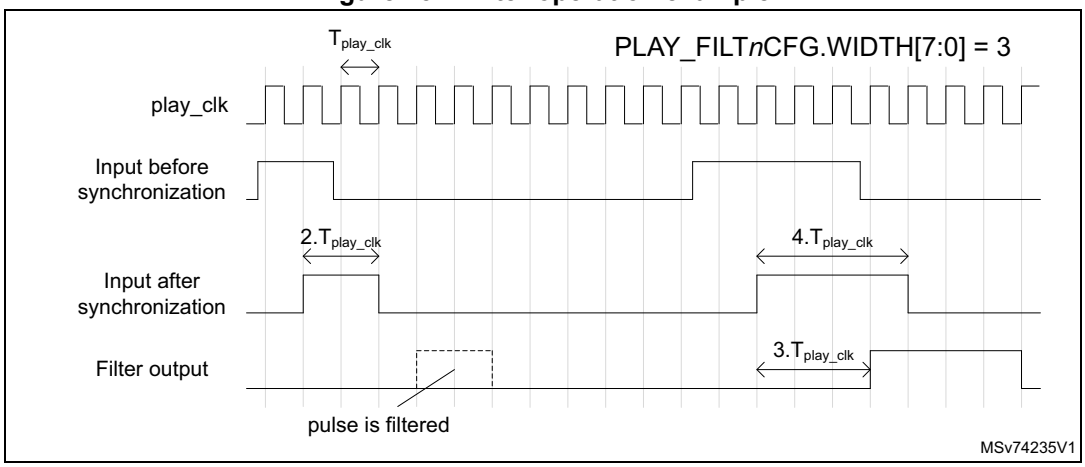


The mapping of signals to logic array inputs is shown in *Table 202*. The left hand column contains the logic array input number. The columns to the right show the play_in signal name as well as the source signal to which it is connected, for each setting of PLAY_FILT*n*CFG.PREMUXSEL[2:0]. Some source signal names appear more than once in the table, which means they can be mapped to more than one input. This offers more flexibility when mapping source signals to logic array inputs.

23.3.5 Input filtering and edge detection

Inputs pass through a filter stage, which can be configured to remove short pulses or glitches and generate a pulse if an edge is detected (see *Figure 156*).

Figure 156. Input filter and edge detection



Filtering

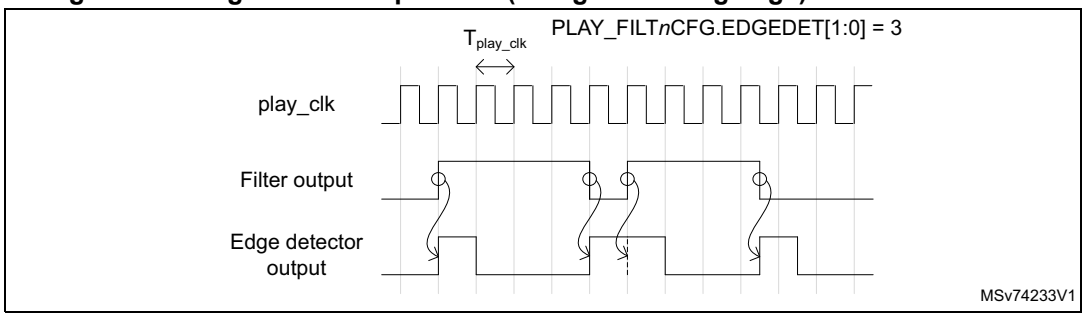
Every input has a filter which removes pulses shorter than a programmable number of play_clk clock cycles (after synchronization). The filter samples the input at the play_clk clock frequency and starts a counter if it detects a change in state. If the input transitions again before the counter reaches zero, the counter is stopped and reloaded, and the filter output state remains unchanged. If the counter reaches zero, it is reloaded and the filter output state toggles.

The minimum pulse width for input *n* can be programmed from 1 to 255 cycles in register bits PLAY_FILTCFG*n*.WIDTH[7:0]. Note that the filter introduces a delay equal to the programmed minimum pulse width.

Figure 157 illustrates the operation of the filter for PLAY_FILTCFG*n*.WIDTH[7:0] = 3. Pulses whose width is less than three periods of play_clk (T_{play_clk}) are filtered. Pulses whose width is three periods or more propagate through the filter, with a delay of three T_{play_clk} periods.

Figure 157. Filter operation example

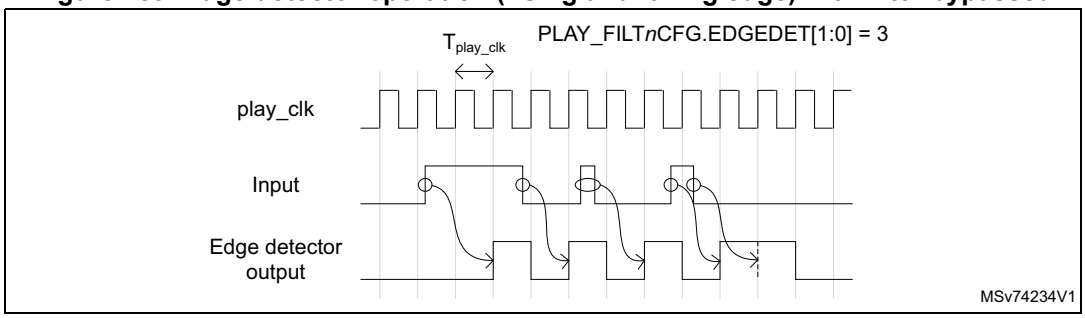
The filter can be bypassed by setting PLAY_FILTnCFG.WIDTH[7:0] = 0.



Edge detection and pulse generation

For all inputs there is an optional edge detection feature which detects a transition and generates a positive pulse of one play_clk clock period. This can be used to detect and lengthen pulses which are shorter than the play_clk clock period, or to trigger actions on an edge rather than a level. The edge detection feature is enabled for input *n* by programming

the PLAY_FILTCFG*n*.EDGEDET[1:0] field with direction of the transition (rising, falling or both edges). Setting the field to 0 disables and bypasses the edge detection.



If the filter is enabled (PLAY_FILTCFG*n*.WIDTH[7:0] > 0), the edge detector generates a pulse when an edge is detected at the output of the filter (see *Figure 158*). Note that if both rising and falling edges are programmed, back-to-back transitions on successive clocks generate a double length pulse.

Figure 158. Edge detector operation (rising and falling edge) with filter enabled

To lengthen a pulse shorter than one play_clk period, the filter must be bypassed. This is done by setting PLAY_FILTCFG*n*.WIDTH[7:0] = 0. The synchronization is done by the edge detection unit. When an edge is detected on the input signal, a positive pulse is generated after a delay of between one and two play_clk periods (see *Figure 159*).

Figure 159. Edge detector operation (rising and falling edge) with filter bypassed

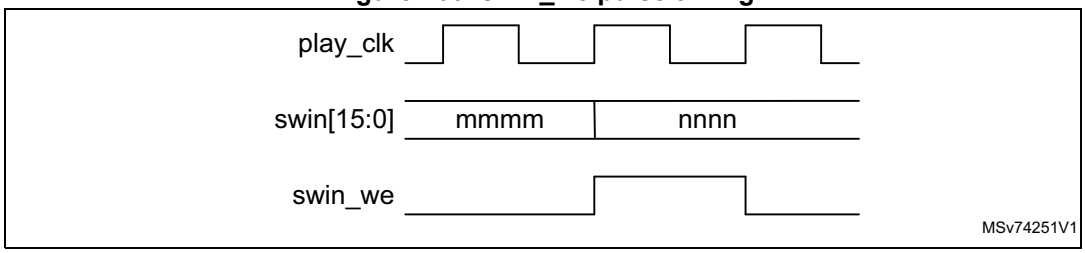
If both rising and falling edges are programmed, and the input pulse width is less than one play_clk period, only one output pulse is generated. Note however that if two transitions occur either side of a clock edge, a double length pulse is generated.

Synchronization

All input signals are considered to be asynchronous to the play_clk clock. If any synchronous logic is connected downstream, it is mandatory to synchronize the inputs to the play_clk clock, to avoid meta-stability. Synchronization introduces a delay of 1 to 2 play_clk periods.

Synchronization is performed by enabling the filter or the edge detector. If both the filter and edge detector are bypassed (PLAY_FILT*n*CFG.WIDTH[7:0] = 0 and PLAY_FILT*n*CFG.EDGEDET[1:0] = 0), the input signal is propagated directly to the logic array without synchronization.

Caution: If both edge detector and filter are bypassed, the input must only be used to drive purely combinatorial logic.



23.3.6 Software programmable inputs

The PLAY_SWIN register contains 16 bits which are connected to inputs swin0 to swin15. This allows software programmable functionality to be included in the logic expression. This can be used for example to enable or disable functionality, or to trigger state transitions, by software. These inputs also allow testing of the programmed logic array functionality.

The PLAY_SWIN register bits can be set independently by writing a 1 to the corresponding bits in the PLAY_SWIN_SET register. In the same way they can be reset by writing a 1 to the corresponding bits in the PLAY_SWIN_CLR register. It is also possible to read and write the bits directly in the PLAY_SWIN register.

Every time there is a write to the PLAY_SWIN, PLAY_SWIN_SET or PLAY_SWIN_CLR register, a positive pulse is generated on the swin_we signal. The pulse lasts one play_clk cycle, starting from the moment the register value is updated (see *Figure 160*). The swin_we signal is connected to the input interconnect and can be used as a clock enable for any of the logic element output registers. This means that writing to the PLAY_SWIN register can trigger a state transition conditioned by the new values on swin0 to swin15, for example.

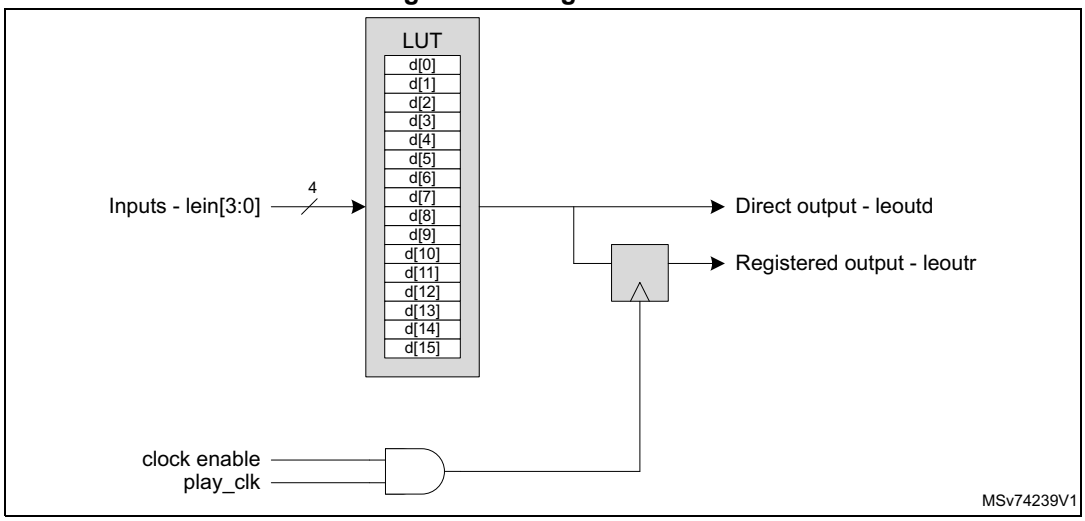


Figure 160. swin_we pulse timing

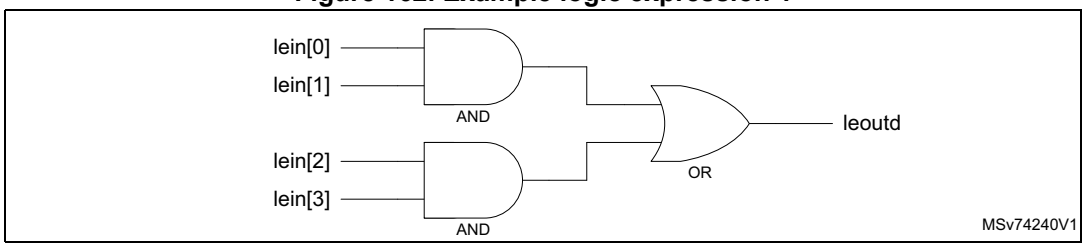
23.3.7 Logic elements

The logic array provides 16 logic elements (LEs), each containing a 4-input, single output look-up table (LUT) and a register (*Figure 161*).

Figure 161. Logic element

Look-up table (LUT)

The LUT is a 16 x 1-bit memory which generates a single output, leoutd, whose value is a function of the four LUT inputs, lein[3:0] which make up the address. The LUT is programmed at configuration time with the required state of the output for every possible combination of lein[3:0].



To implement a Boolean logic expression, the full truth table for the expression must be detailed.

This is demonstrated using the following logic expression as an example:

leoutd = lein[0] AND lein[1] OR lein[2] AND lein[3]

This expression corresponds to the diagram in *Figure 162*.

Figure 162. Example logic expression 1

The truth table is given in *Table 204*.

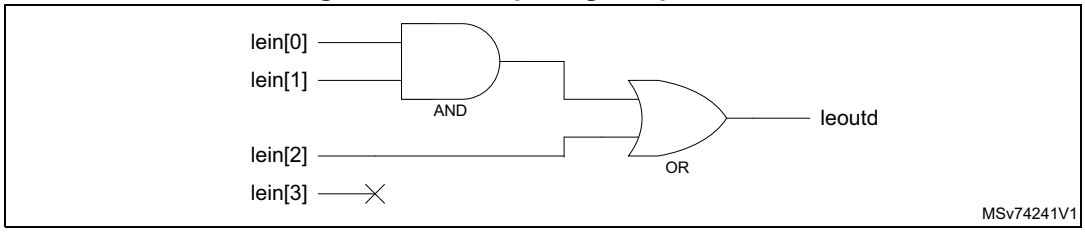
Table 204. Truth table example 1

Inputs - lein[3:0]	Output - leoutd
0000	0
0001	0
0010	0
0011	1
0100	0

Table 204. Truth table example 1 (continued)

Inputs - lein[3:0]	Output - leoutd
0101	0
0110	0
0111	1
1000	0
1001	0
1010	0
1011	1
1100	1
1101	1
1110	1
1111	1

The left hand column lists the address formed by the combination of the four LUT inputs, lein[3:0], and the right hand column lists the required output value on leoutd for each input combination.



During configuration, the LUT is programmed as a single 16-bit register, with the data read from the output column of the truth table, read from bottom (MSB) to top (LSB). In this example the LUT configuration register would be programmed with 1111 1000 1000 1000 (0xF888).

If any of the inputs are unused or “don’t care”, the output must be the same for both possible values of the unused input. In other words, the contents of address 0bxnnn must be the same for x = 0 or x = 1.

For example, in the following logic expression, lein[3] is unused:

leoutd = lein[0] AND lein[1] OR lein[2]

Figure 163. Example logic expression 2

The truth table for this expression is shown in *Table 205*. To obtain the full LUT, each row containing an ‘x’ is split into two identical rows. Then the ‘x’ is replaced by ‘0’ and ‘1’ respectively.

In this example the configuration register is programmed with 1111 1000 1111 1000 (0xF8F8).

Table 205. Truth table example 2

lein[3:0]	leoutd
x000	0
x001	0
x010	0
x011	1
x100	1
x101	1
x110	1
x111	1

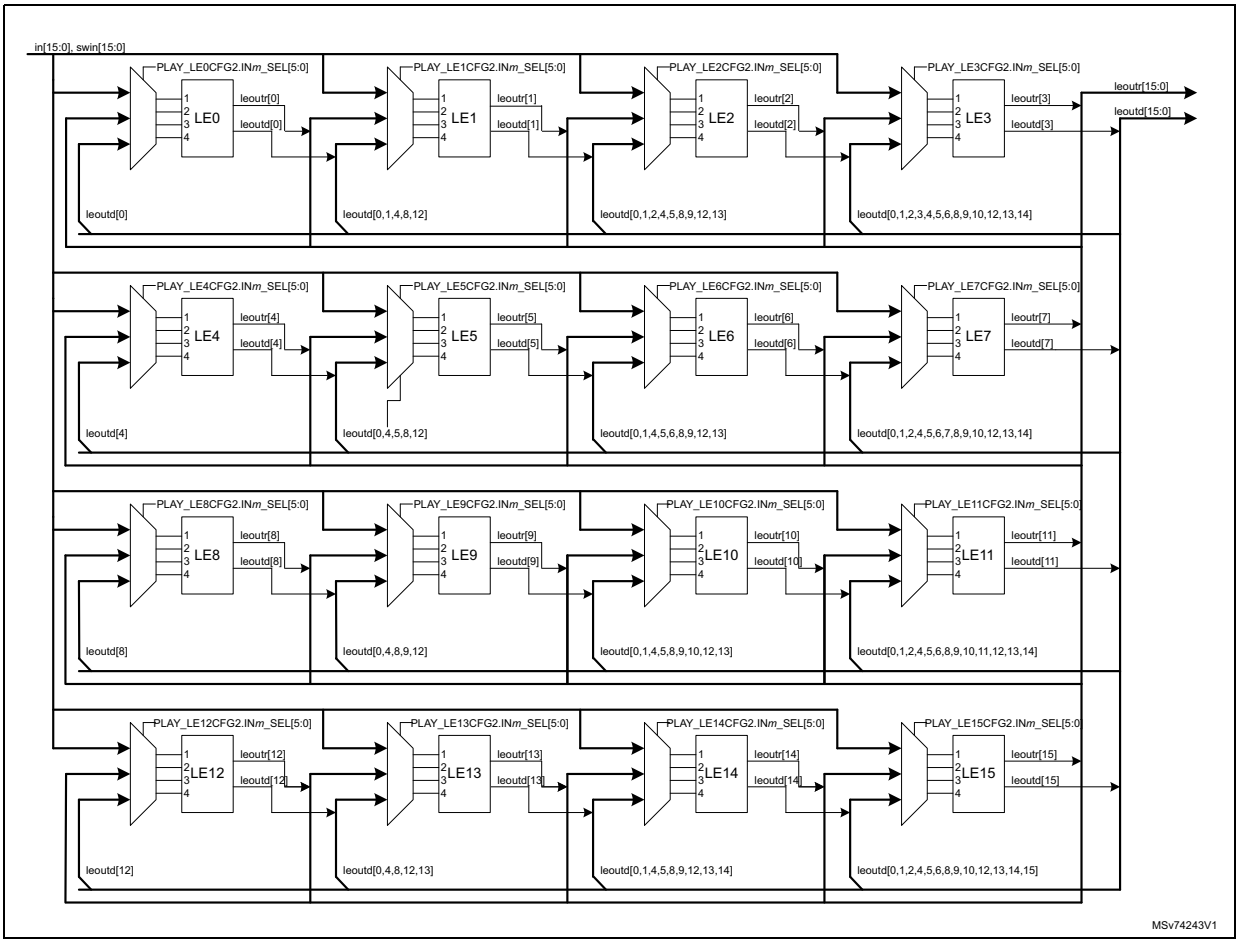
Alternatively, the unused input can be connected to an unused input with value 0 (see *Table 206*), so that addresses with x = 1 are never accessed and can be left at 0.

The LUT configuration registers are directly mapped in the PLAY APB address space. The LUT configuration for logic element *n* is programmed in the register bit field PLAY_LE*n*CFG1.LUT[15:0].

LE output register

The LUT output can be direct or registered. Output registers are clocked by the play_clk, optionally qualified by a clock enable signal. When the clock enable signal is high, the register is updated with the LUT output every play_clk cycle. A clock enable must be high for at least one play_clk cycle. This constraint is guaranteed for input signals using edge detection or filtering (see *Section 23.3.5: Input filtering and edge detection*). It is also guaranteed for the synchronous feedback signals leoutr[15:0].

Caution: Asynchronous signals must not be selected as clock enables.



During configuration (when PLAY_CFGCR.UNLOCK = 1), the logic element registers are held in reset.

Logic element registers are also reset by play_rstn and play_app_rstn.

23.3.8 Input interconnect

The input interconnect selects which signals are connected to each logic element, as shown in *Figure 164*.

Figure 164. Input interconnect

LUT input selection

For each logic element, up to four input signals can be configured as LUT inputs, and one as a clock enable for the LE register. The LUT inputs can be selected from among the following signals:

- in[15:0] - 16 inputs from I/Os or other functional blocks, via the filter and edge detection unit
- swin[15:0] - 16 register bits (PLAY_SWIN register)
- leoutr[15:0] - 16 feedback signals from LE registered outputs
- logic 0

Each logic element's direct output can be fed back to one of its inputs. This allows implementation of asynchronous latches.

It is also possible to connect the direct outputs of certain logic elements to the inputs of others - see *Combining logic elements*.

For logic element *n* (0 to 15), the signals connected to input *m* (0 to 3), are selected by configuration register PLAY_LE*n*CFG2, bit field IN*m*_SEL[5:0].

The selection of the LUT input signals is summarized in *Table 206*.

For example, to connect input signal in15 to input 2 of logic element 0, program PLAY_LE0CFG2.IN2_SEL[5:0] = 47. To connect input 3 of logic element 1 to the direct output of logic element 0, leoutd0, program PLAY_LE1CFG2.IN3_SEL[5:0] = 0.

Table 206. Logic element *n* LUT input selection

32 to 47	in0 to in15	input signals
48 to 63	swin0 to swin15	PLAY_SWIN

LE clock enable selection

The LE register clock enable can be selected from any of these signals:

- in[15:0] - 16 inputs from I/Os or other functional blocks, via the filter and edge detection
- swin[15:0] - 16 register bits (PLAY_SWIN register)
- swin_we - pulse indicating that a write to the PLAY_SWIN register has taken place
- leoutr[15:0] - 16 feedback signals from LE registered outputs
- 0- clock disabled
- 1- always enabled

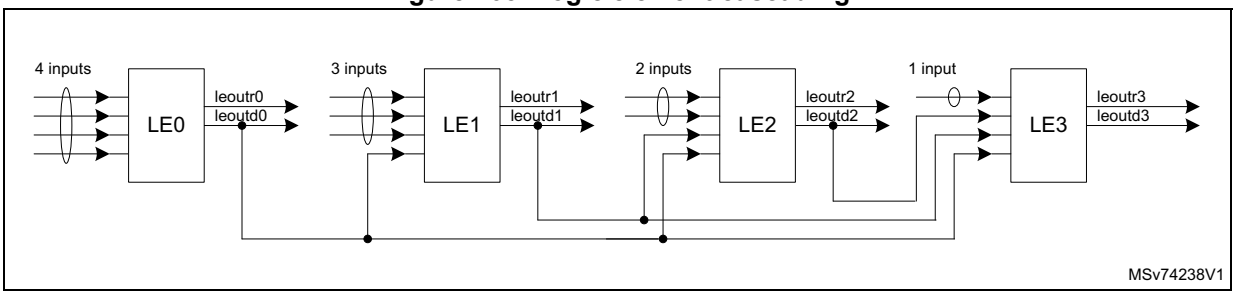
For logic element n the clock enable is selected by configuration register bits PLAY_LE*n*CFG2.CK_SEL[5:0].

The selection of the LE register clock is summarized in *Table 207*.

Table 207. Logic element *n* register clock selection

PLAY_LE*n*CFG2.CK_SEL[5:0]	Clock enable signal[(1)]	Source
0	0 (clock disabled)	-
1	1 (always enabled)	-
2	swin_we	APB interface
3 to 15	reserved	-
16 to 31	leoutr0 to leoutr15 (excluding leoutr*n*)	LE registered outputs
32 to 47	in0 to in15	input signals
48 to 63	swin0 to swin15	PLAY_SWIN

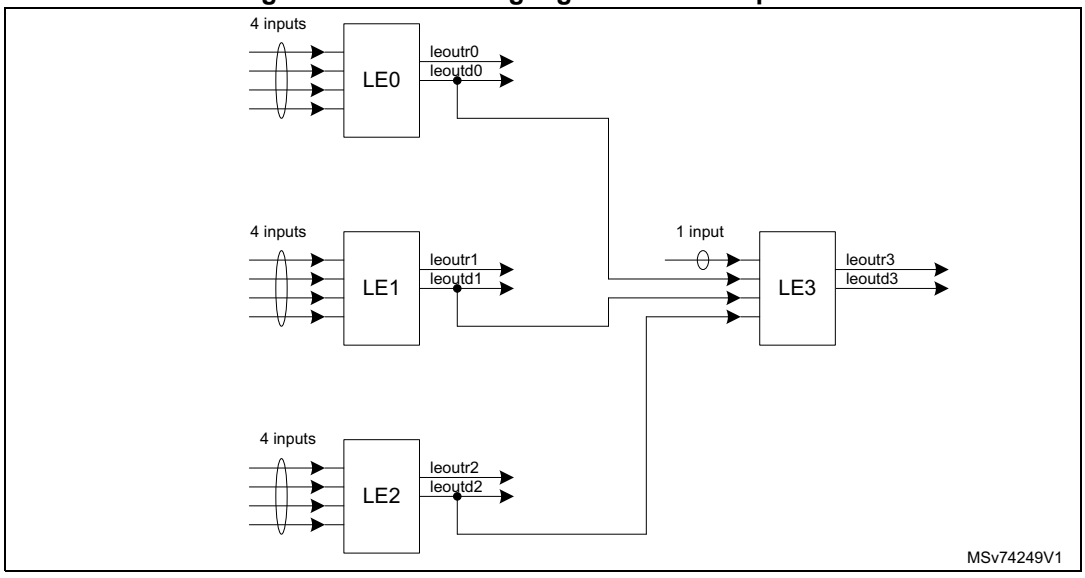
1. Reserved values select 0



Combining logic elements

LE 0-3 form a group which can be cascaded combinatorially from left to right (see *Figure 165*):

- LE0 direct output can be connected to LE1-3 inputs
- LE1 direct output can be connected to LE2-3 inputs
- LE2 direct output can be connected to LE3 inputs



The other groups of four (LE 4-7, LE 8-11, LE12-15) can be cascaded in the same way. Furthermore, logic elements from different groups can be connected together, provided the left to right logic flow is respected. For example, LE4 direct output can be connected to LE1 input, but not to LE0 input.

Figure 165. Logic element cascading

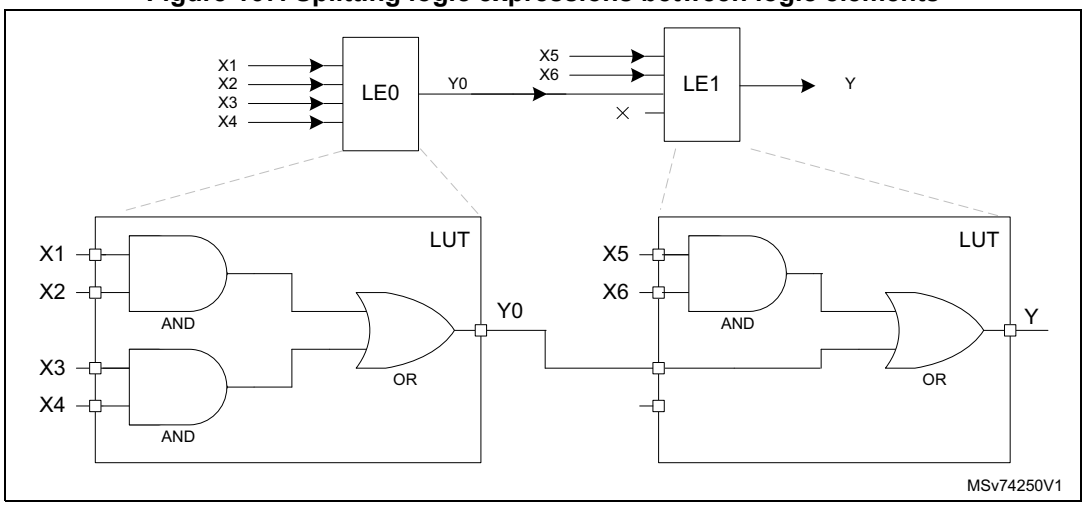
It is also possible to use one logic element to combine the outputs of up to three others, as shown in *Figure 166*. In this example, the direct outputs of LE0-2 are connected to the inputs of LE3. This allows up to 13 different inputs to be combined in a single logic expression.

Figure 166. Combining logic elements in parallel

Note that combining logic elements in this way requires the logic expression to be split into partial expressions, with up to four inputs each.

For example, consider the following expression:

Y = (X1 AND X2) OR (X3 AND X4) OR (X5 AND X6).



This expression has six inputs (X1 to X6) and one output (Y). It therefore requires at least two logic elements, for example LE0 and LE1, as illustrated in *Figure 167*. The expression for Y can be split into two expressions:

a) Y0 = (X1 AND X2) OR (X3 AND X4)

b) Y = Y0 OR (X5 AND X6)

Then LE0 is configured with expression ‘a’, and LE1 with expression ‘b’. Inputs X1 to X4 are connected to LE0. Inputs X5 and X6, are connected to LE1, together with Y0, the direct output of LE0.

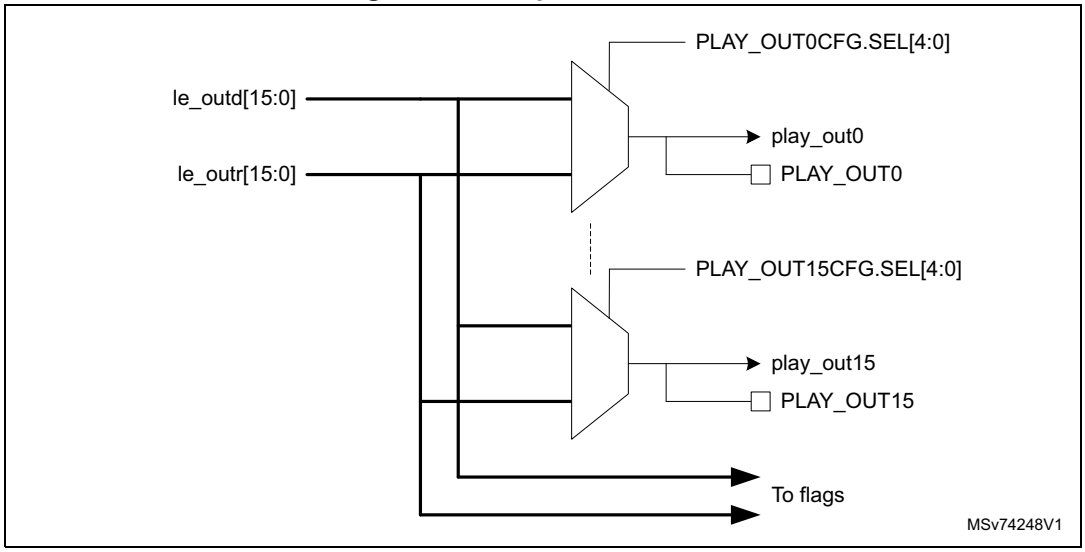


Figure 167. Splitting logic expressions between logic elements

23.3.9 Output interconnect

The output interconnect selects which logic element or eFPGA outputs are connected to which PLAY outputs, as shown in *Figure 168*.

Figure 168. Output interconnect

The PLAY outputs include the following signals:

- play_out[15:0] - 16 outputs to I/Os or other functional blocks

Each output can be connected to any one of the logic element outputs, registered or direct. The signal connected to output *n* is selected by configuration register bits PLAY_OUT*n*CFG.SEL[4:0].

The output selection is summarized in *Table 208*.

Table 208. Output n source selection

PLAY_OUT*n*CFG.SEL[4:0]	Source
0	leoutd0 - LE0 direct output
1	leoutd1 - LE1 direct output
2	leoutd2 - LE2 direct output
3	leoutd3 - LE3 direct output
4	leoutd4 - LE4 direct output
5	leoutd5 - LE5 direct output
6	leoutd6 - LE6 direct output
7	leoutd7 - LE7 direct outpu
8	leoutd8 - LE8 direct output
9	leoutd9 - LE9 direct output
10	leoutd10 - LE10 direct output

Table 208. Output n source selection (continued)

PLAY_OUT*n*CFG.SEL[4:0]	Source

23.3.10 Flags

A transition on any of the logic element outputs leoutd[15:0] or leoutr[15:0] can set the corresponding flag in the PLAY_FLSTAT register.

The direction of the transition (rising or falling) can be selected in the PLAY_FLCTL register. Once set, the flag can only be reset by software writing to the PLAY_FLCLR register (or by a reset). Setting a flag generates an interrupt to the CPU on the play_irq signal, if the enable bit for the flag is set in the PLAY_FLIER register. To clear the interrupt the software must reset the flag, or mask it by resetting the enable.

Due to the asynchronous relationship between play_clk and the pclk, a resynchronisation delay is incurred between a transition on the logic element output and the setting of the corresponding flag. The maximum delay is approximately one period of play_clk plus three periods of pclk. The play_irq interrupt is not asserted until the flag goes high. Note that if successive transitions occur on the same output before the flag is cleared, they are not taken into account. However if a subsequent transition on another logic element output occurs during the resynchronization delay, a second resynchronization starts as soon as the first is finished, at the end of which the second flag is set.

The raw state of the signals can also be read by software via the PLAY_OSR register. This is primarily intended for debugging the programmed logic. The user must be aware that the logic element outputs can change asynchronously and the value that is read from PLAY_OSR may not correspond to the actual state of the outputs at the moment of reading.

23.3.11 Miscellaneous status bits

The software input register (PLAY_SWIN), and the flag edge control register (PLAY_FLCTL) are in the play_clk domain. When a write occurs to one of these registers (including to PLAY_SWINSET/CLR), the write data is stored temporarily in the APB bus clock (pclk) domain until the next play_clk pulse at which point the data is transferred to the target register. If play_clk is slow compared to pclk, or if it is inactive, the update could take an indefinitely long time to complete. To avoid stalling the processor, any subsequent writes to the same register before the target register update has completed, are ignored.

To ensure that updates are not lost, the PLAY_MSR register contains two read-only status bits, SWIN write busy flag (SWIN_WBFS) and FLCTL write busy flag (FLCTL_WBFS). When one of these bits is set to 1, it indicates that an update is pending to the corresponding register, PLAY_SWIN or PLAY_FLCTL. The busy flags are automatically reset to 0 when the update completes.

If play_clk is significantly slower than pclk, it is recommended to poll the busy flag in the PLAY_MSR prior to writing to the corresponding register, to be sure that it has reset to 0 indicating that the previous update has completed.

Alternatively, software can enable the write complete interrupts in the PLAY_IER register to generate an interrupt request when a pending write completes (see *Section 23.5*).

23.4 PLAY in low-power modes

The play_clk can be maintained when the system is in low-power mode (Stop mode). The full functionality of the logic array is available, but the memory-mapped registers are not accessible and the flags are not updated.

When the play_clk is stopped, the logic element output registers do not operate, neither does the edge detection and filtering. However combinatorial logic continues to function as programmed.

If a logic element direct output is mapped to an asynchronous wake-up event, a transition on the output can wake the system from Stop mode. It is recommended to configure one of the software programmable inputs to reset the output so that software can deassert the wake-up event, if it is not otherwise deasserted.

In Standby mode, the PLAY is powered down and no longer functional. It must be reconfigured on exit from Standby.

23.5 PLAY interrupts

There is one interrupt request, play_irq, which can be configured to interrupt the processor when any of the following conditions occurs:

1. One or more of the flags are set, as indicated by the PLAY_FLSTAT register
2. An outstanding write to the PLAY_FLCTL register has completed, as indicated by the FLCTLWBFS bit in the PLAY_MSR register.
3. An outstanding write to the PLAY_SWIN register has completed, as indicated by the SWINWBFS bit in the PLAY_MSR register.

An interrupt handler must first read the PLAY interrupt status register (PLAY_ISR) to determine the source of the interrupt.

If the FLCTL write complete (FLCTLWC) or SWIN write complete (SWINWC) bits are set, it means that a previous write respectively to the PLAY_FLCTL or PLAY_SWIN register has completed. The write complete status bits can be cleared by writing a one to the corresponding bit in the interrupt clear (PLAY_ICR) register. The write complete interrupts are enabled and disabled by writing to the PLAY_IER register.

If the PLAY_ISR.FLAGS bit is set, the interrupt handler must read the PLAY_FLSTAT register to determine which flag(s) caused the interrupt. The FLAGS bit is reset by hardware when all the flags are inactive or masked. See *Section 23.3.10* for more details.

23.6 PLAY registers

There are three types of PLAY registers:

- Access control registers:

  PLAY_SECCFGR

  PLAY_PRIVCFGR

  These registers control software access rights to the PLAY registers.
- Configuration registers: PLAY_CFGCR, PLAY_FILTxCFGR, PLAY_LExCFG1, PLAY_LExCFG2, PLAY_OUTxCFG

  These registers configure the logic elements, input and output interconnects, input multiplexers and filters.
- Functional registers: PLAY_SWIN, PLAY_SWINSET, PLAY_SWINCLR, PLAY_OSR, PLAY_FLSTAT, PLAY_FLSET, PLAY_FLCLR, PLAY_FLIER, PLAY_FLCTL, PLAY_MSR, PLAY_ISR, PLAY_IER, PLAY_ICR

  These registers are used by the application software to interact with the logic array during operation.

23.6.1 PLAY configuration control register (PLAY_CFGCR)

Address offset: 0x000

Reset value: 0x0000 0001

This register contains miscellaneous configuration bits. It is a configuration register and is reset by play_rstn.

If PLAY_SECCFGR.SEC[0] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[0] = 1, the register requires privileged access (unprivileged accesses are ignored).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UNLOCK
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **UNLOCK**: Unlock configuration

When configuration is complete, it must be set to 0 to prevent accidental corruption of the configuration registers and enable operation of the logic element registers.

0: Configuration is locked. All configuration registers are write protected.

1: Configuration is unlocked. Configuration registers can be programmed.

23.6.2 PLAY security attributes configuration register (PLAY_SECCFGR)

Address offset: 0x004

Reset value: 0x0000 0000

This register controls the security attributes of the PLAY registers. It is an access control register and is reset by play_rstn.

The register can only be modified by a secure, privileged write access. It can be read by any access. A nonsecure write access is ignored. An unprivileged write access is ignored.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEC[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **SEC**[1:0]: Secure access control

0: All registers are accessible in nonsecure or secure state

1: Configuration registers can only be accessed in secure state. All other registers can be accessed in secure or nonsecure state.

2: Reserved

3: All registers are accessible in secure state only.

23.6.3 PLAY privilege attributes configuration register (PLAY_PRIVCFGR)

Address offset: 0x008

Reset value: 0x0000 0000

This register controls the privilege attributes of the PLAY registers. It is an access control register and is reset by play_rstn. It can only be modified by a privileged write access. It can be read by any access.

If PLAY_SECFGR.SEC[n] = 1, PLAY_PRIVCFG.PRIV[n] can only be modified by a secure write access. A nonsecure write access to PLAY_PRIVCFG.PRIV[n] is ignored.

If PLAY_SECCFGR.SEC[n] = 0, PLAY_PRIVCFG.PRIV[n] can be modified by secure or nonsecure write access.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV[1:0]	
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bits 1:0 **PRIV**[1:0]: Privilege access control

0: All registers are accessible in unprivileged or privileged state

1: Configuration registers can only be accessed in privileged state. All other registers can be accessed in privileged or unprivileged state.

2: Reserved

3: All registers are accessible in privileged state only.

23.6.4 PLAY filter x configuration register (PLAY_FILTxCFG)

Address offset: 0x020 + 0x04 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register configures the filter, edge detector and premultiplexer for logic array input x. It is a configuration register and is reset by play_rstn. Write accesses to this register are ignored if PLAY_CFGCR.UNLOCK = 0.

If PLAY_SECCFGR.SEC[0] = 1, the register requires secure access (nonsecure accesses are ignored, and signaled on play_sec_ilac).

If PLAY_PRIVCFGR.PRIV[0] = 1, the register requires privileged access (unprivileged accesses are ignored, and signaled on play_priv_ilac).

Res.	Res.	Res.	Res.	Res.	Res.	EDGEDET[1:0]		WIDTH[7:0]							
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **PREMUXSEL[2:0]**: Input pre-multiplexer select

Selects the signal to be connected to the input. See *Table 202* for details.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:8 **EDGEDET[1:0]**: Edge detection mode.

0: Edge detection is bypassed

1: A rising edge transition on the input is converted into a positive pulse of 1 play_clk cycle.

2: A falling edge transition on the input is converted into a positive pulse of 1 play_clk cycle.

3: A rising or falling edge transition on the input is converted into a positive pulse of 1 play_clk cycle.

Bits 7:0 **WIDTH[7:0]**: Minimum pulse width

0: Filter is bypassed.

1 to 255: Minimum pulse width, in play_clk cycles. Any pulse on the input shorter than this is ignored.

23.6.5 PLAY logic element x configuration register 1 (PLAY_LExCFG1)

Address offset: 0x060 + 0x04 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register configures the look-up table contents for logic element x. It is a configuration register and is reset by play_rstn. Write accesses to this register are ignored if PLAY_CFGCR.UNLOCK = 0.

If PLAY_SECCFGR.SEC[0] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[0] = 1, the register requires privileged access (unprivileged accesses are ignored).

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **LUT[15:0]**: Look-up table contents.
Truth table output for the logic element.

23.6.6 PLAY logic element x configuration register 2 (PLAY_LExCFG2)

Address offset: 0x0A0 + 0x04 * x, (x = 0 to 15)

Reset value: 0x00FF FFFF

This register configures the input source and the register clock source for logic element x. It is a configuration register and is reset by play_rstn. Write accesses to this register are ignored if PLAY_CFGCR.UNLOCK = 0.

If PLAY_SECCFGR.SEC[0] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[0] = 1, the register requires privileged access (unprivileged accesses are ignored).

IN2_SEL[3:0]				IN1_SEL[5:0]						IN0_SEL[5:0]					
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **CK_SEL[5:0]**: Clock enable selection
Selects source to be used as the clock enable for the logic element register. See *Table 207* for details.
After reset, this bit field is set to 0x0 (disabled)

Bits 23:18 **IN3_SEL[5:0]**: Logic element input 3 selection
Selects source for LUT input 3. See *Table 206* for details.
After reset, this bit field is set to 0x1F: PLAY_SWIN[15]

Bits 17:12 **IN2_SEL[5:0]**: Logic element input 2 selection
Selects source for LUT input 2. See *Table 206* for details.
After reset, this bit field is set to 0x1F: PLAY_SWIN[15]

Bits 11:6 **IN1_SEL[5:0]**: Logic element input 1 selection
Selects source for LUT input 1. See *Table 206* for details.
After reset, this bit field is set to 0x1F: PLAY_SWIN[15]

Bits 5:0 **IN0_SEL[5:0]**: Logic element input 0 selection
Selects source for LUT input 0. See *Table 206* for details.
After reset, this bit field is set to 0x1F: PLAY_SWIN[15]

23.6.7 PLAY output x configuration register (PLAY_OUTxCFG)

Address offset: 0x100 + 0x04 * x, (x = 0 to 15)

Reset value: 0x0000 0000

This register selects the source for play_out[x]. It is a configuration register and is reset by play_rstn. Write accesses to this register are ignored if PLAY_CFGCR.UNLOCK = 0.

If PLAY_SECCFGR.SEC[0] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[0] = 1, the register requires privileged access (unprivileged accesses are ignored).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEL[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **SEL[4:0]**: Output source selection.
The value of this field selects which LE output is connected to the output. See *Table 208* for details.

23.6.8 PLAY software input status register (PLAY_SWIN)

Address offset: 0x200

Reset value: 0x0000 0000

This register is used to read and write the state of the software programmable inputs. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored, and signaled on play_sec_ilac).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Caution: play_clk must be active when writing to this register. Any subsequent write access to this register (or PLAY_SWINSET or PLAY_SWINCLR) is ignored until the write completes. Software must poll the PLAY_SWIN write busy flag in the *PLAY miscellaneous status register (PLAY_MSR)* to make sure that no writes are pending. If play_clk is slow compared to the bus clock, pclk, a write may take a long time to complete. In this case, the PLAY_SWIN register write complete interrupt - see *PLAY interrupt status register (PLAY_ISR)* - can be used to signal to the software when the registers can be accessed again.

Bits 15:0 **SWINy**: Input swiny state (y = 15 to 0)
0: Input low
1: Input high

23.6.9 PLAY software input set register (PLAY_SWINSET)

Address offset: 0x204

Reset value: 0x0000 0000

This register is used to set the state of the software programmable inputs. It is a functional register and is reset automatically by hardware.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Caution: play_clk must be active when writing to this register. Any subsequent write access to this register (or PLAY_SWIN or PLAY_SWINCLR) is ignored until the write completes. Software must poll the PLAY_SWIN write busy flag in the *PLAY miscellaneous status register (PLAY_MSR)* to make sure that no writes are pending. If play_clk is slow compared to the

bus clock, pclk, a write may take a long time to complete. In this case, the PLAY_SWIN register write complete interrupt - see *PLAY interrupt status register (PLAY_ISR)* - can be used to signal to the software when the register can be accessed again.

0: Input low
1: Input high

23.6.10 PLAY software input clear register (PLAY_SWINCLR)

Address offset: 0x208

Reset value: 0x0000 0000

This register is used to reset the state of the software programmable inputs. It is a functional register and is reset automatically by hardware.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Caution: play_clk must be active when writing to this register. Any subsequent write access to this register (or PLAY_SWIN or PLAY_SWINSET) is ignored until the write completes. Software must poll the PLAY_SWIN write busy flag in the *PLAY miscellaneous status register (PLAY_MSR)* to make sure that no writes are pending. If play_clk is slow compared to the bus clock, pclk, a write may take a long time to complete. In this case, the PLAY_SWIN register write complete interrupt - see *PLAY interrupt status register (PLAY_ISR)* - can be used to signal to the software when the registers can be accessed again.

0: Input low
1: Input high

23.6.11 PLAY output status register (PLAY_OSR)

Address offset: 0x210

Reset value: 0x0000 0000

This register allows software to read the state of the LE direct and registered outputs. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Bits 15:0 **LEOUTDy**: State of LE direct outputs leoutdy (y = 15 to 0)

23.6.12 PLAY flag status register (PLAY_FLSTAT)

Address offset: 0x220

Reset value: 0x0000 0000

This register allows software to read the state of the LE output flags. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

0: Flag reset

1: Flag set

Bits 15:0 **FLAGDy**: Flag state for LEy direct output (y = 15 to 0)
0: Flag reset
1: Flag set

23.6.13 PLAY flag set register (PLAY_FLSET)

Address offset: 0x224

Reset value: 0x0000 0000

This register allows software to set the LE output flags. It is a functional register and is reset automatically by hardware.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Bits 31:16 **FLAGR_SETy**: Flag set for LEy registered output (y = 15 to 0)
0: No effect
1: Set flag

Bits 15:0 **FLAGD_SETy**: Flag set for LEy direct output (y = 15 to 0)
0: No effect
1: Set flag

23.6.14 PLAY flag clear register (PLAY_FLCLR)

Address offset: 0x228

Reset value: 0x0000 0000

This register allows software to clear the state of the LE output flags. It is a functional register and is reset automatically by hardware.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

0: No effect
1: Clear flag

Bits 15:0 **FLAGD_CLRy**: Flag clear for LEy direct output (y = 15 to 0)
0: No effect
1: Clear flag

23.6.15 PLAY flag interrupt enable register (PLAY_FLIER)

Address offset: 0x22C

Reset value: 0x0000 0000

This register enables interrupt requests based on LE output flag state. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **FLAGR_IENy**: Flag interrupt enable for LEy registered output (y = 15 to 0)
0: No interrupt is generated on play_irq
1: An interrupt is generated on play_irq if PLAY_FLSTAT.FLAGRy = 1

Bits 15:0 **FLAGD_IENy**: Flag interrupt enable for LEy direct output (y = 15 to 0)
0: No interrupt is generated on play_irq
1: An interrupt is generated on play_irq if PLAY_FLSTAT.FLAGDy = 1

23.6.16 PLAY flag control register (PLAY_FLCTL)

Address offset: 0x230

Reset value: 0x0000 0000

This register selects the direction of signal transition to set the corresponding LE output flag. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Caution: play_clk must be active when writing to this register. Any subsequent write access to this register is ignored until the write completes. Software must poll the PLAY_FLCTL write busy flag in the *PLAY miscellaneous status register (PLAY_MSR)* to make sure that no writes are pending. If play_clk is slow compared to the bus clock, pclk, a write may take a long time to complete. In this case, the PLAY_FLCTL register write complete interrupt - see *PLAY interrupt status register (PLAY_ISR)* - can be used to signal to the software when the register can be accessed again.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
FLAGR_EDGE15	FLAGR_EDGE14	FLAGR_EDGE13	FLAGR_EDGE12	FLAGR_EDGE11	FLAGR_EDGE10	FLAGR_EDGE9	FLAGR_EDGE8	FLAGR_EDGE7	FLAGR_EDGE6	FLAGR_EDGE5	FLAGR_EDGE4	FLAGR_EDGE3	FLAGR_EDGE2	FLAGR_EDGE1	FLAGR_EDGE0
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **FLAGR_EDGEy**: Edge direction for LEy registered output (y = 15 to 0)
0: FLAGRy is set by a falling edge on leoutry
1: FLAGRy is set by a rising edge on leoutry

Bits 15:0 **FLAGD_EDGEy**: Edge direction for LEy direct output (y = 15 to 0)
0: FLAGDy is set by a falling edge on leoutdy
1: FLAGDy is set by a rising edge on leoutdy

23.6.17 PLAY miscellaneous status register (PLAY_MSR)

Address offset: 0x234

Reset value: 0x0000 0000

This register allows software to read the state of miscellaneous status flags (not including LE output flags). It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FLCTL WBFS	SWIN WBFS
														r	r

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **FLCTLWBFS**: PLAY_FLCTL register write busy flag status
0: PLAY_FLCTL register can be written
1: Write is pending, any new write access to PLAY_FLCTL register is ignored

Bit 0 **SWINWBFS**: PLAY_SWIN register write busy flag status
0: PLAY_SWIN register can be written
1: Write is pending, any new write access to PLAY_SWIN, PLAY_SWINCLR or PLAY_SWINSET registers is ignored

23.6.18 PLAY interrupt status register (PLAY_ISR)

Address offset: 0x238

Reset value: 0x0000 0000

This register allows software to read the state of the interrupt request sources. The PLAY_ISR register must be read first of all when the play_irq is asserted, to identify the source(s) of the interrupt request. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FLAGS	FLCTL WC	SWIN WC
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **FLAGS**: Flag interrupts status
0: No flag interrupts active
1: One or more bits in PLAY_FLSTAT register is active and has generated an interrupt request

Bit 1 **FLCTLWC**: PLAY_FLCTL register write complete interrupt status
0: Interrupt request is not pending
1: Interrupt request is pending

Bit 0 **SWINWC**: PLAY_SWIN register write complete interrupt status
0: Interrupt request is not pending
1: Interrupt request is pending

23.6.19 PLAY interrupt clear register (PLAY_ICR)

Address offset: 0x23C

Reset value: 0xXXXX XXXX

This register allows software to clear active interrupt requests, except for those generated by flags - see *Section 23.6.14: PLAY flag clear register (PLAY_FLCLR)*. It is a functional register.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	FLCTL WC_CLR	SWIN WC_CLR
														w	w

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **FLCTLWC_CLR**: PLAY_FLCTL register write complete interrupt clear
0: No action
1: Clear interrupt request

Bit 0 **SWINWC_CLR**: PLAY_SWIN register write complete interrupt clear
0: No action
1: Clear interrupt request

23.6.20 PLAY interrupt enable register (PLAY_IER)

Address offset: 0x240

Reset value: 0x0000 0000

This register allows software to enable or disable interrupt requests, except for those generated by flags - see *Section 23.6.15: PLAY flag interrupt enable register (PLAY_FLIER)*. It is a functional register and is reset by play_rstn and play_app_rstn.

If PLAY_SECCFGR.SEC[1] = 1, the register requires secure access (nonsecure accesses are ignored).

If PLAY_PRIVCFGR.PRIV[1] = 1, the register requires privileged access (unprivileged accesses are ignored).

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

24 Extended-SPI interface (XSPI)

This section applies only for STM32G55x/56x devices.

24.1 XSPI introduction

The XSPI supports most external serial memories such as serial PSRAMs, serial NAND and serial NOR flash memories, HyperRAM™ and HyperFlash™ memories, with the following functional modes:

- indirect mode: all the operations are performed using the XSPI registers to preset commands, addresses, data, and transfer parameters.
- automatic status-polling mode: the external memory status register is periodically read and an interrupt can be generated in case of flag setting. This feature is only available in regular-command protocol.
- memory-mapped mode: the external memory is memory mapped and it is seen by the system as if it was an internal memory, supporting both read and write operations.

The XSPI supports the following protocol with associated frame format:

- the regular-command frame format with the command, address, alternate byte, dummy cycles, and data phase
- the HyperBus™ frame format

24.2 XSPI main features

- Functional modes: indirect, automatic status-polling, and memory-mapped
- Read and write support in memory-mapped mode
- External (P)SRAM memory support
- Support for single, dual, quad, octal communication
- Dual-memory configuration, where eight bits can be sent/received simultaneously by accessing two quad memories in parallel
- SDR (single-data rate) and DTR (double-transfer rate) support
- Data strobe support
- Fully programmable opcode
- Fully programmable frame format
- Support wrapped-type access to memory in read direction
- HyperBus support
- Integrated FIFO for reception and transmission
- Asynchronous bus clock versus kernel clock support
- 8-, 16-, and 32-bit data accesses allowed
- DMA protocol support
- DMA channel for indirect mode operations
- Interrupt generation on FIFO threshold, timeout, operation complete, and access error
- XSPI interface with transaction acceptance limited to one: the interface accepts the next transfer on AHB bus only once the previous is completed on memory side.

- Dual chip select support (NCS1 and NCS2)
- Extended external memory support: if two same size external memories (extmem1 and extmem2) are connected to the same I/O port, contiguously in the memory map and driven by a single XSPI. This XSPI automatically switches CS to extmem1 or extmem2, according to the address on interconnect side.
- Possibility to disable the automatic prefetch

24.3 XSPI implementation

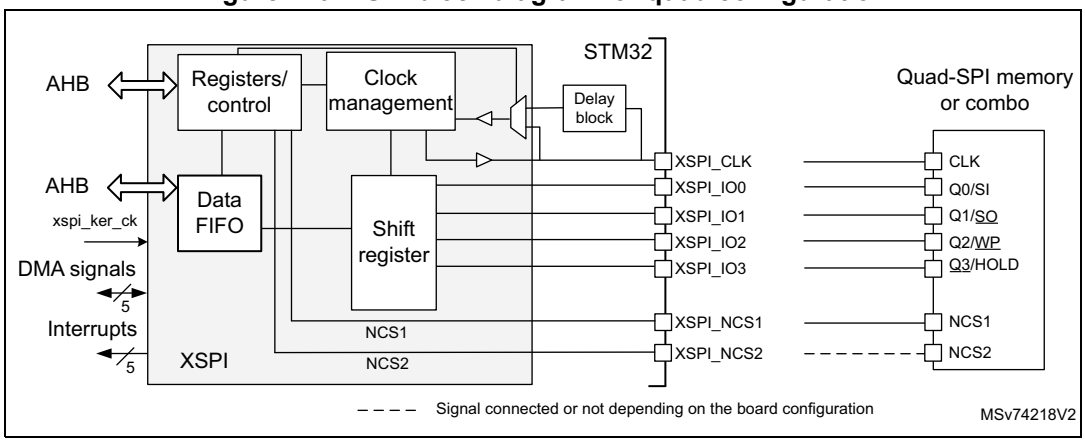

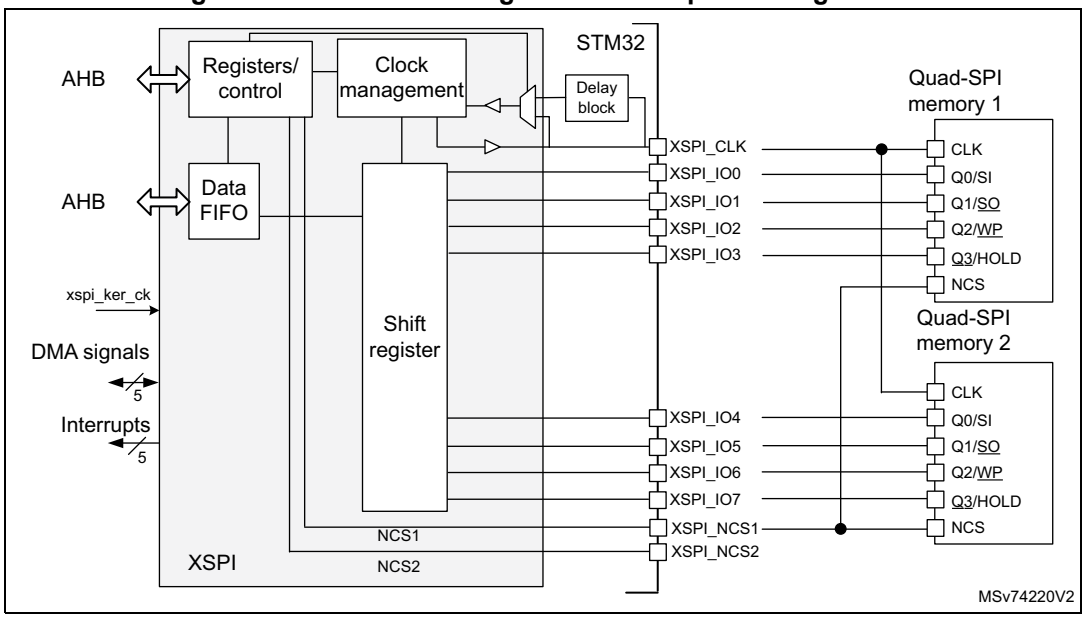

Figure 171. XSPI block diagram for dual-quad configuration

24.4.2 XSPI pins and internal signals

Table 211. XSPI input/output pins

Pin name	Type	Description
XSPI_CLK	Output	XSPI clock
XSPI_IOn (n = 0 to 7)	Input/output	XSPI data pins
XSPI_NCS1,2	Output	Chip select for the memory
XSPI_DQS	Input/output	Data strobe/write mask signal from/to the memory

Caution: Use the same configuration (output speed, HSLV[(a)]) for all XSPI input/output pins to avoid any data corruption.

Table 212. XSPI internal signals

Signal name	Type	Description
xspi_hclk	Input	XSPI AHB clock
xspi_ker_ck	Input	XSPI kernel clock
xspi_dma	N/A	DMA request signal
xspi_it	Output	Global interrupt line (see *Table 216* for the multiple sources of interrupt)

a. When applicable.

24.4.3 XSPI interface to memory modes

The XSPI supports the following protocol:

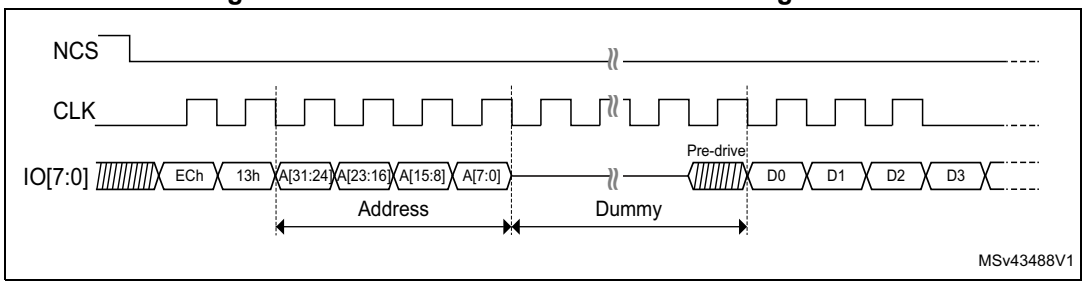
- regular-command protocol
- HyperBus protocol

The XSPI uses from 6 to 12 signals to interface with a memory, depending on the functional mode:

- NCS: chip-select (in the following sections, unless otherwise specified, NCS applies for NCS1 or NCS2. Only one of these two signals is active at a given moment in time)
- CLK: communication clock
- DQS: data strobe used only in regular-command protocol as input only
- IO[3:0]: data bus LSB
- IO[7:4]:
  - data bus MSB used in dual-quad and octal configurations
  - data bus can be used as possible remap for quad-SPI mode

24.4.4 XSPI regular-command protocol

When in regular-command protocol, the XSPI communicates with the external device using commands. Each command can include the following phases:



- Instruction phase
- Address phase
- Alternate-byte phase
- Dummy-cycle phase
- Data phase

Any of these phases can be configured to be skipped but, in case of single-phase command, the only use case supported is instruction-phase-only.

The NCS falls before the start of each command and rises again after each command finishes.

In memory-mapped mode, both read and write operations are supported: as a consequence, some of the configuration registers are duplicated to specify write operations (read operations are configured using regular registers).

Figure 172. SDR read command in octal configuration

The specific regular-command protocol features are configured through the registers in the 0x0100-0x01FC offset range.

Instruction phase

During this phase, a 1- to 4-byte instruction is sent to the external device specifying the type of operation to be performed. The size of the instruction to be sent is configured by ISIZE[1:0] in XSPI_CCR and the instruction is programmed in INSTRUCTION[31:0] of XSPI_IR.

The instruction phase can optionally send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using IMODE[2:0] of XSPI_CCR.

The instruction can be sent in DTR mode on each rising and falling edge of the clock, by setting IDTR in XSPI_CCR.

When IMODE[2:0] = 000 in XSPI_CCR, the instruction phase is skipped, and the command sequence starts with the address phase, if present.

In memory-mapped mode, the instruction used for the write operation is specified in XSPI_WIR, and the instruction format is specified in XSPI_WCCR. The instruction used for the read operation and the instruction format are specified in XSPI_IR and XSPI_CCR.

Address phase

In the address phase, 1 to 4 bytes are sent to the external device, to indicate the address of the operation. The number of address bytes to be sent is configured by ADSIZE[1:0] in XSPI_CCR.

In indirect and automatic status-polling modes, the address bytes to be sent are specified by ADDRESS[31:0] in XSPI_AR. In memory-mapped mode, the address is given directly via the AHB (from any master in the system).

The address phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ADMODE[2:0] in XSPI_CCR.

The address can be sent in DTR mode (on each rising and falling edge of the clock) setting ADDTR in XSPI_CCR.

When ADMODE[2:0] = 000, the address phase is skipped and the command sequence proceeds directly to the next phase, if any.

In memory-mapped mode, the address format for the write operation is specified in XSPI_WCCR. The address format for the read operation is specified in XSPI_CCR.

Alternate-byte phase

In the alternate-byte phase, 1 to 4 bytes are sent to the external device, generally to control the mode of operation. The number of alternate bytes to be sent is configured by ABSIZE[1:0] in XSPI_CCR. The bytes to be sent are specified in XSPI_ABR.

The alternate-byte phase can send:

- 1 bit at a time (over IO0, SO signal in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using ABMODE[2:0] in XSPI_CCR.

The alternate bytes can be sent in DTR mode (on each rising and falling edge of the clock) setting ABDTR in XSPI_CCR.

When ABMODE[2:0] = 000, the alternate-byte phase is skipped and the command sequence proceeds directly to the next phase, if any.

There may be times when only a single nibble needs to be sent during the alternate-byte phase rather than a full byte, such as when the dual-SPI mode is used and only two cycles are used for the alternate bytes.

In this case, the firmware can use the quad-SPI mode (ABMODE[2:0] = 011) and send a byte with bits 7 and 3 of ALTERNATE[31:0] set to 1 (keeping the IO3 line high), and bits 6 and 2 set to 0 (keeping the IO2 line low), in XSPI_IR.

The upper two bits of the nibble to be sent are then placed in bits 5:4 of ALTERNATE[31:0] while the lower two bits are placed in bits 1:0. For example, if the nibble 2 (0010) is to be sent over IO0/IO1, then ALTERNATE[31:0] must be set to 0x8A (1000_1010).

In memory-mapped mode, the alternate bytes used for the write operation are specified in XSPI_WABR, and the alternate byte format is specified in XSPI_WCCR. The alternate bytes used for read operation and the alternate byte format are specified in XSPI_ABR and XSPI_CCR.

Dummy-cycle phase (memory latency)

In the dummy-cycle phase, 1 to 31 cycles are given without any data being sent or received, in order to give the external device, the time to prepare for the data phase when higher clock frequencies are used. The number of cycles given during this phase is specified by DCYC[4:0] in XSPI_TCR. In both SDR and DTR modes, the duration is specified as a number of full CLK cycles.

When DCYC[4:0] = 00000, the dummy-cycle phase is skipped, and the command sequence proceeds directly to the data phase, if present.

In order to assure enough “turn-around” time for changing the data signals from the output mode to the input mode, there must be at least one dummy cycle when using the dual-, the quad-, or the octal-SPI mode, to receive data from the external device.

In memory-mapped mode, the dummy cycles for the write operations are specified in XSPI_WTCR. The dummy cycles for the read operation are specified in XSPI_TCR.

Data phase

During the data phase, any number of bytes can be sent to or received from the external device.

In indirect mode, the number of bytes to be sent/received is specified in XSPI_DLR. In this mode, the data to be sent to the external device must be written to XSPI_DR, while in indirect-read mode the data received from the external device is obtained by reading XSPI_DR.

In automatic status-polling mode, the number of bytes to be received is specified in XSPI_DLR, and the data received from the external device can be obtained by reading XSPI_DR.

In memory-mapped mode, the data read or written, is sent or received directly over the AHB to the Cortex core or to a DMA.

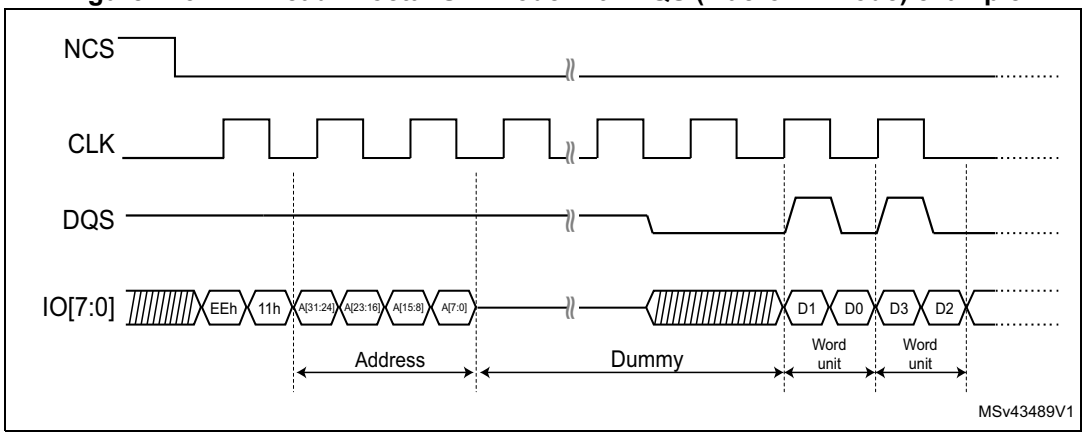
The data phase can send/receive:

- 1 bit at a time (over IO0/IO1 (SO/SI respectively) in single-SPI mode)
- 2 bits at a time (over IO0/IO1 in dual-SPI mode)
- 4 bits at a time (over IO0 to IO3 in quad-SPI mode)
- 8 bits at a time (over IO0 to IO7 in octal-SPI mode)

This can be configured using DMODE[2:0] in XSPI_CCR.

The data can be sent or received in DTR mode (on each rising and falling edge of the clock) setting DDTR in XSPI_CCR.

When DMODE[2:0] = 000, the data phase is skipped, and the command sequence finishes immediately by raising the NCS. This configuration must be used only in indirect-write mode.



In memory-mapped mode, the data format for the write operation is specified in XSPI_WCCR. The data format for the read operation is specified in XSPI_CCR.

DQS use

The DQS signal can be used for data strobing during the read transactions when the device toggles the DQS aligned with the data.

The DQS management can be enabled by setting DQSE in XSPI_CCR.

Figure 173. DTR read in octal-SPI mode with DQS (Macronix mode) example

24.4.5 XSPI regular-command protocol signal interface

Single-SPI mode

The legacy SPI mode allows just a single bit to be sent/received serially. In this mode, the data is sent to the external device over the SO signal (Single-SPI Output) (whose I/Os are shared with IO0). The data received from the external device arrives via SI (Single-SPI Input) (whose I/Os are shared with IO1).

Compared to the SPI legacy mode, I0/SO and I1/SI are respectively equivalent to MOSI and MISO, having the XSPI generating the clock.

The different phases can each be configured separately to use this single-SPI mode by setting to 001 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in single-SPI mode:

- IO0 (SO) is in output mode.
- IO1 (SI) is in input mode (high impedance).
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1 (to deactivate the “hold” function).
- IO4 to IO7 are in output mode and forced to 0.

This is the case even for the dummy phase if DMODE[2:0] = 001.

Dual-SPI mode

In dual-SPI mode, two bits are sent/received simultaneously over the IO0/IO1 signals.

The different phases can each be configured separately to use dual-SPI mode by setting to 010 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in dual-SPI mode:

- IO0/IO1 are at high-impedance (input) during the data phase for the read operations, and outputs in all other cases.
- IO2 is in output mode and forced to 0.
- IO3 is in output mode and forced to 1.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 010, IO0 and IO1 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

Quad-SPI mode

In quad-SPI mode, four bits are sent/received simultaneously over the IO0/IO1/IO2/IO3 signals.

The different phases can each be configured separately to use the quad-SPI mode by setting to 011 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase configured in quad-SPI mode:

- IO0 to IO3 are all at high-impedance (inputs) during the data phase for the read operations, and outputs in all other cases.
- IO4 to IO7 are in output mode and forced to 0.

In the dummy phase, when DMODE[2:0] = 011, IO0 to IO3 are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.

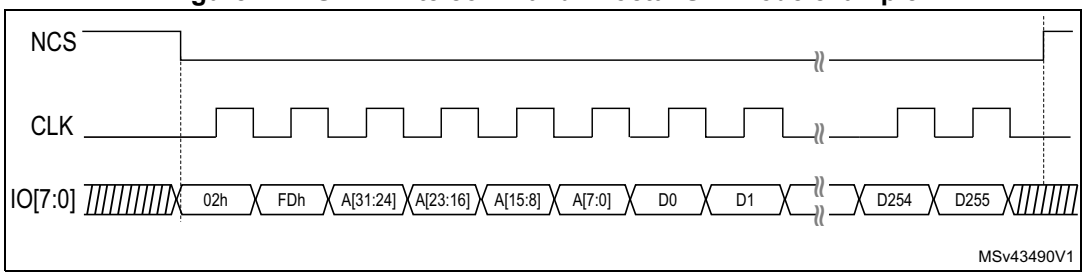
Octal-SPI mode

In regular octal-SPI mode, the eight bits are sent/received simultaneously over the IO[0:7] signals.

The different phases can each be configured separately to use the octal-SPI mode by setting to 100 the IMODE, ADMODE, ABMODE, and DMODE fields in XSPI_CCR and XSPI_WCCR.

In each phase that is configured in octal-SPI mode, IO[0:7] are all at high-impedance (input) during the data phase for read operations, and outputs in all other cases.

In the dummy phase, when DMODE[2:0] = 100, IO[0:7] are in a high-impedance state during read transactions, and are forced to either high or low levels during write transactions.



Single-data rate (SDR) mode

By default, all the phases operate in single-data rate (SDR) mode.

In SDR mode, when the XSPI drives the IO0/SO, IO1 to IO7 signals, these signals transition only with the falling edge of CLK.

When receiving data in SDR mode, the XSPI assumes that the external devices also send the data using CLK falling edge. By default (when SSHIFT = 0 in XSPI_TCR), the signals are sampled using the following (rising) edge of CLK.

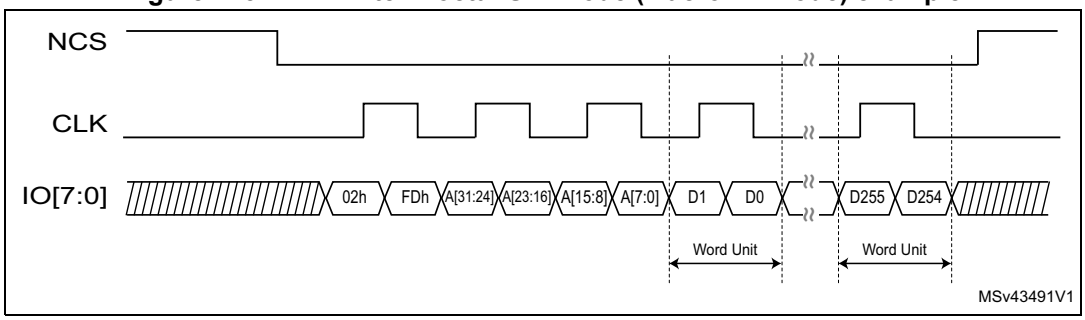
Figure 174. SDR write command in octal-SPI mode example

Double-transfer rate (DTR) mode

Each of the instruction, address, alternate-byte, and data phases can be configured to operate in DTR mode setting IDTR, ADDTR, ABDTR, and DDTR in XSPI_CCR.

In memory-mapped mode, the DTR mode for each phase of the write operations is specified in XSPI_WCCR. The DTR mode for each phase of the read operations is specified in XSPI_CCR.

In DTR mode, when the XSPI drives the IO0/SO and IO1 to IO7 signals in the instruction, address, and alternate-byte phases, a bit is sent or received on each of the falling and rising edges of CLK.



In DTR mode, when the XSPI drives the IO0 to IO7 signals in the data phases, a bit is sent or received on each of the falling and rising edges of CLK.

When receiving data in DTR mode, the XSPI assumes that the external devices also send the data using both CLK rising and falling edges. When DDTR = 1 in XSPI_CCR, the software must clear SSHIFT in XSPI_TCR. Thus, the signals are sampled one half of a CLK cycle later (on the following, opposite edge).

In DTR mode, it is recommended to set DHQC of XSPI_TCR, to shift the outputs by a quarter of cycle and avoid holding issues on the memory side.

Note: DHQC must not be set when the prescaler value is 0, as this action leads to unpredictable behavior.

Figure 175. DTR write in octal-SPI mode (Macronix mode) example

Dual-quad configuration

When DMM = 1 in XSPI_CR, the XSPI is in dual-memory configuration: if DMODE = 011, two external quad-SPI devices (device A and device B) are used in order to send/receive eight bits (or 16 bits in DTR mode) every cycle, effectively doubling the throughput.

Each device (A or B) uses the same CLK and NCS signals, but each has separate IO0 to IO3 signals.

The dual-quad configuration can be used in conjunction with the single-SPI, dual-SPI, and quad-SPI modes, as well as with either the SDR or DTR mode.

The device size, as specified by DEVSIZE[4:0] in XSPI_DCR1, must reflect the total external device capacity that is the double of the size of one individual component.

If address X is even, then the byte that the XSPI gives for address X is the byte at the address X/2 of device A, and the byte that the XSPI gives for address X + 1 is the byte at the address X/2 of device B. In other words, the bytes at even addresses are all stored in device A and the bytes at odd addresses are all stored in device B.

When reading the status registers of the devices in dual-quad configuration, twice as many bytes must be read compared to the same read in regular-command protocol: if each device gives eight valid bits after the instruction for fetching the status register, then the XSPI must be configured with a data length of 2 bytes (16 bits), and the XSPI receives one byte from each device.

If each device gives a status of 16 bits, then the XSPI must be configured to read 4 bytes to get all the status bits of both devices in dual-quad configuration. The least-significant byte of the result (in the data register) is the least-significant byte of device A status register. The next byte is the least-significant byte of device B status register. Then, the third byte of the data register is the device A second byte. The fourth byte is the device B second byte (if devices have 16-bit status registers).

An even number of bytes must always be accessed in dual-quad configuration. For this reason, bit 0 of DL[31:0] in XSPI_DLR is stuck at 1 when DMM = 1.

In dual-quad configuration, the behavior of device A interface signals is basically the same as in normal mode. Device B interface signals have exactly the same waveforms as device A ones during the instruction, address, alternate-byte, and dummy-cycle phases. In other words, each device always receives the same instruction and the same address.

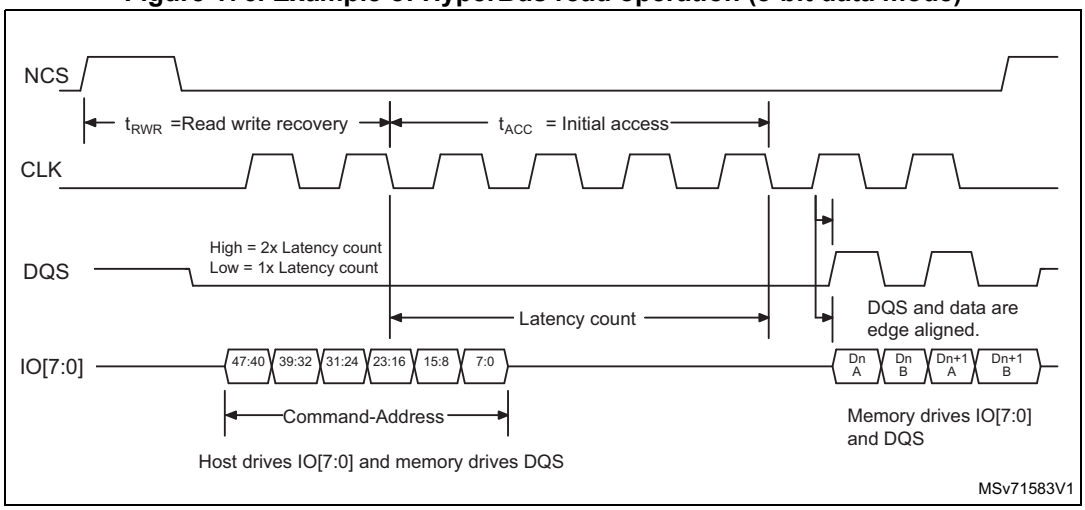
Then, during the data phase, the AIOx and the BIOx buses both transfer data in parallel, but the data that is sent to (or received from) device A is distinct than the one from device B.

24.4.6 HyperBus protocol

The XSPI can communicate with the external device using the HyperBus protocol.

The HyperBus uses 11 to 12 pins depending on the operating voltage:

- IO[7:0] as bidirectional data bus
- DQS for read and write data strobe and latency insertion
- NCS
- CLK



The HyperBus does not require any command specification nor any alternate bytes. As a consequence, a separate register set is used to define the timing of the transaction.

The HyperBus frame is composed of the following phases:

- Command/address phase
- Data phase

The NCS falls before the start of a transaction and rises again after each transaction finishes.

Figure 176. Example of HyperBus read operation (8-bit data mode)

The specific HyperBus features are configured through the registers in the 0x0200-0x02FC offset range.

Command/address phase

During this initial phase, the XSPI sends 48 bits over IO[7:0] to specify the operations to be performed with the external device.

Table 213. Command/address phase description

CA bit	Bit name	Description
47	R/W#	Identifies the transaction as a read or a write.
46	Address space	Indicates if the transaction accesses the memory or the register space.

Table 213. Command/address phase description

CA bit	Bit name	Description
45	Burst type	Indicates if the burst is linear or wrapped.
44-16	Row and upper column address	Selects the row and the upper column addresses.
15-3	Reserved	-
2-0	Lower column address	Selects the starting 16-bit word within the half page.

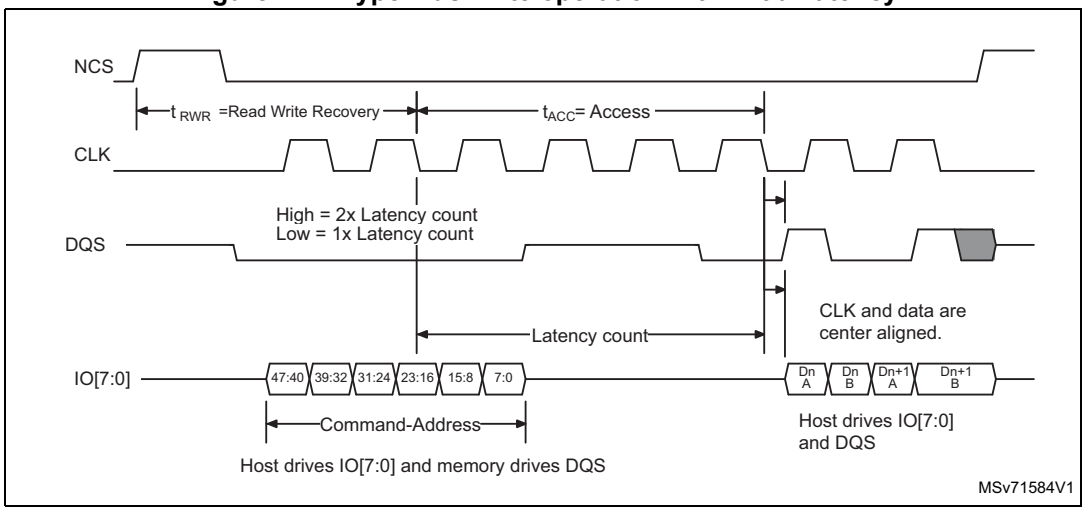
The address space is configured through the memory type MTYP[2:0] in XSPI_DCR1.

The total size of the device must be configured through DEVSIZE[4:0] of XSPI_DCR1. In case of multi-chip product (MCP), the device size is the sum of all the sizes of all the MCP dies.

Read/write operation with initial latency

The HyperBus read and write operations need to respect two timings:

- t_{RWR}: minimal read/write recovery time for the device (defined by TRWR[7:0] in XSPI_HLCR)
- t_{ACC}: access time for the device (defined by TACC[7:0] in XSPI_HLCR) according to the memory latency



During the read operation, the DQS is used by the device, in two ways (see *Figure 176*):

- during the command/address phase, to request an additional latency
- during the data phase, for data strobing

During the write operation, the DQS is used:

- by the device, during the command/address phase, to request an additional latency.
- by the XSPI, during the data phase, for write data masking.

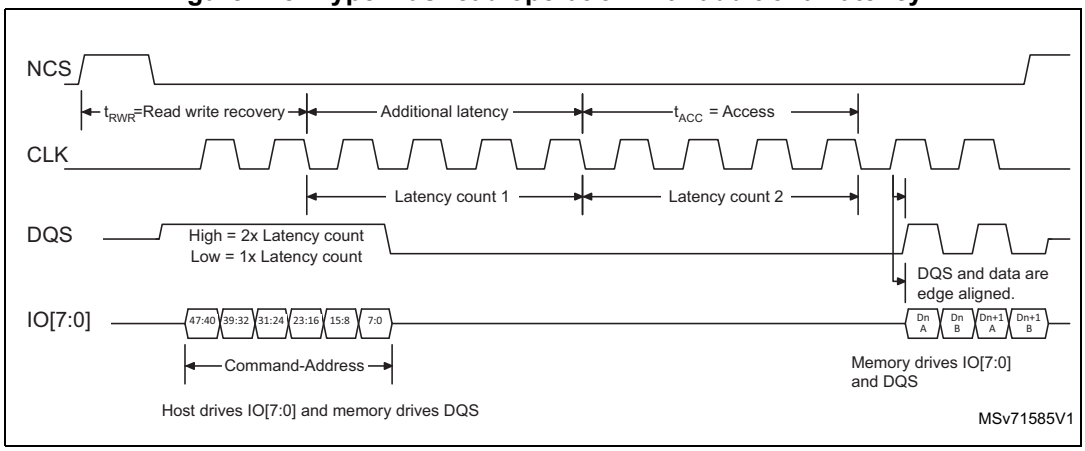
Figure 177. HyperBus write operation with initial latency

Read/write operation with additional latency

If the device needs an additional latency (during refresh period of an SDRAM for example), DQS must be tied to one during one of the DQS signals, during the command/address phase.

An additional t_{ACC} duration is added by the XSPI to meet the device request.

Figure 178. HyperBus read operation with additional latency



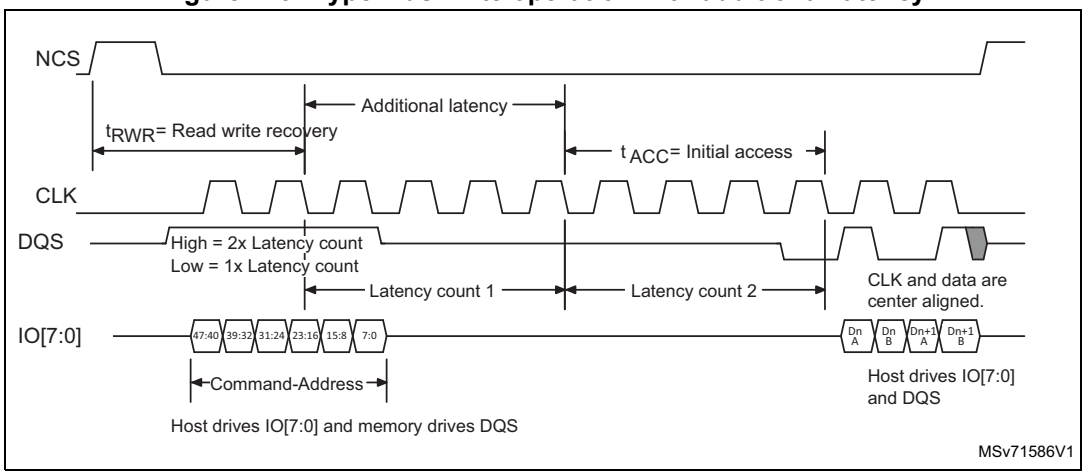


Figure 179. HyperBus write operation with additional latency

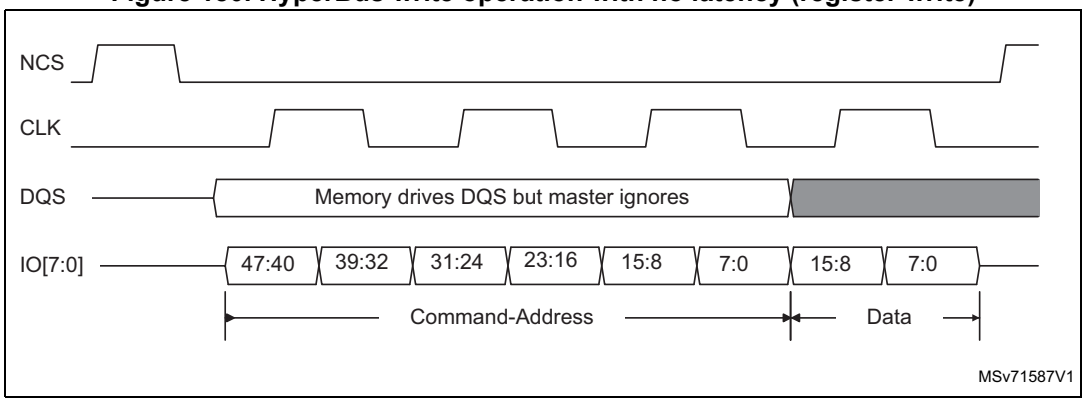
Fixed-latency mode

Some devices or some applications may not want to operate with a variable latency time as described above.



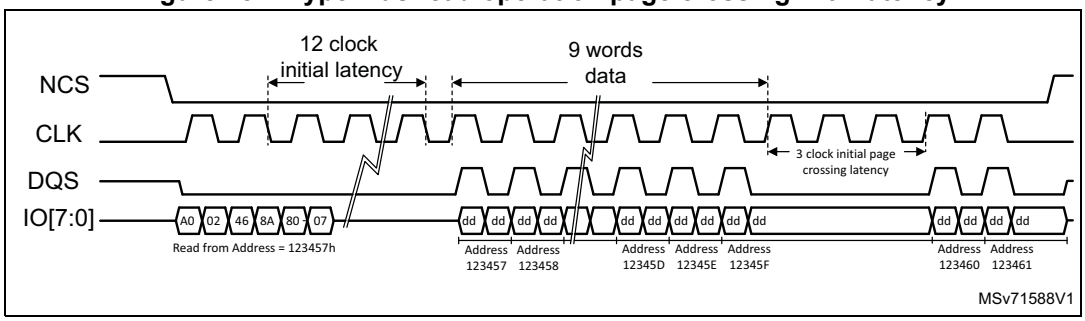
The latency can be forced to 2 x t_{ACC} by setting LM in XSPI_HLCR.

In this XSPI latency mode, the state of the DQS signal is not taken into account by the XSPI, and an additional latency is always added, leading to a fixed 2 x t_{ACC} latency time.

Write operation with no latency

Some devices can also require a zero latency for the write operations. This write-zero latency can be forced by setting WZL in XSPI_HLCR.

Figure 180. HyperBus write operation with no latency (register write)



Latency on page-crossing during the read operations

An additional latency can be needed by some devices for the read operation when crossing pages.

The initial latency must be respected for any page access, as a consequence, when the first access is close to the page boundary, a latency is automatically added at the page crossing to respect the t_{ACC} time.

Figure 181. HyperBus read operation page crossing with latency

24.4.7 Specific features

The XSPI supports some specific features, such as:

- Wrap support
- NCS boundary and refresh

Wrap support

The XSPI supports a hybrid wrap as defined by the HyperBus protocol. A hybrid wrap is also supported in the regular-command protocol.

In hybrid wrap, the transaction can continue after the initial wrap with an incremental access.

The wrap size supported by the target memory is configured by WRAPSIZE in XSPI_DCR2.

Wrap is supported only in memory-read direction and only for data size = 4 bytes. Wrapped reads are supported for both HyperBus and regular-command protocols. To enable wrapped-read accesses, the dedicated XSPI_WPxxx registers must be programmed according to the wrapped-read access characteristics. These registers apply for both HyperBus and regular-command protocols.

If the target memory is not supporting the hybrid wrap, WRAPSIZE must be set to 0.

Note: Hybrid wrap requires that the nonwrapped registers (XSPI_CCR, XSPI_TCR, XSPI_IR) are set according to the memory configuration to satisfy its correct data prefetch (initiated after the wrap command).

The wrap operation cannot be interrupted by a refresh. The refresh event is only considered after the wrap completion.

NCS boundary and refresh

Two processes can be activated to regulate the XSPI transactions:

- NCS boundary
- Refresh

The NCS boundary feature limits a transaction to a boundary of aligned addresses. The size of the address to be aligned with, is configured by CSBOUND[4:0] in XSPI_DCR3: it is equal to $2^{CSBOUND}$.

As an example, if CSBOUND(4:0] = 0x4, the boundary is set to 2^4 = 16 bytes. The NCS is then released each time the LSB address is equal to 0xF, and each time a new transaction is issued to address the next data.

If CSBOUND[4:0] = 0, the feature is disabled. A minimum value of three is recommended.

The NCS boundary feature cannot be used for flash memory devices in write mode since a command is necessary to program another page of the flash memory.

The refresh feature limits the duration of the transactions to the value programmed by REFRESH[31:0] in XSPI_DCR4. The duration is expressed in number of cycles. This allows an external RAM to perform its internal refresh operation regularly.

The refresh value must be greater than the minimal transaction size in terms of number of cycles including the command/address/alternate/dummy phases.

If NCS boundary and refresh are enabled at the same time, the NCS is released on the first condition met.

24.4.8 XSPI operating mode introduction

The XSPI has the following operating modes regardless of the low-level protocol used (either regular-command or HyperBus):

- indirect mode (read or write)
- automatic status-polling mode (only in regular-command protocol)
- memory-mapped mode

24.4.9 XSPI indirect mode

In indirect mode, the commands are started by writing to the XSPI registers, and data are transferred by writing or reading the data register, in a similar way to other communication peripherals.

When FMODE[1:0] = 00 in XSPI_CR, the XSPI is in indirect-write mode: bytes are sent to the external device during the data phase. Data are provided by writing to XSPI_DR.

When FMODE[1:0] = 01, the XSPI is in indirect-read mode: bytes are received from the external device during the data phase. Data are recovered by reading XSPI_DR.

In indirect mode, when the XSPI is configured in DTR mode over eight lanes with DQS disabled, the given starting address and the data length must be even.

Note: The XSPI_AR register must be updated even if the start address is the same as the start address of the previous indirect access.

The number of bytes to be read/written is specified in XSPI_DLR:

- If DL[31:0] = 0xFFFF FFFF, the data length is considered undefined and the XSPI simply continues to transfer data until it reaches the end of the external device (as defined by DEVSIZE). If no bytes are to be transferred, DMODE[2:0] must be set to 0 in XSPI_CCR.
- If DL[31:0] = 0xFFFF FFFFF and DEVSIZE[4:0] = 0x1F (its maximum value indicating at 4-Gbyte device), the transfers continue indefinitely, stopping only after an abort request or after the XSPI is disabled. After the last memory address is read (at address 0xFFFF FFFF), reading continues with address = 0x0000 0000.

When the programmed number of bytes to be transmitted or received is reached, the TCF bit is set in XSPI_SR, and an interrupt is generated if TCIE = 1 in XSPI_CR. In the case of an undefined number of data, TCF is set when the limit of the external SPI memory is reached, according to the device size defined in XSPI_DCR1.

Triggering the start of a transfer in regular-command protocol

Depending on the XSPI configuration, there are three different ways to trigger the start of a transfer in indirect mode when using the regular-command protocol. In general, the start of transfer is triggered as soon as the software gives the last information that is necessary for the command. More specifically in indirect mode, a transfer starts when one of the following sequence of events occurs:

- if no address is necessary (ADMODE[2:0] = 000) and if no data need to be provided by the software (FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to INSTRUCTION[31:0] in XSPI_IR
- if an address is necessary (when ADMODE[2:0] ≠ 000) and if no data need to be provided by the software (when FMODE[1:0] = 01 or DMODE[2:0] = 000), and at the moment when a write is performed to ADDRESS[31:0] in XSPI_AR
- if data need to be provided by the software (when FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), and at the moment when a write is performed to DATA[31:0] in XSPI_DR

A write to XSPI_ABR never triggers the communication start. If alternate bytes are required, they must have been programmed before.

As soon as a command is started, the BUSY bit is automatically set in XSPI_SR.

Triggering the start of a transfer in HyperBus protocol

Depending on the XSPI configuration, there are different ways to trigger the start of a command in indirect mode. In general, it is triggered as soon as the firmware gives the last information that is necessary for the transfer to start, and more specifically, a communication

in indirect mode is triggered by one of the following register settings, when it is the last one to be executed:

- when a write is performed to ADDRESS[31:0] (XSPI_AR) with ADMODE[2:0] ≠ 000 in indirect read mode (FMODE[1:0] = 01).
- when a write is performed to DATA[31:0] (XSPI_DR) in indirect-write mode (when FMODE = 00).
- when a (dummy) write is performed to INSTRUCTION[31:0] (XSPI_IR) for indirect read mode (with ADMODE[2:0] = 000 and FMODE = 01).

As soon as a transfer is started, the BUSY bit (XSPI_SR[5]) is automatically set.

FIFO and data management

Data in indirect mode pass through a 32-byte FIFO that is internal to the XSPI. FLEVEL in XSPI_SR indicates how many bytes are currently being held in the FIFO.

AHB burst transactions are supported. Data of the burst are successively written in XSPI_DR, and immediately transferred in the internal FIFO.

In indirect-write mode (FMODE[1:0] = 00), the software adds data to the FIFO when it writes in XSPI_DR. A word write adds 4 bytes to the FIFO, a half-word write adds 2 bytes, and a byte write adds only 1 byte. If the software adds too many bytes to the FIFO (more than indicated in DL[31:0]), the extra bytes are flushed from the FIFO at the end of the write operation (when TCF is set).

The byte/half-word accesses to XSPI_DR must be done only to the least significant byte/halfword of the 32-bit register.

FTHRES is used to define a FIFO threshold after which point the FIFO threshold flag, FTF, gets set. In indirect-read mode, FTF is set when the number of valid bytes to be read from the FIFO is above the threshold. FTF is also set if there is any data left in the FIFO after the last byte is read from the external device, regardless of FTHRES setting. In indirect-write mode, the FTF is set when the number of empty bytes in the FIFO is above the threshold.

If FTIE = 1, there is an interrupt when the FTF is set. If DMAEN = 1, a DMA transfer is initiated when the FTF is set. The FTF is cleared by hardware as soon as the threshold condition is no longer true (after enough data has been transferred by the CPU or DMA).

The last data read in RX FIFO remains valid as long as there is no request for the next line. This means that, when the application reads several times in a row at the same location, the data is provided from the RX FIFO and not read again from the distant memory.

24.4.10 XSPI automatic status-polling mode

In automatic status-polling mode, the XSPI periodically starts a command to read a defined number of status bytes (up to four). The received bytes can be masked to isolate some status bits and an interrupt can be generated when the selected bits have a defined value. The automatic status-polling mode must be used only in regular-command protocol. For HyperBus protocol, it is not exploitable since the read status register into the HyperFlash memory must be performed in two steps (a write operation followed by a read operation).

The access to the device begins in the same manner as in indirect-read mode. BUSY in XSPI_SR goes high at this point and stays high even between the periodic accesses.

The content of MASK[31:0] in XSPI_PSMAR is used to mask the data from the external device in automatic status-polling mode:

- If the MASK[n] = 0, then bit n of the result is masked and not considered.
- If MASK[n] = 1, and the content of bit[n] is the same as MATCH[n] in XSPI_PSMAR, then there is a match for bit n.

If PMM = 0 in XSPI_CR, the AND-match mode is activated: SMF is set in XSPI_SR only when there is a match on all of the unmasked bits.

If PMM = 1 in XSPI_CR, the OR-match mode is activated: SMF gets set if there is a match on any of the unmasked bits.

An interrupt is called when SMF = 1 if SMIE = 1.

If APMS is set in XSPI_CR, the operation stops and BUSY goes to 0 as soon as a match is detected. Otherwise, BUSY stays at 1 and the periodic accesses continue until there is an abort or until the XSPI is disabled (EN = 0).

XSPI_DR contains the latest received status bytes (FIFO deactivated). The content of this register is not affected by the masking used in the matching logic. FTF in XSPI_SR is set as soon as a new reading of the status is complete. FTF is cleared as soon as the data is read.

In automatic status-polling mode, variable latency is not supported. As a consequence, the memory must then be configured in fixed latency.

24.4.11 XSPI memory-mapped mode

When configured in memory-mapped mode, the external SPI device is seen as an internal memory.

Note: No more than 256 Mbytes can be addressed even if the external device capacity is larger.

If an access is made to an address outside of the range defined by DEVSIZE[4:0] but still within the 256-Mbyte range, then an AHB error is given. The effect of this error depends on the AHB master that attempted the access:

- If it is the Cortex CPU, a hard-fault interrupt is generated.
- If it is a DMA, a DMA transfer error is generated, and the corresponding DMA channel is automatically disabled.

Byte, half-word, and word access types are all supported.

A support for execute in place (XIP) operation is implemented, where the XSPI continues to load the bytes to the addresses following the most recent access. If subsequent accesses are continuous to the bytes that follow, then these operations end up quickly since their results were prefetched.

By default, the XSPI never stops its prefetch operation. It either keeps the previous read operation active with the NCS maintained low or it relaunches a new transfer, even if no access to the external device occurs for a long time. This prefetch feature can be disabled by setting the NOPREF bit in XSPI_DCR1. Disabling the prefetch can be beneficial for performance when the transfer requests are short and jumping frequently between non-consecutive addresses.

Since external devices tend to consume more power when the NCS is held low, the application may want to activate the timeout counter (TCEN = 1 in XSPI_CR): the NCS is released after a period defined by TIMEOUT[15:0] in XSPI_LPTR, when x cycles have elapsed without access since the clock is inactive.

BUSY goes high as soon as the first memory-mapped access occurs. Because of the prefetch operations, BUSY does not fall until there is an abort, or the peripheral is disabled.

It is not recommended to program the flash memory using the memory-mapped writes. The indirect-write mode fulfills this operation.

However, if the application requires the use of the MCE for encryption (check MCE product availability), the memory-mapped write mode may be used to program encrypted data to external flash memory under the following conditions:

- Prefetch must be enabled.
- In block cipher mode, the CPU must write a complete 128-bit data block to prevent the MCE from initiating read-modify-write operations when only a few bytes need to be programmed. This precaution avoids incorrect programming operations. There are no specific constraints to respect if the MCE is used in stream cipher mode.
- Apply the abort sequence to exit memory-mapped mode when the data linked to the page has been written in the external memory buffers. The abort sequence triggers the start of the page programming.
- Switch to the automatic status-polling mode to monitor the completion of the page programing phase.
- Relaunch the write enable command in indirect mode, then switch back to the memory-mapped mode configuration to continue to program additional pages if any.

It is recommended to add a synchronization barrier between the end of the controller registers configuration and the first memory-mapped access to the external memory when the controller is configured in memory-mapped mode.

24.4.12 XSPI configuration introduction

The XSPI configuration is done in three steps:

1. XSPI system configuration
2. XSPI device configuration
3. XSPI mode configuration

24.4.13 XSPI system configuration

The XSPI is configured using XSPI_CR. The user must program:

- the functional mode with FMODE[1:0]
- the automatic status-polling mode behavior if needed with PMM and APMS
- the FIFO level with FTHRES
- the DMA use with DMAEN
- the timeout counter use with TCEN
- the dual-memory configuration, if needed, with DMM

In case of an interrupt use, the respective enable bit can also be set during this phase.

If the timeout counter is used, the timeout value is programmed in XSPI_LPTR.

The DMA channel must not be enabled during the XSPI configuration: it must be enabled only when the operation is fully configured, to avoid any unexpected request generation.

The DMA and XSPI must be configured in a coherent manner regarding data length: FTHRES value must reflect the DMA burst size.

24.4.14 XSPI device configuration

The parameters related to the external device targeted are configured through XSPI_DCR1 and XSPI_DCR2.The user must program:

- the device size with DEVSIZE[4:0]
- the chip-select minimum high time with CSHT[5:0]
- the clock mode with FRCK and CKMODE
- the associated delay block DLYB connected externally to the peripheral
- the device frequency with PRESCALER[7:0]

DEVSIZE[4:0] defines the size of external memory using the following formula:

$$\text{Number of bytes in the device} = 2^{[\text{DEVSIZE}+1]}$$

where DEVSIZE+1 is the number of address bits required to address the external device. The external device capacity can go up to 4 Gbytes (addressed using 32 bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.

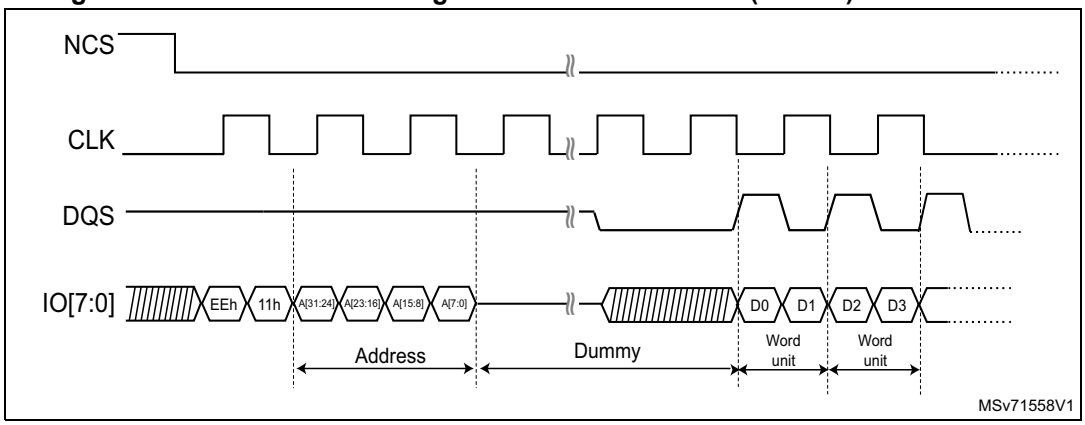
If DMM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

When the XSPI executes two commands, one immediately after the other, it raises the chip-select signal (NCS) high between the two commands for at least one CLK cycle by default.

If the external device requires more time between commands, CSHT[5:0] can be used to specify the minimum number of CLK cycles for which the NCS must remain high.

CKMODE indicates the level that the CLK takes between commands (when NCS = 1).

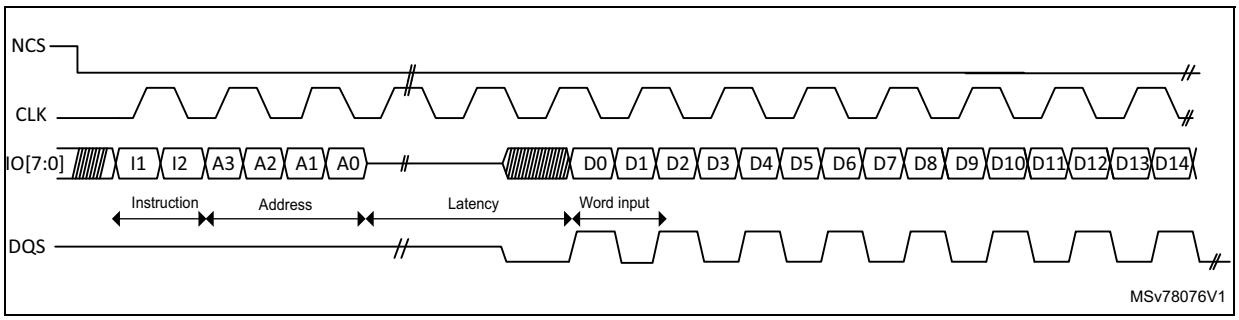
In HyperBus protocol, the device timing (t_{ACC} and t_{RWR}) and the latency mode must be configured in XSPI_HLCR.



Memory types

External memory providers may present some architecture and slight data formatting differences between them. The bitfield MTYP[2:0] into the XSPI_CR register allows targeting the right controller configuration depending on the associated memory type selected in the application. This is the responsibility of the software developer to align the controller configuration to fit with the targeted memory type.

The memory types are grouped in a such way:



- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 000. For instance, Micron is using such data ordering. In this configuration, the DQS is sent with a polarity inverted respect to the clock polarity.

Figure 182. D0/D1 data ordering in octal-SPI DTR mode (Micron) - Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 001. For instance, Macronix is using this reverse data ordering in its Octaflash portfolio (this configuration is not adapted to its OctaRAM™ memories). DQS is keeping the same polarity as the clock when reading data from the memory. Refer to *Figure 173: DTR read in octal-SPI mode with DQS (Macronix mode) example*.
- D0/D1 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 010. DQS is keeping the same polarity as the clock when reading data from the memory. It is defined as the standard mode since it is the configuration to select when the targeted memory does not fit with any others modes proposed by the MTYP configuration values.

Figure 183. D0/D1 data ordering in octal-SPI DTR mode with DQS and CLK polarity aligned during Read access

- D1/D0 data ordering in octal-SPI data mode (DMODE[2:0] = 100) in DTR mode by configuring MTYP[2:0] = 011 with specific address phase built with row and column to fit with Macronix OctaRAM™ memories requirement (refer to *Table 214: OctaRAM command address bit assignment (based on 64 Mb OctaRAM)*. This is the controller which translates internally the targeted address provided by the software in row/column address formatting to sent to the memory. DQS is keeping the same polarity as the clock one when reading data from the memory.

Figure 184. OctaRAM read operation with reverse data ordering D1/D0

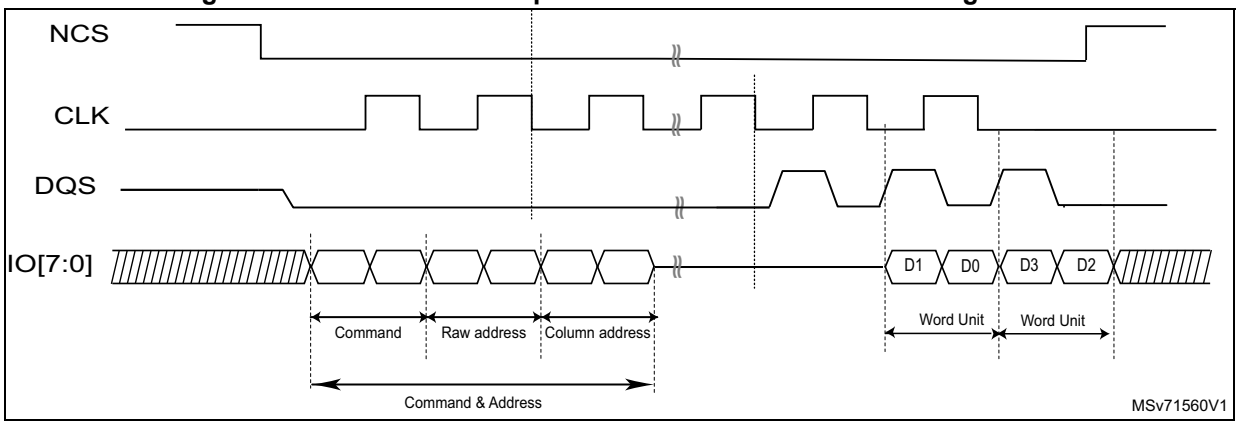


Table 214. OctaRAM command address bit assignment (based on 64 Mb(1) OctaRAM)

Clock	1st clock	2nd clock		3rd clock	
Function	Command	Row address		Column address	
SIO[7]	Command	Reserved	RA7	CA9	Reserved
SIO[6]		Reserved	RA6	CA8	Reserved
SIO[5]		Reserved	RA5	CA7	Reserved
SIO[4]		RA12	RA4	CA6	Reserved
SIO[3]		RA11	RA3	CA5	CA3
SIO[2]		RA10	RA2	CA4	CA2
SIO[1]		RA9	RA1	Reserved	CA1
SIO[0]		RA8	RA0	Reserved	CA0(2)

1. Example of 64 Mb OctaRAM address assignment:
   Row Address [RA12:RA0]: 8K. Column Address [CA9:CA0]: 1K. 64 Mb density = 8K x 1K x 8 bits
2. Column address A0 must be always 0.

- HyperBus memories need to be selected when targeted by the application. The configuration to set depends on the access type:
  - HyperBus memory mode: The protocol follows the HyperBus specification. MTYP[2:0] = 100 is the configuration to use to access the memory space.
  - HyperBus register mode (addressing register space): the memory-mapped accesses in this mode must be noncacheable, or the indirect read/write modes must be used. The configuration to be set for this particular register space access is MTYP[2:0] = 101.

24.4.15 XSPI regular-command mode configuration

Indirect mode configuration

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected, and data can be read from the external device.

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the frame timing in XSPI_TCR.
3. Specify the frame format in XSPI_CCR.
4. Specify the instruction in XSPI_IR.
5. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
6. Specify the targeted address in XSPI_AR.
7. Enable the DMA channel if needed.
8. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

If neither the address register (XSPI_AR) nor the data register (XSPI_DR) need to be updated for a particular command, then the command sequence starts as soon as XSPI_IR is written. This is the case when both ADMODE[2:0] and DMODE[2:0] equal 000, or if just ADMODE[2:0] = 000 when in indirect-read mode (FMODE[1:0] = 01).

When an address is required (ADMODE[2:0] ≠ 000) and the data register does not need to be written (FMODE[1:0] = 01 or DMODE[2:0] = 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In case of data transmission (FMODE[1:0] = 00 and DMODE[2:0] ≠ 000), the communication start is triggered by a write in the FIFO through XSPI_DR.

Automatic status-polling mode configuration

The automatic status-polling mode is enabled by setting FMODE[1:0] = 10. In this mode, the programmed frame is sent and data are retrieved periodically.

The maximum amount of data read in each frame is 4 bytes. If more data is requested in XSPI_DLR, it is ignored, and only 4 bytes are read. The periodicity is specified in XSPI_PIR.

Once the status data has been retrieved, the following can be processed:

- Set SMF (an interrupt is generated if enabled).
- Stop automatically the periodic retrieving of the status bytes.

The received value can be masked with the value stored in XSPI_PSMKR, and can be ORed or ANDed with the value stored in XSPI_PSMAR.

In case of a match, SMF is set and an interrupt is generated if enabled. The XSPI can be automatically stopped if AMPS is set. In any case, the latest retrieved value is available in XSPI_DR.

When the XSPI is used in automatic status-polling mode, the frames are constructed in the following way:

1. Specify the input mask in XSPI_PSMKR.
2. Specify the comparison value in XSPI_PSMAR.

3. Specify the read period in XSPI_PIR.
4. Specify a number of data bytes to read in XSPI_DLR.
5. Specify the frame timing in XSPI_TCR.
6. Specify the frame format in XSPI_CCR.
7. Specify the instruction in XSPI_IR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR.
9. Specify the optional targeted address in XSPI_AR.

If the address register (XSPI_AR) does not need to be updated for a particular command, then the command sequence starts as soon as XSPI_CCR is written. This is the case when ADMODE[2:0] = 000.

When an address is required (ADMODE[2:0] ≠ 000), the command sequence starts as soon as the address is updated with a write to XSPI_AR.

Memory-mapped mode configuration

In memory-mapped mode, the external device is seen as an internal memory but with some latency during accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using memory-mapped writes, as the internal flags for erase or programming status have to be polled. The indirect-write mode fulfills this operation, possibly in conjunction with the automatic status-polling mode.

The memory-mapped mode is entered by setting FMODE[1:0] = 11 in XSPI_CR.

The programmed instruction and frame are sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

When the XSPI is used in memory-mapped mode, the frames are constructed in the following way:

1. Specify the frame timing in XSPI_TCR for read operation.
2. Specify the frame format in XSPI_CCR for read operation.
3. Specify the instruction in XSPI_IR.
4. Specify the optional alternate byte to be sent right after the address phase in XSPI_ABR for read operation.
5. Specify the frame timing in XSPI_WTCR for write operation.
6. Specify the frame format in XSPI_WCCR for write operation.
7. Specify the instruction in XSPI_WIR.
8. Specify the optional alternate byte to be sent right after the address phase in XSPI_WABR for write operation.

All configuration operations must be completed (ensured by checking BUSY = 0) before the first access to the memory area: any register write operation when BUSY = 1 has no effect and is not signaled with an error response. On the first access, the XSPI becomes busy, and no further configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit or to abort by setting the ABORT bit.

XSPI delayed data sampling when no DQS is used

By default, when no DQS is used, the XSPI samples the data driven by the external device one half of a CLK cycle after the external device drives the signal.

In case of any external signal delays, it may be useful to sample the data later. Using SSHIFT in XSPI_TCR, the sampling of the data can be shifted by half of a CLK cycle.

The firmware must clear SSHIFT when the data phase is configured in DTR mode (DDTR = 1).

XSPI delayed data sampling when DQS is used

When external DQS is used as a sampling clock, it is shifted precisely by one quarter of the SPI clock cycle, for all frequencies above freq_min, to compensate the data propagation delay in the “high-speed interface” when the product embeds one.

This shift is performed by an external delay block (DLYB) located outside the XSPI. This external delay block has to be calibrated (by enabling FRCK) before starting the first transfer, and recalibrated regularly. The control of this feature depends on the device implementation (see the delay block (DLYB) section in this document for more details about DLYB and calibration procedure, and the product datasheet for freq_min value).

In configurations where delay does not need to be compensated, the external delay block can be bypassed by setting DLYBYP in XSPI_DCR1.

24.4.16 XSPI HyperBus protocol configuration

Indirect mode configuration (HyperBus)

When FMODE[1:0] = 00, the indirect-write mode is selected and data can be sent to the external device. When FMODE[1:0] = 01, the indirect-read mode is selected where data can be read from the external device. ADMODE must be configured with a value different from 000 (for instance ADMODE = 100).

When the XSPI is used in indirect mode, the frames are constructed in the following way:

1. Specify a number of data bytes to read or write in XSPI_DLR.
2. Specify the targeted address in XSPI_AR.
3. Enable the DMA channel if needed.
4. Read/write the data from/to the FIFO through XSPI_DR (if no DMA usage).

In indirect-read mode, the command sequence starts as soon as the address is updated with a write to XSPI_AR.

In indirect-write mode, the communication start is triggered by a write in the FIFO through XSPI_DR.

Memory-mapped mode configuration (HyperBus)

In memory-mapped mode, the external device is seen as an internal memory but with some latency during the accesses. Read and write operations are allowed to the external device in this mode.

It is not recommended to program the flash memory using the memory-mapped writes: the indirect-write mode fulfills this operation.

The memory-mapped mode is entered by setting FMODE[1:0] = 11. The programmed instruction and frame is sent when an AHB master accesses the memory-mapped space.

The FIFO is used as a prefetch buffer to anticipate any linear reads. Any access to XSPI_DR in this mode returns zero.

The data length register (XSPI_DLR) has no meaning in memory-mapped mode.

All the configuration operation must be completed before the first access to the memory area. On the first access, the XSPI becomes busy, and no configuration is allowed. Then, the only way to get BUSY low is to clear the ENABLE bit, or to abort by setting the ABORT bit.

24.4.17 XSPI error management

The following errors set the TEF flag in XSPI_SR and generates an interrupt if enabled (TEIE = 1 in XSPI_CR):

- in indirect or automatic status-polling mode, when a wrong address has been programmed in XSPI_AR (according to the device size defined by DEVSIZE[4:0]).
- in indirect mode, if the address plus the data length exceed the device size: TEF is set as soon as the access is triggered.

In memory-mapped mode, the XSPI generates an AHB slave error in the following situations, setting the BERRF flag in XSPI_SR and generating an interrupt if enabled (BERRIE = 1 in XSPI_CR) (if the Bus error bit feature is available in the product implementation table, otherwise the Slave bus error response is generated at system level as transaction response with no dedicated bit into the controller status register):

- The memory-mapped mode is disabled and an AHB read or write request occurs.
- A read or write address exceeds the size of the external memory.
- An abort is received while a read or write burst is ongoing when the abort condition is present at the moment of transfer phases preceding the data phase (In incremental or wrap burst type modes). To avoid the error, refer to *Section 24.4.18: XSPI BUSY and ABORT*.
- The XSPI is disabled while a read or write burst is requested.
- A write wrap burst is received.
- A write request is received while DQSE = 0 in XSPI_WCCR in octal DTR mode, in dual-memory configuration, in HyperBus mode or 16-bit mode.
- A read or write request is received while DMODE[2:0] = 000 (no data phase), except when MTYP[2:0] is HyperBus.
- Illegal access size when wrap read burst. This means that the AHB bus transfer size (HSIZE) is different from 4 bytes (only for memory-mapped mode).
- Bit DMM is set in XSPI_CR (dual-memory configuration) and octal mode is set.

24.4.18 XSPI BUSY and ABORT

Once the XSPI starts an operation with the external device, BUSY is automatically set in XSPI_SR.

In indirect mode, BUSY is reset once the XSPI has completed the requested command sequence and the FIFO is empty.

In automatic status-polling mode, BUSY goes low only after the last periodic access is complete, due to a match when APMS = 1 or due to an abort.

After the first access in memory-mapped mode, BUSY goes low only on an abort.

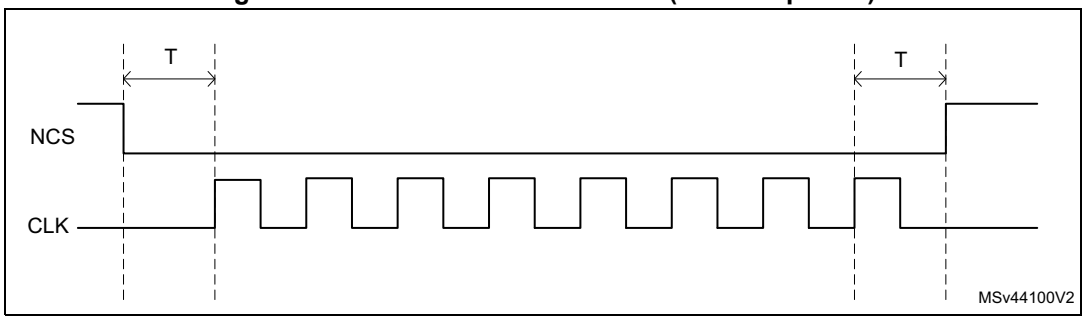
Any operation can be aborted by setting ABORT in XSPI_CR. Once the abort is completed, BUSY and ABORT are automatically reset, and the FIFO is flushed.

Before setting ABORT, the software must ensure that all the current transactions are finished using the synchronization barriers. When DMA is enabled to handle the data read or write operations in XSPI_DR, it is recommended to disable the DMA channel before aborting the SPI.

Note: Some devices may misbehave if a write operation to a status register is aborted.

24.4.19 XSPI reconfiguration or deactivation

Before any XSPI reconfiguration, the software must ensure that all the transactions are completed:



- After a memory-mapped write, the software must perform a dummy read followed by a synchronization barrier, then an abort.
- After a memory-mapped read, the software must perform a synchronization barrier than an abort.

24.4.20 NCS behavior

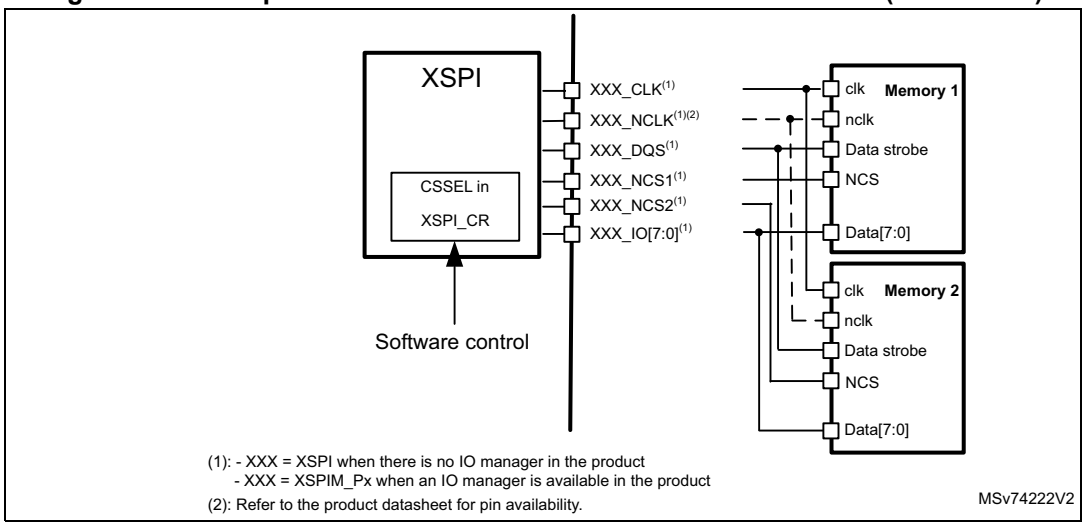
By default, NCS is high, deselecting the external device. NCS falls before an operation begins and rises as soon as it finishes.

When CKMODE = 0 (clock mode 0: CLK stays low when no operation is in progress), NCS falls one CLK cycle before an operation first rising CLK edge, and NCS rises one CLK cycle after the operation final rising CLK edge (see the figure below).

Figure 185. NCS when CKMODE = 0 (T = CLK period)

Note: Clock mode 3 is not supported.

In dual-memory configuration, the NCS2 behaves exactly the same as the NCS1.
The quad-SPI/octal-SPI memory 2 can then use the NCS1, and the NCS2 pin can be used for other functions.



24.4.21 Software control of two external memories

One XSPI instance is able to control the generation of the two chip-select signals (NCS1 and NCS2). This allows two external memories to be connected to the same I/O port driven by the XSPI.

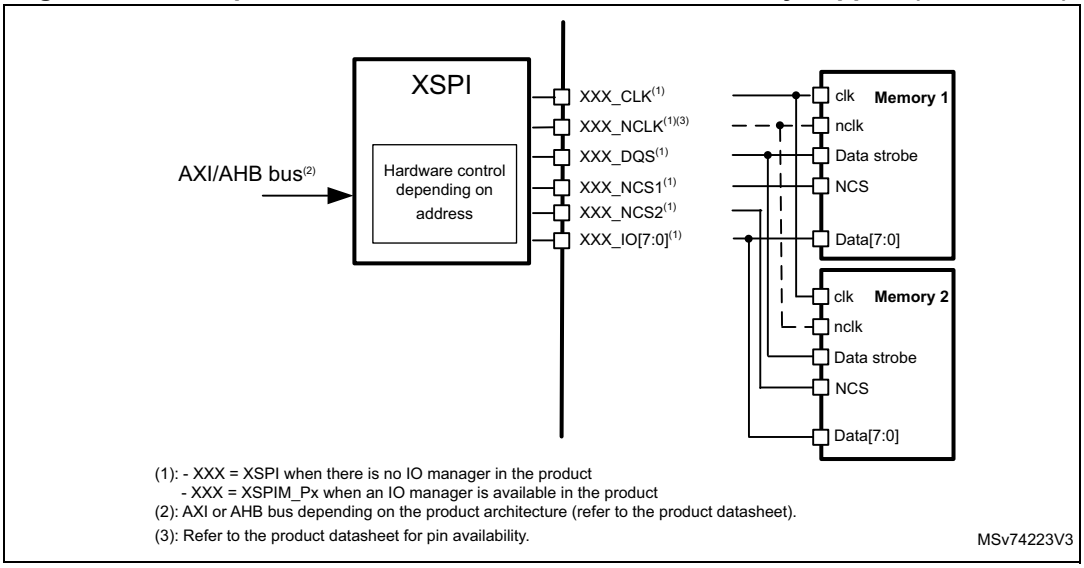
The XSPI generates one NCS signal and the user defines how the NCS is directed to NCS1 or NCS2, by setting the CSSEL bit in XSPI_CR. Intended operation is semistatic commutation, such as starting an application reading an external flash memory and then, for the rest of the application, use an external SRAM connected to the same I/O bus.

From a memory-map point of view, these two memories are located in the same address range.

Figure 186. Example of software control of two external memories (octal mode)

24.4.22 Hardware-controlled extended memory support

One XSPI instance is able to control autonomously the generation of the two chip-select signals (NCS1 and NCS2). This feature is activated by setting EXTENDMEM in XSPI_DCR1 and allows two external memories to be connected to the same I/O port driven by the XSPI.



The aim is to extend by a factor two, the available external memory size. Both memories must be contiguous in the memory map. Both external memories must be of the same type and size. The size of one external memory must be set in DEVSIZE of XSPI_CR.

- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address: XSPI_base_address + $2^{DEVSIZE}$ - 1], NCS1 is generated.
- When the address presented on the interconnect bus in memory-mapped mode or in XSPI_AR in indirect mode is in the range [XSPI_base_address + $2^{DEVSIZE}$: XSPI_base_address + 2 × $2^{DEVSIZE}$ - 1], NCS2 is generated.

Note: If the access crosses the middle boundary of the external memory, CS changes automatically (no write into XSPI_AR in indirect mode, or new memory access in memory-mapped mode is needed).

The EXTENDMEM feature (set in bit 21 of XSPI_DCR1) and the Dual-memory mode (set in bit 6 of XSPI_CR) are exclusive: EXTENDMEM = 1 and DMM = 1 as this configuration is not supported.

Figure 187. Example of hardware-controller extended memory support (octal mode)

Note: It is recommended to set EXTENDMEM = 0 for write transfers targeting flash memories (HyperFlash, NOR Flash, etc.).

These memories require preliminary commands that do not include an address phase used by the controller to select the targeted memory.

This recommendation does not apply to RAM memories, as those extra commands are not needed for RAM access.

24.5 Address alignment and data number

The table below summarizes the effect of the address alignment and programmed data number depending on the use case.

Table 215. Address alignment cases

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Single, dual, quad flash or SRAM (DMM = 0)	IND(2) read	None	None	None	None
	MM(3) read				
	IND write				
	MM write				
Single, dual, quad flash or SRAM (DMM = 1)	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.

Table 215. Address alignment cases (continued)

Memory type	Transaction type	Constraint on address(1)	Impact if constraint on address not respected	Constraint on number of bytes(1)	Impact if constraint on bytes not respected
Octal flash in SDR mode	IND read	None	None	None	None
	MM read				
	IND write				
	MM write				
Octal memory in DTR mode without WDM(6) or 8-bit HyperFLASH	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM write	Even	Slave error	Even	Last byte is lost.
Octal flash or RAM in DTR mode with WDM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				
8-bit HyperRAM	IND read	Even	ADDR[0] is set to 0.(4)	Even	DLR[0] is set to 1.(5)
	MM read	None	None	None	None
	IND write(7)				
	MM write				

1. To be respected by the software.
2. IND = indirect mode.
3. MM = memory-mapped mode.
4. Extra data at transfer start.
5. Extra data at transfer end.
6. WDM = write data mask.
7. If the FTHRES bitfield is set to the maximum value with DLR value greater than the data burst length, and if the DMA is enabled or the interrupt based on FIFO THRESHOLD Flag is enabled (FTF), the address must be modulo 2 aligned in DTR mode when the initiator (DMA, CPU, ...) is writing the data with a burst length equal to the FIFO size.

24.6 XSPI interrupts

An interrupt can be produced on the following events:

- Timeout
- Status match
- FIFO threshold
- Transfer complete
- Transfer error

Separate interrupt enable bits are available to provide more flexibility.

Table 216. XSPI interrupt requests

Interrupt event	Event flag	Enable control bit
Timeout	TOF	TOIE
Status match	SMF	SMIE
FIFO threshold	FTF	FTIE
Transfer complete	TCF	TCIE
Transfer error	TEF	TEIE

24.7 XSPI registers

24.7.1 XSPI control register (XSPI_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	MSEL	FMODE[1:0]		Res.	Res.	NOPREF	CSSEL	PMM	APMS	Res.	TOIE	SMIE	FTIE	TCIE	TEIE
	rw	rw	rw			rw	rw	rw	rw		rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	FTHRES[4:0]					Res.	DMM	Res.	Res.	TCEN	DMAEN	ABORT	EN
			rw	rw	rw	rw	rw		rw			rw	rw	w	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **MSEL**: External memory select

This bit selects the external memory to be addressed in single-, dual-, quad-SPI mode in single-memory configuration (when DMM = 0).

0: External memory 1 selected (data exchanged over IO[3:0])

1: External memory 2 selected (data exchanged over IO[7:4])

This bit is ignored when DMM = 1 or when octal-SPI mode is selected.

Note: This bitfield can be modified only when BUSY = 0.

Bits 29:28 **FMODE[1:0]**: Functional mode

This bitfield defines the XSPI functional mode of operation.

00: Indirect-write mode

01: Indirect-read mode

10: Automatic status-polling mode (relevant in regular-command protocol only)

11: Memory-mapped mode

If DMAEN = 1 already, then the DMA controller for the corresponding channel must be disabled before changing the FMODE[1:0] value.

Note: This bitfield can be modified only when BUSY = 0.

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **NOPREF**: No prefetch data
This bit disables the automatic prefetch in the external memory.
0: Automatic prefetch enabled
1: Automatic prefetch disabled

Bit 24 **CSSEL**: Chip-select selection
This bit indicates if it must copy NCS to NCS1 or NCS2.
0: NCS1 active
1: NCS2 active
Note: This bit can be modified only when BUSY = 0.

Bit 23 **PMM**: Polling match mode
This bit indicates which method must be used to determine a match during the automatic status-polling mode.
0: AND-match mode, SMF is set if all the unmasked bits received from the device match the corresponding bits in the match register.
1: OR-match mode, SMF is set if any of the unmasked bits received from the device matches its corresponding bit in the match register.
Note: This bit can be modified only when BUSY = 0.

Bit 22 **APMS**: Automatic status-polling mode stop
This bit determines if the automatic status-polling mode is stopped after a match.
0: Automatic status-polling mode is stopped only by abort or by disabling the XSPI.
1: Automatic status-polling mode stops as soon as there is a match.
Note: This bit can be modified only when BUSY = 0.

Bit 21 Reserved, must be kept at reset value.

Bit 20 **TOIE**: Timeout interrupt enable
This bit enables the timeout interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 19 **SMIE**: Status-match interrupt enable
This bit enables the status-match interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 18 **FTIE**: FIFO threshold interrupt enable
This bit enables the FIFO threshold interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 17 **TCIE**: Transfer complete interrupt enable
This bit enables the transfer complete interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bit 16 **TEIE**: Transfer error interrupt enable
This bit enables the transfer error interrupt.
0: Interrupt disabled
1: Interrupt enabled

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **FTHRES[4:0]**: FIFO threshold level

This bitfield defines, in indirect mode, the threshold number of bytes in the FIFO that causes the FIFO threshold flag FTF in XSPI_SR, to be set.

00000: FTF is set if there are one or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are one or more valid bytes can be read from the FIFO in indirect-read mode.

00001: FTF is set if there are two or more free bytes available to be written to in the FIFO in indirect-write mode, or if there are two or more valid bytes can be read from the FIFO in indirect-read mode.

...

11111: FTF is set if there are 32 free bytes available to be written to in the FIFO in indirect-write mode, or if there are 32 valid bytes can be read from the FIFO in indirect-read mode.

Note: If DMAEN = 1, the DMA controller for the corresponding channel must be disabled before changing the FTHRES[4:0] value.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **DMM**: Dual-memory configuration

This bit activates the dual-memory configuration, where two external devices are used simultaneously to double the throughput and the capacity

0: Dual-memory configuration disabled

1: Dual-memory configuration enabled

Note: This bit can be modified only when BUSY = 0.

Bits 5:4 Reserved, must be kept at reset value.

Bit 3 **TCEN**: Timeout counter enable

This bit is valid only when the memory-mapped mode (FMODE[1:0] = 11) is selected. This bit enables the timeout counter.

0: The timeout counter is disabled, and thus the chip-select (NCS) remains active indefinitely after an access in memory-mapped mode.

1: The timeout counter is enabled, and thus the chip-select is released in the memory-mapped mode after TIMEOUT[15:0] cycles of external device inactivity.

Note: This bit can be modified only when BUSY = 0.

Bit 2 **DMAEN**: DMA enable

In indirect mode, the DMA can be used to input or output data via XSPI_DR. DMA transfers are initiated when FTF is set.

0: DMA disabled for indirect mode

1: DMA enabled for indirect mode

Note: Resetting the DMAEN bit while a DMA transfer is ongoing, breaks the handshake with the DMA. Do not write this bit during DMA operation.

Bit 1 **ABORT**: Abort request

This bit aborts the ongoing command sequence. This bit stops the current transfer.

0: No abort requested

1: Abort requested

Note: This bit is always read as 0.

Bit 0 **EN**: Enable

This bit enables the XSPI.

0: XSPI disabled

1: XSPI enabled

Note: The DMA request can be aborted without having received the ACK in case this EN bit is cleared during the operation.
In case this bit is set to 0 during a DMA transfer, the REQ signal to DMA returns to inactive state without waiting for the ACK signal from DMA to be active.

24.7.2 XSPI device configuration register 1 (XSPI_DCR1)

Address offset: 0x008

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	MTYP[2:0]			Res.	Res.	EXTENDMEM	DEVSIZE[4:0]				
					rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	CSHT[5:0]						Res.	Res.	Res.	Res.	DLYBYP	Res.	FRCK	CKMODE
		rw	rw	rw	rw	rw	rw					rw		rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **MTYP[2:0]**: Memory type

This bitfield indicates the type of memory to be supported.

000: Micron mode, D0/D1 ordering in DTR 8-data-bit mode. regular-command protocol in single-, dual-, quad- and octal-SPI modes.

Note: In this mode, DQS signal polarity is inverted with respect to the memory clock signal. This is the default value and care must be taken to change MTYP[2:0] for memories different from Micron.

001: Macronix mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes.

010: Standard mode. D0/D1 ordering with DQS and CLK having the same polarity during read operation. This is the mode to use when the targeted memory does not fit with any others MTYP configuration values. This mode is typically the one targeting the APmemory 8-bit memories for instance.

011: Macronix RAM mode, D1/D0 ordering in DTR 8-data-bit mode. Regular-command protocol in single-, dual-, quad-, and octal-SPI modes with dedicated address mapping (address is built with row and column to fit with Macronix requirements).

100: HyperBus memory mode, the protocol follows the HyperBus specification.

101: HyperBus register mode, addressing register space. The memory-mapped accesses in this mode must be noncacheable, or indirect-read/write modes must be used.

Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **EXTENDMEM**: Extended memory support

This bit is only relevant when one XSPI drives two same size external memories located in contiguous places in the memory map. In this case, DEVSIZE[4:0] represents the size of each external memory. When this bit is set, the XSPI automatically controls which of NCS1 or NCS2 is active.

0: NCS1 and NCS2 values depend from CSSEL bit in XSPI_CR (software controlled).

1: NCS1 and NCS2 values depend from the address of transfer (hardware controlled).

Note: It is recommended to keep EXTENDMEM = 0 for write operations targeting flash memories (such as NOR Flash and HyperFlash).

Bits 20:16 **DEVSIZE[4:0]**: Device size

This bitfield defines the size of the external device using the following formula:
Number of bytes in device = $2^{[DEVSIZE+1]}$.
DEVSIZE + 1 is effectively the number of address bits required to address the external device. The device capacity can be up to 4 Gbytes (addressed using 32-bits) in indirect mode, but the addressable space in memory-mapped mode is limited to 256 Mbytes.
In regular-command protocol, if DMM = 1 or EXTENDMEM = 1, DEVSIZE[4:0] must reflect the total capacity of the two devices together considering the above formula (DEVSIZE[4:0] value is so equal to one of the two memory capacities).

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **CSHT[5:0]**: Chip-select high time

CSHT + 1 defines the minimum number of CLK cycles where the chip-select (NCS) must remain high between commands issued to the external device.

0x0: NCS stays high for at least 1 cycle between external device commands.

0x1: NCS stays high for at least 2 cycles between external device commands.

...

0x3F: NCS stays high for at least 64 cycles between external device commands.

Bits 7:4 Reserved, must be kept at reset value.

Bit 3 **DLYBYP**: Delay block bypass

0: The internal sampling clock (called feedback clock) or the DQS data strobe external signal is delayed by the delay block (for more details on this block, refer to the dedicated section of the reference manual as it is not part of the peripheral).

1: The delay block is bypassed, so the internal sampling clock or the DQS data strobe external signal is not affected by the delay block. The delay is shorter than when the delay block is not bypassed, even with the delay value set to minimum value in delay block.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **FRCK**: Free running clock

This bit configures the free running clock.

0: CLK is not free running.

1: CLK is free running (always provided).

Note: Free running clock mode is intended for delay calibration only. No memory or other device access is possible when FRCK is set. Once the bit has been set to 1, the BSY bit is set, the NCS signal remains set to 1 and the clock is sent. The only way to stop the clock is to perform an abort (which clears the BSY bit). Then, the FRCK bit must be cleared by software to allow controller transactions to take place with the external memory.

Bit 0 **CKMODE**: Clock mode 0

This bit is read-only and is read as zero.

24.7.3 XSPI device configuration register 2 (XSPI_DCR2)

Address offset: 0x00C

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	WRAPSIZE[2:0]		
													rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRESCALER[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:19 Reserved, must be kept at reset value.

Bits 18:16 **WRAPSIZE[2:0]**: Wrap size

This bitfield indicates the wrap size to which the memory is configured. For memories which have a separate command for wrapped instructions, this bitfield indicates the wrap-size associated with the command held in the XSPI_WPIR register.

000: Wrapped reads are not supported by the memory.

010: External memory supports wrap size of 16 bytes.

011: External memory supports wrap size of 32 bytes.

100: External memory supports wrap size of 64 bytes.

101: External memory supports wrap size of 128 bytes.

Other: Reserved

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **PRESCALER[7:0]**: Clock prescaler

This bitfield defines the scaler factor for generating the CLK based on the kernel clock (value + 1).

0: $F_{CLK} = F_{KERNEL}$, kernel clock used directly as XSPI CLK (prescaler bypassed). In this case, if the DTR mode is used, it is mandatory to provide to the XSPI a kernel clock that has 50% duty-cycle.

1: $F_{CLK} = F_{KERNEL}/2$

2: $F_{CLK} = F_{KERNEL}/3$

...

255: $F_{CLK} = F_{KERNEL}/256$

For odd clock division factors, the CLK duty cycle is not 50 %. The clock signal remains low one cycle longer than it stays high.

24.7.4 XSPI device configuration register 3 (XSPI_DCR3)

Address offset: 0x010

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CSBOUND[4:0]				
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **CSBOUND[4:0]**: NCS boundary

This bitfield enables the transaction boundary feature. When active, a minimum value of 3 is recommended. The NCS is released on each boundary of $2^{CSBOUND}$ bytes.

0: NCS boundary disabled

Other: NCS boundary set to $2^{CSBOUND}$ bytes

Bits 15:0 Reserved, must be kept at reset value.

24.7.5 XSPI device configuration register 4 (XSPI_DCR4)

Address offset: 0x014

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFRESH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFRESH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFRESH[31:0]**: Refresh rate

This bitfield enables the refresh rate feature. The NCS is released every REFRESH + 1 clock cycles for writes, and REFRESH + 4 clock cycles for reads. These two values can be extended with few clock cycles when refresh occurs during a byte transmission in single-, dual- or quad-SPI mode, because the byte transmission must be completed.

0: Refresh disabled

Other: Maximum communication length is set to REFRESH + 1 clock cycles.

Note: REFRESH count is based on the memory clock period: if XSPI_DCR2 PRESCALER bitfield is changed, the REFRESH field must be updated accordingly.

24.7.6 XSPI status register (XSPI_SR)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	FLEVEL[5:0]						Res.	Res.	BUSY	TOF	SMF	FTF	TCF	TEF
		r	r	r	r	r	r			r	r	r	r	r	r

Bits 31:14 Reserved, must be kept at reset value.

Bits 13:8 **FLEVEL[5:0]**: FIFO level

This bitfield gives the number of valid bytes that are being held in the FIFO. FLEVEL = 0 when the FIFO is empty, and 32 when it is full.

In automatic status-polling mode, FLEVEL is zero.

Bits 7:6 Reserved, must be kept at reset value.

Bit 5 **BUSY**: Busy

This bit is set when an operation is ongoing. It is cleared automatically when the operation with the external device is finished and the FIFO is empty.

Bit 4 **TOF**: Timeout flag

This bit is set when timeout occurs. It is cleared by writing 1 to CTOF.

Bit 3 **SMF**: Status match flag

This bit is set in automatic status-polling mode when the unmasked received data matches the corresponding bits in the match register (XSPI_PSMAR).

It is cleared by writing 1 to CSMF.

Bit 2 **FTF**: FIFO threshold flag

In indirect mode, this bit is set when the FIFO threshold has been reached, or if there is any data left in the FIFO after the reads from the external device are complete.

It is cleared automatically as soon as the threshold condition is no longer true.

In automatic status-polling mode, this bit is set every time the status register is read, and the bit is cleared when the data register is read.

Bit 1 **TCF**: Transfer complete flag

This bit is set in indirect mode when the programmed number of data has been transferred or in any mode when the transfer has been aborted.It is cleared by writing 1 to CTCF.

Bit 0 **TEF**: Transfer error flag

This bit is set in indirect mode when an invalid address is being accessed in indirect mode.

It is cleared by writing 1 to CTEF.

24.7.7 XSPI flag clear register (XSPI_FCR)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CTOF	CSMF	Res.	CTCF	CTEF
											w	w		w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 4 **CTOF**: Clear timeout flag
Writing 1 clears the TOF flag in the XSPI_SR register.

Bit 3 **CSMF**: Clear status match flag
Writing 1 clears the SMF flag in the XSPI_SR register.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CTCF**: Clear transfer complete flag
Writing 1 clears the TCF flag in the XSPI_SR register.

Bit 0 **CTEF**: Clear transfer error flag
Writing 1 clears the TEF flag in the XSPI_SR register.

24.7.8 XSPI data length register (XSPI_DLR)

Address offset: 0x040

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DL[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DL[31:0]**: Data length

Number of data to be retrieved (value+1) in indirect and automatic status-polling modes. A value not greater than three (indicating 4 bytes) must be used for automatic status-polling mode.

All 1's in indirect mode means undefined length, where XSPI continues until the end of the memory, as defined by DEVSIZE.

0x0000_0000: 1 byte is to be transferred.

0x0000_0001: 2 bytes are to be transferred.

0x0000_0002: 3 bytes are to be transferred.

0x0000_0003: 4 bytes are to be transferred.

...

0xFFFF_FFFD: 4,294,967,294 (4G-2) bytes are to be transferred.

0xFFFF_FFFE: 4,294,967,295 (4G-1) bytes are to be transferred.

0xFFFF_FFFF: undefined length; all bytes, until the end of the external device, (as defined by DEVSIZE) are to be transferred. Continue reading indefinitely if DEVSIZE = 0x1F.

DL[0] is stuck at 1 in dual-memory configuration (DMM = 1) even when 0 is written to this bit, thus assuring that each access transfers an even number of bytes.

This bitfield has no effect in memory-mapped mode.

24.7.9 XSPI address register (XSPI_AR)

Address offset: 0x048

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0 and FMODE ≠ 11.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDRESS[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ADDRESS[31:0]**: Address

Address to be sent to the external device. In dual-memory configuration, AR[0] is forced to 0.

Caution: Some memory specifications consider that each address corresponds to a 16-bit value. XSPI considers that each address corresponds to an 8-bit value. So the software needs to multiply the address by two when accessing the memory registers.

24.7.10 XSPI data register (XSPI_DR)

Address offset: 0x050

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATA[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATA[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DATA[31:0]**: Data

Data to be sent/received to/from the external SPI device

In indirect-write mode, data written to this register is stored on the FIFO before it is sent to the external device during the data phase. If the FIFO is too full, a write operation is stalled until the FIFO has enough space to accept the amount of data being written.

In indirect-read mode, reading this register gives (via the FIFO) the data that was received from the external device. If the FIFO does not have as many bytes as requested by the read operation and if BUSY = 1, the read operation is stalled until enough data is present or until the transfer is complete, whichever happens first.

In automatic status-polling mode, this register contains the last data read from the external device (without masking).

Word, half-word, and byte accesses to this register are supported. In indirect-write mode, a byte write adds 1 byte to the FIFO, a half-word write 2 bytes, and a word write 4 bytes.

Similarly, in indirect-read mode, a byte read removes 1 byte from the FIFO, a halfword read 2 bytes, and a word read 4 bytes. Accesses in indirect mode must be aligned to the bottom of this register: A byte read must read DATA[7:0] and a half-word read must read DATA[15:0].

24.7.11 XSPI polling status mask register (XSPI_PSMKR)

Address offset: 0x080

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MASK[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MASK[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MASK[31:0]**: Status mask

Mask to be applied to the status bytes received in automatic status-polling mode

For bit n:

0: Bit n of the data received in automatic status-polling mode is masked and its value is not considered in the matching logic.

1: Bit n of the data received in automatic status-polling mode is unmasked and its value is considered in the matching logic.

24.7.12 XSPI polling status match register (XSPI_PSMAR)

Address offset: 0x088

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
MATCH[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MATCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **MATCH[31:0]**: Status match
Value to be compared with the masked status register to get a match

24.7.13 XSPI polling interval register (XSPI_PIR)

Address offset: 0x090

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

INTERVAL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **INTERVAL[15:0]**: Polling interval
Number of CLK cycles between a read during the automatic status-polling phases

24.7.14 XSPI communication configuration register (XSPI_CCR)

Address offset: 0x100

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

		rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **DQSE**: DQS enable
This bit enables the data strobe management.
0: DQS disabled
1: DQS enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **DDTR**: Data double transfer rate
This bit sets the DTR mode for the data phase.
0: DTR mode disabled for data phase
1: DTR mode enabled for data phase

Bits 26:24 **DMODE[2:0]**: Data mode
This bitfield defines the data phase mode of operation.
000: No data
001: Data on a single line
010: Data on two lines
011: Data on four lines
100: Data on eight lines
Other: Reserved

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **ABSIZE[1:0]**: Alternate-byte size
This bitfield defines the alternate-byte size.
00: 8-bit alternate bytes
01: 16-bit alternate bytes
10: 24-bit alternate bytes
11: 32-bit alternate bytes

Bit 19 **ABDTR**: Alternate- byte double transfer rate
This bit sets the DTR mode for the alternate-byte phase.
0: DTR mode disabled for the alternate-byte phase
1: DTR mode enabled for the alternate-byte phase

Bits 18:16 **ABMODE[2:0]**: Alternate-byte mode
This bitfield defines the alternate-byte phase mode of operation.
000: No alternate bytes
001: Alternate bytes on a single line
010: Alternate bytes on two lines
011: Alternate bytes on four lines
100: Alternate bytes on eight lines
Other: Reserved

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:12 **ADSIZE[1:0]**: Address size
This bitfield defines the address size.
00: 8-bit address
01: 16-bit address
10: 24-bit address
11: 32-bit address

Bit 11 **ADDTR**: Address double transfer rate
This bit sets the DTR mode for the address phase.
0: DTR mode disabled for the address phase
1: DTR mode enabled for the address phase

Bits 10:8 **ADMODE[2:0]**: Address mode
This bitfield defines the address phase mode of operation.
000: No address
001: Address on a single line
010: Address on two lines
011: Address on four lines
100: Address on eight lines
Other: Reserved

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **ISIZE[1:0]**: Instruction size
This bitfield defines instruction size.
00: 8-bit instruction
01: 16-bit instruction
10: 24-bit instruction
11: 32-bit instruction

Bit 3 **IDTR**: Instruction double transfer rate
This bit sets the DTR mode for the instruction phase.
0: DTR mode disabled for the instruction phase
1: DTR mode enabled for the instruction phase

Bits 2:0 **IMODE[2:0]**: Instruction mode
This bitfield defines the instruction phase mode of operation.
000: No instruction
001: Instruction on a single line
010: Instruction on two lines
011: Instruction on four lines
100: Instruction on eight lines
Other: Reserved

24.7.15 XSPI timing configuration register (XSPI_TCR)

Address offset: 0x108

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	SSHIFT	Res.	DHQC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The software must ensure that SSHIFT = 0 when the data phase is configured in DTR mode (when DDTR = 1.)

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
0: No delay hold
1: 1/4 cycle hold

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.16 XSPI instruction register (XSPI_IR)

Address offset: 0x110

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]

TIMEOUT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TIMEOUT[15:0]**: Timeout period

After each access in memory-mapped mode, the XSPI prefetches the subsequent bytes and hold them in the FIFO.

This bitfield indicates how many CLK cycles the XSPI waits after the clock becomes inactive and until it raises the NCS, putting the external device in a lower-consumption state.

24.7.19 XSPI wrap communication configuration register (XSPI_WPCCR)

Address offset: 0x140

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Bit 31 Reserved, must be kept at reset value.

Bit 30 **SSHIFT**: Sample shift
By default, the XSPI samples data 1/2 of a CLK cycle after the data is driven by the external device.
This bit allows the data to be sampled later in order to consider the external signal delays.
0: No shift
1: 1/2 cycle shift
The firmware must assure that SSHIFT=0 when the data phase is configured in DTR mode (when DDTR = 1).

Bit 29 Reserved, must be kept at reset value.

Bit 28 **DHQC**: Delay hold quarter cycle
Add a quarter cycle delay on the outputs in DTR communication to match hold requirement.
0: No quarter cycle delay
1: 1/4 cycle delay inserted

Bits 27:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency.
In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.21 XSPI wrap instruction register (XSPI_WPIR)

Address offset: 0x150

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCYC[4:0]				
											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **DCYC[4:0]**: Number of dummy cycles
This bitfield defines the duration of the dummy phase according to the memory latency. In both SDR and DTR modes, it specifies a number of CLK cycles (0-31).

24.7.25 XSPI write instruction register (XSPI_WIR)

Address offset: 0x190

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
INSTRUCTION[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
INSTRUCTION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **INSTRUCTION[31:0]**: Instruction
Instruction to be sent to the external SPI device

24.7.26 XSPI write alternate bytes register (XSPI_WABR)

Address offset: 0x1A0

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0. Its content has a meaning only when requesting write operations in memory-mapped mode.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ALTERNATE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ALTERNATE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ALTERNATE[31:0]**: Alternate bytes

Optional data to be sent to the external SPI device right after the address

24.7.27 XSPI HyperBus latency configuration register (XSPI_HLCR)

Address offset: 0x200

Reset value: 0x0000 0000

This register can be modified only when BUSY = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRWR[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TACC[7:0]								Res.	Res.	Res.	Res.	Res.	Res.	WZL	LM
rw	rw	rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **TRWR[7:0]:** Read-write minimum recovery time

Device read-to-write/write-to-read minimum recovery time expressed in number of communication clock cycles

Bits 15:8 **TACC[7:0]**: Access time

Device access time according to the memory latency, expressed in number of communication clock cycles

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **WZL:** Write zero latency

This bit enables zero latency on write operations.

0: Latency on write accesses

1: No latency on write accesses

Bit 0 **LM:** Latency mode

This bit selects the latency mode.

0: Variable initial latency

1: Fixed latency

Note: This bit must be set when using the dual-octal HyperRAM configuration. It must be kept cleared for HyperFLASH memory.

24.7.28 XSPI register map

Table 217. XSPI register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
