25 Delay block (DLYB)

25.1 DLYB introduction

The delay block (DLYB) is used to generate an output clock that is dephased from the input clock. The phase of the output clock must be programmed by the user application. The output clock is then used to clock the data received by another peripheral such as an XSPI interface.

The delay is voltage- and temperature-dependent, that may require the application to re-configure and recenter the output clock phase with the receive data.

25.2 DLYB main features

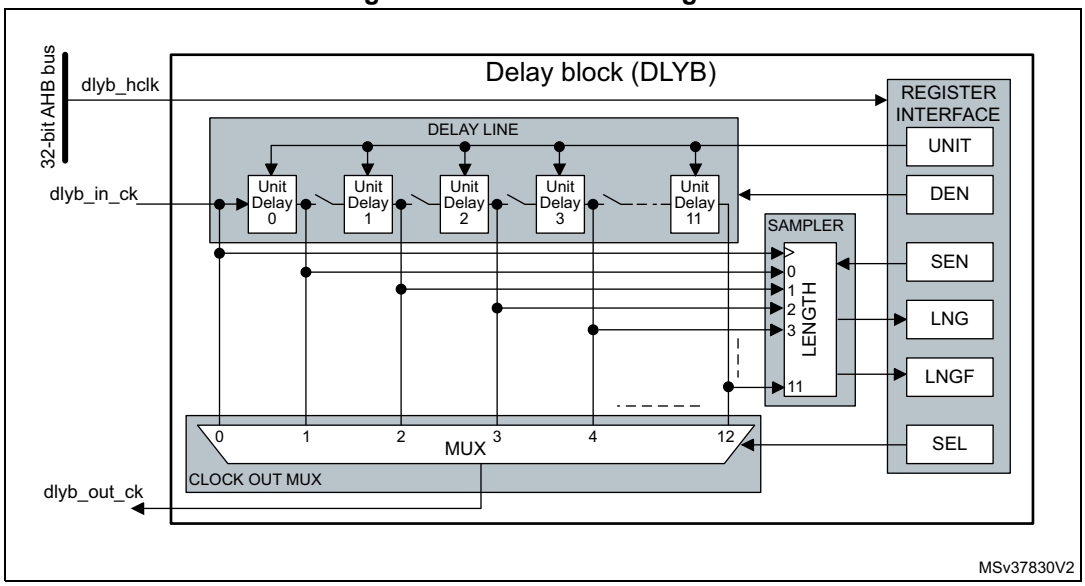
The delay block has the following features:

- Input clock frequency ranging from 25 MHz to the maximum frequency supported by the communication interface (see datasheet)
- Up to 12 oversampling phases.

25.3 DLYB implementation

Table 218. STM32G56x/55x/54x/53x features

DLYB associated peripheral	DLYBXS1
XSPI1	X



25.4 DLYB functional description

25.4.1 DLYB diagram

The delay block includes the following sub-blocks (shown in the figure below):

- register interface block providing AHB access to the DLYB registers
- delay line supporting the unit delays
- delay line length sampling
- output clock selection multiplexer

Figure 188. DLYB block diagram

25.4.2 DLYB pins and internal signals

Table 219 lists the DLYB internal signals.

Table 219. DLYB internal input/output signals

Signal name	Signal type	Description
dlyb_hclk	Digital input	Delay block register interface clock
dlyb_in_ck	Digital input	Delay block input clock
dlyb_out_ck	Digital output	Delay block output clock

Table 220. DLYB interconnection

Signal name	Source/destination
	XSPI1
dlyb_in_ck	DQS
dlyb_out_ck	DQS delayed for data sampling

25.4.3 General description

The delay block is enabled by setting the DEN bit in the DLYB control register (DLYB_CR). The length sampler is enabled through the SEN bit in DLYB_CR register.

When the delay block is enabled, the delay added by a unit delay is defined by the UNIT[6:0] field in the DLYB configuration register (DLYB_CFGR).

Note: UNIT[6:0] can be programmed only when the output clock is disabled (SEN = 1).

When the delay block is enabled, the output clock phase is selected through the SEL[3:0] field in DLYB_CFGR register.

Note: SEL can be programmed only when the output clock is disabled (SEN = 1).

The output clock can be de-phased over one input clock period by configuring the delay line length to span one period. The delay line length can be configured by enabling the length sampler through the SEN bit, that gives access to the delay line length (LNG[11:0]) and length valid flag (LNGF) in DLYB_CFGR.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced. This allows a smaller unit delay providing higher resolution.

Once the delay line length is configured, a dephased output clock can be selected by the output clock multiplexer. This is done through SEL[3:0]. The output clock is only available on the selected phase when SEN is set to 0.

The table below gives a summary of the delay block control.

Table 221. Delay block control

DEN	SEN	UNIT	SEL	LNG	LNGF	Output clock
0	0	Don't care	Don't care	Don't care	Don't care	Enabled (= Input clock)
x	1	Unit delay	Output clock phase	Length	Length flag	Disabled
1	0	Unit delay(1)	Output clock phase(2)	Don't care	Don't care	Enabled (= selected phase)

1. The unit delay can only be changed when SEN = 1.
2. The output clock phase can only be changed when SEN = 1.

25.4.4 Delay line length configuration procedure

LNG[11:0] is used to determine the delay line length with respect to the input clock period. The length must be configured so that one full input clock period is covered by the delay line length.

Note that despite the delay line has 12 unit delay elements, the following procedure description returns a length between 0 and 10, as the upper delay output value is used to ensure that the delay is calibrated over one full input clock cycle. Depending on the clock frequency and UNIT value, unit delay element 10 may also be truncated from the clock cycle length.

A clock input (free running clock) must be present during the whole tuning procedure.

To configure the delay line length to one period of the Input clock, follow the sequence below:

1. Enable the delay block by setting DEN bit to 1.
2. Enable the length sampling by setting SEN bit to 1.
3. Enable all delay cells by setting SEL[3:0] to 12.
4. For UNIT[6:0] = 0 to 127 (this step must be repeated until the delay line length is configured):
   a) Update the UNIT[6:0] value and wait till the length flag LNGF is set to 1.
   b) Read LNG[11:0].

   If (LNG[10:0] > 0) and (LNG[11] or LNG[10] = 0), the delay line length is configured to one input clock period.
5. Determine how many unit delays (N) span one input clock period: for N = 0 to 10, if LNG[N] = 1, the number of unit delays spanning the input clock period = N.
6. Disable the length sampling by clearing SEN to 0.

If an output clock delay smaller than one input clock period is needed the delay line length can be reduced smaller than one input clock period. This allows a smaller unit delay, providing a higher resolution spanning a shorter time interval.

25.4.5 Output clock phase configuration procedure

When the delay line length is configured to one input clock period, the output clock phase can be selected between the unit delays spanning one Input clock period.

Follow the steps below to select the output clock phase:

1. Disable the output clock and enable the access to the phase selection SEL[3:0] bits by setting SEN bit to 1.
2. Program SEL[3:0] with the desired output clock phase value.
3. Enable the output clock on the selected phase by clearing SEN to 0.

XSPI use case:

The delay block is used in conjunction with XSPI interface to allow shifting the input data sampling signal. This sampling signal can be the feedback clock or the data strobe (DQS) signal, which is delivered by certain type of devices. Note that in case DQS is used, the calibration procedure must be performed beforehand with a free running clock, as DQS is a discontinuous signal.

In case of SDR (single data rate) mode the user must typically shift the sampling signal by half period, so that the sampling edges are positioned in the middle of the valid data phase.

In case of DDR (dual data rate) mode, for which data are transitioning at start and middle of period, typical value must be close to N/4, once the calibration is completed.

In case of high frequencies and tight timing constraints, the delay setting granularity (10) might be too coarse. Since in most cases it is not necessary to have a possible delay value covering the whole sampling clock period, the "Unit" value can be overridden by application in order to improve the accuracy of the sampling edge position (example: providing a twice as small “Unit” gives twice better timing accuracy. The counterpart being that the maximum possible delay is divided by 2).

25.5 DLYB registers

All registers can be accessed in word, half-word and byte access.

25.5.1 DLYB control register (DLYB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEN	DEN
														rw	rw

Bits 31:2 Reserved, must be kept at reset value.

Bit 1 **SEN:** Sampler length enable bit

0: Sampler length and register access to UNIT[6:0] and SEL[3:0] disabled, output clock enabled.

1: Sampler length and register access to UNIT[6:0] and SEL[3:0] enabled, output clock disabled.

Bit 0 **DEN:** Delay block enable bit

0: DLYB disabled.

1: DLYB enabled.

25.5.2 DLYB configuration register (DLYB_CFGR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LNGF	Res.	Res.	Res.	LNG[11:0]											
r				r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	UNIT[6:0]							Res.	Res.	Res.	Res.	SEL[3:0]			
	rw	rw	rw	rw	rw	rw	rw					rw	rw	rw	rw

Bit 31 **LNGF:** Length valid flag

This flag indicates when the delay line length value contained in LNG[11:0] is valid after UNIT[6:0] bits changed.

0: Length value in LNG is not valid.

1: Length value in LNG is valid.

Bits 30:28 Reserved, must be kept at reset value.

Bits 27:16 **LNG[11:0]:** Delay line length value

These bits reflect the 12 unit delay values sampled at the rising edge of the input clock. The value is only valid when LNGF = 1.

Bit 15 Reserved, must be kept at reset value.

Bits 14:8 **UNIT[6:0]:** Delay of a unit delay cell.
These bits can only be written when SEN = 1.
Unit delay = initial delay + UNIT[6:0] x delay step

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **SEL[3:0]:** Phase for the output clock.
These bits can only be written when SEN = 1.
Output clock phase = input clock + SEL[3:0] x unit delay

25.5.3 DLYB register map

Table 222. DLYB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

26 Analog-to-digital converters (ADC)

26.1 ADC introduction

This section describes the implementation of up to 3 ADCs:

- ADC1 and ADC2 are tightly coupled and can operate in dual mode (ADC1 is master).
- ADC3 is controlled independently.

Each ADC consists of one 12-bit successive approximation analog-to-digital converter.

Each ADC has up to 20 multiplexed channels. A/D conversion of the various channels can be performed in single, continuous, scan, or discontinuous mode. The result of the ADC is stored in a left-aligned or right-aligned (default configuration) 32-bit data register.

The ADCs are mapped on the AHB bus to allow fast data handling.

The analog watchdog features allow the application to detect if the input voltage goes outside the user-defined high or low thresholds.

A built-in hardware oversampler allows improving analog performances while off-loading the related computational burden from the CPU.

An efficient low-power mode is implemented to allow very low consumption at low frequency.

26.2 ADC main features

- High-performance features
  - Up to 3 ADCs, out of which two of them can operate in dual mode:
    ADC1 is connected to 15 external channels + 5 internal channels
    ADC2 is connected to 17 external channels + 4 internal channels
    ADC3 is connected to 16 external channels + 4 internal channels
  - 12, 10, 8 or 6-bit configurable resolution
  - ADC conversion time independent from the AHB bus clock frequency
  - Faster conversion time by lowering resolution
  - Management of single-ended, pseudodifferential, and differential inputs (programmable per channels)
  - AHB slave bus interface to allow fast data handling
  - Channel-wise programmable sampling time
  - Flexible sampling time control
  - Fixed latency for a trigger to start of sampling
  - Up to 4 injected channels (analog inputs assignment to regular or injected channels is fully configurable)
  - Hardware assistant to prepare the context of the injected channels to allow fast context switching
  - Data alignment with in-built data coherency
  - Data can be managed by DMA for regular channel conversions
  - Four dedicated data registers for the injected channels

- Low-power features
  - Speed adaptive low-power mode to reduce ADC consumption when operating at low frequency
  - Allows slow bus frequency application while keeping optimum ADC performance
  - Provides automatic control to avoid ADC overrun in low AHB bus clock frequency application (autodelayed mode)
- Oversampler
  - 32-bit data register
  - Oversampling ratio adjustable from 2 to 1024
  - Programmable data right and left shifts
  - Dedicated accumulator for each regular and injected channel
  - Parallel oversampling mode for injected channels (access to the intermediate oversampling result)
- Data preconditioning
  - Gain compensation
  - Offset compensation
- Analog input channels
  - External analog inputs (per ADC): up to 17 GPIO pads
  - 3 channels for the internal reference voltage (V_{REFINT})
  - 1 channel for the internal temperature sensor (V_{SENSE})
  - 3 channels for monitoring V_{DDCORE} internal voltage
  - Connection to OPAMP internal channels
- Start-of-conversion can be initiated:
  - By software for both regular and injected conversions
  - By hardware triggers with configurable polarity (internal timer events or GPIO input events) for both regular and injected conversions
- Conversion modes
  - Each ADC can convert a single channel or can scan a sequence of channels
  - Single mode converts selected inputs once per trigger
  - Continuous mode converts selected inputs continuously
  - Discontinuous mode
- Interrupt generation at ADC ready, the end of sampling, the end of conversion (regular or injected), end of sequence conversion (regular or injected), analog watchdog 1, 2 or 3 or overrun events
- 3 analog watchdogs per ADC, with filters
- ADC input range: $V_{SSA} \leq V_{IN} \leq V_{REF+}$

Figure 189 shows the block diagram of one ADC.

26.3 ADC implementation

Table 223. ADC features

ADC modes/features	ADC1, ADC2	ADC3[1]

2. This input can be selected through the option register.

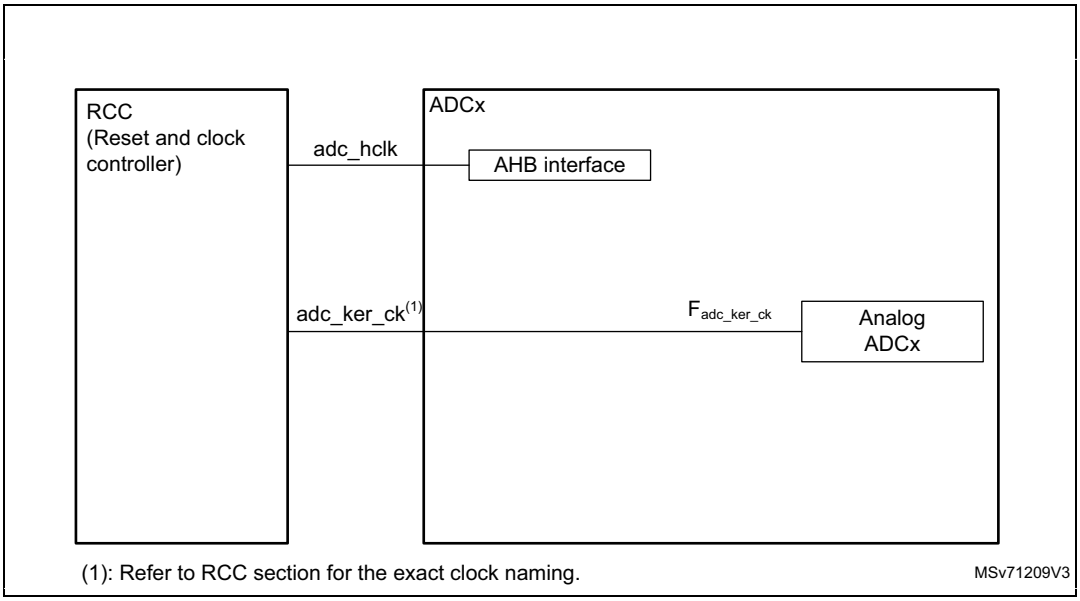
26.4.3 ADC clocks

Dual clock domain architecture

The dual clock-domain architecture means that the ADC kernel clock is independent from the AHB bus clock that is used to access ADC registers.

The adc_ker_ck input clock can be selected between different clock sources (see *Figure 190: ADC clock scheme*). This selection is done in the RCC (refer to section *Reset and clock control (RCC)* for more information):

1. The ADC clock can be provided by an internal or external clock source, which is independent and asynchronous from the AHB clock.
2. The ADC clock can be derived from AHB clock (selected in RCC).



Option **1** has the advantage of achieving the maximum ADC clock frequency whatever the AHB clock scheme selected.

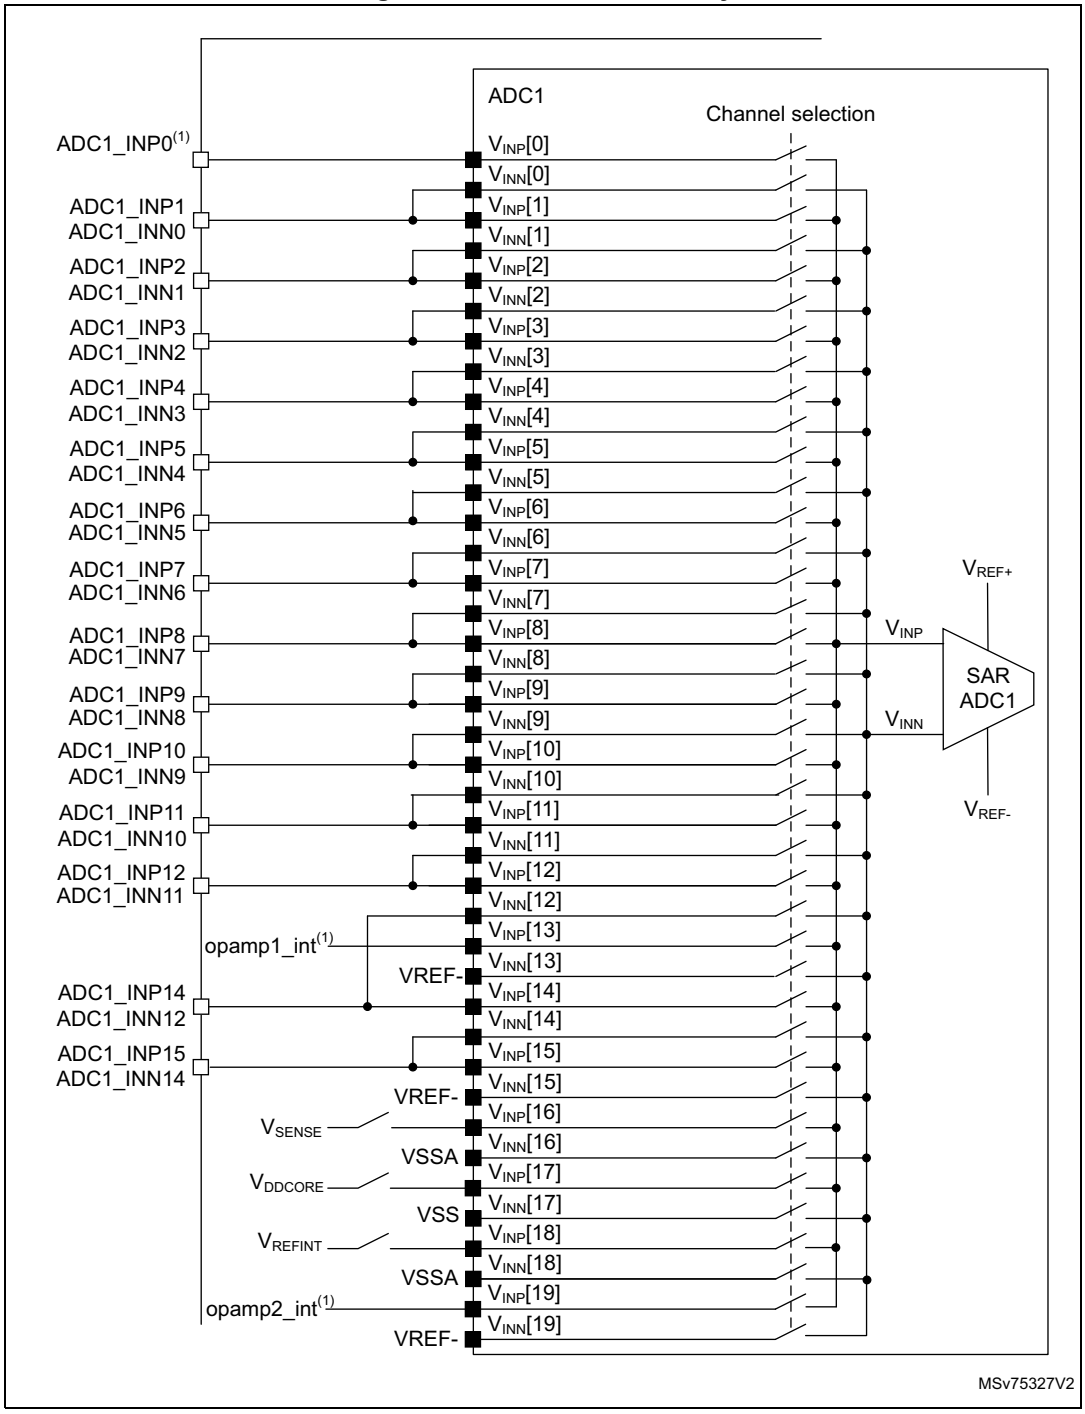
Option **2** corresponds to a pseudosynchronous clock. This can be useful when the ADC is triggered by a timer and the application requires that the ADC is accurately triggered without any uncertainty (otherwise, an uncertainty of the trigger instant time is added by the resynchronizations between the two clock domains). This accurate trigger is supported only by trgo or trgo2 timer triggers.

For further details on the synchronization between ADC and timers, refer to section *ADC synchronization* in each timer section, and to section *Peripheral clock distribution* in the RCC section.

The clock is configured through the RCC and must be compliant with the operating frequency specified in the device datasheet.

Figure 190. ADC clock scheme

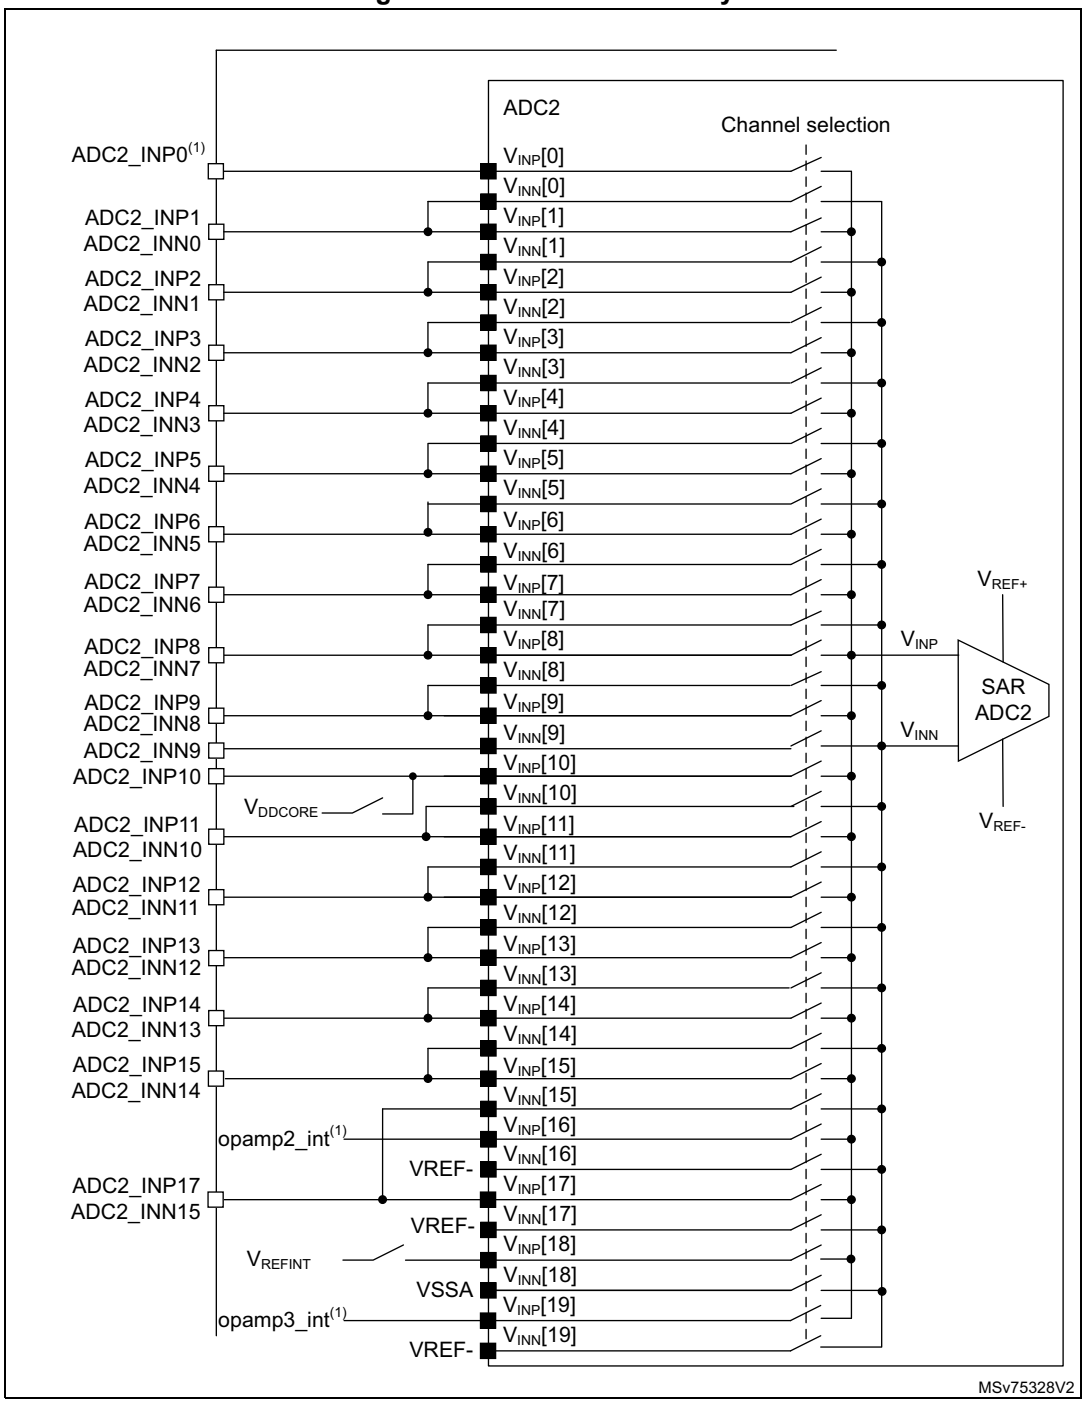
Clock ratio constraint between ADC clock and AHB clock



There are no constraints to respect for the ratio between the ADC clock and the AHB clock. However, the ratio must be carefully chosen to avoid any overrun especially if the clock AHB is much slower than the ADC clock.

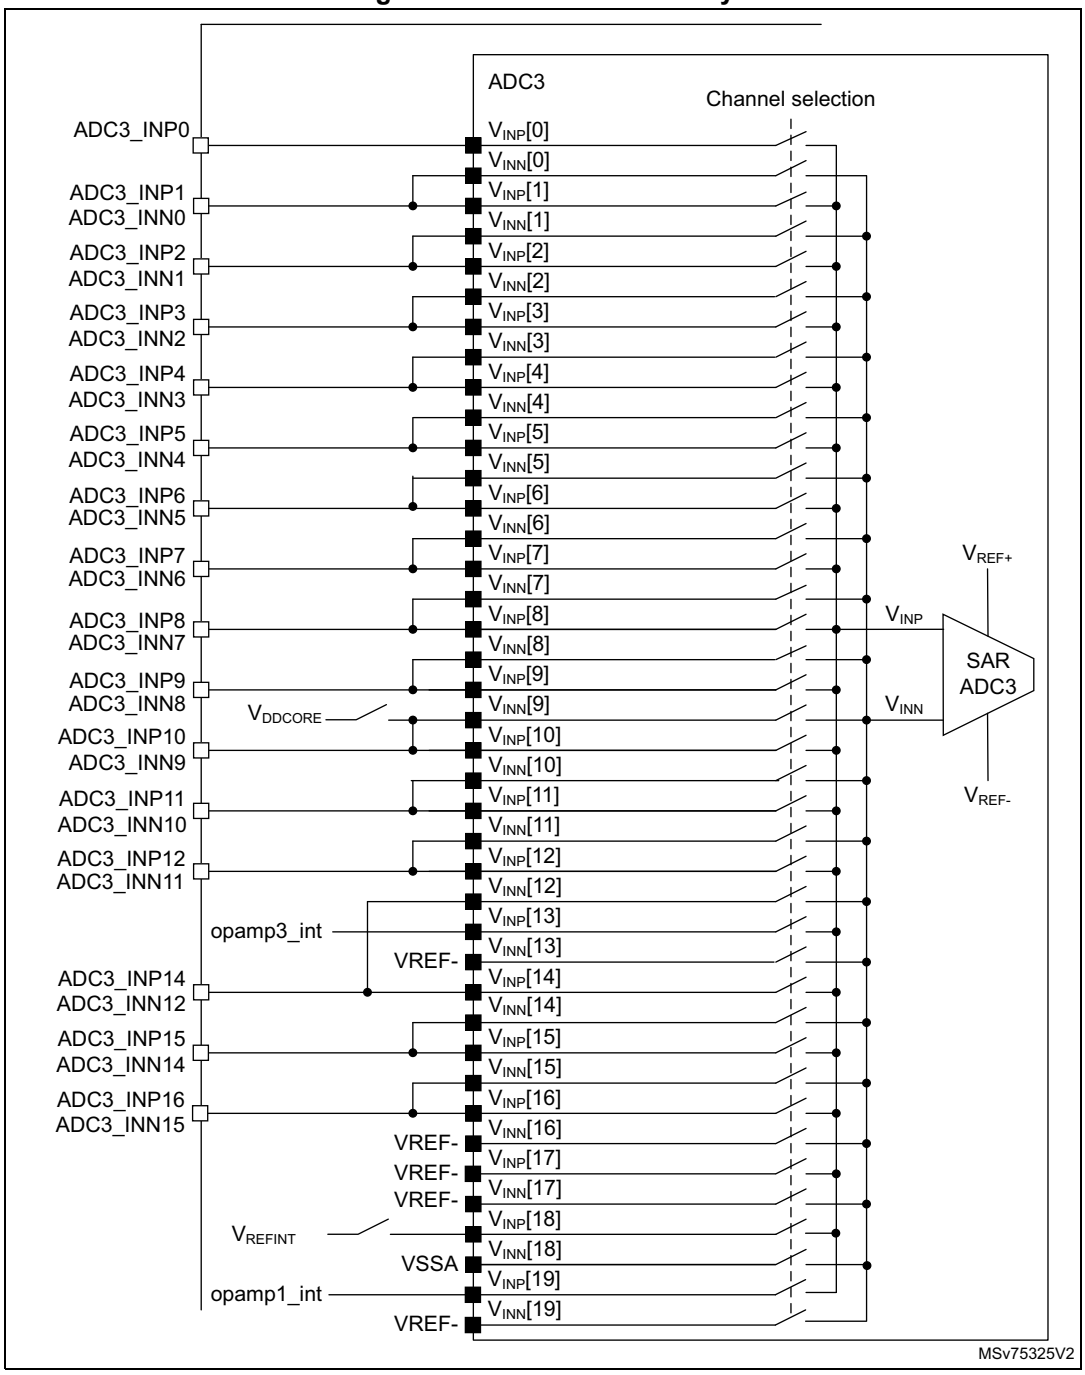
When adc_hclk operates at a higher frequency than adc_ker_ck, writing to the AHB register does not immediately update the ADC configuration due to clock domain crossing delays. To guarantee that the configuration is properly applied within the adc_ker_ck domain, it is necessary to wait for four adc_ker_ck clock cycles after the AHB register update.

26.4.4 ADC connectivity



ADC inputs are connected to external channels as well as internal sources as described below.

Figure 191. ADC1 connectivity



1. This connection is only available on STM32G55x/56x devices.

Figure 192. ADC2 connectivity

1. This connection is only available on STM32G55x/56x devices.

Figure 193. ADC3 connectivity

26.4.5 Slave AHB interface

The ADCs implement an AHB slave port for control/status register and data access. The features of the AHB interface are listed below:

- Word accesses
- Single cycle response
- Response to all read/write accesses to the registers with zero wait states.

The AHB slave interface does not support split/retry requests, and it can generate AHB error in case of wrong HSIZE.

26.4.6 ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)

By default, the ADC is in deep-power-down mode where its supply voltage is internally switched off to reduce the leakage currents (the reset state of the DEEPPWD bit is 1 in the ADC_CR register).

To activate the ADC, first exit the Deep-power-down mode by clearing the DEEPPWD bit.

Then, it is mandatory to enable the ADC internal voltage regulator by setting the ADVREGEN bit of the ADC_CR register. The software must wait for the startup time of the ADC voltage regulator ($T_{ADCVREG_STUP}$) before launching a calibration or enabling the ADC. This delay must be implemented by software. For the startup time of the ADC voltage regulator, refer to the device datasheet for $T_{ADCVREG_STUP}$ parameter.

When ADC operations are complete, the ADC can be disabled by clearing the ADEN bit of the ADC_CR register. Power can then be saved by disabling the ADC voltage regulator (by clearing ADVREGEN).

Additional power can be saved by entering ADC Deep-power-down mode again (by setting DEEPPWD of ADC_CR register). This is particularly interesting before entering Stop mode.

Note: Setting DEEPPWD automatically disables the ADC voltage regulator and the ADVREGEN bit is automatically cleared.

When the internal voltage regulator is disabled (ADVREGEN cleared), the internal analog calibration is kept.

In ADC Deep-power-down mode (DEEPPWD = 1), the internal analog calibration is lost and it is necessary to either relaunch a calibration or reapply the calibration factor, which was previously saved (refer to *Section Calibration*).

26.4.7 Single-ended and differential input channels

ADC channels can be configured to be either single-ended inputs or differential inputs by programming DIFSEL[i] bits in the ADC_DIFSEL register. This configuration must be programmed when no ADC conversion is ongoing. Note that the DIFSEL[i] bits corresponding to single-ended channels must be programmed at 0.

In single-ended input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ and V_{REF-}.

In differential input mode, the analog voltage to be converted for channel "*i*" is the difference between the external voltage $V_{INP[i]}$ (positive input) and $V_{INN[i]}$ (negative input).

In differential mode, the output data are unsigned data. When $V_{INP[i]}$ equals V_{REF-}, $V_{INN[i]}$ equals V_{REF+} and the output data is 0x000 (12-bit resolution mode). When $V_{INP[i]}$ equals V_{REF+}, $V_{INN[i]}$ equals V_{REF-} and the output data is 0xFFF.

$$\text{Converted value} = \frac{\text{ADC_Full_Scale}}{2} \times \left[1 + \frac{V_{INP} - V_{INN}}{V_{REF+}}\right]$$

When the ADC is configured in differential mode, the input signals are supposed to be differential (the common-mode voltage must be fixed at V_{REF+}/2 voltage).

Internal channels are used in single-ended mode only.

For a complete description of how the input channels are connected for each ADC, refer to *Section 26.4.4: ADC connectivity*.

Caution: When configuring channel "*i*" in differential input mode, its negative input voltage $V_{INN[i]}$ is connected to another channel. As a consequence, this channel is no longer usable in single-ended or differential mode, and must never be configured to be converted. Some channels are shared between ADCs: this can make the channel on the other ADCs unusable. The only exception is interleaved mode for ADC master and the slave.

26.4.8 Pseudodifferential mode

The ADC can operate in pseudodifferential mode instead of differential modes when DIFSELx = 1. In this mode, differential inputs are supported but the negative input $V_{INN[i]}$ is fixed to V_{REF-} or to V_{REF+}/2 voltage.

The pseudodifferential mode is selected by setting the PDIFF bit of the ADC_CFGR2 register. This changes the behavior of the differential channel selected via the ADC_DIFSEL register. In addition, the negative input reference voltage can be selected between V_{REF-} and V_{REF+}/2 through the PDIFFREF bit of the ADC_CFGR2 register.

When the ADC is configured in pseudodifferential mode:

- When $V_{INP[i]}$ equals 0 V, the output data is 0x000.
- When $V_{INP[i]}$ equals V_{REF+}, the output data is 0xFFF,

Note: The behavior is the same as in single-ended mode except that $V_{INN[i]}$ is fixed to 0 V or V_{REF+}/2.

The pseudodifferential mode can be used to reject the common mode noise that exists between the ADC shunt resistor bottom voltage (ground) and top voltage (voltage to be converted by the ADC).

The pseudodifferential mode does not affect single-end channel conversions.

The pseudodifferential and standard differential modes cannot be used simultaneously in the same scan conversion sequence. If pseudodifferential or differential conversion is required, stop and disable the ADC to change the PDIFF setting.

26.4.9 Calibration (ADCAL, ADCALDIF, ADC_CALFACT)

Each ADC provides an automatic calibration procedure that drives all the calibration sequences including the power-on/off sequence of the ADC. During the procedure, the ADC calculates a calibration factor, which is 7-bit wide and is applied internally to the ADC until

the next ADC power-off. During the calibration procedure, the application must not use the ADC and must wait until calibration is complete.

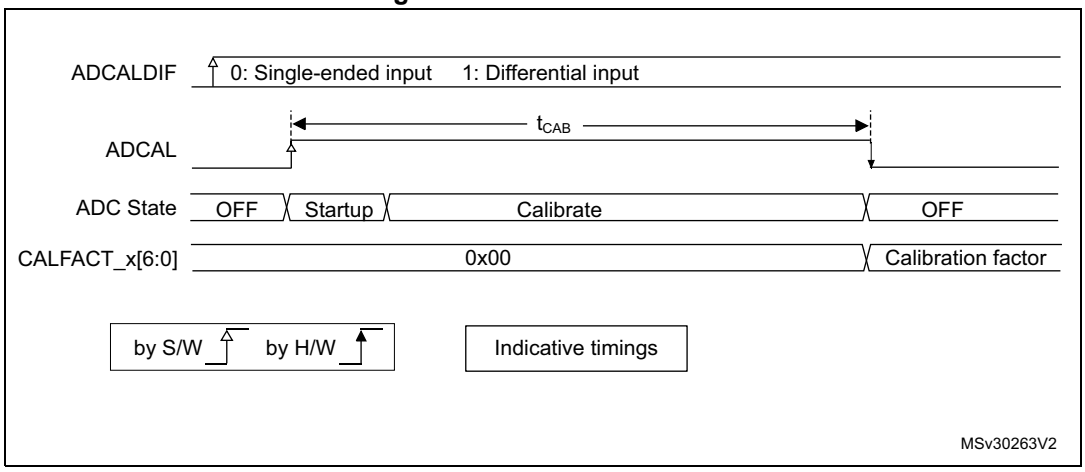
Calibration is preliminary to any ADC operation. It removes the offset error which may vary from chip to chip due to process or bandgap variation.

The calibration factor to be applied for single-ended input conversions is different from the factor to be applied for differential input conversions:

- Clear ADCALDIF before launching a calibration that is applied for single-ended input conversions.
- Set ADCALDIF before launching a calibration that is applied for differential input conversions.

The calibration is then initiated by software by setting bit ADCAL = 1. Calibration can only be initiated when the ADC is disabled (when ADEN = 0). The ADCAL bit stays at 1 during all the calibration sequence. It is then cleared by hardware as soon the calibration completes. At this time, the associated calibration factor is stored internally in the analog ADC and also in the bits CALFACT_S[6:0] or CALFACT_D[6:0] of the ADC_CALFACT register (depending on single-ended or differential input calibration)

The internal analog calibration is kept if the ADC is disabled (ADEN = 0). However, if the ADC is disabled for extended periods, then it is recommended that a new calibration cycle is run before reenabling the ADC.



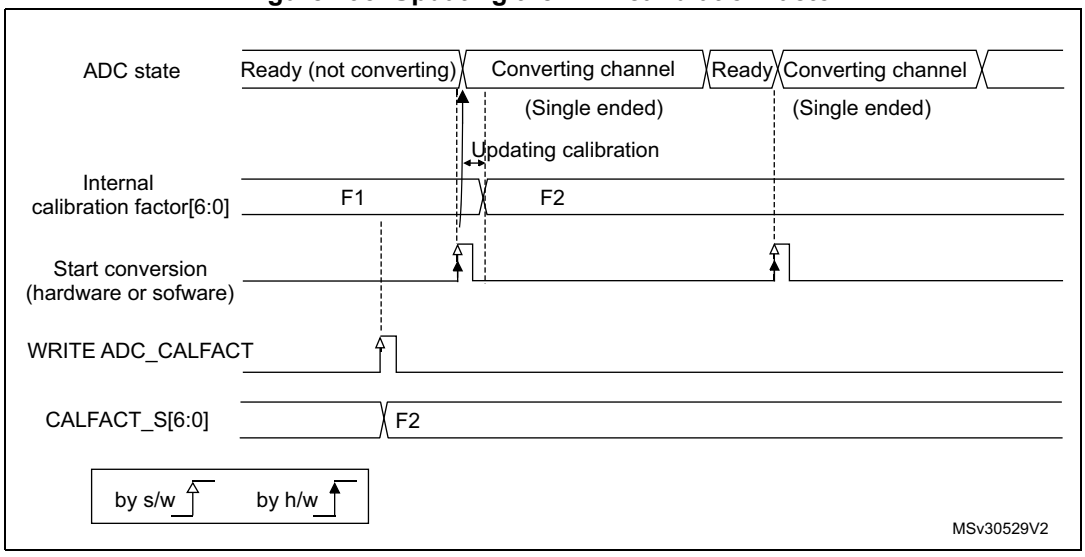
The internal analog calibration is lost each time the power of the ADC is removed (for example, when the product enters Standby). In this case, to avoid spending time recalibrating the ADC, it is possible to rewrite the calibration factor into the ADC_CALFACT register without recalibrating, supposing that the software has previously saved the calibration factor delivered during the previous calibration.

The calibration factor can be written if the ADC is enabled but not converting (ADEN = 1 and ADSTART = 0 and JADSTART = 0). Then, at the next start of conversion, the calibration factor is automatically injected into the analog ADC. This loading is transparent and does not add any cycle latency to the start of the conversion. It is recommended to recalibrate when the V_{REF+} voltage changed more than 10% (see *Section 26.4.35: Monitoring the internal voltage reference*).

Software procedure to calibrate the ADC

1. Ensure DEEPPWD = 0, ADVREGEN = 1 and that ADC voltage regulator startup time has elapsed.
2. Ensure that ADEN = 0.
3. Select the input mode for this calibration by clearing ADCALDIF (single-ended input) or by setting ADCALDIF (differential input).
4. Set ADCAL.
5. Wait until ADCAL = 0.
6. The calibration factor can be read from the ADC_CALFACT register.

Figure 194. ADC calibration

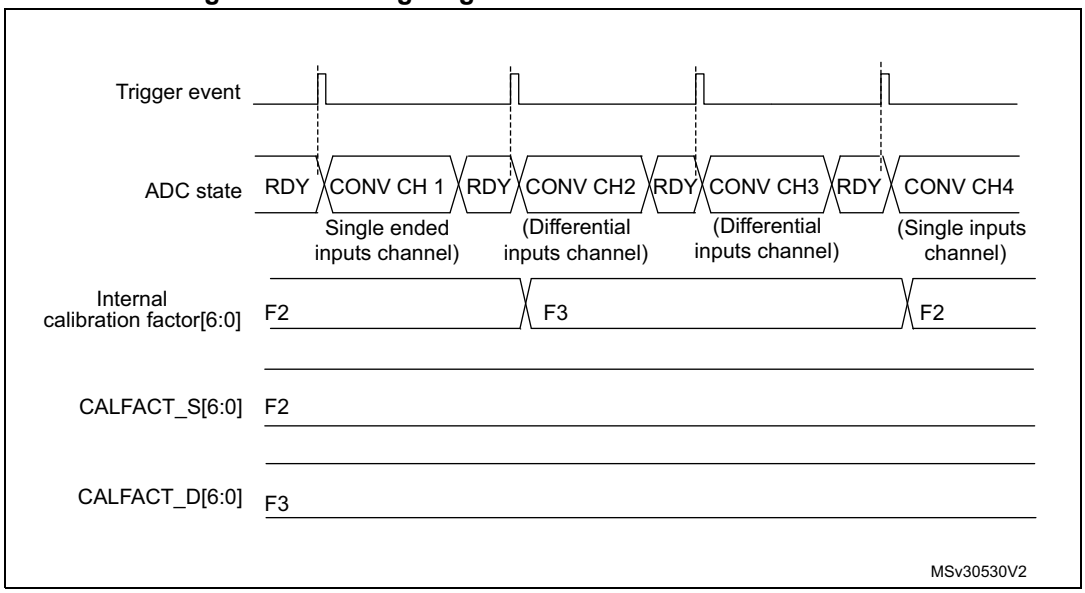


Software procedure to reinject a calibration factor into the ADC

1. Ensure ADSTART = 0 and JADSTART = 0 (no conversion is ongoing).
2. Write CALFACT_S and CALFACT_D with the new calibration factors.
3. When a conversion is launched, the calibration factor is injected into the analog ADC only if the internal analog calibration factor differs from the one stored in bits CALFACT_S for single-ended input channel or bits CALFACT_D for differential input channel.

Note: In pseudodifferential mode, only the CALFACT_D calibration factor is used.

Figure 195. Updating the ADC calibration factor



Converting single-ended and differential analog inputs with a single ADC

If the ADC is supposed to convert both differential and single-ended inputs, two calibrations must be performed, one with ADCALDIF = 0 and one with ADCALDIF = 1. The procedure is the following:

1. Disable the ADC.
2. Calibrate the ADC in single-ended input mode (with ADCALDIF = 0). This updates the register CALFACT_S[6:0].
3. Calibrate the ADC in differential input modes (with ADCALDIF = 1). This updates the register CALFACT_D[6:0].
4. Enable the ADC, configure the channels and launch the conversions. Each time there is a switch from a single-ended to a differential input channel (and vice versa), the calibration is automatically injected into the analog ADC.

Figure 196. Mixing single-ended and differential channels

Note: The offset calibration in pseudodifferential mode is controlled by the CALFACF_D register.

26.4.10 ADC on-off control (ADEN, ADDIS, ADRDY)

First, follow the procedure described in *Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*).

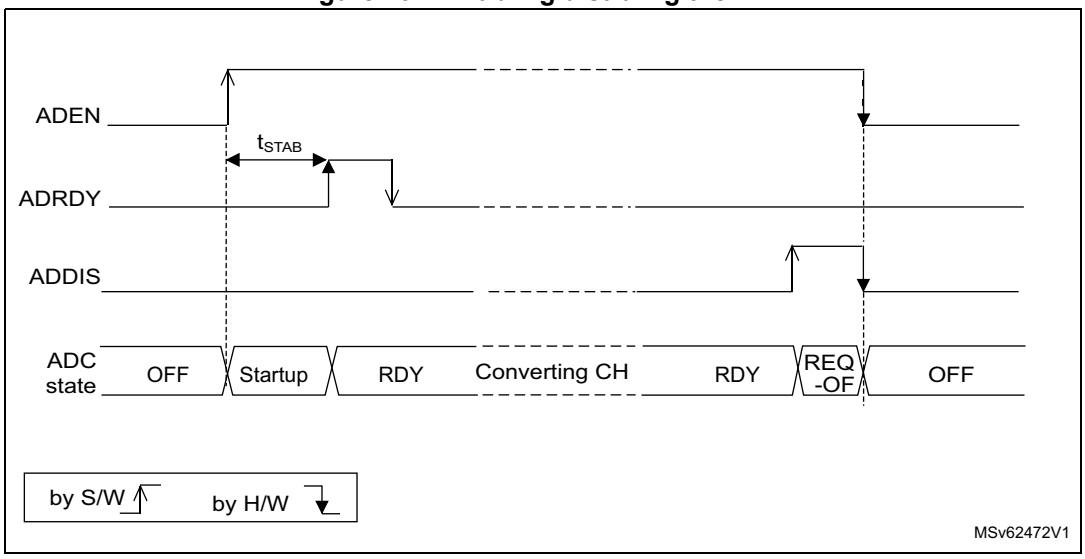
Once DEEPPWD is cleared and ADVREGEN is set, the ADC can be enabled. It requires a t_{STAB} stabilization time before starting converting accurately (see *Figure 197*).

Two control bits enable or disable the ADC:

- Set ADEN to enable the ADC. The ADRDY flag is set once the ADC is ready for operation.
- Set ADDIS to disable the ADC. ADEN and ADDIS are automatically deasserted by hardware as soon as the analog ADC is effectively disabled.

Regular conversions can then start either by setting ADSTART (refer to *Section 26.4.21: Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)*) or when an external trigger event occurs if regular triggers are enabled.

Injected conversions start by setting JADSTART or when an external injected trigger event occurs, if injected triggers are enabled.



Software procedure to enable the ADC

1. Clear the ADRDY bit in the ADC_ISR register by programming it to 1.
2. Set ADEN.
3. Wait until ADRDY = 1 (ADRDY is set after the ADC startup time). This can be done by using the associated interrupt (ADRDYIE must be set).
4. Clear the ADRDY bit in the ADC_ISR register by programming it to 1 (optional).

Software procedure to disable the ADC

1. Check that both ADSTART = 0 and JADSTART = 0 to ensure that no conversion is ongoing. If required, stop all regular and injected ongoing conversions by setting ADSTP and JADSTP. Then wait until ADSTP = 0 and JADSTP = 0.
2. Set ADDIS.
3. If required by the application, wait for ADEN = 0, until the analog ADC is effectively disabled (ADDIS is automatically reset once ADEN = 0).

Figure 197. Enabling/disabling the ADC

26.4.11 Constraints when writing the ADC control bits

The software is allowed to write the RCC control bits to configure and enable the ADC clock (refer to RCC section) and configure the ADEN bit in the ADC_CR register, only if the ADC is disabled (ADEN must be cleared).

The software can modify the PDIFF and PDIFFREF of the ADC_CFGR2 only when ADEN is cleared.

The software can write the ADSTART, JADSTART and ADDIS control bits in the ADC_CR register only if the ADC is enabled and there is no pending request to disable the ADC (ADEN must be equal to 1 and ADDIS to 0).

The following constraints apply to all the other control bits of the ADC_CFGRx, ADC_SMPRx, ADC_TRy, ADC_SQRy, ADC_JDRy, ADC_OFRy, ADC_OFCHRy and ADC_IER registers:

- For control bits related to configuration of regular conversions, the software is allowed to write them only if no regular conversions are ongoing (ADSTART must be cleared).
- For control bits related to configuration of injected conversions, the software is allowed to write them only if no injected conversions are ongoing (JADSTART must be cleared).
- ADC_TRy register thresholds can be modified when an analog-to-digital conversion is ongoing (refer to *Section 26.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)* for details).
- To modify the all above control bits when the software trigger function is used, an ADSTP or JADSTP must be issued to make sure all activities are stopped, even if ADSTART and JADSTART are cleared.

The software is allowed to write the ADSTP or JADSTP control bits in the ADC_CR register only if the ADC is enabled and if there is no pending request to disable the ADC. In addition, the software can write the ADC_JSQR register, when injected queue are disabled by JQDIS = 1, only if JADSTART is cleared and no injected conversion is ongoing. Refer to *Section 26.6.14: ADC injected sequence register (ADC_JSQR)* for additional details.

Note: Not all forbidden write accesses to ADC control bits are protected by hardware. In some cases, the ADC state may become unknown. To recover from this situation, the ADC must be disabled (ADEN = 0 as well as all the bits of the ADC_CR register).

26.4.12 Channel selection (ADC_SQRy, ADC_JSQR)

The ADC features up to 20 multiplexed channels per ADC, out of which:

- Up to 17 analog inputs coming from GPIO pads (ADCx_INN/INP[i]). Depending on the device, not all of them are available on GPIO pads.
- The ADC is connected to up to 6 internal analog inputs:
  - internal reference voltage (V_{REFINT})
  - Internal temperature sensor (V_{SENSE})
  - V_{DDCORE} voltage
  - OPAMP internal channel

  To convert one of the internal analog channels, the corresponding analog sources must first be enabled by programming VREFEN, TSEN in the ADCC_CCR registers, or by enabling the corresponding bit in the *ADC option register (ADC_OR)*.

Refer to *ADC interconnection* tables in *Section 26.4.2: ADC pins and internal signals* for the connection of the above internal analog inputs to ADC pins.

The conversions can be organized in two groups: regular and injected. A group consists of a sequence of conversions that can be done on any channel and in any order. For instance, it is possible to implement the conversion sequence in the following order: ADCx_INN/INP3, ADCx_INN/INP8, ADCx_INN/INP2, ADCx_INN/INP2, ADCx_INN/INP0, ADCx_INN/INP2, and ADCx_INN/INP2.

- A **regular group** is composed of up to 16 conversions. The regular channels and their order in the conversion sequence must be selected in the ADC_SQRy registers. The

total number of conversions in the regular group must be written in the LEN[3:0] bits in the ADC_SQR1 register.

- An **injected group** is composed of up to four conversions. The injected channels and their order in the conversion sequence must be selected in the ADC_JSQR register. The total number of conversions in the injected group must be written in the JLEN[1:0] bits in the ADC_JSQR register.

ADC_SQRy registers must not be modified while a regular conversion is ongoing. ADC regular conversions must consequently be stopped by setting ADSTP (refer to *Section 26.4.20: Stopping an ongoing conversion (ADSTP, JADSTP)*).

In addition, the ADC_JSQR register must not be modified while an injected conversion is ongoing. ADC injected conversions must consequently be stopped by setting JADSTP, except when JQDIS is cleared.

26.4.13 Channel preselection register (ADC_PCSEL)

The PCSEL bit of the ADC_PCSEL register controls the analog switch integrated in the I/O.

For each channel selected through SQRx or JSQRx bits, the corresponding PCSEL bit must be configured in advance in the ADC_PCSEL register. The ADC input multiplexer selects the ADC input according to SQRx and JSQRx configuration with very high speed. The analog switch integrated in the I/O cannot react as fast as the ADC multiplexer. To avoid the delay due to the analog switch control on the I/O, it is necessary to preselect the input channels that are selected through the SQRx and JSQRx. The selection is based on the V_{INP} of each ADC input. For example, if the ADC converts ADCx_INN/INP1, PCSEL1 bit must also be set in ADC_PCSEL register. If ADCx_INN/INP1 is configured as a differential channel, both PCSEL1 and PCSEL0 must be set, which corresponds to ADC1_INN1 and ADC2_INN1.

Note: Configuring the PCSEL bit is not necessary for the internal channels (such as V_{REFINT}).

26.4.14 Channel-wise programmable sampling time (SMPR1, SMPR2)

Before starting a conversion, the ADC must establish a direct connection between the voltage source under measurement and the embedded sampling capacitor of the ADC. This sampling time must be sufficient for the input voltage source to charge the embedded capacitor to the input voltage level.

Each channel can be sampled with a different sampling time, which is programmable through the SMP[2:0] bits of the ADC_SMPR1 and ADC_SMPR2 registers. It is therefore possible to select among the following sampling time values:

- SMP = 000: 2.5 ADC clock cycles
- SMP = 001: 4.5 ADC clock cycles
- SMP = 010: 7.5 ADC clock cycles
- SMP = 011: 12.5 ADC clock cycles
- SMP = 100: 24.5 ADC clock cycles
- SMP = 101: 47.5 ADC clock cycles
- SMP = 110: 256.5 ADC clock cycles
- SMP = 111: 848.5 ADC clock cycles

The total conversion time is calculated as follows (12-bit mode):

$$T_{CONV} = \text{Sampling time} + 13 \text{ ADC clock cycles}$$

Example

With $F_{adc_ker_ck}$ = 32 MHz and a sampling time of 3 ADC clock cycles:

$$T_{CONV} = (3 + 13) \times \text{ADC clock cycles} = 16 \text{ ADC clock cycles} = 500 \text{ ns}$$

The ADC notifies the end of the sampling phase by asserting the EOSMP flag (only for regular conversion).

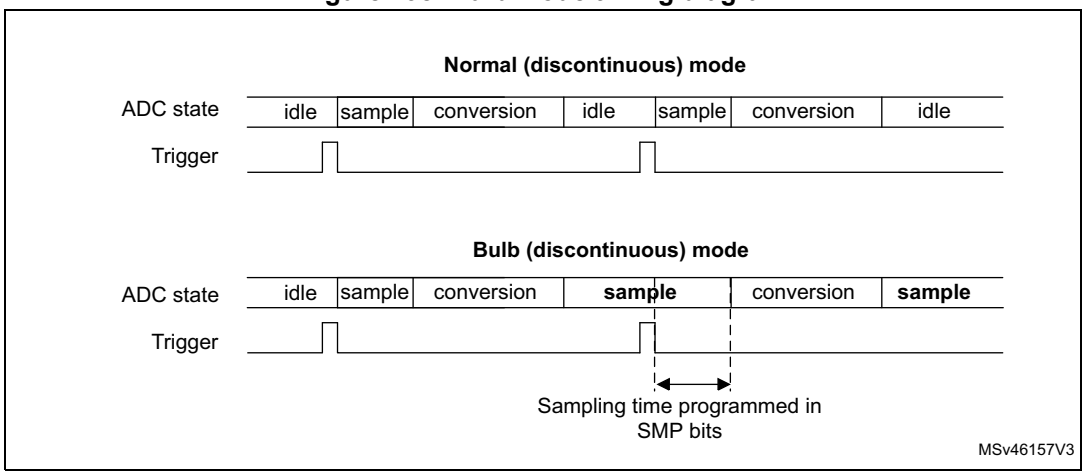
Constraints on the sampling time

For each channel, SMP[2:0] bits must be programmed to respect a minimum and a maximum sampling times as specified in the ADC characteristics section of the datasheets.

Bulb sampling mode

The bulb sampling mode enables to obtain longer sampling time.

When the BULB bit is set in the ADC_CFGR2 register, the sampling period starts immediately after the last ADC conversion. A hardware or software trigger starts the conversion after the sampling time has been programmed in ADC_SMPRx registers. The very first ADC conversion after the ADC is enabled, is performed with the sampling time programmed in SMP bits. The bulb mode is effective starting from the second conversion.



The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

Bulb mode is supported exclusively in regular conversion; dual mode is not supported.

The BULB bit can be modified only when the ADEN bit of the ADC_CR register is cleared.

When the BULB bit is set, it is not allowed to set the SMPTRIG bit in ADC_CFGR2.

Figure 198. Bulb mode timing diagram

Sampling time control trigger mode

When the SMPTRIG bit is set, the sampling time programmed through SMPx bits is not applicable. The sampling time is controlled by the trigger signal edge.

When a hardware trigger is selected (EXTEN[1:0] = 01), each rising edge of the trigger signal starts the sampling period. A falling edge ends the sampling period and starts the conversion.

Due to the synchronization mechanism, the minimum allowed pulse width is seven adc_ker_ck periods.

When a software trigger is selected (EXTEN[1:0] = 00), the software trigger is not the ADSTART bit of ADC_CR but the SWTRIG bit. The SWTRIG bit has to be set to start the sampling period, and it has to be cleared to end the sampling period and start the conversion. In this mode, the minimum sampling time is limited to seven ADC clock cycles.

The maximum sampling time is limited (refer to the ADC characteristics section of the datasheet).

This mode is only compatible with the discontinuous mode. DISCNUM must be cleared for regular conversion mode. It is not supported for injected conversion mode and autoinjection mode.

When the SMPTRIG bit is set, setting the BULB bit is not allowed and only regular conversion is supported.

The sampling time control trigger mode is not compatible with the following dual modes: DUAL[4:0] = 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, and 0b01001.

26.4.15 Single conversion mode

To enable the single conversion mode for regular channels, clear both CONT and DISCEN bits in ADC_CFGR1 register. To enable it on injected channel, clear JDISCEN bit.

In single conversion mode, the ADC performs once all the regular conversions of the programmed channels. This mode is started by one of the following events:

- ADSTART bit set in the ADC_CR register (for a regular channel)
- JADSTART bit set in the ADC_CR register (for an injected channel)
- An external hardware trigger event (for a regular or injected channel)

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the 32-bit 8-level FIFO accessible through the ADC_DR register,
- The EOC (end of regular conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

Inside the injected sequence, after each conversion is complete:

- The converted data are stored into one of the four 32-bit ADC_JDRy registers,
- The JEOC (end of injected conversion) flag is set, and
- An interrupt is generated if the JEOCIE bit is set.

After the regular sequence is complete:

- The EOS (end of regular sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

After the injected sequence is complete:

- The JEOS (end of injected sequence) flag is set, and
- An interrupt is generated if the JEOSIE bit is set.

The ADC then stops until a new external regular or injected trigger occurs or until the ADSTART or JADSTART bit is set again.

Note: To convert a single channel, program a sequence with a length of 1.

26.4.16 Continuous conversion mode (CONT = 1)

This mode applies to regular channels only.

In continuous conversion mode, when a software or hardware regular trigger event occurs, the ADC performs once all the regular conversions of the channels and then automatically restarts and continuously converts all the conversions of the sequence. This mode is started by setting the CONT bit of the ADC_CFGR1 register, either by an external trigger or by setting the ADSTART bit in the ADC_CR register.

Inside the regular sequence, after each conversion is complete:

- The converted data are stored into the eight 32-bit word FIFO accessible through the ADC_DR register.
- The EOC (end of conversion) flag is set, and
- An interrupt is generated if the EOCIE bit is set.

After the sequence of conversions is complete:

- The EOS (end of sequence) flag is set, and
- An interrupt is generated if the EOSIE bit is set.

Then, a new sequence restarts immediately and the ADC continuously repeats the conversion sequence.

Note: To convert a single channel, program a sequence with a length of 1.

It is not possible to have both discontinuous mode and continuous mode enabled, this means that it is forbidden to set both DISCEN and CONT bits.

Injected channels cannot be converted continuously. The only exception is when an injected channel is configured to be converted automatically after regular channels in continuous mode (using JAUTO bit) (refer to Section : Autoinjection mode).

26.4.17 Discontinuous mode (DISCEN, DISCNUM, JDISCEN)

Regular group mode

This mode is enabled by setting the DISCEN and CONT = 0 bit in the ADC_CFGR1 register.

It is used to convert a short sequence (subgroup) of n conversions (n ≤ 8) that is part of the sequence of conversions selected in the ADC_SQRy registers. The value of n is specified by writing to the DISCNUM[2:0] bits in the ADC_CFGR1 register.

When an external trigger occurs, it starts the next n conversions selected in the ADC_SQRy registers until all the conversions in the sequence are done. The total sequence length is defined by the LEN[3:0] bits in the ADC_SQR1 register.

Example:

- DISCEN = 1, n = 3, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10, 11

  - First trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - Second trigger: channels converted are 6, 7, 8 (an EOC event is generated at the end of each conversion).
  - Third trigger: channels converted are 9, 10, 11 (an EOC event is generated at the end of each conversion) and an EOS event is generated after the conversion of channel 11.
  - Fourth trigger: channels converted are 1, 2, 3 (an EOC event is generated at the end of each conversion).
  - ...
- DISCEN = 0, channels to be converted = 1, 2, 3, 6, 7, 8, 9, 10,11
  - First trigger: the complete sequence is converted: channel 1, then 2, 3, 6, 7, 8, 9, 10 and 11. Each conversion generates an EOC event and the last one also generates an EOS event.
  - All the next trigger events relaunch the complete sequence.

Note: The channel numbers referred to in the above example might not be available on all devices.

When a regular group is converted in discontinuous mode, no rollover occurs (the last subgroup of the sequence can have less than n conversions).

When all subgroups are converted, the next trigger starts the conversion of the first subgroup. In the example above, the fourth trigger reconverts the channels 1, 2 and 3 in the first subgroup.

It is not possible to have both discontinuous mode and continuous mode enabled. In this case (if DISCEN = 1, CONT = 1), the ADC behaves as if continuous mode was disabled.

Injected group mode

This mode is enabled by setting the JDISCEN bit in the ADC_CFGR1 register. It converts the sequence selected in the ADC_JSQR register, channel by channel, after an external injected trigger event. This is equivalent to discontinuous mode for regular channels with DISCNUM = 0.

When an external trigger occurs, it starts the next channel conversions selected in the ADC_JSQR registers until all the conversions in the sequence are done. The total sequence length is defined by the JLEN[1:0] bits in the ADC_JSQR register.

Example:

- JDISCEN = 1, channels to be converted = 1, 2, 3
  - First trigger: channel 1 converted (a JEOC event is generated)
  - Second trigger: channel 2 converted (a JEOC event is generated)
  - Third trigger: channel 3 converted and a JEOC event + a JEOS event are generated
  - ...

Note: The channel numbers referred to in the above example might not be available on all devices.

When all injected channels have been converted, the next trigger starts the conversion of the first injected channel. In the example above, the fourth trigger reconverts the first injected channel 1.

It is not possible to use both autoinjection mode and discontinuous mode simultaneously: the bits DISCEN and JDISCEN must be kept cleared by software when JAUTO is set.

26.4.18 Starting conversions (ADSTART, JADSTART)

ADC regular conversions can be started by setting ADSTART.

When ADSTART is set, the conversion starts:

- Immediately if EXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected regular hardware trigger, if EXTEN[1:0] is not equal to 00.

The application software starts ADC injected conversions by setting JADSTART.

When JADSTART is set, the conversion starts:

- Immediately if JEXTEN[1:0] = 00 (software trigger), or
- At the next active edge of the selected injected hardware trigger, if JEXTEN[1:0] is not equal to 00.

Note: In autoinjection mode (JAUTO = 1), use the ADSTART bit to start regular conversions followed by autoinjected conversions (JADSTART must be kept cleared).

When the hardware trigger is enabled, ADSTART and JADSTART also indicate whether an ADC operation is ongoing. The ADC can be reconfigured while ADSTART and JADSTART are both cleared, indicating that the ADC is idle.

In the case of software triggering, ADSTP and/or JADSTP must be set before ADC reconfiguration.

ADSTART is deasserted by hardware:

- In single mode with software regular trigger (CONT = 0, EXTEN = 0x0): at any end of regular conversion sequence (EOS assertion)
- In discontinuous mode (CONT = 0, DISCEN = 1, DISCNUM= x): at any of subgroup sequence
- In all cases (CONT and EXTEN don’t care), after execution of the ADSTP procedure asserted by the software

Note: In continuous mode (CONT = 1), ADSTART is not deasserted by hardware when EOS is asserted because the sequence is automatically relaunched.

When a hardware trigger is selected in single mode (CONT = 0 and EXTEN ≠ 0x00), ADSTART is not deasserted by hardware when EOS is asserted to help the software that does not need to reset ADSTART again for the next hardware trigger event. This ensures that no further hardware triggers are missed.

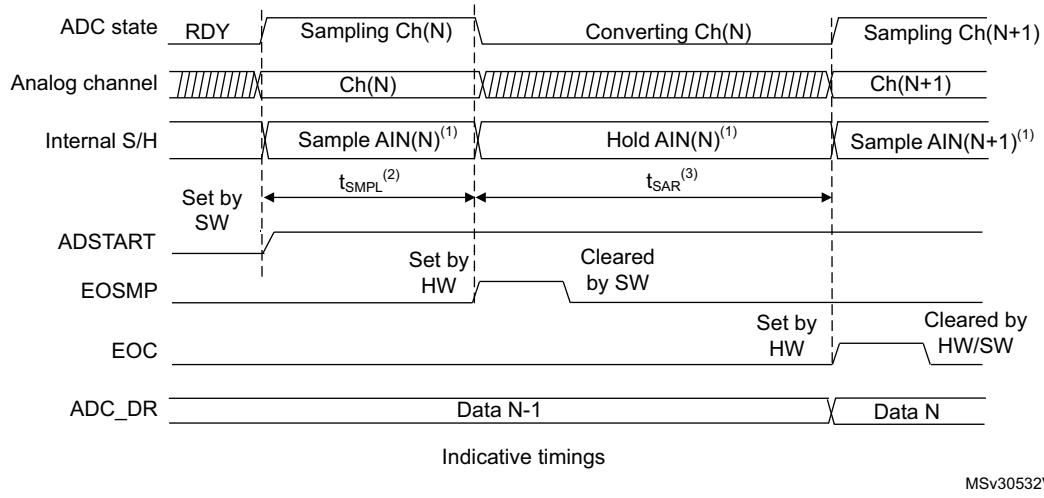
JADSTART is deasserted by hardware:

- In single mode with software injected trigger (JEXTEN = 0x0): at the end of each injected conversion sequence (JEOS assertion)
- In discontinuous mode (JDISCEN = 1): at the end of any conversion
- In all cases (JEXTEN=x), after execution of the JADSTP procedure asserted by the software

Note: When the software trigger is selected, the ADSTART bit must not be set if the EOC flag is still high.

In bulb mode (BULB = 1), the previous end-of-conversion automatically starts the sampling, then setting ADSTART starts the conversion including the programmed sampling time.

In sampling time control trigger mode (SMPTRIG = 1), SWTRIG bit must be set to start the conversion.



26.4.19 Timing

The elapsed time between the start of a conversion and the end of a conversion is the sum of the configured sampling time plus the successive approximation time depending on data resolution:

$T_{CONV} = T_{SMPL} + T_{SAR} = [3\ _{|min} + 13\ _{|12bit}] \times T_{ADC_CLK}$

$T_{CONV} = T_{SMPL} + T_{SAR} = 93.75\ ns\ _{|min} + 406.25\ ns\ _{|12bit} = 500\ ns$ (for $F_{adc_ker_ck} = 32\ MHz$)

Figure 199. Analog-to-digital conversion time

1. AIN represents the input voltage captured by the internal Sample and Hold (S/H) capacitor.
2. t_{SMPL} depends on SMP[2:0].
3. t_{SAR} depends on RES[2:0].

Note: The bulb and the sampling time control trigger modes are not described in Figure 199: Analog-to-digital conversion time.

26.4.20 Stopping an ongoing conversion (ADSTP, JADSTP)

The software can decide to stop ongoing regular conversions by setting ADSTP and ongoing injected conversions by setting JADSTP.

Stopping conversions resets the ongoing ADC operation. The ADC can then be reconfigured (for example by changing the channel selection or the trigger). It is then ready for a new operation.

Injected conversions can be stopped while regular conversions are still ongoing and vice versa. This allows, for instance, the reconfiguration of the injected conversion sequence and triggers while regular conversions are still ongoing (and vice versa).

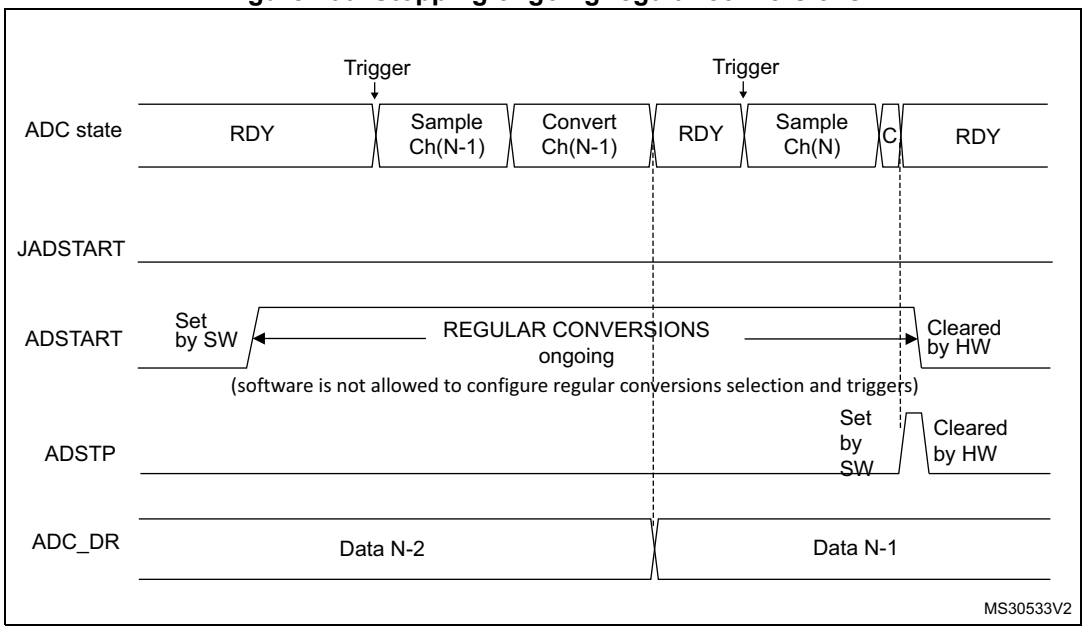
When the ADSTP bit is set by software, any ongoing regular conversion is aborted with the partial result discarded (the ADC_DR register is not updated with the current conversion).

When the JADSTP bit is set by software, any ongoing injected conversion is aborted with partial result discarded (the ADC_JDRy register is not updated with the current conversion). The scan sequence is also aborted and reset (meaning that relaunching the ADC restarts a new sequence).

Once this procedure is complete, ADSTP/ADSTART bits (for regular conversion), or JADSTP/JADSTART bits (for injected conversion) are deasserted by hardware and the software must poll ADSTART (or JADSTART) until the bit is reset before assuming the ADC is completely stopped.

Note: In autoinjection mode (JAUTO = 1), setting the ADSTP bit aborts both regular and injected conversions (JADSTP must not be used).

Figure 200. Stopping ongoing regular conversions



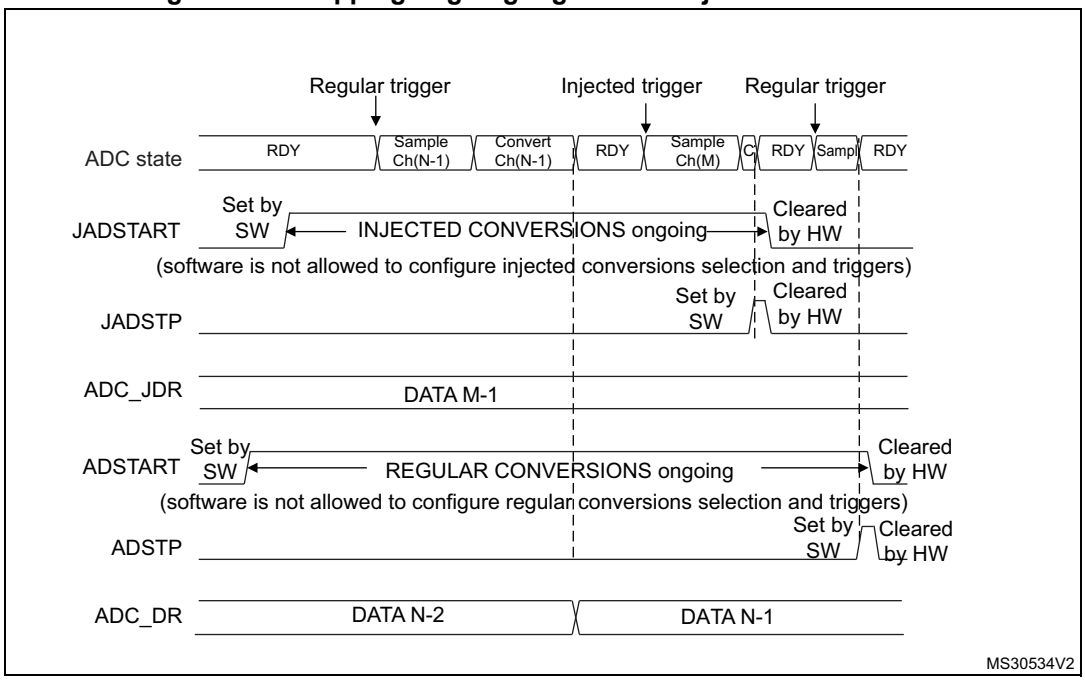


Figure 201. Stopping ongoing regular and injected conversions

26.4.21 Conversion on external trigger and trigger polarity (EXTSEL, EXTEN, JEXTSEL, JEXTEN)

A conversion or a sequence of conversions can be triggered either by software or by an external event (for example timer capture, input pins). If the EXTEN[1:0] control bits (for a regular conversion) or JEXTEN[1:0] bits (for an injected conversion) are different from 0b00, then external events are able to trigger a conversion with the selected polarity.

The regular trigger selection is effective once the software has set ADSTART while the injected trigger selection is effective once the software has set JADSTART bit.

All hardware triggers that occur while a conversion is ongoing are ignored:

- If ADSTART = 0, regular hardware triggers are ignored.
- If JADSTART = 0, injected hardware triggers are ignored.

Table 227 provides the correspondence between the EXTEN[1:0] and JEXTEN[1:0] values and the trigger polarity.

Table 227. Configuring the trigger polarity for regular external triggers

EXTEN[1:0]	Source
00	Hardware trigger detection disabled, software trigger detection enabled
01	Hardware trigger with detection on the rising edge (sampling time controlled in SMPTRIG mode)
10	Hardware trigger with detection on the falling edge
11	Hardware trigger with detection on both the rising and falling edges

Note: The polarity of the regular trigger cannot be changed on-the-fly.

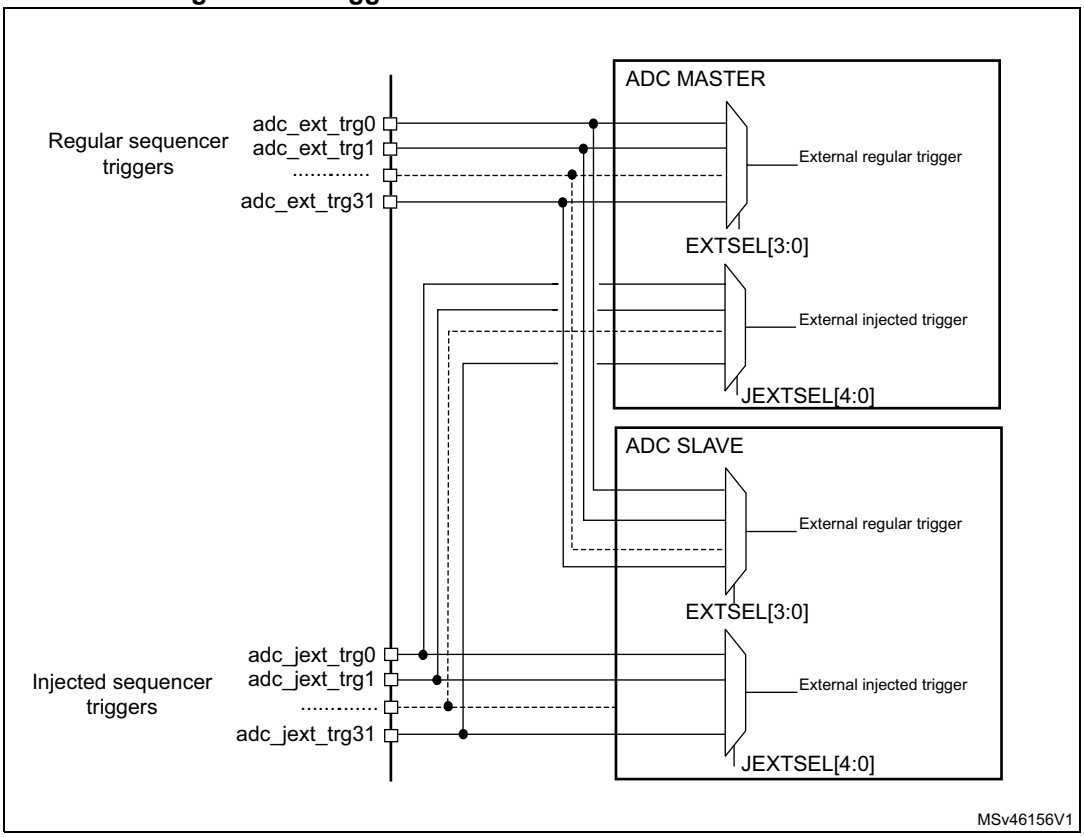

Table 228. Configuring the trigger polarity for injected external triggers

JEXTEN[1:0]	Source
00	Hardware Trigger detection disabled, software trigger detection enabled
01	Hardware Trigger with detection on the rising edge
10	Hardware Trigger with detection on the falling edge
11	Hardware Trigger with detection on both the rising and falling edges

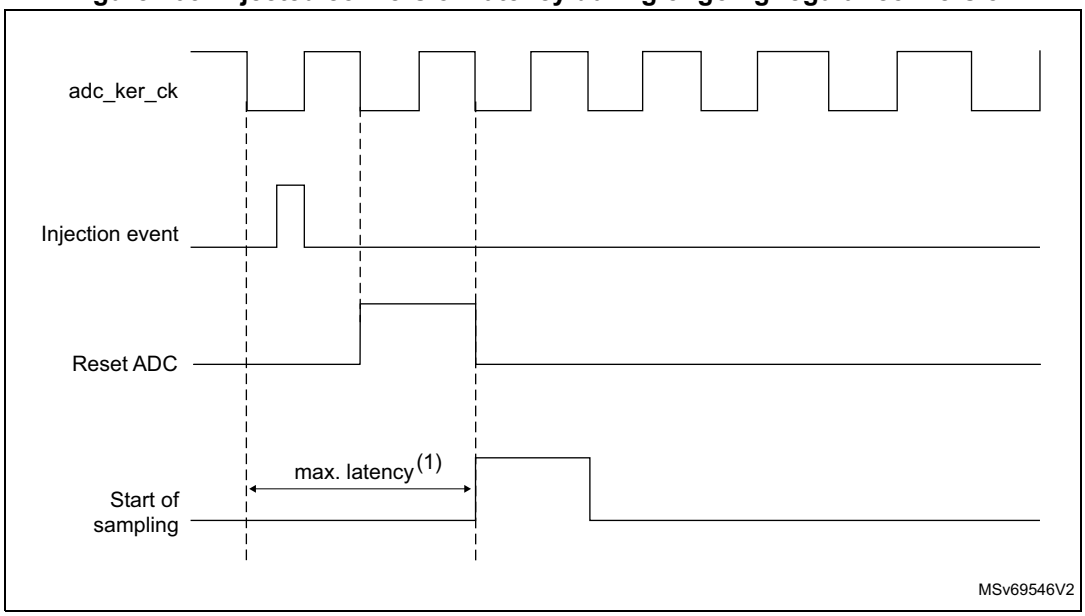
The EXTSEL and JEXTSEL control bits select which, out of 32 possible events, can trigger the conversion of the regular and injected groups.

A regular group conversion can be interrupted by an injected trigger.

Figure 202. Triggers shared between ADC master and slave

Refer to *ADC interconnection* tables in *Section 26.4.2: ADC pins and internal signals* for the list of the external triggers.

26.4.22 Injected channel management



Triggered injection mode

To use triggered injection, the JAUTO bit in the ADC_CFGR1 register must be cleared.

1. Start the conversion of a group of regular channels either by an external trigger or by setting the ADSTART bit in the ADC_CR register.
2. If an external injected trigger occurs, or if the JADSTART bit in the ADC_CR register is set during the conversion of a regular group of channels, the current conversion is reset and the injected channel sequence switches are launched (all the injected channels are converted once if JDISCEN = 0).
3. Then, the regular conversion of the regular group of channels is resumed from the last interrupted regular conversion.
4. If a regular event occurs during an injected conversion, the injected conversion is not interrupted but the regular sequence is executed at the end of the injected sequence. *Figure 203* shows the corresponding timing diagram.

Note: When using triggered injection, one must ensure that the interval between trigger events is longer than the injection sequence.

Figure 203. Injected conversion latency during ongoing regular conversion

1. The maximum latency value can be found in the electrical characteristics of the device datasheet.

Autoinjection mode

If the JAUTO bit in the ADC_CFGR1 register is set, then the channels in the injected group are automatically converted after the regular group of channels. This can be used to convert a sequence of up to 20 conversions programmed in the ADC_SQRy and ADC_JSQR registers.

In this mode, the ADSTART bit in the ADC_CR register must be set to start regular conversions, followed by injected conversions (JADSTART must be kept cleared). Setting the ADSTP bit aborts both regular and injected conversions (JADSTP bit must not be used).

In this mode, external trigger on injected channels must be disabled.

Note: Autoinjection mode is compatible with discontinuous mode.

26.4.23 Queue of context for injected conversions

A queue of context is implemented to anticipate up to two contexts for the next injected sequence of conversions. JQDIS bit of the ADC_CFGR1 register must be reset to enable this feature. Only hardware-triggered conversions are possible when the context queue is enabled. The queue of context is not supported in dual modes or in auto delay mode.

This context consists of:

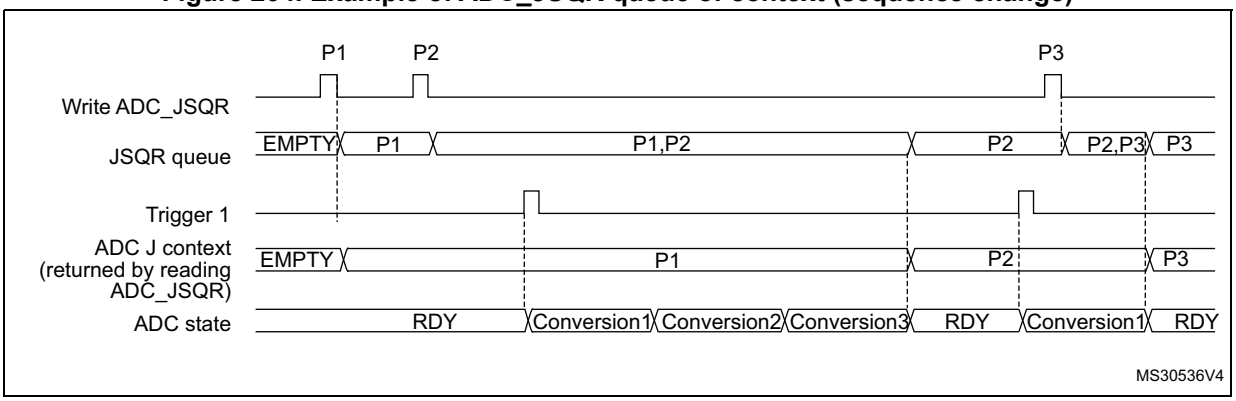
- Configuration of the injected triggers (bits JEXTEN[1:0] and JEXTSEL bits in the ADC_JSQR register)
- Definition of the injected sequence (bits JSQx[4:0] and JLEN[1:0] in the ADC_JSQR register)

All the parameters of the context are defined in a single register ADC_JSQR and this register implements a queue of two buffers, allowing the bufferization of up to two sets of parameters:

- The ADC_JSQR register can be written at any moment even when injected conversions are ongoing.
- Each data written to the ADC_JSQR register is stored into the queue of context.
- At the beginning, the queue is empty and the first write access to the ADC_JSQR register defines the first context and the ADC is ready to receive injected triggers if JADSTART = 1.
- Once an injected sequence is complete, the queue is consumed and the context changes according to the next ADC_JSQR parameters stored in the queue. This new context is applied for the next injected sequence of conversions.
- A queue overflow occurs when writing to the ADC_JSQR register while the queue is full. This overflow is signaled by the assertion of the flag JQOVF. When an overflow occurs, the write access of ADC_JSQR register which has created the overflow is ignored and the queue of context is unchanged. An interrupt can be generated if bit JQOVFIE is set.
- Two behaviors are possible when the queue becomes empty, depending on the value of the JQM control bit of the ADC_CFGR1 register:
  - If JQM = 0, the queue is empty just after enabling the ADC, but then it can never be empty during run operations: the queue always maintains the last active.
  - If JQM = 1, the queue becomes empty when end of injected sequence of last context occurs or if the queue is flushed by JADSTP = 1. When this occurs, there

is no more context in the queue and software needs to write new injected context in the ADC_JSQR register.

- Reading the ADC_JSQR register returns the current the ADC_JSQR context which is active at that moment. If JQM = 0, when the ADC_JSQR context is empty, the JSQi is read as 0x00.
- The queue is flushed when stopping injected conversions by setting JADSTP or when disabling the ADC by setting ADDIS:
  - If JQM = 0, the queue is flushed, but the last active context is maintained (ADC_JSQR register kept last value).
  - If JQM = 1, the queue becomes empty.



Note: When discontinuous mode (bit JDISCEN = 1) is configured, only JEOS, which marks the end of injected sequence, triggers the transfer of the queue to the active context (JSQR register). See example below (length = 3 for both contexts):

- *First trigger, discontinuous. Sequence 1: context 1, first conversion carried out.*
- *Second trigger, discontinuous. Sequence 1: context 1, second conversion carried out.*
- *Third trigger, discontinuous. Sequence 1: context 1, third conversion carried out. Then context change occurs to context 2.*
- *Fourth trigger, discontinuous. Sequence 2: context 2, first conversion carried out.*
- *Fifth trigger, discontinuous. Sequence 2: context 2, second conversion carried out.*
- *Sixth trigger, discontinuous. Sequence 2: context 2, third conversion carried out. Then context change occurs to next context.*

Behavior when changing the trigger or sequence context

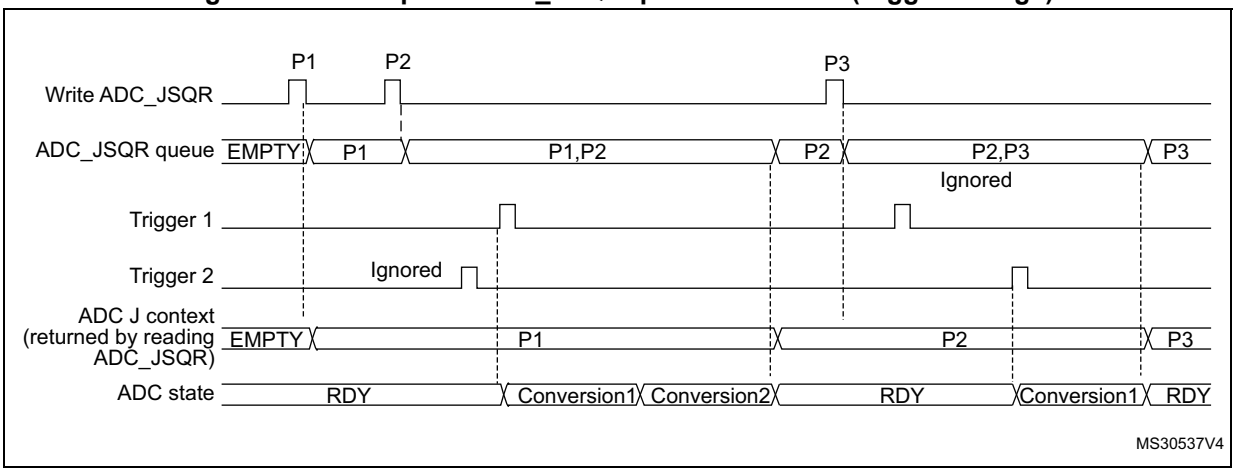


Figure 204 and *Figure 205* show the behavior of the context queue when changing the sequence or the triggers.

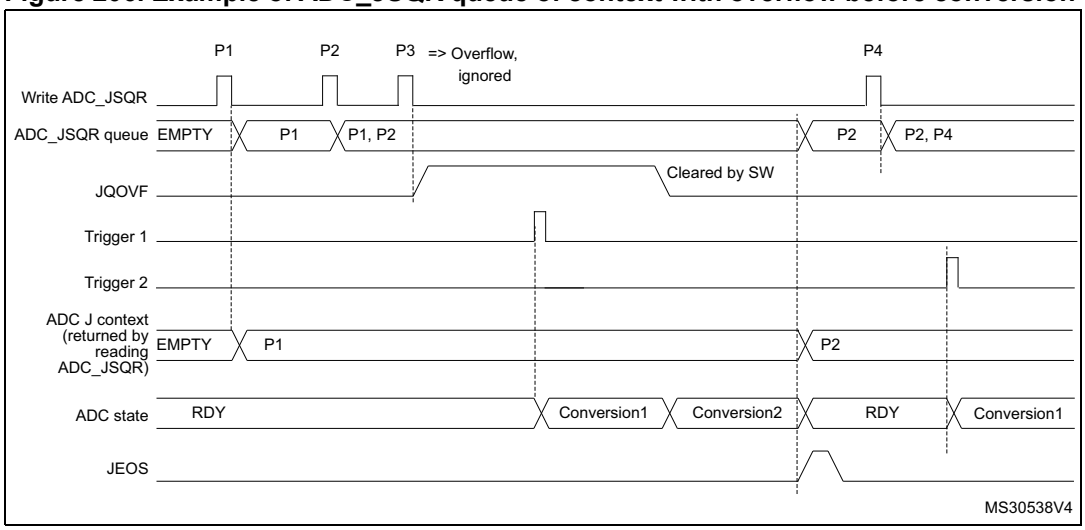
Figure 204. Example of ADC_JSQR queue of context (sequence change)

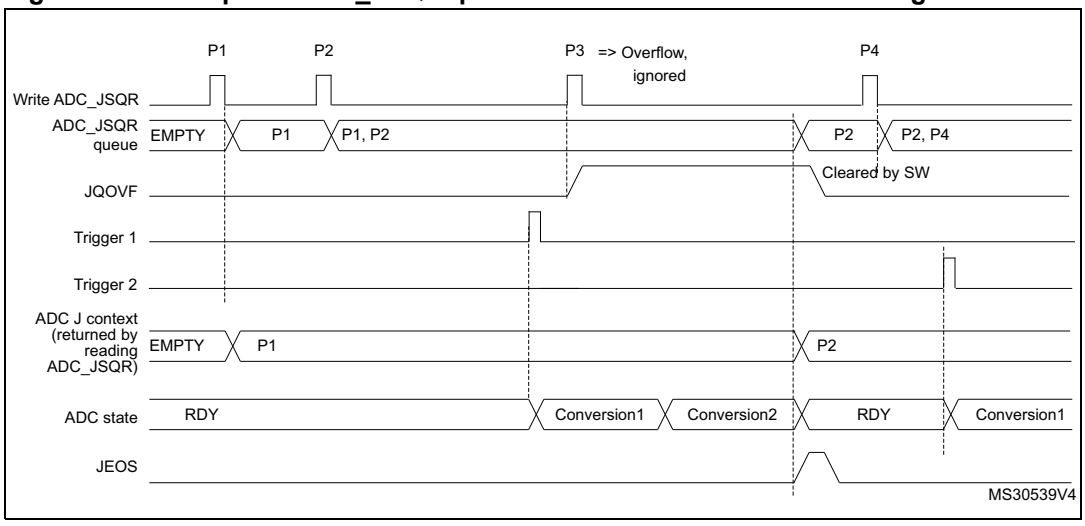
1. Parameters:
   P1: sequence of 3 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 4 conversions, hardware trigger 1

Figure 205. Example of ADC_JSQR queue of context (trigger change)



1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 4 conversions, hardware trigger 1

Queue of context: Behavior when a queue overflow occurs



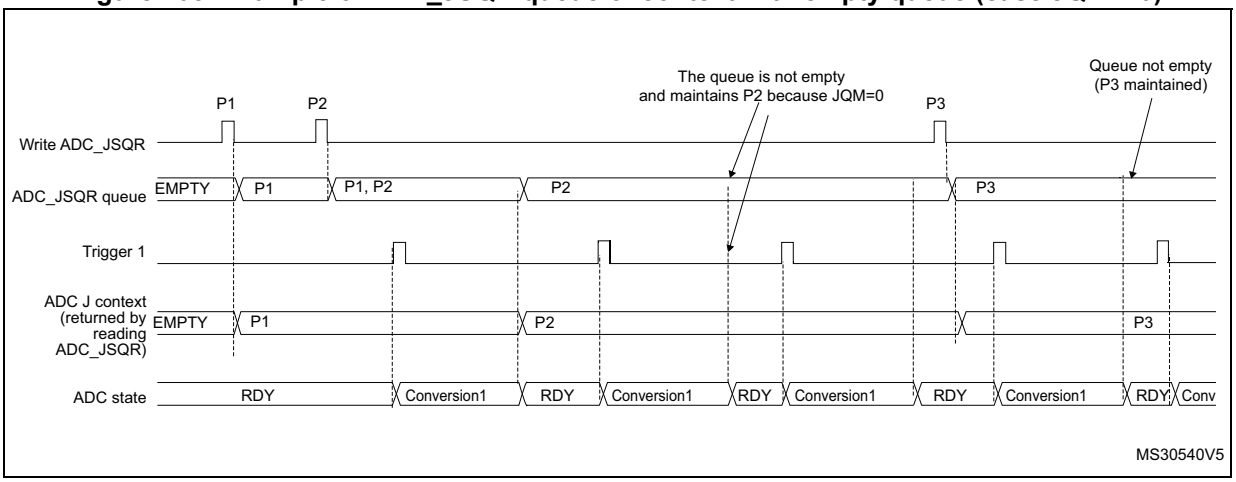
The *Figure 206* and *Figure 207* show the behavior of the context queue if an overflow occurs before or during a conversion.

Figure 206. Example of ADC_JSQR queue of context with overflow before conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1

Figure 207. Example of ADC_JSQR queue of context with overflow during conversion

1. Parameters:
   P1: sequence of 2 conversions, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 2
   P3: sequence of 3 conversions, hardware trigger 1
   P4: sequence of 4 conversions, hardware trigger 1



It is recommended to manage the queue overflows as described below:

- After each P context write to the ADC_JSQR register, the JQOVF flag shows if the write has been ignored or not (an interrupt can be generated).
- Avoid queue overflows by writing the third context (P3) only once the flag JEOS of P1 is generated, then the previous context P2 has been set. This ensures that the previous context has been consumed and that the queue is not full.

Queue of context: Behavior when the queue becomes empty

Figure 208 and *Figure 209* show the behavior of the context queue when the queue becomes empty in both cases JQM = 0 or 1.

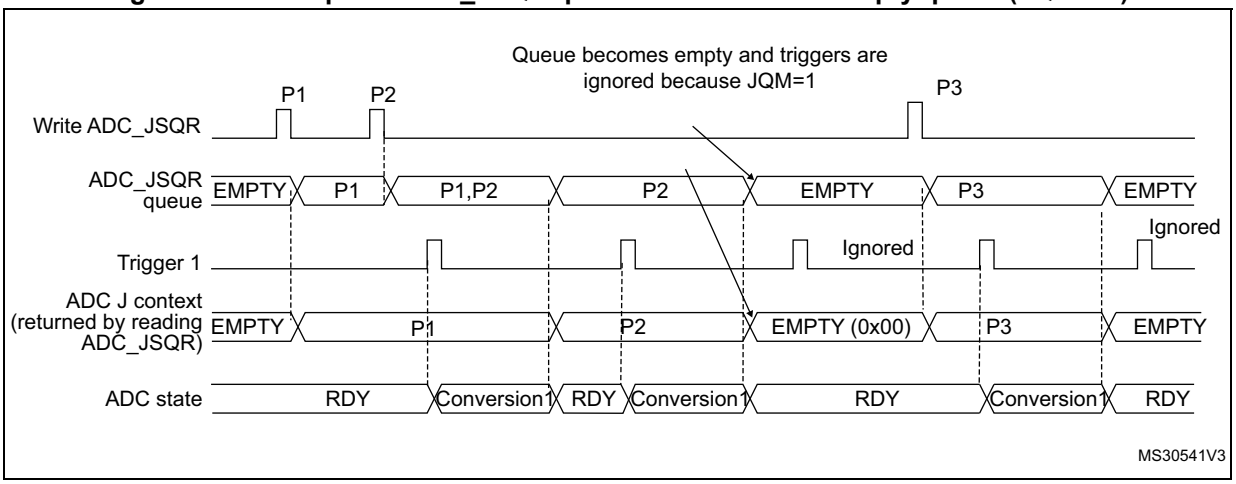


Figure 208. Example of ADC_JSQR queue of context with empty queue (case JQM = 0)

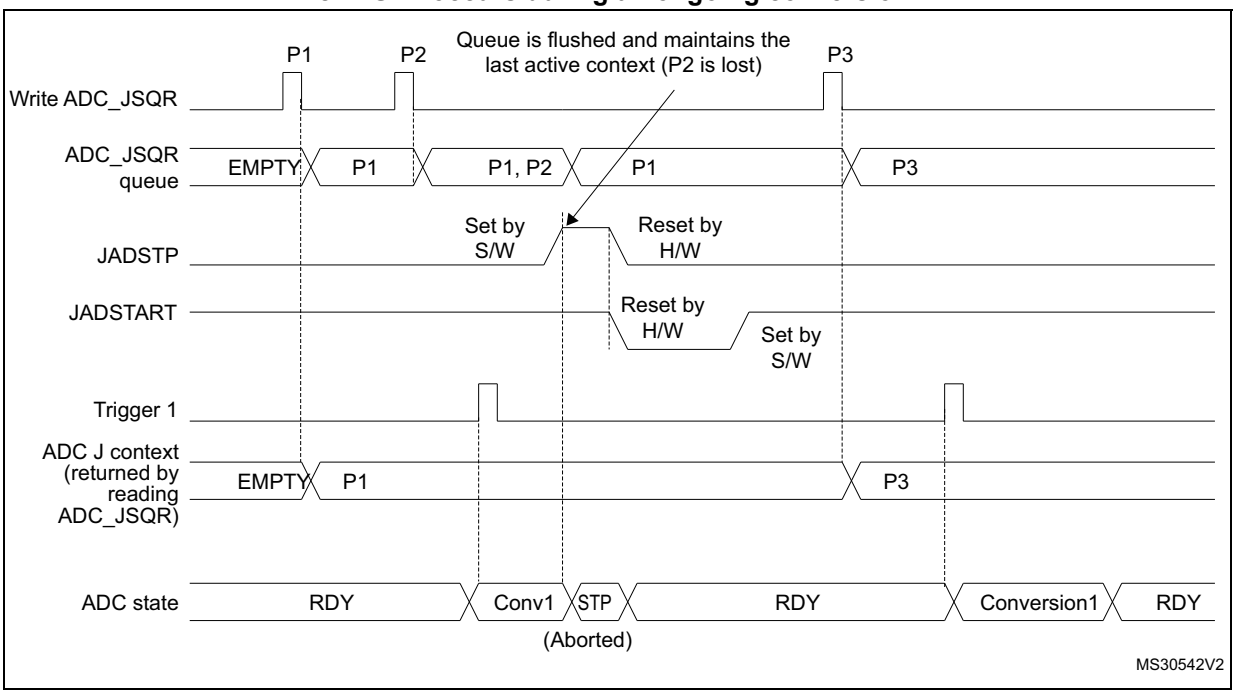
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

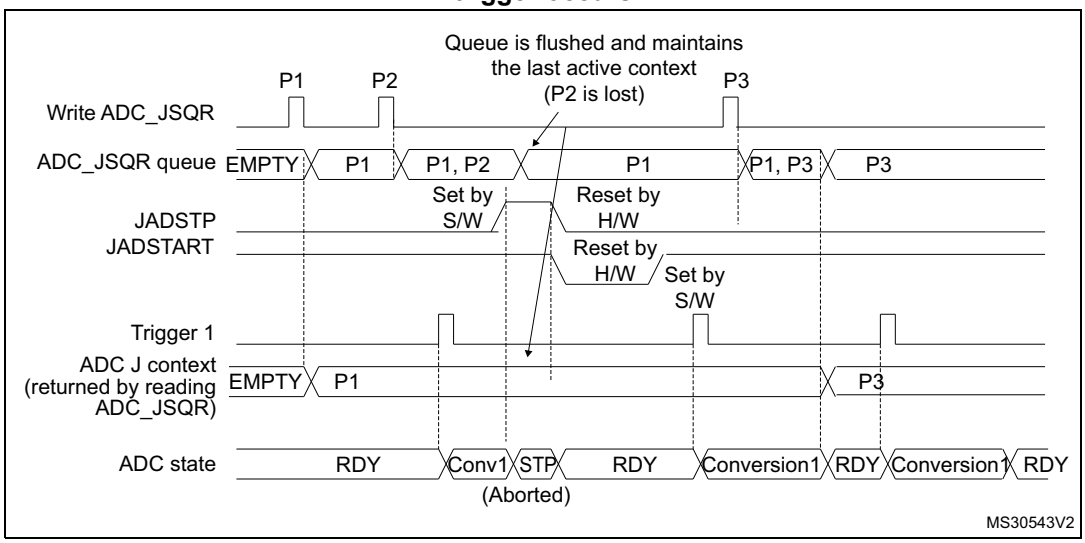
Note: When writing P3, the context changes immediately as the context of P2 is already converted (JEOS is generated). However, because of internal resynchronization, there is a latency and if a trigger occurs just after or before writing P3, it can happen that the conversion is launched considering the context P2. To avoid this situation, the user must ensure that there is no ADC trigger happening when writing a new context that applies immediately. It is recommended to program the new context before the JEOS timing, otherwise the previous context is used.

Figure 209. Example of ADC_JSQR queue of context with empty queue (JQM = 1)



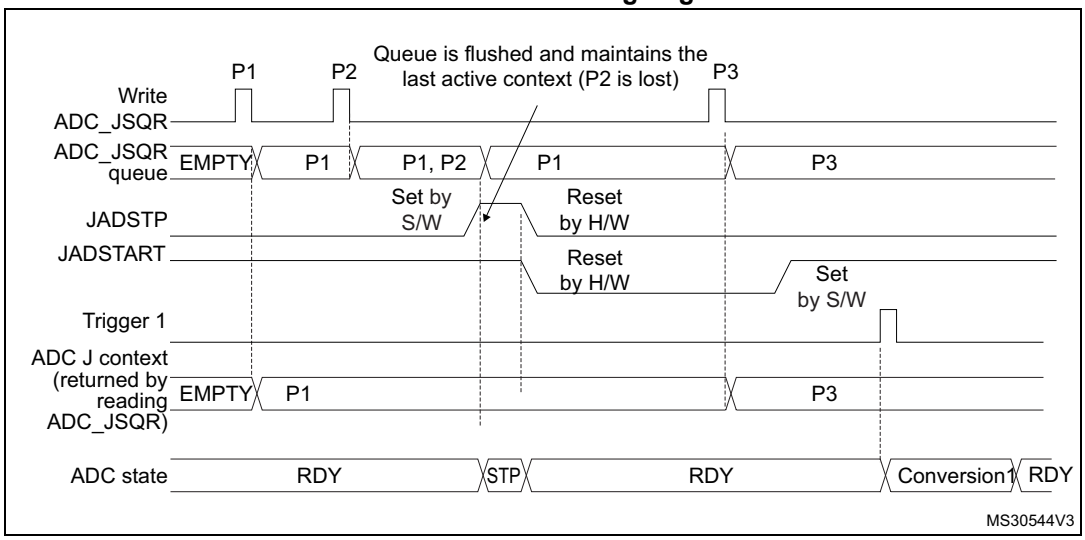
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Flushing the queue of context



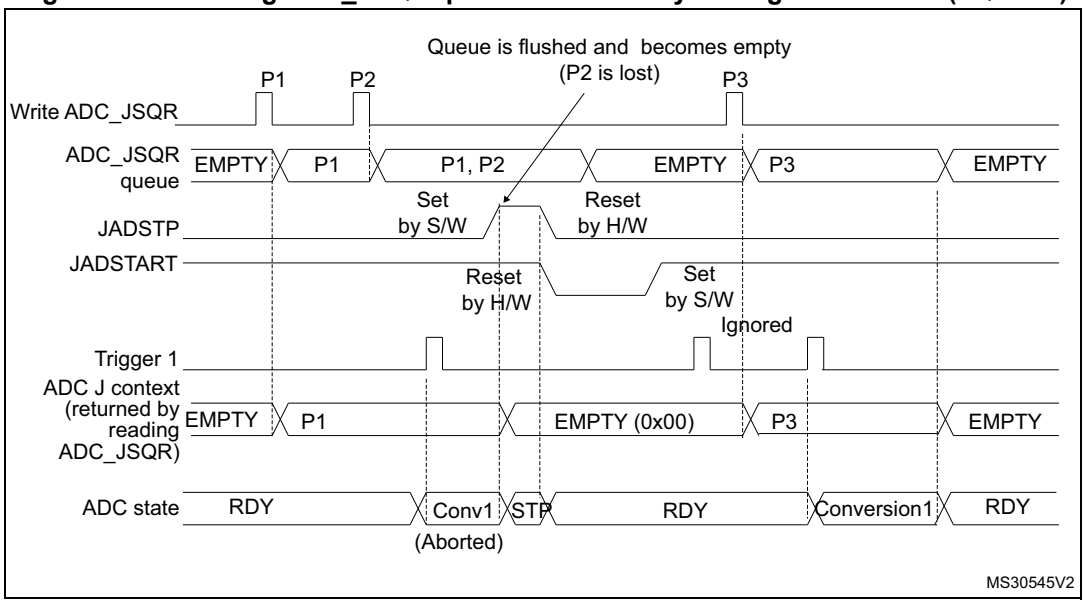
The figures below show the behavior of the context queue in various situations when the queue is flushed.

Figure 210. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion.



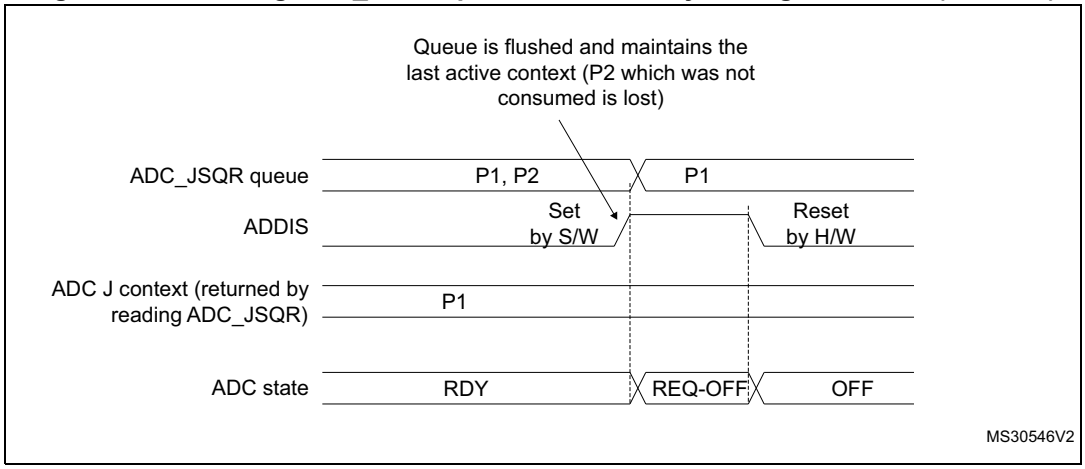
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 211. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs during an ongoing conversion and a new trigger occurs



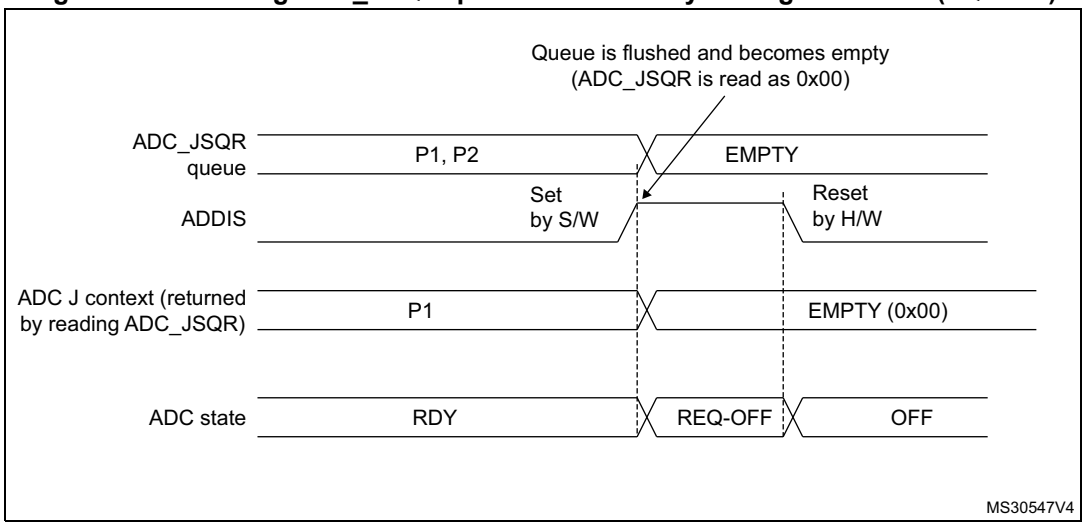
1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 212. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 0) - JADSTP occurs outside an ongoing conversion



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 213. Flushing ADC_JSQR queue of context by setting JADSTP = 1 (JQM = 1)



1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 214. Flushing ADC_JSQR queue of context by setting ADDIS = 1 (JQM = 0)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Figure 215. Flushing ADC_JSQR queue of context by setting ADDIS = 1 (JQM = 1)

1. Parameters:
   P1: sequence of 1 conversion, hardware trigger 1
   P2: sequence of 1 conversion, hardware trigger 1
   P3: sequence of 1 conversion, hardware trigger 1

Queue of context: Clear the context

- Setting JQDIS to 0 and then to 1 clears the context.
- Setting JADSTP to 0, writing a new context, and then setting JADSTART to 1 clears the previous context.

Disabling the queue

It is possible to disable the queue by setting the JQDIS bit of the ADC_CFGR1 register.

To clear the context queue, write 0 to JQDIS first, then write 1.

26.4.24 Programmable resolution (RES) - fast conversion mode

Faster conversions can be performed by reducing the ADC resolution.

The resolution can be configured to be either 12, 10, 8, or 6 bits by programming the RES[1:0] control bits. *Figure 220*, *Figure 221*, *Figure 222* and *Figure 223* show the conversion result format with respect to the resolution as well as to the data alignment.

Lower resolution allows faster conversion time for applications where high-data precision is not required. It reduces the conversion time spent by the successive approximation steps according to *Table 229*.

Table 229. T_{SAR} timings depending on resolution

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 32 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 2.5 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 32 MHz
12	13.5 ADC clock cycles	421.875 ns	16 ADC clock cycles	500.0 ns
10	11.5 ADC clock cycles	359.375 ns	14 ADC clock cycles	433.33 ns

Table 229. T_{SAR} timings depending on resolution (continued)

RES (bits)	T_{SAR} (ADC clock cycles)	T_{SAR} (ns) at $F_{adc_ker_ck}$ = 32 MHz	T_{CONV} (ADC clock cycles) (with Sampling time= 2.5 ADC clock cycles)	T_{CONV} (ns) at $F_{adc_ker_ck}$ = 32 MHz
8	9.5 ADC clock cycles	296.875 ns	12 ADC clock cycles	366.67 ns
6	7.5 ADC clock cycles	156.25 ns	10 ADC clock cycles	300 ns

26.4.25 End of conversion and end of sampling phase (EOC, JEOC, EOSMP)

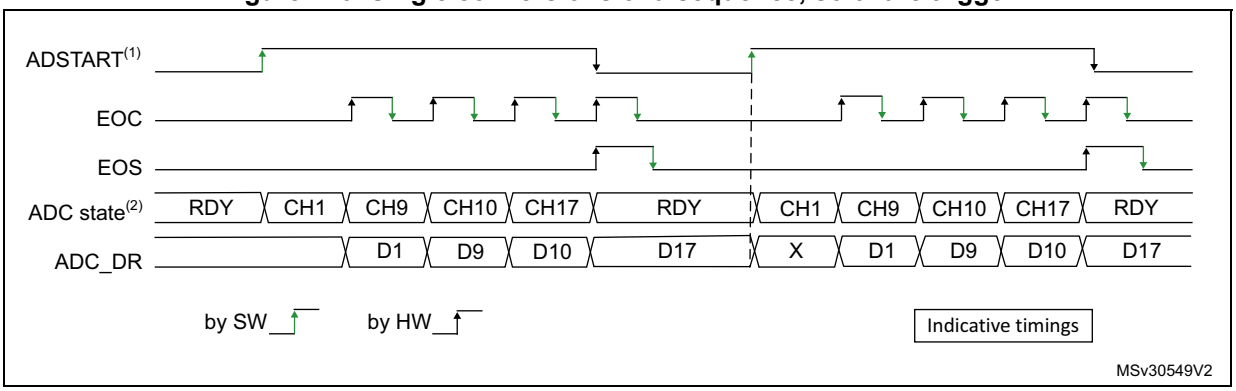
The ADC notifies the application at the end of each regular conversion (EOC) event and injected conversion (JEOC) event.

The ADC sets the EOC flag as soon as a new regular conversion data is available in the ADC_DR register. An interrupt can be generated if the EOCIE bit is set. The software can clear the EOC flag either by programming it to 1 or by reading ADC_DR. If ADC_DR FIFO is not emptied, the EOC flag is set again and an interrupt can be generated again.

The ADC sets the JEOC flag as soon as new injected conversion data is available in one of the ADC_JDRy registers. An interrupt can be generated if the JEOCIE bit is set. The software can clear the JEOC flag either by programming it to 1 or by reading the corresponding ADC_JDRy register.

The ADC also notifies the end of the sampling phase by setting the EOSMP flag (for regular conversions only). The EOSMP flag is cleared by software by programming it to 1. An interrupt can be generated if the EOSMPIE bit is set.

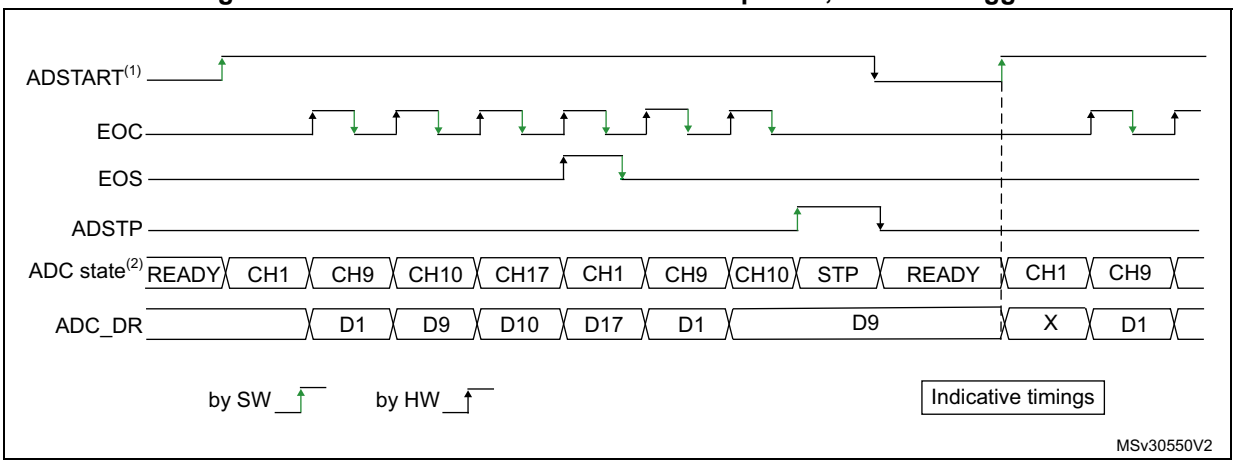
26.4.26 End of conversion sequence (EOS, JEOS)



The ADC notifies the application at the end of each regular sequence (EOS) and injected sequence (JEOS) event.

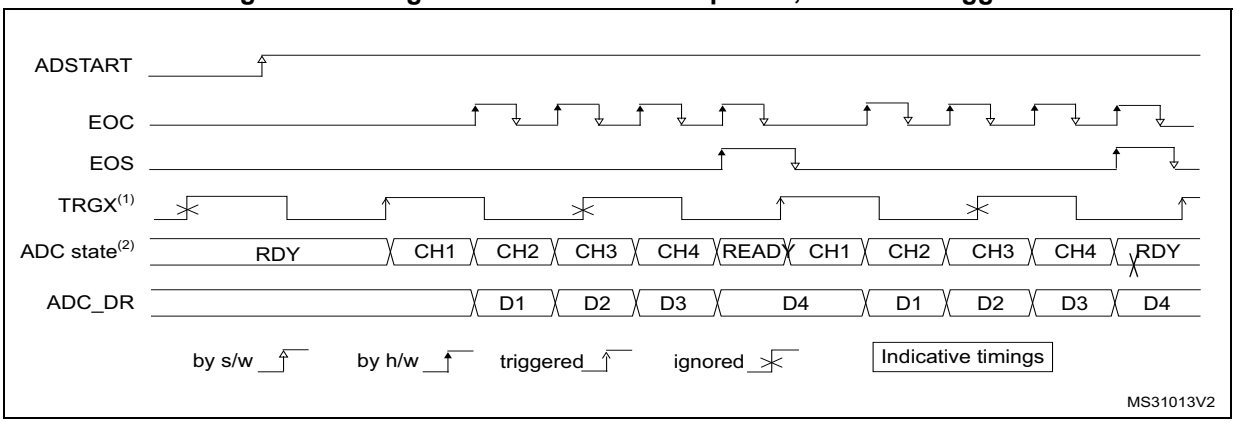
The ADC sets the EOS flag as soon as the conversion of the last data of the regular sequence is complete. An interrupt can be generated if the EOSIE bit is set. The EOS flag is cleared by the software by programming it to 1.

The ADC sets the JEOS flag as soon as the conversion of the last data of the injected sequence is complete. An interrupt can be generated if the JEOSIE bit is set. The JEOS flag is cleared by the software by programming it to 1.



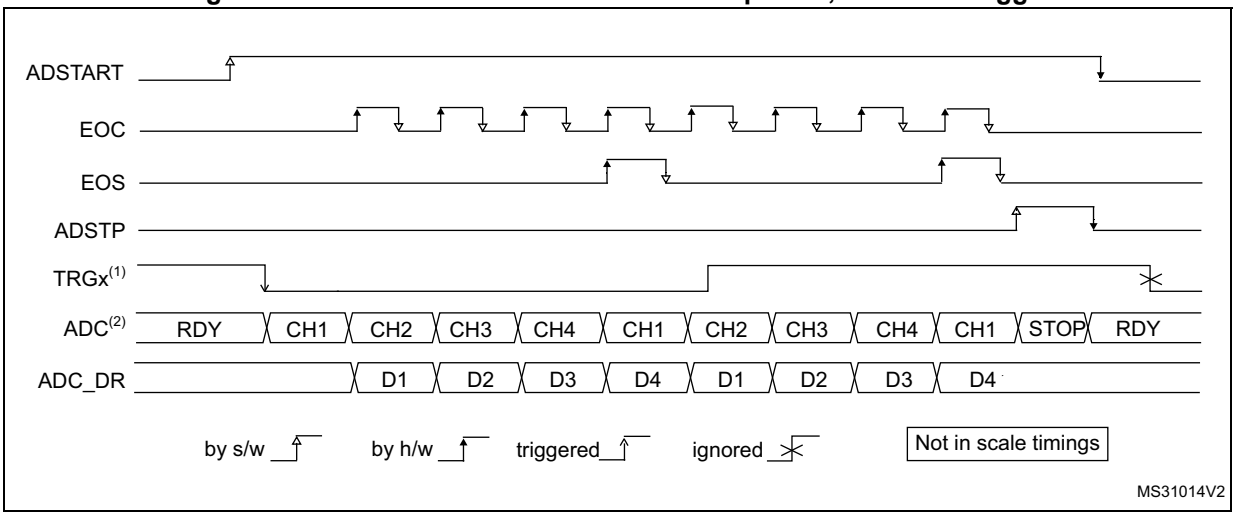
26.4.27 Timing diagram examples (single/continuous modes, hardware/software triggers)

Figure 216. Single conversions of a sequence, software trigger



1. EXTEN[1:0] = 00, CONT = 0
2. Channels selected = 1, 9, 10, 17; AUTDLY = 0.

Figure 217. Continuous conversion of a sequence, software trigger



1. EXTEN[1:0] = 00, CONT = 1
2. Channels selected = 1, 9, 10, 17; AUTDLY = 0.

Figure 218. Single conversions of a sequence, hardware trigger

1. TRGx (overfrequency) is selected as trigger source, EXTEN[1:0] = 01, CONT = 0
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

Figure 219. Continuous conversions of a sequence, hardware trigger

1. TRGx is selected as trigger source, EXTEN[1:0] = 10, CONT = 1.
2. Channels selected = 1, 2, 3, 4; AUTDLY = 0.

26.4.28 Data management

Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS[a], JLSHIFT[a], USAT, SSAT, POSOFF)

Data and alignment

At the end of each regular channel conversion (when an EOC event occurs), the result of the converted data is stored in the 32-bit wide ADC_DR data register with FIFO (when OVRMOD = 0). Since the data register has eight levels of FIFO, the EOC flag is raised again as far as the FIFO is not emptied.

At the end of each injected channel conversion (when a JEOC event occurs), the result of the converted data is stored in the 32-bit wide corresponding ADC_JDRy data register.

The OVSS[3:0], LSHIFT[3:0], JOVSS[3:0], and JLSHIFT[3:0] bitfields in the ADC_CFGR2 register select the alignment of the data stored after the conversion. By default, data are right-aligned. Refer to *Figure 220*, *Figure 221*, *Figure 222*, and *Figure 223* for examples of data alignment.

Note: The data can be aligned in normal and oversampling mode. The OVSS[3:0] bitfield is only effective in oversampling mode.

JOVSS[3:0] and JLSHIFT[3:0] is reserved for injected conversions. Their usage is the same as OVSS[3:0] and LSHIFT[3:0], unless otherwise specifically described.

Offset

An unsigned offset value y (y = 1, 2, 3, 4) can be applied to a channel by programming a value different from 0 in the OFFSET[21:0] bitfield of the ADC_OFRy register. The channel to which the offset is applied is programmed to the OFFSETy_CH[4:0] bits of ADC_OFCFGRy register. The offset can be positive or negative depending on the value of POSOFF bit. When POSOFF is cleared, the converted value is subtracted by the user-defined offset written in OFFSET[21:0] bits. The result can be a negative value. The read data is consequently signed and the SEXT bit represents the extended sign value.

The offset value must be lower than the maximum conversion value (for example the maximum offset value is 0xFFF in 12-bit mode).

The offset can be used to convert unsigned data to signed data (for example the offset value is equal to 0x800 in 12-bit mode).

The offset correction is also supported in oversampling mode. In this mode, the offset is subtracted when all the oversampling operations are complete.

Note: If the OFFSET channel is selected but the offset value is 0x0000, this offset programming is ignored. If the same OFFSET channel is programmed in different registers multiple times, the first programmed register takes priority.

Table 235 describes how the computation is performed for all the possible ADC resolutions and offset settings.

a. Only for products that include this bit.

Table 230. Offset computation versus data resolution

Resolution (RES[1:0] bits)	Subtraction between raw converted data and offset		Result	Comments
	Raw converted Data, left aligned	Offset		
00: 12-bit	DATA[11:0]	OFFSET[11:0]	Signed or unsigned 24-bit data, right aligned to [11:0]	-
01: 10-bit	DATA[11:2],00	OFFSET[11:2]	Signed or unsigned 24-bit data, right aligned to [9:0]	The user must configure OFFSET[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	OFFSET[11:4]	Signed or unsigned 24 bit data right aligned to [7:0]	The user must configure OFFSET[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	OFFSET[11:6]	Signed or unsigned 24 bit data right aligned to [5:0]	The user must configure OFFSET[5:0] to 0b000000.

Figure 220, *Figure 221*, *Figure 222* and *Figure 223* show alignments for signed and unsigned data. JOVSS and JLSHIFT are not described here, but they behave the same as OVSS and LSHIFT.

Figure 220. Right alignment (offset disabled, unsigned value)

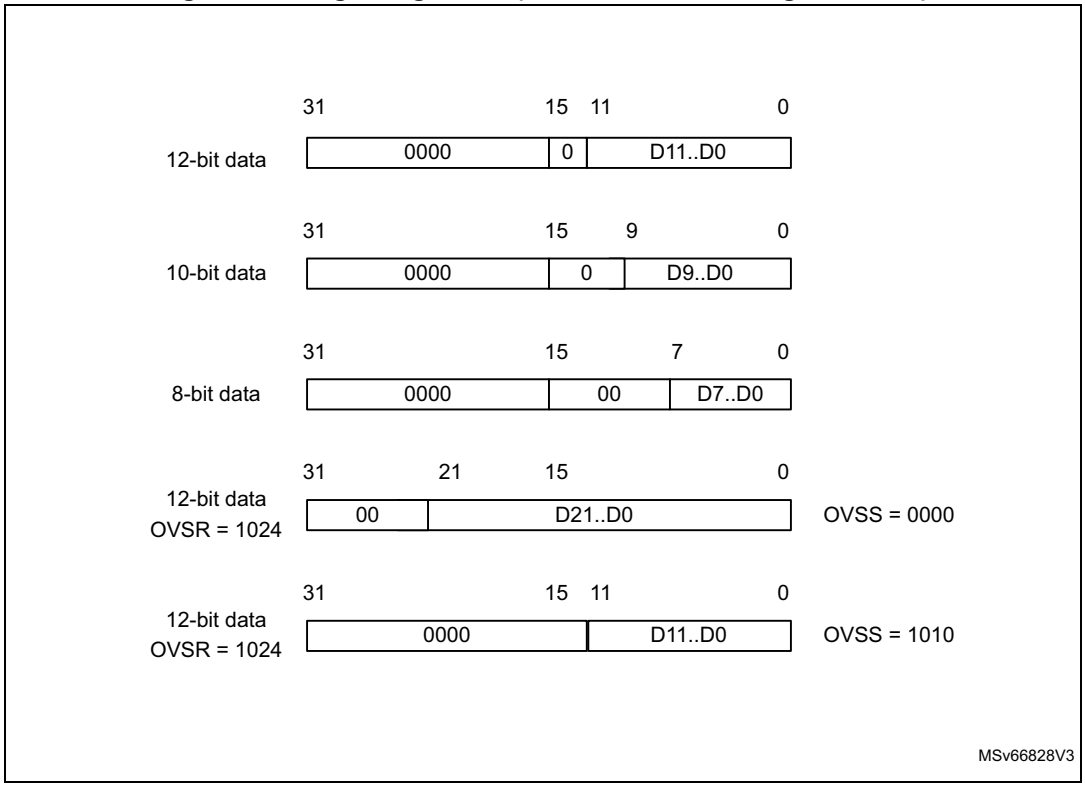


Figure 221. Right alignment (offset enabled, signed value)

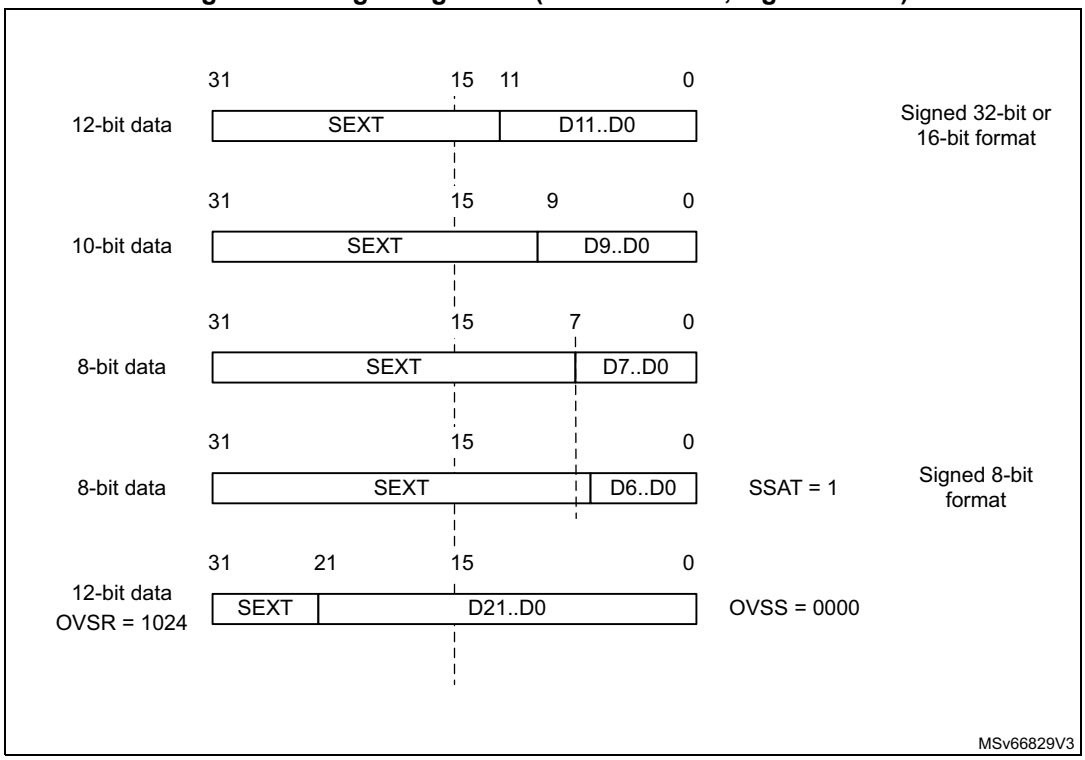

Figure 222. Left alignment (offset disabled, unsigned value)

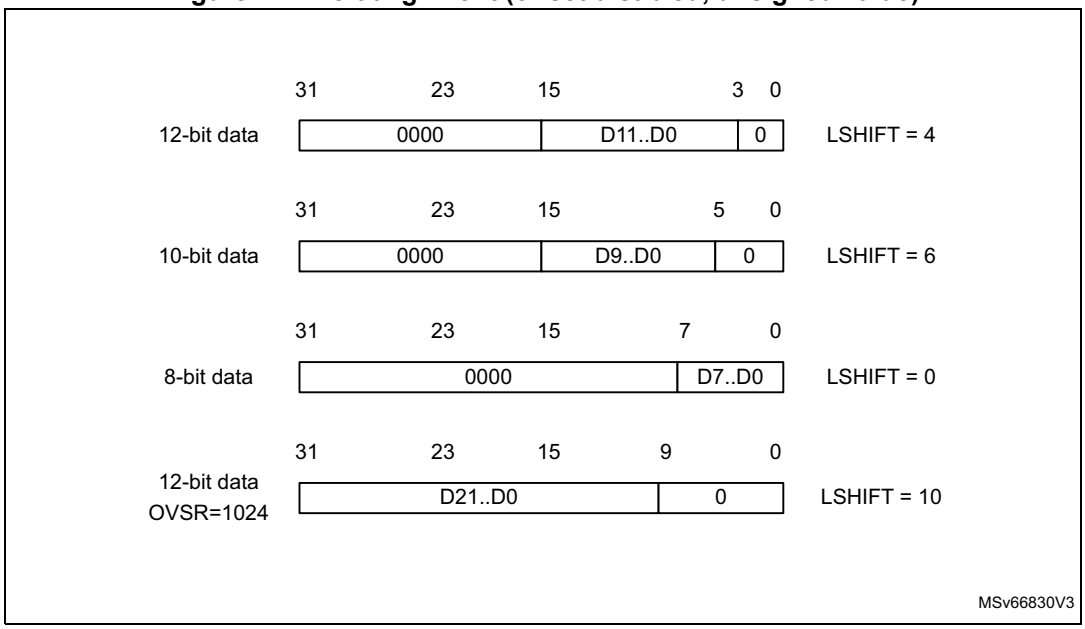

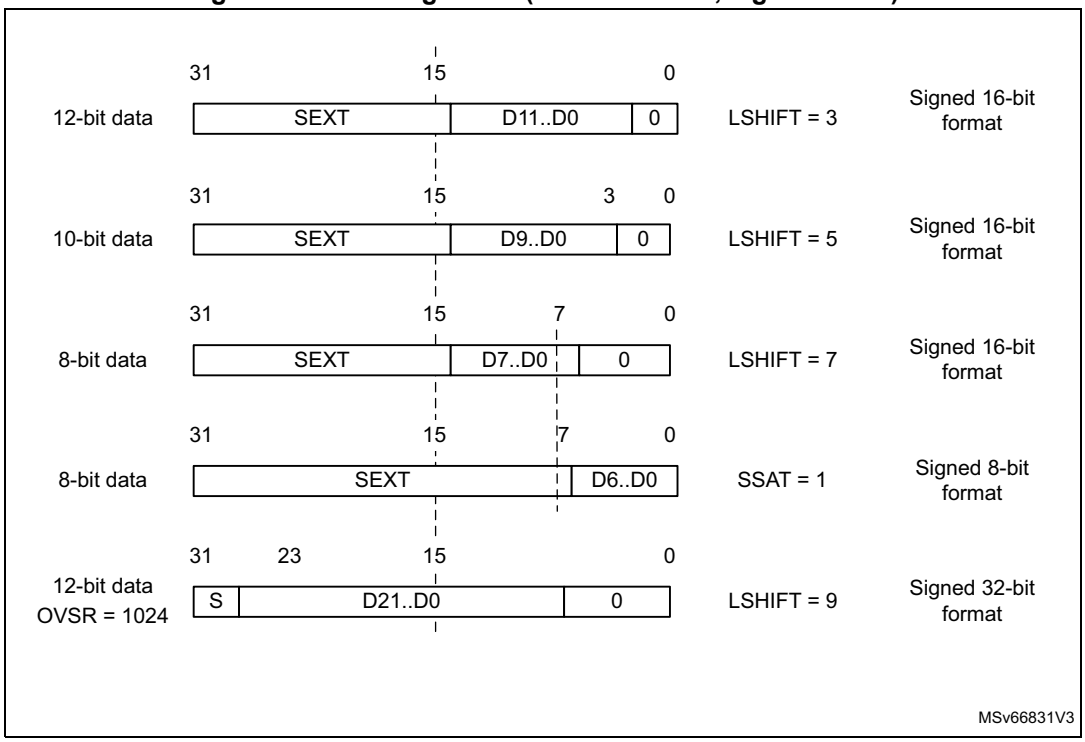

Figure 223. Left alignment (offset enabled, signed value)

Management of signed and unsigned saturation format (SSAT, USAT)

The offset correction might result in the data width to be wider than the original data.

To limit the original data width, the data saturation can be enabled through the SSAT and USAT bits of the ADC_OFCFGRy register.

Unsigned 12-bit data can be extended to 13-bit signed data by using an offset value different from 0x800.

The original data width can be preserved by setting SSAT bit to limit the data width to 12 bits.

Unsigned data can be saturated to the original data width by setting the USAT bit.

Table 231 shows the sign-extended data format corresponding to different resolutions.

Table 231.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	0	Sign-extended 13-bit significant data: SEXT[31:13] DATA[12:0]	0x0000 07FF - 0xFFFF F800
1	0	Sign-extended 12-bit significant data: SEXT[31:12] DATA[11:0]	0x7FF - 0x800

Table 231.12-bit data formats

SSAT	USAT	Format	Data range (offset =0x800)
0	1	Unsigned saturation 12-bit signification data: DATA[11:0]	0xFFF - 0x000
1	1	Reserved	-

Table 232 provides numerical examples for four different offset values.

Table 232. Numerical examples for 32-bit or 16-bit format (POSSPFF = 0)

Raw conversion result	Offset value	Result SSAT = 0 USAT = 0	Result SSAT = 0 USAT = 1	Result SSAT = 1 USAT = 0
0xFFF	0x800	0x0000 07FF	0x07FF	0x07FF
0x800		0x0000 0000	0x0000	0x0000
0x000		0xFFFF F800	0x0000	0xF800
0xFFF	0x820	0x0000 07DF	0x07DF	0x07DF
0x800		0xFFFF FFE0	0x0000	0xFFE0
0x000		0xFFFF F7E0	0x0000	0xF7E0
0xFFF	0x7E0	0x0000 081F	0x081F	0x07FF
0x800		0x0000 0020	0x0020	0x0020
0x000		0xFFFF F820	0x0000	0xF820
0xFFF	0x020	0x0000 0FDF	0x0FDF	0x0FDF
0x800		0x0000 07E0	0x07E0	0x07E0
0x000		0xFFFF FFE0	0x0000	0xFFE0

Caution: SSAT must not be used in conjunction with USAT. No hardware check is performed to ensure that this condition is respected.

Gain compensation

When the GCOMP bit is set in the ADC_GCOMP register, the gain compensation is activated on all the converted data. After each conversion, data is calculated using the following formula.

$$DATA = DATA(\text{adc result}) \times (GCOMPCOEFF) / 4096$$

As GCOMPCOEFF can be programmed from 0 to 16383, the actual gain compensation factor can range from 0 to 3.999756.

Before storing the resulting data in RDATAx or JDATAx bitfields, the LSB - 1 value is evaluated to round up the data and minimize the error.

The gain compensation is also effective for the oversampling. When the gain compensation is used in oversampling mode, the gain calculation is performed after the accumulation and

right-shift operations to minimize the power consumption (the gain calculation is done only once and not at each conversion).

The internal multiplier width is 32 bits and the input data width for the gain compensation must be less than 18 bits. When using oversampling with injected and regular conversion mode, the ROVSM bit of the ADC_CFGR2 register must be set to resume the pending conversion with the correct value.

When the gain compensation is activated, the ADC data latency is increased by one clock cycle. In continuous and scan conversion modes, the ADC conversion rate does not change.

ADC overrun (OVR, OVRMOD)

The overrun flag (OVR) issues a notification that the regular converted data has not been read (by the CPU or the DMA) before the ADC_DR FIFO (eight stages) is overflowed, or adc_hclk clock is too slow to manage the data. If the CPU clears the EOC flag without reading the data register, the OVR flag may still be triggered.

The OVR flag is set when a new conversion completes while ADC_DR as single register or FIFO output is full. An interrupt is generated if the OVRIE bit is set.

When an overrun condition occurs, the ADC is still operating and can continue converting unless the software decides to stop and reset the sequence by setting ADSTP. The OVR flag is cleared by software by programming it to 1.

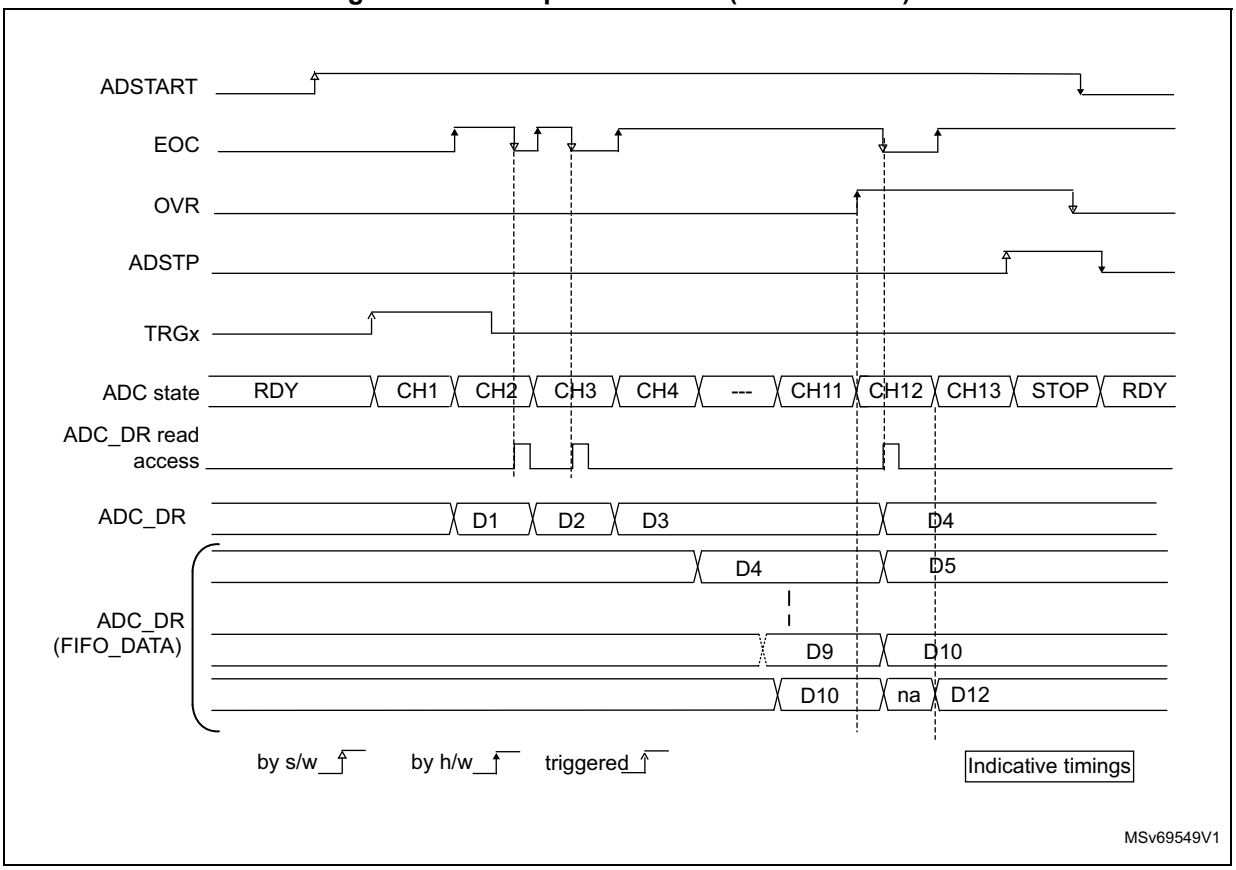
Data can be configured to be preserved or overwritten when an overrun event occurs by programming the control bit OVRMOD:

- OVRMOD = 0

  The overrun event preserves the data register from being overwritten: the old data are maintained up to ADC_DR FIFO depth (eight data) and the new conversion is discarded and lost. If OVR remains at 1, further conversions occur but the result data is also discarded. The FIFO can be emptied through ADC_DR read access by the CPU while the OVR flag is set.
- OVRMOD = 1

  The data register is overwritten with the last conversion result and the previous unread data is lost. In this mode, ADC_DR FIFO is disabled. If OVR remains at 1, any further conversion is performed normally and the ADC_DR register always contains the latest converted data. In this mode, DMA burst mode cannot be supported.

Figure 224. Example of overrun (OVRMOD = 0)



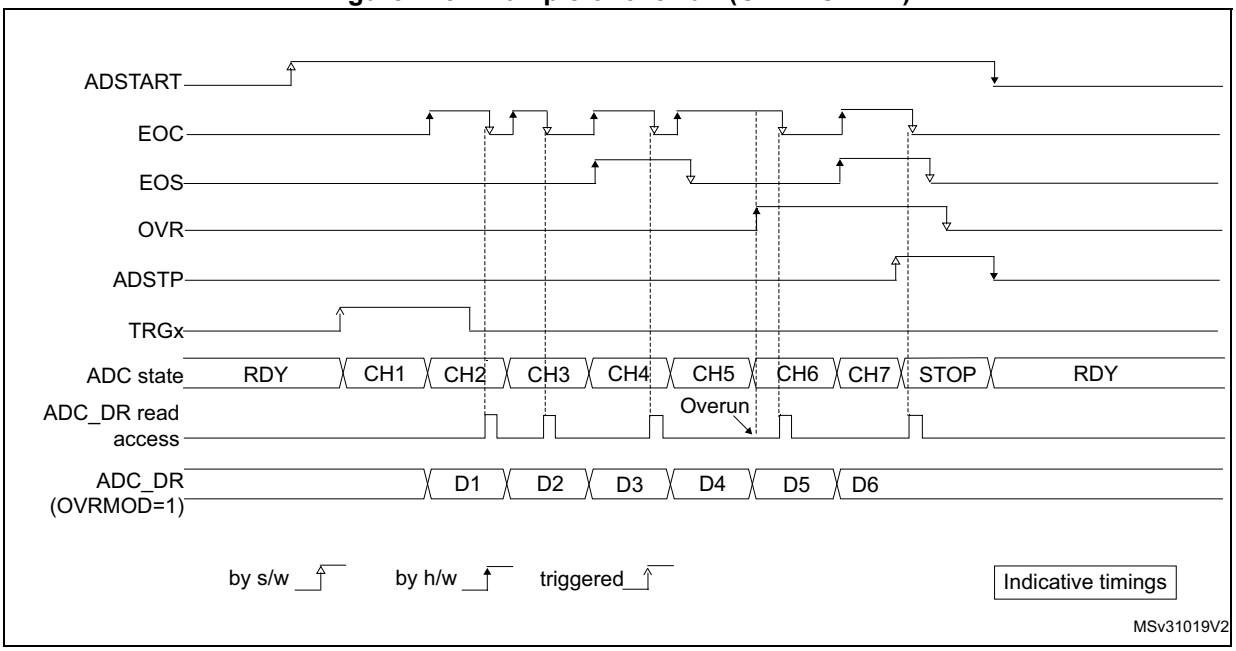


Figure 225. Example of overrun (OVRMOD = 1)

Note: Even if overrun may occur for injected channels, there is no overrun detection on these channels since there is a dedicated data register for each of the four injected channels.

Managing a sequence of conversions without using the DMA

If the conversions are slow enough, the conversion sequence can be handled by the software. In this case the software must use the EOC flag and its associated interrupt to handle each data. Each time a conversion is complete, EOC is set and the ADC_DR register can be read. OVRMOD must be configured to 0 to manage overrun events or FIFO overflow as errors.

Managing conversions without using the DMA and without overrun

It may be useful to let the ADC convert one or more channels without reading the data each time (if there is an analog watchdog for instance). In this case, the OVRMOD bit must be configured to 1 and the OVR flag must be ignored by the software. An overrun event does not prevent the ADC from continuing to convert and the ADC_DR register always contains the latest conversion.

Managing conversions using the DMA

When the DMA mode is enabled (DMNGT[1:0] = 01 or 11 in the ADC_CFGR1 register in single ADC mode), a DMA request is generated after each channel conversion. This allows the transfer of the converted data from the ADC_DR register to the destination location configured in the DMA.

Despite this, if an overrun occurs (OVR = 1) because the DMA cannot serve the DMA transfer request in time, the ADC stops generating DMA requests and the data corresponding to the new conversion is not transferred by the DMA, which means that all the data transferred to the RAM can be considered as valid. (OVRMOD = 0).

When OVRMOD = 1, even if DMA does not transfer the data immediately, new data overwrite ADC_DR, causing DMA to potentially skip data. As a result, some conversion results may be missed in the data transferred to RAM.

Depending on the configuration of the OVRMOD bit, the data are either preserved or overwritten (refer to *Section : ADC overrun (OVR, OVRMOD)*). If OVRMOD = 0 (data preserved), DMA transfer requests are blocked.

DMA can be configured through the DMNGT[1:0] bitfield of the ADC_CFGR1 register. Refer to *Section 26.4.33: Dual ADC modes* for information on DMA usage with dual ADC mode.

- DMA one-shot mode (DMNGT[1:0] = 01)

  This mode is suitable when the DMA is programmed to transfer a fixed number of data.
- DMA circular mode (DMNGT[1:0] = 11)

  This mode is suitable when programming the DMA when the number of transfers is unknown.

DMA one-shot mode (DMNGT[1:0] = 01)

In one-shot mode, the ADC generates a DMA transfer request each time a new conversion data is available and stops generating DMA requests once the DMA has reached the last DMA transfer (that is when DMA_LACK interrupt occurs, see *Direct-memory controller* section) even if a new conversion has been started.

When DMA transfers are complete (all the transfers configured in the DMA controller have been done):

- The content of the ADC data register is frozen.
- All ongoing conversions are aborted with the partial result discarded.
- The scan sequence is stopped and reset.
- The DMA and ADC are stopped.

DMA circular mode (DMNGT[1:0] = 11)

In circular mode, the ADC generates a DMA transfer request each time a new conversion data is available in the data register. This allows the configuration of the DMA in circular mode to handle a continuous analog input data stream.

DMA single-transfer or burst mode with FIFO (OVRMOD = 0)

The output data register features an eight-stage FIFO. Two different DMA requests are generated in parallel. When a data is available, an “SREQ single request” is generated. When four data are available, a “BREQ burst request” is generated. The DMA can be programmed either in single-transfer mode or in burst mode (four beats). The appropriate request line is selected by the DMA according to the mode selected. Refer to *Section Direct memory access controller* for further information.

Due to the existence of FIFO, DMA requests are generated until the FIFO is emptied. To stop DMA requests even when the FIFO is not emptied, set the ADSTP bit.

DMA for dual mode

Refer to *Section 26.4.33: Dual ADC modes*.

26.4.29 Dynamic low-power features

Autodelayed conversion mode (AUTDLY)

The ADC implements an autodelayed conversion mode controlled by the AUTDLY configuration bit in ADC_CFGR1. Autodelayed conversions are useful to simplify the software as well as to optimize performance of an application clocked at low frequency where there is a risk of encountering an ADC overrun.

Regular conversion mode

When AUTDLY is set, a new conversion can start if the following conditions are met:

- The ADC_DR register is read or the EOC bit is cleared (see *Figure 226*).

This is a way to automatically adapt the speed of the ADC to the speed of the system that reads the data and prevent overrun errors.

The delay is inserted after each regular conversion.

Injected conversion mode

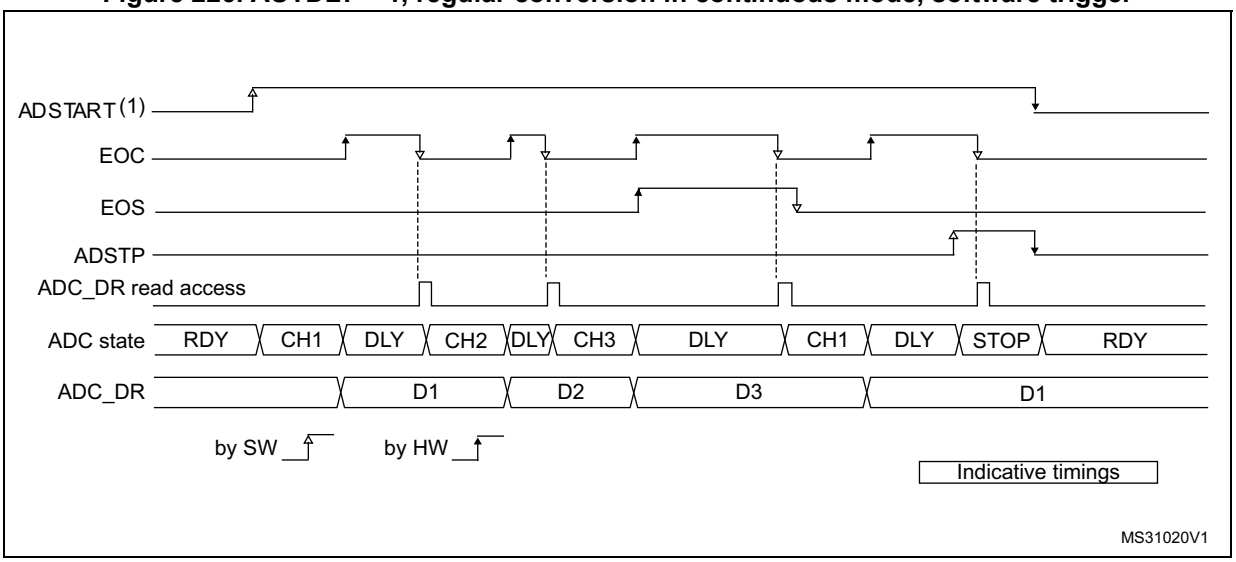
When AUTDLY is set, a new conversion can start only if the JEOS bit has been cleared (see *Figure 227*). Since there are four ADC_JDRy registers, the autodelay is performed at the end on the injected conversion sequence.

There is no delay inserted between each conversion of the injected sequence, except after the last one.

A hardware trigger event occurring during this delay is ignored.

No delay is inserted between regular and injected conversions. The autodelay for regular and injected modes is managed separately.

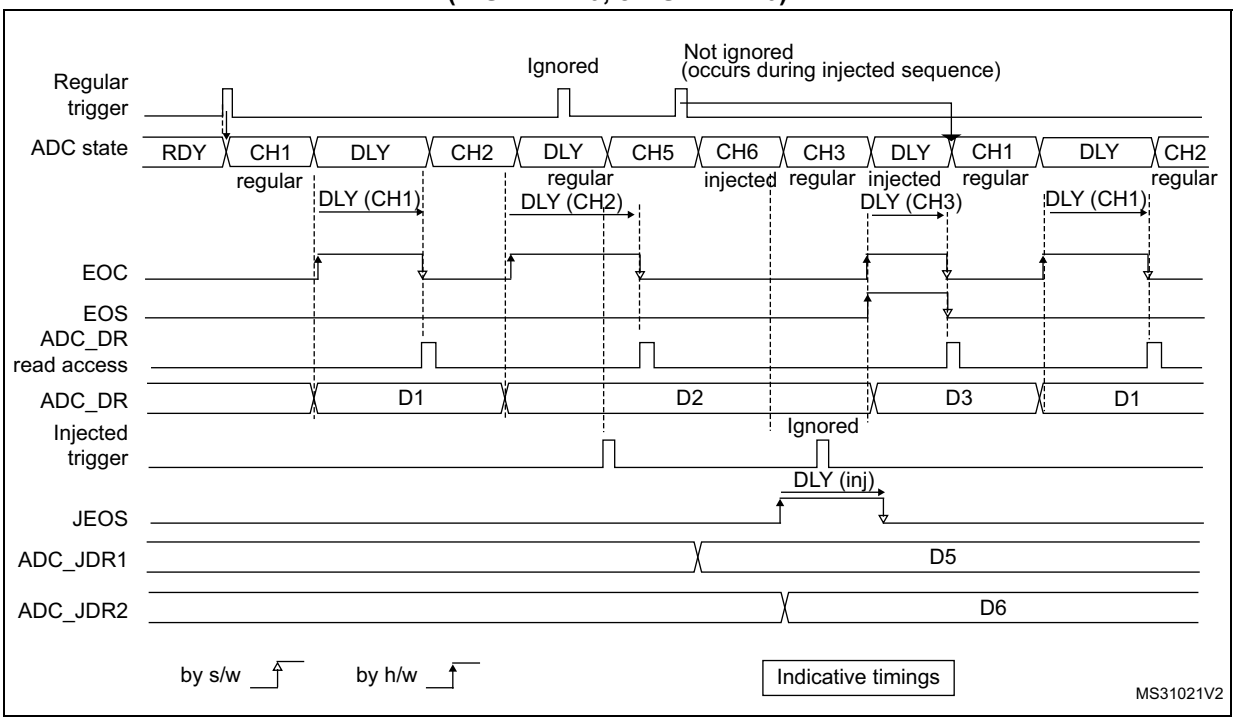
Caution: The behavior is slightly different in autoinjection mode (JAUTO = 1) where a new regular conversion can start only when the automatic delay of the previous injected sequence of conversion has ended (when JEOS has been cleared). This is to ensure that the software can read all the data of a given sequence before starting a new sequence (see *Figure 230*).



In autoinjection mode, there is no delay between the last regular conversion and the first injected conversion. The user must clear the last EOC flag before clearing the JEOS flag, otherwise the next sequence might start before EOC flag is cleared.

In autodelay mode, a hardware regular trigger event is ignored if it occurs during an already ongoing regular sequence or during the delay that follows the last regular conversion of the sequence. It is however considered pending if it occurs after this delay, even if it occurs during an injected sequence of the delay that follows it. The conversion then starts at the end of the delay of the injected sequence.

In autodelay mode with JAUTO = 0, a hardware injected trigger event is ignored if it occurs during an already ongoing injected sequence or during the delay that follows the last injected conversion of the sequence.



Note: AUTDLY mode is not supported with injected queue, SMPTRIG, or BULB mode.

26.4.30 Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT)

Table 233. Analog window watchdog features

Feature	AWD1	AWD2	AWD3
Enable control	AWD1EN or JAWD1EN	ADC_AWD2CR	ADC_AWD3CR
Channel selection	AWD1CH[4:0]/AWD1SGL	ADC_AWD2CR	ADC_AWD3CR
Channel selection limitation	One or all channels	Any number of channels	
	Regular or injected	-	-
Threshold control	ADC_AWD1LTR/ ADC_AWD1HTR	ADC_AWD2LTR/ ADC_AWD2HTR	ADC_AWD3LTR/ ADC_AWD3HTR
Filter configuration	AWDFILT[2:0] in ADC_AWDyHTR		
Interrupt	AWDy in ADC_ISR		

The three AWD analog watchdogs monitor whether some channels remain within a configured voltage range (window).

Figure 231. Analog watchdog guarded area

AWDy flag and interrupt

An interrupt can be enabled for each of the three analog watchdogs by setting AWDyIE in the ADC_IER register (y = 1, 2, 3).

AWDy (y = 1, 2, 3) flag is cleared by software by writing 1 to it, or by setting ADDIS.

The ADC conversion result is compared to the lower and higher thresholds before alignment.

AWD source channel register

The software can identify which ADC channel has generated the AWDy flag by reading the AWDS_CH[19:0] bitfield of the ADC_AWDySR register: AWDS_CH*i* bit is set to indicate that channel *i* has generated the flag. It is cleared by writing 1 to it or by disabling the ADC through setting the ADDIS bit.

Description of analog watchdog 1

The AWD analog watchdog 1 is enabled by setting the AWD1EN or JAWD1EN bit in the ADC_CFGR1 register. This watchdog monitors whether either one selected channel or all enabled channels remain within a configured voltage range (window).

Table 234 shows how the ADC_CFGR1 registers must be configured to enable the analog watchdog on one or more channels.

Table 234. Analog watchdog 1 channel selection

Channels guarded by the analog watchdog	AWD1SGL bit	AWD1EN bit	JAWD1EN bit
None	x	0	0
All injected channels	0	0	1
All regular channels	0	1	0
All regular and injected channels	0	1	1
Single(1) injected channel	1	0	1
Single(1) regular channel	1	1	0
Single(1) regular or injected channel	1	1	1

1. Selected by the AWD1CH[4:0] bits. The channels must also be programmed to be converted in the appropriate regular or injected sequence.

The AWD1 analog watchdog flag is set if the analog voltage converted by the ADC is below a lower threshold or above a higher threshold.

These thresholds are programmed through HTR[22:0] bits of the ADC_AWD1HTR register and LTR[22:0] bits of the ADC_AWD1LTR register for the analog watchdog 1.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024, offset and gain compensation)

When converting data with a resolution of less than 12 bits (defined by RES[1:0] bits), the LSB of the programmed thresholds must be kept cleared because the internal comparison is always performed on the full 12-bit raw converted data.

Table 235 describes how the comparison is performed for all the possible resolutions and for analog watchdog 1.

Table 235. Analog watchdog 1, 2, 3 comparison

Resolution (RES[1:0] bits)	Analog watchdog comparison between:		Comments
	Raw converted data, left aligned(1)	Thresholds	
00: 12-bit	DATA[11:0]	LTR[22:0] and HTR[22:0]	-
01: 10-bit	DATA[11:2],00	LTR[22:0] and HTR[22:0]	The user must configure LTR[1:0] to 0b00 and HTR[1:0] to 0b00.
10: 8-bit	DATA[11:4],0000	LTR[22:0] and HTR[22:0]	The user must configure LTR[3:0] to 0b0000 and HTR[3:0] to 0b0000.
11: 6-bit	DATA[11:6],000000	LTR[22:0] and HTR[22:0]	The user must configure LTR[5:0] to 0b000000 and HTR[5:0] to 0b000000.

1. Refer to *Section : Gain compensation* for additional details on analog watchdog comparison.

Description of analog watchdog 2 and 3

The second and third analog watchdogs are more flexible and can guard several selected channels by programming the corresponding bits in AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR).

The corresponding watchdog is enabled when any bit of AWDCH[19:0] (of ADC_AWD2CR and ADC_AWD3CR) is set.

The threshold can be up to 23 bits (12-bit resolution with oversampling, OVSR = 1024 and offset compensation in signed format with gain compensation) and is programmed through the ADC_AWD2HTR, ADC_AWD2LTR, ADC_AWD3HTR and ADC_AWD3LTR registers.

When converting data with a resolution of less than 12 bits (defined by RES[1:0]) bits), the LSBs of the programmed threshold must be kept cleared, the internal comparison being performed on the full 12-bits converted data (left aligned).

ADCx_AWDy_OUT signal output generation

Each analog watchdog is associated with an internal hardware signal ADC_AWDy_OUT (*y* being the watchdog number), which is directly connected to the ETR input (external trigger) of some of the on-chip timers. Refer to the on-chip timers sections to understand how to select the ADC_AWDy_OUT signal as ETR.

ADC_AWDy_OUT is activated when the associated analog watchdog is enabled:

- ADC_AWDy_OUT is set when a guarded conversion is outside the programmed thresholds.
- ADC_AWDy_OUT is reset after the end of the next guarded conversion that is inside the programmed thresholds (It remains at 1 if the next guarded conversions are still outside the programmed thresholds).
- ADC_AWDy_OUT is also reset when disabling the ADC (when setting ADDIS). Note that stopping regular or injected conversions (by setting ADSTP or JADSTP) has no influence on the generation of ADCx_AWDy_OUT.

Note: The AWDy flag is set by hardware and reset by software: the AWDy flag has no influence on the generation of ADC_AWDy_OUT (ex: ADC_AWDy_OUT can toggle while the AWDy flag remains at 1 if the software did not clear the flag).

The AWDy flag is cleared by programming it to 1 or by set ADDIS bit. ADSTP and JADSTP bits do not reset the AWDy flag.

Figure 232. ADC_AWDy_OUT signal generation (on all regular channels)

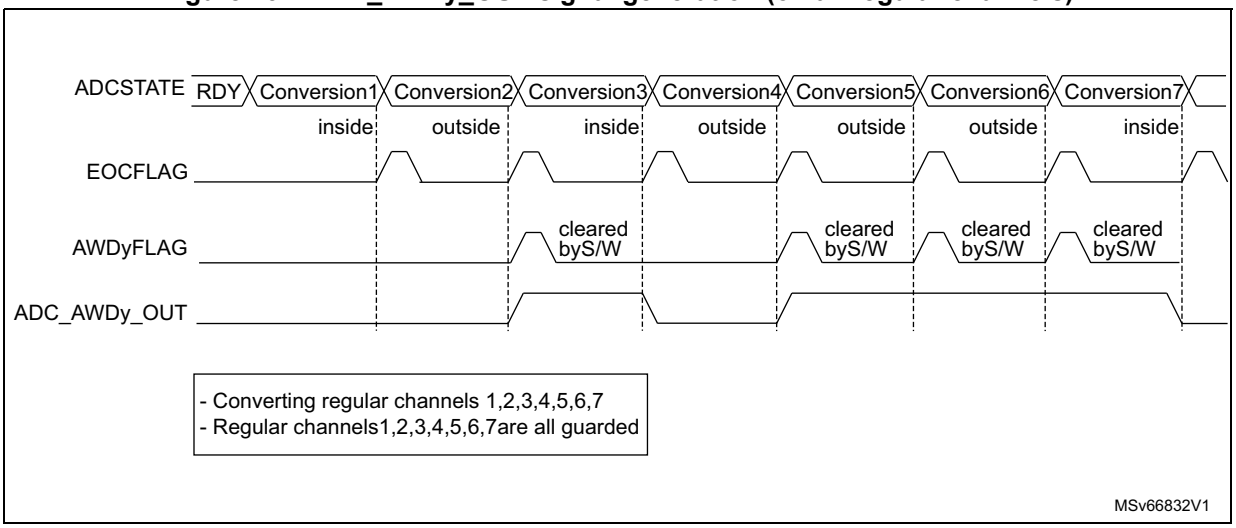

Figure 233. ADC_AWDy_OUT signal generation (AWDy flag not cleared by software)

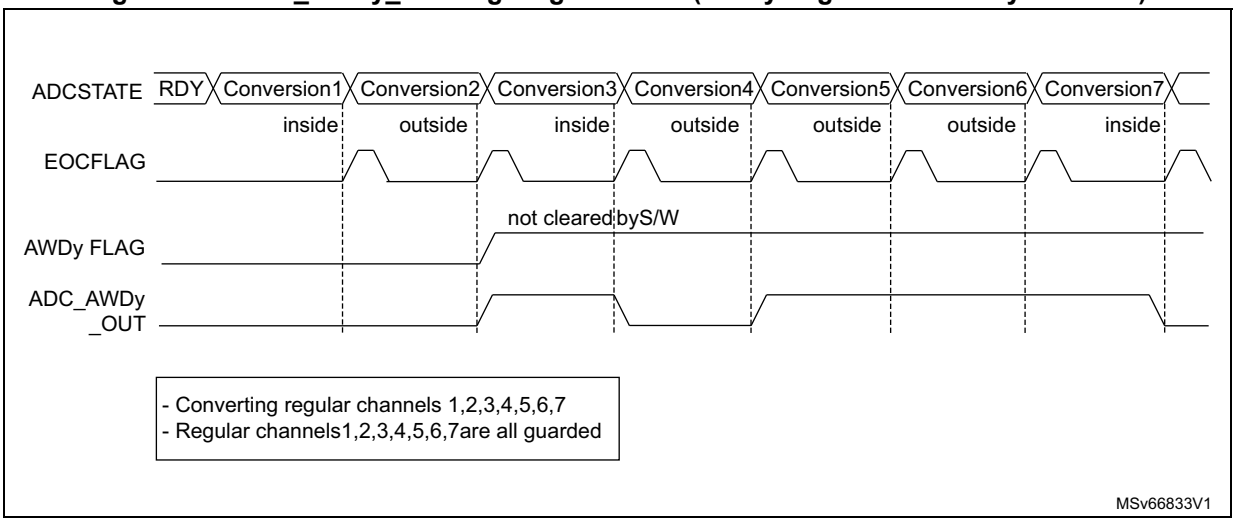

Figure 234. ADC_AWDy_OUT signal generation (on a single regular channel)

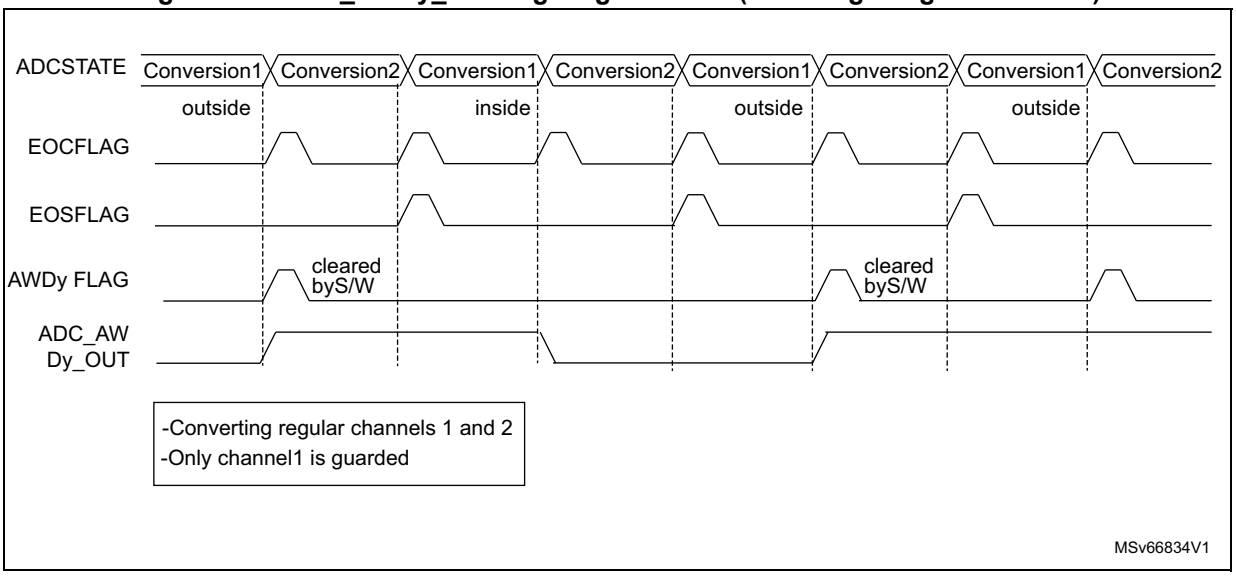

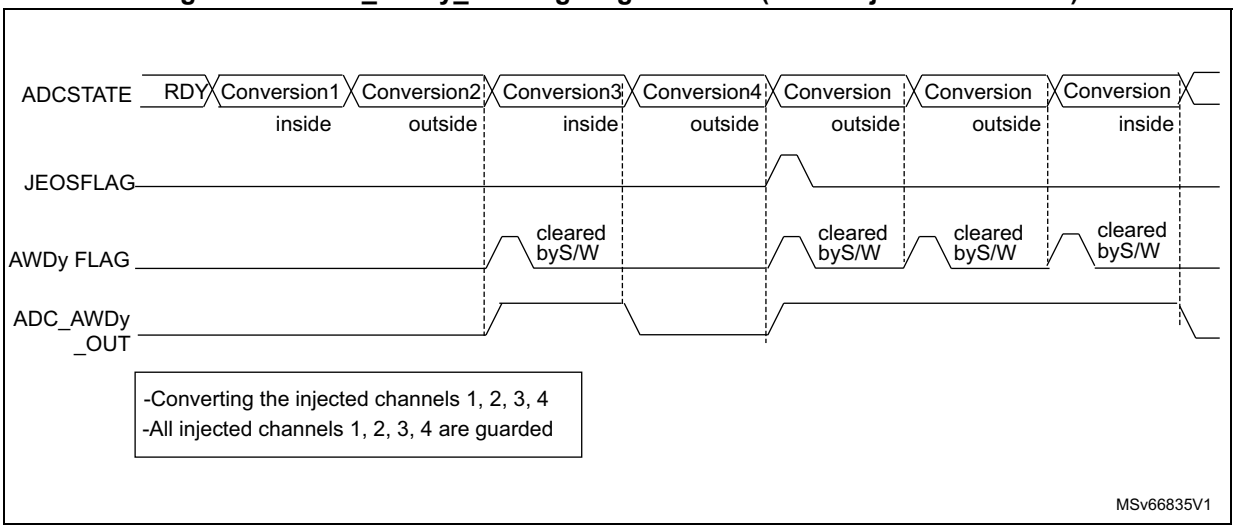

Figure 235. ADC_AWDy_OUT signal generation (on all injected channels)

Analog watchdog threshold control on the fly

LTR[22:0] and HTR[22:0] can be changed when an analog-to-digital conversion is ongoing (that is between the start of conversion and the end of conversion of the ADC internal state). If LTR[22:0] and HTR[22:0] are updated during the ADC conversion of the ADC guarded channel, resulting in analog watchdog thresholds to be applied from the next ADC conversion. The analog watchdog comparison is performed at each end of conversion. If the current ADC data is out of the new modified threshold, no interrupt and AWDy_OUT signal are issued. The Interrupt and the AWD generation only happen at the end of the conversion that started after the threshold update. If AWDy_OUT is already asserted, programming the new thresholds does not deassert the AWDy_OUT signal. However, the watchdog threshold must not be changed twice during the four adc_ker_ck periods.

Analog watchdog filter

With analog watchdog, a valid ADC conversion data range can be configured through the ADC_AWDxLTR and ADC_AWDxHTR registers. When the conversion results have consecutively passed the threshold for more than the watchdog filter value (AWDFILT[2:0] + 1), AWDx_OUT is generated as well as the AWDx flag. Before this value is reached, AWDx output is not activated. The analog watchdog filter can be used only when a single channel is selected for an AWD.

Analog watchdog with gain and offset compensation

When the gain and offset compensation are enabled, the analog watchdog compares the data after the compensation.

26.4.31 Oversampler

The oversampling unit performs data preprocessing to offload the device. It is able to handle multiple conversions and average them into a single data with increased data width, up to 22 bits.

It provides a result with the following form, where N and M can be adjusted:

$$\text{Result} = \frac{1}{M} \times \sum_{n=0}^{n=N-1} \text{Conversion}(t_n)$$

It enables the following functions to be performed by hardware: averaging, data rate reduction, SNR improvement and basic filtering.

The oversampling ratio N is defined by the OVSR[9:0] bits in the ADC_CFGR2 register for regular conversion, or by the JOVSR[3:0] bits in the ADC_CFGR3 register for injected conversion. They can range from 2x to 1024x. The division coefficient *M* consists of a right bit shift up to 10 bits. It is defined through the OVSS[3:0] bits of the ADC_CFGR2 register, for regular conversion or JOVSS[3:0] bits of the ADC_CFGR3 for injected conversion.

The summation unit can yield a result up to 22 bits, which can be left or right shifted at the end. When the right shift is selected, it is rounded to the nearest value using the least significant bits left apart by the shifting, before being finally transferred to the ADC_DR data register.

In this section, OVSS, LSHIFT, and OVSR are used to explain the functionality; however, the same descriptions also apply to JOVSS, JLSHIFT, and JOVSR for injected conversions.

Figure 236 gives a numerical example of the processing, from a raw 22-bit accumulated data to the final 12-bit result.

Figure 236. 12-bit result oversampling with 10-bit right shift and rounding

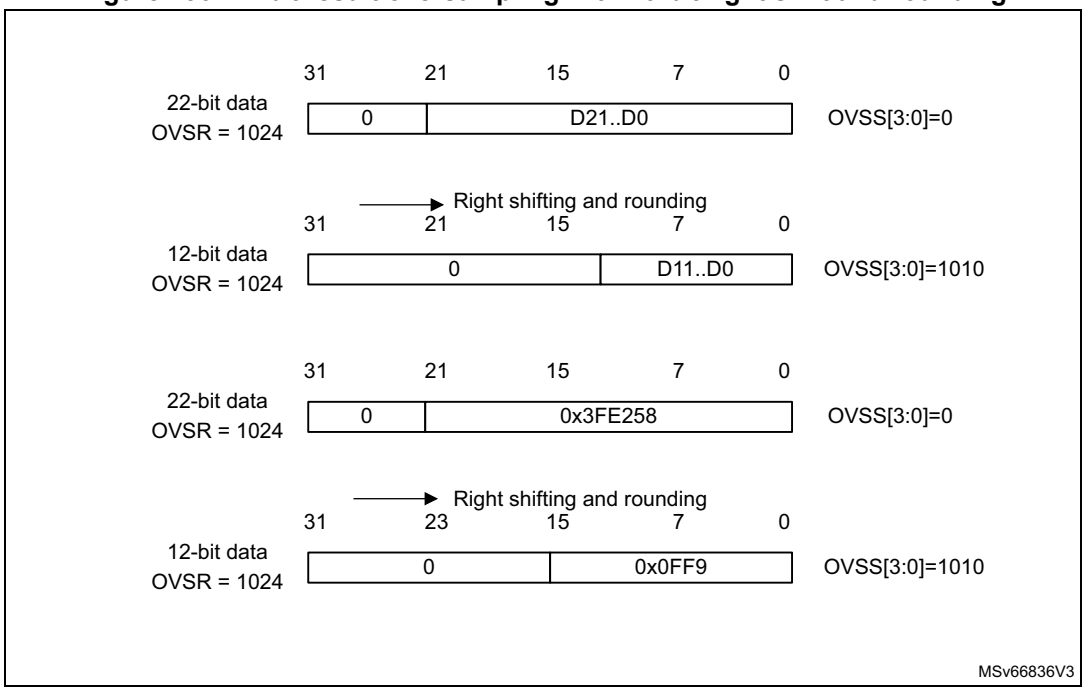

Table 224 gives data format for the various N and M combinations, for a raw conversion data equal to 0xFFF.

Table 236. Maximum output results versus N and M

Over sampling ratio	Max Raw data	No-shift OVSS = 0000	1-bit shift OVSS = 0001	2-bit shift OVSS = 0010	3-bit shift OVSS = 0011	4-bit shift OVSS = 0100	5-bit shift OVSS = 0101	6-bit shift OVSS = 0110	7-bit shift OVSS =0111	8-bit shift OVSS = 1000
x2	0x1FFE	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040	0x0020
x4	0x3FFC	0x3FFC	x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100	0x0080	0x0040
x16	0xFFF0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400	0x0200	0x0100
x64	0x3FFC0	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF	0x0800	0x0400
x256	0xFFF00	0xFFF00	0x7FF80	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC	0x1FFE	0x0FFF
x1024	0x3FFC00	0x3FFC00	0x1FFE00	0xFFF00	0x7FF80	0x3FFC0	0x1FFE0	0xFFF0	0x7FF8	0x3FFC

The conversion timing rate does not change in oversampling mode: the sample time is maintained equal during the whole oversampling sequence. A new data is provided every N conversion, with an equivalent delay equal to N x T_{CONV} = N x (t_{SMPL} + t_{SAR}). The flags are set as follows:

- The end of the sampling phase (EOSMP) is set after each sampling phase for regular conversion.
- The end of conversion (EOC) occurs once every N conversion, when the oversampled result is available.
- The end of sequence (EOS) occurs once the sequence of oversampled data is completed (that is after a total of N x sequence length conversions).

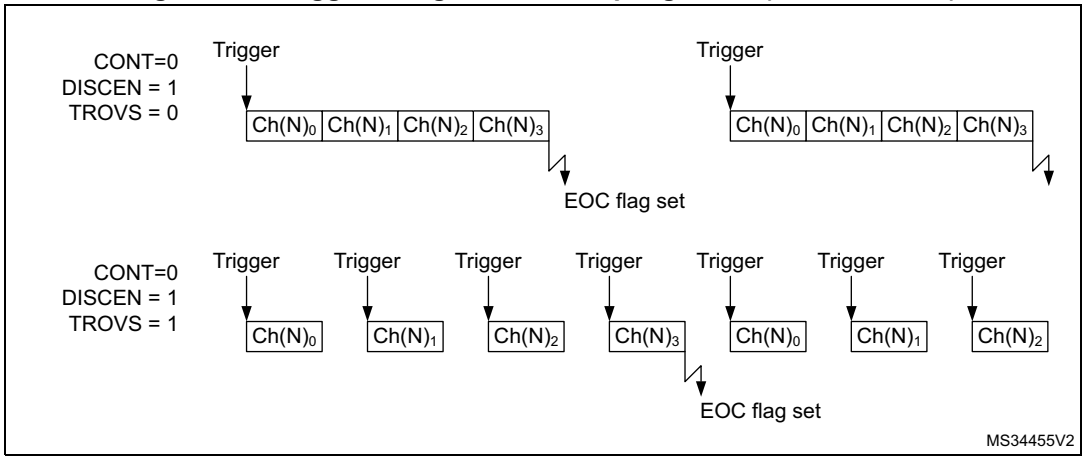
Unlike the conversion rate, the data latency changes in oversampling mode: each single conversion introduces an additional accumulation. As a result, an additional clock cycle is required when all the conversions are complete, after the accumulation and shift.
The EOC flag is set two additional clock cycles after the conversion is complete.

Analog watchdog

The analog watchdog functionality is maintained, with the following differences:

- The RES[1:0] bits are ignored and the comparison is always done using the full 23-bit values HTR[22:0] and LTR[22:0].
- The comparison is performed on the oversampled accumulated value before shifting.

Triggered mode



The oversampling can also be used for basic filtering purpose. Although it not a very powerful filter (slow roll-off and limited stop band attenuation), it can act as a notch filter to reject constant parasitic frequencies (typically coming from the mains or from a switched-mode power supply). For this purpose, a specific discontinuous mode can be enabled through the TROVS bit in ADC_CFGR2, to be able to achieve an oversampling frequency defined by the user and independent from the conversion time itself. The TROVS bit is supported with hardware trigger mode.

Figure 237 shows how conversions are started in response to triggers during discontinuous mode.

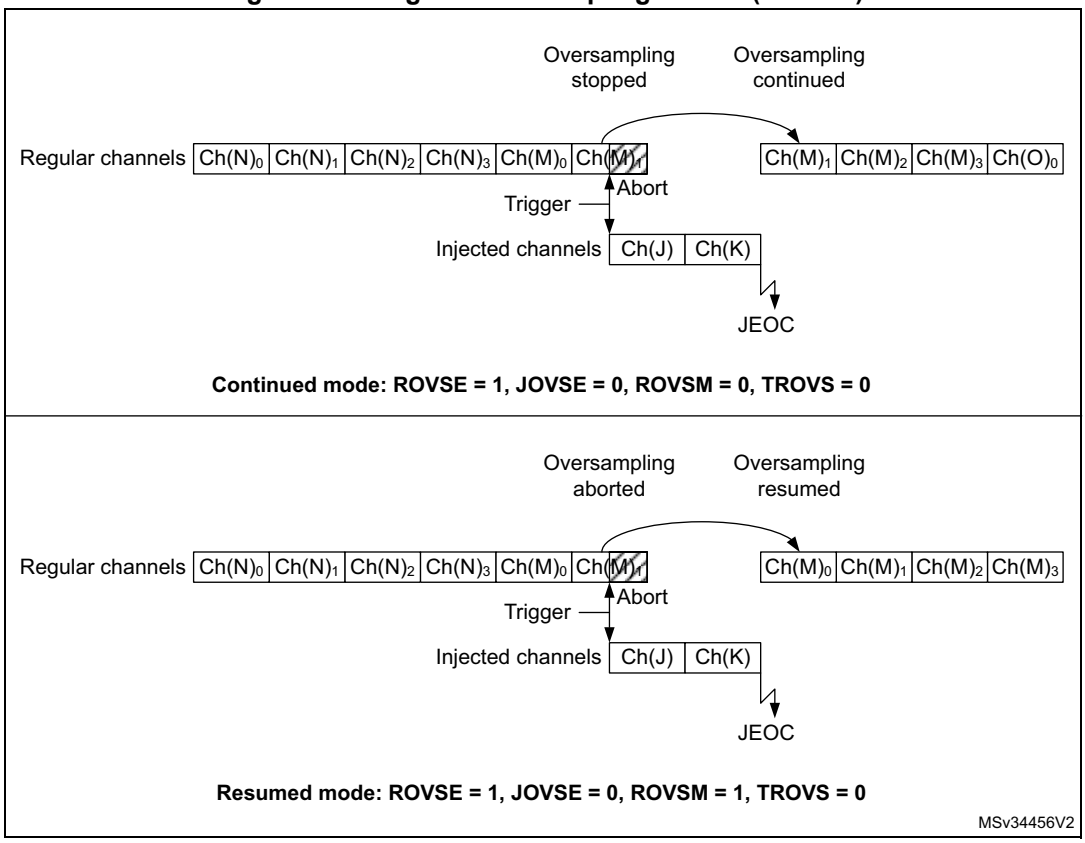
If the TROVS bit is set and OVSR ≠ 0, the content of the DISCEN bit is ignored and considered as 1.

If the TROVS bit is set, neither software trigger nor JAUTO is supported.

Figure 237. Triggered regular oversampling mode (TROVS bit = 1)

Injected and regular sequencer management in oversampling mode

In oversampling mode, injected and regular sequencers can have different behaviors. The oversampling can be enabled for both sequencers with some limitations if they have to be used simultaneously.



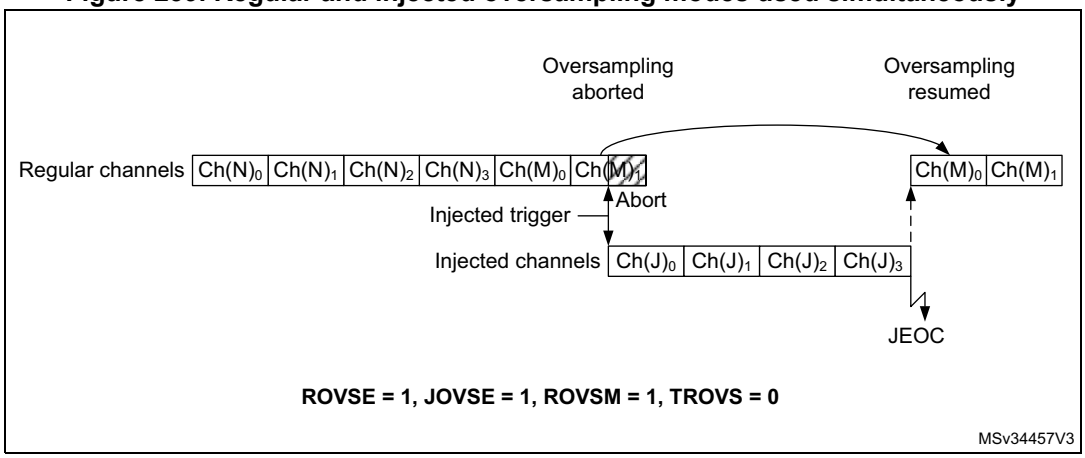
Oversampling regular channels only

The regular oversampling mode ROVSM bit defines how the regular oversampling sequence is resumed if it is interrupted by an injected conversion:

- In continuous mode (ROVSM = 0), the accumulation restarts from the last valid data (prior to the conversion abort request due to the injected trigger). This ensures that oversampling is complete whatever the injection frequency (providing at least one regular conversion can be complete between triggers);
- In resumed mode (ROVSM = 1), the accumulation restarts from 0 (previous conversion results are ignored). This mode guarantees that all the data used for oversampling were converted back-to-back within a single time slot.

Figure 238 gives examples for a 4x oversampling ratio.

Figure 238. Regular oversampling modes (4x ratio)



Oversampling injected channels only

The injected oversampling mode bit JOVSE enables oversampling solely for conversions in the injected sequencer.

Oversampling regular and injected channels

It is possible to have both ROVSE and JOVSE bits set. In this case, the regular oversampling must be resumed (ROVSM bit = 1), as shown in *Figure 239*. This limitation no longer applies in parallel injected oversampling mode.

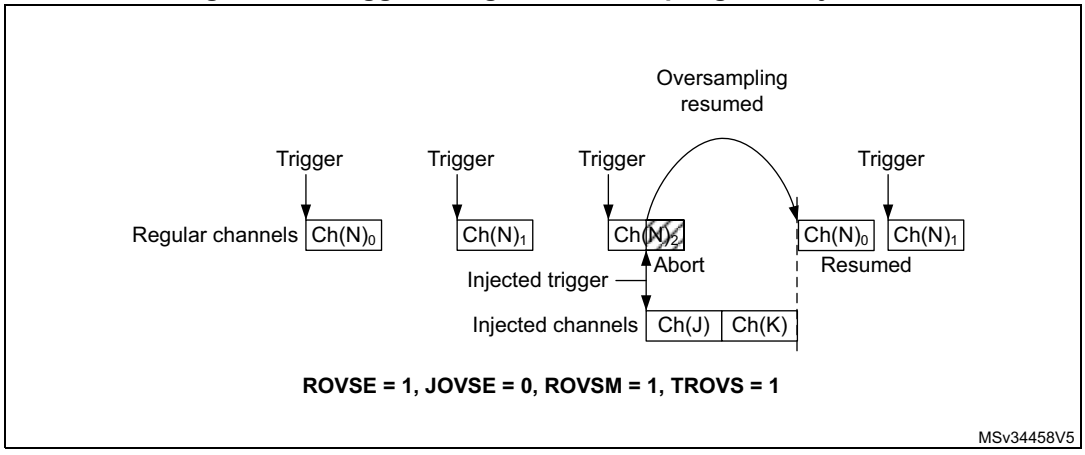


Figure 239. Regular and injected oversampling modes used simultaneously

Triggered regular oversampling with injected conversions

It is possible to have triggered regular mode with injected conversions. In this case, the injected oversampling mode must be disabled and the ROVSM bit set (the resumed mode is forced). The JOVSE bit must be reset. The behavior is shown in *Figure 240*.

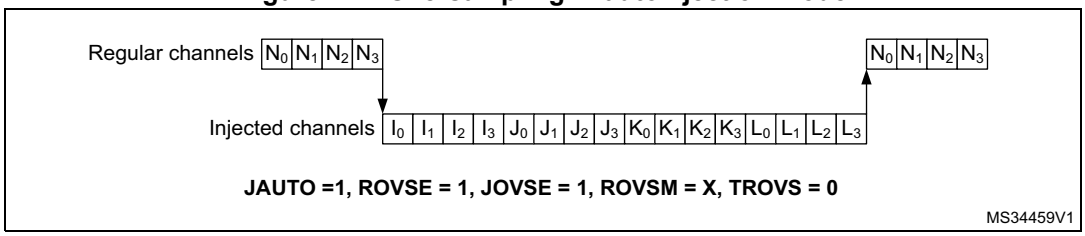

Figure 240. Triggered regular oversampling with injection

Autoinjection mode

It is possible to oversample autoinjected sequences and store all conversion results in registers. This mode is available only with both regular and injected oversampling active: JAUTO = 1, ROVSE = 1 and JOVSE = 1. Other combinations are not supported. The ROVSM bit is ignored in autoinjection mode. *Figure 241* shows how the conversions are sequenced.

Figure 241. Oversampling in autoinjection mode

Combined modes summary

Table 237 summarizes all combinations, including the modes that are not supported.

Table 237. Oversampler operating mode summary

Regular oversampling ROVSE	Injected oversampling JOVSE	Oversampler mode ROVSM 0 = continued 1 = resumed	Triggered regular mode TROVS	Comment
1	0	0	0	Regular continued mode
1	0	0	1	Not supported
1	0	1	0	Regular resumed mode
1	0	1	1	Triggered regular resumed mode
1	1	0	X	Not supported
1	1	1	0	Injected and regular resumed mode
1	1	1	1	Not supported
0	1	X	X	Injected oversampling

26.4.32 Parallel injected oversampling mode

The parallel injected oversampling mode is enabled by setting the JOVSPAR bit of the ADC_CFGR3 register.

To support parallel injected oversampling mode, four dedicated accumulators are implemented for injected conversions, one associated with each JDRy register.

This changes the injected and regular conversion sequences in oversampling mode described in *Section 26.4.31: Oversampler*, because the oversampling can be enabled simultaneously for all injected channels by setting the JOVSPAR bit.

For example, when the oversampling is enabled on two injected channels for scan conversion, the ADC performs the injected conversion (CH1[0], CH2[0], ... CH1[N-1], CH2[N-1]), then each channel is accumulated to ADC_JDR1 and ADC_JDR2 register.

The TJOVS bit of the ADC_CFGR3 register controls each individual conversion:

- When TJOVS is cleared, all conversions in the injected sequence are performed until the oversampling counter is reached.
- When TJOVS is set, each conversion requires an individual trigger.

TJOVS and TJOVSIVE can be used only when JOVSPAR = 1 and TJOVS is compatible with JDISCEN. When the JOVSIVE bit is set in the ADC_CFGR3 register, all intermediate accumulated values stored in the ADC_JDRy registers can be accessed.

When the JADSTP command is executed, the ADC_JDRy registers contain the intermediate accumulated data, and the JOVSCy[9:0] bitfield in the ADC_JOVSCRy register indicates how many accumulations have been performed.

The accumulation counter decrements from the selected ratio value minus one down to 0. Therefore, a value of 0 means that injected oversampling has completed the programmed number of accumulations. The initial counter value is 0, meaning no oversampling has been performed yet.

As long as the intermediate accumulated data count has not reached 0, the oversampling sequence is not complete, and the conversion data available in JDRy corresponds to the raw accumulated value without any right bit shift. The right bit shift is applied only once the oversampling sequence is fully completed.

If for any reason the injected oversampling needs to be stopped, the software can retrieve the intermediate data and the accumulation count, and calculate the data based on oversampling data divided by the accumulation counter.

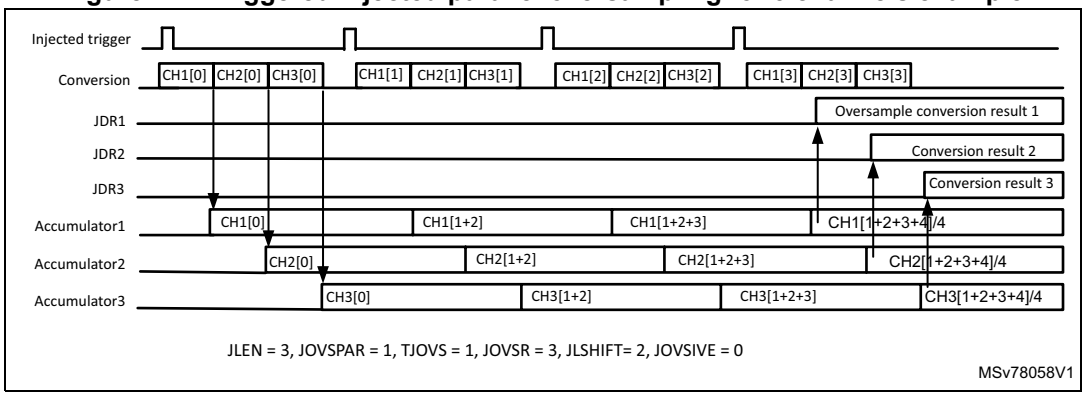

Figure 243. Injected oversampling with intermediate value enabled example

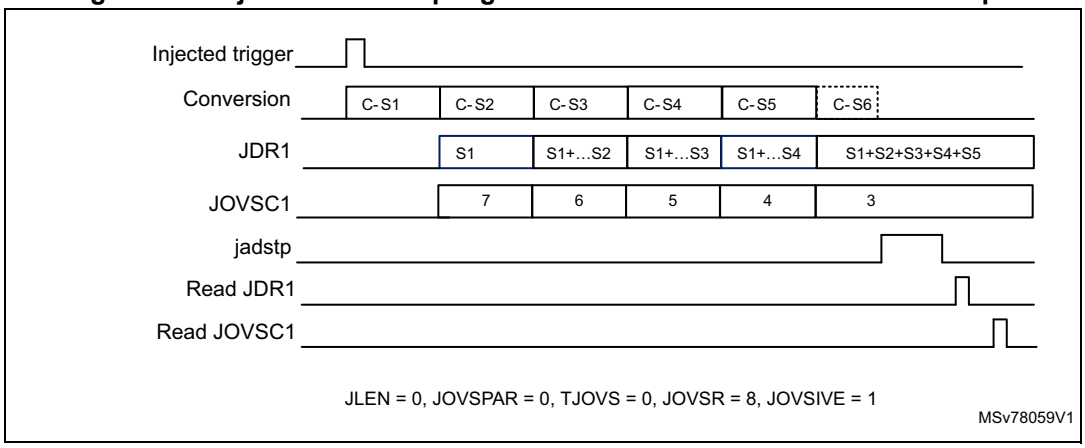

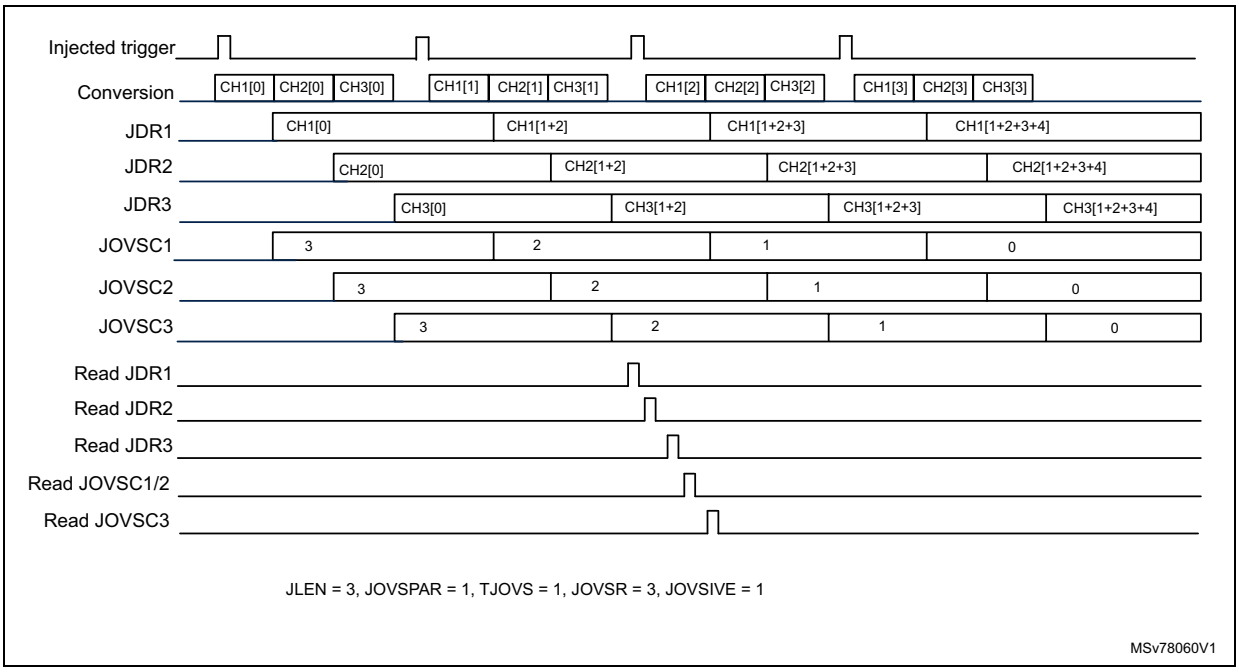

Figure 244. Triggered injected parallel oversampling for 3 channels with accumulated data example

26.4.33 Dual ADC modes

Dual ADC modes can be used in devices with two ADCs or more (see *Figure 245*).

In dual ADC mode the start of conversion is triggered alternately or simultaneously by the ADC master to the ADC slave, depending on the mode selected by the bits DUAL[4:0] in the ADCC_CCR register.

Four possible modes are implemented:

- Injected simultaneous mode
- Regular simultaneous mode
- Interleaved mode
- Alternate trigger mode

It is also possible to use these modes combined in the following ways:

- Injected simultaneous mode + regular simultaneous mode
- Regular simultaneous mode + alternate trigger mode
- Injected simultaneous mode + interleaved mode

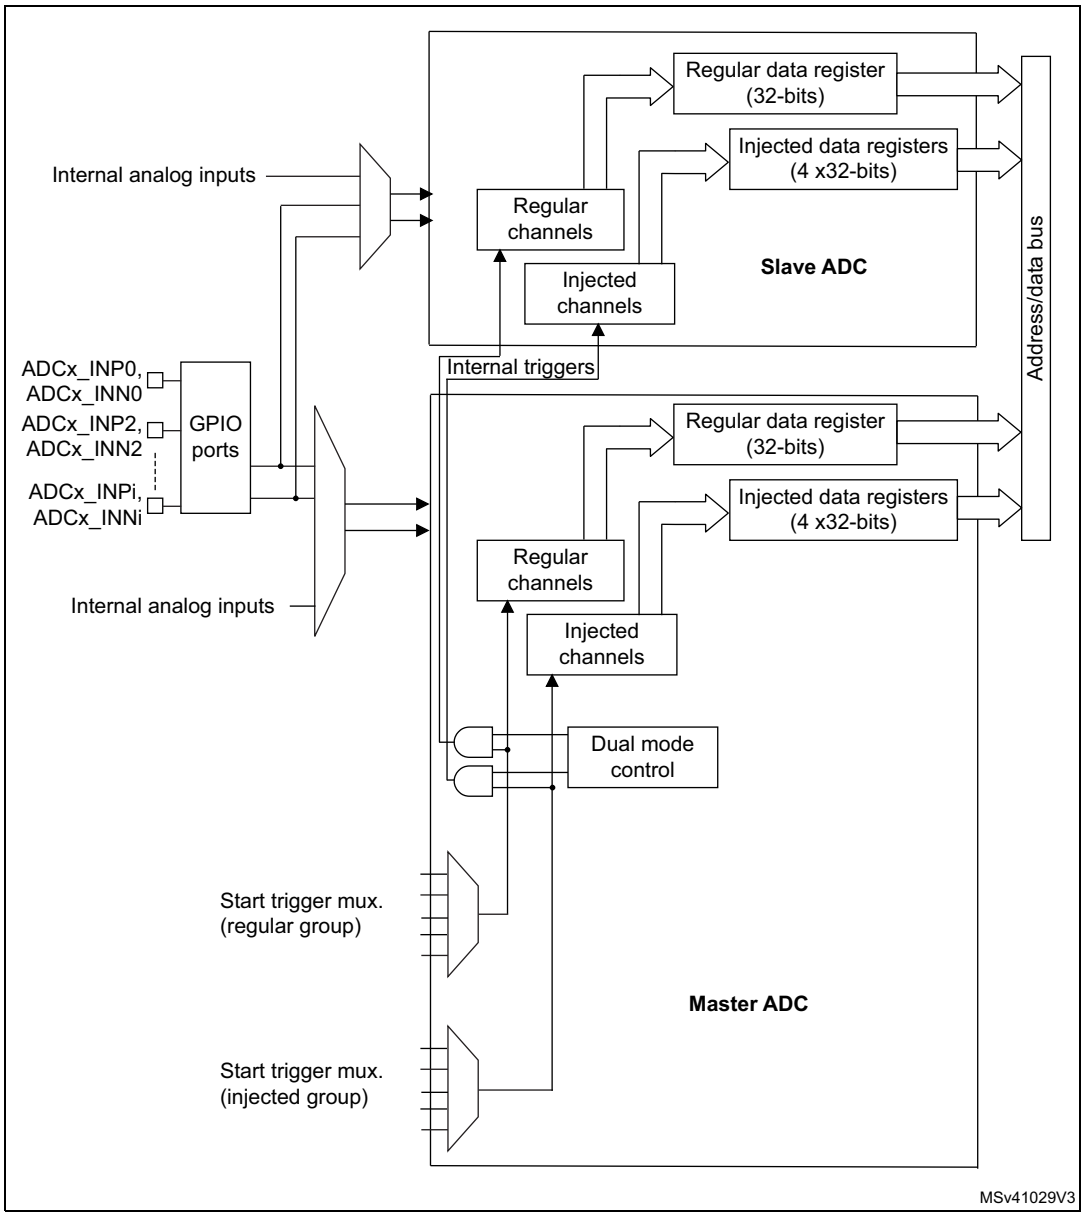
In dual ADC mode (when the DUAL[4:0] bits in the ADCC_CCR register are not equal to zero), the following bits are shared between the master and slave ADCs, with the slave ADC bits being ignored and always applying to the corresponding bits of the master ADC:

- ADC_CFGR1 register: DMNGT[2:0], RES[1:0], EXTEN[1:0], OVRMOD, AUTDLY, DISCEN, DISCNUM[2:0], JDISCEN, JAUTO, JDISCEN.
- ADC_CFGR2 register: ROVSE, JOVSE, TROVS, ROVSM, BULB, SWTRIG, SMPTRIG, OVSR[9:0].
- ADC_GCOMP register: GCOMP.
- ADC_CR register: ADSTART, ADSTP, JADSTART, JADSTP.
- ADC_CFGR1 register: CONT, DISCEN, DISCNUM[2:0].
- ADC_SQR1 register: LEN (for the regular conversion).
- ADC_JSQR register: JLEN[1:0], JEXTSEL[4:0], JEXTEN[1:0] (for the injected conversion).
- ADC_CFGR3 register: JOVSPAR, JOVSE, JOVSIVE, TJOVS, JOVSR[9:0] (for the injected conversion).

For dual mode usage, the sampling time of the master and slave channels must be equal.

To start a conversion in dual mode, the user must program the EXTEN[1:0], EXTSEL, JEXTEN[1:0] and JEXTSEL bits of the master ADC only to configure a software or hardware trigger and a regular or injected trigger. The EXTEN[1:0], JEXTEN[1:0], and JEXTSEL bits of the slave ADC are don’t care).

In regular simultaneous or interleaved modes, once the user sets the ADSTART or ADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, ADSTART or ADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.



In injected simultaneous or alternate trigger modes, once the user sets the JADSTART or JADSTP bit of the master ADC, the corresponding bit of the slave ADC is automatically set. However, JADSTART or JADSTP bit of the slave ADC is not necessarily cleared at the same time as the master ADC bit.

In dual ADC mode, the converted data of the master and slave ADC can be read in parallel, by reading the ADC common data register (ADCC_CDR). The flags can also be read in parallel by reading the dual-mode status register (ADCC_CSR).

Note: In dual mode, BULB, JAUTO, SMPTRIG, and the injected queue are not supported.

During ADC calibration, the DUAL[4:0] bits must be set to 00000.

Figure 245. Dual ADC block diagram

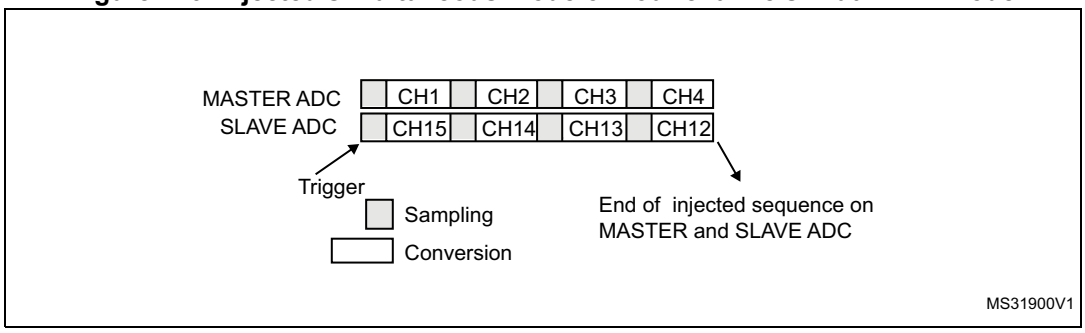
1. External triggers also exist on slave ADC but are not shown for the purposes of this diagram.
2. The ADC common data register (ADCC_CDR) contains both the master and slave ADC regular converted data.

Injected simultaneous mode with independent regular conversion

The injected simultaneous mode is selected by programming DUAL[4:0] bits to 0b00101.

This mode converts an injected group of channels. The external trigger source comes from the injected group multiplexer of the master ADC (selected by the JEXTSEL bits in the ADC_JSQR register).

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).



In simultaneous mode, the user software must convert sequences with the same length. Sampling times for channels with the same sequence number must be equal.

Regular conversions can be performed on one or all ADCs. In that case, they are independent of each other and are interrupted when an injected event occurs. They are resumed at the end of the injected conversion group.

The software is notified by interrupts when it can read the data:

- If the duration of the master-injected sequence is equal to the duration of the slave injected one (as shown in *Figure 246*), the software can enable only one of the two JEOS interrupts (for example the master JEOS) and read both converted data (from master ADC_JDRy and slave ADC_JDRy registers).

Figure 246. Injected simultaneous mode on four channels: Dual ADC mode

If JDISCEN is set, each simultaneous conversion of the injected sequence requires an injected trigger event to occur.

This mode can be combined with the AUTDLY mode:

- Once a simultaneous injected sequence of conversions has ended, a new injected trigger event is accepted only if both JEOS bits of the master and the slave ADC have been cleared (delay phase). Any new injected trigger events occurring during the ongoing injected sequence and the associated delay phase are ignored.
- Once a regular sequence of conversions of the master ADC has ended, a new regular trigger event of the master ADC is accepted only if the master data register (ADC_DR) has been read. Any new regular trigger events occurring for the master ADC during the ongoing regular sequence and the associated delay phases are ignored.
  There is the same behavior for regular sequences occurring on the slave ADC.

In this mode, the following register bits are shared between the master and slave ADCs:

JADSTART, JADSTP, JDISCEN, JOVSE, JLEN, JEXTEN, JEXTSEL, and GCOMPEN, JOVSPAR, JOVSIVE, JOVSE, and TJOVS.

Regular simultaneous mode with independent injected conversions

The regular simultaneous mode is selected by programming DUAL[4:0] bits to 0b00110.

This mode applies to a regular group of channels. The external trigger source comes from the regular group multiplexer of the master ADC (selected by the EXTSEL bits in the ADC_CFGR1 register). A simultaneous trigger is provided to the slave ADC.

In this mode, independent injected conversions are supported. An injection request (either on the master or on the slave) aborts the current simultaneous conversions both for master and slave. They are restarted once the injected conversion is completed.

Note: Do not convert the same channel on the two ADCs (no overlapping sampling times for the two ADCs when converting the same channel).

In regular simultaneous mode, the user software must convert sequences with the same length. Sampling times for channels with the same sequence number must be equal.

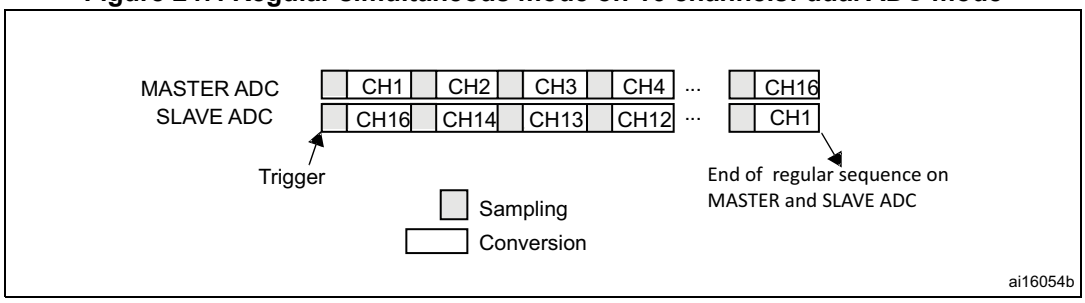
The software is notified by interrupts when it can read the data:

- As the duration of the master regular sequence is equal to the duration of the slave one (as shown in *Figure 247*), the software can enable only one of the two EOC interrupts (for example the master EOC) and read both converted data from the common data register (ADCC_CDR).
  The user can read data from either ADCC_CDR or ADCC_CDR2. Once software selects one of these registers, it must continue using the same register until the ADSTP procedure is executed.

The regular data can also be read using the DMA. Several methods are possible:

- Use two DMA channels (one for the master and one for the slave). In this case DAMDF[1:0] bits must be kept cleared:
  a) Configure the DMA master ADC channel to read ADC_DR from the master. DMA requests are generated at each EOC event of the master ADC.
  b) Configure the DMA slave ADC channel to read ADC_DR from the slave. DMA requests are generated at each EOC event of the slave ADC.
- Configure the dual ADC mode data format DAMDF[1:0] bits, which leaves one DMA channel free for other uses:
  a) Set DAMDF[1:0] = 0b10 or 0b11 (depending on resolution).
  b) A single DMA channel is used (the one corresponding to the master). Configure the DMA master ADC channel to read the common ADC data register (ADCC_CDR or ADCC_CDR2).
  c) A single DMA request is generated each time both the master and slave EOC events occur. At that moment:
  – The slave ADC converted data is available in the upper half-word of the 32-bit ADCC_CDR register
  – The master ADC converted data is available in the lower half-word of the ADCC_CDR register.

Alternatively, data can be read from ADCC_CDR2:



– The first read returns the master ADC data.

– The second read returns the slave ADC data.
After these reads, a DMA request is generated. The DMA transfers the slave data from the same data register and handles two transfers for dual mode operation.

d) Both EOC flags are cleared when the DMA reads the ADCC_CDR register.

Note: When DAMDF[1:0] = 0b10 or 0b11, the user must program the same number of conversions in the master and in the slave sequence. Otherwise, the remaining conversions do not generate a DMA request.

Figure 247. Regular simultaneous mode on 16 channels: dual ADC mode

If the DISCEN bit is set, each "*n*" simultaneous conversion of the regular sequence require a regular trigger event to occur ("n" is defined by DISCNUM).

This mode can be combined with the AUTDLY mode:

- Once a simultaneous conversion of the sequence has completed, the next conversion in the sequence starts only after the EOC flag of both the master and the slave are cleared.
- Once a simultaneous regular sequence of conversions has completed, a new regular trigger event is accepted only after the EOC flag of both the master and the slave are cleared. Any new regular trigger events occurring during the ongoing regular sequence and the associated delay phases are ignored.

The DMA can be used to handle data in regular simultaneous mode combined with AUTDLY mode, assuming that multi-DMA mode is used: bits DAMDF must be set to 0b10 or 0b11.

Interleaved mode with independent injected conversions

This mode is selected by programming DUAL[4:0] bits to 0b00111.

It can be started only on a regular group (usually one channel). The external trigger source comes from the regular channel multiplexer of the master ADC.

After an external trigger occurs:

- The master ADC starts immediately,
- The slave ADC starts after a delay of several ADC clock cycles after the sampling phase of the master ADC has completed (during the master ADC conversion period).

The minimum delay between two conversions in interleaved mode is configured in the DELAY bits in the ADCC_CCR register (see *Table DELAY bits versus ADC resolution*). This delay starts counting one half cycle after the end of the sampling phase of the master

conversion. This way, an ADC cannot start a conversion if the complementary ADC is still sampling its input (only one ADC can sample the input signal at a given time).

- The minimum possible DELAY is 1 to ensure that there is at least one cycle time between the opening of the analog switch of the master ADC sampling phase and the closing of the analog switch of the slave ADC sampling phase.
- The maximum DELAY is equal to the number of cycles corresponding to the selected resolution. However, the user must properly calculate this delay to ensure that an ADC does not start a conversion while the other ADC is still sampling its input.

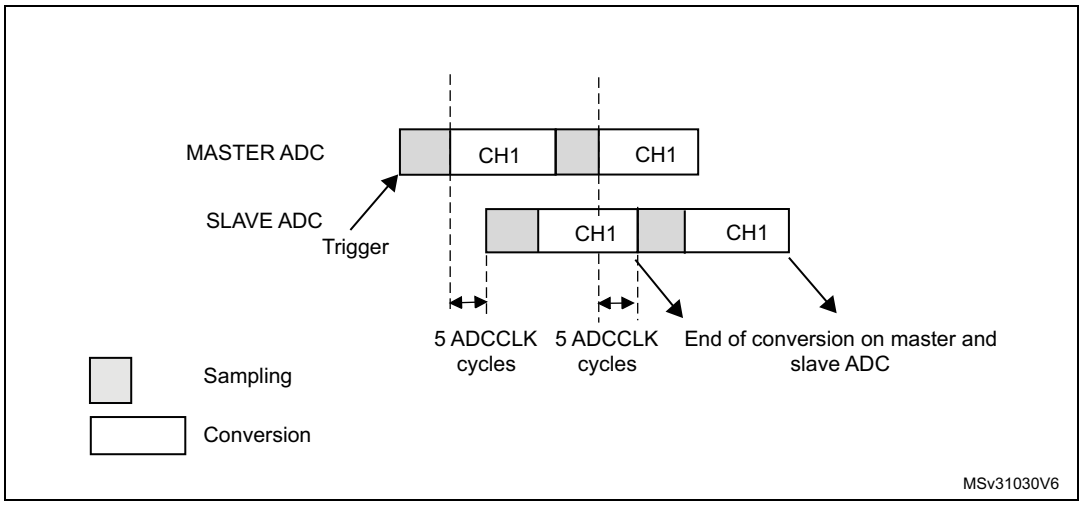
As the CONT bit is set on both the master and slave ADCs, the selected regular channels of both ADCs are continuously converted.

The software is notified by interrupts when it can read the data at the end of each conversion event (EOC) on the master or slave ADC. A slave and master EOC interrupts are generated (if EOCIE is enabled) and the software can read the ADC_DR of the slave/master ADC.

Table 238. DELAY bits versus ADC resolution

DELAY bits	12-bit resolution	10-bit resolution	8-bit resolution	6-bit resolution
0000	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$	1 * $T_{adc_ker_ck}$
0001	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$	2 * $T_{adc_ker_ck}$
0010	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$	3 * $T_{adc_ker_ck}$
0011	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$	4 * $T_{adc_ker_ck}$
0100	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$	5 * $T_{adc_ker_ck}$
0101	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$	6 * $T_{adc_ker_ck}$
0110	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
0111	8 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	8 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1000	9 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1001	10 * $T_{adc_ker_ck}$	10 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1010	11 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1011	12 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
1100	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$
others	13 * $T_{adc_ker_ck}$	11 * $T_{adc_ker_ck}$	9 * $T_{adc_ker_ck}$	7 * $T_{adc_ker_ck}$

Figure 248. Interleaved mode on 1 channel in continuous conversion mode: Dual ADC mode



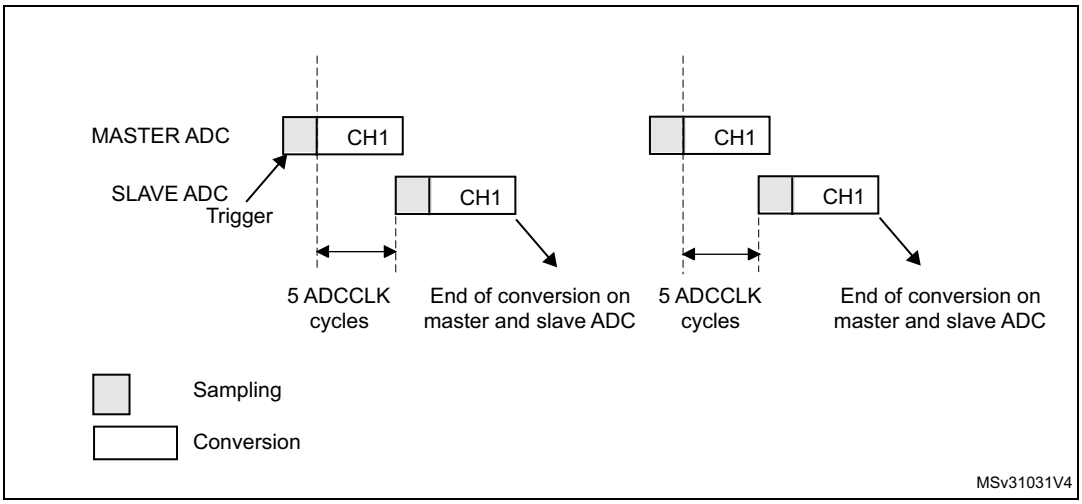


Figure 249. Interleaved mode on 1 channel in single conversion mode: Dual ADC mode

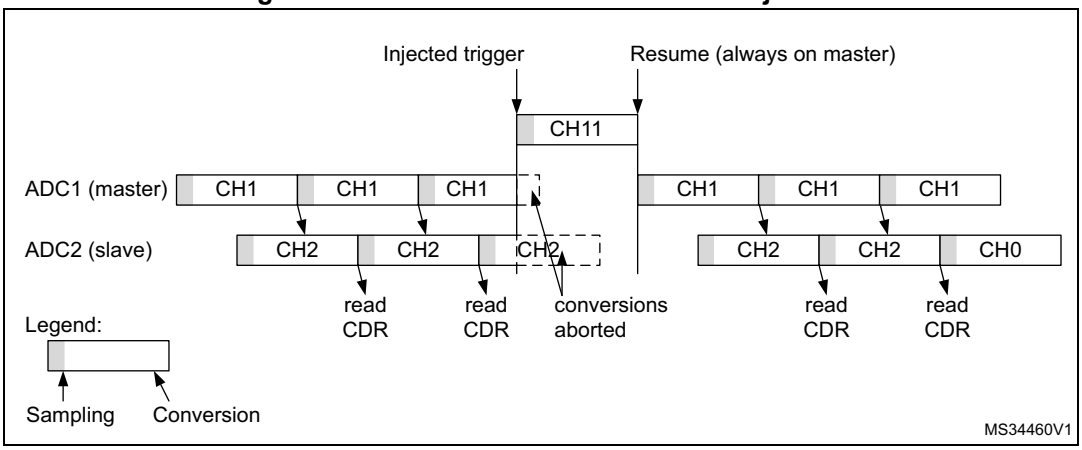


If the DISCEN bit is set, each "*n*" simultaneous conversion ("*n*" is defined by DISCNUM) of the regular sequence require a regular trigger event to occur.

In interleaved mode, injected conversions are supported. When injection is done (either on master or slave), both master and the slave regular conversions are aborted and the sequence is restarted from the master (see *Figure 250*).

Note: In interleaved mode, the ADCx_AWDy_OUT signal for the master ADC is synchronized with the EOC of the master ADC, but the interrupt flag is synchronized with the EOC/JEOC flag of the slave ADC.

In addition, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 250. Interleaved conversion with injection

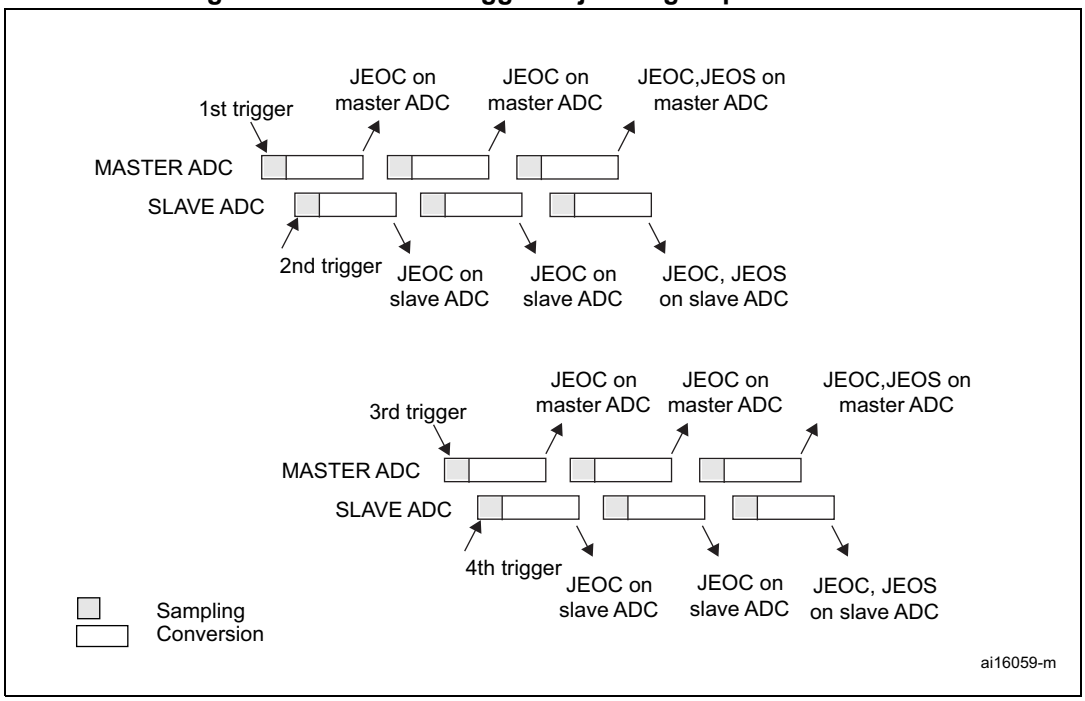
Alternate trigger mode with independent regular conversions

The alternate trigger mode is selected by programming DUAL[4:0] bits to 0b01001.

This mode can only be started on an injected group. The source of the external trigger comes from the multiplexer injected group of the master ADC.

This mode is only possible when selecting hardware triggers: JEXTEN[1:0] must not be 0x0.

Injected discontinuous mode disabled (JDISCEN = 0)



1. When the first trigger occurs, all injected master ADC channels in the group are converted.
2. When the second trigger occurs, all injected slave ADC channels in the group are converted.
3. And so on...

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

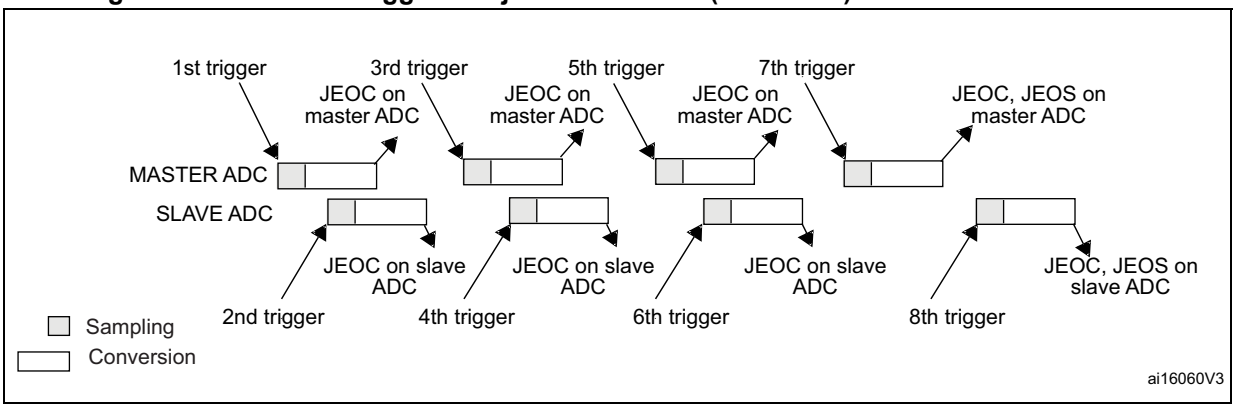
Figure 251. Alternate trigger: injected group of each ADC

Note: Regular conversions can be enabled on one or all ADCs. In this case, the regular conversions are independent of each other. A regular conversion is interrupted when the ADC has to perform an injected conversion. It is resumed when the injected conversion is finished.

The time interval between two trigger events must be greater than or equal to one ADC clock period. The minimum time interval between two trigger events that start conversions on the same ADC is the same as in the single ADC mode.

Injected discontinuous mode enabled (JDISCEN = 1)

If the injected discontinuous mode is enabled for both master and slave ADCs:



1. When the first trigger occurs, the first injected channel of the master ADC is converted.
2. When the second trigger occurs, the first injected channel of the slave ADC is converted.
3. And so on...

A JEOS interrupt, if enabled, is generated after all injected channels of the master ADC in the group have been converted.

A JEOS interrupt, if enabled, is generated after all injected channels of the slave ADC in the group have been converted.

JEOC interrupts, if enabled, can also be generated after each injected conversion.

Figure 252. Alternate trigger: 4 injected channels (each ADC) in discontinuous mode

Combined regular/injected simultaneous mode

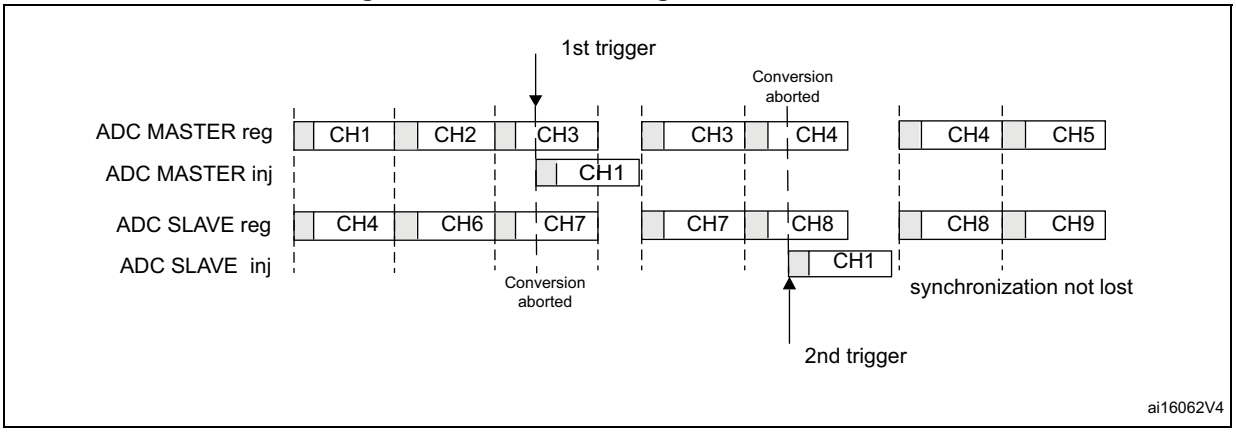
This mode is selected by programming DUAL[4:0] bits to 0b00001.

The simultaneous conversion of a regular group can be interrupted to start the simultaneous conversion of an injected group.

Note: In combined regular/injected simultaneous mode, the user software must convert sequences with the same length.

Combined regular simultaneous and alternate trigger mode

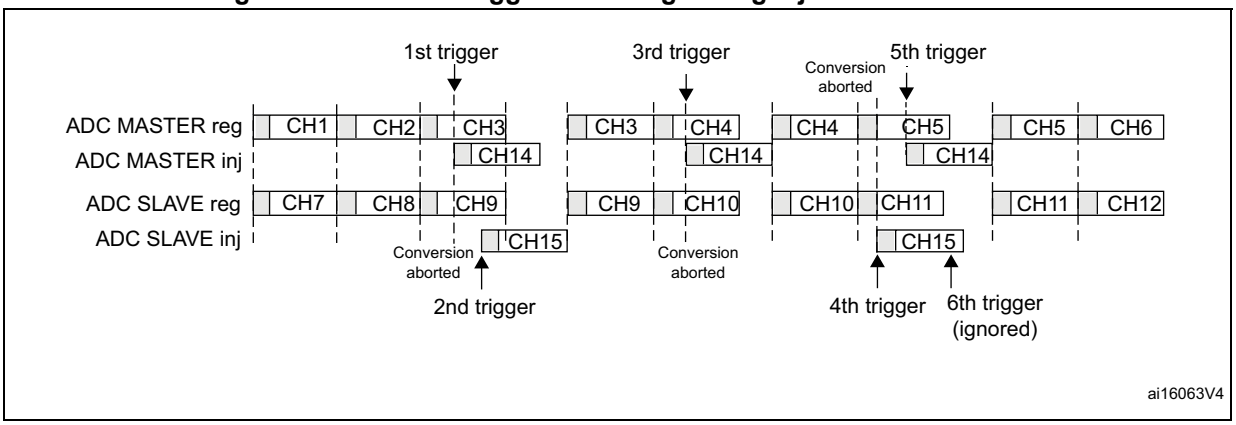
This mode is selected by programming DUAL[4:0] bits to 0b00010.



The simultaneous conversion of a regular group can be interrupted to start the alternate trigger conversion of an injected group. *Figure 253* shows the behavior of an alternate trigger interrupting a simultaneous regular conversion.

The injected alternate conversion immediately starts after the injected event. If a regular conversion is already running, in order to ensure synchronization after the injected conversion, the regular conversion of all (master/slave) ADCs is stopped and resumed synchronously at the end of the injected conversion.

Note: In combined regular simultaneous + alternate trigger mode, the user software must convert sequences with the same length.



The software trigger is not supported for injected conversions.

Figure 253. Alternate + regular simultaneous

If a trigger occurs during an injected conversion that has interrupted a regular conversion, the alternate trigger is served. *Figure 254* shows the behavior in this case (note that the sixth trigger is ignored because the associated alternate conversion is not complete).

Figure 254. Case of trigger occurring during injected conversion

Combined injected simultaneous and interleaved mode

This mode is selected by programming DUAL[4:0] bits to 0b00011.

An interleaved conversion can be interrupted with a simultaneous injected event.

In this case, the interleaved conversion is immediately interrupted and the simultaneous injected conversion starts. At the end of the injected sequence, the interleaved conversion is resumed. When the interleaved regular conversion resumes, the first regular conversion which is performed is always the master's one. *Figure 255*, *Figure 256*, and *Figure 257* show examples of this behavior.

Note: In this mode, the ROVSM = 0 setting is not supported in oversampling mode.

Figure 255. Interleaved single channel CH0 with injected sequence CH11, CH12

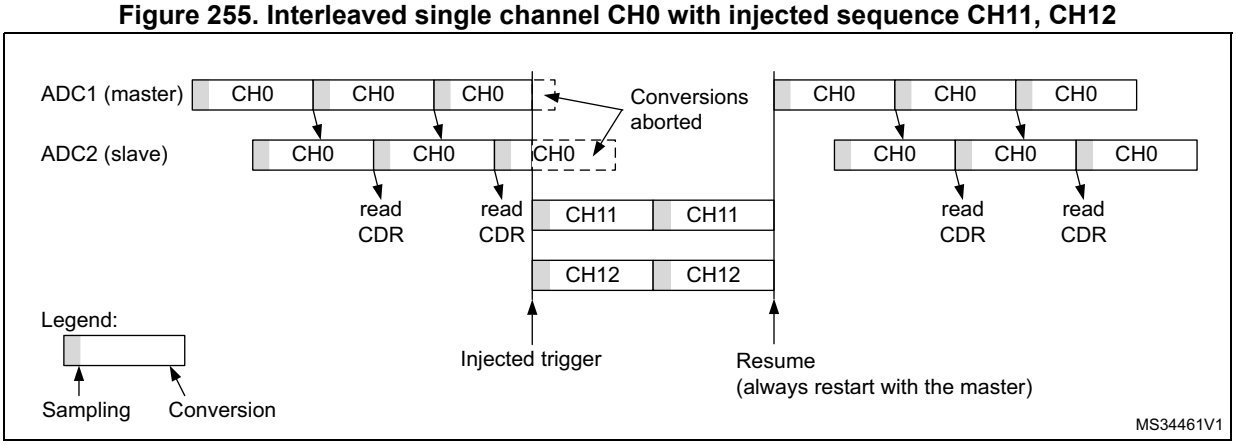


Figure 256. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 case 1: Master interrupted first

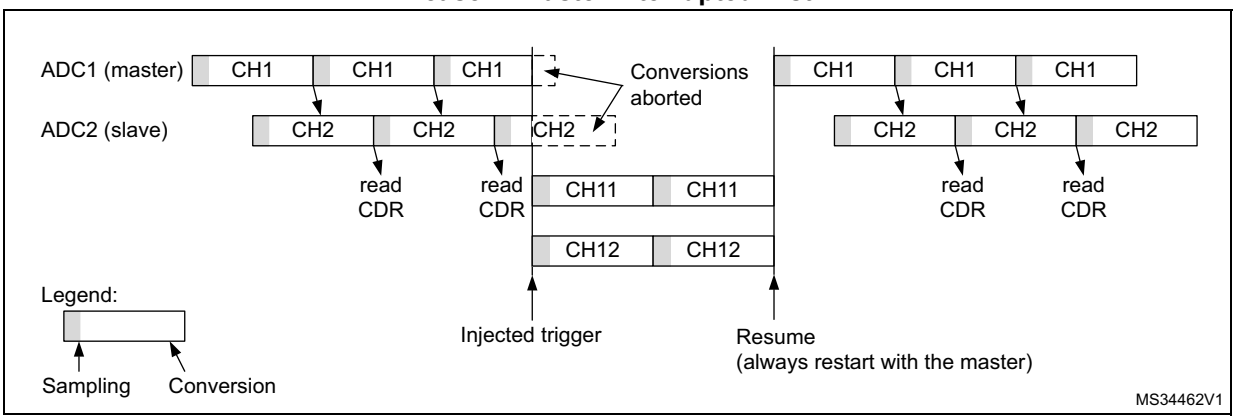

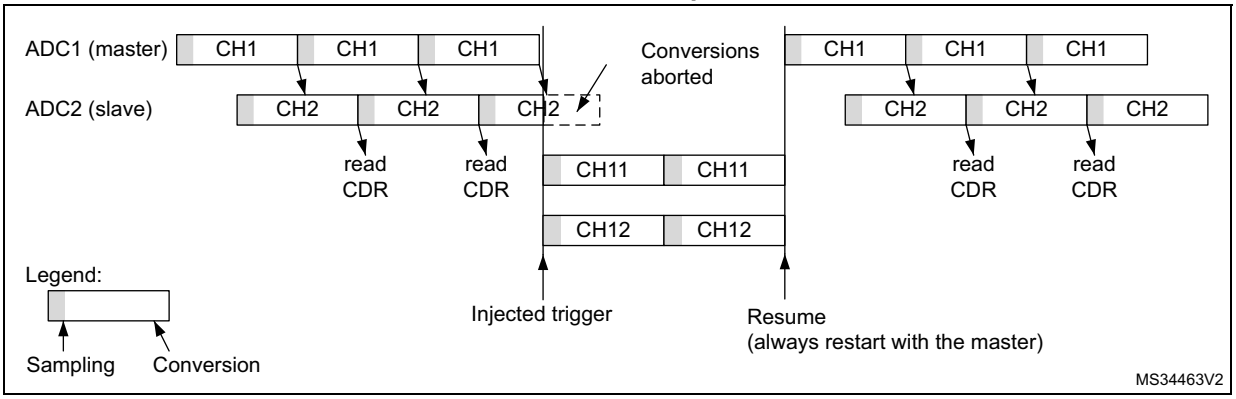

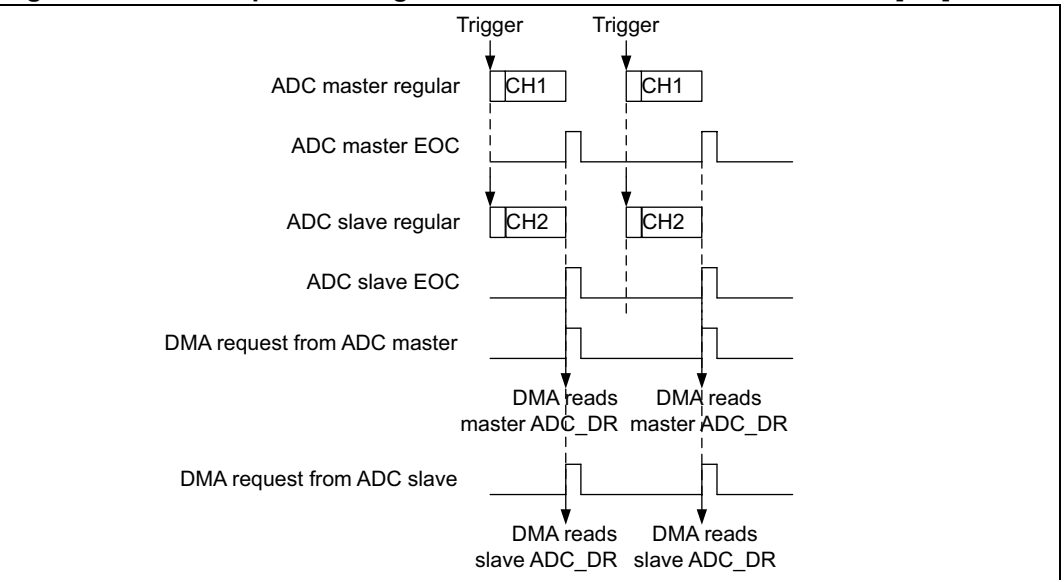

Figure 257. Two interleaved channels (CH1, CH2) with injected sequence CH11, CH12 case 2: Slave interrupted first

DMA requests in dual ADC mode

In all dual ADC modes, it is possible to use two DMA channels (one for the master, one for the slave) to transfer the data, like in single mode (refer to *Figure 258: DMA requests in regular simultaneous mode when DAMDF[1:0] = 0b00*).

Figure 258. DMA requests in regular simultaneous mode when DAMDF[1:0] = 0b00

Configuration where each sequence contains only one conversion. Master and slave timings are equal.

MSv31032V3

In interleaved mode or in simultaneous regular mode, it is also possible to save one DMA channel and transfer both data using a single DMA channel. To do this, the DAMDF[1:0] bits must be configured in the ADCC_CCR register:

- **DAMDF[1:0] = 0b10, 32-bit format:**

  A DMA request is generated alternatively after the master and slave EOC events have occurred. At that time, the data are alternatively available in the 32-bit register ADCC_CDR2 32-bit register.

  This mode is used when the data width is above 16 bits (conversion data width can exceed 16 bits when functions such as oversampling, compensation and left-bit shift, are used).

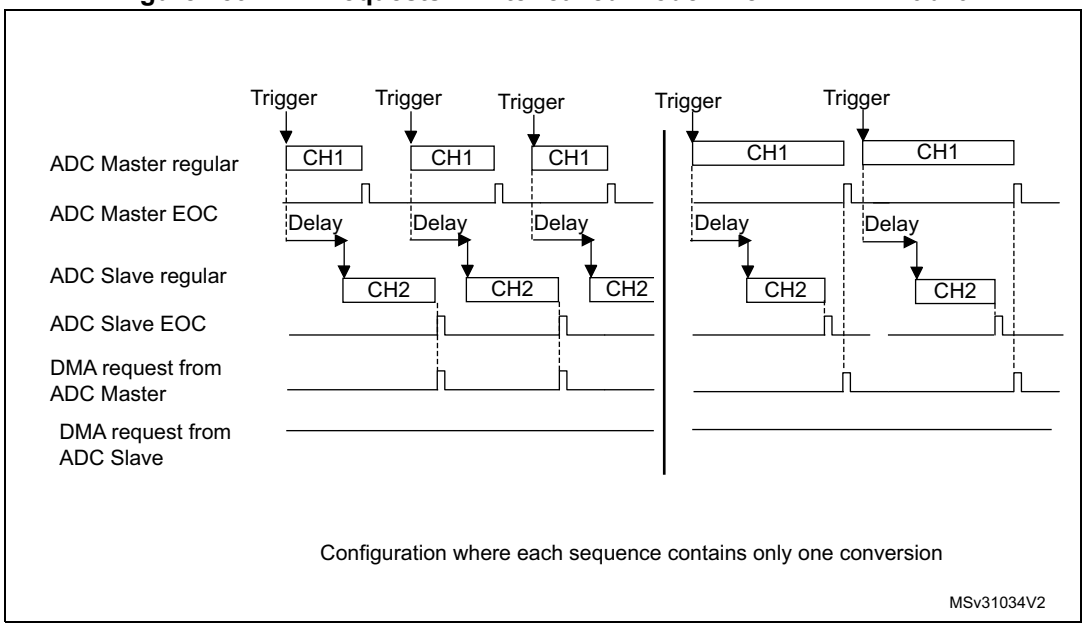
  Behavior: A DMA request is generated each time a new 32-bit data is available:

  – First DMA request: ADCC_CDR2[31:0] = MST_ADC_DR[31:0]

  – Second DMA request: ADCC_CDR2[31:0] = SLV_ADC_DR[31:0]

- **DAMDF[1:0] = 0b10, 16-bit format**:

  A DMA request is generated alternatively after the master and slave EOC events have occurred. At that time, two data items are available and the 32-bit register ADCC_CDR contains the two half-words representing two ADC-converted data. The slave ADC data takes the upper half-word and the master ADC data takes the lower half-word. DMA transfers two data by one request.



Any value above 16-bit in the master or the slave-converted data is truncated to the least 16 significant bits.

Behavior: A DMA request is generated each time a new 32-bit data is available:

– First DMA request:
ADCC_CDR[31:0] = (SLV_ADC_DR[15:0] << 16) | MST_ADC_DR[15:0]

– Second DMA request:
ADCC_CDR[31:0] = SLV_ADC_DR[15:0] | MST_ADC_DR[15:0]

Figure 259. DMA requests in interleaved mode when DAMDF = 0b10

Note: When using dual ADC mode, the user must take care to configure properly the duration of the master and slave conversions so that a DMA request is generated and served for reading both data (master + slave) before a new conversion data is available.

- **DAMDF[1:0] = 0b11**:

  This mode is similar to the DAMDF[1:0] = 0b10 configuration. The only difference is that on each DMA request (two data are available), two bytes representing two ADC converted data are transferred as a half-word.

  This mode is used when the resolution is 6 bits or 8 bits and data are not signed.

  Behavior: A DMA request is generated each time two data items are available:

  – First DMA request:
  ADCC_CDR[15:0] = (SLV_ADC_DR[7:0] << 8)| MST_ADC_DR[7:0]

  – Second DMA request:
  ADCC_CDR[15:0] = SLV_ADC_DR[7:0] | MST_ADC_DR[7:0]

Note: DMA burst mode is not supported in ADC dual mode.

Overrun detection when OVRMOD = 0

In dual ADC mode (when DUAL[4:0] is not equal to b00000), if an overrun is detected on one of the ADCs, DMA requests are no longer issued to ensure that all the data transferred to the RAM are valid (this behavior occurs whatever the DAMDF configuration). The EOC bit

corresponding to one ADC might remains set because the data register of this ADC contains valid data.

Overrun detection when OVRMOD = 1

In dual ADC mode, if an overrun occurs on either ADC, the data register is overwritten, causing continuous DMA requests. This results in loss of data coherency.

DMA one-shot mode/ DMA circular mode when multi-ADC mode is selected

When DAMDF mode is selected (0b10 or 0b11), DMNGT[1:0] bits of the ADCC_CCR register must also be configured to select between DMA one-shot mode and circular mode, as explained in section *Section : Managing conversions using the DMA*

Stopping the conversions in dual ADC modes

In dual ADC mode, the user software must set the ADSTP/JADSTP control bits in the master ADC to stop the conversions of both ADC. The other ADSTP control bit on the slave ADC has no effect in dual ADC mode.

Once both ADCs are effectively stopped, the ADSTART/JADSTART bits on the master and slave ADCs are both deasserted by hardware.

Analog watchdog in dual mode

The analog watchdog is supported in all dual modes.

Disabling the ADC in dual mode

During a dual-mode operation, the master ADC shares the ADC clock with the slave ADC. To disable the ADC correctly through the ADDIS bit of ADC_CR, set the ADSTP (or JADSP) bit on the master ADC. Once ADSTP (or JADSTP) becomes 0 both for the master and slave ADCs, set the ADDIS bit on the master ADC, then set the ADDIS bit on the slave ADC.

Autoinjection mode in dual mode

Autoinjection mode is not supported when DUAL[4:0] equals 0b00010, 0b00011, 0b00101, 0b00110, 0b00111, or 0b01001.

Additionally, parallel injected oversampling mode is not supported in autoinjection mode.

Dual ADC modes supported in oversampling mode

It is possible to have oversampling enabled when working in dual ADC configuration. In this case, the two ADCs must be programmed with the very same settings (including oversampling).

All other dual ADC modes are not supported when either regular or injected oversampling is enabled (that means when ROVSE = 1 or JOVSE = 1).

26.4.34 Temperature sensor

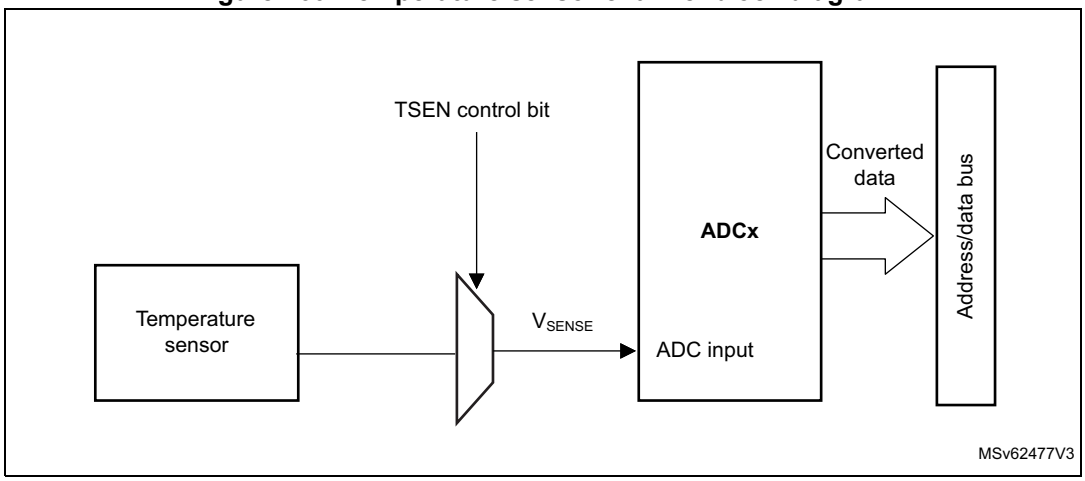
The temperature sensor can be used to measure the junction temperature (T_J) of the device.

The temperature sensor is internally connected to the ADC input channels, which are used to convert the sensor output voltage to a digital value (see *Table: ADC interconnection* in *Section 26.4.2: ADC pins and internal signals* for more details). When not in use, the sensor can be put in power-down mode. It supports the temperature range specified in the product datasheet.

Figure 260 shows the block diagram of connections between the temperature sensor and the ADC.

The temperature sensor output voltage changes linearly with temperature. The offset of this line varies from chip to chip due to process variation (up to 45 °C from one chip to another).

The uncalibrated internal temperature sensor is more suited for applications that detect temperature variations instead of absolute temperatures. To improve the accuracy of the temperature sensor measurement, calibration values are stored in system memory for each device by ST during production.



During the manufacturing process, the calibration data of the temperature sensor and the internal voltage reference are stored in the system memory area. The user application can then read them and use them to improve the accuracy of the temperature sensor or the internal reference (refer to the datasheet for additional information).

The temperature sensor is internally connected to the ADC input channel, which is used to convert the sensor's output voltage to a digital value. Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal temperature sensor.

When not in use, the sensor can be put in power-down mode.

Figure 260 shows the block diagram of the temperature sensor.

Figure 260. Temperature sensor channel block diagram

Reading the temperature

To use the sensor:

1. Select the ADC input channel that is connected to V_{SENSE}.
2. Program with the appropriate sampling time (refer to the electrical characteristics section of the device datasheet).
3. Set the TSEN bit in the ADCC_CCR register to wake up the temperature sensor from power-down mode.
4. Start the ADC conversion.
5. Read the resulting V_{SENSE} data in the ADC data register.
6. Calculate the actual temperature using the following formula:

$$\text{Temperature (in °C)} = \frac{\text{TS_CAL2_TEMP} - \text{TS_CAL1_TEMP}}{\text{TS_CAL2} - \text{TS_CAL1}} \times (\text{TS_DATA} - \text{TS_CAL1}) + \text{TS_CAL1_TEMP}$$

Where:

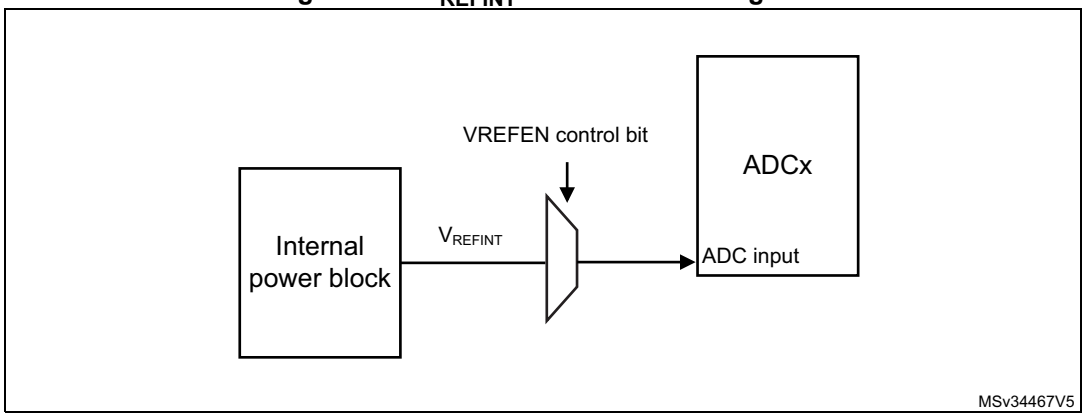
- TS_CAL2 is the temperature sensor calibration value acquired at TS_CAL2_TEMP.
- TS_CAL1 is the temperature sensor calibration value acquired at TS_CAL1_TEMP.
- TS_DATA is the actual temperature sensor output value converted by ADC.

  Refer to the device datasheet for more information about TS_CAL1 and TS_CAL2 calibration points.

Caution: The above formula is valid only if the V_{REF+} condition specified in the table *Temperature sensor calibration values* of the datasheet are respected.

Note: The sensor has a startup time after waking from power-down mode before it can output V_{SENSE} at the correct level. The ADC also has a startup time after power-on, so to minimize the delay, the ADEN, and TSEN bits must be set simultaneously.

26.4.35 Monitoring the internal voltage reference



It is possible to monitor the internal voltage reference (V_{REFINT}) to have a reference point for evaluating the ADC V_{REF+} voltage level.

Refer to the *ADC interconnection* table in *Section 26.4.2: ADC pins and internal signals* for details on the ADC input channels to which the internal voltage reference is internally connected.

Refer to the electrical characteristics section of the device datasheet for the sampling time value to be applied when converting the internal voltage reference voltage.

Figure 261 shows the block diagram of the V_{REFINT} sensing feature.

Figure 261. V_{REFINT} channel block diagram

1. The VREFEN bit of the ADCC_CCR register must be set to enable the conversion of internal channels (V_{REFINT}).

Calculating the actual V_{REF+} voltage using the internal reference voltage

The power supply voltage applied to the device may be subject to variations or not precisely known. When V_{DDA} is connected to V_{REF+}, it is possible to compute the actual V_{DDA} voltage using the embedded internal reference voltage (V_{REFINT}). V_{REFINT} and its calibration data acquired by the ADC during the manufacturing process at V_{REF+} can be used to evaluate the actual V_{DDA} voltage level.

The following formula gives the actual V_{REF+} voltage supplying the device:

$$V_{REF+} = V_{REF+_Charac} \times VREFINT_CAL / VREFINT_DATA$$

Where:

- V_{REF+_Charac} is the value of V_{REF+} voltage characterized at V_{REFINT} during the manufacturing process. It is specified in the device datasheet.
- VREFINT_CAL is the VREFINT calibration value.
- VREFINT_DATA is the actual VREFINT output value converted by ADC.

Converting a supply-relative ADC measurement to an absolute voltage value

The ADC is designed to deliver a digital value corresponding to the ratio between V_{REF+} and the voltage applied on the converted channel.

For some applications, the V_{REF+} value is unknown and ADC converted values are right-aligned. In this case, it is necessary to convert this ratio into a voltage independent from V_{REF+}:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

By replacing V_{REF+} by the formula provided above, the absolute voltage value is given by the following formula

$$V_{CHANNELx} = \frac{V_{REF+_Charac} \times VREFINT_CAL \times ADC_DATA}{VREFINT_DATA \times FULL_SCALE}$$

For applications where V_{REF+} is known and ADC converted values are right-aligned, the absolute voltage value can be obtained by using the following formula:

$$V_{CHANNELx} = \frac{V_{REF+}}{FULL_SCALE} \times ADC_DATA$$

Where:

– VREFINT_CAL is the VREFINT calibration value.
– ADC_DATA is the value measured by the ADC on channel x (right-aligned).
– VREFINT_DATA is the actual VREFINT output value converted by the ADC.
– FULL_SCALE is the maximum digital value of the ADC output. For example with 12-bit resolution, we obtain $2^{12} – 1 = 4095$, or $2^8 – 1 = 255$ with 8-bit resolution.

Note: If ADC measurements are done using an output format other than 12-bit right-aligned, all the parameters must first be converted to a compatible format before the calculation is done.

26.4.36 Monitoring the OPAMP output voltage

The ADC is connected to a OPAMP internal channel. To measure the OPAMP output voltage, enable the OPAMP internal channel through OPAMP registers.

26.4.37 Monitoring the supply voltage

The ADCs are connected to the internal supply voltage. To use the ADC to measure this voltage, enable the connection through ADC option register.

26.5 ADC interrupts

For each ADC, an interrupt can be generated:

- After ADC power-up, when the ADC is ready (ADRDY flag)
- On the end of any conversion for regular groups (EOC flag)
- On the end of a sequence of conversion for regular groups (EOS flag)
- On the end of any conversion for injected groups (JEOC flag)
- On the end of a sequence of conversion for injected groups (JEOS flag)
- When an analog watchdog detection occurs (AWD1, AWD2, and AWD3 flags)
- When the end of the sampling phase occurs (EOSMP flag)
- When the data overrun occurs (OVR flag)
- When the ADC internal voltage regulator output is ready (LDORDY flag)
- When the injected sequence context queue overflows (JQOVF flag)

Separate interrupt enable bits are available for flexibility.

Note: Interrupts are generated by the AHB clock domain. Since the ADC clock is adc_ker_ck, interrupt flags are delayed due to the synchronization between adc_ker_ck and AHB clock domains.

Table 239. ADC interrupts

Interrupt vector	Interrupt event	Event flag	Enable Control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop, Standby mode
ADC	ADC ready	ADRDY	ADRDYIE	Set by hardware and cleared by software	Yes	No
	End of conversion of a regular group	EOC	EOCIE			
	End of conversion sequence of a regular group	EOS	EOSIE			
	End of conversion of an injected group	JEOC	JEOCIE			
	End of conversion sequence of an injected group	JEOS	JEOSIE			
	Analog watchdog 1 flag is set	AWD1	AWD1IE			
	Analog watchdog 2 flag is set	AWD2	AWD2IE			
	Analog watchdog 3 flag is set	AWD3	AWD3IE			
	End of sampling phase	EOSMP	EOSMPIE			
	Overrun	OVR	OVRIE			
	ADC internal voltage regulator ready	LDORDY	LDORDYIE			
	Injected context queue overflows	JQOVF	JQOVFIE			

26.6 ADC registers (for each ADC)

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

26.6.1 ADC interrupt and status register (ADC_ISR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDY	Res.	JQOVF	AWD3	AWD2	AWD1	JEOS	JEOC	OVR	EOS	EOC	EOSMP	ADRDY
			rc_w1		rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1	rc_w1

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY**: ADC internal voltage regulator output ready flag

This bit is set by hardware and cleared by software. It indicates that the ADC internal voltage regulator output is ready and that the ADC can be enabled or calibrated.

0: ADC LDO internal voltage regulator disabled

1: ADC LDO internal voltage regulator enabled

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVF**: Injected context queue overflow

This bit is set by hardware when an overflow of the injected queue of context occurs. It is cleared by software writing 1 to it or when ADEN = 0.

Refer to *Section 26.4.23: Queue of context for injected conversions* for more information.

0: No injected context queue overflow occurred (or the flag event was already acknowledged and cleared by software)

1: Injected context queue overflow has occurred

Bit 9 **AWD3**: Analog watchdog 3 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD3LTR and ADC_AWD3HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 3 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 3 event occurred

Bit 8 **AWD2**: Analog watchdog 2 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD2LTR and ADC_AWD2HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 2 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 2 event occurred

Bit 7 **AWD1**: Analog watchdog 1 flag

This bit is set by hardware when the converted voltage crosses the values programmed in the fields LTR[22:0] and HTR[22:0] of ADC_AWD1LTR and ADC_AWD1HTR registers. It is cleared by software writing 1 to it or when ADEN = 0.

0: No analog watchdog 1 event occurred (or the flag event was already acknowledged and cleared by software)

1: Analog watchdog 1 event occurred

Bit 6 **JEOS:** Injected channel end of sequence flag

This bit is set by hardware at the end of the conversions of all injected channels in the group. It is cleared by software writing 1 to it or when ADEN = 0.

0: Injected conversion sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Injected conversions complete

Bit 5 **JEOC:** Injected channel end of conversion flag

This bit is set by hardware at the end of each injected conversion of a channel when a new data is available in the corresponding ADC_JDRy register. It is cleared by software writing 1 to it, when ADEN = 0, or by reading the corresponding ADC_JDRy register.

0: Injected channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Injected channel conversion complete

Bit 4 **OVR**: ADC overrun

This bit is set by hardware when an overrun occurs on a regular channel (a new conversion has completed while the EOC flag was already set) or when adc_hclk clock is too slow to manage the data.

It is cleared by software writing 1 to it or when ADEN = 0.

0: No overrun occurred (or the flag event was already acknowledged and cleared by software)

1: Overrun has occurred

Bit 3 **EOS**: End of regular sequence flag

This bit is set by hardware at the end of the conversions of a regular sequence of channels. It is cleared by software writing 1 to it or when ADEN = 0.

0: Regular conversions sequence not complete (or the flag event was already acknowledged and cleared by software)

1: Regular conversions sequence complete

Bit 2 **EOC**: End of conversion flag

This bit is set by hardware at the end of each regular conversion of a channel when a new data is available in the ADC_DR register. It is cleared by software writing 1 to it, when ADEN = 0, or by reading the ADC_DR register.

0: Regular channel conversion not complete (or the flag event was already acknowledged and cleared by software)

1: Regular channel conversion complete

Bit 1 **EOSMP**: End of sampling flag

This bit is set by hardware during the conversion of any channel (only for regular channels), at the end of the sampling phase. It is cleared by software writing 1 or when ADEN = 0.

0: not at the end of the sampling phase (or the flag event was already acknowledged and cleared by software)

1: End of sampling phase reached

Bit 0 **ADRDY**: ADC ready

This bit is set by hardware after the ADC has been enabled (bit ADEN = 1) and when the ADC reaches a state where it is ready to accept conversion requests.

It is cleared by software writing 1 to it or when ADEN = 0.

0: ADC not yet ready to start conversion (or the flag event was already acknowledged and cleared by software)

1: ADC is ready to start conversion

26.6.2 ADC interrupt enable register (ADC_IER)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	LDORDYIE	Res.	JQOVFIE	AWD3IE	AWD2IE	AWD1IE	JEOSIE	JEOCIE	OVRIE	EOSIE	EOCIE	EOSMPIE	ADRDYIE
			rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **LDORDYIE**: ADC internal voltage regulator interrupt enable

This bit is set and cleared by software to enable/disable the ADC internal voltage regulator interrupt.

0: Internal voltage regulator interrupt disabled

1: Internal voltage regulator interrupt enabled

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVFIE**: Injected context queue overflow interrupt enable

This bit is set and cleared by software to enable/disable the injected context queue overflow interrupt.

0: Injected context queue overflow interrupt disabled

1: Injected context queue overflow interrupt enabled. An interrupt is generated when the JQOVF bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 9 **AWD3IE**: Analog watchdog 3 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 3 interrupt disabled

1: Analog watchdog 3 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 8 **AWD2IE**: Analog watchdog 2 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 2 interrupt.

0: Analog watchdog 2 interrupt disabled

1: Analog watchdog 2 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 7 **AWD1IE**: Analog watchdog 1 interrupt enable

This bit is set and cleared by software to enable/disable the analog watchdog 1 interrupt.

0: Analog watchdog 1 interrupt disabled

1: Analog watchdog 1 interrupt enabled

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 6 **JEOSIE**: End of injected sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of injected sequence of conversions interrupt.

0: JEOS interrupt disabled

1: JEOS interrupt enabled. An interrupt is generated when the JEOS bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 5 **JEOCIE**: End of injected conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of an injected conversion interrupt.

0: JEOC interrupt disabled.

1: JEOC interrupt enabled. An interrupt is generated when the JEOC bit is set.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 4 **OVRIE**: Overrun interrupt enable

This bit is set and cleared by software to enable/disable the Overrun interrupt of a regular conversion.

0: Overrun interrupt disabled

1: Overrun interrupt enabled. An interrupt is generated when the OVR bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 3 **EOSIE**: End of regular sequence of conversions interrupt enable

This bit is set and cleared by software to enable/disable the end of regular sequence of conversions interrupt.

0: EOS interrupt disabled

1: EOS interrupt enabled. An interrupt is generated when the EOS bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 2 **EOCIE**: End of regular conversion interrupt enable

This bit is set and cleared by software to enable/disable the end of a regular conversion interrupt.

0: EOC interrupt disabled.

1: EOC interrupt enabled. An interrupt is generated when the EOC bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 1 **EOSMPIE**: End of sampling flag interrupt enable for regular conversions

This bit is set and cleared by software to enable/disable the end of the sampling phase interrupt for regular conversions.

0: EOSMP interrupt disabled.

1: EOSMP interrupt enabled. An interrupt is generated when the EOSMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 0 **ADRDYIE**: ADC ready interrupt enable

This bit is set and cleared by software to enable/disable the ADC Ready interrupt.

0: ADRDY interrupt disabled

1: ADRDY interrupt enabled. An interrupt is generated when the ADRDY bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.3 ADC control register (ADC_CR)

Address offset: 0x008

Reset value: 0x2000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ADCAL	ADCALDIF	DEEPPWD	ADVREGEN	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rs	rw	rw	rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	JADSTP	ADSTP	JADSTART	ADSTART	ADDIS	ADEN
										rs	rs	rs	rs	rs	rs

Bit 31 **ADCAL**: ADC calibration

This bit is set by software to start the calibration of the ADC. Program first the bit ADCALDIF to determine if this calibration applies for single-ended or differential inputs mode.

It is cleared by hardware after calibration is complete.

0: Calibration complete

1: Write 1 to calibrate the ADC. Read at 1 means that a calibration in progress.

Note: The software is allowed to launch a calibration by setting ADCAL only when ADEN = 0.

The software is allowed to update the calibration factor by writing ADC_CALFACT only when ADEN = 1 and ADSTART = 0 and JADSTART = 0 (ADC enabled and no conversion is ongoing)

Bit 30 **ADCALDIF**: Differential mode for calibration

This bit is set and cleared by software to configure the single-ended or differential input mode for the calibration.

0: Single-ended input calibration mode when ADCAL = 1

1: Differential input calibration mode when ADCAL = 1

Note: The software is allowed to write this bit only when the ADC is disabled and is not calibrating (ADCAL = 0, JADSTART = 0, JADSTP = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bit 29 **DEEPPWD**: Deep-power-down enable

This bit is set and cleared by software to put the ADC in Deep-power-down mode.

0: ADC not in Deep-power down

1: ADC in Deep-power-down (default reset state)

Note: The software is allowed to write this bit only when the ADC is disabled (ADCAL = 0 and ADEN =0).

Bit 28 **ADVREGEN**: ADC internal voltage regulator enable

This bits is set by software to enable the ADC internal voltage regulator.

Before performing any operation such as launching a calibration or enabling the ADC, the ADC voltage regulator must first be enabled and the software must wait for the regulator start-up time.

0: ADC internal voltage regulator disabled

1: ADC internal voltage regulator enabled.

For more details about the ADC voltage regulator enable and disable sequences, refer to *Section 26.4.6: ADC Deep-power-down mode (DEEPPWD) and ADC voltage regulator (ADVREGEN)*.

The software can program this bit field only when the ADC is disabled (ADCAL = 0, JADSTART=0, ADSTART=0, ADSTP=0, ADDIS=0 and ADEN=0).

Bits 27:6 Reserved, must be kept at reset value.

Bit 5 **JADSTP**: ADC stop of injected conversion command

This bit is set by software to stop and discard an ongoing injected conversion (JADSTP command).

It is cleared by hardware when the conversion is effectively discarded and the ADC injected sequence and triggers can be reconfigured. The ADC is then ready to accept a new start of injected conversions (JADSTART command).

When a software trigger is used, JADSTART bit is cleared by hardware, but JADSTP bit must be programmed to reconfigure the ADC.

0: No ADC stop injected conversion command ongoing

1: Write 1 to stop injected conversions ongoing. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use JADSTP).

Bit 4 **ADSTP**: ADC stop of regular conversion command

This bit is set by software to stop and discard an ongoing regular conversion (ADSTP command).

It is cleared by hardware when the conversion is effectively discarded. and the ADC regular sequence and triggers can be re-configured. The ADC is then ready to accept a new start of regular conversions (ADSTART command).

When a software trigger is used, ADSTART bit is cleared by hardware. However it is necessary to write ADSTP bit to reconfigure the ADC.

0: No ADC stop regular conversion command ongoing

1: Write 1 to stop ongoing regular conversions. Read 1 means that an ADSTP command is in progress.

Note: In autoinjection mode (JAUTO = 1), setting ADSTP bit aborts both regular and injected conversions (do not use ADSTP).

Bit 3 **JADSTART**: ADC start of injected conversion

This bit is set by software to start ADC conversion of injected channels. Depending on the configuration bits JEXTEN[1:0], a conversion starts immediately (software trigger configuration) or once an injected hardware trigger event occurs (hardware trigger configuration).

- In single conversion mode when software trigger is selected (JEXTSEL = 0x0 and JDISEN = 1), this bit is cleared by hardware immediately after injected conversion starts.
- In all cases, after the execution of the JADSTP command, this bit and JADSTP are cleared by hardware simultaneously.

0: No ADC injected conversion is ongoing.

1: Write 1 to start injected conversions. Read 1 means that the ADC is operating and eventually converting an injected channel.

Note: The software is allowed to set JADSTART only when ADEN = 1, ADDIS = 0 and JAUTO = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared).

Bit 2 **ADSTART**: ADC start of regular conversion

This bit is set by software to start ADC conversion of regular channels. Depending on the configuration bits EXTEN[1:0], a conversion starts immediately (software trigger configuration) or once a regular hardware trigger event occurs (hardware trigger configuration).

- In single conversion mode when software trigger is selected (EXTSEL = 0x0 and DISEN = 1), this bit is cleared by hardware immediately after regular conversion starts.
- In all cases, after the execution of the ADSTP command, this bit and ADSTP are cleared by hardware simultaneously.

0: No ADC regular conversion is ongoing.

1: Write 1 to start regular conversions. Read 1 means that the ADC is operating and eventually converting a regular channel.

Note: The software is allowed to set ADSTART only when ADEN = 1 and ADDIS = 0 (ADC is enabled and there is no pending request to disable the ADC).

Note: In autoinjection mode (JAUTO = 1), regular and autoinjected conversions are started by setting ADSTART bit (JADSTART must be kept cleared)

Bit 1 **ADDIS**: ADC disable command

This bit is set by software to disable the ADC (ADDIS command) and place it into power-down state (OFF state).

It is cleared by hardware once the ADC is effectively disabled (ADEN is also cleared by hardware at this time).

0: no ADDIS command ongoing

1: Write 1 to disable the ADC. Read 1 means that an ADDIS command is in progress.

Note: The software is allowed to set ADDIS only when ADEN = 1, ADDIS = 0 and both ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **ADEN**: ADC enable control

This bit is set by software to enable the ADC. The ADC is effectively ready to operate once the ADRDY flag has been set.

It is cleared by hardware when the ADC is disabled, after the execution of the ADDIS command.

0: ADC is disabled (OFF state)

1: Write 1 to enable the ADC.

Note: The software is allowed to set ADEN only when all the bits of ADC_CR registers are cleared (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0), except for ADVREGEN bit which must be set. In addition, the software must wait for the startup time of the voltage regulator.

26.6.4 ADC configuration register (ADC_CFGR1)

Address offset: 0x00C

Reset value: 0x8000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JQDIS	AWD1CH[4:0]					JAUTO	JAWD1EN	AWD1EN	AWD1SGL	JQM	JDISCEN	DISCNUM[2:0]			DISCEN
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	AUTDLY	CONT	OVRMOD	EXTEN[1:0]		EXTSEL[4:0]					Res.	RES[1:0]		DMNGT[1:0]	
	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw	rw

Bit 31 **JQDIS**: Injected queue disable

This bit is set and cleared by software to disable the injected queue mechanism:

0: Injected queue enabled

1: Injected queue disabled

Note: The software is allowed to write this bit only when ADEN = 0, ADSTART = 0, and JADSTART = 0.

Note: A set or reset of JQDIS bit causes the injected queue to be flushed and the ADC_JSQR register is cleared.

Bits 30:26 **AWD1CH[4:0]**: Analog watchdog 1 channel selection

These bits are set and cleared by software. They select the input channel to be guarded by the analog watchdog.

00000: ADC analog input channel 0 monitored by AWD1

00001: ADC analog input channel 1 monitored by AWD1

.....

10011: ADC analog input channel 19 monitored by AWD1

Others: reserved, must not be used

Note: Some channels are not connected physically. Keep the corresponding AWD1CH[4:0] setting to the reset value.

Note: The channel selected by AWD1CH must be also selected into the SQRi or JSQRi registers.

The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **JAUTO:** Automatic injected group conversion

This bit is set and cleared by software to enable/disable automatic injected group conversion after regular group conversion.

0: Automatic injected group conversion disabled

1: Automatic injected group conversion enabled

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 24 **JAWD1EN**: Analog watchdog 1 enable on injected channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on injected channels

1: Analog watchdog 1 enabled on injected channels

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 23 **AWD1EN**: Analog watchdog 1 enable on regular channels

This bit is set and cleared by software

0: Analog watchdog 1 disabled on regular channels

1: Analog watchdog 1 enabled on regular channels

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 22 **AWD1SGL**: Enable the watchdog 1 on a single channel or on all channels

This bit is set and cleared by software to enable the analog watchdog on the channel identified by the AWD1CH[4:0] bits or on all the channels

0: Analog watchdog 1 enabled on all channels

1: Analog watchdog 1 enabled on a single channel

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 21 **JQM**: ADC_JSQR queue mode

This bit is set and cleared by software.

It defines how an empty Queue is managed.

0: ADC_JSQR mode 0: The Queue is never empty and maintains the last written configuration to ADC_JSQR.

1: ADC_JSQR mode 1: The Queue can be empty and when this occurs, the software and hardware triggers of the injected sequence are both internally disabled just after the completion of the last valid injected sequence.

Refer to *Section 26.4.23: Queue of context for injected conversions* for more information.

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Bit 20 **JDISCEN:** Discontinuous mode on injected channels

This bit is set and cleared by software to enable/disable discontinuous mode on the injected channels of a group.

0: Discontinuous mode on injected channels disabled

1: Discontinuous mode on injected channels enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no injected conversion is ongoing).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: When dual mode is enabled (DUAL bits of ADCC_CCR register are not equal to zero), the JDISCEN bit of the slave ADC is not valid and controlled by the JDISCEN bit of the master ADC.

Bits 19:17 **DISCNUM[2:0]:** Discontinuous mode channel count

These bits are written by software to define the number of regular channels to be converted in discontinuous mode, after receiving an external trigger.

000: 1 channel

001: 2 channels

...

111: 8 channels

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCNUM[2:0] bits of the slave ADC are not valid and controlled by the DISCNUM[2:0] bits of the master ADC.

Bit 16 **DISCEN**: Discontinuous mode for regular channels

This bit is set and cleared by software to enable/disable discontinuous mode for regular channels.

0: Discontinuous mode for regular channels disabled

1: Discontinuous mode for regular channels enabled

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: It is not possible to use autoinjection mode and discontinuous mode simultaneously: the DISCEN and JDISCEN bits must be kept cleared by software when JAUTO is set.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When regular dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the DISCEN bit of the slave ADC is not valid and controlled by the DISCEN bit of the master ADC.

Bit 15 Reserved, must be kept at reset value.

Bit 14 **AUTDLY**: Delayed conversion mode

This bit is set and cleared by software to enable/disable the autodelayed conversion mode.

0: Autodelayed conversion mode off

1: Autodelayed conversion mode on

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: When dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the AUTDLY bit of the slave ADC is not valid and controlled by the AUTDLY bit of the master ADC.

Bit 13 **CONT**: Single/continuous conversion mode for regular conversions

This bit is set and cleared by software. If it is set, regular conversion takes place continuously until it is cleared.

0: Single conversion mode

1: Continuous conversion mode

Note: It is not possible to have both discontinuous mode and continuous mode enabled: DISCEN and CONT cannot both be set (DISCEN takes priority).

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: When regular dual mode is enabled (DUAL bits in ADCC_CCR register are not equal to zero), the CONT bit of the slave ADC is not valid and controlled by the CONT bit of the master ADC.

Bit 12 **OVRMOD**: Overrun mode

This bit is set and cleared by software and configure the way data overrun is managed.

0: ADC_DR register is preserved with the old data when an overrun is detected.

1: ADC_DR register is overwritten with the last conversion result when an overrun is detected.

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 11:10 **EXTEN[1:0]**: External trigger enable and polarity selection for regular channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of a regular group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 9:5 **EXTSEL[4:0]**: External trigger selection for regular group

These bits select the external event used to trigger the start of conversion of a regular group:

00000: adc_ext_trg0
00001: adc_ext_trg1
00010: adc_ext_trg2
00011: adc_ext_trg3
00100: adc_ext_trg4
00101: adc_ext_trg5
00110: adc_ext_trg6
00111: adc_ext_trg7
...
11111: adc_ext_trg31

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bits 3:2 **RES[1:0]**: Data resolution

These bits are written by software to select the resolution of the conversion.

00: 12-bit
01: 10-bit
10: 8-bit
11: 6-bit

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 1:0 **DMNGT[1:0]**: Data management configuration

These bits are set and cleared by software to select how the ADC interface output data are managed.

00: Regular conversion data stored in DR only
01: DMA one-shot mode selected
10: Reserved
11: DMA circular mode selected

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no conversion is ongoing).

26.6.5 ADC configuration register 2 (ADC_CFGR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LSHIFT[3:0]				Res.	Res.	OVSR[9:0]									
rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMPTRIG	SWTRIG	BULB	Res.	Res.	ROVSM	TROVS	OVSS[3:0]				Res.	PDIFFREF	PDIFF	Res.	ROVSE
rw	rw	rw			rw	rw	rw	rw	rw	rw		rw	rw		rw

Bits 31:28 **LSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift
1000: 8-bit left shift
1001: 9-bit left shift
1010: 10-bit left shift
1011: 11-bit left shift
1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **OVSR[9:0]**: Oversampling ratio

This bitfield is set and cleared by software to define the oversampling ratio.

0: 1x (no oversampling)
1: 2x
2: 3x
...
1023: 1024x

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 15 **SMPTRIG**: Sampling time control trigger mode

This bit is set and cleared by software to enable the sampling time control trigger mode.

0: Sampling time control trigger mode disabled
1: Sampling time control trigger mode enabled

If EXTEN[1:0] bits are set to 01, the sampling time starts on the trigger rising edge, and the conversion starts on the trigger falling edge.

The SMPTRIG bit must not be set when the BULB bit is set.

When EXTEN[1:0] bits are set to 00, set SWTRIG to start the sampling.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with sampling time control trigger mode*.*

Bit 14 **SWTRIG**: Software trigger bit for sampling time control trigger mode

This bit is set and cleared by software to trigger the conversion in sampling time control trigger mode.

0: Software trigger starts the conversion for sampling time control trigger mode
1: Software trigger starts the sampling for *sampling time control trigger mode*

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing), SMPTRIG = 1, and EXTEN[0:1] = 00.

Bit 13 **BULB**: Bulb sampling mode

This bit is set and cleared by software to enable the bulb sampling mode.

0: Bulb sampling mode disabled

1: Bulb sampling mode enabled. The sampling period starts just after the previous end of conversion.

BULB bit must not be set when the SWTRIG bit is set.

The very first ADC conversion is performed with the sampling time specified in SMPx bits.

Note: The software is allowed to write this bit only when ADEN = 0. When the discontinuous mode is used, only DISCNUM[2:0] = 000 configuration is compatible with bulb mode.

Bits 12:11 Reserved, must be kept at reset value.

Bit 10 **ROVSM**: Regular oversampling mode

This bit is set and cleared by software to select the regular oversampling mode.

0: Continued mode: When injected conversions are triggered, the oversampling is temporary stopped and continued after the injection sequence (oversampling buffer is maintained during injected sequence)

1: Resumed mode: When injected conversions are triggered, the current oversampling is aborted and resumed from start after the injection sequence (oversampling buffer is zeroed by injected sequence start)

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing). It is recommended to clear both JOVSE and GCOMP when ROVSM = 0.

Bit 9 **TROVS**: Triggered regular oversampling

This bit is set and cleared by software to enable triggered oversampling

0: All oversampled conversions for a channel are done consecutively following a trigger

1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **OVSS[3:0]**: Oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift

0001: 1-bit shift

0010: 2-bit shift

0011: 3-bit shift

0100: 4-bit shift

0101: 5-bit shift

0110: 6-bit shift

0111: 7-bit shift

1000: 8-bit shift

1001: 9-bit shift

1010: 10-bit shift

Other: reserved, must not be used

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing).

Bit 4 Reserved, must be kept at reset value.

Bit 3 **PDIFFREF**: Pseudodifferential mode reference voltage selection

This bit is set and cleared by software to select the reference voltage used in pseudodifferential mode.

0: V_{REF-}

1: $V_{REF+}/2$

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 2 **PDIFF**: Pseudodifferential mode enable

This bit is set and cleared by software to enable/disable the pseudodifferential mode.

0: Standard differential mode selected

1: Pseudodifferential mode selected

Note: The software is allowed to write this bit only when ADEN = 0.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **ROVSE**: Regular oversampling enable

This bit is set and cleared by software to enable regular oversampling.

0: Regular oversampling disabled

1: Regular oversampling enabled

Note: The software is allowed to write this bit only when ADSTART = 0 (which ensures that no conversion is ongoing)

26.6.6 ADC sample time register 1 (ADC_SMPR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP9[2:0]			SMP8[2:0]			SMP7[2:0]			SMP6[2:0]			SMP5[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP5[0]	SMP4[2:0]			SMP3[2:0]			SMP2[2:0]			SMP1[2:0]			SMP0[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 9 to 0)

These bits are written by software to select the sampling time individually for each channel. During sample cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles

001: 4.5 ADC clock cycles

010: 7.5 ADC clock cycles

011: 12.5 ADC clock cycles

100: 24.5 ADC clock cycles

101: 47.5 ADC clock cycles

110: 256.5 ADC clock cycles

111: 848.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

26.6.7 ADC sample time register 2 (ADC_SMPR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SMP19[2:0]			SMP18[2:0]			SMP17[2:0]			SMP16[2:0]			SMP15[2:1]	
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SMP15[0]	SMP14[2:0]			SMP13[2:0]			SMP12[2:0]			SMP11[2:0]			SMP10[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:0 **SMPx[2:0]:** Channel x sampling time selection (x = 19 to 10)

These bits are written by software to select the sampling time individually for each channel. During sampling cycles, the channel selection bits must remain unchanged.

000: 2.5 ADC clock cycles
001: 4.5 ADC clock cycles
010: 7.5 ADC clock cycles
011: 12.5 ADC clock cycles
100: 24.5 ADC clock cycles
101: 47.5 ADC clock cycles
110: 256.5 ADC clock cycles
111: 848.5 ADC clock cycles

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically. Keep the corresponding SMPx[2:0] setting to the reset value.

26.6.8 ADC channel preselection register (ADC_PCSEL)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PCSEL[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PCSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **PCSEL[19:0]**: Channel i ($V_{INP[i]}$) preselection

These bits are written by software to preselect the input channel I/O to be converted.

0: Input channel i ($V_{INP[i]}$) is not preselected for conversion, the result of the ADC conversion for this channel is wrong

1: Input channel i ($V_{INP[i]}$) is preselected for conversion

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Configuring the PCSEL bit is not necessary for the internal channels (such as VREFINT).

26.6.9 ADC regular sequence register 1 (ADC_SQR1)

Address offset: 0x030

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ4[4:0]					Res.	SQ3[4:0]					Res.	SQ2[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ2[3:0]				Res.	SQ1[4:0]					Res.	Res.	LEN[3:0]			
rw	rw	rw	rw		rw	rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ4[4:0]:** 4th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ3[4:0]:** 3rd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ2[4:0]:** 2nd conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ1[4:0]:** 1st conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 1st in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **LEN[3:0]:** Regular channel sequence length
These bits are written by software to define the total number of conversions in the regular channel conversion sequence.
0000: 1 conversion
0001: 2 conversions
...
1111: 16 conversions
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.10 ADC regular sequence register 2 (ADC_SQR2)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ9[4:0]					Res.	SQ8[4:0]					Res.	SQ7[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ7[3:0]				Res.	SQ6[4:0]					Res.	SQ5[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ9[4:0]:** 9th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 9th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ8[4:0]:** 8th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 8th in the regular conversion sequence
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ7[4:0]:** 7th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 7th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ6[4:0]:** 6th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 6th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ5[4:0]:** 5th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 5th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.11 ADC regular sequence register 3 (ADC_SQR3)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	SQ14[4:0]					Res.	SQ13[4:0]					Res.	SQ12[4]
			rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SQ12[3:0]				Res.	SQ11[4:0]					Res.	SQ10[4:0]				
rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:24 **SQ14[4:0]:** 14th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 14th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 23 Reserved, must be kept at reset value.

Bits 22:18 **SQ13[4:0]:** 13th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 13th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 17 Reserved, must be kept at reset value.

Bits 16:12 **SQ12[4:0]:** 12th conversion in regular sequence

These bits are written by software with the channel number (0 to 19) assigned as the 12th in the regular conversion sequence.

Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 11 Reserved, must be kept at reset value.

Bits 10:6 **SQ11[4:0]:** 11th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 11th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ10[4:0]:** 10th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 10th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.12 ADC regular sequence register 4 (ADC_SQR4)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

					rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:6 **SQ16[4:0]:** 16th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 16th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Bit 5 Reserved, must be kept at reset value.

Bits 4:0 **SQ15[4:0]:** 15th conversion in regular sequence
These bits are written by software with the channel number (0 to 19) assigned as the 15th in the regular conversion sequence.
Note: The software is allowed to write these bits only when ADSTART = 0 (which ensures that no regular conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.13 ADC regular data register (ADC_DR)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA[31:0]**: Regular data converted

These bits are read-only. They contain the conversion result from the last converted regular channel. The data are left- or right-aligned as described in *Section 26.4.28: Data management*.

26.6.14 ADC injected sequence register (ADC_JSQR)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
JSQ4[4:0]					Res.	JSQ3[4:0]					Res.	JSQ2[4:1]			
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
JSQ2[0]	Res.	JSQ1[4:0]					JEXTEN[1:0]		JEXTSEL[4:0]					JLEN[1:0]	
rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 **JSQ4[4:0]:** 4th conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 4th in the injected conversion sequence.

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bit 26 Reserved, must be kept at reset value.

Bits 25:21 **JSQ3[4:0]:** 3rd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 3rd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bit 20 Reserved, must be kept at reset value.

Bits 19:15 **JSQ2[4:0]:** 2nd conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 2nd in the injected conversion sequence.

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **JSQ1[4:0]:** 1st conversion in the injected sequence

These bits are written by software with the channel number (0 to 19) assigned as the 1st in the injected conversion sequence.

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bits 8:7 **JEXTEN[1:0]**: External trigger enable and polarity selection for injected channels

These bits are set and cleared by software to select the external trigger polarity and enable the trigger of an injected group.

00: Hardware trigger detection disabled (conversions can be launched by software)

01: Hardware trigger detection on the rising edge

10: Hardware trigger detection on the falling edge

11: Hardware trigger detection on both the rising and falling edges

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bits 6:2 **JEXTSEL[4:0]**: External trigger selection for injected group

These bits select the external event used to trigger the start of conversion of an injected group:

00000: adc_jext_trg0

00001: adc_jext_trg1

00010: adc_jext_trg2

00011: adc_jext_trg3

00100: adc_jext_trg4

00101: adc_jext_trg5

00110: adc_jext_trg6

00111: adc_jext_trg7

...

11111: adc_jext_trg31

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Bits 1:0 **JLEN[1:0]:** Injected channel sequence length

These bits are written by software to define the total number of conversions in the injected channel conversion sequence.

00: 1 conversion

01: 2 conversions

10: 3 conversions

11: 4 conversions

Note: The software is allowed to write these bits only when JQDIS = 0 or when JADSTART = 0 and JQDIS = 1 (which ensures that no injected conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for conversion.

26.6.15 ADC offset y configuration register (ADC_OFCFGRy)

Address offset: 0x050 + 0x004 * (y -1), (y = 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OFFSET_CH[4:0]					SSAT	USAT	POS OFF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:27 **OFFSET_CH[4:0]:** Channel selection for the data offset y

These bits are written by software to define the channel to which the offset programmed in bits OFFSET[21:0] applies.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the data offset y.

Bit 26 **SSAT**: Signed saturation enable

This bit is set and cleared by software to enable the signed saturation feature.(see *Section : Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*).

0: Offset is subtracted maintaining the data integrity and extending converted data size (13-bit signed format)

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 25 **USAT**: Unsigned saturation enable

This bit is set and cleared by software to enable the unsigned saturation feature.

0: Offset is subtracted maintaining the data integrity

1: Offset is subtracted and result is saturated to maintain the converted data size

Note: The software is allowed to write these bits only when ADSTART = and JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 24 **POSOFF**: Positive offset enable

This bit is set and cleared by software to enable the positive offset

0: Negative offset

1: Positive offset

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 23:0 Reserved, must be kept at reset value.

26.6.16 ADC offset y register (ADC_OFRy)

Address offset: 0x060 + 0x004 * (y -1), (y= 1 to 4)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

OFFSET[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bits 21:0 **OFFSET[21:0]:** Data offset y for the channel programmed in OFFSETy_CH[4:0] bits

These bits are written by software to define the offset y to be subtracted from the raw converted data when converting a channel (can be regular or injected). The channel to which applies the data offset y must be programmed in the OFFSETy_CH[4:0] bits. The conversion result can be read from in the ADC_DR (regular conversion) or from in the ADC_JDRyi registers (injected conversion).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.17 ADC gain compensation register (ADC_GCOMP)

Address offset: 0x070

Reset value: 0x0000 1000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
G COMP	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	GCOMPCOEFF[13:0]													
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GCOMP:** Gain compensation mode

This bit is set and cleared by software to enable the Gain compensation mode.

0: Regular ADC operation mode

1: Gain compensation enabled and applied on all channels.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing)

Bits 30:14 Reserved, must be kept at reset value.

Bits 13:0 **GCOMPCOEFF[13:0]:** Gain compensation coefficient

These bits are set and cleared by software to program the gain compensation coefficient.

00 1000 0000 0000: gain factor of 0.5

...

01 0000 0000 0000: gain factor of 1

10 0000 0000 0000: gain factor of 2

11 0000 0000 0000: gain factor of 3

...

The coefficient is divided by 4096 to get the gain factor ranging from 0 to 3.9999756

Note: This gain compensation is only applied when GCOMP bit is set.

Note: The software is allowed to write this bit only when ADSTART = 0 and JADSTART = 0 (which ensure that no conversion is ongoing).

26.6.18 ADC analog watchdog y source channel register (ADC_AWDySR)

Address offset: 0x070 + 0x004 * (y -1), (y = 1 to 3)

Reset value: 0x0000 0000

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDS_CH[19:0]:** Analog watchdog source for channel *i* (V_{INP}[i])

These bits are set by hardware when channel *i* has generated the flag. They are cleared by software by writing 1 to it, or by setting the ADDIS bit. Each bit corresponds to the input channel that created the analog watchdog flag.

26.6.19 ADC injected channel y data register (ADC_JDRy)

Address offset: 0x080 + 0x004 * (y - 1), (y = 1 to 4)

Reset value: 0x0000 0000

						rw	rw	rw	rw	rw			rw	rw	rw

Bits 31:28 **JLSHIFT[3:0]**: Left shift factor

This bitfield is set and cleared by software to define the left shifting applied to the final result with or without oversampling.

0000: No left shift
0001: 1-bit left shift
0010: 2-bit left shift
0011: 3-bit left shift
0100: 4-bit left shift
0101: 5-bit left shift
0110: 6-bit left shift
0111: 7-bit left shift

1100: 12-bit left shift
1101: 13-bit left shift
1110: 14-bit left shift
1111: 15-bit left shift

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 27:26 Reserved, must be kept at reset value.

Bits 25:16 **JOVSR[9:0]**: Injected channel oversampling ratio

This bitfield is set and cleared by software to define the injected channel oversampling ratio.

00 0000 0000: 1x (no oversampling)

00 0000 0001-11 1111 1111: {val+1}x

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 15:10 Reserved, must be kept at reset value.

Bit 9 **TJOVS**: Triggered injected channel oversampling

This bit is set and cleared by software to enable triggered injected channel oversampling.

0: All oversampled conversions for a channel are done consecutively following a trigger
1: Each oversampled conversion for a channel needs a new trigger

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 8:5 **JOVSS[3:0]**: Injected channel oversampling shift

This bitfield is set and cleared by software to define the right shifting applied to the raw oversampling result.

0000: No shift
0001: Shift 1-bit
0010: Shift 2-bits
0011: Shift 3-bits
0100: Shift 4-bits
0101: Shift 5-bits
0110: Shift 6-bits
0111: Shift 7-bits
1000: Shift 8-bits
Others: reserved

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 4:3 Reserved, must be kept at reset value.

Bit 2 **JOVSIVE**: Injected oversampling intermediate value enable

This bit is set and cleared by software to enable the access to the injected oversampling intermediate value on JDATA register.

0: Injected oversampling intermediate data not available on JDATA
1: Injected oversampling intermediate data available on JDATA

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 1 **JOVSE**: Injected oversampling enable

This bit is set and cleared by software to enable injected oversampling.

0: Injected oversampling disabled
1: Injected oversampling enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing).

Bit 0 **JOVSPAR**: Parallel injected oversampling enable

This bit is set and cleared by software to enable parallel injected oversampling.

0: Parallel Injected oversampling disabled
1: Parallel Injected oversampling enabled

Note: The software is allowed to write this bit only when JADSTART = 0 (which ensures that no conversion is ongoing), it is necessary to set JOVSE bit when JOVSPAR bit set.

26.6.21 ADC injected oversampling counter register 1 (ADC_JOVSCR1)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						r	r	r	r	r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **JOVSC2[9:0]:** Oversampling counter number for injected channel 2
This bitfield is set by hardware and cleared by hardware when JADSTART or ADDIS is set.
00 0000 0000: No oversampling or oversampling conversion finished
00 0000 0001 - 11 1111 1111: Number of remaining conversions to complete the oversampling

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **JOVSC1[9:0]:** Oversampling counter number for injected channel 1
This bitfield is set by hardware and cleared by hardware when JADSTART or ADDIS is set.
00 0000 0000: No oversampling or oversampling conversion finished
00 0000 0001 - 11 1111 1111: Number of remaining conversions to complete the oversampling

26.6.22 ADC injected oversampling counter register 2 (ADC_JOVSCR2)

Address offset: 0x098

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

						r	r	r	r	r	r	r	r	r	r

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:16 **JOVSC4[9:0]:** Oversampling counter number for injected channel 4
This bitfield is set by hardware and cleared by hardware when JADSTART or ADDIS is set.
00 0000 0000: Number of remaining conversions to complete the oversampling
00 0000 0001 - 11 1111 1111: Number of remaining conversions to complete the oversampling

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **JOVSC3[9:0]:** Oversampling counter number for injected channel 3
This bitfield is set by hardware and cleared by hardware when JADSTART or ADDIS is set.
00 0000 0000: No oversampling or oversampling conversion finished
00 0000 0001 - 11 1111 1111: Number of remaining conversions to complete the oversampling

26.6.23 ADC analog watchdog 2 configuration register (ADC_AWD2CR)

Address offset: 0x0A0

Reset value: 0x0000 0000

AWDCH[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 2 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 2.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD2

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD2

When AWDCH[19:0] = 000..0, the analog Watchdog 2 is disabled

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

26.6.24 ADC analog watchdog 3 configuration register (ADC_AWD3CR)

Address offset: 0x0A4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **AWDCH[19:0]**: Analog watchdog 3 channel selection

These bits are set and cleared by software. They enable and select the input channels to be guarded by the analog watchdog 3.

AWDCH[i] = 0: ADC analog input channel i is not monitored by AWD3

AWDCH[i] = 1: ADC analog input channel i is monitored by AWD3

When AWDCH[19:0] = 000..0, the analog Watchdog 3 is disabled.

Note: The channels selected by AWDCH must be also selected in the SQi or JSQi bits.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Note: Some channels are not connected physically and must not be selected for the analog watchdog.

26.6.25 ADC analog watchdog 1 lower threshold register (ADC_AWD1LTR)

Address offset: 0x0A8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:0 **LTR[22:0]**: Analog watchdog 1 lower threshold

These bits are set and cleared by software to define the lower threshold for analog watchdog 1.
Refer to *Section 26.4.30: Analog window watchdog (AWD1EN, JAWD1EN, AWD1SGL, AWD1CH, AWDCH of ADC_AWD2CR and ADC_AWD3CR, HTR, LTR, AWDFILT).*

26.6.26 ADC analog watchdog 1 higher threshold register (ADC_AWD1HTR)

Address offset: 0x0AC

Reset value: 0x003F FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
AWDFILT[2:0]			Res.	Res.	Res.	Res.	Res.	Res.	HTR[22:16]						
rw	rw	rw							rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.
000: No filtering, one detection generates an AWD1 flag or an interrupt
001: two consecutive detections generate an AWD1 flag or an interrupt
...
111: Eight consecutive detections generate an AWD1 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 1 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 1.
Refer to *Analog windows watchdog* section.

26.6.27 ADC analog watchdog 2 lower threshold register (ADC_AWD2LTR)

Address offset: 0x0B0

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.

000: No filtering, one detection generates an AWD2 flag or an interrupt

001: two consecutive detections generate an AWD2 flag or an interrupt

...

111: Eight consecutive detections generate an AWD2 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 2 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 2. Refer to *Analog windows watchdog* section.

26.6.29 ADC analog watchdog 3 lower threshold register (ADC_AWD3LTR)

Address offset: 0x0B8

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

HTR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:29 **AWDFILT[2:0]**: Analog watchdog filtering parameter

These bits are set and cleared by software.

000: No filtering, one detection generates an AWD3 flag or an interrupt

001: two consecutive detections generate an AWD3 flag or an interrupt

...

111: Eight consecutive detections generate an AWD3 flag or an interrupt

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

Bits 28:23 Reserved, must be kept at reset value.

Bits 22:0 **HTR[22:0]**: Analog watchdog 3 higher threshold

These bits are set and cleared by software to define the higher threshold for analog watchdog 3. Refer to *Analog windows watchdog* section.

26.6.31 ADC differential mode selection register (ADC_DIFSEL)

Address offset: 0x0C0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIFSEL[19:16]			
												rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIFSEL[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	r

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **DIFSEL[19:0]:** Differential mode for channels 19 to 0.

These bits are set and cleared by software. They allow to select if a channel is configured as single-ended or differential or pseudodifferential mode.

DIFSEL[i] = 0: ADC analog input channel is configured in single-ended mode

DIFSEL[i] = 1: ADC analog input channel i is configured in differential or pseudodifferential mode

Note: The DIFSEL bits corresponding to channels that are either connected to a single-ended I/O port or to an internal channel must be kept their reset value (single-ended input mode).

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (which ensures that no conversion is ongoing).

26.6.32 ADC calibration factors (ADC_CALFACT)

Address offset: 0x0C4

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_D[6:0]						
									rw	rw	rw	rw	rw	rw	rw

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALFACT_S[6:0]						
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:16 **CALFACT_D[6:0]**: Calibration factors in differential mode

These bits are written by hardware or by software.

Once a differential input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new differential conversion is launched.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

Bits 15:7 Reserved, must be kept at reset value.

Bits 6:0 **CALFACT_S[6:0]**: Calibration factors In single-ended mode

These bits are written by hardware or by software.

Once a single-ended input calibration is complete, they are updated by hardware with the calibration factors.

The software can write these bits with a new calibration factor. If the new calibration factor is different from the current one stored in the analog ADC, it is applied once a new single-ended conversion is launched.

Note: The software is allowed to write these bits only when ADSTART = 0 and JADSTART = 0 (ADC is enabled, no calibration is ongoing and no conversion is ongoing).

This bit can only be cleared by a power-on reset.

26.6.33 ADC option register (ADC_OR)

Address offset: 0x0D0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OP7	OP6	OP5	OP4	OP3	OP2	OP1	OP0
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **OP7:** Option bit 7

This bit is set and cleared by software to select the optional trigger source
Condition: ADC1 and ADC2
0: Reserved
1: Reserved
Condition: ADC3
0: adc_jext_trg9 = tim8_oc4
1: adc_jext_trg9 = tim4_trgo

Note: The software is allowed to write this bit only when the JADSTART = 0.

Bit 6 **OP6:** Option bit 6

This bit is set and cleared by software to select the optional trigger source
Condition: ADC1 and ADC2
0: adc_jext_trg9 = tim3_trgo
1: adc_jext_trg9 = tim4_trgo. This bit affects both ADC1 and ADC2.
Condition: ADC3
0: adc_jext_trg8 = tim8_oc2
1: adc_jext_trg8 = tim4_oc3

Note: The software is allowed to write this bit only when the JADSTART = 0.

Bit 5 **OP5:** Option bit 5

This bit is set and cleared by software to select the optional trigger source
0: adc_ext_trg9 = tim3_trgo
1: adc_ext_trg9 = tim4_trgo. This bit affects both ADC1 and ADC2; ADC3 has independent control.

Note: The software is allowed to write this bit only when the ADSTART = 0.

Bit 4 **OP4:** Option bit 4

This bit is set and cleared by software to select the optional trigger source
Condition: ADC1 and ADC2
0: adc_ext_trg8 = tim3_oc4
1: adc_ext_trg8 = tim4_oc4. This bit affects both ADC1 and ADC2
Condition: ADC3
0: adc_ext_trg8 = tim3_oc2
1: adc_ext_trg8 = tim4_oc1

Note: The software is allowed to write this bit only when the ADSTART = 0.

Bit 3 **OP3:** Option bit 3

This bit is set and cleared by software to enable/disable the internal reference buffer.

0: Internal reference buffer disabled

1: Internal reference buffer enabled

Note: The software is allowed to write this bit only when the ADC is disabled.

Bit 2 **OP2:** Option bit 2

This bit is set and cleared by software to select the redundancy bit.

0: Redundancy on bit 5

1: Redundancy on bit 3

Note: The software is allowed to write this bit only when the ADC is disabled.

Bit 1 **OP1:** Option bit 1

This bit is set and cleared by software to enable/disable the redundancy.

0: Redundancy enabled

1: Redundancy disabled

Note: The software is allowed to write this bit only when the ADC is disabled.

Bit 0 **OP0:** Option bit 0

This bit is set and cleared by software to enable/disable the V_{DDCORE} channel.

0: V_{DDCORE} disabled

1: V_{DDCORE} enabled

26.7 ADC common registers

These registers define the control and status registers common to master and slave ADCs.

26.7.1 ADC common status register (ADCC_CSR)

Address offset: 0x000

Reset value: 0x0000 0000

This register provides an image of the flags of the different ADCs. Nevertheless it is read-only and does not allow to clear the different flags. Instead each flag must be cleared by writing 0 to it in the corresponding ADC_ISR register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	LDORDY_SLV	Res.	JQOVF_SLV	AWD3_SLV	AWD2_SLV	AWD1_SLV	JEOS_SLV	JEOC_SLV	OVR_SLV	EOS_SLV	EOC_SLV	EOSMP_SLV	ADRDY_SLV
			r		r	r	r	r	r	r	r	r	r	r	r

			r		r	r	r	r	r	r	r	r	r	r	r

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **LDORDY_SLV:** ADC internal voltage regulator flag of the slave ADC

This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bit 27 Reserved, must be kept at reset value.

Bit 26 **JQOVF_SLV:** Injected context queue overflow flag of the slave ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 25 **AWD3_SLV:** Analog watchdog 3 flag of the slave ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 24 **AWD2_SLV:** Analog watchdog 2 flag of the slave ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 23 **AWD1_SLV:** Analog watchdog 1 flag of the slave ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 22 **JEOS_SLV:** End of injected sequence flag of the slave ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 21 **JEOC_SLV:** End of injected conversion flag of the slave ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 20 **OVR_SLV:** Overrun flag of the slave ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 19 **EOS_SLV:** End of regular sequence flag of the slave ADC. This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 18 **EOC_SLV:** End of regular conversion of the slave ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 17 **EOSMP_SLV:** End of sampling phase flag of the slave ADC
This bit is a copy of the EOSMP2 bit in the corresponding ADC_ISR register.

Bit 16 **ADRDY_SLV:** Slave ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **LDORDY_MST:** ADC internal voltage regulator flag of the master ADC
This bit is a copy of the LDORDY bit in the corresponding ADC_ISR register.

Bit 11 Reserved, must be kept at reset value.

Bit 10 **JQOVF_MST:** Injected context queue overflow flag of the master ADC
This bit is a copy of the JQOVF bit in the corresponding ADC_ISR register.

Bit 9 **AWD3_MST:** Analog watchdog 3 flag of the master ADC
This bit is a copy of the AWD3 bit in the corresponding ADC_ISR register.

Bit 8 **AWD2_MST:** Analog watchdog 2 flag of the master ADC
This bit is a copy of the AWD2 bit in the corresponding ADC_ISR register.

Bit 7 **AWD1_MST:** Analog watchdog 1 flag of the master ADC
This bit is a copy of the AWD1 bit in the corresponding ADC_ISR register.

Bit 6 **JEOS_MST:** End of injected sequence flag of the master ADC
This bit is a copy of the JEOS bit in the corresponding ADC_ISR register.

Bit 5 **JEOC_MST:** End of injected conversion flag of the master ADC
This bit is a copy of the JEOC bit in the corresponding ADC_ISR register.

Bit 4 **OVR_MST:** Overrun flag of the master ADC
This bit is a copy of the OVR bit in the corresponding ADC_ISR register.

Bit 3 **EOS_MST:** End of regular sequence flag of the master ADC
This bit is a copy of the EOS bit in the corresponding ADC_ISR register.

Bit 2 **EOC_MST:** End of regular conversion of the master ADC
This bit is a copy of the EOC bit in the corresponding ADC_ISR register.

Bit 1 **EOSMP_MST:** End of Sampling phase flag of the master ADC
This bit is a copy of the EOSMP bit in the corresponding ADC_ISR register.

Bit 0 **ADRDY_MST:** Master ADC ready
This bit is a copy of the ADRDY bit in the corresponding ADC_ISR register.

26.7.2 ADC common control register (ADCC_CCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TSEN	VREFEN	Res.	Res.	Res.	Res.	Res.	Res.
								rw	rw						

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DAMDF[1:0]		Res.	Res.	DELAY[3:0]				Res.	Res.	Res.	DUAL[4:0]				
rw	rw			rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TSEN**: Temperature sensor voltage enable
This bit is set and cleared by software to control V_{SENSE} channel.
0: Temperature sensor channel disabled
1: Temperature sensor channel enabled
Note: The temperature sensor is not available on all ADC instances. Refer to Section 26.4.4: ADC connectivity for details.
Note: The software is allowed to write this bit only when ADEN = 0.

Bit 22 **VREFEN**: V_{REFINT} enable
This bit is set and cleared by software to enable/disable the V_{REFINT} channel.
0: V_{REFINT} channel disabled
1: V_{REFINT} channel enabled
Note: V_{REFINT} is not available on all ADC instances. Refer to Section 26.4.4: ADC connectivity for details.
Note: The software is allowed to write this bit only when ADEN = 0.

Bits 21:16 Reserved, must be kept at reset value.

Bits 15:14 **DAMDF[1:0]:** Dual ADC mode data format

This bitfield are set and cleared by software. It specifies the data format in the common data register ADCC_CDR and ADCC_CDR2.

00: Dual ADC mode without data packing (ADCC_CDR and ADCC_CDR2 registers not used).

01: Reserved

10: Data formatting mode for any data width (ADCC_CDR data register is used when the data width is less than 16 bits, otherwise ADCC_CDR2 register is used)

11: Data formatting mode for data width lower that 8 bits (ADCC_CDR data register is used)

Note: The software is allowed to write these bits only when ADEN = 0 (ADC is disabled).

Bit 13 Reserved, must be kept at reset value.

Bit 12 Reserved, must be kept at reset value.

Bits 11:8 **DELAY[3:0]:** Delay between two sampling phases

These bits are set and cleared by software. These bits are used in dual interleaved modes. Refer to *Table 238* for the value of ADC resolution versus DELAY bits values.

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DUAL[4:0]:** Dual ADC mode selection

These bits are written by software to select the operating mode.

All the ADCs independent:

00000: Independent mode

The following settings apply to dual mode, master and slave ADCs working together

00001: Combined regular simultaneous + Injected simultaneous mode

00010: Combined regular simultaneous + Alternate trigger mode

00011: Combined interleaved mode + Injected simultaneous mode

00101: Injected simultaneous mode only

00110: Regular simultaneous mode only

00111: Interleaved mode only

01001: Alternate trigger mode only

Others: Reserved

All other combinations are reserved and must not be programmed

Note: The software is allowed to write these bits only when the ADCs are disabled (ADCAL = 0, JADSTART = 0, ADSTART = 0, ADSTP = 0, ADDIS = 0 and ADEN = 0).

26.7.3 ADC common regular data register for dual mode (ADCC_CDR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RDATA_SLV[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

RDATA_MST[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 **RDATA_SLV[15:0]:** Regular data of the slave ADC

In dual mode, these bits contain the regular data of the slave ADC. Refer to *Section 26.4.33: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

Bits 15:0 **RDATA_MST[15:0]**: Regular data of the master ADC.

In dual mode, these bits contain the regular data of the master ADC. Refer to *Section 26.4.33: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

In MDMA=0b11 mode, bits 15:8 contains SLV_ADC_DR[7:0], bits 7:0 contains MST_ADC_DR[7:0].

26.7.4 ADC common regular data register for dual mode (ADCC_CDR2)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RDATA_ALT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RDATA_ALT[31:0]**: Regular data of the master/slave alternated ADCs.

In dual mode, these bits contain the regular 32-bit data of the master and the slave ADC. Refer to *Section 26.4.33: Dual ADC modes*.

The data alignment is applied as described in *Data register, data alignment and offset (ADC_DR, ADC_JDRy, OFFSETy, OFFSETy_CH, OVSS, LSHIFT, JOVSS, JLSHIFT[a], USAT, SSAT, POSOFF)*)

26.8 ADC register map

ADC1 and ADC3 are master ADCs.

ADC2 operates as a slave from ADC1.

Table 240. ADC register map and reset values for each ADC

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

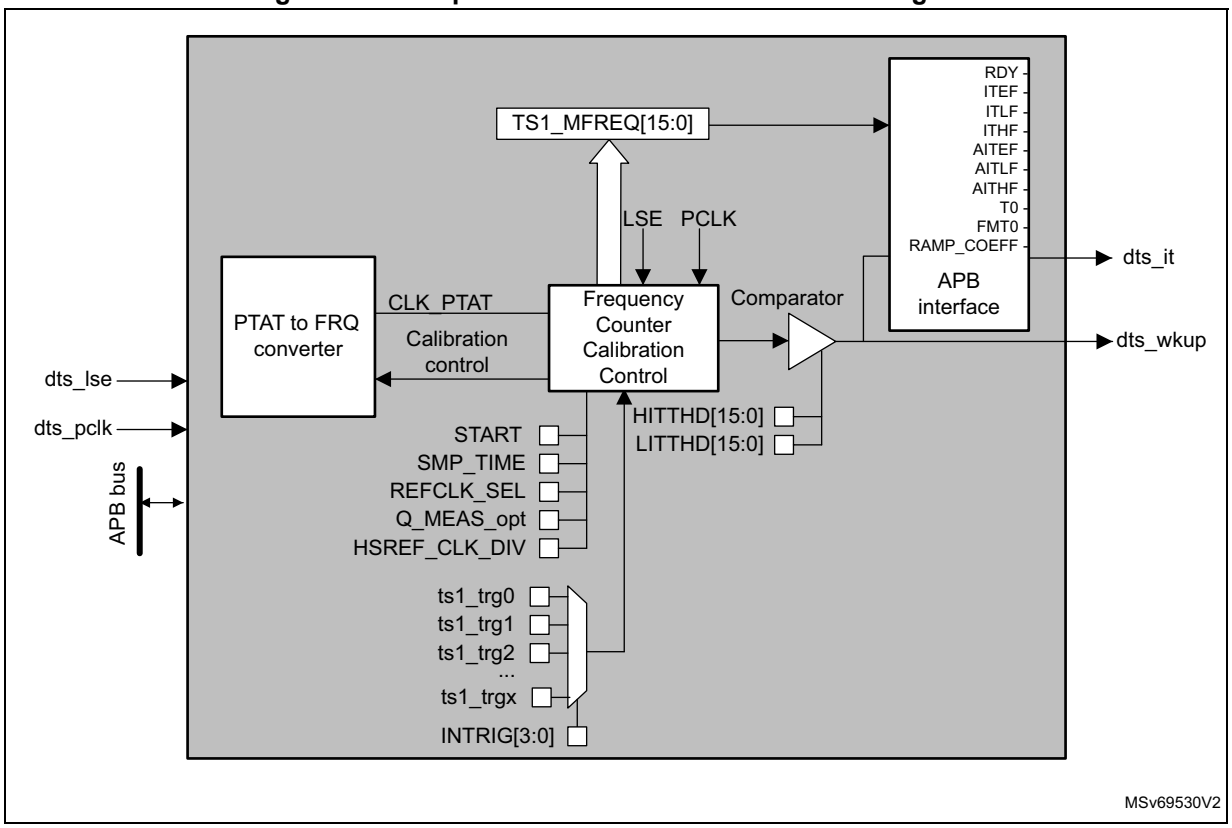
27 Digital temperature sensor (DTS)

27.1 DTS introduction

The device embeds a sensor that converts the temperature into a square wave which frequency is proportional to the temperature. The frequency is measured either with the PCLK or the LSE clock.

27.2 DTS main features

The temperature sensor block main features are the following:



- Start of measurement triggered by software or 4 hardware sources
- Programmable sampling time to increase temperature measurement precision
- Counter synchronized on LSE or PCLK clock
- Temperature watchdog on low and high threshold
- Interrupt generation when the temperature is lower or higher than predefined thresholds and at the end of measurement.
- Asynchronous wake-up signal generation when the temperature is higher/lower than a predefined threshold (LSE mode only)
- Quick measurement using LSE clock

27.3 DTS functional description

27.3.1 DTS block diagram

The temperature sensor block diagram is shown in *Figure 262*.

Figure 262. Temperature sensor functional block diagram

27.3.2 DTS internal signals

Table 242. DTS internal input/output signals

Signal name	Signal type	Description
dts_lse	Digital input	LSE clock
dts_pclk	Digital input	APB clock
dts_it	Digital output	Temperature sensor interrupt
dts_wkup	Digital output	Temperature sensor wake-up

27.3.3 DTS block operation

The analog part of the temperature sensor outputs a frequency that is proportional to the absolute temperature (CLK_PTAT). The frequency measurement is based on the PCLK or the LSE clock.

Before each measurement, the temperature sensor performs a calibration of the frequency generation blocks.

27.3.4 Operating modes

Several operating modes can be selected by setting the REFCLK_SEL bit in *Temperature sensor configuration register 1 (DTS_CFGR1)*:

- PCLK only (REFCLK_SEL = 0)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using PCLK clock
- PCLK and LSE (REFCLK_SEL = 1)

  The temperature sensor registers can be accessed. The interface can consequently be reconfigured and the measurement sequence is performed using the LSE clock.
- LSE only (REFCLK_SEL = 1) and PCLK OFF

  The registers cannot be accessed. The measurement can be performed using the LSE clock. This mode is used to exit from Sleep mode by using hardware triggers and the asynchronous interrupt line.

27.3.5 Calibration

The temperature sensor must run the calibration prior to any frequency measurement. The calibration is performed automatically when the temperature measurement is triggered except for quick measurement mode (Q_MEAS_OPT set to 1 in DTS_CFGR1).

27.3.6 Prescaler

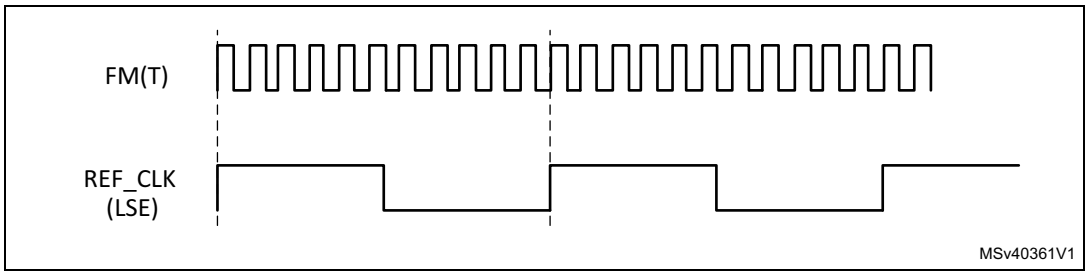
When a calibration is ongoing, the counter clock must be slower than 1 MHz. This is achieved by the PCLK clock prescaler embedded in the temperature sensor.

During the temperature measurement period, the prescaler is bypassed.

- When PCLK is used as reference clock (REFCLK_SEL set to 0 in DTS_CFGR1), a prescaler is used. Its division ratio must be configured up to 127 (refer to the HSREF_CLK_DIV[6:0] register definition for the divider setting).
- When LSE is used as reference clock (REFCLK_SEL set to 1 in DTS_CFGR1), the timebase is equal to 2 LSE periods. In this case, no prescaler is used.

27.3.7 Temperature measurement principles

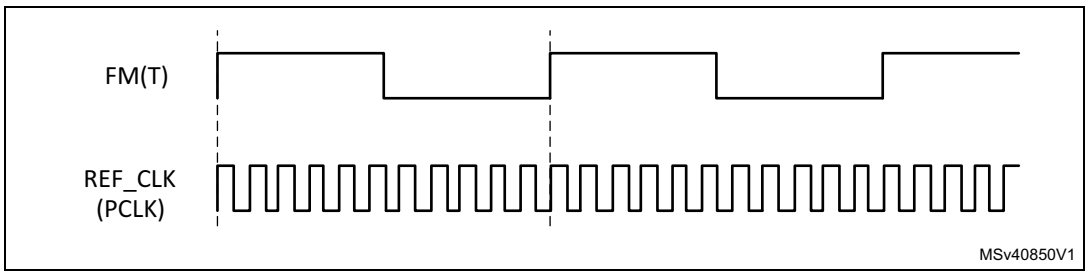
The analog part of temperature sensor outputs a signal (CLK_PTAT) which FM(T) frequency is temperature-dependent.



Either PCLK or LSE can be selected as reference clock (REF_CLK) through the REFCLK_SEL bit in DTS_CFGR1.

The counting method depends on the REF_CLK frequency. This is due to the fact that two counters are implemented in the temperature sensor block:

- For low REF_CLK frequencies, a counting of FM(T) cycles is performed during one or several REF_CLK cycles.
- For high REF_CLK frequencies, a counting of REF_CLK cycles is performed during one or several FM(T) cycles.



This counter behavior is shown in *Figure 263* and *Figure 264*.

Figure 263. Method for low REF_CLK frequencies

1. To increase the precision, FM(T) measurement can be done on several LSE periods.

Figure 264. Method for high REF_CLK frequencies

1. To increase the precision, PCLK measurement can be done on several FM(T) periods.

The counting result is stored in the DTS_DR register (see *Temperature sensor data register (DTS_DR)*.

Once the FM(T) frequency has been obtained, the corresponding temperature can be calculated by software using the following formula:

- When PCLK is used:

$$T = T_0 + ((F_{PCLK} / TS1_MFREQ) \times TS1_SMP_TIME - 100 \times TS1_FMT0) / TS1_RAMP_COEFF$$

where

T0 (factory calibration temperature) is equal to 30 °C.

TS1_FMT0 is measured and stored in the DTS_T0VALR1 register. It is expressed in hundreds of Hertz.

TS1_RAMP_COEFF is measured during tests in factory and stored in DTS_RAMPVALR register. This value is expressed in Hz/°C.

- When the LSE clock is used

$$T = T_0 + ((F_{LSE} \times TS1_MFREQ / TS1_SMP_TIME) - (100 \times TS1_FMT0)) / TS1_RAMP_COEFF$$

27.3.8 Sampling time

The sampling period can be increased to improve measurement accuracy. This is useful when the reference frequency (REF_CLK) is close to the FM(T) frequency. The default value is one REF_CLK cycle in LSE mode, and one FM(T) cycle in PCLK mode.

The sampling time is configured through TS1_SMP_TIME bits in DTS_CFGR1 register (see *Table 243*).

Table 243. Sampling time configuration

TS1_SMP_TIME[3:0]	LSE or FM(T) clock cycle(s)
0000	1
0001	1
0010	2
0011	3
0100	4
0101	5
0110	6
0111	7
1000	8
1001	9
1010	10
1011	11
1100	12
1101	13
1110	14
1111	15

27.3.9 Quick measurement mode

If a high precision is not required, the calibration step included in each measurement sequence can be skipped by setting Q_MEAS_OPT to 1 in the DTS_CFGR1 register. This method must used only when the LSE clock is selected as reference clock (LSREF_CLK set to 1). This mode can reduce the measurement time.

27.3.10 Trigger input

The temperature measurement can be triggered either by software or by an external event. The trigger source can be selected through TS1_INTRIG[3:0] bits in DTS_CFGR1.

Table 244. Trigger configuration

Name	TS1_INTRIG[3:0]				Comment

ts1_trg13	1	1	1	0	
ts1_trg14	1	1	1	1	

Note: Hardware triggers are active only on the rising edge.

The temperature sensor can only capture a hardware trigger rising edge when TS1_RDY bit is set (see Section 27.3.11: On-off control and ready flag), otherwise the trigger is ignored.

If a trigger source changes on-the-fly, the new trigger source signal must be low. If the new source signal is high, the temperature sensor detects a rising edge and start the measurement sequence.

27.3.11 On-off control and ready flag

The DTS block can be enabled by setting TS1_EN bit in DTS_CFGR1 register. The TS1_RDY flag in the *Temperature sensor status register (DTS_SR)* indicate that the DTS block is ready for temperature measurement: when TS1_RDY bit is set to 1, the measurement can be started. Once a measurement has started, TS1_RDY bit is reset. New measurement requests are then ignored. Once the measurement is finished, TS1_RDY bit is set again to indicate the sensor is ready to start a new measurement.

27.3.12 Temperature measurement sequence

Start of measurement can be triggered by software or hardware.

Software trigger

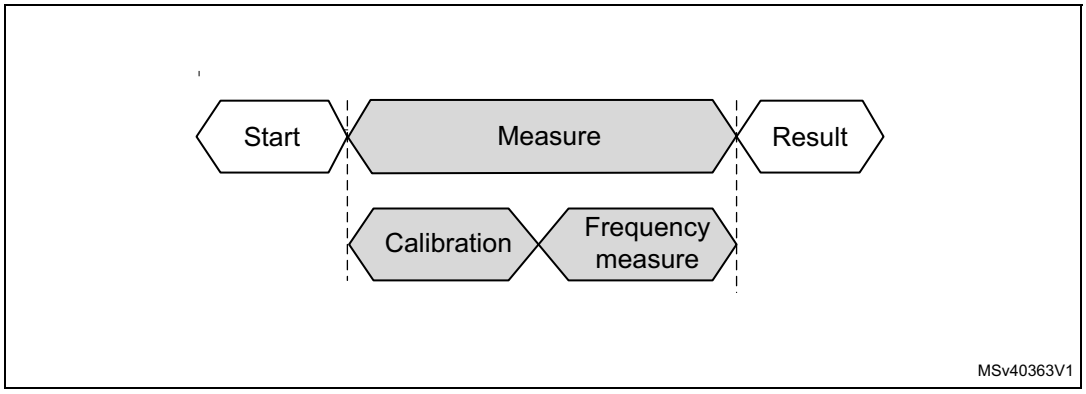
The software trigger is selected when TS1_INTRIG_SEL[3:0] is set to ‘0000’ in DTS_CFGR1.

If TS1_RDY is set to 1, writing TS1_START bit to 1 in DTS_CFGR1 starts the measurement.

If TS1_RDY equals 0, the software trigger does not start until TS1_RDY is set.

If TS1_START bit is kept at 1 once the measurement is finished, then the TS1_RDY flag become 1 and the measurement restarts.

Hardware trigger



TS1_INTRIG_SEL[3:0] bits allow selecting one hardware trigger out of 4. If TS1_RDY is set to 1, a rising edge on the trigger signal starts the measurement. When TS1_RDY is 0, the rising edge is ignored.

Temperature measurement sequence

One measurement contains two steps: the calibration of the analog blocks and the measurement. The calibration automatically starts when the measurement is triggered (see *Section 27.3.5: Calibration*). The measurement period depends on the following DTS_CFGR1 bits:

- the reference clock selected through REFCLK_SEL bit
- the divider ratio configured by HSREF_CLK_DIV bits
- the sampling time defined by TS1_SMP_TIME bits.

Figure 265. Temperature sensor sequence

27.4 DTS low-power modes

Table 245. Temperature sensor behavior in low-power modes

Mode	Description
Sleep	Only works in LSE mode. DTS interrupt causes the device to exit from Sleep mode.
Stop	Only works in LSE mode. DTS interrupt cause the device to exit from Stop mode.

27.5 DTS interrupts

There are two ways to use the DTS block as an interrupt source.The DTS interrupt line can be connected to the EXTI controller (see *Section 27.5.3: Asynchronous wake-up*) or to the CPU NVIC (see *Section 27.5.2: Synchronous interrupt*).

27.5.1 Temperature window comparator

The DTS_ITR1 register allows defining the high and low threshold that are used for temperature comparison. If the temperature data is equal or higher than TS1_HITTHD, or equal or lower than TS1_LITTHD bit, an interrupt is generated and the corresponding flag, TS1_ ITLF, TS1_ITHF, TS1_AITLF and TS1_AITHF, is set in the DTS_SR register (see *Section 27.6.6*).

27.5.2 Synchronous interrupt

A global interrupt output line is available on the DTS block. The interrupt can be generated at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three interrupt events can be select via 3 bits in DTS_ITENR register (see *Section 27.6.7*). All combinations of interrupts are allowed.

The TS1_ITEF, TS1_ITLF and TS1_ITHF flags in the DTS_SR register reflect the interrupt event. They can be reset with the correspond bits of the DTS_ICIFR register (see *Section 27.6.8*).

27.5.3 Asynchronous wake-up

The DTS block also provides an asynchronous interrupt line. It is used only when the LSE is selected as reference clock (REFCLK_SEL=1).

This line can generate a signal that wakes up the system from Sleep mode at the end of measurement and/or when the measurement result is equal/higher or equal/lower than a predefined threshold (see *Section 27.5.1: Temperature window comparator*).

Three asynchronous wake-up events can be selected via 3 bits in DTS_ITENR register. All combination of interrupts are allowed.

The TS1_AITEF, TS1_AITLF and TS1_AITHF flags in the DTS_SR register reflect the interrupt status. They can be reset with the correspond bits of the DTS_ICIFR register.

The following table shows the interrupt bits an the their description.

27.6 DTS registers

The registers of this peripheral can only be accessed by-word (32-bit).

27.6.1 Temperature sensor configuration register 1 (DTS_CFGR1)

DTS_CFGR1 is the configuration register for temperature sensor 1.

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	HSREF_CLK_DIV[6:0]							Res.	Res.	Q_MEAS_OPT	REFCLK_SEL	TS1_SMP_TIME[3:0]			
	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	TS1_INTRIG_SEL[3:0]				Res.	Res.	Res.	TS1_START	Res.	Res.	Res.	TS1_EN
				rw	rw	rw	rw				rw				rw

Bit 31 Reserved, must be kept at reset value.

Bits 30:24 **HSREF_CLK_DIV[6:0]**: High speed clock division ratio

These bits are set and cleared by software. They can be used to define the division ratio for the main clock in order to obtain the internal frequency lower than 1 MHz required for the calibration. They are applicable only for calibration when PCLK is selected as reference clock (REFCLK_SEL=0).

0000000: No divider

0000001: No divider

0000010: 1/2 division ratio

...

1111111: 1/127 division ratio

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **Q_MEAS_OPT**: Quick measurement option bit

This bit is set and cleared by software. It is used to increase the measurement speed by suppressing the calibration step. It is effective only when the LSE clock is used as reference clock (REFCLK_SEL=1).

0: Measurement with calibration

1: Measurement without calibration

Bit 20 **REFCLK_SEL**: Reference clock selection bit

This bit is set and cleared by software. It indicates whether the reference clock is the high speed clock (PCLK) or the low speed clock (LSE).

0: High speed reference clock (PCLK)

1: Low speed reference clock (LSE)

Bits 19:16 **TS1_SMP_TIME[3:0]**: Sampling time for temperature sensor 1
These bits allow increasing the sampling time to improve measurement precision.
When the PCLK clock is selected as reference clock (REFCLK_SEL = 0), the measurement is performed at TS1_SMP_TIME period of CLK_PTAT.
When the LSE is selected as reference clock (REFCLK_SEL = 1), the measurement is performed at TS1_SMP_TIME period of LSE.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TS1_INTRIG_SEL[3:0]**: Input trigger selection bit for temperature sensor 1
These bits are set and cleared by software. They select which input triggers a temperature measurement. Refer to *Section 27.3.10: Trigger input*.

Bits 7:5 Reserved, must be kept at reset value.

Bit 4 **TS1_START:** Start frequency measurement on temperature sensor 1
This bit is set and cleared by software.
0: No software trigger.
1: Software trigger for a frequency measurement. (only if TS1 is ready).

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **TS1_EN:** Temperature sensor 1 enable bit
This bit is set and cleared by software.
0: Temperature sensor 1 disabled
1: Temperature sensor 1 enabled

Note: Once enabled, the temperature sensor is active after a specific delay time. The TS1_RDY flag is set when the sensor is ready.

27.6.2 Temperature sensor T0 value register 1 (DTS_T0VALR1)

DTS_T0VALR1 contains the value of the factory calibration temperature (T0) for temperature sensor 1. The reset value is factory trimmed.

Address offset: 0x08

Reset value: 0x000X XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_T0[1:0]

TS1_FMT0[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bits 17:16 **TS1_T0[1:0]**: Engineering value of the T0 temperature for temperature sensor 1.
00: 30 °C
01: 130 °C
Others: Reserved, must not be used.

Bits 15:0 **TS1_FMT0[15:0]**: Engineering value of the frequency measured at T0 for temperature sensor 1
This value is expressed in 0.1 kHz.

27.6.3 Temperature sensor ramp value register (DTS_RAMPVALR)

The DTS_RAMPVALR is the ramp coefficient for the temperature sensor. The reset value is factory trimmed.

Address offset: 0x10

Reset value: 0xXXXX XXXX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

TS1_RAMP_COEFF[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **TS1_RAMP_COEFF[15:0]**: Engineering value of the ramp coefficient for the temperature sensor 1.

This value is expressed in Hz/°C.

27.6.4 Temperature sensor interrupt threshold register 1 (DTS_ITR1)

DTS_ITR1 contains the threshold values for sensor 1.

Address offset: 0x14

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

TS1_LITTHD[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **TS1_HITTHD[15:0]:** High interrupt threshold for temperature sensor 1

These bits are set and cleared by software. They indicate the highest value than can be reached before raising an interrupt signal.

Bits 15:0 **TS1_LITTHD[15:0]:** Low interrupt threshold for temperature sensor 1

These bits are set and cleared by software. They indicate the lowest value than can be reached before raising an interrupt signal.

27.6.5 Temperature sensor data register (DTS_DR)

The DTS_DR contains the number of REF_CLK cycles used to compute the FM(T) frequency.

Address offset: 0x1C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

r									r	r	r		r	r	r

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **TS1_RDY:** Temperature sensor 1 ready flag
This bit is set and reset by hardware.
It indicates that a measurement is ongoing.
0: Temperature sensor 1 busy
1: Temperature sensor 1 ready

Bits 14:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHF:** Asynchronous interrupt flag for high threshold on temperature sensor 1
This bit is set by hardware when the high threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITHFEN bit is set

Bit 5 **TS1_AITLF:** Asynchronous interrupt flag for low threshold on temperature sensor 1
This bit is set by hardware when the low threshold is reached.
It is cleared by software by writing 1 to the TS1_CAITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_AITLFEN bit is set

Bit 4 **TS1_AITEF:** Asynchronous interrupt flag for end of measure on temperature sensor 1
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS1_CAITEF bit in the DTS_ICIFR register.
0: End of measure not detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_AITEFEN bit is set

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHF:** Interrupt flag for high threshold on temperature sensor 1, synchronized on PCLK
This bit is set by hardware when the high threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITHF bit in the DTS_ICIFR register.
0: High threshold not reached on temperature sensor 1
1: High threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITHFEN bit is set

Bit 1 **TS1_ITLF:** Interrupt flag for low threshold on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when the low threshold is set and reached.
It is cleared by software by writing 1 to the TS1_CITLF bit in the DTS_ICIFR register.
0: Low threshold not reached on temperature sensor 1
1: Low threshold reached on temperature sensor 1
Note: This bit is active only when the TS1_ITLFEN bit is set

Bit 0 **TS1_ITEF:** Interrupt flag for end of measurement on temperature sensor 1, synchronized on PCLK.
This bit is set by hardware when a temperature measure is done.
It is cleared by software by writing 1 to the TS2_CITEF bit in the DTS_ICIFR register.
0: No end of measurement detected on temperature sensor 1
1: End of measure detected on temperature sensor 1
Note: This bit is active only when the TS1_ITEFEN bit is set

27.6.7 Temperature sensor interrupt enable register (DTS_ITENR)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_AITHEN	TS1_AITLEN	TS1_AITEEN	Res.	TS1_ITHEN	TS1_ITLEN	TS1_ITEEN
									rw	rw	rw		rw	rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_AITHEN:** Asynchronous interrupt enable flag on high threshold for temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is above the high threshold (only when REFCLK_SEL= 1")
0: Asynchronous interrupt on high threshold disabled for temperature sensor 1
1: Asynchronous interrupt on high threshold enabled for temperature sensor 1

Bit 5 **TS1_AITLEN:** Asynchronous interrupt enable flag for low threshold on temperature sensor 1.
This bit are set and cleared by software.
It enables the asynchronous interrupt when the temperature is below the low threshold (only when REFCLK_SEL= 1)
0: Asynchronous interrupt on low threshold disabled for temperature sensor 1
1: Asynchronous interrupt on low threshold enabled for temperature sensor 1

Bit 4 **TS1_AITEEN:** Asynchronous interrupt enable flag for end of measurement on temperature sensor 1
This bit are set and cleared by software.
It enables the asynchronous interrupt for end of measurement (only when REFCLK_SEL = 1).
0: Asynchronous interrupt for end of measurement disabled on temperature sensor 1
1: Asynchronous interrupt for end of measurement enabled on temperature sensor 1

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_ITHEN:** Interrupt enable flag for high threshold on temperature sensor 1, synchronized on PCLK.
This bit are set and cleared by software.
It enables the interrupt when the measure reaches or is above the high threshold.
0: Synchronous interrupt for high threshold disabled on temperature sensor 1
1: Synchronous interrupt for high threshold enabled on temperature sensor 1

Bit 1 **TS1_ITLEN:** Interrupt enable flag for low threshold on temperature sensor 1, synchronized on PCLK.
This bit are set and cleared by software.
It enables the synchronous interrupt when the measure reaches or is below the low threshold.
0: Synchronous interrupt for low threshold disabled on temperature sensor 1
1: Synchronous interrupt for low threshold enabled on temperature sensor 1

Bit 0 **TS1_ITEEN:** Interrupt enable flag for end of measurement on temperature sensor 1, synchronized on PCLK.
This bit are set and cleared by software.
It enables the synchronous interrupt for end of measurement.
0: Synchronous interrupt for end of measurement disabled on temperature sensor 1
1: Synchronous interrupt for end of measurement enabled on temperature sensor 1

27.6.8 Temperature sensor clear interrupt flag register (DTS_ICIFR)

DTS_ICIFR is the control register for the interrupt flags.

Address offset: 0x28

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TS1_ CAITHF	TS1_ CAITLF	TS1_ CAITEF	Res.	TS1_ CITHF	TS1_ CITLF	TS1_ CITEF
									rc_w1	rc_w1	rc_w1		rc_w1	rc_w1	rc_w1

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **TS1_CAITHF:** Asynchronous interrupt clear flag for high threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITHF flag in the DTS_SR register.

Bit 5 **TS1_CAITLF:** Asynchronous interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_AITLF flag in the DTS_SR register.

Bit 4 **TS1_CAITEF:** Write once bit. Clear the asynchronous IT flag for End Of Measure for thermal sensor 1.
Writing 1 clears the TS1_AITEF flag of the DTS_SR register.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **TS1_CITHF:** Interrupt clear flag for high threshold on temperature sensor 1
Writing this bit to 1 clears the TS1_ITHF flag in the DTS_SR register.

Bit 1 **TS1_CITLF:** Interrupt clear flag for low threshold on temperature sensor 1
Writing 1 to this bit clears the TS1_ITLF flag in the DTS_SR register.

Bit 0 **TS1_CITEF:** Interrupt clear flag for end of measurement on temperature sensor 1
Writing 1 to this bit clears the TS1_ITEF flag in the DTS_SR register.

27.6.9 Temperature sensor option register (DTS_OR)

The DTS_OR contains general-purpose option bits.

Address offset: 0x2C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

28 Digital-to-analog converter (DAC)

28.1 DAC introduction

The DAC module is a 12-bit, voltage output digital-to-analog converter. The DAC can be configured in 8- or 12-bit mode and may be used in conjunction with the DMA controller. In 12-bit mode, the data can be left- or right-aligned. The DAC features one single channel. Two input reference pins, VREFDAC+ and VREFDAC-, are available for better resolution.

The DACx_OUT1 pin can be used as general purpose input/output (GPIO) when the DAC output is disconnected from output pad and connected to an on-chip peripheral. The DAC output buffer can be optionally enabled to obtain a high drive output current. A calibration can be applied on the buffered DAC output channel. The DAC output channel supports a low power mode, the sample and hold mode.

28.2 DAC main features

The DAC main features are the following (see *Figure 266: DAC block diagram*):

- One DAC interface, one output channel
- Left or right data alignment in 12-bit mode
- Synchronized update capability
- Noise-wave and Triangular-wave generation
- Sawtooth wave generation
- Extended sawtooth wave generation
- DMA capability including DMA underrun error detection
- Double data DMA capability to reduce the bus activity
- External triggers for conversion
- DAC output channel buffered/unbuffered modes
- Buffer offset calibration
- The DAC output can be disconnected from the DACx_OUT1 output pin
- DAC output connection to on-chip peripherals
- Sample and hold mode for low power operation in Stop mode
- Input voltage reference from VREFDAC+ and VREFDAC- pins

Figure 266 shows the block diagram of a DAC channel and *Table 248* gives the pin description.

28.3 DAC implementation

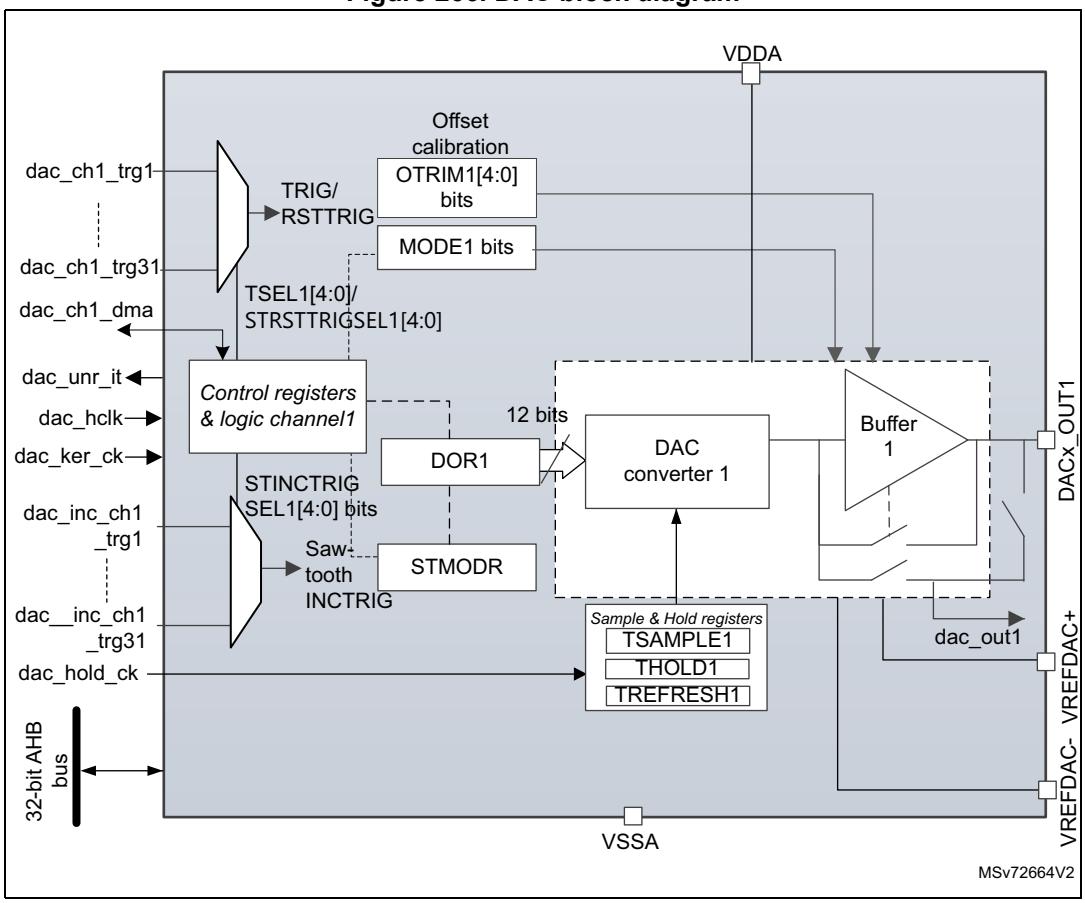

Table 247. DAC features

DAC features	DAC1/2	DAC5/6/7/8/9/10
Dual channel	-	
Output buffer	X	-
I/O connection	DAC1_OUT1 on PA4 DAC2_OUT1 on PA5	-
Maximum sampling time	1 Msps	15 Msps
Autonomous mode	-	
VREFDAC+ pin	X	
Extended sawtooth wave generation	X	
Sample and hold mode	X	-
Option register	-	X

28.4 DAC functional description

28.4.1 DAC block diagram

Figure 266. DAC block diagram

1. MODE1 bits in the DAC_MCR control the output mode and allow switching between the normal mode in buffer/unbuffered configuration and the sample and hold mode.

28.4.2 DAC pins and internal signals

The DAC includes:

- One output channel
- The DACx_OUT1 can be disconnected from the output pin and used as an ordinary GPIO.
- The dac_outx can use an internal pin connection to on-chip peripherals such as comparator, operational amplifier and ADC (if available).
- DAC output channel buffered or non buffered
- Sample and hold block and registers operational in Stop mode, using the LSI/LSE clock source (dac_hold_ck) for static conversion.

The DAC includes one output channel. The output channel can be connected to on-chip peripherals such as comparator, operational amplifier and ADC (if available). In this case,

the DAC output channel can be disconnected from the DACx_OUT1 output pin and the corresponding GPIO can be used for another purpose.

The DAC output can be buffered or not. The sample and hold block and its associated registers can run in Stop mode using the LSI/LSE clock source (dac_hold_ck).

Table 248. DAC input/output pins

Pin name	Signal type	Remarks
VREFDAC+	Input, analog positive reference	The higher/positive reference voltage for the DAC, $V_{REFDAC+} \leq V_{DDAmax}$ (refer to the product datasheet)
VREFDAC-	Input, analog negative reference	The lower/negative reference voltage for the DAC.
VDDA	Input, analog supply	Analog power supply
VSSA	Input, analog supply ground	Ground for analog power supply
DACx_OUT1	Analog output signal	DACx channel1 analog output

Table 249. DAC internal input/output signals

Internal signal name	Signal type	Description
dac_ch1_dma	Bidirectional	DAC channel1 DMA request/acknowledge
dac_ch1_trgx (x = 1 to 31)	Inputs	DAC channel1 trigger inputs
dac_unr_it	Output	DAC underrun interrupt
dac_hclk	Input	DAC peripheral clock
dac_ker_ck	Input	DAC kernel clock
dac_hold_ck	Input	DAC low-power clock used in sample and hold mode
dac_out1	Analog output	DAC channel1 output for on-chip peripherals

28.4.3 DAC channel enable

The DAC channel can be powered on by setting its corresponding EN1 bit in the DAC_CR register. The DAC channel is then enabled after a t_{WAKEUP} startup time.

DACxRDY bit is set in the DAC_SR register when the DAC interface is ready to accept data. Writing new data or asserting the trigger is not allowed when ENx bit is set while DACxRDY signal is reset.

Note: The EN1 bit enables the analog DAC channel1 only. The DAC channel1 digital interface is enabled even if the EN1 bit is reset.

28.4.4 DAC data format

Depending on the selected configuration mode, the data have to be written into the specified register as described below:

- Single DAC channel

  There are three possibilities:

  – 8-bit right alignment: the software has to load data into the DAC_DHR8R1[7:0] bits (stored into the DHR1[11:4] bits)

  – 12-bit left alignment: the software has to load data into the DAC_DHR12L1[15:4] bits (stored into the DHR1[11:0] bits)

  – 12-bit right alignment: the software has to load data into the DAC_DHR12R1[11:0] bits (stored into the DHR1[11:0] bits)

Depending on the loaded DAC_DHRyyyx register, the data written by the user is shifted and stored into the corresponding DAC_DHR1 (data holding registerx, which are internal non-memory-mapped registers). The DAC_DHR1 register is then loaded into the DAC_DOR1 register either automatically, by software trigger or by an external event trigger.

Figure 267. Data registers in single DAC channel mode

Signed/unsigned data

DAC input data are unsigned: 0x000 corresponds to the minimum value and 0xFFF to the maximum value for 12-bit mode.

The DAC can also handle signed input data in 2’s complement format. This is done by setting SINFORMATx bit in the DAC_MCR register.

When SINFORMATx bit is set, the MSB of the data written to DAC_DHRx registers is inverted when it is copied to the DAC_DORx register, and the DAC interface can accept signed data (Q1.15, Q1.11 or Q1.7 format). DAC_DHR12Lx register can be used to store 16-bit signed data in the data holding registers. The 12 MSBs of 16-bit data are used for the DAC output data and the MSB is inverted. The four LSBs are simply ignored.

Table 251. Data format (case of 12-bit data)

SINFORMATx bit	DATA written to DAC_DHRx register	DATA transfered to DAC_DORx register
0	0x000	0x000
0	0xFFF	0xFFF
1	0x7FF	0xFFF
1	0x000	0x800
1	0xFFF	0x7FF
1	0x800	0x000

28.4.5 DAC conversion

The DAC_DOR1 cannot be written directly and any data transfer to the DAC channel1 must be performed by loading the DAC_DHR1 register (write operation to DAC_DHR8R1, DAC_DHR12L1, DAC_DHR12R1).

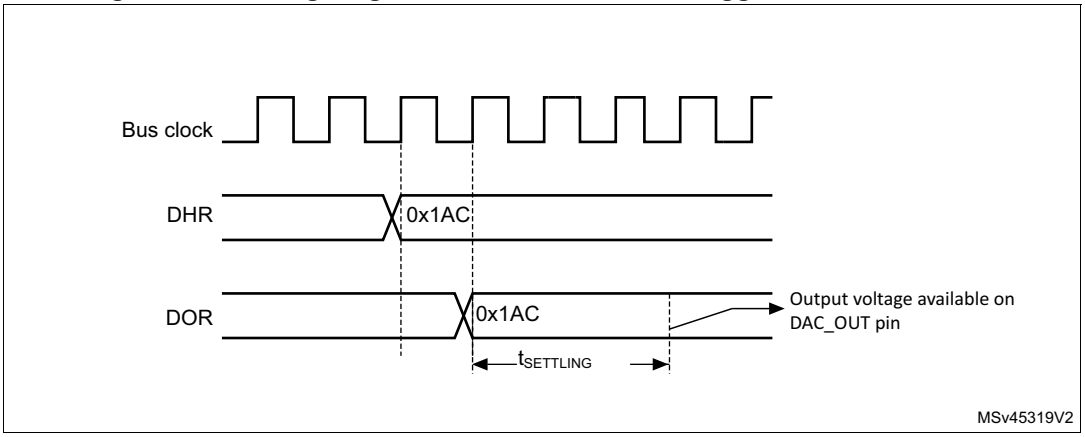
Data stored in the DAC_DHR1 register are automatically transferred to the DAC_DOR1 register after one dac_ker_ck clock cycle, if no hardware trigger is selected (TEN1 bit in DAC_CR register is reset). However, when a hardware trigger is selected (TEN1 bit in DAC_CR register is set) and a trigger occurs, the transfer is performed three dac_ker_ck clock cycles after the trigger signal.

When DAC_DOR1 is loaded with the DAC_DHR1 contents, the analog output voltage becomes available after a time $t_{SETTLING}$ that depends on the power supply voltage and the analog output load.

HFSEL bits of DAC_MCR must be set when dac_ker_ck clock speed is faster than 80 MHz.

Refer to Table *HFSEL description* below for the limitation of the DAC_DORx update rate depending on HFSEL bits and hclk or dac_ker_ck clock frequency.

If the data is updated or a software/hardware trigger event occurs during the non-allowed period, the peripheral behavior is unpredictable.



The above timing is only related to the limitation of the DAC interface. Refer also to the $t_{SETTLING}$ parameter value in the product datasheet.

Table 252. HFSEL description

HFSEL[2:0]	dac_ker_ck frequency	Latency using dac_ker_ck clock	Function
000	< 80 MHz	4	DAC_DOR update rate up to 4 dac_ker_ck cycles.
001	≥ 80 MHz(1)	5	DAC_DOR update rate up to 5 dac_ker_ck cycles.
010	≥ 160 MHz	6	DAC_DOR update rate up to 6 dac_ker_ck cycles.

1. Refer to the device datasheet for the value of the maximum kernel clock frequency.

Figure 268. Timing diagram for conversion with trigger disabled TEN = 0

28.4.6 DAC output voltage

Digital inputs are converted to output voltages on a linear conversion between $V_{REFDAC-}$ and $V_{REFDAC+}$.

The analog output voltage on the DAC channel pin is determined by the following equation:

$$\text{DAC output} = V_{REFDAC} \times \frac{DOR}{4096}$$

where all voltages are expressed in Volt.

$$V_{REFDAC} = V_{REFDAC+} - V_{REFDAC-}$$

28.4.7 DAC trigger selection

If the TEN1 control bit is set, the conversion can then be triggered by an external event (timer counter, external interrupt line). The TSEL1[4:0] control bits determine which out of 32 possible events triggers the conversion as shown in TSEL1[4:0] bits of the DAC_CR register. These events can be either the software trigger or hardware triggers (see the interconnection table in *Section 28.4.2*).

Each time a DAC interface detects a rising edge on the selected trigger source (refer to the table below), the last data stored into the DAC_DHR1 register are transferred into the DAC_DOR1 register. The DAC_DOR1 register is updated three dac_ker_ck cycles after the trigger occurs.

If the software trigger is selected, the conversion starts once the SWTRIG bit is set. SWTRIG is reset by hardware once the DAC_DOR1 register has been loaded with the DAC_DHR1 register contents.

The reset trigger selection and the increment trigger selection of the sawtooth generation are performed through STRSTTRIGSELx and STINCTRIGSELx control bits, respectively. STRSTTRIGSELx mapping is similar to TSELx. Refer to the *Section 28.4.2: DAC pins and internal signals* for TSELx, STRSTTRIGSELx, and STINCTRIGSELx mappings.

Note: TSEL1[4:0] bit cannot be changed when the EN1 bit is set.

When software trigger is selected, the transfer from the DAC_DHR1 register to the DAC_DOR1 register takes only one dac_ker_ck clock cycle.

28.4.8 DMA requests

The DAC channel has a DMA capability. One DMA channel is used to service DAC channel DMA request.

When an external trigger (but not a software trigger) occurs while the DMAEN1 bit is set, the value of the DAC_DHR1 register is transferred into the DAC_DOR1 register when the transfer is complete, and a DMA request is generated.

As DAC_DHR1 to DAC_DOR1 data transfer occurred before the DMA request, the very first data has to be written to the DAC_DHR1 before the first trigger event occurs.

DMA underrun

The DAC DMA request is not queued so that if a second external trigger arrives before the acknowledgment for the first external trigger is received (first request), then no new request is issued and the DMA channel1 underrun flag DMAUDR1 in the DAC_SR register is set, reporting the error condition. The DAC channel1 continues to convert old data.

The software must clear the DMAUDR1 flag by writing 1, clear the DMAEN bit of the used DMA stream and re-initialize both DMA and DAC channel1 to restart the transfer correctly. The software must modify the DAC trigger conversion frequency or lighten the DMA workload to avoid a new DMA underrun. Finally, the DAC conversion can be resumed by enabling both DMA data transfer and conversion trigger.

For DAC channel1, an interrupt is also generated if its corresponding DMAUDRIE1 bit in the DAC_CR register is enabled.

DMA double data mode

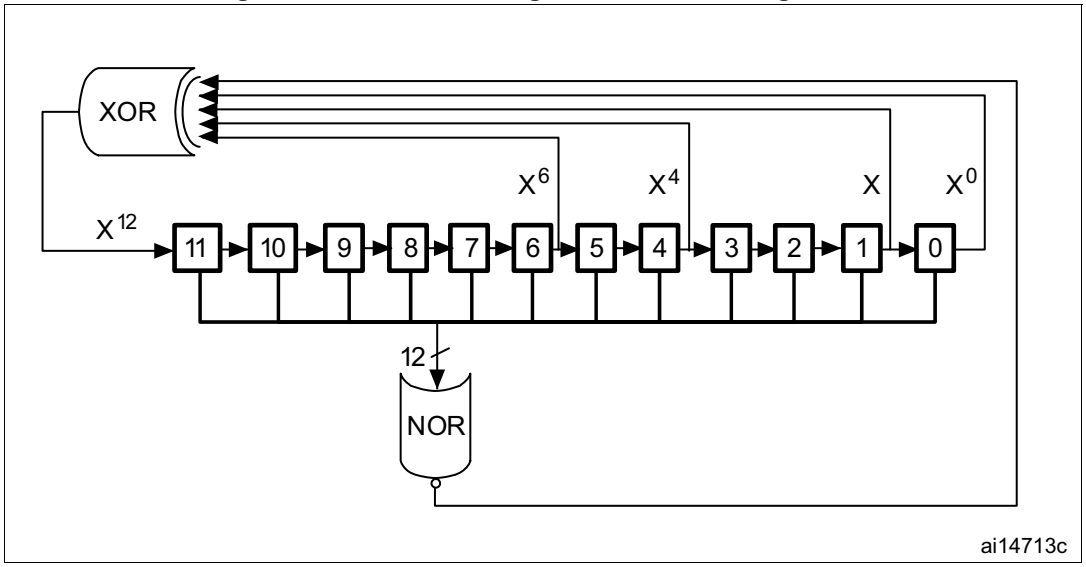
When the DMA controller is used in normal mode, only 12-bit (or 8-bit) data are transferred by a DMA request. As the AHB width is 32 bits, two 12-bit data may be transferred simultaneously. To use this mode, set the DMADOUBLEx bit of DAC_MCR register.

A DAC DMA request is generated every two external triggers (except for software triggers) when the DMAENx bit is set:

1. When the first trigger is detected, the value of the DAC_DHRx and DAC_DHRBx registers are transferred into the DAC_DORx and DAC_DORBx registers. The actual DAC data is loaded into the DAC_DORx register. A DMA request is then generated. The DMA writes the new data to the DAC_DHRx and DAC_DHRBx data registers.
2. When the next trigger is detected, the actual DAC data is loaded into the DAC_DHRBx register. This second trigger does not generate any DMA request. The DORSTATx bit indicates which DOR data is actually loaded into the analog DAC input.

DMA underrun function is also supported in DMA double data mode.

The following conditions must be met to change from double data to single data mode or vice versa:



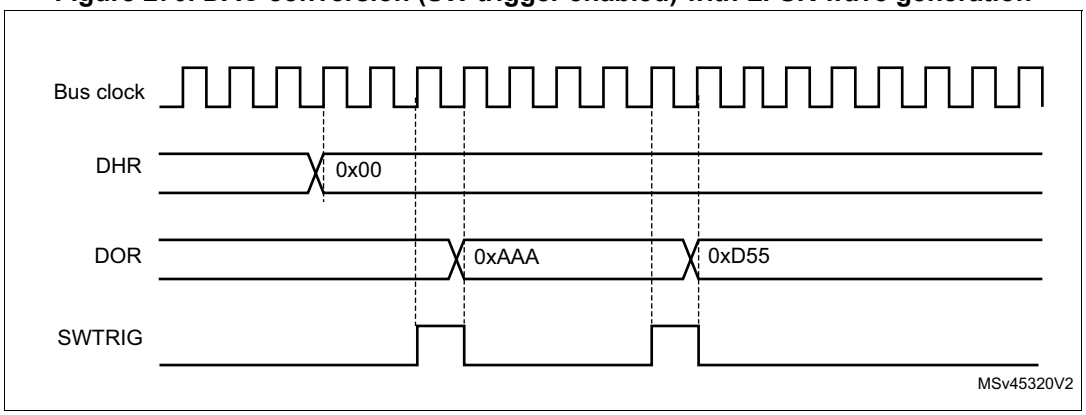
- The DAC must be disabled.
- DMAEN bit must be cleared (ENx = 0 and DMAEN = 0).

28.4.9 Noise generation

In order to generate a variable-amplitude pseudonoise, an LFSR (linear feedback shift register) is available. DAC noise generation is selected by setting WAVE1[1:0] to 01. The

preloaded value in LFSR is 0xAAA. This register is updated three dac_ker_ck clock cycles after each trigger event, following a specific calculation algorithm.

Figure 269. DAC LFSR register calculation algorithm



The LFSR value, that may be masked partially or totally by means of the MAMP1[3:0] bits in the DAC_CR register, is added up to the DAC_DHR1 contents without overflow and this value is then transferred into the DAC_DOR1 register.

If LFSR is 0x0000, a 1 is injected into it (antilock-up mechanism).

It is possible to reset LFSR wave generation by resetting the WAVE1[1:0] bits.

Figure 270. DAC conversion (SW trigger enabled) with LFSR wave generation

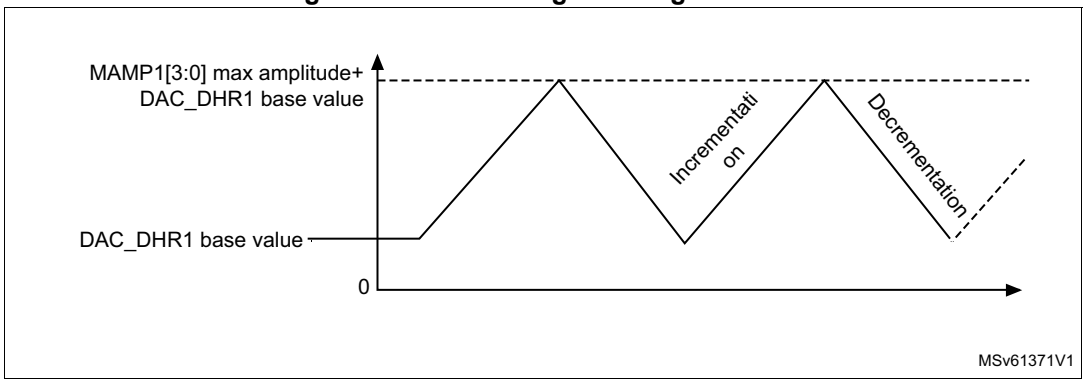
Note: The DAC trigger must be enabled for noise generation by setting the TEN1 bit in the DAC_CR register.

28.4.10 Triangle-wave generation

It is possible to add a small-amplitude triangular waveform on a DC or slowly varying signal. DAC triangle-wave generation is selected by setting WAVE1[1:0] to 10. The amplitude is configured through the MAMP[3:0] bits in the DAC_CR register. An internal triangle counter is incremented three dac_ker_ck clock cycles after each trigger event. The value of this counter is then added to the DAC_DHR1 register without overflow and the sum is transferred into the DAC_DOR1 register. The triangle counter is incremented as long as it is less than the maximum amplitude defined by the MAMP1[3:0] bits. Once the configured amplitude is reached, the counter is decremented down to 0, then incremented again and so on.

It is possible to reset triangle wave generation by resetting the WAVE1[1:0] bits.

Figure 271. DAC triangle wave generation



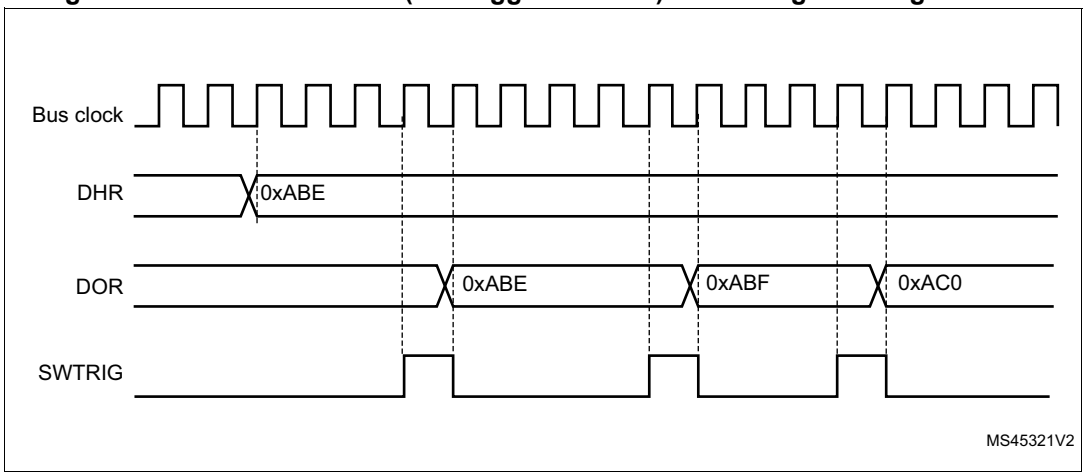


Figure 272. DAC conversion (SW trigger enabled) with triangle wave generation

Note: The DAC trigger must be enabled for triangle wave generation by setting the TEN1 bit in the DAC_CR register.

The MAMP1[3:0] bits must be configured before enabling the DAC, otherwise they cannot be changed.

28.4.11 DAC sawtooth wave generation

The DAC can generate a sawtooth waveform. Specific register settings for the initial value, increment value and direction control are required:

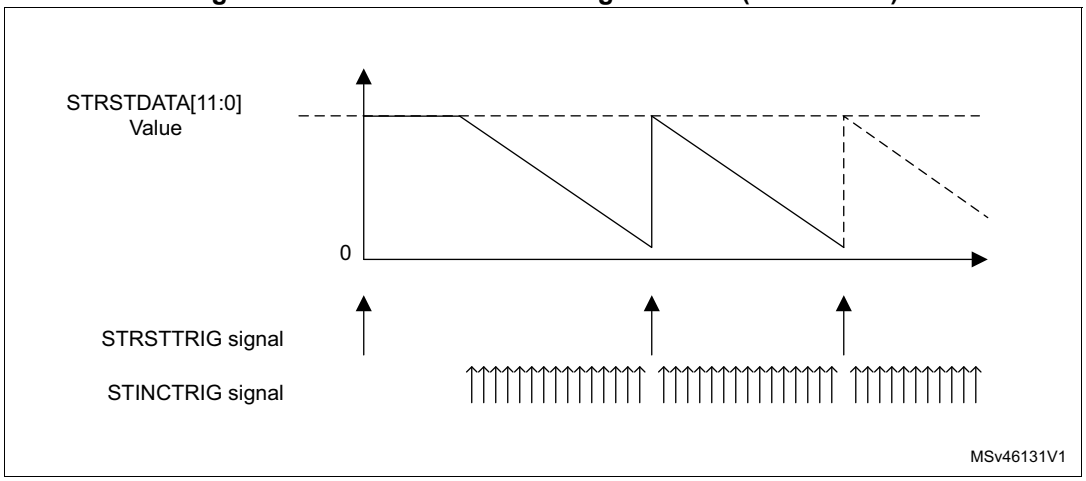
- DAC sawtooth wave generation is selected by setting WAVEx[1:0] to 11 in the DAC_CR register.
- The sawtooth counter initial value (reset value) is configured through STRSTDATAx[11:0] bits in the DAC_STRx register.
- The increment value is defined by the STINCDATAx[15:0] bits in the DAC_STRx register.
- The sawtooth direction is defined by STDIRx bit in the DAC_STRx register.

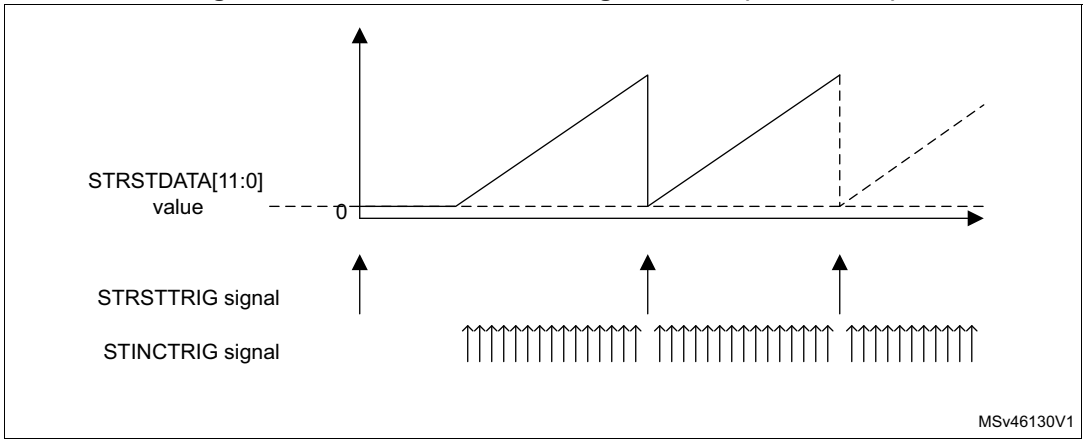
The sawtooth counter starts from STRSTDATAx[11:0] (bits 12 to 15 are set to 0b0000), each increment trigger then increments (or decrements) STINCDATAx[15:0] value.

The DAC output is used from 12 MSBs of those counter value. When the counter reaches 0x0000 or 0xFFFF, the value is saturated. The sawtooth reset trigger signal initializes the counter value to the STRSTDATAx[11:0] (bits 12 to 15 are set to 0b0000) value.

The increment trigger (STINCTRIG) and reset trigger (STRSTTRIG) must be selected through the STINCTRIGSELx[3:0] and the STRSTTRIGSELx[3:0] bits.

Figure 273. DAC sawtooth wave generation (STDIRx = 0)





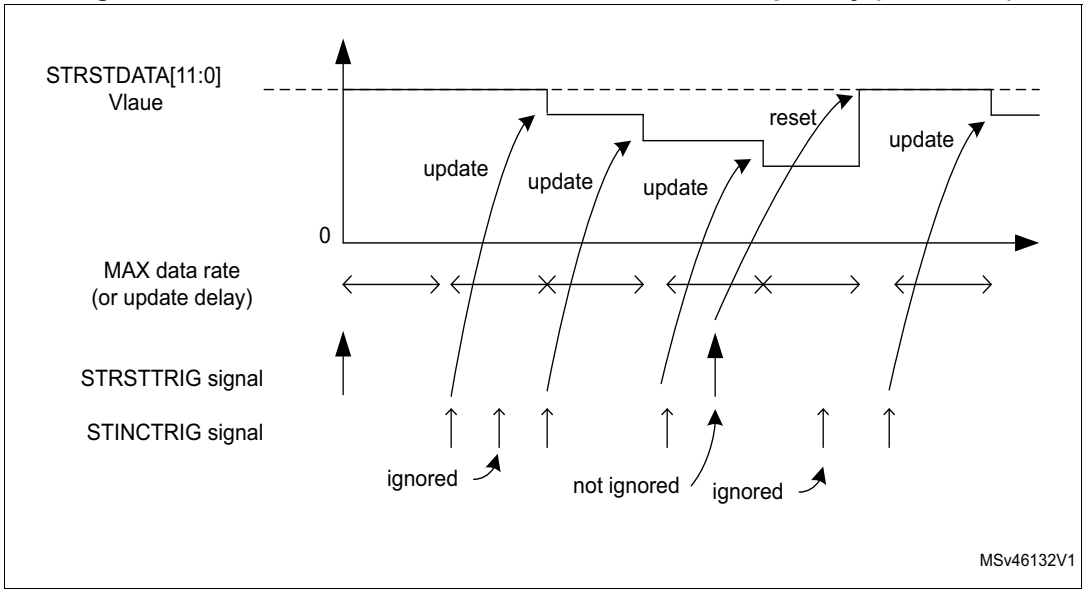


Figure 274. DAC sawtooth wave generation (STDIRx = 1)

The STRSTTRIG signal has higher priority than STINCTRIG. The trigger signal cannot be faster than the DAC_DORx update rate (see *Table HFSEL description - if available - for details)*. If STINCTRIG is asserted faster than the allowed data update rate, the STINCTRIG trigger is ignored. If the STRSTTRIG signal is applied after the STINCTRIG and before DAC_DORx update rate constraints, STRSTTRIG is put on hold. Then, immediately after the data increment, the reset trigger is applied.

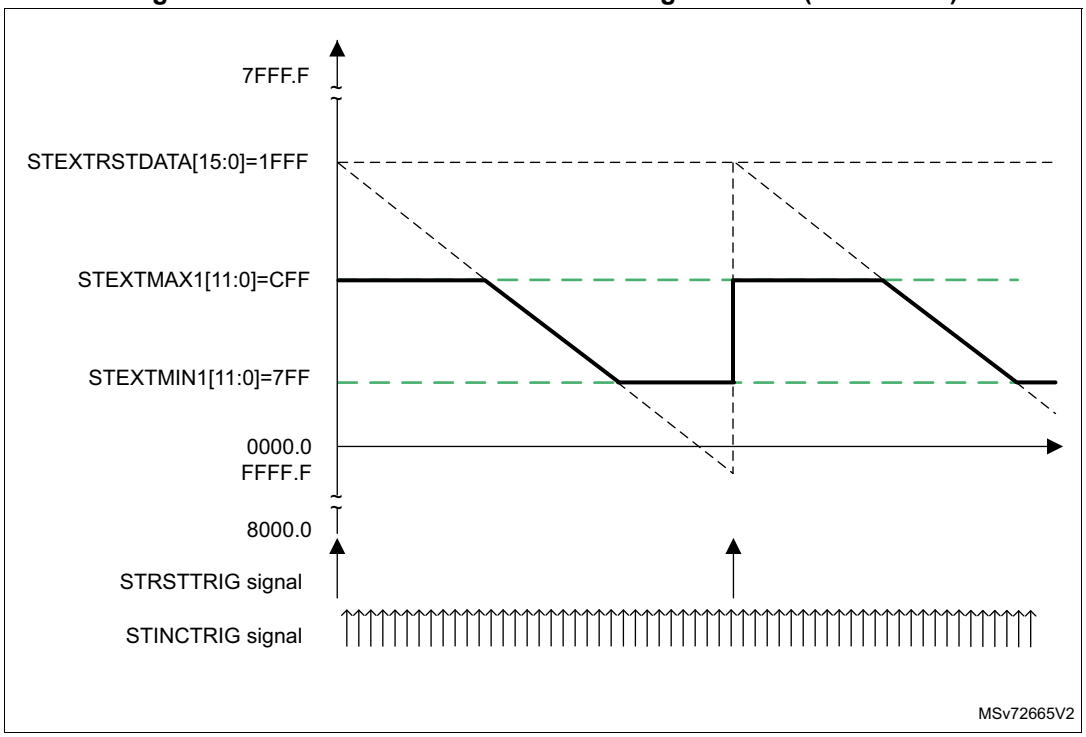
Figure 275. DAC sawtooth STINCTRIG and STRSTTRIG priority (STDIR = 0)

28.4.12 DAC extended sawtooth wave generation

The extended sawtooth wave generation is more flexible than the standard sawtooth wave generation described in *Section 28.4.11: DAC sawtooth wave generation*:

- It is possible to define the minimum and maximum output values.
- The extended sawtooth is managed by a signed 20-bit internal counter, enabling to convert data in 16.4 format.

  The first MSB is the sign bit, the second to the forth MSBs contain the overflow part, the middle 12 bits (5 to 16 MSBs) are used for the DAC output data, and the four LSBs consist of the fractional part. When the four MSBs equal 0b0000, the counter value is transferred to the DAC output. Otherwise, the DAC output value is saturated at 0x000, 0xFFF, or at the minimum or maximum value, programmed in the DAC_STEXTMM1 register.



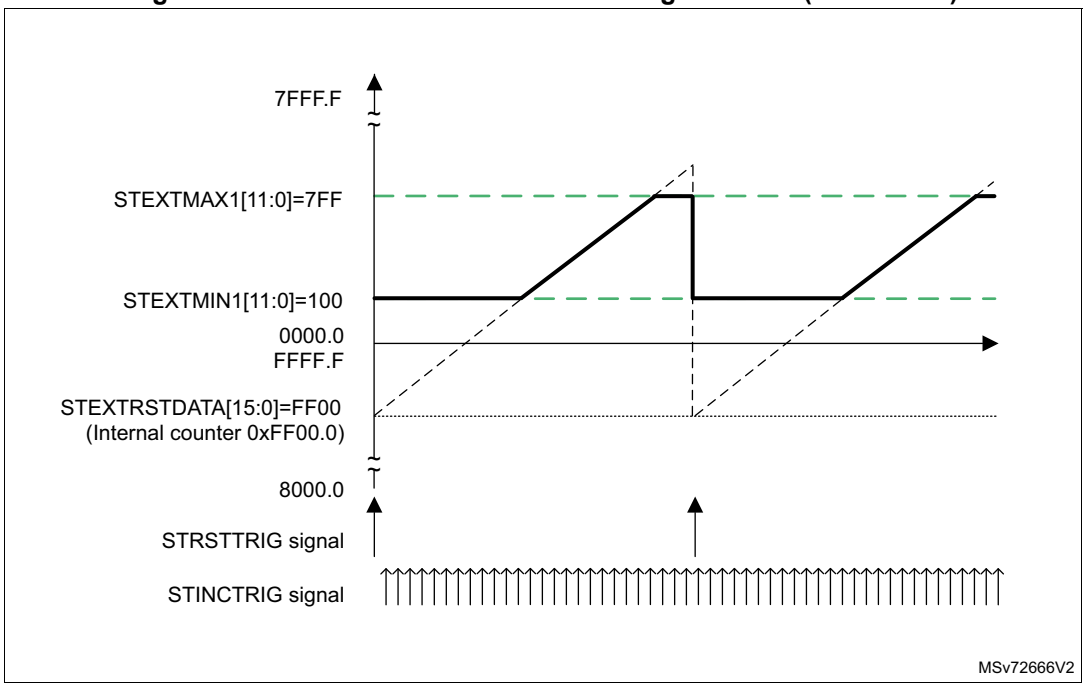
The following sequence is required to configure and start the extended sawtooth generation:

1. Clear the EN1 bit of the DAC_CR register.
2. Activated the extended sawtooth mode by setting the STEXT1 bit of the DAC_STR1 register.
3. Configure the sawtooth counter initial value (reset value) through the STEXTRSTDATA1[15:0] bitfield of the DAC_STEXTRST register.
4. Configure the increment value through the STINCDATA1[15:0] bitfield of the DAC_STRx register whose four LSBs correspond to the fractional part.
5. Configure the sawtooth minimum and maximum values through the STEXTMIN1[11:0] and STEXTMAX1[11:0] bitfield of the DAC_STEXTMM1 register
6. Configure the sawtooth direction through the STDIR1 bit of the DAC_STR1 register.
7. Select the sawtooth reset and increment trigger through the STRSTTRIGSEL1[3:0] and STINCTRIGSEL1[3:0] bitfields.
8. Set WAVE1[1:0] to 0b11 and EN1 to 1.
9. Generate a sawtooth reset trigger to start the sawtooth generation.

When STDIR1 is cleared (decrement case), the internal counter operates as follows:

- When the STRSTTRIG is applied, the counter 16 MSBs are reset to the signed 20-bit STEXTRSTDATA1[15:0] value, and the four LSBs are reset to 0b0000.
- When the STINCTRIG is applied, the counter is subtracted from STINCDATA1[15:0].
- When the counter four MSBs are greater than or equal to 0b0001, the DAC output is saturated at the STEXTMAX1[11:0] value.
- When the counter four MSBs are equal to 0b0000, the counter middle 12-bit value is evaluated. If it is lower than STEXTMAX1[11:0] and greater than STEXTMIN1[11:0], the value is transferred to the DAC output.
- When the counter middle 12-bit value is lower than STEXTMIN1[11:0], the DAC output value is saturated at STEXTMIN1[11:0].
- When the counter value reaches 0x0000.0, the counter continues down-counting below the negative value 0xFFFFF. If the value reaches 0x8000.0, the internal counter value is saturated at 0x8000.0.

Figure 276. DAC extended sawtooth wave generation (STDIR1 = 0)



1. The line in bold represents the DAC output, the dashed line in black the internal counter value, and the dashed lines in green the extended sawtooth minimum and maximum values.

When STDIR1 is set (increment case), the internal counter operates as follows:

- When the STRSTTRIG is applied, the counter 16 MSBs are reset to STEXTRSTDATA1[15:0] value, and the four LSBs are reset to 0x0.
- When the STINCTRIG is applied, the counter is added to STINCDATA1[15:0].
- When the counter is negative (MSB = 1), the DAC output is saturated at the STEXTMIN1[11:0] value.
- When the counter four MSBs are equal to 0b0000, the counter middle 12-bit value is evaluated. If it is lower than STEXTMAX1[11:0] and greater than STEXTMIN1[11:0], the value is transferred to the DAC output.
- When the counter middle 12-bit value is greater than the STEXTMAX1[11:0] value, the DAC output value is saturated at STEXTMAX1[11:0].
- When the value reaches 0x7FFF.F, the counter is saturated.

Figure 277. DAC extended sawtooth wave generation (STDIR1 = 1)

1. The line in bold represents the DAC output, the dashed line in black the internal counter value, and the dashed lines in green the extended sawtooth minimum and maximum values.

Dynamic modification of the extended sawtooth parameters

The STEXTRSTDATA1[15:0] bitfield can be modified while an extended sawtooth generation is ongoing. The new value is taken into account when a new STRSTTRIG is triggered.

When STINCDATA1[15:0] and/or STDIR1 are modified, the new value is applied when a new STINCTRIG is triggered.

When either or both of STEXTMAX1[11:0] and STEXTMIN1[11:0] are modified, the new value is applied when the next STRSTTRIG or STINCTRIG is triggered. To ensure STEXTMAX1[11:0] is always greater than STEXTMIN1[11:0], it is recommended to program them simultaneously through the DAC_STEXTMM1 register.

Since all the extended sawtooth parameters are stored in registers located in the AHB domain, and the DAC operates from the kernel clock, if an STRSTTRIG or an STINCTRIG signal arrives while a sawtooth parameter is being updated, the old value may be taken into account instead of the new one. To prevent this issue from occurring, the extended sawtooth parameters must be written much before the next trigger.

28.4.13 DAC channel modes

The DAC channel can be configured in normal mode or sample and hold mode. The output buffer can be enabled to obtain a high drive capability. Before enabling output buffer, the voltage offset needs to be calibrated. This calibration is performed at the factory (loaded after reset) and can be adjusted by software during application operation.

Normal mode

In normal mode, there are four combinations, by changing the buffer state and by changing the DACx_OUT1 pin interconnections.

To enable the output buffer, the MODE1[2:0] bits in DAC_MCR register must be:

- 000: DAC is connected to the external pin
- 001: DAC is connected to external pin and to on-chip peripherals

To disable the output buffer, the MODE1[2:0] bits in DAC_MCR register must be:

- 010: DAC is connected to the external pin
- 011: DAC is connected to on-chip peripherals

Sample and hold mode

In sample and hold mode, the DAC core converts data on a triggered conversion, and then holds the converted voltage on a capacitor. When not converting, the DAC cores and buffer are completely turned off between samples and the DAC output is tri-stated, therefore reducing the overall power consumption. A stabilization period, which value depends on the buffer state, is required before each new conversion.

In this mode, the DAC core and all corresponding logic and registers are driven by the LSI/LSE low-speed clock (dac_hold_ck) in addition to the dac_ker_ck clock, allowing using the DAC channel in deep low power modes such as Stop mode.

The LSI/LSE low-speed clock (dac_hold_ck) must not be stopped when the sample and hold mode is enabled.

The sample/hold mode operations can be divided into three phases:

1. Sample phase: the sample/hold element is charged to the desired voltage. The charging time depends on capacitor value (internal or external, selected by the user). The sampling time is configured with the TSAMPLE1[9:0] bits in DAC_SHSR1 register. During the write of the TSAMPLE1[9:0] bits, the BWST1 bit in DAC_SR register is set to 1 to synchronize between both clocks domains (AHB and low speed clock) and allowing the software to change the value of sample phase during the DAC channel operation
2. Hold phase: the DAC output channel is tri-stated, the DAC core and the buffer are turned off, to reduce the current consumption. The hold time is configured with the THOLD1[9:0] bits in DAC_SHHR register
3. Refresh phase: the refresh time is configured with the TREFRESH1[7:0] bits in DAC_SHRR register

The timings for the three phases above are in units of LSI/LSE clock periods. As an example, to configure a sample time of 350 µs, a hold time of 2 ms and a refresh time of 100 µs assuming LSI/LSE ~32 KHz is selected:

- 12 cycles are required for sample phase: TSAMPLE1[9:0] = 11.
- 62 cycles are required for hold phase: THOLD1[9:0] = 62.
- and 4 cycles are required for refresh period: TREFRESH1[7:0] = 4.

In this example, the power consumption is reduced by almost a factor of 15 versus normal modes.

The formulas to compute the right sample and refresh timings are described in the table below, the Hold time depends on the leakage current.

Table 253. Sample and refresh timings

Buffer State	t_{SAMP}(1)(2)	$t_{REFRESH}$(2)(3)
Enable	7 µs + (10*R_{BON}*C_{SH})	7 µs + (R_{BON}*C_{SH})*ln(2*N_{LSB})
Disable	3 µs + (10*R_{BOFF}*C_{SH})	3 µs + (R_{BOFF}*C_{SH})*ln(2*N_{LSB})

1. In the above formula, the settling to the desired code value with ½ LSB or accuracy requires 10 constant time for 12 bits resolution. For 8-bit resolution, the settling time is 7 constant time.
2. C_{SH} is the capacitor in sample and hold mode.
3. The tolerated voltage drop during the hold phase “Vd” is represented by the number of LSBs after the capacitor discharging with the output leakage current. The settling back to the desired value with ½ LSB error accuracy requires ln(2*Nlsb) constant time of the DAC.

Example of the sample and refresh time calculation with output buffer on

The values used in the example below are provided as indication only (refer to the datasheet for product data):

C_{SH} = 100 nF

$V_{REFDAC+}$ = 3.0 V

Sampling phase:

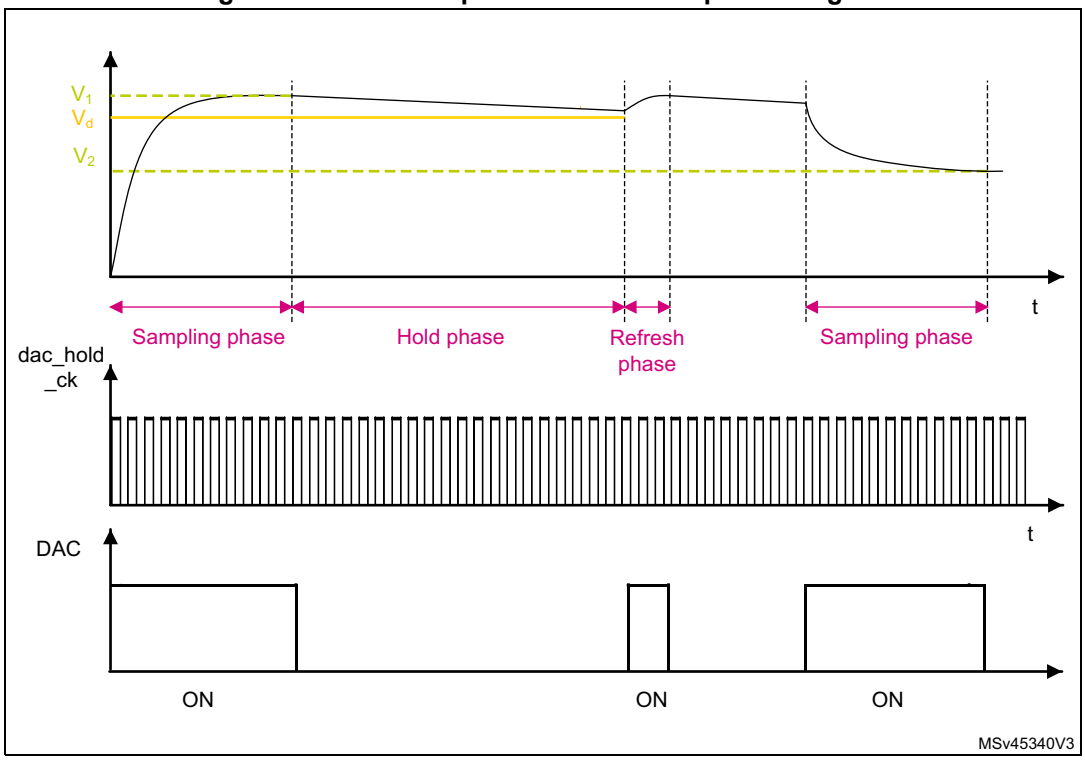
t_{SAMP} = 7 µs + (10 * 2000 * 100 * 10^{-9}) = 2.007 ms

(where R_{BON} = 2 kΩ)

Refresh phase:

$t_{REFRESH}$ = 7 µs + (2000 * 100 * 10^{-9}) * ln(2*10) = 606.1 µs

(where N_{LSB} = 10 (10 LSB drop during the hold phase)



Hold phase:

D_v = i_{leak} * t_{hold} / C_{SH} = 0.0073 V (10 LSB of 12bit at 3 V)

i_{leak} = 150 nA (worst case on the IO leakage on all the temperature range)

t_{hold} = 0.0073 * 100 * 10^{-9} / (150 * 10^{-9}) = 4.867 ms

Figure 278. DAC sample and hold mode phase diagram

Like in normal mode, the sample and hold mode has different configurations.

To enable the output buffer, MODE1[2:0] bits in DAC_MCR register must be set to:

- 100: DAC is connected to the external pin
- 101: DAC is connected to external pin and to on chip peripherals

To disabled the output buffer, MODE1[2:0] bits in DAC_MCR register must be set to:

- 110: DAC is connected to external pin and to on chip peripherals
- 111: DAC is connected to on chip peripherals

  When MODE1[2:0] bits are equal to 111, an internal capacitor, C_{Lint}, holds the voltage output of the DAC core and then drive it to on-chip peripherals.

All sample and hold phases are interruptible, and any change in DAC_DHR1 immediately triggers a new sample phase.

Note: The sawtooth wave generation is not supported in sample and hold mode operation.

Table 254. Channel output modes summary

MODE1[2:0]			Mode	Buffer	Output connections
0	0	0	Normal mode	Enabled	Connected to external pin
0	0	1			Connected to external pin and to on chip-peripherals (such as comparators)
0	1	0		Disabled	Connected to external pin
0	1	1			Connected to on chip peripherals (such as comparators)

Table 254. Channel output modes summary (continued)

MODE1[2:0]			Mode	Buffer	Output connections
1	0	0	Sample and hold mode	Enabled	Connected to external pin
1	0	1			Connected to external pin and to on chip peripherals (such as comparators)
1	1	0		Disabled	Connected to external pin and to on chip peripherals (such as comparators)
1	1	1			Connected to on chip peripherals (such as comparators)

28.4.14 DAC channel buffer calibration

The transfer function for an N-bit digital-to-analog converter (DAC) is:

$$V_{out} = ((D / 2^N) \times G \times V_{REFDAC}) + V_{OS}$$

Where V_{OUT} is the analog output, D is the digital input, G is the gain, V_{REFDAC} is the nominal full-scale voltage, and V_{OS} is the offset voltage. For an ideal DAC channel, G = 1 and V_{OS} = 0.

Due to output buffer characteristics, the voltage offset may differ from part-to-part and introduce an absolute offset error on the analog output. To compensate the V_{OS}, a calibration is required by a trimming technique.

The calibration is only valid when the DAC channel is operating with buffer enabled (MODE1[2:0] = 0b000 or 0b001 or 0b100 or 0b101). if applied in other modes when the buffer is off, it has no effect. During the calibration:

- The buffer output is disconnected from the pin internal/external connections and put in tristate mode (HiZ).
- The buffer acts as a comparator to sense the middle-code value 0x800 and compare it to V_{REFDAC}/2 signal through an internal bridge, then toggle its output signal to 0 or 1 depending on the comparison result (CAL_FLAG1 bit).

Two calibration techniques are provided:

- Factory trimming (default setting)

  The DAC buffer offset is factory trimmed. The default value of OTRIM1[4:0] bits in DAC_CCR register is the factory trimming value and it is loaded once DAC digital interface is reset.
- User trimming

  The user trimming can be done when the operating conditions differs from nominal factory trimming conditions and in particular when V_{DDA} voltage, temperature, V_{REFDAC} values change and can be done at any point during application by software.

Note: Refer to the datasheet for more details of the nominal factory trimming conditions.

In addition, when V_{DD} is removed (example the device enters in Standby mode) the calibration is required.

The steps to perform a user trimming calibration are as below:

1. If the DAC channel is active, write 0 to EN1 bit in DAC_CR to disable the channel.
2. Select a mode where the buffer is enabled, by writing to DAC_MCR register, MODE1[2:0] = 0b000 or 0b001 or 0b100 or 0b101.
3. Start the DAC channel calibration, by setting the CEN1 bit in DAC_CR register to 1.
4. Apply a trimming algorithm:
   a) Write a code into OTRIM1[4:0] bits, starting by 0b00000.
   b) Wait for t_{TRIM} delay.
   c) Check if CAL_FLAG1 bit in DAC_SR is set to 1.
   d) Until the CAL_FLAG1 is read as 1 or the maximum trimming code is reached, increment OTRIM1[4:0] and repeat substeps from (b) to (d).

The software algorithm may use either a successive approximation or dichotomy techniques to compute and set the content of OTRIM1[4:0] bits in a faster way.

Note: A t_{TRIM} delay must be respected between the write to the OTRIM1[4:0] bits and the read of the CAL_FLAG1 bit in DAC_SR register in order to get a correct value.This parameter is specified into datasheet electrical characteristics section.

If V_{DDA}, V_{REFDAC} and temperature conditions do not change during device operation while it enters more often in Standby mode, the software may store the OTRIM1[4:0] bits found in the first user calibration in the flash or in back-up registers. then to load/write them directly when the device power is back again thus avoiding to wait for a new calibration time.

When CEN1 bit is set, it is not allowed to set EN1 bit.

28.4.15 DAC channel conversion modes

Four conversion modes are possible.

Independent trigger without wave generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TEN1.
2. Configure the trigger sources by setting different values in the TSEL1[4:0] bits.
3. Load the DAC channel data into the desired DHR registers (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DHR1 register is transferred into DAC_DOR1 (three dac_ker_ck clock cycles later).

Independent trigger with single LFSR generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bit, TEN1.
2. Configure the trigger sources by setting different values in the TSEL1[4:0] bits.
3. Configure the DAC channel WAVE1[1:0] bits as 01 and the same LFSR mask value in the MAMP1[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the LFSR1 counter, with the same mask, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_ker_ck clock cycles later). Then the LFSR1 counter is updated.

Independent trigger with single triangle generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Set the DAC channel trigger enable bits, TEN1.
2. Configure the trigger sources by setting different values in the TSEL1[4:0] bits.
3. Configure the DAC channel WAVE1[1:0] bits as 1x and the same maximum amplitude value in the MAMP1[3:0] bits.
4. Load the DAC channel data into the desired DHR register (DAC_DHR12R1, DAC_DHR12L1 or DAC_DHR8R1).

When a DAC channel trigger arrives, the DAC channel triangle counter, with the same triangle amplitude, is added to the DHR1 register and the sum is transferred into DAC_DOR1 (three dac_ker_ck clock cycles later). The DAC channel triangle counter is then updated.

Independent trigger with single sawtooth generation

To configure the DAC in this conversion mode, the following sequence is required:

1. Configure the trigger sources by setting different values in STRSTTRIGSELx[3:0] and STINCTRIGSELx[3:0] bits.
2. Configure the DAC channel WAVEx[1:0] bits to 11 and set the same STRSTDATAx[11:0], STINCDATAx[15:0] and STDIRx values for each register.

When a DAC channel trigger arrives, the DAC channel sawtooth counter updates the DHRx register and transfers it into DAC_DOR1 (three AHB clock cycles later).

28.5 DAC in low-power modes

Table 255. Effect of low-power modes on DAC

Mode	Description
Sleep	No effect, DAC used with DMA.
Stop(1)	The DAC remains active with a static value. The sample and hold mode can be selected using LSE/LSI clock.
Standby	The DAC peripheral is powered down and must be reinitialized after exiting Standby mode.

1. Refer to *Section 28.3: DAC implementation* for information on the Stop modes supported by the DAC peripheral.

28.6 DAC interrupts

Table 256. DAC interrupts

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit Sleep mode	Exit Stop mode	Exit Standby mode
DAC	DMA underrun	DMAUDR1	DMAUDRIE1	Write DMAUDRx = 1	Yes	No	No

28.7 DAC registers

Refer to *Section 1* for a list of abbreviations used in register descriptions.

The peripheral registers have to be accessed by words (32-bit).

28.7.1 DAC control register (DAC_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TSEL1[4]	CEN1	DMAUDRIE1	DMAEN1	MAMP1[3:0]				WAVE1[1:0]		TSEL1[3:0]				TEN1	EN1
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 14 **CEN1**: DAC channel1 calibration enable

This bit is set and cleared by software to enable/disable DAC channel1 calibration, it can be written only if bit EN1 = 0 into DAC_CR (the calibration mode can be entered/exit only when the DAC channel is disabled) Otherwise, the write operation is ignored.

0: DAC channel1 in normal operating mode

1: DAC channel1 in calibration mode

Bit 13 **DMAUDRIE1**: DAC channel1 DMA Underrun Interrupt enable

This bit is set and cleared by software.

0: DAC channel1 DMA Underrun Interrupt disabled

1: DAC channel1 DMA Underrun Interrupt enabled

Bit 12 **DMAEN1**: DAC channel1 DMA enable

This bit is set and cleared by software.

0: DAC channel1 DMA mode disabled

1: DAC channel1 DMA mode enabled

Bits 11:8 **MAMP1[3:0]**: DAC channel1 mask/amplitude selector

These bits are written by software to select mask in wave generation mode or amplitude in triangle generation mode.

0000: Unmask bit0 of LFSR/ triangle amplitude equal to 1
0001: Unmask bits[1:0] of LFSR/ triangle amplitude equal to 3
0010: Unmask bits[2:0] of LFSR/ triangle amplitude equal to 7
0011: Unmask bits[3:0] of LFSR/ triangle amplitude equal to 15
0100: Unmask bits[4:0] of LFSR/ triangle amplitude equal to 31
0101: Unmask bits[5:0] of LFSR/ triangle amplitude equal to 63
0110: Unmask bits[6:0] of LFSR/ triangle amplitude equal to 127
0111: Unmask bits[7:0] of LFSR/ triangle amplitude equal to 255
1000: Unmask bits[8:0] of LFSR/ triangle amplitude equal to 511
1001: Unmask bits[9:0] of LFSR/ triangle amplitude equal to 1023
1010: Unmask bits[10:0] of LFSR/ triangle amplitude equal to 2047
≥ 1011: Unmask bits[11:0] of LFSR/ triangle amplitude equal to 4095

Bits 7:6 **WAVE1[1:0]**: DAC channel1 noise/triangle wave generation enable

These bits are set and cleared by software.
00: wave generation disabled
01: Noise wave generation enabled
10: Triangle wave generation enabled
11: Sawtooth wave generation enabled
Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bits 15, 5:2 **TSEL1[4:0]**: DAC channel1 trigger selection

These bits select the external event used to trigger DAC channel1
00000: SWTRIG1
00001: dac_ch1_trg1
00010: dac_ch1_trg2
...
11111: dac_ch1_trg31
For details on trigger configuration and mapping, refer to *Section 28.4.2: DAC pins and internal signals*.

Note: Only used if bit TEN1 = 1 (DAC channel1 trigger enabled).

Bit 1 **TEN1**: DAC channel1 trigger enable

This bit is set and cleared by software to enable/disable DAC channel1 trigger.
0: DAC channel1 trigger disabled and data written into the DAC_DHR1 register are transferred one dac_ker_ck clock cycle later to the DAC_DOR1 register
1: DAC channel1 trigger enabled and data from the DAC_DHR1 register are transferred three dac_ker_ck clock cycles later to the DAC_DOR1 register

Note: When software trigger is selected, the transfer from the DAC_DHR1 *register to the DAC_DOR1 register takes only one dac_ker_ck clock cycle.*

Bit 0 **EN1**: DAC channel1 enable

This bit is set and cleared by software to enable/disable DAC channel1.
0: DAC channel1 disabled
1: DAC channel1 enabled

28.7.2 DAC software trigger register (DAC_SWTRGR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWTRIGB1

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SWTRIG1
															w

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **SWTRIGB1**: DAC channel1 software trigger B

This bit is set by software to trigger the DAC in software trigger mode (sawtooth generation) It is cleared by hardware.

0: No trigger

1: Trigger for sawtooth increment

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **SWTRIG1**: DAC channel1 software trigger

This bit is set by software to trigger the DAC in software trigger mode, or software reset trigger mode for the sawtooth wave generation.

0: No trigger

1: Trigger

Note: This bit is cleared by hardware (one dac_ker_ck clock cycle later) once the DAC_DHR1 register value has been loaded into the DAC_DOR1 register.

28.7.3 DAC channel1 12-bit right-aligned data holding register (DAC_DHR12R1)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	DACC1DHR[11:0]											
				rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DHRB[11:0]**: DAC channel1 12-bit right-aligned data B

These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DHR[11:0]**: DAC channel1 12-bit right-aligned data
These bits are written by software. They specify 12-bit data for DAC channel1.

28.7.4 DAC channel1 12-bit left aligned data holding register (DAC_DHR12L1)

Address offset: 0x0C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DACC1DHR[11:0]												Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw				

Bits 31:20 **DACC1DHRB[11:0]**: DAC channel1 12-bit left-aligned data B
These bits are written by software. They specify 12-bit data for DAC channel1 when the DAC operates in double data mode.

Bits 19:16 Reserved, must be kept at reset value.

Bits 15:4 **DACC1DHR[11:0]**: DAC channel1 12-bit left-aligned data
These bits are written by software.
They specify 12-bit data for DAC channel1.

Bits 3:0 Reserved, must be kept at reset value.

28.7.5 DAC channel1 8-bit right aligned data holding register (DAC_DHR8R1)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:16 **DACC1DORB[11:0]**: DAC channel1 data output
These bits are read-only. They contain data output for DAC channel1 B.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:0 **DACC1DOR[11:0]**: DAC channel1 data output
These bits are read-only, they contain data output for DAC channel1.

28.7.7 DAC status register (DAC_SR)

Address offset: 0x34

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	rc_w1	r	r											

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **BWST1**: DAC channel1 busy writing sample time flag
This bit is systematically set just after sample and hold mode enable and is set each time the software writes the register DAC_SHSR1, It is cleared by hardware when the write operation of DAC_SHSR1 is complete. (It takes about 3 LSI/LSE periods of synchronization).
0:There is no write operation of DAC_SHSR1 ongoing: DAC_SHSR1 can be written
1:There is a write operation of DAC_SHSR1 ongoing: DAC_SHSR1 cannot be written

Bit 14 **CAL_FLAG1**: DAC channel1 calibration offset status
This bit is set and cleared by hardware
0: calibration trimming value is lower than the offset correction value
1: calibration trimming value is equal or greater than the offset correction value

Bit 13 **DMAUDR1**: DAC channel1 DMA underrun flag

This bit is set by hardware and cleared by software (by writing it to 1).

0: No DMA underrun error condition occurred for DAC channel1

1: DMA underrun error condition occurred for DAC channel1 (the currently selected trigger is driving DAC channel1 conversion at a frequency higher than the DMA service capability rate)

Bit 12 **DORSTAT1**: DAC channel1 output register status bit

This bit is set and cleared by hardware. It is applicable only when the DAC operates in double data mode.

0: DOR[11:0] is used actual DAC output

1: DORB[11:0] is used actual DAC output

Bit 11 **DAC1RDY**: DAC channel1 ready status bit

This bit is set and cleared by hardware.

0: DAC channel1 is not yet ready to accept the trigger nor output data

1: DAC channel1 is ready to accept the trigger or output data

Bits 10:0 Reserved, must be kept at reset value.

28.7.8 DAC calibration control register (DAC_CCR)

Address offset: 0x38

Reset value: 0x0000 00XX

											rw	rw	rw	rw	rw

Bits 31:5 Reserved, must be kept at reset value.

Bits 4:0 **OTRIM1[4:0]**: DAC channel1 offset trimming value

28.7.9 DAC mode control register (DAC_MCR)

Address offset: 0x3C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HFSEL[2:0]			Res.	Res.	Res.	SINFORMAT1	DMADOUBLE1	Res.	Res.	Res.	Res.	Res.	MODE1[2:0]		
rw	rw	rw				rw	rw						rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:13 **HFSEL[2:0]**: High frequency interface mode selection
000: High frequency interface mode disabled
001: High frequency interface mode enabled for 80 MHz ≤ dac_ker_ck ≤ 160 MHz
010: High frequency interface mode enabled for 160 MHz ≤ dac_ker_ck
≤≤≤≤Others: Reserved, must not be used.

Bits 12:10 Reserved, must be kept at reset value.

Bit 9 **SINFORMAT1**: Enable signed format for DAC channel1
This bit is set and cleared by software.
0: Input data is in unsigned format
1: Input data is in signed format (2's complement). The MSB bit represents the sign.

Bit 8 **DMADOUBLE1**: DAC channel1 DMA double data mode
This bit is set and cleared by software.
0: DMA normal mode selected
1: DMA double data mode selected

Bits 7:3 Reserved, must be kept at reset value.

Bits 2:0 **MODE1[2:0]:** DAC channel1 mode
These bits can be written only when the DAC is disabled and not in the calibration mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.
They can be set and cleared by software to select the DAC channel1 mode:
– DAC channel1 in normal mode
000: DAC channel1 is connected to external pin with Buffer enabled
001: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
010: DAC channel1 is connected to external pin with Buffer disabled
011: DAC channel1 is connected to on chip peripherals with Buffer disabled
– DAC channel1 in sample & hold mode
100: DAC channel1 is connected to external pin with Buffer enabled
101: DAC channel1 is connected to external pin and to on chip peripherals with Buffer enabled
110: DAC channel1 is connected to external pin and to on chip peripherals with Buffer disabled
111: DAC channel1 is connected to on chip peripherals with Buffer disabled
Note: This register can be modified only when EN1 = 0.

28.7.10 DAC channel1 sample and hold sample time register (DAC_SHSR1)

Address offset: 0x40

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	TSAMPLE1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:0 **TSAMPLE1[9:0]:** DAC channel1 sample time (only valid in sample and hold mode)

These bits can be written when the DAC channel1 is disabled or also during normal operation. in the latter case, the write can be done only when BWST1 of DAC_SR register is low, If BWST1 = 1, the write operation is ignored.

*Note: It represents the number of LSI/LSE clocks to perform a sample phase. Sampling time = (*TSAMPLE1[9:0] + 1) x *LSI/LSE clock period.*

28.7.11 DAC sample and hold time register (DAC_SHHR)

Address offset: 0x48

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	THOLD1[9:0]									
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:10 Reserved, must be kept at reset value.

Bits 9:0 **THOLD1[9:0]:** DAC channel1 hold time (only valid in sample and hold mode)
Hold time = (THOLD[9:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.

28.7.12 DAC sample and hold refresh time register (DAC_SHRR)

Address offset: 0x4C

Reset value: 0x0001 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TREFRESH1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **TREFRESH1[7:0]:** DAC channel1 refresh time (only valid in sample and hold mode)
Refresh time = (TREFRESH[7:0]) x LSI/LSE clock period
Note: This register can be modified only when EN1 = 0.

Note: These bits can be written only when the DAC channel is disabled and in normal operating mode (when bit EN1 = 0 and bit CEN1 = 0 in the DAC_CR register). If EN1 = 1 or CEN1 = 1 the write operation is ignored.

28.7.13 DAC channel1 sawtooth register (DAC_STR1)

Address offset: 0x58

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	STEXT1	STDIR1	STRSTDATA1[11:0]											
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 **STINCDATA1[15:0]:** DAC channel1 sawtooth increment value (12.4 bit format)

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **STEXT1**: DAC channel1 sawtooth extended setting
0: Sawtooth reset value defined by STRSTDATA[11:0]
1: Sawtooth reset value defined by STEXTRSTDATA[15:0]

Bit 12 **STDIR1:** DAC channel1 sawtooth direction setting
This bit is written by software to select the direction of sawtooth step direction:
0: Decrement
1: Increment

Bits 11:0 **STRSTDATA1[11:0]:** DAC channel1 sawtooth reset value

28.7.14 DAC sawtooth mode register (DAC_STMODR)

Address offset: 0x60

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

29 Voltage reference buffer (VREFBUF)

29.1 VREFBUF introduction

The devices embed a voltage reference buffer which can be used as voltage reference for the on-chip ADCs, and also as voltage reference for external components through the VREF+ pin.

29.2 VREFBUF implementation

The table below describes the VREFBUF voltage typical values:

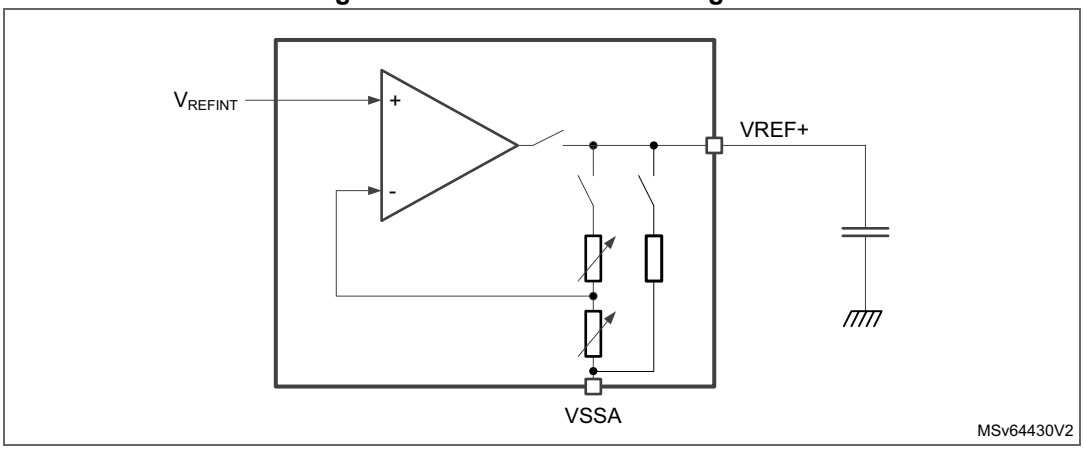

Table 258. VREFBUF typical values

Symbol	Value
$V_{REFBUF0}$	2.9 V
$V_{REFBUF1}$	2.5 V
$V_{REFBUF2}$	2.048 V
$V_{REFBUF3}$	1.8 V

Note: Refer to the product datasheet for more details.

29.3 VREFBUF functional description

Figure 279. VREFBUF block diagram

The internal voltage reference buffer is an operational amplifier, with programmable gain. The amplifier input is connected to the internal voltage reference V_{REFINT}. The VREFBUF supports four voltages[(a)], which are configured with VRS bits in the VREFBUF_CSR register:

- VRS = 000: $V_{REFBUF0}$ voltage selected
- VRS = 001: $V_{REFBUF1}$ voltage selected
- VRS = 010: $V_{REFBUF2}$ voltage selected
- VRS = 011: $V_{REFBUF3}$ voltage selected

The internal voltage reference can be configured in four different modes depending on ENVR and HIZ bits configuration. These modes are provided in the table below:

Table 259. VREF buffer modes

ENVR	HIZ	VREF buffer configuration
0	0	VREFBUF buffer off mode: – VREF+ pin pulled-down to V_{SSA}
0	1	External voltage reference mode (default value): – VREFBUF buffer off – VREF+ pin input mode
1	0	Internal voltage reference mode: – VREFBUF buffer on – VREF+ pin connected to VREFBUF buffer output
1	1	Hold mode: – VREF is enable without output buffer, VREF+ pin voltage is hold with the external capacitor – VRR detection disabled and VRR bit keeps last state

After enabling the VREFBUF by setting ENVR bit and clearing HIZ bit in the VREFBUF_CSR register, the user must wait until VRR bit is set, meaning that the voltage reference output has reached its expected value.

29.4 VREFBUF trimming

The VREFBUF output voltage is factory-calibrated by ST. At reset, and each time the VRS setting is changed, the calibration data is automatically loaded to the TRIM register.

Optionally user can trim the output voltage by changing the TRIM register bits directly. In this case, the VRS setting has no more effect on the TRIM register until the device is reset.

a. The minimum V_{DDA} voltage depends on VRS setting, refer to the product datasheet.

29.5 VREFBUF registers

29.5.1 VREFBUF control and status register (VREFBUF_CSR)

Address offset: 0x00

Reset value: 0x0000 0002

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	VRS[2:0]			VRR	Res.	HIZ	ENVR
									rw	rw	rw	r		rw	rw

Bits 31:7 Reserved, must be kept at reset value.

Bits 6:4 **VRS[2:0]**: Voltage reference scale

These bits select the value generated by the voltage reference buffer.

VRS = 000: $V_{REFBUF0}$ voltage selected.
VRS = 001: $V_{REFBUF1}$ voltage selected.
VRS = 010: $V_{REFBUF2}$ voltage selected.
VRS = 011: $V_{REFBUF3}$ voltage selected.
Others: Reserved

Note: Refer to the product datasheet for each $V_{REFBUFx}$ voltage setting value.
The software can program this bitfield only when the VREFBUF is disabled (ENVR=0).

Bit 3 **VRR:** Voltage reference buffer ready

0: the voltage reference buffer output is not ready.
1: the voltage reference buffer output reached the requested level.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **HIZ:** High impedance mode

This bit controls the analog switch to connect or not the VREF+ pin.
0: VREF+ pin is internally connected to the voltage reference buffer output.
1: VREF+ pin is high impedance.
Refer to *Table 259: VREF buffer modes* for the mode descriptions depending on ENVR bit configuration.

Bit 0 **ENVR:** Voltage reference buffer mode enable

This bit is used to enable the voltage reference buffer mode.
0: Internal voltage reference mode disable (external voltage reference mode).
1: Internal voltage reference mode (reference buffer enable or hold mode) enable.

29.5.2 VREFBUF calibration control register (VREFBUF_CCR)

Address offset: 0x04

Reset value: 0x0000 00XX

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TRIM[5:0]					
										rw	rw	rw	rw	rw	rw

Bits 31:6 Reserved, must be kept at reset value.

Bits 5:0 **TRIM[5:0]**: Trimming code

The TRIM code is a 6-bit unsigned data (minimum 000000, maximum 111111) that is set and updated according the mechanism described below.

Reset:

TRIM[5:0] is automatically initialized with the VRS = 0 trimming value stored in the flash memory during the production test.

VRS change:

TRIM[5:0] is automatically initialized with the trimming value (corresponding to VRS setting) stored in the flash memory during the production test.

Write in TRIM[5:0]:

User can modify the TRIM[5:0] with an arbitrary value. This is permanently disabling the control of the trimming value with VRS (until the device is reset).

Note: If the user application performs the trimming, the trimming code must start from 000000 to 111111 in ascending order.

29.5.3 VREFBUF register map

The following table gives the VREFBUF register map and the reset values.

Table 260. VREFBUF register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

	Reset value																											X	X	X	X	X	X

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

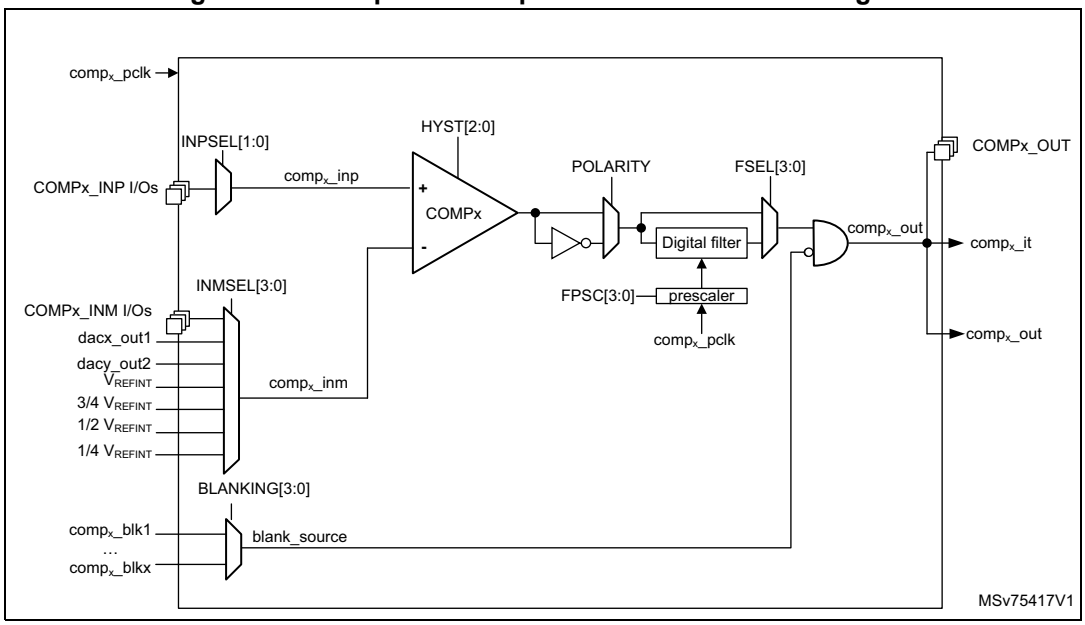
30 Comparator (COMP)

30.1 COMP introduction

The device embeds up to eight comparators, which can be used for a variety of functions including:

- Wake-up from low-power mode triggered by an analog signal
- Analog signal conditioning
- Cycle-by-cycle current control loop when combined with a PWM output from a timer

30.2 COMP main features



- Selectable inverting analog inputs:
  - Multiplexed I/O pins
  - DAC channels
  - Internal reference voltage and three sub-multiple values (1/4, 1/2, 3/4) provided by the scaler (buffered voltage divider)
- Programmable hysteresis
- Digital filtering
- Secured window mode
- Output redirection to I/Os or to timer inputs for triggering break events for fast PWM shutdowns
- Output blanking for immunity to switching noise
- Interrupt generation capability with wake up from Sleep and Stop modes (through the EXTI controller)

30.3 COMP functional description

30.3.1 COMP simplified block diagram

The simplified block diagram of the comparators is shown in the figure below.

Figure 280. Comparator simplified functional block diagram

30.3.2 COMP pins and internal signals

The I/Os used as comparator inputs must be configured in analog mode in the GPIO registers.

The comparator outputs can be connected to the I/Os through their alternate functions. Refer to the product datasheet for more information.

The outputs can also be internally redirected to a variety of timer inputs for the following purposes:

- emergency shutdown of PWM signals, using BKIN and BKIN2 inputs
- cycle-by-cycle current control, using ETR inputs of timers
- input capture for timing measurements

The comparator output can be routed simultaneously internally and to the I/O pins.

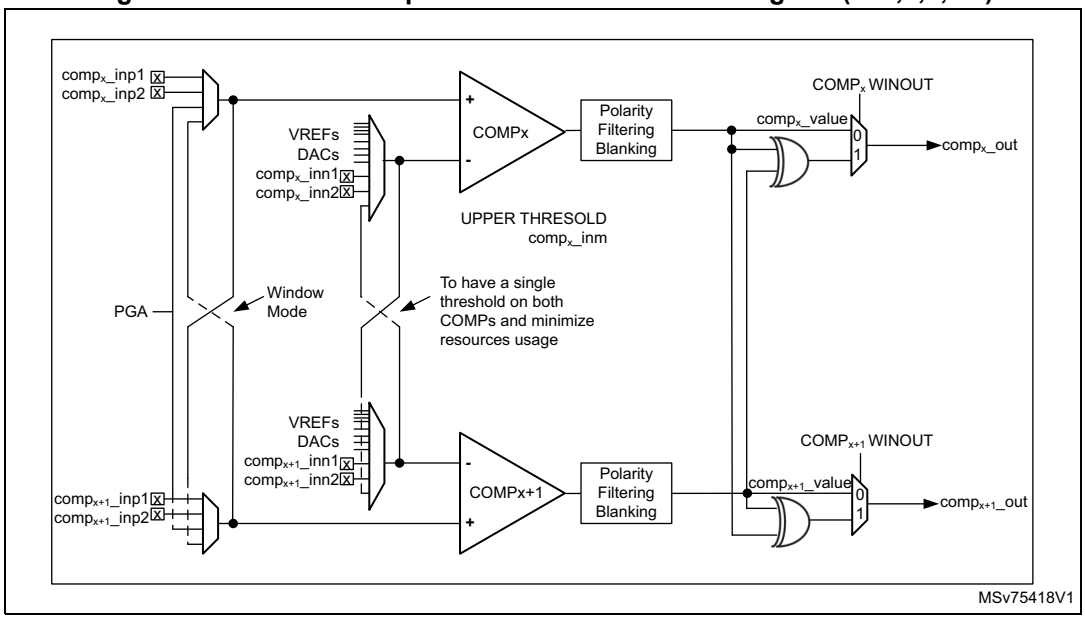
30.3.3 COMP reset and clocks

The COMP peripheral clock comp_pclk is provided by the clock controller is synchronous with the APB clock.

Warning: The polarity selection logic and the output redirection to the port work independently from the APB clock. This allows the comparator to work even in Stop mode. The interrupt line, connected to the NVIC of CPU, requires the APB clock (comp_pclk) to work. In absence of the APB clock, the interrupt signal comp_it cannot be generated.

30.3.4 Comparator LOCK mechanism

The comparators can be used for safety purposes, such as over-current or thermal protection. For applications having specific functional safety requirements, it is necessary to ensure that the comparator programming cannot be altered in case of spurious register access or program counter corruption. For this purpose, the comparator control and status registers can be write-protected (read only). Once the programming is completed, the COMPx LOCK bit can be set. This causes the whole register to become read-only, including the COMPx LOCK bit. The write protection can only be removed by an MCU reset.



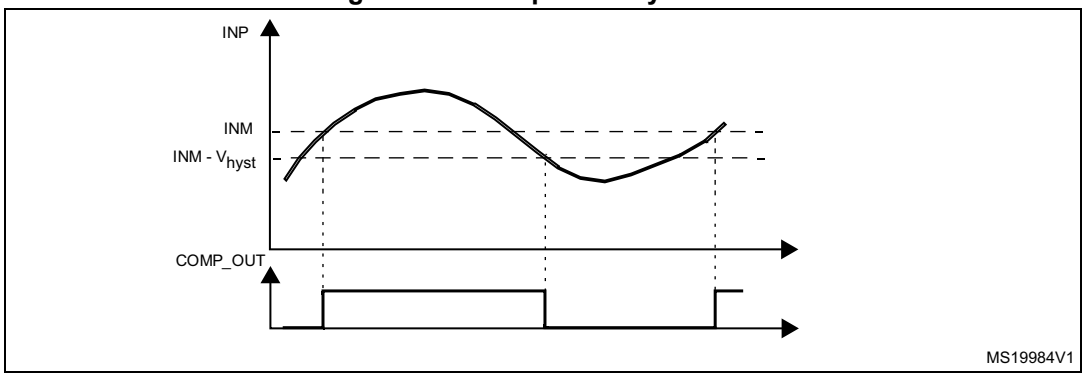
30.3.5 Window comparator

The purpose of the window comparator is to monitor the analog voltage if it is within the voltage range defined by the lower and upper threshold.

The two embedded comparators $COMP_x$ and $COMP_{x+1}$ with x=1,3,5,7... can be used to create a window comparator. The monitored analog voltage is connected to the non-inverting (plus) inputs of comparators connected together ($COMP_x$ or $COMP_{x+1}$). The upper and lower threshold voltages are connected to the inverting (minus) inputs of the comparators.

The output of the window comparator ($COMP_x$ or $COMP_{x+1}$) is selected with the control bit WINOUT.

Figure 281. Window comparators functional block diagram (x=1,3,5,7...)



Important: when $COMP_x$ or $COMP_{x+1}$ have different secure mode, the window mode feature is disabled for both comparators with the following configuration (registers COMPx_CSR and COMPx+1_CSR unchanged) :

- WINOUT bit is forced internally to reset value
- In case INPSEL[1:0]=0x3, INPSEL[1:0] is forced internally to reset value
- In case INMSEL[3:0]=0x9, INMSEL[3:0] is forced internally to reset value

30.3.6 Hysteresis

The comparator includes a programmable hysteresis to avoid spurious output transitions in case of noisy signals. The hysteresis can be disabled if it is not needed (for instance when exiting from low-power mode) to be able to force the hysteresis value using external components.

Figure 282. Comparator hysteresis

30.3.7 Deglitcher feature

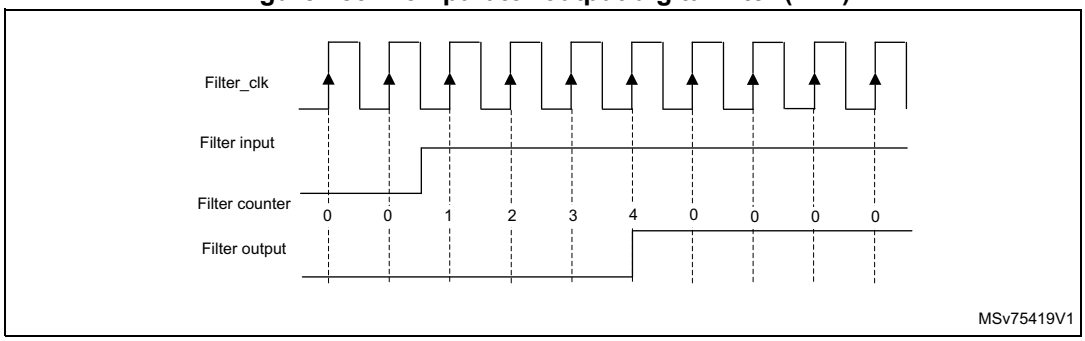
In addition of the programmable hysteresis which is filtering a voltage amplitude, comparator high frequency noise on signal input can be filtered with the embedded deglitcher analog feature enabling the DGLT. The usage of the deglitcher is increasing the propagation delay of the comparator with few nanoseconds (refer to product datasheet).

High speed comparator are highly sensitive to noise. As a consequence, output comparator can oscillate for low input slope signal even if hysteresis is enabled. The deglitcher is an analog feature allowing to remove these comparator output toggling. The advantage is that the solution is purely analog : no need of extra digital circuitry and high speed clock, no extra latency due to digital filtering, negligible consumption. It is recommended to use the deglitcher coupled with hysteresis.

30.3.8 Digital signal filter

In addition of the programmable hysteresis and deglitcher features, comparator low frequency noise on input signal can be filtered with the digital signal filter. Based on a internal counter clocked by filter_clk (divided from comp_pclk): the output of the comparator is filtered considering if the logical level is stable for a programmable number of consecutive periods. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected). In the FLTR register, FSEL[3:0] register allows the selection of various filter_clk divider ratio and N value while FPSC[1:0] register controls the prescaler ratio from comp_pclk to filter_clk.

Figure 283. Comparator output digital filter (N=4)



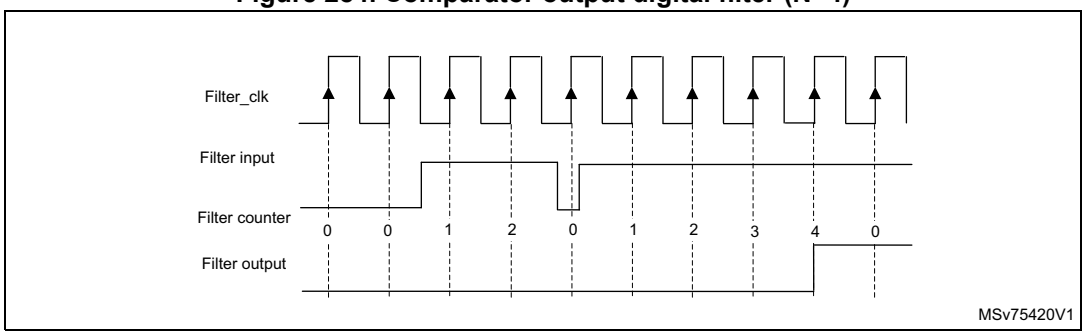


Figure 284. Comparator output digital filter (N=4)

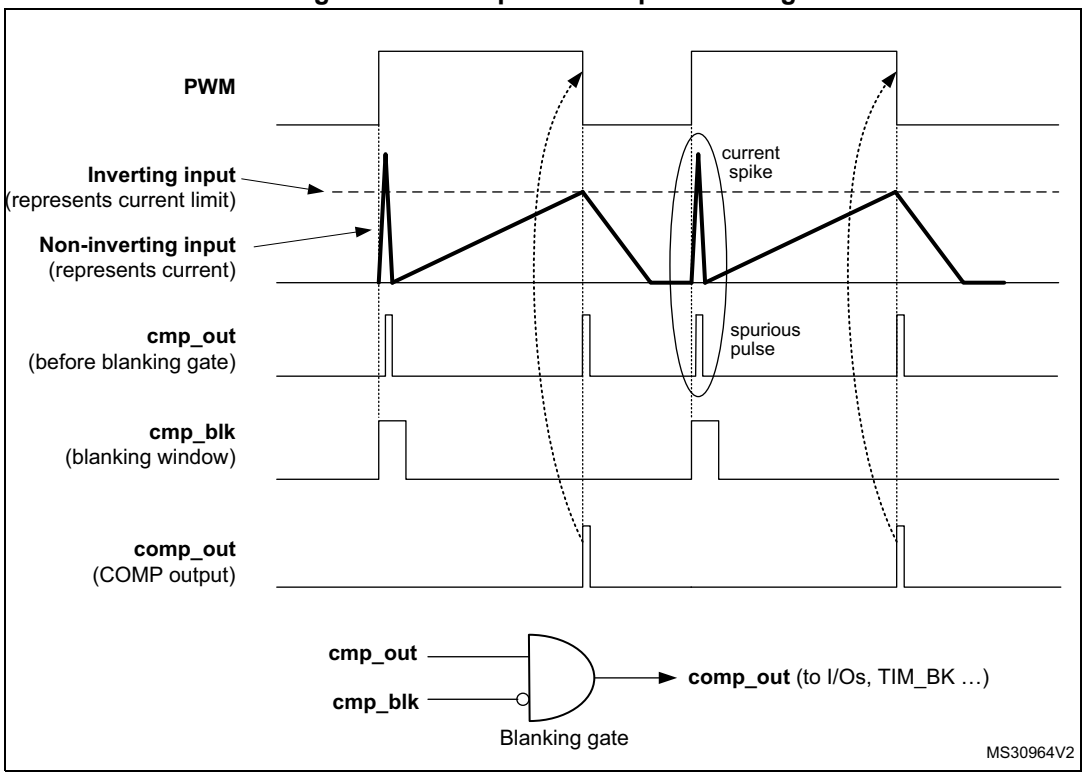

30.3.9 Comparator output blanking function

The purpose of the blanking function is to prevent the current regulation to trip upon short current spikes at the beginning of the PWM period (typically the recovery current in power switches anti parallel diodes). It uses a blanking window defined with a timer output compare signal. Refer to the register description for selectable blanking signals.

The blanking signal gates the internal comparator output such as to clean the comp_out from spurious pulses due to current spikes, as depicted in *Figure 285* (the COMP channel number is not represented).

Figure 285. Comparator output blanking

30.3.10 COMP startup stabilization time

The comparator parameters and its output is undefined after the COMP enable (power-on) for a period defined as startup stabilization time, see the product datasheet for more details. If the comparator output is driving any critical stage of the design, it is recommended to redirect the comparator output to the device I/O through the GPIO alternate function or through IP configuration (such as Timers) after the stabilization time elapses.

30.4 COMP low-power modes

Table 264. Comparator behavior in low-power modes

Mode	Description
Sleep	No effect on the comparators. Comparator interrupts cause the device to exit the Sleep mode.
Stop	No effect on the comparators. Comparator interrupts cause the device to exit the Stop mode.

Note: The comparators cannot be used to exit the device from Sleep or Stop mode when the internal reference voltage is switched off.

30.5 COMP interrupts

The comparator outputs are internally connected to the extended interrupt and event controller (EXTI). Each comparator has its own EXTI line and can generate either interrupts or events to make the device exit low-power modes.

Interrupt through EXTI

Refer to interrupt and events section for more details.

Sequence to enable the COMP interrupt through EXTI block:

1. Enable the COMP and wait for stabilization.
2. Configure the EXTI line, receiving the compx_it signal, in interrupt mode, select the rising, falling or either-edge sensitivity and enable the EXTI line.
3. Configure and enable the NVIC IRQ channel mapped to the corresponding EXTI lines.

Table 265. Interrupt through EXTI control bits

Interrupt event	Event flag	Enable control bit	Exit Sleep mode	Exit Stop modes	Exit Standby mode
compx_it	Through EXTI	Through EXTI	Yes	Yes	N/A

30.6 COMP registers

30.6.1 Comparator x configuration register (COMPx_CSR)

Address offset: 0x00 + 0x400 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

The COMPx_CSR is the COMPx main configuration register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw					rw	rw	rw	rw	rw	rw				rw

Bit 31 **LOCK:** Lock

This bit is set by software and cleared by a hardware system reset. It locks the whole content of the comparator x control register COMPx_CSR[31:0] and COMPx_FLTR[31:0]. When locked, all control bits and flags can be read only but not written. When unlocked, the control bits can also be written by software.

0: COMP_CxCR[31:0] and COMPx_FLTR[31:0] registers are read/write.

1: COMP_CxCR1[31:0] and COMPx_FLTR[31:0] are locked.

Bit 30 **VALUE**: COMPx output value

This bit is read-only. It reflects the level of the compx_value signal.

Bits 29:26 Reserved, must be kept at reset value.

Bit 25 **DGLT**: DEGLITCHER enable

This bit, controlled by software, enables the operation of DEGLITCHER.

0: Disable

1: Enable

Bit 24 **SCALEN**: VREFINT scaler enable

This bit, controlled by software, enables the operation of VREFINT scaler at the inverting input of all comparator. To disable the VREFINT scaler, SCALEN bits of all COMPx_CSR registers must be reset. When the VREFINT scaler is disabled, the 1/4 VREFINT, 1/2 VREFINT, 3/4 VREFINT, and VREFINT inputs of the multiplexer must not be selected.

0: Disable

1: Enable

Bit 23 **BRGEN**: VREFINT scaler resistor bridge enable

This bit, controlled by software, enables the operation of resistor bridge in the VREFINT scaler. To disable the resistor bridge, BRGEN bits of all COMPx_CSR registers must be reset. When the resistor bridge is disabled, the 1/4 VREFINT, 1/2 VREFINT, and 3/4 VREFINT inputs of the input selector receive VREFINT voltage.

0: Disable

1: Enable

Bits 22:19 **BLANKSEL[3:0]**: Comparator x blanking signal select

This bitfield, controlled by software, selects the blanking signal for comparator channel x, as shown in *Table 263: COMPx blanking source assignment (COMP1 to COMP8)*.

Bits 18:16 **HYST[2:0]:** Comparator x hysteresis

This bitfield, controlled by software, selects the hysteresis of the comparator x.

000: No hysteresis

001: hysteresis level 1

010: hysteresis level 2

011: hysteresis level 3

100: hysteresis level 4

101: hysteresis level 5

110: hysteresis level 6

111: hysteresis level 7

Note: Refer to the datasheet for the real hysteresis level values.

Bit 15 **POL**: Comparator x polarity

This bit, controlled by software, selects the comparator x output polarity.

0: Non-inverted

1: Inverted

Bit 14 **WINOUT**: COMPx output selector

This bit, controlled by the software (if not locked), selects the COMPx window mode output.

0: $comp_x_out = comp_x_value$

1: $comp_x_out = WINOUT(comp_x)$

Note: WINOUT is forced to reset state when $COMP_x$ and $COMP_{x+1}$ secure mode differ.

Bits 13:10 Reserved, must be kept at reset value.

Bits 9:8 **INPSEL[1:0]**: COMPx channel non-inverting input selection

These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input plus of COMPx channel.

Note: See Table 261: COMPx_INP non-inverting input assignment (COMP1 to COMP8) for more details. INPSEL[2:0] is forced to reset state when $COMP_x$ and $COMP_{x+1}$ secure mode differ.

Bits 7:4 **INMSEL[3:0]**: COMPx channel inverting input selection

These bits are set and cleared by software (only if LOCK not set). They select which input is connected to the input minus of COMPx channel.

Note: See Table 262: COMPx_INM inverting input assignment (COMP1 to COMP8) for more details. INMSEL[3:0] is forced to reset state when $COMP_x$ and $COMP_{x+1}$ secure mode differ.

Bits 3:1 Reserved, must be kept at reset value.

Bit 0 **EN:** COMPx channel enable

This bit is set and cleared by software (only if LOCK not set). It enables the COMPx channel.

0: Disable

1: Enable

30.6.2 Comparator x filter configuration register (COMPx_FLTR)

Address offset: 0x04 + 0x400 * (x - 1), (x = 1 to 8)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	FSEL[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	FPSC[1:0]	
				rw	rw	rw	rw							rw	rw

Bits 31:12 Reserved, must be kept at reset value.

Bits 11:8 **FSEL[3:0]:** COMPx digital filter configuration selection
Bits of this field are set and cleared by software (only if LOCK not set).They select the digital filter configuration of the COMPx.
0000: Filter disabled
0001: filter_sampling = comp_pclk, N = 2
0010: filter_sampling = comp_pclk, N = 4
0011: filter_sampling = comp_pclk, N = 8
0100: filter_sampling = filter_clk/2, N = 6
0101: filter_sampling = filter_clk/2, N = 8
0110: filter_sampling = filter_clk/4, N = 6
0111: filter_sampling = filter_clk/4, N = 8
1000: filter_sampling = filter_clk/8, N = 6
1001: filter_sampling = filter_clk/8, N = 8
1010: filter_sampling = filter_clk/16, N = 5
1011: filter_sampling = filter_clk/16, N = 6
1100: filter_sampling = filter_clk/16, N = 8
1101: filter_sampling = filter_clk/32, N = 5
1110: filter_sampling = filter_clk/32, N = 6
1111: filter_sampling = filter_clk/32, N = 8

Bits 7:2 Reserved, must be kept at reset value.

Bits 1:0 **FPSC[1:0]:** COMPx digital filter configuration selection
Bits of this field are set and cleared by software (only if LOCK not set). They select the digital filter clock configuration of the COMPx:
00: filter_clk = comp_pclk
01: filter_clk = comp_pclk/2
10: filter_clk = comp_pclk/4
11: filter_clk = comp_pclk/8

30.6.3 COMPx register map

Table 266. COMPx register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3.2* for the register boundary addresses.

31 Operational amplifier (OPAMP)

This section does not apply to the STM32G53x/54x devices as they do not include OPAMP.

31.1 Introduction

The devices embed three operational amplifier instances, OPAMP1, OPAMP2, and OPAMP3. OPAMPx used in the OPAMP section denotes any of these instances.

OPAMP contains an operational amplifier, an internal resistor divider, and multiplexers to set the OPAMP peripheral into a specific operating mode. In one of these, the operational amplifier inputs (INP and INM) and the output (OUT) are connected to external pins, which allows the use of OPAMP as a stand-alone operational amplifier device. The other OPAMP configurations allow the operation as a follower and as noninverting or inverting operational amplifier with programmable gain (with or without external filtering and/or biasing).

The programmable gain and the operating mode can be controlled through primary and secondary control register sets that can be activated in a time multiplex by the timer.

The operational amplifier output can be connected, through a multiplexer, to the OPAMP_VOUT pin or internally to an ADC or a COMP input channel.

The INP input of the OPAMP1 and OPAMP3 instances can be connected to an output of the internal DAC.

The operational amplifier allows normal and high speed (slew rate). Its input offset is compensated for through factory trimming that can be user modified if required.

As long as OPAMP is not required, it can be disabled to save power.

31.2 OPAMP main features

- Rail-to-rail input voltage range
- Low input bias current
- Low input offset voltage (factory compensated for)
- High frequency bandwidth
- Normal and high speed (slew rate)
- Timer-controlled operation

Note: Refer to the product datasheet for detailed OPAMP characteristics.

31.3 OPAMP implementation

The device has three OPAMP instances, OPAMP1, OPAMP2, and OPAMP3. *Table 267* shows the pin and internal signal per-instance specific naming and provides the assignment to I/Os and the possible connection of the internal signals.

The *Generic name* column provides the generic pin and internal signal names as per *Figure 286: OPAMP block diagram*. The *Instance specific name* column provides specific pin and internal signal names pertaining to each instance. The *Assignment or possible*

connection column provides the assignment to I/O pins for signals on pins (in upper-case letters) and the possible connections of internal signals (in lower-case letters).

Table 267. OPAMP pin and signal assignment per instance

Generic name	Instance-specific name	Assignment or possible connection	Comment
OPAMP1			
OPAMP_VINM0	OPAMP1_VINM0	PA3	Selected as additional I/O function.
OPAMP_VINM1	OPAMP1_VINM1	PC5	
OPAMP_VINP0	OPAMP1_VINP0	PA1	
OPAMP_VINP1	OPAMP1_VINP1	PA3

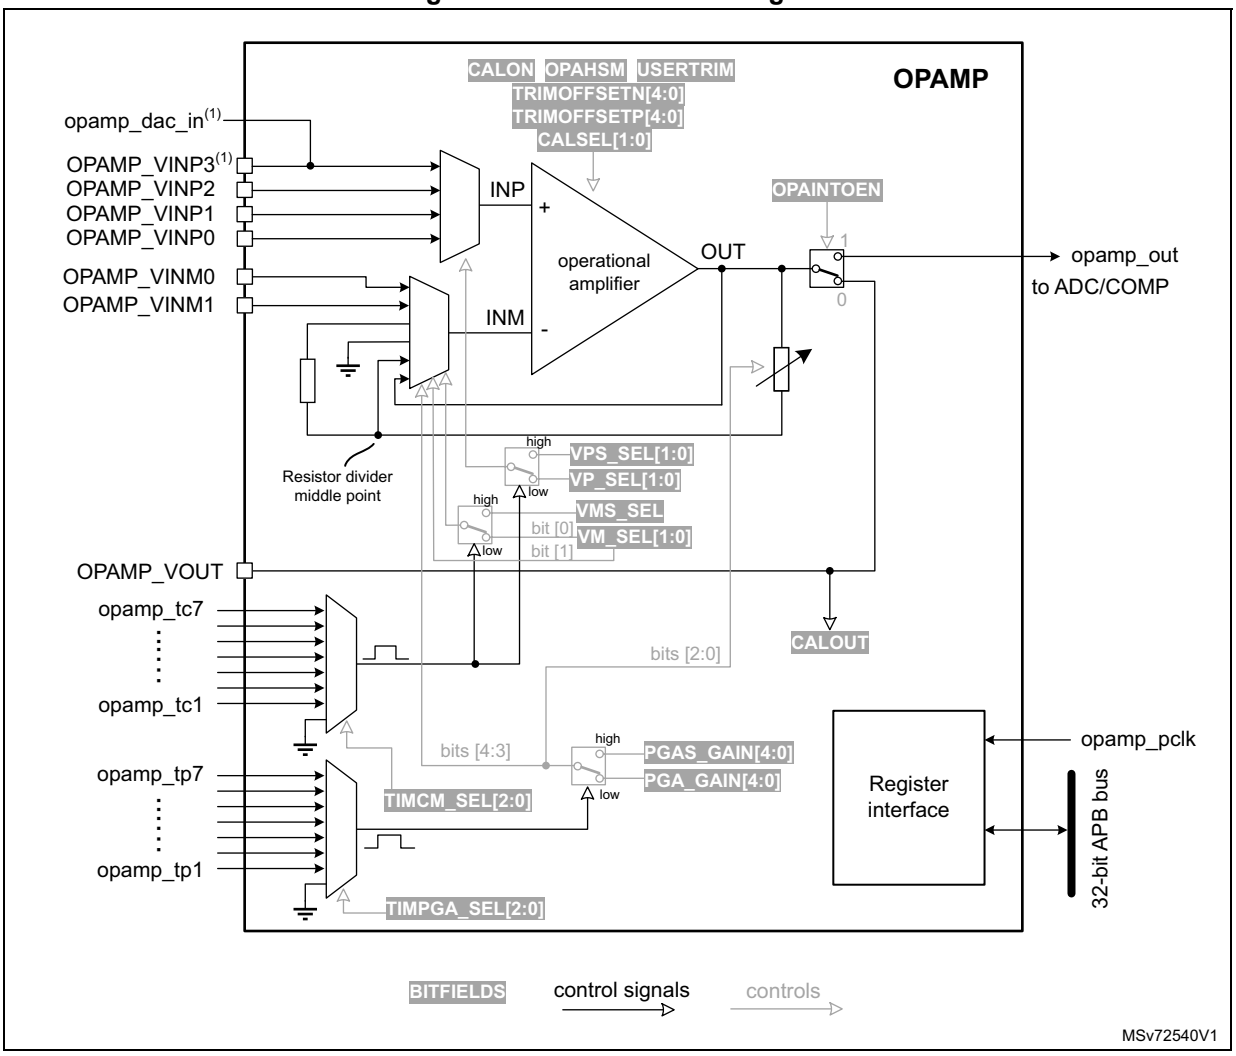
opamp_pclk	opamp3_pclk3	-	Enabled/disabled through RCC.

31.4 OPAMP functional description

Each OPAMP instance can individually be enabled. When disabled, its output is in a high-impedance state. When enabled, it can either operate in functional mode or in calibration mode.



In functional mode, the inputs and the output of the operational amplifier are connected as described in *Section 31.4.8*. In calibration mode, they are all disconnected.

Caution: The GPIOs connected to the operational amplifier terminals through the OPAMP multiplexers must be configured in analog mode (default state), through the corresponding GPIOx_MODER register.

31.4.1 OPAMP block diagram

The following figure shows the block diagram of the OPAMP peripheral. The calibration multiplexers and some control bitfields are not shown.

Figure 286. OPAMP block diagram

1. Either OPAMP_VINP3 pin or DAC output, depending on the OPAMP instance. Refer to *Section 31.3: OPAMP implementation*.

31.4.2 OPAMP pins and internal signals

The following table shows the pins used by the OPAMP peripheral. The pin names correspond to their configuration for use as OPAMP inputs or outputs. Refer to *Section 31.3: OPAMP implementation* for assignment of each to an I/O.

Table 268. OPAMP pins

Pin name	Pin type	Description
OPAMP_VINP0 OPAMP_VINP1 OPAMP_VINP2 OPAMP_VINP3	I	Selectable as INP noninverting input of the operational amplifier.

Table 268. OPAMP pins (continued)

Pin name	Pin type	Description
OPAMP_VINM0 OPAMP_VINM1	I	Selectable as INM inverting input of the operational amplifier.
OPAMP_VOUT	O	Operational amplifier output. Usable for other purposes when the operational amplifier output OUT is redirected to an internal ADC/COMP channel.

Caution: The input and output pins connected, through the OPAMP multiplexers, to the operational amplifier terminals INP, INM, and OUT must be configured in analog mode (default state), through the corresponding GPIOx_MODER register.

The following table lists the OPAMP internal signals. Refer to *Section 31.3: OPAMP implementation* for possible connection of each to internal resources and for specialization of the signal name for each OPAMP instance.

Table 269. OPAMP internal input/output signals

Pin name	Pin type	Description
opamp_tc1 opamp_tc2 opamp_tc3 opamp_tc4 opamp_tc5 opamp_tc6 opamp_tc7	I	Signal from a timer channel, selectable as control signal switching between primary and secondary controls for the input multiplexers.
opamp_tp1 opamp_tp2 opamp_tp3 opamp_tp4 opamp_tp5 opamp_tp6 opamp_tp7	I	Signal from a timer channel, selectable as control signal switching between primary and secondary controls for the programmable gain and for setting the PGA flavor.
opamp_dac_in	I	Output of a DAC channel, selectable as noninverting operational amplifier input. Exclusive with the OPAMP_VINP3 pin.
opamp_pclk	I	Clock for OPAMP registers.
opamp_out	O	Operational amplifier output to an internal ADC/COMP channel, when redirected through the OPAINTOEN bit.

31.4.3 OPAMP reset and clocks

The OPAMP clock opamp_pclk provided by the clock controller is generated from the PCLK3 (APB3 clock). To access the OPAMP control registers, it is necessary to set the corresponding OPAMPxEN bit of the RCC_APB3ENR register.

The OPAMP registers can be reset through the corresponding OPAMPxRST bit of the RCC_APB3RSTR register.

31.4.4 OPAMP output redirection to an internal ADC/COMP channel

The operational amplifier output OUT can be redirected internally to an ADC or a COMP channel, by setting the OPAINTOEN bit of the OPAMP_CSR register. In this case, the I/O pin OPAMP_VOUT on which the operation amplifier output OUT is mapped can be used for another purpose. See *Table 267* for possible ADC or COMP input channel assignment to OPAMP instances.

When OUT is connected to an ADC/COMP input channel, it is not connected to the OPAMP_VOUT pin. When the output on the OPAMP_VOUT and the connection to an ADC channel are required simultaneously, the output OUT must be routed to the OPAMP_VOUT pin and the ADC input selected from the OPAMP_VOUT pin.

31.4.5 OPAMP initial configuration

By default (upon reset):

- The operational amplifier inputs INP and INM and output OUT are connected to I/O pins.
- The registers for offset compensation contain factory trimming values and are in read-only access mode.
- The speed (slew rate) is set to normal.
- The timer-controlled operation of multiplexers is disabled.
- OPAMP is disabled.

31.4.6 OPAMP operational amplifier speed

The initial operational amplifier speed (slew rate, response) is normal. Setting the OPAHSM bit of the OPAMP_CSR register increases the speed. Both normal and high-speed mode characteristics are defined in the datasheet.

31.4.7 OPAMP enable

When disabled (default upon reset), the OPAMP control and calibration registers can still be modified. The operational amplifier output OUT is in high impedance state.

It is recommended to update the OPAMP registers while the OPAMP peripheral is disabled, to avoid spurious effects on the output.

OPAMP is enabled by setting the OPAEN bit of the OPAMP_CSR register. The INP and INM inputs and the OUT output are connected through the embedded multiplexers according to the control register settings and the timer control signals.

31.4.8 OPAMP operating modes

OPAMP can be configured to different operating modes or use cases, through:

- OPAMP control registers
- GPIOx_MODER registers, configuring the I/Os selected as OPAMP inputs and output
- ADC registers, selecting an ADC input channel when the operational amplifier output is redirected to the ADC
- COMP registers, selecting a COMP input channel when the operational amplifier output is redirected to the COMP
- External components, defining the gain, bias, or filtering parameters

The principal operating modes are:

- A stand-alone operational amplifier
- A follower
- A programmable-gain amplifier (PGA)

Refer to the following subsections for details and for different PGA flavors.

Through the OPAINTOEN bit of the *OPAMP control/status register (OPAMP_CSR)*, the operational amplifier output OUT can either be connected to the I/O pin selected as OPAMP output (default) or to an internal ADC/COMP input channel. However, the latter option cannot be used when the operational amplifier output on the pin is required.

The OPAHSM bit (at zero by default) allows increasing the operational amplifier speed (slew rate).

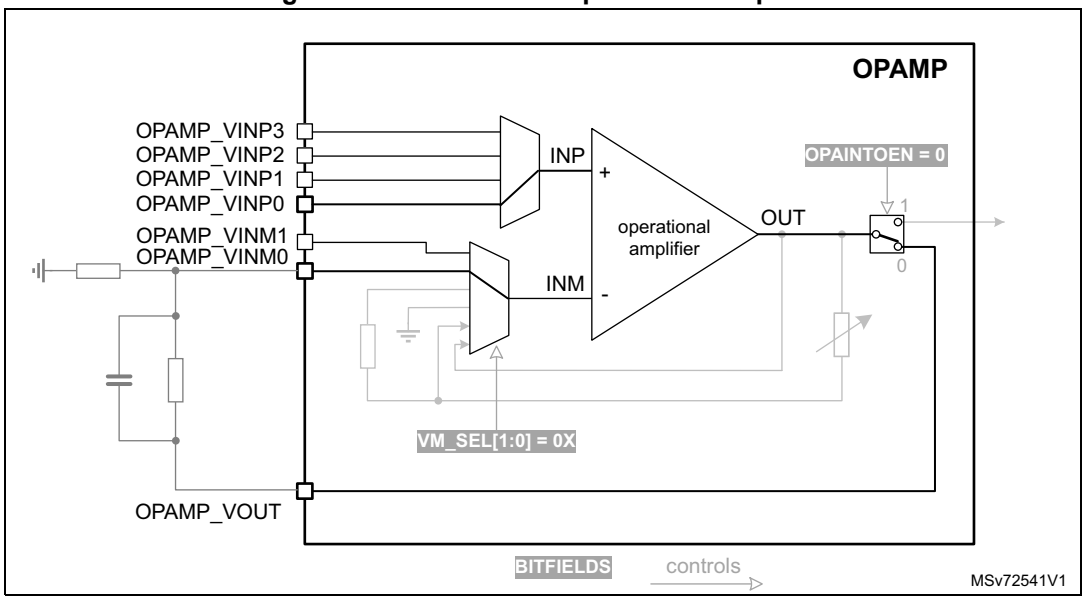
The USERTRIM bit can enable writing to the input offset trimming register, to allow modifying the by-default factory trimming values by the user.

The impedance of the input signal must be low enough to prevent the OPAMP input current from creating a voltage drop in the source, thus altering the input voltage. Refer to the electrical characteristics section in the datasheet for further details.

Stand-alone operational amplifier

For this use, ensure the following settings.

- Select a pin for the INP input (as opposed to a DAC output), with VP_SEL[2:0] and VPS_SEL[2:0] bitfields.
- Set the VM_SEL[1:0] bitfield to 0X, to ensure that a pin is selected for the INM input.
- Clear OPAINTOEN bit, to direct the operational amplifier output to the OPAMP_VOUT pin.



With these settings, the INP, INM inputs and the OUT output of the operational amplifier are connected to pins and to no other internal structure.

Note: The OPAMP_CSR, OPAMP_TCMR, and GPIOx_MODER registers in their default state configure OPAMP as stand-alone operational amplifier, with normal speed, factory offset trimming values, and with OPAMP_VINP0 and OPAMP_VINM0 selected for INP and INM, respectively. The OPAMP is disabled so the OUT and OPAMP_OUT are in high-Z state.

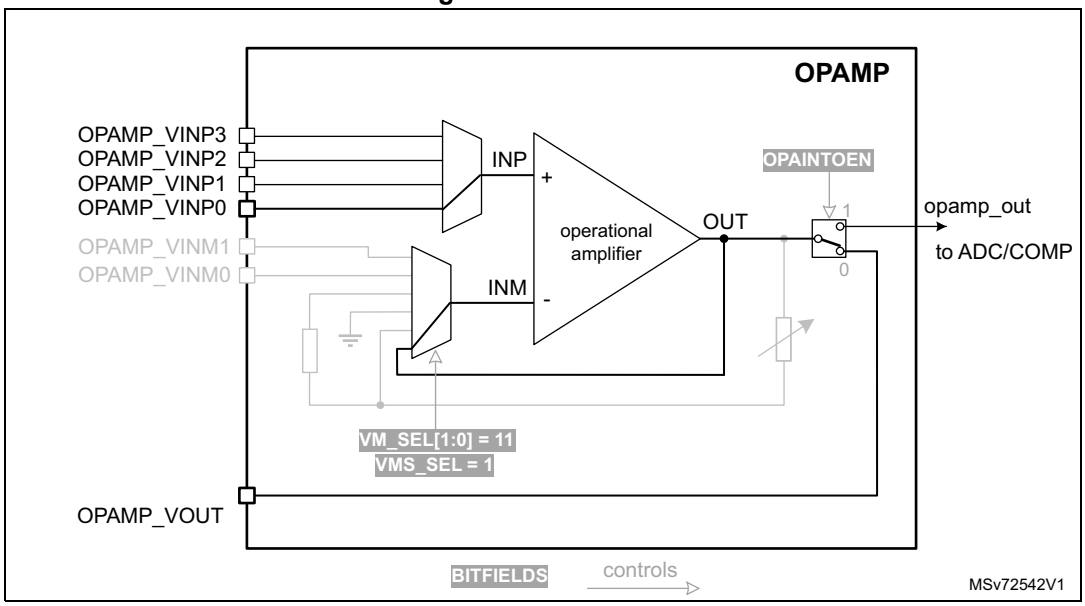
Once enabled, OPAMP operates as a stand-alone operational amplifier, with the gain, filtering, and biasing determined by external routing and components.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal ADC/COMP channel.

Figure 287. Stand-alone operational amplifier

Follower

To use OPAMP as a follower with an internal feedback, set the following bitfields as indicated:



- VM_SEL[1:0] to 11 and VMS_SEL to 1, to loop the operational amplifier output back to its inverting input INM
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select for the noninverting input INP

Once enabled, the operational amplifier buffers the voltage selected on its noninverting input INP.

Note: The GPIOs corresponding to OPAMP_VINMy are free for another use.

In this mode, OPAMP only takes two pins if a pin is selected for INP noninverting input. It only takes a single pin if an internal DAC output is selected for INP noninverting input (on instances supporting this). Refer to Figure 31.3: OPAMP implementation.

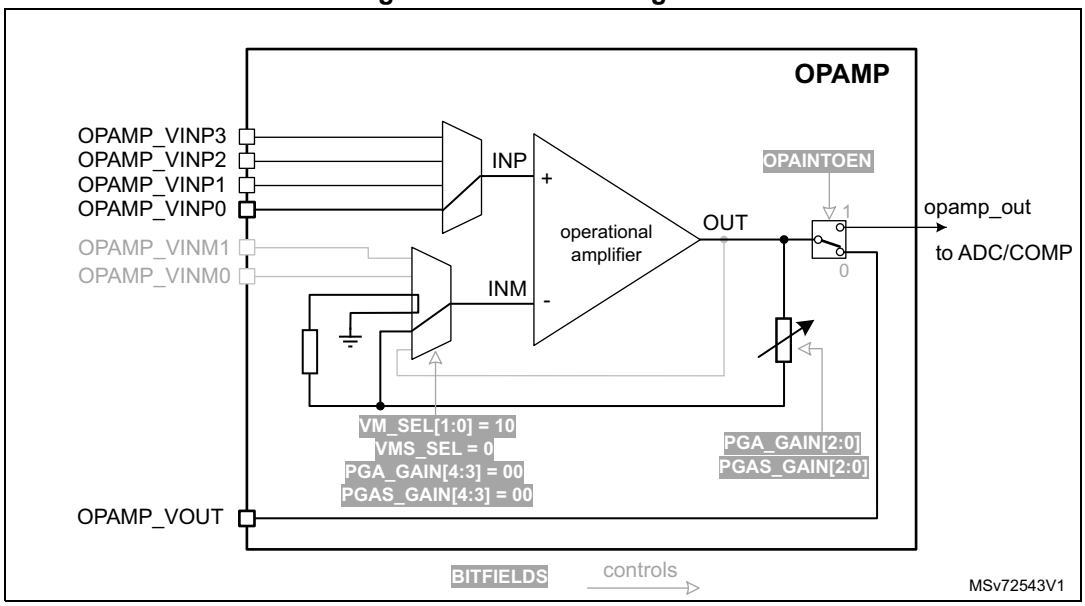
Figure 288. Follower

Programmable-gain amplifier

When OPAMP is configured as a a programmable-gain amplifier (PGA), the internal resistor divider with a programmable resistor value determines the amplifier gain. Refer to the datasheet for the values of the internal resistors.

The following sections describe different PGA flavors.

Noninverting PGA



To use OPAMP as a noninverting PGA without filtering, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 00XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

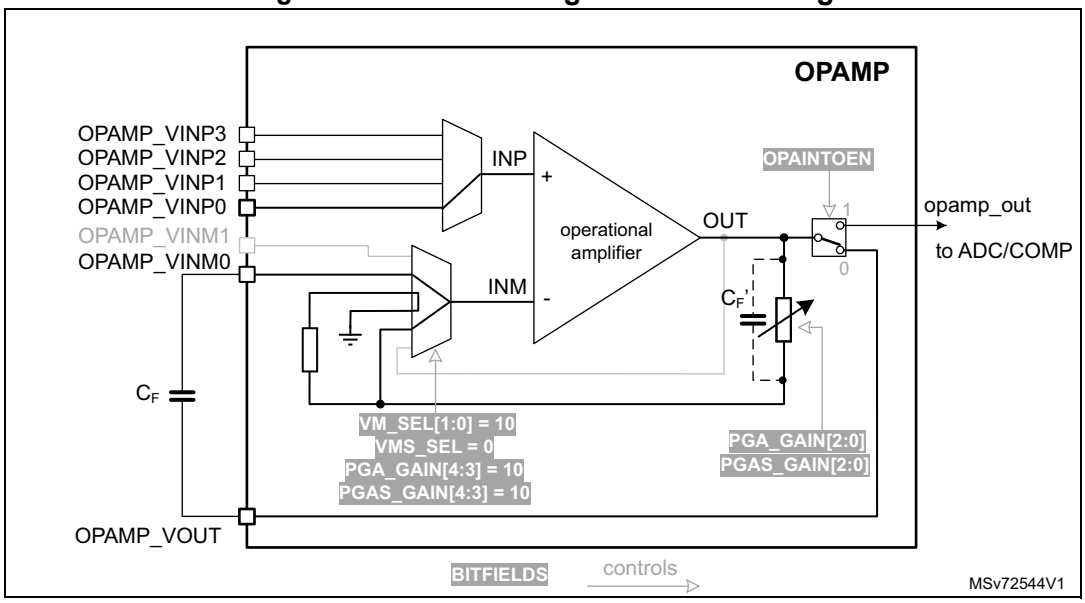
Once enabled, OPAMP outputs a voltage that corresponds to the selected input pin voltage multiplied by the selected gain value.

Note: To avoid saturation, keep the product of the input voltage and the selected gain value below V_{DDA}.

Figure 289. Noninverting PGA

Noninverting PGA with filtering

To use OPAMP as a noninverting PGA with filtering, set the following bitfields as indicated:



- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 10XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

Once enabled, OPAMP outputs a voltage that corresponds to the selected input pin voltage multiplied with the selected gain (for static signals).

Any external components connected between the OPAMP_VOUT pin and the OPAMP_VINM0 pin are put in parallel with the internal programmable resistor. For example, connecting a capacitor C_F as shown in the following figure has a filtering effect equivalent to C_F' of the same capacitance. The gain for dynamic signals then also depends on the signal frequency and the cut-off frequency of the filter.

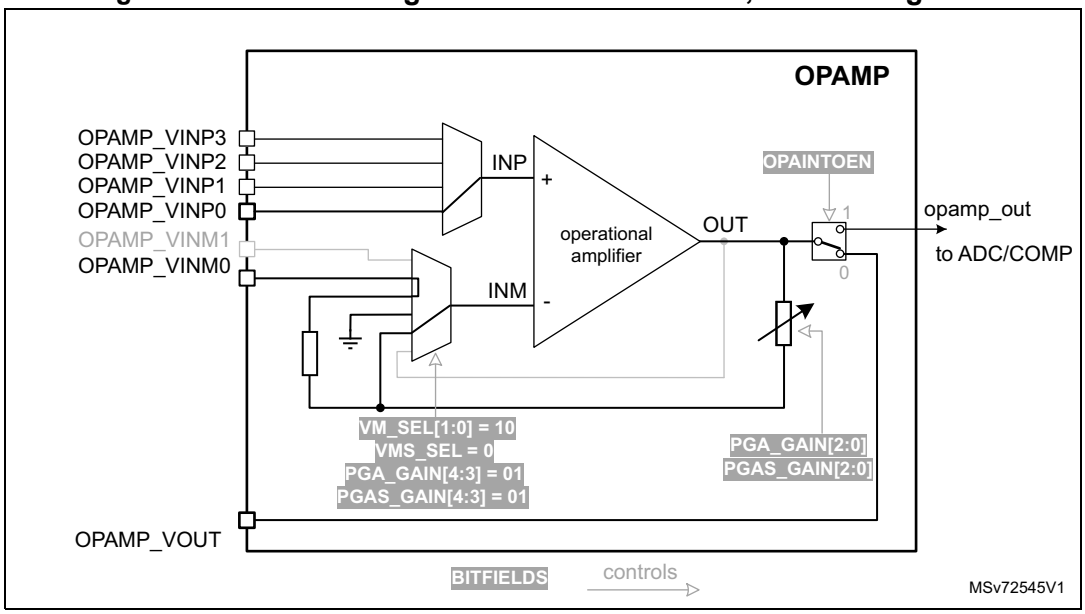
For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal ADC/COMP channel.

Figure 290. Noninverting PGA with filtering

Noninverting PGA with external bias, or inverting PGA

To use OPAMP as a noninverting PGA with external bias or as an inverting PGA, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 01XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input



For the signal on the selected OPAMP_VINPy pin, OPAMP operates as a noninverting amplifier with the selected positive gain. The OPAMP_VINM0 pin is used as a reference (bias).

For the signal on the OPAMP_VINM0 pin, OPAMP operates as an inverting amplifier with the selected negative gain. The selected OPAMP_VINPy pin is used as a reference.

Note: The final gain depends on the output impedance of source connected to the OPAMP_VINM0 pin.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal ADC/COMP channel.

Figure 291. Noninverting PGA with external bias, or inverting PGA

Inverting or noninverting PGA with external bias or/and filtering

To use OPAMP as a noninverting PGA with external bias, or as an inverting PGA with filtering, set the following bitfields as indicated:

- VM_SEL[1:0] to 10 and VMS_SEL to 0, to connect the resistor divider middle point to the inverting operational amplifier input
- PGA_GAIN[4:0] and PGAS_GAIN[4:0] to 11XXX, with XXX according to the desired positive gain
- VP_SEL[1:0] and VPS_SEL[1:0] according to the pin or internal DAC output to select as noninverting operational amplifier input

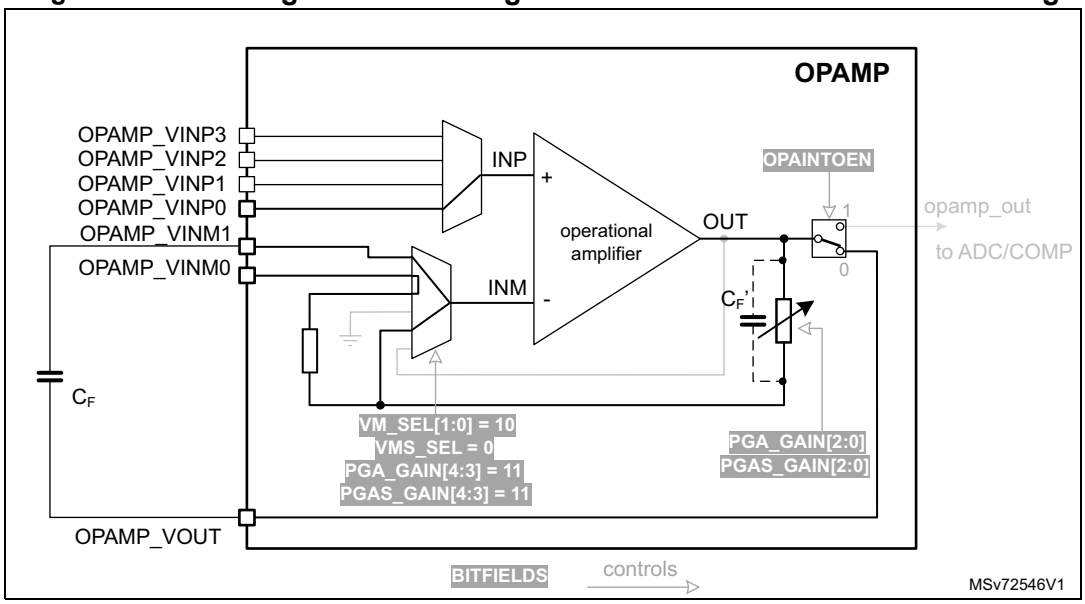
For the signal on the selected OPAMP_VINPy pin, OPAMP operates as a noninverting amplifier with the selected positive gain. The voltage on the OPAMP_VINM0 pin is used as a reference (bias).

For the signal on the OPAMP_VINM0 pin, OPAMP operates as an inverting amplifier with the selected negative gain. The voltage on the selected OPAMP_VINPy pin is used as a reference (bias). The output impedance of the biasing voltage source impacts the total gain.

In both cases, any external components connected between the OPAMP_VOUT pin and the OPAMP_VINM1 pin are put in parallel with the internal programmable resistor. For example, connecting a capacitor C_F as shown in the following figure has a filtering effect equivalent to C_F' of the same capacitance. The gain for dynamic signals then also depends on the signal frequency and the cut-off frequency of the filter.

For this use, the operational amplifier output OUT must be directed to the OPAMP_VOUT pin and not to the internal ADC/COMP channel.

Figure 292. Inverting or noninverting PGA with external bias or/and filtering



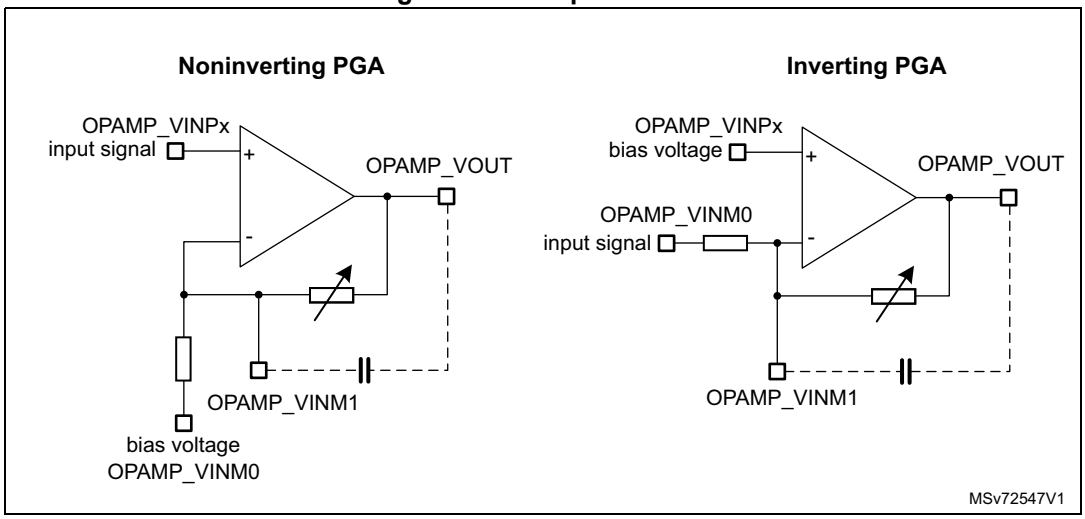


Figure 293. Simplified view

31.4.9 OPAMP programmable gain

In PGA mode, OPAMP allows selecting one of discrete positive (noninverting configuration) or negative (inverting configuration) gain values. The selection is done through the bits [2:0] of the PGA_GAIN[4:0] bitfield of the OPAMP_CSR register or through the bits [2:0] of the PGAS_GAIN[4:0] bitfield of the OPAMP_TCMR register. The control bitfield is selected with the control signal at the output of the opamp_tpX selector.

In noninverting mode, the programmable gain solely depends on the internal resistive divider. In inverting mode, it not only depends on the internal resistors but also on the output impedance of the signal source. The higher it is, the greater impact it has to the final gain.

31.4.10 OPAMP operational amplifier offset compensation

The peripheral incorporates a trimming circuitry that impacts the operational amplifier input offset. The trimming circuitry is controlled through the TRIMOFFSETN[4:0] (for the N differential pair) and TRIMOFFSETP[4:0] (for the P differential pair) bitfields of the *OPAMP control/status register (OPAMP_CSR)*.

The TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields keep the trimming value for the N differential pair and P differential pair, respectively.

Upon reset, these registers are loaded with factory trimming values stored in the nonvolatile memory. As the USERTRIM bit is low, the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] control bitfields are read-only.

Note: The factory trimming values result from a calibration procedure run on the production line at specific production conditions.

When the offset compensation obtained with the factory trimming values is not acceptable for a specific use case (supply voltage, operating temperature), the user software can apply different trimming values.

To modify the trimming values, the user software has first to set the USERTRIM bit to allow writing into the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] control bitfields.

To retain the user trimming values, the user software has to write them into a nonvolatile memory. It typically retrieves them from the non-volatile memory and writes into TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] at the startup, before the first use of OPAMP.

The resolution of the offset trimming allows reducing the input offset voltage to a value defined in the datasheet, at a defined supply voltage and die temperature.

31.4.11 OPAMP calibration

The calibration allows finding the trimming values that minimize the operational amplifier offset.

Setting the CALON bit isolates the operational amplifier INP and INM inputs and connects them to the internal reference voltage level selected through the CALSEL[1:0] bitfield. The operational amplifier is in a comparator (high gain, open loop) mode in which its output transits from one rail to another when the voltage level on one input crosses the voltage level on the other input.

The CALOUT flag reflects this digital value (lower rail or upper rail) of the OPAMP_VOUT pin.

The CALSEL[1:0] bitfield values 01 (low reference voltage) and 11 (high reference voltage) are intended for use in the calibration procedure. The value 01 is for trimming the PMOS through the TRIMOFFSETP[4:0] bitfield, the value 11 for trimming the NMOS through the TRIMOFFSETN[4:0] bitfield.

The calibration is carried out by software. Starting from the trimming bitfield at 0x1 and the CALOUT flag at one, the procedure consists in incrementing the trimming value until the CALOUT flag toggles to zero. The last trimming value is the one that compensates for the operational amplifier offset of the given OPAMP instance, and for the given supply voltage, die temperature, and differential pair stage (PMOS or NMOS). Upon each trimming value incrementation, the software must wait for at least the $t_{OFFTRIM}$max period defined in the product datasheet, before reading the CALOUT flag and potentially proceeding to the next incrementation step.

Note: The closer is the trimming value to the offset compensation point, the longer takes the output voltage to respond (without ever exceeding $t_{OFFTRIM}max$).

The full calibration consists of four calibration loops as listed in the following table. They can be executed in any order. The CALON bit must be set for executing any calibration loop. The calibration loops for the operational amplifier speed (slew rate) that is not required in the application can be omitted.

Table 270. Calibration loops

Calibration loop	Control bitfield		
	CALSEL[1:0]	TRIMOFFSETN[4:0]	TRIMOFFSETP[4:0]
NMOS	11	increment	keep as is
PMOS	01	keep as is	increment

Different OPAMP instances can be calibrated at any time, even at the same time.

Calibration initialization

To initialize the offset trimming value calibration:

- Enable OPAMP, by setting OPAEN.
- Make the trimming bitfields writable, by setting USERTRIM.
- Write TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields with 0b00001.

Calibration loop sequence

To execute a calibration loop, go through the following steps:

1. Select the calibration loop, with the CALSEL[1:0] bitfield. That is, the speed (slew rate) and the differential pair end (NMOS or PMOS) to calibrate.
2. Increment the appropriate trimming bitfield (TRIMOFFSETN[4:0] for NMOS, TRIMOFFSETP[4:0] for PMOS), keeping the other trimming bitfield as is.
3. Wait for at least the $t_{OFFTRIMmax}$ period.
4. Check the CALOUT flag (OPAINTOEN = 0) or the ADC output (OPAINTOEN = 1). If high, go to step 2 (loop back).
5. The trimming bitfield is calibrated. Store the calibrated trimming value if required.

For a given speed (slew rate), execute both the NMOS and the PMOS calibration loops.

Note: During the calibration loop execution, the external connection of the operational amplifier output must not pull up or down currents exceeding 500 µA.

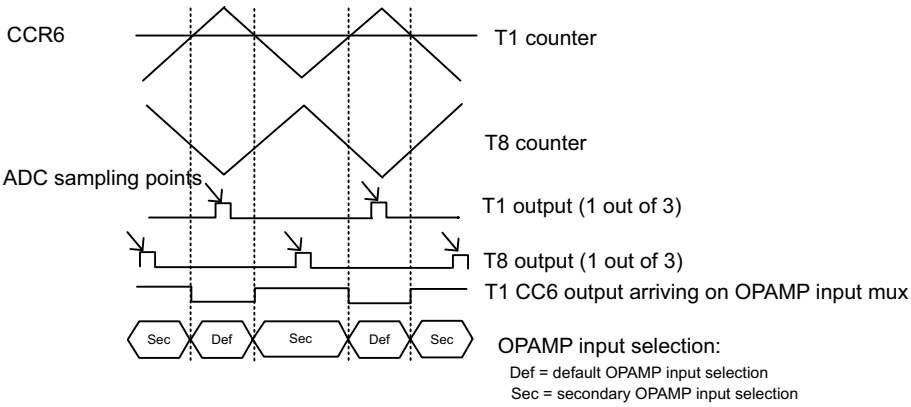
Calibrating when operational amplifier output goes to an ADC/COMP input

With the operational amplifier output redirected to an internal ADC/COMP input channel (OPAINTOEN bit set), the CALOUT flag does not reflect the operational amplifier output. There are two options to address this.

The first option is to use, during the calibration, the ADC output as indicator of reaching the target trimming value. An ADC output value close to the maximum is equivalent to CALOUT at 1. An ADC output value close to zero is equivalent to CALOUT at zero.

The second option is to clear the OPAINTOEN bit for the time of calibration to make the CALOUT flag operate. When the calibration is completed, set OPAINTOEN to redirect the

operational amplifier output back to an ADC/COMP input channel. As during the calibration the internal signal sent to the OPAMP_VOUT pin toggles, care must be taken to prevent any conflict on the pin. For example, use the pin in the application as an input.



31.4.12 Timer-controlled operation

Certain timer channels (see *Table 271*) can toggle the control of the operational amplifier multiplexers between the primary configuration defined through the OPAMP_CSR register and the secondary configuration defined through the OPAMP_TCMR register.

Once configured, the mechanism operates even when the OPAMP clock is disabled.

As an example, this can be used for dual motor control. The following figure illustrates the use of a timer compare output toggling the OPAMP primary (default) and secondary configurations, to measure alternatively the currents of the three phases of one motor then of the other motor.

Figure 294. Timer-controlled operation for a dual motor application

Timer-controlled input selection

This operation is activated by writing a value other than zero to the TIMCM_SEL[2:0] bitfield of the OPAMP_TCMR register, thus selecting one of opamp_tcX signals. As long as the selected signal is low, the input selectors are controlled with the VP_SEL[1:0] and VM_SEL[1:0] bitfields of the OPAMP_CSR register. As long as it is high, the input selectors are controlled with the VPS_SEL[1:0] and VMS_SEL bitfields of the OPAMP_TCMR register. Writing zero to TIMCM_SEL[2:0] (default upon reset) makes the input selectors steadily controlled with VP_SEL[1:0] and VM_SEL[1:0].

The following table gives the correspondence of the opamp_tcX signals to timer signals.

Table 271. Timer-controlled input selection

TIMCM_SEL[2:0]	Signal name	Timer connection
000	-	None
001	opamp_tc1	tim1_oc6
010	opamp_tc2	tim2_oc4
011	opamp_tc3	tim8_oc6

Table 271. Timer-controlled input selection (continued)

TIMCM_SEL[2:0]	Signal name	Timer connection
100	opamp_tc4	tim12_oc1
101	opamp_tc5	tim15_oc2
110	opamp_tc6	tim20_oc6
111	opamp_tc7	Reserved

Timer-controlled programmable gain and PGA flavor

This operation is activated by writing a value other than zero to the TIMPGA_SEL[2:0] bitfield of the OPAMP_TCMR register, thus selecting one of opamp_tpX signals. As long as the selected signal is low, the programmable gain and PGA flavor selectors are controlled with the PGA_GAIN[4:0] bitfield of the OPAMP_CSR register. As long as it is high, the input selectors are controlled with the PGAS_GAIN[4:0] bitfield of the OPAMP_TCMR register. Writing zero to TIMPGA_SEL[2:0] (default upon reset) makes the programmable gain and PGA flavor selectors steadily controlled with PGA_GAIN[4:0].

The following table gives the correspondence of the opamp_tpX signals to timer signals.

Table 272. Timer-controlled programmable gain selection

TIMPGA_SEL[2:0]	Signal name	Timer connection
000	-	None
001	opamp_tp1	tim1_oc6
010	opamp_tp2	tim3_oc2
011	opamp_tp3	tim8_oc6
100	opamp_tp4	tim9_oc1
101	opamp_tp5	tim15_oc2
110	opamp_tp6	tim20_oc6
111	opamp_tp7	Reserved

31.5 OPAMP in low-power modes

Table 273. Effect of low-power modes on OPAMP

Mode	Description
Sleep	No effect.
Stop	No effect, OPAMP register contents are kept.
Standby	The OPAMP registers are powered down and must be re-initialized after exiting Standby mode.

31.6 OPAMP registers

31.6.1 OPAMP control/status register (OPAMP_CSR)

Address offset: 0x00

Reset value: 0xXXXX 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	CAL OUT	Res.	TRIMOFFSETN[4:0]					TRIMOFFSETP[4:0]					PGA_GAIN[4:2]

rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: OPAMP_CSR register lock

This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit is used to configure the OPAMP_CSR register as read-only.
0: OPAMP_CSR is read-write
1: OPAMP_CSR is read-only

Bit 30 **CALOUT:** Operational amplifier calibration output

This bit reflects the digital value of OPAMP output when OPAINTOEN bit is low. During the input offset calibration procedure, it provides the indication that the target trimming value is reached, by transiting from 1 to 0.
The bit cannot be used as long as the OPAINTOEN bit is high.

Bit 29 Reserved, must be kept at reset value.

Bits 28:24 **TRIMOFFSETN[4:0]**: Trim for NMOS differential pairs

Upon reset, this bitfield is loaded with the factory trimming value. It can only be modified when the USERTRIM bit is set.
0x00 Reserved (should not be used for the triming value)
0x01 minimum triming value
0x1F maximum triming value

Bits 23:19 **TRIMOFFSETP[4:0]**: Trim for PMOS differential pairs

Upon reset, this bitfield is loaded with the factory trimming value. It can only be modified when the USERTRIM bit is set.
0x00 Reserved (should not be used for the triming value)
0x01 minimum triming value
0x1F maximum triming value

Bits 18:14 **PGA_GAIN[4:0]:** Operational amplifier programmable gain and PGA flavor primary control
This bitfield selects the programmable gain (bits [2:1]) and the PGA flavor ([bits 4:3]). Positive numbers represent positive gain (noninverting PGA), negative numbers negative gain (inverting PGA).
00000: gain 2
00001: gain 4
00010: gain 8
00011: gain 16
01000: gain -1 / gain 2 with bias on OPAMP_VINM0
01001: gain -3 / gain 4 with bias on OPAMP_VINM0
01010: gain -7 / gain 8 with bias on OPAMP_VINM0
01011: gain -15 / gain 16 with bias on OPAMP_VINM0
10000: gain 2 with filtering on OPAMP_VINM0
10001: gain 4 with filtering on OPAMP_VINM0
10010: gain 8 with filtering on OPAMP_VINM0
10011: gain 16 with filtering on OPAMP_VINM0
11000: gain -1 / gain 2 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11001: gain -3 / gain 4 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11010: gain -7 / gain 8 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11011: gain -15 / gain 16 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
Other: Not used

Bits 13:12 **CALSEL[1:0]:** Calibration selection
This bitfield selects the offset calibration reference voltage applied on the operational amplifier inputs when CALON and FORCE_VP bits are set.
00: $0.033*V_{DDA}$
01: $0.1*V_{DDA}$ (for PMOS calibration)
10: $0.5*V_{DDA}$
11: $0.9*V_{DDA}$ (for NMOS calibration)

Bit 11 **CALON:** Calibration mode enable
This bitfield disables or enables the calibration mode.
0: Calibration mode disabled
1: Calibration mode enabled

Bits 10:9 Reserved, must be kept at reset value.

Bit 8 **OPAINTOEN:** Operational amplifier internal output enable
This bit determines where the operational amplifier output is connected, either to the OPAMP_VOUT pin or internally to an ADC/COMP channel.
0: OPAMP_VOUT pin
1: ADC/COMP channel

Bit 7 **OPAHSM:** Operational amplifier high-speed mode
This bit determines the speed (slew rate) of the operational amplifier.
0: Normal speed
1: High speed
Only change this configuration when OPAMP is disabled.

Bits 6:5 **VM_SEL[1:0]:** Inverting input primary selection
This bitfield determines where the operational amplifier inverting input is connected to.
00: OPAMP_VINM0 pin
01: OPAMP_VINM1 pin
10: Internal resistor divider middle point
11: Operational amplifier output
The setting 10 is for the PGA use cases. With this setting, the connection of the OPAMP_VINM0 and OPAMP_VINM1 pins is determined by the PGA_GAIN[4:0] bitfield.
The setting 11 sets OPAMP in follower mode. With the other two settings, OPAMP is configured as a stand-alone operational amplifier.

Bit 4 **USERTRIM**: User trimming enable
This bit enables the user trimming of the operational amplifier input offset. When set, the TRIMOFFSETN[4:0] and TRIMOFFSETP[4:0] bitfields, loaded with factory trimming values upon reset, become writable. This allows modifying the input offset trimming values by the user.
0: Disable (trimming by user not possible)
1: Enable (trimming by user possible)

Bits 3:2 **VP_SEL[1:0]:** Noninverting input primary selection
This bitfield determines where the operational amplifier noninverting input is connected to.
00: OPAMP_VINP0 pin
01: OPAMP_VINP1 pin
10: OPAMP_VINP2 pin
11: OPAMP_VINP3 pin or DAC output channel
Refer to *Section 31.3: OPAMP implementation* for OPAMP instance-dependent information.

Bit 1 **FORCE_VP:** Force internal reference on noninverting input
This bit is reserved for test. It allows forcing the calibration reference voltage selected through the CALSEL[1:0] bitfield on the operational amplifier noninverting input.
0: Do not force (normal operation)
1: Force

Bit 0 **OPAEN:** Operational amplifier enable
This bit enables and disables the operational amplifier.
0: Disable
1: Enable

31.6.2 OPAMP timer-controlled mode register (OPAMP_TCMR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
LOCK	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TIMPGA_SEL[2:0]			PGAS_GAIN[4:0]					Res.	Res.	TIMCM_SEL[2:0]			VPS_SEL[1:0]		VMS_SEL
rw	rw	rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw

Bit 31 **LOCK**: OPAMP_TCMR register lock

This bit is write-once. It is set by software. It can only be cleared by a system reset.
This bit determines whether the OPAMP_TCMR register is read-write or read-only.
0: Read-write
1: Read-only (OPAMP_TCMR locked)

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:13 **TIMPGA_SEL[2:0]**: Timer toggle signal selection for programmable gain control

This bitfield is set and cleared by software. It selects the signal (coming from timer to OPAMP multiplexers) that toggles the programmable gain control bitfields between the primary (PGA_GAIN[4:0], signal at low level) and secondary (PGAS_GAIN[4:0], signal at high level).
000: None (gain permanently controlled through PGA_GAIN[4:0] and VM_SEL[1:0])
001: opamp_tp1
010: opamp_tp2
011: opamp_tp3
100: opamp_tp4
101: opamp_tp5
110: opamp_tp6
111: opamp_tp7

Bits 12:8 **PGAS_GAIN[4:0]**: Operational amplifier programmable gain and PGA flavor secondary control
This bitfield selects the programmable gain (bits [2:1]) and the PGA flavor ([bits 4:3]) when the timer signal selected through TIMPGA_SEL[2:0] is high. Positive numbers represent positive gain (noninverting PGA), negative numbers negative gain (inverting PGA).
00000: gain 2
00001: gain 4
00010: gain 8
00011: gain 16
01000: gain -1 / gain 2 with bias on OPAMP_VINM0
01001: gain -3 / gain 4 with bias on OPAMP_VINM0
01010: gain -7 / gain 8 with bias on OPAMP_VINM0
01011: gain -15 / gain 16 with bias on OPAMP_VINM0
10000: gain 2 with filtering on OPAMP_VINM0
10001: gain 4 with filtering on OPAMP_VINM0
10010: gain 8 with filtering on OPAMP_VINM0
10011: gain 16 with filtering on OPAMP_VINM0
11000: gain -1 / gain 2 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11001: gain -3 / gain 4 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11010: gain -7 / gain 8 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
11011: gain -15 / gain of 16 with bias on OPAMP_VINM0 and filtering on OPAMP_VINM1
Other: Not used

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:3 **TIMCM_SEL[2:0]**: Timer toggle signal selection for operational amplifier input control
This bitfield is set and cleared by software. It selects the signal (coming from timer to OPAMP multiplexers) that toggles the operational amplifier input configuration control bitfields between the primary (VP_SEL[1:0] / VM_SEL, signal at low level) and secondary (VPS_SEL[1:0] / VMS_SEL, signal at high level).
000: None (input configuration permanently controlled through VP_SEL[1:0] and VM_SEL)
001: opamp_tc1
010: opamp_tc2
011: opamp_tc3
100: opamp_tc4
101: opamp_tc5
110: opamp_tc6
111: opamp_tc7

Bits 2:1 **VPS_SEL[1:0]**: OPAMP noninverting input secondary selection.
This bitfield is set and cleared by software. It selects the signal to connect to the operational amplifier noninverting input as long as the level of the timer signal selected through the TIMCM_SEL[2:0] bitfield is high.
00: OPAMP_VINP0
01: OPAMP_VINP1
10: OPAMP_VINP2
11: OPAMP_VINP3 pin or DAC output channel
Refer to *Section 31.3: OPAMP implementation* for OPAMP instance-dependent information.

Bit 0 **VMS_SEL**: OPAMP inverting input secondary selection

This bitfield is set and cleared by software. It selects the signal to connect to the operational amplifier inverting input as long as the level of the timer signal selected through the TIMCM_SEL[2:0] bitfield is high. The effect also depends on the VM_SEL[1:0] bitfield.

Condition: VM_SEL[1:0] = 00 or 01

0: OPAMP_VINM0 (operation as stand-alone operational amplifier)

1: OPAMP_VINM1 (operation as stand-alone operational amplifier)

Condition: VM_SEL[1:0] = 10 or 11

0: Internal resistor divider middle point (operation as PGA)

1: Operational amplifier output (operation as follower)

31.6.3 OPAMP register map

Table 274. OPAMP register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3 on page 122* for the register boundary addresses.

32 Coupling and chaining bridge (CCB)

In this section, any references to CCB only apply to STM32G56x products. The STM32G53x/54x/55x products do not have the CCB peripheral.

32.1 CCB introduction

The coupling and chaining bridge (CCB) is a sophisticated security mechanism designed to ensure that private keys are protected, even against CPU access, and are wrapped with unique device keys, and stored securely in a secure storage.

The CCB can be programmed to implement special coupling and chaining operations required to protect private keys used in PKA protected operations.

These coupling and chaining operations involve the PKA, the SAES, and sometimes the RNG peripherals.

32.2 CCB main features

The principal features of the CCB are listed below:

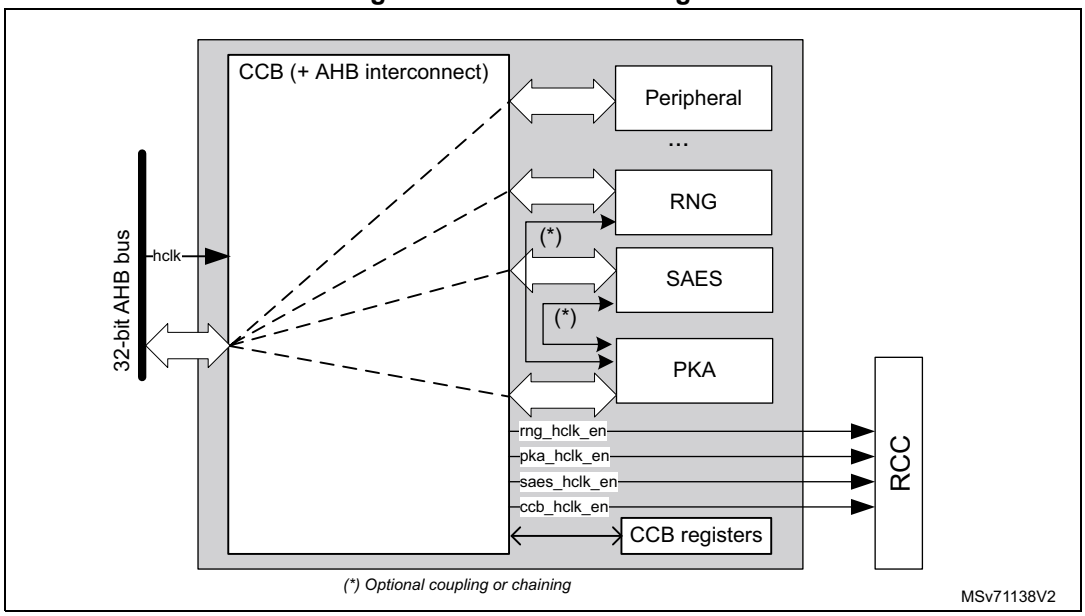
- AHB system slave port, mapping multiple peripherals (see *Section 32.3*)
- AHB configuration slave port (CCB peripheral), accessible in write through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored). There is no limitation for reads.
- Optional coupling of PKA RAM writes to SAES input data register
- Support for multiple optional chaining options:
  - Read and write chaining between PKA RAM and SAES
  - SAES to CCB read chaining, with comparison to a 128-bit reference tag
  - RNG output chaining with either PKA RAM or SAES_IVR registers
- Dedicated sequences to support three PKA protected operations (modular exponentiation, scalar multiplication, ECDSA signature)
  - One-time sequence to prepare a PKA protected operation (blob creation)
  - Many-time sequence to execute PKA protected operation (blob usage)
- Optional private key generation for ECDSA signature, and for ECC private key cryptography (key never accessible to the application in clear-text)
- Possibility to encrypt, with AES-256, any PKA blob encryption key using the device unique secret key DHUK (in the SAES), which makes the PKA encrypted blob usable only on this device
- Software-reset capability
- Repository for cryptographic subsystem tamper event flags

32.3 CCB implementation

The CCB connects the peripherals listed in *Table 275*.

Table 275. Peripherals connected by CCB interconnect

Peripheral	Coupling and chaining feature(1)	Tamper status flag in CCB_SR
RNG	Yes	TAMP_EVT0
SAES	Yes	TAMP_EVT1
PKA	Yes	TAMP_EVT2 (registers + PKA RAM)
		TAMP_EVT3 (PKA operations)
CCB	Yes	TAMP_EVT4
AES	No	TAMP_EVT5
HASH	No	-



1. See *Section 32.4.4* for details.

32.4 CCB functional description

32.4.1 CCB block diagram

Figure 295 shows the CCB block diagram. Peripherals connected to the CCB interconnect, with optional coupling/chaining features, are defined in *Section 32.3*.

Figure 295. CCB block diagram

32.4.2 CCB internal signals

Table 276 describes the relevant internal signals interfacing the CCB peripheral. Signals targeting peripherals connected to the CCB are not listed.

Table 276. CCB internal input/output signals

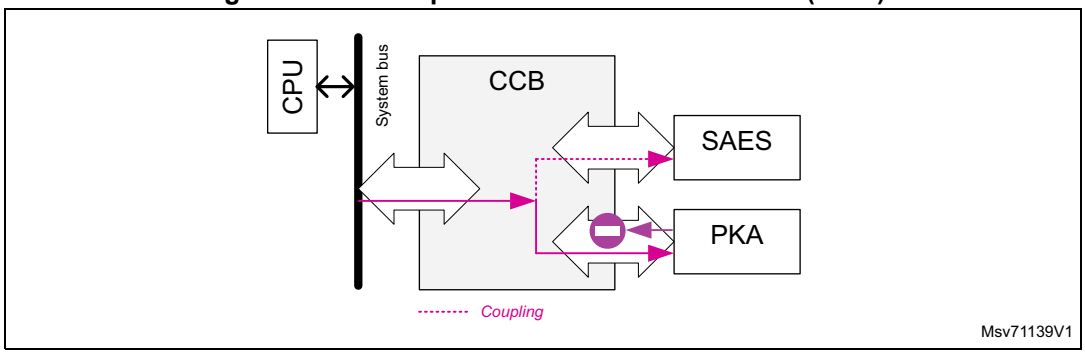
Signal name	Signal type	Description
hclk	Digital input	Interconnect system clock input
ccb_hclk_en	Digital output	CCB clock request to the RCC
x_hclk_en	Digital output	Peripheral x clock request to the RCC (x = SAES, PKA, or RNG)

32.4.3 CCB reset and clocks

The CCB shares the same clock used by the AHB bus. Once the CCB clock is activated in the RCC, and coupling and chaining activity is activated by setting CCOP ≠ 0 in CCB_CR, the CCB automatically requests the RCC to enable RNG, SAES, and PKA clocks . These clocks remain enabled until the application gates them in the RCC, with CCOP cleared in the CCB_CR register.

The CCB has a dedicated reset bit in the RCC, and a system reset input. Locally to the CCB it is also possible to trigger a reset of the peripheral based on IPRST (do not use it when the application does not use CCB)in the CCB_CR register (refer to the bitfield description for details). Status register CCB_SR has a specific reset behavior (see *Section 32.7.2*).

When at least a cryptographic peripheral raises a tamper event, the CCB requests its clock to the RCC. The tamper status TAMP_EVTi of these peripherals can be found in the CCB_SR register, as defined in *Section 32.3*.



32.4.4 CCB coupling and chaining

Note: The selection of these chaining modes is defined in Section 32.5. In most of these operations, a read of the PKA RAM returns 0 (shown with a purple circle in the following figures).

Coupling CPU → PKA + SAES (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and sends them to SAES_DINR, as shown in *Figure 296*. Write to SAES_DINR is not coupled to the PKA. The CCB sends both data and address to SAES_DINR.

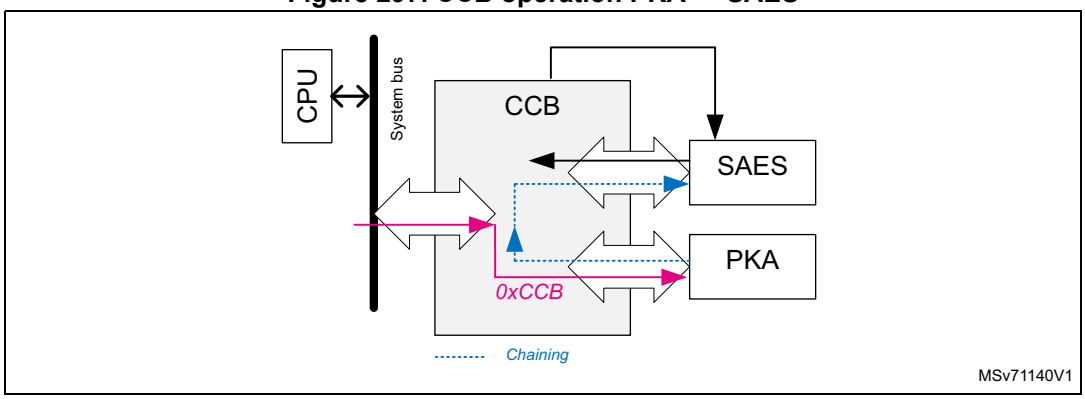


Figure 296. CCB operation CPU → PKA + SAES (write)

Chaining PKA → SAES

When the corresponding OPSTEP is selected, for each 32-bit write request to the PKA RAM of magic number 0xCCB, the CCB generates a read request from the write target (in the PKA RAM) to SAES_DINR.

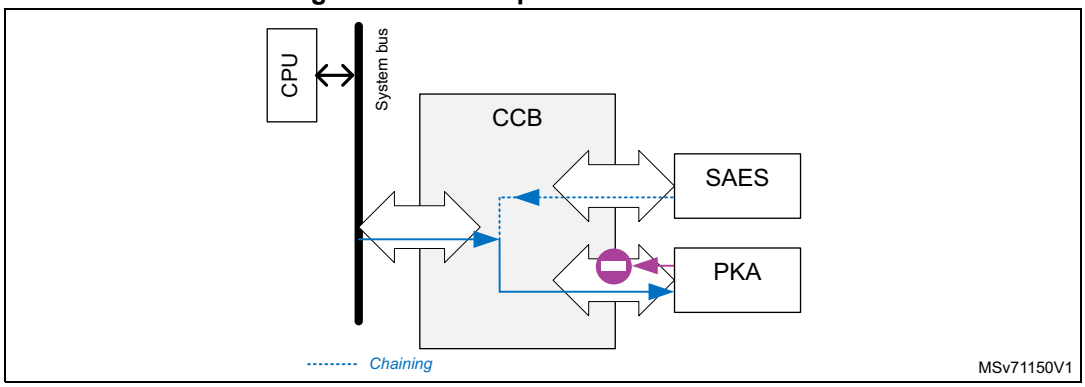

Figure 297. CCB operation PKA → SAES

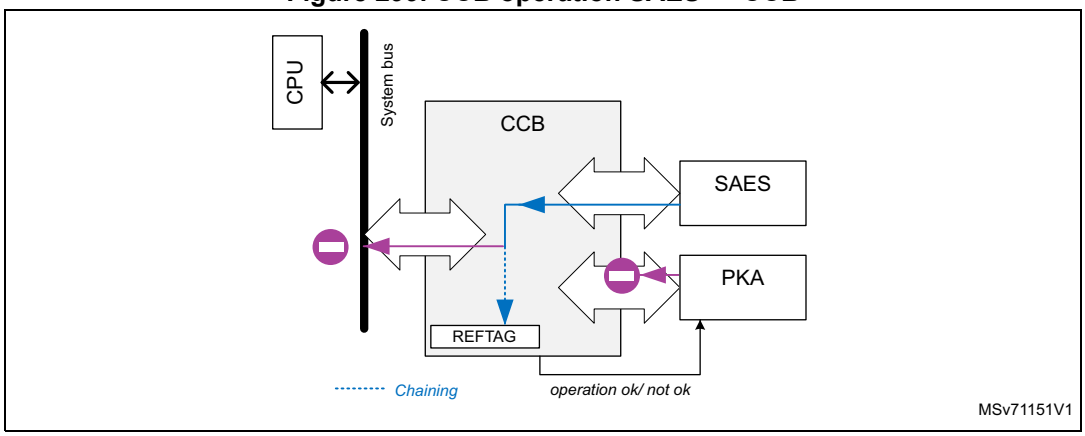
Chaining SAES → PKA

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and substitutes these data by a 32-bit word coming from SAES_DOUTR. When available, this chaining is activated when the application writes 0xCCB to PKA RAM.

Figure 298. CCB operation SAES → PKA



Chaining SAES → CCB

When the corresponding OPSTEP is selected, the CCB takes the read requests to SAES_DOUTR, and sends them to the system interconnect and to CCB_REFTAGRx holding the reference TAG information. For confidentiality reason, read data toward system bus are zeroed by the CCB.

If the CCB finds that the transfered value matches its reference information, it signals to the PKA that it can proceed with the protected PKA operation (START bit can be set).

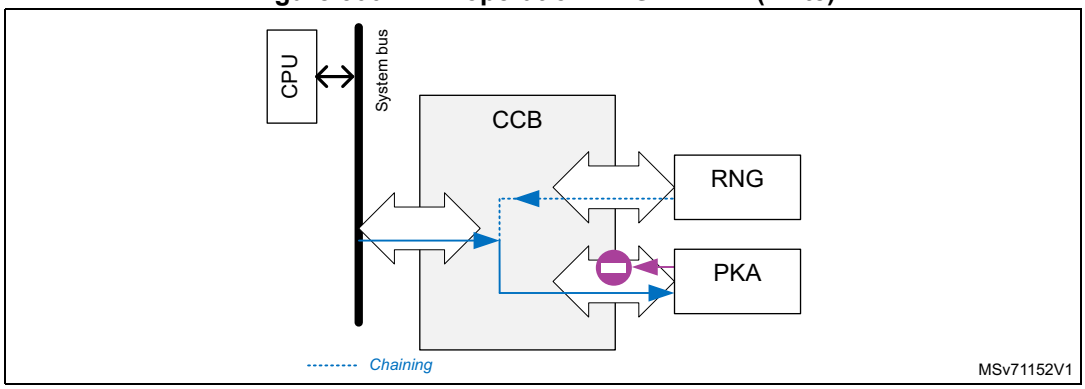


Figure 299. CCB operation SAES → CCB

Chaining RNG → PKA (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to the PKA RAM, and substitutes these data with random numbers coming from RNG_DR. For consistency, the application can write 0xCCB to activate this chaining.

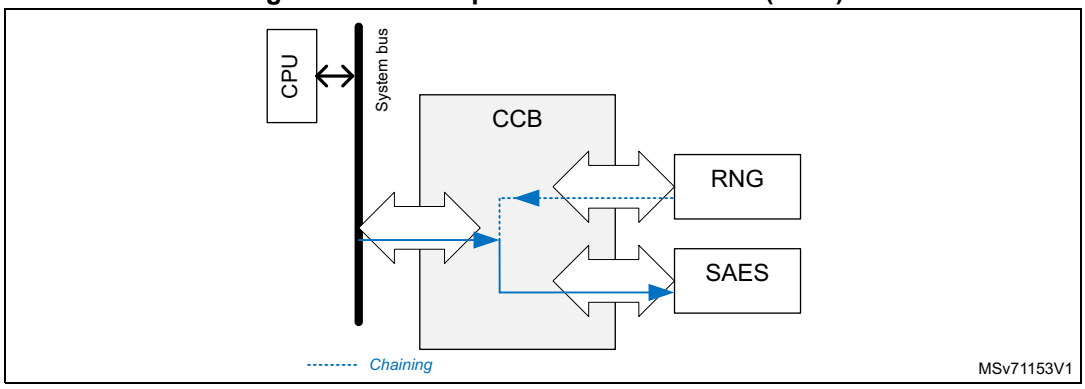

Figure 300. CCB operation RNG → PKA (write)

Chaining RNG → SAES (write)

When the corresponding OPSTEP is selected, the CCB takes the write requests that go to SAES_IVR1 to IVR3, and substitutes these data with random numbers coming from RNG_DR. For consistency, the application can write 0xCCB to activate this chaining.

Figure 301. CCB operation RNG → SAES (write)

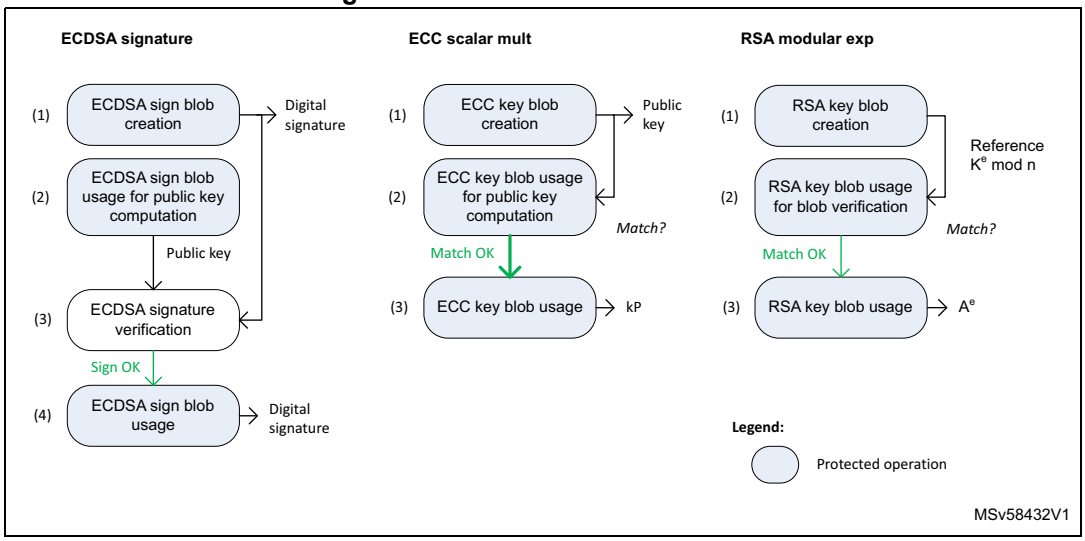
32.4.5 CCB error management

When the CCB detects an error during a coupling and chaining operation (see *Section 32.5*), it sets accordingly OPERR[5:0] in CCB_SR (see *Section 32.7.2* for the possible errors).

When OPERR[5:0] ≠ 0 in CCB_SR, the CCB raises IPRST in CCB_CR, sets OPSTEP[4:0] to 0x1F, and sets CCB_BUSY bit to 1. The application must clear IPRST to be able to use again the CCB and the peripheral(s) used by the coupling and chaining operation.

32.5 CCB coupling and chaining operations

When an application must enforce private key confidentiality by wrapping them with a 256-bit hardware unique key, the following steps are needed:



1. Select the protected operation in the PKA that uses this private key (ECDSA signature, scalar multiplication, modular exponentiation). Then, choose the CCOP value in the CCB that corresponds to the selected operation, as defined in this section. Then, as multiple cryptographic peripherals are used, make sure to follow the guidelines described in *Section 32.5.1*
2. When CCB is active (OPSTEP=0x1), select in the SAES the DHUK (with optional XOR with BHK), or unwrap in the SAES an existing blob encryption key that has been encrypted (in wrapped-key mo.de) using the DHUK. A 256-bit KEYSIZE must be selected.
   As the DHUK value is different when CCB is active or inactive, the operation of wrapping or unwrapping blob encryption key in SAES (with KMOD[1:0]=0x1) must be done when OPSTEP=0x1. Refer to operation with wrapped keys in *Section 35: Secure AES coprocessor (SAES)* for details.
3. When the application uses this protected operation in the PKA, it must load the related blob information in the PKA RAM and in SAES_DINR.
   – If the information exactly matches the conditions of the blob generation (choice and order of the writes of protected parameters in the PKA RAM, selection of blob

encryption key, use of original encrypted secrets), the CCB allows the application to set START bit in PKA_CR.

– If the blob information does not match the conditions of the blob generation, the application can only reset the sequence by setting IPRST bit in CCB_CR. CCB, PKA, and SAES become available when CCB_BUSY is cleared in CCB_SR.

4. At any time, the application can abort the executing protected operation by using the IPRST bit in CCB_CR.
5. When creating a blob, always use it once before trusting it to be stored in non-volatile memory or given to a less trusted code (see *Figure 302*). More specifically, each time a blob is created:
   – For ECDSA signature blob: use it to compute the public key, and use this key to verify the signature computed during the blob creation.
   – For ECC key blob: use it to compute the public key, and verify key coordinates match those of the key computed during the blob creation.
   – For RSA key blob: use it to compute a reference modular exponentiation and verify it matches the one computed during the blob creation.

Figure 302. Blob creation scenarios

This section describes how to do the above steps, for all available protected operations in the PKA. Note that:

- **Bold** elements in the following tables are key inputs that the application must save in non-volatile memory after the newly created blob has been confirmed by its first usage.
- The CCB automatically goes to the next step, updating the OPSTEP value, when the application clears or performs the end-step event described in tables of *Section 32.5.2* to *Section 32.5.4*.
- When an incremental read or write is mentioned, the application must write four bytes in the PKA memory, with an incremental memory address (modulo 0x8). Otherwise, the CMF error flag is triggered, and the process must be restarted.
- When writing to SAES_CR register the application must write the configuration expected by the CCB, otherwise an OPERR might be raised. Refer to the OPSTEP “CPU action” instructions in the application tables (*Table 277* through *Table 283*).
- When the CCB uses the RNG, the application must check in RNG_SR that no error occurred (SEIS = CEIS = 0), and that a random number is ready (DRDY = 1). In case of issue, RNGOKF is not set, and the application must ensure that the RNG is functional before running again the OPSTEP sequence that uses the RNG.
- For each OPSTEP>0, the application must manage the error flags that could occur in the RNG, SAES or PKA blocks. During a normal protected operation, no error flags are expected. Refer to *Section 32.4.5: CCB error management* for details on CCB error management.
- When CCB draws random number to compute ECC private keys, it implements the testing candidates method defined by NIST in FIPS PUB 186-4 section B.4.

Note: It is not possible to generate RSA key pairs with the CCB, they must be generated outside the device.

32.5.1 Preliminary steps before any protected operation

The following steps are required before running any operation described in this section:

1. Initialize the GTZC using the same security/privilege configuration protections for the SAES, PKA, RNG and CCB peripherals (see *Section 5: Global TrustZone® controller (GTZC)*). Otherwise OPERR = 0x1A occurs (see *Section 32.7.2*).
2. Activate both RNG clocks, then initialize the peripheral to be fully functional, without pending errors.
3. Activate the PKA clock, then release the PKA reset. The PKA is functional once its RAM is automatically erased, and it has fetched the necessary random numbers. For further details refer to enabling/disabling PKA in *Section 37: Public key accelerator (PKA)*.
4. Activate the SAES clock, then release the SAES reset. The SAES is functional once it has fetched necessary random numbers.
5. Activate the CCB clock, set IPRST bit in CCB_CR, then clear it when CCB_BUSY = 0x0 in CCB_SR.

Note: Step 4 can be done before step 3, as CCOP = 0x0.

32.5.2 ECDSA signature

This PKA operation is protected against side-channel attacks. When CCOP = 0x0, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0xC3, the private key d can be manipulated by the application only if encrypted, using a special blob called “ECDSA signature blob”.

ECDSA signature blob creation

The ECDSA signing operation is prepared by generating and then encrypting the private key d, and computing the reference GCM tag. This process is summarized *Table 277*, with coupling and chaining operations described in *Section 32.4.4*. This sequence starts by setting CCOP to 0xC0 or 0xC2 in CCB_CR.

Table 277. Blob creation steps for ECDSA signature (CCOP = 0b110000<i>0)

OP STEP	MODE in PKA	GCMPH in SAES	Coupling or chaining	End-step event(1)	CPU action in the step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x24 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt the blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set AES-GCM up in 256-bit encryption mode, with the DHUK or the decrypted key in register (if applicable). – Write hash z in the PKA RAM.
0x2		0x0	RNG -> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. SAES_IVR1 to SAES_IVR3 are loaded with randoms. – Read back **blob IV** in SAES_IVR registers.
0x3	0x24	0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in the SAES triggered after each 2x32-bit write.
0x6 (<i>=1)	0x24	0x2	RNG -> PKA	RNGOKF set	Write incrementally d in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if sanity check fails).
0x4 (<i>=0)			n/a	DATAOKF set	Write incrementally d in the PKA.
0x8	0x24		PKA -> SAES	DATAOKF set	– Read incrementally d from the PKA (writing 0xCCB magic numbers), and run AES encryption rounds. Special rule must be used for the last 64-bit word (see step 7 after the table). – Read **encrypted d** in SAES_DOUTR. – Repeat for each 16 bytes block of data.
0x9			RNG -> PKA	RNGOKF set, GCMPH = 0x3	– Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0xA(2)		0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR For the first two steps keep the SAES enabled (EN bit set).

Table 277. Blob creation steps for ECDSA signature (CCOP = 0b110000<i>0) (continued)

OP STEP	MODE in PKA	GCMPH in SAES	Coupling or chaining	End-step event(1)	CPU action in the step
0x19(3)	0x24	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM reads as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read signature (r,s) in PKA RAM, and save it in SRAM. It is used (at least once) for blob creation verification. – Set IPRST in CCB
0x0	N/A	N/A	N/A	N/A	– Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR. – Verify the newly created blob, running the *ECDSA signature blob use for public-key computation* with it.

1. The application must clear and/or perform the described event for the CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

The sequence described in *Table 277* is detailed below. Refer to the table for OPSTEP values and related coupling/chaining modes.

1. Write CCOP = 0xC0 or 0xC2 in CCB_CR.
2. Enable the PKA in the correct mode, writing in PKA_CR MODE=0x24 and EN=1 (repeat if the EN bit stays clear). Wait for INITOK=1 in PKA_SR.
3. Write the hash of the message in the PKA RAM
4. Initialize the ECC signature blob key in the SAES. This key can be the DHUK (KEYSEL = 0x1 or 0x4), or a key decrypted in 256-bit wrapped key mode by the DHUK (KEYSEL = 0x1 or 0x4, KMOD = 0x1, MODE = 0x1 or 0x2). See *Section 35: Secure AES coprocessor (SAES)* for details.
5. In the SAES, set the GCM chaining mode in encryption mode (CHMOD = 0x3, GCMPH = 0x0, MODE = 0x0, DATATYPE = 0x0). Then:
   a) Configure the 256-bit key size using KEYSIZE.
   b) Write SAES_IVRx, with any value (except SAES_IVR0 that must be equal to 0x2). For SAES_IV1 to IV3, random values are loaded into the SAES by the CCB. If an error occurs, RNGERRF is set in CCB_SR.
   c) Read back SAES_IVR1 to SAES_IVR3, and **save the value** in non-volatile memory after blob verification.
   d) Set EN in SAES_CR, and wait until CCF = 1 in SAES_ISR (end of GCM init).
   e) Clear CCF flag in SAES_ICR.
6. Select the header phase of the running GCM chaining mode (GCMPH = 0x1). Write the protected operation (ECDSA signature) mandatory parameters in the PKA RAM, as described in *Section 37: Public key accelerator (PKA)*. Do the following when writing data in the PKA:
   a) Write two 32-bit word in the PKA RAM, then wait until CCF is set in SAES_ISR. An SAES interrupt can be triggered when this flag is set.
   b) Clear CCF in SAES_ICR.

7. Select the payload phase of the running GCM chaining mode (GCMPH = 0x2). Write the private key *d* in the PKA RAM using the following sequence:
   a) If CCOP = 0xC0, write the private key d value in the PKA RAM. If CCOP = 0xC2, write the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The CCB then draws the value of *d* from the RNG, with PKA running a special sanity check to verify random compliance with NIST standard.
   b) Complete parameter information with the mandatory two 32-bit zeroed words. At the end of this process, the private key d of size *d_size* is written in the PKA RAM. Clear the error flag, then restart step 6 if the PKA sets RNGERRF when BUSY is cleared.
8. When the PKA sets its completion flag (RNGOKF if CCOP = 0xC2, DATAOKF if CCOP = 0xC0), clear it, then read the private key d in the PKA RAM using the sequence below (starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8):
   a) For each 64-bit word in the PKA RAM, write twice the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The target content of the PKA memory is transfered to SAES_DINR by the CCB. Wait until CCF is set in SAES_ISR (end of AES encryption). An SAES interrupt can be triggered when this flag is set.
   b) Clear CCF flag in SAES_ICR. Then read the encrypted private key d in SAES_DOUT, **to save it** in the non-volatile memory after blob verification.
   c) For the final 64-bit word (mandatory zeroed word): if the *d_size* is proportional to 16 bytes (for example, for 192- and 521-bit curves), the final 64 bits must be written to with two 32-bit magic numbers 0xCCB. If the *d_size* is not proportional to 16 bytes (for example, for 256- and 512-bit curves), the final 64 bits must be written with 0s.
9. When DATAOKF = 1 in PKA_SR (private key d ok), clear this flag. Then write to the integer k parameter addresses in the PKA memory, starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8. The CCB draws the value of k from the RNG. The PKA then runs a special sanity check to verify random compliance with NIST standard. Clear the error flag then restart this step if the PKA sets RNGERRF when BUSY is cleared.
10. When RNGOKF = 1 in PKA_SR (random k OK), clear this flag. Then select the final phase of the running GCM chaining mode (GCMPH = 0x3). Write the last GCM block in SAES_DINR. Then wait until CCF is set in SAES_ISR (end of GCM final).
11. Read SAES_DOUTR four times to retrieve the ECDSA signature blob reference tag. Save it in the non-volatile memory after blob verification. Do not disable SAES by clearing the EN bit.
12. Set START bit in PKA_CR to run the ECDSA signature operation.
13. When the PROCENDF completion flag is set save the ECDSA signature (r,s) of the hash z in SRAM to use it after using the new blob for public-key computation.
14. Clear CCOP by setting IPRST bit in CCB_CR. After CCB_BUSY is cleared in CCB_SR, clear the IPRST bit. The SAES, and PKA can again be used for any tasks. They are unprotected by the CCB until CCOP is written different from 0.

ECDSA signature blob usage for ECDSA signature

Table 278 summarizes the ECDSA signing operation using the encrypted private key d, the reference blob IV, and the computed GCM tag of *Table 277*. Coupling and chaining traffic options are described in *Section 32.4.4*. This sequence starts by setting CCOP to 0xC3 in the CCB_CR register.

Table 278. Blob use steps for ECDSA signature (CCOP = 0b11000011)

OPSTEP	MODE in PKA	GCMPH	Coupling or chaining operations	End-step event(1)	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x24 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt the blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set AES-GCM up in 256-bit encryption mode, with the DHUK or the decrypted key in register (if applicable). – Write hash z.
0x12		0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13	0x24	0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in the SAES, triggered after each 64-bit write.
0x14		0x2	SAES –> PKA	DATAOKF set	– Write encrypted d in SAES_DINR, and runs AES decryption round. – Write incrementally private key d in the PKA, using 0xCCB magic number. A special rule must be used for the last 64-bit write (see step 7 in the sequence detailed after this table). – Repeat for each 16-byte block of data.
0x16			RNG –> PKA	RNGOKF set, GCMPH = 0x3	Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0x17		0x3	SAES –> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x24	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)		N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM is read as 0.
0x1A		N/A	N/A	N/A	Read **signature (r,s)** in the PKA RAM.

1. The application must clear and/or perform the described event for the CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons..

The sequence described in *Table 278* is detailed below. Refer to the table for the OPSTEP values and related coupling and chaining modes.

1. Write CCOP = 0xC3 in CCB_CR.
2. Enable the PKA in the correct mode, writing in PKA_CR MODE=0x24 and EN=1(repeat if the EN bit stays clear). Wait for INITOK=1 in PKA_SR.
3. Write the hash of the message in the PKA RAM.
4. Initialize the ECC signature blob key in the SAES. This key can be the DHUK (KEYSEL = 0x1 or 0x4), or a key decrypted in 256-bit wrapped key mode by the DHUK (KEYSEL = 0x1 or 0x4, KMOD = 0x1, MODE = 0x1). Refer to *Section 35: Secure AES coprocessor (SAES)* for details.
5. Set the GCM chaining mode in decryption in the SAES (CHMOD = 0x3, GCMPH = 0x0, MODE = 0x2, DATATYPE = 0x0). Then:
   a) Configure the 256-bit key size using KEYSIZE.
   b) Write to SAES_IVRx registers the value saved in non-volatile memory.
   c) Set EN in SAES_CR, and wait until CCF is set in SAES_ISR (end of GCM init).
   d) Clear CCF flag in SAES_ICR.
   e) Write to CCB_REFTAGR registers, the ECDSA signature blob reference tag value saved in non-volatile memory.
6. Select the header phase of the running GCM chaining mode (GCMPH = 0x1). Write the protected operation (ECDSA signature) mandatory parameters in the PKA RAM, exactly as done during the blob creation. See step 5 in *ECDSA signature blob creation* for details.
7. Select the payload phase of the running GCM chaining mode (GCMPH = 0x2). Write the protected private key d in the PKA RAM, following the below sequence (starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8):
   a) Writetwo 64-bit words of encrypted private key d in SAES_DINR. Wait until CCF is set in SAES_ISR (end of AES decryption). An SAES interrupt can be triggered when this flag is set.
   b) Clear the CCF flag in the SAES_ICR register. Then, for both 64-bit words, write four times the 32-bit magic number 0xCCB to the private key d parameter addresses in the PKA memory. The CCB transfers the clear-text content of SAES_DOUTR to the PKA.
   c) For the final 64-bit word (mandatory zeroed word): If *d_size* defined in step 6 in *ECDSA signature blob creation* is not proportional to 16-bytes (for example, for 256- and 512-bit curves), the final 64 bits must be written with 0s.
8. When DATAOKF = 1 in PKA_SR (private key d ok), clear this flag. Then write to the integer k parameter addresses in the PKA memory, starting from the LSB word in the PKA RAM, and increasing the addresses modulo 0x8. The CCB draws the value of k from the RNG. The PKA then runs a special sanity check to verify random compliance with NIST standard. Clear the error flag, then restart step 7 if the PKA sets RNGERRF when BUSY is cleared.
9. When RNGOKF = 1 in PKA_SR (random k ok), clear this flag. Then select the final phase of the running GCM chaining mode (GCMPH = 0x3). Write the last GCM block in SAES_DINR. Then wait until CCF is set in SAES_ISR (end of GCM final).
10. Read four times SAES_DOUTR (returns 0s). If PKA parameters were written exactly like during the blob creation, and the correct private key d was used, and all expected DATAOKF/RNGOKF flags were raised then cleared, the application can set START bit

in PKA_CR to run the ECDSA signature operation. Otherwise, IPRST in CCB_CR must be used to restart the sequence from step 1.

11. Clear CCOP by setting IPRST in CCB_CR. After CCB_BUSY is cleared in CCB_SR, clear the IPRST bit. The SAES, and PKA can again be used for any tasks. They are unprotected by the CCB until CCOP in CCB_CR is written different from 0.

ECDSA signature blob use for public-key computation

The ECC public key computation using the encrypted private key d, the reference blob IV, and the computed GCM tag of *Table 277* is summarized in *Table 279*. The additional ECDSA verification at the end of the sequence must be used before saving a new ECDSA signature blob in non-volatile memory. Shown coupling and chaining traffic options are described in *Section 32.4.4*. This sequence starts by setting CCOP to 0x81 in the CCB_CR register.

Table 279. Blob use steps for signing public key computation (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable).
0x12	0x20	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13		0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC signature parameters in the PKA RAM, clearing CCF flags in SAES, triggered after each 2x32-bit write.
0x14		0x2	SAES -> PKA	DATAOKF set, GCMPH = 0x3	– Write encrypted d in SAES DINR and run AES decryption round. – Write incrementallyscalar multiplier k in the PKA, using 0xCCB magic number. – Repeat for each 16 bytes block of data.
0x17		0x3	SAES -> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x20	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)		N/A	N/A	PROCENDF set	The PKA computes the operation. PKA RAM is read as 0.
0x1A	0x20	N/A	N/A	N/A	– Read **public key point Q** in PKA RAM

Table 279. Blob use steps for signing public key computation (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1A	0x20	N/A	N/A	IPRST set in the CCB	– Read public key point Q in PKA RAM – Set IPRST in CCB
0x0	0x26	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR. Before writing new ECDSA signature blob in non-volatile memory do the following: – Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x26 and EN=1. Wait for INITOK=1. – Write the hash z used during blob creation (see *Table 277*) – Write ECDSA verification parameters in PKA, including the public key coordinates computed in step 0x1A. – Start the operation setting START bit in PKA_CR – Wait for PROCENDF bit is set. If the signature is valid save the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

32.5.3 ECC scalar multiplication

This operation consists in the computation of k x P, where P is a point on a curve over prime fields, and “x” is the elliptic curve scalar point multiplication. The computation result is a point that belongs to the same curve, or a point at infinity.

The scalar multiplication operation is protected against side-channel attacks. When CCOP = 0x0 in CCB_CR, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0x81, the scalar multiplier k can be manipulated by the application only if encrypted, using a special blob called “ECC key blob”.

Scalar multiplication “ECC key” blob creation

The scalar multiplication operation is prepared by generating then encrypting the scalar multiplier k, and computing the reference GCM tag. This process is summarized in *Table 280*. Coupling and chaining operations described in *Section 32.4.4*. This sequence starts by setting CCOP to 0x80 or 0x82 in CCB_CR register.

Table 280. Blob creation steps for scalar multiplication (CCOP = 0b100000<i>0)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in 256-bit encryption mode with DHUK or the decrypted key in register (if applicable) – Write base point G coordinates as input in PKA RAM.
0x2		0x0	RNG –> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. Registers IVR1 to 3 are loaded with randoms. – Read back **blob IV** in IVR registers.
0x3	0x20	0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write ECC scalar multiplication parameters in the PKA RAM, clearing CCF flags in SAES, triggered after each 64-bit write.
0x6 (<i>=1)	0x20	0x2	RNG –> PKA	RNGOKF set	Write incrementally k in the PKA, using 0xCCB magic number. Values are drawn from the RNG. The PKA runs a special sanity check to verify random compliance with NIST standard (RNGERRF is set if the sanity check fails).
0x4 (<i>=0)			N/A	DATAOKF set	Write incrementally k in the PKA.
0x8	0x20	0x2	PKA –> SAES	DATAOKF set, GCMPH = 0x3	– Read incrementally k from the PKA (writing 0xCCB magic numbers), and runs AES encryption rounds. – Read **encrypted k** in SAES DOUTR. – Repeat for each 16-byte block of data..
0xA(2)		0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR For the first two steps keep the SAES enabled (EN bit set).
0x19(3)	0x20	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM reads as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read reference public key point Q in PKA RAM, and save it in SRAM to verify the new blob. – Set IPRST in CCB.
0x0	N/A	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

Scalar multiplication blob use for example for ECC decryption

ECC scalar multiplication computation using the encrypted k, the reference blob IV and the computed GCM tag of *Table 280* is summarized in *Table 281*. Shown coupling and chaining traffic options are described in *Section 32.4.4*. This sequence starts by setting CCOP to 0x81 in CCB_CR register.

Table 281. Blob use steps for scalar multiplication (CCOP = 0b10000001)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x20 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally, decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable). – Write input point P coordinates in the PKA RAM. When computing a public key, write basepoint G coordinates.
0x12	0x20	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CBB_REFTAGR.
0x13		0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write ECC scalar multiplication parameters in the PKA RAM, clearing CCF flags in the SAES, triggered after each 64-bit write.
0x14		0x2	SAES -> PKA	DATAOKF set, GCMPH = 0x3	– Write encrypted k in SAES_DINR, and runs AES decryption round. – Write incrementally scalar multiplier k in the PKA, using 0xCCB magic number. – Repeat for each 16 bytes block of data.
0x17		0x3	N/A	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x20	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR. Do not use SAES during this step (under reset).
0x19(2)				PROCENDF set	The PKA computes the operation. The PKA RAM is read as 0.
0x1A				N/A	Read **kP point coordinates** in the PKA RAM. If this point is the public key verify it matches the reference public key computed in *Table 280* before saving the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

32.5.4 RSA modular exponentiation

The modular exponentiation operation is commonly used to perform a single-step RSA operation. It consists in the computation of A^e mod n.

This modular exponentiation operation (MODE = 0x3) is protected against side-channel attacks. When CCOP = 0x0, all parameters loaded in the PKA RAM are managed in the clear by the application. When CCOP = 0x45, the exponent e and phi value can only be manipulated encrypted by application, using a special blob called “RSA key blob”.

Modular exponentiation “RSA key” blob creation

Modular exponentiation operation is prepared by generating then encrypting the scalar multiplier *k* and computing the reference GCM tag. This process is summarized in *Table 282*. The coupling and chaining operations described in *Section 32.4.4*. This sequence starts by setting CCOP to 0x44 in CCB_CR register.

Table 282. Blob creation steps for modular exponentiation (CCOP = 0b01000100)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action in step
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x3 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in 256-bit encryption mode with DHUK or the decrypted key in register (if applicable). – Write a constant K as operand A in the PKA RAM.
0x2		0x0	RNG -> SAES	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in encryption mode. SAES_IVR1 to 3 registers are loaded with randoms. – Read back blob IV in SAES_IVR registers.
0x3	0x03	0x1	CPU -> PKA + SAES	GCMPH = 0x2	Write protected modular exponentiation parameters (PKA mode 0x3) in the PKA RAM, clearing CCF flags in the SAES triggered after each 2x32-bit write.
0x4	0x3	0x2	N/A	DATAOKF set	Write incrementally clear-text exponent e.
0x5				DATAOKF set	Write incrementally clear-text phi.
0x8			PKA -> SAES	DATAOKF set	– Read incrementallye from the PKA (writing 0xCCB magic numbers), and runs AES encryption rounds. – Read **encrypted e** in SAES_DOUTR. – Repeat for each 16 bytes block of data.
0x9				DATAOKF set, GCMPH = 0x3	– Read incrementally phi from the PKA (writing 0xCCB magic numbers), and run AES encryption rounds. – Read **encrypted phi** in SAES_DOUTR. – Repeat for each 16 bytes block of data
0xA(2)	0x3	0x3	N/A	START= 0x1	– Complete GCM final. – Read **reference tag** in the SAES. – Start the operation in PKA setting START bit in PKA_CR. For the first two steps keep the SAES enabled (EN bit set).

Table 282. Blob creation steps for modular exponentiation (CCOP = 0b01000100)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action in step
0x19(3)	0x3	N/A	N/A	PROCENDF set	The PKA computes the operation, PKA RAM is read as 0
0x1A		N/A	N/A	IPRST set in the CCB	– Read the reference modular exponentiation K^e mod *n* in PKA RAM, and save it in SRAM to verify the new blob. – Set IPRST in CCB
0x0	N/A	N/A	N/A	N/A	Clear the IPRST bit in CCB when CCB_BUSY and OPSTEP are cleared in CCB_SR.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. Once START bit is set SAES is reset, and OPERR linked to SAES are deactivated. Also when START bit is set, CCB sets OPSTEP to 0x19 after a few cycles.
3. SAES cannot be used for any operations, for security reasons.

Modular exponentiation blob use (for example for RSA decryption)

The modular exponentiation computation using the encrypted *e* and *phi*, the reference blob IV, and the computed GCM tag of *Table 282* is summarized on *Table 283*. Shown coupling and chaining traffic options are described in *Section 32.4.4*. This sequence starts by setting CCOP to 0x45 in CCB_CR register.

Table 283. Blob use steps for modular exponentiation (CCOP = 0b01000101)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x1	N/A	N/A	N/A	AES GCM selected, GCMPH = 0x0	– Enable the PKA in the correct mode, writing in PKA_CR MODE= 0x3 and EN=1 (repeat if EN bit stays clear). Wait for INITOK=1 in PKA_SR. – Optionally decrypt blob encryption key in the SAES, using DHUK in 256-bit wrapped key mode. – Set up AES-GCM in decryption mode with DHUK or the decrypted key in register (if applicable). – Write operand A in the PKA RAM. Write constant K as operand A defined in *Table 282* when verifying the created blob.

Table 283. Blob use steps for modular exponentiation (CCOP = 0b01000101)

OPSTEP	MODE in PKA	GCMPH in SAES	Coupling or chaining operations	End-step event(1)	CPU action
0x12	0x03	0x0	N/A	GCMPH = 0x1 (following GCM initialization)	– Complete GCM initialization in decryption mode, using saved random IV. – Write reference tag in CCB_REFTAGR.
0x13		0x1	CPU –> PKA + SAES	GCMPH = 0x2	Write protected modular exponentiation parameters (PKA mode 0x3) in the PKA RAM, clearing CCF flags in the SAES, triggered after each -bit write.
0x14		0x2	SAES –> PKA	DATAOKF set	– Write encrypted e in SAES_DINR, and runs AES decryption round. – Write incrementally exponent e in the PKA, using 0xCCB magic number. – Repeat for each 16-byte block of data.
0x15				DATAOKF set, GCMPH = 0x3	– Write encrypted phi in SAES_DINR, and runs AES decryption round. – Write incrementally phi in the PKA, using 0xCCB magic number. – Repeat for each 16-byte block of data.
0x17		0x3	SAES –> CCB	Tag matches REFTAGR?	– Complete GCM final. – Read computed tag in the SAES (returns 0).
0x18	0x03	N/A	N/A	START = 0x1	Start the operation in PKA setting START bit in PKA_CR.
0x19(2)				PROCENDF set	The PKA computes the operation, PKA RAM is read as 0.
0x1A				N/A	Read $\mathbf{A^e}$ **mod** n in the PKA RAM. If the result is K^e mod n verify it matches the reference computed in *Table 282* before saving the created blob in non-volatile memory.

1. The application must clear and/or perform described event for CCB to automatically go to the next step.
2. SAES cannot be used for any operations, for security reasons.

32.6 CCB interrupts

The CCB does not support any interrupt.

32.7 CCB registers

The following section provides information on registers.

Reserved bits (marked as Res.) must be kept at their reset values, unless otherwise specified.

For general information relative to register description, refer to Document conventions.

These registers are accessible through the AHB interface of the CCB (32-bit words only). All reads are supported. Writes accesses must be 32-bit word only (other access types generate an AHB error).

32.7.1 CCB control register (CCB_CR)

Address offset: 0x000

Reset value: 0x0000 0000

Following a CCB hardware reset, the above reset value applies if OPERR[5:0] = 0x0 and no TAMP_EVT bit is set.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCOP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: CCB reset

Set this bit to start or abort any PKA protected operation defined in *Section 32.5*. IPRST bit must be low while writing to any CCB register.

After setting this bit, the application must clear it when CCB_BUSY and OPSTEP are cleared in CCB_SR (IPRST clear is ignored otherwise). After this clear all CCB registers are read with their reset valuesSetting IPRST clears any data stored in the SAES and the PKA.

When IPRST and CCB_BUSY are set, SAES registers are not accessible (read as 0, write ignored), and writes to EN and START bits in PKA_CR are ignored.

This bit is set by CCB when OPERR[5:0] ≠ 0 or any TAMP_EVT bit is set.

Bits 30:8 Reserved, must be kept at reset value.

Bits 7:0 **CCOP[7:0]**: Coupling and chaining operation

These bits must be set according to the chosen PKA protected operation (see *Section 32.5*).

0x044: Modular exponentiation blob creation with priv key from the CPU

0x045: Modular exponentiation blob use

0x080: ECC scalar multiplication blob creation with priv key from the CPU

0x082: ECC scalar multiplication blob creation with priv key from the RNG

0x081: ECC scalar multiplication blob use, or ECDSA signature blob use for public key computation

0x0C0: ECDSA signature blob creation with priv key from the CPU

0x0C2: ECDSA signature blob creation with priv key from the RNG

0x0C3: ECDSA signature blob use for ECDSA signature

Note: When an operation not listed here is written by the application, the write to CCOP[7:0] is ignored. All these operations implement protections against side-channel attacks. Write to CCOP is ignored when CCB_BUSY is set in CCB_SR.

32.7.2 CCB status register (CCB_SR)

Address offset: 0x004

Reset value: 0x0000 0000

This register is reset by a system reset, or after clearing IPRST in CCB_CR. The CCB reset input from the RCC has no effect on this register.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	TAMP_EVT5	TAMP_EVT4	TAMP_EVT3	TAMP_EVT2	TAMP_EVT1	TAMP_EVT0	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCB_BUSY
		r	r	r	r	r	r								r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	OPERR[5:0]						Res.	Res.	Res.	OPSTEP[4:0]				
		r	r	r	r	r	r				r	r	r	r	r

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **TAMP_EVTi**: Tamper i flag (i = 5 to 0)

0: No event

1: Tamper event i has been raised. Global tamper event is raised. See *Section 32.3* for details on the events.

This bit is cleared by writing 0 to IPRST bit in CCR_CR. When at least one TAMP_EVT bit is set, CCB sets IPRST bit.

Bits 23:17 Reserved, must be kept at reset value.

Bit 16 **CCB_BUSY**: CCB busy

This flag is set when CCB is busy, or when OPSTEP[4:0] ≠ 0 following a CCB reset (hardware reset or use of IPRST in CCB_CR).

0: CCB idle

1: CCB busy or PKA RAM is being cleared following a peripheral reset.

When IPRST and CCB_BUSY are set, the SAES registers are not accessible (write ignored, read returns 0), and writes to EN or START bits in PKA_CR are ignored.

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **OPERR[5:0]**: Operation error

When an error is detected during a protected PKA operation, the CCB raises IPRST in CCB_CR, and OPSTEP[4:0] is set to 0x1F. The bitfield is cleared by setting IPRST to 0.

0x0: No error detected during protected PKA operation (if applicable)

0x1: CCB RCC reset has been detected when OPSTEP > 0x0

0x2: SAES RCC reset has been detected when OPSTEP > 0x0

0x3: PKA RCC reset has been detected when OPSTEP > 0x0

0x4: RNG RCC reset has been detected when OPSTEP > 0x0

0x5: The RCC has gated the CCB clock when OPSTEP > 0x0.

0x6: The RCC has gated the SAES clock when OPSTEP > 0x0.

0x7: The RCC has gated the PKA clock when OPSTEP > 0x0.

0x8: The RCC has gated the RNG clock when OPSTEP > 0x0.

0x9: Random in SAES_IV1 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xA: Random in SAES_IV2 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xB: Random in SAES_IV3 is trivial (all 0s or all 1s) when OPSTEP = 0x2

0xC: When OPSTEP = 0x17 SAES GCM TAG comparison with CCB_REFTAG failed, or a register different from SAES_DOUT was read in the SAES.

0xD: KEYSIZE ≠ 256 bits in SAES_CR when the SAES is enabled, and OPSTEP > 0x0.

0xE: CHMOD ≠ GCM in SAES_CR when 0x1 < OPSTEP < 0x18, or the SAES is not enabled, or KEYVALID is cleared when GCMPH > 0x0.

0xF: KMOD different from wrapped key mode in SAES_CR when the SAES is enabled, and OPSTEP = 0x1, or 0x1A.

0x10: KEYSEL ≠ 0x1 or 0x4 in SAES_CR when the SAES is enabled, KEYVALID is set, and OPSTEP = 0x1.

0x11: GCMPH not correct (not incremented) in SAES_CR when OPSTEP > 0x1.

0x12: MODE in SAES_CR does not match the expected value (selected by CCOP in CCB_CR) when OPSTEP > 0x1.

0x13: BUSY = 1 in SAES_SR when OPSTEP= 0x18 or 0x19. SAES must not be used when PKA is computing a protected operation.

0x14: EN = 0 in PKA_CR when OPSTEP > 0x2 (except 0x12). In other words, PKA must be enabled in any OPSTEP except 0x1, 0x2, or 0x12.

0x15: INITOK = 0 in PKA_SR when OPSTEP > 0x2 (except 0x12).

0x16: Authorized by local firewall, but unexpected AHB error detected when OPSTEP > 0x0.

0x17: LMF = 1 in PKA_SR (only ECDSA verification available) when OPSTEP > 0x0.

0x18: CCB_REFTAGRx registers are equal to 0 when OPSTEP > 0x12.

0x1A: Security, privilege protections inconsistent (see *Section 5: Global TrustZone® controller (GTZC)*) for the peripherals SAES, PKA, RNG, and CCB when OPSTEP > 0x0. This error is also triggered when the protections change while OPSTEP > 0x0,

0x1B: MODE in PKA_CR does not match the expected value (selected by CCOP in CCB_CR) when OPSTEP > 0x0.

0x1C: OPSTEP end-step event not found at OPSTEP= 0x0 (SAES KEYVALID is set). Use CCB IPRST before starting a coupling and chaining operation.

0x1D: OPSTEP end-step event not found at OPSTEP = 0x1.

0x1E: OPSTEP end-step event not found at OPSTEP = 0x2.

0x1F: OPSTEP end-step event not found at OPSTEP = 0x3.

0x20: OPSTEP end-step event not found at OPSTEP = 0xA.

0x21: OPSTEP end-step event not found at OPSTEP = 0x12.

0x22: OPSTEP end-step event not found at OPSTEP = 0x13.

0x23: OPSTEP end-step event not found at OPSTEP = 0x17.

For error codes 0x1C to 0x23, details on end-step events are found in *Section 32.5*. Those errors are also triggered when values written in SAES_CR register do not correspond to the selected CCOP and the expectations in the current OPSTEP.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **OPSTEP[4:0]**: Operation step

This read-only information indicates the current step of the coupling and chaining operation (indicated by CCOP). See *Section 32.5* for details. .

This bitfield can be cleared only using IPRST in CCB_CR. OPSTEP[4:0] = 0x1F when the IPRST procedure is in progress.

32.7.3 CCB reference tag register (CCB_REFTAGRx)

Address offset: 0x010 + 0x4 * x (x = 0 to 3)

Reset value: 0x0000 0000

Writes to this register are ignored when CCB_BUSY is set in the CCB_SR register. The register is cleared when IPRST is set and CCB_BUSY is cleared.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REFTAG{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REFTAG{i + 32 * x}															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REFTAG{i + 32 * x}**: Reference tag bits {i + 32 * x} (i = 31 to 0)

The application must write in these registers, the reference GCM tag of the required operation blob (respectively ECC signature, ECC key, or RSA key). This enables the PKA protected operation (respectively ECC signature/public key computation, scalar multiplication, or modular exponentiation). Refer to *Section 32.5* for details.

Write to this register is ignored unless OPSTEP = 0x12 in CCB_SR.

32.7.4 CCB register map

Table 284. CCB register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

33 True random number generator (RNG)

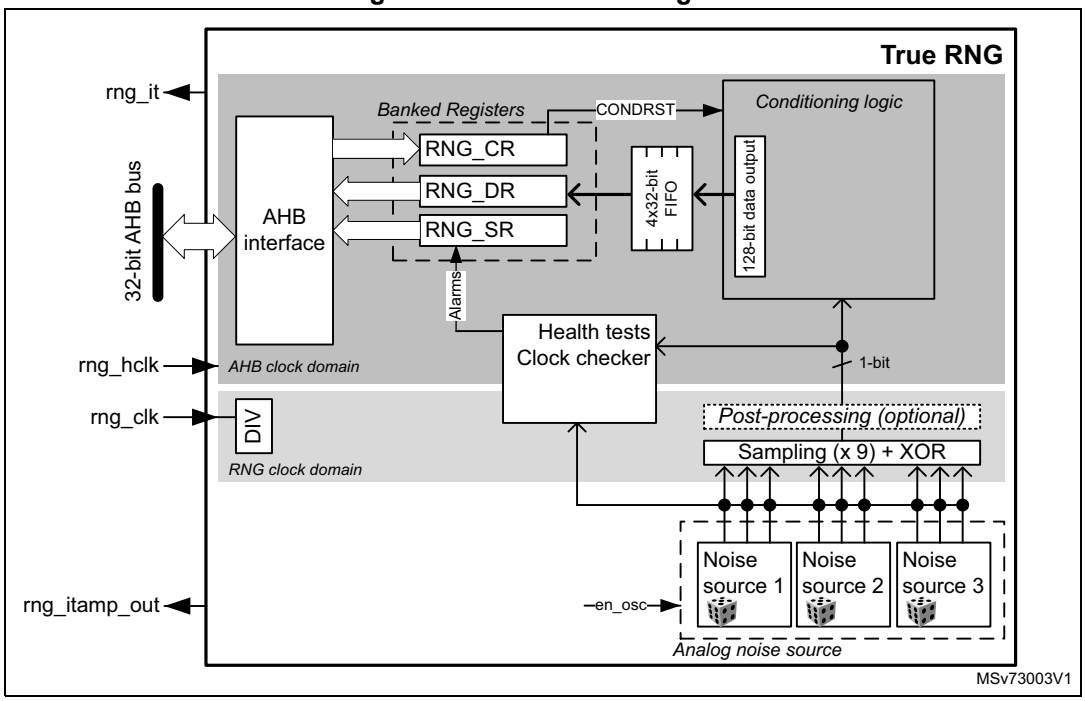
33.1 RNG introduction

The RNG is a true random number generator that provides full entropy outputs to the application as 32-bit samples. It is composed of a live entropy source (analog) and an internal conditioning component.

The RNG is an NIST SP 800-90B compliant entropy source that can be used to construct a nondeterministic random bit generator (NDRBG).

The RNG true random number generator can be certified NIST SP 800-90B. It can also be tested using the German BSI statistical tests of AIS-31 (T0 to T8).

33.2 RNG main features



- The RNG delivers 32-bit true random numbers, produced by an analog entropy source conditioned by an NIST SP800-90B approved conditioning stage.
- It can be used as the entropy source to construct a non-deterministic random bit generator (NDRBG).
- In the default configuration, it produces four 32-bit random samples every 412 AHB clock cycles if $f_{AHB} < f_{threshold}$ (256 RNG clock cycles otherwise).
- Embeds startup and NIST SP800-90B approved continuous health tests (repetition count and adaptive proportion tests), associated with specific error management.
- Can be disabled to reduce power consumption, or enabled with an automatic low power mode (default configuration).
- Has an AMBA® AHB slave peripheral, accessible through 32-bit word single accesses only (else an AHB bus error is generated, and the write accesses are ignored).

33.3 RNG functional description

33.3.1 RNG block diagram

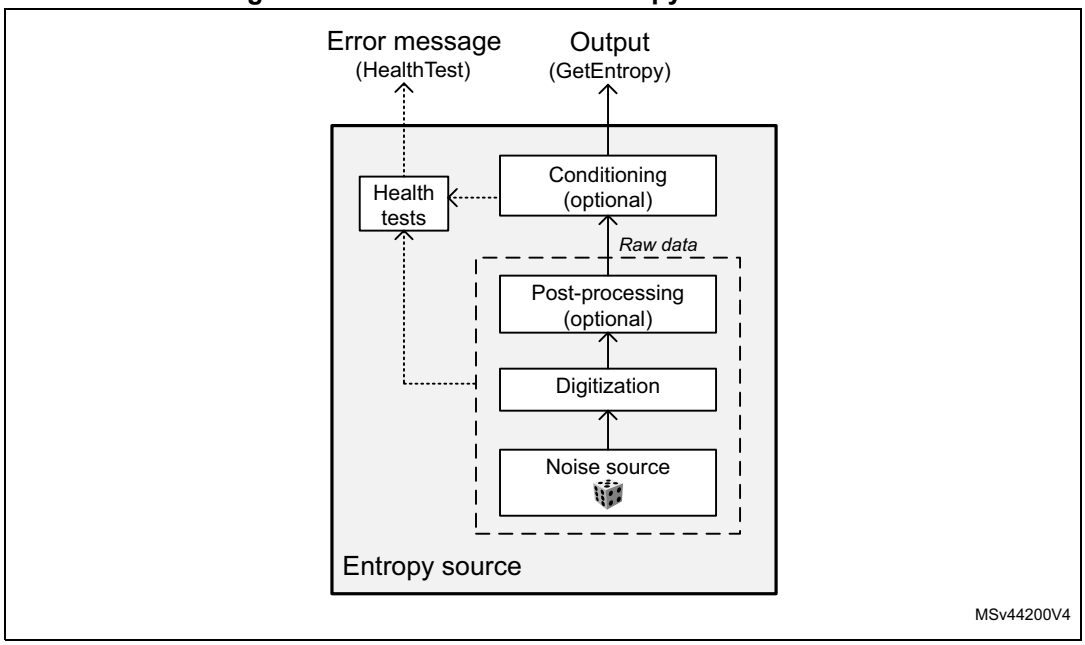
Figure 303 shows the RNG block diagram.

Figure 303. RNG block diagram

33.3.2 RNG internal signals

Table 285 describes internal signals available at the RNG level, not at the STM32 product level (on pads).

Table 285. RNG internal input/output signals



Signal name	Signal type	Description
rng_it	Digital output	RNG global interrupt request
rng_hclk	Digital input	AHB clock
rng_clk	Digital input	RNG dedicated clock, asynchronous to rng_hclk
rng_itamp_out	Digital output	RNG internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, RNG stops delivering random samples. A reset and a new initialization are needed to use it again.

33.3.3 Random number generation

The true random number generator (RNG) delivers truly random data through its AHB interface at deterministic intervals.

Within its boundary, it integrates all the required NIST components shown in *Figure 304*: an analog noise source, a digitization stage, a conditioning algorithm, a health monitoring block, and two interfaces used to interact with the entropy source (GetEntropy and HealthTest).

Figure 304. NIST SP800-90B entropy source model

Noise source

This component contains the nondeterministic, entropy-providing activity, ultimately responsible for the uncertainty associated with the bit string output by the entropy source. This noise source provides 1-bit samples. It is composed of:

- Multiple analog noise sources (x3), each based on three XOR-ed free-running ring oscillator outputs. It is possible to disable those analog oscillators to save power, as described in *Section 33.3.8*. Multiple oscillators are also disabled for configuration A (see *Table 287*).
- The XOR-ing of all the noise sources into a single analog output.
- A sampling stage of this output is clocked by a dedicated clock input (rng_clk with integrated divider), delivering a 1-bit raw data output.

This noise source sampling is independent from the AHB interface clock frequency (rng_hclk), with the possibility, for the software, to decrease the sampling frequency by using the integrated divider.

Note: The recommended clock frequencies and associated divider value are detailed in Section 33.6.

Post processing

In the NIST configuration no post-processing is applied to the sampled noise source. In the non-NIST configuration B (as defined in *Section 33.6.2*) a normalization debiasing is applied: half of the bits are taken from the sampled noise source, the other half from the inverted sampled noise source.

Conditioning

The conditioning component in the RNG is a deterministic function that increases the entropy rate of the resulting fixed-length bit string output (128-bit). The NIST SP800-90B target is full entropy on the output (128-bit).

The time intervals required between two random number generations, and between the RNG initialization and availability of the first sample are detailed in *Section 33.5*.

Output buffer

A data output buffer can store up to four 32-bit words that have been output from the conditioning component. When four words have been read from the output FIFO through the RNG_DR register, the content of the 128-bit conditioning output register is pushed into the output FIFO, and a new conditioning round is automatically started. Four new words are added to the conditioning output register after a number of clock cycles specified in *Section 33.5*.

Whenever a random number is available through the RNG_DR register, the DRDY flag changes from 0 to 1. This flag remains high until the output buffer becomes empty after reading four words from the RNG_DR register.

Note: When the interrupts are enabled, an interrupt is generated when this flag transitions from 0 to 1. The interrupt is then cleared automatically by the RNG, as explained above.

Health checks

This component ensures that the entire entropy source (with its noise source) starts, then operates as expected, obtaining the assurance that failures are caught quickly, with high probability and reliability.

The RNG implements the following health check features in accordance with NIST SP800-90B. The described thresholds correspond to the default RNG_HTCR0 configuration.

1. Startup health tests, performed after reset and before the first use of the RNG as entropy source:
   - Repetition count test, flagging an error when the noise source has provided more than 28 consecutive bits at a constant value (0 or 1).
   - Adaptive proportion test running on a window of 1024 consecutive bits: the RNG verifies that the first bit on the outputs of the noise source is not repeated more than 684 times.
   - Known-answer tests, to verify the conditioning stage.
2. Continuous health tests, running indefinitely on the outputs of the noise source (XORed output and individual oscillator outputs, see *Figure 303: RNG block diagram*):
   - Repetition count test, similar to the one running in startup tests.
   - Adaptive proportion test, similar to the one running in startup tests.
3. Vendor specific continuous test:

  - Real-time “too slow” sampling clock detector, flagging an error when one RNG clock cycle (before divider) is smaller than the AHB clock cycle divided by 32.

4. On-demand test of digitized noise source (raw data)
   - Supported by restarting the entropy source and rerunning the startup tests (see software reset sequence in *Section 33.3.4*). Other kinds of on-demand testing (software based) are *not supported*.

The CECS and SECS status bits in the RNG_SR register indicate when an error condition is detected, as detailed in *Section 33.3.7*.

Note: An interrupt can be generated when an error is detected.

The health test thresholds are modified by changing the value in the corresponding RNG_HTCRx registers. See Section 33.6 for details.

33.3.4 RNG initialization

The RNG simplified state machine is shown in *Figure 305*.

After enabling the RNG (RNGEN = 1 in RNG_CR), the following chain of events occurs:

1. The analog noise source is enabled, and by default the RNG waits 16 RNG clock cycles (before divider) before starting to sample the analog output and filling the 128-bit conditioning shift register.
2. The conditioning hardware initializes, automatically triggering the startup behavior test on the raw data samples and known-answer tests.
3. Start-up health tests are completed, with the conditioning stage ready to use.
4. The conditioning stage internal input data buffer is filled again with 128-bit and a number of conditioning rounds defined by the RNG configuration (NIST or non-NIST) is performed. The output buffer is then filled with the post processing result.
5. The output buffer is refilled automatically according to the RNG usage.

The associated initialization time can be found in *Section 33.5*.

Figure 305. RNG initialization overview

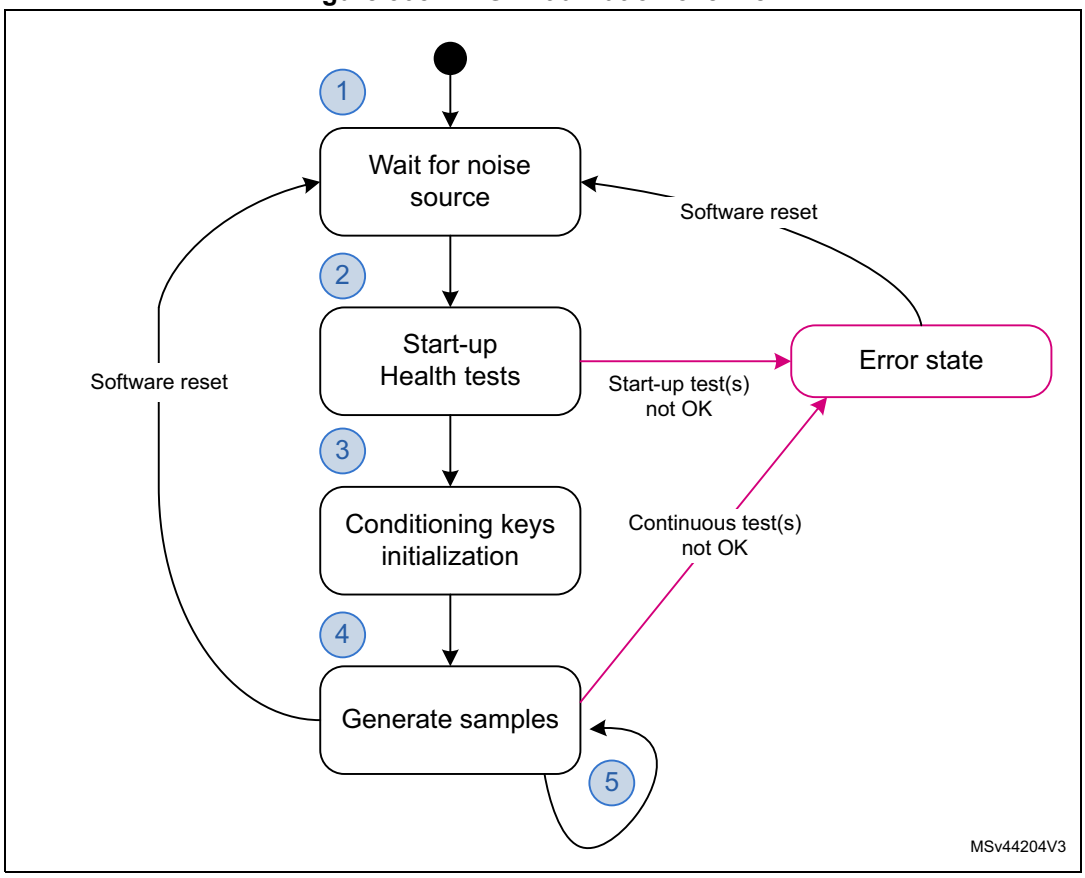


Figure 305 also highlights a possible software reset sequence, implemented by:

1. Write RNGEN = 0, then wait for BUSY = 0 in the RNG_SR register.
2. Write bits RNGEN = 0 and CONDRST = 1 in the RNG_CR register with the same RNG configuration and a new CLKDIV if needed.
3. Write RNGEN = 1 and CONDRST = 0 in the RNG_CR register.
4. Wait for a random number to be ready, after initialization completes.

Note: When the RNG is reset by RCC (hardware reset), the configuration for optimal randomness is lost in the registers.

33.3.5 RNG operation

Normal operation

To run the RNG using interrupts, the following steps are recommended:

1. Check in *Section 33.6* if a specific RNG configuration is required for the application.
   – If this is the case, when bits RNGEN and BUSY=0, write in the RNG_CR register bit CONDRST = 1, together with the correct RNG configuration. Then perform a second write with bit CONDRST = 0, interrupt enable bit IE = 1, and RNG enable bit RNGEN = 1.

- If this is not the case, perform a write to the RNG_CR register with interrupt enable bit IE = 1 and RNG enable bit RNGEN = 1.

2. An interrupt is now generated when a random number is ready or when an error occurs. Therefore, at each interrupt, check that:
   - No error occurred. The SEIS and CEIS bits must be set to 0 in the RNG_SR register.
   - A random number is ready. The DRDY bit must be set to 1 in the RNG_SR register.
   - If the above two conditions are true the content of the RNG_DR register can be read up to four consecutive times. If valid data are available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, the error recovery sequence described in *Section 33.3.7* must be used.

To run the RNG in polling mode the following steps are recommended:

1. Check in *Section 33.6* if a specific RNG configuration is required for the application.
   - If this is the case, when bits RNGEN and BUSY = 0, write in the RNG_CR register bit CONDRST = 1, together with the correction RNG configuration. Then perform a second write to the RNG_CR register with bit CONDRST = 0 and the RNG enable bit RNGEN = 1.
   - If this is not the case, only enable the RNG by setting the RNGEN bit to 1 in the RNG_CR register.
2. Read the RNG_SR register and check that:
   - No error occurred (the SEIS and CEIS bits must be set to 0)
   - A random number is ready (the DRDY bit must be set to 1)
3. If the above conditions are true, read the content of the RNG_DR register up to four consecutive times. If valid data are available in the conditioning output buffer, four additional words can be read by the application (in this case the DRDY bit is still high). If one or both of the above conditions are false, the RNG_DR register must not be read. If an error occurred, use the recovery sequence described in *Section 33.3.7*.

Note: When data are not ready (DRDY = 0) RNG_DR returns 0. It is recommended to verify that RNG_DR is different from 0. When this happens, a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

If the random number generation period is a concern to the application and if NIST compliance is not required, it is possible to select a faster configuration by using the configuration B, described in *Section 33.6*. The gain in random number generation speed is summarized in *Section 33.5*.

Low-power operation

If power consumption is a concern, low-power strategies can be used, as described in *Section 33.3.8*.

Software post-processing

No specific software post-processing/conditioning is expected to meet the AIS-31 or NIST SP800-90B approvals.

Built-in health check functions are described in *Section 33.3.3*.

33.3.6 RNG clocking

The RNG runs on two different clocks: the AHB bus clock and a dedicated RNG clock.

The AHB clock is used to clock the AHB banked registers and conditioning component. The RNG clock, coupled with a programmable divider (see CLKDIV bitfield in the RNG_CR register) is used for noise source sampling. Recommended clock configurations are detailed in *Section 33.6*.

*Note: When the CED bit in the RNG_CR register is set to 0, the RNG clock frequency before the internal divider **must be higher** than the AHB clock frequency divided by 32, otherwise the clock checker flags a clock error (CECS = 1 in the RNG_SR register).*

See *Section 33.3.1* for details (AHB and RNG clock domains).

33.3.7 Error management

In parallel to random number generation a health check block verifies the correct noise source behavior and the frequency of the RNG source clock as detailed in this section. Associated error state is also described.

Clock error detection

When the clock error detection is enabled (CED = 0) and if the RNG clock frequency is too low, the RNG sets to 1 both the CEIS and CECS bits to indicate that a clock error occurred. In this case, the application must check that the RNG clock is configured correctly (see *Section 33.3.6*), and then it must clear the CEIS bit interrupt flag. The CECS bit is automatically cleared when the clocking condition is normal.

When CECS is set, values are available in the RNG_DR register, but it must not be used as described in *Section 33.3.5*.

Note: CEIS is set only when CECS is set to 1 by RNG.

Noise source error detection

When a noise source (or seed) error occurs, the RNG stops generating random numbers and sets to 1 both SEIS and SECS bits to indicate that a seed error occurred.

When SECS is set, values are available in the RNG_DR register, but it must not be used as described in *Section 33.3.5*.

To manage a seed error, follow the recommended sequence below.

It requires the CONFIGLOCK bit to be cleared.

- When ARDIS is cleared (auto-reset enabled):
  - Clear the SEIS bit in the RNG_SR register
  - If SECS is cleared RNG can be used as usual. If SECS is still set in RNG_SR it means a new seed error occurred (unlikely). In this case, executes following step 1)
- When ARDIS is set (auto-reset disabled) the following sequence must be used to recover from a seed error.

1. Read both RNG_HTSRx registers. Using the previous HTSR values saved in RAM, compute the accumulated number of errors per oscillator (can be RPERR or ADERR errors). In a *nsmr* variable, mask the oscillators with accumulated number of errors greater than 3. This variable is used in step 3). Save the updated HTSR values in RAM.
   - During the first iteration, initialize *nsmr* variable with the RNG_NSCR value.
2. If fewer than 6 oscillators are active in the *nsmr* variable, reinitialize it with the RNG_NSCR value.
   - When RNG configuration is Configuration B, and the third time you reach this loop, go to Step 3 changing the RNG configuration to Configuration C. Both configurations are defined in *Section 33.6.2*.
3. Write CONDRST at 1 in RNG_CR, then update RNG_NSMR with *nsmr* value. Refer to *Section 33.7.8* for details.
4. Write CONDRST at 0 to finalize the reset of the RNG conditioning logic.
5. Wait for the CONDRST bit to be cleared by hardware, or poll for BUSY bit= 0. Then clear the SEIS interrupt status bit in the RNG_SR register.
6. If SECS is still set in RNG_SR a new seed error occurred (unlikely). In this case go back to step 1). If SECS is cleared, restart the generation of random numbers by setting RNGEN in RNG_CR.

If application has set the CONFIGLOCK bit (not recommended), do the following:

- When ARDIS is cleared (auto-reset enabled) clear the SEIS interrupt status bit in the RNG_SR register before drawing random numbers again.
- When ARDIS is set (auto-reset disabled), the following sequence must be used to fully recover from a seed error:

1. Write CONDRST at 1 and at 0 in the RNG_CR register to reset the conditioning logic.
2. Wait for the CONDRST bit to be cleared by hardware, or poll for BUSY = 0. Then clear the SEIS interrupt status bit in the RNG_SR register.
3. If SECS is still set in RNG_SR it means a new seed error occurred (unlikely). In this case go back to step 1).

Note: After a seed error RNG restarts generating random numbers when SECS is cleared.

RNG tamper errors

When an unexpected error is found by the RNG, an internal tamper event is triggered in the TAMP peripheral, and the RNG stops delivering random data.

When this event occurs, the secure application needs to reset the RNG peripheral, using the central reset management or the global SoC reset. A proper initialization of the RNG is required again.

Note: Seed errors do not trigger tamper errors.

33.3.8 RNG low-power use

If power consumption is a concern, the RNG can be disabled as soon as the DRDY bit is set to 1 by setting the RNGEN bit to 0 in the RNG_CR register. As the post-processing logic and the output buffer remain operational while the RNGEN = 0, the following features are available to the software:

- If there are valid words in the output buffer, four random numbers can still be read from the RNG_DR register.
- If there are valid bits in the conditioning output internal register, four additional random numbers can be still be read from the RNG_DR register. If it is not the case, RNG must be re-enabled by the application until the expected new noise source bits threshold is reached (128-bit in NIST mode), and a complete conditioning round is done. Four new random words are then available only if the expected number of conditioning round is reached (two if NISTC = 0). The overall time can be found in *Section 33.5*.

When disabling the RNG, the user deactivates all the analog seed generators, whose power consumption is given in the datasheet electrical characteristics section. The user also gates all the logic clocked by the RNG clock. Note that this strategy is adding latency before a random sample is available on the RNG_DR register, because of the RNG initialization time.

If the RNG block is disabled during initialization (that is well before the DRDY bit rises for the first time), the initialization sequence resumes from where it was stopped when the RNGEN bit is set to 1, unless the application resets the conditioning logic using the CONDRST bit in the RNG_CR register.

When the application wants to gate the RNG kernel clock, the software must issue the following sequence: first, disable the RNG by clearing the RNGEN bit in the RNG_CR register, then wait for the BUSY bit to be cleared in the RNG_SR, and finally, disable the RNG kernel clock using the RCC.

Before entering a power mode where RNG is deactivated (like Stop mode), the software must first disable the RNG by clearing the RNGEN bit in the RNG_CR register, then wait for the BUSY bit to be cleared in the RNG_SR.

Note: The power modes where RNG is deactivated (retained or not available) can be found in the PWR section.

33.4 RNG interrupts

In the RNG an interrupt can be produced on the following events:

- Data ready flag
- Seed error, see *Section 33.3.7*
- Clock error, see *Section 33.3.7*

Dedicated interrupt enable control bits are available as shown in *Table 286*.

Table 286. RNG interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
RNG	Data ready flag	DRDY	IE	None (automatic)
	Seed error flag	SEIS	IE	Write CONDRST to 1 then to 0 unless ARDIS is cleared (see *Section 33.3.7*). Write 0 to SEIS.
	Clock error flag	CEIS	IE	Write 0 to CEIS

The user can enable or disable the above interrupt sources globally by using the general interrupt control bit IE in the RNG_CR register. The status of the individual interrupt sources can be read from the RNG_SR register.

Note: Interrupts are generated only when RNG is enabled.

33.5 RNG processing time

In the recommended configuration described in *Table 287*, the time between two sets of four 32-bit data is either:

- 206 x N AHB cycles if $f_{AHB} < f_{threshold}$ (conditioning stage is limiting), or
- 128 x N RNG cycles $f_{AHB} \geq f_{threshold}$ (noise source stage is limiting).

If f_{RNG}= 48 MHz, $f_{threshold}$ = 1.6 x f_{RNG} = 77 MHz. The value of N is defined in *Section 33.6*.

Note: When CLKDIV is different from 0, f_{RNG} must take into account the internal divider ratio.

33.6 RNG entropy source validation

33.6.1 Introduction

To assess the amount of entropy available from the RNG, the peripheral has been tested using the German BSI AIS-31 statistical tests (T0 to T8), and NIST SP800-90B test suite.

33.6.2 Validation conditions

The RNG true random number generator has been tested in the following conditions:

- RNG clock rng_clk = 48 MHz, with CED bit cleared in RNG_CR.
- Configurations are described in *Table 287* and *Table 288*. Only configuration A can be certified NIST SP800-90B. Refer to *Table 289* to select the best configuration for the application.
- Configuration B or C can be used when configuration A is not present in AN4230, or is not flagged as certified.

Table 287. RNG configurations

Configuration	RNG_CR bits					Loop number (N)	RNG_HTCR0 register	RNG_NSCR register
	NISTC bit	RNG_CONFIG1 [7:0]	CLKDIV [3:0]	RNG_CONFIG2 [2:0]	RNG_CONFIG3 [3:0](1)			
A	Refer to *NIST compliant RNG configuration* table in AN4230 available from *www.st.com*. This application note also indicates if this configuration is part of an existing NIST SP800-90B Entropy Certificate listed on *https://csrc.nist.gov/projects/cryptographic-module-validation-program.*							
B	1	0x83	0x0	0x0	0xF	3	0x0000 AAC7(2)	Default
C	1	0x84	0x5(3)	0x0	0xF	4		Default

1. RNG_CONFIG1[3:0] = i defines the loop number N. If i = 0, N =1. If NISTC = 0, N = 2 regardless of i.
2. This value can be fixed in the RNG driver (it does not depend upon the STM32 product).
3. The noise source sampling must be 48 MHz or less. If the RNG clock is different from 48 MHz, this value of CLKDIV must be adapted. See the CLKDIV bitfield description in *Section 33.7.1* for details.

Table 288. Additional health test configurations

Configuration	RNG_HTCR1 register (oscillator set 1)	RNG_HTCR2 register (oscillator set 2)	RNG_HTCR3 register (oscillator set 3)
A	Refer to NIST compliant RNG configuration table in AN4230 available from *www.st.com*.		
B and C	Default	Default	Default

Table 289. Configuration selection

Section criteria	Configuration A	Configuration B	Configuration C
Suitable to generate NIST compliant cryptographic keys	Yes	No	
Entropy(1)	Certified	Not certified	
Speed(2)	Baseline	Faster	Baseline

1. For configurations B and C entropy is verified using the AIS-31 test suite (T0 to T8).
2. When the speed is not enough for the application, an NIST compliant DRBG can be used to increase throughput.

For details on data collection and the running of statistical test suites refer to AN4230 "*Introduction to random number generation validation using the NIST statistical test suite for STM32 MCUs and MPUs*", available on *www.st.com*.

33.7 RNG registers

The RNG is associated with a control register, a data register, and a status register.

33.7.1 RNG control register (RNG_CR)

Address offset: 0x000

Reset value: 0x0080 0D00

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CONFIGLOCK	CONDRST	Res.	Res.	RNG_CONFIG1[7:0]								CLKDIV[3:0]			
rs	rw			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNG_CONFIG2[2:0]			NISTC	RNG_CONFIG3[3:0]				ARDIS	Res.	CED	Res.	IE	RNGEN	Res.	Res.
rw	rw	rw	rw	rw	rw	rw	rw	rw		rw		rw	rw		

Bit 31 **CONFIGLOCK**: RNG configuration lock

Set this bit to lock the RNG configuration. Since CONFIGLOCK prevents the implementation of robust seed error management described in *Section 33.3.7*, it is recommended not to use it.

0: Writes to the RNG_NSMR, RNG_NSCR, RNG_HTCR and the RNG_CR configuration bits [29:4] are allowed.

1: Writes to the RNG_NSMR, RNG_NSCR, RNG_HTCR and the RNG_CR configuration bits [29:4] are ignored until the next RNG reset.

Once set, this bit can only be cleared when RNG is reset (set once bit).

Bit 30 **CONDRST**: Conditioning soft reset

Write 1 and then write 0 to reset the conditioning logic, clear all the FIFOs and start a new RNG initialization process, with RNG_SR cleared. Registers RNG_NSMR, RNG_NSCR, RNG_CR and RNG_HTCR are not changed by CONDRST.

This bit must be set to 1 in the same access that sets any configuration bits [29:4]. In other words, when CONDRST bit is set to 1 correct configuration in bits [29:4] must also be written.

Before setting this bit to 1 RNGEN must be set to 0, and BUSY flag must be cleared in RNG_SR.

When CONDRST is set to 0, wait for BUSY flag to be cleared in RNG_SR. CONDRST bit then reads as 0.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:20 **RNG_CONFIG1[7:0]:** RNG configuration 1

Reserved to the RNG configuration (bitfield 1). Must be initialized using the recommended value documented in *Section 33.6*.

Writing to this bitfield is only effective when CONFIGLOCK = 0. The new value is only taken into account if CONDRST bit is set in the same access.

Bits 19:16 **CLKDIV[3:0]**: Clock divider factor

This value used to configure an internal programmable divider (from 1 to 16) acting on the incoming RNG clock. These bits can be written only when the core is disabled (RNGEN = 0).

0x0: internal RNG clock after divider is similar to incoming RNG clock.

0x1: two RNG clock cycles per internal RNG clock.

0x2: 2^2 (= 4) RNG clock cycles per internal RNG clock.

...

0xF: 2^{15} RNG clock cycles per internal clock (for example. an incoming 48 MHz RNG clock becomes a 1.5 kHz internal RNG clock)

Writing to this bitfield is only effective when CONFIGLOCK = 0. The new value is only taken into account if CONDRST bit is set in the same access.

Bits 15:13 **RNG_CONFIG2[2:0]:** RNG configuration 2

Reserved to the RNG configuration (bitfield 2). Refer to the RNG_CONFIG1 bitfield for details.

Bit 12 **NISTC**: NIST custom

0: Hardware default values for NIST compliant RNG. In this configuration for 128-bit output, two conditioning loops are performed and 256 bits of noise source are used.

1: Custom values for NIST compliant RNG. See *Section 33.6* for recommended configurations.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bits 11:8 **RNG_CONFIG3[3:0]:** RNG configuration 3

Reserved to the RNG configuration (bitfield 3). Refer to RNG_CONFIG1 bitfield for details.

If the NISTC bit is cleared in this register RNG_CONFIG3 bitfield values are ignored by RNG.

Bit 7 **ARDIS**: Auto reset disable

Set this bit to deactivate the auto-reset feature.

0: Auto-reset is enabled

1: Auto-reset is disabled

Keeping the auto-reset enabled (automatic clearance of the SECS bit) simplifies the management of noise source errors, as described in *Section 33.3.7*.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CED:** Clock error detection

0: Clock error detection is enabled.

1: Clock error detection is disabled

The clock error detection cannot be enabled nor disabled on-the-fly when the RNG is enabled, that is to enable or disable CED, the RNG must be disabled.

Writing to this bit is only effective when CONFIGLOCK = 0. The new value is only taken into account if the CONDRST bit is set in the same access.

Bit 4 Reserved, must be kept at reset value.

Bit 3 **IE:** Interrupt enable

0: RNG interrupt is disabled

1: RNG interrupt is enabled. An interrupt is pending as soon as the DRDY, SEIS, or CEIS flag is set in the RNG_SR register.

Bit 2 **RNGEN:** True random number generator enable

This bit enables/disables the true random number generator.

0: True random number generator disabled.

1: True random number generator enabled.

Clearing RNGEN powers off the analog noise sources and gates the logic clocked by the RNG clock.

When clearing this bit verify that BUSY flag is cleared in RNG_SR before updating this register again.

Bits 1:0 Reserved, must be kept at reset value.

33.7.2 RNG status register (RNG_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	SEIS	CEIS	BUSY	Res.	SECS	CECS	DRDY
									rc_w0	rc_w0	r		r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **SEIS:** Seed error interrupt status

This bit is set at the same time as SECS. It is cleared by writing 0 (unless CONDRST is used). Writing 1 has no effect.

0: No faulty sequence detected

1: At least one faulty sequence is detected. See SECS bit description for details.

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 5 **CEIS:** Clock error interrupt status

This bit is set at the same time as CECS. It is cleared by writing 0. Writing 1 has no effect.

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$)

1: The RNG clock before the internal divider is detected too slow ($f_{RNGCLK} < f_{HCLK}/32$)

An interrupt is pending if IE = 1 in the RNG_CR register.

Bit 4 **BUSY:** Busy

This flag indicates whether RNG is idle or busy.

0: Idle

1: Busy

RNG is flagged as busy when a conditioning soft reset (using CONDRST) is in progress. It is also flagged busy when RNG is activated by application setting RNGEN bit, or when a connected peripheral fetches randoms via the dedicated RNG hardware bus.

More information on BUSY usage can also be found in *Section 33.3.8*.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **SECS:** Seed error current status

0: No faulty sequence has currently been detected. If the SEIS bit is set, this means that a faulty sequence was detected and the situation has been recovered.

1: At least one of the following faulty sequence has been detected:

– Start-up or continuous repetition count test on noise source failed.

– Start-up or continuous adaptive proportion test on noise source failed.

– Start-up post-processing/conditioning sanity check failed.

After enabling the RNG, SECS bit clears once startup health tests completes successfully. If SECS does not clear, run the software reset sequence with CONDRST described in *Section 33.3.4*.

Bit 1 **CECS:** Clock error current status

0: The RNG clock is correct ($f_{RNGCLK} > f_{HCLK}/32$). If the CEIS bit is set, this means that a slow clock was detected and the situation has been recovered.

1: The RNG clock is too slow ($f_{RNGCLK} < f_{HCLK}/32$).

CECS bit is valid only if the CED bit in the RNG_CR register is set to 0.

Bit 0 **DRDY:** Data ready

This flag is raised to indicate valid (non-0) random data available in the RNG_DR register. It is cleared by hardware upon reading the RNG_DR register (which empties the RNG buffer). The DRDY flag can also be raised upon disabling RNG (upon clearing the RNGEN bit).

0: No valid random data ready.

1: Valid random data ready.

Raising DRDY generates an interrupt if enabled with the IE bit of the RNG_CR register.

33.7.3 RNG data register (RNG_DR)

Address offset: 0x008

Reset value: 0x0000 0000

This register is a read-only register that delivers a 32-bit random value when read. The content of this register is valid when the DRDY = 1 and the value is not 0x0, even if RNGEN = 0.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
RNDATA[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RNDATA[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **RNDATA[31:0]:** Random data

32-bit random data, valid when DRDY = 1. When DRDY = 0, the RNDATA value is 0.

The 0 value means that a seed error occurred between RNG_SR polling and RND_DR output reading (a rare event).

33.7.4 RNG noise source control register (RNG_NSCR)

Address offset: 0x00C

Reset value: 0x0000 01FF

Writing in RNG_NSCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in RNG_CR. Writing to this register is ignored if CONFIGLOCK= 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	EN_OSC3[2:0]			EN_OSC2[2:0]			EN_OSC1[2:0]		
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:6 **EN_OSC3[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 3. The bitfield has no effect otherwise.

Bits 5:3 **EN_OSC2[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 2. The bitfield has no effect otherwise.

Bits 2:0 **EN_OSC1[2:0]:**

When the RNG is enabled (RNGEN bit set), each bit of this bitfield enables one of the three inputs from the oscillator instance number 1. The bitfield has no effect otherwise.

33.7.5 RNG health test control register x (RNG_HTCRx)

Address offset: 0x010 + 0x4 * x (x=0 to 3)

Reset value: 0x0000 72AC, 0x0003 FFFF, 0x0003 FFFF, 0x0003 FFFF

Writing in RNG_HTCR is taken into account only if the CONDRST bit is set, and the CONFIGLOCK bit is cleared in the RNG_CR. Writing to this register is ignored if CONFIGLOCK = 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
HTCFG[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HTCFG[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **HTCFG[31:0]:** health test configuration

This configuration is used by RNG to configure the health tests (repetition count test, adaptive proportion test) at position x. See *Section 33.6* for the recommended value. With its default value, health tests have a very small probability of triggering any error at position x.

Note: The RNG behavior, including the read to this register, is not guaranteed if a different value from the recommended value is written.

33.7.6 RNG health test status register 0 (RNG_HTSR0)

Address offset: 0x020

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	RPERR9	RPERR8	RPERR7	RPERR6	RPERR5	RPERR4	RPERR3	RPERR2	RPERR1	RPERRX
						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:1 **RPERR{i}:** Repetitive error for oscillator *i* (i=1 to 9)

This bit is set when the health test logic associated to the oscillator *i* finds a repetitive test error. The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error. Repetition count test is defined in *Health checks* section.

0: No repetitive test error found in oscillator *i*.
1: Repetitive test error found in oscillator *i*.

Bit 0 **RPERRX:** Repetitive error after the XOR

This bit is set when the health test logic finds a repetitive test error after the XOR clock tree (see *Figure 303*). The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error.

0: No repetitive test error found after the XOR clock tree.
1: Repetitive test error found after the XOR clock tree.

33.7.7 RNG health test status register 1 (RNG_HTSR1)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

						r	r	r	r	r	r	r	r	r	r

Bits 31:10 Reserved, must be kept at reset value.

Bits 9:1 **ADERR{i}:** Adaptative error for oscillator *i* (i=1 to 9)

This bit is set when the health test logic associated to the oscillator *i* finds an adaptative test error. The bit is cleared when application clears SEIS bit in RNG_SR. If ARDIS is cleared auto-reset prevents RNG to capture more than one test error. Adaptive proportion test is defined in *Health checks* section.

0: No adaptative test error found in oscillator *i*.
1: Adaptative test error found in oscillator *i*.

Bit 0 **ADERRX:** Adaptative error after the XOR

This bit is set when the health test logic finds an adaptative test error after the XOR clock tree (see *Figure 303*). The bit is cleared when application clears SEIS bit in RNG_SR If ARDIS is cleared auto-reset prevents RNG to capture more than one test error.

0: No adaptative test error found after the XOR clock tree.
1: Adaptative test error found after the XOR clock tree.

33.7.8 RNG noise source mask register (RNG_NSMR)

Address offset: 0x030

Reset value: 0x0000 01FF

Writing to this register is ignored if CONFIGLOCK = 1. It is recommended to have at least 6 oscillators running when loop number N = 3 (or higher). See *Section 33.6.2* for details.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	MOSC 9	MOSC 8	MOSC 7	MOSC 6	MOSC 5	MOSC 4	MOSC 3	MOSC 2	MOSC 1
							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bits 8:0 **MOSC{i}:** Mask oscillator i (i = 1 to 9)

Clear this bit to masks the oscillator *i*, and deactivate its related health tests. The bit has no effect if the oscillator *i* is deactivated with the bit RNG_NSCR[i].

Application can mask an oscillator when it is not contributing to the generation of entropy.

0: Oscillator *i* is masked, and related health tests are deactivated.
1: Oscillator *i* is not masked. Related health tests are running.

33.7.9 RNG register map

Table 290. RNG register map and reset map

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

34 AES hardware accelerator (AES)

This section only applies to STM32G54x/56x products.

In this section, any references to SAES only apply to STM32G56x products. The STM32G53x/54x/55x products do not have the SAES peripheral.

34.1 AES introduction

The AES hardware accelerator (AES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST.

AES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits.

AES has the possibility to load by hardware the key stored in SAES peripheral, under SAES control.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required).

34.2 AES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 51 or 75 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Using dedicated key bus, optional key sharing with side-channel resistant SAES peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data

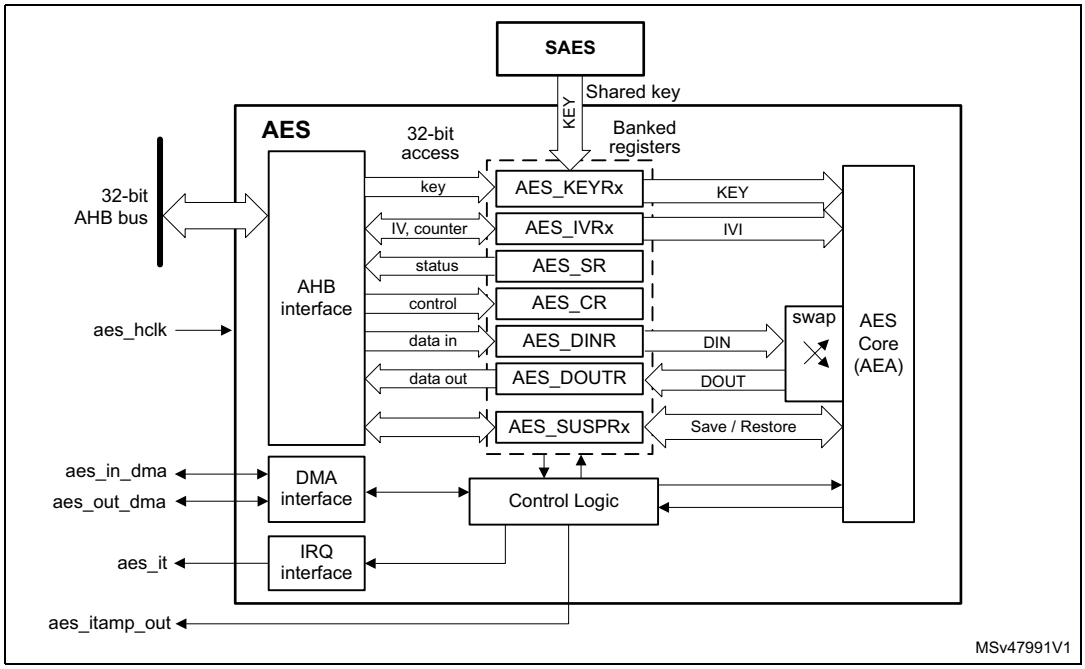
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software (in CPU mode only, not in DMA mode) to suspend a message if AES needs to process another message with a higher priority, then resume the original message

34.3 AES implementation

The devices have one AES peripheral, implemented as per the following table. It can use the key generated by the SAES peripheral. For comparison, the SAES peripheral is also included in the table.

Table 291. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection	-	X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256



1. X = supported.

34.4 AES functional description

34.4.1 AES block diagram

Figure 306 shows the block diagram of AES.

Figure 306. AES block diagram

34.4.2 AES internal signals

Table 292 describes the user relevant internal signals interfacing the AES peripheral.

Table 292. AES internal input/output signals

Signal name	Signal type	Description
aes_hclk	Input	AHB bus clock
aes_it	Output	AES interrupt request
aes_in_dma	Input/Output	AES incoming data DMA single request/acknowledge
aes_out_dma	Input/Output	AES processed data DMA single request/acknowledge
aes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, AES automatically clears key registers. A reset is required for AES to be usable again.

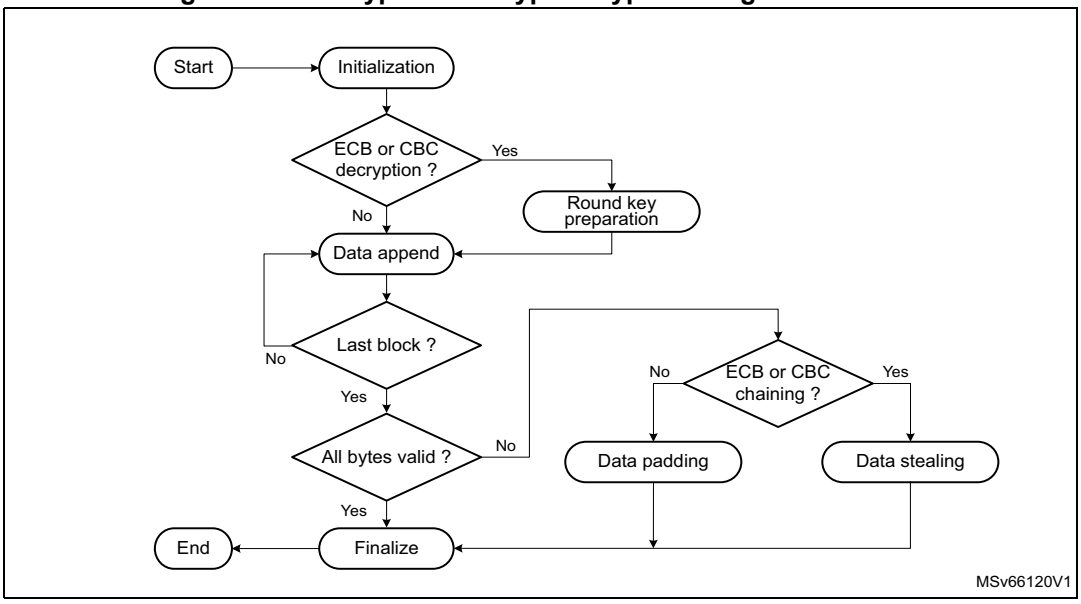
34.4.3 AES reset and clocks

The AES peripheral is clocked by the AHB bus clock. It has a dedicated reset bit controlled through the RCC.

34.4.4 AES symmetric cipher implementation

The AES hardware accelerator (AES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 293*. Those functions can be certified NIST PUB 140-3.

Table 293. AES approved symmetric key functions



Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

AES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any AES processing, following the sequence described in *Section 34.4.8*.

34.4.5 AES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 307. Encryption/ decryption typical usage

Initialization

The AES peripheral is initialized according to the chaining mode. Refer to *Section 34.4.9: AES basic chaining modes (ECB, CBC)* and *Section 34.4.10: AES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 34.4.7: AES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. Enable the AES peripheral when KEYVALID is set, by setting the EN bit of the AES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the AES_DINR register.
   b) Wait until the status flag CCF is set in the AES_ISR register, then read the four data words from the AES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).
3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the AES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the AES_DINR register, to allow sending the key to the AES processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the AES peripheral to control the data append, through the following sequence:

1. Enable interrupts from AES, by setting the CCFIE bit of the AES_IER register.
2. Enable the AES peripheral when KEYVALID is set, by setting EN (if not already done).
3. Write first four input data words into the AES_DINR register.
4. Handle the data in the AES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the AES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the AES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the AES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the AES_DINR register and quit the interrupt service routine.

Note: AES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two AES computations.

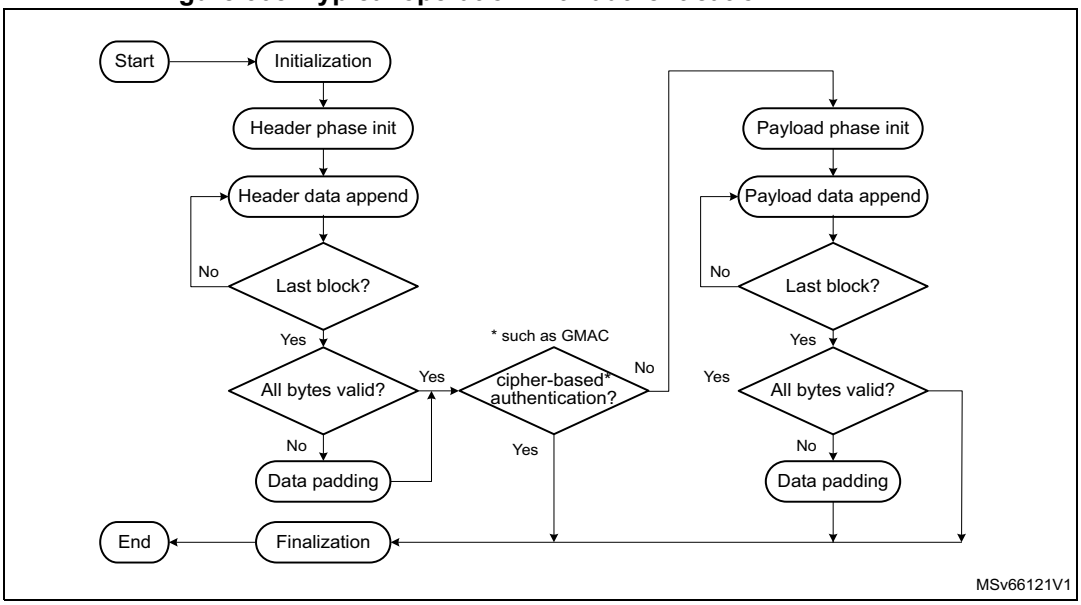
The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

With this method, all the transfers and processing are managed by DMA and AES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the AES peripheral input and the processed data from the AES peripheral output to the memory, as described in *Section 34.6: AES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the NPBLB[3:0] bitfield must be set up before processing the block, for AES to compute a correct tag.
3. Enable the AES peripheral when KEYVALID is set, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the AES-processed data from the memory.

When appending data using DMA, the suspend/resume operation as described in *Section 34.4.8* is not supported.



Note: The CCF flag has no use with this method because the reading of the AES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

34.4.6 AES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 308. Typical operation with authentication

Section 34.4.11: AES Galois/counter mode (GCM) and *Section 34.4.13: AES counter with CBC-MAC (CCM)* describe detailed sequences supported by AES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by AES is described in *Section 34.4.12: AES Galois message authentication code (GMAC)*.

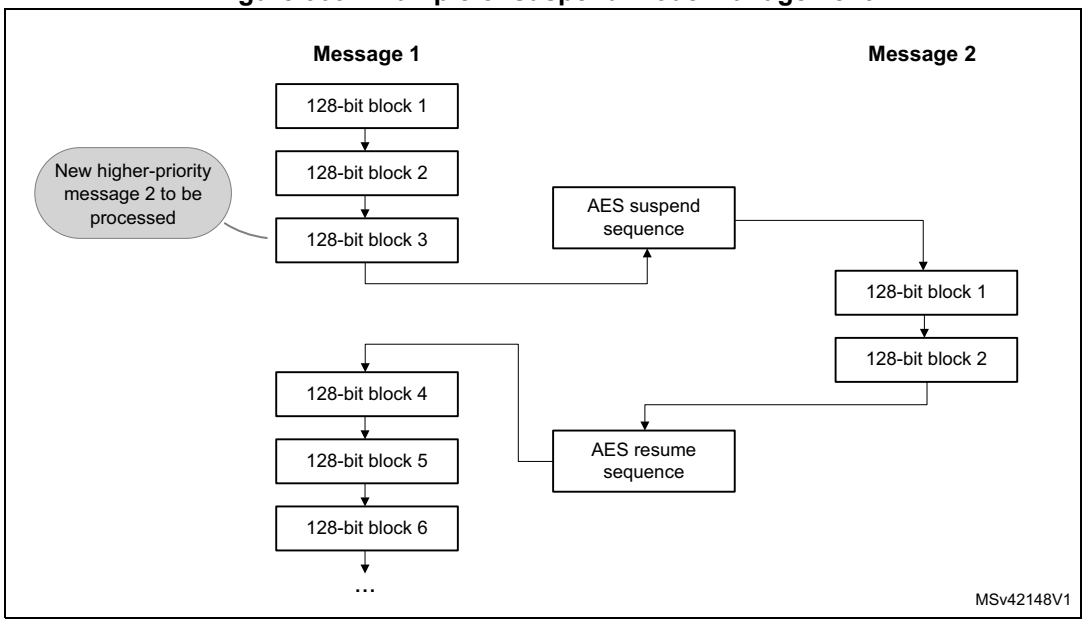
34.4.7 AES ciphertext stealing and data padding

When using AES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since AES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since AES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

34.4.8 AES suspend and resume operations



A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as AES is enabled again, to receive a next data block.

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

Figure 309 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 309. Example of suspend mode management

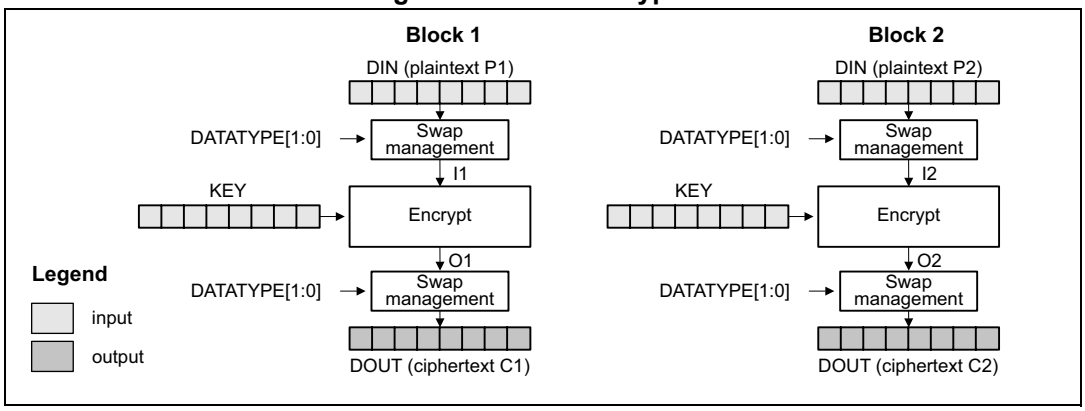
A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

34.4.9 AES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 310 and *Figure 311* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 310. ECB encryption



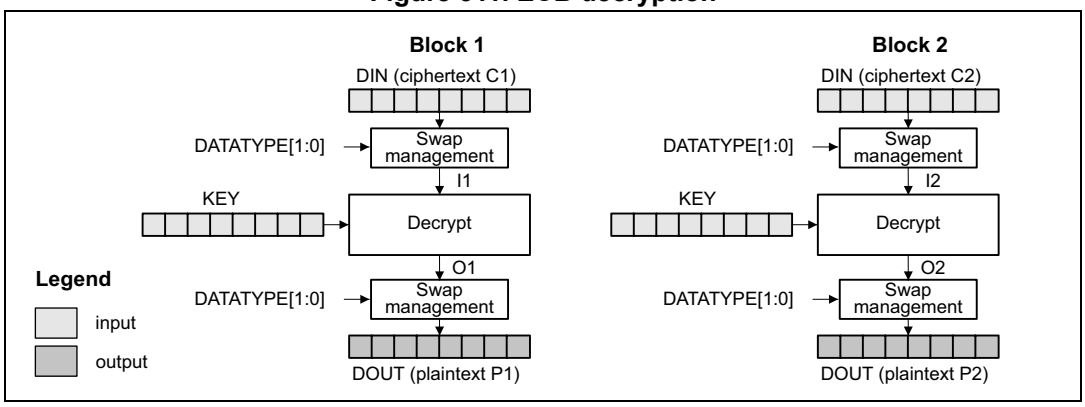


Figure 311. ECB decryption

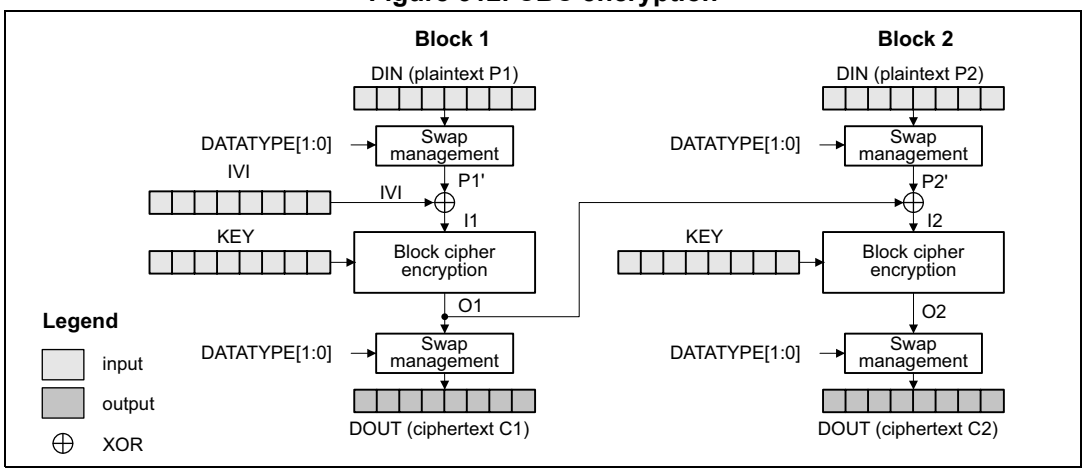
In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 312 and *Figure 313* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 312. CBC encryption



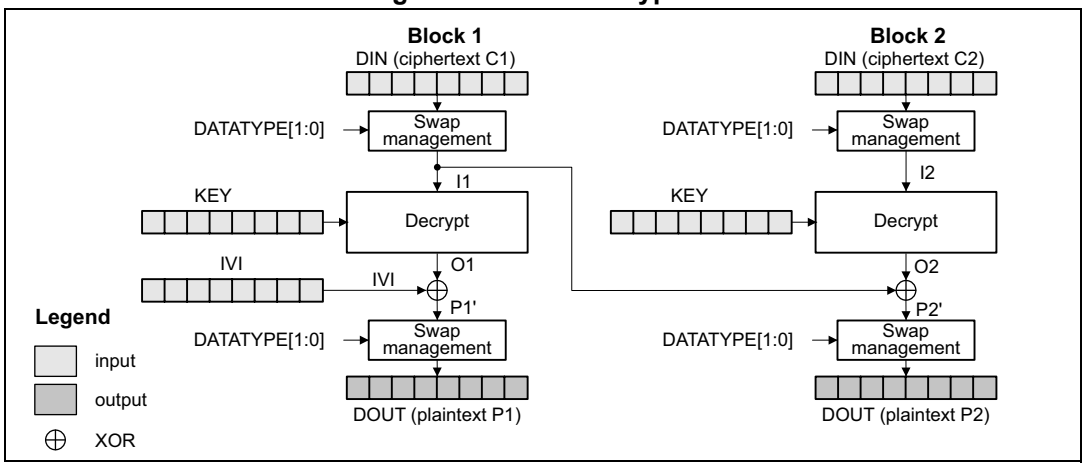


Figure 313. CBC decryption

For more details, refer to NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.
7. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 34.4.7*.
   b) Append the cleartext block into AES as described in *Section 34.4.5*, then read the AES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
8. Finalize the sequence: disable the AES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register as follows:
   - Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
4. Wait until KEYVALID is set (the key loading completed).
5. Enable the AES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
6. Wait until the CCF flag in the AES_ISR register is set.
7. Clear the CCF flag, by setting the CCF bit of the AES_ICR register. The decryption key is available in the AES core and AES is disabled automatically.
8. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
9. Write the initialization vector into the AES_IVRx registers if CBC mode is selected in the previous step.
10. Enable the AES peripheral, by setting EN.
11. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 34.4.7*.
    b) Append the ciphertext block into AES as described in *Section 34.4.5*, then read the AES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
12. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

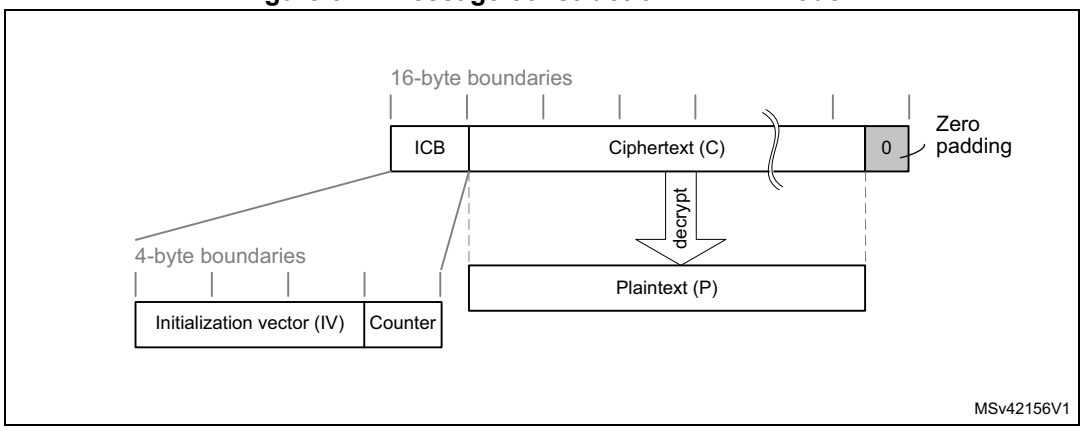
To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the AES_ISR register is set (computation completed).
2. Read four times the AES_DOUTR register to save the last processed block.
3. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
4. Save initialization vector registers (only required in CBC mode as the AES_IVRx registers are altered during the data processing).

5. Disable the AES peripheral, by clearing EN.
6. Save the AES_CR register and clear the key registers if they are not needed, to process the higher-priority message.

To resume the processing of a message, proceed as follows:

1. Disable the AES peripheral, by clearing EN.
2. Restore the AES_CR register (with correct KEYSIZE) then restore the AES_KEYRx registers. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 34.4.14*).
3. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).
4. Restore the AES_IVRx registers, using the saved configuration (only required in CBC mode).
5. Enable the AES peripheral, by setting EN.



Note: It is not required to save the key registers as the application knows the original key.

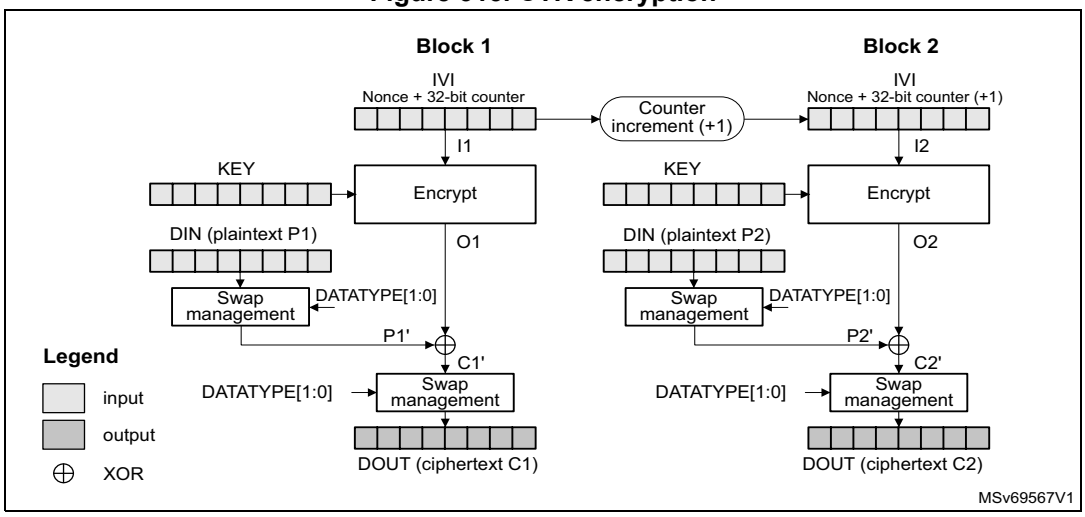
34.4.10 AES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 314*.

Figure 314. Message construction in CTR mode

The structure of this message is:



- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 315 describes the counter (CTR) chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 315. CTR encryption

Initialization vectors in AES must be initialized as shown in *Table 294*.

Table 294. Counter mode initialization vector definition

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 34.4.5*, with the following sequence of events:

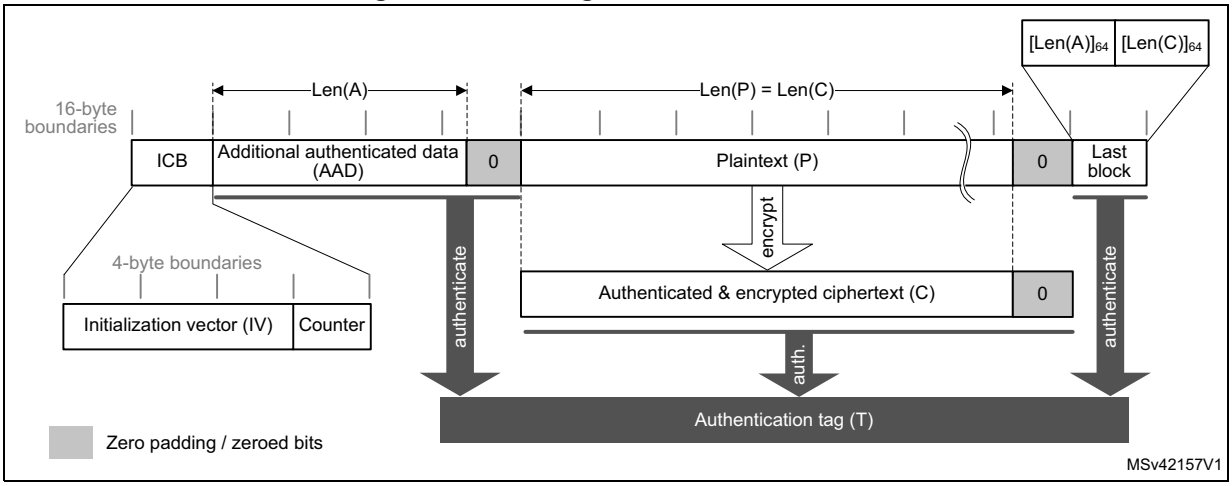
1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
3. Write the initialization vector into the AES_IVRx registers according to *Table 294*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the AES peripheral, by setting EN.

7. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into AES as described in *Section 34.4.5*, then read the AES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
8. Finalize the sequence: disable the AES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 34.4.9: AES basic chaining modes (ECB, CBC)*.

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.



Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

34.4.11 AES Galois/counter mode (GCM)

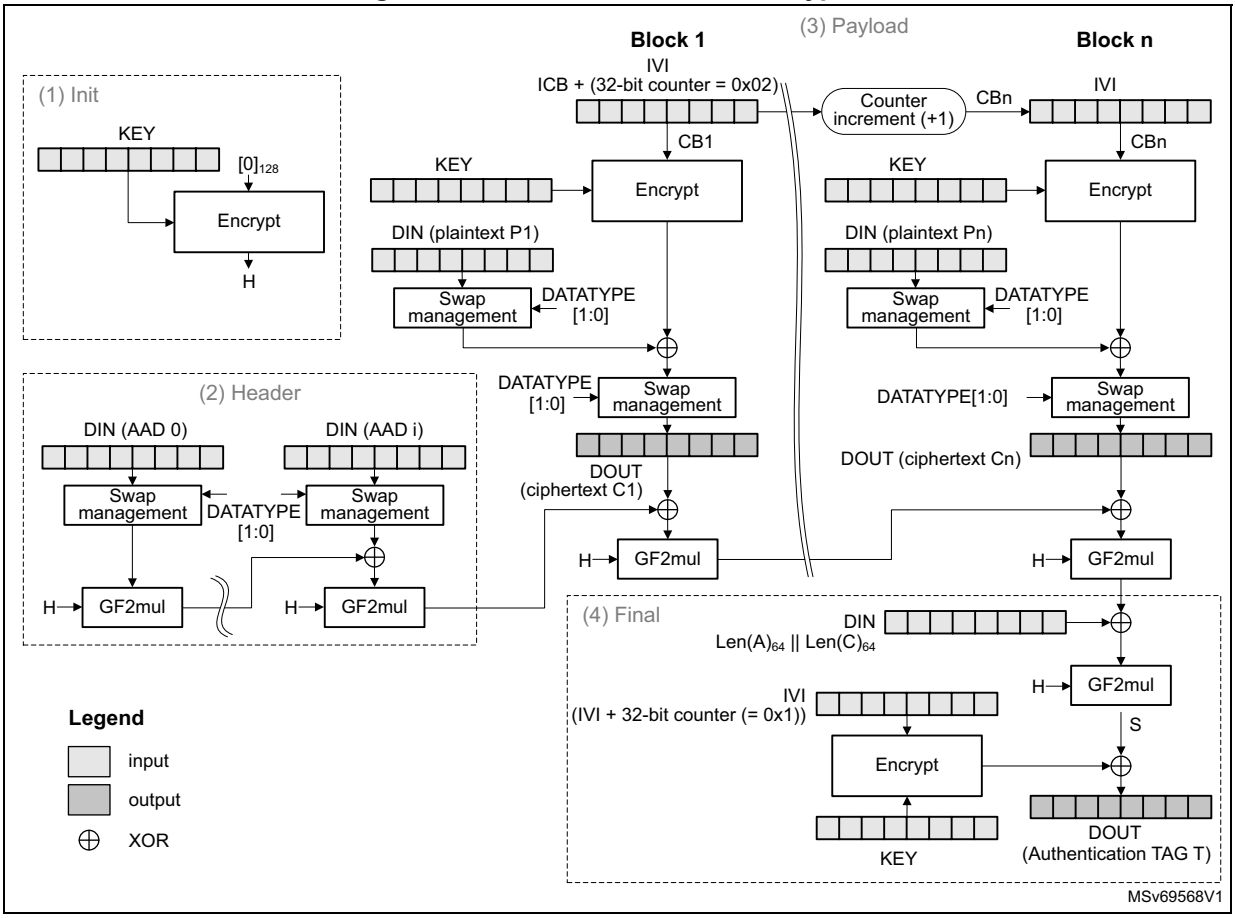
The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 316. Message construction in GCM

The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed $2^{32} - 2$ 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 296*.



The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 317 describes the GCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 317. GCM authenticated encryption

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 295*.

Table 295. Initialization of IV registers in GCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 296*.

Table 296. GCM last block definition

Word order to AES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 34.4.6*, with the following sequence of events:

GCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the GCM initialization phase, by writing CPHASE[1:0] with 0x0.
3. Write the initialization vector in AES_IVRx registers according to *Table 295*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
7. Wait until the CCF flag is set in the AES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
8. Clear the CCF flag by setting the CCF bit of the AES_ICR register.

GCM header phase

9. Initialize header phase:
   a) Select the GCM header phase, by writing 0x1 to CPHASE[1:0]. Do not change the other configurations written during GCM initialization.
   b) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 34.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

11. Initialize payload phase:
    a) Select the GCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the AES peripheral by setting EN.

12. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 34.4.5*, then read the AES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

GCM finalization

13. Select the GCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
14. Write the final GCM block into the AES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 296*.
15. Wait until the CCF flag in the AES_ISR register is set.
16. Get the GCM authentication tag, by reading the AES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
18. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to AES_DINR normally (no swapping), while swapping is applied to tag data read from AES_DOUTR.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

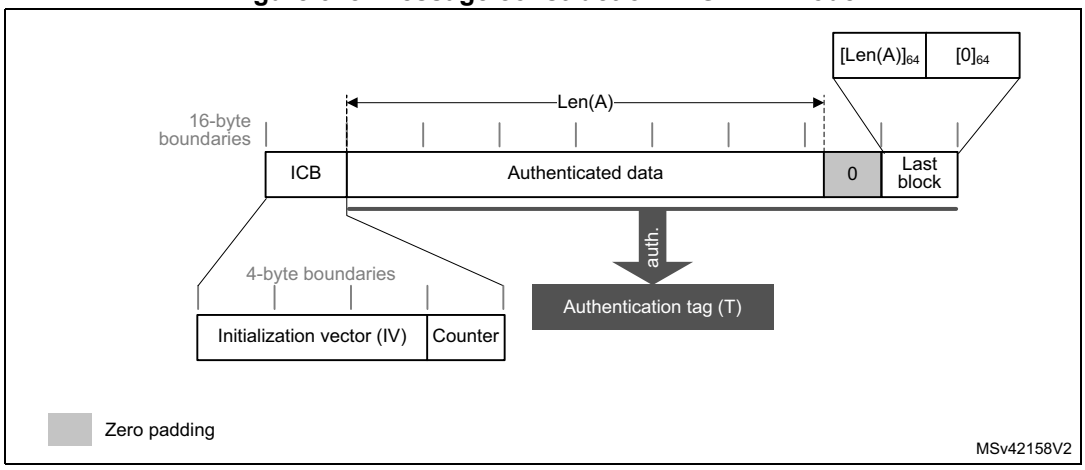
Suspend/resume operations in GCM mode

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the AES_ISR register is set (computation completed).
2. In the payload phase, read four times the AES_DOUTR register to save the last-processed block.
3. Clear the CCF flag of the AES_ISR register, by setting the CCF bit of the AES_ICR register. When GCM encryption payload phase is selected, verify that BUSY is cleared in AES_SR, to ensure that GF2mul hash function is completed.
4. Save the AES_SUSPRx registers in the memory.
5. In the payload phase, save the AES_IVRx registers as, during the data processing, they changed from their initial values. In the header phase, this step is not required.
6. Disable the AES peripheral, by clearing EN.
7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:



1. Disable the AES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
3. In the payload phase, write the initialization vector register values, previously saved in the memory, back into their corresponding AES_IVRx registers. In the header phase, write initial setting values back into the AES_IVRx registers.
4. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
5. Enable the AES peripheral, by setting EN.

34.4.12 AES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

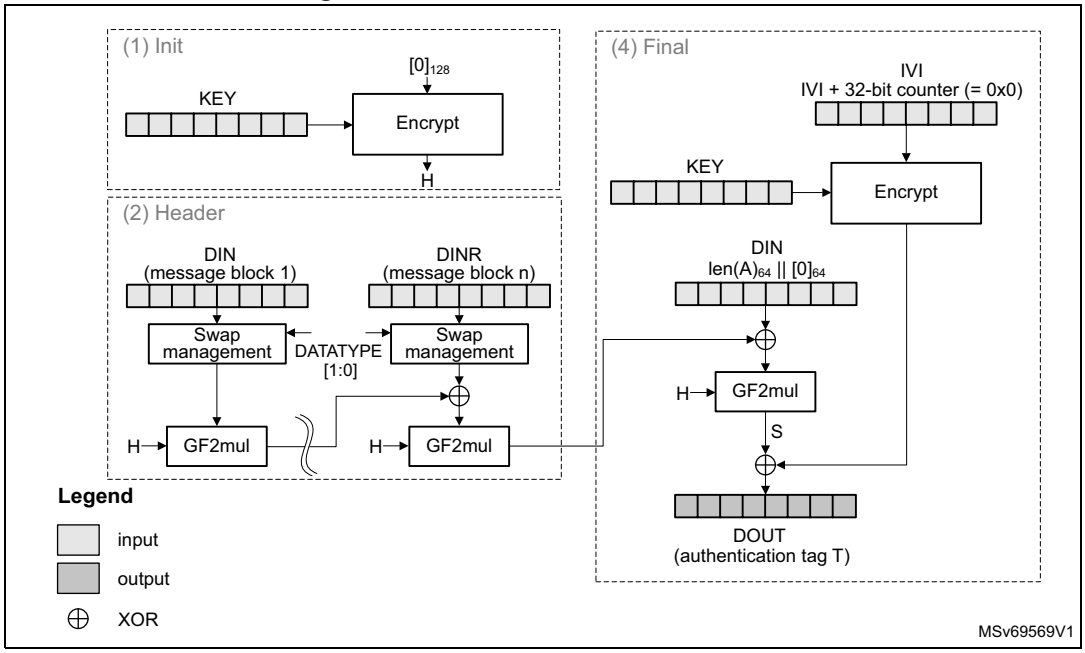


Figure 318. Message construction in GMAC mode

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

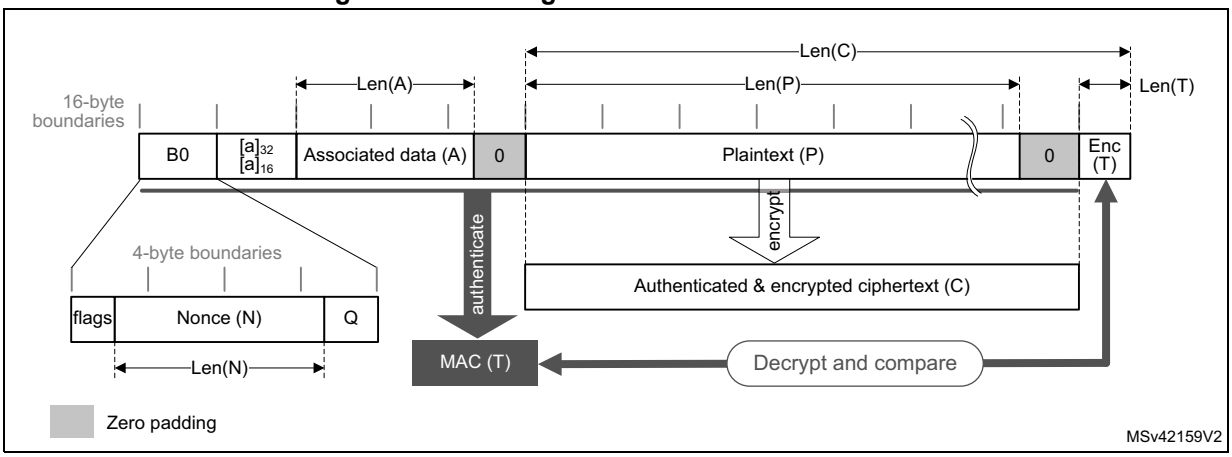
Figure 319 describes the GMAC chaining implementation in the AES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 319. GMAC authentication mode

The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

In GMAC mode, the sequence described for the GCM applies except that only the header phase can be interrupted.



34.4.13 AES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 320. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 320*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.
- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 320*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

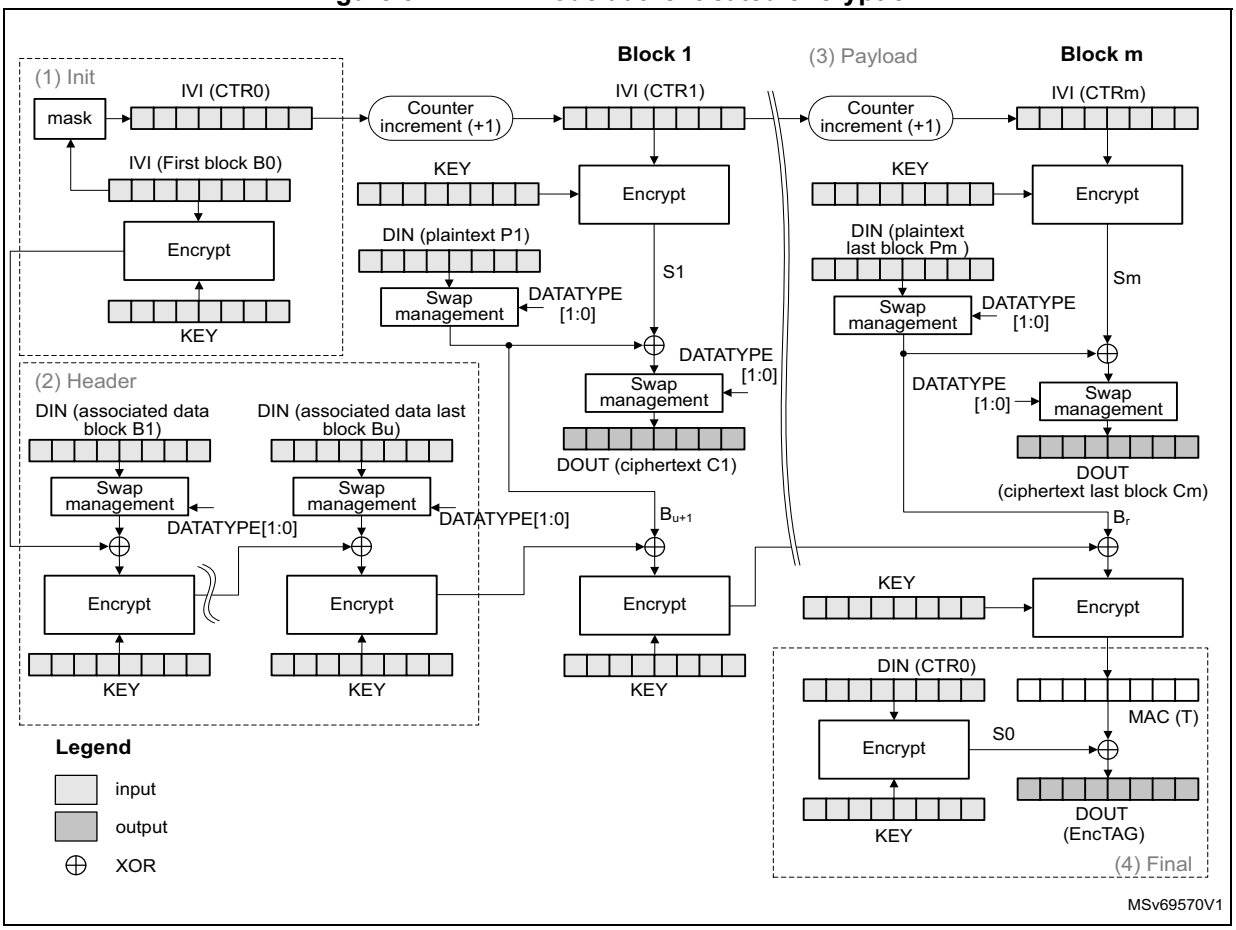
N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000



CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C, *Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 321 describes the CCM chaining implementation in the AES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 321. CCM mode authenticated encryption

The first block of a CCM message (B0) must be prepared by the application as defined in *Table 297*.

Table 297. Initialization of IV registers in CCM mode

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The five most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

AES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 34.4.6*, with the following sequence of events:

CCM initialize

1. Disable the AES peripheral, by clearing EN.
2. Initialize the AES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE.
   - Select the key mode, using KMOD[1:0]. If the key comes from the SAES peripheral, write KMOD[1:0] with 0x2, otherwise keep it at 0x0.
   - Select the CCM initialization phase, by writing CPHASE[1:0] with 0x0.
3. Write the B0 data in AES_IVRx registers according to *Table 297*.
4. Write the key into the AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key is transferred from the SAES peripheral (see *Section 34.4.14*).
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
7. Wait until the CCF flag in the AES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.

CCM header phase

9. Initialize header phase:
   a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
   b) Select the CCM header phase, by writing CPHASE[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
   c) Enable the AES peripheral, by setting EN.
10. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 34.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

11. Initialize payload phase:
    a) Select the CCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the AES peripheral, by setting EN.
12. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into AES as described in *Section 34.4.5*, then read the AES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

13. Select the CCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
14. Wait until CCF flag in the AES_ISR register is set.
15. Get the CCM authentication tag, by reading the AES_DOUTR register four times.
16. Clear the CCF flag, by setting the CCF bit of the AES_ICR register.
17. Disable the AES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from AES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the AES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

The suspend and resume operations are only supported when AES is used in CPU mode, not in DMA mode.

To suspend the processing of a message in header or payload phase, proceed as follows:

1. Wait until the CCF flag of the AES_ISR register is set (computation completed).
2. In the payload phase, read four times the AES_DOUTR register to save the last-processed block.
3. Clear the CCF flag in the AES_ISR register, by setting the CCF bit of the AES_ICR register.
4. Save the AES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the AES peripheral, by clearing EN.

7. Save the current AES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:

1. Disable the AES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding AES_SUSPRx registers.
3. Restore AES_IVRx registers using the saved configuration.
4. Restore the initial setting values in the AES_CR and AES_KEYRx registers if KMOD[1:0] is at 0x0. If KMOD[1:0] is at 0x2, the key must be transferred again from the SAES peripheral (see *Section 34.4.14*).
5. Enable the AES peripheral, by setting EN.

34.4.14 AES key sharing with secure AES co-processor

The AES peripheral can use the SAES peripheral as security co-processor. The secure application prepares the key in the robust SAES peripheral and when it is ready, the AES application can load this prepared key through a dedicated hardware key bus.

The recommended sequence is described hereafter and in the section *SAES operations with shared keys* in the *SAES* section of this document.

1. In SAES peripheral, the application encrypts (wraps) the key to share in Shared-key mode (KMOD[1:0] at 0x2).
2. Each time the shared key is required in AES peripheral, the application decrypts it in the SAES peripheral in Shared-key mode (KMOD[1:0] at 0x2).
3. Once the shared key is decrypted (unwrapped) and loaded in SAES_KEYRx registers it can be shared with AES. To load the shared key in AES, the application sets KEYSIZE as appropriate and writes KMOD[1:0] with 0x2. When KEYVALID is cleared, the key is automatically transfered by hardware into the AES_KEYRx registers and the BUSY flag in the AES_SR register set.
4. Once the key transfer is completed, the BUSY flag is cleared and the KEYVALID flag set in the AES_SR register. If KEYVALID is not set when BUSY bit is cleared, or if the KEIF flag is set in the AES_ISR register, either the KEYSIZE value is incorrect or an unexpected event occurred during the transfer (such as DPA error, tamper event or KEYVALID cleared before the end of the transfer). When such errors occur, reset both peripherals through their IPRST bits and restart the whole key sharing process.

When the key sharing sequence is completed, the AES is initialized with a valid, shared key. The application can then process data in normal key mode, by writing KMOD[1:0] with 0x0.

Note: This sequence in AES peripheral can be run multiple times (for example, to manage a suspend/resume situation), as long as SAES peripheral is unused and duly remains in key sharing state.

34.4.15 AES data registers and data swapping

Data input and output

A 16-byte data block enters the AES peripheral with four successive 32-bit word writes into the AES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

A 16-byte data block is retrieved from the AES peripheral with four successive 32-bit word reads of the AES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 298* “no swapping” option for details.

Data swapping

The AES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the AES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the AES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both AES input and output.

Note: The data in AES key registers (AES_KEYRx) and initialization vector registers (AES_IVRx) are not sensitive to the swap mode selection.

The AES data swapping feature is summarized in *Table 298* and *Figure 322*.

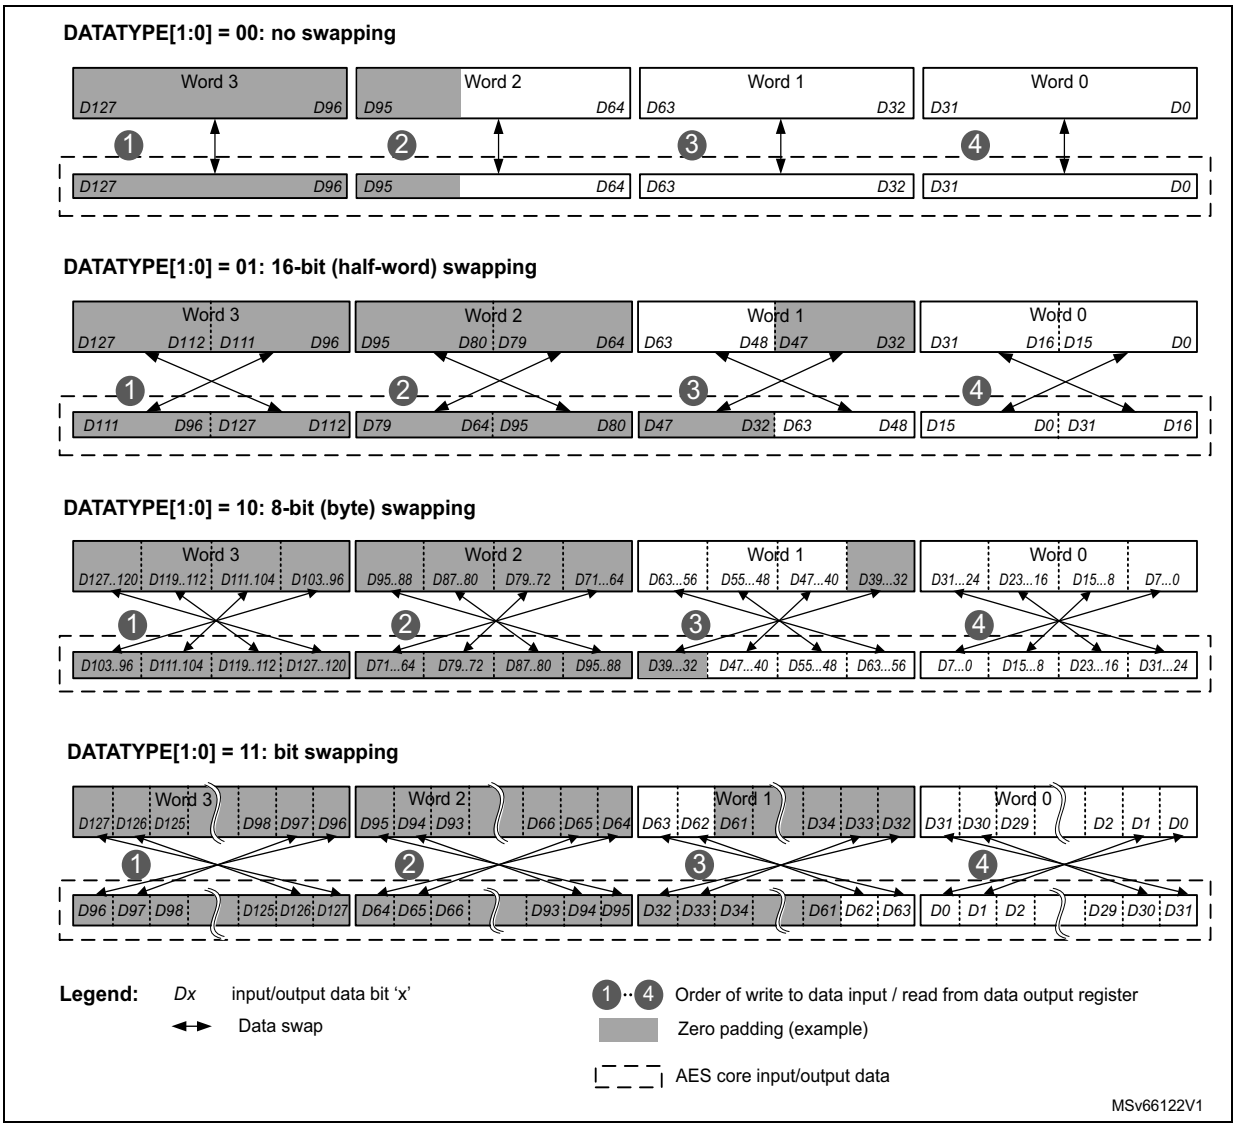


Table 298. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**

Table 298. AES data swapping example (continued)

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100
		Address @, word[63..32]: 0x04EE F672 0000 0100 1110 1110 1111 0110 0111 0010 Address @ + 0x4, word[31..0]: 0x2E04 CE96 0010 1110 0000 0100 1100 1110 1001 0110

Figure 322. 128-bit block construction according to the data type

Data padding

Figure 322 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

34.4.16 AES key registers

The eight AES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 299*. Reads are not allowed for security reason.

Note: In memory and in AES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 299. Key endianness in AES_KEYRx registers (128/256-bit keys)

AES_KEYR7 [31:0]	AES_KEYR6 [31:0]	AES_KEYR5 [31:0]	AES_KEYR4 [31:0]	AES_KEYR3 [31:0]	AES_KEYR2 [31:0]	AES_KEYR1 [31:0]	AES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the AES_KEYRx registers are ignored when AES peripheral is enabled (EN bit set). The application must check this before modifying key registers.

The entire key must be written before starting an AES computation.

In normal key mode (KMOD[1:0] at 0x0), the key registers must always be written in either ascending or descending order. The write sequence becomes:

- AES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- AES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 34.4.18*).

34.4.17 AES initialization vector registers

The four AES_IVRx registers store the initialization vector (IV) information, as shown in *Table 300*. They can only be written if the AES peripheral is disabled (EN cleared).

Note: In memory and in AES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 300. IVI bitfield spread over AES_IVRx registers

AES_IVR3[31:0]	AES_IVR2[31:0]	AES_IVR1[31:0]	AES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, AES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

34.4.18 AES error management

The AES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the AES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: AES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 34.5: AES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Write error flag (WRERRF)

Unexpected write attempt of the AES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: AES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 34.5: AES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the AES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the AES_ISR register and clear the KEYVALID bit of the AES_SR register:

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 34.4.16: AES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.

- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 34.4.14: AES key sharing with secure AES co-processor* for details.

The KEIF flag is cleared with corresponding bit of the AES_ICR register. An interrupt is generated if the KEIE bit of the AES_IER register is set. For more details, refer to *Section 34.5: AES interrupts*.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring AES.

34.5 AES interrupts

There are multiple individual maskable interrupt sources generated by the AES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)

See *Section 34.4.18: AES error management* for details on AES errors.

These sources are combined into a common interrupt signal from the AES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable AES interrupt sources individually by setting/clearing the corresponding enable bit of the AES_IER register.

The status of the individual maskable interrupt sources can be read from the AES_ISR register. They are cleared by setting the corresponding bit of the AES_ICR register.

Table 301 gives a summary of the available features.

Table 301. AES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
AES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)

1. Bit of the AES_ICR register.
2. Flag of the AES_SR register, mirrored by the flag RWEIF of the AES_ISR register.

34.6 AES DMA requests

The AES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the AES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

AES only supports single DMA requests.

Suspend and resume operations are not supported in DMA mode.

Detailed usage of DMA with AES can be found in *Appending data using DMA* subsection of *Section 34.4.5: AES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into AES. AES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the AES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 34.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from AES. AES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the AES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, AES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the AES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when AES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

34.7 AES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 302. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles
128-bit	Encryption or decryption(1)	ECB, CBC, CTR	51
	Key preparation	-	59
256-bit	Encryption or decryption(1)	ECB, CBC, CTR	75
	Key preparation	-	82

1. Excluding key preparation time (ECB and CBC only).

Table 303. Processing latency for GCM and CCM (in clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Encryption/ Decryption	GCM	64	35	51	59
		CCM	63	55	114	58
256-bit	Encryption/ Decryption	GCM	88	35	75	75
		CCM	87	79	162	82

1. Data insertion can include wait states forced by AES on the AHB bus (maximum 3 cycles, typical 1 cycle).

34.8 AES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

34.8.1 AES control register (AES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: AES peripheral software reset

Setting the bit resets the AES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the AES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:26 Reserved, must be kept at reset value.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the AES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable.

0x2: Shared key mode. If shared key mode is properly initialized in SAES peripheral, the AES peripheral automatically loads its key registers with the data stored in the SAES key registers. The key value is available in AES key registers when BUSY bit is cleared and KEYVALID is set in the AES_SR register. Key error flag KEIF is set otherwise in the AES_ISR register.

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 Reserved, must be kept at reset value.

Bit 18 **KEYSIZE:** Key size selection
This bitfield defines the key length in bits of the key used by AES.
0: 128-bit
1: 256-bit
Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **CPHASE[1:0]:** Chaining phase selection
This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable
This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable
This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to AES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode
This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode
This bitfield selects the AES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the AES_DINR register or read from the AES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 34.4.15: AES data registers and data swapping*.

0x0: No swapping (32-bit data).

0x1: Half-word swapping (16-bit data)

0x2: Byte swapping (8-bit data)

0x3: Bit-level swapping

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the AES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the AES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

– The bit cannot be set as long as KEYVALID is cleared

34.8.2 AES status register (AES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in AES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KMOD[1:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KMOD[1:0] is different from zero, the BUSY flag is automatically set by AES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is usually set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the AES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 34.4.16: AES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether AES is idle or busy.
0: Idle
1: Busy
AES is flagged as idle when disabled (when EN is low) or when the last processing is completed.
AES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), or transferring a shared key from the SAES peripheral.
When GCM encryption payload phase is selected, this flag must be at zero before suspending current process to manage a higher-priority message.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the AES_DINR register occurred. When set WRERRF bit has no impact on the AES operations.
0: No error
1: Unexpected write to AES_DINR register occurred during computation or data output phase.
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the AES_DOUTR register occurred. When set RDERRF bit has no impact on the AES operations.
0: No error
1: Unexpected read to AES_DOUTR register occurred during computation or data input phase.
The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.
The flag is cleared by setting the RWEIF bit of the AES_ICR register.

Bit 0 Reserved, must be kept at reset value.

34.8.3 AES data input register (AES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the AES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.
Reads return zero.

34.8.4 AES data output register (AES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the AES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

34.8.5 AES key register 0 (AES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the AES_CR register.

Writes to AES_KEYRx registers are ignored when AES is enabled (EN bit set). When the key comes from the SAES peripheral (KMOD[1:0] at 0x2), writes to key registers are also ignored and they result in setting the KEIF bit of the AES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

34.8.6 AES key register 1 (AES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

AES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in AES_CR register

34.8.10 AES initialization vector register 1 (AES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the AES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing AES_KEYRx registers.

34.8.17 AES suspend registers (AES_SUSPRx)

Address offset: 0x040 + 0x4 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

AES_SUSPRx registers contain the complete internal register states of the AES when the GCM, GMAC or CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 34.4.8: AES suspend and resume operations* for more details.

Clearing EN bit of the AES_CR register clears this register to zero.

AES_SUSPRx registers are not used in other chaining modes than GCM, GMAC or CCM.

34.8.18 AES interrupt enable register (AES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIE	RWEIE	CCFIE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE:** Key error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the AES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable

This bit enables or disables (masks) the AES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

34.8.19 AES interrupt status register (AES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	RWEIF	CCF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers.

0: No key error detected

1: Key information failed to load into key registers

The flag setting generates an interrupt if the KEIE bit of the AES_IER register is set. It also clears the key registers and the KEYVALID flag in the AES_SR register.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

KEIF is raised upon any of the following events:

–AES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 register, or reverse. For KEYSIZE set, AES_KEYR0 then AES_KEYR1 then AES_KEYR2 then AES_KEYR3 then AES_KEYR4 then AES_KEYR5 then AES_KEYR6 then AES_KEYR7, or reverse).

–AES fails to load the key shared by the SAES peripheral (KMOD[1:0] = 0x2).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the AES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the AES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the AES_IER register is set.

The flag is cleared by setting the corresponding bit of the AES_ICR register.

34.8.20 AES interrupt clear register (AES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag clear
Setting this bit clears the KEIF status bit of the AES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear
Setting this bit clears the RWEIF status bit of the AES_ISR register, and clears both RDERRF and WRERRF flags in the AES_SR register.

Bit 0 **CCF:** Computation complete flag clear
Setting this bit clears the CCF status bit of the AES_ISR register.

35 Secure AES coprocessor (SAES)

This section only applies to STM32G56x products.

35.1 SAES introduction

The secure AES coprocessor (SAES) encrypts or decrypts data in compliance with the advanced encryption standard (AES) defined by NIST. It incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.

SAES supports ECB, CBC, CTR, GCM, GMAC, and CCM chaining modes for key sizes of 128 or 256 bits, as well as special modes such as hardware secret key encryption/ decryption (wrapped-key mode) and key sharing with faster AES peripheral (shared-key mode).

SAES has the possibility to load by hardware STM32 hardware secret master keys (boot hardware key BHK and derived hardware unique key DHUK), usable but not readable by the application.

The peripheral supports DMA single transfers for incoming and outgoing data (two DMA channels are required). It is hardware-linked with the true random number generator (TRNG) and with the AES peripheral.

35.2 SAES main features

- Compliant with NIST FIPS publication 197 *"Advanced encryption standard (AES)"* (November 2001)
- Encryption and decryption with multiple chaining modes:
  - Electronic codebook (ECB) mode
  - Cipher block chaining (CBC) mode
  - Counter (CTR) mode
  - Galois counter mode (GCM)
  - Galois message authentication code (GMAC) mode
  - Counter with CBC-MAC (CCM) mode
- Protection against side-channel attacks (SCA), incl. differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target
- 128-bit data block processing, supporting cipher key lengths of 128-bit and 256-bit
  - 480 or 680 clock cycle latency in ECB mode for processing one 128-bit block with, respectively, 128-bit or 256-bit key
- Hardware secret key encryption/ decryption (Wrapped-key mode)
- Using dedicated key bus, optional key sharing with faster AES peripheral (shared-key mode), controlled by SAES
- Integrated key scheduler to compute the last round key for ECB/CBC decryption
- 256-bit of write-only registers for storing cryptographic keys (eight 32-bit registers)
  - Optional 128-bit or 256-bit hardware loading of two hardware secret keys (BHK, DHUK) that can be XOR-ed together

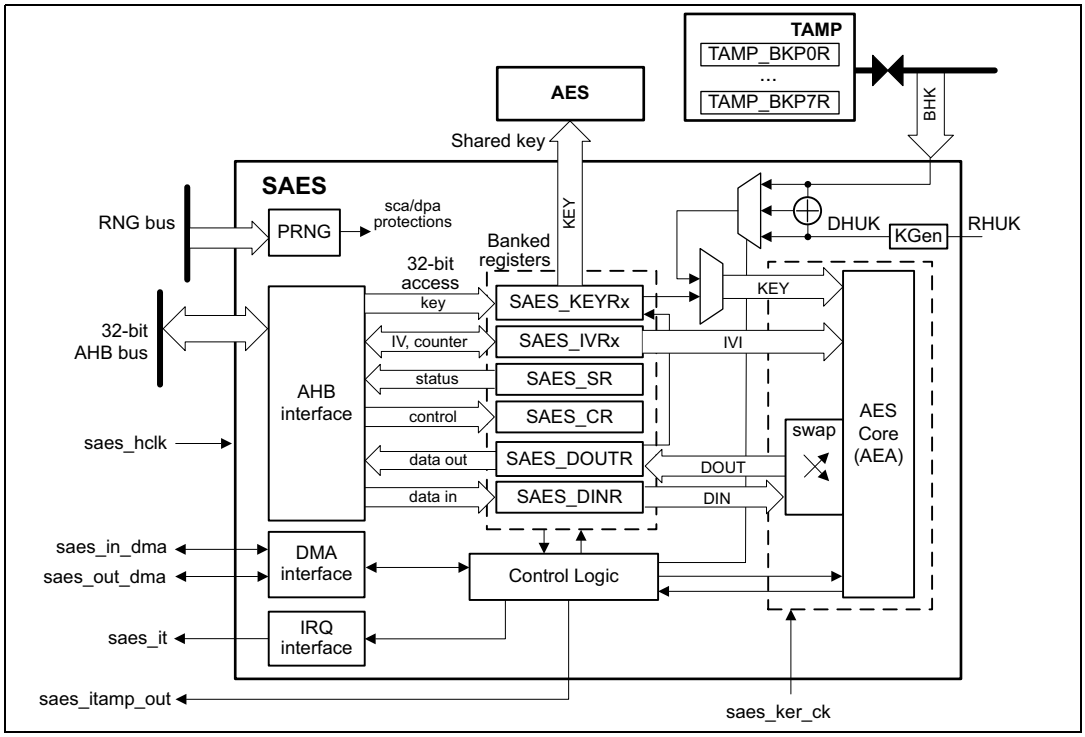
- Security context enforcement for keys
- 128-bit of registers for storing initialization vectors (four 32-bit registers)
- 32-bit buffer for data input and output
- Automatic data flow control supporting two direct memory access (DMA) channels, one for incoming data, one for processed data. Only single transfers are supported.
- Data-swapping logic to support 1-, 8-, 16-, or 32-bit data
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.
- Possibility for software (in CPU mode only, not in DMA mode) to suspend a message if SAES needs to process another message with a higher priority, then resume the original message

35.3 SAES implementation

The devices have one SAES peripheral, implemented as per the following table. It shares the key with the AES peripheral. For comparison, the AES peripheral is also included in the table.

Table 305. AES versus SAES features

Modes or features(1)	AES	SAES
ECB, CBC chaining	X	X
CTR, CCM, GCM chaining	X	X
AES 128-bit ECB encryption in cycles	51	480
DHUK and BHK key selection	-	X
Resistance to side-channel attacks	-	X
Shared key between SAES and AES	X	
Key sizes in bits	128, 256	128, 256



1. X = supported.

35.4 SAES functional description

35.4.1 SAES block diagram

Figure 323 shows the block diagram of SAES.

Figure 323. SAES block diagram

Note: AES represents the AES peripheral.

35.4.2 SAES internal signals

Table 306 describes the user relevant internal signals interfacing the SAES peripheral.

Table 306. SAES internal input/output signals

Signal name	Signal type	Description
saes_hclk	Input	AHB bus clock
saes_ker_ck	Input	SAES kernel clock.
saes_it	Output	SAES interrupt request
saes_in_dma	Input/Output	SAES incoming data DMA single request/acknowledge
saes_out_dma	Input/Output	SAES processed data DMA single request/acknowledge
saes_itamp_out	Output	Tamper event signal to TAMP (XOR-ed), triggered when an unexpected hardware fault occurs. When this signal is triggered, SAES automatically clears key registers. A reset is required for SAES to be usable again.
RHUK	Input	256-bit root hardware unique key (nonvolatile, unique per device and secret to software), used to internally compute the derived hardware unique key (DHUK)
BHK(1)	Input	256-bit boot hardware key (BHK) stored in tamper-resistant secure backup registers and written by a secure code during boot. Once written, this key cannot be read nor written by any application until the next product reset.

1. Connected to a set of backup registers in TAMP peripheral that are written, then read/write locked, by the application software (see *Section 35.4.17* for details).

35.4.3 SAES reset and clocks

The SAES peripheral is clocked by the AHB bus clock. It has a dedicated reset bit and a dedicated kernel clock, controlled through the RCC.

The SAES reset in RCC is mandatory when a hardware tamper event occurs in SAES. Refer to *Managing tamper errors* in *Section 35.4.19* for details.

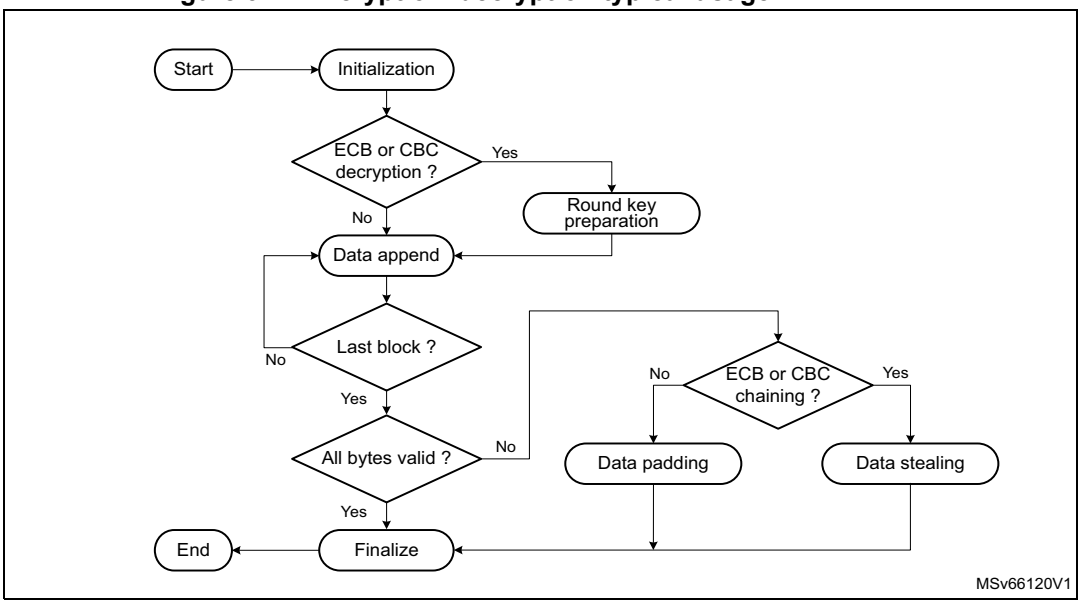
After clocking then releasing the reset of the SAES peripheral in the RCC, SAES automatically draws random numbers from the RNG, setting the BUSY bit of the SAES_SR register. Refer to the *RNG error interrupt flag (RNGEIF)* in *Section 35.4.19* for details.

This background task must be completed before the device enters a low-power mode.

35.4.4 SAES symmetric cipher implementation

The secure AES coprocessor (SAES) is a 32-bit AHB peripheral that encrypts or decrypts 16-byte blocks of data using the advanced encryption standard (AES). It also implements a set of approved AES symmetric key security functions summarized in *Table 307*. Those functions can be certified NIST PUB 140-3.

Table 307. SAES approved symmetric key functions



Operations	Algorithm	Specification	Key bit lengths	Chaining modes
Encryption, decryption	AES	FIPS PUB 197 NIST SP800-38A	128, 256	ECB, CBC, CTR
Authenticated encryption or decryption		NIST SP800-38C NIST SP800-38D		GCM, CCM
Cipher-based message authentication code		NIST SP800-38D		GMAC

SAES can be used directly by the CPU, or indirectly, using two DMA channels (one for the plaintext, one for the ciphertext).
It is possible to suspend then resume any SAES processing, following the sequence described in *Section 35.4.8*.

35.4.5 SAES encryption or decryption typical usage

The following figure shows a typical operation for encryption or decryption.

Figure 324. Encryption/ decryption typical usage

Initialization

The SAES peripheral is initialized according to the chaining mode. Refer to *Section 35.4.9: SAES basic chaining modes (ECB, CBC)* and *Section 35.4.10: SAES counter (CTR) mode* for details.

Data append

This section describes different ways of appending data for processing. For ECB or CBC chaining modes, refer to *Section 35.4.7: SAES ciphertext stealing and data padding* if the size of data to process is not a multiple of 16 bytes. The last block management in these cases is more complex than what is described in this section.

Appending data using the CPU in polling mode

This method uses flag polling to control the data append through the following sequence:

1. Enable the SAES peripheral when KEYVALID is set, by setting the EN bit of the SAES_CR register (if not already done).
2. Repeat the following sub-sequence until the payload is entirely processed:
   a) Write four input data words into the SAES_DINR register.
   b) Wait until the status flag CCF is set in the SAES_ISR register, then read the four data words from the SAES_DOUTR register.
   c) Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
   d) If the next processing block is the last block, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (using

NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong).

3. As the data block just processed is the last block of the message, optionally discard the data that is not part of the message/payload, then disable the SAES peripheral by clearing EN.

Note: Up to three wait cycles are automatically inserted between two consecutive writes to the SAES_DINR register, to allow sending the key to the AES co-processor.

NPBLB[3:0] bitfield is not used in header phase of GCM, GMAC and CCM chaining modes.

Appending data using the CPU in interrupt mode

The method uses interrupt from the SAES peripheral to control the data append, through the following sequence:

1. Enable interrupts from SAES, by setting the CCFIE bit of the SAES_IER register.
2. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
3. Write first four input data words into the SAES_DINR register.
4. Handle the data in the SAES interrupt service routine. Upon each interrupt:
   a) Read four output data words from the SAES_DOUTR register.
   b) Clear the CCF flag and thus the pending interrupt, by setting the CCF bit of the SAES_ICR register.
   c) If the next processing block is the last block of the message, pad (when applicable) the data with zeros to obtain a complete block, and specify the number of non-valid bytes (through NPBLB[3:0]) in case of GCM payload encryption or CCM payload decryption (otherwise the tag computation is wrong). Then proceed with point 4e).
   d) If the data block just processed is the last block of the message, optionally discard the data that are not part of the message/payload, then disable the SAES peripheral by clearing EN and quit the interrupt service routine.
   e) Write next four input data words into the SAES_DINR register and quit the interrupt service routine.

Note: SAES is tolerant of delays between consecutive read or write operations, which allows, for example, an interrupt from another peripheral to be served between two SAES computations.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

Appending data using DMA

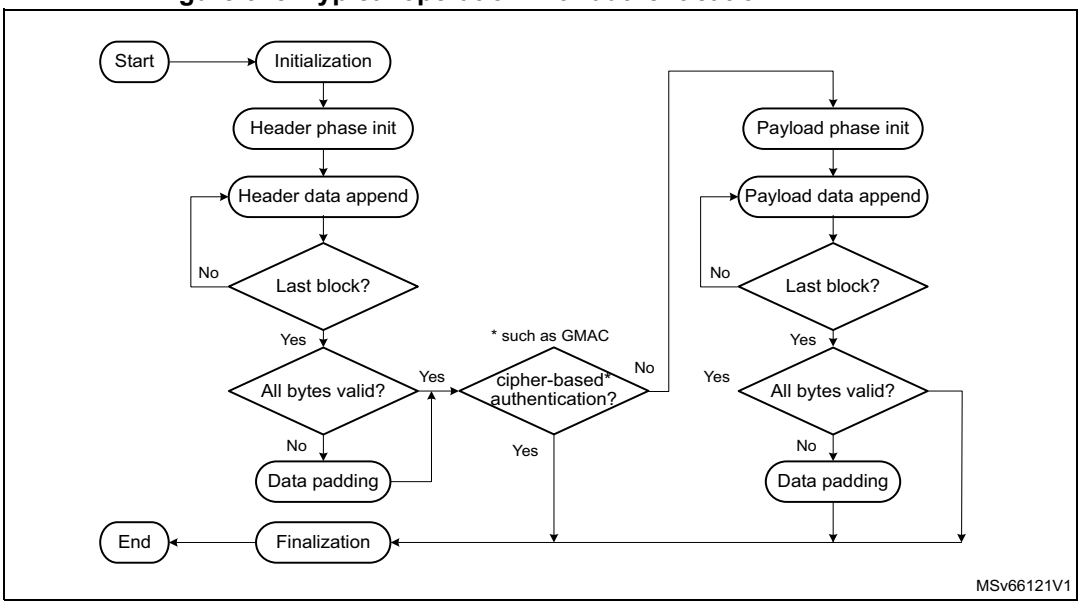
With this method, all the transfers and processing are managed by DMA and SAES. Proceed as follows:

1. If the last block of the message to process is shorter than 16 bytes, prepare the last four-word data block by padding the remainder of the block with zeros.
2. Configure the DMA controller so as to transfer the data to process from the memory to the SAES peripheral input and the processed data from the SAES peripheral output to the memory, as described in *Section 35.6: SAES DMA requests*. Configure the DMA controller so as to generate an interrupt on transfer completion. For GCM payload encryption or CCM payload decryption, the DMA transfer **must not** include the last four-word block if padded with zeros. The sequence described in *Appending data using the CPU in polling mode* must be used instead for this last block, because the

NPBLB[3:0] bitfield must be set up before processing the block, for SAES to compute a correct tag.

3. Enable the SAES peripheral when KEYVALID is set, by setting EN (if not already done).
4. Enable DMA requests, by setting DMAINEN and DMAOUTEN.
5. Upon DMA interrupt indicating the transfer completion, get the SAES-processed data from the memory.

When appending data using DMA, the suspend/resume operation as described in *Section 35.4.8* is not supported.



Note: The CCF flag has no use with this method because the reading of the SAES_DOUTR register is managed by DMA automatically, without any software action, at the end of the computation phase.

The NPBLB[3:0] bitfield is not used in the header phase of GCM, GMAC, and CCM chaining modes.

35.4.6 SAES authenticated encryption, decryption, and cipher-based message authentication

The following figure shows a typical operation for authenticated encryption or decryption, and for cipher-based message authentication.

Figure 325. Typical operation with authentication

Section 35.4.11: SAES Galois/counter mode (GCM) and *Section 35.4.13: SAES counter with CBC-MAC (CCM)* describe detailed sequences supported by SAES.

Cipher-based message authentication flow omits the payload phase, as shown in the figure. Detailed sequence supported by SAES is described in *Section 35.4.12: SAES Galois message authentication code (GMAC)*.

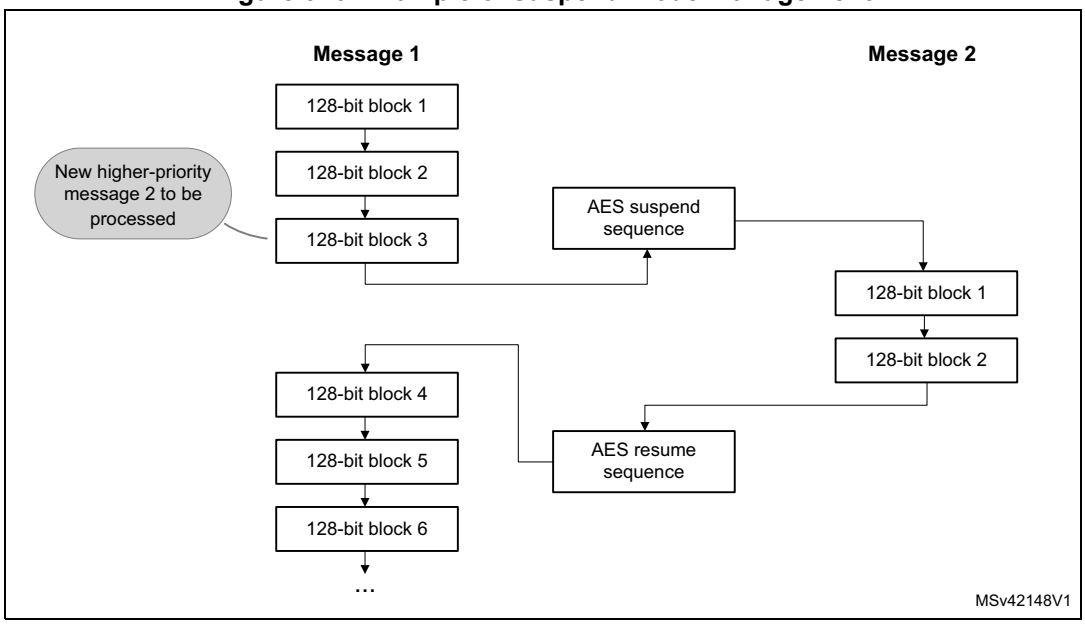
35.4.7 SAES ciphertext stealing and data padding

When using SAES in ECB or CBC modes to manage messages the size of which is not a multiple of the block size (16 bytes), the application must use ciphertext stealing techniques such as those described in NIST Special Publication 800-38A*, Recommendation for Block Cipher Modes of Operation: Three Variants of Ciphertext Stealing for CBC Mode*. Since SAES does not implement such techniques, the application must complete the *last block* of input data using data from the *second last* block.

Note: Ciphertext stealing techniques are not documented in this reference manual.

Similarly, in modes other than ECB or CBC, an incomplete input data block (that is, a block with input data shorter than 16 bytes) must be padded with zeros prior to encryption. That is, extra bits must be appended to the trailing end of the data string. After decryption, the extra bits must be discarded. Since SAES does not implement automatic data padding operation to the *last block*, the application must follow the recommendation given in this document to manage messages the size of which is not a multiple of 16 bytes.

35.4.8 SAES suspend and resume operations



A message can be suspended to process another message with a higher priority. When the higher-priority message is sent, the suspended message can resume. This applies to both encryption and decryption mode.

Suspend and resume operations do not break the chaining operation. The message processing can resume as soon as SAES is enabled again, to receive a next data block.

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

Figure 326 gives an example of suspend and resume operations: Message 1 is suspended in order to send a shorter and higher-priority Message 2.

Figure 326. Example of suspend mode management

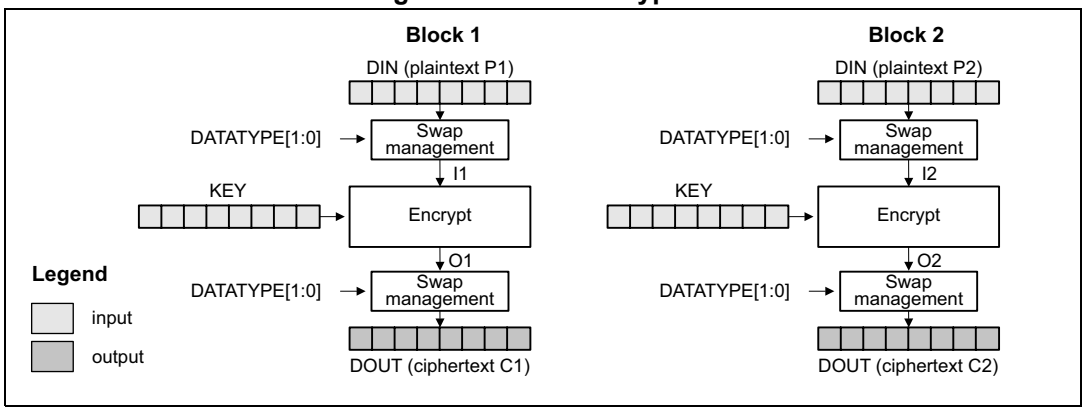
A detailed description of suspend and resume operations is in the sections dedicated to each chaining mode.

35.4.9 SAES basic chaining modes (ECB, CBC)

ECB is the simplest mode of operation. There are no chaining operations, and no special initialization stage. The message is divided into blocks and each block is encrypted or decrypted separately. When decrypting in ECB, a special key scheduling is required before processing the first block.

Figure 327 and *Figure 328* describe the electronic codebook (ECB) chaining implementation in encryption and in decryption, respectively. To select ECB chaining mode, write CHMOD[2:0] with 0x0.

Figure 327. ECB encryption



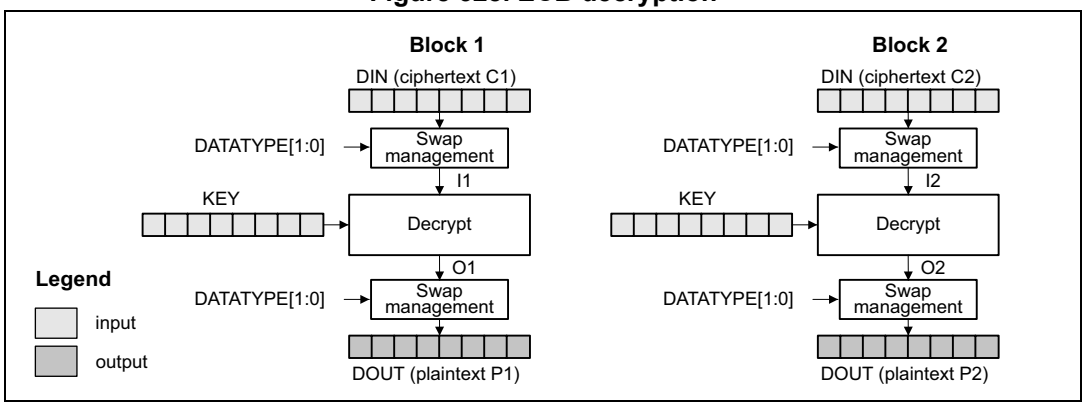


Figure 328. ECB decryption

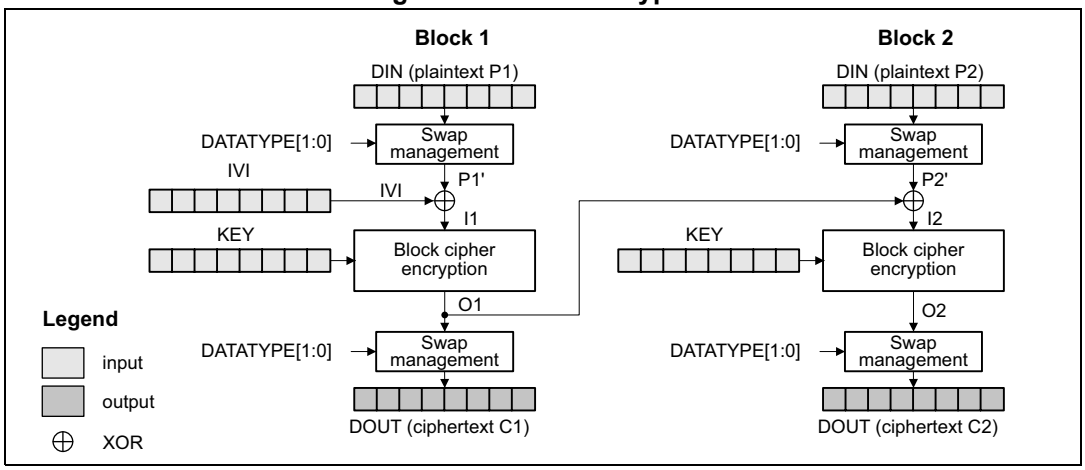
In CBC encryption mode the output of each block chains with the input of the following block. To make each message unique, an initialization vector is used during the first block processing. When decrypting in CBC, a special key scheduling is required before processing the first block.

Figure 329 and *Figure 330* describe the cipher block chaining (CBC) implementation in encryption and in decryption, respectively. To select this chaining mode, write CHMOD[2:0] with 0x1.

Figure 329. CBC encryption



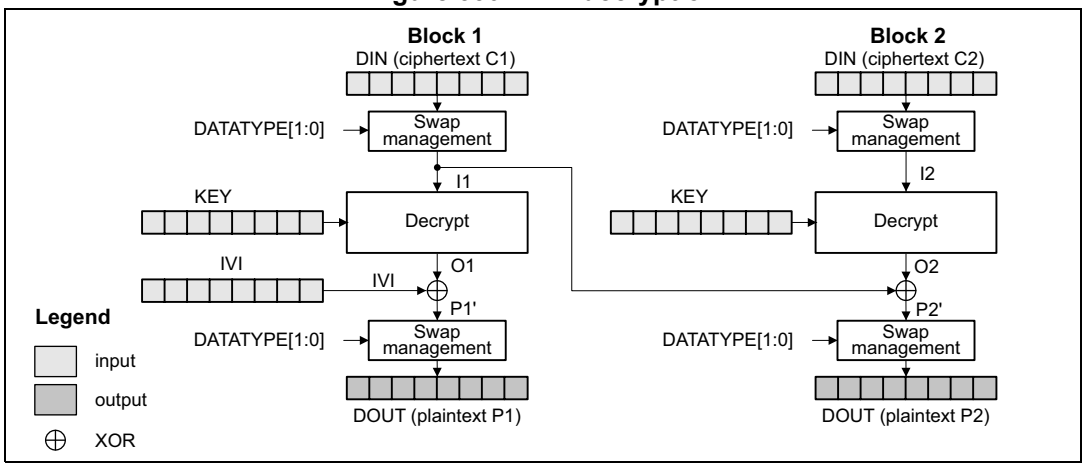


Figure 330. CBC decryption

For more details, refer to NIST Special Publication 800-38A, *Recommendation for Block Cipher Modes of Operation.*

ECB and CBC encryption process

This process is described in *Section 35.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (write MODE[1:0] with 0x0).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 35.4.14* (wrapped keys) and *Section 35.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 35.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Append cleartext data:
   a) If it is the second-last or the last block and the plaintext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 35.4.7*.
   b) Append the cleartext block into SAES as described in *Section 35.4.5*, then read the SAES_DOUTR register four times to save the ciphertext block.
   c) Repeat the step *b)* until the third-last plaintext block is encrypted. For the last two blocks, follow the steps *a)* and *b)*.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

ECB/CBC decryption process

This process is described in *Section 35.4.5*, with the following sequence of events:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follows:
   - Select the *key derivation* mode (write MODE[1:0] with 0x1). The CHMOD[2:0] bitfield is not significant during this operation.
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 35.4.14* (wrapped keys) and *Section 35.4.15* (shared keys).

4. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 35.4.17: SAES key registers* for details.
5. Wait until KEYVALID is set (the key loading completed).
6. Enable the SAES peripheral, by setting EN. The peripheral immediately starts an AES round for key preparation.
7. Wait until the CCF flag in the SAES_ISR register is set.
8. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register. The decryption key is available in the AES core and SAES is disabled automatically.
9. Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *decryption* mode (write MODE[1:0] with 0x2). Do not change other parameters.
10. Write the initialization vector into the SAES_IVRx registers if CBC mode is selected in the previous step.
11. Enable the SAES peripheral, by setting EN.
12. Append encrypted data:
    a) If it is the second-last or the last block and the ciphertext size of the message is not a multiple of 16 bytes, follow the guidance in *Section 35.4.7*.
    b) Append the ciphertext block into SAES as described in *Section 35.4.5*, then read the SAES_DOUTR register four times to save the cleartext block (MSB first).
    c) Repeat the step *b)* until the third-last ciphertext block is decrypted. For the last two blocks, follow the steps *a)* and *b)*.
13. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in ECB/CBC modes

The following sequences are valid for normal key mode (KMOD[1:0] at 0x0).

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

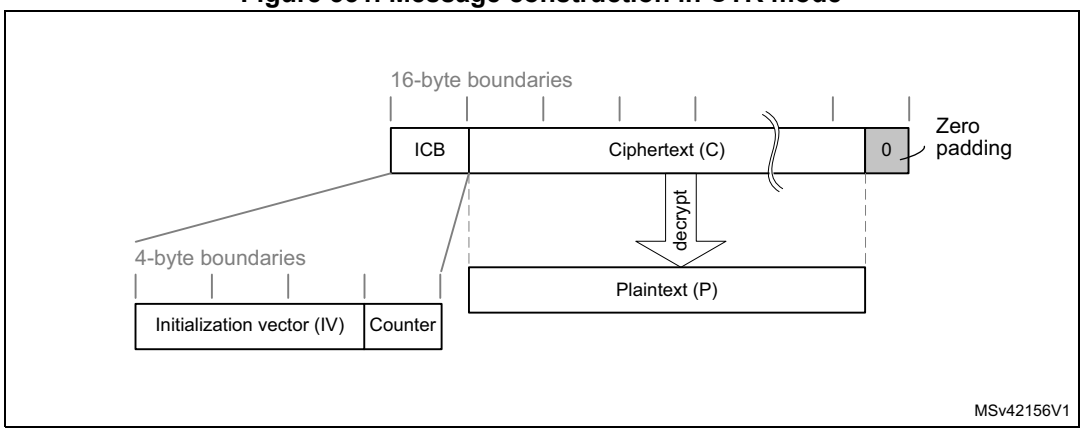
To suspend the processing of a message, proceed as follows:

1. Wait until the CCF flag in the SAES_ISR register is set (computation completed).
2. Read four times the SAES_DOUTR register to save the last processed block.
3. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
4. Save initialization vector registers (only required in CBC mode as the SAES_IVRx registers are altered during the data processing).
5. Disable the SAES peripheral, by clearing EN.
6. Save the SAES_CR register and clear the key registers if they are not needed, to process the higher-priority message.

To resume the processing of a message, proceed as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Restore the SAES_CR register (with correct KEYSIZE) then restore the SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from key registers, refer to *Section 35.4.17: SAES key registers* for details.
3. Prepare the decryption key, as described in *ECB/CBC decryption process* (only required for ECB or CBC decryption).

4. Restore the SAES_IVRx registers, using the saved configuration (only required in CBC mode).
5. Enable the SAES peripheral, by setting EN.



Note: It is not required to save the key registers as the application knows the original key.

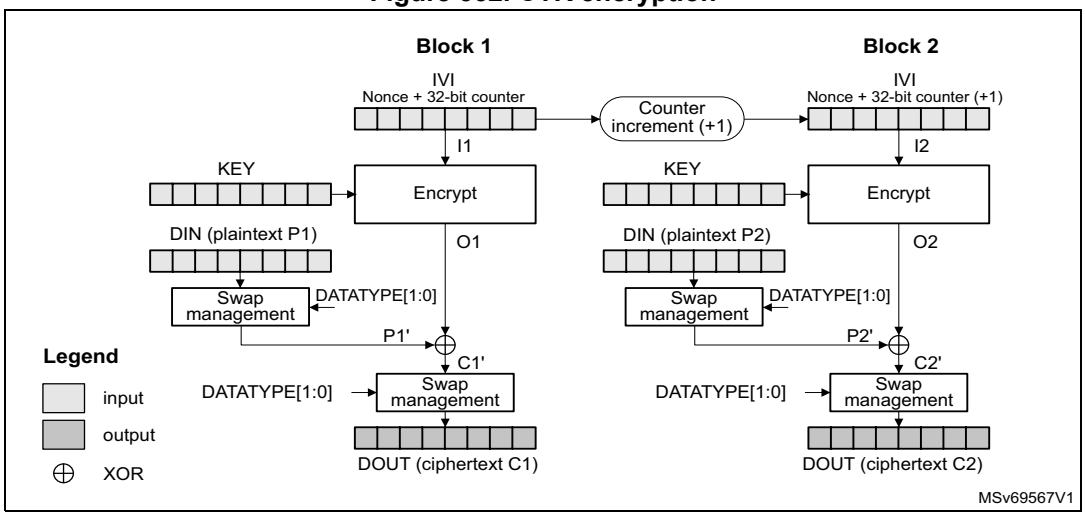
35.4.10 SAES counter (CTR) mode

The CTR mode uses the AES core to generate a key stream. The keys are then XOR-ed with the plaintext to obtain the ciphertext. Unlike with ECB and CBC modes, no key scheduling is required for the CTR decryption since the AES core is always used in encryption mode.

A typical message construction in CTR mode is given in *Figure 331*.

Figure 331. Message construction in CTR mode

The structure of this message is:



- A 16-byte initial counter block (ICB), composed of two distinct fields:
  - **Initialization vector** (IV): a 96-bit value that must be unique for each encryption cycle with a given key.
  - **Counter**: a 32-bit big-endian integer that is incremented each time a block processing is completed. The initial value of the counter must be set to 1.
- The plaintext P is encrypted as ciphertext C, with a known length. This length can be non-multiple of 16 bytes, in which case a plaintext padding is required.

For more details, refer to NIST *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation.*

CTR encryption and decryption

Figure 332 describes the counter (CTR) chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x2.

Figure 332. CTR encryption

Initialization vectors in SAES must be initialized as shown in *Table 308*.

Table 308. Counter mode initialization vector definition

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0] 32-bit counter = 0x0001

CTR encryption and decryption process

This process is described in *Section 35.4.5*, with the following sequence of events:

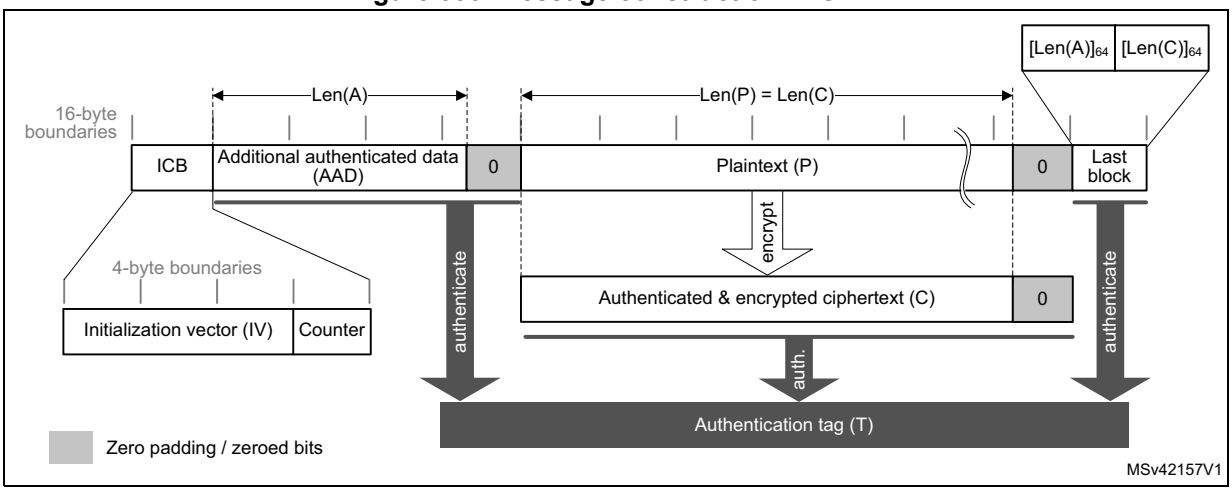
1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CTR chaining mode (write CHMOD[2:0] with 0x2) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2).
   - Configure the data type, through DATATYPE[1:0].
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (different secure attribute), the KEYPROT bit must also be set.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 35.4.14* (wrapped keys) and *Section 35.4.15* (shared keys).
4. Write the initialization vector into the SAES_IVRx registers according to *Table 308*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 35.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).

7. Enable the SAES peripheral, by setting EN.
8. Append data:
   a) If it is the last block and the plaintext (encryption) or ciphertext (decryption) size in the block is less than 16 bytes, pad the remainder of the block with zeros.
   b) Append the data block into SAES as described in *Section 35.4.5*, then read the SAES_DOUTR register four times to save the resulting block (MSB first).
   c) Repeat the step *b)* until the second-last block is processed. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the message when the last block is smaller than 16 bytes.
9. Finalize the sequence: disable the SAES peripheral, by clearing EN.

Suspend/resume operations in CTR mode

Like for the CBC mode, it is possible to interrupt a message to send a higher-priority message, then resume the interrupted message. Detailed CBC suspend and resume sequence is described in *Section 35.4.9: SAES basic chaining modes (ECB, CBC)*.

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.



Note: Like for CBC mode, the IV registers must be reloaded during the resume operation.

35.4.11 SAES Galois/counter mode (GCM)

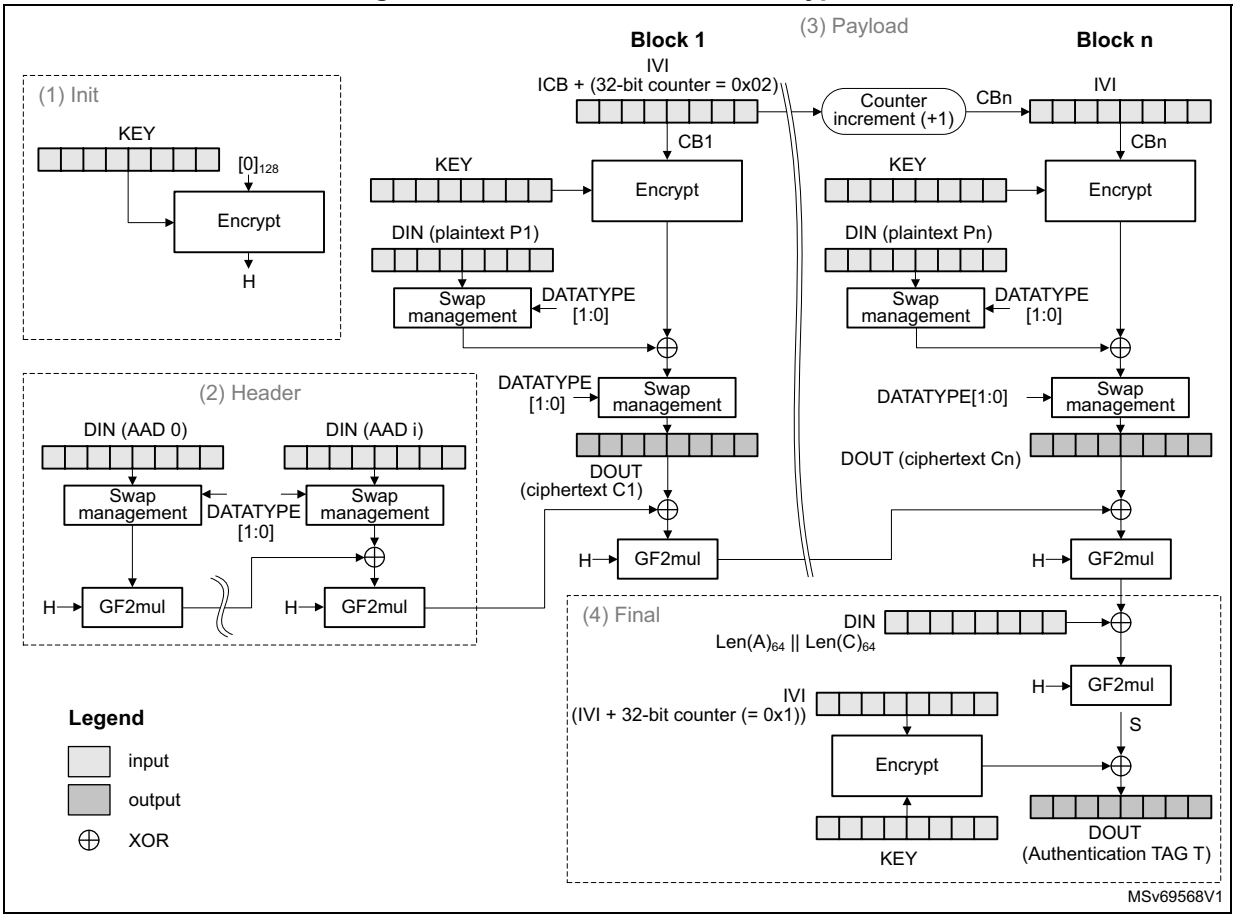
The AES Galois/counter mode (GCM) allows encrypting and authenticating a plaintext message into the corresponding ciphertext and tag (also known as message authentication code).

GCM mode is based on AES in counter mode for confidentiality. It uses a multiplier over a fixed finite field for computing the message authentication code. The following figure shows a typical message construction in GCM mode.

Figure 333. Message construction in GCM

The message has the following structure:

- **16-byte initial counter block (ICB)**, composed of two distinct fields:
  - **Initialization vector (IV):** a 96-bit value that must be unique for each encryption cycle with a given key. The GCM standard supports IVs with less than 96 bits, but in this case strict rules apply.
  - **Counter:** a 32-bit big-endian integer that is incremented each time a block processing is completed. According to NIST specification, the counter value is 0x2 when processing the first block of payload.
- **Authenticated header AAD** (also knows as additional authentication data) has a known length Len(A) that may be a non-multiple of 16 bytes, and must not exceed $2^{64} – 1$ bits. This part of the message is only authenticated, not encrypted.
- **Plaintext message P** is both authenticated and encrypted as ciphertext C, with a known length Len(P) that may be non-multiple of 16 bytes, and cannot exceed 2^{32} - 2 16-byte blocks.
- **Last block** contains the AAD header length (bits [32:63]) and the payload length (bits [96:127]) information, as shown in *Table 310*.



The GCM standard specifies that ciphertext C has the same bit length as the plaintext P.

When a part of the message (AAD or P) has a length that is a non-multiple of 16-bytes a special padding scheme is required.

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

Figure 334 describes the GCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 334. GCM authenticated encryption

The first counter block (CB1) is derived from the initial counter block ICB by the application software, as defined in *Table 309*.

Table 309. Initialization of IV registers in GCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
ICB[127:96]	ICB[95:64]	ICB[63:32]	ICB[31:0] 32-bit counter = 0x0002

The last block of a GCM message contains the AAD header length and the payload length information, as shown in *Table 310*.

Table 310. GCM last block definition

Word order to SAES_DINR	First word	Second word	Third word	Fourth word
Input data	AAD length[63:32]	AAD length[31:0]	Payload length[63:32]	Payload length[31:0]

GCM encryption and decryption process

This process is described in *Section 35.4.6*, with the following sequence of events:

GCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select GCM chaining mode (write CHMOD[2:0] with 0x3) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context (such as secure, nonsecure, specific CPU), also set KEYPROT.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 35.4.14* (wrapped keys) and *Section 35.4.15* (shared keys).
   - Select the GCM initialization phase, by writing CPHASE[1:0] with 0x0.
4. Write the initialization vector in SAES_IVRx registers according to *Table 309*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 35.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the calculation of the hash key. EN is automatically cleared when the calculation is completed.
8. Wait until the CCF flag is set in the SAES_ISR register, indicating that the GCM hash subkey (H) computation is completed.
9. Clear the CCF flag by setting the CCF bit of the SAES_ICR register.

GCM header phase

10. Initialize header phase:
    a) Select the GCM header phase, by writing 0x1 to CPHASE[1:0]. Do not change the other configurations written during GCM initialization.
    b) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the AAD in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 35.4.5*.
    c) Repeat the step *b)* until the second-last AAD data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no AAD, that is, Len(A) = 0.

No data are read during header phase.

GCM payload phase

12. Initialize payload phase:
    a) Select the GCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during GCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral by setting EN.
13. Append payload data:
    a) If it is the last block and the message in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 35.4.5*, then read the SAES_DOUTR register four times to save the resulting block
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(C)=0 (see GMAC mode).

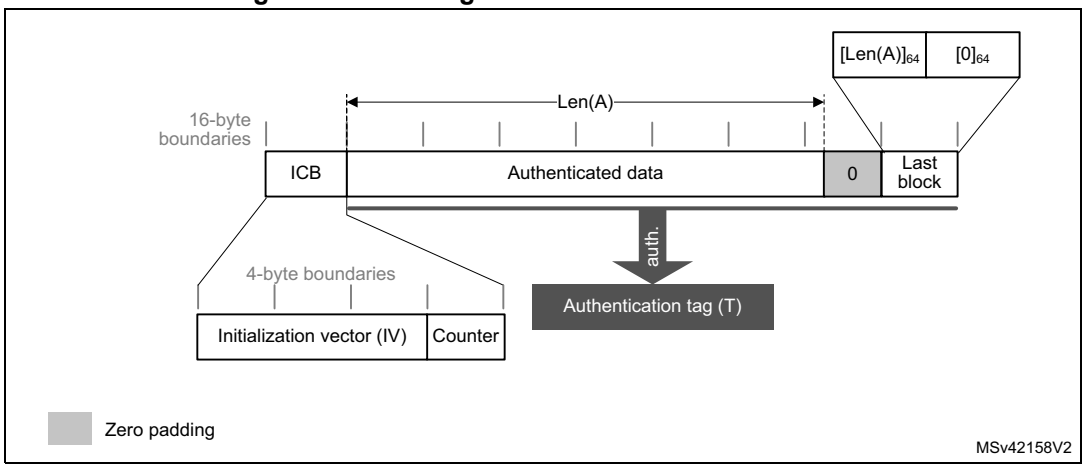
GCM finalization

14. Encryption only: wait until the BUSY flag in the SAES_SR register is cleared.
15. Select the GCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during GCM initialization.
16. Write the final GCM block into the SAES_DINR register. It is the concatenated AAD bit and payload bit lengths, as shown in *Table 310*.
17. Wait until the CCF flag in the SAES_ISR register is set.
18. Get the GCM authentication tag, by reading the SAES_DOUTR register four times.
19. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
20. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message.

Note: In the final phase, data are written to SAES_DINR normally (no swapping), while swapping is applied to tag data read from SAES_DOUTR.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend/resume operations in GCM mode



Suspend/resume operations are not supported in GCM mode.

35.4.12 SAES Galois message authentication code (GMAC)

The Galois message authentication code (GMAC) allows the authentication of a plaintext, generating the corresponding tag information (also known as message authentication code).

GMAC is similar to GCM, except that it is applied on a message composed only by plaintext authenticated data (that is, only header, no payload). The following figure shows typical message construction for GMAC.

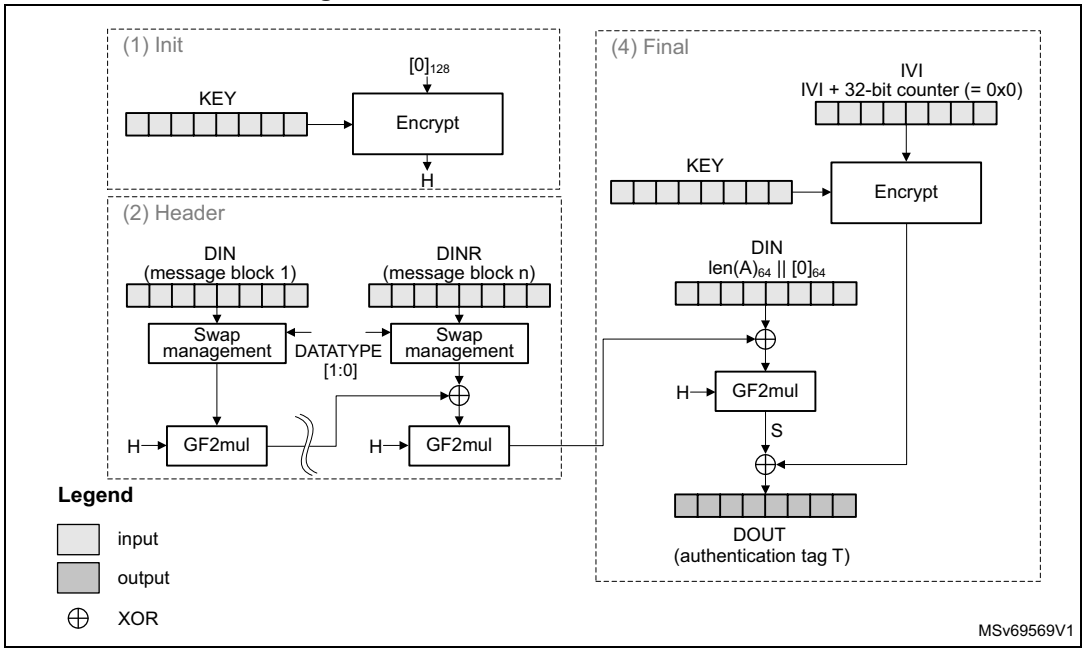


Figure 335. Message construction in GMAC mode

For more details, refer to NIST Special Publication 800-38D*, Recommendation for Block Cipher Modes of Operation - Galois/Counter Mode (GCM) and GMAC.*

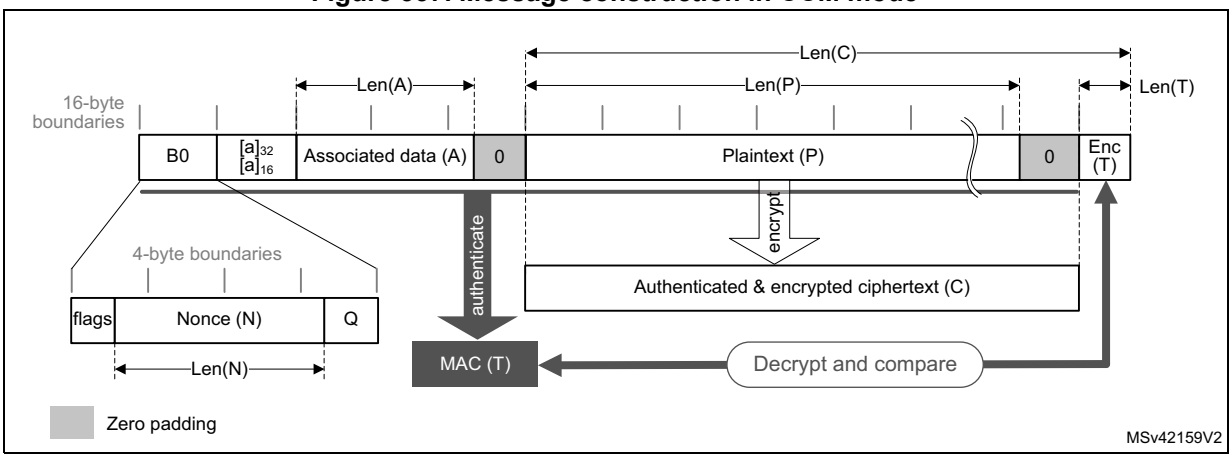
Figure 336 describes the GMAC chaining implementation in the SAES peripheral. To select this chaining mode, write CHMOD[2:0] with 0x3.

Figure 336. GMAC authentication mode

The GMAC algorithm corresponds to the GCM algorithm applied on a message that only contains a header. As a consequence, all steps and settings are the same as with the GCM, except that the payload phase is omitted.

Suspend/resume operations in GMAC

Suspend/resume operations are not supported in GMAC mode.



35.4.13 SAES counter with CBC-MAC (CCM)

The AES counter with cipher block chaining-message authentication code (CCM) algorithm allows encryption and authentication of plaintext, generating the corresponding ciphertext and tag (also known as message authentication code). To ensure confidentiality, the CCM algorithm is based on AES counter mode processing. It uses cipher block chaining technique to generate the message authentication code. This is commonly called CBC-MAC.

Note: NIST does not approve CBC-MAC as an authentication mode outside the context of the CCM specification.

The following figure shows typical message construction for CCM.

Figure 337. Message construction in CCM mode

The structure of the message is:

- **16-byte first authentication block (B0)**, composed of three distinct fields:
  - **Q:** a bit string representation of the octet length of P (Len(P))
  - **Nonce (N):** a single-use value (that is, a new nonce must be assigned to each new communication) of Len(N) size. The sum Len(N) + Len(P) must be equal to 15 bytes.
  - **Flags:** most significant octet containing four flags for control information, as specified by the standard. It contains two 3-bit strings to encode the values **t** (MAC length expressed in bytes) and **Q** (plaintext length such that Len(P) < 2^{8Q} bytes). The counter blocks range associated to **Q** is equal to 2^{8Q-4}, that is, if the maximum value of **Q** is 8, the counter blocks used in cipher must be on 60 bits.
- **16-byte blocks (B)** associated to the associated data (A).
  This part of the message is only authenticated, not encrypted. This section has a known length Len(A) that can be a non-multiple of 16 bytes (see *Figure 337*). The standard also states that, on MSB bits of the first message block (B1), the associated data length expressed in bytes (a) must be encoded as follows:
  - If $0 < a < 2^{16} - 2^8$, then it is encoded as $[a]_{16}$, that is, on two bytes.
  - If $2^{16} - 2^8 < a < 2^{32}$, then it is encoded as 0xff || 0xfe || $[a]_{32}$, that is, on six bytes.
  - If $2^{32} < a < 2^{64}$, then it is encoded as 0xff || 0xff || $[a]_{64}$, that is, on ten bytes.

- **16-byte blocks (B)** associated to the plaintext message P, which is both authenticated and encrypted as ciphertext C, with a known length Len(P). This length can be a non-multiple of 16 bytes (see *Figure 337*).
- **Encrypted MAC (T)** of length Len(T) appended to the ciphertext C of overall length Len(C).

When a part of the message (A or P) has a length that is a non-multiple of 16-bytes, a special padding scheme is required.

Note: CCM chaining mode can also be used with associated data only (that is, no payload).

As an example, the C.1 section in NIST Special Publication 800-38C gives the following values (hexadecimal numbers):

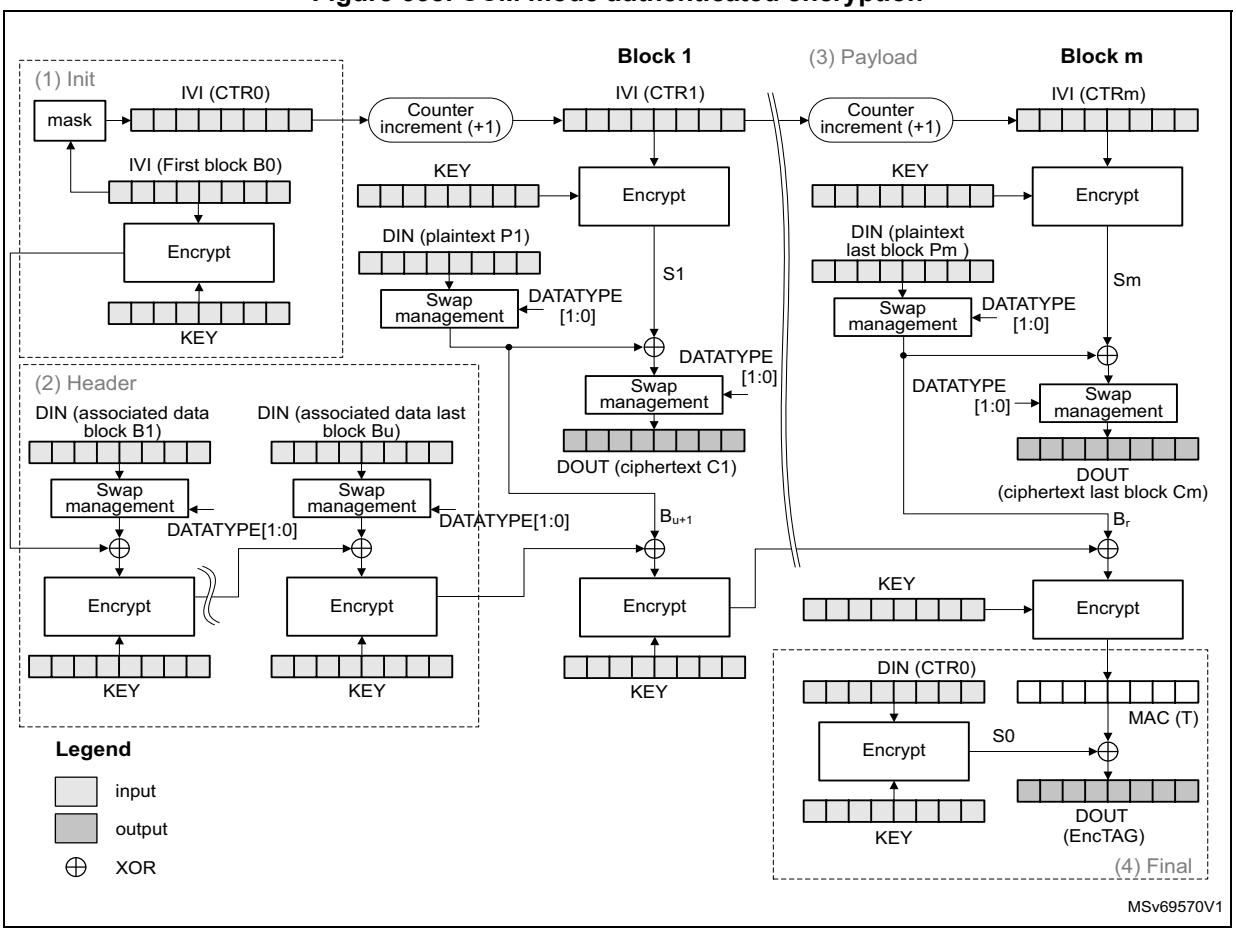
N: 10111213 141516 (Len(N) = 56 bits or 7 bytes)

A: 00010203 04050607 (Len(A) = 64 bits or 8 bytes)

P: 20212223 (Len(P) = 32 bits or 4 bytes)

T: 6084341B (Len(T) = 32 bits or t = 4)

B0: 4F101112 13141516 00000000 00000004
B1: 00080001 02030405 06070000 00000000
B2: 20212223 00000000 00000000 00000000



CTR0: 0710111213 141516 00000000 00000000

CTR1: 0710111213 141516 00000000 00000001

For more details, refer to NIST Special Publication 800-38C*, Recommendation for Block Cipher Modes of Operation - The CCM Mode for Authentication and Confidentiality*.

Figure 338 describes the CCM chaining implementation in the SAES peripheral (encryption). To select this chaining mode, write CHMOD[2:0] with 0x4.

Figure 338. CCM mode authenticated encryption

The first block of a CCM message (B0) must be prepared by the application as defined in *Table 311*.

Table 311. Initialization of IV registers in CCM mode

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
B0[127:96](1)	B0[95:64]	B0[63:32]	B0[31:0](2)

1. The five most significant bits are cleared (flag bits).
2. Q length bits are cleared, except for the bit 0 that is set.

SAES supports counters up to 64 bits, as specified by NIST.

CCM encryption and decryption process

This process is described in *Section 35.4.6*, with the following sequence of events:

CCM initialize

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register:
   - Select CCM chaining mode (write CHMOD[2:0] with 0x4) in encryption or decryption mode (write MODE[1:0] with 0x0 or 0x2). Do not write MODE[1:0] with 0x1.
   - Configure the data type, through DATATYPE[1:0]
   - Configure the key size, through KEYSIZE. If the key must not be shared with a different security context, also set the KEYPROT bit.
   - Select normal key mode, by writing KMOD[1:0] with 0x0. For the other KMOD[1:0] values, refer to *Section 35.4.14* (wrapped keys) and *Section 35.4.15* (shared keys).
   - Select the CCM initialization phase, by writing CPHASE[1:0] with 0x0.
4. Write the B0 data in SAES_IVRx registers according to *Table 311*.
5. Write the key into the SAES_KEYRx registers. Alternatively, select a key source different from the key registers by writing KEYSEL[2:0] with a value different from 0x0. Refer to *Section 35.4.17: SAES key registers* for details.
6. Wait until KEYVALID is set (the key loading completed).
7. Set EN to start the first mask calculation. The EN bit is automatically cleared when the calculation is completed.
8. Wait until the CCF flag in the SAES_ISR register is set.
9. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.

CCM header phase

10. Initialize header phase:
    a) Prepare the first block of the (B1) data associated with the message, in accordance with CCM chaining rules.
    b) Select the CCM header phase, by writing CPHASE[1:0] with 0x1. Do not change the other configurations written during the CCM initialization.
    c) Enable the SAES peripheral, by setting EN.
11. Append header data:
    a) If it is the last block and the associated data in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 35.4.5*.
    c) Repeat the step *b)* until the second-last associated data block is processed. For the last block, follow the steps *a)* and *b)*.

Note: This phase can be skipped if there is no associated data, that is, Len(A) = 0

No data are read during the header phase.

CCM payload phase

12. Initialize payload phase:
    a) Select the CCM payload phase, by writing CPHASE[1:0] with 0x2. Do not change the other configurations written during the CCM initialization.
    b) If the header phase is skipped, enable the SAES peripheral, by setting EN.
13. Append payload data:
    a) In encryption only, if it is the last block and the plaintext in the block is smaller than 16 bytes, pad the remainder of the block with zeros.
    b) Append the data block into SAES as described in *Section 35.4.5*, then read the SAES_DOUTR register four times to save the resulting block.
    c) Repeat the step *b)* until the second-last plaintext block is encrypted or until the last block of ciphertext is decrypted. For the last block of plaintext (encryption only), follow the steps *a)* and *b)*. For the last block, discard the bits that are not part of the payload when the last block is smaller than 16 bytes.

Note: This phase can be skipped if there is no payload, that is, Len(P) = 0 or Len(C) = Len(T).

Remove $LSB_{Len(T)}(C)$ encrypted tag information when decrypting ciphertext C.

CCM finalization

14. Select the CCM final phase, by writing CPHASE[1:0] with 0x3. Do not change the other configurations written during the CCM initialization.
15. Wait until CCF flag in the SAES_ISR register is set.
16. Get the CCM authentication tag, by reading the SAES_DOUTR register four times.
17. Clear the CCF flag, by setting the CCF bit of the SAES_ICR register.
18. Disable the SAES peripheral, by clearing EN. If it is an authenticated decryption, compare the generated tag with the expected tag passed with the message. Mask the authentication tag output with tag length to obtain a valid tag.

Note: In the final phase, swapping is applied to tag data read from SAES_DOUTR register.

When transiting from the header or the payload phase to the final phase, the SAES peripheral must not be disabled, otherwise the result is wrong.

Suspend and resume operations in CCM mode

The suspend and resume operations are only supported when SAES is used in CPU mode, not in DMA mode.

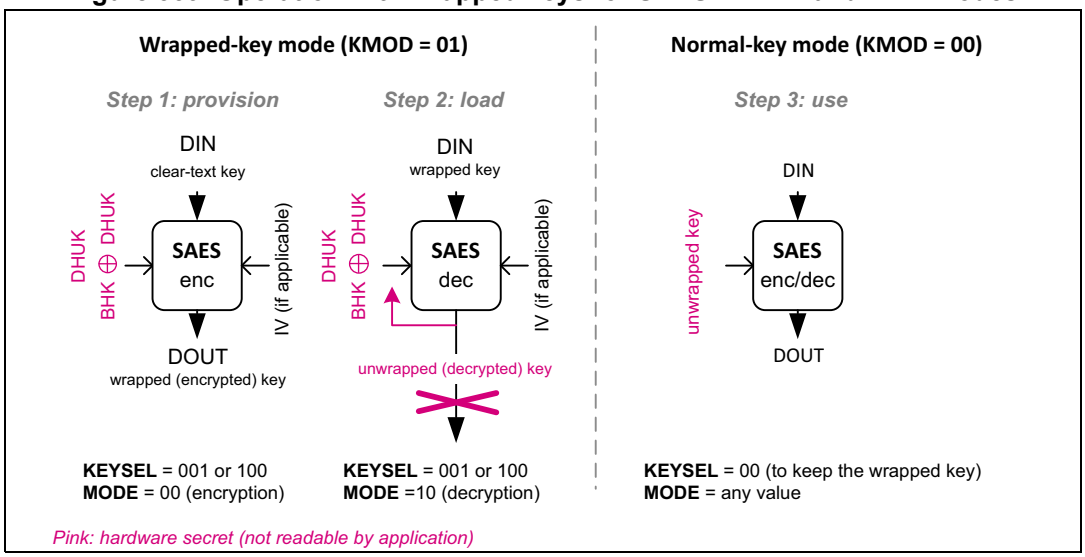
To suspend the processing of a message in header or payload phase, proceed as follows:

1. Wait until the CCF flag of the SAES_ISR register is set (computation completed).
2. In the payload phase, read four times the SAES_DOUTR register to save the last-processed block.
3. Clear the CCF flag in the SAES_ISR register, by setting the CCF bit of the SAES_ICR register.
4. Save the SAES_SUSPRx registers in the memory.
5. Save the IV registers as they are altered during the data processing.
6. Disable the SAES peripheral, by clearing EN.
7. Save the current SAES_CR configuration in the memory. Key registers do not need to be saved as the original key value is known by the application.

To resume the processing of a message, proceed as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Write the suspend register values, previously saved in the memory, back into their corresponding SAES_SUSPRx registers.
3. Restore SAES_IVRx registers using the saved configuration.
4. Restore the initial setting values in the SAES_CR and SAES_KEYRx registers. For KEYSEL[2:0] selecting a key source different from the key registers, refer to *Section 35.4.17: SAES key registers* for details.
5. Enable the SAES peripheral, by setting EN.

35.4.14 SAES operation with wrapped keys



SAES peripheral can wrap (encrypt) and unwrap (decrypt) application keys using hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, AES keys can be made usable by application software without being exposed in clear-text (unencrypted).

Wrapped key sequences are too small to be suspended/resumed. SAES cannot unwrap a key using an unwrapped key.

Operation with wrapped keys for SAES in ECB and CBC modes

Figure 339 summarizes how to wrap or unwrap keys for SAES in ECB and CBC modes. To protect the wrapped key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 339. Operation with wrapped keys for SAES in ECB and CBC modes

Note: DHUK value depends on privilege, security, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

Key wrapping for SAES

The recommended sequence to wrap (that is, encrypt) a key is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select ECB or CBC chaining mode (write CHMOD[2:0] with 0x0 or 0x1) in *encryption* mode (MODE[1:0] at 0x0)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. This information is used both for the encryption key and for the key to be encrypt.
   - Select wrapped key mode by writing KMOD[1:0] with 0x1
4. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to *Section 35.4.17* for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (DHUK loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Write the SAES_DINR register four times to input the key to encrypt (MSB first, see *Table 313*).
9. Wait until CCF flag is set in the SAES_ISR register.
10. Get the encrypted key (MSB first) by reading the SAES_DOUTR register four times. Then clear the CCF flag, by setting the CCF bit in SAES_ICR register.
11. Repeat steps *8.* to *10.* if KEYSIZE is set.
12. Disable the SAES peripheral, by clearing EN.

Note: Encryption in Wrapped-key mode is only supported when ECB or CBC is selected.

Key unwrapping for SAES

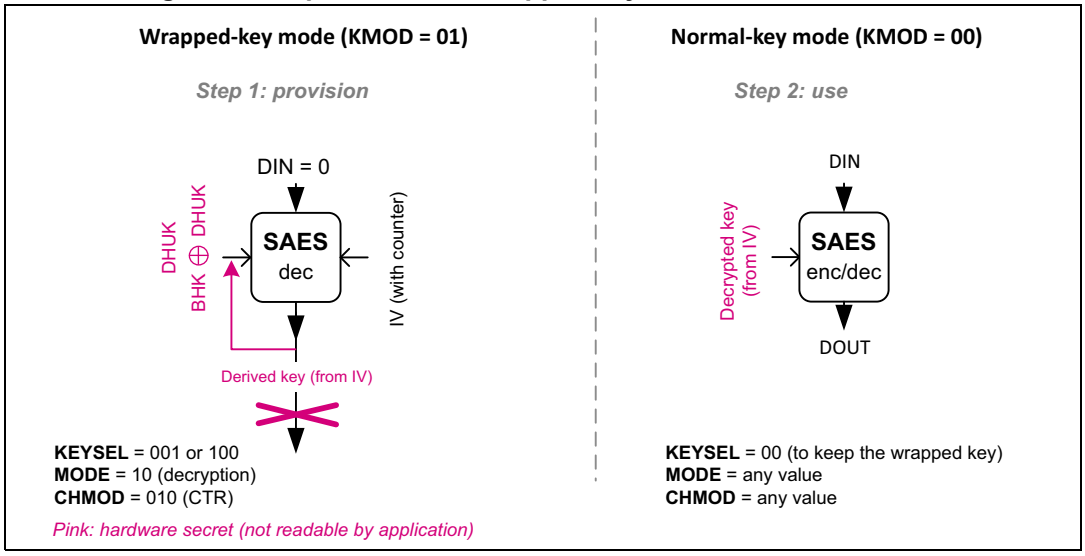
The recommended sequence to unwrap (or decrypt) a wrapped (encrypted) key using ECB/CBC is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the chaining mode used during the wrapping process (CHMOD[2:0] at 0x0 or 0x1) in *key derivation* mode (MODE[1:0] at 0x1)
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size used during the wrapping process, with KEYSIZE. This information is used both for the decryption key and for the key to decrypt.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. With KEYSEL[2:0], select the same key source as when the key was wrapped/encrypted.
5. Wait until KEYVALID is set (the key loading completed).
6. Set EN bit in SAES_CR to enable the peripheral
7. Wait until CCF flag is set in the SAES_ISR register.
8. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The decryption key is available in the AES core, and SAES is disabled automatically.
9. Select the *decryption* mode (MODE[1:0] at 0x2). Other parameters are unchanged.
10. Write the initialization vector in SAES_IVRx registers if CBC mode has been selected in previous step.
11. Enable the SAES peripheral, by setting EN.
12. Write the SAES_DINR register four times to input the key to decrypt (MSB first, see *Table 313*).
13. Wait until CCF flag is set in the SAES_ISR register. Then clear the CCF flag by setting the CCF bit in SAES_ICR register. Reading SAES_DOUTR returns zero and triggers a read error (RDERRF).
14. Repeat steps *12.* and *13.* if KEYSIZE is set.
15. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the decrypted wrapped key is immediately usable by the application for any AES operation (normal key mode, that is, with KMOD[1:0] = 0x0).

Decrypted wrapped key can be shared with an application running in a different security context (different security attribute) if KEYPROT bit was cleared during step 3.

Note: When KMOD[1:0] = 0x1 (wrapped key) and MODE[1:0] = 0x2 (decryption) a read access to SAES_DOUTR register triggers a read error (RDERRF).



When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0], CHMOD[2:0] and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

Operation with wrapped keys for SAES in CTR mode

Figure 340 summarizes how to unwrap keys for SAES in CTR mode. To protect the derived key, select DHUK by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by

writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 340. Operation with wrapped keys for SAES in CTR mode

Note: DHUK value depends on privilege, security, KMOD[1:0], KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

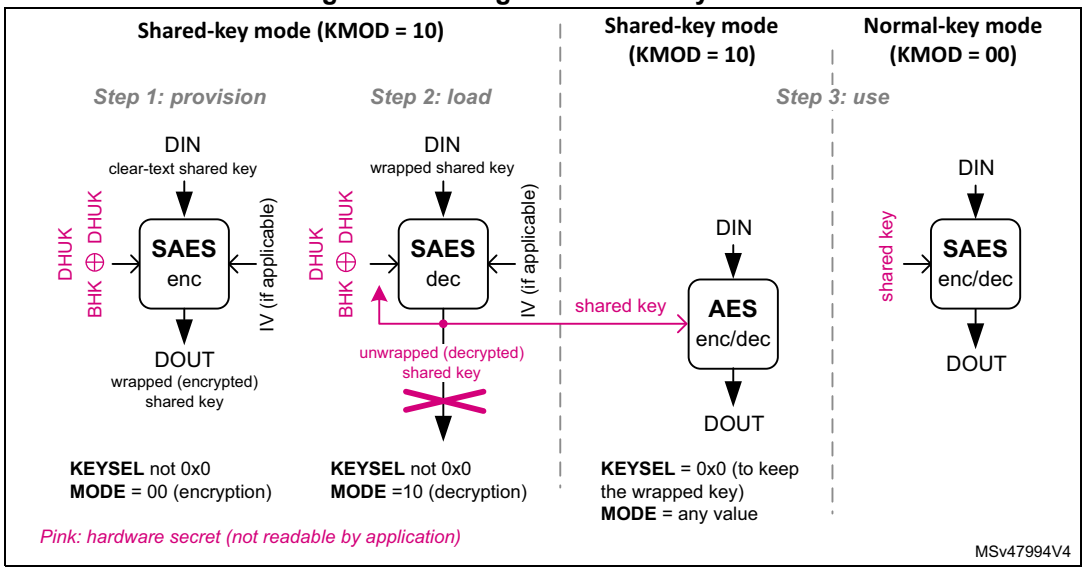
The recommended sequence for SAES wrapped key mode using CTR is as follows:

1. Disable the SAES peripheral, by clearing EN.
2. Wait until BUSY is cleared (no RNG random number fetch in progress).
3. Initialize the SAES_CR register as follow:
   - Select the CTR chaining mode (CHMOD[2:0] at 0x2) in decryption mode (MODE[1:0] at 0x2). Other MODE[1:0] values are not supported.
   - Select 32-bit data type (DATATYPE[1:0] at 0x0)
   - Configure the key size with KEYSIZE. It is used for encryption key and for the key to share.
   - Select wrapped key mode, by writing KMOD[1:0] with 0x1.
4. Write the initialization vector in SAES_IVRx registers, keeping the two least significant bits of SAES_IVR0 at zero.
5. Select the DHUK key source by writing KEYSEL[2:0] with 0x1 or 0x4. Optionally, select the BHK, by writing KEYSEL[2:0] with 0x2. Refer to *Section 35.4.17* for details on the use of KEYSEL[2:0].
6. Wait until KEYVALID is set (the key loading completed).
7. Enable the SAES peripheral, by setting EN.
8. Wait until CCF flag is set in the SAES_ISR register.
9. Clear the CCF flag, by setting the CCF bit in SAES_ICR register. The derived hardware secret key is available in SAES_KEYRx registers.
10. Repeat steps *8.* and *9.* if KEYSIZE is set.
11. Disable the SAES peripheral, by clearing EN.

At the end of this sequence, the hardware secret key derived from the public data in the SAES_IVRx registers is then immediately usable by the application for any AES operation (normal key mode, that is, with KMOD[1:0] = 0x0).

Note: The configuration KMOD[1:0] at 0x1 (wrapped key), CHMOD[2:0] at 0x2 (CTR chaining), and MODE at 0x0 (encryption) disables the peripheral, by automatically clearing the EN bit of the SAES_*CR register.*

35.4.15 SAES operation with shared keys



SAES peripheral can share application keys wrapped with hardware-secret key DHUK, XOR-ed or not with application key BHK. With this feature, the application software can make the AES keys available to the AES peripheral, without exposing them in clear-text (unencrypted).

Shared key sequences are too small to be suspended/resumed. SAES cannot unwrap a shared key using an unwrapped key.

Note: When a key stored in SAES is shared with AES, the protection given by KEYPROT bit is lost. The protection is detailed in Section 35.4.17: SAES key registers.

Figure 341 summarizes how to wrap or unwrap keys to share with *AES* peripheral. To protect the shared key, DHUK must be selected, by writing KEYSEL[2:0] with 0x1 or 0x4. Alternatively, select BHK by writing KEYSEL[2:0] with 0x2 if the corresponding registers are read/write-locked in the TAMP peripheral.

Figure 341. Usage of Shared-key mode

Note: DHUK value depends on privilege, security, KMOD[1:0], KSHAREID, KEYSEL[2:0], CHMOD[2:0], and KEYSIZE.

In the step 3, AES represents the AES peripheral.

Key wrapping for AES peripheral

Before SAES can share a key with the AES peripheral, the key must be encrypted (wrapped) once. The encryption sequence of a shared key is the same as for a wrapped

key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 341*. See *Key wrapping for SAES* for details.

Note: Encryption in Shared-key mode is only supported when ECB or CBC is selected.

Key unwrapping for AES peripheral (shared key)

Each time SAES needs to share a key with the AES peripheral, shared encrypted key must be decrypted (unwrapped) in SAES, then loaded by AES. The overall sequence is described next.

Sequence in the SAES peripheral

The decryption sequence of a shared key is the same as for a wrapped key, with KMOD[1:0] at 0x2 (shared key) and KSHAREID[1:0] kept at 0x0 in the step 3 in *Figure 341*. See *Key unwrapping for SAES* for details.

In shared key mode when decryption mode is selected (MODE[1:0] at 0x2), a read access to the SAES_DOUTR register triggers a read error (RDERRF).

Note: Instead of being shared, a decrypted shared key can be used directly in SAES as the KEYSEL[2:0] bitfield is automatically cleared. In this case, KMOD[1:0] must be written with 0x0 (normal key mode).

Sequence in the AES peripheral

Once the shared key is decrypted in SAES key registers, it can be shared with the AES peripheral, while SAES peripheral remains in key sharing state, that is, with KMOD[1:0] at 0x2 and KEYVALID set. The sequence in the AES key share target peripheral is described in *AES key sharing with secure AES co-processor* of the corresponding section in this document. It can be run multiple times (for example, to manage a suspend/resume situation) as long as SAES is unused and duly remains in key sharing state.

Note: When KMOD[1:0] is at 0x2 and BUSY set in the AES peripheral, and KEYSIZE value of AES and SAES differs, the key sharing fails and the KEIF flag is raised in both peripherals.

When KEYSEL[2:0] is at 0x1 (DHUK) or 0x4 (DHUK XOR BHK), the application software must use the same privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], and KEYSIZE context for encryption and decryption. Otherwise, the result is incorrect.

35.4.16 SAES data registers and data swapping

Data input and output

A 16-byte data block enters the SAES peripheral with four successive 32-bit word writes into the SAES_DINR register (bitfield DIN[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

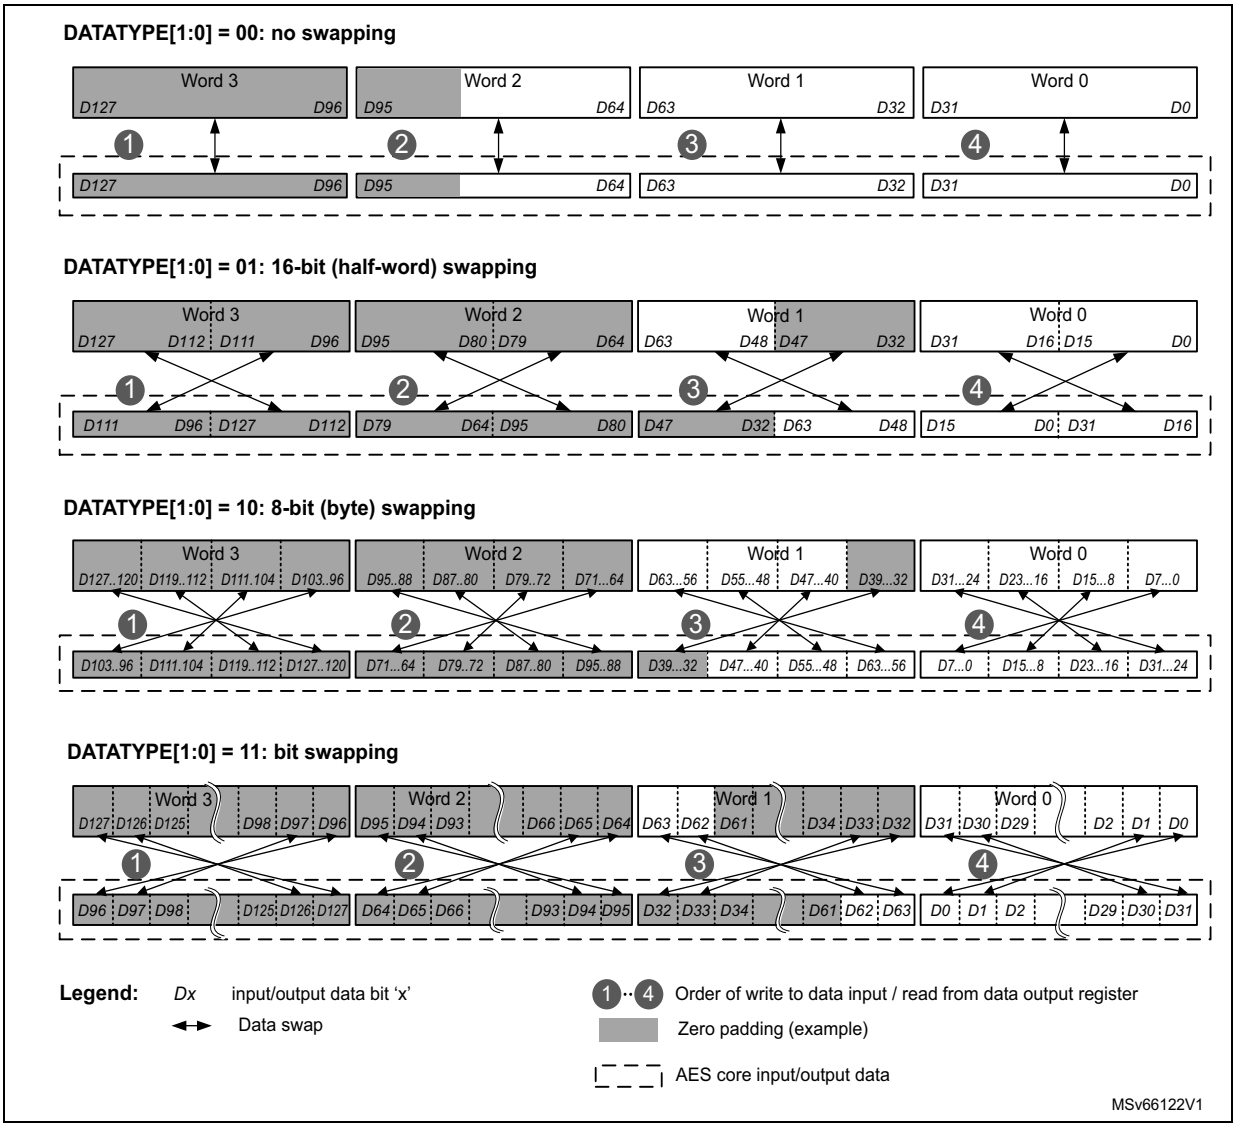
A 16-byte data block is retrieved from the SAES peripheral with four successive 32-bit word reads of the SAES_DOUTR register (bitfield DOUT[31:0]), the most significant word (bits [127:96]) first, the least significant word (bits [31:0]) last.

The four 32-bit words of a 16-byte data block must be stored in the memory consecutively and in big-endian order, that is, with the most significant word on the lowest address. See *Table 312* “no swapping” option for details.

Data swapping

The SAES peripheral can be configured to perform a bit-, a byte-, a half-word-, or no swapping on the input data word in the SAES_DINR register, before loading it to the AES processing core, and on the data output from the AES processing core, before sending it to the SAES_DOUTR register. The choice depends on the type of data. For example, a byte swapping is used for an ASCII text stream.

The data swap type is selected through DATATYPE[1:0]. The selection applies to both SAES input and output.



Note: The data in SAES key registers (SAES_KEYRx) and initialization vector registers (SAES_IVRx) are not sensitive to the swap mode selection.

The SAES data swapping feature is summarized in *Table 312* and *Figure 342*.

Table 312. AES data swapping example

DATATYPE[1:0]	Swapping performed	Data block
		System memory data (big-endian)
0x0	No swapping	Block[127..64]: 0x04EEF672 2E04CE96 Block[63..0]: 0x4E6F7720 69732074
		Address @, word[127..96]: 0x04EEF672 Address @ + 0x4, word[95..64]: 0x2E04CE96 Address @ + 0x8, word[63..32]: 0x4E6F7720 Address @ + 0xC, word[31..0]: 0x69732074
0x1	Half-word (16-bit) swapping	Block[63..0]: 0x**4E6F** 7720 **6973** 2074
		Address @, word[63..32]: 0x7720 **4E6F** Address @ + 0x4, word[31..0]: 0x2074 **6973**
0x2	Byte (8-bit) swapping	Block[63..0]: 0x**4E** 6F **77** 20 **69** 73 **20** 74
		Address @, word[63..32]: 0x20**77** 6F**4E** Address @ + 0x4, word[31..0]: 0x74**20** 73**69**
0x3	Bit swapping	Block[63..32]: 0x4E6F7720 0100 1110 0110 1111 0111 0111 0010 0000 Block[31..0]: 0x69732074 0110 1001 0111 0011 0010 0000 0111 0100

Figure 342. 128-bit block construction according to the data type

Data padding

Figure 342 also gives an example of memory data block padding with zeros such that the zeroed bits after the data swap form a contiguous zone at the MSB end of the AES core input buffer. The example shows the padding of an input data block containing:

- 84 message bits, with DATATYPE[1:0] = 0x0
- 48 message bits, with DATATYPE[1:0] = 0x1
- 56 message bits, with DATATYPE[1:0] = 0x2
- 34 message bits, with DATATYPE[1:0] = 0x3

35.4.17 SAES key registers

The eight SAES_KEYRx write-only registers store the encryption or decryption key information, as shown on *Table 313*. Reads are not allowed for security reason.

Note: In memory and in SAES *key registers, keys are stored in little-endian format, with most significant byte on the highest address.*

Table 313. Key endianness in SAES_KEYRx registers (128/256-bit keys)

SAES_KEYR7 [31:0]	SAES_KEYR6 [31:0]	SAES_KEYR5 [31:0]	SAES_KEYR4 [31:0]	SAES_KEYR3 [31:0]	SAES_KEYR2 [31:0]	SAES_KEYR1 [31:0]	SAES_KEYR0 [31:0]
-	-	-	-	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
KEY[255:224]	KEY[223:192]	KEY[191:160]	KEY[159:128]	KEY[127:96]	KEY[95:64]	KEY[63:32]	KEY[31:0]
TAMP_BKP7R [31:0]	TAMP_BKP6R [31:0]	TAMP_BKP5R [31:0]	TAMP_BKP4R [31:0]	TAMP_BKP3R [31:0]	TAMP_BKP2R [31:0]	TAMP_BKP1R [31:0]	TAMP_BKP0R [31:0]

The key registers are not affected by the data swapping feature controlled by the DATATYPE[1:0] bitfield.

Write operations to the SAES_KEYRx registers are ignored when SAES peripheral is enabled (EN bit set) and KEYSEL[2:0] is different from zero. The application must check this before modifying key registers.

The entire key must be written before starting an AES computation.

In normal key mode (KMOD[1:0] at 0x0), with KEYSEL[2:0] at 0x0, the key registers must always be written in either ascending or descending order. The write sequence becomes:

- SAES_KEYRx (x = 0 to 3 or x=3 to 0) for KEYSIZE cleared
- SAES_KEYRx (x = 0 to 7 or x=7 to 0) for KEYSIZE set

Note: KEYSIZE must be written before the key.

As soon as the first key register is written, the KEYVALID flag is cleared. Once the key registers writing sequence is completed, KEYVALID is set and EN becomes writable. If an error occurs, KEYVALID is cleared and KEIF set (see *Section 35.4.19*).

Key selection

With KEYSEL[2:0] at 0x0, the application must write the key in the SAES_KEYRx registers.

With KEYSEL[2:0] at 0x1, a derived hardware unique key (DHUK), computed inside SAES from a nonvolatile and secret root hardware unique key, is loaded directly into key registers, based on KEYSIZE information. Thanks to the key derivation function, the computed DHUK depends on the SAES usage (privilege, security, KMOD[1:0] / KSHAREID[1:0], CHMOD[2:0], CPU, and KEYSIZE context).

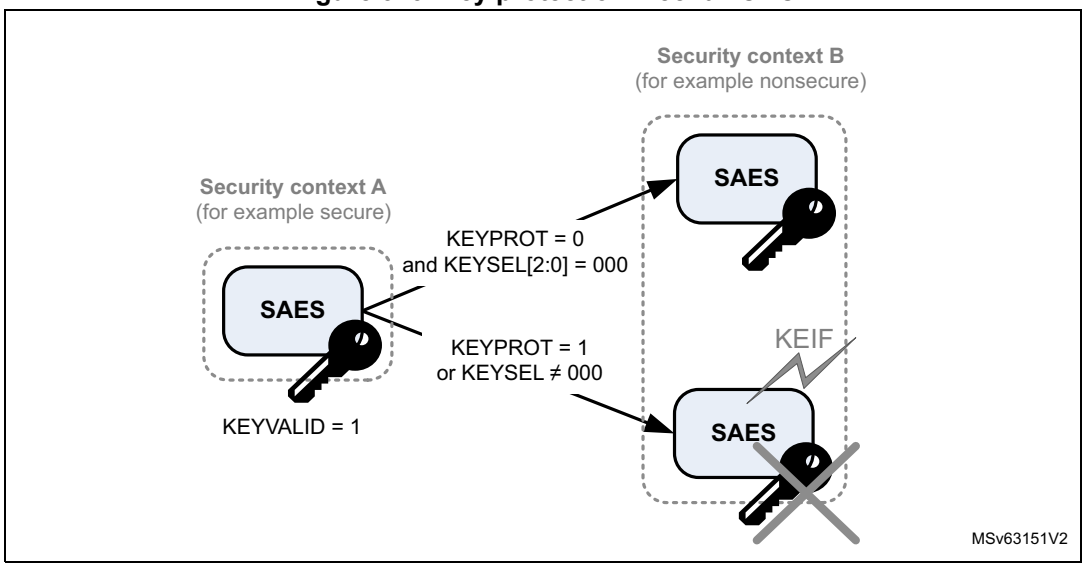
With KEYSEL[2:0] at 0x2, the boot hardware key (BHK), stored in tamper-resistant secure backup registers, is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to *Table 313*.

With KEYSEL[2:0] at 0x4, the XOR combination of DHUK and BHK is entirely transferred into key registers upon a secure application performing a single read of all TAMP_BKPxR

registers (x = 0 to 3 for KEYSIZE cleared, x = 0 to 7 for KEYSIZE set) in ascending order. Refer to *Table 313*.

Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK if KEYVALID is cleared. The recommended method to clear KEYVALID is to set IPRST. Such method is required for example when switching from ECB decryption to ECB encryption, selecting the same BHK (KEYSEL[2:0] at 0x2).

For all KEYSEL[2:0] values, initiating the key-loading sequence sets the BUSY flag and clears the KEYVALID flag. Once the amount of bits defined by KEYSIZE is transfered to the SAES_KEYRx registers, BUSY is cleared, KEYVALID set and the EN bit becomes writable. If an error occurs, BUSY and KEYVALID are cleared and KEIF set (see *Section 35.4.19*).



Note: DHUK, BHK and their XOR combination are not readable by any software (even secure).

Key protection

As depicted in *Figure 343*, when an application sets the KEYPROT bit before writing a key in SAES_KEYRx, any application executing in a different security context (that is, different security attribute) triggers a KEIF error flag upon access to any SAES register when KEYVALID is set.

Note: KEYSEL[2:0] values different from zero (normal key) automatically protect the key registers.

Figure 343. Key protection mechanisms

35.4.18 SAES initialization vector registers

The four SAES_IVRx registers store the initialization vector (IV) information, as shown in *Table 314*. They can only be written if the SAES peripheral is disabled (EN cleared).

Note: In memory and in SAES IV registers, initialization vectors are stored in little-endian format, with most significant byte on the highest address.

Table 314. IVI bitfield spread over SAES_IVRx registers

SAES_IVR3[31:0]	SAES_IVR2[31:0]	SAES_IVR1[31:0]	SAES_IVR0[31:0]
IVI[127:96]	IVI[95:64]	IVI[63:32]	IVI[31:0]

Initialization vector information depends on the chaining mode selected. When used, SAES_IVRx registers are updated upon each AES computation cycle (useful for managing suspend mode).

The initialization vector registers are not affected by the data swapping feature controlled through DATATYPE[1:0].

35.4.19 SAES error management

The SAES peripheral manages the errors described in this section.

Read error flag (RDERRF)

Unexpected read attempt of the SAES_DOUTR register returns zero, setting the RDERRF flag and the RWEIF flag. RDERRF is triggered during the computation phase or during the input phase.

Note: Unless otherwise indicated, SAES is not disabled when RDERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 35.5: SAES interrupts*.

The RDERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Write error flag (WRERRF)

Unexpected write attempt of the SAES_DINR register is ignored, setting the WRERRF and the RWEIF flags. WRERRF is triggered during the computation phase or during the output phase.

Note: Unless otherwise indicated, SAES is not disabled when WRERRF rises and it continues processing.

An interrupt is generated if the RWEIE bit is set. For more details, refer to *Section 35.5: SAES interrupts*.

The WRERRF and RWEIF flags are cleared by setting the RWEIF bit of the SAES_ICR register.

Key error interrupt flag (KEIF)

There are multiple sources of errors that set the KEIF flag of the SAES_ISR register and clear the KEYVALID bit of the SAES_SR register:

- **Key protection error:** while KEYVALID is set, then if KEYPROT is set or KEYSEL[2:0] is different from zero, this error is triggered when an application executing in a security context different from the one used to load the key (that is, different security attribute) accesses SAES.

- **Key writing sequence error:** triggered upon detecting an incorrect sequence of writing key registers. See *Section 35.4.17: SAES key registers* for details.
- **Key sharing size mismatch error:** triggered when KMOD[1:0] is at 0x2 and KEYSIZE in AES peripheral does not match KEYSIZE in SAES peripheral.
- **Key sharing error:** triggered upon failing transfer of SAES shared key to AES peripheral. See *Section 35.4.15: SAES operation with shared keys* for details.
- **Hardware secret key loading error:** triggered upon failing load of DHUK or BHK into SAES. KEYSEL[2:0] at 0x1 (DHUK), 0x2 (BHK) or 0x4 (DHUK XOR BHK) is not functional.

The KEIF flag is cleared with corresponding bit of the SAES_ICR register. An interrupt is generated if the KEIE bit of the SAES_IER register is set. For more details, refer to *Section 35.5: SAES interrupts*.

Upon a key selection error, clearing the KEIF flag automatically restarts the key selection process. Persisting problems (for example, RHUK load failing) may require a power-on reset.

Upon a key sharing error, reset both AES and SAES peripherals through the IPRST bit of their corresponding control register, then restart the key sharing sequence.

Note: For any key error, clear KEIF flag prior to disabling and re-configuring SAES.

RNG error interrupt flag (RNGEIF)

SAES fetches random numbers from the RNG peripheral automatically after an IP reset triggered in the RCC. SAES cannot be used when RNGEIF is set.

An error detected while fetching a random number from RNG peripheral (due to, for example, bad entropy) sets the RNGEIF flag of the SAES_ISR register. The flag is cleared by setting the corresponding bit of the SAES_ICR register. An interrupt is generated if the RNGEIE bit of the SAES_IER register is set. For more details, refer to *Section 35.5: SAES interrupts*.

Upon an RNG error:

- Make sure that the RNG peripheral is properly configured.
- Verify that the RNG peripheral AHB clock is enabled and no noise source (or seed) error is pending in this peripheral.
- Clear RNGEIF or reset the peripheral by setting IPRST. The clearance of the BUSY flag then indicates the completion of the random number fetch from RNG.

Note: To avoid RNGEIF errors, it is recommended to activate the RNG AHB clock each time SAES AHB clock is activated.

Managing tamper errors

An unexpected error triggers an SAES internal tamper event in the TAMP peripheral, and stops any SAES co-processor processing.

To resume normal operation, reset the SAES peripheral through RCC or global reset.

35.5 SAES interrupts

There are multiple individual maskable interrupt sources generated by the SAES peripheral to signal the following events:

- computation completed (CCF)
- read error (RDERRF)
- write error (WRERRF)
- key error (KEIF)
- RNG error (RNGEIF)

See *Section 35.4.19: SAES error management* for details on SAES errors.

These sources are combined into a common interrupt signal from the SAES peripheral that connects to the Cortex® CPU interrupt controller. Application can enable or disable SAES interrupt sources individually by setting/clearing the corresponding enable bit of the SAES_IER register.

The status of the individual maskable interrupt sources can be read from the SAES_ISR register. They are cleared by setting the corresponding bit of the SAES_ICR register.

Table 315 gives a summary of the available features.

Table 315. SAES interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable bit	Interrupt clear method
SAES	computation completed flag	CCF	CCFIE	set CCF(1)
	read error flag	RDERRF(2)	RWEIE	set RWEIF(1)
	write error flag	WRERRF(2)		
	key error flag	KEIF	KEIE	set KEIF(1)
	RNG error flag	RNGEIF	RNGEIE	set RNGEIF(1)

1. Bit of the SAES_ICR register.
2. Flag of the SAES_SR register, mirrored by the flag RWEIF of the SAES_ISR register.

35.6 SAES DMA requests

The SAES peripheral provides an interface to connect to the DMA (direct memory access) controller. The DMA operation is controlled through the DMAINEN and DMAOUTEN bits of the SAES_CR register. When key derivation is selected (MODE[1:0] is at 0x1), setting those bits has no effect.

SAES only supports single DMA requests.

Suspend and resume operations are not supported in DMA mode.

Detailed usage of DMA with SAES can be found in *Appending data using DMA* subsection of *Section 35.4.5: SAES encryption or decryption typical usage*.

Data input using DMA

Setting DMAINEN enables DMA writing into SAES. SAES then initiates, during the input phase, a set of single DMA requests for each 16-byte data block to write to the SAES_DINR register (quadruple 32-bit word, MSB first).

Note: According to the algorithm and the mode selected, special padding / ciphertext stealing might be required (see Section 35.4.7).

Data output using DMA

Setting DMAOUTEN enables DMA reading from SAES. SAES then initiates, during the output phase, a set of single DMA requests for each 16-byte data block to read from the SAES_DOUTR register (quadruple 32-bit word, MSB first).

After the output phase, at the end of processing of a 16-byte data block, SAES switches automatically to a new input phase for the next data block, if any.

In DMA mode, the CCF flag has no use because the reading of the SAES_DOUTR register is managed by DMA automatically at the end of the computation phase. The CCF flag must only be cleared when transiting back to managing the data transfers by software.

Note: According to the message size, extra bytes might need to be discarded by application in the last block.

Stopping DMA transfers

All DMA request signals are de-asserted when SAES is disabled (EN cleared) or the DMA enable bit (DMAINEN for input data, DMAOUTEN for output data) is cleared.

35.7 SAES processing latency

The following tables provide the 16-byte data block processing latency per operating mode.

Table 316. Processing latency for ECB, CBC and CTR

Key size	Mode of operation	Chaining algorithm	Clock cycles(1)
128-bit	Encryption or decryption(2)	ECB, CBC, CTR	**480**
	Key preparation	-	**145**
256-bit	Encryption or decryption(2)	ECB, CBC, CTR	**680**
	Key preparation	-	**230**

1. SAES kernel clock
2. Excluding key preparation time (ECB and CBC only).

Table 317. Processing latency for GCM and CCM (in SAES kernel clock cycles)

Key size	Mode of operation	Chaining algorithm	Initialization phase	Header phase(1)	Payload phase(1)	Final phase(1)
128-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	490	72(2)	480(3)	490
		CCM	490	490	800	490
256-bit	Mode 1: Encryption/ Mode 3: Decryption	GCM	650	72(2)	690(3)	650
		CCM	650	680	1350	650

1. Data insertion can include wait states forced by SAES on the AHB bus (maximum 3 cycles, typical 1 cycle).
2. SAES AHB clock cycles instead of kernel clock cycle (Galois multiplier only).
3. As a worst case in encryption mode, add extra 72 AHB clock cycles for the last block computation.

35.8 SAES registers

The registers are accessible through 32-bit word single accesses only. Other access types generate an AHB error, and other than 32-bit writes may corrupt the register content.

35.8.1 SAES control register (SAES_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
IPRST	KEYSEL[2:0]			KSHAREID[1:0]		KMOD[1:0]		NPBLB[3:0]				KEYPROT	KEYSIZE	Res.	CHMOD[2]
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	CPHASE[1:0]		DMAOUTEN	DMAINEN	Res.	Res.	Res.	Res.	CHMOD[1:0]		MODE[1:0]		DATATYPE[1:0]		EN
	rw	rw	rw	rw					rw	rw	rw	rw	rw	rw	rw

Bit 31 **IPRST**: SAES peripheral software reset

Setting the bit resets the SAES peripheral, putting all registers to their default values, except the IPRST bit itself. Hence, any key-relative data are lost. For this reason, it is recommended to set the bit before handing over the SAES to a less secure application.

The bit must be kept low while writing any configuration registers.

Bits 30:28 **KEYSEL[2:0]**: Key selection

The bitfield defines the source of the key information to use in the AES cryptographic core.

0x0: Software key, loaded in key registers SAES_KEYx

0x1: Derived hardware unique key (DHUK)

0x2: Boot hardware key (BHK)

0x4: XOR of DHUK and BHK

Others: Reserved (if used, unfreeze SAES with IPRST)

When KEYSEL[2:0] is different from zero, selected key value is available in key registers when BUSY bit is cleared and KEYVALID is set in the SAES_SR register. Otherwise, the key error flag KEIF is set. Repeated writing of KEYSEL[2:0] with the same non-zero value only triggers the loading of DHUK or BHK when KEYVALID is cleared.

When the application software changes the key selection by writing the KEYSEL[2:0] bitfield, the key registers are immediately erased and the KEYVALID flag cleared.

At the end of the decryption process, if KMOD[1:0] is other than zero, KEYSEL[2:0] is cleared.

With the bitfield value other than zero and KEYVALID set, the application cannot transfer the ownership of SAES with a loaded key to an application running in another security context (such as secure, nonsecure). More specifically, when security of an access to any register does not match the information recorded by SAES, the KEIF flag is set.

Attempts to write the bitfield are ignored when the BUSY flag of SAES_SR register is set, as well as when the EN bit of the SAES_CR register is set before the write access and it is not cleared by that write access.

Bits 27:26 **KSHAREID[1:0]**: Key share identification

This bitfield defines, at the end of a decryption process with KMOD[1:0] at 0x2 (shared key), which target can read the SAES key registers using a dedicated hardware bus.

0x0: AES peripheral

Others: Reserved

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 25:24 **KMOD[1:0]**: Key mode selection

The bitfield defines how the SAES key can be used by the application. KEYSIZE must be correctly initialized when setting KMOD[1:0] different from zero.

0x0: Normal key mode. Key registers are freely usable and no specific use or protection applies to SAES_DINR and SAES_DOUTR registers.

0x1: Wrapped key for SAES mode. Key loaded in key registers can only be used to encrypt or decrypt AES keys. Hence, when a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

0x2: Shared key mode. After a successful decryption process (unwrapping), SAES key registers are shared with the peripheral described in KSHAREID[1:0] bitfield. This sharing is valid only while KMOD[1:0] at 0x2 and KEYVALID=1. When a decryption is selected, read-as-zero SAES_DOUTR register is automatically loaded into SAES key registers after a successful decryption process.

Others: Reserved

With KMOD[1:0] other than zero, any attempt to configure the SAES peripheral for use by an application belonging to a different security context (such as secure or nonsecure) results in automatic key erasure and setting of the KEIF flag.

Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 23:20 **NPBLB[3:0]:** Number of padding bytes in last block

This padding information must be filled by software before processing the last block of GCM payload encryption or CCM payload decryption, otherwise authentication tag computation is incorrect.

0x0: All bytes are valid (no padding)

0x1: Padding for the last LSB byte

...

0xF: Padding for the 15 LSB bytes of last block.

Bit 19 **KEYPROT**: Key protection

When set, hardware-based key protection is enabled.

0: When KEYVALID is set and KEYSEL[2:0] = 0 application can transfer the ownership of the SAES, with its loaded key, to an application running in another security context (such as nonsecure, secure).

1: When KEYVALID is set, key error flag (KEIF) is set when an access to any registers is detected, this access having a security context (for example, secure, nonsecure) that does not match the one of the application that loaded the key.

Attempts to write the bit are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 18 **KEYSIZE:** Key size selection

This bitfield defines the key length in bits of the key used by SAES.

0: 128-bit

1: 256-bit

When KMOD[1:0] is at 0x1 or 0x2, KEYSIZE also defines the length of the key to encrypt or decrypt.

Attempts to write the bit are ignored when BUSY is set, as well as when the EN is set before the write access and it is not cleared by that write access.

Bit 17 Reserved, must be kept at reset value.

Bit 15 Reserved, must be kept at reset value.

Bits 14:13 **CPHASE[1:0]:** Chaining phase selection

This bitfield selects the phase, applicable only with GCM, GMAC or CCM chaining modes.
0x0: Initialization phase
0x1: Header phase
0x2: Payload phase
0x3: Final phase

Bit 12 **DMAOUTEN**: DMA output enable

This bit enables automatic generation of DMA requests during the data phase, for outgoing data transfers from SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bit 11 **DMAINEN**: DMA input enable

This bit enables automatic generation of DMA requests during the data phase, for incoming data transfers to SAES via DMA.
0: Disable
1: Enable
Setting this bit is ignored when MODE[1:0] is at 0x1 (key derivation).

Bits 10:7 Reserved, must be kept at reset value.

Bits 16, 6:5 **CHMOD[2:0]**: Chaining mode

This bitfield selects the AES chaining mode:
0x0: Electronic codebook (ECB)
0x1: Cipher-block chaining (CBC)
0x2: Counter mode (CTR)
0x3: Galois counter mode (GCM) and Galois message authentication code (GMAC)
0x4: Counter with CBC-MAC (CCM)
others: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 4:3 **MODE[1:0]**: Operating mode

This bitfield selects the SAES operating mode:
0x0: Encryption
0x1: Key derivation (or key preparation), for ECB/CBC decryption only
0x2: Decryption
0x3: Reserved
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bits 2:1 **DATATYPE[1:0]**: Data type

This bitfield defines the format of data written in the SAES_DINR register or read from the SAES_DOUTR register, through selecting the mode of data swapping. This swapping is defined in *Section 35.4.16: SAES data registers and data swapping*.
0x0: No swapping (32-bit data).
0x1: Half-word swapping (16-bit data)
0x2: Byte swapping (8-bit data)
0x3: Bit-level swapping
Attempts to write the bitfield are ignored when BUSY is set, as well as when EN is set before the write access and it is not cleared by that write access.

Bit 0 **EN**: Enable

This bit enables/disables the SAES peripheral.

0: Disable

1: Enable

At any moment, clearing then setting the bit re-initializes the SAES peripheral. When KMOD[1:0] is different from 0x0, using IPRST bit is recommended instead.

This bit is automatically cleared by hardware upon the completion of the key preparation (MODE[1:0] at 0x1) and upon the completion of GCM/GMAC/CCM initialization phase.

The bit cannot be set as long as KEYVALID is cleared, or when SAES is in one of the following configurations:

– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x3 (GCM)

– KMOD[1:0] at 0x1 (wrap), CHMOD[2:0] at 0x2 (CTR), MODE[1:0] at 0x0 (encryption).

35.8.2 SAES status register (SAES_SR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEYVALID	Res.	Res.	Res.	BUSY	WRERRF	RDERRF	Res.
								r				r	r	r	

Bits 31:8 Reserved, must be kept at reset value.

Bit 7 **KEYVALID**: Key valid flag

This bit is set by hardware when the key of size defined by KEYSIZE is loaded in SAES_KEYRx key registers.

0: Key not valid

1: Key valid

The EN bit can only be set when KEYVALID is set.

In normal mode when KEYSEL[2:0] is at zero, the key must be written in the key registers in the correct sequence, otherwise the KEIF flag is set and KEYVALID remains cleared.

When KEYSEL[2:0] is different from zero, the BUSY flag is automatically set by SAES. When the key is loaded successfully, BUSY is cleared and KEYVALID set. Upon an error, KEIF is set, BUSY cleared and KEYVALID remains cleared.

If set, KEIF must be cleared through the SAES_ICR register, otherwise KEYVALID cannot be set. See the KEIF flag description for more details.

For further information on key loading, refer to *Section 35.4.17: SAES key registers*.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy

This flag indicates whether SAES is idle or busy.

0: Idle

1: Busy

SAES is flagged as idle when disabled (when EN is low) or when the last processing is completed.

SAES is flagged as busy when processing a block data, preparing a key (ECB or CBC decryption only), fetching random number from the RNG, or transferring a shared key to the target peripheral.

When GCM encryption payload phase is selected, this flag must be at zero before suspending current process to manage a higher-priority message. BUSY must also be cleared before selecting the GCM final phase.

Bit 2 **WRERRF**: Write error flag

This bit is set when an unexpected write to the SAES_DINR register occurred. When set WRERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected write to SAES_DINR register occurred during computation or data output phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 1 **RDERRF**: Read error flag

This bit is set when an unexpected read to the SAES_DOUTR register occurred. When set RDERRF bit has no impact on the SAES operations.

0: No error

1: Unexpected read to SAES_DOUTR register occurred during computation or data input phase.

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the RWEIF bit of the SAES_ICR register.

Bit 0 Reserved, must be kept at reset value.

35.8.3 SAES data input register (SAES_DINR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DIN[31:0]**: Data input

A four-fold sequential write to this bitfield during the Input phase results in writing a complete 16-bytes block of input data to the SAES peripheral. From the first to the fourth write, the corresponding data weights are [127:96], [95:64], [63:32], and [31:0]. Upon each write, the data from the 32-bit input buffer are handled by the data swap block according to the DATATYPE[1:0] bitfield, then written into the AES core 16-bytes input buffer.

Reads return zero.

35.8.4 SAES data output register (SAES_DOUTR)

Address offset: 0x00C

Reset value: 0x0000 0000

Read when KMOD[1:0] is at 0x1 or 0x2 while MODE[1:0] is at 0x2 and EN is set triggers a read error.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DOUT[31:16]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DOUT[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:0 **DOUT[31:0]**: Data output

This read-only bitfield fetches a 32-bit output buffer. A four-fold sequential read of this bitfield, upon the computation completion (CCF flag set), virtually reads a complete 16-byte block of output data from the SAES peripheral. Before reaching the output buffer, the data produced by the AES core are handled by the data swap block according to the DATATYPE[1:0] bitfield.

Data weights from the first to the fourth read operation are: [127:96], [95:64], [63:32], and [31:0].

35.8.5 SAES key register 0 (SAES_KEYR0)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[31:0]**: Cryptographic key, bits [31:0]

These are bits [31:0] of the write-only bitfield KEY[255:0] AES encryption or decryption key, depending on the MODE[1:0] bitfield of the SAES_CR register.

Writes to SAES_KEYRx registers are ignored when SAES is enabled (EN bit set). When KEYSEL[2:0] is different from 0 and KEYVALID is 0, writes to key registers are also ignored and they result in setting the KEIF bit of the SAES_ISR register.

With KMOD[1:0] at 0x0, a special writing sequence is required. In this sequence, any valid write to AES_KEYRx register clears the KEYVALID flag except for the sequence-completing write that sets it. Also refer to the description of the KEYVALID flag in the AES_SR register.

35.8.6 SAES key register 1 (SAES_KEYR1)

Address offset: 0x014

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[47:32]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[63:32]**: Cryptographic key, bits [63:32]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

35.8.7 SAES key register 2 (SAES_KEYR2)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
KEY[95:80]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEY[79:64]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **KEY[95:64]**: Cryptographic key, bits [95:64]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

35.8.8 SAES key register 3 (SAES_KEYR3)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IVI[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **IVI[31:0]**: Initialization vector input, bits [31:0]

SAES_IVRx registers store the 128-bit initialization vector or the nonce, depending on the chaining mode selected. This value is updated by hardware after each computation round (when applicable). Write to this register is ignored when EN bit is set in SAES_CR register

35.8.10 SAES initialization vector register 1 (SAES_IVR1)

Address offset: 0x024

Reset value: 0x0000 0000

Bits 31:0 **KEY[255:224]**: Cryptographic key, bits [255:224]

Refer to the SAES_KEYR0 register for description of the KEY[255:0] bitfield and for information relative to writing SAES_KEYRx registers.

35.8.17 SAES suspend registers (SAES_SUSPRx)

Address offset: 0x040 + 0x4 * x, (x = 0 to 7)

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
SUSP[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SUSP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **SUSP[31:0]**: Suspend data

SAES_SUSPRx registers contain the complete internal register states of the SAES when the CCM processing of the current task is suspended to process a higher-priority task. Refer to *Section 35.4.8: SAES suspend and resume operations* for more details.

Clearing EN bit of the SAES_CR register clears this register to zero.

SAES_SUSPRx registers are not used in other chaining modes than CCM.

35.8.18 SAES interrupt enable register (SAES_IER)

Address offset: 0x300

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIE	KEIE	RWEIE	CCFIE
												rw	rw	rw	rw

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIE:** RNG error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RNGEIF (RNG error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 2 **KEIE:** Key error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when KEIF (key error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 1 **RWEIE:** Read or write error interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when RWEIF (read and/or write error flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

Bit 0 **CCFIE:** Computation complete flag interrupt enable

This bit enables or disables (masks) the SAES interrupt generation when CCF (computation complete flag) is set.

0: Disabled (masked)

1: Enabled (not masked)

35.8.19 SAES interrupt status register (SAES_ISR)

Address offset: 0x304

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												r	r	r	r

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag

This read-only bit is set by hardware when an error is detected on RNG bus interface (for example bad entropy).

0: RNG bus is functional

1: Error detected on RNG bus interface (random seed fetching error)

The flag setting generates an interrupt if the RNGEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register. The clear action triggers the reload of a new random number from the RNG peripheral.

Bit 2 **KEIF:** Key error interrupt flag

This read-only bit is set by hardware when the key information fails to load into key registers or when the key register use is forbidden.

0: No key error detected

1: Key information failed to load into key registers or the key register use is forbidden

The flag setting generates an interrupt if the KEIE bit of the SAES_IER register is set. It also clears the key registers and the KEYVALID flag in the SAES_SR register.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

KEIF is raised upon any of the following events:

–SAES fails to load the DHUK (KEYSEL[2:0] = 0x1 or 0x4).

–SAES fails to load the BHK (KEYSEL[2:0] = 0x2 or 0x4).

–AES fails to load the key shared by SAES peripheral (KMOD[1:0] = 0x2).

–KEYVALID is set and either KEYPROT is set or KEYSEL[2:0] is other than 0x0. The security context of the application that loads the key (secure or nonsecure) does not match the security attribute of the access to SAES_CR or SAES_DOUT. In this case, KEYVALID and EN bits are cleared.

–SAES_KEYRx register write does not respect the correct order. (For KEYSIZE cleared, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 register, or reverse. For KEYSIZE set, SAES_KEYR0 then SAES_KEYR1 then SAES_KEYR2 then SAES_KEYR3 then SAES_KEYR4 then SAES_KEYR5 then SAES_KEYR6 then SAES_KEYR7, or reverse).

KEIF must be cleared by the application software, otherwise KEYVALID cannot be set.

Bit 1 **RWEIF:** Read or write error interrupt flag

This read-only bit is set by hardware when a RDERRF or a WRERRF error flag is set in the SAES_SR register.

0: No read or write error detected

1: Read or write error detected

The flag setting generates an interrupt if the RWEIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

The flags has no meaning when key derivation mode is selected.

See the SAES_SR register for details.

Bit 0 **CCF:** Computation complete flag

This flag indicates whether the computation is completed. It is significant only when the DMAOUTEN bit is cleared, and it may stay high when DMAOUTEN is set.

0: Not completed

1: Completed

The flag setting generates an interrupt if the CCFIE bit of the SAES_IER register is set.

The flag is cleared by setting the corresponding bit of the SAES_ICR register.

35.8.20 SAES interrupt clear register (SAES_ICR)

Address offset: 0x308

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	RNGEIF	KEIF	RWEIF	CCF
												w	w	w	w

Bits 31:4 Reserved, must be kept at reset value.

Bit 3 **RNGEIF:** RNG error interrupt flag clear

Application must set this bit to clear the RNGEIF status bit in SAES_ISR register.

Bit 2 **KEIF:** Key error interrupt flag clear

Setting this bit clears the KEIF status bit of the SAES_ISR register.

Bit 1 **RWEIF:** Read or write error interrupt flag clear

Setting this bit clears the RWEIF status bit of the SAES_ISR register, and clears both RDERRF and WRERRF flags in the SAES_SR register.

Bit 0 **CCF:** Computation complete flag clear

Setting this bit clears the CCF status bit of the SAES_ISR register.

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

36 Hash processor (HASH)

36.1 HASH introduction

The hash processor is a fully compliant implementation of the secure hash algorithm (SHA-1, SHA-2 family) and the HMAC (keyed-hash message authentication code) algorithm. HMAC is suitable for applications requiring message authentication.

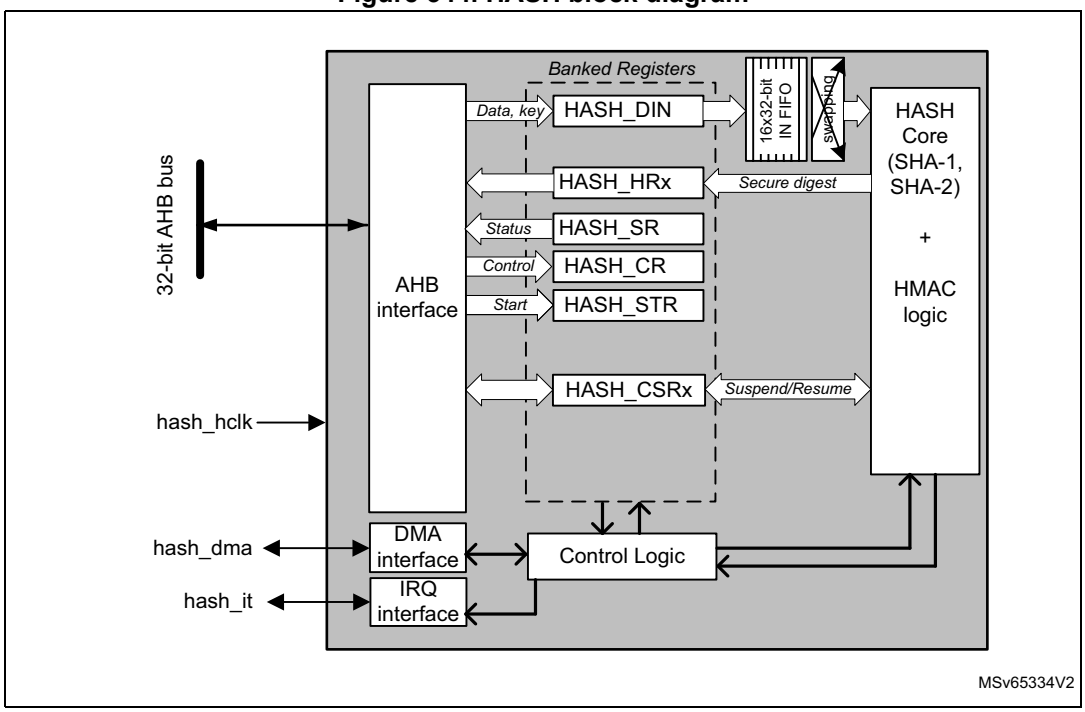
The hash processor computes FIPS (Federal Information Processing Standards) approved digests of length of 160, 224, 256 bits, for messages of any length less than 2^{64} bits (for SHA-1, SHA-224 and SHA-256) or less than 2^{128} bits (for SHA-384, SHA-512).

36.2 HASH main features

- Suitable for data authentication applications, compliant with:
  - Federal Information Processing Standards Publication FIPS PUB 180-4, *Secure Hash Standard* (SHA-1 and SHA-2 family)
  - Federal Information Processing Standards Publication FIPS PUB 186-4, *Digital Signature Standard (DSS)*
  - Internet Engineering Task Force (IETF) Request For Comments RFC 2104, *HMAC: Keyed-Hashing for Message Authentication* and Federal Information Processing Standards Publication FIPS PUB 198-1, *The Keyed-Hash Message Authentication Code (HMAC)*
- Fast computation of SHA-1, SHA2-224, SHA2-256, SHA2-384, and SHA2-512
  - 82 (respectively 66) clock cycles for processing one 512-bit block of data using SHA-1 (respectively SHA-256) algorithm
  - 98 clock cycles for processing one 1024-bit block of data using either SHA2-384 or SHA2-512 algorithm
  - Support for SHA-2 truncated outputs (SHA2-512/224, SHA2-512/256)
- Support for HMAC mode with all supported algorithm
- Corresponding 32-bit words of the digest from consecutive message blocks are added to each other to form the digest of the whole message
  - Automatic 32-bit words swapping to comply with the internal little-endian representation of the input bit-string
  - Supported word swapping format: bits, bytes, half-words, and 32-bit words
- Single 32-bit, write-only, input register associated to an internal input FIFO that can receive a single data block of size depending on the selected algorithm
- Automatic padding to complete the input bit string to fit digest minimum block size
- AMBA AHB target peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- 8 × 32-bit words (H0 to H15) for output message digest
- Automatic data flow control supporting direct memory access (DMA) using one channel.
- Support for both single and fixed DMA burst transfers of four words.
- Interruptible message digest computation, on a per-block basis
  - Reloadable digest registers

– Hashing computation suspend/resume mechanism, including DMA

36.3 HASH implementation



The devices have a single instance of HASH peripheral.

36.4 HASH functional description

36.4.1 HASH block diagram

Figure 344 shows the block diagram of the hash processor.

Figure 344. HASH block diagram

36.4.2 HASH internal signals

Table 319 describes a list of useful to know internal signals available at HASH level, not at product level (on pads).

Table 319. HASH internal input/output signals

Signal name	Signal type	Description
hash_hclk	digital input	AHB bus clock
hash_it	digital output	Hash processor global interrupt request
hash_dma	digital input/output	DMA burst request/ acknowledge

36.4.3 About secure hash algorithms

The hash processor is a fully compliant implementation of the secure hash algorithm defined by FIPS PUB 180-4 standard.

With each algorithm, the HASH computes a condensed representation of a message or data file. More specifically, when a message is presented on the input, the HASH processing core produces a fixed-length output string called a message digest (see *Table 320*).

Table 320. Information on supported hash algorithms

Algorithm	Message digest size (in bits)	Block size (in bytes)(1)	Message length	Bit string message
SHA-1	160	64	$< 2^{64}$ bits	Yes
SHA2-224	224			
SHA2-256	256			
SHA2-384	384	128	$< 2^{128}$ bits	Yes
SHA2-512	512(2)			

1. Block size = (NBWE-1) * 4 bytes. NBWE[4:0] bitfield can be read from the HASH_SR register after ALGO and INIT bits are written in the HASH_CR register.
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes).

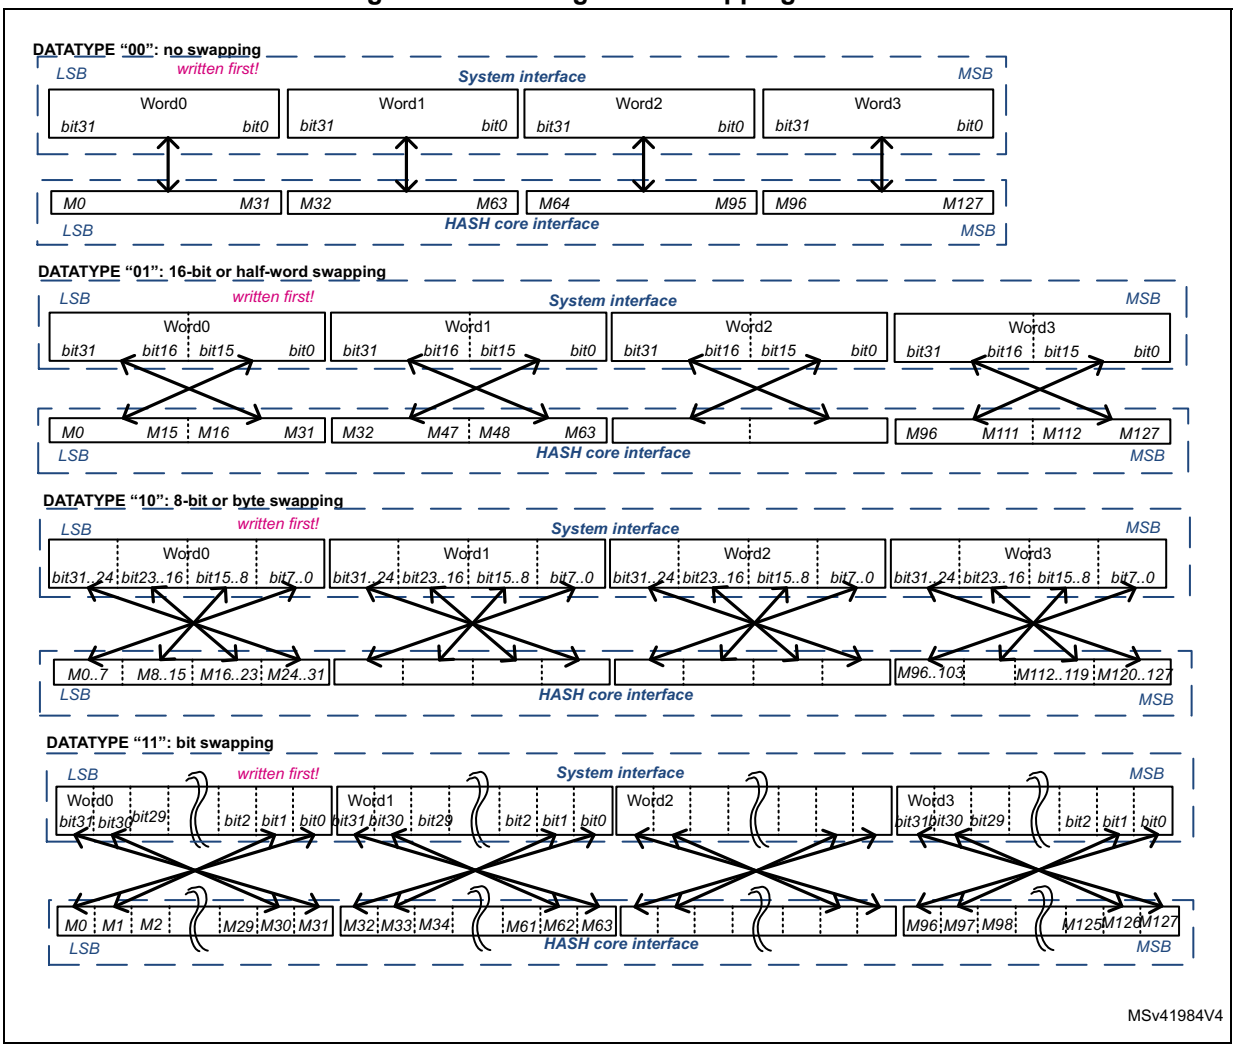
The message digest can then be processed with a digital signature algorithm in order to generate or verify the signature for the message.

Signing the message digest rather than the message often improves the efficiency of the process since the message digest is usually much smaller in size than the message. The verifier of a digital signature has to use the same hash algorithm as the one used by the creator of the digital signature.

The SHA-2 functions supported by the hash processor are qualified as “secure” by NIST because it is computationally infeasible to find a message that corresponds to a given message digest, or to find two different messages that produce the same message digest (SHA-1 does not qualify as secure since February 2017).

36.4.4 Message data feeding

The message (or data file) to be processed by the HASH must be considered as a bit string. Per FIPS PUB 180-4 standard this message bit string grows from left to right, with hexadecimal words expressed in “big-endian” convention, so that within each word, the most significant bit is stored in the left-most bit position. For example message string “abc” with a bit string representation of “**01100001 01100010 01100011**” is represented by a 32-bit word **0x00636261**, and 8-bit words **0x61626300**.



Data are entered into the HASH one 32-bit word at a time, by writing them into the HASH_DIN register. The current contents of the HASH_DIN register are transferred to the 16 words input FIFO each time the register is written with new data. Hence, HASH_DIN and the FIFO form a seventeen 32-bit words length FIFO (named the IN buffer).

In accordance to the kind of data to be processed (for example byte swapping when data are ASCII text stream) there must be a bit, byte, half-word, or no swapping operation to be performed on data from the input FIFO before entering the little-endian hash processing core. *Figure 345* shows how the hash processing core 32-bit data block M0...31 is

constructed from one 32-bit words popped into input FIFO by the driver, according to the DATATYPE bitfield in the HASH control register (HASH_CR)

HASH_DIN data endianness when bit swapping is disabled (DATATYPE = 00) can be described as following: the least significant bit of the message has to be at MSB position in the first word entered into the hash processor, the 32nd bit of the bit string has to be at MSB position in the second word entered into the hash processor and so on.

Figure 345. Message data swapping feature

36.4.5 Message digest computing

The hash processor sequentially processes several blocks when computing the message digest. Block sizes can be found in *Table 320: Information on supported hash algorithms*.

Each time the DMA or the CPU writes a block to the hash processor, the HASH automatically starts computing the message digest. This operation is known as partial digest computation.

As described in *Section 36.4.4: Message data feeding*, the message to be processed is entered into the HASH 32-bit word at a time, writing to the HASH_DIN register to fill the

input FIFO. In order to perform the hash computation on this data the application must follow below sequence.

1. Initialize the hash processor using the HASH_CR register:
   - Write to the HASH_CR register to select the right algorithm using the ALGO bitfield, and set the INIT bit (other bits are kept at zero). Then read the NBWE bitfield from the HASH_SR register to deduce the algorithm block size, which equals **(NBWE-1) * 4**. This step is not required if the block size is already known (see *Table 320* for details).
   - Select the right algorithm using the ALGO[3:0] field. If needed, program the correct swapping operation on the message input words using the DATATYPE[1:0] bitfield.
   - When HMAC mode is required, set the MODE bit as well as the LKEY bit if the HMAC key size is greater than the known block size of the algorithm (otherwise keep LKEY cleared). Refer to *Section 36.4.7: HMAC operation* for details.
   - Update NBLW[4:0] in the HASH_STR register to define the number of valid bits in the last word of the message if it is different from 32 bits. NBLW information is used to correctly perform the automatic message padding before the final message digest computation.
2. Complete the initialization by setting the INIT bit in HASH_CR register. Also set the DMAE bit if data are transferred via DMA.

Caution: When programming step 2, it is important that the correct configuration values (ALGO, DATATYPE, HMAC mode, key length, NBLW) are set up before or at the same time.

3. Start filling data by writing to the HASH_DIN register, unless data are automatically transferred via DMA. Note that the processing of a block can start only once the last value of the block has entered the input FIFO. The way the partial or final digest computation is managed depends on the way data are fed into the processor:
   - Data are filled by software:

     Partial digest computations are triggered each time the application writes the first word of the next block, the block size being defined by NBWE bits in HASH_SR. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write new data to HASH_DIN. This mechanism avoids the introduction of wait states by the HASH.

     The final digest computation is triggered when the last block is entered and the software sets the DCAL bit. If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to writing DCAL bit (see *Section 36.4.6* for details).
   - Data are filled as a single DMA transfer (MDMAT = 0):

     Partial digest computations are triggered automatically each time the FIFO is full.

     The final digest computation is triggered automatically when the last block has been transferred to the HASH_DIN register by DMA (DCAL bit is set by hardware). If the message length is not an exact multiple of the block size, the NBLW field in HASH_STR register must be written prior to enabling the DMA (see *Section 36.4.6* for details).
   - Data are filled using multiple DMA transfers (MDMAT = 1):

     Partial digest computations are triggered as for single DMA transfers (refer to the above description). However, the final digest computation is not triggered automatically when the last block has been transferred by DMA to the HASH_DIN register (DCAL bit is not set by hardware). It enables the hash processor to

receive a new DMA transfer as part of this digest computation. To launch the final digest computation, the software must clear MDMAT bit before the last DMA transfer in order to trigger the final digest computation as it is done for single DMA transfers.

4. Once the digest calculation is completed (DCIS = 1), the resulting digest can be read from the output registers, as described in *Table 321*. When set, the DMAEN bit is automatically cleared by hardware.

Table 321. Hash processor outputs

Algorithm	Valid output registers(1)	Most significant bit	Digest size (in bits)
SHA-1	HASH_H0 to HASH_H4	HASH_H0[31]	160
SHA2-224	HASH_H0 to HASH_H6	HASH_H0[31]	224
SHA2-256	HASH_H0 to HASH_H7		256
SHA2-384	HASH_H0 to HASH_H11	HASH_H0[31]	384
SHA2-512	HASH_H0 to HASH_H15		512(2)

1. Aliased HASH_HRAx registers are not used with SHA-3 or SHAKE algorithm (registers read as zero).
2. Digest size is 224 bits for SHA2-512/224 and 256 bits for SHA2-512/256 (truncated modes)

For more information about HMAC detailed instructions, refer to *Section 36.4.7: HMAC operation*.

Aborting HASH operation

HASH can be disabled at any time by writing 0x4 to HASH_CR, after stopping any running DMA transfer to HASH (if applicable).

36.4.6 Message padding

Overview

When computing a condensed representation of a message, the process of feeding data into the hash processor (with automatic partial digest computation every block size transfer) loops until the last bits of the original message are written to the HASH_DIN register.

As the length (number of bits) of a message can be any integer value, the last word written to the hash processor may have a valid number of bits between 1 and 32. This number of valid bits in the last word, NBLW, has to be written to the HASH_STR register, so that message padding is correctly performed before the final message digest computation.

Padding processing

Detailed hashing sequences with padding are described in *Section 36.4.5: Message digest computing*. As mentioned in these sequences, the padding is done automatically using the information provided in NBLW[4:0].

Hashing example

Below is an example of SHA-1 digest computation with HASH. Message processing and padding are defined in Federal Information Processing Standards PUB 180-4.

Let us assume that the original message is the ASCII binary-coded form of “abc”, of length L = 24 (‘**U**’ means don’t care):

```
byte 0    byte 1   byte 2   byte 3
01100001 01100010 01100011 UUUUUUUU
<-- 1st word written to HASH_DIN -->
```

NBLW has to be loaded with the value 24: a “**1**” is appended at bit location 24 in the bit string (starting counting from left to right in the above bit string), which corresponds to bit 31 in the HASH_DIN register (little-endian convention):

```
01100001 01100010 01100011 1UUUUUUU
```

Since L = 24, the number of bits in the above bit string is 25, and 423 “0” bits are automatically appended, making now 448 bits.

This gives in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000
```

The message length value, **L**, in two-word format (that is 00000000 00000018) is appended. Hence, the final padded message in hexadecimal (byte words in big-endian format):

```
61626380 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000000
00000000 00000000 00000000 00000018
```

If the hash processor is programmed to swap byte within HASH_DIN input register (DATATYPE = 10 in HASH_CR), the above message has to be entered using following sequence:

1. **0xUU636261** is written to the HASH_DIN register (where ‘**U**’ means don’t care)
2. **0x18** is written to the HASH_STR register (the number of valid bits in the last word written to the HASH_DIN register is 24, as the original message length is 24 bits)
3. **0x100** is written to the HASH_STR register to run the final digest computation.
4. The hash computing is complete with the message digest available in the HASH_HRx registers (x = 0 to 4) for the SHA-1 algorithm. For this FIPS example, the expected value is as follows:

```
HASH_HR0 = 0xA9993E36
HASH_HR1 = 0x4706816A
HASH_HR2 = 0xBA3E2571
HASH_HR3 = 0x7850C26C
HASH_HR4 = 0x9CD0D89D
```

36.4.7 HMAC operation

Overview

As specified by Internet Engineering Task Force RFC2104 and NIST FIPS PUB 198-1, the HMAC algorithm is used for message authentication by irreversibly binding the message being processed to a key chosen by the user. The algorithm consists of two nested hash operations:

```
HMAC(message)= Hash((Key | pad) XOR opad |
               Hash((Key | pad) XOR ipad | message))
```

Where:

- **opad** = $[0x5C]_n$ (outer pad) and **ipad** = $[0x36]_n$ (inner pad)
- $[X]_n$ represents a repetition of X *n* times, where *n* equal to the byte size of the underlying hash function data block (n = 64 when block size is 512 bits).
- **pad** is a sequence of zeroes needed to extend the key to the length *n* defined above. If the key length is greater than *n*, the application must first hash the key using Hash() function and then use the resultant byte string as the actual key to HMAC.
- | represents the concatenation operator.

Note: HMAC mode of the hash processor can be used with all supported algorithms.

HMAC processing

Four different steps are required to compute the HMAC:

1. The software sets the INIT bit, with the MODE bit set and the ALGO bits selecting the desired algorithm. The LKEY bit must also be set if the key being used is longer than the block size. In this case, as required by HMAC specifications, the hash processor uses the hash of the key instead of the real key.
2. The software provides the key to be used for the inner hash function, using the same mechanism as the message string loading that is by writing the key data into HASH_DIN register and then completing the transfer by setting DCAL bit and the correct NBLW to HASH_STR register.
3. Once the processor is ready again (DINIS = 1 in HASH_SR), the software can write the message string to HASH_DIN. When the last word of the last block is entered and the software sets DCAL bit in HASH_STR register, the NBLW bitfield must be programmed at the same time to a value different from zero if the message length is not an exact multiple of the block size. Note that the DMA can also be used to feed the message string, as described in *Section 36.4.5: Message digest computing*.
4. Once the processor is ready again (DINIS = 1 in HASH_SR), the software provides the key to be used for the outer hash function, writing the key data into HASH_DIN register, and then completing the transfer by setting DCAL bit and programming the correct NBLW to HASH_STR register. The HMAC result can be found in the valid output registers (HASH_HRx) as soon as DCIS bit is set.

Note: The computation latency of the HMAC primitive depends on the lengths of the keys and message, as described in Section 36.4.11: HASH processing time.

Endianness management details can be found in Section 36.4.4: Message data feeding.

HMAC example

Below is an example of HMAC SHA-1 algorithm (ALGO = 00 and MODE = 1 in HASH_CR) as specified by NIST. SHA-1 block size is 64 bytes.

Let us assume that the original message is the ASCII binary-coded form of "**`Sample message for keylen = blocklen`**", of length L = 34 bytes. If the HASH is programmed in no swapping mode (DATATYPE = 00 in HASH_CR), the following data must be loaded sequentially into HASH_DIN register:

1. **Inner hash key** input (length = 64, that is, no padding), specified by NIST. As key length = 64, LKEY bit is cleared in HASH_CR register

   ```
   00010203 04050607 08090A0B 0C0D0E0F 10111213 14151617
   18191A1B 1C1D1E1F 20212223 24252627 28292A2B 2C2D2E2F
   30313233 34353637 38393A3B 3C3D3E3F
   ```

2. **Message** input (length = 34, that is, padding required). HASH_STR must be set to **`0x20`** to start message padding and inner hash computation (see **'U**' as don't care)

   ```
   53616D70 6C65206D 65737361 67652066 6F72206B 65796C65
   6E3D626C 6F636B6C 656EUUUU
   ```

3. **Outer hash key** input (length = 64, that is, no padding). A key identical to the inner hash key is entered here.
4. **Final outer hash computing** is then performed by the HASH. The HMAC-SHA1 digest result is available in the HASH_HRx registers, as shown below:

   ```
   HASH_HR0 = 0x5FD596EE
   HASH_HR1 = 0x78D5553C
   HASH_HR2 = 0x8FF4E72D
   HASH_HR3 = 0x266DFD19
   HASH_HR4 = 0x2366DA29
   ```

36.4.8 HASH suspend/resume operations

Overview

It is possible to interrupt a hash/HMAC operation to perform another processing with a higher priority. The interrupted process completes later when the higher-priority task has been processed, as shown in *Figure 346*.

Figure 346. HASH suspend/resume mechanism

To do so, the context of the interrupted task must be saved from the HASH registers to memory, and then be restored from memory to the HASH registers.

The procedures where the data flow is controlled by software or by DMA are described hereafter.

Data loaded by software

When the DMA is not used to load the message into the hash processor, the context can be saved only when no block processing is ongoing.

To suspend the processing of a message, proceed as follows after writing the number of words defined in NBWE:

1. In Polling mode, wait for BUSY = 0 then poll if the DINIS status bit is set.
   In Interrupt mode, implement the next step in DINIS interrupt handler (recommended).
2. Store the contents of the following registers into memory:
   - HASH_IMR
   - HASH_STR
   - HASH_CR
   - HASH_CSR0 to HASH_CSR37, when SHA-1 or SHA2-256 is selected, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing
   - HASH_CSR0 to HASH_CSR90, when SHA2-384 or SHA2-512 (truncated or not) is selected, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message, proceed as follows:

1. Write the following registers with the values saved in memory: HASH_IMR, HASH_STR, HASH_CR.
2. Initialize the hash processor by setting the INIT bit in the HASH_CR register
3. Write the HASH_CSRx registers with the values saved in memory.
4. Restart the processing from the point where it has been interrupted.

Data loaded by DMA

When the DMA is used to load the message into the hash processor, it is recommended to suspend and then restore a secure digest computing as described below.

In this sequence the DMA channel allocated to the hash peripheral remains allocated to the processing of message 1 (see *Figure 346*).

To suspend the processing of a message using DMA, proceed as follows:

1. Clear the DMAE bit to disable the DMA interface. The hash peripheral automatically fetches enough data via the DMA to complete the current burst transfer.
2. Wait until the last DMA transfer is complete (DMAS = 0 in HASH_SR).
3. Disable the DMA channel.
4. In Polling or Interrupt mode (recommended), wait until the hash processor is ready (no block is being processed), that is wait for DINIS = 1 in HASH_SR. If DCIS is also set in HASH_SR, the hash result is available and the context swapping is useless. Else go to step 5.
5. Save HASH_IMR, HASH_STR and HASH_CR registers. Also save a number of HASH_CSRx registers depending on the SHA algorithm that is used:
   - When SHA-1 or SHA2-256 is selected, save HASH_CSR0 to HASH_CSR37, plus HASH_CSR38 to HASH_CSR53 if an HMAC operation was ongoing.
   - When SHA2-384 or SHA2-512 is selected, save HASH_CSR0 to HASH_CSR90, plus HASH_CSR91 to HASH_CSR102 if an HMAC operation was ongoing.

To resume the processing of a message using DMA, proceed as follows:

1. Reconfigure the DMA controller so that it proceeds with the transfer of the message up to the end if it is not interrupted again.
2. Program the values saved in memory to HASH_IMR, HASH_STR and HASH_CR registers.
3. Initialize the hash processor by setting the INIT bit in the HASH_CR register.
4. Program the values saved in memory to the HASH_CSRx registers.
5. Restart the processing from the point where it was interrupted by setting the DMAE bit.

36.4.9 HASH DMA interface

The HASH supports both single and fixed DMA burst transfers of four words.

The hash processor provides an interface to connect to the DMA controller. This DMA can be used to write data to the HASH by setting the DMAE bit in the HASH_CR register. When this bit is set, the HASH initiates a DMA request each time a block has to be written to the HASH_DIN register.

Once four 32-bit words have been received, the HASH automatically triggers a new request to the DMA. For more information, refer to *Section 36.4.5: Message digest computing*.

Before starting the DMA transfer, the software must program the number of valid bits in the last word that is copied into HASH_DIN register. This is done by writing in HASH_STR register the following value:

`NBLW = Len(Message)% 32` where "**`x%32`**" gives the remainder of x divided by 32.

The DMAS bit of the HASH_SR register provides information on the DMA interface activity. This bit is set with DMAE and cleared when DMAE is cleared and no DMA transfer is ongoing.

Note: No interrupt is associated to DMAS bit.

When MDMAT is set, the size of the transfer must be a multiple of four words.

36.4.10 HASH error management

No error flags are generated by the hash processor.

36.4.11 HASH processing time

Table 322 summarizes the time required to process an intermediate block for each mode of operation.

Table 322. Processing time (in clock cycle)

Mode of operation	Block size (in bytes)	FIFO load(1)	Computation phase	Total
SHA-1	64	16	66	**82**
SHA2-224		16	50	**66**
SHA2-256				
SHA2-384	128	32	66	**98**
SHA2-512(2)				

1. Add the time required to load the block into the processor.
2. SHA2-512 includes SHA2-512/224 and SHA2-512/256 modes.

The time required to process the last block of a message (or of a key in HMAC) can be longer. This time depends on the length of the last block and the size of the key (in HMAC mode).

Compared to the processing of an intermediate block, it can be increased by the factor below:

- **1 to 2.5** for a hash message
- **~2.5** for an HMAC input-key
- **1 to 2.5** for an HMAC message
- **~2.5** for an HMAC output key in case of a short key
- **3.5 to 5** for an HMAC output key in case of a long key

36.5 HASH interrupts

Two individual maskable interrupt sources are generated by the hash processor to signal the following events:

- Digest calculation completion (DCIS)
- Data input buffer ready (DINIS)

Both interrupt sources are connected to the same global interrupt request signal (hash_it), which is in turn connected to the device interrupt controller. Each interrupt source can individually be enabled or disabled by changing the mask bits in the HASH_IMR register. Setting the appropriate mask bit enables the interrupt.

The status of each maskable interrupt source can be read from the HASH_SR register. *Table 323* gives a summary of the available features.

Table 323. HASH interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method
HASH	Digest computation completed	DCIS	DCIE	Clear DCIS or set INIT
	Data input buffer ready to get a new block	DINIS	DINIE	Clear DINIS or write to HASH_DIN

36.6 HASH registers

The hash core is associated with several control and status registers and several message digest registers. All these registers are accessible through 32-bit word accesses only, else an AHB error is generated.

36.6.1 HASH control register (HASH_CR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ALGO[3:0]				LKEY
											rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MDMAT	DINNE	NBW[3:0]				Res.	MODE	DATATYPE[1:0]		DMAE	INIT	Res.	Res.
		rw	r	r	r	r	r		rw	rw	rw	rw	w		

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:17 **ALGO[3:0]**: Algorithm selection

These bits select the hash algorithm. This selection is only taken into account when the INIT bit is set. Changing this bitfield during a computation has no effect

When the ALGO bitfield is updated and INIT bit is set, NBWE in HASH_SR is automatically updated to 0x11.

0000: SHA-1

0001: reserved

0010: SHA2-224

0011: SHA2-256

1100: SHA2-384

1101: SHA2-512/224

1110: SHA2-512/256

1111: SHA2-512

Bit 16 **LKEY**: Long key selection

The application must set this bit if the HMAC key is greater than the block size corresponding to the hash algorithm (see *Table 320: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.

This selection is only taken into account when the INIT and MODE bits are set (HMAC mode selected). Changing this bit during a computation has no effect.

0: HMAC key is shorter or equal to the block size (short key). The actual key value written in HASH_DIN is used during the HMAC computation.

1: HMAC key is longer than the block size (long key). The hash of the key is used instead of the real key during the HMAC computation.

Bit 15 Reserved, must be kept at reset value.

Bit 14 Reserved, must be kept at reset value.

Bit 13 **MDMAT**: Multiple DMA transfers

This bit is set when hashing large files when multiple DMA transfers are needed.

0: DCAL is automatically set at the end of a DMA transfer.

1: DCAL is not automatically set at the end of a DMA transfer.

Bit 12 **DINNE**: DIN not empty

Refer to DINNE bit of HASH_SR for a description of DINNE bit.

This bit is read-only.

Bits 11:8 **NBW[3:0]:** Number of words already pushed

Refer to NBWP[3:0] bitfield of HASH_SR for a description of NBW[3:0] bitfield.

This bitfield is read-only.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **MODE:** Mode selection

This bit selects the normal or the keyed HMAC mode for the selected algorithm. This selection is only taken into account when the INIT bit is set. Changing this bit during a computation has no effect.

0: Hash mode selected

1: HMAC mode selected. LKEY bit must be set if the key being used is longer than the algorithm block size.

Bits 5:4 **DATATYPE[1:0]:** Data type selection

This bitfield defines the format of the data entered into the HASH_DIN register:
00: 32-bit data. The data written into HASH_DIN are directly used by the HASH processing, without reordering.
01: 16-bit data or half-word. The data written into HASH_DIN are considered as two half-words, and are swapped before being used by the HASH processing.
10: 8-bit data or bytes. The data written into HASH_DIN are considered as four bytes, and are swapped before being used by the HASH processing.
11: bit data or bit string. The data written into HASH_DIN are considered as 32 bits (1st bit of the string at position 0), and are swapped before being used by the HASH processing (1st bit of the string at position 31).

Bit 3 **DMAE:** DMA enable

Setting this bit enables DMA transfers. After this bit is set, it is cleared by hardware while the last data of the message is written into the hash processor.
Clearing this bit while a DMA transfer is ongoing does not abort the current transfer. Instead, the DMA interface of the HASH remains internally enabled until the transfer is complete or INIT is set.
Setting INIT bit does not clear DMAE bit.
0: DMA transfers disabled
1: DMA transfers enabled. A DMA request is sent as soon as the hash core is ready to receive data.

Bit 2 **INIT:** Initialize message digest calculation

This is a write-only bit always returning zero upon reading. Setting this bit resets the hash processor core, so that HASH is ready to compute the message digest of a new message. Clearing this bit has no effect.

Bits 1:0 Reserved, must be kept at reset value.

36.6.2 HASH data input register (HASH_DIN)

Address offset: 0x004

Reset value: 0x0000 0000

HASH_DIN is the data input register. It is 32-bit wide. This register is used to enter the message by blocks defined by the hash algorithm (see *Table 320: Information on supported hash algorithms* for details). For example the block size is 64 bytes for SHA2-256.

When the HASH_DIN register is programmed, the value presented on the AHB bus is ‘pushed’ into the hash core and the register takes the new value presented on the AHB bus. To get a correct message format, the DATATYPE bits must have been previously configured in the HASH_CR register.

When a complete block has been written to the HASH_DIN register, an intermediate digest calculation is launched:

- by writing first data of the next block into the HASH_DIN register, if the DMA is not used
- automatically, if the DMA is used

When the last block has been written to the HASH_DIN register, the final digest calculation (including padding) is launched by setting the DCAL bit in the HASH_STR register (final digest calculation). This operation is automatic if the DMA is used and MDMAT bit is cleared.

Reading the HASH_DIN register returns zeros.

Note: When HASH is busy, a write access to the HASH_DIN register might stall the AHB bus if the digest calculation (intermediate or final) is not complete.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DATAIN[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DATAIN[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **DATAIN[31:0]:** Data input

Writing this register pushes the current register content into the FIFO, and the register takes the new value presented on the AHB bus.

Do not write to this register when BUSY is set.

Reading this register returns zeros.

36.6.3 HASH start register (HASH_STR)

Address offset: 0x008

Reset value: 0x0000 0000

The HASH_STR register has two functions:

- It is used to define the number of valid bits in the last word of the message entered in the hash processor (that is the number of valid least significant bits in the last data written to the HASH_DIN register)
- It is used to start the processing of the last block in the message by setting the DCAL bit.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	DCAL	Res.	Res.	Res.	NBLW[4:0]				
							w				rw	rw	rw	rw	rw

Bits 31:9 Reserved, must be kept at reset value.

Bit 8 **DCAL:** Digest calculation

This is a write-only bit always returning zero upon reading. Setting this bit starts the message padding using the previously written value of NBLW, and starts the calculation of the final message digest with all the data words written to the input FIFO since the INIT bit was last set.

Do not set DCAL when BUSY is set.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **NBLW[4:0]:** Number of valid bits in the last word

When the last word of the message bit string is written to HASH_DIN register, the hash processor takes only the valid bits, specified as below, after internal data swapping.

The above mechanism is valid only if DCAL = 0. If NBLW bits are written while DCAL is set, the NBLW bitfield remains unchanged. In other words it is not possible to configure NBLW and set DCAL at the same time.

Reading NBLW bits returns the last value written to NBLW.

0x00: All the 32 bits of the last data written are valid message bits, that is M[31:0]

0x01: Only one bit of the last data written (after swapping) is valid, that is M[0]

0x02: Only two bits of the last data written (after swapping) are valid, that is M[1:0]

0x03: Only three bits of the last data written (after swapping) are valid that is M[2:0]

...

0x1F: Only 31 bits of the last data written (after swapping) are valid that is M[30:0]

Note:

36.6.4 HASH digest registers

These registers contain the message digest result defined as follows:

- HASH_HR0, HASH_HR1, HASH_HR2, HASH_HR3 and HASH_HR4 registers return the SHA-1 digest result.
- HASH_HR0 to HASH_HR6 registers return the SHA2-224, SHA2-512/224 digest result.
- HASH_HR0 to HASH_HR7 registers return the SHA2-256, SHA2-512/256 digest result.
- HASH_HR0 to HASH_HR11 registers return the SHA2-384 digest result.
- HASH_HR0 to HASH_HR15 registers return the SHA2-512 digest result

In all cases, the digest most significant bit is stored in HASH_HR0[31], and unused HASH_HRx registers reads as zero.

If a read access to one of these registers is performed while the hash core is calculating an intermediate digest or a final message digest (DCIS bit equals 0), then the read operation returns zeros.

Note: When starting a digest computation for a new message (by setting the INIT bit), HASH_HRx registers are forced to their reset values.

HASH_HR0 to HASH_HR4 registers can be accessed through two different addresses (register aliasing).

HASH aliased digest register x (HASH_HRAx)

Address offset: 0x00C + 0x4 * x, (x = 0 to 4)

Reset value: 0x0000 0000

The content of the HASH_HRAx registers is identical to the one of the HASH_HRx registers located at address offset 0x310.

Bit 1 **DCIE:** Digest calculation completion interrupt enable
0: Digest calculation completion interrupt disabled
1: Digest calculation completion interrupt enabled.

Bit 0 **DINIE:** Data input interrupt enable
0: Data input interrupt disabled
1: Data input interrupt enabled

36.6.6 HASH status register (HASH_SR)

Address offset: 0x024

Reset value: 0x0011 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	NBWE[4:0]				
											r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DINNE	Res.	NBWP[4:0]					Res.	Res.	Res.	Res.	Res.	BUSY	DMAS	DCIS	DINIS
r		r	r	r	r	r						r	r	rc_w0	rc_w0

Bits 31:21 Reserved, must be kept at reset value.

Bits 20:16 **NBWE[4:0]:** Number of words expected
This bitfield reflects the number of words in the message that must be pushed into the FIFO to trigger a partial computation. NBWE is decremented by 1 when a write access is performed to the HASH_DIN register.
NBWE is set to the expected block size +1 in words (0x11) when INIT bit is set in HASH_CR. It is set to the expected block size (0x10) when the partial digest calculation ends.

Bit 15 **DINNE:** DIN not empty
This bit is set when the HASH_DIN register holds valid data (that is after being written at least once). It is cleared when either the INIT bit (initialization) or the DCAL bit (completion of the previous message processing) is set.
0: No data are present in the data input buffer
1: The input buffer contains at least one word of data

Bit 14 Reserved, must be kept at reset value.

Bits 13:9 **NBWP[4:0]:** Number of words already pushed

This bitfield is the exact number of words in the message that have already been pushed into the FIFO. NBWP is incremented by 1 when a write access is performed to the HASH_DIN register.

When a digest calculation starts, NBWP is updated to NBWP- block size (in words), and NBWP goes to zero when the INIT bit is set.

Bits 8:4 Reserved, must be kept at reset value.

Bit 3 **BUSY:** Busy bit

0: No block is currently being processed
1: The hash core is processing a block of data

Bit 2 **DMAS:** DMA Status

This bit provides information on the DMA interface activity. It is set with DMAE and cleared when DMAE = 0 and no DMA transfer is ongoing. No interrupt is associated with this bit.

0: DMA interface is disabled (DMAE = 0) and no transfer is ongoing
1: DMA interface is enabled (DMAE = 1) or a transfer is ongoing

Bit 1 **DCIS:** Digest calculation completion interrupt status

This bit is set by hardware when a digest becomes ready (the whole message has been processed). It is cleared by writing it to 0 or by setting the INIT bit in the HASH_CR register.

0: No digest available in the HASH_HRx registers (zeros are returned)

1: Digest calculation complete, a digest is available in the HASH_HRx registers. An interrupt is generated if the DCIE bit is set in the HASH_IMR register.

Bit 0 **DINIS:** Data input interrupt status

This bit is set by hardware when the FIFO is ready to get a new block (16 locations are free). It is cleared by writing it to 0 or by writing the HASH_DIN register.

When DINIS = 0, HASH_CSRx registers reads as zero.

0: Less than 16 locations are free in the input buffer
1: A new block can be entered into the input buffer. An interrupt is generated if the DINIE bit is set in the HASH_IMR register.

36.6.7 HASH context swap registers

These registers contain the complete internal register states of the hash processor. They are useful when a suspend/resume operation has to be performed because a high-priority task needs to use the hash processor while it is already used by another task.

When such an event occurs, the HASH_CSRx registers have to be read and the read values have to be saved in the system memory space. Then the hash processor can be used by the preemptive task. When the hash computation is complete, the saved context can be read from memory and written back into the HASH_CSRx registers.

HASH_CSRx registers can be read only when DINIS equals to 1, otherwise zeros are returned.

HASH context swap register x (HASH_CSRx)

Address offset: 0x0F8 + 0x4 * x, (x = 0 to 102)

Reset value: 0x0022 0002 (HASH_CSR0)

Reset value: 0x0000 0000 (others)

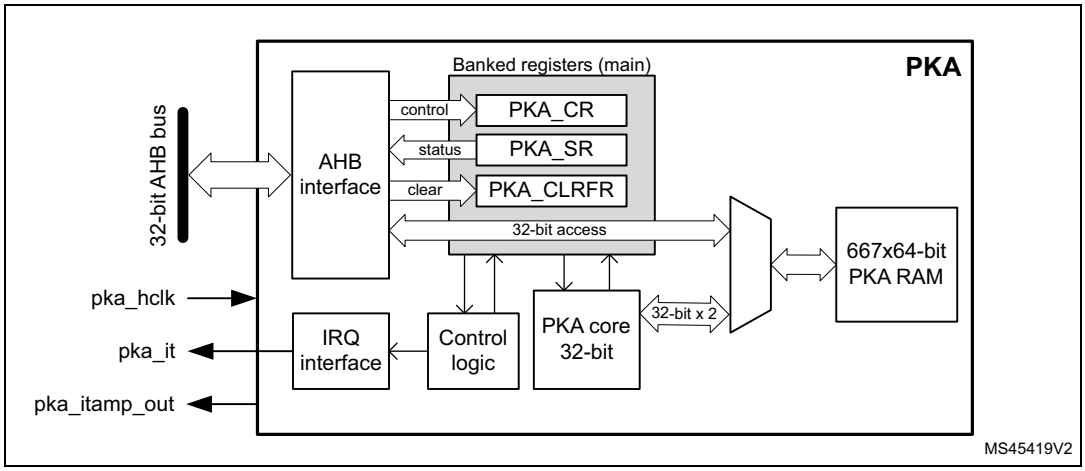
37 Public key accelerator (PKA)

This section only applies to the STM32G54x (fully) and STM32G53x (only the ECDSA signature verification part) devices.

37.1 PKA introduction

PKA (public key accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, the accelerator performs all computations with no further hardware or software elaboration required to process the inputs or the outputs.



37.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)

37.3 PKA functional description

37.3.1 PKA block diagram

Figure 347. PKA block diagram

Note: Ignore pka_itamp_out, it is not applicable.

37.3.2 PKA internal signals

Table 325 lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

Table 325. Internal input/output signals

Signal name	Signal type	Description
pka_hclk	Digital input	AHB bus clock
pka_it	Digital output	Public key accelerator IP global interrupt request

37.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 667 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored. Once EN bit is set, refer to *Section 37.3.6* for details about PKA initialization sequence.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).

37.3.4 PKA public key acceleration

Overview

Public key accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b$ (mod p). More information can be found in *Section 37.5.1*.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in *Table 326* and *Table 327*, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

Table 326. PKA integer arithmetic functions list

0x07	000111	RSA CRT exponentiation	*Section 37.4.13*

Table 327. PKA prime field (Fp) elliptic curve functions list

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x28	101000	Point on elliptic curve Fp check	*Section 37.4.14*
0x20	100000	ECC scalar multiplication kP	*Section 37.4.15*
0x23	100011	ECC complete addition	*Section 37.4.18*
0x24	100100	ECDSA sign	*Section 37.4.16*
0x26	100110	ECDSA verification	*Section 37.4.17*
0x27	100111	ECC double base ladder	*Section 37.4.19*
0x2F	101111	ECC projective to affine	*Section 37.4.20*

Each of these operating modes has an associated code that has to be written to the MODE[5:0] bitfield in the PKA_CR register. If the application selects any value that is not documented below the write to MODE[5:0] bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Montgomery space and fast mode operations

For efficiency reasons, the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming, the application can decide to use a faster mode of operation during which the precomputed Montgomery parameter is supplied before starting the operation. The performance improvement is detailed in *Section 37.5.2: Computation times*.

37.3.5 Typical applications for PKA

Introduction

The PKA can be used to accelerate a number of public key cryptographic functions such as:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement

The following publications specify the listed functions:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories
- IEEE1363-2000, IEEE Standard Specifications for Public-Key Cryptography, January 2000
- ANSI X9.62-2005, Public Key Cryptography for the Financial Services Industry, The Elliptic Curve Digital Signature Algorithm (ECDSA), November 2005

Refer to these documents for full details. This document limits itself to describing principles.

RSA key pair

For the following RSA operations, a public key and a private key information are defined as follows:

- Alice transmits her public key (*n*, *e*) to Bob. Numbers *n* and *e* are very large positive integers.
- Alice keeps secret her private key d, also a very large positive integer. Alternatively, this private key can also be represented by a quintuple (p, q, dp, dq, qInv).

For more information, refer to the RSA specification.

RSA encryption/decryption principle

As recommended by the PKCS#1 specification, Bob, to encrypt message M using Alice's public key (n, e), must go through the following steps:

1. Compute the encoded message EM = ENCODE(M), where ENCODE is an encoding method.
2. Turn EM into an integer m, with $0 \leq m < n$ and (m, n) being coprimes.
3. Compute ciphertext $c = m^e \bmod n$.
4. Convert the integer c into a string ciphertext C.

Alice, to decrypt ciphertext c using her private key d, follows the steps indicated below:

1. Convert the ciphertext C to an integer ciphertext representative c.
2. Recover plaintext $m = c^d \bmod n = (m^e)^d \bmod n$. If the private key is the quintuple (p, q, dp, dq, qInv), then plaintext m is obtained by performing the operations:
   a) $m_1 = c^{dp} \bmod p$
   b) $m_2 = c^{dq} \bmod q$
   c) $h = qInv\ (m_1 - m_2) \bmod p$
   d) $m = m_2 + h\ q$
3. Convert the integer message representative m to an encoded message EM.
4. Recover message M = DECODE(EM), where DECODE is a decoding method.

To accelerate these operations with the PKA, use *Modular exponentiation* $A^e \bmod n$ if the private key is d, or *RSA CRT exponentiation* if the private key is the quintuple (p, q, dp, dq, qInv).

Note: The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.

Elliptic curve selection

For the following ECC operations, the curve parameters are defined as follows:

- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in *Section 37.5.1: Supported elliptic curves*.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (that is, $n \times G$ = identity element O).

ECDSA message signature generation

This section describes the ECDSA (elliptic curve digital signature algorithm) signature generation function principle.

Alice, to sign a message m using her private key integer d_A, goes through the following steps:

1. Calculate e = HASH(m), where HASH is a cryptographic hash function.
2. Let z be the L_n leftmost bits of e, where L_n is the bit length of the group order n.
3. Select a cryptographically secure random integer k where $0 < k < n$.
4. Calculate the curve point $(x_1, y_1) = k \times G$.
5. Calculate $r = x_1 \bmod n$. If $r = 0$ go back to step 3.
6. Calculate $s = k^{-1} (z + rd_A) \bmod n$. If $s = 0$ go back to step 3.

7. The signature is the pair (r, s).

The PKA accelerates the steps 4. to 7. by using:

- *ECDSA sign*, or
- All of the following operations:
  - *ECC Fp scalar multiplication* $k \times P$
  - *Modular reduction* A mod n
  - *Modular inversion* A^{-1} mod n
  - *Modular addition* and *Modular and Montgomery multiplication*

ECDSA signature verification

This section describes the ECDSA (elliptic curve digital signature algorithm) signature verification function principle.

Bob, to authenticate Alice's signature, must have a copy of her public key curve point Q_A. Bob can verify that Q_A is a valid curve point by going through the following steps:

1. Check that Q_A is not equal to the identity element O
2. Check that Q_A is on the agreed curve
3. Check that $n \times Q_A = O$.

Then Bob executes the following procedure:

1. Verify that r and s are integer in [1, n-1]
2. Calculate e = HASH(m), where HASH is the agreed cryptographic hash function
3. Let z be the L_n leftmost bits of e
4. Calculate $w = s^{-1}$ mod n
5. Calculate $u_1 = zw$ mod n and $u_2 = rw$ mod n
6. Calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$
7. The signature is valid if $r = x_1$ (mod n), it is invalid otherwise.

The PKA accelerates the steps 4. to 7. by using *ECDSA verification*.

37.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit in the PKA_CR register enables the PKA peripheral. The PKA becomes available when the INITOK bit is set in the PKA_SR register. When EN = 0, the PKA peripheral is kept under reset, with its memory still accessible by the application through the AHB interface.

Note: When the PKA is in the process of clearing its memory, the EN bit cannot be set.

When setting the EN bit in PKA_CR, make sure that the MODE[5:0] bitfield value corresponds to an authorized PKA operation (see OPERRF in Section 37.3.7).

Clearing the EN bit while a calculation is in progress aborts the operation. In this case, the content of the PKA memory is not guaranteed.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in *Section 37.4*.

Executing a PKA operation

To execute any of the supported PKA operations, proceed as follows:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE[5:0] bitfield of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1), any access by the application to PKA RAM is ignored, and the RAMERRF flag is set in PKA_SR.

Selecting an illegal or unknown operation in step *2* triggers an OPERRF error and prevents the PROCENDF flag from being set and the procedure step *3* from being completed. See *Section 37.3.7* for details.

Using precomputed Montgomery parameters (PKA fast mode)

As explained in *Section 37.3.4*, when computing many operations with the same modulus, it can be beneficial for the application to compute the corresponding Montgomery parameter only once (see, for example, *Section 37.4.5*). This is referred to as *fast mode*.

To use the PKA peripheral in fast mode, follow this recommended procedure:

1. Load the modulus size and value information into the PKA RAM. Refer to *Section 37.5.1* for detail.
2. Configure the PKA_CR register to *Montgomery parameter computation* mode (MODE[5:0] = 0x1), then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set. Then, read the corresponding Montgomery parameter from the PKA memory and clear the PROCENDF bit by setting PROCENDFC in PKA_CLRFR.
4. Continue with the required PKA operation, loading the Montgomery information R2 mod *m* on top of the regular input data. Relevant addresses are provided in *Section 37.4*.

37.3.7 PKA error management

The following error flags in the PKA_SR register are set to indicate errors that may occur when using the PKA:

- **ADDRERRF** flags that the access to PKA RAM falls outside the expected range.
- **RAMERRF** flags an AHB access to the PKA RAM occurring while the PKA core uses the PKA RAM. While the flag is set, reads form the PKA RAM return 0 and writes are ignored.
- **OPERRF** flags that the selected operating mode using MODE[5:0] bitfield is not listed in PKA operating modes (see the bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). While the flag is set, writes to the MODE[5:0] bitfield are ignored.

For each error flag, the PKA generates an interrupt if enabled with the corresponding bit in the PKA_CR register (see *Section 37.6* for details).

The ADDRERRF, OPERRF, and RAMERRF error flags are cleared by setting the ADDRERRFC, OPERRFC, and RAMERRFC bit in PKA_CLRFR, respectively. The OPERRF error flag must be cleared before a new operation is initiated via the PKA_CR register.

Note: The PKA can be re-initialized at any moment by clearing the EN bit in the PKA_CR register.

37.4 PKA operating modes

37.4.1 Introduction

The operations supported by the PKA are detailed in the following subsections, which define the format of both input data and results stored in the PKA RAM.

Warning: Before starting any operation, ensure that all input parameters to the PKA are valid and consistent, as the PKA assumes their correctness. Additionally, input parameters must not exceed the operand sizes specified in the operation tables.

The following information applies to all PKA operations:

- The PKA core processes 64-bit words in its RAM. Accordingly, in the PKA section of this document, 'word' denotes a 64-bit unit.
- When writing an element as input in the PKA RAM, append an additional 64-bit word of zeros after the most significant word, except when the operand size is fixed at one word.
- All RAM storage addresses refer to the least significant word of the data. To obtain the actual address, the application must add the base address of the PKA to the indicated offset.
- Supported operand sizes are:
  - **ROS (RSA operand size)**: Data size is calculated as *(rsa_size / 64) + 1* words, where *rsa_size* is the modulus length in bits. For example, a 1024-bit RSA operand corresponds to 17 words (1088 bits).
  - **EOS (ECC operand size)**: Data size is *(ecc_size / 64) + 1* words, where *ecc_size* is the prime modulus length in bits. For example, a 192-bit ECC operand corresponds to four words (256 bits).

  Note: Both ROS and EOS include the additional zero word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Any fractional results in the formulas must be rounded to the nearest integer, as the PKA core processes data in 64-bit words.

Note: The maximum ROS is 66 words (4160-bit maximum exponent size), while the maximum EOS is 11 words (640-bit max operand size).

Example 1: Understanding endianness in PKA memory during ECC Fp scalar multiplication preparation

Write the *x*-coordinate of point P for an ECC P256 curve (EOS = 5 words) by placing the least significant bit at bit 0 of the word at address offset 0x578, and the most significant bit at bit 63 of the word at address offset 0x590. Then, write a zero word (0x0000000000000000) at address offset 0x598.

Example 2: Writing the curve coefficient '*a*' for ECC Fp scalar multiplication

To write the value *a* = -3 for a curve with a modulus length of 224 bits (rounded up to five 64-bit words), write the PKA memory with data as in the following table:

Table 328. Example of *'a'* curve coefficient for ECC Fp scalar

RAM offset	Value	Note
0x410	0x0000000000000001	Curve coefficient *a* sign without extra word
0x418	0x0000000000000011	Value of |*a*| LSB
0x420	0x0000000000000000	-
0x428	0x0000000000000000	-
0x430	0x0000000000000000	Value of |*a*| MSB
0x438	0x0000000000000000	Additional zero word

37.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter (R^2 mod n) used by the PKA to convert operands into the Montgomery residue system representation. This operation can be very useful for fast mode operation because passing the Montgomery parameter as input saves the time for its computation.

Note: This operation also supports ECC curves when specifying the prime modulus length and EOS size.

The following table summarizes operation instructions for Montgomery parameter computation.

Table 329. Montgomery parameter computation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x01	PKA_CR	6 bits
	Modulus length	(in bits, 0 ≤ value < 4160)	RAM@0x408	64 bits
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	ROS
OUT	Result: R^2 mod *n*	-	RAM@0x620	

37.4.3 Modular addition

The following table summarizes operation instructions for modular addition operation that calculates *A* + *B* mod *n*.

Table 330. Modular addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0E	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < n$)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: $A + B \bmod n$	($0 \le$ result $< n$)	RAM@0xE78	

37.4.4 Modular subtraction

Modular subtraction operation calculates:

- ***A* - *B* mod *n***, when $A \ge B$
- ***A* + *n* - *B* mod *n***, when $A < B$

The following table summarizes the operation instructions.

Table 331. Modular subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0F	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < n$)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: $A - B \bmod n$	($0 \le$ result $< n$)	RAM@0xE78	

37.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications, the PKA accelerates a multiplication that has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \bmod n$

The method to perform these operations is described next. The *x* function is this operation, and the *A*, *B*, and *C* operands are in the natural domain.

1. Inward or outward conversion to or from the Montgomery domain
   a) Assuming that *A* is an integer in the natural domain:
      – Compute *r2modn* using *Montgomery parameter computation*.
      – The result of *AR* = *A* × *r2modn* mod *n* is *A* in the Montgomery domain.
   b) Assuming that *BR* is an integer in the Montgomery domain:
      – The result of *B* = *BR* × 1 mod *n* is *B* in the natural domain.
      – Similarly, the *AR* value computed in *a)* can be converted into the natural domain by computing *A* = *AR* × 1 mod *n.*
2. Simple modular multiplication *A* × *B* mod *n*
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute *AR* = *A* × *r2modn* mod *n*. The output is in the Montgomery domain.
   c) Compute *AB* = *AR* × *B* mod *n*. The output is in the natural domain.
3. Multiple modular multiplication *A* × *B* × *C* mod *n*
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute *AR* = *A* × *r2modn* mod *n*. The output is in the Montgomery domain.
   c) Compute *BR* = *B* × *r2modn* mod *n*. The output is in the Montgomery domain.
   d) Compute *ABR* = *AR* × *BR* mod *n*. The output is in the Montgomery domain.
   e) Compute *CR* = *C* × *r2modn* mod *n*. The output is in the Montgomery domain.
   f) Compute *ABCR* = *ABR* × *CR* mod *n*. The output is in the Montgomery domain.
   g) (optional) Repeat the two previous steps if multiplying with additional operands is required.
   h) Compute *ABC* = *ABCR* × 1 mod *n* to retrieve the result in the natural domain.

The following table summarizes the operation instructions.

Table 332. Montgomery multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x10	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	(0 ≤ *A* < *n*)	RAM@0xA50	ROS
	Operand *B*	(0 ≤ *B* < *n*)	RAM@0xC68	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: *A* × *B* mod *n*(1)	-	RAM@0xE78	

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples *2* and *3*).

37.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It calculates of A^e mod *n*.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

Operation instructions for modular exponentiation are summarized in *Table 333* (normal mode) and *Table 334* (fast mode). Fast mode usage is explained in *Section 37.3.6*.

Table 333. Modular exponentiation (normal mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x00	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: $A^e \bmod n$	($0 \le$ result $< n$)	RAM@0x838	

Table 334. Modular exponentiation (fast mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x02	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
IN/OUT	Montgomery parameter $R^2 \bmod n$	(mandatory)	RAM@0x620	
OUT	Result: $A^e \bmod n$	($0 \le$ result $< n$)	RAM@0x838	

37.4.7 Modular inversion

The modular inversion operation calculates multiplicative inverse $A^{-1} \bmod n$. If the modulus *n* is prime, for all values of *A* ($1 \le A < n$) modular inversion output is valid. If the modulus *n* is not prime, *A* has an inverse only if the greatest common divisor between *A* and *n* is 1.

If the operand *A* is a divisor of the modulus *n* the result is a multiple of a factor of *n*.

The following table summarizes the operation instructions.

Table 335. Modular inversion

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x08	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result: $A^{-1} \bmod n$	$0 < \text{result} < n$	RAM@0xE78	

37.4.8 Modular reduction

The modular reduction operation calculates the remainder of *A* divided by *n*.

The following table summarizes the operation instructions.

Table 336. Modular reduction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0D	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x400	64 bits
	Modulus length	(in bits, 8 < value < 4160)	RAM@0x408	
	Operand *A*	($0 \le A < 2n < 2^{4160}$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result *A* mod *n*	($0 < \text{result} < n$)	RAM@0xE78	

37.4.9 Arithmetic addition

The arithmetic addition operation calculates *A* + *B*.

The following table summarizes the operation instructions.

Table 337. Arithmetic addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x09	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	Result: *A* + *B*	($0 \le \text{result} < 2^{M+1}$)	RAM@0xE78	ROS + 1

37.4.10 Arithmetic subtraction

The arithmetic subtraction operation calculates:

- ***A - B****,* when $A \geq B$
- $\boldsymbol{A + 2^{int(M / 32) \times 32 + 1} - B}$*,* when $A < B$ and the residue of $M / 32$ is greater than zero
- $\boldsymbol{A + 2^{int(M / 32) \times 32} - B}$*,* when $A < B$ and the residue of $M / 32$ is zero

For the last two list items, the 32-bit word following the most significant word of the output is 0xFFFF FFFF, as the result is negative.

The following table summarizes the operation instructions.

Table 338. Arithmetic subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0A	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \leq < A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \leq < B < 2^M$)	RAM@0xC68	
OUT	Result: *A* - *B*	($0 \leq$ result $< 2^M$)	RAM@0xE78	

37.4.11 Arithmetic multiplication

The arithmetic multiplication operation calculates A × B.

The following table summarizes the operation instructions.

Table 339. Arithmetic multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0B	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \leq A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \leq B < 2^M$)	RAM@0xC68	
OUT	Result: *A* × *B*	($0 \leq$ result $< 2^{2M}$)	RAM@0xE78	2xROS

37.4.12 Arithmetic comparison

The arithmetic comparison operation yields the following results:

- **0xED2C**, when $A = B$
- **0x7AF8**, when $A > B$
- **0x916A**, when $A < B$

The following table summarizes the operation instructions.

Table 340. Arithmetic comparison

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0C	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	If result *A* = *B*	0xED2C, 0x7AF8, or 0x916A	RAM@0xE78	64 bits

37.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- p and q are precomputed primes, stored as part of the private key
- $d_P = d \bmod (p - 1)$
- $d_Q = d \bmod (q - 1)$ and
- $q_{inv} = q^{-1} \bmod p$

These values allow the recipient to compute the exponentiation m = $A^d \pmod{pq}$ more efficiently as follows:

- $m_1 = A^{dP} \bmod p$
- $m_2 = A^{dQ} \bmod q$
- $h = q_{inv} (m_1 - m_2) \bmod p$, with $m_1 > m_2$
- $m = m_2 + hq \bmod pq$

Operation instructions for computing CRT exponentiation $A^d \bmod pq$ are summarized in *Table 341*.

Table 341. CRT exponentiation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x07	PKA_CR	6 bits
IN	Operand length	(in bits, not null)	RAM@0x408	64 bits
IN	Operand d_P	($0 < d_P < 2^{M/2}$)	RAM@0x730	ROS / 2
	Operand d_Q	($0 < d_Q < 2^{M/2}$)	RAM@0xE78	
	Operand q_{inv}	($0 < q_{inv} < 2^{M/2}$)	RAM@0x948	
	Prime $p^{(1)}$	($0 < p < 2^{M/2}$)	RAM@0xB60	
	Prime $q^{(1)}$	($0 < q < 2^{M/2}$)	RAM@0x1088	
IN	Operand *A*	($0 < A < 2^M$)	RAM@0x12A0	ROS
OUT	Result: $A^d \bmod pq$	($0 \le$ result $<$ pq)	RAM@0x838	

1. Must be different from 2.

37.4.14 Point on elliptic curve Fp check

This operation checks whether a given point P (x, y) satisfies or not the curves over prime fields equation $y^2 = (x^3 + ax + b) \bmod p$, where a and b are elements of the curve.

The following table summarizes the operation instructions.

Table 342. Point on elliptic curve *Fp* check

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x28	PKA_CR	6 bits
	Modulus length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |a|	(absolute value, $\|a\| < p$)	RAM@0x418	EOS
	Curve coefficient *b*	($\|b\| < p$)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2640$)	RAM@0x470	
	Point P coordinate *x*	($x < p$)	RAM@0x578	
	Point P coordinate *y*	($y < p$)	RAM@0x5D0	
	Montgomery parameter $R^2 \bmod n$	-	RAM@0x4C8	
OUT	Result: point *P* on curve	0xD60D: point on curve 0xA3B7: point not on curve 0xF946: *x* or *y* coordinate is not smaller than modulus *p*	RAM@0x680	64 bits

37.4.15 ECC Fp scalar multiplication

This operation calculates $k \times P$ (x_P, y_P), where P is a point on a curve over prime fields and x is the elliptic curve scalar point multiplication. The result is a point that belongs to the same curve or a point at infinity.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

The following table summarizes the operation instructions.

Table 343. ECC Fp scalar multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x20	PKA_CR	6 bits
IN	Scalar multiplier *k* length	(in bits, not null, 8 < value < 640)	RAM@0x400	64 bits
	Modulus length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	

Table 343. ECC Fp scalar multiplication (continued)

Parameters with direction		Value (note)	Storage	Size
IN	Curve coefficient $\|a\|$	(absolute value, $\|a\| < p$)	RAM@0x418	EOS
	Curve modulus value p	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Scalar multiplier k	($0 \le k < n$)	RAM@0x520	
	Point P coordinate x_P	($x_P < p$)	RAM@0x578	
	Point P coordinate y_P	($y_P < p$)	RAM@0x5D0	
OUT	Result: $k \times P$ coordinate x'	(result < p)	RAM@0x578	EOS
	Result: $k \times P$ coordinate y'	(result < p)	RAM@0x5D0	

When performing this operation the following special cases must be noted:

- For $k = 0$ this function returns a point at infinity (0, 0) if curve parameter b is nonzero, (0, 1) otherwise. For k different from 0 it might happen that a point at infinity is returned. When the application detects this behavior, a new computation must be carried out.
- For $k < 0$ (that is, a negative scalar multiplication is required) the multiplier absolute value
  $k = |-k|$ must be provided to the PKA. After the computation completion, the formula $-P = (x, -y)$ can be used to compute the y coordinate of the effective final result (the x coordinate remains the same).

37.4.16 ECDSA sign

Table 344 (input parameters) and *Table 345* (output parameters) summarize the ECDSA signing operation.

Upon an output error different from 0xD60D, the application must generate a new k and repeat the ECDSA sign operation.

Note: As long as this operation is ongoing (BUSY = 1), the PKA control register and the PKA memory are not accessible. The access is restored when the PKA clears the BUSY bit.

Table 344. ECDSA sign - Inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x24	PKA_CR	6 bits
	Curve prime order *n* length (*nlen*)	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Integer *k*(1)	(0 ≤ *k* < n)	RAM@0x520	
	Curve base point *G* coordinate *x*	(*x* < *p*)	RAM@0x578	
	Curve base point *G* coordinate *y*	(*y* < *p*)	RAM@0x5D07	
	Hash of message *z*	(hash size equal to *nlen*)(2)	RAM@0xED0	
	Private key *d*	(0 < *d*)	RAM@0xF28	
	Curve prime order *n*	(integer prime)	RAM@0xF88	

1. This integer is usually a cryptographically secure random number, but in some cases *k* can be deterministically generated.
2. To match the hash parameter size to the length of the curve prime order *n,* pad the result with zeros or use the hash truncation.

Table 345. ECDSA sign - Outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Signature part *r*	(0 < *r* < *n*)	RAM@0x730	EOS
	Signature part *s*	(0 < *s* < *n*)	RAM@0x788	
ERROR	Result of signature	0xD60D: successful computation, no error 0xCBC9: failed computation 0xA3B7: signature part r is equal to 0 0xF946: signature part s is equal to 0	RAM@0xFE0	64 bits

Note:

Extended ECDSA support

The PKA also supports the extended ECDSA signature, which accepts the same inputs as the standard ECDSA signature (see *Table 344*) and produces similar outputs (see *Table 345*), with the addition of the point *kG* coordinates. The following table defines these additional outputs.

Table 346. Extended ECDSA sign - additional outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Curve point kG coordinate x_1	($0 \le x_1 < p$)	RAM@0x1400	EOS
	Curve point kG coordinate y_1	($0 \le y_1 < p$)	RAM@0x1458	

37.4.17 ECDSA verification

Table 347 (input parameters) and *Table 348* (output parameters) summarize the ECDSA verification operation.

Upon an output error different from 0xD60D, the signature is not verified.

Table 347. ECDSA verification - inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x26	PKA_CR	6 bits
	Curve prime order n length (*nlen*)	(in bits, not null)	RAM@0x408	64 bits
	Curve modulus p length	(in bits, not null, 8 < value < 640)	RAM@0x4C8	
	Curve coefficient a sign	0x0: positive 0x1: negative	RAM@0x468	
	Curve coefficient $\|a\|$	(absolute value, $\|a\| < p$)	RAM@0x470	EOS
	Curve modulus value p	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x4D0	
	Curve base point G coordinate x	($x < p$)	RAM@0x678	
	Curve base point G coordinate y	($y < p$)	RAM@0x6D0	
	Public-key curve point Q coordinate x_Q	($x_Q < p$)	RAM@0x12F8	
	Public-key curve point Q coordinate y_Q	($y_Q < p$)	RAM@0x1350	
	Signature part r	($0 < r < n$)	RAM@0x10E0	
	Signature part s	($0 < s < n$)	RAM@0xC68	
	Hash of message z	(hash size equal to *nlen*)(1)	RAM@0x13A8	
	Curve prime order n	(integer prime)	RAM@0x1088	

1. To match the hash parameter size to the length of the curve prime order n, pad the result with zeros or use the hash truncation.

Table 348. ECDSA verification - outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Result: ECDSA verify	– 0xD60D: valid signature – 0xA3B7: invalid signature	RAM@0x5D0	64 bits
	Computed signature part *r*	– ($0 < r < n$)	RAM@0x578	EOS

37.4.18 ECC complete addition

The ECC complete addition operation calculates the sum of two points on an elliptic curve.

Operation instructions are summarized in *Table 349*.

Note: The two input points and the resulting point are represented in Jacobian coordinates (X,Y,Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. To convert resulting point to Jacobian coordinates conversion (x, y)= (X / Z^2, Y / Z^3) can be used.

Table 349. ECC complete addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x23	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	– 0x0: positive 0x1: negative	RAM@0x410	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Curve coefficient $\|a\|$	(absolute value, $\|a\| < p$)	RAM@0x418	
	First point P coordinate *X*	($x < p$)	RAM@0x628	
	First point P coordinate *Y*	($y < p$)	RAM@0x680	
	First point P coordinate *Z*	($z < p$)	RAM@0x6D8	
	Second point Q coordinate *X*	($x < p$)	RAM@0x730	
	Second point Q coordinate *Y*	($y < p$)	RAM@0x788	
	Second point Q coordinate *Z*	($z < p$)	RAM@0x7E0	
OUT	Result coordinate *X*	($x < p$)	RAM@0xD60	
	Result coordinate *Y*	($y < p$)	RAM@0xDB8	
	Result coordinate *Z*	($z < p$)	RAM@0xE10	

37.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of $k \times P + m \times Q$, where (P, Q) are two points on an elliptic curve and (k, m) are two scalars. Operation instructions are summarized in *Table 350*.

If the resulting point is the point at infinity (error code 0xA3B7), the resulting coordinate equals to (0, 0).

Note: The two input points are represented in Jacobian coordinates (X, Y , Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. The result is represented in affine coordinates (x ,y)

This operation requires the input point Z coordinate to be equal to 1 (input point represented in affine coordinates).

Table 350. ECC double base ladder

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x27	PKA_CR	6 bits
	Curve prime order *n* length	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	– 0x0: positive – 0x1: negative	RAM@0x410	EOS
	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Integer *k*	($0 < k < 2^{640}$)	RAM@0x520	
	Integer *m*	($0 < m < 2^{640}$)	RAM@0x578	
	First point *P* coordinate *X*	($x < p$)	RAM@0x628	
	First point *P* coordinate *Y*	($y < p$)	RAM@0x680	
	First point *P* coordinate *Z*	($z < p$)	RAM@0x6D8	
	Second point *Q* coordinate *X*	($x < p$)	RAM@0x730	
	Second point *Q* coordinate *Y*	($y < p$)	RAM@0x788	
	Second point *Q* coordinate *Z*	($z < p$)	RAM@0x7E0	
OUT	Result coordinate *x*	($x < p$)	RAM@0x578	EOS
	Result coordinate *y*	(y < *p*)	RAM@0x5D0	
	Error code	– Point not at infinity: 0xD60D – Point at infinity: 0xA3B7	RAM@0x520	64 bits

37.4.20 ECC projective to affine

ECC projective to affine operation calculates the conversion between the representation of a point P in homogeneous projective coordinates and the representation of the point P in affine coordinates. Namely, if the point is represented by the triple (*X*, *Y*, *Z*), it calculates the affine coordinates (*x*, *y*) = (*X* / *Z*, *Y* / *Z*).

All the operations are performed modulo the modulus p of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0,0).

Operation instructions are summarized in *Table 351*.

Table 351. ECC projective to affine

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x2F	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	64 bits
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Point P coordinate *X* (projective)	($x < p$)	RAM@0xD60	
	Point P coordinate *Y* (projective)	($y < p$)	RAM@0xDB8	
	Point P coordinate *Z* (projective)	($z < p$)	RAM@0xE10	
	Montgomery parameter R^2 mod *n*	-	RAM@0x4C8	
OUT	Point P coordinate *x* (affine)	($x < p$)	RAM@0x578	
	Point P coordinate *y* (affine)	($y < p$)	RAM@0x5D0	
ERROR	Error code	Point not at infinity: 0xD60D Point at infinity: 0xA3B7	RAM@0x680	64 bits

37.5 Example of configurations and processing times

37.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, $y^2 = x^3 + ax + b$ (mod p).

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.
The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer *p*, used as the modulus for all point arithmetic in the finite field *GF(p)*
- the (usually prime) integer *n*, the order of the group generated by *G*, defined below
- the base point of the curve *G*, defined by its coordinates (*Gx*, *Gy*)
- the integers *a* and *b*, coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define *a* as negative, PKA supports two representations:

1. ***a* defined as *p*-|*a*|** in the finite field *GF(p)*, for example ***p*-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**F**
   Curve coefficient a sign= 0x0 (positive)
   Curve coefficient a = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**C**
2. ***a* defined as negative**, for example **-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF
   Curve coefficient a sign= 0x**1** (negative)
   Curve coefficient a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 0000000**3**

Table 352 summarizes the family of curves supported by PKA for ECC operations.

37.5.2 Computation times

The following tables summarize the PKA computation times, expressed in AHB clock cycles.

Table 353. Modular exponentiation

Exponent length (in bits)	Mode	Modulus length (in bits)			
		1024	2048	3072	4096
3	Normal	124600	491000	684000	1133200
	Fast	22700	82000	178000	311000
17	Normal	135700	531400	772400	1288000
	Fast	33800	122500	266500	465800
$2^{16} + 1$	Normal	180000	693700	1126200	1907200
	Fast	78200	284700	620400	1085000
1024	Normal	5850000	-	-	-
	Fast	5748000	-	-	-
	CRT(1)	1775000	-	-	-
2048	Normal	-	42240000	-	-
	Fast	-	41832000	-	-
	CRT(1)	-	11670000	-	-
3072	Normal	-	-	136830000	-
	Fast	-	-	136325000	-
	CRT(1)	-	-	36886000	-
4096	Normal	-	-	-	316000000
	Fast	-	-	-	315226000
	CRT(1)	-	-	-	84577000

1. CRT stands for chinese remainder theorem optimization (MODE[5:0] bitfield= 0x07).

Table 354. ECC scalar multiplication(1)

Modulus length (in bits)							
160	192	256	320	384	512	521	640
830000	1248000	2480000	4257000	6849000	14529000	16565000	25795000

1. These times depend on the number of 1s included in the scalar parameter, and include the computation of Montgomery parameter R2.

Table 355. ECDSA signature average computation time(1) (2)

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
885000	1329000	2624000	4536000	7232000	15334000	17669000	26978000

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 356. ECDSA verification average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
1011000	1495000	2938000	5014000	7979000	16804000	19254000	29582000

Table 357. ECC double base ladder average computation times

Modulus length (in bits)

967000	1419000	2768000	4784000	7547000	15854000	18257000	28257000

Table 358. ECC projective to affine average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
47600	78000	148300	253000	419000	838400	1049300

Table 359. ECC complete addition average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
10000	12000	18000	26000	39000	63000	89000

Table 360. Point on elliptic curve Fp check average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
3400	4200	6100	8300	10900	17200	-	-

Table 361. Montgomery parameters average computation times(1)

Modulus length (in bits)							
192	**256**	**320**	**512**	**1024**	**2048**	**3072**	**4096**
8600	8710	11870	17000	102000	410000	506000	822000

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

37.6 PKA interrupts

There are four individual maskable interrupt sources generated by the public key accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see *Section 37.3.7*
2. Access to unmapped address (ADDRERRF), see *Section 37.3.7*
3. PKA RAM access while PKA operation is in progress (RAMERRF), see *Section 37.3.7*
4. PKA end of operation (PROCENDF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the *PKA control register (PKA_CR)*. Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

Table 362 gives a summary of the available features.

Table 362. PKA interrupt requests

Acronym	Event	Event flag	Enable control bit	Clear method
PKA	Unsupported operation	OPERRF	OPERRIE	Set OPERRFC bit
	Access to unmapped address error	ADDRERRF	ADDRERRIE	Set ADDRERRFC bit
	PKA RAM access error	RAMERRF	RAMERRIE	Set RAMERRFC bit
	PKA end of operation	PROCENDF	PROCENDIE	Set PROCENDFC bit

37.7 PKA registers

37.7.1 PKA control register (PKA_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPERRIE	ADDRERRIE	RAMERRIE	Res.	PROCENDIE	Res.
										rw	rw	rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MODE[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	START	EN
		rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:8 **MODE[5:0]**: PKA operation code

000000: Montgomery parameter computation then modular exponentiation
000001: Montgomery parameter computation only
000010: Modular exponentiation only (Montgomery parameter must be loaded first)
100000: Montgomery parameter computation then ECC scalar multiplication
100100: ECDSA sign
100110: ECDSA verification
101000: Point on elliptic curve Fp check
000111: RSA CRT exponentiation
001000: Modular inversion
001001: Arithmetic addition
001010: Arithmetic subtraction
001011: Arithmetic multiplication
001100: Arithmetic comparison
001101: Modular reduction
001110: Modular addition
001111: Modular subtraction
010000: Montgomery multiplication
100011: ECC complete addition
100111: ECC double base ladder
101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE[5:0] bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE[5:0] different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE[5:0] bit is ignored.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **START**: start the operation

Set this bit to start the operation selected by the MODE[5:0] bitfield, using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

Note: START is ignored if PKA is busy.

Bit 0 **EN**: PKA enable

0: Disable PKA
1: Enable PKA

When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE[5:0] bitfield for details.

Note: When EN = 0, PKA RAM can still be accessed by the application.

37.7.2 PKA status register (PKA_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPERRF	ADDRERRF	RAMERRF	Res.	PROCENDF	BUSY
										r	r	r		r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	LMF	INITOK
														r	r

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRF**: Operation error flag

0: No event error

1: An illegal or unknown operation has been selected in PKA_CR register

This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag

0: No address error

1: Address access is out of range (unmapped address)

This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag

0: No PKA RAM access error

1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).

This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag

0: Operation in progress

1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag

This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.

0: No operation is in progress (default)

1: An operation is in progress

If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bits 15:2 Reserved, must be kept at reset value.

Bit 1 **LMF**: Limited mode flag

This bit is updated when EN bit in PKA_CR is set

0: All values documented in MODE[5:0] bitfield can be used.

1: Only ECDSA verification (MODE[5:0] = 0x26) is supported by the PKA.

Bit 0 **INITOK**: PKA initialization OK

This bit is asserted when PKA initialization is complete.

0: PKA is not initialized correctly. START bit cannot be set.

1: PKA is initialized correctly and can be used normally.

37.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OPERRFC	ADDRERRFC	RAMERRFC	Res.	PROCENDFC	Res.
										w	w	w		w	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:22 Reserved, must be kept at reset value.

Bit 21 **OPERRFC**: Clear operation error flag
- 0: No action
- 1: Clear the OPERRF flag in PKA_SR

Bit 20 **ADDRERRFC**: Clear address error flag
- 0: No action
- 1: Clear the ADDRERRF flag in PKA_SR

Bit 19 **RAMERRFC**: Clear PKA RAM error flag
- 0: No action
- 1: Clear the RAMERRF flag in PKA_SR

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDFC**: Clear PKA end of operation flag
- 0: No action
- 1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

Note: Reading PKA_CLRFR returns all 0s.

37.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA.AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

Note: PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 37.3.3: PKA reset and clocks.

37.7.5 PKA register map

Table 363. PKA register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

38 Public key secure accelerator (PKA)

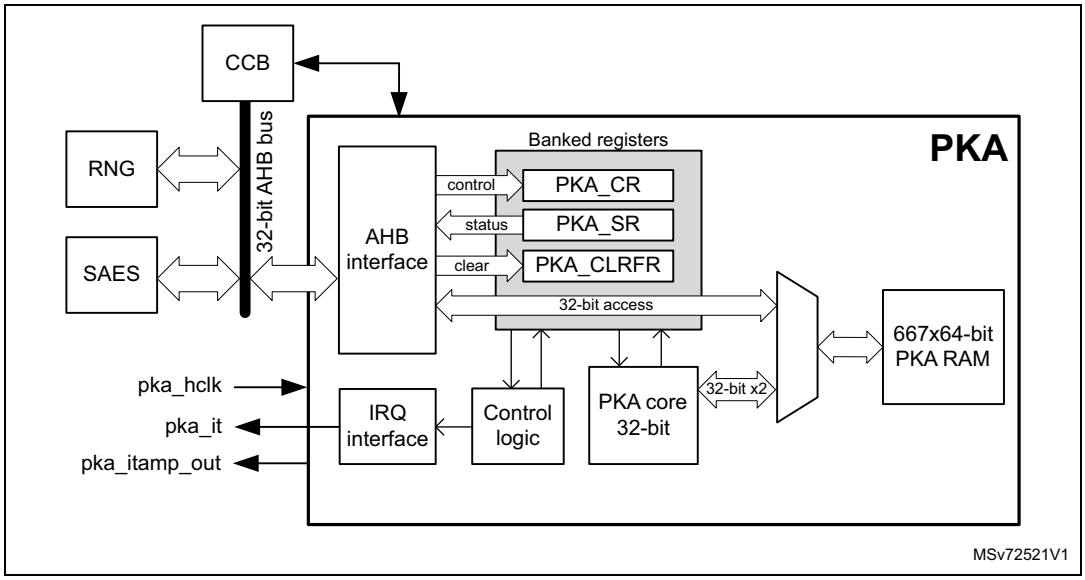
This section only applies to the STM32G56x (fully) and STM32G55x (only the ECDSA signature verification part) devices.

38.1 PKA introduction

PKA (public key secure accelerator) is intended for the computation of cryptographic public key primitives, specifically those related to RSA, Diffie-Hellmann or ECC (elliptic curve cryptography) over GF(p) (Galois fields). To achieve high performance at a reasonable cost, these operations are executed in the Montgomery domain.

For a given operation, the accelerator performs all computations with no further hardware or software elaboration required to process the inputs or the outputs.

For manipulating secrets, the PKA incorporates a protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.



38.2 PKA main features

- Acceleration of RSA, DH and ECC over GF(p) operations, based on the Montgomery method for fast modular multiplications. More specifically:
  - RSA modular exponentiation, RSA chinese remainder theorem (CRT) exponentiation
  - ECC scalar multiplication, point on curve check, complete addition, double base ladder, projective to affine
  - ECDSA signature generation and verification
- Capability to handle operands up to 4160 bits for RSA/DH and 640 bits for ECC
- When manipulating secrets: protection against side-channel attacks (SCA), including differential power analysis (DPA), required for SESIP and PSA security assurance level 3 target.
  - Applicable to modular exponentiation, ECC scalar multiplication and ECDSA signature generation
- Arithmetic and modular operations such as addition, subtraction, multiplication, modular reduction, modular inversion, comparison, and Montgomery multiplication
- Built-in Montgomery domain inward and outward transformations
- AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Support for CCB chaining operations required to protect private key used in PKA protected operations
- Hardware protections to monitor usage of private keys during protected operation initialization

38.3 PKA functional description

38.3.1 PKA block diagram

Figure 348. PKA block diagram

38.3.2 PKA internal signals

Table 364 lists the internal signals available at the PKA level, not necessarily available on product bonding pads.

Table 364. Internal input/output signals

Signal name	Signal type	Description
pka_hclk	Digital input	AHB bus clock
pka_it	Digital output	Public key secure accelerator IP global interrupt request
pka_itamp_out	Digital output	PKA internal tamper event signal to TAMP (XOR-ed), triggered when an unexpected fault occurs while PKA manipulates secrets, or when the programmed input point is not found on the input curve (ECDSA signature and ECC scalar multiplication only). A tamper is also generated if application does not respect the maximum supported size of operands, or when PKA finds a fault in critical configuration registers(1). This signal is asserted as soon as a fault is detected. When asserted, read access to PKA registers are reset to 0 and writes are ignored. The signal is de-asserted when PKA memory is cleared.

1. When tamper is active, the AHB interface is blocked: RAM and register reads are 0-ed and writes are ignored. There is no PKA RAM erase.

38.3.3 PKA reset and clocks

PKA is clocked on the AHB bus clock. When the PKA peripheral reset signal is released PKA_RAM is cleared automatically, taking 2000 clock cycles. During this time the setting of bit EN in PKA_CR register is ignored. Once EN bit is set, refer to *Section 38.3.6* for details about PKA initialization sequence.

According to the security policy applied to the device, PKA RAM can also be reset following a tamper event. Refer to *Tamper detection and response* in the System security section (if applicable to this product).

38.3.4 PKA public key acceleration

Overview

Public key secure accelerator (PKA) is used to accelerate Rivest, Shamir and Adleman (RSA), Diffie-Hellman (DH) as well as ECC over prime field operations. Supported operand sizes is up to 4160 bits for RSA and DH, and up to 640 bits for ECC.

The PKA supports all non-singular elliptic curves defined over prime fields, that can be described with a short Weierstrass equation $y^2 = x^3 + ax + b$ (mod p). More information can be found in *Section 38.5.1*.

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.

A memory of 5336 bytes (667 words of 64 bits) called PKA RAM is used to provide initial data to the PKA, and to hold the results after computation is completed. Access is done though the PKA AHB interface.

PKA operating modes

The list of operations the PKA can perform is detailed in *Table 365* and *Table 366*, respectively, for integer arithmetic functions and prime field (Fp) elliptic curve functions.

Table 365. PKA integer arithmetic functions list

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x01	000001	Montgomery parameter computation R^2 mod *n*	*Section 38.4.2*
0x0E	001110	Modular addition (A+B) mod n	*Section 38.4.3*
0x0F	001111	Modular subtraction (A-B) mod n	*Section 38.4.4*
0x10	010000	Montgomery multiplication (AxB) mod n	*Section 38.4.5*
0x00	000000	Modular exponentiation A^e mod n	*Section 38.4.6*
0x02	000010	Modular exponentiation A^e mod n (fast mode)	
0x03	000011	Modular exponentiation A^e mod n (protected)	*Section 38.4.6*
0x08	001000	Modular inversion A^{-1} mod n	*Section 38.4.7*
0x0D	001101	Modular reduction A mod n	*Section 38.4.8*
0x09	001001	Arithmetic addition A+B	*Section 38.4.9*
0x0A	001010	Arithmetic subtraction A-B	*Section 38.4.10*
0x0B	001011	Arithmetic multiplication AxB	*Section 38.4.11*

Table 365. PKA integer arithmetic functions list (continued)

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x0C	001100	Arithmetic comparison (A=B, A>B, A<B)	*Section 38.4.12*
0x07	000111	RSA CRT exponentiation	*Section 38.4.13*

Table 366. PKA prime field (Fp) elliptic curve functions list

PKA_CR.MODE[5:0]		Performed operation	Reference
Hex	Binary		
0x28	101000	Point on elliptic curve Fp check	*Section 38.4.14*
0x20	100000	ECC scalar multiplication kP (protected)	*Section 38.4.15*
0x23	100011	ECC complete addition	*Section 38.4.18*
0x24	100100	ECDSA sign (protected)	*Section 38.4.16*
0x26	100110	ECDSA verification	*Section 38.4.17*
0x27	100111	ECC double base ladder	*Section 38.4.19*
0x2F	101111	ECC projective to affine	*Section 38.4.20*

Each of these operating modes has an associated code that has to be written to the MODE[5:0] bitfield in the PKA_CR register. If the application selects any value that is not documented below the write to MODE[5:0] bitfield is ignored, and an operation error (OPERRF) is triggered. When this happens, a new operation must be selected after the error is cleared.

Some operations in *Table 365* and *Table 366* are indicated as protected. Those operations are used when manipulating secret keys (modular exponentiation for RSA decryption, scalar multiplication and signature for ECC). Those secrets (protected against side channel attacks) and any intermediate values are automatically erased when PKA RAM is cleared at the end of the protected operations (BUSY goes low). They are also protected against side channel attacks.

Caution: For security reason it is very important to select protected modular exponentiation (MODE[5:0] = 0x3) when performing RSA decryption.

Montgomery space and fast mode operations

For efficiency reasons, the PKA internally performs modular multiply operations in the Montgomery domain, automatically performing inward and outward transformations.

As Montgomery parameter computation is time consuming, the application can decide to use a faster mode of operation during which the precomputed Montgomery parameter is supplied before starting the operation. The performance improvement is detailed in *Section 38.5.2: Computation times*.

The only operation using fast mode is the modular exponentiation (MODE[5:0] = 0x02).

38.3.5 Typical applications for PKA

Introduction

The PKA can be used to accelerate a number of public key cryptographic functions such as:

- RSA encryption and decryption
- RSA key finalization
- CRT-RSA decryption
- DSA and ECDSA signature generation and verification
- DH and ECDH key agreement

The following publications specify the listed functions:

- FIPS PUB 186-4, Digital Signature Standard (DSS), July 2013 by NIST
- PKCS #1, RSA Cryptography Standard, v1.5, v2.1 and v2.2. by RSA Laboratories
- IEEE1363-2000, IEEE Standard Specifications for Public-Key Cryptography, January 2000
- ANSI X9.62-2005, Public Key Cryptography for the Financial Services Industry, The Elliptic Curve Digital Signature Algorithm (ECDSA), November 2005

Refer to these documents for full details. This document limits itself to describing principles.

RSA key pair

For the following RSA operations, a public key and a private key information are defined as follows:

- Alice transmits her public key (*n*, *e*) to Bob. Numbers *n* and *e* are very large positive integers.
- Alice keeps secret her private key d, also a very large positive integer. Alternatively, this private key can also be represented by a quintuple (p, q, dp, dq, qInv).

For more information, refer to the RSA specification.

RSA encryption/decryption principle

As recommended by the PKCS#1 specification, Bob, to encrypt message M using Alice's public key (*n*, *e*), must go through the following steps:

1. Compute the encoded message EM = ENCODE(M), where ENCODE is an encoding method.
2. Turn EM into an integer *m*, with $0 \leq m < n$ and (*m*, *n*) being coprimes.
3. Compute ciphertext $c = m^e \bmod n$.
4. Convert the integer c into a string ciphertext C.

Alice, to decrypt ciphertext c using her private key *d*, follows the steps indicated below:

1. Convert the ciphertext C to an integer ciphertext representative c.
2. If necessary, retrieve the prime factors (p, q) using (n, e, d) information, then compute phi = (p - 1) × (q - 1). Refer to NIST SP800-56B Appendix C for details.
3. Recover plaintext $m = c^d \bmod n = (m^e)^d \bmod n$. If the private key is the quintuple (p, q, dp, dq, qInv), then plaintext *m* is obtained by performing the operations:
   a) $m_1 = c^{dp} \bmod p$
   b) $m_2 = c^{dq} \bmod q$
   c) $h = qInv\,(m_1 - m_2) \bmod p$
   d) $m = m_2 + h\,q$
4. Convert the integer message representative *m* to an encoded message EM.
5. Recover message M = DECODE(EM), where DECODE is a decoding method.

To accelerate these operations with the PKA, use *Modular exponentiation* $A^e \bmod n$ if the private key is *d*, or *RSA CRT exponentiation* if the private key is the quintuple (p, q, dp, dq, qInv).

Note: The decoding operation and the conversion operations between message and integers are specified in PKCS#1 standard.

For the decryption process, the protected version of modular exponentiation (MODE[5:0] = 0x3) is strongly recommended for security reason. For the encryption process, the MODE[5:0] = 0x3 setting cannot be used as it requires the knowledge of the private key.

Elliptic curve selection

For the following ECC operations, the curve parameters are defined as follows:

- Curve corresponds to the elliptic curve field agreed among actors (Alice and Bob). Supported curves parameters are summarized in *Section 38.5.1: Supported elliptic curves*.
- G is the chosen elliptic curve base point (also known as generator), with a large prime order n (that is, $n \times G$ = identity element O).

ECDSA message signature generation

This section describes the ECDSA (elliptic curve digital signature algorithm) signature generation function principle.

Alice, to sign a message *m* using her private key integer d_A, goes through the following steps:

1. Calculate e = HASH(*m*), where HASH is a cryptographic hash function.
2. Let z be the L_n leftmost bits of e, where L_n is the bit length of the group order *n*.
3. Select a cryptographically secure random integer k where $0 < k < n$.
4. Calculate the curve point $(x_1, y_1) = k \times G$.
5. Calculate $r = x_1 \bmod n$. If $r = 0$ go back to step 3.
6. Calculate $s = k^{-1}\,(z + rd_A) \bmod n$. If $s = 0$ go back to step 3.
7. The signature is the pair (*r*, *s*).

The PKA accelerates the steps 4. to 7. by using:

- *ECDSA sign*, or
- All of the following operations:
  - *ECC Fp scalar multiplication* $k \times P$
  - *Modular reduction* A mod n
  - *Modular inversion* A^{-1} mod n
  - *Modular addition* and *Modular and Montgomery multiplication*

ECDSA signature verification

This section describes the ECDSA (elliptic curve digital signature algorithm) signature verification function principle.

Bob, to authenticate Alice's signature, must have a copy of her public key curve point Q_A. Bob can verify that Q_A is a valid curve point by going through the following steps:

1. Check that Q_A is not equal to the identity element O
2. Check that Q_A is on the agreed curve
3. Check that $n \times Q_A = O$.

Then Bob executes the following procedure:

1. Verify that r and s are integer in [1, n-1]
2. Calculate e = HASH(m), where HASH is the agreed cryptographic hash function
3. Let z be the L_n leftmost bits of e
4. Calculate $w = s^{-1}$ mod n
5. Calculate $u_1 = zw$ mod n and $u_2 = rw$ mod n
6. Calculate the curve point $(x_1, y_1) = u_1 \times G + u_2 \times Q_A$
7. The signature is valid if $r = x_1$ (mod n), it is invalid otherwise.

The PKA accelerates the steps 4. to 7. by using *ECDSA verification*.

38.3.6 PKA procedure to perform an operation

Enabling/disabling PKA

Setting the EN bit in the PKA_CR register enables the PKA peripheral. The PKA becomes available when the INITOK bit is set in the PKA_SR register. When EN = 0, the PKA peripheral is kept under reset, with its memory still accessible by the application through the AHB interface.

Note: When the PKA is in the process of clearing its memory, the EN bit cannot be set.

When setting the EN bit in PKA_CR, make sure that the MODE[5:0] bitfield value corresponds to an authorized PKA operation (see OPERRF in Section 38.3.8).

Clearing the EN bit while a calculation is in progress aborts the operation. In this case, the content of the PKA memory is not guaranteed, with the exception of the PKA modes 0x03, 0x20 and 0x24. For these operations, the PKA memory is cleared after abort, making the memory unavailable for 667 cycles. During this clearing time only the PKA registers can be accessed, with writes to EN bits ignored.

If the INITOK bit stays at 0, make sure that the RNG peripheral is clocked and properly initialized, then try to enable the PKA again.

Data formats

The format of the input data and the results in the PKA RAM are specified, for each operation, in *Section 38.4*.

Executing a PKA operation

To execute any of the supported PKA operations, proceed as follows:

1. Load initial data into the PKA internal RAM, which is located at address offset 0x400.
2. Write in the MODE[5:0] bitfield of PKA_CR register, specifying the operation which is to be executed and then assert the START bit, also in PKA_CR register.
3. Wait until the PROCENDF bit in the PKA_SR register is set, indicating that the computation is complete.
4. Read the result data from the PKA internal RAM, then clear PROCENDF bit by setting PROCENDFC bit in PKA_CLRFR.

Note: When PKA is busy (BUSY = 1), any access by the application to PKA RAM is ignored, and the RAMERRF flag is set in PKA_SR.

Selecting an illegal or unknown operation in step *2* triggers an OPERRF error and prevents the PROCENDF flag from being set and the procedure step *3* from being completed. See *Section 38.3.8* for details.

Using precomputed Montgomery parameters (PKA fast mode)

As explained in *Section 38.3.4*, when computing many operations with the same modulus, it can be beneficial for the application to compute the corresponding Montgomery parameter only once (see, for example, *Section 38.4.5*). This is referred to as *fast mode*.

To use the PKA peripheral in fast mode, follow this recommended procedure:

1. Load the modulus size and value information into the PKA RAM. Refer to *Section 38.5.1* for detail.
2. Configure the PKA_CR register to *Montgomery parameter computation* mode (MODE[5:0] = 0x1), then assert the START bit.
3. Wait until the PROCENDF bit in the PKA_SR register is set. Then, read the corresponding Montgomery parameter from the PKA memory and clear the PROCENDF bit by setting PROCENDFC in PKA_CLRFR.
4. Continue with the required PKA operation, loading the Montgomery information R2 mod *m* on top of the regular input data. Relevant addresses are provided in *Section 38.4*.

38.3.7 Private keys protection using CCB

Chaining modes

As shown in *Figure 349*, setting CCOP to a value different from 0 in the CCB peripheral automatically activates a chaining mechanism between PKA, RNG, and SAES, depending on the OPSTEP value (see *Table 367*), then sets the CCEN bit in the PKA_SR register.

For the effect of different OPSTEP values in each protected operation (ECDSA signature, scalar multiplication, modular exponentiation), refer to *Section 38.3.7: Private keys protection using CCB*.

Figure 349. Chaining of PKA with SAES or RNG

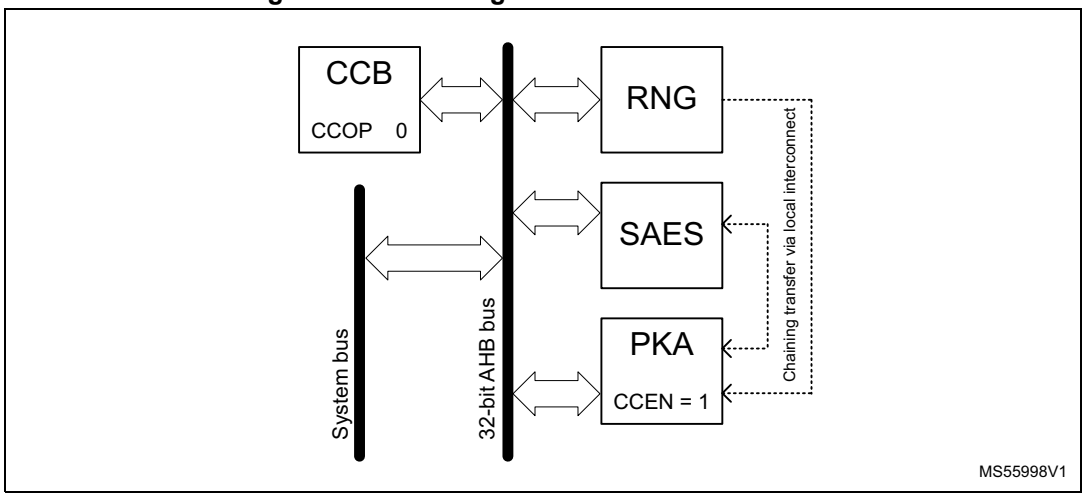


Table 367. Chaining mode to/from PKA

CCOP		OP STEP	Expected MODE[5:0] (1)	Chaining traffic(2)	Protected parameter written to PKA RAM	Expected flags(3)
x	0xC3	0x1	0x24	N/A	Hash (unprotected)	N/A
ECDSA signature	0xC0 or 0xC2	0x3	0x24	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0xC3	0x13				
		0x14		SAES → PKA	Decrypted private key d	DATAOKF or CMF error
		0x16		RNG → PKA	Random integer k	RNGOKF or CMF error
	0xC0	0x4		N/A	Clear text private key d	DATAOKF or CMF error
	0xC2	0x6		RNG → PKA	Random private key d	RNGOKF or CMF error
	0xC0 or 0xC2	0x8		PKA → SAES	Clear-text private key d	DATAOKF or CMF error
Scalar multiplication	0x80 or 0x82	0x3	0x20	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0x81	0x13				
		0x14		SAES → PKA	Decrypted k	DATAOKF or CMF error
	0x80	0x04		N/A	Clear text scalar mult k	
	0x82	0x6		RNG → PKA	Random scalar mult k	RNGOKF or CMF error
	0x80 or 0x82	0x8		PKA → SAES	Clear-text scalar mult k	DATAOKF or CMF error

Table 367. Chaining mode to/from PKA (continued)

CCOP		OP STEP	Expected MODE[5:0] (1)	Chaining traffic(2)	Protected parameter written to PKA RAM	Expected flags(3)
Modular exponentiation	0x44	0x3	0x3	CPU → PKA + SAES(4)	Integrity protected parameters(5)	CMF error only
	0x45	0x13				
		0x14		SAES → PKA	Decrypted exponent e	DATAOKF or CMF error
		0x15			Decrypted phi	
	0x44	0x4		N/A	Clear text exponent e	
		0x5			Clear text phi	
		0x8		PKA → SAES	Clear text exponent e	
		0x9			Clear text phi	

1. This mode must be written in PKA_CR before the START bit is set in PKA_CR.
2. Chaining traffic triggered by the CPU access to PKA RAM. “N/A” means no chaining traffic, only CPU traffic.
3. In PKA_SR bits 8 to 15 (“CMF error” refers to error flag bits 8 to 14).
4. In this mode chaining traffic includes the 32-bit data word plus the 32-bit physical address to PKA RAM.
5. Defined in *Table 368*.

When the application uses a PKA protected operation (with its private key), it must load the related blob information in the PKA RAM and in the SAES_DINR register. If the information exactly matches the conditions of the blob generation (the choice and order of writing protected parameters in PKA RAM, the selection of blob encryption key, and the usage of the original encrypted secrets), the CCB allows it to set the START bit in PKA_CR. When the PKA ignores the setting of the START bit, the application must reset the CCB using the IPRST bit in CCB_CR, then start the protected operation sequence again.

A protected application typically uses the PKA in the following sequence composed of three phases.

Step 1: Public phase

Before using a protected operation, the application may need to write unprotected parameters to the PKA RAM, as defined in *Table 367*.

Step 2: Integrity protected phase

To use a PKA operation, the application must load specific parameters in PKA RAM. When CCEN bit is set in PKA_SR, the integrity protected parameters defined in *Table 368* must always be written in the same way. Integrity protection is enforced in specific OPSTEPs, as defined in *Table 367*.

Typical issues with integrity of protected operation parameters are:

- The blob encryption key loaded in SAES registers is not correct.
- At least one confidentiality protected parameter defined in *Table 369* has an incorrect value, or was not properly written (DATAOKF = 0 or RNGOKF = 0, see *PKA status register (PKA_SR)*).
- At least one integrity protected parameter defined in *Table 368* has an incorrect value, is written at an incorrect address, or its write sequence to PKA RAM does not match

the sequence used during the blob creation. On this specific point, the application must follow the sequence detailed in *Table 368* when writing each item described in the column *Parameters*.

CCB feeds integrity protected parameters to SAES during the header phase of AES-GCM (GCMPH = 0x1).

Table 368. Integrity protected parameters list

Protected operation blob(1)	Parameters
ECC key blob	Curve prime order *n* length, curve modulus *p* length, curve coefficient *a* sign, curve coefficient |*a*|, curve coefficient *b*, curve modulus value *p*, curve prime order *n*
ECC signature blob	Same as scalar multiplication operation, adding curve base point G coordinates *x* and *y*
RSA key blob	Exponent *e* length, operand length, modulus value *n*

1. See *Table 369* for more details.

Step 3: Confidentiality phase

To use any PKA protected operation, the application must load confidentiality protected parameters in the PKA RAM. When the CCEN bit is set in PKA_SR, the parameters defined in *Table 369* are protected in confidentiality by:

- Making PKA RAM write-only
- Triggering a MODE[5:0] error (MDERRF) in PKA_SR when MODE[5:0] bitfiled in PKA_CR does not match the expected value when application sets START bit in PKA_CR
- Monitoring the correct management of protected parameters through DATAOKF and RNGOKF flags (see *PKA status register (PKA_SR)*)
- Optionally, generating ECC secrets from the on-chip TRNG when CCOP = 0xC2 or 0x82 and OPSTEP = 0x6, and when CCOP = 0xC3 and OPSTEP = 0x16. The PKA performs a sanity check before accepting this random value (see the RNGERRF flag).

Confidentiality protected parameters are described in *Table 369*. CCB feeds them to SAES during the payload phase of the AES-GCM (GCMPH = 0x2).

Table 369. Confidentiality protected parameter list

PKA operation	Secrets	Protected operation blob(1)	Start offset in PKA RAM	Size(2)
Modular exponentiation (protected, MODE[5:0] = 0x3)	Exponent e	RSA key blob	@0x14B8	ROS
	Phi value		@0xC68	
Scalar multiplication (MODE[5:0] = 0x20)	Scalar k	ECC key blob	@0x12A0	EOS
ECDSA signature (MODE[5:0] = 0x24)	Integer k	Not available	@0x12A0	EOS
	Private key d	ECC signature blob	@0xF28	

1. Information blob where confidentiality and integrity protected parameters are stored (see also *Table 368*)
2. See *Section 38.4.1* for details

Step 4: Running PKA protected operation

Set the START bit in PKA_CR. When the whole sequence executes correctly, the PKA RAM becomes inaccessible for reading and writing. Input parameters are automatically erased when the PROCENDF flag in PKA_SR is set, or if the application aborts the current operation by clearing the EN bit in PKA_CR.

38.3.8 PKA error management

The following error flags in the PKA_SR register are set to indicate errors that may occur when using the PKA:

- **ADDRERRF** flags that the access to PKA RAM falls outside the expected range.
- **RAMERRF** flags an AHB access to the PKA RAM occurring while the PKA core uses the PKA RAM. While the flag is set, reads form the PKA RAM return 0 and writes are ignored.
- **OPERRF** flags that the selected operating mode using MODE[5:0] bitfield is not listed in PKA operating modes (see the bitfield description), or PKA is running in limited mode (see LMF bit in PKA_SR). While the flag is set, writes to the MODE[5:0] bitfield are ignored.
- An ongoing chaining mode sequence error raises the chaining mode flag **CMF** and the corresponding error flag:
  - **INCRERRF** flags increment error
  - **DATAZF** flags data zeroed error
  - **TRZERRF** flags trailing zeros error
  - **MDERRF** flags mode error
  - **RNGERRF** flags RNG error

  For details on each flag and on enabling the chaining mode sequence, see *Section 38.7.2*.

For each error flag, the PKA generates an interrupt if enabled with the corresponding bit in the PKA_CR register (see *Section 38.6* for details).

The ADDRERRF, OPERRF, and RAMERRF error flags are cleared by setting the ADDRERRFC, OPERRFC, and RAMERRFC bit in PKA_CLRFR, respectively. The OPERRF error flag must be cleared before a new operation is initiated via the PKA_CR register.

Upon an ongoing chaining mode sequence error, the application must set the CMFC bit in the PKA_CLRFR register, then restart the ongoing protected operation sequence in the CCB peripheral.

Note: The PKA can be re-initialized at any moment by clearing the EN bit in the PKA_CR register.

38.4 PKA operating modes

38.4.1 Introduction

The operations supported by the PKA are detailed in the following subsections, which define the format of both input data and results stored in the PKA RAM.

Warning: Before starting any operation, ensure that all input parameters to the PKA are valid and consistent, as the PKA assumes their correctness. Additionally, input parameters must not exceed the operand sizes specified in the operation tables.

The following information applies to all PKA operations:

- The PKA core processes 64-bit words in its RAM. Accordingly, in the PKA section of this document, 'word' denotes a 64-bit unit.
- When writing an element as input in the PKA RAM, append an additional 64-bit word of zeros after the most significant word, except when the operand size is fixed at one word.
- All RAM storage addresses refer to the least significant word of the data. To obtain the actual address, the application must add the base address of the PKA to the indicated offset.
- Supported operand sizes are:
  - **ROS (RSA operand size)**: Data size is calculated as *(rsa_size / 64) + 1* words, where *rsa_size* is the modulus length in bits. For example, a 1024-bit RSA operand corresponds to 17 words (1088 bits).
  - **EOS (ECC operand size)**: Data size is *(ecc_size / 64) + 1* words, where *ecc_size* is the prime modulus length in bits. For example, a 192-bit ECC operand corresponds to four words (256 bits).

  Note: Both ROS and EOS include the additional zero word.
- Unless indicated otherwise, all operands in the tables are integers.

Note: Any fractional results in the formulas must be rounded to the nearest integer, as the PKA core processes data in 64-bit words.

Note: The maximum ROS is 66 words (4160-bit maximum exponent size), while the maximum EOS is 11 words (640-bit max operand size).

Example 1: Understanding endianness in PKA memory during ECC Fp scalar multiplication preparation

Write the *x*-coordinate of point P for an ECC P256 curve (EOS = 5 words) by placing the least significant bit at bit 0 of the word at address offset 0x578, and the most significant bit at bit 63 of the word at address offset 0x590. Then, write a zero word (0x0000000000000000) at address offset 0x598.

Example 2: Writing the curve coefficient '*a*' for ECC Fp scalar multiplication

To write the value *a* = -3 for a curve with a modulus length of 224 bits (rounded up to five 64-bit words), write the PKA memory with data as in the following table:

Table 370. Example of *'a'* curve coefficient for ECC Fp scalar

RAM offset	Value	Note
0x410	0x0000000000000001	Curve coefficient *a* sign without extra word
0x418	0x0000000000000011	Value of |*a*| LSB

Table 370. Example of *'a'* curve coefficient for ECC Fp scalar

RAM offset	Value	Note
0x420	0x0000000000000000	-
0x428	0x0000000000000000	-
0x430	0x0000000000000000	Value of |*a*| MSB
0x438	0x0000000000000000	Additional zero word

38.4.2 Montgomery parameter computation

This function is used to compute the Montgomery parameter (R^2 mod n) used by the PKA to convert operands into the Montgomery residue system representation. This operation can be very useful for fast mode operation because passing the Montgomery parameter as input saves the time for its computation.

Note: This operation also supports ECC curves when specifying the prime modulus length and EOS size.

The following table summarizes operation instructions for Montgomery parameter computation.

Table 371. Montgomery parameter computation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x01	PKA_CR	6 bits
	Modulus length	(in bits, 0 ≤ value < 4160)	RAM@0x408	64 bits
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	ROS
OUT	Result: R^2 mod *n*	-	RAM@0x620	

38.4.3 Modular addition

The following table summarizes operation instructions for modular addition operation that calculates *A* + *B* mod *n*.

Table 372. Modular addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0E	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	(0 ≤ *A* < *n*)	RAM@0xA50	ROS
	Operand *B*	(0 ≤ *B* < *n*)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: *A* + *B* mod *n*	(0 ≤ result < *n*)	RAM@0xE78	

38.4.4 Modular subtraction

Modular subtraction operation calculates:

- ***A* - *B* mod *n***, when $A \geq B$
- ***A* + *n* - *B* mod *n***, when $A < B$

The following table summarizes the operation instructions.

Table 373. Modular subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0F	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \leq A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \leq B < n$)	RAM@0xC68	
	Modulus value *n*	($n < 2^{4160}$)	RAM@0x1088	
OUT	Result: *A* - *B* mod *n*	($0 \leq$ result $< n$)	RAM@0xE78	

38.4.5 Modular and Montgomery multiplication

To be more efficient when performing a sequence of multiplications, the PKA accelerates a multiplication that has at least one input in the Montgomery domain. The two main uses of this operation are:

- Map a value from natural domain to Montgomery domain and vice-versa
- Perform a modular multiplication $A \times B \bmod n$

The method to perform these operations is described next. The *x* function is this operation, and the *A*, *B*, and *C* operands are in the natural domain.

1. Inward or outward conversion to or from the Montgomery domain
   a) Assuming that *A* is an integer in the natural domain:
      – Compute *r2modn* using *Montgomery parameter computation*.
      – The result of $AR = A \times r2modn \bmod n$ is *A* in the Montgomery domain.
   b) Assuming that *BR* is an integer in the Montgomery domain:
      – The result of $B = BR \times 1 \bmod n$ is *B* in the natural domain.
      – Similarly, the *AR* value computed in *a)* can be converted into the natural domain by computing $A = AR \times 1 \bmod n$.
2. Simple modular multiplication $A \times B \bmod n$
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute $AR = A \times r2modn \bmod n$. The output is in the Montgomery domain.
   c) Compute $AB = AR \times B \bmod n$. The output is in the natural domain.
3. Multiple modular multiplication $A \times B \times C \bmod n$
   a) Compute *r2modn* using *Montgomery parameter computation*.
   b) Compute $AR = A \times r2modn \bmod n$. The output is in the Montgomery domain.
   c) Compute $BR = B \times r2modn \bmod n$. The output is in the Montgomery domain.
   d) Compute $ABR = AR \times BR \bmod n$. The output is in the Montgomery domain.
   e) Compute $CR = C \times r2modn \bmod n$. The output is in the Montgomery domain.
   f) Compute $ABCR = ABR \times CR \bmod n$. The output is in the Montgomery domain.
   g) (optional) Repeat the two previous steps if multiplying with additional operands is required.
   h) Compute $ABC = ABCR \times 1 \bmod n$ to retrieve the result in the natural domain.

The following table summarizes the operation instructions.

Table 374. Montgomery multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x10	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < n$)	RAM@0xC68	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: $A \times B \bmod n$(1)	-	RAM@0xE78	

1. Result in Montgomery domain or in natural domain, depending upon the inputs nature (see examples *2* and *3*).

38.4.6 Modular exponentiation

Modular exponentiation operation is commonly used to perform a single-step RSA operation. It calculates of $A^e \bmod n$.

RSA operation involving public information (RSA encryption) can use the normal or fast mode detailed on *Table 375* and *Table 376*. RSA operation involving secret information (RSA decryption) must use the protected mode detailed on *Table 377*, for security reason.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware.

Note: When MODE[5:0] = 0x03, the error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

Operation instructions for modular exponentiation are summarized in *Table 375* (normal mode), *Table 376* (fast mode), and *Table 377* (protected mode). Fast mode usage is explained in *Section 38.3.6*.

Table 375. Modular exponentiation (normal mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x00	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	

Table 376. Modular exponentiation (fast mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x02	PKA_CR	6 bits
IN	Exponent length	(in bits, not null)	RAM@0x400	64 bits
	Operand length	(in bits, not null)	RAM@0x408	
IN/OUT	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0xC68	ROS
IN	Exponent *e*	($0 \le e < n$)	RAM@0xE78	
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0x1088	
IN/OUT	Montgomery parameter R^2 mod *n*	(mandatory)	RAM@0x620	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	

Table 377. Modular exponentiation (protected mode)

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x03	PKA_CR	6 bits
	Exponent *e* length	(in bits, not null)	RAM@0x400	64 bits
	Modulus or operand length	(in bits, not null)	RAM@0x408	
	Operand *A* (base of exponentiation)	($0 \le A < n$)	RAM@0x16C8	ROS
	Exponent *e*	($0 \le e < n$)	RAM@0x14B8	
	Modulus value *n*	(odd integer only, $n < 2^{4096}$)	RAM@0x0838	
	Phi value(1)	-	RAM@0x0C68	
OUT	Result: A^e mod *n*	($0 \le$ result $< n$)	RAM@0x838	
ERROR	Error A^e mod *n*	No errors: 0xD60D Errors: 0xCBC9	RAM@0x1298	64 bits

1. Euler totient function of n[1] with phi = (p - 1) × (q - 1), where p and q are prime factors of modulus n (see NIST SP800-56B Appendix C or *RSA encryption/decryption principle* for details). As optimization it is recommended to keep phi information as part of the key pair generation. Alternative is to store the key as (p, q, e, d) instead of (N, e, d, *phi*), in this case, to derive N and *phi* using PKA arithmetic multiplier: $N = p \times q$, and *phi* = (p - 1) × (q - 1).

38.4.7 Modular inversion

The modular inversion operation calculates multiplicative inverse A^{-1} mod n. If the modulus n is prime, for all values of A ($1 \le A < n$) modular inversion output is valid. If the modulus n is not prime, A has an inverse only if the greatest common divisor between A and n is 1.

If the operand A is a divisor of the modulus n the result is a multiple of a factor of n.

The following table summarizes the operation instructions.

Table 378. Modular inversion

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x08	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < n$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result: A^{-1} mod *n*	0 < result < *n*	RAM@0xE78	

38.4.8 Modular reduction

The modular reduction operation calculates the remainder of A divided by n.

The following table summarizes the operation instructions.

Table 379. Modular reduction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0D	PKA_CR	6 bits
	Operand length	(in bits, not null)	RAM@0x400	64 bits
	Modulus length	(in bits, 8 < value < 4160)	RAM@0x408	
	Operand *A*	($0 \le A < 2n < 2^{4160}$)	RAM@0xA50	ROS
	Modulus value *n*	(odd integer only, $n < 2^{4160}$)	RAM@0xC68	
OUT	Result *A* mod *n*	(0 < result < *n*)	RAM@0xE78	

38.4.9 Arithmetic addition

The arithmetic addition operation calculates *A* + *B*.

The following table summarizes the operation instructions.

Table 380. Arithmetic addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x09	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	Result: *A* + *B*	($0 \le$ result $< 2^{M+1}$)	RAM@0xE78	ROS + 1

38.4.10 Arithmetic subtraction

The arithmetic subtraction operation calculates:

- $\boldsymbol{A - B}$, when $A \ge B$
- $\boldsymbol{A + 2^{int(M / 32) \times 32 + 1} - B}$, when $A < B$ and the residue of $M / 32$ is greater than zero
- $\boldsymbol{A + 2^{int(M / 32) \times 32} - B}$, when $A < B$ and the residue of $M / 32$ is zero

For the last two list items, the 32-bit word following the most significant word of the output is 0xFFFF FFFF, as the result is negative.

The following table summarizes the operation instructions.

Table 381. Arithmetic subtraction

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0A	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le < A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le < B < 2^M$)	RAM@0xC68	
OUT	Result: *A* - *B*	($0 \le$ result $< 2^M$)	RAM@0xE78	

38.4.11 Arithmetic multiplication

The arithmetic multiplication operation calculates A × B.

The following table summarizes the operation instructions.

Table 382. Arithmetic multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0B	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	Result: *A* × *B*	($0 \le$ result $< 2^{2M}$)	RAM@0xE78	2xROS

38.4.12 Arithmetic comparison

The arithmetic comparison operation yields the following results:

- **0xED2C**, when *A* = *B*
- **0x7AF8**, when *A* > *B*
- **0x916A**, when *A* < *B*

The following table summarizes the operation instructions.

Table 383. Arithmetic comparison

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x0C	PKA_CR	6 bits
	Operand length *M*	(in bits, not null)	RAM@0x408	64 bits
	Operand *A*	($0 \le A < 2^M$)	RAM@0xA50	ROS
	Operand *B*	($0 \le B < 2^M$)	RAM@0xC68	
OUT	If result *A* = *B*	0xED2C, 0x7AF8, or 0x916A	RAM@0xE78	64 bits

38.4.13 RSA CRT exponentiation

For efficiency many popular crypto libraries such as OpenSSL RSA use the following optimization for decryption and signing based on the chinese remainder theorem (CRT):

- *p* and *q* are precomputed primes, stored as part of the private key
- $d_P = d \bmod (p - 1)$
- $d_Q = d \bmod (q - 1)$ and
- $q_{inv} = q^{-1} \bmod p$

These values allow the recipient to compute the exponentiation m = A^d (mod pq) more efficiently as follows:

- $m_1 = A^{dP} \bmod p$
- $m_2 = A^{dQ} \bmod q$
- $h = q_{inv} (m_1 - m_2) \bmod p$, with $m_1 > m_2$
- $m = m_2 + hq \bmod pq$

Operation instructions for computing CRT exponentiation A^d mod pq are summarized in *Table 384*.

Table 384. CRT exponentiation

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x07	PKA_CR	6 bits
IN	Operand length	(in bits, not null)	RAM@0x408	64 bits
IN	Operand d_P	$(0 < d_P < 2^{M/2})$	RAM@0x730	ROS / 2
	Operand d_Q	$(0 < d_Q < 2^{M/2})$	RAM@0xE78	
	Operand q_{inv}	$(0 < q_{inv} < 2^{M/2})$	RAM@0x948	
	Prime p(1)	$(0 < p < 2^{M/2})$	RAM@0xB60	
	Prime q(1)	$(0 < q < 2^{M/2})$	RAM@0x1088	
IN	Operand A	$(0 < A < 2^M)$	RAM@0x12A0	ROS
OUT	Result: A^d mod pq	(0 ≤ result < pq)	RAM@0x838	

1. Must be different from 2.

38.4.14 Point on elliptic curve Fp check

This operation checks whether a given point $P(x, y)$ satisfies or not the curves over prime fields equation $y^2 = (x^3 + ax + b) \bmod p$, where a and b are elements of the curve.

The following table summarizes the operation instructions.

Table 385. Point on elliptic curve *Fp* check

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x28	PKA_CR	6 bits
	Modulus length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(|*b*| < *p*)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, 0 < *p* < 2640)	RAM@0x470	
	Point P coordinate *x*	(*x* < p)	RAM@0x578	
	Point P coordinate *y*	(*y* < *p*)	RAM@0x5D0	
	Montgomery parameter R^2 mod *n*	-	RAM@0x4C8	
OUT	Result: point *P* on curve	0xD60D: point on curve 0xA3B7: point not on curve 0xF946: *x* or *y* coordinate is not smaller than modulus *p*	RAM@0x680	64 bits

38.4.15 ECC Fp scalar multiplication

This operation calculates $k \times P\,(x_P, y_P)$, where *P* is a point on a curve over prime fields and *x* is the elliptic curve scalar point multiplication. The result is a point that belongs to the same curve or a point at infinity.

Note: Once this operation is started PKA control register and PKA memory is no more available. Access is restored once BUSY bit is set to 0 by the PKA.

When this operation completes with errors due to unexpected hardware events, a PKA tamper event is triggered to TAMP peripheral, and access to PKA RAM becomes blocked until erased by hardware. PKA tamper is also triggered when the programmed input point is not found on the input ECC curve. PKA operation *point on elliptic curve* can be used to avoid this.

The following table summarizes the operation instructions.

Table 386. ECC Fp scalar multiplication

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x20	PKA_CR	6 bits
IN	Curve prime order *n* length	(in bits, not null,)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	

Table 386. ECC Fp scalar multiplication (continued)

Parameters with direction		Value (note)	Storage	Size
IN	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Scalar multiplier *k*	($0 \le k < n$)	RAM@0x12A0	
	Point P coordinate x_P	($x_P < p$)	RAM@0x578	
	Point P coordinate y_P	($y_P < p$)	RAM@0x470	
	Curve prime order *n*	(integer prime)	RAM@0xF88	
OUT	Result: *k* × *P* coordinate *x'*	(result < *p*)	RAM@0x578	EOS
	Result: *k* × *P* coordinate *y'*	(result < *p*)	RAM@0x5D0	
ERROR	Error *k* × *P*	No errors: 0xD60D Errors: 0xCBC9	RAM@0x680	64 bits

When performing this operation the following special cases must be noted:

- For *k* = 0 this function returns a point at infinity (0, 0) if curve parameter *b* is nonzero, (0, 1) otherwise. For *k* different from 0 it might happen that a point at infinity is returned. When the application detects this behavior, a new computation must be carried out.
- For *k* < 0 (that is, a negative scalar multiplication is required) the multiplier absolute value
  k = |-*k*| must be provided to the PKA. After the computation completion, the formula -*P* = (*x*, -*y*) can be used to compute the *y* coordinate of the effective final result (the *x* coordinate remains the same).

Note: The error code is not affected when PKA automatically clears the PKA RAM at the end of this protected operation. When the error output equals 0xD60D, the result output is not affected either.

38.4.16 ECDSA sign

Table 387 (input parameters) and *Table 388* (output parameters) summarize the ECDSA signing operation.

Upon an output error different from 0xD60D, the application must generate a new *k* and repeat the ECDSA sign operation.

Note: As long as this operation is ongoing (BUSY = 1), the PKA control register and the PKA memory are not accessible. The access is restored when the PKA clears the BUSY bit.

The operation completion with errors due to unexpected hardware events triggers a PKA tamper event in the TAMP peripheral and blocks access to the PKA RAM until the hardware erases the event. Missing programmed input point on the input ECC curve also triggers a PKA tamper event. The use of the *point on elliptic curve* PKA operation prevents this.

Table 387. ECDSA sign - Inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x24	PKA_CR	6 bits
	Curve prime order *n* length (*nlen*)	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	0x0: positive 0x1: negative	RAM@0x410	
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	EOS
	Curve coefficient *b*	(positive integer)	RAM@0x520	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x1088	
	Integer *k*(1)	($0 \leq k <$ n)	RAM@0x12A0	
	Curve base point *G* coordinate *x*	($x < p$)	RAM@0x578	
	Curve base point *G* coordinate *y*	($y < p$)	RAM@0x470	
	Hash of message *z*	(hash size equal to *nlen*)(2)	RAM@0xFE8	
	Private key *d*	($0 < d < n$)	RAM@0xF28	
	Curve prime order *n*	(integer prime)	RAM@0xF88	

1. This integer is usually a cryptographically secure random number, but in some cases *k* can be deterministically generated.
2. To match the hash parameter size to the length of the curve prime order *n,* pad the result with zeros or use the hash truncation.

Table 388. ECDSA sign - Outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Signature part *r*	($0 < r < n$)	RAM@0x730	EOS
	Signature part *s*	($0 < s < n$)	RAM@0x788	
ERROR	Result of signature	0xD60D: successful computation, no error 0xCBC9: failed computation 0xA3B7: signature part r is equal to 0 0xF946: signature part s is equal to 0	RAM@0xFE0	64 bits

Note: The error code is not affected when the PKA automatically clears the PKA RAM at the end of this protected operation. The error output 0xD60D does not affect the result output either.

Extended ECDSA support

The PKA also supports the extended ECDSA signature, which accepts the same inputs as the standard ECDSA signature (see *Table 387*) and produces similar outputs (see *Table 388*), with the addition of the point *kG* coordinates. The following table defines these additional outputs.

Table 389. Extended ECDSA sign - additional outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Curve point kG coordinate x_1	($0 \le x_1 < p$)	RAM@0x1400	EOS
	Curve point kG coordinate y_1	($0 \le y_1 < p$)	RAM@0x1458	

38.4.17 ECDSA verification

Table 390 (input parameters) and *Table 391* (output parameters) summarize the ECDSA verification operation.

Upon an output error different from 0xD60D, the signature is not verified.

Table 390. ECDSA verification - inputs

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x26	PKA_CR	6 bits
	Curve prime order n length (*nlen*)	(in bits, not null)	RAM@0x408	64 bits
	Curve modulus p length	(in bits, not null, 8 < value < 640)	RAM@0x4C8	
	Curve coefficient a sign	0x0: positive 0x1: negative	RAM@0x468	
	Curve coefficient $\|a\|$	(absolute value, $\|a\| < p$)	RAM@0x470	EOS
	Curve modulus value p	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x4D0	
	Curve base point G coordinate x	($x < p$)	RAM@0x678	
	Curve base point G coordinate y	($y < p$)	RAM@0x6D0	
	Public-key curve point Q coordinate x_Q	($x_Q < p$)	RAM@0x12F8	
	Public-key curve point Q coordinate y_Q	($y_Q < p$)	RAM@0x1350	
	Signature part r	($0 < r < n$)	RAM@0x10E0	
	Signature part s	($0 < s < n$)	RAM@0xC68	
	Hash of message z	(hash size equal to *nlen*)(1)	RAM@0x13A8	
	Curve prime order n	(integer prime)	RAM@0x1088	

1. To match the hash parameter size to the length of the curve prime order n, pad the result with zeros or use the hash truncation.

Table 391. ECDSA verification - outputs

Parameters with direction		Value (note)	Storage	Size
OUT	Result: ECDSA verify	– 0xD60D: valid signature – 0xA3B7: invalid signature	RAM@0x5D0	64 bits
	Computed signature part *r*	– (0 < *r* < *n*)	RAM@0x578	EOS

38.4.18 ECC complete addition

The ECC complete addition operation calculates the sum of two points on an elliptic curve.

Operation instructions are summarized in *Table 392*.

Note: The two input points and the resulting point are represented in Jacobian coordinates (X,Y,Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. To convert resulting point to Jacobian coordinates conversion (x, y)= (X / Z^2, Y / Z^3) can be used.

Table 392. ECC complete addition

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x23	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	64 bits
	Curve coefficient *a* sign	– 0x0: positive 0x1: negative	RAM@0x410	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Curve coefficient |*a*|	(absolute value, |*a*| < *p*)	RAM@0x418	
	First point P coordinate *X*	(*x* < *p*)	RAM@0x628	
	First point P coordinate *Y*	(*y* < *p*)	RAM@0x680	
	First point P coordinate *Z*	(*z* < *p*)	RAM@0x6D8	
	Second point Q coordinate *X*	(*x* < *p*)	RAM@0x730	
	Second point Q coordinate *Y*	(*y* < *p*)	RAM@0x788	
	Second point Q coordinate *Z*	(*z* < *p*)	RAM@0x7E0	
OUT	Result coordinate *X*	(*x* < *p*)	RAM@0xD60	
	Result coordinate *Y*	(*y* < *p*)	RAM@0xDB8	
	Result coordinate *Z*	(*z* < *p*)	RAM@0xE10	

38.4.19 ECC double base ladder

ECC double base ladder operation consists in the computation of $k \times P + m \times Q$, where (P, Q) are two points on an elliptic curve and (k, m) are two scalars. Operation instructions are summarized in *Table 393*.

If the resulting point is the point at infinity (error code 0xA3B7), the resulting coordinate equals to (0, 0).

Note: The two input points are represented in Jacobian coordinates (X, Y , Z). To input a point in affine coordinates (x, y) conversion (X, Y, Z) = (x, y, 1) can be used. The result is represented in affine coordinates (x ,y)

This operation requires the input point Z coordinate to be equal to 1 (input point represented in affine coordinates).

Table 393. ECC double base ladder

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x27	PKA_CR	6 bits
	Curve prime order *n* length	(in bits, not null)	RAM@0x400	64 bits
	Curve modulus *p* length	(in bits, not null, 8 < value < 640)	RAM@0x408	
	Curve coefficient *a* sign	– 0x0: positive – 0x1: negative	RAM@0x410	EOS
	Curve coefficient |*a*|	(absolute value, |a| < p)	RAM@0x418	
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	
	Integer *k*	($0 < k < 2^{640}$)	RAM@0x520	
	Integer *m*	($0 < m < 2^{640}$)	RAM@0x578	
	First point *P* coordinate *X*	($x < p$)	RAM@0x628	
	First point *P* coordinate *Y*	($y < p$)	RAM@0x680	
	First point *P* coordinate *Z*	($z < p$)	RAM@0x6D8	
	Second point *Q* coordinate *X*	($x < p$)	RAM@0x730	
	Second point *Q* coordinate *Y*	($y < p$)	RAM@0x788	
	Second point *Q* coordinate *Z*	($z < p$)	RAM@0x7E0	
OUT	Result coordinate *x*	($x < p$)	RAM@0x578	EOS
	Result coordinate *y*	(y < *p*)	RAM@0x5D0	
	Error code	– Point not at infinity: 0xD60D – Point at infinity: 0xA3B7	RAM@0x520	64 bits

38.4.20 ECC projective to affine

ECC projective to affine operation calculates the conversion between the representation of a point P in homogeneous projective coordinates and the representation of the point P in affine coordinates. Namely, if the point is represented by the triple (*X*, *Y*, *Z*), it calculates the affine coordinates (*x*, *y*) = (*X* / *Z*, *Y* / *Z*).

All the operations are performed modulo the modulus p of the curve, which the point belongs to. If the resulting point is the point at infinity (error code 0xA3B7), resulting coordinate equals (0,0).

Operation instructions are summarized in *Table 394*.

Table 394. ECC projective to affine

Parameters with direction		Value (note)	Storage	Size
IN	MODE[5:0]	0x2F	PKA_CR	6 bits
	Curve modulus *p* length	(in bits, 8 < value < 640)	RAM@0x408	64 bits
	Curve modulus value *p*	(odd integer prime, $0 < p < 2^{640}$)	RAM@0x470	EOS
	Point P coordinate *X* (projective)	($x < p$)	RAM@0xD60	
	Point P coordinate *Y* (projective)	($y < p$)	RAM@0xDB8	
	Point P coordinate *Z* (projective)	($z < p$)	RAM@0xE10	
	Montgomery parameter R^2 mod *n*	-	RAM@0x4C8	
OUT	Point P coordinate *x* (affine)	($x < p$)	RAM@0x578	
	Point P coordinate *y* (affine)	($y < p$)	RAM@0x5D0	
ERROR	Error code	Point not at infinity: 0xD60D Point at infinity: 0xA3B7	RAM@0x680	64 bits

38.5 Example of configurations and processing times

38.5.1 Supported elliptic curves

The PKA supports all non-singular elliptic curves defined over prime fields. Those curves can be described with a short Weierstrass equation, $y^2 = x^3 + ax + b$ (mod p).

Note: Binary curves, Edwards curves and Curve25519 are not supported by the PKA.
The maximum supported operand size for ECC operations is 640 bits.

When publishing the ECC domain parameters of those elliptic curves, standard bodies define the following parameters:

- the prime integer *p*, used as the modulus for all point arithmetic in the finite field *GF(p)*
- the (usually prime) integer *n*, the order of the group generated by *G*, defined below
- the base point of the curve *G*, defined by its coordinates (*Gx*, *Gy*)
- the integers *a* and *b*, coefficients of the short Weierstrass equation.

For the last bullet, when standard bodies define *a* as negative, PKA supports two representations:

1. ***a* defined as *p*-|*a*|** in the finite field *GF(p)*, for example ***p*-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**F**
   Curve coefficient a sign= 0x0 (positive)
   Curve coefficient a = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFF**C**
2. ***a* defined as negative**, for example **-3**:
   Curve coefficient p = 0xFFFFFFFE FFFFFFFF FFFFFFFF FFFFFFFF FFFFFFFF 00000000 FFFFFFFF FFFFFFFF
   Curve coefficient a sign= 0x**1** (negative)
   Curve coefficient a = 0x00000000 00000000 00000000 00000000 00000000 00000000 00000000 00000000 0000000**3**

Table 395 summarizes the family of curves supported by PKA for ECC operations.

38.5.2 Computation times

The following tables summarize the PKA computation times, expressed in AHB clock cycles.

Table 396. Modular exponentiation

Exponent length (in bits)	Mode	Modulus length (in bits)			
		1024	2048	3072	4096
3	Normal	124600	491000	684000	1133200
	Fast	22700	82000	178000	311000
17	Normal	135700	531400	772400	1288000
	Fast	33800	122500	266500	465800
2^{16} + 1	Normal	180000	693700	1126200	1907200
	Fast	78200	284700	620400	1085000
1024	Protected	9958000	-	-	-
	Normal	5850000	-	-	-
	Fast	5748000	-	-	-
	CRT(1)	1775000	-	-	-
2048	Protected	-	63886000	-	-
	Normal	-	42240000	-	-
	Fast	-	41832000	-	-
	CRT(1)	-	11670000	-	-
3072	Protected	-	-	199403000	-
	Normal	-	-	136830000	-
	Fast	-	-	136325000	-
	CRT(1)	-	-	36886000	-
4096	Protected	-	-	-	454318000
	Normal	-	-	-	316000000
	Fast	-	-	-	315226000
	CRT(1)	-	-	-	84577000

1. CRT stands for chinese remainder theorem optimization (MODE[5:0] bitfield= 0x07).

Table 397. ECC scalar multiplication(1)

Modulus length (in bits)							
160	192	256	320	384	512	521	640
-	1590000	3083000	5339000	8518000	17818000	21053000	31826000

1. These times depend on the number of 1s included in the scalar parameter, and include the computation of Montgomery parameter R2.

Table 398. ECDSA signature average computation time(1) (2)

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
-	1500000	2744000	4579000	7184000	14455000	16685000	24965000

1. These values are average execution times of random moduli of given length, as they depend upon the length and the value of the modulus.
2. The execution time for the moduli that define the finite field of NIST elliptic curves is shorter than that needed for the moduli used for Brainpool elliptic curves or for random moduli of the same size.

Table 399. ECDSA verification average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
1011000	1495000	2938000	5014000	7979000	16804000	19254000	29582000

Table 400. ECC double base ladder average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
967000	1419000	2768000	4784000	7547000	15854000	18257000	28257000

Table 401. ECC projective to affine average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
47600	78000	148300	253000	419000	838400	1049300

Table 402. ECC complete addition average computation times

Modulus length (in bits)						
160	**192**	**256**	**320**	**384**	**512**	**640**
10000	12000	18000	26000	39000	63000	89000

Table 403. Point on elliptic curve Fp check average computation times

Modulus length (in bits)							
160	**192**	**256**	**320**	**384**	**512**	**521**	**640**
3400	4200	6100	8300	10900	17200	-	-

Table 404. Montgomery parameters average computation times(1)

Modulus length (in bits)							
192	**256**	**320**	**512**	**1024**	**2048**	**3072**	**4096**
8600	8710	11870	17000	102000	410000	506000	822000

1. The computation times depend upon the length and the value of the modulus, hence these values are average execution times of random moduli of given length.

38.6 PKA interrupts

There are five individual maskable interrupt sources generated by the public key secure accelerator, signaling the following events:

1. PKA unsupported operation error (OPERRF), see *Section 38.3.8*
2. Access to unmapped address (ADDRERRF), see *Section 38.3.8*
3. PKA RAM access while PKA operation is in progress (RAMERRF), see *Section 38.3.8*
4. PKA end of operation (PROCENDF)
5. Chaining mode flags (CMF)

The interrupt sources are connected to the same global interrupt request signal pka_it.

The user can enable or disable above interrupt sources individually by changing the mask bits in the *PKA control register (PKA_CR)*. Setting the appropriate mask bit to 1 enables the interrupt. The status of the individual interrupt events can be read from the PKA status register (PKA_SR), and it is cleared in PKA_CLRFR register.

CMF interrupt is triggered by the end of an operation (DATAOKF, RNGOKF) or by a chaining mode error (see *Section 38.3.8*). Chaining modes are described in *Section 38.3.7*.

Table 405 gives a summary of the available features.

Table 405. PKA interrupt requests

Acronym	Event	Event flag	Enable control bit	Clear method
PKA	Unsupported operation	OPERRF	OPERRIE	Set OPERRFC bit
	Access to unmapped address error	ADDRERRF	ADDRERRIE	Set ADDRERRFC bit
	PKA RAM access error	RAMERRF	RAMERRIE	Set RAMERRFC bit
	PKA end of operation	PROCENDF	PROCENDIE	Set PROCENDFC bit
	Chaining mode flag	CMF	CMFIE	Set CMFC bit

38.7 PKA registers

38.7.1 PKA control register (PKA_CR)

Address offset: 0x00

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMFIE	OPERRIE	ADDRERRIE	RAMERRIE	Res.	PROCENDIE	Res.
									rw	rw	rw	rw		rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	MODE[5:0]						Res.	Res.	Res.	Res.	Res.	Res.	START	EN
		rw	rw	rw	rw	rw	rw							rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMFIE**: Chaining mode flags interrupt enable
0: No interrupt is generated when any flag in bits 8 to 15 is set in PKA_SR.
1: An interrupt is generated when any flag in bits 8 to 15 is set in PKA_SR.

Bit 21 **OPERRIE**: Operation error interrupt enable
0: No interrupt is generated when OPERRF flag is set in PKA_SR.
1: An interrupt is generated when OPERRF flag is set in PKA_SR.

Bit 20 **ADDRERRIE**: Address error interrupt enable
0: No interrupt is generated when ADDRERRF flag is set in PKA_SR.
1: An interrupt is generated when ADDRERRF flag is set in PKA_SR.

Bit 19 **RAMERRIE**: RAM error interrupt enable
0: No interrupt is generated when RAMERRF flag is set in PKA_SR.
1: An interrupt is generated when RAMERRF flag is set in PKA_SR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDIE**: End of operation interrupt enable
0: No interrupt is generated when PROCENDF flag is set in PKA_SR.
1: An interrupt is generated when PROCENDF flag is set in PKA_SR.

Bits 16:14 Reserved, must be kept at reset value.

Bits 13:8 **MODE[5:0]**: PKA operation code

000000: Montgomery parameter computation then modular exponentiation
000001: Montgomery parameter computation only
000010: Modular exponentiation only (Montgomery parameter must be loaded first)
000011: Modular exponentiation (protected, used when manipulating secrets)
100000: Montgomery parameter computation then ECC scalar multiplication (protected)
100100: ECDSA sign (protected)
100110: ECDSA verification
101000: Point on elliptic curve Fp check
000111: RSA CRT exponentiation
001000: Modular inversion
001001: Arithmetic addition
001010: Arithmetic subtraction
001011: Arithmetic multiplication
001100: Arithmetic comparison
001101: Modular reduction
001110: Modular addition
001111: Modular subtraction
010000: Montgomery multiplication
100011: ECC complete addition
100111: ECC double base ladder
101111: ECC projective to affine

When an operation not listed here is written by the application with EN bit set, OPERRF bit is set in PKA_SR register, and the write to MODE[5:0] bitfield is ignored. When PKA is configured in limited mode (LMF = 1 in PKA_SR), writing a MODE[5:0] different from 0x26 with EN bit to 1 triggers OPERRF bit to be set and write to MODE[5:0] bit is ignored.

Bits 7:2 Reserved, must be kept at reset value.

Bit 1 **START**: start the operation

Set this bit to start the operation selected by the MODE[5:0] bitfield, using the operands and data already written to the PKA RAM. This bit is always read as 0.

When an illegal operation is selected while START bit is set no operation is started, and OPERRF bit is set in PKA_SR.

Note: START is ignored if PKA is busy.

Bit 0 **EN**: PKA enable

0: Disable PKA

1: Enable PKA; PKA becomes functional when INITOK is set by hardware in PKA_SR. When an illegal operation is selected while EN = 1, OPERRF bit is set in PKA_SR. See PKA_CR.MODE[5:0] bitfield for details.

Note: When EN = 0, PKA RAM can still be accessed by the application.

38.7.2 PKA status register (PKA_SR)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMF	OPERRF	ADDRERRF	RAMERRF	Res.	PROCENDF	BUSY
									r	r	r	r		r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	RNGERRF	MDERRF	TRZERRF	DATAZF	INCRERRF	DATAOKF	RNGOKF	Res.	Res.	Res.	Res.	Res.	CCEN	LMF	INITOK
	r	r	r	r	r	r	r						r	r	r

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMF**: Chaining mode flags

This status bit is only used when CCEN status bit is set in this register.

0: No chaining mode events.

1: Ongoing chaining mode sequence triggered at least one flag status in bits 8 to 14 of this register.

This bit is cleared using CMFC bit in PKA_CLRFR.

Bit 21 **OPERRF**: Operation error flag

0: No event error

1: An illegal or unknown operation has been selected in PKA_CR register

This bit is cleared using OPERRFC bit in PKA_CLRFR.

Bit 20 **ADDRERRF**: Address error flag

0: No address error

1: Address access is out of range (unmapped address)

This bit is cleared using ADDRERRFC bit in PKA_CLRFR.

Bit 19 **RAMERRF**: PKA RAM error flag

0: No PKA RAM access error

1: An AHB access to the PKA RAM occurred while the PKA core was computing and using its internal RAM (AHB PKA_RAM access are not allowed while PKA operation is in progress).

This bit is cleared using RAMERRFC bit in PKA_CLRFR.

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDF**: PKA end of operation flag

0: Operation in progress

1: PKA operation is completed. This flag is set when the BUSY bit is deasserted.

Bit 16 **BUSY**: Busy flag

This bit is set whenever a PKA operation is in progress (START = 1 in PKA_CR). It is automatically cleared when the computation is complete, making PKA RAM accessible again.

0: No operation is in progress (default)

1: An operation is in progress

When CCEN = 1 PKA sets BUSY bit when it runs a sanity check on a random number that CCB wrote to the PKA RAM during a chaining sequence (see *Section 38.3.7*).

If PKA is started with a wrong opcode, it stays busy for a couple of cycles, then it aborts automatically the operation and goes back to ready (BUSY = 0).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RNGERRF**: RNG error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No random number drawn from RNG, or generated ECC private key is NIST compliant.

1: Random number drawn from RNG did not pass NIST “key pair generation by testing candidates” equivalent algorithm (see FIPS 186-4 annex B.4.2). The last chaining operation must be restarted, otherwise the selected PKA operation remains unusable.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 13 **MDERRF**: Mode error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No mode error

1: The value written in MODE[5:0] of PKA_CR registers is different from the expected value corresponding to the CCOP mode selected in the CCB peripheral. Refer to *Section 38.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 12 **TRZERRF**: Trailing zeroes error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No trailing 0s error

1: Clear-text coming from CPU, or decrypted data coming from SAES does not have the required trailing 0s.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 11 **DATAZF**: Data zeroed error flag

This read-only chaining mode error flag is active only when CCEN is set in this register. DATAZF is set when PKA finds the complete data written to PKA RAM equal to 0, with all the expected 32-bit words null. This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 10 **INCRERRF**: Increment error flag

This read-only chaining mode error flag is active only when CCEN is set in this register.

0: No increment error

1: During the reading or writing of protected parameters from or to the PKA RAM, the application did not properly incremented the address. Refer to *Section 38.3.7* for details.

During the read or write of an operand, and before DATAOKF or RNGOKF is set, the INCRERRF flag stays cleared if the application reads or writes again this operand (starting from the lowest address). This bit is cleared by setting the CMFC bit in PKA_CLRFR.

Bit 9 **DATAOKF**: Data OK flag

This read-only chaining mode status flag is active only when CCEN is set in this register.

0: Data not OK (if applicable), otherwise no event.

1: Sequential writes or reads to or from the PKA RAM successfully transfered the expected amount of data from or to SAES. Alternatively, the CPU wrote the correct amount of data in the PKA RAM. Refer to *Section 38.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bit 8 **RNGOKF**: RNG OK flag

This read-only chaining mode status flag is active only when CCEN is set in this register.

0: Random number not OK (if applicable). No event otherwise.

1: Sequential writes to PKA RAM successfully transfered the expected amount of random data from the RNG. Refer to *Section 38.3.7* for details.

This bit is cleared when CMFC bit is set in PKA_CLRFR.

Bits 7:3 Reserved, must be kept at reset value.

Bit 2 **CCEN**: Coupling and chaining mode enable

This bit is set when the application configures the CCB to run coupling and chaining sequences that perform protected PKA operation using the SAES and (optionally) RNG peripherals.

0: Access to PKA RAM and programming of PKA_CR has no extra limitation.

1: The PKA RAM is write-only until START is set (it is no access then), and the MODE[5:0] value written in PKA_CR must correspond to the CCOP mode selected in the CCB peripheral. The application must also follow the coupling and chaining sequences described in *Section 38.3.7*.

Bit 1 **LMF**: Limited mode flag

This bit is updated when EN bit in PKA_CR is set

0: All values documented in MODE[5:0] bitfield can be used.

1: Only ECDSA verification (MODE[5:0] = 0x26) is supported by the PKA.

Bit 0 **INITOK**: PKA initialization OK

This bit is asserted when PKA initialization is complete.

0: PKA is not initialized correctly. START bit cannot be set.

1: PKA is initialized correctly and can be used normally.

When RNG is not able to output proper random numbers or when SAES is using the RNG bus, INITOK remains at 0. If it happens, make sure the RNG peripheral is properly clocked and initialized, and the SAES peripheral is clocked with BUSY bit cleared in SAES_SR to release the RNG bus, then enable PKA again.

38.7.3 PKA clear flag register (PKA_CLRFR)

Address offset: 0x08

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CMFC	OPERRFC	ADDRERRFC	RAMERRFC	Res.	PROCENDFC	Res.
									w	w	w	w		w

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **CMFC**: Clear chaining mode flag

0: No action

1: Clear the CMF flag and the chaining mode status bits in 8 to 15 in PKA_SR

Bit 21 **OPERRFC**: Clear operation error flag

0: No action

1: Clear the OPERRF flag in PKA_SR

Bit 20 **ADDRERRFC**: Clear address error flag

0: No action

1: Clear the ADDRERRF flag in PKA_SR

Bit 19 **RAMERRFC**: Clear PKA RAM error flag

0: No action

1: Clear the RAMERRF flag in PKA_SR

Bit 18 Reserved, must be kept at reset value.

Bit 17 **PROCENDFC**: Clear PKA end of operation flag
0: No action
1: Clear the PROCENDF flag in PKA_SR

Bits 16:0 Reserved, must be kept at reset value.

Note: Reading PKA_CLRFR returns all 0s.

38.7.4 PKA RAM

The PKA RAM is mapped at the offset address of 0x0400 compared to the PKA base address. Only 32-bit word single accesses are supported, through PKA.AHB interface.

RAM size is 5336 bytes (max word offset: 0x14D0)

Note: PKA RAM cannot be used just after a PKA reset or a product reset, as described in Section 38.3.3: PKA reset and clocks.

38.7.5 PKA register map

Table 406. PKA register map and reset values

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

39 On-the-fly decryption engine (OTFDEC)

This section only applies to STM32G56x devices.

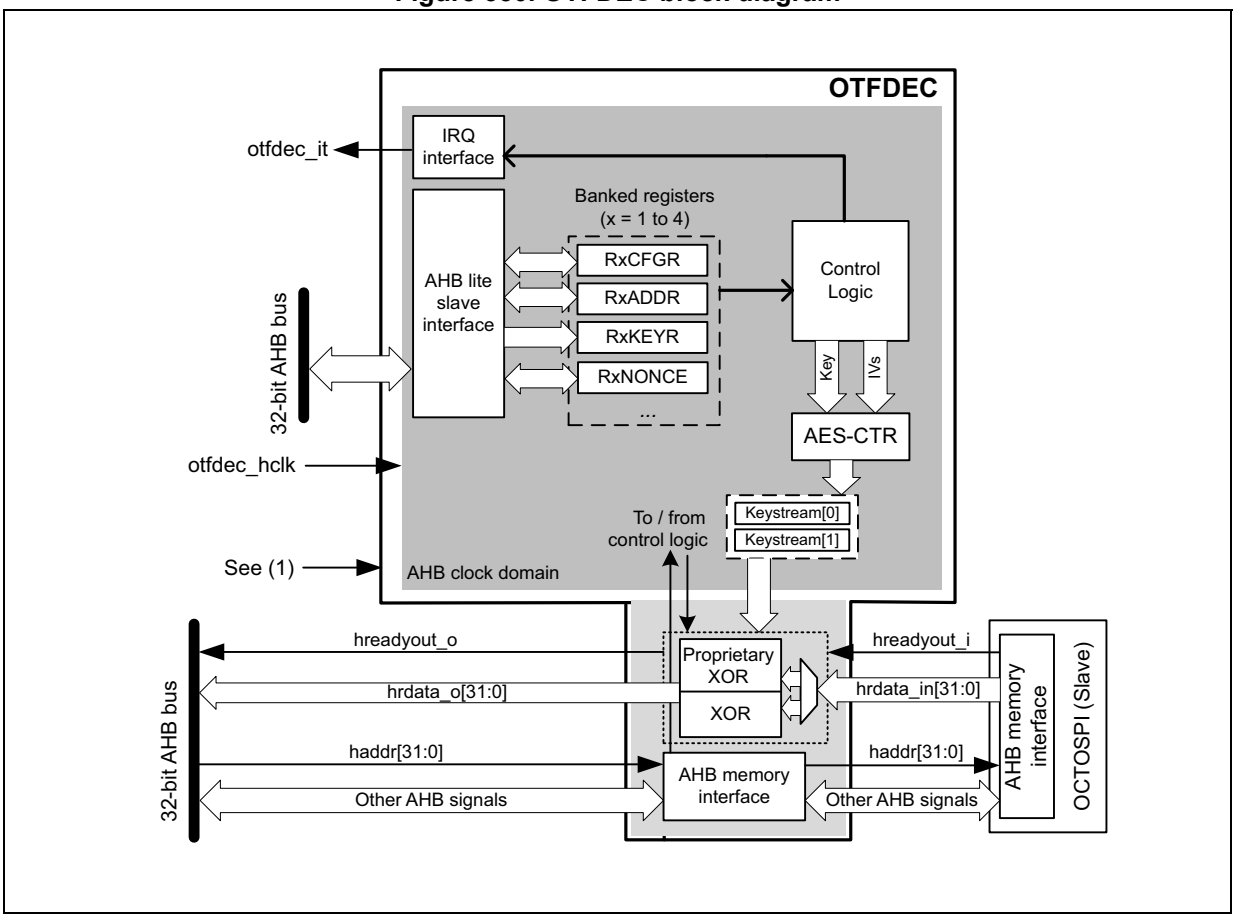
39.1 OTFDEC introduction

OTFDEC allows on-the-fly decryption of the AHB traffic based on the read request address information. Four independent and non-overlapping encrypted regions can be defined in OTFDEC.

OTFDEC uses AES-128 in counter mode to achieve the lowest possible latency. As a consequence, each time the content of one encrypted region is changed, the entire region must be re-encrypted with a different cryptographic context (key or initialization vector). This constraint makes OTFDEC suitable to decrypt read-only data or code, stored in external NOR flash.

Note: When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to access the flash memory using the memory-mapped mode of the flash memory controller.

When security is enabled in the product, OTFDEC can be programmed only by a secure host.



39.2 OTFDEC main features

- On-the-fly 128-bit decryption during the OCTOSPI Memory-mapped read operations (single or multiple).
  - Use of AES in counter (CTR) mode, with two 128-bit keystream buffers
  - Support for any read size
  - Physical address of the reads used for the encryption/decryption
- Up to four independent encrypted regions
  - Granularity of the region definition: 4096 bytes
  - Region configuration write-locking mechanism
  - Each region has its own 128-bit key, two bytes firmware version, and eight bytes application-defined nonce. At least one of those must be changed each time an encryption is performed by the application.
- Encryption keys confidentiality and integrity protection
  - Write-only registers, with software locking mechanism
  - Availability of 8-bit CRC as public key information
- Support for OCTOSPI pre-fetching mechanism
- Possibility to select an enhanced encryption mode to add a proprietary layer of protection on top of AES stream cipher (execute only)
- Privileged-aware AMBA AHB slave peripheral, accessible through 32-bit word single accesses only (otherwise an AHB bus error is generated, and write accesses are ignored)
- Secure only programming if TrustZone security is enabled in the product
- Encryption mode

39.3 OTFDEC functional description

39.3.1 OTFDEC block diagram

Figure 350. OTFDEC block diagram

1. otfdec_tzen

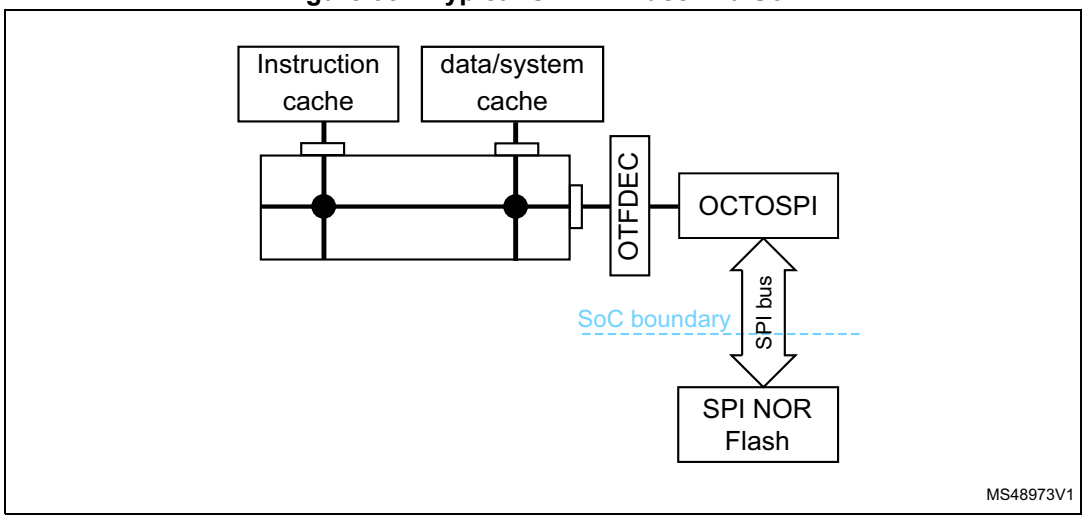
39.3.2 OTFDEC internal signals

Table 407 describes a list of useful to know internal signals available at OTFDEC level, not at the product level (on pads).

Table 407. OTFDEC internal input/output signals

Signal name	Signal type	Description
otfdec_hclk	Digital input	AHB bus clock
otfdec_it	Digital output	OTFDEC global interrupt request
otfdec_tzen	Digital input	OTFDEC TrustZone enable, controlling TrustZone features of the peripheral (TZEN)

The TZEN option bit in FLASH is used to activate TrustZone in the device.



- TZEN = 1: TrustZone security is enabled in the product.
- TZEN = 0: TrustZone security is disabled in the product.

39.3.3 OTFDEC on-the-fly decryption

Introduction

Typical usage for OTFDEC is shown on *Figure 351*.

Figure 351. Typical OTFDEC use in a SoC

Original purpose of OTFDEC is to protect the confidentiality of read-only firmware libraries stored in external SPI NOR flash devices.

A special locking scheme is available in OTFDEC in order to protect the integrity of the decryption keys and also to protect the other configurations against software denial of services attacks. OTFDEC access to most registers can be made privileged-only by setting PRIV bit in OTFDEC_PRIVCFGR register. OTFDEC is only writeable by TrustZone CPU, when TrustZone security is activated.

When OTFDEC is used in conjunction with OCTOSPI, it is mandatory to read the flash memory using the Memory-mapped mode of the flash controller.

On top of decrypting on-the-fly, OTFDEC can also encrypt 32-bit word at a time (see *Section 39.5.3: Encrypting for OTFDEC* for more details).

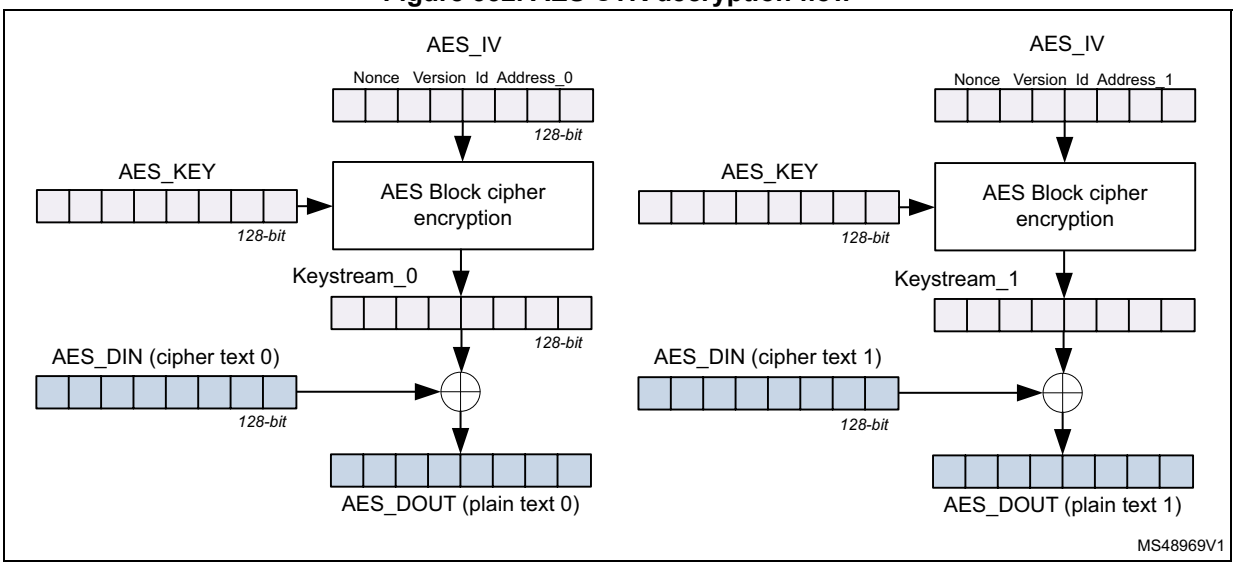
OTFDEC architecture

OTFDEC analyzes all AHB read transfers on the associated AHB bus. If the read request is within one of the four regions programmed in OTFDEC, the control logic triggers a keystream computation based on AES algorithm in counter mode. This keystream is then used to decrypt on-the-fly the data present in the read transfer from the OCTOSPI AHB master, tying low the HREADYOUT signal of this master while the keystream information is being computed (this takes up to 11 cycles). Any accesses outside the enabled OTFDEC regions belong to a non-encrypted region.

Each OTFDEC region is programmed through OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR, OTFDEC_RxNONCER and

OTFDEC_RxKEYR registers, where x = 1 to 4. In OTFDEC_RxCFGR, the MODE bits define the OTFDEC operating mode (standard or enhanced encryption).

Granularity for the region determination is 4096 bytes.



Note: Although OTFDEC does not prevent region overlapping, it is not a valid programming and it must be avoided by application software.

OTFDEC can decrypt incremental or wrap bursts only if they do not cross the 4096-byte aligned address boundaries.

39.3.4 OTFDEC usage of AES in counter mode decryption

Figure 352 shows how OTFDEC uses industry standard Advanced Encryption Standard (AES) algorithm in counter chaining mode. This mode is specified by NIST in *Special Publication 800-38A, Recommendation for Block Cipher Modes of Operation*.

Figure 352. AES CTR decryption flow

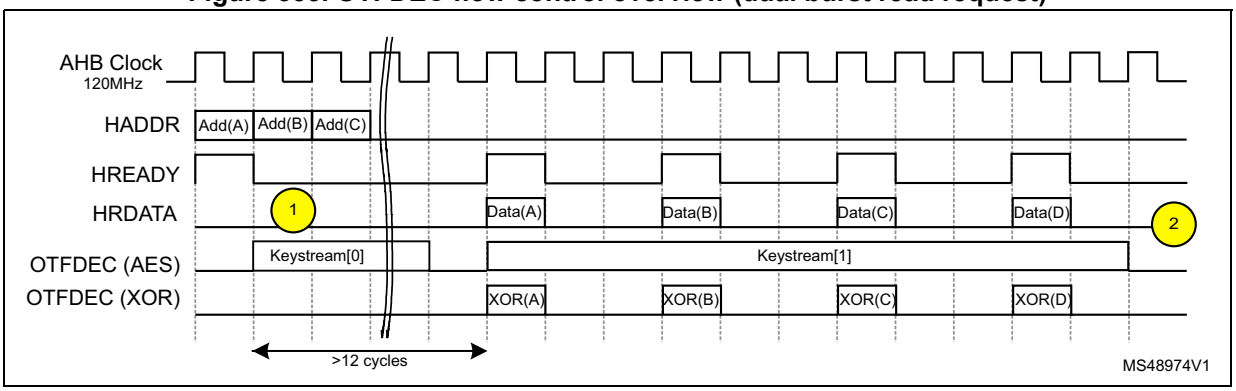
Every 128-bit data block, a special keystream information is computed using AES block cipher, as defined below:

- initialization vector AES_IV[127:0] = RxNONCER1[31:0] || RxNONCER0[31:0] || 0b0000 0000 0000 0000 || RxCFGR[31:16] || 0b00 || (x-1) || ReadAddress[31:4]
- key material AES_KEY[127:0] = R*x*KEYR3[31:0] || R*x*KEYR2[31:0] || R*x*KEYR1[31:0] || R*x*KEYR0[31:0]

Note: Above x is the RegionID of the selected encrypted region (x=1 to 4).
ReadAddress is the AHB address of the encrypted data block, modulo 128-bit.

Resulting 128-bit keystream is XORed with 128-bit cipher text data to produce the 128-bit clear text data.

- AES_DIN and AES_DOUT data blocks are constructed following the rule below (“|” represents a binary concatenation):
  AES_Dx[127:0]= AHB_word(@ | 0xC)[31:0] | AHB_word(@ | 0x8)[31:0] | AHB_word(@ | 0x4)[31:0] || AHB_word(@ | 0x0)[31:0], where @ is the hexadecimal address used to compute the keystream (ReadAddress[31:4] above).



When the read request is not within an encrypted region, or the decryption is not enabled in this region, the AHB data is not changed.

Note: When the application sets the MODE bitfield to 11 in OTFDEC_RxCFGR, an additional layer of protection is added on top of the AES stream cipher. This enhanced encryption mode can only be used with instructions (execute-only region).

39.3.5 Flow control management

Figure 353 shows how OTFDEC manages one INCR4 AHB burst that corresponds to one 128-bit AES data block.

Figure 353. OTFDEC flow control overview (dual burst read request)

with the following notes:

1. OTFDEC enforces HREADY signal from the AHB master low as it is not ready to decrypt data (keystream computation).
2. Thanks to the keystream buffer, OTFDEC can be ready to process a new batch of data within 12 cycles in this configuration (120 MHz AHB clock, 104 MHz SPI bus delivering 2 bytes per SPI clock).

39.3.6 OTFDEC error management

OTFDEC automatically manages errors defined as below:

- Illegal read to OTFDEC_RxKEYR registers
- Illegal write to OTFDEC_RxKEYR registers while CONFIGLOCK or KEYLOCK = 1 in OTFDEC_RxCFGR, while the access is secure. If the security is disabled in the product, the same error occurs when the access is nonsecure.
- Illegal write to OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR or OTFDEC_RxNONCER registers while CONFIGLOCK = 1 in OTFDEC_RxCFGR (x = 1 to 4), while the access is secure. If the security is disabled in the product the same error occurs when the access is nonsecure.
- Illegal read to an execute-only region (MODE[1:0] = 11). Such illegal request returns 0x0, without bus error.
- Execution request to a region while encryption is enabled (ENC = 1). The request returns 0x0, without bus error.
- Key error: read request to an encrypted region while its key registers are null or not properly initialized (KEYCRC = 0x0). Source of the error can be an incorrect key loading sequence (see KEYCRC in OTFDEC_RxCFGR) or it can be an abort event

(tamper detection, unauthorized debug connection, untrusted boot, RDP level regression). Such read request returns 0x0, without bus error.

- Write to any registers while the access is nonsecure, if TrustZone security is enabled in the product.

  This last error is managed and cleared through TrustZone interrupt controller, as described in the GTZC section of the product reference manual.

For these errors (except the last one), an interrupt can be generated if the SEIE, XONEIE or KEIE bit is set in OTFDEC_IER register (see *Section 39.4*).

Note: After a key error, OTFDEC keys must be properly initialized again, and a reset of OTFDEC may be needed if registers are locked.

39.4 OTFDEC interrupts

There are three independent maskable interrupt sources generated by the OTFDEC, signaling following security events:

- Illegal read or write access to keys (SEIF flag), see *Section 39.3.6*
- Illegal write to a region configuration while CONFIGLOCK = 1 (SEIF flag), see *Section 39.3.6*
- Read access to an execute-only region (MODE[1:0] = 11), triggering the XONEIF flag
- Executing while encryption is enabled (XONEIF flag)
- Key error (encrypted regions read as zero) triggering the KEIF flag, see *Section 39.3.6*.

Interrupt sources are connected to the same global interrupt request signal.

OTFDEC interrupt sources can be enabled/disabled by setting the corresponding SEIE, XONEIE or KEIE bit in OTFDEC_IER, as described in *Table 408*. Status of the interrupt event is found in OTFDEC_ISR, and this event can be cleared using OTFDEC_ICR.

Table 408. OTFDEC interrupt requests

Interrupt acronym	Interrupt event	Event flag(1)	Enable control bit	Interrupt clear method
OTFDEC	Security error	SEIF	SEIE	Set SEIF in OTFDEC_ICR
	Execute-only Execute while encryption	XONEIF	XONEIE	Set XONEIF in OTFDEC_ICR
	Key error	KEIF	KEIE	Set KEIF in OTFDEC_ICR

1. The event flags are found in the OTFDEC_ISR register.

39.5 OTFDEC application information

39.5.1 OTFDEC initialization process

Introduction

One key aspect of OTFDEC is the trusted initialization of its registers, as it involves secret keys. Two trusted initialization schemes are recommended here below.

Note: Those sequences are for production code, as during firmware development, it is not always recommended to lock the key or the region configuration.

Writes to configuration registers are effective when the configuration locks allow it, even if the region is enabled.

Initialization scheme 1: one key for all regions

In this scheme, one entity owns the secret key used to decrypt the four protected regions. The recommended OTFDEC configuration sequence is described below:

1. For *x* = 1 to 4, write the correct MODE[1:0] value in OTFDEC_RxCFGR.
2. For *x* = 1 to 4, program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
3. For *x* = 1 to 4, check the key CRC. If OK, set KEYLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (key registers in this region *x* are no more writable).
4. To do to decrypt a region x (task that does not necessarily have to be performed by the entity that owns the decryption keys):
   a) Verify if the key CRC corresponds to the encrypted binary stored in the region.
   b) Fill the detailed information corresponding to this binary (nonce, start address, end address, version number).
   c) Enable decryption of this region using REG_EN.
   d) Set CONFIGLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence, step 1 above must be done before step 2, and MODE bits must not be modified after step 2.

Initialization scheme 2: one key per region

In this scheme, one entity can own the secret used to decrypt one (or more) protected region. The recommended OTFDEC configuration sequence is described below:

1. To do to decrypt a region x (this task **must** be performed by the entity that owns the corresponding key):
   a) Write the correct MODE[1:0] value in OTFDEC_R*x*CFGR.
   b) Program OTFDEC_RxKEYR registers using the sequence described in KEYCRC (to have a valid CRC). Warning as key registers are write only.
   c) Check the key CRC. If OK, set KEYLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (key registers are no more writable).
   d) Fill the detailed information corresponding to the protected firmware (nonce, start address, end address, version number).
   e) Enable decryption of this region using REG_EN.
   f) Set CONFIGLOCK bit in OTFDEC_R*x*CFGR. This bit cannot be cleared (the region configuration is no more writable).

Caution: For a given region, when MODE bits are changed, the key registers and associated CRC are cleared by hardware. As a consequence step a) above must be done before step b), and MODE bits must not be modified after step b).

39.5.2 OTFDEC and power management

Each time OTFDEC is reset, the correct key loading sequence described in *Section 39.5.1* must be performed (in this case KEYCRC = 0 in OTFDEC_RxCFGR).

It is recommended for application software to verify this point each time OTFDEC is reset by hardware.

39.5.3 Encrypting for OTFDEC

Code and data standard encryption

OTFDEC uses standard AES in counter mode when processing a binary stored in a protected region with MODE[1:0] = 10. When this mode is selected, any AES compatible hardware accelerator or library can be used to encrypt those protected libraries. OTFDEC can be used as well, as described in enhanced encryption section below (with MODE[1:0] = 10).

Definition and endianness of the AES inputs and outputs are defined in *Section 39.3.4: OTFDEC usage of AES in counter mode decryption*.

Enhanced encryption with OTFDEC

OTFDEC uses a proprietary layer of protection on top of the standard AES in counter mode when processing a code stored in a protected region with MODE[1:0] = 11.

Enhanced encryption mode can be used to increase the robustness against tampering.

Recommended sequence to encrypt using OTFDEC is described below:

1. The application in charge of the encryption sets the ENC bit in OTFDEC_CR. This application must run in TrustZone secure mode when TrustZone security is enabled in the product. If PRIV bit is set in OTFDEC_PRIVCFGR, this application must be privileged.
2. Encryption application initializes OTFDEC as described in *Section 39.5.1: OTFDEC initialization process*. OCTOSPI must also be properly clocked, so that OTFDEC is fully functional in encryption mode. This step can also be done before step 1.
3. Encryption application writes 32-bit of clear-text data at the expected protected address, then reads it back encrypted at the same address to store it in RAM. Note that this data stays inside the device, as it is intercepted by OTFDEC in encryption mode.
4. Encryption application goes back to previous step (changing the address) until the whole binary is processed.
5. Encryption application clears the ENC bit in OTFDEC_CR. Another application can then take the encrypted binary and flash it to the correct address in external flash.

There are few important notes about this procedure:

- Encryption granularity is 32-bit (single 32-bit access is mandatory).
- While ENC bit is set, reads to non-encrypted regions return normal data (such as no encryption nor decryption). While in encryption mode, no access to OCTOSPI (including registers) must be done. This is because the OTFDEC cuts the communication with OCTOPSI while ENC bit is set.
- OTFDEC does not support execution while ENC = 1 (only encrypted data reads). Upon illegal execution detection a XONEIF flag is raised and zero is returned.

39.5.4 OTFDEC key CRC source code

Below is the CRC source code that can be used to compare with the result of the computation provided by OTFDEC in KEYCRC bitfield after loading the keys in OTFDEC_RxKEYR registers.

```
uint8_t getCRC(uint32_t * keyin)
{
  const uint8_t CRC7_POLY = 0x7;
  const uint32_t key_strobe[4] = {0xAA55AA55, 0x3, 0x18, 0xC0};
  uint8_t  i, j, k, crc = 0x0;
  uint32_t  keyval;

  for (j = 0; j < 4; j++)
  {
    keyval = *(keyin+j);
    if (j == 0)
    {
      keyval ^= key_strobe[0];
    }
    else
    {
      keyval ^= (key_strobe[j] << 24) | (crc << 16) | (key_strobe[j] << 8)
| crc;
    }

    for (i = 0, crc = 0; i < 32; i++)
    {
      k = (((crc >> 7) ^ (keyval >> (31-i))&0xF)) & 1;
      crc <<= 1;
      if (k)
      {
        crc ^= CRC7_POLY;
       }
    }
    crc^=0x55;
  }
  return crc;
}
```

39.6 OTFDEC registers

39.6.1 OTFDEC control register (OTFDEC_CR)

Address offset: 0x0

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ENC
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **ENC**: Encryption mode bit

When this bit is set, OTFDEC is used in encryption mode, during which application can write clear text data then read back encrypted data. When this bit is cleared (default), OTFDEC is used in decryption mode, during which application only read back decrypted data. For both modes, cryptographic context (keys, nonces, firmware versions) must be properly initialized. When this bit is set, only data accesses are allowed (zeros are returned otherwise, and XONEIF is set). When MODE = 11, enhanced encryption mode is automatically selected.

0: OTFDEC working in decryption mode

1: OTFDEC working in encryption mode

Note: When ENC bit is set, no access to OCTOSPI must be done (registers and Memory-mapped region).

39.6.2 OTFDEC privileged access control configuration register (OTFDEC_PRIVCFGR)

Address offset: 0x10

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	PRIV
															rw

Bits 31:1 Reserved, must be kept at reset value.

Bit 0 **PRIV:** Privileged access protection.

0: No additional protection is added on OTFDEC register accesses.

1: An additional protection is added when accessing all registers except OTFDEC_PRIVCFGR:

- Unprivileged read accesses to registers return zeros
- Unprivileged write accesses to registers are ignored.

Note: This bit can only be written in privileged mode. There is no limitations on reads.

39.6.3 OTFDEC region x configuration register (OTFDEC_RxCFGR)

Address offset: 0x20 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

Writes are ignored if CONFIGLOCK bit is set to 1.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_VERSION[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
KEYCRC[7:0]								Res.	Res.	MODE[1:0]		Res.	KEYLOCK	CONFIGLOCK	REG_EN
r	r	r	r	r	r	r	r			rw	rw		rs	rs	rw

Bits 31:16 **REG_VERSION[15:0]**: region firmware version

This 16-bit bitfield must be correctly initialized before the region corresponding REG_EN bit is set in OTFDEC_RxCFGR.

Bits 15:8 **KEYCRC[7:0]**: region key 8-bit CRC

When KEYLOCK = 0, KEYCRC bitfield is automatically computed by hardware while loading the key of this region in this exact sequence: KEYR0 then KEYR1 then KEYR2 then finally KEYR3 (all written once). A new computation starts as soon as a new valid sequence is initiated, and KEYCRC is read as zero until a valid sequence is completed.

When KEYLOCK = 1, KEYCRC remains unchanged until the next reset.

CRC computation is an 8-bit checksum using the standard CRC-8-CCITT algorithm $X^8 + X^2 + X + 1$ (according the convention). Source code is available in *Section 39.5.4*.

This field is read only.

Note: CRC information is updated only after the last bit of the key has been written.

Bits 7:6 Reserved, must be kept at reset value.

Bits 5:4 **MODE[1:0]**: operating mode

This bitfield selects the OTFDEC operating mode for this region:

10: All read accesses are decrypted (instruction or data).

11: Enhanced encryption mode is activated, and only instruction accesses are decrypted

Others: Reserved

When MODE ≠ 11, the standard AES encryption mode is activated.

When either of the MODE bits are changed, the region key and associated CRC are zeroed.

Bit 3 Reserved, must be kept at reset value.

Bit 2 **KEYLOCK**: region key lock

0: Writes to this region KEYRx registers are allowed.

1: Writes to this region KEYRx registers are ignored until next OTFDEC reset. KEYCRC bitfield is locked.

Note: This bit is set once: if this bit is set, it can only be reset to 0 if the OTFDEC is reset.

Bit 1 **CONFIGLOCK**: region config lock

0: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are allowed.

1: Writes to this region OTFDEC_RxCFGR, OTFDEC_RxSTARTADDR, OTFDEC_RxENDADDR and OTFDEC_RxNONCERy registers are ignored until next OTFDEC reset.

Note: This bit is set once. If this bit is set, it can only be reset to 0 if OTFDEC is reset. Setting this bit forces KEYLOCK bit to 1.

Bit 0 **REG_EN**: region on-the-fly decryption enable

0: On-the-fly decryption is disabled for this region.

1: On-the-fly decryption is enabled for this region. Data are XORed with the corresponding keystream.

Note: Garbage is decrypted if region context (version, key, nonce) is not valid when this bit is set.

39.6.4 OTFDEC region x start address register (OTFDEC_RxSTARTADDR)

Address offset: 0x24 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_START_ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_START_ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_START_ADDR[31:0]**: Region AHB start address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR register is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.

When this register is accessed in read the 4 MSB bits and the 12 LSB bits return zeros .

39.6.5 OTFDEC region x end address register (OTFDEC_RxENDADDR)

Address offset: 0x28 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0FFF

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_END_ADDR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_END_ADDR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_END_ADDR[31:0]**: Region AHB end address

This register must be written before the region corresponding REG_EN bit in the OTFDEC_RxCFGR register is set, and OTFDEC_RxENDADDR must be strictly greater than OTFDEC_RxSTARTADDR to be valid.

Writing to this register is discarded if performed while the region CONFIGLOCK bit in OTFDEC_RxCFGR is set.

Note: When determining the region the first 12 bits (LSB) and the last 4 bits (MSB) are ignored.

When this register is accessed in read the 4 MSB bits return zeros and the 12 LSB bits return ones.

39.6.6 OTFDEC region x nonce register 0 (OTFDEC_RxNONCER0)

Address offset: 0x2C + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_NONCE[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_NONCE[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_NONCE[31:0]**: Region nonce, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Writing is discarded in this register if performed while the region CONFIGLOCK bit in the OTFDEC_RxCFGR is set.

39.6.7 OTFDEC region x nonce register 1 (OTFDEC_RxNONCER1)

Address offset: 0x30 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
REG_NONCE[63:48]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REG_NONCE[47:32]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **REG_NONCE[63:32]**: Region nonce, bits [63:32]

Refer to the OTFDEC_RxNONCER0 register for description of the NONCE[63:0] bitfield.

39.6.8 OTFDEC region x key register 0 (OTFDEC_RxKEYR0)

Address offset: 0x34 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[31:0]**: Region key, bits [31:0]

This register must be written before the region corresponding REG_EN bit in OTFDEC_RxCFGR is set.

Reading this register returns a zero value. Writing to this register is discarded if performed while the region CONFIGLOCK or KEYLOCK bit is set in the OTFDEC_RxCFGR.

Note: When application successfully changes MODE bits in OTFDEC*_RxCFGR and* OTFDEC*_RxKEYR, and associated KEYCRC are erased.*

39.6.9 OTFDEC region x key register 1 (OTFDEC_RxKEYR1)

Address offset: 0x38 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[47:32]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[63:32]**: Region key, bits [63:32]
Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

39.6.10 OTFDEC region x key register 2 (OTFDEC_RxKEYR2)

Address offset: 0x3C + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[79:64]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[95:64]**: Region key, bits [95:64]
Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

39.6.11 OTFDEC region x key register 3 (OTFDEC_RxKEYR3)

Address offset: 0x40 + 0x30 * (x - 1), (x = 1 to 4)

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

REG_KEY[111:96]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **REG_KEY[127:96]**: Region key, bits [127:96]

Refer to the OTFDEC_RxKEYR0 register for description of the KEY[127:0] bitfield.

39.6.12 OTFDEC interrupt status register (OTFDEC_ISR)

Address offset: 0x300

Reset value: 0x0000 0000

Unprivileged reads return zero if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	XONEIF	SEIF
													r	r	r

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag status

This bit is set by hardware and read only by application. The bit is set when a read access occurs on an encrypted region, while its key registers is null or not properly initialized (KEYCRC = 0x0).

This bit is cleared when the application sets in OTFDEC_ICR the corresponding bit to 1.

0: OTFDEC operates properly.

1: Read access detected on an enabled encrypted region with its key registers null or not properly initialized (KEYCRC = 0x0). OTFDEC returns a zeroed value for the read, and an optional interrupt is generated if bit KEIE is set to 1 in OTFDEC_IER.

After KEIF is set any subsequent read to the region with bad key registers returns a zeroed value. This state remains until those key registers are properly initialized (KEYCRC not zero).

Bit 1 **XONEIF:** Execute-only execute-never error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when a read access and not an instruction fetch is detected on any encrypted region with MODE bits set to 11. Lastly, XONEIF is also set when an execute access is detected while encryption mode is enabled.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No execute-only error status. No interrupt pending.

1: Read access detected on one region with MODE bits set to 11 or execute access detected while ENC = 1. OTFDEC returns a zeroed value for the illegal access, and an optional interrupt is generated if bit XONEIE is set to 1 in OTFDEC_IER.

Bit 0 **SEIF:** Security error interrupt flag status

This bit is set by hardware and read only by application. This bit is set when at least one security error has been detected.

This bit is cleared when application sets in OTFDEC_ICR the corresponding bit to 1.

0: No security error status. No interrupt pending.

1: Security error flag status, with interrupt pending. Actual interrupt generation is dependent on OTFDEC_IER corresponding bit SEIE.

39.6.13 OTFDEC interrupt clear register (OTFDEC_ICR)

Address offset: 0x304

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIF	XONEIF	SEIF
													w	w	w

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIF:** Key error interrupt flag clear
This bit is written by application, and always read as 0.
0: KEIF flag status is not affected.
1: KEIF flag status is cleared in OTFDEC_ISR.
Note: Clearing KEIF does not solve the source of the problem (bad key registers). To be able to access again any encrypted region, OTFDEC key registers must be properly initialized again.

Bit 1 **XONEIF:** Execute-only execute-never error interrupt flag clear
This bit is written by application, and always read as 0.
0: XONEIF flag status is not affected.
1: XONEIF flag status is cleared in OTFDEC_ISR.

Bit 0 **SEIF:** Security error interrupt flag clear
This bit is written by application, and always read as 0.
0: SEIF flag status is not affected.
1: SEIF flag status is cleared in OTFDEC_ISR.

39.6.14 OTFDEC interrupt enable register (OTFDEC_IER)

Address offset: 0x308

Reset value: 0x0000 0000

Nonsecure AHB write access (HNONSEC = 1) is discarded if the TrustZone security is enabled in the product.

Unprivileged reads return zero and unprivileged writes are ignored if PRIV bit is set in OTFDEC_PRIVCFGR.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	KEIE	XONEIE	SEIE
													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **KEIE:** Key error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when KEIF flag status is set.

0: Interrupt generation on key error flag KEIF is disabled (masked).

1: Interrupt generation on key error flag KEIF is enabled (not masked).

Bit 1 **XONEIE:** Execute-only execute-never error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when XONEIF flag status is set.

0: Interrupt generation on execute-only error XONEIF is disabled (masked).

1: Interrupt generation on execute-only error XONEIF is enabled (not masked).

Bit 0 **SEIE:** Security error interrupt enable

This bit is read and written by application. It controls the OTFDEC interrupt generation when SEIF flag status is set.

0: Interrupt generation on security error SEIF is disabled (masked).

1: Interrupt generation on security error SEIF is enabled (not masked).

39.6.15 OTFDEC register map

Table 409. OTFDEC register map and reset values

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

40 High-resolution timer (HRTIM)

40.1 Introduction

The high-resolution timer can generate up to 12 digital signals with highly accurate timings. It is primarily intended to drive power conversion systems such as switch mode power supplies or lighting systems, but can be of general purpose usage, whenever a very fine timing resolution is expected.

Its modular architecture is used to generate either independent or coupled waveforms. The wave-shape is defined by self-contained timings (using counters and compare units) and a broad range of external events, such as analog or digital feedback and synchronization signals. This is used to produce a large variety of control signals (PWM, phase-shifted, constant Ton,...) and address most of the conversion topologies.

For control and monitoring purposes, the timer also has timing measure capabilities and links to built-in ADC and DAC converters. Last, it features a light-load management mode and is able to handle various fault schemes for safe shut-down purposes.

40.2 Main features

- High-resolution timing units
  - 112 ps resolution, compensated against voltage and temperature variations
  - Duty cycle, frequency, phase shift, and pulse width (triggered one-pulse mode) can be adjusted with full resolution, on all outputs
  - 6 16-bit timing units (each one with an independent counter and four compare units)
  - 12 outputs that can be controlled by any timing unit, up to 32 set/reset sources per channel
  - Modular architecture to address either multiple independent converters with one or two switches or few large multiswitch topologies
- Up to 16 external events, available for any timing unit
  - Suitable for peak current control, zero voltage, and zero current detection (ZVS and ZCS operation) and counter reset (variable frequency operation)
  - 4 sources per external events (digital inputs, built-in comparators outputs, ADC's analog watchdogs, and general purpose timer's trigger outputs)
  - Programmable polarity and edge sensitivity
  - 8 events with a fast asynchronous mode
  - 8 events with a programmable digital filter
  - Spurious events filtering with blanking and windowing modes
- Direct connections to built-in analog peripherals
  - 10 triggers to ADC converters
  - 9 triggers for DAC converters, among which 6 with slope compensation capabilities
  - Comparator outputs (including filtering and blanking features)
- Versatile protection scheme
  - Suitable for overcurrent, short-circuit, and over-voltage/under-voltage protection
  - 8 fault inputs can be combined and associated with any timing unit
  - 3 sources per fault channel (digital inputs, built-in comparators outputs, and external events)
  - Programmable polarity, edge sensitivity, and programmable digital filter
  - Dedicated delayed protections for resonant converters
- Multiple HRTIM instances can be synchronized with external synchronization inputs/outputs
- Versatile output stage
  - High-resolution deadtime insertion (down to 446 ps)
  - Programmable output polarity
  - Chopper mode
- Burst mode controller to handle light-load operation synchronously on multiple converters
- 8 interrupt vectors, each one with up to 14 sources
- 7 DMA requests with up to 14 sources, with a burst mode for multiple registers update

40.3 Functional description

40.3.1 General description

The HRTIM can be partitioned into several subentities:

- The master timer
- The timing units (timer A to timer F)
- The output stage
- The burst mode controller
- An external event and fault signal conditioning logic that is shared by all timers
- The system interface

The master timer is based on a 16-bit up counter. It can set/reset any of the 12 outputs via four compare units and it provides synchronization signals to the six timer units. Its main purpose is to have the timer units controlled by a unique source. An interleaved buck converter is a typical application example where the master timer manages the phase-shifts between the multiple units.

The timer units are working either independently or coupled with the other timers including the master timer. Each timer contains the controls for two outputs. The outputs set/reset events are triggered either by the timing units compare registers or by events coming from the master timer, from the other timers, or from external events.

The output stage has several duties

- Addition of deadtime when the two outputs are configured in complementary PWM mode
- Addition of a carrier frequency on top of the modulating signal
- Management of fault events, by asynchronously asserting the outputs to a predefined safe level

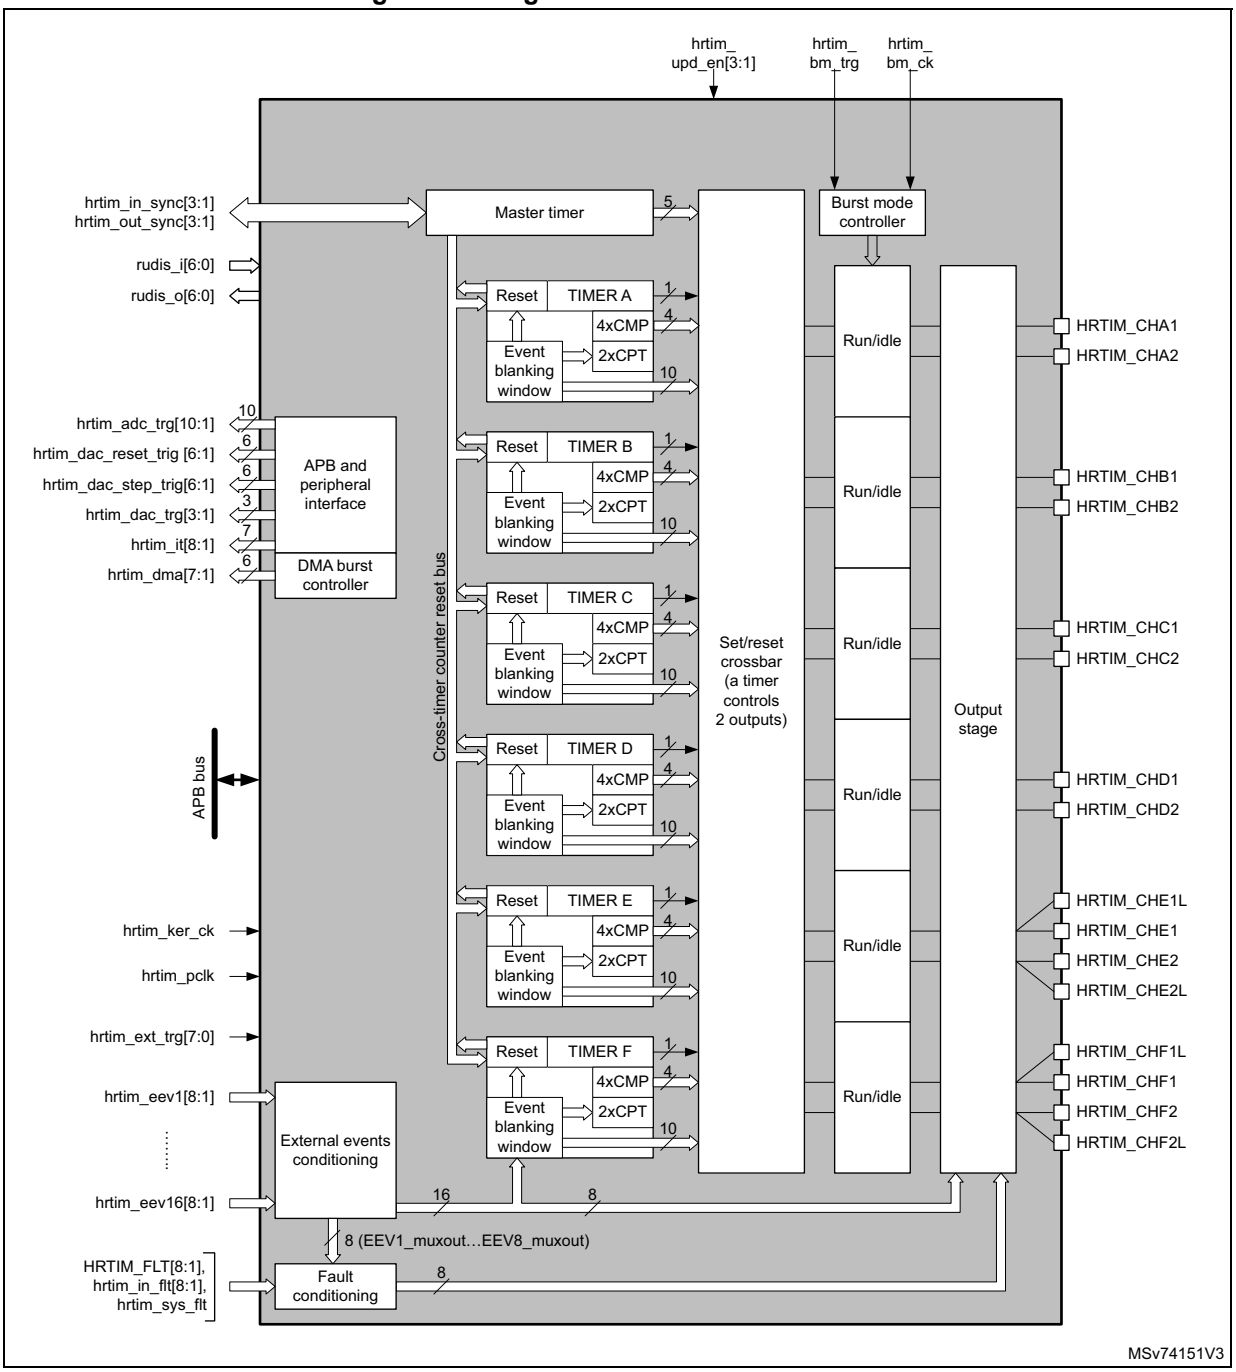
The burst mode controller can take over the control of one or multiple timers in case of light-load operation. The burst length and period can be programmed, as well as the idle state of the outputs.

The external event and fault signal conditioning logic includes:

- The input selection MUXes (for instance for selecting a digital input or an on-chip source for a given external event channel)
- Polarity and edge-sensitivity programming
- Digital filtering (for 5 channels out of 12)

The system interface allows the HRTIM to interact with the rest of the MCU:

- Interrupt requests to the CPU
- DMA controller for automatic accesses to/from the memories, including an HRTIM specific burst mode
- Triggers for the ADC and DAC converters



The HRTIM registers are split into eight groups:

- Master timer registers
- Timer A to timer F registers
- Common registers for features shared by all timer units

Note: As a writing convention, references to the six timing units in the text and in the registers are generalized using the "x" letter, where x can be any value from A to F.

The block diagram of the timer is shown in *Figure 354*.

Figure 354. High-resolution timer overview

40.3.2 HRTIM pins and internal signals

The tables in this section summarize the HRTIM inputs and outputs, both on-chip and off-chip.

Table 410. HRTIM inputs/outputs summary

Signal name	Signal type	Description
HRTIM_CHA1, HRTIM_CHA2, HRTIM_CHB1, HRTIM_CHB2, HRTIM_CHC1, HRTIM_CHC2, HRTIM_CHD1, HRTIM_CHD2, HRTIM_CHE1, HRTIM_CHE2, HRTIM_CHF1, HRTIM_CHF2	Outputs	Main HRTIM timer outputs. They can be coupled by pairs (HRTIM_CHx1 & HRTIM_CHx2) with deadtime insertion or work independently.
HRTIM_CHE1L HRTIM_CHE2L HRTIM_CHF1L HRTIM_CHF2L	Outputs	Low-resolution HRTIM timer outputs.These outputs are derived from the main HRTIM outputs before entering the high-resolution stage. The maximum resolution is determined by f_{HRTIM} instead of f_{HRCK}. For more information, see *Section : Timer clock and prescaler*. This section applies only to STM32G53x and STM32G54x devices.
HRTIM_FLT[8:1] hrtim_in_flt[8:1]	Input	Fault inputs: immediately disable the HRTIM outputs when asserted (8 on-chip inputs and 8 off-chip HRTIM_FLTx inputs).
hrtim_sys_flt	Input	System fault gathering MCU internal fault events (clock security system, SRAM, D-cache and flash memory double error detection, Cortex-M33 lockup (HardFault), PVD output.
hrtim_in_sync[3:1]	Input	Synchronization inputs to synchronize the whole HRTIM with other internal or external timer resources: hrtim_in_sync1: Reserved hrtim_in_sync2: the source is an internal timer output hrtim_in_sync3: the source is HRTIM_SCIN input pins or a PLAY output(1)
hrtim_out_sync[2:1]	Output	The purpose of this output is to cascade or synchronize several HRTIM instances, either on-chip or off-chip: hrtim_out_sync1: Reserved hrtim_out_sync2: the destination is an off-chip HRTIM or peripheral (via HRTIM_SCOUT output pins)

Table 410. HRTIM inputs/outputs summary (continued)

Signal name	Signal type	Description
hrtim_eev1[8:1]	Input	External events. Each of the 16 events can be selected among 8 sources, either on-chip (from other built-in peripherals: comparator, ADC analog watchdog, TIMx timers, trigger outputs) or off-chip (HRTIM_EEVx input pins).
hrtim_eev2[8:1]		
hrtim_eev3[8:1]		
hrtim_eev4[8:1]		
hrtim_eev5[8:1]		
hrtim_eev6[8:1]		
hrtim_eev7[8:1]		
hrtim_eev8[8:1]		
hrtim_eev9[8:1]		
hrtim_eev10[8:1]		
hrtim_eev11[8:1]		
hrtim_eev12[8:1]		
hrtim_eev13[8:1]		
hrtim_eev14[8:1]		
hrtim_eev15[8:1]		
hrtim_eev16[8:1]		
hrtim_ext_trg[7:0]	Input	External triggers, for crossbar override and extra faults inputs
hrtim_upd_en[3:1]	Input	A pulse on the update enable inputs hrtim_upd_end[3:1] (on-chip interconnect) triggers the transfer from shadow to active registers
hrtim_bm_trg	Input	A pulse on this input triggers a burst mode entry.
hrtim_bm_ck[4:1]	Input	Burst mode clock (on-chip interconnect)
hrtim_adc_trg[10:1]	Output	ADC start of conversion triggers. The hrtim_adc_trg1 .. hrtim_adc_trg10 outputs are here-after referred to as ADC trigger 1 to ADC trigger 10.
hrtim_dac_trg[3:1]	Output	DAC conversion update triggers
hrtim_dac_reset_trg[6:1] hrtim_dac_step_trg[6:1]	Output	Dual channel DAC triggers
hrtim_it[8:1]	Output	Interrupt requests
hrtim_dma[7:1]	Output	DMA requests
hrtim_pclk	Input	APB clock
hrtim_ker_ck	-	HRTIM kernel clock

1. Not available on all STM32G5 devices. Refer to the device datasheet for availability.

40.3.3 Clocks

The HRTIM must be supplied by the highest possible kernel clock frequency hrtim_ker_ck (here-after referred as f_{HRTIM}) to offer full resolution. The t_{HRTIM} clock period is evenly divided into up to 32 intermediate steps using an edge positioning logic. All clocks present in the HRTIM are derived from this reference clock.

Definition of terms

f_{HRTIM}: Main HRTIM clock (hrtim_ker_ck). All subsequent clocks are derived and synchronous with this source.

f_{HRCK}: High-resolution equivalent clock. Considering the f_{HRTIM} clock period division by 32, it is equivalent to a frequency of 32 × f_{HRTIM}.

f_{DTG}: Deadtime generator clock. For convenience, only the t_{DTG} period (t_{DTG} = $1/f_{DTG}$) is used in this document.

f_{CHPFRQ}: Chopper stage clock source.

f_{1STPW}: Clock source defining the length of the initial pulse in chopper mode. For convenience, only the t_{1STPW} period (t_{1STPW} = $1/f_{1STPW}$) is used in this document.

f_{BRST}: Burst mode controller counter clock.

$f_{SAMPLING}$: Clock needed to sample the fault or the external events inputs.

f_{FLTS}: Clock derived from f_{HRTIM} which is used as a source for $f_{SAMPLING}$ to filter fault events.

f_{EEVS}: Clock derived from f_{HRTIM} which is used as a source for $f_{SAMPLING}$ to filter external events.

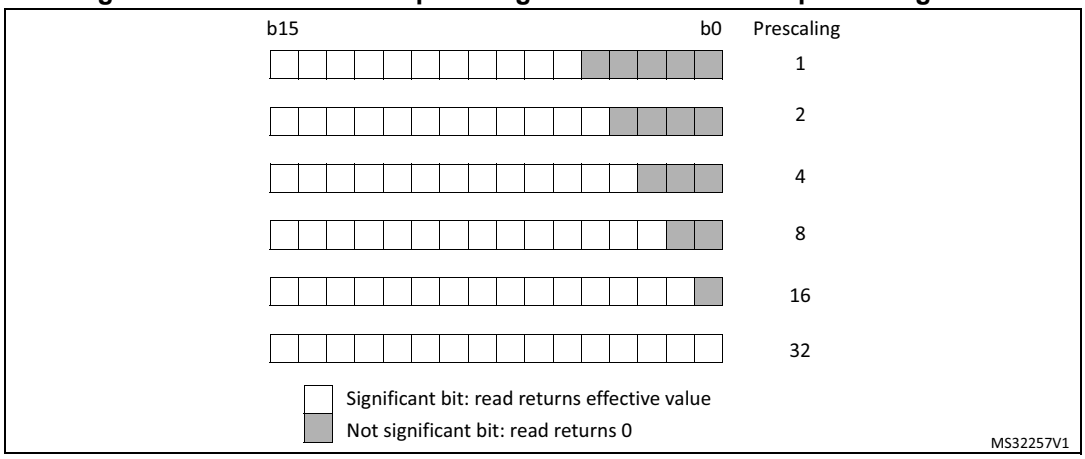
Timer clock and prescaler

Each timer in the HRTIM has its own individual clock prescaler, which is used to adjust the timer resolution (see *Table 419*).

Table 419. Timer resolution and min. PWM frequency for f_{HRTIM} = 280 MHz

CKPSC[2:0]	Prescaling ratio	f_{HRCK} equivalent frequency	Resolution	Min PWM frequency
000	1	280 × 32 MHz = 8.96 GHz	112 ps	136 kHz
001	2	280 × 16 MHz = 4.48 GHz	225 ps	68 kHz
010	4	280 × 8 MHz = 2.24 GHz	450 ps	34 kHz
011	8	280 × 4 MHz = 1.12 GHz	900 ps	17 kHz
100	16	280 × 2 MHz = 560 MHz	1.8 ns	8.5 kHz
101	32	280 MHz	3.6 ns	4.2 kHz
110	64	280/2 MHz = 140 MHz	7.2 ns	2.12 kHz
111	128	280/4 MHz = 70 MHz	14.4 ns	1.06 kHz

The high-resolution is available for edge positioning, PWM period adjustment, and externally triggered pulse duration.



The high-resolution is not available for the following features

- Timer counter read and write accesses
- Capture unit

For clock prescaling ratios below 32 (CKPSC[2:0] < 5), the least significant bits of the counter and capture registers are not significant. The least significant bits cannot be written (counter register only) and return 0 when read.

For instance, if CKPSC[2:0] = 2 (prescaling by 4), writing 0xFFFF into the counter register yields an effective value of 0xFFF8. Conversely, any counter value between 0xFFFF and 0xFFF8 is read as 0xFFF8.

Figure 355. Counter and capture register format vs clock prescaling factor

Low-resolution HRTIM timer outputs

Besides the main outputs, alternate low-resolution outputs are available on some packages. These outputs operate as if the clock prescaler is set to a value greater than or equal to five (CKPSC[2:0] ≥ 5), with the same functionality as the main outputs and a maximum resolution determined by f_{HRTIM} instead of f_{HRCK}.

These outputs are relevant for applications that operate with limited PWM frequencies and do not require high resolution.

Note: It is not mandatory to set CKPSC to a value greater than or equal to five to use these outputs. Setting an identical CKPSC value for all timing units allows events to propagate from one timing unit to another (see warning below).

Initialization

At startup, it is mandatory to initialize first the prescaler bitfields before writing the compare and period registers. Once the timer is enabled (MCEN or TxCEN bit set in the HRTIM_MCR register), the prescaler cannot be modified.

When multiple timers are enabled, the prescalers are synchronized with the prescaler of the timer that was started first.

Warning: It is possible to have different prescaling ratios in the master and TIMA..E timers only if the counter and output behavior does not depend on other timers' information and signals. It is mandatory to configure identical prescaling ratios in these timers when one of the following events is propagated from one timing unit (or master timer) to another: output set/reset event, counter reset event, update event, external event filter, or capture triggers. Prescaler factors not equal yield to unpredictable results.

Deadtime generator clock

The deadtime prescaler is supplied by (f_{HRTIM} × 8) / $2^{(DTPRSC[2:0])}$, programmed with DTPRSC[2:0] bits in the HRTIM_DTxR register.

t_{DTG} ranges from 446 ps to 57 ns for f_{HRTIM} = 280 MHz.

Chopper stage clock

The chopper stage clock source f_{CHPFRQ} is derived from f_{HRTIM} with a division factor ranging from 16 to 256, so that 1.09 MHz ≤ f_{CHPFRQ} ≤ 17.5 MHz for f_{HRTIM} = 280 MHz.

t_{1STPW} is the length of the initial pulse in chopper mode, programmed with the STRPW[3:0] bits in the HRTIM_CHPxR register, as follows:

t_{1STPW} = (STRPW[3:0]+1) × 16 × t_{HRTIM}.

It uses f_{HRTIM} / 16 as clock source (17.5 MHz for f_{HRTIM}= 280 MHz).

Burst mode prescaler

The burst mode controller counter clock f_{BRST} can be supplied by several sources, among which one is derived from f_{HRTIM}.

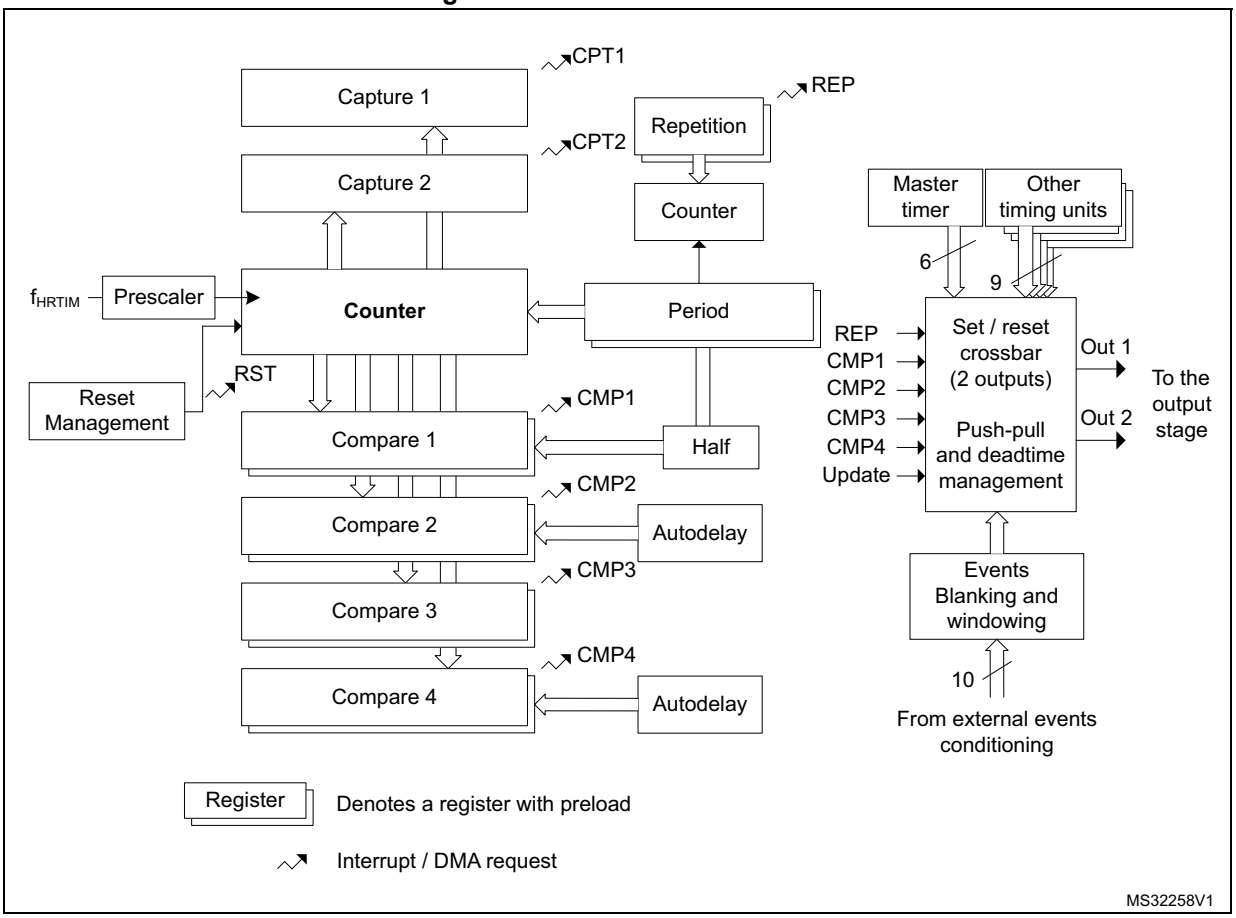
In this case, f_{BRST} ranges from f_{HRTIM} to f_{HRTIM} / 32768 (8.55 kHz for f_{HRTIM} = 280 MHz).

Fault input sampling clock

The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either f_{HRTIM} or f_{FLTS}.

f_{FLTS} is derived from f_{HRTIM} and ranges from 280 MHz to 35 MHz for f_{HRTIM} = 280 MHz.

External event input sampling clock



The fault input noise rejection filter has a time constant defined with $f_{SAMPLING}$ which can be either f_{HRTIM} or f_{EEVS}.

f_{EEVS} is derived from f_{HRTIM} and ranges from 280 MHz to 35 MHz for f_{HRTIM} = 280 MHz.

40.3.4 Timer A..F timing units

The HRTIM embeds six identical timing units made of a 16-bit upcounter with an autoreload mechanism to define the counting period, four compare, and two capture units, as per *Figure 356*. Each unit includes all control features for 2 outputs, so that it operates as a standalone timer.

Figure 356. Timer A..F overview

The period and compare values must be within a lower and an upper limit related to the high-resolution implementation and listed in *Table 420*:

- The minimum value must be greater than or equal to three periods of the f_{HRTIM} clock. The value 0x0000 can be written in CMP1 and CMP3 registers only, to skip a PWM pulse. See *Section : Null duty cycle exception case* for details
- The maximum value must be less than or equal to 0xFFFF - 1 periods of the f_{HRTIM} clock.

Table 420. Period and compare registers min and max values

CKPSC[2:0] value	Min(1)	Max
0	0x0060	0xFFDF
1	0x0030	0xFFEF
2	0x0018	0xFFF7
3	0x000C	0xFFFB
4	0x0006	0xFFFD
≥ 5	0x0003	0xFFFD

1. The value 0x0000 can be written in CMP1 and CMP3 registers only, to skip a PWM pulse. See *Section : Null duty cycle exception case* for details.

Note: A compare value greater than the period register value does not generate a compare match event.

Counter operating mode

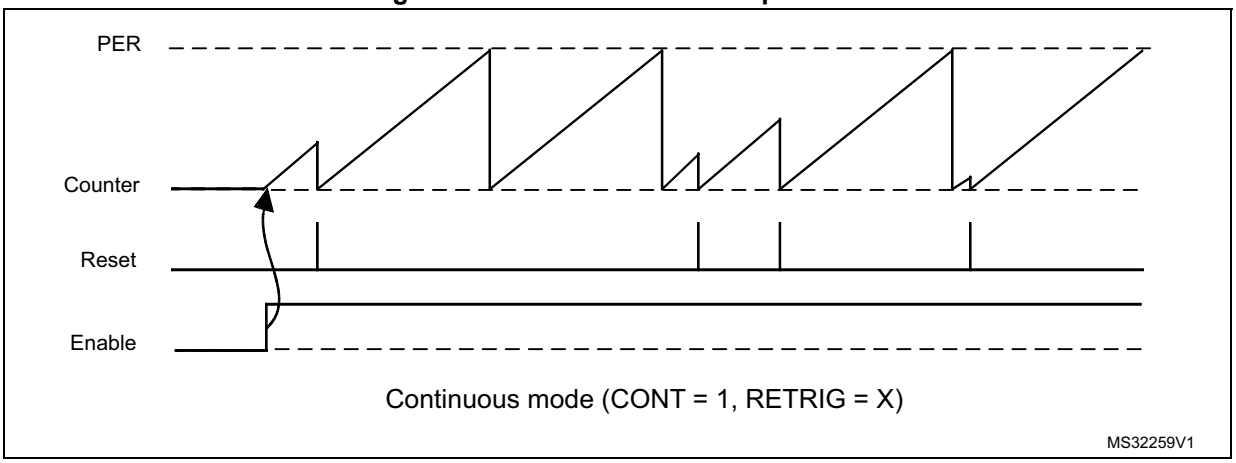
Timer A..F operate in continuous (free-running) mode or in single-shot manner where counting is started by a reset event, using the CONT bit in the HRTIM_TIMxCR control register. An additional RETRIG bit allows you to select whether the single-shot operation is retriggerable or nonretriggerable. Details of the operation are summarized on *Table 421* and on *Figure 357* and *Figure 358*.

Table 421. Timer operating modes

CONT	RETRIG	Operating mode	Start / stop conditions Clocking and event generation
0	0	Single-shot Non-retriggerable	Setting the TxEN bit enables the timer but does not start the counter. A first reset event starts the counting and any subsequent reset is ignored until the counter reaches the PER value. The PER event is then generated and the counter is stopped. A reset event re-starts the counting operation from 0x0000.
0	1	Single-shot Retriggerable	Setting the TxEN bit enables the timer but does not start the counter. A reset event starts the counting if the counter is stopped, otherwise it clears the counter. When the counter reaches the PER value, the PER event is generated and the counter is stopped. A reset event re-starts the counting operation from 0x0000.
1	X	Continuous mode	Setting the TxEN bit enables the timer and starts the counter simultaneously. When the counter reaches the PER value, it rolls-over to 0x0000 and resumes counting. The counter can be reset at any time.

The TxEN bit can be cleared at any time to disable the timer and stop the counting.

Figure 357. Continuous timer operation



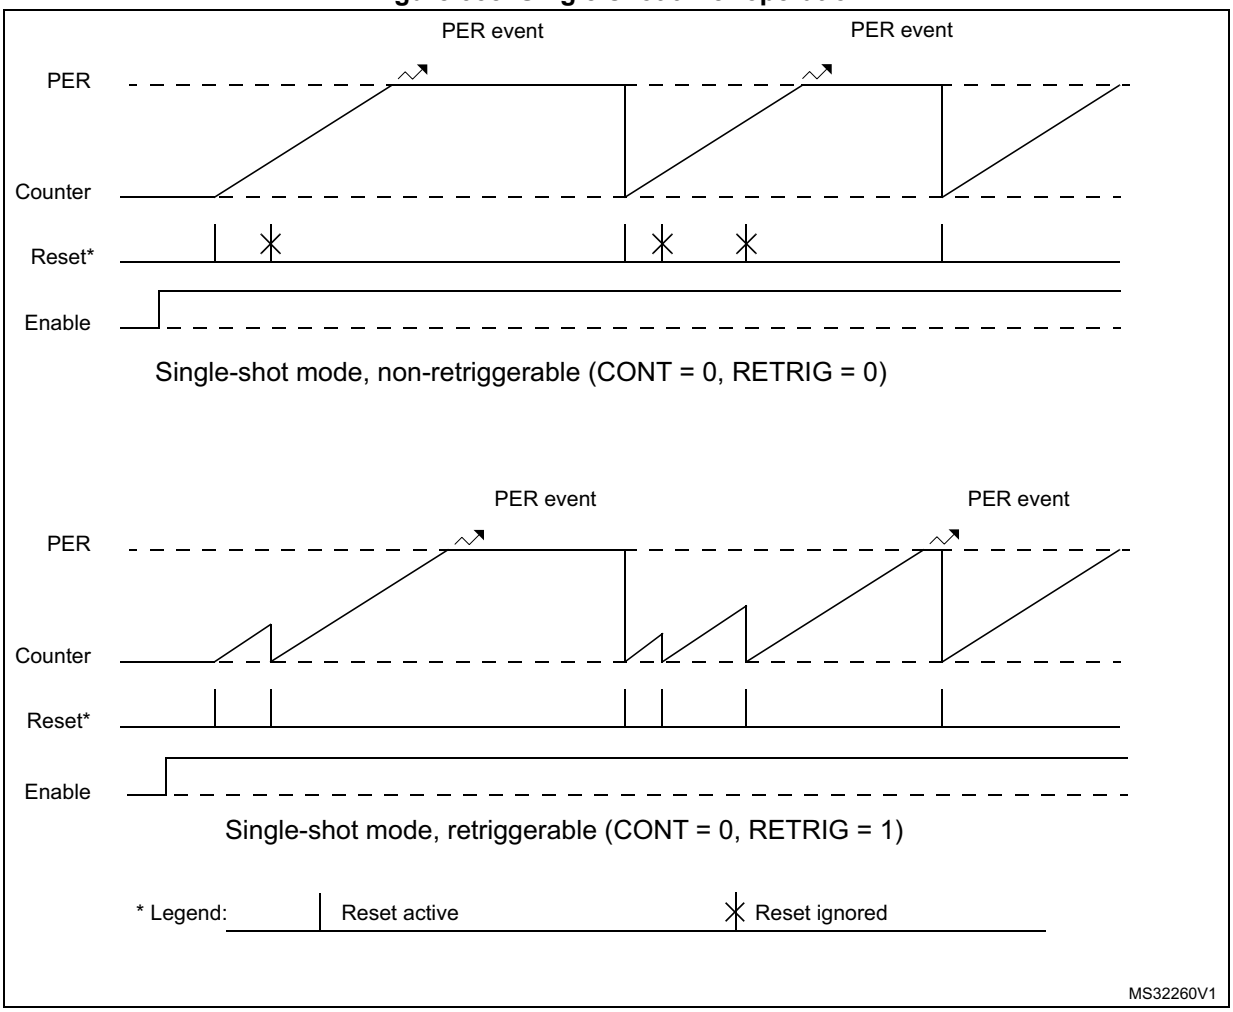


Figure 358. Single-shot timer operation

Roll-over event

A counter roll-over event is generated when the counter goes back to 0 after having reached the period value set in the HRTIM_PERxR register in continuous mode.

This event is used for multiple purposes in the HRTIM:

- To set/reset the outputs
- To trigger the register content update (transfer from preload to active)
- To trigger an IRQ or a DMA request
- To serve as a burst mode clock source or a burst start trigger
- As an ADC trigger
- To decrement the repetition counter

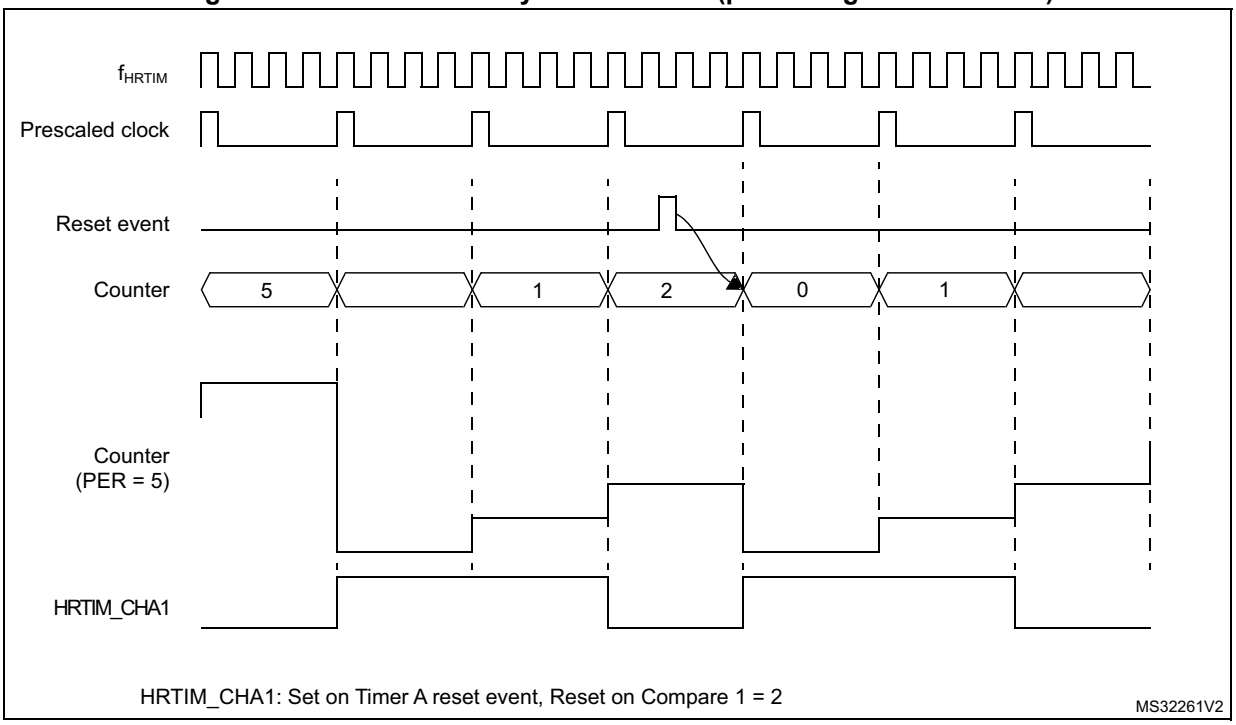
If the initial counter value is above the period value when the timer is started, or if a new period is set while the counter is already above this value, the counter is not reset: it overflows at the maximum period value and the repetition counter does not decrement.

Timer reset

The reset of the timing unit counter can be triggered by up to 30 events that can be selected simultaneously in the HRTIM_RSTxR register, among the following sources:

- The timing unit: compare 2, compare 4 and update (three events)
- The master timer: reset and compare 1..4 (five events)
- The external events EXTEVNTA..J (10 events)
- All other timing units (e.g. timer B..F for timer A): compare 1, 2 and 4 (12 events)

Several events can be selected simultaneously to handle multiple reset sources. In this case, the multiple reset requests are ORed. When two counter reset events are generated within the same f_{HRTIM} clock cycle, the last counter reset is taken into account.



Additionally, it is possible to do a software reset of the counter using the TxRST bits in the HRTIM_CR2 register. These control bits are grouped into a single register to allow the simultaneous reset of several counters.

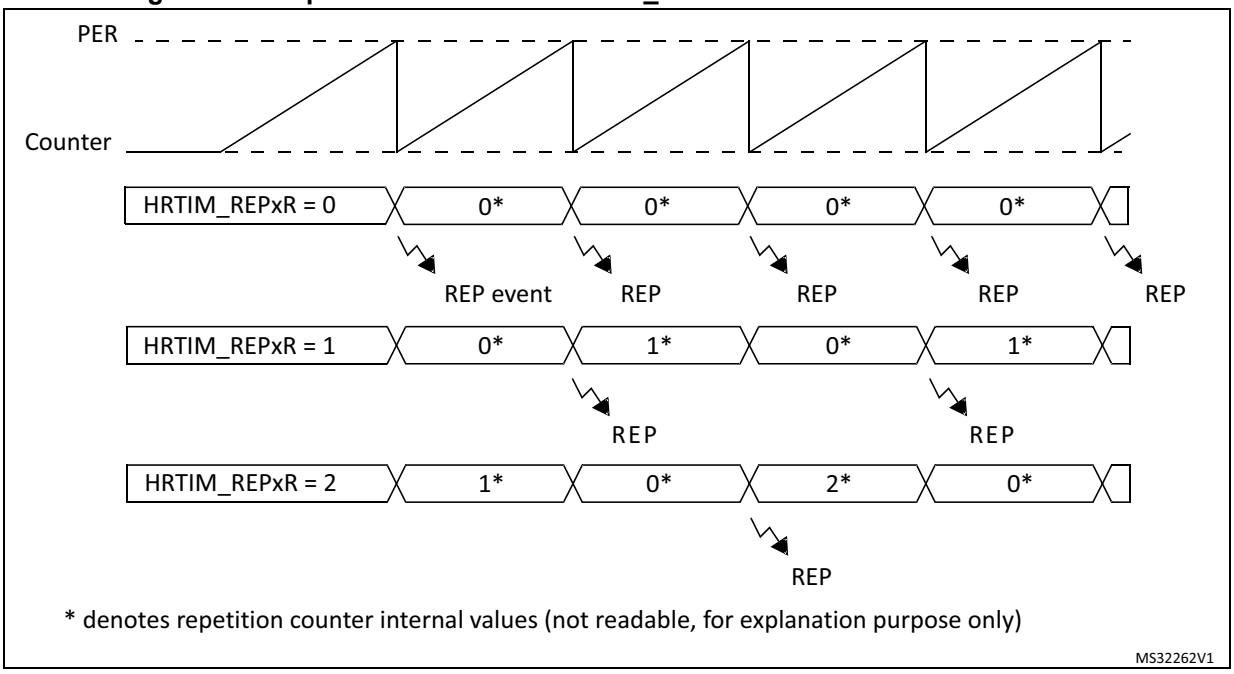
The reset requests are taken into account only once the related counters are enabled (TxCEN bit set).

When the f_{HRTIM} clock prescaling ratio is above 32 (counting period above f_{HRTIM}), the counter reset event is delayed to the next active edge of the prescaled clock. This is used to maintain a jitterless waveform generation when an output transition is synchronized to the reset event (typically a constant Ton time converter).

Figure 359 shows how the reset is handled for a clock prescaling ratio of 128 (f_{HRTIM} divided by 4).

Figure 359. Timer reset resynchronization (prescaling ratio above 32)

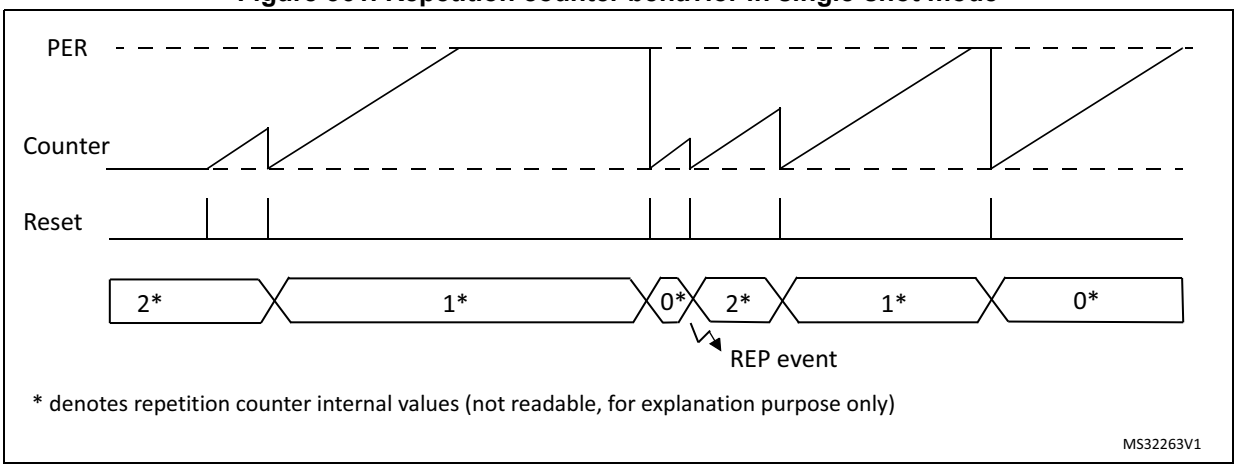
Repetition counter



A common software practice is to have an interrupt generated when the period value is reached, so that the maximum amount of time is left for processing before the next period begins. The main purpose of the repetition counter is to adjust the period interrupt rate and off-load the CPU by decoupling the switching frequency and the interrupt frequency.

The timing units have a repetition counter. This counter cannot be read, but solely programmed with an autoreload value in the HRTIM_REPxR register.

The repetition counter is initialized with the content of the HRTIM_REPxR register when the timer is enabled (TXCEN bit set). Once the timer has been enabled, anytime the counter is cleared, either due to a reset event or due to a counter roll-over, the repetition counter is decreased. When it reaches zero, a REP interrupt or a DMA request is issued if enabled (REPIE and REPDE bits in the HRTIM_DIER register).



If the HRTIM_REPxR register is set to 0, an interrupt is generated for each and every period. For any value above 0, a REP interrupt is generated after (HRTIM_REPxR + 1) periods. *Figure 360* presents the repetition counter operation for various values, in continuous mode.

Figure 360. Repetition rate versus HRTIM_REPxR content in continuous mode

The repetition counter can also be used when the counter is reset before reaching the period value (variable frequency operation) either in continuous or in single-shot mode (*Figure 361* here-below). The reset causes the repetition counter to be decremented, at the exception of the very first start following counter enable (TxCEN bit set).

Figure 361. Repetition counter behavior in single-shot mode

A reset or start event from the HRTIM_SCIN[3:1] source causes the repetition to be decremented as any other reset. However, in SYNCIN-started single-shot mode (SYNCSTRTx bit set in the HRTIM_TIMxCR register), the repetition counter is decremented only on the first reset event following the period. Any subsequent restarted by a new request on HRTIM_SCIN[3:1] inputs.

Set/reset crossbar

A “set” event correspond to a transition to the output active state, while a “reset” event corresponds to a transition to the output inactive state.

The polarity of the waveform is defined in the output stage to accommodate positive or negative logic external components: an active level corresponds to a logic level 1 for a positive polarity (POLx = 0), and to a logic level 0 for a negative polarity (POLx = 1).

Each of the timing units handles the set/reset crossbar for two outputs. These two outputs can be set, reset, or toggled by up to 32 events that can be selected among the following sources:

- The timing unit: period, compare 1..4, register update (six events)
- The master timer: period, compare 1..4, HRTIM synchronization (six events)
- All other timing units (e.g. timer B..F for timer A): TIMEVNT1..9 (nine events described in *Table 422*)
- The external events EXTEVNTA..J (10 events)
- A software forcing (one event)

Note: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

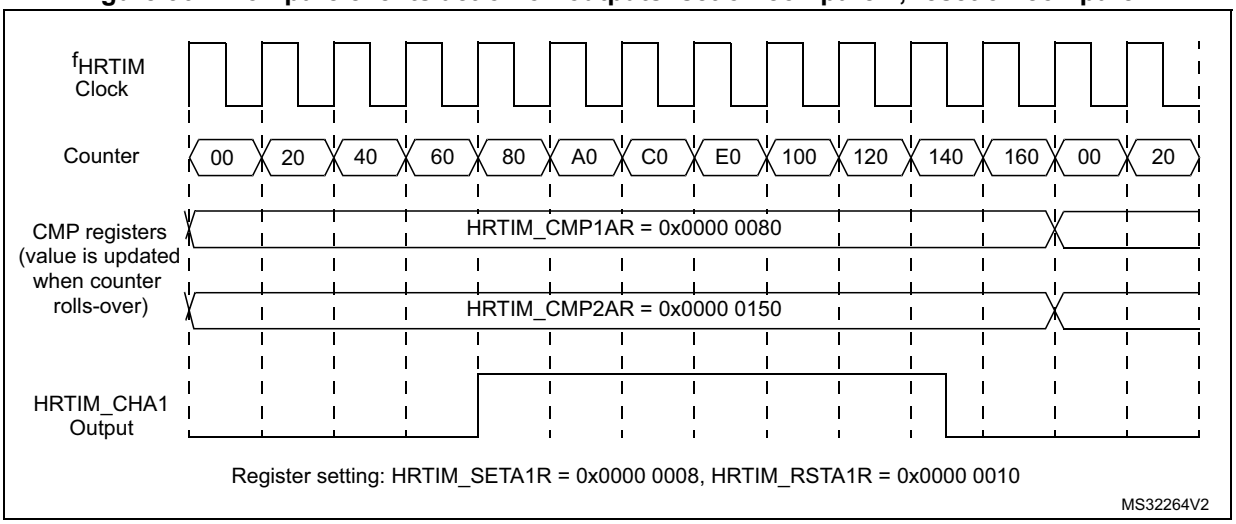
The event sources are ORed and multiple events can be simultaneously selected.

Each output is controlled by two 32-bit registers, one coding for the set (HRTIM_SETxyR) and another one for the reset (HRTIM_RSTxyR), where x stands for the timing unit: A..F and y stands for the output 1or 2 (e.g. HRTIM_SETA1R, HRTIM_RSTC2R,...).

If the same event is selected for both set and reset, it toggles the output. It is not possible to toggle the output state more than one time per t_{HRTIM} period: in case of two consecutive toggling events within the same cycle, only the first one is considered.

The set and reset requests are taken into account only once the counter is enabled (TxCEN bit set), except if the software is forcing a request to allow the prepositioning of the outputs at timer startup.

Table 422 summarizes the events from other timing units that can be used to set and reset the outputs. The number corresponds to the timer events (such as TIMEVNTx) listed in the register, and empty locations are indicating nonavailable events.



For instance, timer A outputs can be set or reset by the following events: timer B compare 1 and 2, timer C compare 2 and 3,... and timer E compare 3 is listed as TIMEVNT7 in HRTIM_SETA1R.

Table 422. Events mapping across timer A to F

Source		Timer A				Timer B				Timer C				Timer D				Timer E				Timer F			
		CMP1	CMP2	CMP3	CMP4	CMP1	CMP2	CMP3	CMP4	CMP1	CMP2	CMP3	CMP4	CMP1	CMP2	CMP3	CMP4	CMP1	CMP2	CMP3	CMP4	CMP1	CMP2	CMP3	CMP4

Figure 362 represents how a PWM signal is generated using two compare events.

Figure 362. Compare events action on outputs: set on compare 1, reset on compare 2

Set/reset on update events

A set or reset event on update is done at low resolution. When CKPSC[2:0] < 5, the high-resolution delay is set to its maximum value so that a set/reset event on update always lags as compared to other compare set/reset events, with a jitter varying between 0 and 31/32 of a f_{HRTIM} clock period.

Half mode

This mode aims at generating a square signal with a fixed 50% duty cycle and variable frequency (typically for converters using resonant topologies). It is used to have the duty cycle automatically forced to half of the period value when a new period is programmed.

This mode is enabled by writing HALF bit to 1 in the HRTIM_TIMxCR register. When the HRTIM_PERxR register is written, it causes an automatic update of the compare one value with HRTIM_PERxR/2 value.

The output on which a square wave is generated must be programmed to have one transition on the CMP1 event, and one transition on the period event, as follows:

- HRTIM_SETxyR = 0x0000 0008, HRTIM_RSTxyR = 0x0000 0004, or
- HRTIM_SETxyR = 0x0000 0004, HRTIM_RSTxyR = 0x0000 0008

The HALF mode overrides the content of the HRTIM_CMP1xR register. The access to the HRTIM_PERxR register only causes compare 1 internal register to be updated. The user-accessible HRTIM_CMP1xR register is not updated with the HRTIM_PERxR / 2 value.

When the preload is enabled (PREEN = 1), compare 1 active register is refreshed on the update event. If the preload is disabled (PREEN= 0), compare 1 active register is updated as soon as HRTIM_PERxR is written.

The period must be greater than or equal to six periods of the f_{HRTIM} clock (0xC0 if CKPSC[2:0] = 0, 0x60 if CKPSC[2:0] = 1, 0x30 if CKPSC[2:0] = 2,...) when the HALF mode is enabled.

Interleaved mode

This mode complements the Half mode and helps the implementation of interleaved topologies.

It is used to recompute automatically the content of compare registers when the HRTIM_PERxR value is updated.

The selection is done using the HALF bit and the INTLVD[1:0] bits in HRTIM_MCR and HRTIM_TIMxCR registers, as shown on the *Table 423* below.

Table 423. Interleaved mode selection

HALF bit	INTLVD [1:0] bits	Mode
0	00	Disabled
0	01	Triple interleaved (120°)
0	10	Quad interleaved (90°)
0	11	Reserved
1	xx	Dual interleaved (180°)

Table 424 gives the compare values for the three available modes. The content of the compare registers is overridden. The corresponding compare events can be used to trigger an output set/reset or to reset a slave timer.

Table 424. Compare 1..3 values in interleaved mode

Mode	Dual interleaved 180°	Triple interleaved 120°	Quad interleaved 90°
CMP1 value	PERxR/2	PERxR/3	PERxR/4
CMP2 value	Not affected	2x (PERxR/3)	PERxR/2
CMP3 value	Not affected	Not affected	3x (PERxR/4)

Note: In half and interleaved modes, the compare registers are controlled by hardware and writing them has no effect. However the written value is stored in the preload register and becomes active on the update event following the exit of these modes.

Note: The triple and quad interleaved modes must not be used simultaneously with other modes using CMP2 (dual channel dac trigger and triggered-half modes).

Null duty cycle exception case

The high-resolution behavior is not supported for pulses narrower than three t_{HRTIM} periods (see *Section 40.3.7: Set/reset events priorities and narrow pulses management*) and any value strictly below 3 periods of the f_{HRTIM} clock (that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...) in the HRTIM_TIMxCMPy register is forbidden (see *40.5.19: HRTIM timer x compare 1 register (HRTIM_CMP1xR) (x = A to F)*).

However, it is possible to skip an output pulse and have a null duty cycle by simply writing a null value in the HRTIM_TIMxCMPy registers, if and only if the following conditions are met:

- The output SET event is generated by the PERIOD event
- The output RESET if generated by the compare event
- The compare event is active within the timer unit itself, and not used for other timing units

For any other use case, this can be done by programming the SET and RESET events with the very same compare values, above three periods of the f_{HRTIM} clock. In this case, the output is reset forced (following the set/reset priority scheme defined in the *Section 40.3.7: Set/reset events priorities and narrow pulses management*).

When a null value is programmed, the CMPx flags are set, and the related interrupt is issued if enabled. An event is also generated on synchronization output when SYNCSRC= 11 (synchronization generated on TIM1 CMP1 event).

The following limitations apply when a null value is programmed:

- ADC and burst mode triggers are not generated
- The CMP1 cannot be used for blanking events or faults

Swap mode

This mode is used to swap the two outputs with a single bit access: the output 1 signal is connected to the output 2 pin and the output 2 signal is connected to output 1 pin. The output swap is triggered with the SWPx bits in the HRTIM_CR2 register and is effective on the next update event.

The outputs are swapped prior to the set/reset crossbar unit, as follows:

- If SWPx = 0, HRTIM_SETx1R and HRTIM_RSTx1R are coding for the output 1, HRTIM_SETx2R and HRTIM_RSTx2R are coding for the output 2
- If SWPx = 1, HRTIM_SETx1R and HRTIM_RSTx1R are coding for the output 2, HRTIM_SETx2R and HRTIM_RSTx2R are coding for the output 1

The swap mode is only affecting the preload register, and not the active registers.

Note: The preload mode must be enabled when using the swap mode.

Consequently, it does not modify the auxiliary outputs in parallel with the regular outputs going to the output stage (see *Section 40.3.18* for details). They provide the following internal status, events, and signals:

- O1CPY, O2CPY, SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset (TA2, TB2, TC2, TD2, TE2, TF2)
- External event filters generated with a Tx2 output copy

For instance the SETx1 flag is related to the output 1 when SWP = 0 and is related to the output 2 when SWPx = 1.

Similarly, the swap mode does not change the attribution of control bits in the HRTIM_OUTxR register (DIDLx, CHPx, FAULTx[1:0], IDLESx, POLx bits). For instance, the POL1 bit controls the output 1 polarity whatever the SWP bit value.

Note: The SWPx bits are ignored in push-pull mode (PSHPLL = 1 in the HRTIM_TIMxCR register).

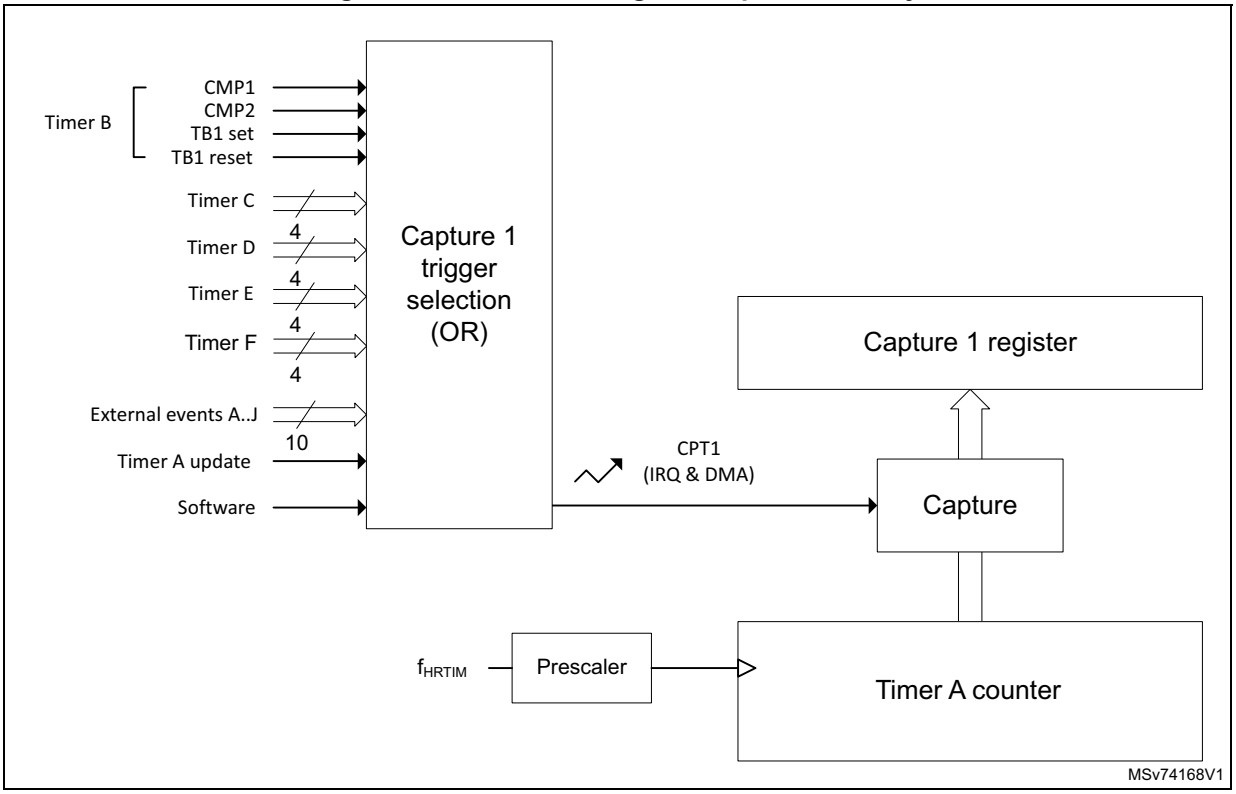
Capture

The timing unit has the capability to capture the counter value, triggered by internal and external events. The purpose is to:

- Measure events arrival timings or occurrence intervals
- Update compare 2 and compare 4 values in autodelayed mode (see *Section : Autodelayed mode*).

The capture is done with f_{HRTIM} resolution: for a clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the register are not significant (read as 0).

The timer has two capture registers: HRTIM_CPT1xR and HRTIM_CPT2xR. The capture triggers are programmed in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers.



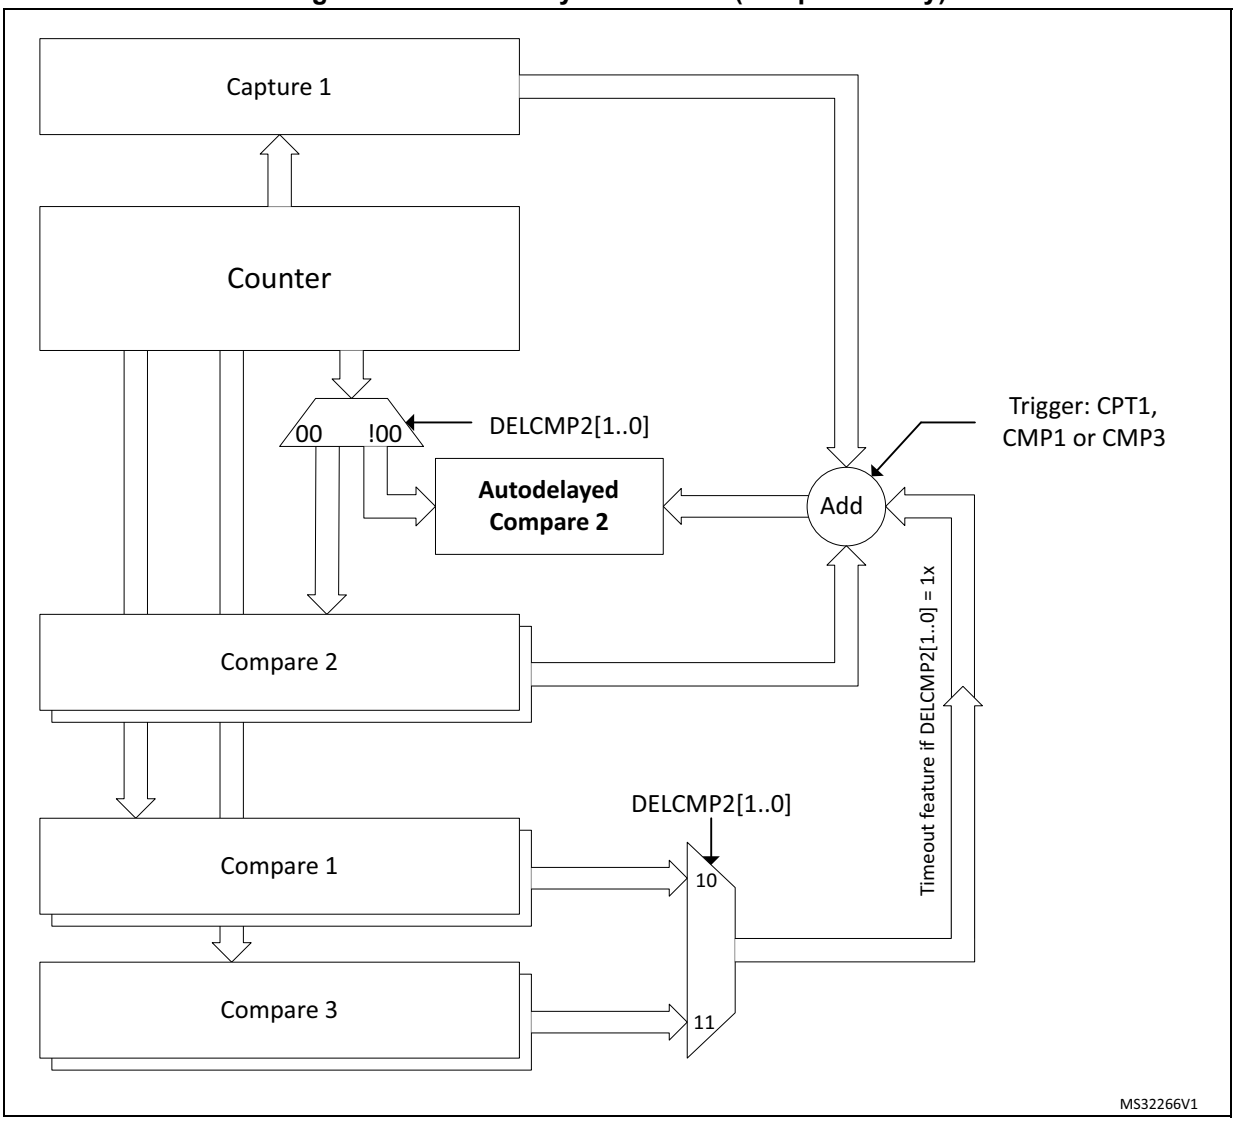
The capture of the timing unit counter can be triggered by up to 28 events that can be selected simultaneously in the HRTIM_CPT1xCR and HRTIM_CPT2xCR registers, among the following sources:

- The external events, EXTEVNTA..J (10 events)
- All other timing units (e.g. timer B..F for timer A): compare 1, 2 and output 1 set/reset events (16 events)
- The timing unit: update (one event)
- A software capture (one event)

Several events can be selected simultaneously to handle multiple capture triggers. In this case, the concurrent trigger requests are ORed. The capture can generate an interrupt or a DMA request when CPTxIE and CPTxDE bits are set in the HRTIM_TIMxDIER register.

Overcapture is not prevented by the circuitry: a new capture is triggered even if the previous value was not read, or if the capture flag was not cleared.

Figure 363. Timer A timing unit capture circuitry



Autodelayed mode

This mode is used to have compare events generated relatively to capture events, so that for instance an output change can happen with a programmed timing following a capture. In this case, the compare match occurs independently from the timer counter value. It enables the generation of waveforms with timings synchronized to external events without the need of software computation and interrupt servicing.

As long as no capture is triggered, the content of the HRTIM_CMPxR register is ignored (no compare event is generated when the counter value matches the compare value. Once the capture is triggered, the compare value programmed in HRTIM_CMPxR is summed with the captured counter value in HRTIM_CPTxyR, and it updates the internal autodelayed compare register, as seen on *Figure 364*. The autodelayed compare register is internal to the timing unit and cannot be read. The HRTIM_CMPxR preload register is not modified after the calculation.

This feature is available only for compare 2 and compare 4 registers. Compare 2 is associated with capture 1, while compare 4 is associated with capture 2. HRTIM_CMP2xR and HRTIM_CMP4xR compares cannot be programmed with a value below three f_{HRTIM} clock periods, as in the regular mode.

Figure 364. Auto-delayed overview (compare 2 only)

The autodelayed compare is only valid from the capture up to the period event: once the counter has reached the period value, the system is rearmed with compare disabled until a capture occurs.

DELCMP2[1:0] and DELCMP4[1:0] bits in HRTIM_TIMxCR register are used to configure the autodelayed mode as follows:

- 00
  Regular compare mode: HRTIM_CMP2xR and HRTIM_CMP4xR register contents are directly compared with the counter value.
- 01
  Autodelayed mode: compare 2 and compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event.
- 10 or 11
  Autodelayed mode with timeout: compare 2 and compare 4 values are recomputed and used for comparison with the counter after a capture 1/2 event or after a compare 1

match (DELCMPx[1:0]= 10) or a compare 3 match (DELCMPx[1:0]= 11) to have a timeout function if capture 1/2 event is missing.

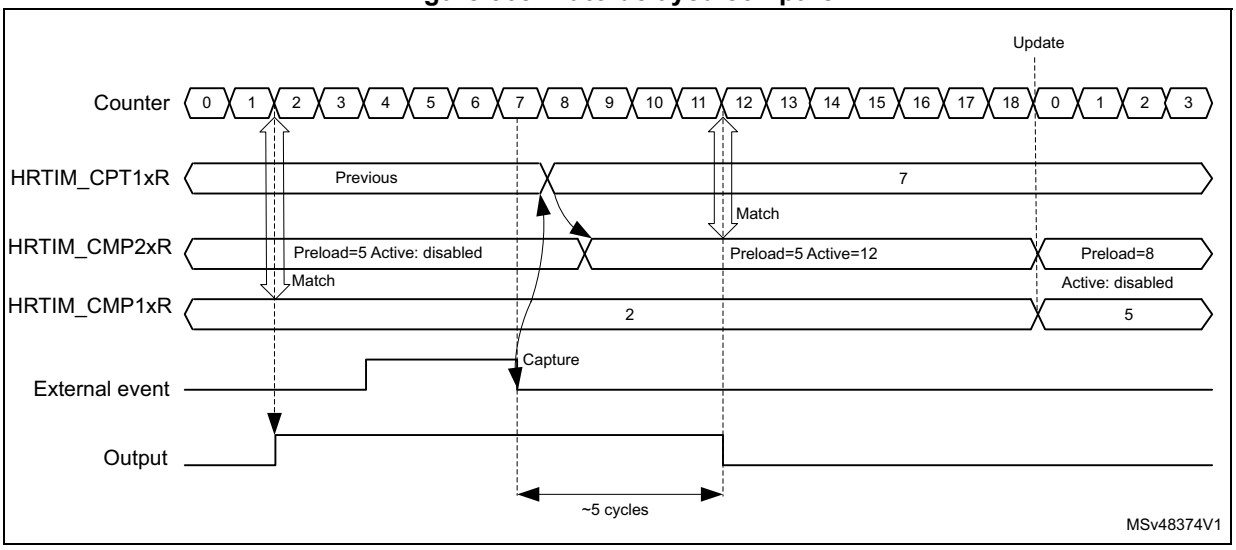
When the capture occurs, the comparison is done with the (HRTIM_CMP2/4xR + HRTIM_CPT1/2xR) value. If no capture is triggered within the period, the behavior depends on the DELCMPx[1:0] value:

- DELCMPx[1:0] = 01: the compare event is not generated
- DELCMPx[1:0] = 10 or 11: the comparison is done with the sum of the two compares (for instance HRTIM_CMP2xR + HRTIM_CMP1xR). The captures are not taken into account if they are triggered after CMPx + CMP1 (resp. CMPx + CMP3).

The captures are enabled again at the beginning of the next PWM period.

If the result of the autodelayed summation is above 0xFFFF (overflow), the value is ignored and no compare event is generated until a new period is started.

Note: DELCMPx[1:0] bitfield must be reset when reprogrammed from one value to the other to reinitialize properly the autodelayed mechanism, for instance:



- DELCMPx[1:0] = 10
- DELCMPx[1:0] = 00
- DELCMPx[1:0] = 11

As an example, *Figure 365* shows how the following signal is generated:

- Output set when the counter is equal to compare 1 value
- Output reset 5 cycles after a falling edge on a given external event

Note: To simplify the figure, the high-resolution is not used in this example (CKPSC[2:0] = 101), thus the counter is incremented at the f_{HRTIM} rate. Similarly, the external event signal is shown without any resynchronization delay: practically, there is a delay of one to two f_{HRTIM} clock periods between the falling edge and the capture event due to an internal resynchronization stage which is necessary to process external input signals.

Figure 365. Auto-delayed compare

A regular compare channel (e.g. compare 1) is used for the output set: as soon as the counter matches the content of the compare register, the output goes to its active state.

A delayed compare is used for the output reset: the compare event can be generated only if a capture event has occurred. No event is generated when the counter matches the delayed compare value (counter = 4). Once the capture event has been triggered by the external event, the content of the capture register is summed to the delayed compare value to have the new compare value. In the example, the autodelayed value 4 is summed to the capture equal to 7 to give a value of 12 in the autodelayed compare register. From this time on, the compare event can be generated and happens when the counter is equal to 12, causing the output to be reset.

Overcapture management in autodelayed mode

Overcapture is prevented when the autodelayed mode is enabled (DELCMPx[1:0] = 01, 10, 11).

When multiple capture requests occur within the same counting period, only the first capture is taken into account to compute the autodelayed compare value. A new capture is possible only:

- Once the autodelayed compare has matched the counter value (compare event)
- Once the counter has rolled over (period)
- Once the timer has been reset

Changing autodelayed compare values

When the autodelayed compare value is preloaded (PREEN bit set), the new compare value is taken into account on the next coming update event (for instance on the period event), regardless of when the compare register was written and if the capture occurred (see *Figure 365*, where the delay is changed when the counter rolls over).

When the preload is disabled (PREEN bit reset), the new compare value is taken into account immediately, even if it is modified after the capture event has occurred, as per the example below:

1. At t1, DELCMP2 = 1.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, a capture event occurs capturing the value CPTR1 = 0x20. => comparison enabled, compare value = 0x60
4. At t4, CMP2_act = 0x100 (before the counter reached value CPTR1 + 0x40) => comparison still enabled, new compare value = 0x120
5. At t5, the counter reaches the period value => comparison disabled, cmp2_act = 0x100

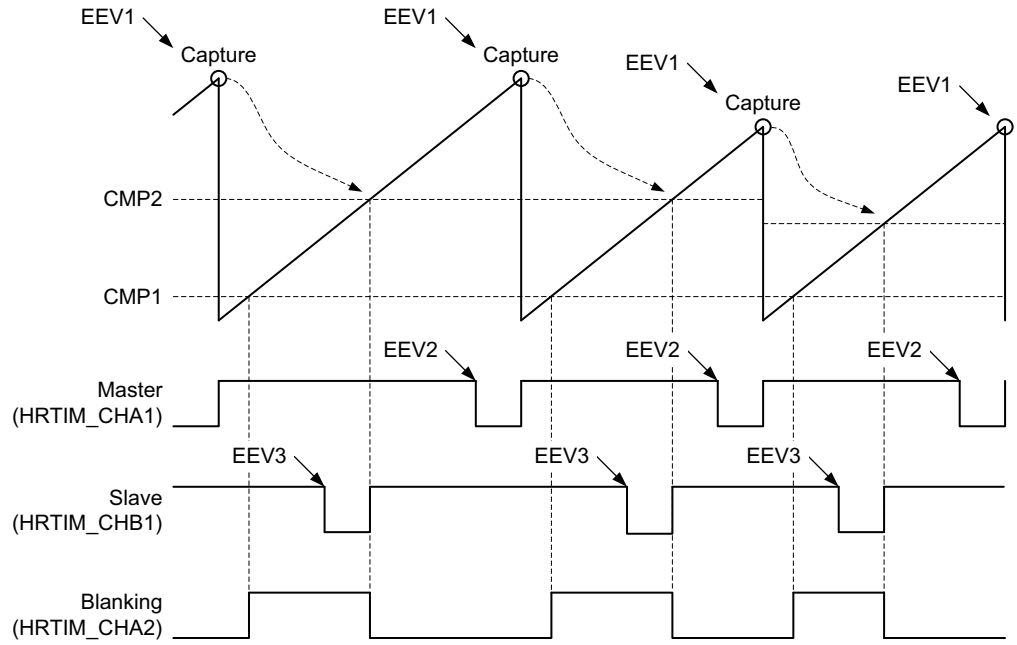
Similarly, if the CMP1(CMP3) value changes while DELCMPx = 10 or 11, and preload is disabled:

1. At t1, DELCMP2 = 2.
2. At t2, CMP2_act = 0x40 => comparison disabled
3. At t3, CMP3 event occurs - CMP3_act = 0x50 before capture 1 event occurs => comparison enabled, compare value = 0x90
4. At t4, CMP3_act = 0x100 (before the counter reached value 0x90) => comparison still enabled, compare 2 event occurs at = 0x140

Triggered-half mode

The purpose of this mode is to allow the synchronization of two interleaved converters that have variable frequency operation, and require a 180° phase-shift. The basic principle is to

have a master-slave system. The slave converter synchronization is continuously adjusted based on the previous switching period of the master converter.



This is done using the capture unit. The switching period of the master converter is captured, divided by two and then stored in the compare 2 register by hardware. The compare 2 register contains a value equal to half of the captured period, which is the master converter switching period. The compare 2 event can then be used to trigger a second timing unit that manages the slave converter.

This mode is enabled by setting the TRGHLF bit in the HRTIM_TIMxCR2 register. This bit cannot be changed once the timer is operating (TxEN bit set).

The triggered-half mode must not be used simultaneously with other modes using CMP2 (dual channel DAC trigger, interleaved and balanced idle modes).

The initial value CMP2 can be written by the user, but is ignored once the first capture is triggered. The preload mechanism is disabled for CMP2 when the TRGHLF bit is reset.

Figure 366. Triggered-half mode example

HRTIM_CHA1
Set on EEV1 (EEV1 triggers Capture1)
Reset on EEV2

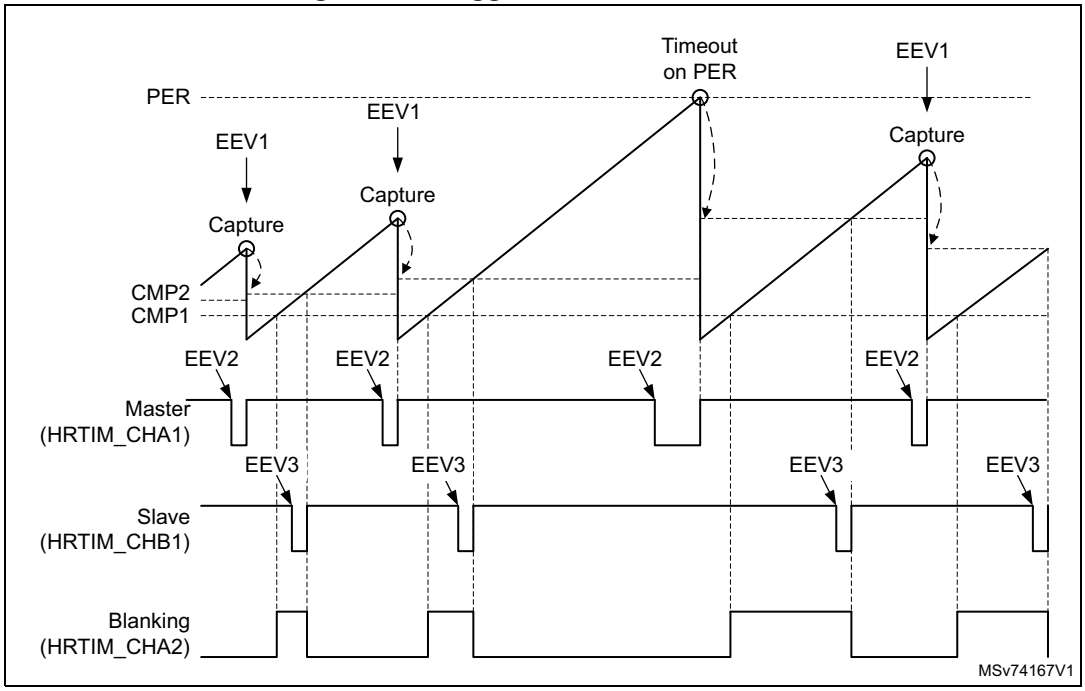
Set on CMP2 (triggered-half) or EEV1 blanking by TIMA_TA2
(TB1 is set if EEV1 occurs between CMP1 and CMP2, else on CMP2)
Reset on EEV3
HRTIM_CHA2
Set on TA_CMP1
Reset on TA_CMP2

MSv45796V3



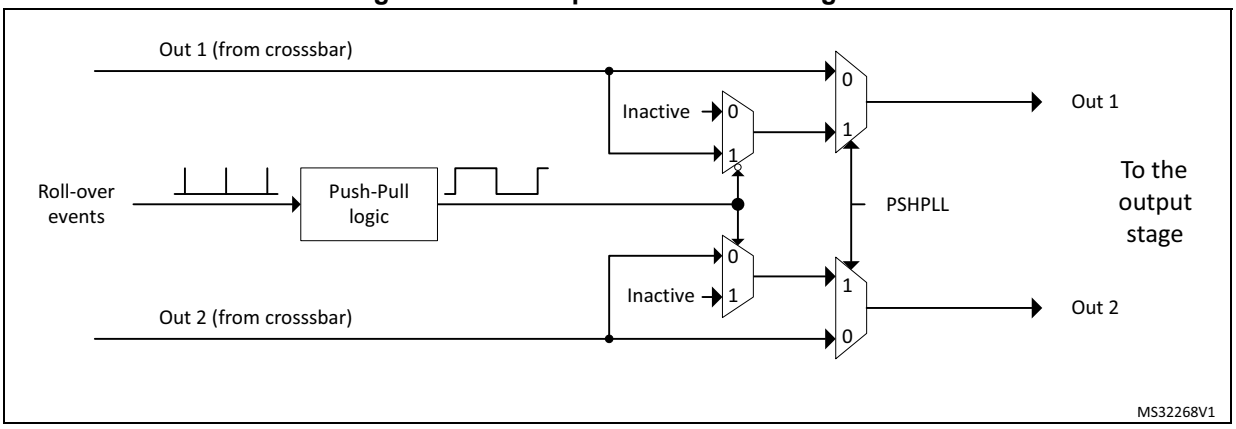
Note: In triggered half mode, the compare2 register is controlled by hardware and writing it has no effect. However the written value is stored in the preload register and becomes active on the update event following the exit of this mode.

It is possible to generate a timeout event when the external event is missing, as shown on *Figure 367* below. This mode is enabled with the TRGHLFT in HRTIM_CR2 register.

No capture event is generated when a timeout occurs. A timeout situation can be detected using the PER interrupt.

The timeout occurs regardless of the repetition value.

Figure 367. Triggered-half mode timeout



Push-pull mode

This mode primarily aims at driving converters using push-pull topologies. It also needs to be enabled when the delayed idle protection is required, typically for resonant converters (refer to *Section 40.3.10: Delayed protection*).

The push-pull mode is enabled by setting the PSHPLL bit in the HRTIM_TIMxCR register.

It applies the signals generated by the crossbar to output 1 and output 2 alternatively, on the period basis, maintaining the other output to its inactive state. The redirection rate (push-pull frequency) is defined by the timer's period event, as shown on *Figure 368*. The push-pull period is twice the timer counting period.

Figure 368. Push-pull mode block diagram

The push-pull mode is available when the timer operates in continuous mode and in single-shot mode. It is necessary to disable the timer to stop a push-pull operation and to reset the counter before reenabling it.

To get a correct behavior, the event selected as source of the counter reset must be also selected for setting (or resetting) the output. It must set the output if the output is set on period, else it must reset it. If it is not done, the output switching from its inactive period to its active period may be incorrect (may unexpectedly rise or may unexpectedly stay low).

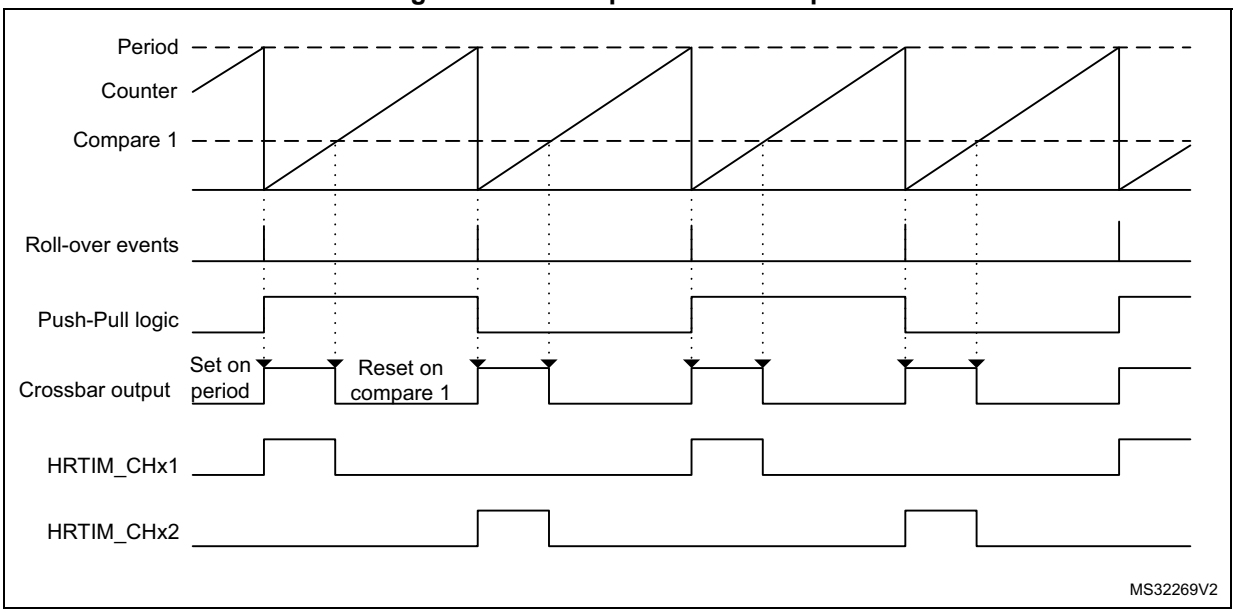
The signal shape is defined using HRTIM_SETxyR and HRTIM_RSTxyR for both outputs. It is necessary to have HRTIM_SETx1R = HRTIM_SETx2R and HRTIM_RSTx1R = HRTIM_RSTx2R to have both outputs with identical waveforms and to achieve a balanced operation. Still, it is possible to have different programming on both outputs for other uses.

The CPPSAT status bit in HRTIM_TIMxISR indicates on which output the signal is currently active. CPPSTAT is reset when the push-pull mode is disabled.

In the example given on *Figure 369*, the timer internal waveform is defined as follows:

- Output set on period event
- Output reset on compare 1 match event

Figure 369. Push-pull mode example



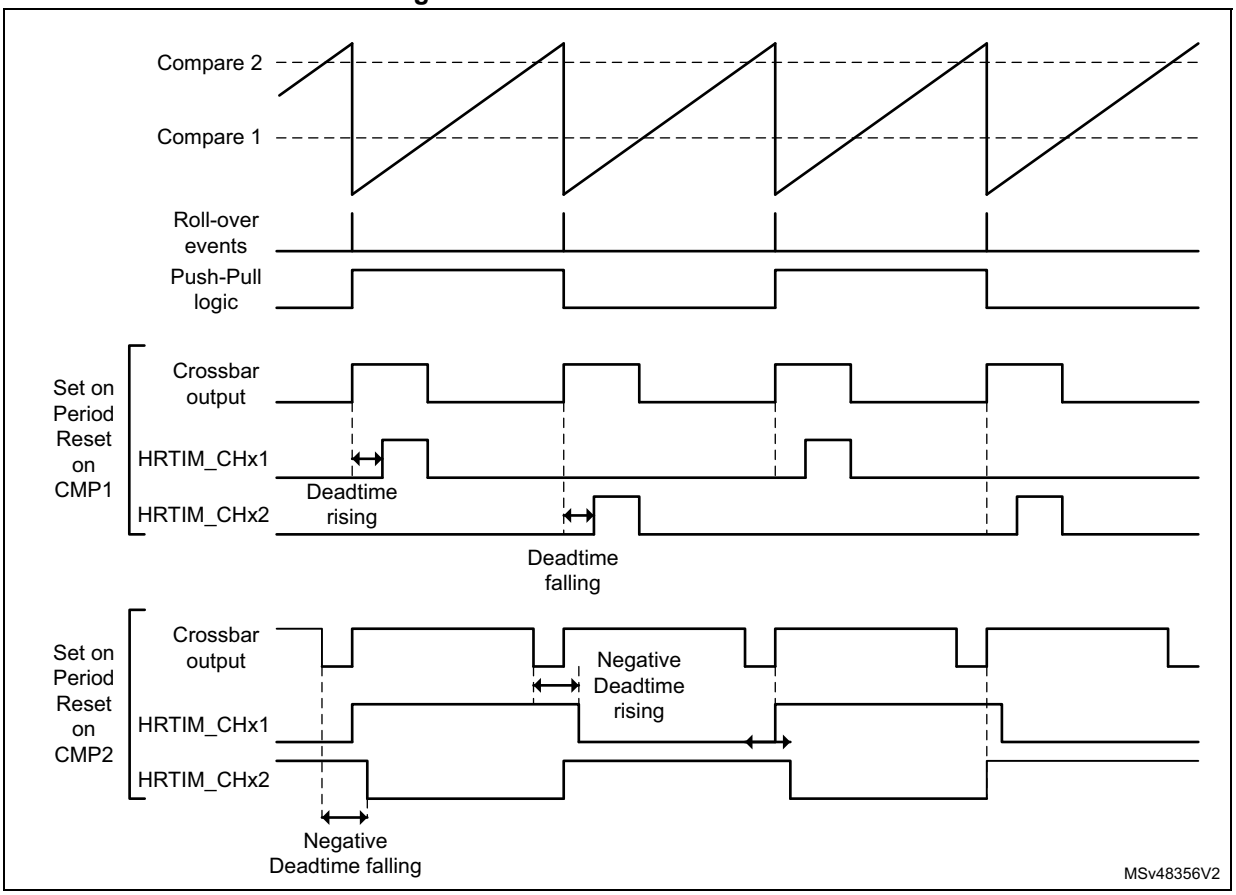


Figure 370 shows how the deadtime is inserted in push-pull mode, for both positive and negative deadtimes. In this case, the outputs are not complemented anymore, and the deadtime is applied on each output individually (both ouput 1 and output 2 of the crossbar are used).

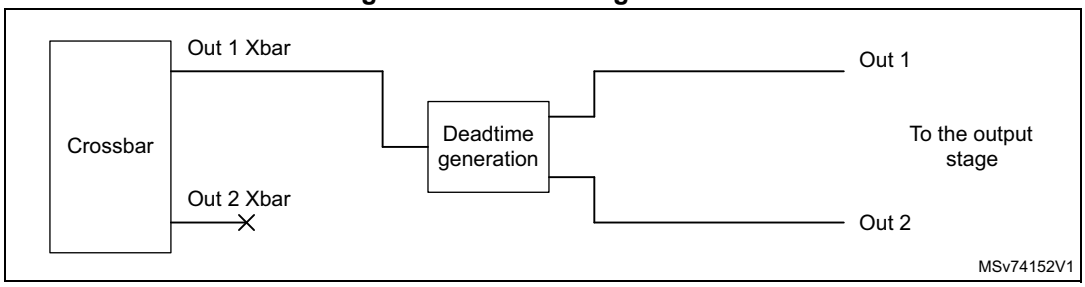
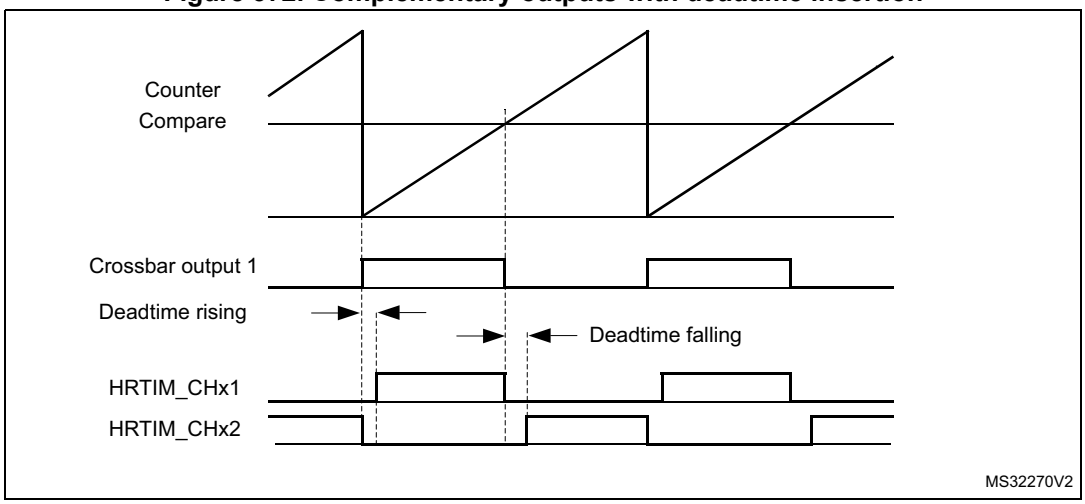
Figure 370. Push-Pull with deadtime



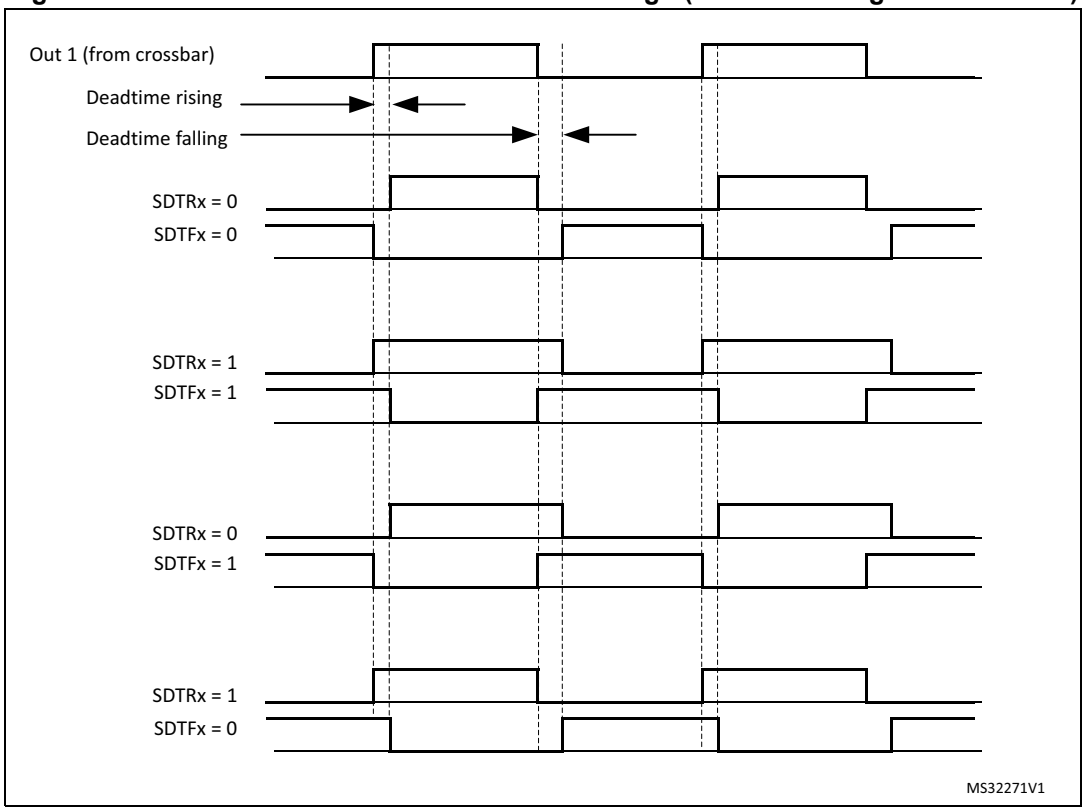
Deadtime

A deadtime unit is used to generate a couple of complementary signals from a single reference waveform, with programmable delays between active state transitions. This is commonly used for topologies using half-bridges or full bridges. It simplifies the software: only one waveform is programmed and controlled to drive two outputs.



The deadtime is enabled by setting DTEN bit in HRTIM_OUTxR register. The complementary signals are built based on the reference waveform defined for output 1, using HRTIM_SETx1R and HRTIM_RSTx1R registers: HRTIM_SETx2R and HRTIM_RSTx2R registers are not significant when DTEN bit is set, as shown on *Figure 371*.

Figure 371. Deadtime generation



Two deadtimes can be defined in relationship with the rising edge and the falling edge of the reference waveform, as in *Figure 372*.

Figure 372. Complementary outputs with deadtime insertion

Negative deadtime values can be defined when some control overlap is required. This is done using the deadtime sign bits (SDTFx and SDTRx bits in HRTIM_DTxR register). *Figure 373* shows complementary signal waveforms depending on respective signs.

Figure 373. Deadtime insertion versus deadtime sign (1 indicates negative deadtime)

The deadtime values are defined with DTFx[8:0] and DTRx[8:0] bitfields and based on a specific clock prescaled according to DTPRSC[2:0] bits, as follows:

$t_{DTx} = \pm DTx[8:0] \times t_{DTG}$

where x is either R or F and $t_{DTG} = (2^{(DTPRSC[2:0])}) \times (t_{HRTIM} / 8)$.

Table 425 gives the resolution and maximum absolute values depending on the prescaler value.

Table 425. Deadtime resolution and max absolute values

DTPRSC[2:0]	t_{DTG}	t_{DTx} max	f_{HRTIM}= 280 MHz	
			t_{DTG} (ns)	$\|t_{DTx}\|$ max (µs)
000	$t_{HRTIM} / 8$	511 * t_{DTG}	0.45	0.23
001	$t_{HRTIM} / 4$		0.9	0.46
010	$t_{HRTIM} / 2$		1.8	0.93
011	t_{HRTIM}		3.6	1.86
100	$2 \times t_{HRTIM}$		7.1	3.71
101	$4 \times t_{HRTIM}$		14.3	7.43
110	$8 \times t_{HRTIM}$		28.6	14.86
111	$16 \times t_{HRTIM}$		57.1	29.71

Figure 374 to *Figure 377* present how the deadtime generator behaves for reference waveforms with pulsewidth below the deadtime values, for all deadtime configurations.

Figure 374. Complementary outputs for low pulsewidth (SDTRx = SDTFx = 0)

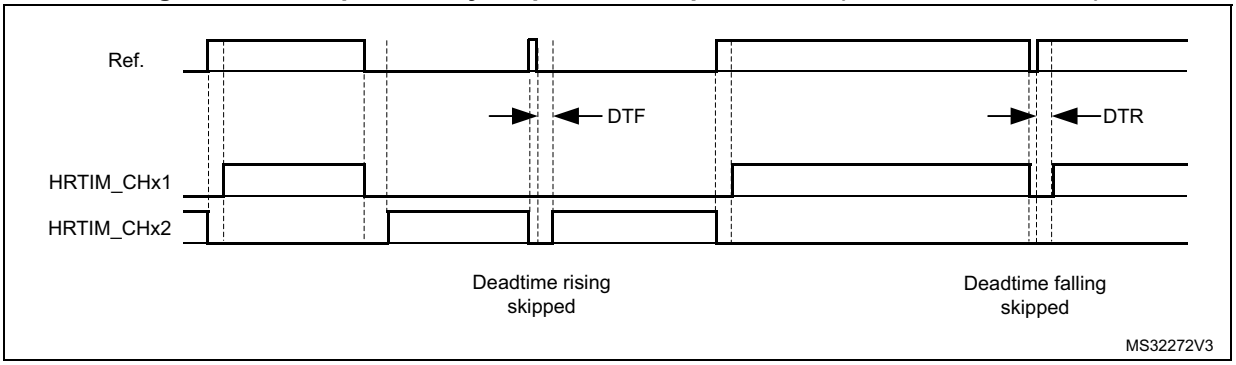


Figure 375. Complementary outputs for low pulsewidth (SDTRx = SDTFx = 1)

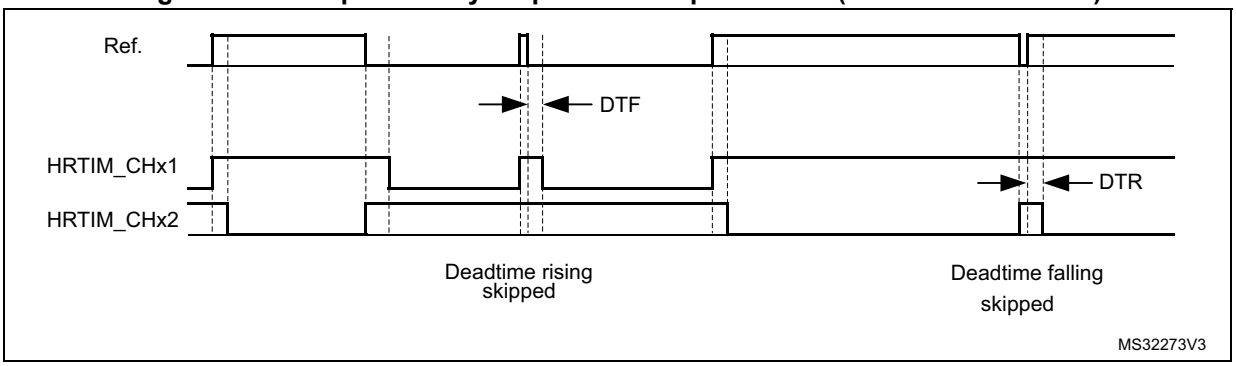

Figure 376. Complementary outputs for low pulsewidth (SDTRx = 0, SDTFx = 1)

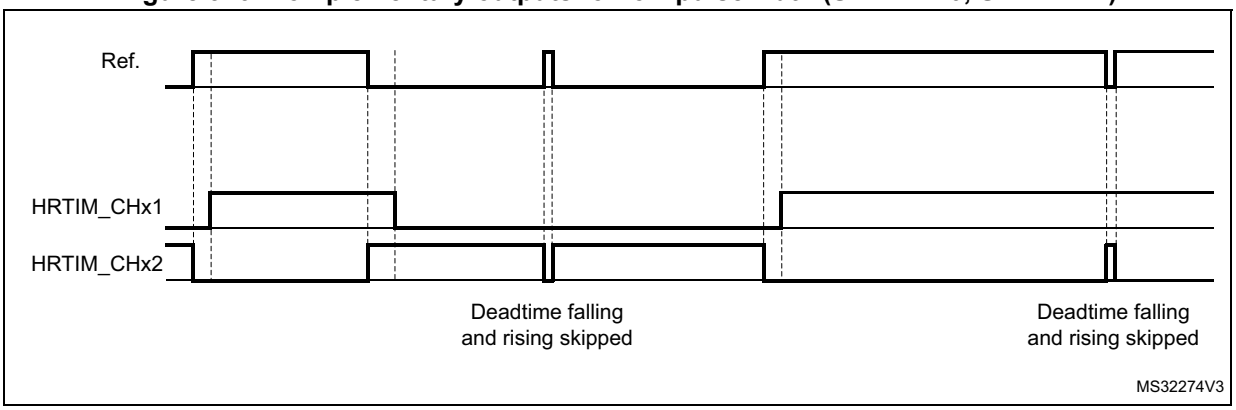

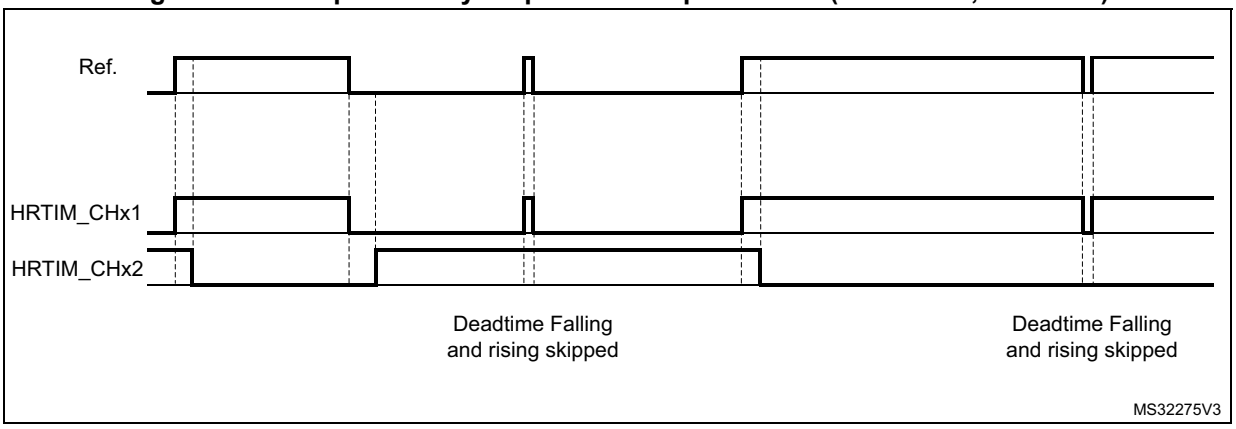

Figure 377. Complementary outputs for low pulsewidth (SDTRx = 1, SDTFx=0)

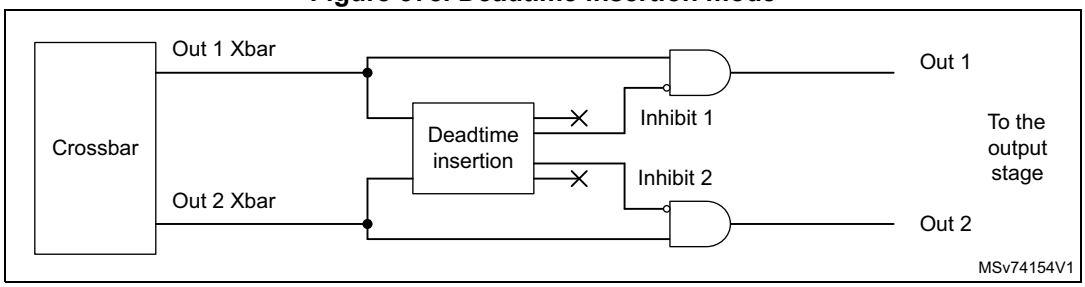
For safety purposes, it is possible to prevent any spurious write into the deadtime registers by locking the sign and/or the value of the deadtime using DTFLKx, DTRLKx, DTFSLKx, and DTRSLKx. Once these bits are set, the related bits and bitfields are becoming read only until the next system reset.

The DTEN bit is preloaded, and can be written while the timer is enabled.



Caution: DTEN bit must not be changed when the timer outputs are set/reset by another timer (while TxEN is reset)

Note: For the particular case where DTEN must be set while the burst mode is enabled with a deadtime upon entry (BME = 1, DIDL = 1, IDLEM = 1), it is necessary to force the two outputs in their IDLES state by software commands (SST, RST bits) before setting DTEN bit. This is to avoid any side effect resulting from a burst mode entry that would happen immediately before a deadtime enable.

Deadtime insertion modes

Two alternative deadtime options are available to handle situations where the signals are not complementary. In this case, the output 1 and output 2 signals are independently defined, and a deadtime insertion will only prevent any deadtime violation, as show on *Figure 378* below.

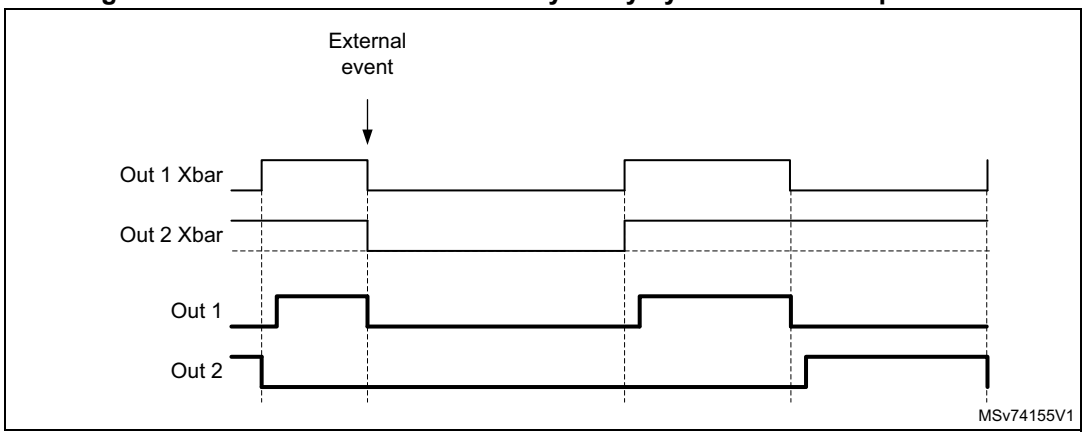


Figure 378. Deadtime insertion mode

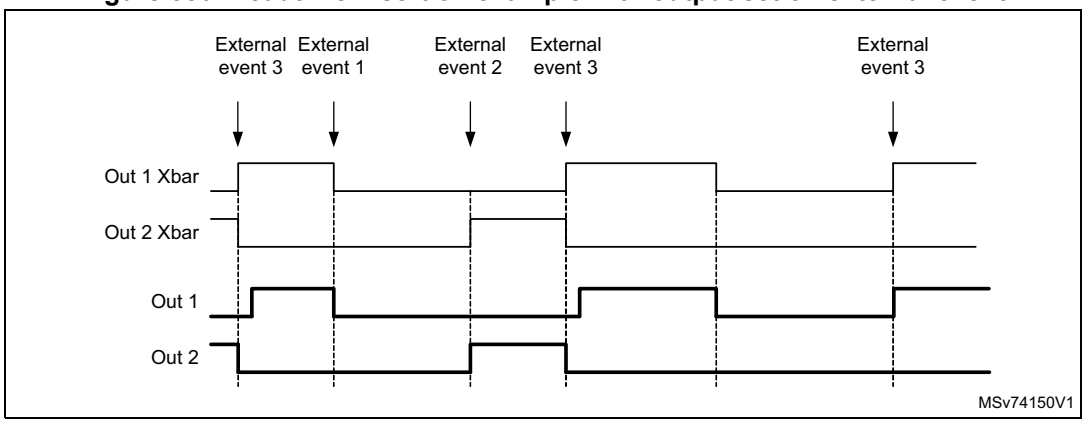
The deadtime insertion mode is enabled by setting DTM[1:0] = 01 in the HRTIM_DTxR register.

The example on *Figure 379* below shows an example of waveform in deadtime insertion mode, with a cycle-by-cycle over-current protection. In this case, the output 2 is set on period and reset on external event.

Figure 379. Deadtime insertion with cycle-by-cycle overcurrent protection

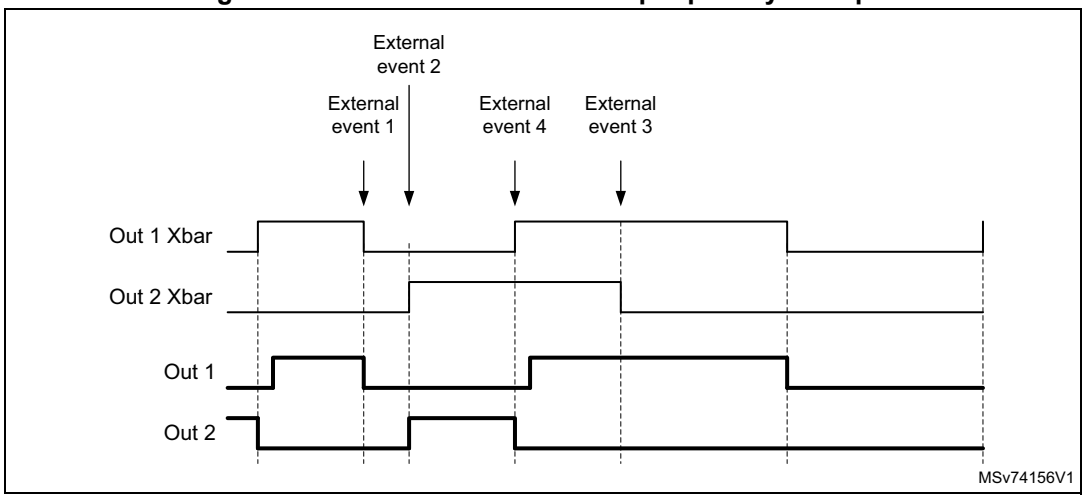


The example on *Figure 380* below shows an example of waveform in deadtime insertion mode, with the following conditions:

- output 1 set on external event 3, reset on external event 1
- output 2 set on external event 2, reset on external event 3
- counter reset on external event 3

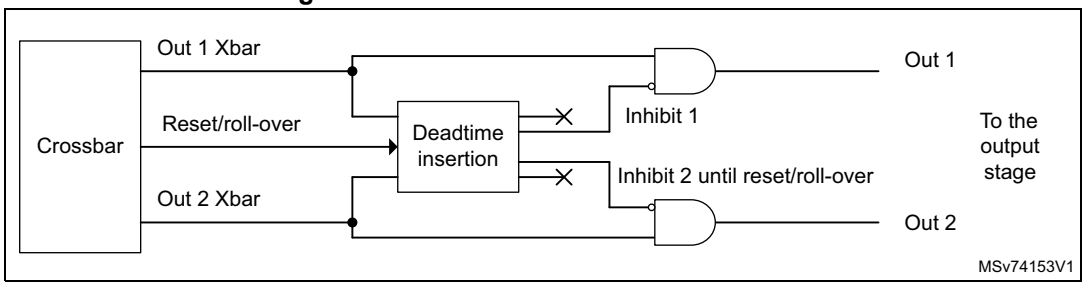
It must be noticed that output 2 is set immediately after external event 2, without any deadtime delay, if the output 1 is inactive.

Figure 380. Deadtime insertion example with output set on external event



The example on *Figure 380* below shows an example of waveform in deadtime insertion mode, with the following conditions:

- output 1 set on external event 4, reset on external event 1
- output 2 set on external event 2, reset on external event 3



It must be noticed that output 1 set event has priority over output 2 active state.

Figure 381. Deadtime insertion: output priority example

The deadtime insertion and disarm mode is enabled by setting DTM[1:0] = 10 in the HRTIM_DTxR register, and prevent the output 2 to be set again until the next reset/roll-over event, as shown on *Figure 382* and *Figure 383* below.

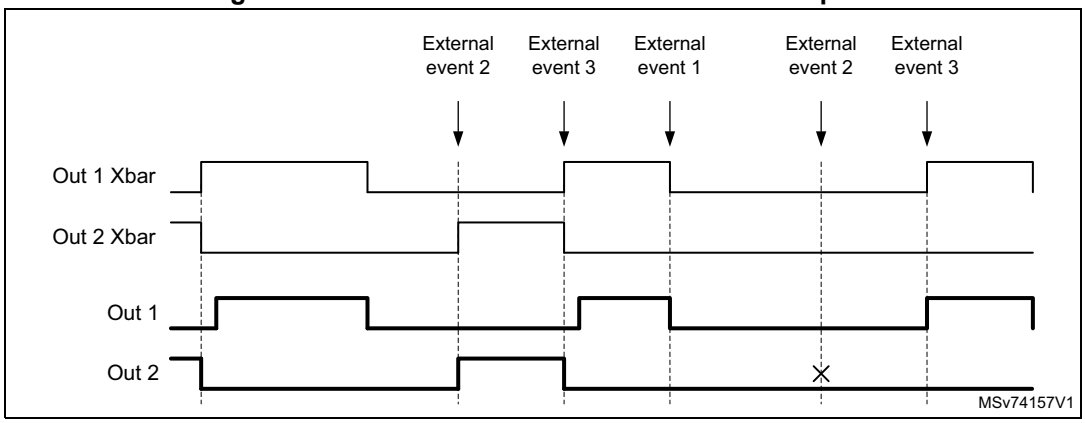
Figure 382. Deadtime insertion and disarm

The conditions to disarm the output 2 (i.e. lock output 2 and ignore any other set events) are the following:

- One (or multiple) external event(s) selected to reset the output 1
- At least one external event enabled

Note: If the output 2 crossbar is active before output 1 is disabled (output 1 and output 2 overlapping), the disarming logic will not reset output 2. If output 2 must be disabled in these conditions (i.e. external event 2 occurring before External event 1, it is necessary to program the same external event for resetting both Out1 and Out2.

Figure 383. Deadtime insertion and disarm example 1



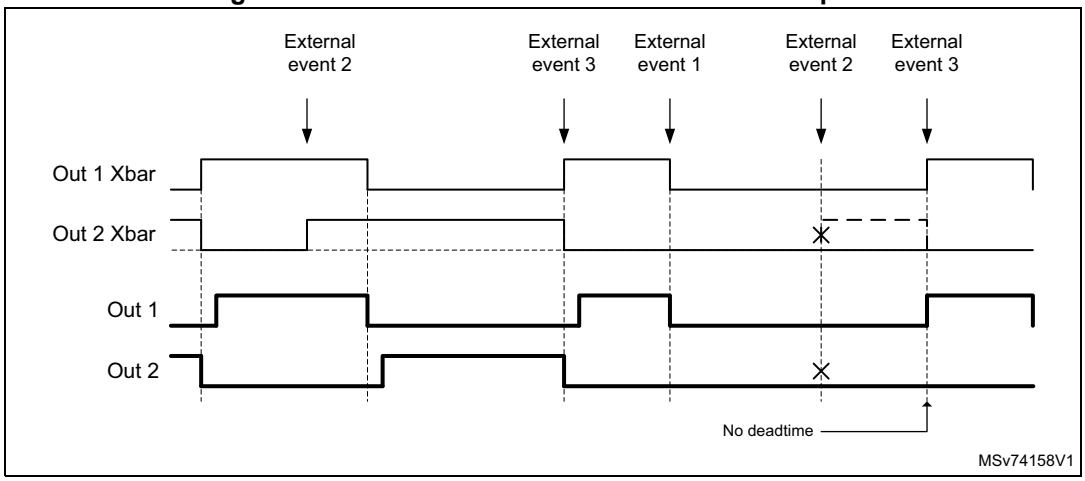


Figure 384 shows that there is no deadtime insertion when an output is set while the deadtime insertion period is over (i.e. output 2 set immediately on External Event 3).

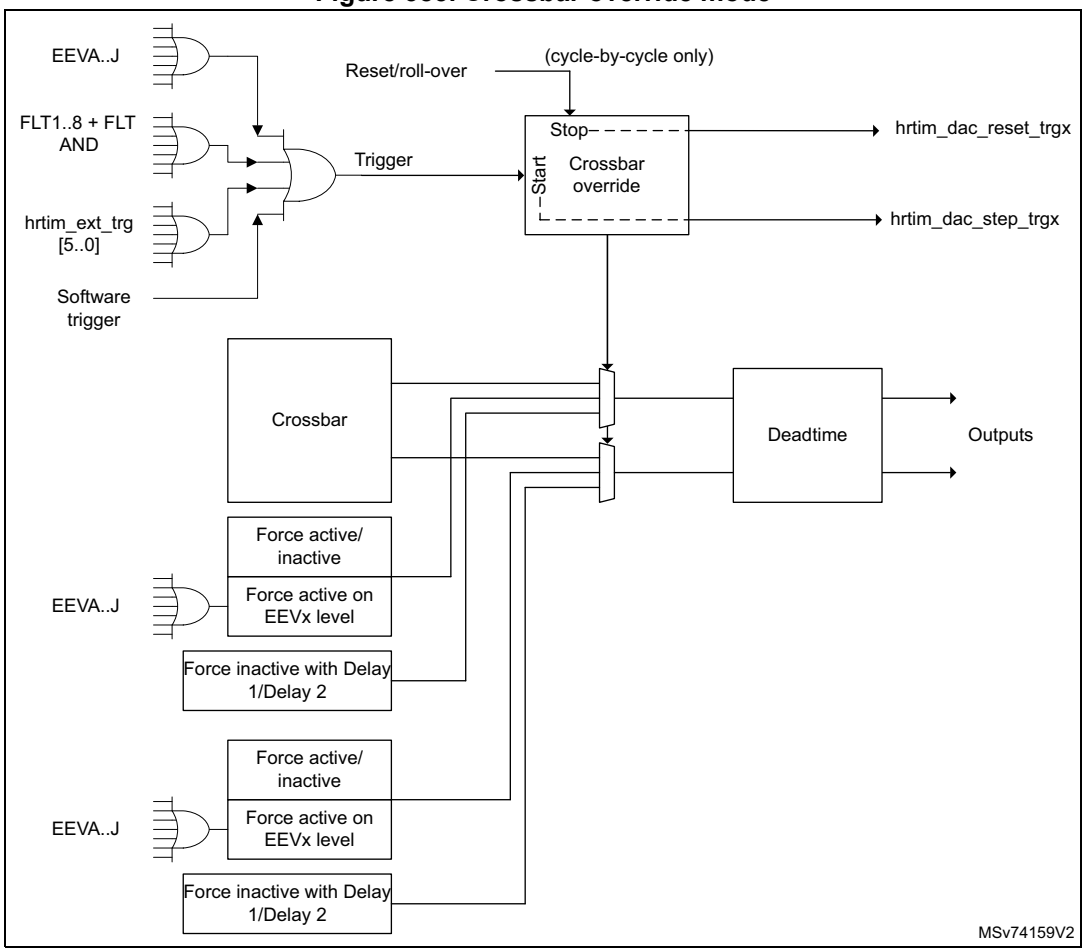

Figure 384. Deadtime insertion and disarm example 2

Crossbar override

This mode gives the possibility to override the output crossbar programming and take over the output control to force a level based on a fixed setting or based on a given external event or fault, as shown on *Figure 385* below.

Figure 385. Crossbar override mode

This mode is triggered on one or multiple sources selected in HRTIM_COTRGxR register:

- Software trigger
- Fault 1..8 and AND combined faults inputs
- External events A..J
- Six external crossbar override triggers hrtim_ext_trg[5:0] (hrtim_ext_trg[7:6] are not available as triggers)

Once the crossbar override mode is entered, specific external events will force high or low the outputs when active.

The crossbar override logic provides 2 options:

- Latched: once triggered, the crossbar override mode is maintained until a software intervention to disengage it.
- Cycle-by-cycle mode: the crossbar override mode exits automatically and normal operation is resumed by hardware. Typically, the system will re-arm once the over-

current condition has disappeared.
This mode is only applicable in force on event mode (COFMx[2:0] = 100).

In cycle-by-cycle mode (COM bit reset in HRTIM_TIMxCR2), the Crossbar override function is disengaged when both:

- The trigger event is inactive
- The next reset/roll-over happens (conditioned by ROM[1:0] in center-aligned mode)

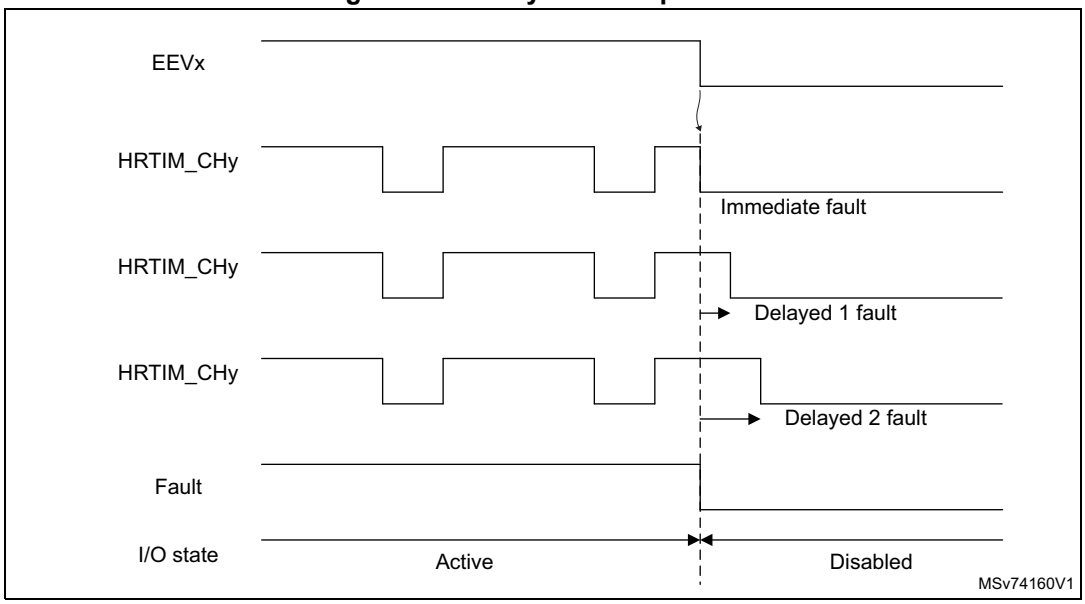
In latched mode (COM bit set in HRTIM_TIMxCR2), the crossbar override mode can be disengaged in two ways:

- With the rearm bit COR in HRTIM_TIMxCR2. The rearming will be effective only of the trigerring condition has disappeared (status can be polled using the COTS bit in the HRTIM_TIMxISR register).
- With the COE bit reset, to disable it permanently.

The DAC values can be updated synchronously with the crossbar override mode triggering. The triggers are generated when the DCDCOE (Dual Channel DAC Crossbar Override Enable) bit is set in HRTIM_TIMxCR2 (the DCDE value is overridden when DCDCOE=1).

- hrtim_dac_reset_trgx triggers are generated only in cycle-by-cycle mode when the crossbar override stops, and DCDR setting applies.
- hrtim_dac_step_trgx triggers are generated when the crossbar override starts.

The crossbar override mode provides several options, defined independently for each output with the COFMA[2:0] and COFMB[2:0] bitfields in the HRTIM_COFExR registers.



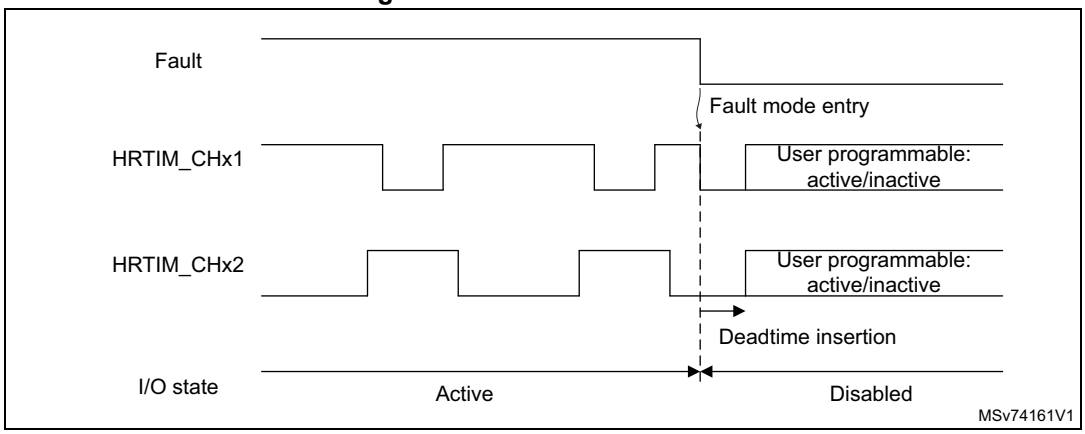
Delayed fault operation

This mode is enabled with COFMx[2:0] = 000 and 001. When the crossbar override mode is triggered, the output level is maintained as it is and forced to the inactive state after a programmable duration. The purpose of this mode is have a delayed shutdown sequence for multi-level inverters. 2 delays can be selected for a given output: Delay 1 with COFMx[2:0] = 000 or Delay 2 with COFMx[2:0] = 001, as shown on *Figure 386*.The delay 1/2 durations are defined with the DLYxFLTD[8:0] bitfields in the HRTIM_CODExR register.

This mode can also be used with deadtime disabled (DTEN=0).

Warning: It is mandatory to program a Delay 2 duration above the Delay 1 duration: DLY2FLTD[8:0] > DLY1FLTD[8:0].

Figure 386. Delayed fault operation

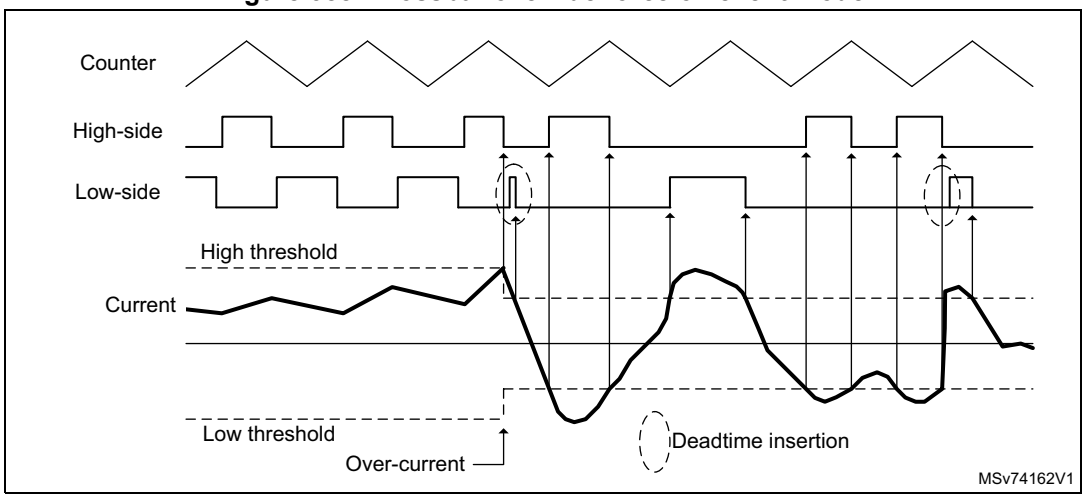


Deadtime on Fault

This mode is enabled with COFMx[2:0] = 010 and 011. When the crossbar override mode is triggered, the output level is forced to an active or inactive state, as shown on *Figure 387* below. As the crossbar override logic is placed prior to the deadtime insertion logic, this mechanism guarantees that an output can be force active without any risk of deadtime violation. If both outputs are forced to the active state, both output 1 and output 2 are forced inactive.

This mode cannot be used with deadtime disabled (DTEN = 0).

Figure 387. Deadtime on Fault



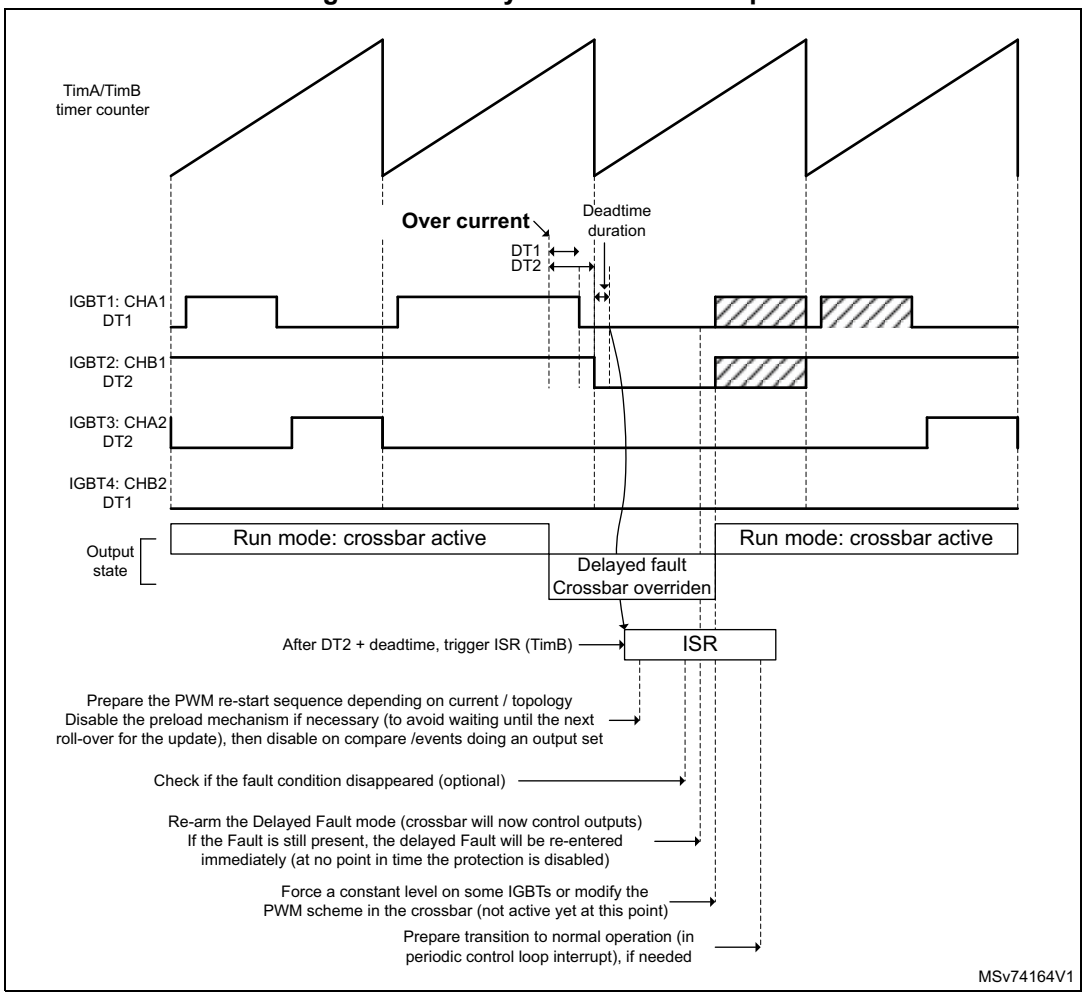
Force on event

This mode is enabled with COFMx[2:0] = 100. When the crossbar override mode is triggered, the output level is forced active on the event selected in the EEVxFRCA and EEVxFRCB bits, in the HRTIM_COFExR register, as shown on *Figure 388* below.

This mode cannot be used with deadtime disabled (DTEN = 0).

Figure 388. Crossbar override force on event mode

Status bits and interrupts



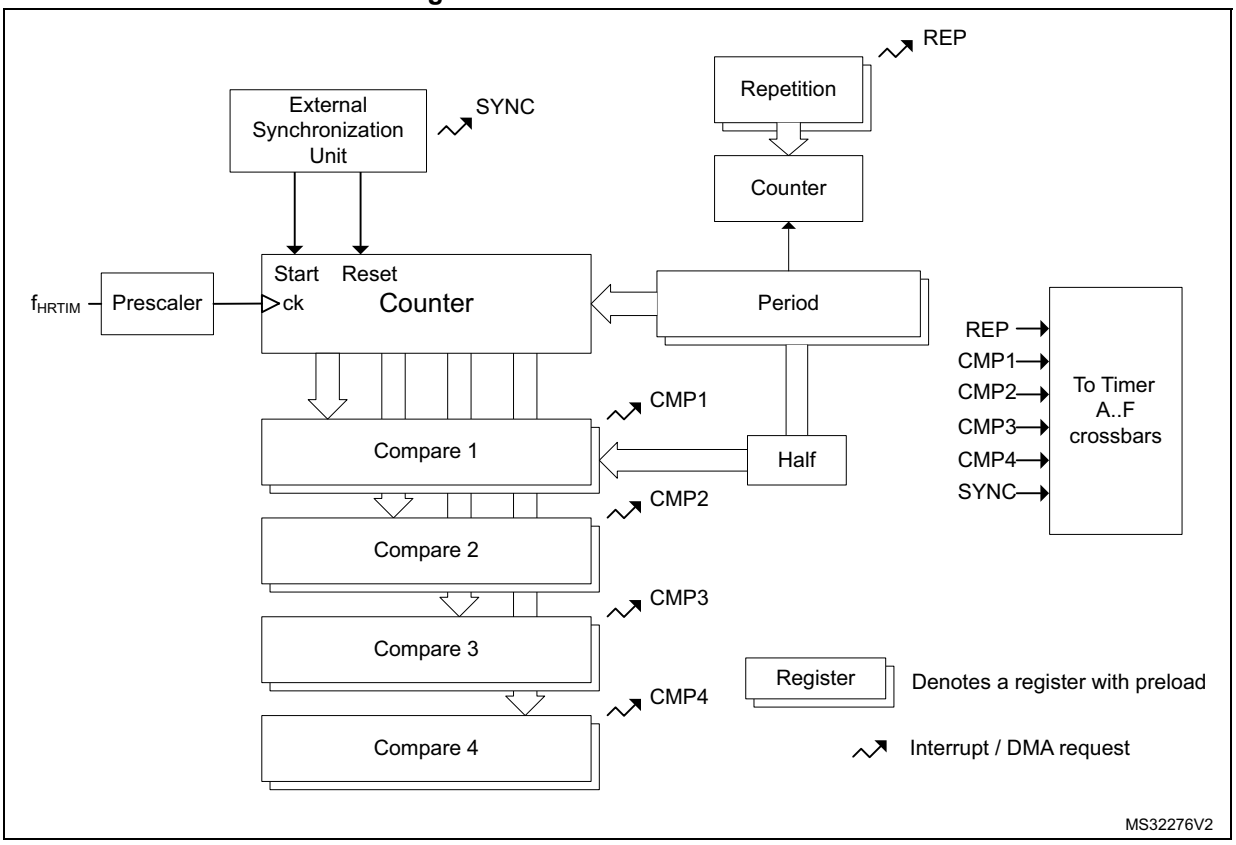
Two status bits are available for software polling, in the HRTIM_TIMxISR register. The COS bit indicates if the crossbar override mode is active, or if the regular crossbar operation is active or was resumed.The COTS bit indicates if the crossbar override trigger is active or not, and can be polled before rearming the crossbar override mode. Both bits are only status bits.

Two interrupts are available. The crossbar override trigger interrupt indicates that regular crossbar operation was interrupted and crossbar override mode was started (COT interrupt flag in HRTIM_TIMxISR). The crossbar override ream delay elapsed interrupt (CORDE interrupt flag in HRTIM_TIMxISR) indicates that the regular crossbar mode can be rearmed. This flag is raised once the Delay 2 period plus the deadtime duration is elapsed, to indicate that the crossbar override delayed fault entry sequence is completed before rearming.

Any rearming attempt before CORDE interrupt is ignored. The *Figure 389* below gives an example of a delayed fault exit sequence [To be completed and reworked].

This CORDE interrupt is generated only when at least on of the one of the 2 channels is configured to Delayed fault force modes (COFMx[2:0] = 000 and 001).

Figure 389. Delayed Fault exit example



40.3.5 Master timer

The main purpose of the master timer is to provide common signals to the 6 timing units, either for synchronization purpose or to set/reset outputs. It does not have direct control over any outputs, but still can be used indirectly by the set/reset crossbars.

Figure 390 provides an overview of the master timer.

Figure 390. Master timer overview

The master timer is based on the very same architecture as the timing units, with the following differences:

- It does not have outputs associated with, nor output related control
- It does not have its own crossbar unit, nor push-pull or deadtime mode
- It can only be reset by the external synchronization circuitry
- It does not have a capture unit, nor the autodelayed mode
- It does not include external event blanking and windowing circuitry
- It has a limited set of interrupt/DMA requests: compare 1..4, repetition, register update and external synchronization event.

The master timer control register includes all the timer enable bits, for the master and timer A..F timing units. This allows to have all timer synchronously started with a single write access.

It also handles the external synchronization for the whole HRTIM timer (see *Section 40.3.19: Synchronizing the HRTIM with other timers or HRTIM instances*), with both MCU internal and external (inputs/outputs) resources.

Master timer control registers are mapped with the same offset as the timing units' registers.

40.3.6 Up-down counting mode

The HRTIM is natively designed with up-counters. It offers however an operating mode with up-down counters, also called center-aligned mode.

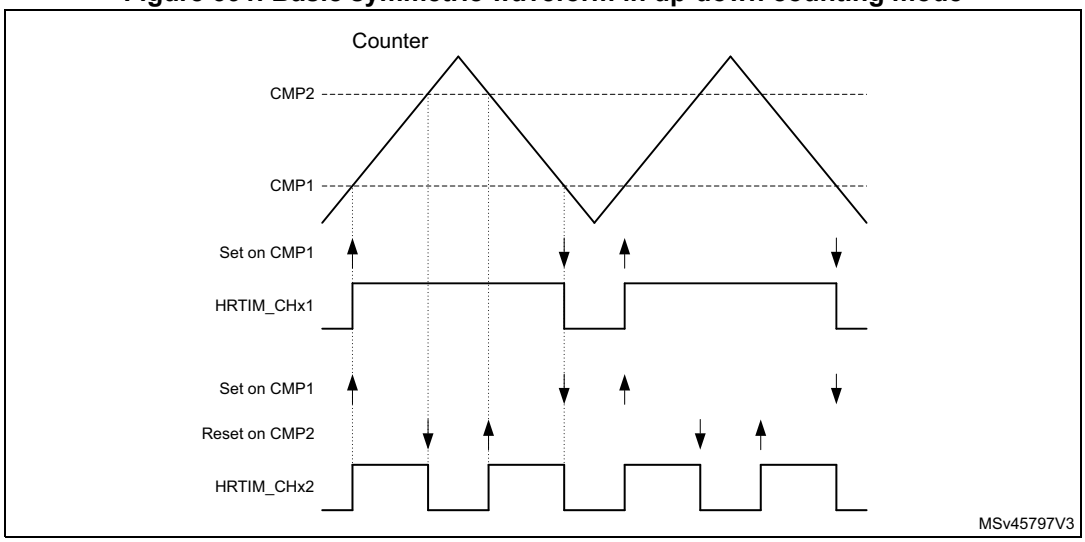
This mode is enabled using the UDM bit in the HRTIM_TIMxCR2 register. This bit must not be changed once the timer is operating (TxEN bit set). It is only available for the TIMA..F. The master timer only works in up-counting mode.

Not all HRTIM features are supported in up-down counting. This section details the functional differences versus up-counting mode.

The period in HRTIM_PERxR must be preloaded (or static) in up-down mode. It can be updated only on period event or on counter reset.

The set/reset crossbar programming differs as follows:

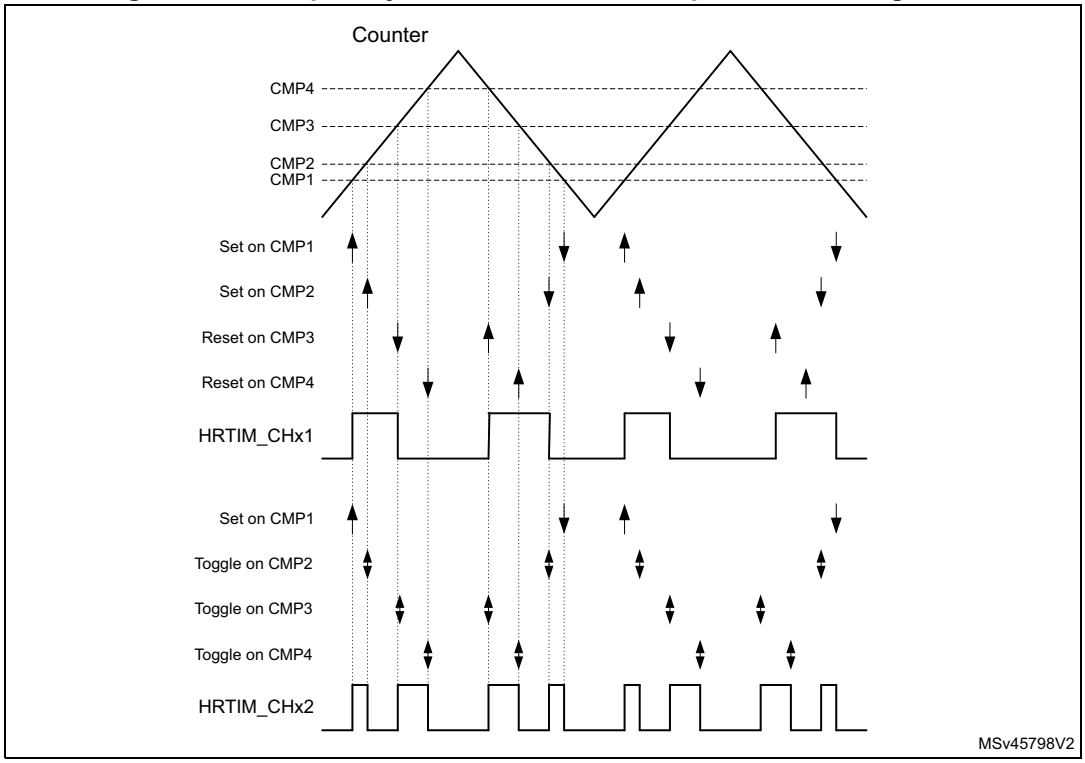
The events coming from the timing units are setting/resetting the outputs depending on the counter up/down direction:



- If the event is enabled in the HRTIM_SETxyR register, it sets the output during up-counting and reset it during down-counting.
- If the event is enabled in the HRTIM_RSTxyR register, it resets the output during up-counting and set it during down-counting.
- If the events are enabled both in HRTIM_SETxyR and HRTIM_RSTxyR registers, the output toggles.

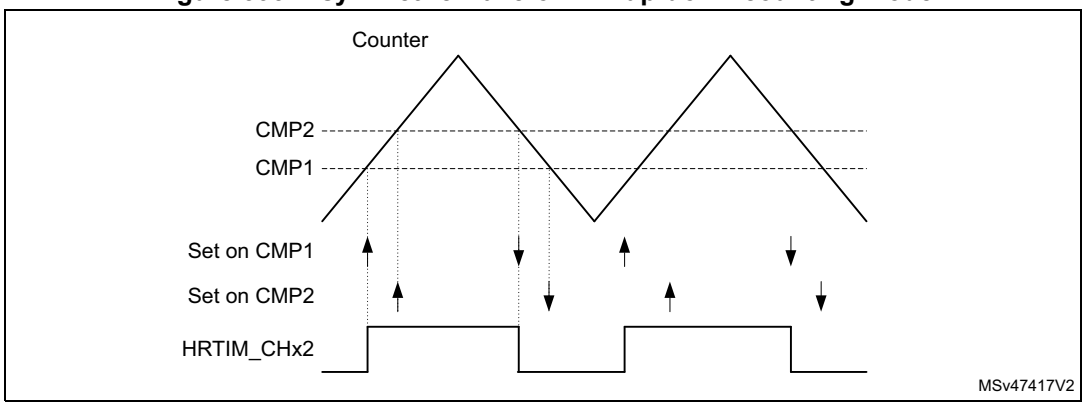
This applies to:

- The timing unit: period, compare 1..4, register update (6 events)
- The master timer: period, compare 1..4, HRTIM synchronization (6 events)
- All other timing units (e.g. timer B..F for timer A): TIMEVNT1..9 (9 events described in *Table 422*).



The *Figure 391* below shows how to generate basic waveforms.

Figure 391. Basic symmetric waveform in up-down counting mode



The *Figure 392* below shows how to generate some more complex waveforms, using the 4 available compare units and the toggle mode.

Figure 392. Complex symmetric waveform in up-down counting mode

The *Figure 393* shows how to generate an asymmetric waveform. In this case, it must be noticed that it is necessary to have compare 2 value greater than compare 1 value for the waveform to be asymmetric.

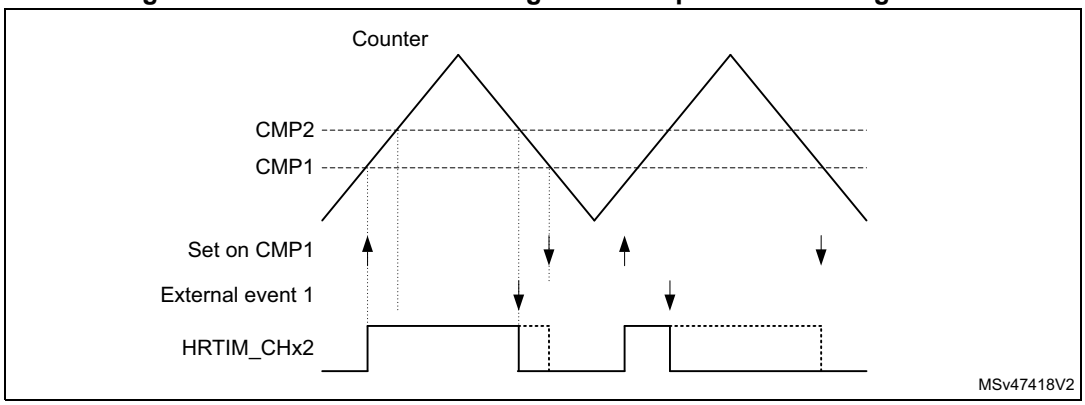


Figure 393. Asymmetric waveform in up-down counting mode

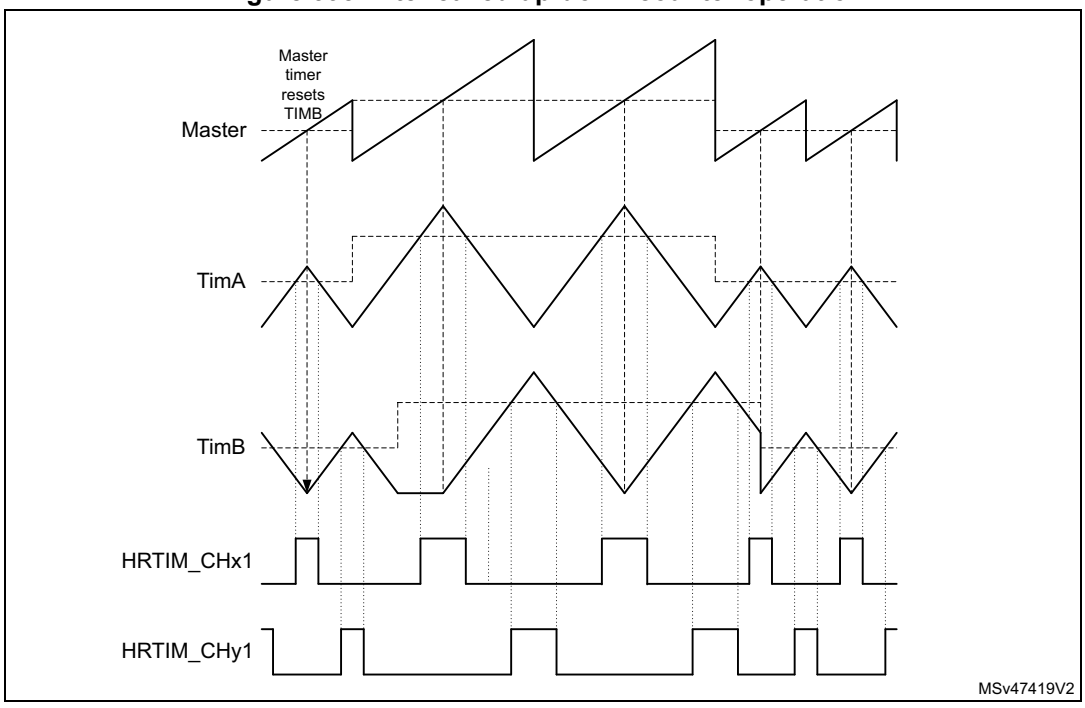
Note: For asymmetric operation, it is required that CMP2 > CMP1.

The behavior of the software forcing bits and external events EXTEVNTA..J is identical for up-only and up-down counting mode. The *Figure 394* below shows how a pulse can be shorten in response to external events.

Figure 394. External event management in up-down counting mode

The up-down counting mode is available for both continuous and single-shot (retriggerable and non-retriggerable) operating modes. A reset causes the counter to re-start from 0. The *Figure 395* below shows the counter behavior in single-shot retriggerable mode, for TIMB.

Figure 395. Interleaved up-down counter operation



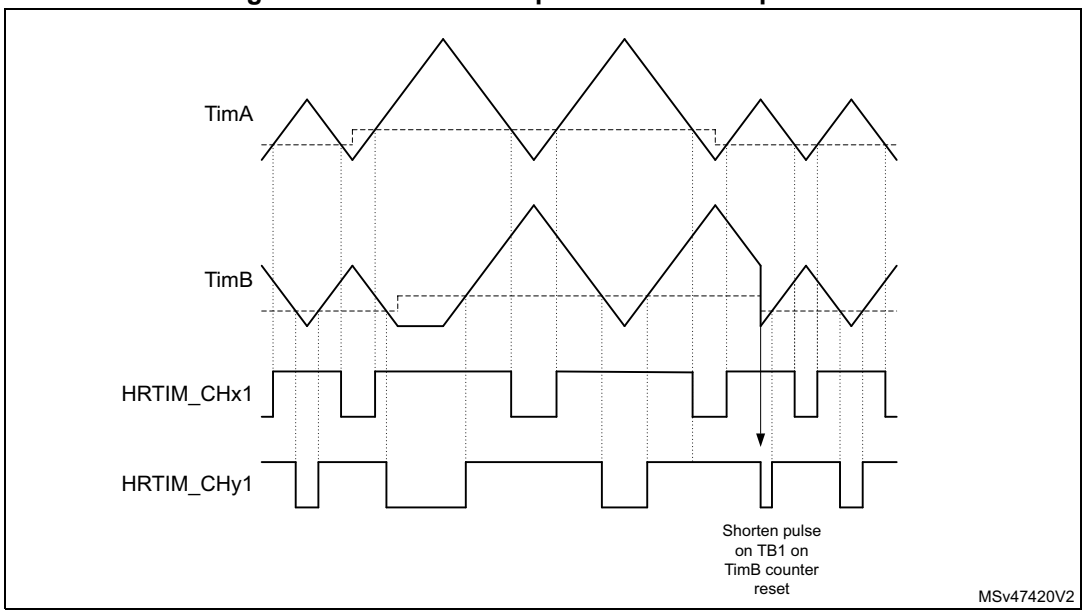


Figure 396. Interleaved up-down counter operation

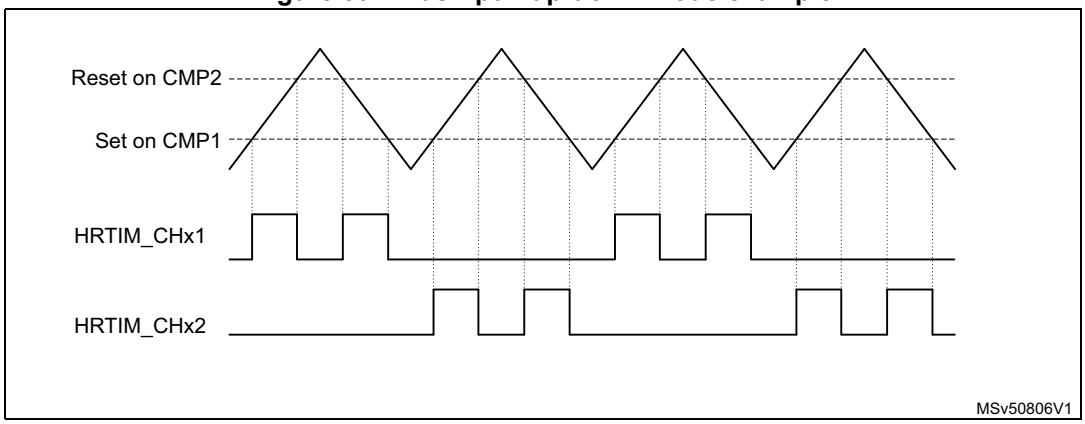
Note: In up-down counting mode, the compare values must be 3 periods of the f_{HRTIM} clock below the period value (TIMx_PER - 0x60 if CKPSC[2:0] = 0, TIMx_PER - 0x30 if CKPSC[2:0] = 1, TIMx_PER - 0x18 if CKPSC[2:0] = 2,...). This applies for the compare events generated inside the timing unit. For compare events generated in other timing units, it is mandatory to avoid any event occurring within less than 1 period of the f_{HRTIM} clock of a counter direction change (counter at 0, period event or counter reset).

The following features are supported in up-down counting mode:

- Half mode
- Deadtime insertion
- Push-pull mode, alternance push-pull done on when counter = 0 (see *Figure 397*).
- Delayed Idle
- Burst mode
- PWM mode with “greater than” comparison (see *Figure 398*).

Figure 397. Push-pull up-down mode example



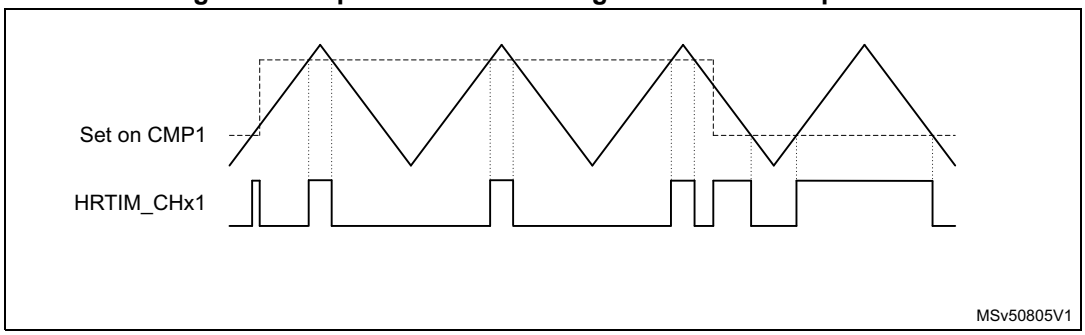


Figure 398. Up-down mode with “greater than” comparison

Caution: The following features are not supported in up-down counting mode:

- Auto-delayed mode
- Balanced Idle
- Triggered-half mode

The capture function is supported with the following differences:

- The capture value is referred to counting start, when up-counting
- The capture value is referred to the PER event when down counting
- The bit 16 of the capture register holds the counting direction status.

The counter roll-over event is defined differently in-up-down counting mode to support various operating condition. It can be either generated:

- When the counter is equal to 0 (“valley” mode)
- When the counter reaches the period value set in the HRTIM_PERxR (“crest” mode)
- When both conditions are met (either 0 or HRTIM_PERxR value).

This event is used for multiple purposes in the HRTIM. The generation mode (valley, crest or both) can be programmed individually depending on the destination. *Table 426* summarizes the use cases and associated roll-over mode (xxROM[1:0]) programming bits in the HRTIM_TIMxCR2 register.

Table 426. Roll-over event destination and mode programming

Roll-over event use	Programming bits
Output set/reset	OUTROM[1:0]
Register content update trigger (transfer from preload to active)	ROM[1:0]
IRQ and/or DMA request trigger	ROM[1:0]
Burst mode clock source and /or burst start trigger	BMROM[1:0]
ADC trigger (see *Section : ADC postscaler* for details)	ADROM[1:0]
External event filtering	ROM[1:0]
Repetition counter decrement	ROM[1:0]
Fault and event counter	FEROM[1:0]

Note: For events where both reset and roll-over are considered (IRQ/DMA and TxRSTU), the xxROM[1:0] influences both the reset and roll-over generation. The reset event is propagated only when xxROM[1:0] = 00 or 01, regardless of the counting direction.

The roll-over event generation is defined as per following xxROM[1:0] bitfield setting:

- xxROM[1:0] = 00: event generated when any of these three conditions are met: counter = 0, counter = HRTIM_PERxR or counter reset.
- xxROM[1:0] = 01: event generated when the counter is equal to 0 (“valley” mode) or when the counter is reset
- xxROM[1:0] = 10: event generated when the counter reaches the period value set in the HRTIM_PERxR (“crest” mode)

The following events are conditioned by the xxROM[1:0] bit fields settings:

- Period event

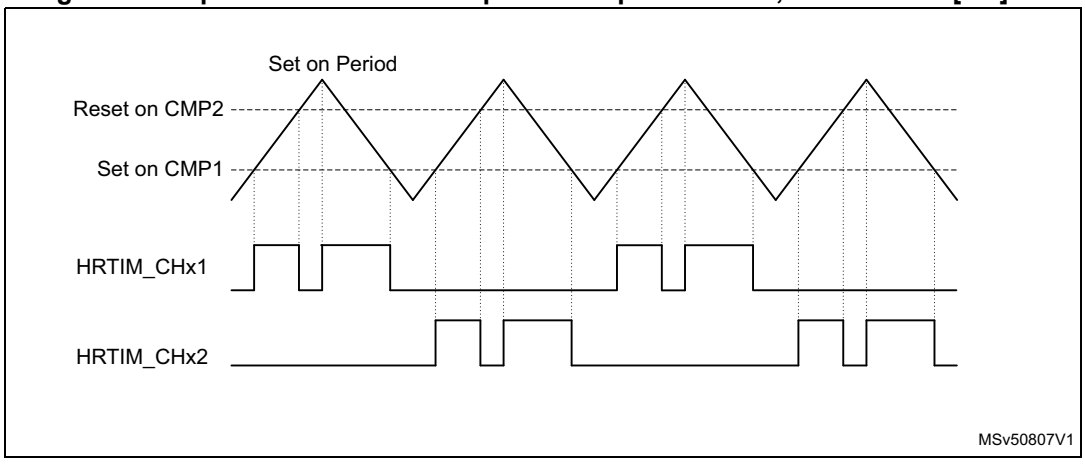
  It can trigger output set/reset (as per OUTROM[1:0] setting), ADC conversions (as per ADROM[1:0] settings) and burst mode (as per BMROM[1:0] settings), both in continuous and single mode, when the period is explicitly listed as trigger source (for instance ADC1TAPER bit set in HRTIM_ADC1R). When both reset and roll-over events are enabled (for instance ADC1TARST bit set in HRTIM_ADC1R), the period event is considered only in continuous mode (roll-over event). In single-shot mode, no event is generated.
- Roll-over event

  This is similar to period event, for what about xxxROM[1:0] programming, and only valid in continuous mode. In single-shot mode, no event is generated.
- Compare event

  It triggers ADC conversion (as per ADROM[1:0] setting):
  - During up-counting if ADROM = 10
  - During down-counting if ADROM = 01
  - During both up and down-counting if ADROM = 00

Figure 399 here-below shows a push-pull up-down mode with set on period event and OUTROM[1:0] =10.

Figure 399. Up-down mode with output set on period event, for OUTROM[1:0]=10



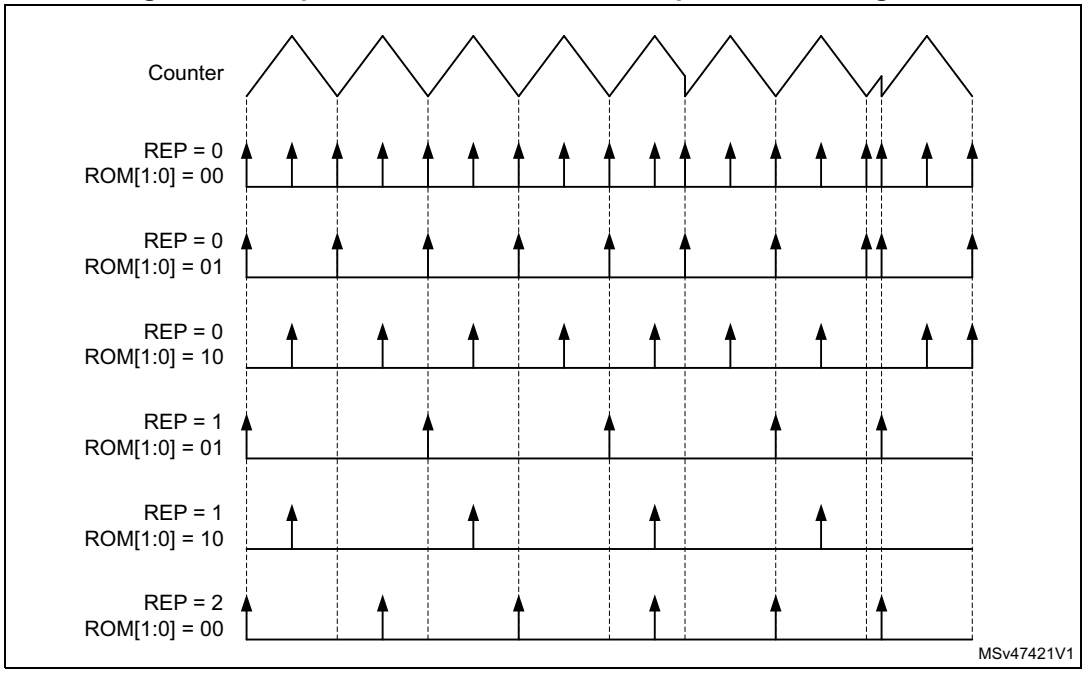


Figure 400 below shows how the repetition counter is decremented in up-down counting mode.

Figure 400. Repetition counter behavior in up-down counting mode

The dual channel DAC triggers are working as for the up-counting mode.

The event blanking and windowing differs so as to have the blanking or windowing done within the output pulse, at a programmable time. The EExFLTR[3:0] codes are depending on the UDM bit setting, as per the *Table 427* below. Whenever the roll-over event is used for blanking or windowing, the ROM[1:0] programming applies for defining when it is generated.

Table 427. EExFLTR[4:0] codes depending on UDM bit setting

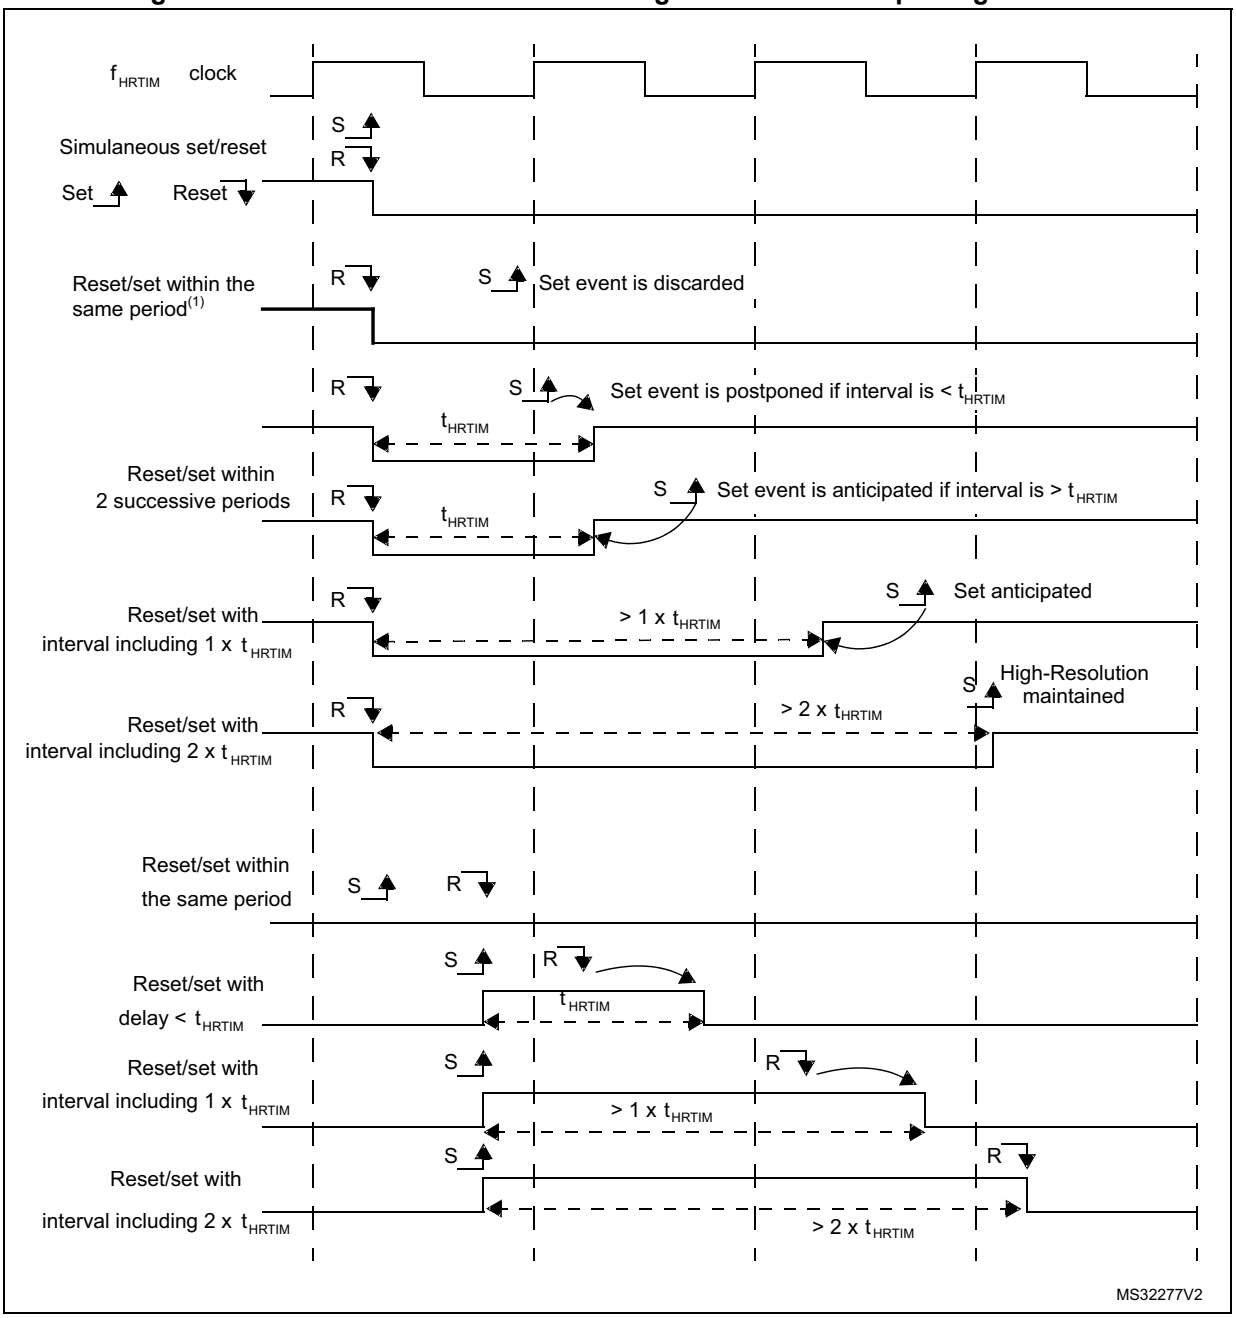
EExFLTR[4:0]	Up-counting mode (UDM = 0)	Up/down-counting mode (UDM = 1)
00010	Blanking from counter reset/roll-over to compare 2	Blanking from compare 1 to compare 2, only during the up-counting phase
00100	Blanking from counter reset/roll-over to compare 4	Blanking from compare 3 to compare 4, only during the up-counting phase
01101	Windowing from counter reset/roll-over to compare 2	Windowing from compare 2 to compare 3, only during the up-counting phase
01110	Windowing from counter reset/roll-over to compare 3	Windowing from compare 2 to compare 3, only during the down-counting phase
01111	Windowing from another timing unit: TIMWIN source (see *Table 432* for details)	Windowing from compare 2 during the up-counting phase to compare 3 during the down-counting phase

40.3.7 Set/reset events priorities and narrow pulses management

This section describes how the output waveform is generated when several set and/or reset requests are occurring within 3 consecutive t_{HRTIM} periods.

Case 1: clock prescaler CKPSC[2:0] < 5

An arbitration is performed during each t_{HRTIM} period, in 3 steps:



1. For each active event, the desired output transition is determined (set, reset or toggle).
2. A predefined arbitration is performed among the active events, see *Section : Concurrent set requests/Concurrent reset requests*).
3. A high-resolution delay-based arbitration is performed with reset having the highest priority, among the low-resolution events and events having won the predefined arbitration.

When set and reset requests from two different sources occur simultaneously or within the same t_{HRTIM} interval, the reset request has the highest priority, unless the set and reset requests originate from the same timing unit. In this case, the CMPx priority scheme applies. For example, consider CMP2 and CMP4:

- If CMP2 performs a set operation and CMP4 performs a reset operation, the output is reset.
- If CMP2 performs a reset operation and CMP4 performs a set operation, the output is set.

If the interval between set and reset requests is below 2 f_{HRTIM} period, the behavior depends on the time interval and on the alignment with the f_{HRTIM} clock, as shown on *Figure 401*.

Figure 401. Short distance set/reset management for narrow pulse generation

1. If reset and set are generated within the same timing unit, the CMPx priority scheme applies. For example, reset on CMP4 and set on CMP2.

If the set and reset events are generated within the same tHRTIM period, the reset event has the highest priority and the set event is ignored, unless the set and reset requests come from the same timing unit. In this case, the CMPx priority scheme applies.

If the set and reset events are generated with an interval below t_{HRTIM} period, across 2 periods, a pulse of 1 t_{HRTIM} period is generated.

If the set and reset events are generated with an interval below 2 t_{HRTIM} periods, a pulse of 2 t_{HRTIM} periods is generated.

If the set and reset events are generated with an interval between 2 and 3 t_{HRTIM} periods, the high-resolution is available if the interval is over 2 complete t_{HRTIM} periods.

If the set and reset events are generated with an interval above 3 t_{HRTIM} periods, the high-resolution is always available.

Concurrent set requests/Concurrent reset requests

When multiple sources are selected for a set event, an arbitration is performed when the set requests occur within the same f_{HRTIM} clock period.

In case of multiple requests from adjacent timers (TIMEVNT1..9), the request which occurs first is taken into account. The arbitration is done in 2 steps, depending on:

1. the source (CMP4 ⟶ CMP3 ⟶ CMP2 ⟶ CMP1),
2. the delay.

If multiple requests from the master timer occur within the same f_{HRTIM} clock period, a predefined arbitration is applied and a single request is taken into account, whatever the effective high-resolution setting (from the highest to the lowest priority):

MSTCMP4 → MSTCMP3 → MSTCMP2 → MSTCMP1 → MSTCMPER

Note: It is advised to avoid generating multiple set (reset) requests from the master timer to a given timer with an interval below 3x t_{HRTIM} to maintain the high-resolution.

When multiple requests internal to the timer occur within the same f_{HRTIM} clock period, a predefined arbitration is applied and the requests are taken with the following priority, whatever the effective timing (from highest to lowest):

CMP4 → CMP3 → CMP2 → CMP1 → PER

Note: Practically, this is of a primary importance when multiple compare events can be simultaneously generated or when using autodelayed compare 2 and compare 4 simultaneously (i.e. when the effective set/reset cannot be determined a priori because it is related to an external event). In this case, the highest priority signal must be affected to the CMP4 event.

Last, the highest priority is given to low-resolution events: EXTEVNT1..10, RESYNC (coming from SYNC event if SYNCRSTx or SYNCSTRTx is set or from a software reset), update and software set (SST). The update event is considered as having the largest delay (0x1F if PSC = 0).

As a summary, in case of a close vicinity (events occurring within the same f_{HRTIM} clock period), the effective set (reset) event is arbitrated between:

- Any TIMEVNT1..9 event
- A single source from the master (as per the fixed arbitration given above)
- A single source from the timer
- The “low-resolution events”.

The same arbitration principle applies to concurrent reset requests. In this case, the reset request has the highest priority, unless the set and reset requests originate from the same timing unit. In this situation, the CMPx priority scheme applies.

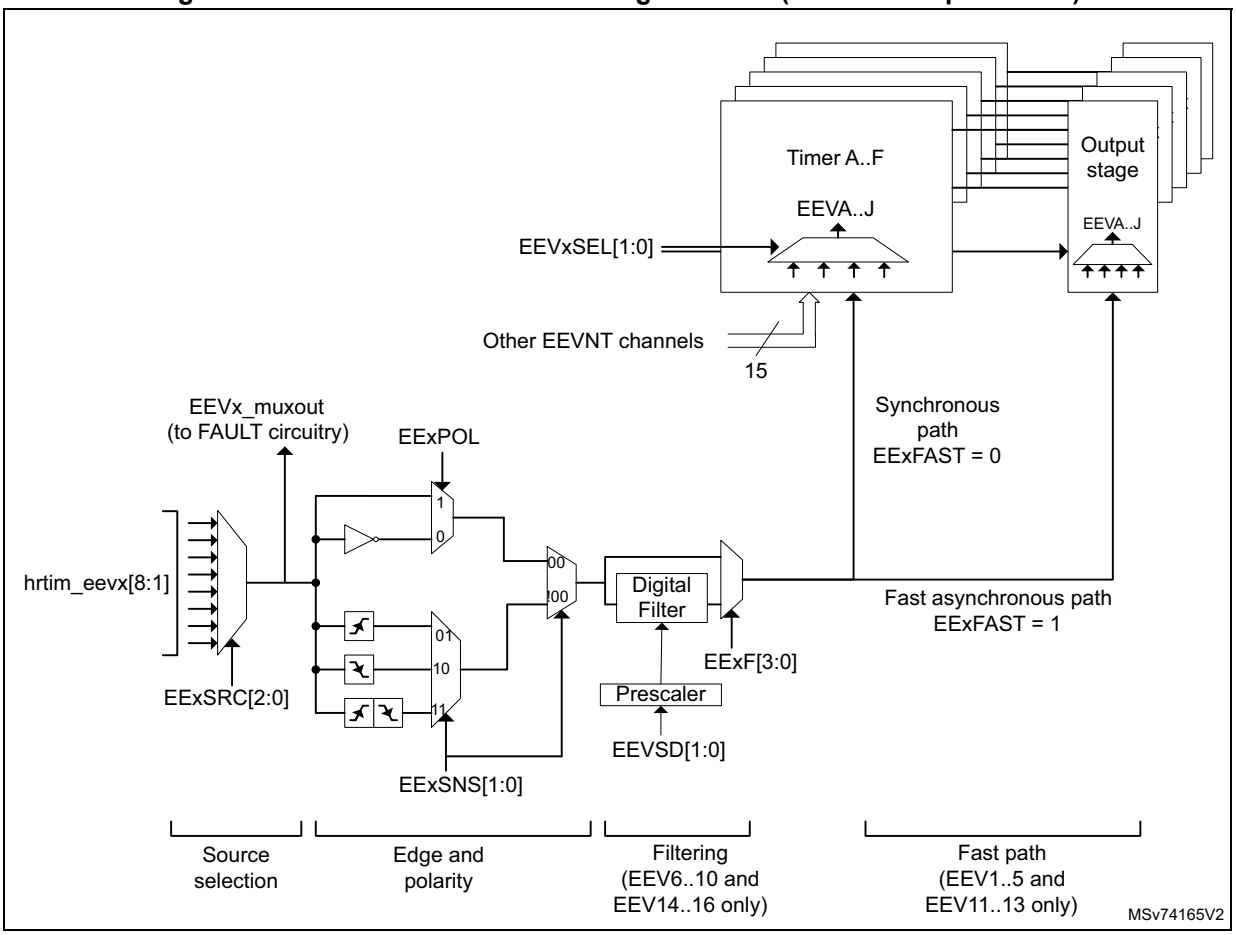
Case 2: clock prescaler CKPSC[2:0] ≥ 5

The narrow pulse management is simplified when the high-resolution is not effective.

A set or reset event occurring within the prescaler clock cycle is delayed to the next active edge of the prescaled clock (as for a counter reset), even if the arbitration is still performed every t_{HRTIM} cycle.

If a reset event is followed by a set event within the same prescaler clock cycle, the latest event is considered.

40.3.8 External events global conditioning



The HRTIM timer can handle events not generated within the timer, referred to as “external event”. These external events come from multiple sources, either on-chip or off-chip:

- built-in comparators,
- digital input pins (typically connected to off-chip comparators and zero-crossing detectors),
- on-chip events for other peripheral (ADC’s analog watchdogs and general purpose timer trigger outputs).

The external events conditioning circuitry allows to select the signal source for a given channel (with a 8:1 multiplexer) and to convert it into an information that can be processed by the crossbar unit (for instance, to have an output reset triggered by a falling edge detection on an external event channel).

Up to 16 external event channels can be conditioned and are available simultaneously for any of the 6 timers. This conditioning is common to all timers, since this is usually dictated by external components (such as a zero-crossing detector) and environmental conditions (typically the filter set-up is related to the applications noise level and signature). *Figure 402* presents an overview of the conditioning logic for a single channel.

Figure 402. External event conditioning overview (1 channel represented)

The 16 external events are initialized using the HRTIM_EECR1, HRTIM EECR2, HRTIM_EECR4, HRTIM_EECR5 and HRTIM EECR7 registers:

- To select up to 8 sources with the EExSRC[2:0] bits,
- To select the sensitivity with EExSNS[1:0] bits, to be either level-sensitive or edge-sensitive (rising, falling or both),
- To select the polarity, in case of a level sensitivity, with EExPOL bit,
- To have a low latency mode, with EExFAST bits (see *Section : Latency to external events*), for external events 1 to 5 and external events 11 to 13.

Note: The external events used as triggers for reset, capture, burst mode, ADC triggers and delayed protection are edge-sensitive even if EESNS bit is reset (level-sensitive selection): if POL = 0 the trigger is active on external event rising edge, while if POL = 1 the trigger is active on external event falling edge.

The external events are discarded as long as the counters are disabled (TxCEN bit reset) to prevent any output state change and counter reset, except if they are used as ADC triggers.

Additionally, it is possible to enable digital noise filters, for external events 6 to 10 using EExF[3:0] bits in the HRTIM_EECR3 register and for external events 14 to 16 using EExF[3:0] bits in the HRTIM_EECR6 register.

A digital filter is made of a counter in which a number N of valid samples is needed to validate a transition on the output. If the input value changes before the counter has

reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered, depending on the sampling clock and on the filter length (number of valid samples expected).

The sampling clock is either the f_{HRTIM} clock or a specific prescaled clock f_{EEVS} derived from f_{HRTIM}, defined with EEVSD[1:0] bits in HRTIM_EECR3 register.

Table 428 summarizes the available features associated with each of the 10 external events channels.The features and sources are summarized in *Table 411*.

Table 428. External events features

External event channel	Fast mode	Digital filter	Balanced fault timer A,B,C	Balanced fault timer D,E,F
hrtim_eev1[8:1]	Yes	-	-	-
hrtim_eev2[8:1]	Yes	-	-	-
hrtim_eev3[8:1]	Yes	-	-	-
hrtim_eev4[8:1]	Yes	-	-	-
hrtim_eev5[8:1]	Yes	-	-	-

hrtim_eev7[8:1]	-	Yes	Yes	-
hrtim_eev8[8:1]	-	Yes	-	Yes
hrtim_eev9[8:1]	-	Yes	-	Yes
hrtim_eev10[8:1]	-	Yes	-	-
hrtim_eev11[8:1]	Yes	-	-	-
hrtim_eev12[8:1]	Yes	-	-	-
hrtim_eev13[8:1]	Yes	-	-	-
hrtim_eev14[8:1]	-	Yes	-	-
hrtim_eev15[8:1]	-	Yes	-	-
hrtim_eev16[8:1]	-	Yes	-	-

The *Table 429* provides the mapping between EEVA..EEVJ events and external events hrtim_eev1 to hrtim_eev16. This is configured using the EEVxSEL[1:0] bitfield in the HRTIM_EESELxR register.

Table 429. External events selection

External event channel x = A..J	EEVxSEL[1:0]=00	EEVxSEL[1:0]=01	EEVxSEL[1:0]=10	EEVxSEL[1:0]=11
EEVA	hrtim_eev1	hrtim_eev11	hrtim_eev1 AND hrtim_eev2	hrtim_eev1 AND hrtim_eev11
EEVB	hrtim_eev2	hrtim_eev12	hrtim_ee2 AND hrtim_eev3	hrtim_eev2 AND hrtim_eev12

Table 429. External events selection

External event channel x = A..J	EEVxSEL[1:0]=00	EEVxSEL[1:0]=01	EEVxSEL[1:0]=10	EEVxSEL[1:0]=11
EEVC	hrtim_eev3	hrtim_eev13	hrtim_ee3 AND hrtim_eev4	hrtim_eev3 AND hrtim_eev13
EEVD	hrtim_eev4	hrtim_eev14	hrtim_ee4 AND hrtim_eev5	hrtim_eev4 AND hrtim_eev14
EEVE	hrtim_eev5	hrtim_eev15	hrtim_ee5 AND hrtim_eev6	hrtim_eev5 AND hrtim_eev15
EEVF	hrtim_eev6	hrtim_eev16	hrtim_ee6 AND hrtim_eev7	hrtim_eev6 AND hrtim_eev16
EEVG	hrtim_eev7	hrtim_eev11	hrtim_ee7 AND hrtim_eev8	hrtim_eev7 AND hrtim_eev11
EEVH	hrtim_eev8	hrtim_eev12	hrtim_ee8 AND hrtim_eev9	hrtim_eev8 AND hrtim_eev12
EEVI	hrtim_eev9	hrtim_eev13	hrtim_ee9 AND hrtim_eev10	hrtim_eev9 AND hrtim_eev13
EEVJ	hrtim_eev10	hrtim_eev14	hrtim_ee10 AND hrtim_eev11	hrtim_eev10 AND hrtim_eev14

The external events can be combined (hrtim_eevy AND hrtim_eevz) with EEVxSEL[1:0] = 10 or 11.

They can be combined solely if they both are in same mode:

- hrtim_eey (with fast mode option) and hrtim_eevz (with fast mode option), with both EEyFAST = EEzFAST = 0 or EEyFAST = EEzFAST = 1
- hrtim_eey (with digital filter option) and hrtim_eevz (with fast mode option) with EEzFAST = 0

It is not possible to combine hrtim_eey (with digital filter option) and hrtim_eevz (with fast mode option) with EEzFAST = 1.

When EEVA..EEVJ is resulting from a combination of 2 external events (EEVxSEL[1:0] = 10 or 11), at least one of the 2 inputs must be level sensitive. Having a level sensitive input combined with an edge sensitive input results in an edge sensitive combined signal. This gives the possibility to let an external event be generated depending on the level of an other external event (AND function).

Latency to external events

The external event conditioning gives the possibility to adjust the external event processing time (and associated latency) depending on performance expectations:

- A regular operating mode, in which the external event is resampled with the clock before acting on the output crossbar. This adds some latency but gives access to all

crossbar functionalities. It enables the generation of an externally triggered high-resolution pulse.

- A fast operating mode, in which the latency between the external event and the action on the output is minimized. This mode is convenient for ultra-fast over-current protections, for instance.

EExFAST bits in the HRTIM_EECR1 and HRTIM_EECR4 registers allow to define the operating for channels 1 to 5 and channels 11 to 13. This influences the latency and the jitter present on the output pulses, as summarized in the table below.

Table 430. Output set/reset latency and jitter versus external event operating mode

EExFAST	Response time latency	Response time jitter	Jitter on output pulse (counter reset by ext. event)
0	5 to 6 cycles of f_{HRTIM} clock	1 cycles of f_{HRTIM} clock	No jitter, pulse width maintained with high-resolution
1	Minimal latency (depends whether the comparator or digital input is used)	Minimal jitter	1 cycle of f_{HRTIM} clock jitter pulse width resolution down to t_{HRTIM}

The EExFAST mode is only available with level-sensitive programming (EExSNS[1:0] = 00); the edge-sensitivity cannot be programmed.

It is possible to apply event filtering to fast external events (both blanking and windowing with EExFLTR[3:0] ≠ 0000, see *Section 40.3.9*). In this case, EExLTCHx bit must be reset: the postponed mode is not supported, neither the windowing timeout feature.

Note: The external event configuration (source and polarity) must not be modified once the related EExFAST bit is set.

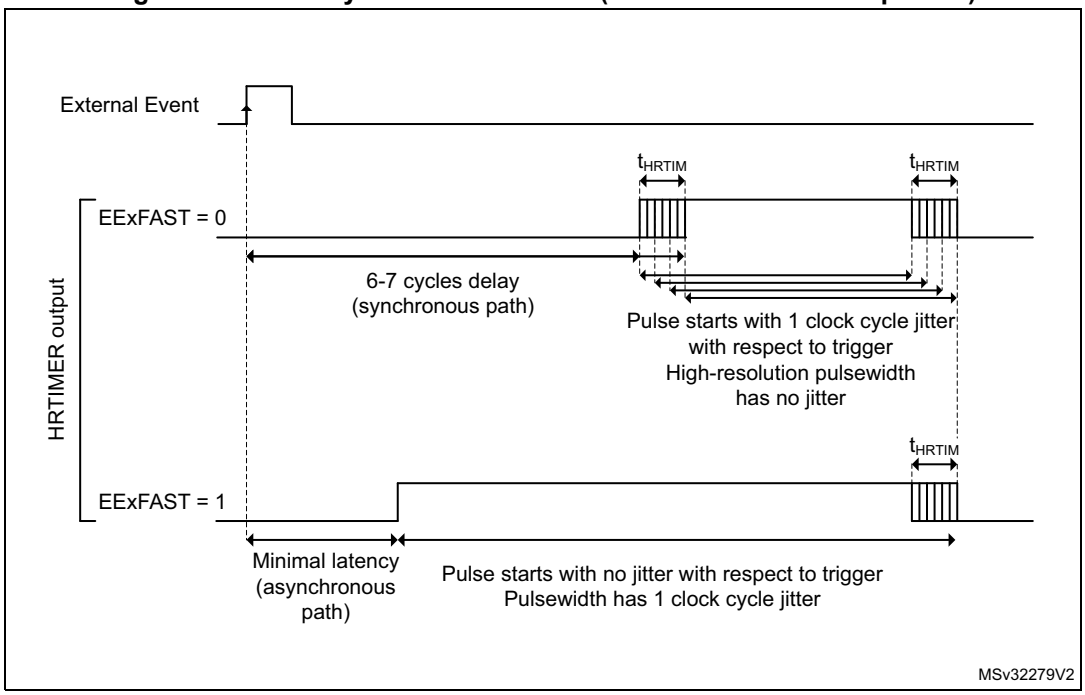
A fast external event cannot be used to toggle an output: if must be enabled either in HRTIM_SETxyR or HRTIM_RSTxyR registers, not in both.

When a set and a reset event - from 2 independent fast external events - occur simultaneously, the reset has the highest priority in the crossbar and the output becomes inactive.

When EExFAST bit is set, the output cannot be changed during the 11 f_{HRTIM} clock periods following the external event.

Figure 403 and *Figure 404* give practical examples of the reaction time to external events, for output set/reset and counter reset.

Figure 403. Latency to external events (counter reset and output set)



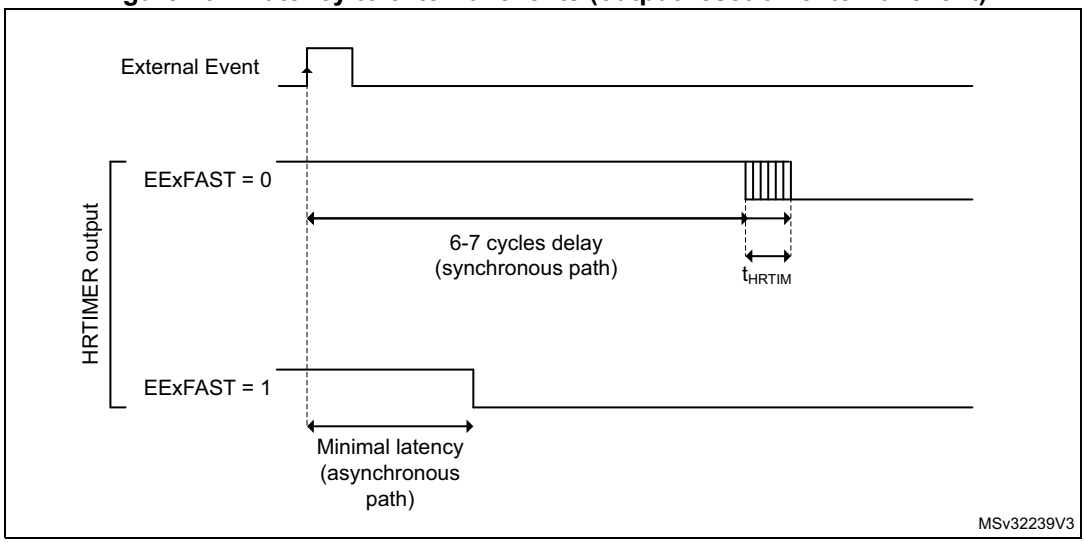


Figure 404. Latency to external events (output reset on external event)

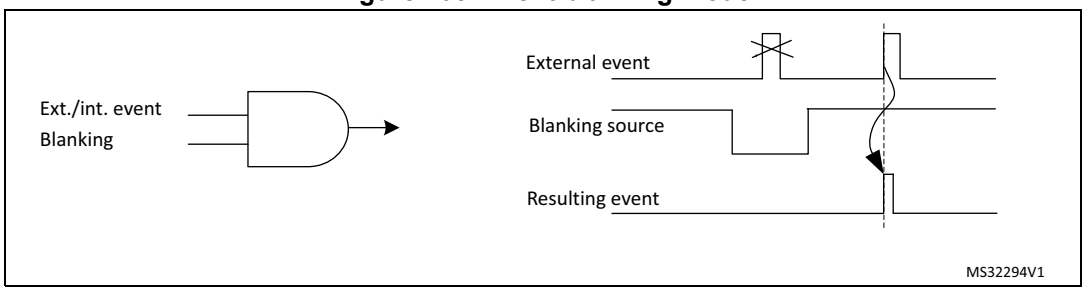
40.3.9 External event filtering in timing units

Once conditioned, the 10 external events are available for all timing units.

They can be used directly and are active as soon as the timing unit counter is enabled (TxCEN bit set).

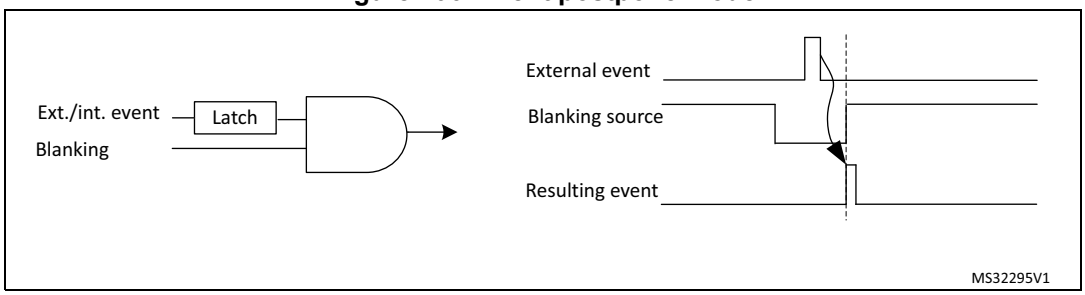
They can also be filtered to have an action limited in time, usually related to the counting period. Two operations can be performed:



- Blanking, to mask external events during a defined time period,
- Windowing, to enable external events only during a defined time period.

These modes are enabled using HRTIM_EExFLTR[4:0] bits in the HRTIM_EEFxR1 and HRTIM_EEFxR2 registers. Each of the 6 timer A..F timing units has its own programmable filter settings for the 10 external events.

Blanking mode



In event blanking mode (see *Figure 405*), the external event is ignored if it happens during a given blanking period. This is convenient, for instance, to avoid a current limit to trip on switching noise at the beginning of a PWM period. This mode is active for EExFLTR[4:0] bitfield values ranging from 00001 to 01100.

Figure 405. Event blanking mode

In event postpone mode, the external event is not taken into account immediately but is memorized (latched) and generated as soon as the blanking period is completed, as shown on *Figure 406*. This mode is enabled by setting EExLTCH bit in HRTIM_EEFxR1 and HRTIM_EEFxR2 registers.

Figure 406. Event postpone mode

The blanking signal comes from several sources:

- the timer itself: the blanking lasts from the counter reset to the compare match (EExFLTR[4:0] = 00001 to 00100 for compare 1 to compare 4). In up/down mode (UDM bit set to 1), the counter reset event is defined as per the ROM[1:0] bit setting.
- from other timing units (EExFLTR[4:0] = 00101 to 01100): the blanking lasts from the selected timing unit counter reset to one of its compare match, or can be fully programmed as a waveform on Tx2 output. In this case, events are masked as long as the Tx2 signal is inactive (it is not necessary to have the output enabled, the signal is taken prior to the output stage).

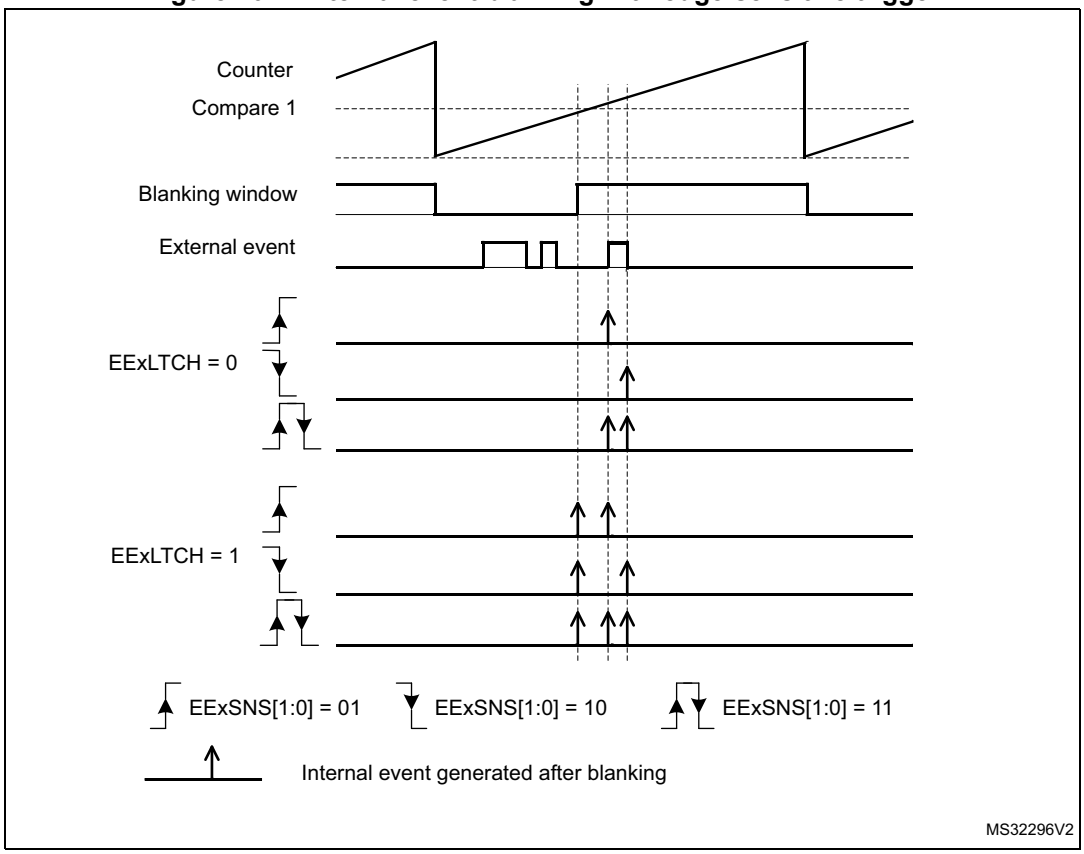
The EExFLTR[4:0] configurations from 00101 to 01100 are referred to as TIMFLTR1 to TIMFLTR8 in the bit description, and differ from one timing unit to the other. *Table 431* gives the 8 available options per timer: CMPx refers to blanking from counter reset to compare match, Tx2 refers to the timing unit TIMx output 2 waveform defined with HRTIM_SETx2 and HRTIM_RSTx2 registers. For instance, timer B (TIMFLTR6) is timer C output 2 waveform.

Table 431. Filtering signals mapping per timer

Source		Timer A				Timer B				Timer C				Timer D				Timer E				Timer F			
		CMP1	CMP2	CMP4	TA2	CMP1	CMP2	CMP4	TB2	CMP1	CMP2	CMP4	TC2	CMP1	CMP2	CMP4	TD2	CMP1	CMP2	CMP4	TE2	CMP1	CMP2	CMP4	TF2
Destination	Timer A	-				1	-	2	3	4	-	5	-	7	-	-	-	-	8	-	-	6	-	-	-
	Timer B	1	-	2	3	-				4	5	-	-	-	7	-	-	8	-	-	-	-	6	-	-
	Timer C	-	1	-	-	2	-	3	-	-				5	-	6	7	-	-	8	-	4	-	-	-
	Timer D	1	-	-	-	-	2	-	-	3	4	-	5	-				6	-	7	-	-	-	8	-
	Timer E	-	1	-	-	2	-	-	-	3	-	-	-	6	-	7	8	-				-	-	4	5
	Timer F	-	-	1	-	-	2	-	-	-	-	3	-	-	4	5	-	6	-	7	8	-			

Figure 407 and *Figure 408* give an example of external event blanking for all edge and level sensitivities, in regular and postponed modes.

Figure 407. External event blanking with edge-sensitive trigger



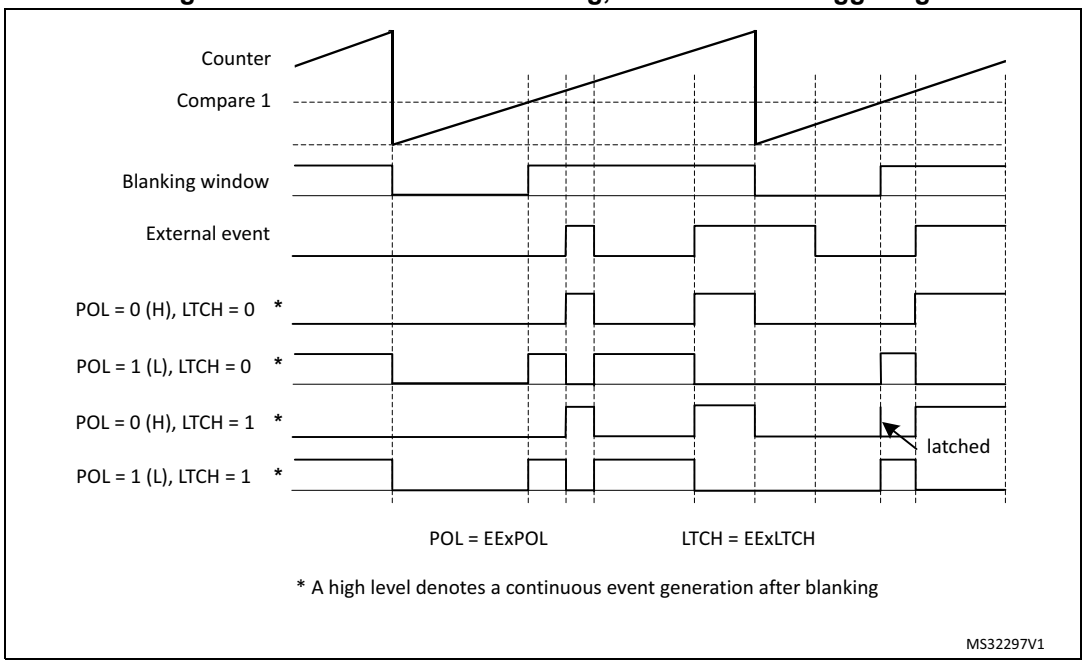


Figure 408. External event blanking, level sensitive triggering

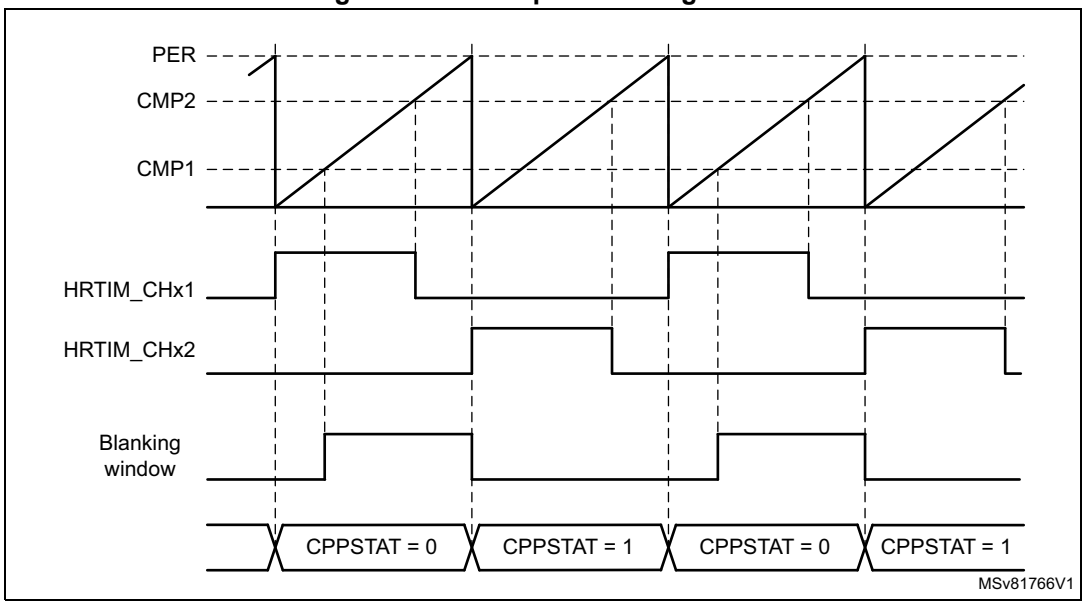
Push-pull blanking mode



A push-pull specific blanking mode differentiates blanking from one period to the other, as shown in *Figure 409*. Select this mode by programming EExFLTR[4:0] = 11100.

It works as follows:

- During the push phase (CPPSTAT = 0), blanking lasts from the reset/roll-over event to the CMP1 match.
- During the pull phase (CPPSAT = 1), the blanking is always active.

This mode ensures that an external event that generates a balanced idle mode is considered only during the push phase and is rejected if it occurs during the pull phase.

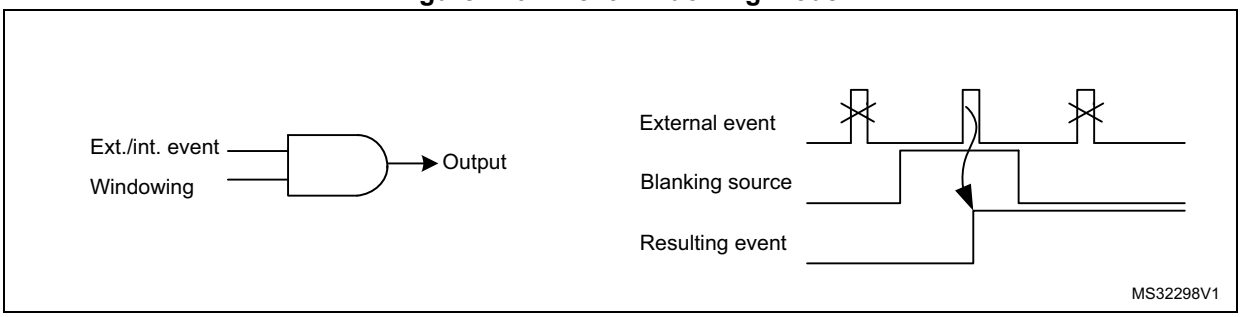


Figure 409. Push-pull blanking mode

Windowing mode

In event windowing mode, the event is taken into account only if it occurs within a given time window, otherwise it is ignored. This mode is active for EExFLTR[4:0] ranging from 01101 to 01111.

Figure 410. Event windowing mode

EExLTCH bit in EEFxR1 and EEFxR2 registers allows to latch the signal, if set to 1: in this case, an event is accepted if it occurs during the window but is delayed at the end of it.

- If EExLTCH bit is reset and the signal occurs during the window, it is passed through directly.
- If EExLTCH bit is reset and no signal occurs, a timeout event is generated at the end of the window.

A use case of the windowing mode is to filter synchronization signals. The timeout generation allows to force a default synchronization event, when the expected synchronization event is lacking (for instance during a converter start-up).

There are 3 sources for each external event windowing, coded as follows:

- 01101 and 01110: the windowing lasts from the counter reset to the compare match (respectively compare 2 and compare 3). In up/down mode (UDM bit set to 1), the counter reset event is defined as per the ROM[1:0] bit setting.
- 01111: the windowing is related to another timing unit and lasts from its counter reset to its compare 2 match. The source is described as TIMWIN in the bit description and is given in *Table 432*. As an example, the external events in timer B can be filtered by a window starting from timer A counter reset to timer A compare 2.

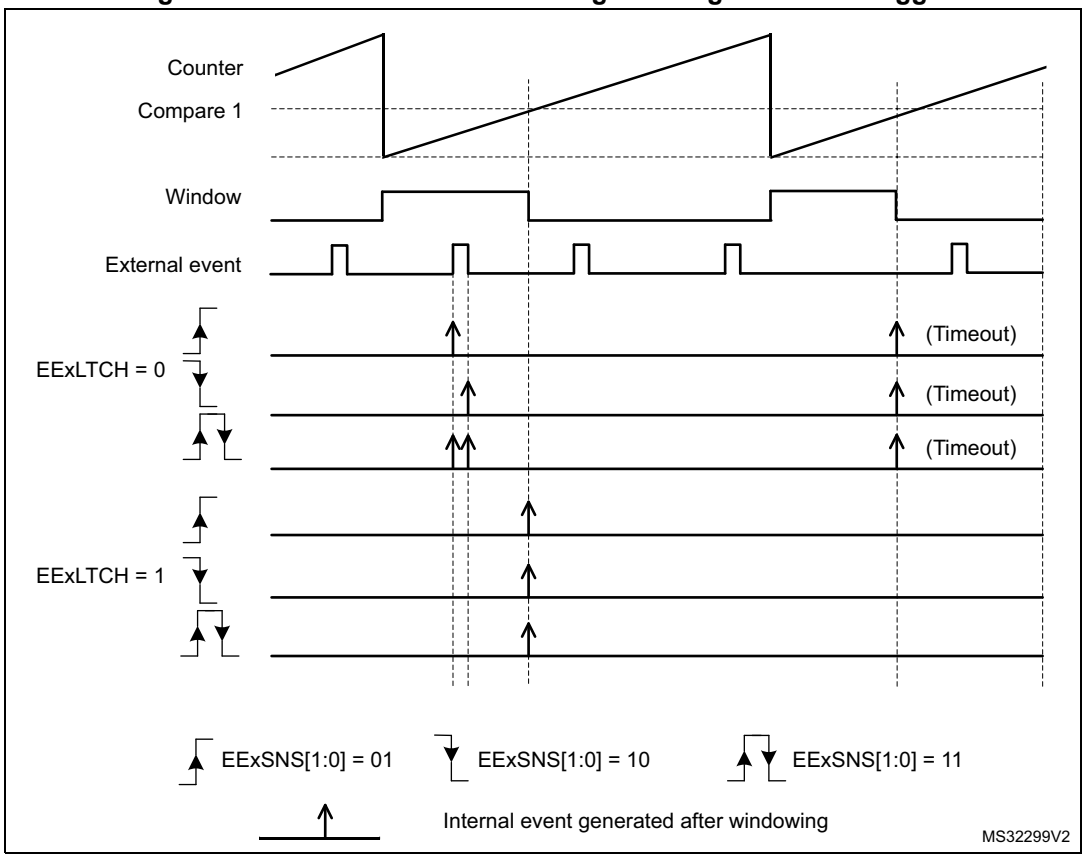
Table 432. Windowing signals mapping per timer (EExFLTR[4:0] = 01111)

Destination	Timer A	Timer B	Timer C	Timer D	Timer E	Timer F
TIMWIN (source)	Timer B CMP2	Timer A CMP2	Timer D CMP2	Timer C CMP2	Timer F CMP2	Timer E CMP2
TIMWIN2 (source)	Timer B CMP2 to reset/roll-over	Timer A CMP2 to reset/roll-over	Timer D CMP2 to reset/roll-over	Timer C CMP2 to reset/roll-over	Timer F CMP2 to reset/roll-over	Timer E CMP2 to reset/roll-over
TIMWIN3 (source)	Timer B CMP1 to CMP2	Timer A CMP1 to CMP2	Timer D CMP1 to CMP2	Timer C CMP1 to CMP2	Timer F CMP1 to CMP2	Timer E CMP1 to CMP2

Note: The timeout event generation is not supported if the external event is programmed in fast mode.

Figure 411 and *Figure 412* present how the events are generated for the various edge and level sensitivities, as well as depending on EExLTCH bit setting. Timeout events are specifically mentioned for clarity reasons.

Figure 411. External event windowing with edge-sensitive trigger



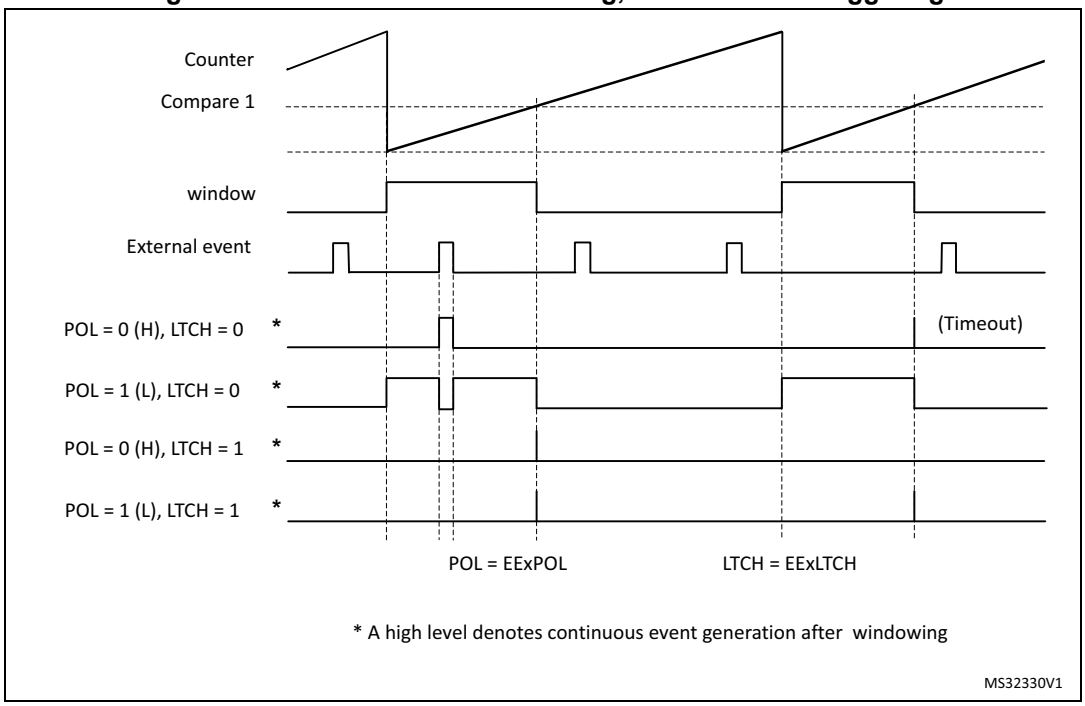


Figure 412. External event windowing, level sensitive triggering

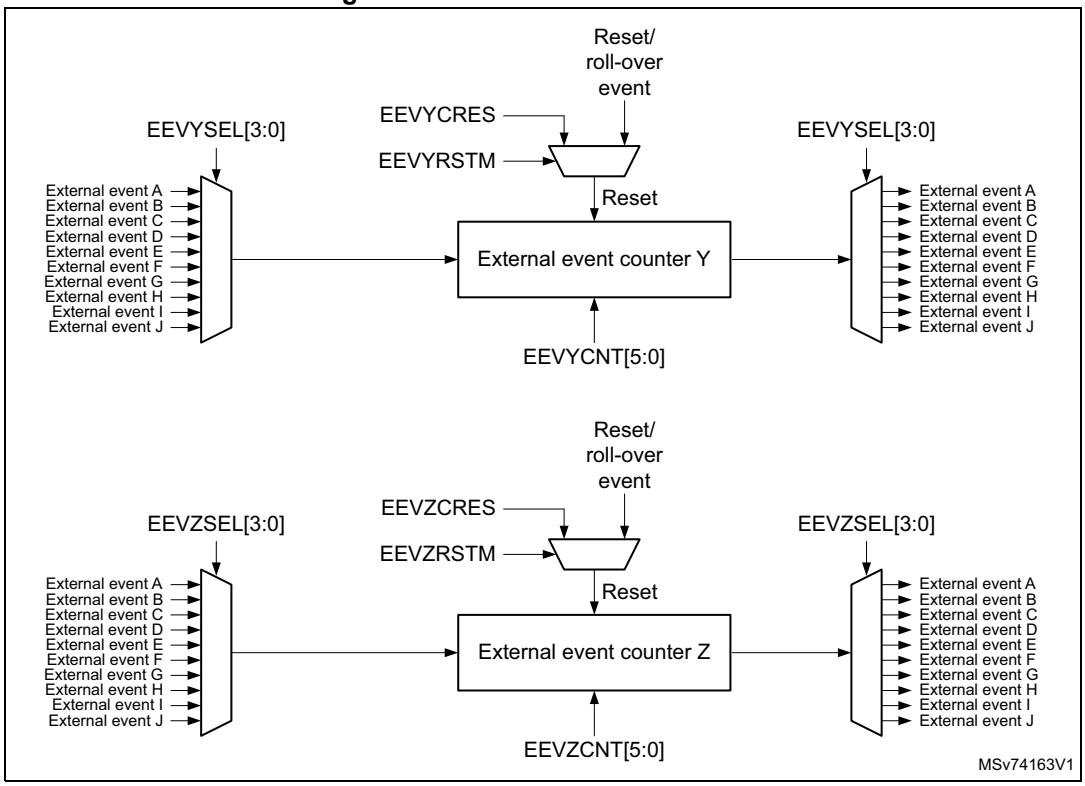


External event counter

Each timing unit also features two external event counters following the filtering unit, typically for valley skipping implementation.

The circuitry allows to filter any of the 10 external events filtered, as shown on *Figure 413*.

Figure 413. External event counters

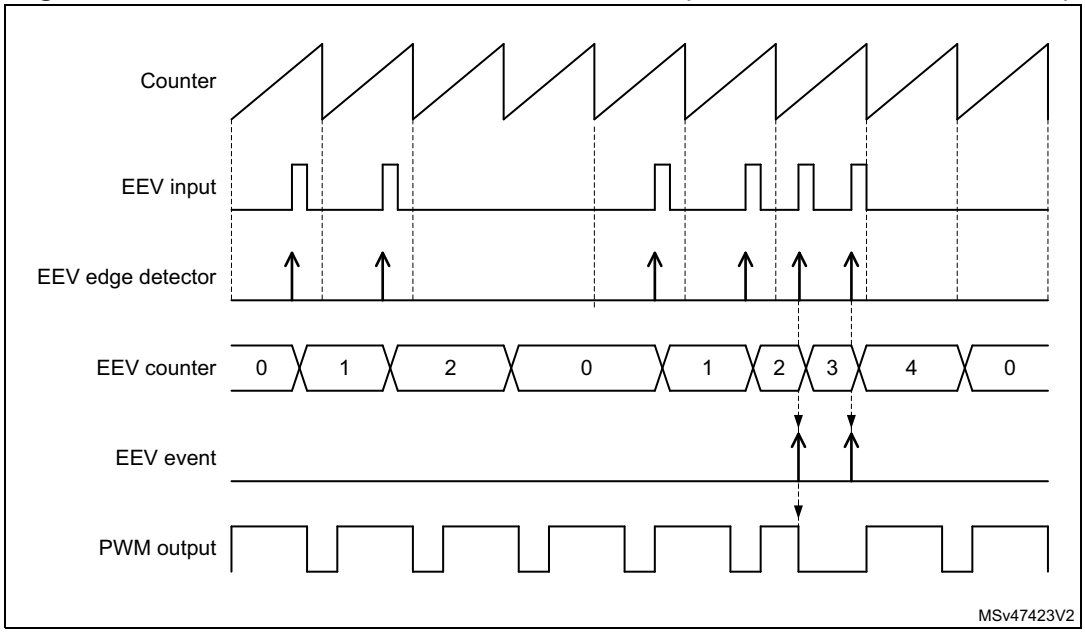
The counters Y and Z are enabled using the EEVxCE bit in the HRTIM_EEFxR3 register. This mode is only valid for edge-sensitive external events (EExSNS[1:0] bitfield = 01, 10 or 11), when EEVA..EEVJ selection is a single external event EEV1..16 (EEVxSEL[1:0] = 00 or 01).

When EEVA..EEVJ is resulting from a combination of 2 external events (EEVxSEL[1:0] = 10 or 11), at least one of the 2 inputs must be level sensitive. Having a level sensitive input combined with an edge sensitive input results in an edge sensitive combined signal. This gives the possibility to let an external event be generated depending on the level of an other external event (AND function).

The external event is propagated to the timer only if the number of active edges is greater or equal to the value programmed in (EEVxCNT[5:0]+1).

Two operating modes are available:

- When the EEVxRSTM bit is reset, the external event counter is reset on each reset/roll-over event: the external event is active only if it appears several times within a given PWM period
- When the EEVxRSTM bit is set, the external event counter is reset only if the event did not on appear during the last PWM period. This a cumulative mode, where the event must occur at least once during multiple PWM period, as shown on *Figure 414* below.



Note: If the 2 external event counters are operating on the same external event (EEVYSEL[3:0] equal to EEVZSEL[3:0]) the external counter Y only is considered.

The external event counter must be enabled after having programmed the counter value (the EEVxCE bit must be set after having written the EEVxCNT[5:0] bits).

Once the counter is enabled, the EEVxCNT[5:0] bits can then be changed on-the-fly at any time. The new value is taken into account on the following reset/rollover event as per the EEVxRSTM bit programming, or after a software reset (EEVxCRES bit set).

The EEVxSEL[3:0] bitfield must not be modified once the EEVxCE bit is set.

Figure 414. External event counter cumulative mode (EEVxRSTM = 1, EEVxCNT = 2)

40.3.10 Delayed protection

The HRTIM features specific protection schemes, typically for resonant converters when it is necessary to shut down the PWM outputs in a delayed manner, either once the active pulse is completed or once a push-pull period is completed. These features are enabled with DLYPRTEN bit in the HRTIM_OUTxR register, and are using specific external event channels.

Delayed idle

In this mode, the active pulse is completed before the protection is activated. The selected external event causes the output to enter in idle mode at the end of the active pulse (defined by an output reset event in HRTIM_RSTx1R or HRTIM_RSTx2R).

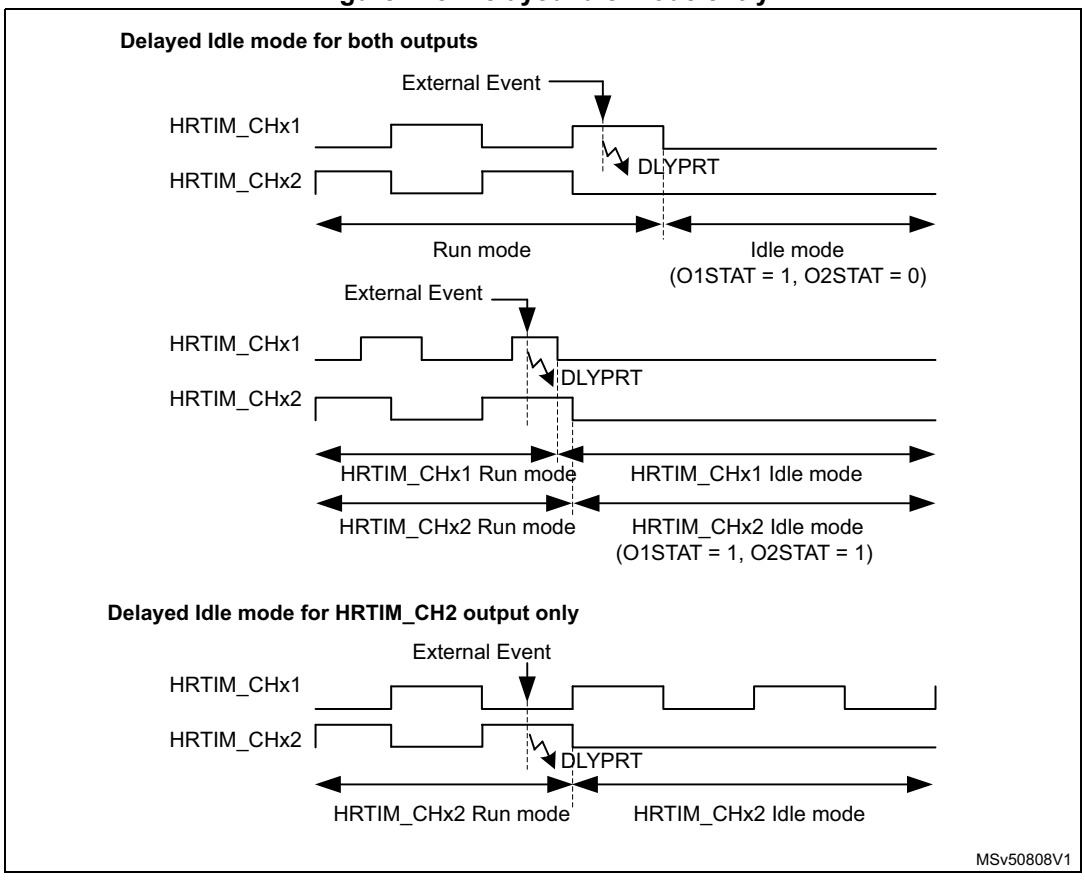
Once the protection is triggered, the idle mode is permanently maintained but the counter continues to run, until the output is re-enabled. Tx1OEN and Tx2OEN bits are not affected by the delayed idle entry. To exit from delayed idle and resume operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1. The output state changes on the first transition to an active state following the output enable command.

Note: The delayed idle mode cannot be exited immediately after having been entered, before the active pulse is completed: it is mandatory to make sure that the outputs are in idle state

before resuming the run mode. This can be done by waiting up to the next period, for instance, or by polling the O1CPY and/or O2CPY status bits in the TIMxISR register.

The delayed idle mode can be applied to a single output (DLYPRT[2:0] = x00 or x01) or to both outputs (DLYPRT[2:0] = x10).

An interrupt or a DMA request can be generated in response to a Delayed Idle mode entry. The DLYPRT flag in HRTIM_TIMxISR is set as soon as the external event arrives, independently from the end of the active pulse on output.



When the Delayed Idle mode is triggered, the output states can be determined using O1STAT and O2STAT in HRTIM_TIMxISR. Both status bits are updated even if the delayed idle is applied to a single output. When the push-pull mode is enabled, the IPPSTAT flag in HRTIM_TIMxISR indicates during which period the delayed protection request occurred.

This mode is available whatever the timer operating mode (regular, push-pull, deadtime). It is available with some external events only:

- EEVF and EEVG for timer A, B and C
- EEVH and EEVI for timer D, E and F

The delayed protection mode can be triggered only when the counter is enabled (TxCEN bit set). It remains active even if the TxEN bit is reset, until the TxyOEN bits are set.

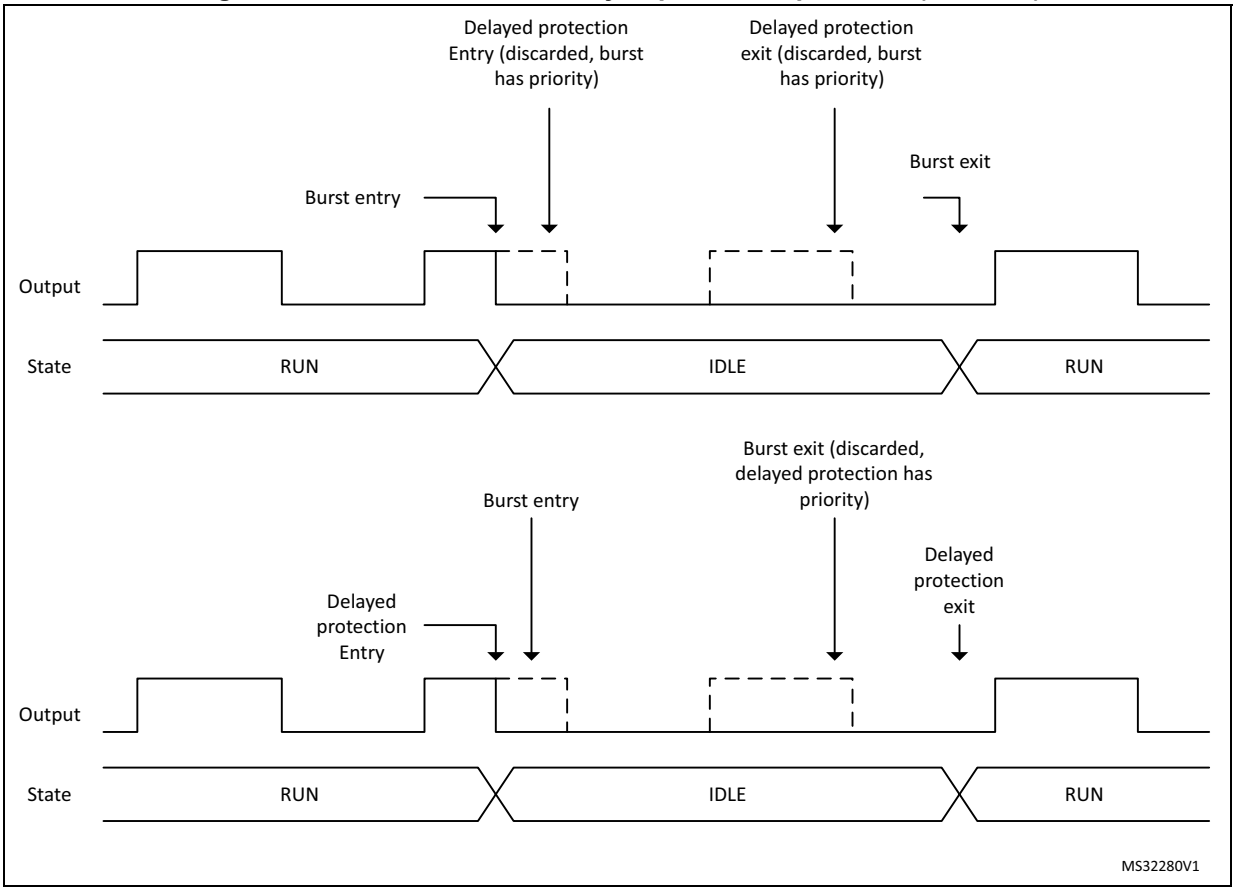


Figure 415. Delayed Idle mode entry

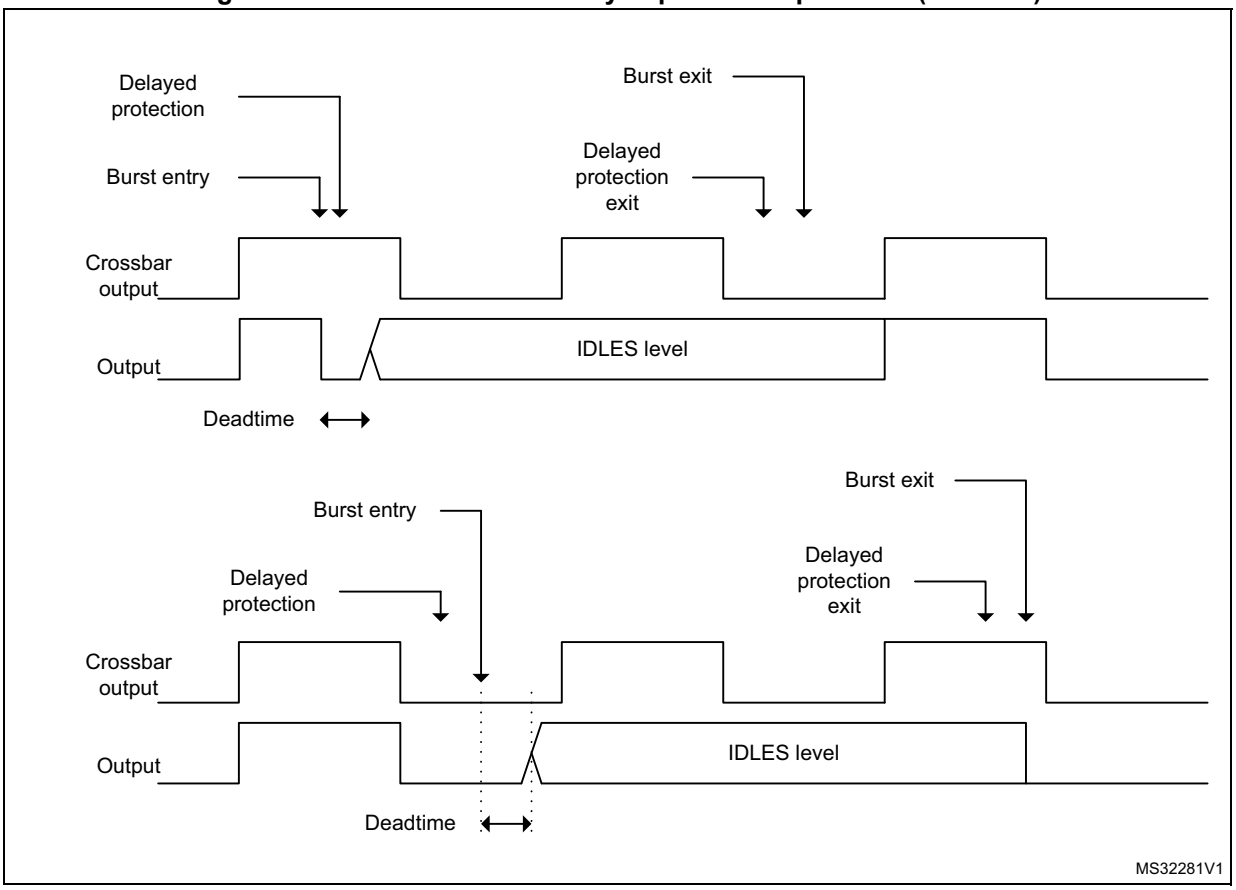
The delayed idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the delayed idle protection has been triggered. On the contrary, If the delayed protection is exited while the burst mode is active, the burst mode is resumed

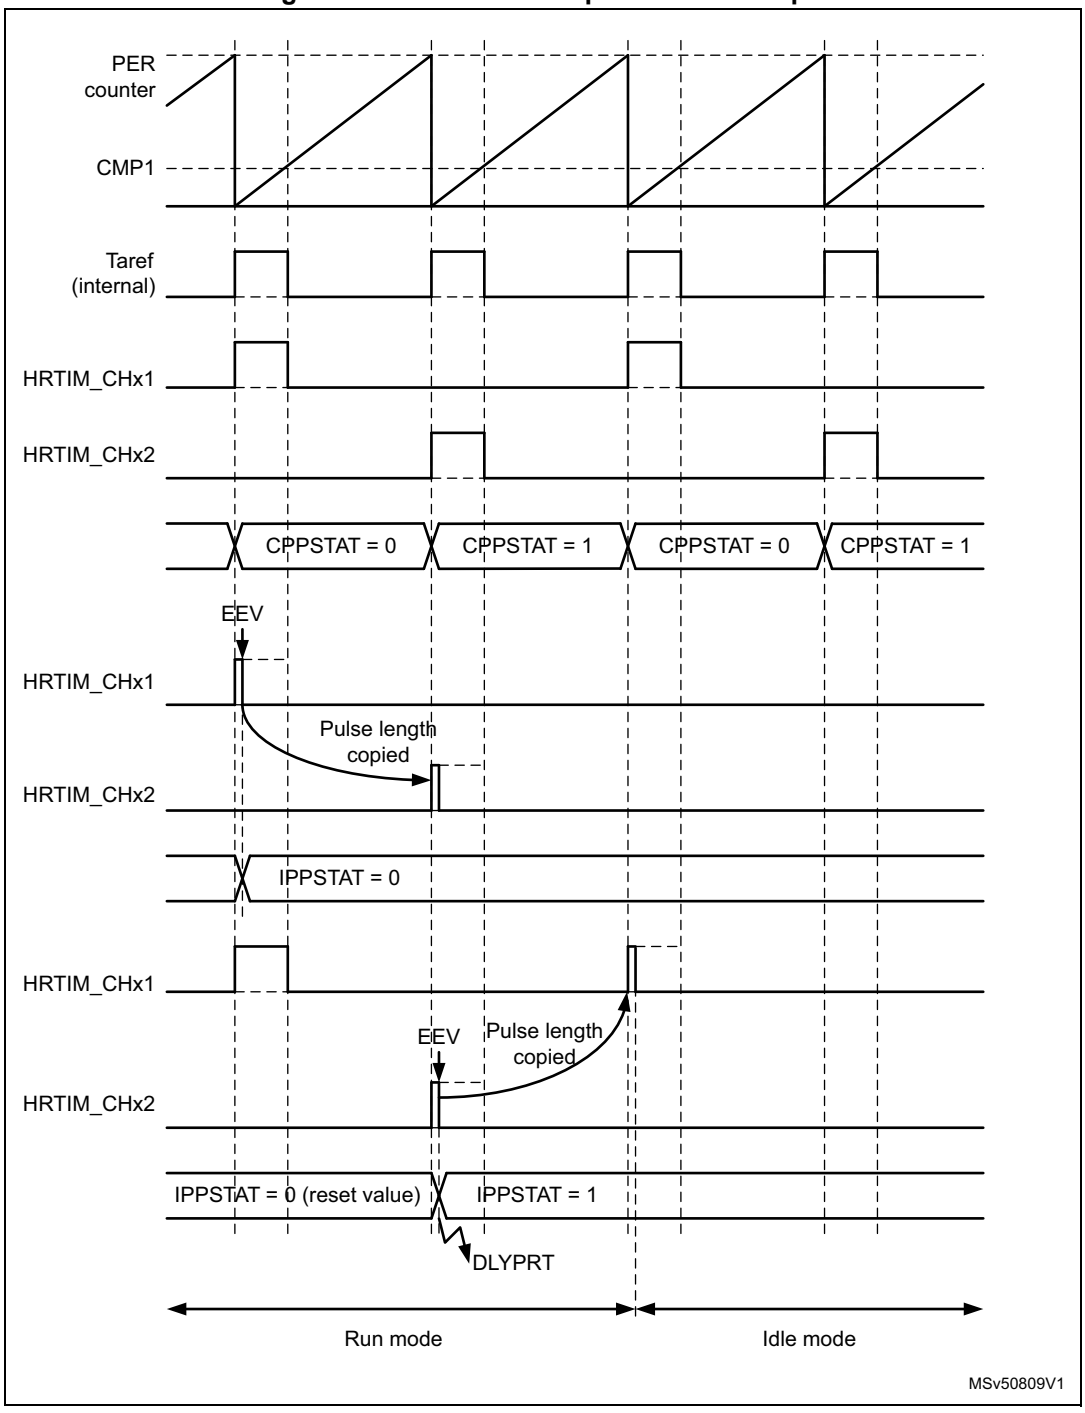


normally and the output is maintained in the idle state until the burst mode exits. *Figure 416* gives an overview of these different scenarios.

Figure 416. Burst mode and delayed protection priorities (DIDL = 0)

The same priorities are applied when the delayed burst mode entry is enabled (DIDL bit set), as shown on *Figure 417* below.

Figure 417. Burst mode and delayed protection priorities (DIDL = 1)



Balanced idle

Only available in push-pull mode, the balanced idle allows to have a balanced pulsewidth on the two outputs when one of the active pulse is shortened due to a protection. The pulsewidth, terminated earlier than programmed, is copied on the alternate output, then the two outputs are put in idle state, until the normal operation is resumed by software. This mode is enabled by writing x11 in DLYPRT[2:0] bitfield in HRTIM_OUTxR.

This mode is available with only 2 external events:

- EEVF and EEVG for timer A, B and C
- EEVH and EEVI for timer D, E and F

Figure 418. Balanced Idle protection example

When the balanced Idle mode is enabled, the selected external event triggers a capture of the counter value into the compare 4 active register (this value is not user-accessible). The push-pull is maintained for one additional period so that the shorten pulse can be repeated: a new output reset event is generated while the regular output set event is maintained.

The Idle mode is then entered and the output takes the level defined by IDLESx bits in the HRTIM_OUTxR register. The balanced idle mode entry is indicated by the DLYPRT flag,

while the IPPSTAT flag indicates during which period the external event occurred, to determine the sequence of shorten pulses (A1 then A2 or vice versa).

The timer operation is not interrupted (the counter continues to run).

To enable the balanced idle mode, it is necessary to have the following initialization:

- Timer operating in continuous mode (CONT = 1)
- Push-pull mode enabled
- HRTIM_CMP4xR must be set to 0 and the content transferred into the active register (for instance by forcing a software update)
- DELCMP4[1:0] bit field must be set to 00 (autodelayed mode disabled)
- DLYPRT[2:0] = x11 (delayed protection enable)

Note: The HRTIM_CMP4xR register must not be written during a balanced idle operation. The CMP4 event is reserved and cannot be used for another purpose.

In balanced idle mode, it is recommended to avoid multiple external events or software-based reset events causing an output reset. If such an event arrives before a balanced idle request within the same period, it causes the output pulses to be unbalanced (1st pulse length defined by the external event or software reset, while the 2nd pulse is defined by the balanced idle mode entry). The balanced idle mode is applicable only when a single pulse is generated per counting period, as on Figure 418: Balanced Idle protection example.

The minimum pulsewidth that can be handled in balanced idle mode is 4 f_{HRTIM} clock periods (0x80 if CKPSC[2:0] = 0, 0x40 if CKPSC[2:0] = 1, 0x20 if CKPSC[2:0] = 2,...).

If the capture occurs before the counter has reached this minimum value, the current pulse is extended up to 4 f_{HRTIM} clock periods before being copied into the secondary output. In any case, the pulsewidths are always balanced.

Tx1OEN and Tx2OEN bits are not affected by the balanced idle entry. To exit from balanced idle and resume the operation, it is necessary to overwrite Tx1OEN and Tx2OEN bits to 1 simultaneously. The output state changes on the first active transition following the output enable.

It is possible to resume operation similarly to the delayed idle entry. For instance, if the external event arrives while output 1 is active (delayed idle effective after output 2 pulse), the re-start sequence can be initiated for output 1 first. To do so, it is necessary to poll CPPSTAT bit in the HRTIM_TIMxISR register. Using the above example (IPPSTAT flag equal to 0), the operation is resumed when CPPSTAT bit is 0.

In order to have a specific re-start sequence, it is possible to poll the CPPSTAT to know which output is active first. This allows, for instance, to re-start with the same sequence as the idle entry sequence: if the external event arrives during output 1 active, the re-start sequence is initiated when the output 1 is active (CPPSTAT = 0).

Note: The balanced idle mode must not be disabled while a pulse balancing sequence is on-going. It is necessary to wait until the CMP4 flag is set, thus indicating that the sequence is completed, to reset the DLYPRTEN bit.

The balanced idle protection mode can be triggered only when the counter is enabled (TxCEN bit set). It remains active even if the TxCEN bit is reset, until TxyOEN bits are set.

Balanced idle can be used together with the burst mode under the following conditions:

- TxBM bit must be reset (counter clock maintained during the burst, see *Section 40.3.15*),
- No balanced idle protection must be triggered while the outputs are in a burst idle state.

The balanced idle mode has a higher priority than the burst mode: any burst mode exit request is discarded once the balanced idle protection has been triggered. On the contrary, if the delayed protection is exited while the burst mode is active, the burst mode is resumed normally.

Note: Although the output state is frozen in idle mode, a number of events are still generated on the auxiliary outputs (see Section 40.3.18) during the idle period following the delayed protection:
- Output set/reset interrupt or DMA requests
- External event filtering based on output signal
- Capture events triggered by set/reset

Balanced idle automatic resuming

The balanced Idle mode can be configured to have an automatic resuming of operation after a trigger.

Once the shorten pulse has been copied to the alternate output, the pulse width is reset to its original value and the timer resumes operation: the two outputs keep on being in RUN mode.

This is enabled by setting the BIAR bit in the HRTIM_OUTxR register.

This mode must be used only when the period in HRTIM_PERxR is greater than 6 periods of the f_{HRTIM} clock (0xC0 if CKPSC[2:0] = 0, 0x60 if CKPSC[2:0] = 1, 0x30 if CKPSC[2:0] = 2, ...).

Note: This bit is only significant if DLYPRT[2:0] = 011 or 111, it is ignored otherwise.

Note: In balanced idle automatic resuming mode, it is mandatory to set the IDLES state to inactive.

40.3.11 Register preload and update management

Most of HRTIM registers are buffered and can be preloaded if needed. Typically, this allows to prevent the waveforms from being altered by a register update not synchronized with the active events (set/reset).

When the preload mode is enabled, accessed registers are shadow registers. Their content is transferred into the active register after an update request, either software or synchronized with an event.

By default, PREEN bits in HRTIM_MCR and HRTIM_TIMxCR registers are reset and the registers are not preloaded: any write directly updates the active registers. If PREEN bit is reset while the timer is running and preload was enabled, the content of the preload registers is directly transferred into the active registers.

Each timing unit and the master timer have their own PREEN bit. If PRREN is set, the preload registers are enabled and transferred to the active register only upon an update event.

There are two options to initialize the timer when the preload feature is needed:

- Enable PREEN bit at the very end of the timer initialization to have the preload registers transferred into the active registers before the timer is enabled (by setting MCEN and TxCEN bits).
- Enable PREEN bit at any time during the initialization and force a software update immediately before starting.

Table 433 lists the registers which can be preloaded, together with a summary of available update events.

Table 433. HRTIM preloadable control registers and associated update sources

Timer	Preloadable registers	Preload enable	Update sources
Master timer	HRTIM_DIER HRTIM_MPER HRTIM_MREP HRTIM_MCMP1R HRTIM_MCMP2R HRTIM_MCMP3R HRTIM_MCMP4R	PREEN bit in HRTIM_MCR	Software Repetition event Burst DMA event Repetition event following a burst DMA event
Timer x x = A..F	HRTIM_TIMxDIER HRTIM_TIMxPER HRTIM_TIMxREP HRTIM_TIMxCMP1R HRTIM_TIMxCMP1CR HRTIM_TIMxCMP2R HRTIM_TIMxCMP3R HRTIM_TIMxCMP4R HRTIM_DTxR HRTIM_SETx1R HRTIM_RSTx1R HRTIM_SETx2R HRTIM_RSTx2R HRTIM_RSTxR	PREEN bit in HRTIM_TIMxCR	Software TIMx repetition event TIMx reset event Burst DMA event Update event from other timers (TIMy, master) Update event following a burst DMA event Update enable inputs hrtim_upd_en[3:1] Update event following an update enable input following an update event on hrtim_upd_en[3:1] inputs
HRTIM Common	HRTIM_ADC1R HRTIM_ADC2R HRTIM_ADC3R HRTIM_ADC4R	TIMx or master timer Update, depending on ADxUSRC[2:0] bits in HRTIM_CR1, if PREEN = 1 in the selected timer	

The master timer has 4 update options:

1. Software: writing 1 into MSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is cancelled.
2. Update done when the master counter rolls over and the master repetition counter is equal to 0. This is enabled when MREPU bit is set in HRTIM_MCR.
3. Update done once burst DMA is completed (see *Section 40.3.23* for details). This is enabled when BRSTDMA[1:0] = 01 in HRTIM_MCR. It is possible to have both MREPU=1 and BRSTDMA=01.
   Note: The update can take place immediately after the end of the burst sequence if SWU bit is set (i.e. forced update mode). If SWU bit is reset, the update is done on the next update event following the end of the burst sequence.
4. Update done when the master counter rolls over following a burst DMA completion. This is enabled when BRSTDMA[1:0] = 10 in HRTIM_MCR.

An interrupt or a DMA request can be generated by the master update event.

Each timer (TIMA..F) can also have the update done as follows:

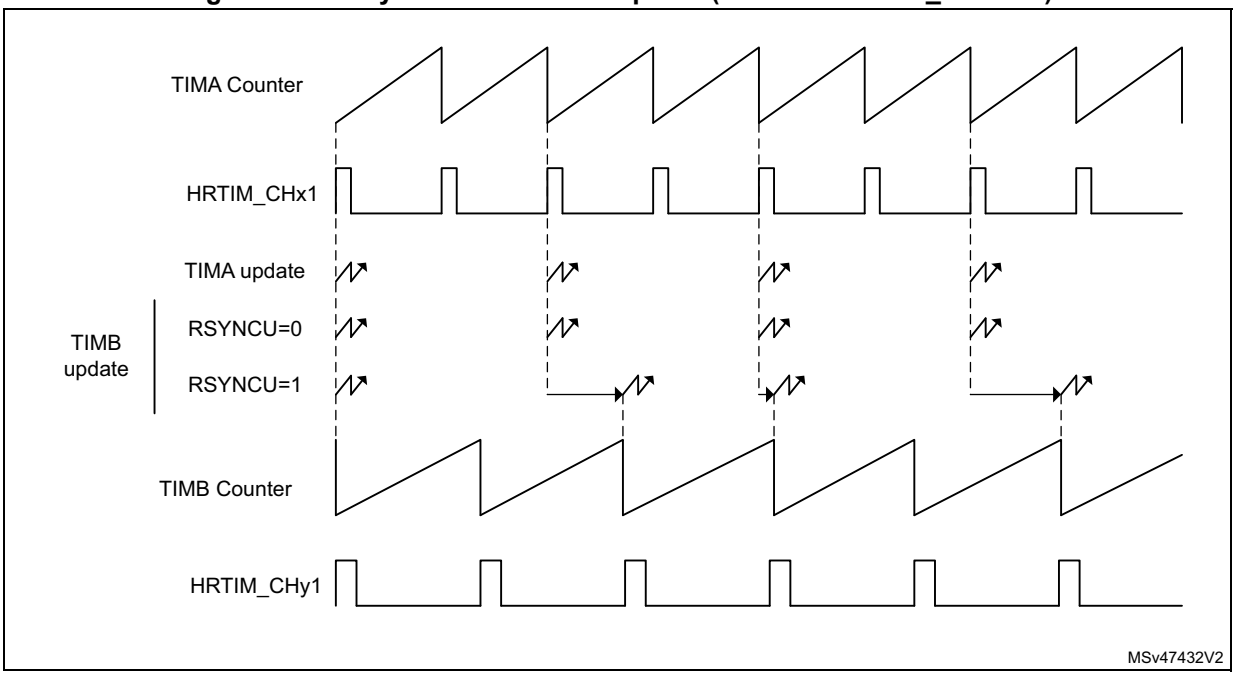
- By software: writing 1 into TxSWU bit in HRTIM_CR2 forces an immediate update of the registers. In this case, any pending hardware update request is canceled.
- Update done when the counter rolls over and the repetition counter is equal to 0. This is enabled when TxREPU bit is set in HRTIM_TIMxCR.
- Update done when the counter is reset or rolls over in continuous mode. This is enabled when TxRSTU bit is set in HRTIM_TIMxCR. This is used for a timer operating in single-shot mode, for instance.
- Update done once a burst DMA is completed. This is enabled when UPDGAT[3:0] = 0001 in HRTIM_TIMxCR.
- Update done on the update event following a burst DMA completion (the event can be enabled with TxRSTU, TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0010 in HRTIM_TIMxCR.
- Update done when receiving a request on hrtim_upd_en[3:1]. This is enabled when UPDGAT[3:0] = 0011, 0100, 0101 in HRTIM_TIMxCR.
- Update done on the update event following a request on hrtim_upd_en[3:1] (the event can be enabled with TxRSTU, TxREPU, MSTU or TxU). This is enabled when UPDGAT[3:0] = 0110, 0111, 1000 in HRTIM_TIMxCR
- Update done synchronously with any other timer or master update (for instance TIMA can be updated simultaneously with TIMB). This is used for converters requiring several timers, and is enabled by setting bits MSTU and TxU in HRTIM_TIMxCR register.

The update enable inputs hrtim_upd_en[3:1] allow to have an update event synchronized with on-chip events coming from the general-purpose timers. These inputs are rising-edge sensitive.

Table 412 lists the connections between update enable inputs and the on-chip sources.

This allows to synchronize low frequency update requests with high-frequency signals (for instance an update on the counter roll-over of a 100 kHz PWM that has to be done at a 100 Hz rate).

Note: The update events are synchronized to the prescaler clock when CKPSC[2:0] > 5.



The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) can either be taken into account immediately or re-synchronized with the timers reset/roll-over event. This is done with the RSYNCU bit in the HRTIM_TIMxCR register, as show on *Figure 419* below):

- RSYNCU = 0: The update coming from adjacent timers is taken into account immediately
- RSYNCU = 1: The update coming from adjacent timers is taken into account on the following reset/roll-over event.

The RSYNCU bit is significant only when UPDGAT[3:0] = 0000, it is ignored otherwise.

An interrupt or a DMA request can be generated by the Timx update event.

Figure 419. Resynchronized timer update (TAU=1 in HRTIM_TIMBCR)

MUDIS and TxUDIS bits in the HRTIM_CR1 register allow to temporarily disable the transfer from preload to active registers, whatever the selected update event. This allows to modify several registers in multiple timers. The register update event takes place once these bits are reset, on the next coming update event.

MUDIS and TxUDIS bits are all grouped in the same register. This allows the update of multiple timers (not necessarily synchronized) to be disabled and resumed simultaneously.

The following example is a practical use case. A first power converter is controlled with the master, TIMB and TIMC. TIMB and TIMC must be updated simultaneously with the master timer repetition event. A second converter works in parallel with TIMA, TIMD and TIME, and TIMD, TIME must be updated with TIMA repetition event.

First converter

In HRTIM_MCR, MREPU bit is set: the update occurs at the end of the master timer counter repetition period. In HRTIM_TIMBCR and HRTIM_TIMCCR, MSTU bits are set to have TIMB and TIMC timers updated simultaneously with the master timer.

When the power converter set-point has to be adjusted by software, MUDIS, TBUDIS and TCUDIS bits of the HRTIM_CR register must be set prior to write accessing registers to update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, MUDIS, TBUDIS and TCUDIS bits must be reset. The transfer from preload to active registers is done as soon as the master repetition event occurs.

Second converter

In HRTIM_TIMACR, TAREPU bit is set: the update occurs at the end of the timer A counter repetition period. In HRTIM_TIMDCR and HRTIM_TIMECR, TAU bits are set to have TIMD and TIME timers updated simultaneously with timer A.

When the power converter set-point has to be adjusted by software, TAUDIS, TDUDIS and TEUDIS bits of the HRTIM_CR register must be set prior to write accessing the registers to

update the values (for instance the compare values). From this time on, any hardware update request is ignored and the preload registers can be accessed without any risk to have them transferred into the active registers. Once the software processing is over, TAUDIS, TDUDIS and TEUDIS bits can be reset: the transfer from preload to active registers is done as soon as the timer A repetition event occurs.

40.3.12 PWM mode with “greater than” comparison

A specific no-latency update mode is available for PWM signals generated with the CMP1 and CMP3 registers. It allows to have a new duty cycle value applied as soon as possible within the PWM cycle, without having to wait the completion of the current PWM period. This reduces the overall delay time in software control loops. As shown on *Figure 420* below, this eventually allows to have:

- An early turn-off of the output if the new compare value is below the current counter value and the current compare value is above the counter, at the time the new value is written.
- An early turn-on of the output, re-enabling the output if the new compare value is above the counter value and the current compare value is below the counter, at the time the new value is written.

The output signal is left unchanged when the new compare value and current compare value are both below the counter.

This feature is only available for CMP1 or CMP3 RESET events, and is enabled using the GTCMP1 and GTCMP3 enable bits in the HRTIM_TIMxCR2 register.

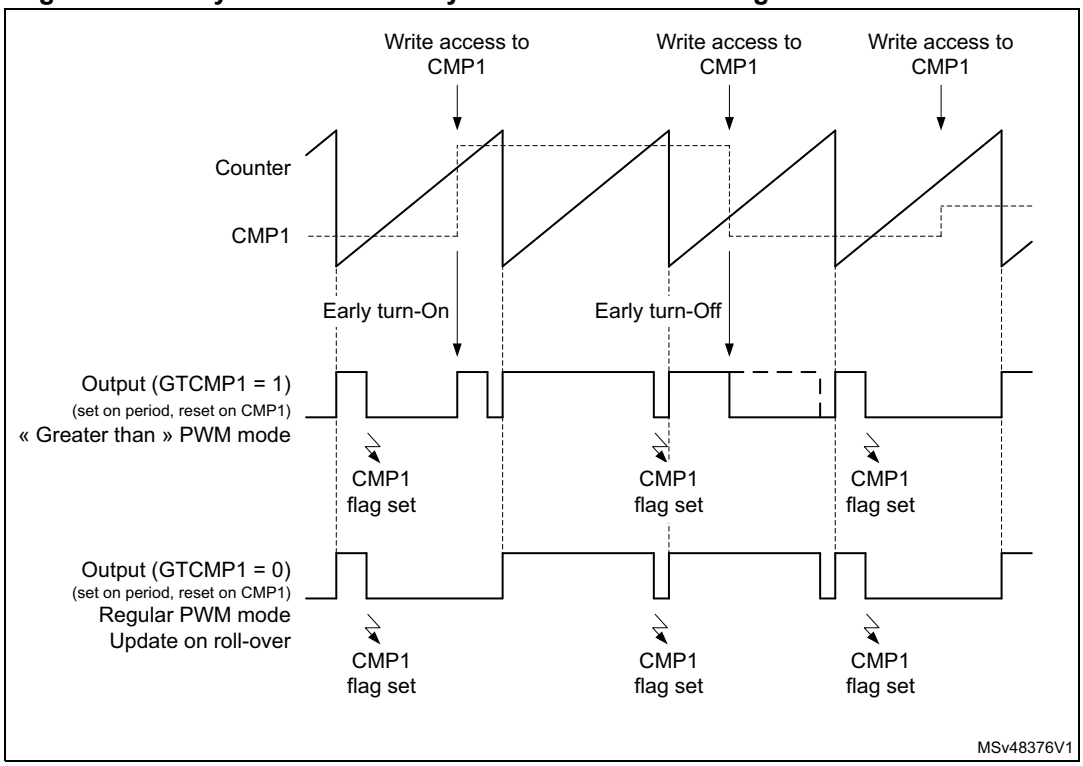
The preload mechanism is inactive for a compare register when the corresponding GTCMPx bit is set, whatever the PREEN bit value. This mode is intended to have the new compare value taken into account as soon as possible after a new value write, without waiting for the preload to active register transfer.

These bits are defining the compare 1 and compare 3 operating modes as following

- GTCMPx = 0: the compare x event is generated when the counter is equal to the compare value (compare match mode). If the compare value is changed on-the-fly, the compare event may not be generated.
- GTCMPx = 1: the compare x event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.

The “greater than” compare mode causes the crossbar to act differently depending on comparison result. Let’s consider the CMP1 event is doing an output RESET. When the new compare value is written, two cases are considered

- If the new compare value is below the counter value, the RESET event is issued and can eventually cause an early turn-OFF
- If the new compare value is above the counter value, a SET event is generated so as to re-arm the output value before it is actually RESET when the counter exceeds the counter value (early turn-ON).



The “greater than” compare mode is supported for both SET and RESET actions.

The “greater than” compare mode must only be used for the following configuration:

1. In the fixed frequency configuration, the period event must trigger the output set and the “greater than” compare triggers the output reset (or vice versa the period must trigger the reset if the “greater-than” compare triggers the set).
2. For variable frequency configuration, the event selected as counter reset source must also be selected as set or reset source for the timer output (opposite direction as the “greater than” compare event).

Note: The “greater-than” modes must not be used when the CMP1 and/or CMP3 modes are controlled by hardware in half and interleaved modes.

Figure 420. Early turn-ON and early turn-OFF behavior in “greater than” PWM mode

The immediate update mode implies that the content of the preload register is transferred into the active register at the very same time the register is written. When GTCMP1 and/or GTCMP3 bits are set, their respective preload mechanism is disabled (for HRTIM_TIMxCMP1 and/or HRTIM_TIMxCMP3 registers), whatever the PREEN bit value.

Note: The compare interrupt flags (CMP1 and CMP3 in HRTIM_TIMxISR) are not generated in case of late turn-ON and early turn-OFF, as shown on Figure 420.

Note: The “Greater than” comparison must not be done on both CMP1 and CMP3 for the same output (GTCMP1 and GTCMP3 bits must not be set simultaneously).

40.3.13 Events propagation within or across multiple timers

The HRTIM offers many possibilities for cascading events or sharing them across multiple timing units, including the master timer, to get full benefits from its modular architecture. These are key features for converters requiring multiple synchronized outputs.

This section summarizes the various options and specifies whether and how an event is propagated within the HRTIM.

TIMx update triggered by the master timer update

The sources listed in *Table 434* are generating a master timer update. The table indicates if the source event can be used to trigger a simultaneous update in any of TIMx timing units.

Operating condition: MSTU bit is set in HRTIM_TIMxCR register.

Table 434. Master timer update event propagation

Source	Condition	Propagation	Comment
Burst DMA end	BRSTDMA[1:0] = 01	No	Must be done in TIMxCR (UPDGAT[3:0] = 0001)
Roll-over event following a burst DMA end	BRSTDMA[1:0] = 10	Yes	-
Repetition event caused by a counter roll-over	MREPU = 1	Yes	-
Repetition event caused by a counter reset (from HRTIM_SCIN or software)		No	-
Software update	MSWU = 1	No	All software update bits (TxSWU) are grouped in the HRTIM_CR2 register and can be used for a simultaneous update

TIMx update triggered by the TIMy update

The sources listed in *Table 435* are generating a TIMy update. The table indicates if the given event can be used to trigger a simultaneous update in another or multiple TIMx timers.

Operating condition: TyU bit set in HRTIM_TIMxCR register (source = TIMy and destination = TIMx).

Table 435. TIMx update event propagation

Source	Condition	Propagation	Comment
Burst DMA end	UPDGAT[3:0] = 0001	No	Must be done directly in HRTIM_TIMxCR (UPDGAT[3:0] = 0001)
Update caused by the update enable inputs hrtim_upd_en[3:1]	UPDGAT[3:0] = 0011, 0100, 0101	No	Must be done directly in HRTIM_TIMxCR (UPDGAT[3:0] = 0011, 0100, 0101
Master update	MSTU = 1 in HRTIM_TIMyCR	No	Must be done with MSTU = 1 in HRTIM_TIMxCR
Another TIMx update (TIMz>TIMy>TIMx)	TzU=1 in HRTIM_TIMyCR TyU=1 in TIMxCR	No	Must be done with TzU=1 in HRTIM_TIMxCR TzU=1 in HRTIM_TIMyCR
Repetition event caused by a counter roll-over	TyREPU = 1	Yes	-
Repetition event caused by a counter reset	TyREPU = 1	-	Refer to counter reset cases below
Counter roll-over	TyRSTU = 1	Yes	-

Table 435. TIMx update event propagation (continued)

Source	Condition	Propagation	Comment
Counter software reset	TyRST=1 in HRTIM_CR2	No	Can be done simultaneously with update in HRTIM_CR2 register
Counter reset caused by a TIMz compare	TIMzCMPn in HRTIM_RSTyR	Yes	-
Counter reset caused by external events	EXTEVNTn in HRTIM_RSTyR	Yes	-
Counter reset caused by a master compare or a master period	MSTCMPn or MSTPER in HRTIM_RSTyR	Yes	-
Counter reset caused by a TIMy compare	CMPn in HRTIM_RSTyR	Yes	-
Counter reset caused by an update	UPDT in HRTIM_RSTyR	No	Propagation would result in a lock-up situation (update causing reset causing update)
Counter reset caused by HRTIM_SCIN	SYNCRSTy in HRTIM_TIMyCR	No	-
Software update	TySWU = 1	No	All software update bits (TxSWU) are grouped in the HRTIM_CR2 register and can be used for a simultaneous update

TIMx counter reset causing a TIMx update

Table 436 lists the counter reset sources and indicates whether they can be used to generate an update.

Operating condition: TxRSTU bit in HRTIM_TIMxCR register.

Table 436. Reset events able to generate an update

Source	Condition	Propagation	Comment
Counter roll-over	-	Yes	-
Update event	UPDT in HRTIM_RSTxR	No	Propagation would result in a lock-up situation (update causing a reset causing an update)
External event	EXTEVNTn in HRTIM_RSTxR	Yes	-
TIMy compare	TIMyCMPn in HRTIM_RSTxR	Yes	-
Master compare	MSTCMPn in HRTIM_RSTxR	Yes	-
Master period	MSTPER in HRTIM_RSTxR	Yes	-
Compare 2 and 4	CMPn in HRTIM_RSTxR	Yes	-
Software	TxRST=1 in HRTIM_CR2	Yes	-
HRTIM_SCIN	SYNCRSTx in HRTIM_TIMxCR	Yes	-

TIMx update causing a TIMx counter reset

Table 437 lists the update event sources and indicates whether they can be used to generate a counter reset.

Operating condition: UPDT bit set in HRTIM_RSTxR.

Table 437. Update event propagation for a timer reset

Source	Condition	Propagation	Comment
Burst DMA end	UPDGAT[3:0] = 0001	Yes	-
Update caused by the update enable inputs hrtim_upd_en[3:1]	UPDGAT[3:0] = 0011, 0100, 0101	Yes	-
Master update caused by a roll-over after a burst DMA	MSTU = 1 in HRTIM_TIMxCR BRSTDMA[1:0] = 10 in HRTIM_MCR	Yes	-

Table 437. Update event propagation for a timer reset (continued)

Source	Condition	Propagation	Comment
Master update caused by a repetition event following a roll-over	MSTU = 1 in HRTIM_TIMxCR MREPU = 1 in HRTIM_MCR	Yes	-
Master update caused by a repetition event following a counter reset (software or due to HRTIM_SCIN)		No	-
Software triggered master timer update	MSTU = 1 in HRTIM_TIMxCR MSWU = 1 in HRTIM_CR2	No	All software update bits (TxSWU) are grouped in the HRTIM_CR2 register and can be used for a simultaneous update
TIMy update caused by a TIMy counter roll-over	TyU = 1 in HRTIM_TIMxCR TyRSTU = 1 in HRTIM_TIMyCR	Yes	-
TIMy update caused by a TIMy repetition event	TyU = 1 in HRTIM_TIMxCR TyREPU = 1 in HRTIM_TIMyCR	Yes	-
TIMy update caused by an external event or a TIMy compare (through a TIMy reset)	TyU = 1 in HRTIM_TIMxCR TyRSTU = 1 in HRTIM_TIMyCR EXTEVNTn or CMP4/2 in HRTIM_RSTyCR	Yes	-
TIMy update caused by sources other than those listed above	TyU = 1 in HRTIM_TIMxCR	No	-
Repetition event following a roll-over	TxREPU = 1 in HRTIM_TIMxCR	Yes	-
Repetition event following a counter reset		No	-
Timer reset	TxRSTU = 1 in HRTIM_TIMxCR	No	Propagation would result in a lock-up situation (reset causing an update causing a reset)
Software	TxSWU in HRTIM_CR2	No	-

40.3.14 Output management

Each timing unit controls a pair of outputs. The outputs have three operating states:

- RUN: this is the main operating mode, where the output can take the active or inactive level as programmed in the crossbar unit.
- IDLE: this state is the default operating state after an HRTIM reset, when the outputs are disabled by software or during a burst mode operation (where outputs are temporarily disabled during a normal operating mode; refer to *Section 40.3.15* for more details). It is either permanently active or inactive.
- FAULT: this is the safety state, entered in case of a shut-down request on FAULTx inputs. It can be permanently active, inactive, or Hi-Z.

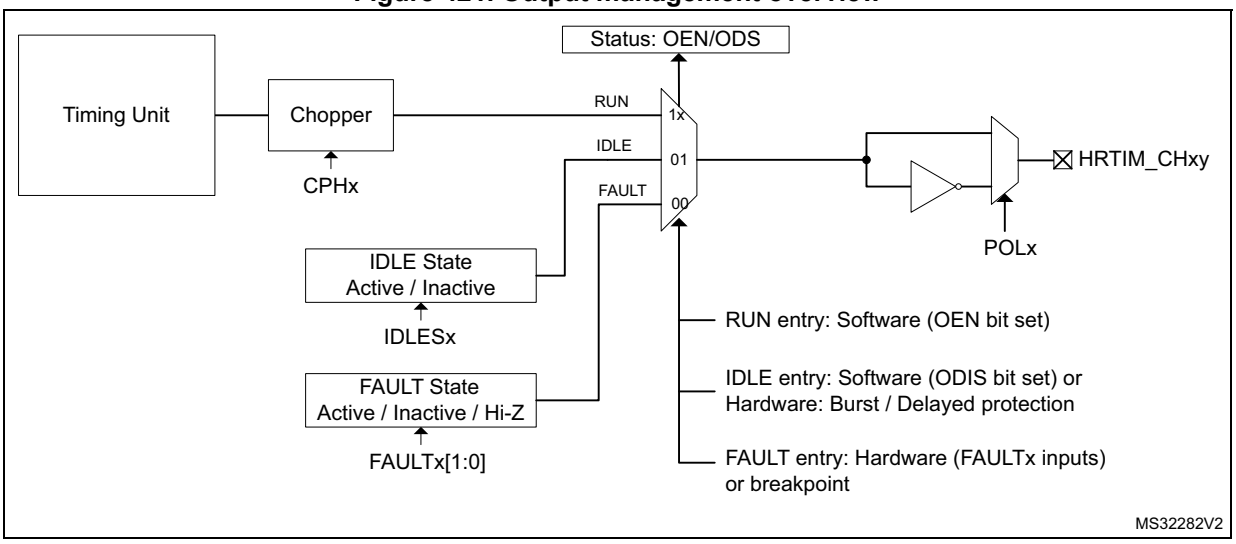
The output status is indicated by TxyOEN bit in HRTIM_OENR register and TxyODS bit in HRTIM_ODSR register, as in *Table 438*.

Table 438. Output state programming, x= A..F, y = 1 or 2

TxyOEN (control/status) (set by software, cleared by hardware)	TxyODS (status)	Output operating state
1	x	RUN
0	0	IDLE
0	1	FAULT

TxyOEN bit is both a control and a status bit: it must be set by software to have the output in RUN mode. It is cleared by hardware when the output goes back in IDLE or FAULT mode. When TxyOEN bit is cleared, TxyODS bit indicates whether the output is in the IDLE or FAULT state. A third bit in the HRTIM_ODISR register is used to disable the output by software.

Figure 421. Output management overview



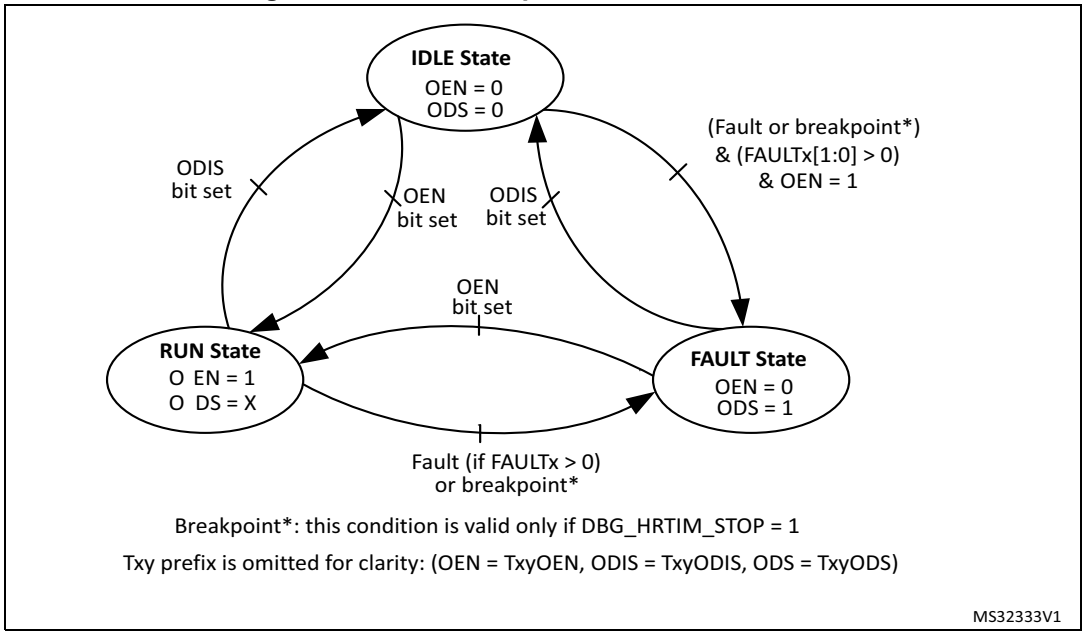


Figure 422 summarizes the bit values for the three states and how the transitions are triggered. Faults can be triggered by any external or internal fault source, as listed in

Section 40.3.17, while the IDLE state can be entered when the burst mode or delayed protections are active.

Figure 422. HRTIM output states and transitions

The FAULT and IDLE levels are defined as active or inactive. Active (or inactive) refers to the level on the timer output that causes a power switch to be closed (or opened for an inactive state).

The IDLE state has the highest priority: the transition FAULT → IDLE is possible even if the FAULT condition is still valid, triggered by ODIS bit set.

The FAULT state has priority over the RUN state: if TxyOEN bit is set simultaneously with a fault event, the FAULT state is entered. The condition is given on the transition IDLE → FAULT, as in *Figure 422*: fault protection needs to be enabled (FAULTx[1:0] bits = 01, 10, 11) and the Txy OEN bit set with a fault active (or during a breakpoint if DBG_HRTIM_STOP = 1).

The output polarity is programmed using POLx bits in HRTIM_OUTxR. When POLx = 0, the polarity is positive (output active high), while it is active low in case of a negative polarity (POLx = 1). Practically, the polarity is defined depending on the power switch to be driven (PMOS versus NMOS) or on a gate driver polarity.

The output level in the FAULT state is configured using FAULTx[1:0] bits in HRTIM_OUTxR, for each output, as follows:

- 00: output never enters the fault state and stays in RUN or IDLE state
- 01: output at active level when in FAULT
- 10: output at inactive level when in FAULT
- 11: output is tri-stated when in FAULT. The safe state must be forced externally with pull-up or pull-down resistors, for instance.

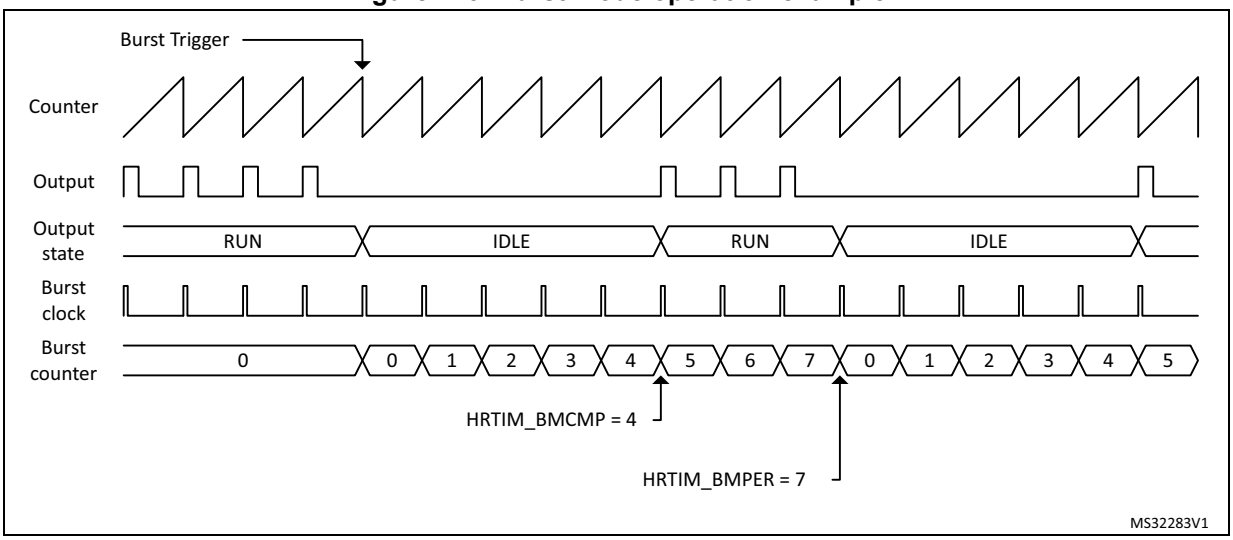
Note: FAULTx[1:0] bits must not be changed as long as the outputs are in FAULT state.

The level of the output in IDLE state is configured using IDLESx bit in HRTIM_OUTxR, as follows:

- 0: output at inactive level when in IDLE
- 1: output at active level when in IDLE

When TxyOEN bit is set to enter the RUN state, the output is immediately connected to the crossbar output. If the timer clock is stopped, the level is either inactive (after an HRTIM reset) or corresponds to the RUN level (when the timer is stopped and the output disabled).

During the HRTIM initialization, the output level can be prepositioned prior to have it in RUN mode, using the software forced output set and reset in the HRTIM_SETx1R and HRTIM_RSTx1R registers.



40.3.15 Burst mode controller

The burst mode controller is used to have the outputs alternatively in IDLE and RUN state, by hardware, so as to skip some switching periods with a programmable periodicity and duty cycle.

Burst mode operation is of common use in power converters when operating under light loads. It can significantly increase the efficiency of the converter by reducing the number of transitions on the outputs and the associated switching losses.

When operating in burst mode, one or a few pulses are outputted followed by an idle period equal to several counting periods, typically, where no output pulses are produced, as shown in the example on *Figure 423*.

Figure 423. Burst mode operation example

The burst mode controller consists of:

- A counter that can be clocked by various sources, either within or outside the HRTIM (typically the end of a PWM period).
- A compare register to define the number of idle periods: HRTIM_BMCMP.
- A period register to define the burst repetition rate (corresponding to the sum of the idle and run periods): HRTIM_BMPER.

The burst mode controller is able to take over the control of any of the 10 PWM outputs. The state of each output during a burst mode operation is programmed using IDLESx and IDLEMx bits in the HRTIM_OUTxR register, as in *Table 439*.

Table 439. Timer output programming for burst mode

IDLEMx	IDLESx	Output state during burst mode
0	X	No action: the output is not affected by the burst mode operation.
1	0	Output inactive during the burst
1	1	Output active during the burst

Note: IDLEMx bit must not be changed while the burst mode is active.

The burst mode controller only acts on the output stage. A number of events are still generated during the idle period:

- Output set/reset interrupt or DMA requests
- External event filtering based on Tx2 output signal
- Capture events triggered by output set/reset

During the burst mode, neither start nor reset events are generated on the hrtim_out_sync[2:1] output, even if TxBM bit is set.

Operating mode

It is necessary to have the counter enabled (TxCEN bit set) before using the burst mode on a given timing unit. The burst mode is enabled with BME bit in the HRTIM_BMCR register.

It can operate in continuous or single-shot mode, using BMOM bit in the HRTIM_BMCR register. The continuous mode is enabled when BMOM = 1. The burst operation is maintained until BMSTAT bit in HRTIM_BMCR is reset to terminate it.

In single-shot mode (BMOM = 0), the idle sequence is executed once, following the burst mode trigger, and the normal timer operation is resumed immediately after.

The duration of the idle and run periods is defined with a burst mode counter and two registers. The HRTIM_BMCMPR register defines the number of counts during which the selected timer(s) are in an idle state (idle period). HRTIM_BMPER defines the overall burst mode period (sum of the idle and run periods). Once the initial burst mode trigger has occurred, the idle period length is HRTIM_BMCMPR+1, the overall burst period is HRTIM_BMPER+1.

Note: The burst mode period must not be less than or equal to the deadtime duration defined with DTRx[8:0] and DTFx[8:0] bitfields.

The counters of the timing units and the master timer can be stopped and reset during the burst mode operation. HRTIM_BMCR holds six control bits for this purpose: MTBM (master) and TABM..TEBM for timer A..E.

When MTBM or TxBM bit is reset, the counter clock is maintained. This is used to keep a phase relationship with other timers in multiphase systems, for instance.

When MTBM or TxBM bit is set, the corresponding counter is stopped and maintained in reset state during the burst idle period. This is used to have the timer restarting a full period when exiting from idle. If SYNCSRC[1:0] = 00 or 10 (synchronization output on the master

start or timer A start), a pulse is sent on the HRTIM_SCOUT output when exiting the burst mode.

Note: TxBM bit must not be set when the balanced idle mode is active (DLYPRT[1:0] = 0x11).

Burst mode clock

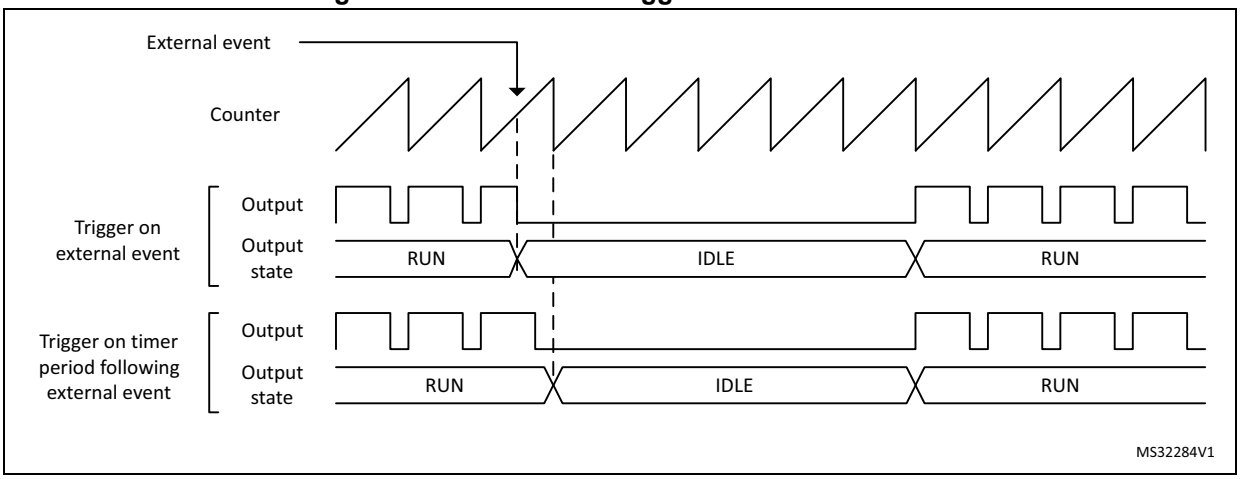
The burst mode controller counter can be clocked by several sources, selected with BMCLK[3:0] bits in the HRTIM_BMCR register:

- BMCLK[3:0] = 0000 to 0101: master timer and TIMA..E reset/roll-over events. This is used to have burst mode idle and run periods aligned with the timing unit counting period (both in free-running and counter reset mode).
- BMCLK[3:0] = 0110 to 1001: The clocking is provided by the hrtim_bm_ck[4:1] inputs connected to general purpose timers, as in *Table 413*. In this case, the burst mode idle and run periods are not necessarily aligned with timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with modified duty cycle for instance.
- BMCLK[3:0] = 1010: The f_{HRTIM} clock prescaled by a factor defined with BMPRSC[3:0] bits in HRTIM_BMCR register. In this case, the burst mode idle and run periods are not necessarily aligned with the timing unit counting period (a pulse on the output may be interrupted, resulting in a waveform with a modified duty cycle, for instance.

The pulse width on TIMx OC output must be at least N f_{HRTIM} clock cycles long to be detected by the HRTIM burst mode controller.

Burst mode triggers

To trigger the burst operation, 32 sources are available and are selected using the HRTIM_BMTRGR register:



- Software trigger (set by software and reset by hardware)
- 6 master timer events: repetition, reset/roll-over, compare 1 to 4
- 5 x 4 events from timers A..F: repetition, reset/roll-over, compare 1 and 2
- External event G (including TIMA event filtering) and H (including TIMD event filtering)
- Timer A period following external event G (including TIMA event filtering)
- Timer D period following external event H (including TIMD event filtering)
- An on-chip event on the hrtim_bm_trg input (connected to the general-purpose timer TRGO output), see *Table 410* for details.

These sources can be combined to have multiple concurrent triggers.

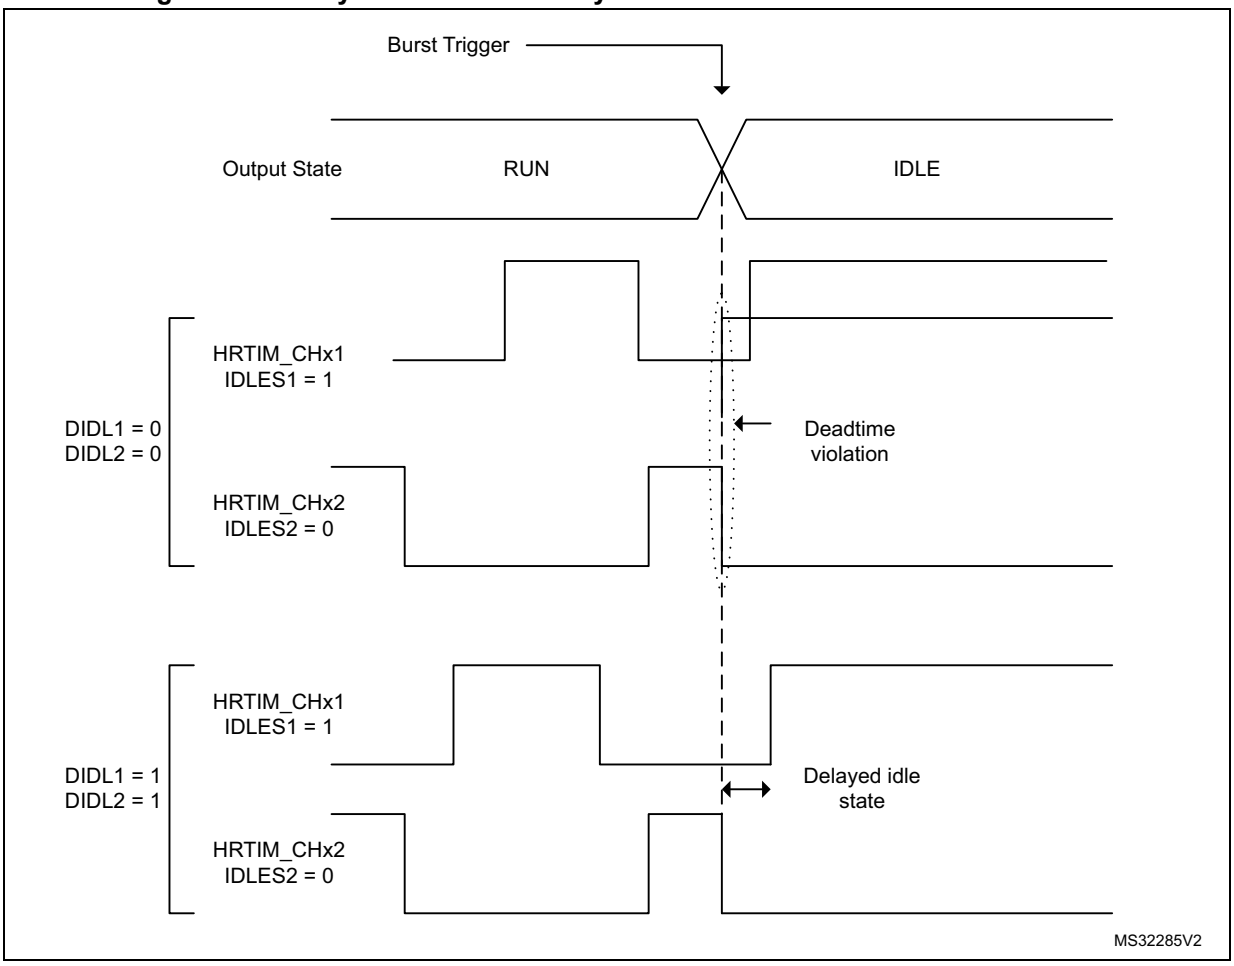
Burst mode is not retriggerable. In continuous mode, new triggers are ignored until the burst mode is terminated, while in single-shot mode, the triggers are ignored until the current burst completion including run periods (HRTIM_BMPER+1 cycles). This is also valid for software trigger (the software bit is reset by hardware even if it is discarded).

Figure 424 shows how the burst mode is started in response to an external event, either immediately or on the timer period following the event.

Figure 424. Burst mode trigger on external event

For TAEEVG and TDEEVH combined triggers (trigger on a timer period following an external event), the external event detection is always active, regardless of the burst mode programming and the ongoing burst operation:

- When the burst mode is enabled (BME=1) or the trigger is enabled (TAEEVG or TDEEVH bit set in the HRTIM_BMTRGR register) in between the external event and the timer period event, the burst is triggered.
- The single-shot burst mode is retriggered even if the external event occurs before the burst end (as long as the corresponding period happens after the burst).



Note: TAEEVG and TDEEVH triggers are valid only after a period event. If the counter is reset before the period event, the pending hrtim_eev7 or hrtim_eev8 event is discarded.

Burst mode delayed entry

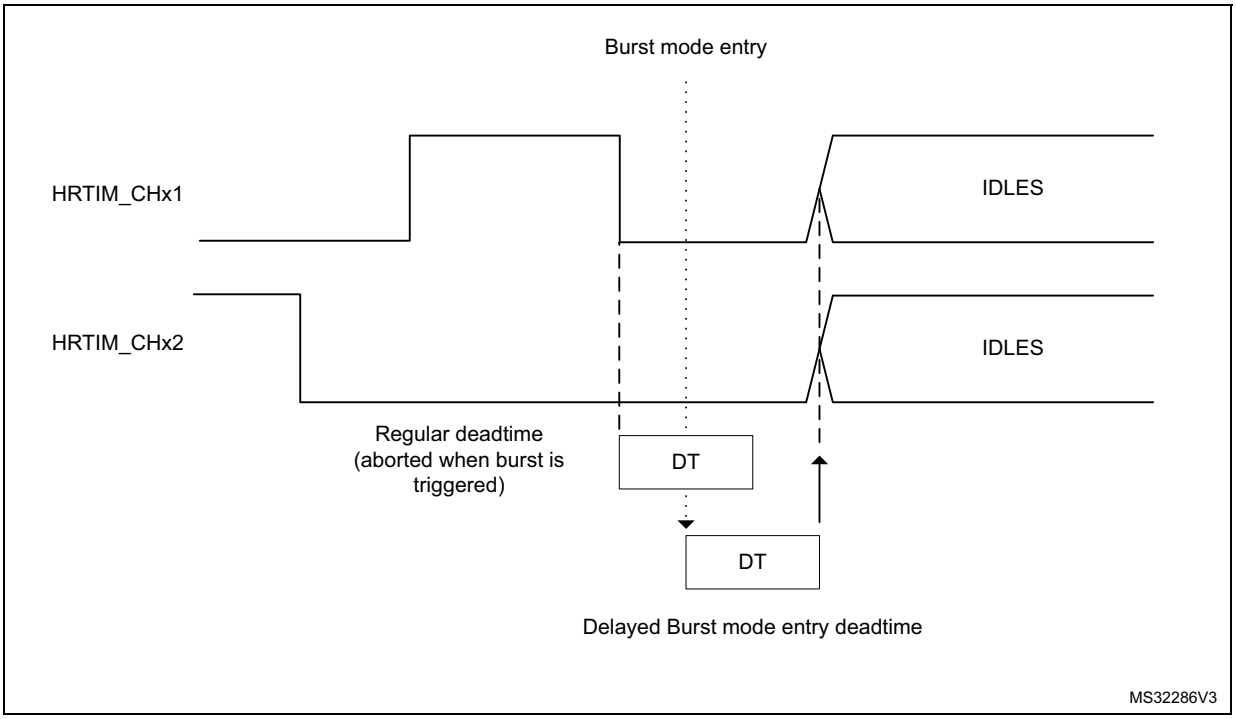
By default, the outputs are taking their idle level (as per IDLES1 and IDLES2 setting) immediately after the burst mode trigger.

It is also possible to delay the burst mode entry and force the output to an inactive state during a programmable period before the output takes its idle state. This is useful when driving two complementary outputs, one of them having an active idle state, to avoid a deadtime violation as shown on *Figure 425*. This prevents any risk of shoot through current in half-bridges, but causes a delayed response to the burst mode entry.

Figure 425. Delayed burst mode entry with deadtime enabled and IDLESx = 1

The delayed burst entry mode is enabled with DIDLx bit in the HRTIM_OUTxR register (one enable bit per output). It forces a deadtime insertion before the output takes its idle state. Each TIMx output has its own deadtime value:

- DTRx[8:0] on output 1 when DIDL1 = 1
- DTFx[8:0] on output 2 when DIDL2 = 1



DIDLx bits can be set only if one of the outputs has an active idle level during the burst mode (IDLES = 1) and only when positive deadtimes are used (SDTR/SDTF set to 0).

Note: The delayed burst entry mode uses deadtime generator resources. Consequently, when any of the two DIDLx bits is set and the corresponding timing unit uses the deadtime insertion (DTEN bit set in HRTIM_OUTxR), it is not possible to use the timerx output 2 as a filter for external events (Tx2 filtering signal is not available).

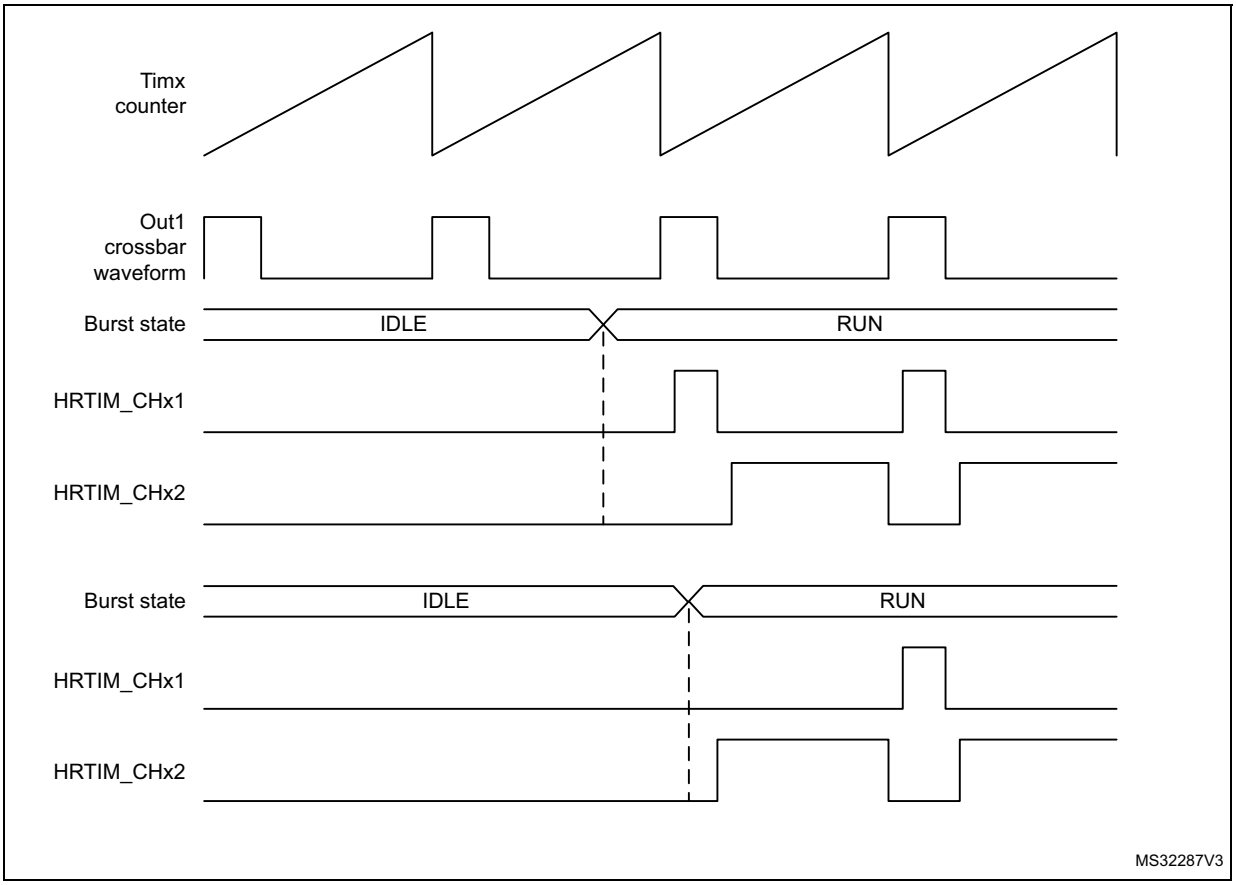
When durations defined by DTRx[8:0] and DTFx[8:0] are lower than three f_{HRTIM} clock cycle periods, the limitations related to the narrow pulse management listed in *Section 40.3.7* must be applied.

When the burst mode entry arrives during the regular deadtime, it is aborted and a new deadtime is restarted corresponding to the inactive period, as on *Figure 426*.

Figure 426. Delayed burst mode entry during deadtime

Burst mode exit

The burst mode exit is either forced by software (in continuous mode) or once the idle period is elapsed (in single-shot mode). In both cases, the counter is re-started immediately (if it was hold in a reset state with MTBM or TxBM bit = 1), but the effective output state transition from the idle to active mode only happens after the programmed set/reset event.



A burst period interrupt is generated in single-shot and continuous modes when BMPERIE enable bit is set in the HRTIM_IER register. This interrupt can be used to synchronize the burst mode exit with a burst period in continuous burst mode.

Figure 427 shows how a normal operation is resumed when the deadtime is enabled. Although the burst mode exit is immediate, this is only effective on the first set event on any of the complementary outputs.

Two different cases are presented:

1. The burst mode ends while the signal is inactive on the crossbar output waveform. The active state is resumed on Tx1 and Tx2 on the set event for the Tx1 output, and the Tx2 output does not take the complementary level on burst exit.
2. The burst mode ends while the crossbar output waveform is active: the activity is resumed on the set event of Tx2 output, and Tx1 does not take the active level immediately on burst exit.

Figure 427. Burst mode exit when the deadtime generator is enabled

The behavior described above is slightly different when the push-pull mode is enabled. The push-pull mode forces an output reset at the beginning of the period if the output is inactive, or symmetrically forces an active level if the output was high during the preceding period.

Consequently, an output with an active idle state can be reset at the time the burst mode is exited even if no transition is explicitly programmed. For symmetrical reasons, an output can be set at the time the burst mode is exited even if no transition is explicitly programmed, in case it was active when it entered in idle state.

Burst mode registers preloading and update

BMPREN bit (burst mode preload enable) is used to have the burst mode compare and period registers preloaded (HRTIM_BMCMP and HRTIM_BMPER).

When BMPREN is set, the transfer from preload to active register happens:

- When the burst mode is enabled (BME = 1),
- At the end of the burst mode period.

A write into the HRTIM_BMPER period register disables the update temporarily, until the HRTIM_BMCMP compare register is written, to ensure the consistency of the two registers when they are modified.

If the compare register only needs to be changed, a single write is necessary. If the period only needs to be changed, it is also necessary to rewrite the compare to have the new values taken into account.

When BMPREN bit is reset, the write access into BMCMPR and BMPER directly updates the active register. In this case, it is necessary to consider when the update is done during the overall burst period, for the two cases below:

a) Compare register update

If the new compare value is above the current burst mode counter value, the new compare is taken into account in the current period.

If the new compare value is below the current burst mode counter value, the new compare is taken into account in the next burst period in continuous mode, and ignored in single-shot mode (no compare match occurs and the idle state lasts until the end of the idle period).

b) Period register update

If the new period value is above the current burst mode counter value, the change is taken into account in the current period.

Note: If the new period value is below the current burst mode counter value, the new period is not taken into account, the burst mode counter overflows (at 0xFFFF) and the change is effective in the next period. In single-shot mode, the counter rolls over at 0xFFFF and the burst mode restarts for another period up to the new programmed value.

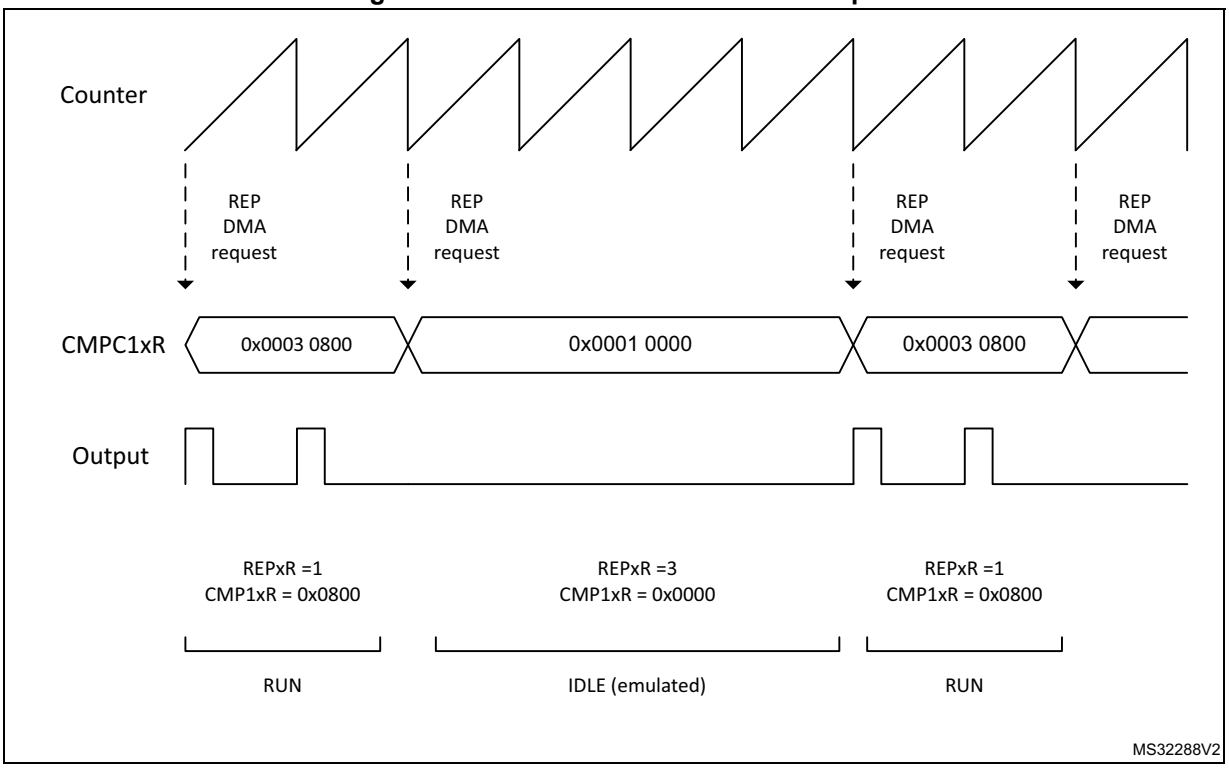
Burst mode emulation using a compound register

The burst mode controller only controls one or a set of timers for a single converter. When the burst mode is necessary for multiple independent timers, it is possible to emulate a simple burst mode controller using the DMA and the HRTIM_CMP1CxR compound register, which holds aliases of both the repetition and the compare 1 registers.

This is applicable to a converter which only requires a simple PWM (typically a buck converter), where the duty cycle only needs to be updated. In this case, the CMP1 register is used to reset the output (and define the duty cycle), while it is set on the period event.

In this case, a single 32-bit write access in CMP1CxR is sufficient to define the duty cycle (with the CMP1 value) and the number of periods during which this duty cycle is maintained (with the repetition value). To implement a burst mode, it is then only necessary to transfer by DMA (upon repetition event) two 32-bit data in continuous mode, organized as follows:

CMPC1xR = {REP_Run; CMP1 = Duty_Cycle}, {REP_Idle; CMP1 = 0}



For instance, the values:

{0x0003 0000}: CMP1 = 0 for four periods

{0x0001 0800}: CMP1 = 0x0800 for two period

provide a burst mode with two periods active every six PWM periods, as shown on Figure 428.

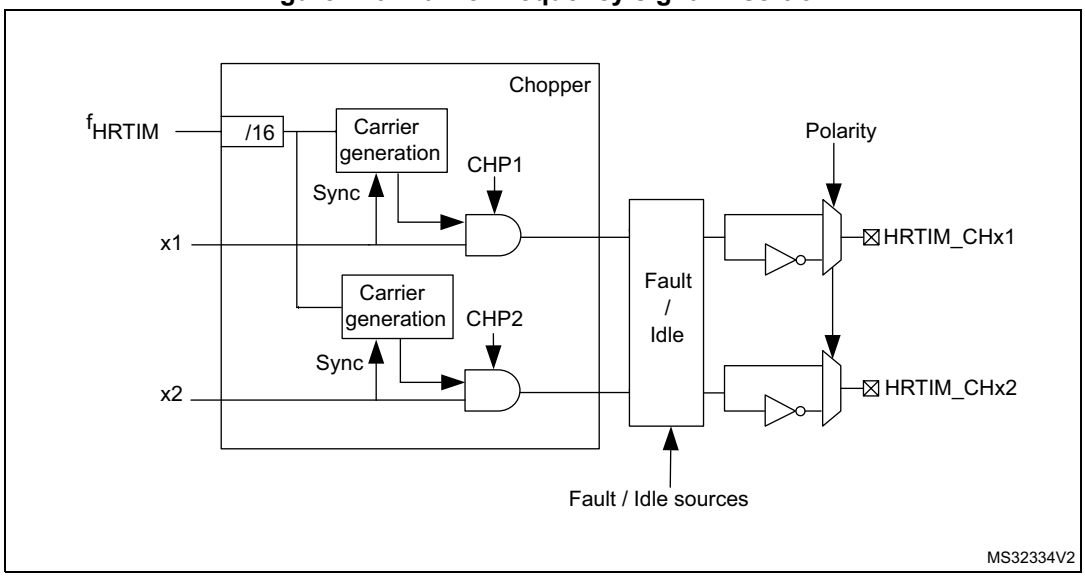


Figure 428. Burst mode emulation example

40.3.16 Chopper

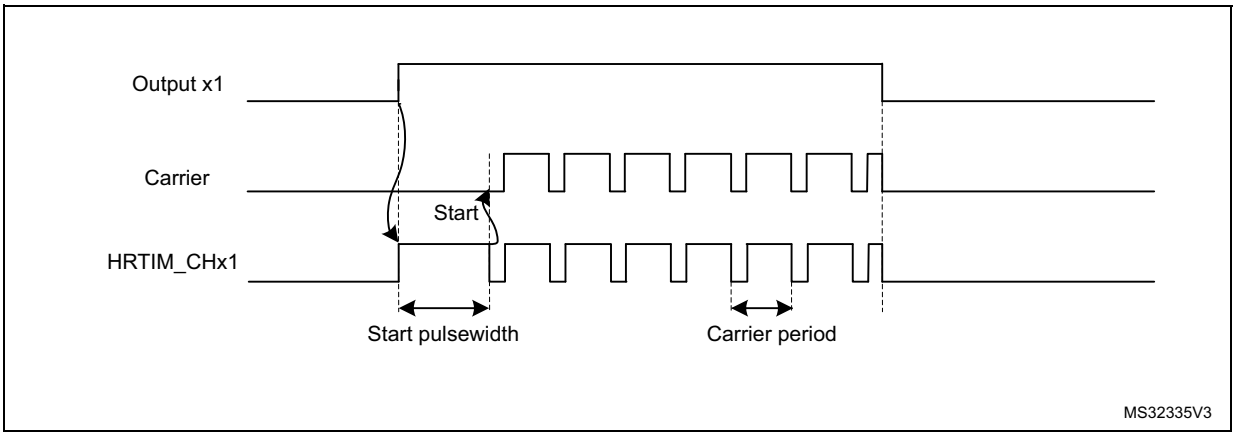
A high-frequency carrier can be added on top of the timing unit output signals to drive isolation transformers. This is done in the output stage before the polarity insertion, as shown on *Figure 429*, using CHP1 and CHP2 bits in the HRTIM_OUTxR register, to enable chopper on outputs 1 and 2, respectively.

Figure 429. Carrier frequency signal insertion

The chopper parameters can be adjusted using the HRIM_CHPxR register, with the possibility to define a specific pulsewidth at the beginning of the pulse, to be followed by a carrier frequency with programmable frequency and duty cycle, as in *Figure 430*.

CARFRQ[3:0] bits define the frequency, ranging from 1.09 MHz to 17.5 MHz (for f_{HRTIM} = 280 MHz) following the formula $F_{CHPFRQ} = f_{HRTIM} / (16 \times (CARFRQ[3:0]+1))$.

The duty cycle can be adjusted by 1/8 step with CARDTY[2:0], from 0/8 up to 7/8 duty cycle. When CARDTY[2:0] = 000 (duty cycle = 0/8), the output waveform only contains the starting pulse following the rising edge of the reference waveform, without any added carrier.



The pulsewidth of the initial pulse is defined using the STRPW[3:0] bitfield as follows: $t_{1STPW} = (STRPW[3:0]+1) \times 16 \times t_{HRTIM}$ and ranges from 57 ns to 910 ns (for f_{HRTIM} = 280 MHz).

The carrier frequency parameters are defined based on the f_{HRTIM} frequency, and do not dependent on the CKPSC[2:0] setting.

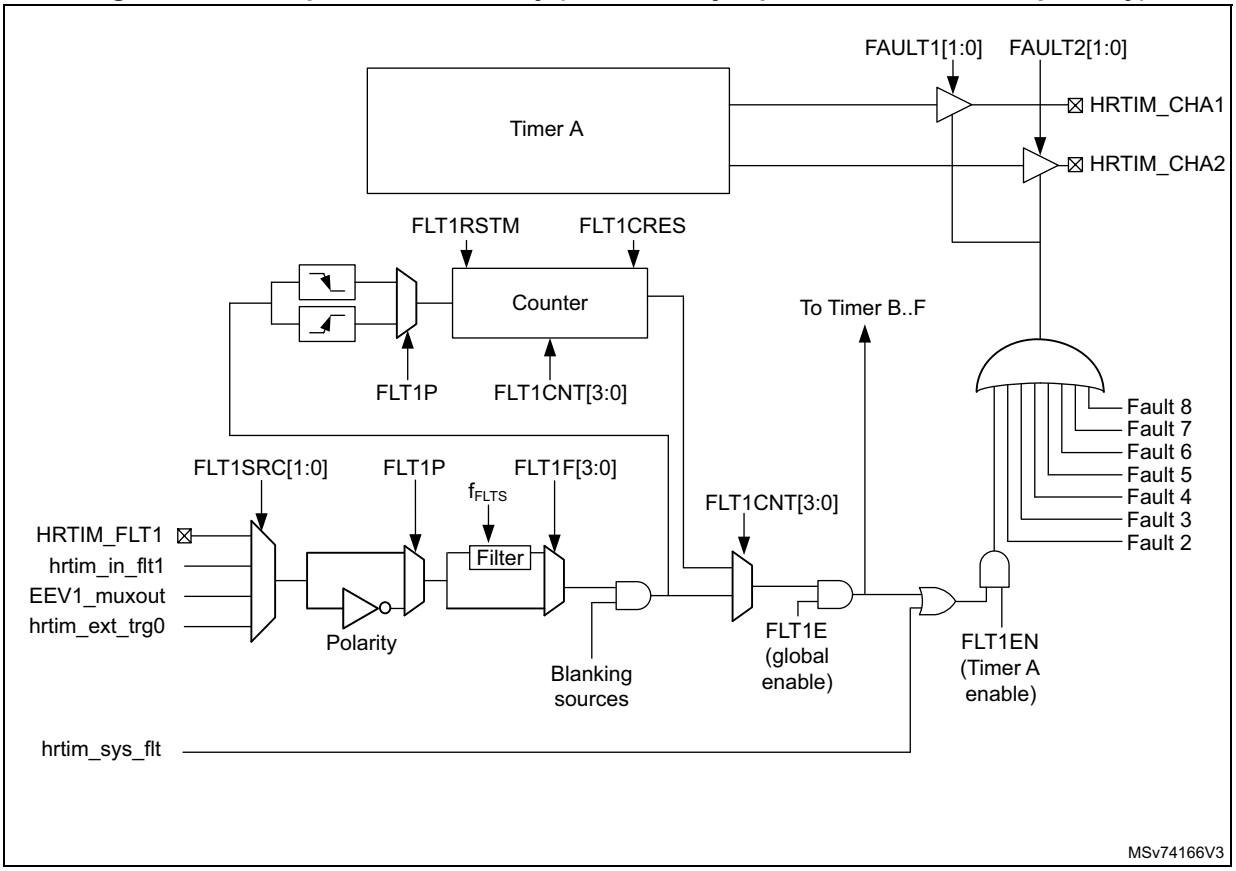
In chopper mode, the carrier frequency and the initial pulsewidth are combined with the reference waveform using an AND function. A synchronization is performed at the end of the initial pulse to have a repetitive signal shape.

The chopping signal is stopped at the end of the output waveform active state, without waiting for the current carrier period to be completed. It can thus contain shorter pulses than programmed.

Figure 430. HRTIM outputs with Chopper mode enabled

Note: CHP1 and CHP2 bits must be set prior to the output enable done with TxyOEN bits in the HRTIM_OENR register.

CARFRQ[2:0], CARDTY[2:0], and STRPW[3:0] bitfields cannot be modified while the chopper mode is active (at least one of the two CHPx bits is set).



Caution: The chopper mode must only be used with inactive IDLE state (IDLES1 = 0 and IDLES2 = 0).

40.3.17 Fault protection

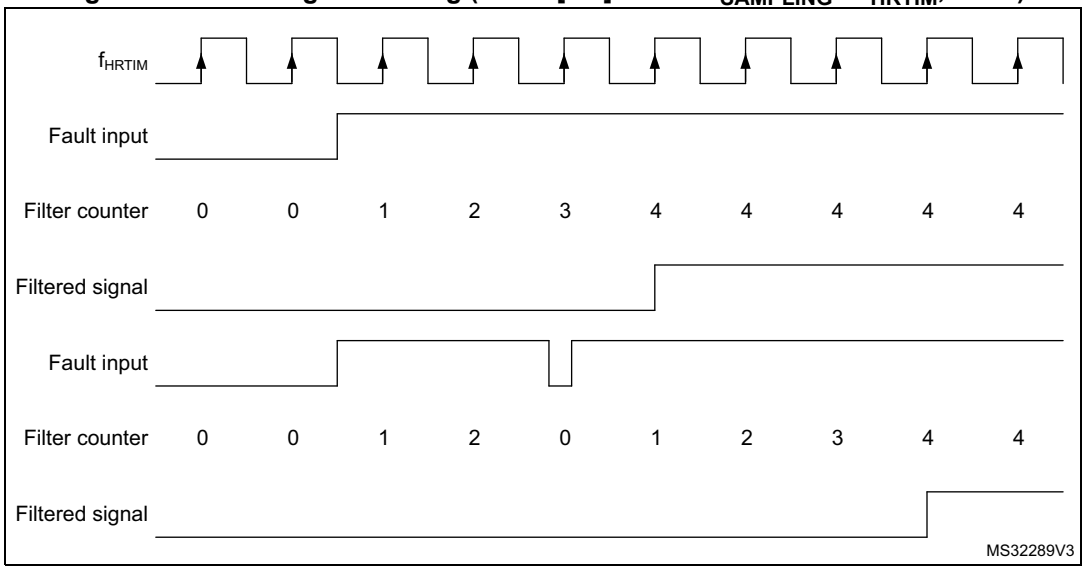
The HRTIM has a versatile fault protection circuitry to disable the outputs in case of an abnormal operation. Once a fault has been triggered, the outputs take a predefined safe state. This state is maintained until the output is reenabled by software. In case of a permanent fault request, the output remains in its fault state, even if the software attempts to re-enable them, until the fault source disappears.

The HRTIM has eight FAULT input channels; all of them are available and can be combined for each of the eight timing units, as shown on *Figure 431*.

Figure 431. Fault protection circuitry (FAULT1 fully represented, FAULT2..8 partially)

Each fault channel is fully configurable using HRTIM_FLTINR1, HRTIM_FLTINR2 and HRTIM_FLTINR5 registers before being routed to the timing units. FLTxSRC FLTxSRC[1:0] bit selects the source of the fault signal that can be either a digital input or an internal event (built-in comparator output).

Table 416 details the three available sources for each of the six faults channels.



The EEVx_muxout event mentioned in *Figure 431* is taken after the hrtim_eevx[8:1] input multiplexer controlled by the EExSRC[2:0]bits. Refer to *Figure 402* for details.

The polarity of the signal can be selected to define the active level, using the FLTxP polarity bit in HRTIM_FLTINRx registers. If FLTxP = 0, the signal is active at low level; if FLTxP = 1, it is active when high.

The fault information can be filtered after the polarity setting. If FLTxF[3:0] bitfield is set to 0000, the signal is not filtered and acts asynchronously, independently from the f_{HRTIM} clock. For all other FLTxF[3:0] bitfield values, the signal is digitally filtered. The digital filter is made of a counter in which a number N of valid samples are needed to validate a transition on the output. If the input value changes before the counter has reached the value N, the counter is reset and the transition is discarded (considered as a spurious event). If the counter reaches N, the transition is considered as valid and transmitted as a correct external event. Consequently, the digital filter adds a latency to the external events being filtered,

depending on the sampling clock and on the filter length (number of valid samples expected). *Figure 432* shows how a spurious fault signal is filtered.

Figure 432. Fault signal filtering (FLTxF[3:0]= 0010: $f_{SAMPLING} = f_{HRTIM}$, N = 4)

The filtering period ranges from two cycles of the f_{HRTIM} clock up to eight cycles of the f_{FLTS} clock divided by 32. f_{FLTS} is defined using FLTSD[1:0] bits in the HRTIM_FLTINR2 register. *Table 440* summarizes the sampling rate and the filter length. A jitter of 1 sampling clock period must be subtracted from the filter length to take into account the uncertainty due to the sampling and have the effective filtering.

Table 440. Sampling rate and filter length vs FLTFxF[3:0] and clock setting

-	f_{FLTS} vs FLTSD[1:0]				Filter length for f_{HRTIM} = 280 MHz	
FLTFxF[3:0]	**00**	**01**	**10**	**11**	**Min**	**Max**
0001,0010,0011	f_{HRTIM}	f_{HRTIM}	f_{HRTIM}	f_{HRTIM}	f_{HRTIM}, N =2 7.1 ns	f_{HRTIM}, N =8 28.6 ns
0100, 0101	f_{HRTIM} /2	f_{HRTIM} /4	f_{HRTIM} /8	f_{HRTIM} /16	f_{HRTIM} /2, N = 6 43 ns	f_{HRTIM} /16, N = 8 457 ns
0110, 0111	f_{HRTIM} /4	f_{HRTIM} /8	f_{HRTIM} /16	f_{HRTIM} /32	f_{HRTIM} /4, N = 6 86 ns	f_{HRTIM} /32, N = 8 0.89 µs
1000, 1001	f_{HRTIM} /8	f_{HRTIM} /16	f_{HRTIM} /32	f_{HRTIM} /64	f_{HRTIM} /8, N = 6 171 ns	f_{HRTIM} /64, N = 8 1.8 µs
1010, 1011, 1100	f_{HRTIM} /16	f_{HRTIM} /32	f_{HRTIM} /64	f_{HRTIM} /128	f_{HRTIM} /16, N = 5 286 ns	f_{HRTIM} /128, N = 8 3.66 µs
1101, 1110, 1111	f_{HRTIM} /32	f_{HRTIM} /64	f_{HRTIM} /128	f_{HRTIM} /256	f_{HRTIM} /32, N = 5 571 ns	f_{HRTIM} /256, N = 8 7.3 µs

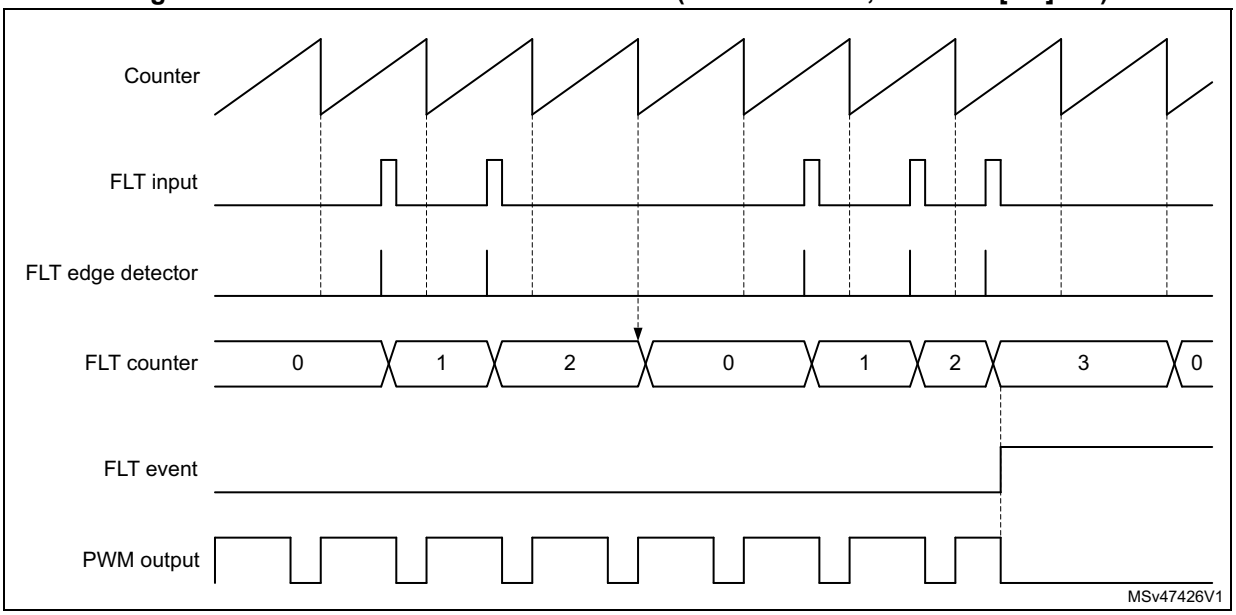
Fault blanking and event counting

The fault inputs can be temporarily disabled to blank spurious fault events. The blanking sources are listed in the *Table 441* below.

Table 441. Fault input blanking events

-	FLTxBLKS = 0, reset-aligned window		FLTxBLKS = 1 moving window	
Fault input	**Blanking window start**	**Blanking window end**	**Blanking window start**	**Blanking window end**
FAULT1	Timer A reset/roll-over	Timer A CMP3 event	Timer A CMP4 event	Timer A CMP3 event
FAULT2	Timer B reset/roll-over	Timer B CMP3 event	Timer B CMP4 event	Timer B CMP3 event
FAULT3	Timer C reset/roll-over	Timer C CMP3 event	Timer C CMP4 event	Timer C CMP3 event
FAULT4	Timer D reset/roll-over	Timer D CMP3 event	Timer D CMP4 event	Timer D CMP3 event
FAULT5	Timer E reset/roll-over	Timer E CMP3 event	Timer E CMP4 event	Timer E CMP3 event
FAULT6	Timer F reset/roll-over	Timer F CMP3 event	Timer F CMP4 event	Timer F CMP3 event
FAULT7	Timer D reset/roll-over	Timer D CMP1 event	Timer D CMP2 event	Timer D CMP1 event
FAULT8	Timer F reset/roll-over	Timer F CMP1 event	Timer F CMP2 event	Timer F CMP1 event

A fault counter is also used to discard multiple spurious fault events and define an acceptance criteria.



The FLTxCNT[3:0] bitfield selects the FAULTx counter threshold. A fault is considered valid when the number of events is equal to the FLTxCNT[3:0] value.

This FLTxRSTM selects the FAULTx counter reset mode

- 0: fault counter hardware reset on reset/roll-over event, as per the *Table 442* below.
- 1: fault counter reset on each reset/roll-over event only if no event occurs during the last counting period, as shown on *Figure 433* below.

The fault counter can be reset by software with the FLTxCRES bit at any time.

Figure 433. Fault counter cumulative mode (FLTxRSTM = 1, FLTxCNT[3:0] = 2)

A given FLTx input counter can be reset by a single source. The *Table 442* indicates which timer unit is associated with a given fault. This does not prevent having a fault line shared by multiple timers (for example FLT1 with event counter enabled, acting on timer A, timer B, and timer C simultaneously).

Table 442. Fault 1..6 counter reset source

Fault Input	Fault counter reset source
hrtim_flt1[4:1]	Timer A reset/roll-over
hrtim_flt2[4:1]	Timer B reset/roll-over
hrtim_flt3[4:1]	Timer C reset/roll-over
hrtim_flt4[4:1]	Timer D reset/roll-over
hrtim_flt5[4:1]	Timer E reset/roll-over
hrtim_flt6[4:1]	Timer F reset/roll-over
hrtim_flt7[4:1]	Timer D reset/roll-over
hrtim_flt8[4:1]	Timer F reset/roll-over

System fault input (hrtim_sys_flt)

This fault is provided by the MCU Class B circuitry (see *Section 14: System configuration, boot, and security (SBS)* for details) and corresponds to a system fault coming from:

- The clock security system
- The SRAM ECC double error detection
- The Cortex-M33 lockup signal
- The PVD detector
- The DCACHE ECC double error detection
- The flash memory ECC double error detection

This input overrides the FAULT inputs and disables all outputs having FAULTy[1:0] = 01, 10, 11.

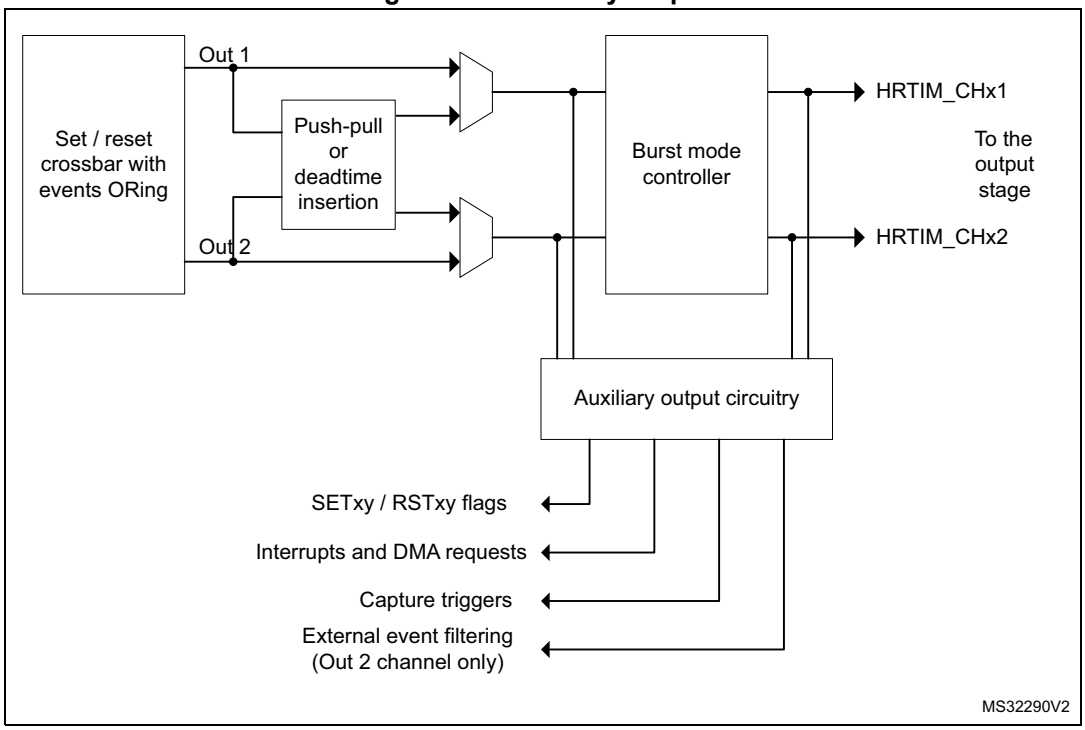
For each FAULT channel, a write-once FLTxLCK bit in the HRTIM_FLTxR register is used to lock FLTxE, FLTxP, FLTxSRC, FLTxF[3:0] bits (it renders them read-only), for functional safety purpose. If enabled, the fault conditioning set-up is frozen until the next HRTIM or system reset.

Once the fault signal is conditioned as explained above, it is routed to the timing units. For any of them, the six fault channels are enabled using bits FLT1EN to FLT6EN in the HRTIM_FLTxR register, and they can be selected simultaneously (the sysfault is automatically enabled as long as the output is protected by the fault mechanism). This is used to have, for instance:

- One fault channel simultaneously disabling several timing units
- Multiple fault channels being ORed to disable a single timing unit

A write-once FLTLCK bit in the HRTIM_FLTxR register is used to lock FLTxEN bits (it renders them read-only) until the next reset, for functional safety purpose. If enabled, the timing unit fault-related set-up is frozen until the next HRTIM or system reset.

For each of the timers, the output state during a fault is defined with FAULT1[1:0] and FAULT2[1:0] bits in the HRTIM_OUTxR register (see *Section 40.3.14*).



40.3.18 Auxiliary outputs

Timer A to E have auxiliary outputs in parallel with the regular outputs going to the output stage. They provide the following internal status, events, and signals:

- SETxy and RSTxy status flags, together with the corresponding interrupts and DMA requests
- Capture triggers upon output set/reset
- External event filters following a Tx2 output copy (see details in *Section 40.3.9*)

The auxiliary outputs are taken either before or after the burst mode controller, depending on the HRTIM operating mode. An overview is given on *Figure 434*.

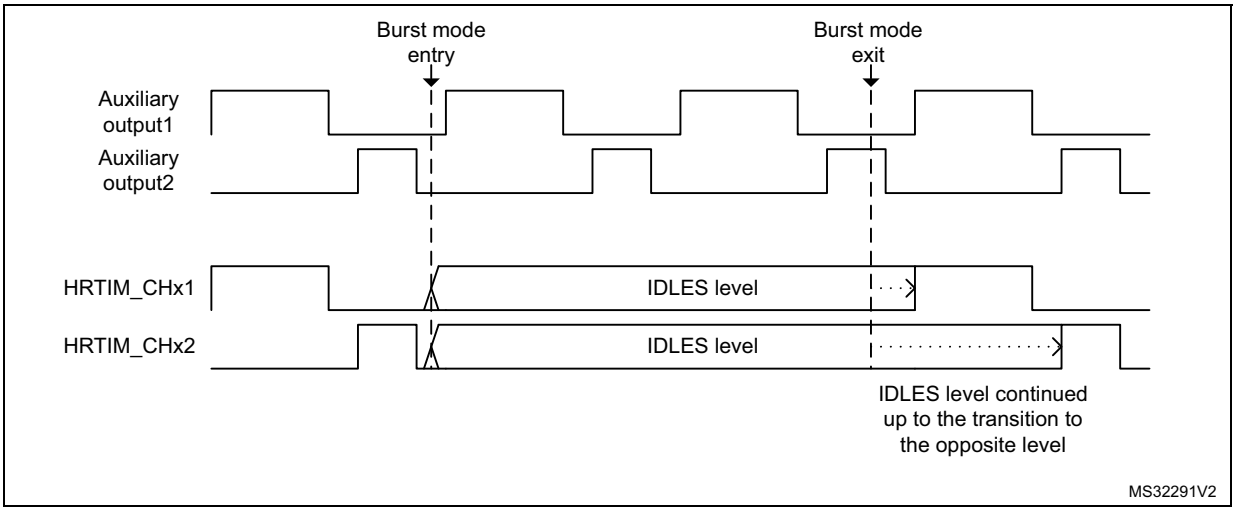


Figure 434. Auxiliary outputs

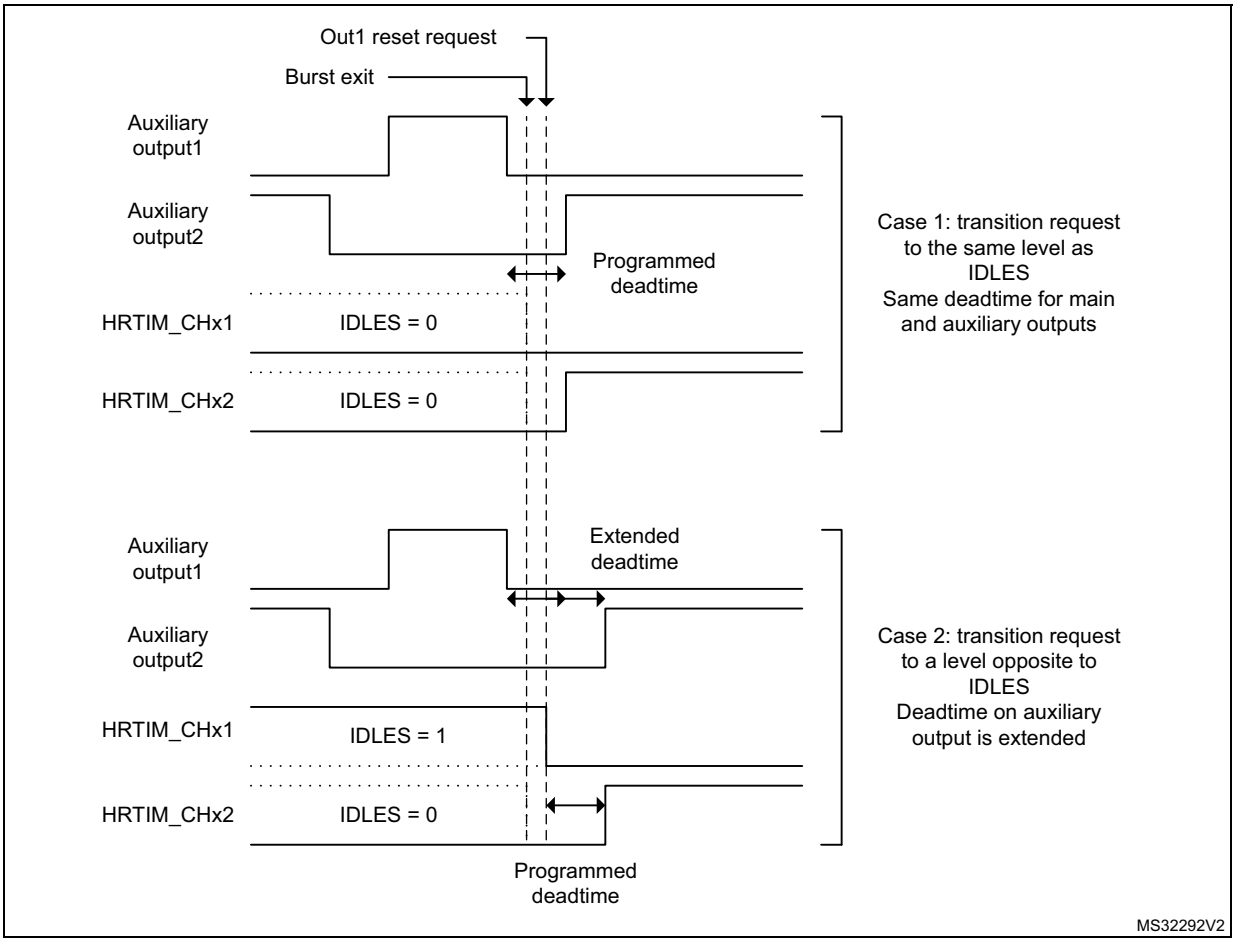
By default, the auxiliary outputs are copies of outputs Tx1 and Tx2. The exceptions are:



- The delayed idle and the balanced idle protections, when the deadtime is disabled (DTEN = 0). When the protection is triggered, the auxiliary outputs are maintained and follow the signal coming out of the crossbar. On the contrary, if the deadtime is enabled (DTEN = 1), both main and auxiliary outputs are forced to an inactive level.
- The burst mode (TCEN=1, IDLEMx=1); there are two cases:
  a) If DTEN=0 or DIDLx=0, the auxiliary outputs are not affected by the burst mode entry and continue to follow the reference signal coming out of the crossbar (see *Figure 435*).
  b) If the deadtime is enabled (DTEN=1) together with the delayed burst mode entry (DIDLx=1), the auxiliary outputs have the same behavior as the main outputs. They are forced to the IDLES level after a deadtime duration, then they keep this level during all the burst period. When the burst mode is terminated, the IDLES level is maintained until a transition occurs to the opposite level, similarly to the main output.

Figure 435. Auxiliary and main outputs during burst mode (DIDLx = 0)

The signal on the auxiliary output can be slightly distorted when exiting from the burst mode or when reenabling the outputs after a delayed protection, if this happens during a deadtime. In this case, the deadtime applied to the auxiliary outputs is extended so that the deadtime on the main outputs is respected. *Figure 436* gives some examples.

Figure 436. Deadtime distortion on auxiliary output when exiting burst mode

40.3.19 Synchronizing the HRTIM with other timers or HRTIM instances

The HRTIM provides options for synchronizing multiple HRTIM instances, as a master unit (generating a synchronization signal) or as a slave (waiting for a trigger to be synchronized). This feature can also be used to synchronize the HRTIM with other timers, either external or on-chip. The synchronization circuitry is controlled inside the master timer.

Synchronization output

This section explains how the HRTIM must be configured to synchronize external resources and act as a master unit.

Four events can be selected as the source to be sent to the synchronization output. This is done using SYNCSRC[1:0] bits in the HRTIM_MCR register, as follows:

- 00: master timer start
  This event is generated when MCEN bit is set or when the timer is restarted after having reached the period value in single-shot mode. It is also generated on a reset which occurs during the counting (when CONT or RETRIG bits are set).
- 01: master timer compare 1 event
- 10: timer A start
  This event is generated when TACEN bit is set or when the counter is reset and restarts counting in response to this reset. The following counter reset events are not propagated to the synchronization output: counter roll-over in continuous mode, and discarded reset request in single-shot nonretriggerable mode. The reset is only taken into account when it occurs during the counting (CONT or RETRIG bits are set).
- 11: timer A compare 1 event

SYNCOUT[1:0] bits in the HRTIM_MCR register specify how the synchronization event is generated.

The synchronization pulses can be generated on the HRTIM_SCOUT output pin, with SYNCOUT[1:0] = 1x. SYNCOUT[0] bit specifies the polarity of the synchronization signal. If SYNCOUT[0] = 0, the HRTIM_SCOUT pin has a low idle level and issues a positive pulse of 16 f_{HRTIM} clock cycles length for the synchronization). If SYNCOUT[0] = 1, the idle level is high and a negative pulse is generated.

Note: The synchronization pulse is followed by an idle level of 16 f_{HRTIM} *clock cycles during which any new synchronization request is discarded. Consequently, the maximum synchronization frequency is* $f_{HRTIM}/32$.

The idle level on the HRTIM_SCOUT pin is applied as soon as the SYNCOUT[1:0] bits are enabled (i.e. the bitfield value is different from 00).

The synchronization output initialization procedure must be done prior to the configuration of the MCU outputs and counter enable, in the following order:

1. SYNCOUT[1:0] and SYNCSRC[1:0] bitfield configuration in HRTIM_MCR
2. HRTIM_SCOUT pin configuration (see the “General-purpose I/Os” section)
3. Master or timer A counter enable (MCEN or TACEN bit set)

When the synchronization input mode is enabled and starts the counter (using SYNCSTRTM/SYNCSTRTx bits) simultaneously with the synchronization output mode (SYNCSRC[1:0] = 00 or 10), the output pulse is generated only when the counter is starting or is reset while running. Any reset request clearing the counter without causing it to start does not affect the synchronization output.

Synchronization input

The HRTIM can be synchronized by external sources, as per the programming of the SYNCIN[1:0] bits in the HRTIM_MCR register:

- 00: synchronization input is disabled
- 01: reserved configuration
- 10: the On-chip timer TRGO output connected to hrtim_in_sync[2] input (refer to *Table 410* for details).
- 11: a positive pulse on the HRTIM_SCIN input pin (hrtim_in_sync[3])

This bitfield cannot be changed once the destination timer (master timer or timing unit) is enabled (MCEN and/or TxCEN bit set).

The HRTIM_SCIN input is rising-edge sensitive. The timer behavior is defined with the following bits present in HRTIM_MCR and HRTIM_TIMxCR registers (see *Table 443* for details):

- Synchronous start: the incoming signal starts the timer's counter (SYNCSTRTM and/or SYNCSTRTx bits set). TxCEN (MCEN) bits must be set to have the timer enabled and the counter ready to start. In continuous mode, the counter does not start until the synchronization signal is received.
- Synchronous reset: the incoming signal resets the counter (SYNCRSTM and/or SYNCRSTx bits set). This event decrements the repetition counter as any other reset event.

The synchronization events are taken into account only once the related counters are enabled (MCEN or TxCEN bit set). A synchronization request triggers a SYNC interrupt.

Note: A synchronized start event resets the counter if the current counter value is above the active period value.

The effect of the synchronization event depends on the timer operating mode, as summarized in *Table 443*.

Table 443. Effect of sync event versus timer operating modes

Operating mode	SYNC RSTx	SYNC STRTx	Behavior following a SYNC reset or start event
Single-shot non-retriggerable	0	1	Start events are taken into account when the counter is stopped and: – once the MCEN or TxCEN bits are set – once the period has been reached. A start occurring when the counter is stopped at the period value resets the counter. A reset request clears the counter but does not start it (the counter can solely be re-started with the synchronization). Any reset occurring during the counting is ignored (as during regular non-retriggerable mode).
	1	X	Reset events are starting the timer counting. They are taken into account only if the counter is stopped and: – once the MCEN or TxCEN bits are set – once the period has been reached. When multiple reset requests are selected (from HRTIM_SCIN and from internal events), only the first arriving request is taken into account.

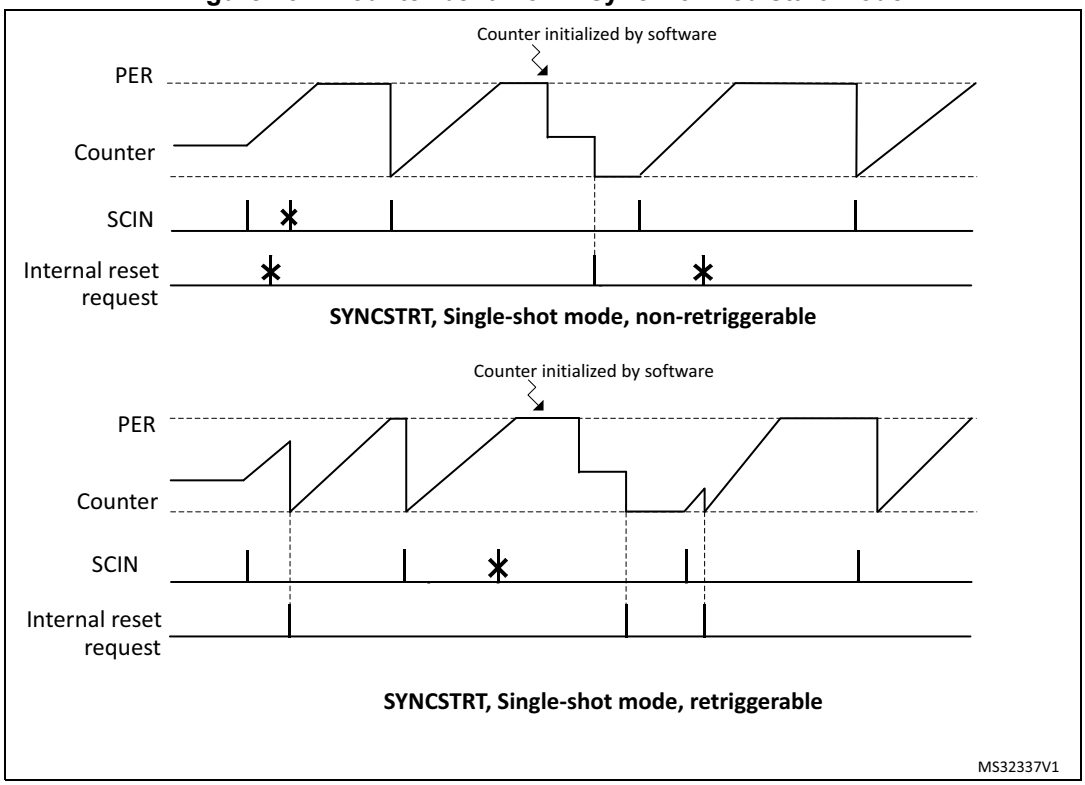


Table 443. Effect of sync event versus timer operating modes (continued)

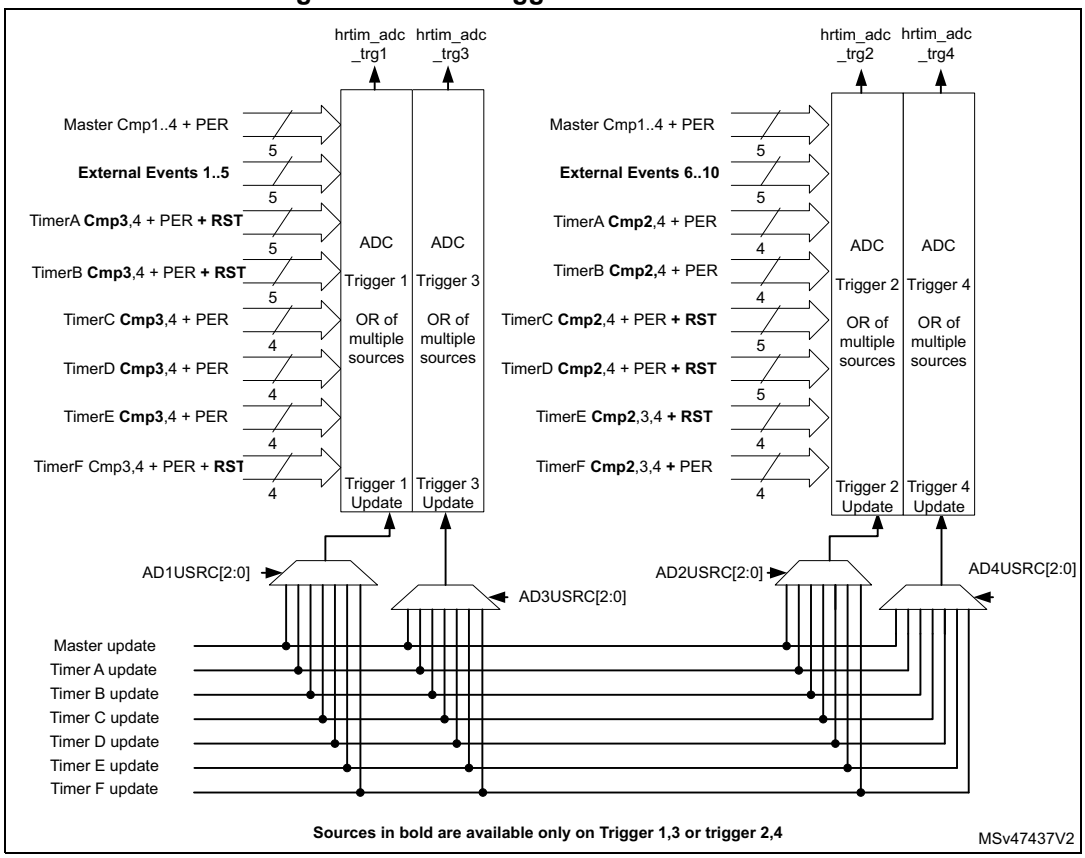
Operating mode	SYNC RSTx	SYNC STRTx	Behavior following a SYNC reset or start event
Single-shot retriggerable	0	1	The counter start is effective only if the counter is not started or period is elapsed. Any synchronization event occurring after counter start has no effect. A start occurring when the counter is stopped at the period value resets the counter. A reset request clears the counter but does not start it (the counter can solely be started by the synchronization). A reset occurring during counting is taken into account (as during regular retriggerable mode).
	1	X	The reset from HRTIM_SCIN is taken into account as any HRTIM's timer counter reset from internal events and is starting or re-starting the timer counting. When multiple reset requests are selected, the first arriving request is taken into account.
Continuous mode	0	1	The timer is enabled (MCEN or TxCEN bit set) and is waiting for the synchronization event to start the counter. Any synchronization event occurring after the counter start has no effect (the counter can solely be started by the synchronization). A reset request clears the counter but does not start it.
	1	X	The reset from HRTIM_SCIN is taken into account as any HRTIM's timer counter reset from internal events and is starting or re-starting the timer counting. When multiple reset requests are selected, the first arriving request is taken into account.

When a synchronization reset event occurs within the same f_{HRTIM} clock cycle as the period event, this reset is postponed to a programmed period event (since both events are causing a counter roll-over). This applies only when the high-resolution is active (CKPSC[2:0] < 5).

Figure 437 presents how the synchronized start is done in single-shot mode.

Figure 437. Counter behavior in synchronized start mode



40.3.20 ADC triggers

The ADCs can be triggered by the master and the six timing units.

10 independent triggers are available for both the regular and the injected sequencers of the ADCs. The external events can be used as triggers. They are taken right after the conditioning defined in the HRTIM_EECRx registers, and are not depending on the EEFxR1 and EEFxR2 register settings.

Up to 32 events can be combined (ORed) for ADC triggers 1 to 4, in HRTIM_ADC1R to HRTIM_ADC4R registers, as shown on *Figure 438*. The ADC triggers 1/3 and 2/4 are using the same source set. A multiple triggering is possible within a single switching period by selecting several sources simultaneously. A typical use case is for a nonoverlapping multiphase converter, where all phases can be sampled in a row using a single ADC trigger output.

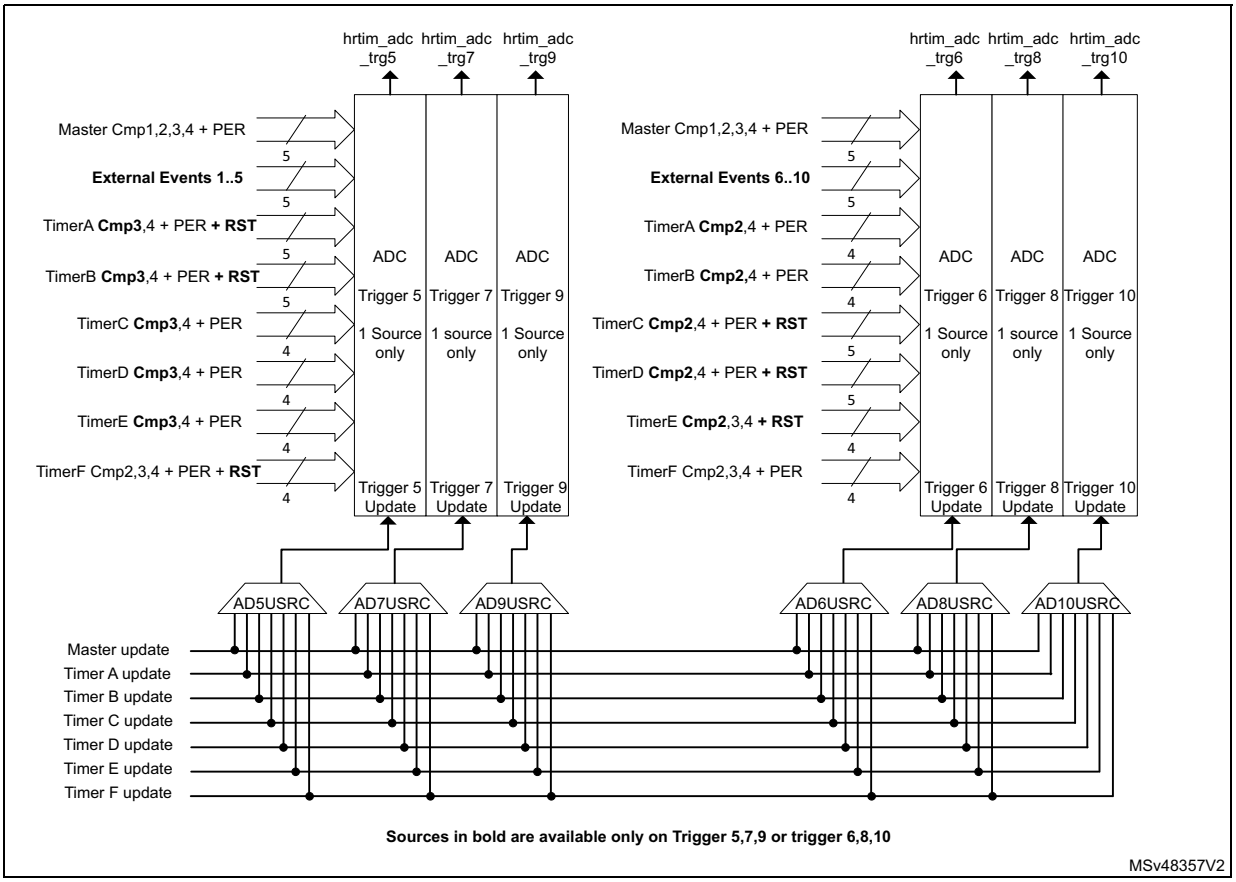


Figure 438. ADC trigger selection overview

The ADC triggers 5 to 10 are configured in the HRTIM_ADCER register, as shown on *Figure 439*. The ADC triggers 5/7/9 and 6/8/10 are using the same source set.

A single source can be selected at once for these triggers (1 out of 32 possible events).

Figure 439. ADC triggers

HRTIM_ADC1R to HRTIM_ADC4R and HRTIM_ADCER registers are preloaded and can be updated synchronously with the timer they are related to. The update sources are defined with ADxUSRC[2:0] bits in the HRTIM_CR1 and HRTIM_ADCUR registers.

For instance, if ADC trigger 1 outputs timer A CMP2 events (HRTIM_ADC1R = 0x0000 0400), HRTIM_ADC1R is typically updated simultaneously with timer A (AD1USRC[2:0] = 001).

When the preload is disabled (PREEN bit reset) in the source timer, the HRTIM_ADCxR registers are not preloaded either: a write access results in an immediate update of the trigger source.

ADC postscaler

A postscaling unit is used to reduce the ADC trigger rate with respect to the switching frequency.

Each ADC trigger rate can be individually adjusted using the ADCxPSC[4:0] bits in the HRTIM_ADCxPS1 and HRTIM_ADCxPS2 registers as shown in *Figure 440* below for the up-counting mode.

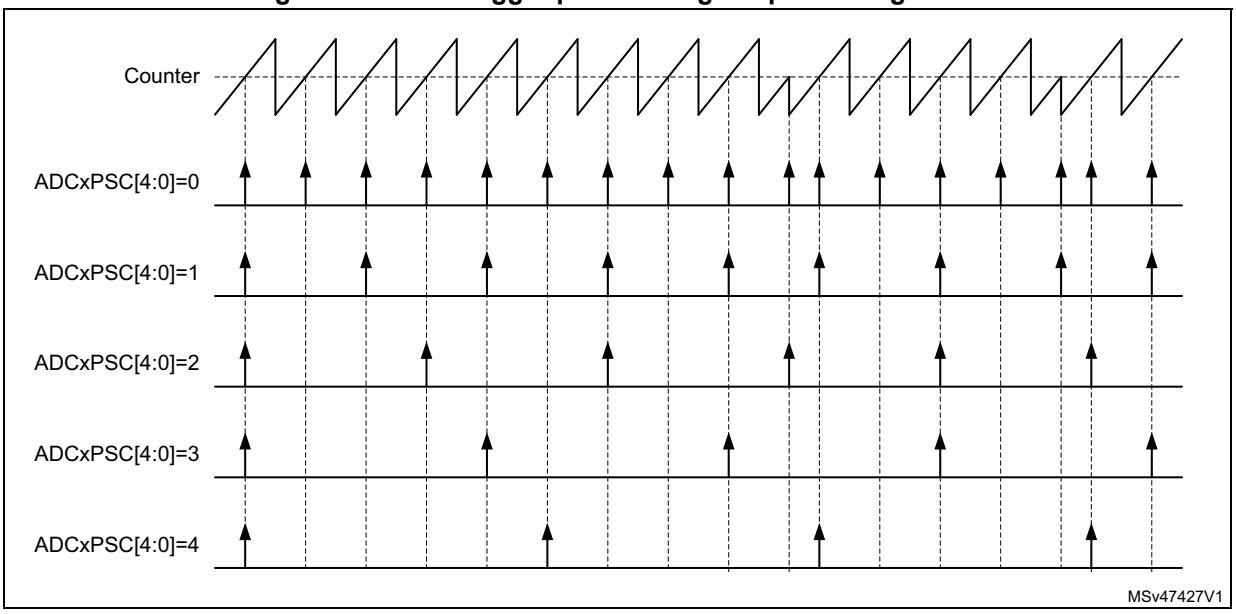
In the center-aligned mode, the ADC postscaling is done on events selected with the ADROM[1:0] bitfield, programmed in the source timer, as shown in *Figure 441*. The

ADROM[1:0] bitfield is coding for any event that can trigger the ADC: reset, roll-over (period) and compare event:

- ADROM[1:0] = 00: event generated both during up and down-counting phases
- ADROM[1:0] = 01: event generated during down-counting phases
- ADROM[1:0] = 10: event generated during up-counting phases

The ADC postscaler programming registers are preloaded and can be updated on-the-fly without stopping the timers.

Figure 440. ADC trigger post-scaling in up-counting mode



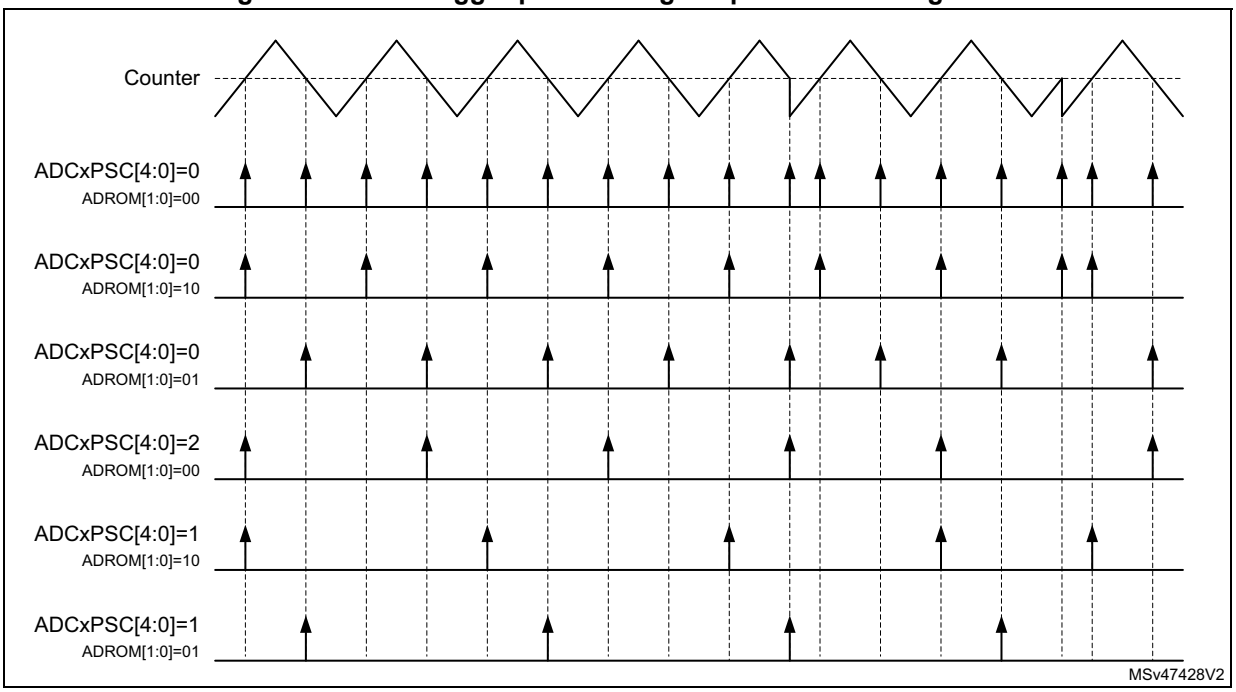


Figure 441. ADC trigger post-scaling in up/down counting mode

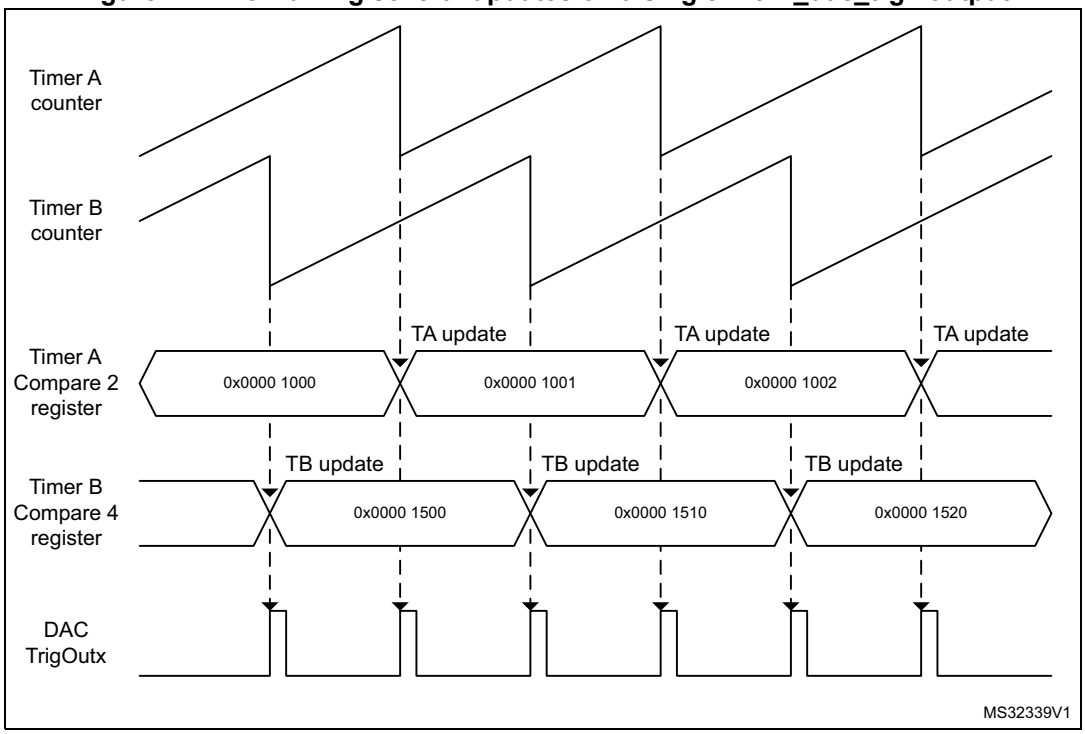
40.3.21 DAC triggers

The HRTIM is used to have the embedded DACs updated synchronously with the timer updates.

The update events from the master timer and the timer units can generate DAC update triggers on any of the three hrtim_dac_trgx outputs.

Note: Each timer has its own DAC-related control register.



DACSYNC[1:0] bits of the HRTIM_MCR and HRTIM_TIMxCR registers are programmed as follows:

- 00: No update generated
- 01: Update generated on hrtim_dac_trg1
- 10: Update generated on hrtim_dac_trg2
- 11: Update generated on hrtim_dac_trg3

An output pulse of one f_{HRTIM} clock period is generated on the hrtim_dac_trgx output.

When DACSYNC[1:0] bits are enabled in multiple timers, the hrtim_dac_trgx output consists of an OR of all timers' update events. For instance, if DACSYNC = 1 in timer A and in timer B, the update event in timer A is ORed with the update event in timer B to generate a DAC update trigger on the corresponding hrtim_dac_trgx output, as shown on *Figure 442*.

Figure 442. Combining several updates on a single hrtim_dac_trgx output

Refer to *Table 418: HRTIM DAC triggers connections* for connections to the DACs.

Dual channel DAC trigger

Slope compensation techniques and hysteretic control to be easily implemented using HRTIM built-in features and the DAC sawtooth generator. The principle is to have a DAC generating a decreasing saw-tooth synchronized with the PWM period, or a square wave synchronized with PWM signal.

This mode is enabled with the DCDE bit in the TIMxCR2 register. This bit cannot be changed once the timer is operating (TxEN bit set).

It uses two trigger outputs, as shown on the *Figure 443* below:

- The hrtim_dac_reset_trgx generates DAC reset/update events
- The hrtim_dac_step_trgx generates requests for incremental DAC value changes

The DCDR bit in the TIMxCR2 register defines when the hrtim_dac_reset_trgx trigger is generated:

- DCDR = 0: the trigger is generated on counter reset or roll-over event
- DCDR = 1: the trigger is generated on output 1 set event

Note: The DCDR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

The DCDS bit in the TIMxCR2 register defines when the hrtim_dac_step_trgx trigger is generated:

- DCDS = 0: the trigger is generated on compare 2 event
- DCDS = 1: the trigger is generated on output 1 reset event

The DCDR and DCDS bits allows the following use cases to be covered:

- Edge-aligned slope compensation (DCDR = DCDS = 0): the DAC's sawtooth starts on PWM period beginning and multiple triggers are generated during the period
- Center-aligned slope compensation (DCDR = 1 DCDS = 0): the DAC's sawtooth starts on the output set event and multiple triggers are generated during the period
- Hysteretic controller: the DAC value must be changed twice per period, when the output state changes. 2 triggers are generated per PWM period. In edge-aligned mode (DCDR=0, DCDS =1), the triggers are generated on counter reset or roll-over. In center-aligned mode (DCDR=1, DCDS=1), the triggers are generated when the output is set.

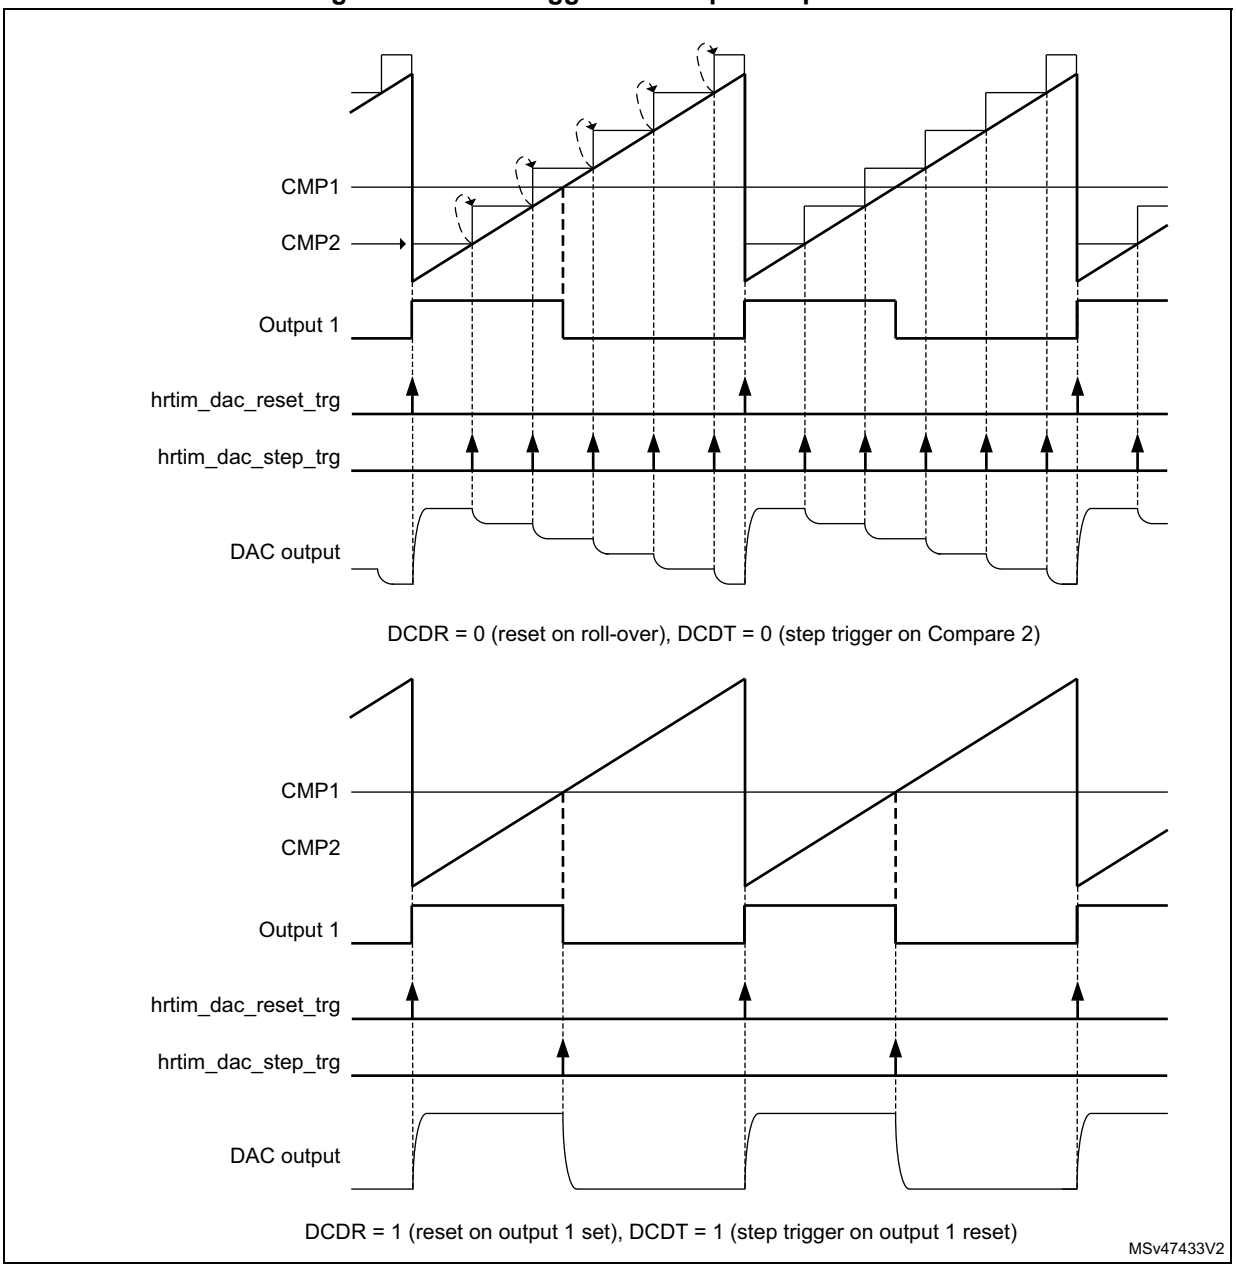
The compare 2 has a particular operating mode when the DCDE is set and the DCDS bit is reset. The active comparison value is automatically updated as soon as a compare match has occurred, so that the trigger can be repeated periodically with a period equal to the CMP2 value, as represented on *Figure 443*.
The dual channel DAC trigger with DCDS bit reset (compare 2 event used) must not be used simultaneously with modes using CMP2 (triple/quad interleaved and triggered-half modes).

Note: The CMP2 value can be changed on-the-fly. The new value is taken into account on the next coming compare match.

Note: When the DCDS bit is reset, the CMP2 value must not be modified by other mechanisms: the interleaved, triggered half and balanced idle modes must be disabled.

Table 444 below gives an example, for generating six triggers within a PWM period. It shows that it is necessary to round up the division result to the upper value.

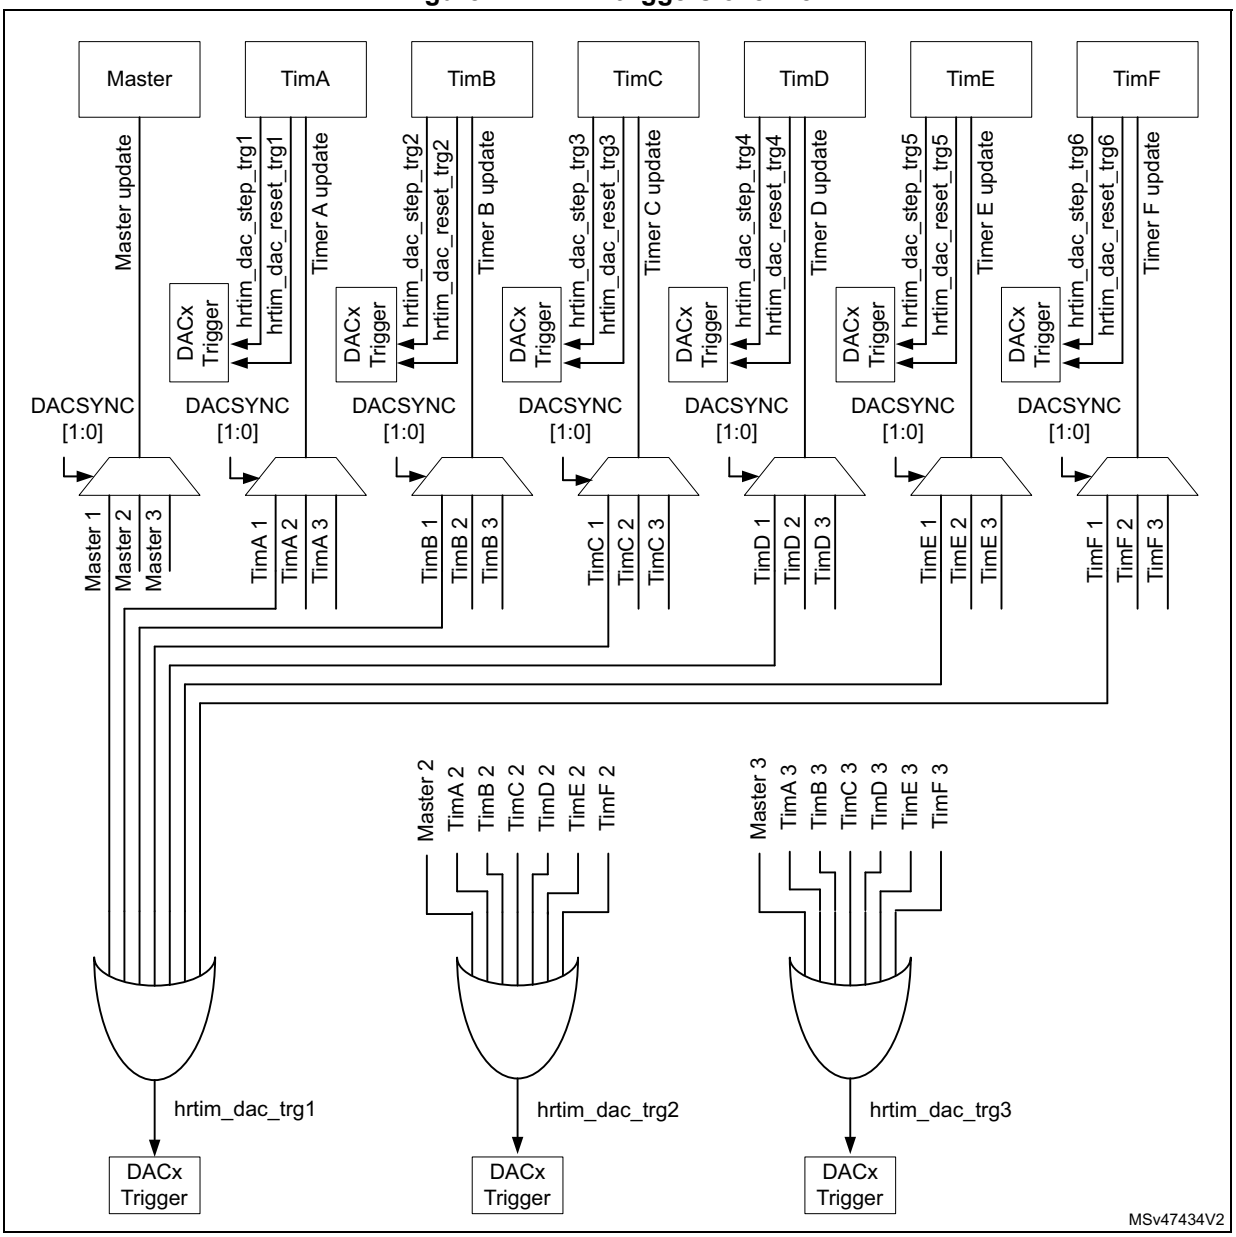
Let's consider a counter period TIMxPER = 8192. Dividing 8192 by 6 yields 1365.33.



- Round down value: 1365: 7 triggers are generated, the 6th and 7th being very close (respectively for counter = 8190 and 8192)
- Round up value:1366: six triggers are generated. The sixth trigger on hrtim_dac_step_trg (for counter = 8192) is aborted by the counter roll-over from 8192 to 0.

Table 444. DAC dual channel trigger example

-	CMP2 = 1365	hrtim_dac_ reset_trg	hrtim_dac_ step_trg	CMP2 = 1366	hrtim_dac_ reset_trg	hrtim_dac_ step_trg
Counter value	1365	-	1	1366	-	1
	2730	-	2	2732	-	2
	4095	-	3	4098	-	3
	5460	-	4	5464	-	4
	6825	-	5	6830	-	5
	8190	-	6	8192	6	-
	8192	7	-	1366	-	1
	1365	-	1	2732	-	2
	...	-	-	...	-	-



Note: In centered-pattern mode, it is mandatory to have an even number of triggers per switching period, so as to avoid unevenly spaced triggers around counter's peak value.

Figure 443. DAC triggers for slope compensation

The *Figure 444* below provides an overview of all the available DAC triggers.

Figure 444. DAC triggers overview

40.3.22 Interrupts

7 interrupts can be generated by the master timer:

- Master timer registers update
- Synchronization event received
- Master timer repetition event
- Master compare 1 to 4 event

14 interrupts can be generated by each timing unit:

- Crossbar override rearm delay elapsed
- Delayed protection triggered
- Counter reset or roll-over event
- Output 1 and output 2 reset (transition active to inactive)
- Output 1 and output 2 set (transition inactive to active)
- Capture 1 and 2 events
- Timing unit registers update
- Crossbar override trigger
- Repetition event
- Compare 1 to 4 event

8 global interrupts are generated for the whole HRTIM:

- System fault and fault 1 to 6 (regardless of the timing unit attribution)
- DLL calibration done
- Burst mode period completed

The interrupt requests are grouped in eight vectors as follows:

- hrtim_it1: master timer interrupts (master update, sync input, repetition, MCMP1..4) and global interrupt except faults (burst mode period and DLL ready interrupts)
- hrtim_it2: TIMA interrupts
- hrtim_it3: TIMB interrupts
- hrtim_it4: TIMC interrupts
- hrtim_it5: TIMD interrupts
- hrtim_it6: TIME interrupts
- hrtim_it7: TIMF interrupts
- hrtim_it8: Dedicated vector all fault interrupts to allow high-priority interrupt handling

Table 445 is a summary of the interrupt requests, their mapping and associated control, and status bits.

Table 445. HRTIM interrupt summary

Interrupt vector	Interrupt event	Event flag	Enable control bit	Flag clearing bit
hrtim_it1	Burst mode period completed	BMPER	BMPERIE	BMPERC
	DLL calibration done	DLLRDY	DLLRDYIE	DLLRDYC
	Master timer registers update	MUPD	MUPDIE	MUPDC
	Synchronization event received	SYNC	SYNCIE	SYNCC

		FLT5	FLT5IE	FLT5C
		FLT6	FLT6IE	FLT6C

40.3.23 DMA

Most of the events able to generate an interrupt can also generate a DMA request, even both simultaneously. Each timer (master, TIMA...F) has its own DMA enable register.

The individual DMA requests are ORed into seven channels as follows:

- 1 channel for the master timer
- 1 channel per timing unit (TIMA...F)

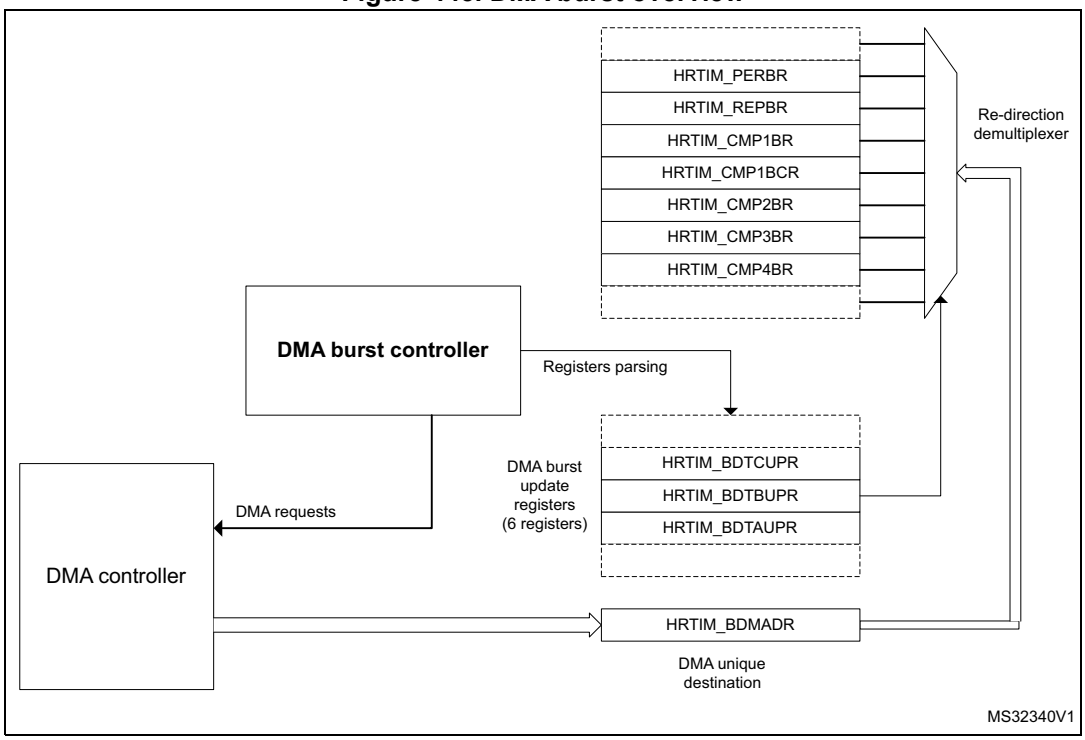
Note: Before disabling a DMA channel (DMA enable bit reset in TIMxDIER), it is necessary to disable first the DMA controller.

Table 446 is a summary of the events with their associated DMA enable bits.

Table 446. HRTIM DMA request summary

DMA Channel	Event	DMA capable	DMA enable bit
hrtim_dma1 (master timer)	Burst mode period completed	No	N/A
	DLL calibration done	No	N/A
	Master timer registers update	Yes	MUPDDE
	Synchronization event received	Yes	SYNCDE
	Master timer repetition event	Yes	MREPDE
	Master compare 1 to 4 event	Yes	MCMP1DE
		Yes	MCMP2DE
		Yes	MCMP3DE
		Yes	MCMP4DE
hrtim_dma2 (timer A) hrtim_dma3 (timer B) hrtim_dma4 (timer C) hrtim_dma5 (timer D) hrtim_dma6 (timer E) hrtim_dma7 (timer F)	Crossbar override rearm delay elapsed	Yes	CORDEDE
	Delayed protection triggered	Yes	DLYPRTDE
	Counter reset or roll-over event	Yes	RSTDE
	Output 1 and output 2 reset (transition active to inactive)	Yes	RSTx1DE
		Yes	RSTx2DE
	Output 1 and output 2 set (transition inactive to active)	Yes	SETx1DE
		Yes	SETx2DE
	Capture 1 and 2 events	Yes	CPT1DE
		Yes	CPT2DE
	Timing unit registers update	Yes	UPDDE
	Crossbar override trigger	Yes	COTDE
	Repetition event	Yes	REPDE
	Compare 1 to 4 event	Yes	CMP1DE
		Yes	CMP2DE
		Yes	CMP3DE
		Yes	CMP4DE
N/A	System fault	No	N/A
	Fault 1 to 6	No	N/A
	Burst mode period completed	No	N/A
	DLL calibration done	No	N/A

Burst DMA transfers



In addition to the standard DMA requests, the HRTIM features a DMA burst controller to have multiple registers updated with a single DMA request. This allows to:

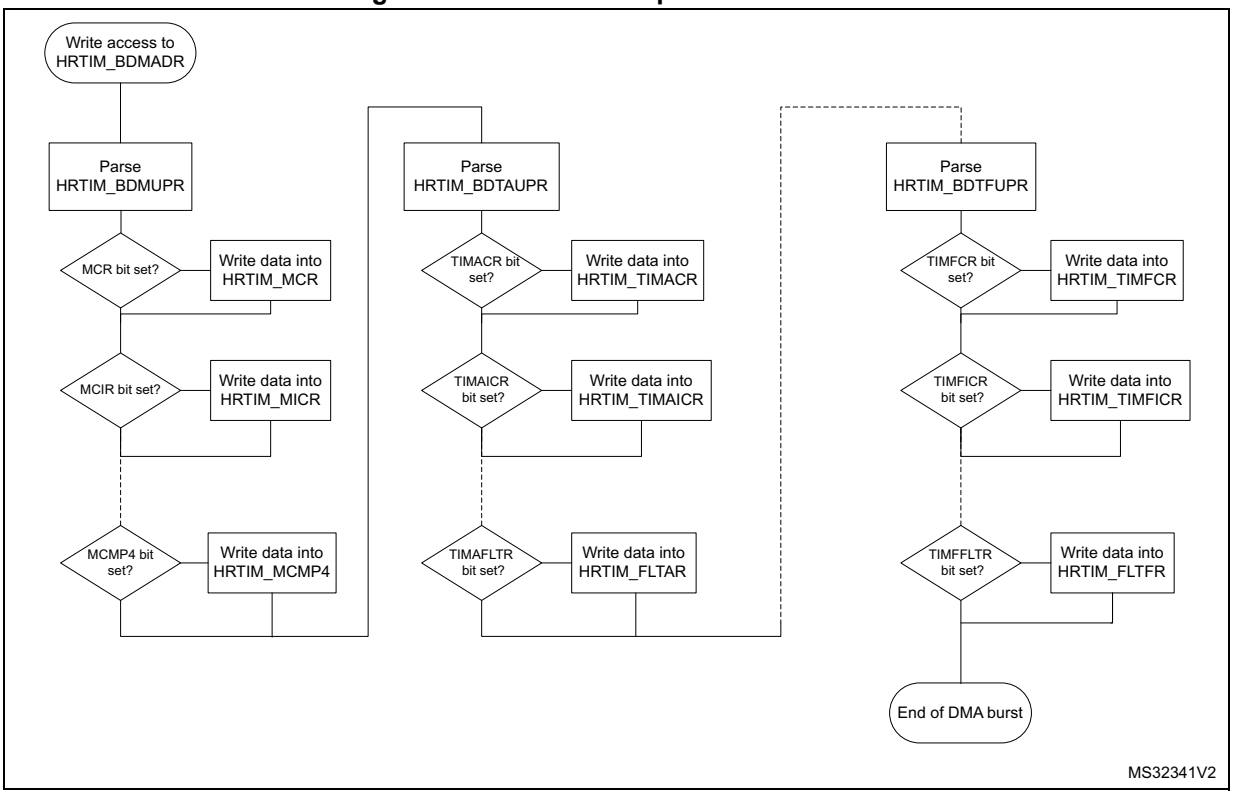
- Update multiple data registers with one DMA channel only,
- Reprogram dynamically one or several timing units, for converters using multiple timer outputs.

The burst DMA feature is only available for one DMA channel, but any of the six channels can be selected for burst DMA transfers.

The principle is to program which registers are to be written by DMA. The master timer and TIMA..E have the burst DMA update register, where most of their control and data registers are associated with a selection bit: HRTIM_BDMUPR, HRTIM_BDTAUPR to HRTIM_BDTEUPR (this is applicable only for registers with write accesses). A redirection mechanism is used to forward the DMA write accesses to the HRTIM registers automatically, as shown on *Figure 445*.

Figure 445. DMA burst overview

When the DMA trigger occurs, the HRTIM generates multiple 32-bit DMA requests and parses the update register. If the control bit is set, the write access is redirected to the associated register. If the bit is reset, the register update is skipped and the register parsing is resumed until a new bit set is detected, to trigger a new request. Once the six update registers (HRTIM_BDMUPR, 5x HRTIM_BDTxUPR) are parsed, the burst is completed and the system is ready for another DMA trigger (see the flowchart on *Figure 446*).



Note: Any trigger occurring while the burst is ongoing is discarded, except if it occurs during the very last data transfer.

The burst DMA mode is permanently enabled (there is no enabled bit). A burst DMA operation is started by the first write access into the HRTIM_BDMADR register.

It is only necessary to have the DMA controller pointing to the HRTIM_BDMADR register as the destination, in the memory, to the peripheral configuration with the peripheral increment mode disabled (the HRTIM handles internally the data rerouting to the final destination register).

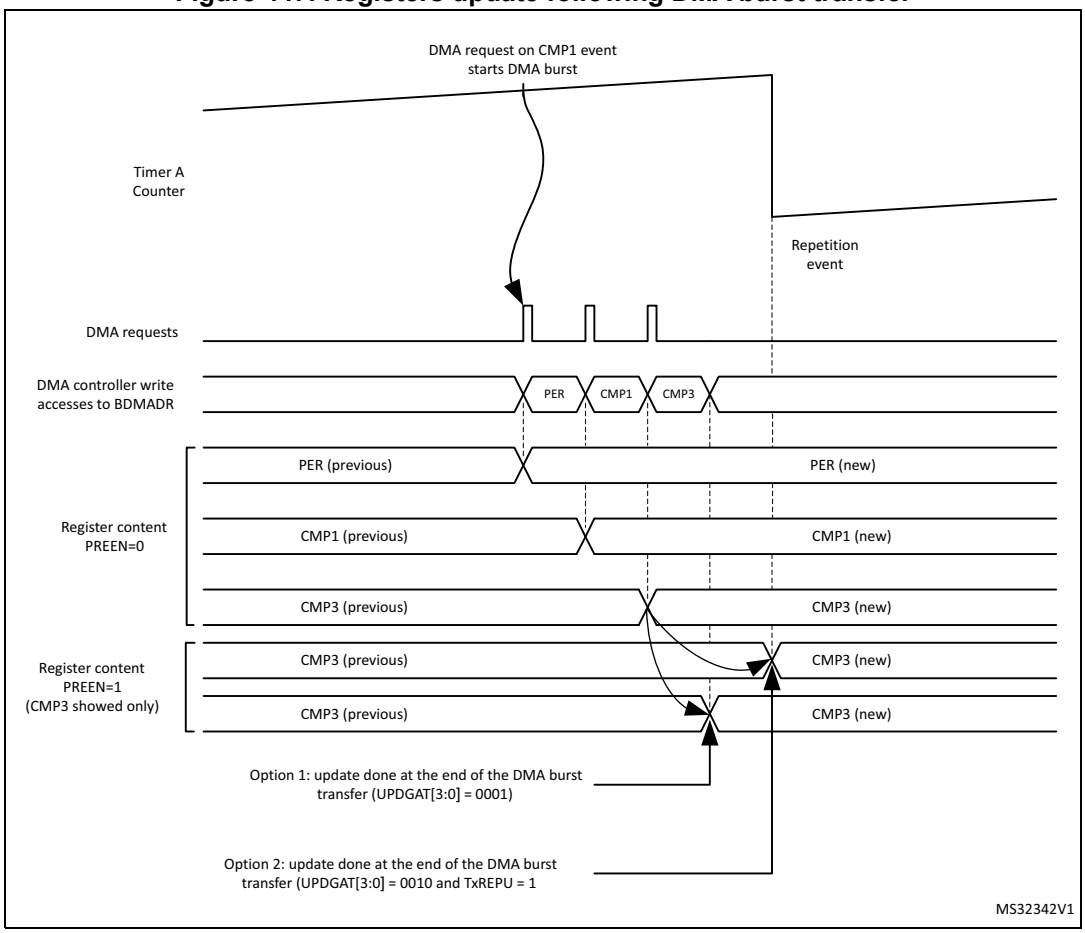
To reinitialize the burst DMA mode if it was interrupted during a transaction, it is necessary to write at least to one of the six update registers.

Figure 446. Burst DMA operation flowchart

Several options are available once the DMA burst is completed, depending on the register update strategy.

If the PREEN bit is reset (preload disabled), the value written by the DMA is immediately transferred into the active register and the registers are updated sequentially, following the DMA transaction pace.

When the preload is enabled (PREEN bit set), there are three use cases:



1. The update is done independently from DMA burst transfers (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 00 in HRTIM_MCR). In this case, and if it is necessary to have all transferred data taken into account simultaneously, the user must check that the DMA burst is completed before the update event takes place. On the contrary, if the update event happens while the DMA transfer is ongoing, only part of the registers is loaded and the complete register update requires two consecutive update events.
2. The update is done when the DMA burst transfer is completed (UPDGAT[3:0] = 0000 in HRTIM_TIMxCR and BRSTDMA[1:0] = 01 in HRTIM_MCR). This mode guarantees that all new register values are transferred simultaneously. This is done independently

from the counter value and can be combined with regular update events, if necessary (for instance, an update on a counter reset when TxRSTU is set).

3. The update is done on the update event following the DMA burst transfer completion (UPDGAT[3:0] = 0010 in HRTIM_TIMxCR and BRSTDMA[1:0] = 10 in HRTIM_MCR). This mode guarantees both a coherent update of all transferred data and the synchronization with regular update events, with the timer counter. In this case, if a regular update request occurs while the transfer is ongoing, it is discarded and the effective update happens on the next coming update request.

The chronogram on *Figure 447* presents the active register content for three cases: PREEN=0, UPDGAT[3:0] = 0001 and UPDGAT[3:0] = 0001 (when PREEN = 1).

Figure 447. Registers update following DMA burst transfer

40.3.24 HRTIM initialization

This section describes the recommended HRTIM initialization procedure, including other related MCU peripherals.

The HRTIM clock source must be enabled in the reset and clock control unit (RCC), while respecting the $_{fHRTIM}$ range for the DLL lock.

The DLL calibration must be started by setting CAL bit in HRTIM_DLLCR register.

The HRTIM master and timing units can be started only once the high-resolution unit is ready. This is indicated by the DLLRDY flag set. The DLLRDY flag can be polled before resuming the initialization or the calibration can run in background while other registers of the HRTIM or other MCU peripherals are initialized. In this case, the DLLRDY flag must be checked before starting the counters (an end-of-calibration interrupt can be issued if necessary, enabled with DLLRDYIE flag in HRTIM_IER). Once the DLL calibration is done, CALEN bit must be set to have it done periodically and compensate for potential voltage and temperature drifts. The calibration periodicity is defined using the CALRTE[1:0] bitfield in the HRTIM_DLLCR register.

The HRTIM control registers can be initialized as per the power converter topology and the timing units use case. All inputs have to be configured (source, polarity, edge-sensitivity).

The HRTIM outputs must be set up eventually, with the following sequence:

- The polarity must be defined using POLx bits in HRTIM_OUTxR
- The FAULT and IDLE states must be configured using FAULTx[1:0] and IDLESx bits in HRTIM_OUTxR

The HRTIM outputs are ready to be connected to the MCU I/Os. In the GPIO controller, the selected HRTIM I/Os have to be configured as per the alternate function mapping table in the product datasheet.

From this point on, the HRTIM controls the outputs, which are in the IDLE state.

The outputs are configured in RUN mode by setting TxyOEN bits in the HRTIM_OENR register. The two outputs are in the inactive state until the first valid set/reset event in RUN mode. Any output set/reset event (except software requests using SST, SRT) are ignored as long as TxCEN bit is reset, as well as burst mode requests (IDLEM bit value is ignored). Similarly, any counter reset request coming from the burst mode controller is ignored (if TxBM bit is set).

Note: When the deadtime insertion is enabled (DTEN bit set), it is necessary to force the output state by software, using SST and RST bits, to have the outputs in a complementary state as soon as the RUN mode is entered.

The HRTIM operation can eventually be started by setting TxCEN or MCEN bits in HRTIM_MCR.

If the HRTIM peripheral is reset with the reset and clock controller, the output control is released to the GPIO controller and the outputs are tri-stated.

40.3.25 Debug

When a microcontroller enters the debug mode (Cortex-M33 core halted), the TIMx counter either continues to work normally or stops, depending on DBG_HRTIM_STOP configuration bit in DBG module:

- DBG_HRTIM_STOP = 0: no behavior change, the HRTIM continues to operate.
- DBG_HRTIM_STOP = 1: all HRTIM timers, including the master, are stopped. The outputs in RUN mode enter the FAULT state if FAULTx[1:0] = 01,10,11, or keep their current state if FAULTx[1:0] = 00. The outputs in idle state are maintained in this state. This is permanently maintained even if the MCU exits the halt mode. This is used to maintain a safe state during the execution stepping. The outputs can be enabled again by setting TxyOEN bit (requires the use of the debugger).

Timer behavior during MCU halt when DBG_HRTIM_STOP = 1

The set/reset crossbar, the dead-time and push-pull unit, the idle/balanced fault detection and all the logic driving the normal output in RUN mode are not affected by debug. The output keeps on toggling internally, so as to retrieve regular signals of the outputs when TxyOEN is set again (during or after the MCU halt). Associated triggers and filters are also following internal waveforms when the outputs are disabled.

FAULT inputs and events (any source) are enabled during the MCU halt.

Fault status bits can be set and TxyOEN bits reset during the MCU halt if a fault occurs at that time (TxyOEN and TxyODS are not affected by DBG_HRTIM_STOP bit state).

Synchronization, counter reset, start, and reset-start events are discarded in debug mode, as well as capture events. This is to keep all related registers stable as long as the MCU is halted.

The counter stops counting when a breakpoint is reached. However, the counter enable signal is not reset; consequently no start event is emitted when exiting from debug. All counter reset and capture triggers are disabled, as well as external events (ignored as long as the MCU is halted). The outputs SET and RST flags are frozen, except in case of forced software set/reset. A level-sensitive event is masked during the debug but is active again as soon as the debug is exited. For edge-sensitive events, if the signal is maintained active during the MCU halt, a new edge is not generated when exiting from debug.

The update events are discarded. This prevents any update trigger on hrtim_upd_en[3:1] inputs. DMA triggers are disabled. The burst mode circuit is frozen: the triggers are ignored and the burst mode counter stopped.

DLL calibration is not blocked while the MCU is halted (the DLLRDY flag can be set).

40.4 Application use cases

40.4.1 Buck converter

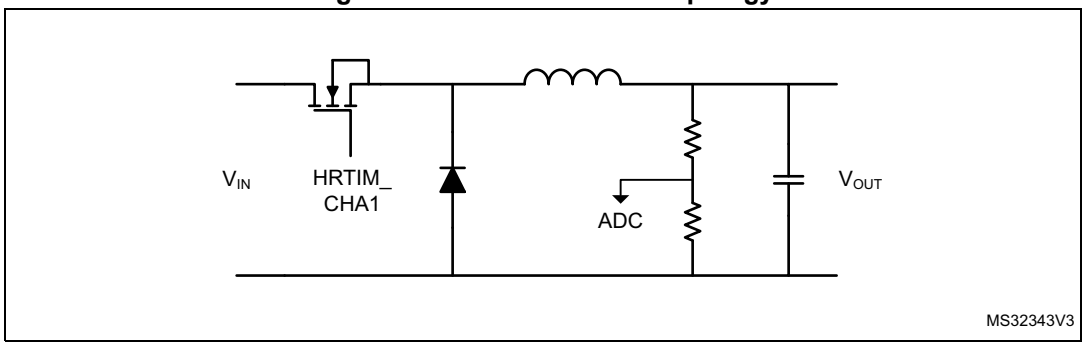
Buck converters are of common use as step-down converters. The HRTIM can control up to 12 buck converters with seven independent switching frequencies.

The converter usually operates at a fixed frequency and the Vin/Vout ratio depends on the duty cycle D applied to the power switch:

$$V_{out} = D \times V_{in}$$

The topology is given on *Figure 448* with the connection to the ADC for voltage reading.

Figure 448. Buck converter topology



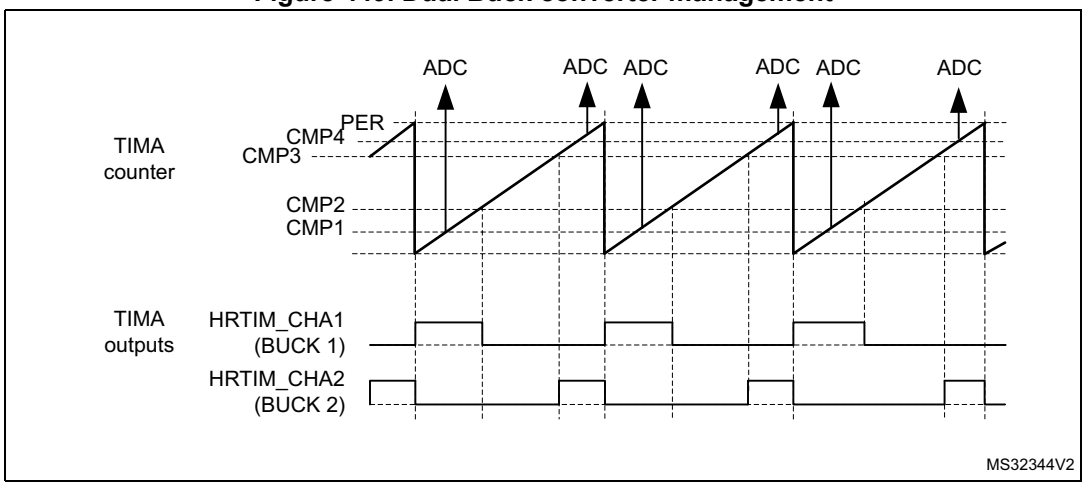


Figure 449 presents the management of two converters with identical frequency PWM signals. The outputs are defined as follows:

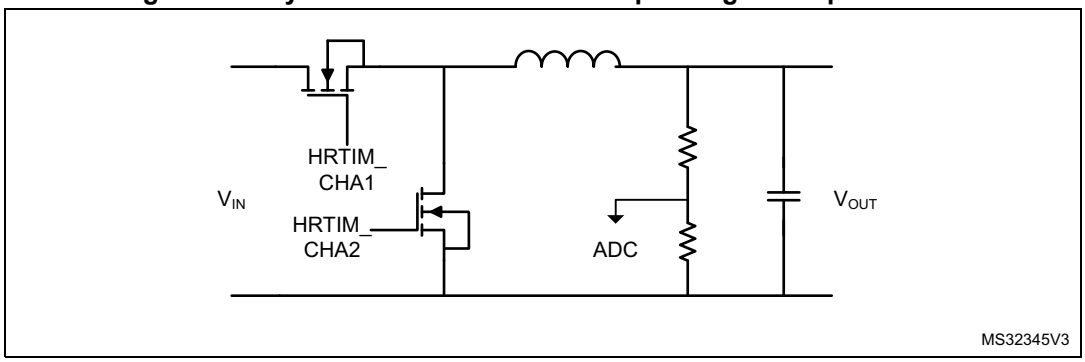
- HRTIM_CHA1 set on period, reset on CMP1
- HRTIM_CHA2 set on CMP3, reset on PER

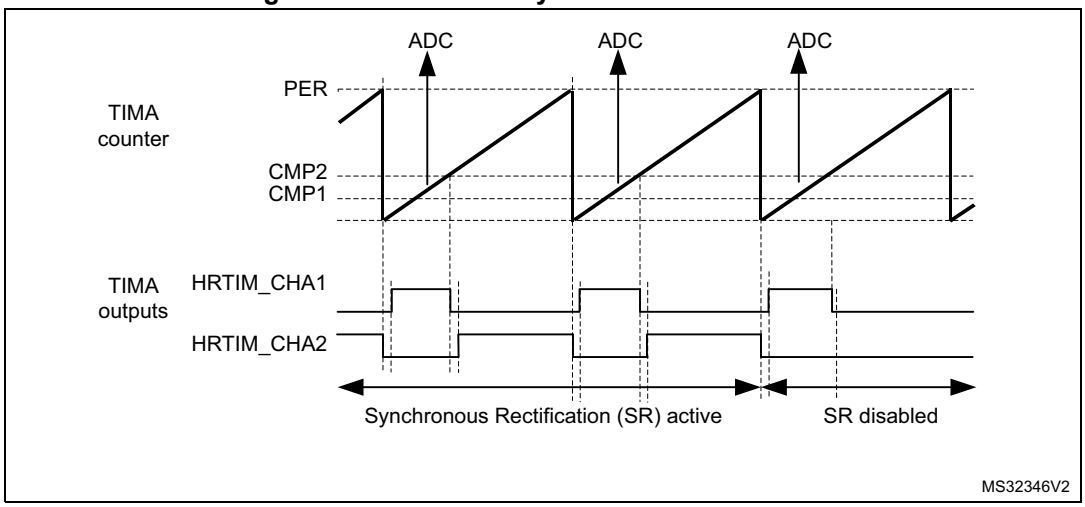
The ADC is triggered twice per period, precisely in the middle of the ON time, using CMP2 and CMP4 events.

Figure 449. Dual Buck converter management



Timers A..E provide either 12 buck converters coupled by pairs (both with identical switching frequencies) or seven completely independent converters (each of them having a different switching frequency), using the master timer as the seventh time base.

40.4.2 Buck converter with synchronous rectification



Synchronous rectification is used to minimize losses in buck converters, by means of a FET replacing the freewheeling diode. Synchronous rectification can be turned on or off on the fly depending on the output current level, as shown on *Figure 450*.

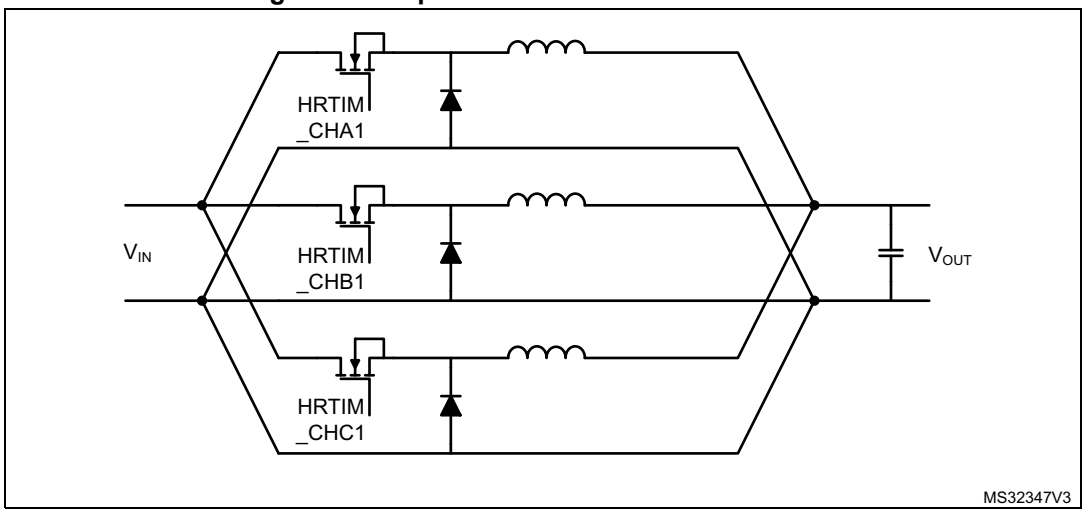
Figure 450. Synchronous rectification depending on output current

The main difference versus a single-switch buck converter is the addition of a deadtime for an almost complementary waveform generation on HRTIM_CHA2, based on the reference waveform on HRTIM_CHA1 (see *Figure 451*).

Figure 451. Buck with synchronous rectification

40.4.3 Multiphase converters

Multiphase techniques can be applied to multiple power conversion topologies (buck, flyback). Their main benefits are:



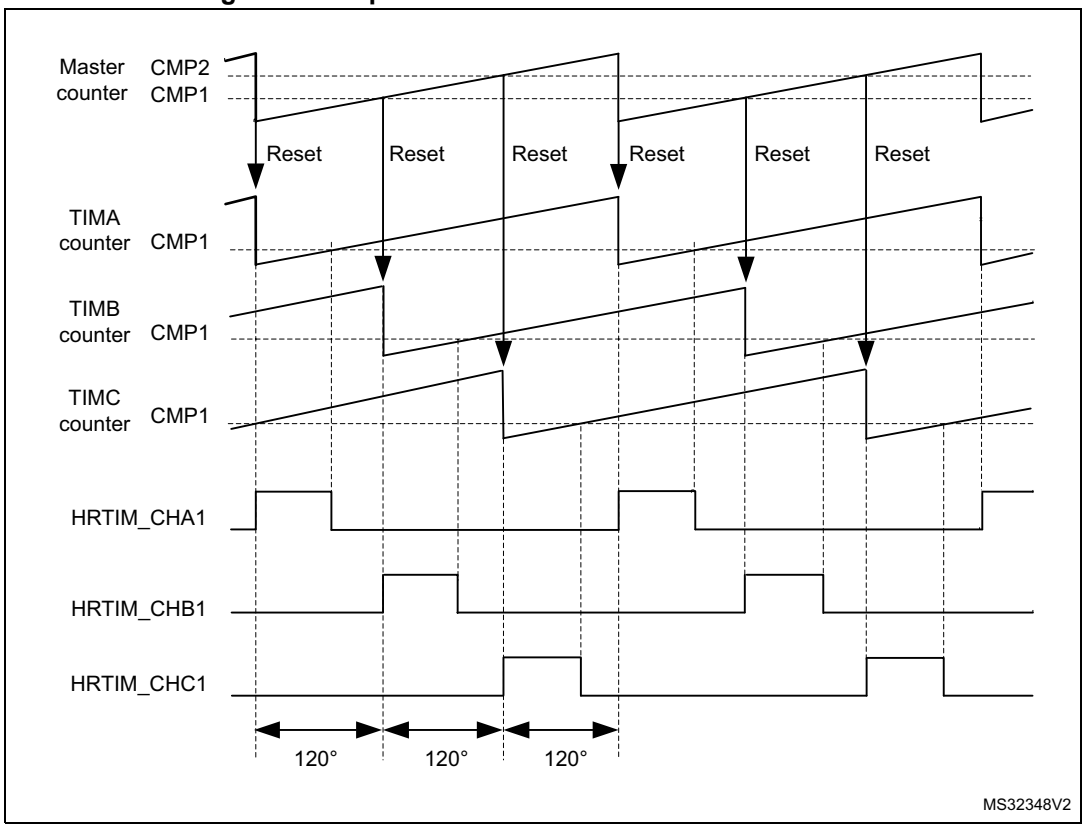
- Reduction of the current ripple on the input and output capacitors
- Reduced EMI
- Higher efficiency at light load by dynamically changing the number of phases (phase shedding)

The HRTIM manages multiple converters. The number of converters that can be controlled depends on the topologies and resources used (including the ADC triggers):

- Five buck converters with synchronous rectification (SR), using the master timer and the five timers
- Four buck converters (without SR), using the master timer and two timers

Figure 452 presents the topology of a 3-phase interleaved buck converter.

Figure 452. 3-phase interleaved buck converter



The master timer is responsible for the phase management: it defines the phase relationship between the converters by resetting the timers periodically. The phase-shift is 360° divided by the number of phases, 120° in the given example.

The duty cycle is then programmed into each of the timers. The outputs are defined as follows:

- HRTIM_CHA1 set on master timer period, reset on TACMP1
- HRTIM_CHB1 set on master timer MCMP1, reset on TBCMP1
- HRTIM_CHC1 set on master timer MCMP2, reset on TCCMP1

The ADC trigger can be generated on TxCMP2 compare event. Since all ADC trigger sources are phase-shifted because of the converter topology, it is possible to have all of them combined into a single ADC trigger to save ADC resources (for instance 1 ADC regular channel for the full multiphase converter).

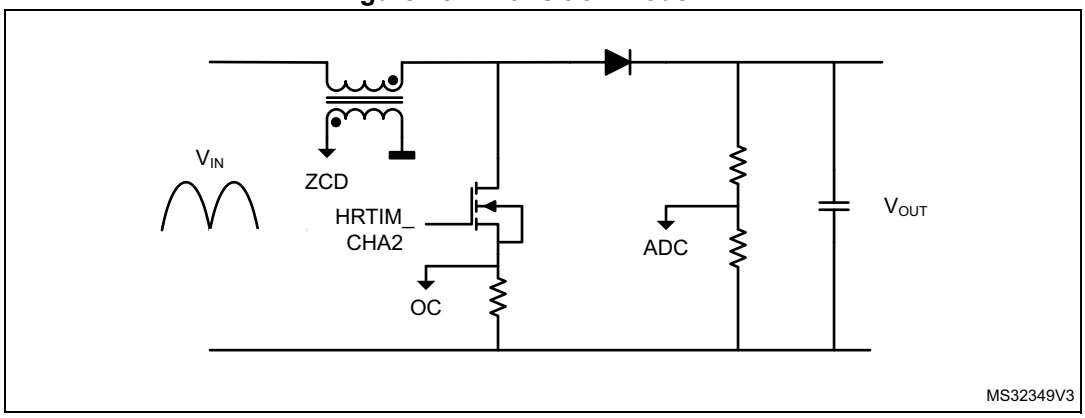


Figure 453. 3-phase interleaved buck converter control

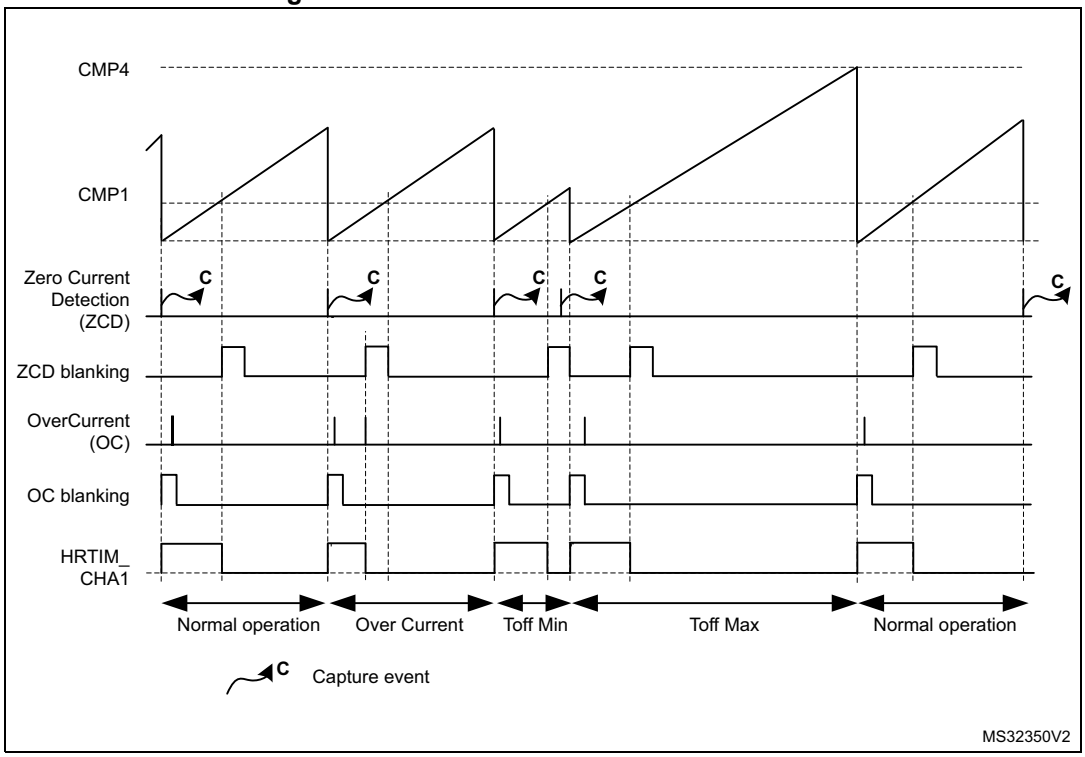
40.4.4 Transition mode power factor correction

The basic operating principle is to build up current into an inductor during a fixed Ton time. This current then decays during the Toff time, and the period is restarted when it becomes null. This is detected using a zero crossing detection circuitry (ZCD), as shown on *Figure 454*. With a constant Ton time, the peak current value in the inductor is proportional to the rectified AC input voltage, which provides the power factor correction.

Figure 454. Transition mode PFC

This converter operates with a constant Ton time and a variable frequency due to the Toff time variation (depending on the input voltage). It must also include some features to operate when no zero-crossing is detected, or to limit the Ton time in case of overcurrent



(OC). The OC feedback is usually conditioned with the built-in comparator and routed onto an external event input.

Figure 455 presents the waveform during the various operating modes, with the following defined parameters:

- Ton Min: masks spurious overcurrent (freewheeling diode recovery current), represented as OC blanking
- Ton Max: practically, the converter set-point. It is defined by CMP1
- Toff Min: limits the frequency when the current limit is close to zero (demagnetization is very fast). It is defined with CMP2.
- Toff Max: prevents the system to be stuck if no ZCD occurs. It is defined with CMP4 in autodelayed mode.

Both Toff values are autodelayed since the value must be relative to the output falling edge.

Figure 455. Transition mode PFC waveforms

40.5 HRTIM registers

40.5.1 HRTIM master timer control register (HRTIM_MCR)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BRSTDMA[1:0]		MREPU	Res.	PREEN	DACSYNC[1:0]		Res.	Res.	TFCEN	TECEN	TDCEN	TCCEN	TBCEN	TACEN	MCEN
rw	rw	rw		rw	rw	rw			rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
SYNCSRC[1:0]		SYNCOUT[1:0]		SYNCSTRTM	SYNCRSTM	SYNCIN[1:0]		INTLVD[1:0]		HALF	RETRIG	CONT	CKPSC[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 **BRSTDMA[1:0]**: Burst DMA update

These bits define how the update occurs relatively to a burst DMA transaction.

00: Update done independently from the DMA burst transfer completion

01: Update done when the DMA burst transfer is completed

10: Update done on master timer roll-over following a DMA burst transfer completion. This mode only works in continuous mode.

11: Reserved

Bit 29 **MREPU**: Master timer repetition update

This bit defines whether an update occurs when the master timer repetition period is completed (either due to roll-over or reset events). MREPU can be set only if BRSTDMA[1:0] = 00 or 01.

0: Update on repetition disabled

1: Update on repetition enabled

Bit 28 Reserved, must be kept at reset value.

Bit 27 **PREEN**: Preload enable

This bit enables the registers preload mechanism and defines whether the write accesses to the memory mapped registers are done into HRTIM's active or preload registers.

0: Preload disabled: the write access is directly done into the active register

1: Preload enabled: the write access is done into the preload register

Bits 26:25 **DACSYNC[1:0]:** DAC synchronization

A DAC synchronization event can be enabled and generated when the master timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to *Section 40.3.21: DAC triggers* for connections details).

00: No DAC trigger generated

01: Trigger generated on hrtim_dac_trg1

10: Trigger generated on hrtim_dac_trg2

11: Trigger generated on hrtim_dac_trg3

Bits 24:23 Reserved, must be kept at reset value.

Bit 22 **TFCEN**: Timer F counter enable

This bit starts the timer F counter.

0: Timer F counter disabled

1: Timer F counter enabled

Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 21 **TECEN**: Timer E counter enable
This bit starts the timer E counter.
0: Timer E counter disabled
1: Timer E counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 20 **TDCEN**: Timer D counter enable
This bit starts the timer D counter.
0: Timer D counter disabled
1: Timer D counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 19 **TCCEN**: Timer C counter enable
This bit starts the timer C counter.
0: Timer C counter disabled
1: Timer C counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 18 **TBCEN**: Timer B counter enable
This bit starts the timer B counter.
0: Timer B counter disabled
1: Timer B counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 17 **TACEN**: Timer A counter enable
This bit starts the timer A counter.
0: Timer A counter disabled
1: Timer A counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bit 16 **MCEN**: Master timer counter enable
This bit starts the master timer counter.
0: Master counter disabled
1: Master counter enabled
Note: This bit must not be changed within a minimum of 8 cycles of f_{HRTIM} clock.

Bits 15:14 **SYNCSRC[1:0]**: Synchronization source
These bits define the source and event to be sent on the synchronization outputs SYNCOUT[2:1]
00: Master timer start
01: Master timer compare 1 event
10: Timer A start/reset
11: Timer A compare 1 event

Bits 13:12 **SYNCOUT[1:0]**: Synchronization output
These bits define the routing and conditioning of the synchronization output event.
00: Disabled
01: Reserved
10: Positive pulse on HRTIM_SCOUT output (16x f_{HRTIM} clock cycles)
11: Negative pulse on HRTIM_SCOUT output (16x f_{HRTIM} clock cycles)
Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 11 **SYNCSTRTM**: Synchronization starts master
This bit enables the master timer start when receiving a synchronization input event:
0: No effect on the master timer
1: A synchronization input event starts the master timer

Bit 10 **SYNCRSTM**: Synchronization resets master

This bit enables the master timer reset when receiving a synchronization input event:

0: No effect on the master timer

1: A synchronization input event resets the master timer

Bits 9:8 **SYNCIN[1:0]**: Synchronization input

These bits are defining the synchronization input source.

00: Disabled. HRTIM is not synchronized and runs in standalone mode.

01: Reserved

10: Internal event on hrtim_in_sync[2]: the HRTIM is synchronized with the on-chip timer (see *Section : Synchronization input*).

11: External event on hrtim_in_sync[3]: a positive pulse on HRTIM_SCIN input triggers the HRTIM.

Note: This parameter cannot be changed once the impacted timers are enabled.

Bits 7:6 **INTLVD[1:0]**: Interleaved mode

This bitfield is significant only when the HALF bit is reset. It enables the interleaved mode.

00: Interleaved mode disabled

01: Triple interleaved mode: when HRTIM_MPER register is written, the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/3 value, and the HRTIM_MCMP2R active register is automatically updated with 2x (HRTIM_MPER/3) value.

10: Quad interleaved mode: when HRTIM_MPER register is written, the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/4 value, the HRTIM_MCMP2R active register is automatically updated with HRTIM_MPER/2 value and the HRTIM_MCMP3R active register is automatically updated with 3x (HRTIM_MPER/4) value.

11: Interleaved mode disabled

Bit 5 **HALF**: Half mode

This bit enables the half duty-cycle mode: the HRTIM_MCMP1R active register is automatically updated with HRTIM_MPER/2 value when HRTIM_MPER register is written.

0: Half mode disabled

1: Half mode enabled

Bit 4 **RETRIG**: Re-triggerable mode

This bit defines the behavior of the master timer counter in single-shot mode.

0: The timer is not re-triggerable: a counter reset can be done only if the counter is stopped (period elapsed)

1: The timer is re-triggerable: a counter reset is done whatever the counter state (running or stopped)

Bit 3 **CONT**: Continuous mode

0: The timer operates in single-shot mode and stops when it reaches the MPER value

1: The timer operates in continuous (free-running) mode and rolls over to zero when it reaches the MPER value

Bits 2:0 **CKPSC[2:0]**: Clock prescaler

These bits define the master timer high-resolution clock prescaler ratio.

The counter clock equivalent frequency ($f_{COUNTER}$) is equal to $f_{HRCK} / 2^{CKPSC[2:0]}$.

The prescaling ratio cannot be modified once the timer is enabled.

40.5.2 HRTIM master timer interrupt status register (HRTIM_MISR)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUPD	SYNC	MREP	MCMP 4	MCMP 3	MCMP 2	MCMP 1
									r	r	r	r	r	r	r

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **MUPD**: Master update interrupt flag
This bit is set by hardware when the master timer registers are updated.
0: No master update interrupt occurred
1: Master update interrupt occurred

Bit 5 **SYNC**: Sync input interrupt flag
This bit is set by hardware when a synchronization input event is received.
0: No sync input interrupt occurred
1: Sync input interrupt occurred

Bit 4 **MREP**: Master repetition interrupt flag
This bit is set by hardware when the master timer repetition period has elapsed.
0: No master repetition interrupt occurred
1: Master repetition interrupt occurred

Bit 3 **MCMP4**: Master compare 4 interrupt flag
Refer to MCMP1 description

Bit 2 **MCMP3**: Master compare 3 interrupt flag
Refer to MCMP1 description

Bit 1 **MCMP2**: Master compare 2 interrupt flag
Refer to MCMP1 description

Bit 0 **MCMP1**: Master compare 1 interrupt flag
This bit is set by hardware when the master timer counter matches the value programmed in the master compare 1 register.
0: No master compare 1 interrupt occurred
1: Master compare 1 interrupt occurred

40.5.3 HRTIM master timer interrupt clear register (HRTIM_MICR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUPDC	SYNCC	MREPC	MCMP4C	MCMP3C	MCMP2C	MCMP1C
									w	w	w	w	w	w	w

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **MUPDC**: Master update interrupt flag clear
Writing 1 to this bit clears the MUPDC flag in HRTIM_MISR register.

Bit 5 **SYNCC**: Sync input interrupt flag clear
Writing 1 to this bit clears the SYNC flag in HRTIM_MISR register.

Bit 4 **MREPC**: Repetition interrupt flag clear
Writing 1 to this bit clears the MREP flag in HRTIM_MISR register.

Bit 3 **MCMP4C**: Master compare 4 interrupt flag clear
Writing 1 to this bit clears the MCMP4 flag in HRTIM_MISR register.

Bit 2 **MCMP3C**: Master compare 3 interrupt flag clear
Writing 1 to this bit clears the MCMP3 flag in HRTIM_MISR register.

Bit 1 **MCMP2C**: Master compare 2 interrupt flag clear
Writing 1 to this bit clears the MCMP2 flag in HRTIM_MISR register.

Bit 0 **MCMP1C**: Master compare 1 interrupt flag clear
Writing 1 to this bit clears the MCMP1 flag in HRTIM_MISR register.

40.5.4 HRTIM master timer DMA interrupt enable register (HRTIM_MDIER)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUPDDE	SYNCDE	MREPDE	MCMP4DE	MCMP3DE	MCMP2DE	MCMP1DE
									rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MUPDIE	SYNCIE	MREPIE	MCMP4IE	MCMP3IE	MCMP2IE	MCMP1IE
									rw	rw	rw	rw	rw	rw	rw

Bits 31:23 Reserved, must be kept at reset value.

Bit 22 **MUPDDE**: Master update DMA request enable
This bit is set and cleared by software to enable/disable the master update DMA requests.
0: Master update DMA request disabled
1: Master update DMA request enabled

Bit 21 **SYNCDE**: Sync input DMA request enable
This bit is set and cleared by software to enable/disable the sync input DMA requests.
0: Sync input DMA request disabled
1: Sync input DMA request enabled

Bit 20 **MREPDE**: Master repetition DMA request enable
This bit is set and cleared by software to enable/disable the master timer repetition DMA requests.
0: Repetition DMA request disabled
1: Repetition DMA request enabled

Bit 19 **MCMP4DE**: Master compare 4 DMA request enable
Refer to MCMP1DE description

Bit 18 **MCMP3DE**: Master compare 3 DMA request enable
Refer to MCMP1DE description

Bit 17 **MCMP2DE**: Master compare 2 DMA request enable
Refer to MCMP1DE description

Bit 16 **MCMP1DE**: Master compare 1 DMA request enable
This bit is set and cleared by software to enable/disable the master timer compare 1 DMA requests.
0: Compare 1 DMA request disabled
1: Compare 1 DMA request enabled

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **MUPDIE**: Master update interrupt enable
This bit is set and cleared by software to enable/disable the master timer registers update interrupts
0: Master update interrupts disabled
1: Master update interrupts enabled

Bit 5 **SYNCIE**: Sync input interrupt enable
This bit is set and cleared by software to enable/disable the sync input interrupts
0: Sync input interrupts disabled
1: Sync input interrupts enabled

Bit 4 **MREPIE**: Master repetition interrupt enable
This bit is set and cleared by software to enable/disable the master timer repetition interrupts
0: Master repetition interrupt disabled
1: Master repetition interrupt enabled

Bit 3 **MCMP4IE**: Master compare 4 interrupt enable
Refer to MCMP1IE description

Bit 2 **MCMP3IE**: Master compare 3 interrupt enable
Refer to MCMP1IE description

Bit 1 **MCMP2IE**: Master compare 2 interrupt enable
Refer to MCMP1IE description

Bit 0 **MCMP1IE**: Master compare 1 interrupt enable
This bit is set and cleared by software to enable/disable the master timer compare 1 interrupt
0: Compare 1 interrupt disabled
1: Compare 1 interrupt enabled

40.5.5 HRTIM master timer counter register (HRTIM_MCNTR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCNT[15:0]**: Counter value

Holds the master timer counter value. This register can only be written when the master timer is stopped (MCEN = 0 in HRTIM_MCR).

Note: For HR clock prescaling ratio below 32 (CKPSCCKPSC[2:0] < 5), the least significant bits of the counter are not significant.

Note: The timer behavior is not guaranteed if the counter value is set above the HRTIM_MPER register value.

40.5.6 HRTIM master timer period register (HRTIM_MPER)

Address offset: 0x014

Reset value: 0x0000 FFDF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MPER[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MPER[15:0]**: Master timer period value

This register defines the counter overflow value.

The period value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

The maximum value is 0x0000 FFDF.

40.5.7 HRTIM master timer repetition register (HRTIM_MREP)

Address offset: 0x018

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MREP[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:8 Reserved, must be kept at reset value.

Bits 7:0 **MREP[7:0]**: Master timer repetition period value

This register holds the repetition period value for the master counter. It is either the preload register or the active register if preload is disabled.

40.5.8 HRTIM master timer compare 1 register (HRTIM_MCMP1R)

Address offset: 0x01C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCMP1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP1[15:0]**: Master timer compare 1 value

This register holds the master timer compare 1 value. It is either the preload register or the active register if preload is disabled.

The compare value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

40.5.9 HRTIM master timer compare 2 register (HRTIM_MCMP2R)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCMP2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP2[15:0]**: Master timer compare 2 value

This register holds the master timer compare 2 value. It is either the preload register or the active register if preload is disabled.

The compare value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

40.5.10 HRTIM master timer compare 3 register (HRTIM_MCMP3R)

Address offset: 0x028

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCMP3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP3[15:0]**: Master timer compare 3 value

This register holds the master timer compare 3 value. It is either the preload register or the active register if preload is disabled.

The compare value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

40.5.11 HRTIM master timer compare 4 register (HRTIM_MCMP4R)

Address offset: 0x02C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MCMP4[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **MCMP4[15:0]**: Master timer compare 4 value

This register holds the master timer compare 4 value. It is either the preload register or the active register if preload is disabled.

The compare value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

40.5.12 HRTIM timer x control register (HRTIM_TIMxCR) (x = A to F)

Address offset: Block A: 0x100

Address offset: Block B: 0x200

Address offset: Block C: 0x300

Address offset: Block D: 0x400

Address offset: Block E: 0x500

Address offset: Block F: 0x600

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UPDGAT[3:0]				PREEN	DACSYNC[1:0]		MSTU	TEU	TDU	TCU	TBU	TAU	TxRSTU	TxREPU	TFU
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DELCMP4[1:0]		DELCMP2[1:0]		SYNCSTRTx	SYNCRSTx	RSYNCU	INTLVD[1:0]		PSHPLL	HALF	RETRIG	CONT	CKPSCx[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 **UPDGAT[3:0]**: Update gating

These bits define how the update occurs relatively to the burst DMA transaction and the external update request on update enable inputs hrtim_upd_en[3:1] (see *Table 412*).

The update events, as mentioned below, can be: MSTU, TFU, TEU, TDU, TCU, TBU, TAU, TxRSTU, TxREPU.

0000: The update occurs independently from the DMA burst transfer

0001: The update occurs when the DMA burst transfer is completed

0010: The update occurs on the update event following the DMA burst transfer completion

0011: The update occurs on a rising edge on hrtim_upd_en1

0100: The update occurs on a rising edge on hrtim_upd_en2

0101: The update occurs on a rising edge on hrtim_upd_en3

0110: The update occurs on the update event following a rising edge on hrtim_upd_en1

0111: The update occurs on the update event following a rising edge on hrtim_upd_en2

1000: The update occurs on the update event following a rising edge on hrtim_upd_en3

Others: Reserved

Note: This bitfield must be reset before programming a new value.

For UPDGAT[3:0] values equal to 0001, 0011, 0100, 0101, it is possible to have multiple concurrent update source (for instance RSTU and DMA burst).

Bit 27 **PREEN**: Preload enable

This bit enables the registers preload mechanism and defines whether a write access into a preload-able register is done into the active or the preload register.

0: Preload disabled: the write access is directly done into the active register

1: Preload enabled: the write access is done into the preload register

Bits 26:25 **DACSYNC[1:0]**: DAC synchronization

A DAC synchronization event is generated when the timer update occurs. These bits are defining on which output the DAC synchronization is sent (refer to *Section 40.3.21: DAC triggers* for connections details).

00: No DAC trigger generated
01: Trigger generated on hrtim_dac_trg1
10: Trigger generated on hrtim_dac_trg2
11: Trigger generated on hrtim_dac_trg3

Bit 24 **MSTU**: Master timer update

Register update is triggered by the master timer update.
0: Update by master timer disabled
1: Update by master timer enabled

Bit 23 **TEU**: Timer E update

Register update is triggered by the timer E update
0: Update by timer E disabled
1: Update by timer E enabled

Note: This bit is reserved for HRTIM_TIMECR. *It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMFCR.*

Bit 22 **TDU**: Timer D update

Register update is triggered by the timer D update
0: Update by timer D disabled
1: Update by timer D enabled

Note: This bit is reserved for HRTIM_TIMDCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMECR, HRTIM_TIMFCR.

Bit 21 **TCU**: Timer C update

Register update is triggered by the timer C update
0: Update by timer C disabled
1: Update by timer C enabled

Note: This bit is reserved for HRTIM_TIMCCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMDCR, HRTIM_TIMECR, HRTIM_TIMFCR.

Bit 20 **TBU**: Timer B update

Register update is triggered by the timer B update
0: Update by timer B disabled
1: Update by timer B enabled

Note: This bit is reserved for HRTIM_TIMBCR. It is only available for HRTIM_TIMACR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR, HRTIM_TIMFCR.

Bit 19 **TAU**: Timer A update

Register update is triggered by the timer A update
0: Update by timer A disabled
1: Update by timer A enabled

Note: This bit is reserved for HRTIM_TIMBCR. It is only available for HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR, HRTIM_TIMFCR.

Bit 18 **TxRSTU**: Timer x reset update

Register update is triggered by timer x counter reset or roll-over to 0 after reaching the period value in continuous mode.
0: Update by timer x reset / roll-over disabled
1: Update by timer x reset / roll-over enabled

Bit 17 **TxREPU**: Timer x repetition update

Register update is triggered when the counter rolls over and HRTIM_REPx = 0

0: Update on repetition disabled

1: Update on repetition enabled

Bit 16 **TFU**: Timer F update

Register update is triggered by the timer F update

0: Update by timer F disabled

1: Update by timer F enabled

Note: This bit is reserved for HRTIM_TIMFCR. It is only available for HRTIM_TIMACR, HRTIM_TIMBCR, HRTIM_TIMCCR, HRTIM_TIMDCR, HRTIM_TIMECR.

Bits 15:14 **DELCMP4[1:0]**: CMP4 auto-delayed mode

This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see *Section : Autodelayed mode*).

00: CMP4 register is always active (standard compare mode)

01: CMP4 value is recomputed and is active following a capture 2 event

10: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 1 match (timeout function if capture 2 event is missing)

11: CMP4 value is recomputed and is active following a capture 2 event, or is recomputed and active after Compare 3 match (timeout function if capture event is missing)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bits 13:12 **DELCMP2[1:0]**: CMP2 auto-delayed mode

This bitfield defines whether the compare register is behaving in standard mode (compare match issued as soon as counter equal compare), or in auto-delayed mode (see *Section : Autodelayed mode*).

00: CMP2 register is always active (standard compare mode)

01: CMP2 value is recomputed and is active following a capture 1 event

10: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after compare 1 match (timeout function if capture event is missing)

11: CMP2 value is recomputed and is active following a capture 1 event, or is recomputed and active after compare 3 match (timeout function if capture event is missing)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 11 **SYNCSTRTx**: Synchronization starts timer x

This bit defines the timer x behavior following the synchronization event:

0: No effect on timer x

1: A synchronization input event starts the timer x

Bit 10 **SYNCRSTx**: Synchronization resets timer x

This bit defines the timer x behavior following the synchronization event:

0: No effect on timer x

1: A synchronization input event resets the timer x

Bit 9 **RSYNCU**: Re-synchronized update

This bit specifies whether update source coming outside from the timing unit must be synchronized:

0: The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) is taken into account immediately

1: The update coming from adjacent timers (when MSTU, TAU, TBU, TCU, TDU, TEU, TFU bit is set) or from a software update (TxSWU bit) is taken into account on the following reset/roll-over event.

Note: This bit is significant only when UPDGAT[3:0] = 0000, it is ignored otherwise.

Bits 8:7 **INTLVD[1:0]**: Interleaved mode

This bitfield is significant only when the HALF bit is reset. It enables the interleaved mode.

00: Interleaved mode disabled

01: Triple interleaved mode: when HRTIM_PERxR register is written, the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/3 value, and the HRTIM_CMP2xR active register is automatically updated with 2x (HRTIM_PERxR/3) value.

10: Quad interleaved mode: when HRTIM_PERxR register is written, the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/4 value, the HRTIM_CMP2xR active register is automatically updated with HRTIM_PERxR/2 value and the HRTIM_CMP3xR active register is automatically updated with 3x (HRTIM_PERxR/4) value.

11: Interleaved mode disabled

Bit 6 **PSHPLL**: Push-pull mode enable

This bit enables the push-pull mode.

0: Push-pull mode disabled

1: Push-pull mode enabled

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 5 **HALF**: Half mode enable

This bit enables the half duty-cycle mode: the HRTIM_CMP1xR active register is automatically updated with HRTIM_PERxR/2 value when HRTIM_PERxR register is written.

0: Half mode disabled

1: Half mode enabled

Bit 4 **RETRIG**: Re-triggerable mode

This bit defines the counter behavior in single shot mode.

0: The timer is not re-triggerable: a counter reset is done if the counter is stopped (period elapsed in single-shot mode or counter stopped in continuous mode)

1: The timer is re-triggerable: a counter reset is done whatever the counter state.

Bit 3 **CONT**: Continuous mode

This bit defines the timer operating mode.

0: The timer operates in single-shot mode and stops when it reaches TIMxPER value

1: The timer operates in continuous mode and rolls over to zero when it reaches TIMxPER value

Bits 2:0 **CKPSCx[2:0]**: HRTIM timer x clock prescaler

These bits define the master timer high-resolution clock prescaler ratio.

The counter clock equivalent frequency ($f_{COUNTER}$) is equal to $f_{HRCK} / 2^{CKPSC[2:0]}$.

The prescaling ratio cannot be modified once the timer is enabled.

40.5.13 HRTIM timer x interrupt status register (HRTIM_TIMxISR) (x = A to F)

Address offset: Block A: 0x104

Address offset: Block B: 0x204

Address offset: Block C: 0x304

Address offset: Block D: 0x404

Address offset: Block E: 0x504

Address offset: Block F: 0x604

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	COTS	COS	O2CPY	O1CPY	O2STAT	O1STAT	IPPSTAT	CPPSTAT
								r	r	r	r	r	r	r	r
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CORDE	DLYPRT	RST	RSTx2	SETx2	RSTx1	SETx1	CPT2	CPT1	UPD	COT	REP	CMP4	CMP3	CMP2	CMP1
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **COTS**: Crossbar Override Trigger status

This status bit is a raw copy of the crossbar override trigger input. It can be polled to verify if the crossbar override mode can be rearmed

0: Crossbar Override trigger is inactive

1: Crossbar Override trigger is active

Bit 22 **COS**: Crossbar Override status

This status bit indicates the crossbar override status.

0: Crossbar Override is inactive (crossbar is active)

1: Crossbar Override is active

Bit 21 **O2CPY**: Output 2 copy

This status bit is a raw copy of the output 2 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.

0: Output 2 is inactive

1: Output 2 is active

Bit 20 **O1CPY**: Output 1 copy

This status bit is a raw copy of the output 1 state, before the output stage (chopper, polarity). It allows to check the current output state before re-enabling the output after a delayed protection.

0: Output 1 is inactive

1: Output 1 is active

Bit 19 **O2STAT**: Output 2 status

This status bit indicates the output 2 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.

0: Output 2 was inactive

1: Output 2 was active

Bit 18 **O1STAT**: Output 1 status

This status bit indicates the output 1 state when the delayed idle protection was triggered. This bit is updated upon any new delayed protection entry. This bit is not updated in balanced idle.

0: Output 1 was inactive

1: Output 1 was active

Bit 17 **IPPSTAT**: Idle push-pull Status

This status bit indicates on which output the signal was applied, in push-pull mode balanced fault mode or delayed idle mode, when the protection was triggered (whatever the output state, active or inactive).

0: Protection occurred when the output 1 was active and output 2 forced inactive

1: Protection occurred when the output 2 was active and output 1 forced inactive

Bit 16 **CPPSTAT**: Current push-pull status

This status bit indicates on which output the signal is currently applied, in push-pull mode. It is only significant in this configuration.

0: Signal applied on output 1 and output 2 forced inactive

1: Signal applied on output 2 and output 1 forced inactive

Bit 15 **CORDE**: Crossbar Override Rearm Delay Elapsed flag

This bit is set when the crossbar override mode can be rearmed. This interrupt flag is asserted when at least on of the one of the 2 channels is configured to Delayed fault force modes (COFMx[2:0] = 000 and 001).

0: No Crossbar override rearm delay elapsed interrupt occurred

1: Crossbar override rearm delay elapsed interrupt occurred

Bit 14 **DLYPRT**: Delayed protection flag

0: No delayed protection interrupt occured

1: Delayed Idle or balanced Idle mode entry occured

Bit 13 **RST**: Reset and/or roll-over interrupt flag

This bit is set by hardware when the timer x counter is reset or rolls over in continuous mode.

0: No TIMx counter reset/roll-over interrupt occurred

1: TIMX counter reset/roll-over interrupt occurred

Bit 12 **RSTx2**: Output 2 reset interrupt flag timer x

Refer to RSTx1 description

Bit 11 **SETx2**: Output 2 set interrupt flag timer x

Refer to SETx1 description

Bit 10 **RSTx1**: Output 1 reset interrupt flag timer x

This bit is set by hardware when the Tx1 output is reset (goes from active to inactive mode).

0: No Tx1 output reset interrupt occurred

1: Tx1 output reset interrupt occurred

Bit 9 **SETx1**: Output 1 set interrupt flag timer x

This bit is set by hardware when the Tx1 output is set (goes from inactive to active mode).

0: No Tx1 output set interrupt occurred

1: Tx1 output set interrupt occurred

Bit 8 **CPT2**: Capture 2 interrupt flag

Refer to CPT1 description

Bit 7 **CPT1**: Capture 1 interrupt flag

This bit is set by hardware when the timer x capture 1 event occurs.

0: No timer x capture 1 interrupt occurred

1: Timer x capture 1 interrupt occurred

Bit 6 **UPD**: Update interrupt flag
This bit is set by hardware when the timer x update event occurs.
0: No timer x update interrupt occurred
1: Timer x update interrupt occurred

Bit 5 **COT**: Crossbar Override Trigger flag
This bit is set when the crossbar override mode is triggered.
0: No Crossbar override trigger interrupt occurred
1: Crossbar override trigger interrupt occured

Bit 4 **REP**: Repetition interrupt flag
This bit is set by hardware when the timer x repetition period has elapsed.
0: No timer x repetition interrupt occurred
1: Timer x repetition interrupt occurred

Bit 3 **CMP4**: Compare 4 interrupt flag
Refer to CMP1 description

Bit 2 **CMP3**: Compare 3 interrupt flag
Refer to CMP1 description

Bit 1 **CMP2**: Compare 2 interrupt flag
Refer to CMP1 description

Bit 0 **CMP1**: Compare 1 interrupt flag
This bit is set by hardware when the timer x counter matches the value programmed in the compare 1 register.
0: No compare 1 interrupt occurred
1: Compare 1 interrupt occurred

40.5.14 HRTIM timer x interrupt clear register (HRTIM_TIMxICR) (x = A to F)

Address offset: Block A: 0x108

Address offset: Block B: 0x208

Address offset: Block C: 0x308

Address offset: Block D: 0x408

Address offset: Block E: 0x508

Address offset: Block F: 0x608

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **CORDEC**: Crossbar Override Rearm Delay Elapsed flag clear
Writing 1 to this bit clears the CORDE flag in HRTIM_TIMxISR register

Bit 14 **DLYPRTC**: Delayed protection flag clear
Writing 1 to this bit clears the DLYPRT flag in HRTIM_TIMxISR register

Bit 13 **RSTC**: Reset interrupt flag clear
Writing 1 to this bit clears the RST flag in HRTIM_TIMxISR register

Bit 12 **RSTx2C**: Output 2 reset flag clear timer x
Writing 1 to this bit clears the RSTx2 flag in HRTIM_TIMxISR register

Bit 11 **SETx2C**: Output 2 set flag clear timer x
Writing 1 to this bit clears the SETx2 flag in HRTIM_TIMxISR register

Bit 10 **RSTx1C**: Output 1 reset flag clear timer x
Writing 1 to this bit clears the RSTx1 flag in HRTIM_TIMxISR register

Bit 9 **SETx1C**: Output 1 set flag clear timer x
Writing 1 to this bit clears the SETx1 flag in HRTIM_TIMxISR register

Bit 8 **CPT2C**: Capture 2 interrupt flag clear
Writing 1 to this bit clears the CPT2 flag in HRTIM_TIMxISR register

Bit 7 **CPT1C**: Capture 1 interrupt flag clear
Writing 1 to this bit clears the CPT1 flag in HRTIM_TIMxISR register

Bit 6 **UPDC**: Update interrupt flag clear
Writing 1 to this bit clears the UPD flag in HRTIM_TIMxISR register

Bit 5 **COTC**: Crossbar Override Trigger flag clear
Writing 1 to this bit clears the COT flag in HRTIM_TIMxISR register

Bit 4 **REPC**: Repetition interrupt flag clear
Writing 1 to this bit clears the REP flag in HRTIM_TIMxISR register

Bit 3 **CMP4C**: Compare 4 interrupt flag clear
Writing 1 to this bit clears the CMP4 flag in HRTIM_TIMxISR register

Bit 2 **CMP3C**: Compare 3 interrupt flag clear
Writing 1 to this bit clears the CMP3 flag in HRTIM_TIMxISR register

Bit 1 **CMP2C**: Compare 2 interrupt flag clear
Writing 1 to this bit clears the CMP2 flag in HRTIM_TIMxISR register

Bit 0 **CMP1C**: Compare 1 interrupt flag clear
Writing 1 to this bit clears the CMP1 flag in HRTIM_TIMxISR register

40.5.15 HRTIM timer x DMA interrupt enable register (HRTIM_TIMxDIER) (x = A to F)

Address offset: Block A: 0x10C

Address offset: Block B: 0x20C

Address offset: Block C: 0x30C

Address offset: Block D: 0x40C

Address offset: Block E: 0x50C

Address offset: Block F: 0x60C

Bit 31 **CORDEDE**: Crossbar override rearm delay elapsed DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on Crossbar override rearm delay elapsed event.
0: Crossbar override rearm delay elapsed DMA request disabled
1: Crossbar override rearm delay elapsed DMA request enabled

Bit 30 **DLYPRTDE**: Delayed protection DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on delayed protection.
0: Delayed protection DMA request disabled
1: Delayed protection DMA request enabled

Bit 29 **RSTDE**: Reset/roll-over DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on timer x counter reset or roll-over in continuous mode.
0: Timer x counter reset/roll-over DMA request disabled
1: Timer x counter reset/roll-over DMA request enabled

Bit 28 **RSTx2DE**: Output 2 reset DMA request enable timer x
Refer to RSTx1DE description

Bit 27 **SETx2DE**: Output 2 set DMA request enable timer x
Refer to SETx1DE description

Bit 26 **RSTx1DE**: Output 1 reset DMA request enable timer x
This bit is set and cleared by software to enable/disable Tx1 output reset DMA requests.
0: Tx1 output reset DMA request disabled
1: Tx1 output reset DMA request enabled

Bit 25 **SETx1DE**: Output 1 set DMA request enable timer x
This bit is set and cleared by software to enable/disable Tx1 output set DMA requests.
0: Tx1 output set DMA request disabled
1: Tx1 output set DMA request enabled

Bit 24 **CPT2DE**: Capture 2 DMA request enable
Refer to CPT1DE description

Bit 23 **CPT1DE**: Capture 1 DMA request enable
This bit is set and cleared by software to enable/disable capture 1 DMA requests.
0: Capture 1 DMA request disabled
1: Capture 1 DMA request enabled

Bit 22 **UPDDE**: Update DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on update event.
0: Update DMA request disabled
1: Update DMA request enabled

Bit 21 **COTDE**: Crossbar Override Trigger DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on Crossbar Override Trigger event.
0: Crossbar Override Trigger DMA request disabled
1: Crossbar Override Trigger DMA request enabled

Bit 20 **REPDE**: Repetition DMA request enable
This bit is set and cleared by software to enable/disable DMA requests on repetition event.
0: Repetition DMA request disabled
1: Repetition DMA request enabled

Bit 19 **CMP4DE**: Compare 4 DMA request enable
Refer to CMP1DE description

Bit 18 **CMP3DE**: Compare 3 DMA request enable
Refer to CMP1DE description

Bit 17 **CMP2DE**: Compare 2 DMA request enable
Refer to CMP1DE description

Bit 16 **CMP1DE**: Compare 1 DMA request enable
This bit is set and cleared by software to enable/disable the compare 1 DMA requests.
0: Compare 1 DMA request disabled
1: Compare 1 DMA request enabled

Bit 15 **CORDEIE**: Crossbar override rearm delay elapsed interrupt enable
This bit is set and cleared by software to enable/disable interrupts on Crossbar override rearm delay elapsed event.
0: Crossbar override rearm delay elapsed interrupts disabled
1: Crossbar override rearm delay elapsed interrupts enabled

Bit 14 **DLYPRTIE**: Delayed protection interrupt enable
This bit is set and cleared by software to enable/disable interrupts on delayed protection.
0: Delayed protection interrupts disabled
1: Delayed protection interrupts enabled

Bit 13 **RSTIE**: Reset/roll-over interrupt enable
This bit is set and cleared by software to enable/disable interrupts on timer x counter reset or roll-over in continuous mode.
0: Timer x counter reset/roll-over interrupt disabled
1: Timer x counter reset/roll-over interrupt enabled

Bit 12 **RSTx2IE**: Output 2 reset interrupt enable timer x
Refer to RSTx1IE description

Bit 11 **SETx2IE**: Output 2 set interrupt enable timer x
Refer to SETx1IE description

Bit 10 **RSTx1IE**: Output 1 reset interrupt enable timer x
This bit is set and cleared by software to enable/disable Tx1 output reset interrupts.
0: Tx1 output reset interrupts disabled
1: Tx1 output reset interrupts enabled

Bit 9 **SETx1IE**: Output 1 set interrupt enable timer x
This bit is set and cleared by software to enable/disable Tx1 output set interrupts.
0: Tx1 output set interrupts disabled
1: Tx1 output set interrupts enabled

Bit 8 **CPT2IE**: Capture interrupt enable
Refer to CPT1IE description

Bit 7 **CPT1IE**: Capture interrupt enable
This bit is set and cleared by software to enable/disable capture 1 interrupts.
0: Capture 1 interrupts disabled
1: Capture 1 interrupts enabled

Bit 6 **UPDIE**: Update interrupt enable
This bit is set and cleared by software to enable/disable update event interrupts.
0: Update interrupts disabled
1: Update interrupts enabled

Bit 5 **COTIE**: Crossbar Override Trigger interrupt enable
This bit is set and cleared by software to enable/disable Crossbar Override Trigger interrupts.
0: Crossbar Override Trigger interrupts disabled
1: Crossbar Override Trigger enabled

Bit 4 **REPIE**: Repetition interrupt enable
This bit is set and cleared by software to enable/disable repetition event interrupts.
0: Repetition interrupts disabled
1: Repetition interrupts enabled

Bit 3 **CMP4IE**: Compare 4 interrupt enable
Refer to CMP1IE description

Bit 2 **CMP3IE**: Compare 3 interrupt enable
Refer to CMP1IE description

Bit 1 **CMP2IE**: Compare 2 interrupt enable
Refer to CMP1IE description

Bit 0 **CMP1IE**: Compare 1 interrupt enable
This bit is set and cleared by software to enable/disable the compare 1 interrupts.
0: Compare 1 interrupt disabled
1: Compare 1 interrupt enabled

40.5.16 HRTIM timer x counter register (HRTIM_CNTxR) (x = A to F)

Address offset: Block A: 0x110

Address offset: Block B: 0x210

Address offset: Block C: 0x310

Address offset: Block D: 0x410

Address offset: Block E: 0x510

Address offset: Block F: 0x610

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

CNTx[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CNTx[15:0]**: Timer x counter value

This register holds the timer x counter value. It can only be written when the timer is stopped (TxCEN = 0 in HRTIM_TIMxCR).

Note: For HR clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be written and return 0 when read.

Note: The timer behavior is not guaranteed if the counter value is above the HRTIM_PERxR register value.

40.5.17 HRTIM timer x period register (HRTIM_PERxR) (x = A to F)

Address offset: Block A: 0x114

Address offset: Block B: 0x214

Address offset: Block C: 0x314

Address offset: Block D: 0x414

Address offset: Block E: 0x514

Address offset: Block F: 0x614

Reset value: 0x0000 FFDF

PERx[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **PERx[15:0]**: Timer x period value

This register holds timer x period value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The period value must be above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

The maximum value is 0x0000 FFDF.

40.5.18 HRTIM timer x repetition register (HRTIM_REPxR) (x = A to F)

Address offset: Block A: 0x118

Address offset: Block B: 0x218

Address offset: Block C: 0x318

Address offset: Block D: 0x418

Address offset: Block E: 0x518

Address offset: Block F: 0x618

Reset value: 0x0000 0000

CMP1x[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP1x[15:0]**: Timer x compare 1 value

This register holds the compare 1 value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The compare value must be either null or above or equal to 3 periods of the f_{HRTIM} clock, that is 0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...

The null value is programmed following the use case described in *Section : Null duty cycle exception case*.

40.5.20 HRTIM timer x compare 1 compound register (HRTIM_CMP1CxR) (x = A to F)

Address offset: Block A: 0x120

Address offset: Block B: 0x220

Address offset: Block C: 0x320

Address offset: Block D: 0x420

Address offset: Block E: 0x520

Address offset: Block F: 0x620

Reset value: 0x0000 0000

CMP1x[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **REPx[7:0]**: Timer x repetition value aliased from HRTIM_REPx register
This bitfield is an alias from the REPx[7:0] bitfield in the HRTIMx_REPxR register.

Bits 15:0 **CMP1x[15:0]**: Timer x compare 1 value
This bitfield is an alias from the CMP1x[15:0] bitfield in the HRTIMx_CMP1xR register.

40.5.21 HRTIM timer x compare 2 register (HRTIM_CMP2xR) (x = A to F)

Address offset: Block A: 0x124

Address offset: Block B: 0x224

Address offset: Block C: 0x324

Address offset: Block D: 0x424

Address offset: Block E: 0x524

Address offset: Block F: 0x624

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CMP2x[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP2x[15:0]**: Timer x compare 2 value

This register holds the compare 2 value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The compare value must be either null or above or equal to 3 periods of the f_{HRTIM} clock (0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...).

The null value is programmed following the use case described in *Section : Null duty cycle exception case*.

This register behaves as an auto-delayed compare register, if enabled with DELCMP2[1:0] bits in HRTIM_TIMxCR. In this case, the compare value must be strictly above or equal to 3 periods of the f_{HRTIM} clock.

40.5.22 HRTIM timer x compare 3 register (HRTIM_CMP3xR) (x = A to F)

Address offset: Block A: 0x128

Address offset: Block B: 0x228

Address offset: Block C: 0x328

Address offset: Block D: 0x428

Address offset: Block E: 0x528

Address offset: Block F: 0x628

Reset value: 0x0000 0000

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP3x[15:0]**: Timer x compare 3 value

This register holds the compare 3 value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The compare value must be either null or above or equal to 3 periods of the f_{HRTIM} clock (0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...).

The null value is programmed following the use case described in *Section : Null duty cycle exception case*.

40.5.23 HRTIM timer x compare 4 register (HRTIM_CMP4xR) (x = A to F)

Address offset: Block A: 0x12C

Address offset: Block B: 0x22C

Address offset: Block C: 0x32C

Address offset: Block D: 0x42C

Address offset: Block E: 0x52C

CMP4x[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **CMP4x[15:0]**: Timer x compare 4 value

This register holds the compare 4 value.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

The compare value must be either null or above or equal to 3 periods of the f_{HRTIM} clock (0x60 if CKPSC[2:0] = 0, 0x30 if CKPSC[2:0] = 1, 0x18 if CKPSC[2:0] = 2,...).

The null value is programmed following the use case described in *Section : Null duty cycle exception case*.

This register can behave as an auto-delayed compare register, if enabled with DELCMP4[1:0] bits in HRTIM_TIMxCR. In this case, the compare value must be strictly above or equal to 3 periods of the f_{HRTIM} clock.

40.5.24 HRTIM timer x capture 1 register (HRTIM_CPT1xR) (x = A to F)

Address offset: Block A: 0x130

Address offset: Block B: 0x230

Address offset: Block C: 0x330

Address offset: Block D: 0x430

Address offset: Block E: 0x530

Address offset: Block F: 0x630

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIR
															r

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CPT1x[15:0]															
r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DIR**: Timer x capture 1 direction status
This register holds the counting direction value when the capture 1 event occurred:
0: timer is up-counting
1: timer is down-counting
In up-counting mode (UDM bit reset), the DIR bit is always read as 0.

Bits 15:0 **CPT1x[15:0]**: Timer x capture 1 value
This register holds the counter value when the capture 1 event occurred.

Note: In up/down mode (UDM bit set to 1), the capture value is referred to:
- counting reset, when up-counting
- the PER event when down counting
The DIR bit is used to discriminate the up-down phases when reading the captured value.

Note: This is a regular resolution register: for HR clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be written and return 0 when read.

40.5.25 HRTIM timer x capture 2 register (HRTIM_CPT2xR) (x = A to F)

Address offset: Block A: 0x134

Address offset: Block B: 0x234

Address offset: Block C: 0x334

Address offset: Block D: 0x434

Address offset: Block E: 0x534

Address offset: Block F: 0x634

Reset value: 0x0000 0000

r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:17 Reserved, must be kept at reset value.

Bit 16 **DIR**: Timer x capture 1 direction status
This register holds the counting direction value when the capture 1 event occurred:
0: timer is up-counting
1: timer is down-counting
In up-counting mode (UDM bit reset), the DIR bit is always read as 0.

Bits 15:0 **CPT2x[15:0]**: Timer x capture 2 value
This register holds the counter value when the capture 2 event occurred.

Note: In up/down mode (UDM bit set to 1), the capture value is referred to:
- counting reset, when up-counting
- the PER event when down counting

The DIR bit is used to discriminate the up-down phases when reading the captured value.

Note: This is a regular resolution register: for HR clock prescaling ratio below 32 (CKPSC[2:0] < 5), the least significant bits of the counter are not significant. They cannot be written and return 0 when read.

40.5.26 HRTIM timer x deadtime register (HRTIM_DTxR) (x = A to F)

Address offset: Block A: 0x138

Address offset: Block B: 0x238

Address offset: Block C: 0x338

Address offset: Block D: 0x438

Address offset: Block E: 0x538

Address offset: Block F: 0x638

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DTFLKx	DTFSLKx	Res.	Res.	DTM[1:0]		SDTFx	DTFx[8:0]								
rwo	rwo			rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DTRLKx	DTRSLKx	Res.	DTPRSC[2:0]			SDTRx	DTRx[8:0]								
rwo	rwo		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **DTFLKx**: Deadtime falling lock timer x

This write-once bit prevents the deadtime (sign and value) to be modified, if enabled.

0: Deadtime falling value and sign is writable

1: Deadtime falling value and sign is read-only

Note: This bit is not preloaded

Bit 30 **DTFSLKx**: Deadtime falling sign lock timer x

This write-once bit prevents the sign of falling deadtime to be modified, if enabled.

0: Deadtime falling sign is writable

1: Deadtime falling sign is read-only

Note: This bit is not preloaded.

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:26 **DTM[1:0]**: Deadtime mode

This bitfield defines the deadtime module behavior.

00: Deadtime complementary mode

01: Deadtime insertion mode

10: Deadtime insertion and disarm mode

11: Reserved. Writing 11 is discarded, and the DTM[1:0] value is maintained at its previous value.

Bit 25 **SDTFx**: Sign deadtime falling value timer x

This register determines whether the deadtime is positive (signals not overlapping) or negative (signals overlapping).

0: Positive deadtime on falling edge

1: Negative deadtime on falling edge

Bits 24:16 **DTFx[8:0]**: Deadtime falling value timer x

This register holds the value of the deadtime following a falling edge of reference PWM signal.

t_{DTF} = DTFx[8:0] x t_{DTG}

Bit 15 **DTRLKx**: Deadtime rising lock timer x
This write-once bit prevents the deadtime (sign and value) to be modified, if enabled.
0: Deadtime rising value and sign is writable
1: Deadtime rising value and sign is read-only
Note: This bit is not preloaded.

Bit 14 **DTRSLKx**: Deadtime rising sign lock timer x
This write-once bit prevents the sign of deadtime to be modified, if enabled.
0: Deadtime rising sign is writable
1: Deadtime rising sign is read-only
Note: This bit is not preloaded.

Bit 13 Reserved, must be kept at reset value.

Bits 12:10 **DTPRSC[2:0]**: Deadtime prescaler
This register holds the value of the deadtime clock prescaler determined by the following formula:
$t_{DTG} = (2^{(DTPRSC[2:0])}) \times (t_{HRTIM} / 8)$
(see *Table 425: Deadtime resolution and max absolute values*)
This bitfield is read-only as soon as any of the lock bit is enabled (DTFLKs, DTFSLKx, DTRLKx, DTRSLKx).

Bit 9 **SDTRx**: Sign deadtime rising value timer x
This register determines whether the deadtime is positive or negative (overlapping signals).
0: Positive deadtime on rising edge
1: Negative deadtime on rising edge

Bits 8:0 **DTRx[8:0]**: Deadtime rising value timer x
This register holds the value of the deadtime following a rising edge of reference PWM signal.
$t_{DTR} = DTRx[8:0] \times t_{DTG}$

40.5.27 HRTIM timer x output 1 set register (HRTIM_SETx1R) (x = A to F)

Address offset: Block A: 0x13C

Address offset: Block B: 0x23C

Address offset: Block C: 0x33C

Address offset: Block D: 0x43C

Address offset: Block E: 0x53C

Address offset: Block F: 0x63C

Reset value: 0x0000 0000

Bit 31 **UPDATE**: Registers update (transfer from preload register to active register)
Register update event forces the output to its active state.

Bit 30 **EXTEVNTJ**: External event J
External event J forces the output to its active state.

Bit 29 **EXTEVNTI**: External event I
External event I forces the output to its active state.

Bit 28 **EXTEVNTH**: External event H
External event H forces the output to its active state.

Bit 27 **EXTEVNTG**: External event G
External event G forces the output to its active state.

Bit 26 **EXTEVNTF**: External event F
External event F forces the output to its active state.

Bit 25 **EXTEVNTE**: External event E
External event E forces the output to its active state.

Bit 24 **EXTEVNTD**: External event D
External event D forces the output to its active state.

Bit 23 **EXTEVNTC**: External event C
External event C forces the output to its active state.

Bit 22 **EXTEVNTB**: External event B
External event B forces the output to its active state.

Bit 21 **EXTEVNTA**: External event A
External event A forces the output to its active state.

Bit 20 **TIMEVNT9**: Timer event 9
Timers event 9 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 19 **TIMEVNT8**: Timer event 8
Timers event 8 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 18 **TIMEVNT7**: Timer event 7
Timers event 7 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 17 **TIMEVNT6**: Timer event 6
Timers event 6 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 16 **TIMEVNT5**: Timer event 5
Timers event 5 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 15 **TIMEVNT4**: Timer event 4
Timers event 4 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 14 **TIMEVNT3**: Timer event 3
Timers event 3 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 13 **TIMEVNT2**: Timer event 2
Timers event 2 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 12 **TIMEVNT1**:Timer event 1
Timers event 1 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4
Master timer compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3**: Master compare 3
Master timer compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2**: Master compare 2
Master timer compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1**: Master compare 1
Master timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER**: Master period
The master timer counter period event (continuous mode), or the master timer counter reset (continous or single-shot mode), forces the output to its active state.

Bit 6 **CMP4**: Timer x compare 4
Timer A compare 4 event forces the output to its active state.

Bit 5 **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its active state.

Bit 2 **PER**: Timer x period

Timer A period event forces the output to its active state.

Note: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

Bit 1 **RESYNC:** Timer A resynchronization

Timer A reset event coming solely from software or SYNC input forces the output to its active state.

Note: Other timer reset are not affecting the output when RESYNC=1.

Bit 0 **SST**: Software set trigger

This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.

Note: This bit is not preloaded.

40.5.28 HRTIM timer x output 1 reset register (HRTIM_RSTx1R) (x = A to F)

Address offset: Block A: 0x140

Address offset: Block B: 0x240

Address offset: Block C: 0x340

Address offset: Block D: 0x440

Address offset: Block E: 0x540

Address offset: Block F: 0x640

Reset value: 0x0000 0000

Bit 31 **UPDATE**: Registers update (transfer from preload register to active register)
Register update event forces the output to its inactive state.

Bit 30 **EXTEVNTJ**: External event J
External event J forces the output to its inactive state.

Bit 29 **EXTEVNTI**: External event I
External event I forces the output to its inactive state.

Bit 28 **EXTEVNTH**: External event H
External event H forces the output to its inactive state.

Bit 27 **EXTEVNTG**: External event G
External event G forces the output to its inactive state.

Bit 26 **EXTEVNTF**: External event F
External event F forces the output to its inactive state.

Bit 25 **EXTEVNTE**: External event E
External event E forces the output to its inactive state.

Bit 24 **EXTEVNTD**: External event D
External event D forces the output to its inactive state.

Bit 23 **EXTEVNTC**: External event C
External event C forces the output to its inactive state.

Bit 22 **EXTEVNTB**: External event B
External event B forces the output to its inactive state.

Bit 21 **EXTEVNTA**: External event A
External event A forces the output to its inactive state.

Bit 20 **TIMEVNT9**: Timer event 9
Timers event 9 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 19 **TIMEVNT8**: Timer event 8
Timers event 8 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 18 **TIMEVNT7**: Timer event 7
Timers event 7 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 17 **TIMEVNT6**: Timer event 6
Timers event 6 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 16 **TIMEVNT5**: Timer event 5
Timers event 5 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 15 **TIMEVNT4**: Timer event 4
Timers event 4 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 14 **TIMEVNT3**: Timer event 3
Timers event 3 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 13 **TIMEVNT2**: Timer event 2
Timers event 2 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 12 **TIMEVNT1**:Timer event 1
Timers event 1 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4
Master timer compare 4 event forces the output to its inactive state.

Bit 10 **MSTCMP3**: Master compare 3
Master timer compare 3 event forces the output to its inactive state.

Bit 9 **MSTCMP2**: Master compare 2
Master timer compare 2 event forces the output to its inactive state.

Bit 8 **MSTCMP1**: Master compare 1
Master timer compare 1 event forces the output to its inactive state.

Bit 7 **MSTPER**: Master period
The master timer counter period event (continuous mode), or the master timer counter reset (continous or single-shot mode), forces the output to its inactive state.

Bit 6 **CMP4**: Timer x compare 4
Timer A compare 4 event forces the output to its inactive state.

Bit 5 **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its inactive state.

Bit 4 **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its inactive state.

Bit 3 **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its inactive state.

Bit 2 **PER**: Timer x period

Timer A period event forces the output to its inactive state.

Note: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

Bit 1 **RESYNC:** Timer A resynchronization

Timer A reset event coming solely from software or SYNC input forces the output to its inactive state.

Note: Other timer reset are not affecting the output when RESYNC=1.

Bit 0 **SRT**: Software reset trigger

This bit forces the output to its inactive state. This bit can only be set by software and is reset by hardware.

Note: This bit is not preloaded.

Bit 31 **UPDATE**: Registers update (transfer from preload register to active register)

Register update event forces the output to its active state.

Bit 30 **EXTEVNTJ**: External event J

External event J forces the output to its active state.

Bit 29 **EXTEVNTI**: External event I

External event I forces the output to its active state.

Bit 28 **EXTEVNTH**: External event H

External event H forces the output to its active state.

Bit 27 **EXTEVNTG**: External event G

External event G forces the output to its active state.

Bit 26 **EXTEVNTF**: External event F

External event F forces the output to its active state.

Bit 25 **EXTEVNTE**: External event E
External event E forces the output to its active state.

Bit 24 **EXTEVNTD**: External event D
External event D forces the output to its active state.

Bit 23 **EXTEVNTC**: External event C
External event C forces the output to its active state.

Bit 22 **EXTEVNTB**: External event B
External event B forces the output to its active state.

Bit 21 **EXTEVNTA**: External event A
External event A forces the output to its active state.

Bit 20 **TIMEVNT9**: Timer event 9
Timers event 9 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 19 **TIMEVNT8**: Timer event 8
Timers event 8 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 18 **TIMEVNT7**: Timer event 7
Timers event 7 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 17 **TIMEVNT6**: Timer event 6
Timers event 6 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 16 **TIMEVNT5**: Timer event 5
Timers event 5 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 15 **TIMEVNT4**: Timer event 4
Timers event 4 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 14 **TIMEVNT3**: Timer event 3
Timers event 3 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 13 **TIMEVNT2**: Timer event 2
Timers event 2 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 12 **TIMEVNT1**:Timer event 1
Timers event 1 forces the output to its active state (refer to *Table 422* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4
Master timer compare 4 event forces the output to its active state.

Bit 10 **MSTCMP3**: Master compare 3
Master timer compare 3 event forces the output to its active state.

Bit 9 **MSTCMP2**: Master compare 2
Master timer compare 2 event forces the output to its active state.

Bit 8 **MSTCMP1**: Master compare 1
Master timer compare 1 event forces the output to its active state.

Bit 7 **MSTPER**: Master period
The master timer counter period event (continuous mode), or the master timer counter reset (continous or single-shot mode), forces the output to its active state.

Bit 6 **CMP4**: Timer x compare 4
Timer A compare 4 event forces the output to its active state.

Bit 5 **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its active state.

Bit 4 **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its active state.

Bit 3 **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its active state.

Bit 2 **PER**: Timer x period
Timer A period event forces the output to its active state.
Note: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

Bit 1 **RESYNC:** Timer A resynchronization
Timer A reset event coming solely from software or SYNC input forces the output to its active state.
Note: Other timer reset are not affecting the output when RESYNC=1.

Bit 0 **SST**: Software set trigger
This bit forces the output to its active state. This bit can only be set by software and is reset by hardware.
Note: This bit is not preloaded.

40.5.30 HRTIM timer x output 2 reset register (HRTIM_RSTx2R) (x = A to F)

Address offset: Block A: 0x148

Address offset: Block B: 0x248

Address offset: Block C: 0x348

Address offset: Block D: 0x448

Address offset: Block E: 0x548

Address offset: Block F: 0x648

Reset value: 0x0000 0000

Bit 31 **UPDATE**: Registers update (transfer from preload register to active register)
Register update event forces the output to its inactive state.

Bit 30 **EXTEVNTJ**: External event J
External event J forces the output to its inactive state.

Bit 29 **EXTEVNTI**: External event I
External event I forces the output to its inactive state.

Bit 28 **EXTEVNTH**: External event H
External event H forces the output to its inactive state.

Bit 27 **EXTEVNTG**: External event G
External event G forces the output to its inactive state.

Bit 26 **EXTEVNTF**: External event F
External event F forces the output to its inactive state.

Bit 25 **EXTEVNTE**: External event E
External event E forces the output to its inactive state.

Bit 24 **EXTEVNTD**: External event D
External event D forces the output to its inactive state.

Bit 23 **EXTEVNTC**: External event C
External event C forces the output to its inactive state.

Bit 22 **EXTEVNTB**: External event B
External event B forces the output to its inactive state.

Bit 21 **EXTEVNTA**: External event A
External event A forces the output to its inactive state.

Bit 20 **TIMEVNT9**: Timer event 9
Timers event 9 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 19 **TIMEVNT8**: Timer event 8
Timers event 8 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 18 **TIMEVNT7**: Timer event 7
Timers event 7 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 17 **TIMEVNT6**: Timer event 6
Timers event 6 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 16 **TIMEVNT5**: Timer event 5
Timers event 5 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 15 **TIMEVNT4**: Timer event 4
Timers event 4 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 14 **TIMEVNT3**: Timer event 3
Timers event 3 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 13 **TIMEVNT2**: Timer event 2
Timers event 2 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 12 **TIMEVNT1**:Timer event 1
Timers event 1 forces the output to its inactive state (refer to *Table 422* for timer events assignments).

Bit 11 **MSTCMP4**: Master compare 4
Master timer compare 4 event forces the output to its inactive state.

Bit 10 **MSTCMP3**: Master compare 3
Master timer compare 3 event forces the output to its inactive state.

Bit 9 **MSTCMP2**: Master compare 2
Master timer compare 2 event forces the output to its inactive state.

Bit 8 **MSTCMP1**: Master compare 1
Master timer compare 1 event forces the output to its inactive state.

Bit 7 **MSTPER**: Master period
The master timer counter period event (continuous mode), or the master timer counter reset (continous or single-shot mode), forces the output to its inactive state.

Bit 6 **CMP4**: Timer x compare 4
Timer A compare 4 event forces the output to its inactive state.

Bit 5 **CMP3**: Timer x compare 3
Timer A compare 3 event forces the output to its inactive state.

Bit 4 **CMP2**: Timer x compare 2
Timer A compare 2 event forces the output to its inactive state.

Bit 3 **CMP1**: Timer x compare 1
Timer A compare 1 event forces the output to its inactive state.

Bit 2 **PER**: Timer x period

Timer A period event forces the output to its inactive state.

Note: In up/down mode (UDM bit set to 1), the counter period event is defined as per the OUTROM[1:0] bit setting.

Bit 1 **RESYNC:** Timer A resynchronization

Timer A reset event coming solely from software or SYNC input forces the output to its inactive state.

Note: Other timer reset are not affecting the output when RESYNC=1.

Bit 0 **SRT**: Software reset trigger

This bit forces the output to its inactive state. This bit can only be set by software and is reset by hardware.

Note: This bit is not preloaded.

40.5.31 HRTIM timer x external event filtering register 1 (HRTIM_EEFxR1) (x = A to F)

Address offset: Block A: 0x14C

Address offset: Block B: 0x24C

Address offset: Block C: 0x34C

Address offset: Block D: 0x44C

Address offset: Block E: 0x54C

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:25 **EEEFLTR[4:0]**: External event E filter
Refer to EEAFLTR[4:0] description.

Bit 24 **EEELTCH**: External event E latch
Refer to EEALTCH description

Bits 23:19 **EEDFLTR[4:0]**: External event D filter
Refer to EEAFLTR[4:0] description.

Bit 18 **EEDLTCH**: External event D latch
Refer to EEALTCH description

Bits 17:13 **EECFLTR[4:0]**: External event C filter
Refer to EEAFLTR[4:0] description.

Bit 12 **EECLTCH**: External event C latch
Refer to EEALTCH description

Bits 11:7 **EEBFLTR[4:0]**: External event B filter
Refer to EEAFLTR[4:0] description.

Bit 6 **EEBLTCH**: External event B latch
Refer to EEALTCH description.

Bits 5:1 **EEAFLTR[4:0]**: External event A filter

00000: No filtering

00001: Blanking from counter reset/roll-over to compare 1

00010: Blanking from counter reset/roll-over to compare 2 in up-counting mode (UDM bit reset)
In up-down counting mode (UDM bit set): blanking from compare 1 to compare 2, only during the up-counting phase.

00011: Blanking from counter reset/roll-over to compare 3

00100: Blanking from counter reset/roll-over to compare 4 in up-counting mode (UDM bit reset)
In up-down counting mode (UDM bit set): blanking from compare 3 to compare 4, only during the up-counting phase.

0XXXX: Blanking from another timing unit: TIMFLTRy source (see *Table 431* for details)
XXXX = 0101 → y = 1, ... , XXXX = 1100 → y = 8

01101: Windowing from counter reset/roll-over to compare 2 in up-counting mode (UDM bit reset)
In up-down counting mode (UDM bit set): windowing from compare 2 to compare 3, only during the up-counting phase.

01110: Windowing from counter reset/roll-over to compare 3 in up-counting mode (UDM bit reset)
In up-down counting mode (UDM bit set): windowing from compare 2 to compare 3, only during the down-counting phase.

01111: Windowing from another timing unit: TIMWIN source (see *Table 432* for details) in up-counting mode (UDM bit reset)
In up-down counting mode (UDM bit set): windowing from compare 2 during the up-counting phase to compare 3 during the down-counting phase.

10000: Blanking from compare 1 to counter reset/roll-over (UDM bit reset).In up-down counting mode (UDM bit set): blanking from compare 1 during down-counting to compare 2 during the following up-counting phase.

10001: Blanking from compare 2 to counter reset/roll-over (UDM bit reset).In up-down counting mode (UDM bit set): blanking from CMP1 (down-counting) to CMP2 (down-counting).

10010: Blanking from compare 1 to compare 2 (UDM bit reset). In up-down counting mode (UDM bit set): blanking from CMP1 (up-counting) to CMP2 (down-counting.

10011: Blanking from compare 3 to compare 4 (UDM bit reset). In up-down counting mode (UDM bit set): blanking from CMP3 (up-counting) to CMP4 (down-counting).

10100: Windowing from compare 1 to counter reset/roll-over. In up-down counting mode (UDM bit set), the reset/roll-over event is conditioned to the ROM[1:0] bitfield setting

10101: Windowing from compare 2 to counter reset/roll-over. In up-down counting mode (UDM bit set), the reset/roll-over event is conditioned to the ROM[1:0] bitfield setting

10110: Windowing from compare 1 to compare 2 (UDM bit reset). In up-down counting mode (UDM bit set): windowing from CMP1 (up-counting) to CMP2 (down-counting).

10111: Windowing from compare 3 to compare 4 (UDM bit reset). In up-down counting mode (UDM bit set): windowing from compare 3 during down-counting to compare 4 during the following up-counting phase

11000: TIMWIN2 source (see *Table 432* for details). In up-down counting mode (UDM bit set), the reset/roll-over event is conditioned to the ROM[1:0] bitfield setting

11001: TIMWIN3 source (see *Table 432* for details)
In up-down counting mode (UDM bit set): windowing from compare 1 during up-counting to compare 2 during the down-counting.

11010: Blanking from Period Event to Compare 1 In up-down counting mode (UDM bit set), the reset/roll-over event is conditioned to the ROM[1:0] bitfield setting

11011: Blanking from Period Event to Compare 2 In up-down counting mode (UDM bit set), the reset/roll-over event is conditioned to the ROM[1:0] bitfield setting

11100: In push-pull mode only, blanking occurs from reset/roll-over to compare 1 when CPPSTAT = 0, and continuously when CPPSTAT = 1.

Note: Whenever a compare register is used for filtering, the value must be strictly above 0. This bitfield must not be modified once the counter is enabled (TxCEN bit set)

Bit 0 **EEALTCH**: External event A latch

0: Event A is ignored if it happens during a blank, or passed through during a window.

1: Event A is latched and delayed till the end of the blanking or windowing period.

Note: A timeout event is generated in window mode (EEAFLTR[4:0]=01101, 01110, 01111) if EEALTCH = 0, except if the external event is programmed in fast mode (EExFAST = 1).

This bitfield must not be modified once the counter is enabled (TxCEN bit set).

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TIMFCMP2**: Timer F compare 2
The timer A counter is reset upon timer F Compare 2 event.

Bit 30 **TIMECMP4**: Timer E compare 4
The timer A counter is reset upon timer E compare 4 event.

Bit 29 **TIMECMP2**: Timer E compare 2
The timer A counter is reset upon timer E compare 2 event.

Bit 28 **TIMECMP1**: Timer E compare 1
The timer A counter is reset upon timer E compare 1 event.

Bit 27 **TIMDCMP4**: Timer D compare 4
The timer A counter is reset upon timer D compare 4 event.

Bit 26 **TIMDCMP2**: Timer D compare 2
The timer A counter is reset upon timer D compare 2 event.

Bit 25 **TIMDCMP1**: Timer D compare 1
The timer A counter is reset upon timer D compare 1 event.

Bit 24 **TIMCCMP4**: Timer C compare 4
The timer A counter is reset upon timer C compare 4 event.

Bit 23 **TIMCCMP2**: Timer C compare 2
The timer A counter is reset upon timer C compare 2 event.

Bit 22 **TIMCCMP1**: Timer C compare 1
The timer A counter is reset upon timer C compare 1 event.

Bit 21 **TIMBCMP4**: Timer B compare 4
The timer A counter is reset upon timer B compare 4 event.

Bit 20 **TIMBCMP2**: Timer B compare 2
The timer A counter is reset upon timer B compare 2 event.

Bit 19 **TIMBCMP1**: Timer B compare 1
The timer A counter is reset upon timer B compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer A counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer A counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer A counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer A counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer A counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer A counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer A counter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer A counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer A counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer A counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer A counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer A counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer A counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer A counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer A counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer A compare 4 reset
The timer A counter is reset upon timer A compare 4 event.

Bit 2 **CMP2**: Timer A compare 2 reset
The timer A counter is reset upon timer A compare 2 event.

Bit 1 **UPDT**: Timer A update reset
The timer A counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer A counter is reset upon timer F compare 1 event.

40.5.34 HRTIM timer B reset register (HRTIM_RSTBR)

Address offset: 0x254

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TIMFCMP2**: Timer F compare 2
The timer B counter is reset upon timer F Compare 2 event.

Bit 30 **TIMECMP4**: Timer E compare 4
The timer B counter is reset upon timer E compare 4 event.

Bit 29 **TIMECMP2**: Timer E compare 2
The timer B counter is reset upon timer E compare 2 event.

Bit 28 **TIMECMP1**: Timer E compare 1
The timer B counter is reset upon timer E compare 1 event.

Bit 27 **TIMDCMP4**: Timer D compare 4
The timer B counter is reset upon timer D compare 4 event.

Bit 26 **TIMDCMP2**: Timer D compare 2
The timer B counter is reset upon timer D compare 2 event.

Bit 25 **TIMDCMP1**: Timer D compare 1
The timer B counter is reset upon timer D compare 1 event.

Bit 24 **TIMCCMP4**: Timer C compare 4
The timer B counter is reset upon timer C compare 4 event.

Bit 23 **TIMCCMP2**: Timer C compare 2
The timer B counter is reset upon timer C compare 2 event.

Bit 22 **TIMCCMP1**: Timer C compare 1
The timer B counter is reset upon timer C compare 1 event.

Bit 21 **TIMACMP4**: Timer A compare 4
The timer B counter is reset upon timer A compare 4 event.

Bit 20 **TIMACMP2**: Timer A compare 2
The timer B counter is reset upon timer A compare 2 event.

Bit 19 **TIMACMP1**: Timer A compare 1
The timer B counter is reset upon timer A compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer B counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer B counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer B counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer B counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer B counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer B counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer B counter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer B counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer B counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer B counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer B counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer B counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer B counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer B counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer B counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer B compare 4 reset
The timer B counter is reset upon timer B compare 4 event.

Bit 2 **CMP2**: Timer B compare 2 reset
The timer B counter is reset upon timer B compare 2 event.

Bit 1 **UPDT**: Timer B update reset
The timer B counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer B counter is reset upon timer F compare 1 event.

40.5.35 HRTIM timer C reset register (HRTIM_RSTCR)

Address offset: 0x354

Reset value: 0x0000 0000

Bit 31 **TIMFCMP2**: Timer F compare 2
The timer C counter is reset upon timer F Compare 2 event.

Bit 30 **TIMECMP4**: Timer E compare 4
The timer C counter is reset upon timer E compare 4 event.

Bit 29 **TIMECMP2**: Timer E compare 2
The timer C counter is reset upon timer E compare 2 event.

Bit 28 **TIMECMP1**: Timer E compare 1
The timer C counter is reset upon timer E compare 1 event.

Bit 27 **TIMDCMP4**: Timer D compare 4
The timer C counter is reset upon timer D compare 4 event.

Bit 26 **TIMDCMP2**: Timer D compare 2
The timer C counter is reset upon timer D compare 2 event.

Bit 25 **TIMDCMP1**: Timer D compare 1
The timer C counter is reset upon timer D compare 1 event.

Bit 24 **TIMBCMP4**: Timer B compare 4
The timer C counter is reset upon timer B compare 4 event.

Bit 23 **TIMBCMP2**: Timer B compare 2
The timer C counter is reset upon timer B compare 2 event.

Bit 22 **TIMBCMP1**: Timer B compare 1
The timer C counter is reset upon timer B compare 1 event.

Bit 21 **TIMACMP4**: Timer A compare 4
The timer C counter is reset upon timer A compare 4 event.

Bit 20 **TIMACMP2**: Timer A compare 2
The timer C counter is reset upon timer A compare 2 event.

Bit 19 **TIMACMP1**: Timer A compare 1
The timer C counter is reset upon timer A compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer C counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer C counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer C counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer C counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer C counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer C counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer Ccounter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer C counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer C counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer C counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer C counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer C counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer C counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer C counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer C counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer C compare 4 reset
The timer C counter is reset upon timer C compare 4 event.

Bit 2 **CMP2**: Timer C compare 2 reset
The timer C counter is reset upon timer C compare 2 event.

Bit 1 **UPDT**: Timer C update reset
The timer C counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer C counter is reset upon timer F compare 1 event.

40.5.36 HRTIM timer D reset register (HRTIM_RSTDR)

Address offset: 0x454

Reset value: 0x0000 0000

Bit 31 **TIMFCMP2**: Timer F compare 2
The timer D counter is reset upon timer F Compare 2 event.

Bit 30 **TIMECMP4**: Timer E compare 4
The timer D counter is reset upon timer E compare 4 event.

Bit 29 **TIMECMP2**: Timer E compare 2
The timer D counter is reset upon timer E compare 2 event.

Bit 28 **TIMECMP1**: Timer E compare 1
The timer D counter is reset upon timer E compare 1 event.

Bit 27 **TIMCCMP4**: Timer C compare 4
The timer D counter is reset upon timer C compare 4 event.

Bit 26 **TIMCCMP2**: Timer C compare 2
The timer D counter is reset upon timer C compare 2 event.

Bit 25 **TIMCCMP1**: Timer C compare 1
The timer D counter is reset upon timer C compare 1 event.

Bit 24 **TIMBCMP4**: Timer B compare 4
The timer D counter is reset upon timer B compare 4 event.

Bit 23 **TIMBCMP2**: Timer B compare 2
The timer D counter is reset upon timer B compare 2 event.

Bit 22 **TIMBCMP1**: Timer B compare 1
The timer D counter is reset upon timer B compare 1 event.

Bit 21 **TIMACMP4**: Timer A compare 4
The timer D counter is reset upon timer A compare 4 event.

Bit 20 **TIMACMP2**: Timer A compare 2
The timer D counter is reset upon timer A compare 2 event.

Bit 19 **TIMACMP1**: Timer A compare 1
The timer D counter is reset upon timer A compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer A counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer A counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer A counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer A counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer A counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer A counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer A counter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer A counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer A counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer A counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer D counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer D counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer D counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer D counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer D counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer D compare 4 reset
The timer D counter is reset upon timer D compare 4 event.

Bit 2 **CMP2**: Timer D compare 2 reset
The timer D counter is reset upon timer D compare 2 event.

Bit 1 **UPDT**: Timer D update reset
The timer D counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer D counter is reset upon timer F compare 1 event.

40.5.37 HRTIM timer E reset register (HRTIM_RSTER)

Address offset: 0x554

Reset value: 0x0000 0000

Bit 31 **TIMFCMP2**: Timer F compare 2
The timer E counter is reset upon timer F Compare 2 event.

Bit 30 **TIMDCMP4**: Timer D compare 4
The timer E counter is reset upon timer D compare 4 event.

Bit 29 **TIMDCMP2**: Timer D compare 2
The timer E counter is reset upon timer D compare 2 event.

Bit 28 **TIMDCMP1**: Timer D compare 1
The timer E counter is reset upon timer D compare 1 event.

Bit 27 **TIMCCMP4**: Timer C compare 4
The timer E counter is reset upon timer C compare 4 event.

Bit 26 **TIMCCMP2**: Timer C compare 2
The timer E counter is reset upon timer C compare 2 event.

Bit 25 **TIMCCMP1**: Timer C compare 1
The timer E counter is reset upon timer C compare 1 event.

Bit 24 **TIMBCMP4**: Timer B compare 4
The timer E counter is reset upon timer B compare 4 event.

Bit 23 **TIMBCMP2**: Timer B compare 2
The timer E counter is reset upon timer B compare 2 event.

Bit 22 **TIMBCMP1**: Timer B compare 1
The timer E counter is reset upon timer B compare 1 event.

Bit 21 **TIMACMP4**: Timer A compare 4
The timer E counter is reset upon timer A compare 4 event.

Bit 20 **TIMACMP2**: Timer A compare 2
The timer E counter is reset upon timer A compare 2 event.

Bit 19 **TIMACMP1**: Timer A compare 1
The timer E counter is reset upon timer A compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer E counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer E counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer E counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer E counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer E counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer E counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer E counter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer E counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer E counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer E counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer E counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer E counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer E counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer E counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer E counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer E compare 4 reset
The timer E counter is reset upon timer E compare 4 event.

Bit 2 **CMP2**: Timer E compare 2 reset
The timer E counter is reset upon timer E compare 2 event.

Bit 1 **UPDT**: Timer E update reset
The timer E counter is reset upon update event.

Bit 0 **TIMFCMP1**: Timer F compare 1
The timer E counter is reset upon timer F compare 1 event.

40.5.38 HRTIM timer F reset register (HRTIM_RSTFR)

Address offset: 0x654

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **TIMECMP2**: Timer E compare 2
The timer F counter is reset upon timer E Compare 2 event.

Bit 30 **TIMDCMP4**: Timer D compare 4
The timer F counter is reset upon timer D compare 4 event.

Bit 29 **TIMDCMP2**: Timer D compare 2
The timer F counter is reset upon timer D compare 2 event.

Bit 28 **TIMDCMP1**: Timer D compare 1
The timer F counter is reset upon timer D compare 1 event.

Bit 27 **TIMCCMP4**: Timer C compare 4
The timer F counter is reset upon timer C compare 4 event.

Bit 26 **TIMCCMP2**: Timer C compare 2
The timer F counter is reset upon timer C compare 2 event.

Bit 25 **TIMCCMP1**: Timer C compare 1
The timer F counter is reset upon timer C compare 1 event.

Bit 24 **TIMBCMP4**: Timer B compare 4
The timer F counter is reset upon timer B compare 4 event.

Bit 23 **TIMBCMP2**: Timer B compare 2
The timer F counter is reset upon timer B compare 2 event.

Bit 22 **TIMBCMP1**: Timer B compare 1
The timer F counter is reset upon timer B compare 1 event.

Bit 21 **TIMACMP4**: Timer A compare 4
The timer F counter is reset upon timer A compare 4 event.

Bit 20 **TIMACMP2**: Timer A compare 2
The timer F counter is reset upon timer A compare 2 event.

Bit 19 **TIMACMP1**: Timer A compare 1
The timer F counter is reset upon timer A compare 1 event.

Bit 18 **EXTEVNTJ**: External event J
The timer F counter is reset upon external event J.

Bit 17 **EXTEVNTI**: External event I
The timer F counter is reset upon external event I.

Bit 16 **EXTEVNTH**: External event H
The timer F counter is reset upon external event H.

Bit 15 **EXTEVNTG**: External event G
The timer F counter is reset upon external event G.

Bit 14 **EXTEVNTF**: External event F
The timer F counter is reset upon external event F.

Bit 13 **EXTEVNTE**: External event E
The timer F counter is reset upon external event E.

Bit 12 **EXTEVNTD**: External event D
The timer F counter is reset upon external event D.

Bit 11 **EXTEVNTC**: External event C
The timer F counter is reset upon external event C.

Bit 10 **EXTEVNTB**: External event B
The timer F counter is reset upon external event B.

Bit 9 **EXTEVNTA**: External event A
The timer F counter is reset upon external event A.

Bit 8 **MSTCMP4**: Master compare 4
The timer F counter is reset upon master timer compare 4 event.

Bit 7 **MSTCMP3**: Master compare 3
The timer F counter is reset upon master timer compare 3 event.

Bit 6 **MSTCMP2**: Master compare 2
The timer F counter is reset upon master timer compare 2 event.

Bit 5 **MSTCMP1**: Master compare 1
The timer F counter is reset upon master timer compare 1 event.

Bit 4 **MSTPER**: Master timer period
The timer F counter is reset upon master timer period event.

Bit 3 **CMP4**: Timer F compare 4 reset
The timer F counter is reset upon timer F compare 4 event.

Bit 2 **CMP2**: Timer F compare 2 reset
The timer F counter is reset upon timer F compare 2 event.

Bit 1 **UPDT**: Timer F update reset
The timer F counter is reset upon update event.

Bit 0 **TIMECMP1**: Timer E compare 1
The timer F counter is reset upon timer E compare 1 event.

40.5.39 HRTIM timer x chopper register (HRTIM_CHPxR) (x = A to F)

Address offset: Block A: 0x158

Address offset: Block B: 0x258

Address offset: Block C: 0x358

Address offset: Block D: 0x458

Address offset: Block E: 0x558

Address offset: Block F: 0x658

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	STRTPW[3:0]				CARDTY[2:0]			CARFRQ[3:0]			
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:11 Reserved, must be kept at reset value.

Bits 10:7 **STRTPW[3:0]**: Timer x start pulsewidth

This register defines the initial pulsewidth following a rising edge on output signal.
This bitfield cannot be modified when one of the CHPx bits is set.
t_{1STPW} = (STRPW[3:0]+1) x 16 x t_{HRTIM}.
0000: 57 ns (1/17.5 MHz)
...
1111: 910 ns (16/17.5 MHz)

Bits 6:4 **CARDTY[2:0]**: Timer x chopper duty cycle value

This register defines the duty cycle of the carrier signal. This bitfield cannot be modified when one of the CHPx bits is set.
000: 0/8 (i.e. only 1st pulse is present)
...
111: 7/8

Bits 3:0 **CARFRQ[3:0]**: Timer x carrier frequency value

This register defines the carrier frequency F_{CHPFRQ} = f_{HRTIM} / (16 x (CARFRQ[3:0]+1)).
This bitfield cannot be modified when one of the CHPx bits is set.
0000: 17.5 MHz (f_{HRTIM}/ 16)
...
1111: 1.09 MHz (f_{HRTIM} / 256)

40.5.40 HRTIM timer A capture 1 control register (HRTIM_CPT1ACR)

Address offset: 0x15C

Reset value: 0x0000 0000

Bit 31 **TECMP2**: Timer E compare 2
Refer to TACMP2 description.

Bit 30 **TECMP1**: Timer E compare 1
Refer to TACMP1 description.

Bit 29 **TE1RST**: Timer E output 1 reset
Refer to TA1RST description.

Bit 28 **TE1SET**: Timer E output 1 set
Refer to TA1SET description.

Bit 27 **TDCMP2**: Timer D compare 2
Refer to TACMP2 description.

Bit 26 **TDCMP1**:Timer D compare 1
Refer to TACMP1 description.

Bit 25 **TD1RST**: Timer D output 1 reset
Refer to TA1RST description.

Bit 24 **TD1SET**: Timer D output 1 set
Refer to TA1SET description.

Bit 23 **TCCMP2**: Timer C compare 2
Refer to TACMP2 description.

Bit 22 **TCCMP1**:Timer C compare 1
Refer to TACMP1 description.

Bit 21 **TC1RST**: Timer C output 1 reset
Refer to TA1RST description.

Bit 20 **TC1SET**: Timer C output 1 set
Refer to TA1SET description.

Bit 19 **TBCMP2**: Timer B compare 2
Refer to TACMP2 description.

Bit 18 **TBCMP1**: Timer B compare 1
Refer to TACMP1 description.

Bit 17 **TB1RST**: Timer B output 1 reset
Refer to TA1RST description.

Bit 16 **TB1SET**: Timer B output 1 set
Refer to TA1SET description.

Bit 15 **TFCMP2**: Timer E compare 2
Refer to TACMP2 description.

Bit 14 **TFCMP1**: Timer F compare 1
Refer to TACMP1 description.

Bit 13 **TF1RST**: Timer F output 1 reset
Refer to TA1RST description.

Bit 12 **TF1SET**: Timer F output 1 set
Refer to TA1SET description.

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 1

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 1

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 1 by software. This bit is set only, reset by hardware.

40.5.41 HRTIM timer B capture 1 control register (HRTIM_CPT1BCR)

Refer to TA1RST description.

Bit 16 **TF1SET**: Timer F output 1 set
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2
0: No action
1: Timer A compare 2 triggers capture 1

Bit 14 **TACMP1**: Timer A compare 1
0: No action
1: Timer A compare 1 triggers capture1

Bit 13 **TA1RST**: Timer B output 1 reset
0: No action
1: Capture 1 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set
0: No action
1: Capture 1 is triggered by TA1 output inactive to active transition

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 1

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 1

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 1 by software. This bit is set only, reset by hardware.

40.5.42 HRTIM timer C capture 1 control register (HRTIM_CPT1CCR)

Address offset: 0x35C

Refer to TACMP2 description.

Bit 30 **TECMP1**: Timer E compare 1
Refer to TACMP1 description.

Bit 29 **TE1RST**: Timer E output 1 reset
Refer to TA1RST description.

Bit 28 **TE1SET**: Timer E output 1 set
Refer to TA1SET description.

Bit 27 **TDCMP2**: Timer D compare 2
Refer to TACMP2 description.

Bit 26 **TDCMP1**:Timer D compare 1
Refer to TACMP1 description.

Bit 25 **TD1RST**: Timer D output 1 reset
Refer to TA1RST description.

Bit 24 **TD1SET**: Timer D output 1 set
Refer to TA1SET description.

Bit 23 **TFCMP2**: Timer F compare 2
Refer to TACMP2 description.

Bit 22 **TFCMP1**:Timer F compare 1
Refer to TACMP1 description.

Bit 21 **TF1RST**: Timer F output 1 reset
Refer to TA1RST description.

Bit 20 **TF1SET**: Timer F output 1 set
Refer to TA1SET description.

Bit 19 **TBCMP2**: Timer B compare 2
Refer to TACMP2 description.

Bit 18 **TBCMP1**: Timer B compare 1
Refer to TACMP1 description.

Bit 17 **TB1RST**: Timer B output 1 reset
Refer to TA1RST description.

Bit 16 **TB1SET**: Timer B output 1 set
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2
0: No action
1: Timer A compare 2 triggers capture 1

Bit 14 **TACMP1**: Timer A compare 1
0: No action
1: Timer A compare 1 triggers capture 1

Bit 13 **TA1RST**: Timer B output 1 reset
0: No action
1: Capture 1 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set
0: No action
1: Capture 1 is triggered by TA1 output inactive to active transition

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 1

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 1

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 1 by software. This bit is set only, reset by hardware.

Refer to TACMP1 description.

Bit 25 **TF1RST**: Timer F output 1 reset
Refer to TA1RST description.

Bit 24 **TF1SET**: Timer F output 1 set
Refer to TA1SET description.

Bit 23 **TCCMP2**: Timer C compare 2
Refer to TACMP2 description.

Bit 22 **TCCMP1**:Timer C compare 1
Refer to TACMP1 description.

Bit 21 **TC1RST**: Timer C output 1 reset
Refer to TA1RST description.

Bit 20 **TC1SET**: Timer C output 1 set
Refer to TA1SET description.

Bit 19 **TBCMP2**: Timer B compare 2
Refer to TACMP2 description.

Bit 18 **TBCMP1**: Timer B compare 1
Refer to TACMP1 description.

Bit 17 **TB1RST**: Timer B output 1 reset
Refer to TA1RST description.

Bit 16 **TB1SET**: Timer B output 1 set
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2
0: No action
1: Timer A compare 2 triggers capture 1

Bit 14 **TACMP1**: Timer A compare 1
0: No action
1: Timer A compare 1 triggers capture 1

Bit 13 **TA1RST**: Timer B output 1 reset
0: No action
1: Capture 1 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set
0: No action
1: Capture 1 is triggered by TA1 output inactive to active transition

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 1

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 1

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 1 by software. This bit is set only, reset by hardware.

Bit 31 **TECMP2**: Timer E compare 2
Refer to TACMP2 description.

Bit 30 **TECMP1**: Timer E compare 1
Refer to TACMP1 description.

Bit 29 **TE1RST**: Timer E output 1 reset
Refer to TA1RST description.

Bit 28 **TE1SET**: Timer E output 1 set
Refer to TA1SET description.

Bit 27 **TDCMP2**: Timer D compare 2
Refer to TACMP2 description.

Bit 26 **TDCMP1**:Timer D compare 1
Refer to TACMP1 description.

Bit 25 **TD1RST**: Timer D output 1 reset
Refer to TA1RST description.

Bit 24 **TD1SET**: Timer D output 1 set
Refer to TA1SET description.

Bit 23 **TFCMP2**: Timer F compare 2
Refer to TACMP2 description.

Bit 22 **TFCMP1**:Timer F compare 1
Refer to TACMP1 description.

Bit 21 **TF1RST**: Timer F output 1 reset
Refer to TA1RST description.

Bit 20 **TF1SET**: Timer F output 1 set
Refer to TA1SET description.

Bit 19 **TBCMP2**: Timer B compare 2
Refer to TACMP2 description.

Bit 18 **TBCMP1**: Timer B compare 1
Refer to TACMP1 description.

Bit 17 **TB1RST**: Timer B output 1 reset
Refer to TA1RST description.

Bit 16 **TB1SET**: Timer B output 1 set
Refer to TA1SET description.

Bit 15 **TACMP2**: Timer A compare 2
0: No action
1: Timer A compare 2 triggers capture 2

Bit 14 **TACMP1**: Timer A compare 1
0: No action
1: Timer A compare 1 triggers capture 2

Bit 13 **TA1RST**: Timer B output 1 reset
0: No action
1: Capture 2 is triggered by TA1 output active to inactive transition

Bit 12 **TA1SET**: Timer B output 1 set
0: No action
1: Capture 2 is triggered by TA1 output inactive to active transition

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 2

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 2

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 2 by software. This bit is set only, reset by hardware.

0: No action
1: Capture 2 is triggered by TA1 output inactive to active transition

Bit 11 **EXEVJCPT**: External event J capture
Refer to EXEVACPT description

Bit 10 **EXEVICPT**: External event I capture
Refer to EXEVACPT description.

Bit 9 **EXEVHCPT**: External event H capture
Refer to EXEVACPT description.

Bit 8 **EXEVGCPT**: External event G capture
Refer to EXEVACPT description.

Bit 7 **EXEVFCPT**: External event F capture
Refer to EXEVACPT description.

Bit 6 **EXEVECPT**: External event E capture
Refer to EXEVACPT description.

Bit 5 **EXEVDCPT**: External event D capture
Refer to EXEVACPT description.

Bit 4 **EXEVCCPT**: External event C capture
Refer to EXEVACPT description.

Bit 3 **EXEVBCPT**: External event B capture
Refer to EXEVACPT description.

Bit 2 **EXEVACPT**: External event A capture
0: No action
1: The external event A triggers the capture 2

Bit 1 **UPDCPT**: Update capture
0: No action
1: The update event triggers the capture 2

Bit 0 **SWCPT**: Software capture
0: No action
1: This bit forces the capture 2 by software. This bit is set only, reset by hardware.

40.5.52 HRTIM timer x output register (HRTIM_OUTxR) (x = A to F)

Address offset: Block A: 0x164

Address offset: Block B: 0x264

Address offset: Block C: 0x364

Address offset: Block D: 0x464

Address offset: Block E: 0x564

Address offset: Block F: 0x664

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DIDL2	CHP2	FAULT2[1:0]		IDLES2	IDLEM 2	POL2	Res.
								rw	rw	rw	rw	rw	rw	rw	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	BIAR	Res.	DLYPRT[2:0]			DLYPR TEN	DTEN	DIDL1	CHP1	FAULT1[1:0]		IDLES1	IDLEM 1	POL1	Res.
	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **DIDL2**: Output 2 deadtime upon burst mode Idle entry

This bit delays the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering in idle state during a burst mode operation.

0: The programmed Idle state is applied immediately to the output 2

1: Deadtime (inactive level) is inserted on output 2 before entering the idle mode. The deadtime value is set by DTFx[8:0].

Note: This parameter cannot be changed once the timer x is enabled.

DIDL=1 is set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).

Bit 22 **CHP2**: Output 2 chopper enable

This bit enables the chopper on output 2.

0: Output signal is not altered

1: Output signal is chopped by a carrier signal

Note: This parameter cannot be changed once the timer x is enabled.

Bits 21:20 **FAULT2[1:0]**: Output 2 fault state

These bits select the output 2 state after a fault event.

00: No action: the output is not affected by the fault input and stays in run mode.

01: Active

10: Inactive

11: High-Z

Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.

Bit 19 **IDLES2**: Output 2 idle state

This bit selects the output 2 idle state.

0: Inactive

1: Active

Note: This parameter must be set prior to have the HRTIM controlling the outputs.

Bit 18 **IDLEM2**: Output 2 idle mode
This bit selects the output 2 idle mode.
0: No action: the output is not affected by the burst mode operation.
1: The output is in idle state when requested by the burst mode controller.
Note: This bit is preloaded and is changed during run-time, but must not be changed while the burst mode is active.

Bit 17 **POL2**: Output 2 polarity
This bit selects the output 2 polarity.
0: Positive polarity (output active high)
1: Negative polarity (output active low)
Note: This parameter cannot be changed once the timer x is enabled.

Bits 16:15 Reserved, must be kept at reset value.

Bit 14 **BIAR**: Balanced Idle Automatic Resume
This bit selects is the outputs are automatically re-enabled after a balanced idle event.
This bit is only significant if DLYPRT[2:0] = 011 or 111, it is ignored otherwise.
0: Disabled
1: Enabled
Note: This parameter cannot be changed once the timer x is enabled.

Bit 13 Reserved, must be kept at reset value.

Bits 12:10 **DLYPRT[2:0]**: Delayed protection
These bits define the source and outputs on which the delayed protection schemes are applied.
In HRTIM_OUTAR, HRTIM_OUTBR, HRTIM_OUTCR:
000: Output 1 delayed idle on external event F
001: Output 2 delayed idle on external event F
010: Output 1 and output 2 delayed idle on external event F
011: Balanced idle on external event F
100: Output 1 delayed idle on external event G
101: Output 2 delayed idle on external event G
110: Output 1 and output 2 delayed idle on external event G
111: Balanced idle on external event G
In HRTIM_OUTDR, HRTIM_OUTER, HRTIM_OUTFR:
000: Output 1 delayed idle on external event H
001: Output 2 delayed idle on external event H
010: Output 1 and output 2 delayed idle on external event H
011: Balanced idle on external event H
100: Output 1 delayed idle on external event I
101: Output 2 delayed idle on external event I
110: Output 1 and output 2 delayed idle on external event I
111: Balanced idle on external event I
Note: This bitfield must not be modified once the delayed protection is enabled (DLYPRTEN bit set).

Bit 9 **DLYPRTEN**: Delayed protection enable
This bit enables the delayed protection scheme.
0: No action
1: Delayed protection is enabled, as per DLYPRT[2:0] bits
Note: This parameter cannot be changed once the timer x is enabled (TxEN bit set).

Bit 8 **DTEN**: Deadtime enable

This bit enables the deadtime insertion on output 1 and output 2.

0: Output 1 and output 2 signals are independent.

1: Deadtime is inserted between output 1 and output 2 (reference signal is output 1 signal generator)

Note: This parameter cannot be changed if the timer outputs are enabled and set/reset by another timer.

Bit 7 **DIDL1**: Output 1 deadtime upon burst mode idle entry

This bit delays the idle mode entry by forcing a deadtime insertion before switching the outputs to their idle state. This setting only applies when entering the idle state during a burst mode operation.

0: The programmed idle state is applied immediately to the output 1

1: Deadtime (inactive level) is inserted on output 1 before entering the idle mode. The deadtime value is set by DTRx[8:0].

Note: This parameter cannot be changed once the timer x is enabled.

DIDL=1 is set only if one of the outputs is active during the burst mode (IDLES=1), and with positive deadtimes (SDTR/SDTF set to 0).

Bit 6 **CHP1**: Output 1 chopper enable

This bit enables the chopper on output 1.

0: Output signal is not altered

1: Output signal is chopped by a carrier signal

Note: This parameter cannot be changed once the timer x is enabled.

Bits 5:4 **FAULT1[1:0]**: Output 1 fault state

These bits select the output 1 state after a fault event

00: No action: the output is not affected by the fault input and stays in run mode.

01: Active

10: Inactive

11: High-Z

Note: This parameter cannot be changed once the timer x is enabled (TxCEN bit set), if FLTENx bit is set or if the output is in FAULT state.

Bit 3 **IDLES1**: Output 1 Idle State

This bit selects the output 1 idle state.

0: Inactive

1: Active

Note: This parameter must be set prior to HRTIM controlling the outputs.

Bit 2 **IDLEM1**: Output 1 Idle mode

This bit selects the output 1 idle mode.

0: No action: the output is not affected by the burst mode operation.

1: The output is in idle state when requested by the burst mode controller.

Note: This bit is preloaded and is changed during runtime, but must not be changed while burst mode is active.

Bit 1 **POL1**: Output 1 polarity

This bit selects the output 1 polarity.

0: Positive polarity (output active high)

1: Negative polarity (output active low)

Note: This parameter cannot be changed once the timer x is enabled.

Bit 0 Reserved, must be kept at reset value.

40.5.53 HRTIM timer x fault register (HRTIM_FLTxR) (x = A to F)

Address offset: Block A: 0x168

Address offset: Block B: 0x268

Address offset: Block C: 0x368

Address offset: Block D: 0x468

Bit 31 **FLTLCK**: Fault sources lock
0: FLT1EN..FLT6EN bits are read/write
1: FLT1EN..FLT6EN bits are read only
The FLTLCK bit is write-once. Once it has been set, it cannot be modified till the next system reset.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **FLT7A8EN**: Fault 7 AND Fault 8 enable
0: Fault 7 AND Fault 8 ignored
1: HRTIM outputs disabled when both Fault 7 AND Fault 8 inputs are active

Bit 21 **FLT6A7EN**: Fault 6 AND Fault 7 enable
0: Fault 6 AND Fault 7 ignored
1: HRTIM outputs disabled when both Fault 6 AND Fault 7 inputs are active

Bit 20 **FLT5A6EN**: Fault 5 AND Fault 6 enable
0: Fault 5 AND Fault 6 ignored
1: HRTIM outputs disabled when both Fault 5 AND Fault 6 inputs are active

Bit 19 **FLT4A5EN**: Fault 4 AND Fault 5 enable
0: Fault 4 AND Fault 5 ignored
1: HRTIM outputs disabled when both Fault 4 AND Fault 5 inputs are active

Bit 18 **FLT3A4EN**: Fault 3 AND Fault 4 enable
0: Fault 3 AND Fault 4 ignored
1: HRTIM outputs disabled when both Fault 3 AND Fault 4 inputs are active

Bit 17 **FLT2A3EN**: Fault 2 AND Fault 3 enable
0: Fault 2 AND Fault 3 ignored
1: HRTIM outputs disabled when both Fault 2 AND Fault 3 inputs are active

Bit 16 **FLT1A2EN**: Fault 1 AND Fault 2 enable
0: Fault 1 AND Fault 2 ignored
1: HRTIM outputs disabled when both Fault 1 AND Fault 2 inputs are active

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **FLT8EN**: Fault 8 enable
0: Fault 8 input ignored
1: Fault 8 input is active and disables HRTIM outputs

Bit 6 **FLT7EN**: Fault 7 enable
0: Fault 7 input ignored
1: Fault 7 input is active and disables HRTIM outputs

Bit 5 **FLT6EN**: Fault 6 enable
0: Fault 6 input ignored
1: Fault 6 input is active and disables HRTIM outputs

Bit 4 **FLT5EN**: Fault 5 enable
0: Fault 5 input ignored
1: Fault 5 input is active and disables HRTIM outputs

Bit 3 **FLT4EN**: Fault 4 enable
0: Fault 4 input ignored
1: Fault 4 input is active and disables HRTIM outputs

Bit 2 **FLT3EN**: Fault 3 enable
0: Fault 3 input ignored
1: Fault 3 input is active and disables HRTIM outputs

Bit 1 **FLT2EN**: Fault 2 enable
0: Fault 2 input ignored
1: Fault 2 input is active and disables HRTIM outputs

Bit 0 **FLT1EN**: Fault 1 enable
0: Fault 1 input ignored
1: Fault 1 input is active and disables HRTIM outputs

40.5.54 HRTIM timer x control register 2 (HRTIM_TIMxCR2) (x = A to F)

Address offset: Block A: 0x16C

Address offset: Block B: 0x26C

Address offset: Block C: 0x36C

Address offset: Block D: 0x46C

Address offset: Block E: 0x56C

Address offset: Block F: 0x66C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw		rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bit 27 **DCDCOE**: Dual channel DAC crossbar override enable

0: Dual Channel DAC Crossbar Override disabled

1: Dual Channel DAC Crossbar Override enabled

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 26 **COM**: Crossbar override mode

This bit defines if the crossbar override mode is entered only once (latched mode), in which case it is necessary to rearm it to resume standard crossbar operation, using the COR bit.

In cycle-by-cycle mode, the standard crossbar operation is automatically resumed on the next following reset/roll-over event, once the triggering condition have disappeared. This mode is only applicable in force on event mode (COFMx[2:0] = 100).

0: Cycle-by-cycle mode

1: latched mode

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 25 **COR**: Crossbar override rearm

This bit is set by software and automatically reset by hardware. It resume standard crossbar operation and rearms the crossbar override mode. The rearm operation is only effective if the crossbar override triggering condition have disappeared. If the trigger is still active, the rearm request is ignored and the crossbar override mode is maintained active.

Bit 24 **COE**: Crossbar override enable

0: Crossbar override disabled

1: Crossbar override enabled

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 23 **ADCTRGCH2**: ADC trigger for channel 2

This bit is significant only in push-pull mode. It gives the possibility to have ADC triggers issued only when Channel 2 output is active

0: ADC triggers generated for both Channel 1 and Channel 2 active phases

1: ADC triggers generated when Channel 2 is active (in push-pull mode)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 22 **ADCTRGCH1**: ADC trigger for channel 1

This bit is significant only in push-pull mode. It gives the possibility to have ADC triggers issued only when Channel 1 output is active

0: ADC triggers generated for both Channel 1 and Channel 2 active phases

1: ADC triggers generated when Channel 1 is active (in push-pull mode)

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 21 **TRGHLFT**: Triggered-half timeout mode

This bit defines if a timeout event must be generated when the synchronization disappear (i.e. no more EEV event

0: No timeout event generated

1: timeout event generated. When the counter matches the PER value, the CMP2 register takes PER/2 value.

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bit 20 **TRGHLF**: Triggered-half mode

This bit defines whether the compare 2 register is behaving in standard mode (compare match issued as soon as counter equal compare), or in triggered-half mode (see *Section : Triggered-half mode*).

0: CMP2 register is written by the user only (standard compare mode)

1: CMP2 value is set by hardware as soon as a capture 1 event occurs. It is loaded with the (capture 1 divided by 2) value. The initial value can be written by the user (as long as TRGHLF is reset), but is ignored once the first capture has been triggered (the preload mechanism is disabled for CMP2 when the TRGHLF bit is set).

Note: This bitfield must not be modified once the counter is enabled (TxCEN bit set).

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **GTCMP3**: Greater than compare 3 PWM mode

This bit defines the compare 3 operating mode.

0: The compare 3 event is generated when the counter is equal to the compare value (compare match mode)

1: The compare 3 event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.

Bit 16 **GTCMP1**: Greater than compare 1 PWM mode

This bit defines the compare 1 operating mode.

0: The compare 1 event is generated when the counter is equal to the compare value (compare match mode)

1: The compare 1 event is generated when the counter is greater than the compare value. If the compare value is changed on-the-fly, the new compare value is compared with the current counter value and an output SET or RESET can be generated.

Bits 15:14 **FEROM[1:0]**: Fault and event roll-over mode

This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the Roll-over event used by the fault and event counters.

00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value

01: Event generated when the counter is equal to 0

10: Event generated when the counter is equal to HRTIM_PERxR

11: Reserved

Note: This setting only applies when the UDM bit is set. It is not significant otherwise.

Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).

Bits 13:12 **BMROM[1:0]**: Burst mode roll-over mode

This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event used in the burst mode controller, as clock as burst mode trigger.

00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value

01: Event generated when the counter is equal to 0

10: Event generated when the counter is equal to HRTIM_PERxR

11: Reserved

Note: This setting only applies when the UDM bit is set. It is not significant otherwise.

Note: This parameter cannot be changed once the timer is operating (TxEN bit set).

Bits 11:10 **ADROM[1:0]**: ADC roll-over mode

This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event which triggers the ADC.

00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value

01: Event generated when the counter is equal to 0

10: Event generated when the counter is equal to HRTIM_PERxR

11: Reserved

Note: This setting only applies when the UDM bit is set. It is not significant otherwise.

Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).

Bits 9:8 **OUTROM[1:0]**: Output roll-over mode

This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event which sets and/or resets the ouputs, as per HRTIM_SETxyR and HRTIM_RSTxyR settings.

00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value

01: Event generated when the counter is equal to 0

10: Event generated when the counter is equal to HRTIM_PERxR

11: Reserved

Note: This setting only applies when the UDM bit is set. It is not significant otherwise.

Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).

Bits 7:6 **ROM[1:0]**: Roll-over mode

This bit defines when the roll-over is generated, in up-down counting mode. It only concerns the roll-over event with the following destinations: update trigger (to transfer content from preload to active registers), IRQ and DMA requests, repetition counter decrement and external event filtering.

00: Event generated when the counter is equal to 0 or to HRTIM_PERxR value

01: Event generated when the counter is equal to 0

10: Event generated when the counter is equal to HRTIM_PERxR

11: Reserved

Note: This setting only applies when the UDM bit is set. It is not significant otherwise.

Note: This bitfield cannot be changed once the timer is operating (TxEN bit set).

Bit 5 Reserved, must be kept at reset value.

Bit 4 **UDM**: Up-Down mode
This bit defines if the counter is operating in up or up-down counting mode.
0: The counter is operating in up-counting mode
1: The counter is operating in up-down counting mode
Note: This bit cannot be changed once the timer is operating (TxEN bit set).

Bit 3 Reserved, must be kept at reset value.

Bit 2 **DCDR**: Dual channel DAC reset trigger
This bit defines when the hrtim_dac_reset_trgx trigger is generated.
0: The trigger is generated on counter reset or roll-over event
1: The trigger is generated on output 1 set event
Note: The DCDR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

Bit 1 **DCDS**: Dual channel DAC Step trigger
This bit defines when the hrtim_dac_step_trgx trigger is generated.
0: The trigger is generated on compare 2 event
1: The trigger is generated on output 1 reset event
Note: The DCDR bit is not significant when the DCDE bit is reset (Dual channel DAC trigger disabled).

Bit 0 **DCDE**: Dual channel DAC trigger enable
This bit enables the dual channel DAC triggering mechanism.
0: Dual channel DAC trigger disabled
1: Dual channel DAC trigger enabled
Note: This bit cannot be changed once the timer is operating (TxEN bit set).

40.5.55 HRTIM timer x external event filtering register 3 (HRTIM_TIMxEEFR3) (x = A to F)

Address offset: Block A: 0x170

Address offset: Block B: 0x270

Address offset: Block C: 0x370

Address offset: Block D: 0x470

Address offset: Block E: 0x570

Address offset: Block F: 0x670

Reset value: 0x0000 0000

		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:24 **EEVZCNT[5:0]**: External event Z counter

This bitfield selects the external event Z counter threshold. An event is considered valid when the number of events is equal to the (EEVZCNT[5:0]+1) value.

Bits 23:20 **EEVZSEL[3:0]**: External event Z selection

This bit selects the external event B source.

0: External event A is used as external event Z source

1: External event B is used as external event Z source

...

9: External event J is used as external event Z source

Others: Reserved

Bit 19 Reserved, must be kept at reset value.

Bit 18 **EEVZRSTM**: External event Z reset mode

This bit selects the external event Z counter reset mode

0: External event counter Z is reset on each reset / roll-over event

1: External event counter Z is reset on each reset / roll-over event only if no event occurs during last counting period

Bit 17 **EEVZCRES**: External event Z counter reset

This bit resets the external event Z counter. It is set by software and reset by hardware.

0: No action

1: External event counter Z counter is reset

Bit 16 **EEVZCE**: External event Z counter enable

This bit enables the external event Z counter.

0: External event Z counter disabled

1: External event Z counter enabled

Bits 15:14 Reserved, must be kept at reset value.

Bits 13:8 **EEVYCNT[5:0]**: External event Y counter
This bitfield selects the external event Y counter threshold. An event is considered valid when the number of events is equal to the (EEVYCNT[5:0]+1) value.

Bits 7:4 **EEVYSEL[3:0]**: External event Y Selection
This bit selects the external event Y source.
0: External event A is used as external event Y source
1: External event B is used as external event Y source
...
9: External event J is used as external event Y source
Others: Reserved

Bit 3 Reserved, must be kept at reset value.

Bit 2 **EEVYRSTM**: External event Y reset mode
This bit selects the external event Y counter reset mode.
0: External event counter Y is reset on each reset / roll-over event
1: External event counter Y is reset on each reset / roll-over event only if no event occurs during last counting period

Bit 1 **EEVYCRES**: External event Y counter reset
This bit resets the external event Y counter. It is set by software and reset by hardware.
0: No action
1: External event counter Y is reset

Bit 0 **EEVYCE**: External event Y counter enable
This bit enables the external event Y counter.
0: External event Y counter disabled
1: External event Y counter enabled

0: No action
1: Output B is forced to the active level when External Event B is active

Bit 20 **EEVAFRCB**: External event A forces output B
0: No action
1: Output B is forced to active level when External Event A is active

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **COFMB[2:0]**: Crossbar override force mode output B
This bitfield defines how the output B is handled once the crossbar override mode is triggered
000: Delayed 1 fault
Output B is forced to the inactive level after Delay 1 duration defined with DLY1FLTD[8:0] bitfield in HRTIM_CODExR register.
001: Delayed 2 fault
Output B is forced to the inactive level after Delay 2 duration defined with DLY2FLTD[8:0] bitfield in HRTIM_CODExR register
010: Output B forced to inactive level
011: Output B forced to active level
100: Output B forced on events, as defined with EEVAFRCB..EEVJFRCB bits.
Others: reserved

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **EEVJFRCA**: External event J forces output A
0: No action
1: Output A is forced to the active level when External Event J is active

Bit 12 **EEVIFRCA**: External event I forces output A
0: No action
1: Output A is forced to the active level when External Event I is active

Bit 11 **EEVHFRCA**: External event H forces output A
0: No action
1: Output A is forced to the active level when External Event H is active

Bit 10 **EEVGFRCA**: External event G forces output A
0: No action
1: Output A is forced to the active level when External Event G is active

Bit 9 **EEVFFRCA**: External event F forces output A
0: No action
1: Output A is forced to the active level when External Event F is active

Bit 8 **EEVEFRCA**: External event E forces output A
0: No action
1: Output A is forced to active level when External Event E is active

Bit 7 **EEVDFRCA**: External event D forces output A
0: No action
1: Output A is forced to the active level when External Event D is active

Bit 6 **EEVCFRCA**: External event C forces output A
0: No action
1: Output A is forced to the active level when External Event C is active

Bit 5 **EEVBFRCA**: External event B forces output A
0: No action
1: Output A is forced to the active level when External Event B is active

Bit 4 **EEVAFRCA**: External event A forces output A
0: No action
1: Output A is forced to active level when External Event A is active

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **COFMA[2:0]**: Crossbar override force mode output A
This bitfield defines how the output A is handled once the crossbar override mode is triggered
000: Delayed 1 fault
Output A is forced to the inactive level after Delay 1 duration defined with DLY1FLTD[8:0] bitfield in HRTIM_CODExR register.
001: Delayed 2 fault
Output A is forced to the inactive level after Delay 2 duration defined with DLY2FLTD[8:0] bitfield in HRTIM_CODExR register
010: Output A forced to inactive level
011: Output A forced to active level
100: Output A forced on events, as defined with EEVAFRCA..EEVJFRCA bits.

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:25 **AD4USRC[2:0]**: ADC trigger 4 update source
Refer to AD1USRC[2:0] description.

Bits 24:22 **AD3USRC[2:0]**: ADC trigger 3 update source
Refer to AD1USRC[2:0] description.

Bits 21:19 **AD2USRC[2:0]**: ADC trigger 2 update source
Refer to AD1USRC[2:0] description.

Bits 18:16 **AD1USRC[2:0]**: ADC trigger 1 update source
These bits define the source which triggers the update of the HRTIM_ADC1R register (transfer from preload to active register). It only defines the source timer. The precise condition is defined within the timer itself, in HRTIM_MCR or HRTIM_TIMxCR.
000: Master timer
001: Timer A
010: Timer B
011: Timer C
100: Timer D
101: Timer E
110: Timer F
111: Reserved

Bit 15 Reserved, must be kept at reset value.

Bit 14 **RTFUDIS**: Remote Timer F update disable
Refer to RTAUDIS description.

Bit 13 **RTEUDIS**: Remote Timer E update disable
Refer to RTAUDIS description

Bit 12 **RTDUDIS**: Remote Timer D update disable
Refer to RTAUDIS description.

Bit 11 **RTCUDIS**: Remote Timer C update disable
Refer to RTAUDIS description.

Bit 10 **RTBUDIS**: Remote Timer B update disable
Refer to RTAUDIS description.

Bit 9 **RTAUDIS**: Remote timer A update disable

This bit is set and cleared by software to enable/disable an update event generation temporarily in another HRTIMER's timer A.

0: Update enabled. The update occurs upon generation of the selected source.

1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bit 8 **RMUDIS**: Remote master update disable

This bit is set and cleared by software to enable/disable an update event generation temporarily in another HRTIMER's master timer

0: Update enabled.

1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TFUDIS**: Timer F update disable

Refer to TAUDIS description.

Bit 5 **TEUDIS**: Timer E update disable

Refer to TAUDIS description

Bit 4 **TDUDIS**: Timer D update disable

Refer to TAUDIS description.

Bit 3 **TCUDIS**: Timer C update disable

Refer to TAUDIS description.

Bit 2 **TBUDIS**: Timer B update disable

Refer to TAUDIS description.

Bit 1 **TAUDIS**: Timer A update disable

This bit is set and cleared by software to enable/disable an update event generation temporarily on timer A.

0: Update enabled. The update occurs upon generation of the selected source.

1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

Bit 0 **MUDIS**: Master update disable

This bit is set and cleared by software to enable/disable an update event generation temporarily.

0: Update enabled.

1: Update disabled. The updates are temporarily disabled to allow the software to write multiple registers that have to be simultaneously taken into account.

40.5.61 HRTIM control register 2 (HRTIM_CR2)

Address offset: 0x704

Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 DBSS[2:0]: DMA burst source selection

This bitfield defines the DMA source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done at the HRTIM_BDMADR register address).

000:Reserved
001:Master timer
010:Timer A
011:Timer B
100:Timer C
101:Timer D
110:Timer E
111:Timer F

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **SWPF**: Swap timer F outputs

Refer to SWPA description.

Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 20 **SWPE**: Swap timer E outputs

Refer to SWPA description.

Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 19 **SWPD**: Swap timer D outputs

Refer to SWPA description.

Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 18 **SWPC**: Swap timer C outputs

Refer to SWPA description.

Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 17 **SWPB**: Swap timer B outputs

Refer to SWPA description.

Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 16 **SWPA**: Swap timer A outputs
This bit allows to swap the timer A outputs.
0: HRTIM_SETA1R and HRTIM_RSTA1R are coding for the output A1, HRTIM_SETA2R and HRTIM_RSTA2R are coding for the output A2
1: HRTIM_SETA1R and HRTIM_RSTA1R are coding for the output A2, HRTIM_SETA2R and HRTIM_RSTA2R are coding for the output A1
Note: This bit is not significant when the Push-pull mode is enabled (PSHPLL = 1).

Bit 15 Reserved, must be kept at reset value.

Bit 14 **TFRST**: Timer F counter software reset
Refer to TARST description.

Bit 13 **TERST**: Timer E counter software reset
Refer to TARST description.

Bit 12 **TDRST**: Timer D counter software reset
Refer to TARST description.

Bit 11 **TCRST**: Timer C counter software reset
Refer to TARST description.

Bit 10 **TBRST**: Timer B counter software reset
Refer to TARST description.

Bit 9 **TARST**: Timer A counter software reset
Setting this bit resets the timer A counter.
The bit is automatically reset by hardware.

Bit 8 **MRST**: Master counter software reset
Setting this bit resets the master timer counter.
The bit is automatically reset by hardware.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TFSWU**: Timer F software update
Refer to TASWU description.

Bit 5 **TESWU**: Timer E software update
Refer to TASWU description.

Bit 4 **TDSWU**: Timer D software update
Refer to TASWU description.

Bit 3 **TCSWU**: Timer C software update
Refer to TASWU description.

Bit 2 **TBSWU**: Timer B software update
Refer to TASWU description.

Bit 1 **TASWU**: Timer A software update
This bit is set by software and automatically reset by hardware. It forces an immediate transfer from the preload to the active register and any pending update request is canceled.

Bit 0 **MSWU**: Master timer software update
This bit is set by software and automatically reset by hardware. It forces an immediate transfer from the preload to the active register in the master timer and any pending update request is canceled.

40.5.62 HRTIM interrupt status register (HRTIM_ISR)

Address offset: 0x708

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							r	r	r	r	r	r	r	r	r

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **BMPER**: Burst mode period interrupt flag
This bit is set by hardware when a single-shot burst mode operation is completed or at the end of a burst mode period in continuous mode. It is cleared by software writing it at 1.
0: No burst mode period interrupt occurred
1: Burst mode period interrupt occurred

Bit 16 **DLLRDY**: DLL Ready Interrupt Flag
This bit is set by hardware when the DLL calibration is completed. It is cleared by software writing it at 1.
0: No DLL calibration ready interrupt occurred
1: DLL calibration ready interrupt occurred

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **FLT8**: Fault 8 interrupt flag
Refer to FLT1 description.

Bit 7 **FLT7**: Fault 7 interrupt flag
Refer to FLT1 description.

Bit 6 **FLT6**: Fault 6 interrupt flag
Refer to FLT1 description.

Bit 5 **SYSFLT**: System fault interrupt flag
Refer to FLT1 description.

Bit 4 **FLT5**: Fault 5 interrupt flag
Refer to FLT1 description.

Bit 3 **FLT4**: Fault 4 interrupt flag
Refer to FLT1 description.

Bit 2 **FLT3**: Fault 3 interrupt flag
Refer to FLT1 description.

Bit 1 **FLT2**: Fault 2 interrupt flag
Refer to FLT1 description.

Bit 0 **FLT1**: Fault 1 interrupt flag
This bit is set by hardware when fault 1 event occurs. It is cleared by software writing it at 1.
0: No fault 1 interrupt occurred
1: Fault 1 interrupt occurred

40.5.63 HRTIM interrupt clear register (HRTIM_ICR)

Address offset: 0x70C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							w	w	w	w	w	w	w	w	w

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **BMPERC**: Burst mode period flag clear
Writing 1 to this bit clears the BMPER flag in HRTIM_ISR register.

Bit 16 **DLLRDYC**: DLL Ready Interrupt flag Clear
Writing 1 to this bit clears the DLLRDY flag in HRTIM_ISR register.

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **FLT8C**: Fault 8 interrupt flag clear
Writing 1 to this bit clears the FLT6 flag in HRTIM_ISR register.

Bit 7 **FLT7C**: Fault 7 interrupt flag clear
Writing 1 to this bit clears the FLT6 flag in HRTIM_ISR register.

Bit 6 **FLT6C**: Fault 6 interrupt flag clear
Writing 1 to this bit clears the FLT6 flag in HRTIM_ISR register.

Bit 5 **SYSFLTC**: System fault interrupt flag clear
Writing 1 to this bit clears the SYSFLT flag in HRTIM_ISR register.

Bit 4 **FLT5C**: Fault 5 interrupt flag clear
Writing 1 to this bit clears the FLT5 flag in HRTIM_ISR register.

Bit 3 **FLT4C**: Fault 4 interrupt flag clear
Writing 1 to this bit clears the FLT4 flag in HRTIM_ISR register.

Bit 2 **FLT3C**: Fault 3 interrupt flag clear
Writing 1 to this bit clears the FLT3 flag in HRTIM_ISR register.

Bit 1 **FLT2C**: Fault 2 interrupt flag clear
Writing 1 to this bit clears the FLT2 flag in HRTIM_ISR register.

Bit 0 **FLT1C**: Fault 1 interrupt flag clear
Writing 1 to this bit clears the FLT1 flag in HRTIM_ISR register.

40.5.64 HRTIM interrupt enable register (HRTIM_IER)

Address offset: 0x710

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

							rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **BMPERIE**: Burst mode period interrupt enable
This bit is set and cleared by software to enable/disable the burst mode period interrupt.
0: Burst mode period interrupt disabled
1: Burst mode period interrupt enabled

Bit 16 **DLLRDYIE**: DLL Ready Interrupt Enable
This bit is set and cleared by software to enable/disable the DLL ready interrupt.
0: DLL ready interrupt disabled
1: DLL ready interrupt enabled

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **FLT8IE**: Fault 8 interrupt enable
Refer to FLT1IE description.

Bit 7 **FLT7IE**: Fault 7 interrupt enable
Refer to FLT1IE description.

Bit 6 **FLT6IE**: Fault 6 interrupt enable
Refer to FLT1IE description.

Bit 5 **SYSFLTIE**: System fault interrupt enable
Refer to FLT1IE description.

Bit 4 **FLT5IE**: Fault 5 interrupt enable
Refer to FLT1IE description.

Bit 3 **FLT4IE**: Fault 4 interrupt enable
Refer to FLT1IE description.

Bit 2 **FLT3IE**: Fault 3 interrupt enable
Refer to FLT1IE description.

Bit 1 **FLT2IE**: Fault 2 interrupt enable
Refer to FLT1IE description.

Bit 0 **FLT1IE**: Fault 1 interrupt enable
This bit is set and cleared by software to enable/disable the fault 1 interrupt.
0: Fault 1 interrupt disabled
1: Fault 1 interrupt enabled

40.5.65 HRTIM output enable register (HRTIM_OENR)

Address offset: 0x714

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

				rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs	rs

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **TF2OEN**: Timer F output 2 enable
Refer to TA1OEN description.

Bit 10 **TF1OEN**: Timer F output 1 enable
Refer to TA1OEN description

Bit 9 **TE2OEN**: Timer E output 2 enable
Refer to TA1OEN description.

Bit 8 **TE1OEN**: Timer E output 1 enable
Refer to TA1OEN description.

Bit 7 **TD2OEN**: Timer D output 2 enable
Refer to TA1OEN description.

Bit 6 **TD1OEN**: Timer D output 1 enable
Refer to TA1OEN description.

Bit 5 **TC2OEN**: Timer C output 2 enable
Refer to TA1OEN description.

Bit 4 **TC1OEN**: Timer C output 1 enable
Refer to TA1OEN description.

Bit 3 **TB2OEN**: Timer B output 2 enable
Refer to TA1OEN description.

Bit 2 **TB1OEN**: Timer B output 1 enable
Refer to TA1OEN description.

Bit 1 **TA2OEN**: Timer A output 2 enable
Refer to TA1OEN description.

Bit 0 **TA1OEN**: Timer A output 1 enable
Setting this bit enables the timer A output 1. Writing “0” has no effect.
Reading the bit returns the output enable/disable status.
This bit is cleared asynchronously by hardware as soon as the timer-related fault input(s) is (are) active.
0: output A1 disabled. The output is either in fault or Idle state.
1: output A1 enabled

Note: The disable status corresponds to both idle and fault states. The output disable status is given by TA1ODS bit in the HRTIM_ODSR register.

40.5.66 HRTIM output disable register (HRTIM_ODISR)

Address offset: 0x718

Reset value: 0x0000 0000

				w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **TF2ODIS**: Timer F output 2 disable
Refer to TA1ODIS description.

Bit 10 **TF1ODIS**: Timer F output 1 disable
Refer to TA1ODIS description

Bit 9 **TE2ODIS**: Timer E output 2 disable
Refer to TA1ODIS description.

Bit 8 **TE1ODIS**: Timer E output 1 disable
Refer to TA1ODIS description.

Bit 7 **TD2ODIS**: Timer D output 2 disable
Refer to TA1ODIS description.

Bit 6 **TD1ODIS**: Timer D output 1 disable
Refer to TA1ODIS description.

Bit 5 **TC2ODIS**: Timer C output 2 disable
Refer to TA1ODIS description.

Bit 4 **TC1ODIS**: Timer C output 1 disable
Refer to TA1ODIS description.

Bit 3 **TB2ODIS**: Timer B output 2 disable
Refer to TA1ODIS description.

Bit 2 **TB1ODIS**: Timer B output 1 disable
Refer to TA1ODIS description.

Bit 1 **TA2ODIS**: Timer A output 2 disable
Refer to TA1ODIS description.

Bit 0 **TA1ODIS**: Timer A output 1 disable
Setting this bit disables the timer A output 1. The output enters the idle state, either from the run state or from the fault state.
Writing “0” has no effect.

40.5.67 HRTIM output disable status register (HRTIM_ODSR)

Address offset: 0x71C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				r	r	r	r	r	r	r	r	r	r	r	r

Bits 31:12 Reserved, must be kept at reset value.

Bit 11 **TF2ODS**: Timer F output 2 disable status
Refer to TA1ODS description.

Bit 10 **TF1ODS**: Timer F output 1 disable status
Refer to TA1ODS description.

Bit 9 **TE2ODS**: Timer E output 2 disable status
Refer to TA1ODS description.

Bit 8 **TE1ODS**: Timer E output 1 disable status
Refer to TA1ODS description.

Bit 7 **TD2ODS**: Timer D output 2 disable status
Refer to TA1ODS description.

Bit 6 **TD1ODS**: Timer D output 1 disable status
Refer to TA1ODS description.

Bit 5 **TC2ODS**: Timer C output 2 disable status
Refer to TA1ODS description.

Bit 4 **TC1ODS**: Timer C output 1 disable status
Refer to TA1ODS description.

Bit 3 **TB2ODS**: Timer B output 2 disable status
Refer to TA1ODS description.

Bit 2 **TB1ODS**: Timer B output 1 disable status
Refer to TA1ODS description.

Bit 1 **TA2ODS**: Timer A output 2 disable status
Refer to TA1ODS description.

Bit 0 **TA1ODS**: Timer A output 1 disable status
Reading the bit returns the output disable status. It is not significant when the output is active (Tx1OEN or Tx2OEN = 1).
0: Output A1 disabled, in Idle state.
1: Output A1 disabled, in fault state.

40.5.68 HRTIM burst mode control register (HRTIM_BMCR)

Address offset: 0x720

Reset value: 0x0000 0000

					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BMSTAT**: Burst mode status

This bit gives the current operating state.

0: Normal operation

1: Burst operation on-going. Writing this bit to 0 causes a burst mode early termination.

Bits 30:23 Reserved, must be kept at reset value.

Bit 22 **TFBM**: Timer F burst mode

Refer to TABM description.

Bit 21 **TEBM**: Timer E burst mode

Refer to TABM description.

Bit 20 **TDBM**: Timer D burst mode

Refer to TABM description.

Bit 19 **TCBM**: Timer C burst mode

Refer to TABM description.

Bit 18 **TBBM**: Timer B burst mode

Refer to TABM description.

Bit 17 **TABM**: Timer A burst mode

This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.

0: TA counter clock is maintained and the timer operates normally

1: TA counter clock is stopped and the counter is reset

Note: This bit must not be set when the balanced idle mode is active (DLYPRT[2:0] = 0x11).

Bit 16 **MTBM**: Master timer burst mode

This bit defines how the timer behaves during a burst mode operation. This bitfield cannot be changed while the burst mode is enabled.

0: Master Timer counter clock is maintained and the timer operates normally

1: Master Timer counter clock is stopped and the counter is reset

Bits 15:11 Reserved, must be kept at reset value.

Bit 10 **BMPREN**: Burst mode preload enable

This bit enables the registers preload mechanism and defines whether a write access into a preloadable register (HRTIM_BMCMPR, HRTIM_BMPER) is done into the active or the preload register.

0: Preload disabled: the write access is directly done into active registers

1: Preload enabled: the write access is done into preload registers

Bits 9:6 **BMPRSC[3:0]**: Burst mode prescaler

Defines the prescaling ratio of the f_{HRTIM} clock for the burst mode controller. This bitfield cannot be changed while the burst mode is enabled.

0000: Clock not divided
0001: Division by 2
0010: Division by 4
0011: Division by 8
0100: Division by 16
0101: Division by 32
0110: Division by 64
0111: Division by 128
1000: Division by 256
1001: Division by 512
1010: Division by 1024
1011: Division by 2048
1100: Division by 4096
1101: Division by 8192
1110: Division by 16384
1111: Division by 32768

Bits 5:2 **BMCLK[3:0]**: Burst mode clock source

This bitfield defines the clock source for the burst mode counter. It cannot be changed while the burst mode is enabled (refer to *Table 413* for on-chip events 1..4 connections details).

0000: Master timer counter reset/roll-over
0001: Timer A counter reset/roll-over
0010: Timer B counter reset/roll-over
0011: Timer C counter reset/roll-over
0100: Timer D counter reset/roll-over
0101: Timer E counter reset/roll-over
0110: On-chip event 1 (hrtim_bm_ck1), acting as a burst mode counter clock
0111: On-chip event 2 (hrtim_bm_ck2) acting as a burst mode counter clock
1000: On-chip event 3 (hrtim_bm_ck3) acting as a burst mode counter clock
1001: On-chip event 4 (hrtim_bm_ck4) acting as a burst mode counter clock
1010: Prescaled f_{HRTIM} clock (as per BMPRSC[3:0] setting)
1011: Timer F counter reset/roll-over
Others: Reserved

Bit 1 **BMOM**: Burst mode operating mode

This bit defines if the burst mode is entered once or if it is continuously operating.

0: Single-shot mode
1: Continuous operation

Bit 0 **BME**: Burst mode enable

This bit starts the burst mode controller which becomes ready to receive the start trigger. Writing this bit to 0 causes a burst mode early termination.

0: Burst mode disabled
1: Burst mode enabled

40.5.69 HRTIM burst mode trigger register (HRTIM_BMTRGR)

Address offset: 0x724

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
OCHPEV	EEVH	EEVG	TDEEVH	TAEEVG	TECMP2	TECMP1	TEREP	TFCMP1	TDCMP2	TFREP	TDREP	TDRST	TFRST	TCCMP1	TCREP
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TCRST	TBCMP2	TBCMP1	TBREP	TBRST	TACMP2	TACMP1	TAREP	TARST	MSTCMP4	MSTCMP3	MSTCMP2	MSTCMP1	MSTREP	MSTRST	SW
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **OCHPEV**: On-chip event

A rising edge on the hrtim_bm_trg input (connected to general purpose timer TRGO output) triggers a burst mode entry (see *Table 410* for details).

Bit 30 **EEVH**: External event H (TIMD filters applied)

The external event H conditioned by TIMD filters is starting the burst mode operation.

Bit 29 **EEVG**: External event G (TIMA filters applied)

The external event G conditioned by TIMA filters is starting the burst mode operation.

Bit 28 **TDEEVH**: Timer D period following external event H

The timer D period following an external event H (conditioned by TIMD filters) is starting the burst mode operation.

Bit 27 **TAEEVG**: Timer A period following external event G

The timer A period following an external event G (conditioned by TIMA filters) is starting the burst mode operation.

Bit 26 **TECMP2**: Timer E compare 2 event

Refer to TACMP1 description.

Bit 25 **TECMP1**: Timer E compare 1 event

Refer to TACMP1 description.

Bit 24 **TEREP**: Timer E repetition

Refer to TAREP description.

Bit 23 **TFCMP1**: Timer F compare 1 event

Refer to TACMP1 description.

Bit 22 **TDCMP2**: Timer D compare 2 event

Refer to TACMP1 description.

Bit 21 **TFREP**: Timer F repetition

Refer to TAREP description.

Bit 20 **TDREP**: Timer D repetition

Refer to TAREP description.

Bit 19 **TDRST**: Timer D reset or roll-over

Refer to TARST description.

Bit 18 **TFRST**: Timer F reset

Refer to TARST description.

Bit 17 **TCCMP1**: Timer C compare 1 event
Refer to TACMP1 description.

Bit 16 **TCREP**: Timer C repetition
Refer to TAREP description.

Bit 15 **TCRST**: Timer C reset or roll-over
Refer to TARST description.

Bit 14 **TBCMP2**: Timer B compare 2 event
Refer to TACMP1 description.

Bit 13 **TBCMP1**: Timer B compare 1 event
Refer to TACMP1 description.

Bit 12 **TBREP**: Timer B repetition
Refer to TAREP description.

Bit 11 **TBRST**: Timer B reset or roll-over
Refer to TARST description.

Bit 10 **TACMP2**: Timer A compare 2 event
Refer to TACMP1 description.

Bit 9 **TACMP1**: Timer A compare 1 event
The timer A compare 1 event is starting the burst mode operation.

Bit 8 **TAREP**: Timer A repetition
The Timer A repetition event is starting the burst mode operation.

Bit 7 **TARST**: Timer A reset or roll-over
The Timer A reset or roll-over event is starting the burst mode operation.

Bit 6 **MSTCMP4**: Master compare 4
Refer to MSTCMP1 description.

Bit 5 **MSTCMP3**: Master compare 3
Refer to MSTCMP1 description.

Bit 4 **MSTCMP2**: Master compare 2
Refer to MSTCMP1 description.

Bit 3 **MSTCMP1**: Master compare 1
The master timer compare 1 event is starting the burst mode operation.

Bit 2 **MSTREP**: Master repetition
The master timer repetition event is starting the burst mode operation.

Bit 1 **MSTRST**: Master reset or roll-over
The master timer reset and roll-over event is starting the burst mode operation.

Bit 0 **SW**: Software start
This bit is set by software and automatically reset by hardware.
When set, It starts the burst mode operation immediately.
This bit is not active if the burst mode is not enabled (BME bit is reset).

40.5.70 HRTIM burst mode compare register (HRTIM_BMCMPR)

Address offset: 0x728

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BMCMP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMCMP[15:0]**: Burst mode compare value

Defines the number of periods during which the selected timers are in idle state.

This register holds either the content of the preload register or the content of the active register if the preload is disabled.

Note: BMCMP[15:0] cannot be set to 0x0000 when using the f_{HRTIM} clock without a prescaler as the burst mode clock source (BMCLK[3:0] = 1010 and BMPRESC[3:0] = 0000).

40.5.71 HRTIM burst mode period register (HRTIM_BMPER)

Address offset: 0x72C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

BMPER[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:0 **BMPER[15:0]**: Burst mode period

Defines the burst mode repetition period.

This register holds either the content of the preload register or the content of the active register if preload is disabled.

Note: The BMPER[15:0] must not be null when the burst mode is enabled.

40.5.72 HRTIM timer external event control register 1 (HRTIM_EECR1)

Address offset: 0x730

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	EE5FAST	EE5SNS[1:0]		EE5POL	EE5SRC[1:0]		EE4FAST	EE4SNS[1:0]		EE4POL	EE4SRC[1:0]		EE3FAST	EE3SNS[1]
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
EE3SNS[0]	EE3POL	EE3SRC[1:0]		EE2FAST	EE2SNS[1:0]		EE2POL	EE2SRC[1:0]		EE1FAST	EE1SNS[1:0]		EE1POL	EE1SRC[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **EE5FAST**: External event 5 fast mode
Refer to EE1FAST description.

Bits 28:27 **EE5SNS[1:0]**: External event 5 sensitivity
Refer to EE1SNS[1:0] description.

Bit 26 **EE5POL**: External event 5 polarity
Refer to EE1POL description.

Bits 25:24 **EE5SRC[1:0]**: External event 5 source
This bitfield is combined with EE5SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 23 **EE4FAST**: External event 4 fast mode
Refer to EE1FAST description.

Bits 22:21 **EE4SNS[1:0]**: External event 4 sensitivity
Refer to EE1SNS[1:0] description.

Bit 20 **EE4POL**: External event 4 polarity
Refer to EE1POL description.

Bits 19:18 **EE4SRC[1:0]**: External event 4 source
This bitfield is combined with EE4SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 17 **EE3FAST**: External event 3 fast mode
Refer to EE1FAST description.

Bits 16:15 **EE3SNS[1:0]**: External event 3 sensitivity
Refer to EE1SNS[1:0] description.

Bit 14 **EE3POL**: External event 3 polarity
Refer to EE1POL description.

Bits 13:12 **EE3SRC[1:0]**: External event 3 source
This bitfield is combined with EE3SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 11 **EE2FAST**: External event 2 fast mode
Refer to EE1FAST description.

Bits 10:9 **EE2SNS[1:0]**: External event 2 sensitivity
Refer to EE1SNS[1:0] description.

Bit 8 **EE2POL**: External event 2 polarity
Refer to EE1POL description.

Bits 7:6 **EE2SRC[1:0]**: External event 2 source
This bitfield is combined with EE2SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 5 **EE1FAST**: External event 1 fast mode
0: External event 1 is re-synchronized by the HRTIM logic before acting on outputs, which adds a f_{HRTIM} clock-related latency
1: External event 1 is acting asynchronously on outputs (low latency mode)
Note: This bit must not be modified once the counter in which the event is used is enabled (TxCEN bit set).

Bits 4:3 **EE1SNS[1:0]**: External event 1 sensitivity
00: On active level defined by EE1POL bit
01: Rising edge, whatever EE1POL bit value
10: Falling edge, whatever EE1POL bit value
11: Both edges, whatever EE1POL bit value

Bit 2 **EE1POL**: External event 1 polarity
This bit is only significant if EE1SNS[1:0] = 00.
0: External event is active high
1: External event is active low
Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.

Bits 1:0 **EE1SRC[1:0]**: External event 1 source
This bitfield is combined with EE1SRC[2] bit. This bitfield selects the External event 1 source. See *Table 411* for details.
000:hrtim_eev1_1
001:hrtim_eev1_2
010:hrtim_eev1_3
011:hrtim_eev1_4
100:hrtim_eev1_5
101:hrtim_eev1_6
110:hrtim_eev1_7
111:hrtim_eev1_8
Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE1FAST bit.

40.5.73 HRTIM timer external event control register 2 (HRTIM_EECR2)

Address offset: 0x734

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw		rw	rw	rw	rw	rw		rw	rw	rw	rw	rw

Bits 31:29 Reserved, must be kept at reset value.

Bits 28:27 **EE10SNS[1:0]**: External event 10 sensitivity
Refer to EE1SNS[1:0] description.

Bit 26 **EE10POL**: External event 10 polarity
Refer to EE1POL description.

Bits 25:24 **EE10SRC[1:0]**: External event 10 source
This bitfield is combined with EE10SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 23 Reserved, must be kept at reset value.

Bits 22:21 **EE9SNS[1:0]**: External event 9 sensitivity
Refer to EE1SNS[1:0] description.

Bit 20 **EE9POL**: External event 9 polarity
Refer to EE1POL description.

Bits 19:18 **EE9SRC[1:0]**: External event 9 source
This bitfield is combined with EE9SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 17 Reserved, must be kept at reset value.

Bits 16:15 **EE8SNS[1:0]**: External event 8 sensitivity
Refer to EE1SNS[1:0] description.

Bit 14 **EE8POL**: External event 8 polarity
Refer to EE1POL description.

Bits 13:12 **EE8SRC[1:0]**: External event 8 source
This bitfield is combined with EE8SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 11 Reserved, must be kept at reset value.

Bits 10:9 **EE7SNS[1:0]**: External event 7 sensitivity
Refer to EE1SNS[1:0] description.

Bit 8 **EE7POL**: External event 7 polarity
Refer to EE1POL description.

Bits 7:6 **EE7SRC[1:0]**: External event 7 source
This bitfield is combined with EE7SRC[2] bit. Refer to EE1SRC[1:0] description.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **EE6SNS[1:0]**: External event 6 sensitivity
Refer to EE1SNS[1:0] description.

Bit 2 **EE6POL**: External event 6 polarity
Refer to EE1POL description.

Bits 1:0 **EE6SRC[1:0]**: External event 6 source
This bitfield is combined with EE6SRC[2] bit. Refer to EE1SRC[1:0] description.

40.5.74 HRTIM timer external event control register 3 (HRTIM_EECR3)

Address offset: 0x738

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw			rw	rw	rw	rw			rw	rw	rw	rw

Bits 31:30 **EEVSD[1:0]**: External event sampling clock division
This bitfield indicates the division ratio between the timer clock frequency (f_{HRTIM}) and the external event signal sampling clock (f_{EEVS}) used by the digital filters.
00: $f_{EEVS}=f_{HRTIM}$
01: $f_{EEVS}=f_{HRTIM}$ / 2
10: $f_{EEVS}=f_{HRTIM}$ / 4
11: $f_{EEVS}=f_{HRTIM}$ / 8

Bits 29:28 Reserved, must be kept at reset value.

Bits 27:24 **EE10F[3:0]**: External event 10 filter
Refer to EE6F[3:0] description.

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:18 **EE9F[3:0]**: External event 9 filter
Refer to EE6F[3:0] description.

Bits 17:16 Reserved, must be kept at reset value.

Bits 15:12 **EE8F[3:0]**: External event 8 filter
Refer to EE6F[3:0] description.

Bits 11:10 Reserved, must be kept at reset value.

Bits 9:6 **EE7F[3:0]**: External event 7 filter
Refer to EE6F[3:0] description.

Bits 5:4 Reserved, must be kept at reset value.

Bits 3:0 **EE6F[3:0]**: External event 6 filter
This bitfield defines the frequency used to sample external event 6 input and the length of the digital filter applied to EEV6. The digital filter is made of a counter in which N valid samples are needed to validate a transition on the output.
0000: Filter disabled
0001: $f_{SAMPLING} = f_{HRTIM}$, N=2
0010: $f_{SAMPLING} = f_{HRTIM}$, N=4
0011: $f_{SAMPLING} = f_{HRTIM}$, N=8
0100: $f_{SAMPLING} = f_{EEVS}/2$, N=6
0101: $f_{SAMPLING} = f_{EEVS}/2$, N=8
0110: $f_{SAMPLING} = f_{EEVS}/4$, N=6

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **ADC1TEPER**: ADC trigger 1 on timer E period
Refer to ADC1TAPER description.

Bit 30 **ADC1TEC4**: ADC trigger 1 on timer E compare 4
Refer to ADC1TFC2 description.

Bit 29 **ADC1TEC3**: ADC trigger 1 on timer E compare 3
Refer to ADC1TFC2 description.

Bit 28 **ADC1TFRST**: ADC trigger 1 on timer F reset and counter roll-over(1)
Refer to ADC1TARST description.

Bit 27 **ADC1TDPER**: ADC trigger 1 on timer D period
Refer to ADC1TAPER description.

Bit 26 **ADC1TDC4**: ADC trigger 1 on timer D compare 4
Refer to ADC1TFC2 description.

Bit 25 **ADC1TDC3**: ADC trigger 1 on timer D compare 3
Refer to ADC1TFC2 description.

Bit 24 **ADC1TFPER**: ADC trigger 1 on timer F period
Refer to ADC1TAPER description.

Bit 23 **ADC1TCPER**: ADC trigger 1 on timer C period
Refer to ADC1TAPER description.

Bit 22 **ADC1TCC4**: ADC trigger 1 on timer C compare 4
Refer to ADC1TFC2 description.

Bit 21 **ADC1TCC3**: ADC trigger 1 on timer C compare 3
Refer to ADC1TFC2 description.

Bit 20 **ADC1TFC4**: ADC trigger 1 on timer F compare 4
Refer to ADC1TAC2 description.

Bit 19 **ADC1TBRST**: ADC trigger 1 on timer B reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer B reset and roll-over event, on ADC trigger 1 output.

Bit 18 **ADC1TBPER**: ADC trigger 1 on timer B period
Refer to ADC1TAPER description.

Bit 17 **ADC1TBC4**: ADC trigger 1 on timer B compare 4
Refer to ADC1TFC2 description.

Bit 16 **ADC1TBC3**: ADC trigger 1 on timer B compare 3
Refer to ADC1TFC2 description.

Bit 15 **ADC1TFC3**: ADC trigger 1 on timer F compare 3
Refer to ADC1TFC2 description.

Bit 14 **ADC1TARST**: ADC trigger 1 on timer A reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer A reset and roll-over event, on ADC trigger 1 output.

Bit 13 **ADC1TAPER**: ADC trigger 1 on timer A period
This bit enables the generation of an ADC trigger upon timer A period event, on ADC trigger 1 output.

Bit 12 **ADC1TAC4**: ADC trigger 1 on timer A compare 4
Refer to ADC1TFC2 description.

Bit 11 **ADC1TAC3**: ADC trigger 1 on timer A compare 3
Refer to ADC1TFC2 description.

Bit 10 **ADC1TFC2**: ADC trigger 1 on timer F compare 2
This bit enables the generation of an ADC trigger upon timer F compare 2 event, on ADC trigger 1 output.

Bit 9 **ADC1EEV5**: ADC trigger 1 on external event 5(1)
Refer to ADC1EEV1 description.

Bit 8 **ADC1EEV4**: ADC trigger 1 on external event 4(1)
Refer to ADC1EEV1 description.

Bit 7 **ADC1EEV3**: ADC trigger 1 on external event 3(1)
Refer to ADC1EEV1 description.

Bit 6 **ADC1EEV2**: ADC trigger 1 on external event 2(1)
Refer to ADC1EEV1 description.

Bit 5 **ADC1EEV1**: ADC trigger 1 on external event 1(1)
This bit enables the generation of an ADC trigger upon external event 1, on ADC trigger 1 output.

Bit 4 **ADC1MPER**: ADC trigger 1 on master period
This bit enables the generation of an ADC trigger upon master timer period event, on ADC trigger 1 output.

Bit 3 **ADC1MC4**: ADC trigger 1 on master compare 4
Refer to ADC1MC1 description.

Bit 2 **ADC1MC3**: ADC trigger 1 on master compare 3
Refer to ADC1MC1 description.

Bit 1 **ADC1MC2**: ADC trigger 1 on master compare 2
Refer to ADC1MC1 description.

Bit 0 **ADC1MC1**: ADC trigger 1 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 1 output.

1. These triggers are differing from HRTIM_ADC2R/HRTIM_ADC4R to HRTIM_ADC1R/HRTIM_ADC3R.

40.5.76 HRTIM ADC trigger 2 register (HRTIM_ADC2R)

Bit 31 **ADC2TERST**: ADC trigger 2 on timer E reset and counter roll-over(1)
Refer to ADC2TCRST description.

Bit 30 **ADC2TEC4**: ADC trigger 2 on timer E compare 4
Refer to ADC2TAC2 description.

Bit 29 **ADC2TEC3**: ADC trigger 2 on timer E compare 3
Refer to ADC2TAC2 description.

Bit 28 **ADC2TEC2**: ADC trigger 2 on timer E compare 2
Refer to ADC2TAC2 description.

Bit 27 **ADC2TDRST**: ADC trigger 2 on timer D reset and counter roll-over(1)
Refer to ADC2TCRST description.

Bit 26 **ADC2TDPER**: ADC trigger 2 on timer D period
Refer to ADC2TAPER description.

Bit 25 **ADC2TDC4**: ADC trigger 2 on timer D compare 4
Refer to ADC2TAC2 description.

Bit 24 **ADC2TFPER**: ADC trigger 2 on timer F period
Refer to ADC2TAPER description.

Bit 23 **ADC2TDC2**: ADC trigger 2 on timer D compare 2
Refer to ADC2TAC2 description.

Bit 22 **ADC2TCRST**: ADC trigger 2 on timer C reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer C reset and roll-over event, on ADC trigger 1 output.

Bit 21 **ADC2TCPER**: ADC trigger 2 on timer C period
Refer to ADC2TAPER description.

Bit 20 **ADC2TCC4**: ADC trigger 2 on timer C compare 4
Refer to ADC2TAC2 description.

Bit 19 **ADC2TFC4**: ADC trigger 2 on timer F compare 4
Refer to ADC2TAC2 description.

Bit 18 **ADC2TCC2**: ADC trigger 2 on timer C compare 2
Refer to ADC2TAC2 description.

Bit 17 **ADC2TBPER**: ADC trigger 2 on timer B period
Refer to ADC2TAPER description.

Bit 16 **ADC2TBC4**: ADC trigger 2 on timer B compare 4
Refer to ADC2TAC2 description.

Bit 15 **ADC2TFC3**: ADC trigger 2 on timer F compare 3
Refer to ADC2TAC2 description.

Bit 14 **ADC2TBC2**: ADC trigger 2 on timer B compare 2
Refer to ADC2TAC2 description.

Bit 13 **ADC2TAPER**: ADC trigger 2 on timer A period
This bit enables the generation of an ADC trigger upon timer A event, on ADC trigger 2 output.

Bit 12 **ADC2TAC4**: ADC trigger 2 on timer A compare 4
Refer to ADC2TAC2 description.

Bit 11 **ADC2TFC2**: ADC trigger 2 on timer F compare 2
Refer to ADC2TAC2 description.

Bit 10 **ADC2TAC2**: ADC trigger 2 on timer A compare 2
This bit enables the generation of an ADC trigger upon timer A compare 2, on ADC trigger 2 output.

Bit 9 **ADC2EEV10**: ADC trigger 2 on external event 10(1)
Refer to ADC2EEV6 description.

Bit 8 **ADC2EEV9**: ADC trigger 2 on external event 9(1)
Refer to ADC2EEV6 description.

Bit 7 **ADC2EEV8**: ADC trigger 2 on external event 8(1)
Refer to ADC2EEV6 description.

Bit 6 **ADC2EEV7**: ADC trigger 2 on external event 7(1)
Refer to ADC2EEV6 description.

Bit 5 **ADC2EEV6**: ADC trigger 2 on external event 6(1)
This bit enables the generation of an ADC trigger upon external event 6, on ADC trigger 2 output.

Bit 4 **ADC2MPER**: ADC trigger 2 on master period
This bit enables the generation of an ADC trigger upon master period event, on ADC trigger 2 output.

Bit 3 **ADC2MC4**: ADC trigger 2 on master compare 4
Refer to ADC2MC1 description.

Bit 2 **ADC2MC3**: ADC trigger 2 on master compare 3
Refer to ADC2MC1 description.

Bit 1 **ADC2MC2**: ADC trigger 2 on master compare 2
Refer to ADC2MC1 description.

Bit 0 **ADC2MC1**: ADC trigger 2 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 2 output.

1. These triggers are differing from HRTIM_ADC1R/HRTIM_ADC3R to HRTIM_ADC2R/HRTIM_ADC4R.

40.5.77 HRTIM ADC trigger 3 register (HRTIM_ADC3R)

Bit 31 **ADC3TEPER**: ADC trigger 3 on timer E period
Refer to ADC3TAPER description.

Bit 30 **ADC3TEC4**: ADC trigger 3 on timer E compare 4
Refer to ADC3TFC2 description.

Bit 29 **ADC3TEC3**: ADC trigger 3 on timer E compare 3
Refer to ADC3TFC2 description.

Bit 28 **ADC3TFRST**: ADC trigger 3 on timer F reset and counter roll-over(1)
Refer to ADC3TARST description.

Bit 27 **ADC3TDPER**: ADC trigger 3 on timer D period
Refer to ADC3TAPER description.

Bit 26 **ADC3TDC4**: ADC trigger 3 on timer D compare 4
Refer to ADC3TFC2 description.

Bit 25 **ADC3TDC3**: ADC trigger 3 on timer D compare 3
Refer to ADC3TFC2 description.

Bit 24 **ADC3TFPER**: ADC trigger 3 on timer F period
Refer to ADC3TAPER description.

Bit 23 **ADC3TCPER**: ADC trigger 3 on timer C period
Refer to ADC3TAPER description.

Bit 22 **ADC3TCC4**: ADC trigger 3 on timer C compare 4
Refer to ADC3TFC2 description.

Bit 21 **ADC3TCC3**: ADC trigger 3 on timer C compare 3
Refer to ADC3TFC2 description.

Bit 20 **ADC3TFC4**: ADC trigger 3 on timer F compare 4
Refer to ADC3TAC2 description.

Bit 19 **ADC3TBRST**: ADC trigger 3 on timer B reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer B reset and roll-over event, on ADC trigger 1 output.

Bit 18 **ADC3TBPER**: ADC trigger 3 on timer B period
Refer to ADC3TAPER description.

Bit 17 **ADC3TBC4**: ADC trigger 3 on timer B compare 4
Refer to ADC3TFC2 description.

Bit 16 **ADC3TBC3**: ADC trigger 3 on timer B compare 3
Refer to ADC3TFC2 description.

Bit 15 **ADC3TFC3**: ADC trigger 3 on timer F compare 3
Refer to ADC3TFC2 description.

Bit 14 **ADC3TARST**: ADC trigger 3 on timer A reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer A reset and roll-over event, on ADC trigger 1 output.

Bit 13 **ADC3TAPER**: ADC trigger 3 on timer A period
This bit enables the generation of an ADC trigger upon timer A period event, on ADC trigger 1 output.

Bit 12 **ADC3TAC4**: ADC trigger 3 on timer A compare 4
Refer to ADC3TFC2 description.

Bit 11 **ADC3TAC3**: ADC trigger 3 on timer A compare 3
Refer to ADC3TFC2 description.

Bit 10 **ADC3TFC2**: ADC trigger 3 on timer F compare 2
This bit enables the generation of an ADC trigger upon timer F compare 2 event, on ADC trigger 3 output.

Bit 9 **ADC3EEV5**: ADC trigger 3 on external event 5(1)
Refer to ADC3EEV1 description.

Bit 8 **ADC3EEV4**: ADC trigger 3 on external event 4(1)
Refer to ADC3EEV1 description.

Bit 7 **ADC3EEV3**: ADC trigger 3 on external event 3(1)
Refer to ADC3EEV1 description.

Bit 6 **ADC3EEV2**: ADC trigger 3 on external event 2(1)
Refer to ADC3EEV1 description.

Bit 5 **ADC3EEV1**: ADC trigger 3 on external event 1(1)
This bit enables the generation of an ADC trigger upon external event 1, on ADC trigger 3 output.

Bit 4 **ADC3MPER**: ADC trigger 3 on master period
This bit enables the generation of an ADC trigger upon master timer period event, on ADC trigger 3 output.

Bit 3 **ADC3MC4**: ADC trigger 3 on master compare 4
Refer to ADC3MC1 description.

Bit 2 **ADC3MC3**: ADC trigger 3 on master compare 3
Refer to ADC3MC1 description.

Bit 1 **ADC3MC2**: ADC trigger 3 on master compare 2
Refer to ADC3MC1 description.

Bit 0 **ADC3MC1**: ADC trigger 3 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 3 output.

1. These triggers are differing from HRTIM_ADC2R/HRTIM_ADC4R to HRTIM_ADC1R/HRTIM_ADC3R.

40.5.78 HRTIM ADC trigger 4 register (HRTIM_ADC4R)

Address offset: 0x748

Reset value: 0x0000 0000

Bit 31 **ADC4TERST**: ADC trigger 4 on timer E reset and counter roll-over(1)
Refer to ADC4TCRST description.

Bit 30 **ADC4TEC4**: ADC trigger 4 on timer E compare 4
Refer to ADC4TAC2 description.

Bit 29 **ADC4TEC3**: ADC trigger 4 on timer E compare 3
Refer to ADC4TAC2 description.

Bit 28 **ADC4TEC2**: ADC trigger 4 on timer E compare 2
Refer to ADC4TAC2 description.

Bit 27 **ADC4TDRST**: ADC trigger 4 on timer D reset and counter roll-over(1)
Refer to ADC4TCRST description.

Bit 26 **ADC4TDPER**: ADC trigger 4 on timer D period
Refer to ADC4TAPER description.

Bit 25 **ADC4TDC4**: ADC trigger 4 on timer D compare 4
Refer to ADC4TAC2 description.

Bit 24 **ADC4TFPER**: ADC trigger 4 on timer F period
Refer to ADC4TAPER description.

Bit 23 **ADC4TDC2**: ADC trigger 2 on timer D compare 2
Refer to ADC4TAC2 description.

Bit 22 **ADC4TCRST**: ADC trigger 4 on timer C reset and counter roll-over(1)
This bit enables the generation of an ADC trigger upon timer C reset and roll-over event, on ADC trigger 1 output.

Bit 21 **ADC4TCPER**: ADC trigger 4 on timer C period
Refer to ADC4TAPER description.

Bit 20 **ADC4TCC4**: ADC trigger 4 on timer C compare 4
Refer to ADC4TAC2 description.

Bit 19 **ADC4TFC4**: ADC trigger 4 on timer F compare 4
Refer to ADC4TAC2 description.

Bit 18 **ADC4TCC2**: ADC trigger 4 on timer C compare 2
Refer to ADC4TAC2 description.

Bit 17 **ADC4TBPER**: ADC trigger 4 on timer B period
Refer to ADC4TAPER description.

Bit 16 **ADC4TBC4**: ADC trigger 4 on timer B compare 4
Refer to ADC4TAC2 description.

Bit 15 **ADC4TFC3**: ADC trigger 4 on timer F compare 3
Refer to ADC4TAC2 description.

Bit 14 **ADC4TBC2**: ADC trigger 4 on timer B compare 2
Refer to ADC4TAC2 description.

Bit 13 **ADC4TAPER**: ADC trigger 4 on timer A period
This bit enables the generation of an ADC trigger upon timer A event, on ADC trigger 2 output.

Bit 12 **ADC4TAC4**: ADC trigger 4 on timer A compare 4
Refer to ADC4TAC2 description.

Bit 11 **ADC4TFC2**: ADC trigger 4 on timer F compare 2
Refer to ADC4TAC2 description.

Bit 10 **ADC4TAC2**: ADC trigger 4 on timer A compare 2
This bit enables the generation of an ADC trigger upon timer A compare 2, on ADC trigger 2 output.

Bit 9 **ADC4EEV10**: ADC trigger 4 on external event 10(1)
Refer to ADC4EEV6 description.

Bit 8 **ADC4EEV9**: ADC trigger 4 on external event 9(1)
Refer to ADC4EEV6 description.

Bit 7 **ADC4EEV8**: ADC trigger 4 on external event 8(1)
Refer to ADC4EEV6 description.

Bit 6 **ADC4EEV7**: ADC trigger 4 on external event 7(1)
Refer to ADC4EEV6 description.

Bit 5 **ADC4EEV6**: ADC trigger 4 on external event 6(1)
This bit enables the generation of an ADC trigger upon external event 6, on ADC trigger 2 output.

Bit 4 **ADC4MPER**: ADC trigger 4 on master period
This bit enables the generation of an ADC trigger upon master period event, on ADC trigger 2 output.

Bit 3 **ADC4MC4**: ADC trigger 4 on master compare 4
Refer to ADC4MC1 description.

Bit 2 **ADC4MC3**: ADC trigger 4 on master compare 3
Refer to ADC4MC1 description.

Bit 1 **ADC4MC2**: ADC trigger 4 on master compare 2
Refer to ADC4MC1 description.

Bit 0 **ADC4MC1**: ADC trigger 4 on master compare 1
This bit enables the generation of an ADC trigger upon master compare 1 event, on ADC trigger 2 output.

1. These triggers are differing from HRTIM_ADC1R/HRTIM_ADC3R to HRTIM_ADC2R/HRTIM_ADC4R.

40.5.79 HRTIM DLL control register (HRTIM_DLLCR)

Address offset: 0x74C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CALRTE[1:0]		CALEN	CAL
												rw	rw	rw	w

Bits 31:4 Reserved, must be kept at reset value.

Bits 3:2 **CALRTE[1:0]**: DLL Calibration rate

This defines the DLL calibration periodicity.
00: 1048576 * t_{HRTIM} (3.744 ms for f_{HRTIM} = 280 MHz)
01: 131072 * t_{HRTIM} (468 µs for f_{HRTIM} = 280 MHz)
10: 16384 * t_{HRTIM} (58.5 µs for f_{HRTIM} = 280 MHz)
11: 2048 * t_{HRTIM} (7.3 µs for f_{HRTIM} = 280 MHz)

Bit 1 **CALEN**: DLL Calibration Enable

This bit enables the periodic DLL calibration, as per CALRTE[1:0] bit setting. When CALEN bit is reset, the calibration can be started in single-shot mode with CAL bit.
0: Periodic calibration disabled
1: Calibration is performed periodically, as per CALRTE[1:0] setting

Note: CALEN must not be set simultaneously with CAL bit

Bit 0 **CAL**: DLL Calibration Start

This bit starts the DLL calibration process. It is write-only.
0: No calibration request
1: Calibration start

Note: CAL must not be set simultaneously with CALEN bit

40.5.80 HRTIM fault input register 1 (HRTIM_FLTINR1)

Address offset: 0x750

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rwo	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **FLT4LCK**: Fault 4 lock
Refer to FLT5LCK description in HRTIM_FLTINR2 register.

Bits 30:27 **FLT4F[3:0]**: Fault 4 filter
Refer to FLT5F[3:0] description in HRTIM_FLTINR2 register.

Bit 26 FLT4SRC[0]: Fault 4 source bit 0
Refer to FLT5SRC[0] description in HRTIM_FLTINR2 register.

Bit 25 **FLT4P**: Fault 4 polarity
Refer to FLT5P description in HRTIM_FLTINR2 register.

Bit 24 **FLT4E**: Fault 4 enable
Refer to FLT5E description in HRTIM_FLTINR2 register.

Bit 23 **FLT3LCK**: Fault 3 lock
Refer to FLT5LCK description in HRTIM_FLTINR2 register.

Bits 22:19 **FLT3F[3:0]**: Fault 3 filter
Refer to FLT5F[3:0] description in HRTIM_FLTINR2 register.

Bit 18 FLT3SRC[0]: Fault 3 source bit 0
Refer to FLT5SRC[0] description in HRTIM_FLTINR2 register.

Bit 17 **FLT3P**: Fault 3 polarity
Refer to FLT5P description in HRTIM_FLTINR2 register.

Bit 16 **FLT3E**: Fault 3 enable
Refer to FLT5E description in HRTIM_FLTINR2 register.

Bit 15 **FLT2LCK**: Fault 2 lock
Refer to FLT5LCK description in HRTIM_FLTINR2 register.

Bits 14:11 **FLT2F[3:0]**: Fault 2 filter
Refer to FLT5F[3:0] description in HRTIM_FLTINR2 register.

Bit 10 FLT2SRC[0]: Fault 2 source bit 0
Refer to FLT5SRC[0] description in HRTIM_FLTINR2 register.

Bit 9 **FLT2P**: Fault 2 polarity
Refer to FLT2P description in HRTIM_FLTINR2 register.

Bit 8 **FLT2E**: Fault 2 enable
Refer to FLT5E description in HRTIM_FLTINR2 register.

Bit 7 **FLT1LCK**: Fault 1 lock
Refer to FLT5LCK description in HRTIM_FLTINR2 register.

Bits 6:3 **FLT1F[3:0]**: Fault 1 filter
Refer to FLT5F[3:0] description in HRTIM_FLTINR2 register.

Bit 2 **FLT1SRC[0]**: Fault 1 source bit 0
Refer to FLT5SRC[0] description in HRTIM_FLTINR2 register.

Bit 1 **FLT1P**: Fault 1 polarity
Refer to FLT5P description in HRTIM_FLTINR2 register.

Bit 0 **FLT1E**: Fault 1 enable
Refer to FLT5E description in HRTIM_FLTINR2 register.

40.5.81 HRTIM fault input register 2 (HRTIM_FLTINR2)

Address offset: 0x754

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	FLTSD[1:0]		FLT8SRC[1]	FLT7SRC[1]	FLT6SRC[1]	FLT5SRC[1]	FLT4SRC[1]	FLT3SRC[1]	FLT2SRC[1]	FLT1SRC[1]
						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
FLT6LCK	FLT6F[3:0]				FLT6SRC[0]	FLT6P	FLT6E	FLT5LCK	FLT5F[3:0]				FLT5SRC[0]	FLT5P	FLT5E
rwo	rw	rw	rw	rw	rw	rw	rw	rwo	rw	rw	rw	rw	rw	rw	rw

Bits 31:26 Reserved, must be kept at reset value.

Bits 25:24 **FLTSD[1:0]**: Fault sampling clock division

This bitfield indicates the division ratio between the timer clock frequency (f_{HRTIM}) and the fault signal sampling clock (f_{FLTS}) used by the digital filters.

00: $f_{FLTS}=f_{HRTIM}$

01: $f_{FLTS}=f_{HRTIM} / 2$

10: $f_{FLTS}=f_{HRTIM} / 4$

11: $f_{FLTS}=f_{HRTIM} / 8$

Note: This bitfield must be written prior to any of the FLTxE enable bits.

Bit 23 **FLT8SRC[1]**: Fault 8 source bit 1

Refer to FLT5SRC[0] description.

Bit 22 **FLT7SRC[1]**: Fault 7 source bit 1

Refer to FLT5SRC[0] description.

Bit 21 **FLT6SRC[1]**: Fault 6 source bit 1

Refer to FLT5SRC[0] description.

Bit 20 **FLT5SRC[1]**: Fault 5 source bit 1

Refer to FLT5SRC[0] description.

Bit 19 **FLT4SRC[1]**: Fault 4 source bit 1

Refer to FLT5SRC[0] description.

Bit 18 **FLT3SRC[1]**: Fault 3 source bit 1

Refer to FLT5SRC[0] description.

Bit 17 **FLT2SRC[1]**: Fault 2 source bit 1

Refer to FLT5SRC[0] description.

Bit 16 **FLT1SRC[1]**: Fault 1 source bit 1

Refer to FLT5SRC[0] description.

Bit 15 **FLT6LCK**: Fault 6 lock

Refer to FLT5LCK description.

Bits 14:11 **FLT6F[3:0]**: Fault 6 filter

Refer to FLT5F[3:0] description.

Bit 10 **FLT6SRC[0]**: Fault 6 source bit 0

Refer to FLT5SRC[0] description.

Bit 9 **FLT6P**: Fault 6 polarity
Refer to FLT5P description.

Bit 8 **FLT6E**: Fault 6 enable
Refer to FLT5E description.

Bit 7 **FLT5LCK**: Fault 5 lock
The FLT5LCK bit modifies the write attributes of the fault programming bit, so that they are protected against spurious write accesses.
This bit is write-once. Once it has been set, it cannot be modified till the next system reset.
0: FLT5E, FLT5P, FLT5SRC[1:0], FLT5F[3:0] and FLT5BLK bits are read/write.
1: FLT5E, FLT5P, FLT5SRC[1:0], FLT5F[3:0] and FLT5BLK bits cannot be written (read-only mode)

Bits 6:3 **FLT5F[3:0]**: Fault 5 filter
This bitfield defines the frequency used to sample FLT5 input and the length of the digital filter applied to FLT5. The digital filter is made of an event counter in which N events are needed to validate a transition on the output.
0000: No filter, FLT5 acts asynchronously
0001: $f_{SAMPLING} = f_{HRTIM}$, N = 2
0010: $f_{SAMPLING} = f_{HRTIM}$, N = 4
0011: $f_{SAMPLING} = f_{HRTIM}$, N = 8
0100: $f_{SAMPLING} = f_{FLTS}/2$, N = 6
0101: $f_{SAMPLING} = f_{FLTS}/2$, N = 8
0110: $f_{SAMPLING} = f_{FLTS}/4$, N = 6
0111: $f_{SAMPLING} = f_{FLTS}/4$, N = 8
1000: $f_{SAMPLING} = f_{FLTS}/8$, N = 6
1001: $f_{SAMPLING} = f_{FLTS}/8$, N = 8
1010: $f_{SAMPLING} = f_{FLTS}/16$, N = 5
1011: $f_{SAMPLING} = f_{FLTS}/16$, N = 6
1100: $f_{SAMPLING} = f_{FLTS}/16$, N = 8
1101: $f_{SAMPLING} = f_{FLTS}/32$, N = 5
1110: $f_{SAMPLING} = f_{FLTS}/32$, N = 6
1111: $f_{SAMPLING} = f_{FLTS}/32$, N = 8
Note: This bitfield can be written only when FLT5E enable bit is reset.
This bitfield cannot be modified when FLT5LOCK has been programmed.

Bit 2 **FLT5SRC[0]**: Fault 5 source bit 0
The FTL5SRC[1:0] bitfield selects the FAULT5 input source (refer to *Table 410* for connection details).
00: Fault 5 input is HRTIM_FLT5 input pin
01: Fault 5 input is connected to a COMPx output
10: Fault 5 input is EEV5_muxout input pin
11: hrtim_ext_trg5
Note: This bitfield can be written only when FLT5E enable bit is reset.

Bit 1 **FLT5P**: Fault 5 polarity
This bit selects the FAULT5 input polarity.
0: Fault 5 input is active low
1: Fault 5 input is active high
Note: This bitfield can be written only when FLT5E enable bit is reset.

Bit 0 **FLT5E**: Fault 5 enable
This bit enables the global FAULT5 input circuitry.
0: Fault 5 input disabled
1: Fault 5 input enabled

40.5.82 HRTIM burst DMA master timer update register (HRTIM_BDMUPR)

Address offset: 0x758

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

						rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:10 Reserved, must be kept at reset value.

Bit 9 **MCMP4**: MCMP4R register update enable
Refer to MCR description.

Bit 8 **MCMP3**: MCMP3R register update enable
Refer to MCR description.

Bit 7 **MCMP2**: MCMP2R register update enable
Refer to MCR description.

Bit 6 **MCMP1**: MCMP1R register update enable
Refer to MCR description.

Bit 5 **MREP**: MREP register update enable
Refer to MCR description.

Bit 4 **MPER**: MPER register update enable
Refer to MCR description.

Bit 3 **MCNT**: MCNTR register update enable
Refer to MCR description.

Bit 2 **MDIER**: MDIER register update enable
Refer to MCR description.

Bit 1 **MICR**: MICR register update enable
Refer to MCR description.

Bit 0 **MCR**: MCR register update enable
This bit defines if the master timer MCR register is part of the list of registers to be updated by the burst DMA.
0: MCR register is not updated by burst DMA accesses
1: MCR register is updated by burst DMA accesses

40.5.83 HRTIM burst DMA timer x update register (HRTIM_BDTxUPR) (x = A to F)

Address offset: Block A: 0x75C

Address offset: Block B: 0x760

Address offset: Block C: 0x764

Address offset: Block D: 0x768

Address offset: Block E: 0x76C

Address offset: Block F: 0x774

Reset value: 0x0000 0000

Bits 31:27 Reserved, must be kept at reset value.

Bit 26 **TIMxCODER**: HRTIM_CODExR register update enable timer x
Refer to TIMxCR description.

Bit 25 **TIMxCOFER**: HRTIM_COFExR register update enable timer x
Refer to TIMxCR description.

Bit 24 **TIMxCOTRGR**: HRTIM_COTRGxR register update enable timer x
Refer to TIMxCR description.

Bit 23 **TIMxEESELR**: HRTIM_EESELxR register update enable timer x
Refer to TIMxCR description.

Bit 22 **TIMxEEFR3**: HRTIM_EEFxR3 register update enable timer x
Refer to TIMxCR description.

Bit 21 **TIMxCR2**: HRTIM_TIMxCR2 register update enable timer x
Refer to TIMxCR description.

Bit 20 **TIMxFLTR**: HRTIM_FLTxR register update enable timer x
Refer to TIMxCR description.

Bit 19 **TIMxOUTR**: HRTIM_OUTxR register update enable timer x
Refer to TIMxCR description.

Bit 18 **TIMxCHPR**: HRTIM_CHPxR register update enable timer x
Refer to TIMxCR description.

Bit 17 **TIMxRSTR**: HRTIM_RSTxR register update enable timer x
Refer to TIMxCR description.

Bit 16 **TIMxEEFR2**: HRTIM_EEFxR2 register update enable timer x
Refer to TIMxCR description.

Bit 15 **TIMxEEFR1**: HRTIM_EEFxR1 register update enable timer x
Refer to TIMxCR description.

Bit 14 **TIMxRST2R**: HRTIM_RST2xR register update enable timer x
Refer to TIMxCR description.

Bit 13 **TIMxSET2R**: HRTIM_SET2xR register update enable timer x
Refer to TIMxCR description.

Bit 12 **TIMxRST1R**: HRTIM_RST1xR register update enable timer x
Refer to TIMxCR description.

Bit 11 **TIMxSET1R**: HRTIM_SET1xR register update enable timer x
Refer to TIMxCR description.

Bit 10 **TIMxDTR**: HRTIM_DTxR register update enable timer x
Refer to TIMxCR description.

Bit 9 **TIMxCMP4**: HRTIM_CMP4xR register update enable timer x
Refer to TIMxCR description.

Bit 8 **TIMxCMP3**: HRTIM_CMP3xR register update enable timer x
Refer to TIMxCR description.

Bit 7 **TIMxCMP2**: HRTIM_CMP2xR register update enable timer x
Refer to TIMxCR description.

Bit 6 **TIMxCMP1**: HRTIM_CMP1xR register update enable timer x
Refer to TIMxCR description.

Bit 5 **TIMxREP**: HRTIM_REPxR register update enable timer x
Refer to TIMxCR description.

Bit 4 **TIMxPER**: HRTIM_PERxR register update enable timer x
Refer to TIMxCR description.

Bit 3 **TIMxCNT**: HRTIM_CNTxR register update enable timer x
Refer to TIMxCR description.

Bit 2 **TIMxDIER**: HRTIM_TIMxDIER register update enable timer x
Refer to TIMxCR description.

Bit 1 **TIMxICR**: HRTIM_TIMxICR register update enable timer x
Refer to TIMxCR description.

Bit 0 **TIMxCR**: HRTIM_TIMxCR register update enable timer x
This bit defines if the master timer MCR register is part of the list of registers to be updated by the burst DMA.
0: HRTIM_TIMxCR register is not updated by burst DMA accesses
1: HRTIM_TIMxCR register is updated by burst DMA accesses

40.5.84 HRTIM burst DMA data register (HRTIM_BDMADR)

Address offset: 0x770

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
BDMADR[31:16]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
BDMADR[15:0]															
w	w	w	w	w	w	w	w	w	w	w	w	w	w	w	w

Bits 31:0 **BDMADR[31:0]**: Burst DMA data register

Write accesses to this register triggers:

– the copy of the data value into the registers enabled in BDTxUPR and BDMUPR register bits

– the increment of the register pointer to the next location to be filled

40.5.85 HRTIM ADC extended trigger register (HRTIM_ADCER)

Address offset: 0x778

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	ADC10TRG[4:0]					ADC9TRG[4:0]					ADC8TRG[4:0]

Bit 31 Reserved, must be kept at reset value.

Bits 30:26 **ADC10TRG[4:0]**: ADC trigger 10 selection
This bit selects the ADC trigger 10 source.
Refer to ADC6TRG[4:0] description.

Bits 25:21 **ADC9TRG[4:0]**: ADC trigger 9 selection
This bit selects the ADC trigger 9 source.
Refer to ADC5TRG[4:0] description.

Bits 20:16 **ADC8TRG[4:0]**: ADC trigger 8 selection
This bit selects the ADC trigger 8 source.
Refer to ADC6TRG[4:0] description.

Bit 15 Reserved, must be kept at reset value.

Bits 14:10 **ADC7TRG[4:0]**: ADC trigger 7 selection
This bit selects the ADC trigger 7 source.
Refer to ADC5TRG[4:0] description.

Bits 9:5 **ADC6TRG[4:0]**: ADC trigger 6 selection
This bit selects the ADC trigger 6 source.
0: Trigger on master compare 1

Bits 31:23 Reserved, must be kept at reset value.

Bits 22:20 **AD10USRC[2:0]**: ADC trigger 10 update source
Refer to AD5USRC[2:0] description.

Bit 19 Reserved, must be kept at reset value.

Bits 18:16 **AD9USRC[2:0]**: ADC trigger 9 update source
Refer to AD5USRC[2:0] description.

Bit 15 Reserved, must be kept at reset value.

Bits 14:12 **AD8USRC[2:0]**: ADC trigger 8 update source
Refer to AD5USRC[2:0] description.

Bit 11 Reserved, must be kept at reset value.

Bits 10:8 **AD7USRC[2:0]**: ADC trigger 7 update source
Refer to AD5USRC[2:0] description.

Bit 7 Reserved, must be kept at reset value.

Bits 6:4 **AD6USRC[2:0]**: ADC trigger 6 update source
Refer to AD5USRC[2:0] description.

Bit 3 Reserved, must be kept at reset value.

Bits 2:0 **AD5USRC[2:0]**: ADC trigger 5 update source
These bits define the source which triggers the update of the ADC5TRG[4:0] bitfield in the HRTIM_ADCER register (transfer from preload to active register). It only defines the source timer. The precise condition is defined within the timer itself, with the BRSTDMA[1:0] bitfield in HRTIM_MCR or the UPDGAT[3:0] bitfield in HRTIM_TIMxCR register.
000: Master timer
001: Timer A
010: Timer B
011: Timer C
100: Timer D
101: Timer E
110: Timer F
111: Reserved

40.5.87 HRTIM ADC post scaler register 1 (HRTIM_ADCPS1)

Address offset: 0x780

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **FLT4RSTM**: Fault 4 reset mode
Refer to FLT5RSTM description.

Bit 30 **FLT4CRES**: Fault 4 counter reset
Refer to FLT5CRES description.

Bits 29:26 **FLT4CNT[3:0]**: Fault 4 counter
Refer to FLT5CNT description.

Bit 25 **FLT4BLKS**: Fault 4 blanking source
Refer to FLT5BLKS description.

Bit 24 **FLT4BLKE**: Fault 4 blanking enable
Refer to FLT5BLKE description.

Bit 23 **FLT3RSTM**: Fault 3 reset mode
Refer to FLT5RSTM description.

Bit 22 **FLT3CRES**: Fault 3 counter reset
Refer to FLT5CRES description.

Bits 21:18 **FLT3CNT[3:0]**: Fault 3 counter
Refer to FLT5CNT description.

Bit 17 **FLT3BLKS**: Fault 3 blanking source
Refer to FLT5BLKS description.

Bit 16 **FLT3BLKE**: Fault 3 blanking enable
Refer to FLT5BLKE description.

Bit 15 **FLT2RSTM**: Fault 2 reset mode
Refer to FLT5RSTM description.

Bit 14 **FLT2CRES**: Fault 2 counter reset
Refer to FLT5CRES description.

Bits 13:10 **FLT2CNT[3:0]**: Fault 2 counter
Refer to FLT5CNT description.

Bit 9 **FLT2BLKS**: Fault 2 blanking source
Refer to FLT5BLKS description.

Bit 8 **FLT2BLKE**: Fault 2 blanking enable
Refer to FLT5BLKE description.

Bit 7 **FLT1RSTM**: Fault 1 reset mode
Refer to FLT5RSTM description.

Bit 6 **FLT1CRES**: Fault 1 counter reset
Refer to FLT5CRES description.

Bits 5:2 **FLT1CNT[3:0]**: Fault 1 counter
Refer to FLT5CNT description.

Bit 1 **FLT1BLKS**: Fault 1 blanking source
Refer to FLT5BLKS description.

Bit 0 **FLT1BLKE**: Fault 1 blanking enable
Refer to FLT5BLKE description.

40.5.90 HRTIM fault input register 4 (HRTIM_FLTINR4)

Address offset: 0x78C

Reset value: 0x0000 0000

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **FLT8RSTM**: Fault 8 reset mode
Refer to FLT5RSTM description.

Bit 30 **FLT8CRES**: Fault 8 counter reset
Refer to FLT5CRES description.

Bits 29:26 **FLT8CNT[3:0]**: Fault 8 counter
Refer to FLT5CNT description.

Bit 25 **FLT8BLKS**: Fault 8 blanking source
Refer to FLT5BLKS description.

Bit 24 **FLT8BLKE**: Fault 8 blanking enable
Refer to FLT5BLKE description.

Bit 23 **FLT7RSTM**: Fault 7 reset mode
Refer to FLT5RSTM description.

Bit 22 **FLT7CRES**: Fault 7 counter reset
Refer to FLT5CRES description.

Bits 21:18 **FLT7CNT[3:0]**: Fault 7 counter
Refer to FLT5CNT description.

Bit 17 **FLT7BLKS**: Fault 7 blanking source
Refer to FLT5BLKS description.

Bit 16 **FLT7BLKE**: Fault 7 blanking enable
Refer to FLT5BLKE description.

Bit 15 **FLT6RSTM**: Fault 6 reset mode
Refer to FLT5RSTM description.

Bit 14 **FLT6CRES**: Fault 6 counter reset
Refer to FLT5CRES description.

Bits 13:10 **FLT6CNT[3:0]**: Fault 6 counter
Refer to FLT5CNT description.

Bit 9 **FLT6BLKS**: Fault 6 blanking source
Refer to FLT5BLKS description.

Bit 8 **FLT6BLKE**: Fault 6 blanking enable
Refer to FLT5BLKE description.

Bit 7 **FLT5RSTM**: Fault 5 reset mode

This bit selects the FAULT5 counter reset mode

0: Fault 5 counter is reset on each reset / roll-over event

1: Fault 5 counter is reset on each reset / roll-over event only if no fault occurred during last counting period.

Note: This bitfield can be written only when FLT5E enable bit is reset.

Bit 6 **FLT5CRES**: Fault 5 counter reset

This bit resets the FAULT5 counter. It is set by software and reset by hardware.

0: No action

1: Fault 5 counter is reset

Bits 5:2 **FLT5CNT[3:0]**: Fault 5 counter

This bitfield selects the FAULT5 counter threshold. A fault is considered valid when the number of events is equal to the (FLT5CNT[3:0]+1) value.

Bit 1 **FLT5BLKS**: Fault 5 blanking source

The FTL5BLKS bit selects the FAULT5 blanking source (refer to *Table 441* for details).

0: Fault 5 reset-aligned blanking window

1: Fault 5 Moving blanking window

Note: This bitfield can be written only when FLT5E enable bit is reset.

Bit 0 **FLT5BLKE**: Fault 5 blanking enable

The FTL5BLKE bit selects the FAULT5 blanking mode. The blanking source is defined by the FLT5BLKS bit.

0: No blanking on fault 5

1: Fault 5 blanking mode

Note: This bitfield can be written only when FLT5E enable bit is reset

40.5.91 HRTIM fault input register 5 (HRTIM_FLTINR5)

Address offset: 0x790

rwo	rw	rw	rw	rw	rw	rw	rw	rwo	rw	rw	rw	rw	rw	rw	rw

Bits 31:16 Reserved, must be kept at reset value.

Bit 15 **FLT8LCK**: Fault 8 lock
Refer to FLT7LCK description.

Bits 14:11 **FLT8F[3:0]**: Fault 8 filter
Refer to FLT7F[3:0] description.

Bit 10 **FLT8SRC[0]**: Fault 8 source bit 0
Refer to FLT7SRC[0] description.

Bit 9 **FLT8P**: Fault 8 polarity
Refer to FLT7P description.

Bit 8 **FLT8E**: Fault 8 enable
Refer to FLT7E description.

Bit 7 **FLT7LCK**: Fault 7 lock
The FLT7LCK bit modifies the write attributes of the fault programming bit, so that they are protected against spurious write accesses.
This bit is write-once. Once it has been set, it cannot be modified till the next system reset.
0: FLT7E, FLT7P, FLT7SRC[1:0], FLT7F[3:0] and FLT7BLK bits are read/write.
1: FLT7E, FLT7P, FLT7SRC[1:0], FLT7F[3:0] and FLT7BLK bits cannot be written (read-only mode)

Bits 6:3 **FLT7F[3:0]**: Fault 7 filter

This bitfield defines the frequency used to sample FLT7 input and the length of the digital filter applied to FLT7. The digital filter is made of an event counter in which N events are needed to validate a transition on the output.

0000: No filter, FLT7 acts asynchronously
0001: $f_{SAMPLING} = f_{HRTIM}$, N = 2
0010: $f_{SAMPLING} = f_{HRTIM}$, N = 4
0011: $f_{SAMPLING} = f_{HRTIM}$, N = 8
0100: $f_{SAMPLING} = f_{FLTS}/2$, N = 6
0101: $f_{SAMPLING} = f_{FLTS}/2$, N = 8
0110: $f_{SAMPLING} = f_{FLTS}/4$, N = 6
0111: $f_{SAMPLING} = f_{FLTS}/4$, N = 8
1000: $f_{SAMPLING} = f_{FLTS}/8$, N = 6
1001: $f_{SAMPLING} = f_{FLTS}/8$, N = 8
1010: $f_{SAMPLING} = f_{FLTS}/16$, N = 5
1011: $f_{SAMPLING} = f_{FLTS}/16$, N = 6
1100: $f_{SAMPLING} = f_{FLTS}/16$, N = 8
1101: $f_{SAMPLING} = f_{FLTS}/32$, N = 5
1110: $f_{SAMPLING} = f_{FLTS}/32$, N = 6
1111: $f_{SAMPLING} = f_{FLTS}/32$, N = 8

Note: This bitfield can be written only when FLT7E enable bit is reset.
This bitfield cannot be modified when FLT7LOCK has been programmed.

Bit 2 **FLT7SRC[0]**: Fault 7 source bit 0

The FTL7SRC[1:0] bitfield selects the FAULT7 input source (refer to *Table 410* for connection details).

00: Fault 7 input is HRTIM_FLT7 input pin
01: Fault 7 input is connected to a COMPx output
10: Fault 7 input is EEV7_muxout input pin
01: hrtim_ext_trg7

Note: This bitfield can be written only when FLT7E enable bit is reset.

Bit 1 **FLT7P**: Fault 7 polarity

This bit selects the FAULT7 input polarity.

0: Fault 7 input is active low
1: Fault 7 input is active high

Note: This bitfield can be written only when FLT7E enable bit is reset.

Bit 0 **FLT7E**: Fault 7 enable

This bit enables the global FAULT7 input circuitry.

0: Fault 7 input disabled
1: Fault 7 input enabled

40.5.92 HRTIM timer external event control register 4 (HRTIM_EECR4)

Address offset: 0x7A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **EE13FAST**: External event 3 fast mode
Refer to EE11FAST description.

Bits 16:15 **EE13SNS[1:0]**: External event 3 sensitivity
Refer to EE11SNS[1:0] description.

Bit 14 **EE13POL**: External event 3 polarity
Refer to EE11POL description.

Bits 13:12 **EE13SRC[1:0]**: External event 3 source
This bitfield is combined with EE13SRC[2] bit. Refer to EE11SRC[1:0] description.

Bit 11 **EE12FAST**: External event 2 fast mode
Refer to EE11FAST description.

Bits 10:9 **EE12SNS[1:0]**: External event 2 sensitivity
Refer to EE11SNS[1:0] description.

Bit 8 **EE12POL**: External event 2 polarity
Refer to EE11POL description.

Bits 7:6 **EE12SRC[1:0]**: External event 2 source
This bitfield is combined with EE12SRC[2] bit. Refer to EE11SRC[1:0] description.

Bit 5 **EE11FAST**: External event 11 fast mode
0: External event 11 is re-synchronized by the HRTIM logic before acting on outputs, which adds a f_{HRTIM} clock-related latency
1: External event 11 is acting asynchronously on outputs (low latency mode)
Note: This bit must not be modified once the counter in which the event is used is enabled (TxCEN bit set).

Bits 4:3 **EE11SNS[1:0]**: External event 11 sensitivity
00: On active level defined by EE11POL bit
01: Rising edge, whatever EE11POL bit value
10: Falling edge, whatever EE11POL bit value
11: Both edges, whatever EE11POL bit value

Bit 2 **EE11POL**: External event 11 polarity
This bit is only significant if EE11SNS[1:0] = 00.
0: External event is active high
1: External event is active low

Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE11FAST bit.

Bits 1:0 **EE11SRC[1:0]**: External event 11 source
This bitfield selects the External event 11 source. This bitfield is combined with EE11SRC[2] bit. See *Table 411* for details.
000:hrtim_eev11_1
001:hrtim_eev11_2
010:hrtim_eev11_3
011:hrtim_eev11_4
100:hrtim_eev11_5
101:hrtim_eev11_6
110:hrtim_eev11_7
111:hrtim_eev11_8

Note: This parameter cannot be changed once the timer x is enabled. It must be configured prior to setting EE11FAST bit.

40.5.93 HRTIM timer external event control register 5 (HRTIM_EECR5)

Bits 16:15 **EE16SNS[1:0]**: External event 16 sensitivity
Refer to EE14SNS[1:0] description.

Bit 14 **EE16POL**: External event 16 polarity
Refer to EE14POL description.

Bits 13:12 **EE16SRC[1:0]**: External event 16 source
This bitfield is combined with EE16SRC[2] bit. Refer to EE14SRC[1:0] description.

Bit 11 Reserved, must be kept at reset value.

Bits 10:9 **EE15SNS[1:0]**: External event 15 sensitivity
Refer to EE14SNS[1:0] description.

Bit 8 **EE15POL**: External event 15 polarity
Refer to EE14POL description.

Bits 7:6 **EE15SRC[1:0]**: External event 15 source
This bitfield is combined with EE15SRC[2] bit. Refer to EE14SRC[1:0] description.

Bit 5 Reserved, must be kept at reset value.

Bits 4:3 **EE14SNS[1:0]**: External event 14 sensitivity
00: On active level defined by EE14POL bit
01: Rising edge, whatever EE14POL bit value
10: Falling edge, whatever EE14POL bit value
11: Both edges, whatever EE14POL bit value

Bit 2 **EE14POL**: External event 14 polarity
This bit is only significant if EE14SNS[1:0] = 00.
0: External event is active high
1: External event is active low

Bits 1:0 **EE14SRC[1:0]**: External event 14 source
This bitfield is combined with EE14SRC[2] bit. This bitfield selects the External event 14 source. See *Table 411* for details.

Bits 31:7 Reserved, must be kept at reset value.

Bit 6 **RTFUDISA**: Remote timer F update disable authorization
Refer to RTAUDISA description.

Bit 5 **RTEUDISA**: Remote timer E update disable authorization
Refer to RTAUDISA description

Bit 4 **RTDUDISA**: Remote timer D update disable authorization
Refer to RTAUDISA description.

Bit 3 **RTCUDISA**: Remote timer C update disable authorization
Refer to RTAUDISA description.

Bit 2 **RTBUDISA**: Remote timer B update disable authorization
Refer to RTAUDISA description.

Bit 1 **RTAUDISA**: Remote timer A update disable authorization
This bit is set and cleared by software to authorize another HRTIMER to disable Timer A's update events.
0: Remote update disable requests are ignored.
1: Remote update disable requests authorized.

Bit 0 **RMUDISA**: Remote master update disable authorization
This bit is set and cleared by software to authorize another HRTIMER to disable master timer's update events.
0: Remote update disable requests are ignored.
1: Remote update disable requests authorized.

40.5.97 HRTIM option register (HRTIM_OR)

Address offset: 0x7FC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

													rw	rw	rw

Bits 31:3 Reserved, must be kept at reset value.

Bit 2 **INSYNCSEL**: Synchronization Input Selection

This bit control a multiplexer for selecting the signal connected to the hrtim_in_sync3 input. See *Table 415: Internal synchronization source* for details.

0: hrtim_in_sync3 is connected to HRTIMx_SCIN

1: hrtim_in_sync3 is connected to play1_out15

Bit 1 **UPDENSEL**: Update Enable Selection

This bit control a multiplexer for selecting the signal connected to the hrtim_upd_en1 input. See *Table 412: Update enable inputs and sources* for details.

0: hrtim_upd_en1 is connected to tim10_oc1

1: hrtim_upd_en1 is connected to play1_out14

Bit 0 **BMTRGSEL**: Update Enable Selection

This bit control a multiplexer for selecting the signal connected to the hrtim_bm_trg input. See *Table 414: Burst mode trigger source* for details.

0: hrtim_bm_trg is connected to tim26_trgo

1: hrtim_bm_trg is connected to play1_out13

40.5.98 HRTIM register map

The tables below summarize the HRTIM registers mapping.

Table 447. HRTIM Register map and reset values – master timer

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

41 Advanced-control timers (TIM1/TIM8/TIM20)

41.1 TIM1/TIM8/TIM20 introduction

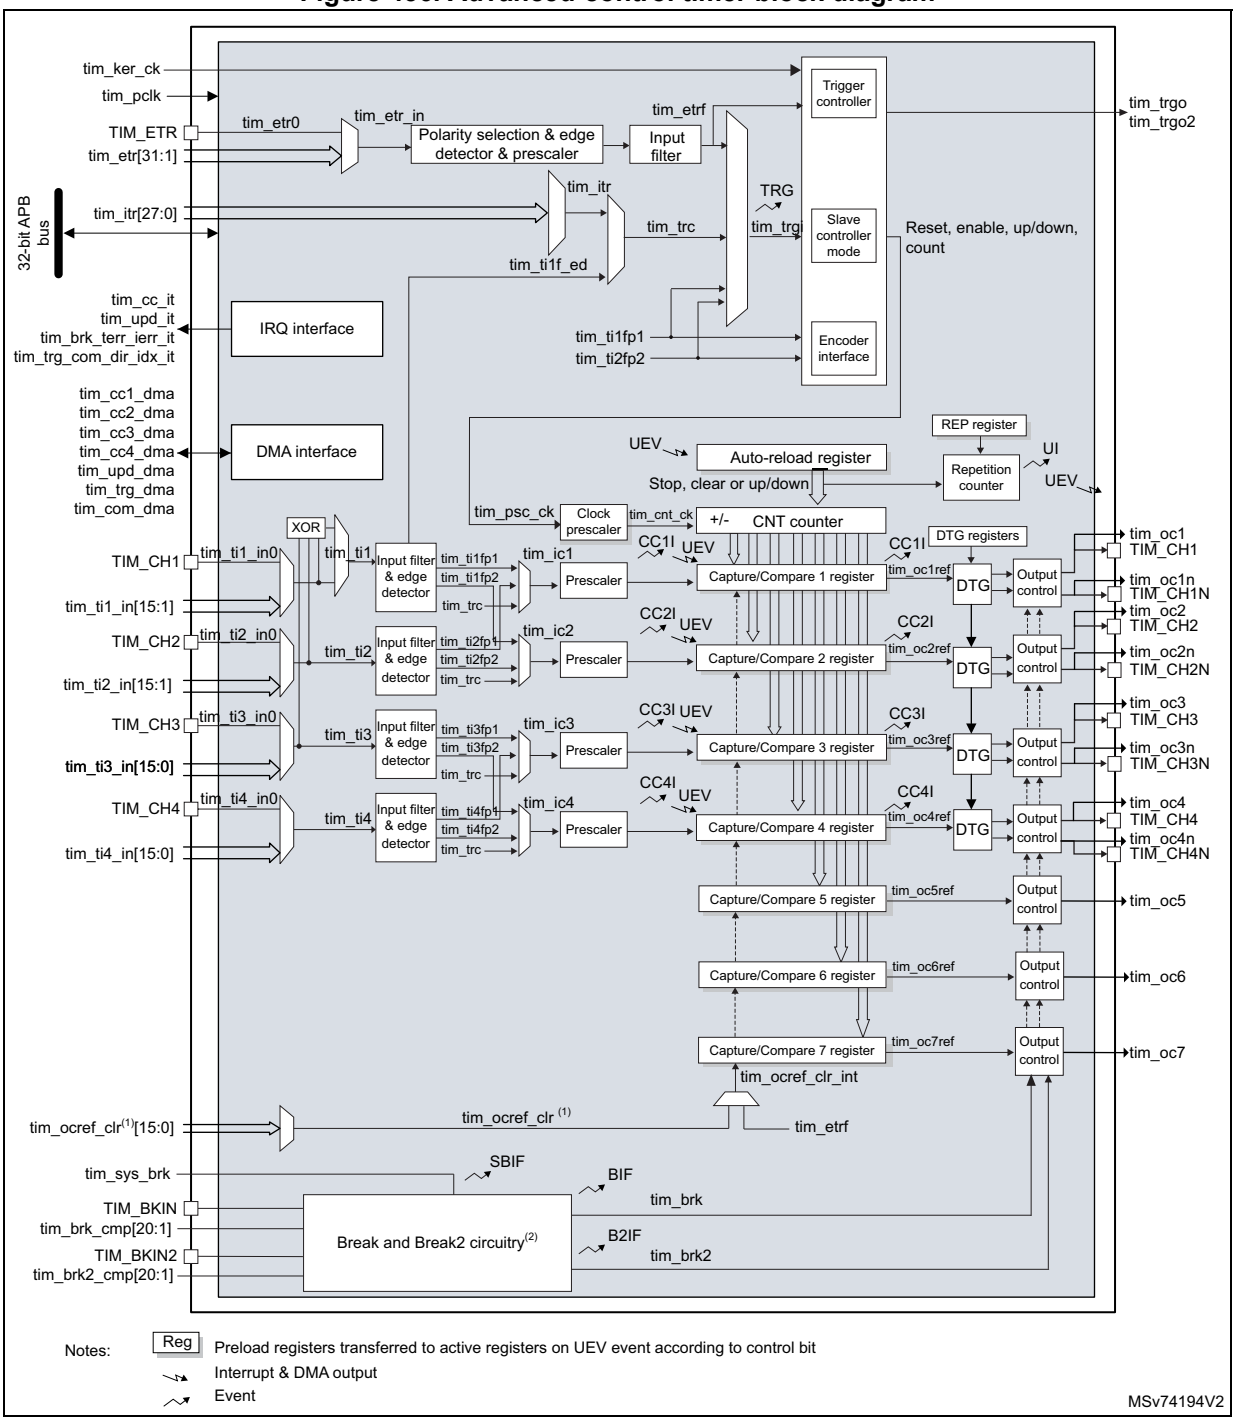
The advanced-control timers (TIM1/TIM8/TIM20) consist of a 16-bit autoreload counter driven by a programmable prescaler.

It may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM, complementary PWM with dead-time insertion).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The advanced-control (TIM1/TIM8/TIM20) and general-purpose (TIMy) timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 41.3.35: Timer synchronization*.

41.2 TIM1/TIM8/TIM20 main features



TIM1/TIM8/TIM20 timer features include:

- 16-bit up, down, up/down autoreload counter.
- 16-bit programmable prescaler allowing dividing (also “on the fly”) the counter clock frequency by any factor from 1 to 65536.
- Seven independent channels for:
  - Input capture (but channels 5, 6 and 7)
  - Output compare
  - PWM generation (edge and center-aligned mode)
  - One-pulse mode output
- Complementary outputs with programmable dead-time
- Synchronization circuit to control the timer with external signals and to interconnect several timers together.
- Repetition counter to update the timer registers only after a given number of cycles of the counter.
- 2 break inputs to put the timer’s output signals in a safe user selectable configuration.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger)
  - Trigger event (counter start, stop, initialization, or count by internal/external trigger)
  - Input capture
  - Output compare
- Incremental encoders, quadrature encoders and hall-sensors support
- Trigger input for external clock or cycle-by-cycle current management
- ADC synchronization for jitter-free sampling points

41.3 TIM1/TIM8/TIM20 functional description

41.3.1 Block diagram

Figure 456. Advanced-control timer block diagram

1. This feature is not available on all timers, refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals*.
2. See *Figure 507: Break and Break2 circuitry overview* for details.

41.3.2 TIM1/TIM8/TIM20 pins and internal signals

The tables in this section summarize the TIM inputs and outputs

Table 450. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2 TIM_CH3 TIM_CH4	Input/Output	Timer multi-purpose channels. Each channel can be used for capture, compare or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock), external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.
TIM_CH1N TIM_CH2N TIM_CH3N TIM_CH4N	Output	Timer complementary outputs, derived from TIM_CHx outputs with the possibility to have deadtime insertion.
TIM_ETR	Input	External trigger input. This input can be used as external trigger or as external clock source. This input can receive a clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
TIM_BKIN TIM_BKIN2	Input / Output	Break and Break2 inputs. These inputs can also be configured in bidirectional mode.

Table 451. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0] tim_ti3_in[15:0] tim_ti4_in[15:0]	Input	Internal timer inputs bus. The tim_ti1_in[15:0] and tim_ti2_in[15:0] inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock) and for quadrature encoder signals.
tim_etr[31:0]	Input	External trigger internal input bus. These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulsewidth control. These inputs can receive clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
tim_itr[27:0]	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo/tim_trgo2	Output	Internal trigger outputs. These triggers are used by other timers and /or other peripherals.

Table 451. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_ocx (x = 1 to 4)	Output	Internal output compare signals of channels 1 to 4. These outputs can be used for triggering/synchronizing other internal peripherals.
tim_ocxn (x = 1 to 4)	Output	Internal timer complementary outputs, derived from tim_ocx internal outputs with the possibility to have deadtime insertion.
tim_ocx (x = 5 to 7)	Output	Internal output compare signals of channels 5 to 7. These outputs can be used for triggering/synchronizing other internal peripherals.
tim_ocref_clr[15:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim ocxref signals, typically for hardware cycle-by-cycle pulsewidth control.
tim_brk_cmp[20:1]	Input	Break input for internal signals
tim_brk2_cmp[20:1]	Input	Break2 input for internal signals
tim_sys_brk[n:0]	Input	System break input. This input gathers the MCU's system level errors.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock
tim_cc_it	Output	Timer capture/compare interrupt
tim_upd_it	Output	Timer update event interrupt
tim_brk_terr_ierr_it	Output	Timer break, break2, transition error and index error interrupt
tim_trgi_com_dir_idx_it	Output	Timer trigger, commutation, direction and index interrupt
tim_cc1_dma tim_cc2_dma tim_cc3_dma tim_cc4_dma	Output	Timer capture / compare 1..4 dma requests
tim_upd_dma	Output	Timer update dma request
tim_trgi_dma	Output	Timer trigger dma request
tim_com_dma	Output	Timer commutation dma request

Table 452, *Table 453*, *Table 454*, and *Table 455* list the sources connected to the tim_ti[4:1] input multiplexers.

41.3.3 Time-base unit

The main block of the programmable advanced-control timer is a 16-bit counter with its related autoreload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software, even when the counter is running.

The time-base unit includes:

- Counter register (TIM_CNT)
- Prescaler register (TIM_PSC)
- Autoreload register (TIM_ARR)
- Repetition counter register (TIM_RCR)

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register are transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIM_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when downcounting) and if the UDIS bit equals 0 in the TIM_CR1 register. It can also be generated by software. The generation of the update event is described in detailed for each configuration.

Note: An update overrun status bit (UIOVRF in TIM_SR register) indicates that an update request occurred while an update interrupt is pending (update interrupt flag set). This bit is useful when debugging closed loop applications, to indicate that:

- the update interrupt service routine is too long with respect to the interval between consecutive update events

- the update interrupt service routine was served too late with respect to the subsequent update event

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIM_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

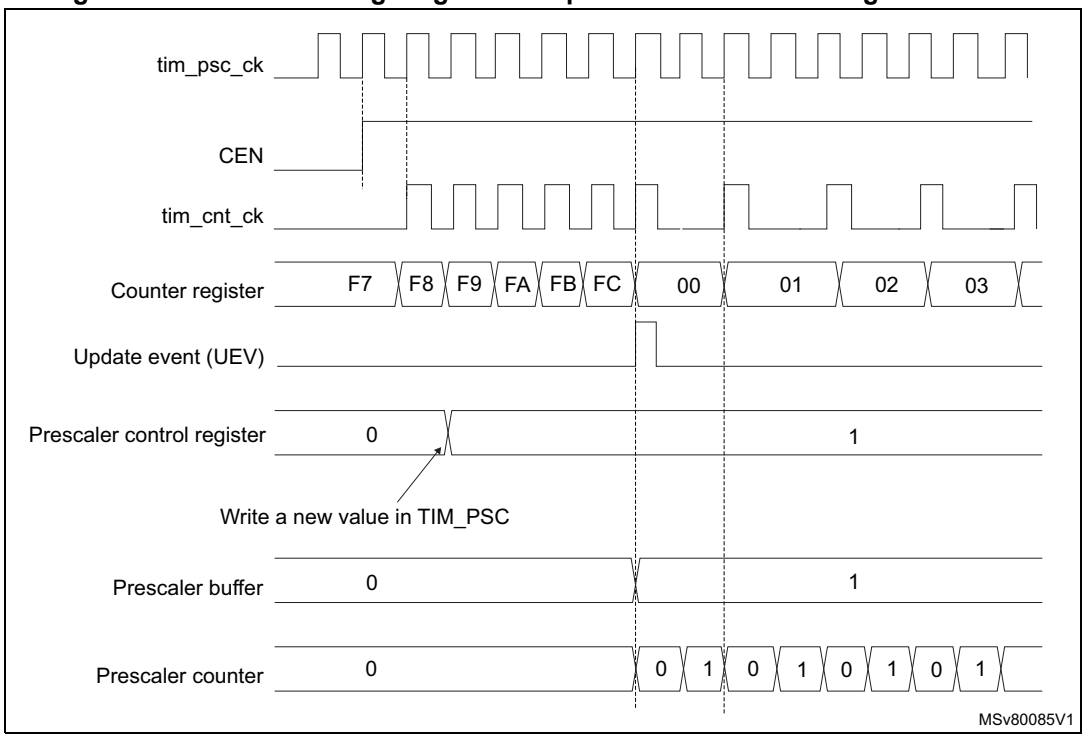
Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIM_CR1 register.

Prescaler description

The prescaler divides the counter clock frequency by any factor from 1 to 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIM_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 457 and *Figure 458* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 457. Counter timing diagram with prescaler division change from 1 to 2



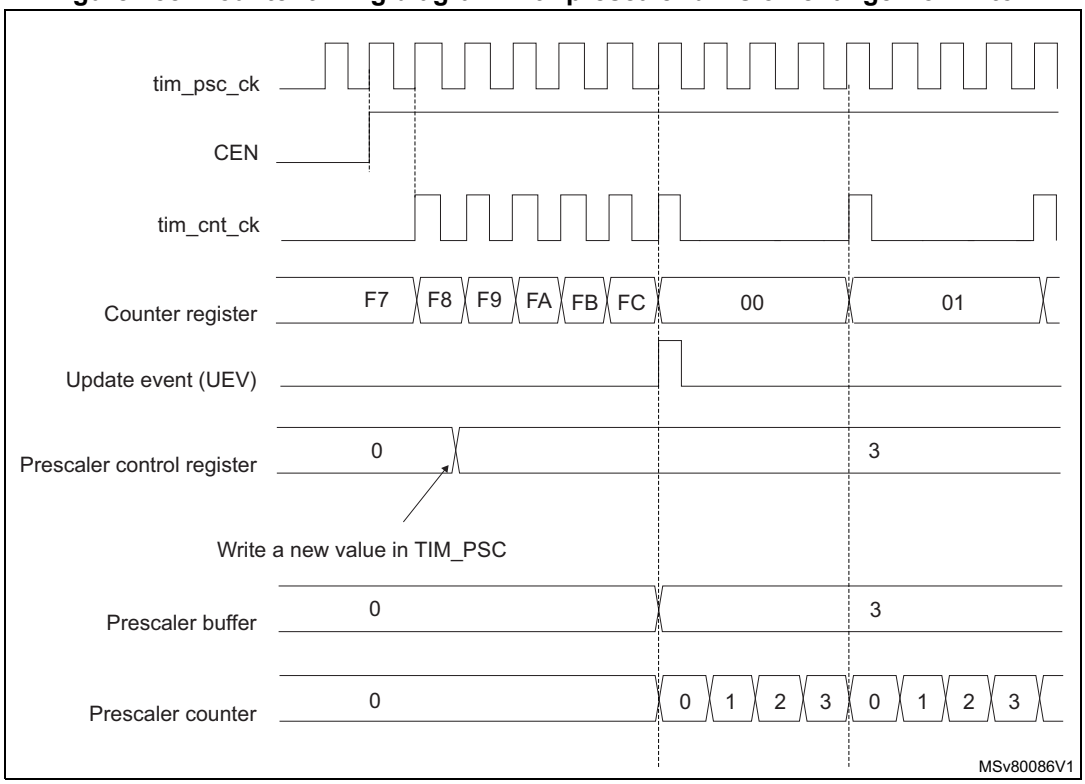


Figure 458. Counter timing diagram with prescaler division change from 1 to 4

41.3.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register), then restarts from 0 and generates a counter overflow event.

If the repetition counter is used, the update event (UEV) is generated after upcounting is repeated for the number of times programmed in the repetition counter register (TIM_RCR) + 1. Else the update event is generated at each counter overflow.

Setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV event can be disabled by software by setting the UDIS bit in the TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register,
- The autoreload shadow register is updated with the preload value (TIM_ARR),
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 459. Counter timing diagram, internal clock divided by 1

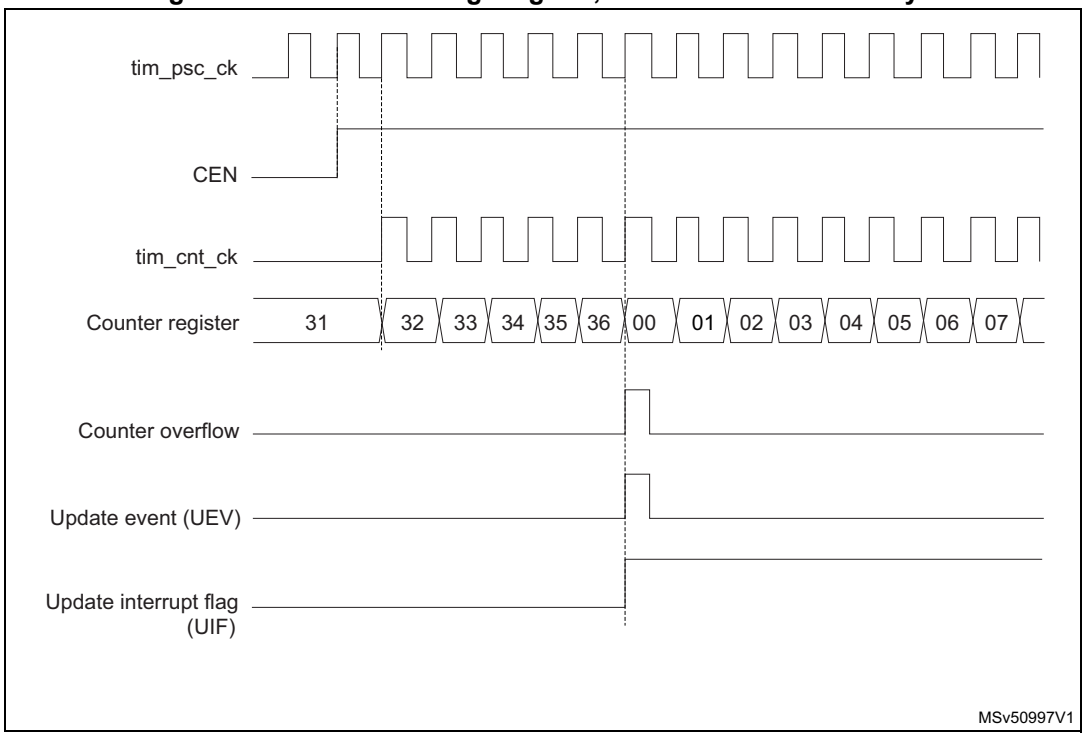

Figure 460. Counter timing diagram, internal clock divided by 2

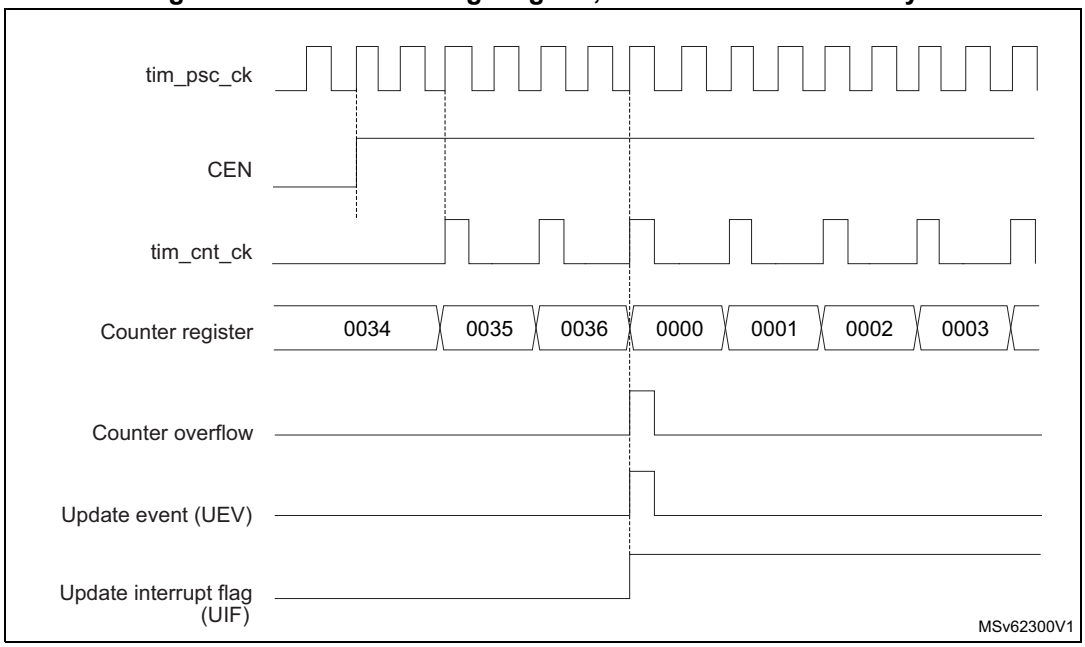

Figure 461. Counter timing diagram, internal clock divided by 4

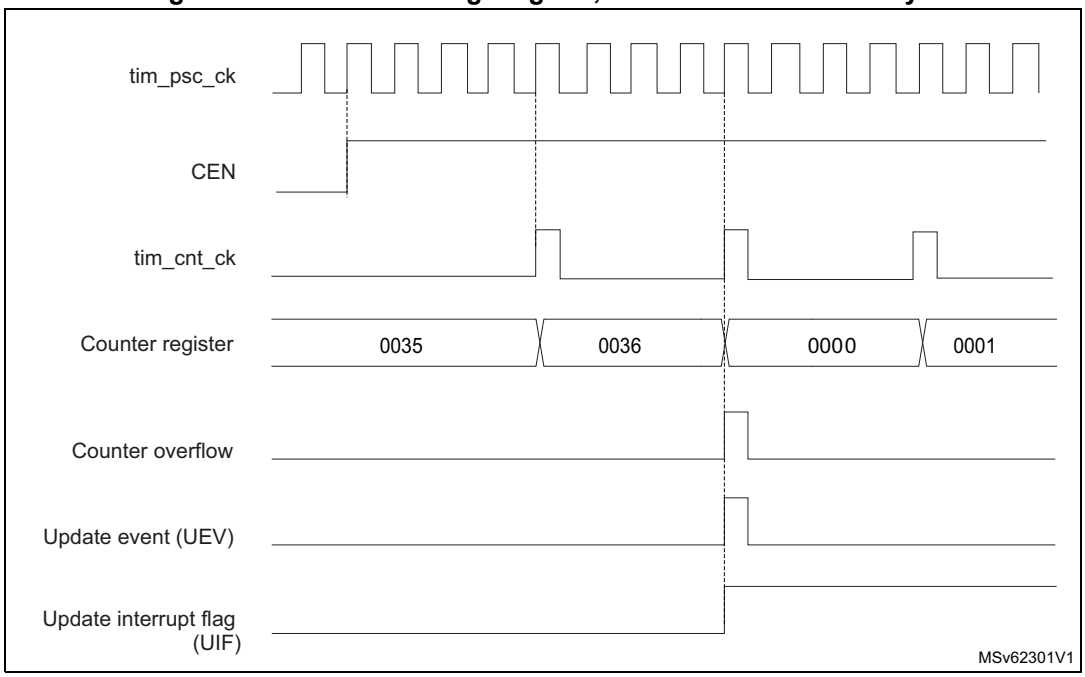

Figure 462. Counter timing diagram, internal clock divided by N

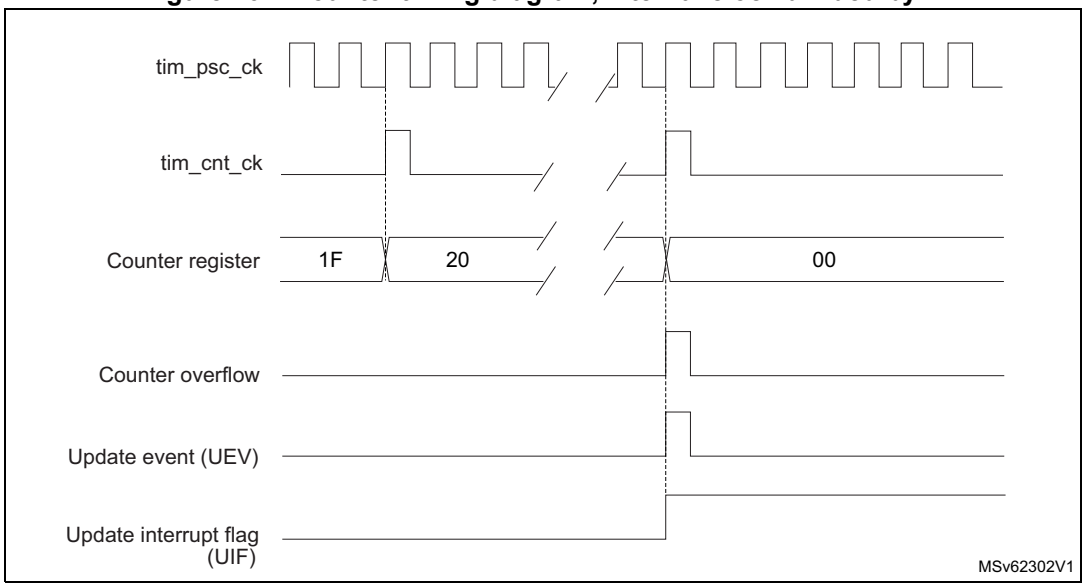

Figure 463. Counter timing diagram, update event when ARPE = 0 (TIM_ARR not preloaded)

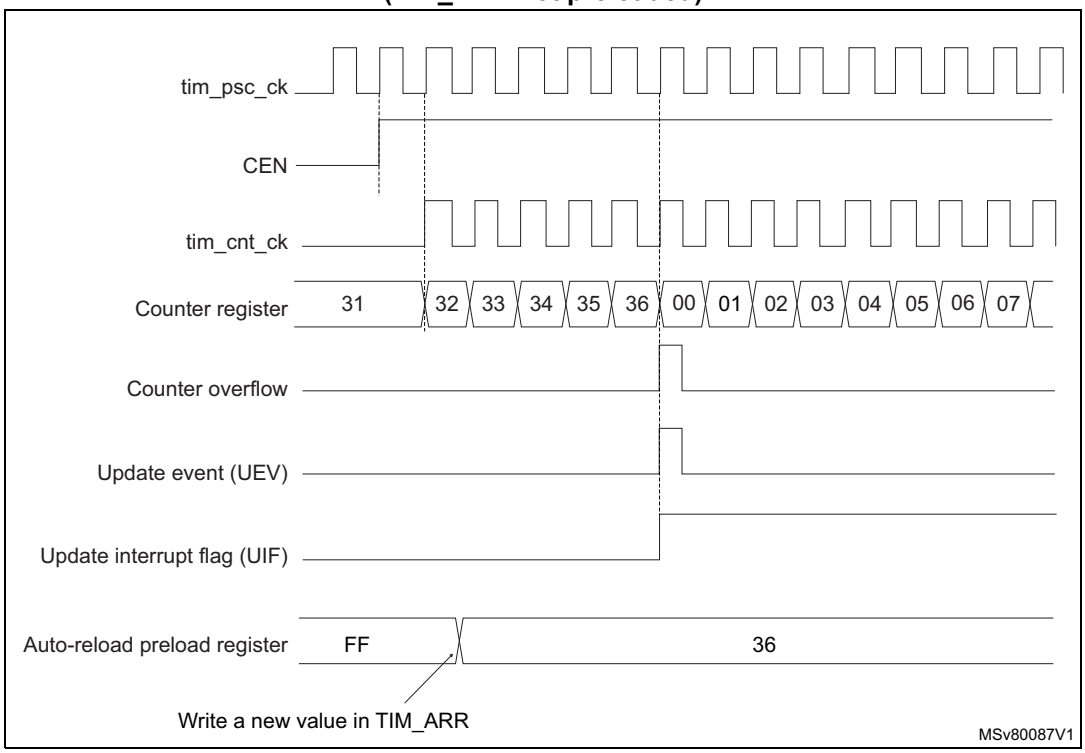

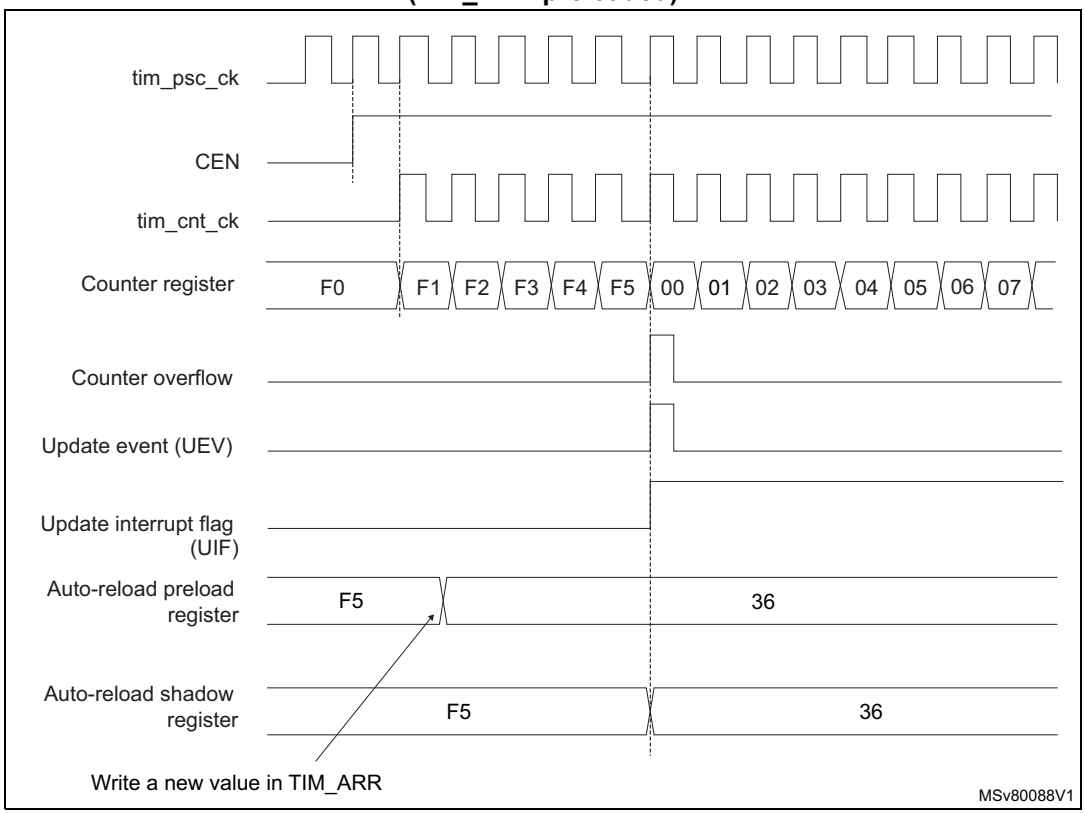

Figure 464. Counter timing diagram, update event when ARPE = 1 (TIM_ARR preloaded)

Downcounting mode

In downcounting mode, the counter counts from the autoreload value (content of the TIM_ARR register) down to 0, then restarts from the autoreload value and generates a counter underflow event.

If the repetition counter is used, the update event (UEV) is generated after downcounting is repeated for the number of times programmed in the repetition counter register (TIM_RCR) + 1. Else the update event is generated at each counter underflow.

Setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event.

The UEV update event can be disabled by software by setting the UDIS bit in TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current autoreload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate doesn't change).

In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register.
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that the autoreload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 465. Counter timing diagram, internal clock divided by 1

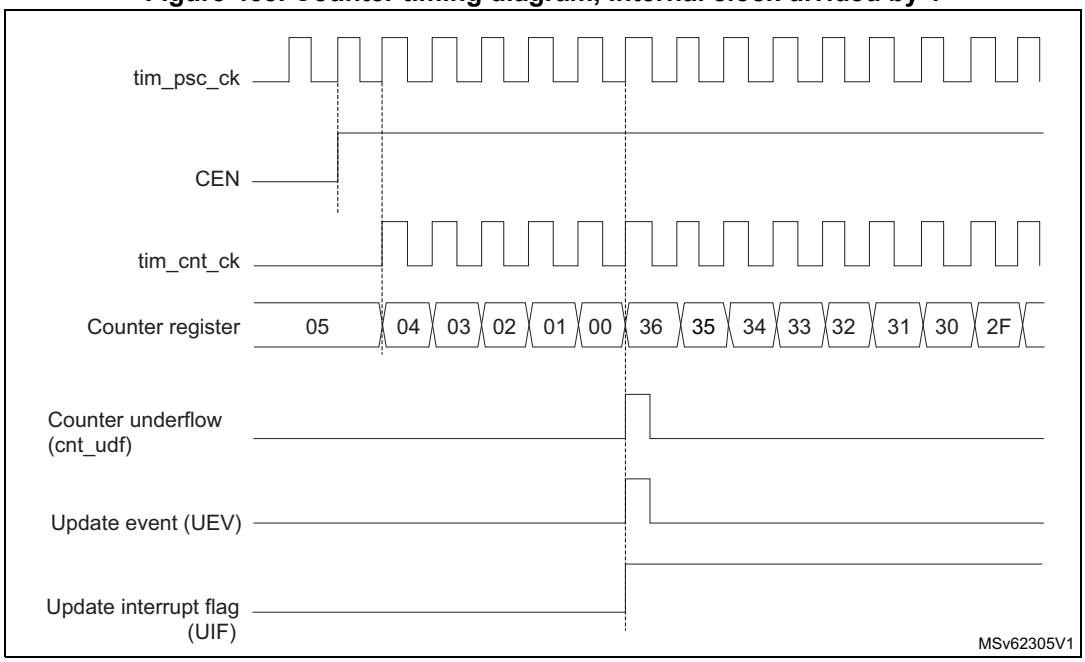

Figure 466. Counter timing diagram, internal clock divided by 2

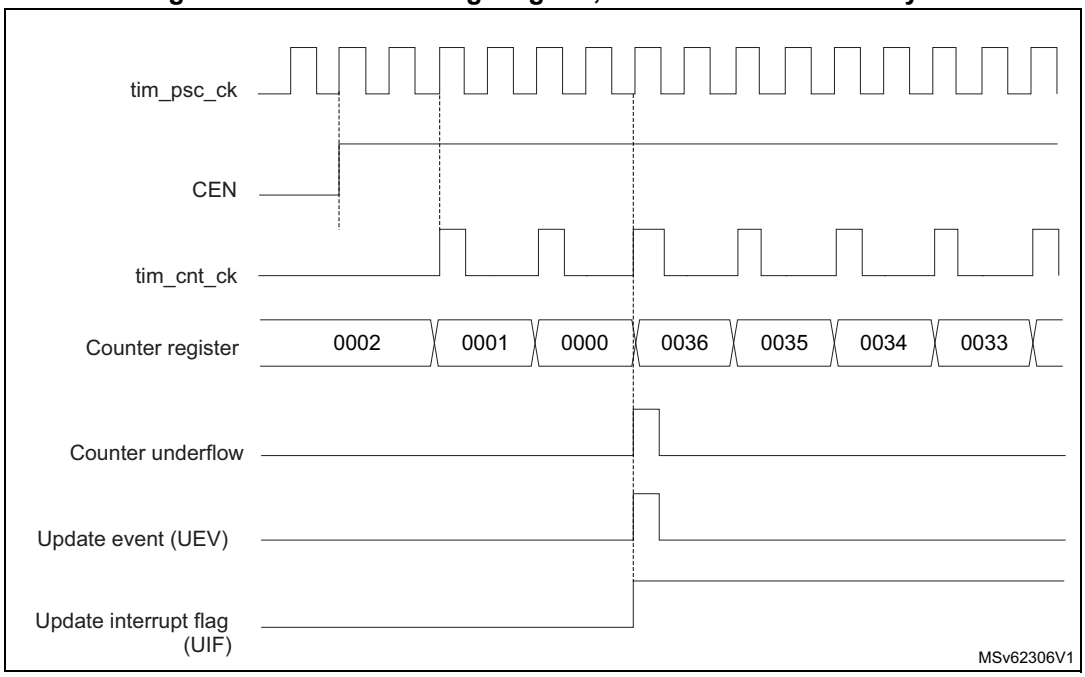

Figure 467. Counter timing diagram, internal clock divided by 4

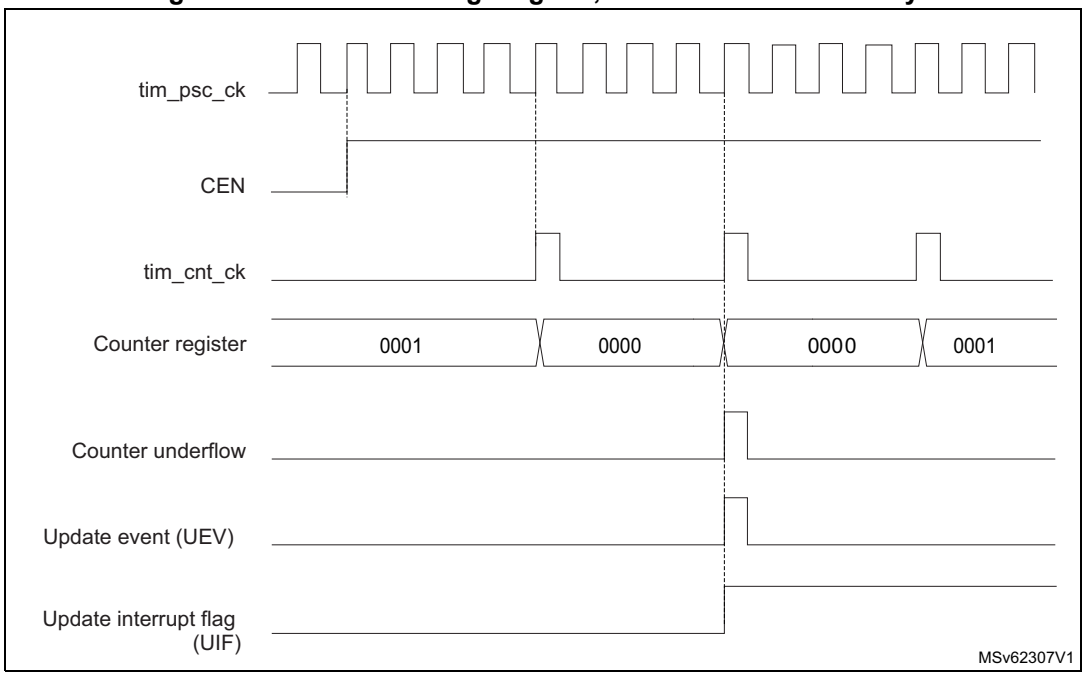

Figure 468. Counter timing diagram, internal clock divided by N

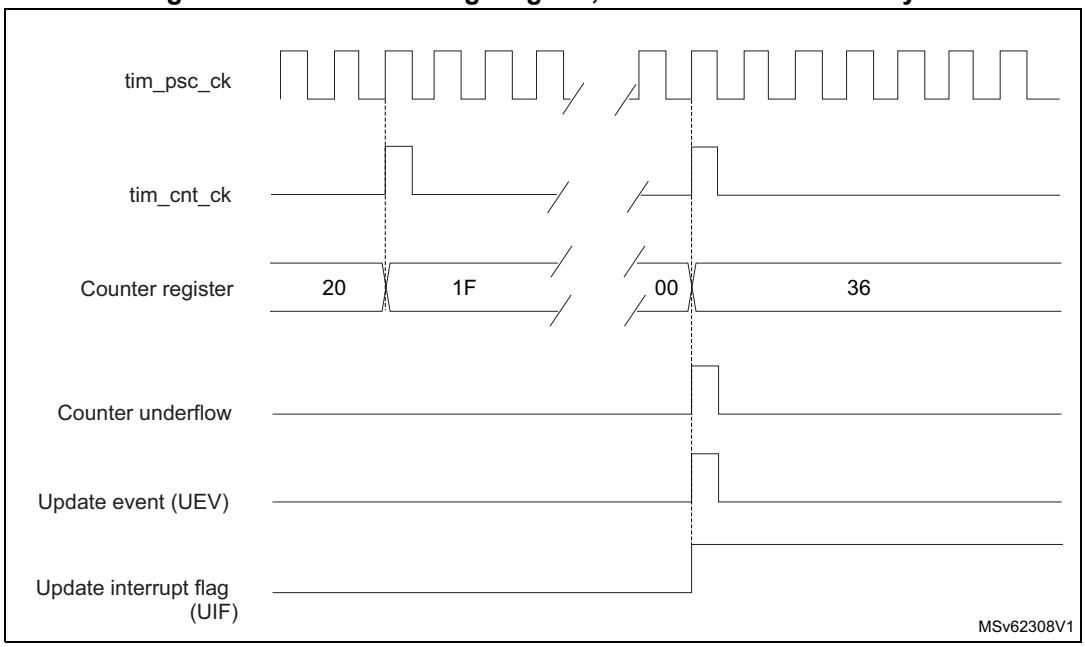

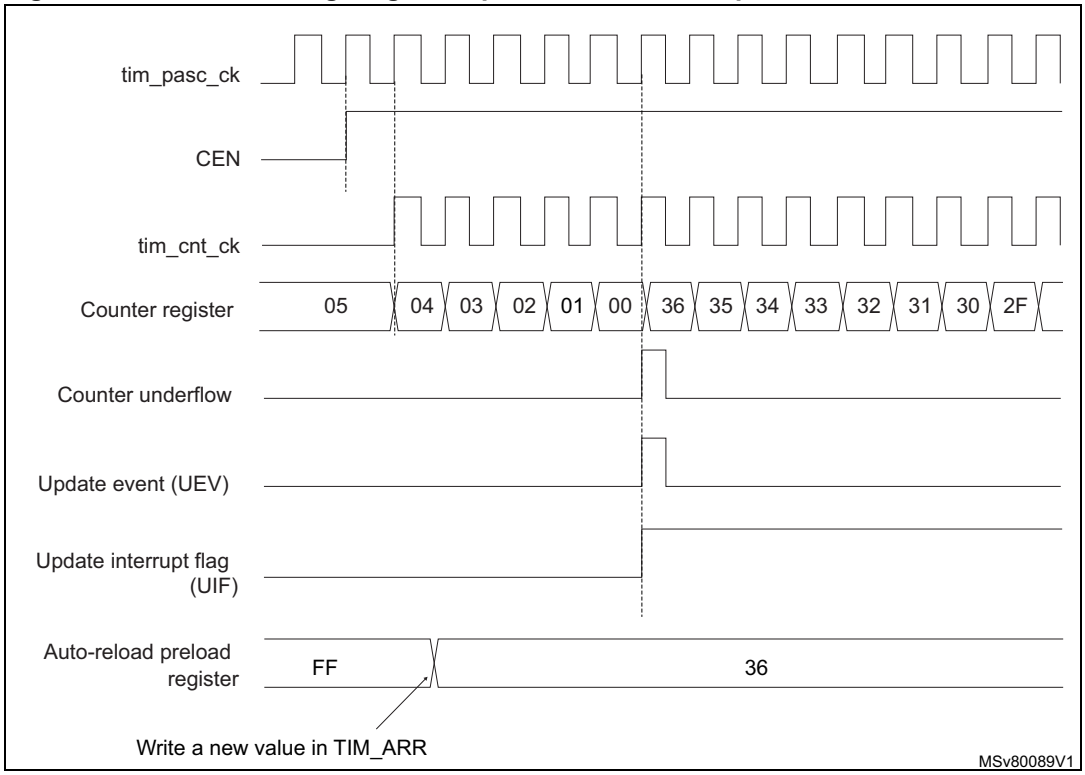

Figure 469. Counter timing diagram, update event when repetition counter is not used

Center-aligned mode (up/down counting)

In center-aligned mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register) – 1, generates a counter overflow event, then counts from the

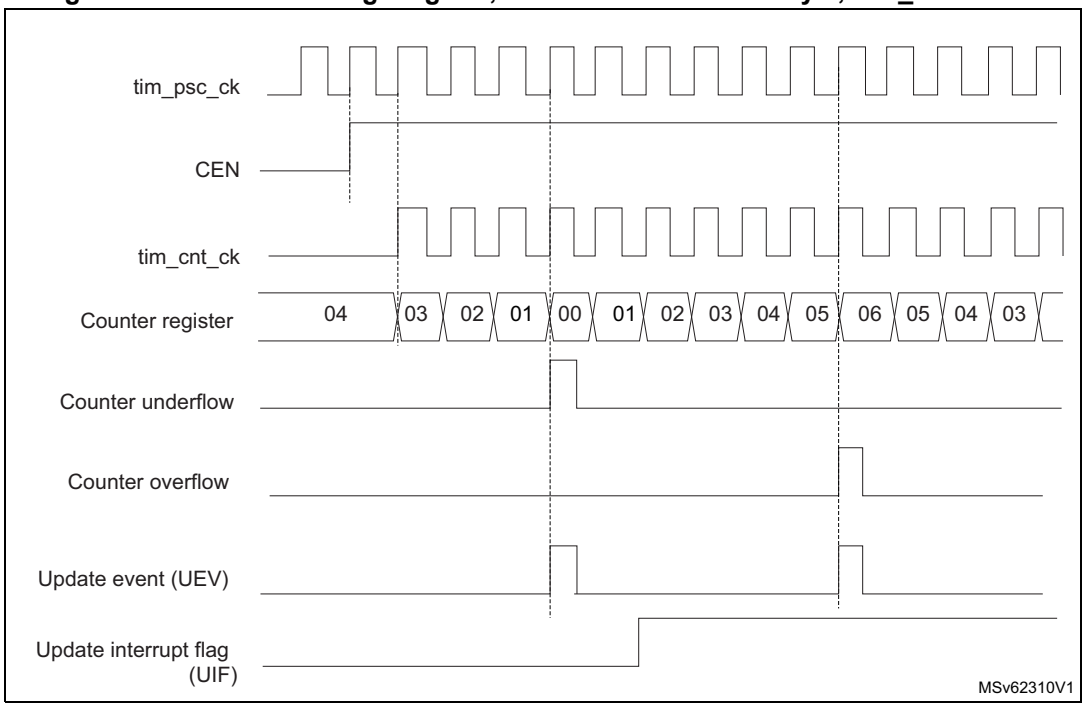
autoreload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIM_CR1 register are not equal to 00. The Output compare interrupt flag of channels configured in output is set when: the counter counts down (Center aligned mode 1, CMS = 01), the counter counts up (Center aligned mode 2, CMS = 10) the counter counts up and down (Center aligned mode 3, CMS = 11).

In this mode, the DIR direction bit in the TIM_CR1 register cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in the TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current autoreload value.



In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an UEV update event but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The repetition counter is reloaded with the content of TIM_RCR register
- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register)
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that if the update source is a counter overflow, the autoreload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 470. Counter timing diagram, internal clock divided by 1, TIM_ARR = 0x6

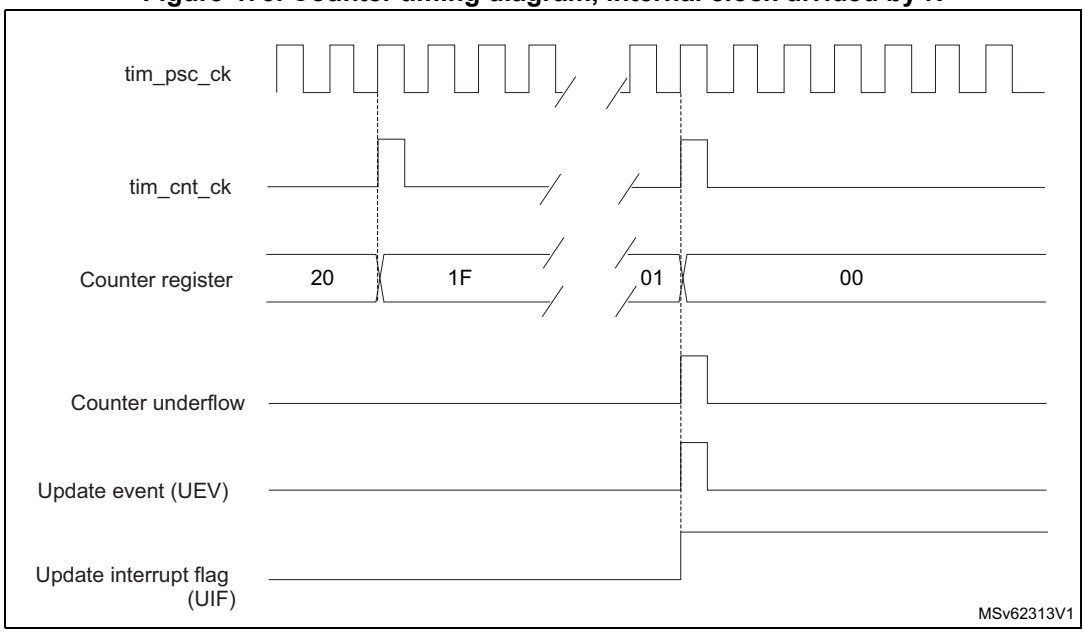

Figure 474. Counter timing diagram, update event with ARPE = 1 (counter underflow)

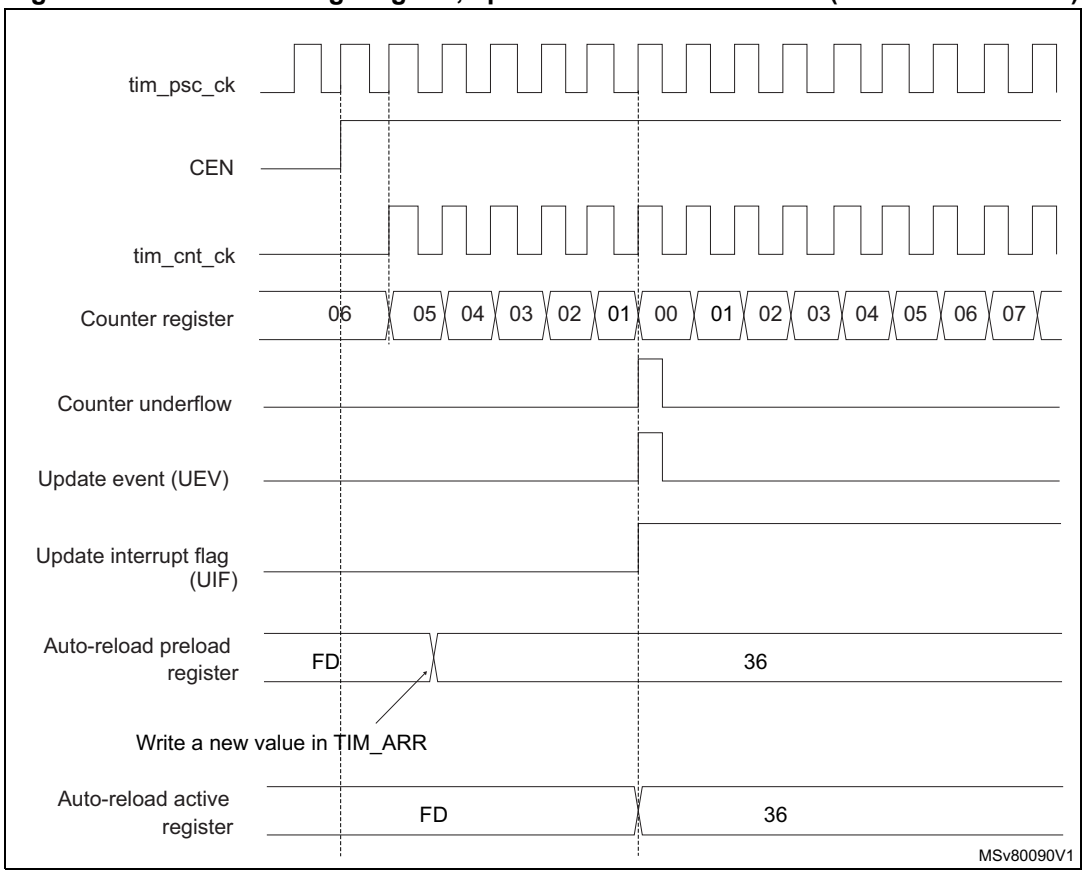

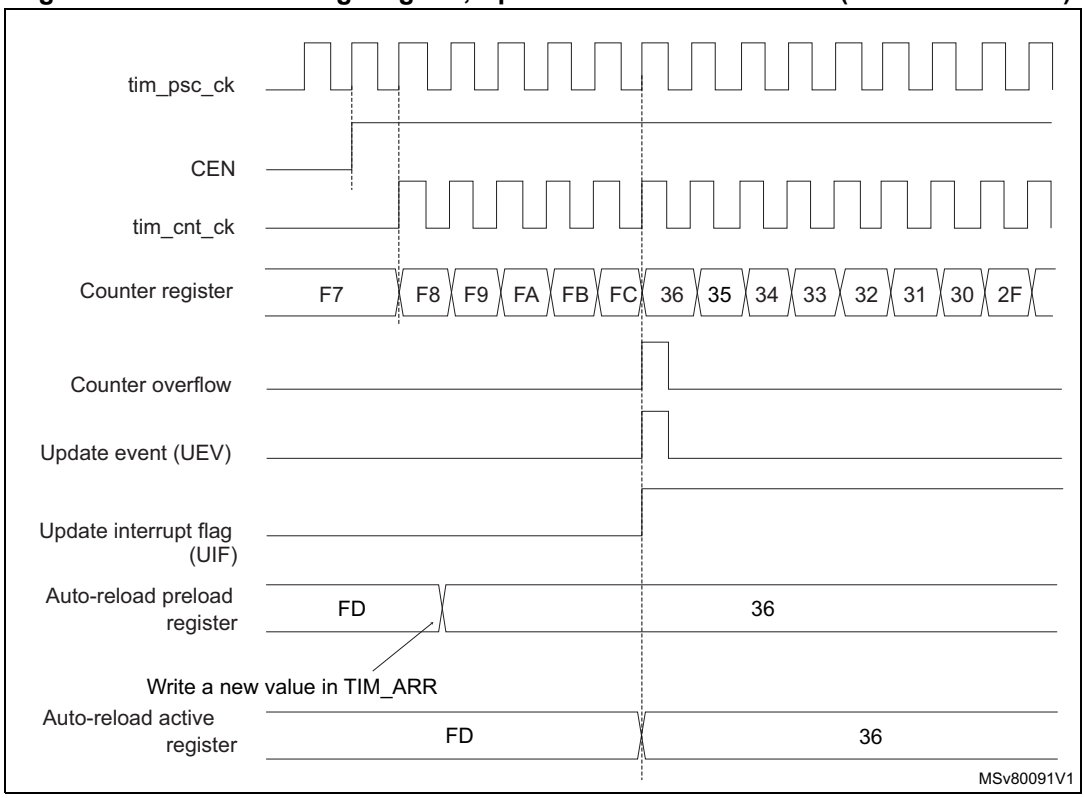

Figure 475. Counter timing diagram, Update event with ARPE = 1 (counter overflow)

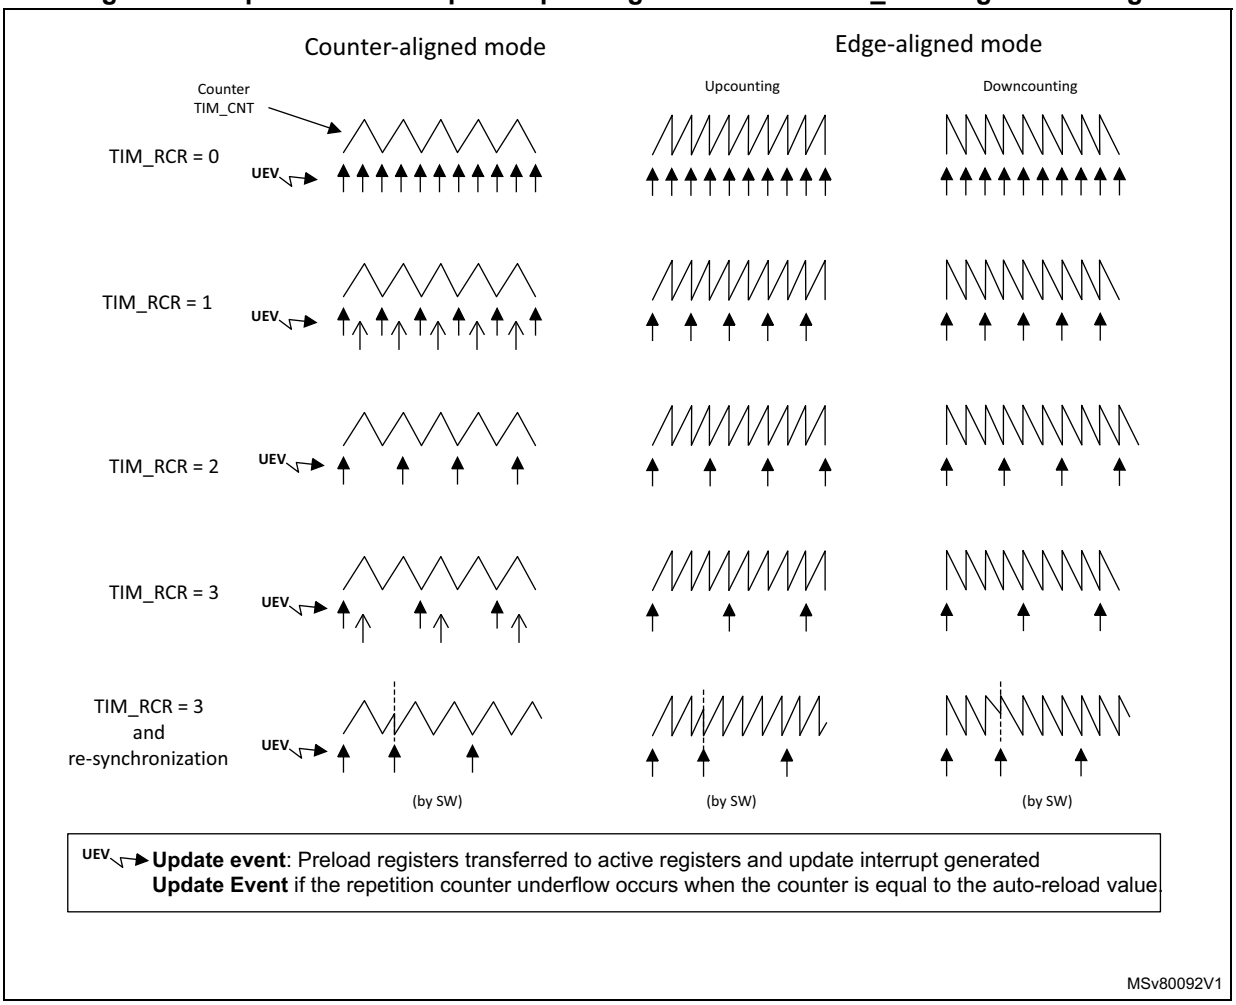
41.3.5 Repetition counter

Section 41.3.3: Time-base unit describes how the update event (UEV) is generated with respect to the counter overflows/underflows. It is actually generated only when the repetition counter has reached zero. This can be useful when generating PWM signals.

This means that data are transferred from the preload registers to the shadow registers (TIM_ARR autoreload register, TIM_PSC prescaler register, but also TIM_CCRx capture/compare registers in compare mode) every N+1 counter overflows or underflows, where N is the value in the TIM_RCR repetition counter register.

The repetition counter is decremented:



- At each counter overflow in upcounting mode,
- At each counter underflow in downcounting mode,
- At each counter overflow and at each counter underflow in center-aligned mode. Although this limits the maximum number of repetition to 32768 PWM cycles, it makes it possible to update the duty cycle twice per PWM period. When refreshing compare registers only once per PWM period in center-aligned mode, maximum resolution is $2xT_{ck}$, due to the symmetry of the pattern.

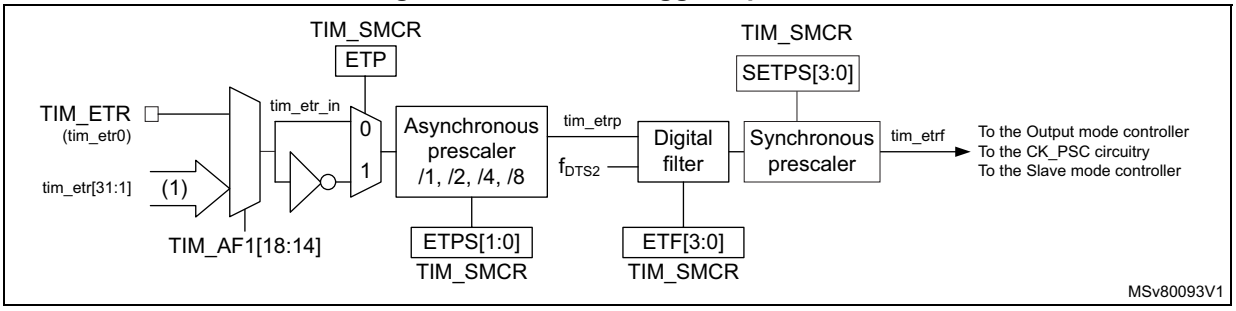
The repetition counter is an autoreload type; the repetition rate is maintained as defined by the TIM_RCR register value (refer to *Figure 476*). When the update event is generated by software (by setting the UG bit in TIM_EGR register) or by hardware through the slave mode controller, it occurs immediately whatever the value of the repetition counter is and the repetition counter is reloaded with the content of the TIM_RCR register.

In Center aligned mode, for odd values of RCR, the update event occurs either on the overflow or on the underflow depending on when the RCR register was written and when the counter was launched: if the RCR was written before launching the counter, the UEV occurs on the underflow. If the RCR was written after launching the counter, the UEV occurs on the overflow.

For example, for RCR = 3, the UEV is generated each 4th overflow or underflow event depending on when the RCR was written.

Figure 476. Update rate examples depending on mode and TIM_RCR register settings

41.3.6 External trigger input



The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see *Section 41.3.7*)
- trigger for the slave mode (see *Section 41.3.35*)
- PWM reset input for cycle-by-cycle current regulation (see *Section 41.3.9*)

Figure 477 below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIM_SMCR register. The trigger frequency can be decreased with the prescalers programmed by the ETPS[1:0] and SETPS[3:0] bitfields and digitally filtered as per the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an

external clock, to condition the output (typically to reset a PWM output for a current limitation), and as a trigger for the Slave mode controller.

Figure 477. External trigger input block

The external trigger input block features 2 prescalers with different functionalities:

- An asynchronous prescaler (division by 1, 2, 4 or 8), able to process tim_etr_in signals with frequencies above tim_ker_ck
- A linear synchronous prescaler (division by 1,2,3,..15), only able to operate with tim_etrp signal frequencies below tim_ker_ck/3

Note: When tim_etrf is used as PWM reset input for cycle-by-cycle current regulation (see Section 41.3.23), SETPS[3:0] must be set to 0 (no prescaling).

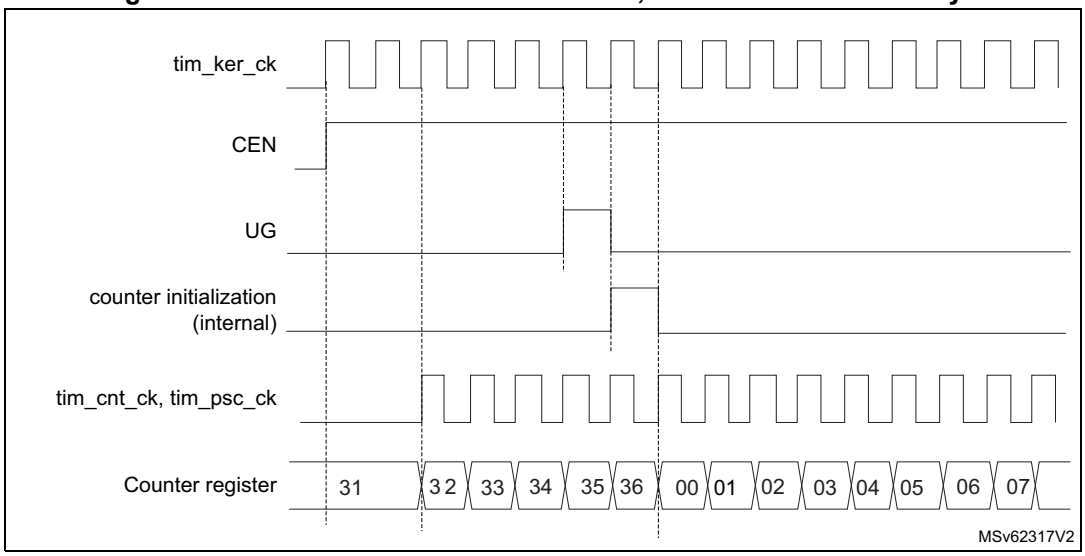
Note: The SETPS[3:0] bitfield is always preloaded: a new value will become active only once an update event has occured.

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[4:0] bitfield in the TIM_AF1 register.

Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for the list of sources connected to the etr_in input in the product.

41.3.7 Clock selection

The counter clock can be provided by the following clock sources:



- Internal clock (tim_ker_ck)
- External clock mode1: external input pin (tim_ti1 or tim_ti2)
- External clock mode2: external trigger input (tim_etr_in)
- Encoder mode

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS = 000), then the CEN, DIR (in the TIM_CR1 register) and UG bits (in the TIM_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 478 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

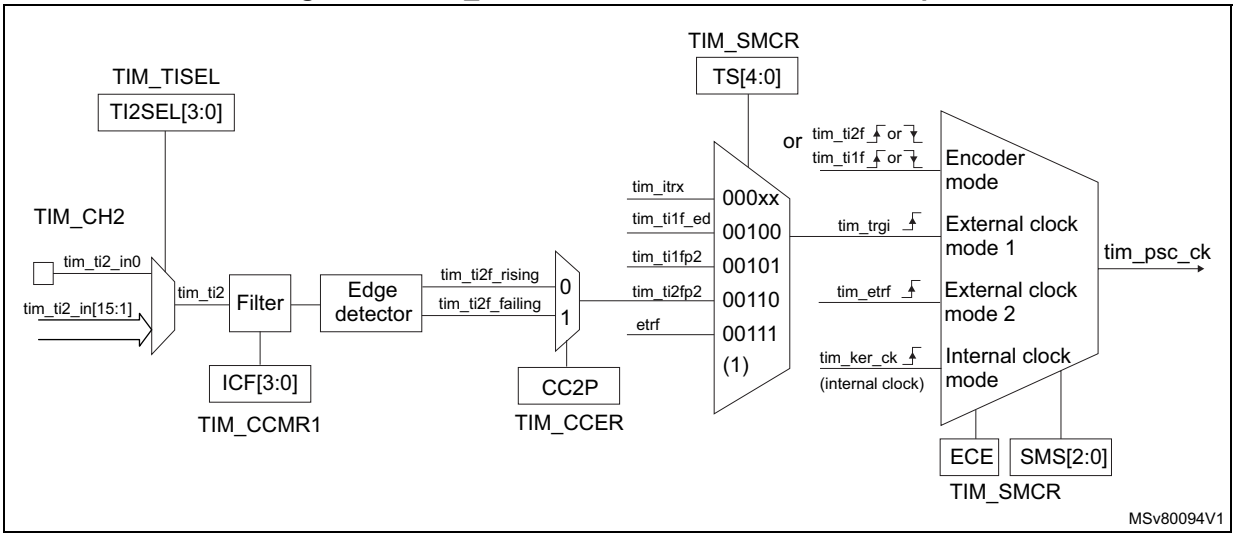


Figure 478. Control circuit in normal mode, internal clock divided by 1

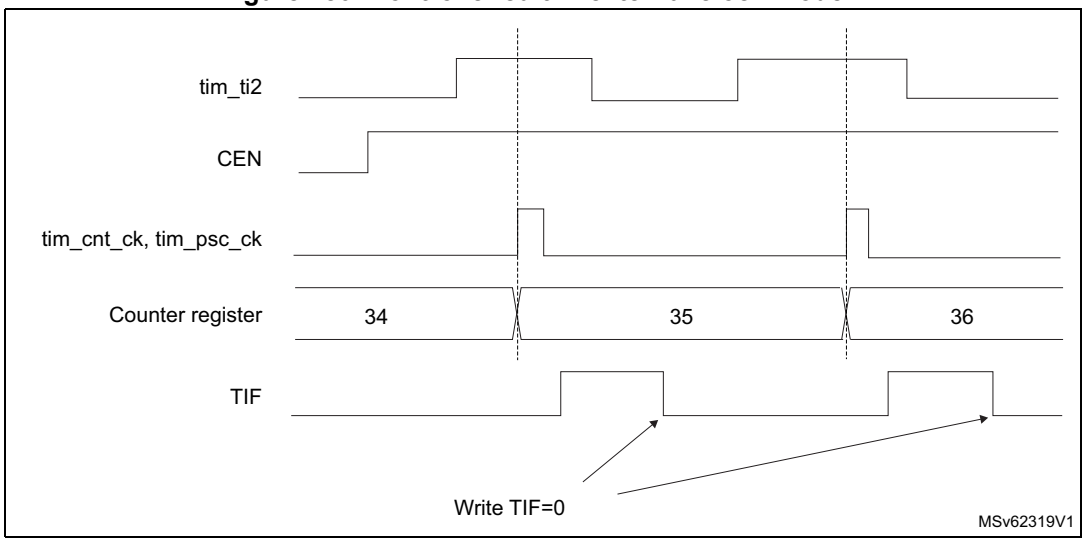
External clock source mode 1

This mode is selected when SMS = 00111 in the TIM_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 479. tim_ti2 external clock connection example

1. Codes ranging from 01000 to 11111 are reserved.

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:



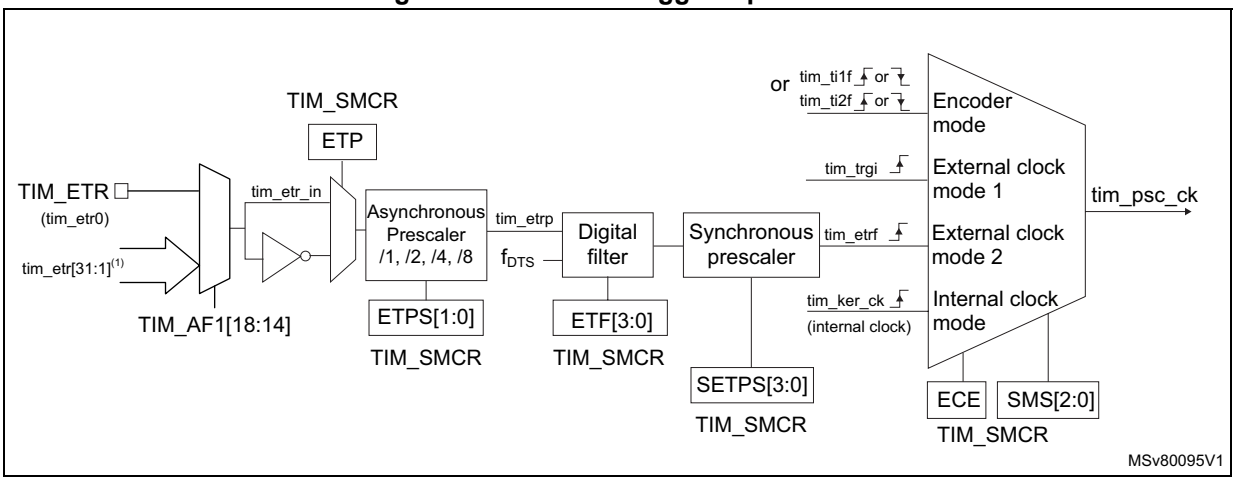
1. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S = 01 in the TIM_CCMR1 register.
2. Configure the input filter duration by writing the IC2F[3:0] bits in the TIM_CCMR1 register (if no filter is needed, keep IC2F = 0000).
3. Select rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
4. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIM_SMCR register.
5. Select tim_ti2 as the trigger input source by writing TS = 00110 in the TIM_SMCR register.
6. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

Note: The capture prescaler is not used for triggering, it is not necessary to configure it.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 480. Control circuit in external clock mode 1



External clock source mode 2

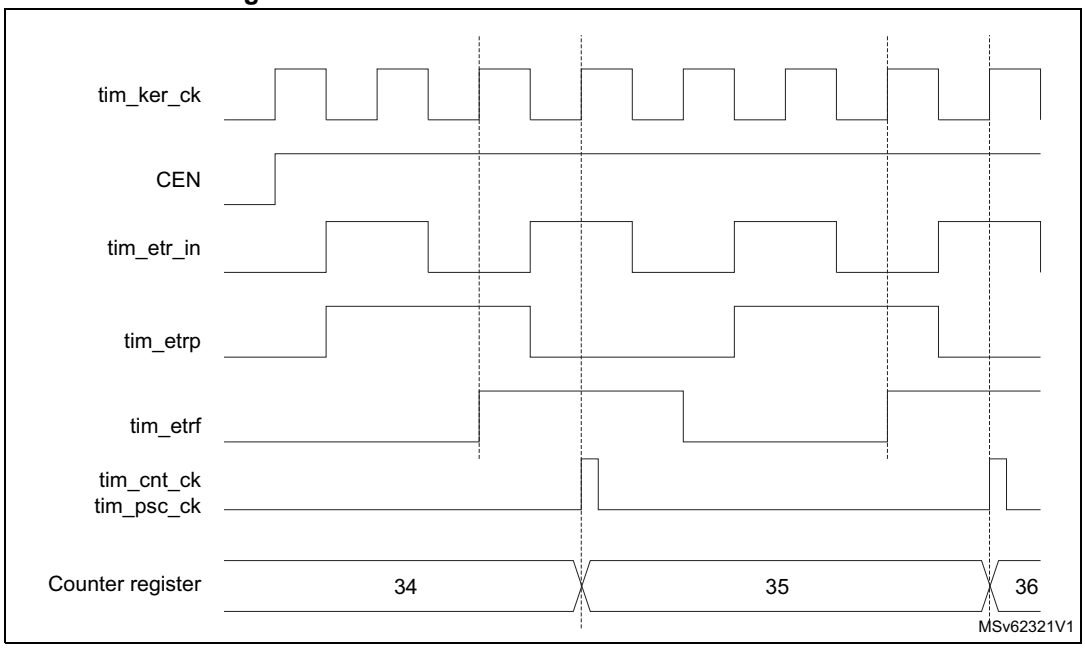
This mode is selected by writing ECE = 1 in the TIM_SMCR register.

The counter counts at each rising or falling edge on the external trigger input tim_etr_in.

The *Figure 481* gives an overview of the external trigger input block.

Figure 481. External trigger input block

1. Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals*.



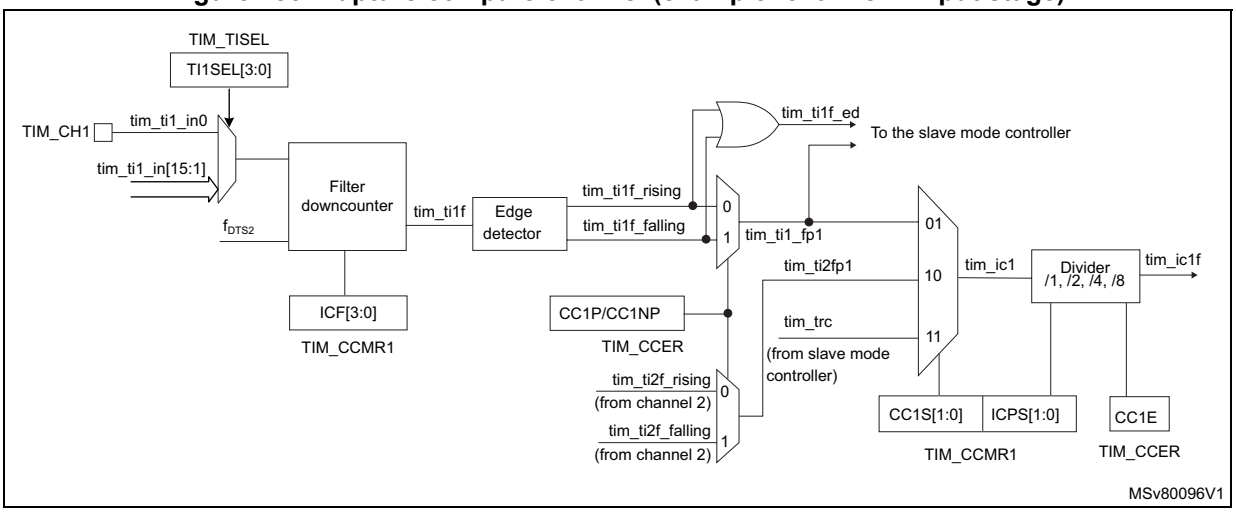
For example, to configure the upcounter to count each 2 rising edges on tim_etr_in, use the following procedure:

1. As no filter is needed in this example, write ETF[3:0] = 0000 in the TIM_SMCR register.
2. Set the prescaler by writing ETPS[1:0] = 01 and SETPS[3:0] = 0 in the TIM_SMCR register
3. Select rising edge detection on the tim_etr_in input by writing ETP = 0 in the TIM_SMCR register
4. Enable external clock mode 2 by writing ECE = 1 in the TIM_SMCR register.
5. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

The counter counts once each 2 tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency which can be correctly captured by the counter is at most ¼ of tim_ker_ck frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.

Figure 482. Control circuit in external clock mode 2



41.3.8 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing, and prescaler, except for channels 5 and 6) and an output stage (with comparator and output control).

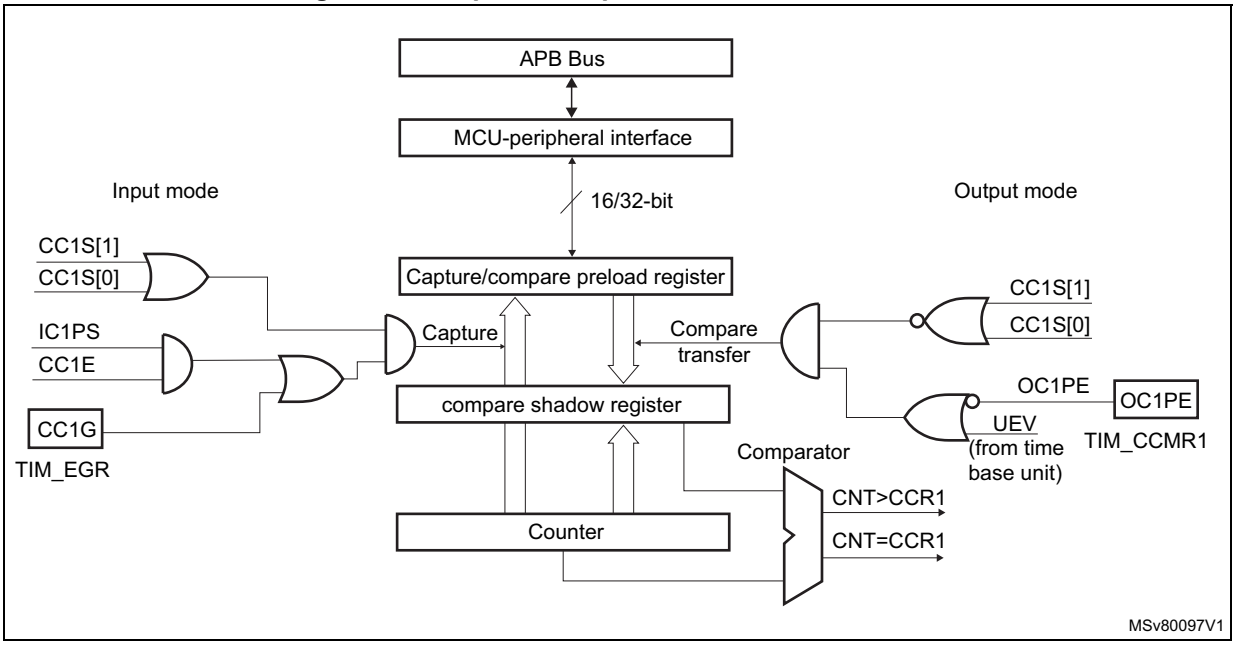
Figure 483 to *Figure 486* give an overview of one capture/compare channel.

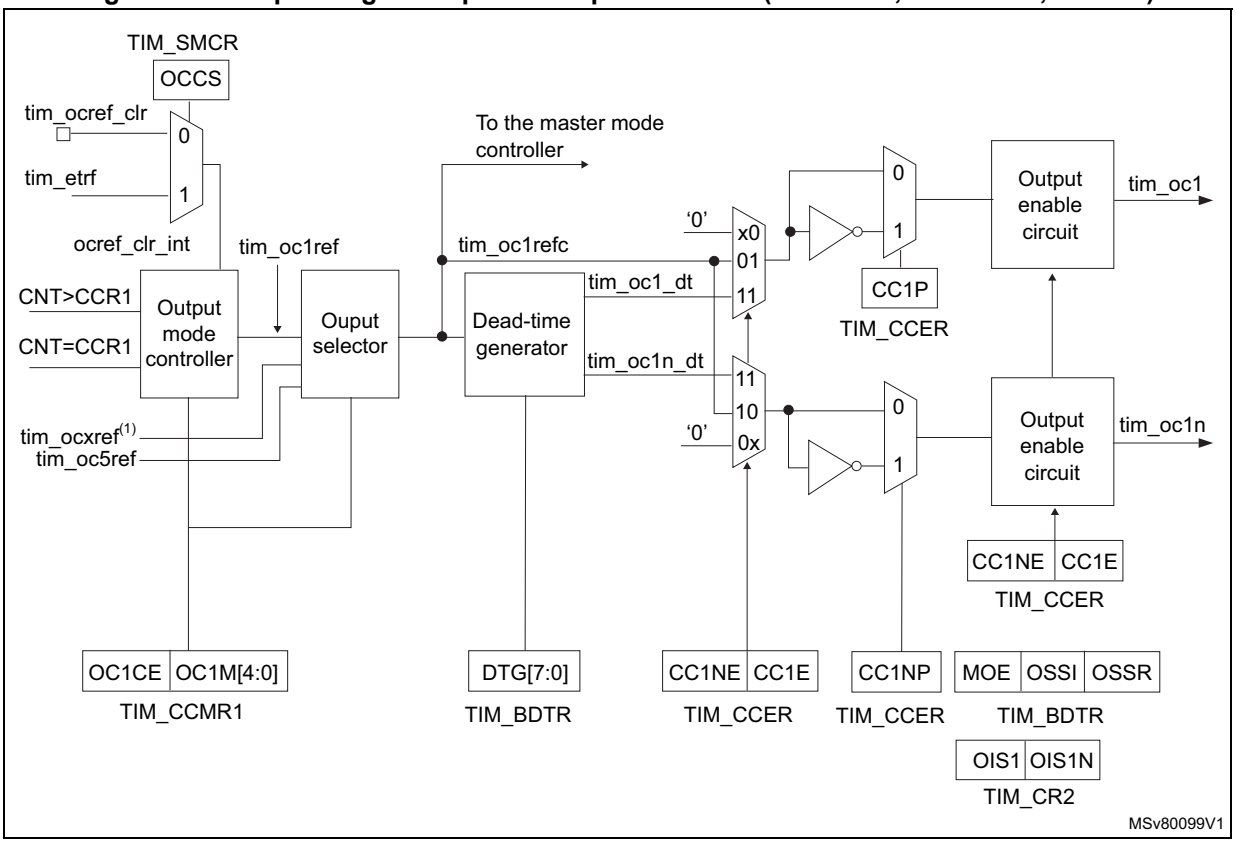
The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 483. Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 484. Capture/compare channel 1 main circuit





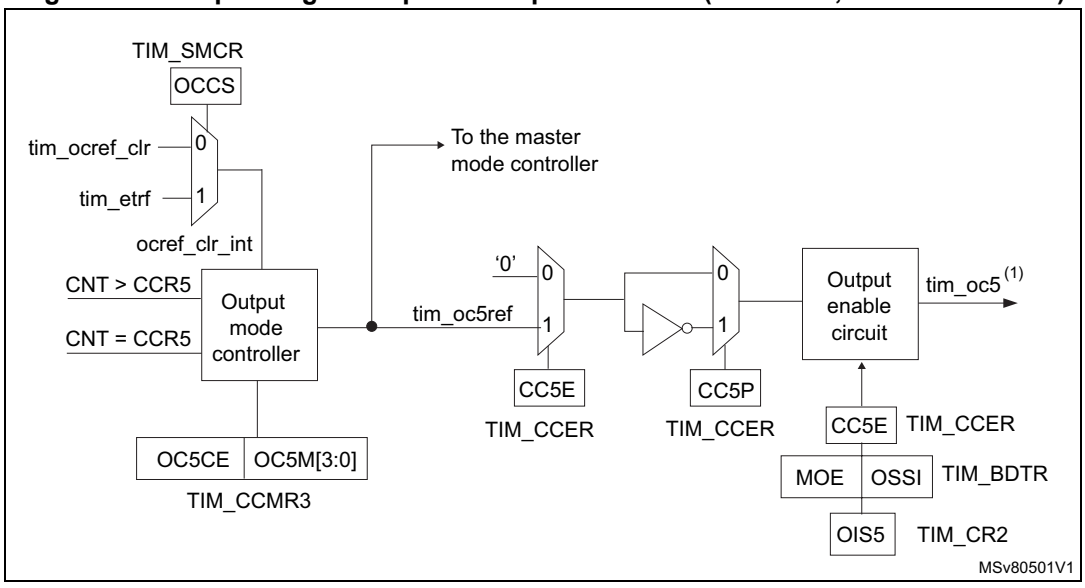


Figure 485. Output stage of capture/compare channel (channel 1, idem ch. 2, 3 and 4)

1. tim_ocxref, where x is the rank of the complementary channel

Figure 486. Output stage of capture/compare channel (channel 5, idem ch. 6 and 7)

1. Not available externally.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

41.3.9 Input capture mode

In Input capture mode, the capture/compare registers (TIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIM_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIM_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIM_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIM_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

- Select the active input: TIM_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIM_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input, and the TIM_CCR1 register becomes read-only.
- Program the appropriate input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIM_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at must five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on tim_ti1 when eight consecutive samples with the new level have been detected (sampled at f_{DTS2} frequency). Then write IC1F bits to 0011 in the TIM_CCMR1 register.
- Select the edge of the active transition on the tim_ti1 channel by writing CC1P and CC1NP bits to 0 in the TIM_CCER register (rising edge in this case).
- Program the input prescaler. In our example, we wish the capture to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIM_CCMR1 register).
- Enable capture from the counter into the capture register by setting the CC1E bit in the TIM_CCER register.
- If needed, enable the related interrupt request by setting the CC1IE bit in the TIM_DIER register, and/or the DMA request by setting the CC1DE bit in the TIM_DIER register.

When an input capture occurs:

- The TIM_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

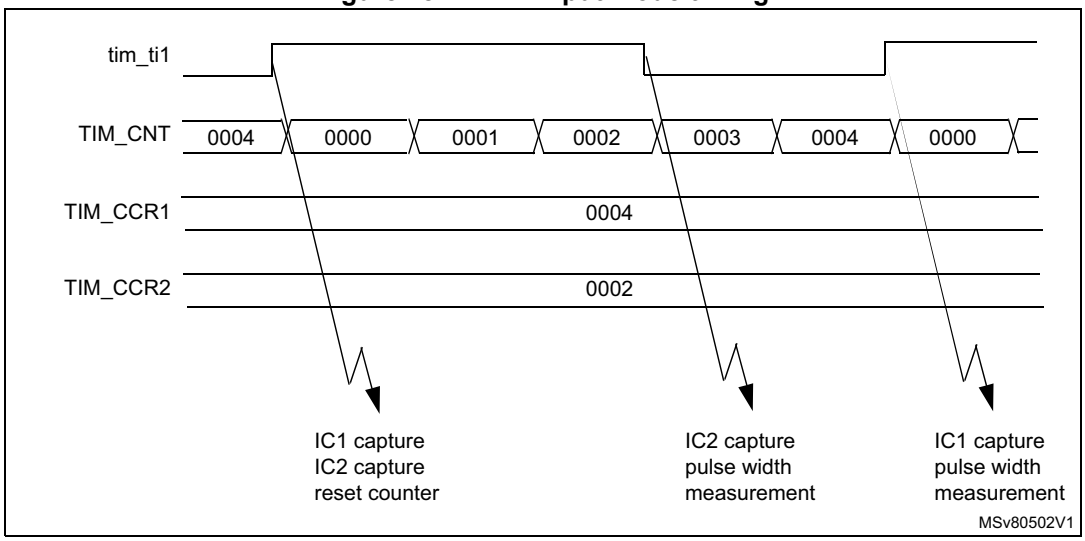
In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIM_EGR register.

41.3.10 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIM_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulsewidth (interval between two consecutive rising and falling edges.



This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tixfp1 input.
- These two ICx signals are active on edges with opposite polarity.
- One of the two tim_tixfp signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulsewidth of a PWM signal applied on tim_ti1 can be measured using the following procedure:

- Select the active input for TIM_CCR1: write the CC1S bits to 01 in the TIM_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp1 (used both for capture in TIM_CCR1 and counter clear): write the CC1P and CC1NP bits to 0 (active on rising edge).
- Select the active input for TIM_CCR2: write the CC2S bits to 10 in the TIM_CCMR1 register (tim_ti1 selected).
- Select the active polarity for tim_ti1fp2 (used for capture in TIM_CCR2): write the CC2P and CC2NP bits to CC2P/CC2NP = 10 (active on falling edge).
- Select the valid trigger input: write the TS bits to 00101 in the TIM_SMCR register (tim_ti1fp1 selected).
- Configure the slave mode controller in reset mode: write the SMS bits to 0100 in the TIM_SMCR register.
- Enable the captures: write the CC1E and CC2E bits to 1 in the TIM_CCER register.

Figure 487. PWM input mode timing

41.3.11 Forced output mode

In output mode (CCxS bits = 00 in the TIM_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx/tim_ocxn) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, user just needs to write 00101 in the OCxM bits in the corresponding TIM_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

The tim_ocxref signal can be forced low by writing the OCxM bits to 00100 in the TIM_CCMRx register.

Anyway, the comparison between the TIM_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section below.

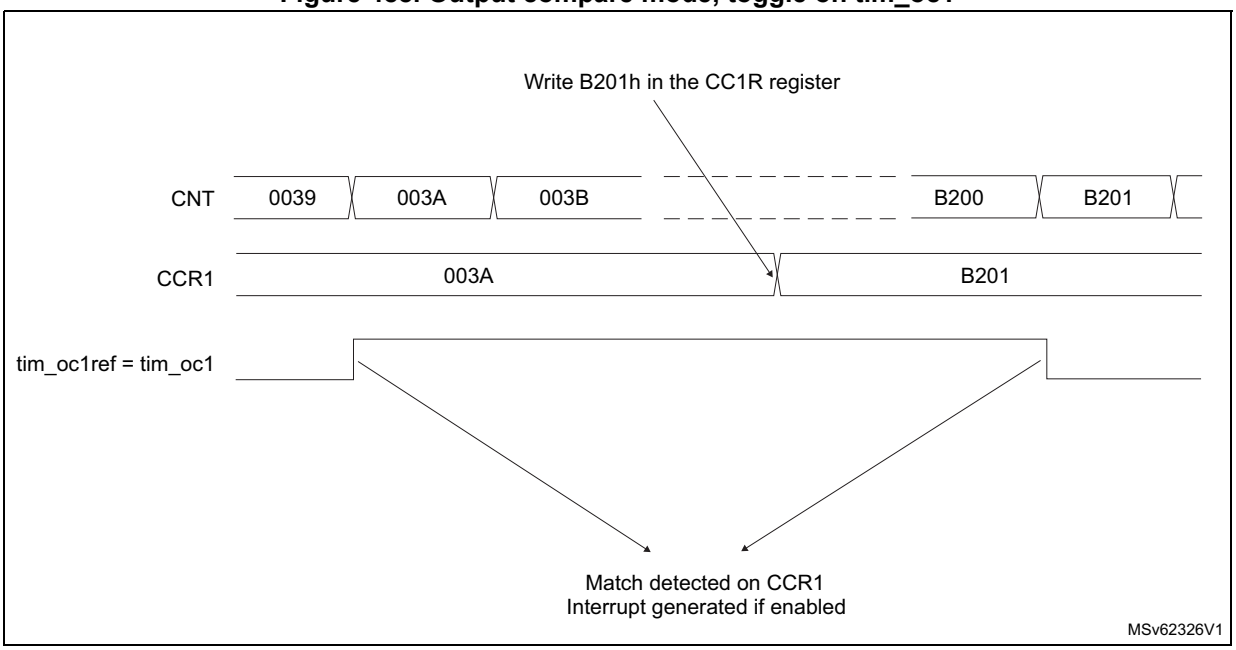
41.3.12 Output compare mode

This function is used to control an output waveform or indicate when a period of time has elapsed. Channels 1 to 4 can be output, while channel 5 to 7 are only available inside the microcontroller (for instance, for compound waveform generation or for ADC triggering).

When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIM_CCMRx register) and the output polarity (CCxP bit in the TIM_CCER register). The output pin can keep its level (OCxM = 00000), be set active (OCxM = 00001), be set inactive (OCxM = 00010) or can toggle (OCxM = 00011) on match.
- Sets a flag in the interrupt status register (CCxIF bit in the TIM_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIM_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIM_DIER register, CCDS bit in the TIM_CR2 register for the DMA request selection).

The TIM_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIM_CCMRx register.



In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in One-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIM_ARR and TIM_CCRx registers.
3. Set the CCxIE bit if an interrupt request is to be generated.
4. Select the output mode. For example:
   - Write OCxM = 00011 to toggle tim_ocx output pin when CNT matches CCRx
   - Write OCxPE = 0 to disable preload register
   - Write CCxP = 0 to select active high polarity
   - Write CCxE = 1 to enable the output
5. Enable the counter by setting the CEN bit in the TIM_CR1 register.

The TIM_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIM_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 488*.

Figure 488. Output compare mode, toggle on tim_oc1

41.3.13 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIM_ARR register and a duty cycle determined by the value of the TIM_CCRx register.

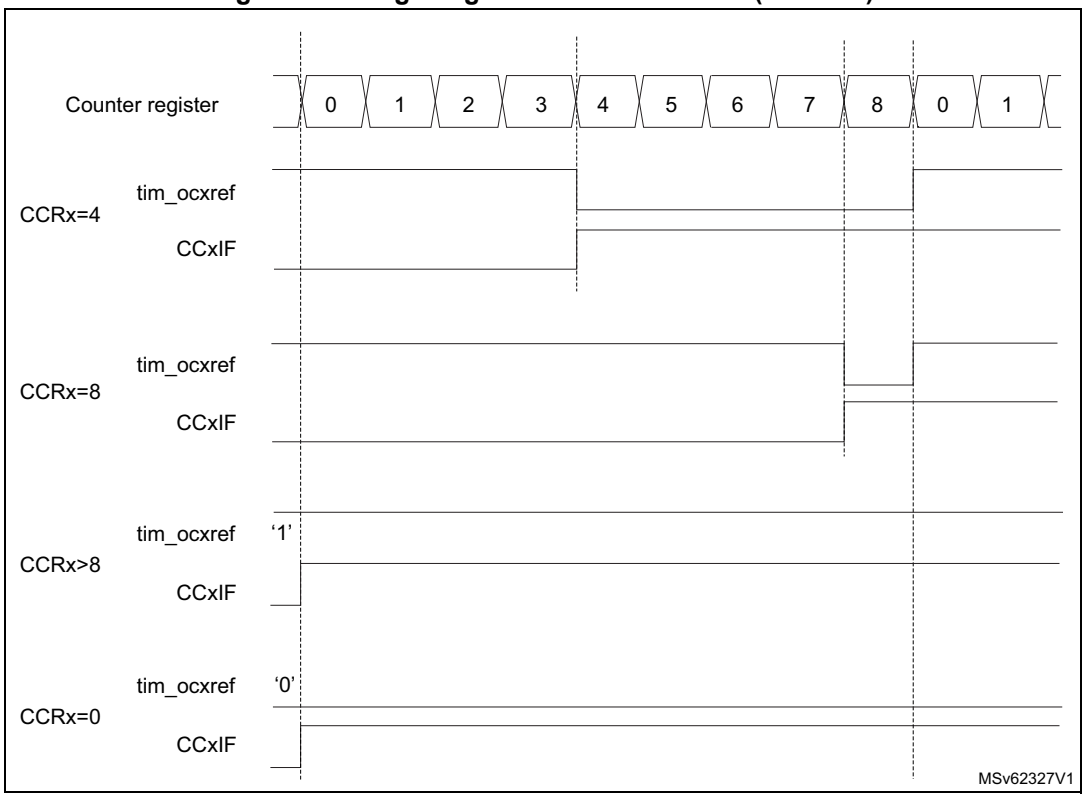
The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 00110 (PWM mode 1) or 00111 (PWM mode 2) in the OCxM bits in the TIM_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIM_CCMRx register, and eventually the autoreload preload register (in upcounting or center-aligned modes) by setting the ARPE bit in the TIM_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIM_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIM_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by a combination of the CCxE, CCxNE, MOE, OSSI, and OSSR bits (TIM_CCER and TIM_BDTR registers). Refer to the TIM_CCER register description for more details.

In PWM mode (1 or 2), TIM_CNT and TIM_CCRx are always compared to determine whether TIM_CCRx ≤ TIM_CNT or TIM_CNT ≤ TIM_CCRx (depending on the direction of the counter).

The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIM_CR1 register.



PWM edge-aligned mode

- Upcounting configuration

  Upcounting is active when the DIR bit in the TIM_CR1 register is low. Refer to *Upcounting mode*.

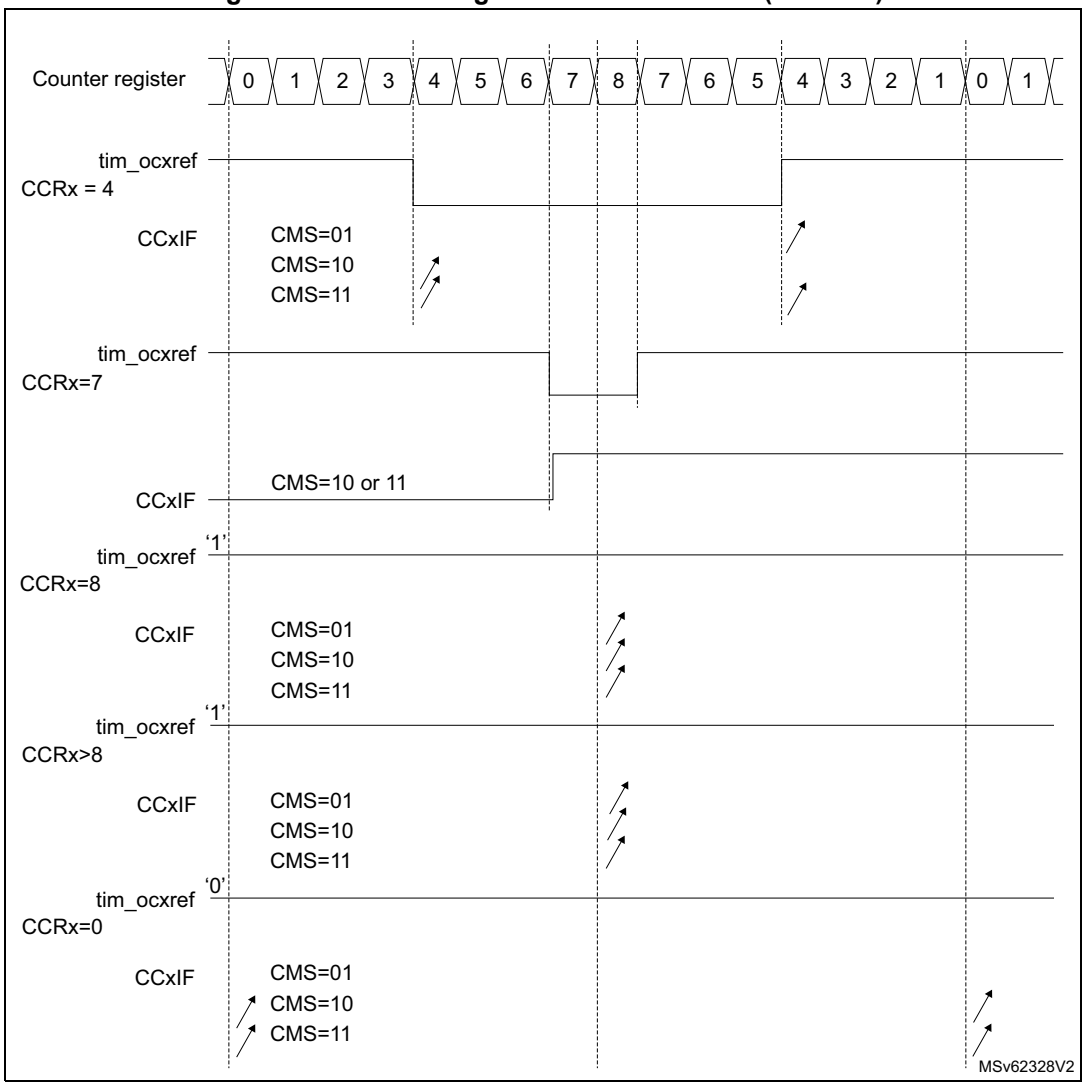
  In the following example, the mode is PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIM_CNT < TIM_CCRx else it becomes low. If the compare value in TIM_CCRx is greater than the autoreload value (in TIM_ARR) then tim_ocxref is held at 1. If the compare value is zero then tim_ocxref is held at 0. *Figure 489* shows some edge-aligned PWM waveforms in an example where TIM_ARR = 8.

Figure 489. Edge-aligned PWM waveforms (ARR = 8)

- Downcounting configuration

  Downcounting is active when DIR bit in TIM_CR1 register is high. Refer to the *Downcounting mode*

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIM_CNT > TIM_CCRx else it becomes high. If the compare value in TIM_CCRx is greater than the autoreload value in TIM_ARR, then tim_ocxref is held at 1. 0% PWM is not possible in this mode.



PWM center-aligned mode

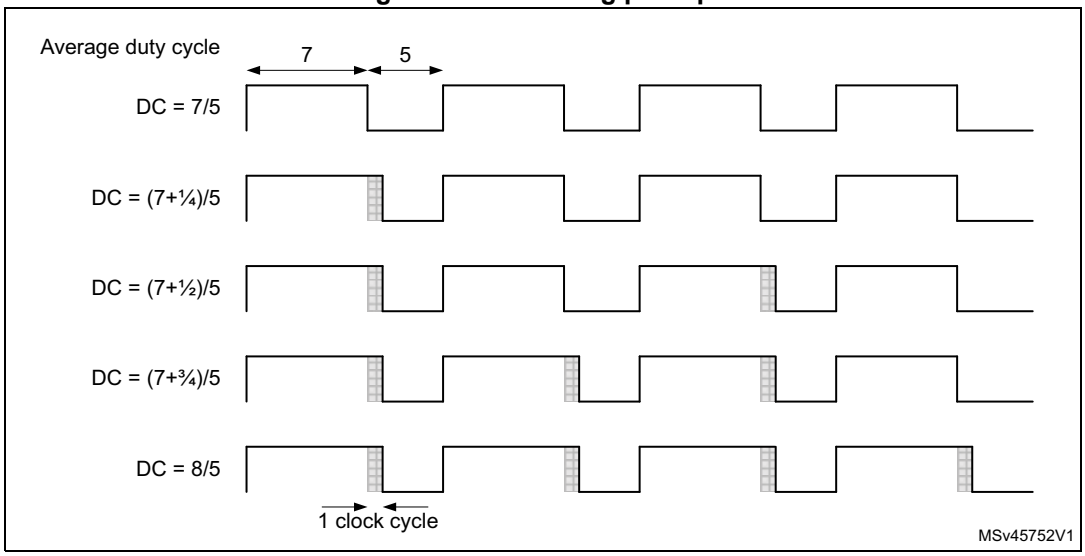
Center-aligned mode is active when the CMS bits in TIM_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the TIM_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down counting)*.

Figure 490 shows some center-aligned PWM waveforms in an example where:

- TIM_ARR = 8
- PWM mode is the PWM mode 1
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIM_CR1 register.

Figure 490. Center-aligned PWM waveforms (ARR = 8)

Hints on using center-aligned mode:



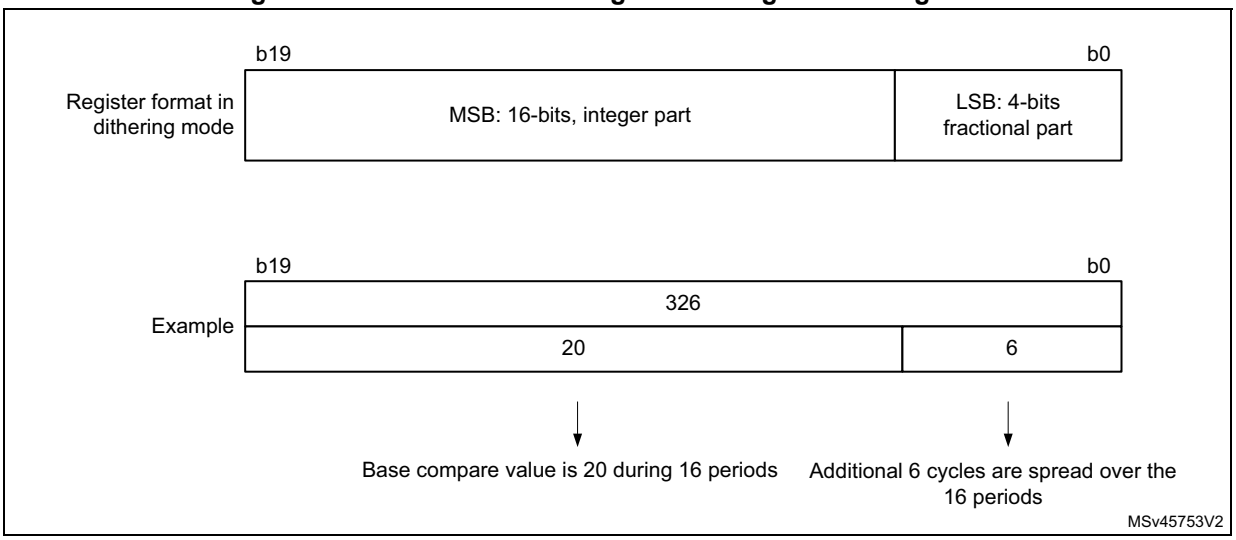
- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit in the TIM_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the autoreload value is written in the counter (TIM_CNT > TIM_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIM_ARR value is written in the counter but no update event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIM_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIM_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. *Figure 491* presents the dithering principle applied to four consecutive PWM cycles.

Figure 491. Dithering principle



When the dithering mode is enabled, the register coding is changed as follows (see *Figure 492* for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

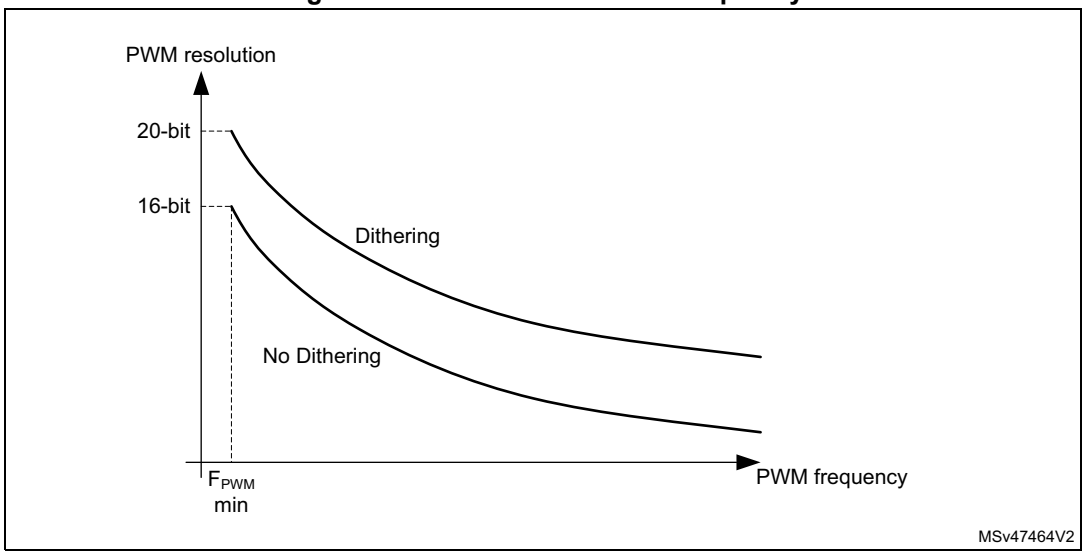
Note: The following sequence must be followed when resetting the DITHEN bit:

1. *CEN and ARPE bits must be reset.*
2. *The DITHEN bit must be reset.*
3. *The CCIF flags must be cleared.*
4. *The CEN bit can be set (eventually with ARPE = 1).*

Figure 492. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

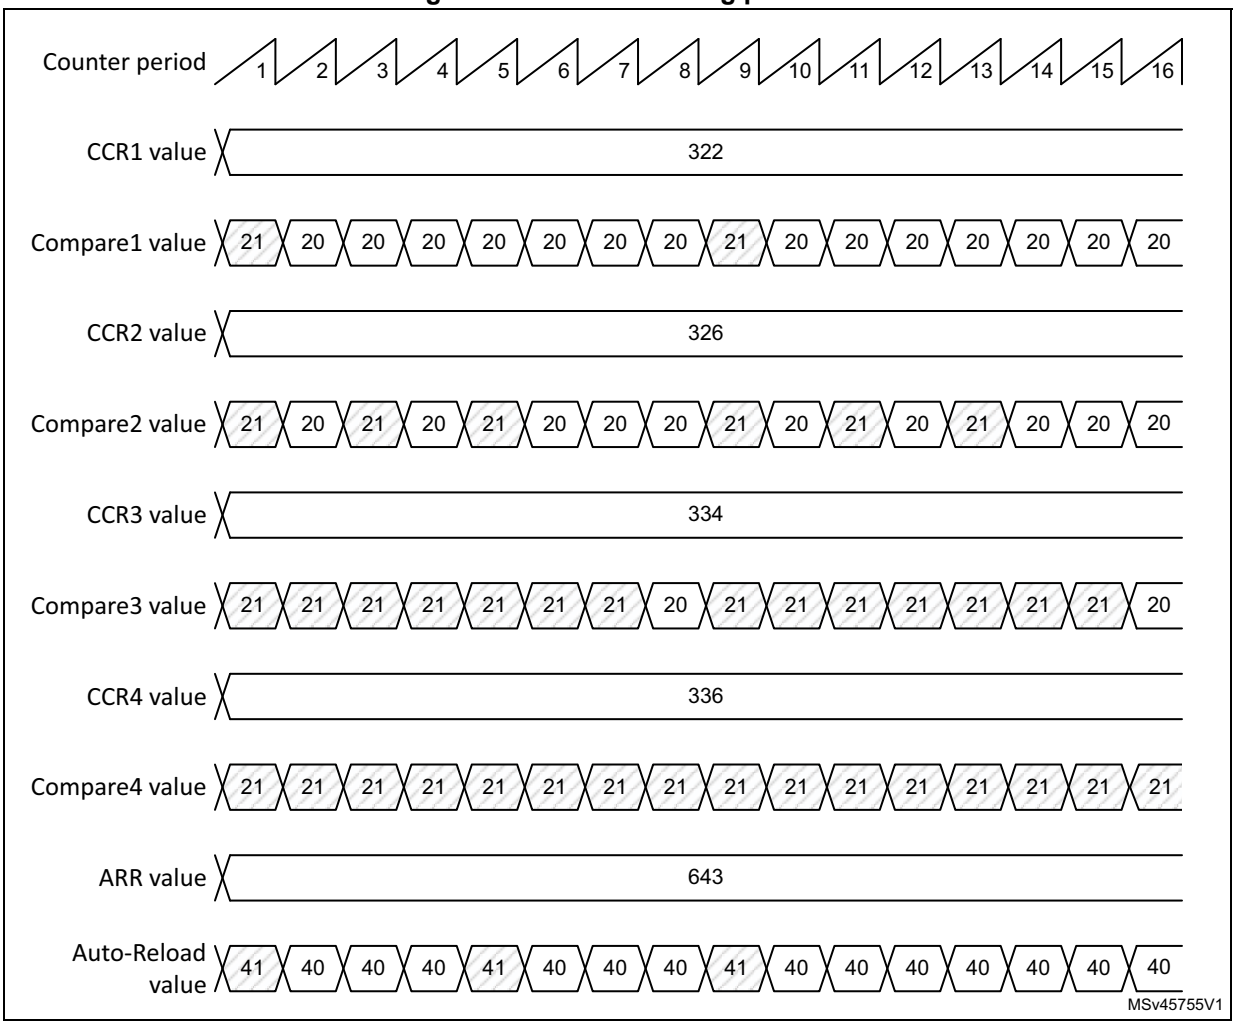
$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$



$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIM_ARR and TIM_CCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).



As shown on *Figure 493*, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 493. PWM resolution vs frequency

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in *Figure 494*.

Figure 494. PWM dithering pattern

The autoreload and compare values increments are spread following specific patterns described in *Table 462*. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 462. CCR and ARR register change dithering pattern

LSB value	PWM period															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16

41.3.14 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and the phase-shift are determined by a pair of TIM_CCRx register. One register controls the PWM during up-counting, the second during down counting, so that PWM is adjusted every half PWM cycle, for instance:

- tim_oc1refc is controlled by TIM_CCR1 and TIM_CCR2
- tim_oc3refc is controlled by TIM_CCR3 and TIM_CCR4
- ...

Figure 496 represents an example of signals that can be generated using asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 2). Together with the deadtime generator, this allows a full-bridge phase-shifted DC to DC converter to be controlled.

Figure 496. Generation of 2 phase-shifted PWM signals with 50% duty cycle

Multiple asymmetric PWM modes are available to combine different pairs of TIM_CCRx registers and generate the required waveform, as listed in *Table 464*. The selection is done

with the OCxM[4:0] bitfield in TIM_CCMRx registers. For each pair of TIM_CCRx registers, two options are given (e.g. Asymmetric PWM mode 3 and 4), one being in PWM mode 1 (channel active as long as the counter is below the TIM_CCRx value), the other one in PWM mode 2 (channel active when the counter is above the TIM_CCRx value).

For the asymmetric PWM modes 1 to 6, it is mandatory to have the same PWM mode for both channels. For instance, it is mandatory to have OC1M[4:0] = OC2M[4:0] = 00110 for the asymmetric PWM mode 1 on oc1refc.

For the asymmetric PWM modes 7 to 10, it is mandatory to have opposite PWM mode for both channels (one being in PWM mode 1 and the other in PWM mode 2). Refer to the *Table 464* for configuration.

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

When a given channel is used as asymmetric PWM channel, its complementary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the regular tim_oc2ref signal on channel 2 or a tim_oc2refc signal resulting from asymmetric PWM mode 1.

Table 464. Asymmetric PWM modes

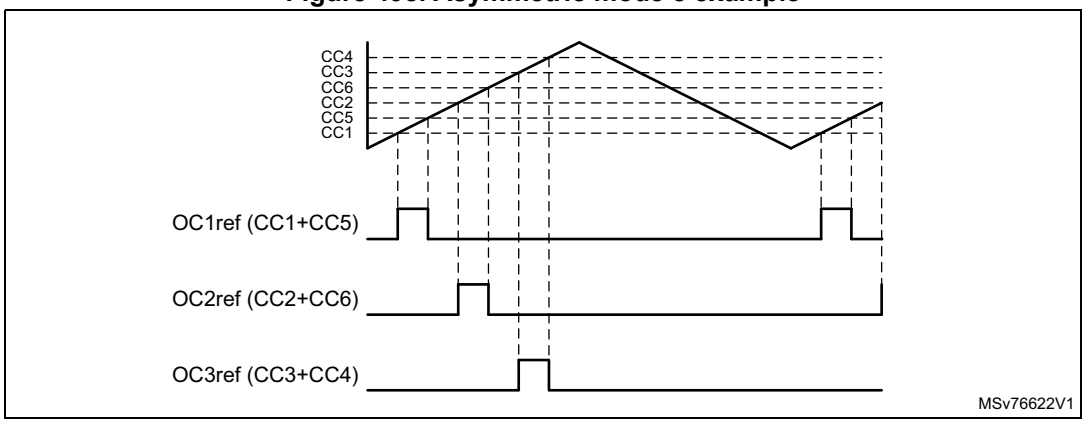
1. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value). PWM mode 2: channel active when the counter is above the TIM_CCRx value. Unless explicitly mentioned, the PWM mode must be identical for the 2 channels used for the asymmetric mode
2. oc5ref, oc6ref, oc4ref and oc7ref must be programmed in PWM mode 2
3. oc5ref, oc6ref, oc4ref and oc7ref must be programmed in PWM mode 1

The *Figure 497* represents an example suitable for single-shunt current sensing techniques requiring phase-shifted PWMs, for 3-phase motor control. This is done using asymmetric PWM mode 3 and 5:



- Channel 1 is configured in asymmetric PWM mode 4
- Channel 2 is configured in asymmetric PWM mode 5
- Channel 3 is configured in regular PWM mode 2
- Compare 4 and 7 are available for ADC triggering purpose

Figure 497. Asymmetric mode example for single-shunt current sensing

The *Figure 498* represents an example of the waveforms that can be generated with asymmetric modes 7 to 10.

Figure 498. Asymmetric mode 8 example

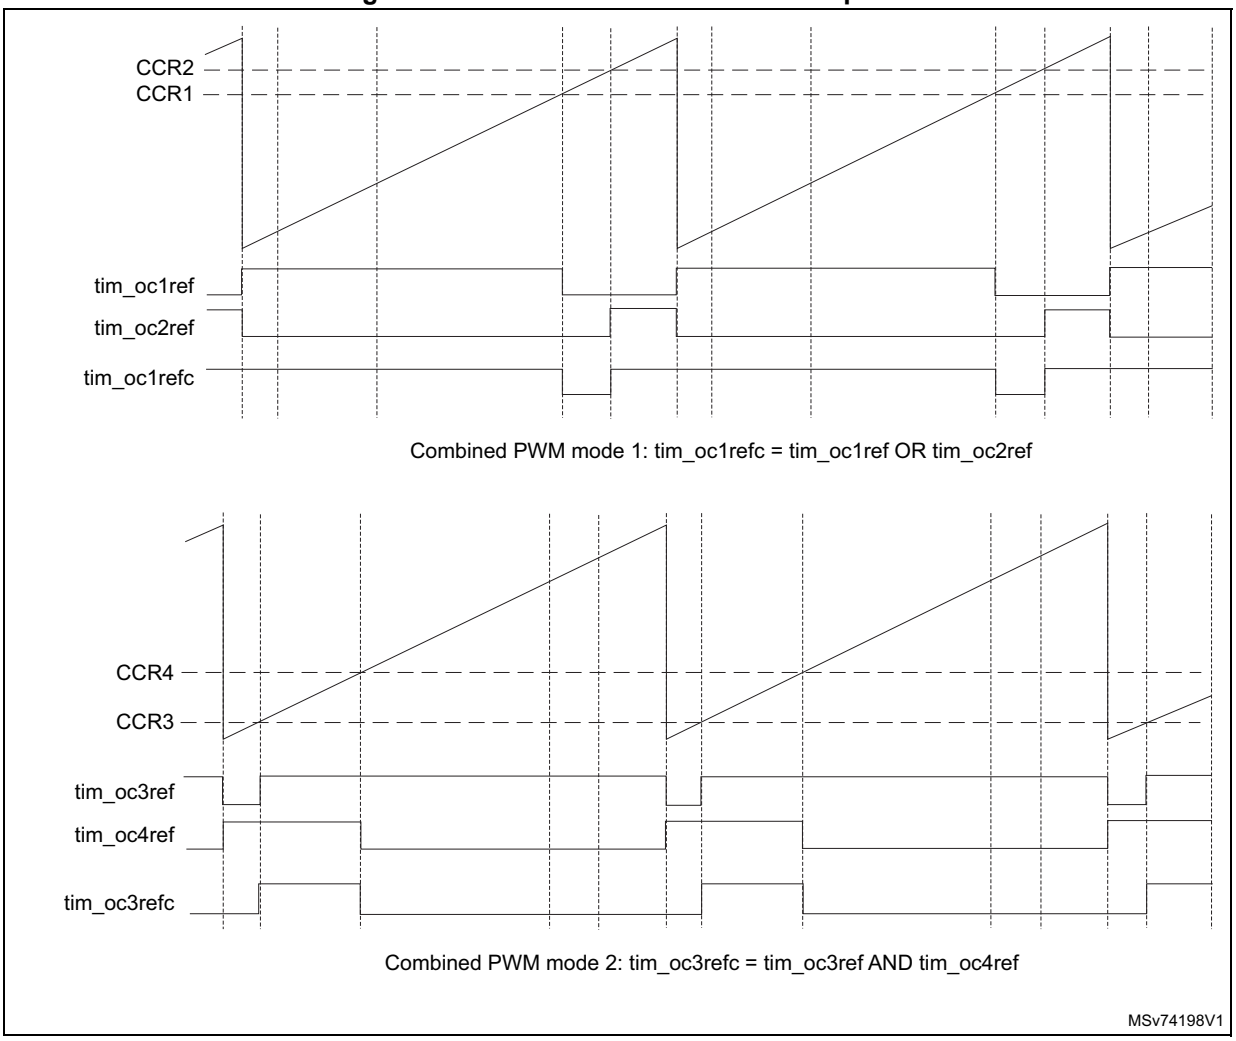
41.3.15 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and delay are determined by the two TIM_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs, as summarized in the below:

Table 465. Combined PWM mode overview

Output compare mode	OCxM[4:0]	oc1refc	oc2refc	oc3refc	oc4refc	oc5refc	oc6refc	oc7refc	PWM mode(1)
Combined PWM mode 1	01100	oc1ref OR oc2ref		oc3ref OR oc4ref		oc5ref OR oc6ref		-	1
Combined PWM mode 2	01101	oc1ref AND oc2ref		oc3ref AND oc4ref		oc5ref AND oc6ref		-	2
Combined PWM mode 3	10000	oc1ref OR oc5ref	oc2ref OR oc6ref	oc3ref OR oc5ref	oc4ref OR oc6ref	-	-	-	1
Combined PWM mode 4	10001	oc1ref AND oc5ref	oc2ref AND oc6ref	oc3ref AND oc5ref	oc4ref AND oc6ref	-	-	-	2

1. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value). PWM mode 2: channel active when the counter is above the TIM_CCRx value.



When a given channel is used as combined PWM channel, its complementary channel must be configured in the opposite PWM mode (for instance, one in PWM mode 1 and the other in PWM mode 2).

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

Figure 499 represents an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in Combined PWM mode 2.
- Channel 2 is configured in PWM mode 1.
- Channel 3 is configured in Combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.

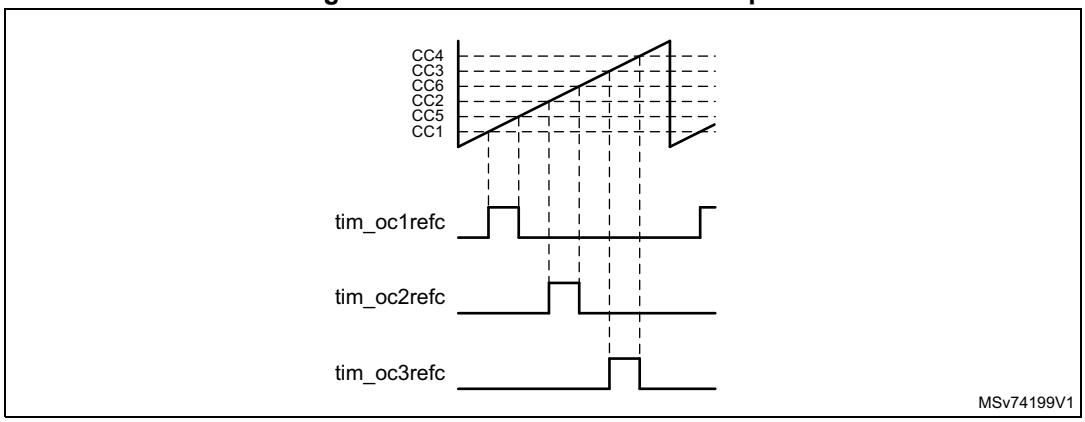


Figure 499. Combined PWM mode examples

The *Figure 500* represents an example suitable for a 3-phase interleaved converter requiring independent control of duty cycle and phase-shift. This is done using Combined PWM mode 2 and 4:

- Channel 1 is configured in Combined PWM mode 4
- Channel 2 is configured in Combined PWM mode 4
- Channel 3 is configured in Combined PWM mode 2

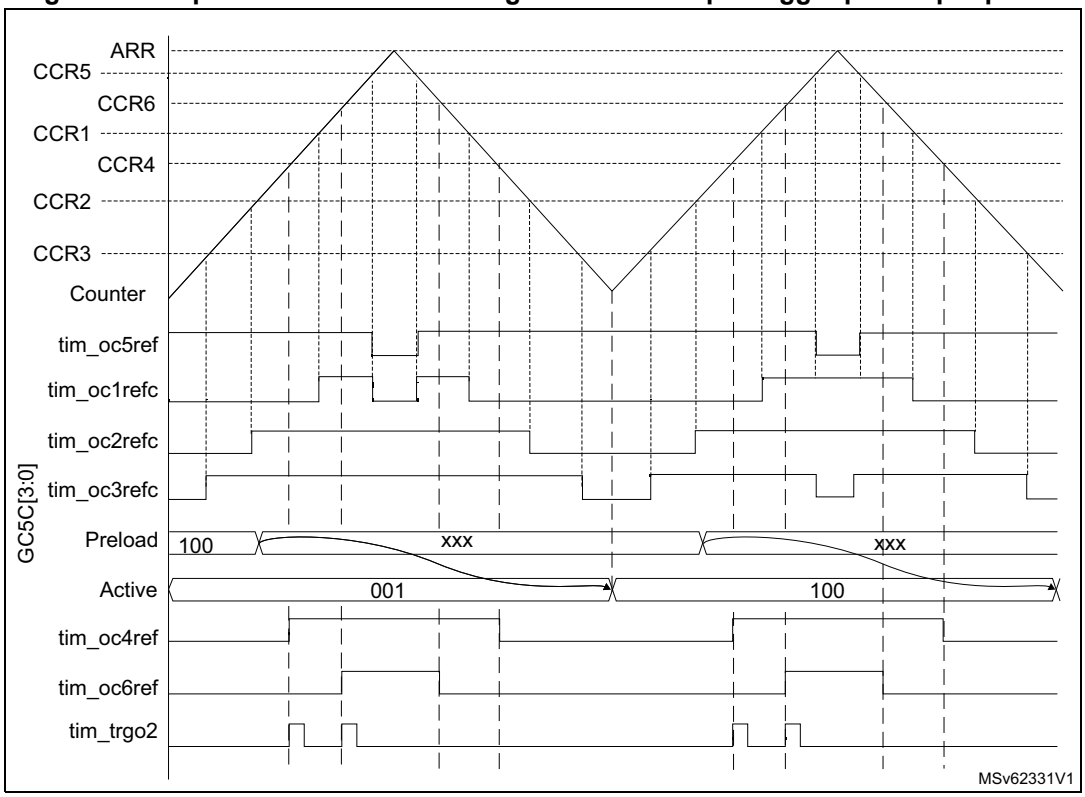
Figure 500. Combined PWM 3 example

41.3.16 Combined 3-phase PWM mode

Combined 3-phase PWM mode allows one to three center-aligned PWM signals to be generated with a single programmable signal ANDed in the middle of the pulses. The tim_oc5ref signal is used to define the resulting combined signal.

The 4 bits GC5C[4:1] in the TIM_CCR5 allow selection on which reference signal the tim_oc5ref is combined. The resulting signals, tim_ocxrefc, are made of an AND logical combination of two reference PWMs:

- If GC5C1 is set, tim_oc1refc is the logical AND of tim_oc1ref and tim_oc5ref
- If GC5C2 is set, tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref
- If GC5C3 is set, tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref
- If GC5C4 is set, tim_oc4refc is the logical AND of tim_oc4ref and tim_oc5ref



It is possible also to select an OR fonction with GC5C1O, GC5C2O, GC5C3O and GC5C4O bits, as following:

- If GC5C1O is set, tim_oc1refc is the logical OR of tim_oc1ref and tim_oc5ref
- If GC5C2O is set, tim_oc2refc is the logical OR of tim_oc2ref and tim_oc5ref
- If GC5C3O is set, tim_oc3refc is the logical OR of tim_oc3ref and tim_oc5ref
- If GC5C4O is set, tim_oc4refc is the logical OR of tim_oc4ref and tim_oc5ref

If both GC5Cx and GC5CxO bits are set, GC5Cx bit overrides GC5CxO programming and tim_ocxrefc is equal to tim_ocxref AND tim_oc5ref.

Combined 3-phase PWM mode can be selected independently on channels 1 to 4 by setting at least one of the bits GC5C[4:1] or GC5CO[4:1].

Figure 501. 3-phase combined PWM signals with multiple trigger pulses per period

The tim_trgo2 waveform shows how the ADC can be synchronized on given 3-phase PWM signals. Refer to *Section 41.3.36: ADC triggers* for more details.

41.3.17 Complementary outputs and dead-time insertion

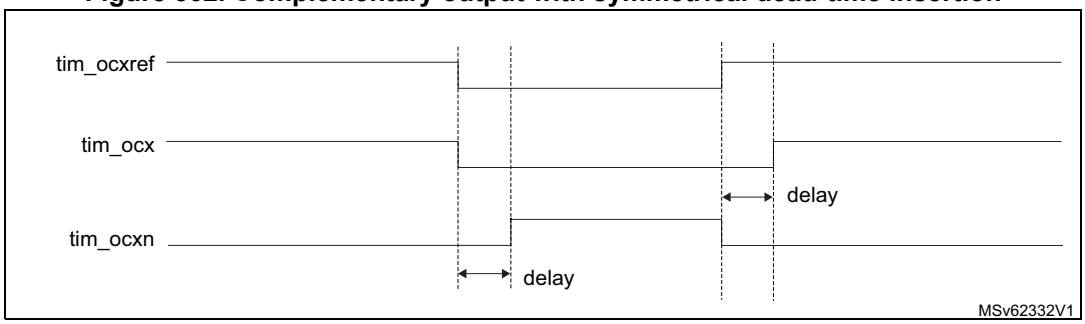
The advanced-control timers (TIM1/TIM8/TIM20) can output two complementary signals and manage the switching-off and the switching-on instants of the outputs.

This time is generally known as dead-time and it has to be adjusted depending on the devices that are connected to the outputs and their characteristics (such as intrinsic delays of level-shifters, or delays due to power switches).

The polarity of the outputs (main output tim_ocx or complementary tim_ocxn) can be selected independently for each output. This is done by writing to the CCxP and CCxNP bits in the TIM_CCER register.

The complementary signals tim_ocx and tim_ocxn are activated by a combination of several control bits: the CCxE and CCxNE bits in the TIM_CCER register and the MOE, OISx, OISxN, OSSI, and OSSR bits in the TIM_BDTR and TIM_CR2 registers. Refer to *Table 473: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature* for more details. In particular, the dead-time is activated when switching to the idle state (MOE falling down to 0).

Dead-time insertion is enabled by setting both CCxE and CCxNE bits, and the MOE bit if the break circuit is present. There is one 10-bit dead-time generator for each channel. From a



reference waveform tim_ocxref, it generates two outputs tim_ocx and tim_ocxn. If tim_ocx and tim_ocxn are active high:

- The tim_ocx output signal is the same as the reference signal except for the rising edge, which is delayed relative to the reference rising edge.
- The tim_ocxn output signal is the opposite of the reference signal except for the rising edge, which is delayed relative to the reference falling edge.

If the delay is greater than the width of the active output (tim_ocx or tim_ocxn) then the corresponding pulse is not generated.

The following figures show the relationships between the output signals of the dead-time generator and the reference signal tim_ocxref considering CCxP = 0, CCxNP = 0, MOE = 1, CCxE = 1 and CCxNE = 1 in these examples.

Figure 502. Complementary output with symmetrical dead-time insertion

The DTAE bit in the TIM_DTR2 is used to differentiate the deadtime values for rising and falling edges of the reference signal, as shown on *Figure 503*.

In asymmetrical mode (DTAE = 1), the rising edge-referred deadtime is defined by the DTG[7:0] bitfield in the TIM_BDTR register, while the falling edge-referred is defined by the DTGF[7:0] bitfield in the TIM_DTR2 register. The DTAE bit must be written before enabling the counter and must not be modified while CEN = 1.

It is possible to have the deadtime value updated on-the-fly during pwm operation, using a preload mechanism. The deadtime bitfield DTG[7:0] and DTGF[7:0] are preloaded when the DTPE bit is set, in the TIM_DTR2 register. The preload value is loaded in the active register on the next update event.

Note: If the DTPE bit is enabled while the counter is enabled, any new value written since last update is discarded and previous value is used.

Figure 503. Asymmetrical deadtime

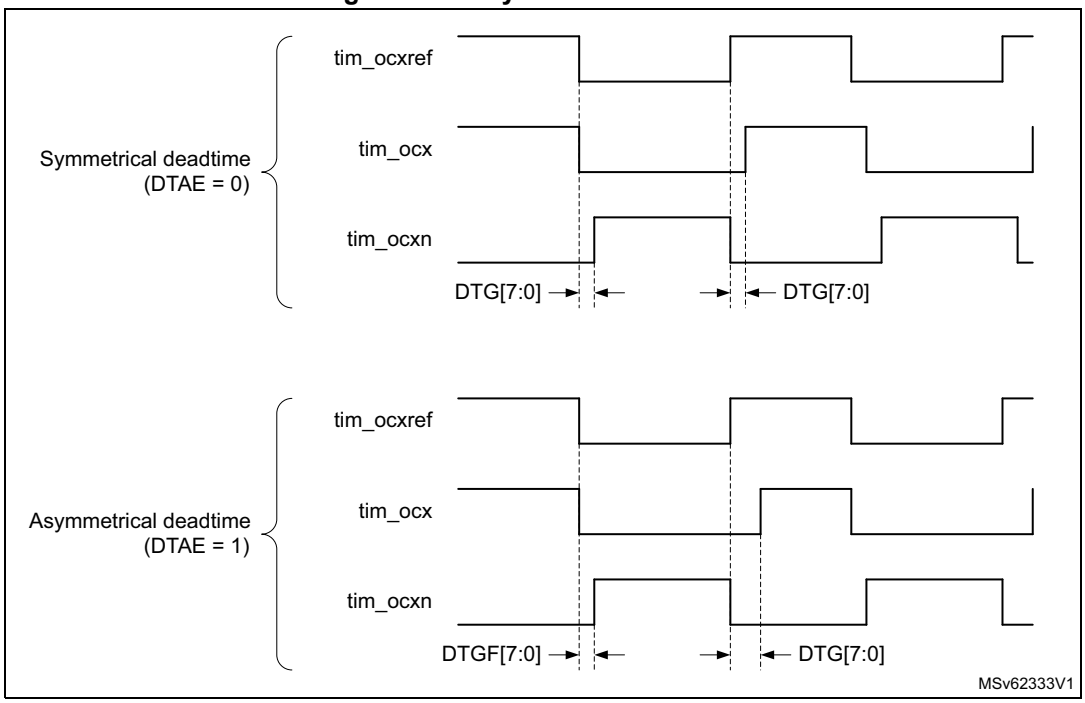


Figure 504. Dead-time waveforms with delay greater than the negative pulse

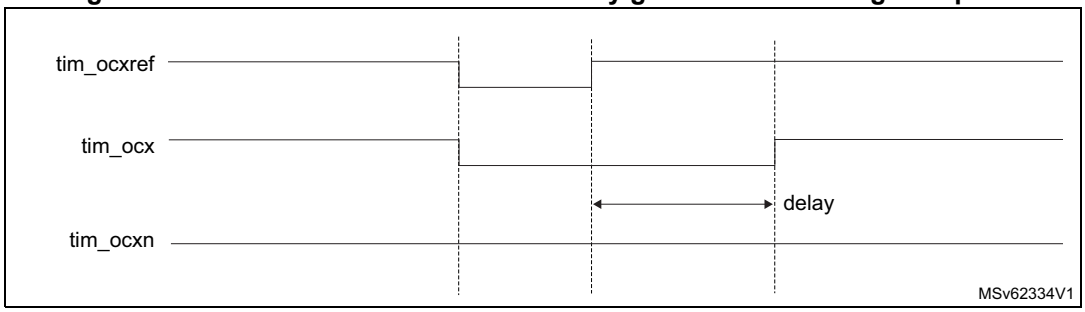

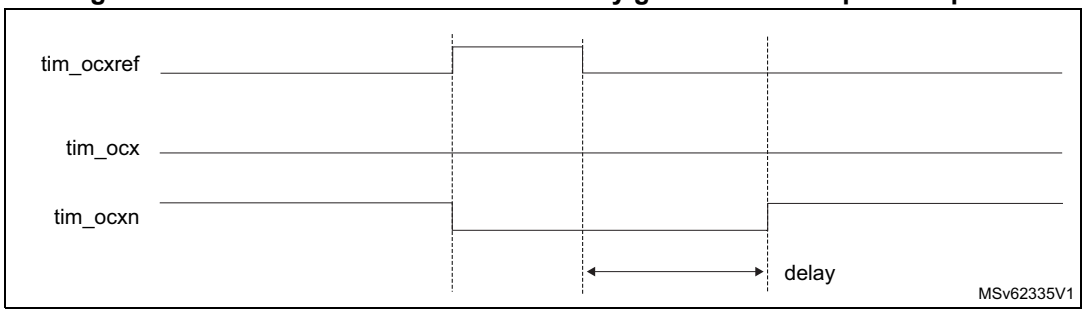

Figure 505. Dead-time waveforms with delay greater than the positive pulse

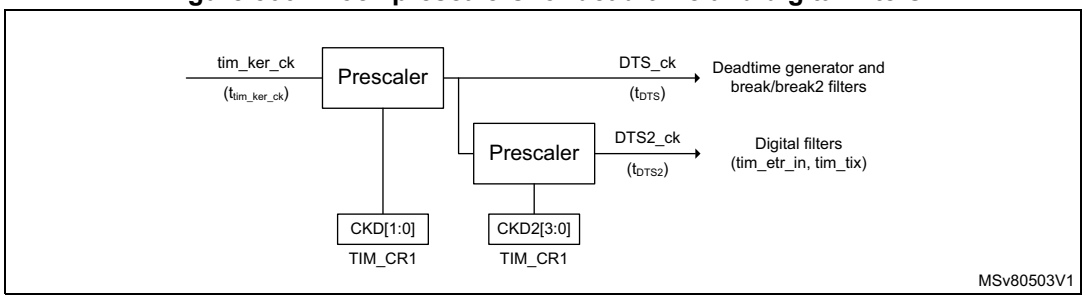
The dead-time delay is the same for each of the channels and is programmable with the DTG bits in the TIM_BDTR register. Refer to *Section 41.6.20: TIM break and dead-time register (TIM_BDTR)* for delay calculation.

Redirecting tim_ocxref to tim_ocx or tim_ocxn

In output mode (forced, output compare or PWM), tim_ocxref can be redirected to the tim_ocx output or to tim_ocxn output by configuring the CCxE and CCxNE bits in the TIM_CCER register.

This is used to send a specific waveform (such as PWM or static active level) on one output while the complementary remains at its inactive level. Other alternative possibilities are to have both outputs at inactive level or both outputs active and complementary with dead-time.



Note: When only tim_ocxn is enabled (CCxE = 0, CCxNE = 1), it is not complemented and becomes active as soon as tim_ocxref is high. For example, if CCxNP = 0 then tim_ocxn = tim_ocxref. On the other hand, when both tim_ocx and tim_ocxn are enabled (CCxE = CCxNE = 1) tim_ocx becomes active when tim_ocxref is high whereas tim_ocxn is complemented and becomes active when tim_ocxref is low.

41.3.18 Clock dividers for dead-time generators and digital filters

The dead-time generators and the digital filters (for tim_etr_in, tim_tix) are using a DTS_ck clock (with a t_{DTS} period), derived from the tim_ker_ck clock.

A prescaler can decrease the frequency to extend the deadtime period programmed with the CKD[1:0] bitfield in the TIM_CR1 register. A second prescaler can decrease the resulting DTS_ck clock to extend solely the digital filters range, with the CKD2[3:0] bitfield in the TIM_CR1 register.

Figure 506. Clock prescalers for dead-time and digital filters

41.3.19 Using the break function

The purpose of the break function is to protect power switches driven by PWM signals generated with the timers. The two break inputs are usually connected to fault outputs of power stages and 3-phase inverters. When activated, the break circuitry shuts down the PWM outputs and forces them to a predefined safe state. A number of internal MCU events can also be selected to trigger an output shut-down.

The break features two channels. A break channel which gathers both system-level fault (clock failure, ECC/parity errors,...) and application fault (from input pins and built-in comparator), and can force the outputs to a predefined level (either active or inactive) after a deadtime duration. A break2 channel which only includes application faults and is able to force the outputs to an inactive state.

The output enable signal and output levels during break are depending on several control bits:

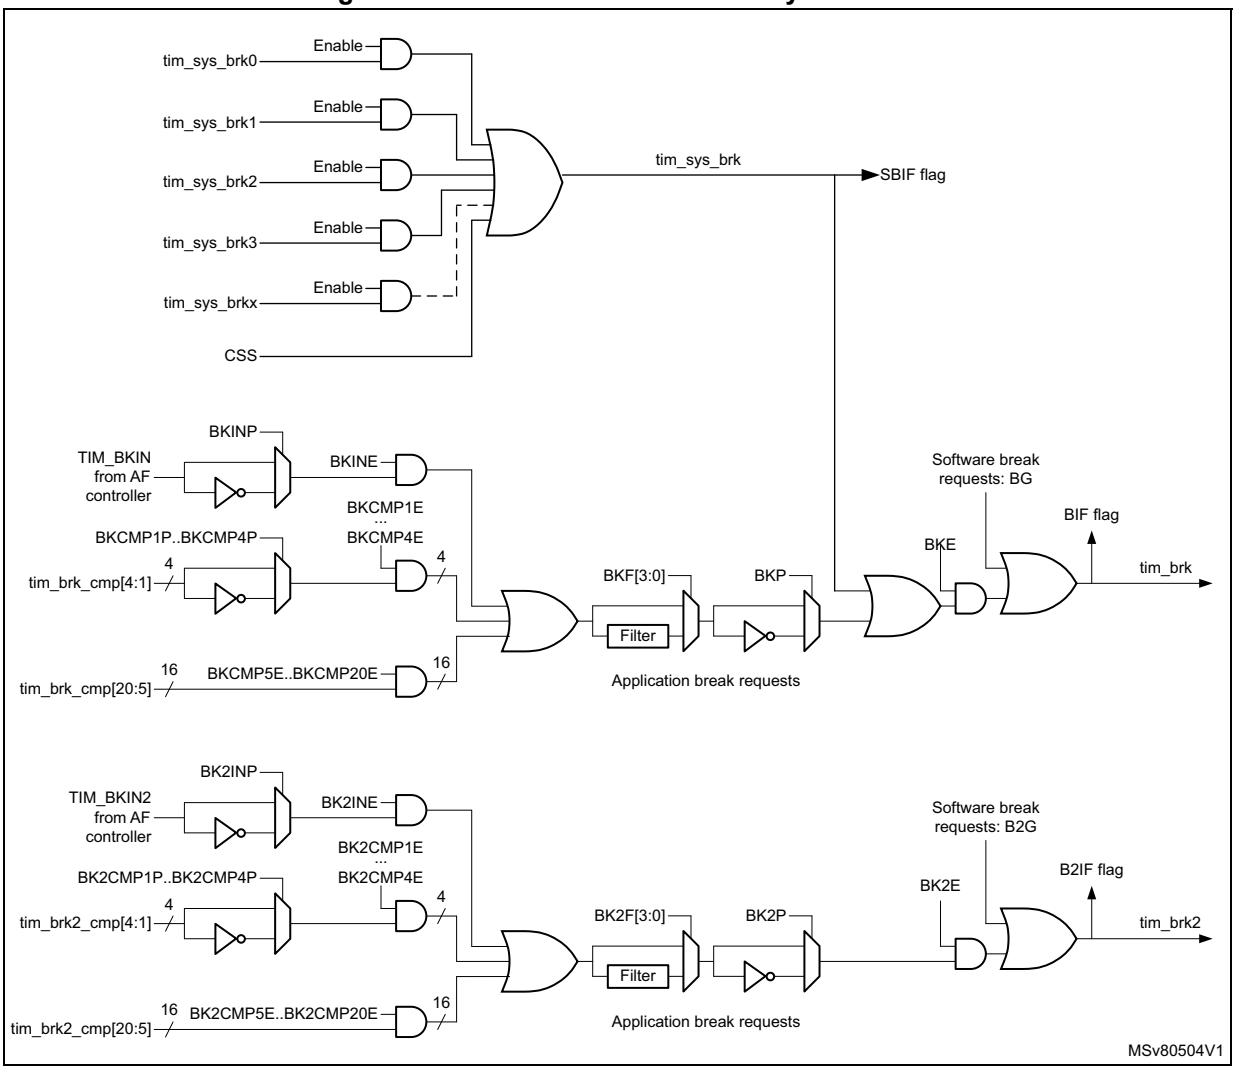
- The MOE bit in TIM_BDTR register is used to enable/disable the outputs by software and is reset in case of break or break2 event.
- The OSSI bit in the TIM_BDTR register defines whether the timer controls the output in inactive state or releases the control to the GPIO controller (typically to have it in Hi-Z mode)
- The OISx and OISxN bits in the TIM_CR2 register which are setting the output shut-down level, either active or inactive. The tim_ocx and tim_ocxn outputs cannot be set both to active level at a given time, whatever the OISx and OISxN values. Refer to *Table 473: Output control bits for complementary tim_ocx and tim_ocxn channels with break feature* for more details.

When exiting from reset, the break circuit is disabled and the MOE bit is low. The break functions can be enabled by setting the BKE and BK2E bits in the TIM_BDTR register. The break input polarities can be selected by configuring the BKP and BK2P bits in the same register. BKEx and BKPx can be modified at the same time. When the BKEx and BKPx bits are written, a delay of one APB clock cycle is applied before the writing is effective. Consequently, it is necessary to wait one APB clock period to correctly read back the bit after the write operation.

Because MOE falling edge can be asynchronous, a resynchronization circuit has been inserted between the actual signal (acting on the outputs) and the synchronous control bit (accessed in the TIM_BDTR register). It results in some delays between the asynchronous and the synchronous signals. In particular, if MOE is set to 1 whereas it was low, a delay must be inserted (dummy instruction) before reading it correctly. This is because the write acts on the asynchronous signal whereas the read reflects the synchronous signal.

The sources for break (tim_brk) channel are:

- External sources connected to one of the TIM_BKIN pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources:
  - coming from a tim_brk_cmpx input (refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for product specific implementation)
  - coming from a system break request (refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for product specific implementation)



The sources for break2 (tim_brk2) are:

- External sources connected to one of the TIM_BKIN2 pin (as per selection done in the GPIO alternate function selection registers), with polarity selection and optional digital filtering
- Internal sources coming from a tim_brk2_cmpx input (refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for product specific implementation)

Break events can also be generated by software using BG and B2G bits in the TIM_EGR register.

All sources are ORed before entering the timer tim_brk or tim_brk2 inputs, as per *Figure 507* below.

Figure 507. Break and Break2 circuitry overview

Note: An asynchronous (clockless) operation is only guaranteed when the programmable filter is disabled. If it is enabled, a fail safe clock mode (for example by using the internal PLL and/or the CSS) must be used to guarantee that break events are handled.

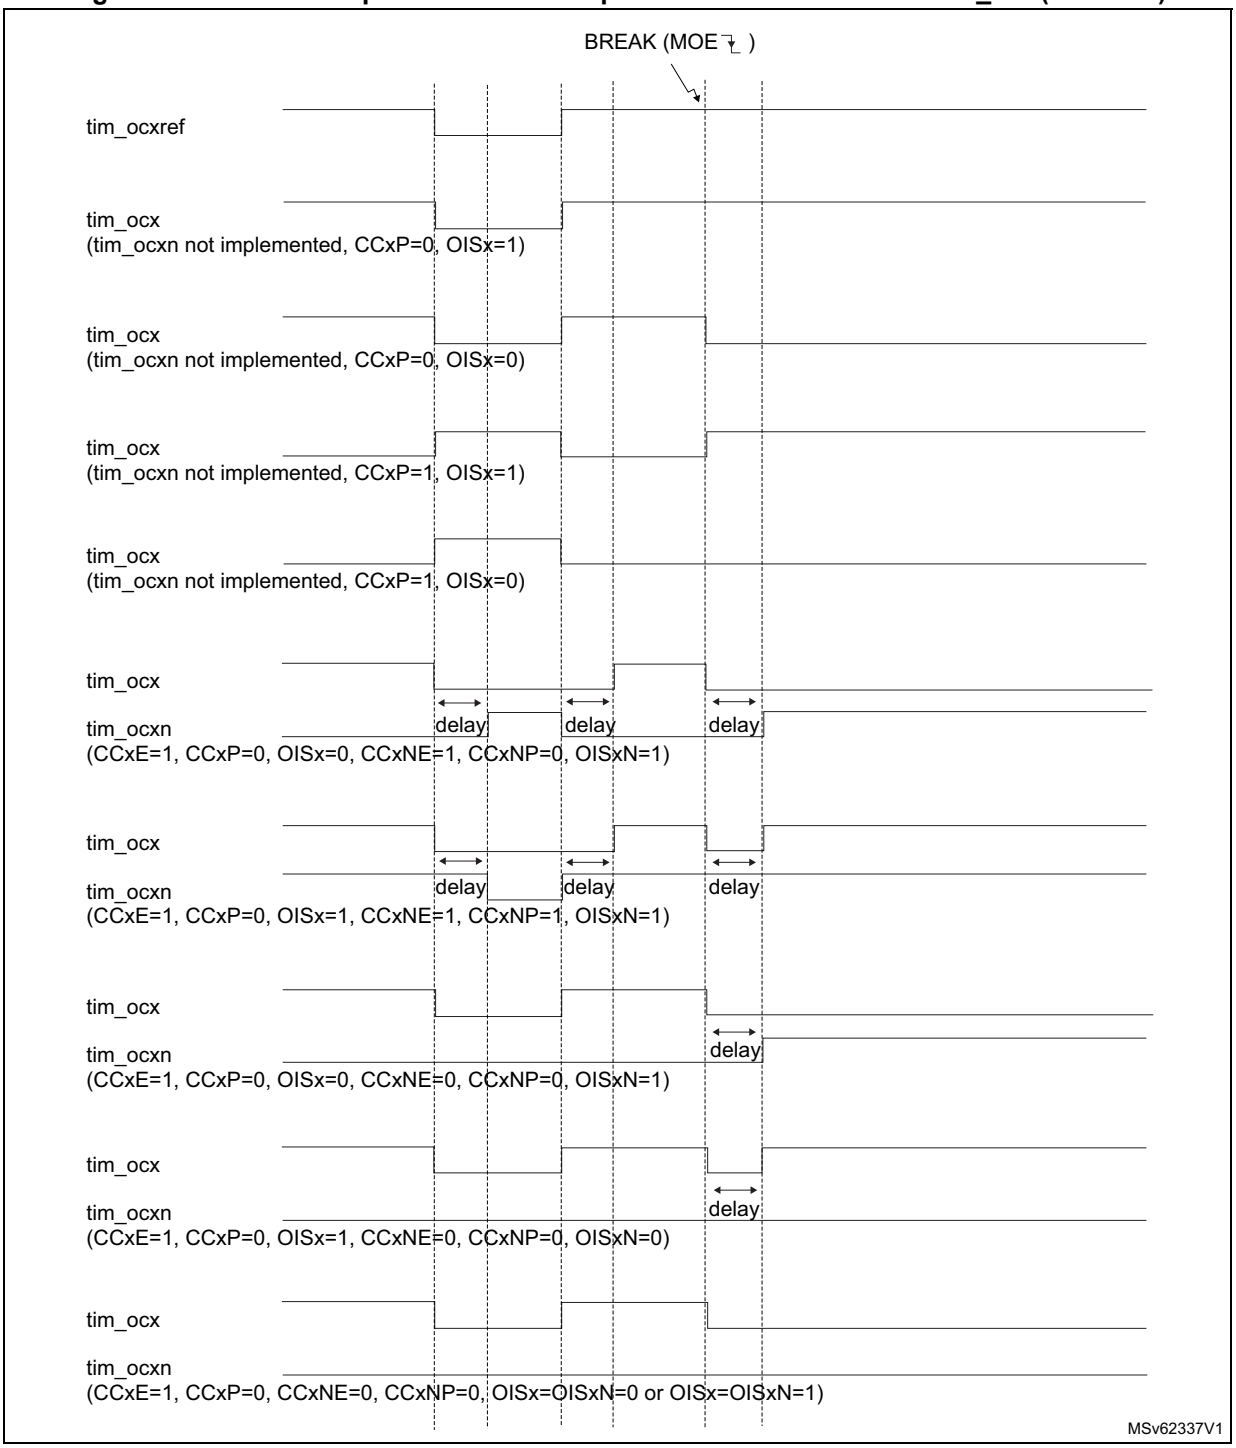
When one of the breaks occurs (selected level on one of the break inputs):

- The MOE bit is cleared asynchronously, putting the outputs in inactive state, idle state, or even releasing the control to the GPIO controller (selected by the OSSI bit). This feature is enabled even if the MCU oscillator is off.
- Each output channel is driven with the level programmed in the OISx bit in the TIM_CR2 register as soon as MOE = 0. If OSSI = 0, the timer releases the output control (taken over by the GPIO controller), otherwise the enable output remains high.
- When complementary outputs are used:
  - The outputs are first put in inactive state (depending on the polarity). This is done asynchronously so that it works even if no clock is provided to the timer.
  - If the timer clock is still present, then the dead-time generator is reactivated in order to drive the outputs with the level programmed in the OISx and OISxN bits after a dead-time. Even in this case, tim_ocx and tim_ocxn cannot be driven to

their active level together. Note that because of the resynchronization on MOE, the dead-time duration is slightly longer than usual (around 2 tim_ker_ck clock cycles).

  - If OSSI = 0, the timer releases the output control (taken over by the GPIO controller which forces a Hi-Z state), otherwise the enable outputs remain or become high as soon as one of the CCxE or CCxNE bits is high.

- The break status flags (B2GF, BGF, SBIF, BIF, and B2IF bits in the TIM_SR register) are set. An interrupt is generated if the BIE bit in the TIM_DIER register is set.
- An output disable status flag (ODS in the TIM_SR register) indicates the status of the outputs:
  - ODS = 0: Idle state. Break was triggered (or MOE was written to 0) and OIS states are forced on tim_ocx and tim_ocxn outputs
  - ODS = 1: Disabled state. Break2 was triggered, tim_ocx and tim_ocxn outputs are inactive
- If the AOE bit in the TIM_BDTR register is set, the MOE bit is automatically set again at the next update event (UEV). As an example, this can be used to perform a regulation. Otherwise, MOE remains low until the application sets it to 1 again. In this case, it can be used for security and the break input can be connected to an alarm from power drivers, thermal sensors, or any security components.



Note: If the MOE is reset by the CPU while the AOE bit is set, the outputs are in idle state and forced to inactive level or Hi-Z depending on OSSI value. If both the MOE and AOE bits are reset by the CPU, the outputs are in disabled state and driven with the level programmed in the OISx bit in the TIM_CR2 register.

The break inputs are active on level. Thus, the MOE cannot be set while the break input is active (neither automatically nor by software). In the meantime, the status flag BIF and B2IF cannot be cleared.

In addition to the break input and the output management, a write protection has been implemented inside the break circuit to safeguard the application. It is used to freeze the configuration of several parameters (dead-time duration, tim_ocx/tim_ocxn polarities and state when disabled, OCxM configurations, break enable, and polarity). The application can choose from three levels of protection selected by the LOCK bits in the TIM_BDTR register. Refer to *Section 41.6.20: TIM break and dead-time register (TIM_BDTR)*. The LOCK bits can be written only once after an MCU reset.

Figure 508 shows an example of behavior of the outputs in response to a break.

Figure 508. Various output behavior in response to a break event on tim_brk (OSSI = 1)

The two break inputs have different behaviors on timer outputs:

- The tim_brk input can either disable (inactive state) or force the PWM outputs to a predefined safe state.
- tim_brk2 can only disable (inactive state) the PWM outputs.

The tim_brk has a higher priority than tim_brk2 input, as described in *Table 466*.

The output disable status flag (ODS in the TIM_SR register) indicates the status of the outputs after a break event and is useful to distinguish break and break2 safe states.

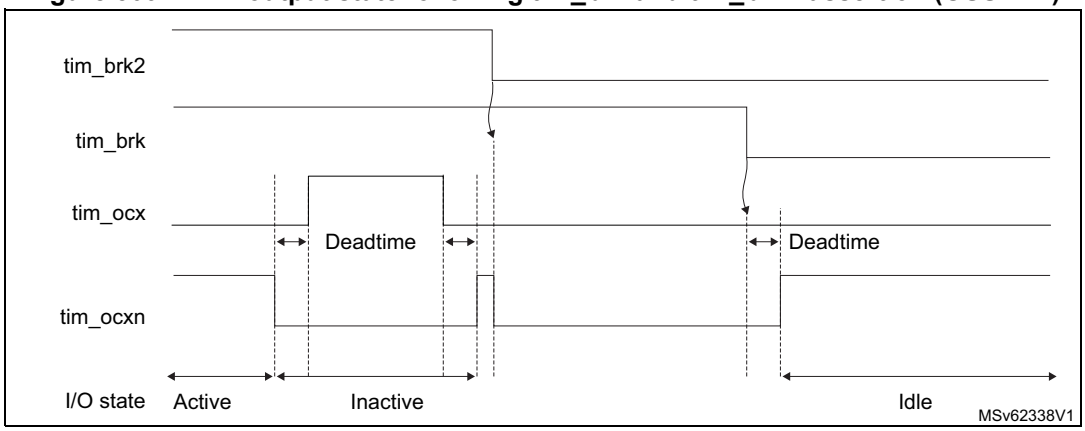
Note: tim_brk2 must only be used with OSSR = OSSI = 1.

Table 466. Behavior of timer outputs versus tim_brk/tim_brk2 inputs

tim_brk	tim_brk2	Timer outputs state	Typical use case	
			tim_ocxn output (low side switches)	tim_ocx output (high side switches)
Active	X	– Inactive then forced output state (after a deadtime) – Outputs disabled if OSSI = 0 (control taken over by GPIO logic)	ON after deadtime insertion	OFF
Inactive	Active	Inactive	OFF	OFF

Figure 509 gives an example of tim_ocx and tim_ocxn output behavior in case of active signals on tim_brk and tim_brk2 inputs. In this case, both outputs have active high polarities (CCxP = CCxNP = 0 in TIM_CCER register).

Figure 509. PWM output state following tim_brk and tim_brk2 assertion (OSSI = 1)



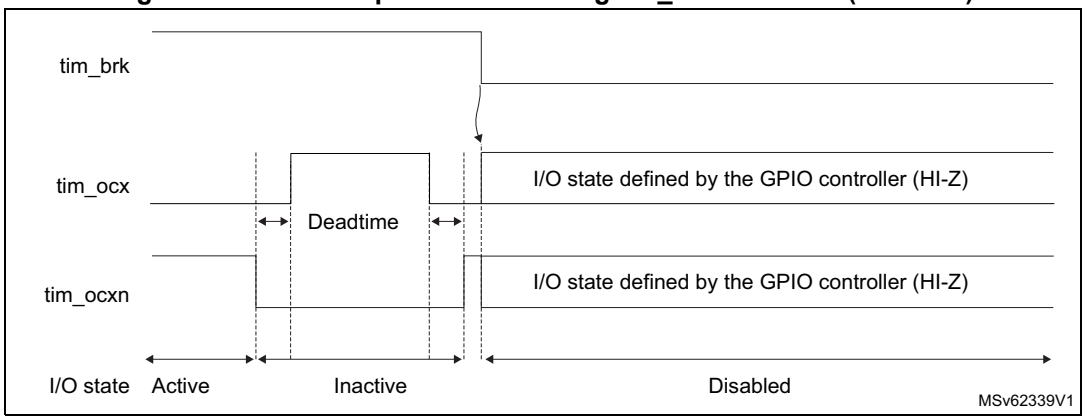


Figure 510. PWM output state following tim_brk assertion (OSSI = 0)

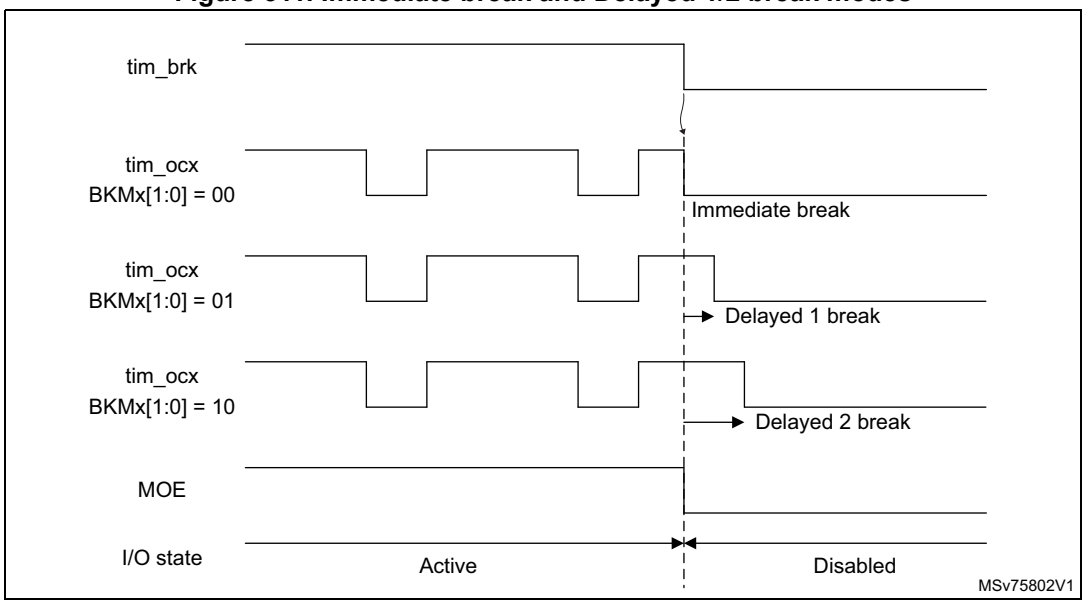
41.3.20 Delayed break



In Neutral-Point Clamped (NPC) multilevel converter topology, a break strategy with immediate outputs shut-down is not suitable, as it may damage the power switches with excessive voltage levels.

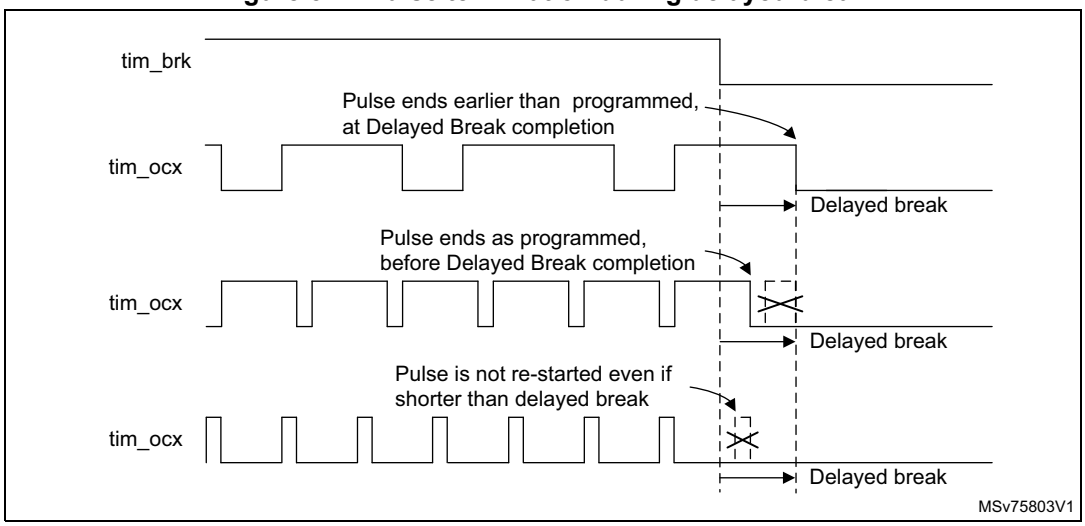
The delayed break features provide 2 options delaying the response to a break event, and implement a safe shut-down sequence.

BKMx[1:0] and BKMxN[1:0] bitfields in TIM_MPR1 provides 3 options for each complementary outputs (tim_oc1/tim_oc1n to tim_oc4/tim_oc4n), as show on *Figure 511* below:

- BKM[1:0] = 00: the break response is immediate
- BKM[1:0] = 01: Delayed 1 break. The break response is delayed with a delay defined in the DBK1[7:0] bitfield of the TIM_MPR2 register
- BKM[1:0] = 10: Delayed 2 break. The break response is delayed with a delay defined in the DBK2[7:0] bitfield of the TIM_MPR2 register

Figure 511. Immediate break and Delayed 1/2 break modes

The delayed break mode is triggered when:



- A break event occurs
- The MOE bit is reset
- When the microcontroller enters debug mode with DBG_TIM_STOP=1

Warning: The break2 feature must be disabled when the delayed mode is enabled.

When delayed break mode is triggered, the MOE bit is immediately cleared, and cannot be set during the delayed break duration. In bidirectional break mode, the break output is reset immediately to indicate the delayed break start to external components. Once the longest of the 2 delays is over, the deadtime generator is enabled to prevent any deadtime violation if OISx/OISxN bits are set.

If the tim_ocx/tim_ocxn signal is reset before the end of the delayed break (due to a compare match in PWM mode, typically), the signal is not maintained during the full delayed break period, to maintain the duty cycle, as shown on *Figure 512* below. Still, the Delayed break circuitry guarantees that the tim_ocx/tim_ocxn signals cannot be set again once the break event occurred.

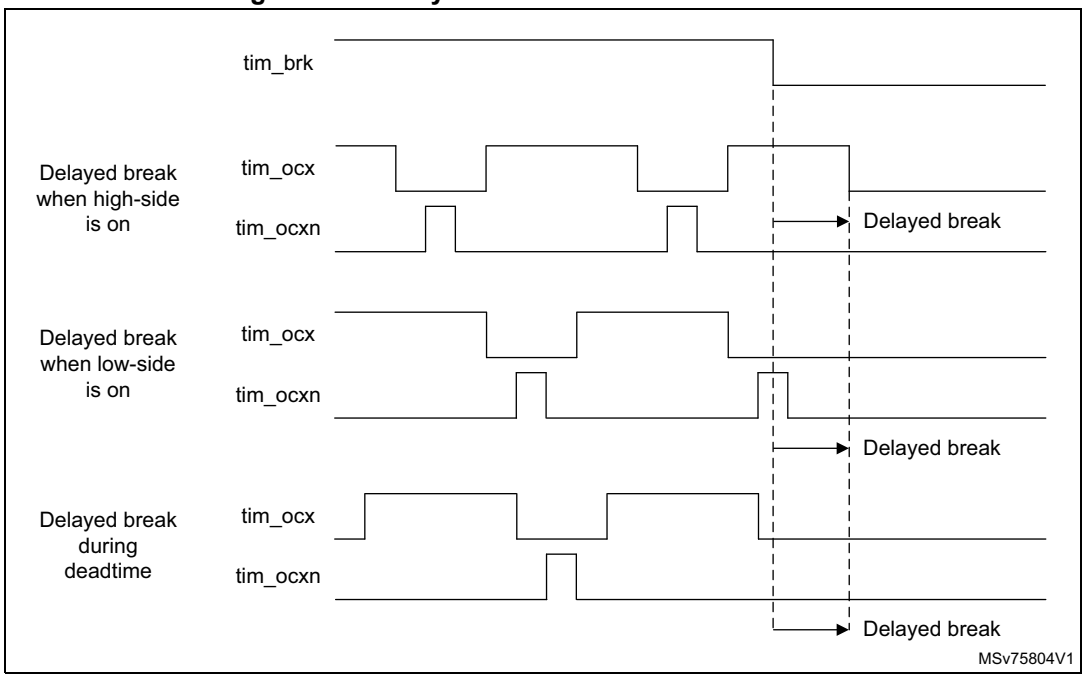


Figure 512. Pulse termination during delayed break

The Figure 563 depicts the behavior when the deadtime generator is enabled, for the 3 cases:

– Delayed break triggered when tim_ocx is set
– Delayed break triggered when tim_ocxn is set
– Delayed break triggered during deadtime interval

Figure 513. Delayed break with deadtime insertion

The delay programming is identical to deadtime generator's, with 2 user-programmable durations in the TIM_MPR2 register: DBK1[7:0] bitfield for the Delayed 1 break and DBK2[7:0] bitfield for the Delayed 2 break.

DBK1[7:0] and DBK2[7:0] bitfields are preloaded: they can be changed during timer operation, and the new value is transferred to the active register when an update event occurs.

DBK1[7:0] and DBK2[7:0] bitfields are partially preloaded: they can be changed during timer operation, and the new value is transferred to the active register when an update event occurs.

The bits coding for t_{DTG} selection are not preloaded.

It is thus recommended to update only the least significant bits to have the expected duration value:

- DBKx[6:0] if DBKx[7] = 0
- DBKx[5:0] if DBKx[7:6] = 10
- DBKx[4:0] if DBKx[7:5] = 110 or 111

The BKMx[1:0] and BKMxN[1:0] bits are static, they can only be modified when the counter is stopped (CEN=0 in TIM_CR1).

The content of the TIM_MPR1 and TIM_MPR2 register can be write protected using the LOCK[1:0] bits in the TIM_BDTR register.

41.3.21 Bidirectional break inputs

The TIM1/TIM8/TIM20 feature bidirectional break I/Os, as represented on *Figure 514*.

This provides support for:

- A board-level global break signal available for signaling faults to external MCUs or gate drivers, with a unique pin being both an input and an output status pin.
- Internal break sources and multiple external open drain sources ORed together to trigger a unique break event, when multiple internal and external break sources must be merged.

The tim_brk and tim_brk2 inputs are configured in bidirectional mode using the BKBID and BK2BID bits in the TIM_BDTR register. The BKBID programming bits can be locked in read-only mode using the LOCK bits in the TIM_BDTR register (in LOCK level 1 or above).

The bidirectional mode is available for both the tim_brk and tim_brk2 inputs, and require the I/O to be configured in open-drain mode with active low polarity (using BKINP, BKP, BK2INP and BK2P bits). Any break request coming either from system (for example CSS), from on-chip peripherals, or from break inputs forces a low level on the break input to signal the fault event. The bidirectional mode is inhibited if the polarity bits are not correctly set (active high polarity), for safety purposes.

The break software events (BG and B2G) also cause the break I/O to be forced to 0 to indicate to the external components that the timer is entered in break state. However, this is valid only if the break is enabled (BKE or B2KE = 1). When a software break event is generated with BKE or B2KE = 0), the outputs are put in safe state and the break flag is set, but there is no effect on the TIM_BKIN and TIM_BKIN2 I/Os.

A safe disarming mechanism prevents the system to be definitively locked-up (a low level on the break input triggers a break which enforces a low level on the same input).

When the BKDSRM (BK2DSRM) bit is set to 1, this releases the break output to clear a fault signal and to give the possibility to re-arm the system.

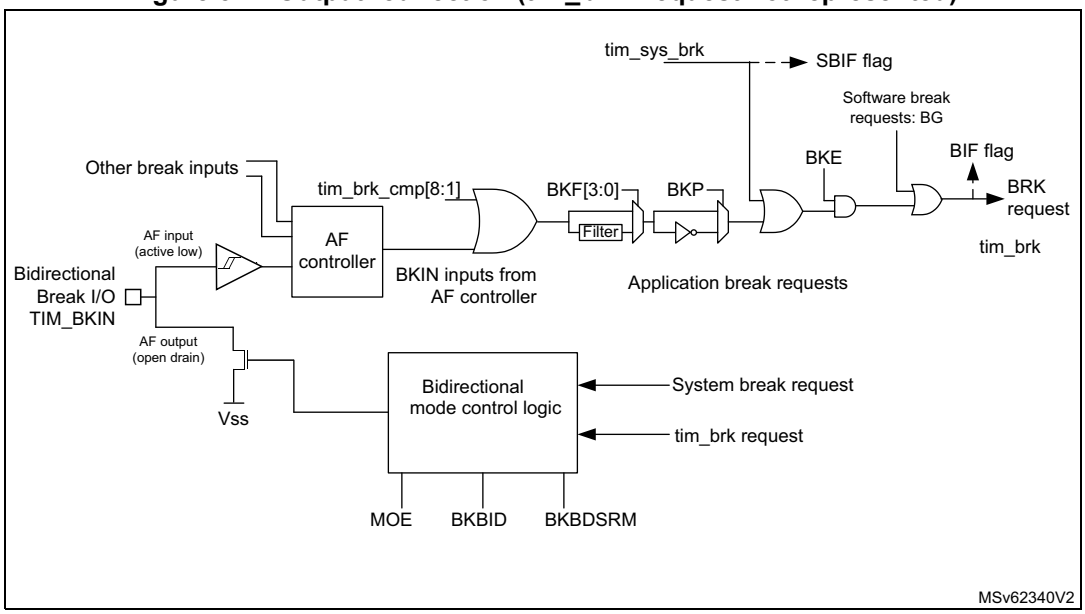
At no point the break protection circuitry can be disabled:

- The break input path is always active: a break event is active even if the BKDSRM (BK2DSRM) bit is set and the open drain control is released. This prevents the PWM output to be restarted as long as the break condition is present.
- The BKDSRM (BK2DSRM) bit cannot disarm the break protection as long as the outputs are enabled (MOE bit is set) (see *Table 467*).

Table 467. Break protection disarming conditions

MOE	BKBID (BK2BID)	BKDSRM (BK2DSRM)	Break protection state
0	0	X	Armed
0	1	0	Armed
0	1	1	Disarmed
1	X	X	Armed

Arming and rearming break circuitry



The break circuitry (in input or bidirectional mode) is armed by default (peripheral reset configuration).

The following procedure must be followed to re-arm the protection after a break (break2) event:

- The BKDSRM (BK2DSRM) bit must be set to release the output control.
- The software must wait until the system break condition disappears (if any) and clear the SBIF status flag (or clear it systematically before rearming).
- The software must poll the BKDSRM (BK2DSRM) bit until it is cleared by hardware (when the application break condition disappears).

From this point, the break circuitry is armed and active, and the MOE bit can be set to re-enable the PWM outputs.

Figure 514. Output redirection (tim_brk2 request not represented)

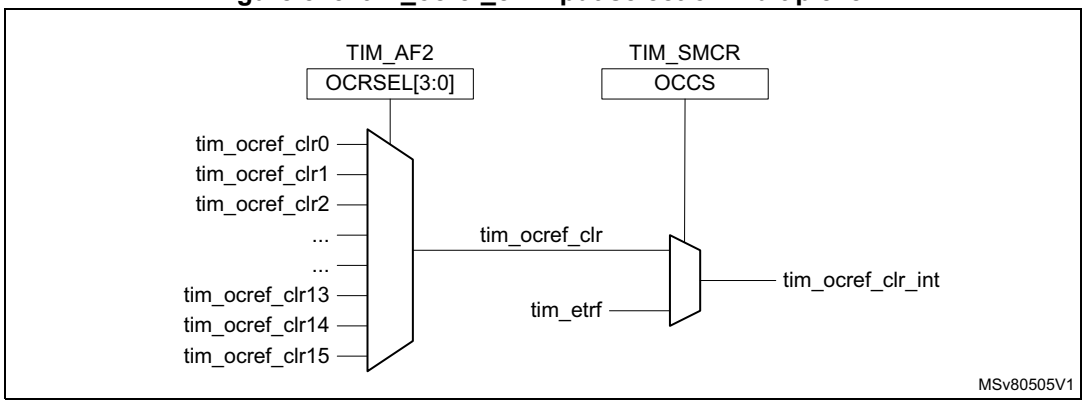
41.3.22 Output idle state override

It is possible to override the outputs states when they are disabled (ie MOE bit reset in TIM_BDTR). This feature can be used to apply specific patterns prior to start PWM operations, for instance to refresh bootstrap capacitors of power switch gate drivers.

The OOC control bit in the TIM_OOR register acts as following:

- OOC= 0: 0: tim_ocx and tim_ocxn outputs are in the default idle state
- OOC=1: tim_ocx and tim_ocxn outputs are forced in an idle state defined with OOSx/OOSxN bits in the TIM_OOR register

The OOC bit can only be modified when the outputs are in idle state (MOE = 0). It is cleared by hardware when the MOE bit is set, and the deadtime generator ensures there's no deadtime violation on complementary outputs.



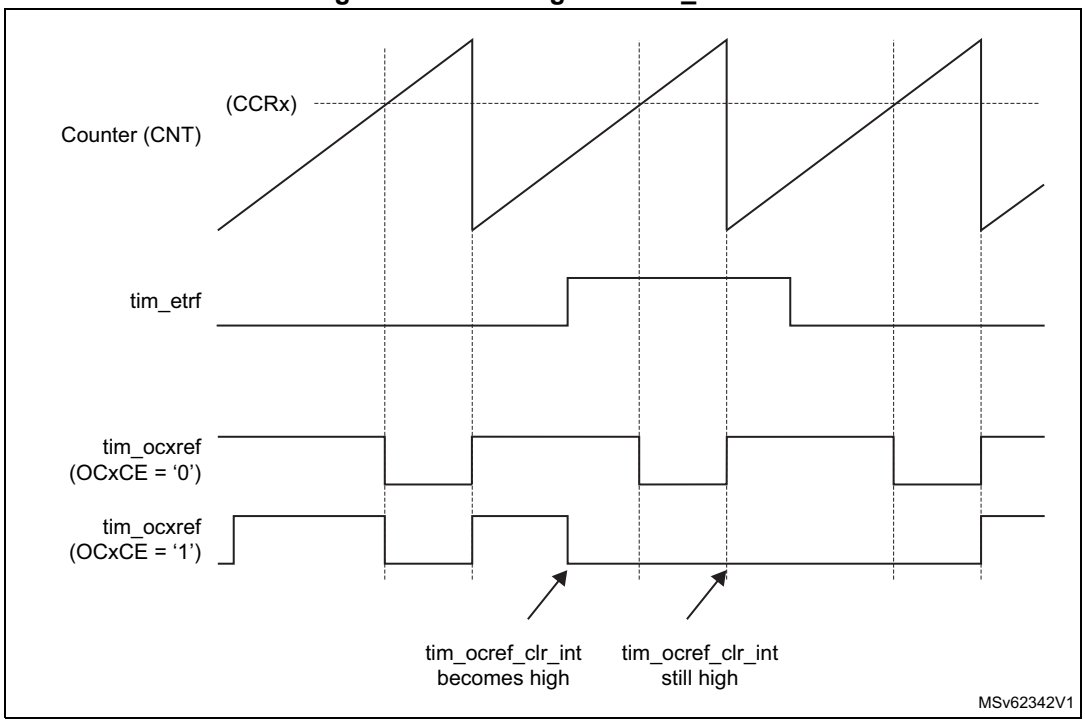
The OOSx/OOSxN bits in the TIM_OOR register cannot be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

41.3.23 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIM_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in Output compare and PWM modes. It must not be used in Forced mode. tim_ocref_clr_int input can be selected between the tim_ocref_clr input and tim_etrf (tim_etr_in after the filter) by configuring the OCCS bit in the TIM_SMCR register.

The tim_ocref_clr input can be selected among several inputs, using the OCRSEL[3:0] bitfield in the TIM_AF2 register, as shown on the *Figure 515* below. Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for a list of sources available in the product.

Figure 515. tim_ocref_clr input selection multiplexer



When tim_etrf is chosen, tim_etr_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] of the TIM_SMCR register set to 00.
2. The external clock mode 2 must be disabled: bit ECE of the TIM_SMCR register set to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to application needs (as per polarity of the source connected to the trigger and eventual need to remove noise using the filter).

Figure 516 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the enable bit OCxCE. In this example, the timer TIMx is programmed in PWM mode.

Figure 516. Clearing TIMx tim_ocxref

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), then tim_ocxref is enabled again at the next counter overflow.

This feature is also supported in combined and asymmetric modes. In this case, it is mandatory to have the OCxCE bit enabled for the channel, the OCxCE bit of the complementary channel (e.g. OC2CE = X for oc2ref in *Figure 517*) is ignored in this case.

Figure 517 to *Figure 520* are describing the output waveforms for some use cases, when the ocref_clr_int signal is asserted.

Figure 517. Asymmetric PWM mode 1

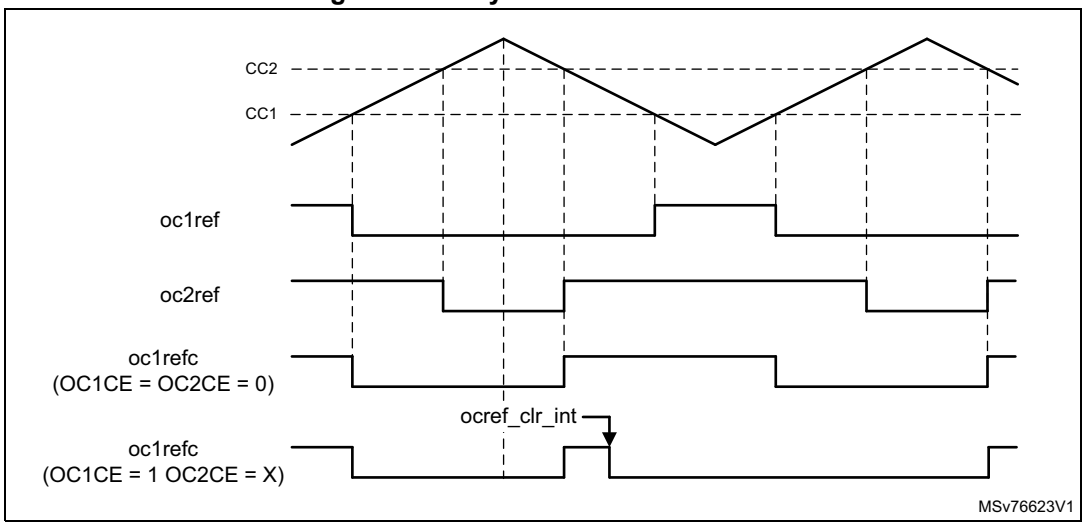


Figure 518. Asymmetric PWM mode 2

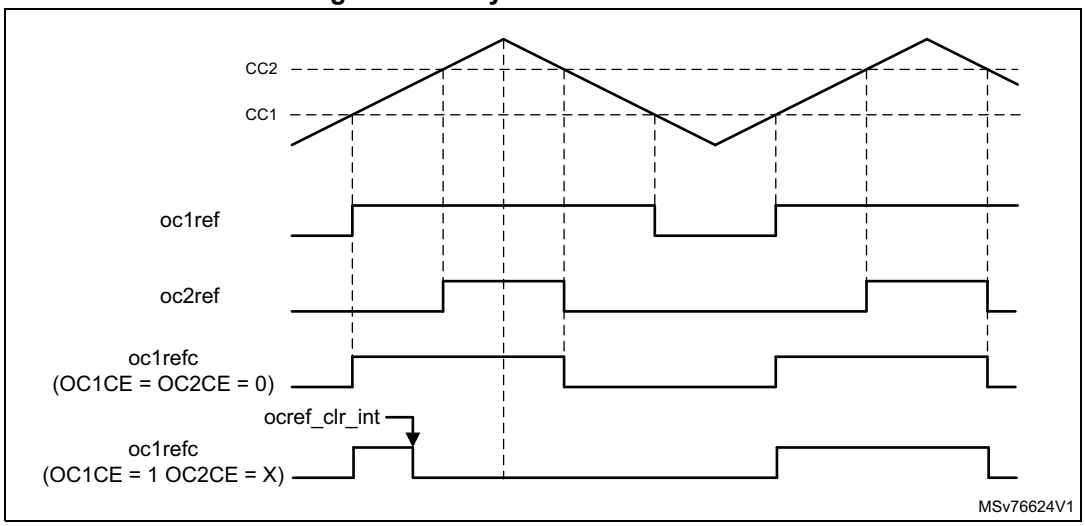

Figure 519. Asymmetric PWM mode 7 (OC1refc = oc1ref OR oc5ref)

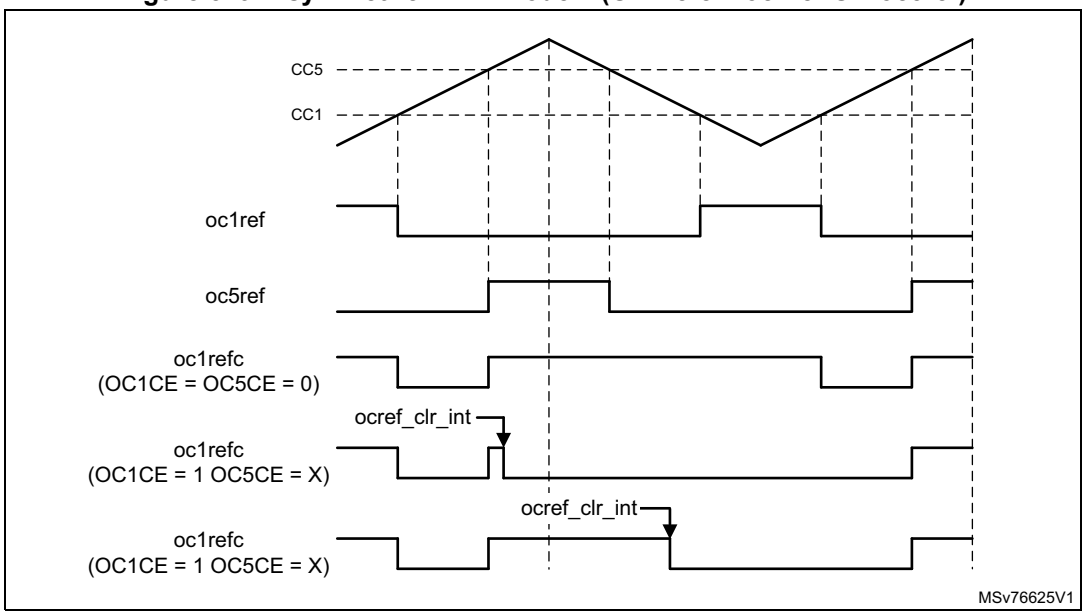

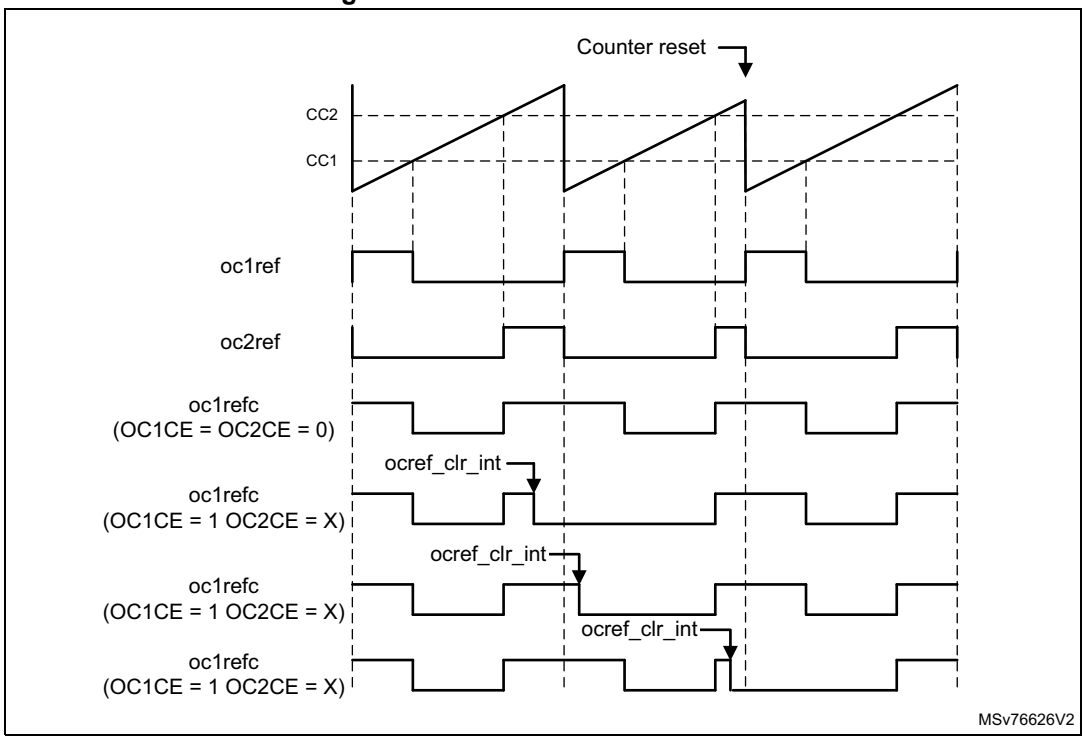

Figure 520. Combined PWM mode 1

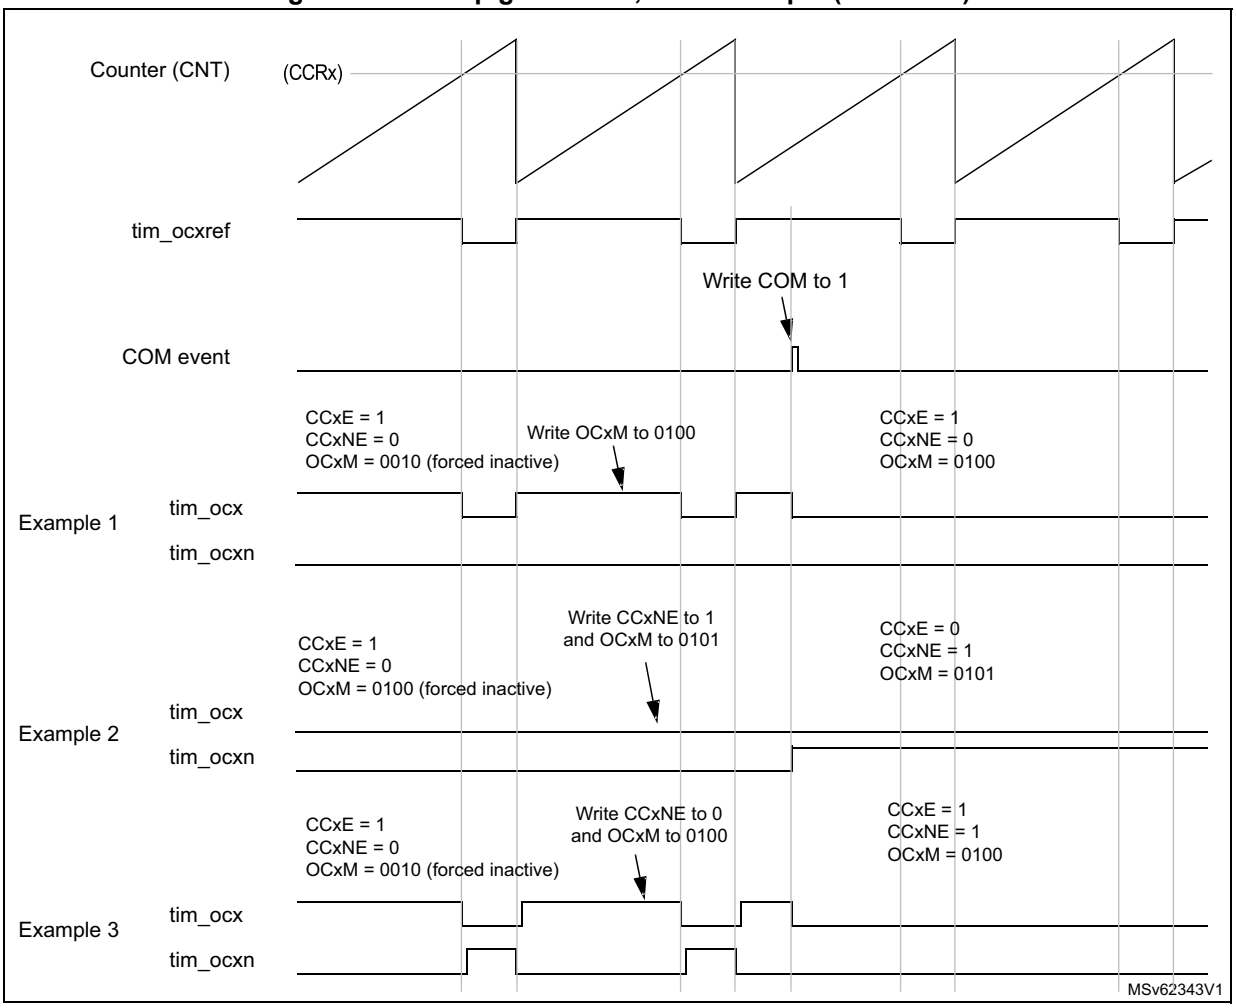
Conditions of use

This feature is intended to support cycle-by-cycle current control loops, typically with a comparator shortening the PWM on-time when a current threshold is exceeded.

It cannot be used for the following modes, where the OCxCE bit must be cleared:

- PWM toggle mode (OCxM[4:0] = 0x03)
- One pulse mode with PWM active on match (OPM=1 and OCxM[4:0] = 0x06, 0x08, 0x0C, 0x0E, 0x10, 0x12, 0x14, 0x16, 0x18)
- Combined 3-phase modes (GC5Cx or GC5CxO = 1)
- Combined PWM mode 1 or 3 in center aligned mode (CMS[1:0] = 1,2,3 and OCxM[4:0] = 0x0C or 0x10)



41.3.24 6-step PWM generation

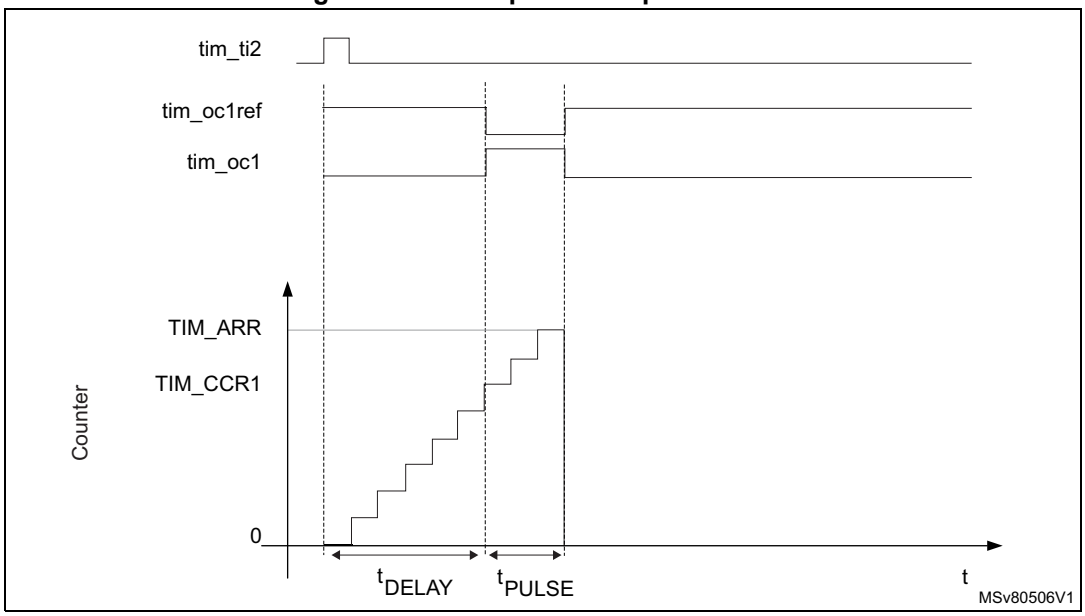
When complementary outputs are used on a channel, preload bits are available on the OCxM, CCxE, and CCxNE bits. The preload bits are transferred to the shadow bits at the COM commutation event. Thus one can program in advance the configuration for the next step and change the configuration of all the channels at the same time. COM can be generated by software by setting the COM bit in the TIM_EGR register or by hardware (on tim_trgi rising edge).

A flag is set when the COM event occurs (COMIF bit in the TIM_SR register), which can generate an interrupt (if the COMIE bit is set in the TIM_DIER register) or a DMA request (if the COMDE bit is set in the TIM_DIER register).

Figure 521 describes the behavior of the tim_ocx and tim_ocxn outputs when a COM event occurs, in three different examples of programmed configurations.

Figure 521. 6-step generation, COM example (OSSR = 1)

41.3.25 One-pulse mode



One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIM_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

- In upcounting: CNT < CCRx ≤ ARR (in particular, 0 < CCRx)
- In downcounting: CNT > CCRx

Figure 522. Example of one pulse mode.

In the following example, the user wants to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:

- Map tim_ti2fp2 to tim_ti2 by writing CC2S = 01 in the TIM_CCMR1 register.
- tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
- Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIM_SMCR register.
- tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIM_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIM_CCR1 register.
- The t_{PULSE} is defined by the difference between the autoreload value and the compare value (TIM_ARR - TIM_CCR1).
- Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the auto-reload value. This is achieved by enabling PWM mode 2 (OC1M = 00111 in TIM_CCMR1). Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIM_CCMR1 register and ARPE in the TIM_CR1 register. In this case one has to write the compare value in the TIM_CCR1 register, the autoreload value in the TIM_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIM_CR1 register must be low.

Since only one pulse (Single mode) is needed, a 1 must be written in the OPM bit in the TIM_CR1 register to stop the counter at the next update event (when the counter rolls over

from the autoreload value back to 0). When OPM bit in the TIM_CR1 register is set to 0, so the Repetitive mode is selected.

Particular case: tim_ocx fast enable:

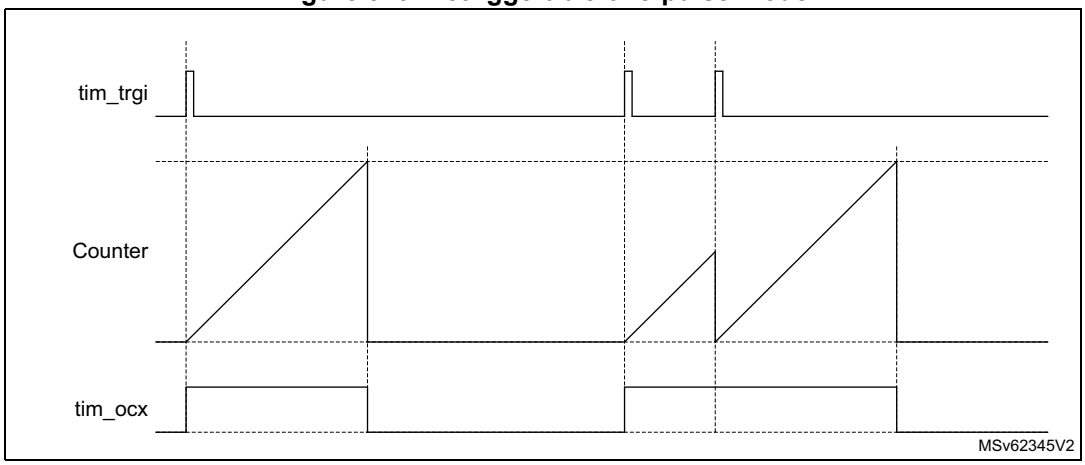
In One-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min that can be achieved.

To output a waveform with the minimum delay, the OCxFE bit can be set in the TIM_CCMRx register. Then tim_ocxref (and tim_ocx) are forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

41.3.26 Retriggerable One-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with nonretriggerable one-pulse mode described in *Section 41.3.25*:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.



The timer must be in Slave mode, with the bits SMS[4:0] = 01000 (Combined Reset + trigger mode) in the TIM_SMCR register, and the OCxM[4:0] bits set to 01000 or 01001 for retriggerable OPM mode 1 or 2.

If the timer is configured in Up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in Down-counting mode, CCRx must be above or equal to ARR.

Note: The OCxM[4:0] and SMS[4:0] bitfields are split into two parts for compatibility reasons, the most significant bit are not contiguous with the three least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIM_CR1.

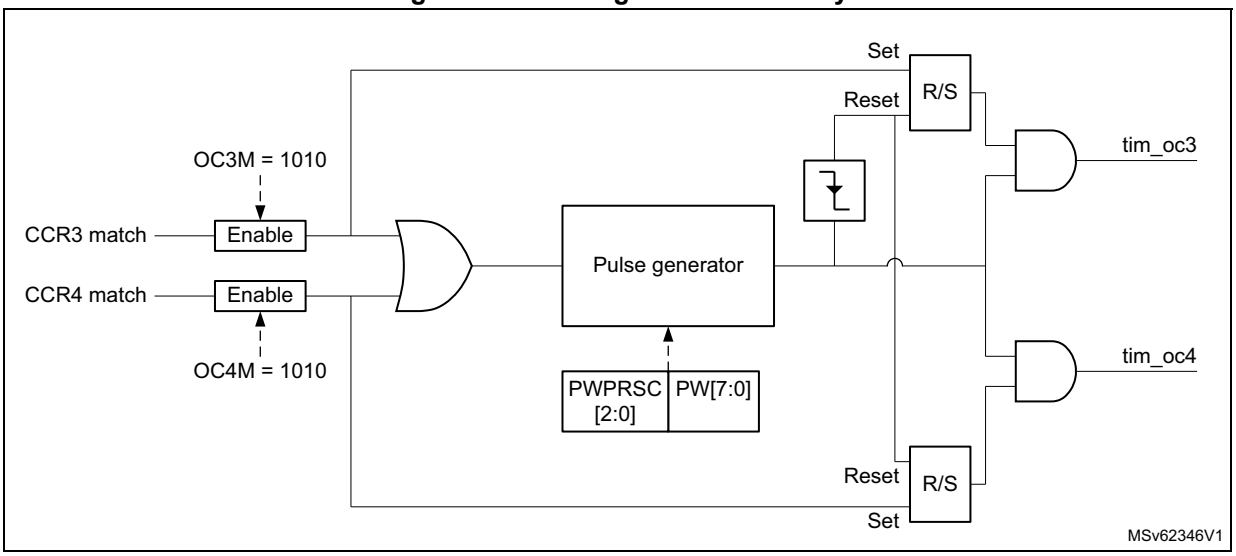
Figure 523. Retriggerable one-pulse mode

41.3.27 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulsewidth generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on *Figure 524*.

Figure 524. Pulse generator circuitry



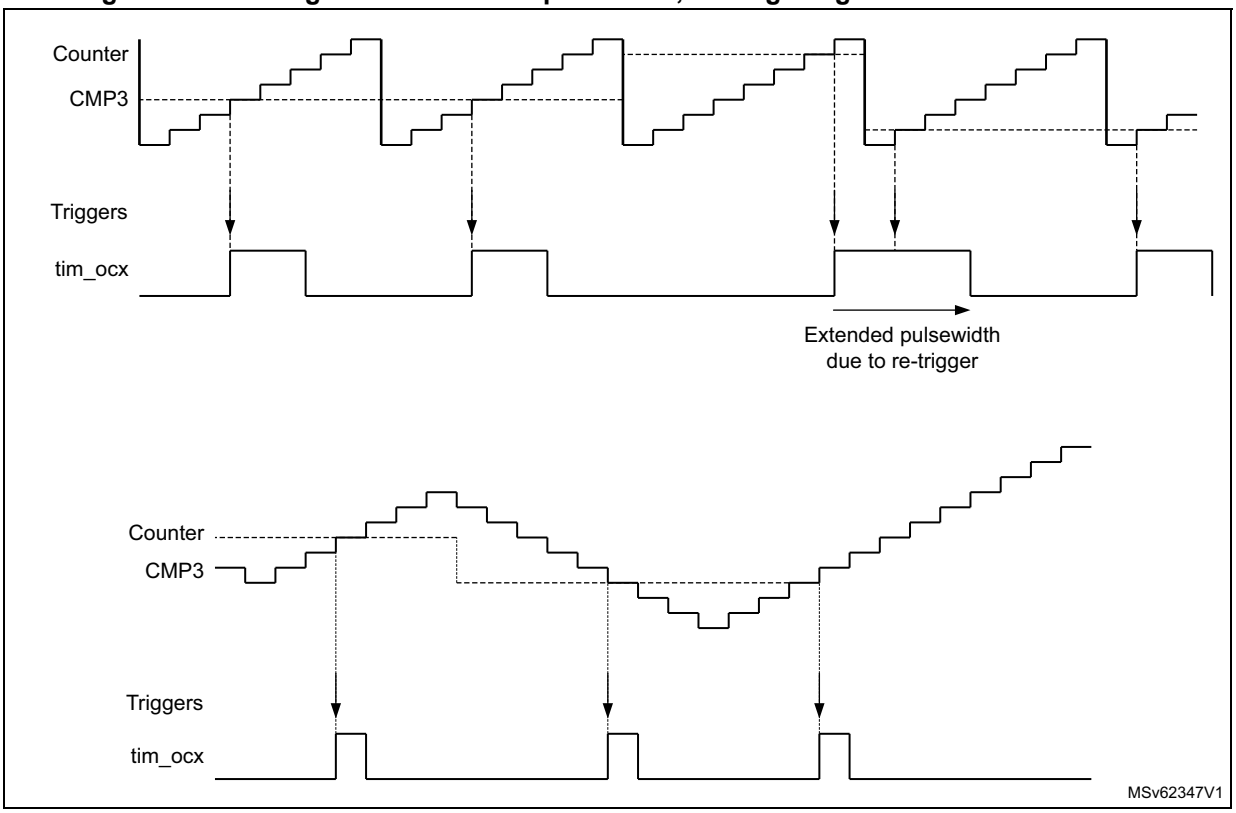


Figure 525 shows how the pulse is generated for edge-aligned and encoder operating modes.

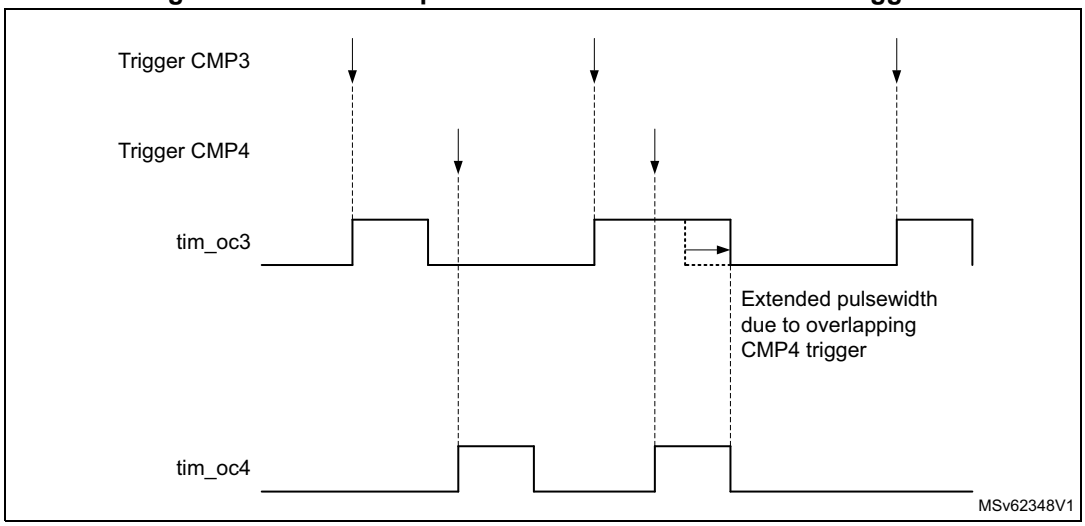
Figure 525. Pulse generation on compare event, for edge-aligned and encoder modes

This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIM_CCMR2 register.

The pulsewidth is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

t_{PW} = PW[7:0] x t_{PWG}



where $t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim_ker_ck}$

gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the first arriving trigger is extended (because of the retrigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 526).

Figure 526. Extended pulsewidth in case of concurrent triggers

41.3.28 Encoder interface mode

Quadrature encoder

To select Encoder Interface mode write SMS = 0001 in the TIM_SMCR register if the counter is counting on tim_ti1 edges only, SMS = 0010 if it is counting on tim_ti2 edges only and SMS = 0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIM_CCER register. When needed, the input filter can be programmed as well. CC1NP and CC2NP must be kept low.

The two inputs tim_ti1 and tim_ti2 are used to interface to an quadrature encoder. Refer to *Table 468*. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1 = tim_ti1 if not filtered and not inverted, tim_ti2fp2 = tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIM_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIM_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the autoreload value in the TIM_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIM_ARR must be configured before starting. In the same way, the capture, compare, prescaler, repetition counter, trigger output features continue to work as normal. Encoder mode and External clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction correspond to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.

Table 468. Counting direction versus encoder signals (CC1P = CC2P = 0)

Active edge	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
Counting on tim_ti1 only x1 mode	01110	High	Down	Up	No count	No count
		Low	No count	No count	No count	No count
Counting on tim_ti2 only x1 mode	01111	High	No count	No count	Up	Down
		Low	No count	No count	No count	No count
Counting on tim_ti1 only x2 mode	00001	High	Down	Up	No count	No count
		Low	Up	Down	No count	No count
Counting on tim_ti2 only x2 mode	00010	High	No count	No count	Up	Down
		Low	No count	No count	Down	Up
Counting on tim_ti1 and tim_ti2 x4 mode	00011	High	Down	Up	Up	Down
		Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicate the mechanical zero position, may be connected to the external trigger input and trigger a counter reset.

Figure 527 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example the configuration is the following:

- CC1S = 01 (TIM_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIM_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P = 0 and CC1NP = 0 (TIM_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1).
- CC2P = 0 and CC2NP = 0 (TIM_CCER register, tim_ti1fp2 noninverted, tim_ti1fp2= tim_ti2).
- SMS = 0011 (TIM_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIM_CR1 register, Counter enabled).

Figure 527. Example of counter operation in encoder interface mode.

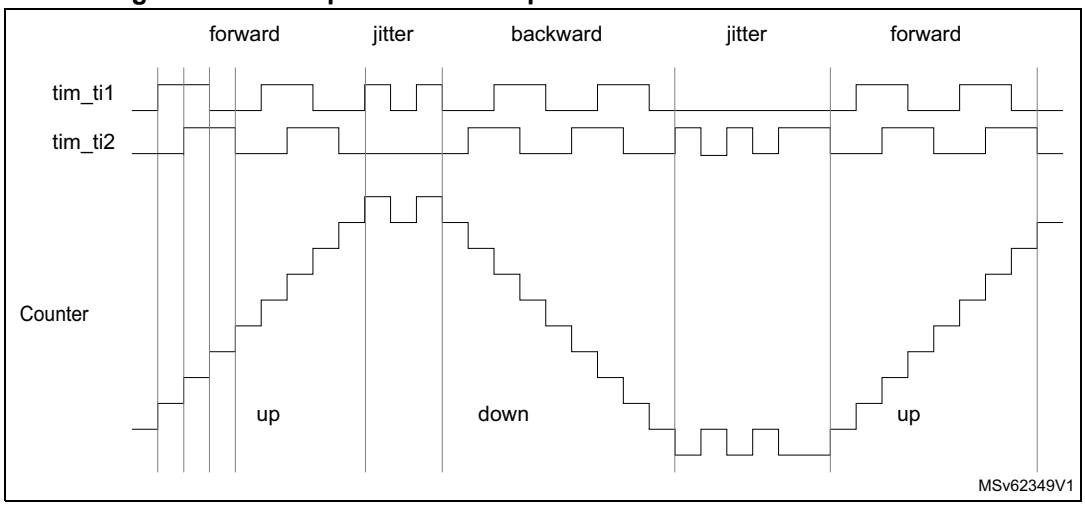


Figure 528 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P = 1).

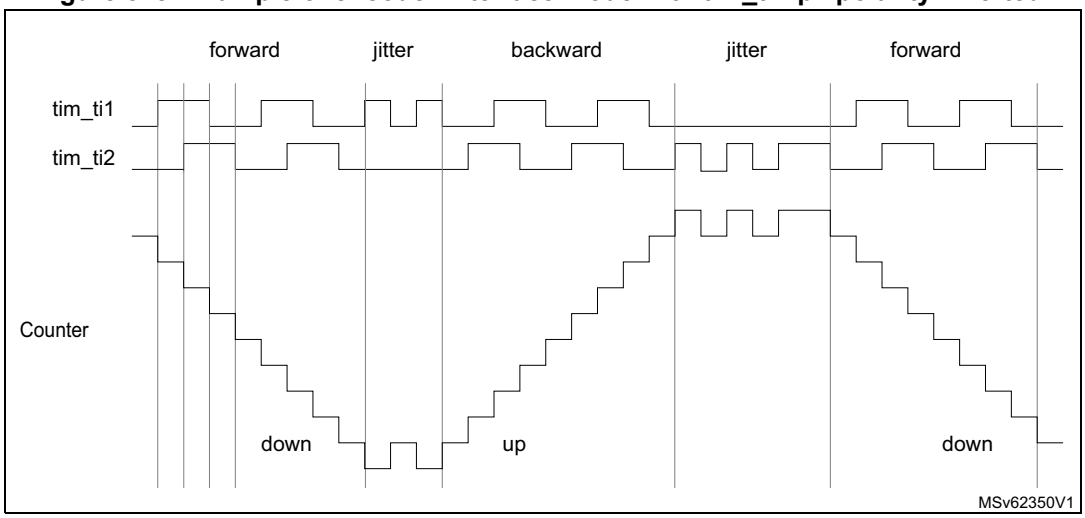
Figure 528. Example of encoder interface mode with tim_ti1fp1 polarity inverted.



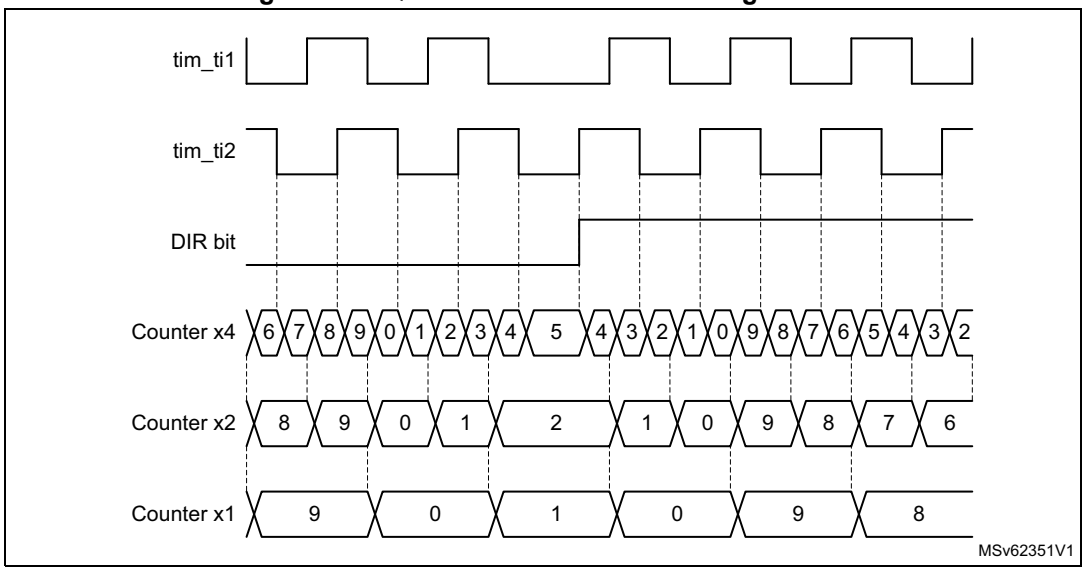


Figure 529 shows the timer counter value during a speed reversal, for various counting modes.

Figure 529. Quadrature encoder counting modes

The timer, when configured in Encoder Interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

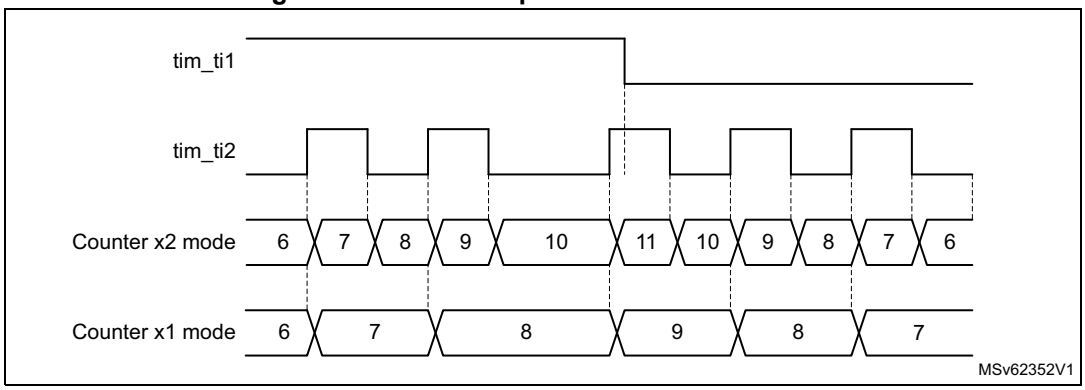
The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIM_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support for other types of encoders.



In the clock plus direction mode shown on *Figure 530*, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01010: x2 mode, the counter is updated on both rising and falling edges of the clock
- 01011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

Figure 530. Direction plus clock encoder mode

Directional clock encoder mode

In the directional clock mode on *Figure 531*, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock line. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to *Figure 531*) and CCxP = 1 corresponds to low-level idle state (refer to *Figure 532*).
- 01101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to *Figure 531*), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to *Figure 532*).

Figure 531. Directional clock encoder mode (CC1P = CC2P = 0)

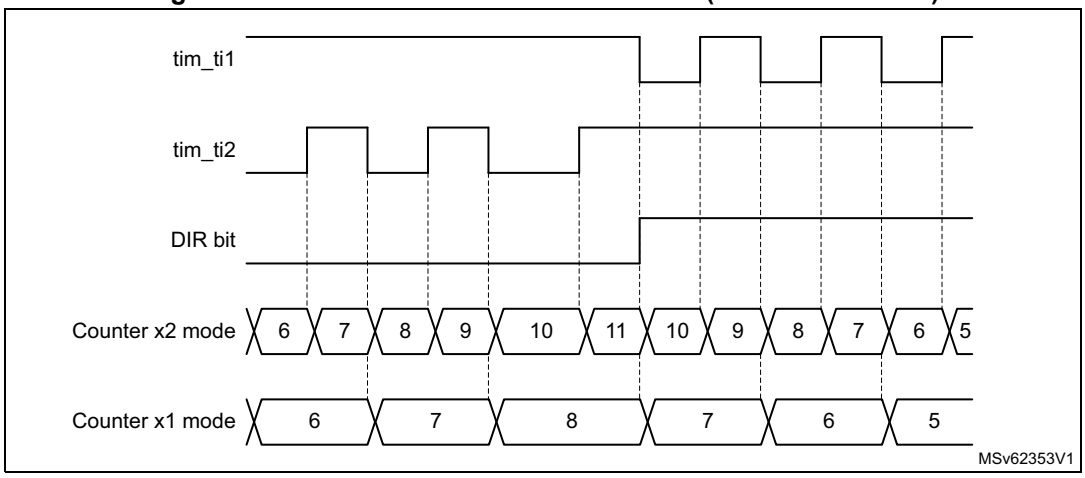


Figure 532. Directional clock encoder mode (CC1P = CC2P = 1)

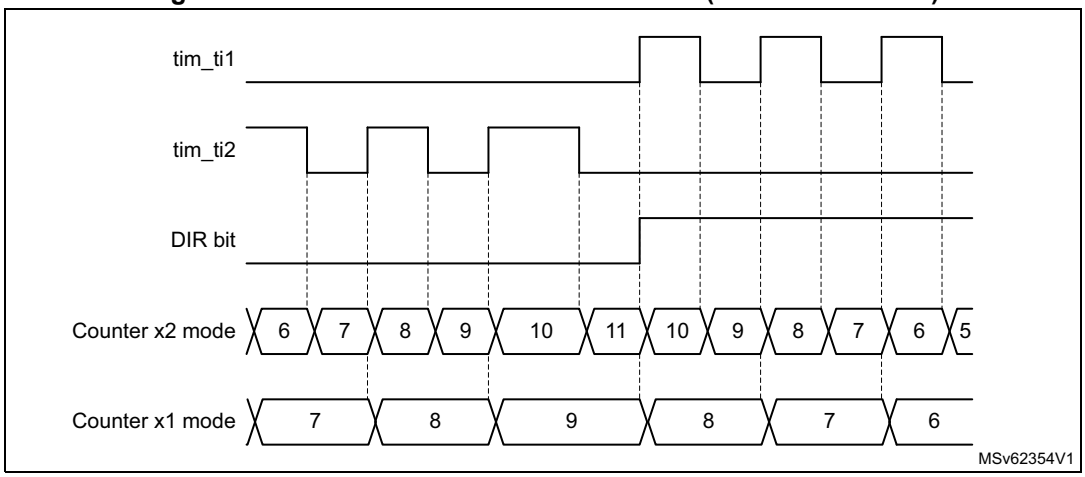

Table 469 here-below details how the directional clock mode operates, for any input transition.

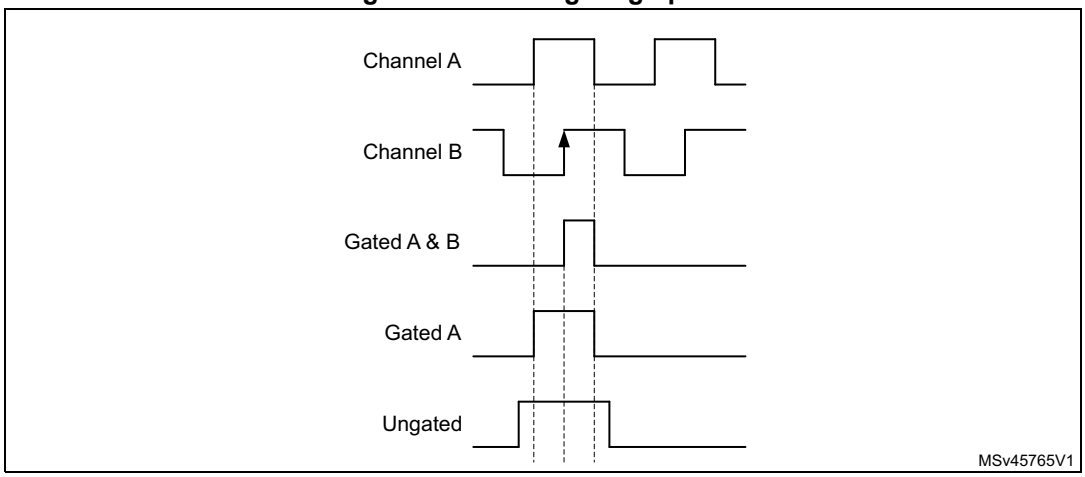
Table 469. Counting direction versus encoder signals and polarity settings

Directional clock mode	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
x2 mode CCxP = 0	01100	High	Down	Down	Up	Up
		Low	No count	No count	No count	No count
x2 mode CCxP = 1	01100	High	No count	No count	No count	No count
		Low	Down	Down	Up	Up
x1 mode CCxP = 0	01101	High	No count	Down	No count	Up
		Low	No count	No count	No count	No count
x1 mode CCxP = 1	01101	High	No count	No count	No count	No count
		Low	Down	No count	Up	No count

Index input



The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIM_ECR register. The IE bit must be set only in encoder mode, when the SMS[4:0] bitfield has the following values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111.

Available encoders are proposed with several options for index pulse conditioning, as per *Figure 533*:

- gated with A and B: the pulsewidth is 1/4 of one channel period, aligned with both A and B edges
- gated with A (or gated with B): the pulsewidth is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B)
- ungated: the pulsewidth is up to one channel period, without any alignment to the edges

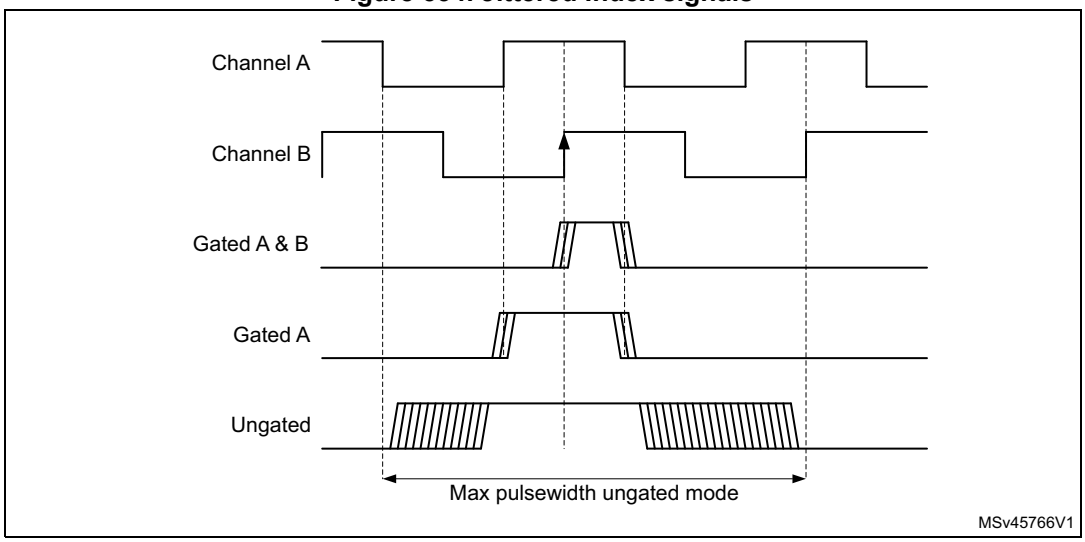


Figure 533. Index gating options

The circuitry tolerates jitter on index signal, whatever the gating mode, as show on *Figure 534*.

In ungated mode, the signal must be strictly below two encoder periods. If the pulsewidth is greater or equal to two encoder period, the counter is reset multiple times.

Figure 534. Jittered Index signals

The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and

channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIM_ECR register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIM_ARR when down counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. *Figure 535* shows at which position is the index generated, for a simplistic example (an encoder providing four edges par mechanical rotation).

Figure 535. Index generation for IPOS[1:0] = 11

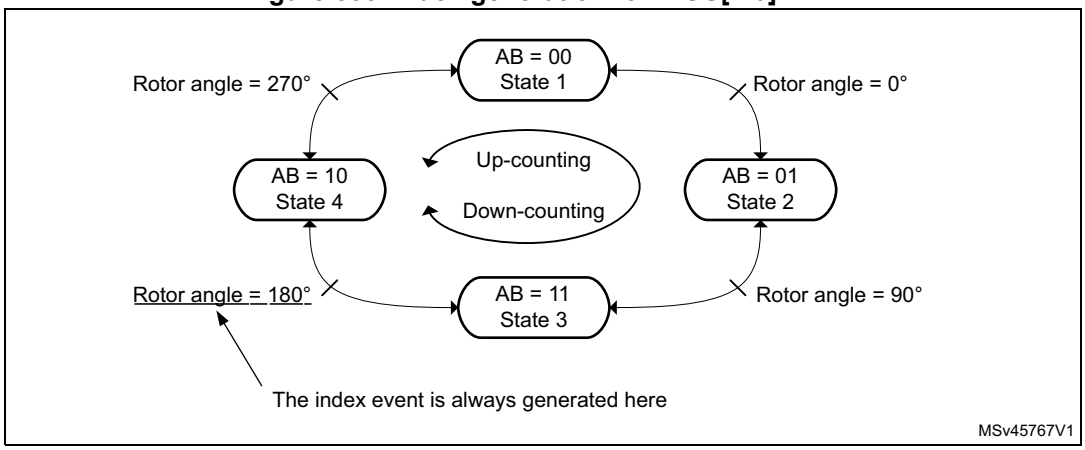

Figure 536 presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is 11 (ChA = 1, ChB = 1), when up-counting (DIR bit = 0).
- Counter set to TIM_ARR when exiting the 11 state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

Figure 536. Counter reading with index gated on channel A (IPOS[1:0] = 11)

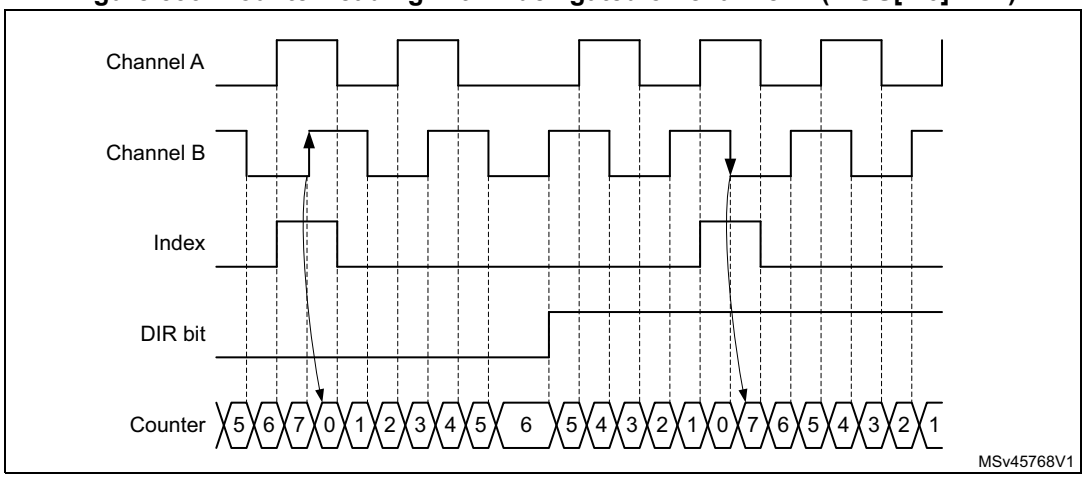

Figure 537. presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 537. Counter reading with index ungated (IPOS[1:0] = 00)

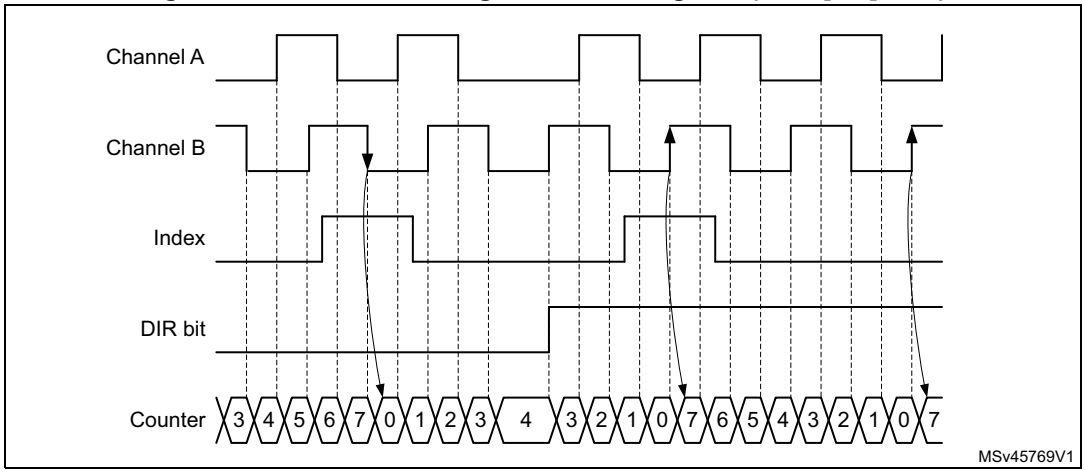

Figure 538. shows how the 'gated on A & B' mode is handled, for various pulse alignment scenario. The arrows are indicating on which transition is the index event generated.

Figure 538. Counter reading with index gated on channel A and B

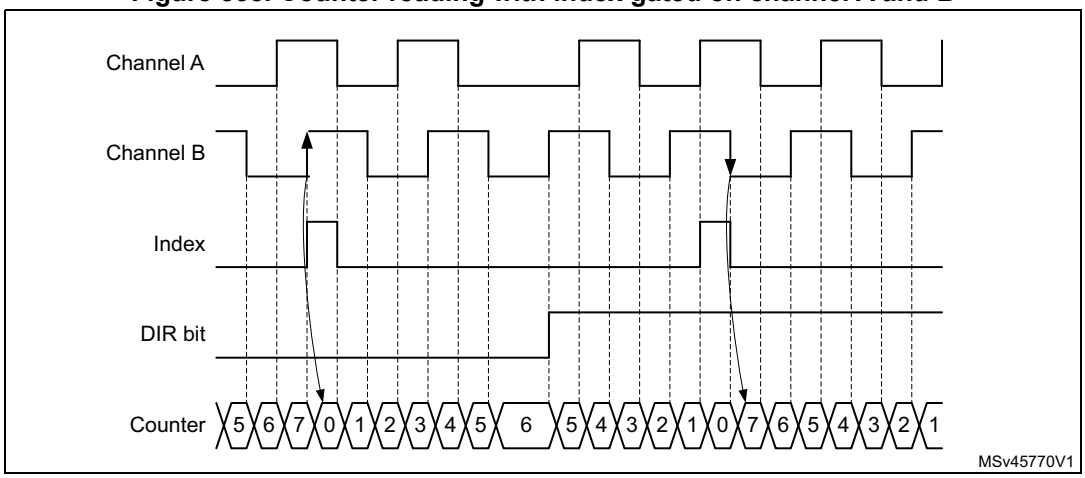

Figure 539 and *Figure 540* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 539. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

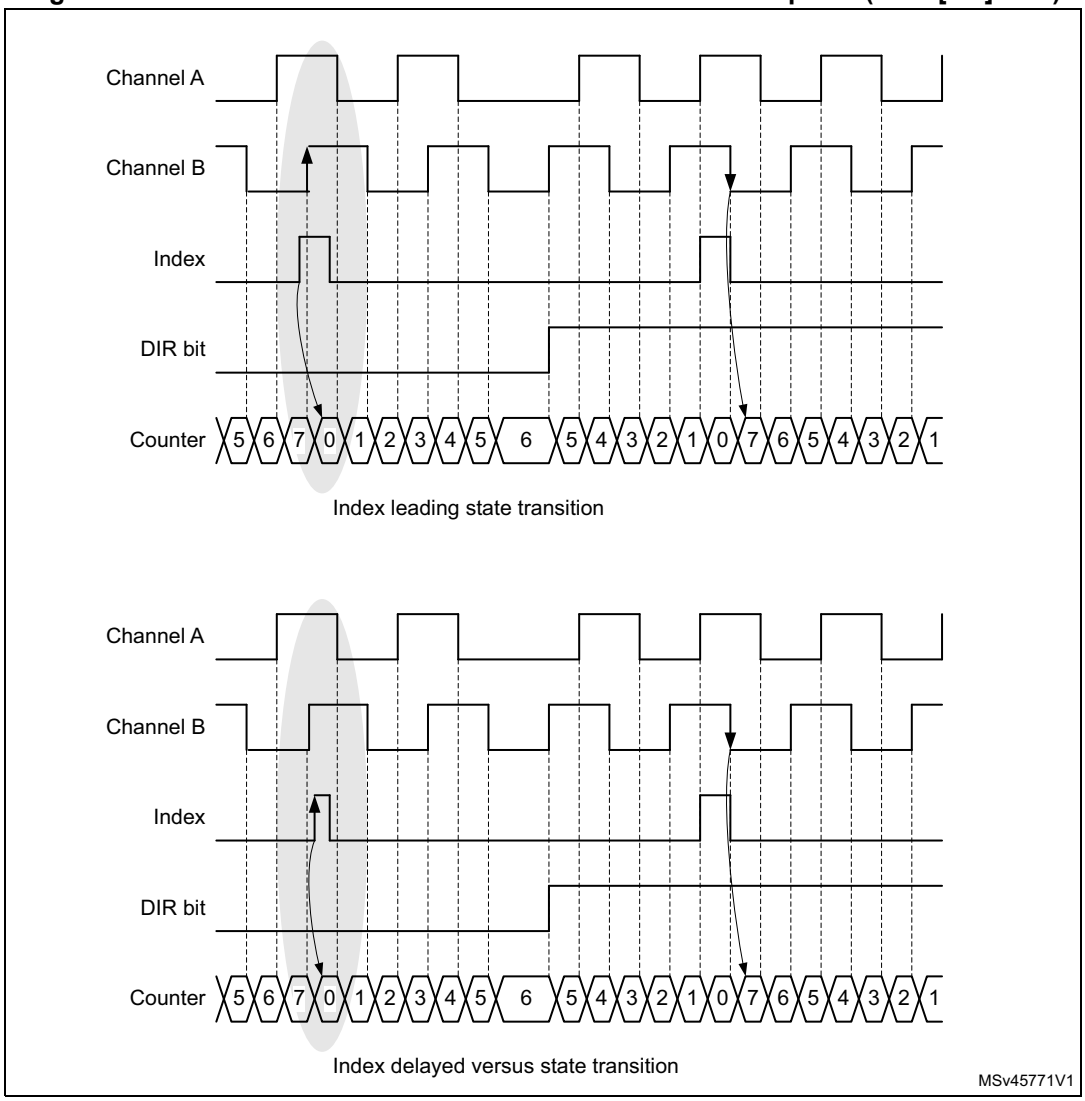

Figure 540. Counter reset Narrow index pulse (closer view, ARR = 0x07)

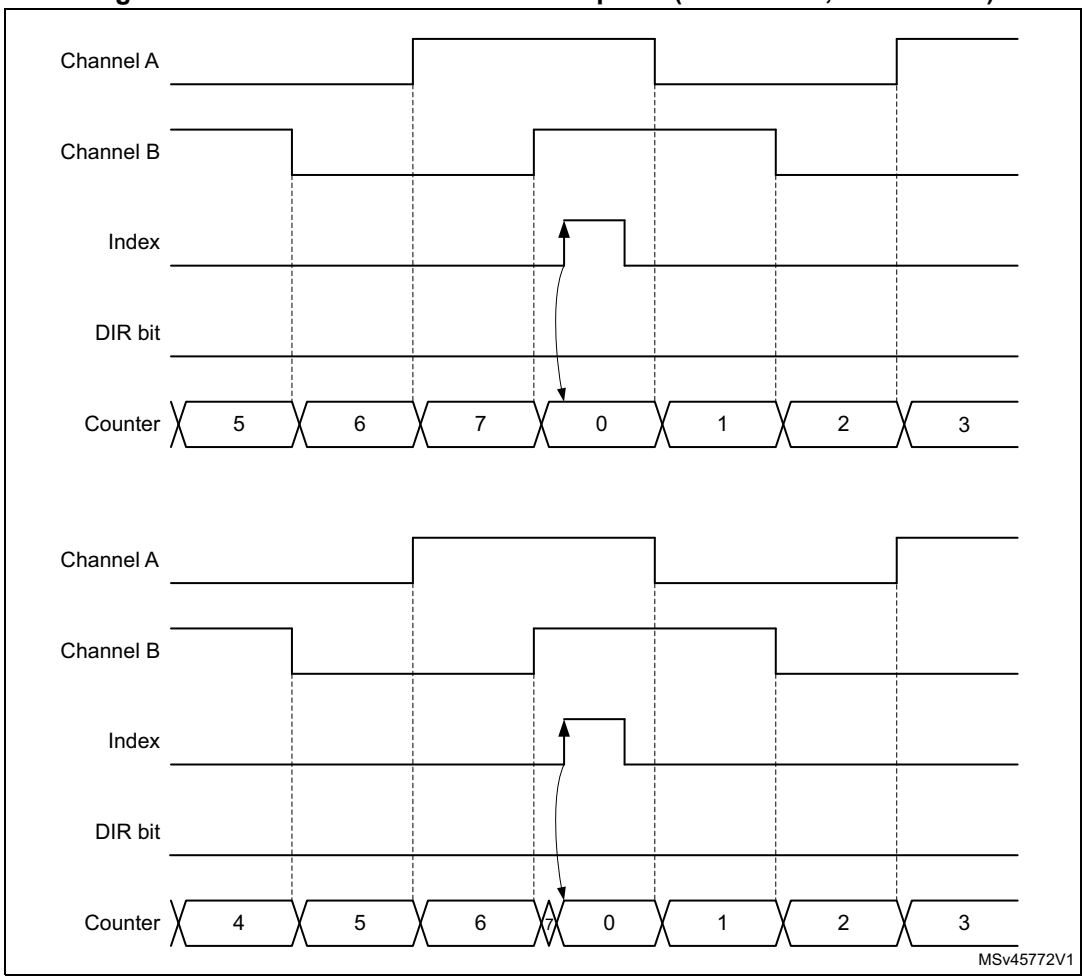

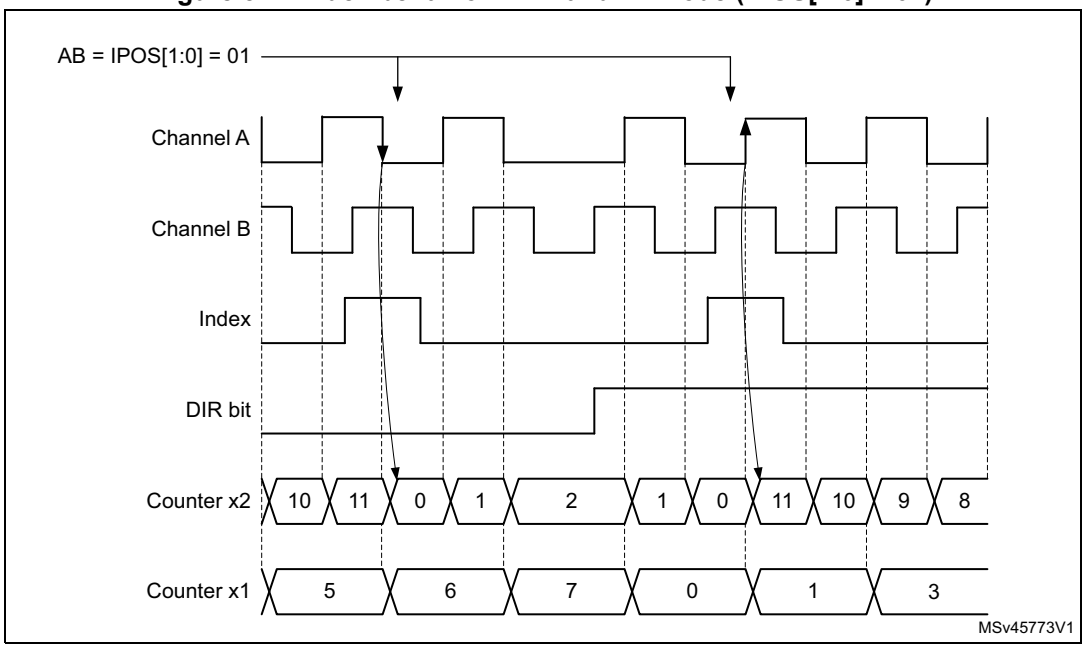

Figure 541 shows how the index is managed in x1 and x2 modes.

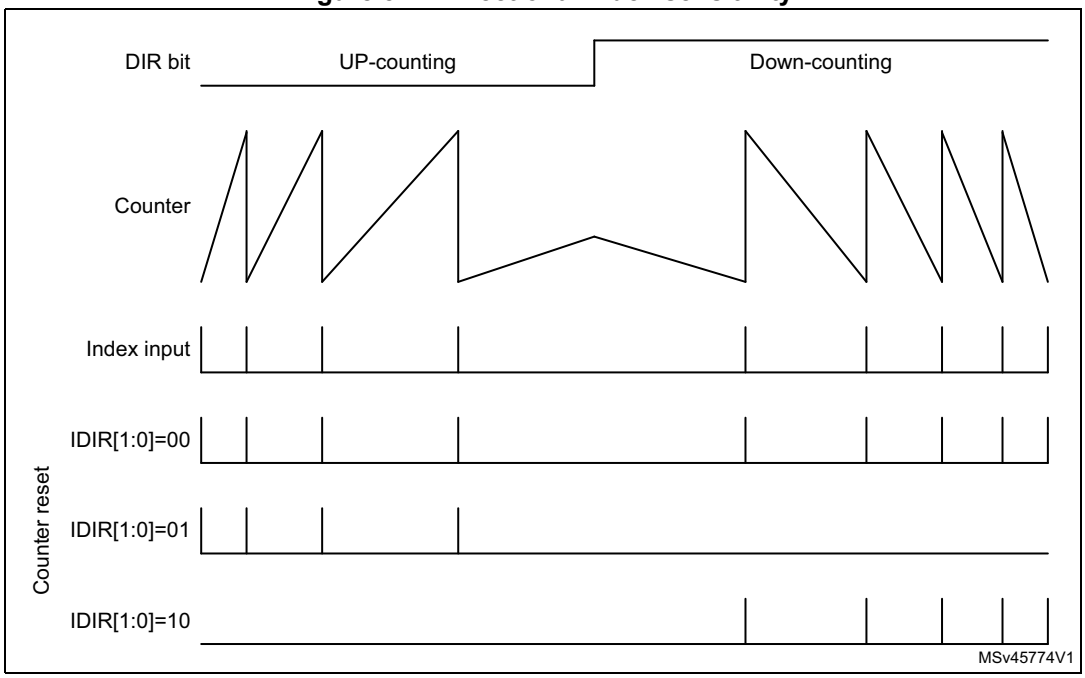
Figure 541. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)



Directional index sensitivity

The IDIR[1:0] bitfield in the TIM_ECR register allows the index to be active only in a selected counting direction.

Figure 542 shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

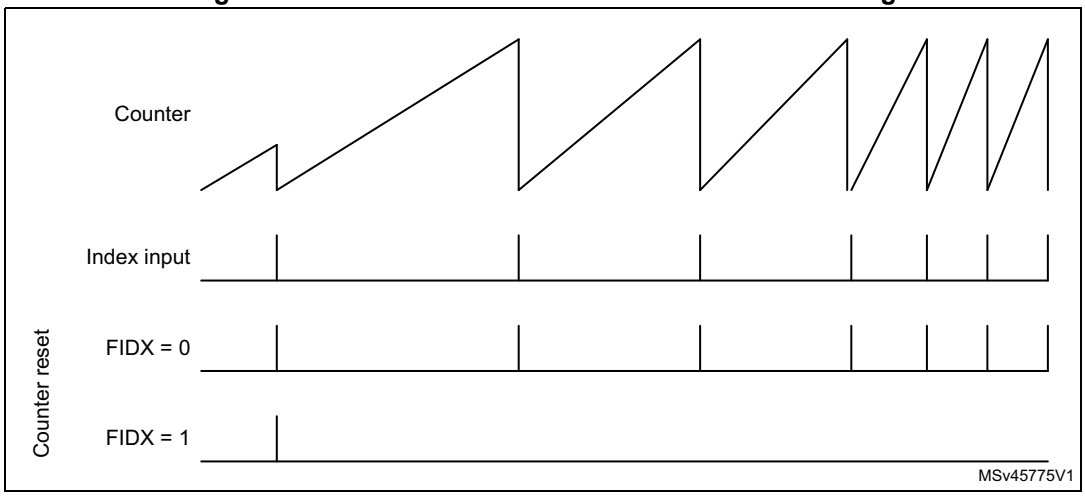


Figure 542. Directional index sensitivity

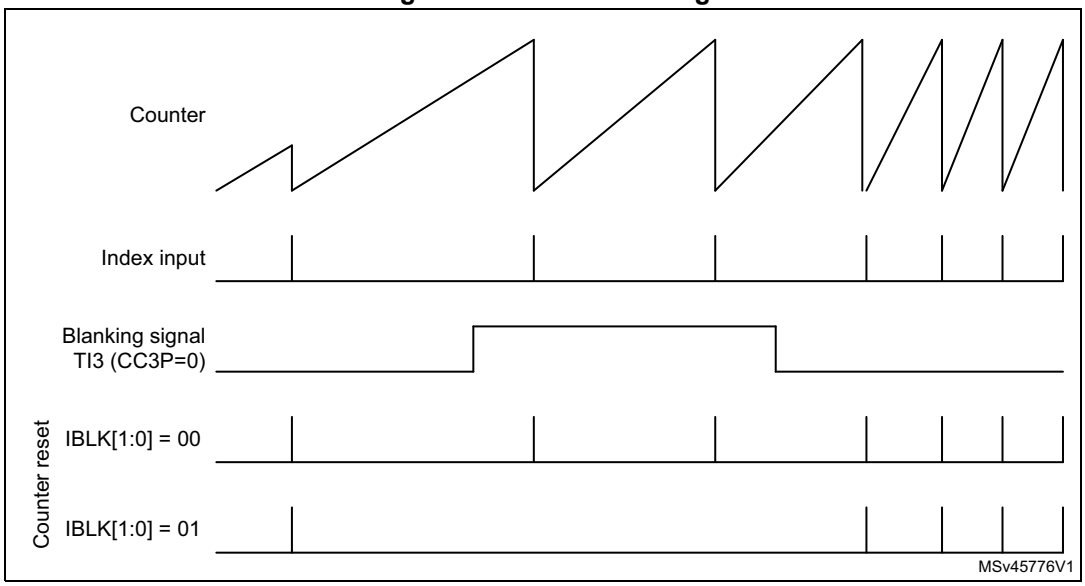
Special first index event management

The FIDX bit in the TIM_ECR register allows the index to be taken only once, as shown on *Figure 543*. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be rearmed by writing the FIDX bit to 0 and setting it again to 1.

Figure 543. Counter reset as function of FIDX bit setting



Index blanking

The index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on the *Figure 544* below.

This mode is enabled using the IBLK[1:0] bitfield in the TIM_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input

Figure 544. Index blanking

Index management in nonquadrature mode

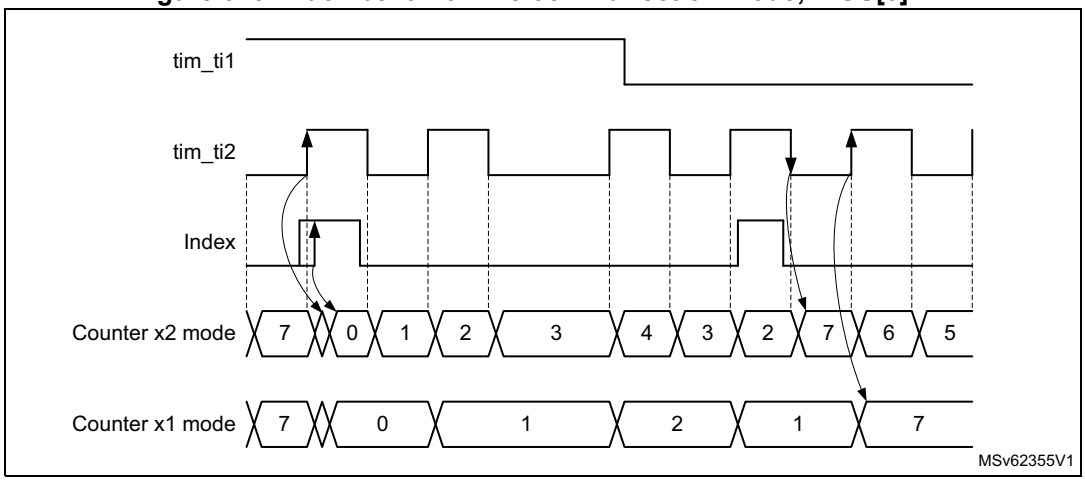
Figure 545 and *Figure 546* detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[4:0] bitfield is equal to 01010, 01011, 01100, 01101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level
- IPOS[0] = 1: Index is detected on clock high level

The IPOS[1] bit is not-significant.

Figure 545. Index behavior in clock + direction mode, IPOS[0] = 1



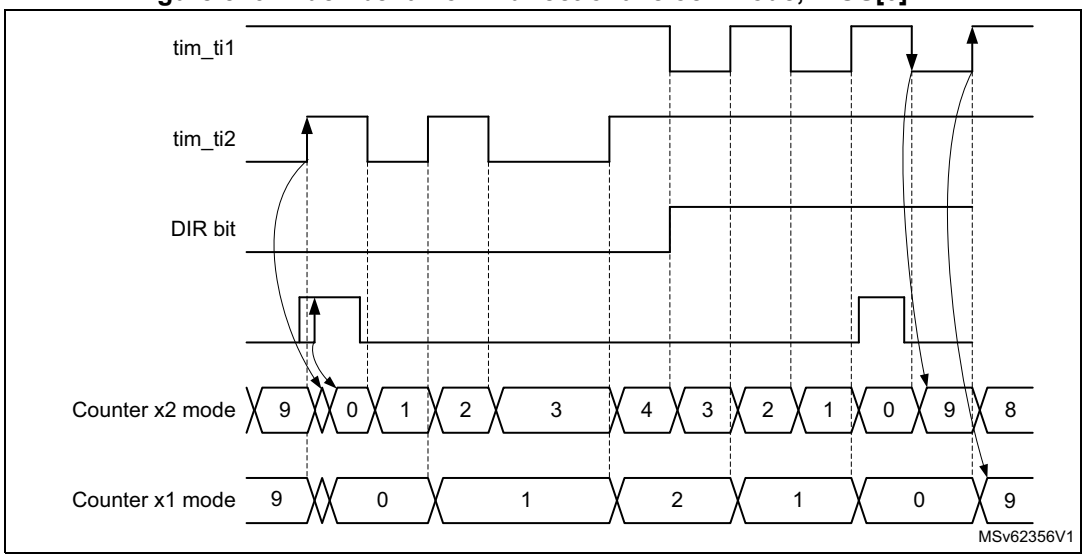


Figure 546. Index behavior in directional clock mode, IPOS[0] = 1

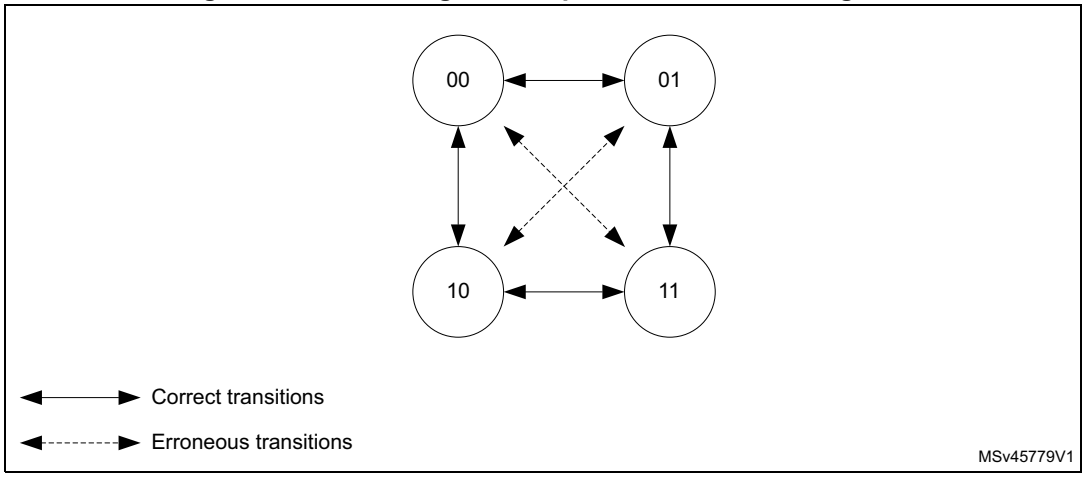
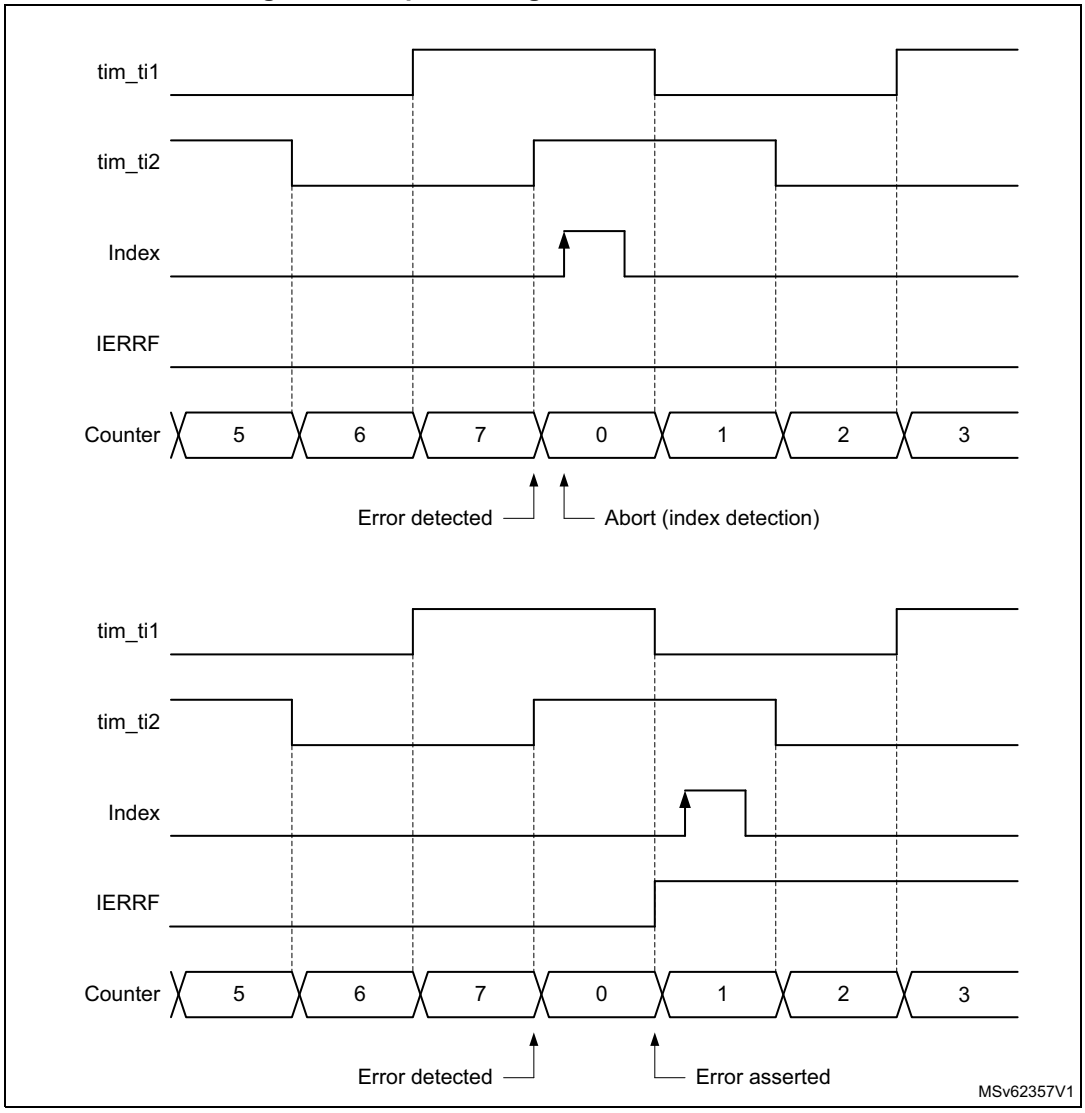


Encoder error management

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on *Figure 547.*. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIM_SR status

register. A transition error interrupt is generated if the TERRIE bit is set in the TIM_DIER register.

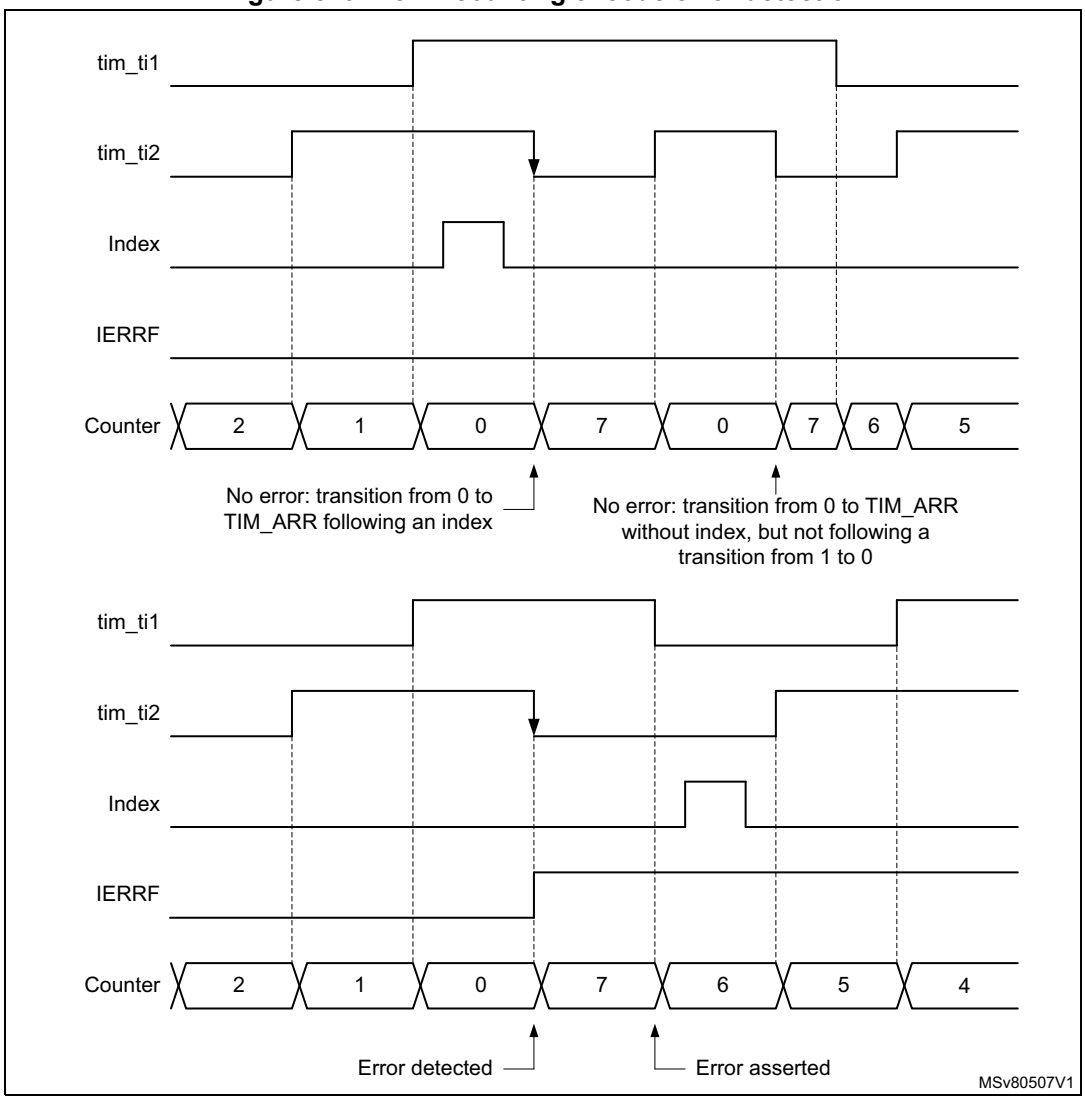
Figure 547. State diagram for quadrature encoded signals



For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIM_ARR to 0 or decremented from 0 to TIM_ARR value without any index event, this is reported as an index position error.

The overflow threshold is programmed using the TIM_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIM_ARR = 3999 + 1 = 4000.



The error assertion is delayed to the transition 0 to 1 when in up-counting. This is cope with narrow index pulses in gated A and B mode, as shown on *Figure 548*.

Figure 548. Up-counting encoder error detection

In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 549*, to avoid any false error detection in case the encoder dithers between TIM_ARR and 0 immediately after the index detection.

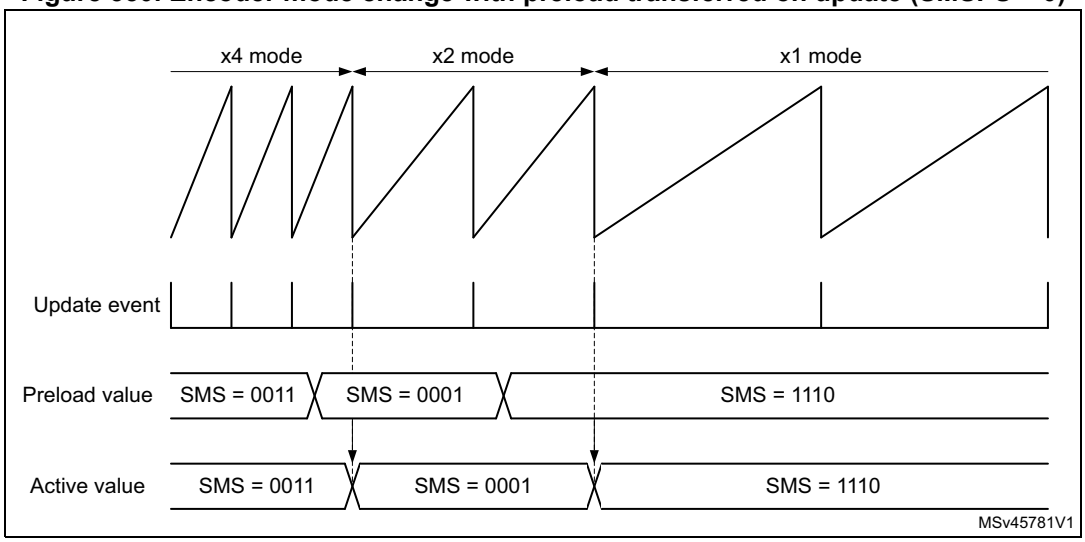
Figure 549. Down-counting encode error detection

An index error sets the IERRF interrupt flag in the TIM_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIM_DIER register.

Functional encoder interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIM_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIM_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIM_DIER register.
- Index event: the index event sets the IDXF interrupt flag in the TIM_SR status register. An index interrupt is generated if the IDXIE bit is set in the TIM_DIER register.



Slave mode selection preload for run-time encoder mode update

It may be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on *Figure 550*.

For this purpose, the SMS[4:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIM_SMCR register. The trigger for the transfer from SMS[4:0] preload to active value can be selected with the SMSPS bit in the TIM_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when upcounting, and underflows when downcounting.
- SMSPS = 1: the transfer is triggered by the index event.

Figure 550. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIM_CR2 register.It is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

41.3.29 Encoder with built-in debouncer

This mode is intended to support noisy digital potentiometers and knobs, providing quadrature encoded signals with potentially long bouncing periods after each transition.

The operating principle consists of working on the first valid transition and discard any other until a second valid transition is detected on the alternate encoder signal.

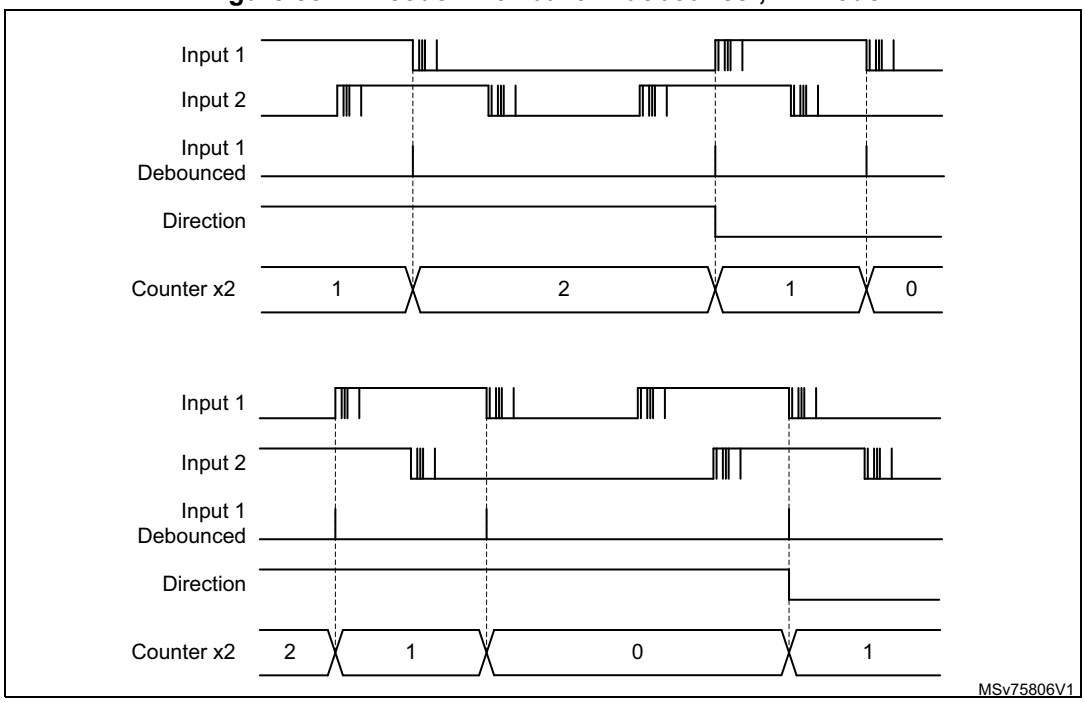
The *Figure 551* below represents the x2 operating mode. It must be noticed that a transition on input 1 is ignored during direction reversal, if there's no edge on input 2.

The *Figure 552* below represents the x4 operating mode. In this case, a transition is always ignored during a direction reversal or when the encoder dithers between 2 positions.

These 2 modes are enabled by writing SMS[4:0] = 10000 or 10001 in TIM_SMCR register.

The encoder with built-in debouncer modes are not suitable for tracking a position or an angle in motor control applications. The transitions ignored during direction reversal will lead to a position/angle error that will build-up over time.

Figure 551. Encoder with built-in debouncer, x2 mode



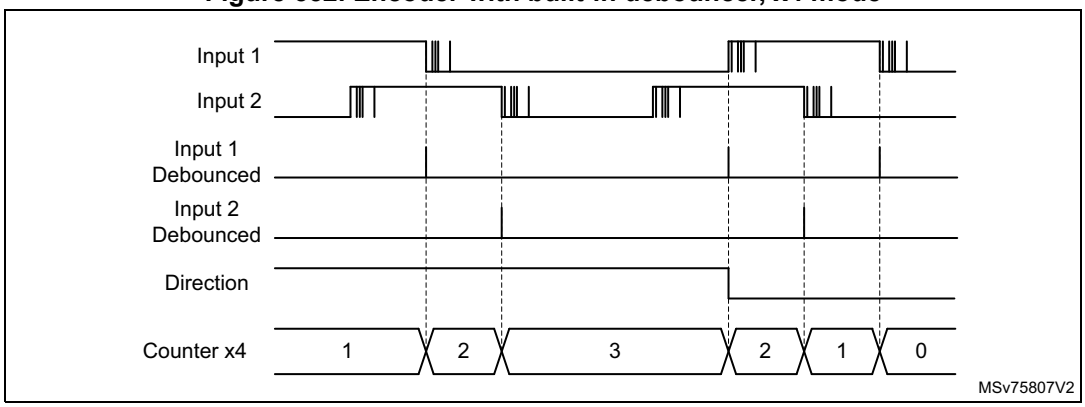


Figure 552. Encoder with built-in debouncer, x4 mode

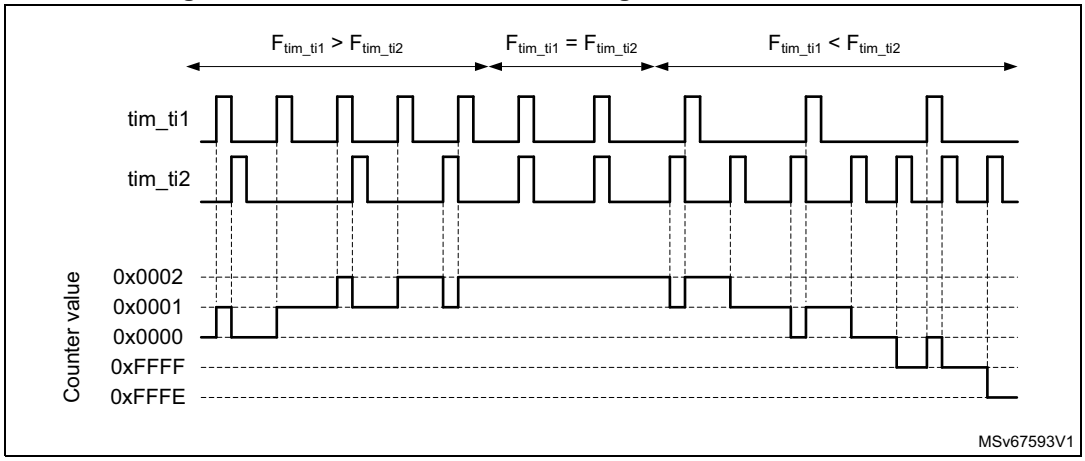
41.3.30 Direction bit output

Its is possible to output a direction signal out of the timer, on the tim_oc3n and tim_oc4 output signals (copy of the DIR bit in the TIM_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIM_CCMR2 register.

This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

41.3.31 Clock drift measurement

It is possible to measure the drift between two clock sources using the directional clock encoder mode. This is useful for audio applications typically, when one need to compute the drift between two streams.



To do so, a signal representing the rate of a first audio stream must be connected to tim_ti1 and a signal representing the rate of a second audio stream must be connected to tim_ti2. The signals representing the audio rates are generally the SAIx_FS_A, SAIx_FS_B, SPIx_WS or spdifrx_frame_sync (this list of signals is provided as example and depends on the audio peripheral availability for a given product line, as detailed on the product datasheet).

In this case, the clocks are present on both tim_ti1 and tim2 simultaneously, as shown on *Figure 553*, and the counter value indicates the drift.

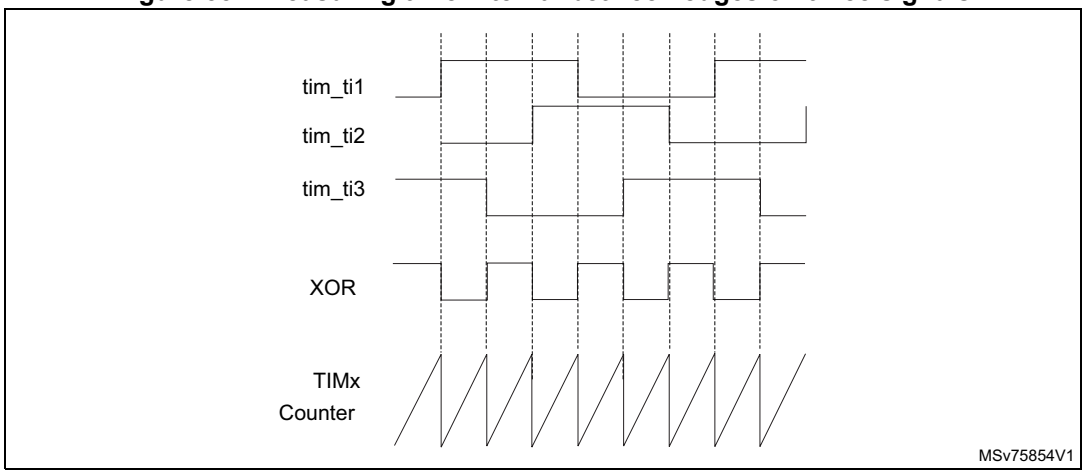
Let's define F_{tim_ti1} and F_{tim_ti2} the frequencies of the signals on tim_ti1 and tim_ti2. The counter value changes as following:

- If $F_{tim_ti1} > F_{tim_ti2}$ the counter value increases
- If $F_{tim_ti1} < F_{tim_ti2}$ the counter value decreases
- If $F_{tim_ti1} = F_{tim_ti2}$ the counter value dithers between two consecutive values, from one clock edge to the other. If the two clocks are perfectly synchronized (clock edges occuring simultaneously on the two inputs), the counter value does not change (as shown on *Figure 553* below).

Figure 553. Clock drift measure using directional clock mode

41.3.32 UIF bit remapping

The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register's bit 31 (TIM_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. In particular cases, it can ease the calculations by avoiding race conditions, caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).



There is no latency between the UIF and UIFCPY flags assertion.

41.3.33 Timer input XOR function

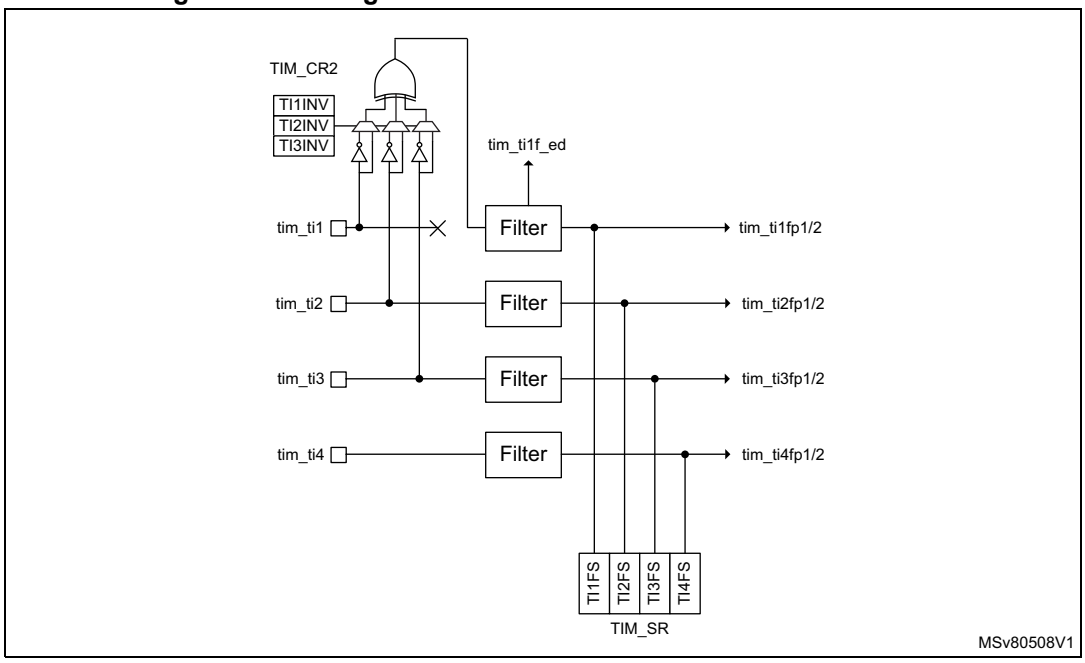
The TI1S bit in the TIM_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture. It is convenient to measure the interval between edges on two input signals, as per *Figure 554*.

Figure 554. Measuring time interval between edges on three signals

The XORPS control bit selects the position of the XOR gate, as shown on the *Figure 555* and *Figure 556* below, when the TI1S bit is set.

Figure 555. XOR gate connection with TI1S = 1 and XORPS = 0



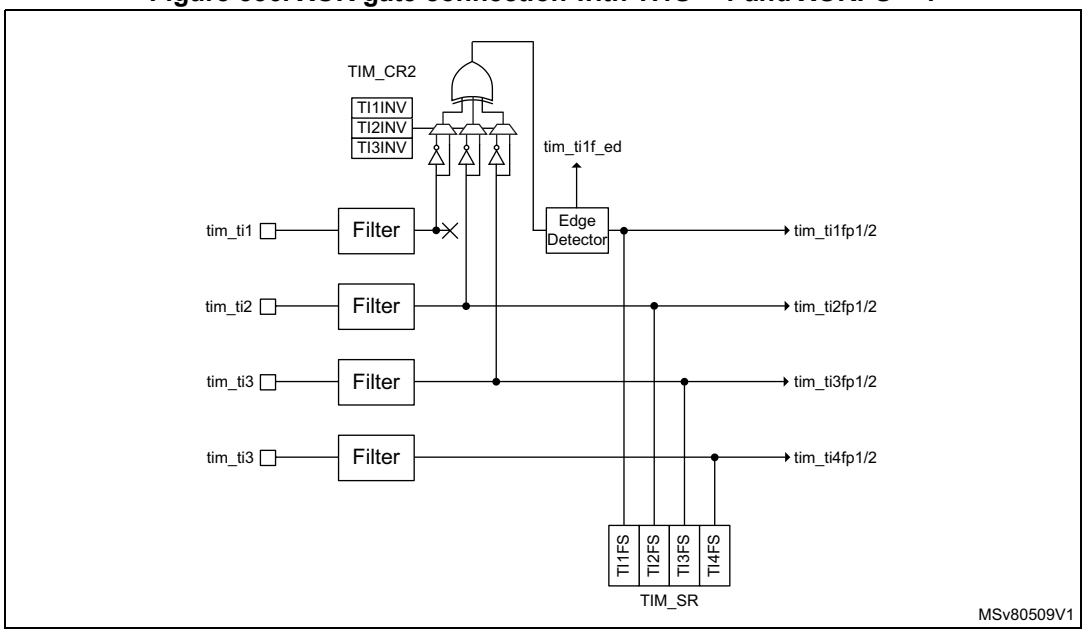


Figure 556. XOR gate connection with TI1S = 1 and XORPS = 1

Three control bits T1INV, T2INV and T3INV in the TIM_CR2 register can invert the tim_in1, tim_in2 and tim_in3 signals prior entering the XOR gate.

The status of the tim_in1, tim_in2, tim_in3 and tim_in4 signals can be software polled using the TI1FS, TI2FS, TI3FS and TI4FS bits in the TIM_SR register (tim_ti4 is not represented on figures above and do not enter into the XOR gate).

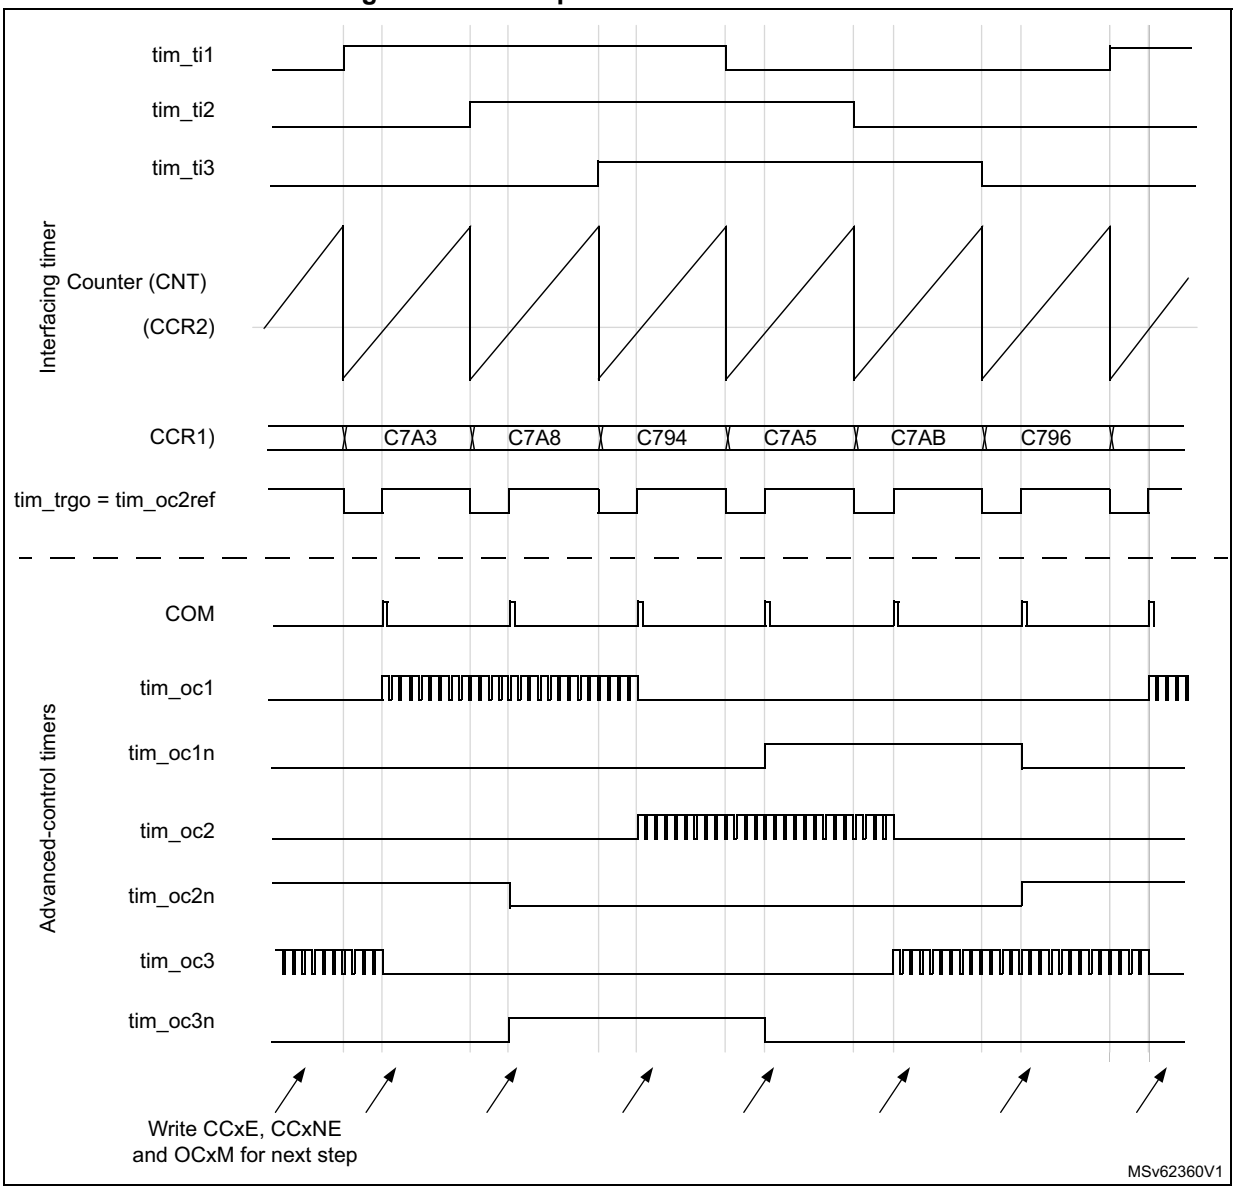
41.3.34 Interfacing with Hall sensors

This is done using the advanced-control timers to generate PWM signals to drive the motor and another timer TIMx referred to as “interfacing timer” in *Figure 557*. The “interfacing timer” captures the three timer input pins (tim_ti1, tim_ti2 and tim_ti3) connected through a XOR to the tim_ti1 input channel (selected by setting the TI1S bit in the TIM_CR2 register, with XORPS bit = 0).

The slave mode controller is configured in reset mode; the slave input is tim_ti1f_ed. Thus, each time one of the three inputs toggles, the counter restarts counting from 0. This creates a time base triggered by any change on the Hall inputs.

On the “interfacing timer”, capture/compare channel 1 is configured in capture mode, capture signal is tim_trc (See *Figure 483*). The captured value, which corresponds to the time elapsed between two changes on the inputs, gives information about motor speed.

The “interfacing timer” can be used in output mode to generate a pulse which changes the configuration of the channels of the advanced-control timer (by triggering a COM event). The advanced-control timer is used to generate PWM signals to drive the motor. To do this, the interfacing timer channel must be programmed so that a positive pulse is generated after a programmed delay (in output compare or PWM mode). This pulse is sent to the advanced-control timer through the tim_trgo output.



In this example the user wants to change the PWM configuration of the advanced-control timer after a programmed delay each time a change occurs on the Hall inputs connected to one of the TIMx timers.

- Configure three timer inputs ORed to the tim_ti1 input channel by writing the TI1S bit in the TIM_CR2 register to 1.
- Program the time base: write the TIM_ARR to the max value (the counter must be cleared by the tim_ti1 change. Set the prescaler to get a maximum counter period longer than the time between two changes on the sensors.
- Program the channel 1 in capture mode (tim_trc selected): write the CC1S bits in the TIM_CCMR1 register to 01. The digital filter can also be programmed if needed.
- Program the channel 2 in PWM 2 mode with the desired delay: write the OC2M bits to 111 and the CC2S bits to 00 in the TIM_CCMR1 register.
- Select tim_oc2ref as trigger output on tim_trgo: write the MMS bits in the TIM_CR2 register to 101.

In the advanced-control timer, the right tim_itrx input must be selected as trigger input, the timer is programmed to generate PWM signals, the capture/compare control signals are preloaded (CCPC = 1 in the TIM_CR2 register) and the COM event is controlled by the trigger input (CCUS = 1 in the TIM_CR2 register). The PWM control bits (CCxE, OCxM) are written after a COM event for the next step (this can be done in an interrupt subroutine generated by the rising edge of tim_oc2ref).

Figure 557 describes this example.

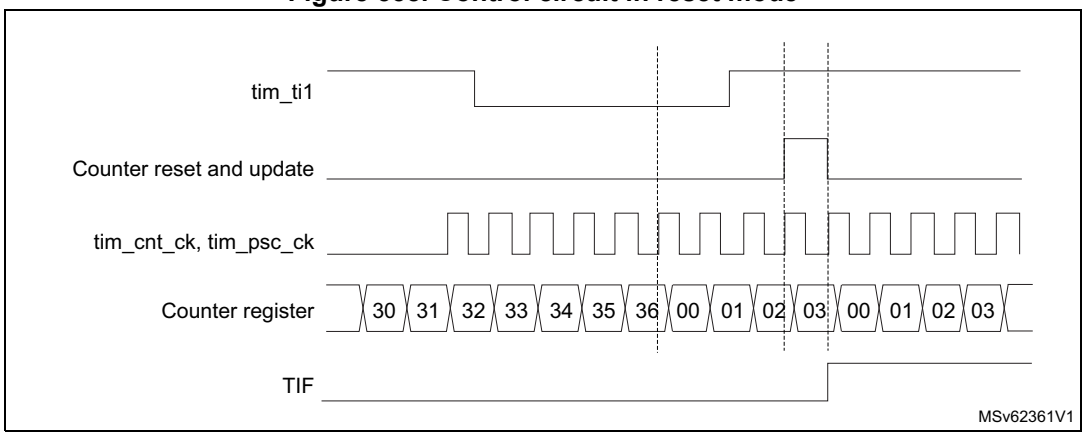
Figure 557. Example of Hall sensor interface

41.3.35 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. Refer to *Section 42.4.27: Timer synchronization* for details. They can be synchronized in several modes: Reset mode, Gated mode, Trigger mode, Reset + trigger, and gated + reset modes.

Slave mode: Reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIM_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIM_ARR, TIM_CCRx) are updated.



In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

- Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIM_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edges only).
- Configure the timer in reset mode by writing SMS = 100 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
- Start the counter by writing CEN = 1 in the TIM_CR1 register.

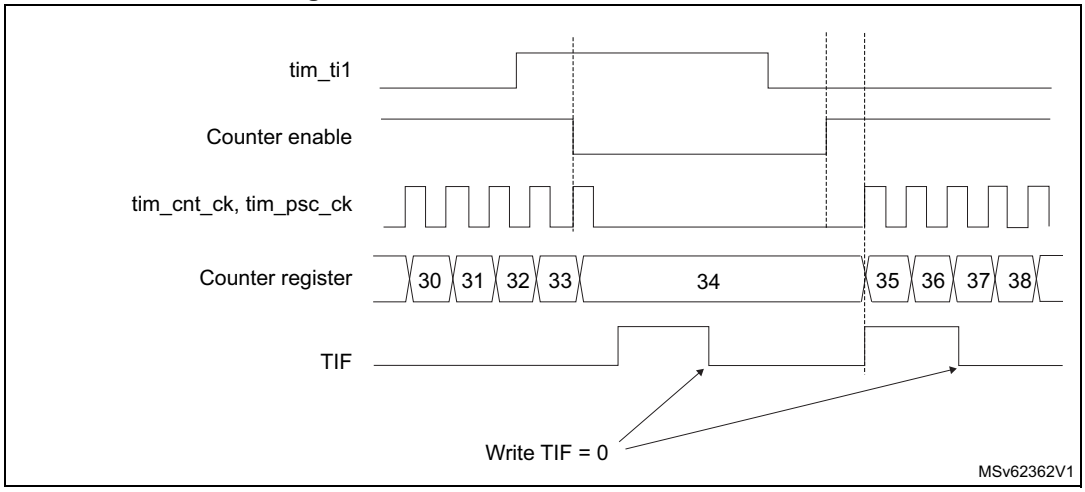
The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIM_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIM_DIER register).

The following figure shows this behavior when the autoreload register TIM_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 558. Control circuit in reset mode

Slave mode: Gated mode

The counter can be enabled depending on the level of a selected input.



In the following example, the upcounter counts only when tim_ti1 input is low:

- Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIM_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).
- Configure the timer in gated mode by writing SMS = 101 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
- Enable the counter by writing CEN = 1 in the TIM_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

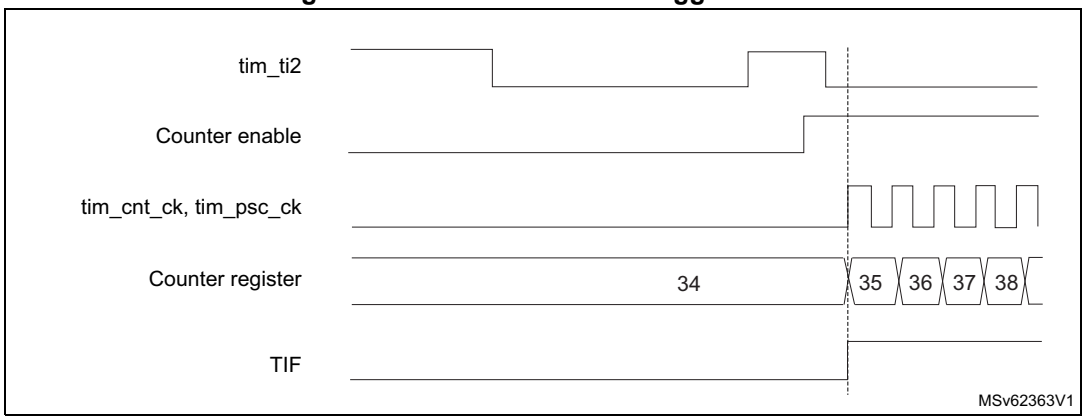
The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIM_SR register is set both when the counter starts or stops.

The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 559. Control circuit in Gated mode

Slave mode: Trigger mode

The counter can start in response to an event on a selected input.



In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

- Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC2S bits are configured to select the input capture source only, CC2S = 01 in TIM_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).
- Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti2 as the input source by writing TS = 00110 in TIM_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 560. Control circuit in trigger mode

Slave mode: Combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for One-pulse mode.

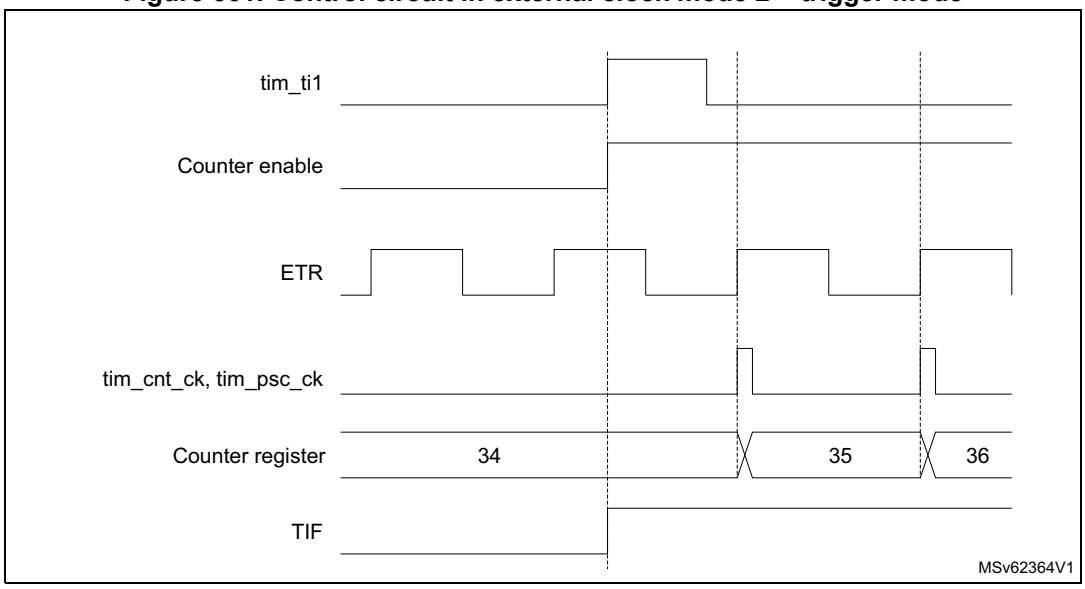
Slave mode: Combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode: external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input (in reset mode, gated mode or trigger mode). It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIM_SMCR register.



In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIM_SMCR register as follows:
   - ETF = 0000: no filter
   - ETPS = 00: prescaler disabled
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01in TIM_CCMR1 register to select only the input capture source
   - CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

Figure 561. Control circuit in external clock mode 2 + trigger mode

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

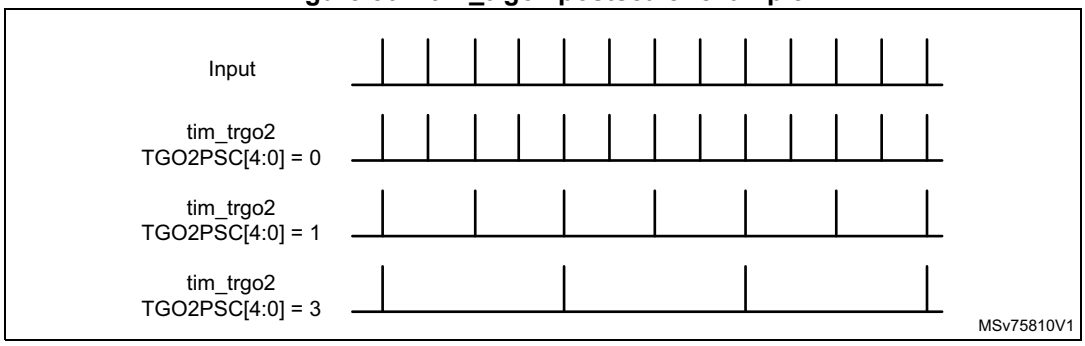
41.3.36 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events. It is also possible to generate a pulse issued by internal edge detectors, such as:

- Rising and falling edges of OC4ref
- Rising edge on OC5ref or falling edge on OC6ref

Refer to MMS2[4:0] bitfield description in TIM_CR2 for the complete list of triggering options.

The triggers are issued on the tim_trgo2 internal line which is redirected to the ADC. There is a total of 24 possible events, which can be selected using the MMS2[4:0] bits in the TIM_CR2 register.



An example of an application for 3-phase motor drives is given in *Figure 501*.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

Note: The clock of the ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the timer.

It is possible to reduce the ADC triggering rate with the tim_tro2 post scaler. This is done by periodically discarding tim_trgo2 events, as per the value programmed in TGO2PSC[4:0] bitfield in TIM_CR1, as shown on *Figure 562* below.

Figure 562. tim_trgo2 postscaler example

The post scaler is able to operate with:

– pulses as shown on *Figure 562* above, when selecting for instance MMS2[4:0] = 10001 to have a trigger on tim_oc7refc rising rising or falling edges

– the tim_ocxrefc signal itself (ie with user-defined duty cycle), when selecting for instance MMS2[4:0] = 10000 to have a trigger on tim_oc7refc

41.3.37 ADC synchronization

The timer operation can be synchronized to the ADC clock to trigger jitter-free ADC sampling. This function is enabled using the ADSYNC bit in the TIM_CR2 register.

This feature is useful when the timers and the ADCs are operating with semisynchronous clocks (clocks derived from a same source with integer ratio tim_ker_ck/adc_ker_ck), for instance adc_ker_ck = 75 MHz and tim_ker_ck = 150 MHz or 300 MHz.

ADSYNC must also be set when both peripherals are operating at the same frequency from the same clock source, when jitter-free operation is needed.

ADSYNC must not be set and jitter-free operation is not supported in the following cases:

- when the clock ratio is not an integer (for example adc_ker_ck = 75 MHz and tim_ker_ck = 100 MHz): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum
- when the ADC is operating in asynchronous mode (adc_ker_ck uncorrelated with tim_ker_ck): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.

When ADSYNC = 1, the timer operation is slightly changed: the counter enable and counter reset events are aligned to the adc_ker_ck ADC clock, to avoid any phase shift due to clocks enable in the RCC.

Jitter-free operation is guaranteed only when one of the two requirements below is met (depending on the selected trigger source).

1. The counter period must be a multiple of the ADC clock period:

$$(\text{TIM_PSC} + 1) \times (\text{TIM_ARR} + 1) \times T_{\text{tim_ker_ck}} = n \times T_{\text{adc_ker_ck}}$$

2. The compare value must be a multiple of the ADC clock period:

$$(\text{TIM_PSC} + 1) \times \text{TIM_CMPy} \times T_{\text{tim_ker_ck}} = m \times T_{\text{adc_ker_ck}}$$

Note: If none of the two above requirements are met, the trigger is still generated, but the latency is not constant and varies with the timer and ADC clocks phase shift.

Programming guidelines

The ADC synchronization feature must not be modified during run-time, once the counter is enabled and once the ADC has been configured for receiving triggers from the timer.

It is mandatory to follow the procedure below to use the ADC synchronization:

1. Enable the destination ADC clock.
2. Configure the timer and set the ADSYNC bit.
3. Configure the ADC and enable it (using ADSTART and/or JADSTART bits).
4. Start the timer (with the CEN counter enable bit).

41.3.38 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to reprogram part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIM_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIM_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIM_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address), i.e. the number of transfers (in words).

The DBA[4:0] bits in the TIM_DCR register define the DMA base address for DMA transfers (when read/write access are done through the TIM_DMAR address). DBA is defined as an offset starting from the address of the TIM_CR1 register:

Example:

00000: TIM_CR1

00001: TIM_CR2

00010: TIM_SMCR

The DBSS[3:0] bits in the TIM_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 41.6.34: TIM DMA control register (TIM_DCR)* for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (see note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bitfields as follows: DBL = 2, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5, and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3, and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

41.3.39 TIM1/TIM8/TIM20 DMA requests

The TIM1/TIM8/TIM20 can generate a DMA request, as shown in the table below.

Table 470. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_cc2_dma	Capture/compare 2	CC2DE
tim_cc3_dma	Capture/compare 3	CC3DE

Table 470. DMA request (continued)

DMA request signal	DMA request	Enable control bit
tim_cc4_dma	Capture/compare 4	CC4DE
tim_com_dma	Commutation (COM)	COMDE
tim_trgi_dma	Trigger	TDE

41.3.40 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stop, depending on DBG_TIM_STOP configuration bit in DBG module.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For safety purposes, when the counter is stopped, the outputs are disabled (as if the MOE bit was reset). The outputs can either be forced to an inactive state (OSSI bit = 1), or have their control taken over by the GPIO controller (OSSI bit = 0), typically to force a Hi-Z.

For more details, refer to section Debug support (DBG).

41.4 TIM1/TIM8/TIM20 low-power modes

Table 471. Effect of low-power modes on TIM1/TIM8/TIM20

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

41.5 TIM1/TIM8/TIM20 interrupts

The TIM1/TIM8/TIM20 can generate multiple interrupts, as shown in *Table 472*.

Table 472. Interrupt requests

Interrupt acronym		Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM_UPD		Update	UIF	UIE	write 0 in UIF	Yes	No
TIM_CC		Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
		Capture/compare 2	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
		Capture/compare 3	CC3IF	CC3IE	write 0 in CC3IF	Yes	No
		Capture/compare 4	CC4IF	CC4IE	write 0 in CC4IF	Yes	No
TIM_TRGI_COM_DIR_IDX	TIM_COM	Commutation (COM)	COMIF	COMIE	write 0 in COMIF	Yes	No
	TIM_TRGI	Trigger	TIF	TIE	write 0 in TIF	Yes	No
	TIM_IDX	Index	IDXF	IDXIE	write 0 in IDXF	Yes	No
	TIM_DIR	Direction	DIRF	DIRIE	write 0 in DIRF	Yes	No
TIM_BRK_TERR_IERR	TIM_BRK	Break	BIF	BIE	write 0 in BIF	Yes	No
		Break2	B2IF		write 0 in B2IF	Yes	No
		System Break	SBIF		write 0 in SBIF	Yes	No
	TIM_IERR	Index Error	IERRF	IERRIE	write 0 in IERRF	Yes	No
	TIM_TERR	Transition Error	TERRF	TERRIE	write 0 in TERRF	Yes	No

41.6 TIM1/TIM8/TIM20 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

41.6.1 TIM control register 1 (TIM_CR1)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CKD2[3:0]				Res.	Res.	Res.	TGO2PSC[4:0]				
				rw	rw	rw	rw				rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **CKD2[3:0]**: Clock division 2

This bit field indicates the division between sampling clock (t_{DTS}) used by the dead-time generators and the digital filters (tim_etr_in, tim_tix).

0000: No Division
0001: $t_{DTS2} = 4*t_{DTS}$
0010: $t_{DTS2} = 16*t_{DTS}$
0011: $t_{DTS2} = 64*t_{DTS}$
0100: $t_{DTS2} = 256*t_{DTS}$
0101: $t_{DTS2} = 1024*t_{DTS}$
0110: $t_{DTS2} = 4096*t_{DTS}$
0111: $t_{DTS2} = 16384*t_{DTS}$
1000: $t_{DTS2} = 65536*t_{DTS}$
1001: $t_{DTS2} = 262144*t_{DTS}$
Others: Reserved, do not program this value

Bits 23:21 Reserved, must be kept at reset value.

Bits 20:16 **TGO2PSC[4:0]**: Trigger output 2 postcaler

The postscaler discards periodically events sent on the tim_trgo2 output, to reduce the ADC triggering rate.
The number of events on tim_trgo2 is divided by (TGO2PSC[4:0] + 1).
When TGO2PSC[4:0] = 0x0, the tim_trgo2 event rate is not affected.
With TGO2PSC[4:0] = 0x1, one event out of 2 is sent on tim_trgo2, with TGO2PSC[4:0] = 0x2, one event out of 3 is sent on tim_trgo2, up to 1 event out of 31 when TGO2PSC[4:0] = 0x1F,...

Note: The postscaler is only applicable when tim_trgo2 transfers a pulse (reset, update, compare pulse). When the tim_trgo2 outputs a level-based information (compare signal or enable bit for gated mode), the postscaler must be set set to 0

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIM_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIM_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division
This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and the dead-time and sampling clock (t_{DTS})used by the dead-time generators and the digital filters (tim_etr_in, tim_tix),
00: $t_{DTS} = t_{tim_ker_ck}$
01: $t_{DTS} = 2*t_{tim_ker_ck}$
10: $t_{DTS} = 4*t_{tim_ker_ck}$
11: $t_{DTS} = 8*t_{tim_ker_ck}$

Bit 7 **ARPE**: Autoreload preload enable
0: TIM_ARR register is not buffered
1: TIM_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection
00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set both when the counter is counting up or down.
Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)

Bit 4 **DIR**: Direction
0: Counter used as upcounter
1: Counter used as downcounter
Note: This bit is read only when the timer is configured in Center-aligned mode or Encoder mode.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

41.6.2 TIM control register 2 (TIM_CR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TI3INV	TI2INV	TI1INV	ADSYNC	XORPS	Res.	MMS[3]	MMS2[4:0]					OIS7	OIS6	Res.	OIS5
rw	rw	rw	rw	rw		rw	rw	rw	rw	rw	rw	rw	rw		rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OIS4N	OIS4	OIS3N	OIS3	OIS2N	OIS2	OIS1N	OIS1	TI1S	MMS[2:0]			CCDS	CCUS	Res.	CCPC
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw		rw

Bit 31 **TI3INV**: tim_ti3 signal inversion on XOR gate input

0: tim_ti3 non-inverted

1: tim_ti3 inverted

Bit 30 **TI2INV**: tim_ti2 signal inversion on XOR gate input

0: tim_ti2 non-inverted

1: tim_ti2 inverted

Bit 29 **TI1INV**: tim_ti1 signal inversion on XOR gate input

0: tim_ti1 non-inverted

1: tim_ti1 inverted

Bit 28 **ADSYNC**: ADC synchronization

0: The timer operates independently from the ADC

1: The timer operation is synchronized with the ADC clock to provide jitter-free sampling point. This mode can be enabled only with specific ADC / timer clock relationship. Refer to *Section 41.3.37* for requirements.

The ADSYNC must not modified when the counter is enabled (CEN bit is set).

Bit 27 **XORPS**: XOR gate position selection

This bit defines the position of the XOR gate with respect to input filters.

0: XOR gate placed before TI1 filter

1: XOR gate placed after TI1, TI2 and TI3 filters

Bit 26 Reserved, must be kept at reset value.

Bits 24:20 **MMS2[4:0]**: Master mode selection 2

These bits allow the information to be sent to ADC for synchronization (tim_trgo2) to be selected. The combination is as follows:

00000:**Reset** - the UG bit from the TIM_EGR register is used as trigger output (tim_trgo2). If the reset is generated by the trigger input (slave mode controller configured in reset mode), the signal on tim_trgo2 is delayed compared to the actual reset.

00001:**Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo2). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between the CEN control bit and the trigger input when configured in Gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo2, except if the Master/Slave mode is selected (see the MSM bit description in TIM_SMCR register).

00010:**Update** - the update event is selected as trigger output (tim_trgo2). For instance, a master timer can then be used as a prescaler for a slave timer.

00011:**Compare pulse** - the trigger output sends a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or compare match occurs (tim_trgo2).

00100:**Compare** - tim_oc1refc signal is used as trigger output (tim_trgo2)

00101:**Compare** - tim_oc2refc signal is used as trigger output (tim_trgo2)

00110:**Compare** - tim_oc3refc signal is used as trigger output (tim_trgo2)

00111:**Compare** - tim_oc4refc signal is used as trigger output (tim_trgo2)

01000:**Compare** - tim_oc5refc signal is used as trigger output (tim_trgo2)

01001:**Compare** - tim_oc6refc signal is used as trigger output (tim_trgo2)

01010:**Compare Pulse** - tim_oc4refc rising or falling edges generate pulses on tim_trgo2

01011:**Compare pulse** - tim_oc6refc rising or falling edges generate pulses on tim_trgo2

01100:**Compare pulse** - tim_oc4refc or tim_oc6refc rising edges generate pulses on tim_trgo2

01101:**Compare pulse** - tim_oc4refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

01110:**Compare pulse** - tim_oc5refc or tim_oc6refc rising edges generate pulses on tim_trgo2

01111:**Compare pulse** - tim_oc5refc rising or tim_oc6refc falling edges generate pulses on tim_trgo2

10000: **Compare** - tim_oc7refc signal is used as trigger output (tim_trgo2)

10001: **Compare Pulse** - tim_oc7refc rising or falling edges generate pulses on tim_trgo2

10010: **Compare Pulse** tim_oc4refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10011: **Compare Pulse** - tim_oc4refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

10100: **Compare Pulse** -tim_oc5refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10101: **Compare Pulse** - tim_oc5refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

10110: **Compare Pulse** - tim_oc6refc or tim_oc7efc rising edges generate pulses on tim_trgo2

10111: **Compare Pulse** - tim_oc6refc rising or tim_oc7refc falling edges generate pulses on tim_trgo2

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 19 **OIS7**: Output idle state 7 (tim_oc7 output)

Refer to OIS1 bit

Bit 18 **OIS6**: Output idle state 6 (tim_oc6 output)
Refer to OIS1 bit

Bit 17 Reserved, must be kept at reset value.

Bit 16 **OIS5**: Output idle state 5 (tim_oc5 output)
Refer to OIS1 bit

Bit 15 **OIS4N**: Output idle state 4 (tim_oc4n output)
Refer to OIS1N bit

Bit 14 **OIS4**: Output idle state 4 (tim_oc4 output)
Refer to OIS1 bit

Bit 13 **OIS3N**: Output idle state 3 (tim_oc3n output)
Refer to OIS1N bit

Bit 12 **OIS3**: Output idle state 3 (tim_oc3n output)
Refer to OIS1 bit

Bit 11 **OIS2N**: Output idle state 2 (tim_oc2n output)
Refer to OIS1N bit

Bit 10 **OIS2**: Output idle state 2 (tim_oc2 output)
Refer to OIS1 bit

Bit 9 **OIS1N**: Output idle state 1 (tim_oc1n output)
0: tim_oc1n = 0 after a dead-time when MOE = 0
1: tim_oc1n = 1 after a dead-time when MOE = 0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bit 8 **OIS1**: Output idle state 1 (tim_oc1 output)
0: tim_oc1 = 0 (after a dead-time) when MOE = 0
1: tim_oc1 = 1 (after a dead-time) when MOE = 0
Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bit 7 **TI1S**: tim_ti1 selection
This bit enables the insertion of a XOR gate to combine tim_ti1_in[15:0], tim_ti2_in[15:0], and tim_ti3_in[15:0] inputs into tim_ti1.
The position of the XOR gate, with respect to input filters, is defined with the XORPS bit.
0: The tim_ti1_in[15:0] multiplexer output is connected to tim_ti1 input
1: tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input

Bits 25, 6:4 **MMS[3:0]**: Master mode selection

These bits select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIM_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter Enable signal CNT_EN is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enable. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode. When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare Pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred. (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder Clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

Other codes reserved

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bit 2 **CCUS**: Capture/compare control update selection

0: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit only

1: When capture/compare control bits are preloaded (CCPC = 1), they are updated by setting the COMG bit or when an rising edge occurs on tim_trgi

Note: This bit acts only on channels that have a complementary output.

Bit 1 Reserved, must be kept at reset value.

Bit 0 **CCPC**: Capture/compare preloaded control

0: CCxE, CCxNE, CCxP, CCxNP and OCxM bits are not preloaded

1: CCxE, CCxNE, CCxP, CCxNP and OCxM bits are preloaded, after having been written, they are updated only when a commutation event (COM) occurs (COMG bit set or rising edge detected on tim_trgi, depending on the CCUS bit).

Note: This bit acts only on channels that have a complementary output.

41.6.3 TIM slave mode control register (TIM_SMCR)

Address offset: 0x008

Reset value: 0x0000 0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:26 **SETPS[3:0]**: Synchronous external trigger prescaler

The linear synchronous prescaler divides the frequency of the tim_etrf signal, by a factor (SETPS[3:0] + 1).

Bit 25 **SMSPS**: SMS preload source

This bit selects whether the events that triggers the SMS[4:0] bitfield transfer from preload to active

0: The transfer is triggered by the Timer's Update event

1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[3:0] bitfield is preloaded

0: SMS[4:0] bitfield is not preloaded

1: SMS[4:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 21:20 **TS[4:3]**: Trigger selection - bit 4:3

Refer to TS[2:0] description - bits 6:4

Bits 19:18 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether tim_etr_in or $\overline{\text{tim_etr_in}}$ is used for trigger operations

0: tim_etr_in is non-inverted, active at high level or rising edge.

1: tim_etr_in is inverted, active at low level or falling edge.

Bit 14 **ECE**: External clock enable

This bit enables External clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111).

It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).

If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of TIMxCLK frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF
01: tim_etr_in frequency divided by 2
10: tim_etr_in frequency divided by 4
11: tim_etr_in frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bit 7 **MSM:** Master/slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 6:4 **TS[2:0]:** Trigger selection

This bitfield is combined with TS[4:3] bits.

This bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal trigger 0 (tim_itr0)
00001: Internal trigger 1 (tim_itr1)
00010: Internal trigger 2 (tim_itr2)
00011: Internal trigger 3 (tim_itr3)
00100: tim_ti1 Edge Detector (tim_ti1f_ed)
00101: Filtered Timer Input 1 (tim_ti1fp1)
00110: Filtered Timer Input 2 (tim_ti2fp2)
00111: External trigger input (tim_etrf)
01000: Internal trigger 4 (tim_itr4)
01001: Internal trigger 5 (tim_itr5)
01010: Internal trigger 6 (tim_itr6)
01011: Internal trigger 7 (tim_itr7)
01100: Internal trigger 8 (tim_itr8)
01101: Internal trigger 9 (tim_itr9)
01110: Internal trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
10100: Internal trigger 16 (tim_itr16)
10101: Internal trigger 17 (tim_itr17)
10110: Internal trigger 18 (tim_itr18)
10111: Internal trigger 19 (tim_itr19)
11000: Internal trigger 20 (tim_itr20)
11001: Internal trigger 21 (tim_itr21)
11010: Internal trigger 22 (tim_itr22)
11011: Internal trigger 23 (tim_itr23)
11100: Internal trigger 24 (tim_itr24)
11101: Internal trigger 25 (tim_itr25)
11110: Internal trigger 26 (tim_itr26)
11111: Internal trigger 27 (tim_itr27)

See *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for more details on tim_itrx meaning for each Timer.

Note: These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS:** OCREF clear selection

This bit is used to select the OCREF clear source.

0: tim_ocref_clr_int is connected to the tim_ocref_clr input
1: tim_ocref_clr_int is connected to tim_etrf

Bits 17:16, 2:0 **SMS[4:0]:** Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIM_SMCR for tim_etr_in and CCxP/CCxNP bits in TIM_CCER register for tim_ti1fp1 and tim_ti2fp2).

00000:Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.

00001:Quadrature encoder mode 1, x2 mode- Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

00010:Quadrature encoder mode 2, x2 mode - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

00011:Quadrature encoder mode 3, x4 mode - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

00100:Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

00101:Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

00110:Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

00111:External Clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

01000:Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

01001:Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

01010:Encoder mode: Clock plus direction, x2 mode.

01011:Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P

01100:Encoder mode: Directional Clock, x2 mode.

01101:Encoder mode: Directional Clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

01110:Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

01111:Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

10000:Quadrature encoder with built-in debouncer: x2 mode.

10001:Quadrature encoder with built-in debouncer: x4 mode.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on TI1F, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (timer, ADC, ...) receiving the tim_trgo or the tim_trgo2 signals must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

41.6.4 TIM DMA/interrupt enable register (TIM_DIER)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TERRIE**: Transition error interrupt enable
0: Transition error interrupt disabled
1: Transition error interrupt enabled

Bit 22 **IERRIE**: Index error interrupt enable
0: Index error interrupt disabled
1: Index error interrupt enabled

Bit 21 **DIRIE**: Direction change interrupt enable
0: Direction Change interrupt disabled
1: Direction Change interrupt enabled

Bit 20 **IDXIE**: Index interrupt enable
0: Index interrupt disabled
1: Index Change interrupt enabled

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable
0: Trigger DMA request disabled
1: Trigger DMA request enabled

Bit 13 **COMDE**: COM DMA request enable
0: COM DMA request disabled
1: COM DMA request enabled

Bit 12 **CC4DE**: Capture/compare 4 DMA request enable
0: CC4 DMA request disabled
1: CC4 DMA request enabled

Bit 11 **CC3DE**: Capture/compare 3 DMA request enable
0: CC3 DMA request disabled
1: CC3 DMA request enabled

Bit 10 **CC2DE**: Capture/compare 2 DMA request enable
0: CC2 DMA request disabled
1: CC2 DMA request enabled

Bit 9 **CC1DE**: Capture/compare 1 DMA request enable
0: CC1 DMA request disabled
1: CC1 DMA request enabled

Bit 8 **UDE**: Update DMA request enable
0: Update DMA request disabled
1: Update DMA request enabled

Bit 7 **BIE**: Break interrupt enable
0: Break interrupt disabled
1: Break interrupt enabled

Bit 6 **TIE**: Trigger interrupt enable
0: Trigger interrupt disabled
1: Trigger interrupt enabled

Bit 5 **COMIE**: COM interrupt enable
0: COM interrupt disabled
1: COM interrupt enabled

Bit 4 **CC4IE**: Capture/compare 4 interrupt enable
0: CC4 interrupt disabled
1: CC4 interrupt enabled

Bit 3 **CC3IE**: Capture/compare 3 interrupt enable
0: CC3 interrupt disabled
1: CC3 interrupt enabled

Bit 2 **CC2IE**: Capture/compare 2 interrupt enable
0: CC2 interrupt disabled
1: CC2 interrupt enabled

Bit 1 **CC1IE**: Capture/compare 1 interrupt enable
0: CC1 interrupt disabled
1: CC1 interrupt enabled

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled
1: Update interrupt enabled

41.6.5 TIM status register (TIM_SR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit 31 **TI4FS**: tim_ti4f status

This flag indicates the value of the tim_ti4f signal (after the digital filtering stage), for polling purpose.
0: tim_ti4f signal is low
1: tim_ti4f signal is high

Bit 30 **TI3FS**: tim_ti3f status

This flag indicates the value of the tim_ti3f signal (after the digital filtering stage), for polling purpose.
0: tim_ti3f signal is low
1: tim_ti3f signal is high

Bit 29 **TI2FS**: tim_ti2f status

This flag indicates the value of the tim_ti2f signal (after the digital filtering stage), for polling purpose.
0: tim_ti2f signal is low
1: tim_ti2f signal is high

Bit 28 **TI1FS**: tim_ti1f status

This flag indicates the value of the tim_ti1f signal (after the digital filtering stage), for polling purpose.
0: tim_ti1f signal is low
1: tim_ti1f signal is high

Bits 27:26 Reserved, must be kept at reset value.

Bit 25 **ODS**: Output disable status

This bit indicates the global output state when a break or break2 event occured, to discriminate the source.
0: Idle state: break was triggered (or MOE was written to 0), and OIS states are forced on tim_ocx and tim_ocxn outputs
1: Disabled state: break2 was triggered, tim_ocx and tim_ocxn outputs are inactive

Bit 24 **UIOVRF**: Update Interrupt Overrun flag

This flag is set by hardware when an update request occurs while an update interrupt is pending (update interrupt flag set). It is cleared by software by writing it to '0'.
0: No Update Interrupt Overrun
1: Update Interrupt Overrun

Bit 23 **TERRF**: Transition error interrupt flag

This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 **IERRF**: Index error interrupt flag

This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.
0: No index error has been detected.
1: An index error has been detected

Bit 21 **DIRF**: Direction change interrupt flag

This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIM_CR is changing). It is cleared by software by writing it to 0.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
0: No index event occurred.
1: An index event has occurred

Bit 19 Reserved, must be kept at reset value.

Bit 18 **CC7IF**: Compare 7 interrupt flag
Refer to CC1IF description
Note: Channel 7 can only be configured as output.

Bit 17 **CC6IF**: Compare 6 interrupt flag
Refer to CC1IF description
Note: Channel 6 can only be configured as output.

Bit 16 **CC5IF**: Compare 5 interrupt flag
Refer to CC1IF description
Note: Channel 5 can only be configured as output.

Bit 15 **B2GF**: Break 2 generation flag
This flag is set by hardware as soon as a break 2 event is forced by software, using the B2G bit. It is useful to distinguish hardware-triggered from software-triggered break events. It is cleared by software by writing it to 0.
0: No break 2 event occurred.
1: A break 2 event was forced with the B2G bit

Bit 14 **BGF**: Break generation flag
This flag is set by hardware as soon as a break event is forced by software, using the BG bit. It is useful to distinguish hardware-triggered from software-triggered break events. It is cleared by software by writing it to 0.
0: No break event occurred.
1: A break event was forced with the BG bit

Bit 13 **SBIF**: System break interrupt flag
This flag is set by hardware as soon as the system break input goes active. It can be cleared by software if the system break input is not active.
This flag must be reset to re-start PWM operation.
0: No break event occurred.
1: An active level has been detected on the system break input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 12 **CC4OF**: Capture/compare 4 overcapture flag
Refer to CC1OF description

Bit 11 **CC3OF**: Capture/compare 3 overcapture flag
Refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
Refer to CC1OF description

Bit 9 **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
0: No overcapture has been detected.
1: The counter value has been captured in TIM_CCR1 register while CC1IF flag was already set

Bit 8 **B2IF**: Break 2 interrupt flag

This flag is set by hardware as soon as the break 2 input goes active. It can be cleared by software if the break 2 input is not active.

0: No break event occurred.

1: An active level has been detected on the break 2 input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 7 **BIF**: Break interrupt flag

This flag is set by hardware as soon as the break input goes active. It can be cleared by software if the break input is not active.

0: No break event occurred.

1: An active level has been detected on the break input. An interrupt is generated if BIE = 1 in the TIM_DIER register.

Bit 6 **TIF**: Trigger interrupt flag

This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.

0: No trigger event occurred.

1: Trigger interrupt pending.

Bit 5 **COMIF**: COM interrupt flag

This flag is set by hardware on COM event (when capture/compare Control bits - CCxE, CCxNE, OCxM - have been updated). It is cleared by software.

0: No COM event occurred.

1: COM interrupt pending.

Bit 4 **CC4IF**: Capture/compare 4 interrupt flag

Refer to CC1IF description

Bit 3 **CC3IF**: Capture/compare 3 interrupt flag

Refer to CC1IF description

Bit 2 **CC2IF**: Capture/compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIM_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred
If channel CC1 is configured as output: this flag is set when the content of the counter TIM_CNT matches the content of the TIM_CCR1 register. When the content of TIM_CCR1 is greater than the content of TIM_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in downcounting mode). There are 3 possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIM_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIM_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIM_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred.
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
–At overflow or underflow regarding the repetition counter value (update if repetition counter = 0) and if the UDIS = 0 in the TIM_CR1 register.
–When CNT is reinitialized by software using the UG bit in TIM_EGR register, if URS = 0 and UDIS = 0 in the TIM_CR1 register.
–When CNT is reinitialized by a trigger event (refer to *Section 41.6.3: TIM slave mode control register (TIM_SMCR)*), if URS = 0 and UDIS = 0 in the TIM_CR1 register.

41.6.6 TIM event generation register (TIM_EGR)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	B2G	BG	TG	COMG	CC4G	CC3G	CC2G	CC1G	UG
							w	w	w	w	w	w	w	w	w

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **B2G**: Break 2 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break 2 event is generated. MOE bit is cleared and B2IF flag is set. Related interrupt can occur if enabled.

Bit 7 **BG**: Break generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A break event is generated. MOE bit is cleared and BIF flag is set. Related interrupt or DMA transfer can occur if enabled.

Bit 6 **TG**: Trigger generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: The TIF flag is set in TIM_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 **COMG**: Capture/compare control update generation

This bit can be set by software, it is automatically cleared by hardware

0: No action

1: CCxE, CCxNE and OCxM bits update (providing CCPC bit is set)

Note: This bit acts only on channels having a complementary output.

Bit 4 **CC4G**: Capture/compare 4 generation

Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation

Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation

Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation

This bit is set by software in order to generate an event, it is automatically cleared by hardware.

0: No action

1: A capture/compare event is generated on channel 1:

If channel CC1 is configured as output:

CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.

If channel CC1 is configured as input:

The current value of the counter is captured in TIM_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action

1: Reinitialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR = 0 (upcounting), else it takes the autoreload value (TIM_ARR) if DIR = 1 (downcounting).

41.6.7 TIM capture/compare mode register 1 (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode:

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter
Refer to IC1F[3:0] bit description

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler
Refer to IC1PSC[1:0] bit description

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC2 channel is configured as output
01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2
10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1
11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIM_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 Selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

41.6.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Output compare mode:

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC2CE:** Output compare 2 clear enable

0: tim_oc2ref is not affected by the tim_ocref_clr_int signal

1: tim_oc2ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC2M[4:0]**: Output compare 2 mode

Refer to OC1M[4:0] bit description

Bit 11 **OC2PE**: Output compare 2 preload enable

0: Preload register on TIM_CCR2 disabled. TIM_CCR2 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR2 enabled. Read/Write operations access the preload register. TIM_CCR2 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 10 **OC2FE**: Output compare 2 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC2 behaves normally depending on counter and CCR2 values even when the trigger is ON. The minimum delay to activate CC2 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC2 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC2 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bit 7 **OC1CE:** Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int signal

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC1M[4:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 and tim_oc1n are derived. tim_oc1ref is active high whereas tim_oc1 and tim_oc1n active level depends on CC1P and CC1NP bits.

00000:Frozen - The comparison between the output compare register TIM_CCR1 and the counter TIM_CNT has no effect on the outputs.This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the output keeps the state (active or inactive) it had before entering the frozen state.

00001:Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00010:Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00011:Toggle - tim_oc1ref toggles when TIM_CNT = TIM_CCR1.

00100:Force inactive level - tim_oc1ref is forced low.

00101:Force active level - tim_oc1ref is forced high.

00110:PWM mode 1 - In upcounting, channel 1 is active as long as TIM_CNT<TIM_CCR1 else inactive. In downcounting, channel 1 is inactive (tim_oc1ref = 0) as long as TIM_CNT>TIM_CCR1 else active (tim_oc1ref = 1).

00111:PWM mode 2 - In upcounting, channel 1 is inactive as long as TIM_CNT<TIM_CCR1 else active. In downcounting, channel 1 is active as long as TIM_CNT>TIM_CCR1 else inactive.

01000:Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001:Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01100-01101:Combined PWM mode 1 and 2. Refer to *Table 465* for details.

01110-01111:Asymmetric PWM mode 1 and 2. Refer to *Table 464* for details.

10000-10001:Combined PWM mode 3 and 4. Refer to *Table 465* for details.

10010-11001: Asymmetric PWM mode 3 to 10. Refer to *Table 464* for details.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Note: On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIM_CR2 register then the OC1M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIM_CCR1 disabled. TIM_CCR1 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR1 enabled. Read/Write operations access the preload register. TIM_CCR1 preload value is loaded in the active register at each update event.

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

41.6.9 TIM capture/compare mode register 2 (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter
Refer to IC3F[3:0] bit description

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler
Refer to IC3PSC[1:0] bit description

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIM_CCER).

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter
This bitfield defines the frequency used to sample tim_ti3 input and the length of the digital filter applied to tim_ti3. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:
0000: No filter, sampling is done at f_{DTS2}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS2}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS2}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS2}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS2}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS2}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS2}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS2}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS2}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS2}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS2}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS2}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS2}/32$, N = 8

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler
This bitfield defines the ratio of the prescaler acting on CC3 input (tim_ic3). The prescaler is reset as soon as CC3E = 0 (TIM_CCER register).
00: no prescaler, capture is done each time an edge is detected on the capture input
01: capture is done once every 2 events
10: capture is done once every 4 events
11: capture is done once every 8 events

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIM_CCER).

41.6.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 3 in input capture mode and channel 4 in output compare mode).

Output compare mode

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable

0: tim_oc4ref is not affected by the tim_ocref_clr_int signal

1: tim_oc4ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC4M[4:0]**: Output compare 4 mode

Refer to OC3M[4:0] bit description

Bit 11 **OC4PE**: Output compare 4 preload enable

0: Preload register on TIM_CCR4 disabled. TIM_CCR4 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR4 enabled. Read/Write operations access the preload register. TIM_CCR4 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 10 **OC4FE**: Output compare 4 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC4 behaves normally depending on counter and CCR4 values even when the trigger is ON. The minimum delay to activate CC4 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC4 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC4 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC4 channel is configured as output

01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4

10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3

11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIM_CCER).

Bit 7 **OC3CE:** Output compare 3 clear enable

0: tim_oc3ref is not affected by the tim_ocref_clr_int signal

1: tim_oc3ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC3M[4:0]**: Output compare 3 mode

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

00000:Frozen - The comparison between the output compare register TIM_CCR3 and the counter TIM_CNT has no effect on the outputs.(this mode is used to generate a timing base).

00001:Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIM_CNT matches the capture/compare register 3 (TIM_CCR3).

00010:Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIM_CNT matches the capture/compare register 3 (TIM_CCR3).

00011:Toggle - tim_oc3ref toggles when TIM_CNT = TIM_CCR3.

00100:Force inactive level - tim_oc3ref is forced low.

00101:Force active level - tim_oc3ref is forced high.

00110:PWM mode 1 - In upcounting, channel 3 is active as long as TIM_CNT<TIM_CCR3 else inactive. In downcounting, channel 3 is inactive (tim_oc3ref = 0) as long as TIM_CNT>TIM_CCR3 else active (tim_oc3ref = 1).

00111:PWM mode 2 - In upcounting, channel 3 is inactive as long as TIM_CNT<TIM_CCR3 else active. In downcounting, channel 3 is active as long as TIM_CNT>TIM_CCR3 else inactive.

01000:Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001:Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01010:Pulse on compare: a pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIM_ECR.

01011:Direction output. The tim_oc3ref signal is overridden by a copy of the DIR bit.

01100-01101:Combined PWM mode 1 and 2. Refer to *Table 465* for details.

01110-01111:Asymmetric PWM mode 1 and 2. Refer to *Table 464* for details.

10000-10001:Combined PWM mode 3 and 4. Refer to *Table 465* for details.

10010-11001: Asymmetric PWM mode 3 to 10. Refer to *Table 464* for details.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Note: On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIM_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC3PE**: Output compare 3 preload enable

0: Preload register on TIM_CCR3 disabled. TIM_CCR3 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR3 enabled. Read/Write operations access the preload register. TIM_CCR3 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 2 **OC3FE**: Output compare 3 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC3 behaves normally depending on counter and CCR3 values even when the trigger is ON. The minimum delay to activate CC3 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC3 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC3 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC3 channel is configured as output

01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3

10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4

11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIM_CCER).

41.6.11 TIM capture/compare enable register (TIM_CCER)

Bits 31:26 Reserved, must be kept at reset value.

Bit 25 **CC7P**: Capture/compare 7 output polarity
Refer to CC1P description

Bit 24 **CC7E**: Capture/compare 7 output enable
Refer to CC1E description

Bits 23:22 Reserved, must be kept at reset value.

Bit 21 **CC6P**: Capture/compare 6 output polarity
Refer to CC1P description

Bit 20 **CC6E**: Capture/compare 6 output enable
Refer to CC1E description

Bits 19:18 Reserved, must be kept at reset value.

Bit 17 **CC5P**: Capture/compare 5 output polarity
Refer to CC1P description

Bit 16 **CC5E**: Capture/compare 5 output enable
Refer to CC1E description

Bit 15 **CC4NP**: Capture/compare 4 complementary output polarity
Refer to CC1NP description

Bit 14 **CC4NE**: Capture/compare 4 complementary output enable
Refer to CC1NE description

Bit 13 **CC4P**: Capture/compare 4 output polarity
Refer to CC1P description

Bit 12 **CC4E**: Capture/compare 4 output enable
Refer to CC1E description

Bit 11 **CC3NP**: Capture/compare 3 complementary output polarity
Refer to CC1NP description

Bit 10 **CC3NE**: Capture/compare 3 complementary output enable
Refer to CC1NE description

Bit 9 **CC3P**: Capture/compare 3 output polarity
Refer to CC1P description

Bit 8 **CC3E**: Capture/compare 3 output enable
Refer to CC1E description

Bit 7 **CC2NP**: Capture/compare 2 complementary output polarity
Refer to CC1NP description

Bit 6 **CC2NE**: Capture/compare 2 complementary output enable
Refer to CC1NE description

Bit 5 **CC2P**: Capture/compare 2 output polarity
Refer to CC1P description

Bit 4 **CC2E**: Capture/compare 2 output enable
Refer to CC1E description

Bit 3 **CC1NP**: Capture/compare 1 complementary output polarity
CC1 channel configured as output:
0: tim_oc1n active high.
1: tim_oc1n active low.
CC1 channel configured as input:
This bit is used in conjunction with CC1P to define the polarity of tim_ti1fp1 and tim_ti2fp1.
Refer to CC1P description.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (channel configured as output).

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM_CR2 register then the CC1NP active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Note: In input mode, this bit is preloaded as per CCPC bit in TIM_CR2.

Bit 2 **CC1NE**: Capture/compare 1 complementary output enable

0: Off - tim_oc1n is not active. tim_oc1n level is then function of MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

1: On - tim_oc1n signal is output on the corresponding output pin depending on MOE, OSSI, OSSR, OIS1, OIS1N and CC1E bits.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM_CR2 register then the CC1NE active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Bit 1 **CC1P**: Capture/compare 1 output polarity

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP = 0, CC1P = 0:non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP = 0, CC1P = 1:inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP = 1, CC1P = 1: non-inverted/both edges/ The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP = 1, CC1P = 0:the configuration is reserved, it must not be used.

Note: This bit is not writable as soon as LOCK level 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM_CR2 register then the CC1P active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Note: In input mode, this bit is preloaded as per CCPC bit in TIM_CR2.

Bit 0 **CC1E**: Capture/compare 1 output enable

0: Capture mode disabled / OC1 is not active (see below)

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

When CC1 channel is configured as output, the OC1 level depends on MOE, OSSI, OSSR, OIS1, OIS1N and CC1NE bits, regardless of the CC1E bits state. Refer to *Table 473* for details.

Note: On channels having a complementary output, this bit is preloaded. If the CCPC bit is set in the TIM_CR2 register then the CC1E active bit takes the new value from the preloaded bit only when a Commutation event is generated.

Table 473. Output control bits for complementary tim_ocx and tim_ocxn channels with break feature

<table>
<tr><th colspan="5">Control bits</th><th colspan="2">Output states(1)</th></tr>

tim_ocxn = CCxNP</td></tr>
<tr><td rowspan="6">0</td><td>0</td><td rowspan="6">X</td><td>X</td><td>X</td><td colspan="2" rowspan="2">Output disabled (not driven by the timer: Hi-Z).</td></tr>
<tr><td rowspan="5">1</td><td>0</td><td>0</td></tr>
<tr><td>0</td><td>1</td><td colspan="2" rowspan="3">Off-State (output enabled with inactive state)
Asynchronously: tim_ocx = CCxP, tim_ocxn = CCxNP (if tim_brk or tim_brk2 is triggered).
Then (this is valid only if tim_brk is triggered), if the clock is present: tim_ocx = OISx and tim_ocxn = OISxN after a dead-time, assuming that OISx and OISxN do not correspond to OCX and tim_ocxn both in active state (may cause a short circuit when driving switches in half-bridge configuration).
Note: tim_brk2 can only be used if OSSI = OSSR = 1.</td></tr>
<tr><td>1</td><td>0</td></tr>
<tr><td>1</td><td>1</td></tr>
</table>

1. When both outputs of a channel are not used (control taken over by GPIO), the OISx, OISxN, CCxP and CCxNP bits must be kept cleared.

Note: The state of the external I/O pins connected to the complementary tim_ocx and tim_ocxn channels depends on the tim_ocx and tim_ocxn channel state and the GPIO registers.

41.6.12 TIM counter (TIM_CNT)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIFCPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
r															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIM_ISR register. If the UIFREMAP bit in the TIM_CR1 is reset, bit 31 is reserved and read at 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

41.6.13 TIM prescaler (TIM_PSC)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency ($f_{tim_cnt_ck}$) is equal to $f_{tim_psc_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIM_EGR register or through trigger controller when configured in “reset mode”).

41.6.14 TIM autoreload register (TIM_ARR)

Address offset: 0x02C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Autoreload value

ARR is the value to be loaded in the actual autoreload register.

Refer to the *Section 41.3.3: Time-base unit* for more details about ARR update and behavior.

The counter is blocked while the autoreload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the autoreload value.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

41.6.15 TIM repetition counter register (TIM_RCR)

Address offset: 0x030

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
REP[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **REP[15:0]**: Repetition counter reload value

This bitfield defines the update rate of the compare registers (i.e. periodic transfers from preload to active registers) when preload registers are enable. It also defines the update interrupt generation rate, if this interrupt is enable.

When the repetition down-counter reaches zero, an update event is generated and it restarts counting from REP value. As the repetition counter is reloaded with REP value only at the repetition update event UEV, any write to the TIM_RCR register is not taken in account until the next repetition update event.

It means in PWM mode (REP+1) corresponds to:

– the number of PWM periods in edge-aligned mode

– the number of half PWM period in center-aligned mode.

41.6.16 TIM capture/compare register 1 (TIM_CCR1)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR1[19:0]**: Capture/compare 1 value

If channel CC1 is configured as output: CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[19:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input: CR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIM_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR1[15:0]. The CCR1[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[19:4]. The CCR1[3:0] bits are reset.

41.6.17 TIM capture/compare register 2 (TIM_CCR2)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR2[19:0]**: Capture/compare 2 value

If channel CC2 is configured as output: CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM_CCMR1 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[19:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input: CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIM_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR2[15:0]. The CCR2[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[19:4]. The CCR2[3:0] bits are reset.

41.6.18 TIM capture/compare register 3 (TIM_CCR3)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR3[19:0]**: Capture/compare value

If channel CC3 is configured as output: CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM_CCMR2 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.
The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc3 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR3[15:0]. The CCR3[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR3[19:4]. The CCR3[3:0] bitfield contains the dithered part.
If channel CC3 is configured as input: CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIM_CCR3 register is read-only and cannot be programmed.
Non-dithering mode (DITHEN = 0)
The register holds the capture value in CCR3[15:0]. The CCR3[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the capture in CCR3[19:4]. The CCR3[3:0] bits are reset.

41.6.19 TIM capture/compare register 4 (TIM_CCR4)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR4[19:0]**: Capture/compare value

If channel CC4 is configured as output: CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM_CCMR2 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signalled on tim_oc4 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR4[15:0]. The CCR4[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR4[19:4]. The CCR4[3:0] bitfield contains the dithered part.

If channel CC4 is configured as input: CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIM_CCR4 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value in CCR4[15:0]. The CCR4[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR4[19:4]. The CCR4[3:0] bits are reset.

41.6.20 TIM break and dead-time register (TIM_BDTR)

Address offset: 0x044

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	BK2BID	BKBID	BK2DSRM	BKDSRM	BK2P	BK2E	BK2F[3:0]				BKF[3:0]			
		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MOE	AOE	BKP	BKE	OSSR	OSSI	LOCK[1:0]		DTG[7:0]							
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Note: As the bits BKBID/BK2BID/BK2P, BK2E, BK2F[3:0], BKF[3:0], AOE, BKP, BKE, OSSI, OSSR, and DTG[7:0] can be write-locked depending on the LOCK configuration, it can be necessary to configure all of them during the first write access to the TIM_BDTR register.

Bits 31:30 Reserved, must be kept at reset value.

Bit 29 **BK2BID**: Break2 bidirectional
Refer to BKBID description

Bit 28 **BKBID**: Break bidirectional
0: Break input tim_brk in input mode
1: Break input tim_brk in bidirectional mode
In the bidirectional mode (BKBID bit set to 1), the break input is configured both in input mode and in open drain output mode. Any active break event asserts a low logic level on the Break input to indicate an internal break event to external devices.
Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).
Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 27 **BK2DSRM**: Break2 disarm
Refer to BKDSRM description

Bit 26 **BKDSRM**: Break disarm
0: Break input tim_brk is armed
1: Break input tim_brk is disarmed
This bit is cleared by hardware when no break source is active.
The BKDSRM bit must be set by software to release the bidirectional output control (open-drain output in Hi-Z state) and then be polled it until it is reset by hardware, indicating that the fault condition has disappeared.
Note: Any write operation to this bit takes a delay of 1 APB clock cycle to become effective.

Bit 25 **BK2P**: Break 2 polarity
0: Break input tim_brk2 is active low
1: Break input tim_brk2 is active high
Note: This bit cannot be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register) and when BK2E bit is set.
Note: Any write operation to this bit takes a delay of 1 tim_ker_ck clock cycle to become effective.

Bit 24 **BK2E**: Break 2 enable
This bit enables the complete break 2 protection, see *Figure 507: Break and Break2 circuitry overview*).
0: Break2 function disabled
1: Break2 function enabled
Note: The BRKIN2 must only be used with OSSR = OSSI = 1.
Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).
Note: Any write operation to this bit takes a delay of 1 tim_ker_ck clock cycle to become effective.

Bits 23:20 **BK2F[3:0]**: Break 2 filter

This bitfield defines the frequency used to sample tim_brk2 input and the length of the digital filter applied to tim_brk2. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk2 acts asynchronously
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register) and when BK2E bit is set.

Bits 19:16 **BKF[3:0]**: Break filter

This bitfield defines the frequency used to sample tim_brk input and the length of the digital filter applied to tim_brk. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, tim_brk acts asynchronously
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register) and when BKE bit is set.

Bit 15 **MOE**: Main output enable

This bit is cleared asynchronously by hardware as soon as one of the break inputs is active (tim_brk or tim_brk2). It is set by software or automatically depending on the AOE bit. It is acting only on the channels which are configured in output.

0: In response to a break 2 event. OC and OCN outputs are disabled
In response to a break event or if MOE is written to 0: OC and OCN outputs are disabled or forced to idle state depending on the OSSI bit.

1: OC and OCN outputs are enabled if their respective enable bits are set (CCxE, CCxNE in TIM_CCER register).
See OC/OCN enable description for more details (*Section 41.6.11: TIM capture/compare enable register (TIM_CCER)*).

Bit 14 **AOE**: Automatic output enable

0: MOE can be set only by software

1: MOE can be set by software or automatically at the next update event (if none of the break inputs tim_brk and tim_brk2 is active)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 13 **BKP**: Break polarity

0: Break input tim_brk is active low

1: Break input tim_brk is active high

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register) and when BKE bit is set.

Note: Any write operation to this bit takes a delay of 1 tim_ker_ck clock cycle to become effective.

Bit 12 **BKE**: Break enable

This bit enables the complete break protection (including all sources connected to tim_sys_brk and BKIN sources, as per *Figure 507: Break and Break2 circuitry overview*).

0: Break function disabled

1: Break function enabled

Note: This bit cannot be modified when LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Note: Any write operation to this bit takes a delay of 1 tim_ker_ck clock cycle to become effective.

Bit 11 **OSSR**: Off-state selection for Run mode

This bit is used when MOE = 1 on channels having a complementary output which are configured as outputs. OSSR is not implemented if no complementary output is implemented in the timer.

See OC/OCN enable description for more details (*Section 41.6.11: TIM capture/compare enable register (TIM_CCER)*).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic, which forces a Hi-Z state).

1: When inactive, OC/OCN outputs are enabled with their inactive level as soon as CCxE = 1 or CCxNE = 1 (the output is still controlled by the timer).

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM_BDTR register).

Bit 10 **OSSI**: Off-state selection for idle mode

This bit is used when MOE = 0 due to a break event or by a software write, on channels configured as outputs.
See OC/OCN enable description for more details (*Section 41.6.11: TIM capture/compare enable register (TIM_CCER)*).

0: When inactive, OC/OCN outputs are disabled (the timer releases the output control which is taken over by the GPIO logic and which imposes a Hi-Z state).

1: When inactive, OC/OCN outputs are first forced with their inactive level then forced to their idle level after the deadtime. The timer maintains its control over the output.

Note: This bit can not be modified as soon as the LOCK level 2 has been programmed (LOCK bits in TIM_BDTR register).

Bits 9:8 **LOCK[1:0]**: Lock configuration

These bits offer a write protection against software errors.

00: LOCK OFF - No bit is write protected.

01: LOCK Level 1 = DTG bits in TIM_BDTR register, OISx and OISxN bits in TIM_CR2 register and BKBID/BK2BID/BKE/BKP/AOE bits in TIM_BDTR register can no longer be written.

10: LOCK Level 2 = LOCK Level 1 + CC Polarity bits (CCxP/CCxNP bits in TIM_CCER register, as long as the related channel is configured in output through the CCxS bits) as well as OSSR and OSSI bits can no longer be written.

11: LOCK Level 3 = LOCK Level 2 + CC Control bits (OCxM and OCxPE bits in TIM_CCMRx registers, as long as the related channel is configured in output through the CCxS bits) can no longer be written.

Note: The LOCK bits can be written only once after the reset. Once the TIM_BDTR register has been written, their content is frozen until the next reset.

Bits 7:0 **DTG[7:0]**: Dead-time generator setup

This bitfield defines the duration of the dead-time inserted between the complementary outputs. DT correspond to this duration.
DTG[7:5] = 0xx => DT = DTG[7:0]x t_{DTG} with $t_{DTG} = t_{DTS}$.
DTG[7:5] = 10x => DT = (64+DTG[5:0])xt_{DTG} with $t_{DTG} = 2xt_{DTS}$.
DTG[7:5] = 110 => DT = (32+DTG[4:0])xt_{DTG} with $t_{DTG} = 8xt_{DTS}$.
DTG[7:5] = 111 => DT = (32+DTG[4:0])xt_{DTG} with $t_{DTG} = 16xt_{DTS}$.
Example if t_{DTS} = 125 ns (8 MHz), dead-time possible values are:
0 to 15875 ns by 125 ns steps,
16 µs to 31750 ns by 250 ns steps,
32 µs to 63 µs by 1 µs steps,
64 µs to 126 µs by 2 µs steps

Note: This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

41.6.21 TIM capture/compare register 5 (TIM_CCR5)

Address offset: 0x048

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCR5[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **GC5C3**: Group channel 5 and channel 3

Distortion on channel 3 output:

0: No effect of tim_oc5ref on tim_oc3refc

1: tim_oc3refc is the logical AND of tim_oc3ref and tim_oc5ref

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 30 **GC5C2**: Group channel 5 and channel 2

Distortion on channel 2 output:

0: No effect of tim_oc5ref on tim_oc2refc

1: tim_oc2refc is the logical AND of tim_oc2ref and tim_oc5ref

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 29 **GC5C1**: Group channel 5 and channel 1

Distortion on channel 1 output:

0: No effect of oc5ref on oc1refc

1: oc1refc is the logical AND of oc1ref and oc5ref

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 28 **GC5C4**: Group channel 5 and channel 4

Distortion on channel 1 output:

0: No effect of oc5ref on oc4refc

1: oc4refc is the logical AND of oc4ref and oc5ref

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 27 **GC5C4O**: Group channel 5 and channel 4 (ORed)

Distortion on channel 4 output:

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

0: No effect of oc5ref on oc4refc

1: oc4refc is the logical OR of oc4ref and oc5ref

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 26 **GC5C3O**: Group channel 5 and channel 3 (ORed)

Distortion on channel 3 output:

This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).

0: No effect of oc5ref on oc3refc

1: oc4refc is the logical OR of oc3ref and oc5ref

Note: it is also possible to apply this distortion on combined PWM signals.

Bit 25 **GC5C2O**: Group channel 5 and channel 2 (ORed)
Distortion on channel 2 output:
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).
0: No effect of oc5ref on oc2refc
1: oc4refc is the logical OR of oc2ref and oc5ref
Note: it is also possible to apply this distortion on combined PWM signals.

Bit 24 **GC5C1O**: Group channel 5 and channel 1 (ORed)
Distortion on channel 1 output:
This bit can either have immediate effect or be preloaded and taken into account after an update event (if preload is enabled with OC5PE in TIM_CCMR3).
0: No effect of oc5ref on oc1refc
1: oc4refc is the logical OR of oc1ref and oc5ref
Note: it is also possible to apply this distortion on combined PWM signals.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR5[19:0]**: compare 5 value
CCR5 is the value to be loaded in the actual compare 5 register (preload value).
It is loaded permanently if the preload feature is not selected in the TIM_CCMR3 register (bit OC5PE). Else the preload value is copied in the active compare 5 register when an update event occurs.
The active compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc5 output.
Non-dithering mode (DITHEN = 0)
The register holds the compare value in CCR5[15:0]. The CCR5[19:16] bits are reset.
Dithering mode (DITHEN = 1)
The register holds the integer part in CCR5[19:4]. The CCR5[3:0] bitfield contains the dithered part.

41.6.22 TIM capture/compare register 6 (TIM_CCR6)

Address offset: 0x04C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR6[19:16]

CCR6[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR6[19:0]**: Compare 6 value

CCR6 is the value to be loaded in the actual compare 6 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM_CCMR3 register (bit OC6PE). Else the preload value is copied in the active compare 6 register when an update event occurs.

The active compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc6 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR6[15:0]. The CCR6[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR6[19:4]. The CCR6[3:0] bitfield contains the dithered part.

41.6.23 TIM capture/compare mode register 3 (TIM_CCMR3)

Address offset: 0x050

Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channels 5 and 6 can only be configured in output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	OC6M[4:3]		Res.	Res.	Res.	Res.	Res.	Res.	OC5M[4:3]	
						rw	rw							rw	rw

rw	rw	rw	rw	rw	rw			rw	rw	rw	rw	rw	rw		

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC6CE**: Output compare 6 clear enable

0: tim_oc6ref is not affected by the tim_ocref_clr_int signal

1: tim_oc6ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC6M[4:0]**: Output compare 6 mode

Refer to OC5M[4:0] bit description

Bit 11 **OC6PE**: Output compare 6 preload enable

0: Preload register on TIM_CCR6 disabled. TIM_CCR6 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR6 enabled. Read/Write operations access the preload register. TIM_CCR6 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 10 **OC6FE**: Output compare 6 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC6 behaves normally depending on counter and CCR6 values even when the trigger is ON. The minimum delay to activate CC6 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC6 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC6 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 9:8 Reserved, must be kept at reset value.

Bit 7 **OC5CE:** Output compare 5 clear enable

0: tim_oc5ref is not affected by the tim_ocref_clr_int signal

1: tim_oc5ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC5M[4:0]**: Output compare 5 mode

These bits define the behavior of the output reference signal tim_oc5ref5. tim_oc5ref is active high whereas tim_oc5 active level depends on CC5P bit.

00000:Frozen - The comparison between the output compare register TIM_CCR5 and the counter TIM_CNT has no effect on the outputs.(this mode is used to generate a timing base).

00001:Set channel 5 to active level on match. tim_oc5ref signal is forced high when the counter TIM_CNT matches the capture/compare register 5 (TIM_CCR5).

00010:Set channel 5 to inactive level on match. tim_oc5ref signal is forced low when the counter TIM_CNT matches the capture/compare register 5 (TIM_CCR5).

00011:Toggle - tim_oc5ref toggles when TIM_CNT = TIM_CCR5.

00100:Force inactive level - tim_oc5ref is forced low.

00101:Force active level - tim_oc5ref is forced high.

00110:PWM mode 1 - In upcounting, channel 5 is active as long as TIM_CNT<TIM_CCR5 else inactive. In downcounting, channel 5 is inactive (tim_oc5ref = 0) as long as TIM_CNT>TIM_CCR5 else active (tim_oc5ref = 1).

00111:PWM mode 2 - In upcounting, channel 5 is inactive as long as TIM_CNT<TIM_CCR5 else active. In downcounting, channel 5 is active as long as TIM_CNT>TIM_CCR5 else inactive.

01000:Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001:Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01010-01011:Reserved.

01100-01101:Combined PWM mode 1 and 2. Refer to *Table 465* for details.

01110-01111:Asymmetric PWM mode 1 and 2. Refer to *Table 464* for details.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit 3 **OC5PE**: Output compare 5 preload enable

0: Preload register on TIM_CCR5 disabled. TIM_CCR5 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR5 enabled. Read/Write operations access the preload register. TIM_CCR5 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 2 **OC5FE**: Output compare 5 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC5 behaves normally depending on counter and CCR5 values even when the trigger is ON. The minimum delay to activate CC5 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC5 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC5 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 Reserved, must be kept at reset value.

41.6.24 TIM timer deadtime register 2 (TIM_DTR2)

Address offset: 0x054

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTPE	DTAE
														rw	rw

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DTGF[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:18 Reserved, must be kept at reset value.

Bit 17 **DTPE**: Deadtime preload enable

0: Deadtime value is not preloaded

1: Deadtime value preload is enabled

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bit 16 **DTAE**: Deadtime asymmetric enable

0: Deadtime on rising and falling edges are identical, and defined with DTG[7:0] register

1: Deadtime on rising edge is defined with DTG[7:0] register and deadtime on falling edge is defined with DTGF[7:0] bits.

Note: This bit can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DTGF[7:0]**: Dead-time falling edge generator setup

This bitfield defines the duration of the dead-time inserted between the complementary outputs, on the falling edge.

DTGF[7:5] = 0xx => DTF = DTGF[7:0]x t_{DTG} with $t_{DTG} = t_{DTS}$.

DTGF[7:5] = 10x => DTF = (64+DTGF[5:0])xt_{DTG} with $t_{DTG} = 2xt_{DTS}$.

DTGF[7:5] = 110 => DTF = (32+DTGF[4:0])xt_{DTG} with $t_{DTG} = 8xt_{DTS}$.

DTGF[7:5] = 111 => DTF = (32+DTGF[4:0])xt_{DTG} with $t_{DTG} = 16xt_{DTS}$.

Example if t_{DTS} = 125 ns (8 MHz), dead-time possible values are:

0 to 15875 ns by 125 ns steps,

16 µs to 31750 ns by 250 ns steps,

32 µs to 63 µs by 1 µs steps,

64 µs to 126 µs by 2 µs steps

Note: This bitfield can not be modified as long as LOCK level 1, 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

41.6.25 TIM timer encoder control register (TIM_ECR)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PWPRSC[2:0]			PW[7:0]							
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPOS[1:0]		FIDX	IBLK[1:0]		IDIR[1:0]		IE
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **PWPRSC[2:0]**: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

$t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim_ker_ck}$

Bits 23:16 **PW[7:0]**: Pulse width

This bitfield defines the pulse duration, as following:

$t_{PW} = PW[7:0] \times t_{PWG}$

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[4:0] = 00001, 00010, 00011, 01110, 01111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[4:0] = 01010, 01011, 01100, 01101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

Note: IPOS[1] bit is not significant

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account

0: Index is always active
1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]**: Index blanking

This bit indicates if the Index event is conditioned by the tim_ti3 or tim_ti4 input

00: Index always active
01: Index disabled when tim_ti3 input is active, as per CC3P bitfield
10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction

This bit indicates in which direction the Index event resets the counter.

00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0 **IE**: Index enable

This bit indicates if the Index event resets the counter.

0: Index disabled
1: Index enabled

41.6.26 TIM timer input selection register (TIM_TISEL)

Address offset: 0x05C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TI4SEL[3:0]**: Selects tim_ti4[15:0] input
0000: tim_ti4_in0: TIM_CH4
0001: tim_ti4_in1
...
1111: tim_ti4_in15
Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for interconnects list.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **TI3SEL[3:0]**: Selects tim_ti3[15:0] input
0000: tim_ti3_in0: TIM_CH2
0001: tim_ti3_in1
...
1111: tim_ti3_in15
Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for interconnects list.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: Selects tim_ti2[15:0] input
0000: tim_ti2_in0: TIM_CH2
0001: tim_ti2_in1
...
1111: tim_ti2_in15
Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for interconnects list.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: Selects tim_ti1[15:0] input
0000: tim_ti1_in0: TIM_CH1
0001: tim_ti1_in1
...
1111: tim_ti1_in15
Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for interconnects list.

41.6.27 TIM alternate function option register 1 (TIM_AF1)

Address offset: 0x060

Reset value: 0x0000 0001

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BKCMP20E**: tim_brk_cmp20 enable

This bit enables the tim_brk_cmp20 for the timer's tim_brk input. tim_brk_cmp20 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp20 input disabled

1: tim_brk_cmp20 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 30 **BKCMP19E**: tim_brk_cmp19 enable

This bit enables the tim_brk_cmp19 for the timer's tim_brk input. tim_brk_cmp19 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp19 input disabled

1: tim_brk_cmp19 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 29 **BKCMP18E**: tim_brk_cmp18 enable

This bit enables the tim_brk_cmp18 for the timer's tim_brk input. tim_brk_cmp18 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp18 input disabled

1: tim_brk_cmp18 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 28 **BKCMP17E**: tim_brk_cmp17 enable

This bit enables the tim_brk_cmp17 for the timer's tim_brk input. tim_brk_cmp17 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp17 input disabled

1: tim_brk_cmp17 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 27 **BKCMP16E**: tim_brk_cmp16 enable

This bit enables the tim_brk_cmp16 for the timer's tim_brk input. tim_brk_cmp16 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp16 input disabled

1: tim_brk_cmp16 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 26 **BKCMP15E**: tim_brk_cmp15 enable

This bit enables the tim_brk_cmp15 for the timer's tim_brk input. tim_brk_cmp15 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp15 input disabled

1: tim_brk_cmp15 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 25 **BKCMP14E**: tim_brk_cmp14 enable

This bit enables the tim_brk_cmp14 for the timer's tim_brk input. tim_brk_cmp14 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp14 input disabled

1: tim_brk_cmp14 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 24 **BKCMP13E**: tim_brk_cmp13 enable
This bit enables the tim_brk_cmp13 for the timer's tim_brk input. tim_brk_cmp13 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp13 input disabled
1: tim_brk_cmp13 input enabled
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 23 **BKCMP12E**: tim_brk_cmp12 enable
This bit enables the tim_brk_cmp12 for the timer's tim_brk input. tim_brk_cmp12 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp12 input disabled
1: tim_brk_cmp12 input enabled
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 22 **BKCMP11E**: tim_brk_cmp11 enable
This bit enables the tim_brk_cmp11 for the timer's tim_brk input. tim_brk_cmp11 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp11 input disabled
1: tim_brk_cmp11 input enabled
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 21 **BKCMP10E**: tim_brk_cmp10 enable
This bit enables the tim_brk_cmp10 for the timer's tim_brk input. tim_brk_cmp10 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp10 input disabled
1: tim_brk_cmp10 input enabled
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 20 **BKCMP9E**: tim_brk_cmp9 enable
This bit enables the tim_brk_cmp9 for the timer's tim_brk input. tim_brk_cmp9 output is 'ORed' with the other tim_brk sources.
0: tim_brk_cmp9 input disabled
1: tim_brk_cmp9 input enabled
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 19 Reserved, must be kept at reset value.

Bits 18:14 **ETRSEL[4:0]**: etr_in source selection
These bits select the etr_in input source.
00000:tim_etr0: TIM_ETR input
00001:tim_etr1
...
11111:tim_etr31
Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for product specific implementation.
Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 13 **BKCMP4P**: tim_brk_cmp4 input polarity

This bit selects the tim_brk_cmp4 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp4 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp4 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 12 **BKCMP3P**: tim_brk_cmp3 input polarity

This bit selects the tim_brk_cmp3 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp3 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp3 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 11 **BKCMP2P**: tim_brk_cmp2 input polarity

This bit selects the tim_brk_cmp2 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp2 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp2 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 10 **BKCMP1P**: tim_brk_cmp1 input polarity

This bit selects the tim_brk_cmp1 input sensitivity. It must be programmed together with the BKP polarity bit.

0: tim_brk_cmp1 input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: tim_brk_cmp1 input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 9 **BKINP**: TIM_BKIN input polarity

This bit selects the TIM_BKIN alternate function input sensitivity. It must be programmed together with the BKP polarity bit.

0: TIM_BKIN input polarity is not inverted (active low if BKP = 0, active high if BKP = 1)

1: TIM_BKIN input polarity is inverted (active high if BKP = 0, active low if BKP = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 8 **BKCMP8E**: tim_brk_cmp8 enable

This bit enables the tim_brk_cmp8 for the timer's tim_brk input. tim_brk_cmp8 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp8 input disabled

1: tim_brk_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 7 **BKCMP7E**: tim_brk_cmp7 enable

This bit enables the tim_brk_cmp7 for the timer's tim_brk input. tim_brk_cmp7 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp7 input disabled

1: tim_brk_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 6 **BKCMP6E**: tim_brk_cmp6 enable

This bit enables the tim_brk_cmp6 for the timer's tim_brk input. tim_brk_cmp6 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp6 input disabled

1: tim_brk_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 5 **BKCMP5E**: tim_brk_cmp5 enable

This bit enables the tim_brk_cmp5 for the timer's tim_brk input. tim_brk_cmp5 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp5 input disabled

1: tim_brk_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 4 **BKCMP4E**: tim_brk_cmp4 enable

This bit enables the tim_brk_cmp4 for the timer's tim_brk input. tim_brk_cmp4 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp4 input disabled

1: tim_brk_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 3 **BKCMP3E**: tim_brk_cmp3 enable

This bit enables the tim_brk_cmp3 for the timer's tim_brk input. tim_brk_cmp3 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp3 input disabled

1: tim_brk_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 2 **BKCMP2E**: tim_brk_cmp2 enable

This bit enables the tim_brk_cmp2 for the timer's tim_brk input. tim_brk_cmp2 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp2 input disabled

1: tim_brk_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 1 **BKCMP1E**: tim_brk_cmp1 enable

This bit enables the tim_brk_cmp1 for the timer's tim_brk input. tim_brk_cmp1 output is 'ORed' with the other tim_brk sources.

0: tim_brk_cmp1 input disabled

1: tim_brk_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 0 **BKINE**: TIM_BKIN input enable

This bit enables the TIM_BKIN alternate function input for the timer's tim_brk input. TIM_BKIN input is 'ORed' with the other tim_brk sources.

0: TIM_BKIN input disabled

1: TIM_BKIN input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Note: Refer to Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation.

41.6.28 TIM alternate function register 2 (TIM_AF2)

Address offset: 0x064

Reset value: 0x0000 0001

		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **BK2CMP20E**: tim_brk2_cmp20 enable

This bit enables the tim_brk2_cmp20 for the timer's tim_brk2 input. tim_brk2_cmp20 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp20 input disabled

1: tim_brk2_cmp20 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 30 **BK2CMP19E**: tim_brk2_cmp19 enable

This bit enables the tim_brk2_cmp19 for the timer's tim_brk2 input. tim_brk2_cmp19 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp19 input disabled

1: tim_brk2_cmp19 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 29 **BK2CMP18E**: tim_brk2_cmp18 enable

This bit enables the tim_brk2_cmp18 for the timer's tim_brk2 input. tim_brk2_cmp18 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp18 input disabled

1: tim_brk2_cmp18 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 28 **BK2CMP17E**: tim_brk2_cmp17 enable

This bit enables the tim_brk2_cmp17 for the timer's tim_brk2 input. tim_brk2_cmp17 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp17 input disabled

1: tim_brk2_cmp17 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 27 **BK2CMP16E**: tim_brk2_cmp16 enable

This bit enables the tim_brk2_cmp16 for the timer's tim_brk2 input. tim_brk2_cmp16 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp16 input disabled

1: tim_brk2_cmp16 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 26 **BK2CMP15E**: tim_brk2_cmp15 enable

This bit enables the tim_brk2_cmp15 for the timer's tim_brk2 input. tim_brk2_cmp15 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp15 input disabled

1: tim_brk2_cmp15 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 25 **BK2CMP14E**: tim_brk2_cmp14 enable

This bit enables the tim_brk2_cmp14 for the timer's tim_brk2 input. tim_brk2_cmp14 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp14 input disabled

1: tim_brk2_cmp14 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 24 **BK2CMP13E**: tim_brk2_cmp13 enable

This bit enables the tim_brk2_cmp13 for the timer's tim_brk2 input. tim_brk2_cmp13 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp13 input disabled

1: tim_brk2_cmp13 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 23 **BK2CMP12E**: tim_brk2_cmp12 enable

This bit enables the tim_brk2_cmp12 for the timer's tim_brk2 input. tim_brk2_cmp12 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp12 input disabled

1: tim_brk2_cmp12 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 22 **BK2CMP11E**: tim_brk2_cmp11 enable

This bit enables the tim_brk2_cmp11 for the timer's tim_brk2 input. tim_brk2_cmp11 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp11 input disabled

1: tim_brk2_cmp11 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 21 **BK2CMP10E**: tim_brk2_cmp10 enable

This bit enables the tim_brk2_cmp10 for the timer's tim_brk2 input. tim_brk2_cmp10 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp10 input disabled

1: tim_brk2_cmp10 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 20 **BK2CMP9E**: tim_brk2_cmp9 enable

This bit enables the tim_brk2_cmp9 for the timer's tim_brk2 input. tim_brk2_cmp9 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp9 input disabled

1: tim_brk2_cmp9 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 19:16 **OCRSEL[3:0]**: ocref_clr source selection

These bits select the ocref_clr input source.

0000:tim_ocref_clr0

0001:tim_ocref_clr1

...

1111: tim_ocref_clr15

Refer to *Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals* for product specific information.

Note: These bits can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 15:14 Reserved, must be kept at reset value.

Bit 13 **BK2CMP4P**: tim_brk2_cmp4 input polarity

This bit selects the tim_brk2_cmp4 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp4 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp4 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 12 **BK2CMP3P**: tim_brk2_cmp3 input polarity

This bit selects the tim_brk2_cmp3 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp3 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp3 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 11 **BK2CMP2P**: tim_brk2_cmp2 input polarity

This bit selects the tim_brk2_cmp2 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 10 **BK2CMP1P**: tim_brk2_cmp1 input polarity

This bit selects the tim_brk2_cmp1 input sensitivity. It must be programmed together with the BK2P polarity bit.

0: tim_brk2_cmp1 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: tim_brk2_cmp1 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 9 **BK2INP**: TIM_BKIN2 input polarity

This bit selects the TIM_BKIN2 alternate function input sensitivity. It must be programmed together with the BK2P polarity bit.

0: TIM_BKIN2 input polarity is not inverted (active low if BK2P = 0, active high if BK2P = 1)

1: TIM_BKIN2 input polarity is inverted (active high if BK2P = 0, active low if BK2P = 1)

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 8 **BK2CMP8E**: tim_brk2_cmp8 enable

This bit enables the tim_brk2_cmp8 for the timer's tim_brk2 input. tim_brk2_cmp8 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp8 input disabled

1: tim_brk2_cmp8 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 7 **BK2CMP7E**: tim_brk2_cmp7 enable

This bit enables the tim_brk2_cmp7 for the timer's tim_brk2 input. tim_brk2_cmp7 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp7 input disabled

1: tim_brk2_cmp7 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 6 **BK2CMP6E**: tim_brk2_cmp6 enable

This bit enables the tim_brk2_cmp6 for the timer's tim_brk2 input. tim_brk2_cmp6 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp6 input disabled

1: tim_brk2_cmp6 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 5 **BK2CMP5E**: tim_brk2_cmp5 enable

This bit enables the tim_brk2_cmp5 for the timer's tim_brk2 input. tim_brk2_cmp5 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp5 input disabled

1: tim_brk2_cmp5 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 4 **BK2CMP4E**: tim_brk2_cmp4 enable

This bit enables the tim_brk2_cmp4 for the timer's tim_brk2 input. tim_brk2_cmp4 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp4 input disabled

1: tim_brk2_cmp4 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 3 **BK2CMP3E**: tim_brk2_cmp3 enable

This bit enables the tim_brk2_cmp3 for the timer's tim_brk2 input. tim_brk2_cmp3 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp3 input disabled

1: tim_brk2_cmp3 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 2 **BK2CMP2E**: tim_brk2_cmp2 enable

This bit enables the tim_brk2_cmp2 for the timer's tim_brk2 input. tim_brk2_cmp2 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp2 input disabled

1: tim_brk2_cmp2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 1 **BK2CMP1E**: tim_brk2_cmp1 enable

This bit enables the tim_brk2_cmp1 for the timer's tim_brk2 input. tim_brk2_cmp1 output is 'ORed' with the other tim_brk2 sources.

0: tim_brk2_cmp1 input disabled

1: tim_brk2_cmp1 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 0 **BK2INE**: TIM_BKIN2 input enable

This bit enables the TIM_BKIN2 alternate function input for the timer's tim_brk2 input. TIM_BKIN2 input is 'ORed' with the other tim_brk2 sources.

0: TIM_BKIN2 input disabled

1: TIM_BKIN2 input enabled

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Note: Refer to Section 41.3.2: TIM1/TIM8/TIM20 pins and internal signals for product specific implementation.

41.6.29 TIM capture/compare register 7 (TIM_CCR7)

Address offset: 0x070

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	CCR7[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR7[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **CCR7[19:0]**: Capture/compare 7 value

CCR7 is the value to be loaded in the actual compare 7 register (preload value).

It is loaded permanently if the preload feature is not selected in the TIM_CCMR4 register (bit OC7PE). Else the preload value is copied in the active compare 7 register when an update event occurs.

The active compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc7 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value in CCR7[15:0]. The CCR7[19:16] bits are reset.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR7[19:4]. The CCR7[3:0] bitfield contains the dithered part.

41.6.30 TIM capture/compare mode register 4 (TIM_CCMR4)

Address offset: 0x078

Reset value: 0x0000 0000

Refer to the above CCMR1 register description. Channel 7 can only be configured in output.

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC7M[4:3]	
														rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	OC7CE	OC7M[2:0]			OC7PE	OC7FE	Res.	Res.
								rw	rw	rw	rw	rw	rw		

Bits 31:18 Reserved, must be kept at reset value.

Bits 15:8 Reserved, must be kept at reset value.

Bit 7 **OC7CE:** Output compare 7 clear enable

0: tim_oc7ref is not affected by the tim_ocref_clr_int signal

1: tim_oc7ref is cleared as soon as a High level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 41.3.23: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC7M[4:0]**: Output compare 7 mode

These bits define the behavior of the output reference signal tim_ocref7. tim_oc7ref is active high whereas tim_oc7 active level depends on CC7P bit.

00000:Frozen - The comparison between the output compare register TIM_CCR7 and the counter TIM_CNT has no effect on the outputs.(this mode is used to generate a timing base).

00001:Set channel 7 to active level on match. tim_oc7ref signal is forced high when the counter TIM_CNT matches the capture/compare register 7 (TIM_CCR7).

00010:Set channel 7 to inactive level on match. tim_oc7ref signal is forced low when the counter TIM_CNT matches the capture/compare register 7 (TIM_CCR7).

00011:Toggle - tim_oc7ref toggles when TIM_CNT = TIM_CCR7.

00100:Force inactive level - tim_oc7ref is forced low.

00101:Force active level - tim_oc7ref is forced high.

00110:PWM mode 1 - In upcounting, channel 7 is active as long as TIM_CNT<TIM_CCR7 else inactive. In downcounting, channel 7 is inactive (tim_oc7ref = 0) as long as TIM_CNT>TIM_CCR7 else active (tim_oc5ref = 1).

00111:PWM mode 2 - In upcounting, channel 7 is inactive as long as TIM_CNT<TIM_CCR7 else active. In downcounting, channel 7 is active as long as TIM_CNT>TIM_CCR7 else inactive.

01000:Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001:Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

Bit 3 **OC7PE**: Output compare 7 preload enable

0: Preload register on TIM_CCR7 disabled. TIM_CCR7 can be written at anytime, the new value is taken in account immediately.

1: Preload register on TIM_CCR7 enabled. Read/Write operations access the preload register. TIM_CCR7 preload value is loaded in the active register at each update event.

These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Bit 2 **OC7FE**: Output compare 7 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.

0: CC7 behaves normally depending on counter and CCR7 values even when the trigger is ON. The minimum delay to activate CC7 output when an edge occurs on the trigger input is 5 clock cycles.

1: An active edge on the trigger input acts like a compare match on CC7 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC7 output is reduced to 3 clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 Reserved, must be kept at reset value.

41.6.31 TIM multilevel protection register 1 (TIM_MPR1)

Address offset: 0x090

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:14 **BK4NM[1:0]**: Break mode for tim_oc4n output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 13:12 **BK4M[1:0]**: Break mode for tim_oc4 output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 11:10 **BK3NM[1:0]**: Break mode for tim_oc3n output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 9:8 **BK3M[1:0]**: Break mode for tim_oc3 output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 7:6 **BK2NM[1:0]**: Break mode for tim_oc2n output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 5:4 **BK2M[1:0]**: Break mode for tim_oc2 output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 3:2 **BK1NM[1:0]**: Break mode for tim_oc1n output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bits 1:0 **BK1M[1:0]**: Break mode for tim_oc1 output
This bit must be modified only when CEN=0 in TIM_CR1.
00: Immediate break
01: Delayed 1 break
10: Delayed 2 break
11: Reserved
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

41.6.32 TIM multilevel protection register 2 (TIM_MPR2)

Address offset: 0x094

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBK2[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBK1[7:0]							
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:24 Reserved, must be kept at reset value.

Bits 23:16 **DBK2[7:0]**: Delayed 2 Break duration

This bitfield defines the duration of the delay in Delayed 2 Break mode.

It is partially preloaded and can be updated during timer operation (new value taken into account after an update event), at the exception of the bits coding for t_{DTG} selection, which are not preloaded.

It is thus recommended to update only the least significant bits to have the expected duration value:

- DBK2[6:0] if DBK2[7] = 0
- DBK2[5:0] if DBK2[7:6] = 10
- DBK2[4:0] if DBK2[7:5] = 110 or 111

DBK2[7:5]=0xx => Delay2=DBK2[7:0]xt_{DTG} with $t_{DTG}=t_{DTS}$.
DBK2[7:5]=10x => Delay2=(64+DBK2[5:0])xt_{DTG} with $t_{DTG}=2xt_{DTS}$.
DBK2[7:5]=110 => Delay2=(32+DBK2[4:0])xt_{DTG} with $t_{DTG}=8xt_{DTS}$.
DBK2[7:5]=111 => Delay2=(32+DBK2[4:0])xt_{DTG} with $t_{DTG}=16xt_{DTS}$.

Note: Due to internal resynchronization of the break event on tim_ker_ck, the effective delayed break time is the programmed Delay2 plus up to two additional timer clock cycles.

Note: This bit can not be modified as long as LOCK level 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:0 **DBK1[7:0]**: Delayed 1 Break duration

This bitfield defines the duration of the delay in Delayed 1 Break mode.

It is partially preloaded and can be updated during timer operation (new value taken into account after an update event), at the exception of the bits coding for t_{DTG} selection, which are not preloaded.

It is thus recommended to update only the least significant bits to have the expected duration value:

- DBK1[6:0] if DBK1[7] = 0
- DBK1[5:0] if DBK1[7:6] = 10
- DBK1[4:0] if DBK1[7:5] = 110 or 111

DBK1[7:5]=0xx => Delay1=DBK1[7:0]xt_{DTG} with $t_{DTG}=t_{DTS}$.
DBK1[7:5]=10x => Delay1=(64+DBK1[5:0])xt_{DTG} with $t_{DTG}=2xt_{DTS}$.
DBK1[7:5]=110 => Delay1=(32+DBK1[4:0])xt_{DTG} with $t_{DTG}=8xt_{DTS}$.
DBK1[7:5]=111 => Delay1=(32+DBK1[4:0])xt_{DTG} with $t_{DTG}=16xt_{DTS}$.

Note: Due to internal resynchronization of the break event on tim_ker_ck, the effective delayed break time is the programmed Delay1 plus up to two additional timer clock cycles.

Note: This bit can not be modified as long as LOCK level 2 or 3 has been programmed (LOCK bits in TIM_BDTR register).

41.6.33 TIM output override register (TIM_OOR)

Address offset: 0x0A0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	OOC	Res.	Res.	Res.	Res.	OOS4N	OOS4	OOS3N	OOS3	OOS2N	OOS2	OOS1N	OOS1
			rw					rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:13 Reserved, must be kept at reset value.

Bit 12 **OOC**: Output override control

This bit forces the idle state of the tim_ocx and tim_ocxn outputs to the values defined with OOSx and OOSxN bits.

0: tim_ocx and tim_ocxn outputs are in the default idle state

1: tim_ocx and tim_ocxn outputs are forced in an idle state defined with OOSx/OOSxN bits

Note: This bit can only be modified when the outputs are in idle state (MOE = 0). It is cleared when the MOE bit is set.

Bits 11:8 Reserved, must be kept at reset value.

Bit 7 **OOS4N**: Output override state for output tim_oc4n

This bit defines the state for output tim_oc4n when OOC = 1

0: tim_oc4n = 0

1: tim_oc4n = 1

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 6 **OOS4**: Output override state for output tim_oc4

This bit defines the state for output tim_oc4 when OOC = 1

0: tim_oc4 = 0

1: tim_oc4 = 1

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 5 **OOS3N**: Output override state for output tim_oc3n

This bit defines the state for output tim_oc3n when OOC = 1

0: tim_oc3n = 0

1: tim_oc3n = 1

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 4 **OOS3**: Output override state for output tim_oc3

This bit defines the state for output tim_oc3 when OOC = 1

0: tim_oc3 = 0

1: tim_oc3 = 1

Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 3 **OOS2N**: Output override state for output tim_oc2n
This bit defines the state for output tim_oc2n when OOC = 1
0: tim_oc2n = 0
1: tim_oc2n = 1
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 2 **OOS2**: Output override state for output tim_oc2
This bit defines the state for output tim_oc2 when OOC = 1
0: tim_oc2 = 0
1: tim_oc2 = 1
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 1 **OOS1N**: Output override state for output tim_oc1n
This bit defines the state for output tim_oc1n when OOC = 1
0: tim_oc1n = 0
1: tim_oc1n = 1
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

Bit 0 **OOS1**: Output override state for output tim_oc1
This bit defines the state for output tim_oc1 when OOC = 1
0: tim_oc1 = 0
1: tim_oc1 = 1
Note: This bit can not be modified as long as LOCK level 1 has been programmed (LOCK bits in TIM_BDTR register).

41.6.34 TIM DMA control register (TIM_DCR)

Address offset: 0x3DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBSS[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address).

0000: Disabled
0001: Update
0010: CC1
0011: CC2
0100: CC3
0101: CC4
0110: COM
0111: Trigger
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address), i.e. the number of transfers.

00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11111: 32 transfers

Example: Let us consider the following transfer: DBL = 6 & DBA = TIM2_CR1.

–If DBL = 6 and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation:

(TIM_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIM_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIM_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

–If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.

–If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIM_DMAR address). DBA is defined as an offset starting from the address of the TIM_CR1 register.

Example:

00000: TIM_CR1
00001: TIM_CR2
00010: TIM_SMCR
...

41.6.35 TIM DMA address for full transfer (TIM_DMAR)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address (TIM_CR1 address) + (DBA + DMA index) x 4

where TIM_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM_DCR).

41.6.36 TIM1/TIM8/TIM20 register map

TIM1/TIM8/TIM20 registers are mapped as 16-bit addressable registers as described in the table below:

Table 474. TIM1/TIM8/TIM20 register map and reset values

Offset	Register	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

42 General-purpose timers (TIM2/TIM3/TIM4/TIM5)

42.1 TIM2/TIM3/TIM4/TIM5 introduction

The general-purpose timers consist of a 16-bit or 32-bit autoreload counter driven by a programmable prescaler.

They can be used for a variety of purposes, including measuring the pulse lengths of input signals (*input capture*) or generating output waveforms (*output compare and PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 42.4.27: Timer synchronization*.

42.2 TIM2/TIM3/TIM4/TIM5 main features

General-purpose TIMx timer features include:

- 16-bit or 32-bit up, down, up/down autoreload counter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Up to four independent channels for:
  - Input capture.
  - Output compare.
  - PWM generation (edge- and center-aligned modes).
  - One-pulse mode output.
- Synchronization circuit to control the timer with external signals and to interconnect several timers.
- Interrupt/DMA generation on the following events:
  - Update: counter overflow/underflow, counter initialization (by software or internal/external trigger).
  - Trigger event (counter start, stop, initialization, or count by internal/external trigger).
  - Input capture.
  - Output compare.
- Supports incremental (quadrature) encoder and hall-sensor circuitry for positioning purposes.
- Trigger input for external clock or cycle-by-cycle current management.
- ADC synchronization for jitter-free sampling points.

42.3 TIM2/TIM3/TIM4/TIM5 implementation

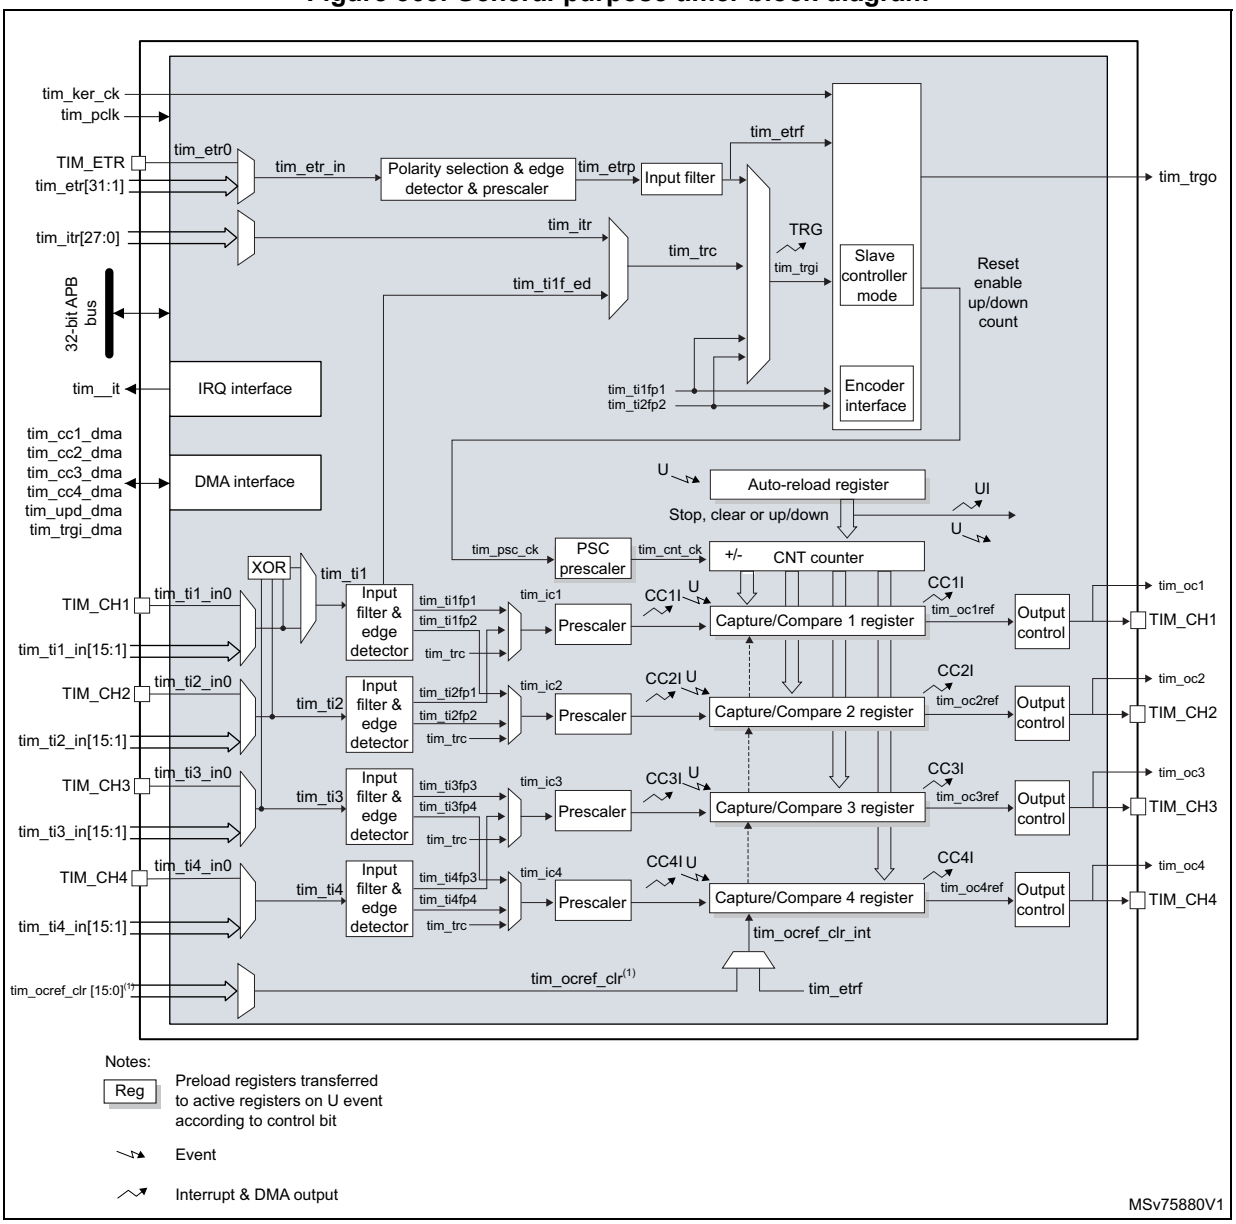

Table 475. STM32G56x/55x/54x/53x general purpose timers

42.4 TIM2/TIM3/TIM4/TIM5 functional description

42.4.1 Block diagram

Figure 563. General-purpose timer block diagram

1. This feature is not available on all timers, refer to *Section 42.3: TIM2/TIM3/TIM4/TIM5 implementation*.

42.4.2 TIM2/TIM3/TIM4/TIM5 pins and internal signals

Table 476 and *Table 477* in this section summarize the TIM inputs and outputs.

Table 476. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2 TIM_CH3 TIM_CH4	Input/output	Timer multi-purpose channels. Each channel be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) , external trigger and quadrature encoder inputs. TIM_CH1, TIM_CH2 and TIM_CH3 can be used to interface with digital hall effect sensors.
TIM_ETR	Input	External trigger input. This input can be used as external trigger or as external clock source. This input can receive a clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.

Table 477. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0] tim_ti3_in[15:0] tim_ti4_in[15:0]	Input	Internal timer inputs bus. The tim_ti1_in[15:0] and tim_ti2_in[15:0] inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock) and for quadrature encoder signals.
tim_etr[31:0]	Input	External trigger internal input bus. These inputs can be used as trigger, external clock or for hardware cycle-by-cycle pulse width control. These inputs can receive clock with a frequency higher than the tim_ker_ck if the tim_etr_in prescaler is used.
tim_itr[27:0]	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_trgo	Output	Internal trigger output. This trigger can trigger other on-chip peripherals.
tim_ocref_clr[15:0]	Input	Timer tim_ocref_clr input bus. These inputs can be used to clear the tim_ocxref signals, typically for hardware cycle-by-cycle pulse width control.
tim_pclk	Input	Timer APB clock.
tim_ker_ck	Input	Timer kernel clock

Table 477. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_it	Output	Global Timer interrupt, gathering capture/compare, update and break trigger requests.
tim_cc1_dma tim_cc2_dma tim_cc3_dma tim_cc4_dma	Output	Timer capture/compare [4:1] dma requests.
tim_upd_dma	Output	Timer update dma request.
tim_trgi_dma	Output	Timer trigger dma request.
tim_ocx (x = 1 to 4)	Output	Internal output compare signals of channels 1 to 4. these outputs can be used for triggering/synchronizing other internal peripherals.

Tables below list the sources connected to the tim_ti[4:1] input multiplexers.

42.4.3 Time-base unit

The main block of the programmable timer is a 16-bit/32-bit counter with its related autoreload register. The counter can count up, down or both up and down. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIM_CNT)
- Prescaler register (TIM_PSC)
- Autoreload register (TIM_ARR)

The autoreload register is preloaded. Writing to or reading from the autoreload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIM_CR1 register. The update event is sent when the counter reaches the overflow (or underflow when down-counting) and if the UDIS bit equals 0 in the TIM_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

Note: An update overrun status bit (UIOVRF in TIM_SR register) indicates that an update request occurred while an update interrupt is pending (update interrupt flag set). This bit is useful when debugging closed loop applications, to indicate that:

- the update interrupt service routine is too long with respect to the interval between consecutive update events

- the update interrupt service routine was served too late with respect to the subsequent update event

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIM_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

Note: The counter starts counting 1 clock cycle after setting the CEN bit in the TIM_CR1 register.

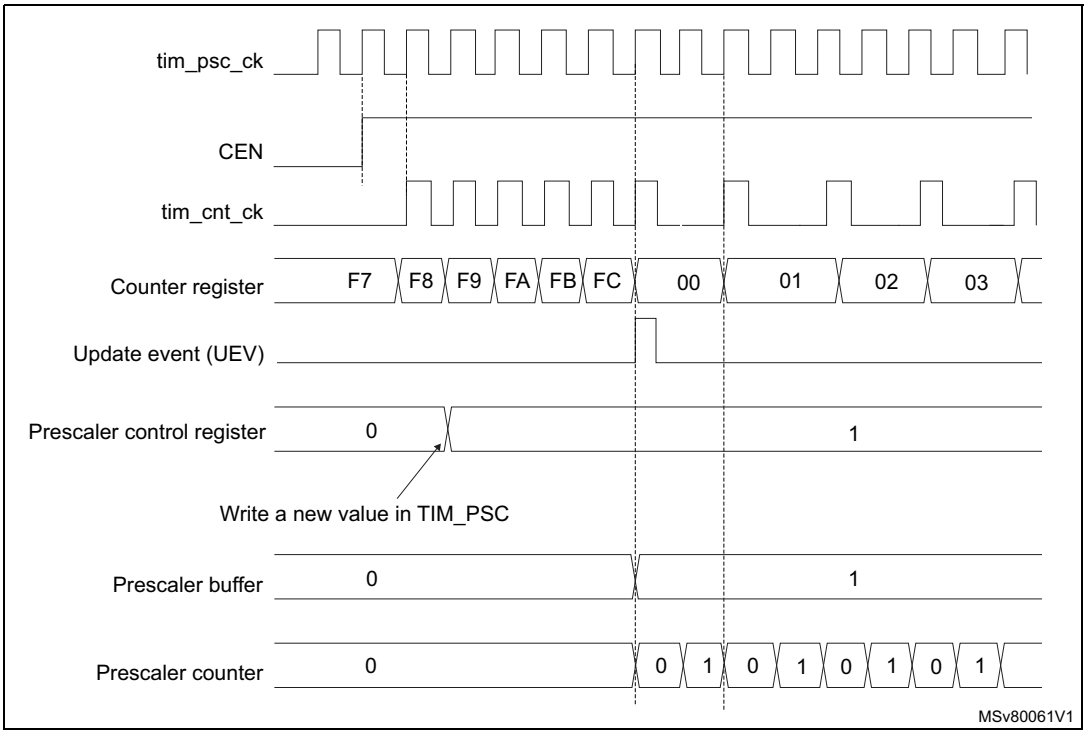
Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit/32-bit register (in the TIM_PSC

register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 564 and *Figure 565* give some examples of the counter behavior when the prescaler ratio is changed on the fly:

Figure 564. Counter timing diagram with prescaler division change from 1 to 2



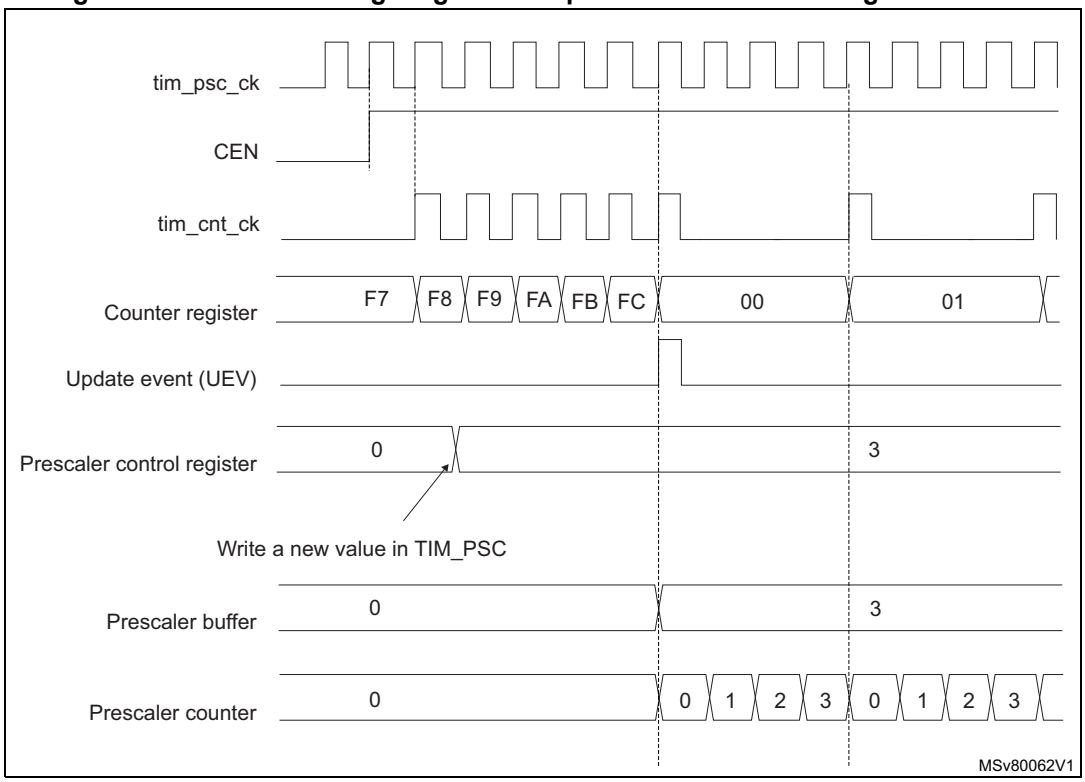


Figure 565. Counter timing diagram with prescaler division change from 1 to 4

42.4.4 Counter modes

Up-counting mode

In up-counting mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter restarts from 0, as well as the counter of the prescaler (but the prescale rate does not change). In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).
- The autoreload shadow register is updated with the preload value (TIM_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 566. Counter timing diagram, internal clock divided by 1

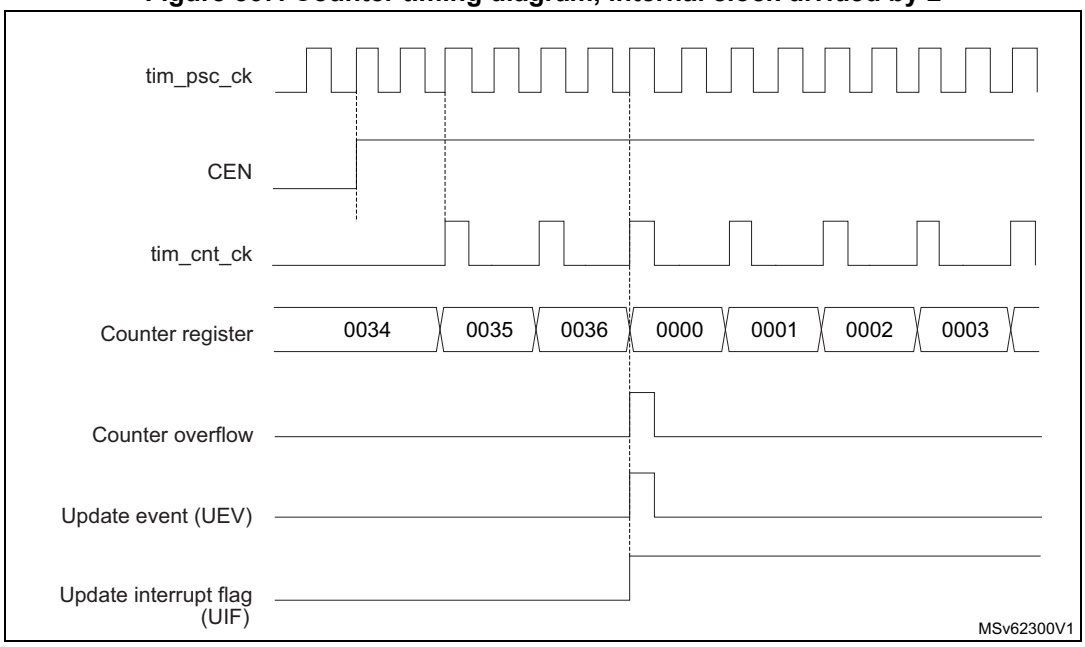

Figure 568. Counter timing diagram, internal clock divided by 4

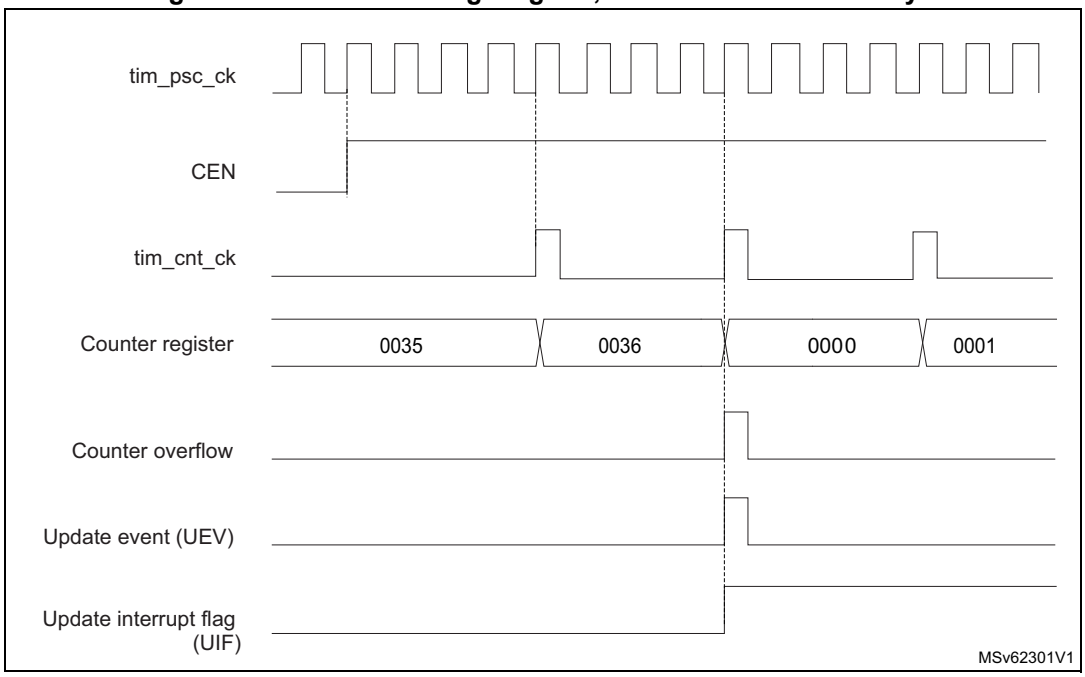

Figure 569. Counter timing diagram, internal clock divided by N

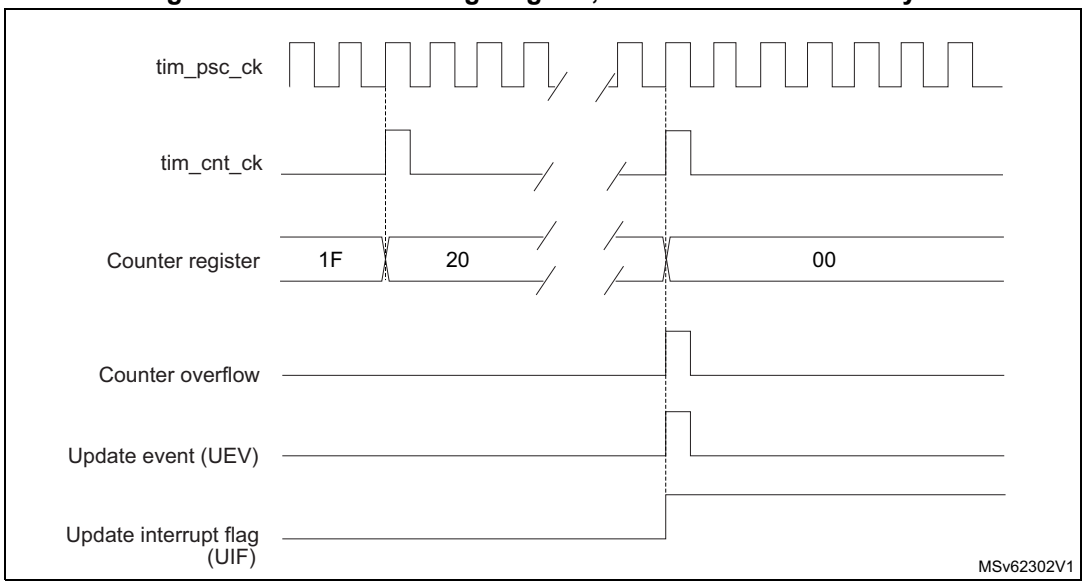

Figure 570. Counter timing diagram, Update event when ARPE = 0 (TIM_ARR not preloaded)

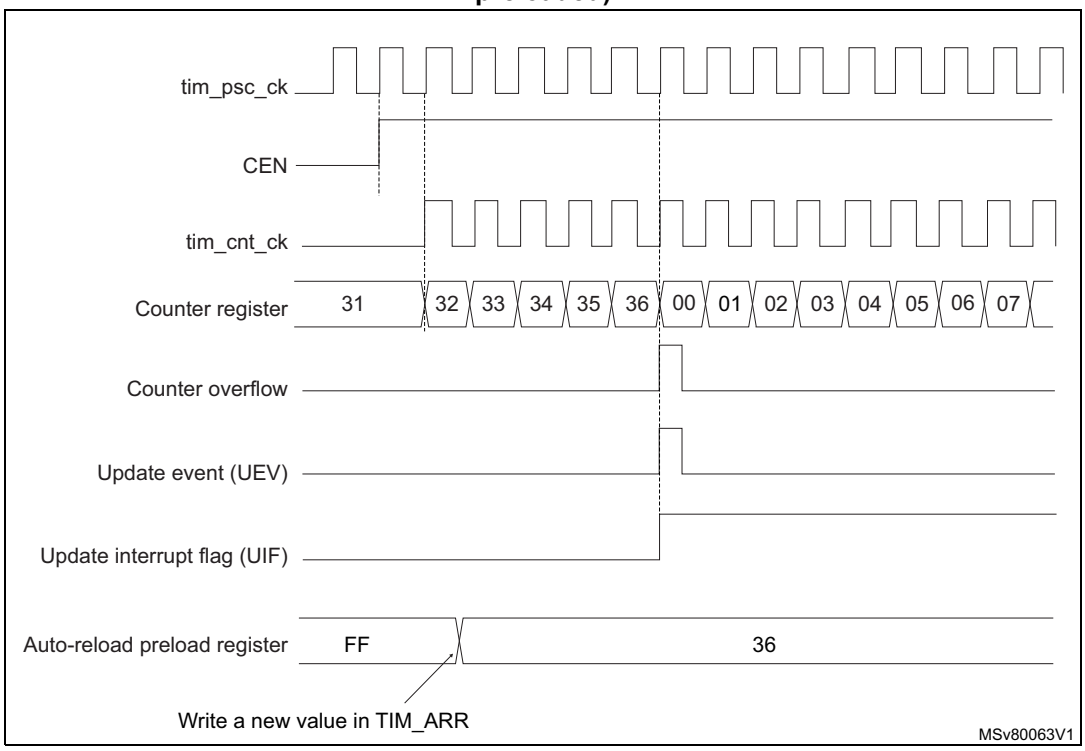

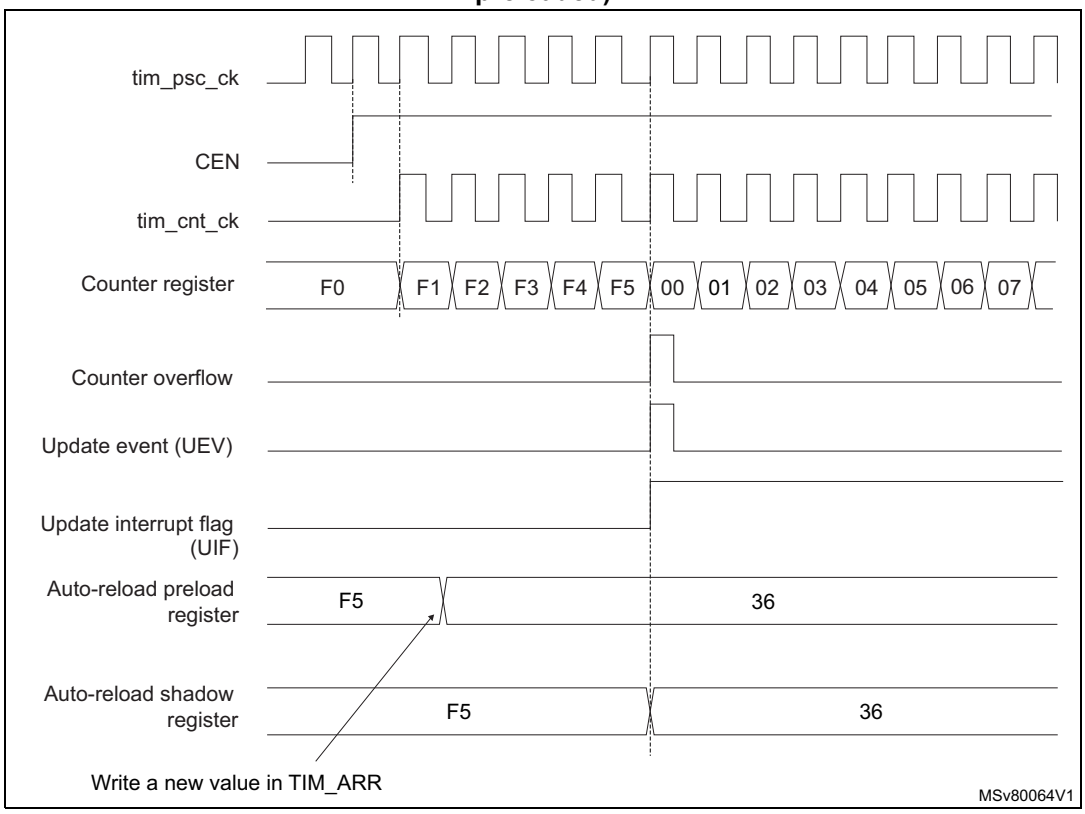

Figure 571. Counter timing diagram, Update event when ARPE = 1 (TIM_ARR preloaded)

Down-counting mode

In down-counting mode, the counter counts from the autoreload value (content of the TIM_ARR register) down to 0, then restarts from the autoreload value and generates a counter underflow event.

An update event can be generated at each counter underflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller)

The UEV update event can be disabled by software by setting the UDIS bit in TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until UDIS bit has been written to 0. However, the counter restarts from the current autoreload value, whereas the counter of the prescaler restarts from 0 (but the prescale rate does not change).

In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that the autoreload is updated before the counter is reloaded, so that the next period is the expected one.

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 572. Counter timing diagram, internal clock divided by 1

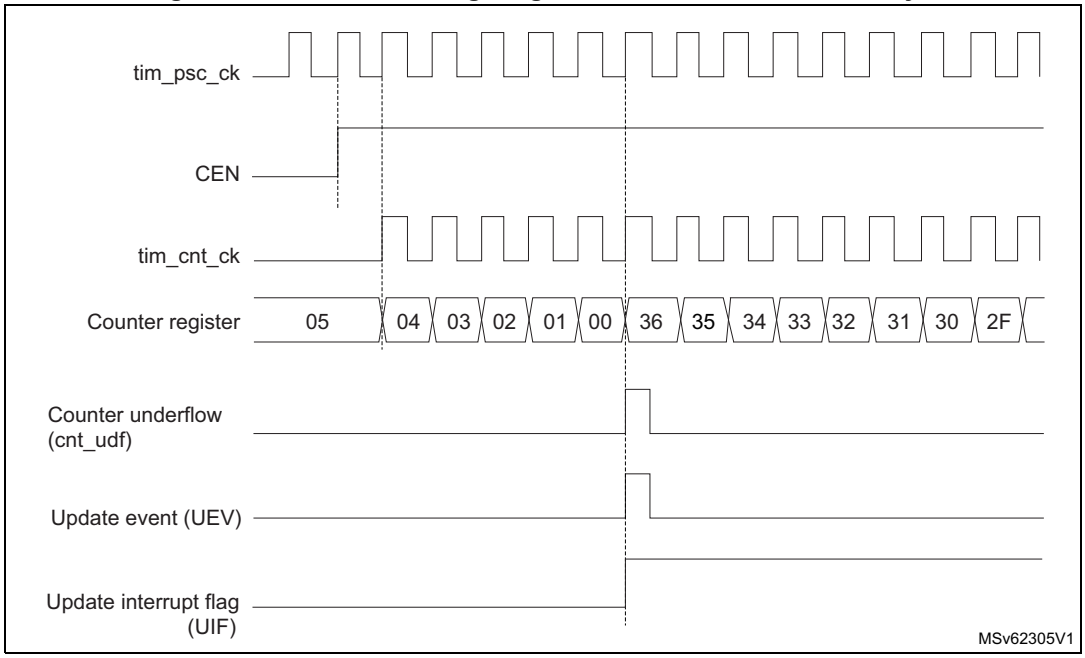

Figure 573. Counter timing diagram, internal clock divided by 2

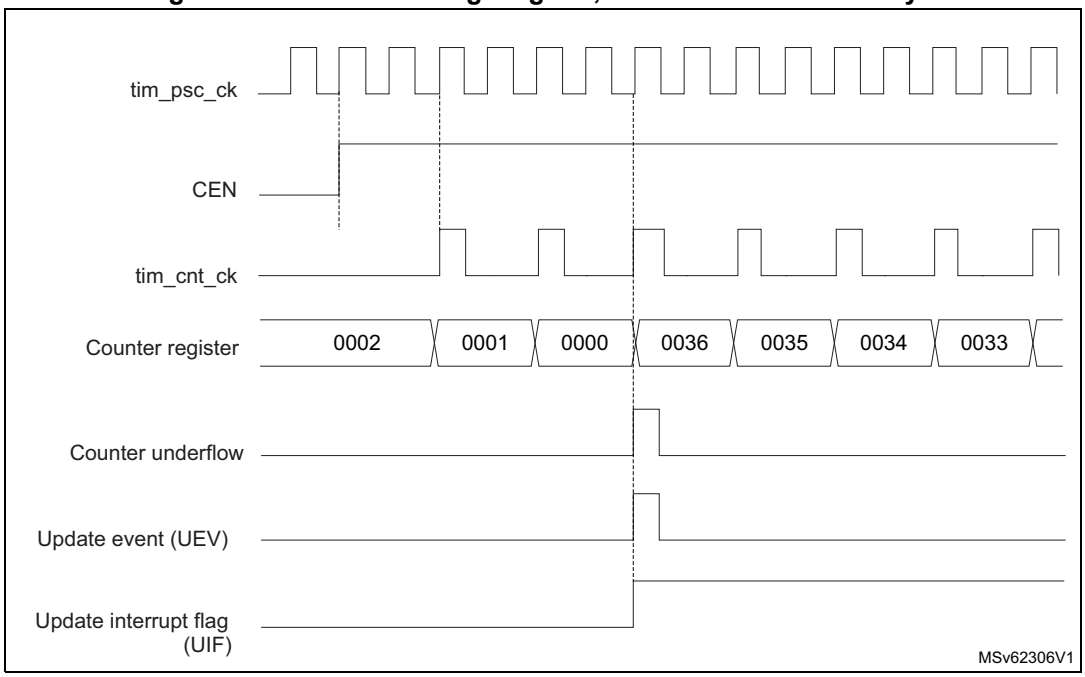

Figure 574. Counter timing diagram, internal clock divided by 4

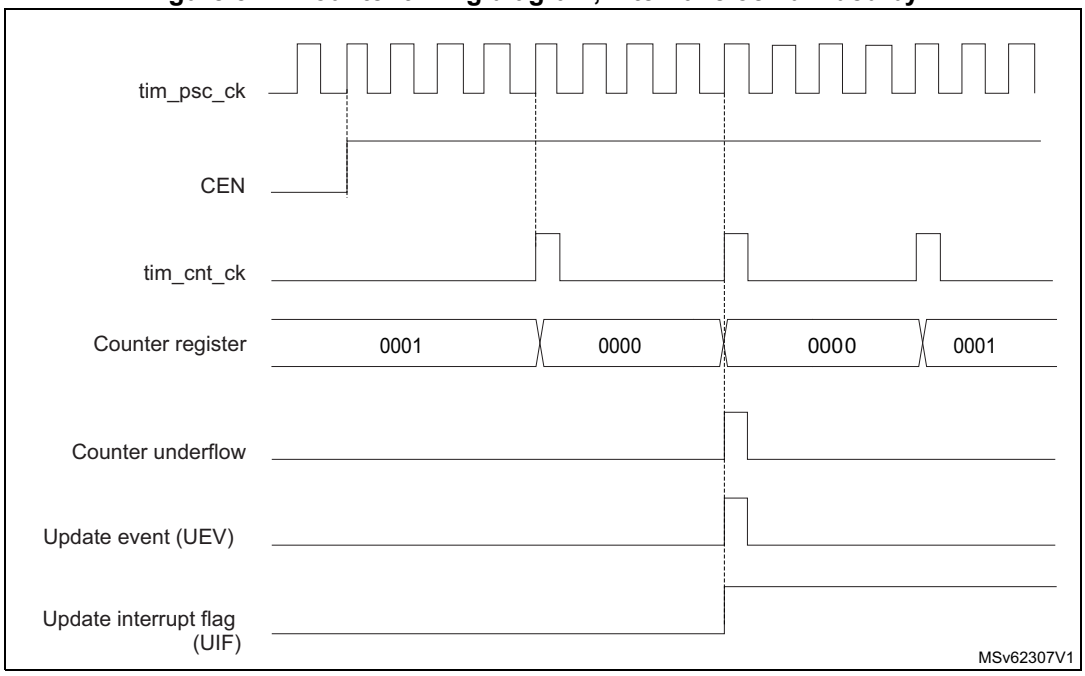

Figure 575. Counter timing diagram, internal clock divided by N

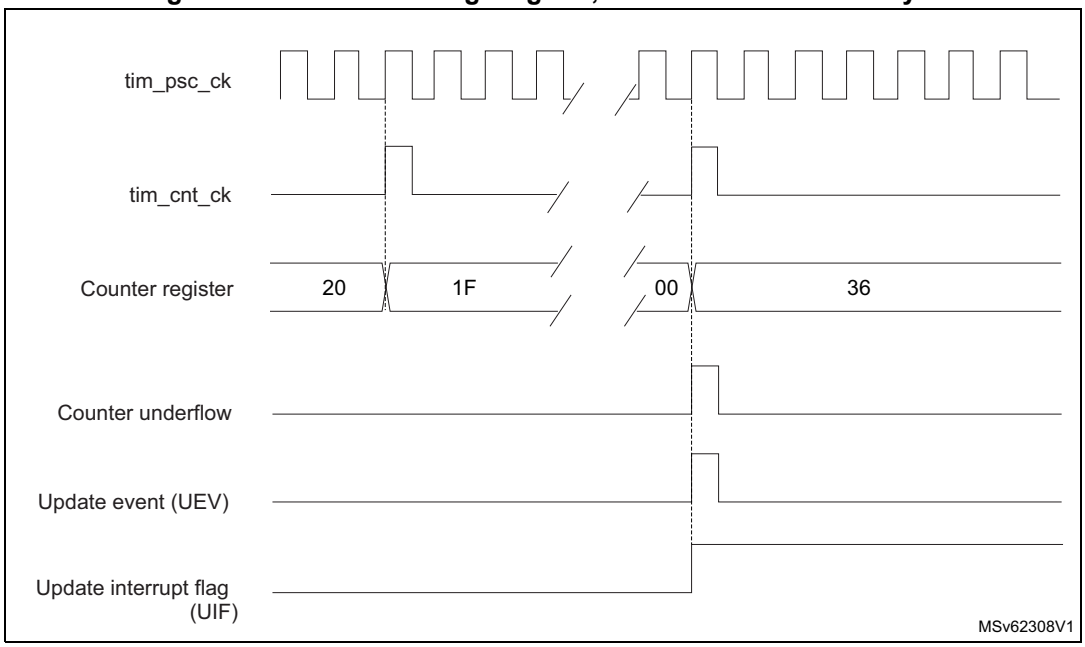

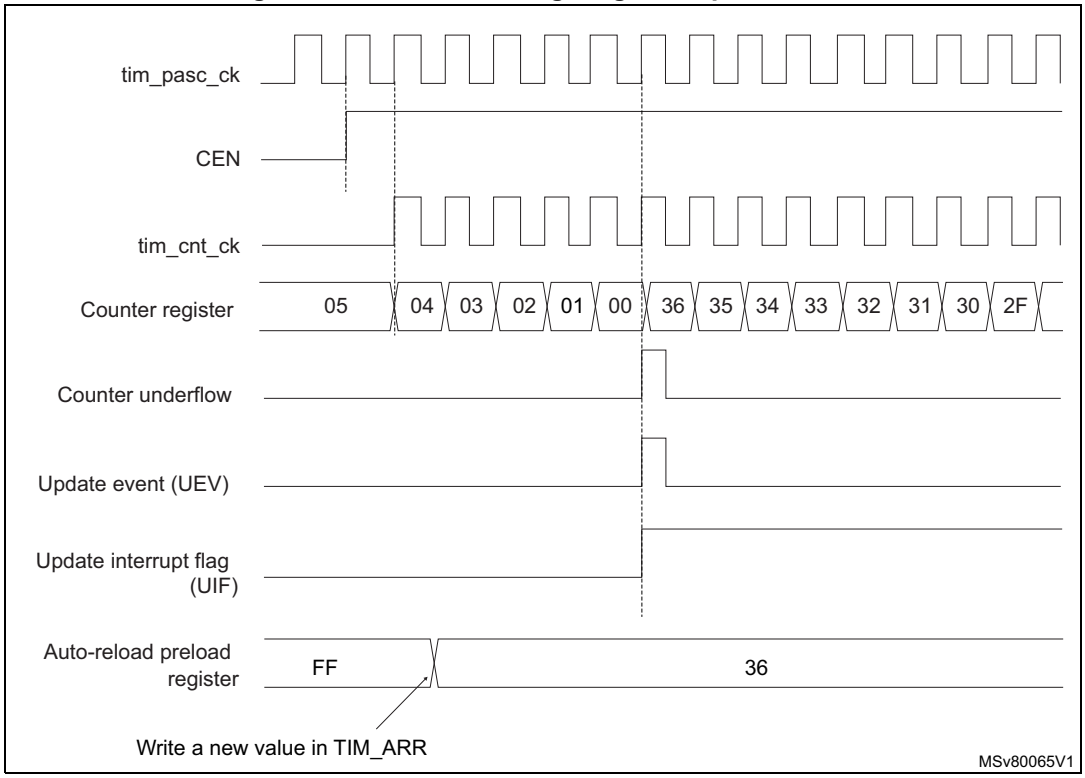

Figure 576. Counter timing diagram, Update event

Center-aligned mode (up/down-counting)

In center-aligned mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register) – 1, generates a counter overflow event, then counts from the

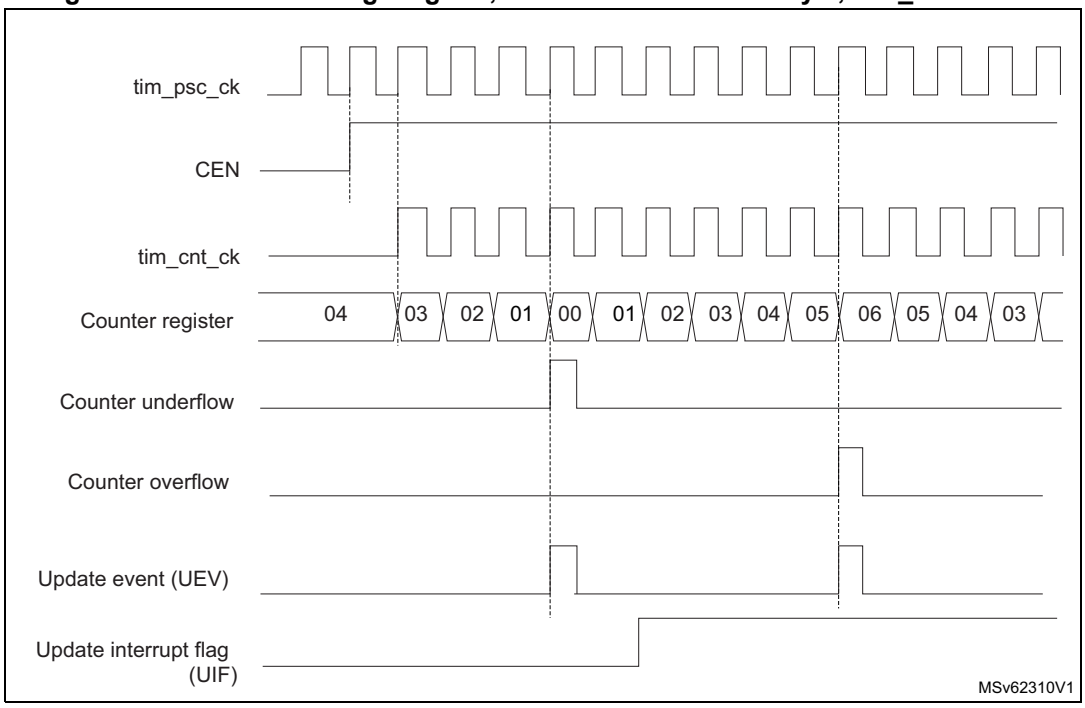
autoreload value down to 1 and generates a counter underflow event. Then it restarts counting from 0.

Center-aligned mode is active when the CMS bits in TIM_CR1 register are not equal to 00. The output compare interrupt flag of channels configured in output is set when: the counter counts down (center aligned mode 1, CMS = 01), the counter counts up (center aligned mode 2, CMS = 10) the counter counts up and down (center aligned mode 3, CMS = 11).

In this mode, the direction bit (DIR from TIM_CR1 register) cannot be written. It is updated by hardware and gives the current direction of the counter.

The update event can be generated at each counter overflow and at each counter underflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller) also generates an update event. In this case, the counter restarts counting from 0, as well as the counter of the prescaler.

The UEV update event can be disabled by software by setting the UDIS bit in TIM_CR1 register. This is to avoid updating the shadow registers while writing new values in the preload registers. Then no update event occurs until the UDIS bit has been written to 0. However, the counter continues counting up and down, based on the current autoreload value.



In addition, if the URS bit (update request selection) in TIM_CR1 register is set, setting the UG bit generates an update event UEV but without setting the UIF flag (thus no interrupt or DMA request is sent). This is to avoid generating both update and capture interrupts when clearing the counter on the capture event.

When an update event occurs, all the registers are updated and the update flag (UIF bit in TIM_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (content of the TIM_PSC register).
- The autoreload active register is updated with the preload value (content of the TIM_ARR register). Note that if the update source is a counter overflow, the autoreload is updated before the counter is reloaded, so that the next period is the expected one (the counter is loaded with the new value).

The following figures show some examples of the counter behavior for different clock frequencies.

Figure 577. Counter timing diagram, internal clock divided by 1, TIM_ARR = 0x6

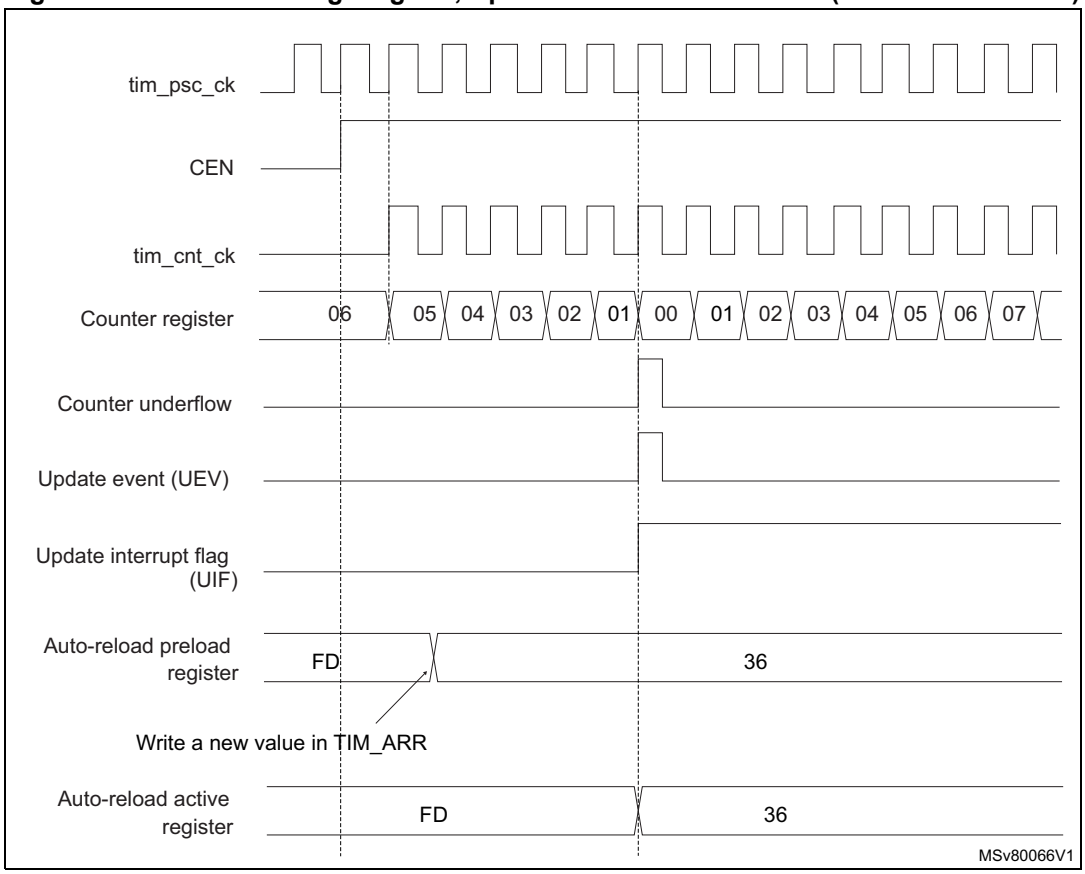

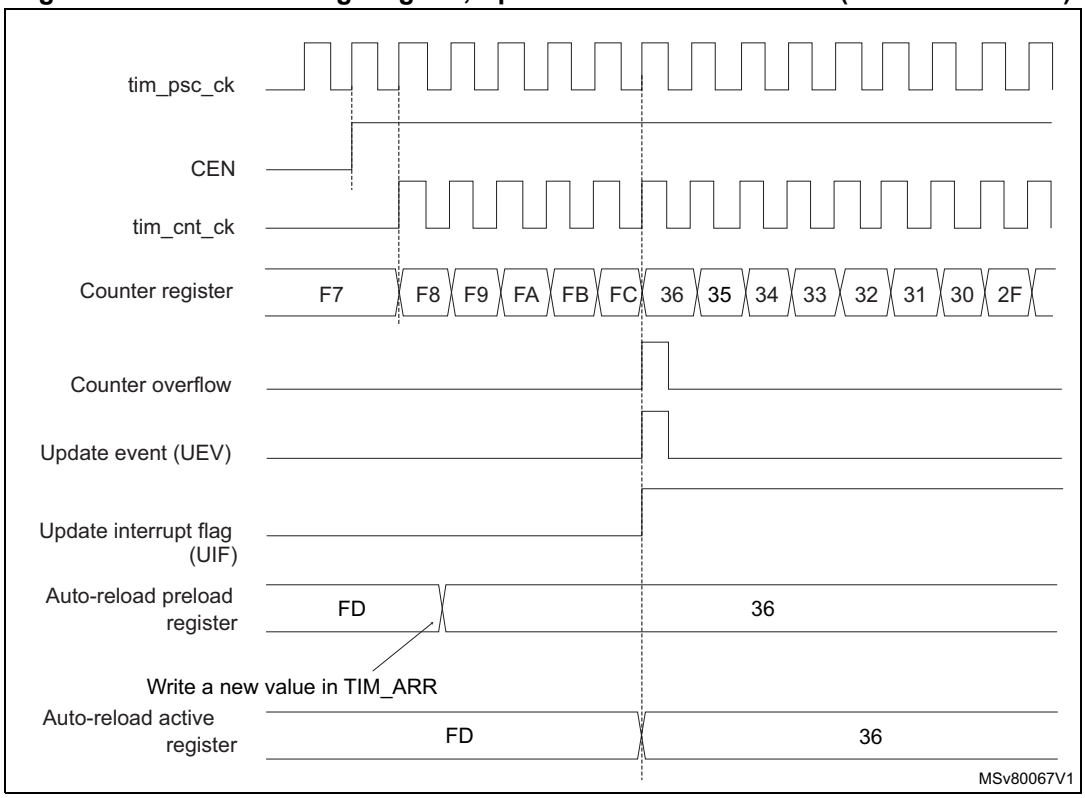

Figure 582. Counter timing diagram, Update event with ARPE = 1 (counter overflow)

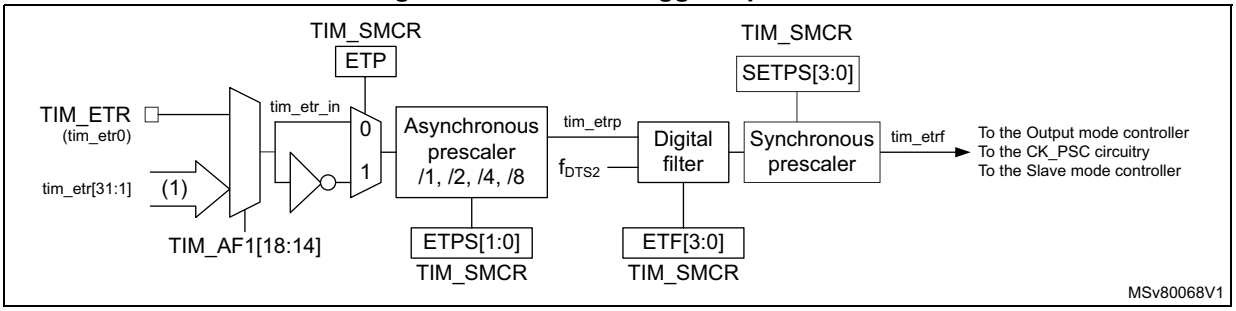


42.4.5 External trigger input

The timer features an external trigger input tim_etr_in. It can be used as:

- external clock (external clock mode 2, see *Section 42.4.6*)
- trigger for the slave mode (see *Section 42.4.27*)
- PWM reset input for cycle-by-cycle current regulation (see *Section 42.4.16*)

Figure 583 below describes the tim_etr_in input conditioning. The input polarity is defined with the ETP bit in TIM_SMCR register. The trigger frequency can be decreased with the prescalers programmed by the ETPS[1:0] and SETPS[3:0] bitfields and digitally filtered as per the ETF[3:0] bitfield. The resulting signal (tim_etrf) is available for three purposes: as an external clock, to condition the output (typically to reset a PWM output for a current limitation), and as a trigger for the slave mode controller.

Figure 583. External trigger input block

The external trigger input block features 2 prescalers with different functionalities:

- An asynchronous prescaler (division by 1, 2, 4 or 8), able to process tim_etr_in signals with frequencies above tim_ker_ck
- A linear synchronous prescaler (division by 1,2,3,..15), only able to operate with tim_etrp signal frequencies below tim_ker_ck/3

Note: When tim_etrf is used as PWM reset input for cycle-by-cycle current regulation (see Section 42.4.16), SETPS[3:0] must be set to 0 (no prescaling).

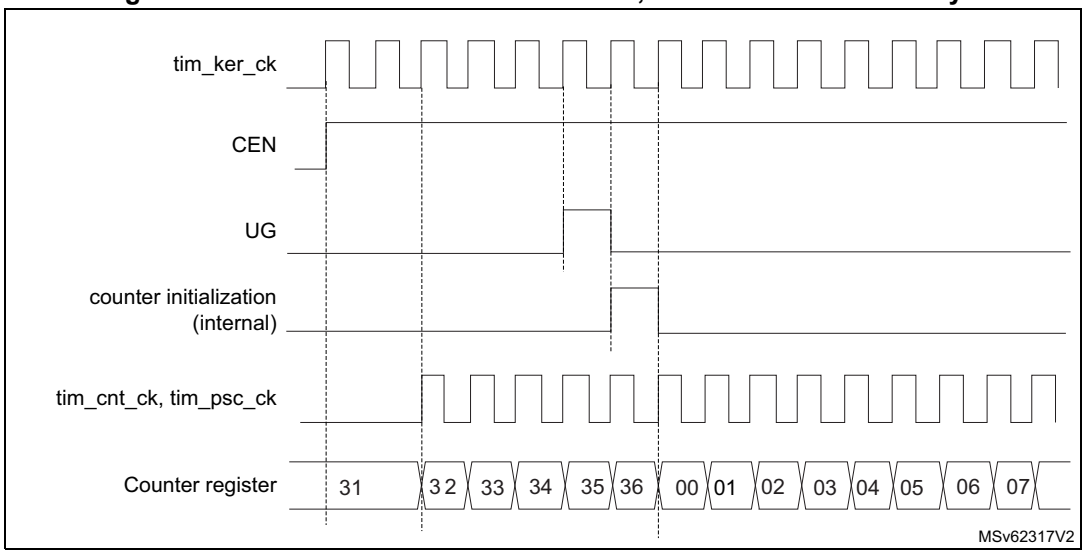
Note: The SETPS[3:0] bitfield is always preloaded: a new value will become active only once an update event has occured.

The tim_etr_in input comes from multiple sources: input pins (default configuration), or internal sources. The selection is done with the ETRSEL[4:0] bitfield in the TIM_AF1 register.

Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for the list of sources connected to the etr_in input in the product.

42.4.6 Clock selection

The counter clock can be provided by the following clock sources:



- Internal clock (tim_ker_ck).
- External clock mode1: external input pin (tim_ti1 or tim_ti2).
- External clock mode2: external trigger input (tim_etr_in).
- Internal trigger inputs (tim_itr): using one timer as prescaler for another timer, for example, timer 1 can be configured to act as a prescaler for timer 2. Refer to *Using one timer as prescaler for another timer* for more details.

Internal clock source (tim_ker_ck)

If the slave mode controller is disabled (SMS = 000 in the TIM_SMCR register), then the CEN, DIR (in the TIM_CR1 register), and UG bits (in the TIM_EGR register) are actual control bits and can be changed only by software (except UG which remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 584 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

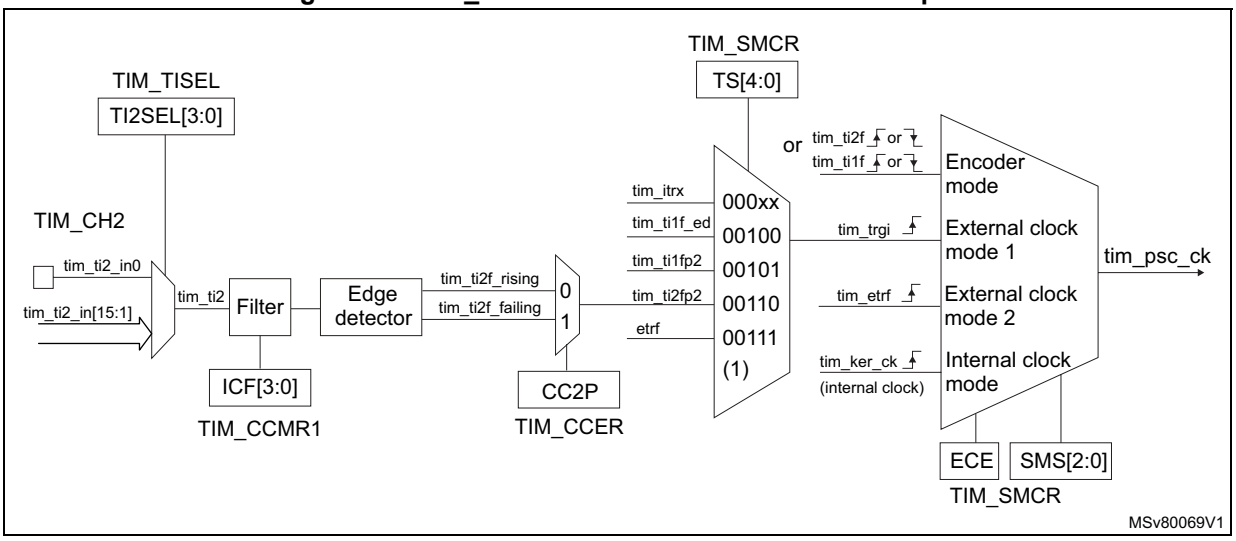


Figure 584. Control circuit in normal mode, internal clock divided by 1

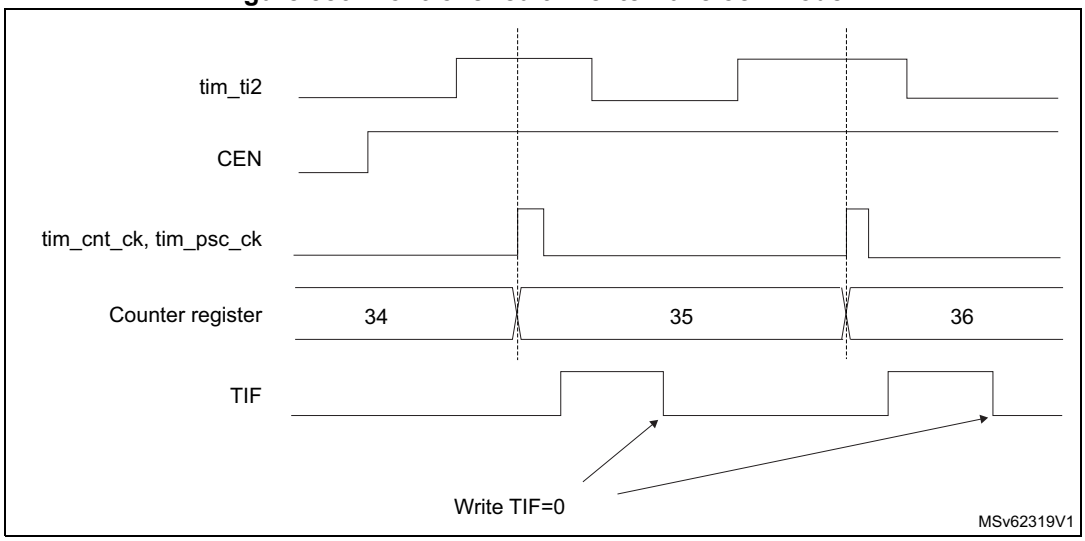
External clock source mode 1

This mode is selected when SMS = 111 in the TIM_SMCR register. The counter can count at each rising or falling edge on a selected input.

Figure 585. tim_ti2 external clock connection example

For example, to configure the upcounter to count in response to a rising edge on the tim_ti2 input, use the following procedure:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIM_TISEL register.
2. Configure channel 2 to detect rising edges on the tim_ti2 input by writing CC2S= 01 in the TIM_CCMR1 register.
3. Configure the input filter duration by writing the IC2F[3:0] bits in the TIM_CCMR1 register (if no filter is needed, keep IC2F = 0000).



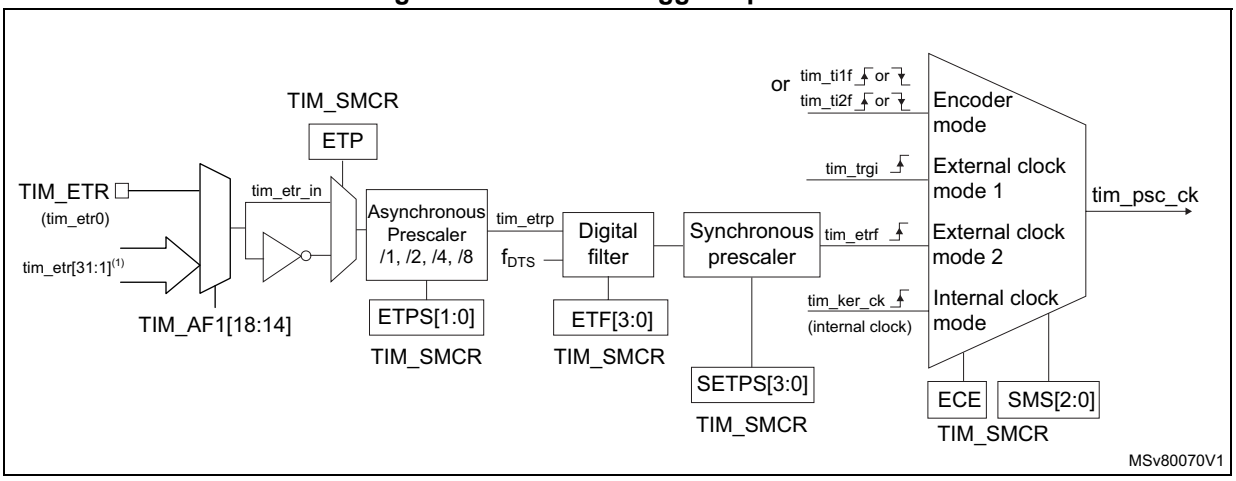
Note: The capture prescaler is not used for triggering, so it does not need to be configured.

4. Select rising edge polarity by writing CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
5. Configure the timer in external clock mode 1 by writing SMS = 111 in the TIM_SMCR register.
6. Select tim_ti2 as the input source by writing TS = 00110 in the TIM_SMCR register.
7. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

When a rising edge occurs on tim_ti2, the counter counts once and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual clock of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 586. Control circuit in external clock mode 1



External clock source mode 2

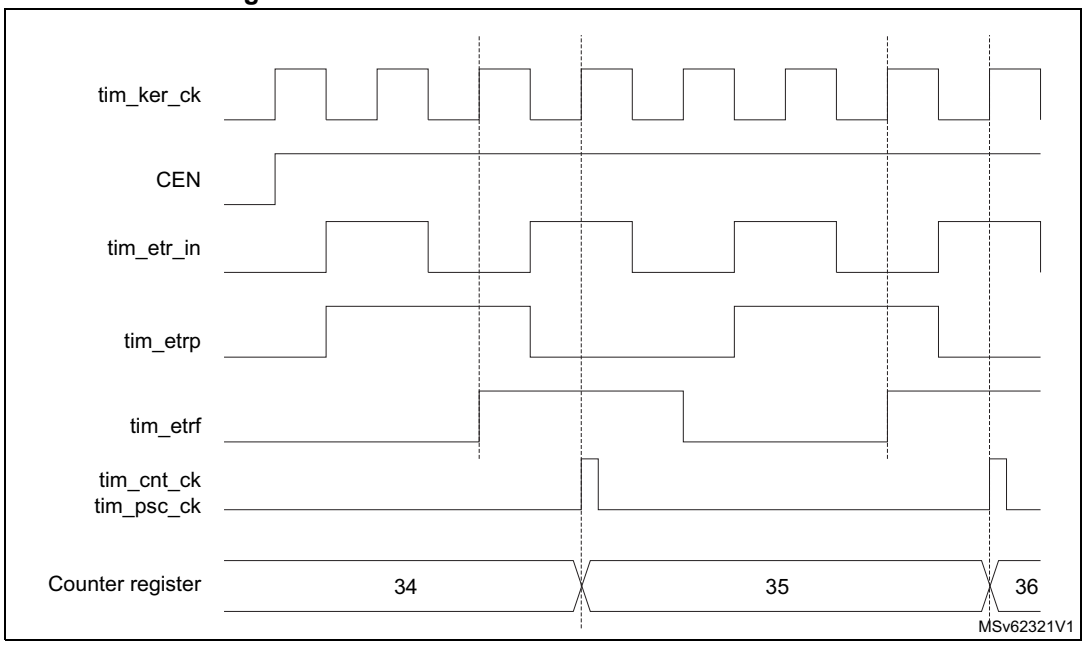
This mode is selected by writing ECE = 1 in the TIM_SMCR register.

The counter can count at each rising or falling edge on the external trigger input tim_etr_in.

Figure 587 gives an overview of the external trigger input block.

Figure 587. External trigger input block

1. Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals*



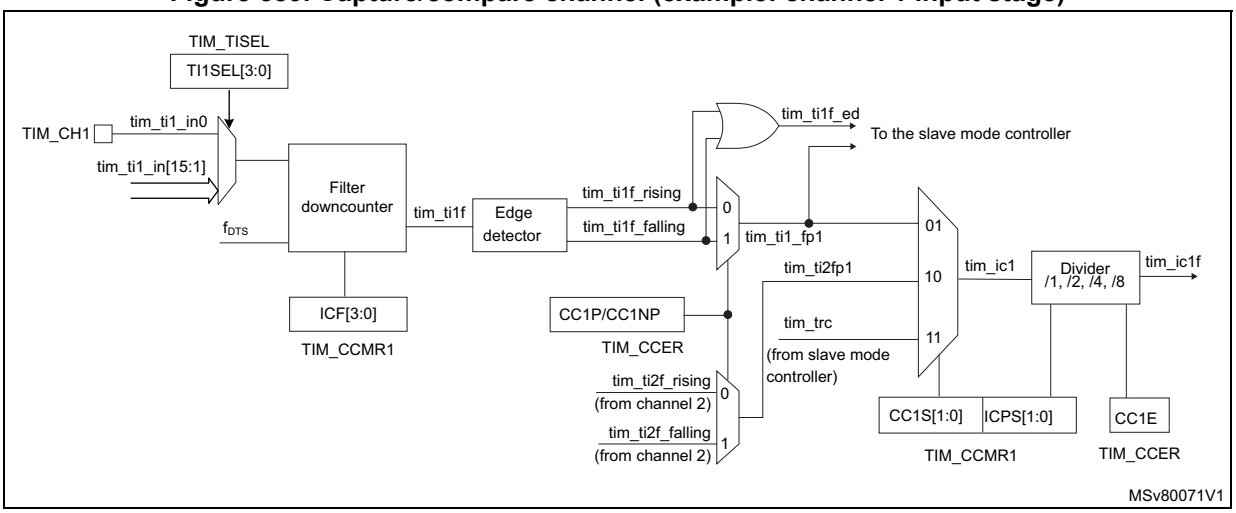
For example, to configure the upcounter to count each two rising edges on tim_etr_in, use the following procedure:

1. Select the proper tim_etr_in source (internal or external) with the ETRSEL[4:0] bits in the TIM_AF1 register.
2. As no filter is needed in this example, write ETF[3:0] = 0000 in the TIM_SMCR register.
3. Set the prescaler by writing ETPS[1:0] = 01 and SETPS[3:0] = 0 in the TIM_SMCR register.
4. Select rising edge detection on the tim_etr_in by writing ETP = 0 in the TIM_SMCR register.
5. Enable external clock mode 2 by writing ECE = 1 in the TIM_SMCR register.
6. Enable the counter by writing CEN = 1 in the TIM_CR1 register.

The counter counts once each two tim_etr_in rising edges.

The delay between the rising edge on tim_etr_in and the actual clock of the counter is due to the resynchronization circuit on the tim_etrp signal. As a consequence, the maximum frequency that can be correctly captured by the counter is at most ¼ of TIMxCLK frequency. When the ETRP signal is faster, the user must apply a division of the external signal by a proper ETPS prescaler setting.

Figure 588. Control circuit in external clock mode 2



42.4.7 Capture/compare channels

Each capture/compare channel is built around a capture/compare register (including a shadow register), an input stage for capture (with digital filter, multiplexing and prescaler) and an output stage (with comparator and output control).

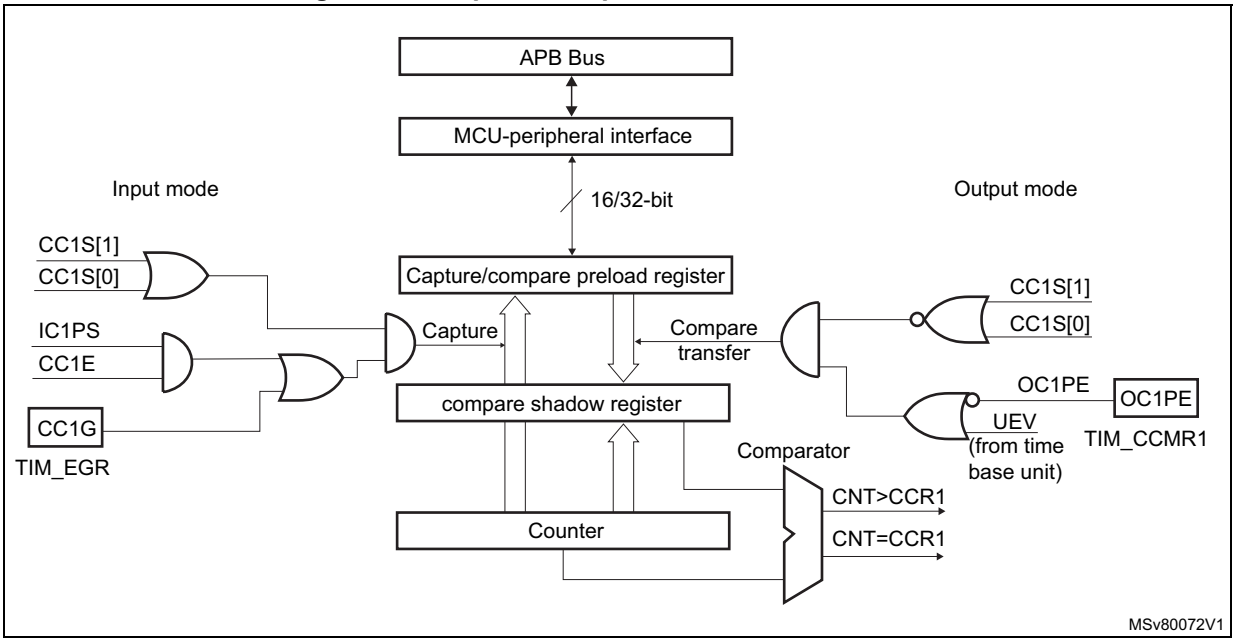
The following figure gives an overview of one capture/compare channel.

The input stage samples the corresponding tim_tix input to generate a filtered signal tim_tixf. Then, an edge detector with polarity selection generates a signal (tim_tixfpy) which can be used as trigger input by the slave mode controller or as the capture command. It is prescaled before the capture register (ICxPS).

Figure 589. Capture/compare channel (example: channel 1 input stage)

The output stage generates an intermediate waveform which is then used for reference: tim_ocxref (active high). The polarity acts at the end of the chain.

Figure 590. Capture/compare channel 1 main circuit



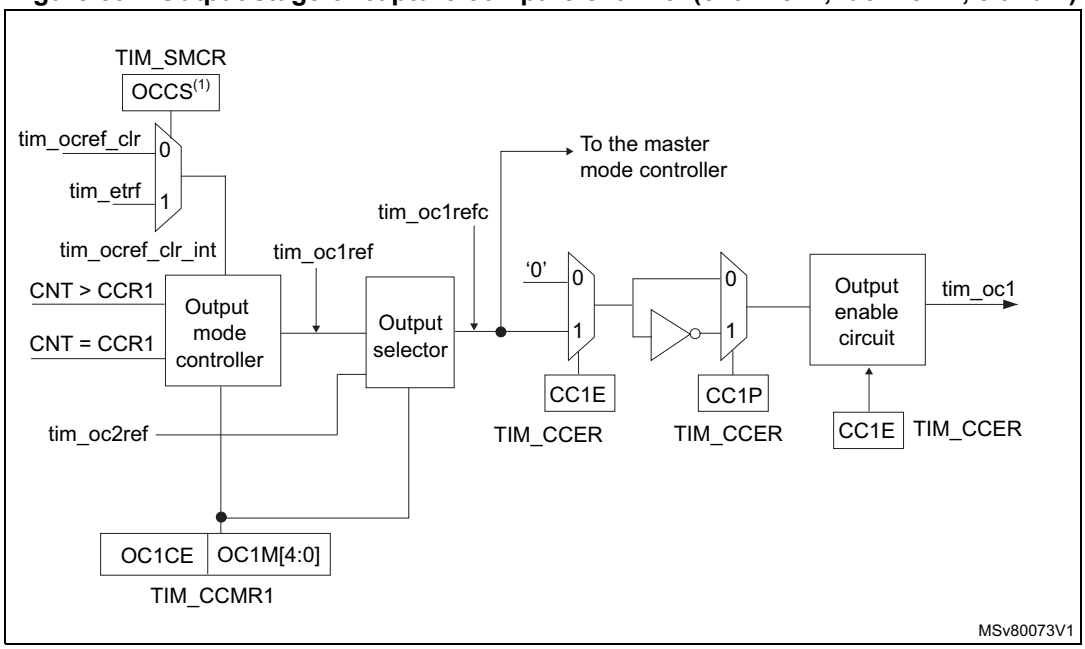


Figure 591. Output stage of capture/compare channel (channel 1, idem ch.2, 3 and 4)

1. Available on some instances only. If not available, tim_etrf is directly connected to tim_ocref_clr_int.

The capture/compare block is made of one preload register and one shadow register. Write and read always access the preload register.

In capture mode, captures are actually done in the shadow register, which is copied into the preload register.

In compare mode, the content of the preload register is copied into the shadow register which is compared to the counter.

42.4.8 Input capture mode

In input capture mode, the capture/compare registers (TIM_CCRx) are used to latch the value of the counter after a transition detected by the corresponding ICx signal. When a capture occurs, the corresponding CCXIF flag (TIM_SR register) is set and an interrupt or a DMA request can be sent if they are enabled. If a capture occurs while the CCxIF flag was already high, then the overcapture flag CCxOF (TIM_SR register) is set. CCxIF can be cleared by software by writing it to 0 or by reading the captured data stored in the TIM_CCRx register. CCxOF is cleared when it is written with 0.

The following example shows how to capture the counter value in TIM_CCR1 when tim_ti1 input rises. To do this, use the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIM_TISEL register.
2. Select the active input: TIM_CCR1 must be linked to the tim_ti1 input, so write the CC1S bits to 01 in the TIM_CCMR1 register. As soon as CC1S becomes different from 00, the channel is configured in input and the TIM_CCR1 register becomes read-only.
3. Program the needed input filter duration in relation with the signal connected to the timer (when the input is one of the tim_tix (ICxF bits in the TIM_CCMRx register). Let's imagine that, when toggling, the input signal is not stable during at most five internal clock cycles. We must program a filter duration longer than these five clock cycles. We can validate a transition on tim_ti1 when eight consecutive samples with the new level have been detected (sampled at f_{DTS} frequency). Then write IC1F bits to 0011 in the TIM_CCMR1 register.
4. Select the edge of the active transition on the tim_ti1 channel by writing the CC1P and CC1NP bits to 000 in the TIM_CCER register (rising edge in this case).
5. Program the input prescaler. In this example, the capture is to be performed at each valid transition, so the prescaler is disabled (write IC1PS bits to 00 in the TIM_CCMR1 register).
6. Enable capture from the counter into the capture register by setting the CC1E bit in the TIM_CCER register.
7. If needed, enable the related interrupt request by setting the CC1IE bit in the TIM_DIER register, and/or the DMA request by setting the CC1DE bit in the TIM_DIER register.

When an input capture occurs:

- The TIM_CCR1 register gets the value of the counter on the active transition.
- CC1IF flag is set (interrupt flag). CC1OF is also set if at least two consecutive captures occurred whereas the flag was not cleared.
- An interrupt is generated depending on the CC1IE bit.
- A DMA request is generated depending on the CC1DE bit.

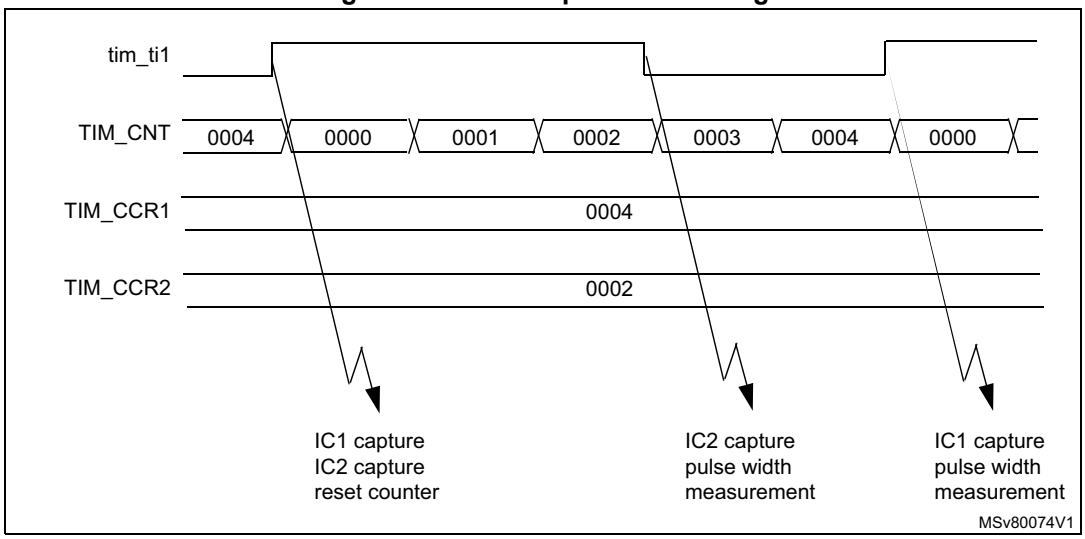
In order to handle the overcapture, it is recommended to read the data before the overcapture flag. This is to avoid missing an overcapture which may happen after reading the flag and before reading the data.

Note: IC interrupt and/or DMA requests can be generated by software by setting the corresponding CCxG bit in the TIM_EGR register.

42.4.9 PWM input mode

This mode is used to measure both the period and the duty cycle of a PWM signal connected to single tim_tix input:

- The TIM_CCR1 register holds the period value (interval between two consecutive rising edges).
- The TIM_CCR2 register holds the pulse width (interval between two consecutive rising and falling edges).



This mode is a particular case of input capture mode. The set-up procedure is similar with the following differences:

- Two ICx signals are mapped on the same tim_tix input.
- These two ICx signals are active on edges with opposite polarity.
- One of the two TIxFP signals is selected as trigger input and the slave mode controller is configured in reset mode.

The period and the pulse width of a PWM signal applied on tim_ti1 can be measured using the following procedure:

1. Select the proper tim_tix_in[15:0] source (internal or external) with the TI1SEL[3:0] bits in the TIM_TISEL register.
2. Select the active input for TIM_CCR1: write the CC1S bits to 01 in the TIM_CCMR1 register (tim_ti1 selected).
3. Select the active polarity for tim_ti1fp1 (used both for capture in TIM_CCR1 and counter clear): write the CC1P to 0 and the CC1NP bit to 0 (active on rising edge).
4. Select the active input for TIM_CCR2: write the CC2S bits to 10 in the TIM_CCMR1 register (tim_ti1 selected).
5. Select the active polarity for tim_ti1fp2 (used for capture in TIM_CCR2): write the CC2P bit to 1 and the CC2NP bit to 0 (active on falling edge).
6. Select the valid trigger input: write the TS bits to 00101 in the TIM_SMCR register (tim_ti1fp1 selected).
7. Configure the slave mode controller in reset mode: write the SMS bits to 100 in the TIM_SMCR register.
8. Enable the captures: write the CC1E and CC2E bits to 1 in the TIM_CCER register.

Figure 592. PWM input mode timing

1. The PWM input mode can be used only with the TIM_CH1/TIM_CH2 signals due to the fact that only tim_ti1fp1 and tim_ti2fp2 are connected to the slave mode controller.

42.4.10 Forced output mode

In output mode (CCxS bits = 00 in the TIM_CCMRx register), each output compare signal (tim_ocxref and then tim_ocx) can be forced to active or inactive level directly by software, independently of any comparison between the output compare register and the counter.

To force an output compare signal (tim_ocxref/tim_ocx) to its active level, the user just needs to write 00101 in the OCxM bits in the corresponding TIM_CCMRx register. Thus tim_ocxref is forced high (tim_ocxref is always active high) and tim_ocx get opposite value to CCxP polarity bit.

For example: CCxP = 0 (tim_ocx active high) => tim_ocx is forced to high level.

tim_ocxref signal can be forced low by writing the OCxM bits to 00100 in the TIM_CCMRx register.

Anyway, the comparison between the TIM_CCRx shadow register and the counter is still performed and allows the flag to be set. Interrupt and DMA requests can be sent accordingly. This is described in the output compare mode section.

42.4.11 Output compare mode

This function is used to control an output waveform or indicating when a period of time has elapsed.

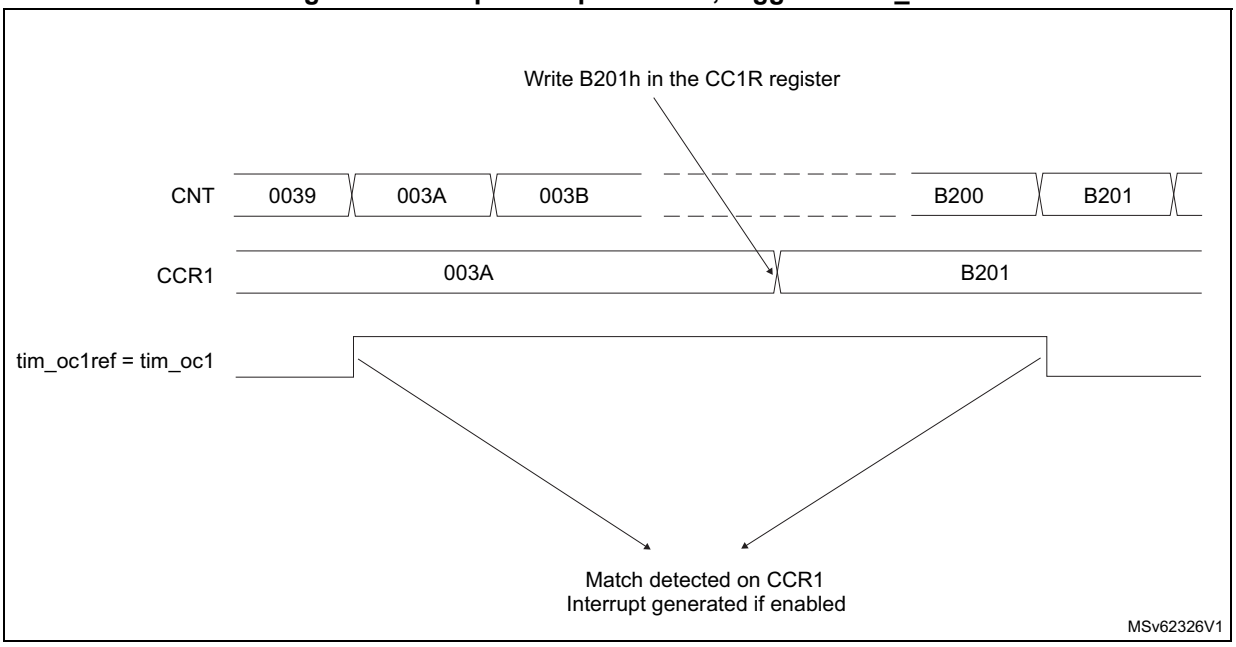
When a match is found between the capture/compare register and the counter, the output compare function:

- Assigns the corresponding output pin to a programmable value defined by the output compare mode (OCxM bits in the TIM_CCMRx register) and the output polarity (CCxP bit in the TIM_CCER register). The output pin can keep its level (OCxM = 00000), be

set active (OCxM = 00001), be set inactive (OCxM = 00010) or can toggle (OCxM = 00011) on match.

- Sets a flag in the interrupt status register (CCxIF bit in the TIM_SR register).
- Generates an interrupt if the corresponding interrupt mask is set (CCXIE bit in the TIM_DIER register).
- Sends a DMA request if the corresponding enable bit is set (CCxDE bit in the TIM_DIER register, CCDS bit in the TIM_CR2 register for the DMA request selection).

The TIM_CCRx registers can be programmed with or without preload registers using the OCxPE bit in the TIM_CCMRx register.



In output compare mode, the update event UEV has no effect on tim_ocxref and tim_ocx output. The timing resolution is one count of the counter. Output compare mode can also be used to output a single pulse (in one-pulse mode).

Procedure

1. Select the counter clock (internal, external, prescaler).
2. Write the desired data in the TIM_ARR and TIM_CCRx registers.
3. Set the CCxIE and/or CCxDE bits if an interrupt and/or a DMA request is to be generated.
4. Select the output mode. For example:
   a) Write OCxM = 00011 to toggle tim_ocx output pin when CNT matches CCRx.
   b) Write OCxPE = 0 to disable preload register.
   c) Write CCxP = 0 to select active high polarity.
   d) Write CCxE = 1 to enable the output.
5. Enable the counter by setting the CEN bit in the TIM_CR1 register.

The TIM_CCRx register can be updated at any time by software to control the output waveform, provided that the preload register is not enabled (OCxPE = 0, else TIM_CCRx shadow register is updated only at the next update event UEV). An example is given in *Figure 593*.

Figure 593. Output compare mode, toggle on tim_oc1

42.4.12 PWM mode

Pulse width modulation mode is used to generate a signal with a frequency determined by the value of the TIM_ARR register and a duty cycle determined by the value of the TIM_CCRx register.

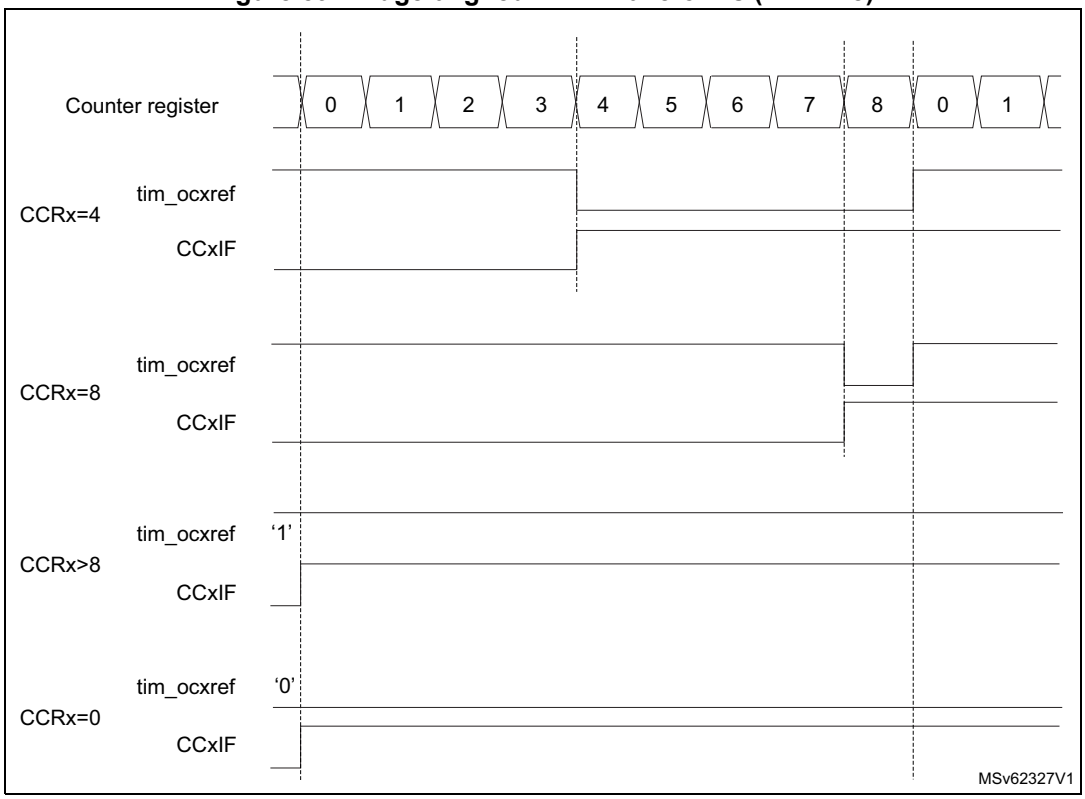
The PWM mode can be selected independently on each channel (one PWM per tim_ocx output) by writing 00110 (PWM mode 1) or 00111 (PWM mode 2) in the OCxM bits in the TIM_CCMRx register. The corresponding preload register must be enabled by setting the OCxPE bit in the TIM_CCMRx register, and eventually the autoreload preload register (in up-counting or center-aligned modes) by setting the ARPE bit in the TIM_CR1 register.

As the preload registers are transferred to the shadow registers only when an update event occurs, before starting the counter, all registers must be initialized by setting the UG bit in the TIM_EGR register.

tim_ocx polarity is software programmable using the CCxP bit in the TIM_CCER register. It can be programmed as active high or active low. tim_ocx output is enabled by the CCxE bit in the TIM_CCER register. Refer to the TIM_CCERx register description for more details.

In PWM mode (1 or 2), TIM_CNT and TIM_CCRx are always compared to determine whether TIM_CCRx ≤ TIM_CNT or TIM_CNT ≤ TIM_CCRx (depending on the direction of the counter). The tim_ocref_clr can be cleared by an external event through the tim_etr_in or the tim_oceref_clr signals. In this case the tim_ocref_clr signal is asserted only:

- After a compare match event.
- When the output compare mode (OCxM bits in TIM_CCMRx register) switches from the “frozen” configuration (no comparison, OCxM = 00000) to one of the PWM modes (OCxM = 00110 or 00111). This forces the PWM by software while the timer is running.



The timer is able to generate PWM in edge-aligned mode or center-aligned mode depending on the CMS bits in the TIM_CR1 register.

PWM edge-aligned mode

- Up-counting configuration
- Up-counting is active when the DIR bit in the TIM_CR1 register is low. Refer to *Up-counting mode*.

  In the following example, we consider PWM mode 1. The reference PWM signal tim_ocxref is high as long as TIM_CNT <TIM_CCRx else it becomes low. If the compare value in TIM_CCRx is greater than the autoreload value (in TIM_ARR) then tim_ocxref is held at 1. If the compare value is 0 then tim_ocxref is held at 0. *Figure 594* shows some edge-aligned PWM waveforms in an example where TIM_ARR = 8.

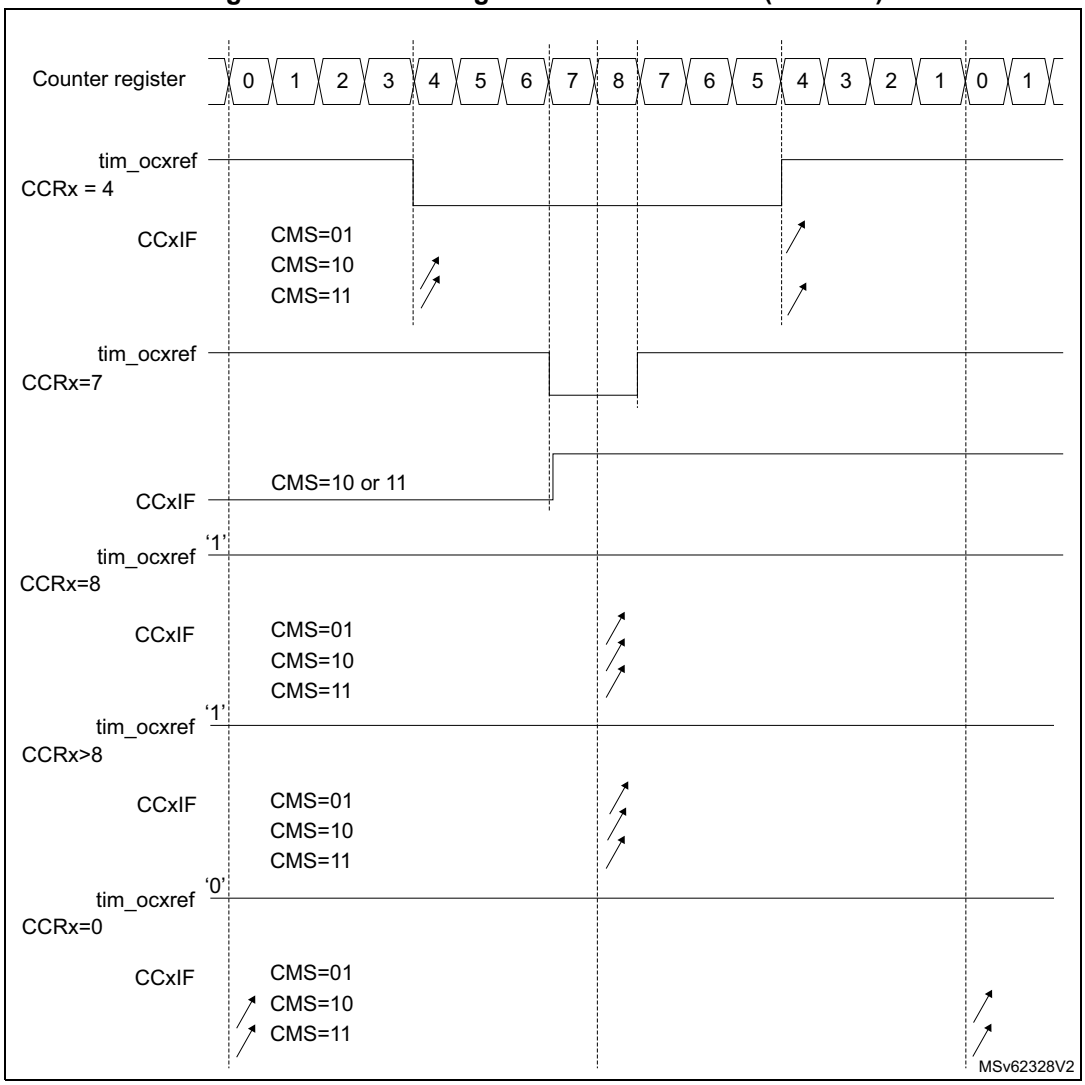
Figure 594. Edge-aligned PWM waveforms (ARR = 8)

Down-counting configuration

- Down-counting is active when DIR bit in TIM_CR1 register is high. Refer to *Down-counting mode*.

  In PWM mode 1, the reference signal tim_ocxref is low as long as TIM_CNT>TIM_CCRx else it becomes high. If the compare value in TIM_CCRx is greater than the autoreload value in TIM_ARR, then tim_ocxref is held at 100%. PWM is not possible in this mode.

PWM center-aligned mode



Center-aligned mode is active when the CMS bits in TIM_CR1 register are different from 00 (all the remaining configurations having the same effect on the tim_ocxref/tim_ocx signals). The compare flag is set when the counter counts up, when it counts down or both when it counts up and down depending on the CMS bits configuration. The direction bit (DIR) in the

TIM_CR1 register is updated by hardware and must not be changed by software. Refer to *Center-aligned mode (up/down-counting)*.

Figure 595 shows some center-aligned PWM waveforms in an example where:

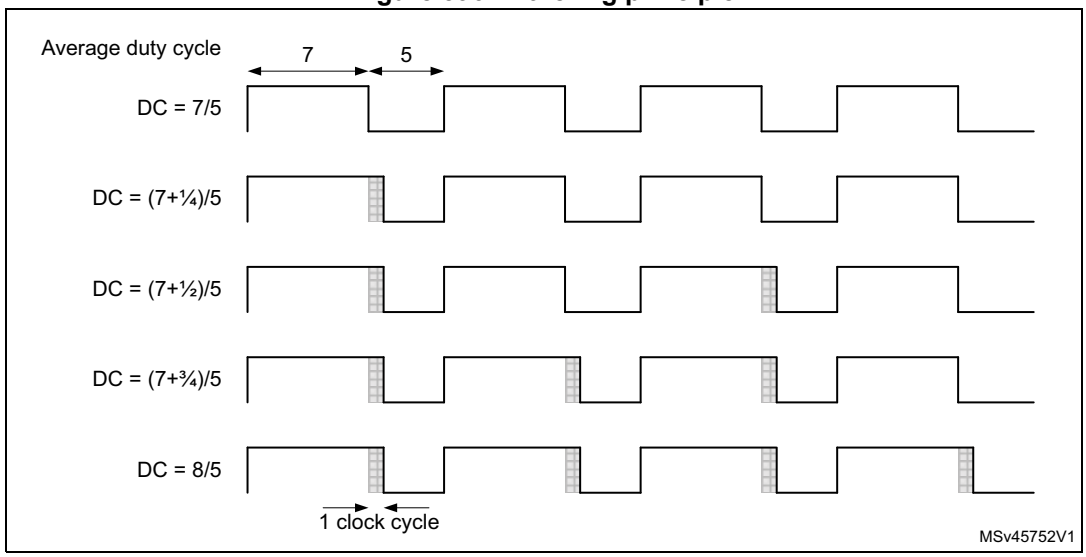
- TIM_ARR = 8.
- PWM mode is the PWM mode 1.
- The flag is set when the counter counts down corresponding to the center-aligned mode 1 selected for CMS = 01 in TIM_CR1 register.

Figure 595. Center-aligned PWM waveforms (ARR = 8)

Hints on using center-aligned mode:

- When starting in center-aligned mode, the current up-down configuration is used. It means that the counter counts up or down depending on the value written in the DIR bit

in the TIM_CR1 register. Moreover, the DIR and CMS bits must not be changed at the same time by the software.



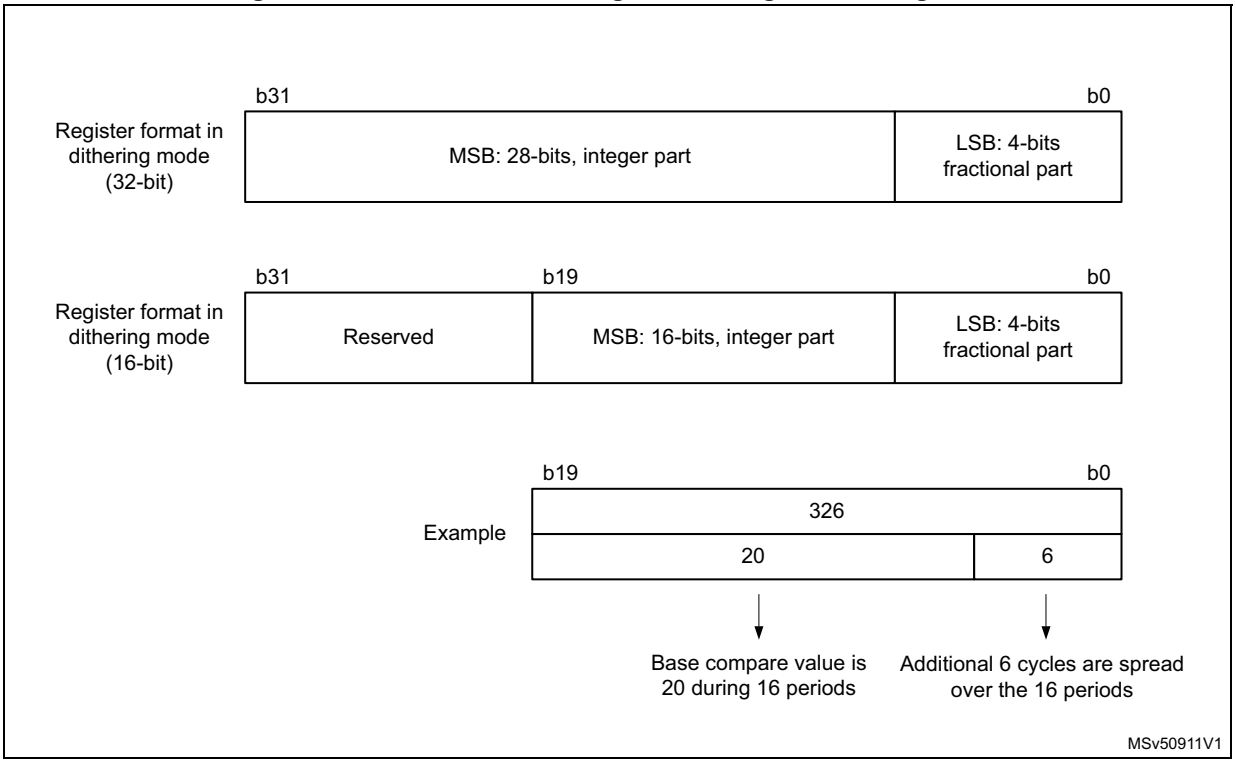
- Writing to the counter while running in center-aligned mode is not recommended as it can lead to unexpected results. In particular:
  - The direction is not updated if a value greater than the autoreload value is written in the counter (TIM_CNT>TIM_ARR). For example, if the counter was counting up, it continues to count up.
  - The direction is updated if 0 or the TIM_ARR value is written in the counter but no update event UEV is generated.
- The safest way to use center-aligned mode is to generate an update by software (setting the UG bit in the TIM_EGR register) just before starting the counter and not to write the counter while it is running.

Dithering mode

The PWM mode effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIM_CR1 register. This applies to both the CCR (for duty cycle resolution increase) and ARR (for PWM frequency resolution increase).

The operating principle is to have the actual CCR (or ARR) value slightly changed (adding or not one timer clock period) over 16 consecutive PWM periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average duty cycle or PWM period. *Figure 596* presents the dithering principle applied to four consecutive PWM cycles.

Figure 596. Dithering principle



When the dithering mode is enabled, the register coding is changed as following (see *Figure 597* for example):

- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted by four places and are coding for the base value. In 16-bit mode, the 16-bit format is maintained.

Note: The following sequence must be followed when resetting the DITHEN bit:

1. *CEN and ARPE bits must be reset.*
2. *The DITHEN bit must be reset.*
3. *The CCIF flags must be cleared.*
4. *The CEN bit can be set (eventually with ARPE = 1).*

Figure 597. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$

$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode (16-bit timer): } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

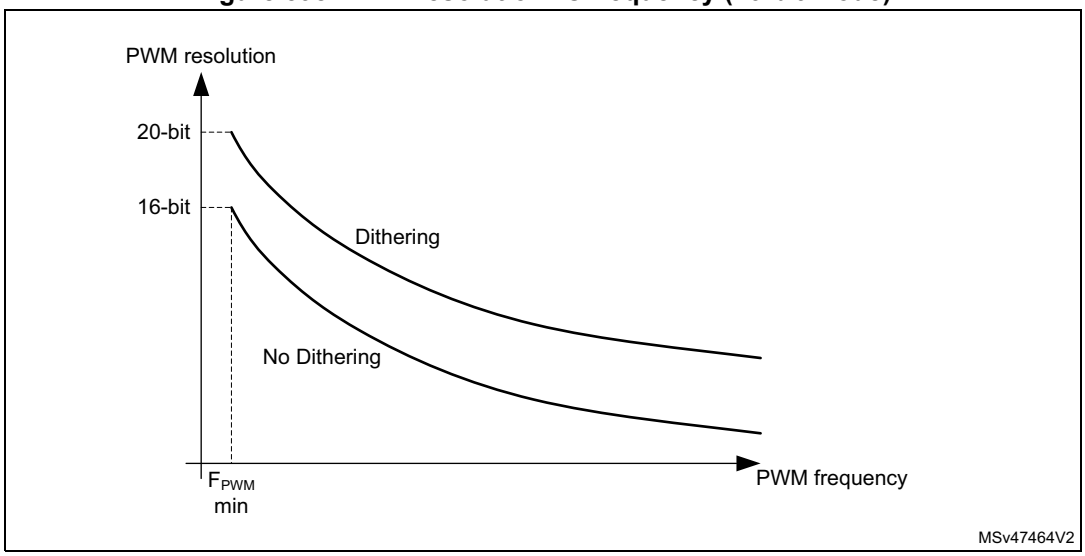
$$\text{Dithering mode (32-bit timer): } F_{pwmMin} = \frac{F_{Tim}}{268435454 + \frac{15}{16}}$$

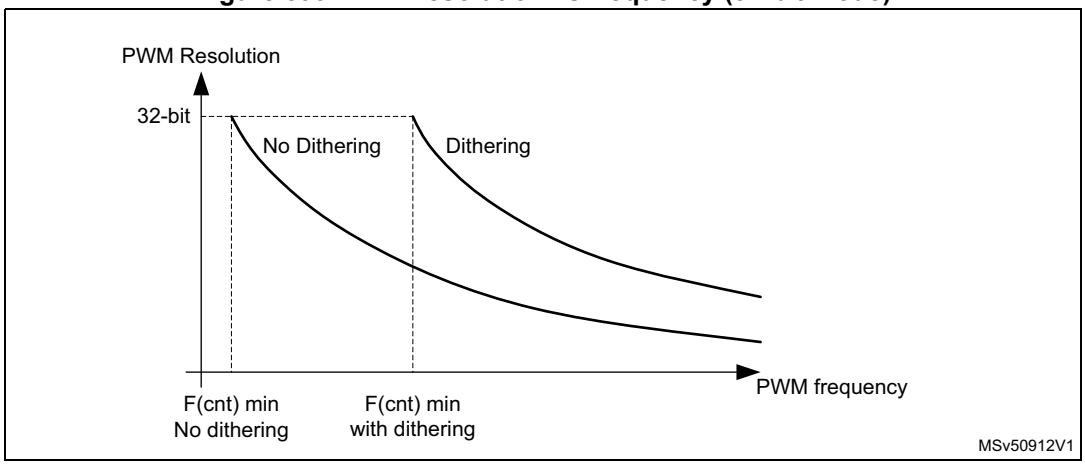
Note: For 16-bit timers, the maximum TIM_ARR and TIM_CCRy values are limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part). For 32-bit timers, the maximum TIM_ARR and TIM_CCRy values are limited to

0xFFFFFFEF in dithering mode (corresponds to 264435454 for the integer part and 15 for the dithered part).

As shown on *Figure 598* and *Figure 599*, the dithering mode is used to increase the PWM resolution.

Figure 598. PWM resolution vs frequency (16-bit mode)





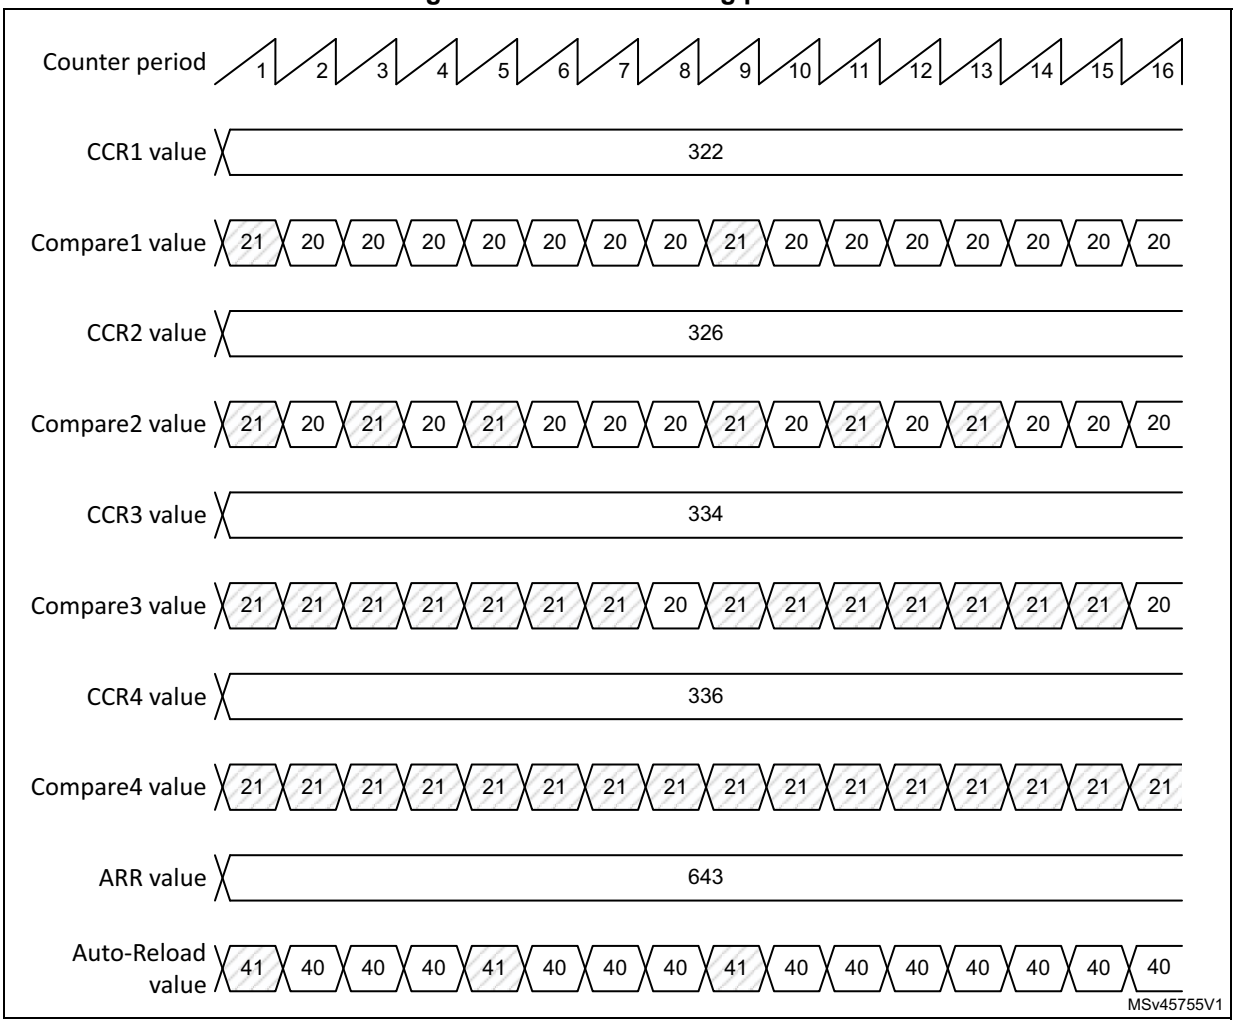


Figure 599. PWM resolution vs frequency (32-bit mode)

The duty cycle and/or period changes are spread over 16 consecutive periods, as described in *Figure 600*.

Figure 600. PWM dithering pattern

The autoreload and compare values increments are spread following specific patterns described in *Table 485*. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 485. CCR and ARR register change dithering pattern

LSB value	PWM period															
	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16
0000	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

42.4.13 Asymmetric PWM mode

Asymmetric mode allows two center-aligned PWM signals to be generated with a programmable phase shift. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and the phase-shift are determined by a pair of TIM_CCRx registers. One register controls the PWM during up-counting, the second during down-counting, so that PWM is adjusted every half PWM cycle, for instance:

- tim_oc1refc is controlled by TIM_CCR1 and TIM_CCR2.
- tim_oc3refc is controlled by TIM_CCR3 and TIM_CCR4.

Figure 602 shows an example of signals that can be generated using asymmetric PWM mode (channels 1 to 4 are configured in asymmetric PWM mode 2).

Figure 602. Generation of two phase-shifted PWM signals with 50% duty cycle

Multiple asymmetric PWM modes are available to combine different pairs of TIM_CCRx registers and generate the required waveform, as listed in *Table 487*. The selection is done with the OCxM[4:0] bitfield in TIM_CCMRx registers. For each pair of TIM_CCRx registers, two options are given (e.g. Asymmetric PWM mode 1 and 2), one being in PWM mode 1 (channel active as long as the counter is below the TIM_CCRx value), the other one in PWM mode 2 (channel active when the counter is above the TIM_CCRx value).

For the asymmetric PWM modes 1 and 2, it is mandatory to have the same PWM mode for both channels. For instance, it is mandatory to have OC1M[4:0] = OC2M[4:0] = 01110 for the asymmetric PWM mode 1 on oc1refc.

For the asymmetric PWM modes 7 to 10, it is mandatory to have opposite PWM mode for both channels (one being in PWM mode 1 and the other in PWM mode 2). Refer to *Table 487* for configuration.

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

When a given channel is used as asymmetric PWM channel, its secondary channel can also be used. For instance, if an tim_oc1refc signal is generated on channel 1 (Asymmetric PWM mode 1), it is possible to output either the regular tim_oc2ref signal on channel 2, or an tim_oc2refc signal resulting from asymmetric PWM mode 2.

Table 487. Asymmetric PWM modes(1)

Output compare mode	OCxM[4:0]	oc1refc	oc2refc	oc3refc	oc4refc	PWM Mode(2)
Asymmetric PWM mode 1	01110	oc1ref (up-counting) oc2ref (down-counting)		oc3ref (up-counting) oc4ref (down-counting)		1
Asymmetric PWM mode 2	01111					2
Asymmetric PWM mode 7	10110	-	-	oc3refc = 1 (up-counting) oc3ref OR oc4ref (down-counting)	-	1(3)
Asymmetric PWM mode 8	10111	-	-	oc3refc = 0 (up-counting) oc3ref AND oc4ref (down-counting)	-	2(4)
Asymmetric PWM mode 9	11000	-	-	oc3ref OR oc4ref (up-counting) oc3refc = 1 (down-counting)	-	1(3)
Asymmetric PWM mode 10	11001	-	-	oc3ref AND oc4ref (up-counting) oc3refc = 0 (down-counting)	-	2(4)

1. Asymmetric PWM mode 7 to 10 are only available on OC3M.

2. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value. PWM mode 2: channel active when the counter is above the TIM_CCRx value. Unless explicitly mentioned, the PWM mode must be identical for the two channels used for the asymmetric mode.
3. oc4ref must be programmed in PWM mode 1.
4. oc4ref must be programmed in PWM mode 2.

42.4.14 Combined PWM mode

Combined PWM mode allows two edge or center-aligned PWM signals to be generated with programmable delay and phase shift between respective pulses. While the frequency is determined by the value of the TIM_ARR register, the duty cycle and delay are determined by the two TIM_CCRx registers. The resulting signals, tim_ocxrefc, are made of an OR or AND logical combination of two reference PWMs,

- tim_oc1refc (or tim_oc2refc) is controlled by TIM_CCR1 and TIM_CCR2
- tim_oc3refc (or tim_oc4refc) is controlled by TIM_CCR3 and TIM_CCR4

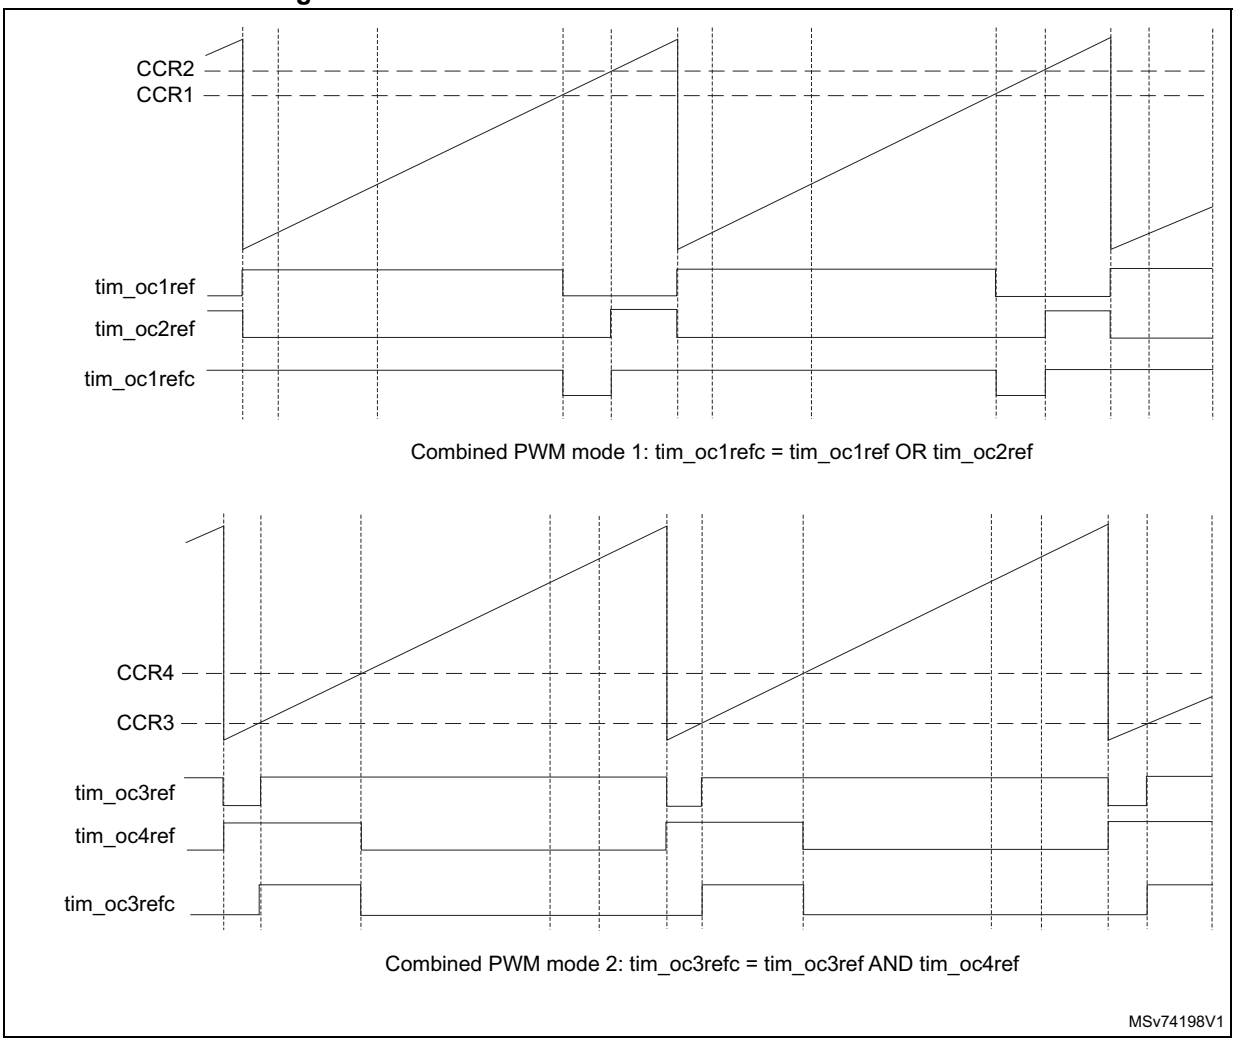
Table 488 summarizes different combinations of PWM combined mode:

Table 488. Combined PWM mode overview

Output compare mode	OCxM[4:0]	oc1refc	oc2refc	oc3refc	oc4refc	PWM mode(1)
Combined PWM mode 1	01100	oc1ref OR oc2ref		oc3ref OR oc4ref		1
Combined PWM mode 2	01101	oc1ref AND oc2ref		oc3ref AND oc4ref		2

1. PWM mode 1: channel active as long as the counter is below the TIM_CCRx value). PWM mode 2: channel active when the counter is above the TIM_CCRx value.

Combined PWM mode can be selected independently on two channels (one tim_ocx output per pair of CCR registers) by writing 01100 (combined PWM mode 1) or 01101 (combined PWM mode 2) in the OCxM bits in the TIM_CCMRx register.



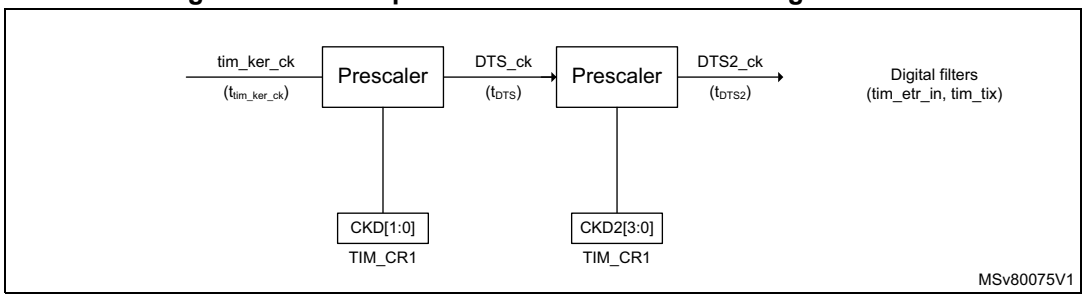
When a given channel is used as combined PWM channel, its secondary channel must be configured in the opposite PWM mode (for instance, one in PWM mode 1 and the other in PWM mode 2).

Note: The OCxM[4:0] bitfield is split into two parts for compatibility reasons, the most significant bits are not contiguous with the three least significant ones.

Figure 603 shows an example of signals that can be generated using combined PWM mode, obtained with the following configuration:

- Channel 1 is configured in combined PWM mode 1.
- Channel 2 is configured in PWM mode 2.
- Channel 3 is configured in combined PWM mode 2.
- Channel 4 is configured in PWM mode 1.

Figure 603. Combined PWM mode on channels 1 and 3

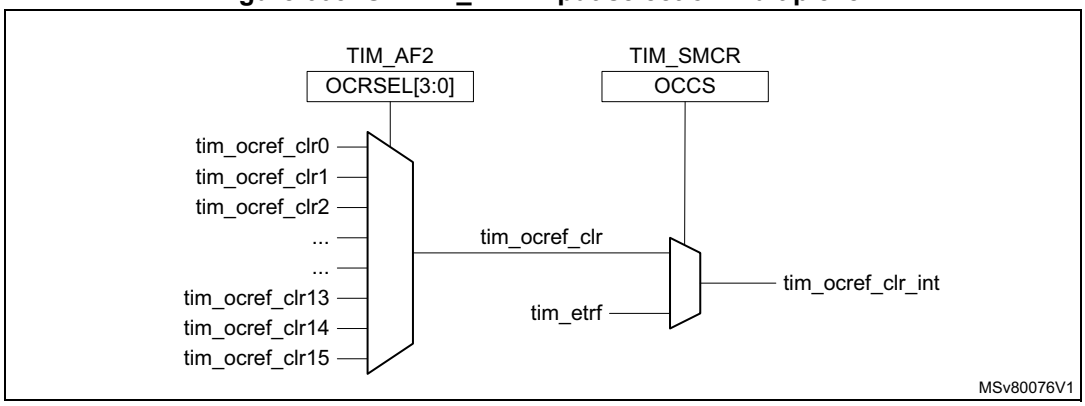


42.4.15 Clock dividers for dead-time generators and digital filters

The digital filters (for tim_etr_in, tim_tix) use a DTS_ck clock (with a t_{DTS} period), derived from the tim_ker_ck clock.

A prescaler can decrease the frequency to extend the DTS_ck clock period programmed with the CKD[1:0] bitfield in the TIM_CR1 register. A second prescaler can decrease the resulting DTS_ck clock to extend the digital filters range, with the CKD2[3:0] bitfield in the TIM_CR1 register.

Figure 604. Clock prescalers for dead-time and digital filters



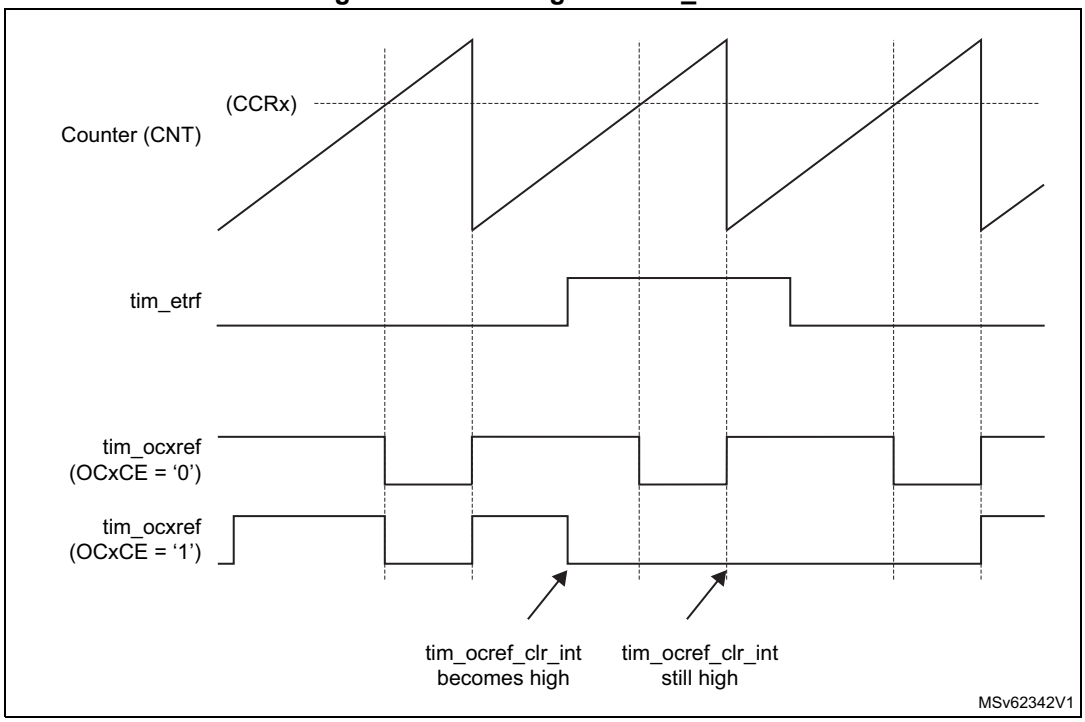
42.4.16 Clearing the tim_ocxref signal on an external event

The tim_ocxref signal of a given channel can be cleared when a high level is applied on the tim_ocref_clr_int input (OCxCE enable bit in the corresponding TIM_CCMRx register set to 1). tim_ocxref remains low until the next transition to the active state, on the following PWM cycle. This function can only be used in output compare and PWM modes. It must not be used in forced mode.

The tim_ocref_clr_int source depends on the OCREF clear selection feature implementation, refer to *Section 42.3: TIM2/TIM3/TIM4/TIM5 implementation*.

If the OCREF clear selection feature is implemented, the tim_ocref_clr_int can be selected between the tim_ocref_clr input and the tim_etrf input (tim_etr_in after the filter) by configuring the OCCS bit in the TIM_SMCR register. The tim_ocref_clr input can be selected among several tim_ocref_clr[15:0] inputs, using the OCRSEL[3:0] bitfield in the TIM_AF2 register, as shown in *Figure 605*.

Figure 605. OCREF_CLR input selection multiplexer



If the OCREF clear selection feature is not implemented, the tim_ocref_clr_int input is directly connected to the tim_etrf input.

For example, the tim_ocref_clr_int signal can be connected to the output of a comparator to be used for current handling. In this case, tim_etr_in must be configured as follows:

1. The external trigger prescaler must be kept off: bits ETPS[1:0] in the TIM_SMCR register are cleared to 00.
2. The external clock mode 2 must be disabled: bit ECE in the TIM_SMCR register is cleared to 0.
3. The external trigger polarity (ETP) and the external trigger filter (ETF) can be configured according to the application's needs.

Figure 606 shows the behavior of the tim_ocxref signal when the tim_etrf input becomes high, for both values of the OCxCE enable bit. In this example, the timer TIMx is programmed in PWM mode.

Figure 606. Clearing TIMx tim_ocxref

Note: In case of a PWM with a 100% duty cycle (if CCRx>ARR), tim_ocxref is enabled again at the next counter overflow.

This feature is also supported in combined and asymmetric modes. In this case, it is mandatory to enable the OCxCE bit for the channel. The OCxCE bit of the complementary channel (for exemple: OC2CE = X for oc2ref in *Figure 607*) is ignored. *Figure 607* to *Figure 609* describe the output waveforms for specific use cases when the ocref_clr_int signal is asserted.

Figure 607. Asymmetric PWM mode 1

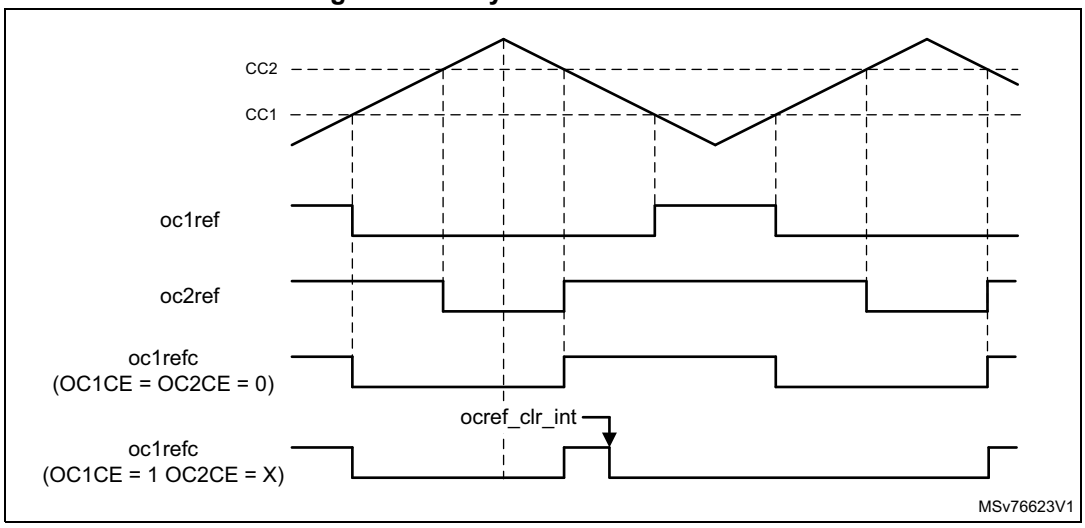


Figure 608. Asymmetric PWM mode 2

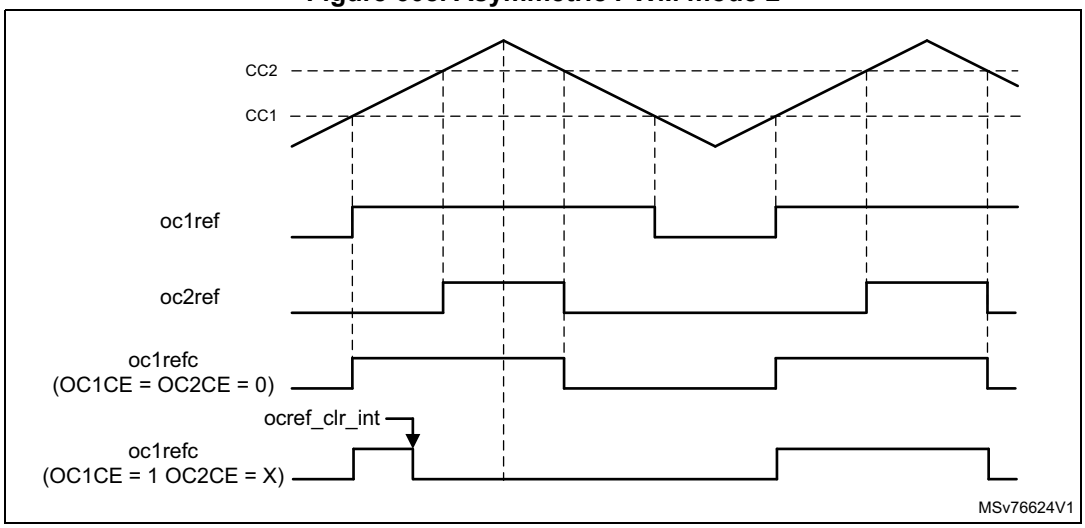

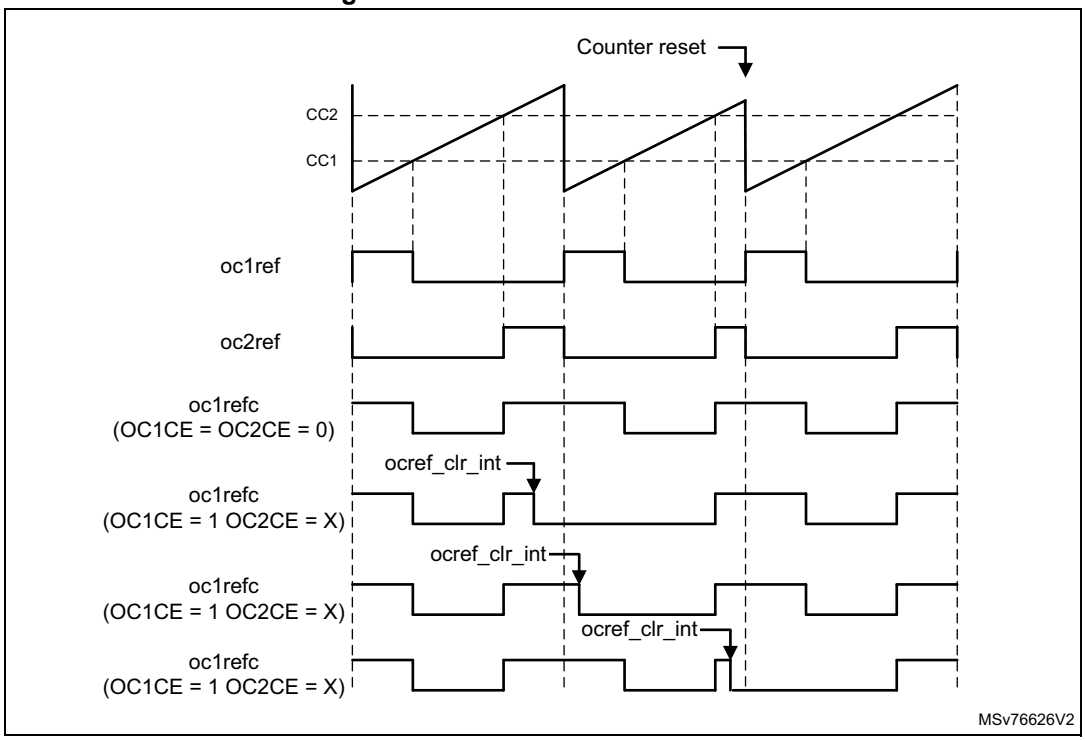

Figure 609. Combined PWM mode 1

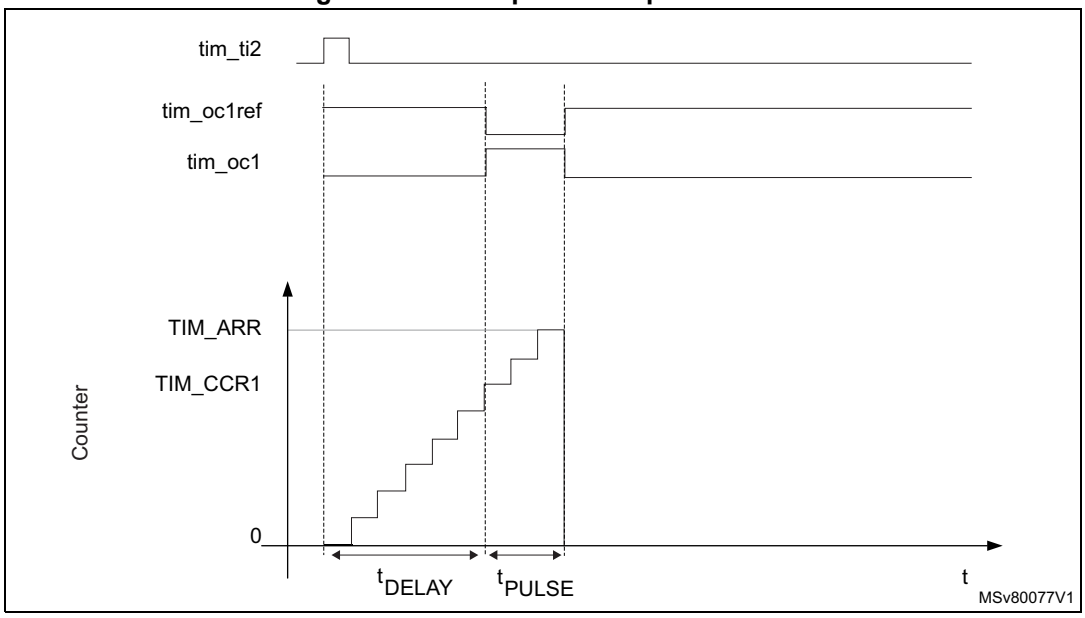
Conditions of use

This feature supports cycle-by-cycle current control loops, typically with a comparator shortening the PWM on-time when a current threshold is exceeded.

It cannot be used in the following modes, where the OCxCE bit must be cleared:

- PWM toggle mode (OCxM[4:0] = 0x03)
- One-pulse mode with PWM active on match (OPM = 1 and OCxM[4:0] = 0x06, 0x08, 0x0C, 0x0E)
- Combined PWM mode 1 or 3 in center-aligned mode (CMS[1:0] = 1, 2, 3 and OCxM[4:0] = 0x0C)

42.4.17 One-pulse mode



One-pulse mode (OPM) is a particular case of the previous modes. It allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length after a programmable delay.

Starting the counter can be controlled through the slave mode controller. Generating the waveform can be done in output compare mode or PWM mode. One-pulse mode is selected by setting the OPM bit in the TIM_CR1 register. This makes the counter stop automatically at the next update event UEV.

A pulse can be correctly generated only if the compare value is different from the counter initial value. Before starting (when the timer is waiting for the trigger), the configuration must be:

CNT<CCRx ≤ ARR (in particular, 0<CCRx).

Figure 610. Example of one-pulse mode

For example if the user wants to generate a positive pulse on tim_oc1 with a length of t_{PULSE} and after a delay of t_{DELAY} as soon as a positive edge is detected on the tim_ti2 input pin.

Use tim_ti2fp2 as trigger 1:

1. Select the proper tim_ti2_in[15:0] source (internal or external) with the TI2SEL[3:0] bits in the TIM_TISEL register.
2. Map tim_ti2fp2 on tim_ti2 by writing CC2S = 01 in the TIM_CCMR1 register.
3. tim_ti2fp2 must detect a rising edge, write CC2P = 0 and CC2NP = 0 in the TIM_CCER register.
4. Configure tim_ti2fp2 as trigger for the slave mode controller (tim_trgi) by writing TS = 00110 in the TIM_SMCR register.
5. tim_ti2fp2 is used to start the counter by writing SMS to 110 in the TIM_SMCR register (trigger mode).

The OPM waveform is defined by writing the compare registers (taking into account the clock frequency and the counter prescaler).

- The t_{DELAY} is defined by the value written in the TIM_CCR1 register.
- The t_{PULSE} is defined by the difference between the autoreload value and the compare value (TIM_ARR - TIM_CCR1).
- Suppose the user wants to build a waveform with a transition from 0 to 1 when a compare match occurs and a transition from 1 to 0 when the counter reaches the autoreload value. To do this PWM mode 2 must be enabled by writing OC1M = 00111 in the TIM_CCMR1 register. Optionally the preload registers can be enabled by writing OC1PE = 1 in the TIM_CCMR1 register and ARPE in the TIM_CR1 register. In this case one has to write the compare value in the TIM_CCR1 register, the autoreload value in the TIM_ARR register, generate an update by setting the UG bit and wait for external trigger event on tim_ti2. CC1P is written to 0 in this example.

In this example, the DIR and CMS bits in the TIM_CR1 register must be low.

Since only one pulse (single mode) is needed, a one must be written in the OPM bit in the TIM_CR1 register to stop the counter at the next update event (when the counter rolls over from the autoreload value back to 0). When OPM bit in the TIM_CR1 register is set to 0, so the repetitive mode is selected.

Particular case: tim_ocx fast enable:

In one-pulse mode, the edge detection on tim_tix input set the CEN bit which enables the counter. Then the comparison between the counter and the compare value makes the output toggle. But several clock cycles are needed for these operations and it limits the minimum delay t_{DELAY} min we can get.

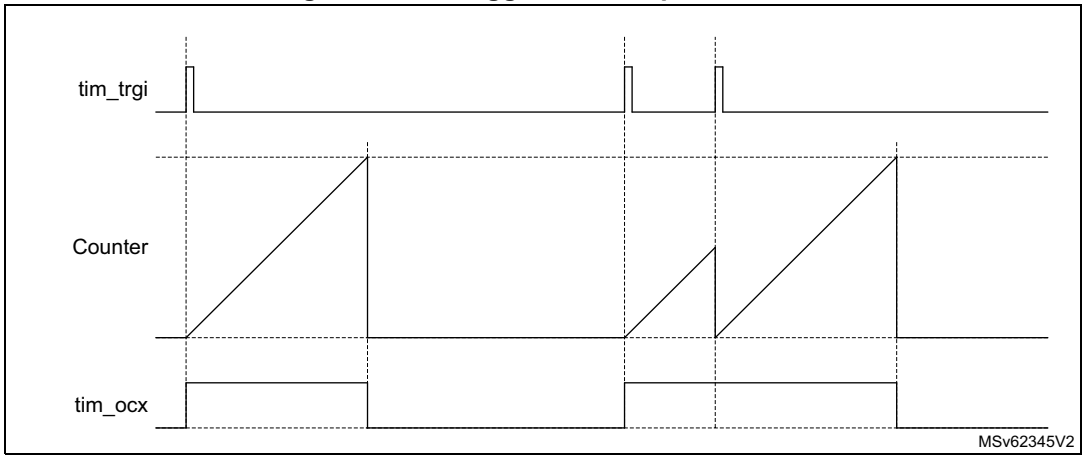
If one wants to output a waveform with the minimum delay, the OCxFE bit can be set in the TIM_CCMRx register. Then tim_ocxref (and tim_ocx) is forced in response to the stimulus, without taking in account the comparison. Its new level is the same as if a compare match had occurred. OCxFE acts only if the channel is configured in PWM1 or PWM2 mode.

42.4.18 Retriggerable one-pulse mode

This mode allows the counter to be started in response to a stimulus and to generate a pulse with a programmable length, but with the following differences with non-retriggerable one-pulse mode described in *Section 42.4.17*:

- The pulse starts as soon as the trigger occurs (no programmable delay).
- The pulse is extended if a new trigger occurs before the previous one is completed.

The timer must be in slave mode, with the bits SMS[4:0] = 01000 (combined reset + trigger mode) in the TIM_SMCR register, and the OCxM[4:0] bits set to 01000 or 01001 for retriggerable OPM mode 1 or 2.



If the timer is configured in up-counting mode, the corresponding CCRx must be set to 0 (the ARR register sets the pulse length). If the timer is configured in down-counting mode CCRx must be above or equal to ARR.

Note: In retriggerable one-pulse mode, the CCxIF flag is not significant.

The OCxM[4:0] and SMS[4:0] bitfields are split into two parts for compatibility reasons, the most significant bit is not contiguous with the three least significant ones.

This mode must not be used with center-aligned PWM modes. It is mandatory to have CMS[1:0] = 00 in TIM_CR1.

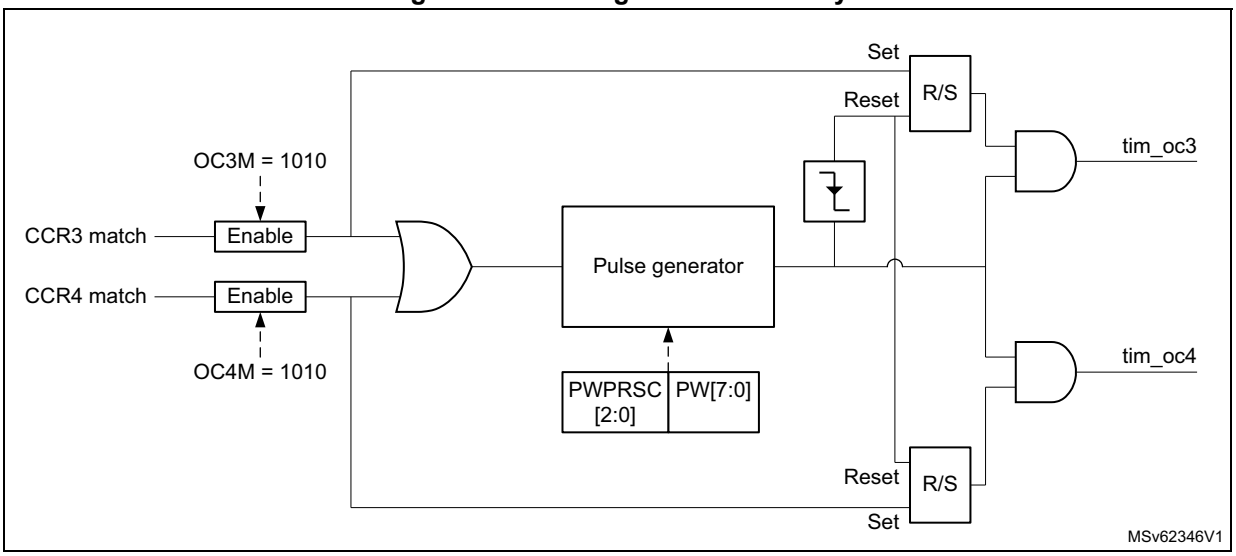
Figure 611. Retriggerable one-pulse mode

42.4.19 Pulse on compare mode

A pulse can be generated upon compare match event. A signal with a programmable pulse width generated when the counter value equals a given compare value, for debugging or synchronization purposes.

This mode is available for any slave mode selection, including encoder modes, in edge and center aligned counting modes. It is solely available for channel 3 and channel 4. The pulse generator is unique and is shared by the two channels, as shown on *Figure 612*.

Figure 612. Pulse generator circuitry



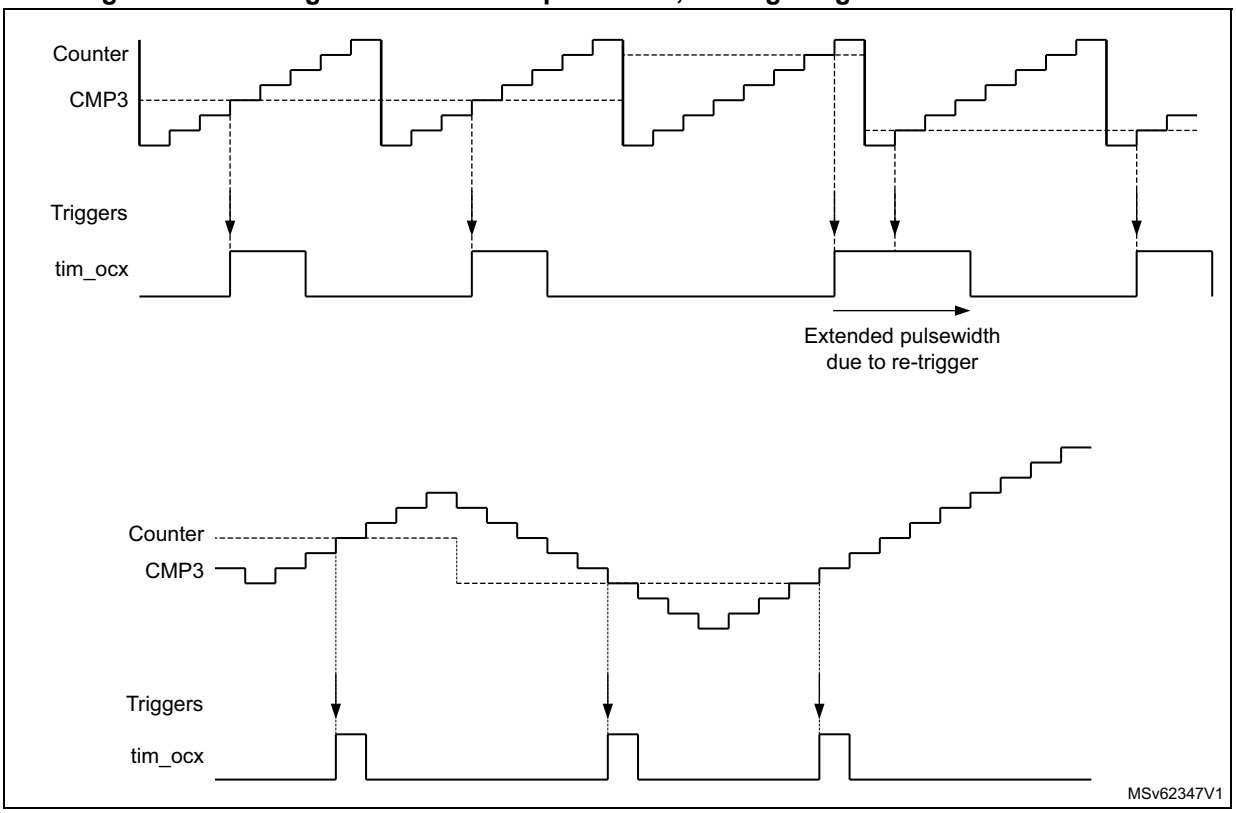


Figure 613 shows how the pulse is generated for edge-aligned and encoder operating modes.

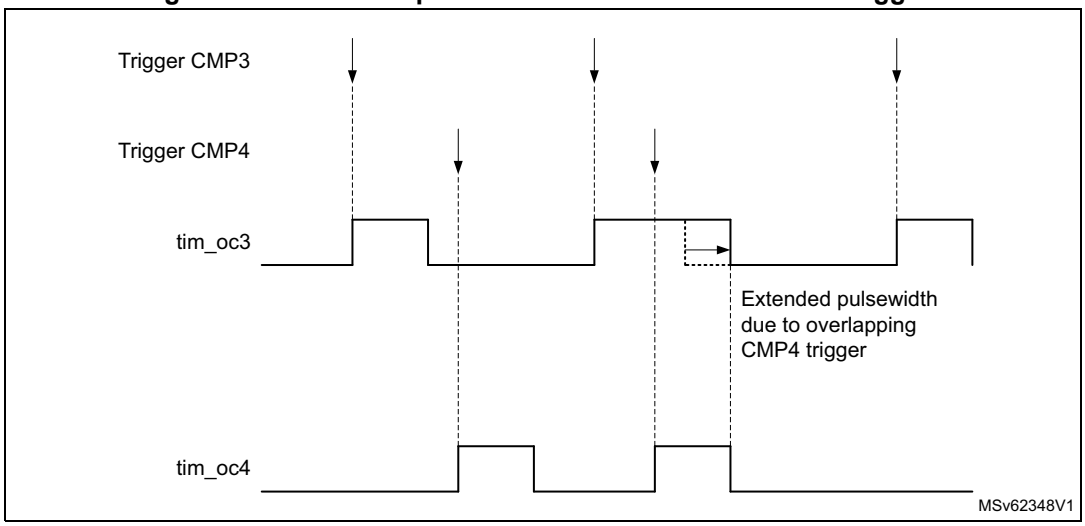
Figure 613. Pulse generation on compare event, for edge-aligned and encoder modes

This output compare mode is selected using the OC3M[3:0] and OC4M[3:0] bitfields in TIM_CCMR2 register.

The pulse width is programmed using the PW[7:0] bitfield in the register, using a specific clock prescaled according to PWPRSC[2:0] bits, as follows:

$t_{PW} = PW[7:0] \times t_{PWG}$



where $t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim_ker_ck}$.

Gives the resolution and maximum values depending on the prescaler value.

The pulse is retriggerable: a new trigger while the pulse is ongoing, causes the pulse to be extended.

Note: If the two channels are enabled simultaneously, the pulses are issued independently as long as the trigger on one channel is not overlapping the pulse generated on the concurrent output. On the opposite, if the two triggers are overlapping, the pulse width related to the first arriving trigger is extended (because of the retrigger), while the pulse width of the last arriving trigger is correct (as shown on Figure 614).

Figure 614. Extended pulse width in case of concurrent triggers

42.4.20 Encoder interface mode

Quadrature encoder

To select encoder interface mode write SMS = 0001 in the TIM_SMCR register if the counter is counting on tim_ti1 edges only, SMS = 0010 if it is counting on tim_ti2 edges only and SMS = 0011 if it is counting on both tim_ti1 and tim_ti2 edges.

Select the tim_ti1 and tim_ti2 polarity by programming the CC1P and CC2P bits in the TIM_CCER register. CC1NP and CC2NP must be kept cleared. When needed, the input filter can be programmed as well.

The two inputs tim_ti1 and tim_ti2 are used to interface to an incremental encoder. Refer to *Table 489*. The counter is clocked by each valid transition on tim_ti1fp1 or tim_ti2fp2 (tim_ti1 and tim_ti2 after input filter and polarity selection, tim_ti1fp1 = tim_ti1 if not filtered and not inverted, tim_ti2fp2 = tim_ti2 if not filtered and not inverted) assuming that it is enabled (CEN bit in TIM_CR1 register written to 1). The sequence of transitions of the two inputs is evaluated and generates count pulses as well as the direction signal. Depending on the sequence the counter counts up or down, the DIR bit in the TIM_CR1 register is modified by hardware accordingly. The DIR bit is calculated at each transition on any input (tim_ti1 or tim_ti2), whatever the counter is counting on tim_ti1 only, tim_ti2 only or both tim_ti1 and tim_ti2.

Encoder interface mode acts simply as an external clock with direction selection. This means that the counter just counts continuously between 0 and the autoreload value in the TIM_ARR register (0 to ARR or ARR down to 0 depending on the direction). So the TIM_ARR must be configured before starting. In the same way, the capture, compare, prescaler, trigger output features continue to work as normal. Encoder mode and external clock mode 2 are not compatible and must not be selected together.

In this mode, the counter is modified automatically following the speed and the direction of the quadrature encoder and its content, therefore, always represents the encoder's position. The count direction corresponds to the rotation direction of the connected sensor. The table summarizes the possible combinations, assuming tim_ti1 and tim_ti2 do not switch at the same time.

Table 489. Counting direction versus encoder signals(CC1P = CC2P = 0)

Active edge	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
Counting on tim_ti1 only x1 mode	01110	High	Down	Up	No count	No count
		Low	No count	No count	No count	No count
Counting on tim_ti2 only x1 mode	01111	High	No count	No count	Up	Down
		Low	No count	No count	No count	No count
Counting on tim_ti1 only x2 mode	00001	High	Down	Up	No count	No count
		Low	Up	Down	No count	Down
Counting on tim_ti2 only x2 mode	00010	High	No count	No count	Up	Down
		Low	No count	No count	Down	Up
Counting on tim_ti1 and tim_ti2 x4 mode	00011	High	Down	Up	Up	Down
		Low	Up	Down	Down	Up

A quadrature encoder can be connected directly to the MCU without external interface logic. However, comparators are normally be used to convert the encoder's differential outputs to digital signals. This greatly increases noise immunity. The third encoder output which indicates the mechanical zero position, can be connected to the external trigger input and trigger a counter reset.

Figure 615 gives an example of counter operation, showing count signal generation and direction control. It also shows how input jitter is compensated where both edges are selected. This might occur if the sensor is positioned near to one of the switching points. For this example we assume that the configuration is the following:

- CC1S = 01 (TIM_CCMR1 register, tim_ti1fp1 mapped on tim_ti1).
- CC2S = 01 (TIM_CCMR1 register, tim_ti2fp2 mapped on tim_ti2).
- CC1P and CC1NP = 0 (TIM_CCER register, tim_ti1fp1 noninverted, tim_ti1fp1 = tim_ti1).
- CC2P and CC2NP = 0 (TIM_CCER register, tim_ti2fp2 noninverted, tim_ti2fp2 = tim_ti2).
- SMS = 0011 (TIM_SMCR register, both inputs are active on both rising and falling edges).
- CEN = 1 (TIM_CR1 register, counter is enabled).

Figure 615. Example of counter operation in encoder interface mode

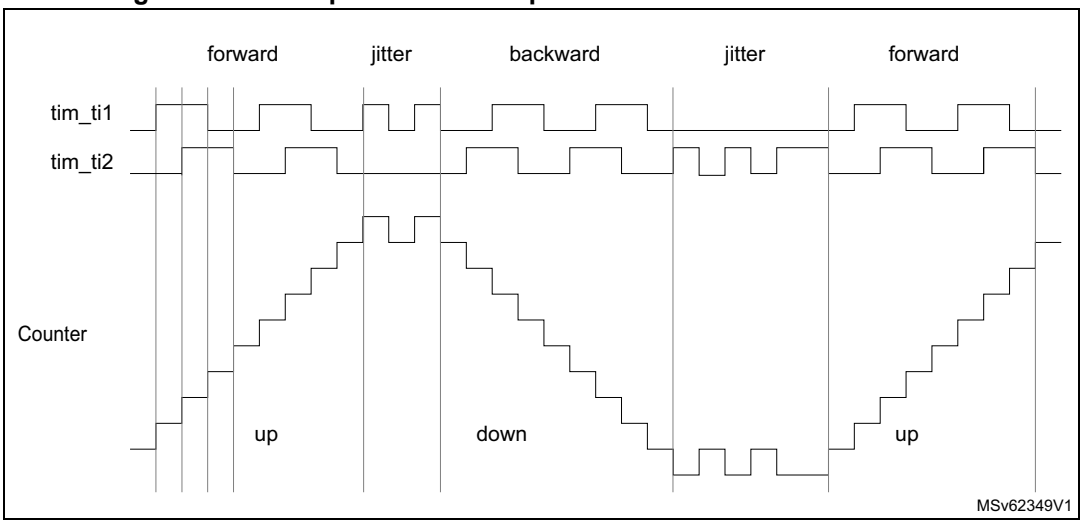


Figure 616 gives an example of counter behavior when tim_ti1fp1 polarity is inverted (same configuration as above except CC1P = 1).

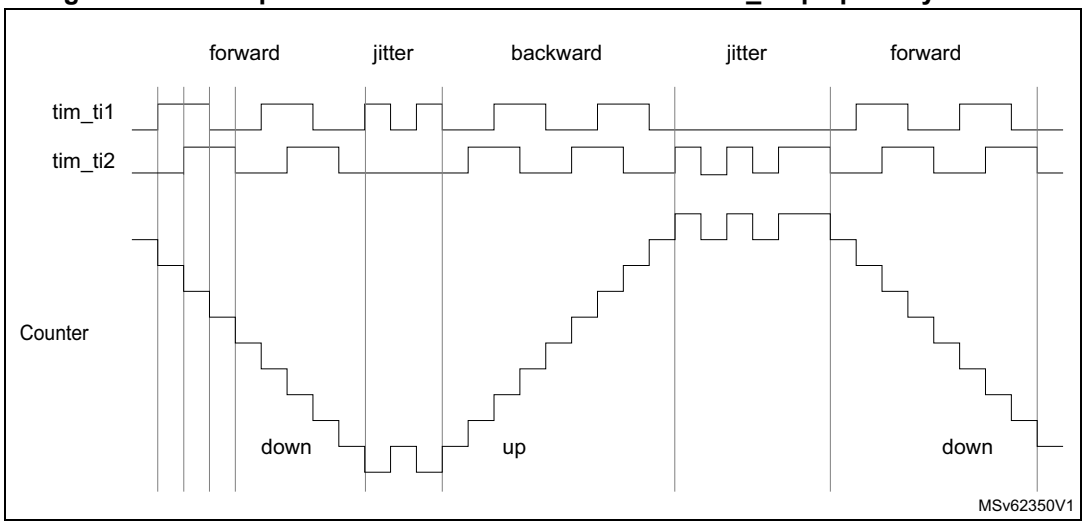
Figure 616. Example of encoder interface mode with tim_ti1fp1 polarity inverted



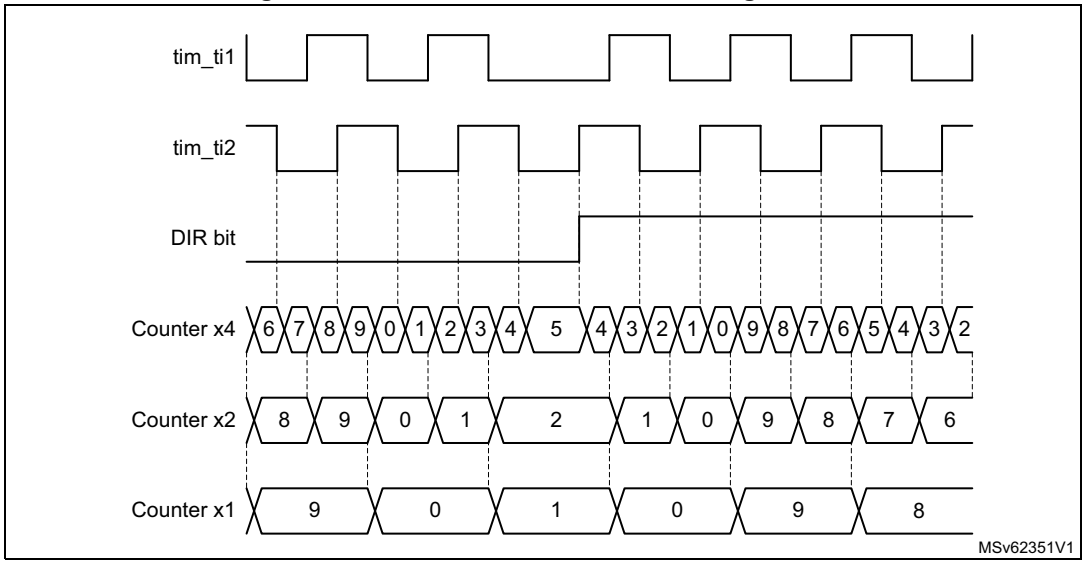


Figure 617 shows the timer counter value during a speed reversal, for various counting modes.

Figure 617. Quadrature encoder counting modes

The timer, when configured in encoder interface mode provides information on the sensor's current position. Dynamic information can be obtained (speed, acceleration, deceleration) by measuring the period between two encoder events using a second timer configured in capture mode. The output of the encoder which indicates the mechanical zero can be used for this purpose. Depending on the time between two events, the counter can also be read at regular times. This can be done by latching the counter value into a third input capture register if available (then the capture signal must be periodic and can be generated by another timer). When available, it is also possible to read its value through a DMA request.

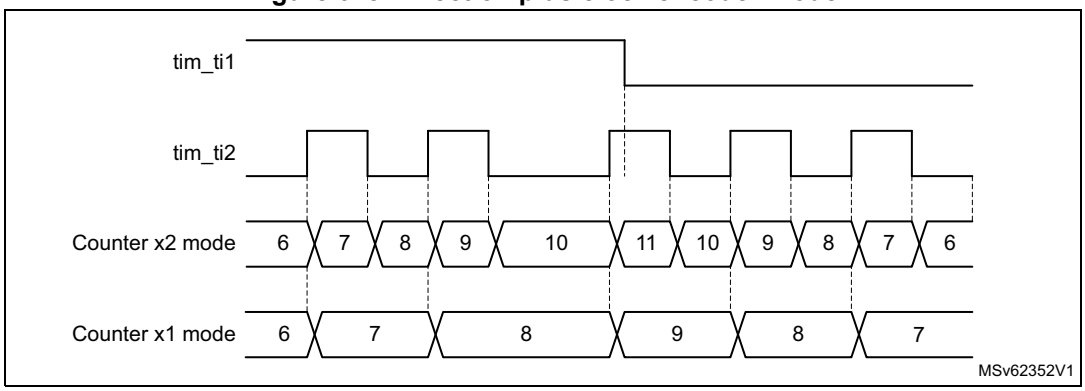
The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag (UIF) into the timer counter register's bit 31 (TIM_CNT[31]). This allows both the counter value and a potential roll-over condition signaled by the UIFCPY flag to be read in an atomic way. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

Clock plus direction encoder mode

In addition to the quadrature encoder mode, the timer offers support for other types of encoders.



In the "clock plus direction" mode shown on *Figure 618*, the clock is provided on a single line, on tim_ti2, while the direction is forced using the tim_ti1 input.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01010: x2 mode, the counter is updated on both rising and falling edges of the clock.
- 01011: x1 mode, the counter is updated on a single clock edge, as per CC2P bit value: CC2P = 0 corresponds to rising edge sensitivity and CC2P = 1 corresponds to falling edge sensitivity.

The polarity of the direction signal on tim_ti1 is set with the CC1P bit: 0 corresponds to positive polarity (up-counting when tim_ti1 is high and down-counting when tim_ti1 is low) and CC1P = 1 corresponds to negative polarity (up-counting when tim_ti1 is low).

Figure 618. Direction plus clock encoder mode

Directional clock encoder mode

In the “directional clock” mode on *Figure 619*, the clocks are provided on two lines, with a single one at once, depending on the direction, so as to have one up-counting clock line and one down-counting clock line.

This mode is enabled with the SMS[4:0] bitfield in the TIM_SMCR register, as following:

- 01100: x2 mode, the counter is updated on both rising and falling edges of any of the two clock lines. The CC1P and CC2P bits are coding for the clock idle state. CCxP = 0 corresponds to high-level idle state (refer to *Figure 619*) and CCxP = 1 corresponds to low-level idle state (refer to *Figure 620*).
- 01101: x1 mode, the counter is updated on a single clock edge, as per CC1P and CC2P bit value. CCxP = 0 corresponds to falling edge sensitivity and high-level idle state (refer to *Figure 619*), CCxP = 1 corresponds to rising edge sensitivity and low-level idle state (refer to *Figure 620*).

Figure 619. Directional clock encoder mode (CC1P = CC2P = 0)

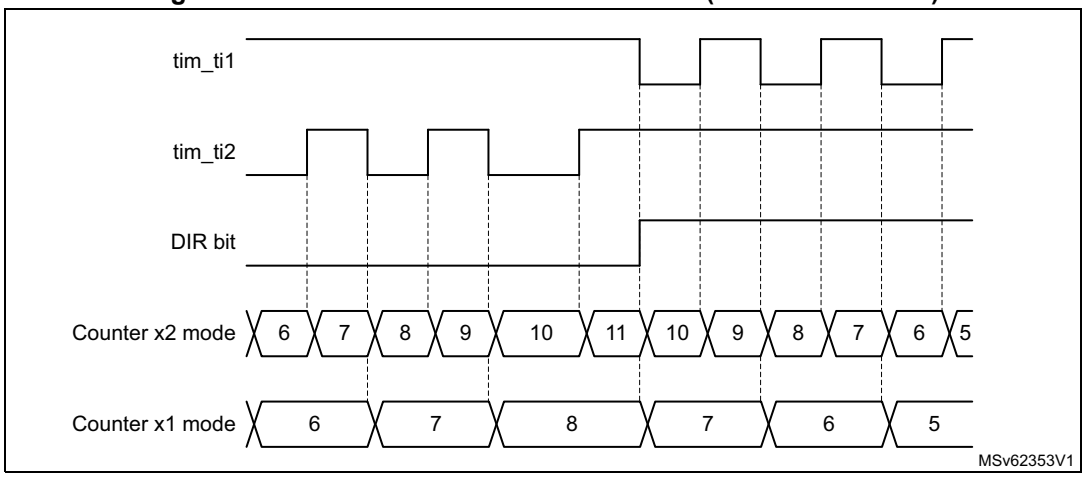


Figure 620. Directional clock encoder mode (CC1P = CC2P = 1)

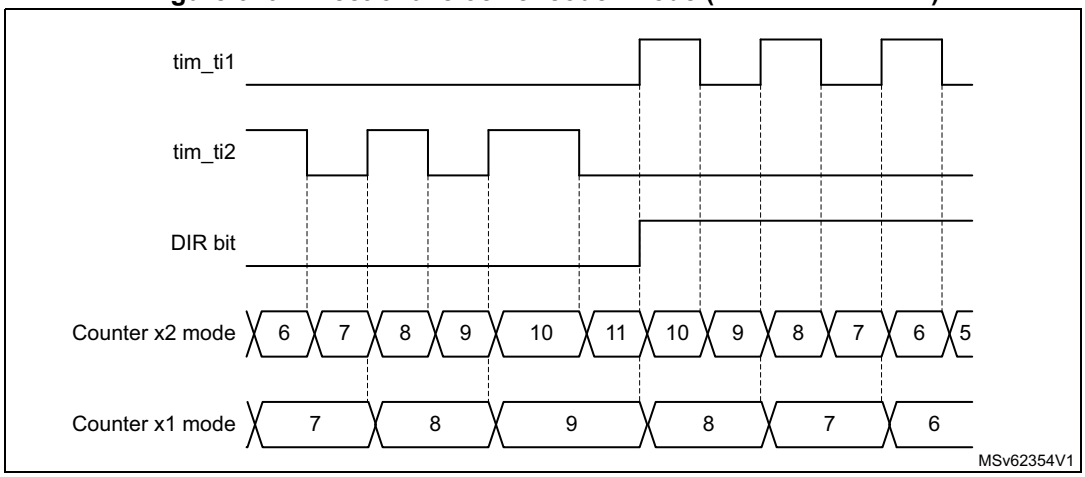

Table 490 details how the directional clock mode operates, for any input transition.

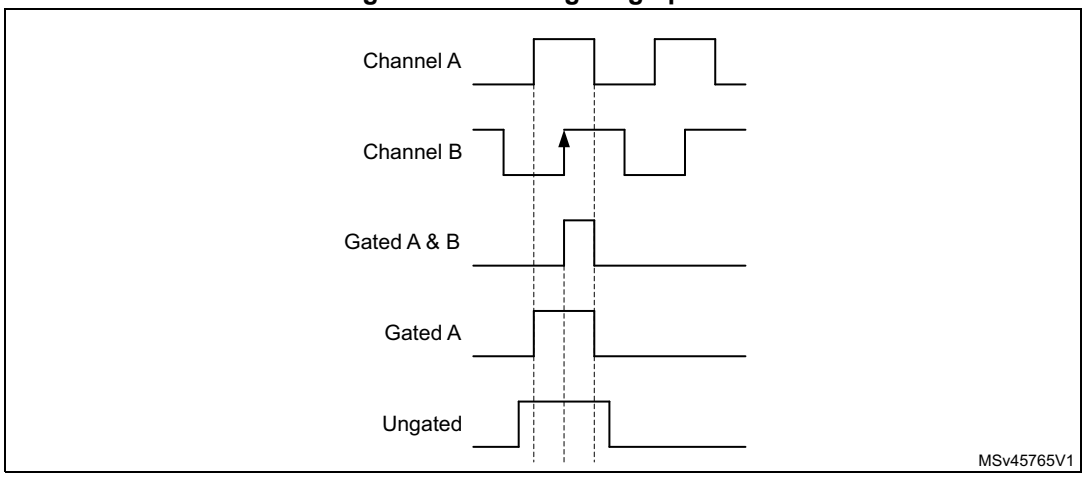
Table 490. Counting direction versus encoder signals and polarity settings

Directional clock mode	SMS[4:0]	Level on opposite signal (tim_ti1fp1 for tim_ti2, tim_ti2fp2 for tim_ti1)	tim_ti1fp1 signal		tim_ti2fp2 signal	
			Rising	Falling	Rising	Falling
x2 mode CCxP = 0	01100	High	Down	Down	Up	Up
		Low	No count	No count	No count	No count
x2 mode CCxP = 1	01100	High	No count	No count	No count	No count
		Low	Down	Down	Up	Up
x1 mode CCxP = 0	01101	High	No count	Down	No count	Up
		Low	No count	No count	No count	No count
x1 mode CCxP = 1	01101	High	No count	No count	No count	No count
		Low	Down	No count	Up	No count

Index input



The counter can be reset by an index signal coming from the encoder, indicating an absolute reference position. The index signal must be connected to the tim_etr_in input. It can be filtered using the digital input filter.

The index functionality is enabled with the IE bit in the TIM_ECR register. The IE bit must be set only in encoder mode, when the SMS[4:0] bitfield has the following values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111.

Available encoders are proposed with several options for index pulse conditioning, as per *Figure 621*:

- Gated with A and B: the pulse width is 1/4 of one channel period, aligned with both A and B edges.
- Gated with A (or gated with B): the pulse width is 1/2 of one channel period, aligned with the two edges on channel A (resp. channel B).
- Ungated: the pulse width is up to one channel period, without any alignment to the edges.

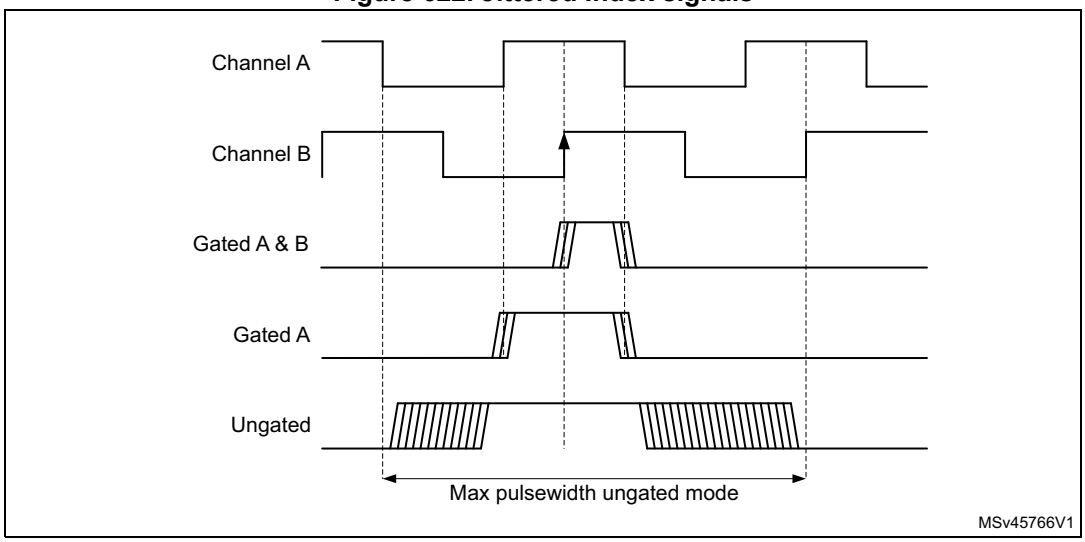


Figure 621. Index gating options

The circuitry tolerates jitter on index signal, whatever the gating mode, as shown on *Figure 622*.

In ungated mode, the signal must be strictly below two encoder periods. If the pulse width is greater or equal to two encoder period, the counter is reset multiple times.

Figure 622. Jittered Index signals

The timer supports the three gating options identically, without any specific programming needed. It is only necessary to define on which encoder state (for example channel A and channel B state combination) the index must be synchronized, using the IPOS[1:0] bitfield in the TIM_ECR register.

The index detection event acts differently depending on counting direction to ensure symmetrical operation during speed reversal:

- The counter is reset during up-counting (DIR bit = 0).
- The counter is set to TIM_ARR when down-counting.

This allows the index to be generated on the very same mechanical angular position whatever the counting direction. *Figure 623* shows at which position is the index generated, for a simplistic example (an encoder providing four edges par mechanical rotation).

Figure 623. Index generation for IPOS[1:0] = 11

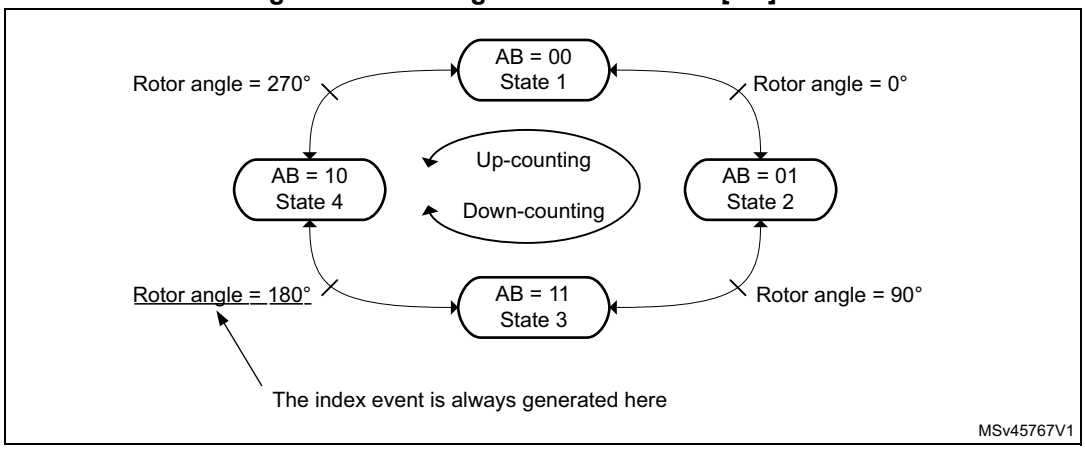

Figure 624 presents waveforms and corresponding values for IPOS[1:0] = 11. It shows that the instant at which the counter value is forced is automatically adjusted depending on the counting direction:

- Counter set to 0 when encoder state is 11 (ChA = 1, ChB = 1), when up-counting (DIR bit = 0).
- Counter set to TIM_ARR when exiting the 11 state, when down-counting (DIR bit = 1).

An interrupt can be issued upon index detection event.

The arrows are indicating on which transition is the index event interrupt generated.

Figure 624. Counter reading with index gated on channel A (IPOS[1:0] = 11)

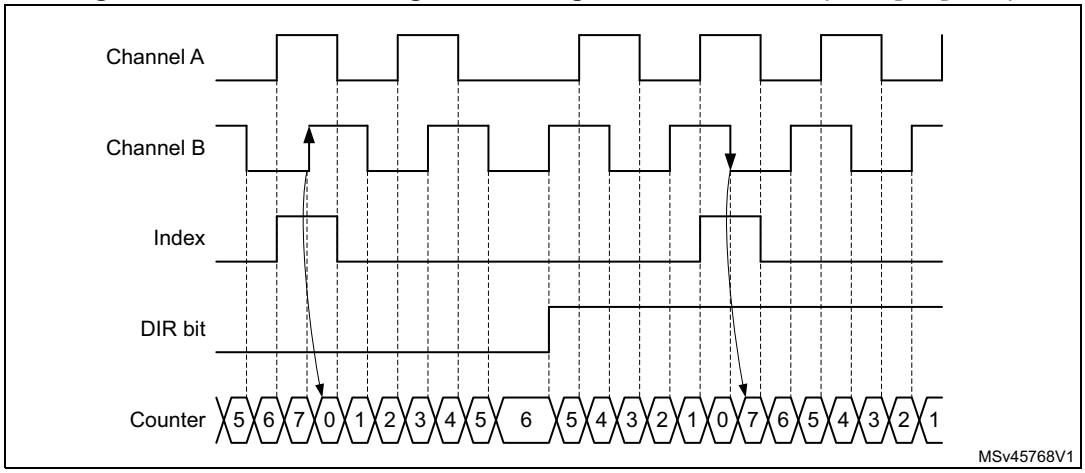

Figure 625 presents waveforms and corresponding values for the ungated mode. The arrows are indicating on which transition is the index event generated.

Figure 625. Counter reading with index ungated (IPOS[1:0] = 00)

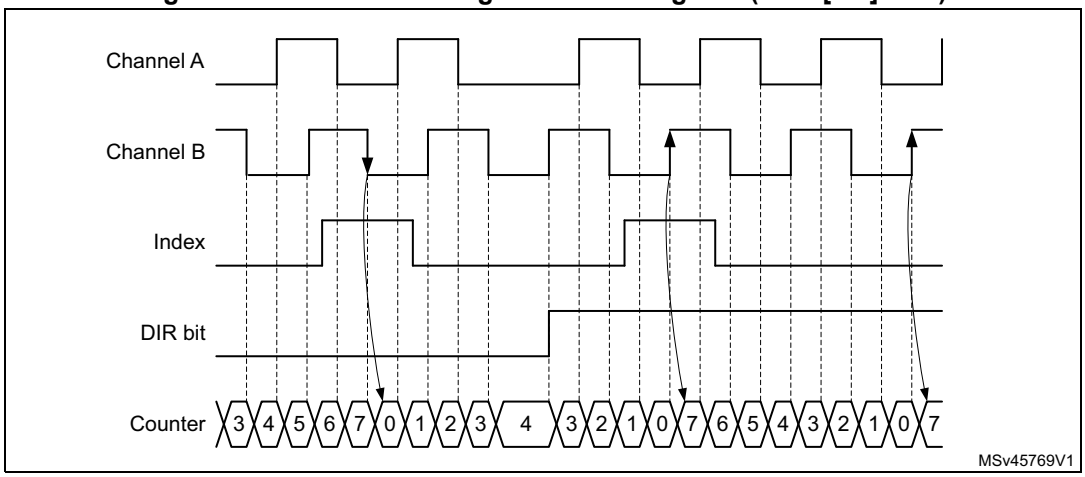

Figure 626 shows how the gated on A & B mode is handled, for various pulse alignment scenarios. The arrows are indicating on which transition is the index event generated.

Figure 626. Counter reading with index gated on channel A and B

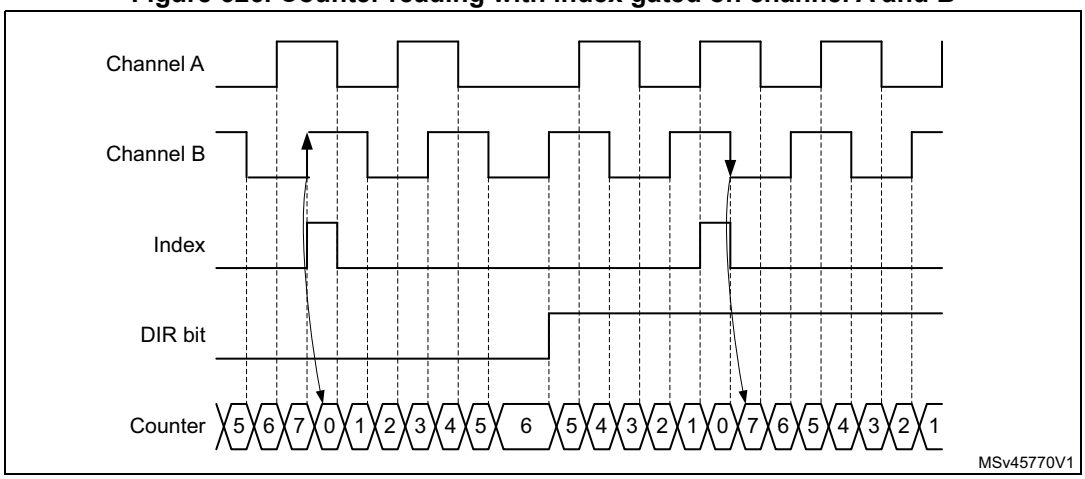

Figure 627 and *Figure 628* detail the case where the subsequent index pulse may be narrower than one quarter of the encoder clock period.

Figure 627. Encoder mode behavior in case of narrow index pulse (IPOS[1:0] = 11)

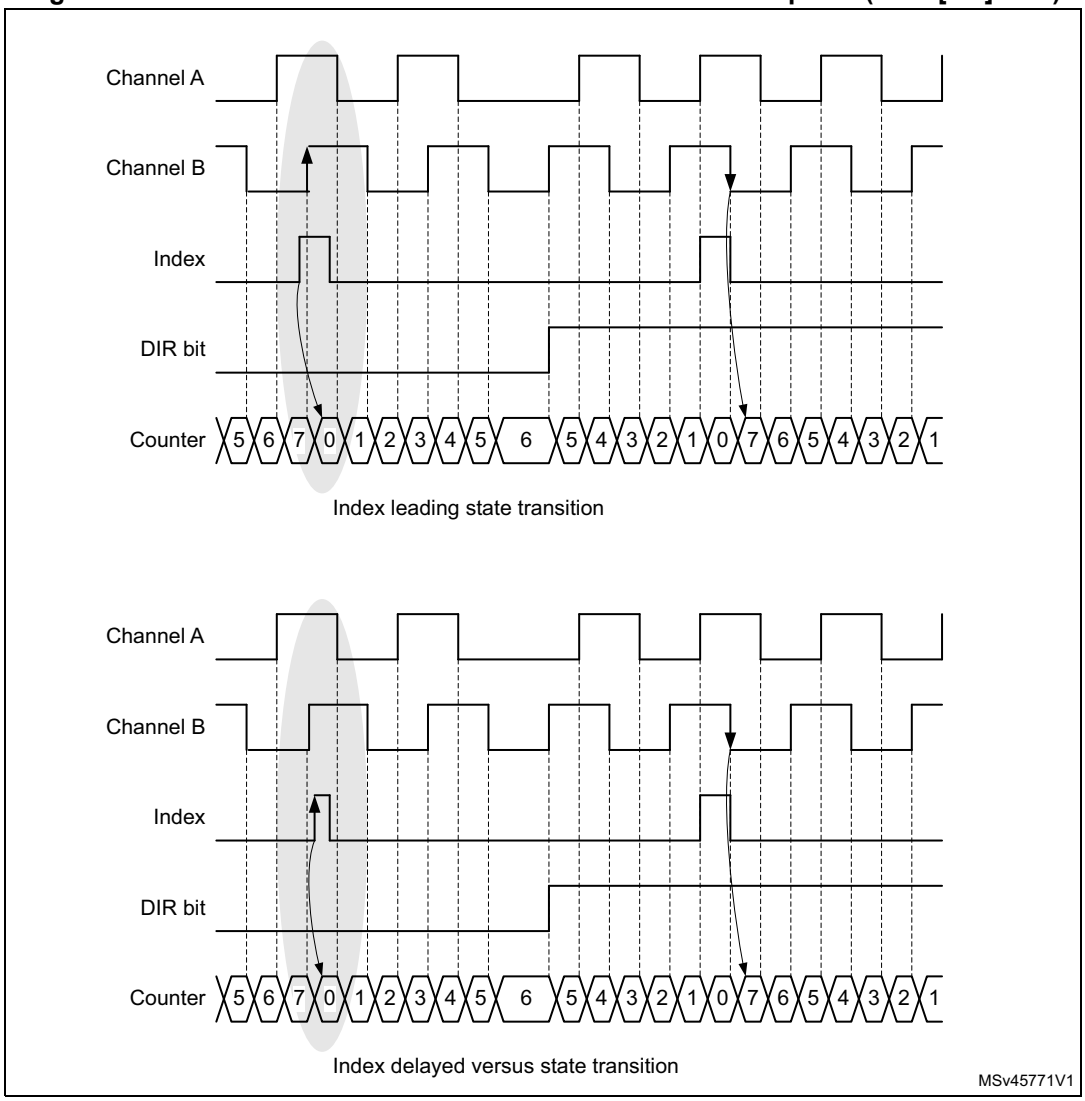

Figure 628. Counter reset Narrow index pulse (closer view, ARR = 0x07)

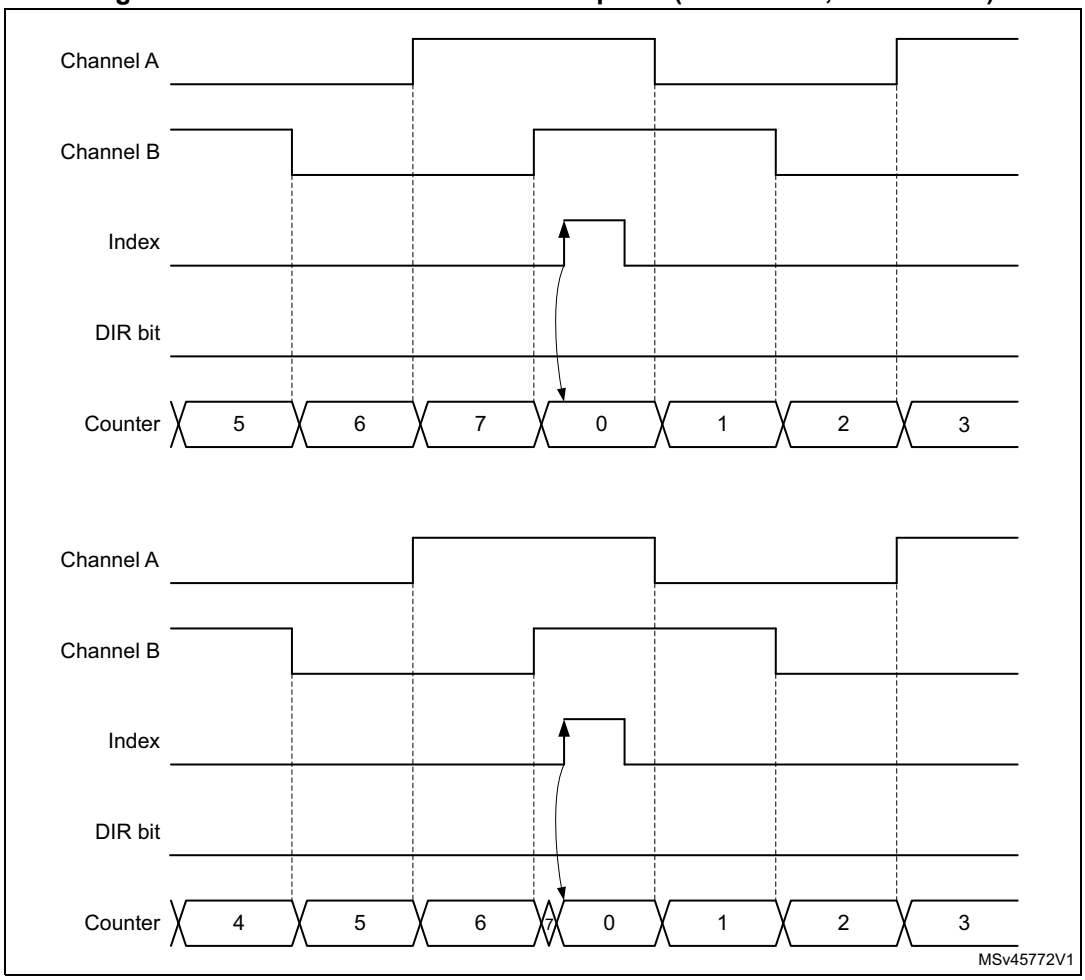

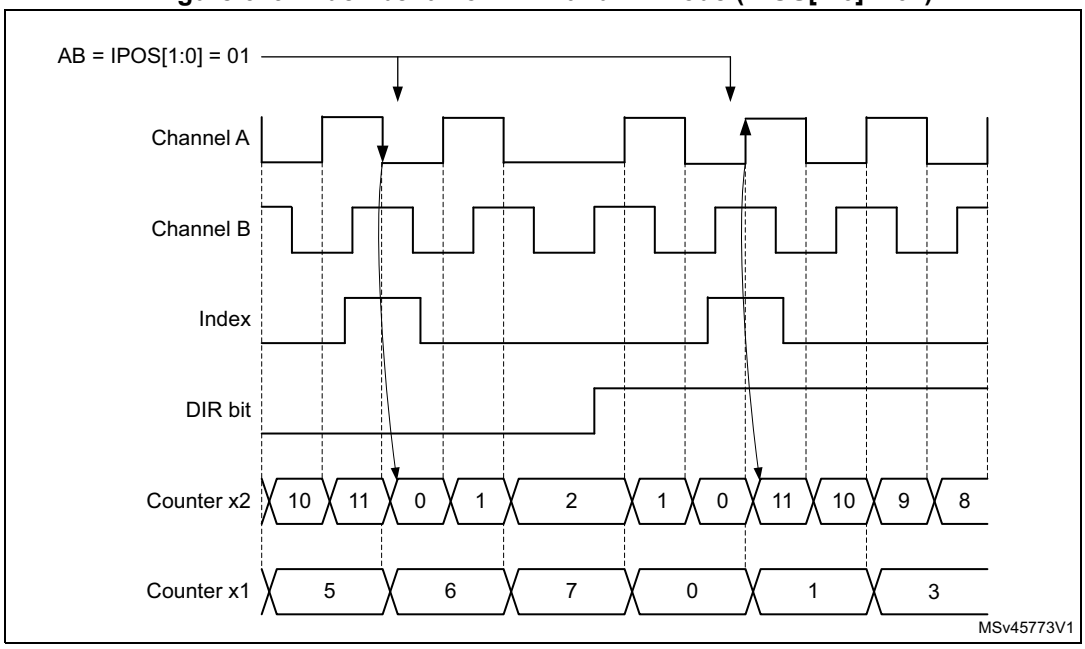

Figure 629 shows how the index is managed in x1 and x2 modes.

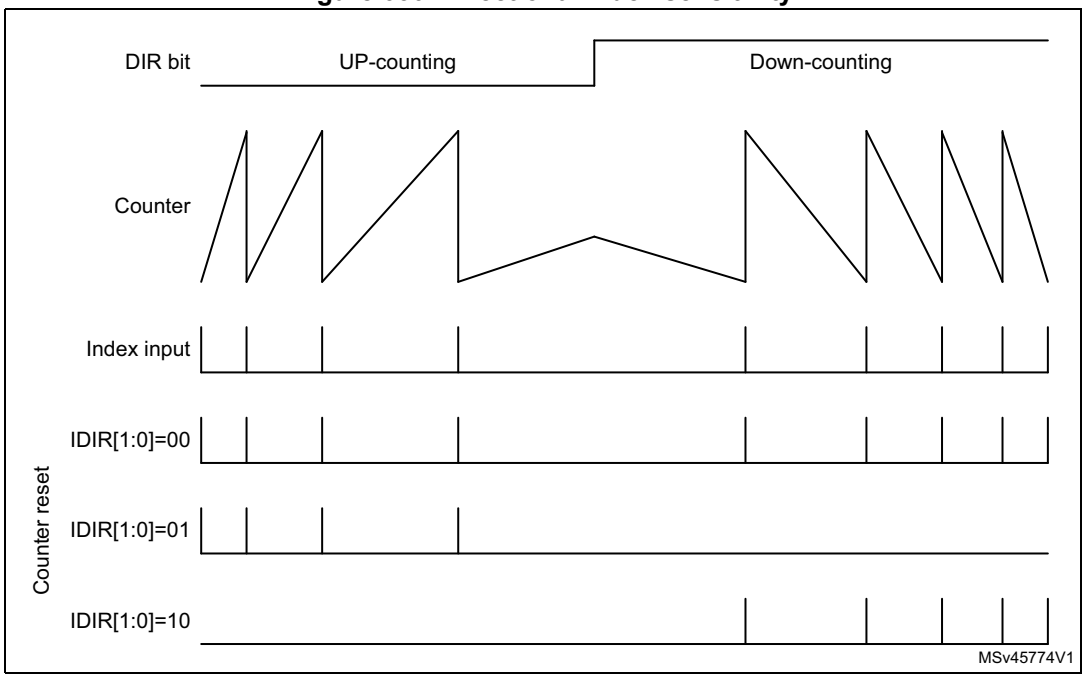
Figure 629. Index behavior in x1 and x2 mode (IPOS[1:0] = 01)



Directional index sensitivity

The IDIR[1:0] bitfield in the TIM_ECR register allows the index to be active only in a selected counting direction.

Figure 630 shows the relationship between index and counter reset events, depending on IDIR[1:0] value.

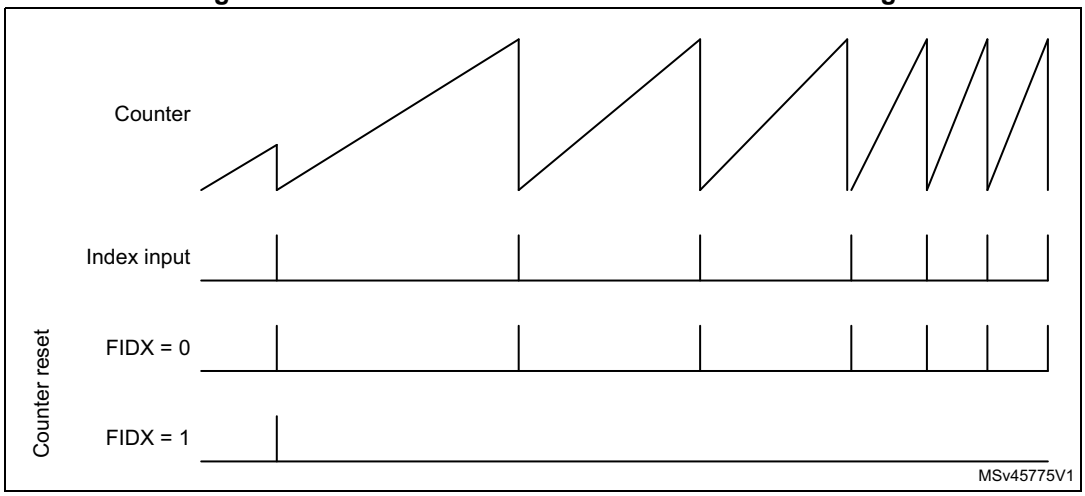


Figure 630. Directional index sensitivity

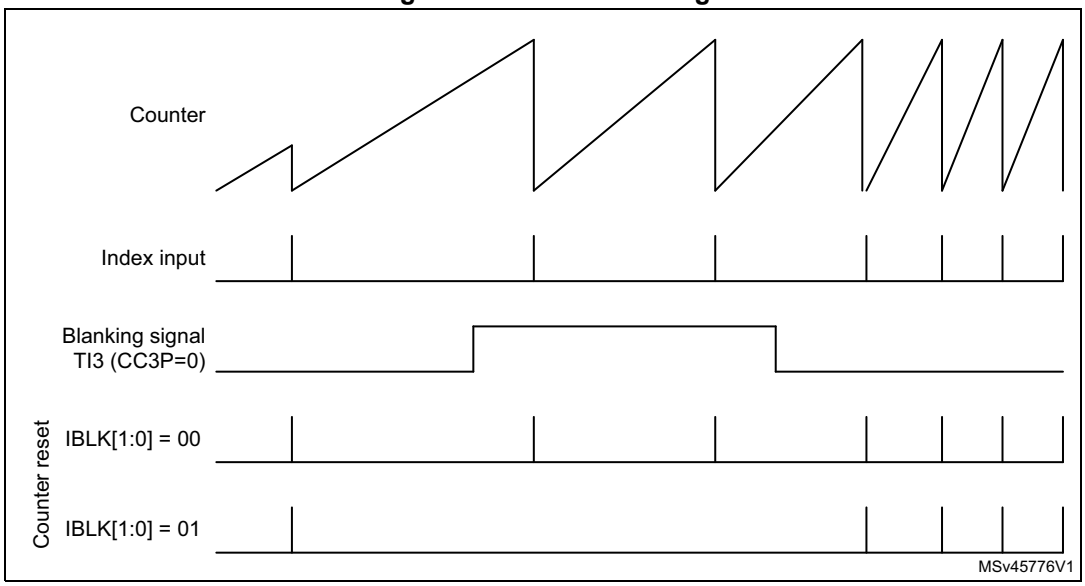
Special first index event management

The FIDX bit in the TIM_ECR register allows the index to be taken only once, as shown on *Figure 631*. Once the first index has arrived, any subsequent index is ignored. If needed, the circuitry can be rearmed by writing the FIDX bit to 0 and setting it again to 1.

Figure 631. Counter reset as function of FIDX bit setting



Index blanking

The index event can be blanked using the tim_ti3 or tim_ti4 inputs. During the blanking window, the index events are no longer resetting the counter, as shown on *Figure 632*.

This mode is enabled using the IBLK[1:0] bitfield in the TIM_ECR register, as following:

- IBLK[1:0] = 00: Index signal always active.
- IBLK[1:0] = 01: Index signal blanking on tim_ti3 input.
- IBLK[1:0] = 10: Index signal blanking on tim_ti4 input.

Figure 632. Index blanking

Index management in nonquadrature mode

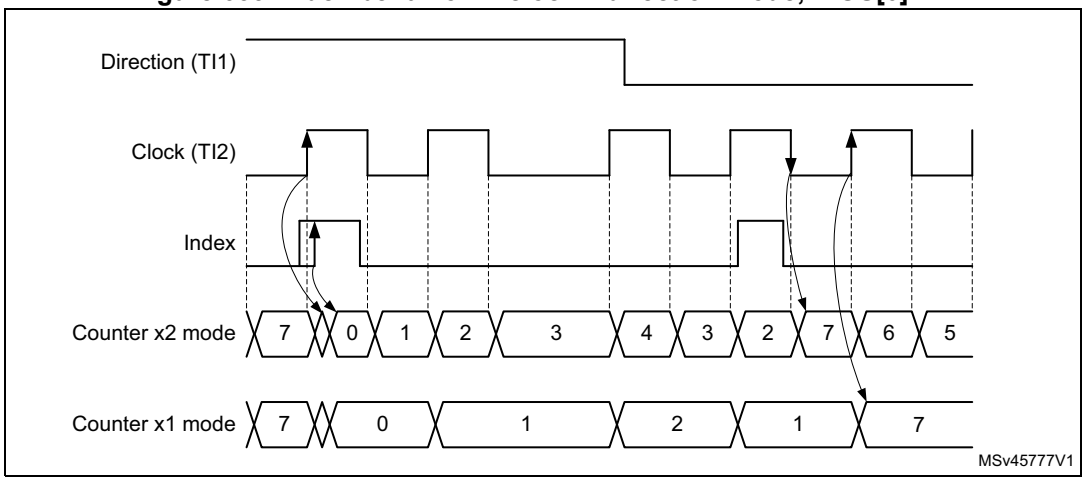
Figure 633 and *Figure 634* detail how the index is managed in directional clock mode and clock plus direction mode, when the SMS[4:0] bitfield is equal to 01010, 01011, 01100, 01101.

For both of these modes, the index sensitivity is set with the IPOS[0] bit as following:

- IPOS[0] = 0: Index is detected on clock low level.
- IPOS[0] = 1: Index is detected on clock high level.

The IPOS[1] bit is not-significant.

Figure 633. Index behavior in clock + direction mode, IPOS[0] = 1



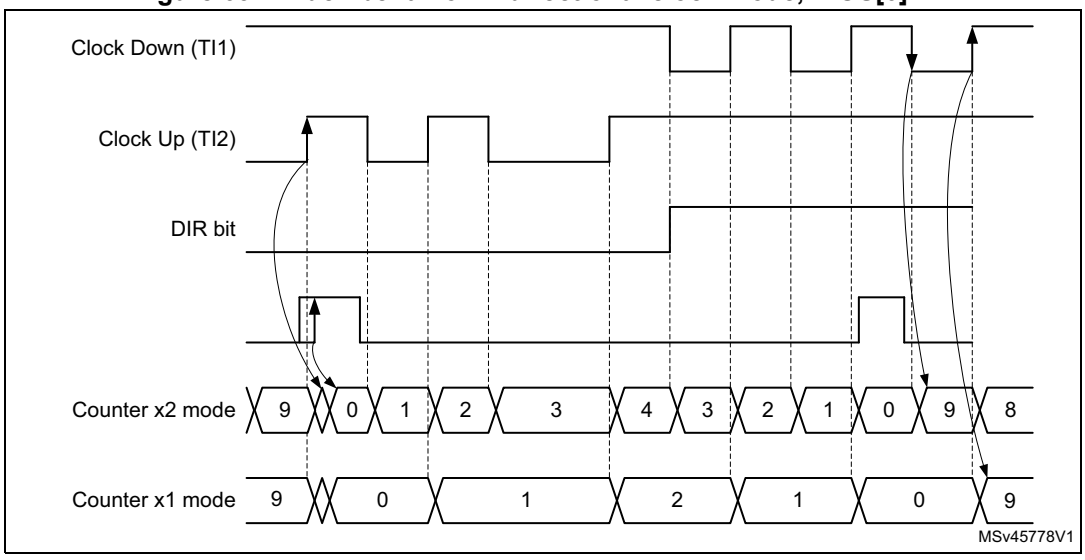


Figure 634. Index behavior in directional clock mode, IPOS[0] = 1

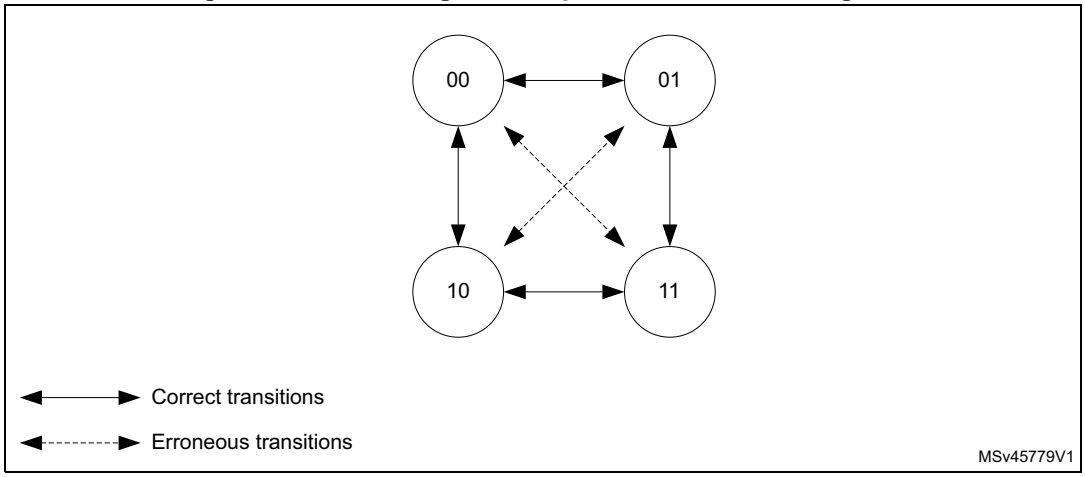
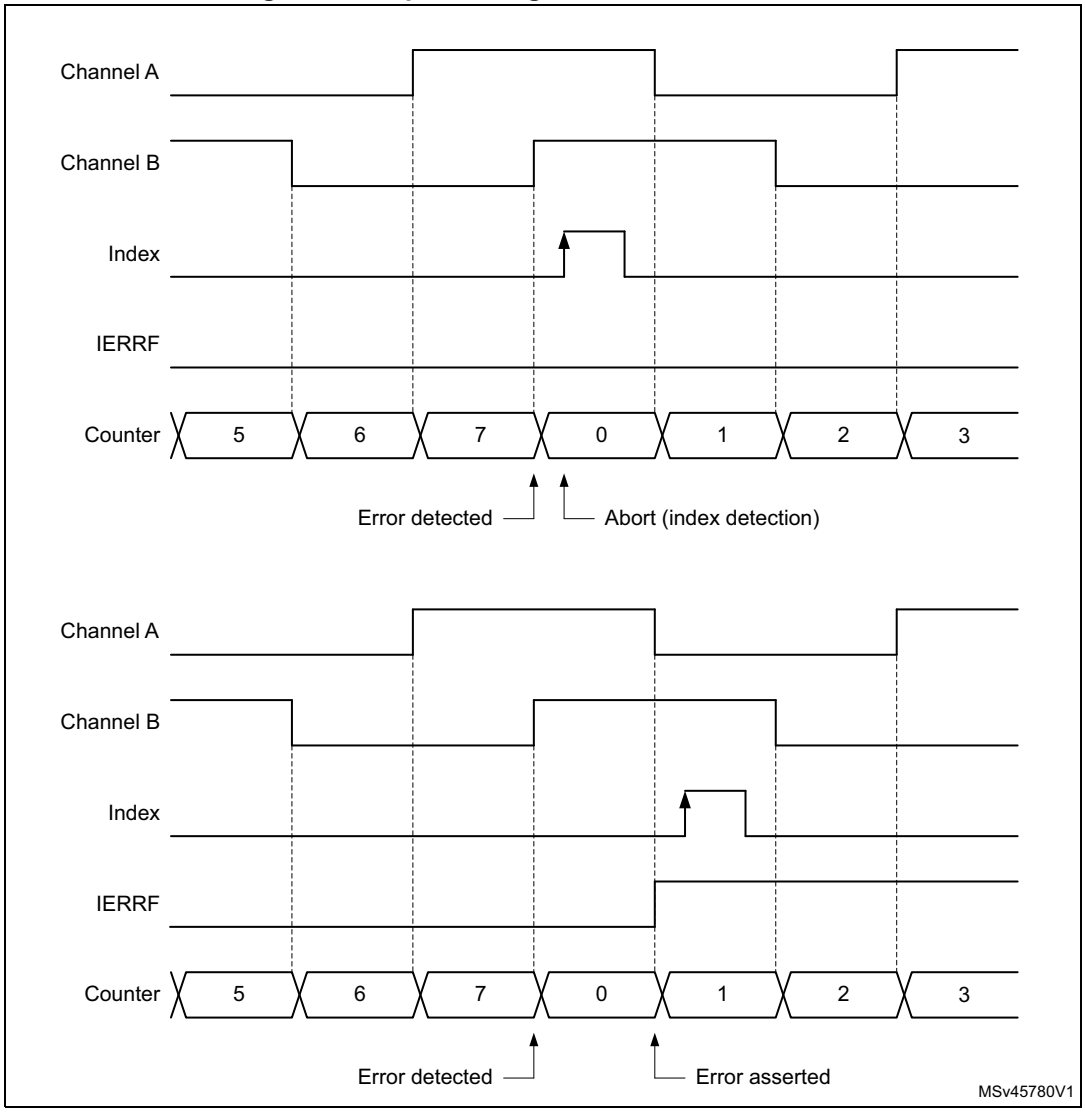


Encoder error management

For encoder configurations where two quadrature signals are available, it is possible to detect transition errors. The reading on the two inputs corresponds to a 2-bit gray code which can be represented as a state diagram, on *Figure 635*. A single bit is expected to change at once. An erroneous transition sets the TERRF interrupt flag in the TIM_SR status

register. A transition error interrupt is generated if the TERRIE bit is set in the TIM_DIER register.

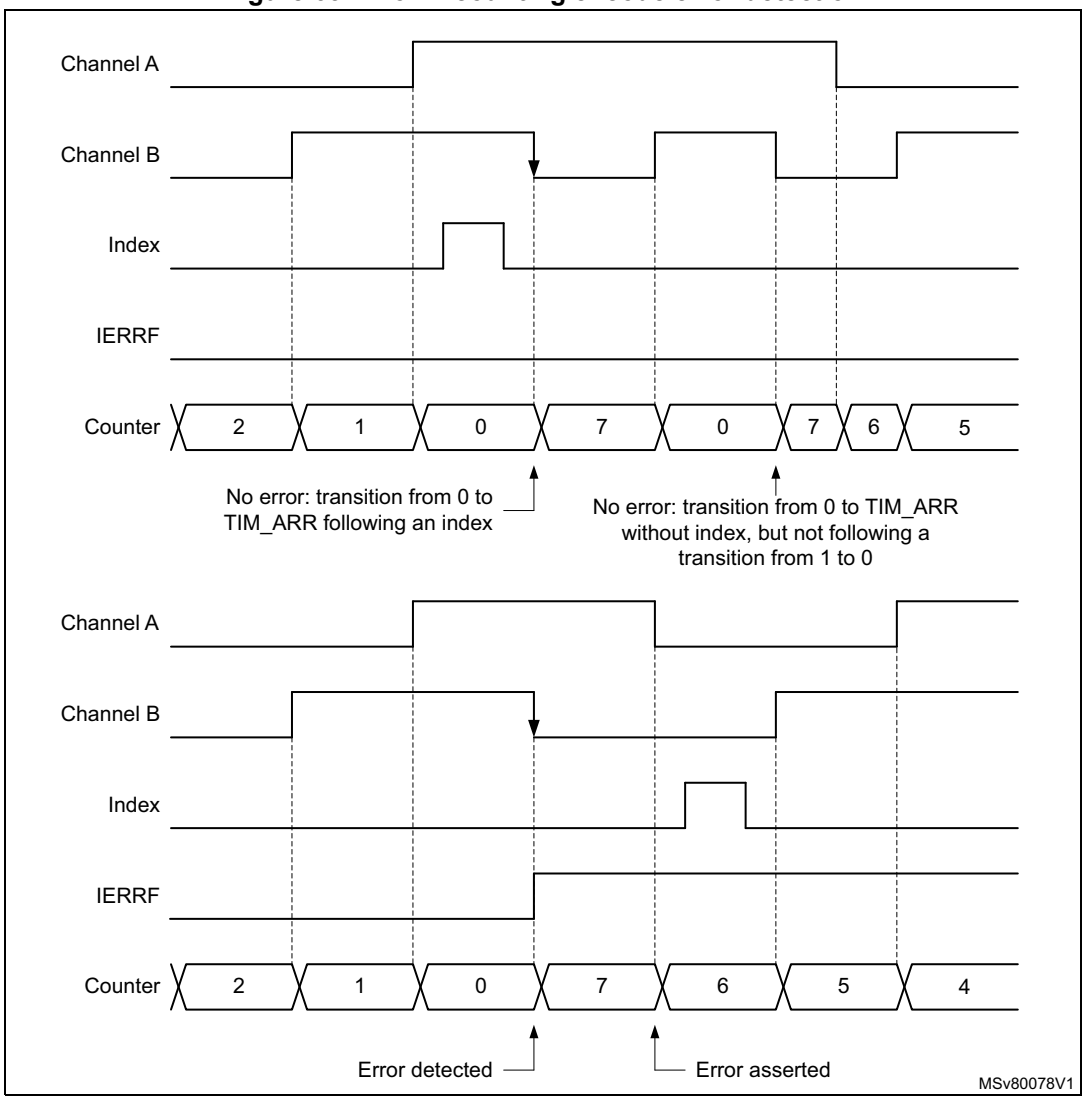
Figure 635. State diagram for quadrature encoded signals



For encoder having an index signal, it is possible to detect abnormal operation resulting in an excess of pulses per revolution. An encoder with N pulses per revolution provides 4xN counts per revolution. The index signal resets the counter every 4xN clock periods.

If the counter value is incremented from TIM_ARR to 0 or decremented from 0 to TIM_ARR value without any index event, this is reported as an index position error.

The overflow threshold is programmed using the TIM_ARR register. A 1000 lines encoder results in a counter value being between 0 and 3999 (in 4x reading mode). The overflow detection threshold must be programmed by setting TIM_ARR = 3999 + 1 = 4000.



The error assertion is delayed to the transition 0 to 1 when in up-counting. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 636*.

Figure 636. Up-counting encoder error detection

In down-counting mode, the detection is conditioned by a preliminary transition from 1 to 0. This is to cope with narrow index pulses in gated A and B mode, as shown on *Figure 637*, to avoid any false error detection in case the encoder dithers between TIM_ARR and 0 immediately after the index detection.

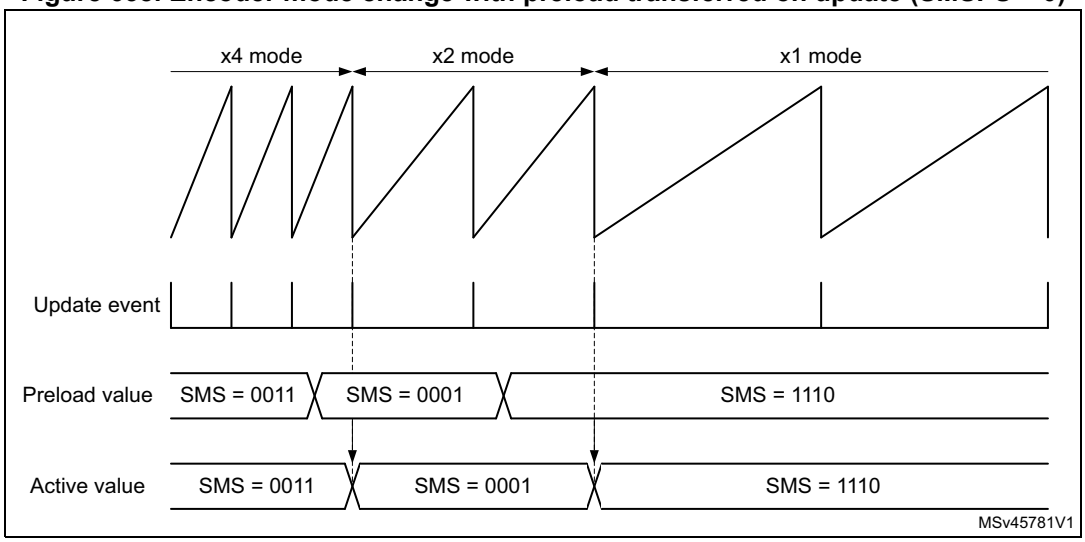
Figure 637. Down-counting encode error detection

An index error sets the IERRF interrupt flag in the TIM_SR status register. An index error interrupt is generated if the IERRIE bit is set in the TIM_DIER register.

Functional encoder interrupts

The following interrupts are also available in encoder mode

- Direction change: any change of the counting direction in encoder mode causes the DIR bit in the TIM_CR1 register to toggle. The direction change sets the DIRF interrupt flag in the TIM_SR status register. A direction change interrupt is generated if the DIRIE bit is set in the TIM_DIER register.
- Index event: the index event sets the IDXF interrupt flag in the TIM_SR status register. An index interrupt is generated if the IDXIE bit is set in the TIM_DIER register.



Slave mode selection preload for run-time encoder mode update

It can be necessary to switch from one encoder mode to another during run-time. This is typically done at high-speed to decrease the update interrupt rate, by switching from x4 to x2 to x1 mode, as shown on *Figure 638*.

For this purpose, the SMS[4:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIM_SMCR register. The trigger for the transfer from SMS[4:0] preload to active value can be selected with the SMSPS bit in the TIM_SMCR register.

- SMSPS = 0: the transfer is triggered by the update event (UEV) occurring when the counter overflows when up-counting, and underflows when down-counting.
- SMSPS = 1: the transfer is triggered by the index event.

Figure 638. Encoder mode change with preload transferred on update (SMSPS = 0)

Encoder clock output

The encoder mode operating principle is not perfectly suited for high-resolution velocity measurements, at low speed, as it requires a relatively long integration time to have a sufficient number of clock edges and a precise measurement.

At low speed, a better solution is to do an edge-to-edge clock period measurement. This can be achieved using a slave timer. The timer can output the encoder clock information on the tim_trgo output. The slave timer can then perform a period measurement and provide velocity information for each and every encoder clock edge.

This mode is enabled by setting the MMS[3:0] bitfield to 1000, in the TIM_CR2 register. It is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

42.4.21 Encoder with built-in debouncer

This mode is intended to support noisy digital potentiometers and knobs, providing quadrature encoded signals with potentially long bouncing periods after each transition.

The operating principle consists of working on the first valid transition and discard any other until a second valid transition is detected on the alternate encoder signal.

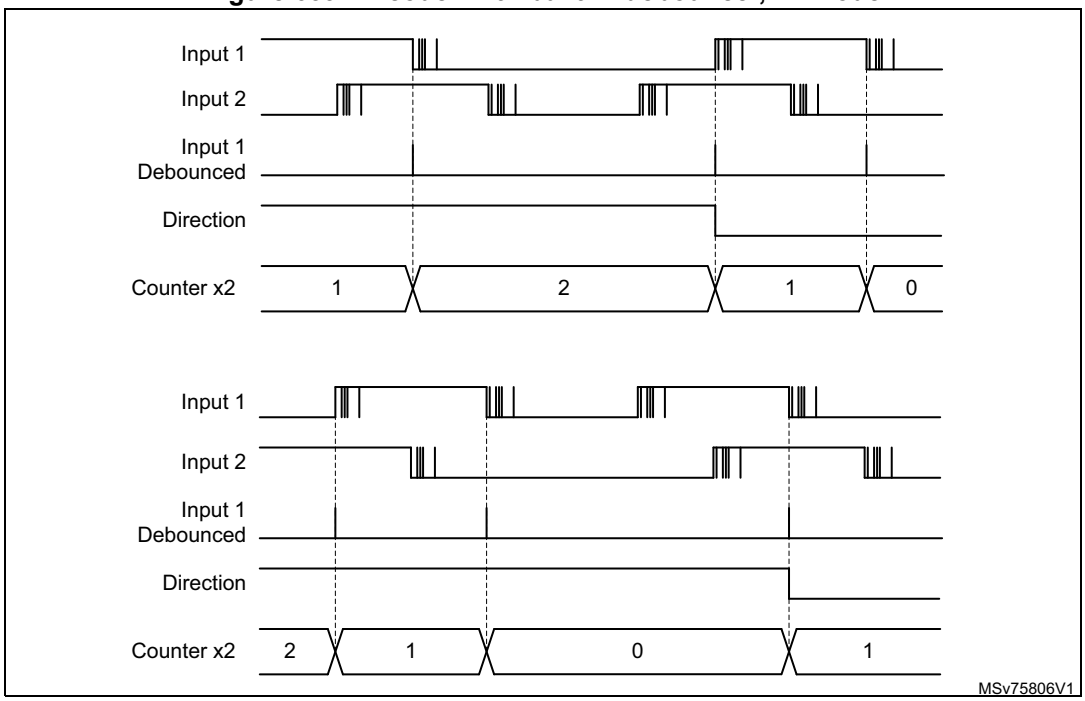
The *Figure 639* below represents the x2 operating mode. It must be noticed that a transition on input 1 is ignored during direction reversal, if there's no edge on input 2.

The *Figure 640* below represents the x4 operating mode. In this case, a transition is always ignored during a direction reversal or when the encoder dithers between two positions.

These two modes are enabled by writing SMS[4:0] = 10000 or 10001 in TIM_SMCR register.

The encoder with built-in debouncer modes are not suitable for tracking a position or an angle in motor control applications. The transitions ignored during direction reversal will lead to a position/angle error that will build-up over time.

Figure 639. Encoder with built-in debouncer, x2 mode



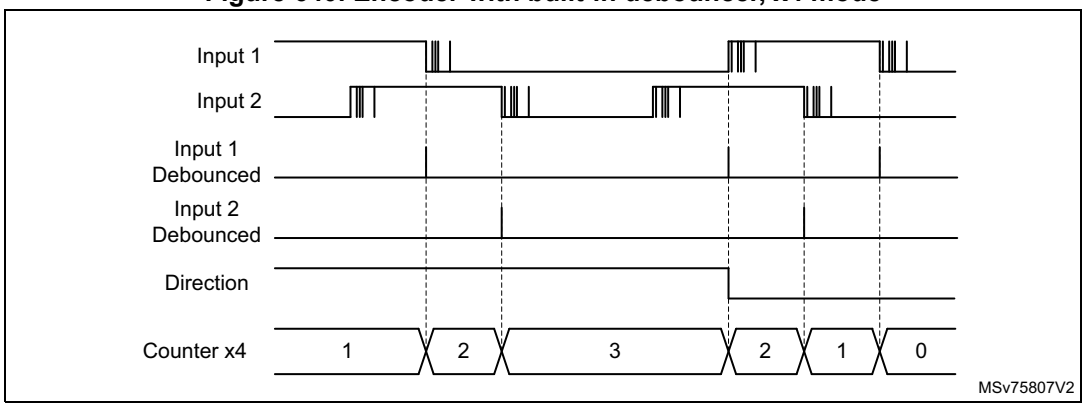


Figure 640. Encoder with built-in debouncer, x4 mode

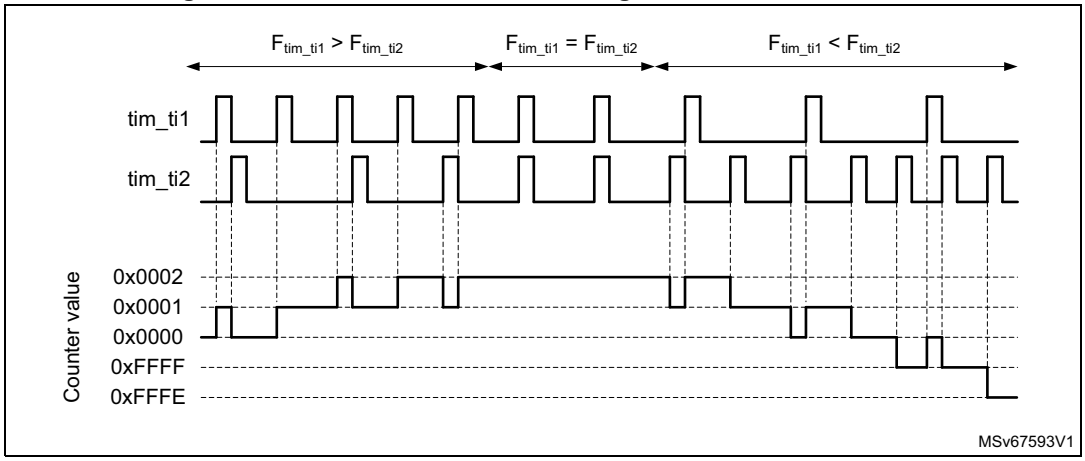
42.4.22 Direction bit output

It is possible to output a direction signal out of the timer, on the tim_oc3 and tim_oc4 output signals (copy of the DIR bit in the TIM_CR1 register). This is achieved by setting the OC3M[3:0] or the OC4M[3:0] bitfield to 1011 in the TIM_CCMR2 register.

This feature can be used for monitoring the counting direction (or rotation direction) in encoder mode, or to have a signal indicating the up/down phases in center-aligned PWM mode.

42.4.23 Clock drift measurement

It is possible to measure the drift between two clock sources using the directional clock encoder mode. This is useful for audio applications typically, when one need to compute the drift between two streams.



To do so, a signal representing the rate of a first audio stream must be connected to tim_ti1 and a signal representing the rate of a second audio stream must be connected to tim_ti2. The signals representing the audio rates are generally the SAIx_FS_A, SAIx_FS_B, SPIx_WS or spdifrx_frame_sync (this list of signals is provided as example and depends on the audio peripheral availability for a given product line, as detailed on the product datasheet).

In this case, the clocks are present on both tim_ti1 and tim2 simultaneously, as shown on *Figure 641*, and the counter value indicates the drift.

Let's define F_{tim_ti1} and F_{tim_ti2} the frequencies of the signals on tim_ti1 and tim_ti2. The counter value will change as following:

- If $F_{tim_ti1} > F_{tim_ti2}$ the counter value increases.
- If $F_{tim_ti1} < F_{tim_ti2}$ the counter value decreases.
- If $F_{tim_ti1} = F_{tim_ti2}$ the counter value will dither between two consecutive values, from one clock edge to the other. If the two clocks are perfectly synchronized (clock edges occurring simultaneously on the two inputs), the counter value does not change (as shown on *Figure 641*).

Figure 641. Clock drift measure using directional clock mode

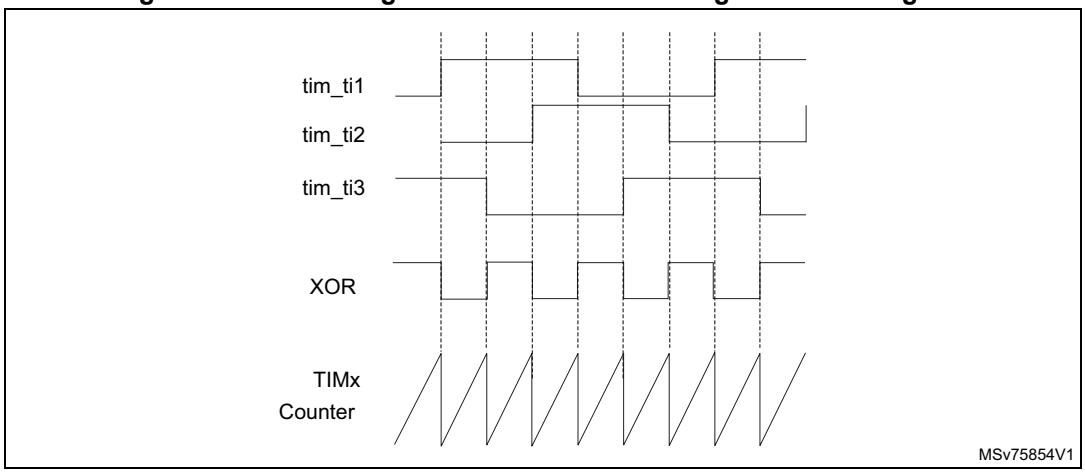
42.4.24 UIF bit remapping

The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag (UIF) into bit 31 of the timer counter register's bit 31 (TIM_CNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. It eases the calculation of angular speed by avoiding race conditions caused, for instance, by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the UIF and UIFCPY flag assertions.

In 32-bit timer implementations, when the IUFREMAP bit is set, bit 31 of the counter is overwritten by the UIFCPY flag upon read access (the counter's most significant bit is only accessible in write mode).

42.4.25 Timer input XOR function



The TI1S bit in the TIM_CR2 register, allows the input filter of channel 1 to be connected to the output of an XOR gate, combining the three input pins tim_ti1, tim_ti2 and tim_ti3.

The XOR output can be used with all the timer input functions such as trigger or input capture.

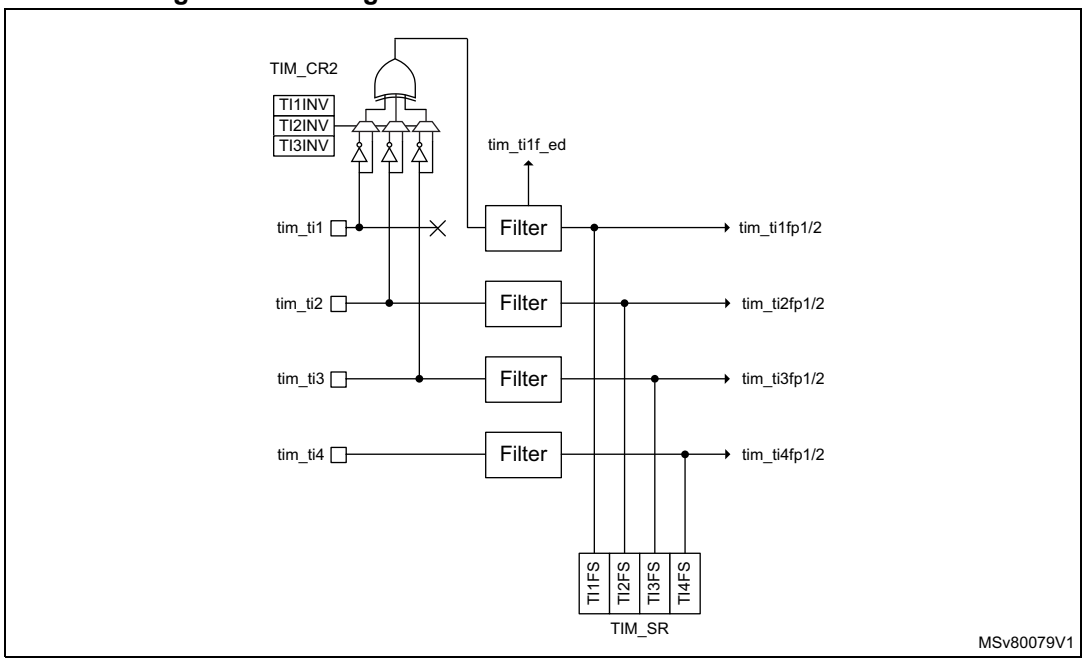
An example of this feature used to interface Hall sensors is given in *Section 41.3.34: Interfacing with Hall sensors*.

It is convenient to measure the interval between edges on two input signals, as per *Figure 642*.

Figure 642. Measuring time interval between edges on three signals

The XORPS control bit selects the position of the XOR gate, as shown on the *Figure 643* and *Figure 644* below, when the TI1S bit is set.

Figure 643. XOR gate connection with TI1S = 1 and XORPS = 0



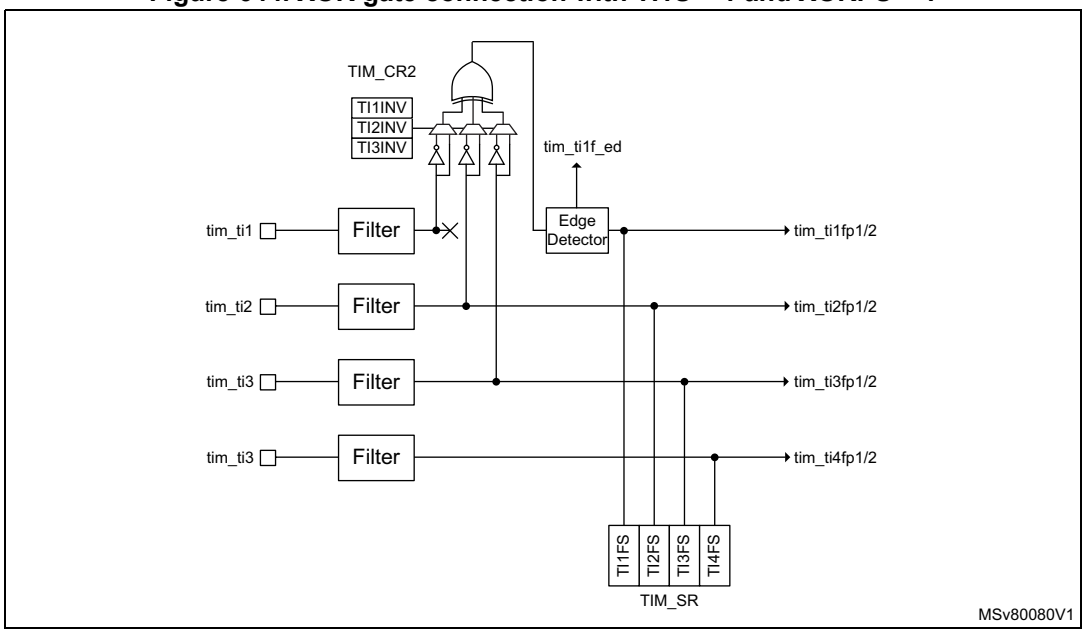


Figure 644. XOR gate connection with TI1S = 1 and XORPS = 1

Three control bits T1INV, T2INV and T3INV in the TIM_CR2 register can invert the tim_in1, tim_in2 and tim_in3 signals prior entering the XOR gate.

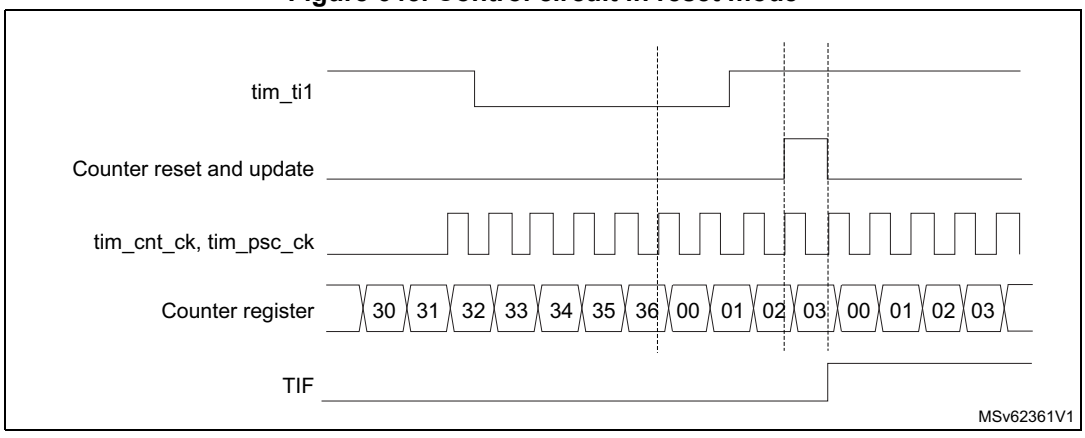
The status of the tim_in1, tim_in2, tim_in3 and tim_in4 signals can be software polled using the TI1FS, TI2FS, TI3FS and TI4FS bits in the TIM_SR register (tim_ti4 is not represented on figures above and do not enter into the XOR gate).

42.4.26 Timers and external trigger synchronization

The TIMx timers can be synchronized with an external trigger in several modes: reset mode, gated mode, trigger mode, reset + trigger and gated + reset modes.

Slave mode: reset mode

The counter and its prescaler can be reinitialized in response to an event on a trigger input. Moreover, if the URS bit from the TIM_CR1 register is low, an update event UEV is generated. Then all the preloaded registers (TIM_ARR, TIM_CCRx) are updated.



In the following example, the upcounter is cleared in response to a rising edge on tim_ti1 input:

1. Configure the channel 1 to detect rising edges on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in the TIM_CCMR1 register. Write CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edges only).
2. Configure the timer in reset mode by writing SMS = 100 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
3. Start the counter by writing CEN = 1 in the TIM_CR1 register.

The counter starts counting on the internal clock, then behaves normally until tim_ti1 rising edge. When tim_ti1 rises, the counter is cleared and restarts from 0. In the meantime, the trigger flag is set (TIF bit in the TIM_SR register) and an interrupt request, or a DMA request can be sent if enabled (depending on the TIE and TDE bits in TIM_DIER register).

The following figure shows this behavior when the autoreload register TIM_ARR = 0x36. The delay between the rising edge on tim_ti1 and the actual reset of the counter is due to the resynchronization circuit on tim_ti1 input.

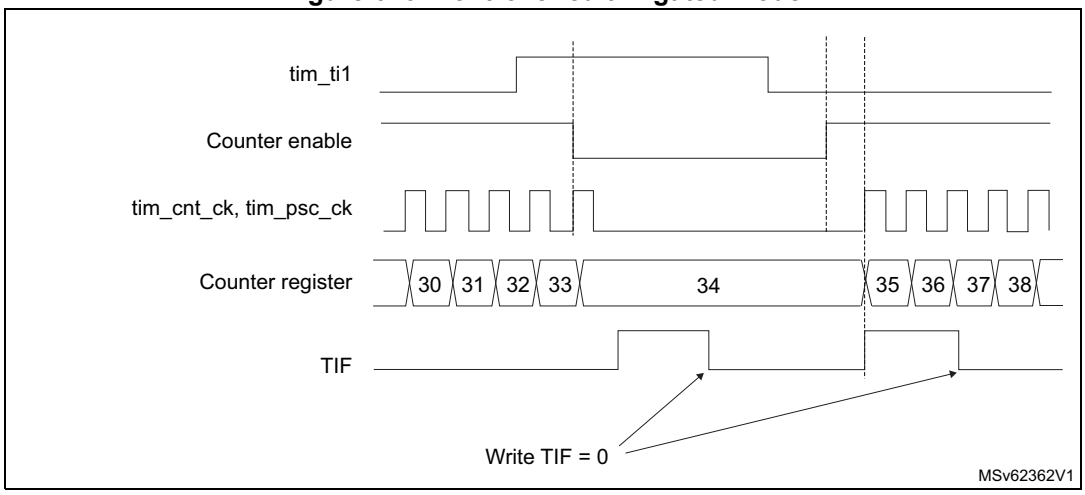
Figure 645. Control circuit in reset mode

Slave mode: gated mode

The counter can be enabled depending on the level of a selected input.

In the following example, the upcounter counts only when tim_ti1 input is low:

1. Configure the channel 1 to detect low levels on tim_ti1. Configure the input filter duration (in this example, we do not need any filter, so we keep IC1F = 0000). The



capture prescaler is not used for triggering, so it does not need to be configured. The CC1S bits select the input capture source only, CC1S = 01 in TIM_CCMR1 register. Write CC1P = 1 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).

2. Configure the timer in gated mode by writing SMS = 101 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.
3. Enable the counter by writing CEN = 1 in the TIM_CR1 register (in gated mode, the counter does not start if CEN = 0, whatever is the trigger input level).

The counter starts counting on the internal clock as long as tim_ti1 is low and stops as soon as tim_ti1 becomes high. The TIF flag in the TIM_SR register is set both when the counter starts or stops.

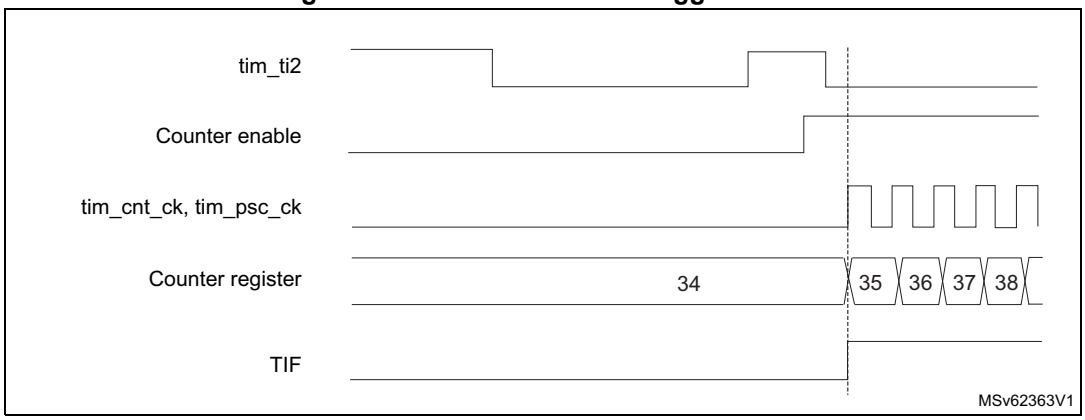
The delay between the rising edge on tim_ti1 and the actual stop of the counter is due to the resynchronization circuit on tim_ti1 input.

Figure 646. Control circuit in gated mode

Note: The configuration "CCxP = CCxNP = 1" (detection of both rising and falling edges) does not have any effect in gated mode because gated mode acts on a level and not on an edge.

Slave mode: trigger mode

The counter can start in response to an event on a selected input.



In the following example, the upcounter starts in response to a rising edge on tim_ti2 input:

1. Configure the channel 2 to detect rising edges on tim_ti2. Configure the input filter duration (in this example, we do not need any filter, so we keep IC2F = 0000). The capture prescaler is not used for triggering, so it does not need to be configured. CC2S bits are selecting the input capture source only, CC2S = 01 in TIM_CCMR1 register. Write CC2P = 1 and CC2NP = 0 in TIM_CCER register to validate the polarity (and detect low level only).
2. Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti2 as the input source by writing TS = 00110 in TIM_SMCR register.

When a rising edge occurs on tim_ti2, the counter starts counting on the internal clock and the TIF flag is set.

The delay between the rising edge on tim_ti2 and the actual start of the counter is due to the resynchronization circuit on tim_ti2 input.

Figure 647. Control circuit in trigger mode

Slave mode selection preload for run-time encoder mode update

The SMS[4:0] bit can be preloaded. This is enabled by setting the SMSPE enable bit in the TIM_SMCR register. The trigger for the transfer from SMS[4:0] preload to active value is the update event (UEV) occurring when the counter overflows.

Slave mode – combined reset + trigger mode

In this case, a rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers, and starts the counter.

This mode is used for one-pulse mode.

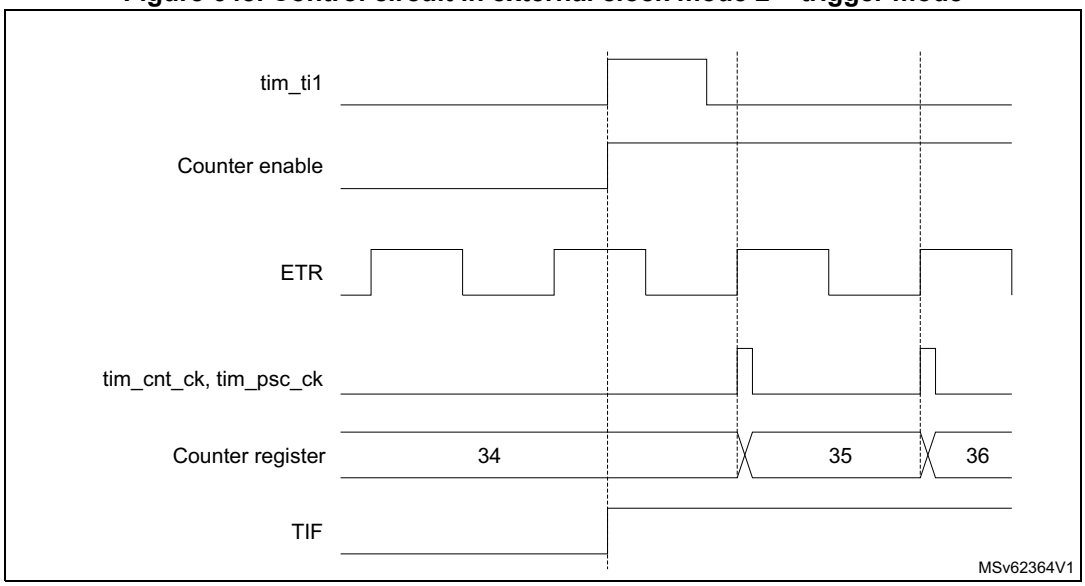
Slave mode – combined gated + reset mode

The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset as soon as the trigger becomes low. Both start and stop of the counter are controlled.

This mode is used to detect out-of-range PWM signal (duty cycle exceeding a maximum expected value).

Slave mode – external clock mode 2 + trigger mode

The external clock mode 2 can be used in addition to another slave mode (except external clock mode 1 and encoder mode). In this case, the tim_etr_in signal is used as external clock input, and another input can be selected as trigger input when operating in reset mode, gated mode, or trigger mode. It is recommended not to select tim_etr_in as tim_trgi through the TS bits of TIM_SMCR register.



In the following example, the upcounter is incremented at each rising edge of the tim_etr_in signal as soon as a rising edge of tim_ti1 occurs:

1. Configure the external trigger input circuit by programming the TIM_SMCR register as follows:
   - ETF = 0000: no filter.
   - ETPS = 00: prescaler disabled.
   - ETP = 0: detection of rising edges on tim_etr_in and ECE = 1 to enable the external clock mode 2.
2. Configure the channel 1 as follows, to detect rising edges on TI:
   - IC1F = 0000: no filter.
   - The capture prescaler is not used for triggering and does not need to be configured.
   - CC1S = 01in TIM_CCMR1 register to select only the input capture source.
   - CC1P = 0 and CC1NP = 0 in TIM_CCER register to validate the polarity (and detect rising edge only).
3. Configure the timer in trigger mode by writing SMS = 110 in TIM_SMCR register. Select tim_ti1 as the input source by writing TS = 00101 in TIM_SMCR register.

A rising edge on tim_ti1 enables the counter and sets the TIF flag. The counter then counts on tim_etr_in rising edges.

The delay between the rising edge of the tim_etr_in signal and the actual reset of the counter is due to the resynchronization circuit on tim_etrp input.

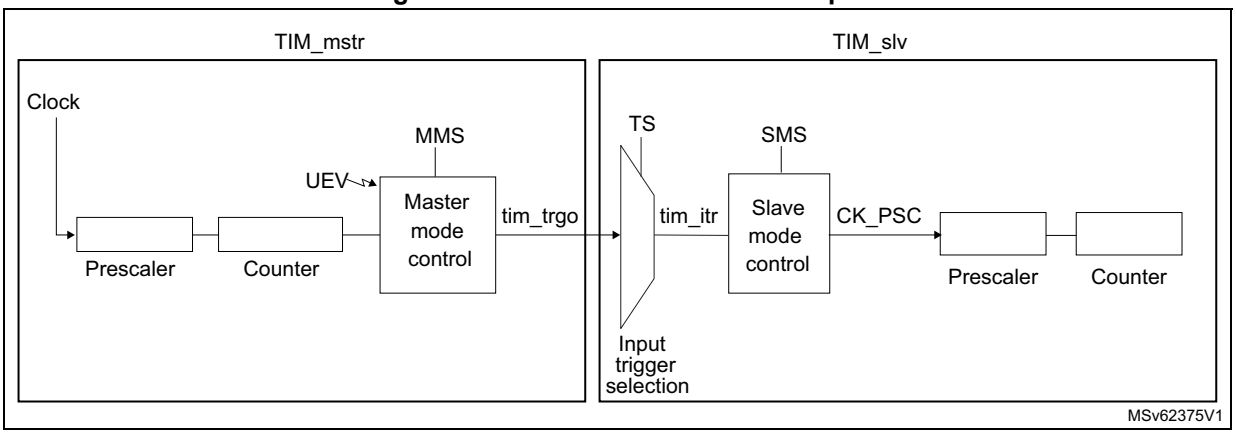
Figure 648. Control circuit in external clock mode 2 + trigger mode

42.4.27 Timer synchronization

The TIMx timers are linked together internally for timer synchronization or chaining. When one timer is configured in master mode, it can reset, start, stop, or clock the counter of another timer configured in slave mode.

Figure 649 and *Figure 650* show examples of master/slave timer connections.

Figure 649. Master/Slave timer example



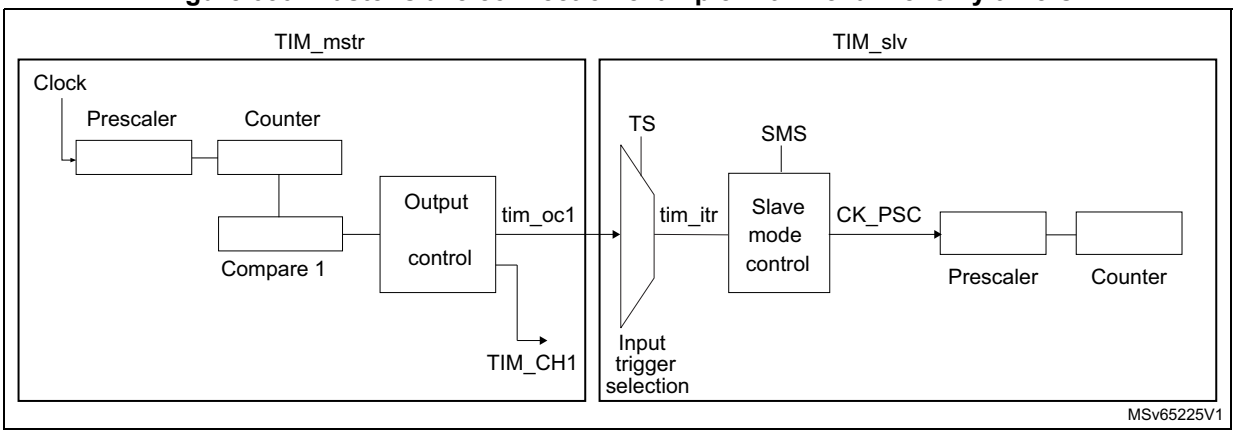


Figure 650. Master/slave connection example with 1 channel only timers

Note: The timers with one channel only (see Figure 650) do not feature a master mode. However, the tim_oc1 output signal can serve as trigger for slave timer (see TIMx internal trigger connection table in Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals). The tim_oc1 signal pulse width must be programmed to be at least two clock cycles of the destination timer, to make sure the slave timer detects the trigger. For instance, if the destination timer tim_ker_ck clock is four times slower than the source timer, the OC1 pulse width must be eight clock cycles.

Using one timer as prescaler for another timer

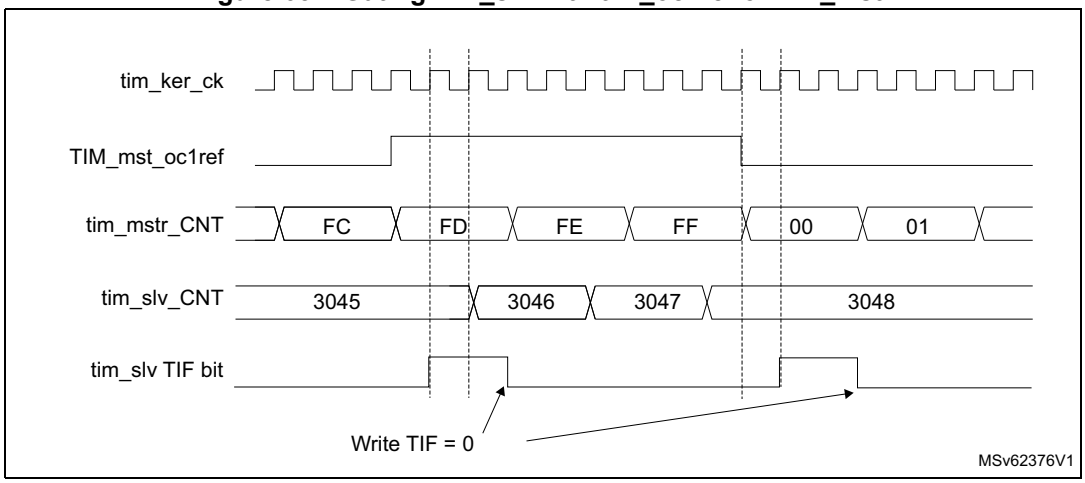
For example, TIM_mstr can be configured to act as a prescaler for TIM_slv. Refer to *Figure 649*. To do this:

1. Configure TIM_mstr in master mode so that it outputs a periodic trigger signal on each update event UEV. If MMS = 010 is written in the TIM_mstr_CR2 register, a rising edge is output on tim_trgo each time an update event is generated.
2. To connect the tim_trgo output of TIM_mstr to TIM_slv, TIM_slv must be configured in slave mode using ITR2 as internal trigger. This is selected through the TS bits in the TIM_slv_SMCR register (writing TS = 00010).
3. Then the slave mode controller must be put in external clock mode 1 (write SMS = 111 in the TIM_slv_SMCR register). This causes TIM_slv to be clocked by the rising edge

of the periodic TIM_mstr trigger signal (which correspond to the TIM_mstr counter overflow).

4. Finally both timers must be enabled by setting their respective CEN bits (TIM_CR1 register).

Note: If tim_ocx is selected on TIM_mstr as the trigger output (MMS = 1xx), its rising edge is used to clock the counter of TIM_slv.



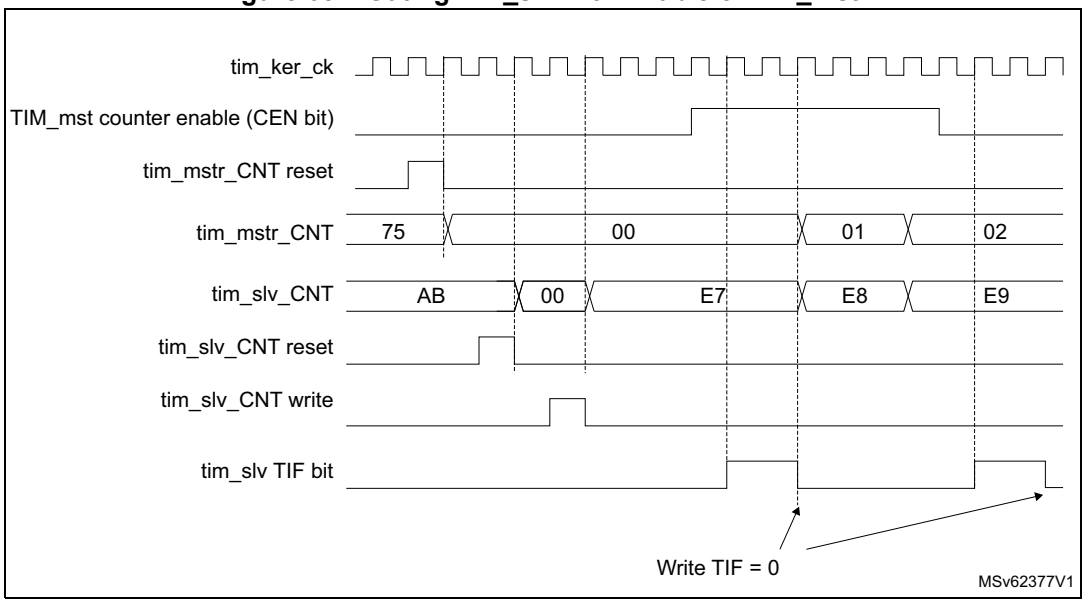
Using one timer to enable another timer

In this example, we control the enable of TIM_slv with the output compare 1 of TIM_mstr. Refer to *Figure 649* for connections. TIM_slv counts on the divided internal clock only when tim_oc1ref of TIM_mstr is high. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{tim_cnt_ck} = f_{tim_ker_ck}/3$).

1. Configure TIM_mstr master mode to send its output compare 1 reference (tim_oc1ref) signal as trigger output (MMS = 100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS = 101 in TIM_slv_SMCR register).
5. Enable TIM_slv by writing 1 in the CEN bit (TIM_slv_CR1 register).
6. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).

Note: The slave timer counter clock is not synchronized with the master timer counter clock, this mode only affects the TIM_slv counter enable signal.

Figure 651. Gating TIM_slv with tim_oc1ref of TIM_mstr

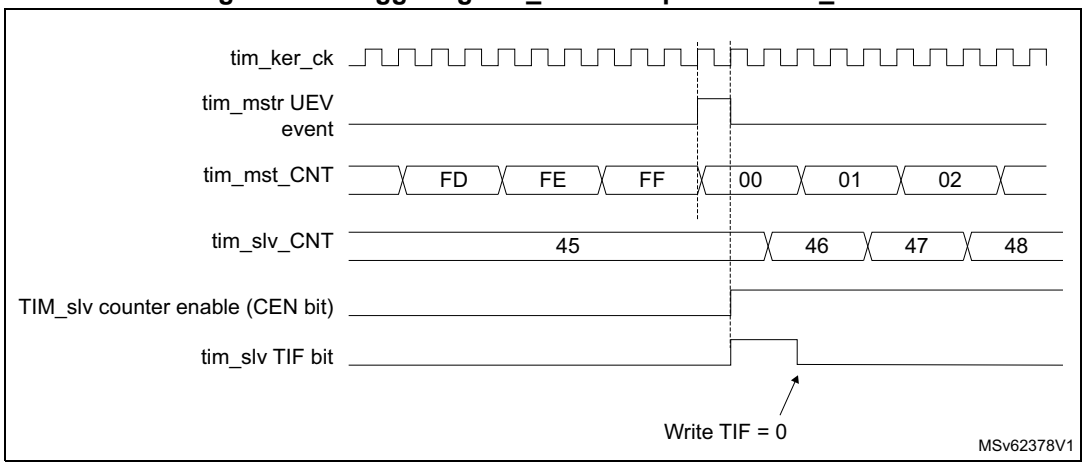


In the example in *Figure 651*, the TIM_slv counter and prescaler are not initialized before being started. So they start counting from their current value. It is possible to start from a given value by resetting both timers before starting TIM_mstr. Then any value can be written in the timer counters. The timers can easily be reset by software using the UG bit in the TIM_EGR registers.

In the next example (refer to *Figure 652*), we synchronize TIM_mstr and TIM_slv. TIM_mstr is the master and starts from 0. TIM_slv is the slave and starts from 0xE7. The prescaler ratio is the same for both timers. TIM_slv stops when TIM_mstr is disabled by writing 0 to the CEN bit in the TIM_mstr_CR1 register:

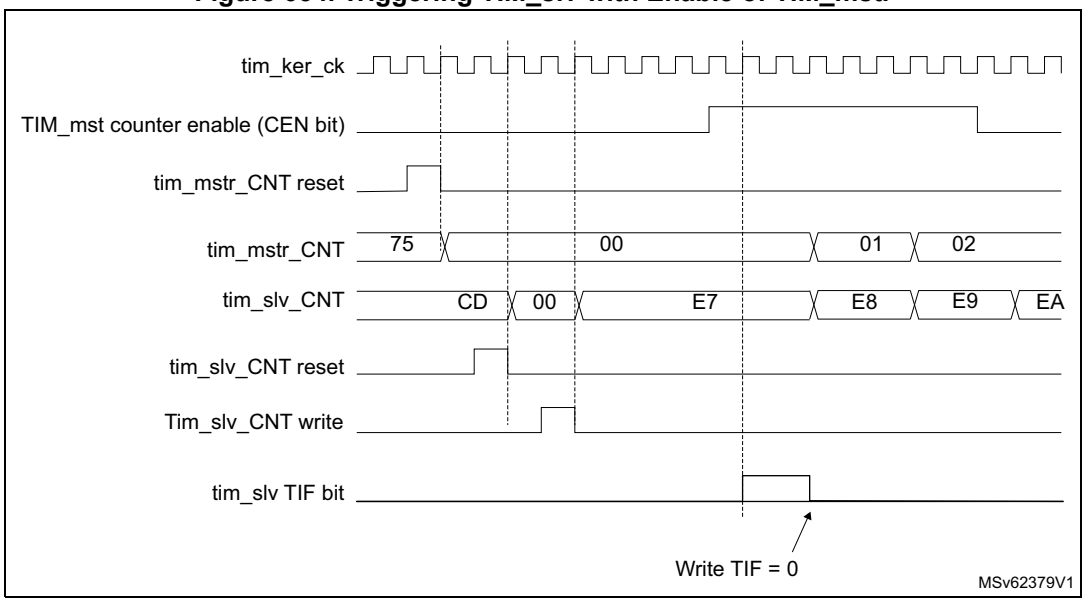
1. Configure TIM_mstr master mode to send its output compare 1 reference (tim_oc1ref) signal as trigger output (MMS = 100 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr tim_oc1ref waveform (TIM_mstr_CCMR1 register).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in gated mode (SMS = 101 in TIM_slv_SMCR register).
5. Reset TIM_mstr by writing 1 in UG bit (TIM_mstr_EGR register).
6. Reset TIM_slv by writing 1 in UG bit (TIM_slv_EGR register).
7. Initialize TIM_slv to 0xE7 by writing 0xE7 in the TIM_slv counter (TIM_slv_CNT).
8. Enable TIM_slv by writing 1 in the CEN bit (TIM_slv_CR1 register).
9. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).
10. Stop TIM_mstr by writing 0 in the CEN bit (TIM_mstr_CR1 register).

Figure 652. Gating TIM_slv with Enable of TIM_mstr



Using one timer to start another timer

In this example, we set the enable of TIM_slv with the update event of TIM_mstr. Refer to *Figure 649* for connections. TIM_slv starts counting from its current value (which can be nonzero) on the divided internal clock as soon as the update event is generated by TIM_mstr. When TIM_slv receives the trigger signal its CEN bit is automatically set and the counter counts until we write 0 to the CEN bit in the TIM_slv_CR1 register. Both counter clock frequencies are divided by 3 by the prescaler compared to tim_ker_ck ($f_{tim_cnt_ck} = f_{tim_ker_ck}/3$).



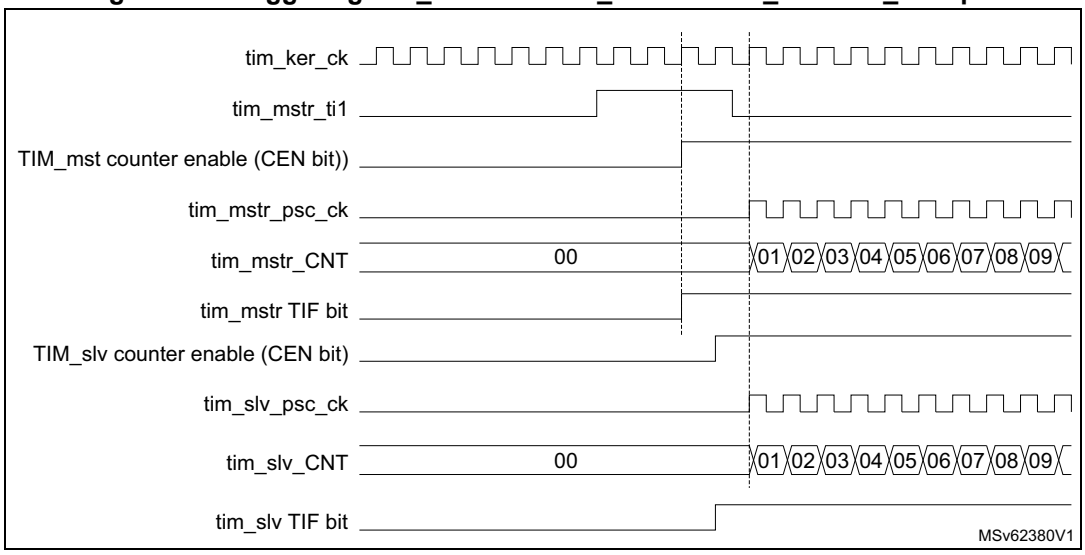
1. Configure TIM_mstr master mode to send its update event (UEV) as trigger output (MMS = 010 in the TIM_mstr_CR2 register).
2. Configure the TIM_mstr period (TIM_mstr_ARR registers).
3. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00010 in the TIM_slv_SMCR register).
4. Configure TIM_slv in trigger mode (SMS = 110 in TIM_slv_SMCR register).
5. Start TIM_mstr by writing 1 in the CEN bit (TIM_mstr_CR1 register).

Figure 653. Triggering TIM_slv with update of TIM_mstr

As in the previous example, both counters can be initialized before starting counting. *Figure 654* shows the behavior with the same configuration as in *Figure 653* but in trigger mode (SMS = 110 in the TIM_slv_SMCR register) instead of gated mode.

Figure 654. Triggering TIM_slv with Enable of TIM_mstr

Starting two timers synchronously in response to an external trigger



In this example, we set the enable of TIM_mstr when its tim_ti1 input rises, and the enable of TIM_slv with the enable of TIM_mstr. Refer to *Figure 649* for connections. To ensure the counters are aligned, TIM_mstr must be configured in master/slave mode (slave with respect to tim_ti1, master with respect to TIM_slv):

1. Configure TIM_mstr master mode to send its enable as trigger output (MMS = 001 in the TIM_mstr_CR2 register).
2. Configure TIM_mstr slave mode to get the input trigger from tim_ti1 (TS = 00100 in the TIM_mstr_SMCR register).
3. Configure TIM_mstr in trigger mode (SMS = 110 in the TIM_mstr_SMCR register).
4. Configure the TIM_mstr in master/slave mode by writing MSM = 1 (TIM_mstr_SMCR register).
5. Configure TIM_slv to get the input trigger from TIM_mstr (TS = 00000 in the TIM_slv_SMCR register).
6. Configure TIM_slv in trigger mode (SMS = 110 in the TIM_slv_SMCR register).

When a rising edge occurs on tim_ti1 (TIM_mstr), both counters start counting synchronously on the internal clock and both TIF flags are set.

Note: In this example both timers are initialized before starting (by setting their respective UG bits). Both counters starts from 0, but an offset can easily be inserted between them by writing any of the counter registers (TIM_CNT). One can see that the master/slave mode inserts a delay between CNT_EN and CK_PSC on TIM_mstr.

Figure 655. Triggering TIM_mstr and TIM_slv with TIM_mstr tim_ti1 input

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.28 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.4.29 ADC synchronization

The timer operation can be synchronized to the ADC clock to trigger jitter-free ADC sampling. This function is enabled using the ADSYNC bit in the TIM_CR2 register.

This feature is useful when the timers and the ADCs are operating with semisynchronous clocks (clocks derived from a same source with integer ratio tim_ker_ck/adc_ker_ck), for instance adc_ker_ck = 75 MHz and tim_ker_ck = 150 MHz or 300 MHz.

ADSYNC must also be set when both peripherals are operating at the same frequency from the same clock source, when jitter-free operation is needed.

ADSYNC must not be set and jitter-free operation is not supported in the following cases:

- When the clock ratio is not an integer (for example adc_ker_ck = 75 MHz and tim_ker_ck = 100 MHz): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.
- When the ADC is operating in asynchronous mode (adc_ker_ck uncorrelated with tim_ker_ck): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.

When ADSYNC = 1, the timer operation is slightly changed: the counter enable and counter reset events are aligned to the adc_ker_ck ADC clock, to avoid any phase shift due to clocks enable in the RCC.

Jitter-free operation is guaranteed only when one of the two requirements below is met (depending on the selected trigger source):

1. The counter period must be a multiple of the ADC clock period.

$$(\text{TIM_PSC} + 1) \times (\text{TIM_ARR} + 1) \times T_{\text{tim_ker_ck}} = n \times T_{\text{adc_ker_ck}}$$

2. The compare value must be a multiple of the ADC clock period.

$$(\text{TIM_PSC} + 1) \times \text{TIM_CMPy} \times T_{\text{tim_ker_ck}} = m \times T_{\text{adc_ker_ck}}$$

Note: If none of the two above requirements is met, the trigger is still generated, but the latency is not constant and varies with the timer and ADC clocks phase shift.

Programming guidelines

The ADC synchronization feature must not be modified during run-time, once the counter is enabled and once the ADC has been configured for receiving triggers from the timer.

It is mandatory to follow the procedure below to use the ADC synchronization:

1. Enable the destination ADC clock.
2. Configure the timer and set the ADSYNC bit.
3. Configure the ADC and enable it (using ADSTART and/or JADSTART bits).
4. Start the timer (with the CEN counter enable bit).

42.4.30 DMA burst mode

The TIMx timers have the capability to generate multiple DMA requests upon a single event. The main purpose is to be able to reprogram part of the timer multiple times without software overhead, but it can also be used to read several registers in a row, at regular intervals.

The DMA controller destination is unique and must point to the virtual register TIM_DMAR. On a given timer event, the timer launches a sequence of DMA requests (burst). Each write into the TIM_DMAR register is actually redirected to one of the timer registers.

The DBL[4:0] bits in the TIM_DCR register set the DMA burst length. The timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address), i.e. the number of transfers (either in half-words or in bytes).

The DBA[4:0] bits in the TIM_DCR registers define the DMA base address for DMA transfers (when read/write accesses are done through the TIM_DMAR address). DBA is defined as an offset starting from the address of the TIM_CR1 register:

Example:

00000: TIM_CR1

00001: TIM_CR2

00010: TIM_SMCR

The DBSS[3:0] bits in the TIM_DCR register defines the interrupt source that triggers the DMA burst transfers (see *Section 42.5.23: TIM DMA control register (TIM_DCR)* for details).

As an example, the timer DMA burst feature is used to update the contents of the CCRx registers (x = 2, 3, 4) upon an update event, with the DMA transferring half words into the CCRx registers.

This is done in the following steps:

1. Configure the corresponding DMA channel as follows:
   - DMA channel peripheral address is the DMAR register address.
   - DMA channel memory address is the address of the buffer in the RAM containing the data to be transferred by DMA into CCRx registers.
   - Number of data to transfer = 3 (See note below).
   - Circular mode disabled.
2. Configure the DCR register by configuring the DBA and DBL bitfields as follows: DBL = 3, DBA = 0xE and DBSS = 1.
3. Enable the TIMx update DMA request (set the UDE bit in the DIER register).
4. Enable TIMx.
5. Enable the DMA channel.

This example is for the case where every CCRx register has to be updated once. If every CCRx register is to be updated twice for example, the number of data to transfer must be 6. Let's take the example of a buffer in the RAM containing data1, data2, data3, data4, data5, and data6. The data is transferred to the CCRx registers as follows: on the first update DMA request, data1 is transferred to CCR2, data2 is transferred to CCR3, data3 is transferred to CCR4 and on the second update DMA request, data4 is transferred to CCR2, data5 is transferred to CCR3, and data6 is transferred to CCR4.

Note: A null value can be written to the reserved registers.

42.4.31 TIM2/TIM3/TIM4/TIM5 DMA requests

The TIM2/TIM3/TIM4/TIM5 can generate a DMA requests, as shown in *Table 491*.

Table 491. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE
tim_cc1_dma	Capture/compare 1	CC1DE
tim_cc2_dma	Capture/compare 2	CC2DE
tim_cc3_dma	Capture/compare 3	CC3DE
tim_cc4_dma	Capture/compare 4	CC4DE
tim_trgi_dma	Trigger	TDE

Note: Some timer's DMA requests may not be connected to the DMA controller. Refer to the DMA section(s) for more details.

42.4.32 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or stops.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

42.4.33 TIM2/TIM3/TIM4/TIM5 low-power modes

Table 492. Effect of low-power modes on TIM2/TIM3/TIM4/TIM5

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

42.4.34 TIM2/TIM3/TIM4/TIM5 interrupts

The TIM2/TIM3/TIM4/TIM5 can generate multiple interrupts, as shown in *Table 493*.

Table 493. Interrupt requests

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM_UPD	Update	UIF	UIE	write 0 in UIF	Yes	No
TIM_CC	Capture/compare 1	CC1IF	CC1IE	write 0 in CC1IF	Yes	No
	Capture/compare 2	CC2IF	CC2IE	write 0 in CC2IF	Yes	No
	Capture/compare 3	CC3IF	CC3IE	write 0 in CC3IF	Yes	No
	Capture/compare 4	CC4IF	CC4IE	write 0 in CC4IF	Yes	No
TIM_TRGI	Trigger	TIF	TIE	write 0 in TIF	Yes	No
TIM_DIR_IDX	Index	IDXF	IDXIE	write 0 in IDXF	Yes	No
	Direction	DIRF	DIRIE	write 0 in DIRF	Yes	No
TIM_IERR	Index Error	IERRF	IERRIE	write 0 in IERRF	Yes	No
TIM_TERR	Transition Error	TERRF	TERRIE	write 0 in TERRF	Yes	No

42.5 TIM2/TIM3/TIM4/TIM5 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

42.5.1 TIM control register 1 (TIM_CR1)

Address offset: 0x000

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	CKD2[3:0]				Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
				rw	rw	rw	rw								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	CKD[1:0]		ARPE	CMS[1:0]		DIR	OPM	URS	UDIS	CEN
			rw	rw		rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **CKD2[3:0]**: Clock division 2

This bit field indicates the division between sampling clock (tDTS) used by the dead-time generators and the digital filters (tim_etr_in, tim_tix).

0000: No Division
0001: $t_{DTS2} = 4*t_{DTS}$
0010: $t_{DTS2} = 16*t_{DTS}$
0011: $t_{DTS2} = 64*t_{DTS}$
0100: $t_{DTS2} = 256*t_{DTS}$
0101: $t_{DTS2} = 1024*t_{DTS}$
0110: $t_{DTS2} = 4096*t_{DTS}$
0111: $t_{DTS2} = 16384*t_{DTS}$
1000: $t_{DTS2} = 65536*t_{DTS}$
1001: $t_{DTS2} = 262144*t_{DTS}$
Others: Reserved, do not program this value

Bits 23:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering Enable

0: Dithering disabled
1: Dithering enabled

Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping

0: No remapping. UIF status bit is not copied to TIM_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIM_CNT register bit 31.

Bit 10 Reserved, must be kept at reset value.

Bits 9:8 **CKD[1:0]**: Clock division

This bitfield indicates the division ratio between the timer clock (tim_ker_ck) frequency and sampling clock used by the digital filters (tim_etr_in, tim_tix),

00: $t_{DTS} = t_{tim_ker_ck}$
01: $t_{DTS} = 2 \times t_{tim_ker_ck}$
10: $t_{DTS} = 4 \times t_{tim_ker_ck}$
11: $t_{DTS} = 8 \times t_{tim_ker_ck}$

Bit 7 **ARPE**: Autoreload preload enable

0: TIM_ARR register is not buffered
1: TIM_ARR register is buffered

Bits 6:5 **CMS[1:0]**: Center-aligned mode selection

00: Edge-aligned mode. The counter counts up or down depending on the direction bit (DIR).
01: Center-aligned mode 1. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting down.
10: Center-aligned mode 2. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set only when the counter is counting up.
11: Center-aligned mode 3. The counter counts up and down alternatively. Output compare interrupt flags of channels configured in output (CCxS = 00 in TIM_CCMRx register) are set both when the counter is counting up or down.

Note: It is not allowed to switch from edge-aligned mode to center-aligned mode as long as the counter is enabled (CEN = 1)

Bit 4 **DIR**: Direction

0: Counter used as upcounter
1: Counter used as downcounter

Note: This bit is read only when the timer is configured in center-aligned mode or encoder mode.

Bit 3 **OPM**: One-pulse mode

0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the bit CEN)

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generate an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC, CCRx). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

Note: External clock, gated mode and encoder mode can work only if the CEN bit has been previously set by software. However trigger mode can set the CEN bit automatically by hardware.

CEN is cleared automatically in one-pulse mode, when an update event occurs.

42.5.2 TIM control register 2 (TIM_CR2)

Address offset: 0x004

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
TI3INV	TI2INV	TI1INV	AD SYNC	XORPS	Res.	MMS[3]	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
rw	rw	rw	rw	rw		rw									
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TI1S	MMS[2:0]			CCDS	Res.	Res.	Res.
								rw	rw	rw	rw	rw			

Bit 31 **TI3INV**: tim_ti3 signal inversion on XOR gate input
0: tim_ti3 non-inverted
1: tim_ti3 inverted

Bit 30 **TI2INV**: tim_ti2 signal inversion on XOR gate input
0: tim_ti2 non-inverted
1: tim_ti2 inverted

Bit 29 **TI1INV**: tim_ti1 signal inversion on XOR gate input
0: tim_ti1 non-inverted
1: tim_ti1 inverted

Bit 28 **ADSYNC**: ADC synchronization
0: The timer operates independently from the ADC
1: The timer operation is synchronized with the ADC clock to provide jitter-free sampling point. This mode can be enabled only with specific ADC / timer clock relationship. Refer to *Section 42.4.29* for requirements.
The ADSYNC must not modified when the counter is enabled (CEN bit is set).

Bit 27 **XORPS**: XOR gate position selection
This bit defines the position of the XOR gate with respect to input filters.
0: XOR gate placed before TI1 filter
1: XOR gate placed after TI1, TI2 and TI3 filters

Bit 26 Reserved, must be kept at reset value.

Bits 24:8 Reserved, must be kept at reset value.

Bit 7 **TI1S**: tim_ti1 selection
This bit enables the insertion of a XOR gate to combine tim_ti1_in[15:0], tim_ti2_in[15:0], and tim_ti3_in[15:0] inputs into tim_ti1.
The position of the XOR gate, with respect to input filters, is defined with the XORPS bit.
0: The tim_ti1_in[15:0] multiplexer output is to tim_ti1 input
1: The tim_ti1_in[15:0], tim_ti2_in[15:0] and tim_ti3_in[15:0] multiplexers outputs are XORed and connected to the tim_ti1 input. See also *Section 41.3.34: Interfacing with Hall sensors*.

Bits 25, 6, 5, 4 **MMS[3:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (tim_trgo). The combination is as follows:

0000: **Reset** - the UG bit from the TIM_EGR register is used as trigger output (tim_trgo). If the reset is generated by the trigger input (slave mode controller configured in reset mode) then the signal on tim_trgo is delayed compared to the actual reset.

0001: **Enable** - the Counter enable signal, CNT_EN, is used as trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated by a logic AND between CEN control bit and the trigger input when configured in gated mode.
When the Counter Enable signal is controlled by the trigger input, there is a delay on tim_trgo, except if the master/slave mode is selected (see the MSM bit description in TIM_SMCR register).

0010: **Update** - The update event is selected as trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

0011: **Compare pulse** - The trigger output send a positive pulse when the CC1IF flag is to be set (even if it was already high), as soon as a capture or a compare match occurred (tim_trgo).

0100: **Compare** - tim_oc1refc signal is used as trigger output (tim_trgo)

0101: **Compare** - tim_oc2refc signal is used as trigger output (tim_trgo)

0110: **Compare** - tim_oc3refc signal is used as trigger output (tim_trgo)

0111: **Compare** - tim_oc4refc signal is used as trigger output (tim_trgo)

1000: **Encoder clock output** - The encoder clock signal is used as trigger output (tim_trgo). This code is valid for the following SMS[4:0] values: 00001, 00010, 00011, 01010, 01011, 01100, 01101, 01110, 01111. Any other SMS[4:0] code is not allowed and may lead to unexpected behavior.

Others: Reserved

Note: The clock of the slave timer or ADC must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bit 3 **CCDS**: Capture/compare DMA selection

0: CCx DMA request sent when CCx event occurs

1: CCx DMA requests sent when update event occurs

Bits 2:0 Reserved, must be kept at reset value.

42.5.3 TIM slave mode control register (TIM_SMCR)

Address offset: 0x008

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	SETPS[3:0]				SMSPS	SMSPE	Res.	Res.	TS[4:3]		Res.	Res.	SMS[4:3]	
		rw	rw	rw	rw	rw	rw			rw	rw			rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ETP	ECE	ETPS[1:0]		ETF[3:0]				MSM	TS[2:0]			OCCS	SMS[2:0]		
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:30 Reserved, must be kept at reset value.

Bits 29:26 **SETPS[3:0]**: Synchronous external trigger prescaler

The linear synchronous prescaler divides the frequency of the tim_etrf signal, by a factor (SETPS[3:0] + 1).

Bit 25 **SMSPS**: SMS preload source

This bit selects whether the events that triggers the SMS[4:0] bitfield transfer from preload to active

0: The transfer is triggered by the Timer's Update event

1: The transfer is triggered by the Index event

Bit 24 **SMSPE**: SMS preload enable

This bit selects whether the SMS[4:0] bitfield is preloaded

0: SMS[4:0] bitfield is not preloaded

1: SMS[4:0] preload is enabled

Bits 23:22 Reserved, must be kept at reset value.

Bits 19:18 Reserved, must be kept at reset value.

Bit 15 **ETP**: External trigger polarity

This bit selects whether tim_etr_in or $\overline{\text{tim_etr_in}}$ is used for trigger operations

0: tim_etr_in is non-inverted, active at high level or rising edge

1: tim_etr_in is inverted, active at low level or falling edge

Bit 14 **ECE**: External clock enable

This bit enables external clock mode 2.

0: External clock mode 2 disabled

1: External clock mode 2 enabled. The counter is clocked by any active edge on the tim_etrf signal.

Note: Setting the ECE bit has the same effect as selecting external clock mode 1 with tim_trgi connected to tim_etrf (SMS = 111 and TS = 00111).
It is possible to simultaneously use external clock mode 2 with the following slave modes: reset mode, gated mode and trigger mode. Nevertheless, tim_trgi must not be connected to tim_etrf in this case (TS bits must not be 00111).
If external clock mode 1 and external clock mode 2 are enabled at the same time, the external clock input is tim_etrf.

Bits 13:12 **ETPS[1:0]**: External trigger prescaler

External trigger signal tim_etrp frequency must be at most 1/4 of tim_ker_ck frequency. A prescaler can be enabled to reduce tim_etrp frequency. It is useful when inputting fast external clocks on tim_etr_in.

00: Prescaler OFF
01: tim_etrp frequency divided by 2
10: tim_etrp frequency divided by 4
11: tim_etrp frequency divided by 8

Bits 11:8 **ETF[3:0]**: External trigger filter

This bitfield then defines the frequency used to sample tim_etrp signal and the length of the digital filter applied to tim_etrp. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000: No filter, sampling is done at f_{DTS}
0001: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 2
0010: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 4
0011: $f_{SAMPLING} = f_{tim_ker_ck}$, N = 8
0100: $f_{SAMPLING} = f_{DTS}/2$, N = 6
0101: $f_{SAMPLING} = f_{DTS}/2$, N = 8
0110: $f_{SAMPLING} = f_{DTS}/4$, N = 6
0111: $f_{SAMPLING} = f_{DTS}/4$, N = 8
1000: $f_{SAMPLING} = f_{DTS}/8$, N = 6
1001: $f_{SAMPLING} = f_{DTS}/8$, N = 8
1010: $f_{SAMPLING} = f_{DTS}/16$, N = 5
1011: $f_{SAMPLING} = f_{DTS}/16$, N = 6
1100: $f_{SAMPLING} = f_{DTS}/16$, N = 8
1101: $f_{SAMPLING} = f_{DTS}/32$, N = 5
1110: $f_{SAMPLING} = f_{DTS}/32$, N = 6
1111: $f_{SAMPLING} = f_{DTS}/32$, N = 8

Bit 7 **MSM**: Master/slave mode

0: No action
1: The effect of an event on the trigger input (tim_trgi) is delayed to allow a perfect synchronization between the current timer and its slaves (through tim_trgo). It is useful if we want to synchronize several timers on a single external event.

Bits 21, 20, 6, 5, 4 **TS[4:0]**: Trigger selection

This bitfield selects the trigger input to be used to synchronize the counter.

00000: Internal trigger 0 (tim_itr0)
00001: Internal trigger 1 (tim_itr1)
00010: Internal trigger 2 (tim_itr2)
00011: Internal trigger 3 (tim_itr3)
00100: tim_ti1 edge detector (tim_ti1f_ed)
00101: Filtered timer input 1 (tim_ti1fp1)
00110: Filtered timer input 2 (tim_ti2fp2)
00111: External trigger input (tim_etrf)
01000: Internal trigger 4 (tim_itr4)
01001: Internal trigger 5 (tim_itr5)
01010: Internal trigger 6 (tim_itr6)
01011: Internal trigger 7 (tim_itr7)
01100: Internal trigger 8 (tim_itr8)
01101: Internal trigger 9 (tim_itr9)
01110: Internal trigger 10 (tim_itr10)
01111: Internal trigger 11 (tim_itr11)
10000: Internal trigger 12 (tim_itr12)
10001: Internal trigger 13 (tim_itr13)
10010: Internal trigger 14 (tim_itr14)
10011: Internal trigger 15 (tim_itr15)
10100: Internal trigger 16 (tim_itr16)
10101: Internal trigger 17 (tim_itr17)
10110: Internal trigger 18 (tim_itr18)
10111: Internal trigger 19 (tim_itr19)
11000: Internal trigger 20 (tim_itr20)
11001: Internal trigger 21 (tim_itr21)
11010: Internal trigger 22 (tim_itr22)
11011: Internal trigger 23 (tim_itr23)
11100: Internal trigger 24 (tim_itr24)
11101: Internal trigger 25 (tim_itr25)
11110: Internal trigger 26 (tim_itr26)
11111: Internal trigger 27 (tim_itr27)

See *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation details.

Note: These bits must be changed only when they are not used (for example when SMS = 000) to avoid wrong edge detections at the transition.

Bit 3 **OCCS**: OCREF clear selection

This bit is used to select the OCREF clear source

0: tim_ocref_clr_int is connected to the tim_ocref_clr input

1: tim_ocref_clr_int is connected to tim_etrf

Note: If the OCREF clear selection feature is not supported, this bit is reserved and forced by hardware to 0. Section 42.3: TIM2/TIM3/TIM4/TIM5 implementation.

Bits 17:16, 2:0 **SMS[4:0]**: Slave mode selection

When external signals are selected the active edge of the trigger signal (tim_trgi) is linked to the polarity selected on the external input (refer to ETP bit in TIM_SMCR for tim_etr_in and CCxP/CCxNP bits in TIM_CCER register for tim_ti1fp1 and tim_ti2fp2).

00000: Slave mode disabled - if CEN = 1 then the prescaler is clocked directly by the internal clock.

00001: Encoder mode 1 - Counter counts up/down on tim_ti1fp1 edge depending on tim_ti2fp2 level.

00010: Encoder mode 2 - Counter counts up/down on tim_ti2fp2 edge depending on tim_ti1fp1 level.

00011: Encoder mode 3 - Counter counts up/down on both tim_ti1fp1 and tim_ti2fp2 edges depending on the level of the other input.

00100: Reset mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter and generates an update of the registers.

00101: Gated mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops (but is not reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

00110: Trigger mode - The counter starts at a rising edge of the trigger tim_trgi (but it is not reset). Only the start of the counter is controlled.

00111: External clock mode 1 - Rising edges of the selected trigger (tim_trgi) clock the counter.

01000: Combined reset + trigger mode - Rising edge of the selected trigger input (tim_trgi) reinitializes the counter, generates an update of the registers and starts the counter.

01001: Combined gated + reset mode - The counter clock is enabled when the trigger input (tim_trgi) is high. The counter stops and is reset) as soon as the trigger becomes low. Both start and stop of the counter are controlled.

01010: Encoder mode: Clock plus direction, x2 mode.

01011: Encoder mode: Clock plus direction, x1 mode, tim_ti2fp2 edge sensitivity is set by CC2P.

01100: Encoder mode: Directional clock, x2 mode.

01101: Encoder mode: Directional clock, x1 mode, tim_ti1fp1 and tim_ti2fp2 edge sensitivity is set by CC1P and CC2P.

01110: Quadrature encoder mode: x1 mode, counting on tim_ti1fp1 edges only, edge sensitivity is set by CC1P.

01111: Quadrature encoder mode: x1 mode, counting on tim_ti2fp2 edges only, edge sensitivity is set by CC2P.

10000: Quadrature encoder with built-in debouncer: x2 mode.

10001: Quadrature encoder with built-in debouncer: x4 mode.

Note: The gated mode must not be used if tim_ti1f_ed is selected as the trigger input (TS = 00100). Indeed, tim_ti1f_ed outputs 1 pulse for each transition on tim_ti1f, whereas the gated mode checks the level of the trigger signal.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receive events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

42.5.4 TIM DMA/interrupt enable register (TIM_DIER)

Address offset: 0x00C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits 31:24 Reserved, must be kept at reset value.

Bit 23 **TERRIE**: Transition error interrupt enable
0: Transition error interrupt disabled
1: Transition error interrupt enabled

Bit 22 **IERRIE**: Index error interrupt enable
0: Index error interrupt disabled
1: Index error interrupt enabled

Bit 21 **DIRIE**: Direction change interrupt enable
0: Direction change interrupt disabled
1: Direction change interrupt enabled

Bit 20 **IDXIE**: Index interrupt enable
0: Index interrupt disabled
1: Index interrupt enabled

Bits 19:15 Reserved, must be kept at reset value.

Bit 14 **TDE**: Trigger DMA request enable
0: Trigger DMA request disabled.
1: Trigger DMA request enabled.

Bit 13 Reserved, must be kept at reset value.

Bit 12 **CC4DE**: Capture/compare 4 DMA request enable
0: CC4 DMA request disabled.
1: CC4 DMA request enabled.

Bit 11 **CC3DE**: Capture/compare 3 DMA request enable
0: CC3 DMA request disabled.
1: CC3 DMA request enabled.

Bit 10 **CC2DE**: Capture/compare 2 DMA request enable
0: CC2 DMA request disabled.
1: CC2 DMA request enabled.

Bit 9 **CC1DE**: Capture/compare 1 DMA request enable
0: CC1 DMA request disabled.
1: CC1 DMA request enabled.

Bit 8 **UDE**: Update DMA request enable
0: Update DMA request disabled.
1: Update DMA request enabled.

Bit 7 Reserved, must be kept at reset value.

Bit 6 **TIE**: Trigger interrupt enable
0: Trigger interrupt disabled.
1: Trigger interrupt enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IE**: Capture/compare 4 interrupt enable
0: CC4 interrupt disabled.
1: CC4 interrupt enabled.

Bit 3 **CC3IE**: Capture/compare 3 interrupt enable
0: CC3 interrupt disabled.
1: CC3 interrupt enabled.

Bit 2 **CC2IE**: Capture/compare 2 interrupt enable
0: CC2 interrupt disabled.
1: CC2 interrupt enabled.

Bit 1 **CC1IE**: Capture/compare 1 interrupt enable
0: CC1 interrupt disabled.
1: CC1 interrupt enabled.

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled.
1: Update interrupt enabled.

42.5.5 TIM status register (TIM_SR)

Address offset: 0x010

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

			rc_w0	rc_w0	rc_w0	rc_w0			rc_w0		rc_w0	rc_w0	rc_w0	rc_w0	rc_w0

Bit 31 **TI4FS**: tim_ti4f status
This flag indicates the value of the tim_ti4f signal (after the digital filtering stage), for polling purpose.
0: tim_ti4f signal is low
1: tim_ti4f signal is high

Bit 30 **TI3FS**: tim_ti3f status
This flag indicates the value of the tim_ti3f signal (after the digital filtering stage), for polling purpose.
0: tim_ti3f signal is low
1: tim_ti3f signal is high

Bit 29 **TI2FS**: tim_ti2f status
This flag indicates the value of the tim_ti2f signal (after the digital filtering stage), for polling purpose.
0: tim_ti2f signal is low
1: tim_ti2f signal is high

Bit 28 **TI1FS**: tim_ti1f status
This flag indicates the value of the tim_ti1f signal (after the digital filtering stage), for polling purpose.
0: tim_ti1f signal is low
1: tim_ti1f signal is high

Bits 27:25 Reserved, must be kept at reset value.

Bit 24 **UIOVRF**: Update Interrupt Overrun flag
This flag is set by hardware when an update request occurs while an update interrupt is pending (update interrupt flag set). It is cleared by software by writing it to '0'.
0: No Update Interrupt Overrun
1: Update Interrupt Overrun

Bit 23 **TERRF**: Transition error interrupt flag
This flag is set by hardware when a transition error is detected in encoder mode. It is cleared by software by writing it to 0.
0: No encoder transition error has been detected.
1: An encoder transition error has been detected

Bit 22 **IERRF**: Index error interrupt flag
This flag is set by hardware when an index error is detected. It is cleared by software by writing it to 0.
0: No index error has been detected.
1: An index error has been detected

Bit 21 **DIRF**: Direction change interrupt flag
This flag is set by hardware when the direction changes in encoder mode (DIR bit value in TIM_CR is changing). It is cleared by software by writing it to 0.
0: No direction change
1: Direction change

Bit 20 **IDXF**: Index interrupt flag
This flag is set by hardware when an index event is detected. It is cleared by software by writing it to 0.
0: No index event occurred.
1: An index event has occurred

Bits 19:13 Reserved, must be kept at reset value.

Bit 12 **CC4OF**: Capture/compare 4 overcapture flag
refer to CC1OF description

Bit 11 **CC3OF**: Capture/compare 3 overcapture flag
refer to CC1OF description

Bit 10 **CC2OF**: Capture/compare 2 overcapture flag
refer to CC1OF description

Bit 9 **CC1OF**: Capture/compare 1 overcapture flag
This flag is set by hardware only when the corresponding channel is configured in input capture mode. It is cleared by software by writing it to 0.
0: No overcapture has been detected.
1: The counter value has been captured in TIM_CCR1 register while CC1IF flag was already set

Bits 8:7 Reserved, must be kept at reset value.

Bit 6 **TIF**: Trigger interrupt flag
This flag is set by hardware on the TRG trigger event (active edge detected on tim_trgi input) when the slave mode controller is enabled in all modes but gated mode. It is set when the counter starts or stops when gated mode is selected. It is cleared by software.
0: No trigger event occurred.
1: Trigger interrupt pending.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4IF**: Capture/compare 4 interrupt flag
Refer to CC1IF description

Bit 3 **CC3IF**: Capture/compare 3 interrupt flag
Refer to CC1IF description

Bit 2 **CC2IF**: Capture/compare 2 interrupt flag
Refer to CC1IF description

Bit 1 **CC1IF**: Capture/compare 1 interrupt flag
This flag is set by hardware. It is cleared by software (input capture or output compare mode) or by reading the TIM_CCR1 register (input capture mode only).
0: No compare match / No input capture occurred
1: A compare match or an input capture occurred
If channel CC1 is configured as output: this flag is set when the content of the counter TIM_CNT matches the content of the TIM_CCR1 register. When the content of TIM_CCR1 is greater than the content of TIM_ARR, the CC1IF bit goes high on the counter overflow (in up-counting and up/down-counting modes) or underflow (in down-counting mode). There are three possible options for flag setting in center-aligned mode, refer to the CMS bits in the TIM_CR1 register for the full description.
If channel CC1 is configured as input: this bit is set when counter value has been captured in TIM_CCR1 register (an edge has been detected on IC1, as per the edge sensitivity defined with the CC1P and CC1NP bits setting, in TIM_CCER).

Bit 0 **UIF**: Update interrupt flag
This bit is set by hardware on an update event. It is cleared by software.
0: No update occurred
1: Update interrupt pending. This bit is set by hardware when the registers are updated:
At overflow or underflow and if UDIS = 0 in the TIM_CR1 register.
When CNT is reinitialized by software using the UG bit in TIM_EGR register, if URS = 0 and UDIS = 0 in the TIM_CR1 register.
When CNT is reinitialized by a trigger event (refer to the synchro control register description), if URS = 0 and UDIS = 0 in the TIM_CR1 register.

42.5.6 TIM event generation register (TIM_EGR)

Address offset: 0x014

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	TG	Res.	CC4G	CC3G	CC2G	CC1G	UG
									w		w	w	w	w	w

Bits 15:7 Reserved, must be kept at reset value.

Bit 6 **TG**: Trigger generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: The TIF flag is set in TIM_SR register. Related interrupt or DMA transfer can occur if enabled.

Bit 5 Reserved, must be kept at reset value.

Bit 4 **CC4G**: Capture/compare 4 generation
Refer to CC1G description

Bit 3 **CC3G**: Capture/compare 3 generation
Refer to CC1G description

Bit 2 **CC2G**: Capture/compare 2 generation
Refer to CC1G description

Bit 1 **CC1G**: Capture/compare 1 generation
This bit is set by software in order to generate an event, it is automatically cleared by hardware.
0: No action
1: A capture/compare event is generated on channel 1:
If channel CC1 is configured as output:
CC1IF flag is set, Corresponding interrupt or DMA request is sent if enabled.
If channel CC1 is configured as input:
The current value of the counter is captured in TIM_CCR1 register. The CC1IF flag is set, the corresponding interrupt or DMA request is sent if enabled. The CC1OF flag is set if the CC1IF flag was already high.

Bit 0 **UG**: Update generation
This bit can be set by software, it is automatically cleared by hardware.
0: No action
1: Re-initialize the counter and generates an update of the registers. Note that the prescaler counter is cleared too (anyway the prescaler ratio is not affected). The counter is cleared if the center-aligned mode is selected or if DIR = 0 (up-counting), else it takes the autoreload value (TIM_ARR) if DIR = 1 (down-counting).

42.5.7 TIM capture/compare mode register 1 (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

IC2F[3:0]				IC2PSC[1:0]		CC2S[1:0]		IC1F[3:0]				IC1PSC[1:0]		CC1S[1:0]	
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC2F[3:0]**: Input capture 2 filter

Bits 11:10 **IC2PSC[1:0]**: Input capture 2 prescaler

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output.

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2.

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1.

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bits 7:4 **IC1F[3:0]**: Input capture 1 filter

This bitfield defines the frequency used to sample tim_ti1 input and the length of the digital filter applied to tim_ti1. The digital filter is made of an event counter in which N consecutive events are needed to validate a transition on the output:

0000:No filter, sampling is done at f_{DTS}

0001:$f_{SAMPLING} = f_{tim_ker_ck}$, N = 2

0010:$f_{SAMPLING} = f_{tim_ker_ck}$, N = 4

0011:$f_{SAMPLING} = f_{tim_ker_ck}$, N = 8

0100:$f_{SAMPLING} = f_{DTS}/2$, N = 6

0101:$f_{SAMPLING} = f_{DTS}/2$, N = 8

0110:$f_{SAMPLING} = f_{DTS}/4$, N = 6

0111:$f_{SAMPLING} = f_{DTS}/4$, N = 8

1000:$f_{SAMPLING} = f_{DTS}/8$, N = 6

1001:$f_{SAMPLING} = f_{DTS}/8$, N = 8

1010:$f_{SAMPLING} = f_{DTS}/16$, N = 5

1011:$f_{SAMPLING} = f_{DTS}/16$, N = 6

1100:$f_{SAMPLING} = f_{DTS}/16$, N = 8

1101:$f_{SAMPLING} = f_{DTS}/32$, N = 5

1110:$f_{SAMPLING} = f_{DTS}/32$, N = 6

1111:$f_{SAMPLING} = f_{DTS}/32$, N = 8

Bits 3:2 **IC1PSC[1:0]**: Input capture 1 prescaler

This bitfield defines the ratio of the prescaler acting on CC1 input (tim_ic1). The prescaler is reset as soon as CC1E = 0 (TIM_CCER register).

00: no prescaler, capture is done each time an edge is detected on the capture input

01: capture is done once every 2 events

10: capture is done once every 4 events

11: capture is done once every 8 events

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC1 channel is configured as output

01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1

10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2

11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

42.5.8 TIM capture/compare mode register 1 [alternate] (TIM_CCMR1)

Address offset: 0x018

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Output compare mode

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC2CE**: Output compare 2 clear enable

0: tim_oc2ref is not affected by the tim_ocref_clr_int signal

1: tim_oc2ref is cleared as soon as a high level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 42.4.16: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC2M[4:0]**: Output compare 2 mode

Refer to OC1M description on bits 17:16, 6:4.

Bit 11 **OC2PE**: Output compare 2 preload enable

Bit 10 **OC2FE**: Output compare 2 fast enable

Bits 9:8 **CC2S[1:0]**: Capture/compare 2 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.

00: CC2 channel is configured as output

01: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti2

10: CC2 channel is configured as input, tim_ic2 is mapped on tim_ti1

11: CC2 channel is configured as input, tim_ic2 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through the TS bit (TIM_SMCR register)

Note: CC2S bits are writable only when the channel is OFF (CC2E = 0 in TIM_CCER).

Bit 7 **OC1CE**: Output compare 1 clear enable

0: tim_oc1ref is not affected by the tim_ocref_clr_int input

1: tim_oc1ref is cleared as soon as a High level is detected on tim_ocref_clr_int input

Note: This mode is not available for all PWM modes. Refer to Section 42.4.16: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC1M[4:0]**: Output compare 1 mode

These bits define the behavior of the output reference signal tim_oc1ref from which tim_oc1 is derived. tim_oc1ref is active high whereas tim_oc1 active level depends on CC1P bit.

00000: Frozen - The comparison between the output compare register TIM_CCR1 and the counter TIM_CNT has no effect on the outputs. This mode can be used when the timer serves as a software timebase. When the frozen mode is enabled during timer operation, the ouput keeps the state (active or inactive) it had before entering the frozen state.

00001: Set channel 1 to active level on match. tim_oc1ref signal is forced high when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00010: Set channel 1 to inactive level on match. tim_oc1ref signal is forced low when the counter TIM_CNT matches the capture/compare register 1 (TIM_CCR1).

00011: Toggle - tim_oc1ref toggles when TIM_CNT = TIM_CCR1.

00100: Force inactive level - tim_oc1ref is forced low.

00101: Force active level - tim_oc1ref is forced high.

00110: PWM mode 1 - In up-counting, channel 1 is active as long as TIM_CNT<TIM_CCR1 else inactive. In down-counting, channel 1 is inactive (tim_oc1ref = 0) as long as TIM_CNT>TIM_CCR1 else active (tim_oc1ref = 1).

00111: PWM mode 2 - In up-counting, channel 1 is inactive as long as TIM_CNT<TIM_CCR1 else active. In down-counting, channel 1 is active as long as TIM_CNT>TIM_CCR1 else inactive.

01000: Retriggerable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001: Retriggerable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01010: Reserved.

01011: Reserved.

01100-01101: Combined PWM mode 1 and 2 - Refer to *Table 488: Combined PWM mode overview* for details.

01110-01111: Asymmetric PWM mode 1 and 2 - Refer to *Table 487: Asymmetric PWM modes* for details.

Others: Reserved.

Note: In PWM mode, the OCREF level changes when the result of the comparison changes, when the output compare mode switches from “frozen” mode to “PWM” mode and when the output compare mode switches from “force active/inactive” mode to “PWM” mode.

Bit 3 **OC1PE**: Output compare 1 preload enable

0: Preload register on TIM_CCR1 disabled. TIM_CCR1 can be written at anytime, the new value is taken in account immediately.
1: Preload register on TIM_CCR1 enabled. Read/Write operations access the preload register. TIM_CCR1 preload value is loaded in the active register at each update event.

Bit 2 **OC1FE**: Output compare 1 fast enable

This bit decreases the latency between a trigger event and a transition on the timer output. It must be used in one-pulse mode (OPM bit set in TIM_CR1 register), to have the output pulse starting as soon as possible after the starting trigger.
0: CC1 behaves normally depending on counter and CCR1 values even when the trigger is ON. The minimum delay to activate CC1 output when an edge occurs on the trigger input is 5 clock cycles.
1: An active edge on the trigger input acts like a compare match on CC1 output. Then, OC is set to the compare level independently from the result of the comparison. Delay to sample the trigger input and to activate CC1 output is reduced to three clock cycles. OCFE acts only if the channel is configured in PWM1 or PWM2 mode.

Bits 1:0 **CC1S[1:0]**: Capture/compare 1 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC1 channel is configured as output.
01: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti1.
10: CC1 channel is configured as input, tim_ic1 is mapped on tim_ti2.
11: CC1 channel is configured as input, tim_ic1 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC1S bits are writable only when the channel is OFF (CC1E = 0 in TIM_CCER).

42.5.9 TIM capture/compare mode register 2 (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for input capture mode (this section) or for output compare mode (next section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Input capture mode

Bits 31:16 Reserved, must be kept at reset value.

Bits 15:12 **IC4F[3:0]**: Input capture 4 filter

Bits 11:10 **IC4PSC[1:0]**: Input capture 4 prescaler

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIM_CCER).

Bits 7:4 **IC3F[3:0]**: Input capture 3 filter

Bits 3:2 **IC3PSC[1:0]**: Input capture 3 prescaler

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection
This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)
Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIM_CCER).

42.5.10 TIM capture/compare mode register 2 [alternate] (TIM_CCMR2)

Address offset: 0x01C

Reset value: 0x0000 0000

The same register can be used for output compare mode (this section) or for input capture mode (previous section). The direction of a channel is defined by configuring the corresponding CCxS bits. All the other bits of this register have a different function for input capture and for output compare modes. It is possible to combine both modes independently (for example channel 1 in input capture mode and channel 2 in output compare mode).

Output compare mode

Bits 31:26 Reserved, must be kept at reset value.

Bits 23:18 Reserved, must be kept at reset value.

Bit 15 **OC4CE**: Output compare 4 clear enable
0: tim_oc4ref is not affected by the tim_ocref_clr_int signal
1: tim_oc4ref is cleared as soon as a high level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)
Note: This mode is not available for all PWM modes. Refer to Section 42.4.16: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 25:24, 14:12 **OC4M[4:0]**: Output compare 4 mode
Refer to OC3M[4:0].

Bit 11 **OC4PE**: Output compare 4 preload enable

Bit 10 **OC4FE**: Output compare 4 fast enable

Bits 9:8 **CC4S[1:0]**: Capture/compare 4 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC4 channel is configured as output
01: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti4
10: CC4 channel is configured as input, tim_ic4 is mapped on tim_ti3
11: CC4 channel is configured as input, tim_ic4 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC4S bits are writable only when the channel is OFF (CC4E = 0 in TIM_CCER).

Bit 7 **OC3CE**: Output compare 3 clear enable

0: tim_oc3ref is not affected by the tim_ocref_clr_int signal
1: tim_oc3ref is cleared as soon as a high level is detected on tim_ocref_clr_int signal (tim_ocref_clr input or tim_etrf input)

Note: This mode is not available for all PWM modes. Refer to Section 42.4.16: Clearing the tim_ocxref signal on an external event for the list of forbidden configurations.

Bits 17:16, 6:4 **OC3M[4:0]**: Output compare 3 mode

These bits define the behavior of the output reference signal tim_oc3ref from which tim_oc3 and tim_oc3n are derived. tim_oc3ref is active high whereas tim_oc3 and tim_oc3n active level depends on CC3P and CC3NP bits.

00000: Frozen - The comparison between the output compare register TIM_CCR3 and the counter TIM_CNT has no effect on the outputs.(this mode is used to generate a timing base).

00001: Set channel 3 to active level on match. tim_oc3ref signal is forced high when the counter TIM_CNT matches the capture/compare register 3 (TIM_CCR3).

00010: Set channel 3 to inactive level on match. tim_oc3ref signal is forced low when the counter TIM_CNT matches the capture/compare register 3 (TIM_CCR3).

00011: Toggle - tim_oc3ref toggles when TIM_CNT = TIM_CCR3.

00100: Force inactive level - tim_oc3ref is forced low.

00101: Force active level - tim_oc3ref is forced high.

00110: PWM mode 1 - In up-counting, channel 3 is active as long as TIM_CNT<TIM_CCR3 else inactive. In down-counting, channel 3 is inactive (tim_oc3ref = 0) as long as TIM_CNT>TIM_CCR3 else active (tim_oc3ref = 1).

00111: PWM mode 2 - In up-counting, channel 3 is inactive as long as TIM_CNT<TIM_CCR3 else active. In down-counting, channel 3 is active as long as TIM_CNT>TIM_CCR3 else inactive.

01000: Retrigerrable OPM mode 1 - In up-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update. In down-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes inactive again at the next update.

01001: Retrigerrable OPM mode 2 - In up-counting mode, the channel is inactive until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 2 and the channels becomes inactive again at the next update. In down-counting mode, the channel is active until a trigger event is detected (on tim_trgi signal). Then, a comparison is performed as in PWM mode 1 and the channels becomes active again at the next update.

01010: Pulse on compare - A pulse is generated on tim_oc3ref upon CCR3 match event, as per PWPRSC[2:0] and PW[7:0] bitfields programming in TIM_ECR.

01011: Direction output - The tim_oc3ref signal is overridden by a copy of the DIR bit.

01100-01101: Combined PWM mode 1 and 2 - Refer to *Table 488: Combined PWM mode overview* for details.

01110-01111: Asymmetric PWM mode 1 and 2 - Refer to *Table 487: Asymmetric PWM modes* for details.

10110-11001: Asymmetric PWM mode 7 to 10 - Available on OC3M only. Refer to *Table 487: Asymmetric PWM modes* for details.

Others: Reserved

Note: These bits can not be modified as long as LOCK level 3 has been programmed (LOCK bits in TIM_BDTR register) and CC1S = 00 (the channel is configured in output).

Note: In PWM mode, the OCREF level changes only when the result of the comparison changes or when the output compare mode switches from “frozen” mode to “PWM” mode.

On channels having a complementary output, this bitfield is preloaded. If the CCPC bit is set in the TIM_CR2 register then the OC3M active bits take the new value from the preloaded bits only when a COM event is generated.

Bit 3 **OC3PE**: Output compare 3 preload enable

Bit 2 **OC3FE**: Output compare 3 fast enable

Bits 1:0 **CC3S[1:0]**: Capture/compare 3 selection

This bitfield defines the direction of the channel (input/output) as well as the used input.
00: CC3 channel is configured as output
01: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti3
10: CC3 channel is configured as input, tim_ic3 is mapped on tim_ti4
11: CC3 channel is configured as input, tim_ic3 is mapped on tim_trc. This mode is working only if an internal trigger input is selected through TS bit (TIM_SMCR register)

Note: CC3S bits are writable only when the channel is OFF (CC3E = 0 in TIM_CCER).

42.5.11 TIM capture/compare enable register (TIM_CCER)

Address offset: 0x020

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CC4NP	Res.	CC4P	CC4E	CC3NP	Res.	CC3P	CC3E	CC2NP	Res.	CC2P	CC2E	CC1NP	Res.	CC1P	CC1E
rw		rw	rw	rw		rw	rw	rw		rw	rw	rw		rw	rw

Bit 15 **CC4NP**: Capture/compare 4 output Polarity.
Refer to CC1NP description

Bit 14 Reserved, must be kept at reset value.

Bit 13 **CC4P**: Capture/compare 4 output Polarity.
Refer to CC1P description

Bit 12 **CC4E**: Capture/compare 4 output enable.
refer to CC1E description

Bit 11 **CC3NP**: Capture/compare 3 output Polarity.
Refer to CC1NP description

Bit 10 Reserved, must be kept at reset value.

Bit 9 **CC3P**: Capture/compare 3 output Polarity.
Refer to CC1P description

Bit 8 **CC3E**: Capture/compare 3 output enable.
Refer to CC1E description

Bit 7 **CC2NP**: Capture/compare 2 output Polarity.
Refer to CC1NP description

Bit 6 Reserved, must be kept at reset value.

Bit 5 **CC2P**: Capture/compare 2 output Polarity.
refer to CC1P description

Bit 4 **CC2E**: Capture/compare 2 output enable.
Refer to CC1E description

Bit 3 **CC1NP**: Capture/compare 1 output Polarity.

CC1 channel configured as output: CC1NP must be kept cleared in this case.

CC1 channel configured as input: This bit is used in conjunction with CC1P to define tim_ti1fp1/tim_ti2fp1 polarity. refer to CC1P description.

Bit 2 Reserved, must be kept at reset value.

Bit 1 **CC1P**: Capture/compare 1 output Polarity.

0: OC1 active high (output mode) / Edge sensitivity selection (input mode, see below)

1: OC1 active low (output mode) / Edge sensitivity selection (input mode, see below)

When CC1 channel is configured as input, both CC1NP/CC1P bits select the active polarity of TI1FP1 and TI2FP1 for trigger or capture operations.

CC1NP = 0, CC1P = 0:non-inverted/rising edge. The circuit is sensitive to TIxFP1 rising edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is not inverted (trigger operation in gated mode or encoder mode).

CC1NP = 0, CC1P = 1:inverted/falling edge. The circuit is sensitive to TIxFP1 falling edge (capture or trigger operations in reset, external clock or trigger mode), TIxFP1 is inverted (trigger operation in gated mode or encoder mode).

CC1NP = 1, CC1P = 1:non-inverted/both edges. The circuit is sensitive to both TIxFP1 rising and falling edges (capture or trigger operations in reset, external clock or trigger mode), TIxFP1is not inverted (trigger operation in gated mode). This configuration must not be used in encoder mode.

CC1NP = 1, CC1P = 0:this configuration is reserved, it must not be used.

Bit 0 **CC1E**: Capture/compare 1 output enable.

0: Capture mode disabled / OC1 is not active

1: Capture mode enabled / OC1 signal is output on the corresponding output pin

Table 494. Output control bit for standard tim_ocx channels

CCxE bit	tim_ocx output state
0	Output disabled (not driven by the timer: Hi-Z)
1	Output enabled (tim_ocx = tim_ocxref + Polarity)

Note: The state of the external IO pins connected to the standard tim_ocx channels depends only on the GPIO registers when CCxE = 0.

42.5.12 TIM counter (TIM_CNT)

Address offset: 0x024

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIFCPY_CNT[31]	CNT[30:16]														
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY_CNT[31]**: Value depends on IUFREMAP in TIM_CR1.
If UIFREMAP = 0
CNT[31]: Most significant bit of counter value
If UIFREMAP = 1
UIFCPY: UIF Copy
This bit is a read-only copy of the UIF bit of the TIM_ISR register

Bits 30:0 **CNT[30:0]**: Least significant part of counter value
Non-dithering mode (DITHEN = 0)
The register holds the counter value.
Dithering mode (DITHEN = 1)
The register holds the non-dithered part in CNT[30:0]. The fractional part is not available.

42.5.13 TIM prescaler (TIM_PSC)

Address offset: 0x028

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value
The counter clock frequency tim_cnt_ck is equal to $f_{tim_psc_ck}$ / (PSC[15:0] + 1).
PSC contains the value to be loaded in the active prescaler register at each update event (including when the counter is cleared through UG bit of TIM_EGR register or through trigger controller when configured in “reset mode”).

42.5.14 TIM autoreload register (TIM_ARR)

Address offset: 0x02C

Reset value: 0xFFFF FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
ARR[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **ARR[31:0]**: Autoreload value

ARR is the value to be loaded in the actual autoreload register.

Refer to the *Section 42.4.3: Time-base unit* for more details about ARR update and behavior.

The counter is blocked while the autoreload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the autoreload value.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[31:4]. The ARR[3:0] bitfield contains the dithered part.

42.5.15 TIM capture/compare register 1 (TIM_CCR1)

Address offset: 0x034

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCR1[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR1[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR1[31:0]**: Capture/compare 1 value

If channel CC1 is configured as output:

CCR1 is the value to be loaded in the actual capture/compare 1 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM_CCMR1 register (bit OC1PE). Else the preload value is copied in the active capture/compare 1 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc1 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR1[31:4]. The CCR1[3:0] bitfield contains the dithered part.

If channel CC1 is configured as input:

CCR1 is the counter value transferred by the last input capture 1 event (tim_ic1). The TIM_CCR1 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR1[31:0]. The CCR1[3:0] bits are reset.

42.5.16 TIM capture/compare register 2 (TIM_CCR2)

Address offset: 0x038

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCR2[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR2[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR2[31:0]**: Capture/compare 2 value

If channel CC2 is configured as output:

CCR2 is the value to be loaded in the actual capture/compare 2 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM_CCMR2 register (bit OC2PE). Else the preload value is copied in the active capture/compare 2 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc2 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR2[31:4]. The CCR2[3:0] bitfield contains the dithered part.

If channel CC2 is configured as input:

CCR2 is the counter value transferred by the last input capture 2 event (tim_ic2). The TIM_CCR2 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR2[31:0]. The CCR2[3:0] bits are reset.

42.5.17 TIM capture/compare register 3 (TIM_CCR3)

Address offset: 0x03C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCR3[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR3[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR3[31:0]**: Capture/compare 3 value

If channel CC3 is configured as output:

CCR3 is the value to be loaded in the actual capture/compare 3 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM_CCMR3 register (bit OC3PE). Else the preload value is copied in the active capture/compare 3 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc3 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR3[31:4]. The CCR3[3:0] bitfield contains the dithered part.

If channel CC3 is configured as input:

CCR3 is the counter value transferred by the last input capture 3 event (tim_ic3). The TIM_CCR3 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR3[31:0]. The CCR3[3:0] bits are reset.

42.5.18 TIM capture/compare register 4 (TIM_CCR4)

Address offset: 0x040

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
CCR4[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCR4[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **CCR4[31:0]**: Capture/compare 4 value

If channel CC4 is configured as output:

CCR4 is the value to be loaded in the actual capture/compare 4 register (preload value). It is loaded permanently if the preload feature is not selected in the TIM_CCMR4 register (bit OC4PE). Else the preload value is copied in the active capture/compare 4 register when an update event occurs.

The active capture/compare register contains the value to be compared to the counter TIM_CNT and signaled on tim_oc4 output.

Non-dithering mode (DITHEN = 0)

The register holds the compare value.

Dithering mode (DITHEN = 1)

The register holds the integer part in CCR4[31:4]. The CCR4[3:0] bitfield contains the dithered part.

If channel CC4 is configured as input:

CCR4 is the counter value transferred by the last input capture 4 event (tim_ic4). The TIM_CCR4 register is read-only and cannot be programmed.

Non-dithering mode (DITHEN = 0)

The register holds the capture value.

Dithering mode (DITHEN = 1)

The register holds the capture in CCR4[31:0]. The CCR4[3:0] bits are reset.

42.5.19 TIM timer encoder control register (TIM_ECR)

Address offset: 0x058

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	PWPRSC[2:0]			PW[7:0]							
					rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	IPOS[1:0]		FIDX	IBLK[1:0]		IDIR[1:0]		IE
								rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:27 Reserved, must be kept at reset value.

Bits 26:24 **PWPRSC[2:0]**: Pulse width prescaler

This bitfield sets the clock prescaler for the pulse generator, as following:

$t_{PWG} = (2^{(PWPRSC[2:0])}) \times t_{tim_ker_ck}$

Bits 23:16 **PW[7:0]**: Pulse width

This bitfield defines the pulse duration, as following:

$t_{PW} = PW[7:0] \times t_{PWG}$

Bits 15:8 Reserved, must be kept at reset value.

Bits 7:6 **IPOS[1:0]**: Index positioning

In quadrature encoder mode (SMS[4:0] = 00001, 00010, 00011, 01110, 01111), this bit indicates in which AB input configuration the Index event resets the counter.

00: Index resets the counter when AB = 00
01: Index resets the counter when AB = 01
10: Index resets the counter when AB = 10
11: Index resets the counter when AB = 11

In directional clock mode or clock plus direction mode (SMS[4:0] = 01010, 01011, 01100, 01101), these bits indicates on which level the Index event resets the counter. In bidirectional clock mode, this applies for both clock inputs.

x0: Index resets the counter when clock is 0
x1: Index resets the counter when clock is 1

Note: IPOS[1] bit is not significant

Bit 5 **FIDX**: First index

This bit indicates if the first index only is taken into account

0: Index is always active
1: the first Index only resets the counter

Bits 4:3 **IBLK[1:0]**: Index blanking

This bit indicates if the Index event is conditioned by the tim_ti3 input

00: Index always active
01: Index disabled hen tim_ti3 input is active, as per CC3P bitfield
10: Index disabled when tim_ti4 input is active, as per CC4P bitfield
11: Reserved

Bits 2:1 **IDIR[1:0]**: Index direction

This bit indicates in which direction the Index event resets the counter.

00: Index resets the counter whatever the direction
01: Index resets the counter when up-counting only
10: Index resets the counter when down-counting only
11: Reserved

Bit 0 **IE**: Index enable

This bit indicates if the Index event resets the counter.

0: Index disabled
1: Index enabled

42.5.20 TIM timer input selection register (TIM_TISEL)

Address offset: 0x05C

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	TI2SEL[3:0]				Res.	Res.	Res.	Res.	TI1SEL[3:0]			
				rw	rw	rw	rw					rw	rw	rw	rw

Bits 31:28 Reserved, must be kept at reset value.

Bits 27:24 **TI4SEL[3:0]**: Selects tim_ti4[15:0] input
0000: tim_ti4_in0: TIMx_CH4
0001: tim_ti4_in1
...
1111: tim_ti4_in15
Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation.

Bits 23:20 Reserved, must be kept at reset value.

Bits 19:16 **TI3SEL[3:0]**: Selects tim_ti3[15:0] input
0000: tim_ti3_in0: TIMx_CH3
0001: tim_ti3_in1
...
1111: tim_ti3_in15
Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation.

Bits 15:12 Reserved, must be kept at reset value.

Bits 11:8 **TI2SEL[3:0]**: Selects tim_ti2[15:0] input
0000: tim_ti2_in0: TIMx_CH2
0001: tim_ti2_in1
...
1111: tim_ti2_in15
Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation.

Bits 7:4 Reserved, must be kept at reset value.

Bits 3:0 **TI1SEL[3:0]**: Selects tim_ti1[15:0] input
0000: tim_ti1_in0: TIMx_CH1
0001: tim_ti1_in1
...
1111: tim_ti1_in15
Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation.

42.5.21 TIM alternate function register 1 (TIM_AF1)

Address offset: 0x060

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **OCRSEL[3:0]**: ocref_clr source selection
These bits select the ocref_clr input source.
0000: tim_ocref_clr0
0001: tim_ocref_clr1
...
0111: tim_ocref_clr15
Refer to *Section 42.4.2: TIM2/TIM3/TIM4/TIM5 pins and internal signals* for product specific implementation.

Bits 15:0 Reserved, must be kept at reset value.

42.5.23 TIM DMA control register (TIM_DCR)

Address offset: 0x3DC

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	DBSS[3:0]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DBL[4:0]					Res.	Res.	Res.	DBA[4:0]				
			rw	rw	rw	rw	rw				rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:16 **DBSS[3:0]**: DMA burst source selection

This bitfield defines the interrupt source that triggers the DMA burst transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address).

0000: Reserved
0001: Update
0010: CC1
0011: CC2
0100: CC3
0101: CC4
0110: COM
0111: Trigger
Others: reserved

Bits 15:13 Reserved, must be kept at reset value.

Bits 12:8 **DBL[4:0]**: DMA burst length

This 5-bit vector defines the length of DMA transfers (the timer recognizes a burst transfer when a read or a write access is done to the TIM_DMAR address), i.e. the number of transfers. Transfers can be in half-words or in bytes (see example below).

00000: 1 transfer
00001: 2 transfers
00010: 3 transfers
...
11111: 32 transfers

Example: Let us consider the following transfer: DBL = 6 bytes & DBA = TIM2_CR1.

–If DBL = 6 bytes and DBA = TIM2_CR1 represents the address of the byte to be transferred, the address of the transfer is given by the following equation: (TIM_CR1 address) + DBA + (DMA index), where DMA index = DBL

In this example, 7 bytes are added to (TIM_CR1 address) + DBA, which gives us the address from/to which the data are copied. In this case, the transfer is done to 7 registers starting from the following address: (TIM_CR1 address) + DBA

According to the configuration of the DMA Data Size, several cases may occur:

–If the DMA Data Size is configured in half-words, 16-bit data are transferred to each of the 7 registers.

–If the DMA Data Size is configured in bytes, the data are also transferred to 7 registers: the first register contains the first MSB byte, the second register, the first LSB byte and so on. So with the transfer Timer, one also has to specify the size of data transferred by DMA.

Bits 7:5 Reserved, must be kept at reset value.

Bits 4:0 **DBA[4:0]**: DMA base address

This 5-bits vector defines the base-address for DMA transfers (when read/write access are done through the TIM_DMAR address). DBA is defined as an offset starting from the address of the TIM_CR1 register.

Example:
00000: TIM_CR1,
00001: TIM_CR2,
00010: TIM_SMCR,
...

42.5.24 TIM DMA address for full transfer (TIM_DMAR)

Address offset: 0x3E0

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
DMAB[31:16]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DMAB[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:0 **DMAB[31:0]**: DMA register for burst accesses

A read or write operation to the DMAR register accesses the register located at the address

(TIM_CR1 address) + (DBA + DMA index) x 4

where TIM_CR1 address is the address of the control register 1, DBA is the DMA base address configured in TIM_DCR register, DMA index is automatically controlled by the DMA transfer, and ranges from 0 to DBL (DBL configured in TIM_DCR).

42.5.25 TIM2/TIM3/TIM4/TIM5 register map

TIM2/TIM3/TIM4/TIM5 registers are mapped as described in the table below.

Table 495. TIM2/TIM3/TIM4/TIM5 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

43 Basic timers (TIM6/TIM7/TIM26/TIM27)

43.1 TIM6/TIM7/TIM26/TIM27 introduction

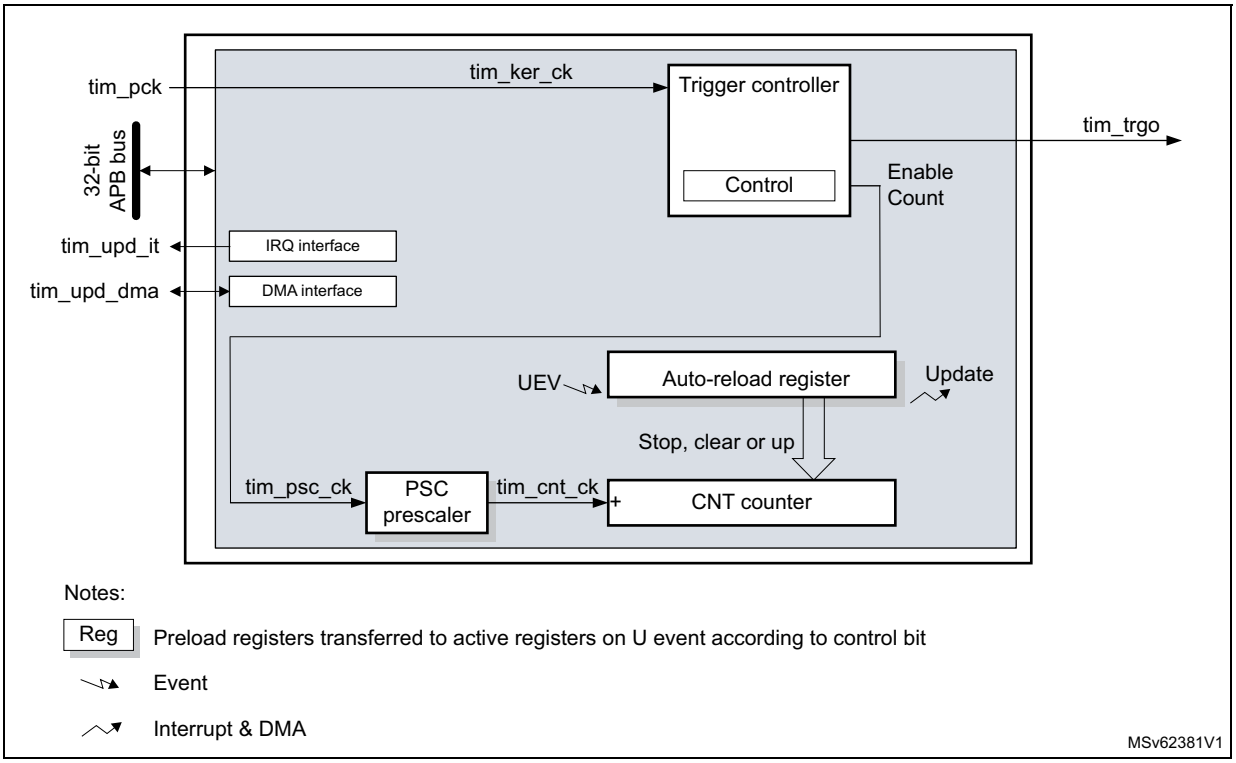
The basic timers TIM6/TIM7/TIM26/TIM27 consist in a 16-bit autoreload counter driven by a programmable prescaler.

They can be used as generic timers for time-base generation.

The basic timer can also be used for triggering the digital-to-analog converter. This is done with the trigger output of the timer.

The timers are completely independent, and do not share any resources.

43.2 TIM6/TIM7/TIM26/TIM27 main features



Basic timer (TIM6/TIM7/TIM26/TIM27) features include:

- 16-bit autoreload upcounter.
- 16-bit programmable prescaler used to divide (also “on the fly”) the counter clock frequency by any factor between 1 and 65535.
- Synchronization circuit to trigger the DAC.
- Interrupt/DMA generation on the update event: counter overflow.
- ADC synchronization for jitter-free sampling points.

43.3 TIM6/TIM7/TIM26/TIM27 functional description

43.3.1 TIM6/TIM7/TIM26/TIM27 block diagram

Figure 656. Basic timer block diagram

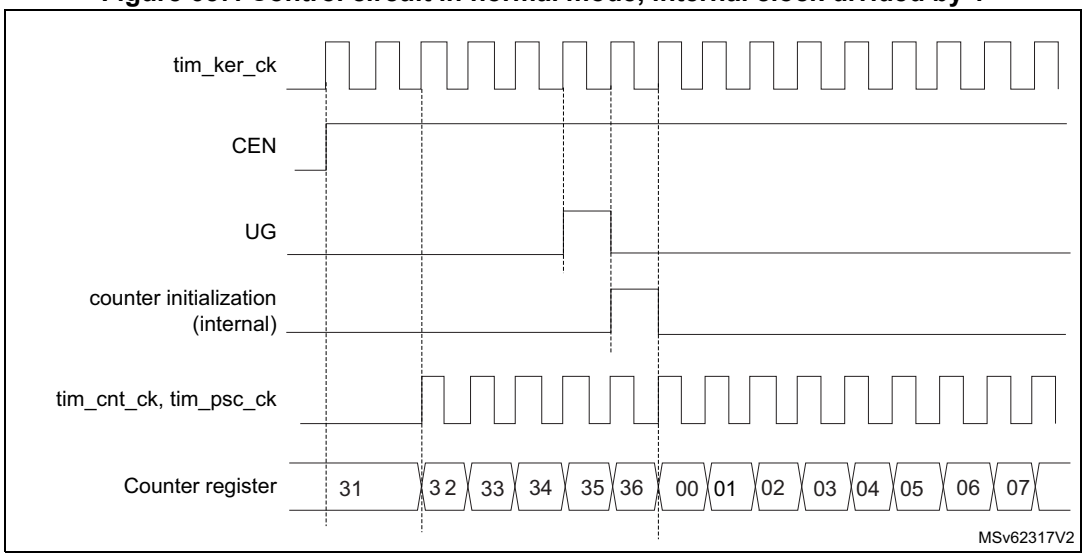
43.3.2 TIM6/TIM7/TIM26/TIM27 internal signals

The table in this section summarizes the TIM inputs and outputs.

Table 496. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock. This clock must be synchronous with tim_pclk (derived from the same source). The clock ratio tim_ker_ck/tim_pclk must be an integer: 1, 2, 3,..., 16 (maximum value)
tim_trgo	Output	Internal trigger output. This trigger can trigger other on-chip peripherals (DAC).
tim_upd_it	Output	Timer update event interrupt
tim_upd_dma	Output	Timer update dma request

43.3.3 TIM6/TIM7/TIM26/TIM27 clocks



The timer bus interface is clocked by the tim_pclk APB clock.

The counter clock tim_ker_ck is connected to the tim_pclk input.

The CEN (in the TIM_CR1 register) and UG bits (in the TIM_EGR register) are actual control bits and can be changed only by software (except for UG that remains cleared automatically). As soon as the CEN bit is written to 1, the prescaler is clocked by the internal clock tim_ker_ck.

Figure 657 shows the behavior of the control circuit and the upcounter in normal mode, without prescaler.

Figure 657. Control circuit in normal mode, internal clock divided by 1

43.3.4 Time-base unit

The main block of the programmable timer is a 16-bit upcounter with its related autoreload register. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIM_CNT)
- Prescaler register (TIM_PSC)
- Auto-Reload register (TIM_ARR).

The autoreload register is preloaded. The preload register is accessed each time an attempt is made to write or read the autoreload register. The contents of the preload register are transferred into the shadow register permanently or at each update event UEV, depending on the autoreload preload enable bit (ARPE) in the TIM_CR1 register. The update event is sent when the counter reaches the overflow value and if the UDIS bit equals 0 in the TIM_CR1 register. It can also be generated by software. The generation of the update event is described in detail for each configuration.

Note: An update overrun status bit (UIOVRF in TIM_SR register) indicates that an update request occurred while an update interrupt is pending (update interrupt flag set). This bit is useful when debugging closed loop applications, to indicate that:

- the update interrupt service routine is too long with respect to the interval between consecutive update events

- the update interrupt service routine was served too late with respect to the subsequent update event

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in the TIM_CR1 register is set.

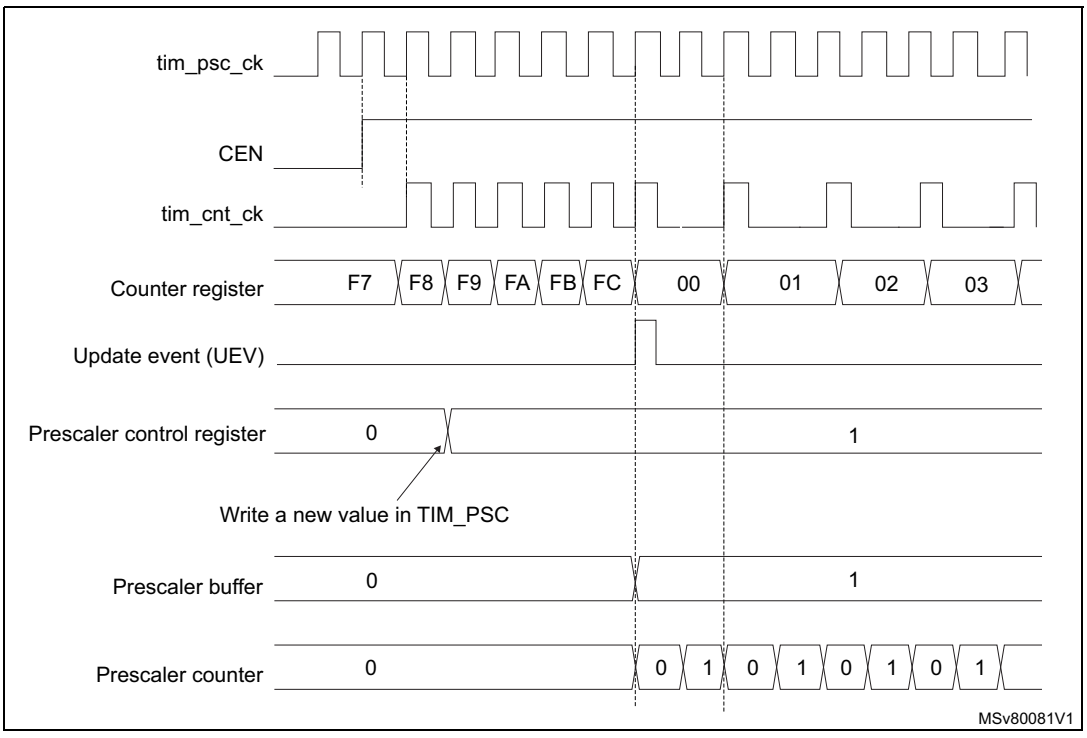
Note that the actual counter enable signal tim_cnt_en is set one clock cycle after CEN bit set.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIM_PSC register). It can be changed on the fly as the TIM_PSC control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 658 and *Figure 659* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 658. Counter timing diagram with prescaler division change from 1 to 2



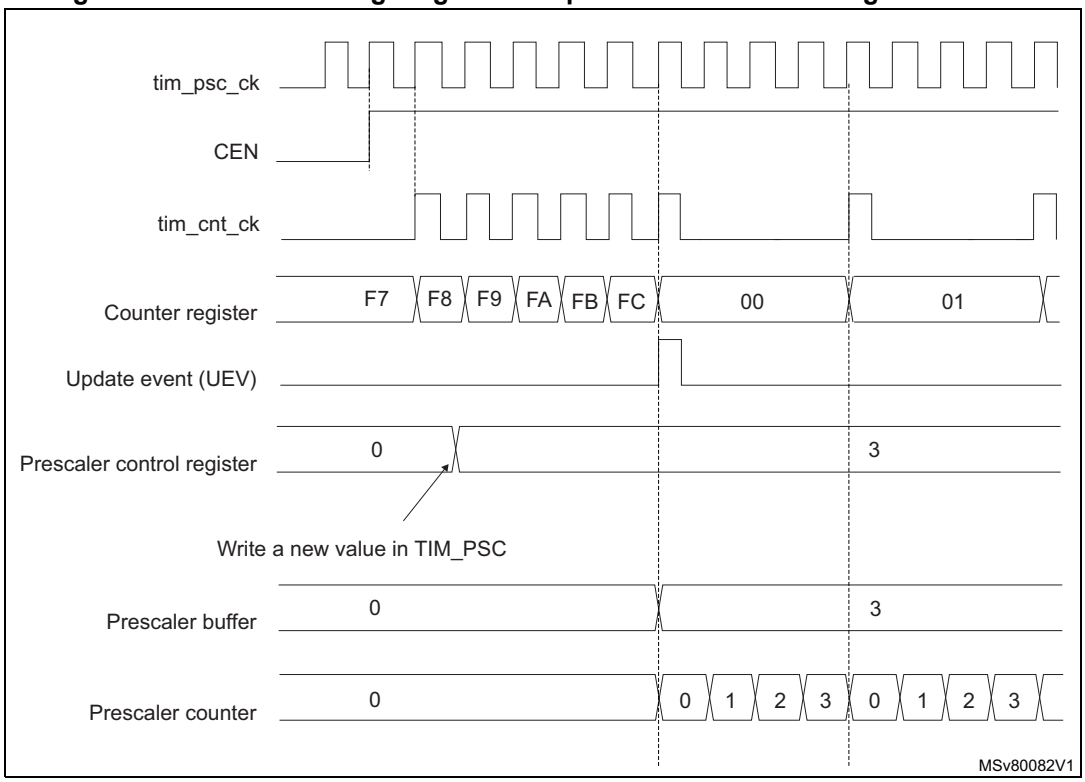


Figure 659. Counter timing diagram with prescaler division change from 1 to 4

43.3.5 Counting mode

The counter counts from 0 to the autoreload value (contents of the TIM_ARR register), then restarts from 0 and generates a counter overflow event.

An update event can be generated at each counter overflow or by setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller).

The UEV event can be disabled by software by setting the UDIS bit in the TIM_CR1 register. This avoids updating the shadow registers while writing new values into the preload registers. In this way, no update event occurs until the UDIS bit has been written to 0, however, the counter and the prescaler counter both restart from 0 (but the prescale rate does not change). In addition, if the URS (update request selection) bit in the TIM_CR1 register is set, setting the UG bit generates an update event UEV, but the UIF flag is not set (so no interrupt or DMA request is sent).

When an update event occurs, all the registers are updated and the update flag (UIF bit in the TIM_SR register) is set (depending on the URS bit):

- The buffer of the prescaler is reloaded with the preload value (contents of the TIM_PSC register).
- The autoreload shadow register is updated with the preload value (TIM_ARR).

The following figures show some examples of the counter behavior for different clock frequencies when TIM_ARR = 0x36.

Figure 660. Counter timing diagram, internal clock divided by 1

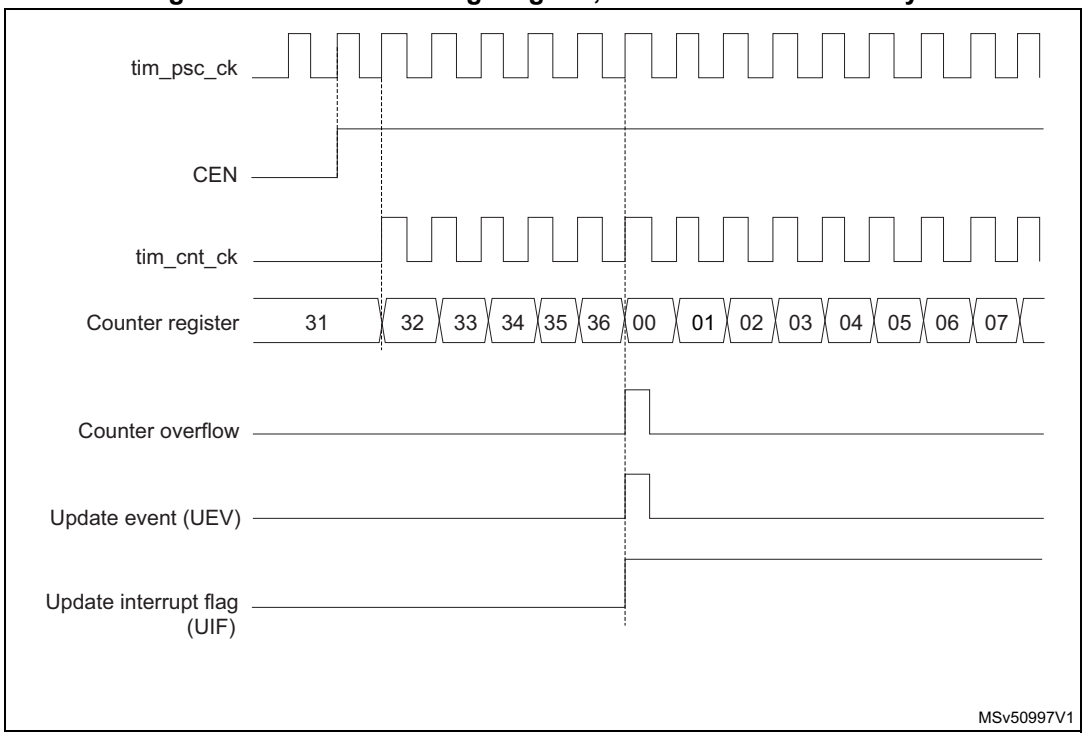

Figure 661. Counter timing diagram, internal clock divided by 2

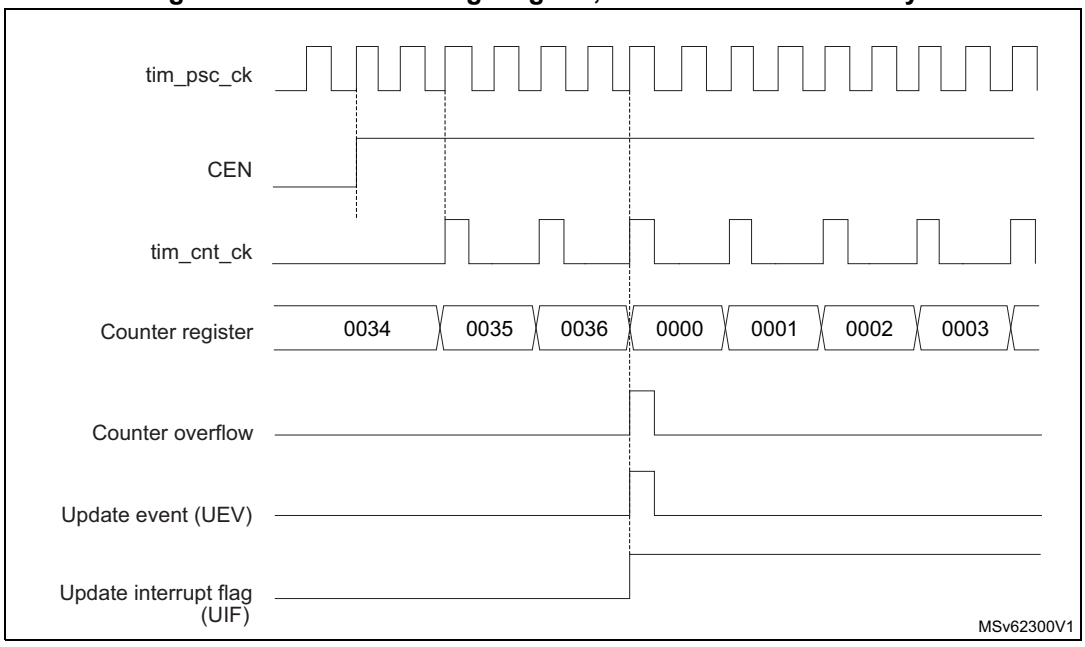

Figure 662. Counter timing diagram, internal clock divided by 4

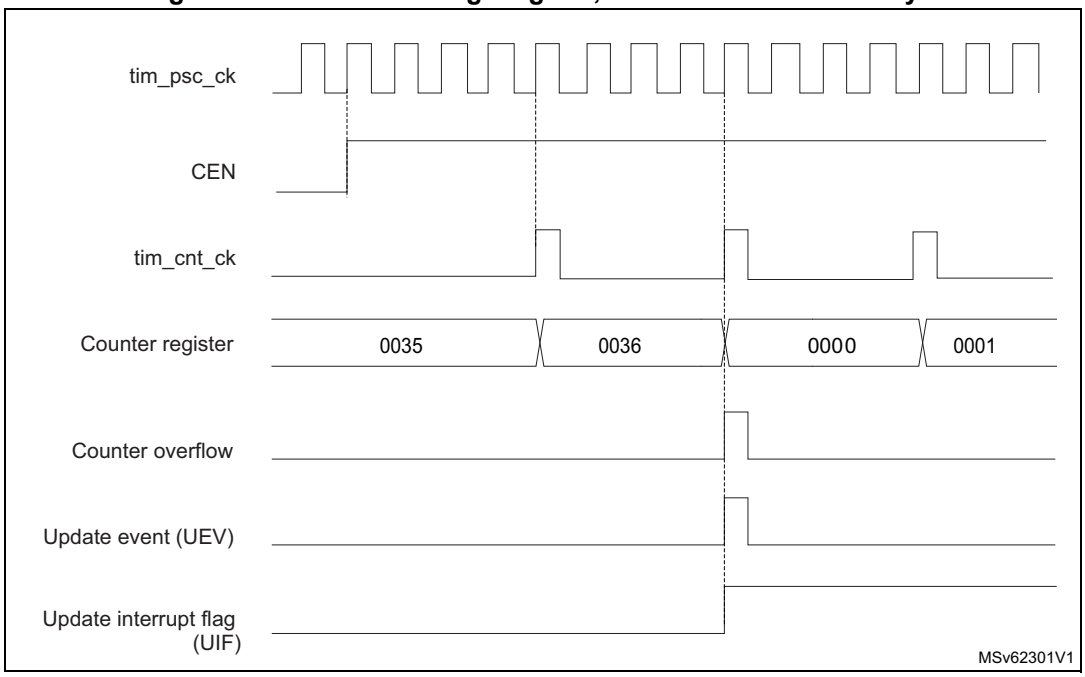

Figure 663. Counter timing diagram, internal clock divided by N

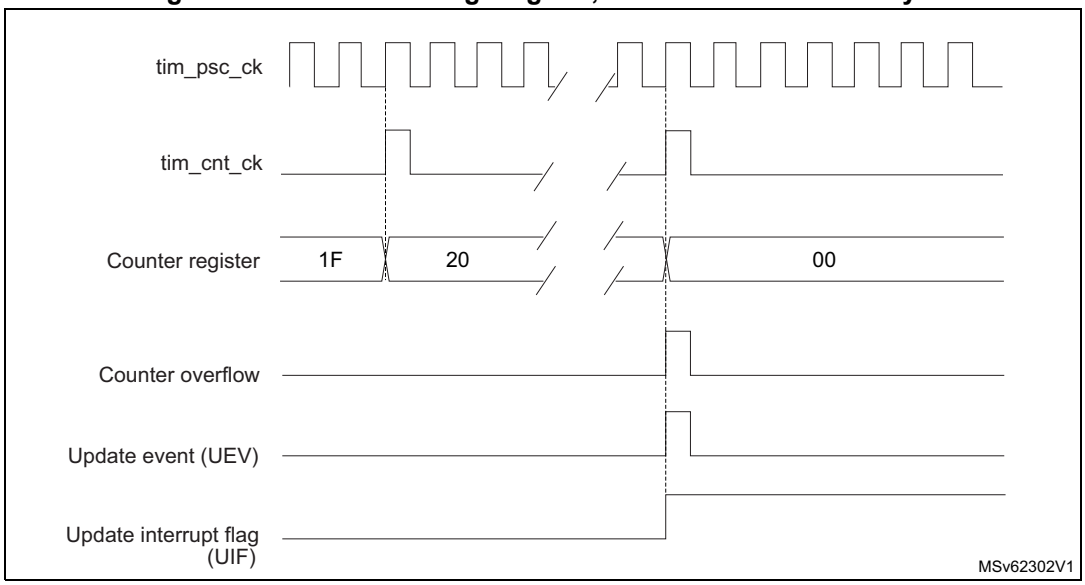

Figure 664. Counter timing diagram, update event when ARPE = 0 (TIM_ARR not preloaded)

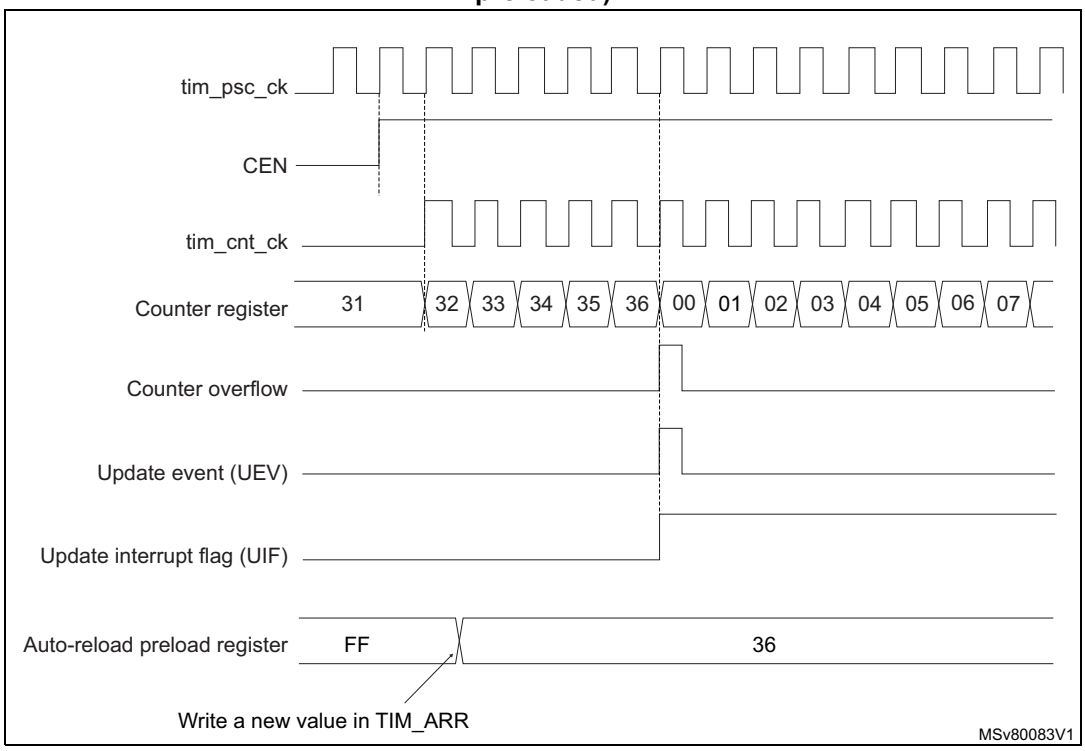

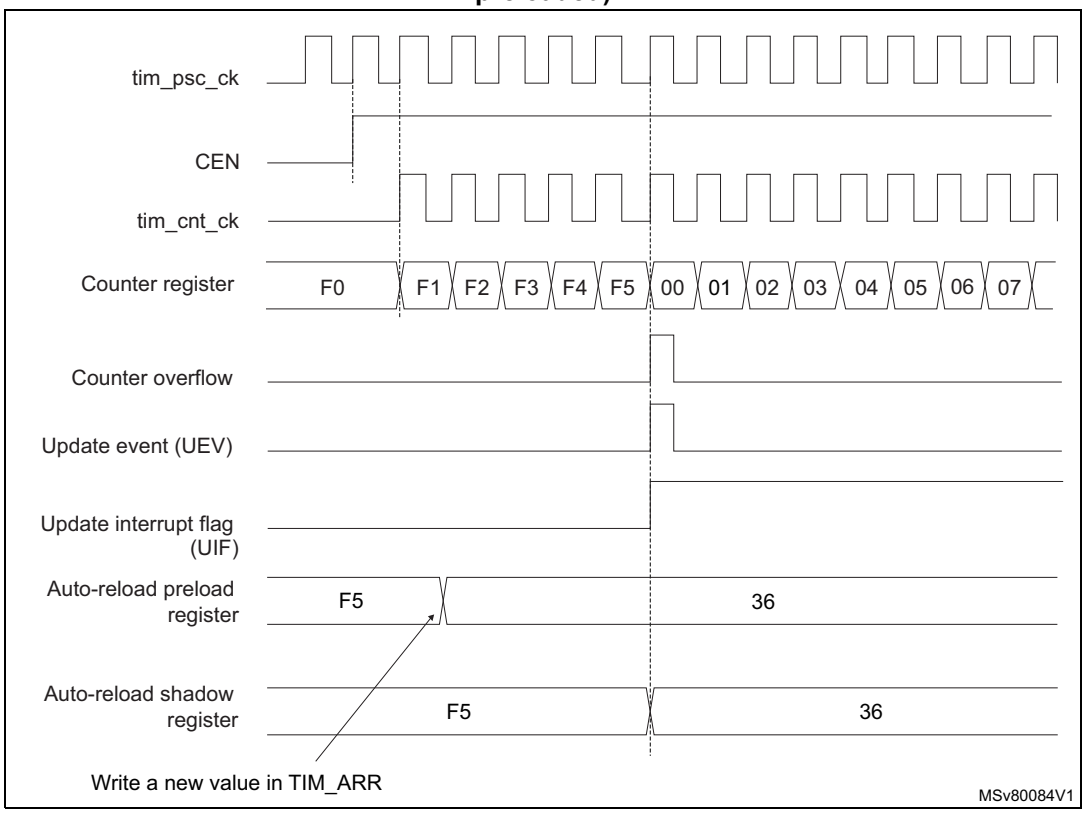

Figure 665. Counter timing diagram, update event when ARPE = 1 (TIM_ARR preloaded)

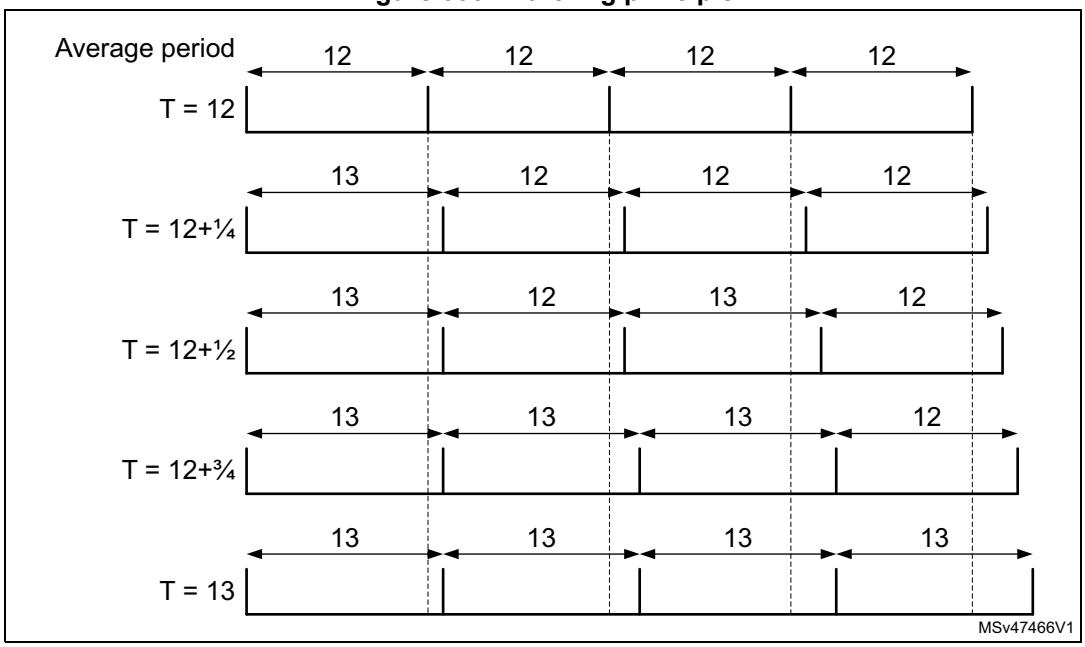


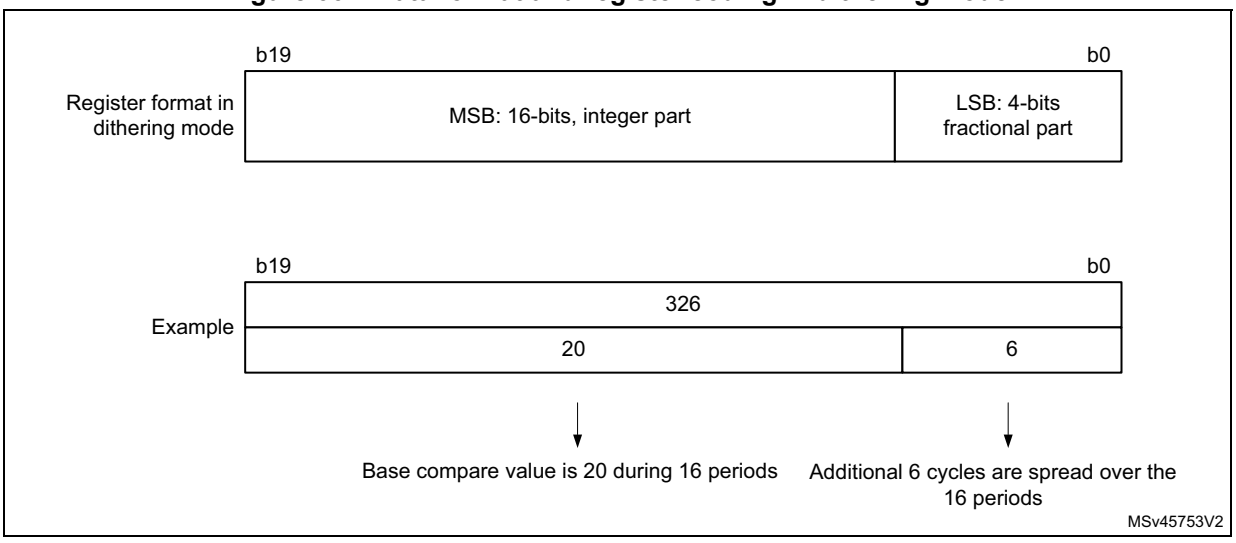
Dithering mode

The time base effective resolution can be increased by enabling the dithering mode, using the DITHEN bit in the TIM_CR1 register. This affects the way the TIM_ARR is behaving, and is useful for adjusting the average counter period when the timer is used as a trigger (typically for a DAC).

The operating principle is to have the actual ARR value slightly changed (adding or not one timer clock period) over 16 consecutive counting periods, with predefined patterns. This allows a 16-fold resolution increase, considering the average counting period.

Figure 666 presents the dithering principle applied to four consecutive counting periods.

Figure 666. Dithering principle



When the dithering mode is enabled, the register coding is changed as follows (see *Figure 667* for example):

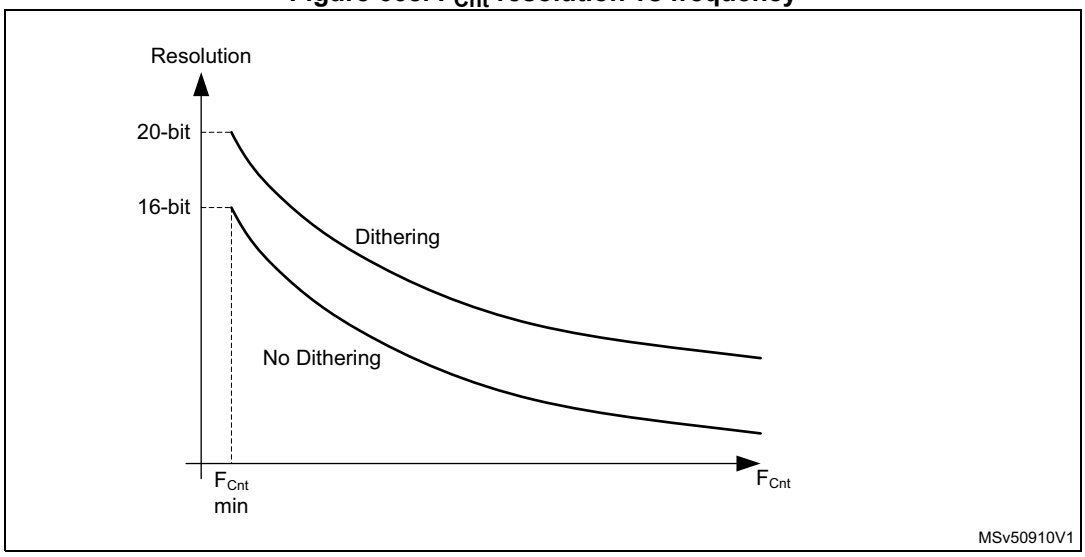
- The four LSBs are coding for the enhanced resolution part (fractional part).
- The MSBs are left-shifted to the bits 19:4 and are coding for the base value.

Note: The following sequence must be followed when resetting the DITHEN bit:
1. CEN and ARPE bits must be reset
2. The DITHEN bit must be reset
3. The CEN bit can be set (eventually with ARPE = 1).

Figure 667. Data format and register coding in dithering mode

The minimum frequency is given by the following formula:

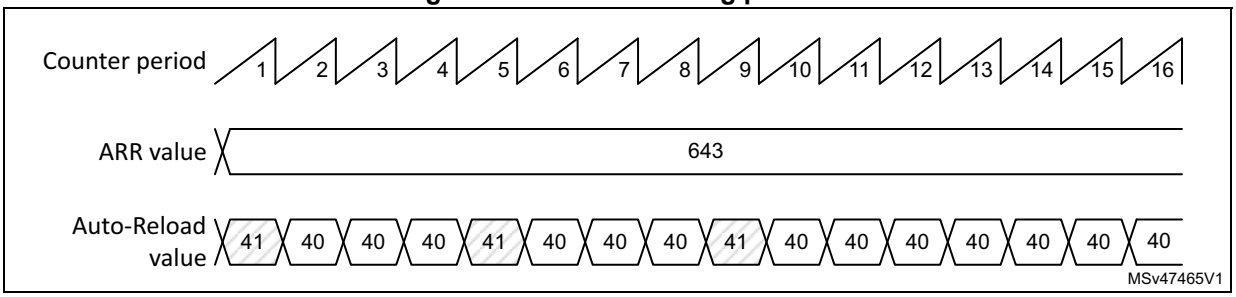
$$\text{Resolution} = \frac{F_{Tim}}{F_{pwm}} \Rightarrow F_{pwmMin} = \frac{F_{Tim}}{Max_{Resolution}}$$



$$\text{Dithering mode disabled: } F_{pwmMin} = \frac{F_{Tim}}{65536}$$

$$\text{Dithering mode enabled: } F_{pwmMin} = \frac{F_{Tim}}{65535 + \frac{15}{16}}$$

Note: The maximum TIM_ARR value is limited to 0xFFFEF in dithering mode (corresponds to 65534 for the integer part and 15 for the dithered part).



As shown on *Figure 668*, the dithering mode is used to increase the PWM resolution whatever the PWM frequency.

Figure 668. F_{Cnt} resolution vs frequency

The period changes are spread over 16 consecutive periods, as described in *Figure 669*.

Figure 669. PWM dithering pattern

The autoreload and compare values increments are spread following the specific patterns described in *Table 497*. The dithering sequence is done to have increments distributed as evenly as possible and minimize the overall ripple.

Table 497. TIM_ARR register change dithering pattern

-	PWM period

43.3.6 UIF bit remapping

The IUFREMAP bit in the TIM_CR1 register forces a continuous copy of the update interrupt flag UIF into the timer counter register's bit 31 (TIM_CNT[31]). This is used to atomically read both the counter value and a potential roll-over condition signaled by the UIFCPY flag. In particular cases, it can ease the calculations by avoiding race conditions caused for instance by a processing shared between a background task (counter reading) and an interrupt (update interrupt).

There is no latency between the assertions of the UIF and UIFCPY flags.

43.3.7 ADC triggers

The timer can generate an ADC triggering event with various internal signals, such as reset, enable or compare events.

Note: The clock of the slave peripherals (such as timer, ADC) receiving the tim_trgo signal must be enabled prior to receiving events from the master timer, and the clock frequency (prescaler) must not be changed on-the-fly while triggers are received from the master timer.

43.3.8 ADC synchronization

The timer operation can be synchronized to the ADC clock to trigger jitter-free ADC sampling. This function is enabled using the ADSYNC bit in the TIM_CR2 register.

This feature is useful when the timers and the ADCs are operating with semisynchronous clocks (clocks derived from a same source with integer ratio tim_ker_ck/adc_ker_ck), for instance adc_ker_ck = 75 MHz and tim_ker_ck = 150 MHz or 300 MHz.

ADSYNC must also be set when both peripherals are operating at the same frequency from the same clock source, when jitter-free operation is needed.

ADSYNC must not be set and jitter-free operation is not supported in the following cases:

- When the clock ratio is not an integer (for example adc_ker_ck = 75 MHz and tim_ker_ck = 100 MHz): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.
- When the ADC is operating in asynchronous mode (adc_ker_ck uncorrelated with tim_ker_ck): in this case, the sampling point jitter due to the timer to ADC signal resynchronization is 1 adc_ker_ck period maximum.

When ADSYNC = 1, the timer operation is slightly changed: the counter enable and counter reset events are aligned to the adc_ker_ck ADC clock, to avoid any phase shift due to clocks enable in the RCC.

Jitter-free operation is guaranteed only when one of the two requirements below is met (depending on the selected trigger source).

1. The counter period must be a multiple of the ADC clock period

$$(\text{TIM_PSC} + 1) \times (\text{TIM_ARR} + 1) \times T_{\text{tim_ker_ck}} = n \times T_{\text{adc_ker_ck}}$$

2. The compare value must be a multiple of the ADC clock period

$$(\text{TIM_PSC} + 1) \times \text{TIM_CMPy} \times T_{\text{tim_ker_ck}} = m \times T_{\text{adc_ker_ck}}$$

Note: If none of the two above requirements are met, the trigger is still generated, but the latency is not constant and varies with the timer and ADC clocks phase shift.

Programming guidelines

The ADC synchronization feature must not be modified during run-time, once the counter is enabled and once the ADC has been configured for receiving triggers from the timer.

It is mandatory to follow the procedure below to use the ADC synchronization:

1. Enable the destination ADC clock
2. Configure the timer and set the ADSYNC bit
3. Configure the ADC and enable it (using ADSTART and/or JADSTART bits)
4. Start the timer (with the CEN counter enable bit)

43.3.9 TIM6/TIM7/TIM26/TIM27 DMA requests

The TIM6/TIM7/TIM26/TIM27 can generate a single DMA request, as shown in *Table 498*.

Table 498. DMA request

DMA request signal	DMA request	Enable control bit
tim_upd_dma	Update	UDE

43.3.10 Debug mode

When the microcontroller enters debug mode (Cortex-M33 core halted), the TIMx counter can either continue to work normally or be stopped.

The behavior in debug mode can be programmed with a dedicated configuration bit per timer in the Debug support (DBG) module.

For more details, refer to section Debug support (DBG).

43.3.11 TIM6/TIM7/TIM26/TIM27 low-power modes

Table 499. Effect of low-power modes on TIM6/TIM7/TIM26/TIM27

Mode	Description
Sleep	No effect, peripheral is active. The interrupts can cause the device to exit from Sleep mode.
Stop	The timer operation is stopped and the register content is kept. No interrupt can be generated.
Standby	The timer is powered-down and must be reinitialized after exiting the Standby mode.

43.3.12 TIM6/TIM7/TIM26/TIM27 interrupts

The TIM6/TIM7/TIM26/TIM27 can generate a single interrupt, as shown in *Table 500*.

Table 500. Interrupt request

Interrupt acronym	Interrupt event	Event flag	Enable control bit	Interrupt clear method	Exit from Sleep mode	Exit from Stop and Standby mode
TIM6 TIM7 TIM26 TIM27	Update	UIF	UIE	write 0 in UIF	Yes	No

43.4 TIM6/TIM7/TIM26/TIM27 registers

Refer to *Section 1.2* for a list of abbreviations used in register descriptions.

The peripheral registers can be accessed by half-words (16-bit) or words (32-bit).

43.4.1 TIM control register 1 (TIM_CR1)

Address offset: 0x00

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	DITHEN	UIFREMAP	Res.	Res.	Res.	ARPE	Res.	Res.	Res.	OPM	URS	UDIS	CEN
			rw	rw				rw				rw	rw	rw	rw

Bits 15:13 Reserved, must be kept at reset value.

Bit 12 **DITHEN**: Dithering enable
0: Dithering disabled
1: Dithering enabled
Note: The DITHEN bit can only be modified when CEN bit is reset.

Bit 11 **UIFREMAP**: UIF status bit remapping
0: No remapping. UIF status bit is not copied to TIM_CNT register bit 31.
1: Remapping enabled. UIF status bit is copied to TIM_CNT register bit 31.

Bits 10:8 Reserved, must be kept at reset value.

Bit 7 **ARPE**: Auto-reload preload enable
0: TIM_ARR register is not buffered.
1: TIM_ARR register is buffered.

Bits 6:4 Reserved, must be kept at reset value.

Bit 3 **OPM**: One-pulse mode
0: Counter is not stopped at update event
1: Counter stops counting at the next update event (clearing the CEN bit).

Bit 2 **URS**: Update request source

This bit is set and cleared by software to select the UEV event sources.

0: Any of the following events generates an update interrupt or DMA request if enabled. These events can be:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

1: Only counter overflow/underflow generates an update interrupt or DMA request if enabled.

Bit 1 **UDIS**: Update disable

This bit is set and cleared by software to enable/disable UEV event generation.

0: UEV enabled. The Update (UEV) event is generated by one of the following events:

- Counter overflow/underflow
- Setting the UG bit
- Update generation through the slave mode controller

Buffered registers are then loaded with their preload values.

1: UEV disabled. The Update event is not generated, shadow registers keep their value (ARR, PSC). However the counter and the prescaler are reinitialized if the UG bit is set or if a hardware reset is received from the slave mode controller.

Bit 0 **CEN**: Counter enable

0: Counter disabled

1: Counter enabled

CEN is cleared automatically in one-pulse mode, when an update event occurs.

43.4.2 TIM control register 2 (TIM_CR2)

Address offset: 0x04

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	AD SYNC	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
			rw												
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	MMS[2:0]			Res.	Res.	Res.	Res.
									rw	rw	rw				

Bits 31:29 Reserved, must be kept at reset value.

Bit 28 **ADSYNC**: ADC synchronization

0: The timer operates independently from the ADC

1: The timer operation is synchronized with the ADC clock to provide jitter-free sampling point. This mode can be enabled only with specific ADC / timer clock relationship. Refer to *Section 43.3.8* for requirements.

The ADSYNC must not modified when the counter is enabled (CEN bit is set).

Bits 27:7 Reserved, must be kept at reset value.

Bits 6:4 **MMS[2:0]**: Master mode selection

These bits are used to select the information to be sent in master mode to slave timers for synchronization (TRGO). The combination is as follows:

000:**Reset** - the UG bit from the TIM_EGR register is used as a trigger output (tim_trgo).

001:**Enable** - the Counter enable signal, tim_cnt_en, is used as a trigger output (tim_trgo). It is useful to start several timers at the same time or to control a window in which a slave timer is enabled. The Counter Enable signal is generated when the CEN control bit is written.

010:**Update** - The update event is selected as a trigger output (tim_trgo). For instance a master timer can then be used as a prescaler for a slave timer.

Note: The clock of the slave timer or he peripheral receiving the tim_trgo must be enabled prior to receive events from the master timer, and must not be changed on-the-fly while triggers are received from the master timer.

Bits 3:0 Reserved, must be kept at reset value.

43.4.3 TIM DMA/interrupt enable register (TIM_DIER)

Address offset: 0x0C

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	UDE	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UIE
							rw								rw

Bits 15:9 Reserved, must be kept at reset value.

Bit 8 **UDE**: Update DMA request enable
0: Update DMA request disabled.
1: Update DMA request enabled.

Bits 7:1 Reserved, must be kept at reset value.

Bit 0 **UIE**: Update interrupt enable
0: Update interrupt disabled.
1: Update interrupt enabled.

43.4.4 TIM status register (TIM_SR)

Address offset: 0x10

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	UIOVRF	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.
							rc_w0								
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UIF
															rc_w0

Bits 31:25 Reserved, must be kept at reset value.

Bit 24 **UIOVRF**: Update Interrupt Overrun flag

This flag is set by hardware when an update request occurs while an update interrupt is pending (update interrupt flag set). It is cleared by software by writing it to '0'.

0: No Update Interrupt Overrun

1: Update Interrupt Overrun

Bits 23:1 Reserved, must be kept at reset value.

Bit 0 **UIF**: Update interrupt flag

This bit is set by hardware on an update event. It is cleared by software.

0: No update occurred.

1: Update interrupt pending. This bit is set by hardware when the registers are updated:

–On counter overflow if UDIS = 0 in the TIM_CR1 register.

–When CNT is reinitialized by software using the UG bit in the TIM_EGR register, if URS = 0 and UDIS = 0 in the TIM_CR1 register.

43.4.5 TIM event generation register (TIM_EGR)

Address offset: 0x14

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	UG
															w

Bits 15:1 Reserved, must be kept at reset value.

Bit 0 **UG**: Update generation

This bit can be set by software, it is automatically cleared by hardware.

0: No action.

1: Re-initializes the timer counter and generates an update of the registers. Note that the prescaler counter is cleared too (but the prescaler ratio is not affected).

43.4.6 TIM counter (TIM_CNT)

Address offset: 0x24

Reset value: 0x0000 0000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
UIF CPY	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.

CNT[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bit 31 **UIFCPY**: UIF copy

This bit is a read-only copy of the UIF bit of the TIM_ISR register. If the UIFREMAP bit in TIM_CR1 is reset, bit 31 is reserved and read as 0.

Bits 30:16 Reserved, must be kept at reset value.

Bits 15:0 **CNT[15:0]**: Counter value

Non-dithering mode (DITHEN = 0)

The register holds the counter value.

Dithering mode (DITHEN = 1)

The register only holds the non-dithered part in CNT[15:0]. The fractional part is not available.

43.4.7 TIM prescaler (TIM_PSC)

Address offset: 0x28

Reset value: 0x0000

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PSC[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 15:0 **PSC[15:0]**: Prescaler value

The counter clock frequency $f_{tim_cnt_ck}$ is equal to $f_{tim_psc_ck}$ / (PSC[15:0] + 1).

PSC contains the value to be loaded into the active prescaler register at each update event. (including when the counter is cleared through UG bit of TIM_EGR register.

43.4.8 TIM autoreload register (TIM_ARR)

Address offset: 0x2C

Reset value: 0x0000 FFFF

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	Res.	ARR[19:16]			
												rw	rw	rw	rw
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ARR[15:0]															
rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw	rw

Bits 31:20 Reserved, must be kept at reset value.

Bits 19:0 **ARR[19:0]**: Auto-reload value

ARR is the value to be loaded into the actual auto-reload register.

Refer to *Section 43.3.4: Time-base unit* for more details about ARR update and behavior.

The counter is blocked while the auto-reload value is null.

Non-dithering mode (DITHEN = 0)

The register holds the auto-reload value in ARR[15:0]. The ARR[19:16] bits are reserved.

Dithering mode (DITHEN = 1)

The register holds the integer part in ARR[19:4]. The ARR[3:0] bitfield contains the dithered part.

43.4.9 TIM6/TIM7/TIM26/TIM27 register map

TIM6/TIM7/TIM26/TIM27 registers are mapped as 16-bit addressable registers as described in the table below:

Table 501. TIM6/TIM7/TIM26/TIM27 register map and reset values

Offset	Register name	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Refer to *Section 2.3: Memory organization* for the register boundary addresses.

44 General-purpose timers (TIM9/TIM10/TIM11/TIM12/TIM13/TIM14)

44.1 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 introduction

The TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 general-purpose timers consist in a 16-bit autoreload counter driven by a programmable prescaler.

They may be used for a variety of purposes, including measuring the pulse lengths of input signals (input capture) or generating output waveforms (output compare, PWM).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the RCC clock controller prescalers.

The TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 timers are completely independent, and do not share any resources. They can be synchronized together as described in *Section 44.4.21: Timer synchronization (TIM9/TIM12 only)*.

44.2 TIM9/TIM12 main features

The features of the TIM9/TIM12 general-purpose timers include:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Up to two independent channels for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Synchronization circuit to control the timer with external signals and to interconnect several timers together
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software or internal trigger)
  - Trigger event (counter start, stop, initialization, or count by internal trigger)
  - Input capture
  - Output compare
- ADC synchronization for jitter-free sampling points

44.3 TIM10/TIM11/TIM13/TIM14 main features

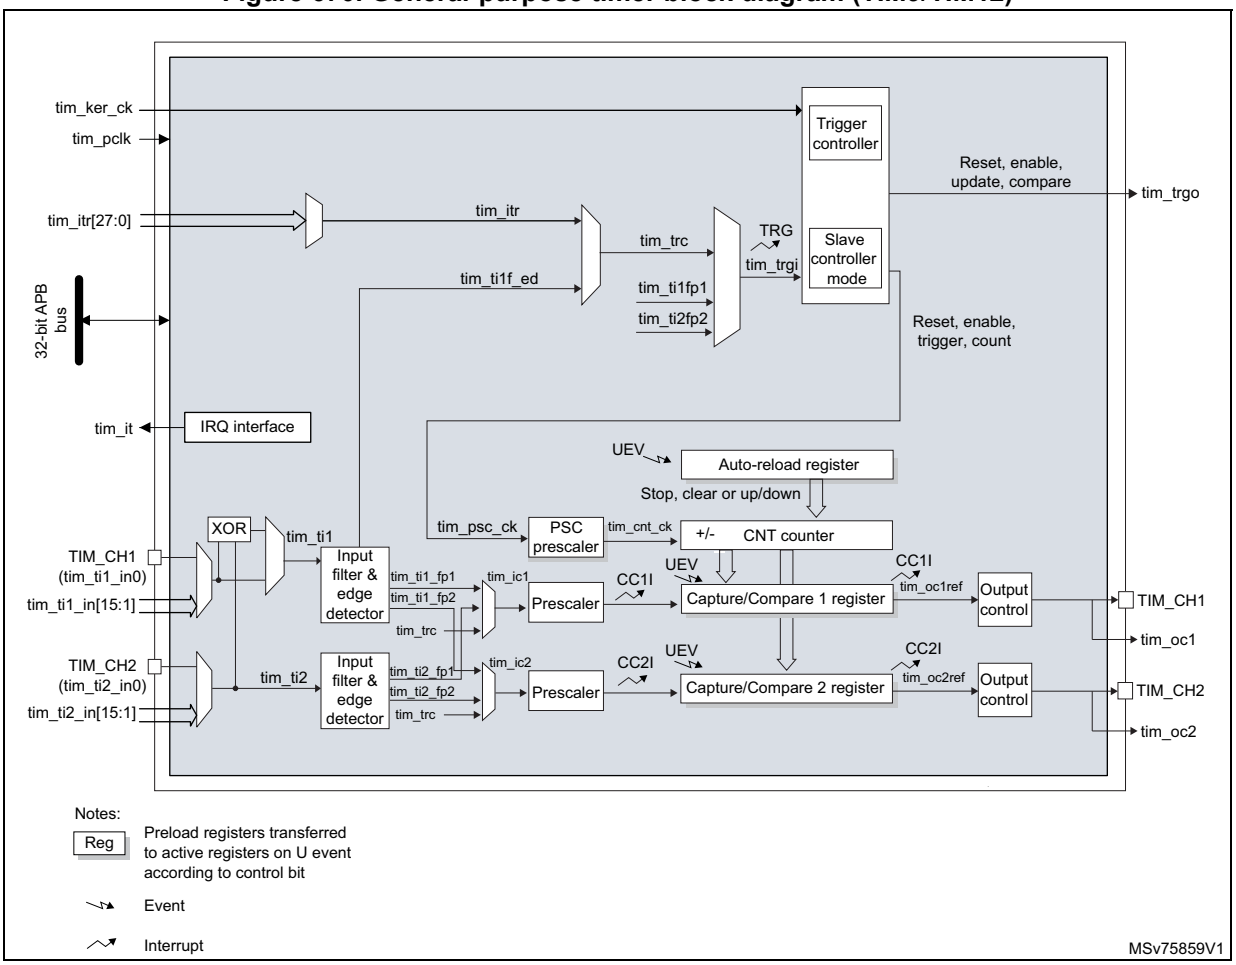
The features of general-purpose timers TIM10/TIM11/TIM13/TIM14 include:

- 16-bit autoreload upcounter
- 16-bit programmable prescaler used to divide the counter clock frequency by any factor between 1 and 65536 (can be changed “on the fly”)
- Independent channel for:
  - Input capture
  - Output compare
  - PWM generation (edge-aligned mode)
  - One-pulse mode output
- Interrupt generation on the following events:
  - Update: counter overflow, counter initialization (by software)
  - Input capture
  - Output compare

44.4 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 functional description

44.4.1 Block diagram

Figure 670. General-purpose timer block diagram (TIM9/TIM12)



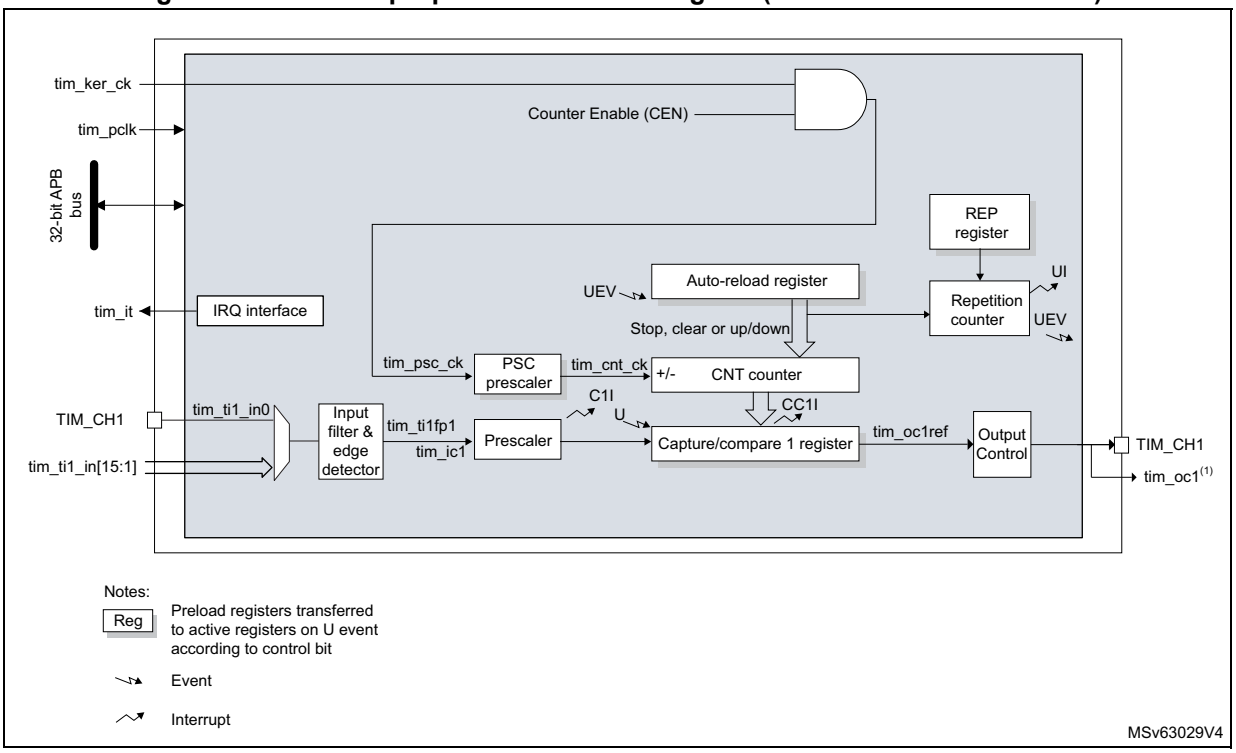


Figure 671. General-purpose timer block diagram (TIM10/TIM11/TIM13/TIM14)

1. This signal can be used as trigger for some slave timer (see internal trigger connection table in next section). See *Section 44.4.22: Using timer output as trigger for other timers (TIM10/TIM11/TIM13/TIM14 only)* for details.

44.4.2 TIM9/TIM10/TIM11/TIM12/TIM13/TIM14 pins and internal signals

Table 502 and *Table 503* in this section summarize the TIM inputs and outputs.

Table 502. TIM input/output pins

Pin name	Signal type	Description
TIM_CH1 TIM_CH2(1)	Input/Output	Timer multi-purpose channels. Each channel be used for capture, compare, or PWM. TIM_CH1 and TIM_CH2 can also be used as external clock (below 1/4 of the tim_ker_ck clock) and external trigger inputs.

1. Available for TIM9/TIM12 only.

Table 503. TIM internal input/output signals

Internal signal name	Signal type	Description
tim_ti1_in[15:0] tim_ti2_in[15:0](1)	Input	Internal timer inputs bus. These inputs can be used for capture or as external clock (below 1/4 of the tim_ker_ck clock).
tim_itr[27:0](1)	Input	Internal trigger input bus. These inputs can be used for the slave mode controller or as a input clock (below 1/4 of the tim_ker_ck clock).
tim_oc1 tim_oc2(1)	Output	Internal timer output. Can be used for triggering other timers or the ADC(s).

Table 503. TIM internal input/output signals (continued)

Internal signal name	Signal type	Description
tim_trgo(1)	Output	Internal trigger output. This trigger can trigger other on-chip peripherals.
tim_pclk	Input	Timer APB clock
tim_ker_ck	Input	Timer kernel clock. This clock must be synchronous with tim_pclk (derived from the same source). The clock ratio tim_ker_ck/tim_pclk must be an integer:1, 2, 3,..., 16 (maximum value)
tim_it	Output	Global Timer interrupt, gathering capture/compare, update, and trigger requests

1. Available for TIM9/TIM12 only.

Table 504 and *Table 505* list the sources connected to the tim_ti[2:1] input multiplexers.

Table 504. Interconnect to the tim_ti1 input multiplexer

tim_ti1 inputs	Sources

44.4.3 Time-base unit

The main block of the timer is a 16-bit up-counter with its related autoreload register. The counter clock can be divided by a prescaler.

The counter, the autoreload register and the prescaler register can be written or read by software. This is true even when the counter is running.

The time-base unit includes:

- Counter register (TIM_CNT)
- Prescaler register (TIM_PSC)
- Autoreload register (TIM_ARR).

The autoreload register is preloaded. Writing to or reading from the auto-reload register accesses the preload register. The content of the preload register is transferred into the shadow register permanently or at each update event (UEV), depending on the autoreload preload enable bit (ARPE) in TIM_CR1 register. The update event is sent when the counter reaches the overflow and if the UDIS bit equals 0 in the TIM_CR1 register. It can also be generated by software. The generation of the update event is described in details for each configuration.

Note: An update overrun status bit (UIOVRF in TIM_SR register) indicates that an update request occurred while an update interrupt is pending (update interrupt flag set). This bit is useful when debugging closed loop applications, to indicate that:

- *The update interrupt service routine is too long with respect to the interval between consecutive update events.*
- *The update interrupt service routine was served too late with respect to the subsequent update event.*

The counter is clocked by the prescaler output tim_cnt_ck, which is enabled only when the counter enable bit (CEN) in TIM_CR1 register is set (refer also to the slave mode controller description to get more details on counter enabling).

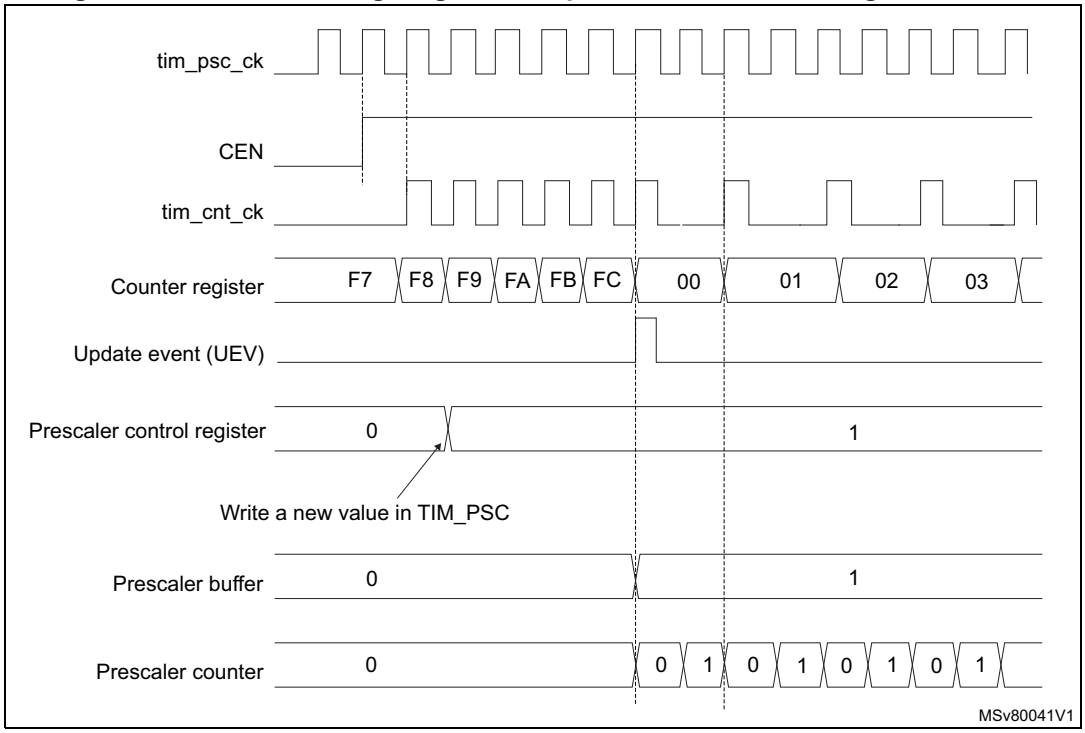
Note that the counter starts counting one clock cycle after setting the CEN bit in the TIM_CR1 register.

Prescaler description

The prescaler can divide the counter clock frequency by any factor between 1 and 65536. It is based on a 16-bit counter controlled through a 16-bit register (in the TIM_PSC register). It can be changed on the fly as this control register is buffered. The new prescaler ratio is taken into account at the next update event.

Figure 672 and *Figure 673* give some examples of the counter behavior when the prescaler ratio is changed on the fly.

Figure 672. Counter timing diagram with prescaler division change from 1 to 2



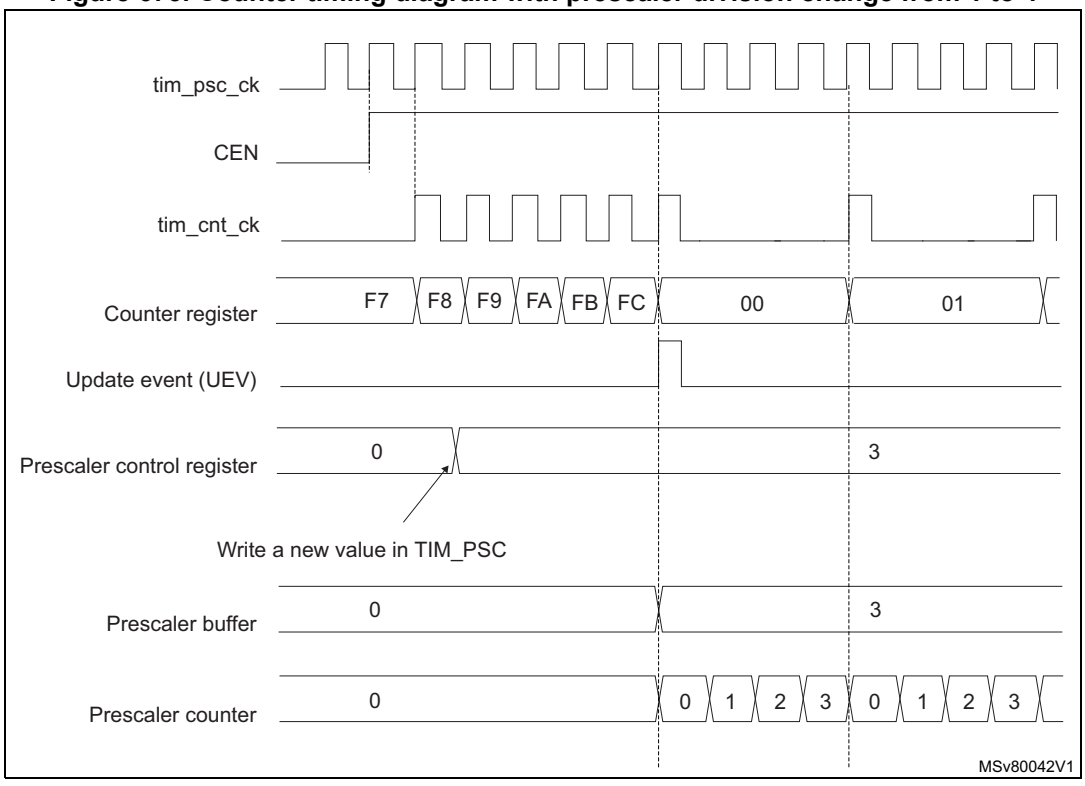


Figure 673. Counter timing diagram with prescaler division change from 1 to 4

44.4.4 Counter modes

Upcounting mode

In upcounting mode, the counter counts from 0 to the autoreload value (content of the TIM_ARR register), then restarts from 0 and generates a counter overflow event.

Setting the UG bit in the TIM_EGR register (by software or by using the slave mode controller on TIM9/TIM12) also generates an update event.
